Alpöge's proof of the Riemann hypothesis for Dirichlet L-functions

Siniša Slijepčević

November 25, 2026

Abstract

On 20 November 2026, L. Alpöge announced a proof of the Riemann hypothesis for Dirichlet L-functions, found with the help of Claude and released as a formal development in the proof assistant Lean. We give an account of this proof in conventional mathematics.

A window form of Landau's theorem reduces the zero-free half-plane $\operatorname{Re} s > \frac{1}{2}$ to one-sided bounds $G(x) \le x^{1/2+O(\varepsilon)}$, on windows $[Y, Y^{3/2}]$, for positive combinations G of von Mangoldt sums twisted by the powers of a primitive character. As in Stepanov's method for curves over finite fields, these bounds come from a slope inequality for hermitian lattices over families of abelian CM fields, in which the divisibility that a chain of theta lifts gains at inert primes plays the role of vanishing to high order. Suitable families exist by three inputs: a supply of fields on windows; a bound for Tate–Shafarevich groups of Tate twists, by Bernoulli numbers and Eisenstein congruences; and the lattice data of the chain of theta lifts.

This work was done with the help of Aleph, a mathematical AI research assistant. The Lean source was translated into structured definitions and results in conventional language; along the way, results already in the literature were identified and more than 1000 citations were inserted in place. We also applied straightforward optimisations of the argument: roughly 35% of this exposition already differs from the Lean source, and known results are cited rather than reproved.

1 Introduction

1.1 The theorem

We give an account, in conventional mathematics, of Alpöge's proof [3] of a zero-free half-plane for Dirichlet L-functions. Notation for Dirichlet characters and their L-functions is that of [180]. For an integer $N \geq 1$, a Dirichlet character χ modulo N is extended to $\mathbb{Z}$ by $\chi(n) = 0$ for $\gcd(n, N) > 1$, and $L(s, \chi)$ is the meromorphic continuation to $\mathbb{C}$ of $\sum_{n \geq 1} \chi(n)\, n^{-s}$. It is entire unless χ is the principal character modulo N, and then its only pole is a simple pole at $s = 1$. The Riemann zeta function $\zeta(s)$ is the case $N = 1$.

The theorem is this. Let $N \geq 1$ be an integer and let χ be a Dirichlet character modulo N. Then

$$L(s, \chi) \neq 0 \qquad \text{for every } s \in \mathbb{C} \text{ with } \operatorname{Re} s > \tfrac{1}{2},$$

except at the pole $s = 1$ when χ is principal. This is Theorem 6.7.

The theorem has two classical consequences. For $N = 1$ it says that $\zeta(s)$ has no zero with $\operatorname{Re} s > \frac{1}{2}$, and the functional equation of ζ then gives the Riemann hypothesis: every zero of $\zeta(s)$ other than the trivial zeros $s = -2n$, $n \geq 1$, has real part $\frac{1}{2}$ (Theorem 6.8). In the same way the functional equation of a primitive L-function gives the generalised Riemann hypothesis for Dirichlet L-functions: for every Dirichlet character χ, primitive or not, every zero of $L(s, \chi)$ with $0 < \operatorname{Re} s < 1$ has real part $\frac{1}{2}$ (Corollary 6.9). For these two classical conjectures and their place in the theory of primes we refer to [75] and [134]. Since the Dedekind zeta function of an abelian number field is the product of the L-functions of its characters [266], the theorem is equivalent to the same zero-free half-plane for the Dedekind zeta functions of all abelian number fields.

The one construction that this paper outlines rather than writes out in full is described in Section 1.3.

The argument is that of a formal development of L. Alpöge [3], written in the proof assistant Lean 4, in which the theorem above and its two consequences are the main theorems. The argument is formalised there and machine-checked. We have not verified the formal development, and no step of this paper appeals to it. Besides the development there is a note of four pages by its author [4], which describes the ideas and contains no proofs; the next subsection follows its description.

1.2 The architecture of the proof

Lineage. In Stepanov's proof of the Riemann hypothesis for curves over finite fields [247], [36], an auxiliary function is made to vanish to high order at the rational points, zeros are counted against poles, and the order of vanishing is chosen so that two error terms balance. Alpöge describes his argument as a descendant of Stepanov's: multiplicity is hard to find over the integers, a chain of theta lifts supplies it, each lift mimicking multiplicity, and for the von Mangoldt sum of length X the chain has length about $\sqrt{X}$ [4]. We follow this description term by term, and say for each term what the paper proves and what is only our reading.

What is bounded. The von Mangoldt sum of length y, with its main term removed, is

$$G(y) = \sum_{1 \leq n \leq y} \Lambda(n)\Big(\frac{y}{n} - 1\Big) - y(\log y - 1 - \gamma),$$

where Λ is the von Mangoldt function and γ is Euler's constant. Since $G(y)/y$ is the Riesz mean of order one of $\sum_n \Lambda(n) n^{-1}$ with its main term removed [117], the paper calls G

the Riesz-weighted Chebyshev function. For a non-principal Dirichlet character χ the twist $g(y,\chi)$ is formed in the same way, with $\Lambda(n)\chi(n)$ in place of $\Lambda(n)$ and with the main term $-y\,L'(1,\chi)/L(1,\chi)$ removed. For a primitive character ψ of order o the function that is bounded is

$$G_{\mathfrak{L}_\psi}(y) = G(y) + \frac{1}{3o+1}\sum_{\chi} \operatorname{Re} g(y,\chi),$$

where χ runs over the non-trivial primitive characters that induce powers of ψ (Definition 2.1). The Laplace transform of $u \mapsto G_{\mathfrak{L}_\psi}(e^u)$ is meromorphic in the half-plane $\operatorname{Re} s > 0$. Its poles there are simple and lie exactly at the zeros ρ of $\zeta(s)$ and of the functions $L(s,\chi)$ of the sum, and the residue at ρ is $S(\rho)/(\rho(1-\rho))$, where $S(\rho) > 0$ is a combination of the multiplicities of ρ with positive weights (Proposition 2.5).

One side, and windows. Only a sign is needed, and it enters twice. The arithmetic gives an upper bound for a sum over primes, and no lower bound (Proposition 4.2). The analytic criterion needs no more, because the residues above are positive at real zeros: it is a window form of Landau's theorem on Dirichlet integrals of functions of one sign [157]. Let $\lambda > 1$ and $0 < \theta < 1$. Suppose that for arbitrarily large Y one has $G_{\mathfrak{L}_\psi}(x) \le x^\theta$ for all $x \in [Y, Y^\lambda]$. Then neither $\zeta(s)$ nor any $L(s,\chi)$ of the sum, and in particular not $L(s,\psi)$, vanishes for $\operatorname{Re} s > \theta$ (Proposition 2.4). It therefore suffices to prove, for every small $\varepsilon > 0$, a bound $G_{\mathfrak{L}_\psi}(x) \le x^{1/2+c\varepsilon}$ for the large x in a set of scales that contains windows $[Y, Y^{3/2}]$ with Y arbitrarily large, where c does not depend on ε (Proposition 2.2). Windows are needed because the auxiliary fields and the arithmetic input below are supplied on windows only (Proposition 9.1, Theorem 36.4).

The prime sum at one scale. The bound at a scale x comes from one abelian CM field E, the field of what the paper calls a host (Definition 3.11, Definition 7.2). Its Galois group is identified with $\{\pm1\}^2 \times A$ for a finite abelian group A with $x^{2+8\varepsilon} \le |A| \le 2x^{2+8\varepsilon}$, so that E has degree $4|A|$. Inside a cyclotomic field it is the fixed field of the automorphisms $\zeta \mapsto \zeta^a$ with $a \equiv \pm1 \pmod{2^{e+2}}$, $\psi(a) = 1$ and $(a/q) = (a/d) = 1$, where 2^e is of the size of $|A|$. Here $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$ are primes with $q \mid d+1$, of size $\log q \asymp Y^{\varepsilon/5}$ and $\log d \asymp Y^{\varepsilon/5}\log^2 Y$ for a scale $Y \le x$; the paper calls (q,d) a window pair (Definition 7.1). The field E contains $K = \mathbb{Q}(\sqrt{-d})$, and the powers of ψ are among its Dirichlet characters. For a height $a > 0$, a translate $t \in A$ and a positive weight function w, the inert prime sum $A_{\mathrm{in}}(a,t,w)$ adds the terms $2\log p\,(a/p^i - w)^+$ over the primes p inert in K and the odd $i \ge 1$, the weight being evaluated at a translate, depending on t, of the Frobenius class of p^i, together with a similar term at d (Definition 3.1). By orthogonality of the characters of $\mathrm{Gal}(E/\mathbb{Q})$, the difference

$$A_{\mathrm{in}}(a,t,w) - a\Big(\log a - 1 - \gamma + \frac{L'(1,\chi_{-d})}{L(1,\chi_{-d})} - \frac{1}{|\Phi|}\sum_{\rho\in\Phi}\log w(\rho)\Big)$$

is an explicit linear combination of the functions $g(y,\chi)$ of the Dirichlet characters χ of E, evaluated at the points $y = a/w(\rho)$ (Lemma 3.8). Here χ_{-d} is the quadratic character of K and $\Phi \subset \mathrm{Gal}(E/\mathbb{Q})$ is the subgroup of index two that fixes K. The subtracted term is the main term, and the sum of these differences over a finite set $T \subseteq A$ of translates, the tops, and over m weight functions is the excess $\Delta(u)$ at a translate $u \in A$. Two averages turn an upper bound for the excess into an upper bound for $G_{\mathfrak{L}_\psi}(x)$ (Proposition 3.3). The first is over the translates u in a cyclic subgroup $A_0 \subseteq A$ of index o; after it only the $4o$ characters of E that are trivial on A_0 remain (Lemma 3.17). The second is over the tops, which are equidistributed over the cosets of A_0 with share $4/(3o+1)$ on A_0 and $3/(3o+1)$ on every other coset; this gives each non-trivial character of A/A_0 the weight $(3o+1)^{-1}$ of the sum $G_{\mathfrak{L}_\psi}$. Among the $4o$ characters, o are the powers of ψ, which make up $G_{\mathfrak{L}_\psi}$, and the other $3o$ are their twists by the quadratic characters modulo q and d. The step leaves the absolute values $|g(x,\chi)|$ of these twists, and the

host conditions ask that each be at most $x^{1/2+\varepsilon}$ (Definition 3.16). The window pair is chosen so that this holds: at every large scale almost all pairs of the relevant sizes have the bound on a long range of scales, by a mean-square argument over quadratic twists (Proposition 10.4, Proposition 10.2). Its inputs are published: Montgomery's zero-density estimate, the Landau–Page theorem, an effective bound for a real zero, and the prime number theorem in progressions of Thorner and Zaman.

The auxiliary object. What remains is an upper bound for the excess, and this is where Stepanov's method enters. In the description of [4] the auxiliary object is a chain of iterated theta lifts $\mathrm{U}(X_0) \to \mathrm{U}(X_1) \to \cdots \to \mathrm{U}(X_m)$ between totally definite unitary groups, which wins multiplicity m. In the body of this paper the chain does not appear. What appears is a record at one scale, a slope datum (Definition 3.14): a finite list of real numbers with an integer m, a prime-sum entry S_u and a lattice term Θ_u for every translate u. In the application the numbers are ranks, slopes, maximal slopes and heights of hermitian lattices. That a slope datum is the record of a chain of theta lifts is our reading: the definition is purely numerical, and so are the eleven slope conditions imposed on it (Definition 3.13). The chain itself is outlined in Appendix A. The order of vanishing is, in our reading, the integer m, the number of lifts. The paper fixes $\sqrt{x\delta_1} \le m \le 2\sqrt{x\delta_1}$ with $\delta_1 = x^{-\varepsilon/8}$ (Definition 11.2).

Divisibility at inert primes. Vanishing at the rational points becomes divisibility at the primes inert in K. In [4], on an elliptic curve with complex multiplication by K, a derivative of order a of the theta function, divided by the a-th power of the period, is divisible at an inert prime p by p to the power $a/p + a/p^3 + \cdots - O(\log a)$, and the m-fold lift keeps a sufficient lower bound for the divisibility. The paper has the same exponent. The gain attached to an inert prime p is built on $\gamma_p = p/(p^2-1) = \sum_{i \text{ odd}} p^{-i}$ (Definition 5.3), and the inert prime sum adds the terms a/p^i over the same odd i. Each of the m weight functions has its own gain, and the lattice term Θ adds, over the inert primes p, the product of $2\log p$ and the sum of the m gains at p less a correction (Definition 5.5). The loss bound says that the prime sum S exceeds Θ by at most a small loss (Theorem 5.6); this is the loss condition (Sl8) of a slope datum, with an exponent $e_{\mathrm{Loss}} = 0$. Its main hypothesis, the linking property, compares the contribution of each inert prime to the prime sum with the gain at that prime, up to explicit local losses, and the deficit is then split prime by prime. That the gains measure the divisibility of theta kernels is the intended reading, and no result of the paper states it. The paper defines the gains as numbers; Appendix A proves that the theta kernels attached to an elliptic curve with complex multiplication by K are integral at the inert primes $\ell \ge 5$, and it does not deduce the gains from this.

Zeros against poles. The count of zeros against poles becomes a slope inequality in the sense of Bost [47], which the note lists among its tools [4]. In the paper it is the dual-slope inequality (Sl9): the mean of the slopes of a family of lattices, each corrected by a height, is bounded by the slope of a common target. It needs the mean slope of the target and not the maximal one, and it comes from Bost's inequality and from frames of maps that are nearly orthogonal at one archimedean place (Theorem 14.4, Theorem 14.2); this is the approximate orthogonality of the note. The norms of the lifts are the divisor bound (Sl2): it bounds the slope of the target, corrected by a height, by a sum in which each of the m lifts contributes $a_t \log a_t - a_t - a_t \log \Omega$ for every top t, with the height a_t of the top and a constant Ω that involves $L'(1,\chi_{-d})/L(1,\chi_{-d})$. Terms of order m at two auxiliary primes occur in two further conditions and cancel. The transfer of slopes (Sl7) passes the lattice term Θ_u into the slopes of the lattices. If the entries S_u are the inert prime sums of the host, the eleven conditions together give $S_u \le \mathrm{Main}(u) + \mathrm{Err}(u)$, where $\mathrm{Main}(u)$ is the sum of the main terms (Proposition 4.2). This is the accounting, and it bounds the excess by $x^{(e_{\mathrm{Div}}+e_{\mathrm{Loss}}+3)\varepsilon}$ times the natural size of its terms, where e_{Div} and e_{Loss} are

the exponents of the error terms in (Sl2) and (Sl8) (Proposition 4.1).

The balance. The note speaks of the cost of each lift [4]. The bound for the excess contains a term of size $|T|\,a$, which does not grow with m, and a term of size $|A|\,m^2 b\,x^{\varepsilon}$, where $b = \exp(x^{\varepsilon})$ and the heights are of size $a = xb$. Divided by the number $|T|\,m$ of summands and by b, they are of the order of x/m and of m, up to factors $x^{O(\varepsilon)}$, and they balance when m is about $\sqrt{x}$. The resulting bound is $G_{\mathfrak{L}_\psi}(x) \le x^{1/2+O(\varepsilon)}$ (Proposition 6.5). In Stepanov's method the order of vanishing is chosen to balance two error terms in the same way; the comparison is our reading.

The existence theorem. A family of hosts over a set of scales is tied with exponents (e_D, e_L) if at every large scale of the set one of its members carries a slope datum as above, with its prime-sum entries equal to its inert prime sums and with $e_{\mathrm{Div}} \le e_D$ and $e_{\mathrm{Loss}} \le e_L$ (Definition 3.16, Definition 6.2). For a tied family whose members satisfy the host conditions,

$$G_{\mathfrak{L}_\psi}(x) \le x^{1/2+(e_D+e_L+7)\varepsilon}$$

at every large scale x of the family (Proposition 6.4). The existence theorem, Proposition 7.8, says that for every primitive character ψ there are real numbers e_D, e_L and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there is a family of hosts with parameter ε that satisfies the host conditions for $\mathfrak{L}_\psi$ at all large scales, is tied with exponents (e_D, e_L), and whose set of scales contains windows $[Y, Y^{3/2}]$ with Y arbitrarily large. The order of the quantifiers is the point: e_D and e_L are chosen before ε. The proof gives $(e_D, e_L) = (1, 0)$, hence the exponent $\frac{1}{2} + 8\varepsilon$ (Theorem 17.7). With the criterion this gives $L(s, \psi) \neq 0$ for $\operatorname{Re} s > \frac{1}{2}$ and every primitive ψ (Proposition 6.3), and the Euler factors at the primes dividing N extend it to every character modulo N.

The arithmetic input. For the Galois cohomology classes over E that the construction cannot remove, the note asks for "a significant weakening of Vandiver" [4]. In the paper this is the window Sha bound (Theorem 36.4). For a number field E, a prime ℓ and an integer k let $\mathrm{len}_\ell(E, k)$ be the length of the Tate–Shafarevich group

$$\mathrm{Sha}^1_\ell(E, k) = \ker\Big(H^1\big(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)\big) \to \prod_{v \mid \ell} H^1\big(E_v, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)\big)\Big),$$

where G_{E,S_ℓ} is the Galois group of the maximal extension of E unramified outside the places above ℓ. The theorem says that for every window pair (q, d) at a large scale there is a range $[Y, Y^2]$ of scales such that for every x in the range the field E described above, formed with ψ, q, d and $x^{2+8\varepsilon} \le 2^e \le 2x^{2+8\varepsilon}$, satisfies

$$\sum_{\ell} \log \ell \sum_{k=1}^{t-1} \mathrm{len}_\ell(E, k) \le \exp(x^{\varepsilon}/2), \qquad t = \lfloor x^{401} \rfloor.$$

The sum runs over all primes ℓ, the prime 2 included. The bound enters the divisor bound, where the defects of the lattices are bounded by these lengths (Theorem 13.2). Its proof is the longest part of the paper. For odd ℓ the groups split into plus and minus parts under complex conjugation, and the length of each part is bounded by a sum over the Dirichlet characters of E. The minus part is bounded through generalised Bernoulli numbers, by Kolyvagin systems of Stickelberger type (Proposition 37.2, Proposition 37.4). The plus part is bounded by Eisenstein congruences on U(3), on GSp_4 and on U(3) over $\mathbb{Q}(i)$: one non-zero integer, whose logarithm is polynomial in the conductor and in the twist, bounds the lengths at all primes ℓ other than one auxiliary prime at once (Proposition 38.5). The automorphy that these congruences need is proved by an $R = T$ theorem for residually reducible representations over auxiliary CM fields, with Hida theory and patching (Theorem 49.3). The prime 2 and finitely many bad primes are treated by a control of twists along cyclotomic towers, which rests on the theorem

of Ferrero and Washington, and by a bound for second cohomology that is uniform in the twist (Proposition 39.2, Theorem 40.1). Since the conductor of E is at most $\exp\bigl(O(Y^{\varepsilon/5}\log^2 Y)\bigr)$, bounds that are polynomial in the conductor and in t fit within $\exp(x^{\varepsilon}/2)$.

The map of the Parts. Part I carries out the reduction: it proves Theorem 6.7 and its two consequences from three statements. The first is the supply of hosts on windows (Proposition 9.1), proved in Part II: every large scale of a set that contains windows $[Y, Y^{3/2}]$ carries a host that satisfies the host conditions, whose field satisfies the bound for Tate–Shafarevich groups, and that is good in the sense required below. The second is the window Sha bound, proved in Parts VII to IX. The third is the existence of one class of families of hosts with the link properties (Proposition 17.6), proved in Parts III and IV. The link properties are design existence, the linking property, a choice of tops, and the properties (Sp1)–(Sp8) of the slope records of the members, with exponents independent of ε; a class with these properties contains tied families (Theorem 7.10, Theorem 8.4). Part III proves the properties of slope records for one explicit class $\mathcal{A}_{\mathrm{prop}}$, from a list of records that each member is required to carry (Theorem 17.7). Its sections on the norms of the lifts and on approximate orthogonality prove the divisor bound and the slope inequality. The divisor bound uses the Ribet budget (Theorem 22.1), in which local losses are bounded place by place with Wach modules and (φ, Γ)-modules; it is proved in Part V. Part IV proves design existence (Proposition 18.1): for every small ε the class contains a family on the given windows. This is where the records of the chain of theta lifts enter: the family is assembled from translate packets, one at each scale, and a packet consists of one loss datum and one slope record for every translate $u \in A$ (Proposition 19.3, Definition 19.1). Two groups of estimates that the class requires are proved from the data that the packets carry. One is the realisation estimate, proved from a budget of local estimates with integer denominators (Theorem 20.2). The other is a pair of bounds for the slopes of integral models, proved in Part VI by arithmetic intersection theory on towers of integral models of unitary Shimura varieties attached to E (Theorem 29.14, Proposition 31.14); we read it as the computation of covolumes of the note [4]. The dependence of the Parts is

$$\mathrm{I} \leftarrow \mathrm{II},\ \mathrm{III},\ \mathrm{VII}; \qquad \mathrm{III} \leftarrow \mathrm{II},\ \mathrm{IV},\ \mathrm{V}; \qquad \mathrm{IV} \leftarrow \mathrm{VI}; \qquad \mathrm{VII} \leftarrow \mathrm{VIII} \leftarrow \mathrm{IX},$$

where an arrow points from the Part whose results are cited to the Part that cites them.

1.3 How this account was obtained

The proof is self-contained, apart from published results quoted with their sources and the detailed construction of a single object, a *theta chain system*: at every large scale, a family of translate packets, the arithmetic records of a chain of theta lifts, which carry loss data, numerical data and, under a bound for Tate–Shafarevich groups, the geometric and local comparison data that the slope inequality needs. The existence of a theta chain system is assumed in a single statement, Hypothesis 21.1: it is named a hypothesis rather than a proposition for logical rigour, as its construction is given here only as an outline, in Appendix A. A faithful reproduction of the construction, which in the Lean source is long and in places repetitive, would roughly double the length of this exposition. We are optimising the construction and will give it, in optimised and possibly partly computer-assisted form, in the final version of this paper.

This work was done with the help of Aleph, a mathematical AI research assistant that runs on an ensemble of Claude, ChatGPT, Gemini and bespoke models. As a first step, Claude Code and Codex agents translated the Lean code of the formal development [3] into the Aleph database, in human-readable form; at this step the citations were identified and verified at their sources, and the obvious optimisations were made. The text of this paper thus contains more than 1000 citations, most of them already verified at their source, and roughly 35% of the

argument already differs from the Lean source. The entire proof is now being optimised and verified in several iterations, with the aim of improving its clarity, its logical structure and its understanding. This work is ongoing, and this is not the final version of the presentation. We have also included contributions of mathematicians who have already optimised parts of the argument, among them J. Adriazola [2] and the author of [261].

Several other accounts of the argument appeared within days of the development. Adriazola [2] wrote the argument as one continuous proof in conventional mathematics, in two parts, with its open steps stated. Zhang [277] wrote a preliminary account of the proof and of its principal ingredients, with an emphasis on their sources and history. Rubinstein [210], [211] maintains a guide to the proof and an exposition of the argument specialised to the Riemann zeta function. Naskręcki [189] built a map of the formal proof and a record of checks, with an atlas of the route. Epstein [85] wrote a human-readable blueprint of the formal development. Brox [54] leads a programme to distil the formal proof into shorter proofs. Jaswal [138] wrote an account of the Riemann hypothesis for Dirichlet L-functions after Alpöge. We thank the author of [261], which gives three simplifications of the argument; we use one of its ideas in the proof of Theorem 14.4. Several other optimisation ideas already available are applied and quoted throughout the paper.

1.4 Organisation and conventions

The paper has nine Parts and five appendices. The Introduction and Part I carry the whole logic of the proof. A reader who stops after Part I knows the theorem, the reduction, and which statement each later Part supplies. Every later Part proves a named statement that an earlier Part uses, as in the map at the end of the subsection on the architecture.

Part I has seven sections, in the order of the argument. It proves the window form of Landau's theorem (Proposition 2.7) and the passage from a bounded excess to the one-sided bound (Proposition 3.3). Then come the two halves of Stepanov's mechanism, side by side: the accounting, which is the count as a slope inequality (Proposition 4.2, Proposition 4.1), and the divisibility at inert primes, which is the loss bound (Theorem 5.6). After them it defines tied families, proves the main theorem and its two consequences from the existence theorem, and proves the existence theorem from its three inputs (Proposition 6.3, Proposition 7.8, Theorem 7.10). It ends with the eight properties (Sp1)–(Sp8) of slope records, which give all the slope conditions except the loss condition (Theorem 8.4); these are what a class of families must supply.

Part II proves the supply of hosts on windows (Proposition 9.1), with the mean-square argument for window pairs (Proposition 10.2), and the supply of good hosts (Proposition 11.5). Part III proves the properties of the class $\mathcal{A}_{\mathrm{prop}}$ (Theorem 17.7) and with them Proposition 17.6; each of its sections names the property of slope records that it proves. Part IV proves design existence (Proposition 18.1) from translate packets (Proposition 19.3, Proposition 19.9, Proposition 21.2).

Part V proves the Ribet budget (Theorem 22.1): it bounds the local losses at the places above ℓ, at the primes of inert type, and at the ramified, split, small and large primes, with Wach modules. Part VI proves the bounds for model slopes (Theorem 29.14) and the existence of good root towers (Proposition 31.14). Part VII reduces the window Sha bound (Theorem 36.4) to three one-character bounds, and it treats the minus part, the prime 2, the bad primes and the bound for second cohomology (Proposition 37.2, Proposition 39.2, Theorem 40.1). Part VIII proves the one-character bounds by Eisenstein congruences (Proposition 42.2, Proposition 44.3, Proposition 46.2). Part IX proves the automorphy theorems that these bounds use (Theorem 47.1, Theorem 47.16, Theorem 51.1). Part V, Part VI and Parts VII to IX do not use

one another, apart from a few general lemmas and quoted results, and each can be read after Part I with the statement it supplies as its goal.

Appendix A outlines the construction of the chain of theta lifts, as described in Section 1.3. Appendix B states the 174 quoted results with their sources, by field, and ends with the computer checks that proofs cite. Appendices C, D and E contain the most technical sections of Parts V, VI and IX: weight words along Frobenius orbits, technical facts on good root towers, and Hecke ideals, patching and Taylor–Wiles levels. The Parts cite the statements of these appendices and do not repeat their proofs.

Throughout, ψ is a primitive Dirichlet character, ε is the small parameter of the argument, with $0 < \varepsilon < \frac{1}{52}$, and x, y, X, Y are large real scales. A set of scales contains λ-windows if it contains intervals $[Y, Y^{\lambda}]$ with Y arbitrarily large; window pairs and the window Sha bound are named after the windows on which they serve. Two names are used twice: the window parameters of a loss datum have nothing to do with these windows, and a Sha-host is a triple of numbers, not a host. Labels such as (Ec4) or (Sl8) refer to the conditions listed in the definition or statement where they occur. The names of the note are used in the Introduction, in the titles and in the text between results; the statements use the names of the paper, and each correspondence between the two that no result states is marked as a reading. The explicit constants, such as the bound $\frac{1}{52}$ for ε, the window ratio $\frac{3}{2}$, the weight $(3o+1)^{-1}$ and the exponent 401 of the Sha bound, are not optimised, and we do not know which of them are forced by the method. Most objects of the argument have no counterpart in the literature, and each is named where it first appears; where the literature has a word, we use it.

Part I
The reduction

Part I contains the whole logic of the proof. It proves the zero-free half-plane for Dirichlet L-functions (Theorem 6.7) and the Riemann hypothesis (Theorem 6.8) from three statements, which the later Parts prove.

- Proposition 9.1 (Part II). Let a primitive character ψ satisfy the window Sha bound, and let a good-host requirement supply good hosts for ψ. Then for every $\varepsilon \in (0, 1/52)$, at all large scales of a set containing $\frac{3}{2}$-windows, there are hosts that satisfy the host conditions for the cyclic level of ψ, whose fields satisfy a Sha bound, and that meet the good-host requirement.
- Theorem 36.4 (Part VII). Every primitive character satisfies the window Sha bound with exponent 401.
- Proposition 17.6 (Part III). There are a good-host requirement that supplies good hosts and a class of parametrised host families with slope records that has design existence, the linking property, the three properties of the top sets, and the properties (Sp1)–(Sp8) of slope records.

Apart from these, Part I uses four classical theorems, restated in Appendix B: Theorem B.1, Theorem B.2, Theorem B.4 and Lemma B.3. The existence of a theta chain system (TCS) enters Part I only through Proposition 17.6, whose clause (Lk1) is proved in Part IV assuming (TCS). The results of Part I that depend on it are Corollary 8.3, Proposition 7.9, Proposition 7.8 and the two theorems; all the others are unconditional.

In Alpöge's description ([4], p. 1) the argument descends from Stepanov's proof of the Riemann hypothesis for curves over finite fields [247], [36]: an auxiliary object that vanishes to high multiplicity bounds a count from above. The sections of Part I follow this pattern. Section 2 shows that an upper bound suffices. The function to be bounded is the von Mangoldt sum $\sum_{n \le x} \Lambda(n)(x/n - 1)$ with its main term removed, together with its twists by the powers of ψ; the statements call it the Riesz-weighted Chebyshev function. A bound $x^{1/2+c\varepsilon}$ from above, on windows $[Y, Y^{\lambda}]$ with Y arbitrarily large, excludes zeros to the right of the critical line. Section 3 obtains such a bound at one scale x from one auxiliary abelian field, a host: an average over translates turns an upper bound for the excess of its inert prime sums into the bound at x. Section 4 bounds the excess by the accounting, eleven inequalities between real numbers which play the part of Stepanov's count of zeros against poles. Only one of the eleven involves the primes, the loss condition (Sl8), and Section 5 proves the loss bound from which it follows; in Stepanov's terms it replaces vanishing at the rational points by divisibility at the inert primes. Section 6 passes from one scale to families of hosts over a set of scales, defines tied families, and deduces the two theorems from the existence of tied admissible families. Section 7 proves this existence theorem from the three statements above, and Section 8 proves the last link, that the properties (Sp1)–(Sp8) give the remaining ten inequalities. It closes with a table that names, for each condition used in Part I, the result that proves it.

A reader who wants the mechanism of the proof should read Sections 3, 4 and 5. In the exposition of these sections we have adopted several devices of [2]: the accounting is stated in real numbers and followed by a dictionary, its error terms are compared with Stepanov's balance, and the averaging step is illustrated by its smallest case.

2 One-sided bounds on windows

This section proves the analytic criterion of the paper, Proposition 2.2. Let $\mathfrak{L}$ be a character level, that is, a finite set of primitive characters with positive weights, and let $G_{\mathfrak{L}}$ be the corresponding combination of the von Mangoldt sum and its twists, with the main terms removed. Suppose that for every small ε the upper bound $G_{\mathfrak{L}}(x) \le x^{1/2+c\varepsilon}$ holds at all large x of a set that contains windows $[Y, Y^{\lambda}]$ with Y arbitrarily large, where c does not depend on ε. Then no L-function of the level vanishes in $\operatorname{Re} s > \frac{1}{2}$. The criterion is used once, in the proof of Proposition 6.3 in Section 6, with $c = e_D + e_L + 7$; the main theorem takes $\lambda = \frac{3}{2}$ and the cyclic level of a primitive character.

The proof is a window form of Landau's theorem on Dirichlet integrals of functions of one sign [157]. In the classical theorem the bound is assumed for all large x [180]. Here it is assumed only on the windows, and nothing is assumed between them (Proposition 2.4). The weaker hypothesis is needed because the auxiliary fields of the proof and the Sha bound for them are supplied on windows only (Proposition 9.1, Theorem 36.4).

The heart of the section is Proposition 2.7, the same statement for a Laplace transform with simple poles, to which the substitution $x = e^u$ reduces the criterion. Its proof compares two estimates of the Taylor coefficients of the transform at the points of one vertical line $\operatorname{Re} s = \sigma$. The bound on a window $[U, \lambda U]$ makes them small for some $k \ge U$ (Lemma 2.10). A pole to the right of θ, chosen nearest to the line and isolated (Lemma 2.9), makes them large for all large k. Positivity enters twice, and this is why a bound from above suffices. The Taylor coefficients at a real point are moments of the function against the positive kernels $u^k e^{-\sigma u}/k!$ (Lemma 2.8), so an upper bound for the function bounds them from above. And the residue at a real pole ρ is positive: it is a combination of multiplicities of zeros with the weights of the level, which are positive, divided by $\rho(1-\rho)$ (Proposition 2.5).

Notation for Dirichlet characters and their L-functions is that of [180]. For an integer $N \ge 1$, a **Dirichlet character modulo** N is a character χ of $(\mathbb{Z}/N\mathbb{Z})^{\times}$, extended to $\mathbb{Z}$ by $\chi(n) = 0$ for $\gcd(n, N) > 1$; the **principal character** modulo N is denoted $\chi_{0,N}$, and χ is **primitive** if its conductor equals N. The complex variable is s. The **Dirichlet L-function** of χ is the meromorphic continuation to $\mathbb{C}$ of

$$L(s,\chi) = \sum_{n\ge 1} \chi(n)\, n^{-s} = \prod_{p} (1 - \chi(p)\, p^{-s})^{-1}, \qquad \operatorname{Re} s > 1,$$

where χ is taken as a character modulo N, so that the Euler factors at the primes $p \mid N$ are equal to 1 also when χ is imprimitive. It is entire unless $\chi = \chi_{0,N}$, in which case its only pole is a simple pole at $s = 1$. The Riemann zeta function is $\zeta(s) = L(s, \chi_{0,1})$; its **trivial zeros** are the points $s = -2n$, $n \ge 1$. The von Mangoldt function is $\Lambda(n)$.

Definition 2.1. Let $\mathcal{P}$ denote the set of **primitive Dirichlet characters**, each regarded as a pair (N, ψ) with ψ primitive modulo $N \ge 1$. Let $\mathbf{1} \in \mathcal{P}$ be the trivial character modulo 1; it is the only principal character in $\mathcal{P}$. For $\psi \in \mathcal{P}$ let $\overline{\psi} \in \mathcal{P}$ be its complex conjugate, and for a Dirichlet character χ let $\chi^* \in \mathcal{P}$ be the primitive character inducing χ. A character is **real** if it takes only real values.

For real $y > 0$ and every non-principal Dirichlet character χ put

$$G(y) = \sum_{1\le n\le y} \Lambda(n)\Big(\frac{y}{n} - 1\Big) - y\big(\log y - 1 - \gamma\big), \tag{2.1}$$

$$g(y,\chi) = \sum_{1\le n\le y} \Lambda(n)\chi(n)\Big(\frac{y}{n} - 1\Big) + y\,\frac{L'(1,\chi)}{L(1,\chi)}, \tag{2.2}$$

where γ is Euler's constant (recall $L(1,\chi) \neq 0$ [180]), and put $g(y,\mathbf{1}) = G(y)$. We call G the **Riesz-weighted Chebyshev function** and $g(\cdot,\chi)$ its **twist** by χ; the subtracted terms $y(\log y - 1 - \gamma)$ and $-y\,L'(1,\chi)/L(1,\chi)$ are their **main terms**.

A **character level** is a tuple $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o)$ consisting of a finite set $K \subset \mathcal{P}$, an optional element ψ_{exc} (either absent or a character of K) and an integer $o \geq 0$, such that

(Le1) $\mathbf{1} \in K$, and $\overline{\psi} \in K$ for every $\psi \in K$;

(Le2) if ψ_{exc} is present, it is odd and real.

The **cyclic level** of $\psi \in \mathcal{P}$ of modulus N is $\mathfrak{L}_\psi = (K_\psi, \mathrm{absent}, o_\psi)$, where $K_\psi = \{(\psi^j)^* : j \in \mathbb{Z}\}$ and o_ψ is the order of ψ in the group of Dirichlet characters modulo N.

For a character level $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o)$ the **weighted Chebyshev function** is

$$G_{\mathfrak{L}}(y) = G(y) + \sum_{\psi \in K \setminus \{\mathbf{1}\}} w_{\mathfrak{L}}(\psi)\ \mathrm{Re}\, g(y,\psi) \quad (y > 0), \qquad w_{\mathfrak{L}}(\psi) = \begin{cases} 1, & \psi = \psi_{\mathrm{exc}}, \\ (3o+1)^{-1}, & \text{otherwise.} \end{cases} \tag{2.3}$$

A character level $\mathfrak{L}$ is **zero-free above** $\theta \in \mathbb{R}$ if for every $\psi \in K$ the function $L(s,\psi)$ has no zero in the half-plane $\mathrm{Re}\, s > \theta$.

Thus $G(y)/y$ is the Riesz mean of order one of the series $\sum_n \Lambda(n) n^{-1}$ with its main term removed [117]; $G(y)$ is the von Mangoldt sum of length y of [4] (item 5 of the list on pp. 3–4), namely $\sum_{n \leq y} \Lambda(n)(y/n - 1) - y \log y + (1+\gamma)y$. The reader should think of a character level as a finite set of primitive characters, closed under complex conjugation, together with the weights with which their twists are added to G. The proof of Theorem 6.7 uses only the cyclic levels $\mathfrak{L}_\psi$; they have no exceptional character, and K_ψ contains ψ itself.

The results of this section use two features of a level, the positivity of the weights and the closure of K under conjugation (Le1). The value $(3o+1)^{-1}$ of the weights plays no role here. It is the weight that the top set of a host produces in Section 3, through condition (Ec4) of Definition 3.16 and Lemma 3.17.

Proposition 2.2. *Let $\mathfrak{L}$ be a character level and let $\lambda > 1$. Suppose that there are $c \in \mathbb{R}$ and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there are a set $W \subseteq \mathbb{R}$ and a real number $x_1 \geq 1$ with the following two properties:*

1. *for every $y \geq 1$ there is $Y \geq y$ with $[Y, Y^\lambda] \subseteq W$;*
2. *$G_{\mathfrak{L}}(x) \leq x^{1/2 + c\varepsilon}$ for every $x \in W$ with $x \geq x_1$.*

Then $\mathfrak{L}$ is zero-free above $\frac{1}{2}$. In particular, if $\psi \in \mathcal{P}$ and the cyclic level $\mathfrak{L}_\psi$ satisfies this hypothesis, then $L(s,\psi) \neq 0$ for every s with $\mathrm{Re}\, s > \frac{1}{2}$.

Proof. Let $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o)$, let $\psi \in K$ and let $s \in \mathbb{C}$ with $\mathrm{Re}\, s > \frac{1}{2}$. Put

$$m = \min(\mathrm{Re}\, s - \tfrac{1}{2}, \tfrac{1}{2}) > 0, \qquad \theta = \tfrac{1}{2} + \tfrac{m}{2}.$$

Then $0 < \theta \leq \frac{3}{4} < 1$ and $\theta < \mathrm{Re}\, s$. Choose $\varepsilon = \min(\varepsilon_0/2,\ m/(2(|c|+1)))$; then $0 < \varepsilon < \varepsilon_0$ and $c\varepsilon \leq |c|\varepsilon \leq m/2$. Let W and $x_1 \geq 1$ be as in the hypothesis for this ε.

Let $y \geq 1$. By property 1 there is $Y \geq \max(y, x_1)$ with $[Y, Y^\lambda] \subseteq W$. For $x \in [Y, Y^\lambda]$ we have $x \in W$ and $x \geq x_1 \geq 1$, so by property 2

$$G_{\mathfrak{L}}(x) \leq x^{1/2 + c\varepsilon} \leq x^{\theta},$$

since $x \geq 1$ and $\frac{1}{2} + c\varepsilon \leq \frac{1}{2} + \frac{m}{2} = \theta$. Thus the hypothesis of Proposition 2.4 holds for $\mathfrak{L}$, λ and θ, and $\mathfrak{L}$ is zero-free above θ. As $\operatorname{Re} s > \theta$, $L(s,\psi) \neq 0$. Since $\psi \in K$ and s were arbitrary, $\mathfrak{L}$ is zero-free above $\frac{1}{2}$.

For the last assertion, $\psi = (\psi^1)^* \in K_\psi$, so the zero-freeness of $\mathfrak{L}_\psi$ above $\frac{1}{2}$ gives the claim for $L(s,\psi)$. □

Definition 2.3. Let $f\colon [0,\infty) \to \mathbb{R}$ be a measurable function, $\widehat{f}\colon \mathbb{C} \to \mathbb{C}$ a function and $\mathcal{Z} \subset \mathbb{C}$ a set. The triple $(f, \widehat{f}, \mathcal{Z})$ is **Laplace pole data** if:

(LP1) there is $C_0 \geq 0$ with $|f(u)| \leq C_0 e^{2u}$ for all $u \geq 0$;

(LP2) $\widehat{f}(s) = \int_0^\infty f(u) e^{-su}\, du$ for every s with $\operatorname{Re} s > 2$;

(LP3) every $\rho \in \mathcal{Z}$ has $\operatorname{Re}\rho > 0$, and $\widehat{f}$ is holomorphic on $\{s : \operatorname{Re} s > 0\} \setminus \mathcal{Z}$;

(LP4) $\mathcal{Z}$ has no accumulation point in $\{s : \operatorname{Re} s > 0\}$;

(LP5) every $\rho \in \mathcal{Z}$ is a simple pole of $\widehat{f}$ with nonzero residue c_ρ, that is, $\widehat{f}(s) - c_\rho/(s-\rho)$ agrees on a punctured neighbourhood of ρ with a function holomorphic at ρ; and if ρ is real, then c_ρ is real and $c_\rho > 0$.

The values of $\widehat{f}$ at the points of $\mathcal{Z}$ and in $\operatorname{Re} s \leq 0$ play no role.

Let $\theta \in \mathbb{R}$ and $\lambda > 1$. A measurable function $f\colon [0,\infty) \to \mathbb{R}$ has **integrated window bounds of exponent θ and ratio λ** if for every $\eta > 0$ and every $U_0 \geq 0$ there are $U \geq U_0$ and a function $R\colon [U, \lambda U] \to [0,\infty)$ such that $u \mapsto R(u)e^{-\theta u}$ is integrable on $[U,\lambda U]$, $f(u) \leq R(u)$ for all $u \in [U,\lambda U]$, and

$$\int_U^{\lambda U} R(u)\, e^{-\theta u}\, du \leq e^{\eta U}.$$

Proposition 2.4. *Let $\mathfrak{L}$ be a character level, let $\lambda > 1$ and let $0 < \theta < 1$. Suppose that for every $y \geq 1$ there is $Y \geq y$ such that*

$$G_{\mathfrak{L}}(x) \leq x^\theta \qquad \text{for all } x \in [Y, Y^\lambda].$$

Then $\mathfrak{L}$ is zero-free above θ.

Proof. Let $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o)$ and $f(u) = G_{\mathfrak{L}}(e^u)$ for $u \geq 0$.

The window hypothesis gives integrated window bounds. Let $\eta > 0$ and $U_0 \geq 0$. Since $\log Y = o(Y^\eta)$, there is $Y_1 \geq 1$ with $(\lambda-1)\log Y \leq Y^\eta$ for all $Y \geq Y_1$. By hypothesis there is $Y \geq \max(e^{U_0}, Y_1)$ with $G_{\mathfrak{L}}(x) \leq x^\theta$ on $[Y, Y^\lambda]$. Put $U = \log Y \geq U_0$ and $R(u) = e^{\theta u} \geq 0$ on $[U,\lambda U]$. For $u \in [U,\lambda U]$ we have $e^u \in [Y, Y^\lambda]$, so $f(u) \leq R(u)$, and

$$\int_U^{\lambda U} R(u) e^{-\theta u}\, du = (\lambda-1)U = (\lambda-1)\log Y \leq Y^\eta = e^{\eta U}.$$

So f has integrated window bounds of exponent θ and ratio λ. (In the multiplicative variable this is $\int_Y^{Y^\lambda} x^\theta\, x^{-\theta-1}\, dx = (\lambda-1)\log Y$.)

Zeros of the L-functions of the level. By Proposition 2.5 there is $\widehat{f}$ such that $(f, \widehat{f}, \mathcal{Z}_{\mathfrak{L}})$ is Laplace pole data, where $\mathcal{Z}_{\mathfrak{L}}$ is the set of zeros with positive real part of the functions $L(s,\psi)$, $\psi \in K$. By Proposition 2.7, $\operatorname{Re}\rho \leq \theta$ for every $\rho \in \mathcal{Z}_{\mathfrak{L}}$.

Conclusion. Let $\psi \in K$ and let s satisfy $\operatorname{Re} s > \theta$ and $L(s,\psi) = 0$. Then $\operatorname{Re} s > \theta > 0$, so $s \in \mathcal{Z}_{\mathfrak{L}}$ and $\operatorname{Re} s \le \theta$, a contradiction. Hence $\mathfrak{L}$ is zero-free above θ.

Remarks. The classical theorem of Landau in this setting (bound for all large x, [157], [180]) is the special case in which every Y works. Only two features of a level are used, both through Proposition 2.5: the positivity of the weights and the closure of K under conjugation (Le1). The statement holds for every character level, with or without an exceptional character, and the value $(3o+1)^{-1}$ of the weights plays no role here. □

Proposition 2.5. *Let $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o)$ be a character level, put $f(u) = G_{\mathfrak{L}}(e^u)$ for $u \ge 0$, and let $\mathcal{Z}_{\mathfrak{L}}$ be the set of $\rho \in \mathbb{C}$ with $\operatorname{Re}\rho > 0$ such that $L(\rho,\psi) = 0$ for some $\psi \in K$. Then there is a function $\widehat{f}$ such that $(f, \widehat{f}, \mathcal{Z}_{\mathfrak{L}})$ is Laplace pole data, and its residue at $\rho \in \mathcal{Z}_{\mathfrak{L}}$ is*

$$c_\rho = \frac{S(\rho)}{\rho(1-\rho)}, \qquad S(\rho) = \sum_{\psi \in K} \frac{\tilde{w}(\psi)}{2}\bigl(m(\rho,\psi) + m(\rho,\overline{\psi})\bigr) > 0,$$

where $\tilde{w}(\mathbf{1}) = 1$, $\tilde{w}(\psi) = w_{\mathfrak{L}}(\psi)$ for $\psi \ne \mathbf{1}$, and $m(\rho,\psi) \ge 0$ is the order of vanishing of $L(s,\psi)$ at $s = \rho$.

Proof. Since $g(y,\mathbf{1}) = G(y)$ is real, (2.3) reads $G_{\mathfrak{L}}(y) = \sum_{\psi\in K} \tilde{w}(\psi) \operatorname{Re} g(y,\psi)$, and $\tilde{w}(\psi) > 0$ for all $\psi \in K$.

Conjugation. For every $\psi \in \mathcal{P}$ and $s \in \mathbb{C}$ we have $L(\overline{s},\overline{\psi}) = \overline{L(s,\psi)}$: both sides are meromorphic in s and agree for $\operatorname{Re} s > 1$ by the Dirichlet series. Hence $L'(1,\overline{\psi}) = \overline{L'(1,\psi)}$, and since $\overline{\psi(n)} = \overline{\psi}(n)$, (2.2) gives $\overline{g(y,\psi)} = g(y,\overline{\psi})$ for $y > 0$ (also for $\psi = \mathbf{1} = \overline{\mathbf{1}}$). Consequently

$$f(u) = \sum_{\psi \in K} \frac{\tilde{w}(\psi)}{2}\bigl(g(e^u,\psi) + g(e^u,\overline{\psi})\bigr) \qquad (u \ge 0). \tag{2.4}$$

The same identity shows that $L(\rho,\overline{\psi}) = 0$ if and only if $L(\overline{\rho},\psi) = 0$; by (Le1), $\overline{\psi} \in K$ whenever $\psi \in K$.

The function $\widehat{f}$. Put

$$\widehat{f}(s) = \sum_{\psi \in K} \frac{\tilde{w}(\psi)}{2}\bigl(\widehat{g}(s,\psi) + \widehat{g}(s,\overline{\psi})\bigr),$$

a meromorphic function on $\mathbb{C}$ (its values at poles are irrelevant). We check (LP1)–(LP5).

(LP1) and measurability. By part 1 of Lemma 2.6 and (2.4), f is measurable and $|f(u)| \le \sum_{\psi\in K} \tilde{w}(\psi) C_\psi\, e^{2u}$ for $u \ge 0$, because $|\operatorname{Re} g| \le |g|$.

(LP2). For $\operatorname{Re} s > 2$ the substitution $y = e^u$ gives $\int_0^\infty f(u) e^{-su}\,du = \int_1^\infty G_{\mathfrak{L}}(y)\, y^{-s-1}\,dy$. By (2.4) and part 2 of Lemma 2.6 (absolute convergence, applied to ψ and to $\overline{\psi}$, which is primitive), this equals $\widehat{f}(s)$.

(LP3) and (LP4). Every $\rho \in \mathcal{Z}_{\mathfrak{L}}$ has $\operatorname{Re}\rho > 0$ by definition. By part 3 of Lemma 2.6, $\widehat{g}(\cdot,\psi)$ and $\widehat{g}(\cdot,\overline{\psi})$ are holomorphic off $\{0\} \cup \mathcal{Z}_\psi \cup \mathcal{Z}_{\overline{\psi}}$; a point of $\mathcal{Z}_{\overline{\psi}}$ with positive real part lies in $\mathcal{Z}_{\mathfrak{L}}$ because $\overline{\psi} \in K$. So $\widehat{f}$ is holomorphic on $\{\operatorname{Re} s > 0\} \setminus \mathcal{Z}_{\mathfrak{L}}$. Moreover $\mathcal{Z}_{\mathfrak{L}} \subseteq \bigcup_{\psi\in K} \mathcal{Z}_\psi$, a finite union of sets without accumulation points.

(LP5). Let $\rho \in \mathcal{Z}_{\mathfrak{L}}$. Then $\rho \ne 0$, and $\rho \ne 1$ since $1 \notin \mathcal{Z}_\psi$. By part 3 of Lemma 2.6, for each $\chi \in \{\psi, \overline{\psi}\}$ the function $\widehat{g}(s,\chi) + \frac{m(\rho,\chi)}{\rho(\rho-1)} \cdot \frac{1}{s-\rho}$ is holomorphic at ρ (if $m(\rho,\chi) = 0$, then $\rho \notin \mathcal{Z}_\chi$ and $\widehat{g}(\cdot,\chi)$ itself is holomorphic at ρ). Summing with the weights, $\widehat{f}(s) - c_\rho/(s-\rho)$ is holomorphic at ρ, with

$$c_\rho = -\frac{S(\rho)}{\rho(\rho-1)} = \frac{S(\rho)}{\rho(1-\rho)}.$$

All terms of $S(\rho)$ are ≥ 0, and $m(\rho,\psi) \geq 1$ for some $\psi \in K$ because $\rho \in \mathcal{Z}_{\mathfrak{L}}$; as $\tilde{w}(\psi) > 0$, $S(\rho) > 0$, and $c_\rho \neq 0$ since $\rho \neq 0, 1$. If ρ is real, then $0 < \rho < 1$, because no $L(s,\psi)$ with $\psi \in K$ vanishes at a real $s \geq 1$: for real $s > 1$ the Euler product of $L(s,\psi)$ converges absolutely and its factors $(1-\psi(p)p^{-s})^{-1}$ are non-zero, and $s = 1$ is excluded by $1 \notin \mathcal{Z}_\psi$ (part 3 of Lemma 2.6). Only real points $s \geq 1$ are needed here, not the line $\operatorname{Re} s = 1$. Hence $\rho(1-\rho) > 0$ and c_ρ is real and positive.

The role of positivity. The positivity of the weights $\tilde{w}(\psi)$ is used only for $S(\rho) > 0$: it prevents the poles contributed by different characters at a common zero from cancelling, and it gives the residue at a real zero the sign of $\rho(1-\rho) > 0$. No sign of the Dirichlet coefficients $\Lambda(n)\sum_{\psi\in K}\tilde{w}(\psi)\operatorname{Re}\psi(n)$ is used. □

Lemma 2.6. *Let $\psi \in \mathcal{P}$, and define meromorphic functions on $\mathbb{C}$ by*

$$\widehat{g}(s,\psi) = -\frac{1}{s(s-1)}\Big(\frac{L'(s,\psi)}{L(s,\psi)} - s\,\frac{L'(1,\psi)}{L(1,\psi)}\Big) \quad (\psi \neq \mathbf{1}),$$
$$\widehat{g}(s,\mathbf{1}) = -\frac{1}{s(s-1)}\Big(\frac{\zeta'(s)}{\zeta(s)} + \frac{1}{s-1} + 1 - (1+\gamma)s\Big).$$

Let $\mathcal{Z}_\psi$ be the set of zeros of $L(s,\psi)$ in $\mathbb{C}$ (for $\psi = \mathbf{1}$, the zeros of $\zeta(s)$).

1. *The function $y \mapsto g(y,\psi)$ is measurable on $[1,\infty)$, and there is $C_\psi \geq 0$ with $|g(y,\psi)| \leq C_\psi y^2$ for all $y \geq 1$.*
2. *For $\operatorname{Re} s > 1$ the integral $\int_1^\infty g(y,\psi)\,y^{-s-1}\,dy$ converges absolutely and equals $\widehat{g}(s,\psi)$.*
3. *The singularity of $\widehat{g}(\cdot,\psi)$ at $s = 1$ is removable, $1 \notin \mathcal{Z}_\psi$, the set $\mathcal{Z}_\psi$ has no accumulation point in $\mathbb{C}$, and $\widehat{g}(\cdot,\psi)$ is holomorphic on $\mathbb{C}\setminus(\{0\}\cup\mathcal{Z}_\psi)$. At every $\rho \in \mathcal{Z}_\psi \setminus \{0\}$ it has a simple pole with residue $-m/(\rho(\rho-1))$, where $m \geq 1$ is the order of the zero of $L(s,\psi)$ at ρ.*

Proof. Part 1. The function $g(\cdot,\psi)$ is continuous on each interval $[n, n+1)$, hence measurable. For $1 \leq n \leq y$ we have $0 \leq \Lambda(n) \leq \log n \leq n$, $|\psi(n)| \leq 1$ and $0 \leq y/n - 1 \leq y/n$, so each of the at most y terms of the sum in (2.2) (or (2.1)) has absolute value at most y, and the sum is at most y^2 in absolute value. For the trivial character the main terms are bounded by $y\log y \leq y^2$ and $|1+\gamma|y \leq |1+\gamma|y^2$; otherwise the main term is bounded by $|L'(1,\psi)/L(1,\psi)|\,y^2$.

Part 2. For an integer $n \geq 1$ and $\operatorname{Re} s > 1$,

$$\int_1^\infty \max\Big(\frac{y}{n} - 1, 0\Big)y^{-s-1}\,dy = \int_n^\infty \Big(\frac{y^{-s}}{n} - y^{-s-1}\Big)dy = \frac{n^{-s}}{s-1} - \frac{n^{-s}}{s} = \frac{n^{-s}}{s(s-1)}. \tag{2.5}$$

The sum in (2.2) equals $\sum_{n\geq 1}\Lambda(n)\psi(n)\max(y/n-1,0)$, the terms with $n > y$ being zero. By (2.5) with s replaced by $\sigma = \operatorname{Re} s$,

$$\sum_n \Lambda(n)\int_1^\infty \max(y/n-1,0)\,y^{-\sigma-1}dy = \sigma^{-1}(\sigma-1)^{-1}\sum_n \Lambda(n)n^{-\sigma} < \infty,$$

so the series can be integrated term by term (dominated convergence), and the integral converges absolutely. Using $-L'(s,\psi)/L(s,\psi) = \sum_n \Lambda(n)\psi(n)n^{-s}$ for $\operatorname{Re} s > 1$ [180] (for $\psi = \mathbf{1}$ this is $-\zeta'/\zeta$),

$$\int_1^\infty \sum_{n\leq y}\Lambda(n)\psi(n)\Big(\frac{y}{n} - 1\Big)y^{-s-1}\,dy = -\frac{1}{s(s-1)}\,\frac{L'(s,\psi)}{L(s,\psi)}.$$

The main terms contribute, by $\int_1^\infty y^{-s}\,dy = 1/(s-1)$ and (integrating by parts) $\int_1^\infty (\log y)\,y^{-s}\,dy = 1/(s-1)^2$: for $\psi \neq \mathbf{1}$, $\frac{L'(1,\psi)}{L(1,\psi)} \cdot \frac{1}{s-1} = \frac{s}{s(s-1)}\frac{L'(1,\psi)}{L(1,\psi)}$; for $\psi = \mathbf{1}$, $-\frac{1}{(s-1)^2} + \frac{1+\gamma}{s-1} = \frac{1}{s(s-1)}\big(-\frac{s}{s-1} + (1+\gamma)s\big)$, and $\frac{s}{s-1} = 1 + \frac{1}{s-1}$. Adding gives $\widehat{g}(s,\psi)$.

Part 3. Put $L^\circ(s) = L(s,\psi)$ and $\delta = 0$ if $\psi \neq \mathbf{1}$, and $L^\circ(s) = (s-1)\zeta(s)$ and $\delta = 1$ if $\psi = \mathbf{1}$. Then L° is entire and $L^\circ(1) \neq 0$. Indeed, a primitive character $\psi \neq \mathbf{1}$ is non-principal (a principal character of modulus $N > 1$ is induced by $\mathbf{1}$, hence not primitive), so $L(s,\psi)$ is entire [180] and $L(1,\psi) \neq 0$ by Dirichlet's theorem [75]. Near $s = 1$ we have $\zeta(s) = \frac{1}{s-1} + \gamma + O(s-1)$ [180], [260], so that $(s-1)\zeta(s)$ extends to an entire function with value 1 and derivative γ at $s = 1$. In both cases

$$\widehat{g}(s,\psi) = -\frac{N(s)}{s(s-1)}, \qquad N(s) = \frac{L^{\circ\prime}(s)}{L^\circ(s)} - s\,\frac{L^{\circ\prime}(1)}{L^\circ(1)} + \delta(1-s).$$

The function N is meromorphic, holomorphic wherever $L^\circ \neq 0$, in particular near $s = 1$, and $N(1) = 0$. Hence $N(s)/(s-1)$ has a removable singularity at $s = 1$, and $\widehat{g}(\cdot,\psi)$ is holomorphic off $\{0\}$ and the zeros of L°. These zeros are exactly $\mathcal{Z}_\psi$ (for $\psi = \mathbf{1}$ the factor $s-1$ adds no zero, the value at 1 being 1), and $1 \notin \mathcal{Z}_\psi$. Since L° is entire and not identically zero, its zeros have no accumulation point. If $\rho \in \mathcal{Z}_\psi$ has order m, write $L^\circ(s) = (s-\rho)^m h(s)$ with h holomorphic and $h(\rho) \neq 0$; then $L^{\circ\prime}/L^\circ = m/(s-\rho) + h'/h$, so near ρ the function $N(s) - m/(s-\rho)$ is holomorphic. For $\rho \neq 0$ (and $\rho \neq 1$) the factor $-1/(s(s-1))$ is holomorphic at ρ with value $-1/(\rho(\rho-1))$, so $\widehat{g}(s,\psi) - \frac{-m/(\rho(\rho-1))}{s-\rho}$ is holomorphic at ρ. □

Proposition 2.7. *Let $(f, \widehat{f}, \mathcal{Z})$ be Laplace pole data, let $0 < \theta < 1$ and $\lambda > 1$, and suppose that f has integrated window bounds of exponent θ and ratio λ. Then $\operatorname{Re}\rho \le \theta$ for every $\rho \in \mathcal{Z}$.*

Proof. Suppose, to the contrary, that some $\rho_0 \in \mathcal{Z}$ has $\operatorname{Re}\rho_0 > \theta$. For an integer $k \ge 0$ write $A_k(s) = (-1)^k \widehat{f}^{(k)}(s)/k!$ wherever $\widehat{f}$ is holomorphic near s. Let $\sigma > 2$ and C_2 be as in Lemma 2.10; since $\widehat{f}$ coincides with the Laplace integral of f on the open half-plane $\operatorname{Re} s > 2$ by (LP2), that lemma applies to the derivatives of $\widehat{f}$ at σ and $\sigma + i\gamma$. By Lemma 2.8, $\operatorname{Re}\rho \le 2 < \sigma$ for every $\rho \in \mathcal{Z}$. We use three elementary facts.

(C) Cauchy's estimate. If $\widehat{f}$ is holomorphic on $B(z,r)$ and $0 < r' < r$, then $|A_k(z)| \le M r'^{-k}$ for all k, with $M = \max_{|s-z|=r'} |\widehat{f}(s)|$.

(P) Coefficients near a simple pole. Let $\rho \in B(z,r)$, $\rho \neq z$, let $\widehat{f}$ be holomorphic on $B(z,r) \setminus \{\rho\}$ and let $\widehat{f}(s) - c/(s-\rho)$ agree near ρ with a function holomorphic at ρ. Then $\widehat{f}(s) - c/(s-\rho)$ extends holomorphically to $B(z,r)$, and the k-th Taylor coefficient of $c/(s-\rho)$ at z is $-c/(\rho-z)^{k+1}$. By (C), for every $r' \in (0,r)$ there is M with

$$\Big|A_k(z) - \frac{c}{(z-\rho)^{k+1}}\Big| \le M r'^{-k} \qquad \text{for all } k.$$

(G) Growth. Let $0 < d < e \le E$, $c > 0$ and $M, C \in \mathbb{R}$. It is impossible that for every $\eta > 0$ and every U_0 there are $U \ge U_0$ and an integer $k \ge U$ with

$$c\,d^{-k} \le M e^{-k} + C\,e^{\eta U} E^{-k}.$$

Indeed, take $\eta = \frac{1}{2}\log(e/d) > 0$ and $U_0 \ge 0$. Then $e^{\eta U} \le e^{\eta k} = (e/d)^{k/2}$ and $E^{-k} \le e^{-k}$, so the inequality gives $c \le (|M| + |C|)(e/d)^{k/2}(d/e)^k = (|M| + |C|)(d/e)^{k/2}$ with $k \ge U_0$ arbitrarily large, whence $c \le 0$.

The set $\mathcal{Z}$ has no accumulation point in $\operatorname{Re} s > 0$ by (LP4), so Lemma 2.9 applies with $\theta < \sigma$ and ρ_0. All discs below have radius at most $\sigma - \theta < \sigma$ and centre on the line $\operatorname{Re} s = \sigma$, so they lie in $\operatorname{Re} s > 0$, where $\widehat{f}$ is holomorphic off $\mathcal{Z}$ by (LP3).

Case 2 of Lemma 2.9: the nearest singularity is real. There are a real $\beta \in \mathcal{Z}$ with $\theta < \beta < \sigma$ and r with $\sigma - \beta < r \le \sigma - \theta$ such that β is the only point of $\mathcal{Z}$ in $B(\sigma, r)$. By (LP5) the residue c_β is real and positive. Apply (P) with $z = \sigma$, $\rho = \beta$ and $r' = (\sigma - \beta + r)/2$: since $c_\beta(\sigma-\beta)^{-k-1}$ is real,

$$A_k(\sigma) \ge \frac{c_\beta}{\sigma - \beta}(\sigma - \beta)^{-k} - M r'^{-k} \qquad \text{for all } k.$$

Given $\eta > 0$ and U_0, Lemma 2.10 with $\gamma = 0$ gives $U \ge U_0$ and $k \ge U$ with $A_k(\sigma) \le |A_k(\sigma)| + A_k(\sigma) \le C_2 e^{\eta U}(\sigma - \theta)^{-k}$. Hence

$$\frac{c_\beta}{\sigma - \beta}(\sigma - \beta)^{-k} \le M r'^{-k} + C_2 e^{\eta U}(\sigma - \theta)^{-k},$$

which contradicts (G) with $d = \sigma - \beta < e = r' < E = \sigma - \theta$.

Case 1 of Lemma 2.9: the nearest singularity is not real. There is $D \le \sigma - \theta$ such that $B(\sigma, D)$ contains no point of $\mathcal{Z}$, and there are $\gamma \in \mathbb{R}$, $\rho \in \mathcal{Z}$ and $r \le D$ such that, with $z = \sigma + i\gamma$ and $d = |z - \rho|$, we have $d < r$ and ρ is the only point of $\mathcal{Z}$ in $B(z, r)$. Moreover, $d > 0$ because $\operatorname{Re}\rho < \sigma$. Put $r' = (d + r)/2$, so $d < r' < r \le D$. By (P) at z there is M with $|A_k(z)| \ge |c_\rho| d^{-k-1} - M r'^{-k}$, and by (C) at σ, applied on $B(\sigma, D)$, there is M' with $|A_k(\sigma)| \le M' r'^{-k}$, for all k. Given $\eta > 0$ and U_0, Lemma 2.10 gives $U \ge U_0$ and $k \ge U$ with

$$|A_k(z)| \le C_2 e^{\eta U}(\sigma - \theta)^{-k} - A_k(\sigma) \le C_2 e^{\eta U}(\sigma - \theta)^{-k} + M' r'^{-k}.$$

Hence $\frac{|c_\rho|}{d} d^{-k} \le (M + M') r'^{-k} + C_2 e^{\eta U}(\sigma - \theta)^{-k}$, with $|c_\rho| > 0$ by (LP5). This contradicts (G) with $d < e = r' < E = \sigma - \theta$.

Both cases are impossible, so $\operatorname{Re}\rho \le \theta$ for all $\rho \in \mathcal{Z}$.

Relation to Landau's theorem. Landau's theorem [157] (see [133], [180]) states that a Laplace integral of an eventually non-negative function has a singularity at the real point of its abscissa of convergence; its proof expands at a real point σ and uses $f \ge 0$ to continue the Taylor series to the left. The argument above never continues the Laplace integral to the left of $\operatorname{Re} s = 2$: the hypothesis holds only on the windows $[U, \lambda U]$, so it compares single Taylor coefficients instead. A singularity at distance d from a point of the line $\operatorname{Re} s = \sigma$ forces coefficients of size d^{-k} there, while Lemma 2.10, for $k \approx \frac{1+\lambda}{2}\sigma U$, bounds them by $e^{\eta U}(\sigma - \theta)^{-k}$. If the singularity nearest to σ is real, the positivity of its residue gives the real coefficient $A_k(\sigma)$ a definite sign (case 2); otherwise the coefficient at σ is negligible and the coefficient at a point $\sigma + i\gamma$ near the singularity is large (case 1). Positivity of residues at real poles thus replaces the non-negativity of f. □

Lemma 2.8. *Let $f\colon [0, \infty) \to \mathbb{R}$ be measurable with $|f(u)| \le C_0 e^{2u}$ for all $u \ge 0$. Then $F(s) = \int_0^\infty f(u) e^{-su}\, du$ converges absolutely and is holomorphic in $\operatorname{Re} s > 2$, $|F(s)| \le C_0/(\sigma - 2)$ whenever $\operatorname{Re} s \ge \sigma > 2$, and for every integer $k \ge 0$*

$$\frac{(-1)^k F^{(k)}(s)}{k!} = \int_0^\infty f(u)\, \frac{u^k}{k!}\, e^{-su}\, du \qquad (\operatorname{Re} s > 2).$$

If $(f, \widehat{f}, \mathcal{Z})$ is Laplace pole data, then $\widehat{f} = F$ on $\operatorname{Re} s > 2$, so $\widehat{f}$ satisfies the same identity there, and every $\rho \in \mathcal{Z}$ has $\operatorname{Re}\rho \le 2$.

Proof. Let $b > 0$. For $\operatorname{Re} z \ge 2 + b$ and $u > 0$,

$$\left| f(u)(-u)^k e^{-zu} \right| \le C_0\, u^k e^{-bu},$$

which is integrable on $(0,\infty)$. Hence all the integrals $\int_0^\infty f(u)(-u)^k e^{-zu}\,du$ converge absolutely in $\operatorname{Re} z > 2$, and differentiation under the integral sign (dominated convergence, with the dominating function $C_0 u^{k+1} e^{-bu}$ on the half-plane $\operatorname{Re} z \geq 2+b$, $b = (\operatorname{Re} s - 2)/2$) shows that the k-th integral is holomorphic with derivative the $(k+1)$-st. By induction $F^{(k)}(s) = \int_0^\infty f(u)(-u)^k e^{-su}\,du$, which is the displayed identity. For $\operatorname{Re} s \geq \sigma > 2$,

$$|F(s)| \leq \int_0^\infty C_0 e^{2u} e^{-\sigma u}\,du = \frac{C_0}{\sigma - 2}.$$

Now let $(f, \widehat{f}, \mathcal{Z})$ be Laplace pole data. By (LP2) $\widehat{f} = F$ on the open half-plane $\operatorname{Re} s > 2$, so the derivatives agree there. Suppose $\rho \in \mathcal{Z}$ had $\operatorname{Re}\rho > 2$, and put $\sigma' = (2 + \operatorname{Re}\rho)/2$. On a neighbourhood of ρ contained in $\operatorname{Re} s > \sigma'$ we have $|\widehat{f}(s)| \leq C_0/(\sigma' - 2)$, so $(s-\rho)\widehat{f}(s) \to 0$ as $s \to \rho$. By (LP5), however, $(s-\rho)\widehat{f}(s) = c_\rho + (s-\rho)h(s)$ near ρ with h holomorphic at ρ, which tends to $c_\rho \neq 0$. Hence $\operatorname{Re}\rho \leq 2$. □

Lemma 2.9. *Let $\mathcal{Z} \subset \mathbb{C}$ be a set without accumulation points in $\{s \in \mathbb{C} : \operatorname{Re} s > 0\}$, and let $0 < \theta < \sigma$ be real numbers such that $\operatorname{Re}\rho < \sigma$ for every $\rho \in \mathcal{Z}$. Suppose that some $\rho_0 \in \mathcal{Z}$ has $\operatorname{Re}\rho_0 > \theta$. Write $B(z,r)$ for the open disc of centre z and radius r. Then one of the following holds.*

1. *There are $D \leq \sigma - \theta$ with $B(\sigma, D) \cap \mathcal{Z} = \emptyset$, and $\gamma \in \mathbb{R}$, $\rho \in \mathcal{Z}$ and $r \leq D$ such that $|\sigma + i\gamma - \rho| < r$ and $B(\sigma + i\gamma, r) \cap \mathcal{Z} = \{\rho\}$.*
2. *There are a real number $\beta \in \mathcal{Z}$ with $\beta > \theta$ and a real r with $\sigma - \beta < r \leq \sigma - \theta$ such that $B(\sigma, r) \cap \mathcal{Z} = \{\beta\}$.*

Proof. Finiteness. If $z \in \mathbb{C}$ and $0 \leq t < \operatorname{Re} z$, the closed disc $\overline{B}(z,t)$ is a compact subset of $\{\operatorname{Re} s > 0\}$; covering it by neighbourhoods each containing at most one point of $\mathcal{Z}$ shows that $\mathcal{Z} \cap \overline{B}(z,t)$ is finite.

The dichotomy at σ. The set $F = \mathcal{Z} \cap \overline{B}(\sigma, \sigma - \theta)$ is finite, since $\sigma - \theta < \sigma$. We first show that one of the following holds:

(i) there are $D \leq \sigma - \theta$ with $B(\sigma, D) \cap \mathcal{Z} = \emptyset$ and $\rho_1 \in \mathcal{Z}$ with $\sigma - \operatorname{Re}\rho_1 < D$;

(ii) conclusion 2 holds.

If $F = \emptyset$, then (i) holds with $D = \sigma - \theta$ and $\rho_1 = \rho_0$. Otherwise let $d = \min_{w \in F} |w - \sigma| \leq \sigma - \theta$, attained at $\rho_s \in F$; then $B(\sigma, d) \cap \mathcal{Z} = \emptyset$. If some $\rho_1 \in \mathcal{Z}$ has $\sigma - \operatorname{Re}\rho_1 < d$, then (i) holds with $D = d$. Otherwise $\sigma - \operatorname{Re} w \geq d$ for all $w \in \mathcal{Z}$. A point w with $|w - \sigma| \leq d$ and $\sigma - \operatorname{Re} w \geq d$ satisfies $(\operatorname{Re} w - \sigma)^2 + (\operatorname{Im} w)^2 \leq d^2 \leq (\operatorname{Re} w - \sigma)^2$, hence $\operatorname{Im} w = 0$ and $w = \sigma - d$. So $\beta = \sigma - d$ is the only point of F at distance d from σ, and it is real. Moreover $d < \sigma - \theta$: otherwise $\sigma - \operatorname{Re}\rho_0 \geq d = \sigma - \theta$, contradicting $\operatorname{Re}\rho_0 > \theta$. Hence $\beta > \theta$. Let $r_1 > d$ be the least distance from σ of a point of $F \setminus \{\beta\}$ (or $r_1 = d + 1$ if there is none) and $r = \min(r_1, \sigma - \theta)$. Then $\sigma - \beta = d < r \leq \sigma - \theta$, and every point of $\mathcal{Z}$ in $B(\sigma, r)$ lies in F and hence equals β: this is conclusion 2.

From (i) to conclusion 1. Assume (i). Choose $\varepsilon > 0$ with $\varepsilon \leq (D - (\sigma - \operatorname{Re}\rho_1))/2$ and $\varepsilon \leq (\sigma - D)/2$ (note $D < \sigma$), and put $c_0 = \sigma + i \operatorname{Im}\rho_1$. The set $F' = \mathcal{Z} \cap \overline{B}(c_0, D + \varepsilon)$ is finite, since $D + \varepsilon < \sigma = \operatorname{Re} c_0$, and it contains ρ_1 because $|c_0 - \rho_1| = \sigma - \operatorname{Re}\rho_1$. For distinct $a, b \in F'$, the points $\sigma + i\gamma$ equidistant from a and b satisfy

$$2\gamma(\operatorname{Im} a - \operatorname{Im} b) = (\sigma - \operatorname{Re} a)^2 + (\operatorname{Im} a)^2 - (\sigma - \operatorname{Re} b)^2 - (\operatorname{Im} b)^2.$$

If $\operatorname{Im} a = \operatorname{Im} b$ this would force $(\operatorname{Re} b - \operatorname{Re} a)((\sigma - \operatorname{Re} a) + (\sigma - \operatorname{Re} b)) = 0$, impossible since $a \neq b$ and both real parts are below σ; so each pair excludes at most one value of γ. Choose $\gamma \in (\operatorname{Im}\rho_1 - \varepsilon, \operatorname{Im}\rho_1 + \varepsilon)$ outside this finite set of values, and put $z = \sigma + i\gamma$. Then the distances $|z - w|$, $w \in F'$, are pairwise distinct; let $\rho \in F'$ be the nearest point to z. Since $|z-\rho| \le |z-\rho_1| \le |\gamma - \operatorname{Im}\rho_1| + (\sigma - \operatorname{Re}\rho_1) < \varepsilon + (\sigma - \operatorname{Re}\rho_1) < D$, there is $r \le D$ with $|z-\rho| < r$ and $|z - w| \ge r$ for all $w \in F' \setminus \{\rho\}$. A point $w \in \mathcal{Z} \cap B(z, r)$ satisfies $|w - c_0| < r + \varepsilon \le D + \varepsilon$, so $w \in F'$ and hence $w = \rho$. Together with $B(\sigma, D) \cap \mathcal{Z} = \emptyset$ from (i), this is conclusion 1. □

Lemma 2.10. *Let $f\colon [0,\infty) \to \mathbb{R}$ be measurable with $|f(u)| \le C_0 e^{2u}$ for all $u \ge 0$, and let $F(s) = \int_0^\infty f(u)e^{-su}\,du$ for $\operatorname{Re} s > 2$. Let $0 < \theta < 1$ and $\lambda > 1$, and suppose that f has integrated window bounds of exponent θ and ratio λ. Put $l = 2 + 6/(\lambda - 1)$ and $\sigma = l\lambda(l+2)$. Then $\sigma > 2$, and there is $C_2 \ge 0$ such that for every $\eta > 0$ and every $U_0 \in \mathbb{R}$ there are $U \ge U_0$ and an integer $k \ge U$ with*

$$\Big|\frac{F^{(k)}(\sigma + i\gamma)}{k!}\Big| + \frac{(-1)^k F^{(k)}(\sigma)}{k!} \le C_2\,\frac{e^{\eta U}}{(\sigma - \theta)^k} \qquad \text{for every } \gamma \in \mathbb{R};$$

here $(-1)^k F^{(k)}(\sigma)/k!$ is real.

Proof. Let C_1 be the constant attached to λ in Lemma 2.11; we show the claim with $C_2 = 2 + 2C_0C_1$. We have $\sigma > 2 > \theta > 0$. Let $\eta > 0$ and $U_0 \in \mathbb{R}$. The window bound for η and $\max(U_0, 1)$ gives $U \ge \max(U_0, 1)$ and $R\colon [U, \lambda U] \to [0,\infty)$ with $f \le R$ on $[U, \lambda U]$ and $\int_U^{\lambda U} R(u)e^{-\theta u}\,du \le e^{\eta U}$. Since $U \ge 1$, part 2 of Lemma 2.11 gives an integer $k \ge U$ with

$$\int_{(0,\infty)\setminus[U,\lambda U]} K_{k,\sigma-2}(u)\,du \le C_1\sigma^{-k}. \tag{2.6}$$

Reduction to the positive part of f. Put $w = K_{k,\sigma}$ and $A(s) = (-1)^k F^{(k)}(s)/k!$. By Lemma 2.8, for every $\gamma \in \mathbb{R}$,

$$A(\sigma + i\gamma) = \int_0^\infty f(u)\,w(u)\,e^{-i\gamma u}\,du, \qquad A(\sigma) = \int_0^\infty f(u)\,w(u)\,du \in \mathbb{R},$$

the integrals converging absolutely because $|f|w \le C_0 K_{k,\sigma-2}$. As $|A(\sigma + i\gamma)| \le \int_0^\infty |f|w$ and $|f| + f = 2\max(f, 0)$,

$$|A(\sigma + i\gamma)| + A(\sigma) \le \int_0^\infty (|f(u)| + f(u))w(u)\,du = 2\int_0^\infty \max(f(u), 0)\,w(u)\,du. \tag{2.7}$$

This is the only place where the sign of f enters. In Landau's classical argument [157] one has $f \ge 0$, and (2.7) reads $|A(\sigma + i\gamma)| \le A(\sigma)$. Here only the positive part of f has to be controlled, and only where w has its mass.

The window. For $u \in [U, \lambda U]$ we have $0 \le \max(f(u), 0) \le R(u)$, since $f \le R$ and $R \ge 0$, and $w(u) = K_{k,\sigma-\theta}(u)\,e^{-\theta u} \le (\sigma - \theta)^{-k} e^{-\theta u}$ by part 1 of Lemma 2.11. Hence

$$2\int_U^{\lambda U} \max(f, 0)\,w\,du \le 2(\sigma - \theta)^{-k}\int_U^{\lambda U} R(u)e^{-\theta u}\,du \le 2(\sigma - \theta)^{-k}e^{\eta U}.$$

Outside the window. There $\max(f, 0) \le |f| \le C_0 e^{2u}$ and $e^{2u}w(u) = K_{k,\sigma-2}(u)$, so by (2.6)

$$2\int_{(0,\infty)\setminus[U,\lambda U]} \max(f, 0)\,w\,du \le 2C_0C_1\sigma^{-k} \le 2C_0C_1\,e^{\eta U}(\sigma - \theta)^{-k},$$

using $0 < \sigma - \theta < \sigma$ and $e^{\eta U} \ge 1$. Adding the two parts in (2.7) gives the claim with $C_2 = 2 + 2C_0C_1$. □

Lemma 2.11. *For an integer $k \geq 0$ and real $a > 0$ put $K_{k,a}(u) = u^k e^{-au}/k!$ for $u \geq 0$.*

1. *$\int_0^\infty K_{k,a}(u)\,du = a^{-k-1}$, and $0 \leq K_{k,a}(u) \leq a^{-k}$ for all $u \geq 0$.*
2. *Let $\lambda > 1$ and put*

$$l = 2 + \frac{6}{\lambda - 1}, \qquad \sigma = l\lambda(l+2), \qquad C_1 = \frac{e}{\sigma - 2 - l} + \frac{1}{\sigma - 2 + l}.$$

Then $\sigma > 2 + l$, and for every real $U \geq 1$ the integer $k = \lceil (1+\lambda)\sigma U/2 \rceil$ satisfies $k \geq U$ and

$$\int_{(0,\infty)\setminus[U,\lambda U]} K_{k,\sigma-2}(u)\,du \leq C_1\,\sigma^{-k}.$$

Proof. Part 1. The substitution $t = au$ gives $\int_0^\infty u^k e^{-au}\,du = a^{-k-1}\Gamma(k+1) = a^{-k-1}k!$. For $u \geq 0$ the number $(au)^k/k!$ is a term of the series of e^{au}, so $a^k K_{k,a}(u) = (au)^k e^{-au}/k! \leq 1$.

Part 2. The kernel $K_{k,\sigma-2}$ has mass $(\sigma-2)^{-k-1}$ and is concentrated near $u = k/(\sigma-2) \approx \frac{1+\lambda}{2} \cdot \frac{\sigma}{\sigma-2}\,U$, a point inside $[U, \lambda U]$ when σ is large. The claim bounds its mass outside this window explicitly. Write $s = \sigma - 2$ and $V = \lambda U$. Since $l > 2$ and $\lambda > 1$ we have $\sigma > l(l+2)$, so $s - l > l^2 + l - 2 > 0$; in particular $\sigma > 2 + l$. We use the two identities

$$\frac{(1+\lambda)(l+2)}{2} = l\lambda - 1, \qquad \frac{(1+\lambda)(l-2)}{2} = l + 1. \tag{2.8}$$

A Chernoff bound. Let $u > 0$ with $u \notin [U, V]$. Then $l(U-u) \geq 0$ or $l(u-V) \geq 0$, hence

$$e^{-su} \leq e^{-su+l(u-V)} + e^{-su+l(U-u)} = e^{-lV}e^{-(s-l)u} + e^{lU}e^{-(s+l)u}.$$

Multiplying by $u^k/k!$, integrating over $(0,\infty)$ and using part 1 (note $s - l > 0$),

$$\int_{(0,\infty)\setminus[U,V]} K_{k,s}(u)\,du \leq e^{-lV}(s-l)^{-k-1} + e^{lU}(s+l)^{-k-1}. \tag{2.9}$$

Conversion to powers of σ. For $a > 0$ and real x, the inequality $1 + t \leq e^t$ with $t = (\sigma - a)/a$ gives $\sigma/a \leq e^{(\sigma-a)/a}$, hence

$$e^x a^{-k-1} = e^x \Big(\frac{\sigma}{a}\Big)^k a^{-1}\sigma^{-k} \leq e^{x+k(\sigma-a)/a}\,a^{-1}\sigma^{-k}. \tag{2.10}$$

First term of (2.9). Here $x = -lV = -l\lambda U$ and $a = s - l = \sigma - 2 - l = (l\lambda - 1)(l+2)$, so $(\sigma - a)/a = (l+2)/a = 1/(l\lambda - 1)$. By the first identity of (2.8), $(1+\lambda)\sigma/2 = (l\lambda - 1)\,l\lambda$, so $k \leq (1+\lambda)\sigma U/2 + 1 = (l\lambda - 1)l\lambda U + 1$ and $k/(l\lambda - 1) \leq l\lambda U + 1$ (as $l\lambda - 1 \geq 1$). The exponent in (2.10) is therefore at most 1, and the first term is at most $e\,(\sigma - 2 - l)^{-1}\sigma^{-k}$.

Second term of (2.9). Here $x = lU$ and $a = s + l = \sigma - 2 + l$, so $(\sigma - a)/a = -(l-2)/(\sigma - 2 + l)$. By the second identity of (2.8), $k(l-2) \geq (1+\lambda)\sigma U(l-2)/2 = (l+1)\sigma U$; and $l(\sigma - 2 + l) \leq (l+1)\sigma$, since this is equivalent to $l^2 - 2l \leq \sigma$, which holds because $\sigma > l(l+2)$. Hence $k(l-2)/(\sigma - 2 + l) \geq lU$, the exponent in (2.10) is at most 0, and the second term is at most $(\sigma - 2 + l)^{-1}\sigma^{-k}$.

Adding the two bounds gives the claimed inequality with $s = \sigma - 2$. Finally $k \geq (1+\lambda)\sigma U/2 \geq U$ because $\sigma > 2$ and $\lambda > 1$. □

3 Hosts, inert prime sums and the excess

Sections 4 and 5 bound a sum over primes from above. Section 2 needs an upper bound for $G_{\mathfrak{L}}$ at one point x. This section proves the step from the first to the second, Proposition 3.3, and introduces the hosts to which it is applied. Both are used in the proof of Proposition 6.5 in Section 6.

The sum over primes is the inert prime sum of an arithmetic datum on a finite abelian group H (Definition 3.1). It is a weighted sum of $\log p$ over the prime powers whose Frobenius element lies outside a subgroup Φ of index two, and its excess $\Delta(u)$ is what remains after its main term is subtracted and the result is summed over a set T of tops and over m weight functions. Proposition 3.3 says that a bound for $\Delta(u)$ at the translates u of a subgroup $A_0 \subseteq H$ gives a bound from above for a weighted sum of twisted Riesz-weighted Chebyshev functions at x, up to the absolute values of finitely many further twists.

The proof rests on two averages. By orthogonality of characters, the excess is a combination of the twisted functions at the cut-offs $a/w(\rho)$, $\rho \in \Phi$ (Lemma 3.8). The weights are close to b at the thick places, which move with the translate u, and small at the other places (Definition 3.2). The average over $u \in A_0$ therefore keeps the characters that are trivial on A_0, at the cut-offs a_t/b (Lemma 3.7). The sum over the tops $t \in T$ then gives each of these characters its weight; it is carried out together with the routine step that moves the cut-offs a_t/b, which lie within 1 of x, to x (Lemma 3.6, Lemma 3.4). The errors are absorbed under the size conditions (Lemma 3.10).

For a host the conclusion is a bound for $G_{\mathfrak{L}}(x)$. The arithmetic datum of a host is of host type (Lemma 3.12), its twisted functions are those of the primitive Dirichlet characters of the host (Lemma 3.18), and under the host conditions the weighted sum is $G_{\mathfrak{L}}$ and the further twists contribute at most $4o\,x^{1/2+\varepsilon}$ (Lemma 3.17).

The section also states the definitions of slope data, slope conditions and size conditions, because the notion of a core-tied host (Definition 3.16) refers to them. Nothing is proved about them here; Section 4 reads them.

Definition 3.1. Let H be a finite abelian group and $\Gamma_H = (\mathbb{Z}/2)^2 \times H$, written additively with elements $((\epsilon,\epsilon'),h)$. Let $\Phi \subset \Gamma_H$ be the subgroup of elements whose first $\mathbb{Z}/2$-coordinate ϵ is 0; it has index 2, so $|\Phi| = 2|H|$ and $|\Gamma_H \setminus \Phi| = |\Phi|$. Put $c_\infty = ((1,1),0)$, and for $t \in H$ let $\sigma_t\colon \Gamma_H \to \Gamma_H$ be the translation $\sigma_t(g) = c_\infty + g + ((0,0),t)$; it maps $\Gamma_H \setminus \Phi$ bijectively onto Φ. Let $\chi_C \in \widehat{\Gamma}_H$ be the character $((\epsilon,\epsilon'),h) \mapsto (-1)^\epsilon$, whose kernel is Φ.

An **arithmetic datum** on H is a tuple $\mathfrak{A} = (q, d, (I_p)_p, (\mathrm{Fr}_p)_p)$ of natural numbers q, d, subgroups $I_p \subseteq \Gamma_H$ and elements $\mathrm{Fr}_p \in \Gamma_H$, indexed by the primes p. It is **of host type with respect to** a finite set S of natural numbers if

(Ah1) d is prime, $2 \in S$, $q \in S$ and $d \notin S$;

(Ah2) $I_p = 0$ for every prime $p \notin S \cup \{d\}$;

(Ah3) $I_p \subseteq \Phi$ and $\mathrm{Fr}_p \in \Phi$ for every prime $p \in S$;

(Ah4) $I_d = \{0, ((1,0),0)\}$.

These are the properties of the Frobenius and inertia data of the abelian fields used later, where S contains the primes that split in $\mathbb{Q}(\sqrt{-d})$ and ramify. They are not a tameness condition.

Coefficients. For $\phi \in \widehat{\Gamma}_H$, a subgroup $I \subseteq \Gamma_H$ and $h \in \Gamma_H$ let $\mu_I(h,\phi) = |I|^{-1}\sum_{x\in I}\phi(h+x)$ be the mean of ϕ over the coset $h + I$, and for $n \geq 1$ put

$$\phi_{\mathfrak{A}}(n) = \prod_{p\mid n} \mu_{I_p}(v_p(n)\mathrm{Fr}_p, \phi).$$

Thus $|\phi_{\mathfrak{A}}(n)| \le 1$, $1_{\mathfrak{A}}(n) = 1$ for the trivial character 1, and $\phi_{\mathfrak{A}}(p^i) = \phi(i\mathrm{Fr}_p)$ when $I_p = 0$.

Twisted Riesz-weighted Chebyshev functions. For a function $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$, a character $\phi \neq 1$ and real $y > 0$,

$$G_{\mathfrak{A},\eta}(y,\phi) = \sum_{1\le n\le y} \Lambda(n)\,\phi_{\mathfrak{A}}(n)\Big(\frac{y}{n} - 1\Big) + y\,\eta(\phi), \qquad G_{\mathfrak{A},\eta}(y,1) = G(y).$$

Sums over a set of characters. For a subgroup $A_0 \subseteq H$ let $X(A_0) \subseteq \widehat{\Gamma}_H$ be the set of characters trivial on $\{0\}\times A_0$. For a real number c and $\phi \in \widehat{\Gamma}_H$ let $w_c(\phi) = 1$ if ϕ is trivial on $\{0\}\times H$ and $w_c(\phi) = c$ otherwise. For $K' \subseteq \widehat{\Gamma}_H$ and real $x > 0$ put

$$G_{K'}(x) = \sum_{\phi\in K'} w_c(\phi)\,\mathrm{Re}\,G_{\mathfrak{A},\eta}(x,\phi), \qquad \Sigma_{K'}(x) = \sum_{\phi\in X(A_0)\setminus K'} |G_{\mathfrak{A},\eta}(x,\phi)|.$$

Inert prime sums. A prime p is **inert** for $\mathfrak{A}$ if $p \notin \{2,q,d\}$ and $\mathrm{Fr}_p \notin \Phi$. For an integer $P \ge 1$, real a, $t \in H$ and $w\colon \Gamma_H \to \mathbb{R}$ the **inert prime sum** is

$$\begin{aligned} A_{\mathrm{in}}(a,t,w) = {} & \sum_{\substack{p\le P\\ p \text{ inert}}} 2\log p \sum_{\substack{1\le i\le P\\ i\mathrm{Fr}_p\notin\Phi}} \Big(\frac{a}{p^i} - w(\sigma_t(i\mathrm{Fr}_p))\Big)^+ \\ & + \log d \sum_{i=1}^{P} \sum_{\substack{g\notin\Phi\\ g - i\mathrm{Fr}_d\in I_d}} \Big(\frac{a}{d^i} - w(\sigma_t(g))\Big)^+, \end{aligned}$$

with $u^+ = \max(u,0)$, and its **main term** is the complex number

$$M_\eta(a,w) = a\Big(\log a - 1 - \gamma + \eta(\chi_C) - \frac{1}{|\Phi|}\sum_{\rho\in\Phi}\log w(\rho)\Big).$$

Excess. For a finite set $T \subseteq H$, numbers a_t ($t \in T$), an integer $m \ge 1$ and weights $w_{u,j}\colon \Gamma_H \to \mathbb{R}$ ($u \in H$, $1 \le j \le m$), the **excess at** u is

$$\Delta(u) = \sum_{t\in T}\sum_{j=1}^{m}\Big(A_{\mathrm{in}}(a_t,t,w_{u,j}) - \mathrm{Re}\,M_\eta(a_t,w_{u,j})\Big).$$

Scope of the notation. In each use the group H, the datum $\mathfrak{A}$, the function η and the cut-off P are fixed, and they are omitted from the notation $A_{\mathrm{in}}(a,t,w)$, $M_\eta(a,w)$ and $\Delta(u)$. Likewise $\mathfrak{A}$, η, A_0 and c are fixed in each use of $G_{K'}(x)$ and $\Sigma_{K'}(x)$ and are omitted. When η is fixed we write $G_{\mathfrak{A}}(y,\phi)$ for $G_{\mathfrak{A},\eta}(y,\phi)$. Where several choices occur we say that Δ is formed with $(\mathfrak{A},\eta,P,T,(a_t),(w_{u,j}))$.

An arithmetic datum records what an abelian field with Galois group Γ_H records about the primes: inertia groups and Frobenius elements. In the application (Definition 3.11) the field contains $\mathbb{Q}(\sqrt{-d})$, the subgroup Φ fixes $\sqrt{-d}$, and the inert primes of the datum are the primes inert in $\mathbb{Q}(\sqrt{-d})$.

Since Φ has index two and $\mathrm{Fr}_p \notin \Phi$ for an inert prime p, the condition $i\,\mathrm{Fr}_p \notin \Phi$ selects the odd i. So the first line of the inert prime sum runs over the odd powers of the inert primes, and the second line is the contribution of the ramified prime d. Each term $(a/p^i - w)^+ = w\,(y/p^i - 1)^+$, with $y = a/w$, is a term of a Riesz-weighted sum with cut-off y, and the cut-off depends on the class $\sigma_t(i\,\mathrm{Fr}_p)$ through the weight function w. By orthogonality of the characters of Γ_H, the

inert prime sum is therefore a combination of the functions $G_{\mathfrak{A}}(y,\phi)$ at the cut-offs $y = a/w(\rho)$, $\rho \in \Phi$; this is Lemma 3.8 below. The main term $M_\eta(a,w)$ collects the main terms of these functions, averaged over Φ, together with the term $a\,\eta(\chi_C)$ of the quadratic character χ_C whose kernel is Φ.

Definition 3.2. Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H and $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$. For a finite set $T_2 \subseteq H$ and $u \in H$, an element $\rho \in \Gamma_H$ is **thick at** u if $\rho = ((0,1), s+u)$ for some $s \in T_2$. Thick elements lie in Φ.

Let $A_0 \subseteq H$ be a subgroup, $T, T_2 \subseteq H$ finite sets, $m, P \geq 1$ integers, a_t ($t \in T$) real numbers, $w_{u,j}\colon \Gamma_H \to \mathbb{R}$ ($u \in H$, $1 \leq j \leq m$) functions, and $x, b, b', \nu, X', \theta$ real numbers with $b > 0$. The tuple $(A_0, T, T_2, (a_t), (w_{u,j}), P)$ is **weight data at scale** x **with parameters** (b, b', ν, X', θ) for $(\mathfrak{A}, \eta)$ if

(Wd1) $\nu \geq 0$, $X' > 0$, $b' > 0$, $b'X' \leq xb$, $\theta \geq 0$, and $T_2 \subseteq A_0$;

(Wd2) $|a_t/b - x| \leq 1$ for every $t \in T$;

(Wd3) for every $u \in A_0$, every j and every $\rho \in \Phi$: $w_{u,j}(\rho) > 0$; $a_t/w_{u,j}(\rho) \leq P$ for all $t \in T$; $b \leq w_{u,j}(\rho) \leq b + \nu + 1$ if ρ is thick at u; and $w_{u,j}(\rho) \leq 2b'$ if ρ is not thick at u;

(Wd4) (thin scales) $|G_{\mathfrak{A}}(y,\phi)| \leq \theta\, y$ for every $\phi \in \widehat{\Gamma}_H$ and every $y \geq X'/3$;

(Wd5) (cost conditions) $2|\Phi|(x+1)\theta \leq 1/x$ and $6|\Phi|(x+1)(\nu+1) \leq b/x$.

Informally, the scales a_t/b lie within 1 of x. On the translate u the weights equal b, up to $\nu+1$, at the thick places $((0,1), T_2+u)$, and they are small (at most $2b'$) at the other places of Φ. Every twisted function is small, relative to its argument, from $X'/3$ on, and the cost conditions make the resulting errors smaller than b/x.

Proposition 3.3. *Let $C \geq 0$, $\varepsilon > 0$ and $C_E, K_o, M, c \in \mathbb{R}$. There is x_1 such that the following holds for every $x \geq x_1$. Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H of host type with respect to a finite set S, $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$, $A_0 \subseteq H$ a subgroup and $K' \subseteq \widehat{\Gamma}_H$. Let $m, P \geq 1$ be integers, $T, T_2 \subseteq H$, (a_t), $(w_{u,j})$, and real numbers $b > 0$, $a_E \geq 0$ and b', ν, X', θ, k. Suppose:*

(Ex1) *$(A_0, T, T_2, (a_t), (w_{u,j}), P)$ is weight data at scale x with parameters (b, b', ν, X', θ) for $(\mathfrak{A}, \eta)$;*

(Ex2) *(size conditions) $x^{1/2-\varepsilon} \leq m \leq x^{1/2+\varepsilon/2}$, $xm \leq k \leq |H|^2 x^{1/2-\varepsilon}$, $a_E \leq 2xb$, $\frac{1}{2}x^{-\varepsilon/8}|H| \leq |T|$ and $x^{-\varepsilon}|H| \leq |T_2|$;*

(Ex3) *(characters) the trivial character lies in K'; $K' \subseteq X(A_0)$; $\phi(((1,0),0)) = 1$ for $\phi \in K'$; $|X(A_0)| \leq M$; $|\sum_{t\in T}\phi((0,t)) - c|T|| \leq Mx^{-1+\varepsilon}|T|$ for $\phi \in K'$ not trivial on $\{0\}\times H$; $|\eta(\phi)| \leq K_o$ for non-trivial $\phi \in K'$; and $|\eta(\phi)| \leq C_E \log x$ for $\phi \in X(A_0)\setminus K'$;*

(Ex4) *(bounded excess) for every $u \in A_0$, with Δ formed with $(\mathfrak{A}, \eta, P, T, (a_t), (w_{u,j}))$,*

$$\Delta(u) \leq x^{C\varepsilon}E, \qquad E = |T|\,a_E\Big(1 + \frac{m^2}{k}\Big) + m\Big(2|H|\,m\,b\,x^{\varepsilon} + \frac{|T_2|\,k\,b\,x^{\varepsilon}}{|H|^2 x^{-\varepsilon}}\Big).$$

Then

$$G_{K'}(x) = \sum_{\phi\in K'} w_c(\phi)\,\mathrm{Re}\,G_{\mathfrak{A}}(x,\phi) \;\leq\; x^{1/2+(C+3)\varepsilon} + \sum_{\phi\in X(A_0)\setminus K'} |G_{\mathfrak{A}}(x,\phi)|.$$

Proof. Let $C_d \geq 0$ be the constant of item 2 of Lemma 3.4, and put $A_1 = 5 + C_d + |K_o| + |M|(4 + C_d + |K_o|) + 4|C_E|$. Choose $x_1 \geq 3$ such that $x^{3\varepsilon/8} \geq 26$ and $x^{1/4} \geq |M|A_1$ for $x \geq x_1$. Fix $x \geq x_1$ and data as in the statement. Write $s = x^{1/4}$ and $e = x^{\varepsilon}$, so $s, e \geq 1$ and $x^{1/2+\varepsilon} = s^2 e$. We also use $\log x = 4 \log s \leq 4s$ and $\log(x+1) \leq \log(2x) \leq 1 + 4s \leq 5s$.

Step 1: moving the scales. Apply Lemma 3.6 with $y_t = a_t/b$, $\rho = |M|x^{-1+\varepsilon}$, $|K_o|$ in place of K_o, $L = |C_E| \log x$ and $R = A_1 se$.

- Hypothesis 1 is (Wd2), and hypotheses 2–4 are (Ex3), since $M \leq |M|$, $K_o \leq |K_o|$ and $C_E \log x \leq L$.
- Hypothesis 5 holds because $C_d \leq A_1 \leq R$ and $\rho\, x = |M|e$, so that $\log(x+1) + C_d + |K_o| + |M|e(\log x + C_d + |K_o|) \leq 5s + C_d + |K_o| + |M|(4 + C_d + |K_o|)se \leq A_1 se$, and similarly $\log(x+1) + C_d + |C_E| \log x \leq (5 + C_d + 4|C_E|)se \leq R$.

Since $|X(A_0)|R \leq |M|A_1 se \leq s^2 e = x^{1/2+\varepsilon}$, the lemma gives, for $\Upsilon = G_{K'}(x) - \Sigma_{K'}(x)$,

$$|T|(\Upsilon - 4x^{1/2+\varepsilon}) \leq \sum_{t \in T} \operatorname{Re} \sum_{\phi \in X(A_0)} \phi(((1,0),t)) G_{\mathfrak{A}}(a_t/b, \phi).$$

Step 2: averaging. Apply Lemma 3.7 with $\mathrm{Err} = x^{C\varepsilon}E$ (hypothesis 1 is (Ex4)) and $Y = \Upsilon - 4x^{1/2+\varepsilon}$ (hypothesis 2 is Step 1). It gives

$$|T|\, m\, b\, \frac{|T_2|}{2|H|}(\Upsilon - 4x^{1/2+\varepsilon}) \leq x^{C\varepsilon}E + \frac{2|T|mb}{x}.$$

Step 3: absorption. The last inequality is the hypothesis of Lemma 3.10 with $n = |H|$, $n_T = |T|$, $n_2 = |T_2|$ and $\mathrm{Err} = x^{C\varepsilon}E$. Its size conditions are (Ex2), together with $x \geq 3$ and $x^{3\varepsilon/8} \geq 26$ (choice of x_1), $C \geq 0$, $\varepsilon > 0$, $b > 0$, $0 \leq a_E$, $|H| > 0$, and $|T_2| \leq |H|$. So $\Upsilon \leq x^{1/2+(C+3)\varepsilon}$, which is the claim. □

The simplest case shows what the proposition does. Take $A_0 = H$ and $K' = \{1\}$. Then $X(A_0)$ consists of the four characters of Γ_H that are trivial on H, and the conclusion bounds $G(x)$ by $x^{1/2+(C+3)\varepsilon}$ plus the three values $|G_{\mathfrak{A}}(x, \phi)|$ at the non-trivial ones. For trivial H the group Γ_H is $(\mathbb{Z}/2)^2$, as for a biquadratic field that contains $\mathbb{Q}(\sqrt{-d})$: a sum over the primes inert in $\mathbb{Q}(\sqrt{-d})$ bounds G only up to the twists of G by the three quadratic characters, and these need a separate bound. In the proof the group H is the group A of a frame, the subgroup A_0 has index o, and the characters that remain on the right-hand side are bounded by condition (Ec5) of Definition 3.16.

The bracket E of (Ex4) is the size of the error term of the accounting (Proposition 4.1). The size conditions (Ex2) are those under which $x^{C\varepsilon}E$ is at most $x^{1/2+(C+3)\varepsilon}$ times the normaliser $|T|\, m\, b\, |T_2|/(2|H|)$ of the average (Lemma 3.10); the remark that closes Section 4 explains why this forces m to be about $\sqrt{x}$.

Lemma 3.4. *1. For every finite abelian group H, every arithmetic datum $\mathfrak{A}$ on H, every function $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$, every $\phi \in \widehat{\Gamma}_H$ and all real $A, w, w' > 0$,*

$$\left| w\, G_{\mathfrak{A},\eta}(A/w, \phi) - w'\, G_{\mathfrak{A},\eta}(A/w', \phi) \right| \leq \frac{3A}{\min(w, w')} |w - w'|.$$

2. There is an absolute constant $C_d \geq 0$ such that for every H, $\mathfrak{A}$, η as in item 1, every $\phi \neq 1$ and all real $y, z \geq 1$,

$$|G_{\mathfrak{A},\eta}(y, \phi) - G_{\mathfrak{A},\eta}(z, \phi)| \leq |y - z|(\log \max(y, z) + C_d + |\eta(\phi)|), \qquad |G(y) - G(z)| \leq C_d\, |y - z|.$$

Proof. We use Chebyshev's and Mertens' estimates in the form of items 2 and 3 of Lemma 3.5, both derived from Chebyshev's bound [180]: for $\psi(Y) = \sum_{n \le Y} \Lambda(n)$ (notation used in this proof only) we have $\psi(Y) \le 3Y$ for all $Y \ge 0$, and

$$\Big| \sum_{n \le Y} \frac{\Lambda(n)}{n} - \log Y \Big| \le c_0 := 3 + \log 2 \qquad (Y \ge 1),$$

which we call Mertens' estimate below.

For $u, v \in \mathbb{R}$ we use $|u^+ - v^+| \le |u - v|$. Recall also $|\phi_{\mathfrak{A}}(n)| \le 1$.

Item 1. Let $\mu = \min(w, w')$ and $M = \lfloor A/\mu \rfloor$. For any $v \ge \mu$ the sum defining $G_{\mathfrak{A}}(A/v, \phi)$ runs over $n \le A/v \le M$. Multiplying by v gives

$$v\, G_{\mathfrak{A}}(A/v, \phi) = \sum_{n \le M} \Lambda(n) \phi_{\mathfrak{A}}(n) \Big(\frac{A}{n} - v \Big)^+ + A\, \eta(\phi) \qquad (\phi \ne 1),$$

because $v(A/(vn) - 1) = A/n - v$, and the terms with $A/v < n \le M$ are zero. For $\phi \ne 1$, subtracting the two instances $v = w, w'$ cancels $A\eta(\phi)$ and leaves a sum of terms of modulus at most $\Lambda(n)|w - w'|$. So the difference is at most $|w - w'| \psi(A/\mu) \le 3A|w - w'|/\mu$.

For $\phi = 1$ assume $w \le w'$, so $\mu = w$. The definition of G gives

$$v\, G(A/v) = S(v) - A \log(A/v) + (1 + \gamma) A, \qquad S(v) = \sum_{n \le M} \Lambda(n) \Big(\frac{A}{n} - v \Big)^+ .$$

Then $wG(A/w) - w'G(A/w') = (S(w) - S(w')) - A \log(w'/w)$. Both brackets lie in $[0, 3A(w' - w)/w]$:

- the first, because each term of S decreases in v by at most $\Lambda(n)(w' - w)$, and $\psi(A/w) \le 3A/w$;
- the second, because $0 \le \log(w'/w) \le w'/w - 1$.

A difference of two numbers in $[0, B]$ has modulus at most B.

Item 2, $\phi \ne 1$. Let $M = \lfloor \max(y, z) \rfloor \ge 1$. Then

$$G_{\mathfrak{A}}(y, \phi) - G_{\mathfrak{A}}(z, \phi) = \sum_{n \le M} \Lambda(n) \phi_{\mathfrak{A}}(n) \Big(\big(\tfrac{y}{n} - 1\big)^+ - \big(\tfrac{z}{n} - 1\big)^+ \Big) + (y - z) \eta(\phi).$$

Each bracket has modulus at most $|y - z|/n$, so the modulus is at most $|y - z| (\sum_{n \le M} \Lambda(n)/n + |\eta(\phi)|) \le |y - z| (\log \max(y, z) + c_0 + |\eta(\phi)|)$, by Mertens' estimate.

Item 2, G. The function G is continuous on $[1, \infty)$: the term $\Lambda(n)(y/n - 1)$ enters at $y = n$ with value 0. On each interval between consecutive integers it is differentiable with

$$G'(y) = \sum_{n \le y} \frac{\Lambda(n)}{n} - \log y + \gamma,$$

so $|G'(y)| \le c_0 + \gamma$ there by Mertens' estimate. Hence $|G(y) - G(z)| \le (c_0 + \gamma)|y - z|$ for $y, z \ge 1$. The constant $C_d = c_0 + \gamma$ serves both parts of item 2. □

Lemma 3.5. *1. For every real $x \ge 1$, $\sum_{n \le x} \Lambda(n) \le (\log 4)\, x + 2\sqrt{x} \log x$.*

2. For every real $x \ge 0$, $\sum_{n \le x} \Lambda(n) \le 3x$.

3. For every real $x \geq 1$,

$$\Big|\sum_{n\leq x}\frac{\Lambda(n)}{n} - \log x\Big| \leq 3 + \log 2.$$

Proof. Write $\vartheta(y) = \sum_{p\leq y}\log p$, so that $\vartheta(y) \leq y\log 4$ for $y \geq 0$ by Chebyshev's bound [180], and $\vartheta(y) = 0$ for $y < 2$.

Item 1. Since $\Lambda(p^k) = \log p$ and Λ vanishes off the prime powers,

$$\sum_{n\leq x}\Lambda(n) = \sum_{k\geq 1}\vartheta(x^{1/k}).$$

The term with $k = 1$ is at most $x\log 4$. A term with $k \geq 2$ is non-zero only if $x^{1/k} \geq 2$, that is, $k \leq \log x/\log 2$, and it is at most $x^{1/k}\log 4 \leq \sqrt{x}\log 4$. There are fewer than $\log x/\log 2$ such k, so these terms total at most $(\log x/\log 2)\sqrt{x}\log 4 = 2\sqrt{x}\log x$.

Item 2. For $x < 2$ the sum is 0. For $x \geq 1$, with $u = \sqrt{x}$ and $\log u \leq u/e$ (valid for $u > 0$), $2\sqrt{x}\log x = 4u\log u \leq \frac{4}{e}x$; as $\log 4 + \frac{4}{e} < 2.9$, item 1 gives the bound $3x$.

Item 3. Let $k = \lfloor x\rfloor \geq 1$ and $S = \sum_{n\leq k}\Lambda(n)/n$, which equals $\sum_{n\leq x}\Lambda(n)/n$.

- Since $\log m = \sum_{d\mid m}\Lambda(d)$ for $m \geq 1$, Legendre's identity $\log k! = \sum_{n\leq k}\Lambda(n)\lfloor k/n\rfloor$ holds.
- $k\log k - k \leq \log k! \leq k\log k$; the lower bound holds because $\log k! = \sum_{m=2}^{k}\log m \geq \int_1^k \log t\,dt = k\log k - k + 1$.
- From $k/n - 1 < \lfloor k/n\rfloor \leq k/n$ and item 2,

$$kS - 3k \leq kS - \sum_{n\leq k}\Lambda(n) \leq \log k! \leq kS.$$

Hence $\log k - 1 \leq S \leq \log k + 3$. Since $\log k \leq \log x < \log(k+1) \leq \log k + \log 2$, we get $-1 - \log 2 < S - \log x \leq 3$, which gives item 3. □

Lemma 3.6. *Let $C_d \geq 0$ be the constant of item 2 of Lemma 3.4. Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H, $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$, $A_0 \subseteq H$ a subgroup and $K' \subseteq X(A_0)$. Let $T \subseteq H$ be finite, y_t ($t \in T$) real numbers, and $x \geq 3$, c, $\rho \geq 0$, $K_o \geq 0$, L, R real numbers, and form w_c, $G_{K'}(x)$ and $\Sigma_{K'}(x)$ with $(\mathfrak{A},\eta)$, A_0 and c. Suppose:*

1. *$|y_t - x| \leq 1$ for every $t \in T$;*
2. *the trivial character lies in K', and $\phi(((1,0),0)) = 1$ for every $\phi \in K'$;*
3. *$\big|\sum_{t\in T}\phi((0,t)) - c|T|\big| \leq \rho|T|$ for every $\phi \in K'$ that is not trivial on $\{0\}\times H$;*
4. *$|\eta(\phi)| \leq K_o$ for every non-trivial $\phi \in K'$, and $|\eta(\phi)| \leq L$ for every $\phi \in X(A_0)\setminus K'$;*
5. *$C_d \leq R$, $\log(x+1) + C_d + K_o + \rho\,x\,(\log x + C_d + K_o) \leq R$ and $\log(x+1) + C_d + L \leq R$.*

Then

$$|T|\Big(G_{K'}(x) - \Sigma_{K'}(x) - |X(A_0)|\,R\Big) \leq \sum_{t\in T}\operatorname{Re}\sum_{\phi\in X(A_0)}\phi(((1,0),t))\,G_{\mathfrak{A}}(y_t,\phi).$$

Proof. For $\phi \in X(A_0)$ let $v(\phi) = w_c(\phi)\,\mathrm{Re}\,G_{\mathfrak{A}}(x,\phi)$ if $\phi \in K'$ and $v(\phi) = -|G_{\mathfrak{A}}(x,\phi)|$ otherwise. Then $\sum_{\phi\in X(A_0)} v(\phi) = G_{K'}(x) - \Sigma_{K'}(x)$. So it suffices to show, for each $\phi \in X(A_0)$,

$$|T|(v(\phi) - R) \le \sum_{t\in T} \mathrm{Re}\Big(\phi(((1,0),t))G_{\mathfrak{A}}(y_t,\phi)\Big), \tag{$*$}$$

and to sum over ϕ. By hypothesis 1 and $x \ge 3$ we have $y_t \ge 2$ and $\max(y_t, x) \le x+1$. We use two consequences of item 2 of Lemma 3.4, valid for $\phi \ne 1$:

$$|G_{\mathfrak{A}}(y_t,\phi) - G_{\mathfrak{A}}(x,\phi)| \le \log(x+1) + C_d + |\eta(\phi)|, \qquad |G_{\mathfrak{A}}(x,\phi)| \le x\big(\log x + C_d + |\eta(\phi)|\big).$$

The second follows from the bound with $z = 1$, since $G_{\mathfrak{A}}(1,\phi) = \eta(\phi)$ (the sum over $n \le 1$ is empty because $\Lambda(1) = 0$). Thus $|G_{\mathfrak{A}}(x,\phi)| \le (x-1)(\log x + C_d + |\eta(\phi)|) + |\eta(\phi)|$.

The trivial character. Here $v = G(x)$ and $\phi(((1,0),t)) = 1$. By item 2 of Lemma 3.4, $G(y_t) \ge G(x) - C_d|y_t - x| \ge G(x) - R$. Summing over t gives $(*)$.

$\phi \in K'$, $\phi \ne 1$. By hypothesis 2, $\phi(((1,0),t)) = \phi(((1,0),0))\phi((0,t)) = \phi((0,t))$. Hypothesis 3 gives $|\sum_t \phi((0,t)) - w_c(\phi)|T|| \le \rho|T|$ (trivially, with left side 0, if ϕ is trivial on $\{0\}\times H$). Write

$$\sum_t \phi((0,t))G_{\mathfrak{A}}(y_t,\phi) - w_c(\phi)|T|G_{\mathfrak{A}}(x,\phi) = \sum_t \phi((0,t))\big(G_{\mathfrak{A}}(y_t,\phi) - G_{\mathfrak{A}}(x,\phi)\big) + \Big(\sum_t \phi((0,t)) - w_c(\phi)|T|\Big)G_{\mathfrak{A}}(x,\phi).$$

By the two consequences and $|\eta(\phi)| \le K_o$, the modulus is at most $|T|\big(\log(x+1) + C_d + K_o\big) + \rho|T|\,x(\log x + C_d + K_o) \le |T|R$. Taking real parts, and using that $w_c(\phi)$ is real, gives $(*)$.

$\phi \in X(A_0)\setminus K'$. Then $\phi \ne 1$, since $1 \in K'$. Each term satisfies

$$\mathrm{Re}\big(\phi(((1,0),t))G_{\mathfrak{A}}(y_t,\phi)\big) \ge -|G_{\mathfrak{A}}(y_t,\phi)| \ge -|G_{\mathfrak{A}}(x,\phi)| - \big(\log(x+1) + C_d + L\big) \ge v(\phi) - R.$$

Summing over t gives $(*)$. □

Lemma 3.7. *Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H of host type with respect to a finite set S, and $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$. Let $(A_0, T, T_2, (a_t), (w_{u,j}), P)$ be weight data at scale $x \ge 3$ with parameters (b, b', ν, X', θ) for $(\mathfrak{A}, \eta)$. Let $\mathrm{Err}, Y \in \mathbb{R}$, and suppose that*

1. *the excess, formed with $(\mathfrak{A}, \eta, P, T, (a_t), (w_{u,j}))$, satisfies $\Delta(u) \le \mathrm{Err}$ for every $u \in A_0$;*
2. $|T|\,Y \le \displaystyle\sum_{t\in T} \mathrm{Re} \sum_{\phi\in X(A_0)} \phi(((1,0),t))\,G_{\mathfrak{A}}(a_t/b,\phi)$.

Then

$$|T|\,m\,b\,\frac{|T_2|}{2|H|}\,Y \le \mathrm{Err} + \frac{2|T|\,m\,b}{x}.$$

Proof. Let D and Th be as in Lemma 3.9, with the set T_2 and the constant b of the weight data.

Step 1: one translate. Fix $u \in A_0$, $t \in T$ and j. By (Wd2) and $x \ge 3$ we have $a_t \ge (x-1)b > 0$. By (Wd3), $w_{u,j} > 0$ on Φ and $a_t/w_{u,j} \le P$ on Φ. So Lemma 3.8 applies and gives

$$\mathrm{Re}\,D(a_t, t, w_{u,j}) = A_{\mathrm{in}}(a_t, t, w_{u,j}) - \mathrm{Re}\,M_\eta(a_t, w_{u,j}),$$

because A_{in} is real. Item 1 of Lemma 3.9 gives $\operatorname{Re}\mathrm{Th}(u,t,a_t/b) \le \operatorname{Re} D(a_t,t,w_{u,j}) + 2|\Phi|B$ with $B = 3(x+1)(\nu+1) + (x+1)b\theta$. By the cost conditions (Wd5), $2|\Phi| \cdot 3(x+1)(\nu+1) \le b/x$ and $2|\Phi|(x+1)b\theta \le b/x$, so $2|\Phi|B \le 2b/x$. Summing over $t \in T$ and $1 \le j \le m$, and using hypothesis 1,

$$\sum_{t\in T}\sum_{j=1}^{m} \operatorname{Re}\mathrm{Th}(u,t,a_t/b) \le \Delta(u) + \frac{2|T|mb}{x} \le \mathrm{Err} + \frac{2|T|mb}{x}.$$

Step 2: average over $u \in A_0$. The summand on the left does not depend on j. By item 2 of Lemma 3.9 (which needs $T_2 \subseteq A_0$, part of (Wd1)), summing Step 1 over $u \in A_0$ gives

$$|A_0|\, m\, b\, \frac{|T_2|}{2|H|} \sum_{t\in T} \operatorname{Re} \sum_{\phi\in X(A_0)} \phi(((1,0),t)) G_{\mathfrak{A}}(a_t/b,\phi) \le |A_0|\Big(\mathrm{Err} + \frac{2|T|mb}{x}\Big).$$

Divide by $|A_0| > 0$. Then hypothesis 2, multiplied by the non-negative number $mb|T_2|/(2|H|)$, gives the claim. □

Lemma 3.8. *Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H of host type with respect to a finite set S, and $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$ any function. Let $a > 0$, $t \in H$, let $w\colon \Gamma_H \to \mathbb{R}$ satisfy $w(\rho) > 0$ for all $\rho \in \Phi$, and let $P \ge 1$ be an integer with $a/w(\rho) \le P$ for all $\rho \in \Phi$. Then, with A_{in} formed with the cut-off P,*

$$A_{\mathrm{in}}(a,t,w) - M_\eta(a,w) = \frac{1}{|\Phi|} \sum_{g\in\Gamma_H\setminus\Phi} \sum_{\phi\in\widehat{\Gamma}_H} \overline{\phi(g)}\, w(\sigma_t(g))\, G_{\mathfrak{A}}\Big(\frac{a}{w(\sigma_t(g))},\phi\Big).$$

Proof. Write $W_g = w(\sigma_t(g))$ for $g \notin \Phi$; since $\sigma_t(g) \in \Phi$, we have $W_g > 0$ and $a/W_g \le P$. We use three facts about the finite abelian group Γ_H, of order $2|\Phi|$.

(i) *Orthogonality on cosets.* For $g, h \in \Gamma_H$ one has $\sum_\phi \overline{\phi(g)}\phi(h) = 2|\Phi|$ if $g = h$ and 0 otherwise. Averaging over $h + I$ gives, for a subgroup I,

$$\frac{1}{|\Phi|}\sum_{\phi} \overline{\phi(g)}\, \mu_I(h,\phi) = \begin{cases} 2/|I|, & g - h \in I, \\ 0, & \text{otherwise.} \end{cases}$$

(ii) *Sums over the non-trivial coset of Φ.* Since the indicator of $\Gamma_H \setminus \Phi$ is $(1-\chi_C)/2$, (i) gives $\sum_{g\notin\Phi} \overline{\phi(g)} = |\Phi|$ for $\phi = 1$, $-|\Phi|$ for $\phi = \chi_C$, and 0 for every other ϕ.

(iii) *Translation.* σ_t maps $\Gamma_H \setminus \Phi$ bijectively onto Φ, since it changes the first coordinate by 1 and is injective.

Step 1: expansion of the inert prime sum. Put

$$R = \frac{1}{|\Phi|}\sum_{g\notin\Phi}\sum_{\phi} \overline{\phi(g)} \sum_{n=1}^{P} \Lambda(n)\, \phi_{\mathfrak{A}}(n)\Big(\frac{a}{n} - W_g\Big)^+ = \sum_{n=1}^{P} \Lambda(n) \sum_{g\notin\Phi} K(n,g)\Big(\frac{a}{n} - W_g\Big)^+,$$

with $K(n,g) = |\Phi|^{-1}\sum_\phi \overline{\phi(g)}\phi_{\mathfrak{A}}(n)$. Only prime powers $n = p^i$ ($i \ge 1$) contribute, and there $\phi_{\mathfrak{A}}(p^i) = \mu_{I_p}(i\mathrm{Fr}_p, \phi)$, so by (i) $K(p^i,g) = 2/|I_p|$ if $g - i\mathrm{Fr}_p \in I_p$ and 0 otherwise. We claim that $R = A_{\mathrm{in}}(a,t,w)$. To see this, we sort the primes using (Ah1)–(Ah4).

- $p \in S$: by (Ah3), $g - i\mathrm{Fr}_p \in I_p \subseteq \Phi$ and $i\mathrm{Fr}_p \in \Phi$ force $g \in \Phi$, so these primes contribute nothing to R; they do not occur in A_{in} either, since $2, q \in S$ by (Ah1) and a prime of S has $\mathrm{Fr}_p \in \Phi$.

- $p = d$: by (Ah4), $|I_d| = 2$ and $K(d^i, g) = 1$ exactly when $g - i\mathrm{Fr}_d \in I_d$. The contribution is $\log d \sum_i \sum_{g\notin\Phi,\, g - i\mathrm{Fr}_d \in I_d} (a/d^i - W_g)^+$, which is the d-part of A_{in}.
- $p \notin S \cup \{d\}$: by (Ah2), $I_p = 0$ and $K(p^i, g) = 2$ exactly when $g = i\mathrm{Fr}_p$. The contribution is $2\log p \sum_{i:\, i\mathrm{Fr}_p \notin \Phi} (a/p^i - w(\sigma_t(i\mathrm{Fr}_p)))^+$. It vanishes unless $\mathrm{Fr}_p \notin \Phi$, because Φ is a subgroup; and $p \notin S$ gives $p \neq 2, q$. So the primes that contribute are exactly the inert ones.

The ranges agree: in R only $p^i \le P$ occurs, whereas A_{in} runs over $p \le P$ and $1 \le i \le P$ (and all d^i, $i \le P$). Every term with $p^i > P$ vanishes, because $a/p^i < a/P \le W_g$ for all $g \notin \Phi$. Hence $R = A_{\mathrm{in}}(a, t, w)$.

Step 2: the inner sums. Fix $g \notin \Phi$. The terms with $n > a/W_g$ vanish, so

$$\sum_{n=1}^{P} \Lambda(n)\phi_{\mathfrak{A}}(n)\Big(\frac{a}{n} - W_g\Big)^+ = W_g \sum_{1 \le n \le a/W_g} \Lambda(n)\phi_{\mathfrak{A}}(n)\Big(\frac{a/W_g}{n} - 1\Big).$$

By the definition of $G_{\mathfrak{A}}$ this equals $W_g G_{\mathfrak{A}}(a/W_g, \phi) - a\,\eta(\phi)$ for $\phi \neq 1$. For $\phi = 1$ it equals $W_g G(a/W_g) + a\log a - a\log W_g - (1+\gamma)a$, since $1_{\mathfrak{A}} = 1$ and $W_g G(a/W_g) = \sum_{n \le a/W_g} \Lambda(n)(a/n - W_g) - a(\log(a/W_g) - 1 - \gamma)$.

Step 3: summation. Insert Step 2 into R. The terms $W_g G_{\mathfrak{A}}(a/W_g, \phi)$ give the right-hand side of the claim. The correction for $\phi = 1$ (where $\overline{\phi(g)} = 1$) gives, by (iii) and $|\Gamma_H \setminus \Phi| = |\Phi|$,

$$\frac{1}{|\Phi|}\sum_{g\notin\Phi}\big(a\log a - a\log W_g - (1+\gamma)a\big) = a\log a - (1+\gamma)a - \frac{a}{|\Phi|}\sum_{\rho\in\Phi}\log w(\rho).$$

The corrections for $\phi \neq 1$ give, by (ii), $-\frac{a}{|\Phi|}\sum_{\phi\neq 1}\eta(\phi)\sum_{g\notin\Phi}\overline{\phi(g)} = a\,\eta(\chi_C)$. The two corrections add up to $M_\eta(a, w)$, so $A_{\mathrm{in}}(a, t, w) = R$ equals the right-hand side plus $M_\eta(a, w)$. □

Lemma 3.9. *Let H be a finite abelian group, $\mathfrak{A}$ an arithmetic datum on H and $\eta\colon \widehat{\Gamma}_H \to \mathbb{C}$. For $a \in \mathbb{R}$, $t \in H$ and $w\colon \Gamma_H \to \mathbb{R}$ with $w > 0$ on Φ let*

$$D(a, t, w) = \frac{1}{|\Phi|}\sum_{g\in\Gamma_H\setminus\Phi}\sum_{\phi\in\widehat{\Gamma}_H}\overline{\phi(g)}\; w(\sigma_t(g))\, G_{\mathfrak{A}}\Big(\frac{a}{w(\sigma_t(g))}, \phi\Big)$$

be the right-hand side of the orthogonality identity of Lemma 3.8, and for a finite $T_2 \subseteq H$, $u, t \in H$ and real b, y let

$$\mathrm{Th}(u, t, y) = \frac{b}{|\Phi|}\sum_{s\in T_2}\sum_{\phi\in\widehat{\Gamma}_H}\overline{\phi\big(((1,0), s+u-t)\big)}\, G_{\mathfrak{A}}(y, \phi)$$

*be its **thick part with constant weight** b (the elements $g = ((1,0), s+u-t)$ are exactly those with $\sigma_t(g)$ thick at u).*

1. *Let $(A_0, T, T_2, (a_t), (w_{u,j}), P)$ be weight data at scale $x \ge 3$ with parameters (b, b', ν, X', θ) for $(\mathfrak{A}, \eta)$. Then for all $u \in A_0$, $t \in T$ and $1 \le j \le m$, where m is the integer of the weight data (the number of weight functions $w_{u,j}$ at each u, Definition 3.2),*

$$\mathrm{Re}\,\mathrm{Th}(u, t, a_t/b) \le \mathrm{Re}\,D(a_t, t, w_{u,j}) + 2|\Phi|\big(3(x+1)(\nu+1) + (x+1)b\theta\big).$$

2. *Let $A_0 \subseteq H$ be a subgroup with $T_2 \subseteq A_0$. Then for all $t \in H$ and real b, y,*

$$\sum_{u\in A_0}\mathrm{Th}(u, t, y) = |A_0|\, b\,\frac{|T_2|}{2|H|}\sum_{\phi\in X(A_0)}\phi\big(((1,0), t)\big)\, G_{\mathfrak{A}}(y, \phi).$$

Proof. The thick elements. For $g \notin \Phi$ we have $\sigma_t(g) = ((0,1), s+u)$ exactly when $g = ((0,1), s+u) - c_\infty - ((0,0), t) = ((1,0), s+u-t)$. Since $s \mapsto ((1,0), s+u-t)$ is injective, $\mathrm{Th}(u,t,y)$ is the sum over the $g \notin \Phi$ with $\sigma_t(g)$ thick at u of the terms of D, with the weight $w(\sigma_t(g))$ replaced by b in both places.

Item 1. Fix u, t, j and write $a = a_t$, $w = w_{u,j}$ and $W_g = w(\sigma_t(g))$. By (Wd2), $(x-1)b \le a \le (x+1)b$, and $a > 0$ since $x \ge 3$. By the description of the thick elements,

$$D(a,t,w) - \mathrm{Th}(u,t,a/b) = \frac{1}{|\Phi|} \sum_{g \notin \Phi} \sum_{\phi} \overline{\phi(g)}\, F(g,\phi),$$

with $F(g,\phi) = W_g G_{\mathfrak{A}}(a/W_g, \phi) - b\, G_{\mathfrak{A}}(a/b, \phi)$ if $\sigma_t(g)$ is thick at u and $F(g,\phi) = W_g G_{\mathfrak{A}}(a/W_g, \phi)$ otherwise. We show $|F(g,\phi)| \le B := 3(x+1)(\nu+1) + (x+1)b\theta$ for every $g \notin \Phi$ and ϕ. Here $\sigma_t(g) \in \Phi$, so $W_g > 0$ by (Wd3).

- If $\sigma_t(g)$ is thick at u, then $b \le W_g \le b + \nu + 1$ by (Wd3). Item 1 of Lemma 3.4 with $(A, w, w') = (a, W_g, b)$ gives $|F| \le (3a/b)(W_g - b) \le 3(x+1)(\nu+1)$.
- Otherwise $W_g \le 2b'$ by (Wd3), and, by (Wd1) and $x \ge 3$,

$$\frac{X'}{3} W_g \le \frac{2}{3}\, b' X' \le \frac{2}{3}\, xb \le (x-1)b \le a,$$

  so $a/W_g \ge X'/3$. Then (Wd4) gives $|F| = W_g |G_{\mathfrak{A}}(a/W_g, \phi)| \le \theta a \le (x+1)b\theta$.

There are $|\Gamma_H \setminus \Phi| = |\Phi|$ elements g and $|\widehat{\Gamma}_H| = 2|\Phi|$ characters, and $|\overline{\phi(g)}| = 1$. Hence $|D - \mathrm{Th}| \le 2|\Phi|B$, and in particular $\mathrm{Re}\,\mathrm{Th} \le \mathrm{Re}\, D + 2|\Phi|B$.

Item 2. Since $\overline{\phi(h)} = \phi(-h)$ and $-((1,0), s+u-t) = ((1,0), t) + ((0,0), -s) + ((0,0), -u)$ in Γ_H,

$$\sum_{u \in A_0} \mathrm{Th}(u,t,y) = \frac{b}{|\Phi|} \sum_{s \in T_2} \sum_{\phi} \phi(((1,0),t))\phi(((0,0),-s)) G_{\mathfrak{A}}(y,\phi) \sum_{u \in A_0} \phi(((0,0),-u)).$$

The inner sum is $|A_0|$ if $\phi \in X(A_0)$ and 0 otherwise (orthogonality for the restriction of ϕ to $\{0\} \times A_0$). For $\phi \in X(A_0)$ also $\phi(((0,0),-s)) = 1$, since $s \in T_2 \subseteq A_0$. Hence the sum equals $(b/|\Phi|)\,|T_2|\,|A_0| \sum_{\phi \in X(A_0)} \phi(((1,0),t)) G_{\mathfrak{A}}(y,\phi)$. With $|\Phi| = 2|H|$ this is the claim. □

Lemma 3.10. *Let $C, \varepsilon, x, b, k, a_E, \mathrm{Err}, \Upsilon \in \mathbb{R}$ and let n, n_T, n_2, m be non-negative integers. Assume the following size conditions*

$$x \ge 3, \quad \varepsilon > 0, \quad C \ge 0, \quad n > 0, \quad b > 0, \quad 0 \le a_E \le 2xb, \quad x^{3\varepsilon/8} \ge 26,$$
$$\tfrac{1}{2} x^{-\varepsilon/8} n \le n_T, \quad x^{-\varepsilon} n \le n_2 \le n,$$
$$x^{1/2-\varepsilon} \le m \le x^{1/2+\varepsilon/2}, \quad xm \le k \le n^2 x^{1/2-\varepsilon},$$
$$\mathrm{Err} \le x^{C\varepsilon}\Big(n_T\, a_E\Big(1 + \frac{m^2}{k}\Big) + m\Big(2n\, m\, b\, x^{\varepsilon} + \frac{n_2\, k\, b\, x^{\varepsilon}}{n^2 x^{-\varepsilon}}\Big)\Big).$$

If

$$n_T\, m\, b\, \frac{n_2}{2n}\Big(\Upsilon - 4x^{1/2+\varepsilon}\Big) \le \mathrm{Err} + \frac{2 n_T m b}{x},$$

then $\Upsilon \le x^{1/2+(C+3)\varepsilon}$.

Proof. We compare powers of x. Put $Q = n_T\, m\, b$, $\delta = n_2/n$, $X = x^{1/2+\varepsilon}$, $Y = x^{1/2+13\varepsilon/8}$ and $\Pi = x^{C\varepsilon}$. From the size conditions, $m > 0$, $n_T > 0$ and $k > 0$, so $Q > 0$. Moreover $Y \geq 1$, $\Pi \geq 1$, $X \leq Y$ and $x^{\varepsilon}\delta \geq 1$.

Step 1: $\mathrm{Err} \leq 10\,\Pi\, Y\, Q$. Each of the four terms of the bracket bounding Err is bounded by a multiple of YQ, as follows.

- $n_T a_E \leq 2xb\, n_T \leq 2Xm\, n_T b \leq 2YQ$, using $x \leq Xm$, that is, $m \geq x^{1/2-\varepsilon}$.
- $n_T a_E m^2/k \leq n_T \cdot 2xb \cdot m^2/(xm) = 2Q \leq 2YQ$, using $k \geq xm$.
- $m \cdot 2nmbx^{\varepsilon} \leq 4x^{9\varepsilon/8}\, m\, Q \leq 4YQ$, using $n \leq 2x^{\varepsilon/8}n_T$ and $m \leq x^{1/2+\varepsilon/2}$.
- $m\, n_2 kbx^{\varepsilon}/(n^2x^{-\varepsilon}) \leq m\, n_2\, b\, x^{1/2+\varepsilon} \leq 2x^{1/2+9\varepsilon/8}Q \leq 2YQ$, using $k \leq n^2x^{1/2-\varepsilon}$, $n_2 \leq n$ and $n \leq 2x^{\varepsilon/8}n_T$.

Step 2. By Step 1 and $2/x \leq 1$, the hypothesis gives $Q\,\frac{\delta}{2}(\Upsilon - 4X) \leq 10\Pi YQ + Q$. Divide by Q and use $1 \leq \Pi Y$; this gives $\delta(\Upsilon - 4X) \leq 22\,\Pi Y$.

Step 3. If $\Upsilon \leq 4X$ there is nothing more to prove, since $4X \leq x^{1/2+(C+3)\varepsilon}$ by $x^{3\varepsilon/8} \geq 26$. Otherwise $x^{\varepsilon}\delta \geq 1$ gives

$$\Upsilon - 4X \leq x^{\varepsilon}\delta(\Upsilon - 4X) \leq 22\,\Pi Y x^{\varepsilon} = 22\,x^{1/2+(C+21/8)\varepsilon}.$$

Since $C \geq 0$, $X \leq x^{1/2+(C+21/8)\varepsilon}$, so $\Upsilon \leq 26\,x^{1/2+(C+21/8)\varepsilon} \leq x^{3\varepsilon/8}x^{1/2+(C+21/8)\varepsilon} = x^{1/2+(C+3)\varepsilon}$. □

The arithmetic data of the proof come from hosts, which we define next. A frame is the abstract shape of a Galois group: a finite abelian group A that maps onto $(\mathbb{Z}/2^{e+2}\mathbb{Z})^{\times}/\{\pm1\}$, with a cyclic subgroup A_0 of index o. In the proof o is the order of the character ψ. A host adds two primes q and d, a modulus N and a surjection α from $(\mathbb{Z}/N\mathbb{Z})^{\times}$ onto $\{\pm1\}^2 \times A$. In the case of interest α is the Artin map of an abelian field inside $\mathbb{Q}(\zeta_N)$, and its second sign is the quadratic character of $\mathbb{Q}(\sqrt{-d})$. The definition keeps only the map α, through which every character of $\{\pm1\}^2 \times A$ becomes a Dirichlet character modulo N; the field itself is introduced in Definition 7.2, where it is first needed.

Definition 3.11. For an integer $e \geq 2$ let $H_e = (\mathbb{Z}/2^{e+2}\mathbb{Z})^{\times}/\{\pm1\}$. A **frame** is a tuple (e, A, h, a_0) of an integer $e \geq 2$, a finite abelian group A, a surjective homomorphism $h\colon A \to H_e$ and an element $a_0 \in A$ such that h is injective on the cyclic subgroup $A_0 = \langle a_0 \rangle$. Its **index** is $o = [A : A_0]$. Its **group** is $\mathcal{G} = \{\pm1\}^2 \times A$, with elements written $((s_1, s_2), a)$. It carries the **sign characters** $\epsilon_1(g) = s_1$ and $\epsilon_2(g) = s_2$ and the element $\iota_d = ((1,-1),0)$. We identify $\mathcal{G}$ with the group $\Gamma_A = (\mathbb{Z}/2)^2 \times A$ of Definition 3.1 by

$$\tau\colon \mathcal{G} \to \Gamma_A, \qquad ((s_1,s_2),a) \mapsto ((\bar{s}_2, \bar{s}_1), a), \qquad \bar{1} = 0,\ \overline{-1} = 1,$$

so that τ carries $\ker \epsilon_2$ onto Φ, ϵ_2 to $\chi_C \circ \tau$, and ι_d to $((1,0),0)$. Characters θ of $\mathcal{G}$ and characters $\phi = \theta \circ \tau^{-1}$ of Γ_A correspond bijectively.

A **host** for the frame is a tuple $\mathfrak{h} = (q, d, Q_S, \alpha)$ such that, with $N = Q_S q d$,

(Hr1) q and d are primes with $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$ and $(-d/q) = 1$;

(Hr2) $Q_S \geq 1$, $2^{e+2} \mid Q_S$, $\gcd(Q_S, qd) = 1$, and $(-d/l) = 1$ for every odd prime $l \mid Q_S$;

(Hr3) $\alpha\colon (\mathbb{Z}/N\mathbb{Z})^{\times} \to \mathcal{G}$ is a surjective homomorphism;

(Hr4) $\epsilon_2(\alpha(u)) = (u/d)$ for every u;

(Hr5) $\alpha(u) \in \{1, \iota_d\}$ for every $u \equiv 1 \pmod{Q_S q}$.

The case of interest is when α is the Artin map of an abelian field $E \subseteq \mathbb{Q}(\zeta_N)$ composed with an isomorphism $\mathrm{Gal}(E/\mathbb{Q}) \cong \mathcal{G}$; then (Hr4) says that ϵ_2 is the quadratic character of $\mathbb{Q}(\sqrt{-d}) \subseteq E$.

Characters of a host. For a character θ of $\mathcal{G}$ let $\chi_\theta = \theta \circ \alpha$, a Dirichlet character modulo N, and let χ_θ^* be the primitive character inducing it. Let $X^{\pm}(\mathfrak{h})$ be the set of θ that are trivial on $\{(1,1)\} \times A_0$ and satisfy $\theta(\iota_d) = \pm 1$.

The arithmetic datum of a host. For a prime p write $N = N_p N_p'$ with N_p a power of p and $p \nmid N_p'$. Let $U_p \subseteq (\mathbb{Z}/N\mathbb{Z})^\times$ be the units $\equiv 1 \pmod{N_p'}$, and let f_p be the unit with $f_p \equiv p \pmod{N_p'}$ and $f_p \equiv 1 \pmod{N_p}$, which exists and is unique by the Chinese remainder theorem (so f_p is the class of p if $p \nmid N$). The **arithmetic datum** $\mathfrak{A}_\mathfrak{h}$ of $\mathfrak{h}$ is the datum on A with the primes q, d, inertia groups $I_p = \tau(\alpha(U_p))$ and Frobenius elements $\mathrm{Fr}_p = \tau(\alpha(f_p))$.

Compatible functions. A function $\eta\colon \widehat{\Gamma}_A \to \mathbb{C}$ is **compatible with** $\mathfrak{h}$ if

$$\eta(\phi') = L'(1,\chi)/L(1,\chi)$$

for every non-trivial $\phi' \in \widehat{\Gamma}_A$ and every primitive Dirichlet character χ such that $\chi(n) = \phi'_{\mathfrak{A}_\mathfrak{h}}(n)$ for all $n \geq 1$.

Lemma 3.12. *Let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for a frame (e, A, h, a_0), and let S be the set of prime factors of $Q_S q$. Then the arithmetic datum $\mathfrak{A}_\mathfrak{h}$ is of host type with respect to S.*

Proof. Write $N = Q_S q d$ and use the notation N_p, N_p', U_p, f_p of Definition 3.11. Recall that τ carries $\ker \epsilon_2$ onto Φ, so an element $\tau(\alpha(u))$ lies in Φ exactly when $(u/d) = 1$, by (Hr4). We check (Ah1)–(Ah4) of Definition 3.1.

(Ah1) d is prime by (Hr1); $2 \in S$ since $2^{e+2} \mid Q_S$; $q \in S$; and $d \notin S$ since $\gcd(Q_S, qd) = 1$ and $d \neq q$.

(Ah2) If $p \notin S \cup \{d\}$, then $p \nmid N$, so $N_p' = N$ and $U_p = \{1\}$; hence $I_p = 0$.

(Ah3) Let $p \in S$. Since $p \neq d$, we have $d \mid N_p'$. A unit $u \in U_p$ satisfies $u \equiv 1 \pmod{d}$, so $(u/d) = 1$ and $I_p \subseteq \Phi$. For the Frobenius element, $f_p \equiv p \pmod{d}$, so it suffices to show $(p/d) = 1$.

- For $p = 2$ this holds because $d \equiv 7 \pmod{16}$.
- For odd p, quadratic reciprocity with $d \equiv 3 \pmod 4$ gives $(p/d) = (-d/p)$. This is 1 by (Hr2) if $p \mid Q_S$, and by (Hr1) if $p = q$.

(Ah4) Here $N_d' = Q_S q$, so U_d consists of the units $\equiv 1 \pmod{Q_S q}$, and $\alpha(U_d) \subseteq \{1, \iota_d\}$ by (Hr5). By the Chinese remainder theorem there is a unit u with $u \equiv 1 \pmod{Q_S q}$ and $u \equiv -1 \pmod d$. Then $\epsilon_2(\alpha(u)) = (-1/d) = -1$ since $d \equiv 3 \pmod 4$, so $\alpha(u) = \iota_d$. Hence $I_d = \tau(\{1, \iota_d\}) = \{0, ((1,0),0)\}$. □

The next three definitions, of slope data, of the slope conditions and of the size conditions, belong to the accounting of Section 4, which explains them. They are stated here because the notion of a core-tied host in Definition 3.16 refers to them. On a first reading they may be skipped until that section.

Definition 3.13. Let $\mathfrak{S}$ be a slope datum, c a constant vector and X'' a real number. Then $\mathfrak{S}$ satisfies the **slope conditions for** (c, X'') if the following hold for all $u \in U$ and $\omega, \omega' \in \mathcal{W}(u)$.

(Sl1) Positivity. $x > 0$, $b > 0$, $a \geq 0$, $b' \geq 0$, $k > 0$, $v > 0$, $f > 0$; $a_\tau \geq 0$ for all τ; $w_{u,j,\rho} > 0$, $d_{u,\omega} > 0$, $T_{u,\omega} > 0$ and $\mu_{u,\omega} \leq \mu^{\max}_{u,\omega}$; $c_{\mathrm{Sl}} \geq 0$; $\bar{\delta} < 1$, $\bar{\eta} \geq 0$ and $0 \leq \bar{e} \leq \frac{1}{4}$.

(Sl2) Divisor bound.

$$\mu^{\vee}_u + h_{u,\omega} - F_u \leq \sum_{\tau \in \mathcal{T}} \Big(m(\varphi(a_\tau) - a_\tau \log \Omega) - a_\tau \log T_{u,\omega} \Big) + c_{\mathrm{Div}} n_{\mathcal{T}} a L_a + c_{\mathrm{Div}} m (B_0 + N_c) x^{e_{\mathrm{Div}} \varepsilon}.$$

(Sl3) Exponent comparison. $\left| E_{u,\omega} - m A l_g \right| \leq c_E m B_0$.

(Sl4) Height comparison. $\Big| (h_{u,\omega} + \sum_\tau a_\tau \log T_{u,\omega}) - (h_{u,\omega'} + \sum_\tau a_\tau \log T_{u,\omega'}) \Big| \leq c_H (n_{\mathcal{T}} a L_a + m B_0)$.

(Sl5) Counting.

$$\frac{1}{f} \sum_{j=1}^{m} \sum_{\rho=1}^{f} \log \frac{w_{u,j,\rho}\, v}{\pi} + m l_g - c_{\mathrm{Count}} \Big(L_a + \frac{m^2 L_a}{k} \Big) \leq \log T_{u,\omega} \leq c_{\mathrm{Count}}\, m\, L,$$

and $\left| \log T_{u,\omega} - \log T_{u,\omega'} \right| \leq c_{\mathrm{Count}} \log k$.

(Sl6) Ambient slopes. $-c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a (1 + \frac{m}{k}) \leq \mu'_{u,\omega}$ and $\mu'^{\max}_{u,\omega} \leq c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a$.

(Sl7) Transfer of slopes. $\mu^{\max}_{u,\omega} \leq \mu'^{\max}_{u,\omega} + \Theta_u + F_u - E_{u,\omega} + c_{\mathrm{Sl}} m B_0$ and $\mu'_{u,\omega} + \Theta_u + F_u - E_{u,\omega} - \mathrm{Lo}''_{u,\omega} \leq \mu_{u,\omega}$.

(Sl8) Losses. $S_u - \Theta_u \leq \mathrm{Lo}$ and $I_u \leq \mathrm{Lo}$.

(Sl9) Dual-slope inequality. If $0 \leq \delta_u < 1$, $\eta_u \geq 0$, $0 \leq e_u \leq \frac{1}{4}$, $s_u - \mu^{\vee}_{\min,u} \leq \mathrm{HH}_u$ and $\mathrm{HH}_u > 0$, then

$$s_u - \log |\mathcal{W}(u)| - \frac{1}{1 - \delta_u} \Big(4 \phi_u \log \Big(1 + \frac{\mathrm{HH}_u}{\phi_u} \Big) + (\eta_u + 4\sqrt{e_u}) \mathrm{HH}_u \Big) \leq \mu^{\vee}_u,$$

where the term $4\phi_u \log(1 + \mathrm{HH}_u/\phi_u)$ is read as 0 when $\phi_u = 0$.

(Sl10) Height bound. $s_u - \mu^{\vee}_{\min,u} \leq \mathrm{HH}_u$ and $0 < \mathrm{HH}_u \leq x^{c_{\mathrm{HH}}} b$.

(Sl11) Parameters. $0 \leq \delta_u \leq \bar{\delta}$, $0 \leq \eta_u \leq \bar{\eta}$ and $0 \leq e_u \leq \bar{e}$.

Definition 3.14. A **slope datum** $\mathfrak{S}$ consists of the following.

- Finite sets U (the **translates**) and $\mathcal{T}$, a non-empty finite set $\mathcal{W}(u)$ for each $u \in U$ (the **words at** u), and integers $m, f \geq 0$.
- Real parameters $x, \varepsilon, a, b, b', k, L, L_a, B_0, N_c, \gamma_0, \beta, v, l_g$, and real numbers $\bar{\delta}, \bar{\eta}, \bar{e}$.
- Real numbers a_τ ($\tau \in \mathcal{T}$) and $w_{u,j,\rho}$ ($u \in U$, $1 \leq j \leq m$, $1 \leq \rho \leq f$).
- For each $u \in U$ and $\omega \in \mathcal{W}(u)$, real numbers

$$d_{u,\omega},\ T_{u,\omega},\ \mu_{u,\omega},\ \mu^{\max}_{u,\omega},\ h_{u,\omega},\ \mu'_{u,\omega},\ \mu'^{\max}_{u,\omega},\ E_{u,\omega,j}\ (1 \leq j \leq m).$$

- For each $u \in U$, real numbers $\mu^{\vee}_u,\ \mu^{\vee}_{\min,u},\ F_u,\ \Theta_u,\ S_u,\ I_u,\ \mathrm{HH}_u,\ \delta_u,\ \eta_u,\ e_u$.

Attached to $\mathfrak{S}$ are the following quantities. Put $n_{\mathcal{T}} = |\mathcal{T}|$, $A = \sum_{\tau\in\mathcal{T}} a_\tau$, $\varphi(y) = y\log y - y$, $\log\Omega = \gamma_0 + \log(\pi/v) - \beta$, and $E_{u,\omega} = \sum_{j=1}^{m} E_{u,\omega,j}$. The **mean slope** and the **spread** at u are

$$s_u = \frac{\sum_{\omega\in\mathcal{W}(u)} d_{u,\omega}\,(\mu_{u,\omega} - h_{u,\omega})}{\sum_{\omega\in\mathcal{W}(u)} d_{u,\omega}}, \qquad \phi_u = \max_{\omega\in\mathcal{W}(u)} \big(\mu^{\max}_{u,\omega} - h_{u,\omega}\big) - s_u,$$

and the **main term** at u is

$$\mathrm{Main}(u) = \sum_{j=1}^{m}\sum_{\tau\in\mathcal{T}} a_\tau\Big(\log a_\tau - 1 - \gamma_0 + \beta - \frac{1}{f}\sum_{\rho=1}^{f}\log w_{u,j,\rho}\Big).$$

A **constant vector** is a tuple $c = (c_{\mathrm{Div}}, e_{\mathrm{Div}}, c_E, c_H, c_{\mathrm{Count}}, c_{\mathrm{Slope}}, c_{\mathrm{Sl}}, c_{\mathrm{Loss}}, e_{\mathrm{Loss}}, c_{\mathrm{HH}})$ of real numbers. For a constant vector c and a real number X'', the **loss bound**, the **loss terms** and the **variance term** are

$$\begin{aligned}
\mathrm{Lo} &= c_{\mathrm{Loss}}\, n_{\mathcal{T}}\, m\, b\, x^{e_{\mathrm{Loss}}\varepsilon},\\
\mathrm{Lo}''_{u,\omega} &= c_{\mathrm{Sl}} I_u + c_{\mathrm{Sl}}\, n_{\mathcal{T}}\, m\,\Big(\frac{a}{k} + b'\Big)\log T_{u,\omega} + c_{\mathrm{Sl}} X'' + 1,\\
V &= 2mc_E B_0 + c_H\big(n_{\mathcal{T}} a L_a + mB_0\big) + c_{\mathrm{Count}} A\log k.
\end{aligned}$$

Definition 3.15. Let $\mathfrak{S}$ be a slope datum, c a constant vector and X'', e_K, C_K real numbers. The datum satisfies the **size conditions for** (c, X'', e_K, C_K) if

(Er1) Scale. $x \ge 1$ and $0 < \varepsilon \le 1$.

(Er2) Sizes. $b \ge 1$, $xb \le a$, $n_{\mathcal{T}} \ge 1$, $m \le x^{1/2+\varepsilon/2}$, $xm \le k$, $e_K \ge 0$, $1 \le k \le \min(a, x^{e_K})$, $0 \le L \le 2x^{\varepsilon}$, $0 \le L_a \le 2x^{\varepsilon}$, $b' \ge 0$, $kb' \le a$, $0 \le X'' \le a$, $0 \le a_\tau \le 2a$ for every τ, $B_0 \ge 0$ and $N_c \ge 0$.

(Er3) Words. $\log|\mathcal{W}(u)| \le (k-3)\log 2$ for every $u \in U$.

(Er4) Parameters. $\bar\delta \le \frac12$, $\bar\eta \ge 0$, $\bar e \ge 0$, and $(\bar\eta + 4\sqrt{\bar e})\, x^{c_{\mathrm{HH}}} b \le C_K\, x^{\varepsilon}\, n_{\mathcal{T}}\, a$.

(Er5) Constants. $0 \le c_{\mathrm{Div}}, c_E, c_H, c_{\mathrm{Count}}, c_{\mathrm{Slope}}, c_{\mathrm{Sl}}, c_{\mathrm{Loss}} \le C_K$, and $e_{\mathrm{Div}}, e_{\mathrm{Loss}}, c_{\mathrm{HH}} \ge 0$.

The scale is **large** for $(\varepsilon, C_K, c_{\mathrm{HH}}, e_K)$ if $\log x \le x^{\varepsilon}$ and $200(1+C_K)^2(1+c_{\mathrm{HH}})(1+e_K) \le x^{\varepsilon}$.

Definition 3.16. Let $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o_{\mathfrak{L}})$ be a character level, $\mathfrak{h}$ a host for a frame (e, A, h, a_0) of index o, $T \subseteq A$ a finite set, and $x > 1$, $\varepsilon > 0$, $C \ge 0$ real numbers. The **controlled characters** of $\mathfrak{h}$ relative to $\mathfrak{L}$ are the $\theta \in X^-(\mathfrak{h})$ together with the $\theta \in X^+(\mathfrak{h})$ with $\chi^*_\theta \notin K$; their twisted functions do not enter $G_{\mathfrak{L}}$. Put $\kappa(b) = 4/(3o+1)$ for $b \in A_0$ and $\kappa(b) = 3/(3o+1)$ for $b \in A\setminus A_0$.

Host conditions. The pair $(\mathfrak{h}, T)$ satisfies the **host conditions for $\mathfrak{L}$ at scale x with parameters** (ε, C) if

(Ec1) $o = o_{\mathfrak{L}}$;

(Ec2) every $\psi \in K$ equals χ^*_θ for some $\theta \in X^+(\mathfrak{h})$;

(Ec3) if ψ_{exc} is present, it equals $\chi^*_{\epsilon_1}$; if it is absent, $\chi^*_{\epsilon_1} \notin K$;

(Ec4) for every $b \in A$, $\big|\#\{t \in T : t - b \in A_0\} - \kappa(b)|T|\big| \le x^{-1+\varepsilon}|T|$;

(Ec5) for every controlled character θ, $|g(x, \chi^*_\theta)| \le x^{1/2+\varepsilon}$ and $|L'(1,\chi^*_\theta)/L(1,\chi^*_\theta)| \le C\log x$.

Core-tied hosts. Let e_D, e_L, C_K, c^*, e_K be real numbers. The pair $(\mathfrak{h}, T)$ is **core-tied at scale x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε** if there exist the following.

- A slope datum $\mathfrak{S}$ with translates U, parameters $x(\mathfrak{S}), \varepsilon(\mathfrak{S}), a, b, b', k, B_0, N_c, \gamma_0, \beta$, integers m, f and numbers a_τ, $w_{u,j,\rho}$.
- A constant vector c, a real X'', a map $\mathrm{tr}\colon U \to A$ whose image contains A_0, and bijections $\mathcal{T} \to T$, $\tau \mapsto t_\tau$, and $\{1, \dots, f\} \to \Phi$, $\rho \mapsto g_\rho$.
- A function η on $\widehat{\Gamma}_A$, an integer $P \geq 1$, a finite set $T_2 \subseteq A$, a function $a\colon A \to \mathbb{R}$, weights $w_{u,j}\colon \Gamma_A \to \mathbb{R}$ ($u \in A$, $1 \leq j \leq m$), and reals ν, X', θ_0.

These are subject to the following conditions.

(Ct1) η is compatible with $\mathfrak{h}$.

(Ct2) $x(\mathfrak{S}) = x$, $\varepsilon(\mathfrak{S}) = \varepsilon$, $e_{\mathrm{Div}} \leq e_D$, $e_{\mathrm{Loss}} \leq e_L$ and $c_{\mathrm{HH}} \leq c^*$ for the entries of c.

(Ct3) (identification) $a_\tau = a(t_\tau)$ for all τ; $w_{u,j,\rho} = w_{\mathrm{tr}(u),j}(g_\rho)$ for all u, j, ρ; $\gamma_0 = \gamma$; $\beta = \operatorname{Re}\eta(\chi_C)$; and for every $u \in U$

$$S_u = \sum_{t \in T} \sum_{j=1}^{m} A_{\mathrm{in}}\big(a(t), t, w_{\mathrm{tr}(u),j}\big),$$

with A_{in} formed with $(\mathfrak{A}_{\mathfrak{h}}, P)$.

(Ct4) $\mathfrak{S}$ satisfies the slope conditions for (c, X'') and the size conditions for (c, X'', e_K, C_K).

(Ct5) $B_0 \leq 2|A|\, m\, b\, x^{\varepsilon}$ and $N_c \leq |T_2|\, k\, b\, x^{\varepsilon}/(|A|^2 x^{-\varepsilon})$.

(Ct6) $(A_0, T, T_2, a|_T, (w_{u,j}), P)$ is weight data at scale x with parameters $(b, b', \nu, X', \theta_0)$ for $(\mathfrak{A}_{\mathfrak{h}}, \eta)$.

(Ct7) $a \leq 2xb$, $\frac{1}{2}x^{-\varepsilon/8}|A| \leq |T|$, $x^{-\varepsilon}|A| \leq |T_2|$, $x^{1/2-\varepsilon} \leq m$ and $k \leq |A|^2 x^{1/2-\varepsilon}$.

The host conditions say that a host sees the characters of a level and that its other characters are harmless at the scale x. Condition (Ec2) puts the characters of the level among those of the host. Condition (Ec4) asks the top set T to meet A_0 in the proportion $4/(3o+1)$ and every other coset of A_0 in the proportion $3/(3o+1)$, up to $x^{-1+\varepsilon}$. Then $\sum_{t \in T} \phi(t)$ equals $|T|/(3o+1)$, up to an error of at most $o\, x^{-1+\varepsilon}|T|$, for every non-trivial character ϕ of A/A_0. This is where the weight $(3o+1)^{-1}$ of a level comes from. Condition (Ec5) asks the controlled characters for a square-root bound at the point x and for a bound on the logarithmic derivative at $s = 1$; Part II supplies it from good window pairs.

The second half of the definition is the hypothesis under which Section 6 bounds $G_{\mathfrak{L}}(x)$. A core-tied host carries a slope datum whose prime-sum entries are, by the identification (Ct3), the inert prime sums of the host, and which satisfies the slope conditions and the size conditions with exponents $e_{\mathrm{Div}} \leq e_D$ and $e_{\mathrm{Loss}} \leq e_L$ ((Ct2), (Ct4)). Conditions (Ct5)–(Ct7) are the size conditions of the averaging step: (Ct5) bounds the two budgets B_0 and N_c of the slope datum, (Ct6) asks for weight data, and (Ct7) is the part of (Ex2) that the size conditions of the slope datum do not contain.

Lemma 3.17. *Let $\mathfrak{h}$ be a host for a frame (e, A, h, a_0) of index o, with $A_0 = \langle a_0 \rangle$.*

1. $|X(A_0)| = 4o$.

Let moreover $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o_{\mathfrak{L}})$ be a character level, $T \subseteq A$ finite, $x > 1$, $\varepsilon > 0$, $C \geq 0$, and suppose that $(\mathfrak{h}, T)$ satisfies the host conditions for $\mathfrak{L}$ at scale x with parameters (ε, C) and that η is compatible with $\mathfrak{h}$. Let $K'_{\mathfrak{h}}$ be the set of characters $\theta \circ \tau^{-1}$ of Γ_A with $\chi^*_\theta \in K$, and $c = (3o+1)^{-1}$. Then:

2. $G_{K'_{\mathfrak{h}}}(y) = G_{\mathfrak{L}}(y)$ *for every* $y > 0$;

3. $\Sigma_{K'_{\mathfrak{h}}}(x) \leq 4o\, x^{1/2+\varepsilon}$;

4. *condition (Ex3) of Proposition 3.3 holds for* $K' = K'_{\mathfrak{h}}$ *with* $c = (3o+1)^{-1}$, $M = 4o$, $K_o = \sum_{\psi \in K \setminus \{\mathbf{1}\}} |L'(1,\psi)/L(1,\psi)|$ *and* $C_E = C$.

Proof. Throughout, θ and ϕ are related by $\phi = \theta \circ \tau^{-1}$. Since τ maps $\{(1,1)\} \times A_0$ onto $\{0\} \times A_0$ and ι_d to $((1,0),0)$, we have $\phi \in X(A_0)$ if and only if $\theta \in X^+(\mathfrak{h}) \cup X^-(\mathfrak{h})$, and then $\phi(((1,0),0)) = \theta(\iota_d)$.

Injectivity. The map $\theta \mapsto \chi^*_\theta$ is injective. Indeed, χ^*_θ determines $\chi_\theta = \theta \circ \alpha$ on the units modulo N, and $\theta \circ \alpha$ determines θ because α is surjective by (Hr3).

Item 1. $X(A_0)$ is the character group of $\Gamma_A/(\{0\} \times A_0)$, a group of order $4|A|/|A_0| = 4o$.

Description of $K'_{\mathfrak{h}}$. Let $\chi^*_\theta \in K$. By (Ec2), $\chi^*_\theta = \chi^*_{\theta'}$ for some $\theta' \in X^+(\mathfrak{h})$, so $\theta = \theta'$ by injectivity. Hence $K'_{\mathfrak{h}} \subseteq X(A_0)$, every $\phi \in K'_{\mathfrak{h}}$ satisfies $\phi(((1,0),0)) = 1$, and $\theta \mapsto \chi^*_\theta$ is a bijection from $\{\theta : \theta \circ \tau^{-1} \in K'_{\mathfrak{h}}\}$ onto K (surjective by (Ec2)). The trivial character lies in $K'_{\mathfrak{h}}$, because $\chi^*_1 = \mathbf{1} \in K$ by (Le1).

Item 2. By item 3 of Lemma 3.18, $G_{\mathfrak{A}_{\mathfrak{h}}}(y, \phi) = g(y, \chi^*_\theta)$. By the bijection, it remains to compare the weights. We show that, for $\phi \in K'_{\mathfrak{h}}$, $w_c(\phi) = 1$ holds exactly when $\chi^*_\theta \in \{\mathbf{1}, \psi_{\mathrm{exc}}\}$, and $w_c(\phi) = (3o+1)^{-1} = w_{\mathfrak{L}}(\chi^*_\theta)$ otherwise (using (Ec1), $o = o_{\mathfrak{L}}$).

- $w_c(\phi) = 1$ means that ϕ is trivial on $\{0\} \times A$, that is, θ is trivial on $\{(1,1)\} \times A$. Since also $\theta(\iota_d) = 1$, θ is determined by $\theta(((-1,1),0)) = \pm 1$, so $\theta \in \{1, \epsilon_1\}$.
- $\theta = 1$ corresponds to $\chi^*_\theta = \mathbf{1}$ (item 2 of Lemma 3.18).
- If $\theta = \epsilon_1$ and $\chi^*_{\epsilon_1} \in K$, then ψ_{exc} is present and equals $\chi^*_{\epsilon_1}$ by (Ec3). Conversely, $\chi^*_\theta = \psi_{\mathrm{exc}} = \chi^*_{\epsilon_1}$ forces $\theta = \epsilon_1$ by injectivity.

Hence $\sum_{\phi \in K'_{\mathfrak{h}}} w_c(\phi) \operatorname{Re} G_{\mathfrak{A}_{\mathfrak{h}}}(y, \phi) = G(y) + \sum_{\psi \in K \setminus \{\mathbf{1}\}} w_{\mathfrak{L}}(\psi) \operatorname{Re} g(y, \psi) = G_{\mathfrak{L}}(y)$.

Item 3. Let $\phi \in X(A_0) \setminus K'_{\mathfrak{h}}$. Then either $\theta \in X^-(\mathfrak{h})$, or $\theta \in X^+(\mathfrak{h})$ with $\chi^*_\theta \notin K$; in both cases θ is controlled. Since $\theta \neq 1$, item 3 of Lemma 3.18 and (Ec5) give $|G_{\mathfrak{A}_{\mathfrak{h}}}(x, \phi)| = |g(x, \chi^*_\theta)| \leq x^{1/2+\varepsilon}$. There are at most $|X(A_0)| = 4o$ such ϕ.

Item 4. The first three clauses of (Ex3) were shown above, and $|X(A_0)| = 4o = M$. Next come the two clauses on η. For non-trivial $\phi \in K'_{\mathfrak{h}}$ we have $\eta(\phi) = L'(1, \chi^*_\theta)/L(1, \chi^*_\theta)$ with $\chi^*_\theta \in K \setminus \{\mathbf{1}\}$, so $|\eta(\phi)| \leq K_o$. For $\phi \in X(A_0) \setminus K'_{\mathfrak{h}}$, θ is controlled and non-trivial, so $|\eta(\phi)| \leq C \log x$ by (Ec5).

It remains to bound the character sums. Let $\phi \in K'_{\mathfrak{h}}$ be non-trivial on $\{0\} \times A$. The map $b \mapsto \phi((0,b))$ factors through a non-trivial character ϑ of A/A_0, a group of order o. For a coset $\beta \in A/A_0$ let $n_\beta = \#\{t \in T : t \in \beta\}$, and let $\kappa(\beta)$ denote the value of κ on β. Then

$$\sum_{t \in T} \phi((0,t)) = \sum_\beta \vartheta(\beta) n_\beta, \qquad \sum_\beta \vartheta(\beta)\kappa(\beta) = \frac{4-3}{3o+1} + \frac{3}{3o+1} \sum_\beta \vartheta(\beta) = \frac{1}{3o+1},$$

since $\vartheta(A_0) = 1$ and $\sum_\beta \vartheta(\beta) = 0$. By (Ec4), $|n_\beta - \kappa(\beta)|T|| \le x^{-1+\varepsilon}|T|$ for each of the o cosets. Hence $|\sum_t \phi((0,t)) - c|T|| \le o\, x^{-1+\varepsilon}|T| \le M x^{-1+\varepsilon}|T|$. □

Lemma 3.18. *Let $\mathfrak{h}$ be a host for a frame (e, A, h, a_0), θ a character of its group $\mathcal{G}$ and $\phi = \theta \circ \tau^{-1}$ the corresponding character of Γ_A.*

1. *$\phi_{\mathfrak{A}_\mathfrak{h}}(n) = \chi_\theta^*(n)$ for every integer $n \ge 1$.*
2. *χ_θ^* is the trivial character $\mathbf{1}$ if and only if $\theta = 1$.*
3. *If $\eta\colon \widehat{\Gamma}_A \to \mathbb{C}$ is compatible with $\mathfrak{h}$, then $\eta(\phi) = L'(1, \chi_\theta^*)/L(1, \chi_\theta^*)$ for $\theta \ne 1$, and $G_{\mathfrak{A}_\mathfrak{h},\eta}(y, \phi) = g(y, \chi_\theta^*)$ for all $y > 0$.*

Proof. Write $N = Q_S q d$ and use N_p, N_p', U_p, f_p from Definition 3.11. Here U_p is the kernel of reduction $(\mathbb{Z}/N\mathbb{Z})^\times \to (\mathbb{Z}/N_p'\mathbb{Z})^\times$, and ϕ is trivial on $I_p = \tau(\alpha(U_p))$ exactly when χ_θ is trivial on U_p.

Item 1. The function χ_θ^* is completely multiplicative, and $\phi_{\mathfrak{A}}(n) = \prod_{p|n} \mu_{I_p}(v_p(n)\mathrm{Fr}_p, \phi)$. So it suffices to show $\mu_{I_p}(i\mathrm{Fr}_p, \phi) = \chi_\theta^*(p)^i$ for every prime p and $i \ge 1$.

- *χ_θ trivial on U_p.* Then ϕ is trivial on I_p, so the coset mean is $\phi(i\mathrm{Fr}_p) = \chi_\theta(f_p)^i$. Moreover, χ_θ factors through $(\mathbb{Z}/N_p'\mathbb{Z})^\times$, so the conductor of χ_θ divides N_p', and $\chi_\theta^*(m) = \chi_\theta(u)$ for every m prime to N_p' and every unit $u \equiv m \pmod{N_p'}$. Taking $m = p$, which is prime to N_p', and $u = f_p$ gives $\chi_\theta^*(p) = \chi_\theta(f_p)$.
- *χ_θ not trivial on U_p.* The mean of a character over a coset of a subgroup on which it is not trivial is 0, so the coset mean vanishes. On the other hand, p divides the conductor c of χ_θ: otherwise $c \mid N_p'$ and χ_θ would be trivial on U_p. Hence $\chi_\theta^*(p) = 0 = \chi_\theta^*(p)^i$.

Item 2. $\chi_\theta^* = \mathbf{1}$ exactly when $\chi_\theta = \theta \circ \alpha$ is the principal character, which happens exactly when $\theta = 1$, because α is surjective by (Hr3).

Item 3. Let $\theta \ne 1$. By item 1, $\chi = \chi_\theta^*$ satisfies the condition in the definition of compatibility for $\phi' = \phi$ (which is non-trivial), so $\eta(\phi) = L'(1, \chi_\theta^*)/L(1, \chi_\theta^*)$. By item 2, χ_θ^* is non-principal. Comparing the definitions of $G_{\mathfrak{A},\eta}(y, \phi)$ and $g(y, \chi_\theta^*)$ term by term, using item 1, gives equality. For $\theta = 1$ both sides are $G(y)$. □

4 The accounting: Stepanov's count as a slope inequality

A slope datum is a finite record of real numbers (Definition 3.14). Among its entries are, for every translate u, a prime-sum entry S_u and a lattice term Θ_u. This section proves that the eleven slope conditions (Sl1)–(Sl11), which are inequalities between the entries, bound the prime-sum entry by an explicit main term:

$$S_u \le \mathrm{Main}(u) + \mathrm{Err}(u)$$

(Proposition 4.2). It then bounds the error under the size conditions (Lemma 4.7). When the prime-sum entries are the inert prime sums of an arithmetic datum, $\mathrm{Main}(u)$ is the sum of their main terms, and the result is an upper bound for the excess (Proposition 4.1). This bound is hypothesis (Ex4) of Proposition 3.3; the two are combined in Step 1 of the proof of Proposition 6.5 in Section 6.

No lattice occurs in the statements of this section. The numbers of a slope datum are ranks, slopes and heights of hermitian lattices only in the construction that produces them, and the accounting does not use this. It uses the eleven inequalities, in the following order. The loss condition (Sl8) bounds S_u by Θ_u plus a loss. The transfer of slopes (Sl7) and the ambient slope bounds (Sl6) bound the slope of every word from below by Θ_u, up to its frame term and its exponent, and the divisor bound (Sl2) bounds the dual slope from above by an archimedean term. Added and averaged over the words, they bound Θ_u plus the dual slope by the mean slope plus the archimedean term (Lemma 4.4). The dual-slope inequality (Sl9) bounds the mean slope by the dual slope, up to a term controlled by the spread of the slopes (Lemma 4.5, Lemma 4.6). The dual slope cancels, and with the counting bounds (Sl5) the archimedean term becomes $\mathrm{Main}(u)$ (Lemma 4.3). On the way the frame terms cancel between (Sl2) and (Sl7), the heights of the words cancel between (Sl2) and the mean slope, and the terms $m\,A\,l_g$ cancel between (Sl3) and (Sl5).

Where the eleven inequalities are proved is the subject of the rest of the paper. The loss condition (Sl8) follows from the loss bound of Section 5, through Corollary 7.11. The other ten follow from the properties (Sp1)–(Sp8) of slope records by Theorem 8.4 in Section 8, and Parts III and IV supply those properties; the table that closes Section 8 gives the result for each.

Proposition 4.1. *Let $\mathfrak{A}$ be an arithmetic datum on a finite abelian group H, $P \geq 1$ an integer, η a function on the characters of Γ_H, $T, T_2 \subseteq H$ finite sets and $\tilde{a}\colon H \to \mathbb{R}$ a function. Let $m \geq 1$, and let $w_{h,j}\colon \Gamma_H \to \mathbb{R}$ be weights for $h \in H$ and $1 \leq j \leq m$. Let $\mathfrak{S}$ be a slope datum with this m, together with a map $\mathrm{tr}\colon U \to H$ and bijections $\mathcal{T} \to T$, $\tau \mapsto t_\tau$, and $\{1, \dots, f\} \to \Phi$, $\rho \mapsto g_\rho$, such that*

(Id) *$a_\tau = \tilde{a}(t_\tau)$ for all τ; $w_{u,j,\rho} = w_{\mathrm{tr}(u),j}(g_\rho)$ for all u, j, ρ; $\gamma_0 = \gamma$; $\beta = \mathrm{Re}\,\eta(\chi_C)$; and $S_u = \sum_{t \in T} \sum_{j=1}^{m} A_{\mathrm{in}}(\tilde{a}(t), t, w_{\mathrm{tr}(u),j})$ for all $u \in U$, the inert prime sums formed with $(\mathfrak{A}, P)$.*

Suppose that $\mathfrak{S}$ satisfies the slope conditions for (c, X'') and the size conditions for (c, X'', e_K, C_K), that $B_0 \leq 2|H|mbx^{\varepsilon}$ and $N_c \leq x^{2\varepsilon}|T_2|kb/|H|^2$, and that the scale is large for $(\varepsilon, C_K, c_{\mathrm{HH}}, e_K)$. Then for every $u \in U$, with Δ formed with $(\mathfrak{A}, \eta, P, T, \tilde{a}, w)$,

$$\Delta(\mathrm{tr}(u)) \leq x^{(e_{\mathrm{Div}}+e_{\mathrm{Loss}}+3)\varepsilon}\Big(|T|\,a\Big(1+\frac{m^2}{k}\Big) + m\Big(2|H|mbx^{\varepsilon} + \frac{x^{2\varepsilon}|T_2|kb}{|H|^2}\Big)\Big).$$

Proof. Fix u and put $h = \mathrm{tr}(u)$.

The main terms match. Since $\rho \mapsto g_\rho$ is a bijection onto Φ, $f = |\Phi|$ and $\frac{1}{f}\sum_\rho \log w_{u,j,\rho} = \frac{1}{|\Phi|}\sum_{g \in \Phi} \log w_{h,j}(g)$ by (Id). With $a_\tau = \tilde{a}(t_\tau)$, $\gamma_0 = \gamma$ and $\beta = \mathrm{Re}\,\eta(\chi_C)$, the summand of $\mathrm{Main}(u)$ at (j, τ) is $\mathrm{Re}\,M_\eta(\tilde{a}(t_\tau), w_{h,j})$; reindexing $\tau \mapsto t_\tau$,

$$\mathrm{Main}(u) = \sum_{t \in T}\sum_{j=1}^{m} \mathrm{Re}\,M_\eta(\tilde{a}(t), w_{h,j}).$$

With the last clause of (Id) this gives $\Delta(h) = S_u - \mathrm{Main}(u)$.

The bound. By Proposition 4.2, $S_u - \mathrm{Main}(u) \leq \mathrm{Err}(u)$, and by Lemma 4.7,

$$\mathrm{Err}(u) \leq x^{(e_{\mathrm{Div}}+e_{\mathrm{Loss}}+3)\varepsilon}\Big(n_{\mathcal{T}}a\Big(1+\frac{m^2}{k}\Big) + m(B_0 + N_c)\Big).$$

Finally, $n_{\mathcal{T}} = |T|$ via the bijection $\mathcal{T} \to T$. Since $m \geq 0$ and the factor $x^{(e_{\mathrm{Div}}+e_{\mathrm{Loss}}+3)\varepsilon}$ is non-negative, the bounds on B_0 and N_c give the bracket of the statement. □

Proposition 4.2. *Let $\mathfrak{S}$ be a slope datum that satisfies the slope conditions for (c, X''). Put*

$$M'' = c_{\mathrm{Sl}}\mathrm{Lo} + c_{\mathrm{Sl}}\, n_{\mathcal{T}}\, m\Big(\frac{a}{k} + b'\Big) c_{\mathrm{Count}}\, m\, L + c_{\mathrm{Sl}} X'' + 1,$$
$$\bar{U}'' = c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a \Big(2 + \frac{m}{k}\Big) + V + c_{\mathrm{Sl}} m B_0 + M'',$$

and, for $u \in U$,

$$\begin{aligned}\mathrm{Err}(u) = {} & c_{\mathrm{Count}} A\Big(L_a + \frac{m^2 L_a}{k}\Big) + c_{\mathrm{Div}} n_{\mathcal{T}} a L_a + c_{\mathrm{Div}} m (B_0 + N_c) x^{e_{\mathrm{Div}}\varepsilon} \\ & + m c_E B_0 + c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a \Big(1 + \frac{m}{k}\Big) + \log|\mathcal{W}(u)| + \mathrm{Lo} + M'' \\ & + \frac{1}{1-\bar{\delta}}\Big(4\log\big(1 + x^{c_{\mathrm{HH}}}\big)\big(\bar{U}'' + b\big) + \big(\bar{\eta} + 4\sqrt{\bar{e}}\big) x^{c_{\mathrm{HH}}} b\Big).\end{aligned}$$

Then $S_u \le \mathrm{Main}(u) + \mathrm{Err}(u)$ for every $u \in U$.

Proof. Fix u and let $\overline{\mathrm{Lo}}''_u$, K_3 and K_0 be as in Lemma 4.4, Lemma 4.5 and Lemma 4.3.

The mean loss term. The coefficient $c_{\mathrm{Sl}} n_{\mathcal{T}} m(a/k + b')$ is non-negative by (Sl1), and $\log T_{u,\omega} \le c_{\mathrm{Count}} m L$ by (Sl5). Hence every $\mathrm{Lo}''_{u,\omega}$ is at most $c_{\mathrm{Sl}} I_u + c_{\mathrm{Sl}} n_{\mathcal{T}} m(a/k + b') c_{\mathrm{Count}} m L + c_{\mathrm{Sl}} X'' + 1$, and so is their weighted mean $\overline{\mathrm{Lo}}''_u$. Since $c_{\mathrm{Sl}} \ge 0$ and $I_u \le \mathrm{Lo}$ by (Sl8), $\overline{\mathrm{Lo}}''_u \le M''$.

The lattice term. By Lemma 4.3,

$$\Theta_u \le \mathrm{Main}(u) + \log|\mathcal{W}(u)| + K_0 + \overline{\mathrm{Lo}}''_u + \frac{1}{1-\bar{\delta}}\Big(4\log\big(1 + x^{c_{\mathrm{HH}}}\big)\big(K_3 + \overline{\mathrm{Lo}}''_u + b\big) + \big(\bar{\eta} + 4\sqrt{\bar{e}}\big) x^{c_{\mathrm{HH}}} b\Big).$$

The term $\overline{\mathrm{Lo}}''_u$ enters with the non-negative coefficients 1 and $4(1-\bar{\delta})^{-1}\log(1 + x^{c_{\mathrm{HH}}})$, so it may be replaced by M''; then $K_3 + M'' = \bar{U}''$, and $\Theta_u \le \mathrm{Main}(u) + \mathrm{Err}(u) - \mathrm{Lo}$.

The prime sum. By (Sl8), $S_u \le \Theta_u + \mathrm{Lo} \le \mathrm{Main}(u) + \mathrm{Err}(u)$. □

In the arithmetic part the entries of a slope datum are filled as follows; this is done in the proof of Theorem 8.4, at one scale x of a parametrised host family with slope records. The index u runs over the group A of the frame, τ over the top set T of the host, ρ over the $2|A|$ elements of Φ, and ω over the words of the slope record of the member that carries the translate u. The parameters are

$$b = \exp(x^{\varepsilon}), \qquad a = xb, \qquad b' = a/X' \ \text{ with } X' = \exp(x^{\varepsilon/3}), \qquad L = x^{\varepsilon}, \qquad X'' = x\,|A|\,X',$$

and k, m are parameters of the loss data of the members (Definition 5.5). The number v is half the root discriminant of the host field, $L_a = \log(2av)$, γ_0 is Euler's constant, $\beta = L'(1,\chi_d)/L(1,\chi_d)$ for the Legendre symbol χ_d modulo d, and $l_g = \log(g_1 g_2)$ for two auxiliary primes. The budgets are $B_0 = 2|A|\, m\, b\, x^{\varepsilon}$ and $N_c = |T_2|\, k\, b\, x^{2\varepsilon}/|A|^2$, where T_2 is the thick set (Definition 8.1). The numbers a_τ are the heights of the tops, and $w_{u,j,\rho}$ are the weights of the loss datum of the member that carries u. For a word ω, the entries d, T, μ, $\mu^{\max}$, h, μ', $\mu'^{\max}$ and E_j are its rank, Gauss prime, slope, maximal slope, height, ambient slope, maximal ambient slope and exponents in the slope record, and $\mu^{\vee}$, $\mu^{\vee}_{\min}$, F, δ are the dual slope, the minimal dual slope, the frame term and the irreducibility defect of the record. Three entries come from the loss datum and not from the slope record: the prime sum S_u, which is the sum of the inert prime sums of the host with the cut-off $\lceil 2x\exp(x^{\varepsilon})\rceil$, the lattice term Θ_u, and the companion sum I_u. The word height has two unrelated uses here, for the numbers a_τ of the tops and for the numbers h of the words.

Under this dictionary the two main terms agree for the following reason. The term $a_\tau(\log a_\tau - 1 - \gamma_0 + \beta)$ of $\mathrm{Main}(u)$ comes from the divisor bound (Sl2), in which β enters through $\log\Omega = \gamma_0 + \log(\pi/v) - \beta$, and the mean of $\log w_{u,j,\rho}$ comes from the counting bounds (Sl5). The main term of an inert prime sum contains the value $\eta(\chi_C)$ at the quadratic character whose kernel is Φ. For a host this character is the Legendre symbol χ_d, so that $\eta(\chi_C) = \beta$ (proof of Theorem 8.4).

The meaning of the entries in the construction beneath (TCS) is described in Appendix A; we state it here as a reading, since no statement of this paper uses it. A word indexes a hermitian lattice inside an ambient lattice. The entries d, μ, $\mu^{\max}$ are the rank, the slope and the maximal slope of the first, μ' and $\mu'^{\max}$ those of the second, and $\mu^\vee$ is the slope of a dual lattice; slopes are those of Arakelov geometry [46]. The integer m is the number of theta lifts in a chain, and Θ_u is the total gain in divisibility of the m lifts at the inert primes. In this reading the divisor bound (Sl2) bounds the norms of the lifts ([4], item 9 of the list on pp. 3–4): each of the m lifts contributes one copy of $a_\tau \log a_\tau - a_\tau - a_\tau \log\Omega$, which is why this term carries the factor m, and $\log\Omega$ has the role of the logarithm of a CM period. The dual-slope inequality (Sl9) is the slope inequality, and (Sl8) says that the divisibility dominates the prime sum.

Lemma 4.3. *Let $\mathfrak{S}$ be a slope datum satisfying (Sl1)–(Sl7) and (Sl9)–(Sl11) for (c, X''), and put*

$$K_0 = c_{\mathrm{Count}} A\Big(L_a + \frac{m^2 L_a}{k}\Big) + c_{\mathrm{Div}} n_{\mathcal{T}} a L_a + c_{\mathrm{Div}} m(B_0 + N_c) x^{e_{\mathrm{Div}}\varepsilon} + m c_E B_0 + c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a \Big(1 + \frac{m}{k}\Big).$$

Then for every $u \in U$,

$$\Theta_u \le \mathrm{Main}(u) + \log|\mathcal{W}(u)| + K_0 + \overline{\mathrm{Lo}}_u'' + \frac{1}{1-\bar\delta}\Big(4\log\big(1 + x^{c_{\mathrm{HH}}}\big)\big(K_3 + \overline{\mathrm{Lo}}_u'' + b\big) + \big(\bar\eta + 4\sqrt{\bar e}\big)x^{c_{\mathrm{HH}}} b\Big).$$

Proof. Fix u, and let $\mathrm{Cnt}(u)$ and $K_5(u)$ be as in Lemma 4.4.

Step 1: $K_5(u) = \mathrm{Main}(u) + K_0$. Since $w_{u,j,\rho} > 0$, $v > 0$ and $f > 0$ by (Sl1),

$$A\,\mathrm{Cnt}(u) = \frac{A}{f}\sum_{j,\rho} \log w_{u,j,\rho} + mA(\log v - \log\pi) + mAl_g - c_{\mathrm{Count}} A\Big(L_a + \frac{m^2 L_a}{k}\Big),$$

and, expanding φ and $\log\Omega$,

$$\sum_\tau m(\varphi(a_\tau) - a_\tau\log\Omega) = m\sum_\tau a_\tau(\log a_\tau - 1 - \gamma_0 + \beta) - mA(\log\pi - \log v).$$

Hence $\sum_\tau m(\varphi(a_\tau) - a_\tau\log\Omega) - A\mathrm{Cnt}(u) + mAl_g = \mathrm{Main}(u) + c_{\mathrm{Count}}A(L_a + m^2L_a/k)$, which is the identity of Step 1 after the remaining terms of $K_5(u)$ are added.

Step 2. By Lemma 4.4 and Step 1,

$$\Theta_u \le \mathrm{Main}(u) + K_0 + \overline{\mathrm{Lo}}_u'' + (s_u - \mu_u^\vee).$$

Step 3: the dual-slope inequality. By (Sl11) and (Sl1), $0 \le \delta_u \le \bar\delta < 1$, $\eta_u \ge 0$ and $0 \le e_u \le \bar e \le \frac14$; by (Sl10), $s_u - \mu^\vee_{\min,u} \le \mathrm{HH}_u$ and $\mathrm{HH}_u > 0$. So the premises of (Sl9) hold, and

$$s_u - \mu_u^\vee \le \log|\mathcal{W}(u)| + \frac{1}{1-\delta_u}\Big(4\phi_u\log\Big(1 + \frac{\mathrm{HH}_u}{\phi_u}\Big) + \big(\eta_u + 4\sqrt{e_u}\big)\mathrm{HH}_u\Big).$$

Step 4: the bracket. The spread is non-negative: by (Sl1) every $\mu_{u,\omega} - h_{u,\omega}$ is at most $\max_{\omega'}(\mu^{\max}_{u,\omega'} - h_{u,\omega'})$, and so is their weighted mean s_u. By Lemma 4.5, $\phi_u \le K_3 + \overline{\mathrm{Lo}}_u''$; by

(Sl10), $0 < \mathrm{HH}_u \le x^{c_{\mathrm{HH}}} b$, where $x^{c_{\mathrm{HH}}} > 0$ and $b > 0$ by (Sl1). So Lemma 4.6, with $u = \phi_u$, $H = \mathrm{HH}_u$, $X = x^{c_{\mathrm{HH}}}$ and $U = K_3 + \overline{\mathrm{Lo}}''_u$, gives

$$\phi_u \log\Big(1 + \frac{\mathrm{HH}_u}{\phi_u}\Big) \le \log(1 + x^{c_{\mathrm{HH}}})(K_3 + \overline{\mathrm{Lo}}''_u + b).$$

Also $(\eta_u + 4\sqrt{e_u})\mathrm{HH}_u \le (\bar\eta + 4\sqrt{\bar e})x^{c_{\mathrm{HH}}} b$ by (Sl10) and (Sl11). The bracket of Step 3 is non-negative, and $(1-\delta_u)^{-1} \le (1-\bar\delta)^{-1}$. Inserting these bounds into Step 3, and Step 3 into Step 2, gives the claim. □

Lemma 4.4. *Let $\mathfrak{S}$ be a slope datum, c a constant vector and $X'' \in \mathbb{R}$, and suppose that $\mathfrak{S}$ satisfies (Sl1), (Sl2), (Sl3), (Sl5), (Sl6) and (Sl7) for (c, X''). For $u \in U$ put*

$$\mathrm{Cnt}(u) = \frac{1}{f}\sum_{j=1}^{m}\sum_{\rho=1}^{f} \log\frac{w_{u,j,\rho}\, v}{\pi} + m l_g - c_{\mathrm{Count}}\Big(L_a + \frac{m^2 L_a}{k}\Big), \qquad \overline{\mathrm{Lo}}''_u = \frac{\sum_\omega d_{u,\omega}\mathrm{Lo}''_{u,\omega}}{\sum_\omega d_{u,\omega}},$$

$$K_5(u) = c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a\Big(1 + \frac{m}{k}\Big) + m(A l_g + c_E B_0) + \sum_\tau m(\varphi(a_\tau) - a_\tau \log\Omega) \\ - A\,\mathrm{Cnt}(u) + c_{\mathrm{Div}} n_{\mathcal{T}} a L_a + c_{\mathrm{Div}} m(B_0 + N_c) x^{e_{\mathrm{Div}}\varepsilon}.$$

Then for every $u \in U$,

$$\Theta_u + \mu_u^\vee - K_5(u) - \overline{\mathrm{Lo}}''_u \le s_u.$$

Proof. Fix u and a word $\omega \in \mathcal{W}(u)$. The second inequality of (Sl7) gives

$$\mu_{u,\omega} \ge \mu'_{u,\omega} + \Theta_u + F_u - E_{u,\omega} - \mathrm{Lo}''_{u,\omega},$$

and (Sl2), using $\sum_\tau a_\tau \log T_{u,\omega} = A \log T_{u,\omega}$, gives

$$-h_{u,\omega} \ge \mu_u^\vee - F_u - \sum_\tau m(\varphi(a_\tau) - a_\tau\log\Omega) + A\log T_{u,\omega} - c_{\mathrm{Div}} n_{\mathcal{T}} a L_a - c_{\mathrm{Div}} m(B_0 + N_c) x^{e_{\mathrm{Div}}\varepsilon}.$$

Adding, the terms F_u cancel. Now $A \ge 0$ by (Sl1), so the lower bound $\log T_{u,\omega} \ge \mathrm{Cnt}(u)$ of (Sl5) gives $A\log T_{u,\omega} \ge A\mathrm{Cnt}(u)$; (Sl3) gives $E_{u,\omega} \le m(A l_g + c_E B_0)$; and (Sl6) gives $\mu'_{u,\omega} \ge -c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a (1 + m/k)$. Together,

$$\mu_{u,\omega} - h_{u,\omega} \ge \Theta_u + \mu_u^\vee - K_5(u) - \mathrm{Lo}''_{u,\omega}.$$

The weights $d_{u,\omega}$ are positive by (Sl1), and $\mathcal{W}(u)$ is non-empty. Taking the weighted mean over $\omega \in \mathcal{W}(u)$ gives the claim, since the left side of the last display has mean s_u and the right side has mean $\Theta_u + \mu_u^\vee - K_5(u) - \overline{\mathrm{Lo}}''_u$. □

Lemma 4.5. *Let $\mathfrak{S}$ be a slope datum satisfying (Sl1), (Sl3), (Sl4), (Sl5), (Sl6) and (Sl7) for (c, X''), and put*

$$K_3 = c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a\Big(2 + \frac{m}{k}\Big) + V + c_{\mathrm{Sl}} m B_0.$$

Then for all $u \in U$ and $\omega, \omega' \in \mathcal{W}(u)$,

$$(E_{u,\omega'} + h_{u,\omega'}) - (E_{u,\omega} + h_{u,\omega}) \le V,$$

and for every $u \in U$, with $\overline{\mathrm{Lo}}''_u = \sum_\omega d_{u,\omega}\mathrm{Lo}''_{u,\omega} / \sum_\omega d_{u,\omega}$,

$$\phi_u \le K_3 + \overline{\mathrm{Lo}}''_u.$$

Proof. First inequality. By (Sl3), applied to ω and to ω', $E_{u,\omega'} - E_{u,\omega} \le 2mc_E B_0$. By (Sl4),

$$h_{u,\omega'} - h_{u,\omega} \le c_H\big(n_{\mathcal{T}} a L_a + mB_0\big) + A\big(\log T_{u,\omega} - \log T_{u,\omega'}\big),$$

and since $A \ge 0$ by (Sl1), the last term is at most $c_{\mathrm{Count}} A \log k$ by (Sl5). Adding gives the bound V.

Second inequality. Fix ω. For every ω', the first part of (Sl7) at ω and the second part at ω' give

$$\mu^{\max}_{u,\omega} - \mu_{u,\omega'} \le \big(\mu'^{\max}_{u,\omega} - \mu'_{u,\omega'}\big) + \big(E_{u,\omega'} - E_{u,\omega}\big) + c_{\mathrm{Sl}} mB_0 + \mathrm{Lo}''_{u,\omega'},$$

the terms $\Theta_u + F_u$ cancelling. By (Sl6), $\mu'^{\max}_{u,\omega} - \mu'_{u,\omega'} \le c_{\mathrm{Slope}} n_{\mathcal{T}} a L_a (2 + m/k)$; with the first part this gives

$$\big(\mu^{\max}_{u,\omega} - h_{u,\omega}\big) - K_3 - \mathrm{Lo}''_{u,\omega'} \le \mu_{u,\omega'} - h_{u,\omega'}.$$

The weights $d_{u,\omega'}$ are positive by (Sl1), and taking the weighted mean over ω' gives $\mu^{\max}_{u,\omega} - h_{u,\omega} - K_3 - \overline{\mathrm{Lo}}''_u \le s_u$. Taking the maximum over ω and subtracting s_u gives $\phi_u \le K_3 + \overline{\mathrm{Lo}}''_u$. □

Lemma 4.6. *Let u, H, X, b, U be real numbers with $0 \le u \le U$, $0 < H \le Xb$, $b > 0$ and $X > 0$. Then*

$$u \log\Big(1 + \frac{H}{u}\Big) \le \log(1 + X)\,(U + b),$$

where the left-hand side is read as 0 when $u = 0$.

Proof. Put $\lambda = \log(1+X) > 0$. If $u = 0$ the left side is 0 and the right side is $\lambda(U+b) \ge \lambda b > 0$. Let $u > 0$. For $y, z > 0$ one has $\log(y/z) \le y/z - 1$; with $y = 1 + H/u$ and $z = 1 + X$ this gives

$$\log\Big(1 + \frac{H}{u}\Big) \le \lambda + \frac{1 + H/u}{1 + X} - 1, \qquad \text{so} \qquad u \log\Big(1 + \frac{H}{u}\Big) \le u\lambda - \frac{uX}{1 + X} + \frac{H}{1 + X}.$$

Here $-uX/(1+X) \le 0$ and $u\lambda \le U\lambda$. Since $H \le Xb$, $H/(1+X) \le b\,X/(1+X) = b(1 - (1+X)^{-1}) \le b\lambda$, the last step by $1 - z^{-1} \le \log z$ for $z = 1 + X$. Adding gives the claim. □

Lemma 4.7. *Let $\mathfrak{S}$ be a slope datum that satisfies the size conditions for (c, X'', e_K, C_K), at a scale that is large for $(\varepsilon, C_K, c_{\mathrm{HH}}, e_K)$. Then for every $u \in U$,*

$$\mathrm{Err}(u) \le x^{(e_{\mathrm{Div}} + e_{\mathrm{Loss}} + 3)\varepsilon}\Big(n_{\mathcal{T}}\, a\Big(1 + \frac{m^2}{k}\Big) + m(B_0 + N_c)\Big).$$

Proof. We bound the terms of $\mathrm{Err}(u)$ one by one. Write $y = x^{\varepsilon} \ge 1$. Each of the finitely many terms of $\mathrm{Err}(u)$ is bounded by a product of at most three factors y, $x^{e_{\mathrm{Div}}\varepsilon}$, $x^{e_{\mathrm{Loss}}\varepsilon}$, a constant at most $200(1 + C_K)^2(1 + c_{\mathrm{HH}})(1 + e_K) \le y$, and one of $n_{\mathcal{T}} a$, $n_{\mathcal{T}} a m^2/k$, mB_0, mN_c. We use the following bounds:

- $A \le 2n_{\mathcal{T}} a$ (from $a_\tau \le 2a$);
- $\log|\mathcal{W}(u)| \le k \le a$ (from (Er3));
- $\log k \le (1 + e_K)y$ and $\log(1 + x^{c_{\mathrm{HH}}}) \le (1 + c_{\mathrm{HH}})y$ (from $k \le x^{e_K}$ and $\log x \le y$);
- $(1 - \bar{\delta})^{-1} \le 2$;
- $L, L_a \le 2y$;

- $m \le k$ and $mb \le a$ (from $xm \le k$, $m \le x$ and $xb \le a$);
- $kb' \le a$ and $X'' \le a$;
- the constants are at most C_K;
- the last clause of (Er4), for the term $(\bar{\eta} + 4\sqrt{\bar{e}})x^{c_{\mathrm{HH}}}b$.

Collecting the terms gives the claim.

□

Remark (Stepanov's count and the balance). Proposition 4.2 has the structure of Stepanov's proof of the Riemann hypothesis for curves over finite fields [247], in the form of Bombieri [36]. There an auxiliary function vanishes to order at least M at every rational point of a curve over $\mathbb{F}_q$. The count of its zeros against its poles bounds the number of rational points from above by q plus two error terms, one decreasing and one increasing in M, and the two balance when M is about $\sqrt{q}$. Alpöge describes the present argument as a descendant of this proof in which multiplicity is hard to find over the integers and a chain of theta lifts supplies it, the chain having length about $\sqrt{X}$ for the von Mangoldt sum of length X ([4], p. 1).

The accounting matches this description term by term, as a reading: the statements above are about real numbers and do not depend on it. The count of zeros against poles is the dual-slope inequality (Sl9), a slope inequality in the sense of Bost [46], [47]. The order of the poles is the archimedean term of the divisor bound (Sl2). The order of vanishing is the integer m, the multiplicity. The vanishing at the rational points is the loss condition (Sl8), divisibility at the inert primes, to which Section 5 is devoted.

The balance is a fact about the error term. By Lemma 4.7 and the bounds (Ct5) for the two budgets, the error is at most $x^{O(\varepsilon)}$ times

$$|T|\,a\Big(1+\frac{m^2}{k}\Big)+m\Big(2|A|\,m\,b\,x^{\varepsilon}+\frac{x^{2\varepsilon}|T_2|\,k\,b}{|A|^2}\Big),$$

and the averaging step of Section 3 divides it by $|T|\,m\,b\,|T_2|/(2|A|)$. Since $a \le 2xb$, $|T| \ge \frac{1}{2}x^{-\varepsilon/8}|A|$ and $|T_2| \ge x^{-\varepsilon}|A|$, the four terms then have, up to factors $x^{O(\varepsilon)}$, the shapes

$$\frac{x}{m}, \qquad \frac{xm}{k}, \qquad m, \qquad \frac{k}{|A|\,|T|}.$$

The first does not grow with the number of lifts, and the third is the cost that each lift adds: the budgets B_0 and N_c enter the divisor bound (Sl2) with the factor m. These two balance at $m = \sqrt{x}$, which is the balance $M \approx \sqrt{q}$ with the number of lifts in the role of the order of vanishing. The second shape is at most 1 because $xm \le k$, and the fourth is at most $x^{1/2+O(\varepsilon)}$ because $k \le |A|^2 x^{1/2-\varepsilon}$. The two conditions on k are compatible only if $|A|^2 \ge x^{1/2+\varepsilon}m$, so the group A must have at least about $\sqrt{x}$ elements. The accounting itself uses only

$$x^{1/2-\varepsilon} \le m \le x^{1/2+\varepsilon/2}, \qquad xm \le k \le |A|^2 x^{1/2-\varepsilon}$$

(conditions (Ex2) of Proposition 3.3 and (Sp8) of Definition 8.2). The hosts supplied in Part II come with rank data that have the rank sizes of Definition 11.2:

$$x^{2+8\varepsilon} \le |A| \le 2x^{2+8\varepsilon}, \qquad \sqrt{x\delta_1} \le m \le 2\sqrt{x\delta_1} \ \text{ with } \delta_1 = x^{-\varepsilon/8}, \qquad x^{9/2+10\varepsilon} \le k \le 2x^{9/2+10\varepsilon}.$$

Thus m is $x^{1/2-\varepsilon/16}$ up to a factor 2, the group A has about $x^{2+8\varepsilon}$ elements, far more than the $\sqrt{x}$ that the balance needs, and the bound that results is $G_{\mathfrak{L}}(x) \le x^{1/2+(e_D+e_L+7)\varepsilon}$ (Proposition 6.5).

5 Divisibility at inert primes: the loss bound

The accounting of Section 4 starts from the loss condition (Sl8): the prime sum S_u exceeds the lattice term Θ_u by at most a small loss. This section proves the bound behind it, Theorem 5.6. For a loss datum $\mathfrak{M}$ at a large scale x that satisfies the conditions (Lm1)–(Lm7),

$$S(\mathfrak{M}) - \Theta(\mathfrak{M}) \le (3C^+ + 13)\,|T|\,m\,b \qquad \text{and} \qquad I(\mathfrak{M}) \le |T|\,m\,b, \qquad b = \exp(x^{\varepsilon}).$$

Its only use is in Corollary 7.11 in Section 7, which applies it to the members of a parametrised host family and obtains (Sl8) with the loss exponent $e_{\mathrm{Loss}} = 0$.

In Stepanov's method the auxiliary function vanishes at the rational points. Here the place of this vanishing is taken by divisibility at the primes inert in $\mathbb{Q}(\sqrt{-d})$: in Alpöge's account, a derivative of order a of a theta function on a CM curve, normalised by the period, is divisible by an inert prime p to the power $a/p + a/p^3 + \cdots$, up to $O(\log a)$, and the lift of multiplicity m inherits a sufficient lower bound ([4], items 2 and 10 of the list on pp. 3–4). The statements of this section contain the same exponent. An inert prime p contributes to the inert prime sum the terms $(a/p^e - w)^+$ with e odd, at most $a\gamma_p$ in total, where $\gamma_p = p/(p^2-1) = \sum_{e\ \mathrm{odd}} p^{-e}$, and the gain of a served orbit starts from γ_p times the sum of the reduced heights of its tops (Definition 5.3). We read the gains as the divisibility of the theta kernels of the lifts. This reading belongs to the construction beneath (TCS), described in Appendix A, and is not used: a loss datum is a record of numbers, and its gains are defined by formulas.

What the theorem proves is a summation over the primes. Its local hypothesis is the linking condition (Lm3), which says, at each served inert prime, that the contribution of the prime to the prime sum is at most its gain, up to a local loss and a floor loss. For the families of this paper the linking condition is proved in Part IV (Theorem 18.4). The theorem sums it over all inert primes and bounds what the local inequality does not cover: the primes that are not served, the tops that are not served at a served prime, and the sums of the local and floor losses. The proof splits the difference $S - \Theta$ prime by prime (Proposition 5.9) and bounds the buckets that arise (Lemma 5.8, Proposition 5.7). Of the remaining lemmas, Lemma 5.10 shows that the primes of the first kind are sparse, and the others check sizes and identifications; they are routine.

Definition 5.1. Let $\mathfrak{A}$ be an arithmetic datum on a finite abelian group H and $T \subseteq H$ a set, whose elements are called **tops**. We write the elements of Φ as pairs $(\epsilon', h) \in \mathbb{Z}/2 \times H$, standing for $((0,\epsilon'),h)$; the places $(0,t)$ with $t \in T$ are the **top places**. Let p be a prime that is inert for $\mathfrak{A}$.

Frobenius translation. Since $\mathrm{Fr}_p \notin \Phi$, the element $f_p = c_\infty + \mathrm{Fr}_p$ lies in Φ; write $f_p = (s_p, h_p)$. The prime p is **sign-changing** if $s_p = 1$. Translation by f_p permutes Φ. Its order, which is the order of f_p in Γ_H, is denoted n_p (so n_p is the order of h_p if $s_p = 0$, and 2 times the order of $2h_p$ if $s_p = 1$). For a top t and an integer $e \ge 1$, the **e-th partner** of t at p is the place

$$z_p(t,e) = (0,t) + e\,f_p = (e\,s_p,\ t + e\,h_p) \in \Phi.$$

For odd e one has $z_p(t,e) = \sigma_t(e\,\mathrm{Fr}_p)$, the place whose weight occurs in the inert prime sum A_{in}.

Orbits. Put $g_p = h_p$ if $s_p = 0$ and $g_p = 2h_p$ if $s_p = 1$. The **orbits of p on H** are the cosets of the subgroup $\langle g_p \rangle$; they are the intersections of the orbits of translation by f_p on Φ with the row $\{0\} \times H$. An **orbit labelling** at p is a map $\rho_p \colon H \to H$ with $\rho_p(t + g_p) = \rho_p(t)$ and $t \in \rho_p(t) + \mathbb{N} g_p$ for all t. Such a map chooses one element in each orbit, the **representative**. Given an orbit labelling, let $R_p = \rho_p(H)$ be the set of representatives, and for $v \in R_p$ let

$$T_p(v) = \{t \in T : \rho_p(t) = v\}, \qquad N_p(v) = |T_p(v)|,$$
$$P_p(v) = \{\, i \in \{0,1,\dots,\mathrm{ord}(h_p) - 1\} : v + i\,h_p \in T \,\}$$

be the tops on the orbit of v, their number, and the **positions** of tops along the orbit of v under translation by h_p. A top t lies at an **even position** if $t = \rho_p(t) + i\,h_p$ for some even i with $0 \le i < n_p$, and at an **odd position** otherwise. (If p is sign-changing, every top lies at an even position.)

First hits. Let $s \neq s'$ be tops and $e \ge 1$. The exponent e is the **first hit** of s' from s if $z_p(s,e) = (0,s')$ and $z_p(s,e') \neq (0,s')$ for $0 < e' < e$. An exponent e is **excluded** for the top s if e is odd and is the first hit from s of some top $s' \neq s$.

Definition 5.2. Let $\mathfrak{A}$ be an arithmetic datum on H with a set of tops $T \subseteq H$ and an orbit labelling ρ_p at every inert prime p. An **orbit selection** for $(\mathfrak{A}, T, (\rho_p))$ consists of real numbers $x > 1$, $0 < \varepsilon < \frac{1}{52}$, X'', p_0 and $\rho \ge 0$, an integer $m \ge 1$, and for every inert prime p a set $G_p \subseteq R_p$ of **good representatives** and numbers $\kappa_p(v) \in [0,1]$ $(v \in G_p)$, the **orbit constants**. Put $X' = \exp(x^{\varepsilon/3})$. The thresholds have the following roles: X' separates the small from the large inert primes, X'' is the cut-off of the gains, p_0 separates the two regimes of the gains (below p_0 the price of an orbit carries an extra rank factor), and ρ is the relative width of the bands around X'.

Candidates. An inert prime p is a **candidate** if p is not sign-changing, $p < X'$, the order of h_p is at least $x^{\varepsilon/4}$, and, when $p \ge p_0$, no power p^i with $i \ge 1$ satisfies $|p^i - X'| \le \rho X'$ (that is, p lies in no **band** around X'). The **orbit mass** at p is $\Sigma_p = m \sum_{v \in G_p} \kappa_p(v)$.

Served orbits and served tops. The orbits of a candidate of small orbit mass are served: put

$$V_p = \begin{cases} G_p & \text{if } p \text{ is a candidate and } \Sigma_p \le x^{-\varepsilon}, \\ \emptyset & \text{otherwise.} \end{cases}$$

The **served tops** at p are $T_p^{\mathrm{s}} = T$ if p is sign-changing or $p \ge X'$, and $T_p^{\mathrm{s}} = \{t \in T : \rho_p(t) \in V_p\}$ otherwise.

Dropped primes. An inert prime p is **dropped** if one of the following holds:

(Dr1) $p > X''$;

(Dr2) p is not sign-changing, and $h_p \neq 0$ has odd order;

(Dr3) p is not sign-changing, $p < X'(1+\rho)$, and either the order of h_p is less than $x^{\varepsilon/4}$, or $p \ge p_0$ and $|p^i - X'| \le \rho X'$ for some $i \ge 1$, or p is a candidate with $\Sigma_p > x^{-\varepsilon}$.

Classes. An inert prime p is **served** if it is not dropped. A dropped prime is **high** if $p > X''$; of the **second kind** if $p \le X''$ and p is a candidate with $\Sigma_p > x^{-\varepsilon}$; and of the **first kind** otherwise. Thus every inert prime is in exactly one of the four classes served, first kind, second kind, high.

Definition 5.3. Fix an arithmetic datum on H with tops T, orbit labellings (ρ_p) and an orbit selection. A **gain datum** on these consists of

- integers a_t, b_t $(t \in T)$, the **heights** and **depths** of the tops;
- functions $w_j \colon \Phi \to \mathbb{R}$ $(1 \le j \le m)$, the **weights**;
- real numbers $\varsigma_1, \dots, \varsigma_m$ (the **shifts**), c_G, $a > 0$, b', η, w'', N and an integer $r_G \ge 1$;
- for every inert prime p, integers $\epsilon_p, D_p \ge 0$ and real numbers $t_p(v)$ $(v \in V_p)$, the **thresholds**.

We write $\log_p y = \log y / \log p$, $y^+ = \max(y, 0)$ and $\lceil y \rceil^+ = \max(\lceil y \rceil, 0)$. A series over the odd integers $e \geq 1$ that does not converge is given the value 0. The series below converge when all capacities are positive.

Reduced heights, capacities, losses. For a top s, an inert prime p, $e \geq 1$ and $1 \leq j \leq m$ put

$$\alpha_s = a_s - 2c_G, \qquad c_j(s,e) = w_j(z_p(s,e)) - \varsigma_j + c_G, \qquad \gamma_p = \frac{p}{p^2-1} = \sum_{e \text{ odd}} p^{-e},$$

and, for $v \in R_p$, let the **orbit loss** be $\delta_p(v) = 5\, n_p\, N^2 \log_p(2a) + 4\, N_p(v) \big(\log_p(2a)\big)^2$.

The two gains of an orbit. The *plain gain* of the orbit of $v \in R_p$ adds, over the tops of the orbit and the odd exponents that are not excluded, the excess of the reduced height over the capacity of the partner place, as in the inert prime sum. The *served gain* counts the tops at even positions in full, and the tops at odd positions as the plain gain does but without exclusions (when all capacities are non-negative, by $y - \min(y,c) = (y-c)^+$):

$$g_j^0(v) = \sum_{s \in T_p(v)} \sum_{\substack{e \text{ odd} \\ e \text{ not excluded for } s}} \Big(\frac{\alpha_s}{p^e} - c_j(s,e) \Big)^+ - \delta_p(v),$$

$$g_j^U(v) = \gamma_p \sum_{s \in T_p(v)} \alpha_s - \sum_{\substack{s \in T_p(v) \\ \text{odd position}}} \sum_{e \text{ odd}} \min\Big(\frac{\alpha_s}{p^e},\, c_j(s,e) \Big) - \delta_p(v).$$

The served gain has a **price**

$$\mathrm{Pr}_j(v) = \begin{cases} \displaystyle\sum_{\substack{s \in T_p(v) \\ \text{odd position}}} \big(w_j(0,s) - \varsigma_j - b_s \big) + n_p\big(w'' + \eta + c_G + N \big) & \text{if } p \geq p_0, \\ r_G\Big(N_p(v)\, (2b' + c_G) + n_p\big(w'' + \eta + c_G + N \big) \Big) & \text{if } p < p_0. \end{cases}$$

Gains. The gain at p takes, on each served orbit, the best of the served gain after its price, the plain gain and 0, and on every other orbit the plain gain if it is positive:

$$\mathrm{gain}_j(p) = \sum_{v \in V_p} \max\big(g_j^U(v) - \mathrm{Pr}_j(v),\ g_j^0(v),\ 0 \big) + \sum_{v \in R_p \setminus V_p} \max\big(g_j^0(v), 0 \big),$$

except that $\mathrm{gain}_j(p) = 0$ if $p > X''$, or if p is not sign-changing and $h_p = 0$. The **gain of the member** at p is $\mathrm{gain}_j^{\mathrm{D}}(p) = 0$ if p is dropped and $\mathrm{gain}_j^{\mathrm{D}}(p) = \mathrm{gain}_j(p)$ otherwise.

Correction. The correction pays for the served orbits:

$$\tau_p = \begin{cases} 0 & \text{if } V_p = \emptyset, \\ \epsilon_p + m \displaystyle\sum_{v \in V_p} \big(\lceil t_p(v) \rceil^+ + D_p + 1 \big) & \text{otherwise.} \end{cases}$$

Companion term. For $v \in V_p$ the **surplus** of the served gain over the plain gain is the integer $S_p(v) = \big\lceil \sum_{j=1}^m \big(g_j^U(v) - \mathrm{Pr}_j(v) - \max(g_j^0(v), 0) \big)^+ \big\rceil \geq 0$, and

$$\mathrm{io}_p = \begin{cases} 0 & \text{if } V_p = \emptyset, \\ 2\, \Sigma_p \max_{v \in V_p} S_p(v) & \text{otherwise.} \end{cases}$$

Definition 5.4. A tuple of **window parameters** is a tuple of real numbers $x, \varepsilon, n, k, N, t, L_a, r_G, S_c, \eta, \rho, \vartheta, K_0, C, \beta, C_{\mathrm{ord}}, Y, s_0, b_o$ and integers $e_2, p_0, d \geq 0$. Its **derived quantities** are

$$b = \exp(x^{\varepsilon}), \quad a = xb, \quad X' = \exp(x^{\varepsilon/3}), \quad b' = a/X', \quad w'' = \frac{b'}{xn}, \quad X'' = \frac{a}{w''} = xnX', \quad f = 2n,$$
$$\lambda = \log x, \quad \delta_1 = x^{-\varepsilon/8}, \quad \theta = x^{-\varepsilon}, \quad S_k = S_c + k + \eta, \quad Q_1 = Cr_G b'\lambda,$$
$$Q_2 = C\Big(\frac{b'}{x} + \eta + S_c + \frac{(w''+t)\lambda}{\delta_1}\Big) + b_o, \qquad J_o = \lfloor x^{\varepsilon/4} \rfloor, \qquad I_b = \lfloor x^{\varepsilon/3} \rfloor.$$

For real numbers e, K the tuple is **admissible for** (e, K) if the following hold.

Scale. $0 < \varepsilon \leq 1$, $e \geq 0$, $K \geq 1$.

Ranks. $x^2 \leq 2^{e_2} \leq n \leq x^e$; $x^2 \leq k \leq x^e$; $0 \leq N \leq x^e$; $0 \leq t \leq x^e$; $0 \leq r_G \leq x^e$.

Thresholds. $x^4 + 1 \leq p_0 \leq x^e$; $x^2 \leq K_0$; $x^2 \leq d$; $1 \leq Y \leq 2X'$.

Small quantities. $0 \leq L_a \leq x^{2\varepsilon}$; $0 \leq \rho \leq x^{-2}$; $0 \leq \vartheta \leq x^{-1}$; $0 \leq s_0 \leq x^{-2}$; $0 \leq \beta \leq Kx^{-2}$.

Moderate quantities. $0 \leq S_c \leq \exp(x^{\varepsilon/4})$; $0 \leq \eta \leq \exp(x^{\varepsilon/4})$; $0 \leq b_o \leq \exp(x^{\varepsilon}/2)$; $0 \leq C \leq K$; $0 \leq C_{\mathrm{ord}} \leq K$.

The scale is **large for** (e, K) if $x \geq 1$, $100Kx^{4\varepsilon} \leq x$, $100Kx^{4e+4} \leq \exp(x^{\varepsilon/3})$ and

$$100Kx^{4e+4}\exp(x^{\varepsilon/3} + x^{\varepsilon/4}) \leq \exp(x^{\varepsilon}/2).$$

Definition 5.5. A **loss datum** $\mathfrak{M}$ consists of the following.

- An arithmetic datum $\mathfrak{A} = (q, d, (I_p), (\mathrm{Fr}_p))$ on a finite abelian group H with $I_d = \{0, ((1,0),0)\}$; a set of tops $T \subseteq H$; an orbit labelling ρ_p at every inert prime p; an orbit selection $(x, \varepsilon, X'', p_0^*, \rho, m, (G_p), (\kappa_p))$; and a gain datum on these, with heights a_t $(t \in T)$, weights $w_j \colon \Phi \to \mathbb{R}$ $(1 \leq j \leq m)$ and parameters $c_G, a, b', \eta, w'', N, r_G$.
- The **size parameters**: integers $k, t_R, e_2 \geq 0$ and $o \geq 1$, and real numbers L_a, S_c.
- A **place record**: a number field K, a finite set S of finite places of K, real numbers $\ell(w)$ for the finite places w of K such that $\sum_{w|p} \ell(w) = \log p$ for every prime p (the sum over all finite places of K above p), and real numbers $g_j(w)$ $(1 \leq j \leq m)$, $\tau(w)$ and $\mathrm{io}(w)$ for $w \in S$. We write $p(w)$ for the residue characteristic of w.

The parameters are tied as follows, where $n = |H|$, $b = \exp(x^{\varepsilon})$ and $X' = \exp(x^{\varepsilon/3})$:

$$a = xb, \quad b' = \frac{a}{X'}, \quad w'' = \frac{b'}{xn}, \quad X'' = xnX', \quad N = k + m(t_R + 1),$$
$$c_G = 4S_c, \quad p_0^* = k^2x^{26}, \quad r_G = \Big\lceil \frac{32 + 64\varepsilon}{\varepsilon} \Big\rceil + 1.$$

Losses. Put $\lambda = \log x$, $\delta_1 = x^{-\varepsilon/8}$, $f = 2n$, and $L_1(p) = \lceil \log_p(k^2x^{78}) \rceil + 1$ for a prime p. Let C and b_o be real numbers, the **loss constants**. The **floor loss** and the **local loss** at a prime p for (C, b_o) are

$$\mathrm{fl}_C(p) = CfN^2 \log_p a + Cf(\log_p a)^2,$$
$$\mathrm{lo}_{C,b_o}(p) = C(S_c + k + \eta)\log_p(2a) + \mathrm{pr}_{C,b_o}(p) + \mathrm{or}_C(p),$$

where $\mathrm{pr}_{C,b_o}(p) = \mathrm{or}_C(p) = 0$ unless p is inert and not sign-changing, and in that case

$$\mathrm{pr}_{C,b_o}(p) = \begin{cases} Cr_G b'\lambda & \text{if } p < p_0^*, \\ C\big(\dfrac{b'}{x} + \eta + S_c + \dfrac{(w''+t_R)\lambda}{\delta_1}\big) + b_o & \text{if } p_0^* \le p < X', \\ 0 & \text{otherwise,} \end{cases}$$

and

$$\mathrm{or}_C(p) = \begin{cases} C\lambda\big(\dfrac{L_a a}{pk} + \begin{cases} a\,p^{-L_1(p)} & \text{if } p < p_0^* \\ a/p^2 & \text{if } p \ge p_0^* \end{cases}\big) & \text{if } p < X', \\ 0 & \text{otherwise.} \end{cases}$$

For an inert prime p, $t \in T$ and $1 \le j \le m$ put $A_p(a_t, t, w_j) = \sum_{e \ge 1 \text{ odd}} \big(a_t/p^e - w_j(z_p(t,e))\big)^+$, a series of non-negative terms. When $w_j \ge w''$ on Φ, only the finitely many e with $p^e < a_t/w''$ contribute.

Prime sum, lattice term, companion sum. Let $P \ge 1$ be an integer, the **cut-off**. Put

$$S(\mathfrak{M}) = \sum_{t \in T} \sum_{j=1}^{m} A_{\mathrm{in}}(a_t, t, w_j), \qquad \Theta(\mathfrak{M}) = 2 \sum_{w \in S} \ell(w) \Big(\sum_{j=1}^{m} g_j(w) - \tau(w) \Big),$$
$$I(\mathfrak{M}) = \sum_{w \in S} \ell(w)\, \mathrm{io}(w),$$

where the inert prime sums are formed with $(\mathfrak{A}, P)$ and each w_j is extended to Γ_H by 0 outside Φ (only its values on Φ enter).

Deficit data. For a cut-off P put $B = \max(P, X'')$ and let $\mathcal{P}$ be the set of inert primes $p \le B$. For $1 \le j \le m$, $t \in T$ and $p \in \mathcal{P}$ let $A(j,t,p) = \sum_{1 \le i \le P,\ i \text{ odd}} \big(a_t/p^i - w_j(z_p(t,i))\big)^+$ if $p \le P$ and $A(j,t,p) = 0$ if $p > P$, and let

$$d(j,t) = \log d \sum_{i=1}^{P} \Big(\frac{a_t}{d^i} - w_j(\sigma_t(g_i)) \Big)^+,$$

where g_i is the element of $i\,\mathrm{Fr}_d + I_d$ that is not in Φ (exactly one of its two elements lies outside Φ, since $((1,0),0) \notin \Phi$). Let $g(j,p) = \mathrm{gain}_j^{\mathrm{D}}(p)$ and $\tau(p) = \tau_p$, assign to each $p \in \mathcal{P}$ its class (served, first kind, second kind, high), and let $T_p = T_p^{\mathrm{s}}$ for served p. These are the **deficit data** of $(\mathfrak{M}, P)$.

Window parameters. For real numbers C, b_o and C_{ord}, the **window parameters of $\mathfrak{M}$ for** $(C, b_o, C_{\mathrm{ord}})$ are

$$(x, \varepsilon, n, k, N, t_R, L_a, r_G, S_c, \eta, \rho, \vartheta, K_0, \max(C,0), \beta, C_{\mathrm{ord}}, Y, s_0, b_o;\ e_2, p_0, d)$$

with $\vartheta = 1/(kx^{13})$, $K_0 = k^2 x^{78}$, $Y = X'(1+\rho)$, $p_0 = \lceil k^2 x^{26} \rceil$ and $\beta = s_0 = 0$. Their derived quantities $b, a, X', b', w'', X'', f$ are the ones above.

Conditions. Let $\varepsilon_z > 0$ and C_t be real numbers. We consider the following conditions on a loss datum.

(Lm1) Frame. For every inert prime p that is not sign-changing, the order of $[p]_{e_2}$ divides the order of h_p, and $[p]_{e_2} = 1$ if h_p has odd order; and h_p has even order whenever its order is at least $x^{\varepsilon/4}$.

(Lm2) Heights and weights. $0 \le a_t \le a(1+\vartheta)$ for $t \in T$, and $w_j(z) \ge w''$ for all j and $z \in \Phi$.

(Lm3) Linking for (C, b_o). Here C and b_o are real numbers. The condition consists of the **served-prime inequality for** (C, b_o), namely that for every served inert prime p

$$\sum_{j=1}^{m} \sum_{t \in T_p^{\mathrm{s}}} \left(A_p(a_t, t, w_j) - \mathrm{lo}_{C,b_o}(p)\right) - m\,\mathrm{fl}_C(p) \le \sum_{j=1}^{m} \mathrm{gain}_j(p) - \tau_p,$$

and the **surplus bound**, which does not involve C and b_o, namely that $S_p(v) \le 2mN_p(v)a/p$ for every inert prime p and every $v \in V_p$.

(Lm4) Few bad tops. $\displaystyle\sum_{p \in s_B} \frac{\log p}{p} \left|\{t \in T : \rho_p(t) \notin G_p\}\right| \le |T|\, x^{-2+\varepsilon}$, where s_B is the set of inert primes $p < X'$ that are not sign-changing and for which h_p has order at least $x^{\varepsilon/4}$.

(Lm5) Small shares. $\displaystyle\sum_{p \text{ candidate}} \frac{\log p}{p}\Big(2 \cdot \mathbf{1}_{\Sigma_p > x^{-\varepsilon}} + 4\Sigma_p\Big) \le x^{-9}$.

(Lm6) Place record. Every finite place w of K with $p(w) \le X''$ lies in S. For $w \in S$ with $p(w)$ inert, $g_j(w) = \mathrm{gain}_j^{\mathrm{D}}(p(w))$ for all j, $\tau(w) = \tau_{p(w)}$ and $\mathrm{io}(w) = \mathrm{io}_{p(w)}$. For $w \in S$ with $p(w)$ not inert, $g_j(w) = \tau(w) = \mathrm{io}(w) = 0$.

(Lm7) Sizes for (ε_z, C_t). With $\theta_s = \varepsilon/100$: $x^{2+8\varepsilon-\theta_s} \le n \le x^{2+8\varepsilon+\theta_s}$; $2^{e_2} \le n \le o\,2^{e_2}$ and $o \le x^{\theta_s}$; $m \le x^{\theta_s}(x\delta_1)^{1/2}$; $x^{9/2+10\varepsilon-\theta_s} \le k \le x^{9/2+10\varepsilon+\theta_s}$; $t_R \le x^{C_t+\theta_s}$; $x^{\varepsilon} \le L_a \le x^{\varepsilon+\theta_s}$; $S_c = 4k\Delta$ for a real $\Delta > 0$ with $\log\Delta \le x^{\varepsilon/4}/2$; $\eta > 0$ and $\log\eta \le x^{\varepsilon/4}$; $\log d \ge x^{\varepsilon_z/5-\varepsilon_z/100}$; and $\rho \le x^{-2}$.

The conditions fall into three groups. Conditions (Lm1), (Lm2), (Lm6) and (Lm7) fix the frame, the heights and weights, the place record and the sizes; for the members of a parametrised host family they are part of the definition (Definition 7.3). Condition (Lm3) is the linking condition, the local comparison of a prime with its gain. Conditions (Lm4) and (Lm5) concern the choice of the tops. The last three are the properties that Section 7 asks of a class of families under the names (Lk2) and (Lk3).

Two features of the definition organise the proof of the loss bound. The lattice term $\Theta(\mathfrak{M})$ is a sum over the places of a number field, with local gains $g_j(w)$; by (Lm6) these are the gains of the inert primes below the places, so $\Theta(\mathfrak{M})$ is a sum over inert primes (Lemma 5.16). And every inert prime lies in exactly one of four classes. Only a served prime has a gain. Under (Lm1), a prime of the first kind has a class of order less than $x^{\varepsilon/4}$ in $(\mathbb{Z}/2^{e_2+2}\mathbb{Z})^{\times}/\{\pm 1\}$, or has a power in a narrow band around X' (Lemma 5.14); such primes are sparse (Lemma 5.10). A prime of the second kind is a candidate of large orbit mass, and the small shares (Lm5) bound the total weight of such primes. A high prime exceeds the cut-off X'' of the gains.

Theorem 5.6. *Let $0 < \varepsilon < \frac{1}{52}$, $\varepsilon_z > 0$, C_t and C be real numbers, and put $C^+ = \max(C, 0)$. There is a real number x_0, depending only on ε, ε_z, C_t and C, with the following property. Let $\mathfrak{M}$ be a loss datum whose orbit selection has parameter ε and scale $x \ge x_0$, whose set of tops T is non-empty, and let b_o be a real number with $0 \le b_o \le \exp(x^{\varepsilon}/2)$. Suppose that $\mathfrak{M}$ satisfies*

- *(Lm1), (Lm2) and (Lm6) (frame, heights and weights, place record);*
- *(Lm3) for (C, b_o), that is, the served-prime inequality for (C, b_o) and the surplus bound;*
- *(Lm4) (few bad tops) and (Lm5) (small shares);*
- *(Lm7) for (ε_z, C_t) (sizes).*

Then, with $b = \exp(x^{\varepsilon})$, for every cut-off $P \geq 1$

$$S(\mathfrak{M}) - \Theta(\mathfrak{M}) \leq (3C^{+} + 13)\,|T|\,m\,b \qquad \textit{and} \qquad I(\mathfrak{M}) \leq |T|\,m\,b.$$

Proof. Let $C_{\mathrm{ord}} \geq 0$ be the absolute constant of Proposition 5.7, and let x_0 be the number that Lemma 5.12 gives for $(\varepsilon, \varepsilon_z, C_t, C, C_{\mathrm{ord}})$, with $e^{*} = \max(40, C_t + 3)$ and $K^{*} = 1 + |C| + C_{\mathrm{ord}}$; it depends only on $\varepsilon, \varepsilon_z, C_t, C$. Let $\mathfrak{M}$, b_o and the cut-off $P \geq 1$ be as in the statement, and write $\mathcal{P}$ for the set of inert primes $p \leq \max(P, X'')$ of the deficit data of $(\mathfrak{M}, P)$.

The window parameters. By Lemma 5.12, applied with (Lm7) and $0 \leq b_o \leq \exp(x^{\varepsilon}/2)$, the window parameters of $\mathfrak{M}$ for $(C, b_o, C_{\mathrm{ord}})$ are admissible for (e^{*}, K^{*}), the scale x is large for (e^{*}, K^{*}) (in particular $x \geq 1$), and $k^2 x^{26} \leq X'$. Their entry in the place of C is C^{+}, and their derived quantity b is $\exp(x^{\varepsilon})$.

The data for the bound at small orbit masses. We apply Proposition 5.7 to these window parameters, with the following data:

- U a set with one element υ;
- the set $\mathcal{P}$ in place of its finite set of primes, $J = \{1, \dots, m\}$ and the set of tops T;
- s the set of candidates and s_B the set of (Lm4);
- $\mathrm{BAD}(p, t)$ the relation $\rho_p(t) \notin G_p$;
- Σ_p the orbit masses ($p \in s$) and $\mathrm{io}(\upsilon, p) = \mathrm{io}_p$;
- $\mathfrak{d}(\upsilon)$ the deficit data of $(\mathfrak{M}, P)$, that is, $A(j,t,p)$, $d(j,t)$, $g(j,p) = \mathrm{gain}^{\mathrm{D}}_j(p)$, $\tau(p) = \tau_p$, the partition of $\mathcal{P}$ into served primes, primes of the first kind, primes of the second kind and high primes (every inert prime has exactly one class), and $T_p = T^{\mathrm{s}}_p$ for served p.

The sets $\mathcal{P}$, s, s_B, J, T are finite, $T \neq \emptyset$, and $\Sigma_p = m \sum_{v \in G_p} \kappa_p(v) \geq 0$ since $\kappa_p(v) \in [0,1]$. We check the hypotheses (1)–(6) of Proposition 5.7.

(1) An inert prime is different from 2, so every $p \in \mathcal{P}$ is an odd prime.

(2) With $\theta = x^{-\varepsilon}$, the small-shares hypothesis is (Lm5).

(3) The few-bad-tops hypothesis is (Lm4).

(4) By Lemma 5.15, item 3, which uses the surplus bound, $\mathrm{io}_p \leq 2\Sigma_p \cdot 2m|T|a/p = 2\Sigma_p \cdot 2|J||T|a/p$ for every $p \in s$.

(5) Lemma 5.13 applies, since $\mathfrak{M}$ satisfies (Lm1), (Lm2) and (Lm3) for (C, b_o); $b_o \geq 0$; by (Lm7), $L_a \geq x^{\varepsilon} > 0$, $S_c = 4k\Delta > 0$ (as $k \geq x^{9/2+10\varepsilon-\theta_s} > 0$ and $\Delta > 0$) and $\eta > 0$; and $k^2 x^{26} \leq X'$. Its items 1–5 are the hypotheses of Lemma 5.8 on the data $\mathfrak{d}(\upsilon)$ formed with the parameters of the window parameters, namely the bounds on heights and weights and the form of $A(j,t,p)$ and $d(j,t)$ (item 1); served primes at most X'' and high primes above X'' (item 2); the inequality of Proposition 5.9 with P_{s} the served primes, P_{n} the others, $\mathrm{lo} = \mathrm{lo}_{C,b_o}$, $\mathrm{fl} = \mathrm{fl}_C$, and $g(j,p) = \tau(p) = 0$ on P_{n} (item 3); $\mathrm{lo}_{C,b_o} \leq \mathrm{lo}^{*}$ and $\mathrm{fl}_C \leq \mathrm{fl}^{*}$, formed with C^{+} (item 4); and $K_0 \leq p^{L_1(p)-1}$ (item 5).

(6) By Lemma 5.14, items 1–3 (which use (Lm1)), a prime of the first kind satisfies $p \le \max(Y, X'')$ with $[p]_{e_2}$ of order less than $x^{\varepsilon/4}$, or $p \ge p_0$ with $X'(1-\rho) \le p^i \le X'(1+\rho)$ for some $i \ge 1$; a prime of the second kind is a candidate with $\Sigma_p > x^{-\varepsilon} = \theta$; and if p is served and $t \in T \setminus T_p^{\mathrm{s}}$, then $p \in s_B$ and $\rho_p(t) \notin G_p$.

The window parameters are admissible for (e^*, K^*) at a scale large for (e^*, K^*), so they satisfy in particular all conditions of admissibility except those on β and s_0. Hence Proposition 5.7 gives, with $S_{\mathfrak{d}}$, $\Theta_{\mathfrak{d}}$ formed from $\mathfrak{d}(\upsilon)$ as in Proposition 5.9,

$$S_{\mathfrak{d}} - \Theta_{\mathfrak{d}} \le (3C^+ + 13)\, m\, |T|\, b, \qquad \sum_{p \in s} \log p \ \mathrm{io}_p \le m\, |T|\, b.$$

The three sums of $\mathfrak{M}$. By Lemma 5.15, item 1, $S(\mathfrak{M}) = \sum_j \sum_t \big(\sum_{p \in \mathcal{P}} 2 \log p\, A(j,t,p) + d(j,t)\big) = S_{\mathfrak{d}}$. For the lattice term apply Lemma 5.16 to the arithmetic datum, tops, orbit labellings, orbit selection and gain datum of $\mathfrak{M}$ and to its place record (K, S, ℓ, g_j, τ): here $X' \le X'' = xnX'$ because $x \ge 1$ and $n = |H| \ge 1$, and the hypotheses 1–3 of Lemma 5.16 are (Lm6). With $B = \max(P, X'') \ge X''$ it gives

$$\Theta(\mathfrak{M}) = 2 \sum_{p \in \mathcal{P}} \log p \Big(\sum_{j=1}^{m} \mathrm{gain}_j^{\mathrm{D}}(p) - \tau_p \Big) = \Theta_{\mathfrak{d}}.$$

By Lemma 5.15, item 2, which uses (Lm6), $I(\mathfrak{M}) = \sum_{p \in s} \log p\ \mathrm{io}_p$. Substituting these three identities in the two inequalities above gives the claim. □

Proposition 5.7. *There is $C_{\mathrm{ord}} \ge 0$ with the following property. Let a tuple of window parameters with this C_{ord} satisfy all conditions of admissibility for (e, K) except those on β and s_0, at a scale that is large for (e, K). Let U be a set, let P, s, s_B be finite sets of primes, and let J, T be finite sets with $T \neq \emptyset$. Let $\mathrm{BAD}(p,t)$ be a relation between primes and elements of T, let $\Sigma_p \ge 0$ $(p \in s)$ and $\mathrm{io}(\upsilon, p)$ $(\upsilon \in U,\ p \in s)$ be real numbers, and for each $\upsilon \in U$ let $\mathfrak{d}(\upsilon)$ be a datum on (P, J, T) as in Lemma 5.8. Suppose that*

1. *every $p \in P$ is an odd prime;*
2. *(*small shares*)* $\displaystyle\sum_{p \in s} \frac{\log p}{p} \Big(2 \cdot \mathbf{1}_{\Sigma_p > \theta} + 4\Sigma_p \Big) \le x^{-9}$;
3. *(*few bad tops*)* $\displaystyle\sum_{p \in s_B} \frac{\log p}{p} \big| \{ t \in T : \mathrm{BAD}(p,t) \} \big| \le |T|\, x^{-2+\varepsilon}$;
4. $\mathrm{io}(\upsilon, p) \le 2\Sigma_p \cdot 2|J||T|a/p$ *for all υ and $p \in s$;*
5. *each $\mathfrak{d}(\upsilon)$ satisfies the hypotheses of Lemma 5.8 on its data (those on the heights, the weights, the classes of primes, the inequality of Proposition 5.9,* lo, fl *and L_1), formed with the parameters $a, \vartheta, w'', X'', X', p_0, d, C, f, N, S_k, Q_1, Q_2, \lambda, L_a, k, K_0$ of the window parameters;*
6. *the primes of each $\mathfrak{d}(\upsilon)$ satisfy the following:*
   - *every first-kind prime p satisfies $p \le \max(Y, X'')$ and $[p]_{e_2}$ has order less than $x^{\varepsilon/4}$, or $p \ge p_0$ and $X'(1-\rho) \le p^i \le X'(1+\rho)$ for some $i \ge 1$;*
   - *every second-kind prime p lies in s and has $\Sigma_p > \theta$;*
   - *for every served prime p and every $t \in T \setminus T_p$, $p \in s_B$ and $\mathrm{BAD}(p,t)$.*

Then for every $\upsilon \in U$, with S, Θ formed from $\mathfrak{d}(\upsilon)$,

$$S - \Theta \le (3C + 13)\,|J|\,|T|\,b \qquad \text{and} \qquad \sum_{p \in s} \log p\ \mathrm{io}(\upsilon, p) \le |J|\,|T|\,b.$$

Proof. Take $C_{\mathrm{ord}} = \max(C_1, 0)$ with C_1 the constant of Lemma 5.10. Write $m = |J|$ and $U_0 = |T|mb$, and let σ and the numbers $T_{\mathrm{fl}}, T_{\mathrm{cp}}, T_{Q_1}, T_{Q_2}, T_{\mathrm{or}}, T_{\mathrm{hi}}, T_d, T_{\mathrm{ord}}, T_{\mathrm{band}}, T_{\mathrm{out}}, T_{\mathrm{sec}}$ be those of Lemma 5.11, formed with m and with the number $|T| \ge 1$ in place of T. Put $\Lambda = \sum_{p \in s} \frac{\log p}{p}(2 \cdot \mathbf{1}_{\Sigma_p > \theta} + 4\Sigma_p)$, so $\Lambda \le x^{-9}$ by (2).

Side conditions. By Lemma 5.11, item 1, the window parameters satisfy the conditions that Lemma 5.8 imposes on its parameters ($a \ge 1$, $0 \le \vartheta \le \frac{1}{2}$, $w'' > 0$, $X'' \ge 2$, $X''w'' = a$, $X' \ge 1$, $p_0 \ge 3$, $d \ge 4$, $C, f, S_k, Q_1, Q_2, \lambda, L_a \ge 0$, $k > 0$, $K_0 > 0$), and moreover $\rho \le \frac{1}{2}$, $p_0 \ge 8$, $X' \ge 2$, $e_2 \ge 1$, $J_o \ge 1$, $\lfloor \log X' \rfloor = I_b$ and $C \ge 0$. With (5), each $\mathfrak{d}(\upsilon)$ satisfies all hypotheses of Lemma 5.8.

The deficit. Fix υ. With the notation of Lemma 5.11, the bound of Lemma 5.8 reads

$$S - \Theta \le T_{\mathrm{fl}} + T_{\mathrm{cp}} + T_{Q_1} + T_{Q_2} + T_{\mathrm{or}} + T_{\mathrm{hi}} + T_d + \sum_{p \text{ served}} 4ma \frac{\log p}{p}\,|T \setminus T_p| + 4m|T|a\Big(\sum_{p \text{ first}} \frac{\log p}{p} + \sum_{p \text{ second}} \frac{\log p}{p}\Big).$$

Unserved tops. By (6), every $t \in T \setminus T_p$ at a served p has $p \in s_B$ and $\mathrm{BAD}(p, t)$; hence, by (3),

$$\sum_{p \text{ served}} 4ma \frac{\log p}{p} |T \setminus T_p| \le 4ma \sum_{p \in s_B} \frac{\log p}{p} |\{t : \mathrm{BAD}(p, t)\}| \le 4am|T|x^{-2+\varepsilon} = T_{\mathrm{out}}.$$

First kind. By (1) and (6), the first-kind primes form a finite set of odd primes that satisfies the hypotheses of Lemma 5.10 with $e = e_2$, $J = J_o$ (an integer order less than $x^{\varepsilon/4}$ is at most $J_o = \lfloor x^{\varepsilon/4} \rfloor$), $\max(Y, X'') \ge 1$ in place of Y, and $\rho \le \frac{1}{2}$, $p_0 \ge 8$, $X' \ge 2$. Hence, using $C_1 \le C_{\mathrm{ord}}$ and $\lfloor \log X' \rfloor = I_b$,

$$4m|T|a \sum_{p \text{ first}} \frac{\log p}{p} \le 4m|T|a\Big(\frac{C_1 J_o \log(2^{e_2} \max(Y, X''))^2}{2^{e_2}} + I_b\Big(4\rho + \frac{1}{p_0}\Big)\log(2X')\Big) \le T_{\mathrm{ord}} + T_{\mathrm{band}}.$$

Second kind. By (6) every second-kind prime lies in s and has $\Sigma_p > \theta$, so it contributes at least $2 \log p/p$ to Λ, and $4m|T|a \sum_{p \text{ second}} \log p/p \le 2am|T|\Lambda \le 2am|T|x^{-9} = T_{\mathrm{sec}}$.

The companion sum. By (4) and $\log p \ge 0$, $\sum_{p \in s} \log p\ \mathrm{io}(\upsilon, p) \le \sum_{p \in s} \frac{\log p}{p}\, 4m|T|a\,\Sigma_p \le am|T|\Lambda \le am|T|x^{-9}$.

Sizes. By Lemma 5.11, item 2, each of $T_{\mathrm{fl}}, T_{\mathrm{cp}}, T_{Q_1}, T_{\mathrm{or}}, T_{\mathrm{hi}}, T_d, T_{\mathrm{ord}}, T_{\mathrm{band}}, T_{\mathrm{out}}, T_{\mathrm{sec}}$ is at most σU_0, $T_{Q_2} \le (2 \log 4 \cdot C + 3\sigma)U_0$, and $am|T|x^{-9} \le \sigma U_0$. Hence $S - \Theta \le (2 \log 4 \cdot C + 13\sigma)U_0 \le (3C + 13)U_0$, since $2 \log 4 \le 3$, $C \ge 0$ and $\sigma \le 1$; and the companion sum is at most $\sigma U_0 \le U_0$. As $U_0 = |J||T|b$, this is the claim. □

Lemma 5.8. *Let P be a finite set of primes, partitioned as $P = P_{\mathrm{s}} \sqcup P_1 \sqcup P_2 \sqcup P_{\mathrm{h}}$ (served primes, primes of the first and of the second kind, high primes), and let J, T be finite sets. Let $p_0 \ge 3$ and $d \ge 4$ be integers, let $a \ge 1$, $0 \le \vartheta \le \frac{1}{2}$, $w'' > 0$, $X'' \ge 2$ with $X''w'' = a$, $X' \ge 1$, N, $C, f, S_k, Q_1, Q_2, \lambda, L_a \ge 0$, $k > 0$ and $K_0 > 0$ be real numbers, and let $L_1 \colon P \to \mathbb{R}$. Put*

$$\mathrm{fl}^*(p) = CfN^2 \log_p a + Cf(\log_p a)^2,$$

$$\mathrm{lo}^*(p) = CS_k \log_p(2a) + \mathbf{1}_{p < X'}\Big(Q(p) + C\lambda\Big(\frac{L_a a}{pk} + \begin{cases} a\,p^{-L_1(p)} & p < p_0 \\ a/p^2 & p \ge p_0 \end{cases}\Big)\Big),$$

with $Q(p) = Q_1$ for $p < p_0$ and $Q(p) = Q_2$ for $p \ge p_0$. Let $a_t \in [0, a(1+\vartheta)]$ for $t \in T$. For finite sets $I(j,t,p)$ of odd positive integers, finite sets $I_d(j,t)$ of positive integers, and weights $w(j,t,p,i) \ge w''$ and $w_d(j,t,i) \ge 0$, let

$$A(j,t,p) = \sum_{i \in I(j,t,p)} \Big(\frac{a_t}{p^i} - w(j,t,p,i)\Big)^+, \qquad d(j,t) = \log d \sum_{i \in I_d(j,t)} \Big(\frac{a_t}{d^i} - w_d(j,t,i)\Big)^+.$$

Let $g(j,p)$, $\tau(p)$ be real numbers, and suppose that

- *every served prime is at most X'' and every high prime exceeds X'';*
- *the hypotheses of the inequality of Proposition 5.9 hold with $P_{\rm n} = P_1 \cup P_2 \cup P_{\rm h}$, and with $\mathrm{lo}(p) \le \mathrm{lo}^*(p)$ and $\mathrm{fl}(p) \le \mathrm{fl}^*(p)$ for $p \in P_{\rm s}$;*
- *$K_0 \le p^{L_1(p)-1}$ for every $p \in P$ with $p < p_0$.*

Then

$$\begin{aligned} S - \Theta \le\ & |J| \cdot 2CfX''(N^2 \log a + 2(\log a)^2) + 2CS_k \log(2a)\, |J|\, |T|\, X'' \\ & + |J|\, |T| \cdot 2 \log 4\, (p_0 Q_1 + X' Q_2) \\ & + |J|\, |T| \cdot 2C\lambda a\Big(\Big(\frac{L_a}{k} + \frac{1}{K_0}\Big)(\log X' + \log 4) + \frac{2(\log(p_0-1)+1)}{p_0 - 1}\Big) \\ & + \sum_{p \in P_{\rm s}} 4|J|\, a\, \frac{\log p}{p}\, |T \setminus T_p| \\ & + 4|J|\, |T|\, a\Big(\sum_{p \in P_1} \frac{\log p}{p} + \sum_{p \in P_2} \frac{\log p}{p}\Big) \\ & + |J|\, |T| \cdot 2 \log(2X'')(a\vartheta^2 + w''\vartheta) + |J|\, |T| \cdot \frac{2a \log d}{d}. \end{aligned}$$

Proof. We bound the three parts of the inequality of Proposition 5.9. Throughout, $a_t \le a(1+\vartheta) \le \frac{3}{2}a$ and all weights are non-negative, so $(a_t/p^i - w)^+ \le a_t/p^i$.

One prime, one top. For $p \ge 2$, $\sum_{i \text{ odd}} p^{-i} = p/(p^2-1) \le \frac{4}{3}p^{-1}$, so $A(j,t,p) \le \frac{4}{3}a_t/p$ and $2\log p\, A(j,t,p) \le 4a \log p/p$. Summing over j,t bounds every term $2\log p \sum_{j,t} A(j,t,p)$ with $p \in P_1 \cup P_2$ by $4|J||T|a \log p/p$, and $2\log p \sum_j \sum_{t \in T \setminus T_p} A(j,t,p)$ by $4|J|a(\log p/p)|T \setminus T_p|$.

The prime d. We have $\sum_{i \ge 1} d^{-i} = 1/(d-1)$ and $\frac{3}{2}a/(d-1) \le 2a/d$ for $d \ge 4$, so $d(j,t) \le 2a \log d/d$.

High primes. Let $p > X''$. For $i \ge 2$, $p^i \ge X''^2 \ge 2X''$, so $a_t/p^i \le 2a/(2X'') = w'' \le w(j,t,p,i)$ and the term vanishes. For $i = 1$: if $p \ge X''(1+\vartheta)$ then $a_t/p \le w''$ and the term vanishes; otherwise $a_t/p - w'' \le a(1+\vartheta)/X'' - w'' = w''\vartheta$. The primes in $(X'', X''(1+\vartheta))$ number at most $X''\vartheta + 1$, and for them $2\log p \le 2\log(2X'')$. Hence $\sum_{p \in P_{\rm h}} 2\log p\, A(j,t,p) \le 2\log(2X'')w''\vartheta(X''\vartheta + 1) = 2\log(2X'')(a\vartheta^2 + w''\vartheta)$.

Served primes: the losses. For $p \in P_{\rm s}$ we have $|J||T_p|\mathrm{lo}(p) \le |J||T|\mathrm{lo}^*(p)$ (as $\mathrm{lo}^* \ge 0$ and $|T_p| \le |T|$) and $|J|\mathrm{fl}(p) \le |J|\mathrm{fl}^*(p)$. The served primes lie in $[2, X'']$, so there are at most X'' of them. We bound the resulting sums in turn. First, $\sum_{p \in P_{\rm s}} 2\log p\, CS_k \log_p(2a) = 2CS_k \log(2a)|P_{\rm s}|$. Second, $\sum_{p \in P_{\rm s}} 2\log p\, \mathrm{fl}^*(p) \le 2CfX''(N^2 \log a + 2(\log a)^2)$, using $\log p \ge \log 2 \ge \frac{1}{2}$. Third, $\sum_{p < X'} 2\log p\, Q(p) \le 2\log 4\, (p_0 Q_1 + X' Q_2)$ by Chebyshev's bound $\sum_{p \le y} \log p \le$

$y\log 4$ ($y \ge 0$) [180]. Finally, writing $ap^{-L_1(p)} = (a/p)p^{-(L_1(p)-1)} \le a/(pK_0)$ for $p < p_0$, we obtain

$$\sum_{p<X'} 2\log p\, C\lambda\Big(\frac{L_a a}{pk} + \dots\Big) \le 2C\lambda a\Big(\Big(\frac{L_a}{k} + \frac{1}{K_0}\Big)\sum_{p<X'}\frac{\log p}{p} + \sum_{p\ge p_0}\frac{\log p}{p^2}\Big),$$

and we use $\sum_{p\le y}\log p/p \le \log y + \log 4$ for $y \ge 1$ (by Legendre's formula, $y\log y \ge \log\lfloor y\rfloor! \ge \sum_{p\le y}\lfloor y/p\rfloor\log p \ge y\sum_{p\le y}\frac{\log p}{p} - \sum_{p\le y}\log p$, and Chebyshev's bound) and $\sum_{n\ge p_0}\log n/n^2 \le 2(\log(p_0-1)+1)/(p_0-1)$.

Adding the bounds gives the claim. □

Proposition 5.9. *Let P be a finite set of primes, J and T finite sets, and let $A(j,t,p)$, $d(j,t)$, $g(j,p)$, $\tau(p)$ be real numbers ($j \in J$, $t \in T$, $p \in P$). Put*

$$S = \sum_{j\in J}\sum_{t\in T}\Big(\sum_{p\in P} 2\log p\, A(j,t,p) + d(j,t)\Big), \qquad \Theta = 2\sum_{p\in P}\log p\,\Big(\sum_{j\in J} g(j,p) - \tau(p)\Big),$$

*and, for $p \in P$, let the **deficit** at p be $\operatorname{def}(p) = \sum_{j,t} A(j,t,p) - \big(\sum_j g(j,p) - \tau(p)\big)$. Then*

$$S - \Theta = \sum_{p\in P} 2\log p\,\operatorname{def}(p) + \sum_{j\in J}\sum_{t\in T} d(j,t). \tag{5.1}$$

Suppose moreover that $P = P_{\mathrm{s}} \sqcup P_{\mathrm{n}}$, and that for each $p \in P_{\mathrm{s}}$ there are a subset $T_p \subseteq T$ and real numbers $\operatorname{lo}(p), \operatorname{fl}(p)$ with

$$\sum_{j\in J}\sum_{t\in T_p}\big(A(j,t,p) - \operatorname{lo}(p)\big) - |J|\operatorname{fl}(p) \le \sum_{j\in J} g(j,p) - \tau(p),$$

while $g(j,p) = 0$ for all j and $\tau(p) = 0$ for $p \in P_{\mathrm{n}}$. Then

$$S - \Theta \le \sum_{p\in P_{\mathrm{s}}} 2\log p\Big(\sum_{j\in J}\sum_{t\in T\setminus T_p} A(j,t,p) + |J|\,|T_p|\operatorname{lo}(p) + |J|\operatorname{fl}(p)\Big) + \sum_{p\in P_{\mathrm{n}}} 2\log p\sum_{j\in J}\sum_{t\in T} A(j,t,p) + \sum_{j\in J}\sum_{t\in T} d(j,t).$$

Proof. The identity (5.1) is obtained by expanding both sides and exchanging the finite sums over j, t and p.

For the inequality, we use (5.1) and bound $2\log p\,\operatorname{def}(p)$ for each p, recalling that $2\log p \ge 0$. If $p \in P_{\mathrm{n}}$, then $\operatorname{def}(p) = \sum_{j,t} A(j,t,p)$. If $p \in P_{\mathrm{s}}$, split $\sum_{t\in T} = \sum_{t\in T\setminus T_p} + \sum_{t\in T_p}$ (as $T_p \subseteq T$) and write $\sum_j\sum_{t\in T_p} A(j,t,p) = \sum_j\sum_{t\in T_p}(A(j,t,p) - \operatorname{lo}(p)) + |J||T_p|\operatorname{lo}(p)$. Then the hypothesis at p gives

$$\operatorname{def}(p) \le \sum_j\sum_{t\in T\setminus T_p} A(j,t,p) + |J|\,|T_p|\operatorname{lo}(p) + |J|\operatorname{fl}(p).$$

Multiplying by $2\log p$ and summing over p gives the claim. □

Lemma 5.10. *For an integer $e \ge 1$ and an odd integer l let $[l]_e$ be the class of l in the group $(\mathbb{Z}/2^{e+2}\mathbb{Z})^\times/\{\pm 1\}$. There is an absolute constant C with the following property. Let $e, J \ge 1$ be integers, let $Y \ge 1$, $0 \le \rho \le \frac{1}{2}$, $p_0 \ge 8$ and $X' \ge 2$ be real numbers, and let s be a finite set of odd primes such that every $p \in s$ satisfies*

1. *$p \le Y$ and $[p]_e$ has order at most J, or*

2. $p \ge p_0$ *and* $X'(1-\rho) \le p^i \le X'(1+\rho)$ *for some integer* $i \ge 1$.

Then

$$\sum_{p \in s} \frac{\log p}{p} \le \frac{C\,J\,\log(2^e Y)^2}{2^e} + \lfloor \log X' \rfloor \Big(4\rho + \frac{1}{p_0}\Big) \log(2X').$$

Proof. Split s into the primes satisfying (1) and those satisfying (2) but not (1); all summands are non-negative.

Primes of small order. The group $(\mathbb{Z}/2^{e+2})^\times/\{\pm 1\}$ is cyclic of order 2^e, generated by the class of 5, and for $0 \le j \le e$ one has $[l]_e^{2^j} = 1$ if and only if $l \equiv \pm 1 \pmod{2^{e+2-j}}$. Indeed, the elements of order dividing 2^j in this cyclic group of order 2^e form its subgroup of order 2^j, generated by the class of $5^{2^{e-j}}$. Its preimage in $(\mathbb{Z}/2^{e+2})^\times$ is $\{\pm 1\} \times \langle 5^{2^{e-j}} \rangle$, of index 2^{e-j}, and as $5^{2^{e-j}}$ generates the subgroup of units $\equiv 1 \bmod 2^{e+2-j}$, this preimage is the set of units $\equiv \pm 1 \bmod 2^{e+2-j}$. If $[p]_e$ has order at most J, its order is 2^j with $2^j \le J$ and $j \le e$. With $j_0 = \min(e, \lfloor \log_2 J \rfloor)$ we get $[p]_e^{2^{j_0}} = 1$, so $p \equiv \pm 1 \pmod M$ with $M = 2^{e+2-j_0} \ge 2^{e+2}/J$ and $M \le 2^{e+2}$. The integers $n \ge 3$, $n \le Y$, in the two classes $\pm 1 \bmod M$ are $n = kM \pm 1$; their contribution is

$$\sum \frac{\log n}{n} \le \frac{2\log M}{M} + \frac{3\log Y}{M} \sum_{1 \le k \le Y} \frac{1}{k} \le \frac{3}{M}\big(\log M + \log Y(1+\log Y)\big) \le \frac{C_1}{M} \log(2^e Y)^2,$$

with an absolute constant C_1, since $\log M \le \log 4 + \log(2^e Y)$ and $\log(2^e Y) \ge \log 2$. With $1/M \le J/2^{e+2}$ this gives the first term.

Primes near a root of X'. Let $p \ge p_0 \ge 8$ and $X'(1-\rho) \le p^i \le X'(1+\rho)$ with $i \ge 1$. Then $8^i \le p^i \le 2X'$, so $i \le \log(2X')/\log 8 \le \log X'$ (as $X' \ge 2$), that is, $1 \le i \le \lfloor \log X' \rfloor$. With $P_i = X'^{1/i}$, from $(1-\rho) \le (1-\rho)^{1/i}$ and $(1+\rho)^{1/i} \le 1+\rho$ we get $P_i(1-\rho) \le p \le P_i(1+\rho)$. For fixed i, the integers in $[P_i(1-\rho), P_i(1+\rho)]$ number at most $2\rho P_i + 1$, and each $n \ge p_0$ there has $\log n/n \le \log(2P_i)\min(2/P_i, 1/p_0)$ (as $n \ge P_i/2$ and $n \le 2P_i$). Hence the primes of this i contribute at most $(2\rho P_i + 1)\min(2/P_i, 1/p_0)\log(2P_i) \le (4\rho + 1/p_0)\log(2X')$. Summing over $1 \le i \le \lfloor \log X' \rfloor$ gives the second term. □

Lemma 5.11. *Let a tuple of window parameters satisfy all conditions of admissibility for* (e, K) *except those on* β *and* s_0*, at a scale that is large for* (e, K)*, and put* $\sigma = 100Kx^{4\varepsilon}/x$*. Then the following hold.*

1. $x \ge 100$, $0 \le \sigma \le 1$, $b \ge 1$, $a \ge 1$, $X' \ge 2$, $X'' = xnX' \ge 2$, $X''w'' = a$, $w'' > 0$, $0 \le \vartheta \le \frac{1}{2}$, $0 \le \rho \le \frac{1}{2}$, $p_0 \ge 8$, $d \ge 4$, $k > 0$, $K_0 > 0$, $e_2 \ge 1$, $J_o \ge 1$, $\lfloor \log X' \rfloor = I_b$, *and* $C, f, S_k, Q_1, Q_2, \lambda, L_a \ge 0$.

2. Let $m \ge 0$ and $T \ge 1$ be real numbers and $U = Tmb$. Each of the ten numbers

$$\begin{aligned}
T_{\mathrm{fl}} &= 2mCfX''(N^2 \log a + 2(\log a)^2),\\
T_{\mathrm{cp}} &= 2CS_k \log(2a)\, mT\, X'',\\
T_{Q_1} &= 2\log 4 \cdot mT\, p_0 Q_1,\\
T_{\mathrm{or}} &= 2C\lambda a\, mT\Big(\Big(\frac{L_a}{k} + \frac{1}{K_0}\Big)(\log X' + \log 4) + \frac{2(\log(p_0-1)+1)}{p_0-1}\Big),\\
T_{\mathrm{hi}} &= 2\log(2X'')\, mT\,(a\vartheta^2 + w''\vartheta),\\
T_d &= 2mT\,\frac{a\log d}{d},\\
T_{\mathrm{ord}} &= 4mTa\,\frac{C_{\mathrm{ord}}\, J_o\, \log(2^{e_2}\max(Y, X''))^2}{2^{e_2}},\\
T_{\mathrm{band}} &= 4mTa\, I_b\Big(4\rho + \frac{1}{p_0}\Big)\log(2X'),\\
T_{\mathrm{out}} &= 4amT\, x^{-2+\varepsilon},\\
T_{\mathrm{sec}} &= 2amT\, x^{-9}
\end{aligned}$$

is at most σU; moreover $amT\, x^{-9} \le \sigma U$, and $T_{Q_2} = 2\log 4 \cdot mT\, X'Q_2 \le (2\log 4 \cdot C + 3\sigma)\, U$.

Proof. Write $z = x^{\varepsilon}$, $u = x^{\varepsilon/3}$, $E = x^e$, $S = \exp(x^{\varepsilon/4})$, $s_b = \exp(x^{\varepsilon}/2)$ and $v = b/X'$; then $b = s_b^2$, $X' = e^u$, $b' = a/X' = xv$, $w'' = v/n$ and $X'' = a/w'' = xnX'$.

Basic facts. Admissibility gives $x^2 \le 2^{e_2} \le n \le E$, $x^2 \le k \le E$, $0 \le N \le E$, $0 \le t \le E$, $x^4 + 1 \le p_0 \le E$, $0 \le L_a \le z^2$, $0 \le r_G \le E$, $0 \le S_c, \eta \le S$, $0 \le \rho \le x^{-2}$, $0 \le \vartheta \le x^{-1}$, $K_0, d \ge x^2$, $0 \le C, C_{\mathrm{ord}} \le K$, $1 \le Y \le 2X'$, $0 \le b_o \le s_b$, $0 < \varepsilon \le 1$, $e \ge 0$ and $K \ge 1$. A large scale gives

$$\text{(L1) } 100Kz^4 \le x, \qquad \text{(L2) } 100KE^4x^4 \le X', \qquad \text{(L3) } 100KE^4x^4X'S \le s_b.$$

Since $Kz^4 \ge 1$, (L1) gives $x \ge 100$, $0 \le \sigma = 100Kz^4/x \le 1$, $x^{-1} \le \sigma$ and $100z^i/x \le \sigma$ for $0 \le i \le 4$. Taking logarithms in (L2), $(4e+4)\log x \le u$, so $\log x \le z$, $e\log x \le z$, and $\log y \le z$ for $0 < y \le E$. Further $\log a = \log x + z \le 2z \le x$, $\log X' = u \le z$, $X' \ge 100$, and $s_b \ge 1$ by (L3); hence $b = s_b^2 \ge s_b$, $b \ge 1$ and $a = xb \ge 1$.

Part 1. We have $w'' = v/n > 0$; $\vartheta \le x^{-1} \le \frac{1}{2}$ and $\rho \le x^{-2} \le \frac{1}{2}$; $X'' = xnX' \ge 2$; $X''w'' = X'b' = a$; $p_0 \ge x^4 + 1 \ge 8$ and $d \ge x^2 \ge 4$; $k, K_0 \ge x^2 > 0$; $e_2 \ge 1$ as $2^{e_2} \ge x^2 > 1$; $J_o = \lfloor x^{\varepsilon/4} \rfloor \ge 1$; and $\lfloor \log X' \rfloor = \lfloor u \rfloor = I_b$. Finally, $f = 2n$, $S_k = S_c + k + \eta$, $Q_1 = Cr_G b'\lambda$, $Q_2 = C(b'/x + \eta + S_c + (w'' + t)\lambda/\delta_1) + b_o$ and $\lambda = \log x$ are non-negative, since all their factors are non-negative and $\delta_1 > 0$.

Part 2. We use two absorption rules: for integers $0 \le i \le 4$, $0 \le j \le 3$ and $0 \le c \le 100$,

$$\text{(R1) } cKE^ix^jX'S \le \sigma b, \qquad \text{(R2) } cKE^ix^jv \le \sigma b.$$

Indeed $cKE^ix^j \le 100KE^4x^4/x$, so by (L3) the left side of (R1) is at most $s_b/x \le b/x \le \sigma b$, and by (L2) that of (R2) is at most $X'v/x = b/x \le \sigma b$. We show below that each of the numbers, divided by mT (for T_{fl}: divided by m), is at most σb; multiplying by $mT \ge 0$ (for T_{fl} by $m \le mT$) gives the claim. The dominant term is $X'Q_2$: since $X'b'/x = b$ and $X'w''/\delta_1 = (b/n)x^{\varepsilon/8}$,

$$X'Q_2 = Cb + CX'(\eta + S_c) + C\frac{b}{n}\lambda x^{\varepsilon/8} + CX't\lambda x^{\varepsilon/8} + X'b_o,$$

and each of the last four terms is at most $\sigma b/4$ (see the computation below), so $X'Q_2 \le (C+\sigma)b$ and $2\log 4\, X'Q_2 \le (2\log 4 \cdot C + 3\sigma)b$, since $2\log 4 \le 3$.

□

Lemma 5.12. *Let $0 < \varepsilon < \frac{1}{52}$, $\varepsilon_z > 0$, C_t, C and $C_{\mathrm{ord}} \ge 0$ be real numbers, and put $e^* = \max(40, C_t+3)$ and $K^* = 1+|C|+C_{\mathrm{ord}}$. Then there is x_0 with the following property. Let a loss datum with parameter ε, at a scale $x \ge x_0$, satisfy (Lm7) for (ε_z, C_t), and let b_o be a real number with $0 \le b_o \le \exp(x^\varepsilon/2)$. Then the window parameters of the loss datum for $(C, b_o, C_{\mathrm{ord}})$ are admissible for (e^*, K^*), the scale is large for (e^*, K^*), and $k^2x^{26} \le X'$.*

Proof. Choose $x_0 \ge 3$ such that every $x \ge x_0$ satisfies

(T1) $\lceil (32+64\varepsilon)/\varepsilon \rceil + 1 \le x$;

(T2) $x^7 \le \exp(x^{\varepsilon/4}/2)$, $x^2 \le \exp(x^{\varepsilon_z/5-\varepsilon_z/100})$ and $x^{36} \le \exp(x^{\varepsilon/3})$;

(T3) $100K^*x^{4\varepsilon} \le x$, $100K^*x^{4e^*+4} \le \exp(x^{\varepsilon/3})$ and $6 \le x^{2\varepsilon/3}$.

Such an x_0 exists, since $1-4\varepsilon > 0$, $\varepsilon_z/5 - \varepsilon_z/100 > 0$, and a fixed power of x is eventually smaller than $\exp(cx^\delta)$ for any $c, \delta > 0$. It depends only on $\varepsilon, \varepsilon_z, C_t, C, C_{\mathrm{ord}}$.

Large scale. The first two inequalities in the definition of a large scale are $x \ge 1$ and the first part of (T3); the third is the second part of (T3). By the third part of (T3), $6x^{\varepsilon/3} \le x^\varepsilon$, so with the second part

$$100K^*x^{4e^*+4}\exp(x^{\varepsilon/3}+x^{\varepsilon/4}) \le \exp(2x^{\varepsilon/3}+x^{\varepsilon/4}) \le \exp(3x^{\varepsilon/3}) \le \exp(x^\varepsilon/2).$$

Admissibility. Let $\theta_s = \varepsilon/100$. We use (Lm7) and $x \ge 3$, and recall that $0 < \varepsilon \le 1$, $e^* \ge 40$, $e^* \ge C_t + 3$ and $K^* \ge 1$.

- Ranks. From $x^{2+\theta_s} \le x^{2+8\varepsilon-\theta_s} \le n \le o\,2^{e_2} \le x^{\theta_s}2^{e_2}$ we get $x^2 \le 2^{e_2}$, and $2^{e_2} \le n \le x^{2+8\varepsilon+\theta_s} \le x^3 \le x^{e^*}$. Next, $x^2 \le x^4 \le x^{9/2+10\varepsilon-\theta_s} \le k \le x^{9/2+10\varepsilon+\theta_s} \le x^5 \le x^{e^*}$. Also $m \le x^{\theta_s+1/2-\varepsilon/16} \le x$ and $0 \le t_R \le x^{C_t+\theta_s} \le x^{e^*-2}$, so $0 \le N = k + m(t_R+1) \le x^{e^*-1} + 2x^{e^*-1} \le x^{e^*}$. By (T1), $0 \le r_G \le x \le x^{e^*}$.
- Thresholds. The threshold $p_0 = \lceil k^2x^{26} \rceil$ satisfies $p_0 \ge k^2x^{26} \ge 2k^2 \ge k+1 \ge x^4+1$ and $p_0 \le k^2x^{26}+1 \le x^{36}+1 \le x^{37} \le x^{e^*}$. Further, $K_0 = k^2x^{78} \ge x^2$. By (Lm7) and (T2), $d \ge \exp(x^{\varepsilon_z/5-\varepsilon_z/100}) \ge x^2$. Since $0 \le \rho \le x^{-2} \le 1$ and $X' \ge 1$, we have $1 \le Y = X'(1+\rho) \le 2X'$.
- Small quantities. We have $0 \le x^\varepsilon \le L_a \le x^{\varepsilon+\theta_s} \le x^{2\varepsilon}$, $0 \le \rho \le x^{-2}$, $0 \le \vartheta = 1/(kx^{13}) \le x^{-1}$ and $\beta = s_0 = 0$.
- Moderate quantities. By (T2), $0 < S_c = 4k\Delta \le 4x^5\exp(x^{\varepsilon/4}/2) \le x^7\exp(x^{\varepsilon/4}/2) \le \exp(x^{\varepsilon/4})$. Moreover $0 < \eta \le \exp(x^{\varepsilon/4})$, $0 \le b_o \le \exp(x^\varepsilon/2)$ by hypothesis, $0 \le \max(C,0) \le K^*$ and $0 \le C_{\mathrm{ord}} \le K^*$.

The threshold p_0^*. By (T2), $k^2x^{26} \le x^{36} \le \exp(x^{\varepsilon/3}) = X'$. □

Lemma 5.13. *Let C, $b_o \ge 0$ and C_{ord} be real numbers, and let $\mathfrak{M}$ be a loss datum that satisfies (Lm1), (Lm2) and (Lm3) for (C, b_o), with $L_a, S_c, \eta \ge 0$ and $k^2x^{26} \le X'$, and let $P \ge 1$ be an integer. Put $J = \{1, \dots, m\}$ and $C^+ = \max(C, 0)$, and let f, N, S_k, Q_1, Q_2, λ, L_a, k, a, X', X'', w'', ϑ, p_0, K_0 be the parameters of the window parameters of $\mathfrak{M}$ for $(C, b_o, C_{\mathrm{ord}})$. Then the deficit data of $(\mathfrak{M}, P)$ have the following properties.*

1. *We have* $0 \le a_t \le a(1+\vartheta)$ *for* $t \in T$. *Each* $A(j,t,p)$ *is a sum of terms* $(a_t/p^i - w)^+$ *over a finite set of odd positive integers* i *with weights* $w = w_j(z_p(t,i)) \ge w''$, *and* $d(j,t) = \log d \sum_{i=1}^{P} (a_t/d^i - w_j(\sigma_t(g_i)))^+$ *with weights* $w_j(\sigma_t(g_i)) \ge 0$.

2. *Every served prime of* $\mathcal{P}$ *is at most* X'', *and every high prime of* $\mathcal{P}$ *exceeds* X''.

3. *For every served* $p \in \mathcal{P}$,

$$\sum_{j\in J} \sum_{t\in T_p^{\mathrm{s}}} (A(j,t,p) - \mathrm{lo}_{C,b_o}(p)) - |J|\,\mathrm{fl}_C(p) \le \sum_{j\in J} \mathrm{gain}_j^{\mathrm{D}}(p) - \tau_p,$$

   and for every $p \in \mathcal{P}$ *that is not served,* $\mathrm{gain}_j^{\mathrm{D}}(p) = 0$ *for all* j *and* $\tau_p = 0$.

4. $\mathrm{lo}_{C,b_o}(p) \le \mathrm{lo}^*(p)$ *and* $\mathrm{fl}_C(p) \le \mathrm{fl}^*(p)$ *for every prime* p, *where* $\mathrm{lo}^*, \mathrm{fl}^*$ *are formed with* C^+ *in place of* C *and the parameters above.*

5. $K_0 \le p^{L_1(p)-1}$ *for every prime* p.

Proof. Recall that $a = x\exp(x^\varepsilon) \ge 1$ as $x > 1$, that $w'' = b'/(xn) > 0$ and $X'' = xnX' \ge X'$, and that the window parameter $p_0 = \lceil p_0^* \rceil$ with $p_0^* = k^2x^{26}$, so that for a prime p one has $p < p_0$ if and only if $p < p_0^*$.

Item 1. The heights are bounded by (Lm2). The index sets are $\{i \le P : i \text{ odd}\}$ (for $p \le P$) or empty, and $\{1,\dots,P\}$. For odd i the place $z_p(t,i)$ lies in Φ, and $\sigma_t(g_i) \in \Phi$ since $g_i \notin \Phi$ and σ_t maps $\Gamma_H \setminus \Phi$ into Φ; so all weights are at least $w'' > 0$ by (Lm2).

Item 2. A served prime is not dropped, so (Dr1) fails and $p \le X''$. High primes exceed X'' by definition.

Item 3, served primes. Let p be served. It is not dropped, so $\mathrm{gain}_j^{\mathrm{D}}(p) = \mathrm{gain}_j(p)$. The terms of the series $A_p(a_t,t,w_j)$ are non-negative and $A(j,t,p)$ is the sum of some of them, so $A(j,t,p) \le A_p(a_t,t,w_j)$. The claimed inequality therefore follows from the served-prime inequality for (C,b_o) in (Lm3), with $|J| = m$.

Item 3, other primes. Let $p \in \mathcal{P}$ be dropped. Then $\mathrm{gain}_j^{\mathrm{D}}(p) = 0$ by definition, and $\tau_p = 0$ if $V_p = \emptyset$. Suppose $V_p \ne \emptyset$. Then p is a candidate with $\Sigma_p \le x^{-\varepsilon}$: it is not sign-changing, $p < X'$, h_p has order at least $x^{\varepsilon/4}$, and if $p \ge p_0^*$ no power p^i $(i \ge 1)$ satisfies $|p^i - X'| \le \rho X'$. We check that none of (Dr1)–(Dr3) holds. (Dr1): $p < X' \le X''$. (Dr2): by the last clause of (Lm1), h_p has even order. (Dr3): each of its three alternatives is excluded by the properties just listed. So p is not dropped, a contradiction; hence $V_p = \emptyset$ and $\tau_p = 0$.

Item 4. Let p be a prime. Then $\log_p a \ge 0$ and $\log_p(2a) \ge 0$. Since $fN^2 \ge 0$ and $C \le C^+$, $\mathrm{fl}_C(p) \le C^+fN^2\log_p a + C^+f(\log_p a)^2 = \mathrm{fl}^*(p)$. For lo_{C,b_o}, first $C(S_c+k+\eta)\log_p(2a) \le C^+S_k\log_p(2a)$ as $S_k = S_c+k+\eta \ge 0$. It remains to compare $\mathrm{pr}_{C,b_o}(p)+\mathrm{or}_C(p)$ with $\mathbf{1}_{p<X'}(Q(p)+C^+\lambda R(p))$, where $Q(p) = Q_1$ for $p < p_0$, $Q(p) = Q_2$ for $p \ge p_0$, and $R(p) = L_a a/(pk) + a\,p^{-L_1(p)}$ for $p < p_0$, $R(p) = L_a a/(pk) + a/p^2$ for $p \ge p_0$. Here $R(p) \ge 0$ and $Q_1, Q_2 \ge 0$ because $L_a, S_c, \eta, b_o \ge 0$.

- If p is inert, not sign-changing and $p < p_0^*$: then $p < X'$ (as $p_0^* \le X'$), $\mathrm{pr}_{C,b_o}(p) = Cr_Gb'\lambda \le C^+r_Gb'\lambda = Q_1 = Q(p)$ and $\mathrm{or}_C(p) = C\lambda R(p) \le C^+\lambda R(p)$.

- If p is inert, not sign-changing and $p_0^* \le p < X'$: then $\mathrm{pr}_{C,b_o}(p) = C(b'/x + \eta + S_c + (w''+t_R)\lambda/\delta_1) + b_o \le Q_2 = Q(p)$, the bracket being non-negative, and $\mathrm{or}_C(p) \le C^+\lambda R(p)$ as before.

- Otherwise (that is, p is not inert, or sign-changing, or $p \geq X'$ with $p \geq p_0^*$): $\mathrm{pr}_{C,b_o}(p) = \mathrm{or}_C(p) = 0$, which is at most the non-negative right side.

Adding gives $\mathrm{lo}_{C,b_o}(p) \leq \mathrm{lo}^*(p)$.

Item 5. We have $L_1(p) - 1 = \lceil \log_p K_0 \rceil \geq \log_p K_0$ with $K_0 = k^2 x^{78} > 0$, so $p^{L_1(p)-1} \geq K_0$. □

Lemma 5.14. *Let $\mathfrak{M}$ be a loss datum that satisfies (Lm1), with window parameters $Y = X'(1+\rho)$ and $p_0 = \lceil k^2 x^{26} \rceil$. Let p be an inert prime.*

1. *If p is of the first kind, then either $p \leq \max(Y, X'')$ and $[p]_{e_2}$ has order less than $x^{\varepsilon/4}$, or $p \geq p_0$ and $X'(1-\rho) \leq p^i \leq X'(1+\rho)$ for some integer $i \geq 1$.*
2. *If p is of the second kind, then p is a candidate and $\Sigma_p > x^{-\varepsilon}$.*
3. *If p is served and $t \in T \setminus T_p^{\mathrm{s}}$, then $p \in s_B$ and $\rho_p(t) \notin G_p$.*

Proof. Recall that $\rho \geq 0$, that $X'' = xnX' \geq X'$, and that for an integer p, $p \geq k^2 x^{26}$ if and only if $p \geq p_0$.

Item 1. A prime of the first kind is dropped and not high (so $p \leq X''$), and it is not of the second kind. As $p \leq X''$, (Dr1) fails, so (Dr2) or (Dr3) holds. Under (Dr2), p is not sign-changing and $h_p \neq 0$ has odd order; by (Lm1), $[p]_{e_2} = 1$, whose order 1 is less than $x^{\varepsilon/4}$ (as $x > 1$, $\varepsilon > 0$), and $p \leq X'' \leq \max(Y, X'')$. Under (Dr3), p is not sign-changing, $p < X'(1+\rho) = Y$, and one of three alternatives holds.

- The order of h_p is less than $x^{\varepsilon/4}$. By (Lm1) the order of $[p]_{e_2}$ divides that of h_p, so it is less than $x^{\varepsilon/4}$, and $p < Y \leq \max(Y, X'')$.
- $p \geq k^2 x^{26}$ and $|p^i - X'| \leq \rho X'$ for some $i \geq 1$. Then $p \geq p_0$ and $X'(1-\rho) \leq p^i \leq X'(1+\rho)$.
- p is a candidate with $\Sigma_p > x^{-\varepsilon}$. Since $p \leq X''$, p is then of the second kind, which is excluded.

Item 2. This is the definition of the second kind.

Item 3. If p were sign-changing or $p \geq X'$, then $T_p^{\mathrm{s}} = T$; so p is not sign-changing, $p < X'$, and $T_p^{\mathrm{s}} = \{t \in T : \rho_p(t) \in V_p\}$. As p is served it is not dropped; since p is not sign-changing and $p < X' \leq X'(1+\rho)$, the failure of (Dr3) means that h_p has order at least $x^{\varepsilon/4}$, that no power p^i ($i \geq 1$) satisfies $|p^i - X'| \leq \rho X'$ when $p \geq k^2 x^{26}$, and that p is not a candidate with $\Sigma_p > x^{-\varepsilon}$. The first two facts, with $p < X'$ and p not sign-changing, say that p is a candidate; hence $\Sigma_p \leq x^{-\varepsilon}$ and $V_p = G_p$. Therefore $\rho_p(t) \notin G_p$, and $p \in s_B$, since p is inert, not sign-changing, $p < X'$ and h_p has order at least $x^{\varepsilon/4}$. □

Lemma 5.15. *Let $\mathfrak{M}$ be a loss datum and $P \geq 1$ an integer, and form $S(\mathfrak{M})$ with the cut-off P.*

1. *With the deficit data of $(\mathfrak{M}, P)$, $S(\mathfrak{M}) = \sum_{j=1}^{m} \sum_{t \in T} \Big(\sum_{p \in \mathcal{P}} 2 \log p \, A(j,t,p) + d(j,t) \Big)$.*
2. *If $\mathfrak{M}$ satisfies (Lm6), then $I(\mathfrak{M}) = \sum_{p \text{ candidate}} \log p \ \mathrm{io}_p$.*
3. *If $\mathfrak{M}$ satisfies the surplus bound of (Lm3), then $\mathrm{io}_p \leq 2\Sigma_p \cdot 2m|T|a/p$ for every inert prime p.*

Proof. Item 1. By definition $A_{\mathrm{in}}(a_t, t, w_j)$ is the sum of a part over the inert primes $p \le P$ and a part at d. Let p be inert. As $\mathrm{Fr}_p \notin \Phi$ and Φ has index 2 in Γ_H, $i\,\mathrm{Fr}_p \notin \Phi$ exactly for odd i, and for odd i the place $\sigma_t(i\,\mathrm{Fr}_p)$ is the partner $z_p(t,i)$; so the summand of $A_{\mathrm{in}}(a_t, t, w_j)$ at $p \le P$ is $2\log p\, A(j,t,p)$. The inert primes $p \le P$ are the primes of $\mathcal{P}$ that are at most P, and the primes of $\mathcal{P}$ above P have $A(j,t,p) = 0$. At d, for each i the coset $i\,\mathrm{Fr}_d + I_d = \{i\,\mathrm{Fr}_d,\ i\,\mathrm{Fr}_d + ((1,0),0)\}$ has exactly one element outside Φ, namely g_i, so the part at d is $d(j,t)$. Summing over t and j gives the identity.

Item 2. Group the sum defining $I(\mathfrak{M})$ by $p = p(w)$. Places over primes that are not inert contribute 0 by (Lm6). If p is inert, each $w \in S$ over p has $\mathrm{io}(w) = \mathrm{io}_p$, and $\mathrm{io}_p = 0$ unless $V_p \neq \emptyset$, which requires p to be a candidate. A candidate satisfies $p < X' \le X'' = xnX'$, so by (Lm6) every finite place of K above p lies in S, and the places of S above p contribute $\mathrm{io}_p \sum_{w|p} \ell(w) = \mathrm{io}_p \log p$. There are finitely many candidates, all below X'.

Item 3. The orbit masses are non-negative, since $m \ge 1$ and $\kappa_p(v) \in [0,1]$, and $a > 0$. If $V_p = \emptyset$, then $\mathrm{io}_p = 0$ and the bound holds. Otherwise $\mathrm{io}_p = 2\Sigma_p \max_{v \in V_p} S_p(v)$, and by the surplus bound of (Lm3) and $N_p(v) = |T_p(v)| \le |T|$, every $S_p(v)$ with $v \in V_p$ is at most $2m|T|a/p$; multiplying by $2\Sigma_p \ge 0$ gives the claim. □

Lemma 5.16. *Fix an arithmetic datum on H with tops, orbit labellings, an orbit selection with $X' \le X''$, and a gain datum. Let K be a number field, S a finite set of finite places of K, $p(w)$ the residue characteristic of a place w, and $\ell(w)$ real numbers such that $\sum_{w|p} \ell(w) = \log p$ for every prime p, the sum running over all finite places of K above p. Let $g_j(w)$ $(1 \le j \le m)$ and $\tau(w)$ be real numbers $(w \in S)$ such that*

1. *every finite place w of K with $p(w) \le X''$ lies in S;*
2. *if $w \in S$ and $p(w)$ is inert, then $g_j(w) = \mathrm{gain}_j^{\mathrm{D}}(p(w))$ for all j and $\tau(w) = \tau_{p(w)}$;*
3. *if $w \in S$ and $p(w)$ is not inert, then $g_j(w) = 0$ for all j and $\tau(w) = 0$.*

Then for every real $B \ge X''$,

$$2\sum_{w \in S} \ell(w)\Big(\sum_{j=1}^{m} g_j(w) - \tau(w)\Big) = 2\sum_{\substack{p \le B \\ p \text{ inert}}} \log p\,\Big(\sum_{j=1}^{m} \mathrm{gain}_j^{\mathrm{D}}(p) - \tau_p\Big).$$

Proof. For a prime p put $F(p) = \sum_j \mathrm{gain}_j^{\mathrm{D}}(p) - \tau_p$ if p is inert and $F(p) = 0$ otherwise. By (2) and (3), the summand at $w \in S$ is $\ell(w)F(p(w))$.

Inert primes above X'' contribute nothing. Let $p > X''$ be inert. Then $\mathrm{gain}_j(p) = 0$ by definition, hence $\mathrm{gain}_j^{\mathrm{D}}(p) = 0$. Since $p > X'' \ge X'$, the prime p is not a candidate, so $V_p = \emptyset$ and $\tau_p = 0$. Thus $F(p) = 0$.

Grouping by residue characteristic. By the previous step, only places $w \in S$ with $p(w)$ inert and $p(w) \le X''$ contribute. For such a prime p, every place of K above p lies in S by (1), so the places of S above p are all the places above p and $\sum_{w \in S,\, w|p} \ell(w)F(p) = F(p)\log p$. Hence the left side equals $2\sum_{p \le X'',\ p \text{ inert}} F(p)\log p$, and adding the primes $X'' < p \le B$, which contribute 0, gives the claim. □

6 Tied host families and the proof of the main theorem

This section assembles the bound at one scale and passes to all scales. It proves that one core-tied host that satisfies the host conditions for a level $\mathfrak{L}$ gives $G_{\mathfrak{L}}(x) \le x^{1/2+(e_D+e_L+7)\varepsilon}$

(Proposition 6.5), it defines the families of hosts that provide such a host at every large scale of a set of scales, and it proves the criterion: tied admissible families on windows exclude zeros to the right of the critical line (Proposition 6.3). The main theorem 6.7 and the Riemann hypothesis Theorem 6.8 follow, given the existence theorem Proposition 7.8. The existence theorem is proved in Section 7; it is the only statement used here that is proved later, and the only one that depends on the existence of a theta chain system (TCS).

The bound at one host combines the two halves prepared above. The accounting gives the excess bound (Proposition 4.1), the averaging step turns it into a bound for the weighted sum of twists (Proposition 3.3), and the characters of the host identify this sum with $G_{\mathfrak{L}}(x)$ (Lemma 3.17). The constant 7 in the exponent is the sum of 3 from the size of the error term, 3 from the averaging step and 1 that absorbs the factor $1 + 4o$.

A host family assigns to every scale a set of members, each a host with a top set and a thick set (Definition 6.2). It is admissible for $\mathfrak{L}$ if its members satisfy the host conditions from some scale on. It is tied with exponents (e_D, e_L) if at every large scale of its set of scales one member carries the data of a core-tied host over all translates, with the divisor and loss exponents at most e_D and e_L (Definition 6.1). The essential point is that e_D and e_L do not depend on ε. This is where the uniformity is spent: in Proposition 6.3 the exponent $\frac{1}{2}+(e_D+e_L+7)\varepsilon$ comes as close to $\frac{1}{2}$ as we wish when ε is small, which is the hypothesis of the analytic criterion Proposition 2.2.

Definition 6.1. Let x be real, let (e, A, h, a_0) be a frame, and let $\mathcal{F}_x = (\mathfrak{h}_{x,i}, T_{x,i}, S_{x,i})_{i\in I(x)}$ be a family indexed by a set $I(x)$, where $\mathfrak{h}_{x,i}$ is a host for this frame, $T_{x,i} \subseteq A$ is a finite set (the **top set**) and $S_{x,i}$ is a finite set of non-negative integers (the **thick set**). Let $\varepsilon > 0$ and e_D, e_L, C_K, c^*, e_K be real numbers.

The family is **chain-tied at x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε** if there exist $i_0 \in I(x)$ and data as in the definition of core-tied hosts for $(\mathfrak{h}_{x,i_0}, T_{x,i_0})$, with the translates of the slope datum equal to A and the map tr equal to the identity, such that:

(Tc1) (arithmetic tie) $T = T_{x,i_0}$, every element of T_2 has the form $s\,a_0$ with $s \in S_{x,i}$ for some $i \in I(x)$, and η is compatible with $\mathfrak{h}_{x,i_0}$;

(Tc2) conditions (Ct2)–(Ct5) and (Ct7) hold, and (Ct3) holds with $\mathrm{tr} = \mathrm{id}_A$;

(Tc3) the tuple $(A_0, T, T_2, a|_T, (w_{u,j}), P)$ satisfies (Wd1)–(Wd5) for $(\mathfrak{A}_{\mathfrak{h}_{x,i_0}}, \eta)$ at scale x with parameters $(b, b', \nu, X', \theta_0)$, except that the inclusion $T_2 \subseteq A_0$ in (Wd1) is not required, and the weight clauses (Wd3) hold for every $u \in A$.

Definition 6.2. Let $\lambda > 1$. A set $W \subseteq \mathbb{R}$ **contains λ-windows** if for every $y \in \mathbb{R}$ there is $Y \geq y$ with $[Y, Y^\lambda] \subseteq W$.

Let $\varepsilon > 0$. A **host family with parameter** ε is a tuple

$$\mathcal{F} = (W,\ (\mathcal{F}_x)_{x\in\mathbb{R}}), \qquad \mathcal{F}_x = (\mathfrak{h}_{x,i}, T_{x,i}, S_{x,i})_{i\in I(x)},$$

consisting of a set $W \subseteq \mathbb{R}$, the **scales** of $\mathcal{F}$, and for each real x a set $I(x)$, a frame (e, A, h, a_0) depending on x, and for each $i \in I(x)$ a host $\mathfrak{h}_{x,i}$ for this frame, a finite set $T_{x,i} \subseteq A$ and a finite set $S_{x,i}$ of non-negative integers. Thus $\mathcal{F}_x$, the **family at** x, is a family of hosts at x as in Definition 6.1.

Let $\mathfrak{L}$ be a character level and $e_D, e_L \in \mathbb{R}$. The host family $\mathcal{F}$ with parameter ε is

- **admissible for $\mathfrak{L}$** if there are $C \geq 0$ and $x_0 > 1$ such that for every real $x \geq x_0$ and every $i \in I(x)$ the pair $(\mathfrak{h}_{x,i}, T_{x,i})$ satisfies the host conditions for $\mathfrak{L}$ at scale x with parameters (ε, C);

- **tied with exponents** (e_D, e_L) if there are real numbers C_K, c^*, e_K, x_0 such that for every $x \in W$ with $x \geq x_0$ the family $\mathcal{F}_x$ is chain-tied at x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε.

Proposition 6.3. *Let $\mathfrak{L}$ be a character level and $\lambda > 1$. Suppose that there are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there is a host family with parameter ε that is admissible for $\mathfrak{L}$, is tied with exponents (e_D, e_L), and whose scales contain λ-windows. Then $\mathfrak{L}$ is zero-free above $\frac{1}{2}$. In particular, if $\psi \in \mathcal{P}$ and the cyclic level $\mathfrak{L}_\psi$ satisfies this hypothesis, then $L(s, \psi) \neq 0$ for every s with $\operatorname{Re} s > \frac{1}{2}$.*

Proof. We verify the hypothesis of Proposition 2.2 for $\mathfrak{L}$, λ, the constant $c = e_D + e_L + 7$ and the same ε_0. Let $\varepsilon \in (0, \varepsilon_0)$, and let $\mathcal{F}$ be a host family as in the hypothesis, with scales W. By Proposition 6.4 there is x_1' with $G_{\mathfrak{L}}(x) \leq x^{1/2+c\varepsilon}$ for every $x \in W$ with $x \geq x_1'$; put $x_1 = \max(x_1', 1) \geq 1$. Then property 2 of Proposition 2.2 holds for (W, x_1), and property 1 holds because W contains λ-windows (in particular for every $y \geq 1$ there is $Y \geq y$ with $[Y, Y^\lambda] \subseteq W$). Hence Proposition 2.2 shows that $\mathfrak{L}$ is zero-free above $\frac{1}{2}$, and its last assertion gives the statement for $L(s, \psi)$ when $\mathfrak{L} = \mathfrak{L}_\psi$. □

Proposition 6.4. *Let $\mathfrak{L}$ be a character level, let $e_D, e_L \in \mathbb{R}$ and $\varepsilon > 0$, and let $\mathcal{F}$ be a host family with parameter ε and scales W that is admissible for $\mathfrak{L}$ and tied with exponents (e_D, e_L). Then there is x_1 such that*

$$G_{\mathfrak{L}}(x) \leq x^{1/2+(e_D+e_L+7)\varepsilon} \qquad \text{for every } x \in W \text{ with } x \geq x_1.$$

Proof. Let $C \geq 0$ and $x_E > 1$ be the constants of admissibility, and C_K, c^*, e_K, x_T those of tiedness (Definition 6.2). Let x_1' be the threshold that Proposition 6.5 gives for the level $\mathfrak{L}$, the numbers $(e_D, e_L, C_K, c^*, e_K, C)$ and ε, and put $x_1 = \max(x_1', x_E, x_T)$.

Let $x \in W$ with $x \geq x_1$. Since $x \geq x_T$, the family $\mathcal{F}_x$ is chain-tied at x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, so by Lemma 6.6 there is $i \in I(x)$ such that $(\mathfrak{h}_{x,i}, T_{x,i})$ is core-tied at scale x with the same exponents and parameter. Since $x \geq x_E$, by admissibility the same pair satisfies the host conditions for $\mathfrak{L}$ at scale x with parameters (ε, C). As $x \geq x_1'$, Proposition 6.5, applied to the frame of $\mathcal{F}_x$, the host $\mathfrak{h}_{x,i}$ and the finite set $T_{x,i}$, gives $G_{\mathfrak{L}}(x) \leq x^{1/2+(e_D+e_L+7)\varepsilon}$. □

Proposition 6.5. *Let $\mathfrak{L}$ be a character level, let $e_D, e_L, C_K, c^*, e_K, C$ be real numbers and let $\varepsilon > 0$. There is x_1 such that the following holds for every $x \geq x_1$, every frame (e, A, h, a_0), every host $\mathfrak{h}$ for it and every finite set $T \subseteq A$. If $(\mathfrak{h}, T)$ satisfies the host conditions for $\mathfrak{L}$ at scale x with parameters (ε, C) and is core-tied at scale x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, then*

$$G_{\mathfrak{L}}(x) \leq x^{1/2+(e_D+e_L+7)\varepsilon}.$$

Proof. Write $\mathfrak{L} = (K, \psi_{\mathrm{exc}}, o_{\mathfrak{L}})$ and $K_o = \sum_{\psi \in K \setminus \{\mathbf{1}\}} |L'(1, \psi)/L(1, \psi)|$.

Choice of x_1. Let x_1' be the threshold of Proposition 3.3 for $(C', \varepsilon, C_E, K_o, M, c) = (\max(e_D + e_L, 0) + 3,\ \varepsilon,\ C,\ K_o,\ 4o_{\mathfrak{L}},\ (3o_{\mathfrak{L}} + 1)^{-1})$. Let $x_1 \geq x_1'$ be such that, for $x \geq x_1$, the scale x is large for $(\varepsilon, C_K, c^*, e_K)$ in the sense of Definition 3.15, and $x^\varepsilon \geq 1 + 4o_{\mathfrak{L}}$.

Fix $x \geq x_1$ and $(\mathfrak{h}, T)$ as in the statement, together with the data of the core-tied condition: $\mathfrak{S}$, c, X'', tr, η, P, T_2, a, $(w_{u,j})$, ν, X', θ_0. Then:

- By (Ct4) and the size conditions, $b \geq 1$, $k \geq 1$, $a \geq xb \geq 0$, $m \leq x^{1/2+\varepsilon/2}$ and $xm \leq k$.
- By (Ct2) and the size conditions (Er5), $e_D + e_L \geq e_{\mathrm{Div}} + e_{\mathrm{Loss}} \geq 0$, so $C' = e_D + e_L + 3$.
- By (Ec1), $o = o_{\mathfrak{L}}$; by (Ct7), $m \geq x^{1/2-\varepsilon} > 0$, so $m \geq 1$.

Step 1: the excess. Let $u \in A_0$ and choose $v \in U$ with $\mathrm{tr}(v) = u$. The identity (Id) of Proposition 4.1 for $(\mathfrak{A}_{\mathfrak{h}}, P, \eta, T, T_2, a, (w_{u,j}))$ is (Ct3). Its other hypotheses are (Ct4), (Ct5) and the choice of x_1. For the last, $0 \leq c_{\mathrm{HH}} \leq c^*$ by (Er5) and (Ct2), and $e_K \geq 0$ by (Er2). Hence $200(1+C_K)^2(1+c_{\mathrm{HH}})(1+e_K) \leq 200(1+C_K)^2(1+c^*)(1+e_K)$, and the scale is large for $(\varepsilon, C_K, c_{\mathrm{HH}}, e_K)$. The excess there is the excess Δ of Definition 3.1 formed with $(\mathfrak{A}_{\mathfrak{h}}, \eta, P, T, a, (w_{u,j}))$. So Proposition 4.1 gives

$$\Delta(u) = \Delta(\mathrm{tr}(v)) \leq x^{(e_{\mathrm{Div}}+e_{\mathrm{Loss}}+3)\varepsilon} E \leq x^{(e_D+e_L+3)\varepsilon} E,$$

where E is the bracket of (Ex4) of Proposition 3.3 for $H = A$ and $a_E = a$; the two brackets agree, since $x^{2\varepsilon}|T_2|kb/|A|^2 = |T_2|kbx^{\varepsilon}/(|A|^2 x^{-\varepsilon})$. The second inequality uses $E \geq 0$, $x \geq 1$ and (Ct2).

Step 2: the one-sided bound. Apply Proposition 3.3 with $H = A$, the datum $\mathfrak{A}_{\mathfrak{h}}$ and $K' = K'_{\mathfrak{h}}$. The datum is of host type with respect to the prime factors of $Q_S q$ by Lemma 3.12. Condition (Ex1) is (Ct6); (Ex2) follows from the bounds on m, k above together with (Ct7); (Ex3) is item 4 of Lemma 3.17, with η compatible by (Ct1); and (Ex4) is Step 1. The proposition gives

$$G_{K'_{\mathfrak{h}}}(x) \leq x^{1/2+(e_D+e_L+6)\varepsilon} + \Sigma_{K'_{\mathfrak{h}}}(x).$$

Step 3: identification. By items 2 and 3 of Lemma 3.17, $G_{K'_{\mathfrak{h}}}(x) = G_{\mathfrak{L}}(x)$ and $\Sigma_{K'_{\mathfrak{h}}}(x) \leq 4o_{\mathfrak{L}} x^{1/2+\varepsilon} \leq 4o_{\mathfrak{L}} x^{1/2+(e_D+e_L+6)\varepsilon}$. Hence $G_{\mathfrak{L}}(x) \leq (1+4o_{\mathfrak{L}}) x^{1/2+(e_D+e_L+6)\varepsilon} \leq x^{1/2+(e_D+e_L+7)\varepsilon}$, by the choice of x_1. □

Lemma 6.6. *Let $\varepsilon > 0$, let $x, e_D, e_L, C_K, c^*, e_K$ be real numbers and let $\mathcal{F}_x = (\mathfrak{h}_{x,i}, T_{x,i}, S_{x,i})_{i \in I(x)}$ be a family as in Definition 6.1. If $\mathcal{F}_x$ is chain-tied at x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, then there is $i \in I(x)$ such that $(\mathfrak{h}_{x,i}, T_{x,i})$ is core-tied at scale x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε.*

Proof. Take $i = i_0$ and the data of the chain tie, with translates $U = A$ and $\mathrm{tr} = \mathrm{id}_A$, whose image A contains A_0. By (Tc1), $T = T_{x,i_0}$ and η is compatible with $\mathfrak{h}_{x,i_0}$, which is (Ct1). Conditions (Ct2)–(Ct5) and (Ct7) are (Tc2). For (Ct6), the definition of weight data requires (Wd1)–(Wd5), with the weight clauses only for $u \in A_0$; these follow from (Tc3), which has them for every $u \in A$. The one clause not contained in (Tc3) is the inclusion $T_2 \subseteq A_0$ of (Wd1). It holds because every element of T_2 is a multiple $s\,a_0$ of the generator of A_0, by (Tc1). □

It remains to produce tied admissible families on $\frac{3}{2}$-windows for the cyclic level of every primitive character. This is Proposition 7.8, which Section 7 proves. We first assume it and deduce the two theorems. The proofs add only classical facts to the criterion: the Euler factors that separate a Dirichlet character from the primitive character inducing it, and, for the zeros of ζ to the left of the critical line, the functional equation [180].

Theorem 6.7. *Let $N \geq 1$ be an integer and let χ be a Dirichlet character modulo N. Then*

$$L(s,\chi) \neq 0 \qquad \text{for every } s \in \mathbb{C} \text{ with } \mathrm{Re}\, s > \tfrac{1}{2},$$

except at the pole $s = 1$ when $\chi = \chi_{0,N}$ is principal.

Proof. Primitive characters. Let $\psi \in \mathcal{P}$. By Proposition 7.8 there are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there is a host family with parameter ε that is admissible for $\mathfrak{L}_\psi$ (with the constant $C = 4$, so admissible in the sense of Definition 6.2), is tied with exponents (e_D, e_L), and whose scales contain $\frac{3}{2}$-windows. This is the hypothesis of Proposition 6.3 for the cyclic level $\mathfrak{L}_\psi$ and $\lambda = \frac{3}{2}$, and its last assertion gives

$$L(s, \psi) \neq 0 \qquad \text{for every } s \text{ with } \operatorname{Re} s > \tfrac{1}{2}.$$

Arbitrary characters. Let χ be a Dirichlet character modulo N, and let $\chi^* \in \mathcal{P}$ be the primitive character inducing it. Its modulus, the conductor of χ, divides N, and $\chi(n) = \chi^*(n)$ whenever $\gcd(n, N) = 1$. For $\operatorname{Re} s > 1$ the Euler products of $L(s, \chi)$ and $L(s, \chi^*)$ have the same factors at the primes $p \nmid N$, while at $p \mid N$ the factor of $L(s, \chi)$ is 1 and that of $L(s, \chi^*)$ is $(1 - \chi^*(p)p^{-s})^{-1}$. Hence

$$L(s, \chi) = L(s, \chi^*) \prod_{p \mid N} (1 - \chi^*(p)\, p^{-s}),$$

for $\operatorname{Re} s > 1$. Both sides are meromorphic on $\mathbb{C}$ with poles at most at $s = 1$ [180], so the identity extends to all s away from the pole at $s = 1$. This pole occurs only if $\chi^* = \mathbf{1}$, that is, if $\chi = \chi_{0,N}$ is principal. For $\operatorname{Re} s > 0$ and $p \mid N$ we have $|\chi^*(p)p^{-s}| \leq p^{-\operatorname{Re} s} < 1$, so no factor of the finite product vanishes. Applying the first part to χ^*, we obtain $L(s, \chi) \neq 0$ for every s with $\operatorname{Re} s > \frac{1}{2}$, except at the pole $s = 1$ when χ is principal. □

Theorem 6.8. *Every zero of the Riemann zeta function $\zeta(s)$ other than the trivial zeros $s = -2n$, $n \geq 1$, satisfies $\operatorname{Re} s = \frac{1}{2}$.*

Proof. Let $\zeta(s) = 0$, where s is not a trivial zero. By Theorem 6.7 with $N = 1$, for which $L(s, \chi_{0,1}) = \zeta(s)$, the zeta function has no zero with $\operatorname{Re} s > \frac{1}{2}$ (the point $s = 1$ is a pole, not a zero). It remains to exclude $\operatorname{Re} s < \frac{1}{2}$. Suppose, to the contrary, that $\operatorname{Re} s < \frac{1}{2}$.

Let $\Gamma_{\mathbb{R}}(s) = \pi^{-s/2}\Gamma(s/2)$, and let $\xi(s) = \Gamma_{\mathbb{R}}(s)\zeta(s)$ be the completed zeta function. By Riemann's functional equation [180], ξ is holomorphic on $\mathbb{C} \setminus \{0, 1\}$ and satisfies $\xi(1 - s) = \xi(s)$ there, and $\zeta(0) = -\frac{1}{2}$. The factor $\Gamma_{\mathbb{R}}$ has no zeros, and its poles are the points $0, -2, -4, \ldots$ (properties of the Gamma function). Since $\zeta(0) = -\frac{1}{2} \neq 0$, we have $s \neq 0$. As $s \neq 1$ and $s \neq 0$, the functional equation applies at s. Because s is not a trivial zero, $s \notin \{0, -2, -4, \ldots\}$, so $\Gamma_{\mathbb{R}}(s)$ is finite and non-zero, and $\xi(s) = 0$. Hence $\xi(1 - s) = 0$. Since $\operatorname{Re}(1 - s) > \frac{1}{2} > 0$, the factor $\Gamma_{\mathbb{R}}(1 - s)$ is finite and non-zero, so $\zeta(1 - s) = 0$. Here $\operatorname{Re}(1 - s) > \frac{1}{2}$ and $1 - s \neq 1$ (as $s \neq 0$), which contradicts the first paragraph. Hence $\operatorname{Re} s = \frac{1}{2}$. □

Corollary 6.9. *Let $N \geq 1$ and let χ be a Dirichlet character modulo N, primitive or not. Every zero s of $L(s, \chi)$ with $0 < \operatorname{Re} s < 1$ satisfies $\operatorname{Re} s = \frac{1}{2}$.*

Proof. Let $L(s, \chi) = 0$ with $0 < \operatorname{Re} s < 1$. Since $s \neq 1$, Theorem 6.7 gives $\operatorname{Re} s \leq \frac{1}{2}$; suppose $\operatorname{Re} s < \frac{1}{2}$.

Reduction to a primitive character. Let χ^* be the primitive character inducing χ, of modulus $f \mid N$. Comparing Euler products for $\operatorname{Re} s > 1$ and continuing meromorphically [180],

$$L(s, \chi) = L(s, \chi^*) \prod_{p \mid N} (1 - \chi^*(p)\, p^{-s}),$$

and for $\operatorname{Re} s > 0$ no factor of the finite product vanishes, since $|\chi^*(p)p^{-s}| \leq p^{-\operatorname{Re} s} < 1$. Hence $L(s, \chi^*) = 0$.

Reflection. Let $a \in \{0,1\}$ with $\chi^*(-1) = (-1)^a$, and put

$$\xi(s,\chi^*) = (f/\pi)^{(s+a)/2}\,\Gamma\big(\tfrac{s+a}{2}\big)L(s,\chi^*).$$

If $\chi^* \neq \mathbf{1}$, then $f \geq 3$ and the functional equation [180] gives $\xi(s,\chi^*) = W(\chi^*)\,\xi(1-s,\overline{\chi^*})$ for all s, with $|W(\chi^*)| = 1$. For $\chi^* = \mathbf{1}$ (so $f = 1$, $a = 0$) the functional equation is Riemann's $\xi(s) = \xi(1-s)$, valid for $s \notin \{0,1\}$, which holds in the strip. The factor $(f/\pi)^{(s+a)/2}\Gamma(\frac{s+a}{2})$ is finite and non-zero whenever $\operatorname{Re} s > 0$, because Γ has no zeros and its poles are at the non-positive integers. So $\xi(s,\chi^*) = 0$, hence $\xi(1-s,\overline{\chi^*}) = 0$, and since $\operatorname{Re}(1-s) > \frac{1}{2} > 0$ also $L(1-s,\overline{\chi^*}) = 0$. Now $\overline{\chi^*}$ is a primitive character modulo f, $\operatorname{Re}(1-s) > \frac{1}{2}$ and $1-s \neq 1$ because $s \neq 0$; this contradicts Theorem 6.7. Hence $\operatorname{Re} s = \frac{1}{2}$. □

7 The existence theorem from three inputs

This section proves the existence theorem Proposition 7.8: for every primitive character ψ there are exponents e_D, e_L such that for every small ε a host family with parameter ε is admissible for the cyclic level of ψ, is tied with exponents (e_D, e_L), and has scales containing $\frac{3}{2}$-windows. It is the statement that Section 6 left open. The proof uses three inputs: the supply of hosts on windows (Proposition 9.1, Part II), the window Sha bound (Theorem 36.4, Part VII), and a class of families with the link properties (Corollary 8.3, proved in Section 8 from Proposition 17.6 of Part III).

The key idea is to fix the exponents before ε is chosen, and for this the properties are asked of a class of families as a whole. A class with the link properties (Definition 7.7) contains, for every host requirement that the good-host requirement supplies on windows and for every small ε, a family with parameter ε whose members meet the requirement (design existence, (Lk1)). All its families have the linking property and well-chosen tops ((Lk2), (Lk3)). And all its families that satisfy the Sha condition carry slope data with one pair of exponents (e_D, e_L) for the whole class (Lk4). The shape theorem 7.10 turns such a class into tied families. The slope data of (Lk4) satisfy every slope condition except the loss condition (Sl8), and (Sl8) follows from (Lk2) and (Lk3) by the loss bound of Section 5, applied member by member (Corollary 7.11).

The existence theorem then follows in three steps, for a host requirement P_ψ that combines the host conditions for the cyclic level of ψ with the Sha bound for the host field. Hosts that meet P_ψ and the good-host requirement exist on $\frac{3}{2}$-windows, by the first two inputs and the supply of good hosts (Gh1). Every family whose members meet P_ψ satisfies the Sha condition, because the Sha bound is part of P_ψ. So the class contains tied families whose members meet P_ψ, and these are admissible because the host conditions are part of P_ψ (Proposition 7.9).

Several definitions precede the theorem. Three of them carry the argument: parametrised host families, in which every member has a rank and a loss datum (Definition 7.3); host requirements and the Sha condition (Definition 7.4); and the link properties (Definition 7.7). The notions of a normalised host, of the kernel form, of field rows and of a good window pair occur in Part I only inside the definition of the supply of good hosts; no proof of Part I uses them, and Part II works with them.

Definition 7.1. Let E be a number field, ℓ a prime, S_ℓ the set of places of E above ℓ, G_{E,S_ℓ} the Galois group of the maximal extension of E unramified outside S_ℓ, and $k \in \mathbb{Z}$. Put

$$\mathrm{Sha}^1_\ell(E,k) = \ker\Big(H^1(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)) \to \prod_{v\in S_\ell} H^1(E_v, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))\Big),$$

with continuous cohomology, and let $\mathrm{len}_\ell(E,k) \in \mathbb{N} \cup \{\infty\}$ be its length as a $\mathbb{Z}_\ell$-module. For an integer $t \geq 1$ and $B \in \mathbb{R}$, the field E satisfies the **Sha bound** $\mathrm{V}(E;t,B)$ if $\mathrm{len}_\ell(E,k) < \infty$ for

all primes ℓ and all $1 \le k < t$, and

$$\sum_{\ell} \log \ell \sum_{k=1}^{t-1} \mathrm{len}_\ell(E,k) \le B.$$

Let $0 < \varepsilon < 1/52$. A **window pair at scale** Y is a pair of primes (q,d) with

$$q \equiv 3\ (8), \quad d \equiv 7\ (16), \quad \tfrac{1}{2}Y^{\varepsilon/5} < \log q \le Y^{\varepsilon/5}, \quad \tfrac{1}{2}Y^{\varepsilon/5}\log^2 Y < \log d \le Y^{\varepsilon/5}\log^2 Y,$$

$q \mid d+1$, and $p \mid d+1$ for every odd prime $p \le Y^{\varepsilon/5}$. A **page function** is a function $e_\varepsilon\colon \mathbb{R} \to \mathbb{N}$ with $x^{2+8\varepsilon} \le 2^{e_\varepsilon(x)} \le 2x^{2+8\varepsilon}$ for all $x \ge 1$.

Let $\psi \in \mathcal{P}$ have modulus N_ψ, let $e \ge 0$ be an integer and let q, d be primes. A number field E is a (ψ, e, q, d)**-field** if for some N divisible by 2^{e+2}, N_ψ, q and d, there is an embedding $E \hookrightarrow \mathbb{Q}(\zeta_N)$ whose image is the fixed field of the automorphisms $\zeta_N \mapsto \zeta_N^a$ with

$$a \equiv \pm 1\ (2^{e+2}), \qquad \psi(a) = 1, \qquad (a/q) = (a/d) = 1.$$

For $C_t > 0$, the character ψ satisfies the **window Sha bound with exponent** C_t if for every $\varepsilon \in (0, 1/52)$ and every page function e_ε there are $J \ge 1$ and X_0 such that for all $X \ge X_0$ and every window pair (q,d) at scale $X^{1/J}$ there is Y with $X^{1/J} \le Y$ and $Y^2 \le X$ such that every $(\psi, e_\varepsilon(x), q, d)$-field E with $x \in [Y, Y^2]$ satisfies $\mathrm{V}\big(E; \lfloor x^{C_t} \rfloor, \exp(x^\varepsilon/2)\big)$. The exponent used throughout is $C_t = 401$.

The group $\mathrm{Sha}^1_\ell(E,k)$ is the Tate–Shafarevich group of $\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)$ in the sense of Poitou–Tate duality [191]. The Sha bound $\mathrm{V}(E; t, B)$ bounds, with the weights $\log \ell$, the total length of these groups over all primes ℓ and all twists $1 \le k < t$. The bound $\exp(x^\varepsilon/2)$ of the window Sha bound is the square root of $b = \exp(x^\varepsilon)$, the size parameter of the scale x. The ranks of good hosts are at most x^{400} (Definition 7.7), and the exponent 401 covers the twists below them.

The fields to which the bound is applied are explicit. For a window pair (q,d), the Galois correspondence shows that a (ψ, e, q, d)-field is the compositum of the field cut out by ψ, of $\mathbb{Q}(\sqrt{-q}, \sqrt{-d})$ and of the real subfield of $\mathbb{Q}(\zeta_{2^{e+2}})$. In a window pair at scale Y one has $\log q \asymp Y^{\varepsilon/5}$ and $\log d \asymp Y^{\varepsilon/5}\log^2 Y$, so the conductors are enormous compared with the scale. Since $d \equiv -1$ modulo q and modulo every odd prime $p \le Y^{\varepsilon/5}$, all these primes split in $\mathbb{Q}(\sqrt{-d})$ (Lemma 9.4). A page function fixes the power of 2 in the conductor at the scale x, with 2^e between $x^{2+8\varepsilon}$ and $2x^{2+8\varepsilon}$.

The Sha bound is used in Parts III and IV. In Part III the divisor package (Sp4) bounds local defects by the lengths of these groups (Theorem 13.18, Theorem 13.2). In Part IV the packets are completed under the hypothesis that the Sha bound holds from some scale on (Proposition 19.3).

Definition 7.2. Let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for a frame (e, A, h, a_0) of index o, and let $N_\mathfrak{h} = Q_S q d$. The **field** $E_\mathfrak{h}$ of $\mathfrak{h}$ is the subfield of $\mathbb{Q}(\zeta_{N_\mathfrak{h}})$ fixed by the automorphisms $\zeta_{N_\mathfrak{h}} \mapsto \zeta_{N_\mathfrak{h}}^a$ with $\alpha(a) = 1$. The map α induces an isomorphism $\mathrm{Gal}(E_\mathfrak{h}/\mathbb{Q}) \cong \mathcal{G}$, and through it we write $\epsilon_1(\sigma)$ for $\sigma \in \mathrm{Gal}(E_\mathfrak{h}/\mathbb{Q})$.

Let $\psi \in \mathcal{P}$ have modulus N, and let $\langle\psi\rangle$ be the group of Dirichlet characters modulo N generated by ψ. The host $\mathfrak{h}$ has

- the **kernel form for** ψ if $N \mid Q_S$ and, for every a coprime to $N_\mathfrak{h}$, $\alpha(a) = 1$ if and only if $a \equiv \pm 1 \pmod{2^{e+2}}$, $\psi(a) = 1$ and $(a/q) = (a/d) = 1$;
- the **twist form for** ψ if for every character θ of $\mathcal{G}$ trivial on $\{(1,1)\} \times A_0$ there are $\xi \in \langle\psi\rangle$ and $i, j \in \{0,1\}$ with $\theta(\iota_d) = (-1)^j$ and $\chi_\theta(a) = \xi(a)(a/q)^i(a/d)^j$ for all a coprime to $N_\mathfrak{h}$.

For an integer $b \geq 0$, the host has **field rows up to** b if

(Fr1) $\epsilon_1(\alpha(u)) = (u/q)$ for every u coprime to $N_\mathfrak{h}$;

(Fr2) there is $s \in E_\mathfrak{h}$ with $s^2 = -q$ and $\sigma(s) = \epsilon_1(\sigma)\, s$ for every $\sigma \in \mathrm{Gal}(E_\mathfrak{h}/\mathbb{Q})$;

(Fr3) for every prime $l \mid Q_S$ there is u coprime to $N_\mathfrak{h}$ with $u \equiv 1 \pmod{N_\mathfrak{h}/l}$ and $\alpha(u) \neq 1$;

(Fr4) $Q_S \leq |A|^2$;

(Fr5) $o^{64} \leq 2^e$;

(Fr6) $q \neq 3$;

(Fr7) $(-d/p) = 1$ for every odd prime $p \leq b$;

(Fr8) $4l \leq b$ for every odd prime $l \mid Q_S$.

Definition 7.3. Let $\varepsilon > 0$. A **parametrised host family with parameter** ε is a host family $\mathcal{F} = (W, (\mathcal{F}_x)_{x \in \mathbb{R}})$ with parameter ε, whose members at x are $(\mathfrak{h}_{x,i}, T_{x,i}, S_{x,i})_{i \in I(x)}$ for the frame (e, A, h, a_0) at x, together with the following data:

- a real number $x_1 > 1$, the **threshold** of $\mathcal{F}$;
- for every real $x > x_1$ and every $i \in I(x)$, an integer $t_{x,i} \geq 1$, the **rank** of the member, and a loss datum $\mathfrak{M}_{x,i}$, the **loss datum** of the member;

subject to the following conditions.

(Pf1) Ties. For every $x > x_1$ and $i \in I(x)$, the loss datum $\mathfrak{M}_{x,i}$ is on the group $H = A$, its arithmetic datum is $\mathfrak{A}_{\mathfrak{h}_{x,i}}$, its set of tops is $T_{x,i}$, its orbit selection has scale x and parameter ε, and its size parameter t_R equals $t_{x,i}$.

(Pf2) Frame, heights, place record. For every $x > x_1$ and $i \in I(x)$, $\mathfrak{M}_{x,i}$ satisfies (Lm1), (Lm2) and (Lm6).

(Pf3) Sizes. There are real numbers $\varepsilon_z > 0$ and C_t such that for every $x > x_1$ and $i \in I(x)$, $\mathfrak{M}_{x,i}$ satisfies (Lm7) for (ε_z, C_t).

Put $b(x) = \exp(x^\varepsilon)$.

Properties of a parametrised host family. The parametrised host family $\mathcal{F}$ with parameter ε has

- the **linking property** if there are real numbers C, x_0 and a function $\delta\colon \mathbb{R} \to \mathbb{R}$ with $\delta(x) \to 0$ as $x \to \infty$ such that for every real $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$ the loss datum $\mathfrak{M}_{x,i}$ satisfies (Lm3) for the loss constants $\big(C,\, b(x)^{\delta(x)}\big)$, that is, the served-prime inequality for $\big(C, b(x)^{\delta(x)}\big)$ and the surplus bound (thus the constant C and the function δ are the same for every x and every i);
- **few bad tops** if there is a real x_0 such that $\mathfrak{M}_{x,i}$ satisfies (Lm4) for every $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$;
- **small shares** if there is a real x_0 such that $\mathfrak{M}_{x,i}$ satisfies (Lm5) for every $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$;

- **non-empty top sets** if there is a real x_0 such that $T_{x,i} \neq \emptyset$ for every $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$.

Definition 7.4. A **host requirement** is a property P of tuples $(x, \varepsilon, \mathfrak{h}, T, t)$ consisting of real numbers x and ε, a host $\mathfrak{h}$ for a frame (e, A, h, a_0), a finite set $T \subseteq A$ and an integer $t \geq 1$.

Let $\lambda > 1$ and let P be a host requirement. The class $\mathcal{C}_\lambda(\mathsf{P})$ consists of the parametrised host families $\mathcal{F}$, with any parameter ε, such that

(Rq1) the set of scales W of $\mathcal{F}$ contains λ-windows;

(Rq2) $\mathsf{P}(x, \varepsilon, \mathfrak{h}_{x,i}, T_{x,i}, t_{x,i})$ holds for every real $x > x_1$ and every $i \in I(x)$.

A parametrised host family $\mathcal{F}$ with parameter ε satisfies the **Sha condition** if there is a real x_0 such that $\mathrm{V}(E_{\mathfrak{h}_{x,i}};\, t_{x,i},\, \exp(x^\varepsilon/2))$ holds for every real $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$.

Definition 7.5. Let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for a frame (e, A, h, a_0), and let $N_\mathfrak{h} = Q_S q d$. For $u \in (\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times$ let $\alpha_A(u) \in A$ be the **component of** $\alpha(u)$ **in** A, so that $\alpha(u) = ((s_1, s_2), \alpha_A(u))$ for some signs s_1, s_2. Since $2^{e+2} \mid Q_S$, every such u has a class $[u]_e \in H_e$, the image of u mod 2^{e+2}. The host $\mathfrak{h}$ is **normalised** if

(Hn1) $\alpha(-1) = ((-1,-1), 0)$;

(Hn2) $h(\alpha_A(u)) = [u]_e$ for every $u \in (\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times$;

(Hn3) $\alpha(u)^2 = 1$ for every $u \in (\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times$ with $u \equiv 1 \pmod{Q_S d}$.

When α is viewed as the Artin map of the field of the host, (Hn1) says that complex conjugation corresponds to $((-1,-1),0)$, (Hn2) that h reads off the action on the 2^{e+2}-th roots of unity modulo ± 1, and (Hn3) that the inertia group at q has exponent dividing 2.

Definition 7.6. Let $Q > 0$. A Dirichlet character χ has a **zero-free box of height** Q if $L(s, \chi) \neq 0$ for every s with $\operatorname{Re} s > 1 - \frac{1}{400}$ and $|\operatorname{Im} s| \leq Q$.

Let $M \geq 1$ be an integer, ξ a Dirichlet character modulo M, q, d odd primes not dividing M, and $(i, j) \in \{0,1\}^2$. The **twist** $\xi_{q,d}^{(i,j)}$ is the Dirichlet character modulo $2Mqd$

$$\xi_{q,d}^{(i,j)}(n) = \xi(n)\Big(\frac{n}{q}\Big)^i \Big(\frac{n}{d}\Big)^j \qquad (\gcd(n, 2Mqd) = 1),$$

and $(\xi_{q,d}^{(i,j)})^*$ is the primitive character inducing it. For $0 < \varepsilon < 1/52$, real $Y \geq 1$ and $j \in \{0,1\}$ put

$$h_j(M, \varepsilon, Y) = 8M \exp\big(Y^{\varepsilon/5}\big) \exp\big(Y^{\varepsilon/5} \log^2 Y\big)^j.$$

Let $0 < \varepsilon < 1/52$ and $Y \leq X$. A window pair (q, d) at scale Y is **good for** (M, X) if

(Wp1) $\gcd(M, qd) = 1$;

(Wp2) for every Dirichlet character ξ modulo M and every $(i, j) \neq (0, 0)$, the character $\chi = (\xi_{q,d}^{(i,j)})^*$ satisfies, for all $y \in [Y, X]$,

$$|g(y, \chi)| \leq y^{1/2+\varepsilon/2}, \qquad \Big|\frac{L'(1,\chi)}{L(1,\chi)}\Big| \leq 4 \log y;$$

(Wp3) for every real primitive character ϱ of modulus dividing $8M$ and every $(i,j) \neq (0,0)$, the character $(\varrho_{q,d}^{(i,j)})^*$ has a zero-free box of height $h_j(M,\varepsilon,Y)$, where the twist is formed with $8M$ in place of M.

Since $q, d \nmid M$ and $q \neq d$ (as $q \equiv 3$ and $d \equiv 7 \pmod 8$), a twist with $(i,j) \neq (0,0)$ has a non-trivial Jacobi-symbol factor modulo q or d that the other factors cannot cancel, so the characters in (Wp2) and (Wp3) are non-principal. Hence $L(1,\chi) \neq 0$ and $g(y,\chi)$ is given by (2.2).

Definition 7.7. A **good-host requirement** is a property $\mathfrak{G}$ of tuples $(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ consisting of real numbers x, ε, J, a finite list κ of real numbers, a host $\mathfrak{h}$ for a frame (e, A, h, a_0), a finite set $T \subseteq A$ and an integer $t \geq 1$. Let $\lambda > 1$. A host requirement P is **supplied by $\mathfrak{G}$ on λ-windows** if for every $\varepsilon \in (0, 1/52)$ there are a finite list κ of real numbers, a real number $J \geq 1$, a set $W \subseteq \mathbb{R}$ containing λ-windows and a real number x_0 such that for every $x \in W$ with $x \geq x_0$ there are a frame (e, A, h, a_0), a host $\mathfrak{h}$ for it, a finite set $T \subseteq A$ and an integer $t \geq 1$ with $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ and $\mathsf{P}(x, \varepsilon, \mathfrak{h}, T, t)$.

Supply of good hosts. Let $\psi \in \mathcal{P}$ have modulus N. A good-host requirement $\mathfrak{G}$ **supplies good hosts for** ψ if for every $\varepsilon \in (0, 1/52)$ and every $C_0 \geq 1$ there are a finite list κ of real numbers and a real number x_B with the following property. Let $x \geq x_B$ and $J \in [1, C_0]$, let (e, A, h, a_0) be a frame of index o_ψ, where $o_\psi \leq C_0$, with $x^{2+8\varepsilon} \leq |A| \leq 2x^{2+8\varepsilon}$, let M be an integer with $0 < M \leq C_0$, and let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for this frame such that

- $Q_S \leq C_0|A|$ and $Q_S \mid \operatorname{lcm}(2^{e+2}, M)$;
- $\mathfrak{h}$ is normalised and has the kernel form for ψ;
- for some scale $Y \in [x^{1/J}, x]$, the pair (q, d) is a window pair at scale Y that is good for (M, x), and $\mathfrak{h}$ has field rows up to $\lfloor Y^{\varepsilon/5} \rfloor$.

Then there are a finite set $T \subseteq A$ for which $(\mathfrak{h}, T)$ satisfies (Ec4) at scale x with parameter ε, and an integer t with $1 \leq t \leq x^{400}$, such that $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ holds. The requirement $\mathfrak{G}$ **supplies good hosts** if it supplies good hosts for every $\psi \in \mathcal{P}$.

Slope data at the members. Let $\mathcal{F}$ be a parametrised host family with parameter ε, threshold x_1, scales W and loss data $\mathfrak{M}_{x,i}$, and let e_D, e_L be real numbers. Then $\mathcal{F}$ has **slope data at its members with exponents** (e_D, e_L) if there is a real number c_0 such that for every real $c_L \geq c_0$ there are real numbers C_K, c^*, e_K, x_0 with the following property: for every $x \in W$ with $x \geq x_0$ and $x > x_1$ there are $i_0 \in I(x)$, data as in the definition of core-tied hosts for $(\mathfrak{h}_{x,i_0}, T_{x,i_0})$ at scale x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, whose slope datum $\mathfrak{S}$ has the translates A, the map $\mathrm{tr} = \mathrm{id}_A$ and the constant vector c with $c_{\mathrm{Loss}} = c_L$ and $e_{\mathrm{Loss}} = 0$, and members $i_u \in I(x)$ $(u \in A)$, such that

- (Tc1), (Tc2) and (Tc3) hold, except that the loss condition (Sl8) is not required in (Ct4);
- the parameter b of $\mathfrak{S}$ is $\exp(x^\varepsilon)$, and for every $u \in A$ the loss datum $\mathfrak{M}_{x,i_u}$ has the integer m of $\mathfrak{S}$, a set of tops with $|\mathcal{T}|$ elements, and $S_u = S(\mathfrak{M}_{x,i_u})$ formed with the cut-off $\lceil 2x\exp(x^\varepsilon) \rceil$, $\Theta_u = \Theta(\mathfrak{M}_{x,i_u})$, $I_u = I(\mathfrak{M}_{x,i_u})$.

Link properties. Let $\mathfrak{G}$ be a good-host requirement. A class $\mathcal{A}$ of parametrised host families has the **link properties for $\mathfrak{G}$** if:

(Lk1) Design existence. For every $\lambda > 1$ and every host requirement P supplied by $\mathfrak{G}$ on λ-windows there is $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ some family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ has parameter ε.

(Lk2) Linking property. Every family in $\mathcal{A}$ has the linking property.

(Lk3) Choice of tops. Every family in $\mathcal{A}$ has few bad tops, small shares and non-empty top sets.

(Lk4) Slope data. There are real numbers e_D, e_L such that every family in $\mathcal{A}$ that satisfies the Sha condition has slope data at its members with exponents (e_D, e_L).

Proposition 7.8. *Let $\psi \in \mathcal{P}$. There are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there is a host family with parameter ε with the following properties: it is admissible for $\mathfrak{L}_\psi$, with the constant $C = 4$ in the definition of admissibility; it is tied with exponents (e_D, e_L); and its scales contain $\frac{3}{2}$-windows.*

Proof. Fix $\psi \in \mathcal{P}$. Let P_ψ be the host requirement such that $\mathsf{P}_\psi(x, \varepsilon, \mathfrak{h}, T, t)$ holds if and only if $x > 1$, the pair $(\mathfrak{h}, T)$ satisfies the host conditions for $\mathfrak{L}_\psi$ at scale x with parameters $(\varepsilon, 4)$, and $\mathrm{V}(E_\mathfrak{h}; t, \exp(x^\varepsilon/2))$ holds. Let $\mathfrak{G}$ be a good-host requirement with (Gh1) and (Gh2) as in Proposition 7.9.

Hosts on windows. By Theorem 36.4, ψ satisfies the window Sha bound with exponent 401, and by (Gh1) $\mathfrak{G}$ supplies good hosts, in particular for ψ, which is hypothesis (Sb) of Proposition 9.1. So Proposition 9.1 gives, for every $\varepsilon \in (0, 1/52)$, a finite list κ, a real $J \geq 1$, a set W_ε containing $\frac{3}{2}$-windows and a real x_0 such that every $x \in W_\varepsilon$ with $x \geq x_0$ carries a frame, a host $\mathfrak{h}$ for it, a finite set $T \subseteq A$ and an integer $t \geq 1$ satisfying its items 1–3. Replace x_0 by $\max(x_0, 2)$. For $x \geq x_0$ items 1 and 2 give $\mathsf{P}_\psi(x, \varepsilon, \mathfrak{h}, T, t)$, since $x > 1$, and item 3 gives $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$. This is hypothesis 1 of (Gh2) for $\lambda = \frac{3}{2}$ and $\mathsf{P} = \mathsf{P}_\psi$.

The Sha condition. Let $\mathcal{F} \in \mathcal{C}_{3/2}(\mathsf{P}_\psi)$ have parameter ε and threshold x_1. By (Rq2), $\mathsf{P}_\psi(x, \varepsilon, \mathfrak{h}_{x,i}, T_{x,i}, t_{x,i})$ holds for every $x > x_1$ and $i \in I(x)$; in particular, $\mathrm{V}(E_{\mathfrak{h}_{x,i}}; t_{x,i}, \exp(x^\varepsilon/2))$ holds. So $\mathcal{F}$ satisfies the Sha condition (with $x_0 = x_1 + 1$). This is hypothesis 2 of (Gh2).

Conclusion. By (Gh2) there are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ some $\mathcal{F} \in \mathcal{C}_{3/2}(\mathsf{P}_\psi)$ with parameter ε is tied with exponents (e_D, e_L). It is a host family with parameter ε. Its scales contain $\frac{3}{2}$-windows by (Rq1). It is admissible for $\mathfrak{L}_\psi$ with $C = 4$: put $x_0' = x_1 + 1 > 1$; for every $x \geq x_0'$ and $i \in I(x)$ we have $x > x_1$, so (Rq2) gives P_ψ at (x, i), whose first clause is that $(\mathfrak{h}_{x,i}, T_{x,i})$ satisfies the host conditions for $\mathfrak{L}_\psi$ at scale x with parameters $(\varepsilon, 4)$. □

Proposition 7.9. *There is a good-host requirement $\mathfrak{G}$ with the following two properties.*

(Gh1) Supply of good hosts. $\mathfrak{G}$ *supplies good hosts.*

(Gh2) Families from hosts. *Let $\lambda > 1$ and let P be a host requirement. Suppose that*

1. *for every $\varepsilon \in (0, 1/52)$ there are a finite list κ of real numbers, a real number $J \geq 1$, a set $W \subseteq \mathbb{R}$ containing λ-windows and a real number x_0 such that for every $x \in W$ with $x \geq x_0$ there are a frame (e, A, h, a_0), a host $\mathfrak{h}$ for it, a finite set $T \subseteq A$ and an integer $t \geq 1$ with $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ and $\mathsf{P}(x, \varepsilon, \mathfrak{h}, T, t)$;*
2. *every parametrised host family in $\mathcal{C}_\lambda(\mathsf{P})$ satisfies the Sha condition.*

Then there are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_1 > 0$ such that for every $\varepsilon \in (0, \varepsilon_1)$ some parametrised host family in $\mathcal{C}_\lambda(\mathsf{P})$ with parameter ε is tied with exponents (e_D, e_L).

Proof. By Corollary 8.3 there are a good-host requirement $\mathfrak{G}$ that supplies good hosts and a class $\mathcal{A}$ of parametrised host families with the link properties for $\mathfrak{G}$. So $\mathfrak{G}$ has (Gh1). For (Gh2), let $\lambda > 1$ and let P be a host requirement satisfying 1 and 2. Hypothesis 1 says exactly that P is supplied by $\mathfrak{G}$ on λ-windows. By hypothesis 2 every family in $\mathcal{C}_\lambda(\mathsf{P})$, in particular every family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$, satisfies the Sha condition. So Theorem 7.10 applies to $(\mathfrak{G}, \mathcal{A}, \lambda, \mathsf{P})$ and gives $e_D, e_L \in \mathbb{R}$ and $\varepsilon_1 > 0$ such that for every $\varepsilon \in (0, \varepsilon_1)$ some family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P}) \subseteq \mathcal{C}_\lambda(\mathsf{P})$ with parameter ε is tied with exponents (e_D, e_L). This is the conclusion of (Gh2). □

Theorem 7.10. *Let $\mathfrak{G}$ be a good-host requirement and let $\mathcal{A}$ be a class of parametrised host families with the link properties for $\mathfrak{G}$. Let $\lambda > 1$, and let P be a host requirement supplied by $\mathfrak{G}$ on λ-windows such that every family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ satisfies the Sha condition. Then there are $e_D, e_L \in \mathbb{R}$ and $\varepsilon_1 > 0$ such that for every $\varepsilon \in (0, \varepsilon_1)$ some family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ with parameter ε is tied with exponents (e_D, e_L).*

Proof. Choice of e_D, e_L, ε_1. Let e_D, e_L be the real numbers of (Lk4) for $\mathcal{A}$, and let $\varepsilon_0 > 0$ be the number that (Lk1) gives for λ and P (which is supplied by $\mathfrak{G}$ on λ-windows). Put $\varepsilon_1 = \min(\varepsilon_0, \frac{1}{52}) > 0$. Let $\varepsilon \in (0, \varepsilon_1)$. By (Lk1) there is a family $\mathcal{F} \in \mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ with parameter ε; let W be its set of scales and x_1 its threshold. We show that $\mathcal{F}$ is tied with exponents (e_D, e_L).

The loss constant. By (Lk2) and (Lk3), $\mathcal{F}$ has the linking property, few bad tops, small shares and non-empty top sets, and $0 < \varepsilon < \frac{1}{52}$. Hence Corollary 7.11 applies to $\mathcal{F}$ and gives real numbers $c_0^{\mathrm{L}} \geq 1$ and x_0^{L} with its properties 1 and 2. By small shares there is x_W such that $\mathfrak{M}_{x,i}$ satisfies (Lm5) for every $x \geq x_W$ with $x > x_1$ and every $i \in I(x)$.

The slope data. By hypothesis $\mathcal{F}$ satisfies the Sha condition, so by (Lk4) it has slope data at its members with exponents (e_D, e_L): there is c_0^{S} such that for every $c_L \geq c_0^{\mathrm{S}}$ there are $C_K, c^*, e_K, x_0^{\mathrm{S}}$ with the property stated there. Take $c_L = \max(c_0^{\mathrm{L}}, c_0^{\mathrm{S}})$, let $C_K, c^*, e_K, x_0^{\mathrm{S}}$ be the corresponding numbers, and put

$$x_0 = \max(x_0^{\mathrm{L}},\, x_W,\, x_0^{\mathrm{S}},\, x_1 + 1).$$

These numbers depend on $\mathcal{F}$ only, not on the scale.

Chain ties at a scale. Let $x \in W$ with $x \geq x_0$; then $x > x_1$. By the choice of $C_K, c^*, e_K, x_0^{\mathrm{S}}$ there are an element $i_0 \in I(x)$, data as in the definition of core-tied hosts for $(\mathfrak{h}_{x,i_0}, T_{x,i_0})$ at scale x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, and members $i_u \in I(x)$ $(u \in A)$, with the following properties.

- The slope datum $\mathfrak{S}$ of these data has the translates A, the map $\mathrm{tr} = \mathrm{id}_A$ and the constant vector c with $c_{\mathrm{Loss}} = c_L$ and $e_{\mathrm{Loss}} = 0$, and its parameter b is $b(x)$.
- (Tc1), (Tc2) and (Tc3) hold except for the loss condition (Sl8) in (Ct4).
- For every $u \in A$, the loss datum $\mathfrak{M}_{x,i_u}$ has m weights, where m is the integer of $\mathfrak{S}$, and a set of tops with $n_{\mathcal{T}}$ elements; moreover $S_u = S(\mathfrak{M}_{x,i_u})$, formed with the cut-off $\lceil 2x \exp(x^\varepsilon) \rceil \geq 1$, $\Theta_u = \Theta(\mathfrak{M}_{x,i_u})$ and $I_u = I(\mathfrak{M}_{x,i_u})$.

We check the hypotheses of Corollary 7.11, property 2, for $\mathfrak{S}$ and c:

- by (Ct2), which is part of (Tc2) and does not involve (Sl8), the parameters $x(\mathfrak{S})$ and $\varepsilon(\mathfrak{S})$ are x and ε; and $x \geq x_0^{\mathrm{L}}$, $x > x_1$, $b = b(x)$;
- $c_{\mathrm{Loss}} = c_L \geq c_0^{\mathrm{L}}$ and $e_{\mathrm{Loss}} = 0 \geq 0$;

- for every translate $u \in A$, the member $i_u \in I(x)$ has a loss datum satisfying (Lm5), because $x \geq x_W$ and $x > x_1$; its number of weights is m; its set of tops is T_{x,i_u} by (Pf1), so $|T_{x,i_u}| = n_{\mathcal{T}}$; and S_u, Θ_u, I_u are its prime sum with the cut-off $P_u = \lceil 2x \exp(x^{\varepsilon}) \rceil$, its lattice term and its companion sum.

Hence, by Corollary 7.11, property 2, $\mathfrak{S}$ satisfies (Sl8). So (Ct4) holds in full, and with it (Tc1), (Tc2) and (Tc3): the family $\mathcal{F}_x$ is chain-tied at x with exponents $(e_D, e_L, C_K, c^*, e_K)$ and parameter ε, with the element i_0 and the data above.

Conclusion. The numbers C_K, c^*, e_K, x_0 do not depend on x, and $\mathcal{F}_x$ is chain-tied at every $x \in W$ with $x \geq x_0$. Thus, for every $\varepsilon \in (0, \varepsilon_1)$, the family $\mathcal{F} \in \mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ has parameter ε and is tied with exponents (e_D, e_L), where e_D, e_L, ε_1 do not depend on ε. □

Corollary 7.11. *Let $0 < \varepsilon < \frac{1}{52}$ and let $\mathcal{F}$ be a parametrised host family with parameter ε and threshold x_1 that has the linking property, few bad tops and non-empty top sets. Then there are real numbers $c_0 \geq 1$ and x_0 with the following properties.*

1. (Loss bound at the members.) *For every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$ whose loss datum $\mathfrak{M}_{x,i}$ satisfies (Lm5), and every cut-off $P \geq 1$,*

$$S(\mathfrak{M}_{x,i}) - \Theta(\mathfrak{M}_{x,i}) \leq c_0 \, |T_{x,i}| \, m \, b(x) \qquad \text{and} \qquad I(\mathfrak{M}_{x,i}) \leq |T_{x,i}| \, m \, b(x),$$

   where m is the number of weights of $\mathfrak{M}_{x,i}$. In particular, if $\mathcal{F}$ also has small shares, there is x_0' such that these bounds hold for every $x \geq x_0'$ with $x > x_1$ and every $i \in I(x)$.

2. (The loss condition.) *Let $\mathfrak{S}$ be a slope datum with parameters x, ε and b, where $x \geq x_0$ is a real number with $x > x_1$, ε is the parameter of $\mathcal{F}$ and $b = b(x)$, and let c be a constant vector with $c_{\mathrm{Loss}} \geq c_0$ and $e_{\mathrm{Loss}} \geq 0$. Suppose that to every translate u of $\mathfrak{S}$ there are attached a member $i_u \in I(x)$ whose loss datum $\mathfrak{M}_{x,i_u}$ satisfies (Lm5) and a cut-off $P_u \geq 1$, such that the number of weights of $\mathfrak{M}_{x,i_u}$ is the parameter m of $\mathfrak{S}$, $|T_{x,i_u}| = n_{\mathcal{T}}$, and*

$$S_u = S(\mathfrak{M}_{x,i_u}) \text{ (formed with the cut-off } P_u), \qquad \Theta_u = \Theta(\mathfrak{M}_{x,i_u}), \qquad I_u = I(\mathfrak{M}_{x,i_u}).$$

   Then $\mathfrak{S}$ satisfies the loss condition (Sl8): $S_u - \Theta_u \leq \mathrm{Lo}$ and $I_u \leq \mathrm{Lo}$ for every translate u.

The constant c_0 depends only on the constant C of the linking property: one may take $c_0 = 3\max(C, 0) + 13$.

Proof. The constants. By the linking property there are real numbers C, x_G and a function δ with $\delta(x) \to 0$ as $x \to \infty$ such that for every $x \geq x_G$ with $x > x_1$ and every $i \in I(x)$ the loss datum $\mathfrak{M}_{x,i}$ satisfies (Lm3) for $(C, b(x)^{\delta(x)})$. By few bad tops there is x_B such that $\mathfrak{M}_{x,i}$ satisfies (Lm4) for $x \geq x_B$, $x > x_1$, $i \in I(x)$. By non-empty top sets there is x_T with $T_{x,i} \neq \emptyset$ for $x \geq x_T$, $x > x_1$, $i \in I(x)$. By (Pf3) there are $\varepsilon_z > 0$ and C_t such that every $\mathfrak{M}_{x,i}$ $(x > x_1)$ satisfies (Lm7) for (ε_z, C_t). Let x^* be the number that Theorem 5.6 gives for $(\varepsilon, \varepsilon_z, C_t, C)$, and choose x_δ with $\delta(x) \leq \frac{1}{2}$ for $x \geq x_\delta$. Put

$$c_0 = 3\max(C, 0) + 13 \geq 1, \qquad x_0 = \max(x_G, x_B, x_T, x^*, x_\delta).$$

Item 1. Let $x \geq x_0$ with $x > x_1$, let $i \in I(x)$ be such that $\mathfrak{M}_{x,i}$ satisfies (Lm5), and let $P \geq 1$ be a cut-off. Put $b_o = b(x)^{\delta(x)} = \exp(\delta(x) x^{\varepsilon})$; then $0 < b_o \leq \exp(x^{\varepsilon}/2)$, since $\delta(x) \leq \frac{1}{2}$ and $x^{\varepsilon} > 0$. We check the hypotheses of Theorem 5.6 for $\mathfrak{M} = \mathfrak{M}_{x,i}$ and this b_o. By (Pf1) the orbit selection of $\mathfrak{M}_{x,i}$ has scale $x \geq x^*$ and parameter ε, and its set of tops is $T_{x,i}$, which

is non-empty as $x \geq x_T$. (Lm1), (Lm2) and (Lm6) hold by (Pf2); (Lm3) for (C, b_o) holds as $x \geq x_G$; (Lm4) holds as $x \geq x_B$; (Lm5) holds by assumption; and (Lm7) for (ε_z, C_t) holds by (Pf3). Hence, by Theorem 5.6, with $b = \exp(x^{\varepsilon}) = b(x)$,

$$S(\mathfrak{M}_{x,i}) - \Theta(\mathfrak{M}_{x,i}) \leq c_0\,|T_{x,i}|\,m\,b(x), \qquad I(\mathfrak{M}_{x,i}) \leq |T_{x,i}|\,m\,b(x).$$

If $\mathcal{F}$ has small shares, there is x_W such that $\mathfrak{M}_{x,i}$ satisfies (Lm5) for every $x \geq x_W$ with $x > x_1$ and every $i \in I(x)$; then $x_0' = \max(x_0, x_W)$ has the stated property.

Item 2. Let u be a translate. By item 1 for the member i_u and the cut-off P_u, and by the identifications,

$$S_u - \Theta_u \leq c_0\,n_{\mathcal{T}}\,m\,b, \qquad I_u \leq n_{\mathcal{T}}\,m\,b \leq c_0\,n_{\mathcal{T}}\,m\,b,$$

the last step because $c_0 \geq 1$ and $n_{\mathcal{T}} mb \geq 0$. Since $x > x_1 > 1$ and $e_{\mathrm{Loss}}\varepsilon \geq 0$, we have $x^{e_{\mathrm{Loss}}\varepsilon} \geq 1$; with $c_{\mathrm{Loss}} \geq c_0 \geq 0$ and $n_{\mathcal{T}} mb \geq 0$ this gives $c_0\,n_{\mathcal{T}}\,m\,b \leq c_{\mathrm{Loss}}\,n_{\mathcal{T}}\,m\,b\,x^{e_{\mathrm{Loss}}\varepsilon} = \mathrm{Lo}$. Hence $S_u - \Theta_u \leq \mathrm{Lo}$ and $I_u \leq \mathrm{Lo}$. □

The constant $c_0 = 3\max(C, 0) + 13$ of the corollary depends only on the constant C of the linking property, and the loss exponent is 0. So the loss condition costs no power of x^{ε}, and the second exponent of a tied family produced by the shape theorem is the one that (Lk4) provides.

With this the existence theorem is reduced to three statements: Proposition 9.1, Theorem 36.4 and Corollary 8.3. Parts II and VII prove the first two. The next section proves the third from Proposition 17.6.

8 Slope records: what a class must supply

This section proves the last link of the reduction and states what the arithmetic Parts must supply. The link property (Lk4) asks for slope data at the members of a family. A slope datum is an abstract record, and Parts III and IV do not produce it directly. They produce, for each member of a family, a slope record (Definition 8.1): the words of the member with their ranks, Gauss primes, slopes, heights, ambient slopes and exponents, the dual slopes, the frame term and two auxiliary primes. The properties (Sp1)–(Sp8) of slope records (Definition 8.2) are the slope conditions other than (Sl8), together with the size and weight conditions of a core-tied host, written for these records, with the constants of the host in place of abstract parameters: half the root discriminant $v(\mathfrak{h})$ of the host field, the number $\beta(\mathfrak{h}) = L'(1, \chi_d)/L(1, \chi_d)$, and $\log \Omega(\mathfrak{h}) = \gamma + \log(\pi/v(\mathfrak{h})) - \beta(\mathfrak{h})$.

The main result is Theorem 8.4: if every family of a class that satisfies the Sha condition has (Sp1)–(Sp8), with the exponent e in the divisor package (Sp4), then every such family has slope data at its members with exponents $(\max(e, 0), 0)$. The proof assembles one slope datum at each scale from the slope records and loss data of the members that carry the translates $u \in A$, and verifies the slope conditions other than (Sl8), the size conditions and the conditions on weight data one by one. It is long and contains no idea beyond the dictionary of Section 4; the table below records which property gives which condition.

Corollary 8.3 then repackages Proposition 17.6 of Part III. That proposition provides a good-host requirement and a class of families with slope records that has (Lk1), (Lk2), (Lk3) and, in place of (Lk4), the property (Lk5): the families of the class that satisfy the Sha condition have (Sp1)–(Sp8). The corollary passes to the underlying families and obtains (Lk4) from (Lk5) by Theorem 8.4. In Part III the divisor exponent is $e = 1$ (Theorem 17.7). The proofs therefore give the tied families of the existence theorem the exponents $(e_D, e_L) = (1, 0)$, and the bound of Proposition 6.4 reads $G_{\mathfrak{L}_\psi}(x) \leq x^{1/2+8\varepsilon}$ at the large scales of these families.

Definition 8.1. Let $m \geq 0$ be an integer. A **slope record** for m is a tuple $\mathfrak{V}$ consisting of

- a non-empty finite set $\mathcal{W}(\mathfrak{V})$, the **words** of $\mathfrak{V}$;
- for every word $\omega \in \mathcal{W}(\mathfrak{V})$: an integer $d(\mathfrak{V},\omega) \geq 0$, the **rank** of ω; a prime $T(\mathfrak{V},\omega)$, the **Gauss prime** of ω; and real numbers $\mu(\mathfrak{V},\omega)$, $\mu^{\max}(\mathfrak{V},\omega)$ (the **slope** and the **maximal slope** of ω), $h(\mathfrak{V},\omega)$ (the **height** of ω), $\mu'(\mathfrak{V},\omega)$, $\mu'^{\max}(\mathfrak{V},\omega)$ (the **ambient slope** and the **maximal ambient slope** of ω) and $E_j(\mathfrak{V},\omega)$ for $1 \leq j \leq m$ (the **exponents** of ω);
- real numbers $\mu^{\vee}(\mathfrak{V})$ and $\mu^{\vee}_{\min}(\mathfrak{V})$ (the **dual slope** and the **minimal dual slope**), $F(\mathfrak{V})$ (the **frame term**) and $\delta(\mathfrak{V})$ (the **irreducibility defect**);
- two primes $g_1(\mathfrak{V})$ and $g_2(\mathfrak{V})$, the **auxiliary primes**.

Attached to $\mathfrak{V}$ are the **total exponent** $E(\mathfrak{V},\omega) = \sum_{j=1}^{m} E_j(\mathfrak{V},\omega)$ of a word ω, the **mean slope** $s(\mathfrak{V})$, the **top slope** $s^{\max}(\mathfrak{V})$ and the **spread** $s^{\max}(\mathfrak{V}) - s(\mathfrak{V})$, where

$$s(\mathfrak{V}) = \frac{\sum_{\omega\in\mathcal{W}(\mathfrak{V})} d(\mathfrak{V},\omega)\big(\mu(\mathfrak{V},\omega) - h(\mathfrak{V},\omega)\big)}{\sum_{\omega\in\mathcal{W}(\mathfrak{V})} d(\mathfrak{V},\omega)}, \qquad s^{\max}(\mathfrak{V}) = \max_{\omega\in\mathcal{W}(\mathfrak{V})} \big(\mu^{\max}(\mathfrak{V},\omega) - h(\mathfrak{V},\omega)\big),$$

and $s(\mathfrak{V}) = 0$ if all ranks are 0.

Let $\mathcal{F}$ be a parametrised host family with parameter ε, threshold x_1 and frame (e, A, h, a_0) at x. **Slope records for** $\mathcal{F}$ are, for every real $x > x_1$ and every $i \in I(x)$, a slope record $\mathfrak{V}_{x,i}$ for the integer m of $\mathfrak{M}_{x,i}$ and an element $u_{x,i} \in A$, the **translate** of the member, such that the following hold.

(Sr1) Ties within a scale. For every $x > x_1$ and all $i, i' \in I(x)$: $\mathfrak{h}_{x,i} = \mathfrak{h}_{x,i'}$, $T_{x,i} = T_{x,i'}$ and $S_{x,i} = S_{x,i'}$; the loss data $\mathfrak{M}_{x,i}$ and $\mathfrak{M}_{x,i'}$ have the same parameters k, m, η and L_a; and $g_1(\mathfrak{V}_{x,i}) = g_1(\mathfrak{V}_{x,i'})$, $g_2(\mathfrak{V}_{x,i}) = g_2(\mathfrak{V}_{x,i'})$.

(Sr2) Carriers of translates. For every $x > x_1$, every $i \in I(x)$ and every $u \in A$ there is $i' \in I(x)$ with $u_{x,i'} = u$ such that $\mathfrak{M}_{x,i'}$ and $\mathfrak{M}_{x,i}$ have the same heights a_t ($t \in T_{x,i}$).

A **parametrised host family with slope records** is a parametrised host family together with slope records for it.

For a member at $x > x_1$ we write $T^{\mathrm{th}}_{x,i} = \{s\, a_0 : s \in S_{x,i}\} \subseteq A$ (the **thick set**). With $n = |A|$, $b(x) = \exp(x^{\varepsilon})$ and the parameters k, m of $\mathfrak{M}_{x,i}$, the **budgets** of the member are

$$B_0(x,i) = 2\,n\,m\,b(x)\,x^{\varepsilon}, \qquad N_c(x,i) = \frac{|T^{\mathrm{th}}_{x,i}|\,k\,b(x)\,x^{2\varepsilon}}{n^2}.$$

Definition 8.2. For a host $\mathfrak{h} = (q, d, Q_S, \alpha)$, put $v(\mathfrak{h}) = \frac{1}{2}\,|\mathrm{disc}(E_{\mathfrak{h}})|^{1/[E_{\mathfrak{h}}:\mathbb{Q}]}$, let χ_d be the Legendre symbol modulo the prime d, and put

$$\beta(\mathfrak{h}) = \frac{L'(1,\chi_d)}{L(1,\chi_d)}, \qquad \log\Omega(\mathfrak{h}) = \gamma + \log\frac{\pi}{v(\mathfrak{h})} - \beta(\mathfrak{h}).$$

Let $\mathcal{F}$ be a parametrised host family with slope records, with parameter ε, threshold x_1, scales W and frame (e, A, h, a_0) at x. In each item below, for a member (x, i) with $x > x_1$, we write $\mathfrak{V} = \mathfrak{V}_{x,i}$ and $\mathfrak{M} = \mathfrak{M}_{x,i}$, with its parameters k, m, η, heights a_t ($t \in T_{x,i}$) and weights w_j ($1 \leq j \leq m$), and

$$n = |A|, \quad f = 2n, \quad b = e^{x^{\varepsilon}}, \quad a = xb, \quad L_a = \log\big(2a\,v(\mathfrak{h}_{x,i})\big), \quad X' = e^{x^{\varepsilon/3}},$$
$$b' = \frac{a}{X'}, \quad X'' = xnX', \quad A_{\mathfrak{M}} = \sum_{t\in T_{x,i}} a_t, \quad B_0 = B_0(x,i), \quad N_c = N_c(x,i).$$

Here L_a is the **analytic loss** of the member, $L_a = \log\bigl(a\,|\mathrm{disc}(E_{\mathfrak{h}_{x,i}})|^{1/[E_{\mathfrak{h}_{x,i}}:\mathbb{Q}]}\bigr)$. It is not the size parameter of the loss datum $\mathfrak{M}$, which is not used in the items below. A statement holds "for all large members" if there is a real x_0 such that it holds for every real $x \ge x_0$ with $x > x_1$, every $i \in I(x)$ and all words $\omega, \omega' \in \mathcal{W}(\mathfrak{V})$. The family $\mathcal{F}$ has each of the following properties if the stated condition holds.

(Sp1) Counting bounds There is a real $C \ge 0$ such that, for all large members,

$$\frac{1}{f}\sum_{j=1}^{m}\sum_{\tau\in\Phi}\log\frac{w_j(\tau)\,v(\mathfrak{h}_{x,i})}{\pi} + m\log(g_1(\mathfrak{V})g_2(\mathfrak{V})) - C\Bigl(L_a + \frac{m^2 L_a}{k}\Bigr) \le \log T(\mathfrak{V},\omega) \le C\,m\,x^{\varepsilon}$$

and $|\log T(\mathfrak{V},\omega) - \log T(\mathfrak{V},\omega')| \le C\log k$.

(Sp2) Ambient slope bounds There is a real $C \ge 0$ such that, for all large members,

$$-C|T_{x,i}|\,a\,L_a(1+m/k) \le \mu'(\mathfrak{V},\omega) \quad\text{and}\quad \mu'^{\max}(\mathfrak{V},\omega) \le C|T_{x,i}|\,a\,L_a.$$

(Sp3) Transfer of slopes There is a real $C \ge 0$ such that, for all large members,

$$\begin{aligned}\mu^{\max}(\mathfrak{V},\omega) &\le \mu'^{\max}(\mathfrak{V},\omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V},\omega) + C\,m\,B_0,\\ \mu(\mathfrak{V},\omega) &\ge \mu'(\mathfrak{V},\omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V},\omega)\\ &\quad - \Bigl(C\,I(\mathfrak{M}) + C|T_{x,i}|\,m\Bigl(\frac{a}{k}+b'\Bigr)\log T(\mathfrak{V},\omega) + CX'' + 1\Bigr).\end{aligned}$$

(Sp4) Divisor package with exponent e Here e is a real number. There is a real C such that, for all large members, the following hold.

- $d(\mathfrak{V},\omega) > 0$ and $\mu(\mathfrak{V},\omega) \le \mu^{\max}(\mathfrak{V},\omega)$.
- We have

$$\mu^{\vee}(\mathfrak{V}) + h(\mathfrak{V},\omega) - F(\mathfrak{V}) \le \sum_{t\in T_{x,i}}\Bigl(m\bigl(a_t\log a_t - a_t - a_t\log\Omega(\mathfrak{h}_{x,i})\bigr) - a_t\log T(\mathfrak{V},\omega)\Bigr) + C|T_{x,i}|\,a\,L_a + C\,m\,(B_0+N_c)\,x^{e\varepsilon}.$$

- $|E(\mathfrak{V},\omega) - m\,A_{\mathfrak{M}}\log(g_1(\mathfrak{V})g_2(\mathfrak{V}))| \le C\,m\,B_0$.
- We have

$$\bigl|(h(\mathfrak{V},\omega) + A_{\mathfrak{M}}\log T(\mathfrak{V},\omega)) - (h(\mathfrak{V},\omega') + A_{\mathfrak{M}}\log T(\mathfrak{V},\omega'))\bigr| \le C(|T_{x,i}|\,a\,L_a + m\,B_0).$$

(Sp5) Dual-slope bound There are real numbers $c_\vee \ge 0$ and x_0 with the following property. For every real $x \ge x_0$ with $x > x_1$ there are real numbers $\bar\eta \ge 0$ and $\bar e \in [0,\frac14]$ with $(\bar\eta + 4\sqrt{\bar e})\,x^{c_\vee} \le 6$ such that, with $H = x^{c_\vee}b$, every $i \in I(x)$ satisfies the following.

- $0 \le \delta(\mathfrak{V}) \le \frac12$ and $s(\mathfrak{V}) - \mu^{\vee}_{\min}(\mathfrak{V}) \le H$.
- There are $\eta_{\mathfrak{V}} \in [0,\bar\eta]$ and $e_{\mathfrak{V}} \in [0,\bar e]$ with

$$s(\mathfrak{V}) - \log|\mathcal{W}(\mathfrak{V})| - \frac{1}{1-\delta(\mathfrak{V})}\Bigl(4\phi\log\Bigl(1+\frac{H}{\phi}\Bigr) + (\eta_{\mathfrak{V}} + 4\sqrt{e_{\mathfrak{V}}})H\Bigr) \le \mu^{\vee}(\mathfrak{V}),$$
$$\phi = s^{\max}(\mathfrak{V}) - s(\mathfrak{V}),$$

where $4\phi\log(1+H/\phi)$ is read as 0 when $\phi = 0$.

(Sp6) Weights at the nodes For all large members, every j and every $\tau \in \Phi$, we have $w_j(\tau) \geq 1$; moreover $b \leq w_j(\tau) \leq b + \eta + 1$ if τ is thick at $u_{x,i}$ for $T^{\mathrm{th}}_{x,i}$, and $w_j(\tau) \leq 2b'$ otherwise.

(Sp7) Thin scales There are real numbers $c > 0$ and x_0 such that, for every real $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$, there is an $\eta \colon \widehat{\Gamma}_A \to \mathbb{C}$ compatible with $\mathfrak{h}_{x,i}$ satisfying $|G_{\mathfrak{A}_{\mathfrak{h}_{x,i}},\eta}(y,\phi)| \leq e^{-cx^{\varepsilon/8}}\, y$ for every $\phi \in \widehat{\Gamma}_A$ and every $y \geq X'/3$.

(Sp8) Sizes We have $\varepsilon \leq 1$, and for every real $c > 0$ there are real numbers $e_K \geq 0$ and x_0 such that, for every real $x \geq x_0$ with $x > x_1$, we have $I(x) \neq \emptyset$ if $x \in W$, and every $i \in I(x)$ satisfies

$$m \leq x^{1/2+\varepsilon/2}, \quad x^{1/2-\varepsilon} \leq m, \quad xm \leq k, \quad k \leq x^{e_K}, \quad k \leq a, \quad k \leq n^2 x^{1/2-\varepsilon},$$
$$0 \leq L_a \leq 2x^{\varepsilon}, \quad kb' \leq a, \quad X'' \leq a, \quad \log|\mathcal{W}(\mathfrak{V})| \leq (k-3)\log 2,$$
$$2f(x+1)e^{-cx^{\varepsilon/8}} \leq 1/x, \quad 6f(x+1)(\eta+1) \leq b/x, \quad x^{-\varepsilon}n \leq |T^{\mathrm{th}}_{x,i}|, \quad \tfrac{1}{2}x^{-\varepsilon/8}n \leq |T_{x,i}|,$$

and $|a_t/b - x| \leq 1$ for every $t \in T_{x,i}$.

Corollary 8.3. *There are a good-host requirement $\mathfrak{G}$ that supplies good hosts and a class $\mathcal{A}$ of parametrised host families that has the link properties for $\mathfrak{G}$.*

Proof. By Proposition 17.6 there are a good-host requirement $\mathfrak{G}$ with (Gh1), that is, a good-host requirement that supplies good hosts, and a class $\mathcal{A}_0$ of parametrised host families with slope records satisfying (Lk1), (Lk2), (Lk3) and (Lk4′) of that statement, the last with a real exponent e. In that statement a family with slope records is identified with its underlying parametrised host family. Let $\mathcal{A}$ be the class of the parametrised host families underlying the members of $\mathcal{A}_0$. We check the link properties of $\mathcal{A}$ for $\mathfrak{G}$.

(Lk1)–(Lk3). The clauses (Lk1), (Lk2), (Lk3) of Proposition 17.6 are conditions on the underlying parametrised host families: membership in $\mathcal{C}_\lambda(\mathsf{P})$, the parameter, the linking property, few bad tops, small shares and non-empty top sets all depend only on the underlying family. Hence they are the clauses (Lk1), (Lk2), (Lk3) of the link properties for $\mathcal{A}$ and $\mathfrak{G}$. For (Lk1), a member of $\mathcal{A}_0$ in $\mathcal{C}_\lambda(\mathsf{P})$ with parameter ε has its underlying family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ with parameter ε; for (Lk2) and (Lk3), every family in $\mathcal{A}$ underlies a member of $\mathcal{A}_0$.

(Lk4). By (Lk4′) of Proposition 17.6, every family in $\mathcal{A}_0$ that satisfies the Sha condition has the properties (Sp1)–(Sp8), with (Sp4) for the exponent e. Hence Theorem 8.4 applies to the class $\mathcal{A}_0$ and the exponent e: every family in $\mathcal{A}_0$ that satisfies the Sha condition has slope data at its members with exponents $(\max(e,0),0)$. The Sha condition and slope data at the members depend only on the threshold, the scales, the members (hosts, top sets, index sets) and the loss data of the underlying parametrised host family. Let $\mathcal{F} \in \mathcal{A}$ satisfy the Sha condition, and let $\mathcal{F}_0 \in \mathcal{A}_0$ have underlying family $\mathcal{F}$. Then $\mathcal{F}_0$ satisfies the Sha condition, so $\mathcal{F}$ has slope data at its members with exponents $(\max(e,0),0)$. This is (Lk4) with $(e_D, e_L) = (\max(e,0),0)$. □

Theorem 8.4. *Let $\mathcal{A}$ be a class of parametrised host families with slope records and let e be a real number. Assume that every family in $\mathcal{A}$ that satisfies the Sha condition has the counting bounds (Sp1), the ambient slope bounds (Sp2), the transfer of slopes (Sp3), the divisor package with exponent e (Sp4), the dual-slope bound (Sp5), the weights at the nodes (Sp6), thin scales (Sp7) and the sizes (Sp8). Put $e_D = \max(e,0)$. Then every family in $\mathcal{A}$ that satisfies the Sha condition has slope data at its members with exponents $(e_D, 0)$.*

Proof. Let $\mathcal{F} \in \mathcal{A}$ satisfy the Sha condition; let ε be its parameter, x_1 its threshold and W its scales. By hypothesis, $\mathcal{F}$ has (Sp1)–(Sp8), with (Sp4) for the exponent e.

Constants. Let $C_1, C_2, C_3 \geq 0$ be the constants of (Sp1), (Sp2), (Sp3), let C_d be the constant of (Sp4) and $C_4 = \max(C_d, 0)$, let $c_\vee \geq 0$ be the constant of (Sp5), and $c > 0$ the constant of (Sp7); apply (Sp8) with this c and let $e_K \geq 0$ be the exponent it gives. Let X_0 be the largest of the thresholds x_0 of (Sp1)–(Sp8) (for (Sp8) the one belonging to c). Put $c_0 = 0$. Given a real $c_L \geq c_0$, put

$$C_K = C_4 + C_1 + C_2 + C_3 + c_L + 6, \qquad c^* = c_\vee, \qquad x_0 = X_0,$$

and let e_K be as above. We show that for every $x \in W$ with $x \geq x_0$ and $x > x_1$ there are i_0, core-tied data and members i_u with the properties required in the definition of slope data at the members with exponents $(e_D, 0)$; since $c_L \geq c_0$ was arbitrary, this proves the theorem.

The members at x. Fix such an x. By (Sp8), $I(x) \neq \emptyset$; fix $i_0 \in I(x)$. By (Sr2), for every $u \in A$ there is $i_u \in I(x)$ with translate $u_{x,i_u} = u$ such that $\mathfrak{M}_{x,i_u}$ has the heights a_t of $\mathfrak{M}_{x,i_0}$; fix such i_u. By (Sr1) all members at x have the host $\mathfrak{h} := \mathfrak{h}_{x,i_0}$, the top set $T := T_{x,i_0}$, the thick set $T_2 := T^{\mathrm{th}}_{x,i_0}$ and the same parameters k, m and $\nu := \eta$ of their loss data, and the same auxiliary primes g_1, g_2; hence also the same $B_0 := B_0(x,i)$, $N_c := N_c(x,i)$ and the same analytic loss $L_a := \log(2x\, e^{x^\varepsilon} v(\mathfrak{h}))$, which depends only on x and the host. By (Pf1), $\mathfrak{M}_u := \mathfrak{M}_{x,i_u}$ is on the group A with arithmetic datum $\mathfrak{A}_\mathfrak{h}$, set of tops T and orbit selection at scale x with parameter ε. Write $\mathfrak{V}_u = \mathfrak{V}_{x,i_u}$, $w_j^{(u)} \colon \Phi \to \mathbb{R}$ for the weights of $\mathfrak{M}_u$, $n = |A|$, $f = 2n$, $b = e^{x^\varepsilon}$, $a = xb$, $X' = e^{x^{\varepsilon/3}}$, $b' = a/X'$, $X'' = xnX'$, $A_T = \sum_{t\in T} a_t$ and $P = \lceil 2a \rceil$. All the properties (Sp1)–(Sp8) apply at x to every member, since $x \geq X_0$.

Elementary facts at x. (i) $x > x_1 > 1$, so $x \geq 1$, $x^\varepsilon \geq 1$, $b > 1$ and $a \geq b > 0$; by (Sp8), $0 < \varepsilon \leq 1$. (ii) By (Sp8), $m \geq x^{1/2-\varepsilon} > 0$, so the integer m is at least 1, and $k \geq xm \geq x^{3/2-\varepsilon} \geq 1$ because $3/2 - \varepsilon > 0$. (iii) By (Sp8), $|T| \geq \frac{1}{2} x^{-\varepsilon/8} n > 0$, so $|T| \geq 1$. (iv) By (Lm2) (through (Pf2)), $0 \leq a_t \leq a(1+\vartheta)$ with $\vartheta = 1/(kx^{13}) \leq 1$, so $0 \leq a_t \leq 2a \leq P$; by (Sp8), $a_t \geq (x-1)b > 0$. (v) $|\Phi| = f$: $\Phi = \tau(\ker \epsilon_2)$ and $|\ker \epsilon_2| = 2|A|$. (vi) $v(\mathfrak{h}) > 0$, since $|\mathrm{disc}(E_\mathfrak{h})| \geq 1$.

The character function. By (Sp7) at i_0 there is $\eta \colon \widehat{\Gamma}_A \to \mathbb{C}$ compatible with $\mathfrak{h}$ such that $|G_{\mathfrak{A}_\mathfrak{h},\eta}(y,\phi)| \leq \theta_0\, y$ for all ϕ and all $y \geq X'/3$, where $\theta_0 = e^{-cx^{\varepsilon/8}}$. We compute $\eta(\chi_C)$. The character $\theta = \chi_C \circ \tau$ of $\mathcal{G}$ is ϵ_2, and $\chi_\theta = \epsilon_2 \circ \alpha$ is $u \mapsto (u/d)$ by (Hr4); since d is prime, the primitive character inducing it is the Legendre symbol χ_d, which is not trivial, so $\chi_C \neq 1$. By Lemma 3.18, item 1, $(\chi_C)_{\mathfrak{A}_\mathfrak{h}}(n) = \chi_d(n)$ for all $n \geq 1$, and by compatibility $\eta(\chi_C) = L'(1,\chi_d)/L(1,\chi_d) = \beta(\mathfrak{h})$, a real number ($\chi_d$ is real and $L(1,\chi_d) \neq 0$). Hence $\mathrm{Re}\,\eta(\chi_C) = \beta(\mathfrak{h})$.

The core-tied data. Choose a bijection $\{1, \dots, f\} \to \Phi$, $\rho \mapsto g_\rho$ (possible by (v)). Put $w_{u,j}(g) = w_j^{(u)}(g)$ for $g \in \Phi$ and $w_{u,j}(g) = 1$ for $g \in \Gamma_A \setminus \Phi$ ($u \in A$, $1 \leq j \leq m$), and $a(t) = a_t$ for $t \in T$, $a(t) = 0$ for $t \in A \setminus T$. Let $\bar\eta \geq 0$, $\bar e \in [0, \frac{1}{4}]$ be the numbers of (Sp5) at x, and for $u \in A$ let $\eta_u = \eta_{\mathfrak{V}_u} \in [0, \bar\eta]$, $e_u = e_{\mathfrak{V}_u} \in [0, \bar e]$ be those of (Sp5) at the member i_u. The slope datum $\mathfrak{S}$ has the following entries.

- The translates $U = A$, $\mathcal{T} = T$, the words $\mathcal{W}(u) = \mathcal{W}(\mathfrak{V}_u)$, and the integers m and f.
- The parameters

$$x,\ \varepsilon,\ a,\ b,\ b',\ k,\ L = x^\varepsilon,\ L_a,\ B_0,\ N_c,\ \gamma_0 = \gamma,$$
$$\beta = \beta(\mathfrak{h}),\ v = v(\mathfrak{h}),\ l_g = \log(g_1 g_2), \qquad \bar\delta = \tfrac{1}{2},\ \bar\eta,\ \bar e.$$

- The numbers a_t ($t \in T$) and $w_{u,j,\rho} = w_{u,j}(g_\rho)$.

- For $\omega \in \mathcal{W}(u)$, the entries $d_{u,\omega}, T_{u,\omega}, \mu_{u,\omega}, \mu_{u,\omega}^{\max}, h_{u,\omega}, \mu'_{u,\omega}, \mu'^{\max}_{u,\omega}, E_{u,\omega,j}$, equal to the rank, Gauss prime, slope, maximal slope, height, ambient slope, maximal ambient slope and exponents of ω in $\mathfrak{V}_u$.
- For $u \in A$,

$$\mu_u^\vee = \mu^\vee(\mathfrak{V}_u),\ \mu_{\min,u}^\vee = \mu_{\min}^\vee(\mathfrak{V}_u),\ F_u = F(\mathfrak{V}_u),\ \Theta_u = \Theta(\mathfrak{M}_u),$$
$$S_u = S(\mathfrak{M}_u),\ I_u = I(\mathfrak{M}_u),\ \mathrm{HH}_u = x^{c_\vee} b,\ \delta_u = \delta(\mathfrak{V}_u),\ \eta_u,\ e_u,$$

  with $S(\mathfrak{M}_u)$ formed with the cut-off $P = \lceil 2x \exp(x^\varepsilon) \rceil$.

The constant vector is $c_{\mathrm{Div}} = c_E = c_H = C_4$, $e_{\mathrm{Div}} = e_D$, $c_{\mathrm{Count}} = C_1$, $c_{\mathrm{Slope}} = C_2$, $c_{\mathrm{Sl}} = C_3$, $c_{\mathrm{Loss}} = c_L$, $e_{\mathrm{Loss}} = 0$, $c_{\mathrm{HH}} = c_\vee$. The remaining core-tied data are $X'' = xnX'$, $\mathrm{tr} = \mathrm{id}_A$, the identity $\mathcal{T} \to T$, the bijection $\rho \mapsto g_\rho$, the function η, the integer $P \geq 1$, the set T_2, the function a, the weights $w_{u,j}$, and the reals ν, X', θ_0. In this slope datum $n_{\mathcal{T}} = |T|$, $A = A_T$ (the sum of the a_τ), $\log \Omega = \gamma + \log(\pi/v(\mathfrak{h})) - \beta(\mathfrak{h}) = \log \Omega(\mathfrak{h})$, $E_{u,\omega} = E(\mathfrak{V}_u, \omega)$; since all ranks are positive by (Sp4), $s_u = s(\mathfrak{V}_u)$ and $\phi_u = s^{\max}(\mathfrak{V}_u) - s(\mathfrak{V}_u)$.

(Tc1), (Ct2), (Ct3), (Ct5), (Ct7) and the identifications. (Tc1): $T = T_{x,i_0}$; every element of T_2 is $s\, a_0$ with $s \in S_{x,i_0}$; η is compatible with $\mathfrak{h}_{x,i_0}$. (Ct2): $x(\mathfrak{S}) = x$, $\varepsilon(\mathfrak{S}) = \varepsilon$, $e_{\mathrm{Div}} = e_D$, $e_{\mathrm{Loss}} = 0$, $c_{\mathrm{HH}} = c_\vee = c^*$. (Ct3) with $\mathrm{tr} = \mathrm{id}_A$: $a_\tau = a(\tau)$, $w_{u,j,\rho} = w_{u,j}(g_\rho)$ and $\gamma_0 = \gamma$ by construction, and $\beta = \mathrm{Re}\, \eta(\chi_C)$ by the computation above. For S_u: $S(\mathfrak{M}_u) = \sum_{t \in T} \sum_j A_{\mathrm{in}}(a_t, t, w_j^{(u)})$ formed with $(\mathfrak{A}_\mathfrak{h}, P)$, the weights extended off Φ in any way, since A_{in} depends on a weight only through its values on Φ; with the extension $w_{u,j}$ this is $\sum_{t \in T} \sum_j A_{\mathrm{in}}(a(t), t, w_{u,j})$, as (Ct3) requires. (Ct5) holds with equality: $B_0 = 2|A| m b x^\varepsilon$ and $N_c = |T_2| k b x^{2\varepsilon} / |A|^2 = |T_2| k b x^\varepsilon / (|A|^2 x^{-\varepsilon})$. (Ct7): $a = xb \leq 2xb$; $\frac{1}{2} x^{-\varepsilon/8} |A| \leq |T|$, $x^{-\varepsilon}|A| \leq |T_2|$, $x^{1/2-\varepsilon} \leq m$ and $k \leq |A|^2 x^{1/2-\varepsilon}$ by (Sp8). Finally $b = \exp(x^\varepsilon)$, and for every u the loss datum $\mathfrak{M}_u$ has the integer m, the set of tops T with $|\mathcal{T}|$ elements, and $S_u = S(\mathfrak{M}_u)$ with the cut-off $\lceil 2x \exp(x^\varepsilon) \rceil$, $\Theta_u = \Theta(\mathfrak{M}_u)$, $I_u = I(\mathfrak{M}_u)$.

The slope conditions other than (Sl8). Fix $u \in A$ and $\omega, \omega' \in \mathcal{W}(u)$; every property below is applied at the member i_u and its slope record $\mathfrak{V}_u$, whose loss datum has the common k, m, ν, tops T and heights a_t, and whose analytic loss is L_a.

- (Sl1): $x, b > 0$, $a, b' \geq 0$, $k \geq 1$, $v > 0$, $f > 0$ by (i), (ii), (vi); $a_\tau \geq 0$ by (iv); $w_{u,j,\rho} = w_j^{(u)}(g_\rho) \geq 1$ by (Sp6); $d_{u,\omega} > 0$ and $\mu_{u,\omega} \leq \mu_{u,\omega}^{\max}$ by (Sp4); $T_{u,\omega} > 0$ as a prime; $c_{\mathrm{Sl}} = C_3 \geq 0$; $\bar{\delta} = \frac{1}{2} < 1$, $\bar{\eta} \geq 0$, $0 \leq \bar{e} \leq \frac{1}{4}$.
- (Sl2): (Sp4) gives the bound with C_d and $x^{e\varepsilon}$; its left side and its sum over t are those of (Sl2), because $m(\varphi(a_t) - a_t \log \Omega) = m(a_t \log a_t - a_t - a_t \log \Omega(\mathfrak{h}))$ (here $a_t > 0$ by (iv)). The two error terms are non-negative after C_d is replaced by $C_4 \geq C_d$, since $L_a \geq 0$ by (Sp8) and $B_0, N_c \geq 0$, and $x^{e\varepsilon} \leq x^{e_D \varepsilon}$ since $x \geq 1$ and $e \leq e_D$; so (Sl2) holds with $c_{\mathrm{Div}} = C_4$ and $e_{\mathrm{Div}} = e_D$.
- (Sl3) and (Sl4): the second and third bounds of (Sp4), with $C_d \leq C_4$ and non-negative right sides, are (Sl3) with $c_E = C_4$ (as $E_{u,\omega} = E(\mathfrak{V}_u, \omega)$ and $A = A_T$) and (Sl4) with $c_H = C_4$.
- (Sl5): (Sp1) with C_1, since $\sum_{\rho=1}^f \log(w_{u,j,\rho} v/\pi) = \sum_{\tau \in \Phi} \log(w_j^{(u)}(\tau) v(\mathfrak{h})/\pi)$ by the bijection $\rho \mapsto g_\rho$, $l_g = \log(g_1 g_2)$ and $L = x^\varepsilon$.
- (Sl6): (Sp2) with C_2, as $n_{\mathcal{T}} = |T|$.
- (Sl7): (Sp3) with C_3; its subtracted term is exactly $\mathrm{Lo}''_{u,\omega} = c_{\mathrm{Sl}} I_u + c_{\mathrm{Sl}} n_{\mathcal{T}} m(a/k + b') \log T_{u,\omega} + c_{\mathrm{Sl}} X'' + 1$, with $\Theta_u + F_u - E_{u,\omega}$ as in (Sl7).

- (Sl9): (Sp5) at i_u gives the inequality of (Sl9) for $\mathrm{HH}_u = x^{c_\vee} b$, δ_u, η_u, e_u, since s_u, ϕ_u and $|\mathcal{W}(u)|$ are the quantities of (Sp5); so (Sl9) holds regardless of its hypotheses.
- (Sl10): $s_u - \mu^\vee_{\min,u} \le x^{c_\vee} b = \mathrm{HH}_u$ by (Sp5), and $0 < \mathrm{HH}_u \le x^{c_{\mathrm{HH}}} b$ with $c_{\mathrm{HH}} = c_\vee$.
- (Sl11): $0 \le \delta_u \le \frac{1}{2} = \bar\delta$ by (Sp5), $0 \le \eta_u \le \bar\eta$ and $0 \le e_u \le \bar e$ by the choice of η_u, e_u.

The size conditions for (c, X'', e_K, C_K). (Er1): $x \ge 1$ and $0 < \varepsilon \le 1$ by (i). (Er2): $b \ge 1$; $xb \le a$; $n_{\mathcal{T}} \ge 1$ by (iii); $m \le x^{1/2+\varepsilon/2}$, $xm \le k$, $k \le x^{e_K}$, $k \le a$, $0 \le L_a \le 2x^\varepsilon$, $kb' \le a$ and $X'' \le a$ by (Sp8); $e_K \ge 0$; $1 \le k$ by (ii); $0 \le L = x^\varepsilon \le 2x^\varepsilon$; $b' \ge 0$; $X'' \ge 0$; $0 \le a_\tau \le 2a$ by (iv); $B_0, N_c \ge 0$. (Er3): $\log|\mathcal{W}(u)| \le (k-3)\log 2$ by (Sp8) at i_u. (Er4): $\bar\delta = \frac{1}{2}$, $\bar\eta, \bar e \ge 0$, and by (Sp5), (iii) and (i) we have $(\bar\eta + 4\sqrt{\bar e}) x^{c_{\mathrm{HH}}} b \le C_K x^\varepsilon n_{\mathcal{T}} a$ (see the computation below). (Er5): $C_4, C_1, C_2, C_3, c_L \in [0, C_K]$ (each is non-negative, $c_L \ge c_0 = 0$, and C_K is their sum plus 6); $e_{\mathrm{Div}} = e_D \ge 0$, $e_{\mathrm{Loss}} = 0$, $c_{\mathrm{HH}} = c_\vee \ge 0$. Hence (Ct4) holds except for (Sl8), and with (Ct2), (Ct3), (Ct5), (Ct7) this is (Tc2).

(Tc3). We check (Wd1)–(Wd5) for $(A_0, T, T_2, a|_T, (w_{u,j}), P)$ with parameters $(b, b', \nu, X', \theta_0)$ for $(\mathfrak{A}_\mathfrak{h}, \eta)$, without the inclusion $T_2 \subseteq A_0$, and (Wd3) for every $u \in A$. (Wd1): $\nu > 0$ by (Lm7) (through (Pf3)); $X' > 0$; $b' > 0$; $b'X' = a = xb$; $\theta_0 \ge 0$. (Wd2): $|a_t/b - x| \le 1$ by (Sp8). (Wd3): let $u \in A$, $1 \le j \le m$, $\rho \in \Phi$; then $w_{u,j}(\rho) = w_j^{(u)}(\rho) \ge 1 > 0$ by (Sp6), so $a_t / w_{u,j}(\rho) \le a_t \le 2a \le P$ by (iv); the member i_u has translate u and thick set $T^{\mathrm{th}}_{x,i_u} = T_2$ (by (Sr1)), so (Sp6) at i_u gives $b \le w_{u,j}(\rho) \le b + \nu + 1$ if ρ is thick at u for T_2, and $w_{u,j}(\rho) \le 2b'$ otherwise. (Wd4) is the property of η chosen above. (Wd5): $2|\Phi|(x+1)\theta_0 \le 1/x$ and $6|\Phi|(x+1)(\nu+1) \le b/x$ by (Sp8) (for the constant c) and (v).

Thus i_0, the data above and the members i_u ($u \in A$) satisfy (Tc1), (Tc2) and (Tc3) except for (Sl8), with exponents $(e_D, 0, C_K, c^*, e_K)$ and parameter ε, the slope datum has translates A, $\mathrm{tr} = \mathrm{id}_A$, $c_{\mathrm{Loss}} = c_L$, $e_{\mathrm{Loss}} = 0$, and the identifications hold. As this holds for every $x \in W$ with $x \ge x_0$ and $x > x_1$, and for every $c_L \ge c_0$, the family $\mathcal{F}$ has slope data at its members with exponents $(e_D, 0)$. □

The reduction of Part I is now complete. The three tables below list the conditions it uses and the result that proves each. The first gives the slope conditions of the slope data at the members of a family, as they are verified in the proof of Theorem 8.4. The second gives the properties of slope records for the families of the class $\mathcal{A}_{\mathrm{prop}}$ of Definition 17.5 that satisfy the Sha condition, as in the proof of Theorem 17.7. The third gives the clauses of Proposition 17.6 and the link property (Lk4). In the second and third tables the words *condition of the class* mean that the condition is part of the definition of $\mathcal{A}_{\mathrm{prop}}$; the result named after these words shows that the families constructed in Part IV satisfy it.

What remains to be proved after Part I is therefore Proposition 9.1 (Part II), Proposition 17.6 (Part III, with inputs from Parts II, IV and V and, through Part IV, from Part VI and (TCS)) and Theorem 36.4 (Part VII, with Parts VIII and IX).

Part II
Hosts on windows

Part II constructs the auxiliary fields of the argument and shows that they exist at the scales where Part I needs them. It proves two statements. The first, Proposition 9.1, is the supply of hosts on windows, the first of the three inputs of the existence theorem Proposition 7.8. Let ψ be a primitive character that satisfies the window Sha bound with exponent 401, as every primitive character does by Theorem 36.4, and let $\mathfrak{G}$ be a good-host requirement that supplies good hosts for ψ. Then for every $\varepsilon \in (0, 1/52)$ there is a set of scales containing $\frac{3}{2}$-windows such that at every large scale x of the set some host satisfies the host conditions (Ec1)–(Ec5) for $\mathfrak{L}_\psi$, its field satisfies the Sha bound $\mathrm{V}\big(E_\mathfrak{h}; t, \exp(x^\varepsilon/2)\big)$, and $\mathfrak{G}$ holds. The second statement, Proposition 11.5, says that the concrete good-host requirement of Definition 11.4 supplies good hosts. It is clause (Gh1) of Proposition 17.6, and the concrete requirement is the one under which Parts III and IV work.

At a scale x the field $E_\mathfrak{h}$ of a host is an abelian CM field of degree $4|A|$, where $x^{2+8\varepsilon} \le |A| \le 2x^{2+8\varepsilon}$. Inside a cyclotomic field it is the fixed field of the automorphisms $\zeta \mapsto \zeta^a$ with $a \equiv \pm 1 \pmod{2^{e+2}}$, $\psi(a) = 1$ and $(a/q) = (a/d) = 1$ (Definition 7.1). By the Galois correspondence it is the compositum of the field cut out by ψ, of $\mathbb{Q}(\sqrt{-q}, \sqrt{-d})$, and of the real subfield of $\mathbb{Q}(\zeta_{2^{e+2}})$, which is the layer of degree 2^e of the cyclotomic $\mathbb{Z}_2$-extension of $\mathbb{Q}$; here $|A| = c\,2^e$ with c depending only on ψ (Lemma 9.2). The primes $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$ have a prescribed size and form what we call a window pair. Alpöge speaks of an Iwasawa tower and of a precise choice of it made with Behrend's construction [4]. We read these as the cyclotomic 2-power layer and as the spacing sets of Proposition 11.12, which are built by Behrend's construction; this identification is our reading, and no statement of the paper depends on it.

The method is analytic number theory, with class field theory for the shape of the fields. Section 9 assembles Proposition 9.1 from three facts: a window pair gives a frame and a host whose field is of the shape just described; if the pair is good, the characters of the host whose twisted functions do not enter $G_{\mathfrak{L}_\psi}$ satisfy a square-root bound at the scale; and the ranges of scales on which pairs are good and on which the Sha bound holds overlap in $\frac{3}{2}$-windows. Section 10 proves that good window pairs exist at every large scale, by a mean square over quadratic twists in two stages; this is the analytic core of the Part. Section 11 constructs, for a host built on a good window pair, the further data that the concrete good-host requirement asks for: rank data, tops, a spacing set, level primes, the CM structure and two character estimates. The external inputs are published: Montgomery's zero-density estimate, the Landau–Page theorem, an effective bound for a real zero, the prime number theorem in progressions and the Chebotarev density theorem in the uniform form of Thorner and Zaman, Linnik's theorem on the least prime in a progression, and class field theory. No result of Part II depends on (TCS).

9 Supply of hosts on windows

This section proves Proposition 9.1, the supply of hosts on $\frac{3}{2}$-windows, which the proof of the existence theorem Proposition 7.8 uses in its first step. There its two hypotheses are met by Theorem 36.4, which gives the window Sha bound with exponent 401, and by clause (Gh1) of Proposition 7.9, which gives hypothesis (Sb). The proof assembles four lemmas. 9.2 attaches to ψ and to two primes q, d of the shape of a window pair a frame and a normalised host whose

field is a (ψ, e, q, d)-field, and checks (Ec1)–(Ec3) for every set of tops; it rests on the Galois theory of cyclotomic fields. Lemma 9.4 records the splitting of the small primes in $\mathbb{Q}(\sqrt{-d})$ that a window pair forces. Lemma 9.5 turns the goodness of the pair into (Ec5): the controlled characters, whose twisted functions do not enter $G_{\mathfrak{L}_\psi}$, satisfy the square-root bound at the scale x and the bound $4\log x$ for the logarithmic derivative at 1. Condition (Ec4), the distribution of the tops over the cosets of A_0, is part of the supply of good hosts and is proved in Section 11.

Lemma 9.3 explains the ratio $\frac{3}{2}$. Three ranges of scales must overlap. A window pair at scale Y can be chosen good up to Y^J (Proposition 10.2). The window Sha bound gives, for that pair, a range $[W', W'^2]$ of scales on which the fields satisfy the Sha bound. And a frame of order $c\,2^e$ must have order between $x^{2+8\varepsilon}$ and $2x^{2+8\varepsilon}$. The third condition is met by multiplying the scale by the constant $c^{1/(2+8\varepsilon)}$, and this shrinks the window of ratio 2 to one of ratio $\frac{3}{2}$. This is the origin of the ratio $\frac{3}{2}$ of the windows in Part I.

Proposition 9.1. *Let $\psi \in \mathcal{P}$ have modulus N and satisfy the window Sha bound with exponent 401. Let $\mathfrak{G}$ be a good-host requirement, and suppose:*

(Sb) *$\mathfrak{G}$ supplies good hosts for ψ.*

Then for every $\varepsilon \in (0, 1/52)$ there are a finite list κ of reals, a real $J \geq 1$, a set $W_\varepsilon \subseteq \mathbb{R}$ containing $\frac{3}{2}$-windows and a real x_0 such that for every $x \in W_\varepsilon$ with $x \geq x_0$ there are a frame (e, A, h, a_0) with $x^{2+8\varepsilon} \leq |A| \leq 2x^{2+8\varepsilon}$, a host $\mathfrak{h}$ for it, a finite set $T \subseteq A$ and an integer $t \geq 1$ with:

1. *$(\mathfrak{h}, T)$ satisfies the host conditions (Ec1)–(Ec5) for $\mathfrak{L}_\psi$ at scale x with parameters $(\varepsilon, 4)$;*
2. *$E_\mathfrak{h}$ is a (ψ, e, q, d)-field and satisfies $\mathrm{V}(E_\mathfrak{h}; t, \exp(x^\varepsilon/2))$;*
3. *$\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ holds.*

Proof. Fix $\varepsilon \in (0, 1/52)$. Let c, e_0 be given by Lemma 9.2 for ψ, and let $J \geq 1$ and the set W_ε (containing $\frac{3}{2}$-windows) be given by Lemma 9.3 for (ψ, ε, c). Put $C_0 = J + o_\psi + 8N \geq 1$, and let κ, x_B be given by (Sb), that is, by the supply of good hosts for ψ, for (ε, C_0). These constants depend only on ψ and ε, not on the scale. Let $x_0 = \max\bigl(x_B,\ c\,2^{e_0} + 1,\ (4N+1)^{5J/\varepsilon}\bigr)$.

Let $x \in W_\varepsilon$ with $x \geq x_0$, and let Y, q, d, e be as in the definition of W_ε (Lemma 9.3): $x^{1/J} \leq Y \leq x$, (q, d) is a window pair at scale Y good for (N, x), $x^{2+8\varepsilon} \leq c2^e \leq 2x^{2+8\varepsilon}$, and every (ψ, e, q, d)-field satisfies $\mathrm{V}(\cdot\,; \lfloor x^{400} \rfloor, \sqrt{\exp(x^\varepsilon)})$. Put $b = \lfloor Y^{\varepsilon/5} \rfloor$. Then:

- $e \geq e_0$, since $c\,2^e \geq x^{2+8\varepsilon} \geq x > c\,2^{e_0}$;
- $Y \geq x^{1/J} \geq (4N+1)^{5/\varepsilon}$, so $b \geq 4N + 1$;
- by Lemma 9.4, $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$, $(-d/q) = 1$ and $(-d/p) = 1$ for every odd prime $p \leq b \leq Y^{\varepsilon/5}$; $q \neq 3$ because $\log q > \frac{1}{2} Y^{\varepsilon/5} \geq \frac{1}{2}(4N+1) > \log 3$; and $\gcd(N, qd) = 1$ by (Wp1).

So Lemma 9.2 gives a frame (e, A, h, a_0) with $|A| = c2^e \in [x^{2+8\varepsilon}, 2x^{2+8\varepsilon}]$ and index o_ψ, and a host $\mathfrak{h}$ with its items 1–6. The hypotheses of (Sb) hold with $M = N$: $J \leq C_0$, $o_\psi \leq C_0$, $0 < N \leq C_0$, $Q_S \leq 4N|A| \leq C_0|A|$ and $Q_S \mid \mathrm{lcm}(2^{e+2}, N)$ by item 1, the kernel form by item 2, field rows up to b by item 5, normalisation by item 6, and the pair is good for (N, x) at the scale $Y \in [x^{1/J}, x]$. So (Sb) gives T and t with (Ec4) and item 3.

Item 1: (Ec1)–(Ec3) are item 4 of Lemma 9.2 (valid for every T), (Ec4) is given by (Sb), and (Ec5) with $C = 4$ is Lemma 9.5, whose hypotheses are $N \mid Q_S$ (part of the kernel form, item 2

of Lemma 9.2), the prime factors of Q_S dividing $2N$ (item 1), the twist form (item 3) and the goodness of (q,d) for (N,x) at the scale $Y \le x$.

Item 2: $E_{\mathfrak{h}}$ is a (ψ,e,q,d)-field by item 2 of Lemma 9.2, so it satisfies $\mathrm{V}(E_{\mathfrak{h}};\lfloor x^{400}\rfloor,\sqrt{\exp(x^{\varepsilon})})$, and $\sqrt{\exp(x^{\varepsilon})}=\exp(x^{\varepsilon}/2)$. Since t is an integer with $t\le x^{400}$, $t\le\lfloor x^{400}\rfloor$, and $\mathrm{V}(E;t',B)$ follows from $\mathrm{V}(E;t,B)$ for $t'\le t$ (fewer non-negative lengths in the sum). □

Lemma 9.2. *Let $\psi\in\mathcal{P}$ have modulus N. There are integers $c\ge 1$ and $e_0\ge 2$ such that for every $e\ge e_0$, all primes q,d with $q\equiv 3 \pmod 8$, $q\ne 3$, $d\equiv 7 \pmod{16}$, $(-d/q)=1$ and $\gcd(N,qd)=1$, and every integer $b\ge 4N$ with $(-d/p)=1$ for all odd primes $p\le b$, there are a frame (e,A,h,a_0) and a host $\mathfrak{h}=(q,d,Q_S,\alpha)$ for it with the following properties.*

1. *$|A|=c\,2^e$; $Q_S\mid \mathrm{lcm}(2^{e+2},N)$, so every prime factor of Q_S divides $2N$; and $Q_S\le 4N|A|$.*
2. *$\mathfrak{h}$ has the kernel form for ψ; hence $E_{\mathfrak{h}}$ is a (ψ,e,q,d)-field.*
3. *$\mathfrak{h}$ has the twist form for ψ.*
4. *The frame has index o_ψ, and $(\mathfrak{h},T)$ satisfies (Ec1)–(Ec3) for $\mathfrak{L}_\psi$, for every $T\subseteq A$.*
5. *$\mathfrak{h}$ has field rows up to b.*
6. *$\mathfrak{h}$ is normalised.*

Proof. Construction. Let $\ker\psi\subseteq(\mathbb{Z}/N)^\times$ be the kernel of ψ (the common kernel of $\langle\psi\rangle$) and $B=(\mathbb{Z}/N)^\times/\ker\psi$, cyclic of order o_ψ; the characters of $(\mathbb{Z}/N)^\times$ trivial on $\ker\psi$ are exactly $\langle\psi\rangle$. Let Q_S be the least multiple of 2^{e+2} dividing $\mathrm{lcm}(2^{e+2},N)$ through which $u\mapsto[u]_B$ factors; since ψ is primitive of modulus N, $N\mid Q_S$, and $Q_S=2^{e+2}N'$ for $e+2\ge v$, where $N=2^vN'$ with N' odd. Let

$$\eta\colon(\mathbb{Z}/Q_S)^\times\to H_e\times B,\qquad u\mapsto(u \bmod 2^{e+2} \bmod\{\pm1\},\ [u]_B),$$

let A be its image (written additively), h the projection to H_e, which is surjective, and $A_0=A\cap(H_e\times\{0\})$, the kernel of the projection to B. The map h is injective on A_0, so A_0 embeds in the cyclic group H_e and is cyclic; let a_0 generate it. The projection $A\to B$ is surjective, so $[A:A_0]=|B|=o_\psi$. Define

$$\alpha\colon(\mathbb{Z}/Q_Sqd)^\times\to\mathcal{G},\qquad \alpha(u)=\Big(\Big(\big(\tfrac{u}{q}\big),\big(\tfrac{u}{d}\big)\Big),\ \eta\big(\big(\tfrac{u}{q}\big)u\big)\Big).$$

The sign (u/q) inside η is the key feature of the construction: since $q\equiv d\equiv 3 \pmod 4$, it gives $\alpha(-1)=((-1,-1),\eta(1))=((-1,-1),0)$, which is (Hn1) in item 6.

The constants. Since $h\colon A\to H_e$ is onto and $|H_e|=2^e$, $|A|=|\ker h|\,2^e$. For $e+2\ge v$ write $\psi=\psi_2\psi'$ with ψ_2 of 2-power modulus and ψ' of modulus N', let o' be the order of ψ' and r that of $\psi_2^{o'}$. Then $h(A_0)$ is the image in H_e of $\ker\psi_2^{o'}$, a subgroup of index r in $(\mathbb{Z}/2^{e+2})^\times$, so $|A|=o_\psi|A_0|=o_\psi 2^{e+1}/(rt)$ with $t=|\ker\psi_2^{o'}\cap\{\pm1\}|\in\{1,2\}$. Hence $c:=|\ker h|=2o_\psi/(rt)$ is an integer ≥ 1 independent of e, and $|A|=c\,2^e\ge 2^e$. Let e_0 be the least integer $\ge\max(v,2)$ with $2^{e_0}\ge 4N$ and $e_0\ge 64\,o_\psi$.

Host axioms. (Hr1) is the hypothesis on q,d. (Hr2): $2^{e+2}\mid Q_S$; $\gcd(Q_S,qd)=1$ as $Q_S\mid 2^{e+2}N$ and q,d are odd primes not dividing N; an odd prime $l\mid Q_S$ divides $N\le b$, so $(-d/l)=1$. (Hr3): let $((s_1,s_2),a)\in\mathcal{G}$. As η is onto A, there is $w\in(\mathbb{Z}/Q_S)^\times$ with $\eta(w)=a$. By the Chinese remainder theorem (Q_S, q, d pairwise coprime by (Hr2) and $q\ne d$, as $q\equiv 3$ and $d\equiv 7 \pmod 8$) there is u coprime to Q_Sqd with $(u/q)=s_1$, $(u/d)=s_2$ and $u\equiv s_1w \pmod{Q_S}$, since each

of ±1 is the Legendre symbol of some residue modulo an odd prime. Then $(u/q)u \equiv s_1^2 w = w \pmod{Q_S}$, so $\alpha(u) = ((s_1,s_2),\eta(w)) = ((s_1,s_2),a)$; hence α is onto. (Hr4): $\epsilon_2(\alpha(u)) = (u/d)$. (Hr5): if $u \equiv 1 \pmod{Q_S q}$ then $(u/q) = 1$ and $\eta(u) = 0$, so $\alpha(u) = ((1,(u/d)),0) \in \{1,\iota_d\}$.

Item 1. $|A| = c2^e$ was shown; $Q_S \mid 2^{e+2}N$, so its prime factors divide $2N$; and $Q_S \le 2^{e+2}N \le 4N|A|$.

Item 2. $N \mid Q_S$, and $\alpha(a) = 1$ if and only if $(a/q) = (a/d) = 1$ and $\eta(a) = 0$, i.e. $a \equiv \pm1 \pmod{2^{e+2}}$ and $\psi(a) = 1$. So $E_\mathfrak{h}$ is the fixed field of exactly the automorphisms in the definition of a (ψ,e,q,d)-field, with $N_\mathfrak{h} = Q_S qd$ divisible by $2^{e+2}, N, q, d$.

Item 3. A character θ trivial on $\{(1,1)\} \times A_0$ factors through $\{\pm1\}^2 \times A/A_0 \cong \{\pm1\}^2 \times B$, so $\theta = \epsilon_1^{i_0}\epsilon_2^j \cdot (\beta \circ \mathrm{pr}_B)$ with β a character of B, and $\xi = \beta([\cdot]_B) \in \langle\psi\rangle$. Then $\theta(\iota_d) = (-1)^j$ and $\chi_\theta(u) = (u/q)^{i_0}(u/d)^j\xi((u/q)u) = \xi(u)(u/q)^{i_0+k}(u/d)^j$, where $\xi(-1) = (-1)^k$; take $i \equiv i_0 + k \pmod 2$.

Item 4. (Ec1) is $[A : A_0] = o_\psi$. (Ec2): for $\psi' = (\psi^m)^* \in K_\psi$ let β_m be the character of B with $\beta_m([u]_B) = \psi^m(u)$ and put $\theta_m((s_1,s_2),a) = \beta_m(\mathrm{pr}_B(a) \cdot [s_1]_B)$. Then $\theta_m(\alpha(u)) = \beta_m([(u/q)^2u]_B) = \psi^m(u)$, θ_m is trivial on $\{(1,1)\} \times A_0$ and $\theta_m(\iota_d) = 1$, so $\theta_m \in X^+(\mathfrak{h})$ and $\chi^*_{\theta_m} = \psi'$. (Ec3): $\mathfrak{L}_\psi$ has no exceptional character, so we need $\chi^*_{\epsilon_1} \notin K_\psi$; but $\chi_{\epsilon_1}(u) = (u/q)$, so $\chi^*_{\epsilon_1}$ is the Legendre symbol modulo q, of modulus $q \nmid N$, while the characters of K_ψ have moduli dividing N.

Item 5. (Fr1) is the first coordinate of α. (Fr2): as $q \equiv 3 \pmod 4$, $\mathbb{Q}(\sqrt{-q})$ is the quadratic subfield of $\mathbb{Q}(\zeta_q) \subseteq \mathbb{Q}(\zeta_{N_\mathfrak{h}})$, and $\zeta \mapsto \zeta^a$ maps $\sqrt{-q}$ to $(a/q)\sqrt{-q}$; since $\alpha(a) = 1$ implies $(a/q) = 1$, $s = \sqrt{-q}$ lies in $E_\mathfrak{h}$ and $\sigma(s) = \epsilon_1(\sigma)s$ by (Fr1). (Fr3): for $l = 2$ take $u \equiv 1 + 2^{e+1} \pmod{2^{e+2}}$ and $u \equiv 1$ modulo the odd part of $N_\mathfrak{h}$; then $u \equiv 1 \pmod{N_\mathfrak{h}/2}$ and $u \not\equiv \pm1 \pmod{2^{e+2}}$ (as $e \ge 2$), so $\alpha(u) \ne 1$ by item 2. For odd $l \mid Q_S$ we have $l \mid N'$ and $v_l(Q_S) = v_l(N)$; by the minimality of Q_S (equivalently, as ψ has conductor N) there is $u \equiv 1 \pmod{Q_S/l}$ with $\psi(u) \ne 1$, and choosing $u \equiv 1 \pmod{qd}$ gives $u \equiv 1 \pmod{N_\mathfrak{h}/l}$ and $\alpha(u) \ne 1$. (Fr4): $Q_S \le 2^{e+2}N \le 2^{2e} \le |A|^2$ since $2^e \ge 4N$. (Fr5): $o_\psi^{64} \le 2^{64o_\psi} \le 2^e$. (Fr6) and (Fr7) are hypotheses. (Fr8): an odd prime $l \mid Q_S$ divides N, so $4l \le 4N \le b$.

Item 6. The component of $\alpha(u)$ in A is $\alpha_A(u) = \eta((u/q)u)$, where η is applied to the class of $(u/q)u$ modulo Q_S. (Hn1) was shown after the construction: $(-1/q) = (-1/d) = -1$ because $q \equiv d \equiv 3 \pmod 4$, so $\alpha(-1) = ((-1,-1),\eta(1)) = ((-1,-1),0)$. (Hn2): h is the projection $A \to H_e$, and the first coordinate of $\eta(v)$ is the class of $v \bmod 2^{e+2}$ modulo $\{\pm1\}$; for $v = (u/q)u = \pm u$ this class is $[u]_e$, so $h(\alpha_A(u)) = [u]_e$. (Hn3): let $u \equiv 1 \pmod{Q_S d}$. Then $(u/d) = 1$ and $(u/q)u \equiv (u/q) = \pm1 \pmod{Q_S}$, so $\alpha(u) = (((u/q),1),\eta(\pm1))$ and

$$\alpha(u)^2 = (((u/q)^2,1),\eta((\pm1)^2)) = ((1,1),\eta(1)) = 1.$$

□

Lemma 9.3. *Let $\psi \in \mathcal{P}$ have modulus N and satisfy the window Sha bound with exponent 401, let $0 < \varepsilon < 1/52$ and let $c \ge 1$. There is $J \ge 1$ such that the set W of real x for which there are a real Y, primes q,d and an integer $e \ge 0$ with*

1. *$x^{1/J} \le Y \le x$,*
2. *(q,d) is a window pair at scale Y that is good for (N,x),*
3. *$x^{2+8\varepsilon} \le c\,2^e \le 2x^{2+8\varepsilon}$,*
4. *every (ψ,e,q,d)-field E satisfies $\mathrm{V}(E;\lfloor x^{400}\rfloor,\sqrt{\exp(x^\varepsilon)})$,*

contains $\frac{3}{2}$-windows.

Proof. Choose a page function e_ε (for $x \geq 1$ let $e_\varepsilon(x)$ be the least integer with $2^{e_\varepsilon(x)} \geq x^{2+8\varepsilon}$). The window Sha bound gives $J \geq 1$ and X_0 such that for all $X \geq X_0$ and every window pair (q,d) at scale $X^{1/J}$ there is W' with $X^{1/J} \leq W'$, $W'^2 \leq X$ and $\mathrm{V}(E; \lfloor x'^{401} \rfloor, \sqrt{\exp(x'^\varepsilon)})$ for every $(\psi, e_\varepsilon(x'), q, d)$-field E and every $x' \in [W', W'^2]$. Let Y_1 be the threshold of Proposition 10.2 for $(N, \varepsilon, A = J)$, and let $k = c^{1/(2+8\varepsilon)} \geq 1$, so that $k^{2+8\varepsilon} = c$.

Let $y \in \mathbb{R}$. Choose $M \geq \max(1, y, Y_1, k^3, k^{400})$ and $X \geq \max(X_0, M^J)$; then $X^{1/J} \geq M \geq Y_1$. By Proposition 10.2 there is a window pair (q,d) at scale $Y := X^{1/J}$ good for $(N, Y^J) = (N, X)$; let W' be given by the window Sha bound for this pair. Put $Z = kW' \geq y$. We show $[Z, Z^{3/2}] \subseteq W$.

Let $x \in [Z, Z^{3/2}]$ and write $x = kx'$. Since $k^3 \leq M \leq W'$, $Z^{3/2} = (kW')^{3/2} \leq W'^2$, so $W' \leq x' \leq x \leq W'^2 \leq X$. Take $e = e_\varepsilon(x')$. Then:

- item 1: $x^{1/J} \leq X^{1/J} = Y \leq W' \leq x$;
- item 2: (q,d) is good for (N, X), hence for (N, x), since $x \leq X$ and the range in (Wp2) only shrinks;
- item 3: $x^{2+8\varepsilon} = k^{2+8\varepsilon} x'^{2+8\varepsilon} = c\, x'^{2+8\varepsilon}$, and $x'^{2+8\varepsilon} \leq 2^e \leq 2x'^{2+8\varepsilon}$;
- item 4: since $x' \in [W', W'^2]$, every (ψ, e, q, d)-field satisfies $\mathrm{V}(E; \lfloor x'^{401} \rfloor, \sqrt{\exp(x'^\varepsilon)})$; and $\mathrm{V}(E; t, B)$ is monotone (it implies $\mathrm{V}(E; t', B')$ for $t' \leq t$, $B' \geq B$), with $x^{400} = k^{400} x'^{400} \leq x' \cdot x'^{400}$ (as $k^{400} \leq M \leq W' \leq x'$) and $x'^\varepsilon \leq x^\varepsilon$.

So $x \in W$. The three ranges fit together as follows. The pair is at the scale $Y = X^{1/J} \leq x$ given by the window Sha bound, and it is good up to $X = Y^J \geq x$. The Sha window is $[W', W'^2]$ in the variable $x' = x/k$. Finally, the factor k converts the page $2^e \approx x'^{2+8\varepsilon}$ into frame orders $c\,2^e \approx x^{2+8\varepsilon}$, at the cost of shrinking the window of ratio 2 to one of ratio $\frac{3}{2}$. □

Lemma 9.4. *Let $0 < \varepsilon < 1/52$, $Y > 0$, and let (q,d) be a window pair at scale Y. Then:*

1. *q and d are primes with $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$ and $(-d/q) = 1$;*
2. *$(-d/p) = 1$ for every odd prime $p \leq Y^{\varepsilon/5}$;*
3. *$(-q/a) = (a/q)$ and $(-d/a) = (a/d)$ for every odd integer $a \geq 1$.*

In particular q, 2 and every odd prime $p \leq Y^{\varepsilon/5}$ split in $\mathbb{Q}(\sqrt{-d})$.

Proof. Items 1 and 2: the congruences are part of the definition. If p is an odd prime with $p \mid d+1$, then $-d \equiv 1 \pmod p$, so $(-d/p) = (1/p) = 1$. This applies to $p = q$ and to every odd prime $p \leq Y^{\varepsilon/5}$, which divide $d+1$ by definition.

Item 3: let $n \in \{q, d\}$; then $n \equiv 3 \pmod 4$. For odd $a \geq 1$, $(-n/a) = (-1/a)(n/a) = (-1)^{(a-1)/2}(n/a)$, and by quadratic reciprocity for the Jacobi symbol $(n/a)(a/n) = (-1)^{\frac{a-1}{2}\cdot\frac{n-1}{2}} = (-1)^{(a-1)/2}$, since $\frac{n-1}{2}$ is odd. Hence $(-n/a) = (a/n)$.

Splitting: $-d \equiv 1 \pmod 8$ because $d \equiv 7 \pmod 8$, so $\mathbb{Q}(\sqrt{-d})$ has discriminant $-d$, the prime 2 splits in it, and an odd prime $p \nmid d$ splits in it if and only if $(-d/p) = 1$; apply items 1 and 2. □

Lemma 9.5. *Let $\psi \in \mathcal{P}$ have modulus N, let $0 < \varepsilon < 1/52$ and $1 \leq Y \leq x$, and let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for a frame (e, A, h, a_0) such that $N \mid Q_S$, every prime factor of Q_S*

divides $2N$, $\mathfrak{h}$ *has the twist form for* ψ, *and* (q,d) *is a window pair at scale* Y *that is good for* (N,x). *Then every character* θ *that is controlled relative to* $\mathfrak{L}_\psi$ *satisfies*

$$|g(x,\chi_\theta^*)| \le x^{1/2+\varepsilon}, \qquad \Big|\frac{L'(1,\chi_\theta^*)}{L(1,\chi_\theta^*)}\Big| \le 4\log x.$$

In particular $(\mathfrak{h},T)$ *satisfies (Ec5) for* $\mathfrak{L}_\psi$ *at scale* x *with parameters* $(\varepsilon,4)$, *for every* $T \subseteq A$.

Proof. Let θ be controlled: $\theta \in X^-(\mathfrak{h})$, or $\theta \in X^+(\mathfrak{h})$ with $\chi_\theta^* \notin K_\psi$. In both cases θ is trivial on $\{(1,1)\} \times A_0$, so the twist form gives $\xi \in \langle\psi\rangle$ and $i,j \in \{0,1\}$ with $\theta(\iota_d) = (-1)^j$ and $\chi_\theta(a) = \xi(a)(a/q)^i(a/d)^j$ for a coprime to $Q_S qd$. We have $(i,j) \neq (0,0)$: if $\theta \in X^-$ then $j = 1$; if $\theta \in X^+$ and $(i,j) = (0,0)$, then χ_θ and ξ agree on the integers coprime to $Q_S qd$, so $\chi_\theta^* = \xi^* = (\psi^m)^* \in K_\psi$ for some m, which is excluded.

An integer a coprime to $2Nqd$ is coprime to $Q_S qd$, because the prime factors of Q_S divide $2N$; for such a, $\chi_\theta(a) = \xi_{q,d}^{(i,j)}(a)$, with ξ regarded as a character modulo N. Two Dirichlet characters that agree on the integers coprime to a common multiple of their moduli are induced by the same primitive character, so $\chi_\theta^* = (\xi_{q,d}^{(i,j)})^*$. Since $q, d \nmid N$ by (Wp1), property (Wp2) of the good pair at $y = x \in [Y,x]$ gives $|g(x,\chi_\theta^*)| \le x^{1/2+\varepsilon/2} \le x^{1/2+\varepsilon}$ (as $x \ge 1$) and $|L'(1,\chi_\theta^*)/L(1,\chi_\theta^*)| \le 4\log x$. □

10 Good window pairs: almost all quadratic twists

A host built on a window pair (q,d) has, besides the characters that make up $G_{\mathfrak{L}_\psi}$, the twists $\xi\cdot(\cdot/q)^i(\cdot/d)^j$ with $(i,j) \neq (0,0)$ and ξ of small modulus. The conductors of these twists exceed every power of the scale, so the square-root bound that (Ec5) asks of them does not follow from a zero-free region for any fixed L-function. This section proves that it holds nevertheless for suitable pairs, on a whole range of scales: Proposition 10.2 gives, for every $A \ge 1$ and every large Y, a window pair at scale Y that is good up to Y^A. Its consumer is Lemma 9.3.

The core is a mean square over a family of prime moduli, and the square root comes from it; no zero-free half-plane is used for any character. For a set P of primes in an arithmetic progression, Proposition 10.8 bounds the mean over $q \in P$ of the square of a smoothed prime sum twisted by $(\cdot/q)$ by $C\,y\log y$. It rests on the equidistribution of the Jacobi symbols (q/s) over $q \in P$ with at most one exceptional modulus s (Lemma 10.6), which comes from the prime number theorem in progressions with an exceptional pair (Proposition 10.7), proved from the theorem of Thorner and Zaman (Theorem B.7) and an effective bound for a real zero (Theorem B.5). By Lemma 10.9, few q have a large smoothed sum anywhere on the range of scales. Under a zero-free box to the right of $1 - \frac{1}{400}$ the smoothed sum controls $g(y,\chi)$ and the logarithmic derivative at 1 (Lemma 10.10, Lemma 10.11), and by Montgomery's zero-density estimate few characters lack such a box (Lemma 10.15). Together these give one stage, Proposition 10.5: almost all quadratic twists over primes in a progression are good.

Proposition 10.4 applies the stage twice. The first stage chooses $q \equiv 3 \pmod 8$ with $\log q$ of size $Y^{\varepsilon/5}$. The second chooses, for a good q, a prime $d \equiv 7 \pmod{16}$ in the progression $d \equiv -1$ modulo q and modulo every odd prime $p \le Y^{\varepsilon/5}$, with $\log d$ of size $Y^{\varepsilon/5}\log^2 Y$. The congruences make every such p split in $\mathbb{Q}(\sqrt{-d})$ (Lemma 9.4), and 2 splits as well since $d \equiv 7 \pmod{16}$; so every prime inert in $\mathbb{Q}(\sqrt{-d})$ exceeds $Y^{\varepsilon/5}$, which the proof of Proposition 11.11 uses. The modulus of the progression has logarithm of order $Y^{\varepsilon/5}$, while $\log d$ is larger by the factor $\log^2 Y$; this ratio is what places the count of the primes d in the range of the prime number theorem in progressions. We follow the exposition of [2] for the two stages.

Definition 10.1. For real numbers Q, τ, Y, X, a primitive Dirichlet character χ of modulus N is (Q,τ,Y,X)**-good** if $\chi \neq \mathbf{1}$, $N \le Q$, χ has a zero-free box of height Q,

$$\Big|\frac{L'(1,\chi)}{L(1,\chi)}\Big| \le 251 \log Y, \qquad \text{and} \qquad |g(y,\chi)| \le y^{1/2+\tau} \ \text{ for all } y \in [Y,X].$$

Proposition 10.2. *Let $M \ge 1$ be an integer, $0 < \varepsilon < 1/52$ and $A \ge 1$. There is Y_1 such that for every $Y \ge Y_1$ there is a window pair (q,d) at scale Y that is good for (M, Y^A).*

Proof. Apply Proposition 10.4 with $N_0 = 8M$, $\tau = \varepsilon/2$, $K = A$, $\eta = \frac12$, and $z' = Y^{\varepsilon/5}\log^2 Y$; let Y_1 be at least its threshold, at least the threshold of item 2 of Lemma 10.11 for $(\varepsilon, 3)$, and at least $e^{1+\log(8M)}$, and large enough that $e^{z/2} > 8M$. For $Y \ge Y_1$ the sets $\mathcal{Q}^{\mathrm{good}}$ and $\mathcal{D}_q^{\mathrm{good}}$ have at least half the elements of the non-empty sets $\mathcal{Q}$ and $\mathcal{D}_q$; choose $q \in \mathcal{Q}^{\mathrm{good}}$ and $d \in \mathcal{D}_q^{\mathrm{good}}$.

Window pair. With $z = Y^{\varepsilon/5}$: $q \equiv 3 \pmod 8$ and $\frac12 Y^{\varepsilon/5} < \log q \le Y^{\varepsilon/5}$; $d \equiv 7 \pmod{16}$ and $\frac12 Y^{\varepsilon/5}\log^2 Y < \log d \le Y^{\varepsilon/5}\log^2 Y$; $q \mid d+1$ and every odd prime $p \le Y^{\varepsilon/5}$ divides $d+1$. These are the conditions of a window pair at scale Y.

(Wp1) holds since $q, d > e^{z/2} > 8M$ are primes.

(Wp2): let ξ be a character modulo M and ξ' the character modulo $8M$ it induces. For n coprime to $2Mqd$, $\xi_{q,d}^{(i,j)}(n) = \xi'(n)(n/q)^i(n/d)^j$, so the two have the same inducing primitive character χ. If $j = 0$ (so $i = 1$), (Aq) for ξ' shows that χ is $(8Me^z, \varepsilon/2, Y, Y^A)$-good; if $j = 1$, (Ad) for ξ' and $a = i$ shows that it is $(8Me^{z+z'}, \varepsilon/2, Y, Y^A)$-good. In both cases $|g(y,\chi)| \le y^{1/2+\varepsilon/2}$ for $y \in [Y, Y^A]$, and χ is non-principal, of modulus at most $Q_j = h_j(M,\varepsilon,Y)$, with a zero-free box of height Q_j. Since

$$Y^{\varepsilon/6} \le \log Q_j = \log(8M) + Y^{\varepsilon/5} + jY^{\varepsilon/5}\log^2 Y \le 3Y^{\varepsilon/5}\log^2 Y$$

(using $\log Y \ge 1 + \log(8M)$), item 2 of Lemma 10.11 gives $|L'(1,\chi)/L(1,\chi)| \le 4\log Y \le 4\log y$ for $y \ge Y$.

(Wp3): a real primitive ϱ of modulus dividing $8M$ induces a character ϱ' modulo $8M$; applying (Aq), (Ad) to $\xi = \varrho'$ gives a zero-free box of height $h_j(M,\varepsilon,Y)$ for $(\varrho_{q,d}^{(i,j)})^*$. □

Definition 10.3. For integers $m_0 \ge 1$, a_0 and a real number $U \ge 1$, let

$$\mathcal{P}(m_0, a_0, U) = \{q \text{ prime} : \ U^{1/2} < q \le U, \ q \equiv a_0 \pmod{m_0}\}.$$

For $\varepsilon > 0$ and $Y > 1$, a triple (U, m_0, a_0) is **admissible at** (ε, Y) if $8 \mid m_0$, $\gcd(a_0, m_0) = 1$ and

$$\tfrac14 \log^2 Y \cdot \log m_0 \le \log U, \qquad Y^{\varepsilon/6} \le \log U \le Y^{\varepsilon/5}\log^2 Y.$$

Proposition 10.4. *Let $0 < \varepsilon < 1/52$, $\tau > 0$, $K \ge 1$, $\eta > 0$ and $N_0 \ge 1$. There is Y_0 such that for every $Y \ge Y_0$, with $z = Y^{\varepsilon/5}$, and every z' with $Y^{\varepsilon/5}\log^2 Y \le z' \le K^2 Y^{\varepsilon/5}\log^2 Y$, the following holds. Let $\mathcal{Q}$ be the set of primes $q \equiv 3 \pmod 8$ with $e^{z/2} < q \le e^z$, and for $q \in \mathcal{Q}$ let $\mathcal{D}_q$ be the set of primes $d \equiv 7 \pmod{16}$ with $e^{z'/2} < d \le e^{z'}$ and $q\prod_{3\le p\le z} p \mid d+1$ (product over primes). Then $\mathcal{Q} \neq \emptyset$, and there is $\mathcal{Q}^{\mathrm{good}} \subseteq \mathcal{Q}$ with $|\mathcal{Q}^{\mathrm{good}}| \ge (1-\eta)|\mathcal{Q}|$ such that for every $q \in \mathcal{Q}^{\mathrm{good}}$:*

(Aq) *for every Dirichlet character ξ modulo N_0, $(\xi\cdot(\cdot/q))^*$ is (N_0e^z, τ, Y, Y^K)-good;*

(Ad) *$\mathcal{D}_q \neq \emptyset$, and there is $\mathcal{D}_q^{\mathrm{good}} \subseteq \mathcal{D}_q$ with $|\mathcal{D}_q^{\mathrm{good}}| \geq (1-\eta)|\mathcal{D}_q|$ such that for every $d \in \mathcal{D}_q^{\mathrm{good}}$, every ξ modulo N_0 and $a \in \{0,1\}$, $(\xi \cdot (\cdot/q)^a \cdot (\cdot/d))^*$ is $(N_0 e^{z+z'}, \tau, Y, Y^K)$-good.*

Proof. Stage 1 (the prime q). Apply Proposition 10.5 with $(\varepsilon, \tau, K, \eta)$, R the number of characters modulo N_0, $U = e^z$, $m_0 = 8$, $a_0 = 3$, $F = N_0$ and $\Xi = \{\xi^* : \xi \bmod N_0\}$. Then $\mathcal{P}(8, 3, e^z) = \mathcal{Q}$. The triple is admissible at (ε, Y) for large Y: $\frac{1}{4}\log^2 Y \log 8 \leq Y^{\varepsilon/5} = \log U \leq Y^{\varepsilon/5}\log^2 Y$ and $Y^{\varepsilon/6} \leq \log U$; the only prime factor of m_0 is $2 \leq Y^{\varepsilon/5}$; and $F = N_0 \leq e^{z/2}$. For $q \in \mathcal{Q}$, $q > e^{z/2} > N_0$, so $(\xi \cdot (\cdot/q))^* = \xi^* \cdot (\cdot/q)$. The proposition gives $\mathcal{Q} \neq \emptyset$ and at most $\eta|\mathcal{Q}|$ primes q failing (Aq), with $FU = N_0 e^z$. Let $\mathcal{Q}^{\mathrm{good}}$ be the set of the remaining primes. We show (Ad) for every $q \in \mathcal{Q}$.

Stage 2 (the prime d, for fixed $q \in \mathcal{Q}$). Put $\varepsilon' = 6\varepsilon/5 \leq \frac{1}{4}$, $o = q\prod_{3 \leq p \leq z} p$, $m_0 = 16o$, and let a_0 be the class with $a_0 \equiv 7 \pmod{16}$ and $a_0 \equiv -1 \pmod{o}$ (Chinese remainder theorem; $\gcd(a_0, m_0) = 1$). Then $\mathcal{P}(m_0, a_0, e^{z'}) = \mathcal{D}_q$. Apply Proposition 10.5 with $(\varepsilon', \tau, K, \eta)$, R twice the number of characters modulo N_0, $U = e^{z'}$, $F = N_0 e^z$ and $\Xi = \{(\xi \cdot (\cdot/q)^a)^* : \xi \bmod N_0,\ a \in \{0,1\}\}$, whose moduli are at most $N_0 q \leq F$. The hypotheses hold for large Y:

- admissibility at (ε', Y): $\log m_0 \leq \log 16 + \log q + \sum_{p \leq z} \log p \leq 4z$, since $\log q \leq z$, $\sum_{p \leq z} \log p \leq z \log 4 \leq 2z$ by Chebyshev's bound [180] and $\log 16 \leq z$ for large Y, so $\frac{1}{4}\log^2 Y \log m_0 \leq z \log^2 Y \leq z'$; $Y^{\varepsilon'/6} = Y^{\varepsilon/5} \leq z'$; $z' \leq K^2 Y^{\varepsilon/5} \log^2 Y \leq Y^{\varepsilon'/5} \log^2 Y$;
- the prime factors of m_0 are 2, the odd primes $p \leq z \leq Y^{\varepsilon'/5}$, and $q > e^{z/2} > Y^{400K}$;
- $1 \leq F = N_0 e^z \leq e^{z'/2} = U^{1/2}$.

For $d \in \mathcal{D}_q$ we have $d > e^{z'/2} \geq F$, so $(\xi \cdot (\cdot/q)^a \cdot (\cdot/d))^* = (\xi \cdot (\cdot/q)^a)^* \cdot (\cdot/d)$. The proposition gives $\mathcal{D}_q \neq \emptyset$ and at most $\eta|\mathcal{D}_q|$ primes d failing (Ad), with $FU = N_0 e^{z+z'}$. □

Proposition 10.5. *Let $0 < \varepsilon \leq \frac{1}{4}$, $\tau > 0$, $K \geq 1$, $\eta > 0$ and $R \geq 1$. There is Y_0 with the following property. Let $Y \geq Y_0$, let (U, m_0, a_0) be a triple admissible at (ε, Y) such that every prime factor of m_0 is at most $Y^{\varepsilon/5}$ or larger than Y^{400K}, let F be real with $1 \leq F \leq U^{1/2}$, and let Ξ be a set of at most R primitive Dirichlet characters of moduli at most F. Then the set $P = \mathcal{P}(m_0, a_0, U)$ is non-empty, and at most $\eta|P|$ primes $q \in P$ have a $\xi \in \Xi$ for which $(\xi \cdot (\cdot/q))^*$ is not (FU, τ, Y, Y^K)-good.*

Proof. Let $q \in P$ and $\xi \in \Xi$, of modulus $f \leq F$. Since $q > U^{1/2} \geq F \geq f$ and $q > U^{1/2} > 2$, q is an odd prime with $q \nmid f$, so $\chi_{q,\xi} : n \mapsto \xi(n)(n/q)$ is a product of primitive characters of coprime moduli, hence primitive of modulus $fq \leq FU$, and $\chi_{q,\xi} \neq \mathbf{1}$. Thus $(\xi \cdot (\cdot/q))^* = \chi_{q,\xi}$ and $S_Z(y, \chi_{q,\xi}) = S_Z(y; q, \xi)$ in the notation of Lemma 10.10. Put $Q = FU$; then $\log U \leq \log Q \leq \frac{3}{2}\log U$, so $Y^{\varepsilon/6} \leq \log Q \leq \frac{3}{2}Y^{\varepsilon/5}\log^2 Y \leq Y^{\varepsilon/4}$ for Y large.

Non-emptiness and size. By item 1 of Lemma 10.6, $|P| \geq U^{9/10} > 0$.

Primes with a zero in the box. Let B_1 be the set of $q \in P$ such that some $\chi_{q,\xi}$ has no zero-free box of height Q. For each such q choose one such ξ. The map $q \mapsto \chi_{q,\xi}$ is injective on B_1, since the modulus fq with $f < q$ determines q. By Lemma 10.15, a consequence of Montgomery's zero-density estimate, there is an absolute constant C_z such that for $Q \geq 3$ at most $C_z Q^{1/4}$ primitive characters of modulus at most Q have a zero s with $\operatorname{Re} s > 1 - \frac{1}{400}$, $|\operatorname{Im} s| \leq Q$. It applies with $Q = FU \geq U \geq 3$, and the characters $\chi_{q,\xi}$, $q \in B_1$, are primitive of modulus at most FU, pairwise distinct for distinct q and each with such a zero. Hence $|B_1| \leq C_z(FU)^{1/4} \leq C_z U^{3/8} \leq \frac{\eta}{2}U^{9/10} \leq \frac{\eta}{2}|P|$ for Y large (recall $\log U \geq Y^{\varepsilon/6}$).

Primes with a large smoothed sum. For $\xi \in \Xi$ let $B_2(\xi)$ be the set of $q \in P$ with $|S_Z(y; q, \xi)| > \frac{1}{2}y^{1/2+\tau}$ for some $y \in [Y, Y^K]$. By Proposition 10.8 the mean-square hypothesis of Lemma 10.9

holds on $[Y, Y^K]$ with its absolute constant C, for every κ' with $|\kappa'| \le 1$; so Lemma 10.9 with $\eta/(2R)$ gives $|B_2(\xi)| \le \frac{\eta}{2R}|P|$, and $|\bigcup_\xi B_2(\xi)| \le \frac{\eta}{2}|P|$.

The other primes are good. Let $q \in P \setminus (B_1 \cup \bigcup_\xi B_2(\xi))$ and $\xi \in \Xi$. Then $\chi_{q,\xi}$ is non-principal of modulus at most Q with a zero-free box of height Q, and $|S_Z(y, \chi_{q,\xi})| \le \frac{1}{2} y^{1/2+\tau}$ on $[Y, Y^K]$. By Lemma 10.10, $|L'(1, \chi_{q,\xi})/L(1, \chi_{q,\xi})| \le 251 \log Y$ and $|g(y, \chi_{q,\xi})| \le y^{1/2+\tau}$ on $[Y, Y^K]$. So $\chi_{q,\xi}$ is (FU, τ, Y, Y^K)-good, and the bad primes lie in $B_1 \cup \bigcup_\xi B_2(\xi)$, of size at most $\eta|P|$. $\square$

Lemma 10.6. *Let $\varepsilon > 0$, $A > 0$, $B > 0$. There is Y_0 such that for every $Y \ge Y_0$ and every triple (U, m_0, a_0) admissible at (ε, Y):*

1. *$|\mathcal{P}(m_0, a_0, U)| \ge U^{9/10}$;*
2. *there is an integer $n^* \ge 0$ such that for every odd squarefree integer $s > 1$ with $\gcd(s, m_0) = 1$, $s \le Y^A$ and $s \ne n^*$,*

$$\Big| \sum_{q \in \mathcal{P}(m_0, a_0, U)} \Big(\frac{q}{s}\Big) \Big| \le Y^{-B} \, |\mathcal{P}(m_0, a_0, U)|.$$

Proof. We use two inputs. The first is the prime number theorem for progressions with relative error and an exceptional pair, Proposition 10.7 (a consequence of the theorem of Thorner and Zaman [259], of the type of Gallagher's theorem [100]): there are $c_3 > 0$, A_0, C_0 such that for every M with $8 \mid M$ there is a choice e_M, either empty or an *exceptional pair* (χ_1, β_1) modulo M (a real non-principal character χ_1 modulo M and a zero $\beta_1 \in (1 - 1/(8 \log M), 1)$ of $L(s, \chi_1)$), such that for $X \ge 2$ with $\log X \ge C_0 \log M \log(\log M + 2)$ and $\gcd(b, M) = 1$,

$$\Big|\pi(X; M, b) - \frac{\mathrm{li} X - \vartheta(b) \, \mathrm{li}(X^{\beta_1})}{\varphi(M)}\Big| \le A_0\Big(e^{-c_3 \log X / \log M} + e^{-\sqrt{c_3 \log X}}\Big) \frac{\mathrm{li} X - \vartheta(b) \, \mathrm{li}(X^{\beta_1})}{\varphi(M)},$$

with $\vartheta(b) = \chi_1(b)$ if $e_M = (\chi_1, \beta_1)$ and $\vartheta = 0$ if e_M is empty (no uniqueness of the pair is used). The second is the Landau–Page theorem [75]: there is $c_0 > 0$ such that for every $Z \ge 3$ at most one real primitive character of modulus at most Z has a real zero in $(1 - c_0/\log Z, 1)$.

Sizes. Put $L = \log Y$ and $u = \log U$. Admissibility gives $\log m_0 \le 4u/L^2$ and $u \ge Y^{\varepsilon/6}$; for $s \le Y^A$ the modulus $M = m_0 s$ satisfies $\log M \le 4u/L^2 + AL$. Hence, for $Y \ge Y_0(\varepsilon, A, B)$ and $X \in \{U^{1/2}, U\}$,

$$\frac{\log X}{\log M} \ge \min\Big(\frac{L^2}{16}, \, \frac{Y^{\varepsilon/6}}{4AL}\Big), \qquad \text{so} \qquad 2A_0\big(e^{-c_3 \log X/\log M} + e^{-\sqrt{c_3 \log X}}\big) \le \tfrac{1}{8} Y^{-B},$$

and $\log X \ge C_0 \log M \log(\log M + 2)$.

Item 1. Apply the prime number theorem with $M = m_0 \ge 8$ and $b = a_0$ at $X = U$; the relative error is at most $\frac{1}{8}$ by the size estimate (the case $s = 1$). We also use the effective bound $1 - \beta_1 \ge c/m_0$, with an absolute $c > 0$, for a real zero $\beta_1 \in (0, 1)$ of a real non-principal character χ_1 modulo m_0. Indeed, χ_1^* is real, primitive and $\ne \mathbf{1}$, of modulus $f \mid m_0$ with $f \ge 3$, and β_1 is a zero of $L(s, \chi_1^*)$, since the finitely many Euler factors $1 - \chi_1^*(p) p^{-\beta_1}$, $p \mid m_0$, by which $L(s, \chi_1)$ and $L(s, \chi_1^*)$ differ do not vanish. The bound for real zeros [75] gives $1 - \beta_1 \ge c_{\mathrm{P}} f^{-1/2} \log^{-2} f \ge c_{\mathrm{P}} m_0^{-1/2} \log^{-2} m_0$, as $x^{1/2} \log^2 x$ increases for $x \ge 1$, and this is at least c/m_0 with $c = c_{\mathrm{P}} \inf_{m \ge 3} m^{1/2} \log^{-2} m > 0$. Then

$$\mathrm{li} U - \vartheta \, \mathrm{li}(U^{\beta_1}) \ge \int_{U^{\beta_1}}^{U} \frac{dt}{\log t} \ge \frac{U(1 - e^{-(1-\beta_1)u})}{u} \ge \frac{U \min(1, cu/m_0)}{2u},$$

and the same lower bound $U/(2u)$ holds without exceptional pair. Hence $\pi(U;m_0,a_0) \ge \frac{7}{8}\,U\min(1,cu/m_0)/(2u\,m_0)$, and $|\mathcal{P}(m_0,a_0,U)| \ge \pi(U;m_0,a_0) - U^{1/2} \ge U^{9/10}$ for $Y \ge Y_0$, because $\log m_0 \le 4u/L^2 \le u/100$ and $u \ge Y^{\varepsilon/6}$.

Item 2. Let s be as in the statement and $M = m_0 s$. The Jacobi symbol $(\cdot/s)$ is a non-principal character modulo s, as $s>1$ is squarefree and odd. Since $\gcd(m_0,s)=1$, the classes b modulo M with $b \equiv a_0 \pmod{m_0}$ and $\gcd(b,s)=1$ map bijectively to $(\mathbb{Z}/s\mathbb{Z})^\times$, so

$$\sum_{q\in\mathcal{P}(m_0,a_0,U)} \Big(\frac{q}{s}\Big) = \sum_{b} \Big(\frac{b}{s}\Big)\big(\pi(U;M,b) - \pi(U^{1/2};M,b)\big).$$

Insert the prime number theorem. The terms $\mathrm{li}(X)/\varphi(M)$ cancel, as $\sum_b (b/s)=0$. If $e_M = (\chi_1,\beta_1)$, its terms are $\mathrm{li}(X^{\beta_1})\varphi(M)^{-1}\sum_b (b/s)\chi_1(b)$; writing $b = a_0' u$ with a fixed $a_0' \equiv a_0 \pmod{m_0}$, the sum over b is $(a_0'/s)\chi_1(a_0')\sum_u (u/s)\chi_1(u)$ over the subgroup of $u \equiv 1 \pmod{m_0}$, which is 0 unless $\chi_1(u) = (u/s)$ on that subgroup. Call s *exceptional* if this happens and $1-\beta_1 < c_0/\log(m_0 Y^A)$. By Landau–Page, applied with $Z = m_0 Y^A \ge 8$, the primitive characters inducing the χ_1 of two exceptional values s_1, s_2 coincide (for an exceptional s, χ_1 is real and non-principal modulo $M = m_0 s \le Z$, so χ_1^* is real, primitive, $\ne \mathbf{1}$, of modulus at most Z, and has the real zero $\beta_1 \in (1 - c_0/\log Z, 1)$, a zero of $L(s,\chi_1^*)$ as in item 1), and then $(u/s_1) = (u/s_2)$ for all $u \equiv 1 \pmod{m_0}$ coprime to $s_1 s_2$, which forces $s_1 = s_2$. Let n^* be the exceptional value if there is one, and $n^* = 0$ otherwise. Write $\mathrm{m}(X,b)$ for the main term of the prime number theorem and $\mathrm{err} \le \frac{1}{16}Y^{-B}$ for its relative error. *Error terms.* Since $\pi(X;M,b) \ge (1-\mathrm{err})\mathrm{m}(X,b)$, they total at most $2\,\mathrm{err}\sum_b(\pi(U;M,b)+\pi(U^{1/2};M,b)) \le 4\,\mathrm{err}\,\pi(U;m_0,a_0) \le 8\,\mathrm{err}\,|\mathcal{P}(m_0,a_0,U)|$, because $|\mathcal{P}(m_0,a_0,U)| \ge \pi(U;m_0,a_0) - U^{1/2} \ge \frac12\pi(U;m_0,a_0)$ by item 1. *Exceptional terms, $s \ne n^*$.* Either they vanish, or χ_1 is not trivial on the $u \equiv 1 \pmod{m_0}$. In the second case $\sum_b \chi_1(b) = 0$, $\sum_b \mathrm{m}(U,b) = \mathrm{li}(U)/\varphi(m_0)$ and $|\mathcal{P}(m_0,a_0,U)| \ge \frac14\mathrm{li}(U)/\varphi(m_0)$. Moreover $1-\beta_1 \ge c_0/\log(m_0 Y^A)$, so $\mathrm{li}(X^{\beta_1}) \le \frac{1}{16}Y^{-B}\mathrm{li}(U)$ for $X \le U$, and the exceptional terms total at most $\frac18 Y^{-B}\mathrm{li}(U)/\varphi(m_0) \le \frac12 Y^{-B}|\mathcal{P}(m_0,a_0,U)|$.

Adding up gives the bound $Y^{-B}|\mathcal{P}(m_0,a_0,U)|$. □

Proposition 10.7. *For real $x>1$ let $\mathrm{li}\,x = \int_2^x \frac{dt}{\log t}$ (an oriented integral, negative for $1<x<2$), and for an integer $M \ge 1$, an integer b and real X let $\pi(X;M,b)$ be the number of primes $p \le X$ with $p \equiv b \pmod M$. For an integer $M \ge 3$, an* exceptional pair modulo M *is a pair (χ_1,β_1) of a real non-principal Dirichlet character χ_1 modulo M and a real number β_1 with*

$$1 - \frac{1}{8\log M} < \beta_1 < 1, \qquad L(\beta_1,\chi_1) = 0.$$

There are real constants $c_3>0$, A_0 and C_0 such that for every integer M with $8 \mid M$ there is e_M, either empty or an exceptional pair modulo M, such that for every real $X \ge 2$ with $\log X \ge C_0 \log M \log(\log M + 2)$ and every integer $b \ge 0$ with $\gcd(b,M)=1$,

$$\Big|\pi(X;M,b) - m(X,b)\Big| \le A_0\Big(e^{-c_3\log X/\log M} + e^{-\sqrt{c_3\log X}}\Big)\, m(X,b),$$

where $m(X,b) = \mathrm{li}\,X/\varphi(M)$ if e_M is empty and $m(X,b) = (\mathrm{li}\,X - \chi_1(b)\,\mathrm{li}(X^{\beta_1}))/\varphi(M)$ if $e_M = (\chi_1,\beta_1)$.

Proof. Constants. We use the prime number theorem for progressions of Thorner and Zaman [259] (Corollary 1.4) with its constants c_4, A_4, and the effective bound $1-\beta \ge c_{\mathrm{P}} q^{-1/2}\log^{-2} q$

for a real zero $\beta \in (0,1)$ of $L(s,\chi)$, χ real primitive of modulus $q \geq 3$ [75]. Put

$$c_5 = \min\Big(1,\ c_{\mathrm{P}} \inf_{n\geq 3} \frac{n^{1/2}}{\log^2 n}\Big) > 0, \qquad C_0 = 32,$$
$$c_3 = \min\Big(\frac{c_4}{2}, \frac{c_4^2}{4}, \frac{3}{4}\Big), \qquad A_0 = A_4 + \frac{16(14A_4+4)}{c_5};$$

the infimum is positive because $n^{1/2}\log^{-2} n \to \infty$. By definition $c_{\mathrm{P}} n^{-1/2}\log^{-2} n \geq c_5/n$ for every integer $n \geq 3$.

Choice of e_M. Let $8 \mid M$. If there is an exceptional zero β_1 modulo M in the sense of item 1 of the theorem of Thorner and Zaman, with its character χ_1, put $e_M = (\chi_1, \beta_1)$; otherwise let e_M be empty. In the first case e_M is an exceptional pair modulo M: χ_1 is real and non-principal, $L(\beta_1,\chi_1) = 0$, $\beta_1 < 1$, and $\beta_1 \geq 1 - 1/(13\log(3M)) > 1 - 1/(8\log M)$ since $13\log(3M) > 8\log M$. In particular $\beta_1 > 1 - 1/(8\log 8) > \frac{9}{10}$.

Fix $X \geq 2$ with $\log X \geq C_0 \log M \log(\log M + 2)$ and $b \geq 0$ with $\gcd(b,M) = 1$. Let $\epsilon_b = \chi_1(b) \in \{1,-1\}$ if $e_M = (\chi_1,\beta_1)$ and $\epsilon_b = 0$ if e_M is empty, and for $t \geq 1$ put

$$f_b(t) = t - \epsilon_b \frac{t^{\beta_1}}{\beta_1}, \qquad f_b'(t) = 1 - \epsilon_b t^{\beta_1 - 1} \in [0,2]$$

(read $f_b(t) = t$ when $\epsilon_b = 0$). Then the main term of the theorem of Thorner and Zaman at (t,M,b) is $f_b(t)/\varphi(M)$, and the main term of the statement is $m(X,b)$.

Step 1. Sizes. As $M \geq 8$, $\log(\log M + 2) \geq \log(\log 8 + 2) > 1.4$, so $\log X \geq 44.8 \log M$. Put $t_0 = X^{1/2}$. Then $t_0 \geq M^{12} \geq 8^{12} > e^2$, $X^{\beta_1} \geq X^{9/10} \geq 2$, $M^2 \leq X^{1/20}$ and $\log X \leq 8X^{1/20}$.

For $t \geq e^2$ one has $f_b(t) \geq 0$ and $f_b(t) \leq 3t$: if $\epsilon_b = 1$, then $t^{\beta_1 - 1}/\beta_1 \leq 1$ because $-\log\beta_1 \leq (1-\beta_1)/\beta_1 \leq 2(1-\beta_1) \leq (1-\beta_1)\log t$; and $t^{\beta_1}/\beta_1 \leq 2t$ for $t \geq 1$.

Step 2. The main term as an integral, and its lower bound. The substitution $u = t^{\beta_1}$ maps $[2,X]$ onto $[2^{\beta_1}, X^{\beta_1}] \subset (1,\infty)$ and turns $t^{\beta_1-1}dt/\log t$ into $du/\log u$; hence

$$\varphi(M)\, m(X,b) = \int_2^X \frac{f_b'(t)}{\log t}\, dt - \epsilon_b \,\mathrm{li}(2^{\beta_1}), \qquad |\mathrm{li}(2^{\beta_1})| = \int_{2^{\beta_1}}^2 \frac{dt}{\log t} \leq \frac{2 - 2^{9/10}}{\log 2^{9/10}} < 1. \tag{10.1}$$

We show

$$\varphi(M)\, m(X,b) \geq \frac{c_5 X}{2M\log X}.$$

If $\epsilon_b \in \{0,-1\}$, then $\varphi(M)m(X,b) \geq \mathrm{li}X$, because $\mathrm{li}(X^{\beta_1}) \geq 0$ as $X^{\beta_1} \geq 2$; and $\mathrm{li}X \geq (X-2)/\log X \geq X/(2\log X) \geq c_5 X/(2M\log X)$. If $\epsilon_b = 1$, then

$$\varphi(M)m(X,b) = \int_{X^{\beta_1}}^X \frac{dt}{\log t} \geq \frac{X - X^{\beta_1}}{\log X} = \frac{X\big(1 - e^{-(1-\beta_1)\log X}\big)}{\log X} \geq \frac{X\min\big(1,(1-\beta_1)\log X\big)}{2\log X},$$

using $1 - e^{-u} \geq \min(1,u)/2$ for $u \geq 0$. Let χ_1^* be the primitive character inducing χ_1, of modulus $M^* \mid M$. It is real and non-principal, so $M^* \geq 3$; and β_1 is a zero of $L(s,\chi_1^*)$, since $L(s,\chi_1) = L(s,\chi_1^*)\prod_{p\mid M}(1 - \chi_1^*(p)p^{-s})$ and the factors do not vanish at $s = \beta_1 > 0$. The effective bound gives $1 - \beta_1 \geq c_{\mathrm{P}} M^{*-1/2}\log^{-2} M^* \geq c_5/M^* \geq c_5/M$. As $\log X \geq 1$ and $c_5/M \leq 1$, the minimum is at least c_5/M, and the claim follows. Since $\varphi(M) \leq M$, we get $m(X,b) \geq c_5 X/(2M^2\log X)$, and by Step 1

$$t_0 \leq \frac{2M^2\log X}{c_5 X^{1/2}}\, m(X,b) \leq \frac{16}{c_5} X^{-2/5} m(X,b) \leq \frac{16}{c_5} e^{-c_3 \log X/\log M}\, m(X,b),$$

the last step because $c_3 \le \frac{3}{4} \le \frac{2}{5}\log 8 \le \frac{2}{5}\log M$.

Step 3. Partial summation on $(t_0, X]$. Write $\vartheta(t) = \vartheta(t; M, b)$, $\pi(t) = \pi(t; M, b)$, $R(t) = \vartheta(t) - f_b(t)/\varphi(M)$ and $I = \int_{t_0}^{X} f_b'(t)\,dt/\log t$. Partial summation (Stieltjes integration of $1/\log t$ against ϑ, and integration by parts for the C^1 function f_b) gives

$$\pi(X) - \pi(t_0) = \frac{\vartheta(X)}{\log X} - \frac{\vartheta(t_0)}{\log t_0} + \int_{t_0}^{X} \frac{\vartheta(t)\,dt}{t\log^2 t}, \qquad I = \frac{f_b(X)}{\log X} - \frac{f_b(t_0)}{\log t_0} + \int_{t_0}^{X} \frac{f_b(t)\,dt}{t\log^2 t},$$

hence

$$\pi(X) - \pi(t_0) - \frac{I}{\varphi(M)} = \frac{R(X)}{\log X} - \frac{R(t_0)}{\log t_0} + \int_{t_0}^{X} \frac{R(t)\,dt}{t\log^2 t}.$$

For $t \in [t_0, X]$ we have $t \ge M^{12}$, so item 2 of the theorem of Thorner and Zaman gives $|R(t)| \le A_4 E(t) f_b(t)/\varphi(M)$ with $E(t) = e^{-c_4\log t/\log M} + e^{-c_4(\log t)^{3/5}(\log\log t)^{-1/5}}$. Since $\log t \ge \frac{1}{2}\log X$ and $(\log t)^{3/5}(\log\log t)^{-1/5} \ge (\log t)^{1/2}$ (equivalent to $\log\log t \le (\log t)^{1/2}$),

$$E(t) \le e^{-\frac{c_4}{2}\log X/\log M} + e^{-\frac{c_4}{\sqrt{2}}\sqrt{\log X}} \le E^* := e^{-c_3\log X/\log M} + e^{-\sqrt{c_3\log X}},$$

by $c_3 \le c_4/2$ and $\sqrt{c_3} \le c_4/2$. As $f_b \ge 0$ on $[t_0, X]$ (Step 1), the bound for R and the identity for I in the first display of this step give

$$\begin{aligned}\Big|\pi(X) - \pi(t_0) - \frac{I}{\varphi(M)}\Big| &\le \frac{A_4E^*}{\varphi(M)}\Big(\frac{f_b(X)}{\log X} + \frac{f_b(t_0)}{\log t_0} + \int_{t_0}^{X}\frac{f_b(t)\,dt}{t\log^2 t}\Big)\\ &= \frac{A_4E^*}{\varphi(M)}\Big(I + \frac{2f_b(t_0)}{\log t_0}\Big) \le \frac{A_4E^*}{\varphi(M)}(I + 6t_0).\end{aligned}$$

Step 4. Assembly. By the identity of Step 2, $\varphi(M)m(X,b) = \int_2^{t_0} f_b'(t)\,dt/\log t + I - \epsilon_b\mathrm{li}(2^{\beta_1})$, so

$$\pi(X) - m(X,b) = \Big(\pi(X) - \pi(t_0) - \frac{I}{\varphi(M)}\Big) + \Big(\pi(t_0) - \frac{1}{\varphi(M)}\int_2^{t_0}\frac{f_b'(t)\,dt}{\log t}\Big) + \frac{\epsilon_b\mathrm{li}(2^{\beta_1})}{\varphi(M)}.$$

The second bracket lies in $[-3t_0, t_0]$, as $0 \le \pi(t_0) \le t_0$ and $0 \le \int_2^{t_0} f_b'(t)\,dt/\log t \le 2t_0/\log 2 \le 3t_0$; the last term is at most $1 \le t_0$ in absolute value. Moreover $I \le \varphi(M)m(X,b) + 1$, since $f_b' \ge 0$ and $|\mathrm{li}(2^{\beta_1})| < 1$; and $E^* \le 2$, $\varphi(M) \ge 1$. With Step 3,

$$|\pi(X) - m(X,b)| \le A_4E^*m(X,b) + A_4E^*(1+6t_0) + 4t_0 \le A_4E^*m(X,b) + (14A_4+4)\,t_0.$$

By Step 2, $(14A_4+4)t_0 \le \frac{16(14A_4+4)}{c_5}e^{-c_3\log X/\log M}m(X,b) \le \frac{16(14A_4+4)}{c_5}E^*m(X,b)$. Hence $|\pi(X;M,b) - m(X,b)| \le A_0E^*m(X,b)$, which is the assertion. □

Proposition 10.8. *For real $y \ge 0$, $Z \ge 1$, a prime q and $\kappa\colon \mathbb{N} \to \mathbb{C}$ put*

$$S_Z(y; q, \kappa) = \sum_{n \le Z} \Lambda(n)\min\Big(1, \frac{y}{n}\Big)\kappa(n)\Big(\frac{n}{q}\Big).$$

There is an absolute constant $C > 0$ with the following property. Let $0 < \varepsilon \le 1$ and $K \ge 1$. There is Y_0 such that the following holds for every $Y \ge Y_0$, with $Z = Y^{400K}$: for every triple (U, m_0, a_0) admissible at (ε, Y) such that every prime factor p of m_0 satisfies $p \le Y^{\varepsilon/5}$ or $p > Y^{400K}$, every $y \in [Y, Y^K]$ and every κ with $|\kappa(n)| \le 1$ for all n,

$$\sum_{q \in \mathcal{P}(m_0, a_0, U)} \big|S_Z(y; q, \kappa)\big|^2 \le C\,y\log y\,|\mathcal{P}(m_0, a_0, U)|.$$

Proof. Write $P = \mathcal{P}(m_0, a_0, U)$, $N = \lfloor Z \rfloor$, $w = Y^{\varepsilon/5}$ and $c_n = \Lambda(n)\min(1, y/n) \geq 0$, which is supported on prime powers. Take $Y_0 \geq 3$ so large that $Y^{\varepsilon/6} \geq 1600K\log Y$, $(400K\log Y)^2 \leq Y$, and item 2 of Lemma 10.6 holds with $A = 800K$, $B = K+1$; let n^* be its exceptional value.

Step 1: expansion. Since $|\kappa| \leq 1$,

$$\sum_{q\in P} |S_Z(y; q, \kappa)|^2 \leq \sum_{n,n'\leq N} c_n c_{n'} \Big|\sum_{q\in P} \Big(\frac{nn'}{q}\Big)\Big|.$$

Step 2: reciprocity. Every $q \in P$ exceeds $U^{1/2} \geq e^{800K\log Y} = Z^2 \geq nn'$. For $n, n' \leq N$ let $s(nn')$ be the product of the primes $p \nmid m_0$ that divide nn' to an odd power; it is odd (as $2 \mid m_0$), squarefree, coprime to m_0 and at most $Z^2 = Y^{800K}$. By quadratic reciprocity, $(nn'/q) = \sigma\,(q/s(nn'))$ with a sign σ independent of $q \in P$. Indeed, for $p \mid m_0$ the symbol (p/q) depends only on q modulo $8p$, hence only on $q \bmod m_0$, which is fixed (for odd p use $(p/q) = \pm(q/p)$ with the sign given by $q \bmod 4$; for $p = 2$ use $q \bmod 8$). A prime to an even power contributes 1. For odd $p \nmid m_0$, $(p/q) = \pm(q/p)$ with the sign given by $q \bmod 4$. Hence $|\sum_{q\in P}(nn'/q)| = |\sum_{q\in P}(q/s(nn'))|$.

Step 3: three classes of pairs. If $s(nn') \notin \{1, n^*\}$, Lemma 10.6 bounds the inner sum by $Y^{-K-1}|P|$. Otherwise we bound it by $|P|$. Let $\mathrm{sP}(p) = \sum_{k\geq 1,\, p^k\leq N} c_{p^k}$ and let R be the sum of c_n over the prime powers $n = p^k \leq N$ with k even or $p \mid m_0$. For prime powers $n = p^a$, $n' = p'^b$: $s(nn') = 1$ exactly when $p = p'$ and ($a + b$ even or $p \mid m_0$), or $p \neq p'$ and both p^a and p'^b have $s = 1$. So these pairs contribute at most $\sum_p \mathrm{sP}(p)^2 + R^2$. The value n^*, if it occurs, is a product of at most two primes, and the pairs with $s(nn') = n^*$ contribute at most $2B_0^2 + 2B_0R$, where $B_0 = \max_p \mathrm{sP}(p)$. Hence

$$\sum_{q\in P} |S_Z|^2 \leq \Big(\sum_p \mathrm{sP}(p)^2 + R^2 + 2B_0^2 + 2B_0R + Y^{-K-1}\Big(\sum_{n\leq N} c_n\Big)^2\Big)|P|.$$

Step 4: the four estimates. We use Chebyshev's and Mertens' estimates in the form of items 2 and 3 of Lemma 3.5, namely $\sum_{n\leq x}\Lambda(n) \leq 3x$ for $x \geq 0$ and $\sum_{n\leq x}\Lambda(n)/n \leq \log x + 3 + \log 2$ for $x \geq 1$. The sums over primes below are bounded by these estimates, by partial summation where a weight $\log p/p^2$ occurs. Hence there are absolute constants $C_1, \dots, C_4$ such that for $y \geq 3$:

1. $\mathrm{sP}(p) \leq C_2 \log y$ for every p (the terms with $p^k \leq y$ give at most $\log y$, those with $p^k > y$ form a geometric series of total at most $2y\log p/\max(p, y) \leq 2\log y$);
2. $\sum_p \mathrm{sP}(p)^2 \leq C_3\, y\log y$ (split at $p \leq \sqrt{y}$, $\sqrt{y} < p \leq y$ and $p > y$; the middle range gives $\sum_{p\leq y} 9\log^2 p \ll y\log y$, the last $\sum_{p>y} 4y^2\log^2 p/p^2 \ll y\log y$);
3. $R \leq C_1(\sqrt{y} + w\log y)$ (prime powers with even exponent contribute $\ll \sqrt{y}$; the primes $p \mid m_0$ with $p \leq N$ satisfy $p \leq w$ by hypothesis and contribute $\leq \sum_{p\leq w} \mathrm{sP}(p)$);
4. $\sum_{n\leq Z} c_n \leq C_4\, y\log Z$.

Step 5: assembly. As $\varepsilon \leq 1$ and $y \geq Y$, $w \leq y^{1/5}$ and $w\log y \leq 4\sqrt{y}$, so $R \leq 5C_1\sqrt{y}$. Then $R^2 \leq 25C_1^2 y$, $2B_0^2 \leq 4C_2^2 y\log y$, $2B_0R \leq 20C_1C_2\, y$, and, with $\log Z = 400K\log Y$, $y \leq Y^K$ and $(400K\log Y)^2 \leq Y$,

$$Y^{-K-1}\Big(\sum_{n\leq N} c_n\Big)^2 \leq C_4^2\, y^2\, Y^{-K-1}(400K\log Y)^2 \leq C_4^2\, y.$$

Since $\log y \geq 1$, the bracket is at most $(C_3 + 25C_1^2 + 4C_2^2 + 20C_1C_2 + C_4^2)\, y\log y$. □

Lemma 10.9. *Let $C \ge 0$, $\tau > 0$ and $\eta > 0$. There is Y_0 such that the following holds for every $Y \ge Y_0$, all $X \ge Y$ and $Z \ge 1$, every finite set P of primes, every $B \subseteq P$ and every κ with $|\kappa(n)| \le 1$. Suppose that*

$$\sum_{q \in P} |S_Z(y; q, \kappa')|^2 \le C\, y \log y\, |P| \qquad \text{for every } y \in [Y, X] \text{ and every } \kappa' \text{ with } |\kappa'| \le 1,$$

and that every $q \in B$ has some $y \in [Y, X]$ with $|S_Z(y; q, \kappa)| > \frac{1}{2} y^{1/2+\tau}$. Then $|B| \le \eta\, |P|$.

Proof. Fix q and write $S(y) = S_Z(y; q, \kappa)$. Since $\frac{d}{dy} \min(1, y/n) = 1/n$ for $y < n$ and 0 for $y > n$, the function S is continuous and piecewise linear, with right derivative

$$D(v) = \sum_{v < n \le Z} \frac{\Lambda(n)\kappa(n)}{n} \Big(\frac{n}{q}\Big), \qquad v\, D(v) = S_Z(v; q, \kappa \mathbf{1}_{(v,\infty)}),$$

the second identity because $\min(1, v/n) = v/n$ for $n > v$. For $i \ge 0$ with $Y_i = 2^i Y \le X$ let $I_i = [Y_i, \min(2Y_i, X)]$. For $y \in I_i$, writing $S(y) = S(Y_i) + \int_{Y_i}^{y} D(v)\, dv$, the Cauchy–Schwarz inequality gives

$$|S(y)|^2 \le 2|S(Y_i)|^2 + 2Y_i \int_{I_i} |D(v)|^2\, dv.$$

Summing over $q \in P$ and applying the hypothesis at $y = Y_i$ with κ, and at each $v \in I_i$ with $\kappa \mathbf{1}_{(v,\infty)}$ (so $\sum_q |D(v)|^2 \le C \log v\, |P|/v$),

$$\sum_{q \in P} \sup_{y \in I_i} |S(y)|^2 \le 2C Y_i \log Y_i\, |P| + 2Y_i\, C \log(2Y_i) \log 2\, |P| \le 4C\, Y_i \log(2Y_i)\, |P|.$$

A prime $q \in B$ whose large value occurs in I_i has $\sup_{I_i} |S|^2 > \frac{1}{4} Y_i^{1+2\tau}$, so there are at most $16C \log(2Y_i)\, Y_i^{-2\tau} |P|$ of them. Summing over i,

$$|B| \le 16C\, |P| \sum_{i \ge 0} \log(2^{i+1}Y)\, (2^i Y)^{-2\tau} \le \frac{16C\, (\log(2Y) + \log 2/(1 - 2^{-2\tau}))}{(1 - 2^{-2\tau})\, Y^{2\tau}}\, |P|,$$

which is at most $\eta |P|$ for $Y \ge Y_0(C, \tau, \eta)$.

□

Lemma 10.10. *For real $y \ge 0$, $Z \ge 1$ and a Dirichlet character χ put*

$$S_Z(y, \chi) = \sum_{n \le Z} \Lambda(n) \min\Big(1, \frac{y}{n}\Big) \chi(n).$$

Let $0 < \varepsilon \le \frac{1}{4}$, $\tau > 0$ and $K \ge 1$. There is Y_0 such that the following holds for every $Y \ge Y_0$, with $Z = Y^{400K}$: for every Q with $Y^{\varepsilon/6} \le \log Q \le Y^{\varepsilon/4}$ and every non-principal Dirichlet character χ of modulus $N \le Q$ with a zero-free box of height Q:

1. *$|L'(1, \chi)/L(1, \chi)| \le 251 \log Y$;*
2. *$|g(y, \chi)| \le |S_Z(y, \chi)| + Y^{\varepsilon}$ for every $y \in [Y, Y^K]$; in particular, if $|S_Z(y, \chi)| \le \frac{1}{2} y^{1/2+\tau}$ for all $y \in [Y, Y^K]$, then $|g(y, \chi)| \le y^{1/2+\tau}$ for all $y \in [Y, Y^K]$.*

Proof. Item 1. Take Y_0 with $Y_0^{\varepsilon/6} \ge l_0$ and $C_0 \le \log Y_0$, where l_0, C_0 are the constants of item 1 of Lemma 10.11. Then $\log Q \ge l_0$, and $|L'(1,\chi)/L(1,\chi)| \le 1000 \log\log Q + C_0 \le 1000 \cdot \frac{\varepsilon}{4} \log Y + \log Y \le 251 \log Y$.

The splitting identity. Let $T_Z(\chi) = -L'(1,\chi)/L(1,\chi) - \sum_{n \le Z} \Lambda(n)\chi(n)/n$. For $0 < y \le Z$,

$$S_Z(y,\chi) = \sum_{n \le y} \Lambda(n)\chi(n) + y \sum_{y < n \le Z} \frac{\Lambda(n)\chi(n)}{n},$$

and comparing with (2.2) gives

$$g(y,\chi) = -S_Z(y,\chi) - y\,T_Z(\chi) \qquad (0 < y \le Z). \tag{$*$}$$

The tail. Let $x = Y^K$, so $Z = x^{400}$; put $\eta = x^{-2}$ and $h = Z\eta$. By (2.2),

$$g(Z+h,\chi) - g(Z,\chi) = -h\,T_Z(\chi) + \sum_{Z < n \le Z+h} \Lambda(n)\chi(n)\Big(\frac{Z+h}{n} - 1\Big).$$

The last sum has at most $h+1$ terms, each of modulus at most $h\log(Z+h)/Z$. By Lemma 10.12 with $\delta = \varepsilon/(1600K) \le 1/800$ (constant K_δ), the left side is at most $K_\delta \log Q(\eta \log Q\, Z^{1-1/400+\delta} + Z^2/Q)$. Hence

$$x\,|T_Z(\chi)| \le K_\delta \log^2 Q \cdot x\, Z^{-1/400+\delta} + K_\delta \log Q\, \frac{xZ}{\eta Q} + \frac{x(h+1)\log(Z+h)}{Z}.$$

Here $xZ^{-1/400+\delta} = x^{400\delta} = Y^{\varepsilon/4}$ and $\log^2 Q \le Y^{\varepsilon/2}$, so the first term is at most $K_\delta Y^{3\varepsilon/4}$. The second is at most $K_\delta Y^{\varepsilon/4} Y^{403K} \exp(-Y^{\varepsilon/6})$, and the third is at most $2x^{-1}(400\log x + 1)$. After enlarging Y_0, each is at most $\frac{1}{3}Y^\varepsilon$, so $x|T_Z(\chi)| \le Y^\varepsilon$.

Item 2. For $y \in [Y, Y^K]$ we have $y \le x \le Z$, so by $(*)$, $|g(y,\chi)| \le |S_Z(y,\chi)| + x|T_Z(\chi)| \le |S_Z(y,\chi)| + Y^\varepsilon$. If moreover $|S_Z(y,\chi)| \le \frac{1}{2} y^{1/2+\tau}$, then $|g(y,\chi)| \le y^{1/2+\tau}$ as soon as $Y^\varepsilon \le \frac{1}{2} Y^{1/2}$, which holds for $Y \ge 16$ since $\varepsilon \le \frac{1}{4}$. □

Lemma 10.11. *1. There are absolute constants C_0 and $l_0 \ge 1$ such that for every real Q with $\log Q \ge l_0$ and every non-principal Dirichlet character χ of modulus $N \le Q$ with a zero-free box of height Q,*

$$\Big|\frac{L'(1,\chi)}{L(1,\chi)}\Big| \le 1000 \log\log Q + C_0.$$

2. Let $0 < \varepsilon < 1/52$ and $A > 0$. There is Y_0 such that for every $Y \ge Y_0$, every Q with $Y^{\varepsilon/6} \le \log Q \le A Y^{\varepsilon/5} \log^2 Y$ and every χ as in item 1,

$$\Big|\frac{L'(1,\chi)}{L(1,\chi)}\Big| \le 4 \log Y.$$

Proof. We use (A) Mertens' estimate in the form $\sum_{n \le z} \Lambda(n)/n \le \log z + 3 + \log 2$ for $z \ge 1$, item 3 of Lemma 3.5, and (B) the increment bound Lemma 10.12.

Item 1. Let K be the constant of Lemma 10.12 for $\delta = 1/4000$, and choose $l_0 \geq 81$ with $l^{1006} \leq e^l$ for $l \geq l_0$. Put $l = \log Q \geq l_0$, $z = l^{1000}$, $\eta = l^{-5}$ and $h = z\eta$, and let $P = \sum_{n\leq z} \Lambda(n)\chi(n)/n$. By (2.2),

$$g(z+h,\chi) - g(z,\chi) = h\Big(P + \frac{L'(1,\chi)}{L(1,\chi)}\Big) + \sum_{z<n\leq z+h} \Lambda(n)\chi(n)\Big(\frac{z+h}{n} - 1\Big),$$

and the last sum has at most $h+1$ terms, each of modulus at most $\log(z+h)\, h/z$. Hence

$$\Big|P + \frac{L'(1,\chi)}{L(1,\chi)}\Big| \leq \frac{Kl(\eta l z^{1-1/400+1/4000} + z^2/Q)}{h} + \frac{(h+1)\log(z+h)}{z} \leq K + K + 2.$$

By (A), $|P| \leq \log z + 3 + \log 2 = 1000 \log\log Q + 3 + \log 2$. So item 1 holds with $C_0 = 2K + 5 + \log 2$.

Item 2. If $Y^{\varepsilon/6} \geq l_0$, item 1 applies, and $\log\log Q \leq \log A + \frac{\varepsilon}{5}\log Y + 2\log\log Y$. Thus

$$\Big|\frac{L'(1,\chi)}{L(1,\chi)}\Big| \leq 200\varepsilon \log Y + 2000 \log\log Y + 1000 \log A + C_0.$$

Since $\varepsilon < 1/52$, $200\varepsilon \log Y \leq \frac{50}{13}\log Y$. Choose Y_0 so that for $Y \geq Y_0$: $Y^{\varepsilon/6} \geq l_0$, $2000\log\log Y \leq \frac{1}{13}\log Y$ and $1000\log A + C_0 \leq \frac{1}{13}\log Y$. Then the right side is at most $(\frac{50}{13} + \frac{2}{13})\log Y = 4\log Y$. This is where the bound $\varepsilon < 1/52$ on the window parameter enters: $1000 \cdot \varepsilon/5 < 4$ with room $\frac{2}{13}\log Y$ for the lower-order terms. □

Lemma 10.12. *For every δ with $0 < \delta \leq 1/800$ there is $K \geq 0$ such that for every non-principal Dirichlet character χ of modulus N, every $Q \geq 2$ with $N \leq Q$ such that χ has a zero-free box of height Q, every $z \geq 1$ and every $\eta \in (0,1]$,*

$$|g(z(1+\eta),\chi) - g(z,\chi)| \leq K \log Q\Big(\eta \log Q \cdot z^{1-1/400+\delta} + \frac{z^2}{Q}\Big).$$

Proof. Write $\sigma_1 = 1 - \frac{1}{400} + \delta$, $T = Q/2$ and $F(y,w) = -\frac{L'}{L}(w,\chi)\,\frac{y^w}{w(w-1)}$. Three inputs are used. (P) Perron's formula for the Riesz kernel, Lemma 10.13, with $c = 2$ and $a_n = \Lambda(n)\chi(n)$: here $\sum_n |a_n| n^{-2} \leq \sum_n \Lambda(n) n^{-2} < \infty$ and $\sum_n a_n n^{-w} = -\frac{L'}{L}(w,\chi)$ for $\operatorname{Re} w > 1$, so for $y \geq 1$

$$\sum_{n\leq y} \Lambda(n)\chi(n)\Big(\frac{y}{n} - 1\Big) = \frac{1}{2\pi i}\int_{(2)} F(y,w)\, dw.$$

(L) The bound Lemma 10.14 for the logarithmic derivative in a zero-free box (its hypotheses $0 < \delta \leq 1/800$, $Q \geq 2$, $N \leq Q$, χ non-principal with a zero-free box of height Q are those of the statement): with $K_B = K_B(\delta) = 100/\delta^2$, $|L'/L(w,\chi)| \leq K_B \log Q$ for $\sigma_1 \leq \operatorname{Re} w \leq 2$, $|\operatorname{Im} w| \leq Q - 1$, for every χ and Q as in the statement. (R) $|L'/L(2+it,\chi)| \leq C_0 := -\zeta'(2)/\zeta(2) = \sum_n \Lambda(n) n^{-2}$, by the Dirichlet series of $-L'/L$.

Contour shift. $L(w,\chi)$ has no zero in the rectangle $\sigma_1 \leq \operatorname{Re} w \leq 2$, $|\operatorname{Im} w| \leq T$ (it lies in the box, as $T \leq Q$), and χ is non-principal, so that $L(w,\chi)$ is entire [180] and the only pole of $F(y,\cdot)$ there is $w = 1$, with residue $-y\,L'(1,\chi)/L(1,\chi)$. By Cauchy's theorem, for $y \geq 1$,

$$g(y,\chi) = \frac{1}{2\pi i}\Big(\int_{\substack{\operatorname{Re} w = 2 \\ |\operatorname{Im} w| > T}} + \int_{[2-iT,\sigma_1-iT]} + \int_{[\sigma_1+iT,2+iT]} + \int_{[\sigma_1-iT,\sigma_1+iT]}\Big) F(y,w)\, dw,$$

since $g(y,\chi)$ is the left side of (P) plus $y\,L'(1,\chi)/L(1,\chi)$ (by (2.2)).

The four pieces, for $y_1 = z(1+\eta)$ and $y_0 = z$, both in $[1,2z]$. Take the difference of the identity at y_1 and y_0.

- Vertical tails: by (R) and $|w(w-1)| \ge t^2$, each is at most $C_0 y^2 \int_{|t|>T} t^{-2}dt \le 4C_0 z^2 \cdot 2/T = 16C_0 z^2/Q$.
- Horizontal segments (length ≤ 2): by (L), as $T \le Q-1$, and $|w(w-1)| \ge T^2$, each is at most $2K_B \log Q \cdot 4z^2/T^2 \le 16K_B \log Q\, z^2/Q$ (using $Q \ge 2$).
- Left side: for $\operatorname{Re} w = \sigma_1 \le 1$ and $0 < \eta \le 1$, $|y_1^w - y_0^w| = z^{\sigma_1}|(1+\eta)^w - 1| \le 2\eta|w|z^{\sigma_1}$, so by (L) the difference of the two left integrals is at most $2\eta z^{\sigma_1} K_B \log Q \int_{-T}^{T} \frac{du}{|\sigma_1 - 1 + iu|} \le 2\eta z^{\sigma_1} K_B \log Q\,(2 + 2\log(1+800T))$, because $1-\sigma_1 \ge 1/800$; and $\log(1+800T) \le 10 \log Q$ for $Q \ge 2$.

Adding up, with $\log Q \ge \log 2$,

$$|g(y_1,\chi) - g(y_0,\chi)| \le K \log Q(\eta \log Q\, z^{\sigma_1} + z^2/Q)$$

with $K = K(\delta)$ depending only on $K_B(\delta)$ and C_0 (for instance $K = 60K_B + 40C_0$).

□

Lemma 10.13. *Let $c > 1$, let $(a_n)_{n\ge1}$ be complex numbers with $\sum_{n\ge1} |a_n| n^{-c} < \infty$, and put $F(w) = \sum_{n\ge1} a_n n^{-w}$ for $\operatorname{Re} w = c$. Then for every real $y > 0$ the integral below converges absolutely and*

$$\sum_{n \le y} a_n \Big(\frac{y}{n} - 1\Big) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} F(w)\, \frac{y^w}{w(w-1)}\, dw.$$

Proof. The kernel. For $a > 0$ let $I(a) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{a^w}{w(w-1)}\, dw$. On $\operatorname{Re} w = c$ we have $|a^w| = a^c$ and $|w(w-1)| \ge \max(c(c-1), |\operatorname{Im} w|^2)$, so the integral converges absolutely, and $I(a) = \lim_{T\to\infty} \frac{1}{2\pi i} \int_{c-iT}^{c+iT}$. We show $I(a) = \max(a-1, 0)$. Let $T > c+1$.

- If $a \ge 1$, apply Cauchy's residue theorem to the rectangle with vertices $c \pm iT$, $-T \pm iT$. The integrand has simple poles at $w = 0$ and $w = 1$, with residues -1 and a. On the left side $\operatorname{Re} w = -T$ we have $|a^w| = a^{-T} \le 1$ and $|w(w-1)| \ge T^2$, so its integral is at most $2T/T^2$; on the two horizontal sides $|a^w| \le a^c$ and $|w(w-1)| \ge T^2$, so each integral is at most $(T+c)a^c/T^2$. Letting $T \to \infty$ gives $I(a) = a - 1$.
- If $0 < a < 1$, use the rectangle with vertices $c \pm iT$, $T \pm iT$, which contains no pole. On the right side $|a^w| = a^T \le 1$ and $|w(w-1)| \ge T(T-1)$, so its integral is at most $2T/(T(T-1))$; on the horizontal sides $|a^w| \le a^c \le 1$ and $|w(w-1)| \ge T^2$, so each integral is at most T/T^2. Letting $T \to \infty$ gives $I(a) = 0$.

The series. By hypothesis

$$\sum_{n\ge1} \int_{c-i\infty}^{c+i\infty} \Big| a_n \Big(\frac{y}{n}\Big)^w \frac{1}{w(w-1)} \Big|\, |dw| = y^c \sum_{n\ge1} |a_n| n^{-c} \int_{-\infty}^{\infty} \frac{dt}{|(c+it)(c-1+it)|} < \infty,$$

so summation and integration may be interchanged (Fubini), and the integral in the statement converges absolutely and equals $\sum_{n\ge1} a_n I(y/n)$. By the first part, $I(y/n) = y/n - 1$ for $n \le y$ and $I(y/n) = 0$ for $n > y$. □

Lemma 10.14. *Let $0 < \delta \le 1/800$ and $Q \ge 2$, and let χ be a non-principal Dirichlet character of modulus $N \le Q$ with a zero-free box of height Q. Then for every w with $1 - \frac{1}{400} + \delta \le \operatorname{Re} w \le 2$ and $|\operatorname{Im} w| \le Q - 1$,*

$$\Big|\frac{L'(w,\chi)}{L(w,\chi)}\Big| \le \frac{100}{\delta^2}\log Q.$$

Proof. Growth. Let $A(u) = \sum_{n \le u} \chi(n)$; since χ is non-principal, the sum over any N consecutive integers vanishes, so $|A(u)| \le N$. For $\operatorname{Re} s > 1$, partial summation gives $L(s,\chi) = s\int_1^\infty A(u)u^{-s-1}\,du$; the integral converges absolutely and locally uniformly on $\operatorname{Re} s > 0$, so both sides are holomorphic there and, $L(s,\chi)$ being entire [180], they agree on $\operatorname{Re} s > 0$. Hence

$$|L(s,\chi)| \le \frac{N|s|}{\operatorname{Re} s} \qquad (\operatorname{Re} s > 0). \tag{10.2}$$

The centre. For $\operatorname{Re} s_0 = \frac{3}{2}$, $1/L(s_0,\chi) = \sum_{n\ge1}\mu(n)\chi(n)n^{-s_0}$, so $|L(s_0,\chi)| \ge 1/\zeta(\frac{3}{2}) \ge \frac{1}{3}$, because $\zeta(\frac{3}{2}) \le 1 + \int_1^\infty u^{-3/2}\,du = 3$.

The disc. Fix w as in the statement, let $t = \operatorname{Im} w$, $s_0 = \frac{3}{2} + it$, $R = \frac{1}{2} + \frac{1}{400} - \frac{\delta}{2}$ and $r = |w - s_0| = |\operatorname{Re} w - \frac{3}{2}|$. As $1 - \frac{1}{400} + \delta \le \operatorname{Re} w \le 2$ and $\delta < \frac{1}{400}$,

$$r \le \max\Big(\tfrac{1}{2} + \tfrac{1}{400} - \delta,\ \tfrac{1}{2}\Big) = \tfrac{1}{2} + \tfrac{1}{400} - \delta = R - \tfrac{\delta}{2}.$$

Every s with $|s - s_0| \le R$ has $\operatorname{Re} s \ge \frac{3}{2} - R = 1 - \frac{1}{400} + \frac{\delta}{2}$ and $|\operatorname{Im} s| \le Q - 1 + R < Q$. So the closed disc $\overline{D} = \{|s - s_0| \le R\}$ lies in the open set $U = \{\operatorname{Re} s > 1 - \frac{1}{400},\ |\operatorname{Im} s| < Q\}$, on which $L(\cdot,\chi)$ is holomorphic and, by the zero-free box, has no zero. Choose $R' > R$ with $\{|s - s_0| < R'\} \subseteq U$. On this disc, which is simply connected, there is a holomorphic h with $e^{h(s)} = L(s,\chi)/L(s_0,\chi)$ and $h(s_0) = 0$; then $h' = L'/L$ and $\operatorname{Re} h(s) = \log|L(s,\chi)| - \log|L(s_0,\chi)|$.

The bound for $\operatorname{Re} h$. For $s \in \overline{D}$ we have $\operatorname{Re} s \ge \frac{1}{2}$ and $|s| \le (\frac{3}{2} + R) + Q \le Q + 3$, so by (10.2) and $N \le Q$, $|L(s,\chi)| \le 2Q(Q+3) \le 5Q^2$ (as $Q \ge 2$). Hence, with the centre bound, $\operatorname{Re} h \le \log(15Q^2) \le M := 6\log Q$ on $\overline{D}$, because $15 \le Q^4$ for $Q \ge 2$.

Borel–Carathéodory. Let $g(z) = h(s_0 + z)$ for $|z| \le R$; then $g(0) = 0$ and $\operatorname{Re} g \le M$. By the Borel–Carathéodory lemma [180], $|g(z)| \le 2\rho M/(R - \rho)$ for $|z| \le \rho < R$. For $|z| \le r$ put $\rho = (R + r)/2$; the circle of radius $(R - r)/2$ about z lies in $\{|\zeta| \le \rho\}$, and Cauchy's estimate gives

$$|g'(z)| \le \frac{2}{R - r}\cdot\frac{2\rho M}{R - \rho} = \frac{8\rho M}{(R-r)^2} \le \frac{8RM}{(R-r)^2}.$$

At $z = w - s_0$, with $R - r \ge \delta/2$ and $R < 0.51$,

$$\Big|\frac{L'(w,\chi)}{L(w,\chi)}\Big| = |g'(w - s_0)| \le \frac{8\cdot 0.51\cdot 6\log Q}{\delta^2/4} \le \frac{100}{\delta^2}\log Q.$$

□

Lemma 10.15. *There is an absolute constant C_z such that for every real $Q \ge 3$ at most $C_z Q^{1/4}$ primitive Dirichlet characters of modulus at most Q have a zero s with $\operatorname{Re} s > 1 - \frac{1}{400}$ and $|\operatorname{Im} s| \le Q$.*

Proof. Put $\alpha = 1 - \frac{1}{400}$ and $T = Q \ge 3$. Let χ be primitive of modulus at most Q with a zero s_0 such that $\operatorname{Re} s_0 > \alpha$ and $|\operatorname{Im} s_0| \le Q$. For $\operatorname{Re} s > 1$ the Euler product of $L(s,\chi)$ converges absolutely and its factors are non-zero, so $\operatorname{Re} s_0 \le 1$; hence s_0 is counted by $N(\alpha, Q, \chi)$,

and $N(\alpha,Q,\chi)\ge 1$. By Montgomery's density theorem ([179, Theorem 12.2], quoted as Theorem B.8), as $3(1-\alpha)/(2-\alpha)=3/401$ and $Q^2T=Q^3$, the number of such χ is at most

$$\sum_{q\le Q}\sideset{}{^*}\sum_{\chi \bmod q} N(\alpha,Q,\chi)\le C_{\mathrm{M}}\,Q^{9/401}(\log Q^2)^9 = 2^9 C_{\mathrm{M}}\,Q^{9/401}(\log Q)^9.$$

Since $\frac14-\frac{9}{401}=\frac{365}{1604}>0$, the number $B=\sup_{Q\ge 3}(\log Q)^9Q^{-365/1604}$ is finite, and the count is at most $C_zQ^{1/4}$ with $C_z=2^9C_{\mathrm{M}}B$. □

11 Good hosts

A host satisfies the host conditions, but Parts III and IV need more of it: integers that fix the ranks of the lattices, a set of tops, a spacing set, auxiliary primes and analytic estimates beyond the scale x. The concrete good-host requirement (Definition 11.4) lists these data as existential witnesses with the conditions (Hg1)–(Hg8), and Proposition 11.5 proves that it supplies good hosts: for every host built on a good window pair, with the sizes of Section 9, the witnesses exist. This is clause (Gh1) of Proposition 17.6, the requirement for which the class of Part III is designed, and through Proposition 7.9 it is hypothesis (Sb) of Proposition 9.1. The proof of Proposition 11.5 takes the witnesses one condition at a time, each from its own result, and the definitions 11.1 and Definition 11.2 fix the sizes: $|A|$ of order $x^{2+8\varepsilon}$, $\sqrt{x\delta_1}\le m\le 2\sqrt{x\delta_1}$ with $\delta_1=x^{-\varepsilon/8}$, and k of order $x^{9/2+10\varepsilon}$.

Three results carry the weight. Proposition 11.11 chooses the tops at random, with density δ_1 on A_0 and $\frac34\delta_1$ off it. Chebyshev's inequality on the o cosets of A_0 gives the shares $4/(3o+1)$ and $3/(3o+1)$ of (Ec4), which produce the weight $(3o+1)^{-1}$ in $G_{\mathfrak{L}_\psi}$, and a first-moment bound with Markov's inequality gives few bad tops along the Frobenius orbits of the inert primes. Proposition 11.12 gives the spacing set: a set of about n_0/L_w small integers, up to a factor $\exp\bigl(-C\sqrt{\log n_0\log L_w}\bigr)$, without any relation $j(s_2-s_1)=i(s_3-s_1)$ with $0<|i|,|j|\le L_w$. Its proof is Behrend's construction of large sets without three-term progressions [20], with the base enlarged so that the relations with small coefficients are excluded as well. Proposition 11.9 gives the level primes: two primes g_1,g_2 of size about $\bigl(k\exp(x^{\varepsilon})\bigr)^8$ that are norms from $\mathbb{Q}(\sqrt{-d})$ of elements congruent to 1 modulo the host modulus, with disjoint exceptional sets (Lemma 11.10), and small primes p_1,p_2,q_0 congruent to 1 modulo it. It uses the Chebotarev density theorem of Thorner and Zaman (Theorem B.10) and ray class fields. In the proof of Proposition 11.5 the prime q_0 is taken instead from Linnik's theorem (Lemma 11.14). The primes g_1,g_2 are the auxiliary primes of the slope records of the packets in Part IV (Definition 19.1).

The other conditions are routine. Rank data with the rank sizes exist on every frame of the right order, with $t\le x^{400}$ (Lemma 11.6), and the primes of a window pair exceed $4tr+1$ (Lemma 11.7). The field of a normalised host is CM, contains a square root of $-d$, and its relative different over $\mathbb{Q}(\sqrt{-d})$ is the product of two conjugate coprime ideals (Lemma 11.13). The zero-free boxes of (Hg7) and the estimates at the scale in (Hg8) are those of a good window pair. The last estimate of (Hg8), a saving $\exp(-c\,x^{\varepsilon/8})$ for every character of the host at arguments $y\ge\frac13\exp(x^{\varepsilon/3})$, is Proposition 11.8, a Chebyshev-type bound that uses the absence of real zeros near 1 guaranteed by the boxes; it matches the thin-scale property (Sp7) of slope records.

Definition 11.1. A **rank datum** is a tuple $\mathfrak{R}=(e,A,h,a_0;k,m,t)$ consisting of a frame (e,A,h,a_0) and integers k,m,t such that

(R1) k and m are even and t is odd;

(R2) $2\le m$, $m+3\le k$, $k+m+4\le t$ and $3m<t$;

(R3) $m \le 2|A| \le k$;

(R4) $m^2 \le k + m(t+1)$.

Its **derived ranks** are

$$f = 2|A|, \qquad r = k + m - 1, \qquad n_V = r + t, \qquad r_S = \tfrac{m}{2} - 1, \qquad k_j = k + j(t+1) \quad (j \ge 0),$$

and its **signatures** are $\mathrm{sig}_Y = (k + r_S,\, r_S + 1)$ and $\mathrm{sig}_W(j) = (k + j - 1,\, m - j)$ for $1 \le j \le m$.

A **Harish-Chandra parameter** for $\mathfrak{R}$ is a tuple $(u, v, b, \tilde{b})$ with $u \in (\frac{1}{2} + \mathbb{Z})^k$, $v \in \mathbb{Z}^{k-1}$ and $b, \tilde{b} \in \mathbb{Z}^m$ such that

(Pa1) $u_1 > v_1 > u_2 > v_2 > \cdots > v_{k-1} > u_k > -b_1$;

(Pa2) $\tilde{b}_j - b_j \ge \frac{t+3}{2}$ for $1 \le j \le m$, and $b_{j+1} - \tilde{b}_j \ge \frac{t+3}{2}$ for $1 \le j < m$.

Its **shift exponents** are the integers $s_j^\sharp = \tilde{b}_j - \frac{1}{2}k_j$ and $s_j^\flat = \tilde{b}_j - \frac{1}{2}k_{j-1}$ for $1 \le j \le m$.

Definition 11.2. A **scale** is a triple $\mathfrak{s} = (x, \varepsilon, J)$ of real numbers such that

$$x > 1, \qquad 0 < \varepsilon < \frac{1}{52}, \qquad J \ge 1.$$

For this scale put

$$L(\mathfrak{s}) = x^{\varepsilon}, \qquad \delta_1(\mathfrak{s}) = x^{-\varepsilon/8}, \qquad \varepsilon_z(\mathfrak{s}) = \frac{\varepsilon}{J}.$$

For a rank datum $\mathfrak{R}$ with derived ranks f, r, define the integer

$$n_W(\mathfrak{R}, \mathfrak{s}) = 8 \left\lceil \frac{10r}{8} \left(f + \frac{f^2 (k-1)^3 L(\mathfrak{s})^2}{m} \right) \right\rceil.$$

The rank datum $\mathfrak{R}$ has the **rank sizes at** $\mathfrak{s}$ if

$$\begin{aligned} x^{2+8\varepsilon} &\le |A| \le 2x^{2+8\varepsilon}, \\ \sqrt{x\delta_1(\mathfrak{s})} &\le m \le 2\sqrt{x\delta_1(\mathfrak{s})}, \\ x^{9/2+10\varepsilon} &\le k \le 2x^{9/2+10\varepsilon}, \\ r + t &= 8fr + 4 + \lceil x^{377} \rceil\, n_W(\mathfrak{R}, \mathfrak{s}). \end{aligned}$$

Definition 11.3. Fix a host $\mathfrak{h}$ for a frame with group A, a set $T \subseteq A$, real numbers $x > 1$ and $0 < \varepsilon < 1/52$, an integer $k \ge 1$, and a total ordering of the finite set A. At each inert prime p, choose $\rho_p(t)$ to be the least element, in this ordering, of the coset containing t of $\langle h_p \rangle$ if p is not sign-changing, and of $\langle 2h_p \rangle$ if p is sign-changing. Thus ρ_p, R_p and $P_p(v)$ are the choices of Definition 5.1 determined by this ordering.

The following auxiliary constants are used only in this definition. Put

$$\begin{aligned} \delta_{\mathrm{orb}} &= x^{-\varepsilon/8}, & h_{\mathrm{orb}} &= 2 + 8\varepsilon, \\ K_{\mathrm{orb}} &= \left\lceil \frac{8(h_{\mathrm{orb}} + 2)}{\varepsilon} \right\rceil, & r_{\mathrm{orb}} &= K_{\mathrm{orb}} + 1, \\ u_{\mathrm{orb}} &= \lceil 1/\delta_{\mathrm{orb}} \rceil, & \ell_{\mathrm{orb}} &= (6r_{\mathrm{orb}} + 1)u_{\mathrm{orb}}, \\ M_{\mathrm{orb}} &= \left\lceil (h_{\mathrm{orb}} + 3) \log x\, 10^{6r_{\mathrm{orb}}+1} \right\rceil, & G_{\mathrm{orb}} &= (M_{\mathrm{orb}} + 5)\ell_{\mathrm{orb}}, \\ N_{\mathrm{orb}} &= \left\lceil \max\left(6\exp(1) G_{\mathrm{orb}} \delta_{\mathrm{orb}},\ (h_{\mathrm{orb}} + 3)\frac{\log x}{\log 2} \right) \right\rceil + 1. \end{aligned}$$

Define also the even nonnegative integer

$$L_{\mathrm{orb}} = 2\max\left(\{0\} \cup \left\{ \left\lceil \frac{\log((kx^{26})^4)}{\log p} \right\rceil : p \text{ is inert and not sign-changing} \right\}\right).$$

The maximum exists, since all its entries are nonnegative integers at most $\lceil \log((kx^{26})^4)/\log 2 \rceil$. The adjoined 0 gives the value when there is no such prime.

For a positive integer n and $P \subseteq \{0, \dots, n-1\}$ consider the following three finite conditions. Here and below the residue modulo n is taken in $\{0, \dots, n-1\}$, and all interval endpoints and quantified indices are integers.

(Go1) For every $0 \le i < n$,

$$|P \cap \{(i+j) \bmod n : 0 \le j < L_{\mathrm{orb}}\}| \le K_{\mathrm{orb}}.$$

(Go2) Put $B = \lfloor n/\ell_{\mathrm{orb}} \rfloor$. For every $0 \le s_0 < B$ there is an integer j with $0 \le j \le M_{\mathrm{orb}}$ such that, for $s = (s_0 + j) \bmod B$ and every $1 \le c \le 6r_{\mathrm{orb}} + 1$, the set

$$P \cap \{s\ell_{\mathrm{orb}} + (c-1)u_{\mathrm{orb}}, \dots, s\ell_{\mathrm{orb}} + cu_{\mathrm{orb}} - 1\}$$

is empty when c is odd and is a singleton whose element is even when c is even. This condition is vacuous if $B = 0$. These intervals do not wrap modulo n.

(Go3) For every $0 \le i < n$,

$$|P \cap \{(i+j) \bmod n : 0 \le j < G_{\mathrm{orb}}\}| \le N_{\mathrm{orb}}.$$

The **good representatives selected by the finite conditions** are

$$G_p = \{v \in R_p : \ P_p(v) \text{ satisfies (Go1)–(Go3) with } n = \mathrm{ord}(h_p)\}.$$

The parity in (Go2) refers to integer positions relative to the chosen representative. These choices depend on the ordering of A.

For a real number $C_b > 0$, these choices satisfy the **bad-top bound with constant** C_b if

$$\sum_{\substack{p \text{ inert, not sign-changing} \\ p < \exp(x^{\varepsilon/3}) \\ \mathrm{ord}(h_p) \ge x^{\varepsilon/4}}} \frac{\log p}{p} \left|\{t \in T : \rho_p(t) \notin G_p\}\right| \le 4C_b x^{-2} \delta_{\mathrm{orb}} |A| \sum_{\substack{p \text{ inert, not sign-changing} \\ p < \exp(x^{\varepsilon/3}) \\ \mathrm{ord}(h_p) \ge x^{\varepsilon/4}}} \frac{\log p}{p}.$$

Both sums are finite and have the same prime range.

Definition 11.4. The following defines a predicate $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$, the **concrete good-host requirement**. It is false unless $x > 1$, $0 < \varepsilon < 1/52$, $J \ge 1$, $\mathfrak{h}$ is a host for a frame (e, A, h, a_0), $T \subseteq A$, t is an integer, and the finite real list κ has the form

$$\kappa = (C_{T_2}, C_8, C_5, c_6, C_b), \qquad C_8 \ge 1, \quad C_5 > 0, \quad c_6 > 0, \quad C_b > 0.$$

There is no sign restriction on C_{T_2}. For such inputs put $\mathfrak{s} = (x, \varepsilon, J)$, $E = E_{\mathfrak{h}}$ and

$$n_0 = |A_0|, \qquad Q_{\mathrm{odd}} = Q_S / 2^{v_2(Q_S)}, \qquad L_w = 10\lceil 405 \log x \rceil + 2\lceil 30/\varepsilon \rceil + 22.$$

Here $v_2(Q_S)$ is the exponent of 2 in the positive integer Q_S.

The predicate holds precisely when there exist a rank datum $\mathfrak{R} = (e, A, h, a_0; k, m, t)$, a total ordering of A, an integer $B \ge 0$, an element $s_d \in E$, a field embedding $\varphi_0 : E \hookrightarrow \mathbb{C}$, an integral ideal $\mathfrak{b}$ of E, five primes g_1, g_2, p_1, p_2, q_0, a finite set S of nonnegative integers, an element $u_0 \in A$ and a real number Y satisfying the following conditions. The integer L_w, the prime ℓ_0 and the set of level primes in (Hg5) are not among these data: they are given by explicit formulas.

(Hg1) Rank and host. The datum $\mathfrak{R}$ has the rank sizes at $\mathfrak{s}$, the host $\mathfrak{h}$ is normalised and has field rows up to B, and

$$4tr+1<q, \qquad 4tr+1<d, \qquad B\geq \left\lfloor x^{\varepsilon/(5J)}\right\rfloor, \qquad J\leq C_8, \quad o\leq C_8, \quad Q_S\leq C_8|A|.$$

(Hg2) Quadratic subfield and relative different. The field E is CM. Under the identification of Galois groups given by the host,

$$s_d^2=-d, \qquad \sigma(s_d)=\epsilon_2(\sigma)s_d \quad (\sigma\in \mathrm{Gal}(E/\mathbb{Q})), \qquad \varphi_0(s_d)=\sqrt{-1}\sqrt{d}.$$

Write $K=\mathbb{Q}(s_d)\subseteq E$ and use a bar for complex conjugation on E. The relative different satisfies

$$\mathcal{D}_{E/K}=\mathfrak{b}\bar{\mathfrak{b}}, \qquad \mathfrak{b}+\bar{\mathfrak{b}}=\mathcal{O}_E, \qquad \sigma(\mathfrak{b})=\mathfrak{b} \quad \big(\sigma\in\mathrm{Gal}(E/\mathbb{Q}),\ \epsilon_2(\sigma)=1\big).$$

The chosen CM type is the set of embeddings $\varphi: E\hookrightarrow\mathbb{C}$ with $\varphi(s_d)=\sqrt{-1}\sqrt{d}$. The auxiliary ideal in K is $\mathcal{O}_K$.

(Hg3) Tops and the spacing set. With $\delta_1=\delta_1(\mathfrak{s})$,

$$\tfrac{1}{2}\delta_1|A|\leq|T|\leq 2\delta_1|A|, \qquad x^{-\varepsilon}|A|\leq|S|, \qquad 4L_w|S|\leq n_0,$$

and

$$\frac{n_0}{L_w}\exp\Big(-C_{T_2}\sqrt{\log n_0\log L_w}\Big)\leq|S|.$$

Every $s\in S$ satisfies $4L_ws<n_0$. For pairwise distinct $s_1,s_2,s_3\in S$ and integers $i\neq j$ with $0<|i|,|j|\leq L_w$,

$$j(s_2-s_1)\neq i(s_3-s_1).$$

The associated thick places in $\ker\epsilon_2$ are $\{((-1,1),sa_0+u_0): s\in S\}$.

(Hg4) Good representatives. Choose ρ_p and G_p by Definition 11.3, using the given total ordering of A and the parameters (x,ε,k). They satisfy its bad-top bound with constant C_b.

(Hg5) Auxiliary and level primes. The primes g_1,g_2 are distinct. The primes p_1,p_2 are distinct and different from both g_1,g_2. We have $q_0\neq p_1,p_2$ and

$$(k\exp(x^\varepsilon))^8\leq g_i\leq 2(k\exp(x^\varepsilon))^8 \quad (i=1,2), \qquad p_1,p_2,q_0\leq N_{\mathfrak{h}}^{C_8},$$

$$g_i\equiv 1 \pmod{N_{\mathfrak{h}}} \quad (i=1,2), \qquad p_1,p_2\equiv 1 \pmod{\mathrm{lcm}(15,N_{\mathfrak{h}})},$$
$$q_0\equiv 1 \pmod{\ell_0N_{\mathfrak{h}}},$$

where ℓ_0 is the least prime not dividing $N_{\mathfrak{h}}(p_1-1)(p_2-1)$ (it exists since $p_1,p_2\geq 2$). For each $i=1,2$ there exists $\pi_i\in\mathcal{O}_E\cap K$ with

$$\pi_i\bar{\pi}_i=g_i, \qquad \pi_i-1\in N_{\mathfrak{h}}\mathcal{O}_E.$$

The primes p_1,p_2 split completely in E. The level primes are exactly $\{g_1,g_2,p_1,p_2,q_0\}$, and every one of them splits in K. The following two sets, for $i=1$ and $i=2$, are disjoint:

$$\{g_i\}\ \cup\ \{\ell:\ \ell \text{ is prime and there is an integer } 1\leq a\leq r \text{ with } g_i^a<\ell^{4v_\ell(g_i^a-1)}\}.$$

Here v_ℓ is the exponent of the prime ℓ in a positive integer.

(Hg6) A common scale for the pair and the boxes. One has $x^{1/J} \le Y \le x$. For use in (Hg6) and (Hg7), put

$$X_1 = \exp(Y^{\varepsilon/5}), \qquad X_2 = \exp(Y^{\varepsilon/5}(\log Y)^2).$$

Then

$$\sqrt{X_1} < q \le X_1, \qquad \sqrt{X_2} < d \le X_2, \qquad (-d/p) = 1 \quad (p \text{ prime},\ p \le Y^{\varepsilon/5}),$$

and $\log N_{\mathfrak{h}} \le 2Y^{\varepsilon/5}(\log Y)^2$. The congruences $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$ and $(-d/q) = 1$ are part of the host conditions.

(Hg7) Zero-free boxes. For every fundamental discriminant D below, let $\chi_D(n) = (D/n)$ be its primitive quadratic Dirichlet character. For $D = -q, -8q$, require $|D| \le 8X_1$ and a zero-free box of height $8X_1$ for χ_D. For $D = -d, -8d, qd, 8qd$, require $|D| \le 8X_1X_2$ and a zero-free box of height $8X_1X_2$ for χ_D. By the congruences in (Hg6), all these integers are fundamental discriminants.

For every character θ of $\mathcal{G}$ such that χ_θ^* is real, write $\mathrm{cond}(\chi_\theta^*)$ for its positive modulus. If $d \mid \mathrm{cond}(\chi_\theta^*)$, require

$$\mathrm{cond}(\chi_\theta^*) \le 8Q_{\mathrm{odd}}X_1X_2 \quad \text{and a zero-free box of height } 8Q_{\mathrm{odd}}X_1X_2 \text{ for } \chi_\theta^*.$$

If $q \mid \mathrm{cond}(\chi_\theta^*)$ and $d \nmid \mathrm{cond}(\chi_\theta^*)$, require

$$\mathrm{cond}(\chi_\theta^*) \le 8Q_{\mathrm{odd}}X_1 \quad \text{and a zero-free box of height } 8Q_{\mathrm{odd}}X_1 \text{ for } \chi_\theta^*.$$

(Hg8) Character estimates. For $D = -q, -d, qd$, with the primitive quadratic characters of (Hg7),

$$|g(x, \chi_D)| \le x^{1/2+\varepsilon}, \qquad \left|\frac{L'(1, \chi_D)}{L(1, \chi_D)}\right| \le C_5 \log x.$$

In addition,

$$\left|\mathrm{Re}\,\frac{L'(1, \chi_{-d})}{L(1, \chi_{-d})}\right| \le x^{\varepsilon}.$$

For every character θ of $\mathcal{G}$ and every real $y \ge \frac{1}{3}\exp(x^{\varepsilon/3})$,

$$|g(y, \chi_\theta^*)| \le y \exp(-c_6 x^{\varepsilon/8}).$$

Proposition 11.5. *Let $\mathfrak{G}$ be the good-host requirement obtained by restricting the concrete good-host requirement to integers $t \ge 1$. Then $\mathfrak{G}$ supplies good hosts.*

Proof. Let $\psi \in \mathcal{P}$ have modulus N; we show that $\mathfrak{G}$ supplies good hosts for ψ.

Choice of κ and x_B. Fix $\varepsilon \in (0, 1/52)$ and $C_0 \ge 1$. Take: $C \ge 1$ and x_0^{lv} from Proposition 11.9 for ε; $C_b > 0$ and x_0^{tp} from Proposition 11.11 for ε, C_0; C_T and x_0^{th} from Proposition 11.12 for ε, C_0; $c > 0$ and x_0^{ch} from Proposition 11.8 for $B = C_0$ and ε; x_B^{sz}, the number x_B of Lemma 11.7 for ε, C_0. Let $A \ge 1$ be the absolute exponent of Theorem B.9 (as in Lemma 11.14) and $X_* = \exp(1 + 2(3 + 2C)A/(4\varepsilon/5)^3)$, the cutoff of Lemma 11.14 for ε and its parameter $C_8 := C$. Let $x_6 \ge 1$ be such that for every $x \ge x_6$

$$4\log x \le x^{\varepsilon}, \qquad \log(2C_0) + 3\log x \le 15\, x^{\varepsilon/(5C_0)}, \qquad C_0 \le x^{\varepsilon/(5C_0)};$$

it exists because $\log x = o(x^\delta)$ for every $\delta > 0$. Put

$$\kappa = (C_{T_2}, C_8, C_5, c_6, C_b) = (C_T,\ \max(C_0, C, (3+2C)A),\ 4,\ c,\ C_b),$$

$$x_B = \max(16,\ 10708^{832/319},\ e^{4C_0},\ x_6,\ x_B^{\mathrm{sz}},\ x_0^{\mathrm{lv}},\ x_0^{\mathrm{tp}},\ x_0^{\mathrm{th}},\ x_0^{\mathrm{ch}},\ X_*).$$

Then $C_8 \geq 1$, $C_5 > 0$, $c_6 > 0$, $C_b > 0$, so κ has the form required in Definition 11.4. Fix $x \geq x_B$ and $J, (e, A, h, a_0), M, \mathfrak{h} = (q, d, Q_S, \alpha), Y$ as in the definition of the supply of good hosts for ψ; put $\mathfrak{s} = (x, \varepsilon, J)$, a scale since $x > 1$, $0 < \varepsilon < 1/52$, $J \geq 1$; and $N_{\mathfrak{h}} = Q_S q d$, $X_1 = \exp(Y^{\varepsilon/5})$, $X_2 = \exp(Y^{\varepsilon/5}(\log Y)^2)$, $Q_{\mathrm{odd}} = Q_S/2^{v_2(Q_S)}$. We construct the data required in Definition 11.4, condition by condition; t will be the last entry of the rank datum.

Elementary consequences of the hypotheses. (a) Since $Y \geq x^{1/J}$ and $J \leq C_0$, $Y^{\varepsilon/5} \geq x^{\varepsilon/(5C_0)}$ and $\log Y \geq (\log x)/C_0 \geq 4$ (as $x \geq e^{4C_0}$); also $Y \leq x$. (b) Q_{odd} divides the odd part of $\mathrm{lcm}(2^{e+2}, M)$, which divides M; so $Q_{\mathrm{odd}} \mid M$, $Q_{\mathrm{odd}} \leq M \leq C_0$, and every odd prime factor of Q_S divides M. (c) By (Wp1), $q, d \nmid M$. (d) For every prime $p \leq Y^{\varepsilon/5}$, $(-d/p) = 1$: for odd p, $p \mid d+1$ by the definition of window pairs, so $p \nmid d$ and $-d \equiv 1 \pmod p$; for $p = 2$, $d \equiv 7 \pmod{16}$ gives $-d \equiv 1 \pmod 8$. (e) From $\frac{1}{2}Y^{\varepsilon/5} < \log q \leq Y^{\varepsilon/5}$ and $\frac{1}{2}Y^{\varepsilon/5}(\log Y)^2 < \log d \leq Y^{\varepsilon/5}(\log Y)^2$: $\sqrt{X_1} < q \leq X_1$, $\sqrt{X_2} < d \leq X_2$, and $d > \exp(\frac{1}{2}\cdot 16) > 100$ by (a). (f) By (a), $|A| \leq 2x^3$ and $x \geq x_6$,

$$\log N_{\mathfrak{h}} \leq \log(C_0|A|) + Y^{\varepsilon/5} + Y^{\varepsilon/5}(\log Y)^2 \leq 15Y^{\varepsilon/5} + Y^{\varepsilon/5} + Y^{\varepsilon/5}(\log Y)^2 \leq 2Y^{\varepsilon/5}(\log Y)^2,$$

using $\log(C_0|A|) \leq \log(2C_0) + 3\log x \leq 15x^{\varepsilon/(5C_0)} \leq 15Y^{\varepsilon/5}$ and $(\log Y)^2 \geq 16$. As $1 < Y \leq x$, also $\log N_{\mathfrak{h}} \leq 2x^{\varepsilon/5}(\log x)^2$.

(Hg1). As $x \geq 16$, Lemma 11.6, item 1, gives integers k, m, t such that $\mathfrak{R} = (e, A, h, a_0; k, m, t)$ is a rank datum with the rank sizes at $\mathfrak{s}$; as $x \geq 10708^{832/319}$, item 2 gives $t \leq x^{400}$; and (R2) gives $t \geq k + m + 4 \geq 1$. Put $r = k + m - 1$. By Lemma 11.7 ($x \geq x_B^{\mathrm{sz}}$, $J \leq C_0$, $t \leq x^{400}$, $x^{1/J} \leq Y \leq x$), $4tr + 1 < q$ and $4tr + 1 < d$. Put $B = \lfloor Y^{\varepsilon/5} \rfloor$. By hypothesis, $\mathfrak{h}$ is normalised and has field rows up to B, and $B \geq \lfloor x^{\varepsilon/(5J)} \rfloor$ since $Y^{\varepsilon/5} \geq x^{\varepsilon/(5J)}$. Finally $J \leq C_0 \leq C_8$, $o_\psi \leq C_0 \leq C_8$ and $Q_S \leq C_0|A| \leq C_8|A|$.

(Hg2). The host is normalised, so $\alpha(-1) = ((-1,-1), 0)$ by (Hn1), and Lemma 11.13 applies to $E = E_{\mathfrak{h}}$: E is CM, with complex conjugation c, and there are $s_d \in E$, an embedding φ_0 and an integral ideal $\mathfrak{b}$ with $s_d^2 = -d$, $\sigma(s_d) = \epsilon_2(\sigma)s_d$, $\varphi_0(s_d) = \sqrt{-1}\sqrt{d}$ and, for $K = \mathbb{Q}(s_d)$, $\mathcal{D}_{E/K} = \mathfrak{b}\bar{\mathfrak{b}}$, $\mathfrak{b} + \bar{\mathfrak{b}} = \mathcal{O}_E$, $\sigma(\mathfrak{b}) = \mathfrak{b}$ whenever $\epsilon_2(\sigma) = 1$. This is (Hg2).

(Hg3) and (Hg4). We have $x \geq x_0^{\mathrm{tp}}$, and $\mathfrak{R}$, $\mathfrak{h}$, Y satisfy the hypotheses of Proposition 11.11 (rank sizes at $\mathfrak{s}$, $J \in [1, C_0]$, index $o_\psi \leq C_0$, a host whose pair (q, d) is a window pair at a scale $Y \geq x^{1/J}$). Fix an arbitrary total ordering of A. By that proposition there is $T \subseteq A$ with $\frac{1}{2}\delta_1(\mathfrak{s})|A| \leq |T| \leq 2\delta_1(\mathfrak{s})|A|$, with (Ec4) for $(\mathfrak{h}, T)$ at scale x with parameter ε, and such that the choices ρ_p, G_p determined by this ordering for (x, ε, k) satisfy the bad-top bound with constant C_b. This is (Hg4) and the first part of (Hg3). As $x \geq x_0^{\mathrm{th}}$, Proposition 11.12 gives a finite set S of non-negative integers with $4L_w s < n_0$ ($s \in S$), $x^{-\varepsilon}|A| \leq |S|$, $4L_w|S| \leq n_0$, $\frac{n_0}{L_w}\exp(-C_{T_2}\sqrt{\log n_0 \log L_w}) \leq |S|$ and no relation $j(s_2 - s_1) = i(s_3 - s_1)$ as in (Hg3), with $n_0 = |A_0|$ and L_w as in Definition 11.4. Take $u_0 = 0 \in A$. This is (Hg3).

(Hg5). The prime d satisfies $d \equiv 7 \pmod{16}$ by (Hr1), so $d \equiv 3 \pmod 4$. Moreover $d \geq 100$ by (e), $d \mid N_{\mathfrak{h}}$, and $\log N_{\mathfrak{h}} \leq 2x^{\varepsilon/5}(\log x)^2$ by (f). As $x \geq x_0^{\mathrm{lv}}$, Proposition 11.9 with $N_{\mathfrak{h}}$ and $\mathfrak{R}$ gives primes g_1, g_2, p_1, p_2 (and a fifth prime, which we do not use) and elements π_i of the ring of integers $\mathcal{O}$ of $\mathbb{Q}(\sqrt{-d})$ with its properties 1–3. As $x \geq X_*$, Lemma 11.14, applied with its parameter $C_8 := C \geq 1$, $N = N_{\mathfrak{h}} \geq d \geq 100$, these p_1, p_2 (primes $\leq N_{\mathfrak{h}}^C$ by property 3), the integer $k \geq 1$ of $\mathfrak{R}$ (rank sizes), $g_1, g_2 \geq (k\exp(x^\varepsilon))^8$ (property 1) and $\log N_{\mathfrak{h}} \leq 2x^{\varepsilon/5}(\log x)^2$ (by (f)), gives a prime q_0 (its q^*) with $q_0 \equiv 1 \pmod{\ell_0 N_{\mathfrak{h}}}$, where ℓ_0 is the least prime not

dividing $N_\mathfrak{h}(p_1-1)(p_2-1)$, $q_0 \le N_\mathfrak{h}^{(3+2C)A}$ and $q_0 \neq p_1, p_2$. Identify $\mathbb{Q}(\sqrt{-d})$ with $K = \mathbb{Q}(s_d)$ by $\sqrt{-d} \mapsto s_d$; then $\mathcal{O} = \mathcal{O}_K \subseteq \mathcal{O}_E$ and its non-trivial automorphism is the restriction of c. We check (Hg5).

- Distinctness: $g_1 \neq g_2$, $p_1 \neq p_2$, $p_1, p_2 \notin \{g_1, g_2\}$ (property 3, 2), and $q_0 \notin \{p_1, p_2\}$ (Lemma 11.14). Sizes: $(k\exp(x^\varepsilon))^8 \le g_i \le 2(k\exp(x^\varepsilon))^8$ (property 1), $p_1, p_2 \le N_\mathfrak{h}^C \le N_\mathfrak{h}^{C_8}$ and $q_0 \le N_\mathfrak{h}^{(3+2C)A} \le N_\mathfrak{h}^{C_8}$, as $N_\mathfrak{h} \ge 1$ and $C, (3+2C)A \le C_8$.
- $\pi_i \in \mathcal{O}_E \cap K$, $\pi_i\bar{\pi}_i = g_i$ and $\pi_i - 1 \in N_\mathfrak{h}\mathcal{O}_K \subseteq N_\mathfrak{h}\mathcal{O}_E$. Hence $g_i \equiv 1 \pmod{N_\mathfrak{h}}$: $\bar{\pi}_i - 1 \in N_\mathfrak{h}\mathcal{O}_K$, so $g_i - 1 = (\pi_i - 1)\bar{\pi}_i + (\bar{\pi}_i - 1) \in N_\mathfrak{h}\mathcal{O}_K$, and $(g_i-1)/N_\mathfrak{h} \in \mathcal{O}_K \cap \mathbb{Q} = \mathbb{Z}$.
- $p_1 \equiv p_2 \equiv 1 \pmod{\operatorname{lcm}(15, N_\mathfrak{h})}$ (property 3), and $q_0 \equiv 1 \pmod{\ell_0 N_\mathfrak{h}}$ as just shown; in particular $q_0 \equiv 1 \pmod{N_\mathfrak{h}}$.
- Splitting. Every $\ell \in \{g_1, g_2, p_1, p_2, q_0\}$ satisfies $\ell \equiv 1 \pmod{N_\mathfrak{h}}$, so $\ell \nmid N_\mathfrak{h}$ and the Frobenius of ℓ in $\mathrm{Gal}(\mathbb{Q}(\zeta_{N_\mathfrak{h}})/\mathbb{Q})$ is $\sigma_\ell = \mathrm{id}$; hence ℓ splits completely in $\mathbb{Q}(\zeta_{N_\mathfrak{h}})$ and in its subfields $E \supseteq K$. In particular p_1, p_2 split completely in E and every level prime splits in K.
- The sets $\{g_i\} \cup \{\ell \text{ prime} : g_i^a < \ell^{4v_\ell(g_i^a-1)} \text{ for some } 1 \le a \le r\}$, $i = 1, 2$, are disjoint (property 2, with $r = k + m - 1$ of $\mathfrak{R}$).

(Hg6). $x^{1/J} \le Y \le x$; $\sqrt{X_1} < q \le X_1$ and $\sqrt{X_2} < d \le X_2$ by (e); $(-d/p) = 1$ for primes $p \le Y^{\varepsilon/5}$ by (d); $\log N_\mathfrak{h} \le 2Y^{\varepsilon/5}(\log Y)^2$ by (f).

(Hg7), the six quadratic characters. For odd $n > 0$ coprime to qd, Jacobi reciprocity and $q \equiv d \equiv 3 \pmod 4$ give

$$\Big(\frac{-q}{n}\Big) = \Big(\frac{n}{q}\Big), \qquad \Big(\frac{-d}{n}\Big) = \Big(\frac{n}{d}\Big), \qquad \Big(\frac{qd}{n}\Big) = \Big(\frac{n}{q}\Big)\Big(\frac{n}{d}\Big), \qquad \Big(\frac{8D'}{n}\Big) = \Big(\frac{8}{n}\Big)\Big(\frac{D'}{n}\Big).$$

Let $\mathbf{1}$ be the trivial character and $\chi_8 = (8/\cdot)$, both real primitive of modulus dividing $8M$. Then χ_{-q} and $(\mathbf{1}_{q,d}^{(1,0)})^*$ are primitive characters agreeing on all n coprime to $16Mqd$, hence equal (a character is induced by a unique primitive character); likewise $\chi_{-8q} = (\chi 8_{q,d}^{(1,0)})^*$, $\chi_{-d} = (\mathbf{1}_{q,d}^{(0,1)})^*$, $\chi_{-8d} = (\chi 8_{q,d}^{(0,1)})^*$, $\chi_{qd} = (\mathbf{1}_{q,d}^{(1,1)})^*$, $\chi_{8qd} = (\chi 8_{q,d}^{(1,1)})^*$, the twists formed with $8M$. By (Wp3) these have zero-free boxes of heights $h_0(M, \varepsilon, Y) = 8MX_1 \ge 8X_1$ for $D = -q, -8q$ and $h_1(M, \varepsilon, Y) = 8MX_1X_2 \ge 8X_1X_2$ for $D = -d, -8d, qd, 8qd$; a zero-free box of some height is one of every smaller height. The size conditions $|D| \le 8X_1$, resp. $|D| \le 8X_1X_2$, hold by (e).

(Hg7), the real characters of the host. Let θ be a character of $\mathcal{G}$ with χ_θ^* real. As $\gcd(Q_S, qd) = 1$ and $q \neq d$, $\chi_\theta = \chi_S\chi_q\chi_d$ with characters modulo Q_S, q, d, and $\chi_\theta^* = \chi_S^*\chi_q^*\chi_d^*$, a product of primitive characters of coprime conductors, each real. A real character modulo an odd prime p is trivial or $(\cdot/p)$; so $\chi_q^* = (\cdot/q)^i$, $\chi_d^* = (\cdot/d)^j$ with $i, j \in \{0, 1\}$, and $\varrho = \chi_S^*$ is real primitive of conductor $f_S \mid Q_S$. The conductor of a real primitive character is $2^a m'$ with $a \in \{0, 2, 3\}$ and m' odd squarefree; here $m' \mid Q_{\mathrm{odd}}$, so $f_S \mid 8Q_{\mathrm{odd}} \mid 8M$ by (b), and $f_S \le 8Q_{\mathrm{odd}}$. For n coprime to $16Mqd$, $\chi_\theta^*(n) = \varrho(n)(n/q)^i(n/d)^j$, so $\chi_\theta^* = (\varrho_{q,d}^{(i,j)})^*$ (twist formed with $8M$) and $\mathrm{cond}(\chi_\theta^*) = f_S q^i d^j$. If $d \mid \mathrm{cond}(\chi_\theta^*)$, then $j = 1$, $\mathrm{cond}(\chi_\theta^*) \le 8Q_{\mathrm{odd}}X_1X_2$ by (e), and (Wp3) gives a zero-free box of height $8MX_1X_2 \ge 8Q_{\mathrm{odd}}X_1X_2$. If $q \mid \mathrm{cond}(\chi_\theta^*)$ and $d \nmid \mathrm{cond}(\chi_\theta^*)$, then $(i, j) = (1, 0)$, $\mathrm{cond}(\chi_\theta^*) \le 8Q_{\mathrm{odd}}X_1$, and (Wp3) gives a zero-free box of height $8MX_1 \ge 8Q_{\mathrm{odd}}X_1$. This is (Hg7).

(Hg8). By the identification above, $\chi_{-q}, \chi_{-d}, \chi_{qd}$ are $(\xi_{q,d}^{(i,j)})^*$ for the trivial character ξ modulo M and $(i, j) = (1, 0), (0, 1), (1, 1)$. As (q, d) is good for (M, x) and $Y \le x$, (Wp2) at $y = x$ gives $|g(x, \chi_D)| \le x^{1/2+\varepsilon/2} \le x^{1/2+\varepsilon}$ and $|L'(1, \chi_D)/L(1, \chi_D)| \le 4\log x = C_5 \log x$;

in particular $|\operatorname{Re} L'(1,\chi_{-d})/L(1,\chi_{-d})| \le 4\log x \le x^{\varepsilon}$ as $x \ge x_6$. For the last bound we apply Proposition 11.8 with $B = C_0$: $x \ge x_0^{\mathrm{ch}}$; $\mathfrak{h}$ is a host; the largest odd divisor Q_{odd} of Q_S is at most C_0 by (b); $\log(Q_S q d) \le 2x^{\varepsilon/5}\log^2 x$ by (f); and for every θ with χ_θ^* real and modulus divisible by q or d, the zero-free box just obtained contains every real $\beta > 1 - \frac{1}{400}$, so $L(\beta,\chi_\theta^*) \ne 0$. Hence $|g(y,\chi_\theta^*)| \le y\exp(-c_6 x^{\varepsilon/8})$ for every θ and every $y \ge \frac{1}{3}\exp(x^{\varepsilon/3})$. This is (Hg8).

Conclusion. All conditions (Hg1)–(Hg8) hold for the data $\mathfrak{R}$, the ordering, B, s_d, φ_0, $\mathfrak{b}$, g_1, g_2, p_1, p_2, q_0, S, u_0 and Y, and the preconditions of Definition 11.4 ($x > 1$, $0 < \varepsilon < 1/52$, $J \ge 1$, $T \subseteq A$, $t \in \mathbb{Z}$, the form of κ) hold. So the concrete good-host requirement holds at $(x,\varepsilon,J,\kappa,\mathfrak{h},T,t)$, with T finite satisfying (Ec4) and $1 \le t \le x^{400}$; as $t \ge 1$, $\mathfrak{G}(x,\varepsilon,J,\kappa,\mathfrak{h},T,t)$ holds. The list κ and x_B depend only on ψ, ε, C_0. Hence $\mathfrak{G}$ supplies good hosts for ψ. Since ψ was arbitrary, $\mathfrak{G}$ supplies good hosts. □

Lemma 11.6. *Let $\mathfrak{s} = (x,\varepsilon,J)$ be a scale.*

1. *If $x \ge 16$, then for every frame (e,A,h,a_0) with $x^{2+8\varepsilon} \le |A| \le 2x^{2+8\varepsilon}$ there are integers k,m,t such that $(e,A,h,a_0;k,m,t)$ is a rank datum with the rank sizes at $\mathfrak{s}$.*
2. *If $x \ge 10708^{832/319}$, then every rank datum $(e,A,h,a_0;k,m,t)$ with the rank sizes at $\mathfrak{s}$ has $t \le x^{400}$.*

Proof. Write $\delta_1 = \delta_1(\mathfrak{s}) = x^{-\varepsilon/8}$, so $x\delta_1 = x^{1-\varepsilon/8}$, and $T = \lceil x^{377}\rceil$.

Item 1: choice of m and k. Since $1-\varepsilon/8 \ge \frac{1}{2}$ and $x \ge 16$, $x\delta_1 \ge x^{1/2} \ge 4$, so $a := \sqrt{x\delta_1} \ge 2$; also $a \le x^{1/2}$. For real $a \ge 2$ the even integer $2\lceil a/2\rceil$ lies in $[a,2a]$ (as $\lceil a/2\rceil < a/2+1 \le a$). Let m be the even integer $2\lceil a/2\rceil \in [a,2a]$ and k the even integer $2\lceil b/2\rceil \in [b,2b]$ for $b = x^{9/2+10\varepsilon} \ge 2$. Then $r := k+m-1$ is odd, and with $f = 2|A|$ put

$$t = 8fr + 4 + T\,n - r, \qquad n = 8\Big\lceil \frac{10r}{8}\Big(f + \frac{f^2(k-1)^3 L(\mathfrak{s})^2}{m}\Big)\Big\rceil.$$

The quantity n depends only on f, r, k, m and $\mathfrak{s}$, so once $(e,A,h,a_0;k,m,t)$ is shown to be a rank datum, $n = n_W(\mathfrak{R},\mathfrak{s})$ and $r + t = 8fr + 4 + T\,n_W(\mathfrak{R},\mathfrak{s})$, which is the last of the rank sizes. The first three hold by the hypothesis on $|A|$ and the choice of m, k, since $\sqrt{x\delta_1(\mathfrak{s})} = a$.

Item 1: (R1)–(R4). (R1): k, m are even and $t = (8fr+4+Tn) - r$ is an even number minus an odd one, hence odd. (R2): $m \ge a \ge 2$. Since $m \le 2a \le 2x^{1/2}$ and $k \ge b \ge x^4 \ge 2x^{1/2} + 3$ for $x \ge 16$, $m+3 \le k$. As $f \ge 2$ and $Tn \ge 0$, $t \ge 16r + 4 - r \ge 7r + 4$, and $7r = 7(k+m-1) \ge k+m$ because $k + m \ge 7$; so $t \ge k + m + 4$, and $t \ge 7r + 4 > 3m$. (R3): $m \le 2x^{1/2} \le 2x^{2+8\varepsilon} \le 2|A|$, and $2|A| \le 4x^{2+8\varepsilon} \le 4x^3 \le x^4 \le b \le k$ (using $8\varepsilon < 1$ and $x \ge 4$). (R4): $t + 1 > 3m \ge m$, so $m^2 \le m(t+1) \le k + m(t+1)$.

Item 2. Let $\mathfrak{R} = (e,A,h,a_0;k,m,t)$ have the rank sizes at $\mathfrak{s}$, and put $E = \frac{797}{2} + \frac{929}{16}\varepsilon$. As $x > 1$, all powers below are ≥ 1. The rank sizes give $f = 2|A| \le 4x^{2+8\varepsilon}$, $k - 1 < k \le 2x^{9/2+10\varepsilon}$, $m \ge \sqrt{x\delta_1} = x^{1/2-\varepsilon/16}$ and $m \le 2x^{1/2}$, hence $r = k + m - 1 \le 4x^{9/2+10\varepsilon}$, and $L(\mathfrak{s})^2 = x^{2\varepsilon}$. Therefore

$$\frac{f^2(k-1)^3 L(\mathfrak{s})^2}{m} \le 16x^{4+16\varepsilon}\cdot 8x^{27/2+30\varepsilon}\cdot x^{2\varepsilon}\cdot x^{-1/2+\varepsilon/16} = 128\,x^{17+\frac{769}{16}\varepsilon}.$$

Moreover $f \le 4x^{2+8\varepsilon} \le 4x^{17+\frac{769}{16}\varepsilon}$, so the bracket in n_W is at most $132x^{17+\frac{769}{16}\varepsilon}$. With $8\lceil y\rceil \le 8y + 8$,

$$n_W(\mathfrak{R},\mathfrak{s}) \le 10r\cdot 132x^{17+\frac{769}{16}\varepsilon} + 8 \le 5280\,x^{\frac{43}{2}+\frac{929}{16}\varepsilon} + 8 \le 5288\,x^{\frac{43}{2}+\frac{929}{16}\varepsilon}.$$

Since $T \le x^{377}+1 \le 2x^{377}$, it follows that $T\,n_W(\mathfrak{R},\mathfrak{s}) \le 10576\,x^E$. Also $8fr \le 128x^{13/2+18\varepsilon} \le 128x^E$ and $4 \le 4x^E$. From the rank equation and $r \ge 0$,

$$t \le 8fr + 4 + T\,n_W(\mathfrak{R},\mathfrak{s}) \le 10708\,x^E.$$

Since $\varepsilon < \frac{1}{52}$, $400 - E = \frac{3}{2} - \frac{929}{16}\varepsilon > \frac{3}{2} - \frac{929}{832} = \frac{319}{832}$, so for $x \ge 10708^{832/319}$ we get $x^{400-E} \ge x^{319/832} \ge 10708$, i.e. $10708\,x^E \le x^{400}$, and $t \le x^{400}$. □

Lemma 11.7. *Let $0 < \varepsilon < 1/52$ and $C_0 \ge 1$, and put $\delta = \varepsilon/(5C_0)$ and*

$$x_B = \max\Bigl(e^{C_0},\ (1700/\delta + 6)^{2/\delta}\Bigr).$$

Let $\mathfrak{s} = (x,\varepsilon,J)$ be a scale with $x \ge x_B$ and $J \le C_0$, let $(e,A,h,a_0;k,m,t)$ be a rank datum with the rank sizes at $\mathfrak{s}$ and $t \le x^{400}$, and let (q,d) be a window pair at a scale Y with $x^{1/J} \le Y \le x$. Then

$$4tr+1 < q \qquad \text{and} \qquad 4tr+1 < d.$$

Proof. Upper bound for $4tr+1$. By (R2) of the rank datum, $m \ge 2$ and $k \ge m+3$, so $r = k+m-1 \ge 1$ and $t \ge k+m+4 \ge 1$. The rank sizes give $k \le 2x^{9/2+10\varepsilon}$ and $m \le 2\sqrt{x\delta_1(\mathfrak{s})} \le 2x^{1/2}$, since $\delta_1(\mathfrak{s}) = x^{-\varepsilon/8} \le 1$. As $x > 1$ and $9/2 + 10\varepsilon < 9/2 + 10/52 < 5$,

$$r < k+m \le 2x^{9/2+10\varepsilon} + 2x^{1/2} \le 4x^5, \qquad 4tr+1 \le 16x^{405}+1 \le 17x^{405},$$

so $\log(4tr+1) \le \log 17 + 405\log x < 3 + 405\log x$.

Lower bounds for $\log q$ and $\log d$. Since $J \le C_0$ and $x > 1$, $Y \ge x^{1/J} \ge x^{1/C_0}$, hence $Y^{\varepsilon/5} \ge x^{\varepsilon/(5C_0)} = x^{\delta}$; and $x \ge e^{C_0}$ gives $Y \ge e$, so $\log^2 Y \ge 1$. By the definition of a window pair at scale Y,

$$\log q > \tfrac{1}{2}Y^{\varepsilon/5} \ge \tfrac{1}{2}x^{\delta}, \qquad \log d > \tfrac{1}{2}Y^{\varepsilon/5}\log^2 Y \ge \tfrac{1}{2}x^{\delta}.$$

Comparison. Put $z = x^{\delta/2}$; then $z \ge 1700/\delta + 6 \ge 1$ because $x \ge (1700/\delta+6)^{2/\delta}$. From $\log w \le w$ for $w > 0$ applied to $w = z$ we get $\log x = \frac{2}{\delta}\log z \le \frac{2}{\delta}z$, so

$$3 + 405\log x \le 3 + \frac{810}{\delta}z < 3z + \frac{850}{\delta}z = \frac{z}{2}\Bigl(6 + \frac{1700}{\delta}\Bigr) \le \frac{z^2}{2} = \frac{1}{2}x^{\delta}.$$

Hence $\log(4tr+1) < \frac{1}{2}x^{\delta} < \log q$ and $\log(4tr+1) < \log d$, which gives both inequalities. □

Proposition 11.8. *There is a real number $c > 0$ such that for every real B and every $\varepsilon \in (0,1/52)$ there is a real number x_0 with the following property. Let $x \ge x_0$, let $\mathfrak{h} = (q,d,Q_S,\alpha)$ be a host for a frame, let Q' be the largest odd divisor of Q_S, and suppose that*

1. *$Q' \le B$ and $\log(Q_S q d) \le 2x^{\varepsilon/5}\log^2 x$;*
2. *for every character θ of $\mathcal{G}$ such that χ_θ^* is real and its modulus is divisible by q or by d, $L(\beta,\chi_\theta^*) \ne 0$ for every real $\beta > 1 - \frac{1}{400}$.*

Then for every character θ of $\mathcal{G}$ and every real $y \ge \frac{1}{3}\exp(x^{\varepsilon/3})$,

$$|g(y,\chi_\theta^*)| \le y\exp\bigl(-c\,x^{\varepsilon/8}\bigr).$$

Proof. We take $c = 1$. The proof applies the prime number theorem in progressions with the exceptional zero as secondary term (Theorem B.7, [259]) with modulus the conductor N of χ_θ^*; the modulus is so small against y ($\log N \ll x^{\varepsilon/5}\log^2 x$, $\log y \gg x^{\varepsilon/3}$) that the error saves $\exp(-x^{2\varepsilon/15+o(1)})$. Hypothesis 2 removes the exceptional zero when q or d divides N; otherwise a real χ_θ^* has modulus dividing $8Q' \le 8B$, one of finitely many characters, whose real zeros stay away from 1 by a margin depending on B only. The Riesz weight is then recovered from ψ by partial summation over $[y,\infty)$.

Constants. Fix B and $\varepsilon \in (0, 1/52)$. Let $\mathcal{X}_B$ be the finite set of real primitive characters $\chi \neq \mathbf{1}$ of modulus at most $8B$. For $\chi \in \mathcal{X}_B$, $L(s,\chi)$ is entire (Theorem B.1) and $L(1,\chi) \neq 0$ (Theorem B.2), so there is $c_\chi \in (0, \frac12)$ with $L(\beta,\chi) \neq 0$ for $\beta \in [1-c_\chi, 1]$. Put $c_B = \min(\{\frac{1}{400}\} \cup \{c_\chi : \chi \in \mathcal{X}_B\}) > 0$. For $x > 1$ write

$$v_0 = \tfrac12 x^{\varepsilon/3}, \qquad \mathcal{L} = 2x^{\varepsilon/5}\log^2 x,$$

$$T_1 = \frac{3A_4\mathcal{L}}{c_4}e^{-c_4 v_0/\mathcal{L}}, \quad T_2 = 6A_4 e^{-c_4\sqrt{v_0}}\Big(\frac{\sqrt{v_0}}{c_4} + \frac{1}{c_4^2}\Big),$$
$$T_3 = \frac{2}{c_B}e^{-c_B v_0}, \quad T_4 = (\log 2)e^{-v_0}, \quad T_5 = 4e^{-v_0/2}(2v_0+4).$$

Since $v_0/\mathcal{L} = x^{2\varepsilon/15}/(4\log^2 x)$, $\sqrt{v_0} \asymp x^{\varepsilon/6}$, and $\varepsilon/8 < 2\varepsilon/15 < \varepsilon/6 < \varepsilon/3$, each $T_i e^{x^{\varepsilon/8}}$ tends to 0; choose $x_0 \ge e$ such that every $x \ge x_0$ satisfies

(a) $x^{\varepsilon/3} \ge 2\log 3$ and $v_0 \ge 12\mathcal{L}$;

(b) $T_1 + T_2 + T_3 + T_4 + T_5 \le \exp(-x^{\varepsilon/8})$.

Fix $x \ge x_0$, a host $\mathfrak{h}$ with hypotheses 1 and 2, a character θ of $\mathcal{G}$ and $y \ge \frac13\exp(x^{\varepsilon/3})$. Let $\chi = \chi_\theta^*$, primitive of modulus N; as χ_θ is a character modulo $Q_S qd$, $N \mid Q_S qd$, so $\log N \le \mathcal{L}$ by hypothesis 1. Put $\delta_\chi = 1$ if $N = 1$ (then $\chi = \mathbf{1}$) and $\delta_\chi = 0$ otherwise, and $M = N$ if $N \ge 2$, $M = 2$ if $N = 1$; $\log M \le \mathcal{L}$, as $\mathcal{L} \ge 2$. By (a), $\log y \ge x^{\varepsilon/3} - \log 3 \ge v_0$.

Step 1. The exceptional zero is harmless. Suppose the exceptional zero β_1 modulo M exists and $\chi_1 = \chi$ as characters modulo M. By Theorem B.7, item 1, $\beta_1 < 1$ lies in the region $\operatorname{Re} s \ge 1 - 1/(13\log(3M))$, so $\beta_1 > \frac12$. As χ_1 is real and non-principal, $N = M \ge 2$, χ is real and $L(\beta_1,\chi) = 0$. If $q \mid N$ or $d \mid N$, hypothesis 2 gives $\beta_1 \le 1 - \frac{1}{400} \le 1 - c_B$. Otherwise $N \mid Q_S$; the modulus of a real primitive character is $2^a m'$ with $a \in \{0,2,3\}$ and m' odd and squarefree, here $m' \mid Q'$, so $N \mid 8Q'$ and $N \le 8B$; thus $\chi \in \mathcal{X}_B$ and $\beta_1 < 1 - c_\chi \le 1 - c_B$. In both cases $\beta_1 \le 1 - c_B$.

Step 2. A bound for ψ. We show that $|\psi(X,\chi) - \delta_\chi X| \le X\eta(X)$ for every $X \ge y$, where

$$\eta(X) = 3A_4\big(X^{-c_4/\mathcal{L}} + e^{-c_4\sqrt{\log X}}\big) + 2X^{-c_B} + \frac{\log 2}{X} + 4X^{-1/2}\log X.$$

Let $X \ge y$. Then $\log X \ge v_0 \ge 12\mathcal{L} \ge 12\log M$, so $X \ge M^{12}$ and Theorem B.7, item 2, applies to every b coprime to M: with $m_b = (X - \chi_1(b)X^{\beta_1}/\beta_1)/\varphi(M)$ (the second term omitted if there is no exceptional zero), $|m_b| \le 3X/\varphi(M)$ as $\beta_1 > \frac12$, and

$$|\vartheta(X;M,b) - m_b| \le A_4 E(X)\,|m_b|, \qquad E(X) = e^{-c_4\log X/\log M} + e^{-c_4(\log X)^{3/5}(\log\log X)^{-1/5}}.$$

Multiply by $\chi(b)$ (of modulus 1) and sum over the $\varphi(M)$ classes b: by orthogonality $\sum_b \chi(b) = \varphi(M)\delta_\chi$ (for $N \ge 2$, χ is non-principal modulo $M = N$) and $\sum_b \chi(b)\chi_1(b) = \varphi(M)$ if $\chi = \chi_1$

and 0 otherwise (χ_1 is real). So

$$\Big|\sum_{p\le X,\ p\nmid M}\chi(p)\log p-\delta_\chi X+[\chi=\chi_1]\frac{X^{\beta_1}}{\beta_1}\Big|\le 3A_4E(X)X.$$

The primes $p\mid M$ contribute 0 if $N\ge 2$ (then $\chi(p)=0$) and $\log 2$ if $N=1$. By Step 1, $[\chi=\chi_1]X^{\beta_1}/\beta_1\le 2X^{1-c_B}$. The prime powers contribute at most $\sum_{2\le k\le \log X/\log 2}\sum_{p\le X^{1/k}}\log p\le \log 4\,(X^{1/2}+X^{1/3}\log X/\log 2)\le 4X^{1/2}\log X$ by Lemma B.3, as $\log X\ge 1$. Finally $\log M\le \mathcal{L}$ gives $e^{-c_4\log X/\log M}\le X^{-c_4/\mathcal{L}}$, and for $v=\log X>e$ the inequality $\log v\le v^{1/2}$ gives $v^{3/5}(\log v)^{-1/5}\ge v^{1/2}$, so the second term of $E(X)$ is at most $e^{-c_4\sqrt{\log X}}$. This proves Step 2.

Step 3. An integral formula for g. We show that $g(y,\chi)=-y\int_y^\infty(\psi(u,\chi)-\delta_\chi u)\,u^{-2}\,du$, the integral converging absolutely. Put $R(u)=\psi(u,\chi)-\delta_\chi u$. By Step 2 and $\int_y^\infty\eta(u)u^{-1}du<\infty$ (Step 4), and as R is bounded on $[1,y]$, $\int_1^\infty|R(u)|u^{-2}du<\infty$. Partial summation ($\frac{y}{n}-1=\int_n^y y\,u^{-2}du$) gives $\sum_{n\le y}\Lambda(n)\chi(n)(\frac{y}{n}-1)=y\int_1^y\psi(u,\chi)u^{-2}du$. For real $s>1$, $-\frac{L'}{L}(s,\chi)=\sum_n\Lambda(n)\chi(n)n^{-s}=s\int_1^\infty\psi(u,\chi)u^{-s-1}du$ (Euler product; Fubini with $\sum_n\Lambda(n)n^{-s}<\infty$), and $s\int_1^\infty\delta_\chi u\cdot u^{-s-1}du=\delta_\chi\frac{s}{s-1}$. Let $s\to 1^+$; by dominated convergence (dominant $|R(u)|u^{-2}$), $s\int_1^\infty R(u)u^{-s-1}du\to\int_1^\infty R(u)u^{-2}du$. If $N\ge 2$, $L(s,\chi)$ is entire with $L(1,\chi)\ne 0$ (Theorem B.1, Theorem B.2), so $\int_1^\infty R(u)u^{-2}du=-\frac{L'}{L}(1,\chi)$ and $g(y,\chi)=y\int_1^y R(u)u^{-2}du+y\frac{L'}{L}(1,\chi)=-y\int_y^\infty R(u)u^{-2}du$ by (2.2). If $N=1$, $\zeta(s)=\frac{1}{s-1}+\gamma+O(|s-1|)$ (Theorem B.1) gives $-\frac{\zeta'}{\zeta}(s)=\frac{1}{s-1}-\gamma+O(|s-1|)$, so $s\int_1^\infty R(u)u^{-s-1}du=-\frac{\zeta'}{\zeta}(s)-\frac{1}{s-1}-1\to -1-\gamma$; then by (2.1), $G(y)=y\int_1^y\psi(u)u^{-2}du-y(\log y-1-\gamma)=y\int_1^y R(u)u^{-2}du+y(1+\gamma)=-y\int_y^\infty R(u)u^{-2}du$.

Step 4. The bound. By Steps 2 and 3, $|g(y,\chi)|\le y\int_y^\infty\eta(u)u^{-1}du$. Substituting $u=e^v$, with $v_y=\log y\ge v_0$, and using that $e^{-aw}(w/a+1/a^2)$ ($a>0$) and $e^{-v/2}(2v+4)$ decrease for $w,v\ge 0$:

$$\int_{v_y}^\infty 3A_4e^{-c_4v/\mathcal{L}}dv\le T_1,$$

$$\int_{v_y}^\infty 3A_4e^{-c_4\sqrt{v}}dv=6A_4e^{-c_4\sqrt{v_y}}\Big(\frac{\sqrt{v_y}}{c_4}+\frac{1}{c_4^2}\Big)\le T_2,\qquad \int_{v_y}^\infty 2e^{-c_Bv}dv\le T_3,$$

$$\int_y^\infty\frac{\log 2}{u^2}du=\frac{\log 2}{y}\le T_4,\qquad \int_{v_y}^\infty 4ve^{-v/2}dv=4e^{-v_y/2}(2v_y+4)\le T_5.$$

By (b), $|g(y,\chi_\theta^*)|\le y(T_1+\cdots+T_5)\le y\exp(-x^{\varepsilon/8})$, which is the claim with $c=1$. □

Proposition 11.9. *There is a real number $C\ge 1$ such that for every $\varepsilon\in(0,1/52)$ there is a real number x_0 with the following property. Let $x\ge x_0$ and $J\ge 1$, let $(e,A,h,a_0;k,m,t)$ be a rank datum with the rank sizes at (x,ε,J), and put $r=k+m-1$. Let $d\ge 100$ be a prime with $d\equiv 3\pmod 4$, let $\mathcal{O}$ be the ring of integers of $\mathbb{Q}(\sqrt{-d})$, and let $N\ge 1$ be an integer with $d\mid N$ and*

$$\log N\le 2x^{\varepsilon/5}(\log x)^2.$$

Then there are primes g_1,g_2,p_1,p_2,q_0 with the following properties.

1. *For $i=1,2$,*

$$\big(k\exp(x^\varepsilon)\big)^8\le g_i\le 2\big(k\exp(x^\varepsilon)\big)^8,$$

and there is $\pi_i\in\mathcal{O}$ with $\pi_i\bar\pi_i=g_i$ and $\pi_i-1\in N\mathcal{O}$.

2. $g_1 \neq g_2$, *and the two sets*

$$B_i = \{g_i\} \cup \{\ell \text{ prime}: \ g_i^a < \ell^{4v_\ell(g_i^a-1)} \text{ for some integer } 1 \le a \le r\} \qquad (i = 1, 2)$$

are disjoint.

3. $p_1 \neq p_2$, $q_0 \notin \{p_1, p_2\}$ *and* $p_1, p_2 \notin \{g_1, g_2\}$; $p_1 \equiv p_2 \equiv 1 \pmod{\operatorname{lcm}(15, N)}$ *and* $q_0 \equiv 1 \pmod N$; *and* $p_1, p_2, q_0 \le N^C$.

Proof. The auxiliary primes g_1, g_2 come from the Chebotarev density theorem of Thorner and Zaman in the ray class field of $\mathbb{Q}(\sqrt{-d})$ modulo N, whose uniformity is in dN^2 only. By Stark's bound, the Landau–Siegel zero costs at most a factor Q^{-2}, which is negligible because $\log N \ll x^{\varepsilon/5}\log^2 x$ while $\log g_i \ge 8x^\varepsilon$. Among the many such primes in $[Z, 2Z]$, two with disjoint exceptional sets exist by Lemma 11.10. The primes p_1, p_2, q_0 come from Linnik's bound, derived here from Theorem B.7.

Step 1 (Linnik's bound). There is an integer $K_0 \ge 12$ such that every integer $M \ge 2$ has a prime $p \equiv 1 \pmod M$ with $p \le M^{K_0}$. Choose $K_0 \ge 12$ with $K_0 \log 2 \ge e$, $A_4 e^{-c_4 K_0} \le \frac14$ and $A_4 e^{-c_4\sqrt{K_0 \log 2}} \le \frac14$. Let $M \ge 2$ and $X = M^{K_0} \ge M^{12}$. By Theorem B.7, item 2, with $b = 1$: $|\vartheta(X; M, 1) - m| \le A_4 E\,|m|$, where $m = X(1 - X^{\beta_1 - 1}/\beta_1)/\varphi(M)$ (or $X/\varphi(M)$ if there is no exceptional zero) and $E = e^{-c_4 \log X/\log M} + e^{-c_4 (\log X)^{3/5}(\log\log X)^{-1/5}}$. Here $\log X/\log M = K_0$; and with $v = \log X \ge K_0 \log 2 \ge e$, $\log v \le v^{1/2}$ gives $v^{3/5}(\log v)^{-1/5} \ge v^{1/2} \ge \sqrt{K_0 \log 2}$; so $A_4 E \le \frac12$. Moreover $m > 0$: by item 1 of Theorem B.7, $\beta_1 \ge 1 - 1/(13\log(3M)) > \frac12 > 1/\log X$, and $f(\beta) = \beta X^{1-\beta}$ decreases on $[1/\log X, 1]$ (its derivative is $X^{1-\beta}(1 - \beta\log X)$) with $f(1) = 1$, so $X^{\beta_1 - 1}/\beta_1 < 1$. Hence $\vartheta(X; M, 1) \ge m/2 > 0$, and some prime $p \le X$ satisfies $p \equiv 1 \pmod M$.

Put $C = K_0(1 + 4K_0 + 2K_0^2) \ge 1$, an absolute constant.

Step 2 (choice of x_0). Fix $\varepsilon \in (0, 1/52)$ and write $\mathcal{L} = 2x^{\varepsilon/5}\log^2 x$. Let $c_6 = \frac12 \min(1, c_S)$. Choose $x_0 \ge e$ such that every $x \ge x_0$ satisfies

(a) $x^{1/2 - 10\varepsilon} \ge 4$, $8x^\varepsilon \ge 4\max(c_2, 1)\mathcal{L}$, $8x^\varepsilon > C\mathcal{L}$ and $20x^{15} < \exp(\frac65 x^\varepsilon)$;

(b) $10A_5(\exp(-2c_3 x^\varepsilon/\mathcal{L}) + \exp(-2\sqrt{c_3}\, x^{\varepsilon/2})) \le \frac{c_6}{2} e^{-8\mathcal{L}}$;

(c) $\dfrac{c_6 Z}{32 e^{10\mathcal{L}} \log(2Z)} \ge 3Z^{9/10} \ge \sqrt{2Z} + 2Z^{9/10}$ for every $Z \ge e^{8x^\varepsilon}$.

This is possible: $\mathcal{L} = x^{\varepsilon/5 + o(1)}$, so $x^\varepsilon/\mathcal{L} \ge x^{3\varepsilon/5}$ dominates $\mathcal{L}$ eventually, $x^{\varepsilon/2}$ dominates $\mathcal{L}$, and in (c) $e^{10\mathcal{L}} \log(2Z) \le Z^{1/20}$ once $\log Z \ge 8x^\varepsilon$ and x is large.

Fix $x \ge x_0$, $J \ge 1$, a rank datum $(e, A, h, a_0; k, m, t)$ with the rank sizes at (x, ε, J), $r = k + m - 1$, d, $\mathcal{O}$ and N as in the statement. By the rank sizes, $1 \le k \le 2x^{9/2 + 10\varepsilon}$ and $m \le 2\sqrt{x}$, so $r \le 4x^{9/2+10\varepsilon} \le x^5$ by (a). As $d \mid N$, $100 \le d \le N$ and $\log N \le \mathcal{L}$. Put

$$Z = \big(k \exp(x^\varepsilon)\big)^8, \qquad \text{so} \qquad \log Z \ge 8x^\varepsilon.$$

Step 3 (the ray class field). Let $K = \mathbb{Q}(\sqrt{-d})$, so $\mathcal{O} = \mathcal{O}_K$, $D_K = d$ (as $d \equiv 3 \pmod 4$), $n_K = 2$ and $\mathcal{O}^\times = \{\pm 1\}$ (as $d > 3$). Let L be the ray class field of K modulo $N\mathcal{O}$ and $G = \operatorname{Gal}(L/K)$. By Theorem B.13, item 2, L/K is finite abelian, unramified at the prime ideals not dividing N, and the Artin map induces an isomorphism of the ray class group $I(N)/P_1(N)$ onto G, where $I(N)$ is the group of fractional ideals prime to N and $P_1(N)$ the subgroup of principal ideals (α) with $\alpha \equiv 1 \pmod{}^\times N\mathcal{O}$. By item 3, every character of G corresponds

to a primitive Hecke character of conductor dividing $N\mathcal{O}$; so $\mathcal{Q} \le \mathrm{N}(N\mathcal{O}) = N^2$ and $Q = D_K \mathcal{Q}\, n_K^{n_K} \le 4dN^2 \le 4N^3$, whence $\log Q \le 4\mathcal{L}$. Also $|G| \le h_K\,|(\mathcal{O}/N\mathcal{O})^\times| \le h_K N^2$ by item 1, and $h_K \le d$: by Minkowski's bound every ideal class of K contains an integral ideal of norm at most $\frac{2}{\pi}\sqrt{d} < \sqrt{d}$, and, as the number of integral ideals of norm n in K is $\sum_{m|n}(\frac{-d}{m}) \le \tau(n)$ (Kronecker symbol), there are at most $\sum_{n<\sqrt{d}} \tau(n) \le \sum_{n<\sqrt{d}} n \le d$ integral ideals of norm $< \sqrt{d}$. So $|G| \le N^3$ and $|G|\,Q^2 \le 16N^9 \le N^{10} \le e^{10\mathcal{L}}$ (as $16 \le N$).

Apply Theorem B.10 with $F = K$, $H = G$, $C = \{1\}$, $g_C = 1$ (so the field fixed by H is K and $\theta_1 = \chi_1(1) = 1$ if the Landau–Siegel zero exists). If a prime ideal $\mathfrak{p}$ of K with $\mathrm{N}\mathfrak{p} = p$ prime is unramified in L, does not divide N, and has trivial Artin symbol, then $\mathfrak{p} \in P_1(N)$ by item 2 of Theorem B.13, i.e. $\mathfrak{p} = (\pi)$ with $\pi \equiv 1 \pmod{}^\times N\mathcal{O}$; as $\mathfrak{p}$ is integral and prime to N, $\pi \in \mathcal{O}$ and $\pi - 1 \in N\mathcal{O}$, and $\pi\bar{\pi} = \mathrm{N}\mathfrak{p} = p$. Let $\mathcal{S}$ be the set of primes $p \in (Z, 2Z]$ admitting such a π. Every prime ideal counted by $\pi_C(2Z) - \pi_C(Z)$ has norm in $(Z, 2Z]$, hence does not divide N (its norm exceeds N^2 by (a)); it has degree one with norm in $\mathcal{S}$, or degree two with norm p^2, $p \le \sqrt{2Z}$; and each p is the norm of at most two prime ideals. Hence

$$|\mathcal{S}| \ge \tfrac{1}{2}\big(\pi_C(2Z) - \pi_C(Z) - \sqrt{2Z}\big). \tag{11.1}$$

Step 4 (counting). By (a), $Z \ge Q^{\max(c_2,1)}$, so item 2 of Theorem B.10 applies at Z and $2Z$ with errors $E(Z)$, $E(2Z)$ of modulus at most

$$\rho = A_5\Big(\exp\Big[-\frac{c_3 \log Z}{\log Q}\Big] + \exp\Big[-\sqrt{c_3 \log Z/2}\Big]\Big) \le A_5\big(\exp(-2c_3 x^{\varepsilon}/\mathcal{L}) + \exp(-2\sqrt{c_3}\,x^{\varepsilon/2})\big).$$

Write $\mathcal{M}(y) = \mathrm{Li}(y) - \theta_1 \mathrm{Li}(y^{\beta_1})$. Then $0 \le \mathcal{M}(y) \le \mathrm{Li}(y) \le 5Z/\log(2Z)$ for $y \in \{Z, 2Z\}$. The first two inequalities: if β_1 exists, $\theta_1 = 1$, $\beta_1 > 1 - 1/(8\log Q) > \frac{1}{2}$ and $y^{\beta_1} \ge Z^{1/2} \ge e^4 > 2$, so $0 \le \mathrm{Li}(y^{\beta_1}) \le \mathrm{Li}(y)$. For the third, $\sqrt{y} \ge 2$ and

$$\mathrm{Li}(y) = \int_2^{\sqrt{y}} \frac{dt}{\log t} + \int_{\sqrt{y}}^{y} \frac{dt}{\log t} \le \frac{\sqrt{y}}{\log 2} + \frac{y}{\log\sqrt{y}} = \frac{\sqrt{y}}{\log 2} + \frac{2y}{\log y} \le \frac{\sqrt{2Z}}{\log 2} + \frac{4Z}{\log(2Z)} \le \frac{5Z}{\log(2Z)},$$

where the fourth step uses $y \le 2Z$ and that $t/\log t$ increases for $t \ge e$, and the last step is $\sqrt{2Z}/\log 2 \le Z/\log(2Z)$, valid as $\log Z \ge 8$.

And, since $\frac{d}{dt}\mathrm{Li}(t^\beta) = t^{\beta-1}/\log t$,

$$\mathcal{M}(2Z) - \mathcal{M}(Z) = \int_Z^{2Z} (1 - \theta_1 t^{\beta_1 - 1}) \frac{dt}{\log t} \ge (1 - \theta_1 Z^{\beta_1 - 1}) \frac{Z}{\log(2Z)}.$$

If β_1 exists, item 3 of Theorem B.10 gives $1 - \beta_1 \ge c_S Q^{-2}/\log Q$; with $w = (1-\beta_1)\log Z \ge c_S Q^{-2}$ (as $\log Z \ge \log Q$) and $1 - e^{-w} \ge \min(\frac{1}{2}, \frac{w}{2})$, we get $1 - Z^{\beta_1 - 1} \ge c_6 Q^{-2}$; this holds trivially if β_1 does not exist. Therefore

$$\begin{aligned}\pi_C(2Z) - \pi_C(Z) &= \frac{1}{|G|}\big(\mathcal{M}(2Z) - \mathcal{M}(Z) + E(2Z)\mathcal{M}(2Z) - E(Z)\mathcal{M}(Z)\big) \\ &\ge \frac{1}{|G|}\big(c_6 Q^{-2} - 10\rho\big)\frac{Z}{\log(2Z)} \ge \frac{c_6 Z}{2|G|Q^2 \log(2Z)},\end{aligned}$$

using $10\rho \le \frac{c_6}{2} e^{-8\mathcal{L}} \le \frac{c_6}{2} Q^{-2}$ by (b) and $Q \le e^{4\mathcal{L}}$. With $|G|Q^2 \le e^{10\mathcal{L}}$, (11.1) and (c), $|\mathcal{S}| \ge \frac{1}{2}(3Z^{9/10} - \sqrt{2Z}) \ge Z^{9/10}$.

Step 5 (the primes g_1, g_2). $Z \ge 2$, $r \ge 1$, and $20r^3 \le 20x^{15} < \exp(\frac{6}{5}x^{\varepsilon}) \le Z^{3/20}$ by (a). By Lemma 11.10 applied to $Y = Z$ and $\mathcal{S} \subseteq [Z, 2Z]$, there are $g_1 \ne g_2$ in $\mathcal{S}$ with $B_r(g_1) \cap B_r(g_2) = \varnothing$. Each g_i is a prime in $(Z, 2Z]$, i.e. $(k\exp(x^{\varepsilon}))^8 \le g_i \le 2(k\exp(x^{\varepsilon}))^8$, and has $\pi_i \in \mathcal{O}$ with

$\pi_i\bar\pi_i = g_i$ and $\pi_i - 1 \in N\mathcal{O}$. This is item 1 and the first half of item 2; $B_r(g_i)$ is the set B_i of item 2.

Step 6 (the primes p_1, p_2, q_0). By Step 1 there are primes $p_1 \equiv 1 \pmod{15N}$ with $p_1 \le (15N)^{K_0} \le N^{2K_0}$ (as $N \ge 15$), $p_2 \equiv 1 \pmod{15Np_1}$ with $p_2 \le (15Np_1)^{K_0} \le N^{K_0(2+2K_0)}$, and $q_0 \equiv 1 \pmod{Np_1p_2}$ with $q_0 \le (Np_1p_2)^{K_0} \le N^{K_0(1+4K_0+2K_0^2)} = N^C$. Then $p_1 \equiv p_2 \equiv 1 \pmod{\operatorname{lcm}(15, N)}$ and $q_0 \equiv 1 \pmod N$; $p_2 \ne p_1$ because $p_2 \equiv 1 \pmod{p_1}$; $q_0 \notin \{p_1, p_2\}$ because $q_0 \equiv 1 \pmod{p_1p_2}$; and $p_1, p_2, q_0 \le N^C$. Finally $p_j \le N^C \le e^{C\mathcal{L}} < e^{8x^\varepsilon} \le Z < g_i$ by (a), so $p_1, p_2 \notin \{g_1, g_2\}$. This is item 3. The constant C is absolute, and x_0 depends only on ε. □

Lemma 11.10. *For integers $r \ge 1$ and $g \ge 2$ put*

$$B_r(g) = \{g\} \cup \{\ell \text{ prime}: \ g^a < \ell^{4v_\ell(g^a-1)} \text{ for some integer } 1 \le a \le r\}.$$

Let $Y \ge 2$ be real and $r \ge 1$ an integer with $20r^3 < Y^{3/20}$, and let $\mathcal{S}$ be a set of integers in $[Y, 2Y]$ with $|\mathcal{S}| \ge Y^{9/10}$. Then there are $g \ne g'$ in $\mathcal{S}$ with $B_r(g) \cap B_r(g') = \varnothing$.

Proof. Size of $B_r(g)$. Fix $g \ge 2$ and $1 \le a \le r$. If $\ell_1, \dots, \ell_4$ were distinct primes with $\ell_j^{v_j} > g^{a/4}$, $v_j = v_{\ell_j}(g^a - 1)$, then $\prod_j \ell_j^{v_j}$ would divide $g^a - 1 \ge 1$ and exceed g^a, which is impossible. So each a contributes at most three primes, and $|B_r(g)| \le 3r + 1$.

How often a given integer lies in $B_r(g)$. Let $\ell \ge 2$ be an integer. We show

$$\#\{g \in \mathbb{Z} \cap [Y, 2Y]: \ \ell \in B_r(g)\} \le 1 + 2r^2(Y^{3/4} + 1).$$

If $\ell \in B_r(g)$ and $\ell \ne g$, then ℓ is prime and for some $1 \le a \le r$, $\ell^v > g^{a/4} \ge Y^{a/4}$ with $v = v_\ell(g^a - 1)$. Let $e_a \ge 1$ be the least integer with $\ell^{e_a} > Y^{a/4}$; then $v \ge e_a$, so $g^a \equiv 1 \pmod{\ell^{e_a}}$ and g is a unit modulo ℓ^{e_a}. The equation $u^a = 1$ has at most $2a$ solutions in $(\mathbb{Z}/\ell^{e_a}\mathbb{Z})^\times$: this group is cyclic for odd ℓ (at most a solutions), and for $\ell = 2$ it is cyclic or the product of a group of order 2 and a cyclic group (at most $2a$ solutions). Each residue class modulo ℓ^{e_a} contains at most $Y/\ell^{e_a} + 1 \le Y^{1-a/4} + 1 \le Y^{3/4} + 1$ integers of $[Y, 2Y]$. Summing over $a \le r$ gives at most $\sum_{a \le r} 2a(Y^{3/4} + 1) = r(r+1)(Y^{3/4} + 1) \le 2r^2(Y^{3/4} + 1)$ such g, plus at most one g with $g = \ell$.

Conclusion. Suppose that $B_r(g) \cap B_r(g') \ne \varnothing$ for all $g \ne g'$ in $\mathcal{S}$. As $|\mathcal{S}| \ge Y^{9/10} > 0$, fix $g_1 \in \mathcal{S}$; then every $g \in \mathcal{S}$ satisfies $B_r(g) \cap B_r(g_1) \ne \varnothing$ (for $g = g_1$ it contains g_1), so g lies in one of the at most $3r + 1$ sets $\{g : \ell \in B_r(g)\}$, $\ell \in B_r(g_1)$. Hence, as $Y^{3/4} \ge 1$ and $r \ge 1$,

$$|\mathcal{S}| \le (3r+1)(1 + 2r^2(Y^{3/4} + 1)) \le 4r \cdot 5r^2 Y^{3/4} = 20r^3 Y^{3/4} < Y^{3/20} Y^{3/4} = Y^{9/10},$$

a contradiction. □

Proposition 11.11. *For every $\varepsilon \in (0, 1/52)$ and every $C_0 \ge 1$ there are real numbers $C_b > 0$ and x_0 with the following property. Let $x \ge x_0$ and $J \in [1, C_0]$, put $\mathfrak{s} = (x, \varepsilon, J)$, let $(e, A, h, a_0; k, m, t)$ be a rank datum with the rank sizes at $\mathfrak{s}$ whose frame has index $o \le C_0$, and let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for the frame (e, A, h, a_0) such that (q, d) is a window pair at a scale $Y \ge x^{1/J}$. Then for every total ordering of A there is a set $T \subseteq A$ such that*

1. *$\frac{1}{2}\delta_1(\mathfrak{s})|A| \le |T| \le 2\delta_1(\mathfrak{s})|A|$;*
2. *$(\mathfrak{h}, T)$ satisfies (Ec4) at scale x with parameter ε, that is, $\big|\#\{u \in T : u - b \in A_0\} - \kappa(b)|T|\big| \le x^{-1+\varepsilon}|T|$ for every $b \in A$, with $\kappa(b) = 4/(3o+1)$ for $b \in A_0$ and $\kappa(b) = 3/(3o+1)$ otherwise;*
3. *the choices ρ_p and G_p prescribed by this ordering for $\mathfrak{h}$, T, the parameters (x, ε) and the integer k satisfy the bad-top bound with constant C_b.*

Proof. The top set is chosen at random, each element of A independently, with probability $\delta = \delta_1(\mathfrak{s})$ on A_0 and $\frac{3}{4}\delta$ off A_0; Chebyshev's inequality on the o cosets of A_0 gives (Ec4) and the size, and a first-moment bound with Markov's inequality gives the bad-top bound. The only arithmetic input is that inert primes are large, which bounds L_{orb}.

Constants. Fix $\varepsilon \in (0, 1/52)$ and $C_0 \geq 1$. Write h_{orb}, $K = K_{\mathrm{orb}}$ and $r = r_{\mathrm{orb}}$ as in Definition 11.3; K and r depend only on ε. Put

$$L_b = 2\Big(\frac{620C_0}{\varepsilon} + 1\Big), \qquad C_b = 2L_b^K + 4 > 0.$$

Choose $x_0 \geq 16$ such that every $x \geq x_0$ satisfies

(a) $x^{\varepsilon/8} \geq 10$ and $x^{\varepsilon} \geq 144C_0^2$;

(b) $2(6r+1)((h_{\mathrm{orb}}+3)10^{6r+1}\log x + 2)x^{\varepsilon/8} \leq x^{\varepsilon/4}$,

possible because $\log x = o(x^{\varepsilon/8})$. Fix $x \geq x_0$, J, $\mathfrak{s}$, the rank datum, the host, Y and a total ordering of A as in the statement, and write $\delta = \delta_1(\mathfrak{s}) = x^{-\varepsilon/8} = \delta_{\mathrm{orb}}$ and $n_0 = |A_0|$, so $|A| = o\, n_0$ and $x^{h_{\mathrm{orb}}} \leq |A| \leq 2x^{h_{\mathrm{orb}}}$. Let $\mathcal{P}$ be the finite set of primes p that are inert for $\mathfrak{A}_{\mathfrak{h}}$, not sign-changing, with $p < \exp(x^{\varepsilon/3})$ and $\mathrm{ord}(h_p) \geq x^{\varepsilon/4}$, and $\omega_p = \log p/p > 0$. The orbit labellings ρ_p are determined by the ordering and do not depend on T; the sets G_p do. Since $\rho_p(t) \in R_p$, a top $t \in T$ has $\rho_p(t) \notin G_p$ exactly when $P_p(\rho_p(t))$ violates one of (Go1)–(Go3) with $n = \mathrm{ord}(h_p)$.

Step 1. Inert primes exceed $Y^{\varepsilon/5}$, and $L_{\mathrm{orb}} \leq L_b$. Let p be inert. Then $\epsilon_2(\alpha(f_p)) = -1$, i.e. $(f_p/d) = -1$ by (Hr4). For an odd prime $l \neq d$, quadratic reciprocity with $d \equiv 3 \pmod 4$ gives $(l/d) = (-d/l)$. If $p \mid Q_S$, then p is odd and $f_p \equiv p \pmod d$ (as $d \mid N_p'$), so $(f_p/d) = (p/d) = (-d/p) = 1$ by (Hr2), a contradiction; hence $p \nmid Q_S q d$, f_p is the class of p, and $(-d/p) = (p/d) = -1$. For an odd prime $p \leq Y^{\varepsilon/5}$, $p \mid d+1$ gives $-d \equiv 1 \pmod p$ and $(-d/p) = 1$. Hence $p > Y^{\varepsilon/5} \geq x^{\varepsilon/(5J)} \geq x^{\varepsilon/(5C_0)}$. By the rank sizes $k \leq 2x^{9/2+10\varepsilon}$, so, using $4\log 2 \leq \log x$ and $40\varepsilon < 1$,

$$\log\big((kx^{26})^4\big) = 4\log k + 104\log x \leq 4\log 2 + (18+40\varepsilon)\log x + 104\log x \leq 124\log x,$$

and $\log\big((kx^{26})^4\big)/\log p < 124\log x/\big(\frac{\varepsilon}{5C_0}\log x\big) = 620C_0/\varepsilon$. So every entry in the definition of L_{orb} is at most $620C_0/\varepsilon + 1$, and $L_{\mathrm{orb}} \leq L_b$.

Step 2. The random set. Put $\vartheta(a) = \delta$ for $a \in A_0$ and $\vartheta(a) = \frac{3}{4}\delta$ for $a \in A \setminus A_0$, and give each $T \subseteq A$ the probability $\prod_{a\in T}\vartheta(a)\prod_{a\notin T}(1-\vartheta(a))$; thus the events $[a \in T]$, $a \in A$, are independent with probabilities $\vartheta(a) \in [\frac{3}{4}\delta, \delta]$, and $0 < \delta < 1$. For $b \in A$ let $Z_b(T) = \#\{u \in T : u - b \in A_0\} = |T \cap (b + A_0)|$, and let

$$W(T) = \sum_{p\in\mathcal{P}} \omega_p \,\big|\{t \in T : \rho_p(t) \notin G_p\}\big|,$$

the left side of the bad-top bound. Since $\delta = \delta_{\mathrm{orb}}$, the bad-top bound with constant C_b reads $W(T) \leq 4C_b x^{-2}\delta|A|\sum_{p\in\mathcal{P}}\omega_p$.

Step 3. One orbit fails with probability at most $C_b x^{-2}$. Let $p \in \mathcal{P}$, $n_p = \mathrm{ord}(h_p)$, so $x^{\varepsilon/4} \leq n_p \leq |A| \leq 2x^{h_{\mathrm{orb}}}$. Let $t \in A$ and $v = \rho_p(t)$; as $t \in v + \mathbb{N}h_p$, $t = v + i_0 h_p$ for a unique $0 \leq i_0 < n_p$. The map $i \mapsto v + ih_p$ is injective on $\{0, \dots, n_p - 1\}$, so the events $[i \in P_p(v)] = [v + ih_p \in T]$ are independent with probabilities $\vartheta_i \in [\frac{3}{4}\delta, \delta]$; conditionally on $t \in T$ (an event of probability $\vartheta(t) > 0$), $i_0 \in P_p(v)$ and the events for $i \neq i_0$ stay independent with the same probabilities. Write $\Pr_t$ for this conditional probability and $P = P_p(v)$. If $I \subseteq \{0, \dots, n_p - 1\} \setminus \{i_0\}$ and $m \geq 1$, then, taking the union over the m-subsets of I,

$$\Pr_t(|P \cap I| \geq m) \leq \binom{|I|}{m}\delta^m. \tag{11.2}$$

- (Go1) fails if $|P \cap W_i| \ge K+1$ for some window $W_i = \{(i+j) \bmod n_p : 0 \le j < L_{\mathrm{orb}}\}$, $0 \le i < n_p$. Then $|P \cap (W_i \setminus \{i_0\})| \ge K$, and $|W_i| \le L_{\mathrm{orb}} \le L_b$; by (11.2) and $\binom{L}{K} \le L^K$, the probability is at most $n_p L_b^K \delta^K$. As $K \ge 8(h_{\mathrm{orb}}+2)/\varepsilon$, $\delta^K = x^{-\varepsilon K/8} \le x^{-h_{\mathrm{orb}}-2}$; so this is at most $2L_b^K x^{-2}$.

- (Go3) fails if some window of G_{orb} consecutive residues contains $N = N_{\mathrm{orb}}+1$ elements of P, hence at least N_{orb} elements other than i_0. By (11.2) and $\binom{G}{N'} \le G^{N'}/N'! \le (eG/N')^{N'}$ (from $N'! \ge (N'/e)^{N'}$), with $G = G_{\mathrm{orb}}$, $N' = N_{\mathrm{orb}}$, the probability is at most $n_p(eG\delta/N')^{N'} \le n_p 6^{-N'} \le n_p 2^{-N'} \le 2x^{h_{\mathrm{orb}}} x^{-(h_{\mathrm{orb}}+3)} = 2x^{-3}$, since $N' \ge 6eG\delta$ and $N' \ge (h_{\mathrm{orb}}+3)\log x/\log 2$.

- (Go2). Put $u = u_{\mathrm{orb}} = \lceil 1/\delta \rceil$, $\ell = \ell_{\mathrm{orb}} = (6r+1)u$, $M = M_{\mathrm{orb}}$ and $B = \lfloor n_p/\ell \rfloor$. As $u \le 2x^{\varepsilon/8}$ and $M+1 \le (h_{\mathrm{orb}}+3)10^{6r+1}\log x + 2$, (b) gives $(M+1)\ell \le x^{\varepsilon/4} \le n_p$, so $B \ge M+1$. For $0 \le s < B$ the tile $\{s\ell, \dots, (s+1)\ell - 1\} \subseteq \{0, \dots, n_p - 1\}$ is the disjoint union of the cells $C_{s,c} = \{s\ell + (c-1)u, \dots, s\ell + cu - 1\}$, $1 \le c \le 6r+1$; call the tile *marked* if $P \cap C_{s,c} = \varnothing$ for odd c and $P \cap C_{s,c}$ is a singleton with even element for even c. (Go2) fails exactly when for some $s_0 < B$ none of the tiles $(s_0 + j) \bmod B$, $0 \le j \le M$, is marked. These are $M+1$ distinct, pairwise disjoint tiles, at least M of which do not contain i_0; whether a tile is marked depends only on P inside it, so for these M tiles the events are independent under $\Pr_t$. Each has probability at least $\mu_0 = 10^{-(6r+1)}$: the cell events are independent; $\delta \le 1/10$ by (a), $u \le 1/\delta + 1$ and $\log(1-\delta) \ge -\delta - \delta^2$ give $(1-\delta)^u \ge e^{-(1+\delta)^2} > \frac{1}{4}$; a cell has u consecutive integers, at least $\lfloor u/2 \rfloor \ge (1/\delta - 1)/2$ of them even, so

$$\Pr_t(P \cap C_{s,c} = \varnothing) \ge (1-\delta)^u > \tfrac{1}{4},$$
$$\Pr_t(P \cap C_{s,c} = \{y\},\ y \text{ even}) \ge \lfloor u/2 \rfloor \tfrac{3}{4}\delta(1-\delta)^{u-1} \ge \tfrac{3(1-\delta)}{8} \cdot \tfrac{1}{4} > \tfrac{1}{12};$$

  with $3r+1$ odd and $3r$ even cells, a tile is marked with probability at least $4^{-(3r+1)}12^{-3r} = \frac{1}{4}\,48^{-3r} \ge \frac{1}{4}\,10^{-6r} \ge \mu_0$. Hence for each s_0 the failure has probability at most $(1-\mu_0)^M \le e^{-\mu_0 M} \le e^{-(h_{\mathrm{orb}}+3)\log x} = x^{-(h_{\mathrm{orb}}+3)}$, as $\mu_0 M \ge (h_{\mathrm{orb}}+3)\log x$; summing over $s_0 < B \le n_p$ gives at most $2x^{-3}$.

Therefore $\Pr_t(\rho_p(t) \notin G_p) \le 2L_b^K x^{-2} + 4x^{-3} \le C_b x^{-2}$.

Step 4. The first moment. By Step 3,

$$\mathbb{E}\,W = \sum_{p \in \mathcal{P}} \omega_p \sum_{t \in A} \vartheta(t) \Pr_t(\rho_p(t) \notin G_p) \le C_b x^{-2} \Big(\sum_{t \in A} \vartheta(t)\Big) \sum_{p \in \mathcal{P}} \omega_p \le C_b x^{-2} \delta |A| \sum_{p \in \mathcal{P}} \omega_p =: \Omega.$$

If $\mathcal{P} = \varnothing$, $W = 0$ and the bad-top bound holds for every T. Otherwise $\Omega > 0$ and Markov's inequality gives $\Pr(W > 4\Omega) \le \frac{1}{4}$.

Step 5. The cosets. For $b \in A$, Z_b is a sum of n_0 independent indicators of probability $\vartheta(b)$ (constant on $b + A_0$); its mean is $n_0\vartheta(b)$ and its variance at most $n_0\delta$. Put $D = 2\sqrt{\delta|A|}$. By Chebyshev's inequality $\Pr(|Z_b - n_0\vartheta(b)| > D) \le n_0\delta/D^2$; Z_b depends only on the coset $b + A_0$, and there are o cosets, so the probability that $|Z_b - n_0\vartheta(b)| > D$ for some b is at most $o\, n_0\delta/D^2 = \frac{1}{4}$.

Step 6. Choice of T. With probability at least $\frac{1}{2}$ both $W \le 4\Omega$ (or $\mathcal{P} = \varnothing$) and $|Z_b - n_0\vartheta(b)| \le D$ for all $b \in A$; fix such a T. Item 3 holds: $W(T) \le 4C_b x^{-2}\delta_{\mathrm{orb}}|A| \sum_{p \in \mathcal{P}} \omega_p$. Summing over a set of representatives of the cosets, $\big||T| - \mu\big| \le oD$ with

$$\mu = n_0\delta + (o-1)n_0\tfrac{3}{4}\delta = \tfrac{3o+1}{4}\,\delta n_0 \in \big[\tfrac{3}{4}\delta|A|,\ \delta|A|\big].$$

Here $\delta|A| \ge x^{2+8\varepsilon-\varepsilon/8} \ge x^{2+7\varepsilon}$, so $\delta|A| \ge x^{\varepsilon} \ge 144C_0^2 \ge 64o^2$ by (a), which gives $oD = 2o\sqrt{\delta|A|} \le \frac14\delta|A|$; hence $\frac12\delta|A| \le |T| \le \frac54\delta|A|$, item 1. For item 2, we have $\kappa(b)\mu = n_0\vartheta(b)$ (for $b \in A_0$: $\frac{4}{3o+1}\cdot\frac{3o+1}{4}\delta n_0$; otherwise $\frac{3}{3o+1}\cdot\frac{3o+1}{4}\delta n_0$) and $\kappa(b)\,o \le \frac{4o}{3o+1} < \frac43$, so

$$\big|Z_b - \kappa(b)|T|\big| \le |Z_b - n_0\vartheta(b)| + \kappa(b)\big||T| - \mu\big| \le D + \kappa(b)oD < 3D = 6\sqrt{\delta|A|}.$$

Finally $6\sqrt{\delta|A|} \le \frac12 x^{-1+\varepsilon}\delta|A|$ is equivalent to $144x^{2-2\varepsilon} \le \delta|A|$, which holds as $\delta|A| \ge x^{2+7\varepsilon}$ and $x^{9\varepsilon} \ge 144$ by (a); with $|T| \ge \frac12\delta|A|$ this gives $|Z_b - \kappa(b)|T|| \le x^{-1+\varepsilon}|T|$ for every $b \in A$, which is (Ec4). □

Proposition 11.12. *There is a real number C_T such that for every $\varepsilon \in (0, 1/52)$ and every $C_0 \ge 1$ there is a real number x_0 with the following property. Let $x \ge x_0$, let (e, A, h, a_0) be a frame of index $o \le C_0$ with $x^{2+8\varepsilon} \le |A| \le 2x^{2+8\varepsilon}$, and put $n_0 = |A_0|$ and*

$$L_w = 10\lceil 405\log x\rceil + 2\lceil 30/\varepsilon\rceil + 22.$$

Then there is a finite set S of non-negative integers such that $4L_w s < n_0$ for every $s \in S$,

$$x^{-\varepsilon}|A| \le |S|, \qquad 4L_w|S| \le n_0, \qquad \frac{n_0}{L_w}\exp\Big(-C_T\sqrt{\log n_0\,\log L_w}\Big) \le |S|,$$

and $j(s_2 - s_1) \ne i(s_3 - s_1)$ for all pairwise distinct $s_1, s_2, s_3 \in S$ and all integers $i \ne j$ with $0 < |i| \le L_w$ and $0 < |j| \le L_w$.

Proof. We take $C_T = 8$. The proof has two steps: a construction for arbitrary integers $N \ge 1$, $L \ge 2$ with $\log N \ge 100\log L$ (Behrend's sphere construction, with the base enlarged so that the linear relations of the statement cannot carry), and the choice $N = n_0$, $L = L_w$ at large x.

Step 1. Let $N \ge 1$ and $L \ge 2$ be integers, $X = \log N$, $Y = \log L$, and suppose $X \ge 100Y$. Then there is a set S of positive integers such that $4Ls < N$ for every $s \in S$, $4L|S| \le N$, $j(s_2 - s_1) \ne i(s_3 - s_1)$ for all pairwise distinct $s_1, s_2, s_3 \in S$ and all integers $i \ne j$ with $0 < |i|, |j| \le L$, and

$$|S| \ge \frac{N}{L}\exp(-8\sqrt{XY}). \tag{11.3}$$

We have $Y \ge \log 2 > 0.69$, $Y \le X/100$ and $\sqrt{XY} \le X/10$.

Parameters. Let $n = \lceil\sqrt{X/Y}\,\rceil$. As $X/Y \ge 100$, $n \ge 10$ and $\sqrt{X/Y} \le n \le 1.1\sqrt{X/Y}$. Let $Z = (N/(4L))^{1/n}$ and $Q = \lfloor Z/(4L)\rfloor$. Since $\log 8 = 3\log 2 \le 3Y$ and $\log 4 \le 2Y$,

$$n\log(8L) \le 4nY \le 4.4\sqrt{XY} \le 0.44X, \qquad \log(4L) \le 3Y \le 0.03X,$$

so $n\log Z = X - \log(4L) \ge 0.97X \ge n\log(8L)$, that is, $Z \ge 8L$. Hence $Z/(4L) \ge 2$, so $Q \ge Z/(4L) - 1 \ge Z/(8L)$ and $Q \ge 2$; and $4LQ \le Z$.

A large sphere. Let $V = \{0, 1, \dots, Q-1\}^n \subseteq \mathbb{Z}^n$, with $\|v\|^2 = \sum_{\nu=1}^n v_\nu^2$ and $\langle v, w\rangle = \sum_\nu v_\nu w_\nu$. For $v \in V$, $\|v\|^2$ is an integer in $[0, n(Q-1)^2]$, which takes at most $n(Q-1)^2 + 1 \le nQ^2$ values. As $|V| = Q^n$, by the pigeonhole principle there is an integer ρ such that $\Sigma = \{v \in V : \|v\|^2 = \rho\}$ has

$$|\Sigma| \ge \frac{Q^n}{nQ^2} = \frac{Q^{n-2}}{n} \ge \frac1n\Big(\frac{Z}{8L}\Big)^{n-2} \ge \frac{Z^n\,Z^{-2}\,(8L)^{-n}}{n} \ge \frac{N}{L}\cdot\frac{1}{4n}\,N^{-2/n}(8L)^{-n},$$

using $n - 2 \ge 8$, $Q \ge Z/(8L)$, $8L > 1$, $Z^n = N/(4L)$ and $Z^2 \le N^{2/n}$. Here $\log(4n) \le n \le 1.1\sqrt{X/Y} = 1.1\sqrt{XY}/Y \le 1.6\sqrt{XY}$ (as $n \ge 10$ and $Y \ge 0.69$), $n\log(8L) \le 4.4\sqrt{XY}$ and $2X/n \le 2X/\sqrt{X/Y} = 2\sqrt{XY}$; so $|\Sigma| \ge \frac{N}{L}\exp(-8\sqrt{XY})$. In particular $|\Sigma| \ge \exp(X - Y -$

$0.8X) \geq \exp(0.19X) \geq \exp(13) > 1$, as $X \geq 100Y \geq 69$. Since $\{v \in V : \|v\|^2 = 0\} = \{0\}$, it follows that $\rho \neq 0$ and $0 \notin \Sigma$.

Digits. Put $B = 4LQ$ and $\phi(v) = \sum_{\nu=1}^{n} v_\nu B^{\nu-1}$, a $\mathbb{Z}$-linear map $\mathbb{Z}^n \to \mathbb{Z}$. If $c \in \mathbb{Z}^n$ satisfies $|c_\nu| < B$ for every ν and $\phi(c) = 0$, then $c = 0$: otherwise let ν_0 be the least index with $c_{\nu_0} \neq 0$; dividing $\phi(c) = 0$ by $B^{\nu_0 - 1}$ gives $c_{\nu_0} = -B \sum_{\nu > \nu_0} c_\nu B^{\nu - \nu_0 - 1}$, a multiple of B with $0 < |c_{\nu_0}| < B$, which is impossible. For $v, w \in V$, $|v_\nu - w_\nu| \leq Q - 1 < B$; so ϕ is injective on V.

The set. Put $S = \phi(\Sigma)$; then $|S| = |\Sigma|$, which gives (11.3). Every $v \in \Sigma$ is non-zero with non-negative entries, so $\phi(v) \geq 1$; and $\phi(v) \leq (Q-1)\sum_{\nu=1}^{n} B^{\nu-1} < B^n$, so $4L\phi(v) < 4LB^n \leq 4LZ^n = N$. As S consists of $|S|$ distinct positive integers, its largest element s^* satisfies $|S| \leq s^*$, hence $4L|S| \leq 4Ls^* < N$.

No relation. Let $s_k = \phi(v_k)$ with $v_k \in \Sigma$ $(k = 1, 2, 3)$ be pairwise distinct, and let $i \neq j$ be integers with $0 < |i|, |j| \leq L$ and $j(s_2 - s_1) = i(s_3 - s_1)$. Put $a = v_2 - v_1$, $b = v_3 - v_1 \in \mathbb{Z}^n$ and $c = ja - ib$. Then $|c_\nu| \leq (|i| + |j|)(Q-1) \leq 2L(Q-1) < B$ and $\phi(c) = j(s_2 - s_1) - i(s_3 - s_1) = 0$, so $c = 0$, that is, $ja = ib$. As v_1, v_2, v_3 lie on the sphere $\|v\|^2 = \rho$, $\|v_1 + a\|^2 = \|v_1\|^2$ and $\|v_1 + b\|^2 = \|v_1\|^2$, i.e. $2\langle v_1, a\rangle + \|a\|^2 = 0 = 2\langle v_1, b\rangle + \|b\|^2$. Hence

$$0 = j^2(2\langle v_1, a\rangle + \|a\|^2) - ij(2\langle v_1, b\rangle + \|b\|^2) = 2j\langle v_1, ja - ib\rangle + \|ja\|^2 - ij\|b\|^2 = i(i-j)\|b\|^2,$$

using $ja = ib$ twice ($\|ja\|^2 = \|ib\|^2 = i^2\|b\|^2$). As $i \neq 0$ and $i \neq j$, $b = 0$, so $v_3 = v_1$ and $s_3 = s_1$, a contradiction. This proves Step 1.

Step 2. The frame. Fix $\varepsilon \in (0, 1/52)$ and $C_0 \geq 1$, and write $u = \log x$. As $\log(4051u)/u \to 0$ and $\sqrt{u\log(4051u)}/u \to 0$ when $u \to \infty$, there is x_0 such that every $x \geq x_0$ satisfies

(a) $x \geq \max(2, C_0)$ and $u \geq 34 + 60/\varepsilon$;

(b) $u \geq 100\log(4051u)$;

(c) $\log C_0 + \log(4051u) + 16\sqrt{u\log(4051u)} \leq \varepsilon u$.

Let $x \geq x_0$ and let (e, A, h, a_0) be a frame of index $o \leq C_0$ with $x^{2+8\varepsilon} \leq |A| \leq 2x^{2+8\varepsilon}$. Put $N = n_0$ and $L = L_w$, an integer with $L \geq 22$; from $\lceil y \rceil \leq y + 1$, $L \leq 4050u + 34 + 60/\varepsilon \leq 4051u$ by (a), so $Y = \log L \leq \log(4051u)$. As $|A| = o\, n_0$ and $o \leq C_0 \leq x$, $N \geq |A|/C_0 \geq x^2/C_0 \geq x$; and $N \leq |A| \leq 2x^3 \leq x^4$ (as $8\varepsilon < 1$ and $x \geq 2$). So $u \leq X \leq 4u$, and $X \geq u \geq 100\log(4051u) \geq 100Y$ by (b). Step 1 gives a set S of positive (in particular non-negative) integers with $4L_w s < n_0$ for $s \in S$, $4L_w|S| \leq n_0$, the absence of the relations of the statement, and

$$|S| \geq \frac{n_0}{L_w}\exp\bigl(-8\sqrt{\log n_0\ \log L_w}\bigr),$$

which is the third displayed inequality with $C_T = 8$. Finally $\sqrt{XY} \leq \sqrt{4u\log(4051u)} = 2\sqrt{u\log(4051u)}$, so by (c)

$$\log L_w + \log C_0 + 8\sqrt{XY} \leq \log(4051u) + \log C_0 + 16\sqrt{u\log(4051u)} \leq \varepsilon \log x,$$

that is, $L_w C_0 \exp(8\sqrt{XY}) \leq x^\varepsilon$; hence $|S| \geq \frac{n_0}{L_w}\exp(-8\sqrt{XY}) \geq x^{-\varepsilon} C_0 n_0 \geq x^{-\varepsilon} o\, n_0 = x^{-\varepsilon}|A|$. All requirements hold, with $C_T = 8$ independent of ε and C_0. □

Lemma 11.13. *Let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a host for a frame such that $\alpha(-1) = ((-1,-1), 0)$, let $E = E_\mathfrak{h}$, and regard ϵ_2 as a character of $\mathrm{Gal}(E/\mathbb{Q})$ via the isomorphism induced by α. Then:*

1. *E is a CM field, and its complex conjugation c is the automorphism corresponding to $((-1,-1), 0)$; for every field embedding $\varphi\colon E \hookrightarrow \mathbb{C}$, $\overline{\varphi(y)} = \varphi(c(y))$ for all $y \in E$.*

2. *There are $s_d \in E$ and a field embedding $\varphi_0 \colon E \hookrightarrow \mathbb{C}$ with $s_d^2 = -d$, $\sigma(s_d) = \epsilon_2(\sigma) s_d$ for every $\sigma \in \mathrm{Gal}(E/\mathbb{Q})$, and $\varphi_0(s_d) = \sqrt{-1}\sqrt{d}$.*

3. *For every s_d as in item 2, put $K = \mathbb{Q}(s_d) \subseteq E$. There is an integral ideal $\mathfrak{b}$ of $\mathcal{O}_E$ such that*

$$\mathcal{D}_{E/K} = \mathfrak{b}\, c(\mathfrak{b}), \qquad \mathfrak{b} + c(\mathfrak{b}) = \mathcal{O}_E, \qquad \sigma(\mathfrak{b}) = \mathfrak{b} \quad \text{for every } \sigma \in \mathrm{Gal}(E/\mathbb{Q}) \text{ with } \epsilon_2(\sigma) = 1.$$

Proof. Put $N = Q_S q d$, fix a primitive N-th root of unity ζ_N, and for a coprime to N let σ_a be the automorphism $\zeta_N \mapsto \zeta_N^a$ of $\mathbb{Q}(\zeta_N)$ and $\bar\sigma_a$ its restriction to E. By definition E is the fixed field of $\{\sigma_a : \alpha(a) = 1\}$, and the isomorphism $\mathrm{Gal}(E/\mathbb{Q}) \to \mathcal{G}$ sends $\bar\sigma_a$ to $\alpha(a)$; so $\epsilon_2(\bar\sigma_a) = \epsilon_2(\alpha(a)) = (a/d)$ by (Hr4).

E is CM with complex conjugation $c = \bar\sigma_{-1}$. Let $\varphi \colon E \hookrightarrow \mathbb{C}$ be an embedding and $\tilde\varphi$ an extension to $\mathbb{Q}(\zeta_N)$. Then $\omega = \tilde\varphi(\zeta_N)$ is a root of unity, $\overline{\omega} = \omega^{-1} = \tilde\varphi(\sigma_{-1}(\zeta_N))$, and hence $\overline{\tilde\varphi(y)} = \tilde\varphi(\sigma_{-1}(y))$ for all $y \in \mathbb{Q}(\zeta_N)$; restricting, $\overline{\varphi(y)} = \varphi(c(y))$ for $y \in E$, with $c = \bar\sigma_{-1}$. By hypothesis c corresponds to $\alpha(-1) = ((-1,-1),0) \neq 1$, so $c \neq \mathrm{id}$ and $c^2 = \mathrm{id}$. Let F be the fixed field of c, so $[E : F] = 2$. For $y \in F$, $\overline{\varphi(y)} = \varphi(y)$, so F is totally real. If $\varphi(E) \subseteq \mathbb{R}$ for some φ, then $\varphi \circ c = \varphi$ and, φ being injective, $c = \mathrm{id}$, a contradiction; so E is totally imaginary. Hence E is a totally imaginary quadratic extension of a totally real field, a CM field, and complex conjugation (under any embedding) is c. This is item 1.

The square root of $-d$. Let $\zeta_d = \zeta_N^{N/d}$ and $\gamma = \sum_{a=1}^{d-1} (a/d)\zeta_d^a \in \mathbb{Q}(\zeta_N)$. By the classical evaluation of the quadratic Gauss sum, $\gamma^2 = (-1/d)\, d = -d$, as $d \equiv 3 \pmod 4$ by (Hr1); and $\sigma_u(\gamma) = (u/d)\gamma$ for u coprime to N. If $\alpha(u) = 1$ then $(u/d) = \epsilon_2(\alpha(u)) = 1$, so $\sigma_u(\gamma) = \gamma$; thus $\gamma \in E$. Put $s_d = \gamma$. For $\sigma = \bar\sigma_u$, $\sigma(s_d) = (u/d) s_d = \epsilon_2(\sigma) s_d$. For any embedding φ, $\varphi(s_d)^2 = -d$, so $\varphi(s_d) = \pm\sqrt{-1}\sqrt{d}$. If the sign is $-$, the embedding $\varphi \circ c$ satisfies $\varphi(c(s_d)) = \overline{\varphi(s_d)} = \sqrt{-1}\sqrt{d}$ by item 1. This gives φ_0 and item 2.

Galois structure over K. Let s_d be as in item 2 and $K = \mathbb{Q}(s_d)$, an imaginary quadratic field, Galois over $\mathbb{Q}$. As $s_d \neq 0$, an automorphism σ of E fixes K if and only if $\epsilon_2(\sigma) = 1$; so $\mathrm{Gal}(E/K) = \ker \epsilon_2$, and c acts on K non-trivially since $\epsilon_2(c) = -1$. Every $\sigma \in \mathrm{Gal}(E/\mathbb{Q})$ satisfies $\sigma(\mathcal{D}_{E/K}) = \mathcal{D}_{E/K}$: indeed $\mathcal{D}_{E/K}^{-1} = \{y \in E : \mathrm{Tr}_{E/K}(y\mathcal{O}_E) \subseteq \mathcal{O}_K\}$, $\sigma(\mathcal{O}_E) = \mathcal{O}_E$, $\sigma(\mathcal{O}_K) = \mathcal{O}_K$, and $\mathrm{Tr}_{E/K}(\sigma(y)) = \sum_{\tau \in \ker\epsilon_2} \tau\sigma(y) = \sigma(\sum_\tau \sigma^{-1}\tau\sigma(y)) = \sigma(\mathrm{Tr}_{E/K}(y))$ because $\mathrm{Gal}(E/\mathbb{Q})$ is abelian. Writing $\mathcal{D}_{E/K} = \prod_{\mathfrak{P}} \mathfrak{P}^{n_{\mathfrak{P}}}$ over the primes of E, it follows that $n_{\sigma(\mathfrak{P})} = n_{\mathfrak{P}}$ for all σ and $\mathfrak{P}$; and $n_{\mathfrak{P}} > 0$ exactly when $\mathfrak{P}$ is ramified in E/K (Dedekind).

Every prime of E ramified over K lies above a rational prime that splits in K. Let $\mathfrak{P}$ be ramified in E/K and ℓ the rational prime below it. Then ℓ is ramified in $E/\mathbb{Q}$, hence in $\mathbb{Q}(\zeta_N)$, so $\ell \mid N$. If $\ell = 2$: $d \equiv 7 \pmod{16}$ gives $-d \equiv 1 \pmod 8$, so 2 splits in $K = \mathbb{Q}(\sqrt{-d})$. If ℓ is an odd prime dividing Q_S: $(-d/\ell) = 1$ by (Hr2) and $\ell \neq d$ since $\gcd(Q_S, qd) = 1$, so ℓ splits in K. If $\ell = q$: $(-d/q) = 1$ by (Hr1) and $q \neq d$, so q splits. The case $\ell = d$ does not occur. Indeed, since $d \nmid Q_S q$, the inertia group in $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$ of a prime above d is $\{\sigma_u : u \equiv 1 \pmod{Q_S q}\}$. So the inertia group I of $\mathfrak{P}$ in $\mathrm{Gal}(E/\mathbb{Q})$ consists of the $\bar\sigma_u$ with $u \equiv 1 \pmod{Q_S q}$, which correspond to elements of $\{1, \iota_d\}$ by (Hr5). As $\epsilon_2(\iota_d) = -1$, the inertia group $I \cap \ker\epsilon_2$ of $\mathfrak{P}$ in E/K is trivial, contradicting the ramification of $\mathfrak{P}$ in E/K.

The ideal $\mathfrak{b}$. Let L be the finite set of rational primes below primes of E ramified in E/K. For $\ell \in L$ we have $\ell\mathcal{O}_K = \mathfrak{p}_\ell\, c(\mathfrak{p}_\ell)$ with $\mathfrak{p}_\ell \neq c(\mathfrak{p}_\ell)$; fix such $\mathfrak{p}_\ell$, and put

$$\mathfrak{b} = \prod_{\ell \in L} \prod_{\mathfrak{P} \mid \mathfrak{p}_\ell} \mathfrak{P}^{n_{\mathfrak{P}}} \qquad (\mathfrak{b} = \mathcal{O}_E \text{ if } L = \varnothing).$$

It is an integral ideal. The map $\mathfrak{P} \mapsto c(\mathfrak{P})$ is a bijection from the primes above $\mathfrak{p}_\ell$ to those above $c(\mathfrak{p}_\ell)$, and $n_{c(\mathfrak{P})} = n_{\mathfrak{P}}$; hence $c(\mathfrak{b}) = \prod_{\ell \in L} \prod_{\mathfrak{P} \mid c(\mathfrak{p}_\ell)} \mathfrak{P}^{n_{\mathfrak{P}}}$. Every $\mathfrak{P}$ with $n_{\mathfrak{P}} > 0$ lies above

$\mathfrak{p}_\ell$ or $c(\mathfrak{p}_\ell)$ for some $\ell \in L$, so $\mathfrak{b}\,c(\mathfrak{b}) = \mathcal{D}_{E/K}$. The ideals $\mathfrak{b}$ and $c(\mathfrak{b})$ are products of powers of two disjoint sets of primes (above the distinct primes $\mathfrak{p}_\ell$, resp. $c(\mathfrak{p}_\ell)$, of K), so they are coprime: $\mathfrak{b} + c(\mathfrak{b}) = \mathcal{O}_E$. Finally, if $\epsilon_2(\sigma) = 1$ then σ fixes K pointwise, hence fixes each $\mathfrak{p}_\ell$ and permutes the primes above it, preserving the exponents $n_{\mathfrak{P}}$; so $\sigma(\mathfrak{b}) = \mathfrak{b}$. This is item 3. □

Lemma 11.14. *Fix $\varepsilon > 0$ and $C_8 \geq 1$, and put*

$$C_8' = (3 + 2C_8)A, \qquad a = \frac{4\varepsilon}{5}, \qquad X_* = \exp\left(1 + \frac{2C_8'}{a^3}\right).$$

Let $x \geq X_*$ be real, let $N \geq 3$ and $p_1, p_2 \geq 2$ be integers, let $k \geq 1$ be real and let g_1, g_2 be positive real numbers such that

$$p_i \leq N^{C_8}, \qquad \log N \leq 2x^{\varepsilon/5}(\log x)^2, \qquad g_i \geq \left(k \exp(x^\varepsilon)\right)^8 \quad (i = 1, 2).$$

Then the following minima exist:

$$M = N(p_1 - 1)(p_2 - 1), \qquad r = \min\{\ell \geq 2 : \ell \text{ is prime and } \ell \nmid M\},$$

$$q^* = \min\{\ell \geq 2 : \ell \text{ is prime and } \ell \equiv 1 \pmod{rN}\}.$$

They satisfy

$$q^* \equiv 1 \pmod{rN}, \qquad q^* \leq N^{C_8'}, \qquad q^* \neq p_1, p_2, \qquad q^* < g_1, g_2, \qquad \gcd(q^*, N) = 1.$$

In particular, consider data satisfying the concrete good-host requirement at such a scale, and take $N = N_{\mathfrak{h}} = Q_S q d$ together with its primes p_1, p_2, g_1, g_2 and the integer k of its rank datum. Then the set of level primes may be replaced by

$$\{g_1, g_2, p_1, p_2, q^*\},$$

using the bound $q^* \leq N_{\mathfrak{h}}^{C_8'}$. This replacement leaves unchanged the list κ, the frame, the host (q, d, Q_S, α) and its arithmetic datum, the chosen field embeddings, the sets T, S, the element u_0, the rank datum, g_1, g_2, the ordering of A, the functions ρ_p and the sets G_p. All heights, weights, correction degrees, thresholds and correction errors that have been fixed keep their values.

Proof. The modulus in the second minimum is the product rN. We first prove that both minima exist and bound the second one. Since $M \geq 1$, choose a prime divisor s of $M + 1$. Then $s \nmid M$, so the first set is nonempty and

$$r \leq s \leq M + 1 \leq 2M.$$

In particular $rN \geq 6$. Linnik's theorem [163], with modulus rN and residue 1, gives a prime in the second set not exceeding $(rN)^A$. The least such prime therefore exists and satisfies

$$q^* \leq (rN)^A.$$

Because $N \geq 3$ and $p_i \geq 2$,

$$rN \leq 2N^2(p_1 - 1)(p_2 - 1) \leq N^3 p_1 p_2 \leq N^{3+2C_8}.$$

Raising this inequality to the positive exponent A proves $q^* \leq N^{C_8'}$.

The congruence implies $r \mid q^* - 1$. If $q^* = p_i$, then $r \mid p_i - 1$ and hence $r \mid M$, contradicting the choice of r. Thus $q^* \neq p_1, p_2$. Also $q^* \equiv 1 \pmod{N}$, which proves $\gcd(q^*, N) = 1$.

It remains to compare q^* with the numbers g_i. Write $y = \log x$. Then

$$y \geq 1 + \frac{2C_8'}{a^3} > 0.$$

The bound $\exp(z) \geq z^3/6$ for $z \geq 0$, from the exponential series, gives

$$8\exp(ay) \geq \frac{4}{3}a^3y^3 > 2C_8'y^2.$$

Multiplying by $x^{\varepsilon/5}$ and using $a = 4\varepsilon/5$, we obtain

$$\log q^* \leq C_8' \log N \leq 2C_8'x^{\varepsilon/5}(\log x)^2 < 8x^{\varepsilon} \leq 8\log k + 8x^{\varepsilon} \leq \log g_i.$$

Thus $q^* < g_i$ for $i = 1, 2$.

For the final assertion, data satisfying the concrete good-host requirement have $N_{\mathfrak{h}} \geq 3$, the required bounds on p_i and g_i, and $k \geq 1$. Their common scale Y satisfies $1 < Y \leq x$, so (Hg6) yields

$$\log N_{\mathfrak{h}} \leq 2Y^{\varepsilon/5}(\log Y)^2 \leq 2x^{\varepsilon/5}(\log x)^2.$$

Therefore the first part applies, with the same X_*, to all such data at every scale $x \geq X_*$. Take the new set of level primes to be the displayed set and keep all other listed data. The arithmetic datum is determined by the host, which is unchanged. The orbit choices are determined by that datum, the ordering of A and the parameters (x, ε, k), which are also unchanged. Hence the functions ρ_p and the sets G_p are the same as before, not merely of the same cardinalities. The listed numerical data are kept, so none of their values changes. Only the set of level primes is replaced. The exponent C_8' bounds the new prime q^*; it does not replace the parameter C_8 in κ. □

Part III
Slope records: the class defined by linking conditions

Part III proves the third input of Part I, Proposition 17.6: there are a good-host requirement and a class of parametrised host families with slope records that has the link properties (Gh1), (Lk1)–(Lk3) and (Lk5). Part I turns this into tied families through Corollary 8.3 and Proposition 7.9. The requirement is the concrete good-host requirement of Part II, and (Gh1) is Proposition 11.5. The class is $\mathcal{A}_{\mathrm{prop}}$ (Definition 17.5): a family belongs to it if it has the linking property and the properties of its tops (Pc1), and if, whenever it satisfies the Sha condition, it carries one compatible collection of records with the properties (Pc2)–(Pc6). Design existence (Lk1) for this class is Proposition 18.1, proved in Part IV. The main theorem of Part III is Theorem 17.7: every family of the class that satisfies the Sha condition has the properties (Sp1)–(Sp8) of its slope records, with the divisor exponent 1, and therefore slope data at its members with exponents $(e_D, e_L) = (1, 0)$. These exponents give the bound $G_{\mathfrak{L}_\psi}(x) \le x^{1/2+8\varepsilon}$ of Part I.

Four of the eight properties, (Sp1), (Sp2), (Sp6) and (Sp7), are required of the class directly. The other four are proved, each from records that the class requires, by theorems about hermitian lattices, Hecke lattices and Hilbert spaces: the sizes (Sp8) and the transfer of slopes (Sp3) in Section 12, the divisor package (Sp4) in Section 13, and the dual-slope bound (Sp5) in Sections 14–16. In the terms of Alpöge's account [4], (Sp4) carries the norms of the lifts and (Sp5) the slope inequality of Bost with approximate orthogonality; no result of Part III is about theta lifts, and the Part sees them only through the records. The Sha condition enters in Section 13, where the defects of the lattices are bounded by lengths of Tate–Shafarevich groups, and the local losses there are bounded by the Ribet budget Theorem 22.1 of Part V. Section 17 defines the class, which quotes the hypothesis lists of the theorems of Sections 12–16 and of the Ribet budget, and proves Theorem 17.7 and Proposition 17.6. Each of Sections 12–16 proves statements about families that carry given records, and can be read without the definition of the class. Nothing in Part III depends on (TCS) except Proposition 17.6, through Proposition 18.1.

12 Sizes and transfer of slopes: (Sp8), (Sp3)

This section proves two of the four properties of slope records that Theorem 17.7 derives, the sizes (Sp8) and the transfer of slopes (Sp3). The sizes are routine. Lemma 12.1 reads the size inequalities of a member off its loss datum and the rank sizes of Part II, and it gives (Sp8), with $k \le x^5$, once the few residual bounds collected in (Pc6) hold.

The transfer of slopes is the step in which divisibility becomes slope. The loss bound of Part I compares the prime sum with the lattice term Θ of the loss datum, which is built from the gains at the inert primes (Definition 5.5); (Sp3) moves Θ into the slope and the maximal slope of the lattices of the slope record, up to the terms F and E and an explicit error. The lattices are described by modification data (Definition 12.2): each is obtained from a level lattice by local twists at a finite set of places, and the modification formulas (Mf3) give its slope as the slope of the level lattice plus a weighted sum of local terms at these places. Theorem 12.3 computes the change place by place, with a rounding bound for the twists (Lemma 12.4). Of its hypotheses (Mf1)–(Mf8), the class requires the first seven, and the correction budget (Mf8) is derived: Lemma 12.5 obtains it from the linking property of the family, with Chebyshev's bound and Lemma 3.5; so (Sp3) uses the same linking property as the loss bound.

Lemma 12.1. *Let $\mathcal{F}$ be a parametrised host family with parameter ε, threshold x_1 and frame (e, A, h, a_0) at x. For a member (x, i) with $x > x_1$ let k, m, η, the size parameter L_c and a_t ($t \in T_{x,i}$) be the data of $\mathfrak{M}_{x,i}$, and put $n = |A|$, $f = 2n$, $b = e^{x^\varepsilon}$, $a = xb$, $X' = e^{x^{\varepsilon/3}}$, $b' = a/X'$, $X'' = xnX'$ and $L_a = \log\bigl(2a\, v(\mathfrak{h}_{x,i})\bigr)$, the analytic loss of the member.*

1. *If $I(x) \neq \emptyset$ for some $x > x_1$, then $\varepsilon < \frac{1}{52}$.*
2. *For every real $c > 0$ there is a real x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$ and every $t \in T_{x,i}$:*

$$m \leq x^{1/2+\varepsilon/2}, \quad xm \leq k, \quad k \leq x^5, \quad k \leq a, \quad k \leq n^2 x^{1/2-\varepsilon},$$
$$0 \leq L_c, \quad 0 \leq L_a, \quad kb' \leq a, \quad X'' \leq a,$$
$$2f(x+1)e^{-cx^{\varepsilon/8}} \leq \frac{1}{x}, \qquad 6f(x+1)(\eta+1) \leq \frac{b}{x}, \qquad \frac{a_t}{b} \leq x+1.$$

3. *Let $\mathcal{F}$ carry slope records, and suppose that $\varepsilon \leq 1$ and that there is a real x_0' such that for every real $x \geq x_0'$ with $x > x_1$: $I(x) \neq \emptyset$ if $x \in W$; and for every $i \in I(x)$, with $\mathfrak{V} = \mathfrak{V}_{x,i}$,*

$$x^{1/2-\varepsilon} \leq m, \quad L_a \leq 2x^\varepsilon, \quad \log|\mathcal{W}(\mathfrak{V})| \leq (k-3)\log 2,$$
$$x^{-\varepsilon} n \leq |T^{\mathrm{th}}_{x,i}|, \quad \tfrac{1}{2}x^{-\varepsilon/8} n \leq |T_{x,i}|, \quad a_t \geq (x-1)\, b \quad (t \in T_{x,i}).$$

Then $\mathcal{F}$ has the sizes (Sp8), with $e_K = 5$.

Proof. **Item 1.** If $i \in I(x)$ with $x > x_1$, then by (Pf1) the orbit selection of $\mathfrak{M}_{x,i}$ has parameter ε, and orbit selections have $0 < \varepsilon < \frac{1}{52}$.

Item 2: choice of x_0. Let $c > 0$. Since $\log y \leq y$ for $y > 0$, applied to $y = x^{\varepsilon/16}$, we have $\log x \leq \frac{16}{\varepsilon} x^{\varepsilon/16}$ for $x \geq 1$. Choose $x_0 \geq 1$ such that for $x \geq x_0$

$$x^{\varepsilon/3-\varepsilon/16} \geq \frac{80}{\varepsilon}, \qquad x^{\varepsilon/16} \geq \frac{1}{c}\Bigl(\log 8 + \frac{80}{\varepsilon}\Bigr), \qquad x^{2\varepsilon/3} \geq \log 48 + 2.$$

Then for $x \geq x_0$ (using $x^{\varepsilon/16} \geq 1$, $x^{\varepsilon/3} \geq 1$):

(L1) $5\log x \leq \frac{80}{\varepsilon} x^{\varepsilon/16} \leq x^{\varepsilon/3}$, i.e. $x^5 \leq X'$;

(L2) $\log 8 + 5\log x \leq (\log 8 + \frac{80}{\varepsilon}) x^{\varepsilon/16} \leq c\, x^{\varepsilon/8}$, i.e. $8x^5 \leq e^{cx^{\varepsilon/8}}$;

(L3) $\log 48 + 2x^{\varepsilon/3} \leq (\log 48 + 2) x^{\varepsilon/3} \leq x^\varepsilon$, i.e. $48\, e^{2x^{\varepsilon/3}} \leq b$; in particular $X'^2 \leq b$.

Item 2: the inequalities. Fix $x \geq x_0$ with $x > x_1$ and $i \in I(x)$. By item 1, $0 < \varepsilon < \frac{1}{52}$; by (Pf1) $\mathfrak{M}_{x,i}$ is on $H = A$, so $n = |H|$; by (Pf3) it satisfies (Lm7), and by (Pf2) it satisfies (Lm2). With $\theta_s = \varepsilon/100$ and $x \geq 1$:

- $m \leq x^{\theta_s}(x\delta_1)^{1/2} = x^{1/2-\varepsilon/16+\varepsilon/100} \leq x^{1/2} \leq x^{1/2+\varepsilon/2}$; also $m \leq x$.
- $k \geq x^{9/2+10\varepsilon-\theta_s} \geq x^{9/2} \geq x^{3/2} \geq xm$.
- $k \leq x^{9/2+10\varepsilon+\theta_s} \leq x^5$, since $10.01\,\varepsilon < \frac{1}{2}$.
- $n \geq x^{2+8\varepsilon-\theta_s}$, so $n^2 x^{1/2-\varepsilon} \geq x^{9/2+15\varepsilon-\varepsilon/50} \geq x^{9/2+10\varepsilon+\varepsilon/100} \geq k$; and $n \leq x^{2+8\varepsilon+\theta_s} \leq x^3$, since $8.01\,\varepsilon < 1$.

- $L_c \geq x^{\varepsilon} > 0$ by (Lm7). Further $L_a = \log a + \log\bigl(2v(\mathfrak{h}_{x,i})\bigr) \geq \log a = \log x + x^{\varepsilon} > 0$, because $2v(\mathfrak{h}_{x,i}) = |\mathrm{disc}(E_{\mathfrak{h}_{x,i}})|^{1/[E_{\mathfrak{h}_{x,i}}:\mathbb{Q}]} \geq 1$ (the discriminant of a number field is a non-zero integer) and $x \geq 1$.
- By (Lm2), $a_t \leq a(1+\vartheta)$ with $\vartheta = 1/(kx^{13}) \leq 1/x$ (as $k \geq 1$), so $a_t/b \leq x(1+\vartheta) \leq x+1$.
- By (L1), $k \leq x^5 \leq X'$; as $a > 0$ and $b' = a/X'$, this is $kb' \leq a$. Since $x^{\varepsilon/3} \leq x^{\varepsilon}$, $X' \leq b \leq xb = a$, so $k \leq a$.
- $n \leq x^3 \leq X'$ by (L1), so $nX' \leq X'^2 \leq b$ by (L3), and $X'' = xnX' \leq xb = a$.
- $f = 2n \leq 2x^3$ and $x+1 \leq 2x$, so $x \cdot 2f(x+1) \leq 8x^5 \leq e^{cx^{\varepsilon/8}}$ by (L2); this is $2f(x+1)e^{-cx^{\varepsilon/8}} \leq 1/x$.
- By (Lm7), $\eta > 0$ and $\log\eta \leq x^{\varepsilon/4}$, so $\eta + 1 \leq 2e^{x^{\varepsilon/4}} \leq 2X'$. Hence $x \cdot 6f(x+1)(\eta+1) \leq 6 \cdot 2x^3 \cdot 2x \cdot x \cdot 2e^{x^{\varepsilon/4}} = 48x^5 e^{x^{\varepsilon/4}} \leq 48X'e^{x^{\varepsilon/3}} = 48e^{2x^{\varepsilon/3}} \leq b$ by (L1) and (L3); this is $6f(x+1)(\eta+1) \leq b/x$.

The number x_0 depends only on ε and c.

Item 3. Let $c > 0$; take $e_K = 5$ and the maximum of x_0' and the x_0 of item 2 for c. For x beyond it with $x > x_1$, (Sp8) requires: $I(x) \neq \emptyset$ if $x \in W$ (hypothesis); and for every $i \in I(x)$ the fifteen inequalities of (Sp8). Of these, $m \leq x^{1/2+\varepsilon/2}$, $xm \leq k$, $k \leq x^{e_K}$, $k \leq a$, $k \leq n^2 x^{1/2-\varepsilon}$, $kb' \leq a$, $X'' \leq a$ and the two inequalities with $f(x+1)$ are in item 2; $x^{1/2-\varepsilon} \leq m$, $\log|\mathcal{W}(\mathfrak{V})| \leq (k-3)\log 2$, $x^{-\varepsilon}n \leq |T^{\mathrm{th}}_{x,i}|$ and $\frac{1}{2}x^{-\varepsilon/8}n \leq |T_{x,i}|$ are hypotheses; $0 \leq L_a \leq 2x^{\varepsilon}$ combines item 2 with the hypothesis; and $|a_t/b - x| \leq 1$ combines $a_t/b \leq x+1$ (item 2) with $a_t \geq (x-1)b$ (hypothesis). Together with $\varepsilon \leq 1$ this is (Sp8). □

Definition 12.2. Let $\mathcal{F}$ be a parametrised host family with slope records, with parameter ε, threshold x_1 and frame (e, A, h, a_0) at x. For a member (x,i) with $x > x_1$, write $\mathfrak{V} = \mathfrak{V}_{x,i}$ and $\mathfrak{M} = \mathfrak{M}_{x,i}$, and let m, $(K, S, \ell, (g_j)_{1\leq j\leq m}, \tau, \mathrm{io})$ and $p(w)$ be the integer, the place record and the residue characteristics of $\mathfrak{M}$. Let d be the prime of the host $\mathfrak{h}_{x,i}$, and put

$$n = |A|, \quad f = 2n, \quad b = e^{x^{\varepsilon}}, \quad a = xb, \quad X' = e^{x^{\varepsilon/3}}, \quad b' = \frac{a}{X'}, \quad X'' = xnX'.$$

Modification data for $\mathcal{F}$ are, for every real $x > x_1$ and every $i \in I(x)$,

- for every $w \in S$ and $1 \leq j \leq m$ a real number $F_j(\mathfrak{V}, w)$, the **local frame numbers**;
- for every word $\omega \in \mathcal{W}(\mathfrak{V})$: an integer $d^{\circ}(\mathfrak{V}, \omega) \geq 1$; real numbers $\mu^{\circ}(\mathfrak{V}, \omega)$ and $\mu^{\circ\max}(\mathfrak{V}, \omega)$, the **slope of the level lattice** and the **maximal slope of the level lattice** of ω; an integer $N_{\Gamma}(\mathfrak{V}, \omega) \geq 1$, the **exceptional modulus** of ω; and for every $w \in S$ and $1 \leq j \leq m$ real numbers $E_j(\mathfrak{V}, \omega, w)$ (the **local exponents**), $\mathrm{len}(\mathfrak{V}, \omega, w)$ (the **local length**) and $\mathrm{tw}^{\flat}(\mathfrak{V}, \omega, w)$ (the **rounded twist**),

such that for every word ω

$$F(\mathfrak{V}) = 2\sum_{j=1}^{m}\sum_{w\in S} \ell(w)\, F_j(\mathfrak{V}, w), \qquad E(\mathfrak{V}, \omega) = 2\sum_{j=1}^{m}\sum_{w\in S} \ell(w)\, E_j(\mathfrak{V}, \omega, w). \tag{12.1}$$

The **twist** of ω at $w \in S$ and the set of places at the Gauss prime are

$$\mathrm{tw}(\mathfrak{V}, \omega, w) = \sum_{j=1}^{m}\bigl(g_j(w) + F_j(\mathfrak{V}, w) - E_j(\mathfrak{V}, \omega, w)\bigr), \qquad S_T(\mathfrak{V}, \omega) = \{w \in S :\ p(w) = T(\mathfrak{V}, \omega)\}.$$

A **parametrised host family with slope records and modification data** is a parametrised host family with slope records together with modification data for it.

As in Definition 8.2, a statement holds "for all large members" if there is a real x_0 such that it holds for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$ and every word $\omega \in \mathcal{W}(\mathfrak{V}_{x,i})$. We write $T = T(\mathfrak{V}, \omega)$. Such a family has each of the following properties if the stated condition holds.

(Mf1) Non-negative local weights For all large members, $\ell(w) \geq 0$ for every finite place w of K.

(Mf2) Level lattices For all large members, $T > 2$ and

$$d(\mathfrak{V}, \omega) = \Big(1 - \frac{1}{T-1}\Big)^f d^\circ(\mathfrak{V}, \omega), \qquad \mu^\circ(\mathfrak{V}, \omega) = \mu'(\mathfrak{V}, \omega) - \frac{f \log(T-1)}{T-2},$$
$$\mu^{\circ\max}(\mathfrak{V}, \omega) \leq \mu'^{\max}(\mathfrak{V}, \omega).$$

(Mf3) Modification formulas For all large members, $d(\mathfrak{V}, \omega) > 0$ and

$$\mu(\mathfrak{V}, \omega) = \mu^\circ(\mathfrak{V}, \omega) + \sum_{w \in S} 2\ell(w)\, \mathrm{tw}^\flat(\mathfrak{V}, \omega, w) - \frac{1}{d(\mathfrak{V}, \omega)} \sum_{w \in S} 2\ell(w)\, \mathrm{len}(\mathfrak{V}, \omega, w),$$
$$\mu^{\max}(\mathfrak{V}, \omega) \leq \mu^{\circ\max}(\mathfrak{V}, \omega) + \sum_{w \in S} 2\ell(w)\big(\mathrm{tw}^\flat(\mathfrak{V}, \omega, w) - \tau(w)\big).$$

(Mf4) Local lengths There is a real $C \geq 0$ such that, for all large members, $\mathrm{len}(\mathfrak{V}, \omega, w) \leq d^\circ(\mathfrak{V}, \omega)(\tau(w) + \mathrm{io}(w))$ for every $w \in S \setminus S_T(\mathfrak{V}, \omega)$, and

$$\sum_{w \in S_T(\mathfrak{V}, \omega)} 2\ell(w)\, \mathrm{len}(\mathfrak{V}, \omega, w) \leq C\, d(\mathfrak{V}, \omega)\, |T_{x,i}|\, m\Big(\frac{a}{k} + b'\Big) \log T,$$

where k is the size parameter of $\mathfrak{M}$.

(Mf5) Rounding For all large members and every $w \in S$, $\mathrm{tw}^\flat(\mathfrak{V}, \omega, w) \leq \mathrm{tw}(\mathfrak{V}, \omega, w) \leq \mathrm{tw}^\flat(\mathfrak{V}, \omega, w) + 1$, and $\mathrm{tw}^\flat(\mathfrak{V}, \omega, w) = 0$ when $\mathrm{tw}(\mathfrak{V}, \omega, w) = 0$.

(Mf6) Support of the twists For all large members, $\mathrm{tw}(\mathfrak{V}, \omega, w) = 0$ for every $w \in S$ with $p(w) > X''$, $p(w) \notin \{T,\, g_1(\mathfrak{V}),\, g_2(\mathfrak{V}),\, d\}$ and $p(w) \nmid N_\Gamma(\mathfrak{V}, \omega)$.

(Mf7) Sizes of the special primes There is a real $C \geq 0$ such that, for all large members, $T \geq b^3$ and

$$\log T + \log g_1(\mathfrak{V}) + \log g_2(\mathfrak{V}) + \log d + \log N_\Gamma(\mathfrak{V}, \omega) \leq C\, X''.$$

(Mf8) Correction budget For all large members, $\sum_{w \in S} 2\ell(w)\, \tau(w) \leq b^2$.

Theorem 12.3. *Let $\mathcal{F}$ be a parametrised host family with slope records and modification data that has the properties (Mf1)–(Mf8). Then $\mathcal{F}$ has the transfer of slopes (Sp3). More precisely, there are real numbers $C \geq 0$ and x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$ and every word $\omega \in \mathcal{W}(\mathfrak{V})$, with $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\mathfrak{M} = \mathfrak{M}_{x,i}$ and the notation of (Sp3),*

$$\mu^{\max}(\mathfrak{V}, \omega) \leq \mu'^{\max}(\mathfrak{V}, \omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V}, \omega),$$
$$\mu(\mathfrak{V}, \omega) \geq \mu'(\mathfrak{V}, \omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V}, \omega)$$
$$- \Big(C\, I(\mathfrak{M}) + C|T_{x,i}|\, m\Big(\frac{a}{k} + b'\Big) \log T(\mathfrak{V}, \omega) + CX'' + 1\Big).$$

Proof. Let ε be the parameter of $\mathcal{F}$. Let $C_4 \geq 0$ be the constant of (Mf4) and $C_R \geq 0$ the constant of Lemma 12.4 (which applies by (Mf1), (Mf5), (Mf6), (Mf7)); put $C = \max(4, C_4, C_R)$. Let $N = \lceil 4/\varepsilon \rceil$ and let x_0 be the largest of $32\,N!$, the thresholds of (Mf1)–(Mf8) and that of Lemma 12.4. Fix $x \geq x_0$ with $x > x_1$, $i \in I(x)$ and $\omega \in \mathcal{W}(\mathfrak{V})$, and write $T = T(\mathfrak{V}, \omega)$, $d_\omega = d(\mathfrak{V}, \omega)$, $d_\omega^\circ = d^\circ(\mathfrak{V}, \omega)$, and n, f, b, a, X', b', X'' as in Definition 12.2; let k be the size parameter of $\mathfrak{M}$.

Signs. (i) By (Pf1) the orbit selection of $\mathfrak{M}$ has parameter ε and integer m, so $0 < \varepsilon < \frac{1}{52}$ and $m \geq 1$; $x > x_1 > 1$. (ii) For $w \in S$: $\tau(w) \geq 0$ and $\mathrm{io}(w) \geq 0$. Indeed, by (Lm6) (through (Pf2)) either $p(w)$ is not inert and $\tau(w) = \mathrm{io}(w) = 0$, or $\tau(w) = \tau_{p(w)}$ and $\mathrm{io}(w) = \mathrm{io}_{p(w)}$; and τ_p is 0 or $\epsilon_p + m \sum_{v \in V_p} (\lceil t_p(v) \rceil^+ + D_p + 1) \geq 0$, while io_p is 0 or $2\Sigma_p \max_{v \in V_p} S_p(v) \geq 0$, as $\Sigma_p \geq 0$ and $S_p(v) \geq 0$. (iii) Hence, with $\ell \geq 0$ (Mf1), the numbers $A := \sum_{w \in S} 2\ell(w)\tau(w)$ and $I(\mathfrak{M})$ are ≥ 0, and $A \leq b^2$ by (Mf8). (iv) By (Lm7) (through (Pf3)) $k > 0$, so $\Lambda := |T_{x,i}|\, m\, (a/k + b') \log T \geq 0$ (T is a prime); also $X'' > 0$ and $B_0(x, i) = 2nmbx^\varepsilon \geq 0$.

Sizes. We show $b \geq 16f$ and $b \geq 4$. By (Lm7), $n \leq x^{2+8\varepsilon+\varepsilon/100} \leq x^3$, since $x \geq 1$ and $8.01\,\varepsilon < 1$; so $f = 2n \leq 2x^3$. As $e^y \geq y^N/N!$ for $y \geq 0$, and $\varepsilon N \geq 4$, $x \geq 1$,

$b \geq 16f$; and $f \geq 2$ gives $b \geq 32 \geq 4$. By (Mf7), $T \geq b^3$. Consequently:

- $T \geq 64$; $\dfrac{2f}{T} \leq \dfrac{b/8}{b^3} \leq \dfrac{1}{2}$; $\dfrac{4fb^2}{T} \leq \dfrac{4f}{b} \leq \dfrac{1}{4}$;
- $\dfrac{f \log(T-1)}{T-2} \leq \dfrac{1}{4}$: since $\log y < y$ for $y > 0$, $\log(T-1) < \log T = 2 \log \sqrt{T} < 2\sqrt{T}$; since $b^2 \leq b^3 \leq T$, $b \leq \sqrt{T}$, so $f \log(T-1) \leq 2f\sqrt{T} \leq \frac{b}{8}\sqrt{T} \leq \frac{T}{8}$, while $T - 2 \geq \frac{T}{2}$.

Hence

$$\frac{4fb^2}{T} + \frac{f \log(T-1)}{T-2} \leq 1. \tag{12.2}$$

The deficit of the level lattice. Put $\delta = 1 - d_\omega/d_\omega^\circ$. By (Mf2), $d_\omega = (1-y)^f d_\omega^\circ$ with $y = 1/(T-1) \in (0,1)$, so $\delta = 1 - (1-y)^f$. By Bernoulli's inequality $(1-y)^f \geq 1 - fy$ (as f is a non-negative integer), so $0 \leq \delta \leq fy = f/(T-1) \leq 2f/T \leq \frac{1}{2}$, the middle step because $2(T-1) \geq T$. Therefore $d_\omega^\circ/d_\omega = 1/(1-\delta) \leq 2$ and $d_\omega^\circ/d_\omega - 1 = \delta/(1-\delta) \leq 2\delta \leq 4f/T$.

The twisting sum. By the definition of the twist, (12.1) and the formula for $\Theta(\mathfrak{M})$,

$$\sum_{w \in S} 2\ell(w)\, \mathrm{tw}(\mathfrak{V}, \omega, w) = 2 \sum_{w \in S} \ell(w) \sum_{j=1}^{m} g_j(w) + F(\mathfrak{V}) - E(\mathfrak{V}, \omega) = \Theta(\mathfrak{M}) + A + F(\mathfrak{V}) - E(\mathfrak{V}, \omega). \tag{12.3}$$

By Lemma 12.4,

$$\sum_{w \in S} 2\ell(w)\, \mathrm{tw}(\mathfrak{V}, \omega, w) - C_R X'' \leq \sum_{w \in S} 2\ell(w)\, \mathrm{tw}^\flat(\mathfrak{V}, \omega, w) \leq \sum_{w \in S} 2\ell(w)\, \mathrm{tw}(\mathfrak{V}, \omega, w). \tag{12.4}$$

Upper bound. By (Mf3), the right half of (12.4), (Mf2) and (12.3),

$$\mu^{\max}(\mathfrak{V}, \omega) \leq \mu^{\circ\,\max}(\mathfrak{V}, \omega) + \sum_{w \in S} 2\ell(w) \mathrm{tw}^\flat(\mathfrak{V}, \omega, w) - A \leq \mu'^{\max}(\mathfrak{V}, \omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V}, \omega).$$

Since $C\, m\, B_0(x, i) \geq 0$ by (iv), this gives the first inequality of (Sp3).

The local lengths. Split S into $S_T = S_T(\mathfrak{V}, \omega)$ and $S \setminus S_T$. By the second part of (Mf4), $\frac{1}{d_\omega} \sum_{w \in S_T} 2\ell(w)\, \mathrm{len}(\mathfrak{V}, \omega, w) \leq C_4 \Lambda$. By the first part, $\ell \geq 0$, and the signs (ii),

$$\frac{1}{d_\omega} \sum_{w \in S \setminus S_T} 2\ell(w)\, \mathrm{len}(\mathfrak{V}, \omega, w) \leq \frac{d_\omega^\circ}{d_\omega} \sum_{w \in S \setminus S_T} 2\ell(w)\big(\tau(w) + \mathrm{io}(w)\big) \leq \frac{d_\omega^\circ}{d_\omega}\big(A + 2I(\mathfrak{M})\big).$$

Lower bound. By (Mf3), the left half of (12.4), (12.3), (Mf2) and the two bounds for the local lengths,

$$\mu(\mathfrak{V},\omega) \geq \mu'(\mathfrak{V},\omega) - \frac{f\log(T-1)}{T-2} + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V},\omega) + A - C_R X'' - C_4\Lambda - \frac{d_\omega^\circ}{d_\omega}(A + 2I(\mathfrak{M})).$$

By the deficit bounds, $0 \leq A \leq b^2$ and $I(\mathfrak{M}) \geq 0$, we have $A - \frac{d_\omega^\circ}{d_\omega} A \geq -\frac{4f}{T} b^2$ and $\frac{d_\omega^\circ}{d_\omega}\, 2I(\mathfrak{M}) \leq 4I(\mathfrak{M})$. With (12.2),

$$\mu(\mathfrak{V},\omega) \geq \mu'(\mathfrak{V},\omega) + \Theta(\mathfrak{M}) + F(\mathfrak{V}) - E(\mathfrak{V},\omega) - \big(4I(\mathfrak{M}) + C_4\Lambda + C_R X'' + 1\big).$$

As $I(\mathfrak{M}), \Lambda, X'' \geq 0$ and $4, C_4, C_R \leq C$, the bracket is at most $C\, I(\mathfrak{M}) + C\Lambda + CX'' + 1$, which is the second inequality of (Sp3). The constants $C \geq 0$ and x_0 do not depend on x, i or ω, so $\mathcal{F}$ has (Sp3). □

Lemma 12.4. *Let $\mathcal{F}$ be a parametrised host family with slope records and modification data that has non-negative local weights (Mf1), rounding (Mf5), support of the twists (Mf6) and sizes of the special primes (Mf7). Then there is a real number $C_R \geq 0$ such that for all large members*

$$0 \leq \sum_{w \in S} 2\ell(w)\big(\mathrm{tw}(\mathfrak{V},\omega,w) - \mathrm{tw}^\flat(\mathfrak{V},\omega,w)\big) \leq C_R\, X''.$$

Proof. Let $C \geq 0$ be the constant of (Mf7), let x_0 be the largest of the thresholds of (Mf1), (Mf5), (Mf6), (Mf7), and put $C_R = 2(\log 4 + C)$. Fix $x \geq x_0$ with $x > x_1$, $i \in I(x)$ and a word $\omega \in \mathcal{W}(\mathfrak{V})$, $\mathfrak{V} = \mathfrak{V}_{x,i}$; write $\mathrm{tw}(w)$, $\mathrm{tw}^\flat(w)$ for $\mathrm{tw}(\mathfrak{V},\omega,w)$, $\mathrm{tw}^\flat(\mathfrak{V},\omega,w)$, and $\Sigma = \sum_{w\in S} 2\ell(w)(\mathrm{tw}(w) - \mathrm{tw}^\flat(w))$.

Each term lies in $[0, 2\ell(w)]$ and vanishes unless $\mathrm{tw}(w) \neq 0$. By (Mf5), $0 \leq \mathrm{tw}(w) - \mathrm{tw}^\flat(w) \leq 1$ for $w \in S$, and $\mathrm{tw}(w) - \mathrm{tw}^\flat(w) = 0$ when $\mathrm{tw}(w) = 0$; by (Mf1), $\ell(w) \geq 0$. Hence every term of Σ is non-negative, so $\Sigma \geq 0$, and

$$\Sigma \leq \sum_{w \in S_0} 2\ell(w), \qquad S_0 = \{w \in S :\ \mathrm{tw}(w) \neq 0\}.$$

The places of S_0 lie over a small set of primes. Let P be the set of primes p with $p \leq X''$, together with T, $g_1(\mathfrak{V})$, $g_2(\mathfrak{V})$, d and the prime divisors of $N_\Gamma(\mathfrak{V},\omega)$. If $w \in S$ and $p(w) \notin P$, then $p(w) > X''$, $p(w) \notin \{T, g_1(\mathfrak{V}), g_2(\mathfrak{V}), d\}$ and $p(w) \nmid N_\Gamma(\mathfrak{V},\omega)$, so $\mathrm{tw}(w) = 0$ by (Mf6). Thus $p(w) \in P$ for every $w \in S_0$. Grouping the places of S_0 by their residue characteristic and using $\ell \geq 0$ on all finite places of K (Mf1) and the normalisation of the place record,

$$\sum_{w \in S_0} 2\ell(w) \leq 2 \sum_{p \in P} \sum_{w \mid p} \ell(w) = 2 \sum_{p \in P} \log p.$$

The primes of P. The set P is the union of $\{p \leq X''\}$, of the four primes $T, g_1(\mathfrak{V}), g_2(\mathfrak{V}), d$ and of the prime divisors of $N_\Gamma(\mathfrak{V},\omega)$; as all $\log p \geq 0$, the sum over the union is at most the sum of the sums over the parts. By Chebyshev's bound $\sum_{p \leq y} \log p \leq y \log 4$ for $y \geq 0$ (here $X'' > 0$); and $\sum_{p \mid N} \log p \leq \log N$ for an integer $N \geq 1$. Hence, by (Mf7),

$$\sum_{p \in P} \log p \leq X'' \log 4 + \log T + \log g_1(\mathfrak{V}) + \log g_2(\mathfrak{V}) + \log d + \log N_\Gamma(\mathfrak{V},\omega) \leq (\log 4 + C)\, X''.$$

Combining the three displays, $0 \leq \Sigma \leq 2(\log 4 + C)X'' = C_R X''$. □

Lemma 12.5. *Let $\mathcal{F}$ be a parametrised host family with parameter ε and threshold x_1 that has the linking property. Then there are real numbers $K_\tau \geq 0$, $E_\tau \geq 0$ and x_0 such that for every real $x \geq x_0$ with $x > x_1$ and every $i \in I(x)$, with $(K, S, \ell, (g_j), \tau, \mathrm{io})$ the place record of $\mathfrak{M}_{x,i}$,*

$$0 \leq \sum_{w \in S} 2\ell(w)\,\tau(w) \leq K_\tau\, x^{E_\tau}\, b(x) \leq b(x)^2.$$

In particular every parametrised host family with slope records and modification data whose underlying parametrised host family has the linking property has the correction budget (Mf8).

Proof. Let C, x_{L} and δ be the constants and the function of the linking property, so that for $x \geq x_{\mathrm{L}}$, $x > x_1$, every $\mathfrak{M}_{x,i}$ satisfies (Lm3) for (C, b_o) with $b_o = b(x)^{\delta(x)}$; let ε_z, C_t be the numbers of (Pf3). Put $C^+ = \max(C, 0)$, $c_t = |C_t| + 1$,

$$E_\tau = 2c_t + 42, \qquad K_\tau = 64 + 192\,C^+ + 4\,C^+\Big(\frac{32}{\varepsilon} + 66\Big),$$

and let $x_0 \geq \max(x_{\mathrm{L}}, 1)$ be such that for every $x \geq x_0$: $|\delta(x)| \leq \frac{1}{2}$, $x^{2\varepsilon/3} \geq 2$ and $K_\tau x^{E_\tau} \leq \exp(x^\varepsilon)$. Such x_0 exists: $\delta(x) \to 0$; and since $\log y \leq y$ for $y > 0$, $\log x \leq \frac{2}{\varepsilon} x^{\varepsilon/2}$, so $\log K_\tau + E_\tau \log x \leq (|\log K_\tau| + \frac{2E_\tau}{\varepsilon}) x^{\varepsilon/2} \leq x^\varepsilon$ as soon as $x^{\varepsilon/2} \geq \max(1, |\log K_\tau| + \frac{2E_\tau}{\varepsilon})$ (here $K_\tau \geq 64$).

Fix $x \geq x_0$ with $x > x_1$ and $i \in I(x)$, and write $\mathfrak{M} = \mathfrak{M}_{x,i}$ with its data as in Definition 5.5, $T = T_{x,i}$ its set of tops, $b = b(x)$, $b_o = b^{\delta(x)}$ and $\Upsilon = \exp(x^{\varepsilon/4})$. By (Pf1) the orbit selection of $\mathfrak{M}$ has scale x and parameter ε, so $0 < \varepsilon < \frac{1}{52}$ and $m \geq 1$; $x > 1$.

Sizes. By (Lm7) (through (Pf3)), with $\theta_s = \varepsilon/100$ and $0 < \varepsilon < \frac{1}{52}$, $x \geq 1$:

- $n \leq x^{2+8\varepsilon+\theta_s} \leq x^3$, $|T| \leq n$ (as $T \subseteq H$), so $m|T| \leq x^4$ by the next item;
- $m \leq x^{\theta_s}(x\delta_1)^{1/2} = x^{1/2-\varepsilon/16+\varepsilon/100} \leq x$;
- $1 \leq x^{9/2+10\varepsilon-\theta_s} \leq k \leq x^{9/2+10\varepsilon+\theta_s} \leq x^5$, hence $p_0^* = k^2 x^{26} \leq x^{36}$;
- $0 \leq t_R \leq x^{C_t+\theta_s} \leq x^{c_t}$, hence $N = k + m(t_R + 1) \leq x^5 + 2x^{c_t+1} \leq 3x^{c_t+5}$;
- $0 < x^\varepsilon \leq L_a \leq x^{\varepsilon+\theta_s} \leq x$;
- $S_c = 4k\Delta$ with $0 < \Delta \leq e^{x^{\varepsilon/4}/2} \leq \Upsilon$, so $0 < S_c \leq 4x^5\Upsilon$ and $c_G = 4S_c > 0$; $0 < \eta \leq \Upsilon$; hence $S_c + k + \eta \leq 6x^5\Upsilon$;
- $r_G = \lceil (32 + 64\varepsilon)/\varepsilon \rceil + 1 \leq \frac{32}{\varepsilon} + 66$; $\vartheta = 1/(kx^{13}) \leq 1$.

Moreover $X' \geq 1$, $b \geq 1$, $b' = a/X' \leq a = xb$, $X'b' = a$, $w'' > 0$, $\lambda = \log x \leq x$, $1/\delta_1 = x^{\varepsilon/8} \leq x$, $\log a = \log x + x^\varepsilon \leq 2x$, $\log(2a) \leq 3x$, and, by the choice of x_0,

$$\Upsilon X' \leq e^{2x^{\varepsilon/3}} \leq b, \qquad X' b^{1/2} \leq b, \qquad b_o \leq b^{1/2}, \qquad K_\tau x^{E_\tau} \leq b, \tag{12.5}$$

the first two because $2x^{\varepsilon/3} \leq x^\varepsilon$ and $x^{\varepsilon/3} \leq x^\varepsilon/2$ follow from $x^{2\varepsilon/3} \geq 2$, the third because $b \geq 1$ and $\delta(x) \leq \frac{1}{2}$.

Reduction to the candidates with served orbits. Let $\mathbb{P}_V$ be the set of candidates p with $V_p \neq \emptyset$; every $p \in \mathbb{P}_V$ is a prime with $p < X'$. For $w \in S$, (Lm6) (through (Pf2)) gives $\tau(w) = \tau_{p(w)}$ if $p(w)$ is inert and $\tau(w) = 0$ otherwise; and $\tau_p = 0$ when $V_p = \emptyset$, while $V_p \neq \emptyset$ forces p to be a candidate. So $\tau(w) \neq 0$ only if $p(w) \in \mathbb{P}_V$. For $p \in \mathbb{P}_V$, $p < X' \leq X''$, so by

(Lm6) every finite place of K above p lies in S, and the normalisation of the place record gives $\sum_{w\in S,\,w|p}\ell(w)=\log p$. Grouping the places of S by residue characteristic,

$$\sum_{w\in S}2\ell(w)\tau(w)=2\sum_{p\in\mathbb{P}_V}\tau_p\log p. \tag{12.6}$$

Each τ_p is ≥ 0: it is 0 or $\epsilon_p+m\sum_{v\in V_p}(\lceil t_p(v)\rceil^+ + D_p+1)$ with $\epsilon_p, D_p\geq 0$. This gives the lower bound 0 of the statement.

The primes of $\mathbb{P}_V$ are served. Let $p\in\mathbb{P}_V$. It is not of kind (Dr1), as $p<X'\leq X''$. It is a candidate, so it is not sign-changing and h_p has order at least $x^{\varepsilon/4}$; by (Lm1) h_p then has even order, so p is not of kind (Dr2). It is not of kind (Dr3): the order of h_p is not below $x^{\varepsilon/4}$; if $p\geq p_0^*$ no power of p lies in a band (definition of a candidate; the threshold p_0 of the orbit selection is p_0^*); and $\Sigma_p\leq x^{-\varepsilon}$ because $V_p\neq\emptyset$. Hence p is served, and the served-prime inequality of (Lm3) for (C,b_o) holds at p.

The gains at $p\in\mathbb{P}_V$ are at most $6m|T|a/p$. Fix j. If $\mathrm{gain}_j(p)=0$ by the exceptional clause of its definition there is nothing to show. Otherwise

$$\mathrm{gain}_j(p)=\sum_{v\in V_p}\max\bigl(g_j^U(v)-\mathrm{Pr}_j(v),\,g_j^0(v),\,0\bigr)+\sum_{v\in R_p\setminus V_p}\max\bigl(g_j^0(v),0\bigr).$$

(a) For $v\in R_p$, $\max(g_j^0(v),0)\leq 2a\gamma_p N_p(v)$. Indeed $g_j^0(v)=\sum_{s\in T_p(v)}\sigma_s-\delta_p(v)$, where σ_s is the series over the odd e not excluded for s of $(\alpha_s/p^e-c_j(s,e))^+$, and $\delta_p(v)\geq 0$ since $2a\geq 1$. We show $0\leq\sigma_s\leq\alpha_s^+\gamma_p$. If the series does not converge, $\sigma_s=0$ by the convention of Definition 5.3. If it converges, its terms tend to 0. Since $z_p(s,e+2n_p)=z_p(s,e)+2n_pf_p=z_p(s,e)$, the capacity $c_j(s,e)$ depends only on e modulo $2n_p$; and only finitely many e are excluded for s (each top $s'\neq s$ has at most one first hit from s). So every odd e_0 has infinitely many non-excluded odd $e\equiv e_0\pmod{2n_p}$, along which the terms tend to $(-c_j(s,e_0))^+$; hence $c_j(s,e_0)\geq 0$ for every odd e_0, each term is at most $(\alpha_s/p^e)^+=\alpha_s^+/p^e$, and $\sigma_s\leq\alpha_s^+\sum_{e\text{ odd}}p^{-e}=\alpha_s^+\gamma_p$. Finally $\alpha_s=a_s-2c_G\leq a_s\leq a(1+\vartheta)\leq 2a$ by (Lm2) and $c_G>0$, so $\alpha_s^+\leq 2a$, and $\max(g_j^0(v),0)\leq\sum_{s\in T_p(v)}\alpha_s^+\gamma_p\leq 2a\gamma_pN_p(v)$.

(b) For $v\in V_p$, using $\max(A,B,0)=\max(B,0)+(A-\max(B,0))^+$ for reals A,B,

$$\sum_{j=1}^m\max\bigl(g_j^U(v)-\mathrm{Pr}_j(v),g_j^0(v),0\bigr)=\sum_{j=1}^m\max(g_j^0(v),0)$$
$$+\sum_{j=1}^m\bigl(g_j^U(v)-\mathrm{Pr}_j(v)-\max(g_j^0(v),0)\bigr)^+\leq\sum_{j=1}^m\max(g_j^0(v),0)+S_p(v),$$

and $S_p(v)\leq 2mN_p(v)a/p$ by the surplus bound of (Lm3).

The sets $T_p(v)$, $v\in R_p$, partition T, so $\sum_{v\in R_p}N_p(v)=|T|$; $V_p\subseteq G_p\subseteq R_p$; and $\gamma_p=p/(p^2-1)\leq 2/p$ as $p^2\geq 2$. Summing (a) over $v\in R_p$ and j, and (b) over $v\in V_p$ (every term of the gains is non-negative),

$$\sum_{j=1}^m\mathrm{gain}_j(p)\leq m\cdot 2a\cdot\frac{2}{p}\,|T|+\frac{2ma}{p}|T|=\frac{6m|T|a}{p}. \tag{12.7}$$

The correction at $p\in\mathbb{P}_V$. The series $A_p(a_t,t,w_j)$ has non-negative terms and, as $w_j\geq w''>0$ on Φ (Lm2), finitely many non-zero ones, so $A_p\geq 0$. Writing $y^+=\max(y,0)$, the served-prime inequality and $T_p^{\mathrm{s}}\subseteq T$ give

$$\tau_p\leq\sum_{j=1}^m\mathrm{gain}_j(p)+\sum_{j=1}^m\sum_{t\in T_p^{\mathrm{s}}}\mathrm{lo}_{C,b_o}(p)+m\,\mathrm{fl}_C(p)\leq\frac{6m|T|a}{p}+m|T|\,\mathrm{lo}_{C,b_o}(p)^+ +m\,\mathrm{fl}_C(p)^+. \tag{12.8}$$

Since $p \in \mathbb{P}_V$ is inert and not sign-changing, $p < X'$, and all brackets in the definitions of the losses are non-negative while $b_o \geq 0$,

$$\mathrm{fl}_C(p)^+ \leq C^+ f(N^2 \log_p a + (\log_p a)^2),$$
$$\mathrm{lo}_{C,b_o}(p)^+ \leq C^+(S_c + k + \eta)\log_p(2a) + \mathrm{pr}^+ + C^+\lambda\Big(\frac{L_a a}{pk} + \frac{a}{p^2}\Big),$$

where $\mathrm{pr}^+ = C^+ r_G b'\lambda$ if $p < p_0^*$ and $\mathrm{pr}^+ = C^+(b'/x + \eta + S_c + (w'' + t_R)\lambda/\delta_1) + b_o$ otherwise; in the last term $p^{-L_1(p)} \leq p^{-2}$ because $k^2 x^{78} > 1$ gives $L_1(p) \geq 2$.

Summation. Insert (12.8) into (12.6) and sum over $p \in \mathbb{P}_V$, a set of fewer than X' primes below X'. We use: $\sum_{p<y} \log p \leq y \log 4 \leq 2y$ (Chebyshev's bound, Lemma B.3); $\sum_{p<X'} \frac{\log p}{p} \leq \sum_{n \leq X'} \frac{\Lambda(n)}{n} \leq \log X' + 3 + \log 2 \leq x^{\varepsilon/3} + 4 \leq 5x$ (Lemma 3.5, item 3, since $X' \geq 1$); $\sum_{p<X'} \frac{\log p}{p^2} \leq 5x$ likewise; and the sizes above. The five contributions are:

Each of them is at most a constant times $x^{E_\tau} b$, and their sum is at most $K_\tau x^{E_\tau} b$. Hence

$$\sum_{w \in S} 2\ell(w)\tau(w) \leq K_\tau x^{E_\tau} b \leq b^2,$$

the last step by (12.5). The numbers K_τ, E_τ, x_0 depend only on $\mathcal{F}$ (through C, x_{L}, δ, C_t, ε), not on x or i.

The correction budget. For a parametrised host family with slope records and modification data, (Mf8) is the requirement that $\sum_{w \in S} 2\ell(w)\tau(w) \leq b^2$ for all large members, where the sum does not depend on the word; this has been shown. □

13 Norms of the lifts and the divisor package: (Sp4)

This section proves the divisor package (Sp4) for the class, with the exponent 1 (Theorem 13.2). Its central inequality, the divisor bound, bounds the dual slope of the target, corrected by a height, by a sum over the tops t in which each of the m lifts contributes $a_t \log a_t - a_t - a_t \log \Omega$, where $\log \Omega = \gamma + \log(\pi/v) - \beta$ involves $\beta = L'(1, \chi_d)/L(1, \chi_d)$ (Definition 8.2). In Alpöge's account these are the norms of the lifts, computed with the Chowla–Selberg formula for the CM period [4]; in this paper they are numbers, and that they are norms of theta lifts is our reading. The package also contains the exponent comparison, in which the terms $m\, A_{\mathfrak{M}} \log(g_1 g_2)$ of order m at the level primes appear; Part I cancels them in the accounting.

The section runs top down, and the point is the role of the Sha condition. Theorem 13.2 obtains (Sp4) from seven lower properties (Dv1)–(Dv7) and the Sha condition. Of these, (Dv5) says that the divisor bound holds as soon as the defects of the lattices are small, and it is proved with exponent 1 from the bridge records (Theorem 13.4); the record inequality (Bk3) among them comes from the numerical records, through which $\log \Omega$ enters as the main term (Nr2) (Lemma 13.6). Property (Dv6) bounds the defects by lengths of Tate–Shafarevich groups: by Theorem 13.18, at large members with finite Sha lengths, each defect is at most its rank times the sum of an explicit budget and the total Sha length $\mathrm{len}(E; t)$. Under the Sha condition $\mathrm{len}(E; t) \leq \exp(x^\varepsilon/2) \leq b = \exp(x^\varepsilon)$, which fits within the budget $B_0 = 2nm\, b\, x^\varepsilon$, so the defects are small in the sense of (Dv5). This is where the window Sha bound of Parts VII–IX is used, through the Sha condition; in our reading it is the "significant weakening of Vandiver" that the note asks for [4].

The bound for the defects is local. The defect sum of a member is a weighted sum over finite places of defects of Hecke lattices, which are controlled by congruence modules and congruence ideals (Definition 13.8, Definition 13.9). Theorem 13.18 derives (Dv6) from the local defect

data (Ld1)–(Ld9); Theorem 13.16 and Theorem 13.17 reduce (Ld7)–(Ld9) to the local bound records (Lq1)–(Lq8); and the key step is the lattice index bound (Lq1), Theorem 13.13, a quantitative form of Ribet's lemma [208]. A congruence ideal is bounded by the lengths of the homomorphisms from a finitely presented module to the constituents of a reducible determinant (Lemma 13.14), and the Ribet records bound these, at a place above ℓ, by a Selmer term, a local term, the Sha length $\mathrm{len}_\ell(E;t)$ and the ℓ-adic valuation of the class number (Lemma 13.15). The local terms are bounded by the Ribet budget Theorem 22.1 of Part V, which supplies (Rf1), (Rf2), (Rf4), (Rf5), (Lq3) and (Lq7) in the proof of Theorem 17.7. The cut lemma 13.19 passes from the cut congruence modules to the defects. The conventions on Galois cohomology, p-adic Hodge theory, Hecke characters, unitary dual pairs and automorphic Galois representations are stated in this section at their first use; Parts V–IX use them as well.

Definition 13.1. For a number field E and an integer $t \geq 1$ the **total Sha length** is

$$\mathrm{len}(E;t) = \sum_{\ell} \log \ell \sum_{k=1}^{t-1} \mathrm{len}_\ell(E,k) \in [0,\infty].$$

Here ℓ runs over all primes and the terms are non-negative. The sum is ∞ if some $\mathrm{len}_\ell(E,k)$ with $1 \leq k < t$ is infinite or the series diverges.

Let $\mathcal{F}$ be a parametrised host family with slope records, with parameter ε and threshold x_1, and write A for the group of the frame of $\mathcal{F}$ at x. **Defect data for $\mathcal{F}$** consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$, where m is the integer of $\mathfrak{M}_{x,i}$:

- real numbers $\mathrm{Df}_j(x,i)$ for $1 \leq j \leq m$, the **defect sums** of the member;
- an integer $\mathrm{rk}_0(x,i) \geq 0$, the **level rank**;
- integers $\mathrm{rk}_j(x,i) \geq 0$ for $1 \leq j \leq m$, the **zero-space ranks**.

A **parametrised host family with slope records and defect data** is a parametrised host family with slope records together with defect data for it.

In each item below, for a member (x,i) with $x > x_1$ we write $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\mathfrak{M} = \mathfrak{M}_{x,i}$ with its parameters k, m and heights a_t ($t \in T_{x,i}$), $E = E_{\mathfrak{h}_{x,i}}$, L_a for the analytic loss of the member, and

$$n = |A|, \quad f = 2n, \quad b = e^{x^\varepsilon}, \quad a = xb, \quad L_a = \log\bigl(2a\, v(\mathfrak{h}_{x,i})\bigr),$$
$$A_{\mathfrak{M}} = \sum_{t \in T_{x,i}} a_t, \quad B_0 = B_0(x,i), \quad N_c = N_c(x,i).$$

The phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, all words $\omega, \omega' \in \mathcal{W}(\mathfrak{V})$ and every integer j with $1 \leq j \leq m$. Let e be a real number. The family has

(Dv1) Ranks and slopes if for all large members $d(\mathfrak{V},\omega) > 0$ and $\mu(\mathfrak{V},\omega) \leq \mu^{\max}(\mathfrak{V},\omega)$;

(Dv2) Non-negative size if $L_a \geq 0$ for all large members;

(Dv3) Exponent comparison if there is a real C such that for all large members $\bigl|E(\mathfrak{V},\omega) - m\, A_{\mathfrak{M}} \log(g_1(\mathfrak{V})g_2(\mathfrak{V}))\bigr| \leq C\, m\, B_0$;

(Dv4) Height comparison if there is a real C such that for all large members

$$\bigl|\bigl(h(\mathfrak{V},\omega) + A_{\mathfrak{M}} \log T(\mathfrak{V},\omega)\bigr) - \bigl(h(\mathfrak{V},\omega') + A_{\mathfrak{M}} \log T(\mathfrak{V},\omega')\bigr)\bigr| \leq C\bigl(|T_{x,i}|\, a\, L_a + m\, B_0\bigr);$$

(Dv5) Divisor bound from small defects, with exponent e if the following holds. Whenever there are real numbers C' and x_0' such that $\mathrm{Df}_j(x,i) \le \mathrm{rk}_0(x,i)\, C'\, x^{\varepsilon}\,(B_0 + N_c)$ for every real $x \ge x_0'$ with $x > x_1$, every $i \in I(x)$ and every $1 \le j \le m$, there is a real C such that for all large members

$$\mu^{\vee}(\mathfrak{V}) + h(\mathfrak{V},\omega) - F(\mathfrak{V}) \le \sum_{t \in T_{x,i}} \Big(m\big(a_t \log a_t - a_t - a_t \log \Omega(\mathfrak{h}_{x,i})\big) - a_t \log T(\mathfrak{V},\omega)\Big) + C|T_{x,i}|\, a\, L_a + C\, m\, (B_0 + N_c)\, x^{e\varepsilon}, \tag{13.1}$$

where $0 \log 0 = 0$;

(Dv6) Defects bounded by Sha lengths if there is a real C such that for all large members at which $\mathrm{len}_\ell(E,k) < \infty$ for every prime ℓ and every $1 \le k < t_{x,i}$, and $\mathrm{len}(E; t_{x,i}) < \infty$,

$$\mathrm{Df}_j(x,i) \le \mathrm{rk}_j(x,i)\Big(C\big(f\, m\, b\, x^{2\varepsilon} + (\log x)^2 N_c\big) + \mathrm{len}(E; t_{x,i})\Big);$$

(Dv7) Level ranks if $\mathrm{rk}_j(x,i) = \mathrm{rk}_0(x,i)$ for all large members.

Theorem 13.2. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, and let e be a real number. Assume that $\mathcal{F}$ has ranks and slopes (Dv1), non-negative size (Dv2), exponent comparison (Dv3), height comparison (Dv4), the divisor bound from small defects with exponent e (Dv5), defects bounded by Sha lengths (Dv6) and level ranks (Dv7). If $\mathcal{F}$ satisfies the Sha condition, then $\mathcal{F}$ has the divisor package with exponent e (Sp4), the expression $a_t \log a_t$ in (Sp4) being read as 0 when $a_t = 0$.*

Proof. Let $\varepsilon > 0$ be the parameter and $x_1 > 1$ the threshold of $\mathcal{F}$. Let C_3, C_4, C_6 be the constants of (Dv3), (Dv4), (Dv6), let $x^{(1)}, x^{(2)}, x^{(3)}, x^{(4)}, x^{(6)}, x^{(7)}$ be the thresholds of (Dv1), (Dv2), (Dv3), (Dv4), (Dv6), (Dv7), and let x_S be a real number such that $\mathrm{V}(E_{\mathfrak{h}_{x,i}}; t_{x,i}, e^{x^{\varepsilon}/2})$ holds for every real $x \ge x_S$ with $x > x_1$ and every $i \in I(x)$ (the Sha condition).

A logarithmic bound. Since $\log x / x^{\varepsilon/2} \to 0$ as $x \to \infty$, there is $x_L \ge 1$ with $0 \le \log x \le x^{\varepsilon/2}$ for all $x \ge x_L$; squaring, $(\log x)^2 \le x^{\varepsilon}$ for all $x \ge x_L$.

The defects are small. Put $X = \max(x_S, x^{(6)}, x^{(7)}, x_L)$. Let $x \ge X$ with $x > x_1$, let $i \in I(x)$, let m be the integer of $\mathfrak{M}_{x,i}$ and $1 \le j \le m$; write $t = t_{x,i}$, $E = E_{\mathfrak{h}_{x,i}}$, $y = x^{\varepsilon}$, $B_0 = B_0(x,i)$, $N_c = N_c(x,i)$. Then $x > 1$ and $\varepsilon > 0$ give $y \ge 1$; $B_0 \ge 0$ and $N_c \ge 0$ since $k \ge 0$; and $m \ge j \ge 1$.

- By the Sha condition, $\mathrm{len}_\ell(E,k) < \infty$ for every prime ℓ and $1 \le k < t$, and the series of non-negative terms $\sum_\ell \log \ell \sum_{k=1}^{t-1} \mathrm{len}_\ell(E,k)$ is at most $e^{x^{\varepsilon}/2}$; hence $\mathrm{len}(E;t) \le e^{x^{\varepsilon}/2} < \infty$. So the member satisfies the hypotheses of (Dv6), and since $x \ge x^{(6)}$,

$$\mathrm{Df}_j(x,i) \le \mathrm{rk}_j(x,i)\Big(C_6\big(f\, m\, b\, x^{2\varepsilon} + (\log x)^2 N_c\big) + \mathrm{len}(E;t)\Big).$$

- By (Dv7), $\mathrm{rk}_j(x,i) = \mathrm{rk}_0(x,i)$, since $x \ge x^{(7)}$.

- Put $P = f\, m\, b\, x^{2\varepsilon} + (\log x)^2 N_c$. Since $f = 2n$, $f\, m\, b\, x^{2\varepsilon} = y\, B_0$; since $x \ge x_L$ and $N_c \ge 0$, $(\log x)^2 N_c \le y\, N_c$. Hence $0 \le P \le y(B_0 + N_c)$ and $C_6 P \le |C_6| P \le |C_6|\, y(B_0 + N_c)$.

- $\mathrm{len}(E;t) \le e^{x^{\varepsilon}/2} \le e^{x^{\varepsilon}} = b$; and $b \le B_0 = f\, m\, y\, b$ because $f\, m\, y \ge 2 \cdot 1 \cdot 1$; and $B_0 \le y(B_0 + N_c)$ because $y \ge 1$ and $B_0, N_c \ge 0$. Hence $\mathrm{len}(E;t) \le y(B_0 + N_c)$.

Since $\mathrm{rk}_0(x,i) \geq 0$, the four points give

$$\mathrm{Df}_j(x,i) \leq \mathrm{rk}_0(x,i)\,(|C_6|+1)\,x^{\varepsilon}\,(B_0(x,i)+N_c(x,i)) \tag{13.2}$$

for every real $x \geq X$ with $x > x_1$, every $i \in I(x)$ and every $1 \leq j \leq m$.

The divisor bound. By (13.2), the hypothesis of (Dv5) holds with $C' = |C_6|+1$ and $x_0' = X$. Hence (Dv5) gives a real C_5 and a threshold $x^{(5)}$ such that the divisor bound (13.1) with the constant C_5 holds for all members (x,i) with $x \geq x^{(5)}$, $x > x_1$, and all words ω.

Assembly. Put $x_0 = \max(x^{(1)}, x^{(2)}, x^{(3)}, x^{(4)}, x^{(5)})$ and $C = \max(C_3, C_4, C_5, 0)$. Let $x \geq x_0$ with $x > x_1$, $i \in I(x)$ and $\omega, \omega' \in \mathcal{W}(\mathfrak{V}_{x,i})$. The error terms $m\,B_0$ of (Dv3), $|T_{x,i}|\,a\,L_a + m\,B_0$ of (Dv4), and $|T_{x,i}|\,a\,L_a$, $m(B_0+N_c)x^{e\varepsilon}$ of (13.1) are non-negative: $a = xb > 0$, $L_a \geq 0$ by (Dv2), $m, B_0, N_c \geq 0$ and $x^{e\varepsilon} > 0$. Each bound therefore stays true when its constant is replaced by the larger constant C. So, at the member (x,i) and for the words ω, ω': $d(\mathfrak{V}_{x,i}, \omega) > 0$ and $\mu(\mathfrak{V}_{x,i}, \omega) \leq \mu^{\max}(\mathfrak{V}_{x,i}, \omega)$ by (Dv1); the divisor bound of (Sp4) with constant C and exponent e is (13.1) with C (the convention $0 \log 0 = 0$ being the stated reading of (Sp4)); the exponent comparison of (Sp4) is (Dv3) with C; and the height comparison of (Sp4) is (Dv4) with C. This is (Sp4) with exponent e, the constant C and the threshold x_0. □

Definition 13.3. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε and threshold x_1, and write A for the group of the frame of $\mathcal{F}$ at x. **Bridge records for** $\mathcal{F}$ consist of the following real numbers, given for every real $x > x_1$ and every $i \in I(x)$, where m is the integer of $\mathfrak{M}_{x,i}$:

- $\mu_{\mathrm{b}}^{\vee}(x,i)$, the **base dual slope**, and $\mathrm{sc}(x,i)$, the **scaling term**;
- $\mathrm{pa}(x,i)$, the **passage allowance**;
- for every word $\omega \in \mathcal{W}(\mathfrak{V}_{x,i})$, $\mathrm{lm}(x,i,\omega)$, the **local main term**, and $\mathrm{le}(x,i,\omega)$, the **local error**;
- $\mathrm{tc}_j(x,i)$ for $1 \leq j \leq m$, the **twisted-place corrections**.

A **parametrised host family with slope records, defect data and bridge records** is a parametrised host family with slope records and defect data together with bridge records for it.

In each item below, for a member (x,i) with $x > x_1$ we write $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\mathfrak{M} = \mathfrak{M}_{x,i}$ with its parameters k, m and heights a_t ($t \in T_{x,i}$), L_a for the analytic loss of the member, and

$$n = |A|, \quad b = e^{x^{\varepsilon}}, \quad a = xb, \quad L_a = \log(2a\,v(\mathfrak{h}_{x,i})), \quad B_0 = B_0(x,i), \quad N_c = N_c(x,i).$$

The phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$ and every word $\omega \in \mathcal{W}(\mathfrak{V})$. The family has

(Bk1) Base divisor inequality if for all large members $\mathrm{rk}_0(x,i) \geq 1$ and

$$\mu_{\mathrm{b}}^{\vee}(x,i) - \mathrm{sc}(x,i) \leq \mathrm{lm}(x,i,\omega) + F(\mathfrak{V}) + \mathrm{le}(x,i,\omega) + \sum_{j=1}^{m}\Big(\frac{\mathrm{Df}_j(x,i)}{\mathrm{rk}_0(x,i)} + \mathrm{tc}_j(x,i)\Big); \tag{13.3}$$

(Bk2) Passage if for all large members $\mu^{\vee}(\mathfrak{V}) \leq \mu_{\mathrm{b}}^{\vee}(x,i) + \mathrm{pa}(x,i)$;

(Bk3) Record inequality if there is a real number C_0 such that for all large members, every word ω, every real $c \geq C_0$ and all real numbers $z, z_{\mathrm{b}}, z_{\mathrm{e}}$ with

$$z \leq z_{\mathrm{b}} + \mathrm{pa}(x,i), \qquad z_{\mathrm{b}} \leq \mathrm{lm}(x,i,\omega) + F(\mathfrak{V}) + z_{\mathrm{e}}, \qquad z_{\mathrm{e}} \leq c\,m\,x^{\varepsilon}(B_0+N_c),$$

one has

$$z + h(\mathfrak{V},\omega) + \mathrm{sc}(x,i) - F(\mathfrak{V}) \le \sum_{t\in T_{x,i}} \Big(m\big(a_t \log a_t - a_t - a_t \log \Omega(\mathfrak{h}_{x,i})\big) - a_t \log T(\mathfrak{V},\omega)\Big) + (50C_0+10)|T_{x,i}|\, a\, L_a + 60\, c\, m\, x^{\varepsilon}(B_0+N_c), \tag{13.4}$$

where $0 \log 0 = 0$;

(Bk4) Error budget if there is a real number c_{G} such that for all large members $\mathrm{le}(x,i,\omega) + \sum_{j=1}^{m} \mathrm{tc}_j(x,i) \le c_{\mathrm{G}}\, m\, x^{\varepsilon}(B_0+N_c)$.

Theorem 13.4. *Let $\mathcal{F}$ be a parametrised host family with slope records, defect data and bridge records. Assume that $\mathcal{F}$ has non-negative size (Dv2), the base divisor inequality (Bk1), the passage (Bk2), the record inequality (Bk3) and the error budget (Bk4). Then $\mathcal{F}$ has the divisor bound from small defects (Dv5) with exponent e for every real $e \ge 1$; in particular with exponent 1.*

Proof. Let $\varepsilon > 0$ be the parameter and $x_1 > 1$ the threshold of $\mathcal{F}$, and let $e \ge 1$ be real. Let $x^{(2)}$ be the threshold of (Dv2), $x^{(\mathrm{b1})}, x^{(\mathrm{b2})}, x^{(\mathrm{b3})}, x^{(\mathrm{b4})}$ those of (Bk1)–(Bk4), C_0 the constant of (Bk3) and c_{G} that of (Bk4).

To verify (Dv5) with exponent e, let C' and x_0' be real numbers such that

$$\mathrm{Df}_j(x,i) \le \mathrm{rk}_0(x,i)\, C'\, x^{\varepsilon}\big(B_0(x,i) + N_c(x,i)\big) \tag{13.5}$$

for every real $x \ge x_0'$ with $x > x_1$, every $i \in I(x)$ and every $1 \le j \le m$. Put

$$c = \max\big(C_0,\ c_{\mathrm{G}} + |C'|\big), \qquad C = \max\big(50C_0+10,\ 60c,\ 0\big),$$
$$x_0 = \max\big(x_0', x^{(2)}, x^{(\mathrm{b1})}, x^{(\mathrm{b2})}, x^{(\mathrm{b3})}, x^{(\mathrm{b4})}\big).$$

Let $x \ge x_0$ with $x > x_1$, let $i \in I(x)$ and $\omega \in \mathcal{W}(\mathfrak{V}_{x,i})$; write $\mathfrak{V} = \mathfrak{V}_{x,i}$, m, k, a_t for the data of $\mathfrak{M}_{x,i}$, L_a for the analytic loss of the member, $a = xb$, $B_0 = B_0(x,i)$, $N_c = N_c(x,i)$, and

$$U = x^{\varepsilon}(B_0 + N_c).$$

The unit is non-negative. Since $x > 1$, $x^{\varepsilon} > 0$ and $b > 0$; with $n \ge 1$, $m \ge 0$ and $k \ge 0$ this gives $B_0 \ge 0$ and $N_c \ge 0$, hence $U \ge 0$ and $mU \ge 0$.

The defect term is at most $|C'|\, m\, U$. By (Bk1), $\mathrm{rk}_0(x,i) \ge 1$. For $1 \le j \le m$, dividing (13.5) by $\mathrm{rk}_0(x,i) > 0$ gives $\mathrm{Df}_j(x,i)/\mathrm{rk}_0(x,i) \le C'U \le |C'|U$, the last step because $U \ge 0$. Summing over the m values of j,

$$\sum_{j=1}^{m} \frac{\mathrm{Df}_j(x,i)}{\mathrm{rk}_0(x,i)} \le |C'|\, m\, U.$$

The error of the base divisor inequality is within the record's budget. Put

$$z_{\mathrm{e}} = \mathrm{le}(x,i,\omega) + \sum_{j=1}^{m}\Big(\frac{\mathrm{Df}_j(x,i)}{\mathrm{rk}_0(x,i)} + \mathrm{tc}_j(x,i)\Big) = \Big(\mathrm{le}(x,i,\omega) + \sum_{j=1}^{m} \mathrm{tc}_j(x,i)\Big) + \sum_{j=1}^{m} \frac{\mathrm{Df}_j(x,i)}{\mathrm{rk}_0(x,i)}.$$

By (Bk4) the first bracket is at most $c_{\mathrm{G}}\, mU$; with the previous display, $z_{\mathrm{e}} \le (c_{\mathrm{G}} + |C'|)\, mU \le c\, mU$, the last step because $mU \ge 0$ and $c_{\mathrm{G}} + |C'| \le c$.

The record inequality applies. Put $z_{\mathrm{b}} = \mu_{\mathrm{b}}^{\vee}(x,i) - \mathrm{sc}(x,i)$ and $z = \mu^{\vee}(\mathfrak{V}) - \mathrm{sc}(x,i)$. By the passage (Bk2), $z \le z_{\mathrm{b}} + \mathrm{pa}(x,i)$. By the base divisor inequality (13.3) and the definition of z_{e}, $z_{\mathrm{b}} \le \mathrm{lm}(x,i,\omega) + F(\mathfrak{V}) + z_{\mathrm{e}}$. With $z_{\mathrm{e}} \le c\,m\,x^{\varepsilon}(B_0+N_c)$ and $c \ge C_0$, the record inequality (13.4) holds for $(c, z, z_{\mathrm{b}}, z_{\mathrm{e}})$. Its left side is $z + h(\mathfrak{V},\omega) + \mathrm{sc}(x,i) - F(\mathfrak{V}) = \mu^{\vee}(\mathfrak{V}) + h(\mathfrak{V},\omega) - F(\mathfrak{V})$. Hence

$$\mu^{\vee}(\mathfrak{V}) + h(\mathfrak{V},\omega) - F(\mathfrak{V}) \le \mathrm{Main} + (50C_0+10)|T_{x,i}|\,a\,L_a + 60\,c\,m\,x^{\varepsilon}(B_0+N_c),$$

where $\mathrm{Main} = \sum_{t\in T_{x,i}} \big(m(a_t \log a_t - a_t - a_t \log \Omega(\mathfrak{h}_{x,i})) - a_t \log T(\mathfrak{V},\omega)\big)$ with $0\log 0 = 0$, which is the main term of (13.1).

Passing to the constant C and the exponent e. By (Dv2), $L_a \ge 0$; with $a > 0$, $|T_{x,i}|\,a\,L_a \ge 0$, so $(50C_0+10)|T_{x,i}|\,a\,L_a \le C|T_{x,i}|\,a\,L_a$. Since $m(B_0+N_c) \ge 0$ and $x^{\varepsilon} > 0$, $60\,c\,m\,x^{\varepsilon}(B_0+N_c) \le C\,m\,(B_0+N_c)\,x^{\varepsilon}$. Finally $x > 1$ and $e\varepsilon \ge \varepsilon$ give $x^{\varepsilon} \le x^{e\varepsilon}$, and $C\,m\,(B_0+N_c) \ge 0$, so $C\,m\,(B_0+N_c)\,x^{\varepsilon} \le C\,m\,(B_0+N_c)\,x^{e\varepsilon}$. Therefore

$$\mu^{\vee}(\mathfrak{V}) + h(\mathfrak{V},\omega) - F(\mathfrak{V}) \le \mathrm{Main} + C|T_{x,i}|\,a\,L_a + C\,m\,(B_0+N_c)\,x^{e\varepsilon},$$

which is (13.1) with the constant C. Since C and x_0 depend only on $\mathcal{F}$, C' and x_0', and the member (x,i) with $x \ge x_0$, $x > x_1$, and the word ω were arbitrary, $\mathcal{F}$ has (Dv5) with exponent e. □

Definition 13.5. Let $\mathcal{F}$ be a parametrised host family with slope records, defect data and bridge records, with parameter ε and threshold x_1. **Numerical records for $\mathcal{F}$** consist of the following data, given for every real $x > x_1$, every $i \in I(x)$ and every word $\omega \in \mathcal{W}(\mathfrak{V}_{x,i})$, where m and k are the integers of $\mathfrak{M}_{x,i}$:

- a finite set $\mathrm{Pl}(x,i,\omega)$ containing $T_{x,i}$, the **record places**;
- for $1 \le j \le m$ a real number $\mathrm{ed}_j(x,i,\omega)$, the **eigenvalue degree** of the j-th lift;
- for $1 \le j \le m$ and $\rho \in \mathrm{Pl}(x,i,\omega)$ real numbers $\mathrm{rw}_j(x,i,\omega,\rho)$, $\mathrm{ms}_j(x,i,\omega,\rho)$ and $\mathrm{en}_j(x,i,\omega,\rho)$, the **record weight**, the **weight mass** and the **entropy term**;
- a real number $\mathrm{eh}(x,i,\omega)$, the **height error**.

A **parametrised host family with slope records, defect data, bridge records and numerical records** is a parametrised host family with slope records, defect data and bridge records together with numerical records for it.

In the items below, for a member (x,i) with $x > x_1$ and a word ω, we write $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\mathfrak{M} = \mathfrak{M}_{x,i}$ with k, m and heights a_t ($t \in T = T_{x,i}$), $b = e^{x^{\varepsilon}}$, $a = xb$, $L_a = \log(2a\,v(\mathfrak{h}_{x,i}))$ for the analytic loss of the member, $B_0 = B_0(x,i)$, $\log\Omega = \log\Omega(\mathfrak{h}_{x,i})$ and $\mathrm{Pl} = \mathrm{Pl}(x,i,\omega)$. We put $\varphi(y) = y\log y - y$ for $y \ge 0$ (with $0\log 0 = 0$). Within one item the arguments (x,i,ω) are suppressed, so that we write ed_j, $\mathrm{rw}_j(\rho)$, $\mathrm{ms}_j(\rho)$, $\mathrm{en}_j(\rho)$, eh. We let $[\rho \in T]$ be 1 if $\rho \in T$ and 0 otherwise; a_ρ and $\varphi(a_\rho)$ are used only for $\rho \in T$. The phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x \ge x_0$ with $x > x_1$, every $i \in I(x)$ and every word $\omega \in \mathcal{W}(\mathfrak{V})$. The family has

(Nr1) Height inequality of the record if for all large members

$$h(\mathfrak{V},\omega) + \mathrm{sc}(x,i) \le -\sum_{t\in T} a_t \log T(\mathfrak{V},\omega) + \sum_{j=1}^{m} \sum_{\rho\in\mathrm{Pl}} \big(\mathrm{en}_j(\rho) - \mathrm{ms}_j(\rho)\log\Omega\big) + \mathrm{eh}; \quad (13.6)$$

(Nr2) Main term of the realisation if for all large members

$$\mathrm{lm}(x,i,\omega)=\sum_{j=1}^{m}\sum_{\rho\in\mathrm{Pl}}\mathrm{ed}_j\,\mathrm{rw}_j(\rho)\log\Omega;$$

(Nr3) Record budget if there is a real number C_{N} such that for all large members

$$\mathrm{pa}(x,i)+\mathrm{eh}+\sum_{j=1}^{m}\sum_{\rho\in\mathrm{Pl}}\Big((\mathrm{en}_j(\rho)-[\rho\in T]\,\varphi(a_\rho))+|\mathrm{ms}_j(\rho)-[\rho\in T]\,a_\rho-k\,\mathrm{rw}_j(\rho)|\,|\log\Omega|$$
$$+\,|\mathrm{ed}_j-k|\,|\mathrm{rw}_j(\rho)|\,|\log\Omega|\Big)\le C_{\mathrm{N}}(|T|\,a\,L_a+m\,x^{\varepsilon}B_0).$$

Lemma 13.6. *Let $\mathcal{F}$ be a parametrised host family with slope records, defect data, bridge records and numerical records that has the height inequality of the record (Nr1), the main term of the realisation (Nr2) and the record budget (Nr3). Then $\mathcal{F}$ has the record inequality (Bk3), with $C_0=\max(C_{\mathrm{N}},0)$, where C_{N} is the constant of (Nr3). More precisely, for all large members, every word ω, every real $c\ge C_0$ and all real $z,z_{\mathrm{b}},z_{\mathrm{e}}$ with $z\le z_{\mathrm{b}}+\mathrm{pa}(x,i)$, $z_{\mathrm{b}}\le\mathrm{lm}(x,i,\omega)+F(\mathfrak{V})+z_{\mathrm{e}}$ and $z_{\mathrm{e}}\le c\,m\,x^{\varepsilon}(B_0+N_c)$,*

$$z+h(\mathfrak{V},\omega)+\mathrm{sc}(x,i)-F(\mathfrak{V})\le\sum_{t\in T_{x,i}}\Big(m(a_t\log a_t-a_t-a_t\log\Omega(\mathfrak{h}_{x,i}))-a_t\log T(\mathfrak{V},\omega)\Big)$$
$$+\,C_0|T_{x,i}|\,a\,L_a+2c\,m\,x^{\varepsilon}(B_0+N_c),$$

with $0\log 0=0$ and the notation of (Bk3).

Proof. Let x_0 be the largest of the thresholds of (Nr1), (Nr2), (Nr3), and $C_0=\max(C_{\mathrm{N}},0)$. Fix $x\ge x_0$ with $x>x_1$, $i\in I(x)$, a word ω, a real $c\ge C_0$ and reals $z,z_{\mathrm{b}},z_{\mathrm{e}}$ as in the statement. Write $T=T_{x,i}$, $\mathrm{Pl}=\mathrm{Pl}(x,i,\omega)$, $\log\Omega=\log\Omega(\mathfrak{h}_{x,i})$, $\log T_\omega=\log T(\mathfrak{V},\omega)$, $\sum_{j,\rho}$ for $\sum_{j=1}^{m}\sum_{\rho\in\mathrm{Pl}}$, and

$$\mathrm{wd}_j(\rho)=\mathrm{ms}_j(\rho)-[\rho\in T]\,a_\rho-k\,\mathrm{rw}_j(\rho)\qquad\text{(local symbol)}.$$

Signs. By (Pf3) and (Lm7), $k>0$; the analytic loss satisfies $L_a=\log a+\log(2v(\mathfrak{h}_{x,i}))\ge\log a>0$, since $2v(\mathfrak{h}_{x,i})=|\mathrm{disc}(E_{\mathfrak{h}_{x,i}})|^{1/[E_{\mathfrak{h}_{x,i}}:\mathbb{Q}]}\ge 1$ and $a=x\,e^{x^{\varepsilon}}>1$ (as $x>x_1>1$); by (Pf2) and (Lm2), $a_t\ge 0$, so $\varphi(a_t)$ is defined; $m\ge 0$, $a>0$, $x^{\varepsilon}>0$, $B_0\ge 0$ and $N_c\ge 0$. Hence $|T|\,a\,L_a\ge 0$ and $m\,x^{\varepsilon}(B_0+N_c)\ge m\,x^{\varepsilon}B_0\ge 0$; and $c\ge C_0\ge 0$.

Chaining the hypotheses. From $z\le z_{\mathrm{b}}+\mathrm{pa}(x,i)$ and $z_{\mathrm{b}}\le\mathrm{lm}(x,i,\omega)+F(\mathfrak{V})+z_{\mathrm{e}}$, and then (13.6),

$$z+h(\mathfrak{V},\omega)+\mathrm{sc}(x,i)-F(\mathfrak{V})\le\mathrm{lm}(x,i,\omega)+z_{\mathrm{e}}+\mathrm{pa}(x,i)-\sum_{t\in T}a_t\log T_\omega$$
$$+\sum_{j,\rho}(\mathrm{en}_j(\rho)-\mathrm{ms}_j(\rho)\log\Omega)+\mathrm{eh}.$$

Separating the main term. Since $T\subseteq\mathrm{Pl}$ and j takes m values, $\sum_{j,\rho}[\rho\in T]\varphi(a_\rho)=m\sum_{t\in T}\varphi(a_t)$ and $\sum_{j,\rho}[\rho\in T]a_\rho=m\sum_{t\in T}a_t$. Writing $\mathrm{en}_j(\rho)=[\rho\in T]\varphi(a_\rho)+(\mathrm{en}_j(\rho)-[\rho\in T]\varphi(a_\rho))$ and $\mathrm{ms}_j(\rho)=[\rho\in T]a_\rho+k\,\mathrm{rw}_j(\rho)+\mathrm{wd}_j(\rho)$,

$$\sum_{j,\rho}(\mathrm{en}_j(\rho)-\mathrm{ms}_j(\rho)\log\Omega)=m\sum_{t\in T}(\varphi(a_t)-a_t\log\Omega)-k\sum_{j,\rho}\mathrm{rw}_j(\rho)\log\Omega$$
$$+\sum_{j,\rho}\Big((\mathrm{en}_j(\rho)-[\rho\in T]\varphi(a_\rho))-\mathrm{wd}_j(\rho)\log\Omega\Big).$$

By (Nr2),

$$\mathrm{lm}(x,i,\omega) - k\sum_{j,\rho}\mathrm{rw}_j(\rho)\log\Omega = \sum_{j,\rho}(\mathrm{ed}_j - k)\,\mathrm{rw}_j(\rho)\log\Omega \le \sum_{j,\rho}|\mathrm{ed}_j - k|\,|\mathrm{rw}_j(\rho)|\,|\log\Omega|,$$

and $-\mathrm{wd}_j(\rho)\log\Omega \le |\mathrm{wd}_j(\rho)|\,|\log\Omega|$. With $\mathrm{Main} = \sum_{t\in T}\big(m(\varphi(a_t) - a_t\log\Omega) - a_t\log T_\omega\big)$ we obtain

$$z + h(\mathfrak{V},\omega) + \mathrm{sc}(x,i) - F(\mathfrak{V}) \le \mathrm{Main} + z_{\mathrm{e}} + \mathcal{E},$$

where $\mathcal{E}$ (local symbol) is the left side of the record budget (Nr3).

The errors. By (Nr3), $\mathcal{E} \le C_{\mathrm{N}}(|T|aL_a + mx^{\varepsilon}B_0) \le C_0|T|aL_a + C_0\,mx^{\varepsilon}B_0$, using the signs. Since $C_0 \le c$ and $mx^{\varepsilon}B_0 \le mx^{\varepsilon}(B_0+N_c)$, and $z_{\mathrm{e}} \le c\,mx^{\varepsilon}(B_0+N_c)$,

$$z + h(\mathfrak{V},\omega) + \mathrm{sc}(x,i) - F(\mathfrak{V}) \le \mathrm{Main} + C_0|T|\,a\,L_a + 2c\,m\,x^{\varepsilon}(B_0+N_c),$$

which is the displayed inequality. As $C_0 \le 50C_0+10$, $2c \le 60c$, and $|T|aL_a \ge 0$, $mx^{\varepsilon}(B_0+N_c) \ge 0$, its right side is at most the right side of (13.4); x_0 and C_0 do not depend on the member, the word, c or $z, z_{\mathrm{b}}, z_{\mathrm{e}}$. Hence $\mathcal{F}$ has (Bk3) with the constant C_0. □

Notation for number fields, local fields and adeles is that of [190] and [63]. Let F be a number field with ring of integers $\mathcal{O}_F$. Places of F are written v, and finite places are identified with the nonzero primes of $\mathcal{O}_F$. We write F_v for the completion and $|\cdot|_v$ for its normalised absolute value. For finite v, ϖ_v is a uniformiser of $\mathcal{O}_{F_v}$ and $q_v = \mathrm{N}v$ is the cardinality of the residue field. For a finite extension E/F, $w \mid v$ means that the place w of E lies above v, and $\mathrm{N}_{E/F}$ is the norm (on elements, ideles and idele classes). A **non-archimedean local field** is a field complete for a discrete valuation with finite residue field. The adele ring is $\mathbb{A}_F = F_\infty \times \mathbb{A}_{F,f}$, where $F_\infty = F\otimes_{\mathbb{Q}}\mathbb{R}$ and $\mathbb{A}_{F,f}$ is the ring of finite adeles. On the ideles $\mathbb{A}_F^\times$ we set $|x|_{\mathbb{A}} = \prod_v |x_v|_v$. The idele class group is $C_F = \mathbb{A}_F^\times/F^\times$; C_F^1 is its subgroup of norm one and C_F^0 the connected component of the identity. We write $G_F = \mathrm{Gal}(\overline{F}/F)$; $G_{F_v} \subset G_F$ is a decomposition group, I_v its inertia subgroup and Frob_v an arithmetic Frobenius. For a finite set S of places, $G_{F,S}$ is the Galois group of the maximal extension of F unramified outside S.

Galois cohomology is continuous cohomology of profinite groups, as in [222] and [172]. For a discrete module M (or, for $\mathbb{Z}_\ell$-coefficients, a continuous ℓ-adic module M), we write $H^i(F,M)$ for $H^i(G_F,M)$ and $H^i(F_v,M)$ for $H^i(G_{F_v},M)$. Tate cohomology of a finite group is denoted $\hat{H}^i$. For a prime ℓ, χ_{cyc} is the ℓ-adic cyclotomic character, $\mathbb{Z}_\ell(k)$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell(k)$ are the twists by χ_{cyc}^k, and μ_{ℓ^r} is the group of ℓ^r-th roots of unity. For a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module M, the Cartier dual is $M^\vee = \mathrm{Hom}(M,\mu_{\ell^r})$. The unramified classes are

$$H^1_{\mathrm{ur}}(F_v,M) = \ker\big(H^1(F_v,M) \to H^1(I_v,M)\big),$$

and inv_v is the invariant map of the local Brauer group. For a finite set S of places containing those above ℓ and ∞,

$$\mathrm{Sha}^i_S(F,M) = \ker\Big(H^i(G_{F,S},M) \to \prod_{v\in S} H^i(F_v,M)\Big).$$

Local Tate duality, the local and global Euler characteristic formulas and Poitou–Tate duality are used in the form of [172], Ch. I, and the Greenberg–Wiles formula for Selmer groups in the form of [72].

Notation for p-adic Hodge theory is that of [94] and [52]. Let K be a finite extension of $\mathbb{Q}_p$, G_K its absolute Galois group and $\mathbb{C}_p$ the completion of $\overline{\mathbb{Q}}_p$. For a perfectoid field L, $L^\flat$ denotes its tilt. Fix a compatible system $\underline{\zeta} = (\zeta_{p^n})_{n\ge 0}$ of p-power roots of unity. The period rings are the following:

- $A_{\mathrm{inf}} = W(\mathcal{O}_{\mathbb{C}_p^\flat})$, with $\theta\colon A_{\mathrm{inf}} \to \mathcal{O}_{\mathbb{C}_p}$;
- B_{dR}^+, the $\ker\theta$-adic completion of $A_{\mathrm{inf}}[1/p]$, and $B_{\mathrm{dR}} = B_{\mathrm{dR}}^+[1/t]$, where $t = \log[\underline{\zeta}]$, with $\mathrm{Fil}^i B_{\mathrm{dR}} = t^i B_{\mathrm{dR}}^+$;
- $A_{\mathrm{cris}} \subset B_{\mathrm{cris}}^+$ and $B_{\mathrm{cris}} = B_{\mathrm{cris}}^+[1/t]$, with Frobenius φ;
- B_{st}.

A finite-dimensional $\mathbb{Q}_p$-representation V of G_K is **de Rham**, **semistable** or **crystalline** if $(B \otimes_{\mathbb{Q}_p} V)^{G_K}$ has dimension $\dim_{\mathbb{Q}_p} V$ over B^{G_K} for $B = B_{\mathrm{dR}}, B_{\mathrm{st}}, B_{\mathrm{cris}}$ respectively. Hodge–Tate weights are normalised so that the cyclotomic character χ_{cyc} has Hodge–Tate weight 1.

Notation follows Tate's thesis [250] and [190], Ch. VII. A **Hecke character** of a number field F is a continuous character $\chi = \prod_v \chi_v\colon C_F \to \mathbb{C}^\times$. Hecke characters are unitary unless stated otherwise. Fix a subgroup of C_F that $|\cdot|_{\mathbb{A}}$ maps isomorphically onto $\mathbb{R}_{>0}$. Every unitary Hecke character can be written $\chi = \chi_0 |\cdot|_{\mathbb{A}}^{i\tau}$ with a unique $\tau \in \mathbb{R}$ and χ_0 trivial on this subgroup. The conductor of χ is $\mathfrak{f}(\chi)$. We write $\mathcal{S}(\mathbb{A}_F)$ for the Schwartz–Bruhat space, $\psi_{\mathrm{add}} = \prod_v \psi_{\mathrm{add},v}$ for the standard additive character of $\mathbb{A}_F/F$ (trivial on F), and $\hat{f}$ for the Fourier transform with respect to the self-dual measure. The **Tate zeta integral** $Z(f,\chi,s)$ is $\int_{\mathbb{A}_F^\times} f(x)\chi(x)|x|_{\mathbb{A}}^s\, d^\times x$ for $\mathrm{Re}\, s > 1$, together with its meromorphic continuation; it satisfies $Z(f,\chi,s) = Z(\hat{f},\chi^{-1},1-s)$. The **Hecke L-function** is $L(s,\chi) = \prod_{v\nmid\infty,\ \chi_v \text{ unramified}} (1-\chi_v(\varpi_v)q_v^{-s})^{-1}$ for $\mathrm{Re}\, s > 1$. For a Dirichlet character, viewed as a Hecke character of $\mathbb{Q}$ through class field theory, this is the Dirichlet L-function of the inducing primitive character. The **completed L-function** is $\xi(s,\chi) = (|d_F|\,\mathrm{N}\mathfrak{f}(\chi))^{s/2} L_\infty(s,\chi)L(s,\chi)$, with the archimedean gamma factors L_∞. The **root number** $W(\chi)$ is defined by $\xi(s,\chi) = W(\chi)\,\xi(1-s,\overline{\chi})$; it satisfies $|W(\chi)| = 1$. The Dirichlet density of a set of primes is meant in the sense of [190], VII.13.

Let E/F be a CM extension of number fields with complex conjugation c, and write $x \mapsto \bar{x}$ for c. Let Y be a finite-dimensional E-vector space with a nondegenerate form $\langle\,,\,\rangle$ that is hermitian ($\langle y,x\rangle = \overline{\langle x,y\rangle}$) or skew-hermitian ($\langle y,x\rangle = -\overline{\langle x,y\rangle}$). Then $\mathrm{U}(Y)$ denotes its unitary group over F, and $[\mathrm{U}(Y)] = \mathrm{U}(Y)(F)\backslash\mathrm{U}(Y)(\mathbb{A}_F)$. The signature of Y at a real place w of F is that of the hermitian form $\langle\,,\,\rangle$, resp. $i\langle\,,\,\rangle$, at the complex place of E above w.

Let V be a hermitian space and W a skew-hermitian space. Then $V \otimes_E W$ with the form $\mathrm{tr}_{E/F}(\langle\,,\,\rangle_V \otimes \overline{\langle\,,\,\rangle_W})$ is a symplectic F-space, and $(\mathrm{U}(V),\mathrm{U}(W))$ is a dual pair in its symplectic group. Let η be the quadratic character of E/F. Fix a nontrivial additive character ψ_{add} of $\mathbb{A}_F/F$ and Hecke characters χ_V, χ_W of $\mathbb{A}_E^\times/E^\times$ whose restrictions to $\mathbb{A}_F^\times$ are $\eta^{\dim V}$, resp. $\eta^{\dim W}$. Then $\omega = \omega_{\psi_{\mathrm{add}},\chi_V,\chi_W}$ denotes the Weil representation of $\mathrm{U}(V)(\mathbb{A}_F) \times \mathrm{U}(W)(\mathbb{A}_F)$ on a model of the Schwartz space $\mathcal{S}(V^{\dim W}(\mathbb{A}_F))$ (Schrödinger or mixed model) [151], [120]. For φ in this space, set

$$\theta(g,h;\varphi) = \sum_{x \in V^{\dim W}(F)} (\omega(g,h)\varphi)(x), \qquad \Theta(\varphi)(h) = \int_{[\mathrm{U}(V)]} \theta(g,h;\varphi)\, dg,$$

when the integral converges. The function $\Theta(\varphi)$ on $[\mathrm{U}(W)]$ is the **theta integral** of φ (the theta lift of the trivial representation). Let P be a parabolic subgroup of $\mathrm{U}(W)$ stabilising an isotropic line $Ex \subset W$. Its Levi factor is $\mathrm{Res}_{E/F}\mathbb{G}_m \times \mathrm{U}(W_1)$, where $W_1 = \langle x,y\rangle^\perp$ for an isotropic y with $\langle x,y\rangle = 1$. The constant term of a function f on $[\mathrm{U}(W)]$ along P is $f_P(h) = \int_{N(F)\backslash N(\mathbb{A}_F)} f(nh)\, dn$, where N is the unipotent radical and the measure has total mass 1. This notation holds throughout the parts of this paper on theta lifting.

Class field theory is normalised as in [190] and [11]: uniformisers correspond to arithmetic Frobenius elements. For a non-archimedean local field F_v, $\mathrm{Art}_{F_v}\colon F_v^\times \to G_{F_v}^{ab}$ is the local Artin

map and F_v^{ur} the maximal unramified extension; for a number field F, $\mathrm{Art}_F\colon C_F \to G_F^{ab}$ is the global Artin map and F^{ab} the maximal abelian extension. The **norm group** of a finite abelian extension E/F (respectively E_w/F_v) is $\mathrm{N}_{E/F}C_E \subseteq C_F$ (respectively $\mathrm{N}_{E_w/F_v}E_w^\times \subseteq F_v^\times$).

Definition 13.7. Let p be a prime, K a finite extension of $\mathbb{Q}_p$, L a finite extension of $\mathbb{Q}_p$, and V a finite-dimensional L-vector space with a continuous L-linear action of G_K. Put

$$D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}, \qquad \mathrm{Fil}^j D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V) \cap (\mathrm{Fil}^j B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V) \quad (j \in \mathbb{Z}).$$

This is a module over $K \otimes_{\mathbb{Q}_p} L$, where $K \subset B_{\mathrm{dR}}$ acts on the first factor and L on V, with a decreasing filtration by $K \otimes_{\mathbb{Q}_p} L$-submodules. For a $\mathbb{Q}_p$-embedding $\tau\colon K \to L$ let

$$D_{\mathrm{dR},\tau}(V) = L \otimes_{K\otimes_{\mathbb{Q}_p} L,\, \tau\otimes\mathrm{id}} D_{\mathrm{dR}}(V),$$

with the filtration $\mathrm{Fil}^j D_{\mathrm{dR},\tau}(V)$ given by the image of $L \otimes \mathrm{Fil}^j D_{\mathrm{dR}}(V)$. An integer a is a **Hodge jump of V at τ** if $\mathrm{Fil}^{a+1} D_{\mathrm{dR},\tau}(V) \neq \mathrm{Fil}^a D_{\mathrm{dR},\tau}(V)$.

If $F \subseteq K$ is a subfield and $\tau_0\colon F \to L$ is a $\mathbb{Q}_p$-embedding, the **embeddings of K over τ_0** are the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$ with $\tau|_F = \tau_0$.

We fix the notation for ℓ-adic coefficients, Galois representations and automorphic representations used in this paper, following [69] and [17].

Coefficients. Let ℓ be a prime, let $\overline{\mathbb{Q}}_\ell$ be an algebraic closure of $\mathbb{Q}_\ell$ with absolute value $|\cdot|_\ell$ and valuation v_ℓ normalised by $v_\ell(\ell) = 1$, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism of fields. A **coefficient ring** is a $\mathbb{Z}_\ell$-subalgebra $\mathcal{O} \subset \overline{\mathbb{Q}}_\ell$ that is a discrete valuation ring finite over $\mathbb{Z}_\ell$. Its ramification index is $e_{\mathcal{O}} = \mathrm{length}_{\mathcal{O}}(\mathcal{O}/\ell\mathcal{O})$. For an $\mathcal{O}$-module M of finite length, the **normalised length** of M is $\mathrm{length}_{\mathcal{O}}(M)/e_{\mathcal{O}}$, so that $\ell^{[\mathcal{O}:\mathbb{Z}_\ell]\cdot \mathrm{length}_{\mathcal{O}}(M)/e_{\mathcal{O}}} = \#M$. For a character θ of a group with values in $\mathcal{O}^\times$, we write $\mathcal{O}^\vee(\theta)$ for $\mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$ with the discrete topology and with the group acting through θ. Dirichlet characters with values in $\mathcal{O}^\times$ are identified with characters of $G_{\mathbb{Q}}$ by class field theory.

Galois representations. An ℓ-adic representation of G_E is a continuous homomorphism $r\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$. We write $r^\vee$ for its contragredient. For a CM field E with complex conjugation c, we set $r^c(g) = r(cgc)$. Two representations are **isomorphic** if they are conjugate in $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$.

Automorphic side. For a number field E, the notion of a **regular algebraic** cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_E)$ is that of [68]. For E CM, π is **conjugate self-dual** if $\pi^\vee \cong \pi^c$. An ℓ-adic representation r of G_E is **attached to** π, written $r \leftrightarrow_\iota \pi$, if the following holds for all but finitely many finite places w of E at which π is unramified: r is unramified at w, and ι carries the characteristic polynomial of $r(\mathrm{Frob}_w^{-1})$ (a geometric Frobenius) to $\prod_\alpha (X - \mathrm{N}w^{(n-1)/2}\alpha)$, where α runs over the Satake parameters of π_w.

The **Satake parameters** of π_w are defined as follows. Let $K_w = \mathrm{GL}_n(\mathcal{O}_{E_w})$. For a uniformiser ϖ_w and $0 \le j \le n$, let $d_j = \mathrm{diag}(\varpi_w, \dots, \varpi_w, 1, \dots, 1)$ with j entries ϖ_w, and let T_j be the Hecke operator of the double coset $K_w d_j K_w$, acting on $\pi_w^{K_w}$ by $x \mapsto \sum_{gK_w \subseteq K_w d_j K_w} \pi_w(g)x$. The Satake parameters of π_w form the multiset $\{\alpha_1, \dots, \alpha_n\} \subset \mathbb{C}^\times$ such that, for every uniformiser ϖ_w and every such j, the operator T_j is the scalar

$$T_j = \mathrm{N}w^{j(n-j)/2}\, e_j(\alpha_1, \dots, \alpha_n),$$

where e_j is the j-th elementary symmetric polynomial. They are the values $\chi_i(\varpi_w)$ of unramified characters $\chi_1, \dots, \chi_n$ of $E_w^\times$ such that π_w is a subquotient of the normalised induction of $\chi_1 \otimes \cdots \otimes \chi_n$ [60], [115]. Thus the relation $r \leftrightarrow_\iota \pi$ is the normalisation $\mathrm{rec}(\pi_w \otimes |\det|^{(1-n)/2})$ of

[121]. For E CM, r is **automorphic of conjugate self-dual type** if $r \leftrightarrow_\iota \pi$ for some regular algebraic conjugate self-dual cuspidal π. A normalised newform f of weight k, level $\Gamma_1(M)$ and character χ has the Galois representation $\rho_{f,\iota}\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ constructed in [76].

Algebraic Hecke characters. Let E be a number field and let $n = (n_\varphi)_\varphi$ be integers indexed by the field embeddings $\varphi\colon E \to \mathbb{C}$. A (not necessarily unitary) Hecke character χ of E is **algebraic of infinity type** n if

$$\chi_\infty(k) = \prod_{\varphi\colon E\to\mathbb{C}} \varphi(k)^{n_\varphi} \qquad \text{for every } k \in E^\times \text{ positive at every real place},$$

where $\chi_\infty = \prod_{v\mid\infty}\chi_v$ and k is embedded diagonally in $\prod_{v\mid\infty} E_v^\times$. For these characters the global Artin map is used in the **geometric normalisation** $\mathrm{Art}_E^{\mathrm{geo}}(x) = \mathrm{Art}_E(x)^{-1}$, which sends uniformisers to geometric Frobenius elements. The **ℓ-adic character attached to** (χ,ι) is the continuous character $\chi_\iota\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ such that

$$\chi_\iota(\sigma) = \iota^{-1}\Big(\chi(x)\prod_{v\mid\infty}\prod_{i} i(x_v)^{-n_i}\Big)\cdot\prod_{w\mid\ell}\prod_{j} j(x_w)^{n_{\iota\circ j}}$$

for every $x \in \mathbb{A}_E^\times$ and every $\sigma \in G_E$ whose image in G_E^{ab} is $\mathrm{Art}_E^{\mathrm{geo}}(x)$. Here i runs over the continuous embeddings $E_v \to \mathbb{C}$, j runs over the continuous embeddings $E_w \to \overline{\mathbb{Q}}_\ell$, and n_i, $n_{\iota\circ j}$ are the exponents of their restrictions to E. This character exists and is unique [220].

Sign of the Hodge jumps. With these normalisations, let $w \nmid \ell$ be a finite place at which χ is unramified. Then χ_ι is unramified at w and $\chi_\iota(\mathrm{Frob}_w^{-1}) = \iota^{-1}\chi_w(\varpi_w)$ for an arithmetic Frobenius Frob_w and a uniformiser ϖ_w. At a place $w \mid \ell$, the restriction $\chi_\iota|_{G_{E_w}}$ is de Rham and, for every embedding $\tau\colon E \to \overline{\mathbb{Q}}_\ell$ inducing w, its only Hodge jump at τ (in the sense of Definition 13.7) is $-n_{\iota\circ\tau}$. In other words, its Hodge–Tate weight at τ is $n_{\iota\circ\tau}$ when χ_{cyc} has weight 1 [220], [94]. For $E = \mathbb{Q}$ and $\chi = |\cdot|_{\mathbb{A}}$, of infinity type 1, we have $\chi_\iota = \chi_{\mathrm{cyc}}$, with Hodge jump -1. The character defined by the same formula with Art_E in place of $\mathrm{Art}_E^{\mathrm{geo}}$ is χ_ι^{-1}, with Hodge jump $n_{\iota\circ\tau}$ at τ.

Definition 13.8. Let ℓ be a prime. A **Hecke lattice over** ℓ is a tuple $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ consisting of

- a coefficient ring $\mathcal{O}$ for ℓ, with fraction field $\mathcal{O}[\ell^{-1}]$;
- a non-empty finite set $\mathcal{Z}$, whose elements are the **eigensystems**;
- an $\mathcal{O}$-subalgebra $\mathbb{T}$ of the algebra $\mathcal{O}^{\mathcal{Z}}$ of functions $\mathcal{Z} \to \mathcal{O}$ (pointwise operations, containing the constants) which separates the points of $\mathcal{Z}$, the **Hecke algebra**;
- a finitely generated free $\mathcal{O}$-module M with a homomorphism of $\mathcal{O}$-algebras $\mathbb{T} \to \mathrm{End}_{\mathcal{O}}(M)$, $f \mapsto f_M$.

Put $V = \mathcal{O}[\ell^{-1}] \otimes_{\mathcal{O}} M$ and regard M as an $\mathcal{O}$-submodule of V (possible since M is free). An $\mathcal{O}$-linear endomorphism α of M extends uniquely to an $\mathcal{O}[\ell^{-1}]$-linear endomorphism α_V of V; we write $f_V = (f_M)_V$. For $\pi \in \mathcal{Z}$ the **eigenspace** and the **multiplicity** of π are

$$V_\pi = \{v \in V :\ f_V v = f(\pi)\, v \text{ for all } f \in \mathbb{T}\}, \qquad m(\pi) = \dim_{\mathcal{O}[\ell^{-1}]} V_\pi,$$

and for a subset $Y \subseteq \mathcal{Z}$ we put $V_Y = \sum_{\pi\in Y} V_\pi$ (so $V_\emptyset = 0$).

Let $Z \subseteq \widehat{Z} \subseteq \mathcal{Z}$; Z is called the **good set** and $\widehat{Z}$ the **kept set**. Let $q\colon V \to V/V_{\mathcal{Z}\setminus\widehat{Z}}$ be the quotient map.

- The **congruence module** of M for Z and the **local defect** are

$$\mathrm{Cong}_Z(M) = \frac{V_Z \cap (M + V_{\mathcal{Z}\setminus Z})}{M \cap V_Z}, \qquad \mathrm{df}_Z(M) \in [0,\infty],$$

  where $\mathrm{df}_Z(M)$ is the normalised length of the $\mathcal{O}$-module $\mathrm{Cong}_Z(M)$ if it has finite length, and ∞ otherwise.

- The **cut lattice** for $\widehat{Z}$ is $q(M)$, and the **cut congruence module** and the **cut local defect** are

$$\mathrm{Cong}_Z^{\widehat{Z}}(M) = \frac{q(V_Z) \cap (q(M) + q(V_{\widehat{Z}\setminus Z}))}{q(M) \cap q(V_Z)}, \qquad \mathrm{df}_Z^{\widehat{Z}}(M) \in [0,\infty],$$

  the latter being the normalised length of $\mathrm{Cong}_Z^{\widehat{Z}}(M)$ if it has finite length, and ∞ otherwise. For $\widehat{Z} = \mathcal{Z}$, q is the identity and $\mathrm{df}_Z^{\mathcal{Z}}(M) = \mathrm{df}_Z(M)$.

- For $\pi \in Z$ the **congruence ideal** of π for $(Z, \widehat{Z})$ and its normalised length are

$$\mathfrak{c}_Z^{\widehat{Z}}(\pi) = \{f(\pi) :\ f \in \mathbb{T},\ f(\rho) = 0 \text{ for all } \rho \in \widehat{Z} \setminus Z\} \subseteq \mathcal{O}, \qquad \mathrm{cg}_Z^{\widehat{Z}}(\pi) \in [0,\infty],$$

  where $\mathfrak{c}_Z^{\widehat{Z}}(\pi)$ is an ideal of $\mathcal{O}$ and $\mathrm{cg}_Z^{\widehat{Z}}(\pi)$ is the normalised length of $\mathcal{O}/\mathfrak{c}_Z^{\widehat{Z}}(\pi)$, equal to ∞ when $\mathfrak{c}_Z^{\widehat{Z}}(\pi) = 0$.

Definition 13.9. For a number field E, a prime ℓ and an integer $t \geq 1$, the **ℓ-part of the Sha length** is $\mathrm{len}_\ell(E;t) = \sum_{k=1}^{t-1} \mathrm{len}_\ell(E,k) \in \mathbb{N} \cup \{\infty\}$; thus $\mathrm{len}(E;t) = \sum_\ell \log \ell \cdot \mathrm{len}_\ell(E;t)$.

Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε and threshold x_1. **Local defect data for $\mathcal{F}$** consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$, where m is the integer of $\mathfrak{M}_{x,i}$:

- a finite set $W_{x,i}$, the **twisted places** of the member, and for every $w \in W_{x,i}$ a prime $\ell_{x,i}(w)$, the **residue characteristic** of w, and a real number $\mathrm{lw}_{x,i}(w) \geq 0$, the **weight** of w;
- for every integer $1 \leq j \leq m$ and every $w \in W_{x,i}$, a finite set $R_{x,i}(j,w)$ of **local components**, such that the sets for distinct pairs (j,w) are disjoint;
- for every $r \in R_{x,i}(j,w)$, a Hecke lattice $(\mathcal{O}_r, \mathcal{Z}_r, \mathbb{T}_r, M_r)$ over $\ell_{x,i}(w)$, with eigenspaces $V_{r,Y}$ ($Y \subseteq \mathcal{Z}_r$) and multiplicities $m_r(\pi)$, together with a good set and a kept set $Z_r \subseteq \widehat{Z}_r \subseteq \mathcal{Z}_r$;
- an integer $N_{\mathrm{lev}}(x,i) \geq 1$, the **order of the level group**;
- a function $\mathrm{ex}_{x,i}$ from the set of primes to $[0,\infty)$, the **error allowances**.

For such a member and $r \in R_{x,i}(j,w)$ we write $\mathrm{df}(r) = \mathrm{df}_{Z_r}(M_r)$, $\mathrm{df}^{\mathrm{cut}}(r) = \mathrm{df}_{Z_r}^{\widehat{Z}_r}(M_r)$, $\mu(r) = \sum_{\pi \in Z_r} m_r(\pi)$ and $\mathrm{cg}(r,\pi) = \mathrm{cg}_{Z_r}^{\widehat{Z}_r}(\pi)$ for $\pi \in Z_r$. For a prime ℓ the **cut defect sum at ℓ** is

$$\mathrm{Df}_j^{\mathrm{cut}}(x,i;\ell) = \sum_{w \in W_{x,i},\ \ell_{x,i}(w) = \ell} \mathrm{lw}_{x,i}(w) \sum_{r \in R_{x,i}(j,w)} \mathrm{df}^{\mathrm{cut}}(r) \in [0,\infty].$$

We also write $P_{x,i} = \{\ell_{x,i}(w) : w \in W_{x,i}\}$, $G_{x,i} = \{g_1(\mathfrak{V}_{x,i}), g_2(\mathfrak{V}_{x,i})\}$, $E = E_{\mathfrak{h}_{x,i}}$ and $t = t_{x,i}$; n, f, b are as in Definition 13.1. A member (x,i) has **finite Sha lengths** if $\mathrm{len}_\ell(E,k) < \infty$ for

every prime ℓ and every $1 \le k < t$. As in Definition 13.1, the phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x \ge x_0$ with $x > x_1$, every $i \in I(x)$ and every integer j with $1 \le j \le m$.

The local defect data have

(Ld1) Defect sums if for all large members every $\mathrm{df}(r)$ is finite and

$$\mathrm{Df}_j(x,i) = \sum_{w \in W_{x,i}} \mathrm{lw}_{x,i}(w) \sum_{r \in R_{x,i}(j,w)} \mathrm{df}(r);$$

(Ld2) Mean condition if for all large members $\sum_{w \in W_{x,i},\, \ell_{x,i}(w) = \ell} \mathrm{lw}_{x,i}(w) \le \log \ell$ for every prime ℓ;

(Ld3) Multiplicities if for all large members $\sum_{r \in R_{x,i}(j,w)} \mu(r) \le \mathrm{rk}_j(x,i)$ for every $w \in W_{x,i}$;

(Ld4) Cut operators if for all large members, every $w \in W_{x,i}$ and every $r \in R_{x,i}(j,w)$ there is an $\mathcal{O}_r$-linear endomorphism α of M_r with $\alpha_V v = N_{\mathrm{lev}}(x,i)\, v$ for $v \in V_{r,Z_r}$ and $\alpha_V v = 0$ for $v \in V_{r,\mathcal{Z}_r \setminus \widehat{\mathcal{Z}}_r}$;

(Ld5) Sizes if there is a real C such that for all large members $\log N_{\mathrm{lev}}(x,i) \le C\, x^C x^{\varepsilon}$ and $\log \#\mathrm{Cl}(E) \le C\, x^C$;

(Ld6) Cut congruence modules if for all large members, every $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$ and every $r \in R_{x,i}(j,w)$,

$$\mathrm{df}^{\mathrm{cut}}(r) \le \sum_{\pi \in Z_r} m_r(\pi)\big(\mathrm{cg}(r,\pi) + v_\ell(N_{\mathrm{lev}}(x,i))\big);$$

(Ld7) Congruence ideals bounded by Sha lengths if for all large members with finite Sha lengths, every $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, every $r \in R_{x,i}(j,w)$ and every $\pi \in Z_r$,

$$\mathrm{cg}(r,\pi) \le \mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{ex}_{x,i}(\ell);$$

(Ld8) Auxiliary primes if for all large members with finite Sha lengths and every $\ell \in G_{x,i}$,

$$\mathrm{Df}_j^{\mathrm{cut}}(x,i;\ell) \le \log \ell \cdot \mathrm{rk}_j(x,i)\big(\mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{ex}_{x,i}(\ell)\big);$$

(Ld9) Error budget if there is a real C such that for all large members with finite Sha lengths $\sum_{\ell \in P_{x,i}} \log \ell \cdot \mathrm{ex}_{x,i}(\ell) \le C\, f\, m\, b\, x^{2\varepsilon}$.

Definition 13.10. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε and threshold x_1, together with local defect data. **Local bound records** for $\mathcal{F}$ consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$, where m is the integer of $\mathfrak{M}_{x,i}$:

- for every integer $1 \le j \le m$, every $w \in W_{x,i}$ with $\ell_{x,i}(w) \notin G_{x,i}$, every $r \in R_{x,i}(j,w)$ and every $\pi \in Z_r$, a real number $\mathrm{sl}(r,\pi)$, the **Selmer length** of π at r;
- for every such r, a real number $\mathrm{lt}(r)$, the **local term** of r;
- functions $\mathrm{sa}_{x,i}$, $\mathrm{la}_{x,i}$, $\mathrm{ga}_{x,i}$ from the set of primes to $\mathbb{R}$, the **Selmer allowances**, the **local allowances** and the **auxiliary allowances**.

Write $E = E_{\mathfrak{h}_{x,i}}$ and $t = t_{x,i}$. The records have

(Lq1) Lattice index bounds if for all large members with finite Sha lengths, every $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, every $r \in R_{x,i}(j,w)$ and every $\pi \in Z_r$,

$$\mathrm{cg}(r,\pi) \le \mathrm{sl}(r,\pi) + \mathrm{lt}(r) + \mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E)) + \ell^{-2};$$

(Lq2) Selmer bounds if for all large members with finite Sha lengths and all w, r, π as in (Lq1), $\mathrm{sl}(r,\pi) \le \mathrm{sa}_{x,i}(\ell) + \ell^{-2}$ with $\ell = \ell_{x,i}(w)$;

(Lq3) Local bounds if for all large members with finite Sha lengths and all w, r as in (Lq1), $\mathrm{lt}(r) \le \mathrm{la}_{x,i}(\ell)$ with $\ell = \ell_{x,i}(w)$;

(Lq4) Auxiliary bounds if for all large members with finite Sha lengths and every $\ell \in G_{x,i}$,

$$\mathrm{Df}_j^{\mathrm{cut}}(x,i;\ell) \le \log \ell \cdot \mathrm{rk}_j(x,i)\big(\mathrm{ga}_{x,i}(\ell) + 2\ell^{-2} + \mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E))\big);$$

(Lq5) Composition of the allowances if for all large members with finite Sha lengths

$$\mathrm{ex}_{x,i}(\ell) = \begin{cases} \mathrm{sa}_{x,i}(\ell) + 2\ell^{-2} + \mathrm{la}_{x,i}(\ell) & \ell \in P_{x,i} \setminus G_{x,i}, \\ \mathrm{ga}_{x,i}(\ell) + 2\ell^{-2} & \ell \in G_{x,i}; \end{cases} \tag{13.7}$$

(Lq6) Selmer budget if there is a real C such that for all large members with finite Sha lengths $\sum_{\ell \in P_{x,i} \setminus G_{x,i}} \log \ell \cdot \mathrm{sa}_{x,i}(\ell) \le C\, f\, m\, b\, x^{2\varepsilon}$;

(Lq7) Local budget if there is a real C such that for all large members with finite Sha lengths $\sum_{\ell \in P_{x,i} \setminus G_{x,i}} \log \ell \cdot \mathrm{la}_{x,i}(\ell) \le C\, f\, m\, b\, x^{2\varepsilon}$;

(Lq8) Auxiliary budget if there is a real C such that for all large members with finite Sha lengths $\sum_{\ell \in P_{x,i} \cap G_{x,i}} \log \ell \cdot \mathrm{ga}_{x,i}(\ell) \le C\, f\, m\, b\, x^{2\varepsilon}$.

Definition 13.11. Let $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ be a Hecke lattice over a prime ℓ, and let $\mathbb{F}_{\mathcal{O}}$ be the residue field of $\mathcal{O}$. For an integer $n \ge 1$ we identify $\mathrm{M}_g(\mathrm{M}_n(\mathcal{O}[\ell^{-1}]))$ with $\mathrm{M}_{gn}(\mathcal{O}[\ell^{-1}])$, and similarly for rectangular matrices.

Determinant algebras. A **determinant algebra** over $\mathbb{T}$ is a tuple $(\mathcal{Z}', \phi, (z_1, \dots, z_{n_z}), n_{\mathcal{R}}, \mathcal{R})$ consisting of

- a finite set $\mathcal{Z}'$, whose elements are the **points**, and a map $\phi\colon \mathcal{Z}' \to \mathcal{Z}$;
- functions $z_1, \dots, z_{n_z}\colon \mathcal{Z}' \to \mathcal{O}$, the **descent functions**;
- an integer $n_{\mathcal{R}} \ge 1$, the **rank**;
- an $\mathcal{O}$-subalgebra $\mathcal{R}$ of $\prod_{x' \in \mathcal{Z}'} \mathrm{M}_{n_{\mathcal{R}}}(\mathcal{O}[\ell^{-1}])$.

For $a \in \mathcal{R}$ and $x' \in \mathcal{Z}'$ we write $a(x') \in \mathrm{M}_{n_{\mathcal{R}}}(\mathcal{O}[\ell^{-1}])$ for its component. For a matrix $\mathbf{X}$ with entries in $\mathcal{R}$, $\mathbf{X}(x')$ is the matrix of the components. For $x' \in \mathcal{Z}'$, $\mathcal{O}[\ell^{-1}]_{x'}^{n_{\mathcal{R}}}$ is the left $\mathcal{R}$-module $\mathcal{O}[\ell^{-1}]^{n_{\mathcal{R}}}$ (column vectors) on which a acts by $a(x')$. For an integer $g \ge 1$ the determinant algebra satisfies the **determinant condition in degree** g if

$$\begin{gathered} \text{for every } \mathbf{X} \in \mathrm{M}_g(\mathcal{R}) \text{ there are } a_1, \dots, a_{n_z} \in \mathbb{T} \text{ with} \\ \det \mathbf{X}(x') = \sum_{k=1}^{n_z} a_k(\phi(x'))\, z_k(x') \text{ for all } x' \in \mathcal{Z}', \end{gathered} \tag{13.8}$$

where the determinant is that of the $gn_{\mathcal{R}} \times gn_{\mathcal{R}}$ matrix $\mathbf{X}(x')$. A subset $\mathcal{Y} \subseteq \mathcal{Z}$ is **detected by the descent functions** if for every $x \in \mathcal{Y}$ and every $(c_1, \dots, c_{n_z}) \in \mathcal{O}^{n_z}$ with $\sum_k c_k z_k(x') = 0$ for all $x' \in \phi^{-1}(x)$, all c_k vanish.

Block forms. Let $\pi' \in \mathcal{Z}'$. A **block form at** π' with $s+1$ blocks ($s \geq 0$) is a sequence of integers $n_{\mathcal{R},0}, \dots, n_{\mathcal{R},s} \geq 1$ with sum $n_{\mathcal{R}}$, defining the consecutive intervals $I_0 < I_1 < \cdots < I_s$ of $\{1, \dots, n_{\mathcal{R}}\}$ of these lengths, such that for every $a \in \mathcal{R}$:

(Bf1) $a(\pi') \in \mathrm{M}_{n_{\mathcal{R}}}(\mathcal{O})$, and $a(\pi')$ is block upper triangular: its entries in rows I_k and columns $I_{k'}$ vanish whenever $k > k'$;

(Bf2) for each k, the map $\rho_k \colon \mathcal{R} \to \mathrm{M}_{n_{\mathcal{R},k}}(\mathcal{O})$ sending a to the diagonal block of $a(\pi')$ in rows and columns I_k is surjective.

By (Bf1) each ρ_k is a homomorphism of $\mathcal{O}$-algebras, since the diagonal blocks of a product of block upper triangular matrices are the products of the diagonal blocks. The **constituent module** of the k-th block is the left $\mathcal{R}$-module

$$\mathrm{Cs}_k = \left(\mathcal{O}[\ell^{-1}]/\mathcal{O}\right)^{n_{\mathcal{R},k}} \qquad \text{(column vectors)}, \qquad a \cdot v = \rho_k(a)\, v.$$

Presented modules. A **presentation** of a left $\mathcal{R}$-module $\mathcal{N}$ with $n_{\mathrm{gen}} \geq 1$ generators and $n_{\mathrm{rel}} \geq 1$ relations is a matrix $\mathbf{P} \in \mathrm{M}_{n_{\mathrm{rel}} \times n_{\mathrm{gen}}}(\mathcal{R})$ together with an isomorphism of left $\mathcal{R}$-modules between $\mathcal{N}$ and the cokernel of $\mathcal{R}^{n_{\mathrm{rel}}} \to \mathcal{R}^{n_{\mathrm{gen}}}$, $u \mapsto u\mathbf{P}$ (row vectors). For a left $\mathcal{R}$-module V, $\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, V)$ is an $\mathcal{O}$-module. Let e_j be the images of the standard basis vectors. The map $\varphi \mapsto (\varphi(e_1), \dots, \varphi(e_{n_{\mathrm{gen}}}))$ identifies $\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, V)$ with $\{v \in V^{n_{\mathrm{gen}}} : \mathbf{P}v = 0\}$, where $(\mathbf{P}v)_i = \sum_j \mathbf{P}_{ij} v_j$.

Definition 13.12. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1, local defect data and local bound records. **Ribet records** for $\mathcal{F}$ consist, for every real $x > x_1$, every $i \in I(x)$, every integer $1 \leq j \leq m$, every $w \in W_{x,i}$ with $\ell_{x,i}(w) \notin G_{x,i}$, every $r \in R_{x,i}(j, w)$ and every $\pi \in Z_r$, of

- a determinant algebra $(\mathcal{Z}'_{r,\pi}, \phi_{r,\pi}, (z_k), n_{\mathcal{R}}, \mathcal{R}_{r,\pi})$ over $\mathbb{T}_r$ and a point $\pi' \in \phi_{r,\pi}^{-1}(\pi)$ with a block form with $t+1$ blocks, numbered $0, 1, \dots, t$, with constituent modules $\mathrm{Cs}_0, \dots, \mathrm{Cs}_t$;
- a left $\mathcal{R}_{r,\pi}$-module $\mathcal{N}_{r,\pi}$, the **module of extensions**, with a presentation with n_{gen} generators;
- real numbers $\mathrm{lc}_0(r,\pi), \dots, \mathrm{lc}_t(r,\pi) \geq 0$, the **local contributions**.

Write $\ell = \ell_{x,i}(w)$, $E = E_{\mathfrak{h}_{x,i}}$ and $t = t_{x,i}$, and let $\mathrm{nl}(\cdot)$ denote the normalised length of an $\mathcal{O}_r$-module. Let $\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}_r[\ell^{-1}]/\mathcal{O}_r)$ be the $\mathcal{O}_r$-module of **unramified homomorphisms**, that is, of the continuous homomorphisms $G_E \to \mathcal{O}_r[\ell^{-1}]/\mathcal{O}_r$ (for the discrete topology on the target) that vanish on the inertia group I_w of every finite place w of E. The records have each of the following properties if the stated condition holds for all large members with finite Sha lengths and all w, r, π as above.

(Rf1) Determinants The determinant algebra satisfies the determinant condition in degree n_{gen}, and $\widehat{Z}_r \setminus Z_r$ is detected by its descent functions.

(Rf2) Extensions away from the good set For every point x' with $\phi_{r,\pi}(x') \in \widehat{Z}_r \setminus Z_r$,

$$\mathrm{Hom}_{\mathcal{R}_{r,\pi}}\left(\mathcal{N}_{r,\pi}, \mathcal{O}_r[\ell^{-1}]^{n_{\mathcal{R}}}_{x'}\right) \neq 0.$$

(Rf3) Sizes The residue field of $\mathcal{O}_r$ has more than $n_{\mathrm{gen}} n_{\mathcal{R}}$ elements, and E has no real place if $\ell = 2$.

(Rf4) Block bounds The modules $\mathrm{Hom}_{\mathcal{R}_{r,\pi}}(\mathcal{N}_{r,\pi}, \mathrm{Cs}_k)$ have finite length, and

$$\begin{aligned}
&\mathrm{nl}\,\mathrm{Hom}(\mathcal{N}_{r,\pi}, \mathrm{Cs}_0) \le \mathrm{sl}(r,\pi) + \mathrm{lc}_0(r,\pi),\\
&\mathrm{nl}\,\mathrm{Hom}(\mathcal{N}_{r,\pi}, \mathrm{Cs}_1) \le \mathrm{nl}\,\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}_r[\ell^{-1}]/\mathcal{O}_r) + \mathrm{lc}_1(r,\pi),\\
&\mathrm{nl}\,\mathrm{Hom}(\mathcal{N}_{r,\pi}, \mathrm{Cs}_k) \le \mathrm{len}_\ell(E, k-1) + \mathrm{lc}_k(r,\pi) \qquad (2 \le k \le t),
\end{aligned}$$

where the homomorphisms are $\mathcal{R}_{r,\pi}$-linear.

(Rf5) Local term $\sum_{k=0}^{t} \mathrm{lc}_k(r,\pi) \le \mathrm{lt}(r)$.

Theorem 13.13. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data and local bound records, and suppose that $\mathcal{F}$ has Ribet records with the properties (Rf1)–(Rf5). Then the local bound records have the lattice index bounds (Lq1), in the stronger form without the term ℓ^{-2}: for all large members (x,i) with finite Sha lengths, every $1 \le j \le m$, every $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, every $r \in R_{x,i}(j,w)$ and every $\pi \in Z_r$,*

$$\mathrm{cg}(r,\pi) \le \mathrm{sl}(r,\pi) + \mathrm{lt}(r) + \mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E)), \qquad E = E_{\mathfrak{h}_{x,i}},\ t = t_{x,i}.$$

Proof. Let $x^{(1)}, \dots, x^{(5)}$ be thresholds for (Rf1)–(Rf5) and $x_0 = \max(x^{(1)}, \dots, x^{(5)})$. Fix a real $x \ge x_0$ with $x > x_1$, a member $i \in I(x)$ with finite Sha lengths, an integer $1 \le j \le m$, a place $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, a local component $r \in R_{x,i}(j,w)$ and $\pi \in Z_r$; all five properties apply. Write $\mathcal{O} = \mathcal{O}_r$, $\mathcal{R} = \mathcal{R}_{r,\pi}$, $\mathcal{N} = \mathcal{N}_{r,\pi}$, $\mathrm{lc}_k = \mathrm{lc}_k(r,\pi)$.

The Fitting step. Put $\mathcal{Y} = \widehat{Z}_r \setminus Z_r$; it does not contain $\pi \in Z_r$, and the ideal $\mathfrak{c} = \{f(\pi) : f \in \mathbb{T}_r,\ f|_{\mathcal{Y}} = 0\}$ is the congruence ideal $\mathfrak{c}_{Z_r}^{\widehat{Z}_r}(\pi)$, so the normalised length of $\mathcal{O}/\mathfrak{c}$ is $\mathrm{cg}(r,\pi)$. The hypotheses of Lemma 13.14 for the Hecke lattice of r, the point π, the set $\mathcal{Y}$, the determinant algebra $\mathcal{R}$ with the block form at $\pi' \in \phi_{r,\pi}^{-1}(\pi)$ and the presented module $\mathcal{N}$ hold: the determinant condition in degree n_{gen} and the detection of $\mathcal{Y}$ by (Rf1), the non-vanishing at the points over $\mathcal{Y}$ by (Rf2), the size of the residue field by (Rf3). Hence

$$\mathrm{cg}(r,\pi) \le \sum_{k=0}^{t} \mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k).$$

The four kinds of terms. By (Rf4) the summand for $k = 0$ is at most $\mathrm{sl}(r,\pi) + \mathrm{lc}_0$, the summand for $k = 1$ at most the normalised length of $\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}[\ell^{-1}]/\mathcal{O})$ plus lc_1, and the summand for $2 \le k \le t$ at most $\mathrm{len}_\ell(E, k-1) + \mathrm{lc}_k$. By (Rf3), ℓ is odd or E has no real place, so Lemma 13.15 gives that the normalised length of $\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}[\ell^{-1}]/\mathcal{O})$ is $v_\ell(\#\mathrm{Cl}(E))$. The substitution $k' = k-1$ gives $\sum_{k=2}^{t} \mathrm{len}_\ell(E, k-1) = \sum_{k'=1}^{t-1} \mathrm{len}_\ell(E, k') = \mathrm{len}_\ell(E;t)$, a finite number because the member has finite Sha lengths (the sum is empty, and $\mathrm{len}_\ell(E;1) = 0$, when $t = 1$). Adding,

$$\mathrm{cg}(r,\pi) \le \mathrm{sl}(r,\pi) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{len}_\ell(E;t) + \sum_{k=0}^{t} \mathrm{lc}_k \le \mathrm{sl}(r,\pi) + \mathrm{lt}(r) + \mathrm{len}_\ell(E;t) + v_\ell(\#\mathrm{Cl}(E)),$$

the last step by (Rf5).

This holds for every real $x \ge x_0$ with $x > x_1$, every member $i \in I(x)$ with finite Sha lengths and all j, w, r, π as in the statement. Since $\ell^{-2} > 0$, it implies (Lq1) with the threshold x_0. □

Lemma 13.14. *Let $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ be a Hecke lattice over a prime ℓ, let $\pi \in \mathcal{Z}$, let $\mathcal{Y} \subseteq \mathcal{Z} \setminus \{\pi\}$, and let*

$$\mathfrak{c} = \{f(\pi) : \ f \in \mathbb{T}, \ f(y) = 0 \text{ for all } y \in \mathcal{Y}\} \subseteq \mathcal{O}.$$

Let $(\mathcal{Z}', \phi, (z_k)_{k \le n_z}, n_{\mathcal{R}}, \mathcal{R})$ be a determinant algebra over $\mathbb{T}$, let $\pi' \in \phi^{-1}(\pi)$ carry a block form with $s+1$ blocks and constituent modules $\mathrm{Cs}_0, \dots, \mathrm{Cs}_s$, and let $\mathcal{N}$ be a left $\mathcal{R}$-module with a presentation with n_{gen} generators and n_{rel} relations. Assume:

- *the determinant algebra satisfies the determinant condition in degree n_{gen}, and $\mathcal{Y}$ is detected by the descent functions;*
- *$\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathcal{O}[\ell^{-1}]^{n_{\mathcal{R}}}_{x'}) \neq 0$ for every $x' \in \phi^{-1}(\mathcal{Y})$;*
- *the residue field $\mathbb{F}_{\mathcal{O}}$ has more than $n_{\mathrm{gen}}\, n_{\mathcal{R}}$ elements.*

Then $\mathfrak{c}$ is an ideal of $\mathcal{O}$ and

$$\mathrm{length}_{\mathcal{O}}(\mathcal{O}/\mathfrak{c}) \le \sum_{k=0}^{s} \mathrm{length}_{\mathcal{O}} \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k) \qquad \text{in } \mathbb{N} \cup \{\infty\};$$

equivalently, the same inequality holds for normalised lengths.

Proof. Write $K = \mathcal{O}[\ell^{-1}]$, fix a uniformiser $\varpi_{\mathcal{O}}$, let v be the valuation of K with $v(\varpi_{\mathcal{O}}) = 1$ and $v(0) = \infty$, and let $\mathbf{P} \in \mathrm{M}_{n_{\mathrm{rel}} \times n_{\mathrm{gen}}}(\mathcal{R})$ be the presentation matrix. Since $\mathbb{T}$ is an $\mathcal{O}$-algebra of functions, $c\,f \in \mathbb{T}$ for $c \in \mathcal{O}$ and $f \in \mathbb{T}$, so $\mathfrak{c}$ is an $\mathcal{O}$-submodule of $\mathcal{O}$, i.e. an ideal; for $y \in \mathfrak{c}$ we have $\mathrm{length}_{\mathcal{O}}(\mathcal{O}/\mathfrak{c}) \le \mathrm{length}_{\mathcal{O}}(\mathcal{O}/y\mathcal{O}) = v(y)$.

Step 1: the determinants of the combinations of the relations lie in $\mathfrak{c}$. Let $\mathbf{Q} \in \mathrm{M}_{n_{\mathrm{gen}} \times n_{\mathrm{rel}}}(\mathcal{R})$ and $\mathbf{X} = \mathbf{Q}\mathbf{P} \in \mathrm{M}_{n_{\mathrm{gen}}}(\mathcal{R})$. By the determinant condition in degree n_{gen} there are $a_1, \dots, a_{n_z} \in \mathbb{T}$ with $\det \mathbf{X}(x') = \sum_k a_k(\phi(x')) z_k(x')$ for all $x' \in \mathcal{Z}'$. Let $x \in \mathcal{Y}$ and $x' \in \phi^{-1}(x)$. On $V = K^{n_{\mathcal{R}}}_{x'}$ the element a acts by $a(x')$, so $V^{n_{\mathrm{gen}}} = K^{n_{\mathrm{gen}} n_{\mathcal{R}}}$ and $\mathbf{P}$ acts on it by the matrix $\mathbf{P}(x')$; by the second hypothesis and the identification of $\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, V)$ there is $w \neq 0$ with $\mathbf{P}(x')w = 0$. Evaluation at x' is a ring homomorphism $\mathcal{R} \to \mathrm{M}_{n_{\mathcal{R}}}(K)$, so $\mathbf{X}(x') = \mathbf{Q}(x')\mathbf{P}(x')$ and $\mathbf{X}(x')w = 0$; hence $\det \mathbf{X}(x') = 0$. Thus $\sum_k a_k(x) z_k(x') = 0$ for every $x' \in \phi^{-1}(x)$, and since $\mathcal{Y}$ is detected by the descent functions, $a_k(x) = 0$ for all k. So every a_k vanishes on $\mathcal{Y}$, $a_k(\pi) \in \mathfrak{c}$, and as $z_k(\pi') \in \mathcal{O}$ and $\phi(\pi') = \pi$,

$$\det \mathbf{X}(\pi') = \sum_k a_k(\pi) z_k(\pi') \in \mathfrak{c}, \qquad \text{hence} \qquad \mathrm{length}_{\mathcal{O}}(\mathcal{O}/\mathfrak{c}) \le v(\det \mathbf{X}(\pi')). \tag{13.9}$$

Step 2: the determinant at π' factors through the blocks. By (Bf1) every entry of $\mathbf{Q}(\pi')$ and $\mathbf{P}(\pi')$, and hence of $\mathbf{X}(\pi')$, is a block upper triangular matrix in $\mathrm{M}_{n_{\mathcal{R}}}(\mathcal{O})$. Index the basis of $\mathcal{O}^{n_{\mathrm{gen}} n_{\mathcal{R}}}$ by pairs (j, a), $1 \le j \le n_{\mathrm{gen}}$, $1 \le a \le n_{\mathcal{R}}$, and let $\beta(a)$ be the block containing a. The entry of $\mathbf{X}(\pi')$ at $((j,a),(j',a'))$ is the (a,a') entry of $\mathbf{X}_{jj'}(\pi')$, which vanishes when $\beta(a) > \beta(a')$. Ordering the basis first by $\beta(a)$ therefore conjugates $\mathbf{X}(\pi')$ by a permutation matrix into a block upper triangular matrix whose k-th diagonal block is $\rho_k(\mathbf{X}) = (\rho_k(\mathbf{X}_{jj'}))_{j,j'}$. Since ρ_k is a ring homomorphism, $\rho_k(\mathbf{X}) = \rho_k(\mathbf{Q})\rho_k(\mathbf{P})$ (entrywise application). Conjugation by a permutation matrix preserves the determinant, so

$$\det \mathbf{X}(\pi') = \prod_{k=0}^{s} \det\big(\rho_k(\mathbf{Q})\, \rho_k(\mathbf{P})\big). \tag{13.10}$$

Step 3: one block. For $B \in \mathrm{M}_{n' \times n}(\mathcal{O})$ let $\kappa(B) \in \mathbb{N} \cup \{\infty\}$ be the length of the kernel of $B \colon (K/\mathcal{O})^n \to (K/\mathcal{O})^{n'}$. By the Smith normal form over the discrete valuation ring $\mathcal{O}$, $B =$

UDW with $U \in \mathrm{GL}_{n'}(\mathcal{O})$, $W \in \mathrm{GL}_n(\mathcal{O})$ and D zero except for $D_{ii} = \varpi_{\mathcal{O}}^{\alpha_i}$, $1 \le i \le \min(n, n')$, with $\alpha_i \in \mathbb{N} \cup \{\infty\}$ and $\varpi_{\mathcal{O}}^{\infty} = 0$. The kernel of B is W^{-1} of the kernel of D. If $n > n'$ or some $\alpha_i = \infty$, the kernel of D contains a copy of $K/\mathcal{O}$, which has infinite length (the submodules $\varpi_{\mathcal{O}}^{-r}\mathcal{O}/\mathcal{O}$ increase strictly), so $\kappa(B) = \infty$. Otherwise the kernel of D is $\bigoplus_{i \le n} \varpi_{\mathcal{O}}^{-\alpha_i}\mathcal{O}/\mathcal{O} \cong \bigoplus_i \mathcal{O}/\varpi_{\mathcal{O}}^{\alpha_i}\mathcal{O}$, and $\kappa(B) = \sum_{i \le n} \alpha_i$. In this case let U_1 be the $n' \times n$ matrix of the first n columns of U and $\Delta = \mathrm{diag}(\varpi_{\mathcal{O}}^{\alpha_1}, \dots, \varpi_{\mathcal{O}}^{\alpha_n})$; then $UD = U_1\Delta$, and for every $C \in \mathrm{M}_{n \times n'}(\mathcal{O})$

$$\det(CB) = \det(CU_1)\,\det(\Delta)\,\det(W), \qquad v\big(\det(CB)\big) = v\big(\det(CU_1)\big) + \kappa(B).$$

So $v(\det(CB)) = \kappa(B)$ as soon as the reduction $\det(\overline{C}\,\overline{U}_1) \in \mathbb{F}_{\mathcal{O}}$ is non-zero. The first n rows C_B of U^{-1} satisfy $C_B U_1 = I_n$.

Step 4: a common choice of Q. We may assume that the right side of the assertion is finite. For each k, $\mathrm{Cs}_k^{n_{\mathrm{gen}}} = (K/\mathcal{O})^{n_{\mathrm{gen}} n_{\mathcal{R},k}}$ and $\mathbf{P}$ acts on it by the matrix $B_k = \rho_k(\mathbf{P}) \in \mathrm{M}_{n_{\mathrm{rel}} n_{\mathcal{R},k} \times n_{\mathrm{gen}} n_{\mathcal{R},k}}(\mathcal{O})$, so by the identification of homomorphisms $\mathrm{length}_{\mathcal{O}} \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k) = \kappa(B_k) < \infty$. Let $U_{k,1}$ and $C_k = C_{B_k}$ be as in Step 3 for B_k. By (Bf2), applied entrywise, there is $\mathbf{Q}^{(k)} \in \mathrm{M}_{n_{\mathrm{gen}} \times n_{\mathrm{rel}}}(\mathcal{R})$ with $\rho_k(\mathbf{Q}^{(k)}) = C_k$. For $c = (c_0, \dots, c_s) \in \mathcal{O}^{s+1}$ put $\mathbf{Q}(c) = \sum_{k'} c_{k'} \mathbf{Q}^{(k')}$. The entries of the matrix $\overline{\rho_k(\mathbf{Q}(c))}\,\overline{U}_{k,1} = \sum_{k'} \bar{c}_{k'}\, \overline{\rho_k(\mathbf{Q}^{(k')})}\,\overline{U}_{k,1}$ of size $n_{\mathrm{gen}} n_{\mathcal{R},k}$ are linear forms in $\bar{c} \in \mathbb{F}_{\mathcal{O}}^{s+1}$, so $F_k(\bar{c}) = \det\big(\overline{\rho_k(\mathbf{Q}(c))}\,\overline{U}_{k,1}\big)$ is a polynomial of total degree at most $n_{\mathrm{gen}} n_{\mathcal{R},k}$, and $F_k(e_k) = \det(\overline{C}_k \overline{U}_{k,1}) = 1$ at the k-th unit vector. The product $F = \prod_k F_k$ is a non-zero polynomial of total degree at most $n_{\mathrm{gen}} \sum_k n_{\mathcal{R},k} = n_{\mathrm{gen}} n_{\mathcal{R}} < \#\mathbb{F}_{\mathcal{O}}$. A non-zero polynomial $F \in \mathbb{F}[X_0, \dots, X_s]$ of total degree $D < \#\mathbb{F}$ over a field $\mathbb{F}$ takes a non-zero value on $\mathbb{F}^{s+1}$: for $s = 0$ it has at most D roots; for $s \ge 1$ write $F = \sum_{i \le D} F_i(X_1, \dots, X_s) X_0^i$, choose j with $F_j \ne 0$ and, by induction, a point $(c_1, \dots, c_s)$ with $F_j(c_1, \dots, c_s) \ne 0$; then $F(X_0, c_1, \dots, c_s)$ is a non-zero polynomial of degree at most D in X_0 and has a non-root. Choose $\bar{c}$ with $F(\bar{c}) \ne 0$, lift it to $c \in \mathcal{O}^{s+1}$ and put $\mathbf{Q} = \mathbf{Q}(c)$. Then $F_k(\bar{c}) \ne 0$ for every k, and Step 3 with $C = \rho_k(\mathbf{Q})$ gives $v\big(\det(\rho_k(\mathbf{Q}) B_k)\big) = \kappa(B_k)$.

Step 5: conclusion. With this $\mathbf{Q}$, (13.9) and (13.10) give

$$\mathrm{length}_{\mathcal{O}}(\mathcal{O}/\mathfrak{c}) \le \sum_{k=0}^{s} v\big(\det(\rho_k(\mathbf{Q})\rho_k(\mathbf{P}))\big) = \sum_{k=0}^{s} \kappa(B_k) = \sum_{k=0}^{s} \mathrm{length}_{\mathcal{O}} \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k).$$

Dividing by $e_{\mathcal{O}} \ge 1$ gives the form with normalised lengths. □

Lemma 13.15. *Let E be a number field, ℓ a prime and $\mathcal{O}$ a coefficient ring for ℓ. Let*

$$\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}[\ell^{-1}]/\mathcal{O})$$

be the $\mathcal{O}$-module of continuous homomorphisms $G_E \to \mathcal{O}[\ell^{-1}]/\mathcal{O}$ (discrete topology) that vanish on the inertia group I_w of every finite place w of E. If ℓ is odd or E has no real place, this module has finite length and its normalised length is $v_\ell(\#\mathrm{Cl}(E))$.

Proof. Write $K = \mathcal{O}[\ell^{-1}]$, $U = \mathrm{Hom}_{\mathrm{ur}}(G_E, K/\mathcal{O})$, and let H be the Hilbert class field of E, the maximal abelian extension of E unramified at all places, finite and infinite; by class field theory the Artin map induces $\mathrm{Gal}(H/E) \cong \mathrm{Cl}(E)$ [190] (Ch. VI, the Hilbert class field).

Every $\varphi \in U$ factors through $\mathrm{Gal}(H/E)$. The kernel of φ is open (continuity into a discrete group) and contains the commutator subgroup (the target is abelian), so its fixed field L is a finite abelian extension of E and φ induces an injection $\mathrm{Gal}(L/E) \hookrightarrow K/\mathcal{O}$. For a finite place w the inertia group of L/E at w is the image of I_w, on which φ vanishes, so L/E is unramified at w. For a real place, the decomposition group of L/E is generated by the image σ of a complex conjugation and has order at most 2, so $2\varphi(\sigma) = 0$; if ℓ is odd, multiplication

by 2 is injective on $K/\mathcal{O}$ and $\varphi(\sigma) = 0$, and if E has no real place there is nothing to check. Hence L/E is unramified at all places, $L \subseteq H$, and φ factors through $\mathrm{Gal}(H/E)$. Conversely, every homomorphism $\mathrm{Gal}(H/E) \to K/\mathcal{O}$ composed with the restriction $G_E \to \mathrm{Gal}(H/E)$ is continuous and vanishes on every I_w, because H/E is unramified at w. So restriction induces an isomorphism of $\mathcal{O}$-modules $U \cong \mathrm{Hom}(\mathrm{Gal}(H/E), K/\mathcal{O}) \cong \mathrm{Hom}(\mathrm{Cl}(E), K/\mathcal{O})$.

The length. Write $\mathrm{Cl}(E) \cong \bigoplus_i \mathbb{Z}/n_i\mathbb{Z}$, a finite sum, and $n_i = \ell^{a_i}u_i$ with $\ell \nmid u_i$. Then $\mathrm{Hom}(\mathbb{Z}/n_i\mathbb{Z}, K/\mathcal{O})$ is the n_i-torsion of $K/\mathcal{O}$; as u_i is a unit of $\mathcal{O}$ this is the ℓ^{a_i}-torsion $\ell^{-a_i}\mathcal{O}/\mathcal{O} \cong \mathcal{O}/\ell^{a_i}\mathcal{O}$, of length $a_i e_{\mathcal{O}}$ (the quotients $\ell^j\mathcal{O}/\ell^{j+1}\mathcal{O} \cong \mathcal{O}/\ell\mathcal{O}$ have length $e_{\mathcal{O}}$). Hence U has length $e_{\mathcal{O}} \sum_i a_i = e_{\mathcal{O}}\, v_\ell(\#\mathrm{Cl}(E))$, and its normalised length is $v_\ell(\#\mathrm{Cl}(E))$. □

Theorem 13.16. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, and suppose that $\mathcal{F}$ has local bound records with the properties (Lq1)–(Lq5). Then the local defect data have the properties (Ld7), congruence ideals bounded by Sha lengths, and (Ld8), auxiliary primes.*

Proof. Let $x^{(1)}, \dots, x^{(5)}$ be thresholds for (Lq1)–(Lq5) and $x_0 = \max(x^{(1)}, \dots, x^{(5)})$. Fix a real $x \geq x_0$ with $x > x_1$, a member $i \in I(x)$ with finite Sha lengths, and an integer $1 \leq j \leq m$, m the integer of $\mathfrak{M}_{x,i}$. All five properties apply at (x, i, j). Write $U(\ell) = \mathrm{len}_\ell(E; t) + v_\ell(\#\mathrm{Cl}(E))$ for a prime ℓ; it is finite, since the member has finite Sha lengths.

(Ld7). Let $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, let $r \in R_{x,i}(j, w)$ and $\pi \in Z_r$. Then $\ell \in P_{x,i} \setminus G_{x,i}$, because ℓ is the residue characteristic of the twisted place w. By (Lq1), then (Lq2) for $\mathrm{sl}(r, \pi)$ and (Lq3) for $\mathrm{lt}(r)$,

$$\mathrm{cg}(r, \pi) \leq \mathrm{sl}(r, \pi) + \mathrm{lt}(r) + U(\ell) + \ell^{-2} \leq \big(\mathrm{sa}_{x,i}(\ell) + \ell^{-2}\big) + \mathrm{la}_{x,i}(\ell) + U(\ell) + \ell^{-2}.$$

By the first case of the composition of the allowances (Lq5), $\mathrm{sa}_{x,i}(\ell) + 2\ell^{-2} + \mathrm{la}_{x,i}(\ell) = \mathrm{ex}_{x,i}(\ell)$, so

$$\mathrm{cg}(r, \pi) \leq \mathrm{len}_\ell(E; t) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{ex}_{x,i}(\ell).$$

(Ld8). Let $\ell \in G_{x,i}$. By (Lq4) and the second case of (Lq5), $\mathrm{ga}_{x,i}(\ell) + 2\ell^{-2} = \mathrm{ex}_{x,i}(\ell)$ and

$$\mathrm{Df}_j^{\mathrm{cut}}(x, i; \ell) \leq \log \ell \cdot \mathrm{rk}_j(x, i)\big(\mathrm{len}_\ell(E; t) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{ex}_{x,i}(\ell)\big).$$

Both bounds hold for every real $x \geq x_0$ with $x > x_1$, every member $i \in I(x)$ with finite Sha lengths and every $1 \leq j \leq m$, which is (Ld7) and (Ld8) with the threshold x_0. □

Theorem 13.17. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, and suppose that $\mathcal{F}$ has local bound records with the properties (Lq5)–(Lq8). Then the local defect data have the error budget (Ld9).*

Proof. **The prime sum $\sum_\ell \log \ell/\ell^2$.** For real $y \geq 1$ we have $\log y \leq \sqrt{y}$: the function $g(y) = \sqrt{y} - \log y$ has $g'(y) = (\sqrt{y} - 2)/(2y)$, so its minimum on $[1, \infty)$ is $g(4) = 2 - \log 4 > 0$, because $4 < e^2$. Hence $\log n/n^2 \leq n^{-3/2}$ for every integer $n \geq 2$, and $n^{-3/2} \leq \int_{n-1}^{n} y^{-3/2}\, dy$ since $y^{-3/2}$ decreases. Therefore, for every finite set S of primes,

$$\sum_{\ell \in S} \frac{\log \ell}{\ell^2} \leq \sum_{n \geq 2} n^{-3/2} \leq \int_1^\infty y^{-3/2}\, dy = 2. \tag{13.11}$$

The budget. Let C_6, C_7, C_8 be constants and $x^{(5)}, \dots, x^{(8)}$ thresholds for (Lq5)–(Lq8), $x_0 = \max(x^{(5)}, \dots, x^{(8)})$, and $C = |C_6| + |C_7| + |C_8| + 2$. Fix a real $x \geq x_0$ with $x > x_1$ and a member $i \in I(x)$ with finite Sha lengths; write $P = P_{x,i}$, $G = G_{x,i}$ and $Y = f\, m\, b\, x^{2\varepsilon}$. Since

$f \ge 2$, $m \ge 1$, $b \ge 1$ and $x^{2\varepsilon} \ge 1$ (as $x > 1$, $\varepsilon > 0$), $Y \ge 2$. Split P into the disjoint sets $P \setminus G$ and $P \cap G$ and insert the composition (Lq5) of the allowances:

$$\sum_{\ell \in P} \log \ell \cdot \mathrm{ex}_{x,i}(\ell) = \sum_{\ell \in P \setminus G} \log \ell \cdot \mathrm{sa}_{x,i}(\ell) + \sum_{\ell \in P \setminus G} \log \ell \cdot \mathrm{la}_{x,i}(\ell) + \sum_{\ell \in P \cap G} \log \ell \cdot \mathrm{ga}_{x,i}(\ell) + 2 \sum_{\ell \in P} \frac{\log \ell}{\ell^2}.$$

By (Lq6), (Lq7), (Lq8) the first three sums are at most $C_6 Y$, $C_7 Y$, $C_8 Y$, hence at most $|C_6| Y$, $|C_7| Y$, $|C_8| Y$ as $Y \ge 0$; by (13.11) the last term is at most $4 \le 2Y$. So

$$\sum_{\ell \in P_{x,i}} \log \ell \cdot \mathrm{ex}_{x,i}(\ell) \le \bigl(|C_6| + |C_7| + |C_8| + 2\bigr)\, f\, m\, b\, x^{2\varepsilon} = C\, f\, m\, b\, x^{2\varepsilon}$$

for every real $x \ge x_0$ with $x > x_1$ and every member $i \in I(x)$ with finite Sha lengths, which is (Ld9) with the constant C and the threshold x_0. □

Theorem 13.18. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε, and suppose that $\mathcal{F}$ has local defect data with the properties (Ld1)–(Ld9). Then there is a real number $C \ge 0$ such that for all large members (x, i) with finite Sha lengths and $\mathrm{len}(E; t_{x,i}) < \infty$, and every $1 \le j \le m$,*

$$\mathrm{Df}_j(x,i) \le \mathrm{rk}_j(x,i)\Bigl(C\, f\, m\, b\, x^{2\varepsilon} + \mathrm{len}(E; t_{x,i})\Bigr).$$

In particular $\mathcal{F}$ has defects bounded by Sha lengths (Dv6).

Proof. Let C_5 and C_9 be the constants of (Ld5) and (Ld9), and $x^{(1)}, \dots, x^{(9)}$ the thresholds of (Ld1)–(Ld9). Since $\log x / x^{\varepsilon} \to 0$ as $x \to \infty$, there is $x_L \ge 1$ with $|C_5| \log x \le x^{\varepsilon}$, hence $x^{|C_5|} \le b$, for all $x \ge x_L$. Put $X = \max(x^{(1)}, \dots, x^{(9)}, x_L)$ and $C = 3|C_5| + |C_9|$.

Fix a real $x \ge X$ with $x > x_1$, a member $i \in I(x)$ with finite Sha lengths and $\mathrm{len}(E; t) < \infty$ (where $E = E_{\mathfrak{h}_{x,i}}$, $t = t_{x,i}$), and an integer $1 \le j \le m$. Write $W = W_{x,i}$, $\ell(w) = \ell_{x,i}(w)$, $\mathrm{lw} = \mathrm{lw}_{x,i}$, $R(w) = R_{x,i}(j, w)$, $P = P_{x,i}$, $G = G_{x,i}$, $N = N_{\mathrm{lev}}(x, i)$, $\mathrm{rk} = \mathrm{rk}_j(x, i) \ge 0$, $y = x^{\varepsilon} \ge 1$. For a prime ℓ put

$$U(\ell) = \mathrm{len}_\ell(E; t) + v_\ell(\#\mathrm{Cl}(E)) + \mathrm{ex}_{x,i}(\ell) + v_\ell(N),$$

a finite non-negative real number, because the member has finite Sha lengths and $\mathrm{ex}_{x,i}(\ell) \ge 0$.

Cut reduction at one component. Let $w \in W$ and $r \in R(w)$. By (Ld4) there is an $\mathcal{O}_r$-linear endomorphism of M_r acting as N on V_{r,Z_r} and as 0 on $V_{r,\mathcal{Z}_r \setminus \widehat{Z}_r}$. By Lemma 13.19, applied to the Hecke lattice $(\mathcal{O}_r, \mathcal{Z}_r, \mathbb{T}_r, M_r)$ over $\ell(w)$, the sets $Z_r \subseteq \widehat{Z}_r$ and the integer $N \ge 1$, $\mathrm{df}^{\mathrm{cut}}(r)$ is finite and

$$\mathrm{df}(r) \le \mathrm{df}^{\mathrm{cut}}(r) + \mu(r)\, v_{\ell(w)}(N). \tag{13.12}$$

Cut reduction of the defect sum. Multiply (13.12) by $\mathrm{lw}(w) \ge 0$ and sum over $r \in R(w)$ and $w \in W$. By (Ld1) the left side becomes $\mathrm{Df}_j(x, i)$. Grouping the places by their residue characteristic, the first term on the right becomes $\sum_{\ell \in P} \mathrm{Df}_j^{\mathrm{cut}}(x, i; \ell)$. In the second, (Ld3) gives $\sum_{r \in R(w)} \mu(r) \le \mathrm{rk}$, and $\mathrm{lw}(w) v_{\ell(w)}(N) \ge 0$, so it is at most

$$\mathrm{rk} \sum_{w \in W} \mathrm{lw}(w)\, v_{\ell(w)}(N) = \mathrm{rk} \sum_{\ell \in P} v_\ell(N) \sum_{w \in W,\, \ell(w) = \ell} \mathrm{lw}(w) \le \mathrm{rk} \sum_{\ell \in P} v_\ell(N) \log \ell \le \mathrm{rk}\, \log N,$$

by the mean condition (Ld2), and because $\sum_\ell v_\ell(N) \log \ell = \log N$ over all primes with non-negative terms. Hence

$$\mathrm{Df}_j(x,i) \le \sum_{\ell \in P} \mathrm{Df}_j^{\mathrm{cut}}(x, i; \ell) + \mathrm{rk}\, \log N. \tag{13.13}$$

The cut defect sum at a prime outside G. Let $\ell \in P \setminus G$, $w \in W$ with $\ell(w) = \ell$, and $r \in R(w)$. By (Ld6), then (Ld7) for each $\pi \in Z_r$ together with $m_r(\pi) \geq 0$,

$$\mathrm{df}^{\mathrm{cut}}(r) \leq \sum_{\pi \in Z_r} m_r(\pi)(\mathrm{cg}(r,\pi) + v_\ell(N)) \leq \sum_{\pi \in Z_r} m_r(\pi)\, U(\ell) = \mu(r)\, U(\ell).$$

Summing over $r \in R(w)$ and using (Ld3) with $U(\ell) \geq 0$ gives $\sum_{r \in R(w)} \mathrm{df}^{\mathrm{cut}}(r) \leq \mathrm{rk}\, U(\ell)$. Multiplying by $\mathrm{lw}(w) \geq 0$, summing over the w with $\ell(w) = \ell$ and using (Ld2) with $\mathrm{rk}\, U(\ell) \geq 0$,

$$\mathrm{Df}_j^{\mathrm{cut}}(x, i; \ell) \leq \mathrm{rk}\, U(\ell) \sum_{w \in W,\, \ell(w) = \ell} \mathrm{lw}(w) \leq \log \ell \cdot \mathrm{rk}\, U(\ell).$$

The cut defect sum at a prime of G. For $\ell \in P \cap G$, (Ld8) gives $\mathrm{Df}_j^{\mathrm{cut}}(x, i; \ell) \leq \log \ell \cdot \mathrm{rk}(U(\ell) - v_\ell(N)) \leq \log \ell \cdot \mathrm{rk}\, U(\ell)$.

Summation over the primes: the Sha lengths enter. By the last two paragraphs and (13.13),

$$\mathrm{Df}_j(x,i) \leq \mathrm{rk}\Big(\sum_{\ell \in P} \log \ell\ \mathrm{len}_\ell(E;t) + \sum_{\ell \in P} \log \ell\, v_\ell(\#\mathrm{Cl}(E)) + \sum_{\ell \in P} \log \ell\, \mathrm{ex}_{x,i}(\ell) + \sum_{\ell \in P} \log \ell\, v_\ell(N)\Big) + \mathrm{rk}\, \log N.$$

The four sums are bounded as follows. The first is a finite partial sum of the series

$$\mathrm{len}(E;t) = \sum_{\ell} \log \ell\ \mathrm{len}_\ell(E;t)$$

of non-negative terms, hence at most $\mathrm{len}(E;t)$. The second is at most $\sum_\ell \log \ell\, v_\ell(\#\mathrm{Cl}(E)) = \log \#\mathrm{Cl}(E)$, and the fourth at most $\log N$, for the same reason. The third is at most $C_9\, f\, m\, b\, x^{2\varepsilon} \leq |C_9|\, f\, m\, b\, x^{2\varepsilon}$ by (Ld9). Since $\mathrm{rk} \geq 0$,

$$\mathrm{Df}_j(x,i) \leq \mathrm{rk}\Big(\mathrm{len}(E;t) + \log \#\mathrm{Cl}(E) + 2 \log N + |C_9|\, f\, m\, b\, x^{2\varepsilon}\Big). \tag{13.14}$$

The sizes. For $x \geq 1$, $C_5 x^{C_5} \leq |C_5| x^{|C_5|}$ (both sides agree if $C_5 \geq 0$, and the left side is ≤ 0 otherwise); and $x^{|C_5|} \leq b$ as $x \geq x_L$. So (Ld5) gives $\log \#\mathrm{Cl}(E) \leq |C_5|\, b$ and $\log N \leq |C_5|\, b\, y$. As $f = 2n \geq 2$, $m \geq j \geq 1$ and $y \geq 1$, we have $b \leq b\, y \leq f\, m\, b\, y^2 = f\, m\, b\, x^{2\varepsilon}$. Hence $\log \#\mathrm{Cl}(E) + 2 \log N \leq 3|C_5|\, f\, m\, b\, x^{2\varepsilon}$, and (13.14) becomes

$$\mathrm{Df}_j(x,i) \leq \mathrm{rk}_j(x,i)\Big(C\, f\, m\, b\, x^{2\varepsilon} + \mathrm{len}(E;t)\Big), \qquad C = 3|C_5| + |C_9| \geq 0.$$

This holds for every real $x \geq X$ with $x > x_1$, every member $i \in I(x)$ with finite Sha lengths and $\mathrm{len}(E;t) < \infty$, and every $1 \leq j \leq m$: the first assertion, with threshold X.

(Dv6). Since $C \geq 0$ and $(\log x)^2 N_c(x,i) \geq 0$, the bound gives

$$\mathrm{Df}_j(x,i) \leq \mathrm{rk}_j(x,i)(C(f\, m\, b\, x^{2\varepsilon} + (\log x)^2 N_c(x,i)) + \mathrm{len}(E;t))$$

at the same members, which is (Dv6) with the constant C and the threshold X. □

Lemma 13.19. *Let $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ be a Hecke lattice over a prime ℓ, let $Z \subseteq \widehat{Z} \subseteq \mathcal{Z}$, let $N \geq 1$ be an integer, and let α be an $\mathcal{O}$-linear endomorphism of M such that $\alpha_V v = Nv$ for every $v \in V_Z$ and $\alpha_V v = 0$ for every $v \in V_{\mathcal{Z} \setminus \widehat{Z}}$. Then $\mathrm{df}_Z(M)$ and $\mathrm{df}_Z^{\widehat{Z}}(M)$ are finite, and*

$$\mathrm{df}_Z(M) \leq \mathrm{df}_Z^{\widehat{Z}}(M) + \Big(\sum_{\pi \in Z} m(\pi)\Big)\, v_\ell(N).$$

Proof. Write $K = \mathcal{O}[\ell^{-1}]$. The map $f \mapsto f_V$ is a homomorphism of rings $\mathbb{T} \to \mathrm{End}_K(V)$, since $f \mapsto f_M$ is one and extension of scalars respects sums and composition.

The eigenspace decomposition. For $\pi \neq \rho$ in $\mathcal{Z}$ choose $f_{\pi,\rho} \in \mathbb{T}$ with $f_{\pi,\rho}(\pi) \neq f_{\pi,\rho}(\rho)$ ($\mathbb{T}$ separates points). Since $\mathbb{T}$ contains the constants,

$$g_\pi = \prod_{\rho \neq \pi} \big(f_{\pi,\rho} - f_{\pi,\rho}(\rho)\big) \in \mathbb{T}, \qquad g_\pi(\rho) = 0 \ (\rho \neq \pi), \qquad c_\pi := g_\pi(\pi) = \prod_{\rho \neq \pi} \big(f_{\pi,\rho}(\pi) - f_{\pi,\rho}(\rho)\big) \neq 0,$$

the last because $\mathcal{O}$ is a domain. Put $d = \prod_{\pi \in \mathcal{Z}} c_\pi \in \mathcal{O} \setminus \{0\}$ and $h_\pi = (d/c_\pi)\, g_\pi \in \mathbb{T}$, so that $h_\pi(\rho) = d$ if $\rho = \pi$ and 0 otherwise. As functions on $\mathcal{Z}$, $\sum_\pi h_\pi = d$, $h_\pi h_\rho = 0$ for $\pi \neq \rho$, $h_\pi^2 = d\, h_\pi$, and $f h_\pi = f(\pi) h_\pi$ for every $f \in \mathbb{T}$. Put $E_\pi = d^{-1}(h_\pi)_V \in \mathrm{End}_K(V)$. Applying the ring homomorphism $f \mapsto f_V$:

$$\sum_\pi E_\pi = \mathrm{id}_V, \qquad E_\pi E_\rho = \begin{cases} E_\pi & \rho = \pi, \\ 0 & \rho \neq \pi, \end{cases} \qquad f_V E_\pi = f(\pi) E_\pi \quad (f \in \mathbb{T}).$$

The last identity gives $E_\pi V \subseteq V_\pi$. Conversely, if $v \in V_\pi$ then $(h_\rho)_V v = h_\rho(\pi) v$, so $E_\rho v = v$ for $\rho = \pi$ and $E_\rho v = 0$ for $\rho \neq \pi$. Hence $V = \bigoplus_{\pi \in \mathcal{Z}} V_\pi$ and E_π is the projection onto V_π along $\bigoplus_{\rho \neq \pi} V_\rho$. For $Y \subseteq \mathcal{Z}$ the map $E_Y = \sum_{\pi \in Y} E_\pi$ is the projection onto V_Y along $V_{\mathcal{Z} \setminus Y}$, and $dE_Y = \big(\sum_{\pi \in Y} h_\pi\big)_V$ maps M into M. In particular $\dim_K V_Y = \sum_{\pi \in Y} m(\pi)$.

The congruence module of M. Put $U = V_Z \cap (M + V_{\mathcal{Z} \setminus Z})$ and $L = M \cap V_Z$, so $\mathrm{Cong}_Z(M) = U/L$ and $L \subseteq U$. We have $U = E_Z(M)$: if $u = x + y$ with $u \in V_Z$, $x \in M$, $y \in V_{\mathcal{Z} \setminus Z}$, then $u = E_Z u = E_Z x$; conversely, for $x \in M$, $E_Z x \in V_Z$ and $E_Z x = x - E_{\mathcal{Z} \setminus Z} x \in M + V_{\mathcal{Z} \setminus Z}$. So $U = d^{-1}((dE_Z)(M))$ is a finitely generated $\mathcal{O}$-module, and $dU = (dE_Z)(M) \subseteq M \cap V_Z = L$. Thus U/L is a finitely generated $\mathcal{O}$-module killed by $d \neq 0$; over the discrete valuation ring $\mathcal{O}$ it is a finite direct sum of modules $\mathcal{O}/\mathfrak{m}^k$, so it has finite length, and $\mathrm{df}_Z(M) < \infty$.

The cut congruence module. Each E_π maps $V_{\mathcal{Z} \setminus \widehat{Z}}$ into itself, so it induces E'_π on $V' = V/V_{\mathcal{Z} \setminus \widehat{Z}}$ with $qE_\pi = E'_\pi q$. Since $V = V_{\widehat{Z}} \oplus V_{\mathcal{Z} \setminus \widehat{Z}}$, the restriction of q to $V_{\widehat{Z}}$ is an isomorphism onto V', and it carries $V_{\widehat{Z}} = V_Z \oplus V_{\widehat{Z} \setminus Z}$ to $V' = q(V_Z) \oplus q(V_{\widehat{Z} \setminus Z})$; the map $E'_Z = \sum_{\pi \in Z} E'_\pi$ is the projection of V' onto $q(V_Z)$ along $q(V_{\widehat{Z} \setminus Z})$. Put $U' = q(V_Z) \cap \big(q(M) + q(V_{\widehat{Z} \setminus Z})\big)$ and $L' = q(M) \cap q(V_Z)$, so $\mathrm{Cong}_Z^{\widehat{Z}}(M) = U'/L'$. The argument of the previous paragraph, applied to the projection E'_Z, gives $U' = E'_Z(q(M)) = q(E_Z(M)) = q(U)$; and $q(L) \subseteq L'$. As q is injective on V_Z, it restricts to an isomorphism of $\mathcal{O}$-modules $U \to U'$ carrying L onto $q(L)$, so $U/L \cong U'/q(L)$. Hence U'/L', a quotient of $U'/q(L)$, has finite length, $\mathrm{df}_Z^{\widehat{Z}}(M) < \infty$, and the exact sequence $0 \to L'/q(L) \to U'/q(L) \to U'/L' \to 0$ gives

$$\mathrm{length}_{\mathcal{O}}(U/L) = \mathrm{length}_{\mathcal{O}}(U'/L') + \mathrm{length}_{\mathcal{O}}(L'/q(L)). \tag{13.15}$$

The operator kills the difference. Let $y \in L'$. Then $y = q(x)$ with $x \in M$, and since $y \in q(V_Z)$ there is $z \in V_Z$ with $x - z \in V_{\mathcal{Z} \setminus \widehat{Z}}$. By the hypotheses on α, $\alpha_V(x) = \alpha_V(z) + \alpha_V(x - z) = Nz$; as $\alpha(x) \in M$, we get $Nz \in M \cap V_Z = L$. Therefore $Ny = q(Nx) = q(Nz) + q\big(N(x - z)\big) = q(Nz) \in q(L)$. So $N\,L' \subseteq q(L)$.

Bounding the difference. L' is a submodule of the finitely generated module U' over the noetherian ring $\mathcal{O}$, hence finitely generated, and it is torsion-free, hence free of some rank r'. An $\mathcal{O}$-basis of $L' \subseteq q(V_Z)$ is linearly independent over K (clear denominators), so $r' \leq \dim_K q(V_Z) = \dim_K V_Z = \sum_{\pi \in Z} m(\pi)$. By the previous paragraph $L'/q(L)$ is a quotient of $L'/NL' \cong (\mathcal{O}/N\mathcal{O})^{r'}$, so

$$\mathrm{length}_{\mathcal{O}}(L'/q(L)) \leq r' \,\mathrm{length}_{\mathcal{O}}(\mathcal{O}/N\mathcal{O}) \leq \Big(\sum_{\pi \in Z} m(\pi)\Big) \,\mathrm{length}_{\mathcal{O}}(\mathcal{O}/N\mathcal{O}).$$

Write $N = \ell^v u$ with $v = v_\ell(N)$ and u an integer prime to ℓ; u is a unit of $\mathbb{Z}_\ell$, hence of $\mathcal{O}$, so $N\mathcal{O} = \ell^v\mathcal{O}$. Multiplication by ℓ^i induces isomorphisms $\mathcal{O}/\ell\mathcal{O} \cong \ell^i\mathcal{O}/\ell^{i+1}\mathcal{O}$, so $\operatorname{length}_{\mathcal{O}}(\mathcal{O}/N\mathcal{O}) = v\, e_{\mathcal{O}}$.

Conclusion. Dividing (13.15) by $e_{\mathcal{O}} \geq 1$ and inserting the bound just proved,

$$\operatorname{df}_Z(M) = \frac{\operatorname{length}_{\mathcal{O}}(U/L)}{e_{\mathcal{O}}} \leq \frac{\operatorname{length}_{\mathcal{O}}(U'/L')}{e_{\mathcal{O}}} + \Big(\sum_{\pi\in Z} m(\pi)\Big) v_\ell(N) = \operatorname{df}_Z^{\widehat{Z}}(M) + \Big(\sum_{\pi\in Z} m(\pi)\Big) v_\ell(N).$$

□

14 Approximate orthogonality and the slope inequality: (Sp5)

This section proves the dual-slope bound (Sp5) for the class (Theorem 14.2). In our reading it is the count of zeros against poles of Stepanov's method, in the form of a slope inequality: the mean of the slopes of the source lattices of a slope record, each corrected by the height of its map, is bounded by the dual slope of the common target, up to the loss that (Sp5) makes explicit. For one map this is Bost's slope inequality (Lemma B.127), which bounds the slope of the source, corrected by the height, by the maximal slope of the target. For the family of maps it is not enough, because the maximal slope of the target can exceed its mean slope by far. Theorem 14.4 replaces the maximal slope by the mean slope. It cuts each source lattice along its Harder–Narasimhan filtration, maps each piece into one step of the filtration of the target by Bost's inequality, and bounds the rank of that step from below by counting dimensions at one complex place, where the maps form a nearly tight frame (Lemma 14.5). We follow the exposition of [2] for this argument. What Theorem 14.2 needs is therefore a frame at one complex place whose Gram blocks are nearly those of random subspaces, which is the approximate orthogonality of Alpöge's account [4].

The rest of the section reduces near-orthogonality (Nf4) to estimates for the Gram blocks $\mathrm{Gr}_{\omega\omega'}$, and the reductions are linear algebra in a finite-dimensional Hilbert space. Theorem 14.8 derives (Nf4) from six lower properties (No1)–(No6). The off-diagonal condition (No3), that $\|\mathrm{Gr}_{\omega\omega'}\|_{\mathrm{HS}}^2$ exceeds the value $D_\omega D_{\omega'}/D^*$ for random subspaces by at most a small factor, follows from pair expansions of the Gram blocks (Theorem 14.9), and these follow from row estimates (Theorem 14.13), whose main row is bounded by that same value (Theorem 14.14). The diagonal near-isometry (No4) follows from diagonal expansions (Theorem 14.16), and the dimension bound (No5) from a splitting of the kernel diagonal into a thick part and a cusp part by reduction theory (Corollary 14.18). The row estimates themselves are the subject of Sections 15 and 16. In the construction beneath (TCS), outlined in Appendix A, the frames are frames of Poincaré series; the present section uses only the Hilbert space, the maps and the estimates.

Notation for Arakelov geometry follows [110], [48] and [183]. An **arithmetic variety** is an integral scheme $\mathcal{X}$, flat and projective over $\operatorname{Spec}\mathbb{Z}$ (or over $\operatorname{Spec}\mathcal{O}_F$), of absolute dimension $D+1$, with generic fibre X. A **Hermitian line bundle** $\overline{\mathcal{L}} = (\mathcal{L}, \|\cdot\|)$ is a line bundle on $\mathcal{X}$ together with a continuous metric on $\mathcal{L}_{\mathbb{C}}$ invariant under complex conjugation. The properties smooth, semipositive, nef and big of Hermitian line bundles are meant in the usual sense. Unless stated otherwise, $\overline{\mathcal{O}}(1)$ on a product of projective spaces carries the Fubini–Study metric. A **Hermitian lattice** $\overline{M} = (M, \|\cdot\|)$ is a projective $\mathcal{O}_F$-module of finite rank with Hermitian norms at the infinite places. It has an Arakelov degree $\widehat{\deg}\,\overline{M}$, a normalised slope $\widehat{\mu}(\overline{M}) = \widehat{\deg}\,\overline{M}/([F:\mathbb{Q}]\operatorname{rk} M)$ and successive minima. We write $\widehat{c}_1(\overline{\mathcal{L}})$ for the arithmetic first Chern class and $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1})$ for the arithmetic self-intersection. For a cycle $\mathcal{Z}$ the **height** is $h_{\overline{\mathcal{L}}}(\mathcal{Z}) = \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{\dim\mathcal{Z}} \mid \mathcal{Z})$. The height of a point is normalised by $[F:\mathbb{Q}]$ only where this is stated. We set $\widehat{h}^0(\mathcal{X}, \overline{\mathcal{L}}) = \log\#\{s \in H^0(\mathcal{X}, \mathcal{L}) : \|s\|_{\sup} \leq 1\}$, and the **arithmetic volume**

is $\widehat{\mathrm{vol}}(\overline{\mathcal{L}}) = \limsup_n \widehat{h}^0(\mathcal{X}, \overline{\mathcal{L}}^{\otimes n})/(n^{D+1}/(D+1)!)$. Sections s with $\|s\|_{\sup} \le 1$ are called **small**. Plurisubharmonic functions and currents are understood in the sense of [79].

Definition 14.1. For a hermitian lattice $\overline{M}$ over $\mathcal{O}_K$ of positive rank, $\widehat{\mu}_{\max}(\overline{M})$ is the largest slope of a non-zero submodule (with the induced norms) and $\widehat{\mu}_{\min}(\overline{M})$ the smallest slope of a non-zero torsion-free quotient (with the quotient norms) [248], [113]. For hermitian lattices $\overline{E}, \overline{F}$ and a K-linear map $\varphi\colon E_K \to F_K$, the **height** of φ is $h(\varphi) = [K:\mathbb{Q}]^{-1} \sum_{\sigma\colon K\to\mathbb{C}} \log \|\varphi_\sigma\|$, where $\|\varphi_\sigma\|$ is the operator norm for the hermitian norms at σ.

Let $\mathcal{F}$ be a parametrised host family with slope records, with parameter ε and threshold x_1. **Frame realisations for** $\mathcal{F}$ consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$, where $\mathfrak{V} = \mathfrak{V}_{x,i}$ and $d_\omega = d(\mathfrak{V}, \omega)$. When the member is fixed, the index (x, i) of these data is suppressed, in this definition and in the results that cite it.

- A number field K, an embedding $v\colon K \to \mathbb{C}$, and a hermitian lattice $\overline{R}$ over $\mathcal{O}_K$, the **realisation lattice** of the member, with dual $\overline{R}^\vee$. For every word $\omega \in \mathcal{W}(\mathfrak{V})$, a hermitian lattice $\overline{N}_\omega$ over $\mathcal{O}_K$ of rank d_ω, the **divisor lattice** of ω, and a K-linear map $B_\omega\colon N_{\omega,K} \to R_K^\vee$. These satisfy

$$\mu(\mathfrak{V},\omega) = 2\widehat{\mu}(\overline{N}_\omega), \quad \mu^{\max}(\mathfrak{V},\omega) = 2\widehat{\mu}_{\max}(\overline{N}_\omega),$$
$$\mu^\vee(\mathfrak{V}) = 2\widehat{\mu}(\overline{R}^\vee), \quad \mu^\vee_{\min}(\mathfrak{V}) = 2\widehat{\mu}_{\min}(\overline{R}^\vee).$$

- The **frame data at** v. These are a finite-dimensional complex Hilbert space $\mathcal{H}$ with a surjective $\mathbb{C}$-linear map $\Pi\colon \mathcal{H} \to R^\vee_{K,v}$, and a real number $D^* > 0$, the **reference dimension**. Moreover, for every word ω, they comprise an integer $D_\omega \ge d_\omega$, the **frame size**; a real number $\kappa_\omega > 0$, the **weight**; $\mathbb{C}$-linear maps $A_\omega\colon \mathbb{C}^{D_\omega} \to \mathcal{H}$ (the **frame map**) and $U_\omega\colon \mathbb{C}^{d_\omega} \to \mathbb{C}^{D_\omega}$ with $U_\omega^* U_\omega = 1$; and a $\mathbb{C}$-linear isomorphism $Z_\omega\colon \mathbb{C}^{d_\omega} \to N_{\omega,K,v}$. These satisfy $\Pi \circ A_\omega \circ U_\omega = B_{\omega,v} \circ Z_\omega$. The **Gram blocks** are $\mathrm{Gr}_{\omega\omega'} = (\kappa_\omega\kappa_{\omega'})^{1/2} A_\omega^* A_{\omega'}$.

A **parametrised host family with slope records and frame realisations** is a parametrised host family with slope records together with frame realisations for it. Let $c > 0$ be a real number. The phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x \ge x_0$ with $x > x_1$, every $i \in I(x)$ and every word ω of $\mathfrak{V}_{x,i}$. The family has

(Nf1) Small irreducibility defect if $0 \le \delta(\mathfrak{V}_{x,i}) \le \frac{1}{2}$ for all large members;

(Nf2) Height bound with exponent c if $s(\mathfrak{V}_{x,i}) - \mu^\vee_{\min}(\mathfrak{V}_{x,i}) \le x^c\, b(x)$ for all large members;

(Nf3) Integral maps of bounded height if for all large members we have $\mathrm{rk}\, R \ge 1$, $d_\omega \ge 1$, $B_\omega(N_\omega) \subseteq R^\vee$, $2h(B_\omega) \le h(\mathfrak{V}_{x,i}, \omega)$ if $B_\omega \ne 0$, and

$$(1 - \delta(\mathfrak{V}_{x,i}))\dim \mathcal{H} \le \mathrm{rk}\, R;$$

(Nf4) Near-orthogonal frames with exponent c if there is a real x_0 with the following property. For every real $x \ge x_0$ with $x > x_1$ there are real numbers $\bar{\varrho} \ge 0$ and $\bar{e} \ge 0$ with $(3\sqrt{\bar{\varrho}} + 4\sqrt{\bar{e}})\, x^c \le 1$ such that, with $\sigma = x^{-c}$, the frame data of every member $i \in I(x)$ satisfy the following for some real numbers $\eta_{\mathrm{off}}, \eta_{\dim}, e_{\mathrm{dg}}$ with $-1 \le \eta_{\mathrm{off}} \le \sigma/2$, $\eta_{\dim} \le \sigma/2$, $0 \le e_{\mathrm{dg}}$, $\sqrt{e_{\mathrm{dg}}} \le \sigma/2$ and $2e_{\mathrm{dg}} \le \bar{e}$:

(i) $\|\mathrm{Gr}_{\omega\omega'}\|^2_{\mathrm{HS}} \le (1 + \eta_{\mathrm{off}})\, D_\omega D_{\omega'}/D^*$ for all words $\omega \ne \omega'$ (*near-orthogonality*);

(ii) $\|\mathrm{Gr}_{\omega\omega} - 1\|^2_{\mathrm{HS}} \le e_{\mathrm{dg}}\, D_\omega$ for every word ω;

(iii) $\dim \mathcal{H} \le (1+\eta_{\mathrm{dim}})\, D^*$;
(iv) $\sum_\omega D_\omega \ge x^c D^*$;
(v) $\sum_\omega (D_\omega - d_\omega) \le \bar\varrho \sum_\omega D_\omega$.

Theorem 14.2. *Let $c > 0$ be a real number and let $\mathcal{F}$ be a parametrised host family with slope records and frame realisations that has a small irreducibility defect (Nf1), the height bound with exponent c (Nf2), integral maps of bounded height (Nf3) and near-orthogonal frames with exponent c (Nf4). Then $\mathcal{F}$ has the dual-slope bound (Sp5) with $c_\vee = c$.*

Proof. Let ε be the parameter and x_1 the threshold of $\mathcal{F}$, and let x_0 be the largest of 1, $20^{1/c}$ and the thresholds of (Nf1)–(Nf4). Fix a real $x \ge x_0$ with $x > x_1$ and put $\sigma = x^{-c}$, $b = b(x)$ and $H = x^c b$. Since $x^c \ge 20$, $0 < \sigma \le \frac{1}{20}$.

The numbers at x. Let $\bar\varrho, \bar e \ge 0$ be the numbers of (Nf4) at x, so $(3\sqrt{\bar\varrho} + 4\sqrt{\bar e})x^c \le 1$; hence $\sqrt{\bar\varrho} \le \frac{1}{3}\sigma$ and $\sqrt{\bar e} \le \frac{1}{4}\sigma$, so $\bar\varrho \le \frac{1}{4}$ and $\bar e \le \frac{1}{4}$. Put $\bar\eta = 5\sigma + 3\sqrt{\bar\varrho} \ge 0$. Then

$$(\bar\eta + 4\sqrt{\bar e})\, x^c = 5 + (3\sqrt{\bar\varrho} + 4\sqrt{\bar e})\, x^c \le 6.$$

A member. Fix $i \in I(x)$, write $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\delta = \delta(\mathfrak{V})$, $s = s(\mathfrak{V})$, $\phi = s^{\max}(\mathfrak{V}) - s$, and use the frame realisation of the member. By (Nf1), $0 \le \delta \le \frac{1}{2}$, and by (Nf2), $s - \mu^\vee_{\min}(\mathfrak{V}) \le H$. It remains to find $\eta_{\mathfrak{V}} \in [0, \bar\eta]$ and $e_{\mathfrak{V}} \in [0, \bar e]$ with the inequality of (Sp5).

Compressed frames. Let $\eta_{\mathrm{off}}, \eta_{\mathrm{dim}}, e_{\mathrm{dg}}$ be the numbers of (Nf4) at the member. Lemma 14.3, applied to $I = \mathcal{W}(\mathfrak{V})$, the integers $D_\omega \ge d_\omega$, the maps A_ω, U_ω, the weights κ_ω, D^*, σ, η_{off}, η_{dim}, $e = e_{\mathrm{dg}}$ and $\delta_{\mathrm{rk}} = \bar\varrho \in [0, \frac{1}{4}]$ (its hypotheses (i)–(v) are (i)–(v) of (Nf4), (iv) because $x^c D^* = D^*/\sigma$), shows for $A'_\omega = A_\omega U_\omega$ and $Q' = \sum_\omega \kappa_\omega A'_\omega A'^*_\omega$:

$$\sum_\omega \|\kappa_\omega A'^*_\omega A'_\omega - 1\|^2_{\mathrm{HS}} \le 2e_{\mathrm{dg}} \sum_\omega d_\omega, \qquad \dim \mathcal{H} \cdot \operatorname{tr}(Q'^2) \le (1+\bar\eta)(\operatorname{tr} Q')^2.$$

Put $e_{\mathfrak{V}} = 2e_{\mathrm{dg}} \in [0, \bar e]$ and $\eta_{\mathfrak{V}} = \bar\eta$; then $e_{\mathfrak{V}} \le \frac{1}{4}$.

The slope bound. Apply Theorem 14.4 with $\overline{E} = \overline{R}^\vee$, of rank $\operatorname{rk} R \ge 1$ by (Nf3); the lattices $\overline{N}_\omega$ of rank $d_\omega \ge 1$ (Nf3) and the maps B_ω, with $B_\omega(N_\omega) \subseteq R^\vee$ and $h(B_\omega) \le h_\omega := h(\mathfrak{V}, \omega)/2$ if $B_\omega \ne 0$ (Nf3); the numbers $s/2$, $u = \phi/2$, $\widetilde{H} = H/2$; the frame data $\mathcal{H}$, Π, A'_ω, Z_ω (with $\Pi \circ A'_\omega = B_{\omega,v} \circ Z_\omega$), κ_ω; and $\delta < 1$, $e = e_{\mathfrak{V}}$, $\eta = \eta_{\mathfrak{V}}$, with $(1-\delta)\dim \mathcal{H} \le \operatorname{rk} R$ by (Nf3). Its hypotheses hold: since all ranks are positive, the identities of the frame realisation give

$$\sum_\omega d_\omega(\widehat{\mu}(\overline{N}_\omega) - h_\omega) = \frac{1}{2}\sum_\omega d_\omega(\mu(\mathfrak{V}, \omega) - h(\mathfrak{V}, \omega)) = \frac{s}{2}\sum_\omega d_\omega,$$

which is (a); (b) is $\widehat{\mu}_{\max}(\overline{N}_\omega) - h_\omega = \frac{1}{2}(\mu^{\max}(\mathfrak{V}, \omega) - h(\mathfrak{V}, \omega)) \le \frac{1}{2}s^{\max}(\mathfrak{V}) = \frac{s}{2} + u$; (c) is $\frac{s}{2} - \widehat{\mu}_{\min}(\overline{R}^\vee) = \frac{1}{2}(s - \mu^\vee_{\min}(\mathfrak{V})) \le \widetilde{H}$; $\widetilde{H} \ge 0$; $u \ge 0$, because $\mu(\mathfrak{V}, \omega) = 2\widehat{\mu}(\overline{N}_\omega) \le 2\widehat{\mu}_{\max}(\overline{N}_\omega) = \mu^{\max}(\mathfrak{V}, \omega)$ for every word, so the weighted mean s of the numbers $\mu(\mathfrak{V}, \omega) - h(\mathfrak{V}, \omega)$ is at most $s^{\max}(\mathfrak{V})$; (d) and (e) are the two displays above. Hence, with $4u\widetilde{H}/(u + \widetilde{H}) = \phi H/(\phi + H)$ (here $H > 0$),

$$\frac{s}{2} - \frac{1}{1-\delta}\Big(\frac{\phi H}{\phi + H} + (\eta_{\mathfrak{V}} + 4\sqrt{e_{\mathfrak{V}}})\frac{H}{2}\Big) \le \widehat{\mu}(\overline{R}^\vee) = \frac{1}{2}\mu^\vee(\mathfrak{V}).$$

Since $\phi H/(\phi + H) \le \phi \log(1 + H/\phi) \le 2\phi \log(1 + H/\phi)$ for $\phi > 0$ (by $v/(1+v) \le \log(1+v)$ for $v = H/\phi \ge 0$), and both sides vanish for $\phi = 0$ under the convention below,

$$\frac{s}{2} - \frac{1}{1-\delta}\Big(2\phi \log\Big(1 + \frac{H}{\phi}\Big) + (\eta_{\mathfrak{V}} + 4\sqrt{e_{\mathfrak{V}}})\frac{H}{2}\Big) \le \frac{1}{2}\mu^\vee(\mathfrak{V}),$$

the logarithmic term read as 0 when $\phi = 0$. Multiplying by 2 and using $\log|\mathcal{W}(\mathfrak{V})| \geq 0$ ($\mathcal{W}(\mathfrak{V})$ is non-empty),

$$s - \log|\mathcal{W}(\mathfrak{V})| - \frac{1}{1-\delta}\Big(4\phi\log\Big(1+\frac{H}{\phi}\Big) + (\eta_{\mathfrak{V}} + 4\sqrt{e_{\mathfrak{V}}})H\Big) \leq \mu^{\vee}(\mathfrak{V}).$$

As $x \geq x_0$ with $x > x_1$ and $i \in I(x)$ were arbitrary, $\mathcal{F}$ has (Sp5) with $c_{\vee} = c$, the threshold x_0 and the numbers $\bar{\eta}, \bar{e}$ at each x. □

Lemma 14.3. *Let $\mathcal{H}$ be a finite-dimensional complex Hilbert space and I a finite set; for $i \in I$ let $D_i \geq d_i \geq 0$ be integers, $A_i\colon \mathbb{C}^{D_i} \to \mathcal{H}$ a linear map, $U_i\colon \mathbb{C}^{d_i} \to \mathbb{C}^{D_i}$ a linear isometric embedding ($U_i^* U_i = 1$) and $\kappa_i > 0$ a real number; the spaces $\mathbb{C}^k$ carry the standard inner product. Put $\mathrm{Gr}_{ij} = (\kappa_i\kappa_j)^{1/2} A_i^* A_j\colon \mathbb{C}^{D_j} \to \mathbb{C}^{D_i}$. Let $D^* > 0$, $0 < \sigma \leq \frac{1}{20}$, and let $\eta_{\mathrm{off}}, \eta_{\dim}, e, \delta_{\mathrm{rk}}$ be real numbers with $-1 \leq \eta_{\mathrm{off}} \leq \sigma/2$, $\eta_{\dim} \leq \sigma/2$, $0 \leq e$, $\sqrt{e} \leq \sigma/2$ and $0 \leq \delta_{\mathrm{rk}} \leq \frac{1}{4}$. Assume*

(i) $\|\mathrm{Gr}_{ij}\|_{\mathrm{HS}}^2 \leq (1+\eta_{\mathrm{off}})\, D_i D_j / D^*$ *for all $i \neq j$;*

(ii) $\|\mathrm{Gr}_{ii} - 1\|_{\mathrm{HS}}^2 \leq e\, D_i$ *for all i;*

(iii) $\dim\mathcal{H} \leq (1+\eta_{\dim})\, D^*$;

(iv) $\sum_i D_i \geq D^*/\sigma$;

(v) $\sum_i (D_i - d_i) \leq \delta_{\mathrm{rk}} \sum_i D_i$.

Let $A_i' = A_i U_i\colon \mathbb{C}^{d_i} \to \mathcal{H}$ and $Q' = \sum_i \kappa_i A_i' A_i'^*$. Then $\dim\mathcal{H} \geq 1$, $\sum_i d_i \geq \frac{3}{4}\sum_i D_i > 0$,

$$\sum_{i\in I} \|\kappa_i A_i'^* A_i' - 1\|_{\mathrm{HS}}^2 \leq 2e\sum_{i\in I} d_i \qquad \text{and} \qquad \dim\mathcal{H}\cdot\mathrm{tr}(Q'^2) \leq (1+5\sigma+3\sqrt{\delta_{\mathrm{rk}}})(\mathrm{tr}\, Q')^2.$$

Proof. Write $R = \sum_i D_i$, $n = \dim\mathcal{H}$, $Q = \sum_i \kappa_i A_i A_i^*$ and $a = \sigma/2 \leq \frac{1}{40}$; then $\eta_{\mathrm{off}}, \eta_{\dim}, \sqrt{e} \leq a$. By (iv), $R \geq D^*/\sigma > 0$, and by (v), $\sum_i d_i \geq (1-\delta_{\mathrm{rk}})R \geq \frac{3}{4}R > 0$.

Traces of Q. $\mathrm{tr}\, Q = \sum_i \kappa_i \mathrm{tr}(A_i^* A_i) = \sum_i \mathrm{tr}\,\mathrm{Gr}_{ii}$ and

$$\mathrm{tr}(Q^2) = \sum_{i,j} \kappa_i\kappa_j \mathrm{tr}(A_i A_i^* A_j A_j^*) = \sum_{i,j} \kappa_i\kappa_j \mathrm{tr}\big((A_i^* A_j)^*(A_i^* A_j)\big) = \sum_{i,j} \|\mathrm{Gr}_{ij}\|_{\mathrm{HS}}^2.$$

For the identity 1 of $\mathbb{C}^{D_i}$, $|\mathrm{tr}(\mathrm{Gr}_{ii} - 1)| = |\langle 1, \mathrm{Gr}_{ii} - 1\rangle_{\mathrm{HS}}| \leq \sqrt{D_i}\,\|\mathrm{Gr}_{ii} - 1\|_{\mathrm{HS}}$, so by (ii) $\mathrm{tr}\,\mathrm{Gr}_{ii} \geq D_i(1-\sqrt{e})$ and

$$\mathrm{tr}\, Q \geq (1-\sqrt{e})R > 0. \tag{14.1}$$

In particular $Q \neq 0$, so $\mathcal{H} \neq 0$ and $n \geq 1$; by (iii) then $1 + \eta_{\dim} > 0$. Further $\|\mathrm{Gr}_{ii}\|_{\mathrm{HS}} \leq \|1\|_{\mathrm{HS}} + \|\mathrm{Gr}_{ii} - 1\|_{\mathrm{HS}} \leq (1+\sqrt{e})\sqrt{D_i}$, and by (i) and $1 + \eta_{\mathrm{off}} \geq 0$,

$$\mathrm{tr}(Q^2) \leq (1+\eta_{\mathrm{off}})\frac{1}{D^*}\sum_{i\neq j} D_i D_j + (1+\sqrt{e})^2 R \leq \big((1+\eta_{\mathrm{off}}) + (1+\sqrt{e})^2\sigma\big)\frac{R^2}{D^*},$$

using $R \leq \sigma R^2/D^*$ (from (iv)). By (iii), $1/D^* \leq (1+\eta_{\dim})/n$, and by (14.1), $R^2 \leq (\mathrm{tr}\, Q)^2/(1-\sqrt{e})^2$. Hence

$$n\,\mathrm{tr}(Q^2) \leq \frac{\big((1+\eta_{\mathrm{off}}) + (1+\sqrt{e})^2\sigma\big)(1+\eta_{\dim})}{(1-\sqrt{e})^2}(\mathrm{tr}\, Q)^2 \leq (1+5\sigma)(\mathrm{tr}\, Q)^2. \tag{14.2}$$

Compression. Let $E_i = 1 - U_i U_i^*$, the orthogonal projection of $\mathbb{C}^{D_i}$ onto $U_i(\mathbb{C}^{d_i})^\perp$, of rank $D_i - d_i$. Then $Q - Q' = \sum_i \kappa_i A_i E_i A_i^*$ is positive semidefinite, and Q' is positive semidefinite, so $0 \le Q' \le Q$ and therefore $\operatorname{tr}(Q'^2) \le \operatorname{tr}(Q'^{1/2} Q Q'^{1/2}) = \operatorname{tr}(Q^{1/2} Q' Q^{1/2}) \le \operatorname{tr}(Q^2)$. For the traces, $\operatorname{tr} Q - \operatorname{tr} Q' = \sum_i \operatorname{tr}(\mathrm{Gr}_{ii} E_i)$ and, as above, $\operatorname{tr}(\mathrm{Gr}_{ii} E_i) = \operatorname{tr} E_i + \langle E_i, \mathrm{Gr}_{ii} - 1\rangle_{\mathrm{HS}} \le (D_i - d_i) + \sqrt{D_i - d_i}\,\sqrt{e\,D_i}$. Summing, with the Cauchy–Schwarz inequality and (v),

$$\operatorname{tr} Q - \operatorname{tr} Q' \le \delta_{\mathrm{rk}} R + \sqrt{\delta_{\mathrm{rk}} R}\sqrt{eR} = \big(\delta_{\mathrm{rk}} + \sqrt{\delta_{\mathrm{rk}} e}\big) R \le \beta \operatorname{tr} Q, \qquad \beta = \frac{\delta_{\mathrm{rk}} + \sqrt{\delta_{\mathrm{rk}} e}}{1 - \sqrt{e}},$$

by (14.1). With $\rho = \sqrt{\delta_{\mathrm{rk}}} \le \frac{1}{2}$ and $\sqrt{e} \le \frac{1}{40}$, $\beta \le \frac{40}{39}\rho(\rho + \frac{1}{40}) < 1$, so $\operatorname{tr} Q' \ge (1 - \beta) \operatorname{tr} Q > 0$, and by (14.2)

$$n \operatorname{tr}(Q'^2) \le n \operatorname{tr}(Q^2) \le \frac{1 + 5\sigma}{(1 - \beta)^2} (\operatorname{tr} Q')^2 \le (1 + 5\sigma + 3\rho)(\operatorname{tr} Q')^2.$$

Diagonal defects after compression. $\kappa_i A_i'^* A_i' - 1 = U_i^* (\mathrm{Gr}_{ii} - 1) U_i$ since $U_i^* U_i = 1$, and $\|U_i^* X U_i\|_{\mathrm{HS}} \le \|X\|_{\mathrm{HS}}$ for the isometry U_i. By (ii), $\sum_i \|\kappa_i A_i'^* A_i' - 1\|_{\mathrm{HS}}^2 \le eR \le \frac{4}{3} e \sum_i d_i \le 2e \sum_i d_i$. □

Theorem 14.4. *Let K be a number field and $v\colon K \to \mathbb{C}$ an embedding. Let $\overline{E}$ be a hermitian lattice over $\mathcal{O}_K$ of rank $r_E \ge 1$ and I a finite non-empty set; for $i \in I$ let $\overline{N}_i$ be a hermitian lattice over $\mathcal{O}_K$ of rank $d_i \ge 1$, let $B_i\colon N_{i,K} \to E_K$ be a K-linear map with $B_i(N_i) \subseteq E$, and let h_i be a real number with $h(B_i) \le h_i$ if $B_i \ne 0$. Let $s, u, \widetilde{H}$ be real numbers with $u \ge 0$, $\widetilde{H} \ge 0$ and*

(a) $\sum_i d_i(\widehat{\mu}(\overline{N}_i) - h_i) \ge s \sum_i d_i$;

(b) $\widehat{\mu}_{\max}(\overline{N}_i) - h_i \le s + u$ *for every* $i \in I$;

(c) $s - \widehat{\mu}_{\min}(\overline{E}) \le \widetilde{H}$.

Let $\mathcal{H}$ be a finite-dimensional complex Hilbert space and $\Pi\colon \mathcal{H} \to E_{K,v}$ a surjective $\mathbb{C}$-linear map; for $i \in I$ let $A_i\colon \mathbb{C}^{d_i} \to \mathcal{H}$ be $\mathbb{C}$-linear and $Z_i\colon \mathbb{C}^{d_i} \to N_{i,K,v}$ a $\mathbb{C}$-linear isomorphism with $\Pi \circ A_i = B_{i,v} \circ Z_i$, and let $\kappa_i > 0$. Let δ, e, η be real numbers with $0 \le \delta < 1$, $(1 - \delta)\dim \mathcal{H} \le r_E$, $0 \le e \le \frac{1}{4}$, $\eta \ge 0$, and with $Q = \sum_i \kappa_i A_i A_i^*$ ($\mathbb{C}^{d_i}$ with the standard inner product)

(d) $\sum_i \|\kappa_i A_i^* A_i - 1\|_{\mathrm{HS}}^2 \le e \sum_i d_i$;

(e) $\dim \mathcal{H} \cdot \operatorname{tr}(Q^2) \le (1 + \eta)(\operatorname{tr} Q)^2$.

Then

$$s - \frac{1}{1 - \delta}\Big(\frac{4u\widetilde{H}}{u + \widetilde{H}} + (\eta + 4\sqrt{e})\widetilde{H}\Big) \le \widehat{\mu}(\overline{E}),$$

where $u\widetilde{H}/(u + \widetilde{H})$ is read as 0 when $u = \widetilde{H} = 0$.

Proof. We use the following standard facts of this theory: (HN1) $\sum_j \lambda_j(\overline{N}) = d\,\widehat{\mu}(\overline{N})$, $\lambda_1 = \widehat{\mu}_{\max}(\overline{N})$, $\lambda_d = \widehat{\mu}_{\min}(\overline{N})$; (HN2) $\operatorname{rk} N^{\ge\vartheta} = \#\{j : \lambda_j(\overline{N}) \ge \vartheta\}$, $\widehat{\mu}_{\min}(\overline{N^{\ge\vartheta}}) \ge \vartheta$ if $N^{\ge\vartheta} \ne 0$, and $\widehat{\mu}_{\max}(\overline{N/N^{\ge\vartheta}}) < \vartheta$ if $N^{\ge\vartheta} \ne N$; (HN3) the last subquotient $\overline{Q}$ of the filtration of $\overline{N}$ is semistable with $\widehat{\mu}(\overline{Q}) = \widehat{\mu}_{\max}(\overline{Q}) = \widehat{\mu}_{\min}(\overline{N})$. Put $d = \sum_i d_i \ge 1$.

Step 1: the integrated count of low slopes in the sources. Consider the d numbers $x_{ij} = \lambda_j(\overline{N}_i) - h_i$ ($i \in I$, $1 \le j \le d_i$) and put $z_{ij} = s - x_{ij}$. By (HN1) and (a), $\sum_{i,j} z_{ij} \le 0$; by

(HN1) and (b), $z_{ij} \geq -u$. For $\tau \geq 0$ let $c(\tau) = \#\{(i,j) : x_{ij} < s - \tau\}$, a step function of τ with finitely many steps. We show

$$\int_0^{\widetilde{H}} c(\tau)\, d\tau \leq \frac{u\widetilde{H}}{u+\widetilde{H}}\, d,$$

the right side read as 0 when $u = \widetilde{H} = 0$. For each (i,j) the set of $\tau \in [0,\widetilde{H}]$ with $x_{ij} < s - \tau$ is $[0,\widetilde{H}] \cap [0, z_{ij})$, of length $\min\{\widetilde{H}, (z_{ij})_+\}$, so $\int_0^{\widetilde{H}} c = \sum_{i,j} \min\{\widetilde{H}, (z_{ij})_+\}$. If $u = \widetilde{H} = 0$ this is 0. Let $u + \widetilde{H} > 0$. For every real $z \geq -u$,

$$\min\{\widetilde{H}, z_+\} \leq \frac{\widetilde{H}\,(z+u)}{u+\widetilde{H}}\,:$$

for $-u \leq z \leq 0$ the left side is 0 and the right side is ≥ 0; for $0 \leq z \leq \widetilde{H}$ the inequality $z(u+\widetilde{H}) \leq \widetilde{H}(z+u)$ reads $zu \leq \widetilde{H}u$; for $z \geq \widetilde{H}$ it reads $u + \widetilde{H} \leq z + u$. (The right side is the line through $(-u, 0)$ and $(\widetilde{H}, \widetilde{H})$.) Applying this to $z = z_{ij}$ and summing,

$$\int_0^{\widetilde{H}} c(\tau)\, d\tau \leq \frac{\widetilde{H}}{u+\widetilde{H}}\Big(\sum_{i,j} z_{ij} + du\Big) \leq \frac{u\widetilde{H}}{u+\widetilde{H}}\, d.$$

The estimate in this form, which integrates the exact count $c(\tau)$ rather than its Markov bound $c(\tau)(u+\tau) \leq du$ (whose integral gives $u\log(1+\widetilde{H}/u)$), is due to [261], Proposition 2.1.

Step 2: the high parts of the sources. For $\tau \geq 0$ let $F_i(\tau) = N_i^{\geq s-\tau+h_i}$, with the induced norms. By (HN2), $d_i - \operatorname{rk} F_i(\tau) = \#\{j : x_{ij} < s - \tau\}$, so $\sum_i (d_i - \operatorname{rk} F_i(\tau)) = c(\tau)$.

Step 3: the images lie in the high part of the target. Let $S(\tau) = E^{\geq s-\tau}$. We show $B_i(F_i(\tau)) \subseteq S(\tau)$ for every i. Assume $B_i(F_i(\tau)) \neq 0$; then $B_i \neq 0$ and $F_i(\tau) \neq 0$. Let $F' = E \cap B_i(F_i(\tau))_K$, a non-zero saturated submodule of E, with the induced norms; it contains $B_i(F_i(\tau))$. First, $\widehat{\mu}_{\min}(\overline{F'}) \geq s - \tau$. Let $\overline{Q}$ be the last subquotient of the filtration of $\overline{F'}$ and $\varphi\colon F_i(\tau)_K \to Q_K$ the composite of B_i with the projection $F'_K \to Q_K$. Then $\varphi(F_i(\tau)) \subseteq Q$, $\varphi \neq 0$ (the image of B_i on $F_i(\tau)_K$ spans F'_K, which maps onto $Q_K \neq 0$), and $\|\varphi_\sigma\| \leq \|B_{i,\sigma}\|$ for every embedding σ, since restriction to a subspace with the induced norm, the isometric inclusion $F' \subseteq E$ and the quotient map (of norm ≤ 1) do not increase operator norms; hence $h(\varphi) \leq h(B_i) \leq h_i$. By Lemma B.127, (HN2) and (HN3),

$$s - \tau + h_i \leq \widehat{\mu}_{\min}(\overline{F_i(\tau)}) \leq \widehat{\mu}_{\max}(\overline{Q}) + h(\varphi) \leq \widehat{\mu}_{\min}(\overline{F'}) + h_i.$$

Second, $F' \subseteq S(\tau)$. Otherwise $S(\tau) \neq E$ and the composite $\psi\colon F'_K \to (E/S(\tau))_K$ of the inclusion and the projection is non-zero, maps F' into the torsion-free quotient $E/S(\tau)$ (quotient norms) and has $\|\psi_\sigma\| \leq 1$, so $h(\psi) \leq 0$; Lemma B.127 and (HN2) give $s - \tau \leq \widehat{\mu}_{\min}(\overline{F'}) \leq \widehat{\mu}_{\max}(\overline{E/S(\tau)}) < s - \tau$, a contradiction. Hence $B_i(F_i(\tau)) \subseteq F' \subseteq S(\tau)$.

Step 4: the place v. Let $T(\tau) = \sum_i B_i(F_i(\tau)_K) \subseteq S(\tau)_K$; then $\dim_K T(\tau) \leq \operatorname{rk} S(\tau)$ and $\dim_{\mathbb{C}} T(\tau)_v = \dim_K T(\tau)$. Let $U_i' = Z_i^{-1}(F_i(\tau)_{K,v}) \subseteq \mathbb{C}^{d_i}$, of dimension $\operatorname{rk} F_i(\tau)$, and $\mathcal{S} = \sum_i A_i(U_i') \subseteq \mathcal{H}$. Since $\Pi(A_i(U_i')) = B_{i,v}(F_i(\tau)_{K,v}) \subseteq T(\tau)_v$, we have $\Pi(\mathcal{S}) \subseteq T(\tau)_v$. As Π is surjective onto $E_{K,v}$, of dimension r_E, $\dim\ker\Pi = \dim\mathcal{H} - r_E$, so $\dim\mathcal{S} \leq \dim\Pi(\mathcal{S}) + \dim\mathcal{H} - r_E$ and

$$r_E - \operatorname{rk} S(\tau) \leq r_E - \dim\Pi(\mathcal{S}) \leq \dim\mathcal{H} - \dim\mathcal{S} = \dim\mathcal{S}^\perp.$$

Lemma 14.5, applied with $U_i = \mathbb{C}^{d_i}$, the subspaces U_i' and $\theta = c(\tau)/d$ (its (a), (b), (c) are (d), (e) and Step 2, and $r = d > 0$), gives $\dim\mathcal{S}^\perp \leq (\eta + 4c(\tau)/d + 4\sqrt{e})\dim\mathcal{H}$. With $\dim\mathcal{H} \leq r_E/(1-\delta)$,

$$r_E - \operatorname{rk} S(\tau) \leq w(\tau)\, r_E, \qquad w(\tau) = \frac{\eta + 4c(\tau)/d + 4\sqrt{e}}{1-\delta} \qquad (\tau \geq 0).$$

Step 5: layer cake for the target. Let $\lambda_j = \lambda_j(\overline{E})$. By (HN2), $\#\{j : \lambda_j < s - \tau\} = r_E - \operatorname{rk} S(\tau) \le w(\tau) r_E$. By (HN1) and (c), $\lambda_j \ge \widehat{\mu}_{\min}(\overline{E}) \ge s - \widetilde{H}$, so for every j, $s - \lambda_j \le \int_0^{\widetilde{H}} \mathbf{1}[\lambda_j < s - \tau]\, d\tau$ (if $\lambda_j < s$ the integral is the length of $[0, s - \lambda_j) \subseteq [0, \widetilde{H}]$; otherwise the left side is ≤ 0). Summing over j and using (HN1),

$$\widehat{\mu}(\overline{E}) = \frac{1}{r_E} \sum_j \lambda_j \ge s - \int_0^{\widetilde{H}} \frac{\#\{j : \lambda_j < s - \tau\}}{r_E}\, d\tau \ge s - \int_0^{\widetilde{H}} w(\tau)\, d\tau$$

(the integrands are step functions of τ). Finally, by Step 1,

$$\int_0^{\widetilde{H}} w(\tau)\, d\tau = \frac{1}{1-\delta}\Big(\frac{4}{d}\int_0^{\widetilde{H}} c(\tau)\, d\tau + (\eta + 4\sqrt{e})\widetilde{H}\Big) \le \frac{1}{1-\delta}\Big(\frac{4u\widetilde{H}}{u + \widetilde{H}} + (\eta + 4\sqrt{e})\widetilde{H}\Big),$$

which is the assertion. □

Lemma 14.5. *Let $\mathcal{H}$ be a finite-dimensional complex Hilbert space and I a finite set; for $i \in I$ let U_i be a finite-dimensional complex Hilbert space, $A_i \colon U_i \to \mathcal{H}$ a $\mathbb{C}$-linear map, $\kappa_i > 0$ a real number and $U_i' \subseteq U_i$ a linear subspace. Put $r = \sum_{i\in I} \dim U_i$ and $Q = \sum_{i\in I} \kappa_i A_i A_i^*$, and let e, η, θ be real numbers with $0 \le e \le \frac{1}{4}$ and $\eta \ge 0$. Assume $r > 0$ and*

(a) $\sum_{i\in I} \|\kappa_i A_i^* A_i - 1\|_{\mathrm{HS}}^2 \le e\, r$;

(b) $\dim \mathcal{H} \cdot \operatorname{tr}(Q^2) \le (1+\eta)\,(\operatorname{tr} Q)^2$;

(c) $\sum_{i\in I} (\dim U_i - \dim U_i') \le \theta\, r$.

Then

$$\dim\Big(\sum_{i\in I} A_i(U_i')\Big)^{\perp} \le (\eta + 4\theta + 4\sqrt{e})\dim \mathcal{H}.$$

Proof. Write $n = \dim \mathcal{H}$, $M_i = \kappa_i A_i^* A_i - 1$ (a self-adjoint operator on U_i), $t = \operatorname{tr} Q$, $W = \big(\sum_i A_i(U_i')\big)^{\perp}$ and $w = \dim W$. If $n = 0$ then $w = 0$ and there is nothing to prove; let $n \ge 1$. By (c), $\theta r \ge 0$, so $\theta \ge 0$. If $\theta \ge \frac{1}{4}$, then $w \le n \le 4\theta n$ and the claim holds since $\eta, \sqrt{e} \ge 0$; let $\theta < \frac{1}{4}$.

Compressed traces. For a self-adjoint operator M on a finite-dimensional Hilbert space U and an orthonormal family $f_1, \dots, f_k$ in U with orthogonal projection P onto its span,

$$\Big|\sum_{m=1}^{k} \langle f_m, M f_m\rangle\Big| = |\operatorname{tr}(PM)| \le \|P\|_{\mathrm{HS}} \|M\|_{\mathrm{HS}} = \sqrt{k}\, \|M\|_{\mathrm{HS}} \tag{14.3}$$

by the Cauchy–Schwarz inequality for the Hilbert–Schmidt inner product. Applied to M_i, with $\langle f_m, M_i f_m\rangle = \kappa_i \|A_i f_m\|^2 - 1$:

$$\Big|\kappa_i \sum_{m=1}^{k} \|A_i f_m\|^2 - k\Big| \le \sqrt{k}\, \|M_i\|_{\mathrm{HS}}. \tag{14.4}$$

Lower bound for t. Let $(f_{i,m})_m$ be an orthonormal basis of U_i. Then $t = \sum_i \kappa_i \operatorname{tr}(A_i^* A_i) = \sum_i \kappa_i \sum_m \|A_i f_{i,m}\|^2$, and (14.4), the Cauchy–Schwarz inequality for sums and (a) give

$$t \ge \sum_i \Big(\dim U_i - \sqrt{\dim U_i}\, \|M_i\|_{\mathrm{HS}}\Big) \ge r - \sqrt{r}\Big(\sum_i \|M_i\|_{\mathrm{HS}}^2\Big)^{1/2} \ge r - \sqrt{r}\sqrt{e\, r} = r(1 - \sqrt{e}).$$

Since $\sqrt{e} \le \frac12$, $t \ge r/2 > 0$.

Upper bound for the trace of Q on W. Let $g_1, \dots, g_w$ be an orthonormal basis of W and $\tau = \sum_l \langle g_l, Q g_l\rangle = \sum_i \kappa_i \sum_l \|A_i^* g_l\|^2$. Fix i; let P_i be the orthogonal projection of U_i onto $U_i'^{\perp}$, of rank $k_i = \dim U_i - \dim U_i'$, and P_W that of $\mathcal{H}$ onto W. For $u \in U_i'$, $\langle A_i^* g_l, u\rangle = \langle g_l, A_i u\rangle = 0$, so $A_i^* g_l \in U_i'^{\perp}$ and $A_i^* P_W = P_i A_i^* P_W$. Hence

$$\sum_l \|A_i^* g_l\|^2 = \|P_i A_i^* P_W\|_{\mathrm{HS}}^2 \le \|P_i A_i^*\|_{\mathrm{HS}}^2 = \|A_i P_i\|_{\mathrm{HS}}^2 = \sum_{m=1}^{k_i} \|A_i f_{i,m}'\|^2$$

for an orthonormal basis $(f_{i,m}')_m$ of $U_i'^{\perp}$, and by (14.4) $\kappa_i \sum_l \|A_i^* g_l\|^2 \le k_i + \sqrt{k_i}\|M_i\|_{\mathrm{HS}}$. Summing over i and using the Cauchy–Schwarz inequality, (c) and (a),

$$\tau \le \sum_i k_i + \Big(\sum_i k_i\Big)^{1/2}\Big(\sum_i \|M_i\|_{\mathrm{HS}}^2\Big)^{1/2} \le \theta r + \sqrt{\theta r}\sqrt{er} = r\big(\theta + \sqrt{\theta e}\big).$$

Lower bound for the trace of Q on W. Put $\bar s = t/n$ and $B = Q - \bar s \cdot 1$, self-adjoint. By (14.3) for B and (g_l), $|\tau - \bar s\, w| = \big|\sum_l \langle g_l, B g_l\rangle\big| \le \sqrt{w}\,\|B\|_{\mathrm{HS}}$, so $\tau \ge \bar s\, w - \sqrt{w}\,\|B\|_{\mathrm{HS}}$. Moreover $\|B\|_{\mathrm{HS}}^2 = \operatorname{tr}(Q^2) - t^2/n \le \eta\, t^2/n$ by (b).

Conclusion. Combining the two bounds for τ and multiplying by $n/t > 0$: with $y = (n/t)\|B\|_{\mathrm{HS}}$, so that $y^2 \le \eta n$,

$$w - \sqrt{w}\, y \le \frac{n\, r}{t}\big(\theta + \sqrt{\theta e}\big) \le 2n\big(\theta + \sqrt{\theta e}\big),$$

using $r \le 2t$. Since $\sqrt{w}\, y \le \frac12(w + y^2)$, this gives $\frac12 w \le \frac12 y^2 + 2n(\theta + \sqrt{\theta e})$, i.e.

$$w \le y^2 + 4n\theta + 4n\sqrt{\theta e} \le (\eta + 4\theta + 4\sqrt{e})n,$$

because $\sqrt{\theta e} \le \sqrt{e}$ for $\theta < \frac14$. □

Definition 14.6. Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be complex Hilbert spaces, $K \in \mathcal{H}_1$, and let $\vartheta \ge 0$, $C_{\mathrm{pr}} \ge 0$ and $C_{\mathrm{mn}}, \beta_{\mathrm{lp}}, \beta_{\mathrm{ng}}$ be real numbers. A **pair expansion** of K at scale ϑ with **price** C_{pr}, **main constant** C_{mn}, **loop share** β_{lp} and **non-generic share** β_{ng} consists of

- a countable set $\mathcal{M}$, the **terms**, with a partition $\mathcal{M} = \mathcal{M}_{\mathrm{g}} \sqcup \mathcal{M}_{\mathrm{n}}$ into **generic** and **non-generic** terms;
- for every term t, vectors $y_t \in \mathcal{H}_1$ and $z_t \in \mathcal{H}_2$;
- an equivalence relation $\sim$ on $\mathcal{M}$ (terms in the same **row**), a finite set I and a map $\mathrm{lb}\colon \mathcal{M} \to I$, the **label**, constant on the rows;
- a real number $c_{\mathrm{rw}} > 0$, the **row normalisation**, and a matrix $\Upsilon \in \mathbb{C}^{I\times I}$, the **label matrix**;
- a function $\mathrm{cr}\colon \mathcal{M}\times\mathcal{M} \to \mathbb{Z}_{\ge 0}$, the **corank**, and a set $\mathrm{Sc} \subseteq \mathcal{M}\times\mathcal{M}$ of **scalar pairs**.

These data are subject to the conditions below. In them we use the **row pairs** $\mathrm{Pr} = \{(t,t') \in \mathcal{M}\times\mathcal{M} : t \sim t'\}$, their parts $\mathrm{Pr}_{\ge 2} = \{(t,t') \in \mathrm{Pr} : \mathrm{cr}(t,t') \ge 2\}$ and $\mathrm{Pr}_1 = \{(t,t') \in \mathrm{Pr} : \mathrm{cr}(t,t') = 1\}$, and, for $S \subseteq \mathcal{M}$ and $i \in I$, the **label sums**

$$z_{S,i} = \sum_{t\in S,\ \mathrm{lb}(t)=i} z_t \in \mathcal{H}_2.$$

(Pe1) Expansion. $\sum_{t\in\mathcal{M}}\|y_t\|<\infty$, $\sum_{t\in\mathcal{M}}\|z_t\|<\infty$ and $K=\sum_{t\in\mathcal{M}}y_t$.

(Pe2) Norm expansion. For $S=\mathcal{M}_{\mathrm{g}}$ and for $S=\mathcal{M}_{\mathrm{n}}$,

$$\Big\|\sum_{t\in S}y_t\Big\|^2=\operatorname{Re}\sum_{i,j\in I}\Upsilon_{ij}\,\langle z_{S,i},z_{S,j}\rangle.$$

(Pe3) Price. The matrix $C_{\mathrm{pr}}\,c_{\mathrm{rw}}\,1_I-\Upsilon$ is positive semidefinite.

(Pe4) Row orthogonality. $\langle z_t,z_{t'}\rangle=0$ whenever $\mathrm{lb}(t)=\mathrm{lb}(t')$ and $t\not\sim t'$.

(Pe5) Positive corank. $\mathrm{cr}(t,t')\geq 1$ for all $(t,t')\in\mathrm{Pr}$.

(Pe6) Loops. $c_{\mathrm{rw}}\sum_{(t,t')\in\mathrm{Pr}_{\geq 2}}|\langle z_t,z_{t'}\rangle|\leq\beta_{\mathrm{lp}}\vartheta$ and $c_{\mathrm{rw}}\sum_{(t,t')\in\mathrm{Pr}_1\cap(\mathcal{M}_{\mathrm{g}}\times\mathcal{M}_{\mathrm{g}})\setminus\mathrm{Sc}}|\langle z_t,z_{t'}\rangle|\leq\beta_{\mathrm{lp}}\vartheta$.

(Pe7) Main row. $c_{\mathrm{rw}}\sum_{(t,t')\in\mathrm{Pr}_1\cap(\mathcal{M}_{\mathrm{g}}\times\mathcal{M}_{\mathrm{g}})\cap\mathrm{Sc}}\operatorname{Re}\langle z_t,z_{t'}\rangle\leq C_{\mathrm{mn}}\vartheta$.

(Pe8) Non-generic row. $c_{\mathrm{rw}}\sum_{(t,t')\in\mathrm{Pr}_1\cap(\mathcal{M}_{\mathrm{n}}\times\mathcal{M}_{\mathrm{n}})}\operatorname{Re}\langle z_t,z_{t'}\rangle\leq\beta_{\mathrm{ng}}\vartheta$.

Definition 14.7. Let $\mathcal{F}$ be a parametrised host family with slope records and frame realisations, with parameter ε and threshold x_1. **Word scales for** $\mathcal{F}$ consist of a real number $\Gamma_{\mathrm{w}}=\Gamma_{\mathrm{w}}(x,i)\geq 1$ for every real $x>x_1$ and every $i\in I(x)$, the **word scale** of the member. The index is suppressed when the member is fixed. For a real number $C_0\geq 1$, a member **has word sizes for** C_0 if

$$C_0^{-1}\leq\frac{D_\omega\,\Gamma_{\mathrm{w}}^2}{D^*}\leq C_0\qquad\text{for every word }\omega.$$

The phrase "for all large members" means that there is a real x_0 such that the statement holds for every real $x\geq x_0$ with $x>x_1$, every $i\in I(x)$ and every word ω (and ω') of $\mathfrak{V}_{x,i}$. Let $C_0\geq 1$ and $c>0$ be real numbers. The family with word scales has

(No1) Word sizes for C_0 if all large members have word sizes for C_0;

(No2) Word count for C_0 **with exponent** c if $|\mathcal{W}(\mathfrak{V}_{x,i})|\geq C_0\,\Gamma_{\mathrm{w}}^2\,x^c$ for all large members;

(No3) Off-diagonal near-orthogonality for C_0 **with exponent** c if for all large members that have word sizes for C_0 and all words $\omega\neq\omega'$

$$\|\mathrm{Gr}_{\omega\omega'}\|_{\mathrm{HS}}^2\leq\Big(1+\frac{x^{-c}}{12}\Big)\frac{D_\omega D_{\omega'}}{D^*};$$

(No4) Diagonal near-isometry for C_0 **with exponent** c if for all large members that have word sizes for C_0 and every word ω, $\|\mathrm{Gr}_{\omega\omega}-1\|_{\mathrm{HS}}^2\leq x^{-2c}D_\omega/144$;

(No5) Dimension bound for C_0 **with exponent** c if $\dim\mathcal{H}\leq(1+x^{-c}/12)\,D^*$ for all large members that have word sizes for C_0;

(No6) Rank deficit with exponent c if $\sum_\omega(D_\omega-d_\omega)\leq\frac{x^{-2c}}{36}\sum_\omega D_\omega$ for all large members;

(No7) Pair expansions of the Gram blocks for C_0 **with exponent** c if for all large members that have word sizes for C_0 and all words $\omega\neq\omega'$, the Gram block $\mathrm{Gr}_{\omega\omega'}$, as an element of the space of linear maps $\mathbb{C}^{D_{\omega'}}\to\mathbb{C}^{D_\omega}$ with the Hilbert–Schmidt inner product, has a pair expansion at scale $D_\omega D_{\omega'}/D^*$ with price at most $1+x^{-c}/100$, main constant at most $1+x^{-c}/100$, and loop share and non-generic share at most $x^{-2c}/10^4$.

Theorem 14.8. *Let $c > 0$ and $C_0 \geq 1$ be real numbers and let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales that has word sizes for C_0 (No1), the word count for C_0 with exponent c (No2), off-diagonal near-orthogonality (No3), diagonal near-isometry (No4) and the dimension bound (No5) for C_0 with exponent c, and the rank deficit with exponent c (No6). Then $\mathcal{F}$ has near-orthogonal frames with exponent c (Nf4).*

Proof. Let x_0 be the largest of the thresholds of (No1)–(No6). Fix a real $x \geq x_0$ with $x > x_1$, put $\sigma = x^{-c}$ and

$$\bar{\varrho} = \frac{x^{-2c}}{36}, \qquad \bar{e} = \frac{x^{-2c}}{72}.$$

Then $\bar{\varrho}, \bar{e} \geq 0$ and $(3\sqrt{\bar{\varrho}} + 4\sqrt{\bar{e}})\, x^c = \frac{1}{2} + \frac{4}{\sqrt{72}} = \frac{1}{2} + \frac{\sqrt{2}}{3} < 1$.

Fix $i \in I(x)$ and take $\eta_{\mathrm{off}} = \eta_{\mathrm{dim}} = \sigma/12$ and $e_{\mathrm{dg}} = \sigma^2/144$. Then $-1 \leq \eta_{\mathrm{off}} \leq \sigma/2$, $\eta_{\mathrm{dim}} \leq \sigma/2$, $e_{\mathrm{dg}} \geq 0$, $\sqrt{e_{\mathrm{dg}}} = \sigma/12 \leq \sigma/2$ and $2e_{\mathrm{dg}} = \bar{e}$. By (No1) the member has word sizes for C_0, so (No3), (No4) and (No5) apply to it and give (i), (ii) and (iii) of (Nf4) with these numbers. (v) is (No6) with $\bar{\varrho}$. For (iv): by word sizes $D_\omega \geq D^*/(C_0\Gamma_{\mathrm{w}}^2)$ for every word, and by (No2) there are at least $C_0\Gamma_{\mathrm{w}}^2 x^c$ words, so

$$\sum_{\omega} D_\omega \geq |\mathcal{W}(\mathfrak{V}_{x,i})|\, \frac{D^*}{C_0\Gamma_{\mathrm{w}}^2} \geq x^c D^*.$$

As $x \geq x_0$ with $x > x_1$ and $i \in I(x)$ were arbitrary, and $\bar{\varrho}, \bar{e}$ depend on x only, $\mathcal{F}$ has (Nf4) with exponent c and threshold x_0. □

Theorem 14.9. *Let $c > 0$ and $C_0 \geq 1$ be real numbers and let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales that has pair expansions of the Gram blocks for C_0 with exponent c (No7). Then $\mathcal{F}$ has off-diagonal near-orthogonality for C_0 with exponent c (No3).*

Proof. Let x_0 be the threshold of (No7) and put $x_0' = \max(x_0, 1)$. Fix a real $x \geq x_0'$ with $x > x_1$, a member $i \in I(x)$ that has word sizes for C_0, and words $\omega \neq \omega'$ of $\mathfrak{V}_{x,i}$; put $a = x^{-c}/100$, so $0 < a \leq \frac{1}{100}$ because $x \geq 1$. Word sizes give $D_\omega, D_{\omega'} \geq D^*/(C_0\Gamma_{\mathrm{w}}^2) > 0$, so $\vartheta = D_\omega D_{\omega'}/D^* > 0$.

By (No7), $\mathrm{Gr}_{\omega\omega'}$, in the space of linear maps $\mathbb{C}^{D_{\omega'}} \to \mathbb{C}^{D_\omega}$ with the Hilbert–Schmidt inner product, has a pair expansion at scale ϑ with price $C_{\mathrm{pr}} \in [0, 1+a]$, main constant $C_{\mathrm{mn}} \leq 1+a$, and loop share β_{lp} and non-generic share β_{ng} at most a^2. By Lemma 14.10,

$$\|\mathrm{Gr}_{\omega\omega'}\|_{\mathrm{HS}} \leq \sqrt{C_{\mathrm{pr}}(C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}})\vartheta} + \sqrt{C_{\mathrm{pr}}(\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}})\vartheta}.$$

Since $C_{\mathrm{pr}} \geq 0$, $C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}} \leq 1 + a + 2a^2$ and $\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}} \leq 2a^2$, the radicands are at most $X\vartheta$ and $Y\vartheta$ with $X = (1+a)(1+a+2a^2)$ and $Y = 2a^2(1+a)$, and the square root is increasing; hence

$$\|\mathrm{Gr}_{\omega\omega'}\|_{\mathrm{HS}}^2 \leq \big(X + Y + 2\sqrt{XY}\big)\vartheta \leq (1+5a)\,\vartheta \leq \Big(1 + \frac{x^{-c}}{12}\Big)\frac{D_\omega D_{\omega'}}{D^*}.$$

As $x \geq x_0'$ with $x > x_1$, the member with word sizes for C_0 and the words $\omega \neq \omega'$ were arbitrary, (No3) holds for C_0 with exponent c and threshold x_0'. □

Lemma 14.10. *Let $\mathcal{H}_1, \mathcal{H}_2$ be complex Hilbert spaces and $K \in \mathcal{H}_1$. Let $\vartheta \geq 0$ and $C_{\mathrm{pr}} \geq 0$, let $C_{\mathrm{mn}}, \beta_{\mathrm{lp}}, \beta_{\mathrm{ng}}$ be real numbers, and suppose that K has a pair expansion at scale ϑ with price C_{pr}, main constant C_{mn}, loop share β_{lp} and non-generic share β_{ng}. Then $C_{\mathrm{pr}}(C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}})\vartheta \geq 0$, $C_{\mathrm{pr}}(\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}})\vartheta \geq 0$ and*

$$\|K\| \leq \sqrt{C_{\mathrm{pr}}\,(C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}})\,\vartheta} + \sqrt{C_{\mathrm{pr}}\,(\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}})\,\vartheta}\,.$$

Proof. Fix the data of the pair expansion. For $S \subseteq \mathcal{M}$ put $Y_S = \sum_{t\in S} y_t$.

Convergence. By (Pe1) the families (y_t) and (z_t) are absolutely summable, so every Y_S and every $z_{S,i}$ is an absolutely convergent sum, and $K = Y_{\mathcal{M}_\mathrm{g}} + Y_{\mathcal{M}_\mathrm{n}}$ because $\mathcal{M} = \mathcal{M}_\mathrm{g} \sqcup \mathcal{M}_\mathrm{n}$. By the Cauchy–Schwarz inequality $\sum_{(t,t')\in\mathcal{M}\times\mathcal{M}} |\langle z_t, z_{t'}\rangle| \le \big(\sum_t \|z_t\|\big)^2 < \infty$, so every sum over a set of pairs below converges absolutely and may be split and rearranged.

The label matrix. Let $M \in \mathbb{C}^{I\times I}$ be positive semidefinite and $a_i \in \mathcal{H}_2$ $(i \in I)$. Choose an orthonormal basis $e_1, \dots, e_n$ of the finite-dimensional span of the a_i and put $w_{k,i} = \langle e_k, a_i\rangle$; then $a_i = \sum_k w_{k,i} e_k$ and $\langle a_i, a_j\rangle = \sum_k \overline{w_{k,i}}\, w_{k,j}$, so

$$\sum_{i,j} M_{ij}\langle a_i, a_j\rangle = \sum_{k=1}^{n} \sum_{i,j} \overline{w_{k,i}}\, M_{ij}\, w_{k,j} \ge 0.$$

With $M = C_\mathrm{pr}c_\mathrm{rw}1_I - \Upsilon$, positive semidefinite by (Pe3), this gives

$$\mathrm{Re}\sum_{i,j} \Upsilon_{ij}\langle a_i, a_j\rangle = C_\mathrm{pr}c_\mathrm{rw}\sum_i \|a_i\|^2 - \sum_{i,j} M_{ij}\langle a_i, a_j\rangle \le C_\mathrm{pr}c_\mathrm{rw}\sum_i \|a_i\|^2.$$

Applied to $a_i = z_{S,i}$, (Pe2) yields for $S \in \{\mathcal{M}_\mathrm{g}, \mathcal{M}_\mathrm{n}\}$

$$\|Y_S\|^2 \le C_\mathrm{pr}\, c_\mathrm{rw} \sum_{i\in I} \|z_{S,i}\|^2. \tag{14.5}$$

Pair form of the label sums. For $S \subseteq \mathcal{M}$ and $i \in I$, $\|z_{S,i}\|^2 = \sum\langle z_t, z_{t'}\rangle$ over the pairs $t, t' \in S$ with $\mathrm{lb}(t) = \mathrm{lb}(t') = i$. By (Pe4) the pairs with $t \not\sim t'$ contribute 0; since lb is constant on rows, the remaining pairs are the $(t, t') \in \mathrm{Pr} \cap (S \times S)$ with $\mathrm{lb}(t) = i$. Summing over $i \in I$, every row pair is counted once, and since the left side is real,

$$\sum_{i\in I} \|z_{S,i}\|^2 = \sum_{(t,t')\in \mathrm{Pr}\cap(S\times S)} \mathrm{Re}\langle z_t, z_{t'}\rangle. \tag{14.6}$$

Generic terms. By (Pe5), $\mathrm{Pr} \cap (\mathcal{M}_\mathrm{g} \times \mathcal{M}_\mathrm{g})$ is the disjoint union of its parts in $\mathrm{Pr}_{\ge 2}$, in $\mathrm{Pr}_1 \setminus \mathrm{Sc}$ and in $\mathrm{Pr}_1 \cap \mathrm{Sc}$. Bounding $\mathrm{Re}\langle z_t, z_{t'}\rangle \le |\langle z_t, z_{t'}\rangle|$ on the first two parts and enlarging the first part to $\mathrm{Pr}_{\ge 2}$, (14.6), (Pe6) and (Pe7) give

$$c_\mathrm{rw} \sum_i \|z_{\mathcal{M}_\mathrm{g},i}\|^2 \le \beta_\mathrm{lp}\vartheta + \beta_\mathrm{lp}\vartheta + C_\mathrm{mn}\vartheta.$$

Non-generic terms. In the same way, by (Pe5) $\mathrm{Pr}\cap(\mathcal{M}_\mathrm{n}\times\mathcal{M}_\mathrm{n})$ is the disjoint union of its parts in $\mathrm{Pr}_{\ge 2}$ and in Pr_1, and (14.6), the first inequality of (Pe6) and (Pe8) give $c_\mathrm{rw}\sum_i \|z_{\mathcal{M}_\mathrm{n},i}\|^2 \le (\beta_\mathrm{lp} + \beta_\mathrm{ng})\vartheta$.

Conclusion. Multiplying the last two bounds by $C_\mathrm{pr} \ge 0$ and using (14.5),

$$0 \le \|Y_{\mathcal{M}_\mathrm{g}}\|^2 \le C_\mathrm{pr}(C_\mathrm{mn} + 2\beta_\mathrm{lp})\vartheta, \qquad 0 \le \|Y_{\mathcal{M}_\mathrm{n}}\|^2 \le C_\mathrm{pr}(\beta_\mathrm{lp} + \beta_\mathrm{ng})\vartheta,$$

which proves the two non-negativity claims. Taking square roots and using $\|K\| \le \|Y_{\mathcal{M}_\mathrm{g}}\| + \|Y_{\mathcal{M}_\mathrm{n}}\|$ proves the bound. □

Definition 14.11. Let S_mn be a real number and let $d, d', D^* > 0$ and $c_\mathrm{rw} > 0$ be real numbers. **Main-row mass data** for $(S_\mathrm{mn}; c_\mathrm{rw}, d, d', D^*)$ with **density factor** e_1 and **Poisson error** δ_P consist of real numbers

$$V,\ J,\ J_\infty,\ e_1,\ \delta_\mathrm{P}$$

and positive real numbers

$$\rho,\ m_0,\ c,\ c',\ C_\infty,\ \deg_\pi,\ U_{\mathrm{loc}},\ M_{\mathrm{loc}},\ v_Z,\ v_B,\ v_G,\ v_H,\ v_{H'},$$
$$v_{H,\infty},\ v_{H',\infty},\ n_\pi,\ n_{\pi'},\ \mu_K,\ \mu_K^\natural,\ \mu_K^\circ,\ \mu_S,\ \mu_{S'},\ \mu_H,\ \mu_{H'},\ \mu_H^\circ,\ \mu_{H'}^\circ$$

such that the following hold.

(Ma1) Form of the main row. $S_{\mathrm{mn}} = \rho\, V$.

(Ma2) Main-row inequality. $e_1 \geq 0$ and $c\, c'\, V \leq (1+\delta_{\mathrm{P}})\, e_1\, m_0\, J$.

(Ma3) Mass of the main orbit. $m_0\, \rho = v_B\, C_\infty\, M_{\mathrm{loc}}/(v_Z\, \mu_K)$.

(Ma4) Poisson error. $\delta_{\mathrm{P}} \geq 0$.

(Ma5) Archimedean integral. $J = v_Z\, J_\infty/(C_\infty\, U_{\mathrm{loc}})$ and $J_\infty \leq 1/\deg_\pi$.

(Ma6) Local product formula. $M_{\mathrm{loc}}/U_{\mathrm{loc}} = \mu_K\, \mu_K^\natural/(\mu_S\, \mu_{S'})$ and $\mu_K^\natural = c_{\mathrm{rw}}\, \mu_K^\circ$.

(Ma7) Unfolding constants. $c\, \mu_S = \mu_H\, v_{H,\infty}/n_\pi$ and $c'\, \mu_{S'} = \mu_{H'}\, v_{H',\infty}/n_{\pi'}$.

(Ma8) Word dimensions. $d = n_\pi\, v_H/(v_{H,\infty}\, \mu_H^\circ)$, $d' = n_{\pi'}\, v_{H'}/(v_{H',\infty}\, \mu_{H'}^\circ)$, $\mu_H = c_{\mathrm{rw}}\, \mu_H^\circ$ and $\mu_{H'} = c_{\mathrm{rw}}\, \mu_{H'}^\circ$.

(Ma9) Volume identity and reference dimension. $v_B\, v_G = v_H\, v_{H'}$ and $D^* = \deg_\pi\, v_G/\mu_K^\circ$.

Definition 14.12. Let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales, with parameter ε and threshold x_1. **Row parameters for $\mathcal{F}$** are, for every real $x > x_1$ and every $i \in I(x)$, integers $k_{\mathrm{d}} \geq 1$ (the **definite rank**), $r_{\mathrm{f}} \geq 0$ (the **flag rank**) and $f_\infty \geq 1$, integers $g_1^{\mathrm{aux}}, g_2^{\mathrm{aux}} \geq 3$ (the **auxiliary moduli**) and a real number $T_{\mathrm{amp}} > 0$ (the **amplitude bound**).

Fix a member and words $\omega \neq \omega'$, and put $\vartheta = D_\omega D_{\omega'}/D^*$. Regard $\mathrm{Gr}_{\omega\omega'}$ as a vector of the space of linear maps $\mathbb{C}^{D_{\omega'}} \to \mathbb{C}^{D_\omega}$ with the Hilbert–Schmidt inner product. A **main-row expansion** of $\mathrm{Gr}_{\omega\omega'}$ with price C_{pr}, loop share β_{lp} and non-generic share β_{ng} consists of data as in Definition 14.6 for this vector at scale ϑ, satisfying (Pe1)–(Pe6) and (Pe8), together with main-row mass data for $(S_{\mathrm{mn}}; c_{\mathrm{rw}}, D_\omega, D_{\omega'}, D^*)$, where

$$S_{\mathrm{mn}} = \sum_{(t,t') \in \mathrm{Pr}_1 \cap (\mathcal{M}_{\mathrm{g}} \times \mathcal{M}_{\mathrm{g}}) \cap \mathrm{Sc}} \mathrm{Re}\langle z_t, z_{t'} \rangle$$

is the **main-row sum**.

Let $C_0 \geq 1$, $C_{\mathrm{A}} \geq 1$, $c_{\mathrm{lp}} > 0$, $C_{\mathrm{ng}} \geq 0$ and $c > 0$ be real numbers. The family with row parameters has each of the following properties if the stated condition holds.

(Rw1) Row estimates for C_0 with constants $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ For all large members that have word sizes for C_0 and all words $\omega \neq \omega'$, the Gram block $\mathrm{Gr}_{\omega\omega'}$ has a main-row expansion with

$$C_{\mathrm{pr}} = \Big(1 + \frac{3}{g_1^{\mathrm{aux}}}\Big)^{f_\infty} \Big(1 + \frac{3}{g_2^{\mathrm{aux}}}\Big)^{f_\infty}, \qquad \beta_{\mathrm{lp}} = \exp(-c_{\mathrm{lp}}\, k_{\mathrm{d}} f_\infty \log k_{\mathrm{d}}),$$
$$\beta_{\mathrm{ng}} = 2^{2r_{\mathrm{f}}+5-k_{\mathrm{d}}} \exp\big(C_{\mathrm{ng}}(2r_{\mathrm{f}}+2)^5 f_\infty \log b(x)\big),$$

whose mass data have density factor $e_1 \leq \exp\big(12 f_\infty\, 2^{2r_{\mathrm{f}}+2-k_{\mathrm{d}}}\big)$ and Poisson error $\delta_{\mathrm{P}} \leq C_{\mathrm{A}}(r_{\mathrm{f}}+1)(C_{\mathrm{A}}/T_{\mathrm{amp}})^{f_\infty}$.

(Rw2) Row sizes with exponent c for $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ For all large members,

$$g_1^{\mathrm{aux}},\, g_2^{\mathrm{aux}} \ge 1300\, f_\infty\, x^c, \qquad C_{\mathrm{A}}(r_{\mathrm{f}}+1)\Big(\frac{C_{\mathrm{A}}}{T_{\mathrm{amp}}}\Big)^{f_\infty} \le \frac{x^{-c}}{400}, \qquad 12 f_\infty\, 2^{2r_{\mathrm{f}}+2-k_{\mathrm{d}}} \le \frac{x^{-c}}{400},$$

$$\exp(-c_{\mathrm{lp}}\, k_{\mathrm{d}} f_\infty \log k_{\mathrm{d}}) \le \frac{x^{-2c}}{10^4}, \qquad 2^{2r_{\mathrm{f}}+5-k_{\mathrm{d}}} \exp\big(C_{\mathrm{ng}}(2r_{\mathrm{f}}+2)^5 f_\infty \log b(x)\big) \le \frac{x^{-2c}}{10^4}.$$

Theorem 14.13. *Let $c > 0$, $C_0 \ge 1$, $C_{\mathrm{A}} \ge 1$, $c_{\mathrm{lp}} > 0$ and $C_{\mathrm{ng}} \ge 0$ be real numbers, and let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations, word scales and row parameters that has row estimates for C_0 with constants $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ (Rw1) and row sizes with exponent c for $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ (Rw2). Then $\mathcal{F}$ has pair expansions of the Gram blocks for C_0 with exponent c (No7).*

Proof. Let x_0 be a real number above which both (Rw1) and (Rw2) hold, and put $x_0' = \max(x_0, 1)$. Fix a real $x \ge x_0'$ with $x > x_1$, a member $i \in I(x)$ that has word sizes for C_0, and words $\omega \ne \omega'$; write $\sigma = x^{-c}$, so $0 < \sigma \le 1$. Word sizes give $D_\omega, D_{\omega'} \ge D^*/(C_0\Gamma_{\mathrm{w}}^2) > 0$, so $\vartheta = D_\omega D_{\omega'}/D^* > 0$.

A pair expansion. By (Rw1), $\mathrm{Gr}_{\omega\omega'}$ has a main-row expansion at scale ϑ with price $C_{\mathrm{pr}} = (1+3/g_1^{\mathrm{aux}})^{f_\infty}(1+3/g_2^{\mathrm{aux}})^{f_\infty}$, loop share β_{lp} and non-generic share β_{ng} as in (Rw1), and with main-row mass data for $(S_{\mathrm{mn}}; c_{\mathrm{rw}}, D_\omega, D_{\omega'}, D^*)$ whose density factor e_1 and Poisson error δ_{P} obey the bounds of (Rw1). By Theorem 14.14,

$$c_{\mathrm{rw}} \sum_{(t,t')\in \mathrm{Pr}_1 \cap (\mathcal{M}_{\mathrm{g}}\times\mathcal{M}_{\mathrm{g}})\cap \mathrm{Sc}} \mathrm{Re}\langle z_t, z_{t'}\rangle = c_{\mathrm{rw}} S_{\mathrm{mn}} \le (1+\delta_{\mathrm{P}})\, e_1\, \vartheta,$$

which is (Pe7) with $C_{\mathrm{mn}} = (1+\delta_{\mathrm{P}})e_1$. Together with (Pe1)–(Pe6) and (Pe8), and since $\vartheta \ge 0$ and $C_{\mathrm{pr}} \ge 0$, the data are a pair expansion of $\mathrm{Gr}_{\omega\omega'}$ at scale ϑ with price C_{pr}, main constant C_{mn}, loop share β_{lp} and non-generic share β_{ng}.

The price. Since $1 + t \le e^t$ for real t, and by the first size condition of (Rw2),

$$C_{\mathrm{pr}} \le \exp\Big(\frac{3f_\infty}{g_1^{\mathrm{aux}}} + \frac{3f_\infty}{g_2^{\mathrm{aux}}}\Big) \le \exp(a), \qquad a = \frac{6f_\infty}{1300 f_\infty x^c} = \frac{3\sigma}{650} \in (0, 1].$$

By convexity $e^a \le 1 + (e-1)a \le 1 + 2a$ for $0 \le a \le 1$, so $C_{\mathrm{pr}} \le 1 + 6\sigma/650 \le 1 + \sigma/100$.

The main constant. By (Ma4) and (Rw1), (Rw2), $0 \le \delta_{\mathrm{P}} \le C_{\mathrm{A}}(r_{\mathrm{f}}+1)(C_{\mathrm{A}}/T_{\mathrm{amp}})^{f_\infty} \le \sigma/400$; by (Ma2) $e_1 \ge 0$, and $e_1 \le \exp(12 f_\infty 2^{2r_{\mathrm{f}}+2-k_{\mathrm{d}}}) \le \exp(\sigma/400)$. Hence, as $1 + \delta_{\mathrm{P}} \ge 0$,

$$C_{\mathrm{mn}} = (1+\delta_{\mathrm{P}})e_1 \le e^{\delta_{\mathrm{P}}} e^{\sigma/400} \le e^{\sigma/200} \le 1 + \frac{\sigma}{100},$$

the last step by $e^a \le 1 + 2a$ with $a = \sigma/200 \in (0, 1]$.

The shares. By the last two size conditions of (Rw2), $\beta_{\mathrm{lp}} \le \sigma^2/10^4 = x^{-2c}/10^4$ and $\beta_{\mathrm{ng}} \le x^{-2c}/10^4$.

As the member with word sizes for C_0 and the words $\omega \ne \omega'$ were arbitrary, (No7) holds for C_0 with exponent c and threshold x_0'. □

Theorem 14.14. *Let S_{mn} be a real number and let $c_{\mathrm{rw}}, d, d', D^* > 0$. Suppose that $(S_{\mathrm{mn}}; c_{\mathrm{rw}}, d, d', D^*)$ has main-row mass data with density factor e_1 and Poisson error δ_{P}. Then*

$$c_{\mathrm{rw}}\, S_{\mathrm{mn}} \le (1+\delta_{\mathrm{P}})\, e_1\, \frac{d\, d'}{D^*}.$$

Proof. **The kernel value is at most the Poisson and density factors times the orbit mass over the formal degree.** By (Ma5) and since $v_Z/(C_\infty U_{\mathrm{loc}}) > 0$, $J = \frac{v_Z}{C_\infty U_{\mathrm{loc}}} J_\infty \le \frac{v_Z}{C_\infty U_{\mathrm{loc}} \deg_\pi}$. By (Ma2) and (Ma4), $e_1 \ge 0$ and $1 + \delta_{\mathrm{P}} \ge 1$, and $m_0 > 0$, $cc' > 0$; so $(1 + \delta_{\mathrm{P}}) e_1 m_0/(cc') \ge 0$ and the inequality of (Ma2) gives

$$V \le \frac{(1+\delta_{\mathrm{P}})\, e_1\, m_0\, J}{c\, c'} \le \frac{(1+\delta_{\mathrm{P}})\, e_1\, m_0\, v_Z}{c\, c'\, C_\infty\, U_{\mathrm{loc}}\, \deg_\pi}. \tag{14.7}$$

The main row. Since $\rho > 0$, (Ma1) and (14.7) give, with $A = m_0\rho = v_B C_\infty M_{\mathrm{loc}}/(v_Z \mu_K)$ by (Ma3),

$$S_{\mathrm{mn}} = \rho V \le (1+\delta_{\mathrm{P}})\, e_1\, A\, \frac{v_Z}{c\, c'\, C_\infty\, U_{\mathrm{loc}}\, \deg_\pi}, \tag{14.8}$$

that is

$$S_{\mathrm{mn}} \le (1+\delta_{\mathrm{P}})\, e_1\, \frac{v_B}{\mu_K \deg_\pi\, c\, c'} \cdot \frac{M_{\mathrm{loc}}}{U_{\mathrm{loc}}}. \tag{14.9}$$

The masses combine to the random-subspace value. By (Ma6), $\frac{M_{\mathrm{loc}}}{U_{\mathrm{loc}}} = \frac{\mu_K\, c_{\mathrm{rw}}\, \mu_K^\circ}{\mu_S\, \mu_{S'}}$. By (Ma7) and (Ma8),

$$c\, \mu_S = \frac{\mu_H v_{H,\infty}}{n_\pi} = \frac{c_{\mathrm{rw}}\, \mu_H^\circ v_{H,\infty}}{n_\pi} = \frac{c_{\mathrm{rw}}\, v_H}{d}, \qquad c'\, \mu_{S'} = \frac{c_{\mathrm{rw}}\, v_{H'}}{d'}.$$

Hence, using (Ma9) in the last two steps,

$$\frac{v_B}{\mu_K \deg_\pi\, c\, c'} \cdot \frac{M_{\mathrm{loc}}}{U_{\mathrm{loc}}} = \frac{v_B\, c_{\mathrm{rw}}\, \mu_K^\circ}{\deg_\pi\, (c\mu_S)(c'\mu_{S'})} = \frac{v_B\, \mu_K^\circ\, d\, d'}{c_{\mathrm{rw}} \deg_\pi\, v_H v_{H'}} = \frac{\mu_K^\circ\, d\, d'}{c_{\mathrm{rw}} \deg_\pi\, v_G} = \frac{d\, d'}{c_{\mathrm{rw}} D^*}.$$

Inserting this into (14.9) and multiplying by $c_{\mathrm{rw}} > 0$ proves the claim. □

Definition 14.15. Let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales, and let $C_0 \ge 1$ and $c > 0$ be real numbers. For a member and a word ω, a **diagonal expansion** of $\mathrm{Gr}_{\omega\omega}$ with **degenerate share** $\epsilon \ge 0$ is a decomposition

$$\mathrm{Gr}_{\omega\omega} - 1 = K_{\mathrm{dg}} + K_{\mathrm{dm}}$$

in the space of linear maps $\mathbb{C}^{D_\omega} \to \mathbb{C}^{D_\omega}$ with the Hilbert–Schmidt inner product, together with a pair expansion of K_{dm} at scale D_ω^2/D^* with price C_{pr}, main constant C_{mn}, loop share β_{lp} and non-generic share β_{ng}, such that $\|K_{\mathrm{dg}}\|_{\mathrm{HS}}^2 \le \epsilon D_\omega$, $C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}} \ge 0$, $\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}} \ge 0$ and

$$C_{\mathrm{pr}}\Big(\sqrt{C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}}} + \sqrt{\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}}}\Big)^2 \le \Gamma_{\mathrm{w}}.$$

The family has

(Dx1) Diagonal expansions for C_0 with exponent c if for all large members that have word sizes for C_0 and every word ω, $\mathrm{Gr}_{\omega\omega}$ has a diagonal expansion with a degenerate share ϵ satisfying

$$2\epsilon + \frac{2C_0}{\Gamma_{\mathrm{w}}} \le \frac{x^{-2c}}{144}.$$

Theorem 14.16. *Let $C_0 \ge 1$ and $c > 0$ be real numbers and let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales that has diagonal expansions for C_0 with exponent c (Dx1). Then $\mathcal{F}$ has the diagonal near-isometry for C_0 with exponent c (No4).*

Proof. Let x_0 be a threshold for (Dx1). Fix a real $x \geq x_0$ with $x > x_1$, a member $i \in I(x)$ that has word sizes for C_0, and a word ω, and take a diagonal expansion $\mathrm{Gr}_{\omega\omega} - 1 = K_{\mathrm{dg}} + K_{\mathrm{dm}}$ with degenerate share ϵ as in (Dx1); let $C_{\mathrm{pr}}, C_{\mathrm{mn}}, \beta_{\mathrm{lp}}, \beta_{\mathrm{ng}}$ be the price, main constant and shares of the pair expansion of K_{dm}, at scale $\vartheta = D_\omega^2/D^* \geq 0$.

The generic part. By Lemma 14.10, and since $C_{\mathrm{pr}} \geq 0$, $\vartheta \geq 0$, $C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}} \geq 0$ and $\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}} \geq 0$,

$$\|K_{\mathrm{dm}}\|_{\mathrm{HS}} \leq \sqrt{C_{\mathrm{pr}}(C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}})\vartheta} + \sqrt{C_{\mathrm{pr}}(\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}})\vartheta} = \sqrt{C_{\mathrm{pr}}\vartheta}\Big(\sqrt{C_{\mathrm{mn}} + 2\beta_{\mathrm{lp}}} + \sqrt{\beta_{\mathrm{lp}} + \beta_{\mathrm{ng}}}\Big),$$

so $\|K_{\mathrm{dm}}\|_{\mathrm{HS}}^2 \leq \Gamma_{\mathrm{w}}\vartheta$ by the defining inequality of a diagonal expansion. Word sizes give $D_\omega\Gamma_{\mathrm{w}}^2/D^* \leq C_0$, hence $\vartheta = D_\omega \cdot D_\omega/D^* \leq C_0 D_\omega/\Gamma_{\mathrm{w}}^2$ and

$$\|K_{\mathrm{dm}}\|_{\mathrm{HS}}^2 \leq \frac{C_0 D_\omega}{\Gamma_{\mathrm{w}}}.$$

Conclusion. By the triangle inequality and $(a+b)^2 \leq 2a^2 + 2b^2$,

$$\|\mathrm{Gr}_{\omega\omega} - 1\|_{\mathrm{HS}}^2 \leq 2\|K_{\mathrm{dg}}\|_{\mathrm{HS}}^2 + 2\|K_{\mathrm{dm}}\|_{\mathrm{HS}}^2 \leq \Big(2\epsilon + \frac{2C_0}{\Gamma_{\mathrm{w}}}\Big)D_\omega \leq \frac{x^{-2c}}{144}D_\omega.$$

As x, the member with word sizes and ω were arbitrary, (No4) holds for C_0 with exponent c and threshold x_0. □

Definition 14.17. The symbols $X, \mu, X_{\mathrm{t}}, X_{\mathrm{c}}, \mathrm{kd}, a, c_{\mathrm{id}}, \epsilon_{\mathrm{o}}, \epsilon_{\mathrm{c}}$ are local to this definition and to the results that apply it. Let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales. For a member, with frame data $\mathcal{H}$ and D^*, and real numbers $\epsilon_{\mathrm{o}}, \epsilon_{\mathrm{c}} \geq 0$, a **kernel splitting** of the member with **off-identity error** ϵ_{o} and **cusp error** ϵ_{c} consists of a measure space (X, μ), disjoint measurable sets $X_{\mathrm{t}}, X_{\mathrm{c}} \subseteq X$ with $X = X_{\mathrm{t}} \cup X_{\mathrm{c}}$ (the **thick part** and the **cusp part**), a measurable function $\mathrm{kd}\colon X \to [0, \infty)$ (the **kernel diagonal**), a measurable function $a\colon X_{\mathrm{t}} \to [0, \infty]$ (the **off-identity majorant**) and a real number $c_{\mathrm{id}} \geq 0$ (the **identity density**), such that

$$\int_X \mathrm{kd}\, d\mu = \dim \mathcal{H}, \qquad c_{\mathrm{id}}\, \mu(X_{\mathrm{t}}) \leq D^*, \tag{14.10}$$

$$\mathrm{kd}(x) \leq c_{\mathrm{id}} + a(x) \quad \text{for every } x \in X_{\mathrm{t}}, \tag{14.11}$$

$$\int_{X_{\mathrm{t}}} a\, d\mu \leq \epsilon_{\mathrm{o}}\, D^*, \qquad \int_{X_{\mathrm{c}}} \mathrm{kd}\, d\mu \leq \epsilon_{\mathrm{c}} \dim \mathcal{H}. \tag{14.12}$$

Let $C_0 \geq 1$ and $c > 0$ be real numbers. The family has

(Dk1) Kernel splittings for C_0 with exponent c if for all large members that have word sizes for C_0 there are real numbers $\epsilon_{\mathrm{o}} \geq 0$ and $\epsilon_{\mathrm{c}} \in [0, 1)$ with

$$1 + \epsilon_{\mathrm{o}} \leq (1 - \epsilon_{\mathrm{c}})\Big(1 + \frac{x^{-c}}{12}\Big),$$

where x is the scale of the member, and a kernel splitting of the member with off-identity error ϵ_{o} and cusp error ϵ_{c}.

Corollary 14.18. *Let $C_0 \geq 1$ and $c > 0$ be real numbers and let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations and word scales. Assume that for all large members that have word sizes for C_0, with frame data $\mathcal{H}$ and D^*, there are a measure space (X, μ) with*

$\mu(X) < \infty$, *a measurable function* $\mathrm{ls}\colon X \to (0,\infty)$, *a real number* $\tau_* > 0$, *measurable functions* $\mathrm{kd}\colon X \to [0,\infty)$ *and* $\mathrm{na}, \mathrm{fa}\colon X \to [0,\infty]$ *and real numbers* $c_{\mathrm{id}}, \epsilon_{\mathrm{N}}, \epsilon_{\mathrm{F}}, \kappa \geq 0$ *with the properties (Kc1)–(Kc4) of Lemma 14.19 (for* $X_{\mathrm{t}} = \{\mathrm{ls} \geq \tau_*\}$, $X_{\mathrm{c}} = X \setminus X_{\mathrm{t}}$*), such that* $\kappa\,\mu(X) < 1$ *and*

$$1 + \epsilon_{\mathrm{N}} + \epsilon_{\mathrm{F}} \leq (1 - \kappa\,\mu(X))\Big(1 + \frac{x^{-c}}{12}\Big),$$

x *the scale of the member. Then* $\mathcal{F}$ *has the dimension bound for* C_0 *with exponent* c *(No5).*

Proof. Let x_0 be a threshold beyond which the assumption holds, and let a member at a scale $x \geq x_0$, $x > x_1$ (x_1 the threshold of the parametrised host family), with word sizes for C_0 be given, with the data of the assumption. By Lemma 14.19 the member has a kernel splitting with off-identity error $\epsilon_{\mathrm{o}} = \epsilon_{\mathrm{N}} + \epsilon_{\mathrm{F}} \geq 0$ and cusp error $\epsilon_{\mathrm{c}} = \kappa\,\mu(X)$. Since $\kappa \geq 0$ and $0 \leq \mu(X) < \infty$, $\epsilon_{\mathrm{c}} \geq 0$, and $\epsilon_{\mathrm{c}} < 1$ by assumption, so $\epsilon_{\mathrm{c}} \in [0,1)$; the displayed inequality is $1 + \epsilon_{\mathrm{o}} \leq (1 - \epsilon_{\mathrm{c}})(1 + x^{-c}/12)$. As the member was arbitrary, $\mathcal{F}$ has kernel splittings for C_0 with exponent c (Dk1), with threshold x_0. By Theorem 14.20, $\mathcal{F}$ has the dimension bound (No5) for C_0 with exponent c. □

Lemma 14.19. *The notation introduced here is local to this result and to the results that apply it. Fix a member of a parametrised host family with slope records, frame realisations and word scales, with frame data* $\mathcal{H}$ *and* D^**. Let* (X,μ) *be a measure space with* $\mu(X) < \infty$, $\mathrm{ls}\colon X \to (0,\infty)$ *a measurable function (the* ***least size****) and* $\tau_* > 0$*; put* $X_{\mathrm{t}} = \{x : \mathrm{ls}(x) \geq \tau_*\}$ *and* $X_{\mathrm{c}} = X \setminus X_{\mathrm{t}}$*. Let* $\mathrm{kd}\colon X \to [0,\infty)$ *and* $\mathrm{na}, \mathrm{fa}\colon X \to [0,\infty]$ *be measurable, and let* $c_{\mathrm{id}}, \epsilon_{\mathrm{N}}, \epsilon_{\mathrm{F}}, \kappa \geq 0$ *be real numbers such that*

(Kc1) Trace and identity term $\int_X \mathrm{kd}\,d\mu = \dim \mathcal{H}$ *and* $c_{\mathrm{id}}\,\mu(X) = D^*$*;*

(Kc2) Thick split $\mathrm{kd}(x) \leq c_{\mathrm{id}} + \mathrm{na}(x) + \mathrm{fa}(x)$ *for* $x \in X_{\mathrm{t}}$*;*

(Kc3) Near and far terms $\int_{X_{\mathrm{t}}} \mathrm{na}\,d\mu \leq \epsilon_{\mathrm{N}} D^*$ *and* $\int_{X_{\mathrm{t}}} \mathrm{fa}\,d\mu \leq \epsilon_{\mathrm{F}} D^*$*;*

(Kc4) Cusp: pointwise bound $\mathrm{kd}(x) \leq \kappa \dim \mathcal{H}$ *for* $x \in X_{\mathrm{c}}$*.*

Then the member has a kernel splitting with off-identity error $\epsilon_{\mathrm{N}} + \epsilon_{\mathrm{F}}$ *and cusp error* $\kappa\,\mu(X)$*.*

Proof. Take the measure space (X,μ), the thick part X_{t} and the cusp part X_{c}, which are measurable (as ls is), disjoint and cover X; the kernel diagonal kd; the off-identity majorant $a = (\mathrm{na} + \mathrm{fa})|_{X_{\mathrm{t}}}$, measurable with values in $[0,\infty]$; and the identity density c_{id}. Then (14.10) holds: the trace identity is (Kc1), and $c_{\mathrm{id}}\mu(X_{\mathrm{t}}) \leq c_{\mathrm{id}}\mu(X) = D^*$. (14.11) is (Kc2). For (14.12): $\int_{X_{\mathrm{t}}} a\,d\mu = \int_{X_{\mathrm{t}}} \mathrm{na}\,d\mu + \int_{X_{\mathrm{t}}} \mathrm{fa}\,d\mu \leq (\epsilon_{\mathrm{N}} + \epsilon_{\mathrm{F}})D^*$ by (Kc3) (additivity of the integral of nonnegative functions), and by (Kc4)

$$\int_{X_{\mathrm{c}}} \mathrm{kd}\,d\mu \leq \kappa \dim \mathcal{H}\,\mu(X_{\mathrm{c}}) \leq \kappa\,\mu(X) \dim \mathcal{H}.$$

□

Theorem 14.20. *Let* $C_0 \geq 1$ *and* $c > 0$ *be real numbers and let* $\mathcal{F}$ *be a parametrised host family with slope records, frame realisations and word scales that has kernel splittings for* C_0 *with exponent* c *(Dk1). Then* $\mathcal{F}$ *has the dimension bound for* C_0 *with exponent* c *(No5).*

Proof. Let x_0 be a threshold for (Dk1). Fix a real $x \geq x_0$ with $x > x_1$ and a member $i \in I(x)$ that has word sizes for C_0; take $\epsilon_{\mathrm{o}} \geq 0$, $\epsilon_{\mathrm{c}} \in [0,1)$ with $1+\epsilon_{\mathrm{o}} \leq (1-\epsilon_{\mathrm{c}})(1+x^{-c}/12)$ and a kernel splitting $(X, \mu, X_{\mathrm{t}}, X_{\mathrm{c}}, \mathrm{kd}, a, c_{\mathrm{id}})$ of the member with these errors, as (Dk1) provides. Put $N_{\mathcal{H}} = \dim \mathcal{H}$, a non-negative integer since $\mathcal{H}$ is finite-dimensional.

Splitting the trace. The sets $X_{\mathrm{t}}, X_{\mathrm{c}}$ are measurable, disjoint and cover X, and $\mathrm{kd} \geq 0$ is measurable, so by additivity of the integral of non-negative functions and (14.10)

$$N_{\mathcal{H}} = \int_X \mathrm{kd}\, d\mu = \int_{X_{\mathrm{t}}} \mathrm{kd}\, d\mu + \int_{X_{\mathrm{c}}} \mathrm{kd}\, d\mu;$$

both summands are finite because their sum is $N_{\mathcal{H}}$.

The thick part. By (14.11), $\mathrm{kd} \leq c_{\mathrm{id}} + a$ on X_{t}, both sides measurable with values in $[0,\infty]$; monotonicity and additivity of the integral, (14.10) and (14.12) give

$$\int_{X_{\mathrm{t}}} \mathrm{kd}\, d\mu \leq c_{\mathrm{id}}\, \mu(X_{\mathrm{t}}) + \int_{X_{\mathrm{t}}} a\, d\mu \leq D^* + \epsilon_{\mathrm{o}} D^*.$$

(If $\mu(X_{\mathrm{t}}) = \infty$, then $c_{\mathrm{id}} = 0$ because $c_{\mathrm{id}}\, \mu(X_{\mathrm{t}}) \leq D^* < \infty$, and the first term is 0.)

The cusp part. By (14.12), $\int_{X_{\mathrm{c}}} \mathrm{kd}\, d\mu \leq \epsilon_{\mathrm{c}} N_{\mathcal{H}}$.

Conclusion. Adding the two bounds, $N_{\mathcal{H}} \leq (1+\epsilon_{\mathrm{o}}) D^* + \epsilon_{\mathrm{c}} N_{\mathcal{H}}$, i.e.

$$(1-\epsilon_{\mathrm{c}})\, N_{\mathcal{H}} \leq (1+\epsilon_{\mathrm{o}})\, D^* \leq (1-\epsilon_{\mathrm{c}})\Big(1+\frac{x^{-c}}{12}\Big) D^*,$$

using $D^* > 0$. Since $1-\epsilon_{\mathrm{c}} > 0$, $\dim \mathcal{H} = N_{\mathcal{H}} \leq (1+x^{-c}/12) D^*$. As x and the member with word sizes were arbitrary, (No5) holds for C_0 with exponent c and threshold x_0. □

15 Row estimates for the Gram blocks

This section proves the row estimates (Rw1) from the row records (Ro1)–(Ro4) that the class requires (Theorem 15.3); Theorem 14.13 of Section 14 turns them into pair expansions of the Gram blocks. A Gram block $\mathrm{Gr}_{\omega\omega'}$ is written as a sum of terms indexed by a countable set (Definition 14.6), and the pairs of terms are grouped into three parts: the main row, the loop pairs and the non-generic row. They are bounded separately and to different standards. The main row is bounded by the value $d\, d'/D^*$ for random subspaces times the factor $(1+\delta_{\mathrm{P}})e_1$ (Theorem 14.14); the loop pairs and the non-generic row need only be small against it. This makes the main row the heart of the section.

The main row is controlled by its mass data (Lemma 15.8), which combine four inputs. A Poisson recursion along a tower of points bounds the energy of coefficients dominated by a positive kernel (Theorem 15.10, Corollary 15.9); its archimedean clauses come from a product structure and Poisson summation (Theorem 15.14). The orbit energy is bounded by an energy bound for orbital integrals of Bessel coefficients of a square-integrable representation, which rests on the Schur orthogonality relations with the formal degree (Proposition 15.18). The mass and the class number of a group compact at infinity are expressed by its covolume (Lemma 15.19), and the stabilisers of nondegenerate tuples have the covolume of the unitary group, by Siegel's formula for unitary groups (Proposition 15.20, Theorem B.158). The loop pairs are bounded through configuration masses, with the share $\exp(-\frac{1}{3} k f \log k)$ (Theorem 15.4). The non-generic row is bounded through point data with a local factor (Theorem 15.5), and the local factor $2^{-(k-2r-5)}$ comes from a gain $q^{-(k-2r-5)}$, with $q \geq 2$, at one non-generic place; Section 16 proves it (Lemma 16.4).

Definition 15.1. Let $C \ge 1$ and $K_0 > 0$ be real numbers, let k, r, f be integers with $k \ge 1$, $r \ge 0$, $f \ge 1$, put $m = 2r + 2$, and let $b \ge 2$, $g > 0$, $v > 0$, $N_T > 0$, $\Gamma \ge 1$ be real numbers and $\Xi = (\Xi(s))_{2 \le s \le k}$ real numbers, the **configuration masses**. Put $\lambda = \log b$ and $h = b^{Cm^2 f}$ (the **height scale**). The **loop-row numbers** are, for $2 \le s \le k$,

$$\begin{aligned} \mathrm{nd}_s &= \Big(\frac{2}{g}\Big)^{(s-1)kf} (kv)^{kf}\, \Xi(s)\, C^{kf}\, h^{C(s+m)m^2} (Csf)^{6sf}\, \Gamma, \\ \mathrm{dg}_s &= \Big(\frac{2}{g}\Big)^{(s-2)kf} (kv)^{kf}\, \Xi(s)\, C^{kf}\, h^{C(s+m)m^2} (Csf)^{6sf}\, \Gamma\, e^{Cm^6 f\lambda} \Big(\frac{C}{k}\Big)^{kf}, \\ \mathrm{on} &= C^f\, h^{Cm^3}\, \Gamma\, e^{Cm^6 f\lambda} \big(C\, g^{-(2r+1)} k^{-r}\big)^{kf/2}. \end{aligned}$$

The data $(C, K_0; k, r, f, b, g, v, N_T, \Gamma, \Xi)$ satisfy

(Lb1) Loop parameter conditions if $m \ge 4$, $m \le f \le k$, $g \ge (kb)^8$, $K_0 m^5 f\lambda \le k$, $v \le b$, $N_T \le b^{Cmf}$ and $v \ge 1$, $N_T \ge 1$, $\Gamma \le \exp(Cm^5 f\lambda)$;

(Lb2) Configuration mass bounds if $0 \le \Xi(s)$ and $(kv)^{kf}\, \Xi(s) \le h^C C^{skf}$ for $2 \le s \le k-2$, and $0 \le \Xi(s) \le (Ck)^{kf} (h^{Cm} N_T)^{Ck}$ for $s \in \{k-1, k\}$.

Let moreover $A \ge 1$ and $\vartheta \ge 0$ be real numbers and let a pair expansion at scale ϑ (with some price, main constant and shares) be given. Its **loop pairs** are the elements of

$$\mathrm{Lp} = \mathrm{Pr}_{\ge 2} \cup \big((\mathrm{Pr}_1 \cap (\mathcal{M}_\mathrm{g} \times \mathcal{M}_\mathrm{g})) \setminus \mathrm{Sc}\big).$$

The pair expansion has

(Lb3) The loop-row bound with constant A for the data above if

$$c_\mathrm{rw} \sum_{(t,t') \in \mathrm{Lp}} |\langle z_t, z_{t'} \rangle| \le A\Big(\sum_{s=2}^{k} \mathrm{nd}_s + \Gamma^2 \sum_{s=2}^{k} \mathrm{dg}_s + \mathrm{on}\Big)\vartheta.$$

Definition 15.2. Let a pair expansion be given and let $r \ge 0$, $k \ge 2r + 5$ be integers. **Non-generic row data** for it consist of sets Cl (the **classes**), P (the **points**) and N (the **normals**), maps $\mathrm{cl}\colon \mathcal{M}_\mathrm{n} \to \mathrm{Cl}$, $\mathrm{pt}\colon \mathcal{M}_\mathrm{n} \to P$, $\mathrm{nm}\colon \mathcal{M}_\mathrm{n} \to N$, functions $w, P_\mathrm{n}\colon P \to (0, \infty)$, $J, n_\mathrm{g}\colon P \to [0, \infty)$ and $a_2\colon \mathrm{Cl} \times P \times N \to [0, \infty)$, and real numbers $S_w, T_\mathrm{pt} \ge 0$. For $(c, \gamma, \nu) \in \mathrm{Cl} \times P \times N$ put

$$u(c, \gamma, \nu) = \sum_{t \in \mathcal{M}_\mathrm{n},\ (\mathrm{cl}(t), \mathrm{pt}(t), \mathrm{nm}(t)) = (c, \gamma, \nu)} z_t \in \mathcal{H}_2$$

(absolutely convergent by (Pe1)); (c, γ, ν) is **occupied** if $z_t \ne 0$ for some term t in this sum, and $P_\mathrm{oc} \subseteq P$ is the set of points γ such that (c, γ, ν) is occupied for some c, ν. The data have

(Ng1) Classes if for all $t, t' \in \mathcal{M}_\mathrm{n}$: $(t, t') \in \mathrm{Pr}_1$ if and only if $\mathrm{cl}(t) = \mathrm{cl}(t')$;

(Ng2) Normals if for all $c \in \mathrm{Cl}$ and $\gamma \in P$ the set of ν with (c, γ, ν) occupied is finite with at most $P_\mathrm{n}(\gamma)$ elements;

(Ng3) Point weights if $\sum_{\gamma \in F} w(\gamma)^{-1} \le S_w$ for every finite $F \subseteq P_\mathrm{oc}$;

(Ng4) Factorisation if $\|u(c, \gamma, \nu)\|^2 \le a_2(c, \gamma, \nu)\, J(\gamma)$ for all (c, γ, ν);

(Ng5) Local gain if $\sum_{(c,\nu) \in F} a_2(c, \gamma, \nu) \le 2^{-(k-2r-5)} n_\mathrm{g}(\gamma)$ for every $\gamma \in P_\mathrm{oc}$ and every finite $F \subseteq \mathrm{Cl} \times N$;

(Ng6) Point sum if $\sum_{\gamma\in F} w(\gamma)P_{\mathrm{n}}(\gamma)n_{\mathrm{g}}(\gamma)J(\gamma)\le T_{\mathrm{pt}}$ for every finite $F\subseteq P_{\mathrm{oc}}$.

Theorem 15.3. *Let $C_0\ge 1$, $C_{\mathrm{A}}\ge 1$, $0<c_{\mathrm{lp}}\le\frac{1}{3}$, $C_{\mathrm{ng}}\ge 0$, $C_{\mathrm{lb}}\ge 1$ and $A_{\mathrm{lb}}\ge 1$ be real numbers, let $C_0^{\mathrm{ng}}\ge 0$ be an integer, and put $K_0=32C_{\mathrm{lb}}^{32}$. Let $\mathcal{F}$ be a parametrised host family with slope records, frame realisations, word scales and row parameters, with parameter ε and threshold x_1. Suppose that for all large members that have word sizes for C_0 and all words $\omega\ne\omega'$, with $\vartheta=D_\omega D_{\omega'}/D^*$ and the row parameters of the member, there are data with the following properties.*

(Ro1) Expansion. *Data as in Definition 14.6 for the vector $\mathrm{Gr}_{\omega\omega'}$ of the space of linear maps $\mathbb{C}^{D_{\omega'}}\to\mathbb{C}^{D_\omega}$ with the Hilbert–Schmidt inner product, at scale ϑ, satisfying (Pe1)–(Pe5) with price*

$$C_{\mathrm{pr}}=\Big(1+\frac{3}{g_1^{\mathrm{aux}}}\Big)^{f_\infty}\Big(1+\frac{3}{g_2^{\mathrm{aux}}}\Big)^{f_\infty}.$$

(Ro2) Loops. *Real numbers $v,N_T>0$ and $\Xi=(\Xi(s))_{2\le s\le k_{\mathrm{d}}}$ such that*

$$(C_{\mathrm{lb}},K_0;k_{\mathrm{d}},r_{\mathrm{f}},f_\infty,b(x),g_1^{\mathrm{aux}}g_2^{\mathrm{aux}},v,N_T,\Gamma_{\mathrm{w}},\Xi)$$

satisfy the loop parameter conditions (Lb1) and the configuration mass bounds (Lb2), the data of (Ro1) have the loop-row bound (Lb3) with constant A_{lb} for these data, and

$$6\log(3A_{\mathrm{lb}})\le k_{\mathrm{d}}f_\infty\log k_{\mathrm{d}}.$$

(Ro3) Non-generic row. *Non-generic row data for the data of (Ro1) with $r=r_{\mathrm{f}}$ and $k=k_{\mathrm{d}}$ having the properties (Ng1)–(Ng4) and (Ng6), with*

$$c_{\mathrm{rw}}\,S_w\,T_{\mathrm{pt}}\le\exp\big(C_{\mathrm{ng}}(2r_{\mathrm{f}}+2)^5f_\infty\log b(x)\big)\,\vartheta,$$

and, for every $\gamma\in P_{\mathrm{oc}}$, data as in Lemma 16.4 with $r=r_{\mathrm{f}}$, $k=k_{\mathrm{d}}$ and $C_0=C_0^{\mathrm{ng}}$ satisfying its items 1 and 2 and (Nv1), (Nv2).

(Ro4) Main row. *With c_{rw} the row normalisation of the data of (Ro1) and*

$$S_{\mathrm{mn}}=\sum_{(t,t')\in\mathrm{Pr}_1\cap(\mathcal{M}_{\mathrm{g}}\times\mathcal{M}_{\mathrm{g}})\cap\mathrm{Sc}}\mathrm{Re}\langle z_t,z_{t'}\rangle$$

its main-row sum, numbers and data satisfying (Mx1)–(Mx5) of Lemma 15.8 for $(S_{\mathrm{mn}};c_{\mathrm{rw}},D_\omega,D_{\omega'},D^*)$, with Poisson recursion data with parameters (r,f,n_{d}), lattice-sum bound β_{L} and block ratio β_{B} in (Mx1), such that

$$e_1\le\exp\big(12f_\infty\,2^{2r_{\mathrm{f}}+2-k_{\mathrm{d}}}\big),$$
$$15\,(r+1)\big(2\cdot 3^f\beta_{\mathrm{L}}+4\beta_{\mathrm{B}}\big)\le C_{\mathrm{A}}(r_{\mathrm{f}}+1)\Big(\frac{C_{\mathrm{A}}}{T_{\mathrm{amp}}}\Big)^{f_\infty}.$$

Then $\mathcal{F}$ has row estimates for C_0 with constants $(C_{\mathrm{A}},c_{\mathrm{lp}},C_{\mathrm{ng}})$ (Rw1).

Proof. Fix a large member that has word sizes for C_0, words $\omega\ne\omega'$ and the data of (Ro1)–(Ro4); write $k=k_{\mathrm{d}}$, r_{f}, $f=f_\infty$, $b=b(x)$. Word sizes give $D_\omega,D_{\omega'}\ge D^*/(C_0\Gamma_{\mathrm{w}}^2)>0$, so $\vartheta>0$. We show that the data of (Ro1), with the mass data of (Ro4), form a main-row expansion of $\mathrm{Gr}_{\omega\omega'}$ with the price, shares and bounds of (Rw1).

Rank. By (Lb1) of (Ro2), $m \ge 4$, $f \ge m$, and $k \ge K_0 m^5 f\lambda$ with $K_0 = 32C_{\mathrm{lb}}^{32} \ge 32$ and $\lambda \ge \log 2 > \frac{1}{2}$ (as $b \ge 2$). Hence $k \ge 16m^6 \ge 2m + 3 = 4r_{\mathrm{f}} + 7$; in particular $k \ge 2r_{\mathrm{f}} + 5$ and $k \ge 1$, so $X := kf \log k \ge 0$.

The loop condition (Pe6). The data of (Ro2) satisfy (Lb1) and (Lb2) with $C = C_{\mathrm{lb}} \ge 1$ and $K_0 = 32C^{32}$, and $A = A_{\mathrm{lb}} \ge 1$ satisfies $6\log(3A) \le X$. The data of (Ro1) are a pair expansion at the scale $\vartheta \ge 0$ with the loop-row bound (Lb3) with constant A. By Theorem 15.4, both sums of (Pe6), multiplied by c_{rw}, are at most $e^{-X/3}\vartheta$. Since $X \ge 0$ and $c_{\mathrm{lp}} \le \frac{1}{3}$, $e^{-X/3} \le e^{-c_{\mathrm{lp}}X}$; so (Pe6) holds with $\beta_{\mathrm{lp}} = \exp(-c_{\mathrm{lp}}k_{\mathrm{d}}f_\infty \log k_{\mathrm{d}})$.

The non-generic condition (Pe8). Since $k \ge 4r_{\mathrm{f}} + 7$, Lemma 16.4 applies to the non-generic row data of (Ro3) with $r = r_{\mathrm{f}}$, k, $C_0 = C_0^{\mathrm{ng}}$ and, at every $\gamma \in P_{\mathrm{oc}}$, the data of (Ro3), so the data have the local gain (Ng5). With (Ng1)–(Ng4) and (Ng6) of (Ro3) they have (Ng1)–(Ng6), and $k \ge 2r_{\mathrm{f}} + 5$. Put $Q = \exp(C_{\mathrm{ng}}m^5 f \log b) \ge 0$; by (Ro3), $c_{\mathrm{rw}}S_w T_{\mathrm{pt}} \le Q\vartheta$. By (ii) of Theorem 15.5, the pair expansion satisfies (Pe8) with non-generic share $2^{-(k-2r_{\mathrm{f}}-5)}Q = 2^{2r_{\mathrm{f}}+5-k_{\mathrm{d}}}\exp\bigl(C_{\mathrm{ng}}(2r_{\mathrm{f}}+2)^5 f_\infty \log b(x)\bigr)$, the β_{ng} of (Rw1).

The main-row mass data. By (Ro4) and Lemma 15.8, $(S_{\mathrm{mn}}; c_{\mathrm{rw}}, D_\omega, D_{\omega'}, D^*)$, with $c_{\mathrm{rw}} > 0$ the row normalisation and $D_\omega, D_{\omega'}, D^* > 0$, has main-row mass data with density factor e_1 and Poisson error $\delta_{\mathrm{P}} = 15(r+1)(2\cdot 3^f\beta_{\mathrm{L}} + 4\beta_{\mathrm{B}})$, and by the two inequalities of (Ro4), $e_1 \le \exp(12f_\infty 2^{2r_{\mathrm{f}}+2-k_{\mathrm{d}}})$ and $\delta_{\mathrm{P}} \le C_{\mathrm{A}}(r_{\mathrm{f}}+1)(C_{\mathrm{A}}/T_{\mathrm{amp}})^{f_\infty}$.

Conclusion. The data of (Ro1) satisfy (Pe1)–(Pe5) with the price C_{pr} of (Rw1), (Pe6) with the loop share and (Pe8) with the non-generic share of (Rw1), and come with main-row mass data for their main-row sum whose density factor and Poisson error obey the bounds of (Rw1). This is a main-row expansion of $\mathrm{Gr}_{\omega\omega'}$ as required in (Rw1). As the large member with word sizes for C_0 and the words $\omega \ne \omega'$ were arbitrary (with the same threshold as in the hypothesis), $\mathcal{F}$ has row estimates for C_0 with constants $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$. □

Theorem 15.4. *Let $C \ge 1$ and put $K_0 = 32C^{32}$. Let $(C, K_0; k, r, f, b, g, v, N_T, \Gamma, \Xi)$ satisfy the loop parameter conditions (Lb1) and the configuration mass bounds (Lb2), and let $A \ge 1$ with $6\log(3A) \le kf\log k$. Then*

$$\sum_{s=2}^{k} \mathrm{nd}_s \le g^{-kf/2} \le e^{-4kf\log k}, \qquad \Gamma^2 \sum_{s=2}^{k} \mathrm{dg}_s \le e^{-\frac{1}{2}kf\log k}, \qquad \mathrm{on} \le e^{-kf\log k},$$

and every pair expansion at a scale $\vartheta \ge 0$ that has the loop-row bound (Lb3) with constant A for these data satisfies the loop condition (Pe6) with loop share $\beta_{\mathrm{lp}} = \exp(-\frac{1}{3}kf\log k)$:

$$c_{\mathrm{rw}} \sum_{(t,t')\in \mathrm{Pr}_{\ge 2}} |\langle z_t, z_{t'}\rangle| \le e^{-\frac{1}{3}kf\log k}\vartheta, \qquad c_{\mathrm{rw}} \sum_{(t,t')\in(\mathrm{Pr}_1\cap(\mathcal{M}_{\mathrm{g}}\times\mathcal{M}_{\mathrm{g}}))\setminus \mathrm{Sc}} |\langle z_t, z_{t'}\rangle| \le e^{-\frac{1}{3}kf\log k}\vartheta.$$

Proof. Write $\kappa = \log k$ and $q = g^{-kf/2}$.

Consequences of (Lb1). Since $f \ge m \ge 4$ and $\lambda \ge \log 2 > 1/2$, $m^5 f\lambda \ge 4^6/2 \ge 2048$, so $k \ge K_0 m^5 f\lambda \ge 2048K_0$. Hence:

(a) $k \ge K_0 \ge C^{32}$, so $C \le k$ and $0 \le \log C \le \kappa/32$; also $k \ge 2048$, so $\kappa \ge 7$;

(b) $k \ge K_0 m^6\lambda \ge 32C^2m^6\lambda$ (as $f \ge m$) and $k \ge K_0 m^5 \ge 8C^3m^5$ (as $f\lambda \ge 2$);

(c) $\log g \ge 8\kappa + 8\lambda$ (as $g \ge (kb)^8$), so $g \ge 2^8$ and $q \le 2^{-4}$, and $q \le (kb)^{-4kf} \le e^{-4kf\kappa}$;

(d) for $2 \le s \le k$, $Csf \le k^3$, so $\log(Csf) \le 3\kappa$; $\log(kv) \le \kappa + \lambda$; $\log N_T \le Cmf\lambda$; $\log\Gamma \le Cm^5 f\lambda$; $\log h = Cm^2 f\lambda$; and $kf\lambda \ge \log 2$.

By (Lb2), $\Xi(s) \geq 0$ for all s; if $\Xi(s) = 0$ then $\mathrm{nd}_s = \mathrm{dg}_s = 0$ and the bounds of Steps 1 and 3 below hold trivially, so we assume $\Xi(s) > 0$ there and take logarithms.

Step 1: $\mathrm{nd}_s \leq \frac{1}{2} q^{s-1}$ for $2 \leq s \leq k$. Put $j = s-1 \geq 1$; we show $\log \mathrm{nd}_s \leq -\frac{jkf}{2} \log g - \log 2$.

Case $2 \leq s \leq k-2$. By (Lb2), $\log\big((kv)^{kf}\Xi(s)\big) \leq C \log h + skf \log C = C^2 m^2 f\lambda + skf \log C$. Hence

$$\log \mathrm{nd}_s \leq -jkf \log g + jkf \log 2 + (s+1)kf \log C + C^2 m^2 f\lambda \\ + C^2 m^4 (s+m) f\lambda + 6sf \log(Csf) + Cm^5 f\lambda.$$

With $s+1 \leq 3j$, $s \leq 2j$, $s+m \leq (m+2)j$ and $1 \leq j$, the right side is at most

$$-jkf \log g + jkf\lambda + 3jkf\kappa + C^2 m^4 (m+3) jf\lambda + 36jf\kappa + Cm^5 f\lambda.$$

By (b), $C^2 m^4 (m+3) \leq 2C^2 m^5 \leq k$ and $Cm^5 \leq k$, and $36 \leq k$; so this is at most $-jkf \log g + 3jkf\lambda + 4jkf\kappa = -\frac{jkf}{2} \log g - jkf\big(\frac{1}{2} \log g - 3\lambda - 4\kappa\big) \leq -\frac{jkf}{2} \log g - jkf\lambda$ by (c), and $jkf\lambda \geq \log 2$.

Case $s \in \{k-1, k\}$. By (Lb2) and (d), $\log \Xi(s) \leq kf \log(Ck) + Ck(C^2 m^3 f\lambda + Cmf\lambda) \leq 2kf\kappa + 2C^3 m^3 kf\lambda$. With $s+m \leq 2k$, $6sf \log(Csf) \leq 18kf\kappa$ and $Cm^5 f\lambda \leq kf\lambda$,

$$\begin{aligned} \log \mathrm{nd}_s &\leq -jkf \log g + jkf\lambda + 22kf\kappa + kf\lambda\,(2 + 2C^3 m^3 + 2C^2 m^4) \\ &\leq -jkf \log g + jkf\lambda + 22kf\kappa + 6C^3 m^4 kf\lambda. \end{aligned}$$

Here $j \geq k-2 \geq k/2$, so by (c) $\frac{jkf}{2} \log g - jkf\lambda \geq jkf(4\kappa + 3\lambda) \geq 2k \cdot kf\kappa + \frac{3}{2}k \cdot kf\lambda$, which exceeds $22kf\kappa + 6C^3 m^4 kf\lambda + \log 2$ because $k \geq 12$ and $\frac{3}{2}k \geq 7C^3 m^4$ by (b). This gives the claim.

Step 2: the nondegenerate rows. Distinct s give distinct $j = s-1 \geq 1$, so by Step 1 and $q \leq \frac{1}{2}$,

$$\sum_{s=2}^{k} \mathrm{nd}_s \leq \frac{1}{2} \sum_{j \geq 1} q^j = \frac{q}{2(1-q)} \leq q = g^{-kf/2} \leq e^{-4kf \log k}.$$

Step 3: $\Gamma^2 \mathrm{dg}_s \leq \frac{1}{2} e^{-kf\kappa/2} q^{s-2}$ for $2 \leq s \leq k$. Put $j' = s-2 \geq 0$, and recall that $\log \Gamma^2 \leq 2Cm^5 f\lambda$ and $\log(C/k)^{kf} = kf \log C - kf\kappa$.

Case $2 \leq s \leq k-2$. As in Step 1,

$$\log(\Gamma^2 \mathrm{dg}_s) \leq -j'kf \log g + j'kf \log 2 + (s+2)kf \log C - kf\kappa \\ + \Big[C^2 m^2 + C^2 m^4 (s+m) + 3Cm^5 + Cm^6\Big] f\lambda + 6sf \log(Csf).$$

Since $s = j' + 2$: $(s+2)kf \log C \leq j'kf\kappa + 4kf \log C \leq j'kf\kappa + \frac{1}{8}kf\kappa$ by (a); the bracket is at most $4C^2 m^6 + C^2 m^4 j'$ (each of $C^2 m^2$, $C^2 m^4 (m+2)$, $3Cm^5$, Cm^6 is at most $C^2 m^6$), and $4C^2 m^6 f\lambda \leq \frac{1}{8}kf \leq \frac{1}{8}kf\kappa$ by (b), while $C^2 m^4 j' f\lambda \leq j'kf\lambda$; and $6sf \log(Csf) \leq 36f\kappa + 18j'f\kappa \leq \frac{1}{8}kf\kappa + j'kf\kappa$ as $k \geq 288$. Hence

$$\log(\Gamma^2 \mathrm{dg}_s) \leq -j'kf \log g + j'kf(\lambda + 2\kappa + \lambda) - \frac{5}{8}kf\kappa \leq -\frac{j'kf}{2} \log g - \frac{1}{2}kf\kappa - \frac{1}{8}kf\kappa,$$

using $\frac{1}{2} \log g \geq 2\kappa + 2\lambda$ and $\log 2 \leq \lambda$; and $\frac{1}{8}kf\kappa \geq \log 2$.

Case $s \in \{k-1, k\}$. Now $j' \geq k-3 \geq k/2$. As in the second case of Step 1, with the additional factors,

$$\begin{aligned} \log(\Gamma^2 \mathrm{dg}_s) &\leq -j'kf \log g + j'kf\lambda + 22kf\kappa + kf\lambda\Big(3 + 2C^3 m^3 + 2C^2 m^4\Big) \\ &\leq -j'kf \log g + j'kf\lambda + 22kf\kappa + 7C^3 m^4 kf\lambda, \end{aligned}$$

where $3Cm^5f\lambda + Cm^6f\lambda \le 2kf\lambda$ by (b) was used and $kf\log C - kf\kappa \le 0$ absorbed the factor $(C/k)^{kf}$ together with one $kf\log C$. As before $\frac{j'kf}{2}\log g - j'kf\lambda \ge 2k\cdot kf\kappa + \frac{3}{2}k\cdot kf\lambda \ge 22kf\kappa + \frac{1}{2}kf\kappa + 7C^3m^4kf\lambda + \log 2$, since $k \ge 12$ and $\frac{3}{2}k \ge 8C^3m^4$.

Step 4: the degenerate rows. Distinct s give distinct $j' \ge 0$, so by Step 3

$$\Gamma^2 \sum_{s=2}^{k} \mathrm{dg}_s \le \frac{1}{2} e^{-kf\kappa/2} \sum_{j'\ge 0} q^{j'} \le \frac{e^{-kf\kappa/2}}{2(1-q)} \le e^{-\frac{1}{2}kf\log k}.$$

Step 5: the non-scalar pairs of corank one. As $m \ge 4$, $r \ge 1$, so $g^{-(2r+1)}k^{-r} \le g^{-3}$ (as $g \ge 1$, $k \ge 1$). Hence, with (d),

$$\begin{aligned}\log \mathrm{on} &\le f\log C + C^2m^5f\lambda + Cm^5f\lambda + Cm^6f\lambda + \frac{kf}{2}\log C - \frac{3kf}{2}\log g \\ &\le kf\kappa + 3C^2m^6f\lambda - 12kf\kappa - 12kf\lambda \le -11kf\kappa,\end{aligned}$$

using $\log C \le \kappa$, (c), and $3C^2m^6 \le k$ from (b). So $\mathrm{on} \le e^{-kf\log k}$.

Step 6: the loop share. Put $X = kf\log k$. By Steps 2, 4, 5 and the hypothesis $\log(3A) \le X/6$,

$$\begin{aligned}A\Big(\sum_s \mathrm{nd}_s + \Gamma^2\sum_s \mathrm{dg}_s + \mathrm{on}\Big) &\le A(e^{-4X} + e^{-X/2} + e^{-X}) \le 3A\,e^{-X/2} \\ &= e^{-X/3}\exp\Big(\log(3A) - \frac{X}{6}\Big) \le e^{-X/3}.\end{aligned}$$

Now let a pair expansion at scale $\vartheta \ge 0$ have (Lb3) with constant A. The sets $\mathrm{Pr}_{\ge 2}$ and $(\mathrm{Pr}_1 \cap (\mathcal{M}_\mathrm{g}\times\mathcal{M}_\mathrm{g})) \setminus \mathrm{Sc}$ are contained in Lp, the summands $|\langle z_t, z_{t'}\rangle|$ are nonnegative and $c_\mathrm{rw} > 0$, so each of the two sums of (Pe6), multiplied by c_rw, is at most $c_\mathrm{rw}\sum_\mathrm{Lp}|\langle z_t, z_{t'}\rangle| \le A(\dots)\vartheta \le e^{-X/3}\vartheta$. □

Theorem 15.5. *(i) Let $\mathcal{H}_2$ be a complex Hilbert space, S a countable set with vectors $z_t \in \mathcal{H}_2$ ($t \in S$) such that $\sum_{t\in S}\|z_t\| < \infty$, let $R \subseteq S\times S$ and let $\lambda \ge 0$ be real. Let sets Cl, P, N, maps $\mathrm{cl}, \mathrm{pt}, \mathrm{nm}$ on S, functions $w, P_\mathrm{n}, J, n_\mathrm{g}, a_2$ and reals $S_w, T_\mathrm{pt} \ge 0$ be given as in Definition 15.2 with S in place of $\mathcal{M}_\mathrm{n}$, having (Ng1)–(Ng4) and (Ng6) with S and R in place of $\mathcal{M}_\mathrm{n}$ and $\mathrm{Pr}_1 \cap (\mathcal{M}_\mathrm{n}\times\mathcal{M}_\mathrm{n})$, and (Ng5) with λ in place of $2^{-(k-2r-5)}$. Then*

$$\sum_{(t,t')\in R} \mathrm{Re}\langle z_t, z_{t'}\rangle \le \lambda\, S_w\, T_\mathrm{pt},$$

the series converging absolutely.

(ii) Let a pair expansion at scale $\vartheta \ge 0$ be given, let $r \ge 0$ and $k \ge 2r+5$ be integers, and let non-generic row data for it have the properties (Ng1)–(Ng6). Then

$$c_\mathrm{rw} \sum_{(t,t')\in \mathrm{Pr}_1\cap(\mathcal{M}_\mathrm{n}\times\mathcal{M}_\mathrm{n})} \mathrm{Re}\langle z_t, z_{t'}\rangle \le 2^{-(k-2r-5)}\, c_\mathrm{rw}\, S_w\, T_\mathrm{pt}.$$

In particular, if $Q \ge 0$ and $c_\mathrm{rw}S_wT_\mathrm{pt} \le Q\vartheta$, the pair expansion satisfies the non-generic row condition (Pe8) with non-generic share $\beta_\mathrm{ng} = 2^{-(k-2r-5)}Q$.

Proof. **(i): the sum over R is a sum of squares over classes.** By (Ng1), $R = \{(t,t') \in S^2 : \mathrm{cl}(t) = \mathrm{cl}(t')\}$. As $\sum_{t\in S}\|z_t\| < \infty$, $\sum_{(t,t')\in S^2}|\langle z_t, z_{t'}\rangle| \le (\sum_t \|z_t\|)^2 < \infty$, and absolutely

convergent series may be regrouped. For a class c put $U_c = \sum_{t \in S,\, \mathrm{cl}(t)=c} z_t$. Grouping the pairs by the common class and using bilinearity of the inner product on absolutely convergent sums,

$$\sum_{(t,t')\in R} \mathrm{Re}\langle z_t, z_{t'}\rangle = \sum_{c\in \mathrm{Cl}} \mathrm{Re}\big\langle U_c, U_c\big\rangle = \sum_{c\in \mathrm{Cl}} \|U_c\|^2,$$

only countably many classes contributing (S is countable).

Cauchy–Schwarz over points and normals. Fix c and let O_c be the set of (γ,ν) with (c,γ,ν) occupied. If (c,γ,ν) is not occupied, every z_t in the sum defining $u(c,\gamma,\nu)$ vanishes and $u(c,\gamma,\nu)=0$; so, regrouping, $U_c = \sum_{(\gamma,\nu)\in O_c} u(c,\gamma,\nu)$, absolutely convergent, O_c countable. For a finite $F \subseteq O_c$, the Cauchy–Schwarz inequality gives

$$\Big\| \sum_{(\gamma,\nu)\in F} u(c,\gamma,\nu)\Big\|^2 \le \Big(\sum_{(\gamma,\nu)\in F} \frac{1}{w(\gamma)P_{\mathrm{n}}(\gamma)}\Big)\Big(\sum_{(\gamma,\nu)\in F} w(\gamma)P_{\mathrm{n}}(\gamma)\|u(c,\gamma,\nu)\|^2\Big).$$

Let $F_P \subseteq P_{\mathrm{oc}}$ be the finite set of points occurring in F. By (Ng2), each $\gamma \in F_P$ occurs with at most $P_{\mathrm{n}}(\gamma)$ normals, so by (Ng3) the first factor is at most $\sum_{\gamma\in F_P} w(\gamma)^{-1} \le S_w$. Letting F exhaust O_c and using continuity of the norm,

$$\|U_c\|^2 \le S_w \sum_{(\gamma,\nu)\in O_c} w(\gamma)P_{\mathrm{n}}(\gamma)\|u(c,\gamma,\nu)\|^2.$$

Local factor and point sum. Summing over c (all terms nonnegative), then using (Ng4), and for each $\gamma \in P_{\mathrm{oc}}$ the bound (Ng5) with λ on every finite set of pairs (c,ν) (hence on their supremum),

$$\begin{aligned}\sum_c \|U_c\|^2 &\le S_w \sum_{\gamma\in P_{\mathrm{oc}}} w(\gamma)P_{\mathrm{n}}(\gamma)J(\gamma) \sum_{(c,\nu):\,(c,\gamma,\nu)\ \text{occupied}} a_2(c,\gamma,\nu)\\ &\le \lambda\, S_w \sum_{\gamma\in P_{\mathrm{oc}}} w(\gamma)P_{\mathrm{n}}(\gamma)n_{\mathrm{g}}(\gamma)J(\gamma),\end{aligned}$$

and the last sum is at most T_{pt} by (Ng6), applied to its finite partial sums. This is (i).

(ii). Take $\mathcal{H}_2$ the second space of the pair expansion, $S = \mathcal{M}_{\mathrm{n}}$ with its vectors z_t, $R = \mathrm{Pr}_1 \cap (\mathcal{M}_{\mathrm{n}} \times \mathcal{M}_{\mathrm{n}})$ and $\lambda = 2^{-(k-2r-5)}$. Then $\sum_{t\in S}\|z_t\| < \infty$ by (Pe1), and (Ng1)–(Ng6) of the non-generic row data are the hypotheses of (i) for these choices. So (i) gives the sum bound with $2^{-(k-2r-5)}S_wT_{\mathrm{pt}}$; multiplying by $c_{\mathrm{rw}} > 0$ gives the inequality. If $c_{\mathrm{rw}}S_wT_{\mathrm{pt}} \le Q\vartheta$, the right side is at most $2^{-(k-2r-5)}Q\vartheta$, which is (Pe8) with $\beta_{\mathrm{ng}} = 2^{-(k-2r-5)}Q$.

□

Definition 15.6. Points and towers. Let K be a field. A **point** is a finite sequence $u = ((m_1,t_1),\dots,(m_n,t_n))$, $n \ge 0$, of **blocks** (m_a,t_a) with $m_a \in \mathbb{Z}_{\ge 1}$ (the **size**) and $t_a \in K^\times$ (the **coordinate**); its **level** is $|u| = m_1+\cdots+m_n$, the block (m_a,t_a) **starts at** $1+m_1+\cdots+m_{a-1}$, $\varnothing$ is the empty point and $u\cdot(m,t)$ is u followed by the block (m,t). A **tower** is a family $\mathcal{S} = (\mathcal{S}_{j,m})_{j,m\ge 1}$ of finite subsets of $K^\times$; for $i \ge 0$, $\mathcal{X}_i(\mathcal{S})$ is the (finite) set of points u of level i such that every block (m_a,t_a) of u has $t_a \in \mathcal{S}_{j,m_a}$, j the place where it starts. A function κ defined on $P\times P$ for a finite set P of points (or on a larger set) is **positive semidefinite on** P if $\sum_{u,u'\in P} \overline{w_u}\,\kappa(u,u')\,w_{u'} \ge 0$ for all $w \in \mathbb{C}^P$. For κ defined on pairs of points and $t,t' \in K^\times$, $m \ge 1$, put $\kappa_m^{t,t'}(h,h') = \kappa(h\cdot(m,t), h'\cdot(m,t'))$.

Data. Let $r \ge 0$, $f \ge 1$ and $n_{\mathrm{d}} \ge 1$ be integers, put $N_{\mathrm{top}} = 4n_{\mathrm{d}}(r+1)$, and let $\beta_{\mathrm{L}}, \beta_{\mathrm{B}} \ge 0$ be real numbers. **Poisson recursion data** over K with parameters (r,f,n_{d}), **lattice-sum bound** β_{L} and **block ratio** β_{B} consist of

- a finite set $\mathcal{A}$ of **derivative words** with a **length** $|\alpha| \in \mathbb{Z}_{\geq 0}$ and a **weight** $\mathrm{wt}(\alpha) > 0$ for each $\alpha \in \mathcal{A}$, and an **empty word** $\alpha_\varnothing \in \mathcal{A}$ with $|\alpha_\varnothing| = 0$, $\mathrm{wt}(\alpha_\varnothing) = 1$; $\mathcal{A}_n = \{\alpha \in \mathcal{A} : |\alpha| \leq n\}$;
- for every real $\eta > 0$, $0 \leq i \leq r+1$ and $\alpha \in \mathcal{A}$ a **wave kernel** $g_{\eta,i,\alpha}$ and for every $0 \leq i \leq r+1$ a **coefficient kernel** k_i, complex functions on pairs of points;
- real numbers $\mathrm{ex}_1, \dots, \mathrm{ex}_{r+1}$ (the **excesses**), additive subgroups $L_{j,m}$, $L'_{j,m}$ $(j, m \geq 1)$ and $L_i^\vee$ $(1 \leq i \leq r+1)$ of K, and real functions $\mathrm{mj}_i^\vee$, $\mathrm{mj}'_{j,m}$ on K (the **majorants**);
- for all $\eta > 0$, $1 \leq i \leq r+1$, $\alpha \in \mathcal{A}$, finite sets P of points of level $i-1$ and functions κ on $P \times P$ a complex function $z \mapsto \widehat{\mathrm{En}}_{\eta,i,\alpha}(P, \kappa; z)$ on K (the **Fourier transform**);
- a real number J, a complex Hilbert space $\mathcal{H}$ and a map W from points to $\mathcal{H}$,

with the following properties, in which, for a finite set P of points, a function κ on $P \times P$, $t, t' \in K^\times$, $m \geq 1$ and $0 \leq i \leq r+1$, the **energies** are

$$\mathrm{En}_{\eta,i,\alpha}(P, \kappa) = \frac{1}{\mathrm{wt}(\alpha)} \operatorname{Re} \sum_{u,u' \in P} \kappa(u, u')\, g_{\eta,i,\alpha}(u, u'),$$

$$\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P, \kappa; t, t') = \frac{1}{\mathrm{wt}(\alpha)} \sum_{h,h' \in P} \kappa(h, h')\, g_{\eta,i,\alpha}(h \cdot (m, t), h' \cdot (m, t')),$$

and $j = i - m + 1$ whenever i and m are given.

(Pt1) Positivity. For all $\eta > 0$, i, α and finite sets P of points, $g_{\eta,i,\alpha}$ and k_i are positive semidefinite on P; $k_0(\varnothing, \varnothing) = 1$.

(Pt2) Support of the coefficient kernels. If $1 \leq m \leq i \leq r+1$, h, h' are points of level $i-m$, $t \neq t'$ in $K^\times$ and $k_i(h \cdot (m, t), h' \cdot (m, t')) \neq 0$, then $(i, m) \neq (r+1, 1)$ and $t^{-1} - t'^{-1} \in L'_{j,m}$.

(Pt3) Theta majorants. $0 \leq \mathrm{ex}_i \leq 1$ for $1 \leq i \leq r+1$, and for every tower $\mathcal{S}$ there are complex functions $\Theta_{i,m,t}$ on pairs of points $(1 \leq m \leq i \leq r+1,\ t \in \mathcal{S}_{j,m})$ such that, with $\mathcal{X} = \mathcal{X}_{i-m}(\mathcal{S})$: (a) $\Theta_{i,m,t} - (k_i)^{t,t}_m$ is positive semidefinite on $\mathcal{X}$; (b) $\Theta_{i,m,t} = \Theta_{i,m,t'}$ on $\mathcal{X} \times \mathcal{X}$ if $t - t' \in L_{j,m}$; (c) $(1 + \mathrm{ex}_i) k_{i-m} - \sum_{t \in R} \Theta_{i,m,t}$ is positive semidefinite on $\mathcal{X}$ for every $R \subseteq \mathcal{S}_{j,m}$ whose elements are pairwise incongruent modulo $L_{j,m}$.

(Pt4) Poisson summation. Let $\eta > 0$, $1 \leq i \leq r+1$, $\alpha \in \mathcal{A}$, P a finite set of points of level $i-1$, κ positive semidefinite on P, $t_0 \in K$ and $B \in \mathbb{R}$ with $\sum_{z \in Z} |\widehat{\mathrm{En}}_{\eta,i,\alpha}(P, \kappa; z)| \leq B$ for every finite $Z \subseteq L_i^\vee \setminus \{0\}$. Then $\sum_{t \in S} \operatorname{Re} \mathrm{En}^{\uparrow}_{\eta,i,1,\alpha}(P, \kappa; t, t) \leq |\widehat{\mathrm{En}}_{\eta,i,\alpha}(P, \kappa; 0)| + B$ for every finite $S \subseteq (t_0 + L_{i,1}) \setminus \{0\}$.

(Pt5) Fourier decay of the wave packets. For all $\eta > 0$, $1 \leq i \leq r+1$ and $\alpha \in \mathcal{A}$ with $|\alpha| + n_{\mathrm{d}} \leq N_{\mathrm{top}}$ there is $\theta \colon \mathcal{A}_{|\alpha|+n_{\mathrm{d}}} \to [0, \infty)$ with $\sum_{\alpha'} \theta(\alpha') \leq 2^f$ such that for every finite set P of points of level $i-1$ and every κ positive semidefinite on P: $\widehat{\mathrm{En}}_{\eta,i,\alpha}(P, \kappa; 0) = \mathrm{En}_{\eta,i-1,\alpha}(P, \kappa)$ and $|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P, \kappa; z)| \leq \mathrm{mj}_i^\vee(z) \sum_{\alpha'} \theta(\alpha') \mathrm{En}_{\eta,i-1,\alpha'}(P, \kappa)$ for $z \in L_i^\vee \setminus \{0\}$.

(Pt6) Off-diagonal decay. For all $\eta > 0$, $1 \leq m \leq i \leq r+1$ with $(i, m) \neq (r+1, 1)$ and $\alpha \in \mathcal{A}$ with $|\alpha| + n_{\mathrm{d}} \leq N_{\mathrm{top}}$ there is $\theta \colon \mathcal{A}_{|\alpha|+n_{\mathrm{d}}} \to [0, \infty)$ with $\sum_{\alpha'} \theta(\alpha') \leq 2 \cdot 3^f$ such that for every finite set P of points of level $i-m$, finite $S \subseteq K^\times$, κ positive semidefinite on

$\{h\cdot(m,t): h\in P,\ t\in S\}$ and $t\neq t'$ in S,

$$|\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa_m^{t,t'};t,t')| \le \mathrm{mj}'_{j,m}(t^{-1}-t'^{-1})\cdot\frac{1}{2}\sum_{\alpha'}\theta(\alpha')\Big(\mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha'}(P,\kappa_m^{t,t};t,t) + \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha'}(P,\kappa_m^{t',t'};t',t')\Big).$$

(Pt7) Degenerate blocks. For all $\eta>0$, $2\le m\le i\le r+1$ and $\alpha\in\mathcal{A}$ with $|\alpha|+(m+1)n_{\mathrm{d}}\le N_{\mathrm{top}}$ there is $\theta\colon \mathcal{A}_{|\alpha|+(m+1)n_{\mathrm{d}}}\to[0,\infty)$ with $\sum_{\alpha'}\theta(\alpha')\le 1$ such that for every finite set P of points of level $i-m$, κ positive semidefinite on P, $t_0\in K$ and finite $S\subseteq(t_0+L_{j,m})\setminus\{0\}$: $\sum_{t\in S}\mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa;t,t)\le\beta_{\mathrm{B}}^{2(m-1)}\sum_{\alpha'}\theta(\alpha')\,\mathrm{En}_{\eta,i-m,\alpha'}(P,\kappa)$.

(Pt8) Lattice sums. For $1\le i\le r+1$ and every finite $Z\subseteq L_i^{\vee}\setminus\{0\}$ we have $\sum_{z\in Z}\mathrm{mj}_i^{\vee}(z)\le\beta_{\mathrm{L}}$; for $1\le m\le i\le r+1$ with $(i,m)\neq(r+1,1)$ and every finite $Z\subseteq L'_{j,m}\setminus\{0\}$ we have $\sum_{z\in Z}\mathrm{mj}'_{j,m}(z)\le\beta_{\mathrm{L}}$.

(Pt9) Limit and cutoff. For every $\alpha\in\mathcal{A}_{N_{\mathrm{top}}}$, $\mathrm{Re}\,g_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}(\alpha)\to J$ as $\eta\to0^+$; for every finite set P of points of level $r+1$ there is $\eta_0>0$ with $g_{\eta,r+1,\alpha_\varnothing}(u,u')=\langle W(u'),W(u)\rangle$ for all $0<\eta<\eta_0$ and $u,u'\in P$ with $k_{r+1}(u,u')\neq0$.

Definition 15.7. Let Poisson recursion data over a field K with parameters (r,f,n_{d}) and block ratio β_{B} be given. A **local point** is a finite sequence of blocks (m,c) with $m\in\mathbb{Z}_{\ge1}$ and $c\in\mathbb{C}^{\times}$; level, $\varnothing$, $p\cdot(m,c)$ and positive semidefiniteness are as for points. For a field embedding $\sigma_v\colon K\to\mathbb{C}$ and a point $u=((m_a,t_a))_a$ put $\sigma_v(u)=((m_a,\sigma_v(t_a)))_a$. An **archimedean product structure** on the data consists of field embeddings $\sigma_1,\dots,\sigma_f\colon K\to\mathbb{C}$, with $\sigma=(\sigma_v)_v\colon K\to\mathbb{C}^f$; real numbers $g>0$, $T\ge1$, $C_4\ge1$ and $\mathrm{vol}(j,m)\ge0$ $(j,m\ge1)$; for each v, **local wave kernels** $g^v_{\eta,i,\alpha}$ ($\eta>0$, $0\le i\le r+1$, $\alpha\in\mathcal{A}$), complex functions on pairs of local points, **local weights** $\mathrm{wt}_v(\alpha)>0$, a real number J_v, a complex Hilbert space $\mathcal{H}_v$ and a map W_v from local points to $\mathcal{H}_v$; such that, with $\langle\xi,c\rangle=\frac{2}{g}\sum_v\mathrm{Re}(\xi_vc_v)$ on $\mathbb{C}^f\cong\mathbb{R}^{2f}$:

(Aw1) Product form. $g_{\eta,i,\alpha}(u,u')=\prod_v g^v_{\eta,i,\alpha}(\sigma_v(u),\sigma_v(u'))$, $\mathrm{wt}(\alpha)=\prod_v\mathrm{wt}_v(\alpha)$, $J=\prod_vJ_v$ and $\langle W(u'),W(u)\rangle=\prod_v\langle W_v(\sigma_v(u')),W_v(\sigma_v(u))\rangle$ for all points u,u', η, i, α.

(Aw2) Positivity. Every $g^v_{\eta,i,\alpha}$ is positive semidefinite on every finite set of local points; every k_i is positive semidefinite on every finite set of points, and $k_0(\varnothing,\varnothing)=1$.

(Aw3) Integration over the new coordinate. For $1\le i\le r+1$: $\Lambda_i=\sigma(L_{i,1})$ is a lattice in $\mathbb{C}^f$; $\sigma(L_i^{\vee})=\{\xi:\langle\xi,\lambda\rangle\in\mathbb{Z}\ \forall\lambda\in\Lambda_i\}$; there is C_i with $\#\{\lambda\in\Lambda_i:|\lambda_v|\le R_v\ \forall v\}\le C_i\prod_v(1+R_v)^2$ for all $R_v\ge0$; there are real numbers $d_v(i)>0$ $(1\le v\le f)$ with $\prod_v d_v(i)=\mathrm{covol}(\Lambda_i)$; for every v, $\eta>0$, $\alpha\in\mathcal{A}$ and local points p,q of level $i-1$ there are a continuous function $c\mapsto G^v_{\eta,i,\alpha}(p,q;c)$ on $\mathbb{C}$ and $C\ge0$ with $G^v_{\eta,i,\alpha}(p,q;c)=g^v_{\eta,i,\alpha}(p\cdot(1,c),q\cdot(1,c))$ for $c\neq0$, $|G^v_{\eta,i,\alpha}(p,q;c)|\le C(1+|c|)^{-3}$ for all $c\in\mathbb{C}$, and $\int_{\mathbb{C}}G^v_{\eta,i,\alpha}(p,q;c)\,dc=d_v(i)\,g^v_{\eta,i-1,\alpha}(p,q)$; and for all $\eta>0$, $\alpha\in\mathcal{A}$, finite sets P of points of level $i-1$, κ positive semidefinite on P and $z\in L_i^{\vee}$, $\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)=\mathrm{covol}(\Lambda_i)^{-1}\int_{\mathbb{C}^f}\varphi_{\eta,i,\alpha}(P,\kappa;c)\,e^{2\pi i\langle\sigma(z),c\rangle}dc$, where $\varphi_{\eta,i,\alpha}(P,\kappa;c)=\frac{1}{\mathrm{wt}(\alpha)}\sum_{h,h'\in P}\kappa(h,h')\prod_v G^v_{\eta,i,\alpha}(\sigma_v(h),\sigma_v(h');c_v)$ (Lebesgue measure on $\mathbb{C}=\mathbb{R}^2$ and on $\mathbb{C}^f=\mathbb{R}^{2f}$; the covolume is taken for the latter).

(Aw4) Wave decay at every set of places. There are $0\le\varrho'_{i,v}\le\varrho_{i,v}$ $(1\le i\le r+1,\ 1\le v\le f)$ with $\mathrm{mj}_i^{\vee}(z)=\prod_v\min(1,(\varrho_{i,v}/|\sigma_v(z)|)^{n_{\mathrm{d}}})$ for $z\in L_i^{\vee}\setminus\{0\}$, such that for all $\eta>0$, $1\le i\le r+1$, α with $|\alpha|+n_{\mathrm{d}}\le N_{\mathrm{top}}$ and $A\subseteq\{1,\dots,f\}$ there is $\theta_A\colon\mathcal{A}_{|\alpha|+n_{\mathrm{d}}}\to[0,\infty)$ with $\sum\theta_A\le1$ and, for all P, κ as in (Aw3) and $z\in L_i^{\vee}\setminus\{0\}$, $\prod_{v\in A}|\sigma_v(z)|^{n_{\mathrm{d}}}\,|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)|\le\prod_{v\in A}\varrho'^{\,n_{\mathrm{d}}}_{i,v}\sum_{\alpha'}\theta_A(\alpha')\mathrm{En}_{\eta,i-1,\alpha'}(P,\kappa)$.

(Aw5) Lift bounds. There are $\varrho_{j,m,v} \geq 0$ with $\mathrm{mj}'_{j,m}(z) = \prod_v \min(1, (\varrho_{j,m,v}/|\sigma_v(z)|)^{n_\mathrm{d}})$ for $z \in K^\times$ $(1 \leq m \leq i \leq r+1,\ (i,m) \neq (r+1,1))$, and $0 \leq \varrho'_{j,m,v} \leq \varrho_{j,m,v}$, $\lambda_{j,m,v} \geq 0$ with $2\lambda_{j,m,v} \leq \varrho_{j,m,v}$, such that for all $\eta > 0$ and α with $|\alpha| + n_\mathrm{d} \leq N_\mathrm{top}$, writing $d(P,\kappa;t;\alpha') = \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha'}(P,\kappa;t,t)$: (a) for $1 \leq m \leq i \leq r$ and every $A \subseteq \{1,\dots,f\}$ there is $\theta_A\colon \mathcal{A}_{|\alpha|+n_\mathrm{d}} \to [0,\infty)$ with $\sum \theta_A \leq 2$ such that for every finite set P of points of level $i-m$, finite $S \subseteq K^\times$, κ positive semidefinite on $\{h\cdot(m,t) : h \in P, t \in S\}$ and $t \neq t'$ in S, $\prod_{v\in A}|\sigma_v(t^{-1}-t'^{-1})|^{n_\mathrm{d}}|\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa^{t,t'}_m;t,t')| \leq \prod_{v\in A}\varrho'^{\,n_\mathrm{d}}_{j,m,v}\cdot \frac{1}{2}\sum_{\alpha'}\theta_A(\alpha')(d(P,\kappa^{t,t}_m;t;\alpha') + d(P,\kappa^{t',t'}_m;t';\alpha'))$; (b) for $i = r+1$, $2 \leq m \leq r+1$ and every $B \subseteq \{1,\dots,f\}$ there is $\theta_B\colon \mathcal{A}_{|\alpha|+n_\mathrm{d}} \to [0,\infty)$ with $\sum\theta_B \leq 1$ such that for every finite set P of points of level $r+1-m$, κ positive semidefinite on P and $t \in K^\times$, $d(P,\kappa;t;\alpha) \leq \prod_{v\in B}(|\sigma_v(t)|\lambda_{j,m,v})^{2n_\mathrm{d}}\sum_{\alpha'}\theta_B(\alpha')d(P,\kappa;t;\alpha')$.

(Aw6) Degenerate blocks. $\beta_\mathrm{B} = (C_4/T)^f$ and $\mathrm{vol}(j,m) \leq T^{-2f}$ for all j,m; for all $\eta > 0$, $2 \leq m \leq i \leq r+1$ and α with $|\alpha|+(m+1)n_\mathrm{d} \leq N_\mathrm{top}$ there are $0 \leq M \leq C_4^{fm}\prod_{1\leq m'<m}\mathrm{vol}(j,m')$ and $\theta\colon \mathcal{A}_{|\alpha|+mn_\mathrm{d}} \to [0,\infty)$ with $\sum\theta \leq 1$ such that for every finite set P of points of level $i-m$, κ positive semidefinite on P, $t_0 \in K$ and finite $S \subseteq (t_0 + L_{j,m}) \setminus \{0\}$, $\sum_{t\in S}\mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa;t,t) \leq M\sum_{\alpha'}\theta(\alpha')\mathrm{En}_{\eta,i-m,\alpha'}(P,\kappa)$.

(Aw7) Limit and top. For every v and $\alpha \in \mathcal{A}_{N_\mathrm{top}}$, $g^v_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}_v(\alpha) \to J_v$ as $\eta \to 0^+$; for every v and every finite set Q of local points of level $r+1$ there is $\eta_0 > 0$ with $g^v_{\eta,r+1,\alpha\varnothing}(p,q) = \langle W_v(q), W_v(p)\rangle$ for $0 < \eta < \eta_0$ and $p,q \in Q$.

Lemma 15.8. *The notation introduced here is local to this result and to the results that apply it. Let S_mn, V, e_1 be real numbers, let $c_\mathrm{rw}, d, d', D^* > 0$, and let $\rho, m_0, c, c', C_\infty, U_\mathrm{loc}, M_\mathrm{loc}, v_Z$, $\mu_K, \mu^\natural_K, \mu^\circ_K, \mu_S, \mu_{S'}, n_\pi, n_{\pi'}, \deg_\pi$ be positive real numbers. Assume the following.*

(Mx1) Poisson part. *Poisson recursion data over a field K with parameters (r,f,n_d), lattice-sum bound β_L and block ratio β_B satisfy (Pt2), (Pt3) and (Pt8), carry an archimedean product structure, and satisfy $(r+1)(2\cdot 3^f\beta_\mathrm{L} + 4\beta_\mathrm{B}) \leq 1$. There are a set I, complex functions a_ι on points $(\iota \in I)$ with $a_\iota(u) \neq 0$ only if u has level $r+1$ and $\sum_u |a_\iota(u)|\,\|W(u)\| < \infty$, and a real number $s \geq 0$ with $\max(s,1)\prod_{i=1}^{r+1}(1+\mathrm{ex}_i) \leq e_1$, such that (Mi1) and (Mi2) hold for these and for c, c', V, m_0.*

(Mx2) Archimedean integral. *There are data satisfying all hypotheses of Proposition 15.18 with $d_\sigma = \deg_\pi$; let $J_\infty \in [0,\infty]$ be the lower integral on the left side of its conclusion. The number J of the Poisson recursion data of (Mx1) satisfies $J = v_Z\,J_\infty/(C_\infty U_\mathrm{loc})$.*

(Mx3) Stabilisers. *There are a CM extension E/F, a nondegenerate hermitian space V over E of dimension n, a Haar measure μ_G on $\mathrm{U}(\mathsf{V})(\mathbb{A}_F)$, and tuples X_1, X_2, X_3 of sizes a_1, a_2, a_3 as in item 1 of Proposition 15.20 (so $a_j \geq 1$, $2a_j < n$, nondegenerate Gram matrices), with stabilisers H_1, H_2, H_3 and Haar measures μ'_1, μ'_2, μ'_3 on their adelic points satisfying (15.12). Put $v_H = \mu'_1([H_1])$, $v_{H'} = \mu'_2([H_2])$, $v_B = \mu'_3([H_3])$, $v_G = \mu_G([\mathrm{U}(\mathsf{V})])$, and assume $D^* = \deg_\pi\, v_G/\mu^\circ_K$.*

(Mx4) Word levels. *H_1 is a connected reductive group over F with $H_1(F_\infty)$ compact, $\mu'_1 = \mu_\infty \otimes \mu_f$ for Haar measures μ_∞ on $H_1(F_\infty)$ and μ_f on $H_1(\mathbb{A}_{F,f})$, and there are compact open subgroups $K'' \subseteq K_1 \subseteq H_1(\mathbb{A}_{F,f})$ with $H_1(F) \cap cK''c^{-1} = \{1\}$ for every $c \in H_1(\mathbb{A}_{F,f})$, $[K_1 : K''] = c_\mathrm{rw}$ and*

$$d = n_\pi\,\big|H_1(F)\backslash H_1(\mathbb{A}_{F,f})/K''\big|.$$

Put $v_{H,\infty} = \mu_\infty(H_1(F_\infty))$, $\mu^\circ_H = \mu_f(K'')$, $\mu_H = \mu_f(K_1)$. The same holds for H_2, d', $n_{\pi'}$, with numbers $v_{H',\infty}$, $\mu^\circ_{H'}$, $\mu_{H'}$.

(Mx5) Relations. *With these numbers, (Ma1), (Ma3), (Ma6) and (Ma7) hold.*

Then $(S_{\mathrm{mn}}; c_{\mathrm{rw}}, d, d', D^*)$ *has main-row mass data, with the numbers* V, J, J_∞, e_1 *and* ρ, m_0, $c, c', C_\infty, \deg_\pi, U_{\mathrm{loc}}, M_{\mathrm{loc}}, v_Z, v_B, v_G, v_H, v_{H'}, v_{H,\infty}, v_{H',\infty}, n_\pi, n_{\pi'}, \mu_K, \mu_K^\natural, \mu_K^\circ, \mu_S, \mu_{S'}, \mu_H, \mu_{H'}$, $\mu_H^\circ, \mu_{H'}^\circ$ *above, density factor* e_1 *and Poisson error*

$$\delta_{\mathrm{P}} = 15\,(r+1)(2\cdot 3^f\beta_{\mathrm{L}} + 4\beta_{\mathrm{B}}).$$

Proof. We check that the numbers listed are real, that those required positive in Definition 14.11 are positive, and (Ma1)–(Ma9).

(Ma2) and (Ma4). By Theorem 15.14, the Poisson recursion data of (Mx1), which carry an archimedean product structure, satisfy (Pt1), (Pt4), (Pt5), (Pt6), (Pt7) and (Pt9); with (Pt2), (Pt3), (Pt8) from (Mx1) they satisfy (Pt1)–(Pt9). Together with $(r+1)(2\cdot 3^f\beta_{\mathrm{L}}+4\beta_{\mathrm{B}}) \le 1$, the functions a_ι with their support and summability conditions, $s \ge 0$, $m_0 > 0$, $\max(s,1)\prod_i(1+\mathrm{ex}_i) \le e_1$ and (Mi1), (Mi2), these are all hypotheses of Corollary 15.9. It gives $\delta_{\mathrm{P}} \ge 0$, $e_1 \ge 1$, and $c\,c'\,V \le (1+\delta_{\mathrm{P}})\,e_1\,m_0\,J$; so $e_1 \ge 0$ and (Ma2), (Ma4) hold.

(Ma5). By Proposition 15.18, applied to the data of (Mx2) with $d_\sigma = \deg_\pi$, $J_\infty \le 1/\deg_\pi$. As a lower integral of a nonnegative function, $J_\infty \ge 0$; hence J_∞ is a real number in $[0, 1/\deg_\pi]$, and $J = v_Z J_\infty/(C_\infty U_{\mathrm{loc}})$ by (Mx2). This is (Ma5).

(Ma8). The group H_1, the measure $\mu_1' = \mu_\infty \otimes \mu_f$ and the subgroups $K'' \subseteq K_1$ satisfy the hypotheses of Lemma 15.19 (with $H = H_1$, $K = K_1$). $H_1(F_\infty)$ is compact and nonempty, so $0 < v_{H,\infty} < \infty$; K_1 and K'' are compact open, so $0 < \mu_H, \mu_H^\circ < \infty$. By item 1 of Lemma 15.19, $v_H = \mu_1'([H_1]) = v_{H,\infty}\,\mu_H \sum_{c\in R(K_1)} |H_1(F) \cap cK_1c^{-1}|^{-1}$ is a finite sum of positive numbers over a nonempty finite set, so $0 < v_H < \infty$. By item 2, $\mu_H = [K_1 : K'']\,\mu_H^\circ = c_{\mathrm{rw}}\,\mu_H^\circ$ and $|H_1(F)\backslash H_1(\mathbb{A}_{F,f})/K''| = v_H/(v_{H,\infty}\,\mu_H^\circ)$; by (Mx4), $d = n_\pi v_H/(v_{H,\infty}\mu_H^\circ)$. The same argument for H_2 gives $0 < v_{H'}, v_{H',\infty}, \mu_{H'}, \mu_{H'}^\circ < \infty$, $d' = n_{\pi'}v_{H'}/(v_{H',\infty}\mu_{H'}^\circ)$ and $\mu_{H'} = c_{\mathrm{rw}}\mu_{H'}^\circ$. This is (Ma8).

(Ma9). By item 1 of Proposition 15.20, applied to X_1 and to X_3, $\mu_1'([H_1]) = \mu_G([\mathrm{U}(\mathsf{V})]) = \mu_3'([H_3]) < \infty$; so $v_G = v_B = v_H \in (0,\infty)$. By item 2, $\mu_3'([H_3])\,\mu_G([\mathrm{U}(\mathsf{V})]) = \mu_1'([H_1])\,\mu_2'([H_2])$, that is $v_B v_G = v_H v_{H'}$; and $D^* = \deg_\pi v_G/\mu_K^\circ$ by (Mx3). This is (Ma9).

The rest. (Ma1), (Ma3), (Ma6), (Ma7) hold by (Mx5). The numbers $\rho, m_0, c, c', C_\infty$, $\deg_\pi, U_{\mathrm{loc}}, M_{\mathrm{loc}}, v_Z, n_\pi, n_{\pi'}, \mu_K, \mu_K^\natural, \mu_K^\circ, \mu_S, \mu_{S'}$ are positive by hypothesis, and $v_B, v_G, v_H, v_{H'}$, $v_{H,\infty}, v_{H',\infty}, \mu_H, \mu_{H'}, \mu_H^\circ, \mu_{H'}^\circ$ were shown positive; $V, J, J_\infty, e_1, \delta_{\mathrm{P}}$ are real. Hence all clauses of Definition 14.11 hold, with density factor e_1 and Poisson error δ_{P}. □

Corollary 15.9. *Let Poisson recursion data over a field* K *with parameters* (r, f, n_{d})*, lattice-sum bound* β_{L} *and block ratio* β_{B} *satisfy (Pt1)–(Pt9) and* $(r+1)(2\cdot 3^f\beta_{\mathrm{L}} + 4\beta_{\mathrm{B}}) \le 1$*, and put* $\delta_{\mathrm{P}} = 15(r+1)(2\cdot 3^f\beta_{\mathrm{L}} + 4\beta_{\mathrm{B}})$*. Let* I *be a set and* a_ι *(*$\iota \in I$*) complex functions on points with* $a_\iota(u) \ne 0$ *only if* u *has level* $r+1$ *and* $\sum_u |a_\iota(u)|\,\|W(u)\| < \infty$*. Let* $s \ge 0$*,* c, c', V, m_0, e_1 *be real numbers with* $m_0 \ge 0$ *and* $\max(s,1)\prod_{i=1}^{r+1}(1+\mathrm{ex}_i) \le e_1$*, such that*

(Mi1) Density domination. $s\,k_{r+1}(u,u') - \sum_{\iota\in R} a_\iota(u)\overline{a_\iota(u')}$ *is positive semidefinite on* P *for every finite set* P *of points of level* $r+1$ *and every finite* $R \subseteq I$*;*

(Mi2) Unfolding link. $c\,c'\,V \le m_0\,M$ *for every real* M *such that* $\sum_{\iota\in R} \|\sum_u a_\iota(u)W(u)\|^2 \le M$ *for all finite* $R \subseteq I$*.*

Then $\delta_{\mathrm{P}} \ge 0$*,* $e_1 \ge 1$*,* $J \ge 0$ *and*

$$c\,c'\,V \le (1+\delta_{\mathrm{P}})\,e_1\,m_0\,J;$$

in particular the numbers $V, J, e_1, \delta_{\mathrm{P}}, c, c', m_0$ satisfy (Ma2) and (Ma4).

Proof. **Signs.** We have $\delta_{\mathrm{P}} \geq 0$ since $\beta_{\mathrm{L}}, \beta_{\mathrm{B}} \geq 0$. By (Pt3), $\mathrm{ex}_i \geq 0$, so $e_1 \geq \max(s,1) \geq 1$. By (Pt1) the kernel $g_{\eta,0,\alpha}$ is positive semidefinite on $\{\varnothing\}$, so $g_{\eta,0,\alpha}(\varnothing,\varnothing) \geq 0$, and by (Pt9) J is a limit of the numbers $\mathrm{Re}\, g_{\eta,0,\alpha_\varnothing}(\varnothing,\varnothing)/\mathrm{wt}(\alpha_\varnothing) \geq 0$; hence $J \geq 0$.

Domination with a positive factor. Put $\beta_{\mathrm{d}} = \max(s,1) > 0$. For P and R as in (Mi1),

$$\beta_{\mathrm{d}}\, k_{r+1}(u,u') - \sum_{\iota\in R} a_\iota(u)\overline{a_\iota(u')} = (\beta_{\mathrm{d}} - s)\, k_{r+1}(u,u') + \Big(s\, k_{r+1}(u,u') - \sum_{\iota\in R} a_\iota(u)\overline{a_\iota(u')}\Big)$$

is positive semidefinite on P, as a nonnegative multiple of k_{r+1} (positive semidefinite by (Pt1)) plus a kernel positive semidefinite by (Mi1).

Conclusion. By Theorem 15.10 with this β_{d}, every finite $R \subseteq I$ has $\sum_{\iota\in R} \| \sum_u a_\iota(u) W(u)\|^2 \leq M$ with $M = \max(s,1)(1+\delta_{\mathrm{P}}) \prod_i (1+\mathrm{ex}_i)\, J$. By (Mi2), $c\,c'\,V \leq m_0 M$, and as $m_0 \geq 0$, $1+\delta_{\mathrm{P}} \geq 0$, $J \geq 0$ and $\max(s,1)\prod_i(1+\mathrm{ex}_i) \leq e_1$, $m_0 M \leq (1+\delta_{\mathrm{P}}) e_1 m_0 J$. The final assertion of the statement is, by definition, (Ma2) and (Ma4) for these numbers. □

Theorem 15.10. *Let Poisson recursion data over a field K with parameters (r, f, n_{d}), lattice-sum bound β_{L} and block ratio β_{B} satisfy (Pt1)–(Pt9), and suppose*

$$(r+1)\big(2\cdot 3^f \beta_{\mathrm{L}} + 4\beta_{\mathrm{B}}\big) \leq 1; \qquad \textit{put} \qquad \delta_{\mathrm{P}} = 15\,(r+1)\big(2\cdot 3^f \beta_{\mathrm{L}} + 4\beta_{\mathrm{B}}\big).$$

Let I be a set and, for $\iota \in I$, a_ι a complex function on points such that

1. *$a_\iota(u) \neq 0$ only if u has level $r+1$;*
2. *$\sum_u |a_\iota(u)|\, \|W(u)\| < \infty$, the sum over all points;*
3. *there is a real $\beta_{\mathrm{d}} > 0$ such that $\beta_{\mathrm{d}}\, k_{r+1}(u,u') - \sum_{\iota\in R} a_\iota(u)\overline{a_\iota(u')}$ is positive semidefinite on P for every finite set P of points of level $r+1$ and every finite $R \subseteq I$.*

Then for every finite $R \subseteq I$ the sums $\sum_u a_\iota(u) W(u)$ converge absolutely in $\mathcal{H}$, and

$$\sum_{\iota\in R} \Big\| \sum_u a_\iota(u)\, W(u) \Big\|^2 \leq \beta_{\mathrm{d}}\,(1+\delta_{\mathrm{P}}) \prod_{i=1}^{r+1} (1+\mathrm{ex}_i)\; J.$$

Proof. **The recursion on one tower.** Fix a tower $\mathcal{S}$ and $\eta > 0$, and let $\sigma_0, \dots, \sigma_{r+1} \geq 0$ be as in Lemma 15.11. Put $\delta_1 = 2\cdot 3^f \beta_{\mathrm{L}}$; then $(r+1)(\delta_1 + 4\beta_{\mathrm{B}}) \leq 1$, in particular $\delta_1 \leq 1$. By Lemma 15.11 the hypothesis of Lemma 15.13 holds with $\beta = \beta_{\mathrm{B}}$ (and $\mathrm{ex}_i \geq 0$ by (Pt3)), so

$$\sigma_{r+1}^2 \leq (1+\delta_{\mathrm{P}}) \prod_{i=1}^{r+1} (1+\mathrm{ex}_i)\, \sigma_0^2.$$

The only point of level 0 is $\varnothing$, so $\mathcal{X}_0 = \{\varnothing\}$, and $k_0(\varnothing,\varnothing) = 1$ by (Pt1); hence $\sigma_0^2 = s_0(\eta)$ with $s_0(\eta) = \max_{\alpha\in\mathcal{A}_{N_{\mathrm{top}}}} \mathrm{Re}\, g_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}(\alpha)$. As $\alpha_\varnothing \in \mathcal{A}_0$ and $\mathrm{wt}(\alpha_\varnothing) = 1$,

$$\begin{aligned} \mathrm{Re} \sum_{u,u'\in\mathcal{X}_{r+1}} k_{r+1}(u,u')\, g_{\eta,r+1,\alpha_\varnothing}(u,u') = \mathrm{En}_{\eta,r+1,\alpha_\varnothing}(\mathcal{X}_{r+1}, k_{r+1}) &\leq \sigma_{r+1}^2 \\ &\leq (1+\delta_{\mathrm{P}}) \prod_{i=1}^{r+1} (1+\mathrm{ex}_i)\, s_0(\eta). \end{aligned} \tag{15.1}$$

The coefficient energy on one tower. Fix a tower $\mathcal{S}$ and a finite $R \subseteq I$; $\mathcal{X} = \mathcal{X}_{r+1}(\mathcal{S})$ is a finite set of points of level $r+1$. Put $\Gamma(u,u') = \langle W(u'), W(u)\rangle$; it is positive semidefinite on $\mathcal{X}$, since $\sum_{u,u'} \overline{w_u}\, w_{u'} \langle W(u'), W(u)\rangle = \|\sum_u \overline{w_u} W(u)\|^2$. Put $C(u,u') = \sum_{\iota \in R} a_\iota(u)\overline{a_\iota(u')}$. Expanding the norms,

$$E_{\mathcal{X}} = \sum_{\iota \in R} \Big\| \sum_{u \in \mathcal{X}} a_\iota(u) W(u) \Big\|^2 = \sum_{u,u' \in \mathcal{X}} C(u,u')\, \Gamma(u,u').$$

By hypothesis 3 and the Schur product theorem, $(\beta_{\mathrm{d}} k_{r+1} - C)\Gamma$ is positive semidefinite on $\mathcal{X}$, so the sum of its entries is real and ≥ 0; hence $E_{\mathcal{X}} \leq \beta_{\mathrm{d}} \operatorname{Re} \sum_{u,u' \in \mathcal{X}} k_{r+1}(u,u')\Gamma(u,u')$. By (Pt9) there is $\eta_0 > 0$ such that for $0 < \eta < \eta_0$, $k_{r+1}(u,u')\Gamma(u,u') = k_{r+1}(u,u') g_{\eta,r+1,\alpha\varnothing}(u,u')$ for all $u, u' \in \mathcal{X}$ (both sides vanish where $k_{r+1}(u,u') = 0$). By (15.1) and $\beta_{\mathrm{d}} > 0$, $E_{\mathcal{X}} \leq \beta_{\mathrm{d}}(1+\delta_{\mathrm{P}}) \prod_i (1 + \mathrm{ex}_i)\, s_0(\eta)$ for $0 < \eta < \eta_0$. By (Pt9), each of the finitely many functions $\eta \mapsto \operatorname{Re} g_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}(\alpha)$, $\alpha \in \mathcal{A}_{N_{\mathrm{top}}}$, tends to J, hence so does their maximum $s_0(\eta)$; letting $\eta \to 0^+$ gives

$$E_{\mathcal{X}} \leq B_{\mathrm{A}} \qquad \text{for every tower } \mathcal{S}; \tag{15.2}$$

in particular $B_{\mathrm{A}} \geq 0$.

Exhaustion by towers. By hypothesis 2 and completeness of $\mathcal{H}$, $v_\iota = \sum_u a_\iota(u) W(u)$ converges absolutely, hence unconditionally: for $\tau > 0$ there is a finite set P_0 of points with $\|v_\iota - \sum_{u \in P} a_\iota(u) W(u)\| \leq \tau$ for every finite $P \supseteq P_0$ and every $\iota \in R$ (R is finite). Let $\mathcal{S}_{j,m}$ be the set of coordinates t of the blocks (m,t) starting at j of the points of P_0 of level $r+1$; this is a tower, and every point of P_0 of level $r+1$ lies in $\mathcal{X} = \mathcal{X}_{r+1}(\mathcal{S})$. For $P = \mathcal{X} \cup P_0$, the points of $P \setminus \mathcal{X}$ have level $\neq r+1$, so a_ι vanishes on them by hypothesis 1 and $\sum_{u \in P} a_\iota(u) W(u) = \sum_{u \in \mathcal{X}} a_\iota(u) W(u)$. Hence, by the triangle inequality in $\mathcal{H}^R$ and (15.2),

$$\Big(\sum_{\iota \in R} \|v_\iota\|^2 \Big)^{1/2} \leq E_{\mathcal{X}}^{1/2} + \tau |R|^{1/2} \leq B_{\mathrm{A}}^{1/2} + \tau |R|^{1/2}.$$

Letting $\tau \to 0$ proves the theorem. □

Lemma 15.11. *Let Poisson recursion data over a field K with parameters (r, f, n_{d}), lattice-sum bound β_{L} and block ratio β_{B} satisfy (Pt1)–(Pt8), and suppose $\delta_1 = 2 \cdot 3^f \beta_{\mathrm{L}} \leq 1$. Fix $\eta > 0$ and a tower $\mathcal{S}$, and let*

$$\sigma_k = \Big(\max_{\alpha \in \mathcal{A}_{4n_{\mathrm{d}}(r+1-k)}} \mathrm{En}_{\eta,k,\alpha}(\mathcal{X}_k(\mathcal{S}), k_k) \Big)^{1/2} \qquad (0 \leq k \leq r+1).$$

Then for $1 \leq i \leq r+1$

$$\sigma_i \leq (1+\delta_1)\sqrt{1+\mathrm{ex}_i}\, \sigma_{i-1} + 2 \sum_{m=2}^{i} \beta_{\mathrm{B}}^{m-1}\, \sigma_{i-m}.$$

Proof. Fix $1 \leq i \leq r+1$ and $\alpha \in \mathcal{A}_{4n_{\mathrm{d}}(r+1-i)}$; it suffices to bound $\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}_i, k_i)^{1/2}$ by the right side.

Splitting by the last block. For $1 \leq m \leq i$ let $\mathcal{X}^{(m)} = \{h \cdot (m,t) : h \in \mathcal{X}_{i-m},\ t \in \mathcal{S}_{j,m}\}$. Every $u \in \mathcal{X}_i$ has level $i \geq 1$, hence a last block (m,t) with $1 \leq m \leq i$, and $u = h \cdot (m,t)$ with $|h| = i - m$; the blocks of h start where they start in u, and the last block starts at $|h| + 1 = j$; so $u \in \mathcal{X}_i$ if and only if $h \in \mathcal{X}_{i-m}$ and $t \in \mathcal{S}_{j,m}$. Hence $\mathcal{X}_i = \bigsqcup_{m=1}^{i} \mathcal{X}^{(m)}$, and $(h,t) \mapsto h \cdot (m,t)$ is a bijection $\mathcal{X}_{i-m} \times \mathcal{S}_{j,m} \to \mathcal{X}^{(m)}$ (the last block and the rest determine the point). The kernel

$M(u,u') = k_i(u,u')g_{\eta,i,\alpha}(u,u')$ is positive semidefinite on $\mathcal{X}_i$ by (Pt1) and the Schur product theorem, so $x \mapsto (\sum_{u,u'} \overline{x_u} M(u,u') x_{u'})^{1/2}$ is a seminorm on $\mathbb{C}^{\mathcal{X}_i}$. Applying it to the indicator vectors $\mathbf{1}_{\mathcal{X}^{(m)}}$, whose sum is $\mathbf{1}_{\mathcal{X}_i}$, and dividing by $\mathrm{wt}(\alpha) > 0$,

$$\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}_i, k_i)^{1/2} \le \sum_{m=1}^{i} \mathrm{En}_{\eta,i,\alpha}(\mathcal{X}^{(m)}, k_i)^{1/2}, \tag{15.3}$$

all energies being ≥ 0 (positive semidefinite kernels have a real nonnegative sum of entries).

Off-diagonal terms of one block size. Fix m. By the bijection,

$$\begin{aligned}\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}^{(m)}, k_i) &= \mathrm{Re} \sum_{t,t' \in \mathcal{S}_{j,m}} \mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X}_{i-m}, (k_i)_m^{t,t'}; t, t') \\ &= D_{i,m}(\alpha) + \mathrm{Re} \sum_{t \ne t'} \mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X}_{i-m}, (k_i)_m^{t,t'}; t, t').\end{aligned}$$

If $(i,m) = (r+1,1)$, every $(k_i)_m^{t,t'}$ with $t \ne t'$ vanishes on points of level $i-m$ by (Pt2), so the off-diagonal sum is 0. Otherwise a pair $t \ne t'$ with $t^{-1} - t'^{-1} \notin L'_{j,m}$ contributes 0, by (Pt2). Let θ be the weight of (Pt6) for (η, i, m, α); $|\alpha| + n_{\mathrm{d}} \le N_{\mathrm{top}}$ as $i \ge 1$. Apply (Pt6) with $P = \mathcal{X}_{i-m}$, $S = \mathcal{S}_{j,m}$, $\kappa = k_i$ (positive semidefinite by (Pt1)), and write $d_{\alpha'}(t) = \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha'}(\mathcal{X}_{i-m}, (k_i)_m^{t,t}; t, t) \ge 0$ (the kernels $(k_i)_m^{t,t}$ and $(h,h') \mapsto g_{\eta,i,\alpha'}(h \cdot (m,t), h' \cdot (m,t))$ are positive semidefinite on $\mathcal{X}_{i-m}$ by (Pt1), as $h \mapsto h \cdot (m,t)$ is injective, and the Schur product theorem applies), so that $\sum_t d_{\alpha'}(t) = D_{i,m}(\alpha')$. Let Π be the set of ordered pairs $(t,t') \in \mathcal{S}_{j,m}^2$ with $t \ne t'$ and $t^{-1} - t'^{-1} \in L'_{j,m}$. For fixed t the elements $t^{-1} - t'^{-1}$, $(t,t') \in \Pi$, are pairwise distinct, nonzero and in $L'_{j,m}$, so their majorants sum to at most β_{L} by (Pt8); likewise for fixed t'. Since $\theta \ge 0$ and $d \ge 0$,

$$\begin{aligned}&\Big| \sum_{(t,t') \in \Pi} \mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X}_{i-m}, (k_i)_m^{t,t'}; t, t') \Big| \\ &\qquad \le \frac{1}{2} \sum_{\alpha'} \theta(\alpha') \sum_{(t,t') \in \Pi} \mathrm{mj}'_{j,m}(t^{-1} - t'^{-1})(d_{\alpha'}(t) + d_{\alpha'}(t')) \le \beta_{\mathrm{L}} \sum_{\alpha'} \theta(\alpha')\, D_{i,m}(\alpha').\end{aligned}$$

With $\sum \theta \le 2 \cdot 3^f$, in all cases

$$\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}^{(m)}, k_i) \le D_{i,m}(\alpha) + \delta_1 \max_{\alpha' \in \mathcal{A}_{|\alpha|+n_{\mathrm{d}}}} D_{i,m}(\alpha'). \tag{15.4}$$

The diagonal blocks. α and every $\alpha' \in \mathcal{A}_{|\alpha|+n_{\mathrm{d}}}$ lie in $\mathcal{A}_{4n_{\mathrm{d}}(r+1-i)+n_{\mathrm{d}}}$, so Lemma 15.12 applies to them. For $m = 1$, as $2^f \beta_{\mathrm{L}} \le \delta_1$, (15.4) gives $\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}^{(1)}, k_i) \le (1+\delta_1)^2(1+\mathrm{ex}_i)\sigma_{i-1}^2$. For $m \ge 2$, as $\delta_1 \le 1$ and $\mathrm{ex}_i \le 1$ by (Pt3), $\mathrm{En}_{\eta,i,\alpha}(\mathcal{X}^{(m)}, k_i) \le (1+\delta_1)(1+\mathrm{ex}_i)\beta_{\mathrm{B}}^{2(m-1)}\sigma_{i-m}^2 \le 4\beta_{\mathrm{B}}^{2(m-1)}\sigma_{i-m}^2$. Taking square roots ($\sigma \ge 0$, $\beta_{\mathrm{B}} \ge 0$, $1 + \mathrm{ex}_i \ge 0$) and inserting into (15.3) gives the bound for α; maximising over α proves the lemma. □

Lemma 15.12. *Let Poisson recursion data over a field K with parameters (r, f, n_{d}), lattice-sum bound β_{L} and block ratio β_{B} satisfy (Pt1)–(Pt8). Fix $\eta > 0$ and a tower $\mathcal{S}$, write $\mathcal{X}_i = \mathcal{X}_i(\mathcal{S})$, and for $1 \le m \le i \le r+1$ and $\alpha \in \mathcal{A}$ put*

$$D_{i,m}(\alpha) = \sum_{t \in \mathcal{S}_{i-m+1,m}} \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X}_{i-m}, (k_i)_m^{t,t}; t, t).$$

Then $\mathrm{En}_{\eta,k,\alpha}(\mathcal{X}_k, k_k) \ge 0$ for all k, α, so that

$$\sigma_k = \Big(\max_{\alpha \in \mathcal{A}_{4n_{\mathrm{d}}(r+1-k)}} \mathrm{En}_{\eta,k,\alpha}(\mathcal{X}_k, k_k) \Big)^{1/2} \qquad (0 \le k \le r+1)$$

is a well-defined nonnegative number; $D_{i,m}(\alpha) \ge 0$*; and for* $1 \le m \le i \le r+1$ *and* $\alpha \in \mathcal{A}_{4n_{\mathrm{d}}(r+1-i)+n_{\mathrm{d}}}$

$$D_{i,1}(\alpha) \le (1+\mathrm{ex}_i)(1+2^f\beta_{\mathrm{L}})\,\sigma_{i-1}^2, \qquad D_{i,m}(\alpha) \le (1+\mathrm{ex}_i)\,\beta_{\mathrm{B}}^{2(m-1)}\,\sigma_{i-m}^2 \quad (m \ge 2).$$

Proof. **Positivity facts.** We use the Schur product theorem: the entrywise product of two kernels positive semidefinite on a finite set P is positive semidefinite on P; and the sum of all entries of a kernel positive semidefinite on P is ≥ 0 (take $w = (1, \dots, 1)$).

(F1) If κ is positive semidefinite on a finite set P of points, then $\mathrm{En}_{\eta,k,\alpha}(P,\kappa) \ge 0$, by (Pt1), the Schur product theorem and $\mathrm{wt}(\alpha) > 0$. With $\kappa = k_k$ and $P = \mathcal{X}_k$ this is the first claim; $\mathcal{A}_n \ni \alpha_\varnothing$ is finite and nonempty, so σ_k is well defined and ≥ 0.

(F2) If P is a finite set of points of level $i-m$ and κ is positive semidefinite on P, then $\mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa;t,t) \ge 0$: the map $h \mapsto h\cdot(m,t)$ is injective, so $(h,h') \mapsto g_{\eta,i,\alpha}(h\cdot(m,t), h'\cdot(m,t))$ is positive semidefinite on P by (Pt1), and the Schur product theorem applies. In particular $D_{i,m}(\alpha) \ge 0$, since $(k_i)^{t,t}_m$ is positive semidefinite on $\mathcal{X}$ by (Pt1) and the same injectivity.

(F3) Both energies are linear in κ (the first over $\mathbb{R}$), and depend only on the values of κ on $P \times P$.

Reduction to the theta majorants. Let $\Theta_{i,m,t}$ be the functions of (Pt3) for the tower $\mathcal{S}$. For $t \in \mathcal{S}_{j,m}$, $\Theta_{i,m,t} = (\Theta_{i,m,t} - (k_i)^{t,t}_m) + (k_i)^{t,t}_m$ is positive semidefinite on $\mathcal{X}$ by (Pt3)(a) and (F2). Congruence modulo the subgroup $L_{j,m}$ is an equivalence relation on the finite set $\mathcal{S}_{j,m}$; let $R \subseteq \mathcal{S}_{j,m}$ contain exactly one element of each class, and for $t_0 \in R$ let $S(t_0) = \{t \in \mathcal{S}_{j,m} : t - t_0 \in L_{j,m}\}$, so that $\mathcal{S}_{j,m} = \bigsqcup_{t_0\in R} S(t_0)$ and $S(t_0) \subseteq (t_0 + L_{j,m}) \setminus \{0\}$. By (F2) and (F3) applied to $\Theta_{i,m,t} - (k_i)^{t,t}_m$, and by (Pt3)(b) with (F3),

$$D_{i,m}(\alpha) \le \sum_{t\in\mathcal{S}_{j,m}} \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X},\Theta_{i,m,t};t,t) = \sum_{t_0\in R}\sum_{t\in S(t_0)} \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(\mathcal{X},\Theta_{i,m,t_0};t,t). \quad (15.5)$$

Moreover, as the elements of R are pairwise incongruent, (Pt3)(c) with (F1) and (F3) gives, for every k and α',

$$\sum_{t_0\in R} \mathrm{En}_{\eta,i-m,\alpha'}(\mathcal{X},\Theta_{i,m,t_0}) = \mathrm{En}_{\eta,i-m,\alpha'}\Big(\mathcal{X}, \sum_{t_0\in R}\Theta_{i,m,t_0}\Big) \le (1+\mathrm{ex}_i)\,\mathrm{En}_{\eta,i-m,\alpha'}(\mathcal{X},k_{i-m}). \quad (15.6)$$

Word lengths. Let $\alpha \in \mathcal{A}_n$, $n = 4n_{\mathrm{d}}(r+1-i)+n_{\mathrm{d}}$. For $m=1$: $|\alpha|+n_{\mathrm{d}} \le N_{\mathrm{top}} - 4n_{\mathrm{d}}i + 2n_{\mathrm{d}} \le N_{\mathrm{top}}$, and $\mathcal{A}_{|\alpha|+n_{\mathrm{d}}} \subseteq \mathcal{A}_{4n_{\mathrm{d}}(r+2-i)}$, which also contains α. For $m \ge 2$: $|\alpha| + (m+1)n_{\mathrm{d}} \le N_{\mathrm{top}} - n_{\mathrm{d}}(4i-m-2) \le N_{\mathrm{top}}$ as $m \le i$ and $i \ge 1$, and $\mathcal{A}_{|\alpha|+(m+1)n_{\mathrm{d}}} \subseteq \mathcal{A}_{4n_{\mathrm{d}}(r+1-i+m)}$ as $m+2 \le 4m$. Hence, by the definition of σ, $\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X}_{i-1},k_{i-1}) \le \sigma_{i-1}^2$ for $\alpha' \in \mathcal{A}_{|\alpha|+n_{\mathrm{d}}} \cup \{\alpha\}$ when $m=1$, and $\mathrm{En}_{\eta,i-m,\alpha'}(\mathcal{X}_{i-m},k_{i-m}) \le \sigma_{i-m}^2$ for $\alpha' \in \mathcal{A}_{|\alpha|+(m+1)n_{\mathrm{d}}}$ when $m \ge 2$.

The case $m = 1$: Poisson summation. Here $j = i$. Let θ be the weight of (Pt5) for (η,i,α); it does not depend on P or κ. Fix $t_0 \in R$ and put $\kappa = \Theta_{i,1,t_0}$, positive semidefinite on $\mathcal{X} = \mathcal{X}_{i-1}$, and $B = \beta_{\mathrm{L}}\sum_{\alpha'}\theta(\alpha')\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X},\kappa)$. For finite $Z \subseteq L_i^\vee \setminus \{0\}$, (Pt5) and (Pt8) give, as $\sum_{\alpha'}\theta(\alpha')\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X},\kappa) \ge 0$ by (F1),

$$\sum_{z\in Z} |\widehat{\mathrm{En}}_{\eta,i,\alpha}(\mathcal{X},\kappa;z)| \le \Big(\sum_{z\in Z}\mathrm{mj}_i^\vee(z)\Big)\sum_{\alpha'}\theta(\alpha')\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X},\kappa) \le B.$$

By (Pt4) with $S = S(t_0)$, and since $\widehat{\mathrm{En}}_{\eta,i,\alpha}(\mathcal{X},\kappa;0) = \mathrm{En}_{\eta,i-1,\alpha}(\mathcal{X},\kappa) \geq 0$ by (Pt5) and (F1),

$$\sum_{t\in S(t_0)} \mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,1,\alpha}(\mathcal{X},\Theta_{i,1,t_0};t,t) \leq \mathrm{En}_{\eta,i-1,\alpha}(\mathcal{X},\Theta_{i,1,t_0}) + \beta_{\mathrm{L}} \sum_{\alpha'} \theta(\alpha')\,\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X},\Theta_{i,1,t_0}).$$

Summing over $t_0 \in R$ and using (15.5), (15.6) (with $\theta \geq 0$, $\beta_{\mathrm{L}} \geq 0$), then the word lengths, $\sum\theta \leq 2^f$ and $1+\mathrm{ex}_i \geq 0$:

$$D_{i,1}(\alpha) \leq (1+\mathrm{ex}_i)\Big(\mathrm{En}_{\eta,i-1,\alpha}(\mathcal{X},k_{i-1}) + \beta_{\mathrm{L}} \sum_{\alpha'} \theta(\alpha')\,\mathrm{En}_{\eta,i-1,\alpha'}(\mathcal{X},k_{i-1})\Big) \leq (1+\mathrm{ex}_i)(1+2^f\beta_{\mathrm{L}})\,\sigma_{i-1}^2.$$

The case $m \geq 2$: degenerate blocks. Let θ be the weight of (Pt7) for (η,i,m,α), independent of P,κ,t_0,S. For $t_0 \in R$, (Pt7) with $P = \mathcal{X}$, $\kappa = \Theta_{i,m,t_0}$ and $S = S(t_0)$ bounds the inner sum of (15.5) by $\beta_{\mathrm{B}}^{2(m-1)} \sum_{\alpha'} \theta(\alpha')\mathrm{En}_{\eta,i-m,\alpha'}(\mathcal{X},\Theta_{i,m,t_0})$. Summing over t_0 and using (15.6), the word lengths and $\sum\theta \leq 1$, $\theta \geq 0$:

$$D_{i,m}(\alpha) \leq (1+\mathrm{ex}_i)\,\beta_{\mathrm{B}}^{2(m-1)} \sum_{\alpha'} \theta(\alpha')\,\mathrm{En}_{\eta,i-m,\alpha'}(\mathcal{X}_{i-m},k_{i-m}) \leq (1+\mathrm{ex}_i)\,\beta_{\mathrm{B}}^{2(m-1)}\,\sigma_{i-m}^2.$$

□

Lemma 15.13. *Let $r \geq 0$ be an integer and $\delta_1,\beta \geq 0$ real numbers with $(r+1)(\delta_1+4\beta) \leq 1$. Let $\mathrm{ex}_1,\dots,\mathrm{ex}_{r+1} \geq 0$ and $\sigma_0,\dots,\sigma_{r+1} \geq 0$ be real numbers such that*

$$\sigma_i \leq (1+\delta_1)\sqrt{1+\mathrm{ex}_i}\;\sigma_{i-1} + 2\sum_{m=2}^{i} \beta^{m-1}\sigma_{i-m} \qquad (1 \leq i \leq r+1).$$

Then

$$\sigma_{r+1}^2 \leq \big(1+15(r+1)(\delta_1+4\beta)\big)\prod_{i=1}^{r+1}(1+\mathrm{ex}_i)\;\sigma_0^2.$$

Proof. **Normalisation.** Put $Q_0 = 1$, $Q_i = \prod_{a=1}^{i}\sqrt{1+\mathrm{ex}_a}$, so $1 \leq Q_{i-m} \leq Q_i$ and $Q_i = \sqrt{1+\mathrm{ex}_i}\,Q_{i-1}$, and $\tau_i = \sigma_i/Q_i \geq 0$. Dividing the hypothesis by Q_i and using $\sigma_{i-m}/Q_i \leq \sigma_{i-m}/Q_{i-m}$,

$$\tau_i \leq (1+\delta_1)\tau_{i-1} + 2\sum_{m=2}^{i}\beta^{m-1}\tau_{i-m} \qquad (1 \leq i \leq r+1).$$

Running maximum. Let $M_i = \max_{0\leq a\leq i}\tau_a$. Since $4\beta \leq 1$, $\beta \leq \frac14$ and $2\sum_{m=2}^{i}\beta^{m-1} \leq 2\beta/(1-\beta) \leq 4\beta$, so $\tau_i \leq (1+\delta_1+4\beta)M_{i-1}$; as also $M_{i-1} \leq (1+\delta_1+4\beta)M_{i-1}$, we get $M_i \leq (1+\delta_1+4\beta)M_{i-1}$ and by induction $\tau_{r+1} \leq M_{r+1} \leq (1+\delta_1+4\beta)^{r+1}\sigma_0$.

The constant. Hence $\sigma_{r+1}^2 = Q_{r+1}^2\tau_{r+1}^2 \leq \prod_i(1+\mathrm{ex}_i)\,(1+\delta_1+4\beta)^{2(r+1)}\sigma_0^2$. With $z = (r+1)(\delta_1+4\beta) \in [0,1]$, $1+w \leq e^w$ and $e^w \leq 1+we^w$ ($w \geq 0$, mean value theorem) give $(1+\delta_1+4\beta)^{2(r+1)} \leq e^{2z} \leq 1+2ze^{2z} \leq 1+2e^2z \leq 1+15z$. □

Theorem 15.14. *Let Poisson recursion data over a field K with parameters (r,f,n_{d}) carry an archimedean product structure. Then the data satisfy (Pt1), (Pt4), (Pt5), (Pt6), (Pt7) and (Pt9).*

Proof. **(Pt1).** The coefficient part is (Aw2). Let P be a finite set of points and fix η,i,α. For each v the kernel $(u,u') \mapsto g^v_{\eta,i,\alpha}(\sigma_v(u),\sigma_v(u'))$ is positive semidefinite on P: for $w \in \mathbb{C}^P$, $\sum_{u,u'}\overline{w_u}g^v(\sigma_v u,\sigma_v u')w_{u'} = \sum_{p,q\in\sigma_v(P)}\overline{W_p}\,g^v(p,q)\,W_q \geq 0$ with $W_p = \sum_{\sigma_v(u)=p} w_u$, by (Aw2) on

the finite set $\sigma_v(P)$ of local points. By (Aw1) and the Schur product theorem, $g_{\eta,i,\alpha}$ is positive semidefinite on P.

Consequences of (Aw3). Fix $\eta>0$, $1\le i\le r+1$, α, a finite set P of points of level $i-1$ and κ positive semidefinite on P; write $\varphi(c)=\varphi_{\eta,i,\alpha}(P,\kappa;c)$ and $G_v(h,h';c)=G^v_{\eta,i,\alpha}(\sigma_v(h),\sigma_v(h');c)$ for $h,h'\in P$ (the local points $\sigma_v(h)$ have level $i-1$), and let $C_v(h,h')$ be the constants of (Aw3) for them. (a) φ is continuous on $\mathbb{C}^f$, being a finite sum of products of continuous functions of single coordinates, and $|\varphi(c)|\le C\prod_v(1+|c_v|)^{-3}$ with $C=\mathrm{wt}(\alpha)^{-1}\sum_{h,h'}|\kappa(h,h')|\prod_v C_v(h,h')$. (b) For $t\in K^\times$ and a point h, $\sigma_v(t)\ne0$ and $\sigma_v(h\cdot(1,t))=\sigma_v(h)\cdot(1,\sigma_v(t))$; so by (Aw3) and (Aw1), $\varphi(\sigma(t))=\mathrm{wt}(\alpha)^{-1}\sum_{h,h'}\kappa(h,h')g_{\eta,i,\alpha}(h\cdot(1,t),h'\cdot(1,t))=\mathrm{En}^{\uparrow}_{\eta,i,1,\alpha}(P,\kappa;t,t)$. (c) Let $c\in(\mathbb{C}^\times)^f$. Then $G_v(h,h';c_v)=g^v_{\eta,i,\alpha}(\sigma_v(h)\cdot(1,c_v),\sigma_v(h')\cdot(1,c_v))$; the map $h\mapsto\sigma_v(h)\cdot(1,c_v)$ sends P to a finite set of local points, so $(h,h')\mapsto G_v(h,h';c_v)$ is positive semidefinite on P by (Aw2) and the pull-back argument of the proof of (Pt1). By the Schur product theorem $\kappa\prod_v G_v(\cdot,\cdot;c_v)$ is positive semidefinite on P, so the sum of its entries (its quadratic form at the vector with all entries 1) is real and ≥0; as $\mathrm{wt}(\alpha)>0$, $\varphi(c)\ge0$. As $(\mathbb{C}^\times)^f$ is dense in $\mathbb{C}^f$ and $\mathrm{Re}\,\varphi$ is continuous, $\mathrm{Re}\,\varphi\ge0$ on $\mathbb{C}^f$. (d) Zero frequency. Since $\int_{\mathbb{C}}(1+|c|)^{-3}dc=2\pi\int_0^\infty\rho(1+\rho)^{-3}d\rho=\pi$, each function $c\mapsto\prod_v G_v(h,h';c_v)$ is integrable on $\mathbb{C}^f$, and by Fubini's theorem and (Aw3) its integral is $\prod_v\int_{\mathbb{C}}G_v(h,h';c_v)\,dc_v=\prod_v d_v(i)\,g^v_{\eta,i-1,\alpha}(\sigma_v(h),\sigma_v(h'))=\mathrm{covol}(\Lambda_i)\,g_{\eta,i-1,\alpha}(h,h')$, the last step by (Aw1). Hence, by the Fourier formula of (Aw3) at $z=0$, $\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)=\mathrm{covol}(\Lambda_i)^{-1}\int\varphi=\mathrm{wt}(\alpha)^{-1}\sum_{h,h'}\kappa(h,h')g_{\eta,i-1,\alpha}(h,h')$. By (Pt1), proved above, and the Schur product theorem this sum of entries of a positive semidefinite kernel is real, so $\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)=\mathrm{En}_{\eta,i-1,\alpha}(P,\kappa)$.

(Pt4). By (a)–(c), the Fourier formula and the lattice conditions of (Aw3), the hypotheses of Lemma 15.15 hold for σ and g with the functions $\varphi_{\eta,i,\alpha}(P,\kappa;\cdot)$ (σ is injective, being a field embedding in each coordinate); it gives (Pt4).

(Pt5). Put $|z|_v=|\sigma_v(z)|$; it is positive for $z\ne0$. By (Pt1), the zero-frequency identity (d) and (Aw4), the hypotheses of Lemma 15.16 hold with these $|\cdot|_v$, $\varrho_{i,v}$, $\varrho'_{i,v}$ and θ_A; it gives (Pt5).

(Pt6). $z\mapsto|\sigma_v(z)|$ is an absolute value on K. By (Pt1) and (Aw5), the hypotheses of Lemma 15.17 hold with these absolute values, $\varrho_{j,m,v}$, $\varrho'_{j,m,v}$, $\lambda_{j,m,v}$ and the weights of (Aw5); it gives (Pt6).

(Pt7). Let $\eta>0$, $2\le m\le i\le r+1$, α with $|\alpha|+(m+1)n_{\mathrm{d}}\le N_{\mathrm{top}}$, and M, θ as in (Aw6); extend θ by 0 to $\mathcal{A}_{|\alpha|+(m+1)n_{\mathrm{d}}}\supseteq\mathcal{A}_{|\alpha|+mn_{\mathrm{d}}}$. As $\mathrm{vol}(j,m')\le T^{-2f}$, $M\le C_4^{fm}T^{-2f(m-1)}$, and as $C_4\ge1$ and $fm\le2f(m-1)$ for $m\ge2$, $C_4^{fm}\le C_4^{2f(m-1)}$; hence $M\le(C_4/T)^{2f(m-1)}=\beta_{\mathrm{B}}^{2(m-1)}$. The energies $\mathrm{En}_{\eta,i-m,\alpha'}(P,\kappa)$ are ≥0 (the kernel $\kappa\,g_{\eta,i-m,\alpha'}$ is positive semidefinite on P by (Pt1) and the Schur product theorem, and $\mathrm{wt}(\alpha')>0$), so the bound of (Aw6) gives that of (Pt7).

(Pt9). Since $\sigma_v(\varnothing)=\varnothing$, (Aw1) gives $g_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}(\alpha)=\prod_v g^v_{\eta,0,\alpha}(\varnothing,\varnothing)/\mathrm{wt}_v(\alpha)$, which tends to $\prod_v J_v=J$ by (Aw7); as J is real, the real parts tend to J. Let P be a finite set of points of level $r+1$; $\sigma_v(P)$ is a finite set of local points of level $r+1$, and let η_0 be the least of the η_0 of (Aw7) for $Q=\sigma_v(P)$, $v=1,\dots,f$. For $0<\eta<\eta_0$ and $u,u'\in P$, by (Aw1) and (Aw7), $g_{\eta,r+1,\alpha\varnothing}(u,u')=\prod_v\langle W_v(\sigma_v u'),W_v(\sigma_v u)\rangle=\langle W(u'),W(u)\rangle$, for all pairs and in particular for those with $k_{r+1}(u,u')\ne0$. □

Lemma 15.15. *Fix Poisson recursion data over a field K with parameters (r,f,n_{d}), an injective additive map $\sigma=(\sigma_1,\dots,\sigma_f)\colon K\to\mathbb{C}^f$ and a real number $g>0$. Put $\langle\xi,c\rangle=\frac{2}{g}\sum_{v=1}^f\mathrm{Re}(\xi_v c_v)$ for $\xi,c\in\mathbb{C}^f$, and identify $\mathbb{C}^f$ with $\mathbb{R}^{2f}$ (Lebesgue measure dc). Suppose that for every $1\le i\le r+1$:*

1. *$\Lambda_i=\sigma(L_{i,1})$ is a lattice in $\mathbb{C}^f$, $\sigma(L_i^\vee)=\{\xi:\langle\xi,\lambda\rangle\in\mathbb{Z}$ for all $\lambda\in\Lambda_i\}$, and there is C_i*

with $\#\{\lambda\in\Lambda_i : |\lambda_v|\le R_v \text{ for all } v\}\le C_i\prod_v(1+R_v)^2$ *for all* $R_1,\dots,R_f\ge 0$*;*

2. *for all* $\eta>0$*,* $\alpha\in\mathcal{A}$*, finite sets* P *of points of level* $i-1$ *and* κ *positive semidefinite on* P *there are a continuous* $\varphi\colon \mathbb{C}^f\to\mathbb{C}$ *and* $C\ge 0$ *with* $\operatorname{Re}\varphi\ge 0$*,* $|\varphi(c)|\le C\prod_v(1+|c_v|)^{-3}$*,* $\varphi(\sigma(t))=\mathrm{En}^{\uparrow}_{\eta,i,1,\alpha}(P,\kappa;t,t)$ *for* $t\in K^\times$*, and*

$$\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)=\operatorname{covol}(\Lambda_i)^{-1}\int_{\mathbb{C}^f}\varphi(c)\,e^{2\pi i\langle\sigma(z),c\rangle}\,dc\qquad(z\in L_i^\vee).$$

Then the data satisfy (Pt4).

Proof. Fix η,i,α,P,κ as in (Pt4), $t_0\in K$, B with $\sum_{z\in Z}|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)|\le B$ for every finite $Z\subseteq L_i^\vee\setminus\{0\}$, and a finite $S\subseteq(t_0+L_{i,1})\setminus\{0\}$. Let φ, C be as in item 2, $\Lambda=\Lambda_i$, $\Lambda'=\sigma(L_i^\vee)$, $x=\sigma(t_0)$.

The periodisation converges. For $\lambda\in\Lambda$ let $k_v(\lambda)=\lfloor\log_2(1+|\lambda_v|)\rfloor\ge 0$. For $k\in\mathbb{Z}^f_{\ge 0}$ the λ with $k(\lambda)=k$ satisfy $|\lambda_v|<2^{k_v+1}$, so there are at most $C_i\prod_v(1+2^{k_v+1})^2\le C_i 9^f\prod_v 2^{2k_v}$ of them by item 1, and each has $\prod_v(1+|\lambda_v|)^{-3}\le\prod_v 2^{-3k_v}$. Hence $\sum_{\lambda\in\Lambda}\prod_v(1+|\lambda_v|)^{-3}\le C_i9^f\sum_k\prod_v 2^{-k_v}=C_i18^f$. If $|y_v|\le R$ for all v, then $1+|y_v+\lambda_v|\ge(1+|\lambda_v|)/(1+R)$, so $|\varphi(y+\lambda)|\le C(1+R)^{3f}\prod_v(1+|\lambda_v|)^{-3}$. Therefore $F(y)=\sum_{\lambda\in\Lambda}\varphi(y+\lambda)$ converges absolutely and uniformly on compact sets; F is continuous and Λ-periodic.

Its Fourier series. The pairing $\langle\cdot,\cdot\rangle$ is a nondegenerate real bilinear form on $\mathbb{R}^{2f}$, so the characters of $\mathbb{R}^{2f}/\Lambda$ are $y\mapsto e^{2\pi i\langle\xi,y\rangle}$, $\xi\in\Lambda'$ (item 1). Let D be a fundamental domain of Λ. By absolute convergence and Fubini, and as $e^{-2\pi i\langle\xi,\lambda\rangle}=1$,

$$\begin{aligned}c_\xi:=\frac{1}{\operatorname{covol}(\Lambda)}\int_D F(y)e^{-2\pi i\langle\xi,y\rangle}dy&=\frac{1}{\operatorname{covol}(\Lambda)}\int_{\mathbb{C}^f}\varphi(y)e^{-2\pi i\langle\xi,y\rangle}dy\\&=\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;-z)\qquad(\xi=\sigma(z)).\end{aligned}$$

As $L_i^\vee=-L_i^\vee$ and finite sums of $|\widehat{\mathrm{En}}(z)|$ over $z\ne 0$ are at most B, $\sum_{\xi\in\Lambda'}|c_\xi|\le|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)|+B<\infty$. The series $\sum_\xi c_\xi e^{2\pi i\langle\xi,y\rangle}$ then converges uniformly to a continuous periodic function with the same Fourier coefficients as F, so it equals F (a continuous function on a torus all of whose Fourier coefficients vanish is zero, by the density of trigonometric polynomials). In particular $|F(x)|\le|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)|+B$.

Comparison with the sum over S**.** For $t\in S$, $t\ne 0$ and $\sigma(t)=x+\sigma(t-t_0)$ with $t-t_0\in L_{i,1}$; distinct t give distinct $\lambda=\sigma(t-t_0)\in\Lambda$ (σ is injective). By item 2 and $\operatorname{Re}\varphi\ge 0$,

$$\sum_{t\in S}\operatorname{Re}\mathrm{En}^{\uparrow}_{\eta,i,1,\alpha}(P,\kappa;t,t)=\sum_{t\in S}\operatorname{Re}\varphi(\sigma(t))\le\sum_{\lambda\in\Lambda}\operatorname{Re}\varphi(x+\lambda)=\operatorname{Re}F(x)\le|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)|+B,$$

which is (Pt4). □

Lemma 15.16. *Let Poisson recursion data over a field* K *with parameters* (r,f,n_{d}) *satisfy (Pt1). Let* $z\mapsto|z|_v$ *(*$1\le v\le f$*) be functions* $K\to[0,\infty)$ *with* $|z|_v>0$ *for* $z\ne 0$*, and let* $0\le\varrho'_{i,v}\le\varrho_{i,v}$ *(*$1\le i\le r+1$*,* $1\le v\le f$*) be real numbers such that*

$$\mathrm{mj}_i^\vee(z)=\prod_{v=1}^f\min\Bigl(1,\Bigl(\frac{\varrho_{i,v}}{|z|_v}\Bigr)^{n_{\mathrm{d}}}\Bigr)\qquad(1\le i\le r+1,\ z\in L_i^\vee\setminus\{0\}).$$

Suppose that for all $\eta>0$*,* $1\le i\le r+1$ *and* $\alpha\in\mathcal{A}$ *with* $|\alpha|+n_{\mathrm{d}}\le N_{\mathrm{top}}$*:*

1. $\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;0)=\mathrm{En}_{\eta,i-1,\alpha}(P,\kappa)$ *for every finite set* P *of points of level* $i-1$ *and every* κ *positive semidefinite on* P*;*

2. *for every subset* $A\subseteq\{1,\dots,f\}$ *there is* $\theta_A\colon \mathcal{A}_{|\alpha|+n_{\mathrm{d}}}\to[0,\infty)$ *with* $\sum_{\alpha'}\theta_A(\alpha')\le 1$ *such that for every finite set* P *of points of level* $i-1$*, every* κ *positive semidefinite on* P *and every* $z\in L_i^\vee\setminus\{0\}$

$$\Big(\prod_{v\in A}|z|_v^{n_{\mathrm{d}}}\Big)\big|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)\big|\le\Big(\prod_{v\in A}\varrho_{i,v}'^{\,n_{\mathrm{d}}}\Big)\sum_{\alpha'\in\mathcal{A}_{|\alpha|+n_{\mathrm{d}}}}\theta_A(\alpha')\,\mathrm{En}_{\eta,i-1,\alpha'}(P,\kappa).$$

Then the data satisfy (Pt5), with the weight $\theta=\sum_{A\subseteq\{1,\dots,f\}}\theta_A$*.*

Proof. Fix $\eta>0$, $1\le i\le r+1$ and $\alpha\in\mathcal{A}$ with $|\alpha|+n_{\mathrm{d}}\le N_{\mathrm{top}}$, and let $(\theta_A)_A$ be as in item 2. Then $\theta=\sum_A\theta_A$ maps $\mathcal{A}_{|\alpha|+n_{\mathrm{d}}}$ to $[0,\infty)$, does not depend on P, κ or z, satisfies $\theta_A\le\theta$ pointwise for every A, and has $\sum_{\alpha'}\theta(\alpha')\le 2^f$, the number of subsets of $\{1,\dots,f\}$. The zero-frequency identity of (Pt5) is item 1.

Let P be a finite set of points of level $i-1$, κ positive semidefinite on P and $z\in L_i^\vee\setminus\{0\}$. Every energy $\mathrm{En}_{\eta,i-1,\alpha'}(P,\kappa)$ is ≥ 0: the kernel $\kappa\,g_{\eta,i-1,\alpha'}$ is positive semidefinite on P by (Pt1) and the Schur product theorem, so the sum of its entries is real and ≥ 0, and $\mathrm{wt}(\alpha')>0$. Let $A=\{v:\varrho_{i,v}<|z|_v\}$. For $v\in A$, $0\le\varrho_{i,v}/|z|_v<1$, so the v-th factor of $\mathrm{mj}_i^\vee(z)$ is $(\varrho_{i,v}/|z|_v)^{n_{\mathrm{d}}}$; for $v\notin A$, $\varrho_{i,v}/|z|_v\ge 1$ and the factor is 1. Hence

$$\mathrm{mj}_i^\vee(z)=\prod_{v\in A}\Big(\frac{\varrho_{i,v}}{|z|_v}\Big)^{n_{\mathrm{d}}}.$$

Dividing item 2 for this A by $\prod_{v\in A}|z|_v^{n_{\mathrm{d}}}>0$, and using $0\le\varrho_{i,v}'\le\varrho_{i,v}$, the nonnegativity of the energies and $0\le\theta_A\le\theta$,

$$\big|\widehat{\mathrm{En}}_{\eta,i,\alpha}(P,\kappa;z)\big|\le\prod_{v\in A}\Big(\frac{\varrho_{i,v}'}{|z|_v}\Big)^{n_{\mathrm{d}}}\sum_{\alpha'}\theta_A(\alpha')\,\mathrm{En}_{\eta,i-1,\alpha'}(P,\kappa)\le\mathrm{mj}_i^\vee(z)\sum_{\alpha'}\theta(\alpha')\,\mathrm{En}_{\eta,i-1,\alpha'}(P,\kappa),$$

which is the decay bound of (Pt5). □

Lemma 15.17. *Let Poisson recursion data over a field* K *with parameters* (r,f,n_{d}) *satisfy (Pt1). Let* $|\cdot|_1,\dots,|\cdot|_f$ *be absolute values on* K*, and for* $1\le m\le i\le r+1$ *with* $(i,m)\ne(r+1,1)$ *and* $1\le v\le f$ *let* $\varrho_{j,m,v}\ge 0$ *be real numbers with*

$$\mathrm{mj}_{j,m}'(z)=\prod_{v=1}^{f}\min\Big(1,\Big(\frac{\varrho_{j,m,v}}{|z|_v}\Big)^{n_{\mathrm{d}}}\Big)\qquad(z\in K^\times).$$

For a finite set P *of points of level* $i-m$*, a kernel* κ *positive semidefinite on* P*,* $t\in K^\times$ *and* $\alpha\in\mathcal{A}$ *write* $d_{\eta,i,m,\alpha}(P,\kappa;t)=\mathrm{Re}\,\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa;t,t)$*. Suppose that for all* $\eta>0$ *and all* $\alpha\in\mathcal{A}$ *with* $|\alpha|+n_{\mathrm{d}}\le N_{\mathrm{top}}$*:*

1. *(below the top) there are* $0\le\varrho_{j,m,v}'\le\varrho_{j,m,v}$*, not depending on* η *or* α*, such that for* $1\le m\le i\le r$ *and every* $A\subseteq\{1,\dots,f\}$ *there is* $\theta_A\colon\mathcal{A}_{|\alpha|+n_{\mathrm{d}}}\to[0,\infty)$ *with* $\sum_{\alpha'}\theta_A(\alpha')\le 2$ *such that for every finite set* P *of points of level* $i-m$*, finite* $S\subseteq K^\times$*,* κ *positive semidefinite on* $\{h\cdot(m,t):h\in P,\ t\in S\}$ *and* $t\ne t'$ *in* S

$$\begin{aligned}&\Big(\prod_{v\in A}|t^{-1}-t'^{-1}|_v^{n_{\mathrm{d}}}\Big)\big|\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa_m^{t,t'};t,t')\big|\\&\qquad\le\Big(\prod_{v\in A}\varrho_{j,m,v}'^{\,n_{\mathrm{d}}}\Big)\frac{1}{2}\sum_{\alpha'}\theta_A(\alpha')\big(d_{\eta,i,m,\alpha'}(P,\kappa_m^{t,t};t)+d_{\eta,i,m,\alpha'}(P,\kappa_m^{t',t'};t')\big);\end{aligned}$$

2. *(the top diagonal) there are $\lambda_{j,m,v} \ge 0$ with $2\lambda_{j,m,v} \le \varrho_{j,m,v}$, not depending on η or α, such that for $i = r+1$, $2 \le m \le r+1$ and every $B \subseteq \{1,\dots,f\}$ there is $\theta_B \colon \mathcal{A}_{|\alpha|+n_{\mathrm{d}}} \to [0,\infty)$ with $\sum_{\alpha'} \theta_B(\alpha') \le 1$ such that for every finite set P of points of level $r+1-m$, κ positive semidefinite on P and $t \in K^\times$*

$$d_{\eta,r+1,m,\alpha}(P,\kappa;t) \le \Big(\prod_{v\in B} \big(|t|_v \lambda_{j,m,v}\big)^{2n_{\mathrm{d}}}\Big) \sum_{\alpha'} \theta_B(\alpha')\, d_{\eta,r+1,m,\alpha'}(P,\kappa;t).$$

Then the data satisfy (Pt6).

Proof. Fix $\eta > 0$, $1 \le m \le i \le r+1$ with $(i,m) \ne (r+1,1)$ and α with $|\alpha| + n_{\mathrm{d}} \le N_{\mathrm{top}}$; then either $i \le r$ (item 1 applies) or $i = r+1$ and $m \ge 2$ (item 2 applies). Let P, S, κ and $t \ne t'$ in S be as in (Pt6). As $t \ne t'$, $t^{-1} - t'^{-1} \ne 0$, so $o_v > 0$ for every v.

Positivity and the Cauchy–Schwarz inequality. Put $Q = \{h \cdot (m,s) : h \in P,\ s \in \{t,t'\}\}$. The maps $h \mapsto h\cdot(m,t)$ and $h \mapsto h\cdot(m,t')$ are injective with disjoint images. The kernel $M = \kappa\, g_{\eta,i,\alpha}$ is positive semidefinite on Q by (Pt1) and the Schur product theorem, hence hermitian on Q. For $a,b \in \mathbb{C}$ take the vector equal to a on $P\cdot(m,t)$ and to b on $P\cdot(m,t')$: with $X = \sum_{h,h'\in P} M(h\cdot(m,t), h'\cdot(m,t))$, $Y = \sum_{h,h'} M(h\cdot(m,t), h'\cdot(m,t'))$ and $Z = \sum_{h,h'} M(h\cdot(m,t'), h'\cdot(m,t'))$ the quadratic form is $|a|^2X + \bar a b Y + a\bar b \bar Y + |b|^2 Z \ge 0$, so $X, Z \ge 0$ and $|Y|^2 \le XZ$. Dividing by $\mathrm{wt}(\alpha)^2$, with $X/\mathrm{wt}(\alpha) = d_{\eta,i,m,\alpha}(P,\kappa_m^{t,t};t)$ etc.,

$$\big|\mathrm{En}^{\uparrow}_{\eta,i,m,\alpha}(P,\kappa_m^{t,t'};t,t')\big| \le \big(d_{\eta,i,m,\alpha}(P,\kappa_m^{t,t};t)\, d_{\eta,i,m,\alpha}(P,\kappa_m^{t',t'};t')\big)^{1/2}. \tag{15.7}$$

In the same way every $d_{\eta,i,m,\alpha'}(P,\kappa_m^{s,s};s)$, $s \in S$, is ≥ 0; write $d_s(\alpha')$ for it.

Below the top, $i \le r$. Let $\theta = \sum_A \theta_A$ over all $A \subseteq \{1,\dots,f\}$; it depends only on (η,i,m,α), and $\sum_{\alpha'} \theta(\alpha') \le 2\cdot 2^f \le 2\cdot 3^f$. Let $A = \{v : \varrho_{j,m,v} < o_v\}$. As in the factorisation of the majorant, $\mathrm{mj}'_{j,m}(t^{-1}-t'^{-1}) = \prod_{v\in A} (\varrho_{j,m,v}/o_v)^{n_{\mathrm{d}}}$ (the factors with $v \notin A$ equal 1). Item 1 for this A, divided by $\prod_{v\in A} o_v^{n_{\mathrm{d}}} > 0$, with $\varrho' \le \varrho$, $d \ge 0$ and $\theta_A \le \theta$, gives the bound of (Pt6).

The top, $i = r+1$, $m \ge 2$. Let $\theta = \sum_B \theta_B$ over all B; $\sum_{\alpha'} \theta(\alpha') \le 2^f \le 2\cdot 3^f$. Write $\lambda_v = \lambda_{j,m,v}$, $\varrho_v = \varrho_{j,m,v}$, and let $A = \{v : 2\lambda_v < o_v\}$, $A_1 = \{v \in A : |t|_v \le |t'|_v\}$, $A_2 = A \setminus A_1$. Item 2 with $B = A_1$ for the kernel $\kappa_m^{t,t}$ and the point t, and with $B = A_2$ for $\kappa_m^{t',t'}$ and t' (both positive semidefinite on P, as $h \mapsto h\cdot(m,s)$ is injective), gives

$$d_t(\alpha) \le \prod_{v\in A_1} (|t|_v\lambda_v)^{2n_{\mathrm{d}}}\, S_1, \qquad d_{t'}(\alpha) \le \prod_{v\in A_2} (|t'|_v\lambda_v)^{2n_{\mathrm{d}}}\, S_2,$$

where $S_1 = \sum_{\alpha'} \theta_{A_1}(\alpha') d_t(\alpha')$ and $S_2 = \sum_{\alpha'} \theta_{A_2}(\alpha') d_{t'}(\alpha')$. For $v \in A_1$, $o_v \le |t|_v^{-1} + |t'|_v^{-1} \le 2|t|_v^{-1}$, so $|t|_v\lambda_v \le 2\lambda_v/o_v < 1$; likewise $|t'|_v\lambda_v \le 2\lambda_v/o_v < 1$ for $v \in A_2$. For $v \in A$, $2\lambda_v/o_v \le \min(1, \varrho_v/o_v)$ as $2\lambda_v \le \varrho_v$; for $v \notin A$, $\varrho_v \ge 2\lambda_v \ge o_v$ and the factor of $\mathrm{mj}'_{j,m}$ at v is 1. Hence, by (15.7) and $\sqrt{S_1S_2} \le (S_1+S_2)/2$,

$$\begin{aligned}\big|\mathrm{En}^{\uparrow}_{\eta,r+1,m,\alpha}(P,\kappa_m^{t,t'};t,t')\big| &\le \prod_{v\in A} \Big(\frac{2\lambda_v}{o_v}\Big)^{n_{\mathrm{d}}} \sqrt{S_1S_2} \le \mathrm{mj}'_{j,m}(t^{-1}-t'^{-1})\,\frac{S_1+S_2}{2}\\ &\le \mathrm{mj}'_{j,m}(t^{-1}-t'^{-1})\,\frac{1}{2}\sum_{\alpha'} \theta(\alpha')\big(d_t(\alpha')+d_{t'}(\alpha')\big),\end{aligned}$$

using $\theta_{A_1}, \theta_{A_2} \le \theta$ and $d \ge 0$. This is the bound of (Pt6). □

Proposition 15.18. *Let G be a second countable, locally compact, unimodular group with Haar measure μ. Let $(\sigma,\mathcal{H})$ be a strongly continuous unitary representation of G and $d_\sigma > 0$ such*

that for all $a, b, a', b' \in \mathcal{H}$ the function $g \mapsto \langle b, \sigma(g)a\rangle\overline{\langle b', \sigma(g)a'\rangle}$ is μ-integrable with

$$\int_G \langle b, \sigma(g)a\rangle\overline{\langle b', \sigma(g)a'\rangle}\, d\mu(g) = \frac{\langle a', a\rangle\langle b, b'\rangle}{d_\sigma},$$

and let $w \in \mathcal{H}$ with $\|w\| = 1$. Let $S \subseteq G$ be a closed unimodular subgroup with Haar measure μ_S that is amenable in the following sense: for every compact $K \subseteq S$ and every $\epsilon > 0$ there is a measurable $\Omega \subseteq S$ with $0 < \mu_S(\Omega) < \infty$ and $\mu_S(\Omega) \le (1+\epsilon)\,\mu_S^*(\{t \in \Omega : Kt \subseteq \Omega\})$, where μ_S^* is the outer measure of μ_S. Let ν be a σ-finite measure on G with $\int_G f\, d\mu = \int_G \int_S f(sx)\, d\mu_S(s)\, d\nu(x)$ for all measurable $f \ge 0$. Let (τ, V) be a unitary representation of S on a finite-dimensional Hilbert space and $W\colon G \to V$ a continuous map such that

1. *$W(sx) = \tau(s)W(x)$ for $s \in S$, $x \in G$;*
2. *for every $x \in G$ the function $y \mapsto d_\sigma\, \overline{\langle w, \sigma(y)w\rangle}\, W(xy)$ is μ-integrable with integral $W(x)$;*
3. *$\int_G \|W\|\, d\nu < \infty$ and $\int_G \|W\|^2\, d\nu = 1$.*

Let $(S', \mu_{S'}, \nu', \tau', V', W')$ be data with the same properties. Let $(\mathcal{C}, m_{\mathcal{C}})$ be a measure space and $\sec\colon \mathcal{C} \to G$ a measurable map with

$$\int_G \varphi\, d\mu = \int_{\mathcal{C}} \int_S \int_{S'} \varphi\big(s \sec(c)\, s'^{-1}\big)\, d\mu_{S'}(s')\, d\mu_S(s)\, dm_{\mathcal{C}}(c)$$

for all measurable $\varphi \ge 0$ on G. Assume that for every $c \in \mathcal{C}$ the map $x \mapsto W(x) \otimes W'(\sec(c)^{-1}x)^*$ is μ-integrable, and that the integrals

$$\iiiint |\langle \sigma(z)w, \sigma(s\sec(c)\, s'^{-1})\sigma(z')w\rangle|\, \|W(z)\|\, \|W'(z')\|\, d\mu_{S'}(s')\, d\mu_S(s)\, d\nu'(z')\, d\nu(z) \quad (c \in \mathcal{C}),$$

$$\iiint |\langle \sigma(z)w, \sigma(s)\sigma(z')w\rangle|\, \|W(z)\|\, \|W(z')\|\, d\mu_S(s)\, d\nu(z')\, d\nu(z)$$

and the analogue of the last one for (S', ν', W') are finite. For $\gamma \in G$ put $\mathrm{Or}(\gamma) = \int_G W(x) \otimes W'(\gamma^{-1}x)^*\, d\mu(x) \in \mathrm{Hom}(V', V)$. Then

$$\int_{\mathcal{C}} \big\|\mathrm{Or}(\sec(c))\big\|_{\mathrm{HS}}^2\, dm_{\mathcal{C}}(c) \le \frac{1}{d_\sigma},$$

the integral being the lower Lebesgue integral (the supremum of the integrals of the measurable simple functions below the integrand) if the integrand is not known to be measurable.

Proof. **Standing facts.** (a) G, S, S' are second countable and locally compact, hence σ-compact; $\mu, \mu_S, \mu_{S'}$ are σ-finite, Borel sets of products are products of Borel sets, continuous functions on products are measurable, and Tonelli's and Fubini's theorems apply to $\mu, \mu_S, \mu_{S'}, \nu, \nu'$. (b) By unimodularity μ and μ_S are invariant under left and right translations and under inversion; these maps preserve measurable sets, hence also outer measures. (c) The quotient identity for ν extends to every μ-integrable complex function f (apply it to the positive and negative parts of the real and imaginary parts): $\int_G f\, d\mu = \int_G \int_S f(sx)\, d\mu_S(s)\, d\nu(x) = \int_G \int_S f(s^{-1}x)\, d\mu_S(s)\, d\nu(x)$, the inner integrals converging absolutely for ν-almost every x; likewise for ν'. (d) $\|W(sx)\| = \|W(x)\|$ for $s \in S$, by item 1 and the unitarity of τ. (e) Pairing item 2 with $e \in V$ (the inner product is conjugate-linear in the first argument) gives, for $x \in G$,

$$\langle W(x), e\rangle = d \int_G \langle w, \sigma(y)w\rangle\, \langle W(xy), e\rangle\, d\mu(y), \tag{15.8}$$

and the same for W'.

Truncated Bessel vectors. For a measurable $\Omega \subseteq S$ with $\mu_S(\Omega) < \infty$ and $e \in V$ put

$$y_\Omega(e) = \int_G \int_\Omega \langle W(s^{-1}z), e\rangle\, \sigma(s^{-1}z) w \, d\mu_S(s)\, d\nu(z) \in \mathcal{H}.$$

The integrand is continuous on $S \times G$ (strong continuity of σ, continuity of W), its norm is at most $\|W(z)\|\,\|e\|$ by (d), and $\int_G \int_\Omega \|W(z)\|\, d\mu_S\, d\nu = \mu_S(\Omega) \int_G \|W\|\, d\nu < \infty$ by item 3; so the Bochner integral exists, and it is linear in e. Put $E(\Omega) = \sum_i \|y_\Omega(e_i)\|^2$. Define $y'_{\Omega'}(e')$ and $E'(\Omega')$ in the same way for measurable $\Omega' \subseteq S'$ of finite measure, and let $X_{\Omega,\Omega'}(g) \in \mathrm{Hom}(V', V)$ be the operator with

$$\langle e, X_{\Omega,\Omega'}(g) e' \rangle = d\, \langle y_\Omega(e), \sigma(g)\, y'_{\Omega'}(e') \rangle \qquad (e \in V,\ e' \in V',\ g \in G);$$

it exists since the right side is conjugate-linear in e and linear in e', and $g \mapsto X_{\Omega,\Omega'}(g)$ is continuous.

Schur orthogonality for the truncations. By the orthogonality hypothesis with $a = a' = y'_{\Omega'}(e'_j)$ and $b = b' = y_\Omega(e_i)$,

$$\int_G \|X_{\Omega,\Omega'}(g)\|_{\mathrm{HS}}^2\, d\mu(g) = d^2 \sum_{i,j} \int_G \big|\langle y_\Omega(e_i), \sigma(g) y'_{\Omega'}(e'_j)\rangle\big|^2 d\mu(g) = d\, E(\Omega)\, E'(\Omega'). \tag{15.9}$$

Translation rule. For $s \in S$, $s' \in S'$ and $\gamma \in G$,

$$X_{\Omega,\Omega'}(s\gamma s'^{-1}) = \tau(s)\, X_{\Omega s, \Omega' s'}(\gamma)\, \tau'(s')^{-1}, \qquad \text{so} \qquad \|X_{\Omega,\Omega'}(s\gamma s'^{-1})\|_{\mathrm{HS}} = \|X_{\Omega s,\Omega' s'}(\gamma)\|_{\mathrm{HS}}. \tag{15.10}$$

Indeed, substituting $t = t_1 s^{-1}$ (right invariance of μ_S; $t \in \Omega$ if and only if $t_1 \in \Omega s$) and using $W(t^{-1}z) = W(st_1^{-1}z) = \tau(s) W(t_1^{-1}z)$ and $\langle \tau(s)v, e\rangle = \langle v, \tau(s)^{-1} e\rangle$, one gets $\sigma(s)^{-1} y_\Omega(e) = y_{\Omega s}(\tau(s)^{-1} e)$, and likewise for S'; hence

$$\langle e, X_{\Omega,\Omega'}(s\gamma s'^{-1}) e' \rangle = d \langle \sigma(s)^{-1} y_\Omega(e), \sigma(\gamma)\sigma(s')^{-1} y'_{\Omega'}(e') \rangle = \langle \tau(s)^{-1} e, X_{\Omega s, \Omega' s'}(\gamma) \tau'(s')^{-1} e' \rangle.$$

The Hilbert–Schmidt norm is invariant under multiplication by unitaries.

Følner sequences. By (a) there are compact sets $K_1 \subseteq K_2 \subseteq \cdots$ in S with $1 \in K_1$ and $\bigcup_N K_N = S$. By the amenability hypothesis there are measurable $\Omega_n \subseteq S$ with $0 < \mu_S(\Omega_n) < \infty$ and $\mu_S(\Omega_n) \le (1 + \frac{1}{n}) \mu_S^*(A_n)$, where $A_n = \{t \in \Omega_n : K_n t \subseteq \Omega_n\}$. Choose K'_N, Ω'_n, A'_n in S' in the same way. If $u \in K_N$ and $n \ge N$, then $A_n \subseteq \{t \in \Omega_n : ut \in \Omega_n\} = \Omega_n \cap u^{-1}\Omega_n$.

The energy of the truncations is $\mu_S(\Omega_n)/d$ asymptotically:

$$\lim_{n\to\infty} \frac{E(\Omega_n)}{\mu_S(\Omega_n)} = \frac{1}{d}, \qquad \lim_{n\to\infty} \frac{E'(\Omega'_n)}{\mu_{S'}(\Omega'_n)} = \frac{1}{d}. \tag{15.11}$$

We prove the first. Write $\|y_\Omega(e_i)\|^2 = \langle y_\Omega(e_i), y_\Omega(e_i)\rangle$ as an integral over $(z, s, z', t) \in (G \times \Omega)^2$; the integrand is bounded by $\|W(z)\|\|W(z')\|$, which is integrable, so we may sum over i inside. By Parseval, item 1 and unitarity, $\sum_i \overline{\langle W(s^{-1}z), e_i\rangle} \langle W(t^{-1}z'), e_i\rangle = \langle W(t^{-1}z'), W(s^{-1}z)\rangle = \langle W(st^{-1}z'), W(z)\rangle$, and $\langle \sigma(s^{-1}z)w, \sigma(t^{-1}z')w\rangle = \langle \sigma(z)w, \sigma(st^{-1})\sigma(z')w\rangle$. So, with

$$k(z, z', u) = \langle W(uz'), W(z)\rangle\, \langle \sigma(z)w, \sigma(u)\sigma(z')w\rangle,$$

$E(\Omega) = \int\int_\Omega\int_\Omega k(z, z', st^{-1})\, d\mu_S(t)\, d\mu_S(s)\, d\nu(z')\, d\nu(z)$. For fixed z, z', s the map $t \mapsto u = st^{-1}$ preserves μ_S (unimodularity), and $t = u^{-1}s \in \Omega$ if and only if $s \in u\Omega$; by Fubini on $\Omega \times S$ (k is bounded for fixed z, z') the inner double integral is $\int_S k(z, z', u)\, \mu_S(\Omega \cap u\Omega)\, d\mu_S(u)$. Hence

$$\frac{E(\Omega_n)}{\mu_S(\Omega_n)} = \int_G \int_G \int_S k(z, z', u)\, a_n(u)\, d\mu_S(u)\, d\nu(z')\, d\nu(z), \qquad a_n(u) = \frac{\mu_S(\Omega_n \cap u\Omega_n)}{\mu_S(\Omega_n)} \in [0, 1],$$

the interchange being justified by $|k(z,z',u)| \le \|W(z)\|\|W(z')\||\langle\sigma(z)w,\sigma(u)\sigma(z')w\rangle|$ (by (d)), whose integral is the second finite integral of the hypotheses. For fixed u, take N with $u^{-1}\in K_N$; for $n\ge N$, $A_n\subseteq\Omega_n\cap u\Omega_n$, so $a_n(u)\ge \mu_S^*(A_n)/\mu_S(\Omega_n)\ge n/(n+1)$; thus $a_n\to 1$ pointwise. By dominated convergence the limit in (15.11) exists and equals $\iint\int k$. For ν-almost every z the function $g_z(x)=\langle W(x),W(z)\rangle\langle\sigma(z)w,\sigma(x)w\rangle$ is μ-integrable with

$$\int_G g_z\,d\mu=\int_G\int_S k(z,z',u)\,d\mu_S(u)\,d\nu(z')$$

by (c), as $k(z,z',u)=g_z(uz')$. Since $\langle\sigma(z)w,\sigma(x)w\rangle=\langle w,\sigma(z^{-1}x)w\rangle$, the substitution $x=zy$ and item 2 give

$$\int_G g_z\,d\mu=\Big\langle\int_G\overline{\langle w,\sigma(y)w\rangle}\,W(zy)\,d\mu(y),\,W(z)\Big\rangle=\frac{1}{d}\,\|W(z)\|^2,$$

so the limit is $\frac{1}{d}\int_G\|W\|^2d\nu=\frac{1}{d}$ by item 3.

Each double coset is bounded below by the averaged truncations. Fix $c\in\mathcal{C}$, put $\gamma=\sec(c)$, and

$$F_n(c)=\frac{1}{\mu_S(\Omega_n)\mu_{S'}(\Omega_n')}\int_S\int_{S'}\big\|X_{\Omega_n,\Omega_n'}(s\gamma s'^{-1})\big\|_{\mathrm{HS}}^2\,d\mu_{S'}(s')\,d\mu_S(s).$$

We show $\|\mathrm{Or}(\gamma)\|_{\mathrm{HS}}^2\le\liminf_n F_n(c)$. Let $M(x,x')=|\langle\sigma(x)w,\sigma(\gamma)\sigma(x')w\rangle|\,\|W(x)\|\,\|W'(x')\|$. Since $\langle\sigma(t^{-1}z)w,\sigma(\gamma)\sigma(t'^{-1}z')w\rangle=\langle\sigma(z)w,\sigma(t\gamma t'^{-1})\sigma(z')w\rangle$ and by (d), the first finite integral of the hypotheses is

$$\Theta=\int_G\int_G\int_S\int_{S'}M(t^{-1}z,t'^{-1}z')\,d\mu_{S'}(t')\,d\mu_S(t)\,d\nu'(z')\,d\nu(z)<\infty,$$

and by (c) applied in each variable $\int_{G\times G}M\,d(\mu\otimes\mu)=\Theta$. Fix unit vectors $e\in V$, $e'\in V'$ and put $\kappa(x,x')=\overline{\langle W(x),e\rangle}\langle W'(x'),e'\rangle\langle\sigma(x)w,\sigma(\gamma)\sigma(x')w\rangle$, so $|\kappa|\le M$.

- By the integrability of $x\mapsto W(x)\otimes W'(\gamma^{-1}x)^*$,

$$\langle e,\mathrm{Or}(\gamma)e'\rangle=\int_G\overline{\langle W(x),e\rangle}\langle W'(\gamma^{-1}x),e'\rangle\,d\mu(x).$$

  By (15.8) for W' at $\gamma^{-1}x$ and the substitution $x'=\gamma^{-1}xy$ (left invariance),

$$\langle W'(\gamma^{-1}x),e'\rangle=d\int_G\langle w,\sigma(x^{-1}\gamma x')w\rangle\langle W'(x'),e'\rangle\,d\mu(x'),$$

  and $\langle w,\sigma(x^{-1}\gamma x')w\rangle=\langle\sigma(x)w,\sigma(\gamma)\sigma(x')w\rangle$. So $\langle e,\mathrm{Or}(\gamma)e'\rangle=d\int_G\int_G\kappa\,d\mu(x')\,d\mu(x)$, and since $M\in L^1(\mu\otimes\mu)$, by Fubini and (c),

$$\langle e,\mathrm{Or}(\gamma)e'\rangle=d\int_G\int_S\int_G\int_{S'}\kappa(t^{-1}z,t'^{-1}z')\,d\mu_{S'}(t')\,d\nu'(z')\,d\mu_S(t)\,d\nu(z).$$

- For measurable $B\subseteq S$, $B'\subseteq S'$ of finite measure, expanding the definitions (Fubini; the integrand is bounded by $\|W(z)\|\|W'(z')\|$) gives the same expression for $\langle e,X_{B,B'}(\gamma)e'\rangle$ with t restricted to B and t' to B'. Hence

$$\big|\langle e,X_{B,B'}(\gamma)e'\rangle-\langle e,\mathrm{Or}(\gamma)e'\rangle\big|\le d\iiint(1-\mathbf{1}_B(t)\mathbf{1}_{B'}(t'))M(t^{-1}z,t'^{-1}z').$$

- Let T_N be the same integral with $\mathbf{1}_{K_N}(t)\mathbf{1}_{K'_N}(t')$ in place of $\mathbf{1}_B(t)\mathbf{1}_{B'}(t')$. Since $K_N \uparrow S$, $K'_N \uparrow S'$ and $\Theta < \infty$, $T_N \to 0$ by dominated convergence. If $K_N \subseteq B$ and $K'_N \subseteq B'$, every matrix entry of $X_{B,B'}(\gamma) - \mathrm{Or}(\gamma)$ is at most dT_N in modulus, so $\|X_{B,B'}(\gamma)\|_{\mathrm{HS}} \geq \|\mathrm{Or}(\gamma)\|_{\mathrm{HS}} - dT_N\sqrt{nn'}$.

Fix N and let $n \geq N$. By (15.10) the integrand of $F_n(c)$ is $f_n(s,s') = \|X_{\Omega_n s,\Omega'_n s'}(\gamma)\|^2_{\mathrm{HS}}$, a continuous function of (s,s'). For $t \in A_n$, $K_N t \subseteq K_n t \subseteq \Omega_n$, i.e. $K_N \subseteq \Omega_n t^{-1}$; likewise for $t' \in A'_n$. With $\beta_N = \max\bigl(0, \|\mathrm{Or}(\gamma)\|_{\mathrm{HS}} - dT_N\sqrt{nn'}\bigr)^2$ we get $f_n \geq \beta_N$ on $A_n^{-1} \times A_n'^{-1}$. Let $P = \{f_n \geq \beta_N\}$, a closed set. For $s \in A_n^{-1}$ the section P_s contains $A_n'^{-1}$, so $\mu_{S'}(P_s) \geq \mu^*_{S'}(A'_n)$ by (b); the measurable set $\{s : \mu_{S'}(P_s) \geq \mu^*_{S'}(A'_n)\}$ contains A_n^{-1}, so its measure is at least $\mu^*_S(A_n)$. By Tonelli,

$$\int_S \int_{S'} f_n \geq \beta_N \int_S \mu_{S'}(P_s)\, d\mu_S(s) \geq \beta_N\, \mu^*_S(A_n)\, \mu^*_{S'}(A'_n), \qquad \text{so} \qquad F_n(c) \geq \beta_N \Bigl(\frac{n}{n+1}\Bigr)^2.$$

Hence $\liminf_n F_n(c) \geq \beta_N$ for every N, and $\beta_N \to \|\mathrm{Or}(\gamma)\|^2_{\mathrm{HS}}$ as $T_N \to 0$.

Fatou's lemma concludes. The map $(c,s,s') \mapsto \|X_{\Omega_n,\Omega'_n}(s\sec(c)\, s'^{-1})\|^2_{\mathrm{HS}}$ is measurable (a continuous function of a measurable map), so F_n is measurable by Tonelli. By the disintegration hypothesis for $\varphi = \|X_{\Omega_n,\Omega'_n}\|^2_{\mathrm{HS}}$ and (15.9),

$$\int_{\mathcal{C}} F_n\, dm_{\mathcal{C}} = \frac{1}{\mu_S(\Omega_n)\mu_{S'}(\Omega'_n)} \int_G \|X_{\Omega_n,\Omega'_n}\|^2_{\mathrm{HS}}\, d\mu = d \cdot \frac{E(\Omega_n)}{\mu_S(\Omega_n)} \cdot \frac{E'(\Omega'_n)}{\mu_{S'}(\Omega'_n)} \longrightarrow d \cdot \frac{1}{d} \cdot \frac{1}{d} = \frac{1}{d}$$

by (15.11). By the pointwise bound, the monotonicity of the lower integral and Fatou's lemma,

$$\int_{\mathcal{C}} \|\mathrm{Or}(\sec(c))\|^2_{\mathrm{HS}}\, dm_{\mathcal{C}}(c) \leq \int_{\mathcal{C}} \liminf_n F_n\, dm_{\mathcal{C}} \leq \liminf_n \int_{\mathcal{C}} F_n\, dm_{\mathcal{C}} = \frac{1}{d}.$$

□

Lemma 15.19. *Let F be a number field and H a connected reductive group over F with $H(F_\infty)$ compact. Let μ_∞ and μ_f be Haar measures on $H(F_\infty)$ and $H(\mathbb{A}_{F,f})$, put $\mu = \mu_\infty \otimes \mu_f$ on $H(\mathbb{A}_F) = H(F_\infty) \times H(\mathbb{A}_{F,f})$, and let $K \subseteq H(\mathbb{A}_{F,f})$ be a compact open subgroup. For $c \in H(\mathbb{A}_{F,f})$ put $\Gamma_c(K) = H(F) \cap cKc^{-1}$.*

1. *The set $H(F)\backslash H(\mathbb{A}_{F,f})/K$ is finite, every $\Gamma_c(K)$ is finite, and for any set $R(K)$ of representatives c of the double cosets*

$$\mu([H]) = \mu_\infty\bigl(H(F_\infty)\bigr)\, \mu_f(K) \sum_{c \in R(K)} \frac{1}{|\Gamma_c(K)|}.$$

2. *If $K'' \subseteq K$ is an open subgroup with $\Gamma_c(K'') = \{1\}$ for every $c \in H(\mathbb{A}_{F,f})$, then $\mu_f(K) = [K : K'']\, \mu_f(K'')$ and*

$$\bigl|H(F)\backslash H(\mathbb{A}_{F,f})/K''\bigr| = \frac{\mu([H])}{\mu_\infty\bigl(H(F_\infty)\bigr)\, \mu_f(K'')}.$$

Proof. **Finiteness.** The double coset set $H(F)\backslash H(\mathbb{A}_{F,f})/K$ is finite by Borel's finiteness of class numbers [38]. Each $\Gamma_c(K)$ is the intersection of a discrete subgroup with the compact group cKc^{-1}, hence finite.

Decomposition of the quotient. Let $R(K)$ be a set of representatives. Then $H(\mathbb{A}_F) = \bigsqcup_{c \in R(K)} H(F)\bigl(H(F_\infty) \times cK\bigr)$, a disjoint union of open sets invariant under left multiplication

by $H(F)$. For fixed c, $\gamma \in H(F)$ and $(h, ck), (h', ck') \in H(F_\infty) \times cK$ with $\gamma(h, ck) = (h', ck')$, one has $\gamma = ck'k^{-1}c^{-1} \in \Gamma_c(K)$. Hence the natural map

$$\Gamma_c(K)\backslash\big(H(F_\infty) \times cK\big) \longrightarrow H(F)\backslash H(F)\big(H(F_\infty) \times cK\big)$$

is a bijection, and the action of the finite group $\Gamma_c(K)$ on $H(F_\infty) \times cK$ by left multiplication is free (already on the first factor). A fundamental domain for this action has measure $\mu(H(F_\infty) \times cK)/|\Gamma_c(K)| = \mu_\infty(H(F_\infty))\mu_f(K)/|\Gamma_c(K)|$, using the left invariance of μ_f. The union over $c \in R(K)$ of these fundamental domains is a fundamental domain of $H(F)$ in $H(\mathbb{A}_F)$, which proves item 1.

Item 2. K is the disjoint union of $[K : K'']$ left cosets kK'', each of measure $\mu_f(K'')$, and $[K : K''] < \infty$ since K is compact and K'' open. Item 1 for K'', with all $|\Gamma_c(K'')| = 1$, gives $\mu([H]) = \mu_\infty(H(F_\infty))\,\mu_f(K'')\,|R(K'')|$. □

Proposition 15.20. *Let E/F be a CM extension, V a nondegenerate hermitian space over E of dimension n, $G = \mathrm{U}(V)$, and μ a Haar measure on $G(\mathbb{A}_F)$.*

1. *Let $X_0 \in V^a$ with $a \geq 1$, $2a < n$ and $T = \mathrm{gram}(X_0)$ nondegenerate, let $H \subseteq G$ be the stabiliser of X_0 (the elements fixing each entry of X_0), and let μ' be a Haar measure on $H(\mathbb{A}_F)$ such that*

$$\int_{G(\mathbb{A}_F)/H(\mathbb{A}_F)} \Phi(gX_0)\, d\dot{\mu}(gH(\mathbb{A}_F)) = g_\infty(\Phi_\infty, T) \prod_{w<\infty} g_w(\Phi_w, T) \tag{15.12}$$

   for every admissible test function Φ on $V^a_{\mathbb{A}_F}$. Then $\mu'([H]) = \mu([G]) < \infty$.

2. *Let X_1, X_2, X_3 be tuples as in item 1, of sizes a_1, a_2, a_3, with stabilisers H_1, H_2, H_3 and Haar measures μ'_1, μ'_2, μ'_3 satisfying* (15.12) *for X_1, X_2, X_3 respectively. Then*

$$\mu'_3([H_3])\,\mu([G]) = \mu'_1([H_1])\,\mu'_2([H_2]).$$

Proof. **Item 1. A positive test function.** Let $L \subset V$ be an $\mathcal{O}_E$-lattice containing the entries of X_0 (enlarge any lattice by the $\mathcal{O}_E$-span of these entries). Put $\Phi_w = \mathbf{1}_{(L\otimes\mathcal{O}_{F_w})^a}$ for every finite w and let $\Phi_\infty \geq 0$ be smooth and compactly supported with $\Phi_\infty(X_0) > 0$. Then $\Phi = \Phi_\infty \otimes \bigotimes_w \Phi_w$ is admissible, $\Phi \geq 0$, Φ is continuous on $V^a_{\mathbb{A}}$ and $\Phi(X_0) = \Phi_\infty(X_0) > 0$. Write I for the right side of (15.12) for this Φ, and $f(g) = \Phi(g^{-1}X_0)$ for $g \in G(\mathbb{A})$. Since $H(\mathbb{A})$ fixes X_0, $f(hg) = f(g)$ for $h \in H(\mathbb{A})$; f is continuous, $f \geq 0$ and $f(1) > 0$.

The rational points of the orbit form one orbit (Witt). Let $X \in V^a$ with $\mathrm{gram}(X) = T$. As T is nondegenerate, the entries of X_0 and of X are linearly independent over E, and the E-linear map from the span of X_0 to the span of X sending the i-th entry of X_0 to that of X preserves $\langle\,,\rangle$; both spans are nondegenerate. By Witt's extension theorem for hermitian forms [214] the map extends to an isometry $\gamma \in G(F)$ of V, so $X = \gamma X_0$. Hence $\gamma \mapsto \gamma X_0$ induces a bijection $G(F)/H(F) \to \{X \in V^a : \mathrm{gram}(X) = T\}$, $H(F) = G(F) \cap H(\mathbb{A})$, and

$$\vartheta_T(g) = \sum_{\gamma \in G(F)/H(F)} \Phi(g^{-1}\gamma X_0) = \sum_{\gamma \in H(F)\backslash G(F)} f(\gamma g) \qquad (g \in G(\mathbb{A})).$$

Unfolding. By the unfolding identity for the discrete subgroups $H(F) \subseteq G(F)$ and the quotient integral formula for $H(F)\backslash H(\mathbb{A})$, with the left $H(\mathbb{A})$-invariance of f,

$$\int_{[G]} \vartheta_T\, d\mu = \int_{H(F)\backslash G(\mathbb{A})} f = \int_{H(\mathbb{A})\backslash G(\mathbb{A})} \int_{H(F)\backslash H(\mathbb{A})} f(hg)\, d\mu'(h)\, d\dot{\mu} = \mu'([H])\, I. \tag{15.13}$$

Siegel's formula. By Theorem B.158 (hypotheses: E/F CM, V nondegenerate, $1 \le a$, $2a < n$, T nondegenerate, Φ admissible), $\mu([G]) < \infty$, ϑ_T is integrable on $[G]$ and $\int_{[G]} \vartheta_T \, d\mu = \mu([G])\, I$. Moreover $\mu([G]) > 0$, since $G(\mathbb{A})$ is the countable union of the $G(F)$-translates of a fundamental domain. In particular $I < \infty$.

The integral is positive. Choose an open neighbourhood U of 1 in $G(\mathbb{A})$ with $f > 0$ on U and $(UU^{-1}) \cap H(F) = \{1\}$ (discreteness of $H(F)$). For $\varphi = \mathbf{1}_U f$ and every g, at most one $h \in H(F)$ has $hg \in U$, so $\sum_{h \in H(F)} \varphi(hg) \le f(g)$ by the invariance of f. Hence $0 < \int_{G(\mathbb{A})} \varphi \, d\mu = \int_{H(F)\backslash G(\mathbb{A})} \sum_{h \in H(F)} \varphi(hg) \le \int_{H(F)\backslash G(\mathbb{A})} f$, the first inequality because U is a nonempty open set and $\varphi > 0$ on it. With (15.13) and Siegel's formula, $\mu([G])\, I > 0$, so $0 < I < \infty$.

Conclusion of item 1. Comparing (15.13) with Siegel's formula gives $\mu'([H])\, I = \mu([G])\, I$, and dividing by $I \in (0, \infty)$ gives $\mu'([H]) = \mu([G]) < \infty$.

Item 2. By item 1 applied to X_1, X_2, X_3, $\mu_i'([H_i]) = \mu([G])$ for $i = 1, 2, 3$, so both sides equal $\mu([G])^2$. □

16 The local gain of the non-generic row

This section proves the local gain (Ng5) of the non-generic row (Lemma 16.4), which the row estimates of Section 15 use (Theorem 15.3). It is the longest section of Part III and it is entirely local: its objects are hermitian lattices over a local quadratic algebra at one finite place, with their unitary groups, masses and local densities. Apart from Lemma 16.4, the only result of the section used elsewhere is Lemma 16.27, the conjugacy of self-dual hermitian lattices over an unramified or split local quadratic algebra, which Appendix D uses as well; a reader who accepts Lemma 16.4 may skip the rest.

The statement to be proved is that the amplitudes of the non-generic terms gain a factor $q^{-(k-2r-5)}$ against the total mass, up to a factor $H^{39(r+1)^2}$, when k is large compared with r (Theorem 16.38); one non-generic place suffices for the global gain (Lemma 16.40). A term is generic when its defect order is 1; otherwise its defect order is q^i with $i \ge 1$ (Proposition 16.8). Three facts produce the gain. Terms of large defect order are rare: a defect of order β costs $\beta^{-(k-1)}$ in mass (Proposition 16.20). Non-generic terms of the first type have fewer defect classes than their defect order by a factor q (Proposition 16.10). Terms of the second type have phases that cancel on average over Eichler moves (Proposition 16.30). Subsection 16.1 reduces (Ng5) to the local non-generic bound at a local frame pair. Subsection 16.2 shows that local frame pairs carry local non-generic records with the properties (Lg1)–(Lg5), Subsection 16.3 proves the mass bound for a given defect order, and Subsection 16.4 proves the cancellation and the local non-generic bound.

16.1 The local gain from frame realisations

This subsection reduces the local gain (Ng5) to a statement at one place. Lemma 16.4 derives (Ng5) from frame realisations of the local amplitudes at the places of a finite set, through Lemma 16.40: if the non-generic amplitudes gain $q_p^{-(k-2r-5)}$ at the places p of a set Ω and the other local amplitudes are bounded, the gain at a single place of Ω passes to the global amplitude. Corollary 16.5 supplies the hypothesis of that lemma for realised local data, and it rests on Corollary 16.6, the local non-generic bound at a local frame pair. The rest of the section proves Corollary 16.6, which follows from Theorem 16.7 and Theorem 16.38.

Definition 16.1. The notation introduced here is local to this definition and to the results that apply it. Let $r \ge 0$ and $k \ge 1$ be integers. **Local non-generic records** (with parameters r, k)

consist of

- a group G acting on a set X and subgroups $K_0 \subseteq \Sigma \subseteq G$; for $x \in X$, $\Sigma_x = \{g \in \Sigma : gx = x\}$; a subgroup $A \subseteq G$ is **commensurable with** K_0 if $[A : A \cap K_0]$ and $[K_0 : A \cap K_0]$ are finite, and then $\mathrm{vol}(A) = [A : A \cap K_0]/[K_0 : A \cap K_0]$;
- a countable set D (the **data**) with weights $\nu\colon D \to [0, \infty)$;
- for every $d \in D$ a Σ-stable subset $X_d \subseteq X$ (the **terms over** d) that is the union of finitely many Σ-orbits, such that for $x \in X_d$ the group Σ_x is commensurable with K_0 and $\mathrm{vol}(\Sigma_{gx}) = \mathrm{vol}(\Sigma_x)$ for $g \in \Sigma$; the **mass** of x is $\mu(x) = 1/\mathrm{vol}(\Sigma_x)$;
- for every d, Σ-invariant functions on X_d: the **phase** $\omega_d\colon X_d \to \mathbb{C}$ with $|\omega_d| \le 1$, the **defect order** $b_d\colon X_d \to \mathbb{Z}_{\ge 1}$ and the **class count** $c_d\colon X_d \to \mathbb{Z}_{\ge 1}$; a Σ-stable subset $X_d^{\mathrm{II}} \subseteq X_d$ (the terms of **second type**) with a Σ-invariant **label** $\lambda_d\colon X_d^{\mathrm{II}} \to \mathbb{Z}^2$;
- integers $q \ge 2$, $a \ge 0$ and a real number $H \ge 1$ (the **height**).

For a Σ-stable subset $Y \subseteq X_d$ put

$$\mathrm{amp}_d(Y) = \sum_{O \in \Sigma\backslash Y} \mu(O)\,\omega_d(O), \qquad \mathrm{mass}_d(Y) = \sum_{O \in \Sigma\backslash Y} \mu(O)$$

(finite sums; μ and ω_d are constant on orbits). A term $x \in X_d$ is **generic** if $b_d(x) = 1$; X_d^{g} and $X_d^{\mathrm{n}} = X_d \setminus X_d^{\mathrm{g}}$ are the sets of generic and non-generic terms, and the **total mass** is

$$\mathrm{nn} = \sum_{d \in D} \nu(d)\,\mathrm{mass}_d(X_d) \in [0, \infty].$$

The records have

(Lg1) Defect orders if $q^a \le H$ and $b_d(x) \in \{q^i : 0 \le i \le a\}$ for all d and $x \in X_d$;

(Lg2) Class counts if $c_d(x) \in \{q^j : j \ge 0\}$ and $c_d(x) \le b_d(x)$ for all d, x, and $q\,c_d(x) \le b_d(x)$ for $x \in X_d^{\mathrm{n}} \setminus X_d^{\mathrm{II}}$;

(Lg3) Mass of a class count if for every d and every integer $c \ge 1$

$$\mathrm{mass}_d(\{x \in X_d : c_d(x) = c\}) \le H^{9(r+1)^2+12(r+1)}\,c^{k-1};$$

(Lg4) Share of a defect order if for every integer $\beta \ge 1$

$$\sum_{d \in D} \nu(d)\,\mathrm{mass}_d(\{x \in X_d : b_d(x) = \beta\}) \le 4H^{4(r+1)}\,\beta^{-(k-1)}\,\mathrm{nn};$$

(Lg5) Averaging kernels on the second type if $X_d^{\mathrm{II}} \subseteq X_d^{\mathrm{n}}$, $\lambda_d(x) \in \{1, \dots, r\} \times \{0, \dots, i-1\}$ whenever $x \in X_d^{\mathrm{II}}$ and $b_d(x) = q^i$, and for all d, $i \ge 1$ and $\lambda \in \mathbb{Z}^2$ the set $\mathcal{P} = \{x \in X_d^{\mathrm{II}} : b_d(x) = q^i,\ \lambda_d(x) = \lambda\}$ carries a function $m\colon \mathcal{P} \times \mathcal{P} \to [0, \infty)$ with $m(gx, gy) = m(x, y)$ for $g \in \Sigma$, $m(x, y) = m(y, x)$, $\{y : m(x, y) \ne 0\}$ finite for every x, and

$$\Big|\sum_{y \in \mathcal{P}} m(x, y) - 1\Big| \le \tfrac{24}{7} q^{-(k-2r-4)}, \qquad \Big|\sum_{y \in \mathcal{P}} m(x, y)\,\omega_d(y)\Big| \le \tfrac{24}{7} q^{-(k-2r-4)} \qquad (x \in \mathcal{P}).$$

Definition 16.2. The notation introduced here is local to this definition and to the results that apply it.

Local setting. Let F be a nonarchimedean local field of characteristic 0, with ring of integers $\mathcal{O}_F$, uniformiser ϖ, normalised valuation v ($v(\varpi)=1$) and $q=|\mathcal{O}_F/\varpi\mathcal{O}_F|$. Let E be either the unramified quadratic field extension of F or the algebra $F\times F$; $x\mapsto\bar{x}$ is its nontrivial F-automorphism ($(x,y)\mapsto(y,x)$ on $F\times F$), $\mathrm{N}(x)=x\bar{x}\in F$, and $\mathcal{O}_E$ is the integral closure of $\mathcal{O}_F$ in E. For $x\in E$ and $m\in\mathbb{Z}$ write $\varpi^m\mid x$ if $x\in\varpi^m\mathcal{O}_E$. Let $\psi_0\colon E\to\mathbb{C}^\times$ be a continuous unitary character of the additive group with $\psi_0(\bar{x})=\psi_0(x)$ for $x\in E$ and with conductor $\mathcal{O}_E$: for $x\in E$, $\psi_0(xy)=1$ for all $y\in\mathcal{O}_E$ if and only if $x\in\mathcal{O}_E$. Let $r\geq 0$ and $k\geq 1$ be integers, and put $n=k+2r+1$.

Local frame pairs. A **local frame pair** with parameters r,k consists of $V=E^n$ with a hermitian form $h\colon V\times V\to E$ (E-linear in the first variable, $h(y,x)=\overline{h(x,y)}$, with invertible Gram matrix), elements $T,T'\in F^\times$ and $\theta\in\{1,\varpi\}$, where $\theta=\varpi$ is allowed only if $E=F\times F$ and $T,T'\in\mathcal{O}_F^\times$, and families $f=(f_0,\dots,f_r)$, $f'=(f'_0,\dots,f'_r)\in V^{r+1}$ and $e^*=(e^*_0,\dots,e^*_{r-1})$, $e'^*\in V^r$, such that

(Fp1) Frames $h(f_a,f_b)=0$ unless $a=b=r$, $h(f_r,f_r)=-T$, $h(f_a,e^*_j)=\delta_{aj}$ ($0\leq a\leq r$, $0\leq j<r$) and $h(e^*_i,e^*_j)=0$; and the same for f',e'^*,T';

(Fp2) Point form for the matrix $Z=(h(f'_b,f_a))_{0\leq a,b\leq r}$, the matrix $((-1)^{r-b}Z_{ab})_{a,b}$ is block diagonal with diagonal blocks $t_1J_{s_1},\dots,t_mJ_{s_m}$, where $t_i\in E^\times$, $s_i\geq 1$, $\sum_i s_i=r+1$ and J_s is the $s\times s$ matrix with ones on the antidiagonal and zeros elsewhere;

(Fp3) Gram quantity with D_l the leading principal $l\times l$ minor of Z ($D_0=1$),

$$G=D_{r+1}\bar{D}_{r+1}-TT'\,D_r\bar{D}_r\neq 0.$$

Flags, groups, characters. For $g\in V^{r+1}$ and $0\leq j\leq r+1$ let $F_j(g)$ be the E-span of $g_0,\dots,g_{j-1}$; put $X=F_r(f)$, $X'=F_r(f')$, $M_E=F_{r+1}(f)+F_{r+1}(f')$ and $W_0=M_E^\perp$. Let $\mathrm{U}(V)$ be the unitary group of h. For $g\in\{f,f'\}$ let $N(g)$ be the group of $u\in\mathrm{U}(V)$ such that for $0\leq j<r$, $uF_{j+1}(g)=F_{j+1}(g)$ and $uw-w\in F_j(g)$ for $w\in F_{j+1}(g)$, and $u(F_r(g)^\perp)=F_r(g)^\perp$ and $uw-w\in F_r(g)$ for $w\in F_r(g)^\perp$. Put $N=N(f)$, $N'=N(f')$, $\Sigma=N\cap N'$, and

$$\psi_N(u)=\psi_0\Big(\theta^{-1}\sum_{j<r}h(uf_{j+1},e^*_j)\Big),\qquad \psi_{N'}(u)=\psi_0\Big(\theta^{-1}\sum_{j<r}h(uf'_{j+1},e'^*_j)\Big).$$

Let K_0 be the group of $u\in\Sigma$ stabilising the $\mathcal{O}_E$-spans of $f_0,\dots,f_r$ and of $f'_0,\dots,f'_r$. For a subgroup $A\subseteq\mathrm{U}(V)$ and a reference subgroup K put $\mathrm{vol}_K(A)^{-1}=[K:A\cap K]/[A:A\cap K]$ if both indices are finite, and $\mathrm{vol}_K(A)^{-1}=0$ otherwise. Let H_0 be the group of $u\in\mathrm{U}(V)$ with $uw=w$ for $w\in M_E$, and K_{ref} its subgroup stabilising $\mathcal{O}_E^n$.

Data and terms. A **datum** is a triple $d=(A,A',\Gamma)$ of $\mathcal{O}_E$-submodules $A,A'\subseteq V$ and a subset $\Gamma\subseteq V\times V$; H_0 acts on data, and the **weight** of d is $\nu(d)=\mathrm{vol}_{K_{\mathrm{ref}}}(\mathrm{Stab}_{H_0}(d))^{-1}$. An $\mathcal{O}_E$-submodule A is **inner** for (f,e^*) if $F_r(f)\subseteq A\subseteq X^\perp$, $A\cap(\mathrm{span}_E e^*)^\perp$ is finitely generated, a vector $y\in X^\perp$ lies in A if and only if $h(A,y)\subseteq\mathcal{O}_E$, and $f_r\in A$ with $h(f_r,y)=1$ for some $y\in A$; then

$$\Lambda_{\mathrm{std}}(A)=\textstyle\sum_{j<r}\mathcal{O}_Ef_j+(A\cap(\mathrm{span}_E e^*)^\perp)+\sum_{j<r}\mathcal{O}_Ee^*_j,$$

and likewise for (f',e'^*). An $\mathcal{O}_E$-submodule $\Lambda\subseteq V$ is a **term over** d if A is inner for (f,e^*), A' is inner for (f',e'^*), and there are $u\in N$, $u'\in N'$ (a **witness**) with

$$\Lambda=u\Lambda_{\mathrm{std}}(A)=u'\Lambda'_{\mathrm{std}}(A'),\qquad u'f'_b-uf_b\in\theta\Lambda\ (0\leq b\leq r),$$

and Γ is the set of pairs $(p,p')\in V\times V$ for which there are $y,y'\in\Lambda$ with $y\perp X$, $y'\perp X'$, $y'-p\in X'$, $y-p'\in X$ and $y'-y\in\theta\Lambda$. For every term we fix one witness (u,u') and put $\mathrm{fr}_b=uf_b$ and $\mathrm{fr}'_b=u'f'_b$. The **mass** of a term is $\mu(\Lambda)=\mathrm{vol}_{K_0}(\mathrm{Stab}_\Sigma(\Lambda))^{-1}$ and its **phase** is $\omega_d(\Lambda)=\psi_N(u)\overline{\psi_{N'}(u')}$.

Joint frame lattice and defects. For a term Λ over d, the **joint frame lattice** is the $\mathcal{O}_E$-span $M(\Lambda)$ of the $2r+2$ vectors fr_b and $\theta^{-1}(\mathrm{fr}'_b-\mathrm{fr}_b)$, the **saturation** is $\mathrm{sat}(\Lambda)=\Lambda\cap M_E$, and the **defect order** is the group index $b_d(\Lambda)=[\mathrm{sat}(\Lambda):M(\Lambda)]$ (set to 0 if $M(\Lambda)\not\subseteq\mathrm{sat}(\Lambda)$ or the index is infinite); Λ is **generic** if $M(\Lambda)=\mathrm{sat}(\Lambda)$. The **level** of $y\in M_E$ is the least $j\in\{0,\dots,r+1\}$ such that $\theta y=\sum_b\alpha_b\mathrm{fr}_b+\sum_b\alpha'_b\mathrm{fr}'_b$ with $\alpha'_b\in\mathcal{O}_E$ and $\alpha_b+\alpha'_b\in\theta\mathcal{O}_E$ for all $b\ge j$ (and 0 if there is none); write $\ell(y)$. A term is of **second type** if it is not generic, $\ell(y)\le r$ for all $y\in\mathrm{sat}(\Lambda)$, and $h(x_1,x'_2)\in\theta\mathcal{O}_E$ whenever $x_1,x_2\in X$ and $x'_1,x'_2\in X'$ satisfy $x_1+x'_1,\ x_2+x'_2\in\theta\Lambda$. Its **label** is $\lambda_d(\Lambda)=(J,e)$, where $J=\max\{\ell(y):y\in\mathrm{sat}(\Lambda)\}$ and e is the integer with $q^e=[\mathrm{sat}(\Lambda)\cap(M(\Lambda)+F_{J-1}(f)+F_{J-1}(f')):M(\Lambda)]$ if this index is a power of q, $e=0$ otherwise.

Class count. Let $\hat I(\Lambda)$ be the sum of $M(\Lambda)$ and the $\mathcal{O}_E$-span of the vectors $y\in V$ for which there are $w\in W_0\cap A\cap A'$ with $(w,w)\in\Gamma$, $\lambda\in X$ and $\lambda'\in X'$ with $w+\lambda\in\Lambda$, $w+\lambda'\in\Lambda$, $\lambda'-\lambda\in\theta\Lambda$ and $y-\theta^{-1}(\lambda'-\lambda)\in M(\Lambda)$. The **class count** is $c_d(\Lambda)=[\hat I(\Lambda):M(\Lambda)]$ (set to 0 if infinite).

Frame classes. A **frame pair** is an element (p,p') of $V^{r+1}\times V^{r+1}$; for a matrix $B\in\mathrm{M}_{r+1}(E)$ put $(pB)_j=\sum_i B_{ij}p_i$. The **class** of a frame pair is

$$\mathrm{cl}(p,p')=\{(pB,p'B'):\ B,B'\in\mathrm{M}_{r+1}(\mathcal{O}_E)\text{ upper unitriangular},\ B'-B\in\theta\,\mathrm{M}_{r+1}(\mathcal{O}_E)\}.$$

A **frame class** is a set $\mathrm{cl}(uf,u'f')$ with $u\in N$, $u'\in N'$; it is **integral** if $h(p'_b,p_a)\in\mathcal{O}_E$ for all (p,p') in it and all a,b. $\mathrm{U}(V)$ acts on frame pairs by $g(p,p')=(gp,gp')$ and hence on sets of frame pairs. The **weight** of a frame class C is $w(C)=\mathrm{vol}_{K_0}(\mathrm{Stab}_\Sigma(C))^{-1}$, and the **class of a term** Λ is $\mathrm{Fr}(\Lambda)=\mathrm{cl}(\mathrm{fr},\mathrm{fr}')$. For a frame pair, $M(p,p')$ is the $\mathcal{O}_E$-span of the p_b and $\theta^{-1}(p'_b-p_b)$ $(0\le b\le r)$; so $M(\Lambda)=M(\mathrm{fr},\mathrm{fr}')$.

Saturated masses. An $\mathcal{O}_E$-submodule $\Lambda\subseteq V$ is **self-dual** if it is finitely generated and $\Lambda=\{y\in V:h(\Lambda,y)\subseteq\mathcal{O}_E\}$. For an $\mathcal{O}_E$-submodule $\hat M\subseteq M_E$, the **saturated mass** is

$$\sigma(\hat M)=\sum_{[\Lambda]}\mathrm{vol}_{K_{\mathrm{ref}}}(\mathrm{Stab}_{H_0}(\Lambda))^{-1}\in[0,\infty],$$

the sum over the H_0-orbits of self-dual Λ with $\Lambda\cap M_E=\hat M$ (one fixed representative per orbit).

Numbers.

$$a=v(G)-2(r+1)v(\theta),\qquad v_D=\sum_{1\le l\le r+1,\ D_l\neq0}v(D_l\bar D_l),\qquad H=q^{\,v(\theta)+a+v_D}.$$

Definition 16.3. The notation introduced here is local to this definition and to the results that apply it. Let $r\ge0$ and $k\ge1$ be integers, Π a finite set, $\Omega\subseteq\Pi$, and for every $p\in\Pi$ let D_p be a set (not assumed finite or countable), $\mathrm{wt}_p\colon D_p\to[0,\infty)$, $a_p^{\mathrm{N}},a_p^{\mathrm{Z}}\colon D_p\to\mathbb{C}$, $n_p\ge0$ and $H_p\ge1$ real numbers and $q_p\ge2$ an integer (**local non-generic data**). Sums over D_p of nonnegative terms, here and in the results citing this definition, are unordered sums in $[0,\infty]$. A **frame realisation** of these data is a family $(S_p,c_p)_{p\in\Pi}$ with

(Fb1) Local frame pairs S_p is a local frame pair with parameters r,k (over a local field with residue field of size q_p) for which some datum has a term, D_p is a set of data of S_p containing exactly one datum from each H_0-orbit of data having a term, each element of D_p has a term, and H_p is the height H of S_p;

(Fb2) Amplitudes $c_p > 0$ is a real number and, for $\delta \in D_p$ and a set R_δ of representatives of the Σ-orbits of terms over δ,

$$\mathrm{wt}_p(\delta) = \nu(\delta),$$
$$a_p^{\mathrm{N}}(\delta) = c_p \sum_{\Lambda \in R_\delta \text{ not generic}} \mu(\Lambda)\,\omega_\delta(\Lambda), \qquad a_p^{\mathrm{Z}}(\delta) = c_p \sum_{\Lambda \in R_\delta \text{ generic}} \mu(\Lambda)\,\omega_\delta(\Lambda),$$
$$n_p = c_p^2 \sum_{\delta \in D_p} \nu(\delta) \sum_{\Lambda \in R_\delta} \mu(\Lambda);$$

(Fb3) Non-generic places $q_p \le H_p$ for every $p \in \Omega$.

Lemma 16.4. *The notation introduced here is local to this result and to the results that apply it. Let $r \ge 0$, $k \ge 4r{+}7$ and $C_0 \ge 0$ be integers, and put $e = (39{+}C_0)(r{+}1)^2{+}2(2r{+}2){+}5$. Fix a pair expansion and non-generic row data for it, with sets* Cl*, P, N. Suppose that for every $\gamma \in P_{\mathrm{oc}}$ there are a finite set Π, a subset $\Omega \subseteq \Pi$, local non-generic data $(D_p, \mathrm{wt}_p, a_p^{\mathrm{N}}, a_p^{\mathrm{Z}}, n_p, H_p, q_p)_{p\in\Pi}$ with a frame realisation with parameters r, k, real numbers $n_p^\circ \ge 0$ ($p \in \Pi$) and $V \ge 0$, and a set X with maps $\rho\colon X \to [0,\infty)$ and $\delta\colon X \to \prod_{p\in\Pi} D_p$ (all depending on γ; X need not be finite, and sums over subsets of X are unordered sums in $[0,\infty]$), such that*

1. *$n_p = n_p^\circ$ for $p \notin \Omega$ and $n_p \le 8H_p^{C_0(r+1)^2+2(2r+2)} n_p^\circ$ for $p \in \Omega$;*
2. *$\sum_{x\in X,\ \delta(x)=\delta_0} \rho(x) \le V \prod_{p\in\Pi} \mathrm{wt}_p(\delta_{0,p})$ for every $\delta_0 \in \prod_p D_p$;*

and, with $\mathrm{amp}(\delta_0) = \sum_{\varnothing\neq B\subseteq\Omega} \prod_{p\in B} a_p^{\mathrm{N}}(\delta_{0,p}) \prod_{p\in\Pi\setminus B} a_p^{\mathrm{Z}}(\delta_{0,p})$,

(Nv1) Amplitude domination *$\sum_{(c,\nu)\in F} a_2(c,\gamma,\nu) \le \sum_{x\in X} \rho(x)\,|\mathrm{amp}(\delta(x))|^2$ for every finite $F \subseteq \mathrm{Cl} \times N$;*

(Nv2) Generic mass $\bigl(\prod_{p\in\Pi} H_p\bigr)^e V \prod_{p\in\Pi} n_p^\circ \le n_{\mathrm{g}}(\gamma)$.

Then the non-generic row data have the local gain (Ng5) with these r and k.

Proof. Fix $\gamma \in P_{\mathrm{oc}}$ and the data attached to it. By Definition 16.3, $\mathrm{wt}_p \ge 0$, $H_p \ge 1$, $n_p \ge 0$ and $q_p \ge 2$ is an integer; D_p is an arbitrary set. Let $X' \subseteq X$ be finite; we show $\sum_{x\in X'} \rho(x)|\mathrm{amp}(\delta(x))|^2 \le 2^{-(k-2r-5)} n_{\mathrm{g}}(\gamma)$. If $X' = \emptyset$, the left side is 0; let $X' \neq \emptyset$. Item 2 holds with X' in place of X, since restricting the sum to X' only decreases its left side. Put $F_p = \{\delta(x)_p : x \in X'\}$, a finite nonempty subset of D_p, so δ maps X' into $\prod_p F_p$. Since $k \ge 4r+7$ and the data have a frame realisation, Corollary 16.5 gives $q_p \le H_p$ for $p \in \Omega$ and hypothesis (1) of Lemma 16.40 with $C_1 = 39$ for the restrictions of $\mathrm{wt}_p, a_p^{\mathrm{N}}, a_p^{\mathrm{Z}}$ to the finite sets F_p: for $p \in \Omega$, $\sum_{\delta_0\in F_p} \mathrm{wt}_p(\delta_0)|a_p^{\mathrm{N}}(\delta_0)|^2 \le H_p^{39(r+1)^2} q_p^{-(k-2r-5)} n_p$, and for every $p \in \Pi$, $\sum_{\delta_0\in F_p} \mathrm{wt}_p(\delta_0)|a_p^{\mathrm{Z}}(\delta_0)|^2 \le H_p^{39(r+1)^2} n_p$. We apply Lemma 16.40 with the finite sets F_p in place of D_p and the finite set X' with $\rho|_{X'}$, $\delta|_{X'}$: hypothesis (2) there is item 1 above, and hypothesis (3) there is item 2 above for X' and $\delta_0 \in \prod_p F_p \subseteq \prod_p D_p$; and $k \ge 4r{+}7 \ge 2r{+}5$. With $C_1 = 39$ the exponent e_{ng} of Lemma 16.40 equals e, and the function amp above is the one defined there. Hence

$$\sum_{x\in X'} \rho(x)\,|\mathrm{amp}(\delta(x))|^2 \le 2^{-(k-2r-5)} \Bigl(\prod_{p\in\Pi} H_p\Bigr)^e V \prod_{p\in\Pi} n_p^\circ \le 2^{-(k-2r-5)}\, n_{\mathrm{g}}(\gamma),$$

the second step by (Nv2). The unordered sum over X of the nonnegative numbers $\rho(x)|\mathrm{amp}(\delta(x))|^2$ is the supremum of its finite partial sums, so $\sum_{x\in X} \rho(x)|\mathrm{amp}(\delta(x))|^2 \le 2^{-(k-2r-5)} n_{\mathrm{g}}(\gamma)$. With (Nv1), $\sum_{(c,\nu)\in F} a_2(c,\gamma,\nu) \le 2^{-(k-2r-5)} n_{\mathrm{g}}(\gamma)$ for every finite $F \subseteq \mathrm{Cl} \times N$. As $\gamma \in P_{\mathrm{oc}}$ was arbitrary, this is (Ng5). □

Corollary 16.5. *Let $r \geq 0$ and $k \geq 4r+7$ be integers and let local non-generic data $(D_p, \mathrm{wt}_p, a_p^{\mathrm{N}}, a_p^{\mathrm{Z}}, n_p, H_p, q_p)_{p\in\Pi}$, $\Omega \subseteq \Pi$, have a frame realisation. Then for every $p \in \Omega$*

$$\sum_{\delta\in D_p} \mathrm{wt}_p(\delta)\,|a_p^{\mathrm{N}}(\delta)|^2 \leq H_p^{39(r+1)^2} q_p^{-(k-2r-5)} n_p \qquad \text{and} \qquad q_p \leq H_p,$$

and for every $p \in \Pi$, $\sum_{\delta\in D_p} \mathrm{wt}_p(\delta)|a_p^{\mathrm{Z}}(\delta)|^2 \leq H_p^{39(r+1)^2} n_p$. In particular, for every choice of finite sets $F_p \subseteq D_p$ ($p \in \Pi$), the restrictions of wt_p, a_p^{N}, a_p^{Z} to F_p satisfy hypothesis (1) of Lemma 16.40 with $C_1 = 39$.

Proof. Let (S_p, c_p) be the realisation and $p \in \Pi$. By (Fb1), S_p is a local frame pair with parameters r and $k \geq 4r+7$ and D_p is a set of data as in Corollary 16.6; its q is q_p and its H is H_p. By (Fb2) the sums of Corollary 16.6 for S_p and D_p are $\mathrm{amp}_\delta^{\mathrm{n}} = a_p^{\mathrm{N}}(\delta)/c_p$, $\mathrm{amp}_\delta^{\mathrm{g}} = a_p^{\mathrm{Z}}(\delta)/c_p$, $\mathrm{nn} = n_p/c_p^2$ and $\nu = \mathrm{wt}_p$. Multiplying the two inequalities of Corollary 16.6 by c_p^2 gives the two amplitude bounds. For $p \in \Omega$, $q_p \leq H_p$ by (Fb3). All sums over D_p here are unordered sums of nonnegative terms (Corollary 16.6 allows an arbitrary set of representatives D); for finite $F_p \subseteq D_p$ the sums over F_p are at most those over D_p, which gives hypothesis (1) of Lemma 16.40 for the restrictions to F_p (with $q_p \leq H_p$ for $p \in \Omega$). □

Corollary 16.6. *Let a local frame pair with parameters r and $k \geq 4r+7$ be given. Let D be a set of representatives of the H_0-orbits of data that contain a datum having a term, every element of D having a term; for $d \in D$ let R_d be a set of representatives of the Σ-orbits of terms over d, and put*

$$\mathrm{amp}_d^{\mathrm{n}} = \sum_{\Lambda\in R_d \ \text{not generic}} \mu(\Lambda)\,\omega_d(\Lambda), \qquad \mathrm{amp}_d^{\mathrm{g}} = \sum_{\Lambda\in R_d \ \text{generic}} \mu(\Lambda)\,\omega_d(\Lambda),$$
$$\mathrm{nn} = \sum_{d\in D} \nu(d) \sum_{\Lambda\in R_d} \mu(\Lambda).$$

Then

$$\sum_{d\in D} \nu(d)\,|\mathrm{amp}_d^{\mathrm{n}}|^2 \leq H^{39(r+1)^2} q^{-(k-2r-5)}\,\mathrm{nn}, \qquad \sum_{d\in D} \nu(d)\,|\mathrm{amp}_d^{\mathrm{g}}|^2 \leq H^{39(r+1)^2}\,\mathrm{nn}.$$

Proof. If no datum has a term, D is empty and both sides vanish. Otherwise Theorem 16.7 shows that these data form local non-generic records with parameters r, k and the properties (Lg1)–(Lg5), with total mass nn; their sets of generic and non-generic terms over d are those of Definition 16.2 (generic means $b_d = 1$, by Proposition 16.8(3)), and since μ, ω_d and genericity are constant on Σ-orbits (Proposition 16.12), $\mathrm{amp}_d^{\mathrm{n}}$ and $\mathrm{amp}_d^{\mathrm{g}}$ are the amplitudes $\mathrm{amp}_d(X_d^{\mathrm{n}})$ and $\mathrm{amp}_d(X_d^{\mathrm{g}})$ of the records. As $k \geq 4r+7 \geq 2r+3$, Theorem 16.38 gives both bounds. □

16.2 Local non-generic records of a frame pair: defect orders and class counts

This subsection proves Theorem 16.7: a local frame pair, with its terms, phases, defect orders, class counts and terms of second type, forms local non-generic records with the properties (Lg1)–(Lg5), which are the hypotheses of the local non-generic bound Theorem 16.38. Most of the properties are structural. The terms are self-dual lattices that meet the flags in the translated frames (Lemma 16.18); their defect order is a power q^i with $0 \leq i \leq a$, and it is 1 exactly for the generic terms (Proposition 16.8); a common unipotent group acts on them and preserves phases,

defects, types and labels (Proposition 16.12). The estimates are three: the class count of a non-generic term of first type is smaller than its defect order by a factor q (Proposition 16.10), proved here; the share of the terms of a given defect order (Proposition 16.20), proved in the next subsection; and the averaging kernel of Eichler moves on the terms of second type (Proposition 16.30), proved in the last one.

Theorem 16.7. *Let a local frame pair with parameters r and $k \geq 4r+7$ be given such that some datum has a term. Let D be a set of representatives of the H_0-orbits of data that contain a datum having a term, every element of D having a term. Then the group $\mathrm{U}(V)$ acting on the set of $\mathcal{O}_E$-submodules of V, the subgroups $K_0 \subseteq \Sigma$, the data D with the weights ν, for $d \in D$ the set X_d of terms over d with the phase ω_d, the defect order b_d, the class count c_d, the set X_d^{II} of terms of second type over d with the label λ_d, and the numbers q, a, H form local non-generic records with parameters r, k; their masses are the masses μ of Definition 16.2, and they have the properties (Lg1)–(Lg5).*

Proof. **Step 1: the data are countable.** Let $d = (A, A', \Gamma)$ have a term Λ. Put $Y = X^\perp \cap (\mathrm{span}_E e^*)^\perp = (X + \mathrm{span}_E e^*)^\perp$; by (Fp1) $X + \mathrm{span}_E e^*$ is a nondegenerate (hyperbolic) subspace, so Y is a nondegenerate complement. For $w \in A$, $w' = w - \sum_j h(w, e_j^*) f_j$ lies in A (as $F_r(f) \subseteq A$), in $X^\perp$ and in $(\mathrm{span}_E e^*)^\perp$; hence $A = F_r(f) + A_0$ with $A_0 = A \cap Y$, a finitely generated $\mathcal{O}_E$-module. If the E-span of A_0 were not Y, nondegeneracy of Y would give $0 \neq y \in Y$ orthogonal to A_0, and the inner condition would put Ey into A_0, which is impossible for a finitely generated $\mathcal{O}_E$-module. So A_0 is a lattice in Y, and likewise for A'; $\Lambda = u\Lambda_{\mathrm{std}}(A)$ is a lattice in V, and Γ is determined by Λ. A finite-dimensional F-vector space has countably many lattices (each lies between $\varpi^s L_0$ and $\varpi^{-s} L_0$ for a fixed lattice L_0 and some s, and is determined by its image in the finite group $\varpi^{-s}L_0/\varpi^s L_0$). So the data having a term form a countable set, and D is countable.

Step 2: the records. $K_0 \subseteq \Sigma \subseteq \mathrm{U}(V)$ by definition, and $\nu \geq 0$. For $d \in D$, X_d is Σ-stable and, for $x \in X_d$, $\Sigma_x = \mathrm{Stab}_\Sigma(x)$ is commensurable with K_0 with $\mathrm{vol}(\Sigma_{gx}) = \mathrm{vol}(\Sigma_x)$ ($g \in \Sigma$), by Proposition 16.12; so the mass $1/\mathrm{vol}(\Sigma_x)$ of the records is $\mu(x)$. X_d is the union of finitely many Σ-orbits by Proposition 16.11. $|\omega_d| \leq 1$ since ψ_0 is unitary. By Proposition 16.8(3),(5), b_d and c_d take values in $\{q^j : j \geq 0\} \subseteq \mathbb{Z}_{\geq 1}$. By Proposition 16.12, ω_d, b_d, c_d and λ_d are Σ-invariant and X_d^{II} is Σ-stable; λ_d takes values in $\mathbb{Z}^2$. Finally $q \geq 2$ is an integer, a is an integer with $a \geq 0$ and $H \geq 1$, by Proposition 16.8(2) applied to a term of some datum. The total mass of the records is $\sum_{d \in D} \nu(d) \sum_{O \in \Sigma \backslash X_d} \mu(O)$.

(Lg1) and (Lg2). By Proposition 16.8(2),(3), $q^a \leq H$ and $b_d(x) = q^i$ with $0 \leq i \leq a$; by (5), $c_d(x) = q^{i'}$ and $c_d(x) \leq b_d(x)$. A term in $X_d^{\mathrm{n}} \setminus X_d^{\mathrm{II}}$ has $b_d \neq 1$, so it is not generic by (3), and it is not of second type; Proposition 16.10 gives $q\, c_d(x) \leq b_d(x)$.

(Lg3). For $c \geq 1$ the set $\{x \in X_d : c_d(x) = c\}$ is Σ-stable, and its mass is $\sum \mu(\Lambda)$ over the representatives Λ with $c_d(\Lambda) = c$ of any set of representatives of the Σ-orbits of X_d; Proposition 16.11 bounds it by $H^{9(r+1)^2+12(r+1)} c^{k-1}$.

(Lg4). Enlarge D to a set D' of representatives of all H_0-orbits of data, adding for each orbit not met by D an arbitrary datum. Such an orbit contains no datum having a term, so the added data contribute 0 to both sides of Proposition 16.20; for D' and representatives R_d of the Σ-orbits of terms it gives, for every $\beta \geq 1$,

$$\sum_{d \in D} \nu(d)\, \mathrm{mass}_d(\{b_d = \beta\}) \leq 4H^{4(r+1)} \beta^{-(k-1)} \sum_{d \in D} \nu(d)\, \mathrm{mass}_d(X_d),$$

the right side being $4H^{4(r+1)}\beta^{-(k-1)}\mathrm{nn}$.

(Lg5): the labels. A term of second type is not generic, so $X_d^{\mathrm{II}} \subseteq X_d^{\mathrm{n}}$. Let $x = \Lambda \in X_d^{\mathrm{II}}$ with $b_d(\Lambda) = q^i$ and $\lambda_d(\Lambda) = (J, e)$. By Proposition 16.8(4) with $j = 0$, $\ell(y) = 0$ exactly for $y \in M(\Lambda)$; as Λ is not generic some $y \in \mathrm{sat}(\Lambda) \setminus M(\Lambda)$ has $\ell(y) \geq 1$, so $J \geq 1$, and $J \leq r$ as Λ is of second type. Put $S = \mathrm{sat}(\Lambda) \cap (M(\Lambda) + F_{J-1}(f) + F_{J-1}(f'))$, a submodule with $M(\Lambda) \subseteq S \subseteq \mathrm{sat}(\Lambda)$; by (4) it is the set of $y \in \mathrm{sat}(\Lambda)$ with $\ell(y) \leq J - 1$, so it does not contain a vector of level J and $S \neq \mathrm{sat}(\Lambda)$. By Lemma 16.9(1) applied to $S/M(\Lambda)$ and to the nonzero module $\mathrm{sat}(\Lambda)/S$, $[S : M(\Lambda)] = q^e$ (so e is the exponent in the definition of the label) and $q^e \leq q^i/q$; so $0 \leq e \leq i - 1$. (By (4) the level is constant on cosets of $M(\Lambda)$, so exactly $q^i - q^e$ cosets have level J.)

(Lg5): the kernels. For $d \in D$, $i \geq 1$ and $\lambda \in \mathbb{Z}^2$, the set $\mathcal{P}$ of (Lg5) is the set of Proposition 16.30, which provides the kernel m with the required invariance, symmetry, finiteness and the two averaging bounds with $\frac{24}{7} q^{-(k-2r-4)}$. □

Proposition 16.8. *Let a local frame pair with parameters r, k be given, d a datum and Λ a term over d. Then:*

1. *$h(\Lambda, \Lambda) \subseteq \mathcal{O}_E$; the $2r+2$ vectors fr_b, $\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ $(0 \leq b \leq r)$ lie in Λ, are E-linearly independent, span M_E over E, and the determinant of their Gram matrix is $(-1)^{r+1}\theta^{-2(r+1)}G$;*
2. *$a \geq 0$, $D_l \in \mathcal{O}_E$ for all l, $v_D \geq 0$, and $1 \leq q^a \leq H$;*
3. *$\varpi^a \mathrm{sat}(\Lambda) \subseteq M(\Lambda) \subseteq \mathrm{sat}(\Lambda)$ and $b_d(\Lambda) = q^i$ for an integer $0 \leq i \leq a$; Λ is generic if and only if $b_d(\Lambda) = 1$; if Λ is not generic, then $q \leq H$;*
4. *for $y \in \mathrm{sat}(\Lambda)$ and $0 \leq j \leq r + 1$: $\ell(y) \leq j$ if and only if $y \in M(\Lambda) + F_j(f) + F_j(f')$;*
5. *$M(\Lambda) \subseteq \hat{I}(\Lambda) \subseteq \mathrm{sat}(\Lambda)$, and $c_d(\Lambda) = q^{i'}$ for an integer $i' \geq 0$ with $c_d(\Lambda) \leq b_d(\Lambda)$.*

Proof. **Step 1: the translated frames are unitriangular.** For $j < r$, $f_j \in F_{j+1}(f)$, so $uf_j - f_j \in F_j(f)$ by the definition of N; and $f_r \in F_r(f)^\perp$ by (Fp1), so $uf_r - f_r \in F_r(f)$. Hence $\mathrm{fr}_b = \sum_{i \leq b} U_{ib} f_i$ with U upper triangular with ones on the diagonal, and $F_j(\mathrm{fr}) = F_j(f)$ for all j; likewise $\mathrm{fr}' = f'U'$ and $F_j(\mathrm{fr}') = F_j(f')$.

Step 2: integrality and membership. The generators of $\Lambda_{\mathrm{std}}(A)$ are the f_j $(j < r)$, the $y \in A \cap (\mathrm{span}_E e^*)^\perp$ and the e_j^*. Their pairings lie in $\mathcal{O}_E$: $h(f_i, f_j) = 0$ and $h(f_i, e_j^*) = \delta_{ij}$, $h(e_i^*, e_j^*) = 0$ by (Fp1); $h(f_i, y) = 0$ as $y \in A \subseteq X^\perp$; $h(y, e_j^*) = 0$; and for $y, y' \in A$, $y' \in X^\perp$ lies in A, so the inner condition gives $h(A, y') \subseteq \mathcal{O}_E$. By sesquilinearity and hermitian symmetry $h(\Lambda_{\mathrm{std}}(A), \Lambda_{\mathrm{std}}(A)) \subseteq \mathcal{O}_E$, and $\Lambda = u\Lambda_{\mathrm{std}}(A)$ with u unitary is integral. For $j < r$, $\mathrm{fr}_j = uf_j \in \Lambda$; $f_r \in A$ (inner) and $h(f_r, e_j^*) = 0$ by (Fp1), so $f_r \in \Lambda_{\mathrm{std}}(A)$ and $\mathrm{fr}_r \in \Lambda$; finally $\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b) \in \Lambda$ by the witness condition.

Step 3: the Gram determinant. As u, u' are isometries, $(h(\mathrm{fr}_a, \mathrm{fr}_b)) = (h(f_a, f_b)) = -T\,E_{rr}$ and $(h(\mathrm{fr}'_a, \mathrm{fr}'_b)) = -T'E_{rr}$ (E_{rr} the matrix unit), by (Fp1). Put $\tilde{Z}_{ab} = h(\mathrm{fr}'_b, \mathrm{fr}_a)$; by Step 1, $\tilde{Z} = \bar{U}^{\mathsf{T}} Z U'$ with $\bar{U}^{\mathsf{T}}$ lower and U' upper unitriangular, so the leading $l \times l$ block of $\tilde{Z}$ is the product of the leading blocks and $\tilde{Z}$ has the same leading principal minors D_l as Z. The Gram matrix of $(\mathrm{fr}, \mathrm{fr}')$ is

$$P = \begin{pmatrix} -TE_{rr} & \overline{\tilde{Z}} \\ \tilde{Z}^{\mathsf{T}} & -T'E_{rr} \end{pmatrix}.$$

Expand $\det P$ by multilinearity in the two rows of index r in the two blocks, each the sum of its part in $-TE_{rr}$ (resp. $-T'E_{rr}$) and its part in the off-diagonal block. With both off-diagonal parts the matrix is $\begin{pmatrix} 0 & \overline{\tilde{Z}} \\ \tilde{Z}^{\mathsf{T}} & 0 \end{pmatrix}$, of determinant $(-1)^{r+1} \det \overline{\tilde{Z}} \det \tilde{Z}^{\mathsf{T}} = (-1)^{r+1} D_{r+1} \bar{D}_{r+1}$. With

exactly one diagonal part, say the first, the expansion along that row leaves the matrix without the first row and column of index r, in which the $r+1$ rows of the second block are supported on the r remaining columns of the first block, so its determinant vanishes; likewise for the second. With both diagonal parts the expansion gives $(-T)(-T')$ times (sign $+1$, both positions diagonal) the determinant of $\begin{pmatrix} 0 & \overline{\tilde{Z}}_{[r]} \\ \tilde{Z}_{[r]}^{\mathsf{T}} & 0 \end{pmatrix}$, $\tilde{Z}_{[r]}$ the leading $r \times r$ block, that is $(-1)^r TT' D_r \bar{D}_r$. So $\det P = (-1)^{r+1} G$. The family $g = (\mathrm{fr}_b, \theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b))_b$ is $(\mathrm{fr}, \mathrm{fr}')C$ with $C = \begin{pmatrix} 1 & -\theta^{-1} \\ 0 & \theta^{-1} \end{pmatrix}$ (blocks of scalar matrices), so its Gram matrix is $C^{\mathsf{T}} P \bar{C}$, of determinant $\det P \cdot \mathrm{N}(\theta^{-(r+1)}) = (-1)^{r+1}\theta^{-2(r+1)}G$, as $\theta \in F$. This is a nonzero element of F, hence a unit of E; if $\sum_i c_i g_i = 0$, then c^{T} times the Gram matrix vanishes and so does c (multiply by the adjugate). So g is independent, and as C is invertible it spans the span of $(\mathrm{fr}, \mathrm{fr}')$, which is $F_{r+1}(f) + F_{r+1}(f') = M_E$ by Step 1. This proves (1).

Step 4: the numbers. The entries of the Gram matrix of g and of $\tilde{Z}$ lie in $\mathcal{O}_E$ by Step 2. By Lemma 16.9(2) (applied below), $v((-1)^{r+1}\theta^{-2(r+1)}G) = v(G) - 2(r+1)v(\theta) = a \geq 0$. The minors D_l of $\tilde{Z}$ lie in $\mathcal{O}_E$, so $D_l \bar{D}_l \in \mathcal{O}_E \cap F = \mathcal{O}_F$ and each summand of v_D is ≥ 0. With $v(\theta) \geq 0$ and $q \geq 2$, $H = q^{v(\theta)+a+v_D} \geq q^a \geq 1$. This proves (2).

Step 5: the defect order. Apply Lemma 16.9(2) to $b = g$ (so $U = M_E$, $M = M(\Lambda)$, $\delta = (-1)^{r+1}\theta^{-2(r+1)}G$) and $N = \mathrm{sat}(\Lambda) = \Lambda \cap M_E$: $M(\Lambda) \subseteq \mathrm{sat}(\Lambda)$ since $g \subseteq \Lambda \cap M_E$, and $h(\mathrm{sat}, \mathrm{sat}) \subseteq \mathcal{O}_E$ by Step 2. It gives $\varpi^a \mathrm{sat}(\Lambda) \subseteq M(\Lambda)$ and $b_d(\Lambda) = q^i$, $0 \leq i \leq a$. Generic means $M(\Lambda) = \mathrm{sat}(\Lambda)$, i.e. index 1. If Λ is not generic, $i \geq 1$, so $a \geq 1$ and $q \leq q^a \leq H$. This proves (3).

Step 6: levels. By Step 3, $(\mathrm{fr}, \mathrm{fr}')$ is an E-basis of M_E, so every $w \in M_E$ has unique coordinates. The set of j for which the condition in the definition of $\ell(y)$ holds is closed upwards and contains $r+1$; so $\ell(y) \leq j$ if and only if it holds at j. Now

$$\theta M(\Lambda) = \Big\{ \sum_b \alpha_b \mathrm{fr}_b + \sum_b \alpha'_b \mathrm{fr}'_b : \ \alpha'_b \in \mathcal{O}_E, \ \alpha_b + \alpha'_b \in \theta\mathcal{O}_E \text{ for all } b \Big\},$$

since $\theta(\beta_b \mathrm{fr}_b + \gamma_b \theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)) = (\theta\beta_b - \gamma_b)\mathrm{fr}_b + \gamma_b \mathrm{fr}'_b$, and conversely $\gamma_b = \alpha'_b$, $\beta_b = \theta^{-1}(\alpha_b + \alpha'_b)$. If the condition holds at j, the part of θy with indices $b \geq j$ lies in $\theta M(\Lambda)$ and the rest in $F_j(\mathrm{fr}) + F_j(\mathrm{fr}')$; if conversely $\theta y = \theta m + w$ with $m \in M(\Lambda)$ and $w \in F_j(\mathrm{fr}) + F_j(\mathrm{fr}')$, the coordinates of θy with $b \geq j$ are those of θm, which satisfy the condition. So $\ell(y) \leq j$ if and only if $\theta y \in \theta M(\Lambda) + F_j(\mathrm{fr}) + F_j(\mathrm{fr}')$, i.e. (dividing by θ and using Step 1) $y \in M(\Lambda) + F_j(f) + F_j(f')$. This proves (4).

Step 7: the class count. Let y be one of the generating vectors of $\hat{I}(\Lambda)$ beyond $M(\Lambda)$, with w, λ, λ' as in the definition. Then $y_1 = \theta^{-1}(\lambda' - \lambda) \in \Lambda$ as $\lambda' - \lambda \in \theta\Lambda$, and $y_1 \in M_E$ as $\lambda \in X$, $\lambda' \in X'$; so $y_1 \in \mathrm{sat}(\Lambda)$ and $y \in M(\Lambda) + y_1 \subseteq \mathrm{sat}(\Lambda)$. Hence $M(\Lambda) \subseteq \hat{I}(\Lambda) \subseteq \mathrm{sat}(\Lambda)$. The quotient $\hat{I}(\Lambda)/M(\Lambda)$ is an $\mathcal{O}_E$-submodule of the finite module $\mathrm{sat}(\Lambda)/M(\Lambda)$ of order q^i; by Lemma 16.9(1) its order is $q^{i'}$, and $q^{i'} \leq q^i$. This proves (5). □

Lemma 16.9. *The notation introduced here is local to this result and to the results that apply it.*

1. *Every $\mathcal{O}_E$-module of finite cardinality has cardinality q^j for an integer $j \geq 0$, and $j \geq 1$ if it is nonzero.*

2. *Let V be a free E-module of finite rank with a hermitian form h (E-linear in the first variable, $h(y,x) = \overline{h(x,y)}$). Let $b_1, \ldots, b_m \in V$ be E-linearly independent with $h(b_i, b_j) \in$*

$\mathcal{O}_E$ for all i, j and $\delta = \det(h(b_i, b_j))_{i,j} \neq 0$, let U and M be their E-span and their $\mathcal{O}_E$-span, and let N be an $\mathcal{O}_E$-submodule with $M \subseteq N \subseteq U$ and $h(N, N) \subseteq \mathcal{O}_E$. Then $\delta \in \mathcal{O}_F$, $a := v(\delta) \geq 0$, $\varpi^a N \subseteq M$, and $[N : M] = q^i$ for an integer $0 \leq i \leq a$.

Proof. **(i).** $\mathcal{O}_E$ is a principal ideal ring: a discrete valuation ring with residue field of q^2 elements and uniformiser ϖ if E is the unramified extension, and $\mathcal{O}_F \times \mathcal{O}_F$ if $E = F \times F$. A finite $\mathcal{O}_E$-module P is finitely generated and torsion. In the first case the structure theorem gives $P \cong \bigoplus_i \mathcal{O}_E/\varpi^{e_i}\mathcal{O}_E$ with $|\mathcal{O}_E/\varpi^e\mathcal{O}_E| = q^{2e}$. In the second, the idempotents $(1,0), (0,1)$ split $P = P_1 \times P_2$ with finite $\mathcal{O}_F$-modules $P_i \cong \bigoplus \mathcal{O}_F/\varpi^e\mathcal{O}_F$, of orders powers of q. So $|P| = q^j$, and $j \geq 1$ if $P \neq 0$.

(ii): the determinant. The Gram matrix $\mathrm{Gm} = (h(b_i, b_j))$ satisfies $\overline{\mathrm{Gm}}^{\mathsf{T}} = \mathrm{Gm}$, so $\bar{\delta} = \det \overline{\mathrm{Gm}}^{\mathsf{T}} = \delta$ and $\delta \in F$; as its entries lie in $\mathcal{O}_E$, $\delta \in \mathcal{O}_E \cap F = \mathcal{O}_F$, and $a = v(\delta) \geq 0$ since $\delta \neq 0$.

(ii): killing. Let $y \in N$; as $y \in U$, $y = \sum_i c_i b_i$ with $c \in E^m$. Since $y, b_j \in N$, the row vector $(h(y, b_j))_j = c^{\mathsf{T}}\mathrm{Gm}$ lies in $\mathcal{O}_E^m$. Multiplying on the right by the adjugate $\mathrm{adj}(\mathrm{Gm}) \in M_m(\mathcal{O}_E)$ gives $\delta\, c^{\mathsf{T}} \in \mathcal{O}_E^m$. Writing $\delta = \varpi^a\varepsilon$ with $\varepsilon \in \mathcal{O}_F^\times$, $\varpi^a c_i \in \mathcal{O}_E$ for all i, so $\varpi^a y \in M$.

(ii): the index. By the previous step $M \subseteq N \subseteq \varpi^{-a}M$, and $\varpi^{-a}M$ is free of rank m with basis $\varpi^{-a}b_i$ (the b_i are independent). Over the principal ideal ring $\mathcal{O}_E$ (componentwise in the split case), the submodule N of a free module of rank m containing M is free of rank m; let $b'_1, \ldots, b'_m$ be a basis and write $b_j = \sum_i A_{ij} b'_i$ with $A \in M_m(\mathcal{O}_E)$. Then $\mathrm{Gm} = A^{\mathsf{T}}\mathrm{Gm}'\bar{A}$ with $\mathrm{Gm}' = (h(b'_k, b'_l))$, hence

$$\delta = \det A \cdot \overline{\det A} \cdot \delta' = \mathrm{N}(\det A)\, \delta', \qquad \delta' = \det \mathrm{Gm}'.$$

As $h(N, N) \subseteq \mathcal{O}_E$, Gm' is an integral hermitian matrix, so $\delta' \in \mathcal{O}_F$ as in the first step, and $\delta' \neq 0$. Thus $v(\mathrm{N}(\det A)) = a - v(\delta') \leq a$, and $v(\mathrm{N}(\det A)) \geq 0$ as $\det A \in \mathcal{O}_E$. By elementary divisors, $[N : M] = |\mathcal{O}_E^m/A\mathcal{O}_E^m| = |\mathcal{O}_E/\det A\, \mathcal{O}_E|$. If E is a field, $\det A = \varpi^e\eta$ with $\eta \in \mathcal{O}_E^\times$, $|\mathcal{O}_E/\varpi^e\mathcal{O}_E| = q^{2e}$ and $v(\mathrm{N}(\det A)) = 2e$. If $E = F \times F$, $\det A = (x, y)$ with $x, y \neq 0$, $|\mathcal{O}_E/\det A\, \mathcal{O}_E| = q^{v(x)+v(y)}$ and $\mathrm{N}(\det A) = xy$. In both cases $[N : M] = q^i$ with $i = v(\mathrm{N}(\det A)) \in [0, a]$. □

Proposition 16.10. *Let a local frame pair with parameters r, k be given, d a datum and Λ a term over d that is neither generic nor of second type. Then $q\, c_d(\Lambda) \leq b_d(\Lambda)$.*

Proof. **Step 1: the frames f, f' are independent.** For $j < r$, $f_j \in F_{j+1}(f)$, so $uf_j - f_j \in F_j(f)$ by the definition of N; and $f_r \in F_r(f)^\perp$ by (Fp1), so $uf_r - f_r \in F_r(f)$. Hence $(\mathrm{fr}_0, \ldots, \mathrm{fr}_r) = (f_0, \ldots, f_r)U$ with U upper unitriangular, and likewise $\mathrm{fr}' = f'U'$. By Proposition 16.8(1) the vectors $g_b = \mathrm{fr}_b$, $g_{r+1+b} = \theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ form an E-basis of M_E; as (f, f') is obtained from g by the invertible matrix $\begin{pmatrix} 1 & -\theta^{-1} \\ 0 & \theta^{-1} \end{pmatrix}^{-1} \mathrm{diag}(U^{-1}, U'^{-1})$ (blocks of size $r+1$), the $2r+2$ vectors f_b, f'_b form an E-basis of M_E. In particular every vector of M_E is uniquely a sum of a vector of $F_{r+1}(f)$ and one of $F_{r+1}(f')$, and $F_{r+1}(f) \cap F_{r+1}(f') = 0$. Also X and X' are totally isotropic ($h(f_a, f_b) = 0$ for $a, b < r$ by (Fp1)), $W_0 \perp M_E$ by definition, and $h(\Lambda, \Lambda) \subseteq \mathcal{O}_E$ by Proposition 16.8(1). Since $\theta \in F$, $h(v, \theta w) = \theta h(v, w)$.

Step 2: the module R of glued vectors. Let R be the set of vectors $\theta^{-1}(\lambda' - \lambda)$ for which there are $w \in W_0$, $\lambda \in X$, $\lambda' \in X'$ with $w + \lambda \in \Lambda$ and $\lambda' - \lambda \in \theta\Lambda$. Componentwise sums and $\mathcal{O}_E$-multiples of such triples (w, λ, λ') are again such triples, so R is an $\mathcal{O}_E$-submodule; $R \subseteq \Lambda$,

and $R \subseteq X + X'$. Every generator y of $\hat{I}(\Lambda)$ beyond M comes with $w \in W_0$, $\lambda \in X$, $\lambda' \in X'$, $w + \lambda \in \Lambda$, $\lambda' - \lambda \in \theta\Lambda$ and $y - \theta^{-1}(\lambda' - \lambda) \in M$, so $y \in M + R$; hence

$$\hat{I}(\Lambda) \subseteq M + R.$$

Step 3: the pairing condition on R. Let $y_1, y_2 \in R$ with triples $(w_i, \lambda_i, \lambda_i')$, and let $x_i \in X$, $x_i' \in X'$ with $x_i + x_i' = \theta y_i$ $(i = 1, 2)$. Then $x_i + \lambda_i = \lambda_i' - x_i' \in F_{r+1}(f) \cap F_{r+1}(f') = 0$, so $x_i = -\lambda_i$ and $x_i' = \lambda_i'$. As $w_1 \perp M_E$ and $h(\lambda_1, \lambda_2) = 0$,

$$h(x_1, x_2') = -h(\lambda_1, \lambda_2') = -h(w_1 + \lambda_1, \lambda_2' - \lambda_2) = -\theta\, h(w_1 + \lambda_1, y_2) \in \theta\mathcal{O}_E,$$

since $w_1 + \lambda_1$ and y_2 lie in Λ.

Step 4: if $\hat{I}(\Lambda) = \mathrm{sat}(\Lambda)$, then Λ is of second type. Assume $\hat{I}(\Lambda) = \mathrm{sat}(\Lambda)$; so $\mathrm{sat}(\Lambda) \subseteq M + R$ by Step 2. Λ is not generic by hypothesis.

Levels. For $y \in \mathrm{sat}(\Lambda)$, $y \in M + R \subseteq M + F_r(f) + F_r(f')$, so $\ell(y) \leq r$ by Proposition 16.8(4).

Pairing. Let $x_i \in X$, $x_i' \in X'$ with $x_i + x_i' = \theta z_i$, $z_i \in \Lambda$ $(i = 1, 2)$. As $X, X' \subseteq M_E$, $z_i \in \mathrm{sat}(\Lambda)$, so $z_i = m_i + y_i$ with $m_i \in M$, $y_i \in R$; write $y_i = u_i + u_i'$ with $u_i = -\theta^{-1}\lambda_i \in X$, $u_i' = \theta^{-1}\lambda_i' \in X'$ for a triple of y_i. From $m = \sum_b \beta_b \mathrm{fr}_b + \sum_b \gamma_b \theta^{-1}(\mathrm{fr}_b' - \mathrm{fr}_b)$ $(\beta_b, \gamma_b \in \mathcal{O}_E)$ one gets $\theta m = \sum_b (\theta\beta_b - \gamma_b)\mathrm{fr}_b + \sum_b \gamma_b \mathrm{fr}_b'$, so $\theta m_i = c_i + c_i'$ with $c_i \in F_{r+1}(f)$ and $c_i' \in F_{r+1}(f') \cap \Lambda$ (by Proposition 16.8(1), $\mathrm{fr}_b' = \mathrm{fr}_b + \theta \cdot \theta^{-1}(\mathrm{fr}_b' - \mathrm{fr}_b) \in \Lambda$). Put $a_i = x_i - \theta u_i \in X$ and $a_i' = x_i' - \theta u_i' \in X'$; then $a_i + a_i' = \theta m_i = c_i + c_i'$, and the uniqueness of Step 1 gives $a_i' = c_i' \in \Lambda$. Now

$$h(x_1, x_2') = h(\theta u_1, \theta u_2') + \theta h(u_1, a_2') + \theta h(a_1, u_2') + h(a_1, a_2'),$$

and each term lies in $\theta\mathcal{O}_E$:

- $\theta u_i \in X$, $\theta u_i' \in X'$ and $\theta u_i + \theta u_i' = \theta y_i$ with $y_i \in R$, so Step 3 gives $h(\theta u_1, \theta u_2') \in \theta\mathcal{O}_E$;
- $h(u_1, a_2') = h(y_1, a_2')$ since $h(u_1', a_2') = 0$, and $y_1, a_2' \in \Lambda$;
- $h(a_1, u_2') = h(a_1, y_2)$ since $h(a_1, u_2) = 0$, and $h(a_1, y_2) = \theta h(m_1, y_2) - h(a_1', y_2) \in \mathcal{O}_E$ as $a_1 = \theta m_1 - a_1'$ and $m_1, a_1', y_2 \in \Lambda$;
- $h(a_1, a_2') = \theta h(m_1, a_2') - h(a_1', a_2') = \theta h(m_1, a_2') \in \theta\mathcal{O}_E$.

So $h(x_1, x_2') \in \theta\mathcal{O}_E$, and Λ is of second type.

Step 5: the index. By hypothesis Λ is not of second type, so $\hat{I}(\Lambda) \neq \mathrm{sat}(\Lambda)$ by Step 4. By Proposition 16.8(3),(5), $M \subseteq \hat{I}(\Lambda) \subseteq \mathrm{sat}(\Lambda)$ and $b_d(\Lambda) = [\mathrm{sat}(\Lambda) : M]$ is finite, so

$$b_d(\Lambda) = [\mathrm{sat}(\Lambda) : \hat{I}(\Lambda)] \cdot [\hat{I}(\Lambda) : M] = [\mathrm{sat}(\Lambda) : \hat{I}(\Lambda)] \cdot c_d(\Lambda).$$

The quotient $\mathrm{sat}(\Lambda)/\hat{I}(\Lambda)$ is a nonzero finite $\mathcal{O}_E$-module, of order at least q by Lemma 16.9(1). Hence $q\, c_d(\Lambda) \leq b_d(\Lambda)$. □

Proposition 16.11. *Let a local frame pair with parameters r, k be given and d a datum. Then the terms over d form finitely many Σ-orbits, and for every set R of representatives of these orbits and every integer $c \geq 1$,*

$$\sum_{\Lambda \in R,\ c_d(\Lambda) = c} \mu(\Lambda) \leq H^{9(r+1)^2 + 12(r+1)}\, c^{\,k-1}.$$

Proof. If d has no term, both claims hold trivially. Let Λ_0 be a term over d. By Proposition 16.8(2), $a \ge 0$, $v_D \ge 0$ and $H = q^{v(\theta)+a+v_D} \ge 1$; hence $q^a \le H$ and $q^{v(\theta)+v_D} \le H$. Let $\mathcal{T}$ be the set of terms over d and, for $c \ge 1$, $\mathcal{T}_c = \{\Lambda \in \mathcal{T} : c_d(\Lambda) = c\}$; by Proposition 16.12 both are Σ-stable, μ is constant on Σ-orbits, and $\mathrm{Fr}\colon \mathcal{T} \to \{\text{integral frame classes}\}$ is Σ-equivariant. By Proposition 16.13 the integral frame classes form finitely many Σ-orbits; let R_{cl} be a set of representatives, and for $C \in R_{\mathrm{cl}}$ let $\mathcal{F}_C = \{\Lambda \in \mathcal{T}_c : \mathrm{Fr}(\Lambda) = C\}$.

Step 1: the fibre formula. By Lemma 16.19 applied to $\mathcal{T}' = \mathcal{T}_c$,

$$\sum_{O \in \Sigma\backslash\mathcal{T}_c} \mu(O) = \sum_{C \in R_{\mathrm{cl}}} w(C)\,|\mathcal{F}_C| \qquad \text{in } [0,\infty].$$

Step 2: the bound. By Proposition 16.16, $|\mathcal{F}_C| \le q^{10a(r+1)} c^{k-1}$ for every C (the bound is trivial if $\mathcal{F}_C$ is empty). With Proposition 16.13 and Step 1, for any set R of representatives of $\Sigma\backslash\mathcal{T}$,

$$\begin{aligned}\sum_{\Lambda \in R,\ c_d(\Lambda)=c} \mu(\Lambda) = \sum_{O \in \Sigma\backslash\mathcal{T}_c} \mu(O) &\le q^{r(r+1)(v(\theta)+v_D)}\, q^{10a(r+1)}\, c^{k-1} \\ &\le H^{r(r+1)+10(r+1)} c^{k-1} \le H^{9(r+1)^2+12(r+1)} c^{k-1},\end{aligned}$$

using $q^{v(\theta)+v_D} \le H$, $q^a \le H$ and $H \ge 1$.

Step 3: finitely many orbits. By Proposition 16.8(3),(5), $c_d(\Lambda) \in \{q^i : 0 \le i \le a\}$ for every term, so $\mathcal{T}$ is the union of finitely many $\mathcal{T}_c$. Every Σ-orbit of $\mathcal{T}_c$ meets $\mathcal{F}_C$ for the representative $C \in R_{\mathrm{cl}}$ of the orbit of its classes (Fr is equivariant), and the finitely many C and the finite sets $\mathcal{F}_C$ (Proposition 16.16) leave finitely many such orbits; so $\mathcal{T}$ is the union of finitely many Σ-orbits. □

Proposition 16.12. *Let a local frame pair with parameters r, k be given, let d be a datum, let Λ be a term over d and let $g \in \Sigma$. Then $g\Lambda$ is a term over d. For every choice of the fixed witnesses of Λ and of $g\Lambda$, we have $\omega_d(g\Lambda) = \omega_d(\Lambda)$, $b_d(g\Lambda) = b_d(\Lambda)$, $c_d(g\Lambda) = c_d(\Lambda)$, $g\Lambda$ is of second type if and only if Λ is, and then $\lambda_d(g\Lambda) = \lambda_d(\Lambda)$. The class $\mathrm{Fr}(\Lambda)$ does not depend on the choice of the witness and is an integral frame class; $M(p,p') = M(\Lambda)$ for every $(p,p') \in \mathrm{Fr}(\Lambda)$, and $\mathrm{Fr}(g\Lambda) = g\,\mathrm{Fr}(\Lambda)$. For every frame class C, the group $\mathrm{Stab}_\Sigma(C)$ is commensurable with K_0 and $w(gC) = w(C)$. Finally, $\mathrm{Stab}_\Sigma(\Lambda)$ is commensurable with K_0, that is, both indices $[\mathrm{Stab}_\Sigma(\Lambda) : \mathrm{Stab}_\Sigma(\Lambda) \cap K_0]$ and $[K_0 : \mathrm{Stab}_\Sigma(\Lambda) \cap K_0]$ are finite, and $\mathrm{vol}_{K_0}(\mathrm{Stab}_\Sigma(g\Lambda)) = \mathrm{vol}_{K_0}(\mathrm{Stab}_\Sigma(\Lambda))$.*

Proof. **Step 0: the groups N, N', Σ.** (a) For $u \in N$ and $j < r$, $uf_j - f_j \in F_j(f)$, and $uf_r - f_r \in F_r(f)$ as $f_r \in F_r(f)^\perp$ by (Fp1); so $uf_b = \sum_{i \le b} s(u)_{ib} f_i$ with $s(u)$ upper unitriangular. From $uvf = (uf)s(v) = fs(u)s(v)$, $s(uv) = s(u)s(v)$, whose superdiagonal is $s(u)_{j,j+1} + s(v)_{j,j+1}$. By (Fp1), $h(f_i, e_j^*) = \delta_{ij}$, so $h(uf_{j+1}, e_j^*) = s(u)_{j,j+1}$ and $\psi_N(u) = \psi_0(\theta^{-1} \sum_{j<r} s(u)_{j,j+1})$; hence ψ_N is a unitary character of N, and likewise $\psi_{N'}(u') = \psi_0(\theta^{-1} \sum_j s'(u')_{j,j+1})$ with $u'f' = f's'(u')$. (b) As Λ is a term, Proposition 16.8(1) gives an E-basis of M_E of $2r+2$ vectors with nonzero Gram determinant; so M_E is nondegenerate, $V = M_E \oplus W_0$, and, the translated frames being f, f' times unitriangular matrices by (a), $f_0, \dots, f_r, f'_0, \dots, f'_r$ is an E-basis of M_E; in particular $F_{r+1}(f) \cap F_{r+1}(f') = 0$. (c) Every $g \in \Sigma$ preserves each $F_j(f)$ and $F_j(f')$ $(j \le r+1)$, hence M_E, and is an isometry, hence preserves $X^\perp$, $X'^\perp$ and W_0. For $w \in W_0 \subseteq X^\perp \cap X'^\perp$, $gw - w \in X \cap X' = 0$: g fixes W_0 pointwise. In the basis (f, f') of M_E, g acts by $\mathrm{diag}(s(g), s'(g))$; so $(g-1)^{r+1} = 0$ on V, and g is determined by $(s(g), s'(g))$.

Step 1: $g\Lambda$ is a term over d. Let (u, u') be a witness of Λ. Then $gu \in N$, $gu' \in N'$, $g\Lambda = gu\Lambda_{\mathrm{std}}(A) = gu'\Lambda'_{\mathrm{std}}(A')$ and $gu'f'_b - guf_b = g(u'f'_b - uf_b) \in \theta g\Lambda$. The set of pairs (p, p')

attached to $g\Lambda$ in the definition of a term is Γ: if $y, y' \in \Lambda$ satisfy the conditions for Λ, then $gy, gy' \in g\Lambda$, $gy \perp X$, $gy' \perp X'$ (Step 0(c)), $gy' - p = (gy' - y') + (y' - p) \in X'$ since $gy' - y' \in X'$ for $y' \in X'^{\perp}$ (definition of N'), likewise $gy - p' \in X$, and $gy' - gy \in \theta g\Lambda$; the converse follows with g^{-1} and $g\Lambda$. So (gu, gu') witnesses that $g\Lambda$ is a term over d.

Step 2: the invariants do not depend on the witness. First, $\Lambda_{\mathrm{std}}(A) \cap F_{r+1}(f) = \sum_b \mathcal{O}_E f_b$. Indeed $f_j \in \Lambda_{\mathrm{std}}(A)$ for $j < r$, and $f_r \in A$ (inner) with $h(f_r, e_j^*) = 0$, so $f_r \in \Lambda_{\mathrm{std}}(A)$. Conversely let $x = \sum_b c_b f_b \in \Lambda_{\mathrm{std}}(A)$. The generators of $\Lambda_{\mathrm{std}}(A)$ pair integrally with each other ($h(f_i, f_j) = 0$, $h(f_i, e_j^*) = \delta_{ij}$, $h(e_i^*, e_j^*) = 0$ by (Fp1), $A \perp X$, $A \cap (X^*)^{\perp} \perp e^*$, and $h(A, y) \subseteq \mathcal{O}_E$ for $y \in A \subseteq X^{\perp}$ by the inner condition); so $c_j = h(x, e_j^*) \in \mathcal{O}_E$ for $j < r$. Take $y \in A$ with $h(f_r, y) = 1$; $y_0 = y - \sum_j h(y, e_j^*) f_j \in A \cap (X^*)^{\perp} \subseteq \Lambda_{\mathrm{std}}(A)$ and $h(f_r, y_0) = 1$, so $c_r = h(c_r f_r, y_0) = h(x - \sum_{j<r} c_j f_j, y_0) \in \mathcal{O}_E$. Now let (u, u') and (v, v') be witnesses of Λ, and $\mathsf{A} = s(u^{-1}v)$, $\mathsf{A}' = s'(u'^{-1}v')$, so $vf_j = \sum_i \mathsf{A}_{ij} u f_i$ and $v' f'_j = \sum_i \mathsf{A}'_{ij} u' f'_i$. As $vf_j \in v\Lambda_{\mathrm{std}}(A) = \Lambda = u\Lambda_{\mathrm{std}}(A)$, $\sum_i \mathsf{A}_{ij} f_i \in \Lambda_{\mathrm{std}}(A) \cap F_{r+1}(f)$, so A is integral; likewise A'. With $y_i = \theta^{-1}(u' f'_i - u f_i)$ and $z_j = \theta^{-1}(v' f'_j - v f_j)$, both in Λ,

$$z_j - \sum_i \mathsf{A}'_{ij} y_i = \sum_i \theta^{-1}(\mathsf{A}'_{ij} - \mathsf{A}_{ij})\, u f_i \in \Lambda,$$

so $\theta^{-1}(\mathsf{A}' - \mathsf{A})$ is integral. Hence $vf_j \in M_u$ and $z_j = \sum_i \mathsf{A}'_{ij} y_i + \sum_i \theta^{-1}(\mathsf{A}'_{ij} - \mathsf{A}_{ij}) u f_i \in M_u$, where M_u, M_v are the joint frame lattices of the two witnesses; so $M_v \subseteq M_u$, and by symmetry $M_u = M_v$. By Step 0(a),

$$\frac{\psi_N(v)}{\psi_{N'}(v')} = \frac{\psi_N(u)}{\psi_{N'}(u')}\, \psi_0\Big(\theta^{-1} \sum_{j<r} (\mathsf{A}_{j,j+1} - \mathsf{A}'_{j,j+1})\Big) = \frac{\psi_N(u)}{\psi_{N'}(u')},$$

since the argument lies in $\mathcal{O}_E$ and ψ_0 has conductor $\mathcal{O}_E$. So $\omega_d(\Lambda)$ and $M(\Lambda)$ do not depend on the witness. By Proposition 16.8(4) (for either witness), for $y \in \mathrm{sat}(\Lambda)$ the level is determined by $\ell(y) \le j \iff y \in M(\Lambda) + F_j(f) + F_j(f')$; and $\mathrm{sat}(\Lambda)$, $\hat{I}(\Lambda)$ (built from $M(\Lambda)$ and witness-free data), b_d, c_d, genericity, the second type and the label are determined by Λ, $M(\Lambda)$ and the levels on $\mathrm{sat}(\Lambda)$. So all of them are independent of the witness, and below the witness (gu, gu') of Step 1 may be used for $g\Lambda$.

Step 3: $\psi_N = \psi_{N'}$ on Σ. Let $g \in \Sigma$, $s = s(g)$, $s' = s'(g)$. As g is an isometry, $h(gf'_b, gf_a) = Z_{ab}$, i.e. $\bar{s}^{\mathsf{T}} Z s' = Z$; with $\mathsf{L} = \bar{s}^{\mathsf{T}}$ (lower unitriangular) and $\mathsf{C} = s'^{-1}$ (upper unitriangular), $\mathsf{L}Z = Z\mathsf{C}$. By (Fp2), $Z_{a\sigma(a)} = z_a \neq 0$ and $Z_{ab} = 0$ for $b \neq \sigma(a)$, where σ is the involution reversing each block; within a block $\sigma(c+1) = \sigma(c) - 1$ and $z_{c+1} = -z_c$ (the sign $(-1)^{r-b}$ changes, t_i does not), and for c, $c+1$ in consecutive blocks $\sigma(c) < \sigma(c+1)$. Comparing the entries $(a, \sigma(c))$ of $\mathsf{L}Z = Z\mathsf{C}$ gives

$$\mathsf{L}_{ac}\, z_c = z_a\, \mathsf{C}_{\sigma(a)\sigma(c)} \qquad (0 \le a, c \le r).$$

For $c, c+1$ in one block, $a = c+1$ gives $\mathsf{L}_{c+1,c} = -\mathsf{C}_{\sigma(c)-1,\sigma(c)}$; for $c, c+1$ in different blocks, $\mathsf{C}_{\sigma(c+1)\sigma(c)} = 0$ (C upper) gives $\mathsf{L}_{c+1,c} = 0$; and for $b, b+1$ in different blocks, $a = \sigma(b)$, $c = \sigma(b+1)$ give $\mathsf{C}_{b,b+1} = 0$ (L lower, $\sigma(b) < \sigma(b+1)$). As $c \mapsto \sigma(c) - 1$ is a bijection between the within-block positions, $\sum_c \mathsf{L}_{c+1,c} = -\sum_b \mathsf{C}_{b,b+1} = \sum_b s'_{b,b+1}$ (the superdiagonal of the inverse of a unitriangular matrix is the negative of its superdiagonal). So $\sum_j s'_{j,j+1} = \overline{\sum_j s_{j,j+1}}$, and since $\theta \in F$ and $\psi_0(\bar{x}) = \psi_0(x)$, $\psi_{N'}(g) = \psi_N(g)$.

Step 4: the invariants of $g\Lambda$. With the witness (gu, gu'): $\mathrm{fr}_b(g\Lambda) = g\,\mathrm{fr}_b(\Lambda)$, so $M(g\Lambda) = gM(\Lambda)$; $\mathrm{sat}(g\Lambda) = g\Lambda \cap M_E = g\,\mathrm{sat}(\Lambda)$ (Step 0(c)). If y is a generator of $\hat{I}(\Lambda)$ with (w, λ, λ'), then gy is one of $\hat{I}(g\Lambda)$ with $(w, g\lambda, g\lambda')$: $gw = w$, $w + g\lambda = g(w + \lambda) \in g\Lambda$, $w + g\lambda' \in g\Lambda$, $g\lambda' - g\lambda \in \theta g\Lambda$, $g\lambda \in X$, $g\lambda' \in X'$ and $gy - \theta^{-1}(g\lambda' - g\lambda) \in gM(\Lambda)$; with g^{-1}, $\hat{I}(g\Lambda) = g\hat{I}(\Lambda)$.

As g is an additive bijection, $b_d(g\Lambda) = b_d(\Lambda)$ and $c_d(g\Lambda) = c_d(\Lambda)$, and $g\Lambda$ is generic if and only if Λ is. By Proposition 16.8(4) and Step 0(c), for $y \in \mathrm{sat}(\Lambda)$, $\ell(gy) \le j \iff gy \in g(M(\Lambda) + F_j(f) + F_j(f')) \iff \ell(y) \le j$; so the maximal level J is the same, and g maps $\mathrm{sat}(\Lambda) \cap (M(\Lambda) + F_{J-1}(f) + F_{J-1}(f'))$ onto the corresponding module of $g\Lambda$, so the labels agree. For the pairing condition, if $x_i \in X$, $x_i' \in X'$ and $x_i + x_i' \in \theta g\Lambda$, then $g^{-1}x_i \in X$, $g^{-1}x_i' \in X'$, $g^{-1}x_i + g^{-1}x_i' \in \theta\Lambda$ and $h(x_1, x_2') = h(g^{-1}x_1, g^{-1}x_2')$; so $g\Lambda$ is of second type if and only if Λ is. Finally, by Steps 0(a) and 3,

$$\omega_d(g\Lambda) = \frac{\psi_N(g)\psi_N(u)}{\psi_{N'}(g)\psi_{N'}(u')} = \omega_d(\Lambda).$$

Step 5: commensurability. Λ *is a lattice.* Put $Y = (X + X^*)^\perp$; $X + X^*$ is nondegenerate by (Fp1), so $V = X \oplus X^* \oplus Y$ with Y nondegenerate. $A_0 = A \cap (X^*)^\perp \subseteq X^\perp \cap (X^*)^\perp = Y$ is finitely generated (inner), and for $w \in A$, $w - \sum_j h(w, e_j^*) f_j \in A_0$, so $A = X + A_0$ (as $X = F_r(f) \subseteq A$). If A_0 did not span Y, some $0 \ne y \in Y$ would be orthogonal to A_0 and to X, hence $h(A, Ey) = 0$, and the inner condition would give $Ey \subseteq A \cap (X^*)^\perp = A_0$, impossible for a finitely generated module. So $\Lambda_{\mathrm{std}}(A)$, and $\Lambda = u\Lambda_{\mathrm{std}}(A)$, are finitely generated $\mathcal{O}_E$-modules spanning V (lattices). *Stabilisers of two lattices are commensurable.* For lattices Λ_1, Λ_2 choose $t \ge 0$ with $\varpi^t\Lambda_1 \subseteq \Lambda_2 \subseteq \varpi^{-t}\Lambda_1$. The kernel Γ_1 of $\mathrm{Stab}(\Lambda_1) \to \mathrm{Aut}(\Lambda_1/\varpi^{2t}\Lambda_1)$ has finite index (the quotient is finite), and for $x \in \Lambda_2$, $(g-1)x \in (g-1)\varpi^{-t}\Lambda_1 \subseteq \varpi^t\Lambda_1 \subseteq \Lambda_2$ ($g \in \Gamma_1$); with $g^{-1} \in \Gamma_1$, $\Gamma_1 \subseteq \mathrm{Stab}(\Lambda_2)$. Hence $[\Sigma \cap \mathrm{Stab}(\Lambda_1) : \Sigma \cap \mathrm{Stab}(\Lambda_1) \cap \mathrm{Stab}(\Lambda_2)] \le [\mathrm{Stab}(\Lambda_1) : \Gamma_1] < \infty$, and symmetrically. K_0 *is a lattice stabiliser.* Let L_W be a lattice in W_0 and $\Lambda_1 = \sum_b \mathcal{O}_E f_b + \sum_b \mathcal{O}_E f_b' + L_W$, a lattice by Step 0(b). For $g \in \Sigma$, by Step 0(c) $g\Lambda_1 = \Lambda_1$ if and only if $s(g)$ and $s'(g)$ are integral (then so are their inverses), if and only if g stabilises $\sum \mathcal{O}_E f_b$ and $\sum \mathcal{O}_E f_b'$. So $K_0 = \Sigma \cap \mathrm{Stab}(\Lambda_1)$, and $\mathrm{Stab}_\Sigma(\Lambda)$ is commensurable with K_0. *Volumes.* For pairwise commensurable subgroups put $[B_1 : B_2] = [B_1 : B_1 \cap B_2]/[B_2 : B_1 \cap B_2]$; computing both through $B_1 \cap B_2 \cap B_3$, which has finite index in each, gives $[B_1 : B_3] = [B_1 : B_2][B_2 : B_3]$, and $[gB_1g^{-1} : gB_2g^{-1}] = [B_1 : B_2]$; $\mathrm{vol}_{K_0}(B) = [B : K_0]$. Let $g \in \Sigma$ and $B = \mathrm{Stab}_\Sigma(\Lambda)$, so $\mathrm{Stab}_\Sigma(g\Lambda) = gBg^{-1}$. By Step 0(c), $\mathsf{n} = g - 1$ is nilpotent, so for any lattice Λ_0 the lattice $\Lambda_g = \sum_{i \le r} \mathsf{n}^i \Lambda_0$ is stable under $g = 1 + \mathsf{n}$ and $g^{-1} = \sum_{i \le r} (-\mathsf{n})^i$; then $B_g = \mathrm{Stab}_\Sigma(\Lambda_g)$ is commensurable with K_0 and $gB_gg^{-1} = B_g$. Hence

$$\mathrm{vol}_{K_0}(gBg^{-1}) = [gBg^{-1} : gB_gg^{-1}]\,[B_g : K_0] = [B : B_g]\,[B_g : K_0] = \mathrm{vol}_{K_0}(B).$$

The same computation applies to every subgroup $B \subseteq \Sigma$ commensurable with K_0.

Step 6: frame classes. The pairs (B, B') of integral upper unitriangular matrices with $B' - B \in \theta \mathrm{M}_{r+1}(\mathcal{O}_E)$ form a group Γ_θ under componentwise multiplication ($B'C' - BC = (B' - B)C' + B(C' - C)$, and $B'^{-1} - B^{-1} = B'^{-1}(B - B')B^{-1}$, inverses of integral unitriangular matrices being integral), acting on frame pairs on the right; the classes are its orbits. By Step 2, two witnesses give frame pairs in one orbit, so $\mathrm{Fr}(\Lambda)$ does not depend on the witness; with the witness (gu, gu'), $\mathrm{Fr}(g\Lambda) = \mathrm{cl}(guf, gu'f') = g\,\mathrm{Fr}(\Lambda)$ (g is linear). $\mathrm{Fr}(\Lambda)$ is the frame class of (u, u'), and it is integral: its pairs $(\mathrm{fr}B, \mathrm{fr}'B')$ consist of vectors of the integral lattice Λ (Proposition 16.8(1)). For $(p, p') = (\mathrm{fr}B, \mathrm{fr}'B') \in \mathrm{Fr}(\Lambda)$, $p_j = \sum_i B_{ij}\mathrm{fr}_i$ and $\theta^{-1}(p_j' - p_j) = \sum_i B_{ij}'\theta^{-1}(\mathrm{fr}_i' - \mathrm{fr}_i) + \sum_i \theta^{-1}(B_{ij}' - B_{ij})\mathrm{fr}_i$ lie in $M(\Lambda)$, so $M(p, p') \subseteq M(\Lambda)$; as $(\mathrm{fr}, \mathrm{fr}') = (p, p')(B, B')^{-1}$ with $(B, B')^{-1} \in \Gamma_\theta$, also $M(\Lambda) \subseteq M(p, p')$. Now let $C = \mathrm{cl}(p, p')$ with $p = uf$, $p' = u'f'$, $u \in N$, $u' \in N'$. By Step 0, $(p, p') = (fs(u), f's'(u'))$ is an E-basis of M_E, and $g \in \Sigma$ acts by $gp = p\tilde{s}(g)$, $gp' = p'\tilde{s}'(g)$ with $\tilde{s}(g) = s(u)^{-1}s(g)s(u)$, $\tilde{s}'(g) = s'(u')^{-1}s'(g)s'(u')$ unitriangular. As p, p' are bases, $gC = \mathrm{cl}(p\tilde{s}, p'\tilde{s}') = C$ if and only if $(\tilde{s}(g), \tilde{s}'(g)) \in \Gamma_\theta$. Put $\Lambda_C = \sum_b \mathcal{O}_E p_b + \sum_b \mathcal{O}_E p_b' + L_W$; as in Step 5, $g\Lambda_C = \Lambda_C$ if and only if $\tilde{s}(g)$, $\tilde{s}'(g)$ are integral. Hence $\mathrm{Stab}_\Sigma(C) \subseteq \mathrm{Stab}_\Sigma(\Lambda_C)$, and it contains the elements of $\mathrm{Stab}_\Sigma(\Lambda_C)$ acting trivially

on the finite module $\Lambda_C/\theta\Lambda_C$ (then $\tilde{s} \equiv 1 \equiv \tilde{s}'$ modulo θ), a subgroup of finite index. So $\mathrm{Stab}_\Sigma(C)$ is commensurable with the lattice stabiliser $\mathrm{Stab}_\Sigma(\Lambda_C)$, hence with K_0 (Step 5); and as $\mathrm{Stab}_\Sigma(gC) = g\,\mathrm{Stab}_\Sigma(C)g^{-1}$, the volume computation of Step 5 gives $w(gC) = w(C)$. □

Proposition 16.13. *Let a local frame pair with parameters r, k be given such that some datum has a term. Then $w(C)$ is a positive integer for every integral frame class C, the integral frame classes form finitely many Σ-orbits, and for every set R of representatives of these orbits*

$$\sum_{C\in R} w(C) \le q^{\,r(r+1)(v(\theta)+v_D)}.$$

Proof. **Step 1: stabilisers of classes stabilise lattices.** If $g \in \Sigma$ and $g\,\mathrm{cl}(p,p') = \mathrm{cl}(p,p')$, then $(gp, gp') \in \mathrm{cl}(p,p')$, so $gp = pB$ with $B \in \mathrm{U}(\mathcal{O})$ and $g\Lambda_p \subseteq \Lambda_p$; the same for g^{-1} gives $g\Lambda_p = \Lambda_p$.

Step 2: a representative in each orbit. Let $C = \mathrm{cl}(nf, n'f')$ be an integral frame class, $n \in N$, $n' \in N'$. Take h, u as in Lemma 16.14(3) and put $u' = s'(h^{-1}n')$ (upper unitriangular, $h^{-1}n' \in N'$). Then $C^\natural := h^{-1}C = \mathrm{cl}(fu, f'u')$ (h^{-1} is linear), and $C^\natural$ is integral because h^{-1} is an isometry. If $g \in \mathrm{Stab}_\Sigma(C^\natural)$, then $hgh^{-1} \in \mathrm{Stab}_\Sigma(C)$ stabilises Λ_{nf} by Step 1, so $g = h^{-1}(hgh^{-1})h \in K_0$ by Lemma 16.14(3). Thus $\mathrm{Stab}_\Sigma(C^\natural) \subseteq K_0$, and by Proposition 16.12 this group is commensurable with K_0 and $w(C) = w(C^\natural)$. Hence

$$w(C) = \frac{[K_0 : \mathrm{Stab}_\Sigma(C^\natural)]}{[\mathrm{Stab}_\Sigma(C^\natural) : \mathrm{Stab}_\Sigma(C^\natural)]} = [K_0 : \mathrm{Stab}_{K_0}(C^\natural)] = |K_0 C^\natural|.$$

In particular $w(C)$ is a positive integer: the index is finite by the commensurability, and $K_0C^\natural \ni C^\natural$ is nonempty.

Step 3: the K_0-orbit of $C^\natural$ lies in a set of normal forms. Let T be the set of integral frame classes of the form $\mathrm{cl}(fx, f'x')$ with x, x' upper unitriangular and $x_{ij} \in \mathcal{O}_E$ whenever i, j lie in one block. For $g \in K_0$, $gC^\natural = \mathrm{cl}(fs(g)u, f's'(g)u')$ is integral; $s(g)$ is block diagonal (Lemma 16.14(1)) and integral (as $g\Lambda_f = \Lambda_f$ and f is linearly independent), so on a block B_β, $(s(g)u)_{B_\beta B_\beta} = s(g)_{B_\beta B_\beta} u_{B_\beta B_\beta} = s(g)_{B_\beta B_\beta}$ is integral. So $K_0C^\natural \subseteq T$.

Step 4: summation. If C_1, C_2 lie in different Σ-orbits, then $K_0C_1^\natural$ and $K_0C_2^\natural$ are disjoint, since $K_0 \subseteq \Sigma$ and $C_i^\natural \in \Sigma C_i$. So for every set R of representatives of the Σ-orbits of integral frame classes, in $[0,\infty]$,

$$\sum_{C\in R} w(C) = \sum_{C\in R} |K_0 C^\natural| \le |T|,$$

and the number of these orbits is at most $|T|$, each $K_0C^\natural$ being nonempty. It remains to show $|T| \le q^{\,r(r+1)(v(\theta)+v_D)}$; this is clear if $T = \emptyset$.

Step 5: counting the normal forms. Let $\mathrm{cl}(fx, f'x') \in T$. Since $(fx, f'x')$ lies in this integral class, the matrix $(h((f'x')_b, (fx)_a))_{ab} = \bar{x}^{\mathsf{T}} Z x'$ is integral, and Lemma 16.15 applies: Δ (which depends only on the frame pair) is an invertible element of $\mathcal{O}_E$ with $v(\Delta\bar{\Delta}) = v_D$, and $\bar{\Delta}x$, $\Delta x'$ are integral. *Cosets.* Let $\delta \in \mathcal{O}_E$ be invertible in E and R_δ a set of representatives of $\delta^{-1}\mathcal{O}_E/\mathcal{O}_E$, which has $|\mathcal{O}_E/\delta\mathcal{O}_E| = q^{v(\delta\bar{\delta})}$ elements (if E is a field, $\delta = \varepsilon\varpi^e$ with ε a unit and $|\mathcal{O}_E/\varpi^e\mathcal{O}_E| = q^{2e}$; if $E = F \times F$, $\delta = (\delta_1, \delta_2)$ and the order is $q^{v(\delta_1)+v(\delta_2)}$). If x is upper unitriangular with δx integral, then $x\,\mathrm{U}(\mathcal{O})$ contains a matrix with all entries above the diagonal in R_δ: column by column, and in column j for $i = j-1, j-2, \dots, 0$, the entry $(xA)_{ij} = x_{ij} + A_{ij} + \sum_{i<c<j} x_{ic}A_{cj}$ lies in $\delta^{-1}\mathcal{O}_E$ and is moved into R_δ by the choice of $A_{ij} \in \mathcal{O}_E$, which changes only the entries $(xA)_{i'j}$ with $i' \le i$. So there are at most $q^{v(\delta\bar{\delta})r(r+1)/2}$ such cosets;

we fix a representative $\hat{x}$ of each, $x = \hat{x}A_x$ with $A_x \in \mathrm{U}(\mathcal{O})$. *Congruences.* Let $R_\theta \subseteq \mathrm{U}(\mathcal{O})$ contain one element of each class of $\mathrm{U}(\mathcal{O})$ modulo $\theta \mathrm{M}_{r+1}(\mathcal{O}_E)$; $|R_\theta| \le |\mathcal{O}_E/\theta\mathcal{O}_E|^{r(r+1)/2} = q^{v(\theta)r(r+1)}$. *The map.* For $\mathrm{cl}(fx, f'x') \in T$ write $x = \hat{x}A$, $x' = \hat{x}'A'$ and choose $B_0 \in R_\theta$ with $A'A^{-1} \equiv B_0$ modulo θ. Then $(A, B_0^{-1}A') \in \Gamma_\theta$, because $B_0^{-1}A' - A = B_0^{-1}(A'A^{-1} - B_0)A$, and $(fx, f'x') = (f\hat{x}, f'\hat{x}'B_0)(A, B_0^{-1}A')$; hence $\mathrm{cl}(fx, f'x') = \mathrm{cl}(f\hat{x}, f'\hat{x}'B_0)$ is determined by the coset of x (with $\delta = \bar{\Delta}$), the coset of x' (with $\delta = \Delta$) and B_0. Since $v(\Delta\bar{\Delta}) = v(\bar{\Delta}\Delta) = v_D$,

$$|T| \le q^{v_D r(r+1)/2} \cdot q^{v_D r(r+1)/2} \cdot q^{v(\theta)r(r+1)} = q^{r(r+1)(v(\theta)+v_D)}.$$

□

Lemma 16.14. *Let a local frame pair with parameters r, k be given such that some datum has a term. Then $f_0, \dots, f_r, f'_0, \dots, f'_r$ is an E-basis of M_E, and:*

1. *for $g \in N$ (resp. $g \in N'$) there is a unique upper unitriangular $s(g)$ (resp. $s'(g)$) in $\mathrm{M}_{r+1}(E)$ with $gf_b = \sum_i s(g)_{ib} f_i$ (resp. $gf'_b = \sum_i s'(g)_{ib} f'_i$) for $0 \le b \le r$; $s(g_1g_2) = s(g_1)s(g_2)$; and for $g \in \Sigma$, $s(g)$ and $s'(g)$ are block diagonal and $\overline{s(g)}^{\mathsf{T}} Z\, s'(g) = Z$;*
2. *for every block-diagonal upper unitriangular $s \in \mathrm{M}_{r+1}(E)$ there is $g \in \Sigma$ with $s(g) = s$;*
3. *for every $n \in N$ there are $h \in \Sigma$ and an upper unitriangular $u \in \mathrm{M}_{r+1}(E)$ whose diagonal blocks are identity matrices such that $h^{-1}nf_b = \sum_i u_{ib} f_i$ for $0 \le b \le r$, and $h^{-1}gh \in K_0$ for every $g \in \Sigma$ with $g\Lambda_n = \Lambda_n$, where $\Lambda_n = \sum_b \mathcal{O}_E\, nf_b$.*

Proof. **Step 1: matrices and the basis.** Let $g \in N$. For $j < r$, $f_j \in F_{j+1}(f)$ gives $gf_j - f_j \in F_j(f)$; and $f_r \perp F_r(f)$ by (Fp1) gives $gf_r - f_r \in F_r(f)$. So $gf = fs$ with s upper unitriangular; likewise for N'. Let Λ be a term over some datum with witness (u_0, u'_0). By Proposition 16.8(1), the $2r+2$ vectors $u_0 f_b$, $\theta^{-1}(u'_0 f'_b - u_0 f_b)$ are E-linearly independent with nonzero Gram determinant and span M_E; so M_E is a nondegenerate free E-module of rank $2r+2$ and $V = M_E \oplus W_0$ orthogonally. As $u_0 f = f s_0$, $u'_0 f' = f' s'_0$ with unitriangular s_0, s'_0, the $2r+2$ vectors f_b, f'_b span M_E, hence form a basis (a surjective endomorphism of a finitely generated free module over a commutative ring is bijective). So $s(g)$, $s'(g)$ are unique, and $g_1 g_2 f = g_1(f s(g_2)) = f s(g_1)s(g_2)$ by linearity.

Step 2: proof of (1). Let $g \in \Sigma$, $s = s(g)$, $s' = s'(g)$. As g is an isometry, $Z_{ab} = h(gf'_b, gf_a) = \sum_{i,j} s'_{ib} \bar{s}_{ja} Z_{ji}$, i.e. $\bar{s}^{\mathsf{T}} Z s' = Z$. Put $\mathsf{M} = (\bar{s}^{\mathsf{T}})^{-1}$, lower unitriangular; then $Zs' = \mathsf{M}Z$, whose (a,b) entries read $z_a s'_{\sigma(a)b} = \mathsf{M}_{a\sigma(b)} z_{\sigma(b)}$. Let $c < b$ lie in different blocks and take $a = \sigma(c)$: since σ maps each block to itself and the blocks are consecutive intervals, $\sigma(c) < \sigma(b)$, so $\mathsf{M}_{\sigma(c)\sigma(b)} = 0$ and $s'_{cb} = 0$. So s' is block diagonal, and then so is $\bar{s}^{\mathsf{T}} = Z s'^{-1} Z^{-1}$, hence s.

Step 3: proof of (2). Let s be block diagonal upper unitriangular and $s' = Z^{-1}(\bar{s}^{\mathsf{T}})^{-1} Z$. On the block B_β, $s'_\beta = \mathcal{E}_\beta J_{s_\beta} (\bar{s}_\beta^{\mathsf{T}})^{-1} J_{s_\beta} \mathcal{E}_\beta$ (t_β cancels); conjugation by J_s maps lower unitriangular matrices to upper unitriangular ones ($(JAJ)_{ab} = A_{s-1-a,s-1-b}$) and conjugation by $\mathcal{E}_\beta$ preserves them, so s' is block diagonal upper unitriangular, and $\bar{s}^{\mathsf{T}} Z s' = Z$. By Step 1 there is a unique E-linear $g\colon V \to V$ with $gf = fs$, $gf' = f's'$ and $g|_{W_0} = \mathrm{id}$. It is an isometry: by (Fp1), $h((fs)_a, (fs)_b) = \sum_{i,j} s_{ia} \bar{s}_{jb} h(f_i, f_j) = -T s_{ra} \bar{s}_{rb} = h(f_a, f_b)$, as the row r of s is that of the identity; likewise for f'; $h((f's')_b, (fs)_a) = (\bar{s}^{\mathsf{T}} Z s')_{ab} = Z_{ab}$, and the reversed pairings follow by hermitian symmetry; g preserves M_E and W_0, which are orthogonal. So $g \in \mathrm{U}(V)$. $g \in N$: for $j < r$, $gF_{j+1}(f) = F_{j+1}(f)$ and $(g-1)F_{j+1}(f) \subseteq F_j(f)$ as s is unitriangular; $gX = X$ and g is an isometry, so $g(X^\perp) = X^\perp$. Let $w \in X^\perp$, $w = m + w_0$ with $w_0 \in W_0$ and $m = \sum_b \alpha_b f_b + \sum_b \beta_b f'_b$. As $W_0 \perp M_E \supseteq X$, $m \perp X$, and for $a < r$, using $h(f_b, f_a) = 0$,

$$0 = h(m, f_a) = \sum_b \beta_b Z_{ab} = \beta_{\sigma(a)} z_a.$$

So $\beta_c = 0$ unless $c = \sigma(r) = l_{m-1}$, the first index of the last block. Hence $(g-1)w = \sum_b \alpha_b(g-1)f_b + \beta_{l_{m-1}}(g-1)f'_{l_{m-1}}$; the first sum lies in $F_r(f) = X$, and $(g-1)f'_{l_{m-1}} = \sum_{i<l_{m-1}} s'_{i,l_{m-1}} f'_i = 0$ because s' is block diagonal and l_{m-1} is the first index of its block. So $(g-1)w \in X$ and $g \in N$. Symmetrically, for $w \in X'^{\perp}$ and $a < r$, $0 = h(m, f'_a) = \sum_b \alpha_b \overline{Z_{ba}} = \alpha_{\sigma(a)}\overline{z_{\sigma(a)}}$, so only $\alpha_{l_{m-1}}$ may be nonzero, $(g-1)f_{l_{m-1}} = 0$ since s is block diagonal, and $(g-1)f'_b \in X'$; so $g \in N'$. Thus $g \in \Sigma$ and $s(g) = s$.

Step 4: proof of (3). Let $n \in N$, $s = s(n)$, and s_0 the block-diagonal part of s (equal to s on $\bigcup_\beta B_\beta \times B_\beta$, zero elsewhere), block diagonal upper unitriangular. By (2) there is $h \in \Sigma$ with $s(h) = s_0$; then $h^{-1}n \in N$ and $u := s(h^{-1}n) = s_0^{-1}s$ by (1). As s_0^{-1} is block diagonal, $u_{B_\beta B_\beta} = (s_{B_\beta B_\beta})^{-1} s_{B_\beta B_\beta} = 1$; and $h^{-1}nf = fu$. Let $g \in \Sigma$ with $g\Lambda_n = \Lambda_n$ and $g' = h^{-1}gh \in \Sigma$, $\sigma_g = s(g')$. Then g' stabilises $h^{-1}\Lambda_n = \sum_b \mathcal{O}_E(fu)_b$, whose generators fu are E-linearly independent; since $g'(fu) = fs(g')u = (fu)(u^{-1}\sigma_g u)$, the matrix $Q = u^{-1}\sigma_g u$ is integral. The matrices u, u^{-1} are upper unitriangular, hence block upper triangular, and σ_g is block diagonal by (1); so the diagonal blocks are $Q_{B_\beta B_\beta} = (u^{-1})_{B_\beta B_\beta}(\sigma_g)_{B_\beta B_\beta} u_{B_\beta B_\beta} = (\sigma_g)_{B_\beta B_\beta}$, and σ_g is integral. By (1), $s'(g') = Z^{-1}(\bar\sigma_g^{\mathsf T})^{-1}Z$, whose block on B_β is $\mathcal{E}_\beta J(\bar\sigma_{g,\beta}^{\mathsf T})^{-1} J\mathcal{E}_\beta$, integral since the inverse of an integral unitriangular matrix is integral. So g' and g'^{-1} map $\sum_b \mathcal{O}_E f_b$ and $\sum_b \mathcal{O}_E f'_b$ into themselves, i.e. $g' \in K_0$. □

Lemma 16.15. *Let a local frame pair with parameters r, k be given, and let $u, u' \in \mathrm{M}_{r+1}(E)$ be upper unitriangular, with $u_{ij} \in \mathcal{O}_E$ whenever i and j lie in one block, such that $P = \bar u^{\mathsf T} Z u'$ has all entries in $\mathcal{O}_E$. Then $D_l \in \mathcal{O}_E$ for $0 \le l \le r+1$, and $D_l \ne 0$ if and only if $l \in \{l_0, \dots, l_m\}$. The element*

$$\Delta = \prod_{1 \le l \le r+1,\ D_l \ne 0} D_l$$

lies in $\mathcal{O}_E$, is invertible in E, satisfies $v(\Delta\bar\Delta) = v_D$, and $\bar\Delta u_{ij} \in \mathcal{O}_E$ and $\Delta u'_{ij} \in \mathcal{O}_E$ for all i, j.

Proof. **Step 1: the shape of Z.** By (Fp2), $Z_{ab} = (-1)^{r-b}(t_\beta J_{s_\beta})_{ab}$ on the block $B_\beta \times B_\beta$ and $Z_{ab} = 0$ off the diagonal blocks. So $Z = \mathrm{diag}(Z_1, \dots, Z_m)$ with $Z_\beta = t_\beta J_{s_\beta}\mathcal{E}_\beta$, $\mathcal{E}_\beta$ diagonal with entries ± 1; Z_β is invertible, $t_\beta Z_\beta^{-1} = \mathcal{E}_\beta J_{s_\beta}$ has entries in $\{0, \pm 1\}$, and $\det Z_\beta = \pm t_\beta^{s_\beta}$. For $l = l_\beta$, $Z_{[l]} = \mathrm{diag}(Z_1, \dots, Z_\beta)$ and $D_{l_\beta} = \prod_{\gamma \le \beta} \det Z_\gamma$ is invertible. For $l_{\beta-1} < l < l_\beta$ the row $l_{\beta-1}$ of $Z_{[l]}$ is zero, because the only nonzero entry of that row of Z is in the column $l_\beta - 1 \ge l$; so $D_l = 0$.

Step 2: the minors. Put $L = \bar u^{\mathsf T}$ (lower unitriangular, $L_{ij} \in \mathcal{O}_E$ for i, j in one block) and $U = u'$, so $P = LZU$. As L is lower and U upper triangular, $P_{[l]} = L_{[l]}Z_{[l]}U_{[l]}$ and $\det P_{[l]} = D_l$ for every l; as P is integral, $D_l \in \mathcal{O}_E$. Hence $\Delta = \prod_{\beta=1}^m D_{l_\beta} \in \mathcal{O}_E$ is invertible, and $v(\Delta\bar\Delta) = \sum_{l \ge 1,\, D_l \ne 0} v(D_l \bar D_l) = v_D$.

Step 3: the columns of L. Fix β, $l = l_\beta$, and $i \ge l$. For $c < l$, $P_{ic} = \sum_{a,b} L_{ia} Z_{ab} U_{bc}$ with $b \le c < l$, and $Z_{ab} \ne 0$ forces a into the block of b, so $a < l$ (l is a block end). Hence $P_{\{i\},[l]} = L_{\{i\},[l]} Z_{[l]} U_{[l]}$, and with $P_{[l]} = L_{[l]}Z_{[l]}U_{[l]}$,

$$L_{\{i\},[l]} = y\, L_{[l]}, \qquad y = P_{\{i\},[l]} P_{[l]}^{-1} = D_l^{-1} P_{\{i\},[l]} \operatorname{adj}(P_{[l]}),$$

so $D_l y$ is integral. For $c \in B_\beta$, $L_{ic} = \sum_{a<l} y_a L_{ac}$, and $L_{ac} \ne 0$ forces $c \le a < l$, i.e. $a \in B_\beta$, where $L_{ac} \in \mathcal{O}_E$. So $D_{l_\beta} L_{ic} \in \mathcal{O}_E$ for $i \ge l_\beta$, $c \in B_\beta$; for $i \in B_\beta$ already $L_{ic} \in \mathcal{O}_E$, and for $i < l_{\beta-1}$, $L_{ic} = 0$.

Step 4: the rows of U. Fix β and $l' = l_{\beta-1}$; write 1 for the indices $< l'$ and 2 for those $\ge l'$. If $\beta = 1$ put $S = P$. If $\beta \ge 2$, block multiplication ($L_{12} = 0$, $U_{21} = 0$, $Z = \mathrm{diag}(Z_{11}, Z_{22})$

since l' is a block end) gives $P_{11} = L_{11}Z_{11}U_{11}$, $P_{12} = L_{11}Z_{11}U_{12}$, $P_{21} = L_{21}Z_{11}U_{11}$, $P_{22} = L_{21}Z_{11}U_{12} + L_{22}Z_{22}U_{22}$, and P_{11} is invertible with determinant $D_{l'}$; hence

$$S := P_{22} - P_{21}P_{11}^{-1}P_{12} = L_{22}Z_{22}U_{22}.$$

By Schur's determinant formula $\det \begin{pmatrix} A & b \\ c & d \end{pmatrix} = \det A\,(d - cA^{-1}b)$, applied to $P_{[l']\cup\{i\},[l']\cup\{j\}}$, $D_{l'}S_{ij} = \det P_{[l']\cup\{i\},[l']\cup\{j\}} \in \mathcal{O}_E$. So in both cases $D_{l'}S$ is integral ($D_0 = 1$). The rows of L_{22} indexed by B_β (the first block of 2) are supported on the columns B_β and Z_{22} is block diagonal, so the rows B_β of $S = L_{22}Z_{22}U_{22}$ are

$$S_{B_\beta,2} = L_{B_\beta B_\beta}\, Z_\beta\, U_{B_\beta,2}, \qquad U_{B_\beta,2} = Z_\beta^{-1} L_{B_\beta B_\beta}^{-1} S_{B_\beta,2}.$$

$L_{B_\beta B_\beta}$ is integral unitriangular, so its inverse is integral; with Step 1, $t_\beta D_{l'} U_{ij} \in \mathcal{O}_E$ for $i \in B_\beta$ and $j \geq l'$, while $U_{ij} = 0$ for $j < l' \leq i$.

Step 5: valuations. Let $w \in \mathcal{W}$ and $i \in B_\beta$. All D_l are integral, so $w(D_{l_\gamma}) \geq 0$ and $w(D_{l_\gamma}) \leq w(\Delta)$ for every γ, and $w(D_{l_\beta}) = s_\beta w(t_\beta) + w(D_{l'})$ by Step 1. If $w(t_\beta) \geq 0$, then $w(t_\beta) + w(D_{l'}) \leq w(D_{l_\beta}) \leq w(\Delta)$; if $w(t_\beta) < 0$, then $w(t_\beta) + w(D_{l'}) < w(D_{l'}) \leq w(\Delta)$ (for $\beta = 1$, $w(D_0) = 0 \leq w(\Delta)$). With Step 4, $w(\Delta U_{ij}) \geq w(\Delta) - w(t_\beta) - w(D_{l'}) \geq 0$ for all j; with Step 3, $w(\Delta L_{ic}) \geq w(\Delta) - w(D_{l_\beta}) \geq 0$ for $c \in B_\beta$ and all i. As β and w are arbitrary, $\Delta u' = \Delta U$ and ΔL are integral, and $\bar{\Delta} u_{ji} = \overline{\Delta L_{ij}} \in \mathcal{O}_E$, since $\mathcal{O}_E$ is stable under conjugation. □

Proposition 16.16. *Let a local frame pair with parameters r, k be given, d a datum, C a set of frame pairs and $c \geq 1$ an integer. If some term over d has class C, then $a \geq 0$ and the number of terms Λ over d with $\mathrm{Fr}(\Lambda) = C$ and $c_d(\Lambda) = c$ is at most $q^{10a(r+1)}c^{k-1}$.*

Proof. **Step 0: set-up.** Let Λ_1 be a term over d with $\mathrm{Fr}(\Lambda_1) = C$. By Proposition 16.8(1),(2), $a \geq 0$, M_E is nondegenerate, $V = M_E \oplus W_0$ orthogonally, and $M := M(\Lambda_1)$ has the basis fr_b, $\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ with Gram determinant $g_M = (-1)^{r+1}\theta^{-2(r+1)}G \in F^\times$, $v(g_M) = a$; hence $[M^\# : M] = |\mathcal{O}_E/g_M\mathcal{O}_E| = q^{2a}$. Let $\mathcal{T}_c$ be the set of terms Λ over d with $\mathrm{Fr}(\Lambda) = C$ and $c_d(\Lambda) = c$. For $\Lambda \in \mathcal{T}_c$, choosing $(p, p') \in C = \mathrm{Fr}(\Lambda) = \mathrm{Fr}(\Lambda_1)$, Proposition 16.12 gives $M(\Lambda) = M(p, p') = M$. By Proposition 16.8(1),(3),(5), $\mathrm{sat}(\Lambda)$ is an integral module with $M \subseteq \hat{I}(\Lambda) \subseteq \mathrm{sat}(\Lambda) \subseteq M_E$ and $[\mathrm{sat}(\Lambda) : M] = b_d(\Lambda) \leq q^a$. We bound $|\mathcal{T}_c|$ through the map $\Lambda \mapsto (\mathrm{sat}(\Lambda), \Lambda \cap W_0)$.

Step 1: saturations. By Lemma 16.17 for Λ_1, $\mathrm{sat}(\Lambda)$ is one of at most $q^{2a(2r+2)}$ modules $\hat{M}$.

Step 2: the gluing homomorphism. Let $L_d = \{w \in W_0 \cap A \cap A' : (w, w) \in \Gamma\}$, and for a term Λ over d write $w \sim_\Lambda y$ if there are $\lambda \in X$, $\lambda' \in X'$ with $w + \lambda \in \Lambda$, $w + \lambda' \in \Lambda$, $\lambda' - \lambda \in \theta\Lambda$ and $y - \theta^{-1}(\lambda' - \lambda) \in M(\Lambda)$. Let $\mathrm{fr}, \mathrm{fr}'$ be the frames of the fixed witness of Λ. (a) *Existence.* For $w \in L_d$, as Γ is the set of pairs attached to Λ, there are $y_1, y'_1 \in \Lambda$ with $y_1 - w \in X$, $y'_1 - w \in X'$, $y'_1 - y_1 \in \theta\Lambda$; with $\lambda = y_1 - w$, $\lambda' = y'_1 - w$, the vector $y = \theta^{-1}(y'_1 - y_1) \in \Lambda \cap M_E = \mathrm{sat}(\Lambda)$ satisfies $w \sim_\Lambda y$. (b) *Uniqueness modulo $M(\Lambda)$.* If $w \sim_\Lambda y$ and $y' - y \in M(\Lambda)$, then $w \sim_\Lambda y'$ (same λ, λ'). Conversely let $w \sim_\Lambda y$ by (λ_1, λ'_1) and $w \sim_\Lambda y'$ by (λ_2, λ'_2). Then $\mu = \lambda_1 - \lambda_2 \in \Lambda \cap X$ and $\mu' = \lambda'_1 - \lambda'_2 \in \Lambda \cap X'$, so by Lemma 16.18(2) $\mu = \sum_{j<r} \alpha_j \mathrm{fr}_j$, $\mu' = \sum_{j<r} \alpha'_j \mathrm{fr}'_j$ with integral coefficients. The vector $\theta^{-1}(\mu' - \mu) = \theta^{-1}(\lambda'_1 - \lambda_1) - \theta^{-1}(\lambda'_2 - \lambda_2)$ lies in Λ and equals $\sum_j \alpha'_j \theta^{-1}(\mathrm{fr}'_j - \mathrm{fr}_j) + z$ with $z = \sum_{j<r} \theta^{-1}(\alpha'_j - \alpha_j)\mathrm{fr}_j$; the first sum lies in $M(\Lambda) \subseteq \Lambda$, so $z \in \Lambda \cap X$, and by Lemma 16.18(2) and linear independence $\theta^{-1}(\alpha'_j - \alpha_j) \in \mathcal{O}_E$, so $z \in M(\Lambda)$. Hence $\theta^{-1}(\mu' - \mu) \in M(\Lambda)$ and $y - y' \in M(\Lambda)$. (c) *Linearity.* If $w_i \sim_\Lambda y_i$ by (λ_i, λ'_i) $(i = 1, 2)$ and $\gamma \in \mathcal{O}_E$, then $\gamma w_1 + w_2 \sim_\Lambda \gamma y_1 + y_2$ by $(\gamma\lambda_1 + \lambda_2, \gamma\lambda'_1 + \lambda'_2)$. (d) *Kernel.* For $w \in W_0$: $w \in \Lambda$ if and only if $w \in L_d$ and $w \sim_\Lambda 0$. If $w \in \Lambda$, then $w \in A \cap A'$ by Lemma 16.18(3),

$(w,w) \in \Gamma$ (take $y = y' = w$; $W_0 \perp X, X'$) and $w \sim_\Lambda 0$ with $\lambda = \lambda' = 0$. Conversely, if $w \sim_\Lambda 0$ by (λ, λ'), then $m = \theta^{-1}(\lambda' - \lambda) \in M(\Lambda)$, $m = \sum_b \mu_b \mathrm{fr}_b + \sum_b \mu'_b \theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ with integral coefficients, and $\lambda' - \lambda = \sum_b (\theta\mu_b - \mu'_b)\mathrm{fr}_b + \sum_b \mu'_b \mathrm{fr}'_b$. As $\mathrm{fr}, \mathrm{fr}'$ is an E-basis of M_E (Proposition 16.8(1)), $\lambda \in F_{r+1}(f) = \operatorname{span} \mathrm{fr}$ and $\lambda' \in X' = \operatorname{span}(\mathrm{fr}'_0, \dots, \mathrm{fr}'_{r-1})$, comparing coordinates gives $\lambda' = \sum_{b<r} \mu'_b \mathrm{fr}'_b \in \Lambda$, so $w = (w + \lambda') - \lambda' \in \Lambda$. By (a)–(c) there is an $\mathcal{O}_E$-linear map $\tau_\Lambda \colon L_d \to \mathrm{sat}(\Lambda)/M$, $w \mapsto y + M$ for any y with $w \sim_\Lambda y$; by (d) and (b) its kernel is $\Lambda \cap W_0$, and by the definition of $\hat{I}(\Lambda)$ its image is $\hat{I}(\Lambda)/M$, of order $c_d(\Lambda)$. *L_d is a lattice of rank $k-1$ in W_0.* By (c) for Λ_1 (applied to the pairs (w,w)), L_d is an $\mathcal{O}_E$-module; by (a), every $w \in L_d$ is the orthogonal projection to W_0 of a vector of Λ_1, so L_d is finitely generated; and $L_d \supseteq \Lambda_1 \cap W_0$ by (d), which spans W_0 since the finitely generated self-dual module Λ_1 (Lemma 16.18(1)) spans V (otherwise a nonzero subspace orthogonal to it would lie in $\Lambda_1^\# = \Lambda_1$). So L_d is free of rank $\dim W_0 = n - (2r+2) = k-1$; fix a basis $b_1, \dots, b_{k-1}$.

Step 3: the complements. Fix $\hat{M}$ and let $\Lambda \in \mathcal{T}_c$ with $\mathrm{sat}(\Lambda) = \hat{M}$; put $D = \hat{M}/M$, of order $b_d(\Lambda) \le q^a$, and $x_i = \tau_\Lambda(b_i)$. Then $I = \hat{I}(\Lambda)/M$ is a submodule of D of order c, $x \in I^{k-1}$, and

$$\Lambda \cap W_0 = \Big\{ \sum_i \gamma_i b_i : \ \gamma \in \mathcal{O}_E^{k-1}, \ \sum_i \gamma_i x_i = 0 \Big\}$$

is determined by x. Since $M \subseteq \hat{M} \subseteq M^\#$ and $M^\#$ is free of rank $2r+2$, every submodule of D is generated by $2r+2$ elements, so D has at most $|D|^{2r+2} \le q^{a(2r+2)}$ submodules. Hence, for fixed $\hat{M}$, $\Lambda \cap W_0$ takes at most $q^{a(2r+2)} c^{k-1}$ values.

Step 4: the gluings. Let Λ be self-dual (Lemma 16.18(1)) with $\Lambda \cap M_E = \hat{M}$ and $\Lambda \cap W_0 = B$, and let π_M, π_W be the orthogonal projections. For $y \in \Lambda$ and $x \in \hat{M}$, $h(\pi_M y, x) = h(y,x) \in \mathcal{O}_E$, so $\pi_M \Lambda \subseteq \hat{M}^\#$; and $\{x \in M_E : h(x, \pi_M \Lambda) \subseteq \mathcal{O}_E\} = M_E \cap \Lambda^\# = \hat{M}$, so the lattice $\pi_M \Lambda$ equals $\hat{M}^\#$; likewise $\pi_W \Lambda = B^\#$. If $\pi_M y \in \hat{M} \subseteq \Lambda$, then $\pi_W y = y - \pi_M y \in \Lambda \cap W_0 = B$; so $y \mapsto \pi_M y + \hat{M}$ and $y \mapsto \pi_W y + B$ are surjections $\Lambda \to \hat{M}^\#/\hat{M}$, $\Lambda \to B^\#/B$, both with kernel $\hat{M} \oplus B$. Hence there is an isomorphism $\varphi \colon \hat{M}^\#/\hat{M} \to B^\#/B$ with

$$\Lambda = \{ x + z : \ x \in \hat{M}^\#, \ z \in B^\#, \ \varphi(x + \hat{M}) = z + B \},$$

and Λ is determined by $(\hat{M}, B, \varphi)$. As $|B^\#/B| = |\hat{M}^\#/\hat{M}| \le [M^\# : M] = q^{2a}$ and $\hat{M}^\#/\hat{M}$ is generated by $2r+2$ elements, there are at most $q^{2a(2r+2)}$ homomorphisms φ.

Step 5: conclusion. By Steps 1, 3 and 4,

$$|\mathcal{T}_c| \le q^{2a(2r+2)} \cdot q^{a(2r+2)} c^{k-1} \cdot q^{2a(2r+2)} = q^{10a(r+1)} c^{k-1}.$$

□

Lemma 16.17. *Fix a local frame pair with parameters r, k and a term Λ over some datum. Then the number of $\mathcal{O}_E$-submodules $\hat{M}$ with $M(\Lambda) \subseteq \hat{M} \subseteq M_E$ and $h(\hat{M}, \hat{M}) \subseteq \mathcal{O}_E$ is at most $q^{2a(2r+2)}$, and each of them satisfies $\varpi^a \hat{M} \subseteq M(\Lambda)$.*

Proof. By Proposition 16.8(1), $M = M(\Lambda)$ has an $\mathcal{O}_E$-basis $g_1, \dots, g_m$ ($m = 2r+2$), which is an E-basis of M_E, with integral Gram matrix $P = (h(g_i, g_j))$ of determinant $\delta = (-1)^{r+1} \theta^{-2(r+1)} G$, and $v(\delta) = a \ge 0$ (Proposition 16.8(2) and Lemma 16.9(2)). Let $\hat{M}$ be as in the statement. By Lemma 16.9(2) (with $N = \hat{M}$), $\varpi^a \hat{M} \subseteq M$. Moreover $\hat{M} \subseteq M^\# = \{x \in M_E : h(x, M) \subseteq \mathcal{O}_E\}$, since $M \subseteq \hat{M}$ and $\hat{M}$ is integral. Writing $x = \sum_i c_i g_i$, $h(x, g_j) = (c^\mathsf{T} P)_j$, so $M^\# = \{\sum c_i g_i : c^\mathsf{T} \in \mathcal{O}_E^m P^{-1}\}$ and $M^\#/M \cong \mathcal{O}_E^m P^{-1} / \mathcal{O}_E^m$. By elementary divisors over $\mathcal{O}_E$ (a principal ideal ring: $\mathcal{O}_E$ is a discrete valuation ring if E is a field and $\mathcal{O}_F \times \mathcal{O}_F$ if $E = F \times F$), this module has order $|\mathcal{O}_E/\delta\mathcal{O}_E| = |\mathcal{O}_E/\varpi^a \mathcal{O}_E| = q^{2a}$ ($\delta \in F$ has valuation a; $\mathcal{O}_E/\varpi\mathcal{O}_E$ has q^2 elements in both cases), and it is generated by the m images of the dual basis. The modules $\hat{M}$ correspond

injectively to the submodules $\hat{M}/M$ of $M^{\#}/M$. A submodule of an $\mathcal{O}_E$-module generated by m elements is generated by m elements (its preimage in $\mathcal{O}_E^m$ is a submodule of a free module of rank m over a principal ideal ring, hence generated by m elements), so it is the image of a map $\mathcal{O}_E^m \to M^{\#}/M$, of which there are at most $|M^{\#}/M|^m = q^{2am}$. Hence there are at most $q^{2a(2r+2)}$ modules $\hat{M}$. □

Lemma 16.18. *Fix a local frame pair with parameters r, k, a datum $d = (A, A', \Gamma)$ and a term Λ over d with witness (u, u'). Then:*

1. *Λ is self-dual;*
2. *$\Lambda \cap F_{r+1}(f) = \sum_{b \le r} \mathcal{O}_E u f_b$ and $\Lambda \cap X = \sum_{j<r} \mathcal{O}_E u f_j$; likewise $\Lambda \cap F_{r+1}(f') = \sum_{b \le r} \mathcal{O}_E u' f'_b$ and $\Lambda \cap X' = \sum_{j<r} \mathcal{O}_E u' f'_j$;*
3. *$\Lambda \cap W_0 \subseteq A \cap A'$.*

Proof. **Step 1: the decomposition.** By (Fp1), $h(f_i, f_j) = 0$, $h(f_i, e_j^*) = \delta_{ij}$, $h(e_i^*, e_j^*) = 0$ for $i, j < r$; so $X + X^*$ is nondegenerate with E-basis $f_0, \dots, f_{r-1}, e_0^*, \dots, e_{r-1}^*$, and $V = (X \oplus X^*) \oplus Y$ orthogonally. For $w \in A$, $w_0 = w - \sum_{j<r} h(w, e_j^*) f_j$ lies in A (as $X \subseteq A$) and satisfies $h(w_0, e_i^*) = 0$; so $A = X + A_0$, and $A_0 \subseteq X^\perp \cap (X^*)^\perp = Y$ since $A \subseteq X^\perp$. By the inner condition, $h(A, y) \subseteq \mathcal{O}_E$ for $y \in A$, so A_0 is integral; and if $y \in Y$ satisfies $h(A_0, y) \subseteq \mathcal{O}_E$, then $h(A, y) = h(X + A_0, y) \subseteq \mathcal{O}_E$ and $y \in X^\perp$, so $y \in A$ by the inner condition, and $y \perp X^*$, so $y \in A_0$. Thus $A_0 = \{y \in Y : h(A_0, y) \subseteq \mathcal{O}_E\}$, and A_0 is finitely generated (inner condition).

Step 2: proof of (1). H is its own dual in $X \oplus X^*$ (dual bases), and A_0 is its own dual in Y (Step 1). For $z = x + y$ with $x \in X \oplus X^*$, $y \in Y$, $h(H + A_0, z) \subseteq \mathcal{O}_E$ holds if and only if $h(H, x) \subseteq \mathcal{O}_E$ and $h(A_0, y) \subseteq \mathcal{O}_E$, i.e. $x \in H$ and $y \in A_0$. So $\Lambda_{\mathrm{std}}(A) = H \oplus A_0$ is finitely generated and self-dual, and so is $\Lambda = u\Lambda_{\mathrm{std}}(A)$, u being an isometry.

Step 3: proof of (2). First $\Lambda_{\mathrm{std}}(A) \cap F_{r+1}(f) = \sum_b \mathcal{O}_E f_b$: the vectors f_j ($j < r$) lie in H, and $f_r \in A$ (inner) with $h(f_r, e_j^*) = 0$, so $f_r \in A_0$. Conversely let $x = \sum_b c_b f_b \in \Lambda_{\mathrm{std}}(A)$. For $j < r$, $c_j = h(x, e_j^*) \in \mathcal{O}_E$ by (1). The inner condition gives $y \in A$ with $h(f_r, y) = 1$; then $y_0 = y - \sum_j h(y, e_j^*) f_j \in A_0 \subseteq \Lambda_{\mathrm{std}}(A)$ and $h(f_r, y_0) = 1$ ($f_r \perp X$), so $c_r = h(x - \sum_{j<r} c_j f_j, y_0) \in \mathcal{O}_E$ by (1). Now $u \in N$ preserves $F_r(f) = X$ and maps f_r into $f_r + X$, so $uF_{r+1}(f) = F_{r+1}(f)$ and $\Lambda \cap F_{r+1}(f) = u(\Lambda_{\mathrm{std}}(A) \cap F_{r+1}(f)) = \sum_b \mathcal{O}_E u f_b$. An element $\sum_b c_b u f_b = u(\sum_b c_b f_b)$ lies in $X = uX$ if and only if $c_r = 0$, as $f_0, \dots, f_r$ are linearly independent ($f_r \notin X$ because $h(f_r, f_r) = -T \neq 0$ while $X \perp f_r$). The statements for f' follow in the same way from $\Lambda = u'\Lambda'_{\mathrm{std}}(A')$.

Step 4: proof of (3). Let $w \in \Lambda \cap W_0$. Since $u^{-1} \in N$ and $w \in W_0 \subseteq X^\perp$, $u^{-1}w - w \in X$, so $u^{-1}w \in X^\perp \cap \Lambda_{\mathrm{std}}(A)$. Write $u^{-1}w = x_0 + a_0 + \sum_j \beta_j e_j^*$ with $x_0 \in \sum_{j<r} \mathcal{O}_E f_j$, $a_0 \in A_0$; then $0 = h(u^{-1}w, f_i) = \beta_i$ for $i < r$ ($a_0 \in Y \perp X$, X isotropic). So $u^{-1}w \in X + A_0 = A$ and $w \in A + X = A$. Likewise $w \in A'$. □

Lemma 16.19. *Let a local frame pair with parameters r, k be given, d a datum, $\mathcal{T}'$ a Σ-stable set of terms over d, and R_{cl} a set of representatives of the Σ-orbits of integral frame classes. Then μ is constant on Σ-orbits and, in $[0, \infty]$,*

$$\sum_{O \in \Sigma \backslash \mathcal{T}'} \mu(O) = \sum_{C \in R_{\mathrm{cl}}} w(C) \, \big|\{\Lambda \in \mathcal{T}' : \mathrm{Fr}(\Lambda) = C\}\big|.$$

Proof. By Proposition 16.12, μ is constant on Σ-orbits, Fr maps $\mathcal{T}'$ to integral frame classes and $\mathrm{Fr}(g\Lambda) = g\,\mathrm{Fr}(\Lambda)$ for $g \in \Sigma$. For $C \in R_{\mathrm{cl}}$ put $\mathcal{F}_C = \{\Lambda \in \mathcal{T}' : \mathrm{Fr}(\Lambda) = C\}$ and $\Sigma_C = \mathrm{Stab}_\Sigma(C)$. Every Σ-orbit $O \subseteq \mathcal{T}'$ has its classes in one Σ-orbit of integral classes, with representative $C \in R_{\mathrm{cl}}$, and meets $\mathcal{F}_C$; if $\Lambda, g\Lambda \in \mathcal{F}_C$ ($g \in \Sigma$), then $gC = \mathrm{Fr}(g\Lambda) = C$, so $g \in \Sigma_C$. Hence $O \mapsto O \cap \mathcal{F}_C$ is a bijection from the orbits over the orbit of C onto the Σ_C-orbits in $\mathcal{F}_C$. For $\Lambda \in \mathcal{F}_C$, $\Sigma_\Lambda = \mathrm{Stab}_\Sigma(\Lambda) \subseteq \Sigma_C$, both commensurable with K_0 (Proposition 16.12), so $[\Sigma_C : \Sigma_\Lambda]$ is finite and equals $|\Sigma_C\Lambda|$, and

$$\mu(\Lambda) = [\Sigma_\Lambda : K_0]^{-1} = \big([\Sigma_\Lambda : \Sigma_C]\,[\Sigma_C : K_0]\big)^{-1} = [\Sigma_C : \Sigma_\Lambda]\,w(C) = |\Sigma_C\Lambda|\,w(C).$$

Summing over the Σ_C-orbits in $\mathcal{F}_C$ gives $w(C)|\mathcal{F}_C|$, and summing over $C \in R_{\mathrm{cl}}$ (all terms nonnegative) gives the formula. □

16.3 The share of the terms of a given defect order

This subsection proves that a defect of order β costs a factor $\beta^{-(k-1)}$ in mass, up to the factor $4H^{4(r+1)}$ (Proposition 16.20). The terms are counted with masses over frame classes (Lemma 16.19, Proposition 16.21). The key estimate is Proposition 16.23: for an integral overlattice of index β of the module of a term, the saturated mass is $\kappa\,\beta^{-(k-1)}$ up to a factor 2, for a constant $\kappa > 0$. Its proof identifies glue masses with primitive local densities (Proposition 16.25), and these with counts of free tuples with a prescribed Gram matrix in a hermitian space over the residue ring (Lemma 16.28). The other lemmas of the subsection describe the self-dual lattices with a given trace on the frame span (Lemma 16.22), the fibre measures of the Gram map (Lemma 16.26), the conjugacy of self-dual lattices (Lemma 16.27) and the exact count of free tuples (Lemma 16.29).

Proposition 16.20. *Let a local frame pair with parameters r and $k \geq 4r+7$ be given, let D be a set of representatives of the H_0-orbits of data and, for $d \in D$, R_d a set of representatives of the Σ-orbits of terms over d. Then for every integer $\beta \geq 1$, in $[0,\infty]$,*

$$\sum_{d\in D} \nu(d) \sum_{\Lambda\in R_d,\ b_d(\Lambda)=\beta} \mu(\Lambda) \leq 4H^{4(r+1)}\beta^{-(k-1)} \sum_{d\in D} \nu(d) \sum_{\Lambda\in R_d} \mu(\Lambda).$$

Proof. If no datum has a term, both sides vanish. Otherwise let $\kappa > 0$ be given by Proposition 16.23 ($k \geq 4r+7 \geq 2r+6$), and let R_{cl} be a set of representatives of the Σ-orbits of integral frame classes. For $d \in D$, a frame class C and $\beta \geq 1$ put

$$n_d(C,\beta) = \big|\{\Lambda \text{ term over } d : \mathrm{Fr}(\Lambda) = C,\ b_d(\Lambda) = \beta\}\big|,$$
$$n_d(C) = \big|\{\Lambda \text{ term over } d : \mathrm{Fr}(\Lambda) = C\}\big|.$$

Step 1: by classes. For $d \in D$ the set of terms over d with $b_d = \beta$ is Σ-stable (Proposition 16.12), so Lemma 16.19 gives

$$\sum_{\Lambda\in R_d,\, b_d(\Lambda)=\beta} \mu(\Lambda) = \sum_{C\in R_{\mathrm{cl}}} w(C) n_d(C,\beta),$$

and likewise $\sum_{\Lambda\in R_d} \mu(\Lambda) = \sum_C w(C) n_d(C)$. Exchanging the sums of nonnegative terms,

$$\sum_{d\in D} \nu(d) \sum_{\Lambda\in R_d,\, b_d(\Lambda)=\beta} \mu(\Lambda) = \sum_{C\in R_{\mathrm{cl}}} w(C)\,S_\beta(C), \qquad \sum_{d\in D} \nu(d) \sum_{\Lambda\in R_d} \mu(\Lambda) = \sum_{C\in R_{\mathrm{cl}}} w(C)\,S(C),$$

with $S_\beta(C) = \sum_d \nu(d) n_d(C,\beta)$ and $S(C) = \sum_d \nu(d) n_d(C)$.

Step 2: one class. We show $S_\beta(C) \le 4H^{4(r+1)}\beta^{-(k-1)} S(C)$ for every $C \in R_{\mathrm{cl}}$. If $S_\beta(C) = 0$ there is nothing to show. Otherwise some term Λ_0 (over some datum) has $\mathrm{Fr}(\Lambda_0) = C$; put $M = M(\Lambda_0)$. By Proposition 16.21 with $Q = \{\beta\}$, then Proposition 16.23 and Lemma 16.17,

$$S_\beta(C) \le \sum_{\hat M:\,[\hat M:M]=\beta} \sigma(\hat M) \le q^{2a(2r+2)} \cdot 2\kappa\, \beta^{-(k-1)},$$

the sum over the integral $\hat M$ with $M \subseteq \hat M \subseteq M_E$. By Proposition 16.23 with $\hat M = M$ (index 1) and the equality of Proposition 16.21,

$$\frac{\kappa}{2} \le \sigma(M) = \sum_d \nu(d)\,\big|\{\Lambda \text{ generic term over } d : \mathrm{Fr}(\Lambda) = C\}\big| \le S(C).$$

Hence $S_\beta(C) \le 4q^{4a(r+1)}\beta^{-(k-1)} S(C) \le 4H^{4(r+1)}\beta^{-(k-1)} S(C)$, as $q^a \le H$ by Proposition 16.8(2) applied to Λ_0.

Step 3: conclusion. Multiplying Step 2 by $w(C)$ and summing over R_{cl}, Step 1 gives the claim. □

Proposition 16.21. *Let a local frame pair with parameters r, k be given, D a set of representatives of the H_0-orbits of data, Λ_0 a term over some datum, $C = \mathrm{Fr}(\Lambda_0)$ and $M = M(\Lambda_0)$. Then for every set Q of positive integers, in $[0,\infty]$,*

$$\sum_{d\in D} \nu(d)\,\big|\{\Lambda \text{ term over } d : \mathrm{Fr}(\Lambda) = C,\ b_d(\Lambda) \in Q\}\big| \le \sum_{\hat M} \sigma(\hat M),$$

the sum over the $\mathcal{O}_E$-submodules $\hat M$ with $M \subseteq \hat M \subseteq M_E$, $h(\hat M, \hat M) \subseteq \mathcal{O}_E$ and $[\hat M : M] \in Q$; and

$$\sum_{d\in D} \nu(d)\,\big|\{\Lambda \text{ generic term over } d : \mathrm{Fr}(\Lambda) = C\}\big| = \sigma(M).$$

Proof. **Step 1: a term determines its datum.** If Λ is a term over $d = (A, A', \Gamma)$ with witness (u, u'), then $A = X + (\Lambda \cap X^\perp)$ and $A' = X' + (\Lambda \cap X'^\perp)$ by Lemma 16.22(1), and Γ is the set of pairs attached to Λ by definition. So Λ is a term over exactly one datum, $d(\Lambda)$.

Step 2: H_0 acts on terms. Let Λ be a term over d with witness (u, u') and $g \in H_0$. As g fixes M_E pointwise, it fixes X, X', every $F_j(f)$, $F_j(f')$ and every vector uf_b, $u'f'_b$, and preserves $X^\perp$, $X'^\perp$. By Lemma 16.18(1),(2), $g\Lambda$ is self-dual and $g\Lambda \cap F_{r+1}(f) = g(\sum_b \mathcal{O}_E u f_b) = \sum_b \mathcal{O}_E u f_b$; by Lemma 16.22(2),(1), $g\Lambda = m\Lambda_{\mathrm{std}}(\tilde A)$ with $m \in N$, $mf = uf$ and $\tilde A = X + (g\Lambda \cap X^\perp) = g(X + (\Lambda \cap X^\perp)) = gA$. Likewise $g\Lambda = m'\Lambda'_{\mathrm{std}}(gA')$ with $m' \in N'$, $m'f' = u'f'$. Then $m'f'_b - mf_b = u'f'_b - uf_b \in \theta\Lambda \cap M_E$ is fixed by g, so it lies in $\theta g\Lambda$; and the set of pairs attached to $g\Lambda$ is the image under g of that of Λ (g maps the vectors y, y' of the definition for Λ to vectors for $g\Lambda$, and g^{-1} conversely). So $g\Lambda$ is a term over gd with witness (m, m'), and by Proposition 16.12 (independence of the witness) $\mathrm{Fr}(g\Lambda) = \mathrm{cl}(uf, u'f') = \mathrm{Fr}(\Lambda)$ and $M(g\Lambda) = M(\Lambda)$; also $\mathrm{sat}(g\Lambda) = g\,\mathrm{sat}(\Lambda) = \mathrm{sat}(\Lambda)$. Hence $b_{gd}(g\Lambda) = b_d(\Lambda)$, and $g\Lambda$ is generic if and only if Λ is.

Step 3: stabilisers of data with a term. Let Λ be a term over d. By Step 1, $\mathrm{Stab}_{H_0}(\Lambda) \subseteq \mathrm{Stab}_{H_0}(d)$. The module $A \cap W_0$ is finitely generated: with $Y = (X + \mathrm{span}_E e^*)^\perp$ and $A_0 = A \cap (\mathrm{span}_E e^*)^\perp$ (finitely generated, inner condition), $A = X + A_0$ with $A_0 \subseteq Y$ (subtract $\sum_j h(w, e_j^*) f_j$ from $w \in A$), and the projection $X \oplus Y \to Y$ along X is injective on W_0 ($W_0 \cap X = 0$) and maps $A \cap W_0$ into A_0. It contains $\Lambda \cap W_0$ (Lemma 16.18(3)), which spans W_0 because the

self-dual Λ spans V. So $L_0 = (A \cap W_0) \oplus M$ is a lattice of V, and $\mathrm{Stab}_{H_0}(d) \subseteq \mathrm{Stab}_{H_0}(L_0)$, as H_0 fixes M and preserves W_0. Being between two lattice stabilisers, $\mathrm{Stab}_{H_0}(d)$ is commensurable with K_{ref}.

Step 4: data-weighted counts are lattice masses. Let $\mathcal{P}$ be a condition on terms preserved by the action of Step 2, and $\mathcal{L}$ the set of lattices that are terms over some datum and satisfy $\mathcal{P}$; $\mathcal{L}$ is H_0-stable. Let $O \subseteq \mathcal{L}$ be an H_0-orbit. By Steps 1 and 2, the data $d(\Lambda)$, $\Lambda \in O$, form one H_0-orbit, which contains exactly one $d_O \in D$, and the elements of O that are terms over a datum in D are those with $d(\Lambda) = d_O$; they form one $\mathrm{Stab}_{H_0}(d_O)$-orbit. Fixing one of them, Λ_O, there are $[\mathrm{Stab}_{H_0}(d_O) : \mathrm{Stab}_{H_0}(\Lambda_O)]$ of them, so the contribution of O to the left side below is, by Step 3,

$$\nu(d_O)\,[\mathrm{Stab}_{H_0}(d_O) : \mathrm{Stab}_{H_0}(\Lambda_O)] = [\mathrm{Stab}_{H_0}(\Lambda_O)].$$

Summing over the orbits, in $[0, \infty]$,

$$\sum_{d \in D} \nu(d)\,\big|\{\Lambda \text{ term over } d \text{ with } \mathcal{P}\}\big| = \sum_{O \subseteq \mathcal{L}} \mathrm{vol}_{K_{\mathrm{ref}}}(\mathrm{Stab}_{H_0}(\Lambda_O))^{-1}.$$

Step 5: the inequality. Take $\mathcal{P}$: $\mathrm{Fr}(\Lambda) = C$ and $b_d(\Lambda) \in Q$ (preserved by Step 2). For $\Lambda \in \mathcal{L}$, choosing $(p, p') \in C = \mathrm{Fr}(\Lambda)$, Proposition 16.12 gives $M(\Lambda) = M(p, p') = M(\Lambda_0) = M$; Λ is self-dual (Lemma 16.18(1)); and $\hat{M} = \mathrm{sat}(\Lambda) = \Lambda \cap M_E$ is integral with $M \subseteq \hat{M} \subseteq M_E$ and $[\hat{M} : M] = b_d(\Lambda) \in Q$ (Proposition 16.8(1),(3)). As $\Lambda \cap M_E$ is constant on H_0-orbits, each orbit $O \subseteq \mathcal{L}$ is one of the orbits summed in $\sigma(\hat{M})$ for exactly one such $\hat{M}$, with the same summand. With Step 4 this gives the inequality.

Step 6: generic terms of class C are the self-dual lattices with saturation M. If Λ is a generic term with $\mathrm{Fr}(\Lambda) = C$, it is self-dual with $\Lambda \cap M_E = M(\Lambda) = M$. Conversely let Λ be self-dual with $\Lambda \cap M_E = M$. By Proposition 16.8(1), $u_0 f$, $u_0' f'$ form an E-basis of M_E, and M is spanned by $u_0 f_b$, $\theta^{-1}(u_0' f_b' - u_0 f_b)$, and also by $u_0' f_b'$, $\theta^{-1}(u_0 f_b - u_0' f_b')$ ($\theta \in \mathcal{O}_F$). An element $\sum_b \alpha_b u_0 f_b + \sum_b \beta_b \theta^{-1}(u_0' f_b' - u_0 f_b)$ of M lies in $F_{r+1}(f)$ only if $\beta = 0$, as $F_{r+1}(f) \cap F_{r+1}(f') = 0$; so $\Lambda \cap F_{r+1}(f) = M \cap F_{r+1}(f) = \sum_b \mathcal{O}_E u_0 f_b$, and likewise $\Lambda \cap F_{r+1}(f') = \sum_b \mathcal{O}_E u_0' f_b'$. By Lemma 16.22(2), $\Lambda = m\Lambda_{\mathrm{std}}(A) = m'\Lambda'_{\mathrm{std}}(A')$ with inner A, A', $m \in N$, $m' \in N'$, $mf = u_0 f$, $m'f' = u_0' f'$; and $m' f_b' - m f_b = \theta \cdot \theta^{-1}(u_0' f_b' - u_0 f_b) \in \theta M \subseteq \theta\Lambda$. With Γ the set of pairs attached to Λ, Λ is a term over (A, A', Γ) with witness (m, m'), $\mathrm{Fr}(\Lambda) = \mathrm{cl}(u_0 f, u_0' f') = C$ (Proposition 16.12) and $M(\Lambda) = M = \mathrm{sat}(\Lambda)$, i.e. generic. Taking $\mathcal{P}$: $\mathrm{Fr}(\Lambda) = C$ and generic, $\mathcal{L}$ is the set of self-dual Λ with $\Lambda \cap M_E = M$, and Step 4 gives the equality with $\sigma(M)$. □

Lemma 16.22. *Fix a local frame pair with parameters r, k.*

1. *If A is inner for (f, e^*) and $m \in N$, then $mA = A$ and $A = X + (m\Lambda_{\mathrm{std}}(A) \cap X^\perp)$.*
2. *Let $\Lambda \subseteq V$ be self-dual and $n \in N$ with $\Lambda \cap F_{r+1}(f) = \sum_{b \le r} \mathcal{O}_E\, n f_b$. Then there are an inner module A for (f, e^*) and $m \in N$ with $m f_b = n f_b$ for $0 \le b \le r$ and $\Lambda = m\Lambda_{\mathrm{std}}(A)$.*

The same holds with $(f', e'^*, X', N', \Lambda'_{\mathrm{std}})$ in place of $(f, e^*, X, N, \Lambda_{\mathrm{std}})$.

Proof. **Step 1: proof of (1).** As $A \subseteq X^\perp$ and $m \in N$, $(m-1)A \subseteq X \subseteq A$, so $mA \subseteq A$, and likewise $m^{-1}A \subseteq A$. Put $A_0 = A \cap (X^*)^\perp$. For $w \in A$, $w - \sum_j h(w, e_j^*) f_j \in A_0$, so $A = X + A_0$, and $A_0 \subseteq X^\perp \cap (X^*)^\perp = Y$. An element $\sum_j \alpha_j f_j + a_0 + \sum_j \beta_j e_j^*$ of $\Lambda_{\mathrm{std}}(A)$ ($a_0 \in A_0$) lies in $X^\perp$ if and only if all $\beta_i = h(\cdot, f_i)$ vanish; so $\Lambda_{\mathrm{std}}(A) \cap X^\perp = \sum_j \mathcal{O}_E f_j + A_0$. Since m preserves $X^\perp$, $m\Lambda_{\mathrm{std}}(A) \cap X^\perp = m(\sum_j \mathcal{O}_E f_j + A_0) \subseteq mA = A$, and $X + m(\sum_j \mathcal{O}_E f_j + A_0) \supseteq X + mA_0 \supseteq X + A_0 = A$, because $mA_0 \subseteq A_0 + X$ and $m^{-1}A_0 \subseteq A_0 + X$. Hence $A = X + (m\Lambda_{\mathrm{std}}(A) \cap X^\perp)$.

Step 2: reduction to $n = 1$. $n^{-1}\Lambda$ is self-dual (n is an isometry) and, as n preserves $F_{r+1}(f)$ (it preserves X and maps f_r into $f_r + X$), $n^{-1}\Lambda \cap F_{r+1}(f) = \sum_b \mathcal{O}_E f_b$. If $n^{-1}\Lambda = m_1\Lambda_{\mathrm{std}}(A)$ with $m_1 \in N$, $m_1 f = f$, then $m = nm_1$ works. So assume $\Lambda \cap F_{r+1}(f) = \sum_b \mathcal{O}_E f_b$.

Step 3: dual vectors. Λ is finitely generated and self-dual, hence free with a basis $(\lambda_i)_i$ whose dual vectors λ_i^* ($h(\lambda_i, \lambda_j^*) = \delta_{ij}$) lie in $\Lambda^\# = \Lambda$; so every $\mathcal{O}_E$-linear map $\phi\colon \Lambda \to \mathcal{O}_E$ is $x \mapsto h(x, c)$ for $c = \sum_j \overline{\phi(\lambda_j)}\lambda_j^* \in \Lambda$. The module $P_0 = \Lambda \cap F_{r+1}(f)$ is saturated in Λ, so Λ/P_0 is finitely generated and torsion-free, hence free ($\mathcal{O}_E$ is a principal ideal ring), and P_0 is a direct summand with basis $f_0, \dots, f_r$. Extending the coordinate functionals by zero on a complement gives $c_0, \dots, c_r \in \Lambda$ with $h(f_b, c_j) = \delta_{bj}$ for $0 \le b, j \le r$.

Step 4: isotropic dual vectors. As E/F is unramified or split, the trace $\mathcal{O}_E \to \mathcal{O}_F$ is surjective; fix $\sigma \in \mathcal{O}_E$ with $\sigma + \bar\sigma = 1$. For $j < r$ put

$$y_j = c_j - \sum_{i<r} \sigma\, h(c_j, c_i)\, f_i \in \Lambda.$$

Then $h(f_a, y_j) = \delta_{aj}$ for $0 \le a \le r$ (as $h(f_a, f_i) = 0$ for $i < r$), and, using $h(c_i, f_l) = \delta_{il}$ for $l < r$,

$$h(y_i, y_j) = h(c_i, c_j) - \overline{\sigma\, h(c_j, c_i)} - \sigma\, h(c_i, c_j) = (1 - \bar\sigma - \sigma)\, h(c_i, c_j) = 0.$$

Step 5: a unipotent element carrying e^* to y. Write $y_j - e_j^* = \xi_j + \zeta_j + \eta_j$ with $\xi_j \in X$, $\zeta_j \in X^*$, $\eta_j \in Y$. For $a < r$, $0 = h(f_a, y_j - e_j^*) = h(f_a, \zeta_j)$, so $\zeta_j = 0$; and $0 = h(f_r, y_j - e_j^*) = h(f_r, \eta_j)$. Define E-linear $u\colon V \to V$ by $u|_X = \mathrm{id}$, $ue_j^* = e_j^* + \xi_j + \eta_j = y_j$, and $uy = y - \sum_{j<r} h(y, \eta_j) f_j$ for $y \in Y$. It is an isometry: $h(ux, ue_j^*) = h(x, e_j^*)$ and $h(ux, uy) = 0$ for $x \in X$, $y \in Y$; $h(ue_i^*, ue_j^*) = h(y_i, y_j) = 0$; $h(uy, ue_j^*) = h(y, \eta_j) - h(y, \eta_j)h(f_j, e_j^*) = 0$; $h(uy, uy') = h(y, y')$, as the f_j are isotropic and orthogonal to Y. It lies in N: it fixes X pointwise, so $uF_{j+1}(f) = F_{j+1}(f)$ and $(u-1)F_{j+1}(f) = 0$ for $j < r$; it preserves $X^\perp = X \oplus Y$ with $(u-1)X^\perp \subseteq X$. And $uf_r = f_r$ since $f_r \in Y$ and $h(f_r, \eta_j) = 0$. So $uf_b = f_b$ for all b.

Step 6: the standard form. $\Lambda_1 = u^{-1}\Lambda$ is self-dual and contains $f_b = u^{-1}f_b$, $e_j^* = u^{-1}y_j$ and $c' = u^{-1}c_r$, with $h(f_b, c') = h(uf_b, c_r) = \delta_{br}$. The module $H = \sum_{j<r}(\mathcal{O}_E f_j + \mathcal{O}_E e_j^*) \subseteq \Lambda_1$ is self-dual in $X \oplus X^*$, and for $v \in \Lambda_1$, $v - \sum_j (h(v, e_j^*)f_j + h(v, f_j)e_j^*) \in \Lambda_1 \cap Y$ (integral coefficients); so $\Lambda_1 = H \oplus A_0$ with $A_0 = \Lambda_1 \cap Y$, and A_0 is self-dual in Y (the dual of an orthogonal sum is the sum of the duals). Put $A = X + A_0$. Then $A \cap (X^*)^\perp = A_0$ (an element $x + a$, $x \in X$, $a \in A_0$, is orthogonal to X^* only if $x = 0$), so $\Lambda_{\mathrm{std}}(A) = H + A_0 = \Lambda_1$. A is inner: $X \subseteq A \subseteq X^\perp$; $A \cap (X^*)^\perp = A_0$ is finitely generated; for $y = x + y_Y \in X^\perp$ ($x \in X$, $y_Y \in Y$), $h(A, y) = h(A_0, y_Y)$, which lies in $\mathcal{O}_E$ if and only if $y_Y \in A_0$, i.e. $y \in A$; $f_r \in \Lambda_1 \cap Y = A_0 \subseteq A$; and $c'_Y = c' - \sum_j (h(c', e_j^*)f_j + h(c', f_j)e_j^*) \in A_0$ has $h(f_r, c'_Y) = h(f_r, c') = 1$. Hence $\Lambda = u\Lambda_{\mathrm{std}}(A)$ with $u \in N$, $uf = f$. □

Proposition 16.23. *Let a local frame pair with parameters r and $k \ge 2r + 6$ be given such that some datum has a term. Then there is a real number $\kappa > 0$ such that for every term Λ_0 over any datum and every $\mathcal{O}_E$-submodule $\hat M$ with $M(\Lambda_0) \subseteq \hat M \subseteq M_E$ and $h(\hat M, \hat M) \subseteq \mathcal{O}_E$,*

$$\frac{\kappa}{2}\,[\hat M : M(\Lambda_0)]^{-(k-1)} \le \sigma(\hat M) \le 2\kappa\,[\hat M : M(\Lambda_0)]^{-(k-1)}.$$

Proof. **Step 1: the reference lattice.** Let Λ_s be a term over some datum; it is self-dual (Lemma 16.18(1)), hence a free $\mathcal{O}_E$-module of rank n whose dual basis lies in Λ_s; so $\Lambda_s/\varpi\Lambda_s$ is a free κ_E-module of rank n with a nondegenerate hermitian form induced by h. By Lemma 16.28, as $n \ge 2m + 3$, for every hermitian $G \in \mathrm{M}_m(\mathcal{O}_E)$,

$$\tfrac{1}{2} \le q^{-(2nm - m^2)} N_{\Lambda_s}(G) \le 2.$$

Let κ_0 be the constant of Proposition 16.25(2) for Λ_s, and put $\kappa = \kappa_0\, q^{(k-1)a} > 0$.

Step 2: the Gram determinant of $\hat M$. Let Λ_0 be a term, $M = M(\Lambda_0)$, and $\hat M$ as in the statement. By Proposition 16.8(1), M has the basis fr_b, $\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ with Gram determinant $(-1)^{r+1}\theta^{-2(r+1)}G$, of valuation $v(G) - 2(r+1)v(\theta) = a$. As $M \subseteq \hat M \subseteq M^{\#} = \{x \in M_E : h(M,x) \subseteq \mathcal{O}_E\}$, $\hat M$ is finitely generated and spans M_E, hence free of rank m; if the basis of M is the basis of $\hat M$ times $C \in \mathrm{M}_m(\mathcal{O}_E)$, then $G_M = \bar C^{\mathsf T} G_{\hat M} C$, so $v(\det G_M) = v(\mathrm{N}(\det C)) + v(\det G_{\hat M})$, and $[\hat M : M] = |\mathcal{O}_E/\det C\,\mathcal{O}_E| = q^{v(\mathrm{N}(\det C))}$ (elementary divisors; $|\mathcal{O}_E/\varpi^e\mathcal{O}_E| = q^{2e}$ if E is a field, and componentwise if $E = F \times F$). Hence $q^{v(\det G_{\hat M})} = q^a[\hat M : M]^{-1}$.

Step 3: conclusion. By Proposition 16.25(2) and Steps 1–2,

$$\sigma(\hat M) = \kappa_0\, q^{(k-1)a}\,[\hat M : M]^{-(k-1)}\, q^{-(2nm-m^2)} N_{\Lambda_s}(G_{\hat M}) \in \left[\tfrac{\kappa}{2}, 2\kappa\right][\hat M : M]^{-(k-1)},$$

with κ independent of Λ_0 and $\hat M$, as a depends only on the frame pair. □

Definition 16.24. The notation introduced here is local to this definition and to the results that apply it. Put $\kappa_E = \mathcal{O}_E/\varpi\mathcal{O}_E$ and $\kappa_F = \mathcal{O}_F/\varpi\mathcal{O}_F$.

Spaces. A **local hermitian space** of rank n is a free E-module V of rank n with a form $h\colon V \times V \to E$, E-linear in the first variable, with $h(y,x) = \overline{h(x,y)}$ and invertible Gram matrix. Its unitary group $\mathrm{U}(V)$ is the group of E-linear $g\colon V \to V$ with $h(gx,gy) = h(x,y)$, with the topology induced from $\mathrm{GL}_E(V)$. An $\mathcal{O}_E$-submodule $\Lambda \subseteq V$ is **self-dual** if it is finitely generated and $\Lambda = \{y \in V : h(\Lambda, y) \subseteq \mathcal{O}_E\}$. An E-submodule $M \subseteq V$ is **nondegenerate** if it is free and the Gram matrix of h on an E-basis of M is invertible; its **rank** is its rank as a free module, $M^{\perp} = \{x \in V : h(M,x) = 0\}$, and

$$H_M = \{u \in \mathrm{U}(V) : uw = w \text{ for all } w \in M\}.$$

Lattices. Let U be a local hermitian space (for instance a nondegenerate M or $M^{\perp}$ with h restricted). A **lattice** in U is a finitely generated $\mathcal{O}_E$-submodule $P \subseteq U$ spanning U over E; it is free over $\mathcal{O}_E$ of rank $\operatorname{rank} U$. Its **dual** is $P^{\#} = \{x \in U : h(P,x) \subseteq \mathcal{O}_E\}$; P is **integral** if $h(P,P) \subseteq \mathcal{O}_E$ (equivalently $P \subseteq P^{\#}$), **maximal integral** if it is integral and no integral lattice in U contains it properly, and then its **discriminant module** is $D_P = P^{\#}/P$. For an $\mathcal{O}_E$-basis $l = (l_1, \dots, l_g)$ of an integral lattice P let $G_l = (h(l_a, l_b))_{a,b}$; put

$$v_{\det}(P) = v(\det G_l) \in \mathbb{Z}_{\geq 0}, \qquad \#\ker(\bar G_l\colon \kappa_E^g \to \kappa_E^g) = q^{2c(P)},$$

$\bar G_l$ the reduction of G_l modulo ϖ; $c(P) \in \{0, \dots, g\}$ is the **corank** of P.

Standard factors. Let $\epsilon = -1$ if E is a field and $\epsilon = 1$ if $E = F \times F$. For integers $j \geq 0$ put

$$\alpha^{\mathrm{st}}(j) = \prod_{i=1}^{j}(1 - \epsilon^i q^{-i}) \qquad (\alpha^{\mathrm{st}}(0) = 1).$$

Glue masses. Let V be a local hermitian space, $M \subseteq V$ a nondegenerate E-submodule and $K \subseteq H_M$ a subgroup. For an $\mathcal{O}_E$-submodule $L \subseteq M$ the **glue mass of L relative to K** is

$$\mathrm{mass}^{\mathrm{gl}}_K(L) = \sum_{[\Lambda]} \mathrm{vol}_K\big(\mathrm{Stab}_{H_M}(\Lambda)\big)^{-1} \in [0, \infty],$$

the sum over the H_M-orbits of self-dual $\Lambda \subseteq V$ with $\Lambda \cap M = L$ (one fixed representative per orbit). For a lattice T in $M^{\perp}$ put $K_T = \{u \in H_M : uT = T\}$ and $\mathrm{mass}^{\mathrm{gl}}_T(L) = \mathrm{mass}^{\mathrm{gl}}_{K_T}(L)$.

Proposition 16.25. *For a local hermitian space (V,h), a self-dual $\Lambda_s \subseteq V$, an integer $m \geq 1$ and a hermitian $G \in \mathrm{M}_m(\mathcal{O}_E)$ let $N_{\Lambda_s}(G)$ be the number of free m-tuples in $\Lambda_s/\varpi\Lambda_s$ whose Gram matrix for the form induced by h is G modulo ϖ.*

1. *Let (V,h) be a local hermitian space of rank n, $\Lambda_s \subseteq V$ self-dual, $M \subseteq V$ a nondegenerate E-submodule of rank $m \geq 1$ and $K \subseteq H_M$ a compact open subgroup. Then there is a real number $\kappa_0 > 0$ such that for every finitely generated $\mathcal{O}_E$-submodule $L \subseteq M$ spanning M with $h(L,L) \subseteq \mathcal{O}_E$, and the Gram matrix G_L of any $\mathcal{O}_E$-basis of L,*

$$\mathrm{mass}_K^{\mathrm{gl}}(L) = \kappa_0\, q^{(n-m)\,v(\det G_L)}\, q^{-(2nm-m^2)}\, N_{\Lambda_s}(G_L).$$

   Moreover, for every such L the self-dual $\Lambda \subseteq V$ with $\Lambda \cap M = L$ form finitely many H_M-orbits, and their stabilisers in H_M are compact open.

2. *Let a local frame pair with parameters r,k be given such that some datum has a term, put $m = 2r+2$, and let $\Lambda_s \subseteq V$ be self-dual. Then M_E is a nondegenerate submodule of rank m of the local hermitian space (V,h), $H_0 = H_{M_E}$, K_{ref} is a compact open subgroup of H_0, and $\sigma(\hat{M}) = \mathrm{mass}_{K_{\mathrm{ref}}}^{\mathrm{gl}}(\hat{M})$ for every $\mathcal{O}_E$-submodule $\hat{M} \subseteq M_E$. Hence there is a real number $\kappa_0 > 0$ such that for every finitely generated $\mathcal{O}_E$-submodule $L \subseteq M_E$ spanning M_E with $h(L,L) \subseteq \mathcal{O}_E$, and the Gram matrix G_L of any $\mathcal{O}_E$-basis of L,*

$$\sigma(L) = \kappa_0\, q^{(n-m)\,v(\det G_L)}\, q^{-(2nm-m^2)}\, N_{\Lambda_s}(G_L).$$

Proof. **Proof of (1). Step 0: the groups and measures.** As M is nondegenerate, $V = M \oplus W_0$ and restriction identifies H_M with $\mathrm{U}(W_0)$ (Definition 16.24). Fix an E-basis y of M; $\det \Phi(y) \neq 0$. G_{U} and H_M are unimodular (unitary groups of nondegenerate hermitian spaces, GL over F in the split case). Fix the Haar measure μ_{U} on G_{U} with $\mu_{\mathrm{U}}(K_s) = 1$, the Haar measure μ_0 on H_M with $\mu_0(K) = 1$, and let ν be the G_{U}-invariant measure on G_{U}/H_M with $\int_{G_{\mathrm{U}}} f = \int_{G_{\mathrm{U}}/H_M} \int_{H_M} f(xh)\, d\mu_0(h)\, d\nu(xH_M)$ (Weil's quotient measure). For $x \in G_{\mathrm{U}}$, applying this to $f = 1_{K_s x}$ (and $\mu_{\mathrm{U}}(K_s x) = \mu_{\mathrm{U}}(K_s)$) gives

$$\nu(K_s x H_M/H_M)\, \mu_0(H_M \cap x^{-1}K_s x) = 1, \tag{16.1}$$

since for $z = kxh_0 \in K_s x H_M$, $\{h \in H_M : zh \in K_s x\} = h_0^{-1}(H_M \cap x^{-1}K_s x)$. For a compact open subgroup $A \subseteq H_M$, $\mathrm{vol}_K(A)^{-1} = [K : A\cap K]/[A : A\cap K] = \mu_0(K)/\mu_0(A) = \mu_0(A)^{-1}$.

Step 1: orbits of tuples. Let L be as in the statement; it is free of rank m (finitely generated, torsion free, spanning M); let l be a basis, $G_L = \Phi(l)$, $\det G_L \neq 0$, and $O_L = \Phi^{-1}(G_L) \subseteq V^m$. If $t \in O_L$, the t_i are independent and $l_i \mapsto t_i$ is an isometry $M \to \mathrm{span}_E(t)$; by Witt's extension theorem for hermitian forms (Scharlau, *Quadratic and Hermitian forms*, Ch. 7; for $E = F \times F$, where V is a pair of F-spaces V_1, V_2 in perfect duality and $\mathrm{U}(V) \cong \mathrm{GL}(V_1)$, extend ι_1 on M_1 by any isomorphism of the annihilators $M_2^{\perp} \subseteq V_1$ and $\iota(M_2)^{\perp}$, and ι_2 by the contragredient) it extends to an element of G_{U}. So $O_L = G_{\mathrm{U}} l$, $\mathrm{Stab}_{G_{\mathrm{U}}}(l) = H_M$, and $\varphi_L : G_{\mathrm{U}}/H_M \to O_L$, $xH_M \mapsto xl$, is a G_{U}-equivariant continuous bijection, a homeomorphism by the open mapping theorem for transitive actions of σ-compact locally compact groups (Arens). O_L is closed in V^m.

Step 2: the glue mass as an orbit volume. Let $T_L = O_L \cap \mathrm{Prim}$, compact open in O_L and K_s-stable. For $t \in T_L$ choose $g \in G_{\mathrm{U}}$ with $t = g^{-1}l$ and put $\Lambda_t = g\Lambda_s$; as $\mathrm{span}_E(t) = g^{-1}M$ and t is primitive, $\Lambda_s \cap \mathrm{span}_E(t) = \mathrm{span}_{\mathcal{O}_E}(t)$, so $\Lambda_t \cap M = g\,\mathrm{span}_{\mathcal{O}_E}(t) = L$. The map $K_s t \mapsto H_M \Lambda_t$ is a bijection from K_s-orbits in T_L onto H_M-orbits of self-dual Λ with $\Lambda \cap M = L$: well defined (another g' with $t = g'^{-1}l$ has $g'g^{-1} \in H_M$; and $kt = (gk^{-1})^{-1}l$ gives $gk^{-1}\Lambda_s = \Lambda_t$); surjective,

because all self-dual lattices in V form one G_{U}-orbit (Lemma 16.27, applied to (V,h); self-dual modules are lattices, Definition 16.24), so $\Lambda = g\Lambda_s$ and $t = g^{-1}l$ lies in Λ_s^m, and $\Lambda_s \cap \mathrm{span}_E(t) = g^{-1}L = \mathrm{span}_{\mathcal{O}_E}(t)$ is a direct summand, so $t \in T_L$; injective, because $g'\Lambda_s = hg\Lambda_s$ with $h \in H_M$ gives $k = g'^{-1}hg \in K_s$ and $g'^{-1}l = kg^{-1}h^{-1}l = kt$. Moreover $\mathrm{Stab}_{H_M}(\Lambda_t) = H_M \cap gK_sg^{-1}$, compact open in H_M, and $K_st = \varphi_L(K_sg^{-1}H_M/H_M)$ is open in O_L; so T_L is a finite disjoint union of K_s-orbits, and by Step 0 and (16.1) with $x = g^{-1}$,

$$\mathrm{mass}_K^{\mathrm{gl}}(L) = \sum_{K_st \subseteq T_L} \mu_0(H_M \cap gK_sg^{-1})^{-1} = \sum_{K_st \subseteq T_L} \nu(K_sg^{-1}H_M/H_M) = \nu(\varphi_L^{-1}(T_L)).$$

Step 3: comparison with the fibre measure. By Lemma 16.26(1), $B \cap O_L \mapsto \lambda_{G_L}(B)$ ($B \subseteq V^m$ compact open; every compact open subset of the closed set O_L is of this form) is a finitely additive, nonnegative, nonzero, G_{U}-invariant function on the compact open subsets of O_L, i.e. a nonzero G_{U}-invariant positive functional on the locally constant compactly supported functions on $O_L \cong G_{\mathrm{U}}/H_M$. By the uniqueness of invariant measures on homogeneous spaces (Weil; Bourbaki, *Intégration*, Ch. VII, §2), $\lambda_{G_L} \circ \varphi_L = c_L\,\nu$ for a constant $c_L > 0$. Write $l = yA$ with $A \in \mathrm{GL}_m(E)$ ($l_j = \sum_i A_{ij}y_i$). Then $G_L = A^{\mathsf{T}}\Phi(y)\bar{A}$, $\varphi_L(Z) = \varphi_y(Z)A$, and Lemma 16.26(2) gives $c_L = |\mathrm{N}(\det A)|_F^{n-m}c_y$. As $\det G_L = \mathrm{N}(\det A)\det\Phi(y)$, $|\mathrm{N}(\det A)|_F^{n-m} = q^{-(n-m)(v(\det G_L)-v(\det\Phi(y)))}$.

Step 4: conclusion of (1). By Steps 2–3 and Lemma 16.26(3) ($\lambda_{G_L}(T_L) = \lambda_{G_L}(\mathrm{Prim})$ as $T_L = \mathrm{Prim} \cap O_L$),

$$\mathrm{mass}_K^{\mathrm{gl}}(L) = \frac{\lambda_{G_L}(T_L)}{c_L} = \kappa_0\, q^{(n-m)v(\det G_L)}\, q^{-(2nm-m^2)} N_{\Lambda_s}(G_L), \qquad \kappa_0 = \frac{q^{-(n-m)v(\det\Phi(y))}}{c_y} > 0,$$

and κ_0 does not depend on L. The finiteness of the set of H_M-orbits and the compactness and openness of the stabilisers were shown in Step 2 (T_L is a finite union of K_s-orbits, in bijection with these orbits). (Explicitly: $\kappa_0^{-1} = q^{(n-m)v(\det\Phi(y))}\,\mu^y(K_s)$, where μ^y is the Haar measure on $\mathrm{U}(V)$ whose quotient by μ_0 is the fibre measure $\lambda_{\Phi(y)}$ transported to $\mathrm{U}(V)/H_M$ by φ_y; the identity holds with y replaced by any basis of any such L.)

Proof of (2). $V = E^n$ with h is a local hermitian space of rank n (its Gram matrix is invertible). Let Λ_0 be a term over some datum. By Proposition 16.8(1) the m vectors $\mathrm{fr}_b, \theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ form an E-basis y of M_E with $\det\Phi(y) = \pm\theta^{-2(r+1)}G$, and $G \in F^\times$ by (Fp3) ($D_l\bar{D}_l \in F$); so M_E is free of rank m with invertible Gram matrix, i.e. nondegenerate. $H_0 = H_{M_E}$ by the two definitions. $K_{\mathrm{ref}} = H_0 \cap \mathrm{Stab}_{\mathrm{U}(V)}(\mathcal{O}_E^n)$, and the stabiliser of a lattice is a compact open subgroup of $\mathrm{U}(V)$ (it is closed in the compact open subgroup $\mathrm{GL}_n(\mathcal{O}_E)$ of $\mathrm{GL}_n(E)$, intersected with $\mathrm{U}(V)$); so K_{ref} is compact open in H_0. Self-dual modules and $\mathrm{vol}_{K_{\mathrm{ref}}}$ have the same meaning in Definition 16.2 and Definition 16.24, so the formula for $\sigma(\hat{M})$ is that for $\mathrm{mass}_{K_{\mathrm{ref}}}^{\mathrm{gl}}(\hat{M})$. Now apply (1) with $M = M_E$ and $K = K_{\mathrm{ref}}$. □

Lemma 16.26. *Let (V,h) be a local hermitian space of rank n, let $\Lambda_s \subseteq V$ be self-dual and let $m \geq 1$. Put*

$$\mathrm{Herm}_m(E) = \{X \in \mathrm{M}_m(E) : \bar{X}^{\mathsf{T}} = X\},$$
$$\Phi\colon V^m \to \mathrm{Herm}_m(E), \qquad \Phi(t) = (h(t_i,t_j))_{i,j}.$$

Give V^m and $\mathrm{Herm}_m(E)$ the Haar measures (of F-vector spaces) with

$$\mathrm{vol}(\Lambda_s^m) = 1, \qquad \mathrm{vol}(\mathrm{Herm}_m(\mathcal{O}_E)) = 1.$$

Let $S \in \mathrm{Herm}_m(E)$ with $\det S \neq 0$ and $O_S = \Phi^{-1}(S)$.

1. *For every compact open $B \subseteq V^m$ there is a lattice $U_0 \subseteq \mathrm{Herm}_m(E)$ such that* $\mathrm{vol}(B \cap \Phi^{-1}(S+U))/\mathrm{vol}(U)$ *has the same value $\lambda_S(B)$ for all $\mathcal{O}_F$-lattices $U \subseteq U_0$. The number $\lambda_S(B)$ depends only on $B \cap O_S$, is finitely additive in B, is > 0 if $B \cap O_S \neq \emptyset$, and $\lambda_S(gB) = \lambda_S(B)$ for $g \in \mathrm{U}(V)$ (acting diagonally).*

2. *Let $A \in \mathrm{GL}_m(E)$ and $BA = \{tA : t \in B\}$, where $(tA)_j = \sum_i A_{ij} t_i$. Then $\lambda_{A^\intercal S \bar{A}}(BA) = |\mathrm{N}(\det A)|_F^{n-m} \lambda_S(B)$.*

3. *Let $\mathrm{Prim} \subseteq \Lambda_s^m$ be the set of tuples whose reduction modulo ϖ is free, $G \in \mathrm{Herm}_m(\mathcal{O}_E)$ with $\det G \neq 0$, and $N_{\Lambda_s}(G)$ the number of free m-tuples in $\Lambda_s/\varpi\Lambda_s$ with Gram matrix G modulo ϖ. Then $\lambda_G(\mathrm{Prim}) = q^{-(2nm-m^2)} N_{\Lambda_s}(G)$.*

Proof. **Step 0: the differential.** For $t, \eta \in V^m$, $\Phi(t+\eta) = \Phi(t) + D_t(\eta) + \Phi(\eta)$ with $D_t(\eta)_{ij} = h(t_i, \eta_j) + h(\eta_i, t_j)$, F-linear in η. If $t_1, \dots, t_m$ are E-linearly independent, $D_t \colon V^m \to \mathrm{Herm}_m(E)$ is surjective: given X, let Y be upper triangular with $Y_{ij} = X_{ij}$ $(i < j)$, $Y_{ii} = \sigma X_{ii}$, so $X = Y + \bar{Y}^\intercal$; as h is nondegenerate there are η_i with $h(\eta_i, t_j) = Y_{ij}$ for all j, and then $D_t(\eta) = \bar{Y}^\intercal + Y = X$. The same argument over κ_E (trace $\kappa_E \to \kappa_F$ surjective, $\bar{h}$ nondegenerate) shows: if $t \in \Lambda_s^m$ has free reduction $\bar{t}$, then $\bar{D}_t \colon (\Lambda_s/\varpi\Lambda_s)^m \to \mathrm{Herm}_m(\kappa_E)$ is surjective ($\bar{t}$ extends to a basis, which has an $\bar{h}$-dual basis), with kernel of order q^{2nm-m^2}.

Step 1: a fibre count. Let P be an $\mathcal{O}_F$-lattice in $\mathrm{Herm}_m(E)$ and $\psi \colon \Lambda_s^m \to P$ a map with $\psi(\delta + \varpi^j \eta) \equiv \psi(\delta) + \varpi^j D(\eta) \pmod{\varpi^{j+1} P}$ for all $j \geq 0$, $\delta, \eta \in \Lambda_s^m$, where $D \colon \Lambda_s^m \to P$ is $\mathcal{O}_F$-linear and surjective. Then for every lattice $U' \subseteq P$ and $c \in P$, $\mathrm{vol}\{\delta : \psi(\delta) \in c + U'\} = [P : U']^{-1}$. Indeed ψ induces maps $\psi_j \colon \Lambda_s^m/\varpi^j\Lambda_s^m \to P/\varpi^j P$; the q^{2nm} lifts $\delta + \varpi^j\eta$ of a class δ map to $\psi(\delta) + \varpi^j \bar{D}(\bar{\eta})$ modulo $\varpi^{j+1}P$, and $\bar{D} \colon \Lambda_s^m/\varpi \to P/\varpi P$ is surjective, so each point of $P/\varpi^{j+1}P$ above $\psi_j(\delta)$ has exactly q^{2nm-m^2} preimages among them. By induction every fibre of ψ_j has $q^{j(2nm-m^2)}$ elements. For $\varpi^j P \subseteq U'$ the set in question is the union of $[U' : \varpi^j P]$ fibres of ψ_j, each a union of classes of volume q^{-2nmj}; its volume is $[U' : \varpi^j P] q^{-jm^2} = [P : U']^{-1}$.

Step 2: good balls. Let $t_0 \in O_S$; t_0 is linearly independent ($\det S \neq 0$), so $P_0 = D_{t_0}(\Lambda_s^m)$ is an $\mathcal{O}_F$-lattice in $\mathrm{Herm}_m(E)$ (Step 0). Choose $M_0 \geq 1$ with $\varpi^{M_0 - 1}\mathrm{Herm}_m(\mathcal{O}_E) \subseteq P_0$. Let $M \geq M_0$ and $t_1 \in O_S$ with $t_1 - t_0 \in \varpi^{M_0}\Lambda_s^m$. Then $D_{t_1} - D_{t_0}$ maps Λ_s^m into $\varpi^{M_0}\mathrm{Herm}_m(\mathcal{O}_E) \subseteq \varpi P_0$, so $D_{t_1}(\Lambda_s^m) = P_0$ (Nakayama). Put $\psi(\delta) = D_{t_1}(\delta) + \varpi^M \Phi(\delta) \in P_0$, so that $\Phi(t_1 + \varpi^M \delta) = S + \varpi^M \psi(\delta)$; ψ satisfies the hypothesis of Step 1 with $D = D_{t_1}$, $P = P_0$, since $\varpi^M(\Phi(\delta + \varpi^j\eta) - \Phi(\delta)) \in \varpi^{M+j}\mathrm{Herm}_m(\mathcal{O}_E) \subseteq \varpi^{j+1}P_0$. Hence, for the ball $\beta = t_1 + \varpi^M\Lambda_s^m$ and every lattice $U \subseteq \varpi^M P_0$,

$$\frac{\mathrm{vol}(\beta \cap \Phi^{-1}(S+U))}{\mathrm{vol}(U)} = \frac{q^{-2nmM}[P_0 : \varpi^{-M}U]^{-1}}{q^{-Mm^2}\mathrm{vol}(P_0)[P_0 : \varpi^{-M}U]^{-1}} = \frac{q^{-M(2nm-m^2)}}{\mathrm{vol}(P_0)} > 0,$$

independent of U. Call such β *good* (for t_0).

Step 3: proof of (1). O_S is closed, so $B \cap O_S$ is compact; cover it by finitely many good balls $t^{(\nu)} + \varpi^{M_\nu}\Lambda_s^m$ (Step 2 with $t_1 = t_0$) and let $M^* = \max_\nu M_\nu$. Partition B into finitely many balls of radius ϖ^{M^*} (translates of $\varpi^{M^*}\Lambda_s^m$). A ball β meeting O_S in a point t_1 is $t_1 + \varpi^{M^*}\Lambda_s^m$, contained (ultrametric) in some $t^{(\nu)} + \varpi^{M_\nu}\Lambda_s^m$, hence good by Step 2. A ball β not meeting O_S has compact image $\Phi(\beta) \not\ni S$, so $\beta \cap \Phi^{-1}(S+U) = \emptyset$ for small U. Summing over the partition gives U_0 and the constant value $\lambda_S(B)$. If B, B' are compact open with $B \cap O_S = B' \cap O_S$, apply this to $B \setminus B'$ and $B' \setminus B$ (which miss O_S) and to $B \cap B'$: $\lambda_S(B) = \lambda_S(B')$. Finite additivity is that of volume; positivity follows from Step 2. For $g \in \mathrm{U}(V)$, $\bar{g}^\intercal H g = H$ for the Gram matrix H of h, so $|\mathrm{N}(\det g)|_F = 1$; the diagonal action on $V^m = E^{n \times m}$ has E-determinant $(\det g)^m$, hence preserves volume ($|\det_F T|_F = |\mathrm{N}(\det_E T)|_F$ for E-linear T), and $\Phi(gt) = \Phi(t)$. So $\lambda_S(gB) = \lambda_S(B)$.

Step 4: proof of (2). $\Phi(tA) = A^{\mathsf T}\Phi(t)\bar A$, so $BA \cap \Phi^{-1}(A^{\mathsf T}S\bar A + U) = (B \cap \Phi^{-1}(S + U'))A$ with $U' = A^{-\mathsf T}U\bar A^{-1}$. Right multiplication by A on $E^{n\times m}$ has E-determinant $(\det A)^n$, so it multiplies volumes by $|\mathrm N(\det A)|_F^n$. The F-linear map $c_A\colon X \mapsto A^{\mathsf T}X\bar A$ of $\mathrm{Herm}_m(E)$ satisfies $c_{AA'} = c_{A'}c_A$, so $A \mapsto |\det_F c_A|_F$ is a character of $\mathrm{GL}_m(E)$; it is 1 on elementary matrices (then c_A is unipotent) and for $A = \mathrm{diag}(a_1,\dots,a_m)$ it is $\prod_i |\mathrm N a_i|_F \prod_{i<j}|\mathrm N(a_ia_j)|_F = |\mathrm N(\det A)|_F^m$ (the entry X_{ij} is multiplied by $a_i\bar a_j$); as these generate $\mathrm{GL}_m(E)$, $\mathrm{vol}(U) = |\mathrm N(\det A)|_F^m \mathrm{vol}(U')$. When U runs through small lattices, so does U'; dividing, $\lambda_{A^{\mathsf T}S\bar A}(BA) = |\mathrm N(\det A)|_F^{n-m}\lambda_S(B)$. (For $E = F \times F$ all of this holds componentwise.)

Step 5: proof of (3). $\Phi(t + \varpi^N\eta) - \Phi(t) \in \varpi^N\mathrm{Herm}_m(\mathcal O_E)$ for $t,\eta \in \Lambda_s^m$, and Prim is a union of classes modulo $\varpi\Lambda_s^m$. Let R_N be the set of classes modulo $\varpi^N\Lambda_s^m$ in Prim with $\Phi \equiv G \pmod{\varpi^N}$; $|R_1| = N_{\Lambda_s}(G)$. For $j \ge 1$ and a class $t \in R_j$, the lifts $t + \varpi^j\eta$ (η modulo ϖ) satisfy $\Phi(t + \varpi^j\eta) \equiv \Phi(t) + \varpi^j D_t(\eta) \pmod{\varpi^{j+1}}$ ($2j \ge j+1$), so the condition $\Phi \equiv G \pmod{\varpi^{j+1}}$ is the affine equation $\bar D_t(\bar\eta) = \varpi^{-j}(G - \Phi(t)) \bmod \varpi$, with exactly q^{2nm-m^2} solutions (Step 0). Hence $|R_N| = q^{(N-1)(2nm-m^2)}N_{\Lambda_s}(G)$ and

$$\frac{\mathrm{vol}(\mathrm{Prim} \cap \Phi^{-1}(G + \varpi^N\mathrm{Herm}_m(\mathcal O_E)))}{\mathrm{vol}(\varpi^N\mathrm{Herm}_m(\mathcal O_E))} = \frac{q^{-2nmN}|R_N|}{q^{-Nm^2}} = q^{-(2nm-m^2)}N_{\Lambda_s}(G)$$

for every $N \ge 1$. By (1) this is $\lambda_G(\mathrm{Prim})$. □

Lemma 16.27. *Let F be a non-archimedean local field with valuation ring $\mathcal O$, and let K be either the unramified quadratic field extension of F or $F \times F$, with its non-trivial F-involution c and maximal order R (R is the valuation ring of K, resp. $\mathcal O \times \mathcal O$). Let W be a free K-module of finite rank with a non-degenerate form $k\colon W \times W \to K$, K-linear in the first variable, with $k(y,x) = c(k(x,y))$. Call an R-lattice $L \subseteq W$ (a finitely generated R-submodule spanning W over K) **self-dual** if $L = \{x \in W :\ k(x,L) \subseteq R\}$. Then for any two self-dual R-lattices L, L' of W there is a K-linear $g\colon W \to W$ with $k(gx,gy) = k(x,y)$ for all x,y and $gL = L'$.*

Proof. ***K a field: a self-dual lattice has an orthonormal basis.*** Here R is a discrete valuation ring with uniformiser ϖ (the extension is unramified), every finitely generated torsion-free R-module is free, and $\mathrm{Tr}\colon R \to \mathcal O$ and $N\colon R^\times \to \mathcal O^\times$ are surjective (unramified extensions of local fields; Serre, *Local fields*, Ch. V, §2). Self-duality of L means $k(L,L) \subseteq R$ and that $x \mapsto k(\cdot,x)$ maps L onto $\mathrm{Hom}_R(L,R)$ (every R-linear $L \to R$ extends to a K-linear form on W, which is $k(\cdot,x)$ for a unique $x \in W$, and then $k(L,x) \subseteq R$ gives $x \in L$). We show by induction on $\mathrm{rk}_R L$ that L has a basis $e_1,\dots,e_r$ with $k(e_i,e_j) = \delta_{ij}$. Let $x \in L \smallsetminus \varpi L$. Then $k(x,\cdot)\colon L \to R$ is onto: otherwise its image lies in ϖR, so the R-linear map $k(\cdot,x) = c \circ k(x,\cdot)$ is ϖ times an element of $\mathrm{Hom}_R(L,R)$, which by self-duality is $k(\cdot,x')$ with $x' \in L$; as $k(\cdot,\varpi x') = \varpi\, k(\cdot,x')$, non-degeneracy gives $x = \varpi x' \in \varpi L$. Choose $y \in L$ with $k(x,y) = 1$. We find $z \in L$ with $u = k(z,z) \in \mathcal O^\times$ ($k(z,z)$ is c-invariant, so lies in $R \cap F = \mathcal O$): take $z = x$ or $z = y$ if $k(x,x)$ or $k(y,y)$ is a unit; otherwise choose $a \in R$ with $\mathrm{Tr}(a) = 1$ and $z = x + ay$, for which

$$k(z,z) = k(x,x) + \mathrm{Tr}\big(\bar a\, k(x,y)\big) + N(a)\, k(y,y) \equiv \mathrm{Tr}(\bar a) = 1 \pmod{\varpi}.$$

Then $L = Rz \oplus L_1$ with $L_1 = \{w \in L :\ k(w,z) = 0\}$, via $w = k(w,z)u^{-1}z + (w - k(w,z)u^{-1}z)$; the Gram matrix of L in a basis adapted to this sum is block diagonal with the unit u in one block, so its other block is invertible over R and L_1 is self-dual in $z^\perp$. Choose $t \in R^\times$ with $N(t) = u$ and put $e_1 = t^{-1}z$, so $k(e_1,e_1) = 1$, and apply the induction hypothesis to L_1. Given orthonormal bases (e_i) of L and (e_i') of L', the K-linear g with $ge_i = e_i'$ preserves k and maps L onto L'.

$K = F \times F$. Let ϵ_1, ϵ_2 be the idempotents of K (interchanged by c) and $W_i = \epsilon_i W$, so $W = W_1 \oplus W_2$. Writing $k = \epsilon_1 k_1 + \epsilon_2 k_2$ with F-valued k_i, linearity in the first variable

and semilinearity in the second give $k_1(x,y) = b(x_1, y_2)$ for an F-bilinear $b\colon W_1 \times W_2 \to F$ ($x = x_1 + x_2$, $x_i \in W_i$), and hermitian symmetry gives $k_2(x,y) = b(y_1, x_2)$; non-degeneracy of k makes b perfect. A K-linear $g = (g_1, g_2)$, $g_i \in \mathrm{GL}(W_i)$, preserves k if and only if $g_2 = (g_1^*)^{-1}$, with g_1^* the adjoint for b. Every R-lattice is $L = L_1 \oplus L_2$ with $L_i = \epsilon_i L$ an $\mathcal{O}$-lattice of W_i, and $\{x :\ k(x,L) \subseteq R\} = \{x_1 :\ b(x_1, L_2) \subseteq \mathcal{O}\} \oplus \{x_2 :\ b(L_1, x_2) \subseteq \mathcal{O}\}$; hence L is self-dual if and only if $L_2 = L_1^\perp := \{x_2 :\ b(L_1, x_2) \subseteq \mathcal{O}\}$ (the condition on L_1 then follows from perfectness of b). For self-dual $L = L_1 \oplus L_1^\perp$ and $L' = L_1' \oplus L_1'^\perp$ choose $g_1 \in \mathrm{GL}(W_1)$ with $g_1 L_1 = L_1'$ (both are free $\mathcal{O}$-modules of rank $\dim W_1$); then $(g_1^*)^{-1} L_1^\perp = (g_1 L_1)^\perp = L_1'^\perp$, and $g = (g_1, (g_1^*)^{-1})$ preserves k and maps L onto L'. □

Lemma 16.28. *Let $\bar V$ be a free κ_E-module of rank n with a nondegenerate hermitian form $\bar h$, and $m \geq 0$ an integer with $n \geq 2m+3$. For every hermitian matrix $\bar G \in \mathrm{M}_m(\kappa_E)$ the number $N(\bar G)$ of free m-tuples $(z_1, \dots, z_m) \in \bar V^m$ with $\bar h(z_a, z_b) = \bar G_{ab}$ for all a, b satisfies*

$$\tfrac{1}{2}\, q^{2nm-m^2} \leq N(\bar G) \leq 2\, q^{2nm-m^2}.$$

Proof. Let c be the integer with $\#\ker \bar G = q^{2c}$; $c \leq m$, since in the field case $\ker \bar G$ is a subspace of κ_E^m, and in the split case $\bar G = (B, B^{\mathsf T})$ with $\ker \bar G = \ker B \times \ker B^{\mathsf T}$, of order $q^{2(m - \mathrm{rk}\, B)}$. As $n \geq 2m+3$, $n - m \geq m + 3 > c$, so Lemma 16.29(2) gives

$$q^{-(2nm-m^2)} N(\bar G) = \frac{\alpha(n)}{\alpha(n-m-c)} = \prod_{i=n-m-c+1}^{n} (1 - \epsilon^i q^{-i}),$$

a product over indices $i \geq n - 2m + 1 \geq 4$. With $q \geq 2$, $\sum_{i \geq 4} q^{-i} \leq \sum_{i \geq 4} 2^{-i} = \frac{1}{8}$, so the product lies between $1 - \frac{1}{8} \geq \frac{1}{2}$ and $\prod_{i \geq 4}(1 + 2^{-i}) \leq e^{1/8} < 2$ (for $m = 0$ it is the empty product 1). □

Lemma 16.29. *The notation introduced here is local to this result and to the results that apply it. Let $\epsilon = -1$ if κ_E is a field and $\epsilon = 1$ otherwise, and $\alpha(j) = \prod_{i=1}^{j}(1 - \epsilon^i q^{-i})$ for integers $j \geq 0$ ($\alpha(0) = 1$). Let $\bar V$ be a free κ_E-module of rank $n \geq 0$ with a form $\bar h$, κ_E-linear in the first variable, with $\bar h(y,x) = \overline{\bar h(x,y)}$ and invertible Gram matrix.*

1. *For $g \in \kappa_F$ the number of $x \in \bar V$ with $\bar h(x,x) = g$ is $q^{2n-1} + \epsilon^n(q^n - q^{n-1})$ if $g = 0$ and $q^{2n-1} - \epsilon^n q^{n-1}$ if $g \neq 0$; the number of free $x \in \bar V$ with $\bar h(x,x) = 0$ is $(q^{n-1} - \epsilon^{n-1})(q^n - \epsilon^n)$.*
2. *Let $m \geq 0$, let $\bar G \in \mathrm{M}_m(\kappa_E)$ be hermitian ($\bar G_{ba} = \overline{\bar G_{ab}}$), and let $c \geq 0$ be the integer with $\#\ker(\bar G\colon \kappa_E^m \to \kappa_E^m) = q^{2c}$. Then the number $N(\bar G)$ of free m-tuples $(z_1, \dots, z_m) \in \bar V^m$ with $\bar h(z_a, z_b) = \bar G_{ab}$ for all a, b is*

$$N(\bar G) = \begin{cases} q^{2nm-m^2}\, \dfrac{\alpha(n)}{\alpha(n-m-c)} & \text{if } c \leq n-m, \\ 0 & \text{if } c > n-m. \end{cases}$$

Proof. **Step 0: orthogonal splittings and orthonormal bases.** (a) Let $x_1, \dots, x_s \in \bar V$ have invertible Gram matrix $C = (\bar h(x_a, x_b))$. If $\sum_i a_i x_i = 0$, pairing with x_b gives $\sum_i a_i C_{ib} = 0$ for all b, so $a = 0$: the family is free. For $v \in \bar V$ there is a unique $c \in \kappa_E^s$ with $\bar h(v - \sum_i c_i x_i, x_b) = 0$ for all b (C invertible), so $\bar V = X \oplus X^\perp$ with $X = \mathrm{span}(x)$, $X^\perp = \{v : \bar h(v, x_b) = 0\ \forall b\}$; $X^\perp$ is free of rank $n - s$ (componentwise dimensions) and its Gram matrix is invertible (an element of $X^\perp$ orthogonal to $X^\perp$ is orthogonal to $\bar V$). (b) $\bar V$ has a basis e with $\bar h(e_a, e_b) = \delta_{ab}$. Field case,

induction on $n \geq 1$: some z has $\bar{h}(z,z) \neq 0$, since otherwise $0 = \bar{h}(x+ay, x+ay) = \mathrm{Tr}(\bar{a}\,\bar{h}(x,y))$ for all x, y, a, so $\bar{h}(x,y) = 0$ (Tr is onto), contradicting invertibility; as $\bar{h}(z,z) \in \kappa_F^\times = \mathrm{N}(\kappa_E^\times)$ we may scale z to norm 1, and apply (a) and the induction hypothesis to $z^\perp$. Split case: let $\epsilon_1 = (1,0)$, $\epsilon_2 = (0,1)$ and $V_i = \epsilon_i \bar{V}$, so $\bar{V} = V_1 \times V_2$, $x = (x_1, x_2)$. Write $\bar{h} = (h_1, h_2)$. Linearity in the first and semilinearity in the second variable give $h_1(x,y) = h_1(\epsilon_1 x, \epsilon_2 y)$, so $h_1(x,y) = b(x_1, y_2)$ for an $\mathbb{F}_q$-bilinear $b\colon V_1 \times V_2 \to \mathbb{F}_q$, and $\bar{h}(y,x) = \overline{\bar{h}(x,y)}$ gives $h_2(x,y) = b(y_1, x_2)$; b is perfect as the Gram matrix is invertible; dual bases (e'_a), (e''_a) for b give $e_a = (e'_a, e''_a)$.

Step 1: proof of (1). Field case: write $\bar{V} = \kappa_E u \oplus u^\perp$ with $\bar{h}(u,u) = 1$ (Step 0). For $x = au + x'$, $\bar{h}(x,x) = \mathrm{N}(a) + \bar{h}(x',x')$, so by induction on n (the count for $g \neq 0$ not depending on g)

$$s_n = s_{n-1} + (q^2-1)t_{n-1}, \qquad t_n = (q+1)s_{n-1} + (q^2-q-1)t_{n-1}, \qquad s_0 = 1,\ t_0 = 0,$$

(for t_n: $a = 0$ contributes t_{n-1}; the $q+1$ elements a with $\mathrm{N}(a) = g$ contribute s_{n-1} each; the $(q+1)(q-2)$ others t_{n-1} each).

Every nonzero vector is free, so $J(n) = s_n - 1 = (q^{n-1} + (-1)^n)(q^n - (-1)^n)$ (expand). Split case: by Step 0(b), $\bar{V} = \mathbb{F}_q^n \times \mathbb{F}_q^n$ with $\bar{h}(x,x) = (x_1 \cdot x_2, x_1 \cdot x_2)$. For $g \neq 0$: $x_1 \neq 0$ ($q^n - 1$ choices) and x_2 in an affine hyperplane (q^{n-1}): $t_n = q^{2n-1} - q^{n-1}$. For $g = 0$: $x_1 = 0$ gives q^n, $x_1 \neq 0$ gives $(q^n-1)q^{n-1}$: $s_n = q^{2n-1} + q^n - q^{n-1}$. Free means $x_1 \neq 0 \neq x_2$: $J(n) = (q^n-1)(q^{n-1}-1)$. In both cases these are the formulas of (1).

Step 2: invariance. For $A \in \mathrm{GL}_m(\kappa_E)$ and $z \in \bar{V}^m$ put $(zA)_b = \sum_a A_{ab} z_a$. Then $\bar{h}((zA)_a, (zA)_b) = (A^\mathsf{T} \bar{G} \bar{A})_{ab}$ if z has Gram matrix $\bar{G}$, $z \mapsto zA$ is a bijection of free m-tuples (inverse $z \mapsto zA^{-1}$), and $\ker(A^\mathsf{T}\bar{G}\bar{A}) = \bar{A}^{-1} \ker \bar{G}$. So $N(\bar{G}) = N(A^\mathsf{T}\bar{G}\bar{A})$ and c is the same for both.

Step 3: normal form. Put $s = m - c$. There is $A \in \mathrm{GL}_m(\kappa_E)$ with $A^\mathsf{T}\bar{G}\bar{A} = \mathrm{diag}(I_s, 0_c)$. Field case: $\beta(x,y) = x^\mathsf{T}\bar{G}\bar{y}$ is a hermitian form on κ_E^m (column vectors) with radical $R = \{y : \bar{G}\bar{y} = 0\} = \overline{\ker \bar{G}}$ of dimension c; on a complement C of R, β is nondegenerate (if $y \in C$ and $\beta(C,y) = 0$ then $\beta(\kappa_E^m, y) = 0$, so $y \in R \cap C = 0$), so C has a β-orthonormal basis $a_1, \ldots, a_s$ (Step 0(b)); with a basis $a_{s+1}, \ldots, a_m$ of R, the matrix A with columns a_j has $A^\mathsf{T}\bar{G}\bar{A} = (\beta(a_i, a_j)) = \mathrm{diag}(I_s, 0_c)$. Split case: $\bar{G} = (B, B^\mathsf{T})$ with $B \in \mathrm{M}_m(\mathbb{F}_q)$, $\ker \bar{G} = \ker B \times \ker B^\mathsf{T}$, so $c = m - \mathrm{rk}\, B$; for $A = (A_1, A_2)$, $\bar{A} = (A_2, A_1)$ and $A^\mathsf{T}\bar{G}\bar{A} = (A_1^\mathsf{T} B A_2, (A_1^\mathsf{T} B A_2)^\mathsf{T})$, and invertible A_1, A_2 with $A_1^\mathsf{T} B A_2 = \mathrm{diag}(I_s, 0_c)$ exist. By Step 2 we may assume $\bar{G} = \mathrm{diag}(I_s, 0_c)$.

Step 4: the nondegenerate part. If $s > n$ there is no orthonormal s-tuple (it would be free, Step 0(a)), so $N(\bar{G}) = 0$; and then $n - m < -c \leq c$, as claimed. Let $s \leq n$. A tuple $(x_1, \ldots, x_s, y_1, \ldots, y_c)$ has Gram matrix $\mathrm{diag}(I_s, 0_c)$ if and only if x is orthonormal, every y_b lies in $X^\perp$ ($X = \mathrm{span}(x)$) and $\bar{h}(y_a, y_b) = 0$ for all a, b; it is free if and only if y is free, as $\bar{V} = X \oplus X^\perp$ with basis x of X (Step 0(a)). Choosing $x_1, \ldots, x_s$ in turn, x_{i+1} is a vector of norm 1 in $(\mathrm{span}(x_1, \ldots, x_i))^\perp$, which has rank $n - i$ and invertible Gram matrix; so by (1) the number of orthonormal s-tuples is

$$\prod_{i=0}^{s-1} t_{n-i} = \prod_{i=0}^{s-1} q^{2(n-i)-1} \frac{\alpha(n-i)}{\alpha(n-i-1)} = q^{2ns-s^2} \frac{\alpha(n)}{\alpha(n-s)}.$$

For each of them $X^\perp$ has rank $d = n - s$ and invertible Gram matrix, so

$$N(\bar{G}) = q^{2ns-s^2} \frac{\alpha(n)}{\alpha(n-s)}\, I(d,c),$$

where $I(d,c)$ is the number of free c-tuples with zero Gram matrix in a space of rank d with invertible Gram matrix (it depends only on d, c by Step 5).

Step 5: the isotropic part. $I(d,0)=1$; for $c\geq 1$, $I(d,c)=0$ if $d\leq 1$ (then $J(d)=0$), and $I(d,c)=J(d)\,q^{2(c-1)}\,I(d-2,c-1)$ if $d\geq 2$. Indeed, choose y_1 free of norm 0 ($J(d)$ ways). As y_1 is free and the Gram matrix is invertible, $v\mapsto \bar{h}(v,y_1)$ is onto κ_E; take w with $\bar{h}(w,y_1)=1$, $\sigma\in\kappa_E$ with $\mathrm{Tr}(\sigma)=1$, and $y^*=w-\sigma\bar{h}(w,w)y_1$. Then $\bar{h}(y^*,y_1)=1$ and $\bar{h}(y^*,y^*)=\bar{h}(w,w)(1-\bar{\sigma}-\sigma)=0$ ($\bar{h}(w,w)\in\kappa_F$). The pair (y_1,y^*) has Gram matrix $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$, so by Step 0(a) $\bar{V}=P\oplus Y'$ with $P=\mathrm{span}(y_1,y^*)$ and $Y'=P^{\perp}$ of rank $d-2$ with invertible Gram matrix. A vector $v=ay_1+by^*+w'$ ($w'\in Y'$) has $\bar{h}(v,y_1)=b$; so the vectors orthogonal to y_1 form $\kappa_E y_1\oplus Y'$. Hence the tuples $(y_2,\dots,y_c)$ completing y_1 are $y_b=a_by_1+w_b$ with $a_b\in\kappa_E$ arbitrary (q^2 choices each) and $w_b\in Y'$; their Gram matrix is that of $(w_2,\dots,w_c)$ (y_1 is isotropic and orthogonal to Y'), and $(y_1,\dots,y_c)$ is free if and only if $(y_1,w_2,\dots,w_c)$ is (a unitriangular change), if and only if $(w_2,\dots,w_c)$ is free in Y' (as $\kappa_E y_1\oplus Y'$ is direct and y_1 is free). This gives the recursion. Solving it with Step 1: if $2c\leq d$,

$$I(d,c)=q^{c(c-1)}\prod_{i=0}^{c-1}J(d-2i)=q^{c(c-1)}\prod_{i=0}^{c-1}q^{2(d-2i)-1}\frac{\alpha(d-2i)}{\alpha(d-2i-2)}=q^{2dc-c^2}\frac{\alpha(d)}{\alpha(d-2c)},$$

and if $2c>d$ the recursion reaches $I(d',c')$ with $c'\geq 1$, $d'\leq 1$, so $I(d,c)=0$.

Step 6: conclusion. With $d=n-s=n-m+c$: $2c\leq d$ if and only if $c\leq n-m$; then $d-2c=n-m-c$ and

$$N(\bar{G})=q^{2ns-s^2}\frac{\alpha(n)}{\alpha(n-s)}\cdot q^{2(n-s)c-c^2}\frac{\alpha(n-s)}{\alpha(n-m-c)}=q^{2nm-m^2}\frac{\alpha(n)}{\alpha(n-m-c)},$$

since $2ns-s^2+2(n-s)c-c^2=2n(s+c)-(s+c)^2$ and $s+c=m$; if $c>n-m$, $N(\bar{G})=0$. □

16.4 Averaging over Eichler moves and the local non-generic bound

This subsection proves the cancellation for the terms of second type and then the local non-generic bound Theorem 16.38. For the terms of second type with a given defect order and label, Proposition 16.30 constructs from Eichler moves an invariant symmetric averaging kernel whose total weight differs from 1, and whose average of the phases differs from 0, by at most $\frac{24}{7}q^{-(k-2r-4)}$. The phases are controlled by Gauss-sum bounds for the quadric condition (Lemma 16.37), and the geometry of the moves reduces the kernel to the orthogonal complement of the frame span (Proposition 16.31, Proposition 16.32). Lemma 16.39 turns such a kernel into cancellation of the orbit sums of the phases. Theorem 16.38 then derives from (Lg1)–(Lg5), which encode the mass bound for the defect orders, the class count of the terms of first type and this cancellation, the bound $H^{39(r+1)^2}q^{-(k-2r-5)}$ for the non-generic amplitudes against the total mass.

Proposition 16.30. *Let a local frame pair with parameters r and $k\geq 4r+7$ be given, d a datum, $i\geq 1$ an integer and $\lambda\in\mathbb{Z}^2$, and let $\mathcal{P}$ be the set of terms Λ over d of second type with $b_d(\Lambda)=q^i$ and $\lambda_d(\Lambda)=\lambda$. Then there is a function $m\colon\mathcal{P}\times\mathcal{P}\to[0,\infty)$ with $m(g\Lambda,g\Lambda_1)=m(\Lambda,\Lambda_1)$ for $g\in\Sigma$, $m(\Lambda,\Lambda_1)=m(\Lambda_1,\Lambda)$, $\{\Lambda_1: m(\Lambda,\Lambda_1)\neq 0\}$ finite for every Λ, and for every $\Lambda\in\mathcal{P}$*

$$\Big|\sum_{\Lambda_1\in\mathcal{P}}m(\Lambda,\Lambda_1)-1\Big|\leq\tfrac{24}{7}q^{-(k-2r-4)},\qquad\Big|\sum_{\Lambda_1\in\mathcal{P}}m(\Lambda,\Lambda_1)\,\omega_d(\Lambda_1)\Big|\leq\tfrac{24}{7}q^{-(k-2r-4)}.$$

Proof. Put $\rho=k-2r-3\geq 2r+4\geq 4$, so $q^{1-\rho}=q^{-(k-2r-4)}$. Take m from Proposition 16.31(Mr1); it has the required invariance, symmetry and finiteness. Fix $\Lambda\in\mathcal{P}$ and write $\lambda=(J,e)$; J is a level, so $0\leq J\leq r+1$ and $F_J(f)+F_J(f')\subseteq M_E$.

Step 1: the complement U_Λ splits off ρ orthonormal vectors. By (Mr0) there are $e_1,\dots,e_\rho \in \Lambda\cap W_0$ with $h(e_a,e_b)=\delta_{ab}$. As $F_J(f)+F_J(f')\subseteq M_E$ and $W_0=M_E^\perp$, $e_a\in U_\Lambda$. For $u\in U_\Lambda$, $h(u,e_a)\in\mathcal{O}_E$ (Λ is integral, Proposition 16.8(1)), so $u'=u-\sum_a h(u,e_a)e_a\in U_\Lambda$ and $u'\perp e_a$; hence $U_\Lambda=\mathcal{O}_Ee_1\oplus\cdots\oplus\mathcal{O}_Ee_\rho\oplus U'$ with $U'=U_\Lambda\cap\{e_1,\dots,e_\rho\}^\perp$, an orthogonal decomposition, $\mathcal{O}_Ee_a\cong\mathcal{O}_E$ (as $h(ce_a,e_a)=c$), and U_Λ is finitely generated ($\Lambda=u\Lambda_{\mathrm{std}}(A)$ is finitely generated by the inner condition, and $\mathcal{O}_E$ is noetherian). So Lemma 16.37 applies to U_Λ with these e_a and a ($a\ge0$ by Proposition 16.8(2)); its set Z is Z_Λ, and $L'_\Lambda\subseteq L$: if $h(u,e_1),\dots,h(u,e_\rho)$ generate $\mathcal{O}_E$, say $\sum_a\gamma_a h(u,e_a)=1$, then $y=\sum_a\bar\gamma_a e_a\in\Lambda\cap W_0$ and $h(u,y)=\sum_a\gamma_a h(u,e_a)=1$.

Step 2: the row sum. By (Mr1) and Lemma 16.37(1),(2),

$$\Big|\sum_{\Lambda_1} m(\Lambda,\Lambda_1)-1\Big|\le|q^a\mathrm{vol}(Z_\Lambda)-1|+q^a\mathrm{vol}(Z_\Lambda\cap L)\le\tfrac{8}{7}q^{1-\rho}+\tfrac{16}{7}q^{1-\rho}=\tfrac{24}{7}q^{-(k-2r-4)}.$$

Step 3: the phase average. By (Mr2), $|\omega_d(\Lambda)|\le1$, $\sum_b p_b=1$ and Lemma 16.37(3) (each $u\mapsto\psi_0(h(y_b,u))$ is a nontrivial continuous character of U_Λ) and (2),

$$\begin{aligned}\Big|\sum_{\Lambda_1} m(\Lambda,\Lambda_1)\,\omega_d(\Lambda_1)\Big|&\le\max_b q^a\Big|\int_{Z_\Lambda}\psi_0(h(y_b,u))\,du\Big|+q^a\mathrm{vol}(Z_\Lambda\cap L)\\&\le\tfrac{8}{7}q^{1-\rho}+\tfrac{16}{7}q^{1-\rho}=\tfrac{24}{7}q^{-(k-2r-4)}.\end{aligned}$$

□

Proposition 16.31. *Let a local frame pair with parameters r and $k\ge4r+7$ be given, d a datum, $i\ge1$ an integer, $\lambda\in\mathbb{Z}^2$, and $\mathcal{P}$ the set of terms over d of second type with $b_d=q^i$ and $\lambda_d=\lambda$. For $\Lambda\in\mathcal{P}$ with $\lambda=(J,e)$ put $U_\Lambda=\{u\in\Lambda: h(u,F_J(f)+F_J(f'))=0\}$ with its Haar probability measure du, $Z_\Lambda=\{u\in U_\Lambda: h(u,u)\in\varpi^a\mathcal{O}_F\}$ and $L'_\Lambda=\{u\in U_\Lambda: h(u,y)\ne1$ for all $y\in\Lambda\cap W_0\}$. Then:*

(Mr0) Orthonormal complement *for every term Λ over d, $\Lambda\cap W_0$ contains $k-2r-3$ vectors $e_1,\dots,e_{k-2r-3}$ with $h(e_a,e_b)=\delta_{ab}$;*

(Mr1) Kernel *there is a function $m\colon\mathcal{P}\times\mathcal{P}\to[0,\infty)$ with $m(g\Lambda,g\Lambda_1)=m(\Lambda,\Lambda_1)$ for $g\in\Sigma$, $m(\Lambda,\Lambda_1)=m(\Lambda_1,\Lambda)$, $\{\Lambda_1: m(\Lambda,\Lambda_1)\ne0\}$ finite for every Λ, and, for every $\Lambda\in\mathcal{P}$,*

$$q^a\mathrm{vol}(Z_\Lambda)-q^a\mathrm{vol}(Z_\Lambda\cap L'_\Lambda)\le\sum_{\Lambda_1\in\mathcal{P}}m(\Lambda,\Lambda_1)\le q^a\mathrm{vol}(Z_\Lambda);$$

(Mr2) Phases *for this m and every $\Lambda\in\mathcal{P}$ there are a nonempty finite set B, weights $p_b\ge0$ with $\sum_b p_b=1$ and vectors $y_b\in V$ ($b\in B$) such that $u\mapsto\psi_0(h(y_b,u))$ is a nontrivial character of U_Λ for every b and*

$$\Big|\sum_{\Lambda_1\in\mathcal{P}}m(\Lambda,\Lambda_1)\,\omega_d(\Lambda_1)-\omega_d(\Lambda)\sum_{b\in B}p_b\,q^a\int_{Z_\Lambda}\psi_0(h(y_b,u))\,du\Big|\le q^a\mathrm{vol}(Z_\Lambda\cap L'_\Lambda).$$

Proof. **Step 0: proof of (Mr0).** Let Λ be a term, $S=\mathrm{sat}(\Lambda)$, $B=\Lambda\cap W_0$. Λ is self-dual (Lemma 16.18(1)) and $V=M_E\oplus W_0$ (Proposition 16.8(1)). With the orthogonal projections, $\pi_M\Lambda\subseteq S^\#$ (as $h(\pi_My,x)=h(y,x)$ for $x\in S$) and $\{x\in M_E: h(x,\pi_M\Lambda)\subseteq\mathcal{O}_E\}=M_E\cap\Lambda^\#=S$, so $\pi_M\Lambda=S^\#$; likewise $\pi_W\Lambda=B^\#$; and $y\mapsto\pi_My+S$, $y\mapsto\pi_Wy+B$ are surjections $\Lambda\to S^\#/S$, $\Lambda\to B^\#/B$ with the common kernel $S\oplus B$ (if $\pi_My\in S\subseteq\Lambda$ then $\pi_Wy\in\Lambda\cap W_0$). Hence

$B^\#/B \cong S^\#/S$, which is generated by $2r+2$ elements ($S^\#$ is a lattice in M_E). Reduce modulo ϖ: $\bar B = B/\varpi B$ is free of rank $k-1$ over κ_E with the hermitian form $\bar h$ induced by h ($h(B,B) \subseteq \mathcal{O}_E$). Its radical is $(B \cap \varpi B^\#)/\varpi B \cong (B^\# \cap \varpi^{-1}B)/B$, the ϖ-torsion of $B^\#/B$, hence generated by $2r+2$ elements; so $\bar B$ has a nondegenerate quotient of rank at least $\rho = k-1-(2r+2) = k-2r-3$. A nondegenerate hermitian κ_E-module $\neq 0$ contains a vector $\bar v$ with $\bar h(\bar v,\bar v) \in \kappa_F^\times$ (if all $\bar h(\bar v,\bar v)$ vanished, polarisation would give $\mathrm{tr}(\lambda \bar h(\bar v,\bar w)) = 0$ for all λ, hence $\bar h = 0$). Lift $\bar v$ to $v \in B$: $h(v,v) \in \mathcal{O}_F^\times$ is a norm $c\bar c$, and $e_1 = c^{-1}v$ has $h(e_1,e_1) = 1$. Then $B = \mathcal{O}_E e_1 \oplus B_1$ with $B_1 = B \cap e_1^\perp$ ($v \mapsto v - h(v,e_1)e_1$), $B_1^\#/B_1 \cong B^\#/B$, and the nondegenerate quotient of $\bar B_1$ has rank one less. After ρ steps we have $e_1,\dots,e_\rho \in \Lambda \cap W_0$ with $h(e_a,e_b) = \delta_{ab}$.

Step 1: set-up. If $\mathcal{P} = \emptyset$ there is nothing to prove; let $\lambda = (J,e)$ with $\mathcal{P} \neq \emptyset$. For $\Lambda \in \mathcal{P}$ the term is not generic, so some $y \in \mathrm{sat}(\Lambda) \setminus M(\Lambda)$ has level ≥ 1 (Proposition 16.8(4)), whence $1 \leq J \leq r$. $\mathrm{sat}(\Lambda)/M(\Lambda)$ is an $\mathcal{O}_E$-module of order $\beta = q^i$; its classes of level $\leq J-1$ form a submodule of order q^e (finite $\mathcal{O}_E$-modules have order a power of q), so $\beta_J = q^i - q^e \geq 1$ classes have level exactly J, the same for all $\Lambda \in \mathcal{P}$; levels are constant on $M(\Lambda)$-classes (Proposition 16.8(4)). Let $\mathfrak{G} = F_J(f) \times F_J(f') \times Y_J^\perp \times E_0$ with $E_0 = \{t \in E : t+\bar t = 0\}$, a finite-dimensional F-vector space, $T = \varpi^a\mathcal{O}_E \cap E_0$, and for $w = (x,x',u,t) \in \mathfrak{G}$ put $s_w = h(u,u)/2 + t$ (then $s_w + \bar s_w = h(u,u)$, and $t \mapsto s_w$ is a bijection onto the solutions of this equation) and $E_w = E(x,u,s_w)$. For $\Lambda \in \mathcal{P}$ let $A_\Lambda = B_\Lambda \times U_\Lambda \times T$ (a compact open subgroup: $F_J(f) \cap F_J(f') = 0$, so B_Λ is the preimage of the lattice $\theta\Lambda \cap Y_J$), $\mathrm{Mv}_\Lambda = \{w : (x,x',u,s_w) \text{ a move of } \Lambda\}$, and $S(\Lambda,\Lambda_1) = \{w \in \mathrm{Mv}_\Lambda : E_w^{-1}\Lambda = \Lambda_1\}$. Fix a Haar measure μ on $\mathfrak{G}$ and define

$$m(\Lambda,\Lambda_1) = q^a \frac{\beta}{\beta_J} \frac{\mu(S(\Lambda,\Lambda_1))}{\mu(A_\Lambda)} \qquad (\Lambda,\Lambda_1 \in \mathcal{P}).$$

Step 2: finiteness. Mv_Λ is compact and open: $(x,x') \mapsto \theta^{-1}(x+x') + M(\Lambda) \in \mathrm{sat}(\Lambda)/M(\Lambda)$ is continuous into a finite discrete set on the open B_Λ, U_Λ is compact open, and $\{(u,t) : s_w \in \varpi^a\mathcal{O}_E\}$ is open, closed and bounded over the compact U_Λ. The map $w \mapsto E_w$ is continuous into $\mathrm{GL}(V)$, and $E_w^{-1}\Lambda = E_{w_0}^{-1}\Lambda$ as soon as $E_{w_0}E_w^{-1}$ lies in the open subgroup $\mathrm{Stab}(\Lambda)$; so $w \mapsto E_w^{-1}\Lambda$ is locally constant on Mv_Λ, takes finitely many values, and the sets $S(\Lambda,\Lambda_1)$ are open and closed. Hence $\{\Lambda_1 : m(\Lambda,\Lambda_1) \neq 0\}$ is finite, and $\sum_{\Lambda_1 \in \mathcal{P}} m(\Lambda,\Lambda_1)\phi(\Lambda_1) = q^a \frac{\beta}{\beta_J} \mu(A_\Lambda)^{-1} \int_{\mathrm{Mv}_\Lambda} 1[E_w^{-1}\Lambda \in \mathcal{P}]\, \phi(E_w^{-1}\Lambda)\, d\mu(w)$ for every bounded ϕ.

Step 3: Σ-invariance. Let $g \in \Sigma$ and $\Lambda \in \mathcal{P}$; then $g\Lambda \in \mathcal{P}$ (Proposition 16.12). $\phi_g(x,x',u,t) = (gx,gx',gu,t)$ is an F-linear automorphism of $\mathfrak{G}$ (g preserves $F_J(f)$, $F_J(f')$, hence $Y_J^\perp$), so $\mu \circ \phi_g = c_g\mu$ for a constant $c_g > 0$. It maps A_Λ onto $A_{g\Lambda}$ and Mv_Λ onto $\mathrm{Mv}_{g\Lambda}$: $x+x' \in \theta\Lambda \iff gx+gx' \in \theta g\Lambda$, $h(gu,gu) = h(u,u)$, and the level of $\theta^{-1}(gx+gx')$ for $g\Lambda$ equals that of $\theta^{-1}(x+x')$ for Λ, by the characterisation $\ell \leq j \iff y \in M + F_j(f) + F_j(f')$ of Proposition 16.8(4) and $M(g\Lambda) = gM(\Lambda)$ (Proposition 16.12). As $gE(x,u,s)g^{-1} = E(gx,gu,s)$ (g is an isometry), $E_{\phi_g w}^{-1} g\Lambda = gE_w^{-1}\Lambda$, so $\phi_g(S(\Lambda,\Lambda_1)) = S(g\Lambda,g\Lambda_1)$, and $m(g\Lambda,g\Lambda_1) = m(\Lambda,\Lambda_1)$.

Step 4: symmetry. Let $\Lambda,\Lambda_1 \in \mathcal{P}$ and $\iota(x,x',u,t) = (x,x',-u,-t)$, an involutive automorphism of $\mathfrak{G}$, so $\mu \circ \iota = \mu$. For $w \in S(\Lambda,\Lambda_1)$, $s_{\iota w} = h(u,u)/2 - t = \bar s_w$ ($h(u,u) \in F$, $\bar t = -t$), so by (Mg4) of Proposition 16.32 $\iota w \in \mathrm{Mv}_{\Lambda_1}$ and $E_{\iota w}^{-1}\Lambda_1 = E_w\Lambda_1 = \Lambda$; thus $\iota S(\Lambda,\Lambda_1) \subseteq S(\Lambda_1,\Lambda)$, and symmetrically, so $\mu(S(\Lambda,\Lambda_1)) = \mu(S(\Lambda_1,\Lambda))$. By (Mg5), $\mu(A_\Lambda) = \mu(A_{\Lambda_1})$ (for commensurable compact open subgroups $\mu(H) = [H:C]\mu(C)$). Hence $m(\Lambda,\Lambda_1) = m(\Lambda_1,\Lambda)$.

Step 5: the measure of the moves. Fix $\Lambda \in \mathcal{P}$ and write $\mu = \mu_1 \otimes \mu_2 \otimes \mu_3$ with Haar measures on $F_J(f) \times F_J(f')$, $Y_J^\perp$, E_0 normalised by $\mu_1(B_\Lambda) = \mu_2(U_\Lambda) = \mu_3(T) = 1$, so $\mu(A_\Lambda) = 1$ and $\mu_2|_{U_\Lambda}$ is the Haar probability du. The indicator of Mv_Λ is the product of $1[(x,x') \in B^J]$, $B^J = \{(x,x') \in B_\Lambda : \ell(\theta^{-1}(x+x')) = J\}$, of $1[u \in U_\Lambda]$ and of $1[s_w \in \varpi^a\mathcal{O}_E]$. (a) The homomorphism $\pi\colon B_\Lambda \to \mathrm{sat}(\Lambda)/M(\Lambda)$, $(x,x') \mapsto \theta^{-1}(x+x') + M(\Lambda)$, is surjective: every $y \in \mathrm{sat}(\Lambda)$ has level $\leq J$, so $y = m_0 + z_1 + z_2$ with $m_0 \in M(\Lambda)$, $z_1 \in F_J(f)$, $z_2 \in F_J(f')$

(Proposition 16.8(4)), $z_1+z_2\in\Lambda$, and $(\theta z_1,\theta z_2)\in B_\Lambda$. B^J is the preimage of the β_J classes of level J, each a coset of $\ker\pi$, of measure $1/\beta$; so $\mu_1(B^J)=\beta_J/\beta$. (b) For $u\in U_\Lambda$, the set $\{t\in E_0: h(u,u)/2+t\in\varpi^a\mathcal{O}_E\}$ is empty unless $h(u,u)\in\varpi^a\mathcal{O}_F$ ($s+\bar s\in\varpi^a\mathcal{O}_E\cap F$), and then contains $\sigma h(u,u)-h(u,u)/2$ and is a coset of T, of measure 1. So the t-fibre has measure $1[u\in Z_\Lambda]$. By Fubini, $\mu(\mathrm{Mv}_\Lambda)=\frac{\beta_J}{\beta}\mathrm{vol}(Z_\Lambda)$ and $\mu(\mathrm{Mv}_\Lambda\cap\{u\in L'_\Lambda\})=\frac{\beta_J}{\beta}\mathrm{vol}(Z_\Lambda\cap L'_\Lambda)$.

Step 6: proof of (Mr1). By Step 2 with $\phi=1$, $\sum_{\Lambda_1\in\mathcal{P}}m(\Lambda,\Lambda_1)=q^a\frac{\beta}{\beta_J}\mu\{w\in\mathrm{Mv}_\Lambda: E_w^{-1}\Lambda\in\mathcal{P}\}$. By (Mg3), every $w\in\mathrm{Mv}_\Lambda$ with $u\notin L'_\Lambda$ (i.e. $h(u,y)=1$ for some $y\in\Lambda\cap W_0$) has $E_w^{-1}\Lambda\in\mathcal{P}$. With Step 5, $q^a\mathrm{vol}(Z_\Lambda)-q^a\mathrm{vol}(Z_\Lambda\cap L'_\Lambda)\le\sum_{\Lambda_1}m(\Lambda,\Lambda_1)\le q^a\mathrm{vol}(Z_\Lambda)$. Steps 2–4 give the other properties of m.

Step 7: proof of (Mr2). For $b=(x,x')\in B^J$ put $y_b=-\theta^{-1}(h(x,e^*_{J-1})\mathrm{fr}_J+h(x',e'^*_{J-1})\mathrm{fr}'_J)$. By (Mg1) and the independence of ω_d of the witness (Proposition 16.12),

$$\omega_d(E_w^{-1}\Lambda)=\omega_d(\Lambda)\psi_0(h(y_b,u))\qquad(w\in\mathrm{Mv}_\Lambda).$$

By Step 2 with $\phi=\omega_d$,

$$\sum_{\Lambda_1}m(\Lambda,\Lambda_1)\omega_d(\Lambda_1)=q^a\frac{\beta}{\beta_J}\,\omega_d(\Lambda)\int_{\mathrm{Mv}_\Lambda}1[E_w^{-1}\Lambda\in\mathcal{P}]\,\psi_0(h(y_b,u))\,d\mu(w),$$

and removing the indicator changes the right side by at most $q^a\frac{\beta}{\beta_J}\mu(\mathrm{Mv}_\Lambda\cap\{u\in L'_\Lambda\})=q^a\mathrm{vol}(Z_\Lambda\cap L'_\Lambda)$ (Step 6, all values of modulus 1). By Fubini and Step 5(b) the full integral is $\int_{B^J}\int_{Z_\Lambda}\psi_0(h(y_b,u))\,du\,d\mu_1(b)$. Since $\mathrm{fr}_J,\mathrm{fr}'_J\in\Lambda$ and $h(\Lambda,\Lambda)\subseteq\mathcal{O}_E$, the open subgroup $B'=\ker\pi\cap\{(x,x')\in B_\Lambda: h(x,e^*_{J-1}),h(x',e'^*_{J-1})\in\theta\mathcal{O}_E\}$ of B_Λ satisfies $h(y_{b+b'}-y_b,u)\in\mathcal{O}_E$ for $b'\in B'$, $u\in U_\Lambda$; so $\psi_0(h(y_b,u))$ depends only on $b+B'$, and B^J is a finite union of cosets $b+B'$, $b\in\mathfrak{B}$. With $p_b=\mu_1(B')/\mu_1(B^J)$ ($\sum_b p_b=1$) the main term is $\omega_d(\Lambda)\sum_{b\in\mathfrak{B}}p_b\,q^a\int_{Z_\Lambda}\psi_0(h(y_b,u))\,du$. Each $u\mapsto\psi_0(h(y_b,u))$ is a nontrivial character of U_Λ by (Mg2), applied to the move $(x,x',0,0)$. This is (Mr2). □

Proposition 16.32. *Let a local frame pair with parameters r,k be given, d a datum, $i\ge1$, $J\ge1$, $e\ge0$ integers, and $\mathcal{P}$ the set of terms over d of second type with $b_d=q^i$ and $\lambda_d=(J,e)$. For $\Lambda\in\mathcal{P}$ put $Y_J=F_J(f)+F_J(f')$, $U_\Lambda=\Lambda\cap Y_J^\perp$, $B_\Lambda=\{(x,x')\in F_J(f)\times F_J(f'): x+x'\in\theta\Lambda\}$, and call (x,x',u,s) a* move *of Λ if $(x,x')\in B_\Lambda$, $\ell(\theta^{-1}(x+x'))=J$, $u\in U_\Lambda$, $s\in\varpi^a\mathcal{O}_E$ and $s+\bar s=h(u,u)$; put $E(x,u,s)v=v+h(v,u)x-h(v,x)(u+sx)$ ($v\in V$). For a move of Λ and $\Lambda_1=E(x,u,s)^{-1}\Lambda$:*

(Mg1) Terms and phases *$E(x,u,s)\in\mathrm{U}(V)$, Λ_1 is a term over d, and*

$$\omega_d(\Lambda_1)=\omega_d(\Lambda)\,\psi_0(h(y,u))\quad\text{with}$$
$$y=-\theta^{-1}(h(x,e^*_{J-1})\mathrm{fr}_J+h(x',e'^*_{J-1})\mathrm{fr}'_J)\qquad(\text{frames of }\Lambda);$$

(Mg2) Nontrivial character *$u\mapsto\psi_0(h(y,u))$ is a nontrivial character of U_Λ;*

(Mg3) Non-leaking moves stay *if $h(u,w)=1$ for some $w\in\Lambda\cap W_0$, then $\Lambda_1\in\mathcal{P}$;*

(Mg4) Reversal *if $\Lambda_1\in\mathcal{P}$, then $(x,x',-u,\bar s)$ is a move of Λ_1 (with the frames of Λ_1), and $E(x,-u,\bar s)=E(x,u,s)^{-1}$;*

(Mg5) Constant reference volume *for $\Lambda,\Lambda_1\in\mathcal{P}$, the subgroups $B_\Lambda\times U_\Lambda$ and $B_{\Lambda_1}\times U_{\Lambda_1}$ of $F_J(f)\times F_J(f')\times Y_J^\perp$ are commensurable and $[B_\Lambda\times U_\Lambda:C]=[B_{\Lambda_1}\times U_{\Lambda_1}:C]$ for C their intersection.*

Proof. **Step 1: facts on $\Lambda \in \mathcal{P}$.** Let $\Lambda \in \mathcal{P}$ with fixed witness (n, n'). $J \le r$, as the second type gives $\ell \le r$ on $\mathrm{sat}(\Lambda)$. By Proposition 16.8(1), $\mathrm{fr}_0, \dots, \mathrm{fr}_r, \mathrm{fr}'_0, \dots, \mathrm{fr}'_r$ are linearly independent, so $F_{r+1}(f) \cap F_{r+1}(f') = 0$ (these spaces are the spans of the fr_b, resp. fr'_b, as $n \in N$ preserves the flag of f and $n' \in N'$ that of f'). For $b < J \le r$, $nf_b - f_b \in F_b(f)$ and $n'f'_b - f'_b \in F_b(f')$ (definition of N, N'), so $F_J(f)$ is spanned by fr_b and $F_J(f')$ by fr'_b ($b < J$), and Y_J by both. (a) For linearly independent (p, p'), $M(p,p') = \{\sum_b \alpha_b p_b + \sum_b \alpha'_b p'_b : \theta\alpha'_b \in \mathcal{O}_E,\ \alpha_b + \alpha'_b \in \mathcal{O}_E\ \forall b\}$: the generators have this form, the set is a module, and $\sum_b \alpha_b p_b + \alpha'_b p'_b = \sum_b (\alpha_b + \alpha'_b) p_b + (\theta\alpha'_b)\theta^{-1}(p'_b - p_b)$. By Proposition 16.12, $M(\Lambda) = M(p,p')$ for the frames (p,p') of every witness of Λ (they lie in $\mathrm{Fr}(\Lambda)$). Consequently $M(\Lambda) \cap Y_J = M_J(\Lambda)$, the $\mathcal{O}_E$-span of fr_b, $\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)$ ($b < J$): the coefficients of $y \in Y_J$ vanish at $b \ge J$. (b) By Proposition 16.8(4), for $y \in \mathrm{sat}(\Lambda)$ and $0 \le j \le r+1$, $\ell(y) \le j$ if and only if $y \in M(\Lambda) + F_j(f) + F_j(f')$; so ℓ is constant on the cosets of $M(\Lambda)$ in $\mathrm{sat}(\Lambda)$ and does not depend on the witness. (c) $\mathrm{sat}(\Lambda) = (\Lambda \cap Y_J) + M(\Lambda)$: every $y \in \mathrm{sat}(\Lambda)$ has $\ell(y) \le J$, so $y = m + z$ with $m \in M(\Lambda)$, $z \in Y_J$, and $z = y - m \in \Lambda$ since $M(\Lambda) \subseteq \mathrm{sat}(\Lambda) \subseteq \Lambda$ (Proposition 16.8(3)). As $(\Lambda \cap Y_J) \cap M(\Lambda) = M_J(\Lambda)$, $[\Lambda \cap Y_J : M_J(\Lambda)] = [\mathrm{sat}(\Lambda) : M(\Lambda)] = b_d(\Lambda) = q^i$. A move (x, x', u, s) of Λ satisfies the hypotheses of Lemma 16.33 ($x + x' \in \theta\Lambda$ as $(x,x') \in B_\Lambda$; $u \in \Lambda$, $h(u, Y_J) = 0$ as $u \in U_\Lambda$).

Step 2: proof of (Mg1). This is Lemma 16.33(4) and (5).

Step 3: proof of (Mg2). Write $x = \sum_{b<J} \alpha_b \mathrm{fr}_b$, $x' = \sum_{b<J} \alpha'_b \mathrm{fr}'_b$. Then $\alpha_{J-1} = h(x, e^*_{J-1})$: $z_0 = n^{-1}x = \sum_{b<J} \alpha_b f_b \in F_J(f)$, $x - z_0 = nz_0 - z_0 \in F_{J-1}(f)$, and $h(f_b, e^*_{J-1}) = \delta_{b,J-1}$; likewise $\alpha'_{J-1} = h(x', e'^*_{J-1})$. So $y = -\theta^{-1}z$ with $z = \alpha_{J-1}\mathrm{fr}_J + \alpha'_{J-1}\mathrm{fr}'_J$. Since the frame vectors are independent, $\theta \cdot \theta^{-1}(x + x')$ has the unique coefficients (α_b, α'_b), zero for $b \ge J$; so $\ell(\theta^{-1}(x+x')) = J$ means that the condition $[\alpha'_{J-1} \in \mathcal{O}_E$ and $\alpha_{J-1} + \alpha'_{J-1} \in \theta\mathcal{O}_E]$ fails. Suppose $\psi_0(h(y,u)) = 1$ for all $u \in U_\Lambda$. For $c \in \mathcal{O}_E$, $\bar{c}u \in U_\Lambda$ and $h(y, \bar{c}u) = ch(y,u)$; by the conductor of ψ_0, $h(y,u) \in \mathcal{O}_E$, i.e. $h(U_\Lambda, y) \subseteq \mathcal{O}_E$. As $U_\Lambda = \Lambda \cap Y_J^\perp$ and $(Y_J^\perp)^\perp = Y_J$, Lemma 16.36(1) gives $\theta^{-1}z = -y = \lambda + w$ with $\lambda \in \Lambda$, $w \in Y_J$. Then $\lambda \in M_E$ ($z \in M_E$ as $J \le r$), so $\lambda \in \mathrm{sat}(\Lambda)$ and $\ell(\lambda) \le J$. But $\theta\lambda = \alpha_{J-1}\mathrm{fr}_J + \alpha'_{J-1}\mathrm{fr}'_J - \theta w$ with θw a combination of $\mathrm{fr}_b, \mathrm{fr}'_b$, $b < J$; its unique coefficients at index J are $(\alpha_{J-1}, \alpha'_{J-1})$, and $\ell(\lambda) \le J$ forces $\alpha'_{J-1} \in \mathcal{O}_E$, $\alpha_{J-1} + \alpha'_{J-1} \in \theta\mathcal{O}_E$: a contradiction. So the character is nontrivial.

Step 4: traces on Y_J under a move. Let $\Lambda \in \mathcal{P}$, (x, x', u, s) a move, $E = E(x,u,s)$, $\Lambda_1 = E^{-1}\Lambda$ (a term over d by Step 2), $B_0 = \Lambda \cap Y_J$. (t1) $B_0 \subseteq \Lambda_1$. Let $y = v + v' \in B_0$, $v \in F_J(f)$, $v' \in F_J(f')$. Then $h(y,u) = 0$ and $h(y,x) = h(v',x)$ (X is isotropic). The pairing condition of the second type for $x_1 = x$, $x'_1 = x'$, $x_2 = \theta v$, $x'_2 = \theta v'$ ($\theta v + \theta v' = \theta y \in \theta\Lambda$) gives $\theta h(x, v') \in \theta\mathcal{O}_E$, so $h(v', x) \in \mathcal{O}_E$, and $Ey = y - h(v',x)(u + sx) \in \Lambda$ (Lemma 16.33(1)). So $y \in \Lambda_1$. (t2) $M(\Lambda_1) \cap Y_J = M(\Lambda) \cap Y_J$. By Step 1(a), $M(\Lambda_1) = M(p,p')$ for the frames (p,p') of the witness of Lemma 16.33(4), which are linearly independent (they span $F_{r+1}(f)$ and $F_{r+1}(f')$) and agree with $(\mathrm{fr}, \mathrm{fr}')$ at $b < J$. An element of Y_J has the same coefficients in both systems (zero at $b \ge J$), so the membership conditions of Step 1(a) coincide. (t3) For $y \in B_0$ (in $\mathrm{sat}(\Lambda) \cap \mathrm{sat}(\Lambda_1)$ by (t1), $Y_J \subseteq M_E$), $\ell_{\Lambda_1}(y) = \ell_\Lambda(y)$. For $j \ge J$ both levels are $\le j$ ($y \in Y_J$). For $j < J$, if $y = m + w$ with $w \in F_j(f) + F_j(f') \subseteq Y_J$, then $m = y - w \in M(\Lambda) \cap Y_J = M(\Lambda_1) \cap Y_J$ by (t2), and conversely; conclude with Step 1(b) for Λ and Λ_1. (t4) If $h(u,w) = 1$ for some $w \in \Lambda \cap W_0$, every $y \in \mathrm{sat}(\Lambda_1)$ is congruent modulo $M(\Lambda_1)$ to an element of B_0. Indeed $Ey \in \Lambda$ and, as $y, x \in M_E \perp w$, $h(Ey, w) = h(y,w) + h(y,u)h(x,w) - h(y,x)(h(u,w) + sh(x,w)) = -h(y,x)$, so $h(y,x) \in \mathcal{O}_E$ ($w \in \Lambda$). Hence $b := y + h(y,u)x = Ey + h(y,x)(u + sx) \in \Lambda \cap M_E = \mathrm{sat}(\Lambda)$, and by Step 1(c) $b = m + y_0$ with $m \in M(\Lambda)$, $y_0 \in B_0$. Let $\tau(v) = v - h(v,u)x$, an E-linear map. For each generator of $M(\Lambda)$ there is $y_1 \in B_0$ with $\tau(\cdot) + y_1 \in M(p,p') = M(\Lambda_1)$: $\tau(\mathrm{fr}_b) = p_b$ ($y_1 = 0$), and $\tau(\theta^{-1}(\mathrm{fr}'_b - \mathrm{fr}_b)) + h(\mathrm{fr}'_b, u)\theta^{-1}(x + x') = \theta^{-1}(p'_b - p_b)$, where $h(\mathrm{fr}'_b, u) \in \mathcal{O}_E$ and $\theta^{-1}(x + x') \in B_0$; by linearity there is $y_1 \in B_0$ with $\tau(m) + y_1 \in M(\Lambda_1)$. Since $h(b,u) = h(y,u)$ ($h(x,u) = 0$) and $h(y_0, u) = 0$, $y = \tau(b) = \tau(m) + y_0$, so $y - (y_0 - y_1) = \tau(m) + y_1 \in M(\Lambda_1)$

with $y_0 - y_1 \in B_0$.

Step 5: a test for the second type. Let Λ' be a non-generic term over d and $B \subseteq \Lambda' \cap (X + X')$ a set such that every $y \in \mathrm{sat}(\Lambda')$ is congruent modulo $M(\Lambda')$ to an element of B, and $h(x_1, x_2') \in \theta\mathcal{O}_E$ whenever $x_1, x_2 \in X$, $x_1', x_2' \in X'$ and $\theta^{-1}(x_1 + x_1'), \theta^{-1}(x_2 + x_2') \in B$. Then Λ' is of second type. Levels: $y \equiv y_0 \in B \subseteq F_r(f) + F_r(f')$, so $\ell(y) \le r$ by Step 1(b). Pairing: let $x_\nu \in X$, $x_\nu' \in X'$ with $x_\nu + x_\nu' = \theta y_\nu$, $y_\nu \in \Lambda'$ ($\nu = 1, 2$). Then $y_\nu \in \mathrm{sat}(\Lambda')$, so $y_\nu = (u_\nu + u_\nu') + m_\nu$ with $u_\nu + u_\nu' \in B$, $u_\nu \in X$, $u_\nu' \in X'$, $m_\nu \in M(\Lambda') \subseteq \Lambda'$. Put $a_\nu = x_\nu - \theta u_\nu \in X$, $a_\nu' = x_\nu' - \theta u_\nu' \in X'$; then $a_\nu + a_\nu' = \theta m_\nu = \xi + \xi'$ with $\xi \in \sum_b \mathcal{O}_E \mathrm{fr}_b$, $\xi' \in \sum_b \mathcal{O}_E \mathrm{fr}_b' \subseteq \Lambda'$ (frames of Λ'), and $a_\nu - \xi = \xi' - a_\nu' \in F_{r+1}(f) \cap F_{r+1}(f') = 0$; so $a_\nu' \in \Lambda'$. Using $h(X, X) = h(X', X') = 0$, $h(\Lambda', \Lambda') \subseteq \mathcal{O}_E$ and $\bar\theta = \theta$:

$$h(x_1, x_2') = h(\theta u_1, \theta u_2') + \theta h(u_1 + u_1', a_2') + \theta(\theta h(m_1, u_2 + u_2') - h(a_1', u_2 + u_2')) + \theta h(m_1, a_2'),$$

and the first term is in $\theta\mathcal{O}_E$ by hypothesis (applied to $\theta u_\nu, \theta u_\nu'$), the others since $u_\nu + u_\nu', a_\nu', m_\nu \in \Lambda'$. So Λ' is of second type.

Step 6: proof of (Mg3). By (t1), $B_0 \subseteq \mathrm{sat}(\Lambda_1)$; by Step 1(c) and (t4), $\mathrm{sat}(\Lambda) = B_0 + M(\Lambda)$ and $\mathrm{sat}(\Lambda_1) = B_0 + M(\Lambda_1)$, and $B_0 \cap M(\Lambda) = B_0 \cap M(\Lambda_1)$ by (t2). So $B_0/(B_0 \cap M(\Lambda))$ maps isomorphically onto $\mathrm{sat}(\Lambda)/M(\Lambda)$ and onto $\mathrm{sat}(\Lambda_1)/M(\Lambda_1)$, and by (t3) and Step 1(b) both isomorphisms preserve levels. Hence $b_d(\Lambda_1) = b_d(\Lambda) = q^i \ne 1$, so Λ_1 is not generic; the maximal level on $\mathrm{sat}(\Lambda_1)$ is J; and by Step 1(b) the classes of level $\le J-1$ form the submodule $\mathrm{sat} \cap (M + F_{J-1}(f) + F_{J-1}(f'))$ modulo M, of the same order for Λ and Λ_1, so $\lambda_d(\Lambda_1) = (J, e)$. Step 5 with $\Lambda' = \Lambda_1$ and $B = B_0$ ($B_0 \subseteq \Lambda_1 \cap Y_J \subseteq \Lambda_1 \cap (X + X')$; representatives by (t4); if $\theta^{-1}(x_\nu + x_\nu') \in B_0 \subseteq \Lambda$, then $h(x_1, x_2') \in \theta\mathcal{O}_E$ by the second type of Λ) shows that Λ_1 is of second type. So $\Lambda_1 \in \mathcal{P}$.

Step 7: proof of (Mg4). Let $\Lambda_1 \in \mathcal{P}$. By Lemma 16.33(3), $x + x' \in \theta\Lambda_1$, so $(x, x') \in B_{\Lambda_1}$; $\theta^{-1}(x + x') \in B_0$, so by (t3) its level for Λ_1 is J; $-u \in \Lambda_1$ and $h(-u, Y_J) = 0$, so $-u \in U_{\Lambda_1}$; $\bar s \in \varpi^a\mathcal{O}_E$ and $\bar s + s = h(-u, -u)$. So $(x, x', -u, \bar s)$ is a move of Λ_1, and $E(x, -u, \bar s) = E(x, u, s)^{-1}$ by Lemma 16.34(2).

Step 8: proof of (Mg5). Let $\Lambda, \Lambda' \in \mathcal{P}$, $Q = \Lambda \cap \Lambda'$, μ a Haar measure on Y_J. For Λ with witness (n, n') let T_Λ be the E-linear automorphism of Y_J with $T_\Lambda f_b = \mathrm{fr}_b$, $T_\Lambda f_b' = \mathrm{fr}_b'$ ($b < J$). As $nf_b - f_b \in F_b(f)$ and $n'f_b' - f_b' \in F_b(f')$, its matrix in the basis $(f_b, f_b')_{b<J}$ is unitriangular in each block, so $\det_E T_\Lambda = 1$; and T_Λ maps $M_J^0 = \sum_{b<J} \mathcal{O}_E f_b + \mathcal{O}_E\theta^{-1}(f_b' - f_b)$ onto $M_J(\Lambda)$. For an E-linear automorphism S of Y_J, $\mu(SP) = |\mathrm{N}_{E/F}(\det_E S)|_F\, \mu(P)$; hence $\mu(M_J(\Lambda)) = \mu(M_J^0) = \mu(M_J(\Lambda'))$, and by Step 1(c) $\mu(\Lambda \cap Y_J) = q^i\mu(M_J(\Lambda)) = \mu(\Lambda' \cap Y_J)$. So $[\Lambda \cap Y_J : Q \cap Y_J] = [\Lambda' \cap Y_J : Q \cap Y_J]$, and Lemma 16.36(2) with $U = Y_J$ (Λ, Λ' self-dual by Lemma 16.18(1)) gives $[U_\Lambda : U_\Lambda \cap U_{\Lambda'}] = [U_{\Lambda'} : U_\Lambda \cap U_{\Lambda'}]$, all finite. The map $\varphi(x, x') = \theta^{-1}(x + x')$ is an isomorphism $F_J(f) \times F_J(f') \to Y_J$ ($F_J(f) \cap F_J(f') = 0$) with $B_\Lambda = \varphi^{-1}(\Lambda \cap Y_J)$, so $[B_\Lambda : B_\Lambda \cap B_{\Lambda'}] = [B_{\Lambda'} : B_\Lambda \cap B_{\Lambda'}]$. With $C = (B_\Lambda \cap B_{\Lambda'}) \times (U_\Lambda \cap U_{\Lambda'})$, the intersection of $B_\Lambda \times U_\Lambda$ and $B_{\Lambda'} \times U_{\Lambda'}$, the index $[B_\Lambda \times U_\Lambda : C]$ is the product of the two indices for Λ, and likewise for Λ'; so the two indices are finite and equal. □

Lemma 16.33. *Fix a local frame pair with parameters r, k, a datum d, an integer $J \ge 1$ and a term Λ over d of second type with $\lambda_d(\Lambda) = (J, e)$ for some e; let (n, n') be the fixed witness of Λ. Put $Y_J = F_J(f) + F_J(f')$. Let $x \in F_J(f)$, $x' \in F_J(f')$, $u \in \Lambda$, $s \in \varpi^a\mathcal{O}_E$ with $x + x' \in \theta\Lambda$, $h(u, Y_J) = 0$ and $s + \bar s = h(u, u)$; put $E = E(x, u, s)$, $E' = E(x', u, s)$ and $\Lambda_1 = E^{-1}\Lambda$. Then:*

1. *$J \le r$, $x \in X$, $x' \in X'$, $h(x', x) \in \theta\mathcal{O}_E$, and $sx, \bar s x, sx', \bar s x' \in \Lambda$;*
2. *$EE'v - v \in \theta\Lambda$ for every $v \in \Lambda$ with $h(v, x') = 0$;*
3. *$x + x' \in \theta\Lambda_1$, $-u \in \Lambda_1$, $\bar s x \in \Lambda_1$;*

4. *$E \in \mathrm{U}(V)$, and Λ_1 is a term over d with a witness $(E^{-1}n, gE'n')$, where $g \in \mathrm{U}(V)$ fixes every vector of $X'^{\perp}$; the frames of this witness are $E^{-1}\mathrm{fr}_b = \mathrm{fr}_b - h(\mathrm{fr}_b, u)x$ and $gE'\mathrm{fr}'_b = \mathrm{fr}'_b + h(\mathrm{fr}'_b, u)x'$ $(0 \le b \le r)$, equal to fr_b, fr'_b for $b < J$;*

5. *$\omega_d(\Lambda_1) = \omega_d(\Lambda)\,\psi_0(h(y,u))$ with $y = -\theta^{-1}\big(h(x, e^*_{J-1})\mathrm{fr}_J + h(x', e'^*_{J-1})\mathrm{fr}'_J\big)$.*

Proof. **Step 0: facts on Λ.** Λ is self-dual (Lemma 16.18(1)), so $h(\Lambda,\Lambda) \subseteq \mathcal{O}_E$; the vectors $\mathrm{fr}_b, \mathrm{fr}'_b$ lie in Λ, and $\mathrm{fr}_0, \dots, \mathrm{fr}_r, \mathrm{fr}'_0, \dots, \mathrm{fr}'_r$ are linearly independent over E (Proposition 16.8(1)); so $f_0, \dots, f_r$ and $f'_0, \dots, f'_r$ are linearly independent and $F_{r+1}(f) \cap F_{r+1}(f') = 0$. As $n \in N$, $nF_j(f) = F_j(f)$ for $j \le r+1$ ($nF_{j+1}(f) = F_{j+1}(f)$ for $j < r$ by definition; $nf_r \in f_r + X$), so $F_j(f)$ is the E-span of $\mathrm{fr}_0, \dots, \mathrm{fr}_{j-1}$; likewise for f'. Also $n(X^{\perp}) = X^{\perp}$ and $f_b \in X^{\perp}$ by (Fp1), so $\mathrm{fr}_b \in X^{\perp}$; likewise $\mathrm{fr}'_b \in X'^{\perp}$.

Step 1: proof of (1). The second type gives $\ell \le r$ on $\mathrm{sat}(\Lambda)$, so $J \le r$ and $x \in F_J(f) \subseteq X$, $x' \in X'$. Applying the pairing condition of the second type to $x_1 = x_2 = x$, $x'_1 = x'_2 = x'$ (with $x + x' \in \theta\Lambda$) gives $h(x,x') \in \theta\mathcal{O}_E$, hence $h(x',x) = \overline{h(x,x')} \in \theta\mathcal{O}_E$. Let $y_0 = \theta^{-1}(x + x') \in \Lambda \cap M_E = \mathrm{sat}(\Lambda)$. By Proposition 16.8(2),(3), $a \ge 0$ and $\varpi^a y_0 \in M(\Lambda)$; as $\theta M(\Lambda)$ is spanned by the $\theta\mathrm{fr}_b$ and the $\mathrm{fr}'_b - \mathrm{fr}_b$, $\varpi^a x + \varpi^a x' = \theta\varpi^a y_0 = \xi + \xi'$ with $\xi \in \sum_b \mathcal{O}_E\mathrm{fr}_b$, $\xi' \in \sum_b \mathcal{O}_E\mathrm{fr}'_b$. Then $\varpi^a x - \xi = \xi' - \varpi^a x'$ lies in $F_{r+1}(f) \cap F_{r+1}(f') = 0$ (Step 0), so $\varpi^a x = \xi \in \Lambda$ and $\varpi^a x' = \xi' \in \Lambda$. Writing $s = \varpi^a c$ with $c \in \mathcal{O}_E$, $sx = c\varpi^a x$ and $\bar{s}x = \bar{c}\varpi^a x$ lie in Λ, and likewise for x'.

Step 2: a congruence. Let L be an $\mathcal{O}_E$-module with $h(L,L) \subseteq \mathcal{O}_E$, $x + x' \in \theta L$, $u_0 \in L$ with $h(x', u_0) = 0$, $s_0 \in E$ with $s_0 x \in L$, and $t \in E$. Write $x + x' = \theta y_1$ ($y_1 \in L$) and $h(x', x) = \theta c_0$ ($c_0 \in \mathcal{O}_E$, by (1)). Then for $v \in L$ with $h(v, x') = 0$:

$$E(x, u_0, s_0)E(x', u_0, t)v - v = \theta\big(\alpha y_1 - (h(v, y_1) + \alpha c_0)(u_0 + s_0 x)\big) \in \theta L, \qquad \alpha = h(v, u_0). \tag{16.2}$$

Indeed $E(x', u_0, t)v = v + \alpha x'$; then $h(v + \alpha x', u_0) = \alpha$ and $h(v + \alpha x', x) = h(v,x) + \alpha\theta c_0$ with $h(v,x) = h(v, x + x') = \theta h(v, y_1)$; so $E(x, u_0, s_0)(v + \alpha x') - v = \alpha(x + x') - \theta(h(v, y_1) + \alpha c_0)(u_0 + s_0 x)$, and $\alpha, h(v, y_1) \in \mathcal{O}_E$. With $L = \Lambda$, $u_0 = u$ ($h(x', u) = 0$ as $x' \in Y_J$), $s_0 = s$, $t = s$, this is (2).

Step 3: proof of (3) and of $E \in \mathrm{U}(V)$. By Lemma 16.34(2) for $g = f$ ($x \in F_J(f)$, $h(F_J(f), u) = 0$, $1 \le J \le r$): $E \in N \subseteq \mathrm{U}(V)$, $E^{-1} = E(x, -u, \bar{s})$, $Ex = x$, $E(\bar{s}x) = \bar{s}x$. Likewise $E' \in N'$, $E'^{-1} = E(x', -u, \bar{s})$. Write $h(x', x) = \theta c_0$. Then $Ex' = x' - \theta c_0(u + sx)$ (as $h(x', u) = 0$), so $E(x + x') = (x + x') - \theta c_0(u + sx) \in \theta\Lambda$, i.e. $x + x' \in \theta\Lambda_1$. $E(-u) = -u - h(u,u)x = -(u + sx + \bar{s}x) \in \Lambda$ ($h(u,x) = 0$), so $-u \in \Lambda_1$; and $\bar{s}x = E(\bar{s}x) \in \Lambda$, so $\bar{s}x \in \Lambda_1$. Λ_1 is self-dual (E is an isometry). So Step 2 applies to $L = \Lambda_1$, $u_0 = -u$, $s_0 = \bar{s}$, $t = \bar{s}$: for $v \in \Lambda_1$ with $h(v, x') = 0$,

$$E^{-1}E'^{-1}v - v \in \theta\Lambda_1. \tag{16.3}$$

Step 4: the trace on $X'^{\perp}$. We show $E'\Lambda \cap X'^{\perp} = \Lambda_1 \cap X'^{\perp}$. As $E' \in N'$, $E'(X'^{\perp}) = X'^{\perp}$. If $v \in E'\Lambda \cap X'^{\perp}$, then $w = E'^{-1}v \in \Lambda \cap X'^{\perp}$, and by (2) $Ev = EE'w \in w + \theta\Lambda \subseteq \Lambda$, so $v \in \Lambda_1$. If $v \in \Lambda_1 \cap X'^{\perp}$, then by (16.3) $E^{-1}E'^{-1}v \in \Lambda_1 = E^{-1}\Lambda$, so $E'^{-1}v \in \Lambda$ and $v \in E'\Lambda$. Now X' is spanned by $f'_0, \dots, f'_{r-1}$, linearly independent (Step 0) with $h(f'_i, f'_j) = 0$ (Fp1), and $E'\Lambda$, Λ_1 are self-dual. By Lemma 16.35 there is $g \in \mathrm{U}(V)$ fixing $X'^{\perp}$ pointwise with $gE'\Lambda = \Lambda_1$.

Step 5: proof of (4). $g \in N'$: g fixes $X'^{\perp} \supseteq F_{r+1}(f')$ (Fp1) pointwise, so all conditions defining N' hold with $gw - w = 0$. Hence $E^{-1}n \in N$ and $gE'n' \in N'$, and $\Lambda_1 = E^{-1}n\Lambda_{\mathrm{std}}(A) = gE'n'\Lambda'_{\mathrm{std}}(A')$; A, A' are inner as before. Frames: as $\mathrm{fr}_b \in X^{\perp}$ and $x \in X$, Lemma 16.34(2) gives $E^{-1}\mathrm{fr}_b = \mathrm{fr}_b - h(\mathrm{fr}_b, u)x$; as $\mathrm{fr}'_b \in X'^{\perp}$, $E'\mathrm{fr}'_b = \mathrm{fr}'_b + h(\mathrm{fr}'_b, u)x' \in X'^{\perp}$, fixed by g. For $b < J$, $\mathrm{fr}_b, \mathrm{fr}'_b \in Y_J$ (Step 0) are orthogonal to u, so the frames are unchanged. Congruence: $gE'\mathrm{fr}'_b - E^{-1}\mathrm{fr}_b = E^{-1}\big((EE'\mathrm{fr}'_b - \mathrm{fr}'_b) + (\mathrm{fr}'_b - \mathrm{fr}_b)\big) \in E^{-1}\theta\Lambda = \theta\Lambda_1$, by (2) ($\mathrm{fr}'_b \in \Lambda \cap X'^{\perp}$)

and the congruence of the witness (n, n'). The congruence graph: let $(p, p') \in \Gamma$, with $y, y' \in \Lambda$, $y \perp X$, $y' \perp X'$, $y' - p \in X'$, $y - p' \in X$, $y' - y \in \theta\Lambda$. Put $y'_1 = E'y'$, $y_1 = E^{-1}y$. Then $Ey'_1 = EE'y' \in y' + \theta\Lambda \subseteq \Lambda$ by (2), so $y'_1 \in \Lambda_1$; $y_1 \in \Lambda_1$; $y'_1 \perp X'$ and $y_1 \perp X$ ($E' \in N'$, $E^{-1} \in N$ preserve $X'^{\perp}$, $X^{\perp}$); $y'_1 - p = (E'y' - y') + (y' - p) \in X'$ and $y_1 - p' \in X$ (elements of N', N move $X'^{\perp}$, $X^{\perp}$ by vectors of X', X); and $E(y'_1 - y_1) = (EE'y' - y') + (y' - y) \in \theta\Lambda$, so $y'_1 - y_1 \in \theta\Lambda_1$. Thus Γ is contained in the congruence graph of Λ_1. The same argument with $(\Lambda_1, E^{-1}, E'^{-1}, (16.3))$ in place of $(\Lambda, E, E', (2))$ (note $\Lambda = E\Lambda_1$, $E^{-1} \in N$, $E'^{-1} \in N'$) gives the converse inclusion. So Λ_1 is a term over d with witness $(E^{-1}n, gE'n')$.

Step 6: proof of (5). $\omega_d(\Lambda_1)$ does not depend on the choice of the fixed witness (Proposition 16.12 with the identity of Σ), so we compute it with $(E^{-1}n, gE'n')$. By Lemma 16.34(1), $\psi_N(E^{-1}n) = \psi_N(E)^{-1}\psi_N(n)$ and $\psi_{N'}(gE'n') = \psi_{N'}(g)\psi_{N'}(E')\psi_{N'}(n') = \psi_{N'}(E')\psi_{N'}(n')$ (g fixes $X'^{\perp} = F_r(f')^{\perp}$ pointwise). All values have modulus one, so

$$\omega_d(\Lambda_1) = \psi_N(E^{-1}n)\overline{\psi_{N'}(gE'n')} = \omega_d(\Lambda)\,\overline{\psi_N(E)}\,\overline{\psi_{N'}(E')}.$$

By Lemma 16.34(2) with $m = n$, resp. $m = n'$:

$$\psi_N(E) = \psi_0(\theta^{-1}h(x, e^*_{J-1})h(\mathrm{fr}_J, u)) \quad \text{and} \quad \psi_{N'}(E') = \psi_0(\theta^{-1}h(x', e'^*_{J-1})h(\mathrm{fr}'_J, u)).$$

As $\overline{\psi_0(z)} = \psi_0(-z)$ and

$$h(y, u) = -\theta^{-1}(h(x, e^*_{J-1})h(\mathrm{fr}_J, u) + h(x', e'^*_{J-1})h(\mathrm{fr}'_J, u)),$$

(5) follows. □

Lemma 16.34. *Let a local frame pair with parameters r, k be given, and let (g, g^*, ψ_g) be (f, e^*, ψ_N) or $(f', e'^*, \psi_{N'})$. For $x, u \in V$, $s \in E$ let $E(x, u, s)v = v + h(v, u)x - h(v, x)(u + sx)$ $(v \in V)$.*

1. *For $w \in N(g)$ and $0 \le j < r$ put $c_j(w) = h(wg_{j+1}, g^*_j)$. Then $c_j(ww_1) = c_j(w) + c_j(w_1)$ for $w, w_1 \in N(g)$; hence ψ_g is a homomorphism $N(g) \to \{z \in \mathbb{C} : |z| = 1\}$, and $\psi_g(w) = 1$ if w fixes every vector of $F_r(g)^{\perp}$.*

2. *Let $1 \le J \le r$, $x \in F_J(g)$, $u \in V$ with $h(F_J(g), u) = 0$, and $s \in E$ with $s + \bar{s} = h(u, u)$. Then $E(x, u, s) \in N(g)$, $E(x, u, s)^{-1} = E(x, -u, \bar{s})$, $E(x, u, s)w = w$ for $w \in F_J(g)$, $E(x, u, s)v - v = h(v, u)x$ for $v \in F_r(g)^{\perp}$, and*

$$\psi_g(E(x, u, s)) = \psi_0(\theta^{-1}h(x, g^*_{J-1})\, h(mg_J, u)) \qquad \text{for every } m \in N(g).$$

Proof. **Step 0: the flag.** By (Fp1), $h(g_a, g_b) = 0$ unless $a = b = r$, so $F_r(g)$ is totally isotropic and $g_b \in F_r(g)^{\perp}$ for $0 \le b \le r$; and $h(g_a, g^*_j) = \delta_{aj}$, so $h(F_j(g), g^*_j) = 0$. Let $w \in N(g)$ and $0 \le j < r$. For $z \in F_{j+1}(g)$, $wz - z \in F_j(g)$ (definition of $N(g)$). Moreover $wg_{j+1} - g_{j+1} \in F_{j+1}(g)$: if $j + 1 < r$ this is the condition for $j + 1$ applied to $g_{j+1} \in F_{j+2}(g)$; if $j + 1 = r$ it is the condition $wv - v \in F_r(g)$ for $v = g_r \in F_r(g)^{\perp}$.

Step 1: proof of (1). Let $w, w_1 \in N(g)$ and $z = w_1g_{j+1} - g_{j+1} \in F_{j+1}(g)$. Then $ww_1g_{j+1} = wg_{j+1} + z + (wz - z)$ with $wz - z \in F_j(g) \perp g^*_j$, so $c_j(ww_1) = c_j(w) + h(z, g^*_j) = c_j(w) + c_j(w_1) - h(g_{j+1}, g^*_j) = c_j(w) + c_j(w_1)$. As $\psi_g(w) = \psi_0(\theta^{-1}\sum_j c_j(w))$ and ψ_0 is a unitary character of $(E, +)$, ψ_g is a homomorphism into the unit circle. If w fixes $F_r(g)^{\perp}$ pointwise, $wg_{j+1} = g_{j+1}$ (Step 0), so $c_j(w) = 0$ for all j and $\psi_g(w) = 1$.

Step 2: isometry and inverse. Write $E = E(x,u,s)$. As $J \le r$, $x \in F_r(g)$, so $h(x,x) = 0$; and $h(x,u) = h(u,x) = 0$. For $v, w \in V$ put $\alpha = h(v,u)$, $\beta = h(v,x)$, $\alpha' = h(w,u)$, $\beta' = h(w,x)$. Then

$$h(Ev, Ew) = h(v,w) + \beta\bar{\beta}'\big(h(u,u) - s - \bar{s}\big) = h(v,w).$$

For $w = Ev$: $h(w,x) = \beta$ and $h(w,u) = \alpha - \beta h(u,u)$, so $E(x,-u,\bar{s})w = w - (\alpha - \beta h(u,u))x - \beta(-u + \bar{s}x) = v + \beta(h(u,u) - s - \bar{s})x = v$. The pair $(-u, \bar{s})$ satisfies the same hypotheses as (u,s), so also $E\,E(x,-u,\bar{s}) = 1$. Hence $E \in \mathrm{U}(V)$ and $E^{-1} = E(x,-u,\bar{s})$.

Step 3: $E \in N(g)$. For $v \in F_r(g)^\perp$, $h(v,x) = 0$, so $Ev - v = h(v,u)x \in F_J(g) \subseteq F_r(g)$; in particular $E(F_r(g)^\perp) \subseteq F_r(g)^\perp$ ($F_r(g) \subseteq F_r(g)^\perp$), and the same for E^{-1}, so $E(F_r(g)^\perp) = F_r(g)^\perp$. Let $0 \le j < r$ and $w \in F_{j+1}(g) \subseteq F_r(g) \subseteq F_r(g)^\perp$, so $Ew - w = h(w,u)x$. If $j+1 \le J$, then $w \in F_J(g)$ and $h(w,u) = 0$, so $Ew = w$; if $j \ge J$, then $x \in F_J(g) \subseteq F_j(g)$. In both cases $Ew - w \in F_j(g)$; hence $EF_{j+1}(g) \subseteq F_{j+1}(g)$, and equality holds by the same for E^{-1}. So $E \in N(g)$, and E fixes $F_J(g)$ pointwise.

Step 4: the character. By Step 0, $g_{j+1} \in F_r(g)^\perp$, so $Eg_{j+1} = g_{j+1} + h(g_{j+1},u)x$ and $c_j(E) = h(g_{j+1},u)\,h(x,g_j^*)$. If $j < J-1$, then $g_{j+1} \in F_J(g)$ and $h(g_{j+1},u) = 0$; if $j \ge J$, then $x \in F_J(g) \subseteq F_j(g)$ and $h(x,g_j^*) = 0$. So $\psi_g(E) = \psi_0(\theta^{-1}h(x,g_{J-1}^*)h(g_J,u))$. Finally, for $m \in N(g)$, Step 0 with $j = J-1$ gives $mg_J - g_J \in F_J(g)$, which is orthogonal to u; so $h(mg_J,u) = h(g_J,u)$. □

Lemma 16.35. *Let (V,h) be the hermitian space of a local frame pair. Let $e_1,\dots,e_m \in V$ be linearly independent over E with $h(e_i,e_j) = 0$ for all i,j, let X be their E-span and $X^\perp = \{w \in V : h(X,w) = 0\}$, and let $\Lambda_a, \Lambda_b \subseteq V$ be self-dual $\mathcal{O}_E$-modules with $\Lambda_a \cap X^\perp = \Lambda_b \cap X^\perp$. Then there is $g \in \mathrm{U}(V)$ with $gw = w$ for all $w \in X^\perp$ and $g\Lambda_a = \Lambda_b$.*

Proof. **Step 1: dual bases.** Since X is totally isotropic, $X \subseteq X^\perp$. $P = \Lambda_a \cap X$ is a finitely generated $\mathcal{O}_E$-module spanning X (Lemma 16.36(1)); X is free of rank m over E, so P (finitely generated, ϖ-torsion free) is free of rank m: let $b_1,\dots,b_m$ be a basis; it is an E-basis of X. Applying Lemma 16.36(1) to the coordinate functionals of this basis gives $c_1,\dots,c_m \in \Lambda_a$ with $h(b_k,c_j) = \delta_{kj}$, hence $h(c_j,b_k) = \delta_{jk}$. Also $b_k \in \Lambda_a \cap X^\perp = \Lambda_b \cap X^\perp$, so $b_k \in \Lambda_b$. For every $v \in V$,

$$v - \sum_j h(v,b_j)c_j \in X^\perp, \tag{16.4}$$

since its pairing with b_k is $h(v,b_k) - h(v,b_k) = 0$ and the b_k span X.

Step 2: translates of the c_j in Λ_b. $h(\Lambda_b \cap X^\perp, c_j) = h(\Lambda_a \cap X^\perp, c_j) \subseteq h(\Lambda_a,\Lambda_a) \subseteq \mathcal{O}_E$. Since h is nondegenerate, $(X^\perp)^\perp = X$, so Lemma 16.36(1) for Λ_b and $U = X^\perp$ gives $c_j \in \Lambda_b + X$: choose $c_j' \in \Lambda_b$ with $d_j^0 = c_j' - c_j \in X$. Put $H_{jk} = h(c_j,d_k^0) + h(d_j^0,c_k)$. As $h(d_j^0,d_k^0) = 0$, $H_{jk} = h(c_j',c_k') - h(c_j,c_k) \in \mathcal{O}_E$, and $\overline{H_{kj}} = H_{jk}$. Put

$$d_j = d_j^0 - \sum_l \tau H_{jl}\, b_l \in X.$$

Then $c_j + d_j = c_j' - \sum_l \tau H_{jl} b_l \in \Lambda_b$, $h(d_j,b_k) = h(d_j,d_k) = 0$, and

$$h(c_j,d_k) + h(d_j,c_k) = \big(h(c_j,d_k^0) - \bar{\tau}\overline{H_{kj}}\big) + \big(h(d_j^0,c_k) - \tau H_{jk}\big) = H_{jk} - (\tau + \bar{\tau})H_{jk} = 0.$$

Step 3: the isometry. Define $g(v) = v + \sum_j h(v,b_j)d_j$. It is E-linear, and $v \mapsto v - \sum_j h(v,b_j)d_j$ is its inverse because $h(d_j,b_k) = 0$. For $v \in V$ and k, (16.4) and $d_k \in X$

give $h(v,d_k)=\sum_j h(v,b_j)h(c_j,d_k)$, and likewise $h(d_j,w)=\sum_k \overline{h(w,b_k)}\,h(d_j,c_k)$. Hence, using $h(d_j,d_k)=0$,

$$\begin{aligned} h(gv,gw)-h(v,w) &= \sum_k \overline{h(w,b_k)}\,h(v,d_k)+\sum_j h(v,b_j)\,h(d_j,w)\\ &= \sum_{j,k} h(v,b_j)\overline{h(w,b_k)}\big(h(c_j,d_k)+h(d_j,c_k)\big)=0, \end{aligned}$$

so $g\in \mathrm{U}(V)$. If $w\in X^\perp$ then $h(w,b_j)=0$ and $gw=w$.

Step 4: $g\Lambda_a=\Lambda_b$. Let $v\in\Lambda_a$ and $\beta_j=h(v,b_j)\in\mathcal{O}_E$ ($b_j\in\Lambda_a$). Then $gv=(v-\sum_j\beta_j c_j)+\sum_j\beta_j(c_j+d_j)$; the first summand lies in $\Lambda_a\cap X^\perp=\Lambda_b\cap X^\perp$ by (16.4), the second in Λ_b. So $g\Lambda_a\subseteq\Lambda_b$. Conversely let $w\in\Lambda_b$ and $\beta_j=h(w,b_j)\in\mathcal{O}_E$ ($b_j\in\Lambda_b$). Then $g^{-1}w=(w-\sum_j\beta_j(c_j+d_j))+\sum_j\beta_j c_j$; the first summand lies in Λ_b and is orthogonal to every b_k (as $h(c_j+d_j,b_k)=\delta_{jk}$), so it lies in $\Lambda_b\cap X^\perp=\Lambda_a\cap X^\perp$, and the second lies in Λ_a. So $g^{-1}\Lambda_b\subseteq\Lambda_a$, and $g\Lambda_a=\Lambda_b$. □

Lemma 16.36. *Let (V,h) be the hermitian space of a local frame pair. Let $\Lambda,\Lambda'\subseteq V$ be self-dual $\mathcal{O}_E$-modules and $Q=\Lambda\cap\Lambda'$, let $U\subseteq V$ be an E-submodule, and put $U^\perp=\{w\in V : h(a,w)=0$ for all $a\in U\}$. Then:*

1. *$\Lambda\cap U$ is a finitely generated $\mathcal{O}_E$-module spanning U over E; every $\mathcal{O}_E$-linear map $\varphi\colon \Lambda\cap U\to\mathcal{O}_E$ is of the form $\varphi(a)=h(a,\lambda)$ for some $\lambda\in\Lambda$; and for $w\in V$, $h(\Lambda\cap U,w)\subseteq\mathcal{O}_E$ if and only if $w\in\Lambda+U^\perp$;*
2. *all indices below are finite and*

$$[\Lambda\cap U^\perp : Q\cap U^\perp]\cdot[\Lambda'\cap U : Q\cap U]=[\Lambda'\cap U^\perp : Q\cap U^\perp]\cdot[\Lambda\cap U : Q\cap U].$$

Proof. **Step 1: lattices.** Λ is finitely generated. If $W=E\Lambda$ were different from V, then $W^\perp\neq 0$ (as h has invertible Gram matrix), and $W^\perp\subseteq\{y : h(\Lambda,y)\subseteq\mathcal{O}_E\}=\Lambda$; but $W^\perp$ contains $\varpi^{-N}w$ for all N and some $w\neq 0$, so it is unbounded, while a finitely generated module is bounded. So Λ is a lattice in V, and $h(\Lambda,\Lambda)\subseteq\mathcal{O}_E$ since $\Lambda\subseteq\Lambda^\#=\Lambda$. Λ contains an E-basis $v_1,\dots,v_n$ of V; for $y=\sum_i c_i v_i\in U$ and N large, $\varpi^N c_i\in\mathcal{O}_E$, so $\varpi^N y\in\Lambda\cap U$. Hence $\Lambda\cap U$ (finitely generated, $\mathcal{O}_E$ being noetherian) spans U: it is a lattice in U; the same holds for Λ' and for $U^\perp$ in place of U.

Step 2: proof of (1). $\Lambda/(\Lambda\cap U)$ embeds into V/U, on which ϖ acts invertibly; so it is finitely generated and ϖ-torsion free, hence projective, and $\Lambda=(\Lambda\cap U)\oplus C$ for a submodule C. Given φ, let $\psi_0\colon\Lambda\to\mathcal{O}_E$ be φ on $\Lambda\cap U$ and 0 on C, and $\psi\colon V\to E$ its unique E-linear extension ($V=E\Lambda$, $\psi(v)=\varpi^{-N}\psi_0(\varpi^N v)$ for $\varpi^N v\in\Lambda$). As the Gram matrix of h is invertible, $\lambda\mapsto h(\cdot,\lambda)$ is a bijection of V onto the E-linear forms on V; so $\psi=h(\cdot,\lambda)$ for some $\lambda\in V$. Then $h(\Lambda,\lambda)=\psi_0(\Lambda)\subseteq\mathcal{O}_E$, so $\lambda\in\Lambda$ by self-duality, and $\varphi(a)=h(a,\lambda)$ on $\Lambda\cap U$. If $w=\lambda+z$ with $\lambda\in\Lambda$, $z\in U^\perp$, then $h(a,w)=h(a,\lambda)\in\mathcal{O}_E$ for $a\in\Lambda\cap U$. Conversely, if $h(\Lambda\cap U,w)\subseteq\mathcal{O}_E$, the map $a\mapsto h(a,w)$ is $\mathcal{O}_E$-linear into $\mathcal{O}_E$, so it equals $h(\cdot,\lambda)$ for some $\lambda\in\Lambda$; then $h(a,w-\lambda)=0$ for $a\in\Lambda\cap U$, hence for $a\in U$ (Step 1 and E-linearity in a), i.e. $w-\lambda\in U^\perp$.

Step 3: dual lattices. For a lattice P in W put $P^\vee=\{\phi\in\mathrm{Hom}_E(W,E) : \phi(P)\subseteq\mathcal{O}_E\}$, a lattice in $\mathrm{Hom}_E(W,E)$. For lattices $P\subseteq R$ in W, $R^\vee\subseteq P^\vee$ and $[P^\vee:R^\vee]=[R:P]$ (elementary divisors: a basis e_i of R with $\varpi^{a_i}e_i$ a basis of P gives the bases e_i^* of $R^\vee$ and $\varpi^{-a_i}e_i^*$ of $P^\vee$). Since $(P+P')^\vee=P^\vee\cap P'^\vee$, for any lattices P,P' in W:

$$[P^\vee : P^\vee\cap P'^\vee]=[P^\vee:(P+P')^\vee]=[P+P':P]=[P':P\cap P']. \tag{16.5}$$

Take $W = V$: the bijection $\lambda \mapsto h(\cdot, \lambda)$ is additive and maps $P^{\#} = \{y : h(P, y) \subseteq \mathcal{O}_E\}$ onto $P^{\vee}$; with $P = \Lambda$, $P' = \Lambda'$ (so $P^{\#} = \Lambda$, $P'^{\#} = \Lambda'$), (16.5) gives $[\Lambda : Q] = [\Lambda' : Q]$.

Step 4: the projection to U^*. Let $U^* = \mathrm{Hom}_E(U, E)$ and $\rho\colon V \to U^*$, $\rho(w)(a) = h(a, w)$. It is F-linear with kernel $U^{\perp}$, and surjective (a form on U extends to V and is then $h(\cdot, w)$). By (1), $\rho(\Lambda) = (\Lambda \cap U)^{\vee}$: $\rho(\Lambda) \subseteq (\Lambda \cap U)^{\vee}$ as $h(\Lambda, \Lambda) \subseteq \mathcal{O}_E$; and for $\phi \in (\Lambda \cap U)^{\vee}$, (1) gives $\lambda \in \Lambda$ with $\phi = \rho(\lambda)$ on $\Lambda \cap U$, hence on U. Likewise $\rho(\Lambda') = (\Lambda' \cap U)^{\vee}$. Write $Z = U^{\perp}$, fix Haar measures μ_Z on Z and μ^* on U^*, an F-linear section σ of ρ, and the Haar measure μ on $V = Z \oplus \sigma(U^*)$ with $\int_V f\,d\mu = \int_{U^*}\int_Z f(\sigma(\phi) + z)\,d\mu_Z(z)\,d\mu^*(\phi)$. For a compact open subgroup $P \subseteq V$ and $\phi \in U^*$, $\{z : \sigma(\phi) + z \in P\}$ is a coset of $P \cap Z$ if $\phi \in \rho(P)$ and empty otherwise, so

$$\mu(P) = \mu_Z(P \cap Z)\,\mu^*(\rho(P)).$$

For commensurable compact open subgroups P, P' of a vector space with Haar measure ν, $\nu(P) = [P : P \cap P']\,\nu(P \cap P')$, so $\nu(P)/\nu(P') = [P : P \cap P']/[P' : P \cap P']$.

Step 5: proof of (2). The indices are finite by Step 1. By Step 3, $\mu(\Lambda) = \mu(\Lambda')$; by Step 4,

$$\frac{\mu_Z(\Lambda \cap Z)}{\mu_Z(\Lambda' \cap Z)} = \frac{\mu^*((\Lambda' \cap U)^{\vee})}{\mu^*((\Lambda \cap U)^{\vee})} = \frac{[(\Lambda' \cap U)^{\vee} : (\Lambda \cap U)^{\vee} \cap (\Lambda' \cap U)^{\vee}]}{[(\Lambda \cap U)^{\vee} : (\Lambda \cap U)^{\vee} \cap (\Lambda' \cap U)^{\vee}]} = \frac{[\Lambda \cap U : Q \cap U]}{[\Lambda' \cap U : Q \cap U]},$$

the last equality by (16.5) in $W = U$ with $P = \Lambda \cap U$, $P' = \Lambda' \cap U$, $P \cap P' = Q \cap U$. The left side is $[\Lambda \cap Z : Q \cap Z]/[\Lambda' \cap Z : Q \cap Z]$. Cross-multiplying gives (2). □

Lemma 16.37. *The notation introduced here is local to this result and to the results that apply it. Let U be a finitely generated $\mathcal{O}_E$-module with a hermitian form h (E-linear in the first variable, $h(y, x) = \overline{h(x, y)}$) such that $h(U, U) \subseteq \mathcal{O}_E$ and*

$$U = \mathcal{O}_E e_1 \oplus \cdots \oplus \mathcal{O}_E e_\rho \oplus U', \qquad h(e_a, e_b) = 0 \ (a \neq b), \quad h(e_a, U') = 0, \quad h(e_a, e_a) \in \mathcal{O}_F^{\times},$$

with $\mathcal{O}_E e_a \cong \mathcal{O}_E$ and $\rho \geq 4$. Let du be the Haar probability measure on U, $a \geq 0$ an integer, $Z = \{u \in U : h(u, u) \in \varpi^a \mathcal{O}_F\}$, and L the set of $u \in U$ for which $h(u, e_1), \ldots, h(u, e_\rho)$ generate a proper ideal of $\mathcal{O}_E$. Then

1. *$|q^a \mathrm{vol}(Z) - 1| \leq \frac{8}{7} q^{1-\rho}$;*
2. *$q^a \mathrm{vol}(Z \cap L) \leq \frac{16}{7} q^{1-\rho}$;*
3. *for every nontrivial continuous character ϕ of the additive group U, $q^a \left|\int_Z \phi(u)\,du\right| \leq \frac{8}{7} q^{1-\rho}$.*

Proof. Write $v_E(x) = \max\{m : x \in \varpi^m \mathcal{O}_E\}$ for $0 \neq x \in \mathcal{O}_E$. As E/F is unramified or split, $|\mathcal{O}_E/\varpi\mathcal{O}_E| = q^2$, the maximal ideals of $\mathcal{O}_E$ are $\varpi\mathcal{O}_E$ (field case) or $\mathfrak{p}_1 = \varpi\mathcal{O}_F \times \mathcal{O}_F$ and $\mathfrak{p}_2 = \mathcal{O}_F \times \varpi\mathcal{O}_F$ (split case), and $\{\mathrm{Tr}(cx) : c \in \mathcal{O}_E\} = \varpi^{v_E(x)}\mathcal{O}_F$ (the trace maps $\mathcal{O}_E$ onto $\mathcal{O}_F$, and $x\varpi^{-v_E(x)}$ is a unit, resp. has a unit component). All characters below are continuous, and dc is the Haar probability measure of $\mathcal{O}_E$.

Step 1: expansion of the condition. For $x \in \mathcal{O}_F$, $\mathbf{1}[x \in \varpi^a \mathcal{O}_F] = q^{-a} \sum_\chi \chi(x)$, the sum over the q^a characters χ of $\mathcal{O}_F/\varpi^a\mathcal{O}_F$. The *conductor* of χ is the least $i \geq 0$ with $\chi(\varpi^i \mathcal{O}_F) = 1$; there are $q^i - q^{i-1}$ characters of conductor exactly $i \geq 1$ (those trivial on $\varpi^i\mathcal{O}_F$ are the q^i characters of $\mathcal{O}_F/\varpi^i\mathcal{O}_F$), and only $\chi = 1$ has conductor 0.

Step 2: one coordinate. Let χ have conductor $i \geq 1$, $\varepsilon \in \mathcal{O}_F^{\times}$, ϕ_1 a character of $\mathcal{O}_E$, and D either $\mathcal{O}_E$ or a maximal ideal of $\mathcal{O}_E$. We show $|G| \leq q^{-i}$ for $G = \int_D \chi(\varepsilon \mathrm{N}(c))\phi_1(c)\,dc$. Since $\mathrm{N}(c' + \delta) = \mathrm{N}(c') + \mathrm{N}(\delta) + \mathrm{Tr}(c'\bar{\delta})$ and D is an additive group, substituting $c = c' + \delta$,

$$|G|^2 = \int_D \chi(\varepsilon \mathrm{N}(\delta))\phi_1(\delta)\Big(\int_D \chi(\varepsilon\,\mathrm{Tr}(c'\bar{\delta}))\,dc'\Big)d\delta \leq \mathrm{vol}(D)\,\mathrm{vol}(D_\chi),$$

because the inner integral of a character over the group D is $\mathrm{vol}(D)$ if it is trivial and 0 otherwise; D_χ is the set of $\delta \in D$ with $\chi(\varepsilon \mathrm{Tr}(D\bar{\delta})) = 1$. If $\mathrm{Tr}(D\bar{\delta}) = \varpi^m \mathcal{O}_F$ with $m \le i-1$, then χ is nontrivial on it (ε is a unit); so $\delta \in D_\chi$ forces $m \ge i$. For $D = \mathcal{O}_E$: $m = v_E(\delta)$, $D_\chi \subseteq \varpi^i \mathcal{O}_E$, and $|G|^2 \le q^{-2i}$. For $D = \varpi \mathcal{O}_E$: $m = 1 + v_E(\delta)$, $D_\chi \subseteq \varpi^{\max(1,i-1)}\mathcal{O}_E$, and $|G|^2 \le q^{-2}q^{-2\max(1,i-1)} \le q^{-2i}$. For $D = \mathfrak{p}_1$ (and symmetrically $\mathfrak{p}_2$): with $c' = (c_1, c_2)$, $\delta = (\delta_1, \delta_2)$, $\bar{\delta} = (\delta_2, \delta_1)$, $\mathrm{Tr}(c'\bar{\delta}) = c_1\delta_2 + c_2\delta_1$ ranges over $\varpi^{\min(1+v(\delta_2), v(\delta_1))}\mathcal{O}_F$; so $D_\chi \subseteq \varpi^i \mathcal{O}_F \times \varpi^{i-1}\mathcal{O}_F$, of volume $q^{-i}q^{-(i-1)}$, and $|G|^2 \le q^{-1}q^{-(2i-1)} = q^{-2i}$.

Step 3: factorisation. Write $u = \sum_a c_a e_a + u'$; the Haar probability measure of U is the product of dc on each $\mathcal{O}_E e_a$ and the Haar probability measure du' of U', and $h(u,u) = \sum_a \varepsilon_a \mathrm{N}(c_a) + h(u',u')$ with $\varepsilon_a = h(e_a, e_a) \in \mathcal{O}_F^\times$ and $h(u',u') \in \mathcal{O}_E \cap F = \mathcal{O}_F$. A character ϕ of U is $\phi(u) = \prod_a \phi(c_a e_a) \cdot \phi(u')$. Hence, for $D_1, \dots, D_\rho \in \{\mathcal{O}_E\} \cup \{\text{maximal ideals}\}$ and χ of conductor $i \ge 1$,

$$\Big| \int_{D_1 e_1 \oplus \cdots \oplus D_\rho e_\rho \oplus U'} \chi(h(u,u))\phi(u)\, du \Big| = \prod_a \Big| \int_{D_a} \chi(\varepsilon_a \mathrm{N}(c))\phi(ce_a)\, dc \Big| \cdot \Big| \int_{U'} \chi(h(u',u'))\phi(u')\, du' \Big| \le q^{-i\rho}$$

by Step 2 (the last factor has modulus at most 1). Since $q \ge 2$ and $\rho \ge 4$, $q^{1-\rho} \le \frac{1}{8}$ and

$$\sum_{i \ge 1} (q^i - q^{i-1}) q^{-i\rho} = \Big(1 - \frac{1}{q}\Big) \frac{q^{1-\rho}}{1 - q^{1-\rho}} \le \frac{8}{7}\Big(1 - \frac{1}{q}\Big) q^{1-\rho}.$$

Step 4: the three bounds. By Step 1, $q^a \int_Y \mathbf{1}_Z \phi\, du = \sum_\chi \int_Y \chi(h(u,u))\phi(u)\, du$ for every product set Y as in Step 3 and every character ϕ (possibly trivial). (1): $Y = U$, $\phi = 1$; the term $\chi = 1$ is 1, the others contribute at most $\frac{8}{7}q^{1-\rho}$ by Step 3. (3): $Y = U$; the term $\chi = 1$ is $\int_U \phi = 0$ as ϕ is nontrivial, and the others contribute at most $\frac{8}{7}q^{1-\rho}$. (2): if the $h(u, e_a) = c_a \varepsilon_a$ generate a proper ideal, it lies in a maximal ideal $\mathfrak{p}$, and then all $c_a \in \mathfrak{p}$ (ε_a is a unit); so $L \subseteq \bigcup_{\mathfrak{p}} Y_{\mathfrak{p}}$ with $Y_{\mathfrak{p}} = \mathfrak{p}e_1 \oplus \cdots \oplus \mathfrak{p}e_\rho \oplus U'$, over the at most two maximal ideals. For each, with $\phi = 1$, the term $\chi = 1$ is $\mathrm{vol}(Y_{\mathfrak{p}}) \le q^{-\rho}$ and the others contribute at most $\frac{8}{7}(1 - \frac{1}{q})q^{1-\rho}$, so

$$q^a \mathrm{vol}(Z \cap Y_{\mathfrak{p}}) \le q^{1-\rho}\Big(\frac{1}{q} + \frac{8}{7} - \frac{8}{7q}\Big) \le \frac{8}{7} q^{1-\rho},$$

and summing over at most two maximal ideals gives (2). □

Theorem 16.38. *Let $r \ge 0$ and $k \ge 2r+3$ be integers and let local non-generic records with parameters r, k have the properties (Lg1)–(Lg5). Then*

$$\sum_{d \in D} \nu(d) \left|\mathrm{amp}_d(X_d^{\mathrm{n}})\right|^2 \le H^{39(r+1)^2} q^{-(k-2r-5)}\, \mathrm{nn}, \qquad \sum_{d \in D} \nu(d) \left|\mathrm{amp}_d(X_d^{\mathrm{g}})\right|^2 \le H^{39(r+1)^2}\, \mathrm{nn}.$$

Proof. Put $A_0 = H^{9(r+1)^2 + 12(r+1)}$, $A_1 = 4H^{4(r+1)}$ and, for a family $Y = (Y_d)_{d \in D}$ of Σ-stable subsets $Y_d \subseteq X_d$, $\mathrm{S}(Y) = \sum_d \nu(d) |\mathrm{amp}_d(Y_d)|^2$. We have $k - 1 \ge 2$, so $x = q^{k-1} \ge 2$ and $\sum_{j=0}^n x^j \le 2x^n$ for $n \ge 0$.

Step 1: the basic inequality. If $B, \varepsilon \ge 0$, $\mathrm{mass}_d(Y_d) \le B$ and $|\mathrm{amp}_d(Y_d)| \le \varepsilon\, \mathrm{mass}_d(Y_d)$ for every d, then

$$\mathrm{S}(Y) \le \sum_d \nu(d) \varepsilon^2 \mathrm{mass}_d(Y_d)^2 \le \varepsilon^2 B \sum_d \nu(d)\, \mathrm{mass}_d(Y_d).$$

Since $|\omega_d| \le 1$, the hypothesis $|\mathrm{amp}_d(Y_d)| \le \mathrm{mass}_d(Y_d)$ holds always ($\varepsilon = 1$).

Step 2: mass bounds per datum. Let $i \ge 0$ and $Y_d \subseteq \{x \in X_d : b_d(x) = q^i\}$ be Σ-stable. By (Lg2) every $x \in Y_d$ has $c_d(x) = q^j$ with $0 \le j \le i$, so by (Lg3) and mass_d being additive over disjoint stable sets,

$$\mathrm{mass}_d(Y_d) \le \sum_{j=0}^{i} A_0 q^{j(k-1)} \le 2A_0 q^{i(k-1)}.$$

If moreover $i \ge 1$ and $Y_d \cap X_d^{\mathrm{II}} = \varnothing$, then (Lg2) gives $q^j \le q^{i-1}$, i.e. $j \le i-1$, and $\mathrm{mass}_d(Y_d) \le 2A_0 q^{(i-1)(k-1)}$. In all cases, by (Lg4) with $\beta = q^i$,

$$\sum_d \nu(d)\,\mathrm{mass}_d(Y_d) \le A_1 q^{-i(k-1)}\,\mathrm{nn}.$$

Step 3: the generic terms. On X_d^{g} we have $c_d \le b_d = 1$, hence $c_d = 1$, so $\mathrm{mass}_d(X_d^{\mathrm{g}}) \le A_0$ by (Lg3), and $\sum_d \nu(d)\mathrm{mass}_d(X_d^{\mathrm{g}}) \le \mathrm{nn}$; Step 1 with $\varepsilon = 1$, $B = A_0$ gives $\mathrm{S}(X^{\mathrm{g}}) \le A_0\,\mathrm{nn} \le H^{39(r+1)^2}\mathrm{nn}$, as $H \ge 1$ and $9(r+1)^2 + 12(r+1) \le 39(r+1)^2$.

Step 4: the pieces of the non-generic terms. If $a = 0$, (Lg1) gives $b_d \equiv 1$, every X_d^{n} is empty and the first bound is trivial. Let $a \ge 1$; then $H \ge q^a \ge 2$. For $1 \le i \le a$ let $Y_d^{\mathrm{I},i} = \{x \in X_d^{\mathrm{n}} \setminus X_d^{\mathrm{II}} : b_d(x) = q^i\}$, and for $\lambda \in \{1,\dots,r\} \times \{0,\dots,i-1\}$ let $Y_d^{i,\lambda} = \{x \in X_d^{\mathrm{II}} : b_d(x) = q^i,\ \lambda_d(x) = \lambda\}$. These sets are Σ-stable (b_d, λ_d, X_d^{II} are), pairwise disjoint, and by (Lg1) (a non-generic term has $b_d = q^i$ with $1 \le i \le a$) and (Lg5) ($X_d^{\mathrm{II}} \subseteq X_d^{\mathrm{n}}$ and the range of λ_d) their union is X_d^{n}. Their number is

$$N \le a + a \cdot ra = a(1+ra) \le 2^a \cdot 2^{ra} \le q^{a(r+1)} \le H^{r+1}.$$

First type. By Steps 1 and 2 ($\varepsilon = 1$, $B = 2A_0 q^{(i-1)(k-1)}$), $\mathrm{S}(Y^{\mathrm{I},i}) \le 2A_0 q^{(i-1)(k-1)} A_1 q^{-i(k-1)}\mathrm{nn} = 2A_0A_1 q^{-(k-1)}\mathrm{nn}$.

Second type. Fix d, i, λ and $\mathcal{P} = Y_d^{i,\lambda}$. By (Lg5) there is a kernel m on $\mathcal{P}$, and Lemma 16.39 applies to G, X, Σ, K_0, $\mathcal{P}$, $\omega_d|_{\mathcal{P}}$, m and $e = \frac{24}{7} q^{-(k-2r-4)}$: $\mathcal{P}$ is Σ-stable and a union of finitely many orbits (as X_d is), (Vk1) is the volume condition of the records, (Vk2) holds as ω_d and m are Σ-invariant with $|\omega_d| \le 1$, and (Vk3), (Vk4) are (Lg5). Its conclusion is $|\mathrm{amp}_d(\mathcal{P})| \le 2e\,\mathrm{mass}_d(\mathcal{P}) \le 7q^{-(k-2r-4)}\mathrm{mass}_d(\mathcal{P})$. Steps 1 and 2 with $\varepsilon = 7q^{-(k-2r-4)}$ and $B = 2A_0 q^{i(k-1)}$ give

$$\mathrm{S}(Y^{i,\lambda}) \le 49q^{-2(k-2r-4)} \cdot 2A_0 q^{i(k-1)} \cdot A_1 q^{-i(k-1)}\mathrm{nn} = 98A_0A_1 q^{-2(k-2r-4)}\mathrm{nn}.$$

Comparison. Since $k-1 \ge k-2r-5$ and $2(k-2r-4) \ge k-2r-5$ (this is $k \ge 2r+3$), and $q \ge 2$, every piece has $\mathrm{S}(Y) \le 98A_0A_1 q^{-(k-2r-5)}\mathrm{nn}$.

Step 5: Cauchy–Schwarz over the pieces. For each d, $\mathrm{amp}_d(X_d^{\mathrm{n}})$ is the sum of the N amplitudes of the pieces, so $|\mathrm{amp}_d(X_d^{\mathrm{n}})|^2 \le N \sum_Y |\mathrm{amp}_d(Y_d)|^2$; multiplying by $\nu(d)$ and summing over d,

$$\begin{aligned}\mathrm{S}(X^{\mathrm{n}}) \le N \sum_Y \mathrm{S}(Y) &\le N^2 \cdot 98A_0A_1 q^{-(k-2r-5)}\mathrm{nn} \\ &\le 392\, H^{2(r+1)+9(r+1)^2+12(r+1)+4(r+1)} q^{-(k-2r-5)}\mathrm{nn}.\end{aligned}$$

As $H \ge 2$, $392 \le 2^9 \le H^9$, and with $x = r+1 \ge 1$ the exponent is $9x^2 + 18x + 9 = 9(x+1)^2 \le 36x^2 \le 39x^2$. This is the first bound. □

Lemma 16.39. *The notation introduced here is local to this result and to the results that apply it. Let G be a group acting on a set X, $\Sigma \subseteq G$ a subgroup and $K_0 \subseteq \Sigma$ a subgroup. A subgroup $A \subseteq G$ is **commensurable with** K_0 if $[A : A \cap K_0]$ and $[K_0 : A \cap K_0]$ are finite; then put*

$$\operatorname{vol}(A) = \frac{[A : A \cap K_0]}{[K_0 : A \cap K_0]} \in (0, \infty).$$

For $x \in X$ let $\Sigma_x = \{g \in \Sigma : gx = x\}$. Let $\mathcal{P} \subseteq X$ be a Σ-stable subset that is the union of finitely many Σ-orbits, $\omega \colon \mathcal{P} \to \mathbb{C}$, $m \colon \mathcal{P} \times \mathcal{P} \to [0, \infty)$ and $e \geq 0$ such that

(Vk1) Volumes *for every $x \in \mathcal{P}$, Σ_x is commensurable with K_0, and $\operatorname{vol}(\Sigma_{gx}) = \operatorname{vol}(\Sigma_x)$ for $g \in \Sigma$;*

(Vk2) Invariance *$\omega(gx) = \omega(x)$ and $m(gx, gy) = m(x, y)$ for all $g \in \Sigma$ and $x, y \in \mathcal{P}$, and $|\omega(x)| \leq 1$;*

(Vk3) Symmetric finite kernel *$m(x, y) = m(y, x)$, and for every x the set $\{y \in \mathcal{P} : m(x, y) \neq 0\}$ is finite;*

(Vk4) Averaging *for every $x \in \mathcal{P}$,*

$$\Big|\sum_{y \in \mathcal{P}} m(x, y) - 1\Big| \leq e, \qquad \Big|\sum_{y \in \mathcal{P}} m(x, y)\, \omega(y)\Big| \leq e.$$

Put $\mu(x) = 1/\operatorname{vol}(\Sigma_x)$ for $x \in \mathcal{P}$. Then μ and ω are constant on Σ-orbits, and

$$\Big|\sum_{O \in \Sigma \backslash \mathcal{P}} \mu(O)\, \omega(O)\Big| \leq 2e \sum_{O \in \Sigma \backslash \mathcal{P}} \mu(O).$$

Proof. **Step 1: indices as volume ratios.** Let $B \subseteq A$ be subgroups of G commensurable with K_0. Then $[A : B]$ is finite and $[A : B] = \operatorname{vol}(A)/\operatorname{vol}(B)$. Indeed, put $A_0 = A \cap K_0 \supseteq B_0 = B \cap K_0$; $[K_0 : B_0]$ is finite and $[K_0 : B_0] = [K_0 : A_0][A_0 : B_0]$, so $[A_0 : B_0]$ is finite, and $[A : B_0] = [A : A_0][A_0 : B_0]$ is finite, hence so is $[A : B]$, with $[A : B][B : B_0] = [A : B_0]$. Therefore

$$\frac{\operatorname{vol}(A)}{\operatorname{vol}(B)} = \frac{[A : A_0]\,[K_0 : B_0]}{[K_0 : A_0]\,[B : B_0]} = \frac{[A : A_0][A_0 : B_0]}{[B : B_0]} = \frac{[A : B_0]}{[B : B_0]} = [A : B].$$

If A, B are commensurable with K_0, so is $A \cap B$: $[K_0 : K_0 \cap A \cap B] \leq [K_0 : K_0 \cap A][K_0 : K_0 \cap B]$, and $[A \cap B : A \cap B \cap K_0] \leq [A : A \cap K_0]$ since $A \cap B \cap K_0 = (A \cap B) \cap (A \cap K_0)$.

Step 2: the pair weight. For $g \in \Sigma$, $\Sigma_{gx} = g \Sigma_x g^{-1}$; with (Vk1) and (Vk2), μ and ω are constant on Σ-orbits. For $x, y \in \mathcal{P}$ put

$$\nu(x, y) = \mu(x)\,[\Sigma_x : \Sigma_x \cap \Sigma_y] = \frac{1}{\operatorname{vol}(\Sigma_x \cap \Sigma_y)},$$

the equality by Step 1 applied to $\Sigma_x \cap \Sigma_y \subseteq \Sigma_x$. So $\nu(x, y) = \nu(y, x)$. For $g \in \Sigma$, conjugation by g carries $\Sigma_x \cap \Sigma_y$ onto $\Sigma_{gx} \cap \Sigma_{gy}$ and Σ_x onto Σ_{gx}, so the index is unchanged, and $\mu(gx) = \mu(x)$; hence $\nu(gx, gy) = \nu(x, y)$. The Σ_x-orbit of y has $[\Sigma_x : \Sigma_x \cap \Sigma_y]$ elements, the stabiliser of y in Σ_x being $\Sigma_x \cap \Sigma_y$.

Step 3: an exchange identity. Fix representatives $x_1, \dots, x_n$ of the Σ-orbits in $\mathcal{P}$. Let $\Phi\colon \mathcal{P}\times\mathcal{P}\to\mathbb{C}$ satisfy $\Phi(gx,gy)=\Phi(x,y)$ for $g\in\Sigma$ and vanish outside $\{(x,y): m(x,y)\neq 0\}$. We claim

$$\sum_{i=1}^{n}\mu(x_i)\sum_{y\in\mathcal{P}}\Phi(x_i,y)=\sum_{i=1}^{n}\mu(x_i)\sum_{y\in\mathcal{P}}\Phi(y,x_i), \tag{16.6}$$

all sums being finite by (Vk3) (the support of $y\mapsto\Phi(y,x_i)$ lies in $\{y: m(y,x_i)\neq 0\}=\{y: m(x_i,y)\neq 0\}$). Let $\mathcal{O}$ be the set of Σ-orbits on $\mathcal{P}\times\mathcal{P}$ (diagonal action). Each $Q\in\mathcal{O}$ contains pairs with first entry x_i for exactly one i, and those pairs form one Σ_{x_i}-orbit $\{(x_i,sy): s\in\Sigma_{x_i}\}$: if $(x_i,y),(x_i,y')\in Q$ then $(x_i,y')=g(x_i,y)$ with $g\in\Sigma$, $gx_i=x_i$. Grouping the inner sum on the left of (16.6) by Σ_{x_i}-orbits of y and using Step 2,

$$\sum_{i}\mu(x_i)\sum_{y}\Phi(x_i,y)=\sum_{Q\in\mathcal{O}}\nu(Q)\,\Phi(Q),$$

where $\nu(Q)$ and $\Phi(Q)$ are the values at any pair of Q (both are Σ-invariant), and only the finitely many Q with $\Phi(Q)\neq 0$ contribute. The same identity for $\Phi^{\top}(x,y)=\Phi(y,x)$ (which is Σ-invariant and vanishes outside $\{m\neq 0\}$, m being symmetric) gives the right side of (16.6) as $\sum_Q\nu(Q)\Phi(Q^{\top})$, $Q^{\top}$ the image of Q under $(x,y)\mapsto(y,x)$. As $Q\mapsto Q^{\top}$ is a bijection of $\mathcal{O}$ and $\nu(Q^{\top})=\nu(Q)$ by the symmetry of ν, the two sums agree.

Step 4: the bound. Put $R(x)=\sum_y m(x,y)$. Then

$$\sum_{i}\mu(x_i)\omega(x_i)=\sum_{i}\mu(x_i)\omega(x_i)\bigl(1-R(x_i)\bigr)+\sum_{i}\mu(x_i)\sum_{y}m(x_i,y)\,\omega(x_i).$$

The first sum has modulus at most $e\sum_i\mu(x_i)$ by $|\omega|\le 1$ and (Vk4). In the second apply (16.6) to $\Phi(x,y)=m(x,y)\omega(x)$, which is Σ-invariant by (Vk2): it equals $\sum_i\mu(x_i)\sum_y m(y,x_i)\omega(y)=\sum_i\mu(x_i)\sum_y m(x_i,y)\omega(y)$, of modulus at most $e\sum_i\mu(x_i)$ by (Vk3) and (Vk4). Adding, and noting that the sums over i are the sums over $\Sigma\backslash\mathcal{P}$, gives the claim. □

Lemma 16.40. *The notation introduced here is local to this result and to the results that apply it. Let $r\ge 0$, $k\ge 2r+5$, $C_1,C_0\ge 0$ be integers and put $e_{\mathrm{ng}}=(C_1+C_0)(r+1)^2+2(2r+2)+5$. Let Π be a finite set (the places), $\Omega\subseteq\Pi$, and for $p\in\Pi$ let D_p be a finite set, $\mathrm{wt}_p\colon D_p\to[0,\infty)$, $a_p^{\mathrm{N}},a_p^{\mathrm{Z}}\colon D_p\to\mathbb{C}$, and $H_p\ge 1$, $n_p\ge 0$, $n_p^{\circ}\ge 0$ real numbers and $q_p\ge 2$ integers with $q_p\le H_p$ for $p\in\Omega$. Let $V\ge 0$, let X be a finite set with $\rho\colon X\to[0,\infty)$ and $d\colon X\to\prod_{p\in\Pi}D_p$. Assume:*

1. *for $p\in\Omega$,*
$$\sum_{\delta\in D_p}\mathrm{wt}_p(\delta)|a_p^{\mathrm{N}}(\delta)|^2\le H_p^{C_1(r+1)^2}q_p^{-(k-2r-5)}n_p,$$
and for every $p\in\Pi$,
$$\sum_{\delta\in D_p}\mathrm{wt}_p(\delta)|a_p^{\mathrm{Z}}(\delta)|^2\le H_p^{C_1(r+1)^2}n_p;$$
2. *$n_p=n_p^{\circ}$ for $p\notin\Omega$, and $n_p\le 8H_p^{C_0(r+1)^2+2(2r+2)}n_p^{\circ}$ for $p\in\Omega$;*
3. *for every $\delta\in\prod_p D_p$, $\sum_{x\in X,\ d(x)=\delta}\rho(x)\le V\prod_{p\in\Pi}\mathrm{wt}_p(\delta_p)$.*

For $\delta\in\prod_p D_p$ put

$$\mathrm{amp}(\delta)=\sum_{\emptyset\neq B\subseteq\Omega}\prod_{p\in B}a_p^{\mathrm{N}}(\delta_p)\prod_{p\in\Pi\backslash B}a_p^{\mathrm{Z}}(\delta_p).$$

Then

$$\sum_{x\in X}\rho(x)\,|\mathrm{amp}(d(x))|^2\le 2^{-(k-2r-5)}\Bigl(\prod_{p\in\Pi}H_p\Bigr)^{e_{\mathrm{ng}}}V\prod_{p\in\Pi}n_p^{\circ}.$$

Proof. If $\Omega = \emptyset$ the sum defining amp is empty, the left side is 0 and the right side is nonnegative. Let $\Omega \neq \emptyset$, let $\mathcal{B}$ be the set of nonempty subsets of Ω, so $|\mathcal{B}| \le 2^{|\Omega|}$, and put $H = \prod_p H_p \ge 1$. For $B \in \mathcal{B}$ and $p \in \Pi$ let $b_p^B = a_p^{\mathrm{N}}$ if $p \in B$ and $b_p^B = a_p^{\mathrm{Z}}$ otherwise, and $\Phi_B(\delta) = \prod_p |b_p^B(\delta_p)|^2 \ge 0$.

Cauchy–Schwarz over the subsets. $|\mathrm{amp}(\delta)|^2 \le |\mathcal{B}| \sum_{B \in \mathcal{B}} \Phi_B(\delta)$.

Unfolding to the local sums. Grouping $x \in X$ by $d(x)$ and using (3) and $\Phi_B \ge 0$,

$$\sum_{x \in X} \rho(x) \Phi_B(d(x)) = \sum_{\delta \in d(X)} \Phi_B(\delta) \sum_{d(x) = \delta} \rho(x) \le V \sum_{\delta \in \prod_p D_p} \prod_p \mathrm{wt}_p(\delta_p) |b_p^B(\delta_p)|^2$$
$$= V \prod_{p \in \Pi} \Big(\sum_{\delta \in D_p} \mathrm{wt}_p(\delta) |b_p^B(\delta)|^2 \Big).$$

The gain. By (1) the product is at most $H^{C_1(r+1)^2} \prod_p n_p \prod_{p \in B} q_p^{-(k-2r-5)}$. As $k - 2r - 5 \ge 0$ and $q_p \ge 2$, each factor $q_p^{-(k-2r-5)}$ is at most 1, and since $B \neq \emptyset$ one of them is at most $2^{-(k-2r-5)}$. By (2) and $H_p \ge 1$, $\prod_p n_p \le 8^{|\Omega|} H^{C_0(r+1)^2 + 2(2r+2)} \prod_p n_p^\circ$. Hence

$$\sum_{x \in X} \rho(x) |\mathrm{amp}(d(x))|^2 \le |\mathcal{B}|^2 \, 8^{|\Omega|} \, 2^{-(k-2r-5)} H^{(C_1 + C_0)(r+1)^2 + 2(2r+2)} \, V \prod_p n_p^\circ.$$

The combinatorial factor. $|\mathcal{B}|^2 8^{|\Omega|} \le 32^{|\Omega|} \le \prod_{p \in \Omega} q_p^5 \le \prod_{p \in \Omega} H_p^5 \le H^5$, since $q_p \ge 2$, $q_p \le H_p$ on Ω and $H_p \ge 1$. This gives the claim with exponent e_{ng}.

□

17 The class and its universal properties

This section defines the class $\mathcal{A}_{\mathrm{prop}}$ and proves the two results for which Part III exists: Theorem 17.7, the universal properties of the class, and Proposition 17.6, the third input of Part I. The class is defined by lower conditions only. A family belongs to it if it has the linking property and the properties of its tops (Pc1), and if, whenever it satisfies the Sha condition, it carries one compatible collection of modification data, defect data, bridge, numerical, local defect, local bound and Ribet records, and frame, expansion, kernel, row and budget data, with the properties (Pc2)–(Pc6). Each of these is a hypothesis of a theorem of Sections 12–16 or of the Ribet budget Theorem 22.1; none of the properties (Sp3), (Sp4), (Sp5) and (Sp8) is required. The class is defined in this way because Part IV must show that it contains a family at every small ε: it asks for data and their lower properties, which a construction can be asked to supply, and the inequalities that follow from them are proved, here and in Part IV, rather than assumed. The four definitions before the class introduce the budget data for the local allowances, the Galois Ribet data, the inert budget data and the coefficient extensions of Hecke lattices, which (Pc5) asks for together with the hypotheses of the Ribet budget.

The proof of Theorem 17.7 is an assembly of the earlier sections, in the order in which their outputs are needed: (Sp3) from Section 12, (Sp4) from Section 13 with the Ribet budget, (Sp5) from Sections 14–16, (Sp8) from Lemma 12.1, while (Sp1), (Sp2), (Sp6) and (Sp7) are (Pc2). With Theorem 8.4 of Part I this gives slope data at the members with exponents $(1, 0)$. The only number in the argument that is the same for every family of the class is the divisor exponent 1, and hence the pair $(1, 0)$; all other constants and thresholds may depend on the family. Proposition 17.6 then takes the concrete good-host requirement for $\mathfrak{G}$, so that (Gh1) is Proposition 11.5; (Lk1) is design existence, Proposition 18.1 of Part IV, which is where (TCS) enters; and (Lk2), (Lk3) and (Lk5) are Theorem 17.7.

Definition 17.1. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε and threshold x_1, with local defect data and local bound records. **Budget data** for $\mathcal{F}$ consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$:

- an integer $\varrho_{x,i} \geq 1$, the **base rank**, and real numbers $H_{x,i} \geq 1$, the **weight bound**, and $\ell^*_{x,i} \geq 3$, the **cut-off**;
- finite sets of primes $\mathcal{P}^{\mathrm{sm}}_{x,i}$, $\mathcal{P}^{\mathrm{rm}}_{x,i}$, $\mathcal{P}^{\mathrm{in}}_{x,i}$ and $\mathcal{P}^{\mathrm{ex}}_{x,i}$, the **small**, **ramified**, **inert** and **exceptional primes**.

For a member (x,i) write $t = t_{x,i}$, $\varrho = \varrho_{x,i}$, $H = H_{x,i}$, $\ell^* = \ell^*_{x,i}$ and $Y = f\,m\,b\,x^{2\varepsilon}$. A prime $\ell \in P_{x,i} \setminus G_{x,i}$ is of **small type** if $\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i} \cup \mathcal{P}^{\mathrm{rm}}_{x,i}$; otherwise it is of **inert type** if $\ell \in \mathcal{P}^{\mathrm{in}}_{x,i}$ and ($\ell \leq \ell^*$ or $\ell \in \mathcal{P}^{\mathrm{ex}}_{x,i}$), of **split type** if $\ell \notin \mathcal{P}^{\mathrm{in}}_{x,i}$ and ($\ell \leq \ell^*$ or $\ell \in \mathcal{P}^{\mathrm{ex}}_{x,i}$), and **large** if $\ell > \ell^*$ and $\ell \notin \mathcal{P}^{\mathrm{ex}}_{x,i}$. The four types partition $P_{x,i} \setminus G_{x,i}$; the set of large primes is written $\mathcal{P}^{\mathrm{lg}}_{x,i}$. The budget data have

(Lz1) Sizes if there is a real C such that for all large members with finite Sha lengths: $1 \leq m \leq t$, $\varrho \leq t$, $t \leq b$, $H \leq C\,b$,

$$\ell^*\,n\,t^2(\varrho+t)\,x^{2\varepsilon} \leq C\,m\,b, \qquad |\mathcal{P}^{\mathrm{ex}}_{x,i}|\Big(1+\frac{b}{\ell^*}\Big)n\,t^2(\varrho+t) \leq C\,m\,b,$$

and $\ell \leq 3b$ for every $\ell \in \mathcal{P}^{\mathrm{ex}}_{x,i}$;

(Lz2) Small type if there is a real C such that for all large members with finite Sha lengths the following hold:

- $\mathrm{la}_{x,i}(\ell) \leq C\big(f\,m\,b\log x + x^C x^{2\varepsilon}\big)$ for $\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i} \setminus G_{x,i}$, and $\sum_{\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i}} \log \ell \leq C\,x^{\varepsilon}$;
- $\mathrm{la}_{x,i}(\ell) \leq C\,f\,m\,b$ and $\log \ell \leq x^{\varepsilon}$ for $\ell \in \mathcal{P}^{\mathrm{rm}}_{x,i}$;
- $|\mathcal{P}^{\mathrm{rm}}_{x,i}| \leq 2$;

(Lz3) Inert type if there is a real C such that for all large members with finite Sha lengths $\sum \log \ell \cdot \mathrm{la}_{x,i}(\ell) \leq C\,Y$, where the sum runs over the primes of inert type;

(Lz4) Split type if there is a real C such that for all large members with finite Sha lengths and every prime ℓ of split type

$$\mathrm{la}_{x,i}(\ell) \leq C\,f\Big(n\,t^2(\varrho+t)(1+\log_\ell(H+t)) + \frac{m\,H}{\ell}\Big);$$

(Lz5) Large primes if for all large members with finite Sha lengths $\mathrm{la}_{x,i}(\ell) \leq \ell^{-2}$ for every $\ell \in \mathcal{P}^{\mathrm{lg}}_{x,i}$.

Definition 17.2. For a square matrix A of size N over a commutative ring and $0 \leq j \leq N$, $\sigma_j(A)$ is the sum of the principal $j \times j$ minors of A, so that $\det(1 - XA) = \sum_{j=0}^{N} (-1)^j \sigma_j(A) X^j$.

Galois Ribet data at a point. Let E be a number field, ℓ a prime, S_ℓ the set of places of E above ℓ, and fix for every finite place v of E a decomposition group $G_{E_v} \subseteq G_E$ with its inertia group I_v. Let $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ be a Hecke lattice over ℓ, put $K = \mathcal{O}[\ell^{-1}]$, and let $t \geq 1$ be an integer. Let $(\mathcal{Z}', \phi, (z_k), n_{\mathcal{R}}, \mathcal{R})$ be a determinant algebra over $\mathbb{T}$, and let $\pi' \in \mathcal{Z}'$ be a point with a block form with $t+1$ blocks numbered $0, 1, \ldots, t$, block sizes $n_{\mathcal{R},0}, \ldots, n_{\mathcal{R},t}$, maps ρ_k and constituent modules Cs_k. Let $\mathcal{N}$ be a left $\mathcal{R}$-module. **Galois Ribet data** on $(\mathcal{R}, \pi', \mathcal{N})$ over E consist of:

- an $\mathcal{O}$-subalgebra $\mathbb{T}'$ of the ring of functions $\mathcal{Z}' \to \mathcal{O}$ (pointwise operations), the **coefficient algebra**; a function $f \in \mathbb{T}'$ is identified with the central element $(f(x') \cdot 1)_{x' \in \mathcal{Z}'}$ of $\prod_{x' \in \mathcal{Z}'} \mathrm{M}_{n_{\mathcal{R}}}(K)$;
- a group homomorphism $\mathbf{r} \colon G_E \to \mathcal{R}^\times$, the **representation**, such that $g \mapsto \mathbf{r}(g)(x') \in \mathrm{GL}_{n_{\mathcal{R}}}(K)$ is continuous for every $x' \in \mathcal{Z}'$ and $\mathcal{R}$ is the $\mathbb{T}'$-submodule spanned by $\mathbf{r}(G_E)$, that is, $\mathcal{R} = \{\sum_{h \in S} f_h \, \mathbf{r}(h) : \ S \subseteq G_E \text{ finite}, \ f_h \in \mathbb{T}'\}$;
- a continuous character $\chi_1 \colon G_E \to \mathcal{O}^\times$; we put $\chi_c = \chi_1 \, \chi_{\mathrm{cyc}}^{1-c}$ for $1 \le c \le t$ and $u(g) = \chi_1(g)^{-1} \mathbf{r}(g) \in \mathcal{R}^\times$;
- an element $\mathcal{E} = \sum_{h \in S_{\mathcal{E}}} t_h \, \mathbf{r}(h) \in \mathcal{R}$, with $S_{\mathcal{E}} \subseteq G_E$ finite and $t_h \in \mathbb{T}'$, the **projector**, and a function $\tilde{\delta} \in \mathbb{T}'$ with $\tilde{\delta}(x') \neq 0$ for every $x' \in \mathcal{Z}'$, its **denominator function**; we put $\delta = \tilde{\delta}(\pi') \in \mathcal{O} \setminus \{0\}$, the **denominator**;
- an $\mathcal{R}$-linear map $\iota \colon \mathcal{N}_{\mathcal{E}} \to \mathcal{N}$, where $\mathcal{N}_{\mathcal{E}} = \sum_{g \in G_E} \mathcal{R} \, y(g) \subseteq \mathcal{R}$ is the left ideal generated by the **Ribet cocycle** $y(g) = (u(g) - 1)\mathcal{E}$;
- disjoint finite sets Σ_{T} and Σ_{P} of finite places of E not above ℓ, the **tame places** and the **polynomial places**, an element $\gamma_v \in I_v$ for each $v \in \Sigma_{\mathrm{T}}$ (we put $\zeta_v = \chi_1(\gamma_v)$), and an element $p_v \in \mathcal{R}$ for each $v \in \Sigma_{\mathrm{P}}$;
- for each $v \in S_\ell$ an $\mathcal{O}$-submodule $F_0(v) \subseteq H^1(G_{E_v}, \mathrm{Cs}_0(u))$, the **local condition** at v;
- real numbers $\kappa_k \ge 0$ and $\lambda_k(v) \ge 0$ for $0 \le k \le t$ and $v \in S_\ell$, the **column losses** and the **local losses**.

For $f \in \mathbb{T}'$ the matrix $f(\pi') \cdot 1$ is block diagonal, so $\rho_k(f) = f(\pi') \cdot 1$ for every k; in particular $\tilde{\delta}$ acts on every Cs_k as the scalar δ. Here $\mathrm{Cs}_k(u)$ is the discrete $\mathcal{O}[G_E]$-module Cs_k on which g acts by $\rho_k(u(g))$. For $\varphi \in \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k)$ put $c_\varphi(g) = \varphi(\iota(y(g)))$, and let $X_k \subseteq H^1(G_E, \mathrm{Cs}_k(u))$ be the set of classes of those c_φ that are continuous 1-cocycles, the **Ribet classes** of block k. Put $F_1(v) = H^1_{\mathrm{ur}}(E_v, \mathrm{Cs}_1(u))$ and $F_k(v) = 0$ for $2 \le k \le t$ and $v \in S_\ell$. The **Selmer group** of block 0 is

$$\mathrm{Sel}_0 = \{x \in H^1(G_E, \mathrm{Cs}_0(u)) : x|_{I_w} = 0 \text{ for every finite } w \notin S_\ell \cup \Sigma_{\mathrm{T}} \cup \Sigma_{\mathrm{P}}, \\ x|_{G_{E_v}} \in F_0(v) \text{ for every } v \in S_\ell\}.$$

We consider the following properties of the data.

(Gd1) Block characters for $1 \le k \le t$, $n_{\mathcal{R},k} = 1$ and $\rho_k(\mathbf{r}(g)) = \chi_k(g)$ for all $g \in G_E$;

(Gd2) Projector $\mathcal{E}^2 = \tilde{\delta} \, \mathcal{E}$, $\rho_1(\mathcal{E}) = \delta$, and $\rho_k(\mathcal{E}) = 0$ for $k \neq 1$;

(Gd3) Unramified places $\mathbf{r}(\gamma) = 1$ for every finite place $w \notin S_\ell \cup \Sigma_{\mathrm{T}} \cup \Sigma_{\mathrm{P}}$ and every $\gamma \in I_w$;

(Gd4) Tame places for $v \in \Sigma_{\mathrm{T}}$: the image of γ_v generates topologically the maximal pro-ℓ quotient of I_v, $\zeta_v \neq 1$, and $(\mathbf{r}(\gamma) - 1)(\mathbf{r}(\gamma) - \chi_1(\gamma)) = 0$ in $\mathcal{R}$ for every $\gamma \in I_v$;

(Gd5) Polynomial places for $v \in \Sigma_{\mathrm{P}}$: $p_v \, (\mathbf{r}(\gamma) - \chi_1(\gamma)) = 0$ in $\mathcal{R}$ for every $\gamma \in I_v$, and $\rho_k(p_v) \in \mathcal{O}^\times$ for $1 \le k \le t$;

(Gd6) Column losses for $0 \le k \le t$ the kernel of $\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k) \to \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}_{\mathcal{E}}, \mathrm{Cs}_k)$, $\varphi \mapsto \varphi \circ \iota$, has normalised length at most κ_k;

(Gd7) Local losses for $0 \le k \le t$ and $v \in S_\ell$ the image of X_k in $H^1(G_{E_v}, \mathrm{Cs}_k(u))/F_k(v)$ under restriction has normalised length at most $\lambda_k(v)$.

For $a \in \mathcal{O} \setminus \{0\}$ put $\nu(a) = \mathrm{length}_{\mathcal{O}}(\mathcal{O}/a\mathcal{O})/e_{\mathcal{O}}$. The **loss sums** of the data are

$$\mathrm{ls}_0 = \kappa_0 + 2\, n_{\mathcal{R},0}\, \nu(\delta) + \sum_{v \in S_\ell} \lambda_0(v), \qquad \mathrm{ls}_1 = \kappa_1 + \sum_{v \in S_\ell} \lambda_1(v) + \sum_{v \in \Sigma_{\mathrm{T}}} \nu(\zeta_v - 1),$$
$$\mathrm{ls}_k = \kappa_k + 2\, \nu(\delta) + \sum_{v \in S_\ell} \lambda_k(v) + \sum_{v \in \Sigma_{\mathrm{T}}} \nu(\zeta_v - 1) \qquad (2 \le k \le t).$$

Galois Ribet records of a family. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records and Ribet records. **Galois Ribet records** for $\mathcal{F}$ consist, for every (x, i, j, w, r, π) for which the Ribet records carry data, of Galois Ribet data on $(\mathcal{R}_{r,\pi}, \pi', \mathcal{N}_{r,\pi})$ over $E = E_{\mathfrak{h}_{x,i}}$, with $\ell = \ell_{x,i}(w)$, $t = t_{x,i}$ and the Hecke lattice $(\mathcal{O}_r, \mathcal{Z}_r, \mathbb{T}_r, M_r)$ of r. Their loss sums are written $\mathrm{ls}_k(r, \pi)$, and their Selmer group $\mathrm{Sel}_0(r, \pi)$. The records have

(Gd8) Records if for all large members with finite Sha lengths and all w, r, π with $\ell_{x,i}(w) \notin G_{x,i}$, $r \in R_{x,i}(j, w)$, $\pi \in Z_r$: the data have (Gd1)–(Gd7), E has no real place, $\mathrm{Sel}_0(r, \pi)$ has normalised length at most $\mathrm{sl}(r, \pi)$, and $\mathrm{lc}_k(r, \pi) \ge \mathrm{ls}_k(r, \pi)$ for $0 \le k \le t$;

(Gd9) Hecke-valued characteristic polynomials if for all large members with finite Sha lengths and all w, r, π as in (Gd8): the $\mathcal{O}$-module $\mathcal{D}_{r,\pi} = \{\sum_k (a_k \circ \phi_{r,\pi})\, z_k : \ a_k \in \mathbb{T}_r\}$ of functions $\mathcal{Z}'_{r,\pi} \to \mathcal{O}$ contains the constant function 1 and the coefficient algebra $\mathbb{T}'$ of the data and is closed under products; $\widehat{Z}_r \setminus Z_r$ is detected by the descent functions; and there is a finite set B of places of E such that for every finite place $w \notin B$ whose residue field has prime order, every $x' \in \mathcal{Z}'_{r,\pi}$ has $\mathbf{r}(\gamma)(x') = 1$ for $\gamma \in I_w$, and the functions $x' \mapsto \sigma_j(\mathbf{r}(\mathrm{Frob}_w)(x'))$, $1 \le j \le n_{\mathcal{R}}$, lie in $\mathcal{D}_{r,\pi}$;

(Gd10) Lossless at the large primes, relative to budget data for $\mathcal{F}$ (Definition 17.1) if for all large members with finite Sha lengths and all w, r, π as in (Gd8) with $\ell_{x,i}(w) \in \mathcal{P}^{\mathrm{lg}}_{x,i}$: $\delta \in \mathcal{O}^\times$, $t \sum_{v \in \Sigma_{\mathrm{T}}} \nu(\zeta_v - 1) \le \ell^{-2}$, $\kappa_k = 0$ for $0 \le k \le t$, and $\lambda_k(v) = 0$ for $0 \le k \le t$ and $v \in S_\ell$.

Definition 17.3. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with parameter ε and threshold x_1, with local defect data, local bound records and budget data. **Inert budget data** for $\mathcal{F}$ consist of the following data, given for every real $x > x_1$ and every $i \in I(x)$:

- a real number $\ell_{\mathrm{A}} \ge 2$, the **orbit cut-off**, and a real number $b^\circ \ge 1$, the **thin scale**;
- real numbers $w^\circ, \eta^\circ, S^\circ \ge 0$, the **thin bound**, the **width** and the **spread**, respectively;
- a real number $c_{\mathrm{bd}} \ge 0$, the **band threshold**;
- sets of primes $\mathcal{P}^{\mathrm{lo}}_{x,i}$ and $\mathcal{P}^{\mathrm{so}}_{x,i}$, the **long-orbit primes** and the **small-order primes**;
- a function $\beta_{x,i}$ from the set of primes to $\{0, 1\}$, the **band indicator**.

For a member (x, i), write $t = t_{x,i}$, write ϱ, H, ℓ^* for the corresponding entries of its budget data, and put $L = x^\varepsilon$. The **row excess** of a prime $\ell \ge 3$ is

$$A_{x,i}(\ell) = \begin{cases} \dfrac{H}{\ell_{\mathrm{A}}(\ell - 1)} + (w^\circ + S^\circ + \eta^\circ + 1)(3 + \log \ell_{\mathrm{A}}) + L, & \ell \in \mathcal{P}^{\mathrm{lo}}_{x,i}, \\ \dfrac{H}{\ell^2} + \dfrac{w^\circ + \eta^\circ}{\ell} + S^\circ + L + \eta^\circ\, \beta_{x,i}(\ell), & \ell \notin \mathcal{P}^{\mathrm{lo}}_{x,i}. \end{cases}$$

The inert budget data have

(Iq1) Sizes if there is a real $C \geq 1$ such that for all large members with finite Sha lengths:

1. $H \leq 2b$, $\ell_{\mathrm{A}} \leq \ell^*$, $(3+\log \ell_{\mathrm{A}})^2 \leq L$, $\varrho\, L \leq 2m\, \ell_{\mathrm{A}}$, $\varrho\, b^\circ \ell_{\mathrm{A}} \leq m\, b$, $L \leq b^\circ$, $w^\circ + S^\circ + \eta^\circ + 1 \leq 11\, b^\circ$, $\varrho\,(S^\circ + L)\,\ell^* \leq 2m\, b$, $\varrho\, \eta^\circ \leq 4m\, b$ and $c_{\mathrm{bd}} \leq C$;
2. every prime ℓ of inert type satisfies $\ell \geq 11$; if moreover $\ell \in \mathcal{P}^{\mathrm{lo}}_{x,i}$ then $\ell < \ell_{\mathrm{A}}$, and if $\ell \notin \mathcal{P}^{\mathrm{lo}}_{x,i} \cup \mathcal{P}^{\mathrm{so}}_{x,i}$ and $\ell \leq \ell^*$ then $\ell \geq \ell_{\mathrm{A}}$;
3. $\varrho \sum_{\ell \in \mathcal{P}^{\mathrm{so}}_{x,i}} \log \ell/\ell^2 \leq 4m\, L^2$ (a finite set);
4. for every prime ℓ with $\beta_{x,i}(\ell) = 1$ and $\ell \geq c_{\mathrm{bd}}$: $\varrho\, \eta^\circ \ell \leq 16\, m\, b$;
5. $\big|\mathcal{P}^{\mathrm{ex}}_{x,i}\big|\, \varrho\,(1 + H/\ell^* + w^\circ + \eta^\circ + S^\circ + L) \leq C\, m\, b$;

(Iq2) Inert allowance if there is a real $C \geq 1$ such that for all large members with finite Sha lengths and every prime ℓ of inert type

$$\mathrm{la}_{x,i}(\ell) \leq C\, f\Big(n\, t^2(\varrho + t)(1 + \log_\ell(H + t)) + \frac{m\, H}{\ell} + \varrho\, A_{x,i}(\ell)\Big).$$

Definition 17.4. Let ℓ be a prime and $\mathcal{O} \subseteq \mathcal{O}'$ coefficient rings for ℓ; put $K = \mathcal{O}[\ell^{-1}]$ and $K' = \mathcal{O}'[\ell^{-1}]$. For an $\mathcal{O}$-submodule X of a K-vector space W, $X_{\mathcal{O}'}$ denotes the $\mathcal{O}'$-span of X in $K' \otimes_K W$, where X is identified with $1 \otimes X$. For $W = K^{\mathcal{Z}}$ or $W = \prod_{x'} \mathrm{M}_n(K)$ we identify $K' \otimes_K W$ with $K'^{\mathcal{Z}}$, respectively $\prod_{x'} \mathrm{M}_n(K')$.

Hecke lattices. The **coefficient extension** of a Hecke lattice $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ over ℓ to $\mathcal{O}'$ is $(\mathcal{O}', \mathcal{Z}, \mathbb{T}_{\mathcal{O}'}, M_{\mathcal{O}'})$. Here $M_{\mathcal{O}'} = \mathcal{O}' \otimes_{\mathcal{O}} M$, and $\sum_i a_i f_i \in \mathbb{T}_{\mathcal{O}'}$ ($a_i \in \mathcal{O}'$, $f_i \in \mathbb{T}$) acts on $M_{\mathcal{O}'}$ by $\sum_i a_i \otimes f_{i,M}$. This is well defined: $\mathcal{O}'$ is a free $\mathcal{O}$-module, so $\mathcal{O}' \otimes_{\mathcal{O}} \mathbb{T} \to \mathbb{T}_{\mathcal{O}'}$ is an isomorphism. The good and kept sets are unchanged.

Determinant algebras and presented modules. The coefficient extension of a determinant algebra $(\mathcal{Z}', \phi, (z_k), n_{\mathcal{R}}, \mathcal{R})$ over $\mathbb{T}$ is $(\mathcal{Z}', \phi, (z_k), n_{\mathcal{R}}, \mathcal{R}_{\mathcal{O}'})$ over $\mathbb{T}_{\mathcal{O}'}$, with the same points, block sizes at a point π' and descent functions. For a left $\mathcal{R}$-module $\mathcal{N}$ with a presentation $\mathbf{P}$, its coefficient extension is $\mathcal{N}_{\mathcal{O}'} = \mathcal{R}_{\mathcal{O}'} \otimes_{\mathcal{R}} \mathcal{N}$, presented by the same matrix $\mathbf{P}$ over $\mathcal{R}_{\mathcal{O}'}$.

Galois Ribet items. Galois Ribet items are the entries of Galois Ribet data other than the losses $\kappa_k, \lambda_k(v)$. The coefficient extension of Galois Ribet items on $(\mathcal{R}, \pi', \mathcal{N})$ over E with the Hecke lattice $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ consists of the following:

- the coefficient algebra $\mathbb{T}'_{\mathcal{O}'}$;
- the representation $\mathbf{r}$ followed by $\mathcal{R} \subseteq \mathcal{R}_{\mathcal{O}'}$, and χ_1 followed by $\mathcal{O}^\times \subseteq \mathcal{O}'^\times$;
- the same projector $\mathcal{E}$, denominator function $\tilde{\delta}$, tame and polynomial places, and elements γ_v and p_v;
- the local conditions $F_0(v)_{\mathcal{O}'}$, the $\mathcal{O}'$-span of the image of $F_0(v)$ in $H^1(G_{E_v}, \mathcal{O}' \otimes_{\mathcal{O}} \mathrm{Cs}_0(u))$;
- the map $\iota_{\mathcal{O}'} \colon (\mathcal{N}_{\mathcal{E}})_{\mathcal{O}'} \to \mathcal{N}_{\mathcal{O}'}$, $\sum_j a_j n_j \mapsto \sum_j a_j \otimes \iota(n_j)$ ($a_j \in \mathcal{O}'$, $n_j \in \mathcal{N}_{\mathcal{E}}$), on the left ideal $(\mathcal{N}_{\mathcal{E}})_{\mathcal{O}'}$ of $\mathcal{R}_{\mathcal{O}'}$ generated by the Ribet cocycle. This map is well defined: since $\mathcal{O}'$ is free over $\mathcal{O}$, the map $\mathcal{O}' \otimes_{\mathcal{O}} \mathcal{N}_{\mathcal{E}} \to (\mathcal{N}_{\mathcal{E}})_{\mathcal{O}'}$ is an isomorphism.

These are Galois Ribet items on $(\mathcal{R}_{\mathcal{O}'}, \pi', \mathcal{N}_{\mathcal{O}'})$ over E with the extended Hecke lattice.

Families. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records, Ribet records, budget data, inert budget data and Galois

Ribet items at points (j, w, r, π) of members. For every local component r, let a coefficient ring $\mathcal{O}'_r \supseteq \mathcal{O}_r$ be given. The **coefficient extension** $\mathcal{F}'$ of $\mathcal{F}$ along $(\mathcal{O}_r \subseteq \mathcal{O}'_r)_r$ is $\mathcal{F}$ with the same data, except that the following are replaced by their coefficient extensions to $\mathcal{O}'_r$: the Hecke lattice of every local component r, the determinant algebras and modules of extensions of the Ribet records at r, and the Galois Ribet items at the points with this r. The local contributions $\mathrm{lc}_k(r, \pi)$, the local bound records, the budget data and the inert budget data are unchanged.

The root-of-unity extension. For a coefficient ring $\mathcal{O}$ for ℓ and an integer $N \geq 1$, $\mathcal{O}(N)$ denotes the integral closure of $\mathcal{O}$ in $K(\zeta) \subseteq \overline{\mathbb{Q}}_\ell$, where ζ is a primitive $\mathrm{lcm}(\ell, N)$-th root of unity.

Definition 17.5. The **class defined by linking and lower slope conditions**, denoted $\mathcal{A}_{\mathrm{prop}}$, consists of the parametrised host families $\mathcal{F}$ with slope records that satisfy (Pc1) below and the following conditional requirement: if $\mathcal{F}$ satisfies the Sha condition, then it admits a compatible collection of the records appearing in (Pc3)–(Pc5), and it satisfies (Pc2)–(Pc6).

Here a compatible collection consists of the given slope records, a choice of modification data, defect data, bridge records, numerical records, local defect data, local bound records and Ribet records, and all the frame, expansion, kernel, row, Galois Ribet, column, weight-word, position and budget data specified in (Pc5). All of them are indexed over the same family, scales and members. Write L_c for the size parameter of a loss datum. The collection is required to satisfy the following identifications; these are equalities of the indicated data, not identifications up to isomorphism.

- The underlying family $\mathcal{F}$, its parameter ε, threshold x_1, index sets $I(x)$, hosts $\mathfrak{h}_{x,i}$, frames, top and spacing sets, ranks $t_{x,i}$, translates $u_{x,i}$, loss data $\mathfrak{M}_{x,i}$ and slope records $\mathfrak{V}_{x,i}$ are the given ones in every record. Thus all records share every entry of $\mathfrak{M}_{x,i}$ and $\mathfrak{V}_{x,i}$, including k, m, η, L_c, a_t, the loss place record, the words and their ranks, slopes, heights, Gauss primes and exponents, the dual slopes, and F, δ, g_1, g_2. Consequently they also share the derived budgets B_0, N_c, the thick set and the host field.

- The modification data use these F and total exponents E in their two defining local sum identities. Their local frame numbers, local exponents, local lengths, rounded twists, level slopes, level ranks and exceptional moduli are the same throughout the collection.

- The defect sums Df_j and ranks $\mathrm{rk}_0, \mathrm{rk}_j$ in the bridge and local defect conditions are those of the defect data of the collection. The base dual slope $\mu^\vee_{\mathrm{b}}$, scaling term sc, passage allowance pa, local main and error terms lm, le and corrections tc_j are those of the bridge records of the collection. In particular the numerical conditions use these $\mathrm{sc}, \mathrm{pa}, \mathrm{lm}$ and the given word heights and Gauss primes.

- The twisted-place sets $W_{x,i}$, residue characteristics $\ell_{x,i}(w)$, weights $\mathrm{lw}_{x,i}(w)$, local component sets $R_{x,i}(j, w)$, Hecke lattices $(\mathcal{O}_r, \mathcal{Z}_r, \mathbb{T}_r, M_r)$, good and kept sets $Z_r, \widehat{Z}_r$, level order N_{lev} and allowances $\mathrm{ex}_{x,i}$ used by the local bound and Ribet conditions are those of the local defect data of the collection. Their eigenspaces, multiplicities, congruence lengths, cut defect sums and sets $P_{x,i}, G_{x,i}$ are the objects derived from these data. The Selmer lengths $\mathrm{sl}(r, \pi)$ and local terms $\mathrm{lt}(r)$ in the Ribet conditions are those of the local bound records of the collection, and so are the functions $\mathrm{sa}_{x,i}, \mathrm{la}_{x,i}, \mathrm{ga}_{x,i}$. The determinant algebra of each Ribet record is over the same $\mathbb{T}_r$.

- At each member there is a single frame realisation, and its data

$$K, v, \overline{R}, \overline{N}_\omega, B_\omega, \mathcal{H}, \Pi, D^*, D_\omega, \kappa_\omega, A_\omega, U_\omega, Z_\omega$$

are used throughout the frame, word-scale and row conditions. Their metric, rank, slope and map identities are the defining identities of Definition 14.1, also where they enter the diagonal, kernel and row data of (Pc5). In particular, every Gram block is the one computed from these A_ω, κ_ω. The word scale Γ_{w} of the member is the same throughout, and every word-size condition uses it together with these D_ω, D^*.

- The row parameters $k_{\mathrm{d}}, r_{\mathrm{f}}, f_\infty, g_1^{\mathrm{aux}}, g_2^{\mathrm{aux}}, T_{\mathrm{amp}}$ are the same in (Rw2) and (Ro1)–(Ro4). Each expansion required there is an expansion of the Gram block just specified; its main-row mass data use the same $D_\omega, D_{\omega'}, D^*$ and its own row normalisation.

The diagonal and row expansions use the Gram blocks just specified. In their main-row data $D^* = \deg_\pi v_G/\mu_K^\circ$, with the same measures and normalisation in every occurrence. The Galois Ribet, column, weight-word and budget data use the same host field, Hecke lattices, good and kept sets, local modules and inclusions specified by (Ub2), and the same Selmer and local-bound entries; the local loss sums and allowances are those required by (Ub9). Compatibility of the collection means these identifications, together with the defining types and identities of the cited data definitions. The numbered conditions imposed on the collection are exactly (Pc2)–(Pc6) below.

(Pc1) Linking and tops. The underlying parametrised host family has the linking property, few bad tops, small shares and non-empty top sets.

(Pc2) Direct slope conditions. The family has counting bounds (Sp1), ambient slope bounds (Sp2), weights at the nodes (Sp6) and thin scales (Sp7).

(Pc3) Modification conditions. The family admits modification data with properties (Mf1)–(Mf7).

(Pc4) Divisor conditions. The family admits defect data, bridge records, numerical records, local defect data, local bound records and Ribet records, with the same defect data and bridge records wherever they are used, having the following properties:

$$\begin{gathered}\text{(Dv1), (Dv2), (Dv3), (Dv4), (Dv7),}\\ \text{(Bk1), (Bk2), (Bk4),}\qquad\text{(Nr1), (Nr2), (Nr3),}\\ \text{(Ld1)–(Ld6),}\qquad\text{(Lq2), (Lq4), (Lq5), (Lq6), (Lq8),}\qquad\text{(Rf3).}\end{gathered}$$

(Pc5) Construction enrichment. The family admits frame realisations, word scales, row parameters, diagonal expansions, kernel and row data, Galois Ribet items, column data, weight words, large-prime position data, budget data and inert budget data, compatible with (Pc3), (Pc4). There are constants

$$\begin{gathered}c > 0,\quad C_0 \geq 1,\quad C_{\mathrm{A}} \geq 1,\quad 0 < c_{\mathrm{lp}} \leq \tfrac{1}{3},\quad C_{\mathrm{ng}} \geq 0,\\ C_{\mathrm{lb}} \geq 1,\quad A_{\mathrm{lb}} \geq 1,\quad C_0^{\mathrm{ng}} \in \mathbb{Z}_{\geq 0},\qquad c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1,\end{gathered}$$

depending only on the family, and in particular not on the scale, the member or any subsequent local index. Put $K_0 = 32C_{\mathrm{lb}}^{32}$. Each property named below is required in full as defined, with its hypotheses, its inner quantifiers and its uniform threshold for large members. The following hold.

- The frame conditions (Nf1), (Nf2) with exponent c, and (Nf3); word sizes (No1) for C_0, (No2) for C_0 with exponent c, and (No6) with exponent c; and (Rw2) with exponent c for $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$.

- The diagonal expansions have (Dx1) of Definition 14.15 for these C_0, c and the same Gram blocks.
- For all large members with word sizes for C_0, there are a measure space (X, μ) with $\mu(X) < \infty$, measurable functions $\mathrm{ls} : X \to (0, \infty)$, $\mathrm{kd} : X \to [0, \infty)$ and $\mathrm{na}, \mathrm{fa} : X \to [0, \infty]$, a real $\tau_* > 0$, and $c_{\mathrm{id}}, \epsilon_{\mathrm{N}}, \epsilon_{\mathrm{F}}, \kappa \geq 0$, satisfying (Kc1)–(Kc4) of Lemma 14.19 for $X_{\mathrm{t}} = \{\mathrm{ls} \geq \tau_*\}$, $X_{\mathrm{c}} = X \setminus X_{\mathrm{t}}$ and the same $\mathcal{H}, D^*$, such that

$$\kappa\mu(X) < 1, \qquad 1 + \epsilon_{\mathrm{N}} + \epsilon_{\mathrm{F}} \leq (1 - \kappa\mu(X))(1 + x^{-c}/12).$$

  These are the kernel hypotheses of Corollary 14.18.
- For all large members with word sizes for C_0 and every $\omega \neq \omega'$, there are data with (Ro1)–(Ro4) of Theorem 15.3, with the constants above, the same row parameters, Gram block and Hilbert–Schmidt metric, and scale $D_\omega D_{\omega'}/D^*$. In particular the loop modulus is $g_1^{\mathrm{aux}} g_2^{\mathrm{aux}}$; all non-generic data refer to this expansion, its a_2 and its n_{g}; and the main-row data are those of its main-row sum and its row normalisation. All hypotheses of (Mx1)–(Mx5) are required, including both word-group data and the complete archimedean product structure on the same Poisson data.
- The Galois Ribet items are given at every point of every member as in the setting of Theorem 22.4. There is a common x_0 such that for every $x \geq x_0$, $x > x_1$, and every member with finite Sha lengths there are an integer $N_{x,i} \geq 1$ with $4 \mid N_{x,i}$ and integers $S_{x,i}^{\mathrm{rm}}, \eta_{x,i}^{\mathrm{rm}} \geq 0$, independent of all subsequent point and local indices, for which the Galois Ribet items of the coefficient extension along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), including (Ub7'), of Theorem 22.1. The extension is that of Definition 17.4 at the local components of these members, and the identity extension at all other local components. The constants $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}}$ are those above, and these properties are required with all their quantifiers over points, lifts, words, primes, places, components and eigensystems. The Galois Ribet items before extension, the local defect data, Ribet records, local bound records, budget data and inert budget data are those of the compatible collection. In particular (Ub9) uses the minimal losses, which are unchanged by Lemma 22.17, and the same allowance defined there, not separately chosen loss bounds.

(Pc6) Residual size conditions. The parameter of the family satisfies $\varepsilon \leq 1$. Moreover, there is a real x_0 such that for every $x \geq x_0$ with $x > x_1$ we have $I(x) \neq \varnothing$ when x lies in the set W of scales of $\mathcal{F}$, and every $i \in I(x)$ satisfies

$$x^{1/2-\varepsilon} \leq m, \qquad \log(2a\, v(\mathfrak{h}_{x,i})) \leq 2x^{\varepsilon}, \qquad \log|\mathcal{W}(\mathfrak{V})| \leq (k-3)\log 2,$$
$$x^{-\varepsilon} n \leq |T_{x,i}^{\mathrm{th}}|, \qquad \tfrac{1}{2}x^{-\varepsilon/8} n \leq |T_{x,i}|, \qquad a_t \geq (x-1)b \quad (t \in T_{x,i}),$$

where, in the usual member notation, $n = |A|$, $b = \exp(x^{\varepsilon})$, $a = xb$ and $\mathfrak{V} = \mathfrak{V}_{x,i}$.

The class $\mathcal{A}_{\mathrm{prop}}$ is a single class: it does not depend on a window ratio, on a supplied host requirement or on a requested parameter. The constants and the records whose existence is required may depend on the family.

Proposition 17.6. *There are a good-host requirement $\mathfrak{G}$ and a class $\mathcal{A}$ of parametrised host families with slope records such that the following hold. In (Lk1), (Lk2), (Lk3), in the intersection $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ and in the Sha condition, a family with slope records is identified with its underlying parametrised host family.*

(Gh1) Supply of good hosts. $\mathfrak{G}$ *supplies good hosts.*

(Lk1) Design existence for $\mathfrak{G}$. *For every $\lambda > 1$ and every host requirement P supplied by $\mathfrak{G}$ on λ-windows there is $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ some family in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ has parameter ε.*

(Lk2) *Every family in $\mathcal{A}$ has the linking property.*

(Lk3) *Every family in $\mathcal{A}$ has few bad tops, small shares and non-empty top sets.*

(Lk4′) Slope records. *There is a real number e such that every family in $\mathcal{A}$ that satisfies the Sha condition has the properties (Sp1)–(Sp8), with (Sp4) for the exponent e.*

Proof. The choice. Let $\mathfrak{G}$ be the concrete good-host requirement of Definition 11.4. It is a predicate on tuples $(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ of real numbers x, ε, J, a finite list κ of real numbers, a host $\mathfrak{h}$ for a frame (e, A, h, a_0), a finite set $T \subseteq A$ and an integer t; restricted to $t \geq 1$ it is a good-host requirement. Let $\mathcal{A} = \mathcal{A}_{\mathrm{prop}}$ be the class defined by linking and lower slope conditions; it is a class of parametrised host families with slope records. Neither $\mathfrak{G}$ nor $\mathcal{A}$ depends on a window ratio, a host requirement or a parameter. We verify the clauses of the statement for this $\mathfrak{G}$ and this $\mathcal{A}$, where, as in the statement, a family with slope records is identified with its underlying parametrised host family in (Lk1)–(Lk3), in $\mathcal{A} \cap \mathcal{C}_\lambda(\mathsf{P})$ and in the Sha condition.

(Gh1). By Proposition 11.5, the concrete good-host requirement, restricted to $t \geq 1$, supplies good hosts.

(Lk1). Let $\lambda > 1$ and let P be a host requirement supplied by $\mathfrak{G}$ on λ-windows. We apply Proposition 18.1 to the requirement $\mathfrak{G}$ and the class $\mathcal{A}_{\mathrm{prop}}$, which do not depend on λ and P. It gives $\varepsilon_0 > 0$ such that for every $\varepsilon \in (0, \varepsilon_0)$ there is a parametrised host family with slope records of parameter ε in $\mathcal{A}_{\mathrm{prop}} \cap \mathcal{C}_\lambda(\mathsf{P})$, where membership in $\mathcal{C}_\lambda(\mathsf{P})$ refers to its underlying parametrised host family. This is (Lk1).

(Lk2) and (Lk3). By Theorem 17.7, every family in $\mathcal{A}_{\mathrm{prop}}$ has the linking property, few bad tops, small shares and non-empty top sets. These are properties of the underlying parametrised host family, as in the identification.

(Lk4′). By Theorem 17.7, every family in $\mathcal{A}_{\mathrm{prop}}$ that satisfies the Sha condition (a condition on its underlying parametrised host family) has the properties (Sp1)–(Sp8), with (Sp4) for the exponent 1, the same for every family of the class. So (Lk4′) holds with $e = 1$. □

Theorem 17.7. *Every family in $\mathcal{A}_{\mathrm{prop}}$ has the linking property, few bad tops, small shares and non-empty top sets. Every family in $\mathcal{A}_{\mathrm{prop}}$ that satisfies the Sha condition has (Sp1)–(Sp8), with (Sp4) for the exponent $e = 1$, which is the same for every family of the class. Consequently every such family has slope data at its members with the same exponents $(e_D, e_L) = (1, 0)$. The coefficients, thresholds and auxiliary exponents in the named family properties may depend on the family; the divisor exponent 1 and the slope-data exponents $(1, 0)$ do not.*

Proof. Fix $\mathcal{F} \in \mathcal{A}_{\mathrm{prop}}$. Its linking property and its three tops properties are (Pc1); they hold without the Sha condition.

Now suppose that $\mathcal{F}$ satisfies the Sha condition. By the definition of $\mathcal{A}_{\mathrm{prop}}$ there is a compatible collection of the records in (Pc3)–(Pc5) with all their stated family-wide properties; fix one. This collection is chosen for the family $\mathcal{F}$ and is the same for all scales and members.

We begin with the transfer of slopes. The linking property and Lemma 12.5 give the correction budget (Mf8) for the modification data of (Pc3). Together with (Mf1)–(Mf7), this verifies the hypotheses of Theorem 12.3, which gives (Sp3).

For the divisor conditions, (Nr1)–(Nr3) of (Pc4) give (Bk3) by Lemma 13.6. Since (Pc4) uses the same numerical and bridge records throughout, (Bk1), (Bk2), (Bk3), (Bk4) and (Dv2) hold for one choice of records. Applying Theorem 13.4 at $e = 1$ gives (Dv5) with exponent 1.

Apply Theorem 22.1 to the Galois Ribet items and the data of (Pc5), whose hypotheses concern the coefficient extension specified there, with the family constants $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}}$. By compatibility, the host, the original Hecke lattices, the point modules, the inclusions, the minimal-loss choices and the allowance records agree; the conclusions of that theorem concern the original family, with the same minimal-loss numbers and allowances. On a common tail of scales, on which moreover $x^{\varepsilon} \geq 3$ and the thresholds of (Lz1), (Iq1) are met, that theorem gives (Rf1), (Rf2), (Rf4), (Rf5), (Lq3), and (Lq7) with its derived coefficient $19C_3^3$. These conclusions keep their finite-Sha antecedents and their local indices. Together with (Rf3) and (Lq2), (Lq4)–(Lq6), (Lq8) of (Pc4), the local bound records therefore have (Lq2)–(Lq8) and the Ribet records have (Rf1)–(Rf5). Hence Theorem 13.13 gives (Lq1) for these same local components and congruence lengths. Thus Theorem 13.16, applied to (Lq1)–(Lq5), gives (Ld7) and (Ld8), and Theorem 13.17, applied to (Lq5)–(Lq8), gives (Ld9). Properties (Ld1)–(Ld6) were required in (Pc4). All nine hypotheses of Theorem 13.18 therefore hold, and that theorem gives (Dv6). Each of these local assertions remains conditional on the member having finite Sha lengths.

We have now obtained (Dv5) with exponent 1 and (Dv6), while (Dv1)–(Dv4) and (Dv7) are part of (Pc4). The family satisfies the Sha condition by assumption. Hence Theorem 13.2 applies with exponent 1 and proves (Sp4) for that exponent.

For the frame bounds, use the family constants of (Pc5). Its diagonal expansions give (No4) by Theorem 14.16. Its kernel hypotheses, including the finite measure, positivity and both scalar inequalities, give (No5) by Corollary 14.18. Its (Ro1)–(Ro4) data give (Rw1) by Theorem 15.3. All three use the same C_0, c, frame Hilbert space, Gram blocks, word scale and row parameters, and keep their word-size antecedents. Thus (Rw1) and (Rw2) hold with the same $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ and exponent c, so the hypotheses of Theorem 14.13 are satisfied, giving (No7) for C_0 with exponent c. By Theorem 14.9 this implies (No3) for the same C_0, c. Properties (No1), (No2), (No6) are in (Pc5), and (No4), (No5) have just been derived. Applying Theorem 14.8 therefore gives (Nf4) with exponent c. The height condition (Nf2) holds with the same exponent, and (Nf1), (Nf3) hold as well. Thus the four hypotheses of Theorem 14.2 hold, and that theorem gives (Sp5). In particular, at each scale its envelopes are common to all members, as (Sp5) requires.

Condition (Pc6) is the residual size hypothesis in item 3 of Lemma 12.1. The family is parametrised as that lemma requires, and $\varepsilon \leq 1$ is part of (Pc6). The lemma gives (Sp8) with $e_K = 5$, with a threshold depending on the requested decay constant as stated there.

Finally (Sp1), (Sp2), (Sp6), (Sp7) are (Pc2). Together with the four consequences just proved, all of (Sp1)–(Sp8) hold, and the divisor exponent in (Sp4) is 1. Applying Theorem 8.4 gives slope data at the members with exponents $(\max(1,0),0) = (1,0)$.

The only number in this argument that is the same for all families of the class is the divisor exponent 1, and hence the pair $(1,0)$; every other constant and threshold depends on the family as in the cited property or theorem. Since $\mathcal{F}$ was arbitrary, all conclusions hold for the class $\mathcal{A}_{\mathrm{prop}}$. □

Part IV
The chain of theta lifts: design existence, assuming (TCS)

In Alpöge's account the auxiliary object of the proof is a chain of iterated theta lifts $\mathrm{U}(X_0) \to \mathrm{U}(X_1) \to \cdots \to \mathrm{U}(X_m)$ between totally definite unitary groups, which wins multiplicity m [4]. This paper sees the chain only through its records: the slope data of Part I, the slope records of the members of a family, and the translate packets of this Part, each of which consists, at one scale, of one loss datum and one slope record for every translate $u \in A$ (Definition 19.1). That these records come from a chain of theta lifts is our reading; Appendix A outlines the construction. Part IV is where the chain would be constructed, and the one standing assumption of the paper, the existence of a theta chain system (TCS), is what is assumed of it. (TCS) is stated in Section 21 as Hypothesis 21.1.

The Part proves design existence, Proposition 18.1: the class $\mathcal{A}_{\mathrm{prop}}$ of Part III contains, for every small ε, a family with parameter ε whose scales contain λ-windows and whose members satisfy a given host requirement supplied by the concrete good-host requirement. This is clause (Lk1) of Proposition 17.6. The family is assembled from packets, one at each scale, and the work of the Part is to prove every property the class asks for that (TCS) does not state. The linking property follows from the numerical data of the packets alone (Theorem 18.4), and it is proved without (TCS). The other properties are derived from the data that (TCS) supplies: the bounds (Ms1) and (Ms3) for model slopes by the tower theorems 29.14 and Proposition 31.14 of Part VI, the realisation estimate (Ri1) by the reference budget Theorem 20.2, and the remaining model-slope and height conditions and eight lower conditions of the class by the results of Section 19. Apart from these two tower theorems, Part IV uses no result of another Part.

(TCS) is used directly only once, in the proof of Proposition 21.2. Nine results depend on it through this use: Proposition 19.9, Proposition 19.3, Proposition 18.1, Proposition 17.6, Corollary 8.3, Proposition 7.9, Proposition 7.8, Theorem 6.7 and Theorem 6.8. They form a chain in this order, each used in the proof of the next, and no other result of the paper depends on (TCS). The sections run from the conclusion to the assumption. Section 18 proves design existence from a joint supply of packets and the linking property. Section 19 derives that joint supply from a supply with realisations, and this from model-level packet supply. Section 20 proves the reference budget, and Section 21 states (TCS) and proves model-level packet supply from it.

18 Packets and design existence

This section proves design existence, Proposition 18.1, which is (Lk1) of Proposition 17.6. The proof takes the joint supply of packets of Proposition 19.3 and builds from it, for every small ε, a family whose members at a scale x are indexed by the translates $u \in A_x$ and carry the host, tops, loss datum and slope record of the packet. Two points need an argument. The first is the linking property (Pc1), which Proposition 19.3 does not provide; it comes from Theorem 18.4, whose four hypotheses are exactly the numerical conditions (Js2) of the packets. The second is the Sha condition. The class requires the records (Pc2)–(Pc6) only of families that satisfy it, and the packets carry their lower completions only on a tail of scales at which the Sha bound holds for every member. The proof therefore splits into two cases: if the family does not satisfy the Sha condition, the conditional requirement is vacuous; if it does, the lower completions supplied

in (Js3) give (Pc2)–(Pc6).

Theorem 18.4 is the main theorem proved in this section, and it does not depend on (TCS). It derives the linking property (Lm3), the main hypothesis of the loss bound Theorem 5.6, from the integer construction alone: heights, depths and weights in prescribed integer boxes (Definition 18.2), the finite good-orbit selections of the good host (Definition 11.3), and numerical orbit corrections (Definition 18.3). The constants of the linking property are uniform over all families with these data. The core of the proof is a counting argument along the Frobenius orbits of the inert primes. The marked tiles that condition (Go2) of the good-orbit selection provides give every good orbit a lower density of tops (Lemma 18.7), and the floor loss of the served-prime inequality pays for the orbit losses and the correction error (Lemma 18.12). Lemma 18.9 combines the orbit counts with the scalar bounds of the integer weights (Lemma 18.6) into the linking property.

Proposition 18.1. *For every real $\lambda > 1$ and every host requirement P supplied by the concrete good-host requirement $\mathfrak{G}$ on λ-windows there is a real $\varepsilon_0 > 0$ with the following property. For every $\varepsilon \in (0, \varepsilon_0)$ there is a parametrised host family with slope records $\mathcal{F}$ of parameter ε such that*

$$\mathcal{F} \in \mathcal{A}_{\mathrm{prop}} \cap \mathcal{C}_\lambda(\mathsf{P}).$$

Here $\mathfrak{G}$ and $\mathcal{A}_{\mathrm{prop}}$ are fixed; they do not depend on λ, P or ε.

Proof. Fix $\lambda > 1$ and a host requirement P supplied by $\mathfrak{G}$ on λ-windows. Let $\varepsilon_* = \varepsilon_*(\lambda, \mathsf{P}) > 0$ be given by Proposition 19.3 for this λ and P, and set

$$\varepsilon_0 = \min(\varepsilon_*, 1/52) > 0.$$

Fix $0 < \varepsilon < \varepsilon_0$. The supply condition gives a fixed $J \geq 1$, a finite list κ, a set W containing λ-windows, and a cutoff above which each $x \in W$ admits a host, tops and rank satisfying both $\mathfrak{G}$ and P. Increase that cutoff to $X_H > 1$. At every $x \in W$ with $x \geq X_H$ choose one such tuple, together with all the data required by $\mathfrak{G}$. Write the tuple as $\mathfrak{h}_x, T_x, t_x$, with frame group A_x and spacing set S_x.

Apply Proposition 19.3, for the same λ and P, to this collection. Its hypotheses hold, since $\varepsilon < \min(\varepsilon_*, 1/52)$ and every chosen tuple satisfies both $\mathfrak{G}$ and P. It gives the common constants, a cutoff $X \geq X_H$, and packets P_x for all $x \in W$ with $x \geq X$. For any real $Q \geq X$ define a family $\mathcal{F}^Q$ with scales W, threshold $x_1 = Q$ and index sets

$$I_Q(x) = \begin{cases} A_x, & x \in W,\ x > Q, \\ \varnothing, & \text{otherwise.} \end{cases}$$

At a nonempty scale use the host, tops, spacing set, rank, loss datum, slope record and translate of the packet, indexed by $u \in A_x$. At an empty scale choose any fixed frame. Such a frame exists because W is unbounded, so that there is a packet at some $x \geq X$. Indeed, a λ-window with left endpoint larger than $\max(X, 1)$ contains such a scale.

We first check that $\mathcal{F}^Q$ is a parametrised host family with slope records. The packet ties give (Pf1), including the group, arithmetic datum, tops, scale, parameter and rank. Conditions (Lm1), (Lm2), (Lm6) of (Js1) give (Pf2), and its common pair (ε_z, C_t) gives (Pf3). The common host, tops, spacing set, scalar parameters and auxiliary primes give (Sr1). For a member and any $u \in A_x$, the member indexed by u has translate u and the same heights, which gives (Sr2). Conditions at empty index sets are vacuous. Moreover $\mathcal{F}^Q \in \mathcal{C}_\lambda(\mathsf{P})$, since its scales are W and every member carries the tuple chosen above, which satisfies P.

The family $\mathcal{F}^Q$ satisfies (Pc1) for every $Q \geq X$. The four hypotheses of Theorem 18.4 are the conditions of (Js2), with the same fixed $\varepsilon, c_D, c_h, \mathfrak{k}_{\mathrm{orb}}, C_e$ at every member. That theorem therefore gives the linking property, with a coefficient, a cutoff and a function δ that do not depend on the member. By (Js1), (Lm4) and (Lm5) hold at every member above its threshold, which gives few bad tops and small shares. Finally (Hg3) gives

$$|T_x| \geq \tfrac{1}{2} x^{-\varepsilon/8} |A_x| > 0$$

because A_x is a finite group. Thus the top set of every member is nonempty.

If $\mathcal{F}^X$ does not satisfy the Sha condition, the conditional requirement defining $\mathcal{A}_{\mathrm{prop}}$ is vacuous. Since $\mathcal{F}^X$ satisfies (Pc1), it is the required family.

Suppose instead that $\mathcal{F}^X$ satisfies the Sha condition. There is a cutoff Z such that every member at every $x \geq Z$ above its threshold satisfies the stated Sha bound. At each $x \in W$ with $x > \max(X, Z)$ the index set is the nonempty group A_x, and all members have host $\mathfrak{h}_x$ and rank t_x. Hence, after increasing the cutoff by 1, there is a single cutoff such that

$$\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^{\varepsilon}/2))$$

holds at every scale $x \in W$ above it. Condition (Js3) now supplies uniform lower completions of these packets at all sufficiently large scales. Let $Y \geq X$, $Y > 1$, and the common scalar parameters be as in (Pl3).

Consider $\mathcal{F}^Y$. Every member has $x > Y$, so its completion is defined. Attach all the record and input-data types of (Pl1) to that member. Their defining identities and compatibility give one compatible collection of family records. The pointwise interpretation (Pl2), with common parameters that do not depend on the scale, gives the corresponding family properties. Here Y serves as their eventual cutoff, all inner quantifiers over words, places, primes and components are kept, and so is each antecedent (finiteness of a Tate–Shafarevich group, a word-size condition, or nonvanishing of a map). The displayed lists in (Pl3), together with its separate kernel requirement, give (Pc2), (Pc3), (Pc4) and (Pc5). The twelve common constants of (Pc5), including the nonnegative integer, are the same in all the properties in which they occur. In its Ribet conditions, the integers attached to a member are chosen after that member's finiteness antecedent for the Tate–Shafarevich group and before all its local indices. Thus the compatible data give the quantified hypotheses required there.

The last inequalities of (Pl3) give the residual bounds in (Pc6), and $\varepsilon \leq 1$ is also part of that condition. For every $x \in W$ with $x > Y$ the index set A_x is nonempty, so the required eventual nonemptiness holds. Thus (Pc6) holds. The family $\mathcal{F}^Y$ still satisfies (Pc1) and lies in $\mathcal{C}_\lambda(\mathsf{P})$ by the checks above. It therefore lies in $\mathcal{A}_{\mathrm{prop}} \cap \mathcal{C}_\lambda(\mathsf{P})$, which completes both cases. Neither $\mathfrak{G}$ nor $\mathcal{A}_{\mathrm{prop}}$ depends on λ, P or ε.

□

Definition 18.2. Fix a loss datum with $x > 1$, $0 < \varepsilon < 1/52$, $k \geq 1$ and $m \geq 1$, a number field E, a subset $\Phi_{\mathrm{th}} \subseteq \Phi \setminus (\{0\} \times T)$ and real constants $c_D \geq 0$, $c_h \geq 402$. In this definition and in the results that refer to it, the following quantities are formed from the scale and these constants:

$$\Delta = \lceil x^{c_D} \rceil, \qquad h_0 = 2\lceil x^{c_h} \rceil, \qquad b = \exp(x^{\varepsilon}), \qquad n = |H|.$$

The places in Φ_{th} are called thick; the places outside $\Phi_{\mathrm{th}} \cup (\{0\} \times T)$ are called thin.

The loss datum has the **integer weights and boxes for** $(E, \Phi_{\mathrm{th}}, c_D, c_h)$ if the following conditions hold.

(Iw1) Its cloud size and total gap are

$$S_c = 4k\Delta, \qquad \eta = mh_0.$$

(Iw2) At every top $t \in T$ its integer heights and depths satisfy

$$\lceil a \rceil \le a_t \le \left\lfloor a + \frac{a}{kx^{13}} \right\rfloor, \qquad \lceil b' \rceil \le b_t.$$

(Iw3) Every $w_1(z)$ is an integer, and

$$\begin{aligned} w_1(0,t) &= b_t + \lfloor b'/x \rfloor + h_0/2 && (t \in T),\\ w_1(z) &= \lceil w'' \rceil + h_0/2 && (z \text{ thin}),\\ \lceil b \rceil + h_0/2 \le w_1(z) &< \lceil b \rceil + |\mathcal{O}_{E\mathrm{tors}}^{\times}| + h_0/2 && (z \text{ thick}). \end{aligned}$$

For $1 \le j \le m$ and $z \in \Phi$, the other weights are

$$w_j(z) = w_1(z) + (j-1)h_0.$$

(Iw4) For every $1 \le j \le m$,

$$\varsigma_j = \frac{k + (2j-1)(t_R+1)}{2}.$$

Definition 18.3. A **tuple of numerical orbit constants** is a tuple of eight nonnegative real numbers

$$\mathfrak{k}_{\mathrm{orb}} = (C_{\mathrm{La}}, C_{\mathrm{band}}, C_{\mathrm{Ds}}, C_{\mathrm{Dl}}, C_{\mathrm{ts}}, C_{\mathrm{t1}}, C_{\mathrm{t2}}, C_{\mathrm{orb}}).$$

The entries C_{La}, C_{band} and C_{orb} do not enter the conditions below. Fix such a tuple, a real number $C_e \ge 0$ and a loss datum with $x > 1$, $0 < \varepsilon < 1/52$, $k, m \ge 1$ and $S_c \ge 0$. In this definition and in the statements that refer to it, we use the following quantities, which depend on the tuple and on the fixed loss datum:

$$\begin{aligned} u_{\mathrm{orb}} &= \lceil \delta_1^{-1} \rceil, & \ell_{\mathrm{orb}} &= (6r_G+1)u_{\mathrm{orb}},\\ M_{\mathrm{orb}} &= \left\lceil (5+8\varepsilon)(\log x) 10^{6r_G+1} \right\rceil, & G_{\mathrm{orb}} &= (M_{\mathrm{orb}}+5)\ell_{\mathrm{orb}},\\ N_{\mathrm{orb}} &= \left\lceil \max\left(6\exp(1) G_{\mathrm{orb}} \delta_1,\ (5+8\varepsilon)\frac{\log x}{\log 2} \right) \right\rceil + 1. \end{aligned}$$

For a prime p and a nonnegative integer d_{cyc} put

$$Q_{\mathrm{cor}}(p) = p^{G_{\mathrm{orb}}}, \qquad \ell_{\mathrm{cor}}(p) = \left\lceil \log_p((kx^{26})^4) \right\rceil, \qquad u_{\mathrm{cor}}(d_{\mathrm{cyc}}) = 40 d_{\mathrm{cyc}} \delta_1.$$

Define nonnegative integers

$$\begin{aligned} D^{\mathrm{s}}_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) = \Big\lceil & C_{\mathrm{Ds}} u_{\mathrm{cor}}(d_{\mathrm{cyc}})(N_{\mathrm{orb}}^3 + r_G^5 + k^2) \log_p a \\ & + 2r_G d_{\mathrm{cyc}} c_G + r_G u_{\mathrm{cor}}(d_{\mathrm{cyc}})(2b' + 2c_G) \Big\rceil, \\ D^{\mathrm{l}}_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) = \Big\lceil & C_{\mathrm{Dl}} u_{\mathrm{cor}}(d_{\mathrm{cyc}}) x^{26} (N_{\mathrm{orb}}^5 + k^3) \log_p a \Big\rceil \end{aligned}$$

and the real number

$$\begin{aligned} c_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) = {} & 8(D^{\mathrm{l}}_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) + 1) + C_{\mathrm{t2}} u_{\mathrm{cor}}(d_{\mathrm{cyc}}) k \log_p a \\ & + 4u_{\mathrm{cor}}(d_{\mathrm{cyc}}) c_G + 2 d_{\mathrm{cyc}} c_G. \end{aligned}$$

The loss datum has the **numerical orbit corrections for** $(\mathfrak{k}_{\mathrm{orb}}, C_e)$ if the following identities hold.

(Nc2) Correction degree. For every inert prime p,

$$D_p = \begin{cases} D^{\mathrm{s}}_{\mathrm{cor}}(p, n_p), & p < k^2 x^{26}, \\ D^{\mathrm{l}}_{\mathrm{cor}}(p, n_p), & p \geq k^2 x^{26}. \end{cases}$$

(Nc3) Orbit thresholds. Let p be a candidate prime and $v \in V_p$. Candidate primes are not sign-changing, so $n_p = \mathrm{ord}(h_p)$. Residues modulo n_p are taken in $\{0, \dots, n_p - 1\}$. For an odd $i \in P_p(v)$ let $d^-_{p,v}(i)$ be the least integer in

$$\{e : 1 \leq e \leq n_p,\ (i-e) \bmod n_p \in P_p(v),\ (i-e) \bmod n_p \text{ is even}\},$$

and put $d^-_{p,v}(i) = 0$ if this set is empty. Set

$$\begin{aligned} t^{\mathrm{s}}_{\mathrm{cor}}(p, v) &= C_{\mathrm{ts}} r_G N_p(v) \left(\frac{L_a a}{pk} + a p^{-\ell_{\mathrm{cor}}(p)} + 2b' + 2c_G + kQ_{\mathrm{cor}}(p) \right) + 2r_G n_p c_G, \\ t^{\mathrm{l}}_{\mathrm{cor}}(p, v) &= \sum_{\substack{i \in P_p(v),\ i \text{ odd} \\ d^-_{p,v}(i) > 0}} \min \left(b_{v+ih_p}, \frac{a_{v+((i-d^-_{p,v}(i)) \bmod n_p)h_p}}{p^{d^-_{p,v}(i)}} \right) \\ &\quad + C_{\mathrm{t1}} N_p(v) N_{\mathrm{orb}} \left(\frac{a}{p^2} + \frac{L_a a}{pk} \right) \\ &\quad + C_{\mathrm{t2}} N_p(v) \left(Q_{\mathrm{cor}}(p) c_{\mathrm{cor}}(p, n_p) + kQ_{\mathrm{cor}}(p) + k \log_p a + c_G \right) + 2n_p c_G. \end{aligned}$$

The condition is

$$t_p(v) = \begin{cases} t^{\mathrm{s}}_{\mathrm{cor}}(p, v), & p < k^2 x^{26}, \\ t^{\mathrm{l}}_{\mathrm{cor}}(p, v), & p \geq k^2 x^{26}. \end{cases}$$

(Nc4) Correction error. For every inert prime p, with $f = 2|H|$,

$$\epsilon_p = \left\lceil C_e f k^2 \log_p a \right\rceil.$$

Theorem 18.4. *Fix*

$$0 < \varepsilon < 1/52, \qquad c_D > 397, \qquad c_h \geq 402,$$

a tuple $\mathfrak{k}_{\mathrm{orb}}$ of eight nonnegative real constants and a real constant $C_e \geq 0$. There are constants $C_0 \geq 0$ and $x_0 > 1$, depending only on these fixed data, with the following property.

Let $\mathcal{F}$ be any parametrised host family with parameter ε and threshold x_1. Suppose that for every $x > x_1$ and every $i \in I(x)$ the following hold.

1. *Its loss datum has the group $H = A$ and parameters k, m, t_R of a rank datum with the rank sizes at (x, ε, J) for some $J \geq 1$, with $t_R = t$.*
2. *Its heights, depths, weights and shifts have the integer weights and boxes for the fixed exponents c_D, c_h. The arithmetic field and thick subset in that condition may depend on the member.*
3. *Its top set, Frobenius translations, orbit representatives and good representatives form a finite good-orbit selection, and these are the choices used in its loss datum.*
4. *Its correction degrees, orbit thresholds and correction errors satisfy (Nc2), (Nc3) and (Nc4) for the fixed tuple $\mathfrak{k}_{\mathrm{orb}}$ and C_e.*

Then $\mathcal{F}$ has the linking property. More precisely, put

$$C = \max(C_0, 11 + C_e, 16)$$

and

$$\delta(x) = \begin{cases} x^{-\varepsilon/2}, & x > 1, \\ 0, & x \le 1. \end{cases}$$

For every such family, every $x \ge x_0$ with $x > x_1$ and every member at x, the loss datum of the member satisfies both inequalities of (Lm3) for

$$(C, b(x)^{\delta(x)}) = (C, \exp(x^{\varepsilon/2})).$$

In particular, C, x_0 and δ are the same for all such families and all their members.

Proof. All thresholds in this proof depend only on the fixed data of the statement. They are increased finitely many times. None depends on a family, a member, an orbit, a prime, a thick subset or an arithmetic field.

Take C_{den} to be the explicit positive constant of Lemma 18.7, and put

$$C_{\mathrm{Norb}} = \max\left(6\exp(1)C_{\mathrm{den}}, \frac{5 + 8\varepsilon}{\log 2}\right) + 2.$$

This constant is local to this proof. For $x \ge \exp(1)$ the estimates proved in that lemma and the definition of N_{orb} give

$$G_{\mathrm{orb}} \le C_{\mathrm{den}} x^{\varepsilon/8} \log x, \qquad N_{\mathrm{orb}} \le C_{\mathrm{Norb}} \log x. \tag{1}$$

Indeed, multiply the first inequality by $\delta_1 = x^{-\varepsilon/8}$, apply the maximum in the definition of N_{orb}, and use $\lceil u \rceil + 1 \le u + 2$ and $\log x \ge 1$ for the second inequality. Choose

$$C_0 = \max\left(12,\ C_{\mathrm{ts}} r_G,\ 13 + 4C_{\mathrm{ts}} + 160C_{\mathrm{den}},\ C_{\mathrm{den}},\ C_{\mathrm{t1}} C_{\mathrm{Norb}}\right). \tag{2}$$

Here $r_G = \lceil (32 + 64\varepsilon)/\varepsilon \rceil + 1$ depends only on ε. Thus C_0 is nonnegative and has the required dependence.

Fix a family satisfying the four hypotheses, a scale $x > x_1$, and a member. By Lemma 18.6, after a uniform increase of the threshold, its scalar inequalities satisfy

$$k \ge 5, \quad S_c \ge 100, \quad N \le S_c, \quad kS_c \le w'', \quad 0 \le \varsigma_j \le S_c,$$

and all the height, depth and weight bounds in item 1 of Lemma 18.9. The top weights also satisfy the upper offset bound needed by Lemma 18.5, since their defining formula gives

$$w_j(0,t) - b_t = \lfloor b'/x \rfloor + (j - \tfrac{1}{2})h_0 \le b'/x + mh_0 = b'/x + \eta. \tag{3}$$

The lower offset bound is supplied by Lemma 18.6.

Every candidate prime is inert and not sign-changing, has $p < X'$ and $n_p = \mathrm{ord}(h_p) \ge x^{\varepsilon/4}$. Its representatives $v \in V_p$ belong to G_p. The second part of Lemma 18.7, applied to these top sets and representatives, therefore gives, uniformly,

$$N_p(v) \ge 1, \qquad n_p \delta_1 \le N_p(v) C_{\mathrm{den}} \log x. \tag{4}$$

Condition (Lm1), which is part of a parametrised host family, gives even n_p at every such prime. This checks the density and parity hypotheses of the finite estimate.

We check its remaining numerical hypotheses. The rank sizes imply, after another uniform increase of the threshold,

$$x^{2+8\varepsilon} \le n = |H| \le x^3, \qquad k \le x^6. \tag{5}$$

The identities for the integer weights give

$$S_c = 4k\lceil x^{c_D}\rceil, \qquad \eta = 2m\lceil x^{c_h}\rceil, \qquad c_G = 4S_c,$$

with $m \le 2x^{1/2}$. Together with $N \le S_c$, (1) and

$$0 < \log_p a \le \frac{\log a}{\log 2} = \frac{\log x + x^{\varepsilon}}{\log 2} \quad (p \ge 2),$$

these show that there is a fixed real exponent $c_{\mathrm{pol}} \ge 26$ such that, for all sufficiently large x, every one of

$$n,\ k,\ N,\ S_c,\ \eta,\ c_G,\ r_G,\ N_{\mathrm{orb}},\ \frac{C_{\mathrm{den}}\log x}{\delta_1},\ C_{\mathrm{den}}\log x,\ x^{26},\ \log_p a \tag{6}$$

is at most $x^{c_{\mathrm{pol}}}$, uniformly for $p \ge 2$. The same bound holds for each fixed nonnegative entry of $\mathfrak{k}_{\mathrm{orb}}$ and for 1. To see the choice explicitly, take c_{pol} strictly greater than

$$26, \quad 7 + c_D, \quad 1 + c_h, \quad 3$$

and increase it if necessary. The estimates $S_c \le 8x^{6+c_D}$, $\eta \le 8x^{1/2+c_h}$, $N \le S_c$, (1), and $\log x = o(x^{\alpha})$ for every fixed $\alpha > 0$ then prove (6), after enlarging the threshold to absorb the finitely many fixed coefficients. We may enlarge c_{pol} once more; it remains fixed.

First consider the scalar inequality containing w''. Since $w'' = b'/(xn)$, (5) gives

$$\frac{1}{b'}\frac{C_{\mathrm{den}}\log x}{\delta_1} w'' \le C_{\mathrm{den}}(\log x)x^{-3-63\varepsilon/8} \longrightarrow 0. \tag{7}$$

Also

$$b' = x\exp(x^{\varepsilon} - x^{\varepsilon/3}),$$

so $x^a/b' \to 0$ for every fixed real exponent a. This follows by taking logarithms and dividing by x^{ε}. From (6),

$$\frac{1}{b'}\frac{C_{\mathrm{den}}\log x}{\delta_1}(\eta + c_G + N) \le \frac{3x^{2c_{\mathrm{pol}}}}{b'} \longrightarrow 0. \tag{8}$$

Choose the threshold so that each expression in (7) and (8) is at most $1/2$. Their sum proves the first common scalar bound in Lemma 18.5. The same exponential comparison gives $2c_G \le b'$, proving $2b' + 2c_G \le 3b'$. It also gives, for every prime p,

$$C_{\mathrm{Ds}}(N_{\mathrm{orb}}^3 + r_G^5 + k^2)\log_p a \le 3x^{7c_{\mathrm{pol}}} \le b' \tag{9}$$

eventually. All replacements in the first inequality use (6).

For a prime $p < k^2x^{26}$, (5) implies $\log p \le 38\log x$. Equation (1) then yields

$$\log Q_{\mathrm{cor}}(p) \le 38C_{\mathrm{den}}x^{\varepsilon/8}(\log x)^2 \le x^{7\varepsilon/48} \tag{10}$$

eventually, since $\varepsilon/8 = 6\varepsilon/48$ and $(\log x)^2/x^{\varepsilon/48} \to 0$. Thus

$$\log(kQ_{\mathrm{cor}}(p)) \le 6\log x + x^{7\varepsilon/48} \le \log x + x^{\varepsilon} - x^{\varepsilon/3} = \log b'$$

eventually. The penultimate inequality follows by dividing its difference by x^{ε}, whose limit is 1. This proves the required small-prime bound uniformly in p.

For every prime $p < X'$, the same argument uses $\log p < x^{\varepsilon/3}$ instead and gives

$$\log Q_{\mathrm{cor}}(p) \le C_{\mathrm{den}}(\log x)x^{11\varepsilon/24} \le x^{23\varepsilon/48} \tag{11}$$

eventually, because $11/24 = 22/48$. We use this to check the last, large-prime budget of the finite estimate.

For every integer $0 \le d_{\mathrm{cyc}} \le n$, (6) and $\delta_1 \le 1$ imply

$$u_{\mathrm{cor}}(d_{\mathrm{cyc}}) = 40d_{\mathrm{cyc}}\delta_1 \le x^{2c_{\mathrm{pol}}}$$

after increasing the threshold. The defining formula and $\lceil u \rceil \le u + 1$ give

$$D^{\mathrm{l}}_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) \le 2x^{10c_{\mathrm{pol}}} + 1 \le x^{11c_{\mathrm{pol}}}. \tag{12}$$

Indeed its product has exponents at most $c_{\mathrm{pol}} + 2c_{\mathrm{pol}} + c_{\mathrm{pol}} + 5c_{\mathrm{pol}} + c_{\mathrm{pol}}$; the factor 2 bounds $N^5_{\mathrm{orb}} + k^3$. Substituting (12) into the four terms of c_{cor} gives

$$\begin{aligned} c_{\mathrm{cor}}(p, d_{\mathrm{cyc}}) &\le 16x^{11c_{\mathrm{pol}}} + x^{5c_{\mathrm{pol}}} + 4x^{3c_{\mathrm{pol}}} + 2x^{2c_{\mathrm{pol}}} \\ &\le x^{12c_{\mathrm{pol}}} \end{aligned} \tag{13}$$

eventually. The bounds are uniform in $p \ge 2$ and $d_{\mathrm{cyc}} \le n$.

In the last budget of Lemma 18.5, take $d_{\mathrm{cyc}} = n_p \le n$. Its first term is at most $3x^{2c_{\mathrm{pol}}}$. The four terms multiplied by C_{t2} are, respectively, at most

$$x^{13c_{\mathrm{pol}}} \exp(x^{23\varepsilon/48}), \quad x^{2c_{\mathrm{pol}}} \exp(x^{23\varepsilon/48}), \quad x^{3c_{\mathrm{pol}}}, \quad x^{2c_{\mathrm{pol}}},$$

by (6), (11) and (13). Its next term is at most $2x^{2c_{\mathrm{pol}}}$. Its term multiplied by 40 is at most $80x^{9c_{\mathrm{pol}}}$, using (6). The final constant is 3. For sufficiently large x, their sum is consequently at most

$$x^{14c_{\mathrm{pol}}} \exp(x^{23\varepsilon/48}).$$

Indeed, first bound $80x^{9c_{\mathrm{pol}}} \le x^{10c_{\mathrm{pol}}}$ and then bound the remaining sum by

$$12x^{13c_{\mathrm{pol}}} \exp(x^{23\varepsilon/48}) \le x^{14c_{\mathrm{pol}}} \exp(x^{23\varepsilon/48}).$$

Finally

$$14c_{\mathrm{pol}} \log x + x^{23\varepsilon/48} \le x^{\varepsilon/2} \tag{14}$$

eventually: the ratio of the left side to $x^{\varepsilon/2}$ tends to 0, because $23/48 < 1/2$ and $\varepsilon > 0$. This proves that last budget with $b_o = \exp(x^{\varepsilon/2})$.

Equations (1) and (2) check all the coefficient inequalities of the finite estimate. Every other hypothesis has been checked in (3)–(14) or by Lemma 18.6. Also $\eta > 0$ and $L_a \ge x^{\varepsilon} > 0$ follow from (Pf3) and (Lm7). Thus Lemma 18.5, with C_0 as coefficient and $b_o = \exp(x^{\varepsilon/2})$, gives item 3 of Lemma 18.9 at every candidate prime, representative and lift.

For its item 2, a served prime satisfies $p \le X''$. Condition (Pf3) supplies (Lm7), and (Nc4) supplies the canonical ceiling. Applying Lemma 18.8 therefore gives

$$\epsilon_p \le (C_e + 1)fk^2 \log_p a.$$

Its item 1 was already checked by Lemma 18.6. Apply Lemma 18.9 with correction coefficient $C_e + 1$. It gives the linking property with

$$\max(C_0, 10 + (C_e + 1), 16) = \max(C_0, 11 + C_e, 16)$$

and the stated function δ. Take x_0 greater than all the finitely many thresholds chosen in this proof. Since each of them depends only on the fixed data, x_0, C and δ are the same for every family and member, as claimed. □

Lemma 18.5. *Consider a loss datum whose correction degrees and orbit thresholds satisfy (Nc2) and (Nc3) of Definition 18.3 for a tuple* $\mathfrak{k}_{\mathrm{orb}}$ *of eight nonnegative real constants, and let* $C_{\mathrm{den}} > 0$, C *and* $b_o > 0$ *be real numbers. Suppose that*

$$x \geq \exp(1), \quad 0 < \varepsilon < 1/52, \quad m \geq 1, \quad k \geq 5, \quad S_c \geq 100,$$
$$N \leq S_c, \quad kS_c \leq w'', \quad \eta > 0, \quad L_a \geq 0,$$

and that for every lift $1 \leq j \leq m$, *place* $z \in \Phi$ *and top* $t \in T$,

$$0 \leq \varsigma_j \leq S_c, \qquad w_j(z) \geq 1, \qquad a \leq a_t \leq a\left(1 + \frac{1}{kx^{13}}\right), \qquad b_t \geq b',$$
$$\frac{b'}{x} \leq w_j(0,t) - b_t \leq \frac{b'}{x} + \eta.$$

Assume the following further inequalities.

1. *For every candidate prime* p *and* $v \in V_p$,

$$n_p \delta_1 \leq N_p(v) C_{\mathrm{den}} \log x.$$

For every candidate $p \geq p_0^* = k^2 x^{26}$, *the integer* n_p *is even.*

2. *The following common scalar bounds hold:*

$$\frac{C_{\mathrm{den}} \log x}{\delta_1}(w'' + \eta + c_G + N) \leq b', \qquad 2b' + 2c_G \leq 3b'.$$

For every candidate prime $p < p_0^*$,

$$kQ_{\mathrm{cor}}(p) \leq b'.$$

For every candidate prime p,

$$C_{\mathrm{Ds}}(N_{\mathrm{orb}}^3 + r_G^5 + k^2) \log_p a \leq b'.$$

3. *The loss coefficient satisfies*

$$C \geq 12, \qquad C_{\mathrm{ts}} r_G \leq C, \qquad 13 + 4C_{\mathrm{ts}} + 160 C_{\mathrm{den}} \leq C, \qquad C_{\mathrm{den}} \leq C,$$
$$C_{\mathrm{t1}} N_{\mathrm{orb}} \leq C \log x.$$

4. *For every candidate prime* $p \geq p_0^*$,

$$\begin{aligned} &\frac{C_{\mathrm{den}} \log x}{\delta_1}(\eta + c_G + N) \\ &\quad + C_{\mathrm{t2}}\left(Q_{\mathrm{cor}}(p) c_{\mathrm{cor}}(p, n_p) + kQ_{\mathrm{cor}}(p) + k \log_p a + c_G\right) \\ &\quad + 2\frac{C_{\mathrm{den}} \log x}{\delta_1} c_G \\ &\quad + 40 C_{\mathrm{den}} (\log x)\, C_{\mathrm{Dl}} x^{26} (N_{\mathrm{orb}}^5 + k^3) \log_p a + 3 \leq b_o. \end{aligned}$$

Then, for every candidate prime p, representative $v \in V_p$ and lift $1 \le j \le m$,

$$\sum_{t \in T_p(v)} (A_p(a_t, t, w_j) - \mathrm{lo}_{C,b_o}(p)) \le g_j^U(v) - \mathrm{Pr}_j(v) + \delta_p(v) - \left(\lceil t_p(v) \rceil^+ + D_p + 1 \right).$$

Proof. Fix a candidate prime p, a representative $v \in V_p$ and a lift j. Thus p is not sign-changing, $p < X'$ and $n_p = \mathrm{ord}(h_p) \ge 1$. The auxiliary notation below depends on these choices and on the fixed loss datum. Put

$$g_{\mathrm{den}} = \frac{C_{\mathrm{den}} \log x}{\delta_1}, \qquad u_{\mathrm{gain}} = w'' + \eta + c_G + N, \qquad z_{\mathrm{orb}} = \log_p(2a).$$

The density hypothesis gives

$$n_p \le N_p(v) g_{\mathrm{den}}, \qquad n_p \delta_1 \le N_p(v) C_{\mathrm{den}} \log x. \tag{1}$$

Since $\delta_1 > 0$, $n_p \ge 1$ and $C_{\mathrm{den}} \log x > 0$, we also have $N_p(v) \ge 1$.

We first check the signs used below. The identities of a loss datum and the scalar hypotheses give

$$b' \ge w'' \ge k S_c \ge 500, \qquad \log x \ge 1, \qquad r_G \ge 1, \qquad g_{\mathrm{den}} u_{\mathrm{gain}} \le b', \qquad 2c_G \le b'. \tag{2}$$

Here $w'' = b'/(x|H|) \le b'$ because $x > 1$ and $|H| \ge 1$. All terms in u_{gain} are nonnegative. Consequently

$$n_p c_G \le n_p u_{\mathrm{gain}} \le N_p(v) b'. \tag{3}$$

Moreover $a = b' X' > b'$, and the height bounds imply

$$0 < a_t - 2c_G \le a_t \le 2a \qquad (t \in T). \tag{4}$$

Every capacity is positive:

$$w_j(z_p(t,e)) - \varsigma_j + c_G \ge 1 - S_c + 4S_c > 0. \tag{5}$$

Since $p < X' < a$, we have $z_{\mathrm{orb}} \ge 1$.

We next compare the positive-part sums with the served gain. For a top $t \in T_p(v)$ put

$$m_{\mathrm{top}}(t) = \sum_{\substack{e \ge 1 \\ e \text{ odd}}} \min\left(\frac{a_t}{p^e}, w_j(z_p(t,e)) \right),$$

and put

$$m_{\mathrm{retained}} = \sum_{\substack{t \in T_p(v) \\ t \text{ at an even position}}} m_{\mathrm{top}}(t).$$

The first series converges by comparison with $a_t \sum_{e \text{ odd}} p^{-e}$. The positive-part series defining $A_p(a_t, t, w_j)$ is eventually zero because $w_j \ge 1$. The identity $y = (y - w)^+ + \min(y, w)$ for $y, w \ge 0$ therefore gives

$$A_p(a_t, t, w_j) + m_{\mathrm{top}}(t) = \gamma_p a_t. \tag{6}$$

For a top at an even position, its contribution on the left of (6) differs from $\gamma_p(a_t - 2c_G)$ by $2c_G\gamma_p \le 3c_G z_{\mathrm{orb}}$. For a top at an odd position, write $\alpha_t = a_t - 2c_G$ and use the capacity $c_j(t,e)$ of the gain datum. The inequality

$$\left(\frac{a_t}{p^e} - w_j(z_p(t,e)) \right)^+ - \left(\frac{\alpha_t}{p^e} - c_j(t,e) \right)^+ \le \frac{2c_G}{p^e} + c_G$$

follows from $c_j(t,e) - w_j(z_p(t,e)) = c_G - \varsigma_j \le c_G$ and the fact that the positive-part function is nondecreasing and has Lipschitz constant 1. If the first positive part is zero, its difference from the second is nonpositive. Otherwise $p^e < a_t \le 2a$, so there are at most z_{orb} such positive integer exponents. The total difference is thus at most

$$2c_G\gamma_p + c_G z_{\mathrm{orb}} \le 3c_G z_{\mathrm{orb}}.$$

Both α_t and the capacities are nonnegative by (4) and (5). Hence their minimum series converges, and

$$\sum_{e \text{ odd}} \left(\frac{\alpha_t}{p^e} - c_j(t,e)\right)^+ = \gamma_p\alpha_t - \sum_{e \text{ odd}} \min(\alpha_t/p^e, c_j(t,e)).$$

Summing these estimates over even and odd top positions, and using the definition of $g_j^U(v)$, proves

$$\sum_{t\in T_p(v)} A_p(a_t,t,w_j) + m_{\mathrm{retained}} \le g_j^U(v) + \delta_p(v) + 3N_p(v)c_G z_{\mathrm{orb}}. \tag{7}$$

The coefficient of this last error is covered by the first part of the local loss, since

$$3c_G z_{\mathrm{orb}} = 12S_c z_{\mathrm{orb}} \le C(S_c + k + \eta)z_{\mathrm{orb}}. \tag{8}$$

It remains to prove the following price and correction estimate:

$$\mathrm{Pr}_j(v) + \lceil t_p(v)\rceil^+ + D_p + 1 \le m_{\mathrm{retained}} + N_p(v)\big(\mathrm{pr}_{C,b_o}(p) + \mathrm{or}_C(p)\big). \tag{9}$$

We prove it separately in the two ranges determined by $p_0^* = k^2x^{26}$, the price threshold of this loss datum.

Suppose first that $p < p_0^*$. Put

$$s_{\mathrm{small}} = \frac{L_a a}{pk} + ap^{-\ell_{\mathrm{cor}}(p)}, \qquad e_{\mathrm{small}} = C_{\mathrm{Ds}}(N_{\mathrm{orb}}^3 + r_G^5 + k^2)\log_p a.$$

Both are nonnegative, using $L_a \ge 0$, and $e_{\mathrm{small}} \le b'$. The correction formulas and the ceiling bound give

$$\begin{aligned} t_p(v) &= C_{\mathrm{ts}} r_G N_p(v)\big(s_{\mathrm{small}} + 2b' + 2c_G + kQ_{\mathrm{cor}}(p)\big) + 2r_G n_p c_G \ge 0,\\ D_p &\le 40n_p\delta_1 e_{\mathrm{small}} + 2r_G n_p c_G + 40r_G n_p\delta_1(2b' + 2c_G) + 1. \end{aligned}$$

Also $2b' + 2c_G \le 3b'$ and

$$\begin{aligned} \mathrm{Pr}_j(v) &= r_G\big(N_p(v)(2b' + c_G) + n_p u_{\mathrm{gain}}\big)\\ &\le 3r_G\big(N_p(v)b' + n_p u_{\mathrm{gain}}\big) \le 6r_G N_p(v)b'. \end{aligned}$$

Since $t_p(v) \ge 0$, its positive ceiling is at most $t_p(v) + 1$. Using (1)–(3), $kQ_{\mathrm{cor}}(p) \le b'$ and the preceding bounds, we obtain

$$\begin{aligned} &\mathrm{Pr}_j(v) + \lceil t_p(v)\rceil^+ + D_p + 1\\ &\quad\le C_{\mathrm{ts}} r_G N_p(v) s_{\mathrm{small}} + (10 + 4C_{\mathrm{ts}})r_G N_p(v)b'\\ &\qquad + 40C_{\mathrm{den}}(\log x)N_p(v)b' + 120r_G C_{\mathrm{den}}(\log x)N_p(v)b' + 3\\ &\quad\le C(\log x)N_p(v)s_{\mathrm{small}}\\ &\qquad + (13 + 4C_{\mathrm{ts}} + 160C_{\mathrm{den}})r_G(\log x)N_p(v)b'\\ &\quad\le N_p(v)\big(C(\log x)s_{\mathrm{small}} + Cr_G b'\log x\big). \end{aligned} \tag{10}$$

For the first inequality, the two terms $2r_G n_p c_G$ contribute at most $4r_G N_p(v)b'$, and the two terms involving $n_p\delta_1$ contribute the displayed 40 and 120 terms. For the second, use $C_{\mathrm{ts}}r_G \le C$, $\log x, r_G \ge 1$ and $r_G(\log x)N_p(v)b' \ge 1$; this last bound absorbs the constant 3.

The cutoff in s_{small} is at least the cutoff in the local loss. Indeed

$$\log_p((kx^{26})^4) = \log_p(k^2x^{78}) + \log_p(k^2x^{26}),$$

and the second summand is greater than 1 because $p < k^2x^{26}$. Taking ceilings therefore gives

$$\ell_{\mathrm{cor}}(p) \ge \lceil \log_p(k^2x^{78}) \rceil + 1 = L_1(p).$$

Thus

$$s_{\mathrm{small}} \le \frac{L_a a}{pk} + ap^{-L_1(p)}.$$

The last expression in (10) is consequently at most $N_p(v)(\mathrm{or}_C(p)+\mathrm{pr}_{C,b_o}(p))$. Since $m_{\mathrm{retained}} \ge 0$, this proves (9) in the small-prime range.

Now suppose that $p \ge p_0^*$. The integer n_p is even by hypothesis. Let k_{back} be the first, finite-sum term in $t^{\mathrm{l}}_{\mathrm{cor}}(p,v)$ of (Nc3), and put

$$h_{\mathrm{top}} = b'/x + \eta.$$

We claim

$$\sum_{\substack{t\in T_p(v)\\ t \text{ at an odd position}}} (w_j(0,t) - \varsigma_j - b_t) + k_{\mathrm{back}} \le m_{\mathrm{retained}} + N_p(v)h_{\mathrm{top}}. \tag{11}$$

To prove this, label the orbit by its residues $0,\dots,n_p-1$ relative to v. For each odd $i \in P_p(v)$ with $d^-_{p,v}(i) > 0$, associate the pair

$$\left((i - d^-_{p,v}(i)) \bmod n_p,\ d^-_{p,v}(i)\right).$$

The first entry is an even top position by definition. The second entry is odd, since subtracting it from odd i gives an even residue modulo the even integer n_p. The association is injective: the pair determines i modulo n_p, hence determines its representative in $\{0,\dots,n_p-1\}$. The bound $b_{v+ih_p} \le w_j(0, v+ih_p)$ shows that the corresponding summand of k_{back} is at most

$$\min\left(w_j(0,v+ih_p), \frac{a_{v+((i-d^-_{p,v}(i)) \bmod n_p)h_p}}{p^{d^-_{p,v}(i)}}\right).$$

This is the term with that odd exponent in m_{top} of the associated even top. Distinct pairs give distinct terms, and all remaining terms are nonnegative. Therefore $k_{\mathrm{back}} \le m_{\mathrm{retained}}$. For each odd-position top the remaining summand in (11) is at most h_{top}, by $\varsigma_j \ge 0$ and the upper top-offset bound. There are at most $N_p(v)$ such tops, proving (11).

Put

$$\begin{aligned} s_{\mathrm{large}} &= \frac{a}{p^2} + \frac{L_a a}{pk},\\ e_{\mathrm{large}} &= C_{\mathrm{Dl}}x^{26}(N_{\mathrm{orb}}^5 + k^3)\log_p a,\\ b_{\mathrm{large}} &= Q_{\mathrm{cor}}(p)c_{\mathrm{cor}}(p,n_p) + kQ_{\mathrm{cor}}(p) + k\log_p a + c_G. \end{aligned}$$

These numbers and k_{back} are nonnegative. Conditions (Nc2) and (Nc3) give

$$\begin{aligned} t_p(v) &= k_{\mathrm{back}} + C_{\mathrm{t1}}N_p(v)N_{\mathrm{orb}}s_{\mathrm{large}} + C_{\mathrm{t2}}N_p(v)b_{\mathrm{large}} + 2n_pc_G \ge 0,\\ D_p &\le 40n_p\delta_1 e_{\mathrm{large}} + 1. \end{aligned}$$

Using the large-prime price, (11), (1), and $C_{\mathrm{t1}}N_{\mathrm{orb}} \le C\log x$, we obtain

$$\begin{aligned}
&\mathrm{Pr}_j(v) + \lceil t_p(v)\rceil^+ + D_p + 1\\
&\quad\le m_{\mathrm{retained}} + N_p(v)h_{\mathrm{top}} + n_p u_{\mathrm{gain}} + C(\log x)N_p(v)s_{\mathrm{large}}\\
&\qquad + C_{\mathrm{t2}}N_p(v)b_{\mathrm{large}} + 2n_p c_G + 40n_p\delta_1 e_{\mathrm{large}} + 3\\
&\quad\le m_{\mathrm{retained}} + N_p(v)\,[h_{\mathrm{top}} + g_{\mathrm{den}}w'' + C(\log x)s_{\mathrm{large}}\\
&\qquad\qquad + g_{\mathrm{den}}(\eta + c_G + N) + C_{\mathrm{t2}}b_{\mathrm{large}} + 2g_{\mathrm{den}}c_G + 40C_{\mathrm{den}}(\log x)e_{\mathrm{large}} + 3]\\
&\quad\le m_{\mathrm{retained}} + N_p(v)\big(h_{\mathrm{top}} + g_{\mathrm{den}}w'' + C(\log x)s_{\mathrm{large}} + b_o\big).
\end{aligned} \tag{12}$$

The factor $N_p(v) \ge 1$ absorbs the constant 3. The last inequality is hypothesis 4.

Finally $C_{\mathrm{den}} \le C$ implies $g_{\mathrm{den}}w'' \le Cw''(\log x)/\delta_1$. Since $C \ge 1$ and $S_c, t_R \ge 0$,

$$\begin{aligned}
h_{\mathrm{top}} + g_{\mathrm{den}}w'' + b_o &\le C\left(\frac{b'}{x} + \eta + S_c + \frac{(w''+t_R)\log x}{\delta_1}\right) + b_o\\
&= \mathrm{pr}_{C,b_o}(p).
\end{aligned}$$

Also $C(\log x)s_{\mathrm{large}} = \mathrm{or}_C(p)$. Thus (12) proves (9) in the large-prime range.

Subtract $N_p(v)\mathrm{lo}_{C,b_o}(p)$ from (7). Using (8), the definition of the local loss and then (9), we find

$$\begin{aligned}
&\sum_{t\in T_p(v)} \big(A_p(a_t,t,w_j) - \mathrm{lo}_{C,b_o}(p)\big)\\
&\quad\le g_j^U(v) + \delta_p(v) - m_{\mathrm{retained}} - N_p(v)\big(\mathrm{pr}_{C,b_o}(p) + \mathrm{or}_C(p)\big)\\
&\quad\le g_j^U(v) - \mathrm{Pr}_j(v) + \delta_p(v) - \big(\lceil t_p(v)\rceil^+ + D_p + 1\big).
\end{aligned}$$

This is the asserted inequality, and p, v and j were arbitrary. □

Lemma 18.6. *Suppose a loss datum has the integer weights and boxes and satisfies*

$$k \ge 5, \qquad S_c \ge 100, \qquad kS_c \le w'', \qquad N = k + m(t_R+1) \le S_c.$$

Then, for every $1 \le j \le m$, every $z \in \Phi$ and every top t,

$$0 \le \varsigma_j \le S_c, \qquad w_j(z) \ge 1, \qquad a \le a_t \le a\left(1 + \frac{1}{kx^{13}}\right), \qquad b_t \ge b', \qquad w_j(0,t) \ge b_t + b'/x.$$

Moreover, fix $0 < \varepsilon < 1/52$, $c_D > 397$ and $c_h \ge 402$. There is a real number $x_0 > 1$, depending only on these constants, with the following property. If $x \ge x_0$, a loss datum at (x,ε) has the integer weights and boxes for these exponents, and its group H and parameters k, m, t_R are the group A and parameters k, m, t of a rank datum with the rank sizes at (x,ε,J) for some $J \ge 1$, then all four hypotheses in the first display, and hence all its conclusions, hold.

Proof. First assume the four displayed scalar hypotheses. Since $x > 1$ and $c_D \ge 0$, $\Delta \ge 1$; also $h_0/2 = \lceil x^{c_h}\rceil \ge 1$. The shifts increase with j, and

$$0 < \varsigma_j \le \varsigma_m = \frac{k + (2m-1)(t_R+1)}{2} < k + m(t_R+1) = N \le S_c.$$

The strict inequality follows because its right side minus its middle expression is $(k+t_R+1)/2 > 0$. The height and depth conclusions follow directly from the integer boxes.

Put $u = b'/x > 0$ for this paragraph. At a top,

$$w_j(0,t) - b_t = \lfloor u\rfloor + (j - \tfrac{1}{2})h_0 \ge \lfloor u\rfloor + 1 \ge u.$$

In particular b_t is a positive integer and all top weights are at least 1. At a thin place, $\lceil w'' \rceil \geq 1$ because $w'' > 0$. At a thick place, $\lceil b \rceil \geq 1$. The positive half-gap and the nonnegative later gaps show that all those weights are at least 1 as well. This proves every conclusion of the first part.

We now find a threshold independent of the rank datum and the weights. Write $n = |A|$ and $f = 2n$. The rank conditions give $m \leq k$ and thus $r = k + m - 1 \leq 2k$. The rank sizes imply

$$\begin{gathered} n \leq 2x^{2+8\varepsilon}, \qquad x^{1/2-\varepsilon/16} \leq m \leq 2x^{1/2-\varepsilon/16}, \\ x^{9/2+10\varepsilon} \leq k \leq 2x^{9/2+10\varepsilon}, \qquad r \leq 4x^{9/2+10\varepsilon}, \qquad f \leq 4x^{2+8\varepsilon}. \end{gathered}$$

Since $\lceil v \rceil \leq v + 1$ for $v \geq 0$, the defining formula for n_W yields

$$\begin{aligned} n_W &\leq 10r \left(f + \frac{f^2 (k-1)^3 x^{2\varepsilon}}{m} \right) + 8 \\ &\leq 160 x^{13/2+18\varepsilon} + 5120 x^{43/2+(929/16)\varepsilon} + 8 \\ &\leq 5288 x^{43/2+(929/16)\varepsilon}. \end{aligned}$$

Every replacement here is an upper bound by the preceding display and $k - 1 \leq k$; the last exponent exceeds the other exponents for $x > 1$. Also $\lceil x^{377} \rceil \leq 2x^{377}$. Using $t_R = t \leq r + t = 8fr + 4 + \lceil x^{377} \rceil n_W$ gives

$$\begin{aligned} t_R &\leq 128 x^{13/2+18\varepsilon} + 4 + 10576 x^{797/2+(929/16)\varepsilon} \\ &\leq 10708 x^{797/2+(929/16)\varepsilon}. \end{aligned}$$

The exponent $797/2 + (929/16)\varepsilon$ is strictly less than 401 for $\varepsilon < 1/52$. We may therefore choose a threshold such that $t_R \leq x^{401}$ for all the data under consideration.

For x above this threshold, the inequalities $9/2 + 10\varepsilon < 5$ and $m \leq 2x^{1/2}$ imply

$$N = k + m(t_R + 1) \leq 2x^5 + 4x^{401+1/2} \leq 6x^{401+1/2}.$$

On the other hand

$$S_c = 4k \lceil x^{c_D} \rceil \geq 4x^{9/2+10\varepsilon+c_D}.$$

Because $c_D - 397 + 10\varepsilon > 0$, increasing the threshold until $x^{c_D - 397 + 10\varepsilon} \geq 3/2$ proves $N \leq S_c$ uniformly. Increasing it also until $x^{9/2+10\varepsilon} \geq 25$ gives $k \geq 25$ and $S_c \geq 4k \geq 100$.

Finally $\Delta \leq 2x^{c_D}$ and the rank sizes give

$$nkS_c = 4nk^2 \Delta \leq 64 x^{11+28\varepsilon+c_D}.$$

The loss identities give

$$nw'' = \exp(x^{\varepsilon} - x^{\varepsilon/3}).$$

For every fixed positive ε and fixed real exponent, this last exponential eventually exceeds $64x^{11+28\varepsilon+c_D}$: taking logarithms reduces this to

$$x^{\varepsilon} - x^{\varepsilon/3} - (11 + 28\varepsilon + c_D) \log x - \log 64 \geq 0,$$

whose left side divided by x^{ε} tends to 1. Thus $kS_c \leq w''$ after one further uniform increase of the threshold. All thresholds used depend only on the fixed exponents and ε. The first part now applies, completing the uniform assertion. $\square$

Lemma 18.7. *Fix $0 < \varepsilon < 1/52$. There is a constant $C_{\mathrm{den}} > 0$, depending only on ε, such that for every $x \geq \exp(1)$, every positive integer $d_{\mathrm{cyc}} \geq 3G_{\mathrm{orb}}$ and every $P_{\mathrm{cyc}} \subseteq \{0, \dots, d_{\mathrm{cyc}} - 1\}$ satisfying (Go2) with $n = d_{\mathrm{cyc}}$,*

$$|P_{\mathrm{cyc}}| \geq 1, \qquad d_{\mathrm{cyc}}\delta_{\mathrm{orb}} \leq |P_{\mathrm{cyc}}| C_{\mathrm{den}} \log x.$$

One may take

$$C_{\mathrm{den}} = 2(6r_{\mathrm{orb}} + 1)\left((5 + 8\varepsilon)10^{6r_{\mathrm{orb}}+1} + 6\right).$$

The integer r_{orb} depends only on ε.

There is also a threshold $x_0 > 1$, depending only on ε, such that for every $x \geq x_0$, every finite good-orbit selection, every inert prime p that is not sign-changing and has $\mathrm{ord}(h_p) \geq x^{\varepsilon/4}$, and every $v \in G_p$,

$$N_p(v) \geq 1, \qquad \mathrm{ord}(h_p)\, x^{-\varepsilon/8} \leq N_p(v) C_{\mathrm{den}} \log x.$$

Proof. Throughout the proof, all numerical orbit quantities have the fixed parameters (x, ε) of the statement. Put $B = \lfloor d_{\mathrm{cyc}}/\ell_{\mathrm{orb}} \rfloor$ and $d_{\mathrm{rem}} = d_{\mathrm{cyc}} - B\ell_{\mathrm{orb}}$, so $0 \leq d_{\mathrm{rem}} < \ell_{\mathrm{orb}}$. The hypothesis on the length gives

$$B \geq 3(M_{\mathrm{orb}} + 5) > M_{\mathrm{orb}}.$$

Every block selected by (Go2) contains a point of P_{cyc} in its second cell. Write this point as $s\ell_{\mathrm{orb}} + a_{\mathrm{cell}}$, where s is the block index and $u_{\mathrm{orb}} \leq a_{\mathrm{cell}} < 2u_{\mathrm{orb}} \leq \ell_{\mathrm{orb}}$.

We show that every integer $0 \leq i < d_{\mathrm{cyc}}$ has a point of P_{cyc} within forward cyclic distance G_{orb}. If $i < B\ell_{\mathrm{orb}}$, write $i = j_{\mathrm{blk}}\ell_{\mathrm{orb}} + i_{\mathrm{cell}}$ with $0 \leq j_{\mathrm{blk}} < B$ and $0 \leq i_{\mathrm{cell}} < \ell_{\mathrm{orb}}$. Apply (Go2) starting from $(j_{\mathrm{blk}} + 1) \bmod B$ and let $0 \leq j \leq M_{\mathrm{orb}}$ be the resulting displacement. Since $M_{\mathrm{orb}} < B$, the selected block index is either $j_{\mathrm{blk}} + 1 + j$ or $j_{\mathrm{blk}} + 1 + j - B$.

In the first case the selected point is strictly after i, with distance

$$(j + 1)\ell_{\mathrm{orb}} + a_{\mathrm{cell}} - i_{\mathrm{cell}} < (M_{\mathrm{orb}} + 2)\ell_{\mathrm{orb}}.$$

In the second case travel once through the end of the cycle; the positive distance is

$$(j + 1)\ell_{\mathrm{orb}} + d_{\mathrm{rem}} + a_{\mathrm{cell}} - i_{\mathrm{cell}} < (M_{\mathrm{orb}} + 3)\ell_{\mathrm{orb}}.$$

If instead $i \geq B\ell_{\mathrm{orb}}$, start (Go2) at block 0. Its selected block has index $j \leq M_{\mathrm{orb}} < B$, and the positive distance through the end of the cycle to its selected point is

$$d_{\mathrm{cyc}} - i + j\ell_{\mathrm{orb}} + a_{\mathrm{cell}} < (M_{\mathrm{orb}} + 2)\ell_{\mathrm{orb}}.$$

In every case the distance is a positive integer at most $G_{\mathrm{orb}} = (M_{\mathrm{orb}} + 5)\ell_{\mathrm{orb}}$.

For each i choose one such pair consisting of a point of P_{cyc} and its distance. The pair determines i by subtracting the distance modulo d_{cyc}, so this is an injection into $P_{\mathrm{cyc}} \times \{1, \dots, G_{\mathrm{orb}}\}$. Hence

$$d_{\mathrm{cyc}} \leq |P_{\mathrm{cyc}}| G_{\mathrm{orb}}, \qquad |P_{\mathrm{cyc}}| \geq 1.$$

To bound the last factor, put $A_{\mathrm{tile}} = (5 + 8\varepsilon)10^{6r_{\mathrm{orb}}+1}$. Since $0 < \delta_{\mathrm{orb}} < 1$ and $\log x \geq 1$,

$$u_{\mathrm{orb}}\delta_{\mathrm{orb}} \leq 2, \qquad M_{\mathrm{orb}} + 5 \leq A_{\mathrm{tile}} \log x + 6 \leq (A_{\mathrm{tile}} + 6) \log x.$$

It follows that

$$G_{\mathrm{orb}}\delta_{\mathrm{orb}} \leq 2(6r_{\mathrm{orb}} + 1)(A_{\mathrm{tile}} + 6) \log x = C_{\mathrm{den}} \log x.$$

Multiplying the finite covering inequality by δ_{orb} proves the first assertion.

For the uniform threshold, the same estimates give

$$G_{\mathrm{orb}} \le C_{\mathrm{den}} x^{\varepsilon/8} \log x \quad (x \ge \exp(1)).$$

As $\log x / x^{\varepsilon/8} \to 0$, one threshold depending only on ε gives $3G_{\mathrm{orb}} \le x^{\varepsilon/4}$ for every larger x. Now take a prime and representative in the second assertion. Its position set satisfies (Go2) by the definition of G_p, and its cycle length is at least $3G_{\mathrm{orb}}$. Since p is not sign-changing, the map $i \mapsto v + ih_p$, for $0 \le i < \mathrm{ord}(h_p)$, is a bijection onto its orbit; restricting to the top positions gives $|P_p(v)| = N_p(v)$. The first assertion applied to this position set gives both required conclusions. □

Lemma 18.8. *Let $\mathfrak{M}$ be a loss datum satisfying (Lm7) for some $\varepsilon_z > 0$ and real C_t. Let $C_e \ge 0$ be real, and let $p \le X''$ be an inert prime. Then*

$$fk^2 \log_p a \ge 1.$$

Consequently, if

$$\epsilon_p = \left\lceil C_e f k^2 \log_p a \right\rceil,$$

then

$$\epsilon_p \le (C_e + 1) f k^2 \log_p a.$$

Proof. Put $\theta_s = \varepsilon/100$, as in (Lm7). A loss datum has $x > 1$ and $0 < \varepsilon < 1/52$. Therefore

$$2 + 8\varepsilon + \theta_s < 3, \qquad \frac{9}{2} + 10\varepsilon - \theta_s > 0.$$

The upper bound for n and lower bound for k in (Lm7) imply

$$1 \le n \le x^3, \qquad k \ge x^{9/2 + 10\varepsilon - \theta_s} > 1.$$

Since k is an integer, $k \ge 2$, and hence $fk^2 = 2nk^2 \ge 8$.

The prime p is at least 2, so $\log p > 0$. Using $p \le X'' = xn \exp(x^{\varepsilon/3})$ and $n \le x^3$ gives

$$\begin{aligned} \log p &\le \log X'' = \log x + \log n + x^{\varepsilon/3} \\ &\le 4 \log x + x^{\varepsilon/3} \le 4 \log x + 4x^{\varepsilon} = 4 \log a. \end{aligned}$$

Here $x^{\varepsilon/3} \le x^{\varepsilon}$ because $x > 1$ and $\varepsilon > 0$, and $a = x \exp(x^{\varepsilon})$. In particular $\log_p a \ge 1/4$. Combining this with $fk^2 \ge 8$ yields $fk^2 \log_p a \ge 2 \ge 1$.

The argument of the ceiling in the assumed formula for ϵ_p is nonnegative. The ceiling of a real number is strictly less than that number plus 1. It follows that

$$\epsilon_p < C_e f k^2 \log_p a + 1 \le (C_e + 1) f k^2 \log_p a,$$

where the last inequality uses the lower bound just proved. This implies the required non-strict bound. □

Lemma 18.9. *Let $\mathcal{F}$ be a parametrised host family with parameter ε. Suppose there are real constants $C_e \ge 0$, C_0 and x_2 such that, for every $x \ge x_2$ with $x > x_1$ and every $i \in I(x)$, the following hold.*

1. *The member satisfies*

$$k \ge 5, \qquad S_c \ge 100, \qquad kS_c \le w'', \qquad 0 \le \varsigma_j \le S_c \quad (1 \le j \le m),$$

and, for all tops t and lifts j,

$$a \le a_t \le a\left(1 + \frac{1}{kx^{13}}\right), \quad b_t \ge b', \quad w_j(z) \ge 1 \ (z \in \Phi), \quad w_j(0,t) \ge b_t + \frac{b'}{x}.$$

2. *At every served inert prime p,*

$$\epsilon_p \le C_e f k^2 \log_p a, \qquad f = 2|A|.$$

3. *At every candidate prime p, every $v \in V_p$ and every $1 \le j \le m$,*

$$\sum_{t \in T_p(v)} (A_p(a_t, t, w_j) - \mathrm{lo}_{C_0, \exp(x^{\varepsilon/2})}(p)) \le g_j^U(v) - \mathrm{Pr}_j(v) + \delta_p(v) - (\lceil t_p(v) \rceil^+ + D_p + 1).$$

Then $\mathcal{F}$ has the linking property. It holds with

$$C = \max(C_0, 10 + C_e, 16), \qquad \delta(x) = \begin{cases} x^{-\varepsilon/2} & x > 1, \\ 0 & x \le 1, \end{cases}$$

and threshold x_2. In particular, the same constant C and the same function δ serve every member.

Proof. Fix $x \ge x_2$ with $x > x_1$ and a member $i \in I(x)$. We prove both inequalities of (Lm3) for its loss datum and for $(C, \exp(x^{\varepsilon/2}))$.

The identities of a loss datum give $c_G = 4S_c$, $N = k + m(t_R + 1) \ge 0$, $b' = a/X' > 0$, $w'' = b'/(x|A|) > 0$, and $X' = \exp(x^{\varepsilon/3}) > 2$. Also $a = x\exp(x^{\varepsilon}) > 2$. Its size conditions give $\eta > 0$ and $L_a \ge x^{\varepsilon} > 0$. Every coefficient of C in $\mathrm{lo}_{C,b_o}(p)$ is therefore nonnegative. This follows term by term from its formula, since $\log x > 0$, $\delta_1 > 0$, $t_R \ge 0$, $r_G \ge 1$ and every positive power of p is positive. Thus increasing C_0 to C can only increase the local loss, with $b_o = \exp(x^{\varepsilon/2})$ fixed. The candidate estimate in item 3 consequently remains valid with C in place of C_0.

Since $C \ge 16$, all terms of the local loss are nonnegative and its first term alone gives

$$\mathrm{lo}_{C,\exp(x^{\varepsilon/2})}(p) \ge CS_c \log_p(2a) \ge 12S_c \log_p(2a) = 3c_G \log_p(2a)$$

at every inert prime. Here the middle-prime summand b_o is positive, and all other summands have the signs just checked. Item 2 and Lemma 18.12, with $C \ge 10 + C_e$ and $C \ge 16$, give

$$\sum_{v \in R_p} \delta_p(v) + \epsilon_p \le \mathrm{fl}_C(p)$$

at every served inert prime. Moreover $k \ge 1$, $c_G \ge 0$, $0 \le \varsigma_j \le S_c \le c_G$, and the assumed top-weight bound implies $w_j(0,t) \ge b' + b'/x$. All scalar hypotheses of Lemma 18.10 are now verified, and that lemma gives the served-prime inequality for these loss constants.

It remains to prove the surplus bound. The identity $b'/x = |A|w''$ and $|A| \ge 1$ imply

$$\frac{b'}{x} \ge kS_c \ge 500, \qquad b' > 500, \qquad a = X'b' > 2b' > 10S_c.$$

The last inequality uses $b' \geq xkS_c > kS_c \geq 5S_c$ and $X' > 2$. Hence, for each top,

$$0 < a_t - 8S_c = \alpha_t \leq a_t \leq a\left(1 + \frac{1}{kx^{13}}\right) \leq \frac{6}{5}a.$$

The capacities satisfy $c_j(t,e) \geq 1 - S_c + 4S_c > 0$, and every orbit loss is nonnegative by its formula. We check both price regimes. If $p \geq p_0^*$, then each summand at an odd-position top obeys

$$w_j(0,t) - \varsigma_j - b_t \geq b'/x - S_c \geq 0,$$

and $n_p(w'' + \eta + c_G + N) \geq 0$. Thus $\mathrm{Pr}_j(v) \geq 0$. If $p < p_0^*$, all factors in

$$r_G\big(N_p(v)(2b' + c_G) + n_p(w'' + \eta + c_G + N)\big)$$

are nonnegative, so its price is nonnegative too.

For $v \in V_p$ the prime p is a candidate, so $p < X'$. If $N_p(v) > 0$, then $mN_p(v) \geq 1$ and

$$\frac{mN_p(v)a}{p} \geq \frac{a}{p} > \frac{a}{X'} = b' > 500 > \frac{5}{2}.$$

If $N_p(v) = 0$ the other alternative of Lemma 18.13 applies. That lemma therefore gives $S_p(v) \leq 2mN_p(v)a/p$ for all such p, v. This proves the surplus bound and hence (Lm3).

Finally $\varepsilon > 0$, so the stated function δ tends to 0 as $x \to \infty$. For $x > 1$, the positive real power identity gives

$$b(x)^{\delta(x)} = \exp(x^{\varepsilon}x^{-\varepsilon/2}) = \exp(x^{\varepsilon/2}).$$

Since C and the threshold do not depend on x or i, and δ is the same function for all of them, the two inequalities proved above are the linking property for $\mathcal{F}$. □

Lemma 18.10. *Let $\mathfrak{M}$ be a loss datum and let C, b_o be real numbers. Suppose that $k \geq 1$, $c_G \geq 0$, and for every top t and $1 \leq j \leq m$,*

$$0 \leq a_t \leq a\left(1 + \frac{1}{kx^{13}}\right), \qquad w_j(z) \geq 1 \quad (z \in \Phi), \qquad w_j(0,t) \geq b' + \frac{b'}{x}, \qquad 0 \leq \varsigma_j \leq c_G.$$

Assume that for every served inert prime p,

$$\mathrm{lo}_{C,b_o}(p) \geq 3c_G \log_p(2a), \qquad \sum_{v \in R_p} \delta_p(v) + \epsilon_p \leq \mathrm{fl}_C(p).$$

Suppose also that for every candidate prime p, every $v \in V_p$ and $1 \leq j \leq m$,

$$\sum_{t \in T_p(v)} \big(A_p(a_t, t, w_j) - \mathrm{lo}_{C,b_o}(p)\big) \leq g_j^U(v) - \mathrm{Pr}_j(v) + \delta_p(v) - \big(\lceil t_p(v) \rceil^+ + D_p + 1\big).$$

Then the served-prime inequality holds: for every served inert prime p,

$$\sum_{j=1}^{m} \sum_{t \in T_p^{\mathrm{s}}} \big(A_p(a_t, t, w_j) - \mathrm{lo}_{C,b_o}(p)\big) - m\,\mathrm{fl}_C(p) \leq \sum_{j=1}^{m} \mathrm{gain}_j(p) - \tau_p.$$

Proof. We begin with signs and convergence. A loss datum has $x > 1$, $\varepsilon > 0$ and $a = x\exp(x^{\varepsilon}) > 1$. Thus its orbit losses are nonnegative by their formula, and the floor-budget hypothesis implies $\mathrm{fl}_C(p) \geq 0$ at a served prime. Also $\mathrm{lo}_{C,b_o}(p) \geq 0$ there. The weight bound makes each original odd-exponent sum finite. Moreover

$$c_j(t,e) = w_j(z_p(t,e)) - \varsigma_j + c_G \geq 1.$$

The reduced positive-part sums are therefore finite too. The series of minima defining the served gains converge by comparison with the geometric series, since their first arguments are α_t/p^e and their second arguments are at least 1.

Fix a served inert prime p. If it is a candidate, all the hypotheses of Lemma 18.11 hold: the orbit losses are nonnegative, the floor budget is assumed, and the stated orbitwise estimate applies at each $v \in V_p$. That lemma gives the conclusion. Hence assume from now on that p is not a candidate. Then $V_p = \emptyset$ and $\tau_p = 0$. Since a served prime is not dropped, $p \leq X''$. All gains are nonnegative, including when their exceptional zero rule applies.

If p is not sign-changing and $p < X'$, its served-top set is empty. The left side of the required inequality is then $-m\,\mathrm{fl}_C(p) \leq 0$, whereas its right side is a sum of nonnegative gains. It remains to treat a sign-changing prime or a prime $p \geq X'$. All tops are served in these cases.

We show first that every excluded exponent contributes zero to the original sum. For a sign-changing prime an odd exponent has partner with first coordinate 1, whereas a top place has first coordinate 0. Thus no odd exponent is excluded. If $p \geq X'$ and $e \geq 1$, then $p^e \geq X'$ and, using $kx^{13} \geq x$ and $b' = a/X'$, we have

$$\frac{a_t}{p^e} \leq b'\left(1 + \frac{1}{kx^{13}}\right) \leq b' + \frac{b'}{x}.$$

At an excluded exponent the partner is a top place, whose weight is at least this last quantity. The corresponding positive part is zero. This includes $p = X'$.

For $v \in R_p$ and a fixed j we next prove

$$\sum_{t \in T_p(v)} \left(A_p(a_t, t, w_j) - 3c_G \log_p(2a)\right) \leq g_j^0(v) + \delta_p(v).$$

At a nonexcluded odd exponent, the original argument of the positive part minus its reduced argument equals

$$\left(\frac{a_t}{p^e} - w_j(z_p(t,e))\right) - \left(\frac{a_t - 2c_G}{p^e} - w_j(z_p(t,e)) + \varsigma_j - c_G\right) = \frac{2c_G}{p^e} + c_G - \varsigma_j \in [0, 3c_G].$$

The positive-part function is increasing and has Lipschitz constant 1. Thus the original positive part is at most the reduced one plus $3c_G$. This extra term is needed only when the original positive part is nonzero, since at every other exponent the original term is zero and the reduced term is nonnegative. A nonzero original term implies $p^e < a_t \leq 2a$, because the weight is at least 1 and $1/(kx^{13}) \leq 1$. There are at most $\log_p(2a)$ positive integer exponents with $p^e < 2a$, and therefore at most that many odd exponents. Summing the termwise comparison, and using the vanishing at excluded exponents already proved, gives the displayed orbit estimate by the definition of $g_j^0(v)$.

Suppose now that the exceptional zero rule for the gain does not apply. Since $V_p = \emptyset$, its formula is

$$\mathrm{gain}_j(p) = \sum_{v \in R_p} \max(g_j^0(v), 0).$$

Sum the orbit estimate over the partition $(T_p(v))_{v\in R_p}$ of T. Replace each plain gain by its nonnegative part, use $\mathrm{lo}_{C,b_o}(p) \geq 3c_G \log_p(2a)$ and then use the floor budget. This gives, for each j,

$$\begin{aligned}\sum_{t\in T}(A_p(a_t,t,w_j) - \mathrm{lo}_{C,b_o}(p)) &\leq \sum_{v\in R_p} g_j^0(v) + \sum_{v\in R_p}\delta_p(v)\\ &\leq \mathrm{gain}_j(p) + \mathrm{fl}_C(p).\end{aligned}$$

Sum over j and subtract $m\,\mathrm{fl}_C(p)$. Since all tops are served and $\tau_p = 0$, the desired inequality follows.

Finally suppose that the exceptional zero rule applies. The alternative $p > X''$ is impossible for a served prime. Thus p is not sign-changing and $h_p = 0$. In the present case this forces $p \geq X'$. Every partner of a top is now that same top place. The preceding height comparison and the top-weight bound show that every term of $A_p(a_t,t,w_j)$ is zero. The left side of the required inequality is therefore a sum of nonpositive local-loss terms and a nonpositive floor-loss term. It is at most 0, which is the value of every gain and of τ_p. This proves the last case. □

Lemma 18.11. *Let $\mathfrak{M}$ be a loss datum, let p be a candidate prime, and let C, b_o be real numbers. Assume that $\delta_p(v) \geq 0$ for every $v \in R_p$ and*

$$\sum_{v\in R_p}\delta_p(v) + \epsilon_p \leq \mathrm{fl}_C(p).$$

Suppose also that for every $v \in V_p$ and $1 \leq j \leq m$,

$$\sum_{t\in T_p(v)}(A_p(a_t,t,w_j) - \mathrm{lo}_{C,b_o}(p)) \leq g_j^U(v) - \mathrm{Pr}_j(v) + \delta_p(v) - (\lceil t_p(v)\rceil^+ + D_p + 1).$$

Then

$$\sum_{j=1}^{m}\sum_{t\in T_p^{\mathrm{s}}}(A_p(a_t,t,w_j) - \mathrm{lo}_{C,b_o}(p)) - m\,\mathrm{fl}_C(p) \leq \sum_{j=1}^{m}\mathrm{gain}_j(p) - \tau_p.$$

Proof. Because p is a candidate, it is not sign-changing and $p < X'$. Its Frobenius element h_p has order at least $x^{\varepsilon/4} > 1$, so $h_p \neq 0$. Moreover $X'' = x|H|X' > X'$, since $x > 1$ and a finite group has at least one element. Thus neither condition suppressing $\mathrm{gain}_j(p)$ applies. Its defining expression is a sum of nonnegative maxima, and in particular $\mathrm{gain}_j(p) \geq 0$.

The orbit selection has $m \geq 1$, and $\epsilon_p \geq 0$ by definition. The nonnegative orbit losses and the floor-budget hypothesis imply $\mathrm{fl}_C(p) \geq 0$. If $V_p = \emptyset$, then $T_p^{\mathrm{s}} = \emptyset$ and $\tau_p = 0$. The required inequality reduces to $-m\,\mathrm{fl}_C(p) \leq \sum_j \mathrm{gain}_j(p)$, which follows from these signs.

Assume now that $V_p \neq \emptyset$. The sets $T_p(v)$ for $v \in V_p$ are pairwise disjoint and have union T_p^{s}, because they are the fibres of the orbit labelling on T and p is neither sign-changing nor at least X'. For each j, summing the assumed orbitwise estimates therefore gives

$$\begin{aligned}&\sum_{t\in T_p^{\mathrm{s}}}(A_p(a_t,t,w_j) - \mathrm{lo}_{C,b_o}(p))\\ &\quad\leq \sum_{v\in V_p}(g_j^U(v) - \mathrm{Pr}_j(v)) + \sum_{v\in V_p}\delta_p(v) - \sum_{v\in V_p}(\lceil t_p(v)\rceil^+ + D_p + 1).\end{aligned}$$

The first sum on the right is at most $\mathrm{gain}_j(p)$: each summand is at most the corresponding maximum in that gain, and every contribution from $R_p \setminus V_p$ is nonnegative. Summing over j

and subtracting $m\,\mathrm{fl}_C(p)$ bounds the desired left-hand side by

$$\sum_{j=1}^{m}\mathrm{gain}_j(p)+m\left(\sum_{v\in V_p}\delta_p(v)-\mathrm{fl}_C(p)\right)\\ -m\sum_{v\in V_p}\bigl(\lceil t_p(v)\rceil^{+}+D_p+1\bigr).$$

Here $V_p\subseteq R_p$. The nonnegative orbit losses and the floor budget give

$$m\left(\sum_{v\in V_p}\delta_p(v)-\mathrm{fl}_C(p)\right)\le -m\epsilon_p\le-\epsilon_p,$$

using $m\ge 1$. Since $V_p\neq\emptyset$, its correction is

$$\tau_p=\epsilon_p+m\sum_{v\in V_p}\bigl(\lceil t_p(v)\rceil^{+}+D_p+1\bigr).$$

Substituting these two relations gives exactly the required upper bound. □

Lemma 18.12. *Let $\mathfrak{M}$ be a loss datum with $a\ge 2$, and let p be an inert prime. Let $C_e\ge 0$ and $C\ge\max(10+C_e,16)$ be real numbers. If*

$$\epsilon_p\le C_e f k^2\log_p a,$$

then

$$\delta_p(v)\ge 0\quad(v\in R_p),\qquad\sum_{v\in R_p}\delta_p(v)+\epsilon_p\le\mathrm{fl}_C(p).$$

Proof. Every orbit on H has $\mathrm{ord}(h_p)$ elements when p is not sign-changing, and $\mathrm{ord}(2h_p)$ elements when p is sign-changing. These orbits partition H. In the former case $n_p=\mathrm{ord}(h_p)$; in the latter case $n_p=2\,\mathrm{ord}(2h_p)$. It follows that

$$|R_p|n_p\le 2|H|=f.$$

The sets $T_p(v)$, $v\in R_p$, partition T, because they are the fibres of the orbit labelling on T. Consequently

$$\sum_{v\in R_p}N_p(v)=|T|\le|H|\le f.$$

Since $p\ge 2$ and $a\ge 2$, we have $\log_p a\ge 0$ and

$$0\le\log_p(2a)\le 2\log_p a.$$

The formula for $\delta_p(v)$ has only nonnegative factors, so each orbit loss is nonnegative. Summing that formula and using the preceding bounds gives

$$\sum_{v\in R_p}\delta_p(v)=5|R_p|n_pN^2\log_p(2a)+4|T|\bigl(\log_p(2a)\bigr)^2\\ \le 10fN^2\log_p a+16f(\log_p a)^2.$$

By the parameter identities of a loss datum, $N=k+m(t_R+1)\ge k\ge 0$. Thus the assumed error bound implies

$$\epsilon_p\le C_e f N^2\log_p a.$$

Adding the last two estimates and using $C \geq 10 + C_e$ and $C \geq 16$ yields

$$\sum_{v \in R_p} \delta_p(v) + \epsilon_p \leq CfN^2 \log_p a + Cf(\log_p a)^2 = \mathrm{fl}_C(p),$$

as required. □

Lemma 18.13. *Let a gain datum be given, let p be an inert prime and let $v \in V_p$. Suppose that*

$$0 \leq \alpha_t \leq \frac{6}{5}a \quad (t \in T_p(v)), \qquad c_j(t,e) \geq 0 \quad (1 \leq j \leq m,\ t \in T_p(v),\ e \geq 1 \text{ odd}),$$

and that $\delta_p(v) \geq 0$ and $\mathrm{Pr}_j(v) \geq 0$ for $1 \leq j \leq m$. Assume also that

$$N_p(v) = 0 \quad \text{or} \quad \frac{mN_p(v)a}{p} \geq \frac{5}{2}.$$

Then

$$S_p(v) \leq \frac{2mN_p(v)a}{p}.$$

Proof. We first bound the served gain. Both entries of each minimum in its definition are nonnegative, and

$$0 \leq \min\left(\frac{\alpha_t}{p^e}, c_j(t,e)\right) \leq \frac{\alpha_t}{p^e}.$$

Consequently the series of these minima converges and is nonnegative, by comparison with the geometric series over the odd positive exponents. Since the orbit loss is nonnegative,

$$g_j^U(v) \leq \gamma_p \sum_{t \in T_p(v)} \alpha_t.$$

The prime p is at least 2, so $p^2 \geq 4$ and

$$0 < \gamma_p = \frac{p}{p^2 - 1} \leq \frac{4}{3p}.$$

Using the upper bound on each reduced height and $N_p(v) = |T_p(v)|$ gives

$$g_j^U(v) \leq \frac{6}{5}\gamma_p N_p(v)a \leq \frac{8}{5}\,\frac{N_p(v)a}{p}.$$

The price and $\max(g_j^0(v), 0)$ are nonnegative. The last upper bound is also nonnegative, because $a > 0$. Subtracting the two nonnegative terms and then taking the positive part therefore yields

$$0 \leq \left(g_j^U(v) - \mathrm{Pr}_j(v) - \max(g_j^0(v), 0)\right)^+ \leq \frac{8}{5}\,\frac{N_p(v)a}{p}.$$

Summing over the m indices shows that the sum inside the defining ceiling for $S_p(v)$ lies between 0 and $8mN_p(v)a/(5p)$.

If $N_p(v) = 0$, that sum is zero, hence $S_p(v) = 0$. Otherwise the second alternative in the hypothesis applies. The elementary inequality $\lceil y \rceil < y + 1$ and the preceding bound give

$$S_p(v) < \frac{8}{5}\,\frac{mN_p(v)a}{p} + 1 \leq \frac{2mN_p(v)a}{p},$$

where the final inequality is equivalent to $mN_p(v)a/p \geq 5/2$. This proves the stated bound. □

19 Joint packet supply from realisations

This section proves the joint supply of packets, Proposition 19.3, which Proposition 18.1 uses. It is the second of three steps that lead from (TCS) to the packets that design existence needs, and each step adds properties that the previous one does not state. Proposition 21.2 of Section 21 supplies packets with model-level data. Proposition 19.9 adds the remaining model-slope and height properties, and Proposition 19.3 adds the conditions on the loss data and the eight lower conditions of the class that the earlier statements leave out. All three statements have the same shape: packets with conditions on their loss data and numerical data at every large scale, and, under the hypothesis that the Sha bound holds eventually, compatible completions on a tail of scales.

The step from Proposition 19.9 to Proposition 19.3 is mostly bookkeeping. Normalised hosts give the frame condition (Lm1) (Lemma 19.21), and the bad-top bound of the good host gives few bad tops (Lm4) (Lemma 19.22). Five lower conditions, (Mf1), (Mf5), (Dv1), (Dv2) and (Nf1), follow from the common data of the members, with the analytic loss of the host bounded by Lemma 19.28. The other three, (Bk1), (Bk2) and (Nf3), are the substance of the step: Theorem 19.23 derives them from the realisation estimates. Its proof passes through the covolume bound from the lattice chain (Theorem 19.26) and the core lower bound from descent along deep covers (Theorem 19.24).

The step from Proposition 21.2 to Proposition 19.9 supplies the model-slope properties (Ms2) and (Ms4), with the constant 83400, by the model-budget attachment Theorem 19.12, whose inputs are explicit bounds for the host field: its discriminant and degree (Lemma 19.16), its roots of unity (Lemma 19.15) and the depths of the tops (Lemma 19.14). From (Ms1)–(Ms4), Theorem 19.18 gives the mean-slope bound (Ht3) at the divided weight, with the Hodge–Tate cost bounded by Lemma 19.19, and Theorem 19.20 then gives the uniform lower bound (Dp6) for the twisted slope. The bounds (Ms1) and (Ms3) themselves come from Part VI through Proposition 21.2. In our reading the model slopes, which through (Dp6) and the descent along deep covers feed the covolume bound, are the "computation of covolumes" of Alpöge's account [4].

Definition 19.1. Fix real numbers $x > 1$ and $\varepsilon > 0$, a frame (e, A, h, a_0), a host $\mathfrak{h}$ for that frame, finite sets $T \subseteq A$ and $S \subseteq \mathbb{Z}_{\geq 0}$, an integer $t \geq 1$, integers $k, m \geq 0$, real numbers η, L_a, integers a_s for $s \in T$, and primes g_1, g_2.

A **base translate packet** over these data is a finite tuple

$$(\mathfrak{h}, T, S, t, \mathfrak{M}_u, \mathfrak{V}_u, u)_{u \in A}$$

satisfying the following conditions.

(Bt1) Loss data. For every $u \in A$, $\mathfrak{M}_u$ is a loss datum on the group A with arithmetic datum $\mathfrak{A}_{\mathfrak{h}}$ and top set T. Its orbit selection has scale x and parameter ε, its number of lifts is m, and its size parameters k, t_R are k, t. Each $\mathfrak{M}_u$ carries its own place record as part of the loss datum.

(Bt2) Common parameters and heights. For every $u \in A$, the parameters η, L_a of $\mathfrak{M}_u$ are the given η, L_a, and the height of $\mathfrak{M}_u$ at each $s \in T$ is a_s.

(Bt3) Slope records and translates. For every $u \in A$, $\mathfrak{V}_u$ is a slope record for m with auxiliary primes g_1, g_2, and the translate of the member indexed by u is u.

Every member of the packet has host $\mathfrak{h}$, top set T, spacing set S and rank t.

Definition 19.2. Fix $\varepsilon > 0$, a set $W \subseteq \mathbb{R}$, a real number $X > 1$ and, for every $x \in W$ with $x \geq X$, a base translate packet P_x over a host $\mathfrak{h}_x$, frame group A_x, top set T_x, spacing set S_x and rank t_x, with loss data $\mathfrak{M}_{x,u}$ and slope records $\mathfrak{V}_{x,u}$ for $u \in A_x$.

(Pl1) Completion data. A **lower completion of the packet at** x consists, for every $u \in A_x$, of the member data of all record and input-data types in (Pc3)–(Pc5) of Definition 17.5, attached to $\mathfrak{M}_{x,u}$ and $\mathfrak{V}_{x,u}$. Precisely, these are the data of the corresponding definitions, with the outer indexing over every real $x > x_1$ and every $i \in I(x)$ replaced by the fixed scale x and an index $u \in A_x$: the objects of the stated types, subject to all their defining identities and all their defining ties. All further indices are kept, among them all words, lifts, places, local components and eigensystems. In particular, a lower completion includes the local sum identities of the modification data, the Hecke lattices and the good and kept sets of the local defect data, the determinant algebras and extension modules of the Ribet records, and every metric, slope and map identity of the frame realisations. The additional expansion, kernel, row, Galois Ribet, column, weight-word, position and budget data of (Pc5) are included as well, with their defining types and identities and for the same frame and arithmetic data. Condition (Pl1) imposes none of the numbered properties and inequalities.

These data form one compatible collection, with the identifications of shared records and shared fields listed in Definition 17.5 and no others, read at the fixed scale x with member set A_x. The loss data, slope records, hosts, heights and all other data of P_x are unchanged. A **lower completion on a tail** is a choice of such completion data at every $x \in W$ with $x \geq Y$, for some real $Y \geq X$.

(Pl2) Pointwise interpretation of the numbered formulas. At a fixed scale x, a numbered property listed in (Pl3) is interpreted as follows. The family data at (x, i) are replaced by the packet and completion data at (x, u), with $I(x) = A_x$. The outer eventual-scale quantifier of the property, namely the assertion that there is a cutoff such that the formula holds at all scales above it, is removed, and the remaining formula is required for every $u \in A_x$. All universal quantifiers over words, pairs of words, lifts, places, primes, components, eigensystems and any other local indices remain in force, including those contained in the property's convention for all large members. All inner existential quantifiers keep their positions.

An existentially quantified scalar bound constant that precedes the eventual-scale quantifier of the property is not quantified there; it is taken from the common list of (Pl3). No other quantifier is moved, and every antecedent is kept. In particular, the following antecedents are kept: the finite-Sha-length antecedents in the remaining (Lq) and (Rf) conditions and in (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), including (Ub7'), for the coefficient extension along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,u})$; the word-size antecedents in (Dx1), the kernel hypotheses and (Ro1)–(Ro4); and the nonzero-map antecedent in (Nf3). Finite Sha lengths are as defined in Definition 13.9. The Galois Ribet items that are required at every point before the finite-Sha antecedent remain original completion data at every point. The coefficient-extended items, with the extended data accompanying them, are obtained from these original completion data by Definition 17.4; they do not replace the original completion records.

For these coefficient-extension hypotheses, again only the eventual-scale quantifier is removed: the integer $N_{x,u} \geq 1$ with $4 \mid N_{x,u}$ and the integers $S^{\mathrm{rm}}_{x,u}, \eta^{\mathrm{rm}}_{x,u} \geq 0$ are chosen together, after the member and the finite-Sha antecedent and before all point and local indices. In this pointwise interpretation all the hypotheses of Theorem 22.1, including

(Ub7'), are taken for that coefficient extension. No family property is evaluated on a family supported at a single scale.

(Pl3) Uniform lower conditions. The collection of packets **admits uniform lower completions on a tail** if $\varepsilon \le 1$ and there exist a finite list of twenty-four scalar constants, a real number $Y \ge X$ with $Y > 1$ and a lower completion at every $x \in W$ with $x \ge Y$ such that the requirements below hold.

The list contains a separate entry for each scalar constant that is existentially quantified in

(Sp1), (Sp2), (Sp7), (Mf4), (Mf7), (Dv3), (Dv4), (Bk4), (Nr3), (Ld5), (Lq6), (Lq8),

subject to the sign restrictions stated in those properties; constants belonging to different properties need not be equal. The remaining twelve entries of the list are

$$c > 0, \quad C_0 \ge 1, \quad C_{\mathrm{A}} \ge 1, \quad 0 < c_{\mathrm{lp}} \le \tfrac{1}{3}, \quad C_{\mathrm{ng}} \ge 0,$$
$$C_{\mathrm{lb}} \ge 1, \quad A_{\mathrm{lb}} \ge 1, \quad C_0^{\mathrm{ng}} \in \mathbb{Z}_{\ge 0}, \qquad c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \ge 1.$$

All entries are real numbers, except C_0^{ng}, which is a nonnegative integer. The same c is used in (Nf2), (No2), (No6), (Rw2), (Dx1) and the kernel scalar bound of (Pc5). The same C_0 is used in (No1), (No2), (Dx1), the kernel hypotheses and (Ro1)–(Ro4). The same $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$ is used in the row data and (Rw2). The four constants $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}}$ are used in (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), including (Ub7'), for the coefficient extension specified in (Pl2); C_{bud} is distinct from the frame constant C_0. The bound of (Lq7), which is removed, is supplied by the original minimal losses and the derived allowance coefficient of Theorem 22.1; these are not additional entries of the list.

For every $x \in W$ with $x \ge Y$, the following numbered formulas hold in the pointwise interpretation (Pl2), with the constants of this list:

(Sp1), (Sp2), (Sp6), (Sp7),
(Mf1)–(Mf7), (Dv1), (Dv2), (Dv3), (Dv4), (Dv7),
(Bk1), (Bk2), (Bk4), (Nr1), (Nr2), (Nr3),
(Ld1)–(Ld6), (Lq2), (Lq4), (Lq5), (Lq6), (Lq8), (Rf3),
(Nf1), (Nf2), (Nf3), (No1), (No2), (No6), (Rw2),
(Dx1), (Ro1)–(Ro4), (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), including (Ub7').

The kernel hypotheses of (Pc5), including (Kc1)–(Kc4) and both displayed scalar inequalities, hold in the same pointwise interpretation. All these formulas are taken with the common constants and the compatible data of (Pc5), and with every hypothesis of the statements they cite. The list of constants and Y do not depend on the scale, the member, the words or any other local index. The completion objects, and the objects whose existence is asserted by the inner existential quantifiers that are kept, may depend on their permitted indices.

Finally, at every such x the packet index set A_x is nonempty and every $u \in A_x$ satisfies, with $n = |A_x|$, $b = \exp(x^{\varepsilon})$, $a = xb$ and $\mathfrak{V} = \mathfrak{V}_{x,u}$,

$$x^{1/2-\varepsilon} \le m, \qquad \log(2a\, v(\mathfrak{h}_x)) \le 2x^{\varepsilon}, \qquad \log|\mathcal{W}(\mathfrak{V})| \le (k-3)\log 2,$$
$$x^{-\varepsilon} n \le |T_x^{\mathrm{th}}|, \qquad \tfrac{1}{2}x^{-\varepsilon/8} n \le |T_x|, \qquad a_s \ge (x-1)b \quad (s \in T_x),$$

where $T_x^{\mathrm{th}} = \{sa_0 : s \in S_x\} \subseteq A_x$, and k, m, a_s are the common packet parameters at x.

Proposition 19.3. *Let $\lambda > 1$ and let P be a host requirement supplied by the concrete good-host requirement $\mathfrak{G}$ on λ-windows. There is a real number $\varepsilon_* = \varepsilon_*(\lambda, \mathsf{P}) > 0$ with the following property. Fix*

$$0 < \varepsilon < \min(\varepsilon_*, 1/52), \qquad J \geq 1,$$

a finite list κ, a set $W \subseteq \mathbb{R}$ containing λ-windows, and a real $X_H > 1$. For every $x \in W$ with $x \geq X_H$, fix a frame, a host $\mathfrak{h}_x$, a top set T_x, an integer $t_x \geq 1$ with $\mathsf{P}(x, \varepsilon, \mathfrak{h}_x, T_x, t_x)$, and a choice of all the data whose existence is asserted by

$$\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}_x, T_x, t_x).$$

In particular this fixes its rank datum, ordering, good-orbit selections, spacing set S_x, spacing translate and auxiliary primes. These choices are made once, simultaneously for all such x.

There are real numbers

$$c_D > 397, \quad c_h \geq 402, \quad C_e \geq 0, \quad \varepsilon_z > 0, \quad C_t, \quad X \geq X_H,$$

a tuple $\mathfrak{k}_{\mathrm{orb}}$ of eight nonnegative real numbers, and, for every $x \in W$ with $x \geq X$, a base translate packet over the chosen frame, host $\mathfrak{h}_x$, top set T_x, spacing set S_x, rank t_x and auxiliary primes, with the following properties.

(Js1) Member conditions. *For every such x and every translate $u \in A_x$, the loss datum of the packet satisfies (Lm1), (Lm2), (Lm4), (Lm5), (Lm6), and (Lm7) for the same (ε_z, C_t).*

(Js2) Numerical conditions. *For every such x and u, the rank datum of the loss datum is the rank datum fixed above, and it has its rank sizes at (x, ε, J), with $t_R = t_x$. Its heights, depths, weights and shifts have the integer weights and boxes for (c_D, c_h), for some number field and thick subset. Its top set, Frobenius translations, orbit representatives and good representatives are those of the finite good-orbit selections fixed above. Its correction degrees, orbit thresholds and correction errors satisfy (Nc2), (Nc3), (Nc4) for the same $(\mathfrak{k}_{\mathrm{orb}}, C_e)$.*

(Js3) Conditional compatible completion. *Suppose that there is a real number X_V such that*

$$\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^{\varepsilon}/2))$$

holds for every $x \in W$ with $x \geq \max(X, X_V)$. Then this system of packets admits a uniform lower completion on a tail, in the sense of Definition 19.2, whose loss data, place records, slope records, heights, depths, weights, orbit selections and orbit masses are those of the packets above.

The constants, the cutoff and the packet system may depend on the whole collection of choices fixed above. The constants do not depend on an individual scale, translate, prime, orbit or word.

Proof. Let $\varepsilon_\dagger = \varepsilon_\dagger(\lambda, \mathsf{P}) > 0$ be given by Proposition 19.9 for the same λ and P, and put $\varepsilon_* = \varepsilon_\dagger$. Fix all the data of the statement. Since W contains λ-windows, there is a scale $x \in W$ above X_H. The good-host requirement at that scale implies that the list κ has the form

$$\kappa = (C_{T_2}, C_8, C_5, c_6, C_b), \qquad C_8 \geq 1, \quad C_5, c_6, C_b > 0.$$

Apply Proposition 19.9 to the data fixed in the statement. Denote its cutoff by X_{R} and its packets by P_x. Let X_{env} be the threshold of Lemma 19.28 with $C_{\mathrm{La}} = 1$, for its analytic conclusion.

We first verify the remaining frame condition at every packet member. By (Hg1), the host is normalised and the frame index is at most C_8. By (Ra1), $e_2 = e$, and $x \geq X_{\mathrm{R}} \geq \max\{2, (2C_8)^{4/\varepsilon}\}$. Thus Lemma 19.21 gives (Lm1). By (Hg4), the good-orbit selections satisfy their bad-top bound with the same constant C_b, and (Hg3) gives $|T_x| \geq \frac{1}{2}x^{-\varepsilon/8}|A_x|$. By Lemma 19.22, (Lm4) therefore holds for every packet above

$$X_{\mathrm{B}} = \max\{2, (8C_b)^{3/\varepsilon}\}.$$

Take $X' = \max(X_{\mathrm{R}}, X_{\mathrm{B}}, X_{\mathrm{env}})$ and keep the same packets at scales $x \in W$, $x \geq X'$. Condition (Ra1), the two deductions just made, and the unchanged common pair (ε_z, C_t) give all of (Js1). Condition (Ra2) is (Js2).

Suppose that the Sha premise of (Js3) holds for these packets. Then the premise of (Ra3) holds as well, after replacing its cutoff X_V by $\max(X', X_V)$ if necessary. This gives a completion on a tail starting at $Y \geq X_{\mathrm{R}}$, its twenty-four common parameters, and the family $\mathcal{F}$ specified there, whose members are the members of the same packets at $x \in W$, $x > Y$.

The rank datum has $m \geq 2$, so there is at least one lift at every member. The chain and deep-cover hypotheses and the coefficient supplied by (Ra3) give every hypothesis of Theorem 19.23. Hence $\mathcal{F}$ has (Bk1), (Bk2) and (Nf3), each with a threshold that is uniform over its members and words. The realisation estimates also have a uniform threshold, say Z_{R}. Choose Z at least X', $Y+1$, Z_{R} and the thresholds for those three conclusions. At every scale $x \geq Z$, all the members indexed by A_x are members of $\mathcal{F}$, and all subsequent deductions concern these members.

Five further lower conditions follow from the common data of these members.

- By (Ml1), at every finite place w the weight is $\ell(w) = e_w f_w \log p(w)/[K : \mathbb{Q}] \geq 0$, since e_w, f_w and $[K : \mathbb{Q}]$ are positive and $p(w) \geq 2$. This gives (Mf1) at all finite places.

- Put $y = e_w \mathrm{tw}(\mathfrak{V}, \omega, w)$. The floor inequalities and $e_w \geq 1$ give

  $$\frac{\lfloor y \rfloor}{e_w} \leq \mathrm{tw}(\mathfrak{V}, \omega, w) < \frac{\lfloor y \rfloor}{e_w} + \frac{1}{e_w} \leq \frac{\lfloor y \rfloor}{e_w} + 1.$$

  By (Ml3), the fraction is the specified rounded twist. If the twist is zero, its floor is zero. This proves (Mf5), for either sign of the twist.

- The divisor lattice N_ω has positive rank by (Ml2). It is one of its own nonzero submodules, so $\widehat{\mu}(N_\omega) \leq \widehat{\mu}_{\max}(N_\omega)$. The frame slope identities therefore give $d(\mathfrak{V}, \omega) > 0$ and $\mu(\mathfrak{V}, \omega) \leq \mu^{\max}(\mathfrak{V}, \omega)$, which is (Dv1).

- The host and Lemma 19.28 give the analytic loss

  $$L_a = \log(a \ \mathrm{rd}_{E_{\mathfrak{h}_x}}) = \log(2a\, v(\mathfrak{h}_x)) \geq x^{\varepsilon} > 0,$$

  which gives (Dv2).

- By (Ri2), $0 \leq \delta(\mathfrak{V}) \leq 1/3 \leq 1/2$, which gives (Nf1).

Besides the constants already supplied, these deductions use only the common host threshold. The other numbered properties of (Pl3) are supplied by (Ra3), with the same twenty-four common parameters. They remain true after restriction to $x \geq Z$, with all their inner quantifiers and antecedents unchanged.

It remains to check the residual requirements. The bound $\varepsilon \leq 1$ follows from $\varepsilon < 1/52$, and A_x is nonempty because it is a group. Rank sizes give

$$m \geq \sqrt{x\, x^{-\varepsilon/8}} = x^{1/2-\varepsilon/16} \geq x^{1/2-\varepsilon}.$$

The top cardinality bound is (Hg3). For the thick cardinality bound put $n_0 = |\langle a_0\rangle|$ and let L_w be the positive integer in the good-host requirement. Its displayed formula gives $L_w \geq 1$, and every $s \in S_x$ satisfies $0 \leq s < n_0/(4L_w) \leq n_0$. If $sa_0 = s'a_0$ for two such integers, then n_0 divides $s - s'$ while $|s - s'| < n_0$, so $s = s'$. Thus

$$|T_x^{\mathrm{th}}| = |\{sa_0 : s \in S_x\}| = |S_x| \geq x^{-\varepsilon}|A_x|$$

by (Hg3). The integer height box gives, for every top s,

$$a_s \geq \lceil a \rceil \geq a = xb \geq (x-1)b.$$

The word-count bound is supplied explicitly in (Ra3). The analytic conclusion of Lemma 19.28, at the same host and scale, gives

$$\log(2a\, v(\mathfrak{h}_x)) \leq 2x^{\varepsilon}.$$

Therefore all the residual inequalities of (Pl3) hold.

Restrict the completion and the packet system to the tail $x \in W$, $x \geq Z$. All numbered formulas, residual bounds and common scalar parameters required by (Pl3) hold there. Its separate kernel requirement is supplied by (Ra3): the data with (Kc1)–(Kc4), the finite measure and both scalar inequalities remain valid on this tail, with all inner quantifiers and antecedents and with the same common constants. No further constant is needed. This is the uniform lower completion required by (Js3), and its loss data, place records, slope records, numerical choices and orbit masses are those of the packets above. Taking X' as the cutoff in the statement proves all its assertions.

□

Definition 19.4. Let $\mathcal{F}$ be a parametrised host family with slope records, modification data and frame realisations. **Simultaneous lattice realisations for** $\mathcal{F}$ consist of the following data and identities for every $x > x_1$ and every $i \in I(x)$. In this definition and in the results that refer to it, the member (x, i) is fixed and its index is suppressed from these data; we write $\mathfrak{V} = \mathfrak{V}_{x,i}$.

(Ml1) One coefficient field and its places. The field K of the frame realisation is the field K of the place record, and every finite place in the records is a finite place of this field. For such a place w, let $\mathfrak{p}_w$ be its prime ideal and let e_w and f_w be its ramification index and residue degree over $p(w)$. Then

$$\ell(w) = \frac{e_w f_w \log p(w)}{[K : \mathbb{Q}]}.$$

(Ml2) The ambient and level lattices. For every word $\omega \in \mathcal{W}(\mathfrak{V})$ there is a hermitian $\mathcal{O}_K$-lattice $\overline{M}_\omega$ of rank $d^\circ(\mathfrak{V}, \omega)$ and an injective K-linear map

$$\iota_{\mathrm{lev},\omega} \colon N_{\omega,K} \longrightarrow M_{\omega,K}.$$

The divisor lattice has positive rank, and its archimedean norms are the pullbacks under this map:

$$d(\mathfrak{V}, \omega) \geq 1, \qquad \|z\|_{\overline{N}_\omega,\sigma} = \|\iota_{\mathrm{lev},\omega,\sigma}(z)\|_{\overline{M}_\omega,\sigma} \quad (\sigma \colon K \hookrightarrow \mathbb{C},\ z \in N_{\omega,K} \otimes_{K,\sigma} \mathbb{C}).$$

Define the level lattice, in the space $N_{\omega,K}$, by

$$M_\omega^{\mathrm{lev}} = \iota_{\mathrm{lev},\omega}^{-1}(M_\omega)$$

with the same pullback norms. The following projection identities hold:

$$\mu'(\mathfrak{V},\omega)=2\widehat{\mu}(\overline{M}_\omega),\qquad \mu'^{\max}(\mathfrak{V},\omega)=2\widehat{\mu}_{\max}(\overline{M}_\omega),$$
$$\mu^\circ(\mathfrak{V},\omega)=2\widehat{\mu}(\overline{M}^{\mathrm{lev}}_\omega),\quad \mu^{\circ\max}(\mathfrak{V},\omega)=2\widehat{\mu}_{\max}(\overline{M}^{\mathrm{lev}}_\omega).$$

The divisor lattices, their norms, the maps B_ω, the dual slopes and the complex frame data are those of the given frame realisation, together with its slope identities.

(Ml3) The intermediate lattice and ideal multiple. For every word ω there is a finitely generated full-rank $\mathcal{O}_K$-submodule N'_ω of $N_{\omega,K}$, with the same archimedean norms. Put

$$\mathfrak{a}_\omega=\prod_{w\in S}\mathfrak{p}_w^{-\lfloor e_w\mathrm{tw}(\mathfrak{V},\omega,w)\rfloor}.$$

Then

$$N_\omega=\mathfrak{a}_\omega N'_\omega,\qquad \mathrm{tw}^\flat(\mathfrak{V},\omega,w)=\frac{\lfloor e_w\mathrm{tw}(\mathfrak{V},\omega,w)\rfloor}{e_w}\quad(w\in S).$$

Here $\mathfrak{a}_\omega N'_\omega$ means the $\mathcal{O}_K$-span of all products of an element of $\mathfrak{a}_\omega$ with an element of N'_ω; the equality is in the common space $N_{\omega,K}$.

(Ml4) The local quotients. Let $\mathcal{O}_{K,w}$ denote the localisation of $\mathcal{O}_K$ at $\mathfrak{p}_w$, and write a subscript w for localisation of a lattice. For every finite place w with $p(w)\neq T(\mathfrak{V},\omega)$,

$$N'_{\omega,w}\subseteq M^{\mathrm{lev}}_{\omega,w},$$

with equality if moreover $p(w)$ is dropped or is not inert. At every $w\in S$, including the places above $T(\mathfrak{V},\omega)$,

$$\mathrm{len}(\mathfrak{V},\omega,w)=\frac{1}{e_w}\,\mathrm{length}_{\mathcal{O}_{K,w}}\left(\frac{M^{\mathrm{lev}}_{\omega,w}}{N'_{\omega,w}\cap M^{\mathrm{lev}}_{\omega,w}}\right).$$

The intersection and quotient are taken in $N_{\omega,K}$. Both lattices have full rank there, so this quotient is a finite-length module.

Definition 19.5. Frames and normalised log-covolumes. Let K be a totally complex number field and fix, for every infinite place v of K, one of its two complex embeddings, also written $v\colon K\to\mathbb{C}$. Let $d\geq 0$ be an integer. A **frame** on K^d is a family $X=(X(v))_v$ of matrices $X(v)\in\mathrm{GL}_d(\mathbb{C})$, one for each infinite place v; it defines the norms $\|y\|_{X,v}=|X(v)\,v(y)|$ on K^d, where $v(y)$ is the coordinatewise image of y and $|\cdot|$ the standard hermitian norm of $\mathbb{C}^d$. Thus the frame matrix is applied directly: if hermitian norms on K^d are given as $y\mapsto|Y(v)^{-1}v(y)|$ by matrices $Y(v)\in\mathrm{GL}_d(\mathbb{C})$, they are the norms of the frame $X=(Y(v)^{-1})_v$; only the induced norms enter ht and lcv below. Let $M\subseteq K^d$ be a finitely generated $\mathcal{O}_K$-submodule and $r=\dim_K(KM)$ its rank. The map $y\mapsto(X(v)\,v(y))_v$ sends M onto a lattice of rank $r[K:\mathbb{Q}]$ in its real span inside $\bigoplus_v\mathbb{C}^d$, which carries the euclidean structure $\mathrm{Re}\sum_v\langle\cdot,\cdot\rangle_{\mathbb{C}^d}$; let $\mathrm{covol}_X(M)$ be its covolume ($=1$ if $M=0$). The **height** and the **normalised log-covolume** of (M,X) are

$$\mathrm{ht}(M,X)=2^{r[K:\mathbb{Q}]/2}\,|\mathrm{disc}(K)|^{-r/2}\,\mathrm{covol}_X(M),\qquad \mathrm{lcv}(M,X)=\frac{2}{[K:\mathbb{Q}]}\log\mathrm{ht}(M,X).\quad(19.1)$$

Covolume records. Let $\mathcal{F}$ be a parametrised host family with parameter ε and threshold x_1. A **parametrised host family with covolume records** is such a family $\mathcal{F}$ together with the following data. For every real $x>x_1$ and every $i\in I(x)$ there is a set $\mathrm{Pt}_{x,i}$, the **realised points** of the member (x,i), and for every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$ there is a **covolume record**, consisting of

- a totally complex number field $K_{\mathfrak{z}}$, with a fixed embedding for each of its infinite places, and an integer $D_{\mathfrak{z}} \geq 1$, the **realisation dimension**;
- for every $j \in \{1, \dots, m\}$, where m is the parameter of $\mathfrak{M}_{x,i}$ (the **lifts**): an integer $d_{\mathfrak{z},j} \geq 0$, a frame $X_{\mathfrak{z},j}$ on $K_{\mathfrak{z}}^{d_{\mathfrak{z},j}}$ and a finitely generated $\mathcal{O}_{K_{\mathfrak{z}}}$-submodule $M_{\mathfrak{z},j} \subseteq K_{\mathfrak{z}}^{d_{\mathfrak{z},j}}$, the **realisation lattice of the lift** j;
- a finite set $\mathrm{RP}_{\mathfrak{z}}$, the **realisation places**, and real numbers $w^{\mathrm{re}}_{\mathfrak{z},j}(\rho)$ for $\rho \in \mathrm{RP}_{\mathfrak{z}}$ and $1 \leq j \leq m$, the **realisation weights**.

The realised points are the points of the construction of the member that satisfy its point conditions and its arithmetic ties. The results based on this definition use only the data listed here.

Main term and unit error. For $x > x_1$, $i \in I(x)$, $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and $1 \leq j \leq m$, with k, m the parameters of $\mathfrak{M}_{x,i}$, put

$$\mathrm{mt}_j(\mathfrak{z}) = \sum_{\rho \in \mathrm{RP}_{\mathfrak{z}}} (k - m + 2j - 1)\, w^{\mathrm{re}}_{\mathfrak{z},j}(\rho)\, \log \Omega(\mathfrak{h}_{x,i}), \qquad \mathrm{ue}(x,i) = B_0(x,i)\, \log\log x, \tag{19.2}$$

the **main term** of the lift j at $\mathfrak{z}$ and the **unit error** of the member.

The covolume bound. The family has the **covolume bound** if there are real numbers $C_0 \geq 0$ and x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, every real $C \geq C_0$ and every $j \in \{1, \dots, m\}$

$$\frac{\mathrm{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})}{D_{\mathfrak{z}}} \leq \mathrm{mt}_j(\mathfrak{z}) + C\, \mathrm{ue}(x,i). \tag{19.3}$$

Definition 19.6. Let $\mathcal{F}$ be a parametrised host family with slope records, modification data, defect data, bridge records, frame realisations, simultaneous lattice realisations and covolume records, all built on the same underlying objects wherever they overlap. **Base covolume realisations for** $\mathcal{F}$ consist, for every real $x > x_1$ and every $i \in I(x)$, of the following data. In these clauses (x,i) is fixed, and K, $\overline{R}$, Φ, m and w_j denote the coefficient field, level realisation lattice, place set, number of lifts and loss weights of the member (x,i).

1. A nonzero hermitian $\mathcal{O}_K$-lattice $\overline{R}_{\mathrm{b}}$, the **base realisation lattice**, and a point $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ with coefficient field K, the **selected point**, such that

   $$K_{\mathfrak{z}} = K, \qquad D_{\mathfrak{z}} = \mathrm{rk}_{\mathcal{O}_K} R_{\mathrm{b}} = \mathrm{rk}_0(x,i) \geq 1, \qquad \mu^{\vee}_{\mathrm{b}}(x,i) = 2\widehat{\mu}(\overline{R}^{\vee}_{\mathrm{b}}).$$

   The reference lattices attached to $\mathfrak{z}$, and their archimedean frames, are those of the covolume record of $\mathfrak{z}$.

2. A bijection $\beta_{\mathfrak{z}} \colon \mathrm{RP}_{\mathfrak{z}} \to \Phi$ such that

   $$w^{\mathrm{re}}_{\mathfrak{z},j}(\rho) = w_j(\beta_{\mathfrak{z}}(\rho)) \qquad (1 \leq j \leq m,\ \rho \in \mathrm{RP}_{\mathfrak{z}}).$$

In these data the level realisation is the lattice $\overline{R}$, and the divisor lattices, intermediate lattices, fractional ideals and maps B_ω are those of the given simultaneous and frame realisations of the member. A parametrised host family **with base covolume realisations** is such a family together with such data.

Realisation estimates. Let $C \geq 0$ be a real number. The family **has realisation estimates for** C if there is a real number $X > 1$ such that the following conditions hold for every real $x \geq X$ with $x > x_1$ and every $i \in I(x)$. In these conditions the index (x,i) is suppressed where convenient: $\mathfrak{V} = \mathfrak{V}_{x,i}$, $\mathfrak{z}$ is the selected point, $D = D_{\mathfrak{z}} = \mathrm{rk}_0(x,i)$ and $\delta = \delta(\mathfrak{V})$.

(Ri1) Reference comparison and numerical budget. For every word ω there is a real number E_ω such that

$$\mu_{\mathrm{b}}^{\vee} - \mathrm{sc} \le \sum_{j=1}^{m} \frac{\mathrm{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})}{D} + F(\mathfrak{V}) + E_\omega,$$

$$\mathrm{lm}(x,i,\omega) = \sum_{j=1}^{m} \sum_{\tau \in \Phi} (k - m + 2j - 1) w_j(\tau) \log \Omega(\mathfrak{h}_{x,i}),$$

and

$$E_\omega + mC\,\mathrm{ue}(x,i) \le \mathrm{le}(x,i,\omega) + \sum_{j=1}^{m} \left(\frac{\mathrm{Df}_j(x,i)}{D} + \mathrm{tc}_j(x,i) \right).$$

(Ri2) Passage. One has $0 \le \delta \le 1/3$, and there are real numbers H_0, L_{grp} such that

$$\mu^{\vee}(\mathfrak{V}) \le \mu_{\mathrm{b}}^{\vee} + 3\delta(\mu_{\mathrm{b}}^{\vee} + H_0 + 28L_{\mathrm{grp}}) + 28L_{\mathrm{grp}}, \qquad 3\delta(\mu_{\mathrm{b}}^{\vee} + H_0 + 28L_{\mathrm{grp}}) + 28L_{\mathrm{grp}} \le \mathrm{pa}(x,i).$$

(Ri3) Valuations before the ideal twist. The level realisation lattice R is nonzero. For a word ω and a finite place w of K, put

$$a_{\omega,w} = \begin{cases} \lfloor e_w \,\mathrm{tw}(\mathfrak{V}, \omega, w) \rfloor, & w \in S, \\ 0, & w \notin S, \end{cases}$$

and let $v_w \colon K^{\times} \to \mathbb{Z}$ be the discrete valuation at w that takes the value 1 on a local uniformizer. Then for every word ω, every finite place w, every $n \in N'_{\omega,w}$ and every $r \in R_w$,

$$B_\omega(n)(r) = 0 \quad \text{or} \quad v_w(B_\omega(n)(r)) \ge a_{\omega,w}.$$

(Ri4) Archimedean norms and the frame quotient. For every word ω with $B_\omega \neq 0$ there are real numbers $q_{\omega,\sigma}$, one for each embedding $\sigma \colon K \hookrightarrow \mathbb{C}$, such that

$$\log \|B_{\omega,\sigma}\|^2 \le q_{\omega,\sigma}, \qquad \frac{1}{[K:\mathbb{Q}]} \sum_{\sigma} q_{\omega,\sigma} \le h(\mathfrak{V}, \omega),$$

where the norms are operator norms for the given divisor and dual-realisation metrics. Moreover, the frame quotient satisfies

$$\dim_{\mathbb{C}} \ker \Pi \le \delta \, \dim_{\mathbb{C}} \mathcal{H}.$$

Definition 19.7. Hermitian spaces. Let K be a totally complex number field with a fixed embedding $v \colon K \to \mathbb{C}$ for each infinite place. A **hermitian space** over K is a finite-dimensional K-vector space V with a hermitian norm $\|\cdot\|_v$ on $V \otimes_{K,v} \mathbb{C}$ for every infinite place v. A finitely generated $\mathcal{O}_K$-submodule $L \subseteq V$ is torsion free, hence projective, and with the restricted norms it is a hermitian lattice; its rank is $\mathrm{rk}\, L = \dim_K(KL)$. For $L \neq 0$ we write $\widehat{\mu}(L)$ for its normalised slope and $\widehat{\mu}_{\max}(L)$ for the maximum of $\widehat{\mu}(L')$ over the non-zero $\mathcal{O}_K$-submodules $L' \subseteq L$. An **orthogonal projection** of V is a K-linear map $\pi \colon V \to V$ with $\pi \circ \pi = \pi$ such that $\pi(V)$ and $\ker \pi$ are orthogonal for every $\|\cdot\|_v$, that is $\|\pi y + (y' - \pi y')\|_v^2 = \|\pi y\|_v^2 + \|y' - \pi y'\|_v^2$ for all $y, y' \in V \otimes_{K,v} \mathbb{C}$.

Chain data. A parametrised host family with covolume records **carries chain data** if for every real $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and every lift $j \in \{1, \dots, m\}$ the following data are given, where $K = K_{\mathfrak{z}}$:

- a hermitian space $V_{\mathfrak{z},j}$ over K and a finitely generated $\mathcal{O}_K$-submodule $L_{\mathfrak{z},j} \subseteq V_{\mathfrak{z},j}$, the **type lattice**;
- an orthogonal projection $\pi_{\mathfrak{z},j}$ of $V_{\mathfrak{z},j}$ and an integer $g_{\mathfrak{z},j} \geq 1$, the **denominator**, with $g_{\mathfrak{z},j}\,\pi_{\mathfrak{z},j}(L_{\mathfrak{z},j}) \subseteq L_{\mathfrak{z},j}$; the **good part** and the **bad part** of the type lattice are
$$L^{\mathrm{g}}_{\mathfrak{z},j} = L_{\mathfrak{z},j} \cap \pi_{\mathfrak{z},j}(V_{\mathfrak{z},j}), \qquad L^{\mathrm{b}}_{\mathfrak{z},j} = L_{\mathfrak{z},j} \cap \ker \pi_{\mathfrak{z},j};$$
- a non-zero hermitian lattice $L^{\mathrm{c}}_{\mathfrak{z},j}$ over K, the **core lattice**.

Properties. "For all large points" means: there is a real x_0 such that the statement holds for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and every $j \in \{1, \dots, m\}$. A family carrying chain data has

(Lc1) Recursion if for all large points $L^{\mathrm{g}}_{\mathfrak{z},j} \neq 0$ and
$$\frac{\mathrm{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})}{D_{\mathfrak{z}}} \leq -2\,\widehat{\mu}(L^{\mathrm{g}}_{\mathfrak{z},j});$$

(Lc2) Small denominators if for all large points $2 \log g_{\mathfrak{z},j} \leq b(x)$;

(Lc3) Small bad parts if there is a real $c > 0$ such that for all large points
$$\mathrm{rk}\, L^{\mathrm{b}}_{\mathfrak{z},j} \leq 3\, e^{-x^c}\, \mathrm{rk}\, L_{\mathfrak{z},j};$$

(Lc4) Maximal slopes if there is a real A such that for all large points $2\,\widehat{\mu}_{\max}(L_{\mathfrak{z},j}) \leq x^A\, b(x)$;

(Lc5) Size of the main terms if there is a real A such that for all large points $|\mathrm{mt}_j(\mathfrak{z})| \leq x^A\, b(x)$;

(Lc6) Core comparison if there is a real $C \geq 0$ such that for all large points $2\,\widehat{\mu}(L_{\mathfrak{z},j}) \geq 2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},j}) - C\,\mathrm{ue}(x,i)$;

(Lc7) Core lower bound if there is a real $C \geq 0$ such that for all large points $2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},j}) \geq -\mathrm{mt}_j(\mathfrak{z}) - C\,\mathrm{ue}(x,i)$.

In (Lc4) and (Lc6) the slopes of $L_{\mathfrak{z},j}$ are taken where $L_{\mathfrak{z},j} \neq 0$; by (Lc1) this holds at all large points.

Definition 19.8. A parametrised host family with covolume records carrying chain data **carries deep-cover data** if for every real $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and every lift j with $1 \leq j < m$ the following data are given:

- a totally complex number field $K' = K'_{\mathfrak{z},j}$, with a fixed embedding for each infinite place, and two hermitian spaces $V^-_{\mathfrak{z},j}$, $V^+_{\mathfrak{z},j}$ over K', with finitely generated $\mathcal{O}_{K'}$-submodules $A_{\mathfrak{z},j} \subseteq V^-_{\mathfrak{z},j}$, the **lowered lattice**, and $B_{\mathfrak{z},j} \subseteq V^+_{\mathfrak{z},j}$, the **deep lattice**;
- an integer $n_{\mathfrak{z},j} \geq 0$ and K'-linear maps $\phi_{\mathfrak{z},j,h} \colon V^-_{\mathfrak{z},j} \to V^+_{\mathfrak{z},j}$ for $1 \leq h \leq n_{\mathfrak{z},j}$, the **descent maps**;
- a real number $\Lambda_{\mathfrak{z},j} > 0$, the **generator size**, and a real number $\sigma_{\mathfrak{z},j}$, the **twisted slope**.

A family carrying deep-cover data has the following properties if the stated condition holds for all large points, where for each of (Dp0), (Dp5) and (Dp6) there is a real constant $C \geq 0$ of its own, chosen before the large points, at the lift $j = m$ for (Dp0) and at every lift $j < m$ for (Dp1)–(Dp6). We write $A = A_{\mathfrak{z},j}$, $B = B_{\mathfrak{z},j}$, $\phi_h = \phi_{\mathfrak{z},j,h}$, $n = n_{\mathfrak{z},j}$, $\Lambda = \Lambda_{\mathfrak{z},j}$, $\sigma = \sigma_{\mathfrak{z},j}$ and $b = b(x)$.

(Dp0) Top lift $2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},m}) \geq -\mathrm{mt}_m(\mathfrak{z}) - C\,\mathrm{ue}(x,i)$.

(Dp1) Sizes $b \leq \Lambda$ and $|\mathrm{mt}_j(\mathfrak{z})| \leq \Lambda$.

(Dp2) Descent maps $A \neq 0$, and $\phi_h(A) \subseteq B$ for every h. If $y \in V^-_{\mathfrak{z},j}$ and $\phi_h(y) = 0$ for all h, then $y = 0$. For every infinite place v of K' and every $y \in V^-_{\mathfrak{z},j} \otimes_{K',v} \mathbb{C}$,

$$\sum_{h=1}^{n} \|\phi_h(y)\|_v^2 \leq e^{2b}\|y\|_v^2.$$

Moreover, $n \operatorname{rk} B \leq (1 + b/\Lambda) \operatorname{rk} A$.

(Dp3) Short generators There is a set $s \subseteq B$ that spans $K'B$ over K' and satisfies $\|y\|_v \leq e^{\Lambda}$ for every $y \in s$ and every infinite place v.

(Dp4) Ring comparison $2\,\widehat{\mu}(B) - 2b \leq 2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},j})$.

(Dp5) Flat bound $2\,\widehat{\mu}(A) \geq \sigma - \mathrm{mt}_j(\mathfrak{z}) - C\,\mathrm{ue}(x,i)$.

(Dp6) Uniform lower bound $\sigma \geq -C\,\mathrm{ue}(x,i)$.

Condition (Dp4) includes the requirement $B \neq 0$, which follows from (Dp2) when $n \geq 1$.

Proposition 19.9. *Let $\lambda > 1$ and let P be a host requirement supplied by the concrete good-host requirement $\mathfrak{G}$ on λ-windows. There is a real $\varepsilon_\dagger = \varepsilon_\dagger(\lambda, \mathsf{P}) > 0$ with the following property. Fix*

$$0 < \varepsilon < \min(\varepsilon_\dagger, 1/52), \quad J \geq 1, \quad \kappa = (C_{T_2}, C_8, C_5, c_6, C_b),$$

where $C_8 \geq 1$ and $C_5, c_6, C_b > 0$, a set W containing λ-windows, and $X_H > 1$. For every $x \in W$ with $x \geq X_H$, fix a frame, a host $\mathfrak{h}_x$, tops T_x, a rank t_x with $\mathsf{P}(x, \varepsilon, \mathfrak{h}_x, T_x, t_x)$, and a choice of all the data whose existence is asserted by the concrete good-host requirement $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}_x, T_x, t_x)$. These choices, including the rank data, orderings, good-orbit choices, spacing sets and auxiliary primes, are fixed once and for all.

Then there are constants

$$c_D > 397, \quad c_h \geq 402, \quad C_e \geq 0, \quad \varepsilon_z > 0, \quad C_t, \quad X \geq \max\{X_H, 2, (2C_8)^{4/\varepsilon}\},$$

a tuple $\mathfrak{k}_{\mathrm{orb}}$ of eight nonnegative real numbers, and, for every $x \in W$ with $x \geq X$, a base translate packet P_x over the chosen frame, host, tops, spacing set, rank and auxiliary primes, with the following properties.

(Ra1) Loss data. *Every packet member satisfies (Lm2), (Lm5), (Lm6), and (Lm7) for the common pair (ε_z, C_t). Its loss parameter e_2 equals the exponent e of its frame.*

(Ra2) Numerical data. *At every packet member, the loss datum has the rank datum fixed above, with its rank sizes at (x, ε, J) and with $t_R = t_x$. Its heights, depths, weights and shifts have the integer weights and boxes for (c_D, c_h), for some number field and thick subset. Its tops, Frobenius translations, orbit representatives and good representatives are given by the finite good-orbit choices fixed above, and these are the choices used by the loss datum. Its correction degrees, orbit thresholds and correction errors satisfy (Nc2)–(Nc4) for the common pair $(\mathfrak{k}_{\mathrm{orb}}, C_e)$.*

(Ra3) Joint realisation under an eventual Sha bound. *Suppose that there is a real number X_V such that the Sha bound*

$$\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^{\varepsilon}/2))$$

holds for all $x \in W$ with $x \geq \max(X, X_V)$. Then there are the twenty-four common scalar constants specified in (Pl3), a real $Y \geq X$, and compatible lower completion data (Pl1) for these packets at every $x \in W$ with $x \geq Y$, with the following properties.

- *All the numbered formulas of (Pl3) hold at those scales with those constants, in the pointwise interpretation (Pl2), except (Mf1), (Mf5), (Dv1), (Dv2), (Bk1), (Bk2), (Nf1) and (Nf3).*
- *The kernel hypotheses of (Pc5), namely its data with (Kc1)–(Kc4), finite total measure and both displayed scalar inequalities, hold there in the pointwise interpretation (Pl2), with the same constants and data.*
- *Every packet member there satisfies*

$$\log |\mathcal{W}(\mathfrak{V})| \leq (k-3)\log 2.$$

Let $\mathcal{F}$ be the family with scales W, threshold Y, and index sets

$$I(x) = \begin{cases} A_x, & x \in W,\ x > Y, \\ \varnothing, & \text{otherwise}, \end{cases}$$

whose members at the nonempty index sets are the packet members with their lower completion data. At empty index sets, take any fixed frame. This family admits base covolume realisations, chain data with (Lc1)–(Lc6), and deep-cover data with (Dp0)–(Dp6), all compatible with the packets and completions above. There are constants $C_6, C_{\mathrm{top}}, C_{\mathrm{F}}, C_{\mathrm{U}} \geq 0$ with which (Lc6), (Dp0), (Dp5), (Dp6) hold, respectively, and a constant

$$C \geq C_6 + \max\{C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\} + 1$$

such that $\mathcal{F}$ has realisation estimates for C.

A field, lattice, metric, map or scalar that occurs in several of these records is the same in all of them. The twenty-four common constants and the additional covolume constants do not depend on the scale, the translate, the word or any other local index. The loss data, place records, slope records, numerical choices and orbit masses are those of the packets above.

All the constants, cutoffs and packets asserted to exist may depend on the whole collection of choices fixed at the start.

Proof. Apply Proposition 21.2 for the same λ and P, and take its $\varepsilon_\dagger(\lambda, \mathsf{P})$ as $\varepsilon_\dagger$. Apply it to the data fixed in the statement, which satisfy its hypotheses, and take its constants and packets. Conditions (Ma1),(Ma2) are (Ra1),(Ra2), and the packets are chosen before the eventual Sha hypothesis is assumed.

Now assume that hypothesis, and take the common constants, the twenty-four common parameters and the compatible data supplied there. We show that these packets and data satisfy (Ra3) after one restriction to a common tail.

Fix a realised point and a lift $1 \le j < m$. Put

$$d = d_{\mathrm{flag}} = f\binom{r}{2}, \quad p = k + j - 1, \quad q = m - j, \quad Z = f^2 r^4.$$

The rank data give $f \ge 1$, $k \ge m + 3$, $m \ge 2$, $r = k + m - 1$, hence $r \ge 1$, $d \ge 1$ and $p + q = r$. In particular $pq \le r^2$, so

$$\binom{fpq+1}{2} \le \frac{fr^2(fr^2+1)}{2} \le f^2 r^4 = Z.$$

Also $r \le Z$, $fr \le Z$ and $Z \ge 1$. Thus

$$r + \binom{fpq+1}{2} + 2 \le 4Z, \qquad 8fr + 4 \le 12Z.$$

The maximum defining c_0 is an integer. Rounding it upwards to a multiple of 8 adds at most 7, and therefore

$$0 \le c_0 \le 12Z + 7 \le 19Z \le 22 f^2 r^4.$$

The length identity, $P \ge 40$ and $k/m \ge 1$ imply

$$T^{\mathrm{d}} = \left\lceil P^2 d^2 k/m \right\rceil \ge 1600 d^2 \ge 4(d+1).$$

For $x \ge 2$, rank sizes and $\varepsilon < 1/52$ give $k \le 2x^{9/2+10\varepsilon} \le 2x^5$. The common bounds $P, d \le x^{C_{\mathrm{prec}}}$ and $m \ge 1$ yield

$$T^{\mathrm{d}} \le 2x^{4C_{\mathrm{prec}}+5} + 1 \le x^{4C_{\mathrm{prec}}+7}.$$

The last inequality follows since $x^2 \ge 4$ and $x^{4C_{\mathrm{prec}}+5} \ge 1$. Set $C_T = 4C_{\mathrm{prec}} + 7$. This constant does not depend on the point or the lift.

Condition (Lm7), for the size parameter L_c, gives directly

$$0 < x^{\varepsilon} \le L_c \le x^{\varepsilon + \varepsilon/100}.$$

These are the size bounds used in Theorem 19.12. The same-host, CM-type, final-depth, numerator, anchored division, norm, spread, weight-bound, derivative and level identities in Theorem 19.12 are those supplied in (Ma3), with its $d = d_{\mathrm{flag}}$. Apply that theorem to the tail family. Outside W the index sets are empty, so its universal hypotheses there are vacuous. It gives (Ms2),(Ms4) with the constant 83400, beyond a cutoff that depends only on the constants already fixed.

On a further tail $x \ge \exp(\exp(1))$, the unit error is nonnegative. Since $B \ge 128$, $\mathrm{rd}_E \ge 1$ and $\mathrm{wn}, \mathrm{wsp} \ge 0$, we also have

$$\mathrm{lz}\,\mathrm{wn} + \mathrm{wsp} \ge 0.$$

Increasing the constants in (Ms3),(Ms4) to $C_{\mathrm{mod}} = \max\{C_{\mathrm{ms}}, 83400\}$ therefore preserves both inequalities. Conditions (Ms1),(Ms2) have no constant. Apply Theorem 19.18 to these component and model data, using the identity for e^{ms} supplied above. It gives (Ht3) with the constant $C_{\mathrm{mod}}(C_{\mathrm{mod}} + 120)$.

Increase the remaining component constant to

$$C_{\mathrm{H}} = \max\{C_{\mathrm{ht}}, C_{\mathrm{mod}}(C_{\mathrm{mod}} + 120)\}.$$

The budget inequalities are preserved since the unit error is nonnegative, and (Ht1),(Ht5) do not involve the constant. All of (Ht1)–(Ht5) now hold with C_{H}. By Theorem 19.20, the twisted slope satisfies (Dp6) with

$$C_{\mathrm{U}} = 8C_{\mathrm{H}} + 4.$$

Let Y' be the maximum of Y, the attachment cutoff, $\exp(\exp(1))$ and the cutoffs of the model and component consequences above. Restrict the family and its data to $x > Y'$. Each packet member, inner datum, shared object and common constant restricts without change. At empty index sets one may use the fixed frame allowed in the statement. The numbered lower formulas also hold at every $x \in W$, $x \geq Y'$, since they already hold at all scales at least Y. The kernel data with (Kc1)–(Kc4), the finite measure and both scalar inequalities, supplied in (Ma3), remain valid after this restriction, with all their inner quantifiers and antecedents and the same common constants. No additional constant is needed.

Conditions (Lc1)–(Lc6),(Dp0)–(Dp5) remain true, and (Dp6) has just been proved. The constant C supplied above already satisfies

$$C \geq C_6 + \max\{C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\} + 1$$

for this C_{U}, and the family has realisation estimates for it, so C is not enlarged. Hence (Ra3) holds on the new tail, including its compatibility requirements and the requirement that the packet data are those of the packets above. Together with (Ra1),(Ra2), which come from Proposition 21.2, this proves the proposition.

□

Definition 19.10. A family carrying deep-cover data **carries component data** if for every real $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and every lift $j < m$ the following data are given; the index $(\mathfrak{z}, j)$ is suppressed below.

- A finite non-empty set $\mathcal{Z}$, the **components**.
- For every $Z \in \mathcal{Z}$, real numbers $\mathrm{rc}(Z)$ and $\mathrm{gc}(Z)$, the rank and the degree of the lattice of sections of the twisted weight on Z, as well as $\mathrm{dg}(Z) > 0$, the **covering degree**, $\mathrm{hc}(Z)$, the **height** of Z, and $\mathrm{vs}(Z)$, the **volume slope** of Z at the divided weight.
- An integer $T^{\mathrm{d}} \geq 1$, the **division length**, and an integer $D^{\mathrm{fl}} \geq 0$, the **flag dimension**.
- Real numbers $N^{\mathrm{b}} > 0$, $\rho^{\mathrm{d}} \in [0, 1)$, $c^{\mathrm{s}}, c^{\mathrm{c}}, e^{\mathrm{ms}} \geq 0$, $a^{\mathrm{hs}} > 0$ and $r^{\mathrm{hs}} \geq 0$.

Put $\mathrm{dg}_{\min} = \min_Z \mathrm{dg}(Z)$.

The family has the following properties if there is a real number $C \geq 0$ such that the conditions below hold for all large points with $j < m$, where $E = \mathrm{ue}(x, i)$.

(Ht1) Degrees and shares $T^{\mathrm{d}} \geq 3D^{\mathrm{fl}} + 5$, and for every Z one has $\mathrm{dg}(Z) \leq \mathrm{dg}_{\min}/(1 - \rho^{\mathrm{d}})$ and $N^{\mathrm{b}} \mathrm{dg}(Z) \leq \mathrm{rc}(Z)$.

(Ht2) Heights from volume slopes For every Z one has $\mathrm{hc}(Z) + c^{\mathrm{s}} \geq 0$ and

$$(1 - \rho^{\mathrm{d}}) \max\bigl(0, \mathrm{vs}(Z) + c^{\mathrm{s}}\bigr) \leq \mathrm{hc}(Z) + c^{\mathrm{s}} + c^{\mathrm{c}};$$

moreover $T^{\mathrm{d}} c^{\mathrm{c}} \leq C\,E$ and $c^{\mathrm{s}}\bigl(6D^{\mathrm{fl}} + 10 + 2\rho^{\mathrm{d}} T^{\mathrm{d}}\bigr) \leq C\,E$.

(Ht3) Mean-slope bound at the divided weight $\frac{1}{|\mathcal{Z}|} \sum_Z \mathrm{vs}(Z) \geq -e^{\mathrm{ms}}$ and $T^{\mathrm{d}} e^{\mathrm{ms}} \leq C\,E$.

(Ht4) Effective Hilbert–Samuel inequality For every Z,

$$N^{\mathrm{b}}\mathrm{dg}(Z)(T^{\mathrm{d}}\mathrm{hc}(Z) - 3(D^{\mathrm{fl}}+1)|\mathrm{hc}(Z)| - a^{\mathrm{hs}}\log(2+|\mathrm{hc}(Z)|) - r^{\mathrm{hs}}) \le \mathrm{gc}(Z),$$

and $a^{\mathrm{hs}}\log\max(a^{\mathrm{hs}},1) + r^{\mathrm{hs}} \le C\,E$.

(Ht5) Sum bound $2\sum_Z \mathrm{gc}(Z)/\sum_Z \mathrm{rc}(Z) \le \sigma_{\mathfrak{z},j}$.

Definition 19.11. The Hodge–Tate cost. Let E be a number field, $M \ge 1$ an integer and $B > 0$ a real number. Let $P_{E,M}(B)$ be the set of primes p with $p \le B$ or $p \mid 2\,\mathrm{disc}(E)\,M$; it is finite. The **Hodge–Tate cost** is

$$c^{\mathrm{HT}}_{E,M}(B) = \sum_{p\in P_{E,M}(B)} \Big(\frac{1}{p-1} + \frac{40\,v_p(\mathrm{disc}(E))}{[E:\mathbb{Q}]} + \delta_{p,2}\Big)\log p, \tag{19.4}$$

where v_p is the p-adic valuation on $\mathbb{Z}$ and $\delta_{p,2}$ is 1 for $p = 2$ and 0 otherwise. The **root discriminant** of E is $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]} \ge 1$.

Model-slope data. A family carrying deep-cover data and component data **carries model-slope data** if for every real $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and every lift $j < m$ the following data are given; the index $(\mathfrak{z}, j)$ is suppressed.

- A number field E, the **host field**, and an integer $M \ge 1$, the **level**.
- Real numbers $B \ge 128$, the **weight bound**, L, the **logarithmic derivative**, $\mathrm{wn} \ge 0$, the **weight norm**, and $\mathrm{wsp} \ge 0$, the **spread term**.
- For every component $Z \in \mathcal{Z}$, a real number $\mathrm{ns}(Z)$, the **model slope** of Z.

Put

$$\mathrm{lz} = \log(B\,\mathrm{rd}_E) + |L|, \tag{19.5}$$

the **logarithmic size**.

The family has the following properties if there is a real number $C \ge 0$ such that the conditions below hold for all large points with $j < m$.

(Ms1) Volume above model slope $\mathrm{vs}(Z) \ge \mathrm{ns}(Z) - 2\,c^{\mathrm{HT}}_{E,M}(B)\,\mathrm{wn}$ for every $Z \in \mathcal{Z}$.

(Ms2) Few bad primes The number of primes dividing $2\,\mathrm{disc}(E)\,M$ is at most $\lfloor B \rfloor$.

(Ms3) Mean model slope $\dfrac{1}{|\mathcal{Z}|}\displaystyle\sum_{Z\in\mathcal{Z}} \mathrm{ns}(Z) \ge -C\,(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp})$.

(Ms4) Budget at the divided weight $T^{\mathrm{d}}(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp}) \le C\,\mathrm{ue}(x,i)$.

Theorem 19.12. *Fix real constants*

$$0 < \epsilon < 1/52, \quad c_D \ge 0, \quad c_h \ge 402, \quad C_T \ge 0, \quad J \ge 1, \quad \kappa = (C_{T_2}, C_8, C_5, c_6, C_b),$$

where $C_8 \ge 1$ and $C_5, c_6, C_b > 0$. Let $\mathcal{F}$ be a parametrised host family of parameter ϵ carrying model-slope data. Suppose that there is $X_{\mathrm{att}} > 1$ such that, for every real $x \ge X_{\mathrm{att}}$ with $x > x_1$ and every $i \in I(x)$, the following hypotheses hold.

The member carries a choice of all the data whose existence is asserted by the concrete good-host requirement $\mathfrak{G}(x,\epsilon,J,\kappa,\mathfrak{h},T,t)$. Its loss datum has the rank datum of these data, with its rank sizes. Write

$$n=|A|,\quad f=2n,\quad r=k+m-1,\quad \theta=\epsilon/100,\quad \delta_1=x^{-\epsilon/8},$$

$$b=\exp(x^{\epsilon}),\quad b'=x\exp(x^{\epsilon}-x^{\epsilon/3}),\quad \Delta=\lceil x^{c_D}\rceil,\quad h=2\lceil x^{c_h}\rceil.$$

The loss datum has integer weights and boxes for the host field $E_{\mathfrak{h}}$, the constants (c_D,c_h), and a thick subset of Φ. Its final integer depths b_t and its parameter L_a satisfy

$$0\le L_a\le x^{\epsilon+\theta},\qquad b_t\le b'+\frac{2n\delta_1 x^{\epsilon}L_a b'}{k}\quad (t\in T).$$

For every realised point $\mathfrak{z}\in \mathrm{Pt}_{x,i}$ and every integer $1\le j<m$, the following ties hold. The model host field E equals $E_{\mathfrak{h}}$. There is a CM type $\mathcal{I}$ of E, choosing one complex embedding from each conjugate pair, and a bijection $\beta:\mathcal{I}\to\Phi$. Put $B_\tau=w_1(\beta(\tau))-h/2$ and $p=k-1+j$. Define

$$U_{\tau,a}=\begin{cases}(4\Delta-1)(k-2-a), & 0\le a<k-1,\\ -B_\tau-(l-1)h+l-r\mathbf{1}_{l>j}, & a=k+l-2,\quad 1\le l\le m.\end{cases}$$

There are a real $d\ge 0$ and an integer c_0 such that

$$0\le c_0\le 22f^2r^4,\qquad 4(d+1)\le T^{\mathrm{d}}\le x^{C_T}.$$

Put $D=T^{\mathrm{d}}+d+1$, let v be the unique integer array on $\mathcal{I}\times\{0,\dots,r-1\}$ determined by

$$v_{\tau,k-2}=0,\qquad v_{\tau,a}-v_{\tau,a+1}=\left\lfloor\frac{U_{\tau,a}-U_{\tau,a+1}+2-(c_0+2r)\mathbf{1}_{a+1=p}}{D}\right\rfloor\quad (0\le a<r-1),$$

and put $V_{\tau,a}=v_{\tau,a}+3r\mathbf{1}_{a\ge p}$. The numerical entries of the model satisfy

$$\begin{aligned}\mathrm{wn}&=\sum_{\tau\in\mathcal{I}}\sum_{a=0}^{r-1}|V_{\tau,a}|,\\ \mathrm{wsp}&=(m-j)\sum_{\tau\in\mathcal{I}}\Big(\max_a V_{\tau,a}-\min_a V_{\tau,a}\Big),\\ B&=4fr^2\left(1+\frac{\max_{\tau,a}|V_{\tau,a}|}{h/(4T^{\mathrm{d}})}\right),\\ L&=\mathrm{Re}\,\frac{L'(1,\chi_{-d_{\mathfrak{h}}})}{L(1,\chi_{-d_{\mathfrak{h}}})},\\ M&=g_1g_2\,15^{a_{\mathrm{lev}}},\end{aligned}$$

where a_{lev} is a nonnegative integer and g_1,g_2 are the auxiliary primes of the good-host data above. The choices $\mathcal{I},\beta,d,c_0,a_{\mathrm{lev}}$ may vary with the point and lift.

Then there exists X_0, depending only on $X_{\mathrm{att}},\epsilon,c_D,c_h,C_T,J,\kappa$, such that for every $x\ge X_0$ with $x>x_1$, every $i\in I(x)$, every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$, and every integer $1\le j<m$, properties (Ms2),(Ms4) hold with the common constant $C=83400$. The theorem assumes the data and identities above; it does not assert that such model data exist.

Proof. Let X_{dw} be the threshold in Lemma 19.13 for $(\epsilon,c_D,c_h,C_T,6)$. Put

$$X_{\mathrm{host}}=\exp\!\left(1+\frac{6}{(4\epsilon/5)^3}\right),\quad X_{\mathrm{tor}}=128^{1/(2-16\epsilon)},\quad X_{\mathrm{top}}=2^{1/(5/2+19\epsilon/200)},\quad X_{\mathrm{slack}}=2^{100/\epsilon}.$$

Choose

$$X_0 = \max\left\{X_{\mathrm{att}}, X_{\mathrm{dw}}, X_{\mathrm{host}}, X_{\mathrm{tor}}, X_{\mathrm{top}}, X_{\mathrm{slack}}, \exp(\exp(1)), 10^{1/\epsilon}\right\}.$$

Fix a member, a point and a lift in the range of the statement, beyond this threshold. Rank sizes give

$$n \le 2x^{2+8\epsilon}, \qquad m \le 2\sqrt{x\delta_1} \le 2\sqrt{x}, \qquad k \le 2x^{9/2+10\epsilon}.$$

Condition (R2) of the rank datum gives $m \ge 2$ and $k \ge m+3$; hence also $r \ge 4$ and $m \le r$. Since $x^\theta \ge 2$, we have $n \le x^{2+8\epsilon+\theta}$. The lower rank-size bound also gives $k \ge x^{9/2+10\epsilon-\theta}$. The assumed bounds on the depths and Lemma 19.14 therefore imply

$$\lceil b' \rceil \le b_t \le 2b' \quad (t \in T)$$

for the final depths.

By Lemma 19.15, the torsion-unit group of the host field has order at most x^6. Pulling (Iw3) back along the given bijection β places every B_τ in the appropriate one of the three permitted intervals in Lemma 19.13: the top interval using the preceding depth bound, the thin singleton, or the thick interval with $C_\mu = 6$. By Lemma 19.16, E is CM of degree $4n$; therefore $|\mathcal{I}| = 2n = f$. All hypotheses of Lemma 19.13 now hold for the displayed arrays, with its $T = T^{\mathrm{d}}$. Its conclusions give the required raw and divided-weight bounds, spread inequality, and scalar and rank-size bounds, including $h \ge fr^2$.

Again Lemma 19.16 gives $Q_S \le n^2$, the discriminant-prime support containment in the primes dividing Q_S together with $q, d_{\mathfrak{h}}$, and

$$\log \mathrm{rd}_E + |L| \le 9x^\epsilon$$

for the real logarithmic derivative specified in the statement. The level identity implies that every prime divisor of M belongs to $\{g_1, g_2, 3, 5\}$; hence M has at most $4 \le 15$ prime divisors. We also have $x^\epsilon \ge 10$ and $\log\log x \ge 1$.

Apply Lemma 19.17, reindexing $a \in \{0, \dots, r-1\}$ as $a+1$, with

$$Q = Q_S, \quad q_{\mathrm{H}} = q, \quad d_{\mathrm{H}} = d_{\mathfrak{h}}, \quad S = 4k\Delta, \quad T = T^{\mathrm{d}}, \quad q_{\mathrm{s}} = m - j.$$

By the identities assumed in the statement, the quantities $\mathrm{wn}, \mathrm{wsp}, B, T$ in that lemma are those of the model. We obtain

$$\#\{p : p \text{ prime},\ p \mid 2\,\mathrm{disc}(E)\,M\} \le \lfloor B \rfloor$$

and

$$T^{\mathrm{d}}\left[(\log(B\mathrm{rd}_E) + |L|)\mathrm{wn} + \mathrm{wsp}\right] \le 83400\,2nmbx^\epsilon \log\log x = 83400\,\mathrm{ue}(x,i).$$

These are (Ms2) and (Ms4). No threshold depends on the member, the point, the lift or the integer a_{lev}, and the common constant is 83400. □

Lemma 19.13. *Fix real constants $0 < \epsilon < 1/52$, $c_D \ge 0$, $c_h > 12$, and $C_T, C_\mu \ge 0$. There exists $X > 1$, depending only on these constants, with the following property for every real $x \ge X$. Put*

$$b = \exp(x^\epsilon), \qquad b' = x\exp(x^\epsilon - x^{\epsilon/3}), \qquad \Delta = \lceil x^{c_D} \rceil, \qquad h = 2\lceil x^{c_h} \rceil.$$

Let n, k, m be integers satisfying

$$1 \le n \le 2x^{2+8\epsilon}, \qquad 2 \le m \le 2x^{1/2}, \qquad m+3 \le k \le 2x^{9/2+10\epsilon},$$

and put $f = 2n$, $r = k + m - 1$, $S_c = 4k\Delta$, and $\eta = mh$. Let I be a finite set of cardinality f. For each $\tau \in I$, let B_τ be a real number belonging to at least one of the following sets:

$$\{b_t + \lfloor b'/x \rfloor : \lceil b' \rceil \le b_t \le 2b'\}, \qquad \left\{ \left\lceil \frac{b'}{xn} \right\rceil \right\}, \qquad [\,\lceil b \rceil, \lceil b \rceil + x^{C_\mu}\,).$$

Let j be an integer with $1 \le j < m$, put $p = k - 1 + j$, and define

$$U_{\tau,a} = \begin{cases} (4\Delta - 1)(k - 2 - a), & 0 \le a < k - 1, \\ -B_\tau - (l-1)h + l - r\mathbf{1}_{l>j}, & a = k + l - 2, \quad 1 \le l \le m. \end{cases}$$

Let real numbers $d \ge 0$, $T > 0$ and an integer c_0 satisfy

$$4(d+1) \le T \le x^{C_T}, \qquad 0 \le c_0 \le 22 f^2 r^4.$$

Set $D = T + d + 1$. Let v be the unique integer array on $I \times \{0, \dots, r-1\}$ determined by

$$v_{\tau,k-2} = 0, \qquad v_{\tau,a} - v_{\tau,a+1} = \left\lfloor \frac{U_{\tau,a} - U_{\tau,a+1} + 2 - (c_0 + 2r)\mathbf{1}_{a+1=p}}{D} \right\rfloor \quad (0 \le a < r-1),$$

and put $V_{\tau,a} = v_{\tau,a} + 3r\mathbf{1}_{a \ge p}$. Then

1. *For $a < r - m$, one has $0 \le U_{\tau,a} \le S_c$; for $r - m \le a < r$, one has $|U_{\tau,a}| \le 8b$.*
2. *For all τ, a,*
$$T|V_{\tau,a}| \le |U_{\tau,a}| + c_0 + 4r, \qquad |V_{\tau,a}| \le \frac{8b}{T}.$$
3. *The rank-size and scalar bounds*
$$rS_c \le 800b, \qquad r(c_0 + 4r) \le 26b, \qquad fr^2 \le b, \qquad h \ge fr^2$$
hold.
4. *One has*
$$(m-j) \sum_{\tau \in I} \left(\max_{0 \le a < r} V_{\tau,a} - \min_{0 \le a < r} V_{\tau,a} \right) \le 6 \sum_{\tau \in I} \sum_{a=0}^{r-1} |V_{\tau,a}|.$$

Proof. We first choose a tail uniform in all the data of the statement. Write $L = x^\epsilon$. For $x \ge 1$, the hypotheses imply

$$f \le 4x^{2+8\epsilon}, \qquad r \le 4x^{9/2+10\epsilon}, \qquad \Delta \le 2x^{c_D}, \qquad h \le 4x^{c_h},$$
$$S_c \le 16x^{c_D+9/2+10\epsilon}, \qquad \eta \le 8x^{c_h+1/2}, \qquad fr^2 \le 64x^{11+28\epsilon}, \qquad c_0 \le 90112x^{22+56\epsilon}.$$

Consequently

$$rS_c \le 64x^{c_D+9+20\epsilon}, \qquad r(c_0 + 4r) \le 360512x^{28}, \qquad rT \le 4x^{9/2+10\epsilon+C_T}.$$

For the middle bound, the two terms are bounded by $360448x^{53/2+66\epsilon}$ and $64x^{9+20\epsilon}$; both exponents are less than 28. Since $11 + 28\epsilon < 12 < c_h$, the bounds $h \ge 2x^{c_h}$ and $fr^2 \le 64x^{11+28\epsilon}$ give $h \ge fr^2$ on a uniform tail.

Put $s = x^{\epsilon/3}$ and $w = b'/(xn) = \exp(L - s)/n$. On a uniform tail $s \le L/3$, since $s/L = x^{-2\epsilon/3} \longrightarrow 0$. Therefore

$$w \ge \tfrac{1}{2} x^{-2-8\epsilon} \exp(2L/3).$$

Thus w dominates each fixed polynomial displayed above. The three permitted sets for B_τ give, uniformly in the choice of B_τ,

$$w \le B_\tau \le 2b$$

on a tail. Indeed, for the first set the upper bound $B_\tau \le 3b'$ suffices, and $b'/b = x\exp(-x^{\epsilon/3}) \to 0$; its lower bound follows from $b' \ge w$. For the second set, $w \le B_\tau \le w+1$. For the third, $B_\tau < b + 1 + x^{C_\mu}$, and $b \ge w$ eventually.

Choose $X > 1$, depending only on the five fixed constants, such that all the preceding bounds hold for every $x \ge X$ and, for every permitted choice of B_τ,

$$\begin{gathered} B_\tau \ge 2(S_c + \eta + 5r), \qquad B_\tau \ge 2c_0 + 6r + 10rT, \\ S_c + c_0 + 4r \le 8b, \qquad B_\tau + \eta + c_0 + 5r \le 8b, \\ rS_c \le 800b, \qquad r(c_0+4r) \le 26b, \qquad fr^2 \le b, \qquad h \ge fr^2. \end{gathered}$$

This simultaneous choice is justified by the explicit polynomial bounds: for every fixed $A, R, a > 0$, $\exp(ax^\epsilon)/(Ax^R) \to \infty$. In particular, the two lower bounds for B_τ follow from the lower bound for w. Its upper bound $2b$, together with the polynomial bounds for the remaining summands, gives the fourth displayed inequality. No threshold depends on $n, k, m, I, j, B_\tau, d, T$, or c_0.

We next estimate the recurrence. The length assumption gives

$$T \le D \le 5T/4, \qquad T \ge 4.$$

All the differences specified for v are integers, so the anchor determines a unique integer array by recursion in both directions. For $a \le k-2$, the steps from a to the anchor have numerator $4\Delta + 1 > 0$ and do not contain the exceptional step. Summing the upper floor inequality gives the stronger bound

$$0 \le v_{\tau,a} \le \frac{U_{\tau,a} + 2r}{D}.$$

Also $0 \le U_{\tau,a} \le S_c$, since $\Delta \ge 1$.

Fix now a node $a = k + l - 2$, $1 \le l \le m$, and write $\delta = \mathbf{1}_{l>j}$. Summing the l recurrence numerators from the anchor to this node telescopes to

$$B_\tau + (l-1)h + l - (c_0 + r)\delta.$$

The sum of the corresponding floors equals $-v_{\tau,a}$. The inequalities $z - 1 \le \lfloor z \rfloor \le z$, and the shift $V_{\tau,a} = v_{\tau,a} + 3r\delta$, imply

$$-V_{\tau,a} \ge \frac{B_\tau - c_0 - 3r}{D} - 4r \ge \frac{B_\tau}{2D} \ge \frac{B_\tau}{4T} > 0.$$

For the middle inequality, use $B_\tau/2 \ge c_0 + 3r + 5rT$ and $D \le 5T/4$. The upper floor inequality also gives

$$-V_{\tau,a} \le \frac{B_\tau + \eta + r}{D}.$$

The node numerator is negative, and $|U_{\tau,a}| \le B_\tau + \eta + r$. When $\delta = 0$, the upper floor inequality gives $T|V_{\tau,a}| \le |U_{\tau,a}| + 2r$. When $\delta = 1$, it gives

$$|V_{\tau,a}| \le \frac{|U_{\tau,a}| + 2r}{D} - 3r \le \frac{|U_{\tau,a}|}{D},$$

since $D \ge 1$. Combining these bounds with the cloud estimate proves $T|V_{\tau,a}| \le |U_{\tau,a}| + c_0 + 4r$ at every index. The chosen tail bounds prove both the claimed node bound for U and $|V_{\tau,a}| \le 8b/T$.

It remains to estimate the spread. The anchor is zero, the cloud values are nonnegative, and all node values are negative. The cloud and node estimates above yield

$$\max_a V_{\tau,a} - \min_a V_{\tau,a} \le \frac{S_c + 2r + B_\tau + \eta + r}{D} \le \frac{3B_\tau}{2T},$$

using $B_\tau \ge 2(S_c + \eta + 5r)$ and $D \ge T$. Each of the m node entries has absolute value at least $B_\tau/(4T)$, whence

$$\sum_a |V_{\tau,a}| \ge \frac{mB_\tau}{4T}.$$

As $m - j \le m$, these two inequalities imply

$$(m-j)\left(\max_a V_{\tau,a} - \min_a V_{\tau,a}\right) \le 6\sum_a |V_{\tau,a}|.$$

Summation over τ proves the last assertion. The remaining scalar assertions are among the uniform tail bounds already established. □

Lemma 19.14. *Fix $\epsilon > 0$, and put*

$$\theta = \epsilon/100, \qquad X_\epsilon = 2^{1/(5/2+19\epsilon/200)}.$$

Let $x \ge \max(1, X_\epsilon)$ be real, and let real numbers n, k, L_a satisfy

$$n > 0, \quad k > 0, \quad L_a \ge 0, \qquad n \le x^{2+8\epsilon+\theta}, \quad L_a \le x^{\epsilon+\theta}, \quad k \ge x^{9/2+10\epsilon-\theta}.$$

Put $\delta_1 = x^{-\epsilon/8}$, and let $b' > 0$ be any real number. Let $\mathcal{T}$ be a set, and let $b_t \in \mathbb{Z}$ for each $t \in \mathcal{T}$. If

$$b' \le b_t \le b' + \frac{2n\delta_1 x^\epsilon L_a b'}{k} \qquad (t \in \mathcal{T}),$$

then

$$\lceil b' \rceil \le b_t \le 2b' \qquad (t \in \mathcal{T}).$$

Proof. All factors in $2n\delta_1 x^\epsilon L_a/k$ are nonnegative, and $k > 0$. Substituting the bounds for n, L_a, k gives

$$\begin{aligned}\frac{2n\delta_1 x^\epsilon L_a}{k} &\le 2x^{(2+8\epsilon+\theta)-\epsilon/8+\epsilon+(\epsilon+\theta)-(9/2+10\epsilon-\theta)} \\ &= 2x^{-5/2-\epsilon/8+3\theta} = 2x^{-5/2-19\epsilon/200} \le 1.\end{aligned}$$

The last inequality follows from $x \ge X_\epsilon$ and $5/2 + 19\epsilon/200 > 0$. Since $b' > 0$, the assumed upper bound for b_t therefore gives $b_t \le (1+1)b' = 2b'$. The lower bound $b' \le b_t$, together with $b_t \in \mathbb{Z}$, gives $\lceil b' \rceil \le b_t$. □

Lemma 19.15. *Let E be a number field of degree $D = [E : \mathbb{Q}]$, and let $\mu(E)$ be its group of roots of unity. Then*

$$|\mathcal{O}_{E\mathrm{tors}}^\times| = |\mu(E)| \le 2D^2.$$

In particular, let E be the field of a host on a finite group A, and put $n = |A|$. If

$$0 < \epsilon < 1/52, \qquad x \ge 128^{1/(2-16\epsilon)}, \qquad n \le 2x^{2+8\epsilon},$$

then

$$|\mu(E)| \le 32n^2 \le 128x^{4+16\epsilon} \le x^6.$$

Consequently, for the integer weights and boxes of Definition 18.2 with this same field E, every thick place z satisfies

$$\lceil b \rceil \le w_1(z) - h_0/2 < \lceil b \rceil + x^6.$$

Thus $w_1(z) - h_0/2$ belongs to the third of the sets listed in Lemma 19.13, with $C_\mu = 6$.

Proof. The finite cyclic assertion in Dirichlet's unit theorem gives $\mu(E) = \langle \zeta \rangle$, where ζ has order $w = |\mu(E)|$; see [190, Chapter I]. A primitive w-th root of unity has degree

$$[\mathbb{Q}(\zeta) : \mathbb{Q}] = \varphi(w),$$

where φ is Euler's totient function. Since $\mathbb{Q}(\zeta) \subseteq E$, one has $\varphi(w) \le D$.

For $w = 1$, the claimed bound is immediate. For $w > 1$, Euler's product formula gives

$$\frac{\varphi(w)^2}{w} = \prod_{p^a \| w} p^{a-2}(p-1)^2.$$

If $a \ge 2$, the corresponding factor is at least 1. If $a = 1$ and p is odd, then $(p-1)^2 - p = p(p-3) + 1 \ge 1$, so that factor is again at least 1. The only possible factor less than 1 occurs for $p = 2, a = 1$, and equals $1/2$. Therefore

$$\frac{\varphi(w)^2}{w} \ge \frac{1}{2}, \qquad w \le 2\varphi(w)^2 \le 2D^2.$$

Every root of unity is an algebraic-integer unit, and every torsion unit is a root of unity. This proves the group identification and the first assertion.

For a host field, Lemma 19.16 gives $D = 4n$. Hence

$$|\mu(E)| \le 2(4n)^2 = 32n^2 \le 128x^{4+16\epsilon}.$$

The exponent $2 - 16\epsilon$ is positive. The stated cutoff therefore implies $128 \le x^{2-16\epsilon}$, proving $|\mu(E)| \le x^6$. Finally, (Iw3) of the integer weights and boxes gives at every thick place

$$\lceil b \rceil \le w_1(z) - h_0/2 < \lceil b \rceil + |\mathcal{O}_{E^{\mathrm{tors}}}^\times|.$$

Substitute the proved bound. This is the third permitted set, with $C_\mu = 6$. □

Lemma 19.16. *Let $\mathfrak{h}$ be a host on a finite group A, and put*

$$n = |A|, \qquad E = E_{\mathfrak{h}}, \qquad N = N_{\mathfrak{h}}, \qquad \mathrm{rd}_E = |\operatorname{disc}(E)|^{1/[E:\mathbb{Q}]}.$$

Then

$$[E : \mathbb{Q}] = 4n, \qquad 1 \le \mathrm{rd}_E \le N, \qquad p \mid |\operatorname{disc}(E)| \implies p \mid N \quad (p \text{ prime}).$$

Since $2 \mid Q_S$,

$$\{p : p \text{ prime},\ p \mid 2|\operatorname{disc}(E)|\} \subseteq \{p : p \text{ prime},\ p \mid Q_S\} \cup \{q, d\}.$$

Suppose that data are given, as in the concrete good-host requirement, for which this requirement holds for $\mathfrak{h}$. Then E is CM, the chosen CM type has cardinality $2n$, and $Q_S \le n^2$.

Fix $\varepsilon > 0$, and define

$$a = \frac{4\varepsilon}{5}, \qquad X_\varepsilon = \exp\Big(1 + \frac{6}{a^3}\Big).$$

For all such data at a scale $x \geq X_\varepsilon$,

$$\log \mathrm{rd}_E \leq 2x^\varepsilon.$$

Consequently every real number L_{der} with $|L_{\mathrm{der}}| \leq x^\varepsilon$ satisfies

$$\log \mathrm{rd}_E + |L_{\mathrm{der}}| \leq 3x^\varepsilon \leq 9x^\varepsilon.$$

In particular, this applies to the real part of $L'(1, \chi_{-d})/L(1, \chi_{-d})$ in (Hg8). The threshold X_ε depends only on ε; it does not depend on the host, the translates or the words.

Proof. The surjection α identifies $\mathrm{Gal}(E/\mathbb{Q})$ with $\{\pm 1\}^2 \times A$. Galois theory therefore gives $[E : \mathbb{Q}] = 4n$. Every character of this Galois group, composed with α, is a Dirichlet character modulo N. Its inducing primitive character has positive conductor dividing N. Under the cyclotomic Artin map these are precisely the characters of the abelian extension $E/\mathbb{Q}$. Applying Theorem B.15 over $\mathbb{Q}$ gives

$$|\operatorname{disc}(E)| = \prod_\chi \operatorname{cond}(\chi),$$

with $4n$ factors, each a positive divisor of N. Hence every prime divisor of the discriminant divides N, and

$$1 \leq |\operatorname{disc}(E)| \leq N^{4n}.$$

Taking $(4n)$-th roots proves the root-discriminant bounds. The support assertion follows from $N = Q_S q d$ and $2 \mid Q_S$. The CM assertion is (Hg2); its type chooses exactly one member from each pair of conjugate embeddings, so its cardinality is $[E : \mathbb{Q}]/2 = 2n$. Finally (Hg1) includes field row (Fr4), which is $Q_S \leq n^2$.

For the scale estimate write $y = \log x$. The chosen cutoff gives $y \geq 1 + 6/a^3 > 0$. The exponential series, whose terms are nonnegative at $ay > 0$, gives

$$e^{ay} \geq \frac{(ay)^3}{6} \geq y^2.$$

Thus $(\log x)^2 \leq x^{4\varepsilon/5}$. The good-host scale Y satisfies $1 < Y \leq x$, and (Hg6) gives

$$\log N \leq 2Y^{\varepsilon/5}(\log Y)^2 \leq 2x^{\varepsilon/5}(\log x)^2 \leq 2x^\varepsilon.$$

Combine this with $\mathrm{rd}_E \leq N$. The assertion for L_{der} follows by addition, and its stated example is the explicit real-part bound in (Hg8). Every cutoff and estimate above is independent of the remaining choices. □

Lemma 19.17. *Fix $\varepsilon > 0$ and $x > 1$ with*

$$x^\varepsilon \geq 10, \qquad \log\log x \geq 1, \qquad b = \exp(x^\varepsilon).$$

Let n, m, r be integers with $n \geq 1$, $1 \leq m \leq r$ and $r \geq 4$. Let E be a CM number field with $[E : \mathbb{Q}] = 4n$, let I be a choice of one embedding $E \hookrightarrow \mathbb{C}$ from each complex-conjugate pair, and put $f = |I| = 2n$. Write

$$\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]}.$$

Let $Q, M \geq 1$ and $q_{\mathrm{H}}, d_{\mathrm{H}} \geq 2$ be integers satisfying

$$Q \leq n^2, \qquad |\{p : p \text{ prime}, \ p \mid M\}| \leq 15,$$
$$\{p : p \text{ prime}, \ p \mid 2|\mathrm{disc}(E)|\} \subseteq \{p : p \text{ prime}, \ p \mid Q\} \cup \{q_{\mathrm{H}}, d_{\mathrm{H}}\}.$$

Let

$$U, V : I \times \{1, \dots, r\} \longrightarrow \mathbb{R}, \qquad T > 0, \quad h \geq fr^2, \quad S \geq 0, \quad c_0 \in \mathbb{R}, \quad q_{\mathrm{s}} \geq 0$$

be data, where T, h, S, q_{s} are real. Suppose, for every $\tau \in I$, that

$$0 \leq U_{\tau,i} \leq S \quad (1 \leq i \leq r - m), \qquad |U_{\tau,i}| \leq 8b \quad (r - m < i \leq r),$$

$$T|V_{\tau,i}| \leq |U_{\tau,i}| + c_0 + 4r, \qquad |V_{\tau,i}| \leq \frac{8b}{T} \quad (1 \leq i \leq r),$$

and suppose also that

$$rS \leq 800b, \qquad r(c_0 + 4r) \leq 26b, \qquad fr^2 \leq b.$$

Put

$$g = \frac{h}{4T}, \qquad H = \max_{\tau \in I, \ 1 \leq i \leq r} |V_{\tau,i}|,$$
$$\mathrm{wn} = \sum_{\tau \in I} \sum_{i=1}^{r} |V_{\tau,i}|, \qquad \mathrm{wsp} = q_{\mathrm{s}} \sum_{\tau \in I} \left(\max_{1 \leq i \leq r} V_{\tau,i} - \min_{1 \leq i \leq r} V_{\tau,i} \right),$$
$$B = 4fr^2 \left(1 + \frac{H}{g}\right).$$

Assume $\mathrm{wsp} \leq 6\,\mathrm{wn}$*, and let $L_{\mathrm{der}} \in \mathbb{R}$ satisfy*

$$\log \mathrm{rd}_E + |L_{\mathrm{der}}| \leq 9x^{\varepsilon}.$$

Then

$$128 \leq B \leq 132b, \qquad |\{p : p \text{ prime}, \ p \mid 2|\mathrm{disc}(E)|M\}| \leq \lfloor B \rfloor,$$

and

$$T\left[(\log(B\,\mathrm{rd}_E) + |L_{\mathrm{der}}|)\mathrm{wn} + \mathrm{wsp}\right] \leq 83400\left[2nmb\,x^{\varepsilon} \log\log x\right].$$

The constant 83400 *does not depend on any of the data above. Consequently, if the displayed hypotheses hold beyond a common threshold at every selected point and for every lift $1 \leq j < m$, then the few-bad-primes inequality and the budget inequality at the divided weight hold at all these points and lifts, with this same constant.*

Proof. The CM field has $4n$ embeddings, in conjugate pairs, so $f = 2n$. There is at most one prime divisor of Q exceeding n: otherwise two distinct such primes would have product greater than n^2, whereas their product divides $Q \leq n^2$. By the discriminant-support and level-prime assumptions, among the primes dividing $2|\mathrm{disc}(E)|M$ at most $1 + 2 + 15 = 18$ exceed n. At most $n + 1$ of them are at most n. Their total number is therefore at most

$$n + 19 \leq 128n = 4f \cdot 16 \leq 4fr^2.$$

Since $h \geq fr^2 > 0$ and $T > 0$, we have $g > 0$; also $H \geq 0$. Hence

$$B \geq 4fr^2 \geq 128.$$

The integer cardinality is at most B, and consequently is at most $\lfloor B \rfloor$.

Summing the pointwise division inequality and then using the bounds on U gives

$$\begin{aligned} T\,\mathrm{wn} &\le \sum_{\tau,i} |U_{\tau,i}| + fr(c_0+4r) \\ &\le f\big(rS + 8mb + r(c_0+4r)\big) \\ &\le f(826b + 8mb) \le 834 fmb. \end{aligned}$$

Here the cloud contribution is at most $f(r-m)S \le frS$, and the last inequality uses $m \ge 1$.

The entry bound gives $H \le 8b/T$. Therefore

$$\frac{H}{g} \le \frac{32b}{h}, \qquad B \le 4fr^2 + \frac{128fr^2 b}{h} \le 4b + 128b = 132b.$$

In particular

$$\log B \le x^{\varepsilon} + \log 132 \le x^{\varepsilon} + 22,$$

because $132 \le 12^2$ and $\log 12 \le 11$. Since $\mathrm{rd}_E \ge 1$, all logarithms in the statement are defined. The norm wn is nonnegative, and the spread assumption and logarithmic-size assumption yield

$$\begin{aligned} \big(\log(B\,\mathrm{rd}_E) + |L_{\mathrm{der}}|\big)\mathrm{wn} + \mathrm{wsp} &\le \big(\log B + \log \mathrm{rd}_E + |L_{\mathrm{der}}| + 6\big)\mathrm{wn} \\ &\le (10x^{\varepsilon} + 28)\mathrm{wn} \le 100 x^{\varepsilon}\,\mathrm{wn}. \end{aligned}$$

Multiplying by T and using the preceding norm bound, $f = 2n$ and $\log\log x \ge 1$, we obtain

$$T\left[\big(\log(B\,\mathrm{rd}_E) + |L_{\mathrm{der}}|\big)\mathrm{wn} + \mathrm{wsp}\right] \le 83400 fmbx^{\varepsilon} \le 83400\left[2nmbx^{\varepsilon}\log\log x\right].$$

The numerical constants in these estimates do not depend on the data, so applying the estimates beyond the common threshold gives the asserted uniform form. □

Theorem 19.18. *Let $\mathcal{F}$ be a parametrised host family with covolume records carrying chain data, deep-cover data, component data and model-slope data with the properties (Ms1)–(Ms4) for the constant $C \ge 0$. At every large point with $j < m$ put*

$$e_* = C\big(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp}\big) + 2\,c^{\mathrm{HT}}_{E,M}(B)\,\mathrm{wn}.$$

Then for all large points with $j < m$

$$e_* \ge 0, \qquad \frac{1}{|\mathcal{Z}|}\sum_{Z\in\mathcal{Z}} \mathrm{vs}(Z) \ge -e_*, \qquad T^{\mathrm{d}} e_* \le C(C+120)\,\mathrm{ue}(x,i).$$

Consequently, if the component data is taken with $e^{\mathrm{ms}} = e_*$, it has the mean-slope bound (Ht3) for the constant $C(C+120)$; and if moreover (Ht1), (Ht2), (Ht4), (Ht5) hold for a constant C', then (Ht1)–(Ht5) hold for the constant $\max\big(C', C(C+120)\big)$.

Proof. Fix a large point with $j < m$ (beyond the threshold of (Ms1)–(Ms4)) and write $c = c^{\mathrm{HT}}_{E,M}(B)$, $N = |\mathcal{Z}| \ge 1$, $U = \mathrm{ue}(x,i)$.

The cost and the logarithmic size. By (Ms2) and $B \ge 128$, Lemma 19.19 gives $0 \le c \le 60\log(B\,\mathrm{rd}_E)$. Since $\mathrm{rd}_E \ge 1$ and $|L| \ge 0$,

$$\log(B\,\mathrm{rd}_E) \le \mathrm{lz}, \qquad \mathrm{lz} \ge \log 128 > 0. \tag{19.6}$$

With $C, \mathrm{wn}, \mathrm{wsp} \ge 0$ every term of e_* is non-negative, so $e_* \ge 0$.

The mean. Summing (Ms1) over $Z \in \mathcal{Z}$, dividing by N and using (Ms3),

$$\frac{1}{N}\sum_{Z} \mathrm{vs}(Z) \geq \frac{1}{N}\sum_{Z} \mathrm{ns}(Z) - 2c\,\mathrm{wn} \geq -C\big(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp}\big) - 2c\,\mathrm{wn} = -e_*.$$

The budget. Since $T^{\mathrm{d}} \geq 1$, $\mathrm{wn} \geq 0$ and $\mathrm{wsp} \geq 0$, the cost bound, (19.6) and (Ms4) give

$$\begin{aligned} T^{\mathrm{d}} e_* &= C\,T^{\mathrm{d}}\big(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp}\big) + 2c\,T^{\mathrm{d}}\mathrm{wn} \\ &\leq C\cdot CU + 120\,T^{\mathrm{d}}\,\mathrm{lz}\cdot\mathrm{wn} \\ &\leq C^2U + 120\,T^{\mathrm{d}}\big(\mathrm{lz}\cdot\mathrm{wn} + \mathrm{wsp}\big) \leq C(C+120)\,U. \end{aligned}$$

The consequences. With $e^{\mathrm{ms}} = e_* \geq 0$ the two displayed inequalities are (Ht3) for the constant $C(C+120)$, for all large points. Each of (Ht2), (Ht3), (Ht4) bounds a quantity by its constant times U. Moreover $U \geq 0$: by Definition 19.5, $U = 2|A|\,m\,b(x)\,x^{\varepsilon}\log\log x$ with $b(x) > 0$, which is ≥ 0 for $x \geq e$. Hence each of these bounds stays true when its constant is replaced by a larger one, while (Ht1) and (Ht5) contain no constant. Taking as threshold the largest of e and the two thresholds, and the constant $\max(C', C(C+120))$, the family has (Ht1)–(Ht5). □

Lemma 19.19. *Let E be a number field, $M \geq 1$ an integer and $B \geq 128$ a real number such that the number of primes dividing $2\,\mathrm{disc}(E)\,M$ is at most $\lfloor B \rfloor$. Then*

$$0 \leq c^{\mathrm{HT}}_{E,M}(B) \leq 60\,\log\big(B\,\mathrm{rd}_E\big).$$

Proof. Every summand of (19.4) is non-negative, since $p \geq 2$ and $v_p(\mathrm{disc}(E)) \geq 0$; this gives the lower bound. For the upper bound split the sum into three parts.

The discriminant part. Every prime dividing $\mathrm{disc}(E)$ lies in $P_{E,M}(B)$, and $\mathrm{disc}(E)$ is a non-zero integer, so

$$\sum_{p\in P_{E,M}(B)} \frac{40\,v_p(\mathrm{disc}(E))}{[E:\mathbb{Q}]}\log p = \frac{40}{[E:\mathbb{Q}]}\log|\mathrm{disc}(E)| = 40\log\mathrm{rd}_E.$$

The term $\delta_{p,2}\log p$ contributes $\log 2$, as $2 \in P_{E,M}(B)$.

The primes $p \leq B$. We use Chebyshev's bound $\theta(y) = \sum_{p\leq y}\log p < y\log 4$ for $y \geq 1$. Let $n = \lfloor B \rfloor \geq 128$. By Legendre's formula, $\log n! = \sum_{p\leq n}\log p\sum_{k\geq 1}\lfloor n/p^k\rfloor \geq \sum_{p\leq n}\log p\,(n/p-1)$, and $\log n! \leq n\log n$. Hence

$$\sum_{p\leq B}\frac{\log p}{p} = \sum_{p\leq n}\frac{\log p}{p} \leq \log n + \frac{\theta(n)}{n} < \log B + \log 4.$$

Since $p - 1 \geq p/2$, the primes $p \leq B$ contribute $\sum_{p\leq B}\frac{\log p}{p-1} \leq 2\sum_{p\leq B}\frac{\log p}{p} < 2\log B + 2\log 4$.

The primes $p > B$ in $P_{E,M}(B)$. They divide $2\,\mathrm{disc}(E)\,M$, so there are at most $\lfloor B\rfloor \leq B$ of them. The function $t \mapsto \log t/(t-1)$ is decreasing on $(1,\infty)$: its derivative is $\big((t-1)/t - \log t\big)/(t-1)^2 < 0$ because $\log t > 1 - 1/t$ for $t > 1$. So each such prime contributes $\log p/(p-1) < \log B/(B-1)$, and together they contribute less than $B\log B/(B-1) \leq \frac{128}{127}\log B < 2\log B$.

Conclusion. Adding the parts,

$$\begin{aligned} c^{\mathrm{HT}}_{E,M}(B) &< 4\log B + 5\log 2 + 40\log\mathrm{rd}_E \leq 5\log B + 40\log\mathrm{rd}_E \\ &\leq 60\big(\log B + \log\mathrm{rd}_E\big) = 60\log\big(B\,\mathrm{rd}_E\big), \end{aligned}$$

using $5\log 2 < 7\log 2 = \log 128 \leq \log B$ and $\log\mathrm{rd}_E \geq 0$. □

Theorem 19.20. *Let $\mathcal{F}$ be a parametrised host family with covolume records carrying chain data, deep-cover data and component data with the properties (Ht1)–(Ht5) for the constant $C \geq 0$. Then $\mathcal{F}$ has the uniform lower bound (Dp6), with the constant $8C + 4$.*

Proof. Let x_0 be the maximum of e^e and the threshold of (Ht1)–(Ht5). Fix $x \geq x_0$ with $x > x_1$, $i \in I(x)$, $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and a lift $j < m$; use the notation of Definition 19.10 and write $E = \mathrm{ue}(x,i)$, $T = T^{\mathrm{d}}$, $D = D^{\mathrm{fl}}$, $\rho = \rho^{\mathrm{d}}$, $N = |\mathcal{Z}|$, $\delta' = \mathrm{dg}_{\min}$, $S = \sum_Z \mathrm{dg}(Z) > 0$. Since $|A|, m \geq 1$ (A the group of the frame at x), $x^{\varepsilon} \geq 1$ and $\log\log x \geq 1$, we have $E = 2|A|\, m\, b(x)\, x^{\varepsilon} \log\log x \geq b(x) \geq 1$.

The weighted mean of the heights. For every Z, (Ht2) gives

$$\mathrm{hc}(Z) + c^{\mathrm{s}} + c^{\mathrm{c}} \geq (1-\rho)\max(0, \mathrm{vs}(Z) + c^{\mathrm{s}}) \geq 0,$$

hence, as $\mathrm{dg}(Z) \geq \delta'$,

$$\mathrm{dg}(Z)\big(\mathrm{hc}(Z) + c^{\mathrm{s}} + c^{\mathrm{c}}\big) \geq \delta'\big(\mathrm{hc}(Z) + c^{\mathrm{s}} + c^{\mathrm{c}}\big) \geq \delta'(1-\rho)\big(\mathrm{vs}(Z) + c^{\mathrm{s}}\big).$$

Summing over Z and using (Ht3), $\sum_Z \mathrm{dg}(Z)(\mathrm{hc}(Z) + c^{\mathrm{s}} + c^{\mathrm{c}}) \geq \delta'(1-\rho)N(c^{\mathrm{s}} - e^{\mathrm{ms}})$. By (Ht1), $N\delta' \leq S \leq N\delta'/(1-\rho)$, so $\kappa = N\delta'/S$ satisfies $(1-\rho)^2 \leq \kappa(1-\rho) \leq 1$. Dividing by S, the weighted mean $\bar{H} = \sum_Z \mathrm{dg}(Z)\mathrm{hc}(Z)/S$ satisfies

$$\bar{H} \geq \kappa(1-\rho)(c^{\mathrm{s}} - e^{\mathrm{ms}}) - c^{\mathrm{s}} - c^{\mathrm{c}} \geq (1-\rho)^2 c^{\mathrm{s}} - c^{\mathrm{s}} - e^{\mathrm{ms}} - c^{\mathrm{c}} \geq -\big(2\rho c^{\mathrm{s}} + e^{\mathrm{ms}} + c^{\mathrm{c}}\big). \tag{19.7}$$

A linear lower bound for the bracket of (Ht4). Let $h = \mathrm{hc}(Z)$ and $f(Z) = Th - 3(D+1)|h| - a^{\mathrm{hs}} \log(2 + |h|) - r^{\mathrm{hs}}$. For $a > 0$ and $y > 0$ one has $a \log y \leq y + a \log \max(a, 1)$ (the function $a \log y - y$ is maximal at $y = a$, with value $a \log a - a$). With $y = 2 + |h|$, and $|h| \leq h + 2c^{\mathrm{s}}$ (since $h \geq -c^{\mathrm{s}}$ by (Ht2)),

$$\begin{aligned} f(Z) &\geq Th - (3D+4)|h| - 2 - a^{\mathrm{hs}} \log \max(a^{\mathrm{hs}}, 1) - r^{\mathrm{hs}} \\ &\geq (T - 3D - 4)h - (6D+8)c^{\mathrm{s}} - 2 - a^{\mathrm{hs}} \log \max(a^{\mathrm{hs}}, 1) - r^{\mathrm{hs}}. \end{aligned}$$

The weighted mean of the bracket. Put $\bar{F} = \sum_Z \mathrm{dg}(Z) f(Z)/S$. By (Ht1), $1 \leq T - 3D - 4 \leq T$, and the right side of (19.7) is ≤ 0, so $(T - 3D - 4)\bar{H} \geq \min(0, T\bar{H}) \geq -T(2\rho c^{\mathrm{s}} + e^{\mathrm{ms}} + c^{\mathrm{c}})$. Hence, with the budgets of (Ht2), (Ht3), (Ht4) and $E \geq 1$,

$$\bar{F} \geq -Te^{\mathrm{ms}} - Tc^{\mathrm{c}} - c^{\mathrm{s}}(6D + 8 + 2\rho T) - 2 - \big(a^{\mathrm{hs}} \log \max(a^{\mathrm{hs}}, 1) + r^{\mathrm{hs}}\big) \geq -(4C+2)E.$$

The twisted slope. By (Ht4), $\sum_Z \mathrm{gc}(Z) \geq N^{\mathrm{b}} S \bar{F}$, and by (Ht1), $\sum_Z \mathrm{rc}(Z) \geq N^{\mathrm{b}} S > 0$. If $\bar{F} \geq 0$ the quotient $\sum \mathrm{gc} / \sum \mathrm{rc}$ is ≥ 0; if $\bar{F} < 0$ it is $\geq N^{\mathrm{b}} S \bar{F} / \sum \mathrm{rc} \geq \bar{F}$. In both cases it is $\geq -(4C+2)E$, and (Ht5) gives

$$\sigma_{\mathfrak{z},j} \geq 2\,\frac{\sum_Z \mathrm{gc}(Z)}{\sum_Z \mathrm{rc}(Z)} \geq -(8C+4)E.$$

This is (Dp6) for all large points with the constant $8C + 4$. □

Lemma 19.21. *Let $x > 1$ and $\varepsilon > 0$. Let $\mathfrak{h} = (q, d, Q_S, \alpha)$ be a normalised host for a frame (e, A, h, a_0), and let $\mathfrak{M}$ be a loss datum at scale x with parameter ε, group $H = A$ and arithmetic datum $\mathfrak{A}_{\mathfrak{h}}$. Assume*

$$e_2 = e, \qquad o < x^{\varepsilon/4}.$$

Then $\mathfrak{M}$ satisfies (Lm1).

In particular, fix $\varepsilon > 0$ and $C_8 \geq 1$, and put

$$x_0 = \max\{2, (2C_8)^{4/\varepsilon}\}.$$

For every such normalised host and loss datum with $x \geq x_0$, $e_2 = e$ and frame index $o \leq C_8$, condition (Lm1) holds. This cutoff is independent of the host and loss datum.

Proof. First consider a prime p inert for $\mathfrak{A}_\mathfrak{h}$. By the definition of inertness, $p \neq 2$, so p is odd. Put $N = Q_S qd$, and write $N = N_p N_p'$ with N_p a power of p and $p \nmid N_p'$. The host condition gives $2^{e+2} \mid Q_S$, hence $2^{e+2} \mid N$. Since N_p is odd, $2^{e+2} \mid N_p'$. Let u_p denote the unit used in the definition of the host's Frobenius: it satisfies

$$u_p \equiv p \pmod{N_p'}, \qquad u_p \equiv 1 \pmod{N_p}.$$

It follows that $u_p \equiv p \pmod{2^{e+2}}$, so $[u_p]_e = [p]_e$. Write α_A for the A-component of α. Normalisation (Hn2) gives

$$h(\alpha_A(u_p)) = [u_p]_e = [p]_e.$$

The identification τ defining the arithmetic datum leaves the A-component unchanged. The element c_∞ has zero A-component. Consequently the A-component h_p of $c_\infty + \mathrm{Fr}_p$ equals $\alpha_A(u_p)$, and therefore

$$h(h_p) = [p]_e. \tag{1}$$

This argument also covers primes dividing Q_S: it uses only that p is odd and the CRT congruence modulo N_p'.

There are 2^{e+1} units modulo 2^{e+2}, namely its odd residue classes. Multiplication by -1 pairs them without fixed points: a fixed unit u would give $2u = 0$ modulo 2^{e+2} and hence $2 = 0$ there, contradicting $e \geq 2$. Thus the quotient group H_e has 2^e elements. By Lagrange's theorem, every element of H_e has order dividing 2^e.

For any element g of a finite group and any homomorphism, the order of its image divides the order of g: applying the homomorphism to $g^{\mathrm{ord}(g)} = 1$ proves this assertion (or use additive multiples for A). By (1), $\mathrm{ord}([p]_e)$ divides $\mathrm{ord}(h_p)$. If the latter order is odd, the former divides both an odd integer and 2^e, so it is 1 and $[p]_e = 1$. Since $e_2 = e$, these are the first two assertions of (Lm1), even without its restriction to primes that are not sign-changing.

It remains to prove the evenness assertion. Put $A_0 = \langle a_0 \rangle$ and $n_0 = |A_0|$. Injectivity of h on A_0 identifies it with a subgroup of H_e, so $n_0 \mid 2^e$. In particular n_0 is a power of 2. Counting the cosets of A_0 gives $|A| = on_0$. If $g \in A$ has odd order d_g, then Lagrange's theorem gives $d_g \mid on_0$. Since $\gcd(d_g, n_0) = 1$, Euclid's divisibility lemma gives $d_g \mid o$. Both integers are positive, whence

$$d_g \leq o < x^{\varepsilon/4}.$$

Thus every element of A with order at least $x^{\varepsilon/4}$ has even order. Applying this to h_p proves the final assertion of (Lm1).

For the uniform assertion, $x \geq x_0$ implies $x^{\varepsilon/4} \geq 2C_8 > C_8 \geq o$, because $\varepsilon > 0$ and $C_8 \geq 1$. The first assertion therefore applies with the same cutoff for every host and loss datum under consideration. □

Lemma 19.22. *Fix $0 < \varepsilon < 1/52$ and $C_b > 0$, and put*

$$x_0 = \max\{2, (8C_b)^{3/\varepsilon}\}.$$

Let $\mathfrak{M}$ be a loss datum with parameter ε and scale $x \geq x_0$, on the group $H = A$ of a host. Suppose that its top set, Frobenius translations, orbit representatives and good representatives are those of a finite good-orbit selection satisfying the bad-top bound with constant C_b, and that

$$|T| \geq \tfrac{1}{2} x^{-\varepsilon/8} |A|.$$

Then $T \neq \varnothing$ and $\mathfrak{M}$ satisfies (Lm4). The cutoff depends only on ε, C_b.

Proof. Put $n = |A|$, $\delta_1 = x^{-\varepsilon/8}$ and $U = \exp(x^{\varepsilon/3})$. The group A contains its identity, so $n \geq 1$. Since $\delta_1 > 0$, the assumed lower bound gives $|T| > 0$, proving nonemptiness.

Let s_B be the prime range in (Lm4), and put $M = \lfloor U \rfloor$. All its primes are less than U. If $M < 2$, there are no such primes and their sum is zero. If $M \geq 2$, nonnegativity, $\log p \leq \log U$, and inclusion of the primes among the integers give

$$\sum_{p \in s_B} \frac{\log p}{p} \leq \sum_{\substack{p \text{ prime} \\ p < U}} \frac{\log p}{p} \leq (\log U) \sum_{j=2}^{M} \frac{1}{j}.$$

For every integer $2 \leq j \leq M$, one has $1/t \geq 1/j$ throughout $[j-1, j]$, hence

$$\frac{1}{j} \leq \int_{j-1}^{j} \frac{dt}{t}.$$

Summing these inequalities yields

$$\sum_{j=2}^{M} \frac{1}{j} \leq \int_{1}^{M} \frac{dt}{t} = \log M \leq \log U.$$

Consequently, in both cases,

$$\sum_{p \in s_B} \frac{\log p}{p} \leq (\log U)^2 = x^{2\varepsilon/3}.$$

The finite good-orbit bad-top bound has the same prime range s_B. Its left-hand side, therefore, is at most

$$4C_b x^{-2} \delta_1 n \sum_{p \in s_B} \frac{\log p}{p} \leq 4C_b \delta_1 n x^{-2+2\varepsilon/3} \leq 8C_b |T| x^{-2+2\varepsilon/3}.$$

Finally $x \geq (8C_b)^{3/\varepsilon}$ implies $x^{\varepsilon/3} \geq 8C_b$. The last expression is at most $|T| x^{-2+\varepsilon}$, which is the bound required by (Lm4). All sums here are finite; if s_B is empty the same inequalities hold with zero left-hand side. □

Theorem 19.23. *Let $\mathcal{F}$ be a parametrised host family with base covolume realisations, with at least one lift at every member. Suppose it carries chain data with (Lc1)–(Lc6) and deep-cover data with (Dp0)–(Dp6). Let $C_6, C_{\mathrm{top}}, C_{\mathrm{F}}, C_{\mathrm{U}} \geq 0$ be constants with which (Lc6), (Dp0), (Dp5), (Dp6) hold, respectively, and put*

$$C_{\mathrm{cv}} = C_6 + \max\{C_{\mathrm{top}},\, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\} + 1.$$

If $\mathcal{F}$ has realisation estimates for some real $C \geq C_{\mathrm{cv}}$, then it has (Bk1), (Bk2) and (Nf3).

Proof. Choose a cutoff $X > 1$ beyond which the realisation estimates for C hold.

By Theorem 19.24, the family has (Lc7) with

$$C_7 = \max\{C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\}.$$

Apply Theorem 19.26. There is one cutoff X_{cv}, uniform over all members, realised points and lifts, such that the covolume inequality holds for every coefficient at least $C_6 + C_7 + 1 = C_{\mathrm{cv}}$. In particular, it holds for the constant C of the hypothesis. Increase the cutoff to $\max(X, X_{\mathrm{cv}})$. All the following assertions concern members above this common cutoff and all their words.

The base divisor inequality follows by summing the covolume inequalities. The weight transport in the base covolume realisation is bijective, so for each lift

$$\mathrm{mt}_j(\mathfrak{z}) = \sum_{\tau \in \Phi} (k - m + 2j - 1) w_j(\tau) \log \Omega(\mathfrak{h}_{x,i}).$$

Consequently (Ri1) and the summed covolume bound give

$$\begin{aligned} \mu_{\mathrm{b}}^{\vee} - \mathrm{sc} &\le \sum_j \mathrm{mt}_j(\mathfrak{z}) + mC\,\mathrm{ue} + F + E_\omega \\ &\le \mathrm{lm}(x, i, \omega) + F + \mathrm{le}(x, i, \omega) + \sum_j \left(\frac{\mathrm{Df}_j(x, i)}{\mathrm{rk}_0(x, i)} + \mathrm{tc}_j(x, i) \right). \end{aligned}$$

The base rank is at least 1 by the base covolume realisation, so this proves every part of (Bk1). The two inequalities in (Ri2) give $\mu^{\vee}(\mathfrak{V}) \le \mu_{\mathrm{b}}^{\vee} + \mathrm{pa}(x, i)$, which is (Bk2).

We next prove integrality of the divisor maps. Fix a word and write $\mathfrak{a}_\omega$ for its fractional ideal in the simultaneous lattice realisation. At every finite place w,

$$\mathfrak{a}_\omega \mathcal{O}_{K,w} = \mathfrak{p}_w^{-a_{\omega,w}} \mathcal{O}_{K,w}, \qquad N_{\omega,w} = \mathfrak{p}_w^{-a_{\omega,w}} N'_{\omega,w}.$$

The valuation condition (Ri3), and linearity in both arguments, therefore imply

$$B_\omega(N_{\omega,w})(R_w) \subseteq \mathcal{O}_{K,w}.$$

Explicitly, multiplication by an element of valuation at least $-a_{\omega,w}$ offsets the lower bound $a_{\omega,w}$ in (Ri3), and finite sums preserve nonnegative valuation. Thus for every $n \in N_\omega$ and $r \in R$, the scalar $B_\omega(n)(r) \in K$ is integral at every finite place. The intersection of these local rings inside K is $\mathcal{O}_K$: a nonzero scalar with nonnegative valuation at every prime has an integral principal fractional ideal, hence belongs to $\mathcal{O}_K$. It follows that $B_\omega(N_\omega) \subseteq \mathrm{Hom}_{\mathcal{O}_K}(R, \mathcal{O}_K) = R^{\vee}$.

For a nonzero map, average (Ri4) over the embeddings. By the definition of its height,

$$2h(B_\omega) = \frac{1}{[K : \mathbb{Q}]} \sum_\sigma \log \|B_{\omega,\sigma}\|^2 \le \frac{1}{[K : \mathbb{Q}]} \sum_\sigma q_{\omega,\sigma} \le h(\mathfrak{V}, \omega).$$

The level lattice is nonzero by (Ri3), hence has rank at least 1. Each divisor lattice has positive rank by the simultaneous realisation. Finally the frame map is surjective, so rank–nullity and (Ri4) give

$$\mathrm{rk}\, R = \dim_{\mathbb{C}} R_{K,v}^{\vee} = \dim_{\mathbb{C}} \mathcal{H} - \dim_{\mathbb{C}} \ker \Pi \ge (1 - \delta) \dim_{\mathbb{C}} \mathcal{H}.$$

These are the positive-rank, integral-image, height and frame-dimension clauses of (Nf3), all with the same common cutoff. □

Theorem 19.24. *Let $\mathcal{F}$ be a parametrised host family with covolume records carrying chain data and deep-cover data with the properties (Dp0)–(Dp6), (Dp0) for the constant C_{top}, (Dp5) for C_{F} and (Dp6) for C_{U}. Then $\mathcal{F}$ has the core lower bound (Lc7), with the constant* $\max\bigl(C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\bigr)$.

Proof. Let x_0 be the maximum of e^e and the thresholds of (Dp0)–(Dp6), and put

$$C_7 = \max\bigl(C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\bigr).$$

Fix $x \geq x_0$ with $x > x_1$, $i \in I(x)$, $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ and a lift j; write $E = \mathrm{ue}(x,i)$, $b = b(x)$ and $M = \mathrm{mt}_j(\mathfrak{z})$. As $|A|, m \geq 1$, $x^{\varepsilon} \geq 1$ and $\log\log x \geq 1$, we have $E \geq b > 0$.

The top lift. If $j = m$, (Dp0) gives $2\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},m}) \geq -M - C_{\mathrm{top}}E \geq -M - C_7E$.

A lift below the top: the lowered lattice. Let $j < m$ and use the notation of Definition 19.8. By (Dp5) and (Dp6),

$$2\,\widehat{\mu}(A) \geq \sigma - M - C_{\mathrm{F}}E \geq -M - (C_{\mathrm{F}} + C_{\mathrm{U}})E. \tag{19.8}$$

Descent to the deep lattice. Apply Lemma 19.25 to $A \subseteq V^-_{\mathfrak{z},j}$, $B \subseteq V^+_{\mathfrak{z},j}$, the descent maps, $P = b$, Λ and $\epsilon = b/\Lambda$: its hypotheses 1, 2 and 4 are (Dp2) and hypothesis 3 is (Dp3); $\Lambda > 0$ and $\epsilon \geq 0$. By (Dp1), $\epsilon \leq 1$, and then $s \mapsto s - \epsilon|s|$ is non-decreasing on $\mathbb{R}$. Since $\tau = \widehat{\mu}(A) - b \geq \tau_0 := -\frac{1}{2}M - \frac{1}{2}(C_{\mathrm{F}} + C_{\mathrm{U}})E - b$ by (19.8), the lemma gives

$$\widehat{\mu}(B) \geq \tau - \epsilon(|\tau| + \Lambda) \geq \tau_0 - \epsilon|\tau_0| - \epsilon\Lambda.$$

Here $\epsilon\Lambda = b$, and $\epsilon|\tau_0| \leq \frac{1}{2}\epsilon|M| + \frac{1}{2}(C_{\mathrm{F}} + C_{\mathrm{U}})E + b \leq \frac{1}{2}b + \frac{1}{2}(C_{\mathrm{F}} + C_{\mathrm{U}})E + b$, using $\epsilon \leq 1$ and $\epsilon|M| \leq (b/\Lambda)\Lambda = b$ by (Dp1). Hence

$$2\,\widehat{\mu}(B) \geq -M - 2(C_{\mathrm{F}} + C_{\mathrm{U}})E - 7b.$$

Back to the core lattice. By (Dp4) and $b \leq E$,

$$2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},j}) \geq 2\,\widehat{\mu}(B) - 2b \geq -M - 2(C_{\mathrm{F}} + C_{\mathrm{U}})E - 9b \geq -M - \bigl(2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\bigr)E \geq -M - C_7E.$$

So (Lc7) holds for all large points with the constant C_7. □

Lemma 19.25. *Let K be a totally complex number field, V and W hermitian spaces over K, $A \subseteq V$ and $B \subseteq W$ finitely generated $\mathcal{O}_K$-submodules with $A \neq 0$, $n \geq 0$ an integer and $\phi_1, \dots, \phi_n \colon V \to W$ K-linear maps. Let P, $\Lambda \geq 0$ and $\epsilon \geq 0$ be real numbers. Assume*

1. *$\phi_h(A) \subseteq B$ for every h, and $y = 0$ whenever $y \in V$ and $\phi_h(y) = 0$ for all h;*
2. *$\sum_{h=1}^{n} \|\phi_h(y)\|_v^2 \leq e^{2P}\|y\|_v^2$ for every infinite place v and every $y \in V \otimes_{K,v} \mathbb{C}$;*
3. *some subset of B spans KB over K and consists of vectors y with $\|y\|_v \leq e^{\Lambda}$ for every infinite place v;*
4. *$n \operatorname{rk} B \leq (1+\epsilon)\operatorname{rk} A$.*

Then $B \neq 0$ and, with $\tau = \widehat{\mu}(A) - P$,

$$\widehat{\mu}(B) \geq \tau - \epsilon(|\tau| + \Lambda).$$

Proof. Write $d_K = [K : \mathbb{Q}]$, $a = \operatorname{rk} A \geq 1$ and $r = \operatorname{rk} B$. In this proof the Arakelov degree uses, for each complex embedding σ, the norm of the place of σ; all standard facts used (additivity in short exact sequences with sub and quotient norms, the degree of a sublattice of full rank, the degree of a free lattice by its Gram determinants) are those of Section 14.

$n \geq 1$ *and* $B \neq 0$. Take $y \in A$, $y \neq 0$. By hypothesis 1 some $\phi_h(y) \neq 0$; it lies in B.

The product map. Give W^n the orthogonal sum norms; $B^n \subseteq W^n$ is a hermitian lattice of rank nr and $\widehat{\deg}(B^n) = n\,\widehat{\deg}(B)$. Let $\Phi = (\phi_1, \dots, \phi_n)\colon V \to W^n$. By hypothesis 1, Φ is injective and $\Phi(A) \subseteq B^n$; by hypothesis 2, $\|\Phi(y)\|_v \leq e^P \|y\|_v$ for every v and $y \in V \otimes_{K,v} \mathbb{C}$. In particular $a \leq nr$.

Degree of the image. Φ restricts to an isomorphism $A \to \Phi(A)$ of $\mathcal{O}_K$-modules, hence induces an isomorphism of the determinant lattices $\det A = \wedge^a A \to \det \Phi(A)$, whose norm at every place is at most $\|\Phi_v\|^a \leq e^{aP}$ (the operator norm of $\wedge^a \Phi_v$ is the product of the a largest singular values of Φ_v restricted to $KA \otimes \mathbb{C}$). For an isomorphism of rank-one hermitian lattices that multiplies norms by at most c at every place, the degree drops by at most $d_K \log c$. Since the degree of a hermitian lattice is that of its determinant,

$$\widehat{\deg}\,\Phi(A) \geq \widehat{\deg}\,A - d_K\, a\, P. \tag{19.9}$$

Quotients of B^n *have slope at least* $-\Lambda$. Let $s \subseteq B$ be the set of hypothesis 3 and $s^{(n)} \subseteq B^n$ the set of its images under the n coordinate inclusions; it spans KB^n and its vectors have norm $\leq e^\Lambda$ everywhere. Let $Q \neq 0$ be a torsion-free quotient of B^n, of rank q, with the quotient norms. The image of $s^{(n)}$ spans KQ, so it contains a K-basis $\bar{y}_1, \dots, \bar{y}_q$ of KQ, with $\|\bar{y}_t\|_v \leq e^\Lambda$ (quotient norms do not exceed the norms). The $\mathcal{O}_K$-span N of the $\bar{y}_t$ is free of rank q and of finite index in Q, so by Hadamard's inequality for the Gram determinants

$$\widehat{\deg}\,Q \geq \widehat{\deg}\,N = -\tfrac{1}{2}\sum_\sigma \log\det\bigl(\langle \bar{y}_t, \bar{y}_{t'}\rangle_\sigma\bigr) \geq -\sum_\sigma \sum_{t=1}^{q} \log\|\bar{y}_t\|_\sigma \geq -q\, d_K\, \Lambda.$$

The slope inequality. Let $S = B^n \cap K\Phi(A)$, saturated in B^n, of rank a; it contains $\Phi(A)$ with finite index, so $\widehat{\deg}\,S \geq \widehat{\deg}\,\Phi(A)$. If $a < nr$, the quotient B^n/S is torsion free of rank $nr - a$, and by additivity, the previous step and (19.9),

$$n\,\widehat{\deg}\,B = \widehat{\deg}\,S + \widehat{\deg}(B^n/S) \geq \widehat{\deg}\,A - d_K aP - (nr - a)\, d_K\Lambda;$$

if $a = nr$ the same inequality holds with $S = B^n$. Dividing by $d_K\, nr$ and writing $\rho = a/(nr) \in (0, 1]$,

$$\widehat{\mu}(B) \geq \rho\,\tau - (1-\rho)\Lambda = \tau - (1-\rho)(\tau + \Lambda) \geq \tau - (1-\rho)\bigl(|\tau| + \Lambda\bigr).$$

By hypothesis 4, $1/\rho = nr/a \leq 1 + \epsilon$, so $1 - \rho \leq \epsilon/(1+\epsilon) \leq \epsilon$; since $|\tau| + \Lambda \geq 0$ the claim follows. □

Theorem 19.26. *Let* $\mathcal{F}$ *be a parametrised host family with covolume records that carries chain data with the properties (Lc1)–(Lc7), (Lc6) for the constant* C_6 *and (Lc7) for the constant* C_7*. Then* $\mathcal{F}$ *has the covolume bound, with* $C_0 = C_6 + C_7 + 1$.

Proof. Choice of the threshold. Let $c > 0$ be the constant of (Lc3), A_4 that of (Lc4) and A_5 that of (Lc5), and put $S(x) = x^{A_4} + x^{A_5} + C_6 + C_7 + 1$. Since $e^{-x^c} x^A \to 0$ as $x \to \infty$ for every real A, there is x_* with $12\, e^{-x^c} S(x) \leq 1$ for $x \geq x_*$. Let x_0 be the maximum of x_*, e^e and the thresholds of (Lc1)–(Lc7). Fix $x \geq x_0$ with $x > x_1$, $i \in I(x)$, $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, a lift j (so $m \geq 1$) and $C \geq C_0$; write $L = L_{\mathfrak{z},j}$, L^{g}, L^{b}, L^{c}, $g = g_{\mathfrak{z},j}$, $b = b(x)$, $E = \mathrm{ue}(x,i)$ and $\mathrm{mt} = \mathrm{mt}_j(\mathfrak{z})$.

The unit error dominates b. Since $n, m \geq 1$, $x^\varepsilon \geq 1$ and $\log\log x \geq 1$ for $x \geq e^e$, we have $E \geq 2b \geq b \geq 1$; in particular $E \geq 0$.

The hypotheses of Lemma 19.27, item 2, hold for $\delta = e^{-x^c}$ *and* $Q = S(x)\,E$. We have $Q \geq 0$, and $S(x) \geq 1$ gives $12\delta \leq 12\delta S(x) \leq 1$, so $0 \leq \delta \leq \frac{1}{12}$. By (Lc1) $L^{\mathrm{g}} \neq 0$, hence $L \neq 0$. By (Lc3)

$\operatorname{rk} L^{\mathrm{b}} \le 3\delta \operatorname{rk} L$. By (Lc4) $2\widehat{\mu}_{\max}(L) \le x^{A_4} b \le x^{A_4} E \le Q$. By (Lc2) $2\log g \le b \le E \le Q$. By (Lc6), (Lc7) and (Lc5),

$$2\,\widehat{\mu}(L) \ge 2\,\widehat{\mu}(L^{\mathrm{c}}) - C_6 E \ge -\mathrm{mt} - (C_6 + C_7)E \ge -x^{A_5} b - (C_6 + C_7)E \ge -Q. \tag{19.10}$$

The orthogonal projection $\pi_{\mathfrak{z},j}$ and the denominator g satisfy $g\,\pi_{\mathfrak{z},j}(L) \subseteq L$ by Definition 19.7.

Conclusion. By Lemma 19.27, item 2, and the second inequality of (19.10),

$$2\,\widehat{\mu}(L^{\mathrm{g}}) \ge 2\,\widehat{\mu}(L) - 12\,\delta\,Q \ge -\mathrm{mt} - (C_6 + C_7)E - 12\,\delta\,S(x)\,E \ge -\mathrm{mt} - (C_6 + C_7 + 1)E,$$

since $12\delta S(x) \le 1$ and $E \ge 0$. With (Lc1),

$$\frac{\operatorname{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})}{D_{\mathfrak{z}}} \le -2\,\widehat{\mu}(L^{\mathrm{g}}) \le \mathrm{mt} + C_0 E \le \mathrm{mt} + C\,E,$$

the last step because $C \ge C_0$ and $E \ge 0$. This is (19.3) for every $x \ge x_0$ with $x > x_1$, every member, realised point, lift and $C \ge C_0$. □

Lemma 19.27. *Let K be a totally complex number field, V a hermitian space over K, $L \subseteq V$ a non-zero finitely generated $\mathcal{O}_K$-submodule, π an orthogonal projection of V and $g \ge 1$ an integer with $g\,\pi(L) \subseteq L$. Put $L^{\mathrm{g}} = L \cap \pi(V)$ and $L^{\mathrm{b}} = L \cap \ker \pi$, of ranks r_{g} and r_{b}.*

1. *$\operatorname{rk} L = r_{\mathrm{g}} + r_{\mathrm{b}}$, and*

$$\operatorname{rk}(L)\,\widehat{\mu}(L) \le r_{\mathrm{g}}\,\widehat{\mu}(L^{\mathrm{g}}) + r_{\mathrm{b}}(\widehat{\mu}_{\max}(L) + \log g),$$

   where a product with a rank 0 is read as 0.

2. *Let $0 \le \delta \le \frac{1}{12}$ and $Q \ge 0$ be real numbers with $r_{\mathrm{b}} \le 3\delta \operatorname{rk} L$, $2\,\widehat{\mu}_{\max}(L) \le Q$, $2\log g \le Q$ and $-Q \le 2\,\widehat{\mu}(L)$. Then $L^{\mathrm{g}} \ne 0$ and*

$$2\,\widehat{\mu}(L^{\mathrm{g}}) \ge 2\,\widehat{\mu}(L) - 12\,\delta\,Q.$$

Proof. Write $W = KL$, $W_v = W \otimes_{K,v} \mathbb{C}$, and $d_K = [K : \mathbb{Q}]$.

The two parts span complementary subspaces of W. Since $g\,\pi(L) \subseteq L$ and L spans W, $\pi(W) \subseteq W$. Hence every $y \in W$ is $y = \pi y + (y - \pi y)$ with $\pi y \in W \cap \pi(V)$ and $y - \pi y \in W \cap \ker \pi$, so $W = (W \cap \pi(V)) \oplus (W \cap \ker \pi)$. Moreover $KL^{\mathrm{g}} = W \cap \pi(V)$: the inclusion $\subseteq$ is clear, and for $y \in W \cap \pi(V)$ there is an integer $N \ge 1$ with $Ny \in L$, so $Ny \in L^{\mathrm{g}}$. In the same way $KL^{\mathrm{b}} = W \cap \ker \pi$. Taking dimensions gives $\operatorname{rk} L = r_{\mathrm{g}} + r_{\mathrm{b}}$, and $(1-\pi)(W) = W \cap \ker \pi = KL^{\mathrm{b}}$.

The quotient by the good part is isometric to $(1-\pi)(L)$. $L \cap KL^{\mathrm{g}} = L \cap \pi(V) = L^{\mathrm{g}}$, so L^{g} is saturated in L and L/L^{g} is torsion free of rank r_{b}; give it the quotient norms. The restriction of $1 - \pi$ to W has kernel $W \cap \pi(V) = KL^{\mathrm{g}}$, so it induces an isomorphism of L/L^{g} onto $(1-\pi)(L) \subseteq V$. It is an isometry: for $y \in W_v$ the quotient norm of its class is $\inf \|y - z\|_v$ over $z \in (KL^{\mathrm{g}})_v = (W \cap \pi(V))_v$; since πy lies in that space and $y - z = (1-\pi)y + (\pi y - z)$ with $(1-\pi)y \perp (\pi y - z)$, we get $\|y - z\|_v^2 = \|(1-\pi)y\|_v^2 + \|\pi y - z\|_v^2$, minimal at $z = \pi y$. By additivity of the Arakelov degree in the short exact sequence $0 \to L^{\mathrm{g}} \to L \to L/L^{\mathrm{g}} \to 0$ with the induced sub and quotient norms,

$$\widehat{\deg}\, L = \widehat{\deg}\, L^{\mathrm{g}} + \widehat{\deg}\,(1-\pi)(L). \tag{19.11}$$

Degree of $(1-\pi)(L)$. If $r_{\mathrm{b}} = 0$ then $(1-\pi)(L) = 0$ and its degree is 0. Let $r_{\mathrm{b}} > 0$. For $y \in L$, $g(1-\pi)y = gy - g\pi y \in L$ and $\pi\big(g(1-\pi)y\big) = 0$, so $g\,(1-\pi)(L) \subseteq L^{\mathrm{b}}$, and

both have rank r_{b} (they span $(1-\pi)(W) = KL^{\mathrm{b}}$). A sublattice $N' \subseteq N$ of the same rank satisfies $\widehat{\deg} N' = \widehat{\deg} N - \log \#(N/N') \le \widehat{\deg} N$, and multiplication by g is an isomorphism $N \to gN$ multiplying every norm by g, so $\widehat{\deg}(gN) = \widehat{\deg} N - d_K \operatorname{rk}(N) \log g$. Hence, using $\widehat{\mu}(L^{\mathrm{b}}) \le \widehat{\mu}_{\max}(L)$ (L^{b} is a non-zero submodule of L),

$$\widehat{\deg}\,(1-\pi)(L) = \widehat{\deg}\, g(1-\pi)(L) + d_K r_{\mathrm{b}} \log g \le \widehat{\deg}\, L^{\mathrm{b}} + d_K r_{\mathrm{b}} \log g \le d_K\, r_{\mathrm{b}} (\widehat{\mu}_{\max}(L) + \log g).$$

Inserting this into (19.11) and dividing by d_K gives item 1, since $\widehat{\deg} N = d_K \operatorname{rk}(N)\, \widehat{\mu}(N)$ for $N \neq 0$ and $\widehat{\deg} 0 = 0$.

Item 2. Put $r = \operatorname{rk} L > 0$, $\mu = 2\widehat{\mu}(L)$, $\mu_{\mathrm{g}} = 2\widehat{\mu}(L^{\mathrm{g}})$. From $r_{\mathrm{b}} \le 3\delta(r_{\mathrm{g}} + r_{\mathrm{b}})$ we get $(1-3\delta) r_{\mathrm{b}} \le 3\delta r_{\mathrm{g}}$, and $1 - 3\delta \ge \frac{3}{4}$ gives $r_{\mathrm{b}} \le 4\delta r_{\mathrm{g}}$; also $r_{\mathrm{g}} = r - r_{\mathrm{b}} \ge (1-3\delta) r > 0$, so $L^{\mathrm{g}} \neq 0$. Twice item 1, with $2\widehat{\mu}_{\max}(L) + 2\log g \le 2Q$ when $r_{\mathrm{b}} > 0$, gives $(r_{\mathrm{g}} + r_{\mathrm{b}})\mu \le r_{\mathrm{g}} \mu_{\mathrm{g}} + 2Q r_{\mathrm{b}}$. With $\mu \ge -Q$ this yields

$$r_{\mathrm{g}} \mu_{\mathrm{g}} \ge r_{\mathrm{g}} \mu + r_{\mathrm{b}} \mu - 2Q r_{\mathrm{b}} \ge r_{\mathrm{g}} \mu - 3Q\, r_{\mathrm{b}} \ge r_{\mathrm{g}} \mu - 12\, \delta\, Q\, r_{\mathrm{g}},$$

and dividing by $r_{\mathrm{g}} > 0$ proves item 2. □

Lemma 19.28. *Fix $0 < \varepsilon < 1/52$ and $C_{\mathrm{La}} > 0$. Put*

$$\begin{aligned}
r_G &= \left\lceil \frac{32 + 64\varepsilon}{\varepsilon} \right\rceil + 1, \qquad A_\varepsilon = (5 + 8\varepsilon) 10^{6 r_G + 1}, \qquad B_\varepsilon = \frac{5 + 8\varepsilon}{\log 2}, \\
K_\varepsilon &= 12 e (6 r_G + 1)(A_\varepsilon + 6) + B_\varepsilon + 2, \qquad \alpha_0 = 4\varepsilon/5, \qquad \theta = \varepsilon/100, \\
y_{\mathrm{env}} &= \max\left\{ 1, \frac{24}{\alpha_0^3}, \frac{4}{\varepsilon^2}, \frac{1}{B_\varepsilon \sqrt{C_{\mathrm{La}}}}, \frac{12 C_{\mathrm{La}} K_\varepsilon^2}{\theta^3} \right\}, \qquad X_{\mathrm{env}} = \exp(y_{\mathrm{env}}).
\end{aligned}$$

For $x > 1$ define

$$\begin{aligned}
L &= x^{\varepsilon}, \qquad a = x \exp(L), \qquad \delta_1 = x^{-\varepsilon/8}, \qquad u_{\mathrm{orb}} = \lceil \delta_1^{-1} \rceil, \qquad M_{\mathrm{orb}} = \lceil A_\varepsilon \log x \rceil, \\
G_{\mathrm{orb}} &= (M_{\mathrm{orb}} + 5)(6 r_G + 1) u_{\mathrm{orb}}, \qquad N_{\mathrm{orb}} = \lceil \max\{ 6 e G_{\mathrm{orb}} \delta_1, B_\varepsilon \log x \} \rceil + 1.
\end{aligned}$$

Then for every $x \ge e$,

$$B_\varepsilon \log x \le N_{\mathrm{orb}} \le K_\varepsilon \log x.$$

Now let $x \ge X_{\mathrm{env}}$ and $J \ge 1$, let κ be admissible, and fix data, as in the concrete good-host requirement, for which $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ holds. Put

$$E = E_{\mathfrak{h}}, \qquad L_a = \log(a \operatorname{rd}_E), \qquad L_c = C_{\mathrm{La}} N_{\mathrm{orb}}^2 \log a.$$

Then

$$x^{\varepsilon} \le L_a \le 2x^{\varepsilon}, \qquad x^{\varepsilon} \le L_c \le x^{\varepsilon + \varepsilon/100}.$$

The threshold X_{env} depends only on ε and C_{La}; it does not depend on the host, on the remaining data or on any integer tables.

Proof. First let $x \ge e$ and write $y = \log x \ge 1$. Since $0 < \delta_1 \le 1$,

$$\delta_1 u_{\mathrm{orb}} \le 1 + \delta_1 \le 2, \qquad M_{\mathrm{orb}} + 5 \le A_\varepsilon y + 6 \le (A_\varepsilon + 6) y.$$

It follows that

$$G_{\mathrm{orb}} \delta_1 \le 2(6 r_G + 1)(A_\varepsilon + 6) y.$$

For nonnegative real numbers u, v, $\max(u,v) \le u+v$, and $\lceil u \rceil + 1 \le u+2$. Consequently

$$\begin{aligned} N_{\mathrm{orb}} &\le 6eG_{\mathrm{orb}}\delta_1 + B_\varepsilon y + 2 \\ &\le \bigl(12e(6r_G+1)(A_\varepsilon+6) + B_\varepsilon + 2\bigr)y = K_\varepsilon y. \end{aligned}$$

Its defining maximum also gives $N_{\mathrm{orb}} \ge B_\varepsilon y$.

Now let $x \ge X_{\mathrm{env}}$ and fix data as in the second part of the statement. By Lemma 19.16, $1 \le \mathrm{rd}_E \le N_{\mathfrak{h}}$. Condition (Hg6) gives $1 < Y \le x$, and hence

$$0 \le \log \mathrm{rd}_E \le \log N_{\mathfrak{h}} \le 2Y^{\varepsilon/5}(\log Y)^2 \le 2x^{\varepsilon/5}y^2.$$

For every $z \ge 0$, the exponential series gives $e^z \ge z^j/j!$ for each nonnegative integer j. Since $y \ge 24/\alpha_0^3$,

$$e^{\alpha_0 y} \ge \frac{\alpha_0^3 y^3}{6} \ge 4y^2,$$

so $2x^{\varepsilon/5}y^2 \le x^\varepsilon/2 = L/2$. Since $y \ge 4/\varepsilon^2$,

$$e^{\varepsilon y} \ge \frac{\varepsilon^2 y^2}{2} \ge 2y,$$

so $y \le L/2$. Therefore

$$L \le L_a = L + y + \log \mathrm{rd}_E \le 2L, \qquad L \le \log a = L + y \le \tfrac{3}{2}L \le 2L.$$

The lower orbit-order bound and $y \ge 1/(B_\varepsilon\sqrt{C_{\mathrm{La}}})$ give $C_{\mathrm{La}}N_{\mathrm{orb}}^2 \ge 1$. Together with $\log a \ge L$, this proves $L_c \ge L$. For the upper bound, the orbit-order estimate and $\log a \le 2L$ give

$$L_c \le 2C_{\mathrm{La}}K_\varepsilon^2 y^2 L.$$

Finally $y \ge 12C_{\mathrm{La}}K_\varepsilon^2/\theta^3$, so

$$e^{\theta y} \ge \frac{\theta^3 y^3}{6} \ge 2C_{\mathrm{La}}K_\varepsilon^2 y^2.$$

Multiplying by L yields $L_c \le Lx^\theta = x^{\varepsilon+\varepsilon/100}$. All these inequalities hold for $x \ge X_{\mathrm{env}}$, and this common threshold depends neither on the host nor on any tables chosen later. □

20 The reference budget

This section proves the reference budget Theorem 20.2, from which Proposition 21.2 obtains the realisation estimate (Ri1) of the base covolume realisations. It is placed before (TCS) because the statement of (TCS) asks for reference comparison data that satisfy every hypothesis of this theorem, and does not ask for (Ri1) itself; the reader can thus see, before reading (TCS), exactly what is assumed and what is proved. The method is a comparison of covolumes. Theorem 20.4 bounds the normalised log-covolume of the base lattice by D times the mean of the logarithms of the archimedean scalings, plus the log-covolumes of the reference lattices, plus a sum over finite places of local index terms. Lemma 20.3 bounds the local terms by local estimates whose denominators are integers: a group index, a level and one denominator for each lift. Theorem 20.2 then sums the local bounds, and its hypotheses bound the logarithms of these integers by the budgets of the record: those of the group index and the level by a multiple of m times a bound for the unit error, and those of the denominators by the terms tc_j. The passage between log-covolumes and slopes is Lemma 20.5. No result of this section depends on (TCS).

Definition 20.1. Reference comparison data consist of the following objects and conditions.

(Rc1) Fields, types and dimensions. A totally complex number field K, an involutive field automorphism $a \mapsto \bar{a}$, a subfield $K_0 \subseteq K$, and an embedding $\sigma_0 : K \hookrightarrow \mathbb{C}$ satisfy

$$\sigma(\bar{a}) = \overline{\sigma(a)} \quad (a \in K_0,\ \sigma : K \hookrightarrow \mathbb{C}), \qquad \sigma_0(\bar{a}) = \overline{\sigma_0(a)} \quad (a \in K).$$

Write $n_K = [K : \mathbb{Q}]$. A set of types $\mathcal{T}$ has a distinguished element t_0 and a map μ from the finite places of K to $\mathcal{T}$, with

$$\mu(\bar{w}) = \mu(w), \qquad \{w : \mu(w) \neq t_0\} \text{ finite.}$$

Here $\bar{w}$ is the conjugate prime under the involution. Finally, the data include an integer $D \geq 1$, a finite set J and integers $d_j \geq 0$ for $j \in J$.

(Rc2) Based spaces, metrics and lattices. The spaces

$$E = K^D, \qquad Q_t = K^D, \qquad W_j = K^{d_j}, \qquad T_{j,t} = K^{d_j}$$

carry their standard bases and positive definite Hermitian metrics at every embedding of K into $\mathbb{C}$. The metrics at a pair of complex-conjugate embeddings are conjugate: their Gram matrices in these bases are complex conjugates. The data include full $\mathcal{O}_K$-lattices

$$R_{\mathrm{b}} \subset E, \qquad L_t \subset Q_t, \qquad M_j \subset W_j, \qquad A_{j,t} \subset T_{j,t}$$

and K-linear isomorphisms

$$\iota_t : Q_t \longrightarrow E, \qquad \theta_{j,t} : T_{j,t} \longrightarrow W_j.$$

Here a lattice is full if it is finitely generated over $\mathcal{O}_K$ and spans the indicated K-space.

For any one of these metrised lattices put

$$\mathrm{lcv}(\overline{L}) = -\frac{2}{n_K}\widehat{\deg}(\overline{L}).$$

In dimension zero the lattice and space are zero, determinants of empty matrices are 1, and $\mathrm{lcv}(0) = 0$. Every occurrence of lcv refers to these metrics.

(Rc3) Algebraic metric matrices. For all j and t the data include a nondegenerate matrix $H_{j,t} \in M_{d_j}(K)$ such that

$$\bar{H}_{j,t}^{T} = H_{j,t}, \qquad \mathrm{Gram}_{T_{j,t},\sigma_0} = \sigma_0(H_{j,t}).$$

At the distinguished type, in addition,

$$H_{j,t_0} \in M_{d_j}(K_0), \qquad \mathrm{Gram}_{T_{j,t_0},\sigma} = \sigma(H_{j,t_0}) \quad \text{for every } \sigma : K \hookrightarrow \mathbb{C}.$$

These are matrix identities in the fixed bases.

(Rc4) Determinant metric ratios. For an isomorphism $f : U \to V$ between two of the metrised spaces of the same dimension, write

$$r_\sigma(f) = \frac{\det\big(\langle fe_a, fe_b\rangle_{V,\sigma}\big)}{\det\big(\langle e_a, e_b\rangle_{U,\sigma}\big)},$$

where (e_a) is the specified basis of U. The data include positive real numbers κ_σ, equal at conjugate embeddings, and elements $\rho_t \in K^\times$ such that

$$\rho_{t_0} = 1, \qquad \sigma_0(\rho_t) \in \mathbb{R}_{>0}, \qquad v_w(\rho_{\mu(w)}) = 0 \quad \text{for every finite } w.$$

For a nonzero element $a \in K$, $v_w(a)$ denotes the exponent of w in the principal fractional ideal $a\mathcal{O}_K$, so v_w takes the value 1 on a local uniformizer. These data satisfy

$$r_\sigma(\iota_{t_0}) = \kappa_\sigma^D \prod_{j\in J} r_\sigma(\theta_{j,t_0}) \quad \text{for every } \sigma,$$

$$r_{\sigma_0}(\iota_t) = \bigl(\kappa_{\sigma_0}\sigma_0(\rho_t)\bigr)^D \prod_{j\in J} r_{\sigma_0}(\theta_{j,t}) \quad \text{for every } t.$$

(Rc5) Local bases, Gram determinants and gluing. For every type t the data include an element $g_t \in K^\times$ with

$$\sigma_0(g_t) = \det \mathrm{Gram}_{Q_t,\sigma_0}\,.$$

For every t, w the data include a K-basis $(e_{t,w,a})_{a=1}^D$ of Q_t; let $E_{t,w}$ be its column matrix in the fixed basis. This basis generates L_t over the semilocal ring

$$\mathcal{O}_{K,\{w,\bar w\}} = S^{-1}\mathcal{O}_K, \qquad S = \mathcal{O}_K \setminus (w \cup \bar w);$$

that is, the spans of this basis and of L_t over that ring are equal. Put

$$G_{t,w} = g_t\, \overline{\det E_{t,w}}\, \det E_{t,w} \in K^\times.$$

The single-prime local gluing identities hold:

$$(R_{\mathrm{b}})_w = \iota_{\mu(w)}(L_{\mu(w)})_w \quad \text{for every finite } w.$$

(Rc6) Signed indices and the base Gram bound. For full lattices A, B in the same K-space put

$$I_w(A,B) = \mathrm{length}_{\mathcal{O}_{K,w}}(A_w/(A\cap B)_w) - \mathrm{length}_{\mathcal{O}_{K,w}}(B_w/(A\cap B)_w).$$

For a nondegenerate conjugate-symmetric matrix H in a fixed basis put

$$A^{\#H} = \{z \in K^d : \bar a^{\,T} H z \in \mathcal{O}_K \text{ for every } a \in A\}, \qquad J_w(H,A) = I_w(A, A^{\#H}).$$

The finite-place weight in these data is

$$\lambda_w = \frac{\log|\mathcal{O}_K/w|}{n_K}.$$

The function $w \mapsto \lambda_w v_w(G_{t_0,w})$ has finite support, and the **base Gram bound** holds:

$$\mathrm{lcv}(\overline{L}_{t_0}) \le \sum_{w \text{ finite}} \lambda_w v_w(G_{t_0,w}).$$

The sum runs over this finite support.

(Rc7) Attachment to a selected base realisation. When the data are attached to a member with a base covolume realisation, K is the field of the member, $\overline{R}_{\mathrm{b}}$ its base lattice with its metric, D its base dimension and J its lift index set, and each $\overline{M}_j$ is the reference lattice of its selected point, with its metric. Objects shared by the data and the realisation are equal. No equality between d_j and D is imposed. Equality of a metric specified by a frame means equality of the induced norms in the fixed coordinates.

Theorem 20.2. *Fix reference comparison data attached to a member with base covolume realisations, a word ω of that member, a real $C \geq 0$, and a finite set $\mathcal{T}_{\mathrm{w}} \subseteq \mathcal{S}$ of finite places. Suppose $C_w = 0$ outside $\mathcal{S}$ and $U_{wj} = 0$ for $w \in \mathcal{S} \setminus \mathcal{T}_{\mathrm{w}}$. Let $a_{\mathrm{grp}}, a_{\mathrm{lev}}, a_{\mathrm{den},j}$ be positive integers, and let $f_{wj}, e_{wj}, a_{wj}, \eta_{wj}, q_w$ be real numbers on the indicated finite sets. Assume*

$$v_w(G_{\mu(w),w}) \leq D v_w(a_{\mathrm{grp}} a_{\mathrm{lev}}) \quad (w \in \mathcal{S}),$$

$$\sum_{j=1}^{m} (I_{wj} + I'_{wj}) \leq D \left(\sum_{j=1}^{m} (2f_{wj} + e_{wj}) + q_w \right) \quad (w \in \mathcal{T}_{\mathrm{w}}),$$

$$J_{wj} \leq D a_{wj} + \eta_{wj} + D\big(v_w(a_{\mathrm{den},j}) + v_w(a_{\mathrm{lev}})\big) \quad (w \in \mathcal{T}_{\mathrm{w}},\ 1 \leq j \leq m).$$

Let $u_\star$ be real and $c_1, c_{\mathrm{G}}, c_{\mathrm{e}} \geq 0$ satisfy

$$0 \leq \mathrm{ue}(x,i) \leq u_\star, \quad 1 \leq m u_\star, \quad c_{\mathrm{e}} \geq C + c_{\mathrm{G}} + c_1 + 1,$$

and suppose

$$\sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w (e_{wj} + a_{wj}) \leq c_1 u_\star, \qquad \sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w \eta_{wj} \leq \mathrm{Df}_j(x,i), \qquad \sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w q_w \leq 1,$$

$$\log a_{\mathrm{grp}} + \log a_{\mathrm{lev}} \leq c_{\mathrm{G}} m u_\star, \qquad \mathrm{tc}_j(x,i) \geq \log a_{\mathrm{den},j} + \log a_{\mathrm{lev}}, \qquad \mathrm{le}(x,i,\omega) = c_{\mathrm{e}} m u_\star.$$

Finally suppose

$$\mathrm{sc}(x,i) = \frac{1}{n_K} \sum_{\sigma} \log \kappa_\sigma, \qquad 2 \sum_{j=1}^{m} \sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w f_{wj} \leq F(\mathfrak{V}),$$

and

$$\mathrm{lm}(x,i,\omega) = \sum_{j=1}^{m} \sum_{\tau \in \Phi} (k - m + 2j - 1) w_j(\tau) \log \Omega(\mathfrak{h}_{x,i}).$$

Then all three inequalities and identities of (Ri1) hold at this member and word, for this C and a suitable real E_ω. In particular, if these hypotheses hold on a common tail of a family, for all its members and words and with the same constants $C, c_1, c_{\mathrm{G}}, c_{\mathrm{e}}$, then the family satisfies (Ri1) there. The theorem does not assert that reference data or such local inputs exist.

Proof. For every positive rational integer a, unique factorisation of its principal ideal and its ideal norm give

$$\sum_{w \text{ finite}} \lambda_w v_w(a) = \frac{\log N_{K/\mathbb{Q}}(a\mathcal{O}_K)}{n_K} = \log a.$$

Indeed $a\mathcal{O}_K$ has index a^{n_K} in the free abelian group $\mathcal{O}_K$, of rank n_K. Each summand is nonnegative. Its sum over any subset of finite places is therefore at most $\log a$.

Apply Lemma 20.3. Use $g_w = v_w(a_{\mathrm{grp}} a_{\mathrm{lev}})$ and

$$L_G = \log a_{\mathrm{grp}} + \log a_{\mathrm{lev}}, \qquad E_{1j} = c_1 u_\star, \qquad E_3 = 1.$$

In the local bound for J_{wj}, use the error

$$\widetilde{\eta}_{wj} = \eta_{wj} + D\big(v_w(a_{\mathrm{den},j}) + v_w(a_{\mathrm{lev}})\big).$$

As $D \geq 1$, the defect assumption and the positive-integer place-sum bound prove

$$\sum_{w \in \mathcal{T}_{\mathrm{w}}} \frac{\lambda_w \widetilde{\eta}_{wj}}{D} \leq E_{2j} := \frac{\mathrm{Df}_j(x,i)}{D} + \log a_{\mathrm{den},j} + \log a_{\mathrm{lev}}.$$

The same place-sum bound gives the required L_G estimate over $\mathcal{S}$. All other local and summed hypotheses of Lemma 20.3 are among those assumed above. Its attachment conclusion, using the specified scaling and frame ties, proves the first inequality of (Ri1) with

$$E_\omega = L_G + \sum_{j=1}^{m} (E_{1j} + E_{2j}) + 1.$$

The second identity is a stated tie. For the remaining budget, the hypotheses give

$$\begin{aligned} E_\omega + mC\,\mathrm{ue}(x,i) &\le (c_{\mathrm{G}} + c_1 + C) m u_\star + 1 + \sum_{j=1}^{m} \left(\frac{\mathrm{Df}_j(x,i)}{D} + \mathrm{tc}_j(x,i) \right) \\ &\le c_{\mathrm{e}} m u_\star + \sum_{j=1}^{m} \left(\frac{\mathrm{Df}_j(x,i)}{D} + \mathrm{tc}_j(x,i) \right). \end{aligned}$$

Here multiplication of $\mathrm{ue} \le u_\star$ by mC is valid since $m, C \ge 0$, and the last step uses $1 \le m u_\star$ and the bound on c_{e}. Substitute the specified value of le. This is the last inequality in (Ri1). The assertion about families follows from the same pointwise argument, with the same common cutoff and constants. □

Lemma 20.3. *Fix reference comparison data and a finite set $\mathcal{T}_{\mathrm{w}} \subseteq \mathcal{S}$ of finite places of K. For a place w and $j \in J$ put*

$$I_{wj} = I_w(M_j, \theta_{j,\mu(w)} A_{j,\mu(w)}), \quad I'_{wj} = I_{\bar{w}}(M_j, \theta_{j,\mu(w)} A_{j,\mu(w)}), \quad J_{wj} = J_w(H_{j,\mu(w)}, A_{j,\mu(w)}),$$

$$U_{wj} = I_{wj} + I'_{wj} + J_{wj}, \qquad C_w = v_w(G_{\mu(w),w}) + \sum_{j \in J} U_{wj}.$$

Suppose $C_w = 0$ for $w \notin \mathcal{S}$, and $U_{wj} = 0$ for every $w \in \mathcal{S} \setminus \mathcal{T}_{\mathrm{w}}$ and $j \in J$. Let g_w, q_w $(w \in \mathcal{S})$, and $f_{wj}, e_{wj}, a_{wj}, \eta_{wj}$ $(w \in \mathcal{T}_{\mathrm{w}},\ j \in J)$ be real numbers. Assume

$$v_w(G_{\mu(w),w}) \le D g_w \quad (w \in \mathcal{S}),$$

$$\sum_{j \in J} (I_{wj} + I'_{wj}) \le D \left(\sum_{j \in J} (2 f_{wj} + e_{wj}) + q_w \right) \quad (w \in \mathcal{T}_{\mathrm{w}}), \qquad J_{wj} \le D a_{wj} + \eta_{wj}.$$

Finally suppose that real numbers L_G, E_3, E_{1j}, E_{2j} satisfy

$$\sum_{w \in \mathcal{S}} \lambda_w g_w \le L_G, \qquad \sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w q_w \le E_3,$$

$$\sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w (e_{wj} + a_{wj}) \le E_{1j}, \qquad \sum_{w \in \mathcal{T}_{\mathrm{w}}} \frac{\lambda_w \eta_{wj}}{D} \le E_{2j} \quad (j \in J).$$

Then

$$\frac{\mathrm{lcv}(R_{\mathrm{b}})}{D} \le \frac{1}{n_K} \sum_{\sigma : K \hookrightarrow \mathbb{C}} \log \kappa_\sigma + \sum_{j \in J} \frac{\mathrm{lcv}(M_j)}{D} + 2 \sum_{j \in J} \sum_{w \in \mathcal{T}_{\mathrm{w}}} \lambda_w f_{wj} + L_G + \sum_{j \in J} (E_{1j} + E_{2j}) + E_3.$$

No sign condition is imposed on the local numbers or on the error bounds above. The notation introduced here is local to this lemma.

Suppose moreover that these data are attached, as in (Rc7), to a member with base covolume realisations as in Definition 19.6. Fix a word ω of that member and suppose

$$\mathrm{sc} = \frac{1}{n_K}\sum_{\sigma}\log\kappa_\sigma, \qquad 2\sum_{j\in J}\sum_{w\in\mathcal{T}_{\mathrm{w}}}\lambda_w f_{wj} \le F(\mathfrak{V}).$$

Set $E_\omega = L_G + \sum_{j\in J}(E_{1j}+E_{2j}) + E_3$. Then the reference comparison in (Ri1) holds:

$$\mu_{\mathrm{b}}^{\vee} - \mathrm{sc} \le \sum_{j=1}^{m}\frac{\mathrm{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})}{D} + F(\mathfrak{V}) + E_\omega.$$

Proof. For a finite place, $\lambda_w = \log|\mathcal{O}_K/w|/n_K > 0$, and $D \ge 1$. By Theorem 20.4 and the support assumption,

$$\frac{\mathrm{lcv}(R_{\mathrm{b}})}{D} \le \frac{1}{n_K}\sum_{\sigma}\log\kappa_\sigma + \sum_{j\in J}\frac{\mathrm{lcv}(M_j)}{D} + \frac{1}{D}\sum_{w\in\mathcal{S}}\lambda_w C_w.$$

The combined signed local term U_{wj} vanishes off $\mathcal{T}_{\mathrm{w}}$. Thus

$$\frac{1}{D}\sum_{w\in\mathcal{S}}\lambda_w C_w = \frac{1}{D}\sum_{w\in\mathcal{S}}\lambda_w v_w(G_{\mu(w),w}) + \frac{1}{D}\sum_{w\in\mathcal{T}_{\mathrm{w}}}\lambda_w\sum_{j\in J}(I_{wj}+I'_{wj}+J_{wj}).$$

The first term is at most L_G. For each place in $\mathcal{T}_{\mathrm{w}}$ the index hypotheses give

$$\frac{1}{D}\sum_{j\in J}(I_{wj}+I'_{wj}+J_{wj}) \le 2\sum_{j\in J}f_{wj} + \sum_{j\in J}(e_{wj}+a_{wj}) + q_w + \frac{1}{D}\sum_{j\in J}\eta_{wj}.$$

Multiply by the nonnegative weight λ_w and sum. Interchange the two finite sums and use the three remaining budget bounds. This gives

$$\frac{1}{D}\sum_{w\in\mathcal{S}}\lambda_w C_w \le L_G + 2\sum_{j\in J}\sum_{w\in\mathcal{T}_{\mathrm{w}}}\lambda_w f_{wj} + \sum_{j\in J}(E_{1j}+E_{2j}) + E_3.$$

Substituting this bound proves the first assertion. The signed index terms are combined before any upper bound is taken, so their individual signs are not used.

For the attachment assertion, the determinant of a hermitian dual is the dual determinant line with the dual norm, so its Arakelov degree is the negative of the original degree. Using the rank and slope identities in the base covolume realisation gives

$$\mu_{\mathrm{b}}^{\vee} = 2\widehat{\mu}(\overline{R}_{\mathrm{b}}^{\vee}) = -\frac{2\widehat{\deg}(\overline{R}_{\mathrm{b}})}{n_K D} = \frac{\mathrm{lcv}(R_{\mathrm{b}})}{D}.$$

By (Rc7), the reference lattices and their metrics in the preceding inequality are the covolume lattices and metrics of the selected point. Their intrinsic log-covolumes agree with the frame log-covolumes by Lemma 20.5, with the stated zero-rank convention if needed. Subtract the specified scaling term from the preceding bound and use the assumed upper bound by $F(\mathfrak{V})$. The result is the reference comparison displayed in the statement. □

Theorem 20.4. *For reference comparison data put*

$$I_{wjt} = I_w(M_j, \theta_{j,t}A_{j,t}), \qquad J_{wjt} = J_w(H_{j,t}, A_{j,t}), \qquad C_{wt} = v_w(G_{t,w}) + \sum_{j\in J}(I_{wjt} + I_{\bar{w}jt} + J_{wjt}).$$

Then $w \mapsto C_{w,\mu(w)}$ has finite support and

$$\operatorname{lcv}(R_{\mathrm{b}}) \le D\,\frac{1}{n_K}\sum_{\sigma:K\hookrightarrow\mathbb{C}}\log\kappa_\sigma + \sum_{j\in J}\operatorname{lcv}(M_j) + \sum_{w\ \text{finite}}\lambda_w C_{w,\mu(w)}.$$

The finite-place sum is taken over its finite support. Here the reference ranks d_j may differ from one another and from D.

Proof. Write $N = [K:\mathbb{Q}]$, and, for a full lattice L in one of the fixed coordinate spaces, let $\mathfrak{a}_L$ be its determinant fractional ideal and $a_L(w) = v_w(\mathfrak{a}_L)$. The determinant-line definition of degree and Lemma 20.5 give

$$\operatorname{lcv}(L) = \frac{2\log N\mathfrak{a}_L + \sum_{\sigma:K\hookrightarrow\mathbb{C}}\log\det H_{L,\sigma}}{N}, \tag{1}$$

where $H_{L,\sigma}$ is the metric matrix in the fixed coordinate basis. This formula is also valid in dimension zero, with determinant 1 and log-covolume 0. Consequently two lattices in the same metrised space satisfy

$$\operatorname{lcv}(L') - \operatorname{lcv}(L) = 2\sum_w \lambda_w(a_{L'}(w) - a_L(w)). \tag{2}$$

For a linear isomorphism f between two of the metrised spaces, the determinant metric ratio in the definition gives

$$\operatorname{lcv}(fL) - \operatorname{lcv}(L) = \frac{1}{N}\sum_\sigma \log r_\sigma(f). \tag{3}$$

Indeed the determinant ideal changes by $\det f$, the principal-ideal norm formula changes its finite term into $2N^{-1}\sum_\sigma \log|\sigma(\det f)|$, and the remaining metric terms give exactly the logarithm of $r_\sigma(f)$.

The signed local index has the formula

$$I_w(A,B) = a_B(w) - a_A(w). \tag{4}$$

To see this, put $C = A_w \cap B_w$. For either $L = A_w$ or $L = B_w$, the length of L/C over the discrete valuation ring is $a_C(w) - a_L(w)$, by diagonalising an inclusion of free modules over that ring. Subtraction proves (4).

Put $h_{jt} = \det H_{j,t}$. These determinants are nonzero: their images at σ_0 are determinants of positive definite metric matrices. Moreover $\bar{H}_{j,t}^T = H_{j,t}$, since the two sides agree at σ_0 and that embedding is injective. The dual for $\bar{x}^T H_{j,t} y$ has determinant ideal valuation

$$a_{(A_{j,t})^{\#H_{j,t}}}(w) = -v_w(h_{jt}) - a_{A_{j,t}}(\bar{w}).$$

This follows by writing its defining pairing in bases over the two conjugate local rings: the matrix $H_{j,t}$ identifies the dual with the ordinary linear dual of the conjugate lattice. Thus (4) gives

$$J_w(H_{j,t}, A_{j,t}) = -v_w(h_{jt}) - a_{A_{j,t}}(w) - a_{A_{j,t}}(\bar{w}). \tag{5}$$

Write $I_{wjt} = I_w(M_j, \theta_{j,t}A_{j,t})$ and $J_{wjt} = J_w(H_{j,t}, A_{j,t})$, and set

$$C_{wt} = v_w(G_{t,w}) + \sum_{j\in J}(I_{wjt} + I_{\bar{w}jt} + J_{wjt}).$$

The same semilocal basis generates L_t at both w and $\bar{w}$. Hence

$$v_w(G_{t,w}) = v_w(g_t) + a_{L_t}(w) + a_{L_t}(\bar{w}).$$

Equations (4),(5) cancel every determinant-ideal valuation of $A_{j,t}$ and give

$$\begin{aligned} C_{wt} = {} & v_w(g_t) + a_{L_t}(w) + a_{L_t}(\bar{w}) \\ & + \sum_{j\in J} (v_w(\det \theta_{j,t}) + v_{\bar{w}}(\det \theta_{j,t}) - v_w(h_{jt}) - a_{M_j}(w) - a_{M_j}(\bar{w})). \end{aligned} \tag{6}$$

The determinant-ratio identities at σ_0, with the fixed metric determinants of E and W_j cancelled, imply the following equality in $K^\times$:

$$\frac{\overline{\det \iota_t}\, \det \iota_t / g_t}{\overline{\det \iota_{t_0}}\, \det \iota_{t_0} / g_{t_0}} = \rho_t^D \prod_{j\in J} \frac{\overline{\det \theta_{j,t}}\, \det \theta_{j,t}/h_{jt}}{\overline{\det \theta_{j,t_0}}\, \det \theta_{j,t_0}/h_{jt_0}}. \tag{7}$$

In fact its two sides have the same image under σ_0, and σ_0 commutes with conjugation on K. Its injectivity proves (7). For $t = \mu(w)$ the factor ρ_t has valuation zero at w. Taking v_w of (7) and using (6) therefore yields, with $\widetilde{L}_t = \iota_t L_t$,

$$C_{w,\mu(w)} - C_{w,t_0} = a_{\widetilde{L}_{\mu(w)}}(w) + a_{\widetilde{L}_{\mu(w)}}(\bar{w}) - a_{\widetilde{L}_{t_0}}(w) - a_{\widetilde{L}_{t_0}}(\bar{w}). \tag{8}$$

The local gluing identities and $\mu(\bar{w}) = \mu(w)$ identify the two selected terms with $a_{R_\mathrm{b}}(w)$ and $a_{R_\mathrm{b}}(\bar{w})$. Since $\lambda_{\bar{w}} = \lambda_w$, summing (8) and applying (2) gives

$$\sum_w \lambda_w (C_{w,\mu(w)} - C_{w,t_0}) = 2 \sum_w \lambda_w (a_{R_\mathrm{b}}(w) - a_{\widetilde{L}_{t_0}}(w)) = \mathrm{lcv}(R_\mathrm{b}) - \mathrm{lcv}(\widetilde{L}_{t_0}). \tag{9}$$

All these sums are finite. At the base type this follows from (6), since each fixed nonzero scalar and each fixed fractional ideal has only finitely many nonzero valuations. The selected type differs from the base at only finitely many places, so selection changes this support by a finite set.

It remains to estimate the base expression. At the base type, H_{j,t_0} is the metric matrix of T_{j,t_0} at every embedding. Equations (1),(5) and the principal-ideal norm formula give

$$\mathrm{lcv}(A_{j,t_0}) = -\sum_w \lambda_w J_{wj,t_0}. \tag{10}$$

Also (2),(4) give

$$\mathrm{lcv}(\theta_{j,t_0} A_{j,t_0}) = \mathrm{lcv}(M_j) + 2 \sum_w \lambda_w I_{wj,t_0}.$$

By (3),(10), and conjugation of the finite-place sum,

$$\frac{1}{N} \sum_\sigma \log r_\sigma(\theta_{j,t_0}) = \mathrm{lcv}(M_j) + \sum_w \lambda_w (I_{wj,t_0} + I_{\bar{w}j,t_0} + J_{wj,t_0}). \tag{11}$$

The base determinant-ratio identity and (3) now yield

$$\mathrm{lcv}(\widetilde{L}_{t_0}) = \mathrm{lcv}(L_{t_0}) + D\, \frac{1}{N} \sum_\sigma \log \kappa_\sigma + \sum_{j\in J} \frac{1}{N} \sum_\sigma \log r_\sigma(\theta_{j,t_0}).$$

The base Gram bound and (11) imply

$$\mathrm{lcv}(\widetilde{L}_{t_0}) \le D\, \frac{1}{N} \sum_\sigma \log \kappa_\sigma + \sum_{j\in J} \mathrm{lcv}(M_j) + \sum_w \lambda_w C_{w,t_0}.$$

Substitute this into (9). The terms with C_{w,t_0} cancel, giving the claimed inequality. No equality between a reference rank d_j and D has been used. □

Lemma 20.5. *Let K be a totally complex number field, let $d \geq 1$, and let X be a frame on K^d. Let $M \subseteq K^d$ be a finitely generated $\mathcal{O}_K$-submodule of rank r with $1 \leq r \leq d$, and let $\overline{M}_X$ be M with the induced hermitian norms $\|y\|_{X,v} = |X(v)v(y)|$ on its K-span. Then*

$$\mathrm{ht}(M, X) = \exp\bigl(-\widehat{\deg}(\overline{M}_X)\bigr), \qquad \mathrm{lcv}(M, X) = -2r\,\widehat{\mu}(\overline{M}_X).$$

Proof. Put $N = [K : \mathbb{Q}] = 2s$. The intrinsic Minkowski space of $\overline{M}_X$ is isometric to the real span of the image of M used to define $\mathrm{covol}_X(M)$. The degree–Minkowski-covolume formula, with one embedding per complex pair and the unweighted real Euclidean metric, therefore gives

$$\mathrm{covol}_X(M) = 2^{-rs}\,|\operatorname{disc}(K)|^{r/2} \exp\bigl(-\widehat{\deg}(\overline{M}_X)\bigr).$$

Substituting this into the definition of the height and using $N/2 = s$ yields

$$\mathrm{ht}(M, X) = 2^{rN/2}\,|\operatorname{disc}(K)|^{-r/2}\,\mathrm{covol}_X(M) = \exp\bigl(-\widehat{\deg}(\overline{M}_X)\bigr).$$

The definitions of normalised log-covolume and slope now give

$$\mathrm{lcv}(M, X) = \frac{2}{N}\log \mathrm{ht}(M, X) = -\frac{2}{N}\widehat{\deg}(\overline{M}_X) = -2r\,\widehat{\mu}(\overline{M}_X).$$

Throughout, r is the rank of M, and the covolume is taken in its real span. □

21 The theta chain system (TCS) and model-level packet supply

This section states the one standing assumption of the paper, the existence of a theta chain system (TCS), as Hypothesis 21.1, and proves from it model-level packet supply, Proposition 21.2. The statement describes a theta chain system only through the records it must carry, its packets; Appendix A explains how chains of theta lifts are expected to produce these records. The proof of Proposition 21.2 is the only place where (TCS) is used directly, and Section 19 carries its conclusion to design existence. The proof keeps the packets of (TCS) and adds three properties. It checks a gap condition in the Chern-root calculus (Definition 21.3) for the integer arrays of the models (Lemma 21.4), using the bounds for the host field and the depths proved in Section 19; with the model identities this verifies the remaining hypothesis (Aj2) of Theorem 29.14, and that theorem gives the bounds (Ms1) and (Ms3) for model slopes. It then applies the reference budget Theorem 20.2 of Section 20, which gives the realisation estimate (Ri1). The definition and the lemma of the gap condition close the section. The existence of a theta chain system (TCS) is not proved in this paper. Appendix A outlines the construction beneath it, the chain of theta lifts of Alpöge's account, and gives the status of each of its steps.

The statement of (TCS) is long because it names every record that the proofs above it use, so we describe it first in words. The data are those of design existence: a window ratio $\lambda > 1$, a host requirement supplied on λ-windows by the concrete good-host requirement, a parameter ε, and, at every large scale x of a set containing λ-windows, a host $\mathfrak{h}_x$ with tops T_x, a rank t_x and a fixed choice of all the witnesses of the good-host requirement, among them the rank datum, the good-orbit choices, the spacing set and the auxiliary primes. (TCS) asserts constants, common to all scales, and at every large scale of the set a base translate packet over exactly these data: one loss datum and one slope record for every translate $u \in A_x$ (Definition 19.1). The packets are subject to three clauses.

The first clause, (Rr1), concerns the loss data. They satisfy the conditions on heights and weights, small shares, the place record and sizes of Definition 5.5, with common constants, and their loss parameter is the exponent of the frame. The second, (Rr2), makes the numerical data explicit. The loss data carry the rank datum fixed by the good host, with its rank sizes. Their heights, depths, weights and shifts are integers in the boxes of Definition 18.2, with exponents $c_D > 397$ and $c_h \geq 402$. Their tops and orbit representatives are the good-orbit choices of the good host, and their orbit corrections satisfy the bounds of Definition 18.3 with common constants. From these numerical data alone Section 18 derives the linking property (Theorem 18.4).

The third clause, (Rr3), asks for models and local comparisons, and only under a condition: that the Sha bound $\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^{\varepsilon}/2))$ holds at all large scales of the set. Under this condition the same packets carry, on a tail of scales, the following data, compatible with one another and with common constants. First, lower completions: the records that the class $\mathcal{A}_{\mathrm{prop}}$ of Part III asks of its members (Definition 19.2), with all the numbered conditions listed there except eight, which Proposition 19.3 derives. Second, the realisation data of the family formed by the packet members, over common realised points: base covolume realisations, chain data, deep-cover data, and component and model-slope data, with the height conditions (Ht1), (Ht2), (Ht4) and (Ht5). Third, the model data: the model field is the host field, and the entries of the models are given by explicit identities in terms of integer arrays built from the weights and the ranks, of a level formed from the auxiliary primes g_1, g_2, and of $\mathrm{Re}\, L'(1, \chi_{-d})/L(1, \chi_{-d})$. At each realised point and each lift $1 \leq j < m$ there is a unitary Shimura datum over the host field, of signature $(k+j-1,\, m-j)$, that satisfies the hypothesis (Aj1) of Theorem 29.14 and carries the data of its hypothesis (Aj3), with a constant from Proposition 31.14. Fourth, the local comparison: the passage, valuation and archimedean conditions (Ri2)–(Ri4) of Definition 19.6, and, for every member and every word, reference comparison data that satisfy every hypothesis of Theorem 20.2.

The clauses do not contain the bounds (Ms1) and (Ms3), nor the realisation estimate (Ri1); these are the three properties that the proof of Proposition 21.2 adds. Besides definitions, the statement of (TCS) refers only to three results, Theorem 29.14, Proposition 31.14 and Theorem 20.2, and all three are proved without it. In one sentence, (TCS) says that the construction of the lattices produces packets whose numerical data are explicit and whose models and local comparisons, once the bound for Tate–Shafarevich groups holds, satisfy explicit identities and local estimates with uniform constants. In our reading the packets are the records of the chain of theta lifts, and (TCS) is what the paper assumes of the chain.

The construction that proves the following statement is outlined in Appendix A. Since this proof is not complete in the form presented here, we state the statement as a hypothesis, for logical rigour.

Hypothesis 21.1. *Let $\lambda > 1$ and let P be a host requirement supplied by the concrete good-host requirement $\mathfrak{G}$ on λ-windows. There is a real $\varepsilon_\dagger = \varepsilon_\dagger(\lambda, \mathsf{P}) > 0$ with the following property. Fix*

$$0 < \varepsilon < \min(\varepsilon_\dagger, 1/52), \quad J \geq 1, \quad \kappa = (C_{T_2}, C_8, C_5, c_6, C_b),$$

where $C_8 \geq 1$ and $C_5, c_6, C_b > 0$, a set W containing λ-windows, and $X_H > 1$. For every $x \in W$ with $x \geq X_H$, fix a frame, a host $\mathfrak{h}_x$, tops T_x, a rank t_x with $\mathsf{P}(x, \varepsilon, \mathfrak{h}_x, T_x, t_x)$, and a choice of all the data whose existence is asserted by the concrete good-host requirement $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}_x, T_x, t_x)$. These choices, including the rank data, orderings, good-orbit choices, spacing sets and auxiliary primes, are fixed once and for all.

Then there are constants

$$c_D > 397, \quad c_h \geq 402, \quad C_e \geq 0, \quad \varepsilon_z > 0, \quad C_t, \quad X \geq \max\{X_H, 2, (2C_8)^{4/\varepsilon}\},$$

a tuple $\mathfrak{k}_{\mathrm{orb}}$ of eight nonnegative real numbers, and, for every $x \in W$ with $x \geq X$, a base translate packet P_x over the chosen frame, host, tops, spacing set, rank and auxiliary primes, with the following properties.

(Rr1) Loss data. *Every packet member satisfies (Lm2), (Lm5), (Lm6), and (Lm7) for a common pair (ε_z, C_t). Its loss parameter e_2 equals the exponent e of its frame.*

(Rr2) Numerical data. *At every packet member, the loss datum has the rank datum fixed above, with its rank sizes at (x, ε, J) and with $t_R = t_x$. Its heights, depths, weights and shifts have integer weights and boxes for (c_D, c_h), for some number field and thick subset. Its tops, Frobenius translations, orbit representatives and good representatives are given by the finite good-orbit choices fixed above, and these are the choices used by the loss datum. Its correction degrees, orbit thresholds and correction errors satisfy (Nc2)–(Nc4) for a common pair $(\mathfrak{k}_{\mathrm{orb}}, C_e)$. The first component C_{La} of that common tuple satisfies $C_{\mathrm{La}} \geq 1$, and the size parameter is*

$$L_c = C_{\mathrm{La}} N_{\mathrm{orb}}^2 \log a,$$

with the numerical orbit expressions of Definition 18.3.

(Rr3) Models and local comparison under an eventual Sha bound. *Suppose that there is a real number X_V such that the Sha bound*

$$\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^{\varepsilon}/2))$$

holds for all $x \in W$ with $x \geq \max(X, X_V)$. Then the following hold.

Lower completions. *There are the twenty-four common scalar constants specified in (Pl3), common constants $C_{\mathrm{prec}}, C_{\mathrm{ms}}, C_{\mathrm{ht}} \geq 0$, a real $Y \geq X$ with $Y > 1$, and compatible lower completion data (Pl1) for these packets at every $x \in W$ with $x \geq Y$, with the following properties.*

- *All numbered formulas of (Pl3) hold there with those constants, in the pointwise interpretation (Pl2), except (Mf1), (Mf5), (Dv1), (Dv2), (Bk1), (Bk2), (Nf1) and (Nf3).*
- *The kernel hypotheses of (Pc5), namely its data with (Kc1)–(Kc4), finite total measure and both displayed scalar inequalities, hold there in the pointwise interpretation (Pl2), with the same constants and data.*
- *Every packet member there satisfies*

$$\log |\mathcal{W}(\mathfrak{V})| \leq (k-3) \log 2.$$

The family. *Let $\mathcal{F}$ be the family with scales W, threshold Y, and index sets*

$$I(x) = \begin{cases} A_x, & x \in W, \quad x > Y, \\ \varnothing, & \text{otherwise}, \end{cases}$$

whose members are the packet members with their lower completions. At scales with empty index set, take any fixed frame. This family admits compatible base covolume realisations, chain data with (Lc1)–(Lc6), deep-cover data with (Dp0)–(Dp5), and component and model-slope data. All of them are over the same realised points and are compatible with the packets and completions above.

Heights and the component identity. *Set*

$$C_{\mathrm{mod}} = \max\{83400, C_{\mathrm{ms}}\}, \quad C_{\mathrm{Hs}} = \max\{C_{\mathrm{ht}}, C_{\mathrm{mod}}(C_{\mathrm{mod}} + 120)\}, \quad C_{\mathrm{U}} = 8C_{\mathrm{Hs}} + 4.$$

Here C_{ms} is the absolute constant of Theorem 29.14. For every $x \in W$ with $x > Y$, every member $u \in A_x$, every realised point, and every $1 \le j < m$, conditions (Ht1), (Ht2), (Ht4), (Ht5) hold with C_{ht}, with all their remaining quantifiers as stated there. The model slopes $\mathrm{ns}(Z)$ may be taken from the tower conclusion below. Moreover, the following component identity holds:

$$e^{\mathrm{ms}} = C_{\mathrm{mod}}(\mathrm{lz}\,\mathrm{wn} + \mathrm{wsp}) + 2c^{\mathrm{HT}}_{E,M}(B)\,\mathrm{wn}.$$

Model data. *At these scales, the number field of the integer weights and boxes of (Rr2) is $E_{\mathfrak{h}_x}$, with the thick subset already chosen and the same final depths. Put*

$$n = |A_x|, \quad f = 2n, \quad r = k + m - 1, \quad \delta_1 = x^{-\varepsilon/8},$$
$$b' = x\exp(x^{\varepsilon} - x^{\varepsilon/3}), \quad \Delta = \lceil x^{c_D}\rceil, \quad h = 2\lceil x^{c_h}\rceil.$$

At every packet member, these depths satisfy

$$b_t \le b' + \frac{2n\delta_1 x^{\varepsilon} L_c b'}{k} \quad (t \in T_x).$$

For every realised point and every $1 \le j < m$, the model field E is $E_{\mathfrak{h}_x}$. There are a CM type $\mathcal{I}$ of E, choosing one embedding from each conjugate pair, and a bijection $\beta : \mathcal{I} \to \Phi$. Put $p_j = k + j - 1$, $q_j = m - j$, and $d_{\mathrm{flag}} = f\binom{r}{2}$. The component flag dimension is $D^{\mathrm{fl}} = d_{\mathrm{flag}}$, and there is a real P such that

$$40 \le P \le x^{C_{\mathrm{prec}}}, \qquad d_{\mathrm{flag}} \le x^{C_{\mathrm{prec}}}, \qquad T^{\mathrm{d}} = \left\lceil P^2 d_{\mathrm{flag}}^2 k/m \right\rceil.$$

Put

$$c_0 = 8\left\lceil \frac{\max\{r + \binom{fp_jq_j+1}{2} + 2,\, 8fr + 4\}}{8} \right\rceil, \qquad B_\tau = w_1(\beta(\tau)) - h/2.$$

Moreover, the following joint inequalities hold:

$$T^{\mathrm{d}} \ge 4(d_{\mathrm{flag}} + 1), \qquad T^{\mathrm{d}} + d_{\mathrm{flag}} + 1 \le 4\Delta + 1, \qquad h \ge 2T^{\mathrm{d}}(3r + 1) + 2(r + c_0).$$

Define

$$U_{\tau,a} = \begin{cases} (4\Delta - 1)(k - 2 - a), & 0 \le a < k - 1, \\ -B_\tau - (l - 1)h + l - r\mathbf{1}_{l>j}, & a = k + l - 2, \quad 1 \le l \le m. \end{cases}$$

Let v be the integer array with $v_{\tau,k-2} = 0$ and

$$v_{\tau,a} - v_{\tau,a+1} = \left\lfloor \frac{U_{\tau,a} - U_{\tau,a+1} + 2 - (c_0 + 2r)\mathbf{1}_{a+1=p_j}}{T^{\mathrm{d}} + d_{\mathrm{flag}} + 1} \right\rfloor \quad (0 \le a < r - 1),$$

and put $V_{\tau,a} = v_{\tau,a} + 3r\mathbf{1}_{a\ge p_j}$. *All array indices* a *run over* $\{0,\dots,r-1\}$. *The model identities*

$$\begin{aligned}
\mathrm{wn} &= \sum_{\tau\in\mathcal{I}}\sum_{a=0}^{r-1}|V_{\tau,a}|,\\
\mathrm{wsp} &= (m-j)\sum_{\tau\in\mathcal{I}}(\max_a V_{\tau,a} - \min_a V_{\tau,a}),\\
B &= 4fr^2\left(1+\frac{\max_{\tau,a}|V_{\tau,a}|}{h/(4T^{\mathrm{d}})}\right),\\
L &= \mathrm{Re}\,\frac{L'(1,\chi_{-d_{\mathfrak{h}_x}})}{L(1,\chi_{-d_{\mathfrak{h}_x}})},\\
M &= g_1g_2\,15^{a_{\mathrm{lev}}}
\end{aligned}$$

hold, where a_{lev} *is a nonnegative integer and* g_1, g_2 *are the auxiliary primes fixed above. The choices* $P, \mathcal{I}, \beta, a_{\mathrm{lev}}$ *may depend on the point and the lift, but* C_{prec} *is common to all of them.*

Towers. *At each of these points and lifts there are a unitary Shimura datum and a component bijection satisfying (Aj1) of Theorem 29.14, with host field* $E = E_{\mathfrak{h}_x}$, *host prime* $d_{\mathfrak{h}_x}$, *signature* (p_j, q_j), *CM type* $\Phi_{\mathsf{H}} = \mathcal{I}$, *and level* $(M, \mathfrak{n}, 1)$. *The component set and the model entries are those specified above. For*

$$u_{\tau,i} = V_{\tau,i-1} \quad (1\le i\le r), \qquad g = \frac{h}{4T^{\mathrm{d}}},$$

all the data and hypotheses of (Aj3) of that theorem are available, with its absolute constants (the constant of Proposition 31.14 and $C' = 4$*), for every attached tower as quantified there. In particular, the counting, transfer and two volume identities there concern these components and the given* $\mathrm{vs}(Z)$. *The integer* M *of the model identities is the one in the level of the datum.*

Local comparison. *There are constants* $C_6, C_{\mathrm{top}}, C_{\mathrm{F}} \ge 0$ *with which (Lc6), (Dp0) and (Dp5) hold, respectively, and a constant*

$$C \ge C_6 + \max\{C_{\mathrm{top}},\, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\} + 1$$

such that the following local-comparison requirements hold. There are a real $Z_{\mathrm{ref}} \ge Y$ *and nonnegative real constants* $c_1, c_{\mathrm{G}}, c_{\mathrm{e}}$, *independent of the scale, the member, the word and all local indices. Every member of* $\mathcal{F}$ *with* $x \ge Z_{\mathrm{ref}}$ *satisfies conditions (Ri2), (Ri3), (Ri4) of Definition 19.6, with all their quantifiers over words, places and vectors as stated there.*

For every $x \ge Z_{\mathrm{ref}}$ *with* $x > Y$, *every* $i \in I(x)$, *and every* $\omega \in \mathcal{W}(\mathfrak{V}_{x,i})$, *there are reference comparison data satisfying (Rc1)–(Rc7) of Definition 20.1. They are attached to the given base point, with the same field* K, *base lattice* $\overline{R}_{\mathrm{b}}$, *dimension* D, *reference lattices and induced metrics, and their local lift index set is* $\{1,\dots,m\}$. *For these data there are finite sets* $\mathcal{T}_{\mathrm{w}} \subseteq \mathcal{S}$, *positive integers* $a_{\mathrm{grp}}, a_{\mathrm{lev}}, a_{\mathrm{den},j}$, *real local arrays* $f_{wj}, e_{wj}, a_{wj}, \eta_{wj}, q_w$, *and a real* $u_\star$, *satisfying all hypotheses of Theorem 20.2. These include* $m \ge 1$ *and all its displayed support conditions, local estimates, summed bounds and scalar record formulas, and its ties to the scaling, frame and main terms. The coefficient of that theorem is the constant* C *above, and its* $c_1, c_{\mathrm{G}}, c_{\mathrm{e}}$ *are the common constants above. In particular, its quantities* $\mathrm{Df}_j, \mathrm{tc}_j, \mathrm{le}, \mathrm{sc}, F(\mathfrak{V}_{x,i}), \mathrm{lm}, \mathrm{ue}$

are the records already specified. The reference data, denominators and local arrays may depend on the member and the word, but the common constants and the cutoff do not. The conclusion (Ri1) is not assumed.

A field, lattice, metric, map or scalar that occurs in several of the requirements above is the same in all of them. The twenty-four common constants and all the other constants above do not depend on the scale, the member, the point, the word, the lift or any other local index. The loss data, place records, slope records, numerical choices, orbit masses and final profiles are those of the packets above.

All the constants, cutoffs and packets asserted to exist may depend on the whole collection of choices fixed at the start.

Proposition 21.2. *Let $\lambda > 1$ and let P be a host requirement supplied by the concrete good-host requirement $\mathfrak{G}$ on λ-windows. There is a real $\varepsilon_\dagger = \varepsilon_\dagger(\lambda, \mathsf{P}) > 0$ with the following property. Fix*

$$0 < \varepsilon < \min(\varepsilon_\dagger, 1/52), \quad J \geq 1, \quad \kappa = (C_{T_2}, C_8, C_5, c_6, C_b),$$

where $C_8 \geq 1$ and $C_5, c_6, C_b > 0$, a set W containing λ-windows, and $X_H > 1$. For every $x \in W$ with $x \geq X_H$, fix a frame, a host $\mathfrak{h}_x$, tops T_x, a rank t_x with $\mathsf{P}(x, \varepsilon, \mathfrak{h}_x, T_x, t_x)$, and a choice of all the data whose existence is asserted by the concrete good-host requirement $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}_x, T_x, t_x)$. These choices, including the rank data, orderings, good-orbit choices, spacing sets and auxiliary primes, are fixed once and for all.

Then there are constants

$$c_D > 397, \quad c_h \geq 402, \quad C_e \geq 0, \quad \varepsilon_z > 0, \quad C_t, \quad X \geq \max\{X_H, 2, (2C_8)^{4/\varepsilon}\},$$

a tuple $\mathfrak{k}_{\mathrm{orb}}$ of eight nonnegative real numbers, and, for every $x \in W$ with $x \geq X$, a base translate packet P_x over the chosen frame, host, tops, spacing set, rank and auxiliary primes, with the following properties.

(Ma1) Loss data. *Every packet member satisfies (Lm2), (Lm5), (Lm6), and (Lm7) for a common pair (ε_z, C_t). Its loss parameter e_2 equals the exponent e of its frame.*

(Ma2) Numerical data. *At every packet member, the loss datum has the rank datum fixed above, with its rank sizes at (x, ε, J) and with $t_R = t_x$. Its heights, depths, weights and shifts have integer weights and boxes for (c_D, c_h), for some number field and thick subset. Its tops, Frobenius translations, orbit representatives and good representatives are given by the finite good-orbit choices fixed above, and these are the choices used by the loss datum. Its correction degrees, orbit thresholds and correction errors satisfy (Nc2)–(Nc4) for a common pair $(\mathfrak{k}_{\mathrm{orb}}, C_e)$.*

(Ma3) Primitive models under an eventual Sha bound. *Suppose that there is a real number X_V such that the Sha bound*

$$\mathrm{V}(E_{\mathfrak{h}_x}; t_x, \exp(x^\varepsilon/2))$$

holds for all $x \in W$ with $x \geq \max(X, X_V)$. Then the following hold.

Lower completions. *There are the twenty-four common scalar constants specified in (Pl3), common constants $C_{\mathrm{prec}}, C_{\mathrm{ms}}, C_{\mathrm{ht}} \geq 0$, a real $Y \geq X$ with $Y > 1$, and compatible lower completion data (Pl1) for these packets at every $x \in W$ with $x \geq Y$, with the following properties.*

- *All numbered formulas of (Pl3) hold there with those constants, in the pointwise interpretation (Pl2), except (Mf1), (Mf5), (Dv1), (Dv2), (Bk1), (Bk2), (Nf1) and (Nf3).*
- *The kernel hypotheses of (Pc5), namely its data with (Kc1)–(Kc4), finite total measure and both displayed scalar inequalities, hold there in the pointwise interpretation (Pl2), with the same constants and data.*
- *Every packet member there satisfies*

$$\log|\mathcal{W}(\mathfrak{V})| \le (k-3)\log 2.$$

The family. *Let $\mathcal{F}$ be the family with scales W, threshold Y, and index sets*

$$I(x) = \begin{cases} A_x, & x \in W, \quad x > Y, \\ \varnothing, & \text{otherwise}, \end{cases}$$

whose members are the packet members with their lower completions. At scales with empty index set, take any fixed frame. This family admits compatible base covolume realisations, chain data with (Lc1)–(Lc6), deep-cover data with (Dp0)–(Dp5), and component and model-slope data. All of them are over the same realised points and are compatible with the packets and completions above.

Heights, model slopes and the component identity. *Set*

$$C_{\mathrm{mod}} = \max\{83400, C_{\mathrm{ms}}\}, \quad C_{\mathrm{H}} = \max\{C_{\mathrm{ht}}, C_{\mathrm{mod}}(C_{\mathrm{mod}}+120)\}, \quad C_{\mathrm{U}} = 8C_{\mathrm{H}} + 4.$$

For every $x \in W$ with $x > Y$, every member $u \in A_x$, every realised point, and every $1 \le j < m$, conditions (Ht1), (Ht2), (Ht4), (Ht5) hold with C_{ht}, and (Ms1), (Ms3) hold with C_{ms}, with all their remaining quantifiers as stated there. Moreover, the following component identity holds:

$$e^{\mathrm{ms}} = C_{\mathrm{mod}}(\mathrm{lz}\,\mathrm{wn} + \mathrm{wsp}) + 2c^{\mathrm{HT}}_{E,M}(B)\,\mathrm{wn}.$$

Model data. *At these scales, the number field of the integer weights and boxes of (Ma2) is $E_{\mathfrak{h}_x}$, with the thick subset already chosen and the same final depths. Put*

$$n = |A_x|, \quad f = 2n, \quad r = k+m-1, \quad \delta_1 = x^{-\varepsilon/8},$$
$$b' = x\exp(x^{\varepsilon} - x^{\varepsilon/3}), \quad \Delta = \lceil x^{c_D}\rceil, \quad h = 2\lceil x^{c_h}\rceil.$$

At every packet member, these depths satisfy

$$b_t \le b' + \frac{2n\delta_1 x^{\varepsilon} L_c b'}{k} \quad (t \in T_x).$$

For every realised point and every $1 \le j < m$, the model field E is $E_{\mathfrak{h}_x}$. There are a CM type $\mathcal{I}$ of E, choosing one embedding from each conjugate pair, and a bijection $\beta : \mathcal{I} \to \Phi$. Put $p_j = k + j - 1$, $q_j = m - j$, and $d_{\mathrm{flag}} = f\binom{r}{2}$. The component flag dimension is $D^{\mathrm{fl}} = d_{\mathrm{flag}}$, and there is a real P such that

$$40 \le P \le x^{C_{\mathrm{prec}}}, \qquad d_{\mathrm{flag}} \le x^{C_{\mathrm{prec}}}, \qquad T^{\mathrm{d}} = \left\lceil P^2 d_{\mathrm{flag}}^2 k/m \right\rceil.$$

Put

$$c_0 = 8\left\lceil \frac{\max\{r + \binom{fp_jq_j+1}{2} + 2,\ 8fr+4\}}{8} \right\rceil, \qquad B_\tau = w_1(\beta(\tau)) - h/2,$$

and define

$$U_{\tau,a} = \begin{cases} (4\Delta-1)(k-2-a), & 0 \le a < k-1, \\ -B_\tau - (l-1)h + l - r\mathbf{1}_{l>j}, & a = k+l-2, \quad 1 \le l \le m. \end{cases}$$

Let v be the integer array with $v_{\tau,k-2} = 0$ and

$$v_{\tau,a} - v_{\tau,a+1} = \left\lfloor \frac{U_{\tau,a} - U_{\tau,a+1} + 2 - (c_0+2r)\mathbf{1}_{a+1=p_j}}{T^{\mathrm{d}} + d_{\mathrm{flag}} + 1} \right\rfloor \quad (0 \le a < r-1),$$

and put $V_{\tau,a} = v_{\tau,a} + 3r\mathbf{1}_{a \ge p_j}$. All array indices a run over $\{0,\dots,r-1\}$. The model identities

$$\begin{aligned} \mathrm{wn} &= \sum_{\tau\in\mathcal{I}} \sum_{a=0}^{r-1} |V_{\tau,a}|, \\ \mathrm{wsp} &= (m-j) \sum_{\tau\in\mathcal{I}} (\max_a V_{\tau,a} - \min_a V_{\tau,a}), \\ B &= 4fr^2 \left(1 + \frac{\max_{\tau,a} |V_{\tau,a}|}{h/(4T^{\mathrm{d}})}\right), \\ L &= \mathrm{Re}\, \frac{L'(1,\chi_{-d_{\mathfrak{h}x}})}{L(1,\chi_{-d_{\mathfrak{h}x}})}, \\ M &= g_1 g_2\, 15^{a_{\mathrm{lev}}} \end{aligned}$$

hold, where a_{lev} is a nonnegative integer and g_1, g_2 are the auxiliary primes fixed above. The choices $P, \mathcal{I}, \beta, a_{\mathrm{lev}}$ may depend on the point and the lift, but C_{prec} is common to all of them.

Realisation estimates. *There are constants $C_6, C_{\mathrm{top}}, C_{\mathrm{F}} \ge 0$ with which (Lc6), (Dp0) and (Dp5) hold, respectively, and a constant*

$$C \ge C_6 + \max\{C_{\mathrm{top}},\, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\} + 1$$

such that $\mathcal{F}$ has realisation estimates for C.

A field, lattice, metric, map or scalar that occurs in several of the requirements above is the same in all of them. The twenty-four common constants and all the other constants above do not depend on the scale, the member, the point, the word, the lift or any other local index. The loss data, place records, slope records, numerical choices, orbit masses and final profiles are those of the packets above.

All the constants, cutoffs and packets asserted to exist may depend on the whole collection of choices fixed at the start.

Proof. Apply Hypothesis 21.1 for the same λ and P, and take its $\varepsilon_\dagger(\lambda, \mathsf{P})$ as $\varepsilon_\dagger$. Apply it to the data fixed in the statement, which satisfy its hypotheses, and use its outer constants and its packets. Conditions (Rr1),(Rr2) imply (Ma1),(Ma2), respectively, and the packets are chosen before the eventual Sha premise is assumed.

Now assume that premise, and keep the twenty-four common constants, the other constants, the lower completions, the base covolume realisations, the chain and deep-cover data and the component and model data supplied there. Write Y_0 for the threshold of the tail supplied there.

We prove the two model-slope properties and the realisation estimates on a common further tail, with the same packets and the same scalar coefficient C.

We first prepare the divided weight at a point and a lift $1 \le j < m$. Put $d = d_{\mathrm{flag}} = f\binom{r}{2}$ and $Z = f^2 r^4$. Rank sizes give

$$n \le 2x^{2+8\varepsilon}, \quad 2 \le m \le 2\sqrt{x}, \quad m+3 \le k \le 2x^{9/2+10\varepsilon}, \quad r = k+m-1.$$

In particular $d \ge 1$, $p_j + q_j = r$ and $p_j q_j \le r^2$. Hence $\binom{fp_jq_j+1}{2} \le Z$, $r \le Z$, $fr \le Z$, and the explicit upward rounding in c_0 gives

$$0 \le c_0 \le 12Z + 7 \le 22 f^2 r^4.$$

The length identity and $P \ge 40$ give $T^{\mathrm{d}} \ge 1600 d^2 \ge 4(d+1)$. For $x \ge 2$, the bounds $k \le 2x^5$ and $P, d \le x^{C_{\mathrm{prec}}}$ give

$$T^{\mathrm{d}} \le 2x^{4C_{\mathrm{prec}}+5} + 1 \le x^{4C_{\mathrm{prec}}+7}.$$

Put $C_T = 4C_{\mathrm{prec}} + 7$; it does not depend on the point or the lift.

Condition (Lm7) gives $0 < L_c \le x^{\varepsilon+\varepsilon/100}$. On a uniform tail, rank sizes also give $n \le x^{2+8\varepsilon+\varepsilon/100}$ and $k \ge x^{9/2+10\varepsilon-\varepsilon/100}$. The depth bound supplied above and Lemma 19.14 therefore give $\lceil b' \rceil \le b_t \le 2b'$ for the final depths. By Lemma 19.15, the order of the torsion units of the host field is at most x^6 on a uniform tail. Consequently (Iw3), pulled back through β, puts every B_τ in one of the three permitted ranges of Lemma 19.13, with $C_\mu = 6$. By Lemma 19.16, $[E : \mathbb{Q}] = 4n$, so $|\mathcal{I}| = 2n = f$. All the data hypotheses of Lemma 21.4 are now verified for these arrays, with $T = T^{\mathrm{d}}$. Its additional joint inequalities are explicit requirements of (Rr3). Thus, after one uniform restriction of the tail,

$$u_{\tau,i} = V_{\tau,i-1}, \qquad g = h/(4T^{\mathrm{d}})$$

satisfy all the gap hypotheses.

We check the remaining conditions in (Aj2) of Theorem 29.14. By the model identities,

$$b_0(u,g) = 4fr^2(1 + \|u\|_\infty/g) = B < \lfloor B \rfloor + 1, \qquad D^{\mathrm{fl}} = f\binom{r}{2}.$$

The signature has $q_j = m - j < p_j = k + j - 1$, so $\min(p_j, q_j)\mathrm{spr}(u) = \mathrm{wsp}$, and $\|u\|_1 = \mathrm{wn}$. The prime $d = d_{\mathfrak{h}_x}$ of the CM host satisfies $d \equiv 7 \pmod{16}$ by (Ud1). Thus the primitive quadratic character χ_{-d} equals the Legendre character $(\cdot/d)$, namely the character χ_d in Proposition 31.14. Since the model field, the host prime and the logarithmic derivative are the same, $L = L_{\mathsf{H}}$. Hence every numerical and weight condition of (Aj2) holds for the datum of (Rr3). Conditions (Aj1),(Aj3) are supplied for this datum, this component set and every attached tower.

Apply Theorem 29.14 to the tail family. That theorem chooses the tower and its compatible model data jointly, and gives (Ms1),(Ms3) with the absolute constant C_{ms} specified there. Choose $\mathrm{ns}(Z)$ as the theorem prescribes. No other entry is changed, since the other required lower, reference, component, chain and deep-cover conditions do not involve the model slopes. Their objects, the component function vs, the fields, the metrics and the scalars stay as before. The hypotheses and the conclusion hold with thresholds uniform over the family, so there is one common tail on which both required model-slope properties hold.

For the realisation estimates, fix a member and a word on the reference tail. The reference comparison data and the local data satisfy every hypothesis of Theorem 20.2, with the given point, its field, base lattice, reference metrics and scalar records, and with the same coefficient C. That theorem gives (Ri1) for this member and word, with an error E_ω that may depend

on the member and the word. The constants $C, c_1, c_{\mathrm{G}}, c_{\mathrm{e}}$ do not depend on the member or the word. Conditions (Ri2),(Ri3),(Ri4) are supplied as stated, with all their quantifiers over places, words and vectors. Together these are the realisation estimates for C.

Choose Y at least Y_0, the reference cutoff and all the uniform cutoffs just obtained, and restrict the lower completion and the family records to this tail. The index sets are then A_x for $x \in W$, $x > Y$, and empty otherwise, as in (Ma3). All numbered lower conditions and residual word bounds persist. The kernel data with (Kc1)–(Kc4), the finite measure and both scalar inequalities are supplied by (Rr3), and they remain valid on this tail with all inner quantifiers, antecedents and common constants. They do not involve the model slopes and need no further constant. The definitions of $C_{\mathrm{mod}}, C_{\mathrm{H}}, C_{\mathrm{U}}$ and the component identity for e^{ms} remain in force, as does the lower bound on C. Thus (Ht1),(Ht2),(Ht4),(Ht5), the properties (Ms1),(Ms3) derived above, and the realisation estimates hold with the data and constants required in (Ma3). The remaining compatibility requirements and the requirement on the final profiles restrict to the same tail. This proves the proposition, assuming Hypothesis 21.1.

□

Definition 21.3. Throughout, Φ is a non-empty finite set (the **embeddings**), $n \geq 2$ an integer (the **rank**) and κ an integer with $1 \leq \kappa < n$ (the **cut**); all objects below depend on (Φ, n, κ), which is suppressed from the notation.

Polynomials and the flag degree. Let $\mathcal{R} = \mathbb{R}[x_{a,i} : a \in \Phi,\ 1 \leq i \leq n]$, the **Chern-root ring**, and $D = |\Phi|\, n(n-1)/2$, the **flag dimension**. For $m \in \mathbb{N}^{\Phi \times \{1,\dots,n\}}$ write $x^m = \prod x_{a,i}^{m_{a,i}}$ and $[x^m]F$ for the coefficient of x^m in $F \in \mathcal{R}$. Let $\delta_{a,i} = n - i$. For $w = (w_a)_{a \in \Phi} \in S_n^{\Phi}$ put $\operatorname{sgn}(w) = \prod_a \operatorname{sgn}(w_a)$ and $(\delta \circ w)_{a,i} = \delta_{a,w_a(i)}$. The **flag degree** is the linear form

$$\deg^{\mathrm{fl}}(F) = (-1)^D \sum_{w \in S_n^{\Phi}} \operatorname{sgn}(w)\, [x^{\delta \circ w}]F \qquad (F \in \mathcal{R}). \tag{21.1}$$

Weights. A **weight** is an element $u = (u_{a,i})$ of $\mathbb{R}^{\Phi \times \{1,\dots,n\}}$; its **linear root form** is $\mathrm{lr}(u) = -\sum_{a,i} u_{a,i} x_{a,i} \in \mathcal{R}$. It is **dominant** if $u_{a,1} \geq u_{a,2} \geq \cdots \geq u_{a,n}$ for every a, and **regular dominant** if these inequalities are strict. Put $\|u\|_1 = \sum_{a,i} |u_{a,i}|$, $\|u\|_\infty = \max_{a,i} |u_{a,i}|$ and $\operatorname{spr}(u) = \sum_a (\max_i u_{a,i} - \min_i u_{a,i})$, the **spread**. The **small block** is $\{1, \dots, \kappa\}$ if $\kappa \leq n - \kappa$ and $\{\kappa + 1, \dots, n\}$ otherwise. A weight u satisfies the **gap hypothesis with gap** $g > 0$ if it is regular dominant, $u_{a,\kappa} - u_{a,\kappa+1} \geq g$ for every a, and $|u_{a,i} - u_{a,i'}| \geq g$ for every a, every i in the small block and every $i' \neq i$; its **threshold** is then $b_0(u, g) = 4|\Phi| n^2 (1 + \|u\|_\infty / g)$.

Power sums and central derivatives. For $a \in \Phi$ and $k \geq 0$ let $\mathrm{ps}_{a,k} = \sum_{i=1}^n x_{a,i}^k$ (the **power sums**). A **label** is a pair $\sigma = (a, \pm) \in \Phi \times \{+, -\}$; its **partial power sums** are

$$\mathrm{ps}_k^{(a,+)} = \sum_{i=1}^{\kappa} x_{a,i}^k, \qquad \mathrm{ps}_k^{(a,-)} = \sum_{i=\kappa+1}^{n} (-x_{a,i})^k \qquad (k \geq 0).$$

The **central derivatives** at a are the derivations $\partial_a^{<} = \sum_{i=1}^{\kappa} \partial/\partial x_{a,i}$ and $\partial_a = \sum_{i=1}^{n} \partial/\partial x_{a,i}$ of $\mathcal{R}$. A **power-sum decomposition** of $F \in \mathcal{R}$ is a family $(Q_{a,k})_{a \in \Phi,\, 1 \leq k \leq n}$ in $\mathcal{R}$ with $Q_{a,k}$ homogeneous of degree $D + 1 - k$ (the zero polynomial allowed) and $F = \sum_{a \in \Phi} \sum_{k=1}^n \mathrm{ps}_{a,k} Q_{a,k}$.

Frobenius terms. A **Frobenius labelling** is a map fr assigning to every prime p, every $a \in \Phi$ and every $m \in \mathbb{N}$ a label $\mathrm{fr}(p, a, m) \in \Phi \times \{+, -\}$ whose sign does not depend on a. For such fr, a prime p, $a \in \Phi$, $1 \leq k \leq n$ and $Q \in \mathcal{R}$ put

$$\Sigma_p(a, k, Q) = \sum_{m=0}^{\infty} p^{-k(m+1)} \deg^{\mathrm{fl}}(\mathrm{ps}_{k-1}^{\mathrm{fr}(p,a,m)} Q)$$

(an absolutely convergent series: the labels form a finite set and $p^{-k} \le 1/2$), the **Frobenius term** $\rho_p(a,k,Q) = k\log p\cdot\Sigma_p(a,k,Q)$ if $k \ge 2$ and $\rho_p(a,1,Q) = 0$, and the **stage-change term**

$$\Delta_p(a,k,Q) = k\log p\Big(\Sigma_p(a,k,Q) - \frac{\deg^{\mathrm{fl}}(\mathrm{ps}_{k-1}^{(a,+)}Q)}{p-1}\Big). \tag{21.2}$$

For a finite set S of primes and an integer B_0, the **Frobenius tail** $\rho_{>B_0}(a,k,Q)$ is the limit, as the integer $B\to\infty$, of $\sum\rho_p(a,k,Q)$ over the primes $p\notin S$ with $B_0 < p \le B$, whenever this limit exists (the dependence on S and fr is suppressed from the notation).

The test class. Let $D^{\mathrm{gr}} = |\Phi|\kappa(n-\kappa)$. The **Grassmannian class** $\mathrm{pl}\in\mathcal{R}$ is $\sum_a\sum_{i=\kappa+1}^{n} x_{a,i}$ if $n-\kappa\le\kappa$ and $-\sum_a\sum_{i=1}^{\kappa}x_{a,i}$ otherwise; the **fibre class** is

$$\mathrm{fb} = \prod_{a\in\Phi}\prod_{\substack{1\le i<i'\le n\\ i,i'\le\kappa \text{ or } i,i'>\kappa}}(x_{a,i'}-x_{a,i}),$$

and the **test class** is $\mathrm{pl}^{D^{\mathrm{gr}}+1}\mathrm{fb}$, with **test degree** $\deg^{\mathrm{fl}}(\mathrm{pl}^{D^{\mathrm{gr}}}\mathrm{fb})$.

Lemma 21.4. *Fix the constants of Lemma 19.13. There exists $X>1$, depending only on these constants, with the following property. Let $x\ge X$ be real, and let the remaining data satisfy the hypotheses of that lemma, with its permitted choices B_τ, its arrays U,v,V and $D = T+d+1$. Then the conclusions of that lemma hold. Suppose moreover that*

$$D\le 4\Delta+1, \qquad h\ge 2T(3r+1)+2(r+c_0),$$

and put

$$u_{\tau,i} = V_{\tau,i-1}\quad(\tau\in I,\ 1\le i\le r), \qquad p = k-1+j, \qquad g = \frac{h}{4T}.$$

Then u satisfies the full gap hypothesis of Definition 21.3 for embeddings I, rank r, cut p, and gap g.

Proof. Take the threshold of Lemma 19.13 and enlarge it uniformly so that $B_\tau+1\ge D$ for every permitted choice. The three allowed ranges for B_τ give

$$B_\tau \ge \frac{b'}{xn} \ge \tfrac{1}{2}x^{-2-8\epsilon}\exp(x^{\epsilon}-x^{\epsilon/3})$$

on a common tail, whereas

$$D = T+d+1 \le \tfrac{5}{4}T \le \tfrac{5}{4}x^{C_T}.$$

The exponential lower bound dominates this fixed polynomial, so the enlargement depends only on the stated constants. No further restriction on C_T is needed. The numerical conclusions of Lemma 19.13 persist.

Fix τ. The defining recurrence and final shift give

$$V_{\tau,a}-V_{\tau,a+1} = \begin{cases} \lfloor(4\Delta+1)/D\rfloor, & 0\le a<k-2,\\ \lfloor(B_\tau+1)/D\rfloor, & a=k-2,\\ \lfloor(h+1)/D\rfloor, & a=k+l-2,\ 1\le l<m,\ l\ne j,\\ \lfloor(h+1-r-c_0)/D\rfloor-3r, & a=p-1. \end{cases}$$

The first two expressions are at least 1. For the last, write $R = r + c_0$ and $Q = 3r + 1$. The additional height inequality gives $TQ \le h/2 - R$, so $h - R > 0$. Since $\lfloor z \rfloor \ge z - 1$ and $D \le 5T/4$,

$$\begin{aligned}\left\lfloor \frac{h+1-R}{D} \right\rfloor - 3r &\ge \frac{h-R}{D} - Q \\ &\ge \frac{4(h-R)}{5T} - Q \\ &\ge \frac{3h/10 + R/5}{T} \ge \frac{h}{4T} = g.\end{aligned}$$

Every nonexceptional node difference is also at least g, because

$$\left\lfloor \frac{h+1}{D} \right\rfloor \ge \left\lfloor \frac{h+1-R}{D} \right\rfloor \ge g + 3r.$$

Thus all adjacent differences are positive and the cut difference is at least g.

Finally $r - p = m - j < p$, since $1 \le j < m$ and $k \ge m + 3$. The small block is therefore $\{p+1, \ldots, r\}$. The difference between a weight in this block and any distinct weight is a sum, up to sign, of positive adjacent differences containing either the cut difference or a difference internal to this small block. At least one summand is at least g. Hence

$$|u_{\tau,i} - u_{\tau,i'}| \ge g \quad (i \in \{p+1, \ldots, r\},\ i' \ne i).$$

This is the remaining part of the gap hypothesis. □

Part V
The Ribet budget

Part V proves one theorem, the Ribet budget Theorem 22.1, and it has one consumer: the proof of Theorem 17.7 in Part III. There it gives the properties (Rf1), (Rf2), (Rf4) and (Rf5) of the Ribet records and the properties (Lq3) and (Lq7) of the local bound records of a family of the class $\mathcal{A}_{\mathrm{prop}}$. With them Theorem 13.13 bounds, at every local component r of a large member and every good eigensystem π, the congruence length $\mathrm{cg}(r,\pi)$ by the Selmer length, the local term $\mathrm{lt}(r)$, the Sha length $\mathrm{len}_\ell(E;t)$ and $v_\ell(\#\mathrm{Cl}(E))$, and this is how the defects of the divisor package (Sp4) come to be bounded by Sha lengths (Section 13).

The mechanism is Ribet's [208]. A homomorphism from a module of extensions to one of the constituent modules of a determinant algebra gives a cocycle (Lemma 22.12), and its class lies in a Selmer group, in a group of unramified homomorphisms or in a Tate–Shafarevich group of a Tate twist, up to two kinds of loss: a global loss κ_k, and local losses $\lambda_k(v)$ at the places v above the residue characteristic ℓ, which measure how far the class is from the local Bloch–Kato condition (Theorem 22.11). The budget bounds the smallest admissible losses at each ℓ by an explicit allowance $a_{x,i}(\ell)$, and the sum over ℓ of $\log\ell\cdot a_{x,i}(\ell)$ by a constant times $f\,m\,b\,x^{2\varepsilon}$.

Everything else in the Part is local theory, done place by place. The primes ℓ are of small type (including at most two ramified primes, such as the primes q and d of the host), of split type, of inert type, or large, and each type has its own allowance. The common tool is a lifting exponent for integral crystalline classes along a surjection of crystalline lattices over an unramified field (Proposition 24.1): the exponent is at most an absolute constant times $2+\mathrm{wt}/\ell+\log_\ell(\mathrm{wt}+1)$, where wt is the width of the Hodge window. It is proved with Wach modules [265], [26], which are obtained here from prismatic F-crystals [31], and with Herr's complex [126]; and at the large primes the local conditions are computed exactly with residual (φ,Γ)-modules [93].

Section 22 states the theorem and assembles it from the local results. Sections 23 and 24 build the theory of Wach modules that is needed and prove the lifting exponents, over unramified fields and over subfields of the first cyclotomic layer. Section 25 turns lifting exponents into losses at the places above ℓ. Sections 26, 27 and 28 bound the total loss at a prime of each type: inert, then ramified, split and small, then large. The bounds at the primes of inert type rest on three colength bounds for weight words along Frobenius orbits; their proofs are combinatorial and long, and they form Appendix C. No result of Part V depends on (TCS), and apart from one lemma of Section 13 (Lemma 13.15) the Part cites no other Part.

22 The Ribet budget theorem

This section states the Ribet budget and assembles it from the local results of Sections 23–28. The statement used in Part III is Theorem 22.1. Its hypotheses are asked of one coefficient extension of the family, along $\mathcal{O}_r\subseteq\mathcal{O}_r(N_{x,i})$, because the local results need coefficient rings that contain certain roots of unity; its conclusions are for the original family. The passage between the two is formal: the extended coefficient ring contains the cyclotomic fields that the budget reads (Lemma 22.16), and a coefficient extension leaves normalised lengths, minimal losses and the Ribet properties unchanged (Lemma 22.17).

The budget itself is Theorem 22.4. Its minimal losses are the normalised lengths of the kernel in (Gd6) and of the local images in (Gd7), and its allowance $a_{x,i}(\ell)$ is an explicit expression in the sizes of the member, one for each type of prime. The proof treats one point (j,w,r,π) at a time: according to the type of $\ell=\ell_{x,i}(w)$ it exhibits losses with (Gd6) and (Gd7) whose

total is at most $a_{x,i}(\ell)$, by Theorem 25.1 and Theorem 27.15 at the split primes, Theorem 26.1 at the inert primes, Proposition 27.16 and Theorem 27.1 at the small and ramified primes, and Proposition 28.1 at the large primes, where the minimal losses vanish. Two summations close the proof: Theorem 22.10 turns the Galois Ribet records into Ribet records with (Rf1), (Rf4) and (Rf5), and Theorem 22.9, with Theorem 22.8 for the primes of inert type, sums the allowances into the local budget (Lq7). Property (Rf2), non-vanishing at the points outside the good set, comes from Proposition 22.7.

The idea of the section is in Lemma 22.12 and Theorem 22.11, Ribet's construction [208] in the form needed here: a homomorphism φ from the module of extensions to the constituent module Cs_k gives a cocycle c_φ, and the normalised length of $\mathrm{Hom}(\mathcal{N}, \mathrm{Cs}_k)$ is bounded by the loss sum ls_k plus the length of a Selmer group ($k = 0$), of a group of unramified homomorphisms ($k = 1$), or of $\mathrm{Sha}^1_\ell(E, k-1)$ ($k \geq 2$). The other results of the section are auxiliary; among them are local facts at the primes q, d of the host, the determinant condition from Hecke-valued characteristic polynomials, and Tate–Shafarevich groups of Tate twists with coefficients in a coefficient ring.

Theorem 22.1. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records, Ribet records, budget data and inert budget data, and Galois Ribet items at every point of every member (x, i), $x > x_1$, as in Theorem 22.4; let $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$. Write (Ub3°) for (Ub3) without its two clauses on K (that K contains $\sigma(E_v(\mu_\ell))$ at primes of split or inert type and large primes, and that K contains a primitive $\mathrm{lcm}(\ell, N_{x,i})$-th root of unity at primes of small type). Suppose there is a real x_0 such that for every $x \geq x_0$ with $x > x_1$ and every member (x, i) with finite Sha lengths there are an integer $N_{x,i} \geq 1$ with $4 \mid N_{x,i}$ and integers $S^{\mathrm{rm}}_{x,i}, \eta^{\mathrm{rm}}_{x,i} \geq 0$ with the following property, where $\mathcal{F}'$ is the coefficient extension of $\mathcal{F}$ along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ for the local components r of these members and along $\mathcal{O}_r \subseteq \mathcal{O}_r$ for all other local components: at every point (j, w, r, π) of (x, i) the Galois Ribet items of $\mathcal{F}'$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), with $K = \mathcal{O}_r(N_{x,i})[\ell^{-1}]$. Then, for all $x \geq x_0$ with $x > x_1$, $x^\varepsilon \geq 3$ and x beyond the thresholds of (Lz1) and (Iq1), and all members with finite Sha lengths:*

1. *at every (j, w, r, π) the minimal losses of the Galois Ribet items of $\mathcal{F}$ are finite and*

$$\sum_{k=0}^{t} \mathrm{ls}_k^{\min}(r, \pi) \leq a_{x,i}(\ell);$$

   the Galois Ribet items of $\mathcal{F}$ with the minimal losses where these are finite (and the losses 0 elsewhere) are Galois Ribet records having (Gd8), (Gd9) and (Gd10);

2. *the Ribet records of $\mathcal{F}$ have (Rf1), (Rf2), (Rf4) and (Rf5);*

3. *the local bound records of $\mathcal{F}$ have (Lq3), and (Lq7) with the constant $19C_3^3$.*

Proof. **Step 1: $\mathcal{F}'$ satisfies the hypotheses of Theorem 22.4.** By item 3 of Lemma 22.17, $\mathcal{F}'$ is a parametrised host family with slope records and defect data, with local defect data, local bound records, Ribet records, budget data and inert budget data, and it carries Galois Ribet items at every point of every member (x, i), $x > x_1$ (the coefficient extensions of those of $\mathcal{F}$, item 2 there), with the same ℓ, t and the extended Hecke lattice of r. Let x_0, a member (x, i) with $x \geq x_0$, $x > x_1$ and finite Sha lengths, and $N = N_{x,i}$, $S^{\mathrm{rm}}_{x,i}$, $\eta^{\mathrm{rm}}_{x,i}$ be as in the hypothesis, and let (j, w, r, π) be a point of (x, i), $\ell = \ell_{x,i}(w)$, $K' = \mathcal{O}_r(N)[\ell^{-1}]$. It remains to check the two clauses on K' in (Ub3). By (Ub3°), E is isomorphic to a subfield of $\mathbb{Q}(\mu_N)$; for $v \mid \ell$ the

completion E_v is then $\mathbb{Q}_\ell$-isomorphic to a subfield of a completion of $\mathbb{Q}(\mu_N)$ at a place above ℓ, that is, of $\mathbb{Q}_\ell(\mu_N)$. Item 3 of Lemma 22.16 with $F = E_v$ and $F_1 = E_v(\mu_\ell)$ gives $\sigma(E_v(\mu_\ell)) \subseteq K'$ for every $\mathbb{Q}_\ell$-embedding σ of $E_v(\mu_\ell)$, at every prime (in particular at the primes of split and inert type and the large primes); item 1 there gives a primitive $\operatorname{lcm}(\ell, N)$-th root of unity in K'. So (Ub1)–(Ub10) hold for $\mathcal{F}'$ at every point of every member with $x \geq x_0$, $x > x_1$ and finite Sha lengths, with the same x_0, $N_{x,i}$, $S^{\mathrm{rm}}_{x,i}$, $\eta^{\mathrm{rm}}_{x,i}$ and constants.

Step 2: the conclusions for $\mathcal{F}'$. By Theorem 22.4, for all x and members as in the conclusion: at every point the minimal losses of the items of $\mathcal{F}'$ are finite with $\sum_k \mathrm{ls}^{\min}_k \leq a_{x,i}(\ell)$, and these items with the minimal losses (losses 0 where they are infinite) are Galois Ribet records with (Gd8), (Gd9), (Gd10); the Ribet records of $\mathcal{F}'$ have (Rf1), (Rf2), (Rf4), (Rf5); the local bound records of $\mathcal{F}'$ have (Lq3) and (Lq7) with the constant $19C_3^3$.

Step 3: descent to $\mathcal{F}$. By item 2 of Lemma 22.17, at every point the minimal losses of the items of $\mathcal{F}$ equal those of $\mathcal{F}'$, and the loss sums formed with them are equal (same $n_{\mathcal{R},0}$, $\nu(\delta)$, $\nu(\zeta_v - 1)$); so they are finite exactly where those of $\mathcal{F}'$ are, and $\sum_k \mathrm{ls}^{\min}_k \leq a_{x,i}(\ell)$, the allowance being the same number. The losses chosen for $\mathcal{F}$ (minimal where finite, 0 elsewhere) are the losses chosen for $\mathcal{F}'$; by item 3 of Lemma 22.17 the items of $\mathcal{F}$ with them are Galois Ribet records with (Gd8), (Gd9), (Gd10). This is item 1. By item 3 of Lemma 22.17, (Rf2), (Rf4), (Rf5) for $\mathcal{F}'$ give them for $\mathcal{F}$, and (Rf1) for $\mathcal{F}'$ gives (Rf1) for $\mathcal{F}$: item 2. The local bound records of $\mathcal{F}$ are those of $\mathcal{F}'$: item 3. □

Definition 22.2. Let $F \subset \overline{\mathbb{Q}}$ be a number field and ℓ a prime. Let L be a field with $\mathbb{Q}_\ell \subseteq L \subseteq \overline{\mathbb{Q}}_\ell$ which is finite over $\mathbb{Q}_\ell$ or equal to $\overline{\mathbb{Q}}_\ell$, with the topology of $|\cdot|_\ell$, and let V be a finite-dimensional L-vector space with a continuous L-linear action of G_F. For a finite place v of F, a **decomposition group at** v is the image $D_j \subseteq G_F$ of $\mathrm{Gal}(\overline{F_v}/F_v)$ under restriction along an embedding $j\colon \overline{\mathbb{Q}} \to \overline{F_v}$ over F; $I_j \subseteq D_j$ is the image of the inertia group. For a closed subgroup $D \subseteq G_F$, $H^1(D, V)$ is computed with continuous cocycles.

Local conditions. Let v be a place of F and D a decomposition group at v (for v archimedean: the image of $\mathrm{Gal}(\mathbb{C}/F_v)$ under an embedding $\overline{\mathbb{Q}} \to \mathbb{C}$ over F). The subspace $H^1_f(D, V) \subseteq H^1(D, V)$ consists of the classes $[c]$ such that:

- if v is finite and $v \nmid \ell$, $D = D_j$: there is $x \in V$ with $c(g) = gx - x$ for all $g \in I_j$;
- if $v \mid \ell$, $D = D_j$: there is $y \in V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $c(g) \otimes 1 = gy - y$ for all $g \in D_j$, where $D_j \cong \mathrm{Gal}(\overline{F_v}/F_v)$ acts on V and on B_{cris} (formed for $\overline{F_v} = \overline{\mathbb{Q}}_\ell$) diagonally;
- if v is archimedean: $H^1_f(D, V) = 0$.

Rational coefficients. A continuous 1-cocycle $c\colon G_F \to V$ is a **Bloch–Kato cocycle** if for every place v of F and every decomposition group D at v the class of $c|_D$ lies in $H^1_f(D, V)$. The **Bloch–Kato Selmer group**

$$H^1_f(F, V) \subseteq H^1(F, V)$$

is the space of classes of Bloch–Kato cocycles.

Divisible coefficients [141], 14.1. Let L be finite over $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$, and let $T \subset V$ be a G_F-stable $\mathcal{O}_L$-lattice; $V/T \cong T \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$ is a discrete G_F-module. The **Selmer group** of T over F is

$$\mathrm{Sel}(F, T) = \{x \in H^1(F, V/T) \ :\ x|_D \in \mathrm{Im}(H^1_f(D, V) \to H^1(D, V/T)) \text{ for every place } v \text{ and every decomposition group } D \text{ at } v\}.$$

Definition 22.3. Let E be a number field, ℓ a prime, $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ a Hecke lattice over ℓ with $K = \mathcal{O}[\ell^{-1}]$, $\mathcal{R}$ a determinant algebra over $\mathbb{T}$, π' a point with a block form with $t+1$ blocks numbered $0, \dots, t$, and $\mathbf{r}$, χ_1, $\mathcal{E}$, δ items of Galois Ribet data over E on $(\mathcal{R}, \pi', \mathcal{N})$ for some $\mathcal{N}$, taken together with the coefficient algebra $\mathbb{T}'$ and the denominator function $\tilde{\delta}$ of these data; these items, and u, y and $\mathcal{N}_{\mathcal{E}}$, do not depend on $\mathcal{N}$. Write $W_0 = K^{n_{\mathcal{R},0}}$ and $\Lambda_0 = \mathcal{O}^{n_{\mathcal{R},0}}$, on which $g \in G_E$ acts by $\rho_0(u(g))$, so that $\mathrm{Cs}_0(u) = W_0/\Lambda_0$; for $\lambda \in \Lambda_0$ and $x \in K/\mathcal{O}$ write $x\lambda = \tilde{x}\lambda + \Lambda_0 \in \mathrm{Cs}_0$ for any lift $\tilde{x} \in K$ of x.

Column data for these items consist of a set $C \subseteq S_\ell$, the **column places**, an idempotent $e_1 \in \mathcal{R}$, and for every $v \in C$ an integer $j_v \geq 0$, maps $\alpha_{v,a} \colon G_{E_v} \to \mathcal{R}$ for $1 \leq a \leq j_v$, and a map $\alpha_v^0 \colon G_{E_v} \to \mathcal{R}\mathcal{E}$, the **column coefficients**. Let $\mathcal{F} = \bigoplus_{v \in C} (\mathcal{R}\epsilon_v \oplus \bigoplus_{a=1}^{j_v} \mathcal{R}\epsilon_{v,a} \oplus \mathcal{R}\epsilon_v^0)$ be the free left $\mathcal{R}$-module on symbols $\epsilon_v, \epsilon_{v,a}, \epsilon_v^0$, and $\mathrm{Rel} \subseteq \mathcal{N}_{\mathcal{E}} \oplus \mathcal{F}$ the left $\mathcal{R}$-submodule generated by the elements, for $v \in C$, $1 \leq a \leq j_v$ and $g \in G_{E_v}$,

$$\mathcal{E}\epsilon_v, \qquad (1-e_1)\epsilon_{v,a}, \qquad (\tilde{\delta} - \mathcal{E})\epsilon_v^0, \qquad \Big(y(g),\ (u(g)-1)\epsilon_v - \delta \sum_{a=1}^{j_v} \alpha_{v,a}(g)\epsilon_{v,a} - \delta\, \alpha_v^0(g)\epsilon_v^0\Big).$$

The **column-enlarged module of extensions** is the left $\mathcal{R}$-module

$$\mathcal{N}^{\mathrm{col}} = (\mathcal{N}_{\mathcal{E}} \oplus \mathcal{F})/\mathrm{Rel}, \qquad \iota^{\mathrm{col}} \colon \mathcal{N}_{\mathcal{E}} \to \mathcal{N}^{\mathrm{col}}, \quad n \mapsto (n, 0) + \mathrm{Rel}. \tag{22.1}$$

At $v \in C$ the column data have the **column properties** if there are a vector $z_1 \in \Lambda_0$, continuous maps $\beta_{v,a} \colon G_{E_v} \to \Lambda_0$ $(1 \leq a \leq j_v)$, integers $e_v' \geq 0$ and $b_v \geq 0$ and an element $g_v \in G_{E_v}$ such that:

(Cm1) The column line $\rho_k(e_1) = 0$ for $1 \leq k \leq t$, and every $m \in \mathrm{Cs}_0$ with $\rho_0(e_1)m = m$ is of the form $m = xz_1$ with $x \in K/\mathcal{O}$;

(Cm2) Realisation each $\beta_{v,a}$ is a 1-cocycle,

$$\beta_{v,a}(gh) = \beta_{v,a}(g) + \rho_0(u(g))\beta_{v,a}(h),$$

and $\rho_0(\alpha_{v,a}(g))\, z_1 = \ell^{e_v'}\, \beta_{v,a}(g)$ for $g \in G_{E_v}$;

(Cm3) Crystalline classes the class of each $\beta_{v,a}$ in $H^1(G_{E_v}, W_0)$ lies in $H^1_f(G_{E_v}, W_0)$;

(Cm4) Independence if $x_1, \dots, x_{j_v} \in K/\mathcal{O}$ and $g \mapsto \sum_a x_a \beta_{v,a}(g)$ is a coboundary of G_{E_v} with values in $\mathrm{Cs}_0(u)$, then $x_1 = \cdots = x_{j_v} = 0$;

(Cm5) The character column $\rho_1(\alpha_v^0(g)) = 0$ for $g \in I_v$, and

$$\rho_1(\alpha_v^0(g_v)) \neq 0 \quad \text{with} \quad \nu(\rho_1(\alpha_v^0(g_v))) \leq b_v.$$

Theorem 22.4. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records, Ribet records, budget data and inert budget data. For Galois Ribet data, the **minimal losses** $\kappa_k^{\min}, \lambda_k^{\min}(v) \in [0, \infty]$ are the normalised lengths of the kernel in (Gd6) and of the image in (Gd7); they depend only on the entries other than the losses, the **Galois Ribet items**. When they are finite, $\mathrm{ls}_k^{\min}$ denotes the loss sums formed with them. For a member (x, i) write t, ϱ, H, ℓ^* for its budget data, $L = x^{\varepsilon}$, and for an integer $N \geq 1$ and a prime ℓ put $s_\ell(N) = \max(1, v_\ell(N))$. Let $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$ be real numbers, $c_1 = \max(c_{\mathrm{sp}}, 3c_{\mathrm{ur}})$,*

$c_2 = \max(c_{\rm in}, 3c_{\rm ur})$, *and define the* ***allowance*** $a_{x,i}(\ell)$ *of* $\ell \in P_{x,i} \setminus G_{x,i}$, *given an integer* $N_{x,i} \geq 1$ *and integers* $S^{\rm rm}_{x,i}, \eta^{\rm rm}_{x,i} \geq 0$, *as*

$$
\begin{aligned}
&c_{\rm cy}\, c_{\rm sm}\, f\Big(m\lceil H\rceil s_\ell(N_{x,i}) \\
&\qquad + f\, t^2(\varrho+t)\big(s_\ell(N_{x,i}) + \log_\ell(2\lceil H\rceil) + \log_\ell N_{x,i} + 1\big)\Big) && (\ell \text{ of small type, } \ell \notin \mathcal{P}^{\rm rm}_{x,i}),\\
&160\, c_{\rm Q}\, c_{\rm sm}\, f\Big(\varrho\big(\tfrac{H}{\ell} + S^{\rm rm}_{x,i} + \eta^{\rm rm}_{x,i} + \log_\ell(2H) + 1\big) + m\,H \\
&\qquad + n\, t^2(\varrho+t)\big(1 + \log_\ell(H+t)\big)\Big) && (\ell \in \mathcal{P}^{\rm rm}_{x,i}),\\
&190\, c_1\, f\Big(n\, t^2(\varrho+t)(1+\log_\ell(H+t)) + \tfrac{m\,H}{\ell}\Big) && (\ell \text{ of split type}),\\
&300\, c_{\rm R}(c_2+1)\, f\Big(n\, t^2(\varrho+t)(1+\log_\ell(H+t)) + \tfrac{m\,H}{\ell} + \varrho\, A_{x,i}(\ell)\Big) && (\ell \text{ of inert type}),\\
&\ell^{-2} && (\ell \text{ large}).
\end{aligned}
$$

Suppose that at every point (j, w, r, π) *(as below) of every member* (x, i), $x > x_1$, *Galois Ribet items on* $(\mathcal{R}_{r,\pi}, \pi', \mathcal{N}_{r,\pi})$ *over* E *are given, with* ℓ, t *and the Hecke lattice of* r, *and that there is a real* x_0 *such that for every* $x \geq x_0$ *with* $x > x_1$ *and every member* (x, i) *with finite Sha lengths there are an integer* $N_{x,i} \geq 1$ *with* $4 \mid N_{x,i}$ *and integers* $S^{\rm rm}_{x,i}, \eta^{\rm rm}_{x,i} \geq 0$ *such that the following hold, where* (j, w, r, π) *runs over* $1 \leq j \leq m$, $w \in W_{x,i}$ *with* $\ell = \ell_{x,i}(w) \notin G_{x,i}$, $r \in R_{x,i}(j, w)$, $\pi \in Z_r$, *and* $E = E_{\mathfrak{h}_{x,i}}$, $K = \mathcal{O}_r[\ell^{-1}]$, $D_v = G_{E_v}$, $n_v = [E_v : \mathbb{Q}_\ell]$:

(Ub1) Items *at every* (j, w, r, π) *the Galois Ribet items have (Gd1)–(Gd5); they have (Gd9); E has no real place; and* $\mathrm{Sel}_0(r, \pi)$ *has normalised length at most* $\mathrm{sl}(r, \pi)$;

(Ub2) Modules *if* ℓ *is of split type, or of small type with* $\ell \notin \mathcal{P}^{\rm rm}_{x,i}$, *there are column data with column places* $C \subseteq S_\ell$ *for the items* $\mathbf{r}, \chi_1, \mathcal{E}, \delta$, *and* $\mathcal{N}_{r,\pi} = \mathcal{N}^{\rm col}$, $\iota = \iota^{\rm col}$; *if* ℓ *is of inert type, large or in* $\mathcal{P}^{\rm rm}_{x,i}$, $\mathcal{N}_{r,\pi} = \mathcal{N}_{\mathcal{E}}$ *and* ι *is the identity;*

(Ub3) Host and coefficients E *is isomorphic to a subfield of* $\mathbb{Q}(\mu_{N_{x,i}})$; *every prime of split type, of inert type and every large prime is prime to* $N_{x,i}$; *every prime of split type is odd; if* ℓ *is of split or inert type or large,* K *contains* $\sigma(E_v(\mu_\ell))$ *for every* $v \mid \ell$ *and every* $\mathbb{Q}_\ell$*-embedding* σ *of* $E_v(\mu_\ell)$; *if* ℓ *is of small type,* K *contains a primitive* $\mathrm{lcm}(\ell, N_{x,i})$*-th root of unity; and (Ll1), (Ll2) hold at every* $v \mid \ell$;

(Ub4) Split type *if* ℓ *is of split type: there are integers* $M_0, h_0 \geq 0$ *with* $M_0 + h_0 \leq H$ *such that at every* $v \mid \ell$ *all Hodge jumps of* $V_{\mathcal{N}}$, *of* $W_0, \ldots, W_t$ *and of* W_0' *lie in* $[-M_0, h_0]$; *at every* $v \in C$ *the column data have the column properties with* $e'_v \leq c_{\rm sp}(1 + H/\ell + \log_\ell H)$ *and* $b_v \leq c_{\rm sp} t$, $H^0(D_v, W_0) = 0$, W_0 *has at most* m *Hodge jumps* $a < 0$ *at each embedding, and* 0 *is not a Hodge jump of* W_0 *at some embedding; at every* $v \mid \ell$, $v \notin C$: $H^0(D_v, W_0') = 0$, W_0 *has at most* m *Hodge jumps* $a \geq 0$ *at each embedding,* 0 *is not a Hodge jump of* W_0' *at some embedding, and* $|J(V_{\mathcal{N}})| \leq c_{\rm sp} n_v(\varrho + t)$; *and* $\sum_{v|\ell} n_v \leq 2f$, $n_{\mathcal{R},0} \leq \varrho$, $\nu(\delta) \leq 2t$, $\sum_{v \in \Sigma_{\rm T}} \nu(\zeta_v - 1) \leq c_{\rm sp}$;

(Ub5) Inert type *if* ℓ *is of inert type: at every* $v \mid \ell$, $H^0(D_v, W_0') = 0$; *there are integers* $M_0, h_0 \geq 0$ *with* $M_0 + h_0 \leq H$ *such that all Hodge jumps of* $V_{\mathcal{N}}$ *and of* $W_0, \ldots, W_t$ *lie in* $[-M_0, h_0]$; $|J(V_{\mathcal{N}})| \leq c_{\rm in} n_v(\varrho + t)$; *and there is a weight word at* v *with the integer* m *above whose integers* b, w, S, η, M, h' *satisfy* $b + 2\eta + S \leq H$, $w + S + \eta + 1 \leq H$, $M + h' \leq H$, $w \leq w^\circ$, $S \leq S^\circ$, $\eta \leq \eta^\circ$, $\beta_v \leq \beta_{x,i}(\ell)$, *and the hypotheses of item 3 of Proposition 26.2 with* $j = \max(1, \lceil \log_{\ell-1} \ell_{\rm A} \rceil)$ *if* $\ell \in \mathcal{P}^{\rm lo}_{x,i}$, *those of item 1 or of item 2 if* $\ell \notin \mathcal{P}^{\rm lo}_{x,i}$; *and* $\sum_{v|\ell} n_v \leq 2f$, $n_{\mathcal{R},0} \leq \varrho$, $\nu(\delta) \leq 2t$, $\sum_{v \in \Sigma_{\rm T}} \nu(\zeta_v - 1) \leq c_{\rm in}$;

(Ub6) Large primes *if ℓ is large: $\delta \in \mathcal{O}_r^\times$, $t\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)\le \ell^{-2}$, and at every $v\mid\ell$ there are a Frobenius numbering and data $h,w,\eta,\mathrm{typ},(U_a)$ with items 1–3 and (Ph1)–(Ph5) of Proposition 28.1;*

(Ub7) Small type *if ℓ is of small type and $\ell\notin\mathcal{P}^{\mathrm{rm}}_{x,i}$: at every $v\mid\ell$ all Hodge jumps of $V_{\mathcal{N}}$, of $W_0,\dots,W_t$ and of W_0' lie in $[-\lceil H\rceil,\lceil H\rceil]$; at every $v\in C$ the column data have the column properties with $e_v'\le c_{\mathrm{sm}}(\lceil H\rceil s_\ell(N_{x,i})+1)$ and $b_v\le c_{\mathrm{sm}}t$, $H^0(D_v,W_0)=0$, W_0 has at most m Hodge jumps $a<0$ at each embedding, and 0 is not a Hodge jump of W_0 at some embedding; at every $v\mid\ell$, $v\notin C$: $H^0(D_v,W_0')=0$, W_0 has at most m Hodge jumps $a\ge 0$ at each embedding, 0 is not a Hodge jump of W_0' at some embedding, and $|J(V_{\mathcal{N}})|\le c_{\mathrm{sm}}n_v(\varrho+t)$; and $\sum_{v\mid\ell}n_v\le 2f$, $n_{\mathcal{R},0}\le\varrho$, $\nu(\delta)\le 2t$, $\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)\le c_{\mathrm{sm}}$;*

(Ub7') Ramified primes *if $\ell\in\mathcal{P}^{\mathrm{rm}}_{x,i}$: at every $v\mid\ell$, with $E_{v,0}$ the maximal unramified subextension of $E_v/\mathbb{Q}_\ell$, either $E_v\subseteq E_{v,0}(\mu_\ell)$ and $[E_v:E_{v,0}]=2$, or $\mathfrak{h}_{x,i}=(q,d,Q_S,\alpha)$ admits a complete good-host witness and $\ell\in\{q,d\}$; $J(V_{\mathcal{N}})\subseteq[-M_0,h_0]$ with integers $M_0,h_0\ge 0$, $M_0+h_0\le H$, and $|J(V_{\mathcal{N}})|\le c_{\mathrm{sm}}n_v(\varrho+t)$; at every $\mathbb{Q}_\ell$-embedding $\tau\colon E_v\to K$ there are a sign $\epsilon_\tau\in\{+1,-1\}$ and an integer $b_\tau>\eta^{\mathrm{rm}}_{x,i}$ such that every Hodge jump a of every $U'_{x'}$, $x'\in\mathcal{Z}'_{r,\pi}$, at τ satisfies $|a|\le 2H$ and either $|a|\le\eta^{\mathrm{rm}}_{x,i}$ or $\epsilon_\tau a\in[b_\tau,b_\tau+S^{\mathrm{rm}}_{x,i}]$, and W_0' has at most m Hodge jumps in $[-\eta^{\mathrm{rm}}_{x,i},\eta^{\mathrm{rm}}_{x,i}]$ at τ, counted with multiplicity; and $\sum_{v\mid\ell}n_v\le 2f$, $n_{\mathcal{R},0}\le\varrho$, $\nu(\delta)\le 2t$, $\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)\le c_{\mathrm{sm}}$;*

(Ub8) Sizes *(Lz1) holds with the constant C_{bud}; $\sum_{\ell\in\mathcal{P}^{\mathrm{sm}}_{x,i}}\log\ell\le C_{\mathrm{bud}}L$, $|\mathcal{P}^{\mathrm{rm}}_{x,i}|\le 2$ and $\log\ell\le L$ for $\ell\in\mathcal{P}^{\mathrm{rm}}_{x,i}$; $a_{x,i}(\ell)\le C_{\mathrm{bud}}(f\,m\,b\log x+x^{C_{\mathrm{bud}}}L^2)$ for $\ell\in\mathcal{P}^{\mathrm{sm}}_{x,i}\setminus G_{x,i}$ and $a_{x,i}(\ell)\le C_{\mathrm{bud}}f\,m\,b$ for $\ell\in\mathcal{P}^{\mathrm{rm}}_{x,i}\setminus G_{x,i}$; and (Iq1) holds with the constant C_{bud};*

(Ub9) Record choices $\mathrm{lc}_k(r,\pi)=\mathrm{ls}^{\min}_k(r,\pi)$ *for $0\le k\le t$ whenever the minimal losses at (r,π) are finite;* $\mathrm{lt}(r)=a_{x,i}(\ell)$; *and* $\mathrm{la}_{x,i}(\ell)=a_{x,i}(\ell)$ *for $\ell\in P_{x,i}\setminus G_{x,i}$,* $\mathrm{la}_{x,i}(\ell)=0$ *for every other prime;*

(Ub10) Points without the character line *for every $x'\in\mathcal{Z}'_{r,\pi}$ with $\phi_{r,\pi}(x')\in\widehat{Z}_r\setminus Z_r$, the hypotheses 1–3 of Proposition 22.7 hold at x' for the column data of (Ub2), or, if ℓ is of inert type, large or in $\mathcal{P}^{\mathrm{rm}}_{x,i}$, for the column data with no column places.*

Then, for all $x\ge x_0$ with $x>x_1$, $x^\varepsilon\ge 3$ and x beyond the thresholds of (Lz1) and (Iq1), and all members with finite Sha lengths:

1. *at every (j,w,r,π) the minimal losses are finite and $\sum_{k=0}^t\mathrm{ls}^{\min}_k(r,\pi)\le a_{x,i}(\ell)$; the Galois Ribet items with the minimal losses where these are finite (and the losses 0 elsewhere) are Galois Ribet records having (Gd8), (Gd9) and (Gd10);*
2. *the Ribet records have (Rf1), (Rf2), (Rf4) and (Rf5);*
3. *the local bound records have (Lq3), and (Lq7) with the constant $19C_3^3$, where*

$$C_2=\max(C_{\mathrm{bud}},300c_{\mathrm{R}}(c_2+1)),\qquad C_3=\max(190c_1,120C_2^3).$$

Proof. **Step 0: minimal losses.** Fix Galois Ribet items at a point. (i) If real numbers $\kappa_k,\lambda_k(v)\ge 0$ make (Gd6) and (Gd7) true, then by definition $\kappa_k^{\min}\le\kappa_k$ and $\lambda_k^{\min}(v)\le\lambda_k(v)$; so the minimal losses are finite, (Gd6) and (Gd7) hold with the minimal losses (the modules there

have normalised length equal to them), and, every loss sum being a non-decreasing function of the losses, $\mathrm{ls}_k^{\min} \le \mathrm{ls}_k$. (ii) For any finite losses,

$$\sum_{k=0}^{t} \mathrm{ls}_k = T(\kappa,\lambda) := \sum_{k=0}^{t} \kappa_k + \sum_{v\in S_\ell} \sum_{k=0}^{t} \lambda_k(v) + t \sum_{v\in\Sigma_{\mathrm{T}}} \nu(\zeta_v - 1) + 2(n_{\mathcal{R},0} + t - 1)\,\nu(\delta),$$

so by (i) it suffices, at each point, to exhibit losses with (Gd6), (Gd7) and $T(\kappa,\lambda) \le a_{x,i}(\ell)$: then $\sum_k \mathrm{ls}_k^{\min} \le a_{x,i}(\ell)$.

Step 1: thresholds and the host. As $\varepsilon > 0$, choose $x_0' \ge x_0$ beyond the thresholds of (Lz1) and (Iq1) with $L = x^\varepsilon \ge 3$ for $x \ge x_0'$. Fix such $x > x_1$, a member (x,i) with finite Sha lengths, $N = N_{x,i}$, a point (j,w,r,π) and $\ell = \ell_{x,i}(w) \in P_{x,i} \setminus G_{x,i}$. By (Lz1), $1 \le m \le t$, $\varrho \le t$ and $\ell^* \ge 3$. If $\ell \nmid N$ then every E_v, $v \mid \ell$, is unramified over $\mathbb{Q}_\ell$: by (Ub3) E_v is isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_N)$, which is unramified over $\mathbb{Q}_\ell$ as $\ell \nmid N$. Two elementary bounds are used: for $0 \le a \le H$ and $\ell \ge 3$,

$$2 + \frac{a}{\ell} + \log_\ell(a+1) \le 3\Big(1 + \frac{H}{\ell} + \log_\ell H\Big), \qquad \text{(B1)}$$

and, for $\ell \ge 11$ and $1 \le H \le 2b$ (the elementary bound of the inert case),

$$1 + \log_\ell(2H) \le L. \qquad \text{(B2)}$$

In (B2) the scale is $L = x^\varepsilon = \log b$, the parameter scale of the family.

Step 2: split type. Here ℓ is odd and prime to N (Ub3), so E_v is unramified, $E_v = E_{v,0} \subseteq E_{v,0}(\mu_\ell)$, K contains every $\sigma(E_{v,0}(\mu_\ell))$, and (Ll1), (Ll2) hold. At $v \mid \ell$, $v \notin C$, apply item 1 of Corollary 25.39 with $a_\tau^- = M_0$, $a_\tau^+ = h_0$ for all τ (admissible by (Ub4), all jumps of $V_{\mathcal{N}}$ and of the W_k being in $[-M_0, h_0]$): (Ll3) holds with $e_0 = \lfloor c_{\mathrm{ur}}(2 + \mathrm{wt}/\ell + \log_\ell(\mathrm{wt}+1))\rfloor$, $\mathrm{wt} = M_0 + h_0 \le H$. Its case $k = 0$ is the inclusion required of $e_0(v)$ in (Lr2) of Theorem 25.1; put $e_0(v) = e_0$, so $e_0(v) \le 3c_{\mathrm{ur}}(1 + H/\ell + \log_\ell H) \le c_1(1 + H/\ell + \log_\ell H)$ by (B1). With $\mu_\tau^{\mp}(v) = m$ and the embeddings τ_v of (Ub4), (Lr1) and (Lr2) hold, the remaining hypotheses of Theorem 25.1 hold by (Ub2)–(Ub4) and (Gd1), (Gd2) (Ub1), so Theorem 25.1 gives losses with (Gd6) and (Gd7). Items 1–4 of Theorem 27.15 hold with $c = c_1$: item 1 by (Ub4) and (Lz1); item 2 by (Ub4); item 3 by $e_v' \le c_{\mathrm{sp}}(1 + H/\ell + \log_\ell H)$ and the bound on $e_0(v)$, as $c_{\mathrm{sp}} \le c_1$; item 4 by (Ub4). So $T(\kappa,\lambda) \le 190c_1 f(n\,t^2(\varrho+t)(1 + \log_\ell(H+t)) + mH/\ell) = a_{x,i}(\ell)$.

Step 3: inert type. By (Iq1) item 2, $\ell \ge 11$; $\ell \nmid N$ (Ub3), so every E_v is unramified, K contains every $\sigma(E_v(\mu_\ell))$, and (Ll1), (Ll2) hold; $\mathcal{N}_{r,\pi} = \mathcal{N}_{\mathcal{E}}$ with ι the identity (Ub2). As in Step 2, item 1 of Corollary 25.39 with $a_\tau^- = M_0$, $a_\tau^+ = h_0$ (Ub5) gives at every $v \mid \ell$ an integer $e_0(v)$ with the inclusion of item 2 of Theorem 26.1. The lifting exponent e_v of the weight word of (Ub5) is the integer e_{A} of Proposition 24.1 for the window $[-M, h']$ and the duals $U'_{x'}$, which are crystalline by (Ll1); by the final assertion of Proposition 24.1 (ℓ odd, E_v unramified, $K \supseteq \sigma(E_v(\mu_\ell))$) and (B1) with $a = M + h' \le H$, $e_v \le c_{\mathrm{ur}}(2 + (M+h')/\ell + \log_\ell(M+h'+1)) \le c_2(1 + H/\ell + \log_\ell H)$. Take $A = A_{x,i}(\ell)$: for $\ell \in \mathcal{P}_{x,i}^{\mathrm{lo}}$ this is the number A_{lo} of Theorem 26.1 formed with $\ell_{\mathrm{A}}, w^\circ, S^\circ, \eta^\circ$ and L, otherwise A_{md} with $\beta = \beta_{x,i}(\ell) \in \{0,1\}$. The hypotheses of Theorem 26.1 hold with $c = c_2$: $n, \varrho, m \ge 1$, $H, c_2, L \ge 1$, $\ell_{\mathrm{A}} \ge 2$, $w^\circ, \eta^\circ, S^\circ \ge 0$; item 1 by (Ub5), (Lz1) and (B2), using $H \le 2b$ from (Iq1) item 1; item 2 by (Ub3), (Ub5), $e_0(v)$ and $c_{\mathrm{in}} \le c_2$; item 3 by (Ub5), with item 3 of Proposition 26.2 for $j = \max(1, \lceil \log_{\ell-1} \ell_{\mathrm{A}} \rceil)$ when $A = A_{\mathrm{lo}}$ and item 1 or 2 when $A = A_{\mathrm{md}}$, and the bound on e_v; item 4 by (Ub5). It gives $\kappa_k = 0$ and losses $\lambda_k(v)$ with (Gd6), (Gd7) and $T(\kappa,\lambda) \le 300c_{\mathrm{R}}(c_2+1)f(n\,t^2(\varrho+t)(1+\log_\ell(H+t)) + mH/\ell + \varrho A) = a_{x,i}(\ell)$.

Step 4: large primes. Here $\ell > \ell^* \ge 3$, so $\ell \ge 5$, and $\ell \nmid N$ (Ub3), so every E_v is unramified and K contains every $\sigma(E_v)$. As $\mathcal{N}_{r,\pi} = \mathcal{N}_{\mathcal{E}}$ and ι is the identity (Ub2), the map

$\varphi \mapsto \varphi \circ \iota$ of (Gd6) is the identity and $\kappa_k^{\min} = 0$. At every $v \mid \ell$, Proposition 28.1 applies: (Gd1), (Gd2) by (Ub1), δ a unit, (Ll1), (Ll2), E_v unramified and $K \supseteq \sigma(E_v(\mu_\ell))$ for every embedding σ by (Ub3), and the data with items 1–3 and (Ph1)–(Ph5) by (Ub6); it gives $\lambda_k^{\min}(v) = 0$. So the minimal losses are finite and, as $\nu(\delta) = 0$, $T(\kappa^{\min}, \lambda^{\min}) = t \sum_{v \in \Sigma_{\mathrm{T}}} \nu(\zeta_v - 1) \leq \ell^{-2} = a_{x,i}(\ell)$ by (Ub6).

Step 5: small type, $\ell \notin \mathcal{P}_{x,i}^{\mathrm{rm}}$. Apply Proposition 27.16 with $N = N_{x,i}$ (so $4 \mid N$), the integer $\lceil H \rceil \geq 1$ in place of H, $c = c_{\mathrm{sm}}$, the integers n, ϱ, m and the column data of (Ub2): its item 1 holds because E_v is isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_N) \subseteq \mathbb{Q}_\ell(\mu_{\mathrm{lcm}(\ell,N)})$ (Ub3), K contains a primitive $\mathrm{lcm}(\ell, N)$-th root of unity (Ub3), (Ll1), (Ll2) hold, and the jumps lie in $[-\lceil H \rceil, \lceil H \rceil]$ (Ub7); items 2–4 hold by (Ub7) and $\varrho \leq t$, $m \leq t$ from (Lz1); there $s = s_\ell(N)$. It gives losses with (Gd6), (Gd7) and $T(\kappa, \lambda) \leq a_{x,i}(\ell)$.

Step 5′: the ramified primes. Let $\ell \in \mathcal{P}_{x,i}^{\mathrm{rm}}$, so $\mathcal{N}_{r,\pi} = \mathcal{N}_{\mathcal{E}}$ and ι is the identity (Ub2). *The local fields.* Let $v \mid \ell$. If the second alternative of the first clause of (Ub7') holds, then $E = E_{\mathfrak{h}_{x,i}}$ for a host with a complete good-host witness and $\ell \in \{q, d\}$, and item 5 of Lemma 22.5 gives $E_v = E_{v,0}(\sqrt{-\ell}) \subseteq E_{v,0}(\mu_\ell)$ and $[E_v : E_{v,0}] = 2$; so in either case $E_v \subseteq E_{v,0}(\mu_\ell)$ and $[E_v : E_{v,0}] = 2$. In particular $[E_{v,0}(\mu_\ell) : E_{v,0}] \geq 2$, so $\mu_\ell \not\subseteq \mathbb{Q}_\ell$ and ℓ is odd. By (Ub3), E_v is isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_N)$, $N = N_{x,i}$; write $N = \ell^a N'$ with $\ell \nmid N'$. The maximal unramified subextension of $\mathbb{Q}_\ell(\mu_N)/\mathbb{Q}_\ell$ is $\mathbb{Q}_\ell(\mu_{N'})$, so $E_{v,0}$ is isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_{N'})$ and $E_{v,0}(\mu_\ell)$ to a subfield of $\mathbb{Q}_\ell(\mu_{N'\ell})$. This field is normal over $\mathbb{Q}_\ell$, so $\sigma(E_{v,0}(\mu_\ell)) \subseteq \mathbb{Q}_\ell(\mu_{N'\ell})$ for every $\mathbb{Q}_\ell$-embedding σ of $E_{v,0}(\mu_\ell)$; and $\mathbb{Q}_\ell(\mu_{N'\ell}) \subseteq K$, since K contains a primitive $\mathrm{lcm}(\ell, N)$-th root of unity (Ub3) and $N'\ell \mid \mathrm{lcm}(\ell, N)$. (Ll1), (Ll2) hold by (Ub3). *The losses.* Apply Theorem 27.1 with the integers n, ϱ, m, $S = S_{x,i}^{\mathrm{rm}}$, $\eta = \eta_{x,i}^{\mathrm{rm}}$, the real number H and $c = c_{\mathrm{sm}}$: its hypothesis 1 holds by (Ub7') and (Lz1) ($\varrho \leq t$, $m \leq t$), its hypothesis 2 by the local fields just discussed and (Ub7'), its hypotheses 3 and 4 by (Ub7'). Its items 1 and 2 give losses with (Gd6), (Gd7) and

$$T(\kappa, \lambda) \leq 160\, c_{\mathrm{Q}}\, c_{\mathrm{sm}}\, f\Big(\varrho\big(\tfrac{H}{\ell} + S_{x,i}^{\mathrm{rm}} + \eta_{x,i}^{\mathrm{rm}} + \log_\ell(2H) + 1\big) + mH + nt^2(\varrho + t)\big(1 + \log_\ell(H + t)\big)\Big) = a_{x,i}(\ell).$$

Step 6: the Galois Ribet records; (Rf1), (Rf2), (Rf4), (Rf5). Since $\ell \in P_{x,i} \setminus G_{x,i}$ is of exactly one of the four types, and a prime of small type either lies in $\mathcal{P}_{x,i}^{\mathrm{rm}}$ or not, Steps 0, 2–5 and 5′ show that at every point the minimal losses are finite and $\sum_k \mathrm{ls}_k^{\min}(r, \pi) \leq a_{x,i}(\ell)$. With them (and with the losses 0 at the points of members below the threshold where minimal losses are infinite; such members are not read by (Gd8)–(Gd10)) the items are Galois Ribet records, and at the points of large members they are Galois Ribet data with (Gd1)–(Gd7) ((Ub1), Step 0); with (Ub1) and $\mathrm{lc}_k = \mathrm{ls}_k^{\min}$ (Ub9) they form Galois Ribet records with (Gd8) and (Gd9), and with (Gd10) by Step 4 and (Ub6). By Theorem 22.10, items 1 and 2, the Ribet records have (Rf4) and (Rf1). (Rf5): $\sum_k \mathrm{lc}_k(r, \pi) = \sum_k \mathrm{ls}_k^{\min}(r, \pi) \leq a_{x,i}(\ell) = \mathrm{lt}(r)$ by (Ub9). (Rf2): let $\phi_{r,\pi}(x') \in \widehat{Z}_r \setminus Z_r$. At a prime of split type or of small type not in $\mathcal{P}_{x,i}^{\mathrm{rm}}$, Proposition 22.7 with the column data of (Ub2) (its hypotheses by (Ub10), and $\mathcal{E}^2 = \tilde{\delta}\mathcal{E}$ for the denominator function $\tilde{\delta}$ of the items by (Gd2)) gives $\mathrm{Hom}_{\mathcal{R}_{r,\pi}}(\mathcal{N}^{\mathrm{col}}, \mathcal{O}_r[\ell^{-1}]_{x'}^{n_{\mathcal{R}}}) \neq 0$, and $\mathcal{N}^{\mathrm{col}} = \mathcal{N}_{r,\pi}$. At a prime of inert type, a large prime or a prime in $\mathcal{P}_{x,i}^{\mathrm{rm}}$, take the column data with no column places and $e_1 = 1$: the free module $\mathcal{F}$ and the relations are then 0, so $\mathcal{N}^{\mathrm{col}} = \mathcal{N}_{\mathcal{E}} = \mathcal{N}_{r,\pi}$ and ι^{col} is the identity, and Proposition 22.7 (hypotheses by (Ub10)) gives the same non-vanishing. This is (Rf2).

Step 7: (Lq3) and (Lq7). (Lq3): $\mathrm{lt}(r) = a_{x,i}(\ell) = \mathrm{la}_{x,i}(\ell)$ by (Ub9). For (Lq7) we check the clauses of the budget data for the local allowances $\mathrm{la}_{x,i}$ of (Ub9). (Lz1) holds with C_{bud} (Ub8). (Lz2) holds with C_{bud}: for $\ell \in \mathcal{P}_{x,i}^{\mathrm{sm}} \setminus G_{x,i}$ and $\ell \in \mathcal{P}_{x,i}^{\mathrm{rm}} \setminus G_{x,i}$ by $\mathrm{la} = a$ and (Ub8), for $\ell \in \mathcal{P}_{x,i}^{\mathrm{rm}} \cap G_{x,i}$ because $\mathrm{la}_{x,i}(\ell) = 0$, and the size parts by (Ub8). (Lz4) holds with

$190c_1$ since $\mathrm{la} = a$ at split type. (Lz5) holds since $\mathrm{la}_{x,i}(\ell) = \ell^{-2}$ at large primes. The inert budget data have (Iq1) with C_{bud} (Ub8) and (Iq2) with $300c_{\mathrm{R}}(c_2 + 1)$, since $\mathrm{la} = a$ at inert type. Each of these clauses remains true when its constant is enlarged, so C_2 is a constant for (Lz1), (Iq1) and (Iq2), and Theorem 22.8 gives (Lz3) with the constant $120C_2^3$. Then $C_3 = \max(190c_1, 120C_2^3) \geq \max(C_{\mathrm{bud}}, 190c_1, 120C_2^3)$ is a constant for each of (Lz1)–(Lz4), and Theorem 22.9 gives (Lq7) with the constant $19C_3^3$. □

Lemma 22.5. *Fix data for which the concrete good-host requirement holds, together with objects satisfying its conditions. Put*

$$E = E_{\mathfrak{h}}, \qquad K = \mathbb{Q}(s_d), \qquad \Phi_{\mathsf{H}} = \{\tau : E \hookrightarrow \mathbb{C} : \tau(s_d) = \varphi_0(s_d)\}.$$

Write a bar for CM conjugation. For a finite prime v of E, let D_v, I_v be its decomposition and inertia subgroups in $\mathrm{Gal}(E/\mathbb{Q})$. *Then:*

1. $q \equiv d \equiv 3 \pmod 4$.
2. *For $\ell \in \{q, d\}$ and every $v \mid \ell$,*
$$e(v/\ell) = 2, \qquad \bar{v} \neq v.$$
3. *For $v \mid q$, $\sigma \in D_v$ and every embedding $\tau : E \hookrightarrow \mathbb{C}$,*
$$\tau \circ \sigma \in \Phi_{\mathsf{H}} \iff \tau \in \Phi_{\mathsf{H}}.$$
4. *For $v \mid d$, $1 \neq \sigma \in I_v$ and every such embedding,*
$$\tau \circ \sigma \in \Phi_{\mathsf{H}} \iff \tau \notin \Phi_{\mathsf{H}}.$$
5. *For $\ell \in \{q, d\}$ and every $v \mid \ell$, fix an algebraic closure of $\mathbb{Q}_\ell$ and a realisation of E_v in it. Let $E_{v,0}$ be the maximal unramified subextension of $E_v/\mathbb{Q}_\ell$. Then*
$$E_v = E_{v,0}(\sqrt{-\ell}) \subseteq E_{v,0}(\mu_\ell), \qquad [E_v : E_{v,0}] = 2.$$

Moreover, fix $0 < \varepsilon < 1/52$, $J \geq 1$ and $R \geq 0$, and put

$$\alpha_0 = \frac{\varepsilon}{5J}, \qquad X_{\varepsilon,J,R} = \exp\!\left(\max\left\{J,\, 1 + \frac{4R}{\alpha_0^2}\right\}\right).$$

For all data for which the concrete good-host requirement holds with these ε, J and with a scale $x \geq X_{\varepsilon,J,R}$, and all objects satisfying its conditions, one has

$$q > x^R, \qquad d > x^R.$$

The threshold $X_{\varepsilon,J,R}$ is the same for every host and for all member, lift and local indices.

Proof. Condition (Hr1) gives $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$, proving the first assertion. In particular $q \neq d$. Write $N = Q_S qd$.

By Theorem B.16, inertia at q is the image under α of

$$U_q = \{u \in (\mathbb{Z}/N\mathbb{Z})^\times : u \equiv 1 \pmod{Q_S d}\}.$$

Condition (Hr2) and the Chinese remainder theorem identify U_q with $\mathbb{F}_q^\times$, so its image is cyclic. Condition (Hn3) makes that image have exponent dividing 2. Condition (Fr1) gives $\epsilon_1(\alpha(u)) =$

(u/q). Choosing a nonsquare modulo q and 1 modulo $Q_S d$ shows that the image is nontrivial. Thus it has order 2.

At d, the same cyclotomic formula and (Hr5) give

$$I_v = \alpha(U_d) \subseteq \{1, \iota_d\}, \qquad U_d = \{u : u \equiv 1 \pmod{Q_S q}\}.$$

A nonsquare modulo d, extended by 1 modulo $Q_S q$, has second sign -1 by (Hr4). Hence $I_v = \{1, \iota_d\}$. The Galois ramification identity $e(v/\ell) = |I_v|$ proves both ramification assertions. By item 1 of Lemma 22.6, every prime of E^+ above a divisor of N splits in E. Consequently $\bar{v} \neq v$ at both distinguished primes.

Since $d \equiv 3 \pmod 4$, the quadratic field K has discriminant $-d$. The relation $(-d/q) = 1$ and $q \neq d$ say that q splits in K. Thus every D_v at q restricts trivially to K, and in particular fixes s_d. This proves assertion 3. At d, the unique nonidentity inertia element is labelled ι_d. Condition (Hg2) gives

$$\iota_d(s_d) = \epsilon_2(\iota_d) s_d = -s_d.$$

Every embedding takes s_d to one of $i\sqrt{d}, -i\sqrt{d}$. Composing with ι_d exchanges these values, proving assertion 4.

We turn to assertion 5. The field E contains an element of square $-q$ by (Fr2), and the chosen s_d has square $-d$. Thus E_v contains $\sqrt{-\ell}$. The unramified field $E_{v,0}$ has uniformiser ℓ, so $X^2 + \ell$ is Eisenstein over it. Since the already proved ramification index is 2, both E_v and $E_{v,0}(\sqrt{-\ell})$ have degree 2 over $E_{v,0}$, and their containment is equality.

It remains to prove the inclusion in assertion 5, which follows from a finite sum. For an odd prime ℓ, write χ for the quadratic character on $\mathbb{F}_\ell^\times$ and choose a primitive ℓ-th root ζ. Put

$$t = \sum_{a \in \mathbb{F}_\ell^\times} \chi(a)\zeta^a, \qquad t^- = \sum_{a \in \mathbb{F}_\ell^\times} \chi(a)\zeta^{-a}.$$

Changing a to $-a$ gives $t^- = \chi(-1)t$. Changing a to ub in the product gives

$$tt^- = \sum_{u \in \mathbb{F}_\ell^\times} \chi(u) \sum_{b \in \mathbb{F}_\ell^\times} \zeta^{b(u-1)} = (\ell - 1) - \sum_{u \neq 0,1} \chi(u) = \ell.$$

Here the inner sum is $\ell - 1$ for $u = 1$ and -1 otherwise, and the nontrivial quadratic character has sum zero. Consequently $t^2 = \chi(-1)\ell = -\ell$ when $\ell \equiv 3 \pmod 4$. This calculation is valid in characteristic zero, including the fixed ℓ-adic closure. Therefore $\sqrt{-\ell} \in \mathbb{Q}_\ell(\mu_\ell)$, proving the inclusion and assertion 5.

For the uniform bounds, set $y = \log x$. The definition of $X_{\varepsilon,J,R}$ gives $y \geq J \geq 1$ and $y > 4R/\alpha_0^2$. The exponential series implies

$$e^{\alpha_0 y} \geq \frac{\alpha_0^2 y^2}{2} > 2Ry,$$

where the strict last inequality also holds for $R = 0$. The real number Y of (Hg6) satisfies $Y \geq x^{1/J} \geq e$. Therefore

$$\log q > \tfrac{1}{2} Y^{\varepsilon/5} \geq \tfrac{1}{2} x^{\alpha_0} > R \log x$$

and

$$\log d > \tfrac{1}{2} Y^{\varepsilon/5} (\log Y)^2 \geq \tfrac{1}{2} x^{\alpha_0} > R \log x.$$

Exponentiating proves both bounds. Every estimate uses only ε, J, R, so the threshold has the asserted uniformity. □

Lemma 22.6. *Fix data for which the concrete good-host requirement of Definition 11.4 holds, together with objects satisfying its conditions. Put $E = E_{\mathfrak{h}}$, $F = E^+$, $K = \mathbb{Q}(s_d)$ and $N = N_{\mathfrak{h}}$. Let φ_0 be the given embedding and Φ the given CM type,*

$$\Phi = \{\tau : E \hookrightarrow \mathbb{C} : \tau(s_d) = i\sqrt{d}\}.$$

Let c, ι and s denote the automorphisms labelled, respectively, by

$$((-1,-1),0), \qquad ((1,-1),0), \qquad ((-1,1),0).$$

Then:

1. *E/F is unramified at every finite place, and every prime of F above a rational prime dividing N splits in E.*

2. *Every prime divisor of the order of a root of unity in E divides N. Moreover ι fixes every root of unity, $s(\zeta) = \zeta^{-1}$, and*

$$N_{E/K}(\zeta) = \prod_{\tau \in \Phi} \tau(\zeta) = 1 \qquad (\zeta \in \mu(E)).$$

   In the norm equality, K is embedded in $\mathbb{C}$ by $\varphi_0|_K$.

3. *For $\zeta \in \mu(E)$, put*

$$d_\zeta = \begin{cases} 1+\zeta, & \zeta \neq -1, \\ s_d, & \zeta = -1. \end{cases}$$

   This is a nonzero element of E, and

$$d_\zeta = \zeta \bar{d}_\zeta, \qquad \mathrm{ord}_v(d_\zeta) = 0 \quad (v \nmid N), \qquad \prod_{\tau \in \Phi} \frac{\tau(d_\zeta)}{|\tau(d_\zeta)|} = 1.$$

4. *For every $u \in \mathcal{O}_E^\times$,*

$$\prod_{\tau \in \Phi} \frac{\tau(u)}{|\tau(u)|} = 1.$$

Proof. The normalization identifies c with complex conjugation. Its restriction to K is nontrivial. We use the cyclotomic inertia and decomposition descriptions of Theorem B.16, including their images in the specified subfield E.

For an odd prime $p \mid Q_S$, (Hr2) says that p splits in K. The prime q splits in K by (Hr1), and 2 splits because $d \equiv 7 \pmod 8$. Therefore c belongs to no decomposition group above any prime dividing $Q_S q$.

Consider a prime above d. Each element of its decomposition group in $E/\mathbb{Q}$ is represented by a unit u modulo N with

$$u \equiv d^a \pmod{Q_S q}$$

for some $a \geq 0$. If its label were c, (Fr1) would give

$$-1 = (u/q) = (d/q)^a = (-1)^a.$$

Here $(d/q) = -1$, since $(-d/q) = 1$ and $q \equiv 3 \pmod 4$. Thus a is odd. On the other hand, the A-component of c is zero, so (Hn2), with $16 \mid 2^{e+2} \mid Q_S$, gives $u \equiv \pm 1 \pmod{16}$. This

contradicts $u \equiv d^a \equiv 7 \pmod{16}$. Consequently c belongs to no decomposition group above any rational divisor of N. Every corresponding prime of F therefore splits in the quadratic extension E/F.

Outside N, $E/\mathbb{Q}$ is unramified, being a subextension of the cyclotomic field of level N. Hence E/F is unramified there too. At primes above N it is split, which proves item 1.

By (Hr5), inertia at d has image contained in $\{1, \iota\}$. By (Hr4), its second sign is the nontrivial quadratic character modulo d, so its image equals this group. In particular its ramification index is 2. Since $d \geq 7$, E cannot contain a primitive d-th root of unity: the subfield generated by such a root would have ramification index $d - 1 > 2$ at d. Thus the order of every root of unity in E is prime to d. The field generated by that root is unramified at d; therefore ι fixes it. Since $s = c\iota$, it follows that $s(\zeta) = \zeta^{-1}$.

If an odd prime $\ell \nmid N$ divided the order of a root of unity in E, then E would contain a primitive ℓ-th root. Its cyclotomic subfield ramifies at ℓ, contrary to the unramifiedness of $E/\mathbb{Q}$ there. The prime 2 already divides N. This proves the prime-support assertion.

The automorphism s is a nonidentity involution fixing K. The embeddings in Φ are exactly $\varphi_0 \circ g$ for $g \in \mathrm{Gal}(E/K)$: the Galois labels with second sign 1 fix s_d, and these embeddings have the specified value on s_d. Composition by s pairs them without fixed points. Their values on a root of unity are inverse pairs, so their product is 1. This product is $\varphi_0(N_{E/K}(\zeta))$, and injectivity of $\varphi_0|_K$ proves the norm assertion of item 2.

Suppose $\zeta \neq -1$. Then $1 + \zeta \neq 0$, and

$$\zeta\overline{(1+\zeta)} = \zeta(1 + \zeta^{-1}) = 1 + \zeta.$$

Let $v \nmid N$, and let p be its residue characteristic. Put $M = \mathrm{lcm}(2, \mathrm{ord}(\zeta))$. The prime-support assertion gives $p \nmid M$. Both ζ and -1 have order dividing M. Reduction is injective on these roots: if distinct M-th roots x, y had equal reductions, the geometric-sum identity

$$(x - y) \sum_{a=0}^{M-1} x^{M-1-a} y^a = x^M - y^M = 0$$

would force the sum to be zero in E; its reduction is $M\bar{y}^{M-1} \neq 0$, a contradiction. Thus ζ does not reduce to -1, and the integral element $1+\zeta$ has valuation zero at v. Composition by s pairs its phase factors into

$$\frac{1+z}{|1+z|}\frac{1+\bar{z}}{|1+\bar{z}|} = 1.$$

This proves item 3 for $\zeta \neq -1$.

For $\zeta = -1$, use $d_\zeta = s_d$. Its square is $-d$, so its valuation vanishes away from d. Its phase under every member of Φ is i. The surjection $A \to H_e$, with $|H_e| = 2^e$ and $e \geq 2$, implies $4 \mid |A|$, hence $4 \mid |\Phi| = 2|A|$. The product of these phases is therefore 1.

Finally take $u \in \mathcal{O}_E^\times$. The quotient $\zeta = u/\bar{u}$ is an algebraic integer unit, and all its conjugates have modulus one. It is a root of unity: the monic characteristic polynomials over $\mathbb{Q}$ of its positive powers have integral coefficients bounded by the binomial coefficients of degree $[E : \mathbb{Q}]$; only finitely many such polynomials, and hence finitely many roots, occur. Two positive powers therefore coincide.

Put $t = u/d_\zeta$. The equation in item 3 gives $t = \bar{t}$, so $t \in F^\times$. At an inert finite place of F, item 1 excludes residue characteristics dividing N, and item 3 gives $\mathrm{ord}(d_\zeta) = 0$. Since u is a unit and E/F is unramified, $\mathrm{ord}(t) = 0$ at that place of F. By Theorem B.17, the quadratic Artin character of E/F is trivial on finite local units; it is also trivial at split places. Its value

on every finite component of t is consequently 1. It is trivial on the principal idele t, and its infinite components are signs. Therefore

$$\prod_{\sigma: F \hookrightarrow \mathbb{R}} \operatorname{sgn} \sigma(t) = 1.$$

Multiplying this identity by the phase identity for d_ζ proves item 4. □

Proposition 22.7. *Let column data be given for items $\mathbf{r}, \chi_1, \mathcal{E}, \delta$ of Galois Ribet data over a number field E on $(\mathcal{R}, \pi', \mathcal{N})$ for some $\mathcal{N}$, with $\mathcal{E}^2 = \tilde{\delta}\mathcal{E}$, and let $K = \mathcal{O}[\ell^{-1}]$, $x' \in \mathcal{Z}'$ and $V = K_{x'}^{n_{\mathcal{R}}}$, on which $a \in \mathcal{R}$ acts by $a(x')$. Suppose:*

1. *the image $\mathcal{E}(x')V$ is a K-line, and, if $C \neq \emptyset$, $e_1^2 = e_1$ and the image $e_1(x')V$ is a K-line;*
2. *for every $0 \neq \eta \in \mathcal{E}(x')V$ there is $g \in G_E$ with $u(g)(x')\eta \neq \eta$;*
3. *for every $v \in C$, the K-subspace L_v of the space of functions $G_{E_v} \to V$ spanned by the coboundaries $g \mapsto (u(g)(x') - 1)m$ ($m \in V$), the functions $g \mapsto \alpha_{v,a}(g)(x')s$ ($1 \leq a \leq j_v$, $s \in e_1(x')V$) and the functions $g \mapsto \alpha_v^0(g)(x')s$ ($s \in \mathcal{E}(x')V$) satisfies*

$$\dim_K L_v \leq \dim_K B_v + j_v + \dim_K V^{G_{E_v}},$$

where B_v is the space of the coboundaries and $V^{G_{E_v}} = \{m \in V : u(g)(x')m = m \text{ for all } g \in G_{E_v}\}$.

Then $\operatorname{Hom}_{\mathcal{R}}(\mathcal{N}^{\mathrm{col}}, V) \neq 0$.

Proof. **Homomorphisms from data.** Let $\psi \colon \mathcal{N}_{\mathcal{E}} \to V$ be $\mathcal{R}$-linear and let $m_v, s_{v,a}, s_v^0 \in V$ ($v \in C$, $1 \leq a \leq j_v$) satisfy, for all v, a and $g \in G_{E_v}$,

$$\begin{gathered} \mathcal{E}m_v = 0, \quad e_1 s_{v,a} = s_{v,a}, \quad \mathcal{E}s_v^0 = \tilde{\delta}(x')s_v^0, \\ \psi(y(g)) = -(u(g) - 1)m_v + \delta \sum_a \alpha_{v,a}(g)s_{v,a} + \delta\, \alpha_v^0(g)s_v^0. \end{gathered} \tag{$*$}$$

The $\mathcal{R}$-linear map $\mathcal{N}_{\mathcal{E}} \oplus \mathcal{F} \to V$ given by ψ on $\mathcal{N}_{\mathcal{E}}$ and by $\epsilon_v \mapsto m_v$, $\epsilon_{v,a} \mapsto s_{v,a}$, $\epsilon_v^0 \mapsto s_v^0$ on the free module $\mathcal{F}$ kills the generators $\mathcal{E}\epsilon_v$, $(1 - e_1)\epsilon_{v,a}$, $(\tilde{\delta} - \mathcal{E})\epsilon_v^0$ and $(y(g), (u(g) - 1)\epsilon_v - \delta \sum_a \alpha_{v,a}(g)\epsilon_{v,a} - \delta\alpha_v^0(g)\epsilon_v^0)$ of Rel, by $(*)$; so it induces $\varphi \in \operatorname{Hom}_{\mathcal{R}}(\mathcal{N}^{\mathrm{col}}, V)$ with $\varphi \circ \iota^{\mathrm{col}} = \psi$ and the values $m_v, s_{v,a}, s_v^0$ on the classes of the symbols.

A kernel vector at each column place. Fix $0 \neq \eta \in \mathcal{E}V$ and, if $C \neq \emptyset$, $0 \neq s_1 \in e_1 V$ (hypothesis 1); if $C = \emptyset$ this paragraph and Case 1 are empty. For $v \in C$ consider the K-linear map

$$\Phi_v \colon V \oplus K^{j_v} \oplus K \to L_v, \qquad (m, (c_a), c_0) \mapsto \Big(g \mapsto \sum_a c_a\, \alpha_{v,a}(g)s_1 + c_0\, \alpha_v^0(g)\eta - (u(g) - 1)m\Big),$$

which takes values in L_v by definition of L_v. As $m \mapsto (g \mapsto (u(g) - 1)m)$ maps V onto B_v with kernel $V^{G_{E_v}}$, $\dim B_v = \dim V - \dim V^{G_{E_v}}$, and hypothesis 3 gives $\dim L_v \leq \dim V + j_v < \dim(V \oplus K^{j_v} \oplus K)$. So there is $p_v = (m_v^\circ, (c_{v,a}), c_{v,0}) \neq 0$ with $\Phi_v(p_v) = 0$, i.e.

$$\sum_a c_{v,a}\, \alpha_{v,a}(g)s_1 + c_{v,0}\, \alpha_v^0(g)\eta = (u(g) - 1)m_v^\circ \qquad (g \in G_{E_v}). \tag{$**$}$$

Since $\mathcal{E}^2 = \tilde{\delta}\mathcal{E}$ and $\eta \in \mathcal{E}V$, $\mathcal{E}\eta = \tilde{\delta}(x')\eta$; since e_1 is idempotent when $C \neq \emptyset$, $e_1 s_1 = s_1$.

Case 1: $\mathcal{E}m^\circ_{v_0} = 0$ for some $v_0 \in C$. Take $\psi = 0$; at v_0 put $m_{v_0} = \delta m^\circ_{v_0}$, $s_{v_0,a} = c_{v_0,a}s_1$, $s^0_{v_0} = c_{v_0,0}\eta$, and all other values 0. Then $\mathcal{E}m_{v_0} = 0$, $e_1 s_{v_0,a} = s_{v_0,a}$, $\mathcal{E}s^0_{v_0} = \tilde\delta(x')s^0_{v_0}$, and the last relation of $(*)$ at v_0 is δ times $(**)$, while at the other places it reads $0 = 0$. The resulting φ is non-zero: if $m^\circ_{v_0} \neq 0$ it sends ϵ_{v_0} to $\delta m^\circ_{v_0} \neq 0$; otherwise either some $c_{v_0,a} \neq 0$, and then φ sends $\epsilon_{v_0,a}$ to $c_{v_0,a}s_1 \neq 0$, or $c_{v_0,0} \neq 0$, and then φ sends $\epsilon^0_{v_0}$ to $c_{v_0,0}\eta \neq 0$.

Case 2: $\mathcal{E}m^\circ_v \neq 0$ for every $v \in C$. As $\mathcal{E}V = K\eta$, $\mathcal{E}m^\circ_v = t_v\eta$ with $t_v \in K^\times$; replacing p_v by $t_v^{-1}p_v$ we may assume $\mathcal{E}m^\circ_v = \eta$. Put $\theta = \delta/\tilde\delta(x') \in K^\times$. Choose $w \in V$ with $\mathcal{E}w = \theta\eta$ (possible as $\mathcal{E}V = K\eta$) and let $\psi(n) = n(x')w$ for $n \in \mathcal{N}_\mathcal{E} \subseteq \mathcal{R}$; it is $\mathcal{R}$-linear, and $\psi(y(g)) = (u(g)-1)\mathcal{E}w = \theta(u(g)-1)\eta$. Put $m_v = \delta m^\circ_v - \theta\eta$, $s_{v,a} = c_{v,a}s_1$, $s^0_v = c_{v,0}\eta$. Then $\mathcal{E}m_v = \delta\eta - \theta\tilde\delta(x')\eta = 0$, $e_1 s_{v,a} = s_{v,a}$, $\mathcal{E}s^0_v = \tilde\delta(x')s^0_v$, and by $(**)$

$$\begin{aligned}&-(u(g)-1)m_v + \delta\sum_a c_{v,a}\alpha_{v,a}(g)s_1 + \delta c_{v,0}\alpha^0_v(g)\eta\\ &\quad= -(u(g)-1)(\delta m^\circ_v - \theta\eta) + \delta(u(g)-1)m^\circ_v = \theta(u(g)-1)\eta = \psi(y(g)),\end{aligned}$$

which is $(*)$. By hypothesis 2 there is $g \in G_E$ with $(u(g)-1)\eta \neq 0$, so $\varphi(\iota^{\mathrm{col}}(y(g))) = \psi(y(g)) = \theta(u(g)-1)\eta \neq 0$ and $\varphi \neq 0$. (If $C = \emptyset$ we are in this case.)

The two cases are exhaustive, which proves the claim. □

Theorem 22.8. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records, budget data having (Lz1), and inert budget data having (Iq1) and (Iq2). Then the budget data have (Lz3). More precisely, if $C \geq 1$ is a constant for each of (Lz1), (Iq1) and (Iq2), then for all large members with finite Sha lengths*

$$\sum_{\ell \text{ of inert type}} \log\ell \cdot \mathrm{la}_{x,i}(\ell) \leq 120\, C^3\, f\, m\, b\, x^{2\varepsilon}.$$

Proof. **Thresholds.** Let $C \geq 1$ be a constant for (Lz1), (Iq1), (Iq2) and x_0' a common threshold. As $\varepsilon > 0$ there is $x_0 \geq \max(x_0', 1)$ such that every real $x \geq x_0$ has, with $L = x^\varepsilon$, $L \geq \log(3(C+1)) + 1$. Fix such an x with $x > x_1$ and a member $i \in I(x)$ with finite Sha lengths; (Lz1), (Iq1), (Iq2) apply. Then $L \geq 1$, $\log 3, \log C, \log(C+1) \leq L$, and we put $Y = f\,m\,b\,L^2$, $Q = n\,t^2(\varrho + t)$, $\lambda_\ell = 1 + \log_\ell(H+t)$.

Consequences of (Lz1) and (Iq1). As $1 \leq m \leq t \leq Q\,L^2$, the first display of (Lz1) gives $\ell^* \leq C\,m\,b/(Q\,L^2) \leq C\,b$, so $\log\ell^* \leq 2L$; as $H \leq C\,b$ and $t \leq b$, $\log(H+t) \leq \log(C+1)+L \leq 2L$. From (Iq1)(1): $\log\ell_\mathrm{A} + 2 \leq (3+\log\ell_\mathrm{A})^2 \leq L$, $\varrho/\ell_\mathrm{A} \leq 2m/L$, $\varrho\, b^\circ \leq \varrho\, b^\circ \ell_\mathrm{A}/2 \leq m\,b/2$ and $w^\circ + \eta^\circ \leq 11 b^\circ$. Two elementary sums are used:

$$\sum_{p \leq y} \frac{\log p}{p} \leq 1 + \frac{(\log y)^2}{2} \quad (y \geq 2), \qquad \sum_{k \geq N} \frac{\log k}{k^2} \leq \frac{2(\log N + 2)}{N} \quad (N \geq 2 \text{ an integer}),$$

and $u \mapsto (\log u + 2)/u$ is decreasing on $[1,\infty)$ (its derivative is $-(1+\log u)/u^2$). In particular $\sum_{p \leq \ell^*} \log p/p \leq 1 + 2L^2 \leq 3L^2$.

The split. By (Iq2), for every prime ℓ of inert type

$$\log\ell \cdot \mathrm{la}_{x,i}(\ell) \leq C\, f \log\ell\Big(Q\lambda_\ell + \frac{m\,H}{\ell}\Big) + C\, f\, \varrho \log\ell \cdot A(\ell),$$

and both summands are non-negative. We bound the sums of the two summands over the primes of inert type, first those with $\ell \leq \ell^*$, then the exceptional ones with $\ell > \ell^*$.

First summand, $\ell \le \ell^*$. Since $\log\ell \cdot \log_\ell(H+t) = \log(H+t)$, the first summand is $C\,f(Q(\log\ell + \log(H+t)) + m\,H\log\ell/\ell)$. Summed over all primes $p \le \ell^*$ (at most ℓ^* of them): $C\,f\,Q\,\ell^* \cdot 4L \le C\,f\,Q \cdot \frac{C\,m\,b}{Q\,L^2} \cdot 4L \le 4C^2Y$, and $C\,f\,m \cdot C\,b \cdot 3L^2 = 3C^2Y$. Total at most $7C^2Y$.

First summand, $\ell > \ell^*$. Such ℓ lies in $\mathcal{P}^{\mathrm{ex}}_{x,i}$, so $\ell \le 3b$ by (Lz1) and $\log\ell \le \log 3 + L \le 2L$; as $\ell > \ell^* \ge 3$, $\log\ell > 1$ and $\log_\ell(H+t) \le 2L$; $H/\ell \le C\,b/\ell^*$. With $m \le Q$ and $C, L \ge 1$: $\log\ell \cdot C\,f(Q(1+2L) + C\,m\,b/\ell^*) \le 2L \cdot C\,f \cdot 3C\,L\,Q(1+b/\ell^*)$. There are at most $|\mathcal{P}^{\mathrm{ex}}_{x,i}|$ such primes, and the second display of (Lz1) gives a total of at most $6C^2L^2f \cdot C\,m\,b = 6C^3Y$.

Second summand: the long-orbit primes. Let $\ell \in \mathcal{P}^{\mathrm{lo}}_{x,i}$ be of inert type; by (Iq1)(2), $5 \le \ell < \ell_{\mathrm{A}} \le \ell^*$. Here $\varrho\log\ell \cdot A(\ell)$ is the sum of $\varrho H\log\ell/(\ell_{\mathrm{A}}(\ell-1))$, $\varrho(w^\circ + S^\circ + \eta^\circ + 1)(3 + \log\ell_{\mathrm{A}})\log\ell$ and $\varrho L\log\ell$. For $\ell \ge 5$, $\frac{1}{\ell-1} \le \frac{5}{4\ell}$, so $\sum_{5\le p<\ell_{\mathrm{A}}} \frac{\log p}{p-1} \le \frac{5}{4}(1 + \frac{(\log\ell_{\mathrm{A}})^2}{2}) \le (3+\log\ell_{\mathrm{A}})^2 \le L$, and $\sum_{p<\ell_{\mathrm{A}}} \log p \le \ell_{\mathrm{A}}\log\ell_{\mathrm{A}}$. Hence the three parts sum over these primes to at most

$$\varrho\frac{H}{\ell_{\mathrm{A}}}L \le 2b \cdot 2m = 4m\,b, \qquad 11\,\varrho\,b^\circ\ell_{\mathrm{A}}(3+\log\ell_{\mathrm{A}})^2 \le 11\,m\,b\,L,$$
$$\varrho\,L\,\ell_{\mathrm{A}}\log\ell_{\mathrm{A}} \le \varrho\,b^\circ\ell_{\mathrm{A}}\log\ell_{\mathrm{A}} \le m\,b\,L,$$

using $H \le 2b$, $\varrho L \le 2m\ell_{\mathrm{A}}$, $w^\circ + S^\circ + \eta^\circ + 1 \le 11b^\circ$, $\varrho b^\circ\ell_{\mathrm{A}} \le mb$, $L \le b^\circ$ and $\log\ell_{\mathrm{A}} \le L$. Total at most $16\,m\,b\,L^2$.

Second summand: the other primes up to ℓ^*. Let $\ell \le \ell^*$ be of inert type, $\ell \notin \mathcal{P}^{\mathrm{lo}}_{x,i}$; then $\varrho\log\ell\cdot A(\ell)$ is the sum of the four non-negative terms $\varrho H\log\ell/\ell^2$, $\varrho(w^\circ+\eta^\circ)\log\ell/\ell$, $\varrho(S^\circ+L)\log\ell$ and $\varrho\eta^\circ\beta(\ell)\log\ell$. (i) The H-terms with $\ell \in \mathcal{P}^{\mathrm{so}}_{x,i}$: by (Iq1)(3), at most $H \cdot 4mL^2 \le 8\,m\,b\,L^2$. (ii) The H-terms with $\ell \notin \mathcal{P}^{\mathrm{so}}_{x,i}$: by (Iq1)(2) these ℓ satisfy $\ell \ge \ell_{\mathrm{A}}$, so they are at least $N = \lceil\ell_{\mathrm{A}}\rceil \ge 2$, and the second elementary sum with the monotonicity of $(\log u + 2)/u$ gives at most $\varrho H \cdot \frac{2(\log\ell_{\mathrm{A}}+2)}{\ell_{\mathrm{A}}} \le 2b \cdot 2L \cdot \frac{2m}{L} = 8\,m\,b$. (iii) The thin terms: at most $\varrho \cdot 11b^\circ \cdot 3L^2 \le \frac{33}{2}m\,b\,L^2$. (iv) The spread terms: at most $\varrho(S^\circ + L)\ell^*\log\ell^* \le 2mb \cdot 2L = 4\,m\,b\,L$. (v) The band terms: if $\beta(\ell) = 1$ and $\ell \ge c_{\mathrm{bd}}$, (Iq1)(4) gives $\varrho\eta^\circ\log\ell \le 16\,m\,b\log\ell/\ell$, which sums to at most $48\,m\,b\,L^2$; if $\ell < c_{\mathrm{bd}}$, then $\varrho\eta^\circ \le 4mb$ and $\sum_{p<c_{\mathrm{bd}}}\log p \le c_{\mathrm{bd}}\log\max(c_{\mathrm{bd}},1) \le C\log C \le C\,L$ (no prime lies below c_{bd} if $c_{\mathrm{bd}} \le 2$), so these sum to at most $4C\,m\,b\,L$. Total at most $(85+4C)\,m\,b\,L^2$.

Second summand: the exceptional primes above ℓ^*. Such ℓ is not long-orbit ($\mathcal{P}^{\mathrm{lo}}$-primes of inert type lie below $\ell_{\mathrm{A}} \le \ell^*$), so with $\ell > \ell^* \ge 3$ and $\beta \le 1$, $A(\ell) \le 1 + H/\ell^* + w^\circ + \eta^\circ + S^\circ + L$, and $\log\ell \le 2L$. By (Iq1)(5) these terms sum to at most $2L \cdot C\,m\,b$.

Total. The second summands sum to at most $C\,f\,(16 + 85 + 4C + 2C)\,m\,b\,L^2 \le 107\,C^2\,Y$. Adding the first summands, $\sum\log\ell \cdot \mathrm{la}_{x,i}(\ell) \le (7C^2 + 6C^3 + 107C^2)\,Y \le 120\,C^3\,f\,m\,b\,x^{2\varepsilon}$ for every real $x \ge x_0$ with $x > x_1$ and every member with finite Sha lengths. This is (Lz3). □

Theorem 22.9. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data and local bound records, and suppose that $\mathcal{F}$ has budget data with the properties (Lz1)–(Lz5). Then the local bound records have the local budget (Lq7). More precisely, if $C \ge 1$ is a constant for each of (Lz1)–(Lz4), then for all large members with finite Sha lengths*

$$\sum_{\ell \in P_{x,i}\setminus G_{x,i}} \log\ell \cdot \mathrm{la}_{x,i}(\ell) \le 19\,C^3\,f\,m\,b\,x^{2\varepsilon}.$$

Proof. **Thresholds.** Let $C \ge 1$ be a constant for each of (Lz1)–(Lz4) and x_0' a common threshold for (Lz1)–(Lz5). As $\varepsilon > 0$, there is $x_0 \ge \max(x_0', 1)$ such that every real $x \ge x_0$ satisfies, with $L = x^\varepsilon$: $L \ge \log(3(C+1)) + 1$, $\log x \le L$ and $x^{C+\varepsilon} \le e^L$ (indeed $L \to \infty$, and $(C+\varepsilon)\log x/x^\varepsilon \to 0$). Fix $x \ge x_0$ with $x > x_1$ and a member $i \in I(x)$ with finite Sha lengths; then (Lz1)–(Lz5) apply. We have $L \ge 1$, $b = e^L$, $Y = f\,m\,b\,L^2$, and $\log 3,\ \log C,\ \log(C+1) \le L$.

Two consequences of (Lz1). Since $1 \le m \le t \le n\,t^2(\varrho+t)L^2$, the first display of (Lz1) gives $\ell^* \le C\,m\,b/(n\,t^2(\varrho+t)L^2) \le C\,b$, hence $\log \ell^* \le \log C + L \le 2L$. Since $H \le C\,b$ and $t \le b$, $\log(H+t) \le \log(C+1) + L \le 2L$.

The split. The types partition $P_{x,i} \setminus G_{x,i}$, so the sum is the sum of the four partial sums $\Sigma_{\mathrm{sm}}, \Sigma_{\mathrm{in}}, \Sigma_{\mathrm{sp}}, \Sigma_{\mathrm{lg}}$ over the primes of small, inert, split type and the large primes. By (Lz5), $\Sigma_{\mathrm{lg}} \le \sum_{k\ge 2} \log k/k^2 = -\zeta'(2) < 1 \le Y$ (the series is the classical value $0.9375\ldots$; $Y \ge 1$ as $f, m, b, L \ge 1$); by (Lz3), $\Sigma_{\mathrm{in}} \le C\,Y$.

Small type. For $\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i} \setminus G_{x,i}$, (Lz2) bounds $\log \ell \cdot \mathrm{la}_{x,i}(\ell)$ by the non-negative number $\log \ell \cdot C(f\,m\,b \log x + x^C L^2)$; summing over all of $\mathcal{P}^{\mathrm{sm}}_{x,i}$ and using $\sum_{\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i}} \log \ell \le C\,L$, $\log x \le L$ and $x^C L^3 = x^{C+\varepsilon} L^2 \le b\,L^2 \le f\,m\,b\,L^2$,

$$\sum_{\ell \in \mathcal{P}^{\mathrm{sm}}_{x,i} \setminus G_{x,i}} \log \ell \cdot \mathrm{la}_{x,i}(\ell) \le C^2\big(f\,m\,b\,L^2 + x^C L^3\big) \le 2C^2\,Y.$$

The remaining primes of small type lie in $\mathcal{P}^{\mathrm{rm}}_{x,i}$, which has at most two elements, each with $\log \ell \le L$ and $\mathrm{la}_{x,i}(\ell) \le C\,f\,m\,b$; their contribution is at most $2C\,f\,m\,b\,L \le 2C\,Y$. So $\Sigma_{\mathrm{sm}} \le 4C^2 Y$.

Split type up to the cut-off. For ℓ of split type with $\ell \le \ell^*$, (Lz4) and $\log \ell \cdot \log_\ell(H+t) = \log(H+t)$ give

$$\log \ell \cdot \mathrm{la}_{x,i}(\ell) \le C\,f\Big(n\,t^2(\varrho+t)\big(\log \ell + \log(H+t)\big) + m\,H\,\frac{\log \ell}{\ell}\Big),$$

a non-negative bound, which we sum over all primes $p \le \ell^*$. There are at most ℓ^* of them, so the first part sums to at most $C\,f\,n\,t^2(\varrho+t)\,\ell^*(\log \ell^* + \log(H+t)) \le C\,f\,n\,t^2(\varrho+t) \cdot \frac{C\,m\,b}{n\,t^2(\varrho+t)L^2} \cdot 4L \le 4C^2\,Y$. For the second part,

$$\sum_{p \le \ell^*} \frac{\log p}{p} \le \sum_{k=2}^{\lfloor \ell^* \rfloor} \frac{\log k}{k} \le 1 + \frac{(\log \ell^*)^2}{2} \le 1 + 2L^2 \le 3L^2,$$

so the second part is at most $C\,f\,m \cdot C\,b \cdot 3L^2 = 3C^2\,Y$. These primes contribute at most $7C^2 Y$.

Exceptional primes of split type. Let ℓ be of split type with $\ell > \ell^*$; then $\ell \in \mathcal{P}^{\mathrm{ex}}_{x,i}$, so $\ell \le 3b$ and $\log \ell \le \log 3 + L \le 2L$; as $\ell > \ell^* \ge 3$, $\log \ell > 1$ and $\log_\ell(H+t) \le \log(H+t) \le 2L$; and $H/\ell \le C\,b/\ell^*$. With $Q = n\,t^2(\varrho+t) \ge m$, (Lz4) gives

$$\log \ell \cdot \mathrm{la}_{x,i}(\ell) \le 2L \cdot C\,f\Big(Q(1+2L) + \frac{C\,m\,b}{\ell^*}\Big) \le 2L \cdot C\,f \cdot 3C\,L\,Q\Big(1 + \frac{b}{\ell^*}\Big) = 6C^2L^2 f\,Q\Big(1 + \frac{b}{\ell^*}\Big).$$

There are at most $|\mathcal{P}^{\mathrm{ex}}_{x,i}|$ such primes, and by the second display of (Lz1) their total is at most $6C^2L^2 f \cdot C\,m\,b = 6C^3\,Y$.

Total. $\sum \log \ell \cdot \mathrm{la}_{x,i}(\ell) \le (1 + 4C^2 + C + 7C^2 + 6C^3)\,Y \le 19C^3\,Y$, for every real $x \ge x_0$ with $x > x_1$ and every member $i \in I(x)$ with finite Sha lengths. This is (Lq7) with the constant $19C^3$ and the threshold x_0. □

Theorem 22.10. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records and Ribet records, and let Galois Ribet records for $\mathcal{F}$ have (Gd8). Then:*

1. *the Ribet records have the block bounds (Rf4);*
2. *if the Galois Ribet records also have (Gd9), the Ribet records have the determinant property (Rf1);*

3. for all (x,i,j,w,r,π) as in (Gd8), with $t=t_{x,i}$, $\ell=\ell_{x,i}(w)$ and $n_{\mathcal{R},0}$ the size of block 0,

$$\sum_{k=0}^{t}\mathrm{ls}_k(r,\pi)=\sum_{k=0}^{t}\kappa_k+\sum_{v\in S_\ell}\sum_{k=0}^{t}\lambda_k(v)+t\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)+2\,(n_{\mathcal{R},0}+t-1)\,\nu(\delta);$$

consequently, if the local contributions are the loss sums, $\mathrm{lc}_k(r,\pi)=\mathrm{ls}_k(r,\pi)$, and the right side is at most $\mathrm{lt}(r)$ for all large members with finite Sha lengths and all such w,r,π, then the Ribet records have (Rf4) and (Rf5).

Proof. Let $x^{(8)}$ be a threshold for (Gd8) and, in item 2, $x^{(9)}$ one for (Gd9); put $x_0=x^{(8)}$, respectively $x_0=\max(x^{(8)},x^{(9)})$. Fix a real $x\geq x_0$ with $x>x_1$, a member $i\in I(x)$ with finite Sha lengths, $1\leq j\leq m$, $w\in W_{x,i}$ with $\ell=\ell_{x,i}(w)\notin G_{x,i}$, $r\in R_{x,i}(j,w)$ and $\pi\in Z_r$; write $E=E_{\mathfrak{h}_{x,i}}$, $t=t_{x,i}$, $\mathcal{O}=\mathcal{O}_r$, $\mathcal{R}=\mathcal{R}_{r,\pi}$, $\mathcal{N}=\mathcal{N}_{r,\pi}$.

Item 1. By (Gd8) the Galois Ribet data on $(\mathcal{R},\pi',\mathcal{N})$ have (Gd1)–(Gd7) and E has no real place; $\mathcal{N}$ has a presentation, so it is finitely generated. Theorem 22.11 gives, for $k=0$, $\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_0)\leq\mathrm{ls}_0(r,\pi)+\mathrm{nl}\,\mathrm{Sel}_0(r,\pi)\leq\mathrm{lc}_0(r,\pi)+\mathrm{sl}(r,\pi)$, using $\mathrm{ls}_0\leq\mathrm{lc}_0$ and $\mathrm{nl}\,\mathrm{Sel}_0\leq\mathrm{sl}$ from (Gd8); for $k=1$, $\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_1)\leq\mathrm{nl}\,\mathrm{Hom}_{\mathrm{ur}}(G_E,\mathcal{O}[\ell^{-1}]/\mathcal{O})+\mathrm{lc}_1(r,\pi)$; for $2\leq k\leq t$, $\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_k)\leq\mathrm{len}_\ell(E,k-1)+\mathrm{lc}_k(r,\pi)$. These are the three inequalities of (Rf4). The right sides are finite: $\mathrm{sl}(r,\pi)$ and $\mathrm{lc}_k(r,\pi)$ are real numbers; $\mathrm{Hom}_{\mathrm{ur}}$ has finite length by Lemma 13.15, as E has no real place; $\mathrm{len}_\ell(E,k-1)<\infty$ for $1\leq k-1<t$ because the member has finite Sha lengths. So the modules $\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_k)$ have finite length, and (Rf4) holds with the threshold $x^{(8)}$.

Item 2. By (Gd9), the $\mathcal{O}$-module $\mathcal{D}_{r,\pi}$ contains 1 and is closed under products, and hypothesis (3) of Lemma 22.14 holds for the representation $\mathbf{r}$ of the data (in the role of the homomorphism of the lemma); hypothesis (2) of that lemma holds with the coefficient algebra $\mathbb{T}'$ of the data: by the definition of Galois Ribet data $\mathcal{R}$ is the $\mathbb{T}'$-span of $\mathbf{r}(G_E)$ and each $g\mapsto\mathbf{r}(g)(x')$ is continuous, and $\mathbb{T}'\subseteq\mathcal{D}_{r,\pi}$ by (Gd9). So the determinant algebra satisfies the determinant condition in every degree, in particular in degree n_{gen}, and by (Gd9) $\widehat{Z}_r\setminus Z_r$ is detected by the descent functions. This is (Rf1), with the threshold x_0.

Item 3. By the definition of the loss sums,

$$\sum_{k=0}^{t}\mathrm{ls}_k=\sum_{k=0}^{t}\kappa_k+\sum_{k=0}^{t}\sum_{v\in S_\ell}\lambda_k(v)+\sum_{k=1}^{t}\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)+2n_{\mathcal{R},0}\nu(\delta)+\sum_{k=2}^{t}2\nu(\delta),$$

and the last three sums are $t\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)$ and $2(n_{\mathcal{R},0}+t-1)\nu(\delta)$. If $\mathrm{lc}_k=\mathrm{ls}_k$, then (Gd8) holds in its clause $\mathrm{lc}_k\geq\mathrm{ls}_k$, so item 1 gives (Rf4), and $\sum_k\mathrm{lc}_k(r,\pi)=\sum_k\mathrm{ls}_k(r,\pi)\leq\mathrm{lt}(r)$ is (Rf5). □

Theorem 22.11. *Let E be a number field, ℓ a prime, and let Galois Ribet data over E on $(\mathcal{R},\pi',\mathcal{N})$, with $t+1$ blocks, have the properties (Gd1)–(Gd7), where $\mathcal{N}$ is finitely generated. Then for every $0\leq k\leq t$ and $\varphi\in\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_k)$ the function c_φ is a continuous 1-cocycle of G_E with values in $\mathrm{Cs}_k(u)$, and, with* nl *the normalised length,*

$$\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_0)\leq\mathrm{ls}_0+\mathrm{nl}\,\mathrm{Sel}_0,$$
$$\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_1)\leq\mathrm{ls}_1+\mathrm{nl}\,\mathrm{Hom}_{\mathrm{ur}}(G_E,\mathcal{O}[\ell^{-1}]/\mathcal{O}),$$

and, if E has no real place,

$$\mathrm{nl}\,\mathrm{Hom}_{\mathcal{R}}(\mathcal{N},\mathrm{Cs}_k)\leq\mathrm{ls}_k+\mathrm{len}_\ell(E,k-1)\qquad(2\leq k\leq t),$$

all inequalities in $[0,\infty]$.

Proof. Write $n_k = n_{\mathcal{R},k}$. Each Cs_k is a left $\mathcal{R}$-module through ρ_k, the scalars $\mathcal{O}$ are central in $\mathcal{R}$, and $\mathrm{Cs}_k(u)$ is Cs_k with g acting by $u(g)$ in the sense of Lemma 22.12.

Step 0: the Ribet cocycles are continuous cocycles. For each $x' \in \mathcal{Z}'$ the set $\mathbf{r}(G_E)(x')$ is compact in $\mathrm{GL}_{n_\mathcal{R}}(K)$, hence contained in $\varpi^{-a}\mathrm{M}_{n_\mathcal{R}}(\mathcal{O})$ for some a; as $\mathcal{Z}'$ is finite and the elements of $\mathbb{T}'$ are $\mathcal{O}$-valued, the component at each x' of an element $\sum_h f_h\mathbf{r}(h)$ ($f_h \in \mathbb{T}'$) of $\mathcal{R}$, the $\mathbb{T}'$-span of $\mathbf{r}(G_E)$, lies in the $\mathcal{O}$-span of $\mathbf{r}(G_E)(x')$; so $\mathcal{R}$ is a submodule of a finitely generated $\mathcal{O}$-module, hence finitely generated and free, and its ϖ-adic topology is the topology induced from $\prod_{x'} \mathrm{M}_{n_\mathcal{R}}(K)$ (a lattice in a finite-dimensional K-space). So $g \mapsto \mathbf{r}(g)$, and with χ_1 also $g \mapsto u(g)$ and $g \mapsto y(g)$, are continuous into $\mathcal{R}$. The left ideal $\mathcal{N}_\mathcal{E}$ is a finitely generated $\mathcal{O}$-module and, by the Artin–Rees lemma, its ϖ-adic topology is induced from $\mathcal{R}$; so $y\colon G_E \to \mathcal{N}_\mathcal{E}$ is continuous for the ϖ-adic topology. Let $\varphi \in \mathrm{Hom}_\mathcal{R}(\mathcal{N}, \mathrm{Cs}_k)$ and $\psi = \varphi \circ \iota \in \mathrm{Hom}_\mathcal{R}(\mathcal{N}_\mathcal{E}, \mathrm{Cs}_k)$. Since $\mathcal{N}$ is finitely generated, $\varphi(\mathcal{N})$ is a finitely generated submodule of $(K/\mathcal{O})^{n_k}$, killed by some ϖ^b; so ψ kills $\varpi^b\mathcal{N}_\mathcal{E}$, and $c_\varphi = \psi \circ y$ is locally constant. By Lemma 22.12(1), applied with $G = G_E$, the ring $\mathcal{R}$, $\mathcal{B} = \mathbb{T}'$ (central in $\mathcal{R}$; $f \in \mathbb{T}'$ acts on Cs_k as the scalar $f(\pi')$ by Definition 17.2), $r = \mathbf{r}$, $\chi = \chi_1$, the element $\mathcal{E}$ and $V = \mathrm{Cs}_k$, the function $c_\varphi = c_\psi$ is a 1-cocycle for $\mathrm{Cs}_k(u)$, and $\psi \mapsto c_\psi$ is injective and $\mathcal{O}$-linear on $\mathrm{Hom}_\mathcal{R}(\mathcal{N}_\mathcal{E}, \mathrm{Cs}_k)$. In particular X_k is the image of the $\mathcal{O}$-linear map $\Theta_k\colon \psi \mapsto [c_\psi]$ on the image J_k of $\iota^*\colon \varphi \mapsto \varphi \circ \iota$.

Step 1: the column kernel. The exact sequence $0 \to \ker \iota^* \to \mathrm{Hom}_\mathcal{R}(\mathcal{N}, \mathrm{Cs}_k) \to J_k \to 0$, the sequence $0 \to \ker\Theta_k \to J_k \to X_k \to 0$, additivity of length and (Gd6) give

$$\mathrm{nl}\,\mathrm{Hom}_\mathcal{R}(\mathcal{N}, \mathrm{Cs}_k) \le \kappa_k + \mathrm{nl}\ker\Theta_k + \mathrm{nl}\,X_k. \tag{22.2}$$

Step 2: coboundaries. For $k = 1$, (Gd1) gives $\rho_1(u(g)) = \chi_1(g)^{-1}\chi_1(g) = 1$: the action on $\mathrm{Cs}_1(u)$ is trivial, there are no non-zero coboundaries, and $\ker\Theta_1 = 0$ by the injectivity of Step 0. Let $k \ne 1$. By (Gd2), $\mathcal{E}^2 = \tilde\delta\mathcal{E}$ with $\tilde\delta \in \mathbb{T}'$, and $\mathcal{E}$ acts on Cs_k by $\rho_k(\mathcal{E}) = 0$. Put $\tau = \sum_h t_h\chi_1(h) \in \mathbb{T}'$. As $f \in \mathbb{T}'$ acts on Cs_k as the scalar $f(\pi')$, $\tilde\delta$ acts as δ and τ as $\tau(\pi') = \sum_h t_h(\pi')\chi_1(h) = \rho_1(\sum_h t_h\mathbf{r}(h)) = \rho_1(\mathcal{E}) = \delta$, by (Gd1), (Gd2) and because ρ_1 is a homomorphism with $\rho_1(t_h) = t_h(\pi')$. If $\psi \in \ker\Theta_k$, then $c_\psi(g) = u(g)v - v$ for some $v \in \mathrm{Cs}_k$, and Lemma 22.12(2), with $\mathcal{B} = \mathbb{T}'$ and $\tilde\delta$ in the role of its δ, gives $\tilde\delta\tau v = \delta^2 v = 0$. The element v is unique modulo the invariants $\mathrm{Cs}_k(u)^{G_E}$, so $\psi \mapsto v$ is a well-defined $\mathcal{O}$-linear map $\ker\Theta_k \to \mathrm{Cs}_k[\delta^2]/(\mathrm{Cs}_k[\delta^2] \cap \mathrm{Cs}_k(u)^{G_E})$; it is injective, because v determines c_ψ, which determines ψ. As $(K/\mathcal{O})[\delta^2] = \delta^{-2}\mathcal{O}/\mathcal{O} \cong \mathcal{O}/\delta^2\mathcal{O}$,

$$\mathrm{nl}\ker\Theta_k \le \mathrm{nl}\,\mathrm{Cs}_k[\delta^2] = n_k\,\nu(\delta^2) = 2\,n_k\,\nu(\delta) \qquad (k \ne 1),$$

with $n_k = 1$ for $k \ge 2$ by (Gd1).

Step 3: the Ribet classes away from ℓ. Let $x = [c] \in X_k$ with $c = c_\psi$. Then $u(\gamma) - 1 = \chi_1(\gamma)^{-1}(\mathbf{r}(\gamma) - \chi_1(\gamma))$.

(a) Let $w \notin S_\ell \cup \Sigma_\mathrm{T} \cup \Sigma_\mathrm{P}$ be finite and $\gamma \in I_w$. By (Gd3) $\mathbf{r}(\gamma) = 1$, so $\chi_1(\gamma) = \rho_1(\mathbf{r}(\gamma)) = 1$ by (Gd1), $u(\gamma) = 1$, $y(\gamma) = 0$ and $c(\gamma) = 0$. Hence $x|_{I_w} = 0$, for every k.

(b) Let $k \ge 1$ and v finite, $v \notin S_\ell$. For $\gamma \in I_v$, $\rho_k(u(\gamma)) = \chi_k(\gamma)\chi_1(\gamma)^{-1} = \chi_\mathrm{cyc}(\gamma)^{1-k} = 1$, since χ_cyc is unramified at v. So I_v acts trivially on $\mathrm{Cs}_k(u)$, hence $H^1(I_v, \mathrm{Cs}_k(u)) = \mathrm{Hom}_\mathrm{cont}(I_v, \mathrm{Cs}_k)$, and $x|_{I_v} = c|_{I_v}$ is a continuous homomorphism; also $\chi_k(\gamma) = \chi_1(\gamma)$.

(c) Let $k \ge 1$, $v \in \Sigma_\mathrm{P}$, $\gamma \in I_v$. By (Gd5), $p_v y(\gamma) = \chi_1(\gamma)^{-1}p_v(\mathbf{r}(\gamma) - \chi_1(\gamma))\mathcal{E} = 0$, and $p_v y(\gamma) \in \mathcal{N}_\mathcal{E}$, so $0 = \psi(p_v y(\gamma)) = \rho_k(p_v)\,c(\gamma)$; as $\rho_k(p_v)$ is a unit, $c(\gamma) = 0$. Hence $x|_{I_v} = 0$.

(d) Let $k \ge 1$, $v \in \Sigma_\mathrm{T}$, $\gamma \in I_v$. By (Gd4), $(\mathbf{r}(\gamma)-1)y(\gamma) = \chi_1(\gamma)^{-1}(\mathbf{r}(\gamma)-1)(\mathbf{r}(\gamma)-\chi_1(\gamma))\mathcal{E} = 0$, so $0 = \psi((\mathbf{r}(\gamma) - 1)y(\gamma)) = (\chi_k(\gamma) - 1)c(\gamma) = (\chi_1(\gamma) - 1)c(\gamma)$ by (b); in particular

$(\zeta_v-1)c(\gamma_v)=0$. By (b), $c|_{I_v}$ is a continuous homomorphism into the discrete ℓ-primary group Cs_k; its image is compact, hence a finite ℓ-group, so $c|_{I_v}$ factors through the maximal pro-ℓ quotient of I_v, which is topologically generated by the image of γ_v (Gd4); a continuous homomorphism from it into a discrete group is determined by its value at that generator. Hence $x|_{I_v}\mapsto c(\gamma_v)$ is an injective $\mathcal{O}$-linear map from the image of X_k in $H^1(I_v,\mathrm{Cs}_k(u))$ into $\mathrm{Cs}_k[\zeta_v-1]\cong\mathcal{O}/(\zeta_v-1)\mathcal{O}$ ($n_k=1$, and $\zeta_v\neq 1$ by (Gd4)). So that image has normalised length at most $\nu(\zeta_v-1)$.

Step 4: the local conditions. Let $\Pi_0=S_\ell$ and $\Pi_k=S_\ell\cup\Sigma_{\mathrm{T}}$ for $k\geq 1$; for $v\in S_\ell$ let $Q_v=H^1(G_{E_v},\mathrm{Cs}_k(u))/F_k(v)$ and for $v\in\Sigma_{\mathrm{T}}$ let $Q_v=H^1(I_v,\mathrm{Cs}_k(u))$, and let $\mathrm{res}\colon X_k\to\bigoplus_{v\in\Pi_k}Q_v$ be the map of restrictions, with components res_v. Then $X_k/\ker\mathrm{res}$ embeds into $\bigoplus_v\mathrm{res}_v(X_k)$, so by (Gd7) and Step 3(d)

$$\mathrm{nl}\,X_k\leq\mathrm{nl}\ker\mathrm{res}+\sum_{v\in S_\ell}\lambda_k(v)+[k\geq 1]\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1). \tag{22.3}$$

We identify $\ker\mathrm{res}$.

- $k=0$: an element of $\ker\mathrm{res}$ vanishes on I_w for every finite $w\notin S_\ell\cup\Sigma_{\mathrm{T}}\cup\Sigma_{\mathrm{P}}$ by Step 3(a) and lies in $F_0(v)$ at $v\in S_\ell$; so $\ker\mathrm{res}\subseteq\mathrm{Sel}_0$.
- $k=1$: $\mathrm{Cs}_1(u)=K/\mathcal{O}$ with trivial action, so $H^1(G_E,K/\mathcal{O})=\mathrm{Hom}_{\mathrm{cont}}(G_E,K/\mathcal{O})$. An element of $\ker\mathrm{res}$ vanishes on I_w for $w\notin S_\ell\cup\Sigma_{\mathrm{T}}\cup\Sigma_{\mathrm{P}}$ (Step 3(a)), for $w\in\Sigma_{\mathrm{P}}$ (Step 3(c)), for $w\in\Sigma_{\mathrm{T}}$ (definition of res), and for $w\in S_\ell$, because its restriction to G_{E_w} lies in $F_1(w)=H^1_{\mathrm{ur}}(E_w,K/\mathcal{O})$. So $\ker\mathrm{res}\subseteq\mathrm{Hom}_{\mathrm{ur}}(G_E,K/\mathcal{O})$.
- $k\geq 2$: by (Gd1), g acts on $\mathrm{Cs}_k(u)=K/\mathcal{O}=\mathcal{O}^\vee$ by $\chi_{\mathrm{cyc}}(g)^{1-k}$, so $\mathrm{Cs}_k(u)=\mathcal{O}^\vee(\chi_{\mathrm{cyc}}^{-(k-1)})$. An element of $\ker\mathrm{res}$ vanishes on I_w for every finite $w\notin S_\ell$ (Step 3(a), 3(c), and the definition of res at Σ_{T}) and restricts to 0 on G_{E_v} for $v\in S_\ell$ ($F_k(v)=0$). So $\ker\mathrm{res}\subseteq\mathrm{Sh}_{\mathcal{O}}(E,k-1)$ in the notation of Lemma 22.13, whose normalised length is $\mathrm{len}_\ell(E,k-1)$ when E has no real place.

Step 5: conclusion. Combining (22.2), Step 2, (22.3) and Step 4, and comparing with the definition of the loss sums ls_k: for $k=0$ the right side is $\kappa_0+2n_0\nu(\delta)+\sum_{v\in S_\ell}\lambda_0(v)+\mathrm{nl}\,\mathrm{Sel}_0=\mathrm{ls}_0+\mathrm{nl}\,\mathrm{Sel}_0$; for $k=1$ it is $\kappa_1+\sum_{v\in S_\ell}\lambda_1(v)+\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)+\mathrm{nl}\,\mathrm{Hom}_{\mathrm{ur}}=\mathrm{ls}_1+\mathrm{nl}\,\mathrm{Hom}_{\mathrm{ur}}$; for $k\geq 2$ it is $\kappa_k+2\nu(\delta)+\sum_{v\in S_\ell}\lambda_k(v)+\sum_{v\in\Sigma_{\mathrm{T}}}\nu(\zeta_v-1)+\mathrm{len}_\ell(E,k-1)=\mathrm{ls}_k+\mathrm{len}_\ell(E,k-1)$. A submodule has at most the length of the module, so the lengths of $\ker\mathrm{res}$ are bounded by those of Sel_0, $\mathrm{Hom}_{\mathrm{ur}}$ and $\mathrm{Sh}_{\mathcal{O}}(E,k-1)$; all steps hold in $[0,\infty]$. □

Lemma 22.12. *Let G be a group, $\mathcal{R}$ a ring, $\mathcal{B}$ a commutative ring with a ring homomorphism into the centre of $\mathcal{R}$ (through which $\mathcal{B}$ acts on every $\mathcal{R}$-module), $r\colon G\to\mathcal{R}^\times$ and $\chi\colon G\to\mathcal{B}^\times$ homomorphisms, and $u(g)=\chi(g)^{-1}r(g)$. Let $\mathcal{E}=\sum_{h\in S}t_h\,r(h)$ for a finite set $S\subseteq G$ and $t_h\in\mathcal{B}$, put $\tau=\sum_{h\in S}t_h\chi(h)\in\mathcal{B}$, and let*

$$y(g)=(u(g)-1)\mathcal{E}\quad(g\in G),\qquad\mathcal{N}_{\mathcal{E}}=\sum_{g\in G}\mathcal{R}\,y(g)\subseteq\mathcal{R}$$

(the Ribet cocycle *and the left ideal it generates). For a left $\mathcal{R}$-module V let $V(u)$ be V with $g\in G$ acting by $u(g)$.*

1. *The map $\varphi\mapsto c_\varphi$, $c_\varphi(g)=\varphi(y(g))$, is an injective $\mathcal{B}$-linear map*

$$\mathrm{Hom}_{\mathcal{R}}(\mathcal{N}_{\mathcal{E}},V)\to Z^1(G,V(u))$$

into the inhomogeneous 1-cocycles.

2. *Suppose $\mathcal{E}^2 = \delta\mathcal{E}$ for some $\delta \in \mathcal{B}$ and $\mathcal{E}$ acts as 0 on V. If c_φ is a coboundary, $c_\varphi(g) = (u(g)-1)v$ for some $v \in V$ and all g, then $\delta\tau\, v = 0$.*

Proof. **(1).** Since u is a homomorphism, $y(gh) = (u(g)u(h)-1)\mathcal{E} = (u(g)-1)\mathcal{E} + u(g)(u(h)-1)\mathcal{E} = y(g) + u(g)\,y(h)$. Applying the $\mathcal{R}$-linear map φ gives $c_\varphi(gh) = c_\varphi(g) + u(g)c_\varphi(h)$, the cocycle identity for $V(u)$. The map is $\mathcal{B}$-linear because $\mathcal{B}$ acts through the centre. It is injective because the $y(g)$ generate $\mathcal{N}_\mathcal{E}$ as a left $\mathcal{R}$-module, so φ is determined by its values on them.

(2). As $\sum_h t_h\chi(h)u(h) = \sum_h t_h r(h) = \mathcal{E}$,

$$(\mathcal{E}-\tau)\mathcal{E} = \sum_{h\in S} t_h\chi(h)(u(h)-1)\mathcal{E} = \sum_{h\in S} t_h\chi(h)\,y(h) \in \mathcal{N}_\mathcal{E},$$

and by $\mathcal{R}$-linearity and the hypothesis on c_φ,

$$\varphi\big((\mathcal{E}-\tau)\mathcal{E}\big) = \sum_h t_h\chi(h)(u(h)-1)v = (\mathcal{E}-\tau)v = -\tau v,$$

because $\mathcal{E}v = 0$. Since τ and δ are central and $\mathcal{E}^2 = \delta\mathcal{E}$, both $\mathcal{E}\cdot(\mathcal{E}-\tau)\mathcal{E}$ and $\delta\cdot(\mathcal{E}-\tau)\mathcal{E}$ equal $\delta(\delta-\tau)\mathcal{E}$. Applying φ and using $\mathcal{R}$-linearity twice,

$$\mathcal{E}\cdot\varphi\big((\mathcal{E}-\tau)\mathcal{E}\big) = \delta\cdot\varphi\big((\mathcal{E}-\tau)\mathcal{E}\big), \qquad \text{i.e.} \qquad -\tau\,\mathcal{E}v = -\delta\tau\, v.$$

The left side is 0 because $\mathcal{E}$ acts as 0 on V; hence $\delta\tau v = 0$. □

Lemma 22.13. *Let E be a number field without real place, ℓ a prime, $\mathcal{O}$ a coefficient ring for ℓ and $k \in \mathbb{Z}$. Let $\mathrm{Sh}_\mathcal{O}(E,k) \subseteq H^1\big(G_E, \mathcal{O}^\vee(\chi_{\mathrm{cyc}}^{-k})\big)$ be the $\mathcal{O}$-submodule of the classes x with $x|_{I_w} = 0$ for every finite place w of E not above ℓ and $x|_{G_{E_v}} = 0$ for every place v above ℓ. Then*

$$\mathrm{length}_\mathcal{O}\,\mathrm{Sh}_\mathcal{O}(E,k) = e_\mathcal{O}\,\mathrm{len}_\ell(E,k) \qquad \text{in } \mathbb{N}\cup\{\infty\};$$

in particular, when $\mathrm{len}_\ell(E,k)$ is finite, the normalised length of $\mathrm{Sh}_\mathcal{O}(E,k)$ is $\mathrm{len}_\ell(E,k)$.

Proof. Write $M = \mathcal{O}^\vee(\chi_{\mathrm{cyc}}^{-k})$, a discrete ℓ-primary $\mathcal{O}[G_E]$-module, and S_ℓ for the set of places above ℓ.

Step 1: inflation from G_{E,S_ℓ}. Let $H \subseteq G_E$ be the closed normal subgroup generated by the inertia groups of all finite places $w \notin S_\ell$ (all conjugates of the I_w). Since E has no real place, the fixed field of H is the maximal extension of E unramified outside S_ℓ, so $G_{E,S_\ell} = G_E/H$. The character χ_{cyc} is unramified at every finite $w \notin S_\ell$, so H acts trivially on M and M is a G_{E,S_ℓ}-module. The inflation–restriction sequence for continuous cohomology with discrete coefficients,

$$0 \to H^1(G_{E,S_\ell}, M) \xrightarrow{\ \mathrm{inf}\ } H^1(G_E, M) \to H^1(H, M) = \mathrm{Hom}_{\mathrm{cont}}(H, M),$$

is exact. Let c be a continuous cocycle of G_E with class x. For a finite $w \notin S_\ell$, I_w acts trivially on M, so $H^1(I_w, M) = \mathrm{Hom}_{\mathrm{cont}}(I_w, M)$ and $x|_{I_w} = 0$ means $c|_{I_w} = 0$. If γ acts trivially on M, then for every g

$$c(g\gamma g^{-1}) = c(g) + g\,c(\gamma) + g\gamma\,c(g^{-1}) = g\,c(\gamma) + \big(c(g) + g\,c(g^{-1})\big) = g\,c(\gamma),$$

because $c(g) + g\,c(g^{-1}) = c(1) = 0$. Hence if $c|_{I_w} = 0$ for all finite $w \notin S_\ell$, then c vanishes on all conjugates of these groups; as $c|_H$ is a continuous homomorphism (the cocycle identity with trivial action), its kernel is a closed subgroup containing them, hence contains H, and x

restricts to 0 on H. Conversely an inflated class vanishes on every $I_w \subseteq H$. So inflation identifies $H^1(G_{E,S_\ell}, M)$ with the classes of $H^1(G_E, M)$ that vanish on I_w for every finite $w \notin S_\ell$. For $v \in S_\ell$ the restriction of an inflated class to G_{E_v} is the restriction of the original class along $G_{E_v} \to G_E \to G_{E,S_\ell}$, which is the map $H^1(G_{E,S_\ell}, M) \to H^1(E_v, M)$ of Definition 7.1 (another choice of the decomposition group is conjugate and has the same kernel). Therefore inflation is an isomorphism of $\mathcal{O}$-modules

$$\mathrm{Sha}_{\mathcal{O}} := \ker\Big(H^1(G_{E,S_\ell}, M) \to \prod_{v \in S_\ell} H^1(E_v, M)\Big) \xrightarrow{\sim} \mathrm{Sh}_{\mathcal{O}}(E, k).$$

Step 2: change of coefficients. Let $d = [\mathcal{O} : \mathbb{Z}_\ell]$ and $b_1, \dots, b_d$ a $\mathbb{Z}_\ell$-basis of $\mathcal{O}$. Since χ_{cyc}^{-k} takes values in $\mathbb{Z}_\ell^\times$, the map $(a_i) \mapsto \sum_i b_i \otimes a_i$ is an isomorphism of discrete $\mathbb{Z}_\ell[G_{E,S_\ell}]$-modules $(\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))^d \cong M$. Continuous cohomology commutes with finite direct sums, compatibly with the restrictions to the G_{E_v}, so $\mathrm{Sha}_{\mathcal{O}} \cong \mathrm{Sha}^1_\ell(E,k)^d$ as $\mathbb{Z}_\ell$-modules and $\mathrm{length}_{\mathbb{Z}_\ell} \mathrm{Sha}_{\mathcal{O}} = d\,\mathrm{len}_\ell(E,k)$.

Step 3: lengths over $\mathcal{O}$ and over $\mathbb{Z}_\ell$. Let $f_{\mathcal{O}}$ be the degree of the residue field $\mathbb{F}_{\mathcal{O}}$ over $\mathbb{F}_\ell$, so $d = e_{\mathcal{O}} f_{\mathcal{O}}$. For an $\mathcal{O}$-module Y, $\mathrm{length}_{\mathbb{Z}_\ell} Y = f_{\mathcal{O}} \mathrm{length}_{\mathcal{O}} Y$ in $\mathbb{N} \cup \{\infty\}$: if $\mathrm{length}_{\mathcal{O}} Y$ is finite, a composition series over $\mathcal{O}$ has factors $\mathbb{F}_{\mathcal{O}}$, each of length $f_{\mathcal{O}}$ over $\mathbb{Z}_\ell$ (its $\mathbb{Z}_\ell$-submodules are its $\mathbb{F}_\ell$-subspaces), and length is additive; if it is infinite, there are arbitrarily long chains of $\mathcal{O}$-submodules, which are chains of $\mathbb{Z}_\ell$-submodules. With Steps 1 and 2,

$$f_{\mathcal{O}} \mathrm{length}_{\mathcal{O}} \mathrm{Sh}_{\mathcal{O}}(E,k) = d\,\mathrm{len}_\ell(E,k) = e_{\mathcal{O}} f_{\mathcal{O}} \mathrm{len}_\ell(E,k),$$

which gives the assertion after division by $f_{\mathcal{O}}$, and after a further division by $e_{\mathcal{O}}$ the statement on normalised lengths. □

Lemma 22.14. *Let $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$ be a Hecke lattice over a prime ℓ, $K = \mathcal{O}[\ell^{-1}]$, and $(\mathcal{Z}', \phi, (z_1, \dots, z_{n_z}), n_{\mathcal{R}}, \mathcal{R})$ a determinant algebra over $\mathbb{T}$. Let $\mathcal{D} = \{\sum_k (a_k \circ \phi)\, z_k : \ a_k \in \mathbb{T}\}$, an $\mathcal{O}$-module of functions $\mathcal{Z}' \to \mathcal{O}$. Let E be a number field and $r \colon G_E \to \mathcal{R}^\times$ a group homomorphism. Assume:*

1. *$\mathcal{D}$ contains the constant function 1 and is closed under products;*
2. *there is an $\mathcal{O}$-subalgebra $\mathbb{T}' \subseteq \mathcal{D}$ of the ring of functions $\mathcal{Z}' \to \mathcal{O}$ such that $\mathcal{R}$ is the $\mathbb{T}'$-span of $r(G_E)$, that is, $\mathcal{R} = \{\sum_{h \in S} f_h\, r(h) : \ S \subseteq G_E \text{ finite}, \ f_h \in \mathbb{T}'\}$ with $f \in \mathbb{T}'$ acting by $f(x')$ at x'; and $g \mapsto r(g)(x') \in \mathrm{GL}_{n_{\mathcal{R}}}(K)$ is continuous for every $x' \in \mathcal{Z}'$;*
3. *there is a finite set B of places of E such that for every finite place $w \notin B$ of E whose residue field has prime order, $r(\gamma)(x') = 1$ for all $\gamma \in I_w$ and $x' \in \mathcal{Z}'$, and the functions $x' \mapsto \sigma_j(r(\mathrm{Frob}_w)(x'))$, $1 \le j \le n_{\mathcal{R}}$, lie in $\mathcal{D}$.*

Then for every $g \in G_E$ and $1 \le j \le n_{\mathcal{R}}$ the function $x' \mapsto \sigma_j(r(g)(x'))$ lies in $\mathcal{D}$, and the determinant algebra satisfies the determinant condition in every degree $g \ge 1$.

Proof. **Step 1: $\mathcal{D}$ is closed in $K^{\mathcal{Z}'}$.** $\mathbb{T}$ is an $\mathcal{O}$-submodule of the finitely generated free module $\mathcal{O}^{\mathcal{Z}}$, hence finitely generated ($\mathcal{O}$ is noetherian), so $\mathcal{D}$, the image of $\mathbb{T}^{n_z}$ under $(a_k) \mapsto \sum_k (a_k \circ \phi) z_k$, is a finitely generated $\mathcal{O}$-module; it is the image of some $\mathcal{O}^d$ under a continuous map, hence compact, hence closed in the Hausdorff space $K^{\mathcal{Z}'}$.

Step 2: all g. Let $A \subseteq G_E$ be the set of g with $x' \mapsto \sigma_j(r(g)(x'))$ in $\mathcal{D}$ for all j. The maps $g \mapsto \sigma_j(r(g)(x'))$ are continuous (polynomials in the entries), so A is closed by Step 1. Since $r(hgh^{-1})(x')$ is conjugate to $r(g)(x')$ for every x', A is stable under conjugation. For w as in (3),

$r(\cdot)(x')$ is trivial on I_w, so every element of $\mathrm{Frob}_w I_w$ and every conjugate lies in A. Let $U \subseteq G_E$ be an open normal subgroup with fixed field L and $s \in G_E$. By the Chebotarev density theorem (Theorem B.18) the finite places of E unramified in L whose Frobenius lies in the conjugacy class of sU in $\mathrm{Gal}(L/E)$ have positive Dirichlet density; the places of residue degree at least 2 over $\mathbb{Q}$ have Dirichlet density 0 (the series $\sum_w \mathrm{N}w^{-\sigma}$ over them converges at $\sigma = 1$, as there are at most $[E:\mathbb{Q}]$ places above each rational prime p and each has norm at least p^2), and B is finite. So there is w as in (3), unramified in L, with a Frobenius element at w mapping to a conjugate of sU; by the stability of A under conjugation, $A \cap sU \neq \emptyset$. Thus A meets every coset of every open normal subgroup, so A is dense, and closed, so $A = G_E$.

Step 3: matrices over $\mathcal{R}$. By (1), $\mathcal{D}$ is a subring of the ring $K^{\mathcal{Z}'}$ of functions $\mathcal{Z}' \to K$: an $\mathcal{O}$-module containing 1 and closed under products. By Step 2, the functions $x' \mapsto \sigma_j(r(h)(x'))$ lie in $\mathcal{D}$ for every $h \in G_E$ and $1 \le j \le n_{\mathcal{R}}$. Let $g \ge 1$ and $\mathbf{X} \in \mathrm{M}_g(\mathcal{R})$. By (2) each entry is $\mathbf{X}_{pq} = \sum_{h \in H_0} f_{pqh}\, r(h)$ with a finite $H_0 \subseteq G_E$ and $f_{pqh} \in \mathbb{T}' \subseteq \mathcal{D}$, so $x' \mapsto \mathbf{X}_{pq}(x')$ is a $\mathcal{D}$-combination in the sense of Lemma 22.15, applied with $F = K$, $Y = \mathcal{Z}'$, the group G_E, the homomorphisms $\varrho_{x'} = r(\cdot)(x') \colon G_E \to \mathrm{GL}_{n_{\mathcal{R}}}(K) \subseteq \mathrm{M}_{n_{\mathcal{R}}}(K)$ and $A = \mathcal{D}$. That lemma gives that $x' \mapsto \det \mathbf{X}(x')$ lies in $\mathcal{D}$: there are $a_1, \dots, a_{n_z} \in \mathbb{T}$ with $\det \mathbf{X}(x') = \sum_k a_k(\phi(x'))z_k(x')$ for all $x' \in \mathcal{Z}'$, which is (13.8) in degree g. □

Lemma 22.15. *Let F be a commutative ring, Y a set, $n \ge 1$, G a monoid, and for every $y \in Y$ let $\varrho_y \colon G \to \mathrm{M}_n(F)$ be a homomorphism of monoids. Let A be a subring of the ring F^Y of functions $Y \to F$ (pointwise operations) such that the functions $y \mapsto \sigma_j(\varrho_y(h))$ lie in A for every $h \in G$ and $1 \le j \le n$. Call a function $f \colon Y \to \mathrm{M}_n(F)$ an* A-combination *if $f(y) = \sum_{h \in H} a_h(y)\, \varrho_y(h)$ for a finite $H \subseteq G$ and $a_h \in A$. Then for every $g \ge 1$ and every $g \times g$ matrix $\mathbf{X} = (\mathbf{X}_{pq})$ of A-combinations, the function $y \mapsto \det \mathbf{X}(y)$ (the determinant of the $gn \times gn$ matrix $(\mathbf{X}_{pq}(y))_{p,q}$) lies in A.*

Proof. **Step 1: words.** Choose a finite $H \subseteq G$ and $a_{pqh} \in A$ with $\mathbf{X}_{pq}(y) = \sum_{h \in H} a_{pqh}(y)\varrho_y(h)$ for all p, q (take the union of the finite sets of the entries and coefficients 0 elsewhere). For $Z \in \mathrm{M}_n(F)$ let $e_{pq} \otimes Z \in \mathrm{M}_{gn}(F)$ be the matrix with Z in the block (p,q) and 0 elsewhere; $(e_{pq} \otimes Z)(e_{p'q'} \otimes Z')$ is $e_{pq'} \otimes ZZ'$ if $q = p'$ and 0 otherwise. Enumerate the triples $i = (p, q, h)$ $(1 \le p, q \le g,\ h \in H)$ as $1, \dots, k$, and for $y \in Y$ put $A_i(y) = a_{pqh}(y)\, e_{pq} \otimes \varrho_y(h)$, so that $\mathbf{X}(y) = \sum_i A_i(y)$, of size $N = gn$. For a word $w = i_1 \cdots i_m$, $i_\nu = (p_\nu, q_\nu, h_\nu)$, put $a_w = \prod_\nu a_{p_\nu q_\nu h_\nu} \in A$ and $h_w = h_1 \cdots h_m \in G$. As ϱ_y is multiplicative, $A_w(y) = A_{i_1}(y) \cdots A_{i_m}(y)$ equals $a_w(y)\, e_{p_1 q_m} \otimes \varrho_y(h_w)$ if $q_\nu = p_{\nu+1}$ for all $\nu < m$, and 0 otherwise. For $j \ge 1$, $\sigma_j(e_{pq} \otimes Z) = 0$ if $p \neq q$ (a principal minor of positive size of this matrix has a zero row or column) and $\sigma_j(e_{pp} \otimes Z) = \sigma_j(Z)$ (the principal minors that do not lie in the block (p,p) vanish). With $\sigma_j(bZ) = b^j \sigma_j(Z)$ for $b \in F$, for every word w and $j \ge 1$

$$\sigma_j\big(A_w(y)\big) = \epsilon_w\, a_w(y)^j\, \sigma_j\big(\varrho_y(h_w)\big), \qquad \epsilon_w \in \{0, 1\},$$

where $\epsilon_w = 1$ exactly when $q_\nu = p_{\nu+1}$ for all $\nu < m$ and $p_1 = q_m$; ϵ_w, a_w, h_w do not depend on y.

Step 2: Amitsur's formula. Fix y. By Theorem B.169 over $C = F$ with the matrices $A_i(y)$,

$$\det\Big(1 - \sum_i t_i A_i(y)\Big) = \prod_{w \text{ Lyndon}} \det(1 - t_w A_w(y)) = \prod_w \sum_{j=0}^{N} (-1)^j \sigma_j\big(A_w(y)\big)\, t_w^j$$

in $F[[t_1, \dots, t_k]]$ (for an $N \times N$ matrix Z, $\det(1 - XZ) = \sum_j (-1)^j \sigma_j(Z) X^j$). The left side is $\sum_{j=0}^{N} (-1)^j \sigma_j(\sum_i t_i A_i(y))$, and $\sigma_j(\sum_i t_i A_i(y))$ is homogeneous of degree j in t; so its homogeneous part of degree N is $(-1)^N \det(\sum_i t_i A_i(y))$. On the right, t_w has degree the length $|w|$ of

w, so only the finitely many Lyndon words of length at most N contribute in degree N, and the homogeneous part of degree N is the finite sum, over the families (j_w) of non-negative integers indexed by these words with $\sum_w j_w|w| = N$, of $\prod_w (-1)^{j_w}\sigma_{j_w}(A_w(y))\,t_w^{j_w}$. Equating the two homogeneous polynomials of degree N and evaluating at $t_1 = \cdots = t_k = 1$, with Step 1,

$$\det \mathbf{X}(y) = (-1)^N \sum_{(j_w)} \prod_w (-1)^{j_w} \left(\epsilon_w a_w(y)^{j_w}\right)^{[j_w \geq 1]} \sigma_{j_w}\big(\varrho_y(h_w)\big),$$

where the index set, the signs, ϵ_w, a_w and h_w do not depend on y, and $\sigma_0 = 1$.

Step 3: conclusion. Each a_w is in A, each function $y \mapsto \sigma_j(\varrho_y(h_w))$ with $j \geq 1$ is in A by hypothesis, and the constants $0, \pm 1$ are in A; A is closed under sums and products. So the right side of the last display, as a function of y, lies in A. □

Lemma 22.16. *Let ℓ be a prime, $N \geq 1$ an integer, $N_\ell = \operatorname{lcm}(\ell, N)$, $s = \max(1, v_\ell(N))$, $\mathcal{O}$ a coefficient ring for ℓ, $K = \mathcal{O}[\ell^{-1}]$, and $K' = \mathcal{O}(N)[\ell^{-1}]$. Then:*

1. *$\mathcal{O}(N)$ is a coefficient ring for ℓ containing $\mathcal{O}$, and $K' = K(\zeta)$ for a primitive N_ℓ-th root of unity ζ; in particular K' contains a primitive N_ℓ-th root of unity;*
2. *the ramification index of K'/K divides $(\ell - 1)\ell^{s-1}$;*
3. *if F is a finite extension of $\mathbb{Q}_\ell$ which is $\mathbb{Q}_\ell$-isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_N)$ and $F_1 = F(\xi)$ with ξ a primitive ℓ-th root of unity in an algebraic closure of F, then $\sigma(F_1) \subseteq K'$ for every $\mathbb{Q}_\ell$-embedding $\sigma\colon F_1 \to \overline{\mathbb{Q}}_\ell$.*

Proof. **Item 1.** Let $\zeta \in \overline{\mathbb{Q}}_\ell$ be a primitive N_ℓ-th root of unity; $K(\zeta)$ is a finite extension of $\mathbb{Q}_\ell$. Since $\mathcal{O}$ is integral over $\mathbb{Z}_\ell$, the integral closure $\mathcal{O}(N)$ of $\mathcal{O}$ in $K(\zeta)$ equals the integral closure of $\mathbb{Z}_\ell$ in $K(\zeta)$, its valuation ring: a discrete valuation ring, finite over $\mathbb{Z}_\ell$, containing $\mathcal{O}$. Every element of $K(\zeta)$ becomes integral after multiplication by a power of ℓ, so $\mathcal{O}(N)[\ell^{-1}] = K(\zeta)$.

Item 2. Write $N_\ell = \ell^s N'$ with $\ell \nmid N'$; indeed $v_\ell(N_\ell) = \max(1, v_\ell(N)) = s$. Then $\zeta_1 = \zeta^{\ell^s}$ has order N', $\zeta_2 = \zeta^{N'}$ has order ℓ^s, and $\zeta \in \mathbb{Q}(\zeta_1, \zeta_2)$ since $\gcd(\ell^s, N') = 1$; so $K' = K_1(\zeta_2)$ with $K_1 = K(\zeta_1)$. The extension K_1/K is unramified, being generated by a root of unity of order prime to ℓ (the polynomial $X^{N'} - 1$ is separable modulo the maximal ideal). The extension $\mathbb{Q}_\ell(\zeta_2)/\mathbb{Q}_\ell$ is Galois with group $(\mathbb{Z}/\ell^s\mathbb{Z})^\times$ of order $(\ell - 1)\ell^{s-1}$, and $K' = K_1 \cdot \mathbb{Q}_\ell(\zeta_2)$, so restriction embeds $\operatorname{Gal}(K'/K_1)$ into it and $[K' : K_1]$ divides $(\ell - 1)\ell^{s-1}$. Hence $e(K'/K) = e(K'/K_1)\,e(K_1/K) = e(K'/K_1)$ divides $e(K'/K_1)f(K'/K_1) = [K' : K_1]$, which divides $(\ell - 1)\ell^{s-1}$.

Item 3. Let $C = \mathbb{Q}_\ell(\zeta)$; it is the splitting field of $X^{N_\ell} - 1$ over $\mathbb{Q}_\ell$, hence normal over $\mathbb{Q}_\ell$, and $C \subseteq K'$ by item 1. Since $N \mid N_\ell$, $\mathbb{Q}_\ell(\mu_N) \subseteq C$, so there is a $\mathbb{Q}_\ell$-embedding $\tau\colon F \to C$. Extend τ to $\tau_1\colon F_1 \to \overline{\mathbb{Q}}_\ell$; $\tau_1(\xi)$ is a primitive ℓ-th root of unity, which lies in C as $\ell \mid N_\ell$, so $\tau_1(F_1) \subseteq C$. For a $\mathbb{Q}_\ell$-embedding $\sigma\colon F_1 \to \overline{\mathbb{Q}}_\ell$, the embedding $\sigma \circ \tau_1^{-1}$ of $\tau_1(F_1)$ extends to a $\mathbb{Q}_\ell$-automorphism of $\overline{\mathbb{Q}}_\ell$, which maps the normal extension C onto itself. So $\sigma(F_1) \subseteq C \subseteq K'$. □

Lemma 22.17. *Let ℓ be a prime and $\mathcal{O} \subseteq \mathcal{O}'$ coefficient rings for ℓ.*

1. *For every $\mathcal{O}$-module X, $\mathcal{O}' \otimes_{\mathcal{O}} X$ has the same normalised length in $[0, \infty]$ (over $\mathcal{O}'$) as X (over $\mathcal{O}$); in particular ν of an element $a \in \mathcal{O} \setminus \{0\}$ is the same over $\mathcal{O}$ and over $\mathcal{O}'$.*
2. *Let Galois Ribet items on $(\mathcal{R}, \pi', \mathcal{N})$ over E with a Hecke lattice over ℓ with coefficient ring $\mathcal{O}$ be given, and consider their coefficient extension to $\mathcal{O}'$. Then the coefficient extension of the block form at π' is a block form with the same block sizes; the items have (Gd1)–(Gd5)*

if and only if the extension has them; at every $v \in S_\ell$ they have (Ll1), respectively (Ll2), if and only if the extension has it; and the minimal losses $\kappa_k^{\min}$, $\lambda_k^{\min}(v)$, the normalised length of Sel_0*, the denominator δ, $\nu(\delta)$ and $\nu(\zeta_v - 1)$ ($v \in \Sigma_{\mathrm{T}}$) are the same for the items and for the extension.*

3. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with local defect data, local bound records, Ribet records, budget data, inert budget data and Galois Ribet items at points, and let $\mathcal{F}'$ be its coefficient extension along coefficient rings $\mathcal{O}'_r \supseteq \mathcal{O}_r$. Then $\mathcal{F}'$ is such a family with such data. For every choice of losses, the items of $\mathcal{F}$ with these losses are Galois Ribet records having (Gd8), (Gd9), respectively (Gd10), if and only if the items of $\mathcal{F}'$ with the same losses are. The Ribet records of $\mathcal{F}$ have (Rf2), (Rf4), respectively (Rf5), if and only if those of $\mathcal{F}'$ have it, and they have (Rf1) if those of $\mathcal{F}'$ have it. The local bound records of $\mathcal{F}$ and $\mathcal{F}'$ coincide. At every member and every integer $N_{x,i}$, (Ub1), (Ub8) and (Ub9) hold for $\mathcal{F}$ if and only if they hold for $\mathcal{F}'$.*

Proof. **Step 0: a basis.** $\mathcal{O}'$ is a finitely generated torsion-free module over the discrete valuation ring $\mathcal{O}$, hence free, of rank $d = [K' : K]$. The quotient $\mathcal{O}'/\mathcal{O}$ is torsion-free: if $x \in \mathcal{O}'$ and $ax \in \mathcal{O}$ with $a \in \mathcal{O} \setminus \{0\}$, then $x \in K$ is integral over $\mathcal{O}$, so $x \in \mathcal{O}$. Hence $\mathcal{O}'$ has an $\mathcal{O}$-basis $\varepsilon_0 = 1, \varepsilon_1, \dots, \varepsilon_{d-1}$, which is also a K-basis of K'. Consequently, for every $\mathcal{O}$-module X, $\mathcal{O}' \otimes_{\mathcal{O}} X = \bigoplus_j \varepsilon_j \otimes X$, and every $\mathcal{O}$-linear map, group action or module structure over an $\mathcal{O}$-algebra extends componentwise; and for an $\mathcal{O}$-submodule X of a K-vector space W, $K' \otimes_K W = \bigoplus_j \varepsilon_j W$ and $X_{\mathcal{O}'} = \bigoplus_j \varepsilon_j X$, so $\mathcal{O}' \otimes_{\mathcal{O}} X \to X_{\mathcal{O}'}$ is an isomorphism, and $X_{\mathcal{O}'} \cap (\varepsilon_0 W) = X$.

Step 1: item 1. Let $\mathfrak{m}, \mathfrak{m}'$ be the maximal ideals and $e = e(K'/K)$, so $\mathfrak{m}\mathcal{O}' = \mathfrak{m}'^e$. Tensoring with the free module $\mathcal{O}'$ is exact, and $\mathcal{O}' \otimes_{\mathcal{O}} \mathcal{O}/\mathfrak{m} = \mathcal{O}'/\mathfrak{m}'^e$ has $\mathcal{O}'$-length e; by induction along a composition series, $\mathrm{length}_{\mathcal{O}'}(\mathcal{O}' \otimes X) = e\,\mathrm{length}_{\mathcal{O}}(X)$ for X of finite length. Applied to $X = \mathcal{O}/\ell\mathcal{O}$, this gives $e_{\mathcal{O}'} = e\,e_{\mathcal{O}}$; dividing, the normalised lengths agree. If X has infinite length, then $\mathcal{O}' \otimes X \supseteq \varepsilon_0 \otimes X \cong X$ has infinite $\mathcal{O}$-length, and since $\mathcal{O}'/\mathfrak{m}'$ is finite over $\mathcal{O}/\mathfrak{m}$, an $\mathcal{O}'$-module of finite length has finite $\mathcal{O}$-length; so $\mathcal{O}' \otimes X$ has infinite length. For $a \in \mathcal{O} \setminus \{0\}$ apply this to $X = \mathcal{O}/a\mathcal{O}$, with $\mathcal{O}' \otimes X = \mathcal{O}'/a\mathcal{O}'$.

Step 2: the extended objects decompose. By Step 0, $\mathcal{R}_{\mathcal{O}'} = \bigoplus_j \varepsilon_j \mathcal{R}$ and $\mathbb{T}'_{\mathcal{O}'} = \bigoplus_j \varepsilon_j \mathbb{T}'$; for $a = \sum_j \varepsilon_j a_j$ ($a_j \in \mathcal{R}$) and $x' \in \mathcal{Z}'$, $a(x') = \sum_j \varepsilon_j a_j(x')$. *Block form.* By (Bf1) for the a_j, $a(\pi') \in \mathrm{M}_{n_{\mathcal{R}}}(\mathcal{O}')$ is block upper triangular, and its k-th diagonal block is $\rho'_k(a) = \sum_j \varepsilon_j \rho_k(a_j)$; as ρ_k is onto $\mathrm{M}_{n_{\mathcal{R},k}}(\mathcal{O})$, ρ'_k is onto $\bigoplus_j \varepsilon_j \mathrm{M}_{n_{\mathcal{R},k}}(\mathcal{O}) = \mathrm{M}_{n_{\mathcal{R},k}}(\mathcal{O}')$. The constituent module of the extension is $(K'/\mathcal{O}')^{n_{\mathcal{R},k}} = \bigoplus_j \varepsilon_j \mathrm{Cs}_k$, on which $a \in \mathcal{R}$ acts by $\rho_k(a)$ in each summand; we write it Cs'_k. *Modules.* As $\mathcal{R}_{\mathcal{O}'} = \mathcal{O}' \otimes_{\mathcal{O}} \mathcal{R}$, $\mathcal{N}_{\mathcal{O}'} = \mathcal{R}_{\mathcal{O}'} \otimes_{\mathcal{R}} \mathcal{N} = \mathcal{O}' \otimes_{\mathcal{O}} \mathcal{N}$. The Ribet ideal of the extension is $\sum_g \mathcal{R}_{\mathcal{O}'} y(g) = \bigoplus_j \varepsilon_j \mathcal{N}_{\mathcal{E}} = (\mathcal{N}_{\mathcal{E}})_{\mathcal{O}'}$, and $\iota_{\mathcal{O}'} = \mathrm{id} \otimes \iota$. For a left $\mathcal{R}$-module Y and any left $\mathcal{R}$-module X, adjunction and $\mathcal{O}' \otimes Y = \bigoplus_j \varepsilon_j Y$ give

$$\mathrm{Hom}_{\mathcal{R}_{\mathcal{O}'}}(\mathcal{R}_{\mathcal{O}'} \otimes_{\mathcal{R}} X,\ \mathcal{O}' \otimes_{\mathcal{O}} Y) = \mathrm{Hom}_{\mathcal{R}}(X, \textstyle\bigoplus_j \varepsilon_j Y) = \bigoplus_j \varepsilon_j \,\mathrm{Hom}_{\mathcal{R}}(X, Y), \qquad (*)$$

naturally in X; we use it for $X = \mathcal{N}, \mathcal{N}_{\mathcal{E}}$ and $Y = \mathrm{Cs}_k$ or $Y = K_{x'}^{n_{\mathcal{R}}}$ (with $\mathcal{O}' \otimes_{\mathcal{O}} K_{x'}^{n_{\mathcal{R}}} = K_{x'}^{\prime n_{\mathcal{R}}}$). *Cohomology.* Continuous cochains with values in $\bigoplus_j \varepsilon_j \mathrm{Cs}_k(u)$ are the sums of their components, a cochain being continuous if and only if its components are; so $H^1(H, \mathrm{Cs}'_k(u)) = \bigoplus_j \varepsilon_j H^1(H, \mathrm{Cs}_k(u))$ for every closed subgroup $H \subseteq G_E$, compatibly with restriction.

Step 3: item 2. *(Gd1)–(Gd5).* The elements $\mathbf{r}(g)$, $\mathcal{E}$, $\tilde{\delta}$, γ_v, p_v and the characters χ_c are the same, ρ'_k restricts to ρ_k on $\mathcal{R}$, and identities in $\mathcal{R}$ hold in $\mathcal{R}_{\mathcal{O}'} \supseteq \mathcal{R}$ and conversely; this gives (Gd1)–(Gd4) in both directions. For (Gd5), $\rho_k(p_v) \in \mathcal{O}$ is a unit of $\mathcal{O}'$ if and only if it is a unit of $\mathcal{O}$, since $\mathcal{O}' \cap K = \mathcal{O}$. The entries of the extension satisfy the requirements of

Galois Ribet data (the coefficient algebra is an $\mathcal{O}'$-subalgebra, $\mathcal{R}_{\mathcal{O}'}$ is the $\mathbb{T}'_{\mathcal{O}'}$-span of $\mathbf{r}(G_E)$, $\tilde{\delta}(x') \neq 0$, $\delta = \tilde{\delta}(\pi') \in \mathcal{O} \setminus \{0\}$ is the same denominator). *Column losses.* By $(*)$, the map $\varphi \mapsto \varphi \circ \iota_{\mathcal{O}'}$ of (Gd6) for the extension is $\bigoplus_j \varepsilon_j$ of the map for the items, so its kernel is $\mathcal{O}'\otimes$ the kernel for the items; by item 1, $\kappa_k^{\min}$ is the same. *Local losses.* For $\varphi = \sum_j \varepsilon_j \varphi_j$, $c_\varphi = \sum_j \varepsilon_j c_{\varphi_j}$, which is a continuous cocycle if and only if every c_{φ_j} is; so the Ribet classes of the extension are $X'_k = \bigoplus_j \varepsilon_j X_k$ (Step 2). The local conditions are $F'_0(v) = \bigoplus_j \varepsilon_j F_0(v)$ by definition, $F'_1(v) = H^1_{\mathrm{ur}}(E_v, \mathrm{Cs}'_1(u)) = \bigoplus_j \varepsilon_j F_1(v)$ (the classes vanishing on inertia, componentwise), and $F'_k(v) = 0$ for $k \geq 2$. Hence the image of X'_k in $H^1(G_{E_v}, \mathrm{Cs}'_k(u))/F'_k(v)$ is $\mathcal{O}'\otimes$ the image of X_k, and $\lambda_k^{\min}(v)$ is the same by item 1. *Selmer group.* Its defining conditions (vanishing on inertia groups, local conditions $F_0(v)$) are componentwise, so the Selmer group of the extension is $\bigoplus_j \varepsilon_j \mathrm{Sel}_0$, of the same normalised length. *ν.* $\delta, \zeta_v - 1 \in \mathcal{O} \setminus \{0\}$, and item 1 applies. *(Ll1), (Ll2).* As a $\mathbb{Q}_\ell$-linear representation of $D = G_{E_v}$, $K'^{n_\mathcal{R}}$ with $g \mapsto \mathbf{r}(g)(x')$ is the direct sum of the d subrepresentations $\varepsilon_j K^{n_\mathcal{R}}$, each isomorphic to $K^{n_\mathcal{R}}$; a finite direct sum of representations is crystalline if and only if each summand is (the functor D_{cris} commutes with finite direct sums and $\dim_{\mathbb{Q}_\ell}$ is additive), so (Ll1) holds for the extension if and only if it holds for the items. For (Ll2), $\mathrm{Cs}'_0(u) = \bigoplus_j \varepsilon_j \mathrm{Cs}_0(u)$ is the quotient of $\bigoplus_j \varepsilon_j V_0$ by $\bigoplus_j \varepsilon_j T_0$ ($V_0 = K^{n_{\mathcal{R},0}}$, $T_0 = \mathcal{O}^{n_{\mathcal{R},0}}$), and the Bloch–Kato condition of Definition 22.2 is compatible with finite direct sums, so $H^1_f(D, \mathrm{Cs}'_0(u)) = \bigoplus_j \varepsilon_j H^1_f(D, \mathrm{Cs}_0(u))$; as $F'_0(v) = \bigoplus_j \varepsilon_j F_0(v)$, the equality (Ll2) holds for the extension if and only if it holds for the items.

Step 4: item 3, the structure. The coefficient extension of a Hecke lattice is a Hecke lattice: $\mathbb{T}_{\mathcal{O}'}$ is an $\mathcal{O}'$-subalgebra of $\mathcal{O}'^{\mathcal{Z}}$ containing the constants and $\mathbb{T}$, so it separates the points; $M_{\mathcal{O}'}$ is free; the action is an algebra homomorphism by Step 0. The extended determinant algebras have, by Step 3, block forms with $t+1$ blocks at the same points $\pi' \in \phi^{-1}(\pi)$, and $\mathcal{N}_{\mathcal{O}'}$ is presented by $\mathbf{P}$ with n_{gen} generators (right exactness of $\mathcal{R}_{\mathcal{O}'} \otimes_\mathcal{R} -$). All other data are unchanged. So $\mathcal{F}'$ is a family with the same kinds of data.

Step 5: item 3, (Gd8)–(Gd10). (Gd8): by item 2 and item 1, for fixed losses the conditions (Gd1)–(Gd7) hold for the items if and only if they hold for the extension (the modules in (Gd6) and (Gd7) have the same normalised lengths); E, $\mathrm{sl}(r,\pi)$, $\mathrm{lc}_k(r,\pi)$ are unchanged, and the loss sums are the same as $n_{\mathcal{R},0}$, $\nu(\delta)$, $\nu(\zeta_v - 1)$ are. (Gd10): $\delta \in \mathcal{O}$ is a unit of $\mathcal{O}'$ if and only if of $\mathcal{O}$; the other conditions are on unchanged numbers. (Gd9): the module of the extension is $\mathcal{D}'_{r,\pi} = \{\sum_k (a_k \circ \phi) z_k : \ a_k \in \mathbb{T}_{r,\mathcal{O}'}\} = \bigoplus_j \varepsilon_j \mathcal{D}_{r,\pi}$ inside $\bigoplus_j \varepsilon_j K^{\mathcal{Z}'}$, and by Step 0 $\mathcal{D}' \cap K^{\mathcal{Z}'} = \mathcal{D}$. If $\mathcal{D}$ contains 1 and $\mathbb{T}'$ and is closed under products, then $\mathcal{D}'$ contains 1 and $\mathbb{T}'_{\mathcal{O}'}$ and is closed under products (products of ε_i-multiples land in $\bigoplus_j \varepsilon_j \mathcal{D}$, as $\varepsilon_i \varepsilon_{i'} \in \mathcal{O}'$); conversely, if $\mathcal{D}'$ has these properties, then $1 \in \mathcal{D}' \cap K^{\mathcal{Z}'} = \mathcal{D}$, $\mathbb{T}' \subseteq \mathcal{D}' \cap K^{\mathcal{Z}'} = \mathcal{D}$ and $\mathcal{D}\mathcal{D} \subseteq \mathcal{D}' \cap K^{\mathcal{Z}'} = \mathcal{D}$. Detection: if $\sum_k c_k z_k(x') = 0$ on $\phi^{-1}(x)$ with $c_k = \sum_j \varepsilon_j c_{kj} \in \mathcal{O}'$, then, the z_k being $\mathcal{O}$-valued, $\sum_k c_{kj} z_k(x') = 0$ for every j; so detection over $\mathcal{O}$ implies detection over $\mathcal{O}'$, and the converse holds as $\mathcal{O} \subseteq \mathcal{O}'$. The functions $x' \mapsto \sigma_j(\mathbf{r}(\mathrm{Frob}_w)(x'))$ are K-valued and $\mathbf{r}(\gamma)(x')$ is unchanged, so they lie in $\mathcal{D}'$ if and only if they lie in $\mathcal{D}' \cap K^{\mathcal{Z}'} = \mathcal{D}$, with the same set B.

Step 6: item 3, (Rf1)–(Rf5), records, (Ub1), (Ub8), (Ub9). (Rf2): by $(*)$ with $Y = K^{n_\mathcal{R}}_{x'}$, $\mathrm{Hom}_{\mathcal{R}_{\mathcal{O}'}}(\mathcal{N}_{\mathcal{O}'}, K'^{n_\mathcal{R}}_{x'}) = \bigoplus_j \varepsilon_j \mathrm{Hom}_\mathcal{R}(\mathcal{N}, K^{n_\mathcal{R}}_{x'})$, nonzero if and only if $\mathrm{Hom}_\mathcal{R}(\mathcal{N}, K^{n_\mathcal{R}}_{x'}) \neq 0$. (Rf4): by $(*)$ and item 1, $\mathrm{Hom}(\mathcal{N}_{\mathcal{O}'}, \mathrm{Cs}'_k)$ has finite length and the same normalised length as $\mathrm{Hom}(\mathcal{N}, \mathrm{Cs}_k)$; likewise $\mathrm{Hom}_{\mathrm{ur}}(G_E, K'/\mathcal{O}') = \bigoplus_j \varepsilon_j \mathrm{Hom}_{\mathrm{ur}}(G_E, K/\mathcal{O})$; $\mathrm{len}_\ell(E, k-1)$, sl and lc_k do not involve the coefficient ring. (Rf5): unchanged numbers. (Rf1): detection is equivalent as in Step 5. Suppose the determinant condition in degree $g = n_{\mathrm{gen}}$ holds for the extension, and let $\mathbf{X} \in \mathrm{M}_g(\mathcal{R}) \subseteq \mathrm{M}_g(\mathcal{R}_{\mathcal{O}'})$. There are $a'_k \in \mathbb{T}_{\mathcal{O}'}$, $a'_k = \sum_j \varepsilon_j a_{kj}$ with $a_{kj} \in \mathbb{T}$, such that $\det \mathbf{X}(x') = \sum_k a'_k(\phi(x')) z_k(x') = \sum_j \varepsilon_j (\sum_k a_{kj}(\phi(x')) z_k(x'))$ for all x'. The left side lies in $K = \varepsilon_0 K$ and the inner sums lie in $\mathcal{O} \subseteq K$; comparing components in $K' = \bigoplus_j \varepsilon_j K$ gives $\det \mathbf{X}(x') = \sum_k a_{k0}(\phi(x')) z_k(x')$ with $a_{k0} \in \mathbb{T}$, the determinant condition for $\mathcal{F}$. *Records.* The

local bound records, budget data and inert budget data are unchanged by definition. (Ub1): (Gd1)–(Gd5) and (Gd9) by item 2 and Step 5, E unchanged, Sel_0 of the same normalised length (item 2). (Ub8): it involves only the budget data, inert budget data and the allowances $a_{x,i}(\ell)$, which are numbers formed from them and from $N_{x,i}$, $S^{\mathrm{rm}}_{x,i}$, $\eta^{\mathrm{rm}}_{x,i}$. (Ub9): the minimal losses, hence $\mathrm{ls}^{\min}_k$, are the same (item 2), as are lc_k, lt, $\mathrm{la}_{x,i}$ and $a_{x,i}(\ell)$. □

23 Wach modules: sites, levels and the crystalline criterion

This section develops the Wach modules on which all local bounds of the Part rest. Let ℓ be odd, F unramified over $\mathbb{Q}_\ell$ of degree n, and K a field with $F \subseteq K \subseteq F(\mu_\ell)$. A Wach module of a crystalline lattice over K with coefficients L is a module over $(\mathcal{O}_F \otimes \mathcal{O}_L)[[X]]$ with a Frobenius, sending X to $(1+X)^\ell - 1$, and an action of Γ_K; it splits into n *sites*, one for each embedding of F in a Frobenius numbering, and Frobenius carries the site a to the site $a+1$. The Hodge jumps enter through a *window* (M_a, h_a) at each site. Most results also have a version of level s, over subfields of $F(\mu_{\ell^s})$ and for every prime ℓ; it serves the small primes.

Four results are used in the rest of the Part. Every crystalline lattice over K has a Wach module with the window of its Hodge jumps (Proposition 23.7); we obtain it from the prismatic F-crystal of the lattice [31], evaluated on the cyclotomic prism (Lemma 23.8). Membership of an element in a site is detected by its *levels*, its images under the maps into $B_{\mathrm{dR}} \otimes T$ attached to the Frobenius twists along an arc of sites (Lemma 23.5). The cokernel of the Wach map of a surjection of lattices is killed at every site by $X^{H_{\max}}$, where $H_{\max}$ is the largest width of the window (Proposition 23.18). And the Herr class [126] of a Wach vector with poles only at the Frobenius twists Q_s of $Q = \varphi(X)/X$, of precision at least $1 + \max_a M_a$, lies in the Bloch–Kato subgroup H^1_f [34] (Proposition 23.27). Their consumers are the lifting exponents of Section 24, the local conditions at large primes in Section 28, the colength bounds of Appendix C, and the ramified places of Section 27.

The section is long because everything is integral and every constant is explicit; the ideas are those of the theory of Wach modules [265], [26] and of (φ, Γ)-modules [93]. The subsections follow the four results: levels and membership (23.1), existence with level maps and horizontal frames (23.2), the length lemma (23.3), and the crystalline criterion (23.4).

23.1 Levels of a Wach module and membership in a site

This subsection fixes the language of the local theory. Definition 23.1 defines onto maps of crystalline lattices over an unramified field, their colength (the normalised length of the cokernel of the induced map on integral Bloch–Kato groups), Frobenius numberings and weight words; the colength is the quantity bounded at the inert primes (Section 26 and Appendix C). The next three definitions introduce Wach modules with sites and windows, the arc coordinates of an element along an arc of consecutive sites, and the level data of an arc. The one result, Lemma 23.5, says that an element of the arc domain lies in the site $\mathbf{N}_c$ exactly when all its level expansions are de Rham integral; it is how membership in a site is verified in Sections 24 and 28 and in Appendix C.

Definition 23.1. Let ℓ be an odd prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $\varphi \in \mathrm{Gal}(F/\mathbb{Q}_\ell)$ its arithmetic Frobenius (inducing $x \mapsto x^\ell$ on the residue field), $D = G_F$, and L a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$ such that L contains $\sigma(F(\mu_\ell))$ for every $\mathbb{Q}_\ell$-embedding σ of $F(\mu_\ell)$ into $\overline{\mathbb{Q}}_\ell$.

Frobenius numberings. A **Frobenius numbering** is a bijection $\mathbb{Z}/n \to \mathrm{Hom}_{\mathbb{Q}_\ell}(F, L)$, $a \mapsto \tau_a$, with $\tau_{a+1} \circ \varphi = \tau_a$ for all a. (It exists: φ generates the cyclic group $\mathrm{Gal}(F/\mathbb{Q}_\ell)$ of

order n, which acts simply transitively on the n embeddings by $\tau \mapsto \tau \circ \varphi^{-1}$; fix τ_0 and put $\tau_a = \tau_0 \circ \varphi^{-a}$.) With this numbering the crystalline Frobenius, which is φ-semilinear, maps the τ_a-component of $D_{\mathrm{cris}}(V) \otimes_F L$ to the τ_{a+1}-component.

Onto maps of crystalline lattices and their colength. An **onto map of crystalline lattices** over F with coefficients L is a tuple $(V_1, T_1, V_2, T_2, \Phi)$ of finite-dimensional L-vector spaces V_1, V_2 with continuous L-linear actions of D that are crystalline as $\mathbb{Q}_\ell$-representations, D-stable $\mathcal{O}_L$-lattices $T_\nu \subseteq V_\nu$, and an L-linear D-equivariant map $\Phi\colon V_1 \to V_2$ with $\Phi(T_1) = T_2$. Since Φ carries $H^1_f(D, V_1)$ into $H^1_f(D, V_2)$, it carries $H^1_f(D, T_1)$ into $H^1_f(D, T_2)$; the **colength** of Φ is

$$\mathrm{nl}\Big(H^1_f(D, T_2)/\Phi_* H^1_f(D, T_1)\Big) \in [0, \infty].$$

Weight words. Fix a Frobenius numbering. A **weight word** for an onto map Φ of crystalline lattices consists of integers $b \geq 1$ and $w, S, \eta, m \geq 0$, **sizes** $s_a > \eta$ and **signs** $\epsilon_a \in \{1, -1\}$ for $a \in \mathbb{Z}/n$, such that:

(Ow1) Windows for every a, every Hodge jump of V_1 at τ_a lies in $[s_a, s_a + S] \cup [-\eta, \eta]$ if $\epsilon_a = 1$, and in $[-s_a - S, -s_a] \cup [-\eta, \eta]$ if $\epsilon_a = -1$;

(Ow2) Low jumps for every a, $\sum_{|j| \leq \eta} \dim_L\big(\mathrm{Fil}^j D_{\mathrm{dR},\tau_a}(V_2)/\mathrm{Fil}^{j+1} D_{\mathrm{dR},\tau_a}(V_2)\big) \leq m$;

(Ow3) Thick and thin sites every a is **thick** ($b \leq s_a \leq b + \eta$) or **thin** ($s_a \leq w$).

Attached quantities: $h = b + \eta + S$ if some site is thick and $h = w + S + \eta + 1$ otherwise; $G = w + S + \eta$; $H' = \max_a s_a + S + \eta$; $d_2 = \dim_L V_2$. For integers $M_a, h_a \geq 0$ ($a \in \mathbb{Z}/n$) such that every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$, the **lifting exponent** $e(M_\bullet, h_\bullet)$ is the integer e_{A} of Proposition 24.1 formed for V_1 with $a^-_{\tau_a} = M_a$ and $a^+_{\tau_a} = h_a$. For a real $c \geq 0$ the **band indicator** $\beta_c \in \{0, 1\}$ is 1 if some thin site a has a thick neighbour $a + 1$ or $a - 1$ and

$$|\ell s_a - b| \leq c(\ell\eta + \ell S + b/\ell + s_a + \ell \log_\ell(2h)),$$

and 0 otherwise.

Definition 23.2. Let ℓ, F, n, φ, L, $\mathcal{O}_L$ be as in the definition of Frobenius numberings and fix a Frobenius numbering $(\tau_a)_{a \in \mathbb{Z}/n}$. Let $\mathcal{O}_F = W(k)$, k the residue field of F, and write φ also for the Frobenius of $\mathcal{O}_F$.

The ring. Let $\mathbf{A}_F = \mathcal{O}_F[[X]]$ with the ring endomorphism φ that is the Frobenius on $\mathcal{O}_F$ and sends X to $(1 + X)^\ell - 1$, and, for $u \in \mathbb{Z}_\ell^\times$, the $\mathcal{O}_F$-linear ring automorphism γ_u with $\gamma_u(X) = (1 + X)^u - 1 = \sum_{k \geq 1} \binom{u}{k} X^k$. Put

$$Q = \frac{\varphi(X)}{X} = \sum_{i=0}^{\ell-1} (1 + X)^i, \qquad Q_j = \varphi^j(Q) \quad (j \geq 0), \qquad \lambda_e = \prod_{j=0}^{e-1} Q_j \quad (e \geq 0),$$

elements of $\mathbb{Z}_\ell[[X]]$.

Sites. The **site ring** is $\mathbf{A}_{F,L} = (\mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L)[[X]]$, with φ and γ_u extended $\mathcal{O}_L$-linearly (on coefficients $\varphi \otimes \mathrm{id}$, resp. the identity). The **site idempotents** $e_a \in \mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, $a \in \mathbb{Z}/n$, are the idempotents of the ring isomorphism

$$\mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \to \prod_{a \in \mathbb{Z}/n} \mathcal{O}_L, \qquad x \otimes \lambda \mapsto (\tau_a(x)\lambda)_a,$$

(an isomorphism because $\mathcal{O}_F$ is finite étale over $\mathbb{Z}_\ell$ of degree n and the τ_a are its n embeddings into $\mathcal{O}_L$). So $\mathbf{A}_{F,L} = \prod_a e_a \mathbf{A}_{F,L}$ with $e_a \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, and $\varphi(e_a) = e_{a+1}$, $\gamma_u(e_a) = e_a$; the elements of $\mathbb{Z}_\ell[[X]]$, such as X, Q_j, λ_e, act on every site.

The base field. Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$ inside a fixed algebraic closure $\overline{\mathbb{Q}}_\ell$, χ_{cyc} the cyclotomic character, $\Gamma_K = \chi_{\mathrm{cyc}}(G_K) \subseteq \mathbb{Z}_\ell^\times$ and Δ_K the torsion subgroup of Γ_K. For $K = F$ one has $\Gamma_F = \mathbb{Z}_\ell^\times$ and $\Delta_F = \mu_{\ell-1}$: $F/\mathbb{Q}_\ell$ is unramified and $\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ totally ramified, so the two are linearly disjoint and χ_{cyc} maps G_F onto $\mathrm{Gal}(\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell) \cong \mathbb{Z}_\ell^\times$.

Wach modules. Let $M_a, h_a \geq 0$ be integers ($a \in \mathbb{Z}/n$). A **Wach module** over K with coefficients L and **window** $(M_a, h_a)_{a\in\mathbb{Z}/n}$ is a finitely generated $\mathbf{A}_{F,L}$-module $\mathbf{N}$ with a φ-semilinear map $\varphi_{\mathbf{N}}\colon \mathbf{N} \to \mathbf{N}[1/Q] = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} \mathbf{A}_{F,L}[1/Q]$ and γ_u-semilinear maps $\gamma_{u,\mathbf{N}}\colon \mathbf{N} \to \mathbf{N}$ ($u \in \Gamma_K$) such that, with the **site components** $\mathbf{N}_a = e_a\mathbf{N}$:

(Wm1) Sites there is $r \geq 0$ such that every $\mathbf{N}_a$ is a free $e_a\mathbf{A}_{F,L}$-module of rank r;

(Wm2) Heights for every $a \in \mathbb{Z}/n$,

$$Q^{M_a}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}) \subseteq \mathbf{N}_a \qquad \text{and} \qquad Q^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\,\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}),$$

where $\mathbf{A}_{F,L}\,S$ denotes the $\mathbf{A}_{F,L}$-submodule generated by a set S;

(Wm3) Γ-action $\gamma_{1,\mathbf{N}} = \mathrm{id}$, $\gamma_{uv,\mathbf{N}} = \gamma_{u,\mathbf{N}} \circ \gamma_{v,\mathbf{N}}$, $\gamma_{u,\mathbf{N}} \circ \varphi_{\mathbf{N}} = \varphi_{\mathbf{N}} \circ \gamma_{u,\mathbf{N}}$ (on $\mathbf{N}[1/Q]$, $\gamma_{u,\mathbf{N}}$ extended semilinearly), and $(\gamma_{u,\mathbf{N}} - 1)(\mathbf{N}) \subseteq X\mathbf{N}$ for all $u, v \in \Gamma_K$.

A **Wach module over** F is a Wach module over $K = F$; its maps $\gamma_{u,\mathbf{N}}$ are given for every $u \in \Gamma_F = \mathbb{Z}_\ell^\times$. A statement that does not name K is about Wach modules over F. Write φ and γ_u for $\varphi_{\mathbf{N}}$ and $\gamma_{u,\mathbf{N}}$ when no confusion arises.

Level s. Let $s \geq 1$ be an integer. The ring $\mathbf{A}_F$, φ, γ_u, Q, Q_j, λ_e, the site ring, the site idempotents and Frobenius numberings are defined by the same formulas for every prime ℓ, including $\ell = 2$ (none of the formulas, and neither the existence of a Frobenius numbering nor the product decomposition of $\mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, uses that ℓ is odd). Let $s \geq 2$ if $\ell = 2$, let L contain $\sigma(F(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ of $F(\mu_{\ell^s})$, and let K be a field with $F \subseteq K \subseteq F(\mu_{\ell^s})$, $\Gamma_K = \chi_{\mathrm{cyc}}(G_K)$ and Δ_K its torsion subgroup. A **Wach module of level s** over K with coefficients L and window $(M_a, h_a)_{a\in\mathbb{Z}/n}$ is defined as a Wach module above with Q replaced by Q_{s-1} throughout: $\varphi_{\mathbf{N}}$ maps $\mathbf{N}$ to $\mathbf{N}[1/Q_{s-1}]$, (Wm2) reads $Q_{s-1}^{M_a}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}) \subseteq \mathbf{N}_a$ and $Q_{s-1}^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\,\varphi_{\mathbf{N}}(\mathbf{N}_{a-1})$, the commutation in (Wm3) holds on $\mathbf{N}[1/Q_{s-1}]$, and (Wm1) and the congruence $(\gamma_{u,\mathbf{N}} - 1)(\mathbf{N}) \subseteq X\mathbf{N}$ for $u \in \Gamma_K$ are unchanged; in addition, with the **level variable**

$$X_{s-1} = \varphi^{s-1}(X) = (1+X)^{\ell^{s-1}} - 1 = X\lambda_{s-1} \in \mathbb{Z}_\ell[[X]],$$

(Wm3') Level congruence $(\gamma_{u,\mathbf{N}} - 1)(\mathbf{N}) \subseteq X_{s-1}\mathbf{N}$ for every $u \in \Gamma_K$ with $u \equiv 1 \bmod \ell^{s-1}$.

For $s = 1$ one has $X_0 = X$ and every $u \in \Gamma_K$ satisfies $u \equiv 1 \bmod \ell^0$, so (Wm3') is the congruence of (Wm3). For $K = F(\mu_{\ell^s})$ one has $\Gamma_K = 1 + \ell^s\mathbb{Z}_\ell$ ($F/\mathbb{Q}_\ell$ is unramified, so F and $\mathbb{Q}_\ell(\mu_{\ell^\infty})$ are linearly disjoint), and (Wm3') holds for every $u \in \Gamma_K$. For ℓ odd a Wach module of level 1 is a Wach module as defined above ($Q_0 = Q$); a Wach module without a named level has level 1.

Frobenius pull-backs and arc factors. Let $\mathbf{N}[1/\lambda_\infty] = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} \mathbf{A}_{F,L}[1/Q_j : j \geq 0]$, which contains $\mathbf{N}$ by (Wm1); $\varphi_{\mathbf{N}}$ extends to the φ-semilinear map $x/f \mapsto \varphi_{\mathbf{N}}(x)/\varphi(f)$ of $\mathbf{N}[1/\lambda_\infty]$ (f a product of the Q_j; $\varphi(Q_j) = Q_{j+1}$). For $c \in \mathbb{Z}/n$ and $e \geq 0$ the **Frobenius pull-back** $P_e(\mathbf{N}_c)$ is the $\mathbf{A}_{F,L}$-submodule of $\mathbf{N}[1/\lambda_\infty]$ generated by $\varphi_{\mathbf{N}}^e(\mathbf{N}_c)$; thus $P_0(\mathbf{N}_c) = \mathbf{N}_c$ and $P_e(\mathbf{N}_c) \subseteq e_{c+e}\mathbf{N}[1/\lambda_\infty]$. For $a \in \mathbb{Z}/n$, $e \geq 0$ and a function $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$ the **arc factor** is

$$\Lambda_{a,e}(H) = \prod_{j=0}^{e-1} Q_j^{H(a-j)} \in \mathbb{Z}_\ell[[X]].$$

Definition 23.3. Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in the existence of Wach modules over unramified fields, and $\mathbf{N}=\mathbf{N}(T)$, of rank $r=\dim_L V$. Put $E=(\mathcal{O}_F\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L)[1/\ell]$. Fix $c\in\mathbb{Z}/n$, an integer $e\geq 0$, $a=c+e$, a function $H\colon \mathbb{Z}/n\to\mathbb{Z}_{\geq 0}$, $\Pi=\Lambda_{a,e}(H)$, and an integer $m\geq 1$. Let $\mathcal{K}_a$ be the fraction field of $e_a\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$; an element $\lambda\in\mathcal{O}_L$ acts on $e_a\mathbf{A}_{F,L}$ and on $\mathcal{K}_a$ as $e_a(1\otimes\lambda)$.

Frame data. A **frame** at c is an $e_c\mathbf{A}_{F,L}$-basis $\mathbf{n}=(n_k)_{k\leq r}$ of $\mathbf{N}_c$. Let $H_k\in\mathbf{N}_E$ be the horizontal section through n_k, and write $H_k=\sum_j h_{kj}n_j$ with $h_{kj}=\sum_{i\geq 0}h_{kj,i}X^i\in e_cE[[X]]$. An integer $\kappa\geq 0$ is **admissible** (for $\mathbf{n}$ and m) if $\ell^\kappa h_{kj,i}\in e_c(\mathcal{O}_F\otimes\mathcal{O}_L)$ for all k,j and $i<m$; then the **κ-truncation** is

$$T_\kappa(H_k)=\sum_j\sum_{i<m}\ell^\kappa h_{kj,i}X^i\,n_j\ \in\ \mathbf{N}_c.$$

The **crystalline frame** is $d_k=\mathrm{Ev}(H_k)\in D_{\mathrm{cris}}(V)=(B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)^{G_F}$. Let $\varphi=\varphi\otimes 1$ on $B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V$ and

$$\mathrm{Fil}^u D_{\mathrm{cris}}(V)=D_{\mathrm{cris}}(V)\cap\big(\mathrm{Fil}^u B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V\big)\quad(u\in\mathbb{Z}),\qquad \delta_e(\mathbf{v})=\sum_k v_k\,\varphi^e(d_k)\quad(\mathbf{v}\in L^r).$$

Coordinate vectors. Let $y\in\mathbf{N}[1/\lambda_\infty]$. A vector $f=(f_k)_{k\leq r}\in\mathcal{K}_a^r$ is an **arc coordinate vector** of y (for $\mathbf{n},e,H,m$) if $\Pi f_k\in e_a\mathbf{A}_{F,L}$ for every k and there are an admissible κ and $\kappa'\geq 0$ with

$$\ell^{\kappa'}\Big(\ell^\kappa\,\Pi\,y-\sum_k\Pi f_k\,\varphi^e\big(T_\kappa(H_k)\big)\Big)\in X\Pi^2\,P_e(\mathbf{N}_c).\tag{23.1}$$

Graded sections. For $\alpha\colon\{0,\dots,e-1\}\to\mathbb{Z}$ put $Q^\alpha=\prod_{s<e}Q_s^{\alpha(s)}\in\mathcal{K}_a^\times$. A **section decomposition** of $f\in\mathcal{K}_a^r$ is a finite family $(g_i,\mathbf{v}_i,\alpha_i)_{i\in I}$ with $g_i\in Q^{\alpha_i}e_a\mathbf{A}_{F,L}$, $\mathbf{v}_i\in\mathcal{O}_L^r$ and $f_k=\sum_i g_i\,v_{i,k}$ for all k. For $B=(B_s)_{s<e}$ with $B_s\in\mathbb{Z}_{\geq 0}\cup\{\infty\}$, the vector f is

(Gs1) Hodge-graded if it has a section decomposition with $\delta_e(\mathbf{v}_i)\in\varphi^{s+4}\big(\mathrm{Fil}^{-\alpha_i(s)}D_{\mathrm{cris}}(V)\big)$ for all i and all $s<e$;

(Gs2) pole-bounded by B if it has a section decomposition such that for all i and $s<e$: $\alpha_i(s)\geq 0$, or $\alpha_i(s)\geq -B_s$ and $\delta_e(\mathbf{v}_i)\in\varphi^{s+4}\big(\mathrm{Fil}^{-\alpha_i(s)}D_{\mathrm{cris}}(V)\big)$.

Since $\delta_e(\mathbf{v})\in\varphi^e(\epsilon_{c+3}D_{\mathrm{cris}}(V))=\epsilon_{a+3}D_{\mathrm{cris}}(V)$ (Lemma 23.10), the vector $\varphi^{-(s+4)}(\delta_e(\mathbf{v}))$ lies in $\epsilon_{a-s-1}D_{\mathrm{cris}}(V)$, the component of the embedding τ_{a-s} ($\epsilon_b=\iota_\Lambda(e_b)$ is the idempotent of τ_{b+1} for the canonical inclusion $F\subset B_{\mathrm{dR}}$, because $\iota=\varphi\circ w$ on $\mathcal{O}_F$): the level-s condition reads the Hodge filtration at τ_{a-s}, the embedding whose exponent $H(a-s)$ the arc factor Π carries at Q_s. f is **polar** if it is pole-bounded by $B\equiv\infty$.

Arc coordinate properties. $\mathbf{N}$ has the **arc coordinate properties** at (c,e,H,m) for the frame $\mathbf{n}$ if:

(Ac1) for every $y\in\mathbf{N}[1/\lambda_\infty]$ with $\Pi y\in P_e(\mathbf{N}_c)$ there are $t\geq 0$ and an arc coordinate vector of $\ell^t y$;

(Ac2) for every $y\in P_e(\mathbf{N}_c)$ there are $t\geq 0$ and an arc coordinate vector f of $\ell^t y$ with all $f_k\in e_a\mathbf{A}_{F,L}$;

(Ac3) for every $y\in\mathbf{N}_a$ with $\Pi y\in P_e(\mathbf{N}_c)$ there are $t,\kappa\geq 0$ and an arc coordinate vector f of $\ell^t y$ such that $\ell^\kappa f$ is Hodge-graded;

(Ac4) if f is an arc coordinate vector of 0, there is $t\geq 0$ with $\ell^t f_k\in X\Pi\,e_a\mathbf{A}_{F,L}$ for every k.

Definition 23.4. Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, and fix $u_0 \in 1+\ell\mathbb{Z}_\ell$ with $v_\ell(u_0-1)=1$.

The arc. Let (V,T) be a pair, $\mathbf{N}=\mathbf{N}(T)$ of rank r, $D=D_{\mathrm{cris}}(V)$. Fix a site $c\in\mathbb{Z}/n$ (the *cut*), an integer $1\le \mathrm{len}\le n$, $c_0=c-\mathrm{len}$, a function $H\colon \mathbb{Z}/n\to\mathbb{Z}_{\ge 0}$, $\Pi=\Lambda_{c,\mathrm{len}}(H)=\prod_{s<\mathrm{len}} Q_s^{H(c-s)}$, and a frame $\mathbf{n}=(n_k)_{k\le r}$ at c_0 with horizontal sections H_k and crystalline frame d_k. The **arc domain** is

$$W=\{w\in\mathbf{N}[1/\lambda_\infty]:\ \Pi w\in P_{\mathrm{len}}(\mathbf{N}_{c_0})\}\ \subseteq\ e_c\mathbf{N}[1/\lambda_{\mathrm{len}}].$$

Levels. For $0\le s<\mathrm{len}$ let $\Lambda_s=\varphi^{-(s+1)}\circ\iota_T$ on $\mathbf{N}[1/\lambda_{\mathrm{len}}]$ and $\lambda_s=\varphi^{-(s+1)}\circ(\iota\otimes\mathrm{id})$ on $\mathbf{A}_{F,L}[1/\lambda_{\mathrm{len}}]$, with values in $B_{\mathrm{dR}}\otimes_{\mathbb{Z}_\ell}T$ and $B_{\mathrm{dR}}\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L$ (the level maps of Lemma 23.13; $\Lambda_s(gx)=\lambda_s(g)\Lambda_s(x)$). Put $\epsilon_s=\epsilon_{c-s-1}=\lambda_s(e_c)$, the idempotent of the embedding τ_{c-s}, $R_s^+=\epsilon_s(B_{\mathrm{dR}}^+\otimes_{\mathbb{Q}_\ell}L)$, $R_s=R_s^+[1/t]$, and the **level frame**

$$D_k^{(s)}=\varphi^{\mathrm{len}-s-4}(d_k)\in\epsilon_sD\qquad(k\le r),$$

so that $\Lambda_s(\varphi^{\mathrm{len}}(H_k))=D_k^{(s)}$ by Lemma 23.13 (1). The $D_k^{(s)}$ are an L-basis of ϵ_sD and an R_s-basis of $\epsilon_s(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)$ (by Lemma 23.10 (2), as φ maps ϵ_bD bijectively onto $\epsilon_{b+1}D$, and by Lemma 23.16 with $b=c-s-1$). For $v\in L^r$ the level-s condition of Definition 23.3 reads $\sum_k v_kD_k^{(s)}=\varphi^{-(s+4)}(\delta_{\mathrm{len}}(v))$.

The algebraic level model. Let $\overline{\mathbb{Q}}_\ell$ be the algebraic closure of $\mathbb{Q}_\ell$ in B_{dR}^+; θ maps it isomorphically onto the algebraic closure of $\mathbb{Q}_\ell$ in $\mathbb{C}_\ell$ (Hensel's lemma in the complete discrete valuation ring B_{dR}^+, whose residue field $\mathbb{C}_\ell$ has characteristic 0), and it contains $W(k)[1/\ell]=F$. Let $\zeta_{\ell^k}\in\overline{\mathbb{Q}}_\ell$ be the element with $\theta(\zeta_{\ell^k})=\theta([\varepsilon^{1/\ell^k}])$. The **level coefficient ring** is

$$K_{(s)}=\epsilon_s\big(F(\zeta_{\ell^{s+1}})\otimes_{\mathbb{Q}_\ell}L\big)\subseteq R_s^+.$$

θ is injective on $K_{(s)}$ (L is flat over $\mathbb{Q}_\ell$) and R_s^+ is t-torsion free and t-adically complete, so $\sum_{i\ge i_0}a_it^i\mapsto$ its sum is an injective ring homomorphism $K_{(s)}((t))\to R_s$ (apply θ to t^{-i_0} times a vanishing sum); we identify $K_{(s)}((t))$ with its image. An element $g\in G_F$ preserves $\overline{\mathbb{Q}}_\ell$, fixes F and ϵ_s, sends t to $\chi(g)t$ (χ the cyclotomic character) and $\zeta_{\ell^{s+1}}$ to $\zeta_{\ell^{s+1}}^{\chi(g)}$; for $u\in\mathbb{Z}_\ell^\times$ let σ_u be the automorphism of $K_{(s)}$ induced by any g with $\chi(g)=u$, and on $K_{(s)}((t))^r$ put, coordinatewise,

$$\gamma_u^{(s)}\Big(\sum_i a_it^i\Big)=\sum_i u^i\sigma_u(a_i)\,t^i.$$

Level expansions. An element $w\in e_c\mathbf{N}[1/\lambda_{\mathrm{len}}]$ is **algebraic at level** s if $\Lambda_s(w)=\sum_k f_kD_k^{(s)}$ with all $f_k\in K_{(s)}((t))$; its **level-s expansion** is then $\mathrm{lv}_s(w)=(f_k)_k\in K_{(s)}((t))^r$ (unique, the $D_k^{(s)}$ being an R_s-basis). For $a\in\mathcal{O}_L^r$ (constants $e_c(1\otimes a_k)$ of $e_c\mathbf{A}_{F,L}$), λ_s maps a to $\epsilon_sa\in L^r\subseteq K_{(s)}^r$.

Filtrations and lattices at level s. Fix integers $G,S,\eta,g,M\ge 0$, $1\le j\le\mathrm{len}$, and for each $s<\mathrm{len}$ a *kind* $\kappa_s\in\{\mathrm{thin},\mathrm{up},\mathrm{down}\}$ and a *size* $b_s\ge 0$. Put

$$\mathrm{Fil}_s(u)=\Big\{v\in L^r:\ \sum_k v_kD_k^{(s)}\in\mathrm{Fil}^uD\Big\}=\{v:\ \delta_{\mathrm{len}}(v)\in\varphi^{s+4}(\mathrm{Fil}^uD)\}\qquad(u\in\mathbb{Z}),$$

the *kind space* $U_s^L=L^r$, $\mathrm{Fil}_s(b_s)$, $\mathrm{Fil}_s(-\eta)$ for $\kappa_s=$ thin, up, down, $U_s=U_s^L\cap\mathcal{O}_L^r$, and the *kind family* $(\mathrm{Nb}_s(i))_{i\in\mathbb{Z}}$: for thin, 0 if $i<0$ and L^r if $i\ge 0$; for up, 0 if $i<-b_s$, U_s^L if $-b_s\le i<0$, L^r if $i\ge 0$; for down, 0 if $i<0$, U_s^L if $0\le i<b_s$, L^r if $i\ge b_s$. For a family $\mathcal{X}=(\mathcal{X}(i))_{i\in\mathbb{Z}}$ of L-subspaces of L^r let $\Xi_s(\mathcal{X})$ be the set of $f\in K_{(s)}((t))^r$ whose t^i-coefficient lies in $K_{(s)}\otimes_L\mathcal{X}(i)$ for every i. A vector $f\in K_{(s)}((t))^r$ is

- **de Rham integral** at s if $f \in \Xi_s((\mathrm{Fil}_s(-i))_i)$;
- **kind integral** at s if $f \in \Xi_s((\mathrm{Nb}_s(i))_i)$;
- **truncation small** at s, written $f \in \mathcal{T}_s$, if

$$\lambda_s(\Pi) f \in \lambda_s(f')\, K_{(s)}[[t]]^r,$$

where $f' = \varphi^{\mathrm{len}-j}(X^{(\ell-1)M} \prod_{s'<j} Q_{s'}^{3g})$.

A family $(f_s)_{s<\mathrm{len}}$, $f_s \in K_{(s)}((t))^r$, is **constant** if there is $v \in L^r$ with $f_s = v$ for every s.

Arc level data of a map. Let $\Phi\colon T_1 \to T_2$ be a G_F-equivariant $\mathcal{O}_L$-linear map of the lattices of pairs (V_1, T_1), (V_2, T_2), of ranks r_1, r_2, and $\mathbf{N}(\Phi)\colon \mathbf{N}(T_1) \to \mathbf{N}(T_2)$ its map of Wach modules. Fix $(c, \mathrm{len}, H, G, S, \eta, g, M, j, (\kappa_s, b_s)_s)$ as above and frames $\mathbf{n}^\nu$ at c_0 of $\mathbf{N}(T_\nu)$. The **frame matrix** $o \in M_{r_2 \times r_1}(\mathcal{O}_L)$ is defined by $\mathbf{N}(\Phi)(n_k^1) \equiv \sum_l o_{lk} n_l^2 \bmod X\mathbf{N}(T_2)_{c_0}$ (via $e_{c_0}\mathbf{A}_{F,L}/X \cong \mathcal{O}_L$). The **arc level data** of Φ are the objects above for T_1 and for T_2 (indices 1, 2), together with $\mathbf{N}(\Phi)\colon W_1 \to W_2$ and o ($\mathbf{N}(\Phi)$ commutes with φ and preserves sites, hence maps W_1 into W_2).

Arc level properties. The arc level data of Φ have the **arc level properties** if, for $\nu = 1, 2$ and every $s < \mathrm{len}$:

(Lp1) Algebraic levels $\lambda_s(e_c\mathbf{A}_{F,L}) \subseteq K_{(s)}[[t]]$, $\lambda_s(Q_s) \in t\,K_{(s)}[[t]]^\times$, $\lambda_s(X), \lambda_s(Q_{s'}) \in K_{(s)}[[t]]^\times$ for $s' \neq s$, and every element of W_ν is algebraic at level s;

(Lp2) Equivariance $\gamma_u(W_\nu) \subseteq W_\nu$ and $\mathrm{lv}_s(\gamma_u w) = \gamma_u^{(s)}(\mathrm{lv}_s(w))$ for $w \in W_\nu$, $u \in \mathbb{Z}_\ell^\times$;

(Lp3) Membership for $w \in W_\nu$: $w \in \mathbf{N}(T_\nu)_c$ if and only if $\mathrm{lv}_{s'}(w)$ is de Rham integral at s' for every $s' < \mathrm{len}$;

(Lp4) Regularity $\lambda_s(\Pi)\,\mathrm{lv}_s(w) \in K_{(s)}[[t]]^{r_\nu}$ for $w \in W_\nu$;

(Lp5) Completeness if $a \in e_c\mathbf{A}_{F,L}$ and $\lambda_s(a) \in t^k K_{(s)}[[t]]$, then $\ell^N a \in Q_s^k e_c \mathbf{A}_{F,L}$ for some $N \geq 0$;

(Lp6) Constants if $x \in \mathbf{N}(T_\nu)_{c_0}$, $(\gamma_{u_0} - 1)x \in X^{(\ell-1)M}\mathbf{N}(T_\nu)_{c_0}$, $x - \sum_k a_k n_k^\nu \in X\mathbf{N}(T_\nu)_{c_0}$ with $a \in \mathcal{O}_L^{r_\nu}$, and $w \in W_\nu$ with $\Pi w = \varphi^{\mathrm{len}}(x)$, then $\mathrm{lv}_s(w) - \lambda_s(\Pi)^{-1} a \in \mathcal{T}_s$;

(Lp7) Windows Fil_s^ν is decreasing, equal to L^{r_ν} for $u \ll 0$ and to 0 for $u \gg 0$, and each jump u ($\mathrm{Fil}_s^\nu(u) \neq \mathrm{Fil}_s^\nu(u+1)$) satisfies $|u| \leq G$ if κ_s is thin, $u \in [b_s, b_s + S] \cup [-\eta, \eta]$ if up, $u \in [-b_s - S, -b_s] \cup [-\eta, \eta]$ if down;

(Lp8) Galois structure $\sigma_u^{\ell^s} = \mathrm{id}$ on $K_{(s)}$ for $u \in 1 + \ell\mathbb{Z}_\ell$, and the elements of $K_{(s)}$ fixed by every σ_u ($u \in \mathbb{Z}_\ell^\times$) are those of $\epsilon_s L = L$;

and, for every $s < \mathrm{len}$:

(Lh1) Level map $\mathrm{lv}_s(\mathbf{N}(\Phi)w) = o\,\mathrm{lv}_s(w)$ for $w \in W_1$;

(Lh2) Kind spaces if κ_s is up, then $o(U_s^1) \subseteq U_s^2$.

Along a weight word. For an onto map Φ of crystalline lattices with a weight word $(b, w, S, \eta, m, (s_a), (\mathrm{sg}_a))$ and a cut c of length len, with $G = w + S + \eta$, $g = \max(G, 1)$ and h_* as in Proposition C.83, the **arc level data along the word** use: κ_s thin if $c - s$ is thin, up (resp. down) if $c - s$ is thick with $\mathrm{sg}_{c-s} = 1$ (resp. -1); $b_s = s_{c-s}$; $H(c-s) = g + G$, $g + s_{c-s} + S$, $g + \eta$ for κ_s thin, up, down; $M = \lfloor (h_* + 2g)/(\ell - 1) \rfloor + 1$; and the j of the cut configuration.

Lemma 23.5. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, (V,T) a pair, $\mathbf{N}=\mathbf{N}(T)$, and fix arc level data for (V,T) (cut c, length $1\le \mathrm{len}\le n$, H, frame at $c-\mathrm{len}$). Then:*

1. *for $s<\mathrm{len}$ and $f\in K_{(s)}((t))^r$: f is de Rham integral at s if and only if $\sum_k f_k D_k^{(s)}\in \epsilon_s(B^+_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell} V)$;*
2. *(Lp3) holds: for $w\in W$, $w\in\mathbf{N}_c$ if and only if $\mathrm{lv}_s(w)$ is de Rham integral at s for every $s<\mathrm{len}$.*

Proof. Write $B=B^+_{\mathrm{dR}}$, $K=K_{(s)}$, $D=D_{\mathrm{cris}}(V)$, $D_k=D_k^{(s)}$.

Step 1: $K((t))\cap t^mR_s^+=t^mK[[t]]$. If $f=\sum_{i\ge i_0}a_it^i\in t^mR_s^+$ with $a_{i_0}\neq 0$ and $i_0<m$, then $t^{-i_0}f\in tR_s^+$ and $\theta(t^{-i_0}f)=a_{i_0}$ (identified with its image) vanishes; θ is injective on K, a contradiction.

Step 2: proof of 1. By Lemma 23.16 (with $b=c-s-1$, so that its ϵ, R^+ are ϵ_s, R_s^+), ϵ_sD has an L-basis $(D_i^{\mathrm{ad}})_i$ adapted to the filtration ($D_i^{\mathrm{ad}}\in\mathrm{Fil}^{u_i}D$, and $\epsilon_s\mathrm{Fil}^jD$ spanned by the D_i^{ad} with $u_i\ge j$), and

$$\epsilon_s(B\otimes_{\mathbb{Q}_\ell}V)=\bigoplus_i t^{-u_i}R_s^+D_i^{\mathrm{ad}}.$$

Let $D_k=\sum_i W_{ki}D_i^{\mathrm{ad}}$, $W\in GL_r(L)$. For $f\in K((t))^r$ put $\phi_i=\sum_k f_kW_{ki}\in K((t))$, so $\sum_k f_kD_k=\sum_i\phi_iD_i^{\mathrm{ad}}$. By Step 1, this lies in $\epsilon_s(B\otimes V)$ iff $\phi_i\in t^{-u_i}K[[t]]$ for all i, i.e. iff for every m the t^m-coefficients satisfy $\phi_i^{(m)}=0$ whenever $u_i<-m$, i.e. iff $\sum_i\phi_i^{(m)}D_i^{\mathrm{ad}}\in K\otimes_L\epsilon_s\mathrm{Fil}^{-m}D$ for every m. Since $\sum_i\phi_i^{(m)}D_i^{\mathrm{ad}}=\sum_k f_k^{(m)}D_k$ ($f^{(m)}$ the t^m-coefficient of f) and the D_k form an L-basis of ϵ_sD, the last condition says $f^{(m)}\in K\otimes_L\mathrm{Fil}_s(-m)$ for every m: f is de Rham integral at s.

Step 3: a basis of the integral level. Let $\mathbf{n}'=(n'_j)_{j\le r}$ be an $e_c\mathbf{A}_{F,L}$-basis of $\mathbf{N}_c$ (Wm1). Then $(\Lambda_s(n'_j))_j$ is an R_s^+-basis of $M=\epsilon_s(B\otimes_{\mathbb{Z}_\ell}T)=\epsilon_s(B\otimes_{\mathbb{Q}_\ell}V)$. This is (Lm2) of Lemma 23.6, applied with the site $c-\mathrm{len}$ in place of its c, $e=\mathrm{len}$ and $a=c$: its λ_s, Λ_s, $\epsilon=\epsilon_{a-s-1}$ and R^+ are our λ_s, Λ_s, ϵ_s and R_s^+.

Step 4: proof of 2. Let $w\in W\subseteq e_c\mathbf{N}[1/\lambda_{\mathrm{len}}]$ and write $w=\sum_j g_jn'_j$ with $g_j\in e_c\mathbf{A}_{F,L}[1/\lambda_{\mathrm{len}}]$. Let $\mathcal{O}=e_c\mathbf{A}_{F,L}[1/\ell]\cong\mathcal{O}_L[[X]][1/\ell]$ (factorial; the $Q_{s'}$ squarefree and pairwise coprime) and, for $g\in\mathcal{O}[1/\lambda_{\mathrm{len}}]$, $\mathrm{ord}_s(g)$ the minimum of $v_\pi(g)$ over the prime factors π of Q_s. (a) $g\in e_c\mathbf{A}_{F,L}$ iff $\mathrm{ord}_s(g)\ge 0$ for all $s<\mathrm{len}$: if so, $g=g'/\lambda_{\mathrm{len}}^{K'}$ with $g'\in e_c\mathbf{A}_{F,L}$ and $\lambda_{\mathrm{len}}^{K'}$ divides g' in $\mathcal{O}$, so $g=\varpi^{-N}h_0$ with $h_0\in\mathcal{O}_L[[X]]$, ϖ a uniformiser of $\mathcal{O}_L$, and $\lambda_{\mathrm{len}}^{K'}h_0=\varpi^Ng'$; if $N>0$, reduction modulo ϖ gives $X^{K'\deg\lambda_{\mathrm{len}}}\bar{h}_0=0$ in the domain $k_L[[X]]$ (λ_{len} is distinguished), so $\varpi\mid h_0$, and induction on N gives $g\in\mathcal{O}_L[[X]]$; the converse is clear. (b) By (Lm3) of Lemma 23.6 (in the setting of Step 3, with $\alpha=0$; its $\mathcal{O}$ and ord_s are ours), $\lambda_s(g)\in R_s^+$ iff $\mathrm{ord}_s(g)\ge 0$. (c) $\Lambda_s(w)=\sum_j\lambda_s(g_j)\Lambda_s(n'_j)$ with $\lambda_s(g_j)\in R_s$, so by Step 3 (a basis of M is a basis of $M[1/t]$), $\Lambda_s(w)\in M$ iff $\lambda_s(g_j)\in R_s^+$ for all j. Combining (a)–(c): $w\in\mathbf{N}_c$ iff $\Lambda_s(w)\in\epsilon_s(B\otimes V)$ for every $s<\mathrm{len}$. Finally w is algebraic at every level with $\Lambda_s(w)=\sum_k\mathrm{lv}_s(w)_kD_k$ (Lemma 23.17 (Lp1)), and 1 turns the condition into de Rham integrality of $\mathrm{lv}_s(w)$. □

23.2 Existence of Wach modules, level maps and horizontal frames

The main result is Proposition 23.7: every crystalline lattice over a field between F and $F(\mu_\ell)$ has a Wach module whose window at each site is the window of its Hodge jumps at the corresponding embeddings, together with a realisation map into $A_{\mathrm{inf}}[1/\mu_\varepsilon]\otimes T$. The proof evaluates the prismatic F-crystal of the lattice [31] on the cyclotomic prism $(\mathbf{A}_F, Q\,\mathbf{A}_F)$, whose maps to Fontaine's ring are set up in Lemma 23.8. The lemmas that follow supply the tools of the later

lifting arguments: level maps, which evaluate a Wach module at the Frobenius twists of μ_ε and land in $B_{\mathrm{dR}} \otimes T$; horizontal sections and frames, which evaluate to bases of D_{cris} site by site; and the algebraicity of the levels (Lemma 23.17), which places the level expansions in $K_{(s)}((t))$ with an explicit Galois structure. These lemmas are technical; their point is integral control, with explicit denominators, at every site.

Lemma 23.6. *Let ℓ, F, L, $(\tau_b)_{b\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $r = \dim_L V$, $D = D_{\mathrm{cris}}(V)$ and $B = B^+_{\mathrm{dR}}$. Fix $c \in \mathbb{Z}/n$, an integer $e \geq 1$, $a = c + e$, an integer s with $0 \leq s < e$, and put $q = e - s - 1$, $\epsilon = \epsilon_{a-s-1}$ and $R^+ = \epsilon(B \otimes_{\mathbb{Q}_\ell} L)$. Let $\mathcal{O} = e_a \mathbf{A}_{F,L}[1/\ell]$ ($\cong \mathcal{O}_L[[X]][1/\ell]$, a factorial domain), and for $g \in \mathcal{O}[1/\lambda_e]$ let $\mathrm{ord}_s(g) \in \mathbb{Z} \cup \{\infty\}$ be the minimum of $v_\pi(g)$ over the prime elements π of $\mathcal{O}$ dividing Q_s.*

(Lm1) Scalars *There is a unique ring homomorphism $\lambda_s \colon \mathbf{A}_{F,L}[1/\lambda_e] \to B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L$ equal to $(\varphi^{-(s+1)} \otimes 1) \circ \iota_L$ on $\mathbf{A}_{F,L}$. It maps $\mathbf{A}_{F,L}$ into $B \otimes_{\mathbb{Q}_\ell} L$, $\lambda_s(e_a) = \epsilon$, $\lambda_s(Q_s) = \xi_0$, and $\lambda_s(X)$ and $\lambda_s(Q_{s'})$ ($s' < e$, $s' \neq s$) are units of B; $\lambda_s(\varphi^e(g)) = (\varphi^q \otimes 1)(\iota_L(g))$ for $g \in \mathbf{A}_{F,L}$.*

(Lm2) Vectors *There is a unique λ_s-semilinear map $\Lambda_s \colon \mathbf{N}[1/\lambda_e] \to B_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} T$ with $\Lambda_s(x) = (\varphi^{-(s+1)} \otimes 1)(\iota_T(x))$ for $x \in \mathbf{N}$. It satisfies $\Lambda_s(\mathbf{N}) \subseteq B \otimes_{\mathbb{Z}_\ell} T$, $\Lambda_s(\varphi^e_{\mathbf{N}}(z)) = (\varphi^q \otimes 1)(\iota_T(z))$ for $z \in \mathbf{N}$, and for every $e_a\mathbf{A}_{F,L}$-basis $(n'_j)_{j\leq r}$ of $\mathbf{N}_a$ the vectors $\Lambda_s(n'_j)$ form a basis of the R^+-module $\epsilon(B \otimes_{\mathbb{Q}_\ell} V)$.*

(Lm3) Orders *For $g \in \mathcal{O}[1/\lambda_e]$ and $\alpha \in \mathbb{Z}$: $\lambda_s(g) \in \xi_0^\alpha R^+$ if and only if $\mathrm{ord}_s(g) \geq \alpha$.*

(Lm4) Lattice criterion *An element $y \in \mathbf{N}_a[1/\lambda_e] = e_a\mathbf{N}[1/\lambda_e]$ lies in $\mathbf{N}_a$ if and only if, for every $s' < e$, the map $\Lambda_{s'}$ (formed with s' in place of s) sends y into $\epsilon_{a-s'-1}(B \otimes_{\mathbb{Q}_\ell} V)$.*

(Lm5) Frobenius pull-backs *Let $\mathbf{n} = (n_k)_{k\leq r}$ be a frame at c, (H_k) the horizontal sections through it, (d_k) its crystalline frame, $D_k = \varphi^{e-s-4}(d_k) \in D$ (φ is bijective on D) and $\Lambda_D = \sum_k R^+ D_k$. Then $D_k \in \epsilon D$, $\Lambda_s(P_e(\mathbf{N}_c)) \subseteq \Lambda_D$, and for every integer $m \geq 1$, every κ admissible for $\mathbf{n}$ and m, and every k,*

$$\Lambda_s(\varphi^e_{\mathbf{N}}(T_\kappa(H_k))) - \ell^\kappa D_k \in \xi_0^m \Lambda_D.$$

Proof. Throughout, B is a complete discrete valuation ring with uniformiser ξ_0 and residue map θ, ℓ is invertible in B, $B_{\mathrm{dR}} = B[1/\xi_0]$ and $t \in \xi_0 B^\times$ (Theorem B.40 (Ai3)); $A_{\mathrm{inf}} \subseteq B$ compatibly with θ, and φ is a ring automorphism of A_{inf} with $\varphi([x]) = [x^\ell]$. Write $\zeta_{\ell^k} = (\varepsilon^{1/\ell^k})^\sharp$, a primitive ℓ^k-th root of unity, and $B_L = B \otimes_{\mathbb{Q}_\ell} L$, a free B-module of rank $[L : \mathbb{Q}_\ell]$, hence ξ_0-torsion free and ξ_0-adically separated; the same holds for its direct summand $R^+ = \epsilon B_L$, and $\epsilon(B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L) = R^+[1/\xi_0]$.

Step 1: the elements $\varphi^j(\xi_0)$ and $\varphi^j(\mu)$. We have $\varphi^j(\xi_0) = \sum_{k<\ell} [\varepsilon^{\ell^{j-1}}]^k$ and $\varphi^j(\mu) = [\varepsilon^{\ell^j}] - 1$ for $j \in \mathbb{Z}$. By (Ai1), $\theta(\varphi^j(\xi_0)) = \ell$ for $j \geq 1$ and $\theta(\varphi^j(\xi_0)) = \sum_{k<\ell} \zeta_{\ell^{1-j}}^k \neq 0$ for $j \leq -1$ (the sum of the powers of a primitive ℓ^{1-j}-th root of unity ζ, $1-j \geq 2$, equals $(\zeta^\ell - 1)/(\zeta - 1)$ and $\zeta^\ell \neq 1$); so $\varphi^j(\xi_0) \in B^\times$ for $j \neq 0$, as B is local with residue map θ. Likewise $\theta(\varphi^{-k}(\mu)) = \zeta_{\ell^k} - 1 \neq 0$ for $k \geq 1$, so $\varphi^{-k}(\mu) \in B^\times$, while $\theta(\varphi^j(\mu)) = 1 - 1 = 0$ for $j \geq 0$, so $\varphi^j(\mu) \in \xi_0 A_{\mathrm{inf}} \subseteq \xi_0 B$ by (Ai1).

Step 2: (Lm1). By Lemma 23.8 (4), $\iota(X) = \mu$, $\iota(Q) = \tilde{\xi} = \sum_{k<\ell} [\varepsilon]^k = \varphi(\xi_0)$ and $\iota \circ \varphi = \varphi \circ \iota$ (ι is a morphism of prisms), so $\iota(Q_{s'}) = \varphi^{s'+1}(\xi_0)$. Hence $(\varphi^{-(s+1)} \otimes 1)\iota_L$ sends X to $\varphi^{-(s+1)}(\mu) \in B^\times$, Q_s to ξ_0 and $Q_{s'}$ to $\varphi^{s'-s}(\xi_0) \in B^\times$ for $s' \neq s$ (Step 1). As $\lambda_e = \prod_{s'<e} Q_{s'}$ goes to ξ_0 times a unit, which is invertible in B_{dR}, the homomorphism $(\varphi^{-(s+1)} \otimes 1) \circ \iota_L \colon \mathbf{A}_{F,L} \to A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \subseteq B_L$ extends uniquely to $\mathbf{A}_{F,L}[1/\lambda_e]$. Further $\lambda_s(e_a) = \varphi^{-(s+1)}(\iota_\Lambda(e_a)) = \iota_\Lambda(e_{a-s-1}) = \epsilon_{a-s-1}$, since

ι_Λ commutes with φ on $\mathcal{O}_F \otimes \mathcal{O}_L$ and $\varphi(e_b) = e_{b+1}$ (Definition 23.2). Finally $\lambda_s(\varphi^e(g)) = (\varphi^{-(s+1)}\varphi^e \otimes 1)(\iota_L(g)) = (\varphi^q \otimes 1)(\iota_L(g))$.

Step 3: (Lm2). For $x \in \mathbf{N}$, $\iota_T(x) \in A_{\mathrm{inf}}[1/\mu] \otimes T$ and $\varphi^{-(s+1)}$ maps $A_{\mathrm{inf}}[1/\mu]$ into $A_{\mathrm{inf}}[1/\varphi^{-(s+1)}(\mu)] \subseteq B$ (Step 1); so $x \mapsto (\varphi^{-(s+1)} \otimes 1)(\iota_T(x))$ maps $\mathbf{N}$ into $B \otimes_{\mathbb{Z}_\ell} T$, and it is λ_s-semilinear on $\mathbf{N}$ by (Ex2) ($\iota_T(fx) = \iota(f)\iota_T(x)$ for $f \in \mathbf{A}_F$, $\mathcal{O}_L$-linearity, and $\mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ as $\mathcal{O}_L$ is finite free over $\mathbb{Z}_\ell$). Since $\mathbf{N}[1/\lambda_e] = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} \mathbf{A}_{F,L}[1/\lambda_e]$ and $\lambda_s(\lambda_e)$ is invertible, it extends uniquely to a λ_s-semilinear Λ_s on $\mathbf{N}[1/\lambda_e]$. *Frobenius.* The elements μ and $\iota(\lambda_e) = \prod_{s'<e} \varphi^{s'+1}(\xi_0)$ are units of $W(\mathbb{C}_\ell^\flat)$ (the image of μ modulo ℓ is $\varepsilon - 1 \neq 0$ in the field $\mathbb{C}_\ell^\flat$, and $\tilde{\xi}$ is a unit there by (Ex2), hence so are its Frobenius twists), so $A^\circ = A_{\mathrm{inf}}[1/\mu, 1/\iota(\lambda_e)] \subseteq W(\mathbb{C}_\ell^\flat)$, and ι_T extends ι_L-semilinearly to $\mathbf{N}[1/\lambda_e] \to A^\circ \otimes T$. Iterating the Frobenius clause of (Ex2) e times gives $\iota_T(\varphi^e_{\mathbf{N}}(z)) = (\varphi^e \otimes 1)(\iota_T(z))$ in $A^\circ \otimes T$ for $z \in \mathbf{N}$ (each $\varphi^j_{\mathbf{N}}(z)$, $j \leq e$, lies in $\mathbf{N}[1/\lambda_j]$, as $\varphi(Q_{s'}) = Q_{s'+1}$). By Steps 1 and 2 the localisation $\varphi^{-(s+1)}\colon A^\circ \to B_{\mathrm{dR}}$ is defined and restricts to λ_s on $\iota_L(\mathbf{A}_{F,L}[1/\lambda_e])$; thus $\Lambda_s = (\varphi^{-(s+1)} \otimes 1) \circ \iota_T$ on $\mathbf{N}[1/\lambda_e]$ (both are λ_s-semilinear and agree on $\mathbf{N}$), and $\Lambda_s(\varphi^e_{\mathbf{N}}(z)) = (\varphi^{e-s-1} \otimes 1)(\iota_T(z))$. *Basis.* By (Ex2), $A_{\mathrm{inf}}[1/\mu] \cdot \iota_T(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu] \otimes T$; applying the ring automorphism $\varphi^{-(s+1)} \otimes 1$ and extending scalars to B, $1 \otimes T \subseteq B \cdot \Lambda_s(\mathbf{N})$, so $B \cdot \Lambda_s(\mathbf{N}) = B \otimes_{\mathbb{Z}_\ell} T = B \otimes_{\mathbb{Q}_\ell} V$. Since $\Lambda_s(e_b x) = \epsilon_{b-s-1}\Lambda_s(x)$ (Step 2 for b in place of a) and the ϵ_b are orthogonal idempotents with sum 1, multiplying by ϵ gives $\epsilon(B \otimes V) = B \cdot \Lambda_s(\mathbf{N}_a)$. Now $\Lambda_s(\mathbf{N}_a) = \sum_j \lambda_s(e_a \mathbf{A}_{F,L})\Lambda_s(n'_j) \subseteq \sum_j R^+ \Lambda_s(n'_j)$, and R^+ contains the image of B acting on $\epsilon(B \otimes V)$; so the r vectors $\Lambda_s(n'_j)$ generate the R^+-module $\epsilon(B \otimes_{\mathbb{Q}_\ell} V) = R^+ \otimes_L V$, which is free of rank r. A surjective endomorphism of a finitely generated module over a commutative ring is bijective, so the map $(R^+)^r \to R^+ \otimes_L V$, $(x_j) \mapsto \sum_j x_j \Lambda_s(n'_j)$, is an isomorphism, i.e. the $\Lambda_s(n'_j)$ form a basis.

Step 4: (Lm3). The $Q_{s'}$ ($s' < e$) are squarefree and pairwise coprime in $\mathcal{O}$: they are monic polynomials (Lemma 23.8 (3)), products of distinct irreducible distinguished polynomials, and distinct cyclotomic polynomials have no common root. Let $g \in \mathcal{O}[1/\lambda_e]$, $g \neq 0$, and $\beta = \mathrm{ord}_s(g)$. Since Q_s is squarefree, $g = Q_s^\beta g_0$ with $g_0 \in \mathcal{O}[1/Q_{s'} : s' \neq s,\ s' < e]$ and $g_0 \notin Q_s\mathcal{O}[1/Q_{s'} : s' \neq s]$. By (Lm1), $\lambda_s(\mathcal{O}) \subseteq \epsilon B_L = R^+$ (note $\lambda_s(1/\ell) = 1/\ell$) and $\lambda_s(Q_{s'}) \in B^\times$ for $s' \neq s$, so $\lambda_s(g_0) \in R^+$ and $\lambda_s(g) = \xi_0^\beta \lambda_s(g_0)$. If $\beta \geq \alpha$ this lies in $\xi_0^\alpha R^+$. Conversely it suffices to show $\lambda_s(g_0) \notin \xi_0 R^+$, for then $\lambda_s(g) \notin \xi_0^{\beta+1} R^+ \supseteq \xi_0^\alpha R^+$ when $\beta < \alpha$ (R^+ is ξ_0-torsion free). Consider $\bar{\lambda} = \theta \circ \lambda_s\colon \mathcal{O} \to R^+/\xi_0 R^+ = \epsilon(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L)$. On $e_a(\mathcal{O}_F \otimes \mathcal{O}_L)[1/\ell] = e_a(1 \otimes L) \cong L$ it is the L-linear map $\lambda \mapsto \epsilon(1 \otimes \lambda)$, and it sends X to $\epsilon(\zeta_{\ell^{s+1}} - 1)$ (Step 1); it is continuous for the X-adic topology on $\mathcal{O}_L[[X]]$ since $\zeta_{\ell^{s+1}} - 1$ has positive valuation. By Weierstrass division by the distinguished polynomial Q_s, $\mathcal{O}/Q_s\mathcal{O} \cong L[X]/(Q_s) \cong \mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} L$, and $\bar{\lambda}$ vanishes on Q_s and induces the map $\mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} L \to \epsilon(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L)$, $x \otimes \lambda \mapsto \epsilon(x \otimes \lambda)$. Write $\epsilon(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L) = \mathbb{C}_\ell \otimes_F L$, where $F \subset \mathbb{C}_\ell$ canonically and F acts on L through the embedding attached to the idempotent ϵ of $F \otimes_{\mathbb{Q}_\ell} L$. The induced map is $(\mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} F) \otimes_F L \to \mathbb{C}_\ell \otimes_F L$; here $\mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} F \cong F(\zeta_{\ell^{s+1}}) \subset \mathbb{C}_\ell$ is a field ($F/\mathbb{Q}_\ell$ unramified, $\mathbb{Q}_\ell(\zeta_{\ell^{s+1}})/\mathbb{Q}_\ell$ totally ramified) and L is flat over F, so the map is injective. Hence $\ker \bar{\lambda} = Q_s\mathcal{O}$, and $\bar{\lambda}(Q_{s'}) \neq 0$ is a unit in each factor for $s' \neq s$; as $g_0 = g_1 / \prod_{s' \neq s} Q_{s'}^k$ with $g_1 \in \mathcal{O} \setminus Q_s\mathcal{O}$, $\theta(\lambda_s(g_0)) \neq 0$, i.e. $\lambda_s(g_0) \notin \xi_0 R^+$.

Step 5: (Lm4). If $y \in \mathbf{N}_a$ then $\Lambda_{s'}(y) \in \Lambda_{s'}(e_a\mathbf{N}) \subseteq \epsilon_{a-s'-1}(B \otimes V)$ by Step 3. Conversely let (n'_j) be a basis of $\mathbf{N}_a$ and $y = \sum_j g_j n'_j$, $g_j \in e_a\mathbf{A}_{F,L}[1/\lambda_e]$. For each $s' < e$, $\Lambda_{s'}(y) = \sum_j \lambda_{s'}(g_j)\Lambda_{s'}(n'_j)$ with $\lambda_{s'}(g_j) \in \epsilon_{a-s'-1}(B_{\mathrm{dR}} \otimes L)$; by the basis property (Lm2) the hypothesis forces $\lambda_{s'}(g_j) \in \epsilon_{a-s'-1}B_L$, so $\mathrm{ord}_{s'}(g_j) \geq 0$ by (Lm3). Write $g_j = h_j/\lambda_e^k$ with $h_j \in e_a\mathbf{A}_{F,L}$. Every prime of $\mathcal{O}$ dividing λ_e divides exactly one $Q_{s'}$, to the first power, so $\mathrm{ord}_{s'}(g_j) \geq 0$ for all $s' < e$ says that λ_e^k divides h_j in $\mathcal{O}$: $h_j = \lambda_e^k u_j$ with $u_j \in \mathcal{O}$. Let ϖ be a uniformiser of $\mathcal{O}_L$ and $i \geq 0$ minimal with $\varpi^i u_j \in e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$. If $i > 0$, reduce $\varpi^i h_j = \lambda_e^k(\varpi^i u_j)$ modulo ϖ: $\lambda_e^k \equiv X^d$ ($d = k \deg \lambda_e$, Lemma 23.8 (3)) and $k_L[[X]]$ is a domain, so $\varpi^i u_j \equiv 0$, contradicting minimality. So $u_j = g_j \in e_a\mathbf{A}_{F,L}$ and $y \in \mathbf{N}_a$.

Step 6: (Lm5). Let $\mathbf{h} = (h_{kj}) \in M_r(e_cE[[X]])$ with $H_k = \sum_j h_{kj} n_j$; by (Hf2) of Lemma 23.9 the H_k are an $e_cE[[X]]$-basis of $e_c\mathbf{N}_E$, so $\mathbf{h}$ is invertible and $n_j = \sum_k (\mathbf{h}^{-1})_{jk} H_k$. The map $\mathrm{ev}^{(q)}$ of Lemma 23.13 is a ring homomorphism (a ξ_0-adically convergent substitution, item 1 there) with $\mathrm{ev}^{(q)}(X) = \varphi^q(\mu)$, and $\mathrm{ev}^{(q)}(e_cE) \subseteq \varphi^q(\iota_\Lambda(e_c))B_L = \epsilon_{c+q}B_L = R^+$ since $c+q = a-s-1$; so $\mathrm{ev}^{(q)}(e_cE[[X]]) \subseteq R^+$. By its definition $G^{(q)}$ is additive with $G^{(q)}(gW) = \mathrm{ev}^{(q)}(g)G^{(q)}(W)$ for $g \in e_cE[[X]]$ and $G^{(q)}(n_j) = (\varphi^q \otimes 1)(\iota_T(n_j))$, and by Lemma 23.13 (1) $G^{(q)}(H_k) = \varphi^{q-3}(d_k) = D_k$. Hence $D_k = \sum_j \mathrm{ev}^{(q)}(h_{kj})(\varphi^q \otimes 1)(\iota_T(n_j)) \in \epsilon(B_{\mathrm{dR}} \otimes V)$, so $D_k \in \epsilon D$ (the idempotent ϵ of $F \otimes L$ acts on $D \subseteq B_{\mathrm{cris}} \otimes V \subseteq B_{\mathrm{dR}} \otimes V$ compatibly), and

$$(\varphi^q \otimes 1)(\iota_T(n_j)) = G^{(q)}(n_j) = \sum_k \mathrm{ev}^{(q)}((\mathbf{h}^{-1})_{jk}) D_k \in \Lambda_D. \tag{1}$$

Pull-backs. $P_e(\mathbf{N}_c)$ is generated over $\mathbf{A}_{F,L}$ by the $\varphi^e_{\mathbf{N}}(n_j)$ (as $\varphi^e_{\mathbf{N}}(\sum f_j n_j) = \sum \varphi^e(f_j)\varphi^e_{\mathbf{N}}(n_j)$) and lies in $e_a\mathbf{N}[1/\lambda_\infty]$, so each $p \in P_e(\mathbf{N}_c)$ is $\sum_j g_j \varphi^e_{\mathbf{N}}(n_j)$ with $g_j \in e_a\mathbf{A}_{F,L}$; then $\Lambda_s(p) = \sum_j \lambda_s(g_j)G^{(q)}(n_j) \in \Lambda_D$ by (Lm2), (1) and $\lambda_s(g_j) \in \epsilon B_L = R^+$. *Truncations.* Write $T_\kappa(H_k) = \sum_j p_{kj} n_j$ with the polynomials $p_{kj} = \sum_{i<m} \ell^\kappa h_{kj,i} X^i \in e_c\mathbf{A}_{F,L}$, and $\ell^\kappa h_{kj} = p_{kj} + X^m \sigma_{kj}$ with $\sigma_{kj} \in e_cE[[X]]$. By (Lm2) and (Lm1), $\Lambda_s(\varphi^e_{\mathbf{N}}(T_\kappa H_k)) = \sum_j (\varphi^q \otimes 1)(\iota_L(p_{kj}))\, G^{(q)}(n_j)$, and $(\varphi^q \otimes 1)(\iota_L(p_{kj})) = \sum_{i<m} \varphi^q(\iota_\Lambda(\ell^\kappa h_{kj,i}))\varphi^q(\mu)^i = \mathrm{ev}^{(q)}(p_{kj})$ (a finite sum; $\iota_L = \iota_\Lambda$ on coefficients and $\iota_L(X) = \mu$). Hence

$$\Lambda_s(\varphi^e_{\mathbf{N}}(T_\kappa H_k)) = G^{(q)}\Big(\sum_j p_{kj} n_j\Big) = \ell^\kappa G^{(q)}(H_k) - \varphi^q(\mu)^m \sum_j \mathrm{ev}^{(q)}(\sigma_{kj}) G^{(q)}(n_j) \in \ell^\kappa D_k + \xi_0^m \Lambda_D,$$

by (1), $\mathrm{ev}^{(q)}(\sigma_{kj}) \in R^+$ and $\varphi^q(\mu) \in \xi_0 B$ (Step 1, $q \geq 0$). □

Proposition 23.7. *Let ℓ be an odd prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, L a finite extension of $\mathbb{Q}_\ell$ containing $\sigma(F(\mu_\ell))$ for every $\mathbb{Q}_\ell$-embedding σ of $F(\mu_\ell)$, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, and K a field with $F \subseteq K \subseteq F(\mu_\ell)$. Call a* pair over K *a pair (V,T) of a finite-dimensional L-vector space V with a continuous L-linear action of G_K, crystalline as a $\mathbb{Q}_\ell$-representation, and a G_K-stable $\mathcal{O}_L$-lattice $T \subseteq V$; a* pair *is a pair over F. To every pair (V,T) over K one can attach a finitely generated $\mathbf{A}_{F,L}$-module $\mathbf{N}(T)$ with maps $\varphi_{\mathbf{N}}$, $\gamma_{u,\mathbf{N}}$ and an injective additive map $\iota_T\colon \mathbf{N}(T) \to A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} T$ such that:*

(Ex1) Window *if $M_a, h_a \geq 0$ are integers such that every Hodge jump of V at every embedding of K over τ_a lies in $[-M_a, h_a]$ ($a \in \mathbb{Z}/n$), then $\mathbf{N}(T)$ is a Wach module over K with coefficients L and window $(M_a,h_a)_a$, with $r = \dim_L V$ in (Wm1); in particular $(\gamma_{\delta,\mathbf{N}} - 1)(\mathbf{N}(T)) \subseteq X\mathbf{N}(T)$ for every $\delta \in \Delta_K$;*

(Ex2) Realisation *$\iota_T(fx) = \iota(f)\,\iota_T(x)$ for $f \in \mathbf{A}_F$, $\iota_T(\lambda x) = (1 \otimes \lambda)\iota_T(x)$ for $\lambda \in \mathcal{O}_L$, $\iota_T(\varphi_{\mathbf{N}}(x)) = (\varphi \otimes 1)(\iota_T(x))$ (in $W(\mathbb{C}^\flat_\ell) \otimes_{\mathbb{Z}_\ell} T$, where $\tilde{\xi} = \iota(Q)$ is a unit, ι_T being extended to $\mathbf{N}(T)[1/Q]$), $\sigma(\iota_T(x)) = \iota_T(\gamma_{\chi_{\mathrm{cyc}}(\sigma),\mathbf{N}}(x))$ for $\sigma \in G_K$ acting diagonally (so $\iota_T(\mathbf{N}(T))$ is fixed by $H_F \subseteq G_K$), and $A_{\mathrm{inf}}[1/\mu_\varepsilon] \cdot \iota_T(\mathbf{N}(T)) = A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} T$;*

(Ex3) Functoriality *for another pair (V',T') over K and every G_K-equivariant $\mathcal{O}_L$-linear map $f\colon T \to T'$ there is an $\mathbf{A}_{F,L}$-linear map $\mathbf{N}(f)\colon \mathbf{N}(T) \to \mathbf{N}(T')$ commuting with $\varphi_{\mathbf{N}}$ and all $\gamma_{u,\mathbf{N}}$, with $\iota_{T'} \circ \mathbf{N}(f) = (1 \otimes f) \circ \iota_T$, $\mathbf{N}(\mathrm{id}) = \mathrm{id}$ and $\mathbf{N}(f' \circ f) = \mathbf{N}(f') \circ \mathbf{N}(f)$;*

(Ex4) Level *s more generally, let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L a finite extension of $\mathbb{Q}_\ell$ containing $\sigma(F(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ of $F(\mu_{\ell^s})$, and K a field with $F \subseteq K \subseteq F(\mu_{\ell^s})$, pairs over K being defined as above. Then to every pair (V,T) over K one can attach a finitely generated $\mathbf{A}_{F,L}$-module $\mathbf{N}_s(T)$ with maps $\varphi_{\mathbf{N}}$, $\gamma_{u,\mathbf{N}}$*

($u \in \Gamma_K$) and an injective additive map $\iota_{s,T}\colon \mathbf{N}_s(T) \to A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} T$ satisfying (Ex1)–(Ex3) with Wach module replaced by Wach module of level s (Definition 23.2, paragraph Level s), $\mathbf{N}(T)$ by $\mathbf{N}_s(T)$, Q by Q_{s-1}, ι by the map ι_s of Lemma 23.8(6) and ι_T by $\iota_{s,T}$. For $s = 1$ and ℓ odd one may take $\mathbf{N}_1(T) = \mathbf{N}(T)$.

(Ex5) Origin *the modules and maps of (Ex1)–(Ex4) can be chosen to arise from prismatic data, as follows. For ℓ, s, L, K as in (Ex4) and every pair (V,T) over K there are a datum $\mathcal{E}_T$ given by Theorem B.41 (for the field K and $p = \ell$) for the $\mathbb{Z}_\ell$-module T with its G_K-action, and an isomorphism c_T with the properties of (Bs3) for $\mathcal{E}_T$, such that, for the object $(\mathbf{A}_F, Q_{s-1}\mathbf{A}_F)$ over $\mathcal{O}_K$ of Lemma 23.8(6): $\mathbf{N}_s(T) = \mathcal{E}_T(\mathbf{A}_F)$; $\varphi_{\mathbf{N}}(x) = \varphi_{\mathcal{E}_T,\mathbf{A}_F}(1 \otimes x)$; $\gamma_{u,\mathbf{N}} = \mathcal{E}_T(\gamma_u)$ for $u \in \Gamma_K$; $\iota_{s,T} = c_T \circ \mathcal{E}_T(\iota_s)$; each $\lambda \in \mathcal{O}_L$ acts on $\mathbf{N}_s(T)$ by $\mathcal{E}(\lambda)_{\mathbf{A}_F}$, the map of (Bs5) for multiplication by λ on T; and $\mathbf{N}_s(f) = \mathcal{E}(f)_{\mathbf{A}_F}$, the map of (Bs5), for f as in (Ex3). For $s = 1$ and ℓ odd this holds with $\mathbf{N}(T) = \mathbf{N}_1(T)$, $\iota_T = \iota_{1,T}$, $\iota_1 = \iota$ and $Q_0 = Q$.*

Proof. We prove (Ex4) for every admissible (ℓ, s); (Ex1)–(Ex3) are its case $s = 1$, ℓ odd, treated in the last paragraph. Fix a prime ℓ, an integer $s \geq 1$ with $s \geq 2$ if $\ell = 2$, a finite extension L of $\mathbb{Q}_\ell$ containing $\sigma(F(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ of $F(\mu_{\ell^s})$, and a field K with $F \subseteq K \subseteq F(\mu_{\ell^s})$. Write $P = Q_{s-1} = \Phi_{\ell^s}(1+X)$ (Lemma 23.8(3)). We use the following facts, all from Lemma 23.8: (i) $(\mathbf{A}_F, P\mathbf{A}_F)$ and $(\mathcal{O}_F, \ell\mathcal{O}_F)$ are objects over $\mathcal{O}_K$, and red, ι_s and γ_u ($u \in \Gamma_K$) are morphisms over $\mathcal{O}_K$ (item 6, which gives item 5 for level s); (ii) ι_s is injective, $\iota_s(P) = \tilde{\xi}$ and $\iota_s^{-1}(\tilde{\xi}^k A_{\mathrm{inf}}) = P^k\mathbf{A}_F$ for $k \geq 0$ (item 6); (iii) $\iota_s = \varphi \circ w$ on $\mathcal{O}_F$ (item 6); (iv) $\sigma \circ \iota_s = \iota_s \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ and $\chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$ for $\sigma \in G_K$ (item 6); (v) $\gamma_u(P) \in P\,\mathbb{Z}_\ell[[X]]^\times$, $\gamma_u\gamma_v = \gamma_{uv}$, $\gamma_1 = \mathrm{id}$, $\gamma_u \circ \varphi = \varphi \circ \gamma_u$ and $\mathrm{red} \circ \gamma_u = \mathrm{red}$ for $u, v \in \mathbb{Z}_\ell^\times$ (item 2 and its proof, which hold for every prime by the paragraph 'No oddness' there). Moreover (vi) L contains $\sigma(K)$ for every $\mathbb{Q}_\ell$-embedding σ of K, since $K \subseteq F(\mu_{\ell^s})$ and every such σ extends to $F(\mu_{\ell^s})$.

The construction. Apply Theorem B.41 to the field K and $p = \ell$ (it holds for every prime). For each pair (V,T) over K fix a datum $\mathcal{E}_T$ attached to T (a free $\mathbb{Z}_\ell$-module of rank $d = [L : \mathbb{Q}_\ell] \dim_L V$), and let $c_T\colon \mathcal{E}_T(A_{\mathrm{inf}}) \otimes W(\mathbb{C}_\ell^\flat) \to T \otimes W(\mathbb{C}_\ell^\flat)$ be the isomorphism of (Bs3). Put $\mathbf{N} = \mathbf{N}_s(T) = \mathcal{E}_T(\mathbf{A}_F)$ for the object $(\mathbf{A}_F, P\mathbf{A}_F)$ of (i), $M = \mathcal{E}_T(A_{\mathrm{inf}})$, $\varphi_{\mathbf{N}}(x) = \varphi_{\mathcal{E},\mathbf{A}_F}(1 \otimes x) \in \mathbf{N}[1/P]$, $\gamma_{u,\mathbf{N}} = \mathcal{E}_T(\gamma_u)$ ($u \in \Gamma_K$), $\iota_{s,T} = c_T \circ \mathcal{E}_T(\iota_s)$, and $\mathbf{N}_s(f) = \mathcal{E}(f)_{\mathbf{A}_F}$ with $\mathcal{E}(f)$ from (Bs5). Since $\mathbf{A}_F$ is local, the finite projective module $\mathbf{N}$ is free of rank d; let (x_j) be a basis. By (Bs2) for ι_s, M is free on $m_j = \mathcal{E}_T(\iota_s)(x_j)$; since ι_s is injective (ii), $\mathcal{E}_T(\iota_s)$ is injective, and c_T is injective on M ($A_{\mathrm{inf}} \subset W(\mathbb{C}_\ell^\flat)$), so $\iota_{s,T}$ is injective; by (Bs3) its image lies in $A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T$ and $A_{\mathrm{inf}}[1/\mu_\varepsilon]\iota_{s,T}(\mathbf{N}) = c_T(M[1/\mu_\varepsilon]) = A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T$.

The $\mathcal{O}_L$-action and the sites. For $\lambda \in \mathcal{O}_L$ multiplication by λ is a G_K-equivariant endomorphism of T; let λ act on $\mathcal{E}_T(A)$ by $\mathcal{E}(\lambda)_A$. This is a ring action commuting with A: by (Bs5), $c_T \circ (\mathcal{E}(g)_{A_{\mathrm{inf}}} \otimes 1) = (g \otimes 1) \circ c_T$ for every endomorphism g, so on M (which embeds into $M \otimes W(\mathbb{C}_\ell^\flat)$) the maps $\mathcal{E}(\lambda+\lambda')$ and $\mathcal{E}(\lambda)+\mathcal{E}(\lambda')$ agree, as do $\mathcal{E}(\lambda\lambda')$ and $\mathcal{E}(\lambda)\mathcal{E}(\lambda')$, and $\mathcal{E}(\lambda)$ for $\lambda \in \mathbb{Z}_\ell$ and multiplication by λ; as $\mathcal{E}_T(\iota_s)$ is injective and intertwines $\mathcal{E}(g)_{\mathbf{A}_F}$ with $\mathcal{E}(g)_{A_{\mathrm{inf}}}$ (Bs5), the same holds on $\mathbf{N}$. So $\mathbf{N}$ is a module over $\mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$; being finite over $\mathbf{A}_F$ it is X-adically complete and separated, so $\mathbf{A}_{F,L} = (\mathcal{O}_F \otimes \mathcal{O}_L)[[X]]$ acts. By (Bs5) the $\mathcal{O}_L$-action commutes with $\varphi_{\mathbf{N}}$ and with every $\gamma_{u,\mathbf{N}}$, so $\varphi_{\mathbf{N}}$ is semilinear for $\varphi \otimes \mathrm{id}$ and $\gamma_{u,\mathbf{N}}$ for γ_u on $\mathbf{A}_{F,L}$, and the clause of (Ex2) for $\lambda \in \mathcal{O}_L$ holds. Each $\mathbf{N}_a = e_a\mathbf{N}$ is a direct summand of the free $\mathbf{A}_F$-module $\mathbf{N}$, hence free over the local ring $\mathbf{A}_F$; it is a finitely generated module over $R = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ (with $\mathcal{O}_F$ acting through τ_a), a regular local ring of dimension 2, finite and free over $\mathbf{A}_F$. Since (ℓ, X) is a regular sequence of $\mathbf{A}_F$, it is regular on $\mathbf{N}_a$, and it generates an ideal primary to the maximal ideal of R; so $\mathrm{depth}_R\mathbf{N}_a = 2$ and, by the Auslander–Buchsbaum formula, $\mathbf{N}_a$ is a free R-module, of rank r_a say.

Frobenius moves the sites. For $x \in \mathcal{O}_F$, $\lambda \in \mathcal{O}_L$ and $y \in \mathbf{N}$, $\varphi_{\mathbf{N}}((x \otimes \lambda)y) = (\varphi(x) \otimes \lambda)\varphi_{\mathbf{N}}(y)$, and $(\varphi \otimes \mathrm{id})(e_{a-1}) = e_a$ because $\tau_a(\varphi(x)) = \tau_{a-1}(x)$; hence $\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}) \subseteq e_a\mathbf{N}[1/P]$. On M let $\mathcal{O}_F \otimes \mathcal{O}_L$ act with $\mathcal{O}_F$ through ι_s; its idempotents e_a^M satisfy $\mathcal{E}_T(\iota_s)(\mathbf{N}_a) \subseteq e_a^M M =: M_a = A_{\mathrm{inf}}\mathcal{E}_T(\iota_s)(\mathbf{N}_a)$, and, since $\varphi \circ \iota_s = \iota_s \circ \varphi$ and φ_M commutes with $\mathcal{O}_L$, $\varphi_M(1 \otimes e_{a-1}^M m) = e_a^M \varphi_M(1 \otimes m)$.

Heights at A_{inf}, site by site. Let V have its Hodge jumps at every embedding of K over τ_a in $[-M_a, h_a]$. The Witt vector Frobenius φ is a G_K-equivariant automorphism of A_{inf} with $\varphi(\xi_0) = \tilde{\xi}$; it induces isomorphisms $A_{\mathrm{inf}}[1/\ell]/\xi_0^b \to A_{\mathrm{inf}}[1/\ell]/\tilde{\xi}^b$, hence, by (Ai3), a G_K-equivariant ring isomorphism $\Phi\colon B_{\mathrm{dR}}^+ \to B'^+$ extending φ, with $\Phi(tB_{\mathrm{dR}}^+) = \tilde{\xi}B'^+$; so B'^+ is a discrete valuation ring with uniformiser $\tilde{\xi}$ and $B'^+/\tilde{\xi} = A_{\mathrm{inf}}[1/\ell]/\tilde{\xi}$. The field $F \subset B_{\mathrm{dR}}^+$ of (Ai3) is $w(\mathcal{O}_F)[1/\ell]$ (both lift the inclusion $F \subset \mathbb{C}_\ell$ through θ, and such a lift is unique as $F/\mathbb{Q}_\ell$ is étale and B_{dR}^+ is complete), and $\Phi(w(x)) = \varphi(w(x)) = \iota_s(x)$ by (iii). Let $D = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)^{G_K}$ with the filtration of (Ai4) (for the finite extension K), a $K \otimes_{\mathbb{Q}_\ell} L$-module with filtration by submodules, and $D_a = e_a D$, where $e_a \in F \otimes_{\mathbb{Q}_\ell} L \subseteq K \otimes_{\mathbb{Q}_\ell} L$. Since $K \otimes_{\mathbb{Q}_\ell} L = K \otimes_F (F \otimes_{\mathbb{Q}_\ell} L)$, $e_a(K \otimes_{\mathbb{Q}_\ell} L) = K \otimes_{F,\tau_a} L$; writing $K = F(y)$ with minimal polynomial R_y over F, this is $L[Y]/(\tau_a R_y)$, and by (vi) $\tau_a R_y$ splits into distinct linear factors $Y - \tau(y)$ over L, one for each embedding τ of K over τ_a. So $e_a(K \otimes_{\mathbb{Q}_\ell} L) \cong \prod_\tau L$, the product over the embeddings τ of K over τ_a, and, as the filtration is by $K \otimes_{\mathbb{Q}_\ell} L$-submodules, $D_a = \bigoplus_\tau D_{\mathrm{dR},\tau}(V)$ as filtered modules. Applying $1 \otimes \Phi$ and e_a to (Ai4) (with $k = 0$) gives in $V \otimes B'_{\mathrm{dR}}$, where $x \otimes \lambda$ acts as $\iota_s(x) \otimes \lambda$,

$$\sum_{j \in \mathbb{Z}} \tilde{\xi}^{-j} B'^+ \Phi(\mathrm{Fil}^j D_a) = e_a(V \otimes B'^+), \qquad \Phi(D) = (V \otimes B'_{\mathrm{dR}})^{G_K}, \qquad e_a\Phi(D) = \Phi(D_a).$$

Every $D_{\mathrm{dR},\tau}(V)$, τ over τ_a, is finite-dimensional with an exhaustive and separated filtration whose jumps lie in $[-M_a, h_a]$; so $\mathrm{Fil}^{-M_a} D_a = D_a$ and $\mathrm{Fil}^{h_a+1} D_a = 0$, and the term $j = -M_a$ gives $\tilde{\xi}^{M_a} B'^+ \Phi(D_a) \subseteq e_a(V \otimes B'^+)$, and only $j \le h_a$ contribute, so $e_a(V \otimes B'^+) \subseteq \tilde{\xi}^{-h_a} B'^+ \Phi(D_a)$. The isomorphism $M \otimes B'_{\mathrm{dR}} \cong T \otimes B'_{\mathrm{dR}}$ of (Bs4) is A_{inf}-linear and $\mathcal{O}_L$-linear (Bs5), so it carries e_a^M to e_a; it carries the image Λ_0 of $M \otimes B'^+$ onto $T \otimes B'^+$ and the B'^+-span Λ_1 of the $\varphi_M(1 \otimes m)$ onto $B'^+\Phi(D)$. With $e_a\Lambda_1 = B'^+\varphi_M(1 \otimes M_{a-1})$ (previous paragraph) we get

$$\tilde{\xi}^{M_a}\, B'^+ \varphi_M(1 \otimes M_{a-1}) \subseteq e_a\Lambda_0, \qquad \tilde{\xi}^{h_a}\, e_a\Lambda_0 \subseteq B'^+\varphi_M(1 \otimes M_{a-1}). \qquad (*)$$

Descent from B'^+: $A_{\mathrm{inf}} \cap \tilde{\xi}^k B'^+ = \tilde{\xi}^k A_{\mathrm{inf}}$. For $k = 1$: if $a \in A_{\mathrm{inf}}$ maps to 0 in $B'^+/\tilde{\xi} = A_{\mathrm{inf}}[1/\ell]/\tilde{\xi}$, then $\ell^m a \in \tilde{\xi}A_{\mathrm{inf}} = \ker\tilde{\theta}$ for some m, so $\tilde{\theta}(a) = 0$ ($\mathcal{O}_{\mathbb{C}_\ell}$ has no ℓ-torsion) and $a \in \tilde{\xi}A_{\mathrm{inf}}$; for $k \ge 2$ write $a = \tilde{\xi}a_1$ and use that B'^+ is a domain. Hence, for a free A_{inf}-module P', an element of $P'[1/\tilde{\xi}]$ whose image in $P' \otimes B'_{\mathrm{dR}}$ lies in the image of $P' \otimes B'^+$ lies in P' (compare coordinates). Apply this to $P' = M$ and to $P' = A_{\mathrm{inf}}\varphi_M(1 \otimes M)$, the image of the free module φ^*M, which maps injectively (φ_M is an isomorphism after inverting $\tilde{\xi}$, and $\tilde{\xi}$ is a non-zero-divisor) and has $P' \otimes B'_{\mathrm{dR}} = M \otimes B'_{\mathrm{dR}}$ with $P' \otimes B'^+$ mapping onto Λ_1. By $(*)$, $\tilde{\xi}^{M_a}\varphi_M(1 \otimes m) \in M$ for $m \in M_{a-1}$, and $\tilde{\xi}^{h_a} m \in P'$ for $m \in M_a$; taking e_a^M-components,

$$\tilde{\xi}^{M_a}\varphi_M(1 \otimes M_{a-1}) \subseteq M_a, \qquad \tilde{\xi}^{h_a} M_a \subseteq A_{\mathrm{inf}}\varphi_M(1 \otimes M_{a-1}).$$

Heights at $\mathbf{A}_F$: (Wm2) of level s. The map $\mathcal{E}_T(\iota_s)$ extends to $\mathbf{N}[1/P] \to M[1/\tilde{\xi}]$ (as $\iota_s(P) = \tilde{\xi}$) and intertwines $\varphi_{\mathbf{N}}$ with $m \mapsto \varphi_M(1 \otimes m)$ (Bs2). Let $x \in \mathbf{N}_{a-1}$ and $z = P^{M_a}\varphi_{\mathbf{N}}(x) = \sum_j (b_j/P^k)x_j$ with $b_j \in \mathbf{A}_F$. Then $\mathcal{E}_T(\iota_s)(z) = \sum_j (\iota_s(b_j)/\tilde{\xi}^k)m_j \in M$, so $\iota_s(b_j) \in \tilde{\xi}^k A_{\mathrm{inf}}$ and, by (ii), $b_j \in P^k\mathbf{A}_F$: $z \in \mathbf{N}$, and $z = e_a z \in \mathbf{N}_a$. Likewise $P_{\mathbf{N}} = \mathbf{A}_F\varphi_{\mathbf{N}}(\mathbf{N})$ is free on the $\varphi_{\mathbf{N}}(x_j)$ (the image of the free module $\mathbf{A}_F \otimes_\varphi \mathbf{N}$, injective as before), $\mathcal{E}_T(\iota_s)$ maps this basis to the basis $\varphi_M(1 \otimes m_j)$ of $A_{\mathrm{inf}}\varphi_M(1 \otimes M)$, and the same comparison of coordinates, with (ii), shows $P^{h_a}\mathbf{N}_a \subseteq P_{\mathbf{N}}$. As $P_{\mathbf{N}}$ is stable under $\mathcal{O}_L$, $e_a P_{\mathbf{N}} = \mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1})$, which gives $P^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1})$. These are the two inclusions of (Wm2) with $Q_{s-1} = P$ in place of Q.

Ranks: (Wm1). By (Wm2),

$$P^{h_a+M_a}\mathbf{N}_a \subseteq P^{M_a}\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}) \subseteq \mathbf{N}_a,$$

and $\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a-1}) = e_aP_{\mathbf{N}}$ is the image of $R \otimes_\varphi \mathbf{N}_{a-1}$, free of rank r_{a-1} over $R = e_a\mathbf{A}_{F,L}$, injectively; as P is a non-zero-divisor on the free R-module $\mathbf{N}_a$, comparing ranks after inverting P gives $r_a = r_{a-1}$ for all a, i.e. $r_a = r$. Over $\mathbf{A}_F$, R is free of rank $[L:\mathbb{Q}_\ell]/n$, so $d = n\,r\,[L:\mathbb{Q}_\ell]/n$, i.e. $r = \dim_L V$.

(Wm3). Let $u, v \in \Gamma_K$. By (Bs2), (i) and (v), $\gamma_{uv,\mathbf{N}} = \mathcal{E}_T(\gamma_u\gamma_v) = \gamma_{u,\mathbf{N}}\gamma_{v,\mathbf{N}}$, $\gamma_{1,\mathbf{N}} = \mathrm{id}$, and $\gamma_{u,\mathbf{N}}$ commutes with $\varphi_{\mathbf{N}}$ (compatibility of (Bs2) with the Frobenius isomorphisms, as $\gamma_u\varphi = \varphi\gamma_u$; $\gamma_u(P) \in P\mathbf{A}_F^\times$ by (v), so $\gamma_{u,\mathbf{N}}$ extends to $\mathbf{N}[1/P]$). Since $\mathrm{red}\circ\gamma_u = \mathrm{red}$, $\mathcal{E}_T(\mathrm{red})\circ\gamma_{u,\mathbf{N}} = \mathcal{E}_T(\mathrm{red})$; by (Bs2) the $\mathcal{O}_F$-linear extension $\mathcal{O}_F \otimes_{\mathrm{red},\mathbf{A}_F} \mathbf{N} = \mathbf{N}/X\mathbf{N} \to \mathcal{E}_T(\mathcal{O}_F)$ is an isomorphism ($\ker\mathrm{red} = X\mathbf{A}_F$), so $\ker\mathcal{E}_T(\mathrm{red}) = X\mathbf{N}$ and $(\gamma_{u,\mathbf{N}} - 1)\mathbf{N} \subseteq X\mathbf{N}$; this holds for every $u \in \Gamma_K$, in particular for $u = \delta \in \Delta_K \subseteq \Gamma_K$.

(Wm3'). Put $Y = X_{s-1} = (1+X)^{\ell^{s-1}} - 1$, $B = \mathbf{A}_F/Y\mathbf{A}_F$, $\pi\colon \mathbf{A}_F \to B$ the quotient map and $\eta = \pi(1+X)$. The δ-structure of the ℓ-torsion-free ring $\mathbf{A}_F$ is $\delta(f) = (\varphi(f) - f^\ell)/\ell$. (a) *The ring B.* Y is a monic polynomial in X of degree ℓ^{s-1} with $Y \equiv X^{\ell^{s-1}} \bmod \ell$, so by Weierstrass division $B = \mathcal{O}_F[X]/(Y)$ is free over $\mathcal{O}_F$ with basis $1, \eta, \dots, \eta^{\ell^{s-1}-1}$, and $\eta^{\ell^{s-1}} = 1$; hence B is ℓ-torsion-free and ℓ-adically complete, and $\pi(X)^{\ell^{s-1}} \in \ell B$. (b) *$Y\mathbf{A}_F$ is a δ-ideal.* As $\varphi(1+X) = (1+X)^\ell$, $\varphi(Y) = (1+Y)^\ell - 1$, so $\delta(Y) = \sum_{0<i<\ell} \ell^{-1}\binom{\ell}{i}Y^i \in Y\mathbf{A}_F$. For $f \in \mathbf{A}_F$, $\delta(fY) = f^\ell\delta(Y) + Y^\ell\delta(f) + \ell\,\delta(f)\delta(Y) \in Y\mathbf{A}_F$, and for $y, y' \in Y\mathbf{A}_F$, $\delta(y+y') = \delta(y)+\delta(y')-\sum_{0<i<\ell}\ell^{-1}\binom{\ell}{i}y^iy'^{\ell-i} \in Y\mathbf{A}_F$. So δ induces a δ-structure on B (with Frobenius $\mathcal{O}_F$-Frobenius-semilinear and $\eta \mapsto \eta^\ell$) for which π is a homomorphism of δ-rings. (c) *$(B, \ell B)$ is an object over $\mathcal{O}_K$ and π a morphism over $\mathcal{O}_K$.* $(B, \ell B)$ is a bounded prism: ℓ is a non-zero-divisor of B, B is ℓ-adically complete, $\ell \in \ell B$, and $B/\ell B$ is killed by ℓ. Since $Q_{s-1} = \Phi_{\ell^s}(1+X) = \Phi_\ell((1+X)^{\ell^{s-1}}) = \Phi_\ell(1+Y)$ (Lemma 23.8(3)), $\pi(Q_{s-1}) = \Phi_\ell(1) = \ell$; so $\pi(P\mathbf{A}_F) \subseteq \ell B$, π induces $\mathbf{A}_F/P\mathbf{A}_F \to B/\ell B$, and with the composite $\mathcal{O}_K \to \mathbf{A}_F/P\mathbf{A}_F \to B/\ell B$ (fact (i)) $(B, \ell B)$ is an object over $\mathcal{O}_K$ and π is a morphism over $\mathcal{O}_K$. (d) *$\pi\circ\gamma_u = \pi$ for $u \in \Gamma_K$ with $u \equiv 1 \bmod \ell^{s-1}$.* Write $u = 1 + \ell^{s-1}w$ with $w \in \mathbb{Z}_\ell$. In $\mathbf{A}_F$, $(1+X)^u = (1+X)(1+Y)^w$, where $(1+Y)^w = \sum_{k\ge0}\binom{w}{k}Y^k$: both sides are continuous in $w \in \mathbb{Z}_\ell$ for the (ℓ, X)-adic topology and agree for $w \in \mathbb{Z}_{\ge0}$. Hence $\pi(\gamma_u(1+X)) = \eta\,\pi(1+Y)^w = \eta$. The maps $\pi\circ\gamma_u$ and π are $\mathcal{O}_F$-linear ring homomorphisms, continuous from the (ℓ, X)-adic topology to the ℓ-adic topology of B (by (a), $\pi(X)$ is topologically nilpotent), and agree on X; as $\mathcal{O}_F[X]$ is dense in $\mathbf{A}_F$, they are equal. (e) *Conclusion.* By (Bs2) for π, the B-linear extension $B \otimes_{\pi,\mathbf{A}_F} \mathbf{N} = \mathbf{N}/Y\mathbf{N} \to \mathcal{E}_T(B)$ of $\mathcal{E}_T(\pi)$ is an isomorphism, so $\ker\mathcal{E}_T(\pi) = Y\mathbf{N}$. For u as in (d), $u \in \Gamma_K$, γ_u is a morphism over $\mathcal{O}_K$ (fact (i)), and by (Bs2) $\mathcal{E}_T(\pi)\circ\gamma_{u,\mathbf{N}} = \mathcal{E}_T(\pi\circ\gamma_u) = \mathcal{E}_T(\pi)$. Hence $(\gamma_{u,\mathbf{N}} - 1)(\mathbf{N}) \subseteq Y\mathbf{N} = X_{s-1}\mathbf{N}$, which is (Wm3'). For $s = 1$, $Y = X$, $B = \mathcal{O}_F$ and $\pi = \mathrm{red}$, and this is the argument for the congruence in (Wm3).

So $\mathbf{N}_s(T)$ is a Wach module of level s over K with coefficients L and window $(M_a, h_a)_a$, with $r = \dim_L V$: this is (Ex1) of level s.

(Ex2), (Ex3) of level s. $\iota_{s,T}(fx) = \iota_s(f)\iota_{s,T}(x)$ because $\mathcal{E}_T(\iota_s)$ is ι_s-semilinear and c_T is A_{inf}-linear; $\iota_{s,T}(\lambda x) = (1\otimes\lambda)\iota_{s,T}(x)$ by the $\mathcal{O}_L$-paragraph and (Bs5). By (Bs2), $\mathcal{E}_T(\iota_s)(\varphi_{\mathbf{N}}(x)) = \varphi_M(1\otimes\mathcal{E}_T(\iota_s)x)$, and by (Bs3) $c_T(\varphi_M(1\otimes m)) = (\varphi\otimes1)(c_T(m))$; so $\iota_{s,T}\circ\varphi_{\mathbf{N}} = (\varphi\otimes1)\circ\iota_{s,T}$ on $\mathbf{N}[1/P]$, where $\tilde\xi = \iota_s(P)$ is a unit of $W(\mathbb{C}_\ell^\flat)$. For $\sigma \in G_K$, c_T is G_K-equivariant, σ acts on M by $\mathcal{E}_T(\sigma)$, and $\mathcal{E}_T(\sigma)\circ\mathcal{E}_T(\iota_s) = \mathcal{E}_T(\sigma\circ\iota_s) = \mathcal{E}_T(\iota_s\circ\gamma_{\chi_{\mathrm{cyc}}(\sigma)}) = \mathcal{E}_T(\iota_s)\circ\gamma_{\chi_{\mathrm{cyc}}(\sigma),\mathbf{N}}$ by (iv), (i) and (Bs2); so $\sigma\circ\iota_{s,T} = \iota_{s,T}\circ\gamma_{\chi_{\mathrm{cyc}}(\sigma),\mathbf{N}}$, and for $h \in H_F$, $\chi_{\mathrm{cyc}}(h) = 1$. The spanning clause was shown in the construction. For (Ex3), $\mathbf{N}_s(f)$ is $\mathbf{A}_F$-linear and commutes with $\varphi_{\mathbf{N}}$ and with $\mathcal{E}(\gamma_u)$ by (Bs5); it commutes with the $\mathcal{O}_L$-action because $\mathcal{E}(f)\mathcal{E}(\lambda) = \mathcal{E}(f\lambda) = \mathcal{E}(\lambda f) = \mathcal{E}(\lambda)\mathcal{E}(f)$, hence is $\mathbf{A}_{F,L}$-linear; and $\iota_{s,T'}\circ\mathbf{N}_s(f) = c_{T'}\circ\mathcal{E}(f)_{A_{\mathrm{inf}}}\circ\mathcal{E}_T(\iota_s) = (f\otimes1)\circ c_T\circ\mathcal{E}_T(\iota_s)$ by (Bs5) twice. The identities for id and composites are those of (Bs5). This proves (Ex4).

(Ex1)–(Ex3). Let ℓ be odd and $s = 1$. Then the hypotheses on ℓ, L, K in (Ex4) are those of the statement, $P = Q_0 = Q$, $\iota_1 = \iota$ (Lemma 23.8(6)), and a Wach module of level 1 is a Wach module (Definition 23.2, paragraph Level s). So $\mathbf{N}(T) = \mathbf{N}_1(T)$, $\iota_T = \iota_{1,T}$, $\mathbf{N}(f) = \mathbf{N}_1(f)$ satisfy (Ex1)–(Ex3).

(Ex5). The construction above defines $\mathbf{N}_s(T)$, $\varphi_{\mathbf{N}}$, $\gamma_{u,\mathbf{N}}$, $\iota_{s,T}$, the $\mathcal{O}_L$-action and $\mathbf{N}_s(f)$ in the terms of (Ex5), with the datum $\mathcal{E}_T$ and the isomorphism c_T of (Bs3) fixed there; for $s = 1$ and ℓ odd, $\mathbf{N}(T) = \mathbf{N}_1(T)$ by the preceding paragraph. □

Lemma 23.8. *Let ℓ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ with residue field k, $F_1 = F(\mu_\ell)$, $H_F = \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/F(\mu_{\ell^\infty}))$, and $w\colon \mathcal{O}_F = W(k) \to A_{\mathrm{inf}}$ the map of Witt vectors induced by the unique ring homomorphism $k \to \mathcal{O}_{\mathbb{C}_\ell^\flat}$ lifting the inclusion of k into the residue field. Then:*

1. *$(\mathbf{A}_F, Q\mathbf{A}_F)$ is a bounded prism; $X \mapsto \zeta_\ell - 1$ induces $\mathbf{A}_F/Q\mathbf{A}_F \cong \mathcal{O}_{F_1}$, which makes it an object over $\mathcal{O}_F$. With $\mathcal{O}_F \to k$ the reduction, $(\mathcal{O}_F, \ell\mathcal{O}_F)$ is an object over $\mathcal{O}_F$, and* $\mathrm{red}\colon \mathbf{A}_F \to \mathcal{O}_F$, $X \mapsto 0$, *is a morphism over $\mathcal{O}_F$.*

2. *For every $u \in \mathbb{Z}_\ell^\times$, γ_u is an automorphism of $(\mathbf{A}_F, Q\mathbf{A}_F)$ over $\mathcal{O}_F$, $\gamma_u\gamma_v = \gamma_{uv}$,* $\mathrm{red} \circ \gamma_u = \mathrm{red}$, *$\gamma_u(X) \in X\mathbf{A}_F^\times$, and $\gamma_u(Q_s) \in Q_s\,\mathbb{Z}_\ell[[X]]^\times$ for every $s \geq 0$.*

3. *For $s \geq 0$, $Q_s = \Phi_{\ell^{s+1}}(1 + X)$ is a monic polynomial of degree $\ell^s(\ell - 1)$ with $Q_s \equiv X^{\ell^s(\ell-1)} \bmod \ell$, its roots are the $\zeta - 1$, ζ running over the primitive ℓ^{s+1}-th roots of unity, and an element of $\mathcal{O}_L[[X]]$ (L any finite extension of $\mathbb{Q}_\ell$) vanishing at all of them is divisible by Q_s in $\mathcal{O}_L[[X]]$.*

4. *The map $\iota\colon \mathbf{A}_F \to A_{\mathrm{inf}}$ equal to $\varphi \circ w$ on $\mathcal{O}_F$ with $\iota(X) = \mu_\varepsilon$ is a well-defined injective ring homomorphism, a morphism $(\mathbf{A}_F, Q\mathbf{A}_F) \to (A_{\mathrm{inf}}, \tilde{\xi}A_{\mathrm{inf}})$ over $\mathcal{O}_F$, with $\iota(Q) = \tilde{\xi}$, $\tilde{\theta} \circ \iota|_{\mathcal{O}_F}$ the inclusion $\mathcal{O}_F \subset \mathcal{O}_{\mathbb{C}_\ell}$, $\sigma \circ \iota = \iota \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ for every $\sigma \in G_F$ (so $h \circ \iota = \iota$ for $h \in H_F$), and*
$$\iota^{-1}(\tilde{\xi}^k A_{\mathrm{inf}}) = Q^k\mathbf{A}_F \qquad (k \geq 0).$$

5. *Let K be a field with $F \subseteq K \subseteq F_1$ and $\Gamma_K = \chi_{\mathrm{cyc}}(G_K)$. Then $(\mathbf{A}_F, Q\mathbf{A}_F)$, through $\mathcal{O}_K \subseteq \mathcal{O}_{F_1} \cong \mathbf{A}_F/Q\mathbf{A}_F$, and $(\mathcal{O}_F, \ell\mathcal{O}_F)$, through the reduction $\mathcal{O}_K \to k$, are objects over $\mathcal{O}_K$;* red *is a morphism over $\mathcal{O}_K$, and ι is a morphism over $\mathcal{O}_K$ to the object $(A_{\mathrm{inf}}, \tilde{\xi}A_{\mathrm{inf}})$ over $\mathcal{O}_K$ of Theorem B.41; for every $u \in \Gamma_K$, γ_u is an automorphism of $(\mathbf{A}_F, Q\mathbf{A}_F)$ over $\mathcal{O}_K$; and $\sigma \circ \iota = \iota \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ with $\chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$ for every $\sigma \in G_K$.*

6. *(Level s.) Let $s \geq 1$ be an integer, $F_s = F(\mu_{\ell^s})$, and $\mu_{\varepsilon,s} = [\varepsilon^{1/\ell^{s-1}}] - 1 \in A_{\mathrm{inf}}$, where $\varepsilon^{1/\ell^{s-1}}$ is the unique ℓ^{s-1}-th root of ε in $\mathcal{O}_{\mathbb{C}_\ell^\flat}$. Then $(\mathbf{A}_F, Q_{s-1}\mathbf{A}_F)$ is a bounded prism and $X \mapsto \zeta_{\ell^s} - 1$ induces $\mathbf{A}_F/Q_{s-1}\mathbf{A}_F \cong \mathcal{O}_{F_s}$. The map $\iota_s\colon \mathbf{A}_F \to A_{\mathrm{inf}}$ equal to $\varphi \circ w$ on $\mathcal{O}_F$ with $\iota_s(X) = \mu_{\varepsilon,s}$ is a well-defined injective ring homomorphism commuting with the Frobenius lifts, with $\iota_s(Q_{s-1}) = \tilde{\xi}$, $\tilde{\theta} \circ \iota_s|_{\mathcal{O}_F}$ the inclusion $\mathcal{O}_F \subset \mathcal{O}_{\mathbb{C}_\ell}$, $\sigma \circ \iota_s = \iota_s \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ for every $\sigma \in G_F$, and $\iota_s^{-1}(\tilde{\xi}^k A_{\mathrm{inf}}) = Q_{s-1}^k\mathbf{A}_F$ ($k \geq 0$). For every field K with $F \subseteq K \subseteq F_s$ and $\Gamma_K = \chi_{\mathrm{cyc}}(G_K)$, the assertions of item 5 hold with Q, F_1, ι replaced by Q_{s-1}, F_s, ι_s. For $s = 1$ ($Q_0 = Q$, $\iota_1 = \iota$) this is items 1, 4 and 5.*

Proof. **Item 3.** Since $\varphi^s(X) = (1 + X)^{\ell^s} - 1$, $Q_s = \varphi^s(Q) = \sum_{i<\ell}(1 + X)^{i\ell^s} = ((1 + X)^{\ell^{s+1}} - 1)/((1 + X)^{\ell^s} - 1) = \Phi_{\ell^{s+1}}(1 + X)$, a monic polynomial of degree $\ell^s(\ell - 1)$ whose roots are the $\zeta - 1$ with ζ primitive of order ℓ^{s+1}; they are pairwise distinct and lie in the maximal ideal of the ring of integers of $\mathbb{Q}_\ell(\zeta)$. Modulo ℓ, $((1+X)^{\ell^s} - 1)Q_s \equiv X^{\ell^{s+1}}$ and $(1+X)^{\ell^s} - 1 \equiv X^{\ell^s}$, and

X^{ℓ^s} is a non-zero-divisor of $\mathbb{F}_\ell[[X]]$, so $Q_s \equiv X^{\ell^s(\ell-1)} \bmod \ell$: Q_s is a distinguished polynomial. Let $f \in \mathcal{O}_L[[X]]$ vanish at its roots. By Weierstrass division $f = Q_s g + R$ with $g \in \mathcal{O}_L[[X]]$ and $R \in \mathcal{O}_L[X]$ of degree $< \deg Q_s$; evaluating at the roots (the series converge there) shows that R has $\deg Q_s$ distinct roots, so $R = 0$.

Item 1. The map φ lifts the Frobenius modulo ℓ: on $\mathcal{O}_F$ it is the Witt vector Frobenius, $\varphi(X) \equiv X^\ell \bmod \ell$, hence $\varphi(f) \equiv f^\ell \bmod \ell$ for all $f \in \mathbf{A}_F$; as $\mathbf{A}_F$ has no ℓ-torsion, $\delta(f) = (\varphi(f) - f^\ell)/\ell$ makes it a δ-ring. By item 3 ($s = 0$) $Q \equiv X^{\ell-1} \bmod \ell$, so (ℓ, Q) and (ℓ, X) have the same radical and $\mathbf{A}_F$ is (ℓ, Q)-adically complete. The map red commutes with the Frobenius lifts ($\mathrm{red}(\varphi(X)) = 0$) and $\mathrm{red}(Q) = \ell$; as $\delta(\ell) = 1 - \ell^{\ell-1}$ is a unit, $\delta(Q) \notin (\ell, X)$, the maximal ideal of the local ring $\mathbf{A}_F$, so $\delta(Q)$ is a unit and Q is distinguished. Since $Q = \Phi_\ell(1 + X)$ is an Eisenstein polynomial over $\mathcal{O}_F$ in the variable X (monic of degree $\ell - 1$, the other coefficients in $\ell\mathcal{O}_F$, constant term ℓ), Weierstrass division gives $\mathbf{A}_F/Q = \mathcal{O}_F[X]/(\Phi_\ell(1+X)) \cong \mathcal{O}_F[\zeta_\ell] = \mathcal{O}_{F_1}$, which has no ℓ-torsion; so the prism is bounded, and $\mathcal{O}_F \subseteq \mathcal{O}_{F_1}$ makes it an object over $\mathcal{O}_F$. The pair $(\mathcal{O}_F, \ell\mathcal{O}_F)$ is a bounded prism ($\delta(\ell)$ is a unit) and an object over $\mathcal{O}_F$ through $\mathcal{O}_F \to k$. Finally $\mathrm{red}(Q\mathbf{A}_F) \subseteq \ell\mathcal{O}_F$ and the induced map $\mathcal{O}_{F_1} \to k$ is the reduction, which restricts to the reduction on $\mathcal{O}_F$; so red is a morphism over $\mathcal{O}_F$.

Item 2. γ_u is well defined since $\gamma_u(X) = uX + \cdots \in X\mathbf{A}_F^\times$ (u a unit), and $\gamma_u\gamma_v = \gamma_{uv}$ because $(1 + \gamma_v(X))^u = (1 + X)^{uv}$; so γ_u is an automorphism with inverse $\gamma_{u^{-1}}$. It commutes with φ: on $\mathcal{O}_F$ the map φ is the Frobenius and γ_u is the identity, and both composites send X to $(1 + X)^{u\ell} - 1$. The element $\gamma_u(Q_s) = \Phi_{\ell^{s+1}}((1 + X)^u)$ vanishes at every root $\zeta - 1$ of Q_s, since ζ^u is again primitive; by item 3, $\gamma_u(Q_s) = Q_s v$ with $v \in \mathbb{Z}_\ell[[X]]$, and symmetrically $\gamma_{u^{-1}}(Q_s) = Q_s v'$; applying γ_u to the second identity gives $Q_s = Q_s v \gamma_u(v')$, so v is a unit. In particular $\gamma_u(Q\mathbf{A}_F) = Q\mathbf{A}_F$, and the induced automorphism of $\mathcal{O}_{F_1}$ sends ζ_ℓ to ζ_ℓ^u and is the identity on $\mathcal{O}_F$: γ_u is an automorphism over $\mathcal{O}_F$. Since $\gamma_u(X) \in X\mathbf{A}_F$, $\mathrm{red} \circ \gamma_u = \mathrm{red}$.

Item 4. The element μ_ε is topologically nilpotent for the topology of (Ai2) (its image modulo ℓ is $\varepsilon - 1$, of positive valuation), so ι is a well-defined continuous ring homomorphism. It commutes with the Frobenius lifts: w is Frobenius-equivariant, and $\varphi(\mu_\varepsilon) = [\varepsilon]^\ell - 1 = (1 + \mu_\varepsilon)^\ell - 1 = \iota(\varphi(X))$; so ι is a map of δ-rings, and $\iota(Q) = \sum_{i<\ell}[\varepsilon]^i = \tilde{\xi}$. On $\mathcal{O}_F$, $\tilde{\theta} \circ \iota = \theta \circ \varphi^{-1} \circ \varphi \circ w = \theta \circ w$, the inclusion $\mathcal{O}_F \subset \mathcal{O}_{\mathbb{C}_\ell}$, and $\tilde{\theta}(\mu_\varepsilon) = \theta([\varepsilon^{1/\ell}]) - 1 = \zeta_\ell - 1$; hence the induced map $\mathcal{O}_{F_1} = \mathbf{A}_F/Q \to A_{\mathrm{inf}}/\tilde{\xi} = \mathcal{O}_{\mathbb{C}_\ell}$ is the inclusion, and ι is a morphism over $\mathcal{O}_F$. For $\sigma \in G_F$: σ fixes the image of k in $\mathcal{O}_{\mathbb{C}_\ell^\flat}$, hence fixes $w(\mathcal{O}_F)$ and $\varphi(w(\mathcal{O}_F))$, and $\sigma(\mu_\varepsilon) = [\varepsilon^{\chi_{\mathrm{cyc}}(\sigma)}] - 1 = (1 + \mu_\varepsilon)^{\chi_{\mathrm{cyc}}(\sigma)} - 1 = \iota(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(X))$ by multiplicativity and continuity of the Teichmüller map and continuity of the binomial series; both sides being continuous ring homomorphisms, $\sigma \circ \iota = \iota \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$. For $h \in H_F$, $\chi_{\mathrm{cyc}}(h) = 1$ and $\gamma_1 = \mathrm{id}$.

Injectivity: modulo ℓ, ι induces $k[[X]] \to \mathcal{O}_{\mathbb{C}_\ell^\flat}$, $f \mapsto f(\varepsilon - 1)$ (coefficients through $k \subset \mathcal{O}_{\mathbb{C}_\ell^\flat}$); if $f \neq 0$ has first non-zero coefficient at X^i, that coefficient is a unit and $|f(\varepsilon - 1)| = |\varepsilon - 1|^i \neq 0$. So $\iota \bmod \ell$ is injective. If $\iota(a) = 0$ with $a \neq 0$, write $a = \ell^m a'$ with $a' \notin \ell\mathbf{A}_F$ ($\mathbf{A}_F$ is ℓ-adically separated); since A_{inf} has no ℓ-torsion, $\iota(a') = 0$, contradicting injectivity modulo ℓ.

We determine the inverse image of $\tilde{\xi}^k A_{\mathrm{inf}}$ by induction on k, the case $k = 0$ being trivial. Let $k \geq 1$ and $\iota(a) \in \tilde{\xi}^k A_{\mathrm{inf}} \subseteq \ker\tilde{\theta}$. By the above, $\tilde{\theta} \circ \iota$ factors as $\mathbf{A}_F \to \mathbf{A}_F/Q = \mathcal{O}_{F_1} \hookrightarrow \mathcal{O}_{\mathbb{C}_\ell}$, so $a \in Q\mathbf{A}_F$, $a = Qa_1$. Then $\tilde{\xi}\,\iota(a_1) \in \tilde{\xi}^k A_{\mathrm{inf}}$, and as A_{inf} is a domain (Ai1), $\iota(a_1) \in \tilde{\xi}^{k-1} A_{\mathrm{inf}}$; by induction $a_1 \in Q^{k-1}\mathbf{A}_F$, so $a \in Q^k\mathbf{A}_F$. The reverse inclusion is $\iota(Q) = \tilde{\xi}$.

The case $\ell = 2$. Items 1 to 5 hold for $\ell = 2$ with the same proofs: $\delta(2) = (2 - 4)/2 = -1$ is a unit, $Q = \Phi_2(1 + X) = 2 + X$ is Eisenstein of degree 1, $F_1 = F$, and $\iota(Q) = 1 + [\varepsilon] = \tilde{\xi}$.

Item 5. The field K lies between F and the totally ramified extension F_1, so $\mathcal{O}_K \subseteq \mathcal{O}_{F_1}$ is a local subring with residue field k. Objects: by item 1, $(\mathbf{A}_F, Q\mathbf{A}_F)$ and $(\mathcal{O}_F, \ell\mathcal{O}_F)$ are bounded prisms, and $\mathcal{O}_K \subseteq \mathcal{O}_{F_1} = \mathbf{A}_F/Q$, $\mathcal{O}_K \to k = \mathcal{O}_F/\ell$ are ring homomorphisms. red: it is a map

of δ-rings with $\mathrm{red}(Q\mathbf{A}_F) \subseteq \ell\mathcal{O}_F$ (item 1), and the induced map $\mathcal{O}_{F_1} \to k$ is the reduction of the local ring $\mathcal{O}_{F_1}$ (proof of item 1), whose restriction to $\mathcal{O}_K$ is the reduction of $\mathcal{O}_K$. ι: it is a map of δ-rings with $\iota(Q) = \tilde{\xi}$, and the induced map $\mathcal{O}_{F_1} \to A_{\mathrm{inf}}/\tilde{\xi} = \mathcal{O}_{\mathbb{C}_\ell}$ (via $\tilde{\theta}$) is the inclusion (proof of item 4), whose restriction to $\mathcal{O}_K$ is the inclusion $\mathcal{O}_K \subseteq \mathcal{O}_{\mathbb{C}_\ell}$ that makes A_{inf} an object over $\mathcal{O}_K$ in Theorem B.41. γ_u: let $u = \chi_{\mathrm{cyc}}(\sigma)$ with $\sigma \in G_K$. By item 2, γ_u is an automorphism of the prism, and the induced automorphism of $\mathcal{O}_{F_1} = \mathcal{O}_F[\zeta_\ell]$ is the identity on $\mathcal{O}_F$ and sends ζ_ℓ to ζ_ℓ^u. The restriction of σ to F_1 has the same two properties ($\sigma \in G_K \subseteq G_F$ and $\sigma(\zeta_\ell) = \zeta_\ell^{\chi_{\mathrm{cyc}}(\sigma)}$), so the two automorphisms of $\mathcal{O}_{F_1}$ coincide; as σ fixes K, the induced automorphism is the identity on $\mathcal{O}_K$, i.e. γ_u is an automorphism over $\mathcal{O}_K$. Finally $G_K \subseteq G_F$, so $\sigma \circ \iota = \iota \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ is item 4, and $\chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$ by definition.

Item 6. *The prism.* By item 3, $Q_{s-1} = \Phi_{\ell^s}(1+X)$ is monic of degree $\ell^{s-1}(\ell-1)$ and $\equiv X^{\ell^{s-1}(\ell-1)} \bmod \ell$, so (ℓ, Q_{s-1}) and (ℓ, X) have the same radical and $\mathbf{A}_F$ is (ℓ, Q_{s-1})-adically complete. As red is a map of δ-rings with $\mathrm{red}(Q_{s-1}) = \Phi_{\ell^s}(1) = \ell$ and $\delta(\ell)$ is a unit, $\delta(Q_{s-1}) \notin (\ell, X)$ is a unit: Q_{s-1} is distinguished. Its constant term is ℓ and its other non-leading coefficients lie in $\ell\mathbb{Z}_\ell$, so it is an Eisenstein polynomial over $\mathcal{O}_F$; by Weierstrass division $\mathbf{A}_F/Q_{s-1} = \mathcal{O}_F[X]/(\Phi_{\ell^s}(1+X)) \cong \mathcal{O}_F[\zeta_{\ell^s}] = \mathcal{O}_{F_s}$, with $X \mapsto \zeta_{\ell^s} - 1$, which has no ℓ-torsion. So the prism is bounded. *The map ι_s.* Its image of X is topologically nilpotent for the topology of (Ai2) ($\mu_{\varepsilon,s} \bmod \ell = \varepsilon^{1/\ell^{s-1}} - 1$ has positive valuation), so ι_s is a well-defined continuous ring homomorphism; $\varphi(\mu_{\varepsilon,s}) = [\varepsilon^{1/\ell^{s-1}}]^\ell - 1 = (1+\mu_{\varepsilon,s})^\ell - 1 = \iota_s(\varphi(X))$ and w is Frobenius-equivariant, so ι_s commutes with the Frobenius lifts; $\iota_s(Q_{s-1}) = \sum_{i<\ell}[\varepsilon^{1/\ell^{s-1}}]^{i\ell^{s-1}} = \sum_{i<\ell}[\varepsilon]^i = \tilde{\xi}$. On $\mathcal{O}_F$, $\tilde{\theta} \circ \iota_s = \theta \circ w$ as in item 4, and $\tilde{\theta}(\mu_{\varepsilon,s}) = \theta([\varepsilon^{1/\ell^s}]) - 1 = \zeta_{\ell^s} - 1$; so the induced map $\mathcal{O}_{F_s} = \mathbf{A}_F/Q_{s-1} \to A_{\mathrm{inf}}/\tilde{\xi} = \mathcal{O}_{\mathbb{C}_\ell}$ is the inclusion. For $\sigma \in G_F$, σ fixes $\varphi(w(\mathcal{O}_F))$, and since σ raises every ζ_{ℓ^n} to the power $\chi_{\mathrm{cyc}}(\sigma)$ it maps $\varepsilon^{1/\ell^{s-1}}$ to $(\varepsilon^{1/\ell^{s-1}})^{\chi_{\mathrm{cyc}}(\sigma)}$; so $\sigma(\mu_{\varepsilon,s}) = (1+\mu_{\varepsilon,s})^{\chi_{\mathrm{cyc}}(\sigma)} - 1 = \iota_s(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(X))$ by multiplicativity and continuity of the Teichmüller map and of the binomial series, and $\sigma \circ \iota_s = \iota_s \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$. Injectivity: modulo ℓ, ι_s induces $f \mapsto f(\varepsilon^{1/\ell^{s-1}} - 1)$ on $k[[X]]$, injective since $|\varepsilon^{1/\ell^{s-1}} - 1| \neq 0$; then as in item 4. The inverse image of $\tilde{\xi}^k A_{\mathrm{inf}}$: as $\tilde{\theta} \circ \iota_s$ factors through the injection $\mathbf{A}_F/Q_{s-1} = \mathcal{O}_{F_s} \hookrightarrow \mathcal{O}_{\mathbb{C}_\ell}$, the induction of item 4 applies with Q_{s-1} in place of Q. *Over $\mathcal{O}_K$.* The extension F_s/F is totally ramified, so $\mathcal{O}_K \subseteq \mathcal{O}_{F_s}$ is a local subring with residue field k, and the argument of item 5 applies with F_s, Q_{s-1}, ι_s: $\mathrm{red}(Q_{s-1}) = \ell$ and the induced map $\mathcal{O}_{F_s} \to k$ is the reduction; the map induced by ι_s is the inclusion; for $u = \chi_{\mathrm{cyc}}(\sigma)$, $\sigma \in G_K$, item 2 (with Q_{s-1}) gives $\gamma_u(Q_{s-1}\mathbf{A}_F) = Q_{s-1}\mathbf{A}_F$, and the induced automorphism of $\mathcal{O}_{F_s} = \mathcal{O}_F[\zeta_{\ell^s}]$ is the identity on $\mathcal{O}_F$ and sends ζ_{ℓ^s} to $\zeta_{\ell^s}^u$, i.e. it is the restriction of σ, which fixes $\mathcal{O}_K$. □

Lemma 23.9. *Let ℓ be an odd prime, F, L as in Definition 23.2, and $\mathbf{N}$ a Wach module over F with coefficients L (any window), of rank r in (Wm1). Put $\Lambda = \mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, $E = \Lambda[1/\ell]$, $h_u = (1+X)^u - 1 \in X\mathbb{Z}_\ell[[X]]$ for $u \in \mathbb{Z}_\ell^\times$, and $\mathbf{N}_E = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} E[[X]]$, with the semilinear operators $\gamma_u(f \otimes x) = (f \circ h_u) \otimes \gamma_u(x)$ ($f \circ h_u$ the formal composition) and the submodules $X^k\mathbf{N}_E = \mathbf{N} \otimes X^k E[[X]]$. For $k \geq 0$ let*

$$s_\ell(k) = J + v_\ell(J!), \qquad J = \Big\lfloor \frac{k}{\ell - 1} \Big\rfloor; \qquad \text{so } s_\ell(k) \leq \frac{k\,\ell}{(\ell-1)^2}.$$

(Hf1) Trivialisation of cocycles *Let $m \geq 1$ and let $(z_u)_{u \in \mathbb{Z}_\ell^\times}$ be elements of $X^m\mathbf{N}$ with $z_{uv} = z_u + \gamma_u(z_v)$ for all u, v. Then there is a unique $W \in X^m\mathbf{N}_E$ with $(\gamma_u - 1)(W) = z_u$ for every $u \in \mathbb{Z}_\ell^\times$; uniqueness already holds for one u that is not a root of unity.*

(Hf2) Horizontal sections *For every $x_0 \in \mathbf{N}$ there is a unique $H \in x_0 + X\mathbf{N}_E$ with $\gamma_u(H) = H$ for every $u \in \mathbb{Z}_\ell^\times$. If $x_1, \ldots, x_r$ is an $\mathbf{A}_{F,L}$-basis of $\mathbf{N}$, the corresponding $H_1, \ldots, H_r$ form an $E[[X]]$-basis of $\mathbf{N}_E$.*

(Hf3) Denominators *Let (n_i) be an $\mathbf{A}_{F,L}$-basis of $\mathbf{N}$. The coordinates $\sum_k a_k X^k \in E[[X]]$ of W in (Hf1) and of H in (Hf2) satisfy $\ell^{s_\ell(k)} a_k \in \Lambda$ for every $k \geq 0$. Consequently, for every $R \geq 1$ there is $x_R \in \mathbf{N}$ with $\ell^{s_\ell(R-1)} W - x_R \in X^R \mathbf{N}_E$ (resp. $\ell^{s_\ell(R-1)} H - x_R \in X^R \mathbf{N}_E$), and for every such x_R and every u,*

$$(\gamma_u - 1)(x_R) - \ell^{s_\ell(R-1)} z_u \in X^R \mathbf{N} \qquad (\text{resp. } (\gamma_u - 1)(x_R) \in X^R \mathbf{N}).$$

In (Hf1) one can take $x_R \in X^m \mathbf{N}$.

Over a base field. *Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$, Γ_K, Δ_K as in Definition 23.2, $d = |\Delta_K|$, and let $\mathbf{N}$ be a Wach module over K with coefficients L. Then (Hf1)–(Hf3) hold with $u, v \in \Gamma_K$ in place of $u, v \in \mathbb{Z}_\ell^\times$ (the operators γ_u of $\mathbf{N}_E$ being defined for $u \in \Gamma_K$) and with $s_\ell(k)$ replaced by*

$$s_{\ell,d}(k) = J + v_\ell(J!), \qquad J = \Big\lfloor \frac{k}{d} \Big\rfloor; \qquad \text{so } s_{\ell,d}(k) \leq \frac{k\,\ell}{d(\ell-1)} \leq \frac{3k}{2}.$$

For $K = F$ one has $\Gamma_F = \mathbb{Z}_\ell^\times$, $d = \ell - 1$ and $s_{\ell,\ell-1} = s_\ell$: this is the statement above.

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L and K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) as in the paragraph Level s of Definition 23.2, and $\mathbf{N}$ a Wach module of level s over K with coefficients L. With Λ, E, h_u, $\mathbf{N}_E$ as above, (Hf1)–(Hf3) hold with $u, v \in \Gamma_K$ in place of $u, v \in \mathbb{Z}_\ell^\times$ and with $s_\ell(k)$ replaced by*

$$\nu_{\ell,s}(k) = sk + v_\ell(k!) \leq (s+1)k.$$

(For $s = 1$ and ℓ odd the paragraph over a base field gives the smaller $s_{\ell,d}$.)

Proof. **Preliminaries.** By (Wm1), each $\mathbf{N}_a$ is free of rank r over $e_a \mathbf{A}_{F,L}$, so $\mathbf{N} = \bigoplus_a \mathbf{N}_a$ is free of rank r over $\mathbf{A}_{F,L} = \Lambda[[X]]$; fix a basis (n_i) (any basis, for (Hf3)). Then $\mathbf{N}_E = \bigoplus_i E[[X]]\, n_i \supseteq \mathbf{N}$, $X^k \mathbf{N}_E$ consists of the elements whose coordinates lie in $X^k E[[X]]$, and $\mathbf{N} \cap X^k \mathbf{N}_E = X^k \mathbf{N}$ (as $\Lambda[[X]] \cap X^k E[[X]] = X^k \Lambda[[X]]$). The Λ-linear ring endomorphism γ_u of $\Lambda[[X]]$ with $\gamma_u(X) = h_u$ is $f \mapsto f \circ h_u$ (for $f = \sum_{k<N} c_k X^k + X^N g$, $\gamma_u(f) - \sum_{k<N} c_k h_u^k = h_u^N \gamma_u(g) \in X^N \Lambda[[X]]$); formal composition with $h \in XE[[X]]$ is a ring endomorphism of $E[[X]]$ preserving each $X^k E[[X]]$, composition is associative, and $h_v \circ h_u = (1+X)^{uv} - 1 = h_{uv}$. Hence γ_u on $\mathbf{N}_E$ is well defined (the map is $\Lambda[[X]]$-balanced because $\gamma_{u,\mathbf{N}}$ is γ_u-semilinear), $\gamma_u \gamma_v = \gamma_{uv}$ (by (Wm3) on $\mathbf{N}$), all γ_u commute, and they preserve each $X^k \mathbf{N}_E$. Let $G_u \in M_r(\Lambda[[X]])$ be the matrix with $\gamma_u(n_i) = \sum_j (G_u)_{ji} n_j$; by (Wm3), $G_u \equiv I$ modulo X, and $\gamma_u(\sum_i w_i n_i) = \sum_j (G_u\,(w \circ h_u))_j n_j$ for $w \in E[[X]]^r$.

The generator and its eigenvalues. Fix a topological generator g of $\mathbb{Z}_\ell^\times$ (procyclic, ℓ odd). For $i \geq 1$ let $\delta_i = v_\ell(g^i - 1)$. If $(\ell-1) \nmid i$, then $g^i \not\equiv 1 \bmod \ell$ (the image of g generates $\mathbb{F}_\ell^\times$), so $\delta_i = 0$. If $i = (\ell-1)j$, then $g^{\ell-1} = 1 + \ell t$ with $t \in \mathbb{Z}_\ell^\times$ ($g^{\ell-1}$ generates $1 + \ell\mathbb{Z}_\ell$), and in $(1+\ell t)^j - 1 = j\ell t + \sum_{q \geq 2} \binom{j}{q} (\ell t)^q$ the first term has valuation $1 + v_\ell(j)$ while $v_\ell(\binom{j}{q} \ell^q) \geq v_\ell(j) - v_\ell(q) + q \geq v_\ell(j) + 2$ for $q \geq 2$ ($\binom{j}{q} = \frac{j}{q}\binom{j-1}{q-1}$, and $q - v_\ell(q) \geq 2$ for $q \geq 2$, $\ell \geq 3$); so $\delta_i = 1 + v_\ell(j)$. Hence, for $k \geq 1$,

$$\sum_{i=1}^{k} \delta_i = \sum_{j=1}^{J} (1 + v_\ell(j)) = J + v_\ell(J!) = s_\ell(k), \qquad J = \lfloor k/(\ell-1) \rfloor,$$

and $s_\ell(k) \leq J + J/(\ell-1) = J\ell/(\ell-1) \leq k\ell/(\ell-1)^2$ by Legendre's formula $v_\ell(J!) \leq J/(\ell-1)$.

(Hf1) for $u = g$: existence, uniqueness, denominators. Write $G = G_g = \sum_{j \geq 0} G_j X^j$ ($G_j \in M_r(\Lambda)$, $G_0 = I$), $h = h_g$ and $h^i = \sum_{j \geq i} h_j^{(i)} X^j$ with $h_j^{(i)} \in \mathbb{Z}_\ell$, $h_i^{(i)} = g^i$. Let $\zeta =$

$\sum_{k\ge m}\zeta_k X^k$ ($\zeta_k\in\Lambda^r$) be the coordinates of z_g. For $w=\sum_{k\ge m}w_kX^k\in(X^mE[[X]])^r$, the coefficient of X^k in $G(w\circ h)-w$ is

$$(g^k-1)w_k+\sum_{m\le i<k}M_{k,i}w_i,\qquad M_{k,i}=\sum_{j=i}^{k}G_{k-j}h_j^{(i)}\in M_r(\Lambda),$$

since w_k enters only through $G_0h_k^{(k)}X^k$. As $g^k\ne1$ for $k\ge1$, the equation $(\gamma_g-1)(\sum_i w_in_i)=z_g$ is equivalent to the recursion $w_k=(g^k-1)^{-1}(\zeta_k-\sum_{m\le i<k}M_{k,i}w_i)$, $k\ge m$, which has exactly one solution. By induction, $\ell^{t_k}w_k\in\Lambda^r$ with $t_k=\sum_{i=m}^{k}\delta_i\le s_\ell(k)$: indeed $\ell^{t_{k-1}}(\zeta_k-\sum_{i<k}M_{k,i}w_i)\in\Lambda^r$ (t is non-decreasing, $t_{m-1}=0$) and $(g^k-1)^{-1}\in\ell^{-\delta_k}\mathbb{Z}_\ell$. So there is a unique $W\in X^m\mathbf{N}_E$ with $(\gamma_g-1)W=z_g$, and its coordinates satisfy the bound of (Hf3). The same lowest-degree argument shows: for any u not a root of unity, $(\gamma_u-1)D=0$ and $D\in X\mathbf{N}_E$ imply $D=0$ (if $D\ne0$ has lowest degree $k\ge1$, its degree-k coefficient is multiplied by $u^k-1\ne0$); this is the uniqueness statement.

(Hf1) for all u. The cocycle relation and $uv=vu$ give $z_u+\gamma_u(z_g)=z_{ug}=z_{gu}=z_g+\gamma_g(z_u)$, i.e. $(\gamma_g-1)(z_u)=(\gamma_u-1)(z_g)$. Let $W'=\gamma_u(W)-z_u\in X^m\mathbf{N}_E$. Then $(\gamma_g-1)W'=\gamma_u(z_g)-(\gamma_u-1)(z_g)=z_g$, so $W'=W$ by uniqueness, i.e. $(\gamma_u-1)W=z_u$.

(Hf2). The elements $z_u=(1-\gamma_u)(x_0)$ lie in $X\mathbf{N}$ by (Wm3) and satisfy $z_{uv}=z_u+\gamma_u(z_v)$. By (Hf1) with $m=1$ there is a unique $W\in X\mathbf{N}_E$ with $(\gamma_u-1)W=(1-\gamma_u)x_0$ for all u, i.e. $H=x_0+W$ is γ_u-invariant; and H is unique in $x_0+X\mathbf{N}_E$ since the difference of two such lies in $X\mathbf{N}_E$ and is γ_g-invariant. The coordinates of H are those of x_0 (in $\Lambda[[X]]$) plus those of W, so they satisfy the bound of (Hf3). For a basis $x_1,\dots,x_r$, write $H_i=\sum_j P_{ji}x_j$ with $P\in M_r(E[[X]])$ ((x_j) is also an $E[[X]]$-basis of $\mathbf{N}_E$); $H_i-x_i\in X\mathbf{N}_E$ gives $P\equiv I$ modulo X, so $\det P\in1+XE[[X]]$ is a unit and (H_i) is a basis.

(Hf3): truncations. Let W be as in (Hf1) with coordinates $w_i=\sum_k w_{i,k}X^k$, and $R\ge1$. Since s_ℓ is non-decreasing, $x_R=\sum_i(\sum_{k<R}\ell^{s_\ell(R-1)}w_{i,k}X^k)n_i$ lies in $X^m\mathbf{N}$ (coefficients in Λ, vanishing below degree m) and $\ell^{s_\ell(R-1)}W-x_R\in X^R\mathbf{N}_E$. For any $x_R\in\mathbf{N}$ with this property, $(\gamma_u-1)(x_R)-\ell^{s_\ell(R-1)}z_u=(\gamma_u-1)(x_R-\ell^{s_\ell(R-1)}W)\in X^R\mathbf{N}_E$, and it lies in $\mathbf{N}$; so it lies in $\mathbf{N}\cap X^R\mathbf{N}_E=X^R\mathbf{N}$. The case of H is identical, with z_u replaced by 0.

Over a base field. Let K, Γ_K, Δ_K, d and $\mathbf{N}$ be as there. The group Γ_K contains $1+\ell\mathbb{Z}_\ell$: by Definition 23.2, $\chi_{\mathrm{cyc}}(G_F)=\mathbb{Z}_\ell^\times$, and $\sigma\in G_F$ fixes μ_ℓ if and only if $\chi_{\mathrm{cyc}}(\sigma)\equiv1\bmod\ell$, so $\chi_{\mathrm{cyc}}(G_{F(\mu_\ell)})=1+\ell\mathbb{Z}_\ell$, and $G_{F(\mu_\ell)}\subseteq G_K$. As ℓ is odd, $\mathbb{Z}_\ell^\times=\mu_{\ell-1}\times(1+\ell\mathbb{Z}_\ell)$, hence $\Gamma_K=\Delta_K\times(1+\ell\mathbb{Z}_\ell)$ with $\Delta_K=\Gamma_K\cap\mu_{\ell-1}$ cyclic of order d, $d\mid\ell-1$; and Γ_K is closed (image of a compact group). In the proof above replace $\mathbb{Z}_\ell^\times$ by Γ_K throughout; the preliminaries are unchanged ((Wm1), (Wm3) for $u\in\Gamma_K$; h_vh_u-composition and commutativity hold in Γ_K). Only the paragraph on the generator changes: let δ_0 generate Δ_K and $g=\delta_0(1+\ell)\in\Gamma_K$. The closure of the group generated by g contains $g^d=(1+\ell)^d$, which generates $1+\ell\mathbb{Z}_\ell$ topologically (d is prime to ℓ), hence contains $(1+\ell)$ and $\delta_0=g(1+\ell)^{-1}$; so g is a topological generator of Γ_K, of infinite order. Reduction modulo ℓ maps $\mu_{\ell-1}$ isomorphically onto $\mathbb{F}_\ell^\times$, so $g\bmod\ell=\delta_0\bmod\ell$ has order d and $\delta_i=v_\ell(g^i-1)=0$ for $d\nmid i$; for $i=dj$, $g^i=(1+\ell)^{dj}$ and $\delta_i=1+v_\ell(dj)=1+v_\ell(j)$ (the identity $v_\ell((1+\ell)^N-1)=1+v_\ell(N)$ for ℓ odd, proved in the paragraph on the generator with $t=1$). Hence $\sum_{i\le k}\delta_i=J+v_\ell(J!)=s_{\ell,d}(k)$ with $J=\lfloor k/d\rfloor$, and by Legendre's formula $s_{\ell,d}(k)\le J\ell/(\ell-1)\le k\ell/(d(\ell-1))\le k\ell/(\ell-1)\le3k/2$. The recursion, the passage to all $u\in\Gamma_K$ (which uses only $uv=vu$ in Γ_K and uniqueness for g), (Hf2) and the truncations then go through unchanged, with $s_{\ell,d}$ in place of s_ℓ. For $K=F$, $\Delta_F=\mu_{\ell-1}$, $d=\ell-1$, and this is the proof above.

Level s. Let ℓ, s, K and $\mathbf{N}$ be as there. The preliminaries are unchanged: they use (Wm1), the congruence $(\gamma_u-1)(\mathbf{N})\subseteq X\mathbf{N}$ and $\gamma_u\gamma_v=\gamma_{uv}$, which a Wach module of level s

has for $u, v \in \Gamma_K$ (Definition 23.2, paragraph Level s), and $h_v \circ h_u = h_{uv}$, which holds for every prime. Only the generator changes. Put $g = 1 + \ell^s$. It lies in Γ_K: $\chi_{\mathrm{cyc}}(G_{F(\mu_{\ell^s})}) = 1 + \ell^s\mathbb{Z}_\ell$ (Definition 23.2, paragraph Level s) and $G_{F(\mu_{\ell^s})} \subseteq G_K$; and it is not a root of unity. For $i \geq 1$ we claim $\delta_i = v_\ell(g^i - 1) = s + v_\ell(i)$. Write $i = \ell^a b$ with $\ell \nmid b$. First $(1+\ell^s)^b - 1 = b\ell^s + \sum_{q \geq 2} \binom{b}{q} \ell^{sq}$ has valuation exactly s. Next, if $v_\ell(y) \geq 1$ for ℓ odd, resp. $v_2(y) \geq 2$ for $\ell = 2$, then $(1+y)^\ell - 1 = \ell y + \sum_{1<q<\ell} \binom{\ell}{q} y^q + y^\ell$ has valuation exactly $v_\ell(y) + 1$: the middle terms have valuation at least $1 + 2v_\ell(y)$, and y^ℓ has valuation $\ell v_\ell(y) \geq v_\ell(y) + 2$ because $(\ell - 1)v_\ell(y) \geq 2$; the hypothesis is kept (valuations only grow). Since $s \geq 1$, resp. $s \geq 2$ for $\ell = 2$, induction on a gives $\delta_i = s + a$. Hence, in the recursion of (Hf1) for $u = g$ (which uses only that the matrix G_g is $\equiv I$ modulo X and that $g^k \neq 1$ for $k \geq 1$, and therefore goes through unchanged), $\ell^{t_k} w_k \in \Lambda^r$ with

$$t_k = \sum_{i=m}^{k} \delta_i \leq \sum_{i=1}^{k} (s + v_\ell(i)) = sk + v_\ell(k!) = \nu_{\ell,s}(k),$$

and $v_\ell(k!) \leq (k-1)/(\ell - 1) \leq k$ by Legendre's formula, so $\nu_{\ell,s}(k) \leq (s+1)k$. Uniqueness for g is the lowest-degree argument; the passage to all $u \in \Gamma_K$ uses only that Γ_K is commutative and uniqueness for g; (Hf2) uses the congruence of (Wm3) of level s; the truncations use only that $\nu_{\ell,s}$ is non-decreasing. All go through unchanged with $\nu_{\ell,s}$ in place of s_ℓ. □

Lemma 23.10. *Let ℓ, F, L, (τ_a) and a pair (V, T) be as in Proposition 23.7, $d = \dim_L V$, $\mathbf{N} = \mathbf{N}(T)$, and $D_{\mathrm{cris}}(V) = (B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)^{G_F}$, a module over $F \otimes_{\mathbb{Q}_\ell} L$ with the orthogonal idempotents $\epsilon_b = \iota_\Lambda(e_b)$, $b \in \mathbb{Z}/n$. For each $a \in \mathbb{Z}/n$ let $(n_{a,i})_{i \leq d}$ be an $e_a\mathbf{A}_{F,L}$-basis of $\mathbf{N}_a$, and $H_{a,i} \in \mathbf{N}_E$ the horizontal section through $n_{a,i}$ ((Hf2)). Then $H_{a,i} \in e_a\mathbf{N}_R$, the elements $d_{a,i} = \mathrm{Ev}(H_{a,i})$ lie in $\epsilon_{a+3}D_{\mathrm{cris}}(V)$, and:*

1. *for each a, $(d_{a,i})_{i \leq d}$ is a basis of $\epsilon_{a+3}(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)$ over $\epsilon_{a+3}(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L)$;*
2. *$(d_{a,i})_{a,i}$ is a basis of $D_{\mathrm{cris}}(V)$ over $F \otimes_{\mathbb{Q}_\ell} L$, and for each a, $(d_{a,i})_{i \leq d}$ is a basis of $\epsilon_{a+3}D_{\mathrm{cris}}(V)$ over $\epsilon_{a+3}(F \otimes_{\mathbb{Q}_\ell} L) \cong L$.*

Over a base field. *Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$ as in Definition 23.2, (V, T) a pair over K as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $D_{\mathrm{cris}}(V) = (B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)^{G_K}$, and $H_{a,i}$ the horizontal sections of (Hf2) over K (Lemma 23.9, over a base field). Then the same holds: $H_{a,i} \in e_a\mathbf{N}_R$, $d_{a,i} = \mathrm{Ev}(H_{a,i}) \in \epsilon_{a+3}D_{\mathrm{cris}}(V)$, and items 1 and 2 hold as stated (still over $F \otimes_{\mathbb{Q}_\ell} L$). For $K = F$ this is the statement above.*

Proof. By (Ex1) and (Wm1), $(n_{a,i})_{a,i}$ is an $\mathbf{A}_{F,L}$-basis of $\mathbf{N} = \bigoplus_a \mathbf{N}_a$, of size nd. Write $H = H_{a,i}$, $x = n_{a,i}$ for the moment.

Sites and growth. Since $\gamma_u(e_a) = e_a$, e_aH is γ_u-invariant for every u and $e_aH - x = e_a(H - x) \in X\mathbf{N}_E$; by the uniqueness in (Hf2), $e_aH = H$. By (Hf3) the coordinates $\sum_k c_k X^k$ of H in the basis $(n_{b,j})$ satisfy $\ell^{s_\ell(k)} c_k \in \Lambda$ with $s_\ell(k) \leq k\ell/(\ell-1)^2 \leq 2k$, so they lie in R and $H \in e_a\mathbf{N}_R$.

Invariance and the site of $d_{a,i}$. For $\sigma \in G_F$, (Ev3) and (Hf2) give

$$\sigma(\mathrm{Ev}(H)) = \mathrm{Ev}(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(H)) = \mathrm{Ev}(H),$$

so $d_{a,i} \in D_{\mathrm{cris}}(V)$. From the defining formula of Ev, $\mathrm{Ev}(fW) = e(f)\mathrm{Ev}(W)$ for $f \in R$, $W \in \mathbf{N}_R$; so $d_{a,i} = e(e_a)d_{a,i}$ with $e(e_a) = \varphi^3(\iota_\Lambda(e_a))$ (Ev2). As ι is φ-equivariant (Lemma 23.8(4)) and $\varphi(e_b) = e_{b+1}$, $\varphi^3(\iota_\Lambda(e_a)) = \iota_\Lambda(e_{a+3}) = \epsilon_{a+3}$. The elements ϵ_b lie in $F \otimes_{\mathbb{Q}_\ell} L \subseteq B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L$ ($\iota|_{\mathcal{O}_F} = \varphi \circ w$ has the same image as the canonical $w\colon W(k) \to A_{\mathrm{inf}}$, φ being an automorphism of $W(k)$), and they are orthogonal idempotents with sum 1, as the e_b are.

Item 1. Write $H_{a,i} = \sum_{b,j} P_{(b,j),(a,i)} n_{b,j}$ with $P \in M_{nd}(R)$; as $H_{a,i} - n_{a,i} \in X\mathbf{N}_E$, $P - I$ has entries in XR. Put $v_{b,j} = \mathrm{Ev}(n_{b,j}) = \varphi^3((\rho \otimes 1)(\iota_T(n_{b,j})))$. Then $d_{a,i} = \sum_{b,j} e(P_{(b,j),(a,i)}) v_{b,j}$, and $e(P) \in M_{nd}(A)$ with $e(P) - I \in \ell M_{nd}(A)$ by (Ev2) ($e(XR) \subseteq \ell A$, as $e(1+f) \in 1 + \ell A$ for $f \in XR$); since A is ℓ-adically complete, $\det e(P) \in 1 + \ell A$ is a unit and $e(P) \in \mathrm{GL}_{nd}(A)$. So it suffices to prove the basis property of item 1 for $(v_{b,j})$ in place of $(d_{b,j})$ (the matrix $e(P)$ respects the components: $P_{(b,j),(a,i)} = 0$ for $b \neq a$, as $H_{a,i} \in e_a \mathbf{N}_E$). By (Ex2), $\iota_T(gx) = \iota_L(g)\iota_T(x)$ for $g \in \mathbf{A}_{F,L}$ (write $g = \sum_j f_j \otimes \lambda_j$ with $f_j \in \mathbf{A}_F$, $\lambda_j \in \mathcal{O}_L$), and $A_{\mathrm{inf}}[1/\mu] \cdot \iota_T(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu] \otimes T$; so the nd elements $\iota_T(n_{b,j})$ generate $A_{\mathrm{inf}}[1/\mu] \otimes_{\mathbb{Z}_\ell} T$ over $A_{\mathrm{inf}}[1/\mu] \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$. This module is free of rank d over $A_{\mathrm{inf}}[1/\mu] \otimes \mathcal{O}_L$; decomposing along the idempotents $\iota_\Lambda(e_b)$, each component $\iota_\Lambda(e_b)(A_{\mathrm{inf}}[1/\mu] \otimes T)$ is free of rank d over $\iota_\Lambda(e_b)(A_{\mathrm{inf}}[1/\mu] \otimes \mathcal{O}_L)$ and generated by the d elements $\iota_T(n_{b,j}) = \iota_\Lambda(e_b)\iota_T(n_{b,j})$, $j \leq d$; a surjective endomorphism of a finitely generated module over a commutative ring is bijective, so these form a basis, and $(\iota_T(n_{b,j}))_{b,j}$ is a basis of $A_{\mathrm{inf}}[1/\mu] \otimes T$ over $A_{\mathrm{inf}}[1/\mu] \otimes \mathcal{O}_L$ in the sense that every element is uniquely $\sum_{b,j} c_{b,j} \iota_T(n_{b,j})$ with $c_{b,j} \in \iota_\Lambda(e_b)(A_{\mathrm{inf}}[1/\mu] \otimes \mathcal{O}_L)$. Applying the ring homomorphism $\rho \otimes 1$ preserves this property over $B_{\mathrm{cris}} \otimes \mathcal{O}_L$. Finally $\varphi^3 = \varphi^3 \otimes 1$ fixes $1 \otimes T$; in a fixed $\mathcal{O}_L$-basis (t_k) of T, the matrix of $(\varphi^3 \rho \iota_T(n_{b,j}))$ is φ^3 applied to that of $(\rho\iota_T(n_{b,j}))$, and a ring endomorphism maps invertible matrices to invertible matrices (and $\varphi^3(\iota_\Lambda(e_b)) = \epsilon_{b+3}$); so $(v_{b,j})$ has the same basis property, with $v_{b,j} \in \epsilon_{b+3}(B_{\mathrm{cris}} \otimes T)$. So for each b, $(v_{b,j})_{j \leq d}$ is a basis of $\epsilon_{b+3}(B_{\mathrm{cris}} \otimes T)$ over $\epsilon_{b+3}(B_{\mathrm{cris}} \otimes \mathcal{O}_L)$; with the invertible block-diagonal $e(P)$ the same holds for $(d_{a,i})_{i \leq d}$, and inverting ℓ ($B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T = B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V$, $B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L = B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L$) gives item 1. Since $\sum_b \epsilon_b = 1$, every element of $B_{\mathrm{cris}} \otimes V$ is then uniquely $\sum_{a,i} c_{a,i} d_{a,i}$ with $c_{a,i} \in \epsilon_{a+3}(B_{\mathrm{cris}} \otimes L)$.

Item 2. Let $v \in D_{\mathrm{cris}}(V)$ and write $v = \sum_{a,i} c_{a,i} d_{a,i}$ with $c_{a,i} \in \epsilon_{a+3}(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L)$, uniquely by the last sentence of the proof of item 1. For $\sigma \in G_F$, $v = \sigma(v) = \sum \sigma(c_{a,i}) d_{a,i}$ (the $d_{a,i}$ are invariant, $\sigma(\epsilon_b) = \epsilon_b$), so $\sigma(c_{a,i}) = c_{a,i}$ by uniqueness. Now $(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L)^{G_F} = B_{\mathrm{cris}}^{G_F} \otimes_{\mathbb{Q}_\ell} L = F \otimes_{\mathbb{Q}_\ell} L$, because L is finite free over $\mathbb{Q}_\ell$ with trivial action and $B_{\mathrm{cris}}^{G_F} = F$ for F unramified [94]. So $c_{a,i} \in \epsilon_{a+3}(F \otimes L)$; conversely every such combination is invariant. Hence $(d_{a,i})$ is an $F \otimes L$-basis of $D_{\mathrm{cris}}(V)$, and multiplying by ϵ_{a+3} (which kills $d_{b,j}$ for $b \neq a$) shows that $(d_{a,i})_i$ is a basis of $\epsilon_{a+3} D_{\mathrm{cris}}(V)$ over $\epsilon_{a+3}(F \otimes L)$, which is L via the isomorphism $\mathcal{O}_F \otimes \mathcal{O}_L \cong \prod_b \mathcal{O}_L$ of Definition 23.2 (transported by ι_Λ).

Over a base field. For a pair over K the proof is the same, with the following three substitutions. (i) Sites and growth: H is the horizontal section of (Hf2) over K (γ_u-invariant for $u \in \Gamma_K$); $e_a H$ is γ_u-invariant for $u \in \Gamma_K$, so $e_a H = H$ by the uniqueness there; its coordinates satisfy $\ell^{s_{\ell,|\Delta_K|}(k)} c_k \in \Lambda$ with $s_{\ell,|\Delta_K|}(k) \leq 3k/2 \leq 2k$ (here d is $\dim_L V$, so the index of s is written $|\Delta_K|$), so $H \in e_a \mathbf{N}_R$. (ii) Invariance: for $\sigma \in G_K$, (Ev3) over K (Lemma 23.11, over a base field) and the invariance of H under $\gamma_{\chi_{\mathrm{cyc}}(\sigma)}$, $\chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$, give $\sigma(d_{a,i}) = d_{a,i}$, so $d_{a,i} \in D_{\mathrm{cris}}(V)$; the computation of the site is unchanged. Item 1 involves no Galois group: it uses (Ex2) and $A_{\mathrm{inf}}[1/\mu] \cdot \iota_T(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu] \otimes T$, which Proposition 23.7 gives for pairs over K. (iii) Item 2: the uniqueness argument runs with $\sigma \in G_K$, and $(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L)^{G_K} = B_{\mathrm{cris}}^{G_K} \otimes_{\mathbb{Q}_\ell} L = F \otimes_{\mathbb{Q}_\ell} L$, because $B_{\mathrm{cris}}^{G_K}$ is the maximal unramified subextension K_0 of $K/\mathbb{Q}_\ell$ [94], and $K_0 = F$: $F \subseteq K_0$, and $K \subseteq F(\mu_\ell)$ with $F(\mu_\ell)/F$ totally ramified, so K/F is totally ramified. This is the only place where the base field enters beyond the substitution $G_F \to G_K$, $\mathbb{Z}_\ell^\times \to \Gamma_K$. □

Lemma 23.11. *Let ℓ, F, L, (τ_a) and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, and ρ: $A_{\mathrm{inf}}[1/\mu] \to B_{\mathrm{cris}}$ the G_F- and φ-equivariant ring homomorphism extending $A_{\mathrm{inf}} \subset A_{\mathrm{cris}} \subset B_{\mathrm{cris}}$. Let $R \subseteq E[[X]]$ be the set of series $\sum_k a_k X^k$ with $\ell^{2k} a_k \in \Lambda$ for all k, and $\mathbf{N}_R = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} R \subseteq \mathbf{N}_E$. Let $\iota_\Lambda \colon E \to (A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L)[1/\ell]$ be $\iota|_{\mathcal{O}_F} \otimes \mathrm{id}$, extended to E, and $A = A_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, with φ and G_F acting on the first factor. Then:*

(Ev1) *R is a subring of $E[[X]]$ containing $\mathbf{A}_{F,L}$, stable under $f \mapsto f \circ h_u$ for every $u \in \mathbb{Z}_\ell^\times$,*

and $\mathbf{N}_R$ is stable under the operators γ_u of $\mathbf{N}_E$.

(Ev2) *For $f = \sum a_k X^k \in R$ the series $e(f) = \sum_{k\ge 0} \varphi^3(\iota_\Lambda(a_k))\varphi^3(\mu)^k$ converges in A, its k-th term lying in $\ell^k A$. The map $e\colon R \to A$ is a ring homomorphism; $e(f) = \varphi^3(\iota_L(f))$ for $f \in \mathbf{A}_{F,L}$, where $\iota_L = \iota \otimes \mathrm{id}\colon \mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \to A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$; $e(f) \in 1 + \ell A$ if $f \in 1 + XR$; and $\sigma(e(f)) = e(f \circ h_{\chi_{\mathrm{cyc}}(\sigma)})$ for $\sigma \in G_F$.*

(Ev3) *There is a unique additive map $\mathrm{Ev}\colon \mathbf{N}_R \to B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T$ with $\mathrm{Ev}(f \otimes x) = e(f) \cdot \varphi^3((\rho \otimes 1)(\iota_T(x)))$ for $f \in R$, $x \in \mathbf{N}$ (with $\varphi = \varphi \otimes 1$ and $B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T$ a module over $B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \supseteq A$). It satisfies $\mathrm{Ev}(x) = \varphi^3((\rho \otimes 1)(\iota_T(x)))$ for $x \in \mathbf{N}$, and $\sigma(\mathrm{Ev}(W)) = \mathrm{Ev}(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(W))$ for $W \in \mathbf{N}_R$ and $\sigma \in G_F$ acting diagonally.*

Over a base field. *Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$, Γ_K as in Definition 23.2, (V,T) a pair over K as in Proposition 23.7 and $\mathbf{N} = \mathbf{N}(T)$. Then (Ev1)–(Ev3) hold with $u \in \Gamma_K$ in the last clause of (Ev1) and with $\sigma \in G_K$ in (Ev3); (Ev2) is unchanged. For $K = F$ this is the statement above.*

Level s. *Let ℓ be any prime, $s \ge 1$ an integer with $s \ge 2$ if $\ell = 2$, and L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and a pair (V,T) over K as in (Ex4) of Proposition 23.7; let $\mathbf{N} = \mathbf{N}_s(T)$ with $\iota_{s,T}$, ι_s as in Lemma 23.8(6), $\iota_{s,L} = \iota_s \otimes \mathrm{id}$, and ρ, Λ, E, ι_Λ, A as above ($\iota_s = \iota$ on $\mathcal{O}_F$, so ι_Λ is unchanged). Let $R_s \subseteq E[[X]]$ be the set of series $\sum_k a_k X^k$ with $\ell^{(s+1)k} a_k \in \Lambda$ for all k, $\mathbf{N}_{R_s} = \mathbf{N} \otimes_{\mathbf{A}_{F,L}} R_s$, and for $f = \sum a_k X^k \in R_s$, $x \in \mathbf{N}$,*

$$e_s(f) = \sum_{k\ge 0} \varphi^{2s+1}(\iota_\Lambda(a_k))\, \varphi^{s+2}(\mu)^k, \qquad \mathrm{Ev}_s(f \otimes x) = e_s(f) \cdot \varphi^{2s+1}((\rho \otimes 1)(\iota_{s,T}(x))).$$

Then (Ev1)–(Ev3), in the form over a base field ($u \in \Gamma_K$, $\sigma \in G_K$), hold with R, $\mathbf{N}_R$, e, Ev, ι_L, ι_T, φ^3 replaced by R_s, $\mathbf{N}_{R_s}$, e_s, Ev_s, $\iota_{s,L}$, $\iota_{s,T}$, φ^{2s+1}; in particular $e_s(f) = \varphi^{2s+1}(\iota_{s,L}(f))$ for $f \in \mathbf{A}_{F,L}$, $\mathrm{Ev}_s(x) = \varphi^{2s+1}((\rho \otimes 1)(\iota_{s,T}(x)))$ for $x \in \mathbf{N}$, and $\sigma(\mathrm{Ev}_s(W)) = \mathrm{Ev}_s(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(W))$ for $W \in \mathbf{N}_{R_s}$, $\sigma \in G_K$. For $s = 1$ and ℓ odd ($R_1 = R$, $e_1 = e$, $\mathrm{Ev}_1 = \mathrm{Ev}$) this is the paragraph over a base field.

Proof. **(Ev1).** The coefficient of X^k in a product is $\sum_{i+j=k} a_i b_j$, and $\ell^{2k} a_i b_j = (\ell^{2i} a_i)(\ell^{2j} b_j) \in \Lambda$; so R is a ring, and it contains $\Lambda[[X]] = \mathbf{A}_{F,L}$. For $h \in X\mathbb{Z}_\ell[[X]]$ write $h^k = \sum_{j\ge k} h_j^{(k)} X^j$ with $h_j^{(k)} \in \mathbb{Z}_\ell$; the coefficient of X^j in $f \circ h$ is $\sum_{k\le j} a_k h_j^{(k)}$, and $\ell^{2j} a_k h_j^{(k)} \in \Lambda$ for $k \le j$; so $f \circ h \in R$. By (Ex1) and (Wm1) of Definition 23.2, every $\mathbf{N}_a$ is free of rank $r = \dim_L V$ over $e_a \mathbf{A}_{F,L}$, so $\mathbf{N} = \bigoplus_a \mathbf{N}_a$ is free over $\mathbf{A}_{F,L}$ and $\mathbf{N}_R = \bigoplus_i R\, n_i$ for a basis (n_i), and $\gamma_u(\sum_i w_i n_i) = \sum_j (G_u(w \circ h_u))_j n_j$ with $G_u \in M_r(\mathbf{A}_{F,L}) \subseteq M_r(R)$ the matrix of $\gamma_{u,\mathbf{N}}$ in this basis; hence $\gamma_u(\mathbf{N}_R) \subseteq \mathbf{N}_R$.

(Ev2). The module A is a finite free A_{cris}-module, hence ℓ-torsion-free and ℓ-adically complete and separated. By (Ac1), $\varphi^3(\mu)^k \in \ell^{3k} A_{\mathrm{cris}}$, and $\ell^{2k} a_k \in \Lambda$ gives $\varphi^3(\iota_\Lambda(a_k)) \in \ell^{-2k}(A_{\mathrm{inf}} \otimes \mathcal{O}_L)$; so the k-th term lies in $\ell^k A$ and the series converges. The map e is additive, and multiplicative because the product of two series in A whose terms tend to 0 is the sum of their Cauchy product, while $\varphi^3 \circ \iota_\Lambda$ is a ring homomorphism on E. If $f \in 1 + XR$, all terms of index $k \ge 1$ lie in ℓA and the term of index 0 is 1. For $f = \sum c_k X^k \in \mathbf{A}_{F,L}$ and $N \ge 0$, $f = \sum_{k<N} c_k X^k + X^N g_N$ with $g_N \in \mathbf{A}_{F,L}$, and since ι_L and φ^3 are ring homomorphisms with $\iota_L(X) = \mu$,

$$\varphi^3(\iota_L(f)) - \sum_{k<N} \varphi^3(\iota_\Lambda(c_k))\varphi^3(\mu)^k = \varphi^3(\mu)^N \varphi^3(\iota_L(g_N)) \in \ell^{3N} A;$$

so $e(f) = \varphi^3(\iota_L(f))$. Let $\sigma \in G_F$, $u = \chi_{\mathrm{cyc}}(\sigma)$. By Lemma 23.8(4), $\sigma \circ \iota = \iota \circ \gamma_u$; as γ_u fixes $\mathcal{O}_F$, σ fixes $\iota_\Lambda(E)$, and, commuting with φ, every $\varphi^3(\iota_\Lambda(a))$; and $\sigma(\varphi^3(\mu)) = \varphi^3(\sigma(\iota(X))) =$

$\varphi^3(\iota_L(h_u)) = e(h_u)$ by the previous identity. The ring automorphism σ of A preserves every $\ell^N A$, hence is continuous, so $\sigma(e(f)) = \sum_k \varphi^3(\iota_\Lambda(a_k))\, e(h_u)^k$. On the other hand, with $h = h_u$,

$$e(f \circ h_u) = \sum_j \sum_{k \le j} \varphi^3(\iota_\Lambda(a_k))\, h_j^{(k)}\, \varphi^3(\mu)^j,$$

whose term of index (j,k) lies in $\ell^{3j-2k}A \subseteq \ell^j A$; so the double family is summable in any order in A, and summing first over $j \ge k$ gives $\sum_k \varphi^3(\iota_\Lambda(a_k))\, e(h_u^k) = \sum_k \varphi^3(\iota_\Lambda(a_k))\, e(h_u)^k$, e being multiplicative.

(Ev3). The map $R \times \mathbf{N} \to B_{\mathrm{cris}} \otimes T$, $(f,x) \mapsto e(f)\,\varphi^3\rho(\iota_T(x))$ (writing ρ for $\rho \otimes 1$; $\iota_T(x) \in A_{\mathrm{inf}}[1/\mu] \otimes T$ by (Ex2)) is biadditive, and $\mathbf{A}_{F,L}$-balanced: for $g \in \mathbf{A}_{F,L}$, (Ex2) gives $\iota_T(gx) = \iota_L(g)\iota_T(x)$ (write $g = \sum_j f_j \otimes \lambda_j$ with $f_j \in \mathbf{A}_F$, $\lambda_j \in \mathcal{O}_L$), and ρ is a ring homomorphism, $A_{\mathrm{inf}} \otimes \mathcal{O}_L$-linear on $A_{\mathrm{inf}}[1/\mu] \otimes T$ and φ-equivariant, so $e(fg)\varphi^3\rho\iota_T(x) = e(f)\varphi^3(\iota_L(g))\varphi^3\rho\iota_T(x) = e(f)\varphi^3\rho\iota_T(gx)$. Hence Ev exists and is unique; $\mathrm{Ev}(1 \otimes x) = \varphi^3\rho\iota_T(x)$ as $e(1) = 1$. For $\sigma \in G_F$, $u = \chi_{\mathrm{cyc}}(\sigma)$: G_F acts $\mathcal{O}_L$-linearly on T, so $\sigma(b \cdot w) = \sigma(b)\sigma(w)$ for $b \in B_{\mathrm{cris}} \otimes \mathcal{O}_L$, $w \in B_{\mathrm{cris}} \otimes T$; σ commutes with φ and ρ, and $\sigma(\iota_T(x)) = \iota_T(\gamma_u(x))$ (Ex2); with (Ev2), $\sigma(e(f)\varphi^3\rho\iota_T(x)) = e(f \circ h_u)\varphi^3\rho\iota_T(\gamma_u(x)) = \mathrm{Ev}(\gamma_u(f \otimes x))$, and both sides of the identity are additive in W.

Over a base field. For a pair over K: the ring R, the map e and (Ev2) do not involve the pair; (Ev2) for $\sigma \in G_F$ contains the case $\sigma \in G_K \subseteq G_F$. In (Ev1), $\mathbf{N}$ is free over $\mathbf{A}_{F,L}$ by (Ex1) and (Wm1) over K, and $\gamma_{u,\mathbf{N}}$ is given for $u \in \Gamma_K$, so the argument gives $\gamma_u(\mathbf{N}_R) \subseteq \mathbf{N}_R$ for $u \in \Gamma_K$. In (Ev3) the pair enters only through (Ex2), which Proposition 23.7 gives for pairs over K with $\sigma \in G_K$ and $u = \chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$; ρ is G_K-equivariant as $G_K \subseteq G_F$. The rest of the argument is unchanged. No step uses that K is unramified.

Level s. (Ev1): the argument is the same, with $2k$ replaced by $(s+1)k$: $\ell^{(s+1)k}a_i b_j = (\ell^{(s+1)i}a_i)(\ell^{(s+1)j}b_j)$ for $i+j=k$, and $\ell^{(s+1)j}a_k h_j^{(k)} \in \Lambda$ for $k \le j$; $\mathbf{N}$ is free over $\mathbf{A}_{F,L}$ by (Wm1) of level s, and $\gamma_{u,\mathbf{N}}$ is given for $u \in \Gamma_K$. (Ev2): by (Ac1) of Lemma 23.12 (paragraph Every prime), $\varphi^{s+2}(\mu)^k \in \ell^{(s+2)k}A_{\mathrm{cris}}$, and $\ell^{(s+1)k}a_k \in \Lambda$ gives $\varphi^{2s+1}(\iota_\Lambda(a_k)) \in \ell^{-(s+1)k}(A_{\mathrm{inf}} \otimes \mathcal{O}_L)$; so the k-th term lies in $\ell^k A$, the series converges, e_s is a ring homomorphism, and $e_s(f) \in 1 + \ell A$ for $f \in 1 + XR_s$, as before. Since $\varphi[x] = [x^\ell]$ and $(\varepsilon^{1/\ell^{s-1}})^{\ell^{s-1}} = \varepsilon$, $\varphi^{s-1}(\mu_{\varepsilon,s}) = \mu$, so $\varphi^{2s+1}(\iota_{s,L}(X)) = \varphi^{2s+1}(\mu_{\varepsilon,s}) = \varphi^{s+2}(\mu)$; the identity $e_s(f) = \varphi^{2s+1}(\iota_{s,L}(f))$ for $f \in \mathbf{A}_{F,L}$ follows as before, the remainder after N terms lying in $\varphi^{s+2}(\mu)^N A \subseteq \ell^{(s+2)N}A$. For $\sigma \in G_K$ and $u = \chi_{\mathrm{cyc}}(\sigma)$, Lemma 23.8(6) gives $\sigma \circ \iota_s = \iota_s \circ \gamma_u$; so σ fixes every $\varphi^{2s+1}(\iota_\Lambda(a))$ and $\sigma(\varphi^{s+2}(\mu)) = \varphi^{2s+1}(\iota_{s,L}(h_u)) = e_s(h_u)$; in $e_s(f \circ h_u)$ the term of index (j,k), $k \le j$, lies in $\ell^{(s+2)j-(s+1)k}A \subseteq \ell^j A$, and the rearrangement is as before. (Ev3): as before, with φ^{2s+1} in place of φ^3 and (Ex2) of level s (Proposition 23.7, (Ex4)): $\iota_{s,T}(x) \in A_{\mathrm{inf}}[1/\mu] \otimes T$, $\iota_{s,T}(gx) = \iota_{s,L}(g)\iota_{s,T}(x)$ for $g \in \mathbf{A}_{F,L}$, and $\sigma(\iota_{s,T}(x)) = \iota_{s,T}(\gamma_u(x))$ for $\sigma \in G_K$; ρ exists and is G_K- and φ-equivariant for every prime because μ is a unit of B_{cris} ((Ac2), Every prime). □

Lemma 23.12. *Let ℓ be an odd prime, use the notation of Theorem B.40 with $p = \ell$, let F be a finite unramified extension of $\mathbb{Q}_\ell$ and write $\mu = \mu_\varepsilon$. Then:*

(Ac1) Divisibility *$\tilde{\xi} \in \ell A_{\mathrm{cris}}$ and $\mu^{\ell-1} \in \ell A_{\mathrm{cris}}$. Hence $\varphi^n(\mu) \in \ell^n A_{\mathrm{cris}}$ for every $n \ge 0$, and $\mu^{(\ell-1)N} A_{\mathrm{inf}} \subseteq \ell^N A_{\mathrm{cris}}$ for every $N \ge 0$.*

(Ac2) Units *For every $j \ge 0$, $\varphi^j(\mu)$ is a unit of $W(\mathbb{C}_\ell^\flat)$ and of B_{cris}. Let S be the subring of $W(\mathbb{C}_\ell^\flat)$ generated by A_{inf} and the elements $\varphi^j(\mu)^{-1}$, $j \ge 0$. Then S is stable under φ and under G_F, and there is a unique ring homomorphism $\rho_S \colon S \to B_{\mathrm{cris}}$ extending the inclusion $A_{\mathrm{inf}} \subset A_{\mathrm{cris}} \subset B_{\mathrm{cris}}$; it satisfies $\rho_S \circ \varphi = \varphi \circ \rho_S$ and $\rho_S \circ \sigma = \sigma \circ \rho_S$ for every $\sigma \in G_F$.*

Every prime. *(Ac1) and (Ac2) hold for every prime ℓ, including $\ell = 2$, with F a finite unramified extension of $\mathbb{Q}_\ell$; for $\ell = 2$, (Ac1) reads $\tilde{\xi} \in 2A_{\mathrm{cris}}$ and $\mu \in 2A_{\mathrm{cris}}$. For ℓ odd this is the statement above.*

Proof. We use the classical facts on A_{cris} [94], [52]: A_{cris} is the ℓ-adic completion of the divided power envelope of A_{inf} with respect to $\ker\theta = \xi_0 A_{\mathrm{inf}}$ (Ai1); it is ℓ-torsion-free and ℓ-adically complete and separated, $A_{\mathrm{inf}} \subset A_{\mathrm{cris}} \subset A_{\mathrm{cris}}[1/\ell] = B^+_{\mathrm{cris}}$, the Frobenius φ and the action of $G_{\mathbb{Q}_\ell}$ on A_{inf} extend to A_{cris} and commute; and $t = \sum_{k\geq 1}(-1)^{k-1}\mu^k/k$, the series converging in A_{cris}.

(Ac1). By definition of ξ_0 in Theorem B.40, $\xi_0 = \sum_{i=0}^{\ell-1}[\varepsilon^{1/\ell}]^i$, so $\varphi(\xi_0) = \sum_{i=0}^{\ell-1}[\varepsilon]^i = \tilde{\xi}$. The Frobenius of $A_{\mathrm{inf}} = W(\mathcal{O}_{\mathbb{C}^\flat_\ell})$ lifts the ℓ-th power map, so $\tilde{\xi} = \varphi(\xi_0) \in \xi_0^\ell + \ell A_{\mathrm{inf}}$; since $\xi_0 \in \ker\theta$ has divided powers in A_{cris}, $\xi_0^\ell = \ell!\,\xi_0^{[\ell]} \in \ell A_{\mathrm{cris}}$. Hence $\tilde{\xi} \in \ell A_{\mathrm{cris}}$. Next, $[\varepsilon] = 1 + \mu$ gives

$$\tilde{\xi} = \frac{(1+\mu)^\ell - 1}{\mu} = \sum_{i=1}^{\ell}\binom{\ell}{i}\mu^{i-1} \in \mu^{\ell-1} + \ell A_{\mathrm{inf}},$$

since ℓ divides $\binom{\ell}{i}$ for $0 < i < \ell$; so $\mu^{\ell-1} \in \ell A_{\mathrm{cris}}$. As $\varphi(\mu) = \mu\tilde{\xi}$, induction gives $\varphi^n(\mu) = \mu\prod_{j=0}^{n-1}\varphi^j(\tilde{\xi})$, and each $\varphi^j(\tilde{\xi})$ lies in $\varphi^j(\ell A_{\mathrm{cris}}) \subseteq \ell A_{\mathrm{cris}}$; so $\varphi^n(\mu) \in \ell^n A_{\mathrm{cris}}$. Finally $\mu^{(\ell-1)N} = (\mu^{\ell-1})^N \in \ell^N A_{\mathrm{cris}}$.

(Ac2): units. The reduction of $\varphi^j(\mu) = [\varepsilon^{\ell^j}] - 1$ modulo ℓ is $\varepsilon^{\ell^j} - 1 \neq 0$ in the field $\mathbb{C}^\flat_\ell$ ($\varepsilon \neq 1$), so $\varphi^j(\mu)$ is a unit of the complete discrete valuation ring $W(\mathbb{C}^\flat_\ell)$. In A_{cris} we have $t = \mu v$ with $v = \sum_{k\geq 1}(-1)^{k-1}\mu^{k-1}/k$: by (Ac1), $\mu^{k-1}/k \in \ell^{\lfloor (k-1)/(\ell-1)\rfloor - v_\ell(k)}A_{\mathrm{cris}}$, and $\lfloor (k-1)/(\ell-1)\rfloor \geq \lfloor (\ell^{v_\ell(k)}-1)/(\ell-1)\rfloor = \sum_{i<v_\ell(k)}\ell^i \geq v_\ell(k)$ with $\lfloor (k-1)/(\ell-1)\rfloor - v_\ell(k) \to \infty$, so the series converges in A_{cris}. Since t is a unit of $B_{\mathrm{cris}} = B^+_{\mathrm{cris}}[1/t]$, so is μ (with inverse vt^{-1}). Applying φ^j and using $\varphi(t) = \ell t$ [94], $\varphi^j(\mu)\varphi^j(v) = \ell^j t$, a unit of B_{cris}; so $\varphi^j(\mu)$ is a unit of B_{cris}.

(Ac2): the ring S and ρ_S. Let $\Sigma \subseteq A_{\mathrm{inf}}$ be the multiplicative set generated by the $\varphi^j(\mu)$, $j \geq 0$. As A_{inf} is a domain (Ai1) contained in $W(\mathbb{C}^\flat_\ell)$, in which the elements of Σ are units, the map $\Sigma^{-1}A_{\mathrm{inf}} \to W(\mathbb{C}^\flat_\ell)$, $a/s \mapsto as^{-1}$, is injective with image S; so $S \cong \Sigma^{-1}A_{\mathrm{inf}}$. By the universal property of localisation, a ring homomorphism $A_{\mathrm{inf}} \to B$ that maps Σ to units of B extends uniquely to S. Applied to $A_{\mathrm{inf}} \subset B_{\mathrm{cris}}$ (units by the previous paragraph), this gives existence and uniqueness of ρ_S. Stability: $\varphi(\varphi^j(\mu)) = \varphi^{j+1}(\mu) \in \Sigma$, so $\varphi(\Sigma) \subseteq \Sigma$ and $\varphi(S) \subseteq S$. For $\sigma \in G_F$ let $u = \chi_{\mathrm{cyc}}(\sigma)$. By Lemma 23.8(4), $\sigma(\mu) = \sigma(\iota(X)) = \iota(\gamma_u(X))$, and by Lemma 23.8(2), $\gamma_u(X) = Xw$ with $w \in \mathbf{A}_F^\times$; so $\sigma(\mu) = \mu\beta_\sigma$ with $\beta_\sigma = \iota(w) \in A_{\mathrm{inf}}^\times$ (ι is a ring homomorphism, so it maps units to units). Since σ commutes with φ, $\sigma(\varphi^j(\mu)) = \varphi^j(\mu)\varphi^j(\beta_\sigma)$ with $\varphi^j(\beta_\sigma) \in A_{\mathrm{inf}}^\times$; so $\sigma(\varphi^j(\mu))^{-1} = \varphi^j(\mu)^{-1}\varphi^j(\beta_\sigma)^{-1} \in S$ and $\sigma(S) \subseteq S$. Equivariance: $\rho_S \circ \varphi$ and $\varphi \circ \rho_S$ are ring homomorphisms $S \to B_{\mathrm{cris}}$ which agree on A_{inf}, because φ on B_{cris} extends φ on A_{inf}; by the uniqueness in the universal property of $S \cong \Sigma^{-1}A_{\mathrm{inf}}$ they are equal. The same argument applies to $\rho_S \circ \sigma$ and $\sigma \circ \rho_S$.

Every prime. No step above uses that ℓ is odd. The facts on A_{cris} recalled at the start hold for every prime [94]. In (Ac1), $\varphi(\xi_0) \in \xi_0^\ell + \ell A_{\mathrm{inf}}$, $\xi_0^\ell = \ell!\,\xi_0^{[\ell]}$ and $\ell \mid \binom{\ell}{i}$ for $0 < i < \ell$ hold for every prime (for $\ell = 2$: $\tilde{\xi} = 2 + \mu$, and $\mu^{\ell-1} = \mu$). In (Ac2), the bound $\lfloor (k-1)/(\ell-1)\rfloor \geq \lfloor (\ell^{v_\ell(k)}-1)/(\ell-1)\rfloor \geq v_\ell(k)$ uses only $k \geq \ell^{v_\ell(k)}$, and $\lfloor (k-1)/(\ell-1)\rfloor - v_\ell(k) \geq (k-1)/(\ell-1) - 1 - \log_\ell k \to \infty$; the stability of S under G_F uses items (2) and (4) of Lemma 23.8, which are stated for every prime. □

Lemma 23.13. *Let ℓ, F, L, $(\tau_b)_{b\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$*

of rank r, $D = D_{\mathrm{cris}}(V)$, and $c \in \mathbb{Z}/n$. For an integer $q \geq 0$ and $f = \sum_{i\geq 0} a_i X^i \in E[[X]]$ put

$$\mathrm{ev}^{(q)}(f) = \sum_{i\geq 0} \varphi^q(\iota_\Lambda(a_i))\,\varphi^q(\mu)^i \;\in\; B^+_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L,$$

and for a frame $\mathbf{n} = (n_j)_{j\leq r}$ at c and $W = \sum_j c_j n_j \in e_c\mathbf{N}_E$ ($c_j \in e_cE[[X]]$) put $G^{(q)}(W) = \sum_j \mathrm{ev}^{(q)}(c_j)\,\varphi^q(\iota_T(n_j)) \in B_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} T$.

1. *The series $\mathrm{ev}^{(q)}(f)$ converges for the topology of the discrete valuation ring B^+_{dR}, $G^{(q)}$ does not depend on the frame, and for the horizontal sections H_k through a frame (n_k) at c, with $d_k = \mathrm{Ev}(H_k)$,*
$$G^{(q)}(H_k) = \varphi^{q-3}(d_k) \qquad (q \geq 0),$$
where φ^{q-3} is the Frobenius of D (bijective on D) and $D \subset B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V \subset B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V$.
2. *Let $e \geq 0$, $a = c + e$, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$, $\Pi = \Lambda_{a,e}(H)$, and $m \geq 1$ an integer with $m \geq 2H(a-s)$ for $0 \leq s < e$. Then for every frame $\mathbf{n}$ of $\mathbf{N}$ at c, $\mathbf{N}$ has the property (Ac3) at (c, e, H, m): for every $y \in \mathbf{N}_a$ with $\Pi y \in P_e(\mathbf{N}_c)$ there are $t, \kappa \geq 0$ and an arc coordinate vector f of $\ell^t y$ such that $\ell^\kappa f$ is Hodge-graded, i.e. has a section decomposition $(g_i, \mathbf{v}_i, \alpha_i)$ with $\delta_e(\mathbf{v}_i) \in \varphi^{s+4}\big(\mathrm{Fil}^{-\alpha_i(s)}D\big)$ for all i and $s < e$.*

Proof. Throughout, $B = B^+_{\mathrm{dR}}$, a complete discrete valuation ring with residue map θ (Theorem B.40 (Ai3)); ℓ is invertible in B, and $B_{\mathrm{dR}} = B[1/t]$ is its fraction field.

Step 0: the elements ξ, $\varphi^j(\xi)$, $\varphi^j(\mu)$ in B. By Theorem B.41, $\tilde\theta = \theta \circ \varphi^{-1}$ is surjective with kernel $\tilde\xi A_{\mathrm{inf}}$; hence $\ker\theta = \xi A_{\mathrm{inf}}$ with $\xi = \varphi^{-1}(\tilde\xi) = \sum_{i<\ell}[\varepsilon^{1/\ell}]^i$, and ξ is a uniformiser of B; as $t \in \mathrm{Fil}^1 \setminus \mathrm{Fil}^2$, $t \in \xi B^\times$. With $\zeta_{\ell^k} = \theta([\varepsilon^{1/\ell^k}])$ a primitive ℓ^k-th root of unity: $\theta(\varphi^j(\xi)) = \ell$ for $j \geq 1$ and $\theta(\varphi^j(\xi)) = \sum_{i<\ell}\zeta_{\ell^{1-j}}^i = (\zeta_{\ell^{-j}} - 1)/(\zeta_{\ell^{1-j}} - 1) \neq 0$ for $j \leq -1$; so $\varphi^j(\xi) \in B^\times$ for $j \neq 0$. Further $\theta(\varphi^q(\mu)) = 0$ for $q \geq 0$, so $\varphi^q(\mu) \in \xi A_{\mathrm{inf}}$, and $\theta(\varphi^{-k}(\mu)) = \zeta_{\ell^k} - 1 \neq 0$ for $k \geq 1$. Since $\iota(Q) = \tilde\xi$ (Lemma 23.8 (4)) and $\iota\varphi = \varphi\iota$, $\iota(Q_{s'}) = \varphi^{s'+1}(\xi)$.

Step 1: $\mathrm{ev}^{(q)}$. The coefficients $\iota_\Lambda(a_i)$ lie in $(W(k)\otimes\mathcal{O}_L)[1/\ell] \subset B \otimes_{\mathbb{Z}_\ell}\mathcal{O}_L$ and $\varphi^q(\mu)^i \in \xi^i B$, so the series converges ξ-adically and $\mathrm{ev}^{(q)}\colon E[[X]] \to B \otimes \mathcal{O}_L$ is a ring homomorphism. (a) For $f \in \mathbf{A}_{F,L}$, $\mathrm{ev}^{(q)}(f) = \varphi^q(\iota_L(f))$ ($\iota_L = \iota \otimes \mathrm{id}$): the tail $\sum_{i\geq b}$ of the series $\varphi^q(\iota_L(f))$, convergent in $A_{\mathrm{inf}} \otimes \mathcal{O}_L$, lies in $\varphi^q(\mu)^b A_{\mathrm{inf}} \otimes \mathcal{O}_L \subseteq \xi^b B \otimes \mathcal{O}_L$, so both sides agree modulo ξ^b for every b. Since $\mathrm{ev}^{(q)}(Q) = \varphi^{q+1}(\xi)$ is a unit, $\mathrm{ev}^{(q)}$ extends to $\mathbf{A}_{F,L}[1/Q]$ with the same formula. (b) $\mathrm{ev}^{(q)}(\varphi(f)) = \mathrm{ev}^{(q+1)}(f)$: $\varphi(f) = \sum\varphi(a_i)\varphi(X)^i$, $\iota_\Lambda\varphi = \varphi\iota_\Lambda$, $\mathrm{ev}^{(q)}(\varphi(X)) = \varphi^q(\iota(\varphi X)) = \varphi^{q+1}(\mu)$, and $\mathrm{ev}^{(q)}$ is continuous for the X-adic and ξ-adic topologies.

Step 2: $G^{(q)}$. If $\mathbf{n}'$ is another frame at c and $n_j = \sum_l g_{jl}n'_l$ ($g_{jl} \in e_c\mathbf{A}_{F,L}$), then $\iota_T(n_j) = \sum_l \iota_L(g_{jl})\iota_T(n'_l)$ by (Ex2), so $\varphi^q(\iota_T(n_j)) = \sum_l \mathrm{ev}^{(q)}(g_{jl})\varphi^q(\iota_T(n'_l))$ by Step 1 (a), and $G^{(q)}$ computed in either frame agrees. $G^{(q)}$ is additive with $G^{(q)}(gW) = \mathrm{ev}^{(q)}(g)G^{(q)}(W)$ and $G^{(q)}(x) = \varphi^q(\iota_T(x))$ for $x \in \mathbf{N}_c$. *Frobenius*: for $W \in e_c\mathbf{N}_E$, $\varphi(W) \in e_{c+1}\mathbf{N}_E$ (Q is a unit of $E[[X]]$, $Q(0) = \ell$) and $G^{(q)}(\varphi(W)) = G^{(q+1)}(W)$: with a frame $\mathbf{n}'$ at $c+1$ and $\varphi(n_j) = \sum_l A_{jl}n'_l$, $A_{jl} \in \mathbf{A}_{F,L}[1/Q]$, (Ex2) gives $\varphi(\iota_T(n_j)) = \sum_l \iota_L(A_{jl})\iota_T(n'_l)$ in $W(\mathbb{C}^\flat_\ell)\otimes T$, hence in $A_{\mathrm{inf}}[1/\mu, 1/\tilde\xi]\otimes T$, and by Step 1

$$\begin{aligned} G^{(q)}(\varphi W) &= \sum_l \mathrm{ev}^{(q)}\Big(\sum_j \varphi(c_j)A_{jl}\Big)\varphi^q(\iota_T n'_l) \\ &= \sum_j \mathrm{ev}^{(q+1)}(c_j)\,\varphi^q\Big(\sum_l \iota_L(A_{jl})\iota_T(n'_l)\Big) = G^{(q+1)}(W). \end{aligned}$$

Step 3: the constant Frobenius matrix of horizontal frames. Let (H_k), (H'_l) be the horizontal sections through frames at c and $c+1$. The operators γ_u of $\mathbf{N}_E$ commute with φ

((Wm3), and $\varphi(f)\circ h_u=\varphi(f\circ h_u)$ since $h_u(\varphi(X))=(1+X)^{\ell u}-1=\varphi(X)\circ h_u$), so $\varphi(H_k)$ is fixed by all γ_u. Write $\varphi(H_k)=\sum_l P_{kl}H'_l$ with $P_{kl}\in e_{c+1}E[[X]]$ ((Hf2): the H'_l are a basis); then $P_{kl}\circ h_u=P_{kl}$ for all u, and comparing the lowest non-constant terms ($h_u(X)=uX+\dots$, u not a root of unity) shows $P_{kl}\in e_{c+1}E$. The matrix P is invertible: by (Wm2) $\varphi(\mathbf{N}_c)$ generates $\mathbf{N}_{c+1}[1/Q]$, so $(\varphi(H_k))$ is an $E[[X]]$-basis of $e_{c+1}\mathbf{N}_E$.

Step 4: comparison with Ev **at** $q=3,4$**.** Let $h\in e_cE[[X]]$ be a coordinate of some H_k, so $\ell^{2i}a_i\in\Lambda$ (Lemma 23.11, Lemma 23.10). By Lemma 23.11 (Ev2) the series $e(h)=\sum_i\varphi^3(\iota_\Lambda(a_i))\varphi^3(\mu)^i$ converges ℓ-adically in $A_{\mathrm{cris}}\otimes\mathcal{O}_L$ with i-th term in $\ell^iA_{\mathrm{cris}}\otimes\mathcal{O}_L$, and so does $\varphi(e(h))=\sum_i\varphi^4(\iota_\Lambda(a_i))\varphi^4(\mu)^i$ (φ is ℓ-adically continuous on A_{cris}). For $b\geq 1$, the image of A_{cris} (the ℓ-adic completion of $A_{\mathrm{inf}}[\xi^j/j!:j\geq 1]$) in $B/\xi^bB=A_{\mathrm{inf}}[1/\ell]/\xi^b$ ((Ai3)) lies in $((b-1)!)^{-1}A_{\mathrm{inf}}/\xi^bA_{\mathrm{inf}}$, which is ℓ-adically separated, and the map is ℓ-adically continuous; the terms with $i\geq b$ vanish modulo ξ^b. Hence the images in $B\otimes\mathcal{O}_L$ of $e(h)$ and $\varphi(e(h))$ agree modulo every ξ^b with $\mathrm{ev}^{(3)}(h)$ and $\mathrm{ev}^{(4)}(h)$, so are equal to them. With $\mathrm{Ev}(H_k)=\sum_j e(h_{kj})\varphi^3(\rho\iota_T(n_j))$ (Ev3) this gives, in $B_{\mathrm{dR}}\otimes T$: $d_k=G^{(3)}(H_k)$ and $\varphi(d_k)=G^{(4)}(H_k)$. By Steps 2 and 3, $G^{(4)}(H_k)=G^{(3)}(\varphi H_k)=\sum_l\varphi^3(\iota_\Lambda(P_{kl}))\,G^{(3)}(H'_l)$, so, $B_{\mathrm{cris}}\to B_{\mathrm{dR}}$ being injective,

$$\varphi(d_k)=\sum_l\varphi^3(\iota_\Lambda(P_{kl}))\,d'_l\qquad\text{in } D.\qquad(\mathrm{R})$$

Step 5: proof of item 1. Convergence was shown in Step 1 and independence of the frame in Step 2. We show $G^{(q)}(H)=\varphi^{q-3}(d)$ for all horizontal frames at all sites, by induction upwards and downwards from $q=3$ (Step 4). If it holds for q (all sites), then by Steps 2, 3 and (R) (with φ^{q-3} semilinear: $\varphi^{q-3}(\varphi^3(\iota_\Lambda(P))d')=\varphi^q(\iota_\Lambda(P))\varphi^{q-3}(d')$)

$$G^{(q+1)}(H_k)=\sum_l\varphi^q(\iota_\Lambda(P_{kl}))\varphi^{q-3}(d'_l)=\varphi^{q-3}(\varphi(d_k))=\varphi^{q-2}(d_k).$$

If it holds for $q+1\geq 1$ (all sites), the same identity read backwards gives $\sum_l\varphi^q(\iota_\Lambda(P_{kl}))(G^{(q)}(H'_l)-\varphi^{q-3}(d'_l))=0$; the matrix $\varphi^q(\iota_\Lambda(P))$ is invertible, so $G^{(q)}(H'_l)=\varphi^{q-3}(d'_l)$ for the horizontal frame at $c+1$; as c and the frames are arbitrary, this is the claim for q.

Step 6: the level map. Fix e, a, H, Π, m, the frame $\mathbf{n}$ as in item 2, and $s<e$; put $q=e-s-1\geq 0$, $h=H(a-s)$. Extend ι_T ι_L-semilinearly to $\mathbf{N}[1/\lambda_e]\to A_{\mathrm{inf}}[1/\mu,1/\iota(\lambda_e)]\otimes T$; then $\iota_T(\varphi^e(z))=\varphi^e(\iota_T(z))$ for $z\in\mathbf{N}$ (iterate (Ex2); $\varphi^e(\mu)=\mu\,\iota(\lambda_e)$). By Step 0, $\varphi^{-(s+1)}$ maps $A_{\mathrm{inf}}[1/\mu,1/\iota(\lambda_e)]$ into B_{dR}, and $A_{\mathrm{inf}}[1/\mu]$ into B. Put $\Lambda_s=\varphi^{-(s+1)}\circ\iota_T\colon\mathbf{N}[1/\lambda_e]\to B_{\mathrm{dR}}\otimes T$ and $\lambda_s=\varphi^{-(s+1)}\circ\iota_L$ on $\mathbf{A}_{F,L}[1/\lambda_e]$. Then: $\Lambda_s(gx)=\lambda_s(g)\Lambda_s(x)$; $\Lambda_s(\mathbf{N})\subseteq B\otimes T$; $\Lambda_s(\varphi^e(z))=\varphi^q(\iota_T(z))=G^{(q)}(z)$ for $z\in\mathbf{N}_c$; $\lambda_s(Q_s)=\xi$, $\lambda_s(Q_{s'})=\varphi^{s'-s}(\xi)\in B^\times$ for $s'\neq s$, $\lambda_s(X)=\varphi^{-(s+1)}(\mu)\in B^\times$; and $\lambda_s(e_a)=\iota_\Lambda(\varphi^{-(s+1)}(e_a))=\varepsilon_{a-s-1}=:\epsilon$. Let $R^+=\epsilon(B\otimes_{\mathbb{Q}_\ell}L)$ (a free B-module, so ξ-torsion free and ξ-adically separated) and $R=R^+[1/\xi]$. Put $D_k=G^{(q)}(H_k)$, which equals $\varphi^{e-s-4}(d_k)$ by item 1; the D_k lie in ϵD and form an L-basis of it (Lemma 23.10 (2); φ maps ε_bD bijectively onto $\varepsilon_{b+1}D$). Put $\Lambda_D=\sum_k R^+D_k$. Then $\Lambda_s(P_e(\mathbf{N}_c))\subseteq\Lambda_D$: for $p=\sum_j g_j\varphi^e(n_j)$, $g_j\in e_a\mathbf{A}_{F,L}$, $\Lambda_s(p)=\sum_j\lambda_s(g_j)G^{(q)}(n_j)$, and $n_j=\sum_k(\mathbf{h}^{-1})_{jk}H_k$ in $\mathbf{N}_E$ with $\mathbf{h}=(h_{kj})\in GL_r(e_cE[[X]])$ ($\mathbf{h}\equiv 1 \bmod X$), so $G^{(q)}(n_j)=\sum_k\mathrm{ev}^{(q)}((\mathbf{h}^{-1})_{jk})D_k$.

Step 7: the de Rham lattice at level s**.** V is crystalline, so $D\subseteq D_{\mathrm{dR}}(V)$ have the same F-dimension and $D=D_{\mathrm{dR}}(V)$; the filtration of Definition 23.3 is that of Theorem B.40 (Ai4). The map of (Ai4) is $F\otimes L$-linear and Fil^jD is an $F\otimes L$-submodule, so applying ϵ to (Ai4) with $k=0$: $\epsilon(B\otimes_{\mathbb{Q}_\ell}V)=\sum_j t^{-j}R^+\otimes_L\epsilon\mathrm{Fil}^jD$ inside $\epsilon(B_{\mathrm{dR}}\otimes V)=R\otimes_L\epsilon D$. Choose an L-basis (D_i^{ad}) of ϵD adapted to the filtration, $D_i^{\mathrm{ad}}\in\mathrm{Fil}^{u_i}$ with $\epsilon\mathrm{Fil}^jD$ spanned by the D_i^{ad} with $u_i\geq j$. Then

$$\epsilon(B\otimes V)=\bigoplus_i\xi^{-u_i}R^+D_i^{\mathrm{ad}},\qquad\Lambda_D=\bigoplus_iR^+D_i^{\mathrm{ad}}.$$

Let $W \in GL_r(L)$ with $D_k = \sum_i W_{ki} D_i^{\mathrm{ad}}$ and $\mathbf{v}_i^{(s)} \in L^r$ the i-th row of W^{-1}; then $\sum_k v_{i,k}^{(s)} D_k = D_i^{\mathrm{ad}}$, i.e. $\varphi^{-(s+4)}(\delta_e(\mathbf{v}_i^{(s)})) = D_i^{\mathrm{ad}} \in \mathrm{Fil}^{u_i} D$.

Step 8: orders at Q_s. $\mathcal{O} = e_a \mathbf{A}_{F,L}[1/\ell] \cong \mathcal{O}_L[[X]][1/\ell]$ is a factorial domain; the $Q_{s'}$ are squarefree and pairwise coprime in it (they are products of distinct irreducible distinguished polynomials, Lemma 23.8 (3), and distinct cyclotomic polynomials are coprime in $L[X]$). For g in $\mathcal{O}[1/\lambda_e]$ let $\mathrm{ord}_s(g)$ be the minimum of $v_\pi(g)$ over the prime factors π of Q_s. We claim that $\lambda_s(g) \in \xi^\alpha R^+$ if and only if $\mathrm{ord}_s(g) \geq \alpha$. Write $g = Q_s^\beta g_0$, $\beta = \mathrm{ord}_s(g)$, $g_0 \in \mathcal{O}[1/Q_{s'} : s' \neq s]$, $Q_s \nmid g_0$; then $\lambda_s(g) = \xi^\beta \lambda_s(g_0)$ with $\lambda_s(g_0) \in R^+$, and it suffices that $\lambda_s(g_0) \notin \xi R^+$. The map $\theta \circ \lambda_s \colon \mathcal{O} \to R^+/\xi R^+ = \epsilon(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L) = \mathbb{C}_\ell \otimes_F L$ (F acting on L through the embedding of ϵ) sends X to $\zeta_{\ell^{s+1}} - 1$ and is L-linear; it factors through $\mathcal{O}/Q_s\mathcal{O} \cong L[X]/(Q_s) \cong \mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} L = (\mathbb{Q}_\ell(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} F) \otimes_F L \cong F(\zeta_{\ell^{s+1}}) \otimes_F L \hookrightarrow \mathbb{C}_\ell \otimes_F L$ (Weierstrass division by the distinguished polynomial Q_s; $F/\mathbb{Q}_\ell$ unramified and $\mathbb{Q}_\ell(\zeta_{\ell^{s+1}})$ totally ramified, so the middle map is an isomorphism; L is flat over F). So $\ker(\theta \circ \lambda_s) = Q_s\mathcal{O}$, the elements $Q_{s'}$ ($s' \neq s$) map to units, and $\theta(\lambda_s(g_0)) \neq 0$.

Step 9: the level-s condition on arc coordinates. Let $y \in \mathbf{N}_a$ with $\Pi y \in P_e(\mathbf{N}_c)$. By Lemma 23.14 (Ac1) there are t and an arc coordinate vector f of $\ell^t y$ for some (κ, κ'): $\ell^{\kappa'}(\ell^{\kappa+t}\Pi y - \sum_k \Pi f_k \varphi^e(T_\kappa(H_k))) = X\Pi^2 p$ with $p \in P_e(\mathbf{N}_c)$. Here $T_\kappa(H_k) = \ell^\kappa H_k - S_k$ with $S_k \in X^m e_c \mathbf{N}_E$, so $\Lambda_s(\varphi^e(T_\kappa H_k)) = G^{(q)}(T_\kappa H_k) = \ell^\kappa D_k - G^{(q)}(S_k)$ and $G^{(q)}(S_k) \in \varphi^q(\mu)^m \Lambda_D \subseteq \xi^m \Lambda_D$ (Step 6). Apply Λ_s and divide by $\ell^{\kappa+\kappa'}\lambda_s(\Pi)$, where $\lambda_s(\Pi) \in \xi^h B^\times$ and $\lambda_s(f_k) \in \xi^{-h} R^+$ ($\Pi f_k \in e_a \mathbf{A}_{F,L}$):

$$\sum_k \lambda_s(f_k) D_k \in \ell^t \Lambda_s(y) + \xi^{m-h}\Lambda_D + \xi^h \Lambda_D \subseteq \epsilon(B \otimes V) + \xi^h \Lambda_D,$$

using $\Lambda_s(y) = \epsilon\Lambda_s(y) \in \epsilon(B \otimes T)$ and $m \geq 2h$. With $\varphi_i^{(s)} = \sum_k f_k W_{ki}$ (so $f = \sum_i \varphi_i^{(s)} \mathbf{v}_i^{(s)}$), Step 7 gives $\lambda_s(\varphi_i^{(s)}) \in \xi^{\min(-u_i, h)} R^+$, and Step 8:

$$\mathrm{ord}_s(\varphi_i^{(s)}) \geq \min(-u_i^{(s)},\, H(a-s)) \qquad (s < e,\ i \leq r). \qquad \text{(L)}$$

Step 10: removing the uncontrolled orders. Let $J \geq 0$ bound the absolute values of all Hodge jumps of V and $N = J + 2\max_{s<e} H(a-s)$. For $s < e$ let $\mathcal{O}_{(s)} = \mathcal{O}[1/X, 1/Q_{s'} : s' \neq s]$; then $\mathcal{O}_{(s)}/Q_s^N \cong L[X]/(Q_s^N)$. Let $z_s \in L[X]^r$ with $z_s \equiv \sum_{i:\, u_i^{(s)} < -H(a-s)} (\varphi_i^{(s)}/(X\Pi)) \mathbf{v}_i^{(s)} \bmod Q_s^N \mathcal{O}_{(s)}^r$ (these quotients lie in $\mathcal{O}_{(s)}$ by (L)), and by the Chinese remainder theorem $z \in L[X]^r$ with $z \equiv z_s \bmod Q_s^N$ for all $s < e$. Choose t_z with $\ell^{t_z} z \in \mathcal{O}_L[X]^r$ and put $f' = \ell^{t_z}(f - X\Pi z)$. Then f' is an arc coordinate vector of $\ell^{t+t_z} y$: $\Pi f_k' \in e_a \mathbf{A}_{F,L}$, and the defining relation for f' is ℓ^{t_z} times that for f minus $\ell^{\kappa'} \sum_k X\Pi^2(\ell^{t_z} z_k)\varphi^e(T_\kappa H_k) \in X\Pi^2 P_e(\mathbf{N}_c)$. Its s-coordinates $\varphi_i'^{(s)} = \ell^{t_z}(\varphi_i^{(s)} - X\Pi z_i^{(s)})$ satisfy: if $u_i^{(s)} < -H(a-s)$, $\varphi_i'^{(s)} \in X\Pi Q_s^N \mathcal{O}_{(s)}$, so $\mathrm{ord}_s \geq N \geq -u_i^{(s)}$; otherwise $z_i^{(s)} \in Q_s^N \mathcal{O}_{(s)}$ and (L) gives $\mathrm{ord}_s(\varphi_i'^{(s)}) \geq \min(-u_i^{(s)}, H(a-s)) = -u_i^{(s)}$. So

$$\mathrm{ord}_s(\varphi_i'^{(s)}) \geq -u_i^{(s)} \qquad (s < e,\ i \leq r), \qquad \text{and } \mathrm{ord}_s(f_k') \geq -H(a-s). \qquad \text{(L')}$$

Step 11: the section decomposition. Let $E_s \in L[X]$ with $E_s \equiv 1 \bmod Q_s^N$ and $E_s \equiv 0 \bmod Q_{s'}^N$ for $s' \neq s$ (Chinese remainder theorem). Then $f' = \sum_{s<e} \sum_i E_s \varphi_i'^{(s)} \mathbf{v}_i^{(s)} + \sum_k ((1 - \sum_s E_s) f_k') \mathbf{e}_k$. Consider the terms $(E_s \varphi_i'^{(s)}, \mathbf{v}_i^{(s)}, \alpha_{s,i})$ with $\alpha_{s,i}(s) = -u_i^{(s)}$ and $\alpha_{s,i}(s') = N - H(a-s')$ for $s' \neq s$, and $((1 - \sum_s E_s) f_k', \mathbf{e}_k, \alpha_0)$ with $\alpha_0(s') = N - H(a-s')$. Each first entry g lies in $\mathcal{O}[1/\lambda_e]$ and has $\mathrm{ord}_{s'}(g) \geq \alpha(s')$ for every $s' < e$ by (L'), $E_s \equiv 1 \bmod Q_s$ and the congruences of the E_s; hence $gQ^{-\alpha}$ has no prime of any $Q_{s'}$ in its denominator and lies in $\mathcal{O}$, i.e. $g \in Q^\alpha e_a \mathbf{A}_{F,L}[1/\ell]$. Conditions (Gs1): for (s,i) at level s, $\delta_e(\mathbf{v}_i^{(s)}) = \varphi^{s+4}(D_i^{\mathrm{ad}}) \in \varphi^{s+4}(\mathrm{Fil}^{u_i} D)$

by Step 7; at every other level s', and for the last terms at every level, $-\alpha(s') = H(a-s') - N \le -J$, so $\mathrm{Fil}^{-\alpha(s')}D = D$ and the condition holds because φ is bijective on D. Finally choose κ with $\ell^{\kappa_1} g \in Q^{\alpha} e_a \mathbf{A}_{F,L}$ and $\ell^{\kappa_2}\mathbf{v} \in \mathcal{O}_L^r$ for all terms, $\kappa = \kappa_1 + \kappa_2$: the terms $(\ell^{\kappa_1} g, \ell^{\kappa_2}\mathbf{v}, \alpha)$ form a section decomposition of $\ell^{\kappa} f'$ which is Hodge-graded. This proves (Ac3) at (c, e, H, m). □

Lemma 23.14. *Let ℓ, F, L, (τ_a) and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $c \in \mathbb{Z}/n$, $e \ge 0$, $a = c + e$, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$, and $m \ge 1$ an integer with $m \ge 2H(a-s)$ for $0 \le s < e$. Then for every frame $\mathbf{n}$ of $\mathbf{N}$ at c, $\mathbf{N}$ has the properties (Ac1), (Ac2) and (Ac4) at (c, e, H, m); in (Ac1) and (Ac2) the exponent t can be chosen depending only on $\mathbf{n}$ and m, and in (Ac4) one can take $t = \kappa'$ for any (κ, κ') for which f satisfies the defining relation of arc coordinate vectors.*

Proof. Let $\Pi = \Lambda_{a,e}(H)$, $\mathbf{n} = (n_k)_{k \le r}$, $H_k = \sum_j h_{kj} n_j$ the horizontal sections and $h = (h_{kj}) \in M_r(e_c E[[X]])$. Since $H_k \in n_k + X\mathbf{N}_E$ (Lemma 23.9 (Hf2)), $h \equiv I \bmod X$, so h is invertible; let $g = h^{-1}$, so $n_j = \sum_k g_{jk} H_k$. Under $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]] \cong e_a\mathbf{A}_{F,L}$ the map $\varphi^e\colon e_c\mathbf{A}_{F,L} \to e_a\mathbf{A}_{F,L}$ is $u(X) \mapsto u((1+X)^{\ell^e} - 1)$, because $\tau_{b+e} \circ \varphi^e = \tau_b$; and $\varphi^e(X) = X\lambda_e$. We use twice:

(T) If $z \in \mathbf{N}_c \cap X^m \mathbf{N}_E$ then $\varphi^e(z) \in X\Pi^2 P_e(\mathbf{N}_c)$. Indeed, in the basis $\mathbf{n}$ the coordinates of z lie in $e_c\mathbf{A}_{F,L} \cap X^m e_c E[[X]] = X^m e_c \mathbf{A}_{F,L}$, so $\varphi^e(z) \in X^m \lambda_e^m P_e(\mathbf{N}_c)$, and $X\Pi^2$ divides $X^m\lambda_e^m = X^m \prod_{s<e} Q_s^m$ since $m \ge 1$ and $m \ge 2H(a-s)$.

(Ac1) and (Ac2). Fix κ admissible (it exists: finitely many coefficients $h_{kj,i}$, $i < m$, are involved), and $\kappa_0 \ge 0$ with $\ell^{\kappa_0} g_{jk,i} \in e_c(\mathcal{O}_F \otimes \mathcal{O}_L)$ for all j, k and $i < m$, where $g_{jk} = \sum_i g_{jk,i} X^i$. Let $\hat{g}_{jk} = \sum_{i<m} \ell^{\kappa_0} g_{jk,i} X^i \in e_c\mathbf{A}_{F,L}$. Then $\ell^{\kappa_0} g_{jk} - \hat{g}_{jk} \in X^m e_c E[[X]]$ and $\ell^{\kappa} H_k - T_\kappa(H_k) \in X^m \mathbf{N}_E$, so

$$z_j := \ell^{\kappa_0+\kappa} n_j - \sum_k \hat{g}_{jk}\, T_\kappa(H_k) = \sum_k (\ell^{\kappa_0} g_{jk} - \hat{g}_{jk}) \ell^{\kappa} H_k + \sum_k \hat{g}_{jk} (\ell^{\kappa} H_k - T_\kappa(H_k)) \in \mathbf{N}_c \cap X^m \mathbf{N}_E,$$

and by (T), $\ell^{\kappa_0+\kappa}\varphi^e(n_j) - \sum_k \varphi^e(\hat{g}_{jk})\varphi^e(T_\kappa(H_k)) \in X\Pi^2 P_e(\mathbf{N}_c)$. Let $y \in \mathbf{N}[1/\lambda_\infty]$ with $\Pi y \in P_e(\mathbf{N}_c)$ (resp. $y \in P_e(\mathbf{N}_c)$), and write $\Pi y = \sum_j \beta_j \varphi^e(n_j)$ (resp. $y = \sum_j \beta_j \varphi^e(n_j)$) with $\beta_j \in e_a\mathbf{A}_{F,L}$, possible since $P_e(\mathbf{N}_c) \subseteq e_a\mathbf{N}[1/\lambda_\infty]$ is generated by $\varphi^e(\mathbf{N}_c)$. Put $f_k = \Pi^{-1} \sum_j \beta_j \varphi^e(\hat{g}_{jk})$ (resp. $f_k = \sum_j \beta_j \varphi^e(\hat{g}_{jk})$). Multiplying the last display by β_j (resp. by $\Pi\beta_j$) and summing over j,

$$\ell^{\kappa}\, \Pi\, (\ell^{\kappa_0} y) - \sum_k \Pi f_k\, \varphi^e(T_\kappa(H_k)) \in X\Pi^2 P_e(\mathbf{N}_c),$$

and $\Pi f_k \in e_a\mathbf{A}_{F,L}$ (resp. $f_k \in e_a\mathbf{A}_{F,L}$). So f is an arc coordinate vector of $\ell^{\kappa_0} y$ (with $\kappa' = 0$), integral in the second case: this is (Ac1) and (Ac2) with $t = \kappa_0$.

(Ac4). Let f be an arc coordinate vector of 0 for (κ, κ') and $F_k = \Pi f_k \in e_a\mathbf{A}_{F,L}$. Write $T_\kappa(H_k) = \sum_j \tau_{kj} n_j$ with $\tau_{kj} = \sum_{i<m} \ell^{\kappa} h_{kj,i} X^i$; since $h \equiv I \bmod X$, $\tau \equiv \ell^{\kappa} I \bmod X$ and $\det\tau \in \ell^{r\kappa} + Xe_c\mathbf{A}_{F,L}$. By Lemma 23.15 (1) the $\varphi^e(n_j)$ form an $e_a\mathbf{A}_{F,L}$-basis of $P_e(\mathbf{N}_c)$, so the defining relation $\ell^{\kappa'} \sum_k F_k \varphi^e(T_\kappa(H_k)) \in X\Pi^2 P_e(\mathbf{N}_c)$ says that the row vector $\ell^{\kappa'} F\vartheta$, $\vartheta = (\varphi^e(\tau_{kj}))$, has entries in $X\Pi^2 e_a\mathbf{A}_{F,L}$. Multiplying on the right by the adjugate of ϑ gives $\ell^{\kappa'} F_k\, \varphi^e(\det\tau) \in X\Pi^2 e_a\mathbf{A}_{F,L}$ for every k.

Identify $e_a\mathbf{A}_{F,L} = \mathcal{O}_L[[X]]$. The element $P = X\Pi^2 = X\prod_{s<e} Q_s^{2H(a-s)}$ is a distinguished polynomial ($Q_s = \Phi_{\ell^{s+1}}(1+X)$ is monic and $\equiv X^{\deg Q_s} \bmod \ell$). Its roots in $\mathbb{C}_\ell$ are 0 and the $\zeta - 1$, ζ a primitive ℓ^{s+1}-th root of unity with $s < e$; at each of them $\delta := \varphi^e(\det\tau)$ takes the value $(\det\tau)(\zeta^{\ell^e} - 1) = (\det\tau)(0) = \ell^{r\kappa} \ne 0$. By Weierstrass division write $\ell^{\kappa'} F_k = PA + R$ with $A \in \mathcal{O}_L[[X]]$ and $R \in \mathcal{O}_L[X]$ of degree $< \deg P$. Then $R\delta \in P\,\mathcal{O}_L[[X]]$, so the analytic function $R\delta$ on the open unit disc vanishes at every root z of P to at least its multiplicity; as $\delta(z) \ne 0$, so does R. Hence P divides R in $\mathbb{C}_\ell[X]$, and $\deg R < \deg P$ forces $R = 0$. Thus $\ell^{\kappa'}\Pi f_k = \ell^{\kappa'} F_k \in X\Pi^2 e_a\mathbf{A}_{F,L}$, i.e. $\ell^{\kappa'} f_k \in X\Pi e_a\mathbf{A}_{F,L}$, which is (Ac4) with $t = \kappa'$. □

Lemma 23.15. *Let* $\mathbf{N}$ *be a Wach module over* F *with coefficients* L *and window* $(M_a, h_a)_{a\in\mathbb{Z}/n}$*, of rank* r*; regard* M *and* h *as functions* $a\mapsto M_a$*,* $a\mapsto h_a$*. Let* $c\in\mathbb{Z}/n$*,* $e\geq 0$*,* $a=c+e$*, and* $R=e_a\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$*.*

1. *$P_e(\mathbf{N}_c)$ is a free R-module of rank r, and the R-linear map $R\otimes_{\varphi^e,\,e_c\mathbf{A}_{F,L}}\mathbf{N}_c\to P_e(\mathbf{N}_c)$, $g\otimes x\mapsto g\varphi^e_{\mathbf{N}}(x)$, is an isomorphism.*
2. *For every function $H\colon\mathbb{Z}/n\to\mathbb{Z}_{\geq 0}$ with $H\geq M$ pointwise, $\Lambda_{a,e}(H)\,P_e(\mathbf{N}_c)\subseteq\mathbf{N}_a$; for every $H\geq h$ pointwise, $\Lambda_{a,e}(H)\,\mathbf{N}_a\subseteq P_e(\mathbf{N}_c)$.*
3. *(Saturation.) Let $S\subset\mathbb{Z}_\ell[[X]]$ be the multiplicative monoid generated by X and the Q_s $(s\geq 0)$, let U be $\mathbf{N}_a$ or $P_e(\mathbf{N}_c)$, $f,f'\in S$, $k\geq 0$, and $x\in U\otimes_R\operatorname{Frac}(R)$. If $f'x\in U$ and $\ell^k x\in fU$, then $x\in fU$.*

Proof. Write $\Lambda(H)=\Lambda_{a,e}(H)$ and, for $e\geq 1$, $a'=a-1$, so that $P_{e-1}(\mathbf{N}_c)\subseteq e_{a'}\mathbf{N}[1/\lambda_\infty]$. Since $\varphi_{\mathbf{N}}$ is φ-semilinear, the $\mathbf{A}_{F,L}$-span of $\varphi_{\mathbf{N}}$ of a set Y equals the $\mathbf{A}_{F,L}$-span of $\varphi_{\mathbf{N}}$ of the $\mathbf{A}_{F,L}$-span of Y; hence

$$P_e(\mathbf{N}_c)=\mathbf{A}_{F,L}\,\varphi_{\mathbf{N}}\big(P_{e-1}(\mathbf{N}_c)\big)\qquad(e\geq 1).\qquad(1)$$

Also $\varphi(\Lambda_{a',e-1}(H))=\prod_{s=0}^{e-2}Q_{s+1}^{H(a'-s)}=\prod_{s=1}^{e-1}Q_s^{H(a-s)}$, so

$$\Lambda_{a,e}(H)=Q^{H(a)}\,\varphi(\Lambda_{a',e-1}(H)).\qquad(2)$$

Item 2, by induction on e; for $e=0$, $\Lambda=1$ and $P_0(\mathbf{N}_c)=\mathbf{N}_c=\mathbf{N}_a$. Let $e\geq 1$, $H\geq M$. By induction $\Lambda_{a',e-1}(H)P_{e-1}(\mathbf{N}_c)\subseteq\mathbf{N}_{a'}$; applying $\varphi_{\mathbf{N}}$ and taking spans, $\varphi(\Lambda_{a',e-1}(H))\,P_e(\mathbf{N}_c)\subseteq\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a'})$ by (1). By (Wm2), $Q^{M_a}\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a'})\subseteq\mathbf{N}_a$, and $Q^{H(a)}=Q^{H(a)-M_a}Q^{M_a}$; with (2), $\Lambda(H)P_e(\mathbf{N}_c)\subseteq\mathbf{N}_a$. For $H\geq h$: by induction $\Lambda_{a',e-1}(H)\mathbf{N}_{a'}\subseteq P_{e-1}(\mathbf{N}_c)$, so $\varphi(\Lambda_{a',e-1}(H))\,\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a'})\subseteq P_e(\mathbf{N}_c)$ by (1); by (Wm2), $Q^{H(a)}\mathbf{N}_a\subseteq\mathbf{A}_{F,L}\varphi_{\mathbf{N}}(\mathbf{N}_{a'})$; with (2), $\Lambda(H)\mathbf{N}_a\subseteq P_e(\mathbf{N}_c)$.

Item 1, by induction on e, trivial for $e=0$. Let $e\geq 1$; by induction $P_{e-1}(\mathbf{N}_c)$ is free of rank r over $R'=e_{a'}\mathbf{A}_{F,L}$, with basis $y_1,\dots,y_r$ the images of $1\otimes x_i$ for a basis (x_i) of $\mathbf{N}_c$. By (1), $P_e(\mathbf{N}_c)$ is generated over R by $\varphi_{\mathbf{N}}(y_1),\dots,\varphi_{\mathbf{N}}(y_r)$, so $\rho\colon R^r\to P_e(\mathbf{N}_c)$, $(g_i)\mapsto\sum g_i\varphi_{\mathbf{N}}(y_i)$, is onto, and the map of the statement is ρ composed with the isomorphism $R\otimes_{\varphi^e}\mathbf{N}_c\cong R\otimes_\varphi P_{e-1}(\mathbf{N}_c)\cong R^r$. By item 2 with $H=h$, $P_e(\mathbf{N}_c)$ contains $\Lambda(h)\mathbf{N}_a$, a free R-module of rank r ($\Lambda(h)\neq 0$ in the domain R); and $P_e(\mathbf{N}_c)\subseteq\mathbf{N}_a\otimes_R\operatorname{Frac}(R)$, a vector space of dimension r. So $P_e(\mathbf{N}_c)\otimes\operatorname{Frac}(R)$ has dimension r, $\rho\otimes\operatorname{Frac}(R)$ is an isomorphism, and $\ker\rho$, a submodule of the torsion-free R^r that vanishes after $\otimes\operatorname{Frac}(R)$, is 0.

Item 3. First, every $g\in S$ is a non-zero-divisor on R/ϖ^jR for every $j\geq 1$, ϖ a uniformiser of $\mathcal{O}_L$: modulo ϖ, X is X and $Q_s\equiv X^{\ell^s(\ell-1)}$ (Lemma 23.8(3); $\ell\in\varpi\mathcal{O}_L$), so $g\equiv X^N\not\equiv 0$ in the domain $R/\varpi R=k_L[[X]]$; if $gy\in\varpi^jR$ with $y\notin\varpi^jR$, write $y=\varpi^iy'$ with $i<j$ and $y'\notin\varpi R$ (R is ϖ-adically separated, R/ϖ is a domain); then $gy'\in\varpi^{j-i}R\subseteq\varpi R$, contradicting $g,y'\not\equiv 0 \bmod\varpi$. Now let $\ell^kx=fy$ with $y\in U$. Then $ff'y=\ell^k(f'x)\in\ell^kU$. Since U is free over R (item 1, (Wm1)) and $\ell^kR=\varpi^jR$ for $j=k\,v_\varpi(\ell)$, the non-zero-divisor ff' on R/ϖ^jR gives $y\in\ell^kU$, $y=\ell^ky'$ with $y'\in U$. Then $\ell^k(x-fy')=0$ in the torsion-free $U\otimes\operatorname{Frac}(R)$, so $x=fy'\in fU$. □

Lemma 23.16. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $D=D_{\mathrm{cris}}(V)=(B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)^{G_F}$ with $\operatorname{Fil}^jD=D\cap(t^jB^+_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)$, $b\in\mathbb{Z}/n$, $\epsilon=\epsilon_b$, $R^+=\epsilon(B^+_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}L)$ and $R=R^+[1/t]$. Then ϵD has an L-basis $(D_i^{\mathrm{ad}})_i$* adapted to the filtration*: there are integers*

u_i with $D_i^{\mathrm{ad}} \in \mathrm{Fil}^{u_i} D$ such that, for every $j \in \mathbb{Z}$, the D_i^{ad} with $u_i \geq j$ form an L-basis of $\epsilon\,\mathrm{Fil}^j D$. For every such basis

$$\epsilon(B_{\mathrm{dR}}^+ \otimes_{\mathbb{Q}_\ell} V) = \bigoplus_i t^{-u_i} R^+ D_i^{\mathrm{ad}},$$

and every L-basis of ϵD is an R-basis of $\epsilon(B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)$.

Proof. D **is the de Rham module.** As $B_{\mathrm{cris}} \subseteq B_{\mathrm{dR}}$ G_F-equivariantly, $D \subseteq D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)^{G_F}$; V is crystalline, hence de Rham, and both spaces have F-dimension $\dim_{\mathbb{Q}_\ell} V$, so $D = D_{\mathrm{dR}}(V)$, and $\mathrm{Fil}^j D$ is the filtration of Theorem B.40 (Ai4). The ring $F \otimes_{\mathbb{Q}_\ell} L$ acts on $B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V$ ($F \subset B_{\mathrm{dR}}^+$ on the left factor, L on V); this action preserves D and every $t^j B_{\mathrm{dR}}^+ \otimes V$, hence every $\mathrm{Fil}^j D$.

Adapted bases. The space ϵD is a finite-dimensional L-vector space ($\epsilon(F \otimes_{\mathbb{Q}_\ell} L) \cong L$), and $(\epsilon \mathrm{Fil}^j D)_j$ is a decreasing family of subspaces. It equals ϵD for $j \ll 0$, since each of finitely many generators of D lies in some $t^j B_{\mathrm{dR}}^+ \otimes V$ ($B_{\mathrm{dR}} = \bigcup_j t^{-j} B_{\mathrm{dR}}^+$), and it is 0 for $j \gg 0$, since a decreasing chain of subspaces stabilises and $\bigcap_j t^j B_{\mathrm{dR}}^+ = 0$. Choosing bases successively from the largest j with $\epsilon \mathrm{Fil}^j D \neq 0$ downwards gives an adapted basis.

The lattice. The isomorphism $B_{\mathrm{dR}} \otimes_F D \to B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V$ of (Ai4) is linear for $B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L$ (acting on the source through B_{dR} and L on D), so it maps $\epsilon(B_{\mathrm{dR}} \otimes_F D) = R \otimes_L \epsilon D$ isomorphically onto $\epsilon(B_{\mathrm{dR}} \otimes V)$; as ϵD is free over L, every L-basis of ϵD is an R-basis of $\epsilon(B_{\mathrm{dR}} \otimes V)$. With $k = 0$, (Ai4) says that $\sum_j t^{-j} B_{\mathrm{dR}}^+ \otimes_F \mathrm{Fil}^j D$ maps onto $B_{\mathrm{dR}}^+ \otimes V$; applying ϵ, and since $\mathrm{Fil}^j D$ is an $F \otimes L$-submodule,

$$\epsilon(B_{\mathrm{dR}}^+ \otimes V) = \sum_j t^{-j} R^+ \,\epsilon \mathrm{Fil}^j D = \sum_j \sum_{i:\, u_i \geq j} t^{-j} R^+ D_i^{\mathrm{ad}} = \sum_i t^{-u_i} R^+ D_i^{\mathrm{ad}},$$

because $t^{-j} R^+ \subseteq t^{-u_i} R^+$ for $j \leq u_i$, with equality at $j = u_i$. The sum is direct, the D_i^{ad} being an R-basis of $\epsilon(B_{\mathrm{dR}} \otimes V)$. □

Lemma 23.17. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, $\Phi \colon T_1 \to T_2$ a G_F-equivariant $\mathcal{O}_L$-linear map of the lattices of pairs (V_1, T_1), (V_2, T_2), and fix arc level data of Φ (any cut c, length $1 \leq \mathrm{len} \leq n$, H, frames, and parameters). Then (Lp1), (Lp2), (Lp4), (Lp5), (Lp8), (Lh1) and (Lh2) hold, for $\nu = 1, 2$ and every $s < \mathrm{len}$. Moreover $\lambda_s(\Pi) \in t^{H(c-s)} K_{(s)}[[t]]^\times$, so $\mathrm{lv}_s(w) \in t^{-H(c-s)} K_{(s)}[[t]]^{r_\nu}$ for $w \in W_\nu$, and the elements σ_u ($u \in \mathbb{Z}_\ell^\times$) commute.*

Proof. Fix ν and $s < \mathrm{len}$ and drop ν from the notation. Write $B = B_{\mathrm{dR}}^+$, $K = K_{(s)}$, $\zeta = \zeta_{\ell^{s+1}}$, $\mu = [\varepsilon] - 1$, $\mu_s = \varphi^{-(s+1)}(\mu) = [\varepsilon^{1/\ell^{s+1}}] - 1$, $q = \mathrm{len} - s - 1 \geq 0$, $D_k = D_k^{(s)}$. Let $\xi = \sum_{i<\ell} [\varepsilon^{1/\ell}]^i$, the element ξ_0 of Theorem B.40; by (Ai1) and (Ai3) there, $\ker\theta = \xi A_{\mathrm{inf}}$ and $\xi B = tB$, so $t \in \xi B^\times$. By (Lm1) and (Lm2) of Lemma 23.6, applied with the site $c - \mathrm{len}$ in place of its c, $e = \mathrm{len}$ and $a = c$ (its λ_s, Λ_s and ϵ are our λ_s, Λ_s and ϵ_s): $\Lambda_s(gx) = \lambda_s(g)\Lambda_s(x)$, $\lambda_s(e_c Q_s) = \epsilon_s \xi$, and $\lambda_s(e_c Q_{s'}) = \epsilon_s v_{s'}$ with $v_{s'} \in B^\times$, so $\theta(v_{s'}) \neq 0$, for $s' < \mathrm{len}$, $s' \neq s$. Finally, as $\iota(X) = \mu$ (Lemma 23.8), $\lambda_s(e_c X) = \epsilon_s \mu_s$, and $\theta(\mu_s) = \theta([\varepsilon^{1/\ell^{s+1}}]) - 1 = \theta(\zeta - 1) \neq 0$ by (Ai1).

Step 1: $[\varepsilon^{1/\ell^{s+1}}] = \zeta \exp(t/\ell^{s+1})$ **in** B**.** Put $N = \ell^{s+1}$. Since θ is injective on $\overline{\mathbb{Q}}_\ell$ and $\theta(\zeta^N) = \theta([\varepsilon]) = 1$, $\zeta^N = 1$. The elements $y = \zeta^{-1}[\varepsilon^{1/N}]$ and $z = \exp(t/N)$ (t-adically convergent, $t \in \mathrm{Fil}^1 B$) satisfy $\theta(y) = \theta(z) = 1$ and $y^N = [\varepsilon] = \exp(t) = z^N$ ($t = \log[\varepsilon]$). If $y/z = 1 + x$ with $0 \neq x \in \mathrm{Fil}^k B \setminus \mathrm{Fil}^{k+1} B$, $k \geq 1$, then $0 = (1+x)^N - 1 \in Nx + \mathrm{Fil}^{2k} B$, so $x \in \mathrm{Fil}^{k+1} B$ (N is invertible in B), a contradiction. So $y = z$.

Step 2: $\lambda_s(e_c \mathbf{A}_{F,L}) \subseteq K[[t]]$**.** Let $a = e_c \sum_i a_i X^i$ with $a_i \in \mathcal{O}_L$ (acting as $e_c(1 \otimes a_i)$) and $P_m = \epsilon_s \sum_{i<m} a_i \mu_s^i$. Since $\iota(\sum_{i \geq m} a_i X^i) = \mu^m \iota(\sum_i a_{i+m} X^i)$, we have $\lambda_s(a) - P_m \in \mu_s^m (A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L)$. As $\zeta - 1$ is a uniformiser of $\mathbb{Q}_\ell(\zeta)$, totally ramified of degree $d = \ell^s(\ell - 1)$, $\theta(\mu_s^d) \in \ell \mathcal{O}_{\mathbb{C}_\ell}$, so

$\mu_s^d \in \ell A_{\inf} + \xi A_{\inf}$ and $\mu_s^{d(b+k)} \in \ell^{k+1} A_{\inf} + \xi^b A_{\inf}$ for $b, k \geq 0$. Let $\mathcal{V}_b = (B/\xi^b) \otimes_{\mathbb{Q}_\ell} L$ with the ℓ-adic topology whose unit ball is the image of $(A_{\inf}/\xi^b) \otimes \mathcal{O}_L$ (separated: $B/\xi^b = A_{\inf}[1/\ell]/\xi^b$ by Theorem B.40 (Ai3), and $A_{\inf}/\xi^b$ is ℓ-torsion free and ℓ-adically separated). The last claim holds by induction on b. For $b = 1$, $A_{\inf}/\xi \cong \mathcal{O}_{\mathbb{C}_\ell}$ via θ (Ai1). For $b \geq 2$, multiplication by ξ gives an exact sequence $0 \to A_{\inf}/\xi^{b-1} \to A_{\inf}/\xi^b \to A_{\inf}/\xi \to 0$ ($A_{\inf}$ is a domain), and an extension of ℓ-torsion free modules is ℓ-torsion free. If $x \in \bigcap_k \ell^k (A_{\inf}/\xi^b)$, its image in $\mathcal{O}_{\mathbb{C}_\ell}$ is 0, so $x = \xi y$ with $y \in A_{\inf}/\xi^{b-1}$; writing $x = \ell^k z_k$, the image of z_k in $\mathcal{O}_{\mathbb{C}_\ell}$ is killed by ℓ^k, hence 0, so $z_k = \xi y_k$, and $\xi(y - \ell^k y_k) = 0$ gives $y = \ell^k y_k$ for every k; by induction $y = 0$. Hence $P_m \to \lambda_s(a)$ in $\mathcal{V}_b$. On the other hand, by Step 1, $\mu_s = \pi + \tau$ with $\pi = \zeta - 1$ and $\tau = \zeta(\exp(t/\ell^{s+1}) - 1) \in t\,\mathbb{Q}_\ell(\zeta)[[t]]$, so in $K[[t]]$ the t^j-coefficient of P_m is $\sum_{i<m} a_i c_{i,j}$ with $c_{i,j} = \epsilon_s \sum_{k \leq j} \binom{i}{k} \pi^{i-k} [t^j](\tau^k)$, and $c_{i,j} \to 0$ in K as $i \to \infty$ ($|\pi| < 1$). So $F(a) = \sum_j (\sum_i a_i c_{i,j}) t^j \in K[[t]]$ is defined, and $F(a) - P_m \equiv \sum_{j<b} \delta_{m,j} t^j \bmod t^b$ with $\delta_{m,j} \to 0$ in K; the $\mathbb{Q}_\ell$-linear map $K^b \to \mathcal{V}_b$, $(x_j) \mapsto \sum_j x_j t^j$, has finite-dimensional source and is continuous, so $P_m \to F(a)$ in $\mathcal{V}_b$ too. Therefore $\lambda_s(a) \equiv F(a) \bmod \xi^b$ for all b, and $\lambda_s(a) = F(a) \in K[[t]]$ (R_s^+ is ξ-adically separated).

Step 3: units, and $\lambda_s(\Pi)$. For $f \in K[[t]]$ with constant term f_0, $\theta(f) = f_0$ in $\epsilon_s(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L)$. If $\theta(f)$ is a unit there, then $f_0 \in K^\times$: K is a finite product of fields, and a primitive idempotent e of K with $ef_0 = 0$ would give $e\theta(f) = 0$ with $e \neq 0$ (θ is injective on K). Hence $f \in K[[t]]^\times$. By Step 2 this applies to $\lambda_s(X)$ ($\theta = \epsilon_s(\zeta - 1)$) and to $\lambda_s(Q_{s'})$, $s' \neq s$. For $f = \lambda_s(Q_s) = \epsilon_s \xi$: $f_0 = \theta(f) = 0$, so $f = tf'$ with $f' \in K[[t]]$; and $\xi = tv$ with $v \in B^\times$, so $f' = \epsilon_s v$ (R_s^+ is t-torsion free), $\theta(f')$ is a unit, and $f' \in K[[t]]^\times$. Thus $\lambda_s(Q_s) \in tK[[t]]^\times$, $\lambda_s(\Pi) = \prod_{s'<\mathrm{len}} \lambda_s(Q_{s'})^{H(c-s')} \in t^{H(c-s)} K[[t]]^\times$, and λ_s maps $e_c \mathbf{A}_{F,L}[1/\lambda_{\mathrm{len}}]$ into $K((t))$.

Step 4: algebraicity and regularity. Let $w \in W$, so $\Pi w = \sum_j g_j \varphi^{\mathrm{len}}(n_j)$ with $g_j \in e_c \mathbf{A}_{F,L}$. By (Ex2), $\Lambda_s(\varphi^{\mathrm{len}}(n_j)) = \varphi^q(\iota_T(n_j)) = G^{(q)}(n_j)$ with $G^{(q)}$ as in Lemma 23.13; writing $n_j = \sum_k (\mathbf{h}^{-1})_{jk} H_k$ in $\mathbf{N}_E$ ($\mathbf{h} = (h_{kj}) \in GL_r(e_{c_0} E[[X]])$, Lemma 23.9 (Hf2)), semilinearity of $G^{(q)}$ and Lemma 23.13 (1) give $G^{(q)}(n_j) = \sum_k \mathrm{ev}^{(q)}((\mathbf{h}^{-1})_{jk}) D_k$. For $f = \sum_i b_i X^i \in e_{c_0} E[[X]]$ ($b_i \in e_{c_0}(1 \otimes L)$), $\mathrm{ev}^{(q)}(f) = \sum_i \varphi^q(\iota_\Lambda(b_i))(\exp(\ell^q t) - 1)^i$ with $\varphi^q(\iota_\Lambda(b_i)) \in \epsilon_{c_0+q} L = \epsilon_s L \subseteq K$ and $\varphi^q(\mu) = [\varepsilon]^{\ell^q} - 1 = \exp(\ell^q t) - 1 \in t\mathbb{Q}_\ell[[t]]$; modulo t^b only the terms $i < b$ contribute, both in B and in $K[[t]]$, so $\mathrm{ev}^{(q)}(f) \in K[[t]]$. With Step 2, $\Lambda_s(\Pi w) = \sum_k c_k D_k$ with $c_k = \sum_j \lambda_s(g_j) \mathrm{ev}^{(q)}((\mathbf{h}^{-1})_{jk}) \in K[[t]]$. As $\Lambda_s(w) = \lambda_s(\Pi)^{-1} \Lambda_s(\Pi w)$, w is algebraic at level s with $\mathrm{lv}_s(w) = \lambda_s(\Pi)^{-1}(c_k)_k \in t^{-H(c-s)} K[[t]]^r$ by Step 3, and $\lambda_s(\Pi)\mathrm{lv}_s(w) = (c_k)_k \in K[[t]]^r$. This proves (Lp1) and (Lp4).

Step 5: (Lp5). Let $\mathcal{O} = e_c \mathbf{A}_{F,L}[1/\ell] \cong \mathcal{O}_L[[X]][1/\ell]$, factorial, with Q_s squarefree. By (Lm3) of Lemma 23.6 with $\alpha = 1$ (setting as above; its $\mathcal{O}$ is ours), $g \in \mathcal{O}$ has $\lambda_s(g) \in \xi R_s^+$ if and only if every prime factor of Q_s divides g, i.e. (Q_s being squarefree) if and only if $Q_s \mid g$; as $\ker\theta \cap R_s^+ = \xi R_s^+$, $\theta \circ \lambda_s \colon \mathcal{O} \to \epsilon_s(\mathbb{C}_\ell \otimes L)$ has kernel $Q_s \mathcal{O}$. Let $a \in e_c \mathbf{A}_{F,L}$, $a \neq 0$, with $\lambda_s(a) \in t^k K[[t]] \subseteq \xi^k R_s^+$, and write $a = Q_s^\beta a_0$ in $\mathcal{O}$ with $\beta \geq 0$ maximal, so $Q_s \nmid a_0$. Then $\theta(\lambda_s(a_0)) \neq 0$, i.e. $\lambda_s(a_0) \notin \xi R_s^+$; as $\lambda_s(a) = \xi^\beta \epsilon_s \lambda_s(a_0)$ and R_s^+ is ξ-torsion free, $\beta \geq k$. So $a = Q_s^k a'$ with $a' \in \mathcal{O}$, and $\ell^N a' \in e_c \mathbf{A}_{F,L}$ for some N.

Step 6: (Lp2). For $u \in \mathbb{Z}_\ell^\times$, $\gamma_u(Q_{s'}) \in Q_{s'} \mathbb{Z}_\ell[[X]]^\times$: by Weierstrass preparation $\gamma_u(Q_{s'}) = Pv$ with v a unit and P distinguished of degree $\deg Q_{s'}$ (modulo ℓ, $Q_{s'} \equiv X^{\deg Q_{s'}}$ and $\gamma_u(X) \in uX + X^2 \mathbb{Z}_\ell[[X]]$), and the zeros of $\gamma_u(Q_{s'})$ in the maximal ideal of $\mathcal{O}_{\mathbb{C}_\ell}$ are the x with $(1+x)^u$ a primitive $\ell^{s'+1}$-th root of unity, i.e. the $\deg Q_{s'}$ distinct zeros of $Q_{s'}$; so $P = Q_{s'}$. Hence $\gamma_u(\Pi) = v_u \Pi$ with v_u a unit. Since γ_u commutes with φ (Wm3) and preserves $\mathbf{N}_{c_0}$, it preserves $P_{\mathrm{len}}(\mathbf{N}_{c_0})$, and $\Pi \gamma_u(w) = v_u^{-1} \gamma_u(\Pi w) \in P_{\mathrm{len}}(\mathbf{N}_{c_0})$ for $w \in W$: $\gamma_u(W) \subseteq W$. Let $g \in G_F$ with $\chi(g) = u$. On $\mathbf{A}_F$, $g \circ \iota = \iota \circ \gamma_u$ (g fixes $W(k)$ and $g(\mu) = [\varepsilon]^u - 1 = \iota((1+X)^u - 1)$), so (Ex2) extends to $\iota_T(\gamma_u w) = g(\iota_T(w))$ on $\mathbf{N}[1/\lambda_{\mathrm{len}}]$, and, g commuting with φ, $\Lambda_s(\gamma_u w) = g(\Lambda_s(w)) = \sum_k g(f_k) D_k$ ($D_k \in D_{\mathrm{cris}}(V)$ is G_F-fixed). The automorphism g of B_{dR} preserves every Fil^b, so $g(\sum_i a_i t^i) = \sum_i g(a_i) u^i t^i = \sum_i \sigma_u(a_i) u^i t^i$ for $\sum_i a_i t^i \in K((t))$. So $\mathrm{lv}_s(\gamma_u w) = \gamma_u^{(s)}(\mathrm{lv}_s(w))$.

Step 7: (Lp8). $F/\mathbb{Q}_\ell$ is unramified and $\mathbb{Q}_\ell(\zeta)/\mathbb{Q}_\ell$ totally ramified, so $F(\zeta)/F$ is Galois with group $(\mathbb{Z}/\ell^{s+1})^\times$, $\bar{u}$ acting by $\zeta \mapsto \zeta^u$; $\sigma_u = \epsilon_s(\rho_{\bar{u}} \otimes \mathrm{id}_L)$ with $\rho_{\bar{u}}$ this automorphism. So the σ_u commute ($\sigma_u\sigma_v = \sigma_{uv}$). For $u \in 1 + \ell\mathbb{Z}_\ell$, $u^{\ell^s} \equiv 1 \bmod \ell^{s+1}$, so $\sigma_u^{\ell^s} = \sigma_{u^{\ell^s}} = \mathrm{id}$. Taking invariants under the finite group commutes with $- \otimes_{\mathbb{Q}_\ell} L$ (L is flat), so the common fixed points of the σ_u in K are $\epsilon_s(F \otimes_{\mathbb{Q}_\ell} L) = \epsilon_s L$.

Step 8: (Lh1), (Lh2). $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ and the γ_u (Ex3), so it maps W_1 into W_2; extend it $E[[X]]$-linearly to $\mathbf{N}(T_1)_E \to \mathbf{N}(T_2)_E$. Then $\mathbf{N}(\Phi)(H_k^1)$ is γ_u-fixed and lies in $\mathbf{N}(\Phi)(n_k^1) + X\mathbf{N}(T_2)_E = \sum_l o_{lk} n_l^2 + X\mathbf{N}(T_2)_E$; by the uniqueness in (Hf2), $\mathbf{N}(\Phi)(H_k^1) = \sum_l o_{lk} H_l^2$. From $\iota_{T_2} \circ \mathbf{N}(\Phi) = (1 \otimes \Phi) \circ \iota_{T_1}$ (Ex3) and the definition of $G^{(q)}$, $G_2^{(q)}(\mathbf{N}(\Phi)Y) = (1 \otimes \Phi)G_1^{(q)}(Y)$ for $Y \in e_{c_0}\mathbf{N}(T_1)_E$; with Lemma 23.13 (1), $(1 \otimes \Phi)(D_k^1) = \sum_l o_{lk} D_l^2$. Also $\Lambda_s^2 \circ \mathbf{N}(\Phi) = (1 \otimes \Phi) \circ \Lambda_s^1$. For $w \in W_1$ with $\Lambda_s^1(w) = \sum_k f_k D_k^1$, the B_{dR}-linearity of $1 \otimes \Phi$ gives $\Lambda_s^2(\mathbf{N}(\Phi)w) = \sum_l (\sum_k o_{lk} f_k) D_l^2$: (Lh1). If κ_s is up and $v \in U_s^1$, then $\sum_l (ov)_l D_l^2 = (1 \otimes \Phi)(\sum_k v_k D_k^1) \in (1 \otimes \Phi)(\mathrm{Fil}^{b_s} D_1) \subseteq \mathrm{Fil}^{b_s} D_2$ ($1 \otimes \Phi$ maps $D_{\mathrm{cris}}(V_1)$ to $D_{\mathrm{cris}}(V_2)$ and $t^b B \otimes V_1$ to $t^b B \otimes V_2$), and $ov \in \mathcal{O}_L^{r_2}$: (Lh2). □

23.3 The Wach length lemma

The Wach length lemma (Proposition 23.18) is the first half of the lifting exponent over unramified fields (Proposition 24.1): for a surjection $T \to T''$ of crystalline lattices, the cokernel of the induced map of Wach modules is killed at every site by $X^{H_{\max}}$, where $H_{\max}$ is the largest width $M_a + h_a$ of the window. The proof first shows that some power of X kills the cokernel (Proposition 23.19), and then reaches the exponent $H_{\max}$ by an induction around the Frobenius cycle of sites, using the Frobenius recursion of Lemma 23.20. The second half is Γ-descent (Lemma 23.21), which turns an X-power annihilator of a Γ-stable quotient of Wach type into an ℓ-power annihilator; the valuations of the operators that occur there are computed in Lemma 23.22. The subsection also introduces the Δ-invariant Wach ring at ramification e (Definition 23.23), the ring of the Δ-invariant lattices of Sections 24, 27 and 28.

Proposition 23.18. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Proposition 23.7, and $f\colon T \to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K (for $K = F$: pairs, G_F, and the embedding τ_a itself below). Let $M_a, h_a \geq 0$ be integers such that every Hodge jump of V at every embedding of K over τ_a lies in $[-M_a, h_a]$ ($a \in \mathbb{Z}/n$), and $H_{\max} = \max_a(M_a + h_a)$. Then for every $c \in \mathbb{Z}/n$*

$$X^{H_{\max}}\,\mathbf{N}(T'')_c \subseteq \mathbf{N}(f)(\mathbf{N}(T)_c).$$

***Level** s. Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7, $X_{s-1} = \varphi^{s-1}(X)$ the level variable of Definition 23.2, $f\colon T \to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K, and M_a, h_a, $H_{\max}$ as above. Then for every $c \in \mathbb{Z}/n$*

$$X_{s-1}^{H_{\max}}\,\mathbf{N}_s(T'')_c \subseteq \mathbf{N}_s(f)(\mathbf{N}_s(T)_c).$$

For $s = 1$ and ℓ odd this is the statement above.

Proof. **Setting.** Put $\mathbf{N} = \mathbf{N}(T'')$, $\mathbf{N}' = \mathbf{N}(f)(\mathbf{N}(T))$ and $H = H_{\max}$; then $\mathbf{N}'_a = e_a\mathbf{N}' = \mathbf{N}(f)(\mathbf{N}(T)_a)$. By (Ex1), $\mathbf{N}(T)$ is a Wach module with window $(M_a, h_a)_a$; by Lemma 23.25 (V is crystalline, hence de Rham) every Hodge jump of V'' at an embedding of K over τ_a is one of V at that embedding, so by (Ex1) $\mathbf{N}$ is a Wach module with the same window. By (Ex3), $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ (extended to $\mathbf{N}(T)[1/Q]$) and with every γ_u.

Hence $(\gamma_u - 1)\mathbf{N}' = \mathbf{N}(f)((\gamma_u - 1)\mathbf{N}(T)) \subseteq X\mathbf{N}'$ by (Wm3) for $\mathbf{N}(T)$, and applying $\mathbf{N}(f)$ to (Wm2) for $\mathbf{N}(T)$ gives $Q^{h_a}\mathbf{N}'_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$; so Lemma 23.20 applies to $\mathbf{N}$, $\mathbf{N}'$. Let $R_a = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ and

$$I_a = \{g \in R_a : \ g\mathbf{N}_a \subseteq \mathbf{N}'_a\},$$

an ideal of R_a. By Proposition 23.19 there is $c_0 \geq 0$ with $X^{c_0}e_a \in I_a$ for all a. We must show $X^H e_a \in I_a$ for all a.

Step 1: if $g \in I_a$, then $Q^H g \in \varphi(I_{a-1})R_a$. By item 1 of Lemma 23.20, $Q^H g = \sum_{k<\ell} X^k\varphi(z_k)$ with $z_k \in R_{a-1}$; we show $z_k \in I_{a-1}$. Let $y \in \mathbf{N}_{a-1}$. By (Wm2) for $\mathbf{N}$, $\rho = Q^{M_a}\varphi(y) \in \mathbf{N}_a$, so $g\rho = \mathbf{N}(f)(x)$ with $x \in \mathbf{N}(T)_a$; by (Wm2) for $\mathbf{N}(T)$, $Q^{h_a}x \in \mathbf{A}_{F,L}\varphi(\mathbf{N}(T)_{a-1})$, and applying $\mathbf{N}(f)$ and multiplying by $Q^{H-M_a-h_a}$,

$$\sum_{k<\ell} X^k\varphi(z_k y) = Q^H g\,\varphi(y) \in \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1}).$$

By item 3 of Lemma 23.20 the right-hand element equals $\sum_k X^k\varphi(u_k)$ with $u_k \in \mathbf{N}'_{a-1}$, and item 2 applied to $z_k y - u_k \in \mathbf{N}_{a-1}$ gives $z_k y = u_k \in \mathbf{N}'_{a-1}$. Hence $z_k \in I_{a-1}$.

Step 2: an induction along the Frobenius cycle. Fix a and suppose $X^H e_a \notin I_a$. Let ϖ be a uniformiser of $\mathcal{O}_L$ and, for every b, identify R_b with $\mathcal{O}_L[[X]]$; then $\varphi\colon R_b \to R_{b+1}$ is $\mathcal{O}_L$-linear and sends X to $(1+X)^\ell - 1 \in (\varpi, X^\ell)$. We show for all $m \geq 0$: if $y \in R_{a+m}$ and $X^H y \in I_{a+m}$, then $y \in (\varpi, X^{m+1})$.

For $m = 0$: if $y \notin (\varpi, X)$, its constant term is a unit, so y is a unit of R_a and $X^H e_a \in I_a$, a contradiction.

For $m \to m+1$: let $y \in R_{a+m+1}$ with $X^H y \in I_{a+m+1}$, and write $y = \sum_{k<\ell} X^k\varphi(z_k)$ with $z_k \in R_{a+m}$ (item 1 of Lemma 23.20). Since $\varphi(X) = XQ$,

$$Q^H X^H y = \sum_{k<\ell} X^k\varphi(X^H z_k),$$

and by Step 1 this lies in $\varphi(I_{a+m})R_{a+m+1}$. Every element $\sum_i r_i\varphi(w'_i)$ of that ideal ($r_i \in R_{a+m+1}$, $w'_i \in I_{a+m}$) can be written, expanding $r_i = \sum_k X^k\varphi(g_{ik})$ by item 1, as $\sum_k X^k\varphi(w_k)$ with $w_k = \sum_i g_{ik}w'_i \in I_{a+m}$. Uniqueness in item 1 gives $X^H z_k = w_k \in I_{a+m}$, so $z_k \in (\varpi, X^{m+1})$ by the induction hypothesis, and $\varphi(z_k) \in (\varpi, \varphi(X)^{m+1}) \subseteq (\varpi, X^{\ell(m+1)}) \subseteq (\varpi, X^{m+2})$. Hence $y \in (\varpi, X^{m+2})$.

Conclusion. Take $m = c_0$ and $y = X^{c_0} \in R_{a+c_0}$: then $X^H y \in I_{a+c_0}$ because $X^{c_0} \in I_{a+c_0}$, so $X^{c_0} \in (\varpi, X^{c_0+1})$. But every element $\varpi\alpha + X^{c_0+1}\beta$ has its coefficient of X^{c_0} in $\varpi\mathcal{O}_L$, while that of X^{c_0} is 1. This contradiction shows $X^H e_a \in I_a$, i.e. $X^H\mathbf{N}_a \subseteq \mathbf{N}'_a$.

Level s. Put $\mathbf{N} = \mathbf{N}_s(T'')$, $\mathbf{N}' = \mathbf{N}_s(f)(\mathbf{N}_s(T))$, $H = H_{\max}$, and R_a, I_a as in the Setting. By (Ex1)–(Ex3) of level s and Lemma 23.25, $\mathbf{N}_s(T)$ and $\mathbf{N}$ are Wach modules of level s with window $(M_a, h_a)_a$, $\mathbf{N}_s(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ, and $Q_{s-1}^{h_a}\mathbf{N}'_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$; items 1–3 of Lemma 23.20 apply (paragraph Level s there), and Proposition 23.19 (paragraph Level s) gives $c_0 \geq 0$ with $X_{s-1}^{c_0}e_a \in I_a$ for all a. Step 1 goes through unchanged with Q_{s-1} in place of Q (it uses only (Wm2) of level s for $\mathbf{N}$ and $\mathbf{N}_s(T)$ and items 1–3): if $g \in I_a$, then $Q_{s-1}^H g \in \varphi(I_{a-1})R_a$. Step 2: suppose $X_{s-1}^H e_a \notin I_a$; we show for all $m \geq 0$: if $y \in R_{a+m}$ and $X_{s-1}^H y \in I_{a+m}$, then $y \in (\varpi, X^{m+1})$. For $m = 0$ this is as before. For $m \to m+1$ write $y = \sum_{k<\ell} X^k\varphi(z_k)$; since $\varphi(X_{s-1}) = X_{s-1}Q_{s-1}$ (indeed $\varphi(X_{s-1}) = (1+X)^{\ell^s} - 1 = X_{s-1}\Phi_\ell(1+X_{s-1})$, and $\Phi_\ell(1+X_{s-1}) = \Phi_{\ell^s}(1+X) = Q_{s-1}$ by Lemma 23.8(3)), $Q_{s-1}^H X_{s-1}^H y = \sum_k X^k\varphi(X_{s-1}^H z_k)$, and the rest of the step is unchanged. Conclusion: take $m = \ell^{s-1}c_0$ and $y = X_{s-1}^{c_0} \in R_{a+m}$; then $X_{s-1}^H y \in I_{a+m}$, so $X_{s-1}^{c_0} \in (\varpi, X^{m+1})$. But $X_{s-1} = (1+X)^{\ell^{s-1}} - 1 \equiv X^{\ell^{s-1}}$ modulo ℓ, so the coefficient of X^m in $X_{s-1}^{c_0}$ is $\equiv 1$ modulo ϖ, while every element of (ϖ, X^{m+1}) has that coefficient in $\varpi\mathcal{O}_L$. This contradiction shows $X_{s-1}^H\mathbf{N}_a \subseteq \mathbf{N}'_a$. □

Proposition 23.19. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F\subseteq K\subseteq F(\mu_\ell)$ as in Proposition 23.7, and $f\colon T\to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K (for $K=F$: pairs and G_F). Then there is an integer $c\geq 0$ with*

$$X^c\,\mathbf{N}(T'')\subseteq \mathbf{N}(f)(\mathbf{N}(T)).$$

***Level** s. Let ℓ be any prime, $s\geq 1$ an integer with $s\geq 2$ if $\ell=2$, L, K ($F\subseteq K\subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7, $X_{s-1}=\varphi^{s-1}(X)$ the level variable of Definition 23.2, and $f\colon T\to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K. Then there is an integer $c\geq 0$ with $X_{s-1}^c\,\mathbf{N}_s(T'')\subseteq \mathbf{N}_s(f)(\mathbf{N}_s(T))$. For $s=1$ and ℓ odd this is the statement above.*

Proof. **Setting.** Put $\mathbf{N}=\mathbf{N}(T'')$, $\mathbf{N}'=\mathbf{N}(f)(\mathbf{N}(T))$, $R_a=e_a\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$, $C_a=\mathbf{N}_a/\mathbf{N}'_a$ and $I_a=\{g\in R_a:\ g\mathbf{N}_a\subseteq\mathbf{N}'_a\}$, the annihilator of the finitely generated R_a-module C_a. Choose $M_a,h_a\geq 0$ with all Hodge jumps of V at every embedding of K over τ_a in $[-M_a,h_a]$ and put $H=\max_a(M_a+h_a)$; by (Ex1), $\mathbf{N}(T)$ is a Wach module with window $(M_a,h_a)_a$; by Lemma 23.25 (V is crystalline, hence de Rham) every Hodge jump of V'' at an embedding of K over τ_a is one of V at that embedding, so by (Ex1) $\mathbf{N}$ is a Wach module with the same window. By (Ex3), $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ (extended to $\mathbf{N}(T)[1/Q]$) and with every γ_u; hence $(\gamma_u-1)\mathbf{N}'=\mathbf{N}(f)((\gamma_u-1)\mathbf{N}(T))\subseteq X\mathbf{N}'$ for all $u\in\Gamma_K$ by (Wm3) for $\mathbf{N}(T)$, and applying $\mathbf{N}(f)$ to (Wm2) for $\mathbf{N}(T)$ gives $Q^{h_a}\mathbf{N}'_a\subseteq\mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$ for all a; so Lemma 23.20 applies to $\mathbf{N},\mathbf{N}'$. Let ϖ be a uniformiser of $\mathcal{O}_L$ and $\kappa_L=\mathcal{O}_L/\varpi$. Ring-theoretic facts: R_a is a two-dimensional regular local ring; its height-one primes are (ϖ) and the (P) with P an irreducible distinguished polynomial, and each (P) is the set of g vanishing at a root z of P in the open unit disc $\mathfrak{m}_{\mathbb{C}_\ell}$ (Weierstrass preparation: every $0\neq g$ is $\varpi^k P_g u$ with u a unit and P_g distinguished, so g has finitely many zeros in $\mathfrak{m}_{\mathbb{C}_\ell}$, and we write $\mathrm{ord}_z(g)$ for the order of vanishing at z).

Step 1: $I_a\not\subseteq(\varpi)$; in particular $I_a\neq 0$. Reduce the realisations modulo ϖ. Since $\ell\in\varpi\mathcal{O}_L$, for a pair (V°,T°) over K we have $(A_{\mathrm{inf}}[1/\mu_\varepsilon]\otimes_{\mathbb{Z}_\ell}T^\circ)/\varpi=\mathbb{C}_\ell^\flat\otimes_{\mathbb{F}_\ell}(T^\circ/\varpi T^\circ)$, because $A_{\mathrm{inf}}[1/\mu_\varepsilon]/\ell=\mathcal{O}_{\mathbb{C}_\ell^\flat}[1/(\varepsilon-1)]=\mathbb{C}_\ell^\flat$. Let $B=\mathbb{C}_\ell^\flat\otimes_{\mathbb{F}_\ell}\kappa_L$, a finite product of copies of $\mathbb{C}_\ell^\flat$ (κ_L is finite separable over $\mathbb{F}_\ell$ and $\mathbb{C}_\ell^\flat$ is algebraically closed), and $B_a=\bar\varepsilon_a B$ with $\bar\varepsilon_a$ the image of $(\iota\otimes\mathrm{id})(e_a)$; so $B=\prod_a B_a$ and each B_a is a non-zero product of fields. Reducing $\iota\otimes\mathrm{id}\colon R_a\to(A_{\mathrm{inf}}\otimes\mathcal{O}_L)\bar\varepsilon_a$ gives a ring map $\kappa_L[[X]]=R_a/\varpi\to B_a$ sending X to the unit $(\varepsilon-1)\bar\varepsilon_a$, hence $k_a:=\kappa_L((X))\to B_a$. By (Ex2), ι_{T° induces a k_a-semilinear map from $\bar{\mathbf{N}}^\circ_a:=(\mathbf{N}(T^\circ)_a/\varpi)[1/X]$ to $Y^\circ_a:=\bar\varepsilon_a(\mathbb{C}_\ell^\flat\otimes_{\mathbb{F}_\ell}T^\circ/\varpi)$, and its B_a-linear extension $\Psi^\circ_a\colon B_a\otimes_{k_a}\bar{\mathbf{N}}^\circ_a\to Y^\circ_a$ is onto, since $A_{\mathrm{inf}}[1/\mu_\varepsilon]\iota_{T^\circ}(\mathbf{N}(T^\circ))=A_{\mathrm{inf}}[1/\mu_\varepsilon]\otimes T^\circ$. Both sides are free B_a-modules of rank $\dim_L V^\circ$: the source by (Wm1) and (Ex1) ($\mathbf{N}(T^\circ)_a$ free of rank $\dim_L V^\circ$), the target because $\mathbb{C}_\ell^\flat\otimes_{\mathbb{F}_\ell}T^\circ/\varpi=B\otimes_{\kappa_L}(T^\circ/\varpi)$ is free of that rank over B. A surjection between free modules of the same finite rank over a finite product of fields is bijective, so Ψ°_a is an isomorphism. Apply this to T'' and T. As f is onto, $(1\otimes f)(Y_a(T))=Y_a(T'')$, and $(1\otimes f)\circ\Psi_a(T)=\Psi_a(T'')\circ(1\otimes\overline{\mathbf{N}(f)})$ by (Ex3); hence $B_a\otimes U=B_a\otimes\bar{\mathbf{N}}_a$, where $U\subseteq\bar{\mathbf{N}}_a$ is the k_a-span of the image of $\mathbf{N}'_a$. Since $B_a\neq 0$ is faithfully flat over the field k_a, $U=\bar{\mathbf{N}}_a$. Now k_a is the residue field of the discrete valuation ring $R_{a,(\varpi)}$, so $\mathbf{N}'_{a,(\varpi)}+\varpi\mathbf{N}_{a,(\varpi)}=\mathbf{N}_{a,(\varpi)}$, and by Nakayama $(C_a)_{(\varpi)}=0$. As C_a is finitely generated, some $s\in R_a\setminus(\varpi)$ kills C_a, i.e. $I_a\not\subseteq(\varpi)$.

Step 2: the annihilators along Frobenius. If $g\in I_a$, then $Q^Hg=\sum_{k<\ell}X^k\varphi(w_k)$ with $w_k\in I_{a-1}$. Indeed, by item 1 of Lemma 23.20, $Q^Hg=\sum_k X^k\varphi(w_k)$ with $w_k\in R_{a-1}$; for $y\in\mathbf{N}_{a-1}$, (Wm2) for $\mathbf{N}$ gives $g\,Q^{M_a}\varphi(y)=\mathbf{N}(f)(x)$ with $x\in\mathbf{N}(T)_a$, (Wm2) for $\mathbf{N}(T)$ and $\mathbf{N}(f)$ give $Q^Hg\varphi(y)=\sum_k X^k\varphi(w_ky)\in\mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$, and items 3 and 2 of Lemma 23.20 give $w_ky\in\mathbf{N}'_{a-1}$.

Step 3: no zeros off 0. In the coordinates $R_b\cong\mathcal{O}_L[[X]]$, $\varphi(g)(X)=g((1+X)^\ell-1)$ (under the identifications $R_b\cong\mathcal{O}_L[[X]]$, $\varphi\colon R_{b-1}\to R_b$ is the $\mathcal{O}_L$-linear ring map sending X

to $(1+X)^\ell - 1$, Definition 23.2). For $z \in \mathfrak{m}_{\mathbb{C}_\ell}$ put $z^{[\ell]} = (1+z)^\ell - 1$; as $(1+X)^\ell - 1 - z^{[\ell]}$ has a simple zero at z (its derivative $\ell(1+z)^{\ell-1}$ is non-zero), $\mathrm{ord}_z(\varphi(g)) = \mathrm{ord}_{z^{[\ell]}}(g)$. For $b \in \mathbb{Z}/n$ let Z_b be the set of $z \in \mathfrak{m}_{\mathbb{C}_\ell} \setminus \{0\}$ at which every element of I_b vanishes; Z_b is finite, as $I_b \neq 0$. Let $w \in Z_{a-1}$ and $z \in \mathfrak{m}_{\mathbb{C}_\ell}$ with $z^{[\ell]} = w$; there are exactly ℓ such z (the roots of $(1+z)^\ell = 1+w$ are distinct as $1+w \neq 0$, and each lies in the open disc because every ℓ-th root of $1+w$ is $\equiv 1$ modulo the maximal ideal), and $z \neq 0$, $Q(z) = w/z \neq 0$. For $g \in I_a$, Step 2 gives $\mathrm{ord}_z(g) = \mathrm{ord}_z(Q^H g) \geq \min_k \mathrm{ord}_z(\varphi(w_k)) = \min_k \mathrm{ord}_w(w_k) \geq 1$. Hence all ℓ such z lie in Z_a. By induction, if $Z_{a-1} \neq \emptyset$ then Z_{a-1+k} contains the ℓ^k distinct solutions of $(1+z)^{\ell^k} = 1+w$ for every $k \geq 1$; taking $k \equiv 0 \pmod{n}$ large contradicts the finiteness of Z_{a-1}. So $Z_b = \emptyset$ for every b.

Step 4: conclusion. Let $\mathfrak{p}$ be a minimal prime of R_a over I_a. Then $\mathfrak{p} \neq 0$ (Step 1), and $\mathfrak{p}$ is either maximal, or of height one; in the latter case $\mathfrak{p} \neq (\varpi)$ by Step 1, so $\mathfrak{p} = (P)$ with P irreducible distinguished, and every element of I_a vanishes at the roots of P; by Step 3 these roots are all 0, so $P = X$. Hence X lies in every minimal prime over I_a, i.e. in $\sqrt{I_a}$, and since R_a is Noetherian, $X^{c_a} \in I_a$ for some c_a. With $c = \max_a c_a$, $X^c \mathbf{N}(T'') = \sum_a X^c \mathbf{N}_a \subseteq \mathbf{N}'$.

Level s. Put $\mathbf{N} = \mathbf{N}_s(T'')$, $\mathbf{N}' = \mathbf{N}_s(f)(\mathbf{N}_s(T))$ and R_a, C_a, I_a, H as in the Setting, with (Ex1)–(Ex3) of level s (Proposition 23.7, (Ex4)) and Wach modules of level s; items 1–3 of Lemma 23.20 hold for them (paragraph Level s there). Step 1 goes through unchanged with ι_s, ι_{s,T° in place of ι, ι_{T°: by Lemma 23.8(6), $\iota_s(X) = \mu_{\varepsilon,s} = [\varepsilon^{1/\ell^{s-1}}] - 1$, whose reduction $\varepsilon^{1/\ell^{s-1}} - 1$ is a non-zero element, hence a unit, of $\mathbb{C}_\ell^\flat$; the spanning clause is (Ex2) of level s; and $\ell \in \varpi\mathcal{O}_L$, κ_L separable over $\mathbb{F}_\ell$, hold for every prime. Step 2 goes through unchanged with Q_{s-1} in place of Q ((Wm2) of level s): if $g \in I_a$, then $Q_{s-1}^H g = \sum_{k<\ell} X^k \varphi(w_k)$ with $w_k \in I_{a-1}$. Step 3 becomes: *every $w \in Z_b$ satisfies* $(1+w)^{\ell^{s-1}} = 1$. Suppose $w \in Z_{a-1}$ with $(1+w)^{\ell^{s-1}} \neq 1$, and let z be one of the ℓ points of the open disc with $z^{[\ell]} = w$ (they are distinct and non-zero, as before). Then $(1+z)^{\ell^s} = (1+w)^{\ell^{s-1}} \neq 1$, so $1+z$ is not a primitive ℓ^s-th root of unity and $Q_{s-1}(z) \neq 0$ (Lemma 23.8(3)); hence for $g \in I_a$, $\mathrm{ord}_z(g) = \mathrm{ord}_z(Q_{s-1}^H g) \geq \min_k \mathrm{ord}_w(w_k) \geq 1$, and $z \in Z_a$; moreover $(1+z)^{\ell^{s-1}} \neq 1$ (its ℓ-th power is $(1+w)^{\ell^{s-1}} \neq 1$). By induction Z_{a-1+k} contains the ℓ^k distinct solutions of $(1+z)^{\ell^k} = 1+w$, and $k \equiv 0 \pmod{n}$ large contradicts the finiteness of Z_{a-1}. Step 4: let $\mathfrak{p}$ be a minimal prime of R_a over I_a; as before $\mathfrak{p}$ is maximal or $\mathfrak{p} = (P)$ with P irreducible distinguished, all of whose roots are zeros of every element of I_a, hence lie in $Z_a \cup \{0\}$, hence are roots of $X_{s-1} = (1+X)^{\ell^{s-1}} - 1$. Weierstrass division $X_{s-1} = qP + \rho$ with $\deg \rho < \deg P$ gives a polynomial ρ vanishing at the $\deg P$ distinct roots of the separable P, so $\rho = 0$ and $X_{s-1} \in (P)$. The maximal ideal (ϖ, X) contains X_{s-1} too. So $X_{s-1} \in \sqrt{I_a}$, $X_{s-1}^{c_a} \in I_a$ for some c_a, and $c = \max_a c_a$ works. □

Lemma 23.20. *Let ℓ be an odd prime, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ as in the definition of sites, K a base field as there, $d = |\Delta_K|$, $\mathbf{N}$ a Wach module over K with coefficients L and window $(M_a, h_a)_{a\in\mathbb{Z}/n}$, and $\mathbf{N}' \subseteq \mathbf{N}$ an $\mathbf{A}_{F,L}$-submodule with $\mathbf{N}'_a = e_a\mathbf{N}'$, such that for all $u \in \Gamma_K$ and $a \in \mathbb{Z}/n$*

$$(\gamma_u - 1)(\mathbf{N}') \subseteq X\mathbf{N}', \qquad Q^{h_a}\mathbf{N}'_a \subseteq \mathbf{A}_{F,L}\,\varphi(\mathbf{N}'_{a-1}).$$

Let $a \in \mathbb{Z}/n$. Then:

1. *every $f \in e_a\mathbf{A}_{F,L}$ can be written uniquely as $f = \sum_{k=0}^{\ell-1} X^k \varphi(g_k)$ with $g_k \in e_{a-1}\mathbf{A}_{F,L}$;*
2. *if $x_0, \ldots, x_{\ell-1} \in \mathbf{N}_{a-1}$ and $\sum_k X^k\varphi(x_k) = 0$, then all $x_k = 0$;*
3. *every element of $\mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$ lying in $e_a\mathbf{N}[1/Q]$ is of the form $\sum_{k<\ell} X^k\varphi(y_k)$ with $y_k \in \mathbf{N}'_{a-1}$; and if $x \in \mathbf{N}_{a-1}$ and $\varphi(x) \in \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$, then $x \in \mathbf{N}'_{a-1}$;*

4. if $s \geq 1$ and b are integers with $X^s \mathbf{N}_a \subseteq \mathbf{N}'_a$ and $b \geq 2 + \log_\ell s$, then

$$X^{M_a + h_a + \lceil s/d \rceil + b} \mathbf{N}_{a-1} \subseteq \mathbf{N}'_{a-1}.$$

For $K = F$ ($\Gamma_F = \mathbb{Z}_\ell^\times$, $d = \ell - 1$) the exponent is $M_a + h_a + \lceil s/(\ell-1) \rceil + b$.

Items 1–3 use neither the hypothesis on γ_u nor the one on $Q^{h_a}\mathbf{N}'_a$.

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, K a field with $F \subseteq K \subseteq F(\mu_{\ell^s})$, $\mathbf{N}$ a Wach module of level s over K with coefficients L and window $(M_a, h_a)_a$ (Definition 23.2, paragraph Level s), and $\mathbf{N}' \subseteq \mathbf{N}$ an $\mathbf{A}_{F,L}$-submodule. Then items 1–3 hold, with $\mathbf{N}[1/Q]$ replaced by $\mathbf{N}[1/Q_{s-1}]$ in item 3.*

Proof. Write $R_a = e_a \mathbf{A}_{F,L}$, a ring isomorphic to $\mathcal{O}_L[[X]]$ by the site decomposition; $\varphi(e_{a-1}) = e_a$, so φ maps R_{a-1} into R_a and $\mathbf{N}_{a-1}$ into $e_a\mathbf{N}[1/Q]$.

Step 1 (item 1): R_a is free over $\varphi(R_{a-1})$ with basis $1, X, \dots, X^{\ell-1}$. On coefficients, $\varphi \otimes \mathrm{id}$ maps $e_{a-1}(\mathcal{O}_F \otimes \mathcal{O}_L)$ isomorphically onto $e_a(\mathcal{O}_F \otimes \mathcal{O}_L)$, and both are identified with $\mathcal{O}_L$ compatibly ($\tau_a \circ \varphi = \tau_{a-1}$). So in the coordinates $R_{a-1} \cong \mathcal{O}_L[[X]] \cong R_a$ the map φ is $g(X) \mapsto g(P)$ with $P = (1+X)^\ell - 1 = X^\ell + \ell(\cdots)$, a distinguished polynomial of degree ℓ with $P(0) = 0$; in particular φ is injective on R_{a-1}. Existence of $f = \sum_{k<\ell} X^k g_k(P)$ for $f \in \mathcal{O}_L[[X]]$: by the Weierstrass division theorem write $f = r_0 + q_1 P$, $q_1 = r_1 + q_2 P$, …, with polynomials r_i of degree $< \ell$; then $f = \sum_{i \geq 0} r_i P^i$ (convergent for the (ℓ, X)-adic topology, as $P^i \in (\ell, X)^i$ and $\mathcal{O}_L[[X]]$ is (ℓ, X)-adically complete), and collecting the coefficient of X^k in the r_i gives the g_k. Uniqueness: if $\sum_{k<\ell} X^k g_k(P) = 0$ with not all $g_k = 0$, divide by the largest power of a uniformiser of $\mathcal{O}_L$ dividing all g_k and reduce modulo it; since $P \equiv X^\ell$, this gives $\sum_k X^k \bar{g}_k(X^\ell) = 0$ with some $\bar{g}_k \neq 0$, impossible because the exponents occurring in $X^k \bar{g}_k(X^\ell)$ lie in $k + \ell\mathbb{Z}$.

Step 2 (item 2): if $x_0, \dots, x_{\ell-1} \in \mathbf{N}_{a-1}$ and $\sum_k X^k \varphi(x_k) = 0$, then all $x_k = 0$. Let $b_1, \dots, b_r$ be an R_{a-1}-basis of $\mathbf{N}_{a-1}$ (Wm1). By (Wm2), $Q^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{a-1}) = \sum_t R_a \varphi(b_t)$; as $\mathbf{N}_a$ is free of rank r over the domain R_a, the r elements $\varphi(b_t)$ span an r-dimensional space over the fraction field of R_a, hence are linearly independent over R_a. Writing $x_k = \sum_t g_{kt} b_t$, the relation becomes $\sum_t (\sum_k X^k \varphi(g_{kt}))\varphi(b_t) = 0$, so $\sum_k X^k \varphi(g_{kt}) = 0$ for every t, and Step 1 gives $g_{kt} = 0$.

Step 3 (item 3): if $x \in \mathbf{N}_{a-1}$ and $\varphi(x) \in \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$, then $x \in \mathbf{N}'_{a-1}$. Write $\varphi(x) = \sum_m f_m \varphi(n'_m)$ with $n'_m \in \mathbf{N}'_{a-1}$ and (multiplying by e_a) $f_m \in R_a$, and by Step 1 $f_m = \sum_{k<\ell} X^k \varphi(g_{mk})$ with $g_{mk} \in R_{a-1}$. Then $\varphi(x) = \sum_k X^k \varphi(y_k)$ with $y_k = \sum_m g_{mk} n'_m \in \mathbf{N}'_{a-1}$; this computation applies to every element $\sum_m f_m \varphi(n'_m)$ of $\mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1}) \cap e_a\mathbf{N}[1/Q]$ and proves the first assertion of item 3. Step 2 applied to $x - y_0, -y_1, \dots, -y_{\ell-1}$ gives $x = y_0 \in \mathbf{N}'_{a-1}$.

Step 4 (item 4): the exponent. Put $k = \lceil s/d \rceil + b$ and $E = M_a + h_a + k$; let $n \in \mathbf{N}_{a-1}$. Since $\varphi(X) = XQ$,

$$\varphi(X^E n) = X^E Q^E \varphi(n) = Q^{h_a} \cdot X^E Q^k \rho, \qquad \rho = Q^{M_a}\varphi(n) \in \mathbf{N}_a$$

by (Wm2). We show $X^E Q^k \rho \in \mathbf{N}'_a$. Then $\varphi(X^E n) \in Q^{h_a}\mathbf{N}'_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$ by hypothesis, and Step 3 gives $X^E n \in \mathbf{N}'_{a-1}$, which is the assertion.

Now $Q = \sum_{m=1}^{\ell} \binom{\ell}{m} X^{m-1} = X^{\ell-1} + \ell w$ with $w \in \mathbb{Z}_\ell[X]$, so

$$X^E Q^k \rho = \sum_{i=0}^{k} \binom{k}{i} w^i \cdot \ell^i X^{j_i} \rho, \qquad j_i = E + (\ell-1)(k-i).$$

Apply Lemma 23.21 with $\Gamma = \Gamma_K$, a closed subgroup of $\mathbb{Z}_\ell^\times$ containing $1 + \ell\mathbb{Z}_\ell$ with $[\Gamma_K : 1 + \ell\mathbb{Z}_\ell] = |\Delta_K| = d$ (Lemma 23.24(Rr7): $\Gamma_K = \Delta_K \cdot (1 + \ell\mathbb{Z}_\ell)$), and $D = N = \mathbf{N}_a$ (free,

so X is injective), $N' = \mathbf{N}'_a$: both are stable under γ_u with $(\gamma_u - 1)\mathbf{N}_a \subseteq X\mathbf{N}_a$ by (Wm3) and $(\gamma_u - 1)\mathbf{N}'_a = e_a(\gamma_u - 1)\mathbf{N}' \subseteq X\mathbf{N}'_a$ ($\gamma_u(e_a) = e_a$), and X^s kills $\mathbf{N}_a/\mathbf{N}'_a$. Fix i and put $t = k - i \geq 0$. If $j_i \geq s$, then $\ell^i X^{j_i}\rho \in X^s\mathbf{N}_a \subseteq \mathbf{N}'_a$. If $j_i < s$, by items 1 and 3 of Lemma 23.21 it suffices that $i \geq (s - j_i)\ell/(d(\ell-1)) + 2 + \log_\ell s$, and for this it suffices, as $b \geq 2 + \log_\ell s$, that $(s - j_i)\ell/(d(\ell-1)) \leq k - t - b$. Since $E \geq k$, $j_i \geq k + (\ell-1)t$, and, as $\ell/d \geq 1$,

$$\frac{(s-j_i)\ell}{d(\ell-1)} \leq \frac{(s-k)\ell}{d(\ell-1)} - \frac{t\ell}{d} \leq \frac{(s-k)\ell}{d(\ell-1)} - t,$$

so it suffices that $s\ell/(d(\ell-1)) + b \leq k(1 + \ell/(d(\ell-1)))$. This holds: $k \geq s/d + b$ and

$$\Big(\frac{s}{d} + b\Big)\Big(1 + \frac{\ell}{d(\ell-1)}\Big) \geq \frac{s}{d} + \frac{s\ell}{d^2(\ell-1)} + b \geq \frac{s}{d} + \frac{s}{d(\ell-1)} + b = \frac{s\ell}{d(\ell-1)} + b,$$

using $\ell/d \geq 1$ in the middle step. Hence every term lies in $\mathbf{N}'_a$, and so does $X^E Q^k \rho$.

Level s. Step 1 concerns only $\mathbf{A}_{F,L}$ and φ, which are defined by the same formulas for every prime (Definition 23.2, paragraph Level s), and it does not use that ℓ is odd: $(1+X)^\ell - 1$ is a distinguished polynomial of degree ℓ with constant term 0 for every prime. Step 2 uses (Wm1) and the second inclusion of (Wm2); for a Wach module of level s the latter reads $Q_{s-1}^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{a-1})$, and the rank argument is unchanged ($Q_{s-1}^{h_a}\mathbf{N}_a$ is free of rank r over the domain R_a). Step 3 uses only Steps 1 and 2, with $\varphi(\mathbf{N}_{a-1}) \subseteq e_a\mathbf{N}[1/Q_{s-1}]$. □

Lemma 23.21. *Let ℓ be an odd prime and $\mathbf{A}_{F,L}$, X, γ_u ($u \in \mathbb{Z}_\ell^\times$) as in the definition of sites. Let $\Gamma \subseteq \mathbb{Z}_\ell^\times$ be a closed subgroup containing $1+\ell\mathbb{Z}_\ell$ and $d = [\Gamma : 1+\ell\mathbb{Z}_\ell]$, a divisor of $\ell-1$ (for a field K as in Definition 23.2: $\Gamma = \Gamma_K$ and $d = |\Delta_K|$; for $K = F$: $\Gamma = \mathbb{Z}_\ell^\times$ and $d = \ell-1$). Let D be an $\mathbf{A}_{F,L}$-module on which multiplication by X is injective, with additive maps $\gamma_{u,D}\colon D \to D$ ($u \in \Gamma$) satisfying $\gamma_{u,D}(fx) = \gamma_u(f)\gamma_{u,D}(x)$ ($f \in \mathbf{A}_{F,L}$, $x \in D$), and let $N' \subseteq N \subseteq D$ be $\mathbf{A}_{F,L}$-submodules with*

$$(\gamma_{u,D} - 1)(N) \subseteq XN, \qquad (\gamma_{u,D} - 1)(N') \subseteq XN' \qquad (u \in \Gamma).$$

Say that $f \in \mathbf{A}_{F,L}$ kills N/N' if $fN \subseteq N'$. For integers $0 \leq j \leq s$ put

$$\mathrm{dsc}_{\ell,d}(j,s) = \sum_{\substack{j<k\leq s \\ d|k}} (1 + v_\ell(k)), \qquad \mathrm{dsc}_\ell(j,s) = \mathrm{dsc}_{\ell,\ell-1}(j,s).$$

1. *If X^s kills N/N', then $\ell^a X^j$ kills N/N' for all integers $0 \leq j \leq s$ and $a \geq \mathrm{dsc}_{\ell,d}(j,s)$.*
2. *$\mathrm{dsc}_{\ell,d}(0,s) = A + v_\ell(A!)$ with $A = \lfloor s/d \rfloor$, and $\mathrm{dsc}_{\ell,d}(0,s) \leq \lfloor s\ell/(d(\ell-1)) \rfloor$.*
3. *If $s \geq 1$, then $\mathrm{dsc}_{\ell,d}(j,s) < (s-j)\ell/(d(\ell-1)) + 2 + \log_\ell s$ for $0 \leq j \leq s$.*

For $\Gamma = \mathbb{Z}_\ell^\times$ ($d = \ell - 1$) the three items read with dsc_ℓ and the bounds $\lfloor s\ell/(\ell-1)^2 \rfloor$ and $(s-j)\ell/(\ell-1)^2 + 2 + \log_\ell s$.

Level s. *In this paragraph $s \geq 1$ is a cyclotomic level and $S \geq 0$ a killing exponent. Let ℓ be any prime, $s \geq 2$ if $\ell = 2$, $X_{s-1} = \varphi^{s-1}(X) = (1+X)^{\ell^{s-1}} - 1$ (the level variable of Definition 23.2) and $u_s = 1 + \ell^s$. Let D be an $\mathbf{A}_{F,L}$-module on which multiplication by X_{s-1} is injective, with an additive map $\gamma_D\colon D \to D$ such that $\gamma_D(fx) = \gamma_{u_s}(f)\gamma_D(x)$, and let $N' \subseteq N \subseteq D$ be $\mathbf{A}_{F,L}$-submodules with $(\gamma_D - 1)(N) \subseteq X_{s-1}N$ and $(\gamma_D - 1)(N') \subseteq X_{s-1}N'$. For integers $0 \leq j \leq S$ and $M \geq 1$ put*

$$\mathrm{dsc}_\ell^{(s)}(j,S) = \sum_{j<k\leq S} (s + v_\ell(k)), \qquad \sigma_M^{(s)} = \sum_{i=1}^{M-1} (s + v_\ell(i)) = (M-1)s + v_\ell((M-1)!).$$

4. *(Descent.) If X_{s-1}^S kills N/N', then $\ell^a X_{s-1}^j$ kills N/N' for all $0 \le j \le S$ and $a \ge \mathrm{dsc}_\ell^{(s)}(j,S)$; and $\mathrm{dsc}_\ell^{(s)}(0,S) = sS + v_\ell(S!) \le (s+1)S$.*

5. *(Precision raise.) For every $M \ge 1$ and $z \in X_{s-1}N$ there is $k \in X_{s-1}N$ with $\ell^{\sigma_M^{(s)}} z - (\gamma_D - 1)(k) \in X_{s-1}^M N$.*

6. *(Rigidity.) Suppose moreover that $N/X_{s-1}N$ has no ℓ-torsion (for instance N a finite free $\mathbf{A}_{F,L}$-module, or a site component e_a of one). If $M \ge 1$, $y \in X_{s-1}N$ and $(\gamma_D - 1)(y) \in X_{s-1}^M N$, then $y \in X_{s-1}^M N$.*

For $s = 1$ and ℓ odd, item 4 with $d = 1$ is item 1 for $\Gamma \supseteq 1 + \ell\mathbb{Z}_\ell$ restricted to the single element $u_1 = 1 + \ell$.

Proof. **The descent step.** Let $c \in \mathbb{Z}_\ell$, $j \ge 0$ and $u \in \Gamma$, and suppose cX^{j+1} kills N/N'; we show that $c(u^{j+1}-1)X^j$ kills N/N'. Write $\gamma = \gamma_{u,D}$. Since $\gamma_u(X) = (1+X)^u - 1 = \sum_{k\ge1} \binom{u}{k} X^k$, we have $\gamma_u(X) = X(u + Xt)$ with $t \in \mathbb{Z}_\ell[[X]]$. Let $n \in N$ and $m = cX^j n \in N$; by hypothesis $Xm \in N'$. Write $\gamma(n) = n + Xn_1$ with $n_1 \in N$. Then

$$\gamma(m) = cX^j(u + Xt)^j(n + Xn_1) = u^j m + cX^{j+1} n_2 \qquad (n_2 \in N),$$

so $\gamma(m) - u^j m \in N'$. Next, $Xm \in N'$ gives $\gamma(Xm) - Xm = Xn'$ with $n' \in N'$, and $\gamma(Xm) = \gamma_u(X)\gamma(m) = X(u + Xt)\gamma(m)$; since X is injective on D, $(u + Xt)\gamma(m) - m = n' \in N'$. Now $X\gamma(m) = u^j Xm + X(\gamma(m) - u^j m) \in N'$, hence $u\gamma(m) - m \in N'$, and with $u(\gamma(m) - u^j m) \in N'$ we get $(u^{j+1} - 1)m \in N'$, which is the claim.

The element u. As ℓ is odd, $\mathbb{Z}_\ell^\times = \mu_{\ell-1} \times (1 + \ell\mathbb{Z}_\ell)$, and since $\Gamma \supseteq 1 + \ell\mathbb{Z}_\ell$, $\Gamma = \Delta \times (1 + \ell\mathbb{Z}_\ell)$ with $\Delta = \Gamma \cap \mu_{\ell-1}$ cyclic of order d. Let δ_0 generate Δ and $u = \delta_0(1 + \ell) \in \Gamma$. Reduction modulo ℓ maps $\mu_{\ell-1}$ isomorphically onto $\mathbb{F}_\ell^\times$, so $u \bmod \ell = \delta_0 \bmod \ell$ has order d, and $u^k - 1 \in \mathbb{Z}_\ell^\times$ when $d \nmid k$. For $k = dm$, $u^k = (1 + \ell)^{dm}$, and the classical identity $v_\ell((1 + \ell)^n - 1) = 1 + v_\ell(n)$ (ℓ odd) with $v_\ell(d) = 0$ gives $v_\ell(u^k - 1) = 1 + v_\ell(m) = 1 + v_\ell(k)$.

Item 1. Applying the descent step with $c = \prod_{k=i+1}^{s}(u^k - 1)$ for $i = s-1, s-2, \ldots, j$ (induction downwards from $c = 1$, $i + 1 = s$) shows that $\prod_{k=j+1}^{s}(u^k - 1)\, X^j$ kills N/N'. By the previous paragraph $\prod_{k=j+1}^{s}(u^k - 1) = \epsilon\, \ell^{\mathrm{dsc}_{\ell,d}(j,s)}$ with $\epsilon \in \mathbb{Z}_\ell^\times$; as N' is an $\mathbf{A}_{F,L}$-module, $\ell^{\mathrm{dsc}_{\ell,d}(j,s)} X^j = \epsilon^{-1} \cdot \epsilon \ell^{\mathrm{dsc}_{\ell,d}(j,s)} X^j$ kills N/N', and so does every $\ell^a X^j$ with $a \ge \mathrm{dsc}_{\ell,d}(j,s)$.

Item 2. The $k \in (0, s]$ divisible by d are $k = dm$, $1 \le m \le A$, and $v_\ell(k) = v_\ell(m)$, so $\mathrm{dsc}_{\ell,d}(0,s) = A + \sum_{m \le A} v_\ell(m) = A + v_\ell(A!)$. For $A = 0$ the bound is trivial. For $A \ge 1$, Legendre's formula $v_\ell(A!) = (A - S_\ell(A))/(\ell - 1)$, with $S_\ell(A) \ge 1$ the sum of the base-ℓ digits, gives $\mathrm{dsc}_{\ell,d}(0,s) \le A + (A-1)/(\ell-1) < A\ell/(\ell-1) \le s\ell/(d(\ell-1))$; an integer below a real number x is at most $\lfloor x \rfloor$.

Item 3. Put $m_1 = \lfloor s/d \rfloor$ and $m_0 = \lfloor j/d \rfloor$; as in item 2, $\mathrm{dsc}_{\ell,d}(j,s) = (m_1 - m_0) + v_\ell(m_1!) - v_\ell(m_0!)$. If $m_1 = m_0$ this is 0 and the bound holds. Otherwise $m_1 \ge 1$ and, by Legendre's formula,

$$\mathrm{dsc}_{\ell,d}(j,s) = (m_1 - m_0)\frac{\ell}{\ell-1} - \frac{S_\ell(m_1) - S_\ell(m_0)}{\ell - 1} \le (m_1 - m_0)\frac{\ell}{\ell-1} + 1 + \log_\ell s,$$

because $S_\ell(m_1) \ge 1$, and $S_\ell(m_0) \le (\ell-1)(1 + \log_\ell m_0)$ for $m_0 \ge 1$ (at most $1 + \log_\ell m_0$ digits, each at most $\ell - 1$) while $S_\ell(0) = 0$, and $m_0 \le s$. Finally $m_1 \le s/d$ and $m_0 \ge (j - d + 1)/d$ give $m_1 - m_0 \le (s - j + d - 1)/d$, so

$$\mathrm{dsc}_{\ell,d}(j,s) \le \frac{(s-j)\ell}{d(\ell-1)} + \frac{(d-1)\ell}{d(\ell-1)} + 1 + \log_\ell s < \frac{(s-j)\ell}{d(\ell-1)} + 2 + \log_\ell s,$$

since $(d-1)\ell < d(\ell-1)$, i.e. $d<\ell$. For $d=\ell-1$ these are the bounds stated for dsc_ℓ.

Level s. Write $\gamma=\gamma_D$, $Y=X_{s-1}$, $u=u_s$. (i) *Graded action.* $\gamma_u(1+Y)=\gamma_u((1+X)^{\ell^{s-1}})=(1+X)^{u\ell^{s-1}}=(1+Y)^u$, so $\gamma_u(Y)=(1+Y)^u-1=\sum_{k\geq 1}\binom{u}{k}Y^k=Y(u+Yt)$ with $t\in\mathbb{Z}_\ell[[X]]$. For $j\geq 0$ and $n\in N$, writing $\gamma(n)=n+Yn_1$ with $n_1\in N$,

$$\gamma(Y^j n)=Y^j(u+Yt)^j(n+Yn_1)\in u^jY^jn+Y^{j+1}N. \qquad (*)$$

(ii) *Eigenvalue gaps.* By item 1 of Lemma 23.22 ($p=\ell$, $m=s$, which is allowed as $s\geq 2$ if $\ell=2$), $u^k-1=\epsilon_k\ell^{s+v_\ell(k)}$ with $\epsilon_k\in\mathbb{Z}_\ell^\times$ for $k\geq 1$. (iii) *Item 4.* The descent step above holds with X replaced by Y: it uses only $\gamma_u(Y)=Y(u+Yt)$, $(\gamma-1)(N)\subseteq YN$, $(\gamma-1)(N')\subseteq YN'$ and the injectivity of Y on D; so if cY^{j+1} kills N/N' then $c(u^{j+1}-1)Y^j$ does. Induction downwards from $j+1=S$ shows that $\prod_{k=j+1}^{S}(u^k-1)\,Y^j=\epsilon\,\ell^{\mathrm{dsc}_\ell^{(s)}(j,S)}Y^j$ (ϵ a unit, by (ii)) kills N/N', hence so does every ℓ^aY^j with $a\geq \mathrm{dsc}_\ell^{(s)}(j,S)$. Finally $\mathrm{dsc}_\ell^{(s)}(0,S)=sS+\sum_{k\leq S}v_\ell(k)=sS+v_\ell(S!)$, and $v_\ell(S!)\leq S$ (Legendre). (iv) *Item 5.* We show by induction on $j=1,\dots,M$: there is $k_j\in YN$ with $\ell^{\sigma_j^{(s)}}z-(\gamma-1)(k_j)\in Y^jN$. For $j=1$ take $k_1=0$ ($\sigma_1^{(s)}=0$). Given k_j with $z_j=\ell^{\sigma_j^{(s)}}z-(\gamma-1)(k_j)\in Y^jN$, $j<M$, put $k'=\epsilon_j^{-1}z_j\in Y^jN\subseteq YN$; by $(*)$, $(\gamma-1)(k')\in\epsilon_j^{-1}(u^j-1)z_j+Y^{j+1}N=\ell^{s+v_\ell(j)}z_j+Y^{j+1}N$. So $k_{j+1}=\ell^{s+v_\ell(j)}k_j+k'$ gives $\ell^{\sigma_{j+1}^{(s)}}z-(\gamma-1)(k_{j+1})=\ell^{s+v_\ell(j)}z_j-(\gamma-1)(k')\in Y^{j+1}N$, as $\sigma_{j+1}^{(s)}=\sigma_j^{(s)}+s+v_\ell(j)$. Take $k=k_M$. (v) *Item 6.* Let $y\in Y^jN$ with $1\leq j<M$, say $y=Y^jn$. By $(*)$, $(\gamma-1)(y)\in(u^j-1)Y^jn+Y^{j+1}N$; as $(\gamma-1)(y)\in Y^MN\subseteq Y^{j+1}N$, we get $Y^j(u^j-1)n\in Y^{j+1}N$, hence $(u^j-1)n\in YN$ (Y is injective on D), hence $\ell^{s+v_\ell(j)}n\in YN$ by (ii), hence $n\in YN$ because N/YN has no ℓ-torsion; so $y\in Y^{j+1}N$. Induction from $j=1$ gives $y\in Y^MN$. For the example in the statement: if N is finite free over $\mathbf{A}_{F,L}=\prod_a e_a\mathbf{A}_{F,L}$, $e_a\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$, then N/YN is a finite direct sum of copies of $\mathcal{O}_L[[X]]/(Y)=\mathcal{O}_L[X]/(Y)$ (Weierstrass division by the distinguished polynomial Y), which is free over $\mathcal{O}_L$. □

Lemma 23.22. *Let p be a prime, $m\geq 1$ an integer with $m\geq 2$ if $p=2$, and $u\in\mathbb{Z}_p$ with $v_p(u-1)=m$.*

1. *For every non-zero integer n, $v_p(u^n-1)=m+v_p(n)$.*
2. *For an integer $e\geq 0$ and a finite set $J\subset\mathbb{Z}$, the polynomial*

$$P_{J,e}(X)=\prod_{i\in J\setminus\{0\}}(X^{p^e}-u^{ip^e})\cdot\sum_{k=0}^{p^e-1}X^k\in\mathbb{Z}_p[X]$$

   satisfies $v_p\big(P_{J,e}(1)\big)=e+\sum_{i\in J\setminus\{0\}}\big(e+m+v_p(i)\big)$.
3. *Let M be a $\mathbb{Z}_p$-module, A a $\mathbb{Z}_p$-linear endomorphism of M, $M'\subseteq M$ an A-stable submodule, $f\in\mathbb{Z}_p$ and $Q\in\mathbb{Z}_p[X]$. There is $Q_1\in\mathbb{Z}_p[X]$ with $Q(A)-Q(f)=Q_1(A)(A-f)$; in particular, if $w\in M$ and $(A-f)w\in M'$, then $Q(A)w-Q(f)w\in M'$.*

Proof. Item 1. As u is a unit and $u^{-n}-1=-u^{-n}(u^n-1)$, we may assume $n>0$; write $n=p^kn'$ with $p\nmid n'$. First, $u^{n'}-1=(u-1)(1+u+\cdots+u^{n'-1})$ and the second factor is $\equiv n'\not\equiv 0 \pmod p$, so $v_p(u^{n'}-1)=m$. Next, if $x\in\mathbb{Z}_p$ has $v_p(x)=t\geq 1$, then

$$(1+x)^p-1=px+\sum_{k=2}^{p-1}\binom{p}{k}x^k+x^p,$$

where $v_p(px) = t+1$, $v_p(\binom{p}{k}x^k) \geq 1+kt > t+1$ for $2 \leq k \leq p-1$, and $v_p(x^p) = pt \geq t+2$ because $(p-1)t \geq 2$ (if $p \geq 3$ since $t \geq 1$; if $p = 2$ since $t \geq m \geq 2$, the valuations met in the induction below being $m, m+1, \ldots$; for $p = 2$ the middle sum is empty); hence $v_p((1+x)^p - 1) = t+1$. Applying this k times, starting from $1 + x = u^{n'}$, gives $v_p(u^n - 1) = m + k = m + v_p(n)$.

Item 2. $P_{J,e}(1) = p^e \prod_{i \in J \setminus \{0\}} (1 - u^{ip^e})$, and by item 1 with $n = ip^e \neq 0$, $v_p(1 - u^{ip^e}) = m + e + v_p(i)$.

Item 3. $X - f$ divides $Q(X) - Q(f)$ in $\mathbb{Z}_p[X]$; write $Q(X) - Q(f) = Q_1(X)(X - f)$ and substitute A (polynomials in A commute). If $(A-f)w \in M'$, then $Q(A)w - Q(f)w = Q_1(A)((A-f)w) \in M'$, since M' is an A-stable $\mathbb{Z}_p$-submodule. □

Definition 23.23. Let ℓ be an odd prime and $\mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ the group of roots of unity of order dividing $\ell - 1$. For $a \in \mathbb{Z}_\ell$ write $(1+X)^a = \sum_{k \geq 0} \binom{a}{k} X^k \in \mathbb{Z}_\ell[[X]]$. Let $\Delta \subseteq \mu_{\ell-1}$ be a subgroup and call $e = (\ell-1)/|\Delta|$ its **ramification index**.

(Dr1) The group $\Gamma_\Delta = \{u \in \mathbb{Z}_\ell^\times : \ u \equiv \delta \pmod{\ell} \text{ for some } \delta \in \Delta\} = \Delta \cdot (1 + \ell\mathbb{Z}_\ell)$.

(Dr2) The invariant uniformiser

$$\pi_\Delta = \sum_{\delta \in \Delta} \big((1+X)^\delta - 1\big) \in \mathbb{Z}_\ell[[X]].$$

For $\Delta = \mu_{\ell-1}$ ($e = 1$) it is written

$$\pi_0 = \pi_{\mu_{\ell-1}} = \sum_{\delta \in \mu_{\ell-1}} (1+X)^\delta - (\ell - 1).$$

(Dr3) The Eisenstein polynomial Fix an algebraic closure $\overline{\mathbb{Q}}_\ell$. Let $S_\Delta \subset \overline{\mathbb{Q}}_\ell$ be the set of values $\pi_\Delta(\zeta - 1)$, ζ running over the primitive ℓ-th roots of unity in $\overline{\mathbb{Q}}_\ell$ (the series converges at $\zeta - 1$, which has positive valuation), and

$$E_\Delta(Y) = \prod_{y \in S_\Delta} (Y - y), \qquad q_\Delta = E_\Delta(\pi_\Delta).$$

(Dr4) The ring For a ring R on which the γ_u act (in particular $R = \mathcal{O}_L[[X]]$ with γ_u the $\mathcal{O}_L$-algebra automorphism with $\gamma_u(X) = (1+X)^u - 1$, or a site ring $e_a \mathbf{A}_{F,L}$), the **Δ-invariant Wach ring** is

$$R^\Delta = \{f \in R : \ \gamma_\delta(f) = f \text{ for every } \delta \in \Delta\}.$$

Lemma 23.24. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$, $R = \mathcal{O}_L[[X]]$, $\Delta \subseteq \mu_{\ell-1}$ a subgroup and $e = (\ell-1)/|\Delta|$.*

(Rr1) Uniformiser *$\gamma_\delta(\pi_\Delta) = \pi_\Delta$ for $\delta \in \Delta$, and $\pi_\Delta = X^{|\Delta|} v_\Delta$ with $v_\Delta \in \mathbb{Z}_\ell[[X]]^\times$, $v_\Delta(0) = 1/(|\Delta| - 1)!$.*

(Rr2) Variable *The $\mathcal{O}_L$-algebra homomorphism $\mathcal{O}_L[[T]] \to R$, $T \mapsto \pi_\Delta$, is injective with image R^Δ; that is, every $f \in R^\Delta$ is $g(\pi_\Delta)$ for a unique $g \in \mathcal{O}_L[[T]]$. Moreover $R^\Delta \cap XR = \pi_\Delta R^\Delta$.*

(Rr3) Eisenstein polynomial *$|S_\Delta| = e$, and $E_\Delta \in \mathbb{Z}_\ell[Y]$ is an Eisenstein polynomial of degree e. Every $y \in S_\Delta$ lies in the subfield $\mathbb{Q}_\ell(\mu_\ell)^\Delta$ of $\mathbb{Q}_\ell(\mu_\ell)$ fixed by the automorphisms $\zeta \mapsto \zeta^\delta$ ($\delta \in \Delta$, read modulo ℓ), which is totally ramified of degree e over $\mathbb{Q}_\ell$, and y is a uniformiser of it. For $\Delta = \mu_{\ell-1}$: $S_\Delta = \{-\ell\}$ and $E_\Delta(Y) = Y + \ell$, $q_\Delta = \pi_0 + \ell$.*

(Rr4) The ideal of Q $q_\Delta = Q\, w_\Delta$ *with* $w_\Delta \in \mathbb{Z}_\ell[[X]]^\times$.

(Rr5) Frobenius $\varphi(\pi_\Delta) = w'_\Delta\, \pi_\Delta\, q_\Delta^{|\Delta|}$ *with* $w'_\Delta \in \mathbb{Z}_\ell[[X]]^\times$.

(Rr6) Gamma *Let $u \in \Gamma_\Delta$. Then $\gamma_u(\pi_\Delta)$ is Δ-invariant and*

$$\gamma_u(\pi_\Delta) - \pi_\Delta = t_u\, \pi_\Delta\, q_\Delta, \qquad \gamma_u(q_\Delta) = h_u\, q_\Delta,$$

with $t_u \in \mathbb{Z}_\ell[[X]]$ and $h_u \in 1 + X\mathbb{Z}_\ell[[X]]$, both Δ-invariant. If moreover $v_\ell(u-1) = 1$, then $t_u \in \mathbb{Z}_\ell[[X]]^\times$.

(Rr7) The field *Let F be a finite unramified extension of $\mathbb{Q}_\ell$ inside $\overline{\mathbb{Q}}_\ell$ and $F \subseteq K \subseteq F(\mu_\ell)$ a field with $[K:F] = e$. Then $\chi(G_K) = \Gamma_\Delta$ and Δ is the torsion subgroup of $\chi(G_K)$; every $y \in S_\Delta$ lies in K and is a uniformiser of K, and E_Δ is its minimal polynomial over F.*

Proof. **Two standard facts.** (a) For $a \in \mathbb{Z}_\ell$, $\gamma_u((1+X)^a) = (1+X)^{ua}$ and $\gamma_u\gamma_{u'} = \gamma_{uu'}$: both hold for $a \in \mathbb{Z}_{\geq 0}$, and $a \mapsto (1+X)^a$ is continuous for the (ℓ, X)-adic topology, as are the ring endomorphisms γ_u ($\gamma_u(X) \in X\mathbb{Z}_\ell[[X]]$). Likewise $(1+x)^a = \zeta^n$ for every integer $n \equiv a \pmod{\ell}$, since $(1+x)^a$ is continuous in a, equals ζ^a for $a \in \mathbb{Z}_{\geq 0}$, and ζ^n depends only on n modulo ℓ. We write ζ^a for this value. (b) *Divisibility criterion.* If $h \in \mathbb{Z}_\ell[[X]]$, $\bar{h}$ has X-adic order exactly $\ell - 1$, and $h(\zeta - 1) = 0$ for all $\ell - 1$ primitive ζ, then $h \in Q\,\mathbb{Z}_\ell[[X]]^\times$: by Weierstrass preparation $h = P\,w$ with w a unit and P distinguished of degree $\ell - 1$; $w(\zeta - 1)$ is a unit, so P vanishes at the $\ell - 1$ distinct roots of the monic Q of degree $\ell - 1$, and $P = Q$. Similarly, if $g \in \mathbb{Z}_\ell[[X]]$ vanishes at all $\zeta - 1$, then $g \in Q\,\mathbb{Z}_\ell[[X]]$: Weierstrass division $g = Qt + r$ by the distinguished polynomial Q leaves $r \in \mathbb{Z}_\ell[X]$ of degree $< \ell - 1$ with $\ell - 1$ distinct roots, so $r = 0$.

(Rr1). By (a), $\gamma_{\delta'}(\pi_\Delta) = \sum_{\delta \in \Delta}((1+X)^{\delta'\delta} - 1) = \pi_\Delta$ for $\delta' \in \Delta$, as $\delta \mapsto \delta'\delta$ permutes Δ. The constant term of π_Δ is 0; for $k \geq 1$ its coefficient of X^k is

$$\sum_{\delta \in \Delta} \binom{\delta}{k} = \frac{1}{k!} \sum_{i=1}^{k} s(k,i) \sum_{\delta \in \Delta} \delta^i,$$

with $s(k,i)$ the Stirling numbers of the first kind. Since Δ is cyclic of order $|\Delta|$, $\sum_{\delta \in \Delta} \delta^i$ is $|\Delta|$ if $|\Delta| \mid i$ and 0 otherwise. For $1 \leq k \leq |\Delta|$ (so $k! \in \mathbb{Z}_\ell^\times$, as $|\Delta| < \ell$) only $k = i = |\Delta|$ contributes, giving the coefficient 0 for $k < |\Delta|$ and $|\Delta|/|\Delta|! = 1/(|\Delta| - 1)! \in \mathbb{Z}_\ell^\times$ for $k = |\Delta|$. So $\pi_\Delta = X^{|\Delta|} v_\Delta$ with $v_\Delta(0) = 1/(|\Delta| - 1)!$ a unit.

(Rr2). $R^\Delta \cap XR = \pi_\Delta R^\Delta$. The inclusion $\supseteq$ holds by (Rr1). Let $f \in R^\Delta \cap XR$, $f \neq 0$, with term of least degree $a_i X^i$, $i \geq 1$. As $\gamma_\delta(X) = \delta X + X^2(\dots)$, the term of least degree of $\gamma_\delta(f) = f$ is $\delta^i a_i X^i$, so $\delta^i = 1$ for all $\delta \in \Delta$ ($\mathcal{O}_L$ is a domain), and $|\Delta|$ divides i. Hence $f \in X^{|\Delta|}R = \pi_\Delta R$; as π_Δ is Δ-invariant and R is a domain, $f/\pi_\Delta \in R^\Delta$. *Image.* The homomorphism $T \mapsto \pi_\Delta$ is well defined as $\pi_\Delta \in XR$, and its image lies in R^Δ by continuity of the γ_δ. Conversely, for $f \in R^\Delta$ put $f_0 = f$, $c_j = f_j(0) \in \mathcal{O}_L$, $f_{j+1} = (f_j - c_j)/\pi_\Delta \in R^\Delta$ (previous paragraph). Then $f - \sum_{j<m} c_j \pi_\Delta^j = \pi_\Delta^m f_m \in X^{|\Delta|m}R$ for every m, so $f = \sum_j c_j \pi_\Delta^j$. *Injectivity.* If $\sum_j c_j \pi_\Delta^j = 0$ with some $c_j \neq 0$ and j_0 is the least such j, then $c_{j_0}\pi_\Delta^{j_0}$ has X-adic order exactly $|\Delta| j_0$ (leading coefficient $c_{j_0} v_\Delta(0)^{j_0} \neq 0$) while the other terms lie in $X^{|\Delta|(j_0+1)}R$; a contradiction.

(Rr3). Let ζ be primitive, $x = \zeta - 1$, so $v(x) = 1/(\ell - 1)$, and put $y_\zeta = \pi_\Delta(x)$. By (Rr1), $y_\zeta = x^{|\Delta|} v_\Delta(x)$ with $v_\Delta(x) \equiv v_\Delta(0)$ modulo the maximal ideal, a unit; so $v(y_\zeta) = |\Delta|/(\ell - 1) = 1/e$. By (a), $y_\zeta = \sum_{\delta \in \Delta}(\zeta^\delta - 1)$. For $a \in (\mathbb{Z}/\ell)^\times$ let $\sigma_a \in \mathrm{Gal}(\mathbb{Q}_\ell(\zeta)/\mathbb{Q}_\ell)$ be $\zeta \mapsto \zeta^a$ (an isomorphism $(\mathbb{Z}/\ell)^\times \to \mathrm{Gal}$, Φ_ℓ being irreducible over $\mathbb{Q}_\ell$). Since π_Δ has coefficients in $\mathbb{Z}_\ell$ and σ_a is continuous, $\sigma_a(y_\zeta) = y_{\zeta^a} = \sum_\delta(\zeta^{a\delta} - 1)$, which equals y_ζ when $a \equiv \delta' \pmod{\ell}$ with $\delta' \in \Delta$

(permutation of Δ). Reduction modulo ℓ is an isomorphism $\mu_{\ell-1} \to (\mathbb{Z}/\ell)^\times$, so the fixed field $F_\Delta = \mathbb{Q}_\ell(\zeta)^\Delta$ of the image of Δ has degree $(\ell-1)/|\Delta| = e$ over $\mathbb{Q}_\ell$; it is totally ramified because $\mathbb{Q}_\ell(\zeta)$ is. So $y_\zeta \in F_\Delta$ with $v(y_\zeta) = 1/e$: y_ζ is a uniformiser of F_Δ, hence $\mathbb{Q}_\ell(y_\zeta)$ has ramification index e and equals F_Δ. Its e conjugates $\sigma_a(y_\zeta) = y_{\zeta^a}$ (a modulo the image of Δ) are therefore distinct, and as ζ^a runs over all primitive roots they exhaust S_Δ (which does not depend on ζ). So $|S_\Delta| = e$ and E_Δ is the minimal polynomial of the uniformiser y_ζ of the totally ramified extension $F_\Delta/\mathbb{Q}_\ell$, which is an Eisenstein polynomial in $\mathbb{Z}_\ell[Y]$. For $\Delta = \mu_{\ell-1}$, $y_\zeta = \sum_{a=1}^{\ell-1} \zeta^a - (\ell-1) = -1-(\ell-1) = -\ell$.

(Rr4). The series $q_\Delta = E_\Delta(\pi_\Delta) \in \mathbb{Z}_\ell[[X]]$ vanishes at every $\zeta - 1$, since $\pi_\Delta(\zeta-1) \in S_\Delta$. Modulo ℓ, $E_\Delta(Y) \equiv Y^e$ (Eisenstein), so $\bar{q}_\Delta = \bar{\pi}_\Delta^e = X^{e|\Delta|}\bar{v}_\Delta^e = X^{\ell-1}\bar{v}_\Delta^e$ has X-adic order exactly $\ell-1$. By (b), $q_\Delta = Q\,w_\Delta$ with w_Δ a unit.

(Rr5). We have $\varphi(X) = (1+X)^\ell - 1 = XQ$, and $\varphi(v_\Delta)$ is a unit (its constant term is $v_\Delta(0)$, as $\varphi(X)(0) = 0$). So, by (Rr1) and (Rr4),

$$\varphi(\pi_\Delta) = X^{|\Delta|}Q^{|\Delta|}\varphi(v_\Delta) = \pi_\Delta\, q_\Delta^{|\Delta|} \cdot v_\Delta^{-1} w_\Delta^{-|\Delta|}\varphi(v_\Delta).$$

(Rr6). By (a), $\gamma_\delta\gamma_u = \gamma_u\gamma_\delta$, so γ_u maps Δ-invariant elements to Δ-invariant elements; in particular $\gamma_u(\pi_\Delta)$ and $\gamma_u(q_\Delta)$ are Δ-invariant. Write $\gamma_u(X) = X\,c_u$ with $c_u = u + X(\dots) \in \mathbb{Z}_\ell[[X]]^\times$; then $\gamma_u(\pi_\Delta) = \pi_\Delta m_u$ with $m_u = c_u^{|\Delta|}\gamma_u(v_\Delta)v_\Delta^{-1} \in \mathbb{Z}_\ell[[X]]^\times$, Δ-invariant (quotient of Δ-invariants in the domain $\mathbb{Z}_\ell[[X]]$). Let $u \equiv \delta_u \pmod{\ell}$ with $\delta_u \in \Delta$. By (a), $\gamma_u(\pi_\Delta)(\zeta-1) = \pi_\Delta(\zeta^u - 1) = \sum_\delta(\zeta^{\delta_u\delta} - 1) = \pi_\Delta(\zeta-1)$, which is non-zero by (Rr3); so $m_u - 1$ vanishes at every $\zeta - 1$. By (b) and (Rr4), $m_u - 1 = t_u\, q_\Delta$ with $t_u \in \mathbb{Z}_\ell[[X]]$, Δ-invariant as m_u and q_Δ are. This is the first identity. Next, $\gamma_u(q_\Delta) = E_\Delta(\gamma_u(\pi_\Delta))$ vanishes at every $\zeta - 1$ (its value there is $E_\Delta(\pi_\Delta(\zeta-1)) = 0$), and $\overline{\gamma_u(q_\Delta)} = \gamma_u(\bar{q}_\Delta) = (Xc_u)^{\ell-1}\gamma_u(\bar{v}_\Delta)^e$ has X-adic order $\ell-1$; by (b) and (Rr4), $\gamma_u(q_\Delta) = q_\Delta h_u$ with h_u a unit, Δ-invariant. Since $\gamma_u(f) \equiv f \pmod{X}$ for $f \in \mathbb{Z}_\ell[[X]]$, $q_\Delta(h_u - 1) \in X\mathbb{Z}_\ell[[X]]$; as $q_\Delta(0) = E_\Delta(0) \neq 0$ and X is prime, $h_u \in 1 + X\mathbb{Z}_\ell[[X]]$. Finally let $v_\ell(u-1) = 1$. Evaluating $m_u - 1 = t_u q_\Delta$ at $X = 0$: $m_u(0) = u^{|\Delta|}$ and $q_\Delta(0) = E_\Delta(0)$ has valuation 1 (Eisenstein). Now $u^{|\Delta|} - 1 = (u-1)(1 + u + \dots + u^{|\Delta|-1})$ and the second factor is $\equiv |\Delta| \not\equiv 0 \pmod{\ell}$, so $v_\ell(u^{|\Delta|} - 1) = 1$ and $t_u(0)$ is a unit; hence t_u is a unit.

(Rr7). As $F/\mathbb{Q}_\ell$ is unramified and $\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ is totally ramified, $F \cap \mathbb{Q}_\ell(\mu_{\ell^\infty}) = \mathbb{Q}_\ell$, so restriction identifies $\mathrm{Gal}(F(\mu_{\ell^\infty})/F)$ with $\mathrm{Gal}(\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell)$ and $\chi(G_F) = \mathbb{Z}_\ell^\times$. Since $K \subseteq F(\mu_\ell)$, $\chi(G_K)$ is a subgroup of index $[K:F] = e$ of $\mathbb{Z}_\ell^\times$ containing $\chi(G_{F(\mu_\ell)}) = 1 + \ell\mathbb{Z}_\ell$. Since $\mathbb{Z}_\ell^\times/(1+\ell\mathbb{Z}_\ell) \cong (\mathbb{Z}/\ell)^\times$ is cyclic, it has exactly one subgroup of index e, the image of Δ; so $\chi(G_K) = \Delta \cdot (1+\ell\mathbb{Z}_\ell) = \Gamma_\Delta$, whose torsion subgroup is Δ ($1+\ell\mathbb{Z}_\ell$ is torsion-free for odd ℓ). For $\sigma \in G_K$ and $y = \pi_\Delta(\zeta-1) \in S_\Delta$, $\sigma(y) = \pi_\Delta(\zeta^{\chi(\sigma)} - 1) = y$ as in (Rr6), so $y \in K$. The extension K/F is totally ramified of degree e (inside the totally ramified $F(\mu_\ell)/F$) and $v(y) = 1/e$ by (Rr3), so y is a uniformiser of K. The polynomial E_Δ is Eisenstein over $\mathcal{O}_F$ as well (ℓ is a uniformiser of F), hence irreducible over F, and it is the minimal polynomial of y over F. □

Lemma 23.25. *Let p be a prime, K and L finite extensions of $\mathbb{Q}_p$, and $\Phi\colon V \to V''$ an L-linear G_K-equivariant surjection of finite-dimensional L-vector spaces with continuous L-linear actions of G_K, with V de Rham as a $\mathbb{Q}_p$-representation. Then V'' is de Rham, and for every $\mathbb{Q}_p$-embedding $\tau\colon K \to L$ every Hodge jump of V'' at τ is a Hodge jump of V at τ.*

Proof. By Fontaine's theory, de Rham representations are stable under quotients, and on de Rham representations the functor D_{dR} is exact and strictly compatible with the filtrations (Fontaine, Représentations p-adiques semi-stables, 1994; Brinon–Conrad, CMI notes on p-adic Hodge theory, §6.3). So V'' is de Rham, and for every j the map $\mathrm{Fil}^j D_{\mathrm{dR}}(V) \to \mathrm{Fil}^j D_{\mathrm{dR}}(V'')$ induced by Φ is onto; hence so is $\mathrm{gr}^j D_{\mathrm{dR}}(V) \to \mathrm{gr}^j D_{\mathrm{dR}}(V'')$. These maps are $K \otimes_{\mathbb{Q}_p} L$-linear. As

$K/\mathbb{Q}_p$ is separable, $K\otimes_{\mathbb{Q}_p}L$ is a finite product of fields, and $\tau\otimes\mathrm{id}\colon K\otimes_{\mathbb{Q}_p}L\to L$ is the projection onto one of them; so $L\otimes_{K\otimes L,\tau\otimes\mathrm{id}}(-)$ is multiplication by an idempotent ϵ_τ, which is exact and carries Fil^j and gr^j of D_{dR} to those of $D_{\mathrm{dR},\tau}$. Hence $\mathrm{gr}^jD_{\mathrm{dR},\tau}(V)\to\mathrm{gr}^jD_{\mathrm{dR},\tau}(V'')$ is onto for every j. An integer a is a Hodge jump of V'' at τ exactly when $\mathrm{gr}^aD_{\mathrm{dR},\tau}(V'')=\mathrm{Fil}^a/\mathrm{Fil}^{a+1}\neq 0$; then $\mathrm{gr}^aD_{\mathrm{dR},\tau}(V)\neq 0$, i.e. a is a Hodge jump of V at τ. □

23.4 Bloch–Kato classes as crystalline extensions

This subsection connects Wach modules with Galois cohomology, and it is what lets the later sections work with Wach vectors in place of classes. A class in H^1_f is the class of a crystalline extension by the trivial lattice, with the Hodge jumps of the lattice together with 0 (Lemma 23.26). Such a class is the Herr class of the Frobenius defect of a lift (Lemma 23.32), where Herr classes of Wach vectors are made explicit in Lemma 23.28. Conversely, the integral crystalline criterion Proposition 23.27 says that a Herr vector of precision at least $1+\max_a M_a$ whose poles lie only at finitely many Q_s has a Bloch–Kato class. The proof trivialises the Γ-part of such a vector crystallinely (Proposition 23.31), which rests on the contraction of Frobenius on $X^m\mathbf{N}$ (Lemma 23.30). The criterion is used by both lifting exponents of Section 24 and by the relay classes there, and again in Section 27 and Appendix C.

Lemma 23.26. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F\subseteq K\subseteq F(\mu_\ell)$ be as in Proposition 23.7, (V,T) a pair over K, $H^1_f(K,T)$ the inverse image in $H^1(K,T)$ of $H^1_f(K,V)=\ker\bigl(H^1(K,V)\to H^1(K,B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)\bigr)$, and $x\in H^1_f(K,T)$. Then there are a pair (V_Y,Y) over K and an exact sequence $0\to T\xrightarrow{\iota'}Y\xrightarrow{\pi}\mathcal{O}_L\to 0$ of G_K-equivariant $\mathcal{O}_L$-linear maps ($\mathcal{O}_L$ the trivial representation) with $[Y]=x$, where $[Y]\in H^1(K,T)$ is the class of the cocycle $g\mapsto\iota'^{-1}(g\tilde e-\tilde e)$ for any $\tilde e\in Y$ with $\pi(\tilde e)=1$, such that for every $a\in\mathbb{Z}/n$ and every embedding τ of K over τ_a, every Hodge jump of V_Y at τ is 0 or a Hodge jump of V at τ. In particular, if $M_a,h_a\geq 0$ are integers such that every Hodge jump of V at every embedding of K over τ_a lies in $[-M_a,h_a]$, the same holds for V_Y. For $K=F$ this is the statement with pairs, G_F, $H^1_f(F,T)$ and the embeddings τ_a. **Level s.** The same holds for any prime ℓ, an integer $s\geq 1$ with $s\geq 2$ if $\ell=2$, L and K ($F\subseteq K\subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7; for $s=1$ and ℓ odd this is the statement above.*

Proof. **The extension.** Let $\xi\colon G_K\to T$ be a continuous cocycle representing x. Put $Y=T\oplus\mathcal{O}_L$ with $g(t,a)=(gt+a\,\xi(g),a)$, $\iota'(t)=(t,0)$, $\pi(t,a)=a$; the cocycle relation makes this a continuous $\mathcal{O}_L$-linear action, Y is a G_K-stable lattice in $V_Y=Y\otimes_{\mathcal{O}_L}L$, and ι', π are equivariant with $0\to T\to Y\to\mathcal{O}_L\to 0$ exact. With $\tilde e=(0,1)$ we get $g\tilde e-\tilde e=\iota'(\xi(g))$, so $[Y]=x$.

V_Y is crystalline. Put $D_{\mathrm{cris}}(W)=(B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}W)^{G_K}$, an $F\otimes_{\mathbb{Q}_\ell}L$-module ($B_{\mathrm{cris}}^{G_K}$ is the maximal unramified subextension of K, which is F, as $K\subseteq F(\mu_\ell)$ is totally ramified over F). Since B_{cris} is flat over $\mathbb{Q}_\ell$, $0\to B_{\mathrm{cris}}\otimes V\to B_{\mathrm{cris}}\otimes V_Y\to B_{\mathrm{cris}}\otimes L\to 0$ is exact, and taking invariants gives the exact sequence of $F\otimes L$-modules

$$0\to D_{\mathrm{cris}}(V)\to D_{\mathrm{cris}}(V_Y)\to D_{\mathrm{cris}}(L)\xrightarrow{\delta}H^1(K,B_{\mathrm{cris}}\otimes V),$$

with δ $F\otimes L$-linear. $D_{\mathrm{cris}}(L)=F\otimes L$ is generated by $1\otimes 1$, which lifts to $1\otimes\tilde e$; $g(1\otimes\tilde e)-1\otimes\tilde e=1\otimes\xi(g)$, so $\delta(1\otimes 1)$ is the image of x in $H^1(K,B_{\mathrm{cris}}\otimes V)$, which vanishes because the image of x in $H^1(K,V)$ lies in $H^1_f(K,V)$. Hence $\delta=0$ and $\dim_F D_{\mathrm{cris}}(V_Y)=\dim_F D_{\mathrm{cris}}(V)+\dim_F(F\otimes L)=\dim_{\mathbb{Q}_\ell}V+\dim_{\mathbb{Q}_\ell}L=\dim_{\mathbb{Q}_\ell}V_Y$, as V is crystalline. So V_Y is crystalline, and (V_Y,Y) is a pair over K.

Hodge jumps. V, V_Y, L are crystalline, hence de Rham. On de Rham representations the functor D_{dR} is exact and strictly compatible with the filtrations (Fontaine), so for every j

the sequences $0 \to \mathrm{gr}^j D_{\mathrm{dR}}(V) \to \mathrm{gr}^j D_{\mathrm{dR}}(V_Y) \to \mathrm{gr}^j D_{\mathrm{dR}}(L) \to 0$ are exact; they are sequences of $K \otimes_{\mathbb{Q}_\ell} L$-modules, and $K \otimes_{\mathbb{Q}_\ell} L \cong \prod_\tau L$ over the $\mathbb{Q}_\ell$-embeddings $\tau\colon K \to L$ (L contains $\sigma(F(\mu_\ell)) \supseteq \sigma(K)$ for every embedding σ), so they stay exact after applying the idempotent of an embedding τ, which gives $\mathrm{gr}^j D_{\mathrm{dR},\tau}$. As $\mathrm{gr}^j D_{\mathrm{dR}}(L) = 0$ for $j \neq 0$, a $j \neq 0$ with $\mathrm{gr}^j D_{\mathrm{dR},\tau}(V_Y) \neq 0$ has $\mathrm{gr}^j D_{\mathrm{dR},\tau}(V) \neq 0$. The last assertion follows because $0 \in [-M_a, h_a]$.

Level s. The proof uses two properties of K and L and nothing about ℓ: $B_{\mathrm{cris}}^{G_K} = F$, the maximal unramified subextension of K, which holds because $K \subseteq F(\mu_{\ell^s})$ is totally ramified over F ($\mathbb{Q}_\ell(\mu_{\ell^s})/\mathbb{Q}_\ell$ is totally ramified and $F/\mathbb{Q}_\ell$ unramified); and $L \supseteq \sigma(K)$ for every embedding σ of K, which holds because $L \supseteq \sigma(F(\mu_{\ell^s}))$ for every embedding of $F(\mu_{\ell^s})$ and every embedding of K extends to one of $F(\mu_{\ell^s})$. So the proof applies without change. □

Proposition 23.27. *Let ℓ, F, L, (τ_a) and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $(M_a, h_a)_a$ a window of V as in (Ex1) and $m \geq 1 + \max_a M_a$. If $y \in \mathbf{N}[1/\lambda_\infty]$ is a Herr vector of precision m and $fy \in \mathbf{N}$ for some finite product f of the Q_s, $s \geq 0$, then $\mathrm{cl}(y) \in H^1_f(F,T)$.*
Over a base field. *Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$ and Γ_K as in Definition 23.2, (V,T) a pair over K as in Proposition 23.7, $(M_a, h_a)_a$ a window as in (Ex1) over K, $m \geq 1 + \max_a M_a$, and y a Herr vector of precision m over K (Lemma 23.28, over a base field) with $fy \in \mathbf{N}$ for a finite product f of the Q_s. Then $\mathrm{cl}(y) \in H^1_f(K,T)$, the inverse image in $H^1(K,T)$ of $H^1_f(K,V) = \ker(H^1(K,V) \to H^1(K, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V))$. For $K = F$ this is the statement above.*
Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and a pair (V,T) over K as in (Ex4) of Proposition 23.7, $\mathbf{N} = \mathbf{N}_s(T)$, $(M_a, h_a)_a$ a window of V as in (Ex1) of level s, $m \geq 1 + \max_a M_a$, and $y \in \mathbf{N}[1/\lambda_\infty]$ a Herr vector of precision m at level s (Lemma 23.28, paragraph Level s) with $fy \in \mathbf{N}$ for a finite product f of the Q_j with $j \geq s-1$. Then its Herr class satisfies $\mathrm{cl}(y) \in H^1_f(K,T)$. For $s = 1$ and ℓ odd this is the paragraph over a base field.*

Proof. Write $\mu = \mu_\varepsilon$ and φ for $\varphi \otimes 1$; fix a $\mathbb{Z}_\ell$-basis of T, so that all equations below in $A_{\mathrm{inf}} \otimes T$ or $W(\mathbb{C}_\ell^\flat) \otimes T$ are coordinatewise.

Step 1: the poles of $\iota_T(y)$. Since $\iota(\varphi(X)) = \varphi(\mu)$ and $\varphi(X) = XQ$, we have $\varphi(\mu) = \mu\tilde{\xi}$ with $\tilde{\xi} = \iota(Q)$, hence $\iota(Q_s) = \varphi^s(\tilde{\xi}) = \varphi^{s+1}(\mu)/\varphi^s(\mu)$ in the domain $W(\mathbb{C}_\ell^\flat)$, where all $\varphi^j(\mu)$ are units (their reductions $(\varepsilon - 1)^{\ell^j}$ are non-zero). Write $f = \prod_s Q_s^{k_s}$. By (Gc0) and (Gc1), $\iota_T(y) = \iota(f)^{-1}\iota_T(fy)$ and $\mu^\kappa \iota_T(fy) \in A_{\mathrm{inf}} \otimes T$, so

$$P_0\, \iota_T(y) \in A_{\mathrm{inf}} \otimes T, \qquad P_0 = \mu^\kappa \prod_s \varphi^{s+1}(\mu)^{k_s}.$$

Step 2: an Artin–Schreier solution with poles. We have $\varphi^i(\mu) \mid \varphi^j(\mu)$ in A_{inf} for $i \leq j$ (apply φ^i to $\varphi^{j-i}(\mu) = \mu \prod_{r<j-i} \varphi^r(\tilde{\xi})$). Let $J = 1 + \max\{s : k_s \neq 0\}$ (or $J = 1$), $c = \kappa + \sum_s k_s$ and $P' = \big(\prod_{j=0}^{J} \varphi^j(\mu)\big)^c$. Then $\varphi(P') = \big(\prod_{j=1}^{J+1} \varphi^j(\mu)\big)^c = P'R$ with $R = (\varphi^{J+1}(\mu)/\mu)^c \in A_{\mathrm{inf}}$, and $P_0 \mid \varphi(P')$ in A_{inf} (each factor μ^κ, $\varphi^{s+1}(\mu)^{k_s}$ divides a corresponding power of some $\varphi^j(\mu)$, $1 \leq j \leq J+1$, and c exceeds the total exponent). Put $a' = (\varphi(P')/P_0)\, P_0 \iota_T(y) \in A_{\mathrm{inf}} \otimes T$. We solve $\varphi(b_0) - Rb_0 = a'$ with $b_0 \in A_{\mathrm{inf}} \otimes T$, coordinatewise: for $a \in A_{\mathrm{inf}}$ with reduction $\bar{a} \in \mathcal{O}_{\mathbb{C}_\ell^\flat}$, the monic polynomial $Y^\ell - \bar{R}Y - \bar{a}$ has a root t_0 in the algebraically closed field $\mathbb{C}_\ell^\flat$, integral since $\mathcal{O}_{\mathbb{C}_\ell^\flat}$ is integrally closed; as reduction modulo ℓ is a ring homomorphism $A_{\mathrm{inf}} \to \mathcal{O}_{\mathbb{C}_\ell^\flat}$ carrying φ to the ℓ-th power map, $\varphi([t_0]) - R[t_0] - a \in \ell A_{\mathrm{inf}}$, say $= -\ell a_1$; repeating with a_1 and summing, $b_0 = \sum_i \ell^i [t_i]$ converges (A_{inf} is ℓ-adically complete) and solves the equation. Put $b = P'^{-1} b_0 \in W(\mathbb{C}_\ell^\flat) \otimes T$. Then

$$(\varphi - 1)(b) = \varphi(P')^{-1}\big(\varphi(b_0) - Rb_0\big) = \varphi(P')^{-1} a' = \iota_T(y).$$

Step 3: the ring S. Let $S \subseteq W(\mathbb{C}_\ell^\flat)$ be the subring generated by A_{inf} and the $\varphi^j(\mu)^{-1}$, $j \geq 0$. By Lemma 23.12(Ac2) it is stable under φ and G_F, and the inclusion $A_{\mathrm{inf}} \subset B_{\mathrm{cris}}$ extends uniquely to a ring homomorphism $\rho_S \colon S \to B_{\mathrm{cris}}$, equivariant for φ and G_F; it extends ρ of Proposition 23.31, since both restrict to the inclusion on A_{inf} and $A_{\mathrm{inf}}[1/\mu] \subseteq S$ is a localisation of A_{inf}.

Step 4: the class is crystalline. Let $u = \chi_{\mathrm{cyc}}(\sigma)$ and $z_u = z_u(y)$. By (Gc1), $\iota_T(z_u) \in \mu^{-\kappa} A_{\mathrm{inf}} \otimes T \subseteq S \otimes T$, and $b \in S \otimes T$, so $c_{y,b}(\sigma) = \iota_T(z_u) - (\sigma - 1)(b)$, which lies in T (Lemma 23.28(Hc1)), is an identity in $S \otimes T$. Applying the G_F-equivariant map $\rho_S \otimes 1 \colon S \otimes_{\mathbb{Z}_\ell} T \to B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T = B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V$, which is the identity on T, and Proposition 23.31,

$$c_{y,b}(\sigma) = (\sigma - 1)(\beta) - (\sigma - 1)(\rho_S(b)) = (\sigma - 1)\big(\beta - \rho_S(b)\big) \qquad (\sigma \in G_F).$$

So the image of the cocycle $c_{y,b}$ in $H^1(F, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)$ is 0, i.e. the image of $\mathrm{cl}(y)$ in $H^1(F, V)$ lies in $H^1_f(F, V)$, and $\mathrm{cl}(y) \in H^1_f(F, T)$.

Over a base field. For a pair over K: Steps 1 and 2 are statements in $A_{\mathrm{inf}} \otimes T$ and $W(\mathbb{C}_\ell^\flat) \otimes T$ that use only (Gc0), (Gc1) (which Lemma 23.29 gives over K), the ring identities $\iota(Q_s) = \varphi^{s+1}(\mu)/\varphi^s(\mu)$ and the Artin–Schreier solution in A_{inf}; no Galois group enters. Step 3: S and ρ_S are G_F-equivariant, hence G_K-equivariant. Step 4 runs with $\sigma \in G_K$, $u = \chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$: (Gc1) over K, (Hc1) of Lemma 23.28 over K ($c_{y,b}(\sigma) \in T$ for $\sigma \in G_K$), and Proposition 23.31 over K give $c_{y,b}(\sigma) = (\sigma - 1)(\beta - \rho_S(b))$ for $\sigma \in G_K$; so the image of $\mathrm{cl}(y)$ in $H^1(K, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)$ is 0 and $\mathrm{cl}(y) \in H^1_f(K, T)$. No step uses that the base is unramified.

Level s. Let the data be as in the paragraph Level s of the statement, $\sigma \in G_K$, $u = \chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$. Step 1: write $f = \prod_{k \geq 0} Q_{s-1+k}^{c_k}$. By Lemma 23.8(6), ι_s commutes with the Frobenius lifts and $\iota_s(Q_{s-1}) = \tilde{\xi} = \varphi(\mu)/\mu$, so $\iota_s(Q_{s-1+k}) = \varphi^k(\tilde{\xi}) = \varphi^{k+1}(\mu)/\varphi^k(\mu)$; with (Gc0), (Gc1) of level s (Lemma 23.29, paragraph Level s; pole factor μ^κ) this gives $P_0\, \iota_{s,T}(y) \in A_{\mathrm{inf}} \otimes T$ with $P_0 = \mu^\kappa \prod_k \varphi^{k+1}(\mu)^{c_k}$. Step 2 goes through unchanged with $J = 1 + \max\{k : c_k \neq 0\}$ (or $J = 1$), $c = \kappa + \sum_k c_k$ and $\iota_{s,T}$ in place of ι_T; the Artin–Schreier argument holds for every prime (the polynomial $Y^\ell - \bar{R}Y - \bar{a}$ has a root in $\mathbb{C}_\ell^\flat$). Step 3: S and ρ_S exist for every prime and are G_F-, hence G_K-equivariant (Lemma 23.12, paragraph Every prime), and ρ_S extends ρ. Step 4: by (Gc1) of level s, $\iota_{s,T}(z_u) \in \mu^{-\kappa} A_{\mathrm{inf}} \otimes T \subseteq S \otimes T$; by (Hc1) of Lemma 23.28, paragraph Level s, $c_{y,b}(\sigma) = \iota_{s,T}(z_u) - (\sigma - 1)(b) \in T$; and Proposition 23.31, paragraph Level s (which applies: y and f satisfy its hypotheses), gives β with $(\sigma - 1)(\beta) = (\rho \otimes 1)(\iota_{s,T}(z_u))$. Applying $\rho_S \otimes 1$, $c_{y,b}(\sigma) = (\sigma - 1)(\beta - \rho_S(b))$ for every $\sigma \in G_K$, so the image of $\mathrm{cl}(y)$ in $H^1(K, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)$ is 0 and $\mathrm{cl}(y) \in H^1_f(K, T)$. □

Lemma 23.28. *Let ℓ, F, L, (τ_a) and a pair (V, T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, let $(M_a, h_a)_a$ be a window of V as in (Ex1), and let $m \geq 1 + \max_a M_a$ be an integer. Call $y \in \mathbf{N}[1/\lambda_\infty]$ a* Herr vector of precision m *if $(\gamma_u - 1)(y) \in X^m \mathbf{N}$ for every $u \in \mathbb{Z}_\ell^\times$; for such y and u let $z_u(y)$ be the unique element of $X^m \mathbf{N}$ with $(\varphi - 1)(z_u(y)) = (\gamma_u - 1)(y)$ (it exists and is unique by Lemma 23.30(2)). Then:*

(Hc1) The class *For a Herr vector y of precision m there is $b \in W(\mathbb{C}_\ell^\flat) \otimes_{\mathbb{Z}_\ell} T$ with $(\varphi \otimes 1 - 1)(b) = \iota_T(y)$. For every such b, the map*

$$c_{y,b} \colon G_F \to W(\mathbb{C}_\ell^\flat) \otimes_{\mathbb{Z}_\ell} T, \qquad c_{y,b}(\sigma) = \iota_T\big(z_{\chi_{\mathrm{cyc}}(\sigma)}(y)\big) - (\sigma - 1)(b),$$

takes values in T and is a continuous 1-cocycle; its class $\mathrm{cl}(y) \in H^1(F, T)$ (the Herr class *of y) does not depend on b, nor on m (if y has precision $m' \geq m$ too).*

(Hc2) One generator suffices *If $y \in \mathbf{N}[1/\lambda_\infty]$ and $(\gamma_u - 1)(y) \in X^m \mathbf{N}$ for all u in a subset of $\mathbb{Z}_\ell^\times$ generating a dense subgroup (for instance a topological generator of $\mathbb{Z}_\ell^\times$, or $\mu_{\ell-1}$ together with a topological generator of $1 + \ell\mathbb{Z}_\ell$), then y is a Herr vector of precision m.*

(Hc3) Additivity *Herr vectors of precision m form an $\mathcal{O}_L$-submodule of $\mathbf{N}[1/\lambda_\infty]$, and* cl *is $\mathcal{O}_L$-linear on it.*

(Hc4) Coboundaries *If $w \in \mathbf{N}[1/\lambda_\infty]$ and $(\gamma_u - 1)(w) \in X^m\mathbf{N}$ for all u, then $(\varphi - 1)(w)$ is a Herr vector of precision m, $z_u((\varphi-1)(w)) = (\gamma_u - 1)(w)$, and $\mathrm{cl}((\varphi-1)(w)) = 0$. In particular every $y \in X^m\mathbf{N}$ is a Herr vector of precision m with $\mathrm{cl}(y) = 0$.*

(Hc5) Naturality *Let (V', T') be another pair with window (M'_a, h'_a), $m \geq 1 + \max_a M'_a$, and $f\colon T \to T'$ a G_F-equivariant $\mathcal{O}_L$-linear map. Then $\mathbf{N}(f)$, extended $\mathbf{A}_{F,L}$-linearly to $\mathbf{N}[1/\lambda_\infty]$, carries Herr vectors of precision m to Herr vectors of precision m, with $z_u(\mathbf{N}(f)(y)) = \mathbf{N}(f)(z_u(y))$ and $\mathrm{cl}(\mathbf{N}(f)(y)) = f_*\,\mathrm{cl}(y)$.*

Over a base field. *Let K be a field with $F \subseteq K \subseteq F(\mu_\ell)$ and Γ_K as in Definition 23.2. For pairs over K as in Proposition 23.7, (Hc1)–(Hc5) hold with u ranging over Γ_K instead of $\mathbb{Z}_\ell^\times$ (in the definition of Herr vectors and of $z_u(y)$, and in (Hc4)), G_F replaced by G_K, $H^1(F,-)$ by $H^1(K,-)$ and G_F-equivariant maps by G_K-equivariant ones; in (Hc2) the subset is one of Γ_K generating a dense subgroup of Γ_K. For $K = F$ this is the statement above.*

Level s. *Let ℓ be any prime, $s \geq 1$ with $s \geq 2$ if $\ell = 2$, and L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7; let $\mathbf{N} = \mathbf{N}_s(T)$, $(M_a, h_a)_a$ a window of V as in (Ex1) of level s, $m \geq 1 + \max_a M_a$, and $X_{s-1} = \varphi^{s-1}(X)$ the level variable of Definition 23.2. Call $y \in \mathbf{N}[1/\lambda_\infty]$ a* Herr vector of precision m at level s *if $(\gamma_u - 1)(y) \in X_{s-1}^m\mathbf{N}$ for every $u \in \Gamma_K$, and let $z_u(y)$ be the unique element of $X_{s-1}^m\mathbf{N}$ with $(\varphi-1)(z_u(y)) = (\gamma_u - 1)(y)$ (Lemma 23.30, Level s). Then (Hc1)–(Hc5), in the form over a base field, hold for Herr vectors of precision m at level s, with $\mathbf{N}(T)$, ι_T, $\mathbf{N}(f)$ replaced by $\mathbf{N}_s(T)$, $\iota_{s,T}$, $\mathbf{N}_s(f)$ and $X^m\mathbf{N}$ by $X_{s-1}^m\mathbf{N}$ throughout (also in (Hc2), (Hc4), (Hc5)); in (Hc5) the second pair is a pair over K with $\mathbf{N}_s(T')$. For $s = 1$ and ℓ odd this is the paragraph over a base field.*

Proof. Write φ for $\varphi \otimes 1$ on $W(\mathbb{C}_\ell^\flat) \otimes_{\mathbb{Z}_\ell} T$; it commutes with the diagonal action of G_F. T is free of finite rank over $\mathbb{Z}_\ell$; fix a $\mathbb{Z}_\ell$-basis, so $W(\mathbb{C}_\ell^\flat) \otimes T$ is a finite power of $W(\mathbb{C}_\ell^\flat)$ with φ acting coordinatewise. For $x \in W(\mathbb{C}_\ell^\flat)$ write $x = \sum_{i \geq 0} \ell^i [x_i]$ (unique, $\mathbb{C}_\ell^\flat$ being perfect); then $\varphi(x) = \sum \ell^i [x_i^\ell]$.

Artin–Schreier. (a) $W(\mathbb{C}_\ell^\flat)^{\varphi=1} = \mathbb{Z}_\ell$: $\varphi(x) = x$ forces $x_i^\ell = x_i$, so $x_i \in \mathbb{F}_\ell$ and $x \in W(\mathbb{F}_\ell) = \mathbb{Z}_\ell$. Hence $(W(\mathbb{C}_\ell^\flat) \otimes T)^{\varphi=1} = T$. (b) $\varphi - 1$ is onto $W(\mathbb{C}_\ell^\flat)$: given a, choose $t_0 \in \mathbb{C}_\ell^\flat$ with $t_0^\ell - t_0 = a_0$ ($\mathbb{C}_\ell^\flat$ is algebraically closed); then $a - (\varphi - 1)[t_0] \in \ell W(\mathbb{C}_\ell^\flat)$ because $[t_0^\ell] - [t_0] \equiv [t_0^\ell - t_0]$ modulo ℓ; iterating and using that $W(\mathbb{C}_\ell^\flat)$ is ℓ-adically complete and separated gives t with $(\varphi - 1)t = a$. Hence $\varphi - 1$ is onto $W(\mathbb{C}_\ell^\flat) \otimes T$.

(Hc1): values in T and the cocycle identity. Let y be a Herr vector of precision m and $z_u = z_u(y)$. A b exists by (b). For $u, v \in \mathbb{Z}_\ell^\times$, $z_u + \gamma_u(z_v) \in X^m\mathbf{N}$ ($\gamma_u(X) \in X\mathbf{A}_F$) and, as γ_u commutes with φ (Wm3) and $\gamma_u\gamma_v = \gamma_{uv}$,

$$(\varphi - 1)(z_u + \gamma_u(z_v)) = (\gamma_u - 1)(y) + \gamma_u(\gamma_v - 1)(y) = (\gamma_{uv} - 1)(y),$$

so $z_{uv} = z_u + \gamma_u(z_v)$ by uniqueness. Let $\sigma, \tau \in G_F$, $u = \chi_{\mathrm{cyc}}(\sigma)$, $v = \chi_{\mathrm{cyc}}(\tau)$. By (Gc0), $\iota_T \circ \varphi = \varphi \circ \iota_T$ and $\sigma \circ \iota_T = \iota_T \circ \gamma_u$, so

$$(\varphi - 1)(c_{y,b}(\sigma)) = \iota_T((\gamma_u - 1)(y)) - (\sigma - 1)(\varphi - 1)(b) = (\sigma - 1)\iota_T(y) - (\sigma - 1)\iota_T(y) = 0,$$

and $c_{y,b}(\sigma) \in T$ by (a). Also $c_{y,b}(\sigma\tau) = \iota_T(z_u) + \sigma\iota_T(z_v) - (\sigma - 1)(b) - \sigma(\tau - 1)(b) = c_{y,b}(\sigma) + \sigma c_{y,b}(\tau)$.

(Hc1): continuity. By the cocycle identity, $c_{y,b}(\sigma\tau) - c_{y,b}(\sigma) = \sigma c_{y,b}(\tau)$, and G_F acts continuously on T, so it suffices to show: for every $n \geq 1$ there is an open subgroup $U \subseteq G_F$

with $c_{y,b}(U) \subseteq \ell^n T$. Give $W_n(\mathbb{C}_\ell^\flat) = W(\mathbb{C}_\ell^\flat)/\ell^n$ the product topology of the valuation topology on its n Witt coordinates. The Witt addition and multiplication are given by integral polynomials in the coordinates, so $W_n(\mathbb{C}_\ell^\flat)$ is a topological ring; G_F acts coordinatewise, continuously since it acts continuously on $\mathbb{C}_\ell^\flat$ [94]; for an ideal I of $\mathcal{O}_{\mathbb{C}_\ell^\flat}$, $W_n(I)$ (coordinates in I) is an ideal of $W_n(\mathcal{O}_{\mathbb{C}_\ell^\flat})$ and $W_n(I)W_n(J) \subseteq W_n(IJ)$ (each coordinate of a product is isobaric of positive degree in both arguments); and $W_n(\mathbb{F}_\ell) = \mathbb{Z}/\ell^n$ is discrete, since a non-zero element has a coordinate in $\mathbb{F}_\ell^\times$. Equip $W_n(\mathbb{C}_\ell^\flat) \otimes T$ with the product topology via the fixed basis; then T/ℓ^n is discrete in it. Now: (i) $\sigma \mapsto (\sigma-1)(b)$ modulo ℓ^n is continuous, with value 0 at $\sigma = 1$. (ii) Let $k \geq 0$. By (Gc3) of Lemma 23.29 (applicable since $(\gamma_u - 1)(y) \in X^m\mathbf{N} \subseteq \mathbf{N}$) there is s with $(\gamma_u - 1)(y) \in (\ell, X)^{k+m}\mathbf{N} \cap X^m\mathbf{N}$ for $u \in 1 + \ell^s\mathbb{Z}_\ell$; in coordinates of $\mathcal{O}_L[[X]]$-bases of the $\mathbf{N}_a$, additivity of the (ϖ, X)-order (ϖ a uniformiser of $\mathcal{O}_L$) shows that this intersection lies in $(\varpi, X)^k X^m\mathbf{N}$. By Lemma 23.30(1), φ maps $(\varpi, X)^k X^m\mathbf{N}$ into itself, and $z_u = -\sum_{j\geq 0} \varphi^j((\gamma_u - 1)(y))$ (Lemma 23.30(2)) lies in this closed submodule. Let K be as in (Gc1), so that $\mu_\varepsilon^K \iota_T(\mathbf{N}) \subseteq A_{\mathrm{inf}} \otimes T$, and let $\iota_L = \iota \otimes \mathrm{id}\colon \mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \to A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ ($\mathcal{O}_L$ is finite free over $\mathbb{Z}_\ell$), a ring homomorphism with $\iota_L(\varpi) = 1 \otimes \varpi$ and $\iota_L(X) = \iota(X) = \mu_\varepsilon$ (Lemma 23.8); by (Ex2), $\iota_T(gx) = \iota_L(g)\iota_T(x)$ for $g \in \mathbf{A}_{F,L}$ and $x \in \mathbf{N}$. Every element of $(\varpi, X)^k X^m\mathbf{N}$ is a finite sum of products gx with $g \in (\varpi, X)^k$ and $x \in \mathbf{N}$, so $\mu_\varepsilon^K \iota_T(z_u) \in (\varpi, \mu_\varepsilon)^k(A_{\mathrm{inf}} \otimes T)$; and for $k \geq en$, e the ramification index of L, $(\varpi, \mu_\varepsilon)^k \subseteq \ell^n(A_{\mathrm{inf}} \otimes \mathcal{O}_L) + \mu_\varepsilon^{k-en}(A_{\mathrm{inf}} \otimes \mathcal{O}_L)$ (a monomial $\varpi^i\mu_\varepsilon^{k-i}$ with $i \geq en$ lies in $\ell^n(\dots)$). Modulo ℓ^n, $\mu_\varepsilon = [\varepsilon] - 1$ has all its coordinates in the maximal ideal (its image in $W(\bar{\mathbb{F}}_\ell)$ is 0), hence of valuation $\geq c$ for some $c > 0$ (finitely many coordinates), so $\mu_\varepsilon^r W_n(\mathcal{O}_{\mathbb{C}_\ell^\flat}) \subseteq W_n(\{v \geq rc\})$, and μ_ε^{-K} is a fixed unit of $W_n(\mathbb{C}_\ell^\flat)$. Hence $\iota_T(z_{\chi_{\mathrm{cyc}}(\sigma)}) \to 0$ in $W_n(\mathbb{C}_\ell^\flat) \otimes T$ as $\chi_{\mathrm{cyc}}(\sigma) \to 1$, i.e. along an open subgroup of G_F. By (i) and (ii), $c_{y,b}(\sigma)$ modulo ℓ^n tends to 0 as $\sigma \to 1$; it lies in the discrete subset T/ℓ^n, so it is 0 on an open subgroup.

(Hc1): independence. Two solutions b, b' differ by an element of $(W(\mathbb{C}_\ell^\flat) \otimes T)^{\varphi=1} = T$, and $c_{y,b'} = c_{y,b} - (\sigma \mapsto (\sigma-1)(b'-b))$ differs by a coboundary. If y has precision $m' \geq m$, the element z_u defined in $X^{m'}\mathbf{N} \subseteq X^m\mathbf{N}$ is the unique solution in $X^m\mathbf{N}$, so the cocycle is the same.

(Hc2). Let S be the set of $u \in \mathbb{Z}_\ell^\times$ with $(\gamma_u - 1)(y) \in X^m\mathbf{N}$. It is a subgroup: $(\gamma_{uv} - 1)(y) = \gamma_u(\gamma_v - 1)(y) + (\gamma_u - 1)(y)$, $(\gamma_{u^{-1}} - 1)(y) = -\gamma_{u^{-1}}(\gamma_u - 1)(y)$, and γ_u preserves $X^m\mathbf{N}$. It is closed: write $y = x/f$ with $x \in \mathbf{N}$, f a product of Q_s's, $v_w = f/\gamma_w(f)$. For $u \in \bar{S}$ choose $u_i \in S$ with $w_i = u_i^{-1}u \to 1$. Then $f(\gamma_u - 1)(y) - f(\gamma_{u_i} - 1)(y) = f\gamma_{u_i}(\gamma_{w_i} - 1)(y)$, and $f(\gamma_w - 1)(y) = v_w(\gamma_w - 1)(x) + (v_w - 1)x \to 0$ in $\mathbf{N}$ as $w \to 1$: the first term by (Gc3) applied to $x \in \mathbf{N}$ (v_w is a unit), the second because $v_w - 1 \in (\ell, X)^{s+1-\deg f}$ for $w \in 1 + \ell^s\mathbb{Z}_\ell$, where $\deg f$ is the number of factors Q_t of f. Indeed, for such w, $\gamma_w(X) - X = (1+X)((1+X)^{w-1} - 1) \in (\ell, X)^{s+1}\mathbb{Z}_\ell[[X]]$, hence $\gamma_w(g) - g \in (\ell, X)^{s+1}$ for $g \in \mathbb{Z}_\ell[[X]]$; in the regular local ring $\mathbb{Z}_\ell[[X]]$ the (ℓ, X)-adic order is additive, each Q_t has order 1 ($Q_t(0) = \ell$), and $\gamma_w(f) \in f\,\mathbb{Z}_\ell[[X]]^\times$ (Lemma 23.8(2)), so f and $\gamma_w(f)$ have order $\deg f$ and $v_w - 1 = (f - \gamma_w(f))/\gamma_w(f)$ has order at least $s + 1 - \deg f$; $\gamma_{u_i}(f)/f$ is a unit, so $f\gamma_{u_i}(\gamma_{w_i} - 1)(y) \to 0$ as well. Hence $f(\gamma_u - 1)(y)$ is a limit of elements of $fX^m\mathbf{N}$, a finitely generated submodule of the finitely generated module $\mathbf{N}$ over the noetherian (ℓ, X)-adically complete ring $\mathbf{A}_{F,L}$, hence closed. So $f(\gamma_u - 1)(y) \in fX^m\mathbf{N}$, and $(\gamma_u - 1)(y) \in X^m\mathbf{N}$ since f is a non-zero-divisor on $\mathbf{N}[1/\lambda_\infty]$. A closed subgroup containing a set that generates a dense subgroup is $\mathbb{Z}_\ell^\times$. ($\mathbb{Z}_\ell^\times = \mu_{\ell-1} \times (1 + \ell\mathbb{Z}_\ell)$ is procyclic for ℓ odd.)

(Hc3). If y_1, y_2 are Herr vectors and $\lambda \in \mathcal{O}_L$, then $y_1 + \lambda y_2$ is one (γ_u is $\mathcal{O}_L$-linear), $z_u(y_1 + \lambda y_2) = z_u(y_1) + \lambda z_u(y_2)$ by uniqueness, $b_1 + (1 \otimes \lambda)b_2$ solves the equation for $y_1 + \lambda y_2$ (ι_T is $\mathcal{O}_L$-linear by (Ex2)), and $c_{y_1+\lambda y_2, b_1+\lambda b_2} = c_{y_1,b_1} + \lambda c_{y_2,b_2}$ since G_F acts $\mathcal{O}_L$-linearly on T.

(Hc4). Put $y = (\varphi - 1)(w)$. Then $(\gamma_u - 1)(y) = (\varphi - 1)((\gamma_u - 1)(w)) \in X^m\mathbf{N}$, because φ maps $X^m\mathbf{N}$ into $X^m\mathbf{N}$ (Lemma 23.30(1)); so y is a Herr vector, and $z_u(y) = (\gamma_u - 1)(w)$ by uniqueness. Take $b = \iota_T(w)$, which satisfies $(\varphi - 1)(b) = \iota_T(y)$ by (Gc0); then $c_{y,b}(\sigma) = \iota_T((\gamma_u - 1)(w)) - (\sigma - 1)\iota_T(w) = 0$ by (Gc0). If $y \in X^m\mathbf{N}$, apply this to $w = -\sum_{j\geq 0} \varphi^j(y) \in X^m\mathbf{N}$,

which satisfies $(\varphi-1)(w)=y$ (Lemma 23.30(2)); $(\gamma_u-1)(w)\in X^m\mathbf{N}$ since γ_u preserves $X^m\mathbf{N}$.

(Hc5). $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ and all γ_u (Ex3), so its extension to $\mathbf{N}[1/\lambda_\infty]$ commutes with them too and maps $X^m\mathbf{N}$ into $X^m\mathbf{N}'$; hence it maps Herr vectors to Herr vectors and, by uniqueness in $X^m\mathbf{N}'$, $z_u(\mathbf{N}(f)(y))=\mathbf{N}(f)(z_u(y))$. As $\iota_{T'}\circ\mathbf{N}(f)=(1\otimes f)\circ\iota_T$ on $\mathbf{N}$ (Ex3), and both sides are ι-semilinear, the identity extends to $\mathbf{N}[1/\lambda_\infty]$. If b solves the equation for y, then $b'=(1\otimes f)(b)$ solves it for $\mathbf{N}(f)(y)$, and $c_{\mathbf{N}(f)(y),b'}(\sigma)=(1\otimes f)(c_{y,b}(\sigma))=f(c_{y,b}(\sigma))$, since $1\otimes f$ commutes with φ and G_F. So $\mathrm{cl}(\mathbf{N}(f)(y))=f_*\mathrm{cl}(y)$.

Over a base field. For pairs over K the proof is unchanged, with $\sigma,\tau\in G_K$, $u=\chi_{\mathrm{cyc}}(\sigma)\in\Gamma_K$, (Gc0) and (Gc3) of Lemma 23.29 over K (its closing paragraph), and the continuity of the action of $G_K\subseteq G_F$ on $\mathbb{C}_\ell^\flat$ and on T; in the continuity step, $\chi_{\mathrm{cyc}}(\sigma)\to1$ along an open subgroup of G_K. In (Hc2), S is a closed subgroup of Γ_K (same argument, with (Gc3) over K) containing a set that generates a dense subgroup of Γ_K, so $S=\Gamma_K$.

Level s. The proof over a base field applies with the replacements of the statement; we list what it uses and where the level-s form comes from. The Artin–Schreier facts (a), (b) do not involve $\mathbf{N}$. The existence, uniqueness and formula of z_u, that φ maps $X^m_{s-1}\mathbf{N}$ into itself and that γ_u preserves it, are Lemma 23.30, Level s; $\gamma_u\gamma_v=\gamma_{uv}$ and the commutation of γ_u with φ are (Wm3) of level s; (Gc0), (Gc1), (Gc3) are those of Lemma 23.29, Level s, with $\iota_{s,T}$ and the ideal $(\ell,\mu_{\varepsilon,s})$. The one step that changes is in the continuity of (Hc1): given k, (Gc3) gives $(\gamma_u-1)(y)\in(\ell,X)^{k'}\mathbf{N}\cap X^m_{s-1}\mathbf{N}$ with $k'=k+\ell^{s-1}m$ for u near 1; in coordinates of $\mathcal{O}_L[[X]]$-bases of the $\mathbf{N}_a$, an element $X^m_{s-1}c$ of $(\varpi,X)^{k'}$ has $c\in(\varpi,X)^{k'-m\ell^{s-1}}=(\varpi,X)^k$, because the (ϖ,X)-order is additive and that of X_{s-1} is at most ℓ^{s-1} (its monomial $X^{\ell^{s-1}}$ has coefficient 1). So $(\gamma_u-1)(y)\in(\varpi,X)^kX^m_{s-1}\mathbf{N}$, a closed submodule mapped into itself by φ, which therefore contains z_u; then $\mu_\varepsilon^\kappa\iota_{s,T}(z_u)\in(\varpi,\mu_{\varepsilon,s})^k(A_{\mathrm{inf}}\otimes T)$ by (Gc1) of level s and the semilinearity argument above, with $\iota_L=\iota_s\otimes\mathrm{id}$, $\iota_s(X)=\mu_{\varepsilon,s}$ (Lemma 23.8(6)) and (Ex2) of level s, and modulo ℓ^n the element $\mu_{\varepsilon,s}$, whose image in $W(\bar{\mathbb{F}}_\ell)$ is 0, has all its Witt coordinates of positive valuation; the rest of the step is unchanged. In (Hc2) the closedness argument uses (Gc3) of level s and that $fX^m_{s-1}\mathbf{N}$ is a finitely generated, hence closed, submodule of $\mathbf{N}$; (Hc4) uses $\varphi(X^m_{s-1}\mathbf{N})\subseteq X^m_{s-1}\mathbf{N}$; (Hc5) uses (Ex3) of level s. The clause (Wm3') is not used. □

Lemma 23.29. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $d=\dim_L V$, and $\mathbf{N}=\mathbf{N}(T)$ with $\varphi=\varphi_{\mathbf{N}}$, $\gamma_u=\gamma_{u,\mathbf{N}}$ and ι_T. Write (ℓ,X) for the ideal of $\mathbf{A}_{F,L}$ generated by ℓ and X, and (ℓ,μ_ε) for the ideal of A_{inf} generated by ℓ and μ_ε.*

(Gc0) Extension to poles *For f a finite product of the Q_s ($s\geq0$) and $x\in\mathbf{N}$, the formulas $\gamma_u(x/f)=\gamma_u(x)/\gamma_u(f)$ and $\iota_T(x/f)=\iota(f)^{-1}\iota_T(x)$ give a well-defined γ_u-semilinear action on $\mathbf{N}[1/\lambda_\infty]$ and a well-defined additive injective map $\iota_T\colon\mathbf{N}[1/\lambda_\infty]\to W(\mathbb{C}_\ell^\flat)\otimes_{\mathbb{Z}_\ell}T$, and for $y\in\mathbf{N}[1/\lambda_\infty]$, $\sigma\in G_F$:*

$$\sigma(\iota_T(y))=\iota_T(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}(y)),\qquad(\varphi\otimes1)(\iota_T(y))=\iota_T(\varphi(y)).$$

(Gc1) Bounded poles *There is an integer $\kappa\geq0$ with $\mu_\varepsilon^\kappa\iota_T(\mathbf{N})\subseteq A_{\mathrm{inf}}\otimes_{\mathbb{Z}_\ell}T$; for such κ, $\mu_\varepsilon^\kappa\iota_T((\ell,X)^k\mathbf{N})\subseteq(\ell,\mu_\varepsilon)^k(A_{\mathrm{inf}}\otimes_{\mathbb{Z}_\ell}T)$ for every $k\geq0$.*

(Gc2) Strictness *For κ as in (Gc1) and every $k\geq0$ there is $j\geq0$ such that every $x\in\mathbf{N}$ with $\mu_\varepsilon^\kappa\iota_T(x)\in(\ell,\mu_\varepsilon)^j(A_{\mathrm{inf}}\otimes_{\mathbb{Z}_\ell}T)$ lies in $(\ell,X)^k\mathbf{N}$.*

(Gc3) Continuity *If $y\in\mathbf{N}[1/\lambda_\infty]$ and $(\gamma_u-1)(y)\in\mathbf{N}$ for every $u\in\mathbb{Z}_\ell^\times$, then for every $k\geq0$ there is $s\geq1$ such that $(\gamma_u-1)(y)\in(\ell,X)^k\mathbf{N}$ for all $u\in1+\ell^s\mathbb{Z}_\ell$.*

Over a base field. *Let K be a field with $F\subseteq K\subseteq F(\mu_\ell)$ and Γ_K as in Definition 23.2. For a pair (V,T) over K as in Proposition 23.7, (Gc0)–(Gc3) hold with G_F replaced by G_K and $\mathbb{Z}_\ell^\times$*

by Γ_K (in (Gc0) for $\sigma \in G_K$; in (Gc3) the hypothesis is for every $u \in \Gamma_K$, and the conclusion for $u \in 1+\ell^s\mathbb{Z}_\ell$, s large, which lies in Γ_K). For $K = F$ this is the statement above.

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, and L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and pairs (V,T) over K as in (Ex4) of Proposition 23.7; let $\mathbf{N} = \mathbf{N}_s(T)$ with its maps and $\iota_{s,T}$, and $\mu_{\varepsilon,s} = [\varepsilon^{1/\ell^{s-1}}] - 1$ and ι_s as in Lemma 23.8(6). Then (Gc0)–(Gc3) hold, in the form over a base field, with $\mathbf{N}(T)$, ι_T, ι replaced by $\mathbf{N}_s(T)$, $\iota_{s,T}$, ι_s, and with the ideal (ℓ, μ_ε) replaced by $(\ell, \mu_{\varepsilon,s})$ in (Gc1) and (Gc2); the pole factor μ_ε^κ in (Gc1), (Gc2) is unchanged. For $s = 1$ and ℓ odd ($\mu_{\varepsilon,1} = \mu_\varepsilon$) this is the paragraph over a base field.*

Proof. Throughout, $R = A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, a free A_{inf}-module of rank $[L : \mathbb{Q}_\ell]$, and ϖ is a uniformiser of $\mathcal{O}_L$, e the ramification index of $L/\mathbb{Q}_\ell$; T is free over $\mathcal{O}_L$ of rank d, so $A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} T = R \otimes_{\mathcal{O}_L} T \cong R^d$ after the choice of an $\mathcal{O}_L$-basis of T, which we fix. If $d = 0$ everything is trivial; let $d \geq 1$.

Topologies. The (ℓ, μ_ε)-adic topology of A_{inf} is the topology of (Ai2): modulo ℓ, μ_ε reduces to $\varepsilon - 1$, of valuation $\ell/(\ell-1) \in (1,2]$, and $p^\flat$ has valuation 1, so $(\ell, \mu_\varepsilon) \subseteq (\ell, [p^\flat])$ and $[p^\flat]^2 \in (\ell, \mu_\varepsilon)$. Hence A_{inf} and R are (ℓ, μ_ε)-adically complete and separated, and G_F acts continuously on A_{inf} for this topology (Ai2). Let $\iota_L \colon \mathbf{A}_{F,L} = (\mathcal{O}_F \otimes \mathcal{O}_L)[[X]] \to R$ be $\sum_k c_k X^k \mapsto \sum_k (\iota \otimes \mathrm{id})(c_k)\mu_\varepsilon^k$ (convergent). It is a ring homomorphism extending ι and $\lambda \mapsto 1 \otimes \lambda$.

(Gc0). By Lemma 23.8(2), $\gamma_u(Q_s) \in Q_s \mathbb{Z}_\ell[[X]]^\times$, so $\gamma_u(f) \in f\,\mathbb{Z}_\ell[[X]]^\times$ and $\gamma_u(x)/\gamma_u(f) \in \mathbf{N}[1/\lambda_\infty]$; if $x/f = x'/f'$ then $f'x = fx'$ ($\mathbf{N}$ is torsion-free, being free over the product of the domains $\mathcal{O}_L[[X]]$ by (Wm1)), so the formula is well defined, and it is semilinear. By Lemma 23.8(4), $\iota(Q_s) = \varphi^s(\iota(Q)) = \varphi^s(\tilde{\xi})$, whose reduction modulo ℓ is $(\varepsilon - 1)^{\ell^s(\ell-1)} \neq 0$ in the field $\mathbb{C}_\ell^\flat$, so it is a unit of $W(\mathbb{C}_\ell^\flat)$; the extension of ι_T is well defined as before and injective because ι_T is (Ex2). For $\sigma \in G_F$ with $u = \chi_{\mathrm{cyc}}(\sigma)$, (Ex2) and $\sigma \circ \iota = \iota \circ \gamma_u$ (Lemma 23.8(4)) give $\sigma(\iota(f)^{-1}\iota_T(x)) = \iota(\gamma_u(f))^{-1}\iota_T(\gamma_u(x)) = \iota_T(\gamma_u(x/f))$; similarly $\varphi \circ \iota = \iota \circ \varphi$ (ι is a morphism of prisms, hence of δ-rings) and (Ex2) give the second identity.

ι_T is ι_L-semilinear. Since $\mathcal{O}_L$ is finite free over $\mathbb{Z}_\ell$, $\mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, so every $g \in \mathbf{A}_{F,L}$ is a finite sum $\sum_j f_j \otimes \lambda_j$ with $f_j \in \mathbf{A}_F = \mathcal{O}_F[[X]]$, $\lambda_j \in \mathcal{O}_L$, and $\iota_L(g) = \sum_j \iota(f_j) \otimes \lambda_j$. By (Ex2), $\iota_T(fx) = \iota(f)\iota_T(x)$ for $f \in \mathbf{A}_F$ and $\iota_T(\lambda x) = (1 \otimes \lambda)\iota_T(x)$; hence $\iota_T(gx) = \iota_L(g)\iota_T(x)$ for all $g \in \mathbf{A}_{F,L}$, $x \in \mathbf{N}$. Let κ be such that $\mu_\varepsilon^\kappa \iota_T(x_i) \in A_{\mathrm{inf}} \otimes T$ for a finite generating set (x_i) of $\mathbf{N}$ (it exists since $\iota_T(\mathbf{N}) \subseteq A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T$ by (Ex2)).

(Gc1). With κ as above, semilinearity gives $\mu_\varepsilon^\kappa \iota_T(\mathbf{N}) = \sum_i \iota_L(\mathbf{A}_{F,L})\mu_\varepsilon^\kappa \iota_T(x_i) \subseteq A_{\mathrm{inf}} \otimes T$, and $\iota_L((\ell, X)^k) \subseteq (\ell, \mu_\varepsilon)^k R$ gives the second claim.

(Gc2): the sites. Put $\epsilon_a = \iota_L(e_a)$, orthogonal idempotents of R with sum 1, and

$$\iota_a \colon \mathcal{O}_L[[X]] \cong e_a \mathbf{A}_{F,L} \to \epsilon_a R$$

the restriction of ι_L. Let $n_{a,1}, \ldots, n_{a,d}$ be an $e_a\mathbf{A}_{F,L}$-basis of $\mathbf{N}_a$ ((Wm1) with $r = d$ by (Ex1)). Multiplying $A_{\mathrm{inf}}[1/\mu_\varepsilon] \cdot \iota_T(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T$ (Ex2) by ϵ_a and using $\epsilon_a \iota_T(\mathbf{N}) = \iota_T(\mathbf{N}_a)$ gives $\epsilon_a R[1/\mu_\varepsilon]^d = \sum_i \epsilon_a R[1/\mu_\varepsilon]\,\iota_T(n_{a,i})$. A surjective endomorphism of a finitely generated module over a commutative ring is bijective, so the matrix A_a with columns $\iota_T(n_{a,i})$ lies in $\mathrm{GL}_d(\epsilon_a R[1/\mu_\varepsilon])$; fix κ' with $\mu_\varepsilon^{\kappa'} A_a^{-1} \in M_d(\epsilon_a R)$ for all a. If $x = \sum_{a,i} c_{a,i} n_{a,i}$ and $\mu_\varepsilon^\kappa \iota_T(x) \in (\ell, \mu_\varepsilon)^j R^d$, then $\epsilon_a \mu_\varepsilon^\kappa \iota_T(x) = A_a\,(\iota_a(X^\kappa c_{a,i}))_i$, hence

$$\iota_a\big(X^{\kappa+\kappa'} c_{a,i}\big) \in \epsilon_a(\ell, \mu_\varepsilon)^j R \subseteq \epsilon_a(\varpi, \mu_\varepsilon)^j R \qquad \text{for all } a, i.$$

(Gc2): strictness of ι_a. Claim: if $g \in \mathcal{O}_L[[X]]$ and $\iota_a(g) \in (\varpi, \mu_\varepsilon)^j R$, then $g \in (\varpi, X)^j$. Modulo ϖ, $R/\varpi R = A_{\mathrm{inf}}/\ell \otimes_{\mathbb{F}_\ell} k_L = \mathcal{O}_{\mathbb{C}_\ell^\flat} \otimes_{\mathbb{F}_\ell} k_L \cong \prod_\rho \mathcal{O}_{\mathbb{C}_\ell^\flat}$, the product over the embeddings $\rho \colon k_L \to \mathcal{O}_{\mathbb{C}_\ell^\flat}$ ($k_L/\mathbb{F}_\ell$ is separable and the residue field of $\mathcal{O}_{\mathbb{C}_\ell^\flat}$ is algebraically closed). The idempotent ϵ_a reduces to the indicator of a set S_a of factors, non-empty ($\epsilon_a \neq 0$ since $\iota_T(n_{a,1}) \neq 0$,

and an idempotent in ϖR is 0 because R is ϖ-adically separated). In a factor $\rho \in S_a$, $\iota_a(\bar{g})$ for $\bar{g} = \sum_{k \geq m} a_k X^k$, $a_m \neq 0$, is $(\varepsilon-1)^m(\rho(a_m)+(\varepsilon-1)(\cdots))$, of valuation exactly $m\ell/(\ell-1)$, while the reduction of $(\varpi, \mu_\varepsilon)^j R$ is $(\varepsilon-1)^j(R/\varpi R)$, of valuation $\geq j\ell/(\ell-1)$ in every factor. So $m \geq j$, i.e. $g = X^j g_0 + \varpi g_1$ with $g_0, g_1 \in \mathcal{O}_L[[X]]$, and $\iota_a(\varpi g_1) \in (\varpi, \mu_\varepsilon)^j R$. If $\varpi w = \sum_{i=0}^{j} \varpi^i \mu_\varepsilon^{j-i} r_i$ in R, then $\mu_\varepsilon^j r_0 \in \varpi R$; as $\varepsilon - 1$ is a non-zero-divisor of $R/\varpi R$, $r_0 \in \varpi R$, and since R is ϖ-torsion-free, $w \in (\varpi, \mu_\varepsilon)^{j-1} R$. So $\iota_a(g_1) \in (\varpi, \mu_\varepsilon)^{j-1} R$ and the claim follows by induction on j.

(Gc2): conclusion. The ring $\mathcal{O}_L[[X]]$ is regular local with maximal ideal (ϖ, X), so its associated graded ring is a polynomial ring over k_L in two variables, a domain, and the (ϖ, X)-adic order is additive. From the claim, $X^{\kappa+\kappa'} c_{a,i} \in (\varpi, X)^j$, hence $c_{a,i} \in (\varpi, X)^{j-\kappa-\kappa'}$. Finally $(\varpi, X)^{ek} \subseteq (\ell, X)^k$: a monomial $\varpi^i X^{ek-i}$ with $i = eq + r$, $0 \leq r < e$, equals a unit times $\ell^q \varpi^r X^{ek-i}$, and $q + (ek - i) \geq k$ since $(e-1)(k-q) \geq r$ when $q < k$ (and $r = 0$ when $q = k$). So $j = ek + \kappa + \kappa'$ works.

(Gc3). Write $y = x/f$ with $x \in \mathbf{N}$ and f a product of Q_s's. For $u \in 1 + \ell^s \mathbb{Z}_\ell$, $\gamma_u(X) - X = (1+X)((1+X)^{u-1}-1) \in (\ell, X)^{s+1}\mathbb{Z}_\ell[[X]]$, hence $\gamma_u(g) - g \in (\ell, X)^{s+1}$ for $g \in \mathbb{Z}_\ell[[X]]$; since each Q_t has (ℓ, X)-order 1 ($Q_t(0) = \ell$) and the order is additive on $\mathbb{Z}_\ell[[X]]$, the unit $v_u = f/\gamma_u(f)$ satisfies $v_u - 1 = (f - \gamma_u(f))/\gamma_u(f) \in (\ell, X)^{s+1-\deg}$ with deg the number of factors of f (in the regular local ring $\mathbb{Z}_\ell[[X]]$ membership in the r-th power of the maximal ideal is order $\geq r$). Now $f\,(\gamma_u - 1)(y) = v_u \gamma_u(x) - x = v_u(\gamma_u - 1)(x) + (v_u - 1)x$. Let $\sigma \in G_F$ with $\chi_{\mathrm{cyc}}(\sigma) = u$ ($\chi_{\mathrm{cyc}} \colon G_F \to \mathbb{Z}_\ell^\times$ is onto, F being unramified). With $w = \mu_\varepsilon^\kappa \iota_T(x) \in A_{\mathrm{inf}} \otimes T$ and $\sigma(\mu_\varepsilon) = \mu_\varepsilon \beta_\sigma$, $\beta_\sigma = \sum_{k \geq 1} \binom{u}{k} \mu_\varepsilon^{k-1} \in A_{\mathrm{inf}}^\times$,

$$\mu_\varepsilon^\kappa \iota_T((\gamma_u - 1)(x)) = \mu_\varepsilon^\kappa (\sigma - 1)\iota_T(x) = \beta_\sigma^{-\kappa}(\sigma(w) - w) + (\beta_\sigma^{-\kappa} - 1)w.$$

Given J, continuity of G_F on A_{inf} (Ai2) and on T gives an open subgroup $U \subseteq G_F$ with $\sigma(w) - w \in (\ell, \mu_\varepsilon)^J (A_{\mathrm{inf}} \otimes T)$ for $\sigma \in U$, and $\beta_\sigma - 1 = (u-1) + \sum_{k \geq 2} \binom{u}{k} \mu_\varepsilon^{k-1} \in (\ell, \mu_\varepsilon)^J$ once u is close enough to 1 ($\binom{u}{k} \to \binom{1}{k} = 0$ for each $k \geq 2$). Since $\chi_{\mathrm{cyc}}(U)$ is open, there is s such that every $u \in 1 + \ell^s \mathbb{Z}_\ell$ is $\chi_{\mathrm{cyc}}(\sigma)$ for such a σ; then (Gc2) gives $(\gamma_u - 1)(x) \in (\ell, X)^{k'} \mathbf{N}$, with k' as large as we like for s large. Together with $v_u - 1 \in (\ell, X)^{s+1-\deg}$, $f\,(\gamma_u - 1)(y) \in (\ell, X)^{k''} \mathbf{N}$ with $k'' \to \infty$ as $s \to \infty$. As $(\gamma_u - 1)(y) \in \mathbf{N}$ by hypothesis, and in coordinates of an $\mathcal{O}_L[[X]]$-basis of each $\mathbf{N}_a$ the (ϖ, X)-order is additive, $(\gamma_u - 1)(y) \in (\varpi, X)^{k''-\deg} \mathbf{N}$; with $(\varpi, X)^{ek} \subseteq (\ell, X)^k$ this gives (Gc3).

Over a base field. For a pair over K the proof is the same, with $\sigma \in G_K$, $u = \chi_{\mathrm{cyc}}(\sigma) \in \Gamma_K$, (Ex1)–(Ex2) of Proposition 23.7 over K, and Lemma 23.8(4), which holds for all $\sigma \in G_F \supseteq G_K$. The one property of F used is in (Gc3): that every $u \in 1 + \ell^s \mathbb{Z}_\ell$, s large, is $\chi_{\mathrm{cyc}}(\sigma)$ for some σ in a given open subgroup U. Over K: $\chi_{\mathrm{cyc}} \colon G_K \to \Gamma_K$ is a continuous surjection of profinite groups, hence open, so $\chi_{\mathrm{cyc}}(U)$ is open in Γ_K; and Γ_K is open in $\mathbb{Z}_\ell^\times$, being closed of finite index ($[\Gamma_F : \Gamma_K] \leq [G_F : G_K] = [K : F]$). So $\chi_{\mathrm{cyc}}(U) \supseteq 1 + \ell^s \mathbb{Z}_\ell$ for s large, and the argument is unchanged.

Level s. Fix the level s (written s_0 in this paragraph, to keep s for the exponent in (Gc3)). The proof above, over K, applies with the following replacements; we list every property of ι and μ_ε it uses. (1) Topology: modulo ℓ, μ_{ε,s_0} reduces to $\varepsilon^{1/\ell^{s_0-1}} - 1$, of valuation $c = \ell/((\ell-1)\ell^{s_0-1}) > 0$, so $(\ell, \mu_{\varepsilon,s_0})^{\lceil 1/c \rceil} \subseteq (\ell, [p^\flat])$ and $[p^\flat]^{\lceil c \rceil} \in (\ell, \mu_{\varepsilon,s_0})$: the $(\ell, \mu_{\varepsilon,s_0})$-adic topology is again that of (Ai2). Put $\iota_L(\sum c_k X^k) = \sum (\iota_{s_0} \otimes \mathrm{id})(c_k) \mu_{\varepsilon,s_0}^k$. (2) (Gc0): $\iota_{s_0}(Q_j) = \Phi_{\ell^{j+1}}([\varepsilon^{1/\ell^{s_0-1}}])$ reduces modulo ℓ to $(\varepsilon^{1/\ell^{s_0-1}} - 1)^{\ell^j(\ell-1)} \neq 0$, so it is a unit of $W(\mathbb{C}_\ell^\flat)$ for every $j \geq 0$; $\gamma_u(Q_j) \in Q_j \mathbb{Z}_\ell[[X]]^\times$ (Lemma 23.8(2)); $\sigma \circ \iota_{s_0} = \iota_{s_0} \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ and $\varphi \circ \iota_{s_0} = \iota_{s_0} \circ \varphi$ (Lemma 23.8(6)); and (Ex1), (Ex2) of level s_0 (Proposition 23.7(Ex4)). (3) κ exists because $\iota_{s_0,T}(\mathbf{N}) \subseteq A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T$ ((Ex2) of level s_0); (Gc1) follows from $\iota_L((\ell, X)^k) \subseteq (\ell, \mu_{\varepsilon,s_0})^k R$. (4) (Gc2): the matrices A_a lie in $\mathrm{GL}_d(\epsilon_a R[1/\mu_\varepsilon])$ by the spanning clause of (Ex2), and, since $\mu_\varepsilon = \iota_{s_0}(X_{s_0-1})$ with $X_{s_0-1} =$

$(1+X)^{\ell^{s_0-1}}-1$, the displayed relation reads $\iota_a(X_{s_0-1}^{\kappa+\kappa'}c_{a,i}) \in \epsilon_a(\varpi,\mu_{\varepsilon,s_0})^j R$. The strictness claim holds with μ_{ε,s_0} in place of μ_ε and the valuation c in place of $\ell/(\ell-1)$: its proof uses only that the reduction $\varepsilon^{1/\ell^{s_0-1}}-1$ has positive valuation and is a non-zero-divisor of $R/\varpi R$. Hence $X_{s_0-1}^{\kappa+\kappa'}c_{a,i} \in (\varpi,X)^j$; as X_{s_0-1} has the monomial $X^{\ell^{s_0-1}}$ with coefficient 1, its (ϖ,X)-order is at most ℓ^{s_0-1}, so $c_{a,i} \in (\varpi,X)^{j-\ell^{s_0-1}(\kappa+\kappa')}$, and $j = ek+\ell^{s_0-1}(\kappa+\kappa')$ works. (5) (Gc3): unchanged (it uses $w = \mu_\varepsilon^\kappa \iota_{s_0,T}(x)$, $\sigma(\mu_\varepsilon) = \mu_\varepsilon\beta_\sigma$, continuity, (Gc2) of level s_0, and the openness of $\chi_{\mathrm{cyc}}(U)$ in Γ_K, which holds for every finite K). □

Lemma 23.30. *Let $\mathbf{N}$ be a Wach module over F with coefficients L and window $(M_a,h_a)_{a\in\mathbb{Z}/n}$, and $m \geq 1+\max_a M_a$ an integer. Then:*

1. *$\varphi_{\mathbf{N}}(X^m\mathbf{N}) \subseteq X^m Q\,\mathbf{N}$, and $\varphi_{\mathbf{N}}^k(X^m\mathbf{N}) \subseteq X^m\lambda_k\mathbf{N}$ for every $k \geq 0$;*
2. *$1-\varphi_{\mathbf{N}}$ is a bijection of $X^m\mathbf{N}$ onto itself, with inverse $w \mapsto \sum_{k\geq 0}\varphi_{\mathbf{N}}^k(w)$ (convergent for the (ℓ,X)-adic topology);*
3. *let $u \in \mathbb{Z}_\ell^\times$ and $\gamma = \gamma_{u,\mathbf{N}}$. For every $y \in \mathbf{N}$ with $(\gamma-1)y \in X^m\mathbf{N}$ there is a unique $z \in X^m\mathbf{N}$ with $(\varphi_{\mathbf{N}}-1)z = (\gamma-1)y$, namely $z_y = -\sum_{k\geq 0}\varphi_{\mathbf{N}}^k((\gamma-1)y)$; $y \mapsto z_y$ is additive; if $y \in X^m\mathbf{N}$, then $w = -\sum_{k\geq 0}\varphi_{\mathbf{N}}^k(y) \in X^m\mathbf{N}$ satisfies $(\varphi_{\mathbf{N}}-1)w = y$ and $(\gamma-1)w = z_y$;*
4. *if $\mathbf{N}'$ is another Wach module over F with coefficients L whose window (M'_a,h'_a) also satisfies $m \geq 1+\max_a M'_a$, and $g\colon \mathbf{N} \to \mathbf{N}'$ is $\mathbf{A}_{F,L}$-linear and commutes with φ and γ_u, then $g(z_y) = z_{g(y)}$ for every y as in item 3.*

Over a base field. *Items 1–4 hold for Wach modules over a base field K as in Definition 23.2, with $u \in \Gamma_K$ in items 3 and 4; for $K = F$ this is the statement above.*

Level s. *Let ℓ be any prime, $s \geq 1$ with $s \geq 2$ if $\ell = 2$, K with $F \subseteq K \subseteq F(\mu_{\ell^s})$, $\mathbf{N}$ (and $\mathbf{N}'$ in item 4) a Wach module of level s over K with coefficients L (Definition 23.2, paragraph Level s, with the level variable X_{s-1} there), and $m \geq 1+\max_a M_a$. Then items 1–4 hold with X, Q, λ_k replaced by X_{s-1}, Q_{s-1}, $\varphi^{s-1}(\lambda_k) = \prod_{j=0}^{k-1} Q_{s-1+j}$ and $u \in \Gamma_K$: in particular $\varphi_{\mathbf{N}}(X_{s-1}^m\mathbf{N}) \subseteq X_{s-1}^m Q_{s-1}\mathbf{N}$, $1-\varphi_{\mathbf{N}}$ is bijective on $X_{s-1}^m\mathbf{N}$ with inverse $\sum_{k\geq 0}\varphi_{\mathbf{N}}^k$, and for $y \in \mathbf{N}$ with $(\gamma_{u,\mathbf{N}}-1)y \in X_{s-1}^m\mathbf{N}$ there is a unique $z_y \in X_{s-1}^m\mathbf{N}$ with $(\varphi_{\mathbf{N}}-1)z_y = (\gamma_{u,\mathbf{N}}-1)y$. For $s = 1$ and ℓ odd this is the statement over a base field.*

Proof. **Item 1.** Let $x \in \mathbf{N}_{a-1}$. Since $\varphi(X) = XQ$,

$$\varphi_{\mathbf{N}}(X^m x) = X^m Q^m \varphi_{\mathbf{N}}(x) = X^m Q^{m-M_a}\big(Q^{M_a}\varphi_{\mathbf{N}}(x)\big) \in X^m Q^{m-M_a}\mathbf{N}_a \subseteq X^m Q\mathbf{N}$$

by (Wm2) and $m - M_a \geq 1$; by additivity and $\mathbf{N} = \bigoplus_a \mathbf{N}_a$ the first claim follows. By induction on k, using $\varphi_{\mathbf{N}}(fy) = \varphi(f)\varphi_{\mathbf{N}}(y)$ and $\varphi(\lambda_k)Q = \lambda_{k+1}$: if $\varphi_{\mathbf{N}}^k(X^m\mathbf{N}) \subseteq \lambda_k X^m\mathbf{N}$ then $\varphi_{\mathbf{N}}^{k+1}(X^m\mathbf{N}) \subseteq \varphi(\lambda_k)\varphi_{\mathbf{N}}(X^m\mathbf{N}) \subseteq \varphi(\lambda_k)X^m Q\mathbf{N} = \lambda_{k+1}X^m\mathbf{N}$.

Item 2. Let $\mathfrak{m} = (\ell,X) \subseteq \mathbf{A}_{F,L}$. Each Q_s lies in $\mathfrak{m}$ ($Q_s(0) = \ell$), so $\lambda_k \in \mathfrak{m}^k$. The ring $\mathbf{A}_{F,L} = \prod_a \mathcal{O}_L[[X]]$ is noetherian and $\mathfrak{m}$-adically complete, and $\mathfrak{m}$ lies in its Jacobson radical; so the finitely generated module $X^m\mathbf{N}$ is $\mathfrak{m}$-adically complete and separated. By item 1, $\varphi_{\mathbf{N}}$ maps $X^m\mathbf{N}$ into itself and $\mathfrak{m}^j X^m\mathbf{N}$ into $\mathfrak{m}^j X^m\mathbf{N}$ ($\varphi(\mathfrak{m}) \subseteq \mathfrak{m}$), so it is continuous there, and $\varphi_{\mathbf{N}}^k(w) \in \mathfrak{m}^k X^m\mathbf{N}$ for $w \in X^m\mathbf{N}$. Hence $s(w) = \sum_{k\geq 0}\varphi_{\mathbf{N}}^k(w)$ converges in $X^m\mathbf{N}$, and $(1-\varphi_{\mathbf{N}})s(w) = w$ by continuity and telescoping. If $w \in X^m\mathbf{N}$ and $\varphi_{\mathbf{N}}(w) = w$, then $w = \varphi_{\mathbf{N}}^k(w) \in \mathfrak{m}^k X^m\mathbf{N}$ for all k, so $w = 0$. Thus $1-\varphi_{\mathbf{N}}$ is bijective on $X^m\mathbf{N}$ with inverse s.

Item 3. By item 2 the equation $(\varphi_{\mathbf{N}}-1)z = (\gamma-1)y$ has the unique solution $z_y = -s((\gamma-1)y)$ in $X^m\mathbf{N}$, and $y \mapsto z_y$ is additive since γ and s are. Let $y \in X^m\mathbf{N}$ and $w = -s(y)$,

so $(\varphi_{\mathbf{N}}-1)w=y$. Since $\gamma_u(X)\in X\mathbf{A}_F$, γ preserves $X^m\mathbf{N}$, so $(\gamma-1)w\in X^m\mathbf{N}$; and γ commutes with $\varphi_{\mathbf{N}}$ (Wm3), so $(\varphi_{\mathbf{N}}-1)(\gamma-1)w=(\gamma-1)(\varphi_{\mathbf{N}}-1)w=(\gamma-1)y$. By uniqueness, $(\gamma-1)w=z_y$.

Item 4. g maps $X^m\mathbf{N}$ into $X^m\mathbf{N}'$, and $(\varphi-1)g(z_y)=g((\varphi-1)z_y)=g((\gamma-1)y)=(\gamma-1)g(y)$, which lies in $X^m\mathbf{N}'$; by uniqueness in $\mathbf{N}'$, $g(z_y)=z_{g(y)}$.

Over a base field. For Wach modules over K the proof is unchanged: items 1 and 2 use only (Wm1), (Wm2), $\varphi(X)=XQ$ and the ring $\mathbf{A}_{F,L}$, none of which involves the base field; items 3 and 4 use, for the given $u\in\Gamma_K$, only that $\gamma_u(X)\in X\mathbf{A}_F$ (true for every $u\in\mathbb{Z}_\ell^\times$) and that $\gamma_{u,\mathbf{N}}$ commutes with $\varphi_{\mathbf{N}}$, which (Wm3) over K gives for $u\in\Gamma_K$.

Level s. The proof above applies with X, Q, λ_k replaced by X_{s-1}, Q_{s-1}, $\varphi^{s-1}(\lambda_k)$; we check the four facts it uses. (i) Applying the ring endomorphism φ^{s-1} to $\varphi(X)=XQ$ gives $\varphi(X_{s-1})=X_{s-1}Q_{s-1}$; with (Wm2) of level s, $\varphi_{\mathbf{N}}(X_{s-1}^m x)=X_{s-1}^m Q_{s-1}^{m-M_a}(Q_{s-1}^{M_a}\varphi_{\mathbf{N}}(x))\in X_{s-1}^m Q_{s-1}\mathbf{N}$ for $x\in\mathbf{N}_{a-1}$, and $\varphi(\varphi^{s-1}(\lambda_k))Q_{s-1}=\varphi^{s-1}(\lambda_{k+1})$ gives the induction of item 1. (ii) Each Q_{s-1+j} lies in $\mathfrak{m}=(\ell,X)$ ($\varphi(f)(0)=\varphi(f(0))$ since $\varphi(X)(0)=0$, and $Q(0)=\ell$, so $Q_{s-1+j}(0)=\ell$), so $\varphi^{s-1}(\lambda_k)\in\mathfrak{m}^k$ and item 2 follows as before. (iii) $\gamma_u(X_{s-1})=(1+X_{s-1})^u-1=\sum_{k\ge1}\binom{u}{k}X_{s-1}^k\in X_{s-1}\mathbf{A}_F$ for every $u\in\mathbb{Z}_\ell^\times$, so $\gamma_{u,\mathbf{N}}$ preserves $X_{s-1}^m\mathbf{N}$. (iv) $\gamma_{u,\mathbf{N}}$ commutes with $\varphi_{\mathbf{N}}$ on $\mathbf{N}[1/Q_{s-1}]$ for $u\in\Gamma_K$ ((Wm3) of level s). Items 3 and 4 then follow as before. (Clause (Wm3') is not used.) □

Proposition 23.31. *Let ℓ, F, L, (τ_a) and a pair (V,T) be as in Proposition 23.7, $\mathbf{N}=\mathbf{N}(T)$, $(M_a,h_a)_a$ a window of V as in (Ex1), $m\ge1+\max_a M_a$, and let $\rho\colon A_{\mathrm{inf}}[1/\mu_\varepsilon]\to B_{\mathrm{cris}}$ be the G_F- and φ-equivariant ring homomorphism extending $A_{\mathrm{inf}}\subset A_{\mathrm{cris}}\subset B_{\mathrm{cris}}$ (μ_ε divides t in A_{cris}, so it is a unit of B_{cris}). Let $y\in\mathbf{N}[1/\lambda_\infty]$ be a Herr vector of precision m such that $fy\in\mathbf{N}$ for some finite product f of the Q_s, $s\ge0$. Then there is $\beta\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V$ such that*

$$(\sigma-1)(\beta)=(\rho\otimes1)\big(\iota_T(z_{\chi_{\mathrm{cyc}}(\sigma)}(y))\big)\qquad\text{for every }\sigma\in G_F.$$

Over a base field. *Let K be a field with $F\subseteq K\subseteq F(\mu_\ell)$ and Γ_K as in Definition 23.2. For a pair (V,T) over K as in Proposition 23.7, a window as in (Ex1) over K, $m\ge1+\max_a M_a$, and a Herr vector y of precision m over K (Lemma 23.28, over a base field: $u\in\Gamma_K$) with $fy\in\mathbf{N}$ as above, there is $\beta\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V$ with $(\sigma-1)(\beta)=(\rho\otimes1)(\iota_T(z_{\chi_{\mathrm{cyc}}(\sigma)}(y)))$ for every $\sigma\in G_K$. For $K=F$ this is the statement above.* ***Level s.*** *Let ℓ be any prime, $s\ge1$ an integer with $s\ge2$ if $\ell=2$, L, K ($F\subseteq K\subseteq F(\mu_{\ell^s})$) and a pair (V,T) over K as in (Ex4) of Proposition 23.7, $\mathbf{N}=\mathbf{N}_s(T)$ with $\iota_{s,T}$, $(M_a,h_a)_a$ a window of V as in (Ex1) of level s, $m\ge1+\max_a M_a$, and ρ as above (it exists for every prime: μ_ε is a unit of B_{cris} by Lemma 23.12, paragraph Every prime). Let $y\in\mathbf{N}[1/\lambda_\infty]$ be a Herr vector of precision m at level s (Lemma 23.28, paragraph Level s) such that $fy\in\mathbf{N}$ for some finite product f of the Q_j with $j\ge s-1$. Then there is $\beta\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V$ with $(\sigma-1)(\beta)=(\rho\otimes1)(\iota_{s,T}(z_{\chi_{\mathrm{cyc}}(\sigma)}(y)))$ for every $\sigma\in G_K$. For $s=1$ and ℓ odd this is the paragraph over a base field.*

Proof. Write $\mu=\mu_\varepsilon$, $z_u=z_u(y)$, and φ for $\varphi\otimes1$ on $W(\mathbb{C}_\ell^\flat)\otimes_{\mathbb{Z}_\ell}T$ and on $B_{\mathrm{cris}}\otimes_{\mathbb{Z}_\ell}T=B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V$; G_F acts diagonally on both and commutes with φ. The plan is to trivialise the Γ-cocycle $u\mapsto z_u$ in power series of geometric growth, evaluate at $\varphi^3(\mu)\in\ell^3A_{\mathrm{cris}}$, where such series converge, and correct the Frobenius twist so introduced by $\sum_{j<3}\varphi^j(\iota_T(y))$.

Step 1: the cocycle relation. For $u,v\in\mathbb{Z}_\ell^\times$, $z_u+\gamma_u(z_v)\in X^m\mathbf{N}$ ($\gamma_u(X)\in X\mathbf{A}_F$) and, as γ_u commutes with φ and $\gamma_u\gamma_v=\gamma_{uv}$ ((Wm3), extended to $\mathbf{N}[1/\lambda_\infty]$ by (Gc0)),

$$(\varphi-1)\big(z_u+\gamma_u(z_v)\big)=(\gamma_u-1)(y)+\gamma_u(\gamma_v-1)(y)=(\gamma_{uv}-1)(y);$$

by the uniqueness in Lemma 23.30(2), $z_{uv}=z_u+\gamma_u(z_v)$.

Step 2: the trivialisation. By (Ex1), $\mathbf{N}$ is a Wach module; fix an $\mathbf{A}_{F,L}$-basis (n_i) of it. By Step 1 and Lemma 23.9(Hf1) there is $W \in X^m(\mathbf{N}\otimes_{\mathbf{A}_{F,L}} E[[X]])$ with $(\gamma_u-1)(W)=z_u$ for every $u\in\mathbb{Z}_\ell^\times$, and by (Hf3) its coordinates $\sum_k a_kX^k$ satisfy $\ell^{s_\ell(k)}a_k\in\Lambda$ with $s_\ell(k)\le k\ell/(\ell-1)^2\le 2k$. So the coordinates lie in R, and

$$W\in\mathbf{N}_R,\qquad (\gamma_u-1)(W)=z_u\quad\text{for every } u\in\mathbb{Z}_\ell^\times. \tag{23.2}$$

Step 3: the poles of $\iota_T(y)$. Write $f=\prod_s Q_s^{k_s}$. By (Gc0), $\iota_T(y)=\iota(f)^{-1}\iota_T(fy)$, where $\iota(f)=\prod_s\varphi^s(\tilde\xi)^{k_s}=\prod_s(\varphi^{s+1}(\mu)/\varphi^s(\mu))^{k_s}$ (Lemma 23.8(4) and $\varphi(\mu)=\mu\tilde\xi$) and $\iota_T(fy)\in\mu^{-\kappa}(A_{\inf}\otimes T)$ (Gc1). Hence $\iota_T(y)\in S\otimes_{\mathbb{Z}_\ell}T$ with S as in (Ac2), and so is each $\varphi^j(\iota_T(y))$ (S is φ-stable). The map $\rho_S\otimes 1\colon S\otimes T\to B_{\mathrm{cris}}\otimes T$ commutes with φ and G_F (Ac2) and restricts to $\rho\otimes1$ on $A_{\inf}[1/\mu]\otimes T$: $\rho_S|_{A_{\inf}[1/\mu]}$ and ρ both extend the inclusion of $A_{\inf}$, and $A_{\inf}[1/\mu]$ is a localisation of $A_{\inf}$.

Step 4: the element β. Define

$$\beta=\mathrm{Ev}(W)-\sum_{j=0}^{2}\varphi^j\big((\rho_S\otimes1)(\iota_T(y))\big)\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V,$$

and let $\sigma\in G_F$, $u=\chi_{\mathrm{cyc}}(\sigma)$. By (Ev3) and (23.2), $(\sigma-1)\mathrm{Ev}(W)=\mathrm{Ev}((\gamma_u-1)W)=\mathrm{Ev}(z_u)=\varphi^3(\rho\otimes1)(\iota_T(z_u))$, as $z_u\in\mathbf{N}$. By (Gc0) and the defining equation of z_u, $(\sigma-1)\iota_T(y)=\iota_T((\gamma_u-1)(y))=\iota_T((\varphi-1)(z_u))=(\varphi-1)\iota_T(z_u)$, and $(\rho_S\otimes1)(\iota_T(z_u))=(\rho\otimes1)(\iota_T(z_u))$ since $z_u\in\mathbf{N}$; so, as σ commutes with φ and with ρ_S,

$$(\sigma-1)\sum_{j=0}^{2}\varphi^j(\rho_S\otimes1)(\iota_T(y))=\sum_{j=0}^{2}\varphi^j(\varphi-1)(\rho\otimes1)(\iota_T(z_u))=\varphi^3(\rho\otimes1)(\iota_T(z_u))-(\rho\otimes1)(\iota_T(z_u)).$$

Subtracting, $(\sigma-1)(\beta)=(\rho\otimes1)\big(\iota_T(z_{\chi_{\mathrm{cyc}}(\sigma)}(y))\big)$ for every $\sigma\in G_F$.

Over a base field. For a pair over K the four steps run with $u,v\in\Gamma_K$ and $\sigma\in G_K$, each input taken in its form over K. Step 1: (Wm3) for $u,v\in\Gamma_K$, (Gc0) over K (Lemma 23.29) and the uniqueness of Lemma 23.30(2) over K give $z_{uv}=z_u+\gamma_u(z_v)$. Step 2: (Hf1), (Hf3) over K (Lemma 23.9, over a base field) give $W\in X^m\mathbf{N}_E$ with $(\gamma_u-1)(W)=z_u$ for every $u\in\Gamma_K$ and coordinates with $\ell^{s_{\ell,d}(k)}a_k\in\Lambda$, $s_{\ell,d}(k)\le 3k/2\le 2k$ ($d=|\Delta_K|$), so $W\in\mathbf{N}_R$. Step 3: (Gc0), (Gc1) over K; S and ρ_S are G_F-, hence G_K-equivariant. Step 4: (Ev3) over K (Lemma 23.11, over a base field) for $\sigma\in G_K$, $u=\chi_{\mathrm{cyc}}(\sigma)\in\Gamma_K$; the computation is the same. No step uses that the base is unramified beyond the denominators of Step 2, which stay below $2k$.

Level s. Let the data be as in the paragraph Level s of the statement; $u,v\in\Gamma_K$, $\sigma\in G_K$, $z_u=z_u(y)\in X_{s-1}^m\mathbf{N}$, $X_{s-1}=\varphi^{s-1}(X)$. Step 1: $\gamma_u(X_{s-1})=(1+X_{s-1})^u-1\in X_{s-1}\mathbf{A}_F$, so $z_u+\gamma_u(z_v)\in X_{s-1}^m\mathbf{N}$; by (Wm3) of level s and (Gc0) of level s (Lemma 23.29, paragraph Level s) the displayed computation of Step 1 holds, and the uniqueness of Lemma 23.30, paragraph Level s, gives $z_{uv}=z_u+\gamma_u(z_v)$. Step 2: $\mathbf{N}$ is a Wach module of level s over K ((Ex1) of level s), and $z_u\in X_{s-1}^m\mathbf{N}\subseteq X^m\mathbf{N}$ since $X_{s-1}=X\lambda_{s-1}$. By (Hf1), (Hf3) of Lemma 23.9, paragraph Level s, there is $W\in X^m\mathbf{N}_E$ with $(\gamma_u-1)(W)=z_u$ for every $u\in\Gamma_K$, whose coordinates satisfy $\ell^{\nu_{\ell,s}(k)}a_k\in\Lambda$ with $\nu_{\ell,s}(k)\le(s+1)k$; so $W\in\mathbf{N}_{R_s}$ (Lemma 23.11, paragraph Level s). Step 3: write $f=\prod_{k\ge0}Q_{s-1+k}^{c_k}$. By Lemma 23.8(6), ι_s commutes with the Frobenius lifts and $\iota_s(Q_{s-1})=\tilde\xi=\varphi(\mu)/\mu$, so $\iota_s(Q_{s-1+k})=\varphi^k(\tilde\xi)=\varphi^{k+1}(\mu)/\varphi^k(\mu)$ and $\iota_s(f)^{-1}\in S$, S as in (Ac2) of Lemma 23.12 (paragraph Every prime). (This is where $j\ge s-1$ is used: for $j<s-1$, $\iota_s(Q_j)=\varphi^{j-s+1}(\tilde\xi)$ is a negative Frobenius twist of $\tilde\xi$, which (Ac2) does not invert.) By (Gc0) and (Gc1) of level s, $\iota_{s,T}(y)=\iota_s(f)^{-1}\iota_{s,T}(fy)$ with $\iota_{s,T}(fy)\in\mu^{-\kappa}(A_{\inf}\otimes T)$ (the pole factor

of (Gc1) is μ_ε^κ at every level); so $\iota_{s,T}(y)$ and all $\varphi^j(\iota_{s,T}(y))$ lie in $S\otimes T$, and $\rho_S\otimes 1$ restricts to $\rho\otimes 1$ on $A_{\mathrm{inf}}[1/\mu]\otimes T$ as before. Step 4: put

$$\beta=\mathrm{Ev}_s(W)-\sum_{j=0}^{2s}\varphi^j\big((\rho_S\otimes 1)(\iota_{s,T}(y))\big)\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V.$$

Let $\sigma\in G_K$, $u=\chi_{\mathrm{cyc}}(\sigma)$. By (Ev3) of level s and Step 2, $(\sigma-1)\mathrm{Ev}_s(W)=\mathrm{Ev}_s(z_u)=\varphi^{2s+1}(\rho\otimes 1)(\iota_{s,T}(z_u))$, as $z_u\in\mathbf{N}$. By (Gc0) of level s and the defining equation of z_u, $(\sigma-1)\iota_{s,T}(y)=\iota_{s,T}((\gamma_u-1)(y))=(\varphi-1)\iota_{s,T}(z_u)$, so

$$\begin{aligned}(\sigma-1)\sum_{j=0}^{2s}\varphi^j(\rho_S\otimes 1)(\iota_{s,T}(y))&=\sum_{j=0}^{2s}\varphi^j(\varphi-1)(\rho\otimes 1)(\iota_{s,T}(z_u))\\&=\varphi^{2s+1}(\rho\otimes 1)(\iota_{s,T}(z_u))-(\rho\otimes 1)(\iota_{s,T}(z_u)).\end{aligned}$$

Subtracting, $(\sigma-1)(\beta)=(\rho\otimes 1)(\iota_{s,T}(z_u))$ for every $\sigma\in G_K$. For $s=1$, ℓ odd, $2s+1=3$ and this is the proof over a base field with the weaker denominators $(s+1)k=2k$. □

Lemma 23.32. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, let (V',T') and (V,T) be pairs as there, $\mathcal{O}_L$ the lattice of the trivial one-dimensional representation, and*

$$0\to T'\xrightarrow{\iota'}T\xrightarrow{\pi}\mathcal{O}_L\to 0$$

an exact sequence of G_F-equivariant $\mathcal{O}_L$-linear maps. Fix $\tilde e\in T$ with $\pi(\tilde e)=1$ and let $[T]\in H^1(F,T')$ be the class of the cocycle $\sigma\mapsto\iota'^{-1}(\sigma\tilde e-\tilde e)$ (independent of $\tilde e$). Let $(M_a,h_a)_a$ be a window of V' as in (Ex1) and $m\ge 1+\max_a M_a$. Let $\tilde x\in\mathbf{N}(T)[1/\lambda_\infty]$ and $c\in\mathcal{O}_L$ satisfy

$$(1\otimes\pi)(\iota_T(\tilde x))=1\otimes c\quad\text{in } W(\mathbb{C}_\ell^\flat)\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L,\qquad(\gamma_u-1)(\tilde x)\in\mathbf{N}(\iota')(X^m\mathbf{N}(T'))\quad\text{for all } u\in\mathbb{Z}_\ell^\times.$$

Then there is a unique $y\in\mathbf{N}(T')[1/\lambda_\infty]$ with $\mathbf{N}(\iota')(y)=(\varphi-1)(\tilde x)$; it is a Herr vector of precision m for $\mathbf{N}(T')$, with $\mathbf{N}(\iota')(z_u(y))=(\gamma_u-1)(\tilde x)$ for every u, and

$$\mathrm{cl}(y)=c\,[T]\qquad\text{in } H^1(F,T').$$

Over a base field. *Let K be a field with $F\subseteq K\subseteq F(\mu_\ell)$ and Γ_K as in Definition 23.2. The same holds for pairs over K (Proposition 23.7), G_K-equivariant maps, the hypothesis on $\tilde x$ for all $u\in\Gamma_K$, the class $[T]\in H^1(K,T')$ of the cocycle on G_K, and Herr vectors and classes over K (closing paragraph of Lemma 23.28). For $K=F$ this is the statement above.* ***Level s.*** *Let ℓ be any prime, $s\ge 1$ with $s\ge 2$ if $\ell=2$, and L, K ($F\subseteq K\subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7. The same holds, in the form over a base field, with $\mathbf{N}$, ι_T, $\mathbf{N}(\iota')$ replaced by $\mathbf{N}_s$, $\iota_{s,T}$, $\mathbf{N}_s(\iota')$, the window of V' as in (Ex1) of level s, the hypothesis $(\gamma_u-1)(\tilde x)\in\mathbf{N}_s(\iota')(X_{s-1}^m\mathbf{N}_s(T'))$ for all $u\in\Gamma_K$ (X_{s-1} the level variable of Definition 23.2), and Herr vectors of precision m at level s and their classes (Lemma 23.28, Level s). For $s=1$ and ℓ odd this is the paragraph over a base field.*

Proof. **The element y.** Let $\pi_1=\iota_{\mathcal{O}_L}$ be the realisation of the trivial pair and $w=(\varphi-1)(\tilde x)\in\mathbf{N}(T)[1/\lambda_\infty]$ (by (Wm2), $Q^M\varphi(\mathbf{N}(T))\subseteq\mathbf{N}(T)$ for some M, and $\varphi(Q_s)=Q_{s+1}$). By (Ex3) and (Gc0),

$$\pi_1(\mathbf{N}(\pi)(w))=(1\otimes\pi)\iota_T(w)=(\varphi\otimes 1-1)\big((1\otimes\pi)\iota_T(\tilde x)\big)=(\varphi\otimes 1-1)(1\otimes c)=0,$$

and π_1 is injective on $\mathbf{N}(\mathcal{O}_L)[1/\lambda_\infty]$ by (Gc0); so $\mathbf{N}(\pi)(w)=0$. Choose a finite product f of the Q_s with $fw\in\mathbf{N}(T)$; then $\mathbf{N}(\pi)(fw)=0$, so $fw=\mathbf{N}(\iota')(x)$ with $x\in\mathbf{N}(T')$ by Lemma 23.33,

and $y = x/f$ satisfies $\mathbf{N}(\iota')(y) = w$. It is unique because $\mathbf{N}(\iota')$ is injective (Lemma 23.33) and remains so on $\mathbf{N}(T')[1/\lambda_\infty]$ (localisation is exact).

Precision. By hypothesis, $(\gamma_u - 1)(\tilde{x}) = \mathbf{N}(\iota')(z_u)$ with $z_u \in X^m\mathbf{N}(T')$, unique by injectivity. Since γ_u and φ commute (Wm3) and $\mathbf{N}(\iota')$ commutes with both (Ex3),

$$\mathbf{N}(\iota')\big((\gamma_u - 1)y\big) = (\gamma_u - 1)(\varphi - 1)\tilde{x} = (\varphi - 1)(\gamma_u - 1)\tilde{x} = \mathbf{N}(\iota')\big((\varphi - 1)z_u\big),$$

so $(\gamma_u - 1)y = (\varphi - 1)z_u$, which lies in $X^m\mathbf{N}(T')$ by Lemma 23.30(1). Hence y is a Herr vector of precision m, and by the uniqueness in Lemma 23.30(2), $z_u(y) = z_u$.

A solution b of the Frobenius equation. The sequence splits over $\mathcal{O}_L$ ($\mathcal{O}_L$ is free), so for $B = A_{\mathrm{inf}}[1/\mu_\varepsilon]$ and for $B = W(\mathbb{C}_\ell^\flat)$ the map $1 \otimes \iota' \colon B \otimes T' \to B \otimes T$ is injective with image $\ker(1 \otimes \pi)$, and it commutes with $\varphi \otimes 1$ and with the diagonal action of G_F. The element $\iota_T(\tilde{x}) - 1 \otimes c\tilde{e}$ lies in $\ker(1 \otimes \pi)$, since $(1 \otimes \pi)(1 \otimes c\tilde{e}) = 1 \otimes c$; let $b \in W(\mathbb{C}_\ell^\flat) \otimes T'$ be its preimage (here $\iota_T(\tilde{x}) \in W(\mathbb{C}_\ell^\flat) \otimes T$ by (Gc0)). As $1 \otimes c\tilde{e}$ is fixed by $\varphi \otimes 1$,

$$(1 \otimes \iota')\big((\varphi \otimes 1 - 1)b\big) = (\varphi \otimes 1 - 1)\iota_T(\tilde{x}) = \iota_T(w) = \iota_T\big(\mathbf{N}(\iota')(y)\big) = (1 \otimes \iota')\big(\iota_{T'}(y)\big),$$

using (Gc0) and (Ex3) (extended to poles by the formula of (Gc0)). Hence $(\varphi \otimes 1 - 1)b = \iota_{T'}(y)$.

The cocycle. By (Hc1) of Lemma 23.28, $\mathrm{cl}(y)$ is the class of $c_{y,b}(\sigma) = \iota_{T'}(z_{\chi_{\mathrm{cyc}}(\sigma)}(y)) - (\sigma - 1)b$. Applying $1 \otimes \iota'$ and using $\sigma(\iota_T(\tilde{x})) = \iota_T(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}\tilde{x})$ (Gc0):

$$(1 \otimes \iota')\big(c_{y,b}(\sigma)\big) = \iota_T\big((\gamma_{\chi_{\mathrm{cyc}}(\sigma)} - 1)\tilde{x}\big) - (\sigma - 1)\iota_T(\tilde{x}) + (\sigma - 1)(1 \otimes c\tilde{e}) = 1 \otimes c(\sigma\tilde{e} - \tilde{e}).$$

Since $\sigma\tilde{e} - \tilde{e} \in \ker \pi = \iota'(T')$, this says $c_{y,b}(\sigma) = c\,\iota'^{-1}(\sigma\tilde{e} - \tilde{e})$ for every $\sigma \in G_F$. Therefore $\mathrm{cl}(y) = c\,[T]$. (Independence of $\tilde{e}$: replacing $\tilde{e}$ by $\tilde{e} + \iota'(t)$ changes the cocycle by the coboundary $\sigma \mapsto \sigma t - t$.)

Over a base field. For pairs over K the proof is unchanged, with $\sigma \in G_K$, $u \in \Gamma_K$, and Lemma 23.33, (Gc0) of Lemma 23.29 and (Hc1) of Lemma 23.28 in their versions over K (closing paragraphs).

Level s. The proof over K applies with the replacements of the statement: the element y uses (Wm2) of level s ($Q_{s-1}^M\varphi(\mathbf{N}_s(T)) \subseteq \mathbf{N}_s(T)$, and $\varphi(Q_j) = Q_{j+1}$), (Ex3) of level s, the injectivity of $\iota_{s,\mathcal{O}_L}$ on $\mathbf{N}_s(\mathcal{O}_L)[1/\lambda_\infty]$ ((Gc0) of Lemma 23.29, Level s) and Lemma 23.33, Level s; the precision step uses (Wm3) of level s and Lemma 23.30, Level s (items 1, 2 with X_{s-1}^m); the solution b and the cocycle use (Gc0) of level s and (Hc1) of Lemma 23.28, Level s. □

Lemma 23.33. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, and let (V', T'), (V, T), (V'', T'') be three pairs as there, with G_F-equivariant $\mathcal{O}_L$-linear maps forming an exact sequence*

$$0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} T'' \to 0.$$

Then $\mathbf{N}(\iota') \colon \mathbf{N}(T') \to \mathbf{N}(T)$ is injective, $\mathbf{N}(\pi) \circ \mathbf{N}(\iota') = 0$, and

$$\ker\big(\mathbf{N}(\pi) \colon \mathbf{N}(T) \to \mathbf{N}(T'')\big) = \mathbf{N}(\iota')\big(\mathbf{N}(T')\big).$$

Equivalently: if $y \in \mathbf{N}(T)$ and $\mathbf{N}(\pi)(y) = 0$, then $y = \mathbf{N}(\iota')(x)$ for a unique $x \in \mathbf{N}(T')$. ***Over a base field.*** *The same holds for three pairs over a field K with $F \subseteq K \subseteq F(\mu_\ell)$ (Proposition 23.7) and G_K-equivariant maps; for $K = F$ this is the statement above.* ***Level s.*** *Let ℓ be any prime, $s \geq 1$ with $s \geq 2$ if $\ell = 2$, and L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7. The same holds for three pairs over K, G_K-equivariant maps, and $\mathbf{N}_s$, $\mathbf{N}_s(\iota')$, $\mathbf{N}_s(\pi)$ in place of $\mathbf{N}$, $\mathbf{N}(\iota')$, $\mathbf{N}(\pi)$. For $s = 1$ and ℓ odd this is the paragraph over a base field.*

Proof. Throughout, $R = \mathcal{O}_L[[X]]$, ϖ is a uniformiser of $\mathcal{O}_L$, $k_L = \mathcal{O}_L/\varpi$, and $r' = \operatorname{rank}_{\mathcal{O}_L} T' = \dim_L V'$, $r = \operatorname{rank}_{\mathcal{O}_L} T$. By definition of the sites, $e_a\mathbf{A}_{F,L} \cong R$ via $x \otimes \lambda \mapsto \tau_a(x)\lambda$ on coefficients; under these identifications $\gamma_u \colon e_a\mathbf{A}_{F,L} \to e_a\mathbf{A}_{F,L}$ is $f(X) \mapsto f((1+X)^u - 1)$, and $\varphi \colon e_{a-1}\mathbf{A}_{F,L} \to e_a\mathbf{A}_{F,L}$ is $f(X) \mapsto f((1+X)^\ell - 1)$, because $\tau_a(\varphi(x))\lambda = \tau_{a-1}(x)\lambda$. For $f \in R$ and z in the maximal ideal $\mathfrak{m}$ of $\mathcal{O}_{\mathbb{C}_\ell}$ the series $f(z)$ converges, and $f \mapsto f(z)$ is a ring homomorphism $R \to \mathcal{O}_{\mathbb{C}_\ell}$; thus $\varphi(f)(z) = f((1+z)^\ell - 1)$. Put $K = \ker \mathbf{N}(\pi)$ and $N' = \mathbf{N}(\iota')(\mathbf{N}(T'))$; both are $\mathbf{A}_{F,L}$-submodules of $\mathbf{N}(T)$, so $K = \bigoplus_a K_a$, $N' = \bigoplus_a N'_a$ with $K_a = e_aK$, $N'_a = e_aN'$, and it suffices to prove $K_a = N'_a$ for every a.

The realisation ring. Let $A' = A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ and $\iota_L = \iota \otimes \mathrm{id} \colon \mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L \to A'$ (the equality holds because $\mathcal{O}_L$ is finite free over $\mathbb{Z}_\ell$). Since ι is injective (Lemma 23.8(4)), A_{inf} is a domain and $\mathcal{O}_L$ is free over $\mathbb{Z}_\ell$, ι_L is injective. Put $\varepsilon_a = \iota_L(e_a)$, an idempotent of A'. By (Ex2), $\iota_T(fx) = \iota_L(f)\iota_T(x)$ for $f \in \mathbf{A}_{F,L}$, $x \in \mathbf{N}(T)$ (write $f = \sum g_i \otimes \lambda_i$), and likewise for T', T''. The module $W = A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} T = A' \otimes_{\mathcal{O}_L} T$ is free of rank r over A'. The ring ε_aA' is non-zero and ϖ is not a unit in it: indeed $A'/\varpi A' = (A_{\mathrm{inf}}/\ell)[1/\bar{\mu}] \otimes_{\mathbb{F}_\ell} k_L = \mathbb{C}_\ell^\flat \otimes_{\mathbb{F}_\ell} k_L$ ($\bar{\mu} = \varepsilon - 1$ has positive valuation in $\mathcal{O}_{\mathbb{C}_\ell^\flat}$), and the image of e_a there is the image of the non-zero idempotent $\bar{e}_a$ of $(\mathcal{O}_F \otimes \mathcal{O}_L)/\varpi = k \otimes_{\mathbb{F}_\ell} k_L \cong \prod_a k_L$ under the map $k \otimes k_L \to \mathbb{C}_\ell^\flat \otimes k_L$ induced by the field embedding $k \to \mathbb{C}_\ell^\flat$ (the reduction of $\varphi \circ w$), which is injective since k_L is flat over $\mathbb{F}_\ell$.

Step 0: $\mathbf{N}(\iota')$ is injective and $\mathbf{N}(\pi)\mathbf{N}(\iota') = 0$. As T'' is free over $\mathcal{O}_L$, the sequence splits over $\mathcal{O}_L$, so $1 \otimes \iota' \colon A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes T' \to W$ is injective and its image W' is the kernel of $1 \otimes \pi$ and a direct summand of W, free of rank r' over A'. By (Ex3), $\iota_T \circ \mathbf{N}(\iota') = (1 \otimes \iota') \circ \iota_{T'}$, which is injective, so $\mathbf{N}(\iota')$ is injective; and $\iota_{T''} \circ \mathbf{N}(\pi) \circ \mathbf{N}(\iota') = (1 \otimes \pi\iota') \circ \iota_{T'} = 0$, so $\mathbf{N}(\pi)\mathbf{N}(\iota') = 0$ by injectivity of $\iota_{T''}$. Hence $N' \subseteq K$, and $N'_a \cong \mathbf{N}(T')_a$ is free of rank r' over R by (Wm1) and (Ex1). Moreover $\iota_T(K) \subseteq W'$, since $(1 \otimes \pi)\iota_T(y) = \iota_{T''}(\mathbf{N}(\pi)y) = 0$ for $y \in K$.

Step 1: K_a is free of rank r', and the index of N'_a in K_a is prime to ϖ. K_a is the kernel of the R-linear map $\mathbf{N}(T)_a \to \mathbf{N}(T'')_a$ between free R-modules (Wm1). Its image I is torsion-free, so $\operatorname{depth}_R I \geq 1$, and the depth lemma for $0 \to K_a \to \mathbf{N}(T)_a \to I \to 0$ gives $\operatorname{depth}_R K_a \geq 2$; since R is regular local of dimension 2, the Auslander–Buchsbaum formula shows that K_a is free, of rank s say. As $N'_a \subseteq K_a$ is free of rank r', $s \geq r'$. Choose R-bases $b = (b_1, \ldots, b_s)$ of K_a, $c = (c_1, \ldots, c_{r'})$ of N'_a and $d = (d_1, \ldots, d_r)$ of $\mathbf{N}(T)_a$, and write $b = dP$, $c = bB$ with matrices $P \in M_{r \times s}(R)$, $B \in M_{s \times r'}(R)$.

By (Ex2), $A_{\mathrm{inf}}[1/\mu_\varepsilon] \cdot \iota_T(\mathbf{N}(T)) = W$; this span is an A'-module ($\iota_T(\lambda x) = (1 \otimes \lambda)\iota_T(x)$), so $\varepsilon_aW = A'\iota_T(\mathbf{N}(T)_a)$ is generated by the r elements $\iota_T(d)$. A generating family of r elements of a free module of rank r over a commutative ring is a basis, so $\iota_T(d)$ is an ε_aA'-basis of ε_aW. In the same way (for the pair (V', T'), transported by $1 \otimes \iota'$) $\iota_T(c)$ is a basis of ε_aW', a free ε_aA'-module of rank r' and a direct summand of ε_aW. Now $\iota_T(b) = \iota_T(d)\,\iota_L(P)$ has entries in ε_aW'. If $s > r'$, the s-fold exterior product of these s elements vanishes ($\wedge^s$ of a free module of rank $r' < s$ is 0, and $\wedge^s\varepsilon_aW' \to \wedge^s\varepsilon_aW$); its coordinates in the basis of $\wedge^s\varepsilon_aW$ induced by $\iota_T(d)$ are the images under ι_L of the $s \times s$ minors of P. Some such minor is non-zero, as b is linearly independent over R; this contradicts the injectivity of ι_L. So $s = r'$ and B is square. Since $c = bB$, the family $\iota_T(b)$ generates $\varepsilon_aW' \supseteq A'\iota_T(c) = \varepsilon_aW'$, so it is a basis of ε_aW', and $\iota_L(B)$ is the matrix of a change of basis. Hence

$$\delta_a := \det B \in R \qquad \text{has} \qquad \iota_L(\delta_a) \in (\varepsilon_aA')^\times.$$

In particular $\delta_a \neq 0$, and $\delta_a \notin \varpi R$, since ϖ is not a unit of ε_aA'.

Step 2: Frobenius forces $\delta_a \in X^{j_a}R^\times$, hence $X^{j_a}K_a \subseteq N'_a$. Let $(M_a, h_a)_a$ be a window of V and $(M'_a, h'_a)_a$ a window of V' as in (Ex1). Write $b^{(a)}$, $c^{(a)}$, B_a, δ_a for the data of Step 1 at the site a. For $x \in K_{a-1}$, $Q^{M_a}\varphi(x) \in \mathbf{N}(T)_a$ by (Wm2), and $\mathbf{N}(\pi)(Q^{M_a}\varphi(x)) = Q^{M_a}\varphi(\mathbf{N}(\pi)x) = 0$

by (Ex3) (all maps extended to the localisations at Q, which are injective on the free modules), so $Q^{M_a}\varphi(K_{a-1}) \subseteq K_a$. Hence $\varphi(b^{(a-1)}) = b^{(a)}Q^{-M_a}G_a$ with $G_a \in M_{r'}(R)$. Since $\mathbf{N}(\iota')$ commutes with φ, (Wm2) for $\mathbf{N}(T')$ gives $\varphi(c^{(a-1)}) = c^{(a)}Q^{-M'_a}H_a$ with $H_a \in M_{r'}(R)$, and $Q^{h'_a}c^{(a)} = \varphi(c^{(a-1)})C_a$ with $C_a \in M_{r'}(R)$ (the module generated by $\varphi(N'_{a-1})$ is generated by $\varphi(c^{(a-1)})$, by semilinearity). As $c^{(a)}$ is linearly independent over $R[1/Q]$, $H_aC_a = Q^{h'_a+M'_a}\cdot 1$, so $\det H_a$ divides a power of Q in R. Applying φ to $c^{(a-1)} = b^{(a-1)}B_{a-1}$ and comparing in the basis $b^{(a)}$ of $K_a[1/Q]$:

$$Q^{M'_a}G_a\,\varphi(B_{a-1}) = Q^{M_a}B_aH_a, \qquad \text{so} \qquad Q^{r'M'_a}\det(G_a)\,\varphi(\delta_{a-1}) = Q^{r'M_a}\,\delta_a\,\det(H_a). \qquad (*)$$

By Step 1 and the Weierstrass preparation theorem, $\delta_a = P_au_a$ with $P_a \in \mathcal{O}_L[X]$ a distinguished polynomial and $u_a \in R^\times$; so the set Z_a of zeros of δ_a in $\mathfrak{m}$ is finite. Let $\alpha \in Z_{a-1}$ with $\alpha \neq 0$, and $\beta \in \mathfrak{m}$ with $(1+\beta)^\ell = 1+\alpha$. Then $\varphi(\delta_{a-1})(\beta) = \delta_{a-1}(\alpha) = 0$; and $Q(\beta) = \Phi_\ell(1+\beta) \neq 0$ because $(1+\beta)^\ell \neq 1$, so also $\det(H_a)(\beta) \neq 0$. Evaluating $(*)$ at β gives $\delta_a(\beta) = 0$, and $\beta \neq 0$. By induction, for every $k \geq 1$ all $\beta \in \mathfrak{m}$ with $(1+\beta)^{\ell^k} = 1+\alpha$ lie in Z_{a-1+k}. There are ℓ^k of them: if $w \in \mathcal{O}_{\mathbb{C}_\ell}$ has $w^{\ell^k} = 1+\alpha$, its residue is an ℓ^k-th root of 1 in characteristic ℓ, so $w \in 1+\mathfrak{m}$, and the $\zeta w - 1$, $\zeta \in \mu_{\ell^k}$, are ℓ^k distinct elements of $\mathfrak{m}$. Taking k a multiple of n gives $|Z_{a-1}| \geq \ell^k$ for arbitrarily large k, a contradiction. Hence $Z_a \subseteq \{0\}$ for all a, so $P_a = X^{j_a}$ with $j_a = \deg P_a$, and $\delta_a = X^{j_a}u_a$. From $B_a\,\mathrm{adj}(B_a) = \delta_a\cdot 1$ we get $\delta_a b^{(a)} = c^{(a)}\mathrm{adj}(B_a)$, so $X^{j_a}K_a \subseteq N'_a$.

Step 3: the Γ-action removes the power of X. Both K and N' are stable under all γ_u (Ex3), and $(\gamma_u - 1)N' \subseteq XN'$ by (Wm3) for $\mathbf{N}(T')$. Also $(\gamma_u-1)K \subseteq XK$: for $y \in K$, (Wm3) gives $(\gamma_u-1)y = Xz$ with $z \in \mathbf{N}(T)$, and $X\,\mathbf{N}(\pi)(z) = (\gamma_u-1)\mathbf{N}(\pi)(y) = 0$, so $\mathbf{N}(\pi)(z) = 0$ as X is a non-zero-divisor on the free modules $\mathbf{N}(T'')_a$. Let $j \geq 0$ be minimal with $X^jK_a \subseteq N'_a$ (it exists by Step 2) and suppose $j \geq 1$. Write $X^jb = cD$ with $D \in M_{r'}(R)$, $\gamma_u(b) = b(1+XE)$, $\gamma_u(c) = c(1+XE')$ with $E, E' \in M_{r'}(R)$, and $\gamma_u(X) = Xw_u$ with $w_u = \sum_{k\geq 1}\binom{u}{k}X^{k-1} \in \mathbb{Z}_\ell[[X]]$, $w_u(0) = u$. Applying γ_u to $X^jb = cD$:

$$w_u^j\,c\,D(1+XE) = X^jw_u^j\,b(1+XE) = \gamma_u(X^jb) = c(1+XE')\gamma_u(D),$$
$$\text{so} \qquad w_u^jD(1+XE) = (1+XE')\gamma_u(D).$$

Reduce modulo X (the reduction $R \to \mathcal{O}_L$, $X \mapsto 0$, satisfies $\mathrm{red}\circ\gamma_u = \mathrm{red}$): $u^j\,\mathrm{red}(D) = \mathrm{red}(D)$. Take $u = 1+\ell$; then $u^j \neq 1$, and $\mathcal{O}_L$ is torsion-free, so $\mathrm{red}(D) = 0$, i.e. $D = XD'$ with $D' \in M_{r'}(R)$. Then $X(X^{j-1}b - cD') = 0$ in the free module $\mathbf{N}(T)_a$, so $X^{j-1}b = cD'$ and $X^{j-1}K_a \subseteq N'_a$, contradicting the minimality of j. Hence $j = 0$, $K_a \subseteq N'_a$, and with Step 0, $K_a = N'_a$. Uniqueness of x is the injectivity of $\mathbf{N}(\iota')$.

Over a base field. For pairs over K the proof is unchanged: (Wm1)–(Wm3), (Ex2), (Ex3) hold over K by Proposition 23.7, the maps γ_u are given for $u \in \Gamma_K$, and the one element used in Step 3, $u = 1+\ell$, lies in Γ_K, since $\Gamma_K = \Delta(1+\ell\mathbb{Z}_\ell)$ for a subgroup Δ of $\mu_{\ell-1}$ by (Rr7) of Lemma 23.24 (applied to the subgroup of order $(\ell-1)/[K:F]$).

Level s. Write $\mathbf{N} = \mathbf{N}_s$, $P = Q_{s-1}$ and $Y = X_{s-1} = (1+X)^{\ell^{s-1}} - 1$. Steps 0 and 1 are unchanged, with ι_s, $\iota_{s,T}$ in place of ι, ι_T: they use (Wm1), (Ex1)–(Ex3) of level s (Proposition 23.7(Ex4)), the injectivity of ι_s and $\iota_s = \varphi\circ w$ on $\mathcal{O}_F$ (Lemma 23.8(6)). Steps 2 and 3 change as follows. *Step 2 at level s: δ_a divides a power of Y.* The identity $(*)$ holds with Q replaced by P ((Wm2) of level s), and $\det H_a$ divides a power of P. Let $\alpha \in Z_{a-1}$ be such that $1+\alpha$ is not a root of unity of order dividing ℓ^{s-1}, and $\beta \in \mathfrak{m}$ with $(1+\beta)^\ell = 1+\alpha$. Then $1+\beta$ is not a primitive ℓ^s-th root of unity (otherwise $1+\alpha$ would have order ℓ^{s-1}), so $P(\beta) = \Phi_{\ell^s}(1+\beta) \neq 0$ and $\det(H_a)(\beta) \neq 0$; evaluating $(*)$ at β gives $\delta_a(\beta) = 0$; and $1+\beta$ is again not a root of unity of order dividing ℓ^{s-1} (its ℓ-th power $1+\alpha$ is not). By induction all ℓ^k elements β with $(1+\beta)^{\ell^k} = 1+\alpha$

lie in Z_{a-1+k}, and taking k a multiple of n contradicts the finiteness of Z_{a-1} as before. Hence every zero of δ_a in $\mathfrak{m}$ is of the form $\zeta - 1$ with $\zeta^{\ell^{s-1}} = 1$, i.e. a root of Y. As $L \supseteq \mu_{\ell^s}$ (the hypothesis on L in (Ex4)), the distinguished polynomial P_a of $\delta_a = P_a u_a$ is $\prod_\zeta (X - (\zeta - 1))^{m_\zeta}$ over these roots, and $Y = \prod_{\zeta^{\ell^{s-1}}=1}(X - (\zeta - 1))$; so with $j_a = \deg P_a$, $Y^{j_a} = P_a G_a$ for a monic $G_a \in \mathcal{O}_L[X]$, and $Y^{j_a} b^{(a)} = c^{(a)} \mathrm{adj}(B_a) u_a^{-1} G_a$ gives $Y^{j_a} K_a \subseteq N'_a$. *Step 3 at level s: the Γ-action removes the power of Y.* Let $u = 1 + \ell^s \in \Gamma_K$ ($\Gamma_K \supseteq \Gamma_{F(\mu_{\ell^s})} = 1 + \ell^s \mathbb{Z}_\ell$, Definition 23.2, paragraph Level s). By (Wm3') of level s, $(\gamma_u - 1)N' \subseteq YN'$, and $(\gamma_u - 1)K \subseteq YK$: for $y \in K$, (Wm3') gives $(\gamma_u - 1)y = Yz$ with $z \in \mathbf{N}(T)$, and $Y\,\mathbf{N}(\pi)(z) = 0$, so $\mathbf{N}(\pi)(z) = 0$ (Y is a non-zero-divisor on the free modules $\mathbf{N}(T'')_a$). Let $j \geq 0$ be minimal with $Y^j K_a \subseteq N'_a$ and suppose $j \geq 1$. Write $Y^j b = cD$, $\gamma_u(b) = b(1 + YE)$, $\gamma_u(c) = c(1 + YE')$ and $\gamma_u(Y) = Y w_u$ with $w_u = \sum_{k \geq 1} \binom{u}{k} Y^{k-1}$. As in Step 3, $w_u^j D(1 + YE) = (1 + YE')\gamma_u(D)$. Let $\rho\colon R \to R/YR$ be the quotient map; $R/YR = \mathcal{O}_L[X]/(Y)$ is free over $\mathcal{O}_L$ (Weierstrass division), $\rho \circ \gamma_u = \rho$ (both are continuous $\mathcal{O}_L$-algebra maps, $\rho(Y) = 0$, and $\gamma_u(1+X) = (1+X)^{1+\ell^s} = (1+X)(1+Y)^\ell$, so they agree on X) and $\rho(w_u) = u$. Hence $u^j \rho(D) = \rho(D)$; as $u^j \neq 1$ and R/YR is $\mathcal{O}_L$-torsion-free, $\rho(D) = 0$, $D = YD'$, and $Y^{j-1} b = cD'$ since Y is a non-zero-divisor on $\mathbf{N}(T)_a$, contradicting minimality. So $K_a = N'_a$. □

24 Relay classes, class splitting and lifting exponents

This section proves the two lifting exponents of the Part. For a surjection $F\colon T_1 \to T_2$ of crystalline lattices whose Hodge jumps lie in a window of width wt, a lifting exponent is an integer e with $\ell^e H^1_f(K, T_2) \subseteq F_* H^1_f(K, T_1)$. Over an unramified field K one can take $e = \lfloor c_{\mathrm{ur}}(2 + \mathrm{wt}/\ell + \log_\ell(\mathrm{wt} + 1)) \rfloor$ with an absolute constant c_{ur} (Proposition 24.1); over a field between K_0 unramified and $K_0(\mu_\ell)$ one can take $e = \lfloor c_{\mathrm{cy}}(\mathrm{wt} + 1) \rfloor$ (Proposition 24.10). The first enters the budget at the primes of split and inert type, through the explicit local losses of Section 25 and the row bound of Section 26; the second serves the small and ramified primes in Section 27.

The core of the unramified case is a conversion of exponents. The length lemma gives the annihilator X^{wt} for the cokernel of a surjection of Wach modules, and Γ-descent turns it into the power ℓ^{r_0} with $r_0 = \lfloor \mathrm{wt}\,\ell/(\ell-1)^2 \rfloor$; this is where the denominator ℓ in wt/ℓ comes from. A class in $H^1_f(K, T_2)$ is then realised as a crystalline extension by the trivial lattice, whose splitting at each site lifts up to ℓ^{r_0}, and the class is split into *relay classes*, one for each cut of a set of sites (Proposition 24.4). A relay class is the Herr class of a Frobenius twist of a Wach vector at the cut, corrected by a truncated horizontal part (Lemma 24.5), and it lifts as soon as the Wach vector lifts modulo X (Lemma 24.9). The one-site lifts of Lemma 24.7 cost the ℓ-adic valuations of the pole indices, which Legendre's formula bounds by a multiple of wt/ℓ; the proof gives in fact an exponent at most $\frac{63}{4}\,\mathrm{wt}/\ell + \frac{11}{4}$. Class splitting and relay classes are used again, with longer arcs between the cuts, in Appendix C.

24.1 Lifting exponents in the unramified case

The subsection opens with the statement Proposition 24.1 and then proves the lemmas on which its proof rests, in the order in which the proof uses them: level filtrations lie in their windows and the Hodge jumps of a quotient are Hodge jumps of the source (Lemma 24.2); the Wach module of the trivial lattice (Lemma 24.3); class splitting (Proposition 24.4) with relay classes and relay truncation (Lemma 24.5, Lemma 24.6); the one-site lift of Γ-almost-invariant Wach vectors, with the killing polynomial of the normalised Γ-operator (Lemma 24.7, Lemma 24.8); and relay lifting (Lemma 24.9). Class splitting and the relay lemmas are stated for general cuts

and arcs, more generally than the proof of Proposition 24.1 needs, because Appendix C applies them to arcs of length greater than one.

Proposition 24.1. *Let p be an odd prime, K a finite unramified extension of $\mathbb{Q}_p$, L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K(\mu_p))$ for every $\mathbb{Q}_p$-embedding σ of $K(\mu_p)$ into $\overline{\mathbb{Q}}_p$, and $\mathcal{O}_L$ its ring of integers. For a continuous L-linear representation V of G_K on a finite-dimensional L-vector space and a G_K-stable $\mathcal{O}_L$-lattice $T \subseteq V$ let $H^1_f(K,T)$ be the inverse image in $H^1(K,T)$ of $H^1_f(K,V) = \ker\bigl(H^1(K,V) \to H^1(K, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_p} V)\bigr)$.*

There is an absolute constant $c_{\mathrm{ur}} \geq 1$ with the following property. Let V_1, V_2 be such representations, crystalline as representations over $\mathbb{Q}_p$, let $T_\nu \subseteq V_\nu$ be G_K-stable $\mathcal{O}_L$-lattices, and let $F\colon V_1 \to V_2$ be an L-linear G_K-equivariant map with $F(T_1) = T_2$. Let $a^-_\tau, a^+_\tau \geq 0$ be integers, for the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$, such that every Hodge jump of V_1 at τ lies in $[-a^-_\tau, a^+_\tau]$, put $\mathrm{wt} = \max_\tau(a^-_\tau + a^+_\tau)$ and

$$e_{\mathrm{A}} = \Bigl\lfloor c_{\mathrm{ur}}\Bigl(2 + \frac{\mathrm{wt}}{p} + \log_p(\mathrm{wt}+1)\Bigr)\Bigr\rfloor.$$

Then

$$p^{e_{\mathrm{A}}}\, H^1_f(K,T_2) \subseteq F_*\bigl(H^1_f(K,T_1)\bigr).$$

The integer e_{A} depends only on p and wt and is non-decreasing in wt, hence in each $a^\pm_\tau$; and $e_{\mathrm{A}} \leq c_{\mathrm{ur}}(2 + \mathrm{wt}/p + \log_p(\mathrm{wt}+1))$.

Proof. We show that $c_{\mathrm{ur}} = 18$ has the property. Write $\ell = p$, F for the field K (the map of the statement is written Φ in this proof), $n = [F : \mathbb{Q}_\ell]$, and fix a Frobenius numbering $(\tau_a)_{a\in\mathbb{Z}/n}$; the τ_a are the n embeddings of F into L. Put $M_a = a^-_{\tau_a}$, $h_a = a^+_{\tau_a}$, $A = \max_a M_a$, $B = \max_a h_a$, $w = \mathrm{wt} = \max_a(M_a + h_a)$; so $A, B \leq w$. The hypotheses on ℓ, F, L are those of Proposition 23.7, so (V_1,T_1) and (V_2,T_2) are pairs. Since $\Phi(T_1) = T_2$ and T_2 spans V_2, $\Phi\colon V_1 \to V_2$ is onto, and by item 1 of Lemma 24.2 every Hodge jump of V_2 at τ_a is one of V_1; so every Hodge jump of V_1 and of V_2 at τ_a lies in $[-M_a, h_a]$.

Step 1: lifting along onto maps up to ℓ^{r_0}, $r_0 = \lfloor w\ell/(\ell-1)^2 \rfloor$. Let $f\colon T \to T''$ be a G_F-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') such that every Hodge jump of V at τ_a lies in $[-M_a, h_a]$, and let $c \in \mathbb{Z}/n$. We claim: for every $y \in \mathbf{N}(T'')_c$ there is $x \in \mathbf{N}(T)_c$ with $\mathbf{N}(f)(x) = \ell^{r_0} y$. By Proposition 23.18, $X^w \mathbf{N}(T'')_c \subseteq \mathbf{N}(f)(\mathbf{N}(T)_c)$ (its $H_{\max}$ is w). Apply item 1 of Lemma 23.21 with $D = N = \mathbf{N}(T'')_c$, $N' = \mathbf{N}(f)(\mathbf{N}(T)_c)$, $\gamma_{u,D} = \gamma_{u,\mathbf{N}}$, $s = w$, $j = 0$: multiplication by X is injective on D, which is free over $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ by (Wm1) for the window of (Ex1); $\gamma_{u,\mathbf{N}}$ is γ_u-semilinear, fixes e_c and has $(\gamma_u - 1)(N) \subseteq e_c X \mathbf{N}(T'') = XN$ by (Wm3); and N' is an $\mathbf{A}_{F,L}$-submodule with $(\gamma_u - 1)(N') = \mathbf{N}(f)\bigl((\gamma_u - 1)\mathbf{N}(T)_c\bigr) \subseteq XN'$, since $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with γ_u (Ex3). So $\ell^a N \subseteq N'$ for $a = \mathrm{dsc}_\ell(0,w)$, and $\mathrm{dsc}_\ell(0,w) \leq r_0$ by item 2 there; hence $\ell^{r_0} N \subseteq N'$.

Step 2: the extension. Let $x \in H^1_f(F,T_2)$. By Lemma 23.26 there are a pair (V_Y, Y) and an exact sequence $0 \to T_2 \xrightarrow{\iota'} Y \xrightarrow{\pi} \mathcal{O}_L \to 0$ of G_F-equivariant $\mathcal{O}_L$-linear maps with $[Y] = x$, every Hodge jump of V_Y at τ_a being 0 or one of V_2, hence in $[-M_a, h_a]$ (as $M_a, h_a \geq 0$). So $(M_a, h_a)_a$ is a window, as in (Ex1), of V_1, V_2 and V_Y. For $c \in \mathbb{Z}/n$, Step 1 for π and $y = e^\circ_c \in \mathbf{N}(\mathcal{O}_L)_c$ (Lemma 24.3) gives $x_c \in \mathbf{N}(Y)_c$ with $\mathbf{N}(\pi)(x_c) = \ell^{r_0} e^\circ_c$, so by (Ex3) $(1 \otimes \pi)(\iota_Y(x_c)) = \iota_{\mathcal{O}_L}(\ell^{r_0} e^\circ_c) = \ell^{r_0}\varepsilon_c$.

Step 3: splitting. Apply Proposition 24.4 to $(V',T') = (V_2,T_2)$, $(V,T) = (V_Y,Y)$, ι', π, the window (M_a,h_a), $C = \mathbb{Z}/n$ with $\mathrm{len}_c = 1$, $j = 1$, $G = g = A$, $m = R = A+1$, $r = r_0$ and the x_c of Step 2. Its hypotheses hold: $c - 1 \in C$ and there is no d with $1 \leq d < 1$; $j \leq \mathrm{len}_c$;

$M_{c+1} \le A = G$; $g \ge G$; $m = \max(g, 1 + \max_a M_a)$; $R \ge m$. With $\sigma = \sigma_\ell(A, A+1, 1)$ it gives $\tau'_c \in P_1(\mathbf{N}(T_2)_c)$ and $w_c \in I_c$ (formed for $\mathbf{N}(T_2)$) with

$$\mathbf{N}(\iota')(w_c) = X_{c-1} - \ell^\sigma x_c, \qquad X_{c-1} = \ell^\sigma \varphi(x_{c-1}) - \mathbf{N}(\iota')(\tau'_{c-1}), \qquad \ell^{r_0+2\sigma} x = \sum_{c \in \mathbb{Z}/n} \rho_{c,1}(w_c).$$

Step 4: the poles of w_c. By (Ry0) of Lemma 24.5, formed at the site $c-1$ with $j = 1$ and $G = A \ge M_c$ for $\mathbf{N}(Y)$ and for $\mathbf{N}(T_2)$, $\varphi(x_{c-1}) \in P_1(\mathbf{N}(Y)_{c-1}) \subseteq Q^{-A}\mathbf{N}(Y)_c$ and $\tau'_{c-1} \in Q^{-A}\mathbf{N}(T_2)_c$; also $x_c \in \mathbf{N}(Y)_c$. Hence $y := \mathbf{N}(\iota')(Q^A w_c) = Q^A \mathbf{N}(\iota')(w_c) \in \mathbf{N}(Y)$, and $\mathbf{N}(\pi)(y) = Q^A\, \mathbf{N}(\pi \circ \iota')(w_c) = 0$. By Lemma 23.33 (with $T'' = \mathcal{O}_L$), $y = \mathbf{N}(\iota')(z)$ with $z \in \mathbf{N}(T_2)$. The map $\mathbf{N}(\iota')$ is injective on $\mathbf{N}(T_2)$ (Lemma 23.33), hence on $\mathbf{N}(T_2)[1/\lambda_\infty]$, its base change along the flat localisation $\mathbf{A}_{F,L} \to \mathbf{A}_{F,L}[1/Q_s :\ s \ge 0]$. So $Q^A w_c = z \in \mathbf{N}(T_2)$.

Step 5: lifting each relay vector. Let J be the set of Hodge jumps of V_1 at the τ_a and $\kappa = \kappa_\ell(J, A)$. By Step 1 for Φ, every $y \in \mathbf{N}(T_2)_c$ has $x \in \mathbf{N}(T_1)_c$ with $\mathbf{N}(\Phi)(x) = \ell^{r_0} y$. So Lemma 24.7, with M_a, J, $G = A \ge \max_a M_a$, $r = r_0$ and $w = w_c \in I_c$ (Step 3) with $Q^A w_c \in \mathbf{N}(T_2)$ (Step 4), gives $u_c \in e_c \mathbf{N}(T_1)[1/\lambda_\infty]$ with $(\gamma_u - 1)(u_c) \in X\mathbf{N}(T_1)$ for all u, $Q^A u_c \in \mathbf{N}(T_1)$ and $\ell^{r_0+\kappa} w_c - \mathbf{N}(\Phi)(u_c) \in X\mathbf{N}(T_2)_c$.

Step 6: the relay classes lift. Apply Lemma 24.9 to (V_1, T_1), (V_2, T_2) with the window (M_a, h_a) for both, Φ, c, $j = 1$, $G = g = A$, $m = R = A + 1$ (so $m \ge 1 + \max_{a,\nu} M_a^\nu$, $R \ge \max(m, g)$, $M_{c+1}^\nu \le G$), $w = w_c$, $u = u_c$, $k = r_0 + \kappa$ and $\lambda' = Q^A = Q_0^A$; the sets and classes I_c^2, $\rho_{c,1}^2$ are those of Step 3. It gives $\ell^{r_0+\kappa}\rho_{c,1}(w_c) \in \Phi_* H_f^1(F, T_1)$, where $H_f^1(F, T_1)$, the group of Proposition 23.27, is the inverse image of $H_f^1(F, V_1)$, as here. Summing over c with Step 3,

$$\ell^e x \in \Phi_* H_f^1(F, T_1), \qquad e = 2r_0 + 2\sigma + \kappa.$$

Step 7: the exponent. For $\ell \ge 3$, $\ell/(\ell-1) \le 3/2$ and $\ell/(\ell-1)^2 \le \frac{9}{4} \cdot \frac{1}{\ell}$. (a) $r_0 \le \frac{9}{4}\, w/\ell$. (b) $\sigma = \lfloor (A + \frac{A+1}{\ell-1}) \frac{\ell}{(\ell-1)^2} \rfloor + 1 \le \frac{9}{4} \cdot \frac{3A+1}{2\ell} + 1 \le \frac{27}{8}\frac{w}{\ell} + \frac{11}{8}$. (c) Every $x \in J'_A$ is non-zero with $-(A-1) \le x \le A + B$, since $J \subseteq [-A, B]$ and $1 \le k \le A$; so by Legendre's formula ($v_\ell(N!) \le N/(\ell-1)$)

$$\sum_{x \in J'_A} v_\ell(x) \le v_\ell((A-1)!) + v_\ell((A+B)!) \le \frac{2A+B}{\ell-1} \le \frac{3w}{\ell-1} \le \frac{9}{2}\frac{w}{\ell}$$

(if $A = 0$ then $J'_A = \emptyset$); this sum is κ. Hence

$$e \le \Big(\frac{9}{2} + \frac{27}{4} + \frac{9}{2}\Big)\frac{w}{\ell} + \frac{11}{4} = \frac{63}{4}\,\frac{w}{\ell} + \frac{11}{4} < 18\Big(2 + \frac{w}{\ell} + \log_\ell(w+1)\Big).$$

As e is an integer, $e \le e_{\mathrm{A}}$ for $c_{\mathrm{ur}} = 18$, and $\ell^{e_{\mathrm{A}}} x = \ell^{e_{\mathrm{A}} - e}(\ell^e x) \in \Phi_* H_f^1(F, T_1)$, a subgroup. As $x \in H_f^1(F, T_2)$ was arbitrary, the inclusion follows. Finally $t \mapsto c_{\mathrm{ur}}(2 + t/\ell + \log_\ell(t+1))$ is increasing on $[0, \infty)$, so e_{A} is non-decreasing in wt, and $e_{\mathrm{A}} \le c_{\mathrm{ur}}(2 + \mathrm{wt}/\ell + \log_\ell(\mathrm{wt}+1))$ by definition of the floor. □

Lemma 24.2. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7 and $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L.*

1. *For every $a \in \mathbb{Z}/n$, every Hodge jump of V_2 at τ_a is a Hodge jump of V_1 at τ_a.*
2. *For a weight word $(b, w, S, \eta, m, (s_a), (\mathrm{sg}_a))$ for Φ, $G = w + S + \eta$, a cut c, a length $1 \le \mathrm{len} \le n$ and frames at $c - \mathrm{len}$, the arc level data of Φ along the word have (Lp7) for $\nu = 1, 2$ and every $s < \mathrm{len}$: the jumps of Fil_s^ν are the Hodge jumps of V_ν at τ_{c-s}.*

Proof. Write $B = B^+_{\mathrm{dR}}$, $D_\nu = D_{\mathrm{cris}}(V_\nu) = D_{\mathrm{dR}}(V_\nu)$ (crystalline, so de Rham), with the filtration of Theorem B.40 (Ai4).

Step 1: components. For $b \in \mathbb{Z}/n$, ϵ_b is the idempotent of $F \otimes_{\mathbb{Q}_\ell} L$ belonging to τ_{b+1} (for the inclusion $F \subset B_{\mathrm{dR}}$ of Theorem B.40 (Ai3); see the remark in Definition 23.3), and $\mathrm{Fil}^j D_\nu$ is an $F \otimes L$-submodule; so $\epsilon_b \mathrm{Fil}^j D_\nu = \mathrm{Fil}^j D_\nu \cap \epsilon_b D_\nu$ and $\epsilon_b D_\nu = D_{\mathrm{dR},\tau_{b+1}}(V_\nu)$ as filtered L-spaces. Fix a, put $\epsilon = \epsilon_{a-1}$, $R^+ = \epsilon(B \otimes_{\mathbb{Q}_\ell} L)$, and choose L-bases $(D^\nu_i)_i$ of ϵD_ν adapted to the filtration, $D^\nu_i \in \mathrm{Fil}^{u_{\nu,i}} D_\nu$ with $\epsilon \mathrm{Fil}^j D_\nu$ spanned by the D^ν_i with $u_{\nu,i} \geq j$. The Hodge jumps of V_ν at τ_a are the $u_{\nu,i}$. Applying ϵ to (Ai4) for $k = 0$ and $k = 1$ (the comparison is $F \otimes L$-linear):

$$\epsilon(B \otimes_{\mathbb{Q}_\ell} V_\nu) = \bigoplus_i t^{-u_{\nu,i}} R^+ D^\nu_i, \qquad \epsilon(tB \otimes_{\mathbb{Q}_\ell} V_\nu) = \bigoplus_i t^{1-u_{\nu,i}} R^+ D^\nu_i.$$

Step 2: proof of 1. Let $M_\nu = \epsilon(B \otimes V_\nu)/\epsilon(tB \otimes V_\nu)$ and, for $u \in \mathbb{Z}$, $M^{(u)}_\nu$ the image of $\bigoplus_{i:\, u_{\nu,i}=u} t^{-u} R^+ D^\nu_i$; by Step 1, $M_\nu = \bigoplus_u M^{(u)}_\nu$, each $M^{(u)}_\nu$ is G_F-stable, and $M^{(u)}_\nu \neq 0$ iff u is a Hodge jump of V_ν at τ_a. The map $1 \otimes \Phi$ is $B \otimes L$-linear and G_F-equivariant and maps $\epsilon(B \otimes V_1)$ onto $\epsilon(B \otimes V_2)$ (Φ is onto), hence induces a surjection $f\colon M_1 \to M_2$. Let $u \neq u'$, i with $u_{1,i} = u$, and write the $M^{(u')}_2$-component of $f(t^{-u} D^1_i)$ as $\sum_{j:\, u_{2,j}=u'} t^{-u'} c_j D^2_j$ with $c_j \in R^+/tR^+ = \epsilon(\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} L)$. For $g \in G_F$, $g(t^{-u} D^1_i) = \chi(g)^{-u} t^{-u} D^1_i$ (D_1 is G_F-fixed), and the projections to the $M^{(u')}_2$ commute with g; so $g(c_j) = \chi(g)^{u'-u} c_j$. Writing $c_j = \sum_m c_{jm} \otimes \lambda_m$ for a $\mathbb{Q}_\ell$-basis (λ_m) of L (G_F acting on $\mathbb{C}_\ell$ only), $\chi(g)^{u-u'} g(c_{jm}) = c_{jm}$ for all g, so $c_{jm} = 0$ by Theorem B.42 (2). Hence $f(M^{(u)}_1) \subseteq M^{(u)}_2$ for every u, and as f is onto, $f(M^{(u)}_1) = M^{(u)}_2$. If u is a Hodge jump of V_2 at τ_a, then $M^{(u)}_2 \neq 0$, so $M^{(u)}_1 \neq 0$ and u is a Hodge jump of V_1 at τ_a.

Step 3: proof of 2. Let $s < \mathrm{len}$ and $a = c - s$, so $\epsilon_s = \epsilon_{c-s-1}$ and $\epsilon_s D_\nu = D_{\mathrm{dR},\tau_{c-s}}(V_\nu)$ by Step 1. The level frame $(D^{(s)}_k)_k$ is an L-basis of $\epsilon_s D_\nu$, and $\sum_k v_k D^{(s)}_k \in \epsilon_s D_\nu$, so $\mathrm{Fil}^\nu_s(u)$ is the coordinate space of $\epsilon_s \mathrm{Fil}^u D_\nu$: Fil^ν_s is decreasing, equal to L^{r_ν} for $u \ll 0$ and to 0 for $u \gg 0$ (the filtration of D_{dR} is exhaustive and separated), and its jumps are the Hodge jumps of V_ν at τ_{c-s}. By 1 these lie among those of V_1, and by (Ow1): if $c - s$ is thin (κ_s thin; $s_{c-s} \leq w$ by (Ow3)), every jump u has $|u| \leq \max(s_{c-s} + S, \eta) \leq w + S + \eta = G$; if $c - s$ is thick with $\mathrm{sg}_{c-s} = 1$ (κ_s up, $b_s = s_{c-s}$), $u \in [b_s, b_s + S] \cup [-\eta, \eta]$; if $\mathrm{sg}_{c-s} = -1$ (κ_s down), $u \in [-b_s - S, -b_s] \cup [-\eta, \eta]$. This is (Lp7). □

Lemma 24.3. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7 and let $\mathcal{O}_L$ be the lattice of the trivial pair $(L, \mathcal{O}_L)$ (G_F acting trivially). Then there is an $\mathbf{A}_{F,L}$-linear isomorphism $\psi\colon \mathbf{N}(\mathcal{O}_L) \to \mathbf{A}_{F,L}$ with*

$$\iota_{\mathcal{O}_L} = (\iota \otimes \mathrm{id}_{\mathcal{O}_L}) \circ \psi.$$

In particular, for every $c \in \mathbb{Z}/n$ the element $e^\circ_c = \psi^{-1}(e_c)$ lies in $\mathbf{N}(\mathcal{O}_L)_c$ and $\iota_{\mathcal{O}_L}(e^\circ_c) = \varepsilon_c := (\iota \otimes \mathrm{id})(e_c)$.

Over a base field. *The same holds for a field K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Definition 23.2 and the trivial pair $(L, \mathcal{O}_L)$ over K (G_K acting trivially), $\mathbf{N}(\mathcal{O}_L)$ and $\iota_{\mathcal{O}_L}$ being those of Proposition 23.7 for pairs over K. For $K = F$ this is the statement above.*

Level s. *Let ℓ be any prime, $s \geq 1$ with $s \geq 2$ if $\ell = 2$, and L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) as in (Ex4) of Proposition 23.7. For the trivial pair $(L, \mathcal{O}_L)$ over K there is an $\mathbf{A}_{F,L}$-linear isomorphism $\psi\colon \mathbf{N}_s(\mathcal{O}_L) \to \mathbf{A}_{F,L}$ with $\iota_{s,\mathcal{O}_L} = (\iota_s \otimes \mathrm{id}_{\mathcal{O}_L}) \circ \psi$ (ι_s as in Lemma 23.8(6)); in particular $e^\circ_c = \psi^{-1}(e_c)$ satisfies $\iota_{s,\mathcal{O}_L}(e^\circ_c) = (\iota_s \otimes \mathrm{id})(e_c)$. For $s = 1$ and ℓ odd this is the paragraph over a base field.*

Proof. **The unit datum.** Put $T_0 = \mathcal{O}_L$, a free $\mathbb{Z}_\ell$-module of rank $[L : \mathbb{Q}_\ell]$ with trivial action, so $T_0[1/\ell]$ is crystalline. For an object (A, I) over $\mathcal{O}_F$ let $\mathcal{U}(A) = A \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, with $\varphi_{\mathcal{U},A}(a \otimes (b \otimes \lambda)) =$

$ab' \otimes \lambda$ where $b' = \varphi_A(b)$, i.e. the linearisation of $\varphi_A \otimes \mathrm{id}$, an isomorphism already before inverting I; and for a morphism f let $\mathcal{U}(f) = f \otimes \mathrm{id}$. Then (Bs1) and (Bs2) of Theorem B.41 hold. For (Bs3) take the identity of $W(\mathbb{C}_\ell^\flat) \otimes \mathcal{O}_L$: it is G_F-equivariant, carries $\varphi_M \otimes \varphi = \varphi \otimes \mathrm{id}$ to $1 \otimes \varphi$, and restricts to the identity of $A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes \mathcal{O}_L$. For (Bs4): the elements $\varphi_M(1 \otimes m)$ generate $M = A_{\mathrm{inf}} \otimes \mathcal{O}_L$, so their B'^+-span is $B'^+ \otimes \mathcal{O}_L$; on the other side $(\mathcal{O}_L \otimes B'_{\mathrm{dR}})^{G_F} = \mathcal{O}_L \otimes (B'_{\mathrm{dR}})^{G_F}$ contains $\mathcal{O}_L \otimes 1$, so its span contains $B'^+ \otimes \mathcal{O}_L$, and equality holds because $(B'_{\mathrm{dR}})^{G_F} \subseteq B'^+$. For the last inclusion: φ is a G_F-equivariant automorphism of A_{inf} with $\tilde{\theta} \circ \varphi = \theta$, hence induces G_F-equivariant isomorphisms $B_{\mathrm{dR}}^+ \to B'^+$ and $B_{\mathrm{dR}} \to B'_{\mathrm{dR}}$; and if $x \in B_{\mathrm{dR}}^{G_F}$ with $x \in t^{-k}B_{\mathrm{dR}}^+ \setminus t^{-k+1}B_{\mathrm{dR}}^+$ for some $k \geq 1$, the image of $t^k x$ in $B_{\mathrm{dR}}^+/tB_{\mathrm{dR}}^+ = \mathbb{C}_\ell$ (Theorem B.40) is a non-zero c with $\chi_{\mathrm{cyc}}(g)^k gc = c$ for all $g \in G_F$, contradicting item 2 of Theorem B.42. So $\mathcal{U}$ is a datum attached to T_0 as in Theorem B.41, with comparison isomorphism $c_{\mathcal{U}} = \mathrm{id}$.

Comparison with the chosen datum. By (Ex5) of Proposition 23.7 (with $K = F$, $s = 1$) there are a datum $\mathcal{E} = \mathcal{E}_{T_0}$ given by Theorem B.41 for T_0 and a comparison c_{T_0} with the properties of (Bs3) such that $\mathbf{N}(\mathcal{O}_L) = \mathcal{E}(\mathbf{A}_F)$, $\iota_{\mathcal{O}_L} = c_{T_0} \circ \mathcal{E}(\iota)$ and $\lambda \in \mathcal{O}_L$ acts on $\mathbf{N}(\mathcal{O}_L)$ by $\mathcal{E}(\lambda)_{\mathbf{A}_F}$. Apply (Bs5) to $\mathrm{id}\colon T_0 \to T_0$ with the data $\mathcal{E}$, $\mathcal{U}$ and with $\mathcal{U}$, $\mathcal{E}$: we get A-linear maps $\psi_A = \mathcal{E}(\mathrm{id})_A\colon \mathcal{E}(A) \to \mathcal{U}(A)$ and $\psi'_A\colon \mathcal{U}(A) \to \mathcal{E}(A)$ with $\psi'_A \circ \psi_A = \mathcal{E}(\mathrm{id} \circ \mathrm{id})_A = \mathrm{id}$ and $\psi_A \circ \psi'_A = \mathrm{id}$, commuting with $\mathcal{E}(g), \mathcal{U}(g)$ for every morphism g, and with $c_{\mathcal{U}} \circ (\psi_{A_{\mathrm{inf}}} \otimes 1) = c_{T_0}$. Let $\psi = \psi_{\mathbf{A}_F}\colon \mathbf{N}(\mathcal{O}_L) \to \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L = \mathbf{A}_{F,L}$, an $\mathbf{A}_F$-linear bijection. It is $\mathcal{O}_L$-linear: $\lambda \in \mathcal{O}_L$ acts on $\mathcal{E}(\mathbf{A}_F) = \mathbf{N}(\mathcal{O}_L)$ by $\mathcal{E}(\lambda)_{\mathbf{A}_F}$ ((Ex5) of Proposition 23.7) and on $\mathcal{U}(A)$ by $\mathcal{U}(\lambda)_A = \mathrm{id} \otimes \lambda$, and (Bs5) gives $\psi_A \circ \mathcal{E}(\lambda)_A = \mathcal{U}(\lambda)_A \circ \psi_A$ (both equal the map attached to $\lambda \circ \mathrm{id} = \mathrm{id} \circ \lambda$); hence ψ is $\mathbf{A}_{F,L}$-linear. Finally, for $x \in \mathbf{N}(\mathcal{O}_L)$,

$$\iota_{\mathcal{O}_L}(x) = c_{T_0}(\mathcal{E}(\iota)x) = c_{\mathcal{U}}(\psi_{A_{\mathrm{inf}}}(\mathcal{E}(\iota)x)) = c_{\mathcal{U}}(\mathcal{U}(\iota)(\psi x)) = (\iota \otimes \mathrm{id})(\psi x).$$

As ψ is $\mathbf{A}_{F,L}$-linear it maps $\mathbf{N}(\mathcal{O}_L)_c = e_c\mathbf{N}(\mathcal{O}_L)$ onto $e_c\mathbf{A}_{F,L}$, which gives the last assertion.

Over a base field. For the trivial pair over K the proof is the same with G_F replaced by G_K and objects and morphisms over $\mathcal{O}_F$ by those over $\mathcal{O}_K$, with (Ex5) of Proposition 23.7 for pairs over K (Theorem B.41 is stated for every finite extension of $\mathbb{Q}_\ell$). The places that involve the field: in (Bs3) the identity is G_K-equivariant; in (Bs4) one needs $(B'_{\mathrm{dR}})^{G_K} \subseteq B'^+$, and the argument given uses only that φ induces G_K-equivariant isomorphisms $B_{\mathrm{dR}}^+ \to B'^+$, $B_{\mathrm{dR}} \to B'_{\mathrm{dR}}$ and item 2 of Theorem B.42, which is stated for every finite extension of $\mathbb{Q}_\ell$, in particular for K; the comparison with the chosen datum uses (Bs5) and (Ex5) of Proposition 23.7 over K in the same way. No step uses that the base is unramified.

Level s. The proof over K applies without change to $K \subseteq F(\mu_{\ell^s})$ and any prime ℓ: the unit datum $\mathcal{U}$ and its properties (Bs1)–(Bs4) do not involve the prism $(\mathbf{A}_F, Q_{s-1}\mathbf{A}_F)$ or ℓ odd (Theorem B.41 and item 2 of Theorem B.42 hold for every prime and every finite extension); the comparison with the chosen datum uses (Bs5) and (Ex5) of Proposition 23.7 at level s, by which $\mathbf{N}_s(\mathcal{O}_L) = \mathcal{E}(\mathbf{A}_F)$ for the object $(\mathbf{A}_F, Q_{s-1}\mathbf{A}_F)$, $\iota_{s,\mathcal{O}_L} = c_{T_0} \circ \mathcal{E}(\iota_s)$ and $\lambda \in \mathcal{O}_L$ acts by $\mathcal{E}(\lambda)_{\mathbf{A}_F}$; the displayed computation then reads $\iota_{s,\mathcal{O}_L}(x) = c_{\mathcal{U}}(\mathcal{U}(\iota_s)(\psi x)) = (\iota_s \otimes \mathrm{id})(\psi x)$. □

Proposition 24.4. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7; let (V', T'), (V, T) be pairs and $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} \mathcal{O}_L \to 0$ an exact sequence of G_F-equivariant $\mathcal{O}_L$-linear maps ($\mathcal{O}_L$ the trivial representation), with extension class $[T] \in H^1(F, T')$. Let $(M_a, h_a)_a$ be a window both of V' and of V as in (Ex1). Let $C \subseteq \mathbb{Z}/n$ be non-empty and $\mathrm{len}\colon C \to \mathbb{Z}_{\geq 1}$ such that for every $c \in C$: $c - \mathrm{len}_c \in C$ and $c - d \notin C$ for $1 \leq d < \mathrm{len}_c$. Let $j \geq 1$, $G \geq 0$, $g \geq G$, $m \geq \max(g, 1 + \max_a M_a)$, $R \geq m$ be integers with $j \leq \mathrm{len}_c$ and $M_{c+s} \leq G$ for all $c \in C$ and $1 \leq s \leq j$; put $\sigma = \sigma_\ell(g, m, j)$, and let I_c, $\rho_{c,j}\colon I_c \to H^1(F, T')$ be formed for $\mathbf{N}(T')$ with these c, j, G, g, m, R. Write $\varepsilon_a = (\iota \otimes \mathrm{id})(e_a) \in A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$. Let $r \geq 0$ and suppose that for every $c \in C$ there is $x_c \in \mathbf{N}(T)_c$ with*

$$(1 \otimes \pi)(\iota_T(x_c)) = \ell^r \varepsilon_c.$$

Then there are $\tau'_c \in P_j(\mathbf{N}(T')_c)$ *and* $w_c \in I_c$ *(*$c \in C$*) such that, with* $X_c = \ell^\sigma \varphi^j(x_c) - \mathbf{N}(\iota')(\tau'_c)$,

$$\mathbf{N}(\iota')(w_c) = \varphi^{\mathrm{len}_c - j}(X_{c-\mathrm{len}_c}) - \ell^\sigma x_c, \qquad (\gamma_u - 1)(X_c) \in \mathbf{N}(\iota')(X^m \mathbf{N}(T'))\ (u \in \mathbb{Z}_\ell^\times),$$

$-\ell^\sigma \tau'_c$ *is a relay correction of* w_c*, and*

$$\ell^{r+2\sigma}\,[T] = \sum_{c \in C} \rho_{c,j}(w_c) \qquad \text{in } H^1(F, T').$$

Proof. Write $\iota_L = \iota \otimes \mathrm{id}$, $p(c) = c - \mathrm{len}_c$, $N' = \mathbf{N}(T')$, $N = \mathbf{N}(T)$, and π_1 for the realisation of the trivial pair.

Step 0: two facts. (F1) The map ι is a morphism of δ-rings (Lemma 23.8(4)), so $(\varphi \otimes 1) \circ \iota_L = \iota_L \circ \varphi$; and $\sigma \circ \iota_L = \iota_L \circ \gamma_{\chi_{\mathrm{cyc}}(\sigma)}$ for $\sigma \in G_F$. As $\gamma_u(e_a) = e_a$ and $\varphi(e_a) = e_{a+1}$, the ε_a are G_F-invariant, $(\varphi \otimes 1)(\varepsilon_a) = \varepsilon_{a+1}$, and $\sum_a \varepsilon_a = 1$. (F2) If $u \in N[1/\lambda_\infty]$ and $(1 \otimes \pi)\iota_T(u) = 0$, then $u = \mathbf{N}(\iota')(t)$ for a unique $t \in N'[1/\lambda_\infty]$, and $t \in X^k N'$ if $u \in X^k N$. Indeed $\pi_1(\mathbf{N}(\pi)u) = (1 \otimes \pi)\iota_T(u) = 0$ and π_1 is injective on $\mathbf{N}(\mathcal{O}_L)[1/\lambda_\infty]$ (Lemma 23.29(Gc0)), so $\mathbf{N}(\pi)u = 0$; clearing poles by a product f of the Q_s and applying Lemma 23.33 gives t; if $u = X^k u'$ with $u' \in N$, then $X^k \mathbf{N}(\pi)(u') = 0$, so $\mathbf{N}(\pi)(u') = 0$, $u' = \mathbf{N}(\iota')(t')$ with $t' \in N'$, and $t = X^k t'$ by injectivity of $\mathbf{N}(\iota')$. Moreover $e_a t = t$ when $e_a u = u$.

Step 1: the arcs. For $c \in C$, len_c is the least $e \geq 1$ with $p(c) + e \in C$ (as $p(c) + e' = c - (\mathrm{len}_c - e') \notin C$ for $1 \leq e' < \mathrm{len}_c$), so c is determined by $p(c)$ and $p\colon C \to C$ is injective, hence bijective. Every $i \in \mathbb{Z}/n$ is $p(c) + k$ for exactly one pair (c, k) with $c \in C$, $0 \leq k < \mathrm{len}_c$: let $d \geq 0$ be least with $c_0 := i - d \in C$, $e \geq 1$ least with $c_0 + e \in C$, and $c = c_0 + e$; then $p(c) = c_0$, and $d < e = \mathrm{len}_c$ (otherwise $i - (d - e) = c_0 + e \in C$ contradicts the choice of d); conversely if $i = p(c) + k$ with $0 \leq k < \mathrm{len}_c$, then $p(c) + k - d' \notin C$ for $0 \leq d' < k$ (it equals $c - (\mathrm{len}_c - k + d')$), so $k = d$ and $p(c) = c_0$, which determines c. Hence $\sum_{i \in \mathbb{Z}/n} f(i) = \sum_{c \in C} \sum_{k < \mathrm{len}_c} f(p(c) + k)$ for every function f.

Step 2: the pieces at a cut. Fix $c \in C$. For $u \in \mathbb{Z}_\ell^\times$ and $\sigma_u \in G_F$ with $\chi_{\mathrm{cyc}}(\sigma_u) = u$, $(1 \otimes \pi)\iota_T(\gamma_u x_c) = \sigma_u(\ell^r \varepsilon_c) = \ell^r \varepsilon_c$ by (Ex2) and (F1); with (Wm3) and (F2), $(\gamma_u - 1)(x_c) = \mathbf{N}(\iota')(t_{c,u})$ with $t_{c,u} \in X N'_c$, and $u \mapsto t_{c,u}$ satisfies the cocycle relation of (Hf1) (it holds for $(\gamma_u - 1)(x_c)$, and $\mathbf{N}(\iota')$ is injective and commutes with γ_u). Let $W_c \in X N'_E$ be the solution of (Hf1) of Lemma 23.9 for $(t_{c,u})_u$. By uniqueness in (Hf1), $e_c W_c = W_c$. Let $(n_i)_i$ be an $e_c \mathbf{A}_{F,L}$-basis of N'_c (Wm1), completed by bases of the other sites to an $\mathbf{A}_{F,L}$-basis of N', and write $W_c = \sum_i W_i n_i$ with $W_i = \sum_{k \geq 1} \omega_{ik} X^k$, $\omega_{ik} \in e_c E$; by (Hf3), $\ell^{s_\ell(k)} \omega_{ik} \in \Lambda = \mathcal{O}_F \otimes \mathcal{O}_L$. Put $V_c = \sum_i \sum_{1 \leq k < R} \omega_{ik} X^k n_i \in N'_c[1/\ell]$, so that $V_c - W_c \in X^R N'_E$. As $\varphi^j(X) = X \lambda_j$ and $\ell^{s_\ell(k)} \varphi^j(\omega_{ik}) \in \Lambda$, (Rt1) of Lemma 24.6 writes each of the finitely many terms $\ell^\sigma \varphi^j(\omega_{ik})(X\lambda_j)^k$ as $\alpha_{ik} + X^m \lambda_j^g \beta_{ik}$ with $\alpha_{ik} \in \Lambda[[X]]$ and $\beta_{ik} \in \Lambda[[X]][1/\ell]$. Then $\tau'_c = \sum_{i,k} \alpha_{ik} \varphi^j(n_i) \in P_j(N'_c)$ and $\tau'_c - \ell^\sigma \varphi^j(V_c) = -X^m \lambda_j^g \sum_{i,k} \beta_{ik} \varphi^j(n_i) \in X^m \lambda_j^g P_j(N'_c)[1/\ell]$. Now $x_c \in I_c(N)$ (the set I_c formed for N, legitimate as (M_a, h_a) is a window of V), and by uniqueness in (Hf1), $\mathbf{N}(\iota')(W_c)$ is the element W_{x_c} for N. Since $\mathbf{N}(\iota')$ maps $P_j(N'_c)$ into $P_j(N_c)$ and $X^R N'_E$ into $X^R N_E$, $\mathbf{N}(\iota')(\tau'_c)$ is a relay correction of x_c for N, with $\mathbf{N}(\iota')(V_c)$ in the role of V in the definition of a relay correction. By (Ry2) for N, $(\gamma_u - 1)(X_c) \in X^m N$. Also, by (Ex2), (F1) and $\pi \circ \iota' = 0$,

$$(1 \otimes \pi)\iota_T(X_c) = \ell^\sigma (\varphi \otimes 1)^j (\ell^r \varepsilon_c) = \ell^{\sigma + r} \varepsilon_{c+j}, \qquad (1)$$

which is G_F-invariant; so $(1 \otimes \pi)\iota_T((\gamma_u - 1)X_c) = 0$, and (F2) gives $(\gamma_u - 1)(X_c) = \mathbf{N}(\iota')(X^m \mu_{c,u})$ with $\mu_{c,u} \in N'$.

Step 3: the global lift and its Herr vector. Put $\tilde{x} = \sum_{c \in C} \sum_{0 \leq k < \mathrm{len}_c} \varphi^k(X_{p(c)}) \in N[1/\lambda_\infty]$. By (1), (F1) and Step 1,

$$(1 \otimes \pi)\iota_T(\tilde{x}) = \sum_{c \in C} \sum_{k < \mathrm{len}_c} \ell^{\sigma + r} \varepsilon_{p(c)+j+k} = \ell^{\sigma + r} \sum_{i \in \mathbb{Z}/n} \varepsilon_{i+j} = 1 \otimes \ell^{\sigma + r}.$$

Further $(\gamma_u-1)(\tilde{x}) = \mathbf{N}(\iota')(\sum_{c,k}\varphi^k(X^m\mu_{p(c),u})) \in \mathbf{N}(\iota')(X^mN')$ by Lemma 23.30(1) for N'. By Lemma 23.32 (with $c=\ell^{\sigma+r}$), there is $y\in N'[1/\lambda_\infty]$ with $\mathbf{N}(\iota')(y)=(\varphi-1)(\tilde{x})$; it is a Herr vector of precision m and $\mathrm{cl}(y)=\ell^{\sigma+r}[T]$.

Step 4: the arc pieces. For $c\in C$ put $u_c=\varphi^{\mathrm{len}_c-j}(X_{p(c)})-\ell^\sigma x_c\in e_cN[1/\lambda_\infty]$. By (1) and $p(c)+\mathrm{len}_c=c$, $(1\otimes\pi)\iota_T(u_c)=\ell^{\sigma+r}\varepsilon_c-\ell^{\sigma+r}\varepsilon_c=0$, so $u_c=\mathbf{N}(\iota')(w_c)$ with $w_c\in e_cN'[1/\lambda_\infty]$ by (F2). Applying γ_u-1 and injectivity of $\mathbf{N}(\iota')$,

$$(\gamma_u-1)(w_c)=\varphi^{\mathrm{len}_c-j}(X^m\mu_{p(c),u})-\ell^\sigma t_{c,u}\in X^mN'+XN'\subseteq XN',$$

using Lemma 23.30(1); so $w_c\in I_c$. The family $z''_u=\varphi^{\mathrm{len}_c-j}(X^m\mu_{p(c),u})=(\gamma_u-1)(w_c)+\ell^\sigma t_{c,u}$ lies in X^mN' and satisfies the cocycle relation (a sum of two cocycles); let $W''\in X^mN'_E$ be its solution in (Hf1). Then $W''-\ell^\sigma W_c\in XN'_E$ solves the equation of w_c, so $W_{w_c}=W''-\ell^\sigma W_c$. Truncating the coordinates of W'' below degree R gives $V''\in X^mN'_c[1/\ell]$ with $V''-W''\in X^RN'_E$ ((Hf3); the coordinates have no terms of degree $<m$). With $V=V''-\ell^\sigma V_c$ we have $V-W_{w_c}\in X^RN'_E$ and

$$-\ell^\sigma\tau'_c-\ell^\sigma\varphi^j(V)=-\ell^\sigma(\tau'_c-\ell^\sigma\varphi^j(V_c))-\ell^\sigma\varphi^j(V'')\in X^m\lambda_j^gP_j(N'_c)[1/\ell],$$

since $\varphi^j(X^mN'_c[1/\ell])=X^m\lambda_j^mP_j(N'_c)[1/\ell]$ and $m\ge g$. As $-\ell^\sigma\tau'_c\in P_j(N'_c)$, it is a relay correction of w_c, and $\rho_{c,j}(w_c)=\mathrm{cl}(v_c)$ with $v_c=\ell^\sigma\varphi^j(w_c)+\ell^\sigma\tau'_c$, a Herr vector of precision m by (Ry2), (Ry3).

Step 5: telescoping. By definition of w_c and X_c,

$$\mathbf{N}(\iota')(v_c)=\ell^\sigma\varphi^{\mathrm{len}_c}(X_{p(c)})-\ell^\sigma(\ell^\sigma\varphi^j(x_c)-\mathbf{N}(\iota')(\tau'_c))=\ell^\sigma(\varphi^{\mathrm{len}_c}(X_{p(c)})-X_c).$$

On the other hand $(\varphi-1)(\tilde{x})=\sum_{c\in C}(\varphi^{\mathrm{len}_c}(X_{p(c)})-X_{p(c)})=\sum_{c\in C}(\varphi^{\mathrm{len}_c}(X_{p(c)})-X_c)$, the second equality because p is a bijection of C (Step 1). Hence $\mathbf{N}(\iota')(\sum_c v_c)=\mathbf{N}(\iota')(\ell^\sigma y)$ and, by injectivity, $\sum_{c\in C}v_c=\ell^\sigma y$.

Step 6: classes. By (Hc3) of Lemma 23.28 (Herr vectors of precision m form an $\mathcal{O}_L$-module on which cl is linear),

$$\sum_{c\in C}\rho_{c,j}(w_c)=\sum_{c\in C}\mathrm{cl}(v_c)=\mathrm{cl}(\ell^\sigma y)=\ell^\sigma\,\mathrm{cl}(y)=\ell^{\,r+2\sigma}[T].$$

□

Lemma 24.5. *Let ℓ, F, L, (τ_a) and a pair (V,T) be as in Proposition 23.7, $\mathbf{N}=\mathbf{N}(T)$ with a window $(M_a,h_a)_a$ as in (Ex1). Let $c\in\mathbb{Z}/n$ and integers $j\ge1$, $G\ge0$, $g\ge G$, $m\ge1+\max_a M_a$ and $R\ge\max(m,g)$, with $M_{c+s}\le G$ for $1\le s\le j$, and put $\sigma=\sigma_\ell(g,m,j)$. Let I_c be the set of $w\in e_c\mathbf{N}[1/\lambda_\infty]$ with $(\gamma_u-1)(w)\in X\mathbf{N}$ for all $u\in\mathbb{Z}_\ell^\times$; for $w\in I_c$ let $W_w\in X\mathbf{N}_E$ be the unique element with $(\gamma_u-1)(W_w)=(\gamma_u-1)(w)$ for all u ((Hf1) with $z_u=(\gamma_u-1)(w)$). An element $\tau\in P_j(\mathbf{N}_c)$ is a* relay correction *of $w\in I_c$ if there is $V\in\mathbf{N}_c[1/\ell]$ with*

$$V-W_w\in X^R\mathbf{N}_E\qquad\text{and}\qquad\tau-\ell^\sigma\varphi^j(V)\in X^m\lambda_j^g\,P_j(\mathbf{N}_c)[1/\ell].$$

(Ry0) Poles $P_j(\mathbf{N}_c)\subseteq\lambda_j^{-G}\mathbf{N}_{c+j}$.

(Ry1) Existence *Every $w\in I_c$ has a relay correction.*

(Ry2) Precision *If τ is a relay correction of w, then $\ell^\sigma\varphi^j(w)-\tau$ is a Herr vector of precision m.*

(Ry3) The relay class $\rho_{c,j}(w) := \mathrm{cl}(\ell^\sigma\varphi^j(w)-\tau) \in H^1(F,T)$ *does not depend on the relay correction* τ.

(Ry4) Linearity I_c *is an* $\mathcal{O}_L$*-submodule of* $e_c\mathbf{N}[1/\lambda_\infty]$ *and* $\rho_{c,j}\colon I_c \to H^1(F,T)$ *is* $\mathcal{O}_L$*-linear.*

(Ry5) Vanishing *If* $w \in X\mathbf{N}_c$*, then* $w \in I_c$ *and* $\rho_{c,j}(w)=0$.

(Ry6) Naturality *Let* (V',T') *be another pair with a window* (M'_a,h'_a) *such that* $m \geq 1+\max_a M'_a$ *and* $M'_{c+s} \leq G$ *for* $1\leq s\leq j$*, and* $f\colon T\to T'$ *a* G_F*-equivariant* $\mathcal{O}_L$*-linear map. Then* $\mathbf{N}(f)(I_c)\subseteq I'_c$ *and* $\rho'_{c,j}(\mathbf{N}(f)(w)) = f_*\rho_{c,j}(w)$*, where* I'_c*,* $\rho'_{c,j}$ *are formed for* $\mathbf{N}(T')$ *with the same* c,j,G,g,m,R.

Proof. Fix a site a and write $R_a = e_a\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$, ϖ a uniformiser of $\mathcal{O}_L$.

Two intersection facts. (C1) For $k,G'\geq 0$: $X^kR_a[1/\ell]\cap\lambda_j^{-G'}R_a = X^kR_a$ inside the fraction field. Indeed, if $f=g_1/\lambda_j^{G'} = X^kh/\ell^b$ with $g_1,h\in R_a$, then $\ell^b g_1 = X^k\lambda_j^{G'}h$; R_a is a unique factorisation domain in which ϖ is prime and does not divide $X^k\lambda_j^{G'}$ (its reduction is $X^{k+G'\deg\lambda_j}$, since each Q_s is monic and $\equiv X^{\deg Q_s} \bmod \ell$ by Lemma 23.8(3)); so $\ell^b \mid h$ and $f\in X^kR_a$. (C2) $R_a[1/\ell]\cap X^kL[[X]] = X^kR_a[1/\ell]$, by comparing coefficients. Since $\mathbf{N}_a$ is free over R_a (Wm1), (C1) and (C2) hold for $\mathbf{N}_a$ in place of R_a, coordinatewise in a basis: $X^k\mathbf{N}_a[1/\ell]\cap\lambda_j^{-G'}\mathbf{N}_a = X^k\mathbf{N}_a$ and $\mathbf{N}_a[1/\ell]\cap X^k\mathbf{N}_E = X^k\mathbf{N}_a[1/\ell]$ (here $\mathbf{N}_a[1/\ell]\subseteq e_a\mathbf{N}_E$, the elements Q_s, λ_j being units of $E[[X]]$ as $Q_s(0)=\ell$).

(Ry0). By induction on $i\leq j$: $\varphi^i(\mathbf{N}_c)\subseteq\prod_{s=0}^{i-1}Q_s^{-M_{c+i-s}}\mathbf{N}_{c+i}$. For $i=1$ this is (Wm2). If it holds for $i<j$, then, as φ is semilinear with $\varphi(Q_s)=Q_{s+1}$, $\varphi^{i+1}(\mathbf{N}_c)\subseteq\prod_{s=0}^{i-1}Q_{s+1}^{-M_{c+i-s}}\varphi(\mathbf{N}_{c+i})\subseteq\prod_{s=0}^{i-1}Q_{s+1}^{-M_{c+i-s}}\cdot Q_0^{-M_{c+i+1}}\mathbf{N}_{c+i+1}$, which is the claim for $i+1$. For $i=j$ all exponents are $M_{c+j-s}\leq G$, so $\varphi^j(\mathbf{N}_c)\subseteq\lambda_j^{-G}\mathbf{N}_{c+j}$, and the same holds for the module $P_j(\mathbf{N}_c)$ it generates.

(Ry1). Let $n_1,\dots,n_r$ be an R_c-basis of $\mathbf{N}_c$ and $W_w=\sum_i W_in_i$, $W_i=\sum_{k\geq 1}a_{ik}X^k$ with $a_{ik}\in e_cE$. By (Hf3) of Lemma 23.9, $\ell^{s_\ell(k)}a_{ik}\in\Lambda$. Put $V=\sum_i\sum_{1\leq k<R}a_{ik}X^kn_i\in\mathbf{N}_c[1/\ell]$; then $V-W_w\in X^R\mathbf{N}_E$. Now $\varphi^j(V)=\sum_i\sum_{k<R}\varphi^j(a_{ik})(X\lambda_j)^k\varphi^j(n_i)$, and $\ell^{s_\ell(k)}\varphi^j(a_{ik})\in\Lambda$. By (Rt1) of Lemma 24.6, $\ell^\sigma\varphi^j(a_{ik})(X\lambda_j)^k = f_{ik}+X^m\lambda_j^gh_{ik}$ with $f_{ik}\in\Lambda[[X]]$ and $h_{ik}\in\Lambda[[X]][1/\ell]$. Then $\tau=\sum_{i,k}f_{ik}\varphi^j(n_i)\in P_j(\mathbf{N}_c)$ and $\tau-\ell^\sigma\varphi^j(V) = -X^m\lambda_j^g\sum_{i,k}h_{ik}\varphi^j(n_i)\in X^m\lambda_j^gP_j(\mathbf{N}_c)[1/\ell]$.

(Ry2). Let τ, V be as in the definition, $d=\tau-\ell^\sigma\varphi^j(V)$, and $v=\ell^\sigma\varphi^j(w)-\tau = \ell^\sigma\varphi^j(w-V)-d$. Since γ_u commutes with φ (Wm3),

$$(\gamma_u-1)(v) = \ell^\sigma\varphi^j((\gamma_u-1)(w-V)) - (\gamma_u-1)(d).$$

First, $(\gamma_u-1)(w-V)=(\gamma_u-1)(W_w-V)$ lies in $X^R\mathbf{N}_E$ ($\gamma_u(X)\in X\mathbb{Z}_\ell[[X]]^\times$; $e_c\mathbf{N}[1/\lambda_\infty]\subseteq e_c\mathbf{N}_E$ as the Q_s are units of $E[[X]]$) and in $\mathbf{N}_c[1/\ell]$ (as $(\gamma_u-1)(w)\in X\mathbf{N}_c$ and $V\in\mathbf{N}_c[1/\ell]$), hence in $X^R\mathbf{N}_c[1/\ell]$ by (C2); so, using $\varphi^j(X)=X\lambda_j$ and (Ry0), $\ell^\sigma\varphi^j((\gamma_u-1)(w-V))\in X^R\lambda_j^{R-G}\mathbf{N}_{c+j}[1/\ell]\subseteq X^m\mathbf{N}_{c+j}[1/\ell]$, as $R\geq m$ and $R\geq g\geq G$. Second, γ_u preserves $P_j(\mathbf{N}_c)$ (it preserves $\mathbf{N}_c$ and commutes with φ) and $\gamma_u(X^m\lambda_j^g)\in X^m\lambda_j^g\mathbb{Z}_\ell[[X]]^\times$ (Lemma 23.8(2)), so $(\gamma_u-1)(d)\in X^m\lambda_j^gP_j(\mathbf{N}_c)[1/\ell]\subseteq X^m\lambda_j^{g-G}\mathbf{N}_{c+j}[1/\ell]\subseteq X^m\mathbf{N}_{c+j}[1/\ell]$. Hence $(\gamma_u-1)(v)\in X^m\mathbf{N}_{c+j}[1/\ell]$. On the other hand $(\gamma_u-1)(v)=\ell^\sigma\varphi^j((\gamma_u-1)(w))-(\gamma_u-1)(\tau)$ with $(\gamma_u-1)(w)\in X\mathbf{N}_c$ and $(\gamma_u-1)(\tau)\in P_j(\mathbf{N}_c)$, so $(\gamma_u-1)(v)\in P_j(\mathbf{N}_c)\subseteq\lambda_j^{-G}\mathbf{N}_{c+j}$ by (Ry0). By (C1), $(\gamma_u-1)(v)\in X^m\mathbf{N}$ for every u, and $v\in\mathbf{N}[1/\lambda_\infty]$: v is a Herr vector of precision m.

(Ry3). Let τ and τ' be two relay corrections of w, with elements V and V' as in the definition. Then $V'-V \in \mathbf{N}_c[1/\ell] \cap X^R\mathbf{N}_E = X^R\mathbf{N}_c[1/\ell]$ (C2), so $\ell^\sigma\varphi^j(V'-V) \in X^R\lambda_j^R P_j(\mathbf{N}_c)[1/\ell] \subseteq X^m\lambda_j^g P_j(\mathbf{N}_c)[1/\ell]$. Hence $\tau'-\tau \in P_j(\mathbf{N}_c) \cap X^m\lambda_j^g P_j(\mathbf{N}_c)[1/\ell] \subseteq \lambda_j^{-G}\mathbf{N}_{c+j} \cap X^m\mathbf{N}_{c+j}[1/\ell] = X^m\mathbf{N}_{c+j}$, by (Ry0), $g \geq G$ and (C1). By (Hc4) of Lemma 23.28, $\tau'-\tau$ is a Herr vector of precision m with class 0, and by (Hc3), $\mathrm{cl}(\ell^\sigma\varphi^j(w)-\tau) = \mathrm{cl}(\ell^\sigma\varphi^j(w)-\tau') + \mathrm{cl}(\tau'-\tau) = \mathrm{cl}(\ell^\sigma\varphi^j(w)-\tau')$.

(Ry4). I_c is an $\mathcal{O}_L$-submodule since the γ_u are additive and $\mathcal{O}_L$-linear. By the uniqueness in (Hf1), $W_{w_1+\lambda w_2} = W_{w_1} + \lambda W_{w_2}$ for $\lambda \in \mathcal{O}_L$; so if (τ_i, V_i) are relay corrections of w_i, then $(\tau_1+\lambda\tau_2, V_1+\lambda V_2)$ is one of $w_1+\lambda w_2$, and (Hc3) gives $\rho_{c,j}(w_1+\lambda w_2) = \rho_{c,j}(w_1) + \lambda\rho_{c,j}(w_2)$.

(Ry5). If $w \in X\mathbf{N}_c$, then $(\gamma_u - 1)(w) \in X\mathbf{N}$ by (Wm3) and $\gamma_u(X) \in X\mathbb{Z}_\ell[[X]]$, so $w \in I_c$, and $W_w = w$ by uniqueness. With $V = w$, $\tau = \ell^\sigma\varphi^j(w) \in P_j(\mathbf{N}_c)$ is a relay correction, and $\rho_{c,j}(w) = \mathrm{cl}(0) = 0$.

(Ry6). $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ and γ_u (Ex3); extend it $E[[X]]$-linearly to $\mathbf{N}_E \to \mathbf{N}(T')_E$, where it commutes with γ_u and preserves $X^k\mathbf{N}_E$. It maps $e_c\mathbf{N}[1/\lambda_\infty]$ into $e_c\mathbf{N}(T')[1/\lambda_\infty]$, $\mathbf{N}_c$ into $\mathbf{N}(T')_c$ and I_c into I'_c, and $W_{\mathbf{N}(f)w} = \mathbf{N}(f)(W_w)$ by uniqueness in (Hf1). If (τ, V) is a relay correction of w, then $(\mathbf{N}(f)\tau, \mathbf{N}(f)V)$ is one of $\mathbf{N}(f)w$, as $\mathbf{N}(f)(P_j(\mathbf{N}_c)) \subseteq P_j(\mathbf{N}(T')_c)$. Hence $\rho'_{c,j}(\mathbf{N}(f)w) = \mathrm{cl}(\mathbf{N}(f)(\ell^\sigma\varphi^j(w)-\tau)) = f_*\rho_{c,j}(w)$ by (Hc5) of Lemma 23.28.

(Ry7). Let τ be a relay correction of w (Ry1) and $v = \ell^\sigma\varphi^j(w)-\tau$, a Herr vector of precision m by (Ry2), with $\rho_{c,j}(w) = \mathrm{cl}(v)$. As $w \in e_c\mathbf{N}[1/\lambda_\infty]$, $fw \in e_c\mathbf{N} = \mathbf{N}_c$, so $\varphi^j(f)\varphi^j(w) = \varphi^j(fw) \in P_j(\mathbf{N}_c) \subseteq \lambda_j^{-G}\mathbf{N}$ by (Ry0), and $\tau \in P_j(\mathbf{N}_c) \subseteq \lambda_j^{-G}\mathbf{N}$. Hence, with the finite product $f' = \lambda_j^G\varphi^j(f)$ of the Q_s ($\varphi^j(Q_s) = Q_{s+j}$),

$$f'v = \ell^\sigma\lambda_j^G\varphi^j(fw) - \varphi^j(f)\,\lambda_j^G\tau \in \mathbf{N}.$$

Since $m \geq 1 + \max_a M_a$, Proposition 23.27 gives $\rho_{c,j}(w) = \mathrm{cl}(v) \in H^1_f(F,T)$. □

Lemma 24.6. *Let ℓ be an odd prime, F, L as in Definition 23.2, $E = \Lambda[1/\ell]$, and let φ also denote the endomorphism of $E[[X]]$ that is $\varphi \otimes \mathrm{id}$ on E and sends X to $(1+X)^\ell - 1$; thus $\varphi^j(X) = X\lambda_j$. For integers $j \geq 1$, $g \geq 0$, $m \geq 0$ put*

$$N_j = (\ell-1)\ell^{j-1}, \qquad \sigma_\ell(g,m,j) = \Big\lfloor \Big(g + \frac{m}{N_j}\Big)\frac{\ell}{(\ell-1)^2} \Big\rfloor + 1.$$

Write $\sigma = \sigma_\ell(g,m,j)$.

(Rt1) One term *For every $k \geq 0$ and every $c \in E$ with $\ell^{s_\ell(k)}c \in \Lambda$,*

$$\ell^\sigma c\,(X\lambda_j)^k \in \Lambda[[X]] + X^m\lambda_j^g\,\Lambda[[X]][1/\ell].$$

(Rt2) Series *For every $W = \sum_{k\geq 0} a_k X^k \in E[[X]]$ with $\ell^{s_\ell(k)}a_k \in \Lambda$ for all k,*

$$\ell^\sigma\varphi^j(W) \in \Lambda[[X]] + X^m\lambda_j^g\,E[[X]].$$

Proof. **An ideal-power inclusion.** Let A be a commutative ring, $a, Y, p \in A$, and $N \geq 1$, $M, z, t \geq 0$ integers with $p \in aA + Y^NA$ and $t + \lceil M/N \rceil \leq z+1$. Then $p^z \in a^tA + Y^MA$. Indeed, write $p = aa' + Y^Nb'$; in $p^z = \sum_{i=0}^z \binom{z}{i} a^i a'^i Y^{N(z-i)} b'^{z-i}$ the terms with $i \geq t$ lie in a^tA, and for $i < t$ we have $z - i \geq z - t + 1 \geq \lceil M/N \rceil$, so $N(z-i) \geq M$ and the term lies in Y^MA.

Proof of (Rt1). Put $\kappa = g + m/N_j$. Since $\ell \geq 3$, $\ell < (\ell-1)^2$, so the function $\rho(x) = x\ell/(\ell-1)^2 - x + \kappa$ is strictly decreasing, with $\rho(\kappa) = \kappa\ell/(\ell-1)^2 < \sigma$ (definition of σ). Recall $s_\ell(k) \leq k\ell/(\ell-1)^2$ (Lemma 23.9).

Case $k \le \kappa$. Then $s_\ell(k) \le \kappa\ell/(\ell-1)^2 < \sigma$, so $\ell^\sigma c = \ell^{\sigma - s_\ell(k)} \cdot \ell^{s_\ell(k)} c \in \Lambda$ and $\ell^\sigma c (X\lambda_j)^k \in \Lambda[[X]]$.

Case $k > \kappa$. Then $z := k - g > m/N_j$, so $z \ge \lceil m/N_j \rceil$ and $t := z + 1 - \lceil m/N_j \rceil \ge 1$. By Lemma 23.8(3), Q_{j-1} is a monic polynomial congruent to X^{N_j} modulo ℓ, so $Q_{j-1} \in \ell\,\mathbb{Z}_\ell[[X]] + X^{N_j}\mathbb{Z}_\ell[[X]]$. The inclusion above (with $A = \mathbb{Z}_\ell[[X]]$, $a = \ell$, $Y = X$, $p = Q_{j-1}$, $N = N_j$, $M = m$) gives $Q_{j-1}^z \in \ell^t \mathbb{Z}_\ell[[X]] + X^m \mathbb{Z}_\ell[[X]]$. As $k = g + z$ and $\lambda_j = \lambda_{j-1} Q_{j-1}$,

$$(X\lambda_j)^k = \lambda_j^g \cdot X^k \lambda_{j-1}^z \cdot Q_{j-1}^z \in \ell^t \mathbb{Z}_\ell[[X]] + X^m \lambda_j^g \mathbb{Z}_\ell[[X]],$$

say $(X\lambda_j)^k = \ell^t f + X^m \lambda_j^g h$. Moreover

$$s_\ell(k) - t \le \frac{k\ell}{(\ell-1)^2} - k + g - 1 + \Big\lceil \frac{m}{N_j} \Big\rceil < \rho(k) < \rho(\kappa) < \sigma,$$

using $\lceil x \rceil < x+1$. Hence $\ell^{\sigma+t} c = \ell^{\sigma+t-s_\ell(k)} \cdot \ell^{s_\ell(k)} c \in \Lambda$, and $\ell^\sigma c (X\lambda_j)^k = (\ell^{\sigma+t} c) f + X^m \lambda_j^g (\ell^\sigma c h)$ is of the required form, since $\ell^\sigma c h \in E \cdot \mathbb{Z}_\ell[[X]] \subseteq \Lambda[[X]][1/\ell]$.

Proof of (Rt2). $\varphi^j(W) = \sum_k \varphi^j(a_k)(X\lambda_j)^k$, the series converging X-adically since $(X\lambda_j)^k \in X^k \mathbb{Z}_\ell[[X]]$; and $\ell^{s_\ell(k)} \varphi^j(a_k) = \varphi^j(\ell^{s_\ell(k)} a_k) \in \Lambda$, as $\varphi \otimes \mathrm{id}$ preserves Λ. Let $k_0 = \max(m, g)$. For $k \ge k_0$, $(X\lambda_j)^k = X^m \lambda_j^g \cdot X^{k-m} \lambda_j^{k-g}$, so

$$\sum_{k \ge k_0} \ell^\sigma \varphi^j(a_k)(X\lambda_j)^k = X^m \lambda_j^g \sum_{k \ge k_0} \ell^\sigma \varphi^j(a_k) X^{k-m} \lambda_j^{k-g} \in X^m \lambda_j^g E[[X]],$$

the inner series converging X-adically. The finitely many terms with $k < k_0$ are of the required form by (Rt1) applied to $c = \varphi^j(a_k)$, as $\Lambda[[X]][1/\ell] \subseteq E[[X]]$. □

Lemma 24.7. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, and let $\Phi\colon T_1 \to T_2$ be a G_F-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V_1, T_1), (V_2, T_2). Let $M_a, h_a \ge 0$ be integers such that every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$ $(a \in \mathbb{Z}/n)$, let J be the set of integers that are Hodge jumps of V_1 at some τ_a, let $G \ge \max_a M_a$ be an integer, and put*

$$J'_G = \{j + k :\ j \in J,\ 1 \le k \le G,\ j + k \ne 0\}, \qquad \kappa_\ell(J, G) = \sum_{x \in J'_G} v_\ell(x).$$

For $\nu = 1, 2$ and $c \in \mathbb{Z}/n$ let I_c^ν be the set of $w \in e_c \mathbf{N}(T_\nu)[1/\lambda_\infty]$ with $(\gamma_s - 1)(w) \in X\mathbf{N}(T_\nu)$ for all $s \in \mathbb{Z}_\ell^\times$. Let $c \in \mathbb{Z}/n$ and $r \ge 0$ be such that for every $y \in \mathbf{N}(T_2)_c$ there is $x \in \mathbf{N}(T_1)_c$ with $\mathbf{N}(\Phi)(x) = \ell^r y$. Then for every $w \in I_c^2$ with $Q^G w \in \mathbf{N}(T_2)$ there is $u \in I_c^1$ with $Q^G u \in \mathbf{N}(T_1)$ and

$$\ell^{\,r + \kappa_\ell(J,G)}\, w - \mathbf{N}(\Phi)(u) \in X\, \mathbf{N}(T_2)_c.$$

Proof. By (Ex1), $\mathbf{N}_1$ and $\mathbf{N}_2$ are Wach modules (for $\mathbf{N}_1$ with the window (M_a, h_a); for $\mathbf{N}_2$ only (Wm1) and (Wm3) are used, valid for any window of V_2). So each $\mathbf{N}_{\nu,c}$ is free of finite rank over the domain A_c, and $\mathbf{N}_\nu[1/\lambda_\infty]$ is torsion-free over $\mathbf{A}_{F,L}[1/Q_s :\ s \ge 0]$.

Step 0: the invariant uniformiser. (i) For $\delta \in \Delta$, $\gamma_\delta((1+X)^a) = (1+X)^{\delta a}$ $(a \in \mathbb{Z}_\ell)$, so γ_δ permutes the summands of π_0 and $\gamma_\delta(\pi_0) = \pi_0$; since the γ_s commute, $\gamma_s(\pi_0)$ is also Δ-fixed. Items (ii)–(iv) are Lemma 23.24 for $\Delta = \mu_{\ell-1}$, where $e = 1$, $\pi_\Delta = \pi_0$ and $\Gamma_\Delta = \mu_{\ell-1}(1 + \ell\mathbb{Z}_\ell) = \mathbb{Z}_\ell^\times$. (ii) By (Rr1), $\pi_0 = X^{\ell-1} v_0$ with $v_0 \in \mathbb{Z}_\ell[[X]]^\times$. (iii) Put $q_0 = \pi_0 + \ell$; by (Rr3) $q_0 = q_\Delta$, so by (Rr4) $q_0 = Q\, v_1$ with $v_1 \in \mathbb{Z}_\ell[[X]]^\times$. In particular $Q^G z \in \mathbf{N}_\nu$ if and only if $q_0^G z \in \mathbf{N}_\nu$. (iv) For $s \in \mathbb{Z}_\ell^\times = \Gamma_\Delta$, by (Rr6) $\gamma_s(q_0) = q_0 h_s$ with $h_s \in 1 + X\mathbb{Z}_\ell[[X]]$ Δ-fixed; h_s is a unit, its constant term being 1.

Step 1: $X\mathbf{N}_{\nu,c} \cap \mathbf{N}_{\nu,c}^{\Delta} = \pi_0 \mathbf{N}_{\nu,c}^{\Delta}$**.** The inclusion $\supseteq$ holds by (i), (ii). Let δ_0 be a generator of Δ; then $\delta_0^i - 1 \in \mathbb{Z}_\ell^\times$ for $1 \le i \le \ell - 2$. Let $y \in \mathbf{N}_{\nu,c}^{\Delta}$ with $y = X^i y_i$, $y_i \in \mathbf{N}_{\nu,c}$, for some $1 \le i \le \ell - 2$. Write $\gamma_{\delta_0}(X) = (1+X)^{\delta_0} - 1 = X(\delta_0 + Xb)$ with $b \in \mathbb{Z}_\ell[[X]]$. Then $X^i y_i = \gamma_{\delta_0}(y) = X^i(\delta_0 + Xb)^i \gamma_{\delta_0}(y_i)$; cancelling X^i (no X-torsion) and reducing modulo $X\mathbf{N}_{\nu,c}$, with $\gamma_{\delta_0}(y_i) \equiv y_i$ by (Wm3), gives $(\delta_0^i - 1)y_i \in X\mathbf{N}_{\nu,c}$, so $y_i \in X\mathbf{N}_{\nu,c}$. By induction from $i = 1$, $y \in X^{\ell-1}\mathbf{N}_{\nu,c} = \pi_0 \mathbf{N}_{\nu,c}$ (by (ii)); if $y = \pi_0 y'$, then $\pi_0 \gamma_\delta(y') = \gamma_\delta(y) = \pi_0 y'$, so y' is Δ-fixed.

Step 2: the normalised operator. Fix $g = 1 + \ell$, so $v_\ell(g-1) = 1$, and let $\beta(x) \in \mathbb{Z}_\ell$ be the numbers with $\ell\beta(x) = 1 - g^{-x}$ (the $c(x)$ of Lemma 24.8 for $u = g$). For $H \ge 0$ put $D_\nu(H) = \{z \in (e_c \mathbf{N}_\nu[1/\lambda_\infty])^{\Delta} : \ q_0^H z \in \mathbf{N}_\nu\}$; thus $D_\nu(0) = \mathbf{N}_{\nu,c}^{\Delta}$. Claim: for $z \in D_\nu(H)$ and $s \in \mathbb{Z}_\ell^\times$, $(\gamma_s - 1)(z) = X\, z'$ with $z' \in q_0^{-H}\mathbf{N}_{\nu,c}$, and $(\gamma_g - 1)(z) = \pi_0\, \delta z$ for a unique $\delta z \in D_\nu(H)$. Indeed, with $n = q_0^H z \in \mathbf{N}_{\nu,c}^{\Delta}$ (by (i)),

$$q_0^H(\gamma_s - 1)(z) = h_s^{-H}\gamma_s(n) - n = (h_s^{-H} - 1)\gamma_s(n) + (\gamma_s - 1)(n) \in X\mathbf{N}_{\nu,c}$$

by (iv) and (Wm3); for $s = g$ this element is Δ-fixed (the γ's commute and q_0 is Δ-fixed), so by Step 1 it equals $\pi_0 n'$ with $n' \in \mathbf{N}_{\nu,c}^{\Delta}$, and $\delta z = q_0^{-H} n'$; uniqueness holds as π_0 is a non-zero-divisor. So δ is an $\mathcal{O}_L$-linear endomorphism of each $D_\nu(H)$, in particular of $\mathbf{N}_{\nu,c}^{\Delta}$, and every polynomial $P \in \mathbb{Z}_\ell[Y]$ gives $P(\delta)$ on these sets. Since $\mathbf{N}(\Phi)$, extended to $\mathbf{N}_1[1/\lambda_\infty]$, is $\mathbf{A}_{F,L}[1/Q_s]$-linear and commutes with all γ_s (Ex3), it maps $D_1(H)$ into $D_2(H)$ and $\mathbf{N}(\Phi) \circ \delta = \delta \circ \mathbf{N}(\Phi)$ there.

Step 3: reduction to Δ-fixed w. Let $w \in I_c^2$ with $Q^G w \in \mathbf{N}_2$ and put $\bar{w} = (\ell - 1)^{-1} \sum_{\delta \in \Delta} \gamma_\delta(w)$ ($\ell - 1$ is a unit). Then $w - \bar{w} = (\ell-1)^{-1} \sum_\delta (1 - \gamma_\delta)(w) \in X\mathbf{N}_{2,c}$ (definition of I_c^2; γ_δ fixes e_c), $\bar{w}$ is Δ-fixed, $\bar{w} \in I_c^2$ (as $(\gamma_s - 1)\gamma_\delta(w) = \gamma_\delta((\gamma_s - 1)w) \in \gamma_\delta(X\mathbf{N}_2) = X\mathbf{N}_2$), and $q_0^G \bar{w} \in \mathbf{N}_2$ since $q_0^G \gamma_\delta(w) = \gamma_\delta(q_0^G w)$ and $q_0^G w \in \mathbf{N}_2$ by (iii). If u satisfies the conclusion for $\bar{w}$, then $\ell^{r+\kappa_\ell(J,G)} w - \mathbf{N}(\Phi)(u) = \ell^{r+\kappa_\ell(J,G)}(w - \bar{w}) + \big(\ell^{r+\kappa_\ell(J,G)}\bar{w} - \mathbf{N}(\Phi)(u)\big) \in X\mathbf{N}_{2,c}$. So we assume w Δ-fixed, that is $w \in D_2(G)$. Then $(\gamma_g - 1)(w) \in X\mathbf{N}_2$ is Δ-fixed, so $\delta w \in \mathbf{N}_{2,c}^{\Delta}$ by Step 1.

Averaging also gives Δ-fixed lifts: if $y \in \mathbf{N}_{2,c}^{\Delta}$ and $x \in \mathbf{N}_{1,c}$ has $\mathbf{N}(\Phi)(x) = \ell^r y$, then $\bar{x} = (\ell-1)^{-1} \sum_\delta \gamma_\delta(x) \in \mathbf{N}_{1,c}^{\Delta}$ has $\mathbf{N}(\Phi)(\bar{x}) = \ell^r y$ (Ex3). $(*)$

Step 4: the construction. Let $Z = \{j + k : \ j \in J,\ 1 \le k \le G\}$, $\epsilon = 1$ if $0 \in Z$ and $\epsilon = 0$ otherwise, and

$$P(Y) = \prod_{x \in Z} (Y - \beta(x)), \qquad R(Y) = \prod_{x \in J'_G} (Y - \beta(x)).$$

Since $\beta(0) = 0$ and $J'_G = Z \setminus \{0\}$, we have $Y\, R(Y) = Y^{1-\epsilon} P(Y)$. Write $R(Y) = R(0) + Y\, S(Y)$ with $S \in \mathbb{Z}_\ell[Y]$. (a) By $(*)$ for $y = q_0^G w \in \mathbf{N}_{2,c}^{\Delta}$ there is $x \in \mathbf{N}_{1,c}^{\Delta}$ with $\mathbf{N}(\Phi)(x) = \ell^r q_0^G w$; put $u_0 = q_0^{-G} x \in D_1(G)$, so $\mathbf{N}(\Phi)(u_0) = \ell^r w$. (b) Put $y_0 = u_0$ and $y_i = (\delta - \beta(x_i))(y_{i-1}) \in D_1(G)$ for an enumeration $x_1, \dots, x_m$ of Z; then $\pi_0(y_i + \beta(x_i) y_{i-1}) = \pi_0 \delta y_{i-1} = (\gamma_g - 1)(y_{i-1})$, y_0 is Δ-fixed and $Q^G y_0 \in \mathbf{N}_1$ by (iii). By Lemma 24.8 for the pair (V_1, T_1), $u = g$, $Y = G$ and the set J of the statement (a finite set containing every Hodge jump of V_1 at τ_c), $y_m = P(\delta)u_0 \in \mathbf{N}_1$, hence $P(\delta)u_0 \in \mathbf{N}_{1,c}^{\Delta}$, and since δ preserves $\mathbf{N}_{1,c}^{\Delta}$ (Step 2),

$$\delta R(\delta) u_0 = \delta^{1-\epsilon} P(\delta) u_0 \in \mathbf{N}_{1,c}^{\Delta}.$$

(c) $n := R(\delta)w - R(0)w = S(\delta)(\delta w) \in \mathbf{N}_{2,c}^{\Delta}$ by Step 3 and Step 2. By $(*)$ there is $x' \in \mathbf{N}_{1,c}^{\Delta}$ with $\mathbf{N}(\Phi)(x') = \ell^r n$. (d) Put $u_2 = R(\delta)u_0 - x' \in D_1(G)$. By Step 2, $\mathbf{N}(\Phi)(u_2) = \ell^r R(\delta) w - \ell^r n = \ell^r R(0)\, w$, and $\delta u_2 = \delta R(\delta) u_0 - \delta x' \in \mathbf{N}_{1,c}^{\Delta}$ by (b) and Step 2.

Step 5: the exponent. For $x \in J'_G$ we have $x \ne 0$, and by item 1 of Lemma 23.22 ($p = \ell$ odd, $m = 1$, $u = g$), $v_\ell(g^{-x} - 1) = 1 + v_\ell(x)$, so $v_\ell(\beta(x)) = v_\ell(x)$ and $v_\ell(R(0)) = \sum_{x \in J'_G} v_\ell(x) =$

$\kappa_\ell(J,G)$. Hence $t = \ell^{\kappa_\ell(J,G)}/R(0) \in \mathbb{Z}_\ell$. Put $u = t\,u_2 \in D_1(G)$. Then $Q^G u \in \mathbf{N}_1$ by (iii), $\mathbf{N}(\Phi)(u) = \ell^{r+\kappa_\ell(J,G)} w$ exactly, and $(\gamma_g - 1)(u) = \pi_0\, t\, \delta u_2 \in \mathbf{N}_1$.

Step 6: $u \in I_c^1$. Let $\bar{M} = D_1(G)/\mathbf{N}_{1,c}^\Delta$. It is a free $\mathcal{O}_L$-module of finite rank: multiplication by q_0^G identifies $q_0^{-G}\mathbf{N}_{1,c}/\mathbf{N}_{1,c}$ with $\mathbf{N}_{1,c}/q_0^G\mathbf{N}_{1,c} \cong (A_c/Q^G A_c)^d$ (d the rank, (Wm1)), free over $\mathcal{O}_L$ of rank $dG(\ell-1)$ by Weierstrass division by the distinguished polynomial Q^G; taking Δ-invariants is exact (averaging), so $\bar{M}$ is the image of the averaging projector on this module, a direct summand, hence free. Each γ_s preserves $D_1(G)$ and $\mathbf{N}_{1,c}^\Delta$ (Step 2 and (Wm3)) and acts $\mathcal{O}_L$-linearly on $\bar{M}$, so $\rho(a) = \gamma_{g^a}$ defines a homomorphism $\rho\colon \mathbb{Z}_\ell \to \mathrm{GL}(\bar{M}) \cong \mathrm{GL}_N(\mathcal{O}_L)$ (by (Wm3) and $g^{a+b} = g^a g^b$). It is continuous: let ℓ^e be the exact power of ℓ dividing $g_0 = |\mathrm{GL}_N(\mathcal{O}_L/\ell\mathcal{O}_L)|$ and $K_i = 1 + \ell^i M_N(\mathcal{O}_L)$; for $a \in \ell^{i+e}\mathbb{Z}_\ell$ write $a = g_0\ell^i b$ with $b \in \mathbb{Z}_\ell$; then $\rho(b)^{g_0} \in K_1$ and $\rho(a) = (\rho(b)^{g_0})^{\ell^i} \in K_{1+i}$, since $(1+\ell^k A)^\ell \in K_{k+1}$ for $k \geq 1$ (binomial expansion). The class $[u] \in \bar{M}$ satisfies $\rho(1)[u] = [u]$ by Step 5, so its stabiliser in $\mathbb{Z}_\ell$, a closed subgroup (preimage of a closed subgroup under a continuous map), contains $\mathbb{Z}$ and therefore $\mathbb{Z}_\ell$. As $\mathbb{Z}_\ell^\times = \Delta \times g^{\mathbb{Z}_\ell}$ and u is Δ-fixed, $(\gamma_s - 1)(u) \in \mathbf{N}_{1,c}$ for every $s \in \mathbb{Z}_\ell^\times$. By Step 2, also $(\gamma_s - 1)(u) = Xz'$ with $q_0^G z' \in \mathbf{N}_{1,c}$. In coordinates for an A_c-basis of $\mathbf{N}_{1,c}$, each coordinate f of z' satisfies $q_0^G f \in A_c$ and $Xf \in A_c$; as $A_c \cong \mathcal{O}_L[[X]]$ is a unique factorisation domain and the prime X does not divide q_0, $f \in A_c$. So $(\gamma_s - 1)(u) \in X\mathbf{N}_{1,c}$ for all s, and $u \in e_c\mathbf{N}_1[1/\lambda_\infty]$: $u \in I_c^1$.

Steps 5 and 6 give $u \in I_c^1$ with $Q^G u \in \mathbf{N}_1$ and $\ell^{r+\kappa_\ell(J,G)} w - \mathbf{N}(\Phi)(u) = 0 \in X\mathbf{N}_{2,c}$ for Δ-fixed w, and Step 3 gives the general case.

Remark. For Δ-fixed w the lift is exact. □

Lemma 24.8. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, let $c \in \mathbb{Z}/n$, and let $J \subset \mathbb{Z}$ be a finite set containing every Hodge jump of V at τ_c (for instance the set of all Hodge jumps of V at all τ_a). Let $u \in 1 + \ell\mathbb{Z}_\ell$, and for $x \in \mathbb{Z}$ let $c(x) \in \mathbb{Z}_\ell$ be defined by $\ell\, c(x) = 1 - u^{-x}$. Let $Y \geq 0$ be an integer and $x_1, \ldots, x_m$ an enumeration, without repetition, of the finite set $\{j + k :\ j \in J,\ 1 \leq k \leq Y\}$. Let $y_0, y_1, \ldots, y_m \in e_c\mathbf{N}[1/\lambda_\infty]$ be such that $Q^Y y_0 \in \mathbf{N}$ and*

$$\pi_0(y_i + c(x_i)\, y_{i-1}) = (\gamma_u - 1)(y_{i-1}) \qquad (1 \leq i \leq m).$$

Then $y_m \in \mathbf{N}$.

Proof. **Step 0: level data at the cut c.** Choose integers $M_a, h_a \geq 0$ such that every Hodge jump of V at τ_a lies in $[-M_a, h_a]$ (there are finitely many). By (Ex1), $\mathbf{N}$ is a Wach module with window $(M_a, h_a)_a$ and rank r. Fix arc level data for id_T (Definition 23.4) with cut c, length $\mathrm{len} = 1$ (so $c_0 = c - 1$), $H(c) = Y + h_c$ (other values of H arbitrary), a frame at $c-1$ (an A_{c-1}-basis of $\mathbf{N}_{c-1}$, which exists by (Wm1)) with its horizontal sections (Hf2) and crystalline frame, and parameters $G = S = \eta = g = M = 0$, $j = 1$, κ_0 thin, $b_0 = 0$. Then $\Pi = Q^{Y+h_c}$ and $W = \{w \in \mathbf{N}[1/\lambda_\infty] :\ Q^{Y+h_c} w \in P_1(\mathbf{N}_{c-1})\}$. By Lemma 23.17 (for $\Phi = \mathrm{id}_T$) the properties (Lp1), (Lp2), (Lp8) hold at $s = 0$, and by Lemma 23.5 (2) so does (Lp3). Explicitly:

(a) $\lambda_0(A_c) \subseteq K[[t]]$ and $\lambda_0(e_c Q) = t\,\eta$ with $\eta \in K[[t]]^\times$ (Lp1);

(b) every $w \in W$ is algebraic at level 0: $\Lambda_0(w) = \sum_k \mathrm{lv}_0(w)_k D_k$ with $\mathrm{lv}_0(w) \in K((t))^r$ (Lp1). Since Λ_0 is additive, $\Lambda_0(gw) = \lambda_0(g)\Lambda_0(w)$, $\epsilon_0 = \lambda_0(e_c)$, $D_k \in \epsilon_0 D$, and the D_k are an R_0-basis, lv_0 is additive and $\mathrm{lv}_0(gw) = \lambda_0(e_c g)\,\mathrm{lv}_0(w)$ for $g \in \mathbf{A}_{F,L}$ and $w, gw \in W$;

(c) $\gamma_u(W) \subseteq W$ and $\mathrm{lv}_0(\gamma_u w) = \gamma_u^{(0)}(\mathrm{lv}_0(w))$ (Lp2);

(d) $\sigma_u = \mathrm{id}$ on K, because $u \in 1 + \ell\mathbb{Z}_\ell$ (Lp8 at $s = 0$); so $\gamma_u^{(0)}(\sum_i a_i t^i) = \sum_i u^i a_i t^i$ coordinatewise, and $\gamma_u^{(0)}(g\,v) = g(ut)\,v$ for $g = \sum_i a_i t^i \in K((t))$, $g(ut) = \sum_i u^i a_i t^i$, and $v \in L^r$;

(e) for $w \in W$: $w \in \mathbf{N}_c$ if and only if $\mathrm{lv}_0(w)$ is de Rham integral at 0 (Lp3).

Step 1: the de Rham integral vectors. Recall $\mathrm{Fil}_0(u) = \{v \in L^r : \sum_k v_k D_k \in \mathrm{Fil}^u D\}$. As V is crystalline and F is unramified, $D \subseteq D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)^{G_F}$, both of F-dimension $\dim_{\mathbb{Q}_\ell} V$, so $D = D_{\mathrm{dR}}(V)$ and $\mathrm{Fil}^u D$ is the Hodge filtration: decreasing, equal to D for $u \ll 0$ and to 0 for $u \gg 0$, by $F \otimes_{\mathbb{Q}_\ell} L$-submodules ($\mathrm{Fil}^u B_{\mathrm{dR}} = t^u B_{\mathrm{dR}}^+$ is stable under $F \subset B_{\mathrm{dR}}^+$, and L acts on V). Hence $\mathrm{Fil}^u D \cap \epsilon_0 D = \epsilon_0 \mathrm{Fil}^u D$. As ϵ_0 is the idempotent of $F \otimes_{\mathbb{Q}_\ell} L$ belonging to τ_c (Definition 23.4), $\epsilon_0 M = L \otimes_{F \otimes L, \tau_c \otimes \mathrm{id}} M$ for every $F \otimes_{\mathbb{Q}_\ell} L$-module M, so $v \mapsto \sum_k v_k D_k$ is an L-linear isomorphism $L^r \to \epsilon_0 D = D_{\mathrm{dR},\tau_c}(V)$ carrying $\mathrm{Fil}_0(u)$ onto $\mathrm{Fil}^u D_{\mathrm{dR},\tau_c}(V)$ for every u. Choose an L-basis $v_1, \dots, v_r$ of L^r adapted to this finite filtration: integers $j_1, \dots, j_r$ with $\mathrm{Fil}_0(u) = \bigoplus_{b:\ j_b \geq u} L v_b$ for all u (choose, for each u, a complement of $\mathrm{Fil}_0(u+1)$ in $\mathrm{Fil}_0(u)$ and put $j_b = u$ on a basis of it). Each j_b satisfies $\mathrm{Fil}_0(j_b + 1) \neq \mathrm{Fil}_0(j_b)$, so it is a Hodge jump of V at τ_c, and $j_b \in J$ by the hypothesis on J. The v_b are also a K-basis of K^r; write $f \in K((t))^r$ as $f = \sum_b g_b v_b$ with $g_b \in K((t))$. The t^i-coefficient of f lies in $K \otimes_L \mathrm{Fil}_0(-i) = \bigoplus_{j_b \geq -i} K v_b$ for every i if and only if $g_b \in t^{-j_b} K[[t]]$ for every b. So the set of de Rham integral vectors at 0 is

$$\Lambda = \bigoplus_{b=1}^{r} t^{-j_b} K[[t]]\, v_b,$$

a $K[[t]]$-submodule of $K((t))^r$.

Step 2: $Q^Y y_i \in \mathbf{N}_c$ and $y_i \in W$ for every i. (i) If $z \in e_c \mathbf{N}[1/\lambda_\infty]$ and $\pi_0 z \in \mathbf{N}_c$, then $z \in \mathbf{N}_c$. Indeed, in an A_c-basis of $\mathbf{N}_c$ (Wm1) the coordinates of z are a/λ_e with $a \in A_c$ and some $e \geq 0$, and $\pi_0 a \in \lambda_e A_c$. Let $\zeta' \neq 1$ be a root of unity of order dividing ℓ^e; the evaluation at $\zeta' - 1$ is a ring homomorphism on $\mathcal{O}_L[[X]]$, and it sends $(1+X)^\delta$ to ζ'^δ (the power by any integer congruent to δ modulo the order of ζ'). In an embedding $\mathbb{Q}(\zeta') \subset \mathbb{C}$, $\left|\sum_\delta \zeta'^\delta\right| \leq \ell - 1$ with equality and value $\ell - 1$ only if all $\zeta'^\delta = 1$, which fails since δ is a unit; so $\pi_0(\zeta' - 1) \neq 0$, hence $a(\zeta' - 1) = 0$. So a vanishes at all roots of every Q_s, $s < e$, and by Lemma 23.8 (3), applied to $Q_0, \dots, Q_{e-1}$ in turn (the roots of different Q_s are distinct), λ_e divides a. (ii) Induction on i. For $i = 0$, $Q^Y y_0 \in \mathbf{N} \cap e_c \mathbf{N}[1/\lambda_\infty] = \mathbf{N}_c$. Let $i \geq 1$ and $n = Q^Y y_{i-1} \in \mathbf{N}_c$. By Lemma 23.8 (2), $\gamma_u(Q) = Qh$ with $h \in \mathbb{Z}_\ell[[X]]^\times$, so $Q^Y \gamma_u(y_{i-1}) = h^{-Y} \gamma_u(n) \in \mathbf{N}_c$ by (Wm3) (γ_u fixes e_c). Hence $\pi_0 Q^Y y_i = Q^Y(\gamma_u - 1)(y_{i-1}) - c(x_i)\pi_0 n \in \mathbf{N}_c$, and (i) for $z = Q^Y y_i$ gives $Q^Y y_i \in \mathbf{N}_c$. (iii) By (Wm2) at $a = c$, $Q^{h_c} \mathbf{N}_c \subseteq \mathbf{A}_{F,L} \varphi_{\mathbf{N}}(\mathbf{N}_{c-1}) = P_1(\mathbf{N}_{c-1})$, so $Q^{Y+h_c} y_i \in P_1(\mathbf{N}_{c-1})$: $y_i \in W$. Likewise $Q^Y y_0 \in W$.

Step 3: the constant term of $\lambda_0(\pi_0)$. Let $p = \lambda_0(e_c \pi_0) \in K[[t]]$ (Step 0 (a)). Its constant term $p_0 \in K$ is determined by $\theta(p) = \theta(p_0)$ (θ extended L-linearly), since $\theta(t) = 0$ and θ is injective on K (Definition 23.4). On $\mathbb{Z}_\ell[[X]]$, $\lambda_0 = \varphi^{-1} \circ \iota$ (followed by $\otimes 1$), and $\psi = \theta \circ \varphi^{-1} \circ \iota \colon \mathbb{Z}_\ell[[X]] \to \mathcal{O}_{\mathbb{C}_\ell}$ is a $\mathbb{Z}_\ell$-algebra homomorphism with $\psi(X) = \theta([\varepsilon^{1/\ell}]) - 1 = \zeta - 1$, ζ a primitive ℓ-th root of unity (ε is a compatible system of primitive ℓ^k-th roots of unity). Such a homomorphism is the evaluation at $\zeta - 1$: for $g \in \mathbb{Z}_\ell[[X]]$ and $k \geq 1$ write $g = g_{<k} + X^k g_k$ with $g_{<k}$ a polynomial; then $\psi(g) - g(\zeta - 1) = (\zeta - 1)^k(\psi(g_k) - g_k(\zeta - 1))$ has absolute value at most $|\zeta - 1|^k \to 0$. Hence, as in (i) and since $\delta \mapsto \delta \bmod \ell$ is a bijection $\mu_{\ell-1} \to \mathbb{F}_\ell^\times$,

$$\psi(\pi_0) = \sum_{\delta \in \mu_{\ell-1}} \zeta^\delta - (\ell - 1) = \sum_{a=1}^{\ell-1} \zeta^a - (\ell - 1) = -1 - (\ell - 1) = -\ell.$$

So $p_0 = -\ell$ (that is, $-\ell\epsilon_0$, the unit of K being ϵ_0); as ℓ is invertible in the $\mathbb{Q}_\ell$-algebra K, $p \in K[[t]]^\times$ and $p^{-1} \equiv -\ell^{-1} \bmod tK[[t]]$.

Step 4: the operator at level 0. Put $f_i = \mathrm{lv}_0(y_i)$ (Step 2). Applying lv_0 to the relation of the statement, by Step 0 (b), (c) (all terms lie in W: W is an $\mathbf{A}_{F,L}$-submodule of $\mathbf{N}[1/\lambda_\infty]$,

as $P_1(\mathbf{N}_{c-1})$ is one, and $\gamma_u(y_{i-1}) \in W$ by (c)),

$$p\,(f_i + c(x_i) f_{i-1}) = \gamma_u^{(0)}(f_{i-1}) - f_{i-1} \qquad (1 \le i \le m).$$

Let $\mathcal{E}$ be the K-linear operator $\mathcal{E}(f) = p^{-1}(\gamma_u^{(0)}(f) - f)$ on $K((t))^r$. Then $f_i = (\mathcal{E} - c(x_i))(f_{i-1})$, and so $f_m = \Omega(\mathcal{E})(f_0)$ with $\Omega(T) = \prod_{x \in Z}(T - c(x))$ (the factors commute). By Step 0 (d), $\mathcal{E}(g\,v) = \mathcal{E}_1(g)\,v$ for $g \in K((t))$ and $v \in L^r$, where $\mathcal{E}_1(g) = p^{-1}(g(ut) - g(t))$. For $q \in \mathbb{Z}$, $\mathcal{E}_1$ maps $t^q K[[t]]$ into itself, and

$$\mathcal{E}_1(g) - c(-q)\,g \in t^{q+1} K[[t]] \qquad (g \in t^q K[[t]]).$$

So for $x = j + k$ (with $q = -x$): $\mathcal{E}_1 - c(j+k)$ maps $t^{-j-k}K[[t]]$ into $t^{-j-k+1}K[[t]]$.

Step 5: conclusion. By Step 2, $Q^Y y_0 \in \mathbf{N}_c \cap W$, so by Step 0 (e), (b), (a), $\lambda_0(e_c Q)^Y f_0 = t^Y \eta^Y f_0 \in \Lambda$, and $f_0 \in t^{-Y}\Lambda$ (Λ is a $K[[t]]$-module). Write $f_0 = \sum_b g_b v_b$ with $g_b \in t^{-j_b - Y} K[[t]]$ (Step 1). Fix b. The set $Z_b = \{j_b + k :\ 1 \le k \le Y\}$ has Y elements and is contained in Z (as $j_b \in J$), so $\Omega(T) = \Omega_b(T) \prod_{k=1}^{Y}(T - c(j_b + k))$ with $\Omega_b(T) = \prod_{x \in Z \setminus Z_b}(T - c(x))$. Applying Step 4 successively for $k = Y, Y-1, \dots, 1$,

$$\prod_{k=1}^{Y} (\mathcal{E}_1 - c(j_b + k))(g_b) \in t^{-j_b} K[[t]],$$

and $\Omega_b(\mathcal{E}_1)$ preserves $t^{-j_b}K[[t]]$. Hence $\Omega(\mathcal{E}_1)(g_b) \in t^{-j_b}K[[t]]$ for every b, and

$$f_m = \Omega(\mathcal{E})(f_0) = \sum_b \Omega(\mathcal{E}_1)(g_b)\,v_b \in \Lambda.$$

So $\mathrm{lv}_0(y_m)$ is de Rham integral at 0; as $y_m \in W$ (Step 2), Step 0 (e) gives $y_m \in \mathbf{N}_c \subseteq \mathbf{N}$.

Remark. In words: at the point $X = \zeta - 1$ the Wach module, expanded in the uniformiser t, is $\bigoplus_b t^{-j_b}K[[t]]v_b$ with γ_u acting by $t \mapsto ut$, so on the k-th pole layer of the line of v_b the operator $\pi_0^{-1}(\gamma_u - 1)$ acts by $c(j_b + k)$ modulo the next layer, and each line is a single Jordan-free chain with distinct eigenvalues; this is why the product over the set Z, each value once, suffices. The proof uses neither invariance under $\mu_{\ell-1}$ nor $v_\ell(u-1) = 1$, and of J only that it contains the Hodge jumps at τ_c. For $Y = 0$ and $\mathbf{N}/Q\mathbf{N}$ after inverting ℓ, the eigenvalue statement is the proposition on the action of Γ_n on $N_V/\varphi^{n-1}(q)$ in [24], §III (case $n = 1$). □

Lemma 24.9. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, let (V_1, T_1), (V_2, T_2) be pairs with windows $(M_a^1, h_a^1)_a$, $(M_a^2, h_a^2)_a$ as in (Ex1), and let $\Phi\colon T_1 \to T_2$ be a G_F-equivariant $\mathcal{O}_L$-linear map. Let $c \in \mathbb{Z}/n$ and integers $j \ge 1$, $G \ge 0$, $g \ge G$, $m \ge 1 + \max_{a,\nu} M_a^\nu$ and $R \ge \max(m, g)$ with $M_{c+s}^\nu \le G$ for $1 \le s \le j$ and $\nu = 1, 2$; let I_c^ν and $\rho_{c,j}^\nu$ be formed for $\mathbf{N}(T_\nu)$ with these c, j, G, g, m, R. Let $w \in I_c^2$, $u \in I_c^1$ and $k \ge 0$ with*

$$\ell^k w - \mathbf{N}(\Phi)(u) \in X\,\mathbf{N}(T_2)_c.$$

Then $\ell^k \rho_{c,j}^2(w) = \Phi_* \rho_{c,j}^1(u)$ in $H^1(F, T_2)$. If moreover $\lambda' u \in \mathbf{N}(T_1)$ for some finite product λ' of the Q_s ($s \ge 0$), then $\ell^k \rho_{c,j}^2(w) \in \Phi_* H_f^1(F, T_1)$.

Proof. By (Ry6) of Lemma 24.5, applied to $f = \Phi\colon T_1 \to T_2$ (its hypotheses on the window of T_2 are among ours), $\mathbf{N}(\Phi)(u) \in I_c^2$ and $\rho_{c,j}^2(\mathbf{N}(\Phi)(u)) = \Phi_* \rho_{c,j}^1(u)$. By (Ry4), I_c^2 is an $\mathcal{O}_L$-submodule and $\rho_{c,j}^2$ is $\mathcal{O}_L$-linear; hence $y := \ell^k w - \mathbf{N}(\Phi)(u) \in I_c^2$ and

$$\ell^k \rho_{c,j}^2(w) = \rho_{c,j}^2(\ell^k w) = \rho_{c,j}^2(\mathbf{N}(\Phi)(u)) + \rho_{c,j}^2(y).$$

Since $y \in X\mathbf{N}(T_2)_c$, (Ry5) gives $\rho_{c,j}^2(y) = 0$, which proves the identity. If $\lambda' u \in \mathbf{N}(T_1)$, then (Ry7) for $\mathbf{N}(T_1)$ gives $\rho_{c,j}^1(u) \in H_f^1(F, T_1)$, and the identity gives $\ell^k \rho_{c,j}^2(w) \in \Phi_* H_f^1(F, T_1)$. □

24.2 Lifting exponents over the first cyclotomic layer

Over a field K with $K_0 \subseteq K \subseteq K_0(\mu_\ell)$ and K_0 unramified, the Wach modules are Δ-invariant: they live over the ring of Definition 23.23, with the uniformiser π_Δ invariant under the torsion Δ_K of Γ_K (Lemma 24.14). The subsection proves Proposition 24.10 along the lines of the unramified case. The two inputs are a Δ-invariant lift along a surjection of lattices up to a power of ℓ of size about $2(\mathrm{wt}+1)/|\Delta_K|$ (Lemma 24.11), and a letter split, which writes a crystalline class, up to a bounded power of ℓ, as a sum of Herr classes of Δ-invariant vectors, one for each site (Lemma 24.12, from Proposition 24.13). The resulting exponent is linear in wt, not in wt/ℓ; this suffices at the small and ramified primes, whose number and size are restricted by (Ub8) of Theorem 22.4, and whose losses are bounded in Section 27. The statement has a version of level s, over $K_0(\mu_{\ell^s})$ and for every prime ℓ, which is the one used at the small primes.

Proposition 24.10. *There is an absolute constant $c_{\mathrm{cy}} \geq 1$ with the following property. Let p be an odd prime, K_0 a finite unramified extension of $\mathbb{Q}_p$ and K a field with $K_0 \subseteq K \subseteq K_0(\mu_p)$ inside $\overline{\mathbb{Q}}_p$. Let L be a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_0(\mu_p))$ for every $\mathbb{Q}_p$-embedding σ of $K_0(\mu_p)$ into $\overline{\mathbb{Q}}_p$, and $\mathcal{O}_L$ its ring of integers. Let V_1, V_2 be continuous L-linear representations of G_K on finite-dimensional L-vector spaces, crystalline as representations over $\mathbb{Q}_p$, G_K-stable $\mathcal{O}_L$-lattices $T_\nu \subseteq V_\nu$, and $F\colon V_1 \to V_2$ an L-linear G_K-equivariant map with $F(T_1) = T_2$. Let $a_\tau^-, a_\tau^+ \geq 0$ be integers, for the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$, such that every Hodge jump of V_1 at τ lies in $[-a_\tau^-, a_\tau^+]$, and put $\mathrm{wt} = \max_\tau(a_\tau^- + a_\tau^+)$ and*

$$e_{\mathrm{B}} = \lfloor c_{\mathrm{cy}}(\mathrm{wt}+1) \rfloor.$$

Then

$$p^{e_{\mathrm{B}}}\, H^1_f(K, T_2) \subseteq F_*(H^1_f(K, T_1)).$$

Level s. *Moreover the same constant c_{cy} has the following property. Let p be any prime, $s \geq 1$ an integer with $s \geq 2$ if $p = 2$, K_0 a finite unramified extension of $\mathbb{Q}_p$, $K = K_0(\mu_{p^s})$, L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K)$ for every $\mathbb{Q}_p$-embedding σ of K, and V_ν, T_ν, F, $a_\tau^\pm$ (for the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$) and* wt *as above. Put $e_{\mathrm{B}}^{(s)} = \lfloor c_{\mathrm{cy}}(\mathrm{wt}+1)(s+1) \rfloor$. Then*

$$p^{e_{\mathrm{B}}^{(s)}}\, H^1_f(K, T_2) \subseteq F_*(H^1_f(K, T_1)).$$

Proof. We show that $c_{\mathrm{cy}} = 24$ has the property. Write $\ell = p$, $F = K_0$ (the map of the statement is written Φ in this proof), $n = [F : \mathbb{Q}_\ell]$, and fix a Frobenius numbering $(\tau_a)_{a \in \mathbb{Z}/n}$; the $\mathbb{Q}_\ell$-embeddings $\tau\colon K \to L$ are the embeddings of K over the τ_a. The hypotheses on ℓ, F, K, L are those of Proposition 23.7, so (V_1, T_1), (V_2, T_2) are pairs over K. Put $d = |\Delta_K|$, $w = \mathrm{wt}$ and $h' = w + 1 \geq 1$. Since $\Phi(T_1) = T_2$ spans V_2, $\Phi\colon V_1 \to V_2$ is onto, and by Lemma 23.25 every Hodge jump of V_2 at τ is one of V_1 at τ. As $a_\tau^\pm \geq 0$, $[-a_\tau^-, a_\tau^+] \subseteq [-w, w]$; so every Hodge jump of V_1 and of V_2 at every τ lies in $[-w, w] \subseteq [-h', h']$, and $M_a = h_a = h'$ ($a \in \mathbb{Z}/n$) is a window as in (Ex1) for both.

Step 1: lifting along onto maps up to ℓ^{r_0}, $r_0 = \mathrm{dsc}_{\ell,d}(0, 2h')$. By Lemma 24.11 for $\Phi\colon T_1 \to T_2$ (onto, and every Hodge jump of V_1 at every embedding of K lies in $[-h', h']$), for every $c \in \mathbb{Z}/n$ every $y \in \mathbf{N}(T_2)_c$ has $x \in \mathbf{N}(T_1)_c$ with $\mathbf{N}(\Phi)(x) = \ell^{r_0} y$, and $r_0 \leq \lfloor 2h'\ell/(d(\ell-1)) \rfloor \leq 3h'$.

Steps 2–3: the letter split. Let $x \in H^1_f(K, T_2)$. By Lemma 24.12 for (V_2, T_2) and h' (every Hodge jump of V_2 lies in $[-h', h']$), with $M = \lceil 4h'/d \rceil$, $m = Md$ and $\sigma = M - 1 +$

$v_\ell((M-1)!)$, there are $w_c \in e_c\mathbf{N}(T_2)[1/\lambda_\infty]$ ($c \in \mathbb{Z}/n$), fixed by every γ_δ, $\delta \in \Delta_K$, with $Q^{h'}w_c \in \mathbf{A}_{F,L}\varphi(\mathbf{N}(T_2)_{c-1})$, $(\gamma_u - 1)(w_c) \in \pi_\Delta^M \mathbf{N}(T_2)_c^\Delta$ for every $u \in \Gamma_K$, and

$$\ell^{\,r_0+\sigma}x = \sum_{c\in\mathbb{Z}/n} \mathrm{cl}(w_c) \qquad \text{in } H^1(K,T_2),$$

each w_c a Herr vector of precision m over K. Moreover $m \geq 4h' \geq 1 + h' = 1 + \max_a M_a$.

Step 4: the poles of w_c. By Steps 2–3, $Q^{h'}w_c \in \mathbf{A}_{F,L}\varphi(\mathbf{N}(T_2)_{c-1})$, and by (Wm2) for the window (h',h') of $\mathbf{N}(T_2)$ (Ex1), $Q^{h'}\varphi(\mathbf{N}(T_2)_{c-1}) \subseteq \mathbf{N}(T_2)_c$. So, with $G = 2h'$, $Q^G w_c \in \mathbf{N}(T_2)$. By Steps 2–3, w_c is Δ_K-fixed; by Steps 2–3 and (Dm2), $(\gamma_s - 1)(w_c) \in \pi_\Delta^M \mathbf{N}(T_2)_c^\Delta \subseteq \pi_\Delta \mathbf{N}(T_2)_c^\Delta \subseteq X\mathbf{N}(T_2)$ for every $s \in \Gamma_K$. So $w_c \in I_c^2$ in the notation of Lemma 24.18.

Step 5: the one-site lift. Let J be the set of Hodge jumps of V_1 at all embeddings of K (a subset of $[-w,w]$), $J' = \{j+k :\ j \in J,\ 1 \leq k \leq G,\ j+k \neq 0\}$ and $\kappa = \sum_{x\in J'}(1+v_\ell(x))$. By Step 1 for Φ, every $y \in \mathbf{N}(T_2)_c$ has $x \in \mathbf{N}(T_1)_c$ with $\mathbf{N}(\Phi)(x) = \ell^{r_0}y$. So Lemma 24.18 (with c, J, G, $r = r_0$, $w = w_c$) gives $u_c \in I_c^1$ with $Q^G u_c \in \mathbf{N}(T_1)$ and $\mathbf{N}(\Phi)(u_c) = \ell^{\,r_0+\kappa}w_c$.

Step 6: precision. Fix $u = 1 + \ell \in 1 + \ell\mathbb{Z}_\ell \subseteq \Gamma_K$, so $v_\ell(u-1) = 1$. Let $z = (\gamma_u - 1)(u_c)$. It lies in $X\mathbf{N}(T_1)$ ($u_c \in I_c^1$), in $e_c\mathbf{N}(T_1)$ (γ_u fixes e_c), and it is Δ_K-fixed (γ_δ commutes with γ_u); so $z \in X\mathbf{N}(T_1)_c \cap \mathbf{N}(T_1)_c^\Delta = \pi_\Delta \mathbf{N}(T_1)_c^\Delta$ by (Dm2). By Lemma 24.16 for $\mathbf{N}(T_1)$ (a Wach module over K by (Ex1)), with M as in Step 3 and $\sigma_M = \sigma$, there is $k \in \pi_\Delta \mathbf{N}(T_1)_c^\Delta$ with $\ell^\sigma z - (\gamma_u - 1)(k) \in \pi_\Delta^M \mathbf{N}(T_1)_c^\Delta$. Put $\bar{u}_c = \ell^\sigma u_c - k$. Then $(\gamma_u - 1)(\bar{u}_c) \in \pi_\Delta^M \mathbf{N}(T_1)_c^\Delta \subseteq X^m\mathbf{N}(T_1)$ (sidecalc above), and $(\gamma_\delta - 1)(\bar{u}_c) = 0$ for $\delta \in \Delta_K$. As $\Delta_K \cup \{u\}$ generates a dense subgroup of $\Gamma_K = \Delta_K \times (1 + \ell\mathbb{Z}_\ell)$, (Hc2) over K shows that $\bar{u}_c$ is a Herr vector of precision m for $\mathbf{N}(T_1)$ (window (h',h'), $m \geq 1 + h'$). Moreover $Q^G\bar{u}_c = \ell^\sigma Q^G u_c - Q^G k \in \mathbf{N}(T_1)$. By Proposition 23.27 over K, $\mathrm{cl}(\bar{u}_c) \in H_f^1(K,T_1)$.

Step 7: the correction term vanishes. Let $k' = \mathbf{N}(\Phi)(k)$. As $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear and commutes with every γ_s, $k' \in \pi_\Delta \mathbf{N}(T_2)_c^\Delta$, and

$$(\gamma_u - 1)(k') = \ell^\sigma \mathbf{N}(\Phi)(z) - \mathbf{N}(\Phi)\big(\ell^\sigma z - (\gamma_u - 1)(k)\big),$$
$$\mathbf{N}(\Phi)(z) = (\gamma_u - 1)\mathbf{N}(\Phi)(u_c) = \ell^{\,r_0+\kappa}(\gamma_u - 1)(w_c).$$

The first term lies in $\pi_\Delta^M \mathbf{N}(T_2)_c^\Delta$ by Steps 2–3, the second by the choice of k. By Lemma 24.21 for $\mathbf{N}(T_2)$, $k' \in \pi_\Delta^M \mathbf{N}(T_2)_c^\Delta \subseteq X^m\mathbf{N}(T_2)$, so by (Hc4) over K it is a Herr vector of precision m with $\mathrm{cl}(k') = 0$.

Step 8: the classes lift. By Steps 5 and 7, $\mathbf{N}(\Phi)(\bar{u}_c) = \ell^{\,\sigma+r_0+\kappa}w_c - k'$. By (Hc5) over K (for Φ, both windows (h',h'), $m \geq 1 + h'$) and (Hc3), (Hc4) over K,

$$\Phi_*\mathrm{cl}(\bar{u}_c) = \mathrm{cl}\big(\mathbf{N}(\Phi)(\bar{u}_c)\big) = \ell^{\,\sigma+r_0+\kappa}\mathrm{cl}(w_c) - \mathrm{cl}(k') = \ell^{\,\sigma+r_0+\kappa}\mathrm{cl}(w_c).$$

Multiplying Step 3 by $\ell^{\sigma+r_0+\kappa}$ and summing over c,

$$\ell^{\,e}x = \sum_{c\in\mathbb{Z}/n} \Phi_*\mathrm{cl}(\bar{u}_c) \in \Phi_*\big(H_f^1(K,T_1)\big), \qquad e = 2r_0 + 2\sigma + \kappa.$$

Step 9: the exponent. (a) $2r_0 \leq 6h'$ (Step 1). (b) $M - 1 < 4h'/d \leq 4h'$, and by Legendre's formula $\sigma \leq (M-1)\ell/(\ell-1) \leq \frac{3}{2}(M-1) < 6h'$; so $2\sigma < 12h'$. (c) $J' \subseteq [-w+1, w+G] \setminus \{0\} = [-w+1, 3w+2] \setminus \{0\}$, so $|J'| \leq 4w+2$, and, the elements of J' being distinct non-zero integers of absolute value at most $3w+2$ with at most $w-1$ of them negative, $\sum_{x\in J'} v_\ell(x) \leq v_\ell((w-1)!) + v_\ell((3w+2)!) \leq (4w+1)/(\ell-1) \leq (4w+1)/2$ (for $w = 0$ the first factorial is absent). So $\kappa \leq 6w + 3 < 6h'$. Hence $e < 24h' = 24(\mathrm{wt}+1) = e_{\mathrm{B}}$ for $c_{\mathrm{cy}} = 24$, and $\ell^{e_{\mathrm{B}}}x = \ell^{e_{\mathrm{B}}-e}(\ell^e x) \in \Phi_* H_f^1(K,T_1)$, a subgroup. As $x \in H_f^1(K,T_2)$ was arbitrary, the inclusion follows.

Level s. Let the data be as in the paragraph Level s of the statement; write $\ell = p$, $F = K_0$, $\Phi = F$ (the map), $n = [F : \mathbb{Q}_\ell]$, fix a Frobenius numbering, and put $w = \mathrm{wt}$, $h' = w + 1$, $Y = X_{s-1}$ (the level variable of Definition 23.2), $u_s = 1 + \ell^s$, $M = 4h'$. The hypotheses on ℓ, s, F, $K = F(\mu_{\ell^s})$, L are those of (Ex4) of Proposition 23.7, so (V_ν, T_ν) are pairs over K; $\Gamma_K = 1 + \ell^s\mathbb{Z}_\ell$, procyclic with generator u_s ($\ell^s \neq 2$), and Δ_K is trivial. As in the first paragraph, every Hodge jump of V_1 and V_2 at every embedding lies in $[-h', h']$, and $(h', h')_a$ is a window of level s for both. All cited clauses are taken in their paragraphs Level s. (1) By Lemma 24.11 for Φ, every $y \in \mathbf{N}_s(T_2)_c$ has $x \in \mathbf{N}_s(T_1)_c$ with $\mathbf{N}_s(\Phi)(x) = \ell^{r_0} y$, $r_0 = 2h's + v_\ell((2h')!)$. (2) Let $x \in H^1_f(K, T_2)$. By Lemma 24.12 for (V_2, T_2) there are $w_c \in e_c\mathbf{N}_s(T_2)[1/\lambda_\infty]$ with $Q^{h'}_{s-1} w_c \in \mathbf{A}_{F,L}\varphi(\mathbf{N}_s(T_2)_{c-1})$, $(\gamma_v - 1)(w_c) \in Y^M\mathbf{N}_s(T_2)_c$ for every $v \in \Gamma_K$, and $\ell^{r_0+\sigma}x = \sum_c \mathrm{cl}(w_c)$, $\sigma = (M-1)s + v_\ell((M-1)!)$. (3) By (Wm2) of level s, $Q^{h'}_{s-1}\varphi(\mathbf{N}_s(T_2)_{c-1}) \subseteq \mathbf{N}_s(T_2)_c$, so $Q^G_{s-1} w_c \in \mathbf{N}_s(T_2)$ with $G = 2h'$, and $w_c \in I^{2,s}_c$ in the notation of Lemma 24.18. (4) Let J be the set of Hodge jumps of V_1 at all embeddings of K ($J \subseteq [-w, w]$), J' as there and $\kappa = \sum_{x \in J'}(s + v_\ell(x))$. By (1), Lemma 24.18 (with $r = r_0$) gives $u_c \in I^{1,s}_c$ with $Q^G_{s-1}u_c \in \mathbf{N}_s(T_1)$ and $\mathbf{N}_s(\Phi)(u_c) = \ell^{r_0+\kappa}w_c$. (5) $z = (\gamma_{u_s} - 1)(u_c) \in Y\mathbf{N}_s(T_1) \cap e_c\mathbf{N}_s(T_1) = Y\mathbf{N}_s(T_1)_c$. Item 5 of Lemma 23.21 ($D = N = \mathbf{N}_s(T_1)_c$, free over $e_c\mathbf{A}_{F,L}$, $\gamma_D = \gamma_{u_s}$, (Wm3')) gives $k \in Y\mathbf{N}_s(T_1)_c$ with $\ell^\sigma z - (\gamma_{u_s} - 1)(k) \in Y^M\mathbf{N}_s(T_1)_c$. Put $\bar{u}_c = \ell^\sigma u_c - k$: $(\gamma_{u_s} - 1)(\bar{u}_c) \in Y^M\mathbf{N}_s(T_1)$, so by (Hc2) of Lemma 23.28 (the subset $\{u_s\}$) $\bar{u}_c$ is a Herr vector of precision $M \geq 1 + h'$ at level s; and $Q^G_{s-1}\bar{u}_c \in \mathbf{N}_s(T_1)$. By Proposition 23.27 ($f = Q^G_{s-1}$), $\mathrm{cl}(\bar{u}_c) \in H^1_f(K, T_1)$. (6) $k' = \mathbf{N}_s(\Phi)(k) \in Y\mathbf{N}_s(T_2)_c$ and $(\gamma_{u_s} - 1)(k') = \ell^\sigma\mathbf{N}_s(\Phi)(z) - \mathbf{N}_s(\Phi)(\ell^\sigma z - (\gamma_{u_s} - 1)(k))$ with $\mathbf{N}_s(\Phi)(z) = \ell^{r_0+\kappa}(\gamma_{u_s} - 1)(w_c)$; both terms lie in $Y^M\mathbf{N}_s(T_2)_c$ by (2) and (5). Item 6 of Lemma 23.21 ($N = \mathbf{N}_s(T_2)_c$, free over $e_c\mathbf{A}_{F,L}$) gives $k' \in Y^M\mathbf{N}_s(T_2)$, so by (Hc4) k' is a Herr vector of precision M at level s with $\mathrm{cl}(k') = 0$. (7) $\mathbf{N}_s(\Phi)(\bar{u}_c) = \ell^{\sigma+r_0+\kappa}w_c - k'$, and (Hc5), (Hc3), (Hc4) give $\Phi_*\mathrm{cl}(\bar{u}_c) = \ell^{\sigma+r_0+\kappa}\mathrm{cl}(w_c)$. Multiplying (2) by $\ell^{\sigma+r_0+\kappa}$ and summing over c, $\ell^e x \in \Phi_* H^1_f(K, T_1)$ with $e = 2r_0 + 2\sigma + \kappa$. (8) The exponent. By Legendre's formula $v_\ell(N!) \leq N - 1$ for $N \geq 1$. So $r_0 \leq 2h's + 2h' - 1$ and $\sigma \leq (4h' - 1)s + 4h' - 2$. As in Step 9(c), $J' \subseteq [-w+1, 3w+2] \setminus \{0\}$ has at most $4w+2 = 4h'-2$ elements, at most $w-1$ of them negative, so $\sum_{x \in J'} v_\ell(x) \leq v_\ell((w-1)!) + v_\ell((3w+2)!) \leq 4w + 1 = 4h' - 3$ and $\kappa \leq (4h' - 2)s + 4h' - 3$. Hence

$$e \leq (16h' - 4)s + 16h' - 9 < 16h'(s+1) \leq 24(\mathrm{wt} + 1)(s+1) = e^{(s)}_{\mathrm{B}} \quad \text{for } c_{\mathrm{cy}} = 24,$$

and $\ell^{e^{(s)}_{\mathrm{B}}} x \in \Phi_* H^1_f(K, T_1)$. □

Lemma 24.11. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Proposition 23.7, $d = |\Delta_K|$, $h' \geq 1$ an integer, and $f\colon T \to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V, T), (V'', T'') over K such that every Hodge jump of V at every embedding of K lies in $[-h', h']$. Put $r_0 = \mathrm{dsc}_{\ell,d}(0, 2h')$; then $r_0 \leq \lfloor 2h'\ell/(d(\ell-1))\rfloor$, and for every $c \in \mathbb{Z}/n$ and every $y \in \mathbf{N}(T'')_c$ there is $x \in \mathbf{N}(T)_c$ with $\mathbf{N}(f)(x) = \ell^{r_0}y$; if y is Δ_K-fixed, x can be taken Δ_K-fixed.* ***Level*** *s. Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and pairs over K as in (Ex4) of Proposition 23.7, $h' \geq 1$, and $f\colon T \to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V, T), (V'', T'') over K with every Hodge jump of V at every embedding of K in $[-h', h']$. Put $r^{(s)}_0 = 2h's + v_\ell((2h')!) \leq 2h'(s+1)$. Then for every $c \in \mathbb{Z}/n$ and every $y \in \mathbf{N}_s(T'')_c$ there is $x \in \mathbf{N}_s(T)_c$ with $\mathbf{N}_s(f)(x) = \ell^{r^{(s)}_0}y$.*

Proof. By (Ex1), $\mathbf{N}(T)$ and $\mathbf{N}(T'')$ are Wach modules over K with window $(h', h')_a$ (the map $V \to V''$ induced by f is onto, so by Lemma 23.25 every Hodge jump of V'' at an embedding is one of V there). By Proposition 23.18 with $M_a = h_a = h'$, $X^{2h'}\mathbf{N}(T'')_c \subseteq \mathbf{N}(f)(\mathbf{N}(T)_c)$. Apply item 1 of Lemma 23.21 with $\Gamma = \Gamma_K$ (index d), $D = N = \mathbf{N}(T'')_c$, $N' = \mathbf{N}(f)(\mathbf{N}(T)_c)$, $\gamma_{u,D} = \gamma_{u,\mathbf{N}}$

$(u \in \Gamma_K)$, $s = 2h'$, $j = 0$. Its hypotheses hold: D is free over $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ (Wm1), so multiplication by X is injective; $\gamma_{u,\mathbf{N}}$ is γ_u-semilinear and fixes e_c; $(\gamma_u - 1)(N) \subseteq XN$ by (Wm3); and N' is an $\mathbf{A}_{F,L}$-submodule with $(\gamma_u - 1)(N') = \mathbf{N}(f)((\gamma_u - 1)\mathbf{N}(T)_c) \subseteq XN'$, as $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with every γ_u (Ex3). So $\ell^{r_0}N \subseteq N'$, which is the lifting assertion; item 2 there gives the bound on r_0. If y is Δ_K-fixed and $\mathbf{N}(f)(x) = \ell^{r_0}y$, put $x' = d^{-1}\sum_{\delta\in\Delta_K}\gamma_\delta(x)$; this is defined since $d \mid \ell - 1$ is a unit of $\mathbb{Z}_\ell$, lies in $\mathbf{N}(T)_c$ (γ_δ preserves $\mathbf{N}(T)$ and fixes e_c), is Δ_K-fixed (Δ_K is a group acting through γ, (Wm3)), and $\mathbf{N}(f)(x') = d^{-1}\sum_\delta \gamma_\delta(\ell^{r_0}y) = \ell^{r_0}y$.

Level s. By (Ex1) of level s (Proposition 23.7, (Ex4)) and Lemma 23.25, $\mathbf{N}_s(T)$ and $\mathbf{N}_s(T'')$ are Wach modules of level s over K with window $(h', h')_a$. By Proposition 23.18 (paragraph Level s) with $M_a = h_a = h'$, $X_{s-1}^{2h'}\mathbf{N}_s(T'')_c \subseteq \mathbf{N}_s(f)(\mathbf{N}_s(T)_c)$. Apply item 4 of Lemma 23.21 (paragraph Level s) with $D = N = \mathbf{N}_s(T'')_c$, $N' = \mathbf{N}_s(f)(\mathbf{N}_s(T)_c)$, $\gamma_D = \gamma_{u_s,\mathbf{N}}$, $S = 2h'$, $j = 0$. Its hypotheses hold: $u_s = 1 + \ell^s$ lies in Γ_K (it lies in $\chi_{\mathrm{cyc}}(G_{F(\mu_{\ell^s})}) = 1 + \ell^s\mathbb{Z}_\ell$, Definition 23.2) and $u_s \equiv 1 \bmod \ell^{s-1}$, so (Wm3') gives $(\gamma_{u_s} - 1)(N) \subseteq X_{s-1}N$; N' is an $\mathbf{A}_{F,L}$-submodule with $(\gamma_{u_s} - 1)(N') = \mathbf{N}_s(f)((\gamma_{u_s} - 1)\mathbf{N}_s(T)_c) \subseteq X_{s-1}N'$ by (Wm3') for $\mathbf{N}_s(T)$ and (Ex3) of level s; D is free over the domain $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ (Wm1), so $X_{s-1} \neq 0$ acts injectively; and $\gamma_{u_s,\mathbf{N}}$ is γ_{u_s}-semilinear and fixes e_c. So $\ell^{r_0^{(s)}}N \subseteq N'$ with $r_0^{(s)} = \mathrm{dsc}_\ell^{(s)}(0, 2h') = 2h's + v_\ell((2h')!)$. □

Lemma 24.12. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Proposition 23.7, $d = |\Delta_K|$, (V, T) a pair over K and $h' \geq 1$ an integer such that every Hodge jump of V at every embedding of K lies in $[-h', h']$. Put $M = \lceil 4h'/d \rceil$, $m = Md$, $\sigma = M - 1 + v_\ell((M-1)!)$ and $r_0 = \mathrm{dsc}_{\ell,d}(0, 2h')$. Then for every $x \in H^1_f(K, T)$ there are $w_c \in e_c\mathbf{N}(T)[1/\lambda_\infty]$ $(c \in \mathbb{Z}/n)$ such that $\gamma_\delta(w_c) = w_c$ for $\delta \in \Delta_K$, $Q^{h'}w_c \in \mathbf{A}_{F,L}\,\varphi(\mathbf{N}(T)_{c-1})$, $(\gamma_u - 1)(w_c) \in \pi_\Delta^M\mathbf{N}(T)_c^\Delta$ for every $u \in \Gamma_K$ (so w_c is a Herr vector of precision m over K), and*

$$\ell^{r_0+\sigma}\,x = \sum_{c\in\mathbb{Z}/n} \mathrm{cl}(w_c) \qquad \text{in } H^1(K, T).$$

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L as in (Ex4) of Proposition 23.7, $K = F(\mu_{\ell^s})$, X_{s-1} the level variable of Definition 23.2, (V, T) a pair over K and $h' \geq 1$ with every Hodge jump of V at every embedding of K in $[-h', h']$. Put $M = 4h'$, $\sigma^{(s)} = (M-1)s + v_\ell((M-1)!)$ and $r_0^{(s)} = 2h's + v_\ell((2h')!)$. Then for every $x \in H^1_f(K, T)$ there are $w_c \in e_c\mathbf{N}_s(T)[1/\lambda_\infty]$ $(c \in \mathbb{Z}/n)$ with $Q_{s-1}^{h'}w_c \in \mathbf{A}_{F,L}\,\varphi(\mathbf{N}_s(T)_{c-1})$, $(\gamma_u - 1)(w_c) \in X_{s-1}^M\mathbf{N}_s(T)_c$ for every $u \in \Gamma_K$ (so w_c is a Herr vector of precision M at level s), and $\ell^{r_0^{(s)}+\sigma^{(s)}}x = \sum_c \mathrm{cl}(w_c)$ in $H^1(K, T)$.*

Proof. By Lemma 23.26 (over K) there are a pair (V_Y, Y) over K and an exact sequence $0 \to T \xrightarrow{\iota'} Y \xrightarrow{p} \mathcal{O}_L \to 0$ of G_K-equivariant $\mathcal{O}_L$-linear maps with $[Y] = x$, every Hodge jump of V_Y at every embedding being 0 or one of V, hence in $[-h', h']$. For $c \in \mathbb{Z}/n$, Lemma 24.11 for p and $y = e_c^\circ \in \mathbf{N}(\mathcal{O}_L)_c$ (Lemma 24.3, over a base field) gives $x_c \in \mathbf{N}(Y)_c$ with $\mathbf{N}(p)(x_c) = \ell^{r_0}e_c^\circ$, so by (Ex3) $(1 \otimes p)(\iota_Y(x_c)) = \iota_{\mathcal{O}_L}(\ell^{r_0}e_c^\circ) = \ell^{r_0}\varepsilon_c$. Now Proposition 24.13 applies to $(V', T') = (V, T)$, (V_Y, Y), ι', p, h', $r = r_0$ and the x_c (the Hodge jumps of V and V_Y lie in $[-h', h']$), with $s' = d$, so its M, m, σ are those defined above; it gives the w_c with (Rs1)–(Rs3) and $\ell^{r_0+\sigma}[Y] = \sum_c \mathrm{cl}(w_c)$.

Level s. By Lemma 23.26 (paragraph Level s) there are a pair (V_Y, Y) over K and an exact sequence $0 \to T \xrightarrow{\iota'} Y \xrightarrow{p} \mathcal{O}_L \to 0$ with $[Y] = x$ and all Hodge jumps of V_Y in $[-h', h']$. For $c \in \mathbb{Z}/n$, Lemma 24.11 (paragraph Level s) for p and $y = e_c^\circ \in \mathbf{N}_s(\mathcal{O}_L)_c$ (Lemma 24.3, paragraph Level s) gives $x_c \in \mathbf{N}_s(Y)_c$ with $\mathbf{N}_s(p)(x_c) = \ell^{r_0^{(s)}}e_c^\circ$, so by (Ex3) of level s, $(1 \otimes p)(\iota_{s,Y}(x_c)) = \iota_{s,\mathcal{O}_L}(\ell^{r_0^{(s)}}e_c^\circ) = \ell^{r_0^{(s)}}(\iota_s \otimes \mathrm{id})(e_c) = \ell^{r_0^{(s)}}\varepsilon_c$. Finally, Proposition 24.13 (paragraph Level s), applied to (V, T), (V_Y, Y), ι', p, h', $r = r_0^{(s)}$ and the x_c, gives the w_c and $\ell^{r_0^{(s)}+\sigma^{(s)}}[Y] = \sum_c \mathrm{cl}(w_c)$. □

Proposition 24.13. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ as in Proposition 23.7, K a field with $F \subseteq K \subseteq F(\mu_\ell)$, $\Delta = \Delta_K$ and $s' = |\Delta|$. Let (V',T'), (V,T) be pairs over K and $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} \mathcal{O}_L \to 0$ an exact sequence of G_K-equivariant $\mathcal{O}_L$-linear maps ($\mathcal{O}_L$ the trivial representation), with extension class $[T] \in H^1(K,T')$. Let $h' \geq 1$ be an integer such that every Hodge jump of V' and of V at every $\mathbb{Q}_\ell$-embedding $K \to L$ lies in $[-h',h']$, and put*

$$M = \lceil 4h'/s' \rceil, \qquad m = Ms', \qquad \sigma = M - 1 + v_\ell((M-1)!).$$

Write $\varepsilon_a = (\iota \otimes \mathrm{id})(e_a) \in A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$. Let $r \geq 0$ and suppose that for every $c \in \mathbb{Z}/n$ there is $x_c \in \mathbf{N}(T)_c$ with $(1\otimes\pi)(\iota_T(x_c)) = \ell^r \varepsilon_c$. Then there are $w_c \in e_c\mathbf{N}(T')[1/\lambda_\infty]$ ($c \in \mathbb{Z}/n$) such that

(Rs1) Invariance *$\gamma_\delta(w_c) = w_c$ for every $\delta \in \Delta$;*

(Rs2) Poles *$Q^{h'} w_c \in \mathbf{A}_{F,L}\,\varphi(\mathbf{N}(T')_{c-1})$;*

(Rs3) Precision *$(\gamma_u - 1)(w_c) \in \pi_\Delta^M\, \mathbf{N}(T')_c^\Delta$ for every $u \in \Gamma_K$; in particular w_c is a Herr vector of precision m over K;*

and

$$\ell^{r+\sigma}\,[T] = \sum_{c\in\mathbb{Z}/n} \mathrm{cl}(w_c) \qquad \text{in } H^1(K,T').$$

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L as in (Ex4) of Proposition 23.7, $K = F(\mu_{\ell^s})$, X_{s-1} the level variable of Definition 23.2, and (V',T'), (V,T) pairs over K with an exact sequence $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} \mathcal{O}_L \to 0$ of G_K-equivariant $\mathcal{O}_L$-linear maps and extension class $[T] \in H^1(K,T')$; let $h' \geq 1$ be such that every Hodge jump of V' and of V at every embedding $K \to L$ lies in $[-h',h']$, and put*

$$M = 4h', \qquad \sigma^{(s)} = (M-1)s + v_\ell((M-1)!).$$

Let $r \geq 0$ and suppose that for every $c \in \mathbb{Z}/n$ there is $x_c \in \mathbf{N}_s(T)_c$ with $(1\otimes\pi)(\iota_{s,T}(x_c)) = \ell^r\varepsilon_c$ (here $\varepsilon_c = (\iota_s \otimes \mathrm{id})(e_c)$, as $\iota_s = \iota$ on $\mathcal{O}_F$). Then there are $w_c \in e_c\mathbf{N}_s(T')[1/\lambda_\infty]$ ($c \in \mathbb{Z}/n$) with $Q_{s-1}^{h'} w_c \in \mathbf{A}_{F,L}\,\varphi(\mathbf{N}_s(T')_{c-1})$ and $(\gamma_u - 1)(w_c) \in X_{s-1}^M \mathbf{N}_s(T')_c$ for every $u \in \Gamma_K$ (so w_c is a Herr vector of precision M at level s, Lemma 23.28), and $\ell^{r+\sigma^{(s)}}[T] = \sum_c \mathrm{cl}(w_c)$ in $H^1(K,T')$.

Proof. **Step 0: preliminaries.** (a) By (Ex1), N' and N are Wach modules over K with window $(h',h')_a$, and $m = Ms' \geq 4h' \geq 1 + h'$, so the Herr calculus of Lemma 23.28 applies to both with precision m. (b) By Lemma 24.14, $(\ell-1)/s' = [K:F]$, and by (Rr7) $\Gamma_K = \Delta \cdot (1+\ell\mathbb{Z}_\ell) = \Delta \times (1+\ell\mathbb{Z}_\ell)$; $u_0 \in \Gamma_K$, $v_\ell(u_0 - 1) = 1$, and $\Delta \cup \{u_0\}$ generates a dense subgroup of Γ_K ($u_0^{\mathbb{Z}}$ is dense in $1+\ell\mathbb{Z}_\ell$, ℓ odd). (c) By Lemma 23.8(4) the ε_a are G_K-invariant, $(\varphi\otimes 1)(\varepsilon_a) = \varepsilon_{a+1}$ and $\sum_a \varepsilon_a = 1$. (d) If $y \in N[1/\lambda_\infty]$ and $(1\otimes\pi)\iota_T(y) = 0$, then $y = \iota_*(t)$ for a unique $t \in N'[1/\lambda_\infty]$; $t \in X^k N'$ if $y \in X^k N$; $e_c t = t$ if $e_c y = y$; t is Δ-fixed if y is. Indeed, by (Ex3) $\iota_{\mathcal{O}_L}(\pi_* y) = (1\otimes\pi)\iota_T(y) = 0$, and $\iota_{\mathcal{O}_L}$ is injective on $\mathbf{N}(\mathcal{O}_L)[1/\lambda_\infty]$ (Gc0), so $\pi_* y = 0$; clearing poles by a product f of the Q_s, Lemma 23.33 gives $fy = \iota_*(t_0)$, $t = t_0/f$, unique as ι_* is injective (also after localisation). If $y = X^k y'$ with $y' \in N$, then $X^k \pi_*(y') = 0$, so $\pi_*(y') = 0$ ($N(\mathcal{O}_L)$ is torsion-free) and $y' = \iota_*(t')$, $t = X^k t'$. The last two claims follow from injectivity, as ι_* is $\mathbf{A}_{F,L}$-linear and commutes with γ_δ. (e) For $k \geq 0$, $X^k N_c' \cap N_c'^\Delta = \pi_\Delta^{\lceil k/s' \rceil} N_c'^\Delta$, and in particular $X^m N_c' \cap N_c'^\Delta = \pi_\Delta^M N_c'^\Delta$. Indeed, in a Δ-fixed basis (Dm1) the coordinates f of such an element lie in $R_c^\Delta \cap X^k R_c$; by (Rr2) $f = \sum_j c_j \pi_\Delta^j$, and by (Rr1) the X-adic order of f is $s'j_0$

for the least j_0 with $c_{j_0} \neq 0$; so $j_0 \geq k/s'$ and $f \in \pi_\Delta^{\lceil k/s' \rceil} R_c^\Delta$. The converse inclusion holds as $\pi_\Delta^j \in X^{s'j} R_c$.

Step 1: Δ-fixed lifts of the units. Replace x_c by $|\Delta|^{-1} \sum_{\delta \in \Delta} \gamma_\delta(x_c)$ ($|\Delta|$ divides $\ell - 1$): for $\delta \in \Delta$ and $\sigma_\delta \in G_K$ with $\chi_{\mathrm{cyc}}(\sigma_\delta) = \delta$, (Gc0) and (c) give $(1 \otimes \pi)\iota_T(\gamma_\delta x_c) = \sigma_\delta(\ell^r \varepsilon_c) = \ell^r \varepsilon_c$. So we may assume $x_c \in N_c^\Delta$.

Step 2: the Γ-defect. By (Dm3), $(\gamma_{u_0} - 1)(x_c) \in \pi_\Delta N_c^\Delta \subseteq X N_c$, and its image under $(1 \otimes \pi)\iota_T$ is $\sigma_0(\ell^r \varepsilon_c) - \ell^r \varepsilon_c = 0$ ($\chi_{\mathrm{cyc}}(\sigma_0) = u_0$). By (d), $(\gamma_{u_0} - 1)(x_c) = \iota_*(z_c)$ with $z_c \in X N_c'$ Δ-fixed, so $z_c \in \pi_\Delta N_c'^\Delta$ by (Dm2). By Lemma 24.16 (for N', u_0, M) there is $k_c \in \pi_\Delta N_c'^\Delta$ with

$$\kappa_c := \ell^\sigma z_c - (\gamma_{u_0} - 1)(k_c) \in \pi_\Delta^M N_c'^\Delta.$$

Put $b_c = \ell^\sigma x_c - \iota_*(k_c) \in N_c^\Delta$. Then $(\gamma_{u_0} - 1)(b_c) = \iota_*(\kappa_c)$ (ι_* commutes with γ_{u_0}, (Ex3)) and $(1 \otimes \pi)\iota_T(b_c) = \ell^{r+\sigma} \varepsilon_c$ ($\pi \circ \iota' = 0$).

Step 3: Frobenius preserves $\pi_\Delta^M N'^\Delta$. Let $y = \pi_\Delta^M n$ with $n \in N_{c-1}'^\Delta$. By (Rr5) and (Rr4), $\varphi(y) = w'^M \pi_\Delta^M q_\Delta^{Ms'} \varphi(n) = w'^M w_\Delta^{Ms'} \pi_\Delta^M Q^{Ms'-h'} \cdot Q^{h'} \varphi(n)$ with units $w' = w'_\Delta$, w_Δ, and $Q^{h'}\varphi(n) \in N_c'$ by (Wm2); as $Ms' \geq h'$, $\varphi(y) \in \pi_\Delta^M N_c'$. It is Δ-fixed because φ commutes with every γ_δ (Wm3). Writing $\varphi(y) = \pi_\Delta^M n'$, n' is Δ-fixed (π_Δ is, and N_c' is torsion-free), so $\varphi(y) \in \pi_\Delta^M N_c'^\Delta$.

Step 4: the vectors w_c. Put $s_c = \varphi(b_{c-1}) \in e_c N[1/Q]$ (by (Wm2) and $\varphi(e_{c-1}) = e_c$); it is Δ-fixed, and $(1 \otimes \pi)\iota_T(s_c) = (\varphi \otimes 1)(\ell^{r+\sigma} \varepsilon_{c-1}) = \ell^{r+\sigma} \varepsilon_c$ by (Gc0) and (c). So $s_c - b_c$ has image 0, and by (d) $s_c - b_c = \iota_*(w_c)$ with $w_c \in e_c N'[1/\lambda_\infty]$ Δ-fixed: this is (Rs1).

(Rs2). Let $P = \mathbf{A}_{F,L}\varphi(N_{c-1})$ and $P' = \mathbf{A}_{F,L}\varphi(N_{c-1}')$. For a Wach module $\mathbf{N}$ over K with an R_{c-1}-basis $(d_j)_{j \leq d}$ of $\mathbf{N}_{c-1}$, the $\varphi(d_j)$ form an R_c-basis of $\mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-1})$: they generate it by semilinearity, and they are independent because by (Wm2) their span contains $Q^{h_c}\mathbf{N}_c$, of rank d over the domain R_c. Hence $R_c \otimes_{\varphi, R_{c-1}} \mathbf{N}_{c-1} \to \mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-1})$, $a \otimes x \mapsto a\varphi(x)$, is an isomorphism, natural in $\mathbf{N}$ for maps commuting with φ. Now $\varphi\colon R_{c-1} \to R_c$ is $f(X) \mapsto f((1+X)^\ell - 1)$, and R_c is free over its image with basis $(1+X)^i$, $0 \leq i < \ell$ (Weierstrass division by the distinguished polynomial $(1+X)^\ell - 1$); so $R_c \otimes_{\varphi, R_{c-1}} -$ is exact. Applied to the exact sequence $0 \to N_{c-1}' \xrightarrow{\iota_*} N_{c-1} \xrightarrow{\pi_*} \mathbf{N}(\mathcal{O}_L)_{c-1}$ (Lemma 23.33), it shows: an element of P killed by π_* lies in $\iota_*(P')$. Now $Q^{h'} s_c \in P$, and $Q^{h'} b_c \in P$ by (Wm2) for N ($h_c \leq h'$), so $Q^{h'}(s_c - b_c) \in P$, and $\pi_*(Q^{h'}(s_c - b_c)) = 0$ (Step 0(d)). Hence $Q^{h'}\iota_*(w_c) = \iota_*(p')$ with $p' \in P'$, and $Q^{h'} w_c = p'$ by injectivity.

(Rs3). Since ι_* and φ commute with γ_{u_0} (Ex3), (Wm3), Step 2 gives

$$\iota_*\big((\gamma_{u_0} - 1)(w_c)\big) = \varphi\big(\iota_*(\kappa_{c-1})\big) - \iota_*(\kappa_c) = \iota_*\big(\varphi(\kappa_{c-1}) - \kappa_c\big),$$

so $(\gamma_{u_0} - 1)(w_c) = \varphi(\kappa_{c-1}) - \kappa_c \in \pi_\Delta^M N_c'^\Delta \subseteq X^m N'$ by Step 3 and (Rr1). Also $(\gamma_\delta - 1)(w_c) = 0$ for $\delta \in \Delta$. By (b) and (Hc2), w_c is a Herr vector of precision m: $(\gamma_u - 1)(w_c) \in X^m N'$ for all $u \in \Gamma_K$. This element lies in $e_c N'$ and is Δ-fixed (γ_u and γ_δ commute, Γ_K being commutative), so by (e) it lies in $\pi_\Delta^M N_c'^\Delta$.

Step 5: the global vector and its class. Put $\tilde{x} = \sum_c s_c \in N[1/\lambda_\infty]$. By Step 4 and (c), $(1 \otimes \pi)\iota_T(\tilde{x}) = \ell^{r+\sigma} \sum_c \varepsilon_c = 1 \otimes \ell^{r+\sigma}$. Further $(\gamma_\delta - 1)(\tilde{x}) = 0$ for $\delta \in \Delta$, and $(\gamma_{u_0} - 1)(\tilde{x}) = \sum_c \varphi(\iota_*(\kappa_{c-1})) = \iota_*(\sum_c \varphi(\kappa_{c-1})) \in \iota_*(X^m N') \subseteq X^m N$ by Step 3. By (b) and (Hc2) for N, $(\gamma_u - 1)(\tilde{x}) \in X^m N$ for all $u \in \Gamma_K$; its image under $(1 \otimes \pi)\iota_T$ is $(\sigma_u - 1)(1 \otimes \ell^{r+\sigma}) = 0$ ((Gc0), $\chi_{\mathrm{cyc}}(\sigma_u) = u$), so by (d) $(\gamma_u - 1)(\tilde{x}) \in \iota_*(X^m N')$. By Lemma 23.32 (over K, $c = \ell^{r+\sigma}$, window (h', h') of V'), the unique $y \in N'[1/\lambda_\infty]$ with $\iota_*(y) = (\varphi - 1)(\tilde{x})$ is a Herr vector of precision m with $\mathrm{cl}(y) = \ell^{r+\sigma}[T]$.

Step 6: telescoping. Let $W = \sum_c w_c$. Then

$$\iota_*(\varphi(W)) = \sum_c \varphi(s_c - b_c) = \sum_c \varphi(s_c) - \sum_c s_{c+1} = \varphi(\tilde{x}) - \tilde{x},$$

so $y = \varphi(W)$ by injectivity of ι_*. By Step 4 and (Hc3), W is a Herr vector of precision m with $(\gamma_u - 1)(W) \in X^m N'$ for all $u \in \Gamma_K$; by (Hc4), $(\varphi - 1)(W)$ is a Herr vector with $\mathrm{cl}((\varphi - 1)(W)) = 0$. By (Hc3),

$$\ell^{r+\sigma}[T] = \mathrm{cl}(\varphi(W)) = \mathrm{cl}(W) + \mathrm{cl}((\varphi - 1)(W)) = \sum_c \mathrm{cl}(w_c).$$

Level s. Let the data be as in the paragraph Level s of the statement; now $N' = \mathbf{N}_s(T')$, $N = \mathbf{N}_s(T)$, $\iota_* = \mathbf{N}_s(\iota')$, $\pi_* = \mathbf{N}_s(\pi)$, $Y = X_{s-1}$, $u_s = 1 + \ell^s$, $\sigma = \sigma^{(s)}$, and every cited clause is taken in its level-s form: (Ex1)–(Ex3) of (Ex4) of Proposition 23.7, (Hc1)–(Hc4) of Lemma 23.28, Lemma 23.32, Lemma 23.33, (Gc0) of Lemma 23.29, items 1–3 of Lemma 23.30, each in its paragraph Level s. *Step 0.* (a) N', N are Wach modules of level s with window $(h', h')_a$, and $M = 4h' \geq 1 + h'$. (b) $\Gamma_K = 1 + \ell^s \mathbb{Z}_\ell$ (Definition 23.2, paragraph Level s), which is procyclic with topological generator u_s ($\ell^s \neq 2$); so $\{u_s\}$ generates a dense subgroup of Γ_K, (Hc2) applies with this subset, and (Wm3') holds for every $u \in \Gamma_K$. (c) By Lemma 23.8(6) the ε_a are G_K-invariant, $(\varphi \otimes 1)(\varepsilon_a) = \varepsilon_{a+1}$ and $\sum_a \varepsilon_a = 1$. (d) If $y \in N[1/\lambda_\infty]$ and $(1 \otimes \pi)\iota_{s,T}(y) = 0$, then $y = \iota_*(t)$ for a unique $t \in N'[1/\lambda_\infty]$, with $t \in Y^k N'$ if $y \in Y^k N$ and $e_c t = t$ if $e_c y = y$: the proof is that of Step 0(d) with Y in place of X ($Y^k \pi_*(y') = 0$ forces $\pi_*(y') = 0$ as $\mathbf{N}_s(\mathcal{O}_L)$ is torsion-free). *Step 1* is void (Δ_K is trivial). *Step 2.* By (Wm3'), $(\gamma_{u_s} - 1)(x_c) \in Y N_c$, and its image under $(1 \otimes \pi)\iota_{s,T}$ is $\sigma_0(\ell^r \varepsilon_c) - \ell^r \varepsilon_c = 0$ ($\chi_{\mathrm{cyc}}(\sigma_0) = u_s$, (Gc0), (c)); by (d), $(\gamma_{u_s} - 1)(x_c) = \iota_*(z_c)$ with $z_c \in Y N'_c$. Item 5 of Lemma 23.21 (paragraph Level s; $D = N = N'_c$, free over $e_c \mathbf{A}_{F,L}$, $\gamma_D = \gamma_{u_s}$, (Wm3')) gives $k_c \in Y N'_c$ with $\kappa_c = \ell^\sigma z_c - (\gamma_{u_s} - 1)(k_c) \in Y^M N'_c$. Put $b_c = \ell^\sigma x_c - \iota_*(k_c) \in N_c$; then $(\gamma_{u_s} - 1)(b_c) = \iota_*(\kappa_c)$ and $(1 \otimes \pi)\iota_{s,T}(b_c) = \ell^{r+\sigma}\varepsilon_c$. *Step 3.* By item 1 of Lemma 23.30 (Level s, $m = M \geq 1 + h'$), $\varphi(Y^M N'_{c-1}) \subseteq Y^M Q_{s-1} N' \cap e_c N'[1/Q_{s-1}]$, so $\varphi(Y^M N'_{c-1}) \subseteq Y^M N'_c$. *Step 4.* Put $s_c = \varphi(b_{c-1}) \in e_c N[1/Q_{s-1}]$; by (Gc0) and (c), $(1 \otimes \pi)\iota_{s,T}(s_c) = \ell^{r+\sigma}\varepsilon_c$, so $s_c - b_c = \iota_*(w_c)$ with $w_c \in e_c N'[1/\lambda_\infty]$ by (d). The pole clause is proved as (Rs2) above with Q_{s-1} in place of Q: the φ-images of an R_{c-1}-basis of $\mathbf{N}_{c-1}$ form an R_c-basis of $\mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-1})$ by (Wm2) of level s, $R_c \otimes_{\varphi, R_{c-1}} -$ is exact, and Lemma 23.33 (Level s) gives $Q_{s-1}^{h'} w_c \in \mathbf{A}_{F,L}\varphi(N'_{c-1})$. As ι_*, φ commute with γ_{u_s}, $(\gamma_{u_s} - 1)(w_c) = \varphi(\kappa_{c-1}) - \kappa_c \in Y^M N'_c$ by Step 3. By (b) and (Hc2), $(\gamma_u - 1)(w_c) \in Y^M N'$ for all $u \in \Gamma_K$, and it lies in $e_c N'$, hence in $Y^M N'_c$. *Step 5.* $\tilde{x} = \sum_c s_c$ has $(1 \otimes \pi)\iota_{s,T}(\tilde{x}) = 1 \otimes \ell^{r+\sigma}$ and $(\gamma_{u_s} - 1)(\tilde{x}) = \iota_*(\sum_c \varphi(\kappa_{c-1})) \in \iota_*(Y^M N') \subseteq Y^M N$; by (Hc2) for N, $(\gamma_u - 1)(\tilde{x}) \in Y^M N$ for all $u \in \Gamma_K$, with image 0 under $(1 \otimes \pi)\iota_{s,T}$, so by (d) it lies in $\iota_*(Y^M N')$. Lemma 23.32 (Level s, $c = \ell^{r+\sigma}$, window (h', h'), $m = M$) gives the Herr vector y of precision M at level s with $\iota_*(y) = (\varphi - 1)(\tilde{x})$ and $\mathrm{cl}(y) = \ell^{r+\sigma}[T]$. *Step 6* is unchanged: $W = \sum_c w_c$ has $\iota_*(\varphi(W)) = \varphi(\tilde{x}) - \tilde{x}$, so $y = \varphi(W)$, and (Hc3), (Hc4) give $\ell^{r+\sigma}[T] = \mathrm{cl}(W) + \mathrm{cl}((\varphi - 1)(W)) = \sum_c \mathrm{cl}(w_c)$. □

Lemma 24.14. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ as in Definition 23.2, K a field with $F \subseteq K \subseteq F(\mu_\ell)$, $\Delta = \Delta_K$, and $\mathbf{N}$ a Wach module over K with coefficients L (any window), of rank r in (Wm1). Then Δ is a subgroup of $\mu_{\ell-1}$ with $(\ell - 1)/|\Delta| = [K : F]$, and for every $a \in \mathbb{Z}/n$, with $R = e_a \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$:*

(Dm1) Invariant basis *$\mathbf{N}_a$ has an R-basis $(n_k)_{k \leq r}$ of Δ-fixed vectors, and for every such basis $\mathbf{N}_a^\Delta = \bigoplus_k R^\Delta n_k$; so $\mathbf{N}_a^\Delta$ is a free module of rank r over $R^\Delta = \mathcal{O}_L[[\pi_\Delta]]$, and an element of $\mathbf{N}_a$ is Δ-fixed if and only if its coordinates in (n_k) lie in R^Δ.*

(Dm2) Divisibility by X *$X\mathbf{N}_a \cap \mathbf{N}_a^\Delta = \pi_\Delta \mathbf{N}_a^\Delta$.*

(Dm3) Gamma *For every $u \in \Gamma_K$ and $y \in \mathbf{N}_a^\Delta$, $\gamma_u(y) \in \mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(y) = \pi_\Delta y'$ for a unique $y' \in \mathbf{N}_a^\Delta$.*

Proof. **The group.** $\Delta = \Delta_K$ is a finite subgroup of $\mathbb{Z}_\ell^\times$, hence of its torsion subgroup $\mu_{\ell-1}$ (ℓ odd). Let $e = [K : F]$; it divides $\ell - 1 = [F(\mu_\ell) : F]$, and $\mu_{\ell-1}$, being cyclic, has exactly one subgroup Δ' of order $(\ell-1)/e$. By (Rr7) for Δ', Δ' is the torsion subgroup of $\chi_{\mathrm{cyc}}(G_K) = \Gamma_K$, i.e. $\Delta' = \Delta$; so $(\ell-1)/|\Delta| = e$.

The operators on R. The γ_u ($u \in \Gamma_K$) fix $\mathcal{O}_F \otimes \mathcal{O}_L$, hence e_a, so they preserve $\mathbf{N}_a$ and act on $R \cong \mathcal{O}_L[[X]]$ as the $\mathcal{O}_L$-algebra automorphisms with $X \mapsto (1+X)^u - 1$; this is the action of (Dr4) of Definition 23.23, so R^Δ is the ring of Lemma 23.24, and by (Rr2) $R^\Delta = \mathcal{O}_L[[\pi_\Delta]]$ (unique expansion) and $R^\Delta \cap XR = \pi_\Delta R^\Delta$.

(Dm1). By Lemma 24.15, $\mathbf{N}_a$ has an R-basis (n_k) with $\gamma_\delta(n_k) = n_k$ for all $\delta \in \Delta$. Let (n_k) be any such basis and $x = \sum_k f_k n_k \in \mathbf{N}_a$, $f_k \in R$. Since γ_δ is γ_δ-semilinear, $\gamma_\delta(x) = \sum_k \gamma_\delta(f_k) n_k$, and by uniqueness of coordinates $\gamma_\delta(x) = x$ if and only if $\gamma_\delta(f_k) = f_k$ for all k. So $x \in \mathbf{N}_a^\Delta$ if and only if every $f_k \in R^\Delta$, i.e. $\mathbf{N}_a^\Delta = \sum_k R^\Delta n_k$, and the sum is direct because the n_k are R-linearly independent. So $\mathbf{N}_a^\Delta$ is free over R^Δ on (n_k), of rank r.

(Dm2). By (Rr1), $\pi_\Delta \in XR$, and π_Δ is Δ-fixed, so $\pi_\Delta \mathbf{N}_a^\Delta \subseteq X\mathbf{N}_a \cap \mathbf{N}_a^\Delta$. Conversely let $x = \sum_k f_k n_k \in X\mathbf{N}_a \cap \mathbf{N}_a^\Delta$. Writing $x = X\sum_k g_k n_k$ with $g_k \in R$ and comparing coordinates, $f_k = Xg_k \in XR$; by (Dm1), $f_k \in R^\Delta$. Hence $f_k \in R^\Delta \cap XR = \pi_\Delta R^\Delta$, say $f_k = \pi_\Delta f_k'$ with $f_k' \in R^\Delta$, and $x = \pi_\Delta \sum_k f_k' n_k \in \pi_\Delta \mathbf{N}_a^\Delta$ by (Dm1).

(Dm3). Let $u \in \Gamma_K$, $\delta \in \Delta \subseteq \Gamma_K$ and $y \in \mathbf{N}_a^\Delta$. As $\Gamma_K \subseteq \mathbb{Z}_\ell^\times$ is commutative, (Wm3) gives $\gamma_\delta\gamma_u = \gamma_{\delta u} = \gamma_{u\delta} = \gamma_u\gamma_\delta$, so $\gamma_\delta(\gamma_u(y)) = \gamma_u(y)$: $\gamma_u(y) \in \mathbf{N}_a^\Delta$, and $(\gamma_u - 1)(y) \in \mathbf{N}_a^\Delta$. By (Wm3), $(\gamma_u - 1)(y) \in X\mathbf{N}$, and as it lies in $\mathbf{N}_a$, $(\gamma_u - 1)(y) = e_a(\gamma_u - 1)(y) \in e_a X\mathbf{N} = X\mathbf{N}_a$. By (Dm2), $(\gamma_u - 1)(y) = \pi_\Delta y'$ with $y' \in \mathbf{N}_a^\Delta$; y' is unique because $\pi_\Delta \neq 0$ and $\mathbf{N}_a$ is free over the domain R. □

Lemma 24.15. *Let ℓ be an odd prime, F, L as in Definition 23.2, K a base field as there, $\mathbf{N}$ a Wach module over K with coefficients L (any window) and $a \in \mathbb{Z}/n$. Then $\mathbf{N}_a$ has an $e_a\mathbf{A}_{F,L}$-basis $(n_k)_{k\le r}$ with $\gamma_u(n_k) = n_k$ for every $u \in \Delta_K$ and every k. For $K = F$, $\Delta_F = \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$.*

Proof. Write $R_0 = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ and $\Delta = \Delta_K$, a finite subgroup of $\mathbb{Z}_\ell^\times$, hence of $\mu_{\ell-1}$, so $|\Delta|$ divides $\ell - 1$ and is a unit of $\mathbb{Z}_\ell$ ($\Delta = \mu_{\ell-1}$ for $K = F$). The ring R_0 is local with maximal ideal $\mathfrak{m} = (\pi_L, X)$ (π_L a uniformiser of $\mathcal{O}_L$), and $\mathbf{N}_a$ is free of rank r over it by (Wm1). The operators γ_u ($u \in \Gamma_K \supseteq \Delta$) preserve $\mathbf{N}_a$ ($\gamma_u(e_a) = e_a$), act as the identity on $\mathcal{O}_F \otimes \mathcal{O}_L$, and satisfy $(\gamma_u - 1)\mathbf{N} \subseteq X\mathbf{N}$ and $\gamma_{uv} = \gamma_u\gamma_v$ by (Wm3). As $|\Delta| \in \mathbb{Z}_\ell^\times$, the map $\pi(x) = |\Delta|^{-1}\sum_{\delta\in\Delta}\gamma_\delta(x)$ sends $\mathbf{N}_a$ into its Δ-invariants ($\gamma_u\pi = \pi$ for $u \in \Delta$, since Δ is a group), and $\pi(x) - x = |\Delta|^{-1}\sum_\delta(\gamma_\delta - 1)(x) \in X\mathbf{N}_a \subseteq \mathfrak{m}\mathbf{N}_a$. Lift a basis of $\mathbf{N}_a/\mathfrak{m}\mathbf{N}_a$ to $x_1, \dots, x_r \in \mathbf{N}_a$ and put $n_k = \pi(x_k)$. The n_k reduce to the same basis, so they generate $\mathbf{N}_a$ by Nakayama's lemma; r generators of a free module of rank r over a commutative ring form a basis. So (n_k) is a Δ-invariant basis. □

Lemma 24.16. *Let ℓ be an odd prime, F, L, K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Lemma 24.14, $\Delta = \Delta_K$, $\mathbf{N}$ a Wach module over K with coefficients L (any window), $a \in \mathbb{Z}/n$, $u \in \Gamma_K$ with $v_\ell(u-1) = 1$, and $M \ge 1$ an integer. Put*

$$\sigma_M = \sum_{i=1}^{M-1}(1 + v_\ell(i)) = M - 1 + v_\ell((M-1)!).$$

Then for every $z \in \pi_\Delta\mathbf{N}_a^\Delta$ there is $k \in \pi_\Delta\mathbf{N}_a^\Delta$ with

$$\ell^{\sigma_M} z - (\gamma_u - 1)(k) \in \pi_\Delta^M \mathbf{N}_a^\Delta.$$

Proof. By (Dm1), $\mathbf{N}_a^\Delta$ has an R^Δ-basis $(n_k)_{k\le r}$, so Lemma 24.17 applies to $\mathbf{N}$, a, u, M and this basis, with the same σ_M. Its item (Gf0) for $\mathbf{N}^\natural = \mathbf{N}_a^\Delta$ is the assertion. □

Lemma 24.17. *Let ℓ be an odd prime, F, L, K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Lemma 24.14, $\Delta = \Delta_K$, $\mathbf{N}$ a Wach module over K with coefficients L (any window), $a \in \mathbb{Z}/n$, $R = e_a\mathbf{A}_{F,L}$, $u \in \Gamma_K$ with $v_\ell(u-1) = 1$, and $M \ge 1$ an integer. Put*

$$\sigma_M = \sum_{i=1}^{M-1} \big(1 + v_\ell(i)\big) = M - 1 + v_\ell\big((M-1)!\big).$$

Let $\mathbf{N}_a^{\Delta\vee} = \mathrm{Hom}_{R^\Delta}(\mathbf{N}_a^\Delta, R^\Delta)$, on which γ_u acts by $\gamma_u(\lambda) = \gamma_u \circ \lambda \circ \gamma_u^{-1}$. Let $(n_k)_{k\le r}$ be an R^Δ-basis of $\mathbf{N}_a^\Delta$ and $(n_k^\vee)_{k\le r}$ the dual basis of $\mathbf{N}_a^{\Delta\vee}$. Then:

(Gf0) Approximate solutions *for $\mathbf{N}^\natural$ either of $\mathbf{N}_a^\Delta$, $\mathbf{N}_a^{\Delta\vee}$ and every $z \in \pi_\Delta\mathbf{N}^\natural$ there is $k \in \pi_\Delta\mathbf{N}^\natural$ with $\ell^{\sigma_M} z - (\gamma_u - 1)(k) \in \pi_\Delta^M\mathbf{N}^\natural$;*

(Gf1) Frames *there are $h_1, \dots, h_r \in \mathbf{N}_a^\Delta$ with $h_k - \ell^{\sigma_M} n_k \in \pi_\Delta\mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(h_k) \in \pi_\Delta^M\mathbf{N}_a^\Delta$ for every k;*

(Gf2) Dual frames *there are $\lambda_1, \dots, \lambda_r \in \mathbf{N}_a^{\Delta\vee}$ with $\lambda_k - \ell^{\sigma_M} n_k^\vee \in \pi_\Delta\mathbf{N}_a^{\Delta\vee}$ and $(\gamma_u - 1)(\lambda_k) \in \pi_\Delta^M\mathbf{N}_a^{\Delta\vee}$ for every k; equivalently, $\lambda_k(\gamma_u x) - \gamma_u(\lambda_k(x)) \in \pi_\Delta^M R^\Delta$ for every $x \in \mathbf{N}_a^\Delta$;*

(Gf3) Rigidity *if $g \in R^\Delta$ satisfies $\gamma_u(g) - g \in \pi_\Delta^M R^\Delta$ and $g = \sum_{i\ge 0} g_i \pi_\Delta^i$ with $g_i \in \mathcal{O}_L$, then $g - g_0 \in \pi_\Delta^M R^\Delta$;*

(Gf4) Products *for any h_k as in (Gf1) and λ_j as in (Gf2), $\lambda_j(h_k) - \ell^{2\sigma_M}\delta_{jk} \in \pi_\Delta^M R^\Delta$ for all j, k (δ_{jk} the Kronecker symbol);*

(Gf5) Reconstruction *for such h_k, λ_k and every $x \in \mathbf{N}_a^\Delta$: $\sum_k \lambda_k(x)\, h_k - \ell^{2\sigma_M} x \in \pi_\Delta^M\mathbf{N}_a^\Delta$;*

(Gf6) Uniqueness *if $d \in \pi_\Delta\mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(d) \in \pi_\Delta^M\mathbf{N}_a^\Delta$, then $d \in \pi_\Delta^M\mathbf{N}_a^\Delta$. In particular the class modulo $\pi_\Delta^M\mathbf{N}_a^\Delta$ of a vector $h \in \mathbf{N}_a^\Delta$ with $h - \ell^{\sigma_M} x \in \pi_\Delta\mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(h) \in \pi_\Delta^M\mathbf{N}_a^\Delta$ depends only on x modulo $\pi_\Delta\mathbf{N}_a^\Delta$, and such an h exists for every $x \in \mathbf{N}_a^\Delta$ ($h = \sum_k o_k h_k$ for $x \equiv \sum_k o_k n_k$, $o_k \in \mathcal{O}_L$).*

Proof. **Step 0: the two modules.** By (Dm1), $\mathbf{N}_a^\Delta$ is free over R^Δ with basis (n_k); hence $\mathbf{N}_a^{\Delta\vee}$ is free with the dual basis $(n_k^\vee)$, and since π_Δ is a non-zero-divisor of the domain R^Δ, a form with values in $\pi_\Delta^j R^\Delta$ lies in $\pi_\Delta^j\mathbf{N}_a^{\Delta\vee}$ (divide its values on the basis). By (Dm3), γ_u and $\gamma_{u^{-1}} = \gamma_u^{-1}$ map $\mathbf{N}_a^\Delta$ into itself, so γ_u is a bijection of $\mathbf{N}_a^\Delta$; it is semilinear, $\gamma_u(fx) = \gamma_u(f)\gamma_u(x)$ for $f \in R^\Delta$, and γ_u is a continuous ring automorphism of R^Δ (it fixes $\mathcal{O}_L$, and $\gamma_u(\pi_\Delta) \in R^\Delta$ by (Rr6)). On $\mathbf{N}_a^{\Delta\vee}$: $\gamma_u(\lambda)(fx) = \gamma_u(\lambda(\gamma_u^{-1}(f)\gamma_u^{-1}(x))) = f\,\gamma_u(\lambda)(x)$, so $\gamma_u(\lambda)$ is R^Δ-linear, and $\gamma_u(g\lambda) = \gamma_u(g)\gamma_u(\lambda)$; so γ_u is a semilinear bijection of $\mathbf{N}_a^{\Delta\vee}$ with inverse $\lambda \mapsto \gamma_u^{-1} \circ \lambda \circ \gamma_u$. The equivalence in (Gf2): for $x \in \mathbf{N}_a^\Delta$ and $y = \gamma_u x$, $(\gamma_u(\lambda) - \lambda)(y) = \gamma_u(\lambda(x)) - \lambda(\gamma_u x)$, and y runs over $\mathbf{N}_a^\Delta$ when x does.

Let $\mathbf{N}^\natural$ denote either of the two modules $\mathbf{N}_a^\Delta$, $\mathbf{N}_a^{\Delta\vee}$. We show

$$(\gamma_u - 1)(\mathbf{N}^\natural) \subseteq \pi_\Delta\mathbf{N}^\natural. \tag{H}$$

For $\mathbf{N}_a^\Delta$ this is (Dm3). For $g \in R^\Delta$, $\gamma_u(g) - g \in \pi_\Delta R^\Delta$: by (Rr2) g is a convergent series $\sum_i g_i\pi_\Delta^i$, $g_i \in \mathcal{O}_L$, and $\gamma_u(\pi_\Delta)^i - \pi_\Delta^i \in \pi_\Delta R^\Delta$ by (Rr6). For $\lambda \in \mathbf{N}_a^{\Delta\vee}$ and $x \in \mathbf{N}_a^\Delta$, (Dm3) for $u^{-1} \in \Gamma_K$ gives $\gamma_u^{-1}(x) = x + \pi_\Delta x'$ with $x' \in \mathbf{N}_a^\Delta$, so

$$(\gamma_u(\lambda) - \lambda)(x) = \big(\gamma_u(\lambda(x)) - \lambda(x)\big) + \gamma_u(\pi_\Delta)\,\gamma_u(\lambda(x')) \in \pi_\Delta R^\Delta,$$

and $\gamma_u(\lambda)-\lambda\in\pi_\Delta\mathbf{N}_a^{\Delta\vee}$ by Step 0.

Step 1: γ_u on π_Δ. By (Rr6), $\gamma_u(\pi_\Delta)=\pi_\Delta m_u$ with $m_u=1+t_uq_\Delta\in R^\Delta$. Write $\gamma_u(X)=(1+X)^u-1=X(u+Xb)$ with $b\in\mathbb{Z}_\ell[[X]]$ and $\pi_\Delta=X^{s'}v_\Delta$ with v_Δ a unit (Rr1). Then $\gamma_u(\pi_\Delta)=X^{s'}(u+Xb)^{s'}\gamma_u(v_\Delta)$ and $\gamma_u(v_\Delta)\equiv v_\Delta(0)\equiv v_\Delta \pmod X$; cancelling $X^{s'}$ in the domain $\mathbb{Z}_\ell[[X]]$ gives $m_uv_\Delta=(u+Xb)^{s'}\gamma_u(v_\Delta)$, so $m_u\equiv u^{s'}\pmod X$, hence $m_u-u^{s'}\in R^\Delta\cap XR=\pi_\Delta R^\Delta$ (Rr2). For $i\ge1$, $m_u^i-u^{is'}=(m_u-u^{s'})\sum_{j<i}m_u^ju^{(i-1-j)s'}\in\pi_\Delta R^\Delta$. Since ℓ is odd and $v_\ell(u-1)=1$, $v_\ell(u^k-1)=1+v_\ell(k)$ for every integer $k\ge1$ (classical), and $v_\ell(is')=v_\ell(i)$; so $u^{is'}-1=\ell^{1+v_\ell(i)}\varepsilon_i$ with $\varepsilon_i\in\mathbb{Z}_\ell^\times$.

Step 2: graded pieces. Let $i\ge1$ and $y\in\mathbf{N}^\natural$. By (H), $\gamma_u(y)=y+\pi_\Delta y'$ with $y'\in\mathbf{N}^\natural$, so

$$(\gamma_u-1)(\pi_\Delta^iy)=(u^{is'}-1)\pi_\Delta^iy+\pi_\Delta^i(m_u^i-u^{is'})y+\pi_\Delta^{i+1}m_u^iy',$$

and the last two terms lie in $\pi_\Delta^{i+1}\mathbf{N}^\natural$ by Step 1. Hence

$$(\gamma_u-1)(\varepsilon_i^{-1}\pi_\Delta^iy)\equiv\ell^{1+v_\ell(i)}\pi_\Delta^iy\pmod{\pi_\Delta^{i+1}\mathbf{N}^\natural}.\tag{1}$$

Step 3: approximate solutions. For $1\le j\le M$ put $\sigma_j=\sum_{i=1}^{j-1}(1+v_\ell(i))$. We show: for every $z\in\pi_\Delta\mathbf{N}^\natural$ there is $k_j\in\pi_\Delta\mathbf{N}^\natural$ with $r_j:=\ell^{\sigma_j}z-(\gamma_u-1)(k_j)\in\pi_\Delta^j\mathbf{N}^\natural$. For $j=1$ take $k_1=0$. Let $1\le j<M$ and k_j be given; $r_j\in\mathbf{N}^\natural$ by (H) and $r_j=\pi_\Delta^jy_j$ with $y_j\in\mathbf{N}^\natural$ (Step 0: π_Δ is a non-zero-divisor on the free module). Put $k'=\varepsilon_j^{-1}\pi_\Delta^jy_j\in\pi_\Delta\mathbf{N}^\natural$ and $k_{j+1}=\ell^{1+v_\ell(j)}k_j+k'$. Then $\sigma_{j+1}=\sigma_j+1+v_\ell(j)$ and, by (1),

$$\ell^{\sigma_{j+1}}z-(\gamma_u-1)(k_{j+1})=\ell^{1+v_\ell(j)}\pi_\Delta^jy_j-(\gamma_u-1)(\varepsilon_j^{-1}\pi_\Delta^jy_j)\in\pi_\Delta^{j+1}\mathbf{N}^\natural.$$

At $j=M$: σ_M is as in the statement, and $k=k_M$ proves (Gf0).

Step 4: (Gf1) and (Gf2). Let y be n_k (in $\mathbf{N}_a^\Delta$) or $n_k^\vee$ (in $\mathbf{N}_a^{\Delta\vee}$). By (H), $z=(\gamma_u-1)(y)\in\pi_\Delta\mathbf{N}^\natural$; let k_M be as in Step 3 and put $h=\ell^{\sigma_M}y-k_M$. Then $h-\ell^{\sigma_M}y=-k_M\in\pi_\Delta\mathbf{N}^\natural$ and $(\gamma_u-1)(h)=\ell^{\sigma_M}z-(\gamma_u-1)(k_M)\in\pi_\Delta^M\mathbf{N}^\natural$. This gives h_k, respectively λ_k.

Step 5: (Gf3). Suppose $g-g_0\notin\pi_\Delta^MR^\Delta$; then there is a least j with $1\le j<M$ and $g_j\ne0$, and $g-g_0=\pi_\Delta^j(g_j+\pi_\Delta w)$ with $w\in R^\Delta$. As $\gamma_u(g_0)=g_0$,

$$\gamma_u(g)-g=\pi_\Delta^jm_u^j\gamma_u(g_j+\pi_\Delta w)-\pi_\Delta^j(g_j+\pi_\Delta w)\equiv(u^{js'}-1)\,g_j\,\pi_\Delta^j\pmod{\pi_\Delta^{j+1}R^\Delta}$$

by Step 1 ($\gamma_u(g_j)=g_j$, $\gamma_u(\pi_\Delta w)\in\pi_\Delta R^\Delta$). Here $(u^{js'}-1)g_j\ne0$ in the domain $\mathcal{O}_L$, so by the uniqueness of the expansion in (Rr2) $\gamma_u(g)-g\notin\pi_\Delta^{j+1}R^\Delta\supseteq\pi_\Delta^MR^\Delta$, a contradiction.

Step 6: (Gf4). Put $g=\lambda_j(h_k)\in R^\Delta$ and write $\gamma_u(\lambda_j)=\lambda_j+\pi_\Delta^M\mu$, $\gamma_u(h_k)=h_k+\pi_\Delta^My$ with $\mu\in\mathbf{N}_a^{\Delta\vee}$, $y\in\mathbf{N}_a^\Delta$. By the definition of the action on forms, $\gamma_u(g)=\gamma_u(\lambda_j)(\gamma_u(h_k))=g+\pi_\Delta^M(\lambda_j(y)+\mu(h_k)+\pi_\Delta^M\mu(y))$, so $\gamma_u(g)-g\in\pi_\Delta^MR^\Delta$. Writing $\lambda_j=\ell^{\sigma_M}n_j^\vee+\pi_\Delta\mu'$ and $h_k=\ell^{\sigma_M}n_k+\pi_\Delta y''$ gives $g\equiv\ell^{2\sigma_M}n_j^\vee(n_k)=\ell^{2\sigma_M}\delta_{jk}\pmod{\pi_\Delta R^\Delta}$, so $g_0=\ell^{2\sigma_M}\delta_{jk}$, and (Gf3) gives $g-\ell^{2\sigma_M}\delta_{jk}\in\pi_\Delta^MR^\Delta$.

Step 7: (Gf5). Write $h_k=\sum_iH_{ki}n_i$ and $\lambda_j=\sum_i\Lambda_{ji}n_i^\vee$ with matrices H,Λ over R^Δ, and put $c=\ell^{2\sigma_M}$. Then $\lambda_j(h_k)=(\Lambda H^{\mathsf T})_{jk}$, so by (Gf4) $\Lambda H^{\mathsf T}\equiv c\,I$ modulo π_Δ^M. Let $\bar A=R^\Delta/\pi_\Delta^MR^\Delta$; by (Rr2) it is isomorphic to $\mathcal{O}_L[[T]]/(T^M)$, a free $\mathcal{O}_L$-module, so ℓ is a non-zero-divisor on $\bar A$ and $\bar A\to\bar A[1/\ell]$ is injective. In the commutative ring $\bar A[1/\ell]$, c is a unit and $\bar\Lambda\,(c^{-1}\bar H^{\mathsf T})=I$, so $c^{-1}\bar H^{\mathsf T}$ is a two-sided inverse of $\bar\Lambda$ (square matrices over a commutative ring) and $\bar H^{\mathsf T}\bar\Lambda=c\,I$ in $\bar A[1/\ell]$, hence in $\bar A$. For $x=n_j$: $\sum_k\lambda_k(n_j)h_k=\sum_i(\sum_k\Lambda_{kj}H_{ki})n_i=\sum_i(H^{\mathsf T}\Lambda)_{ij}\,n_i\equiv c\,n_j$ modulo $\pi_\Delta^M\mathbf{N}_a^\Delta$. Both sides of (Gf5) are R^Δ-linear in x and (n_j) is a basis, so (Gf5) holds for every x.

Step 8: (Gf6). Suppose $d \notin \pi_\Delta^M \mathbf{N}_a^\Delta$. Since $\mathbf{N}_a^\Delta \cong (R^\Delta)^r$ and $\bigcap_j \pi_\Delta^j R^\Delta = 0$ (Rr2), there is a largest j with $d \in \pi_\Delta^j \mathbf{N}_a^\Delta$, and $1 \le j < M$; write $d = \pi_\Delta^j y$ with $y \notin \pi_\Delta \mathbf{N}_a^\Delta$. By Step 2 (for $\mathbf{N}^\natural = \mathbf{N}_a^\Delta$), $(\gamma_u - 1)(d) \equiv (u^{js'} - 1)\pi_\Delta^j y$ modulo $\pi_\Delta^{j+1}\mathbf{N}_a^\Delta$, and $(\gamma_u - 1)(d) \in \pi_\Delta^M \mathbf{N}_a^\Delta \subseteq \pi_\Delta^{j+1}\mathbf{N}_a^\Delta$; cancelling π_Δ^j (a non-zero-divisor on the free module), $(u^{js'}-1)y \in \pi_\Delta \mathbf{N}_a^\Delta$. But $\mathbf{N}_a^\Delta/\pi_\Delta \mathbf{N}_a^\Delta \cong \mathcal{O}_L^r$ (as $R^\Delta/\pi_\Delta R^\Delta = \mathcal{O}_L$ by (Rr2)) is torsion-free and $u^{js'} - 1 \neq 0$ in $\mathcal{O}_L$ (Step 1), so $y \in \pi_\Delta \mathbf{N}_a^\Delta$, a contradiction. For the second sentence: if h, h' are two such vectors for $x \equiv x'$ modulo $\pi_\Delta \mathbf{N}_a^\Delta$, then $d = h - h' \in \pi_\Delta \mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(d) \in \pi_\Delta^M \mathbf{N}_a^\Delta$, so $d \in \pi_\Delta^M \mathbf{N}_a^\Delta$; and $\sum_k o_k h_k$ has both properties by (Gf1), since γ_u fixes $o_k \in \mathcal{O}_L$. □

Lemma 24.18. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ be as in Proposition 23.7, $\Delta = \Delta_K$, and $\Phi\colon T_1 \to T_2$ a G_K-equivariant $\mathcal{O}_L$-linear map of the lattices of pairs (V_1, T_1), (V_2, T_2) over K. Let $c \in \mathbb{Z}/n$, let $J \subset \mathbb{Z}$ be a finite set containing every Hodge jump of V_1 at every embedding of K over τ_c, $G \ge 0$ an integer, and*

$$J' = \{j + k :\ j \in J,\ 1 \le k \le G,\ j + k \neq 0\}, \qquad \kappa = \sum_{x \in J'} \big(1 + v_\ell(x)\big).$$

For $\nu = 1, 2$ let I_c^ν be the set of $w \in e_c \mathbf{N}(T_\nu)[1/\lambda_\infty]$ with $\gamma_\delta(w) = w$ for every $\delta \in \Delta$ and $(\gamma_s - 1)(w) \in X\mathbf{N}(T_\nu)$ for every $s \in \Gamma_K$. Let $r \ge 0$ be such that for every $y \in \mathbf{N}(T_2)_c$ there is $x \in \mathbf{N}(T_1)_c$ with $\mathbf{N}(\Phi)(x) = \ell^r y$. Then for every $w \in I_c^2$ with $Q^G w \in \mathbf{N}(T_2)$ there is $u \in I_c^1$ with $Q^G u \in \mathbf{N}(T_1)$ and

$$\mathbf{N}(\Phi)(u) = \ell^{\,r+\kappa}\, w.$$

Level s. *Let ℓ be any prime, $s \ge 1$ an integer with $s \ge 2$ if $\ell = 2$, L as in (Ex4) of Proposition 23.7, $K = F(\mu_{\ell^s})$, X_{s-1} the level variable of Definition 23.2, $\Phi\colon T_1 \to T_2$ a G_K-equivariant $\mathcal{O}_L$-linear map of the lattices of pairs (V_1, T_1), (V_2, T_2) over K, and c, J, G, J' as above, with*

$$\kappa^{(s)} = \sum_{x \in J'} \big(s + v_\ell(x)\big).$$

For $\nu = 1, 2$ let $I_c^{\nu,s}$ be the set of $w \in e_c \mathbf{N}_s(T_\nu)[1/\lambda_\infty]$ with $(\gamma_v - 1)(w) \in X_{s-1}\mathbf{N}_s(T_\nu)$ for every $v \in \Gamma_K$. Let $r \ge 0$ be such that every $y \in \mathbf{N}_s(T_2)_c$ has $x \in \mathbf{N}_s(T_1)_c$ with $\mathbf{N}_s(\Phi)(x) = \ell^r y$. Then for every $w \in I_c^{2,s}$ with $Q_{s-1}^G w \in \mathbf{N}_s(T_2)$ there is $u \in I_c^{1,s}$ with $Q_{s-1}^G u \in \mathbf{N}_s(T_1)$ and $\mathbf{N}_s(\Phi)(u) = \ell^{\,r+\kappa^{(s)}} w$.

Proof. By (Ex1) (for any window of V_ν) each $\mathbf{N}_{\nu,c}$ is free of finite rank over the domain A_c (Wm1), and $(\gamma_s - 1)(\mathbf{N}_\nu) \subseteq X\mathbf{N}_\nu$, $\gamma_s(e_c) = e_c$ (Wm3), so γ_s preserves $\mathbf{N}_{\nu,c}$ for $s \in \Gamma_K$.

Step 0: the element q. By (Rr7), $\Gamma_K = \Gamma_\Delta = \Delta \cdot (1 + \ell\mathbb{Z}_\ell)$. By (Rr4), $q = Q\, w_\Delta$ with $w_\Delta \in \mathbb{Z}_\ell[[X]]^\times$, so $Q^G z \in \mathbf{N}_\nu$ if and only if $q^G z \in \mathbf{N}_\nu$. By (Rr2), (Rr3), $q = E_\Delta(\pi_\Delta)$ is Δ-fixed and $q(0) = E_\Delta(0) \neq 0$, so the prime X of A_c does not divide q. By (Rr6), $\gamma_s(q) = h_s q$ with $h_s \in 1 + X\mathbb{Z}_\ell[[X]]$, a unit, for $s \in \Gamma_K$.

Step 1: vectors with poles along q. For $H \ge 0$ let $D_\nu(H) = \{z \in (e_c \mathbf{N}_\nu[1/\lambda_\infty])^\Delta : q^H z \in \mathbf{N}_\nu\}$; so $D_\nu(0) = \mathbf{N}_{\nu,c}^\Delta$. For $z \in D_\nu(H)$, $n = q^H z \in \mathbf{N}_{\nu,c}$ and $s \in \Gamma_K$,

$$q^H(\gamma_s - 1)(z) = h_s^{-H}\gamma_s(n) - n = (h_s^{-H} - 1)\gamma_s(n) + (\gamma_s - 1)(n) \in X\mathbf{N}_{\nu,c},$$

so $(\gamma_s - 1)(z) = Xz'$ with $q^H z' \in \mathbf{N}_{\nu,c}$; and $\gamma_s(z) \in D_\nu(H)$ (the γ's commute, $q^H\gamma_s(z) = h_s^{-H}\gamma_s(n)$). So every polynomial in γ_s with coefficients in $\mathbb{Z}_\ell$ preserves $D_\nu(H)$ and $\mathbf{N}_{\nu,c}^\Delta$. $\mathbf{N}(\Phi)$ commutes with every γ_s (Ex3) and maps $D_1(H)$ into $D_2(H)$.

Step 2: invariant lifts. $|\Delta|$ divides $\ell - 1$, so it is a unit of $\mathbb{Z}_\ell$. If $y \in \mathbf{N}_{2,c}^\Delta$ and $x \in \mathbf{N}_{1,c}$ has $\mathbf{N}(\Phi)(x) = \ell^r y$, then $\bar{x} = |\Delta|^{-1} \sum_{\delta\in\Delta} \gamma_\delta(x) \in \mathbf{N}_{1,c}^\Delta$ and $\mathbf{N}(\Phi)(\bar{x}) = \ell^r y$ (Ex3). $(*)$

Step 3: the construction. Let $g = 1+\ell \in \Gamma_K$, $Z = \{j+k:\ j\in J,\ 1\le k\le G\}$, $\epsilon = 1$ if $0\in Z$ and $\epsilon = 0$ otherwise, and

$$P(Y) = \prod_{x\in Z}(Y - g^{-x}), \qquad R(Y) = \prod_{x\in J'}(Y-g^{-x}) \in \mathbb{Z}_\ell[Y].$$

As $J' = Z\setminus\{0\}$ and $g^0 = 1$, $(Y-1)R(Y) = (Y-1)^{1-\epsilon}P(Y)$. Write $R(Y) = R(1)+(Y-1)S(Y)$ with $S\in\mathbb{Z}_\ell[Y]$. Let $w\in I_c^2$ with $Q^Gw\in\mathbf{N}_2$; then $w\in D_2(G)$ by Step 0. (a) $q^Gw\in\mathbf{N}_{2,c}^\Delta$; by $(*)$ there is $x\in\mathbf{N}_{1,c}^\Delta$ with $\mathbf{N}(\Phi)(x) = \ell^r q^G w$. Put $u_0 = q^{-G}x\in D_1(G)$; then $\mathbf{N}(\Phi)(u_0) = \ell^r w$ and $Q^Gu_0\in\mathbf{N}_1$. (b) By Lemma 24.19 for the pair (V_1,T_1), c, J, $u = g\in 1+\ell\mathbb{Z}_\ell$, $Y = G$, an enumeration $x_1,\dots,x_m$ of Z and $y_0 = u_0$, the vector $y_m = P(\gamma_g)(u_0)$ lies in $\mathbf{N}_{1,c}$ (the factors $\gamma_g - g^{-x_i}$ commute). Hence

$$(\gamma_g-1)R(\gamma_g)(u_0) = (\gamma_g-1)^{1-\epsilon}P(\gamma_g)(u_0)\in\mathbf{N}_{1,c}.$$

(c) $(\gamma_g-1)(w)\in X\mathbf{N}_2\cap e_c\mathbf{N}_2[1/\lambda_\infty] = X\mathbf{N}_{2,c}$ is Δ-fixed, so $n := R(\gamma_g)(w) - R(1)w = S(\gamma_g)((\gamma_g-1)(w))\in\mathbf{N}_{2,c}^\Delta$ (Step 1). By $(*)$ there is $x'\in\mathbf{N}_{1,c}^\Delta$ with $\mathbf{N}(\Phi)(x') = \ell^r n$. (d) Put $u_2 = R(\gamma_g)(u_0) - x'\in D_1(G)$ (Step 1). Then $\mathbf{N}(\Phi)(u_2) = R(\gamma_g)(\ell^r w) - \ell^r n = \ell^r R(1)\,w$, and $(\gamma_g-1)(u_2)\in\mathbf{N}_{1,c}$ by (b) and since γ_g preserves $\mathbf{N}_{1,c}$.

Step 4: the exponent. Let $x\in J'$. Then $x\neq 0$, and by item 1 of Lemma 23.22 ($p=\ell$ odd, $m=1$, $u=g$), $v_\ell(1-g^{-x}) = 1+v_\ell(x)$. So $v_\ell(R(1)) = \kappa$ and $t = \ell^\kappa/R(1)\in\mathbb{Z}_\ell^\times$. Put $u = t\,u_2\in D_1(G)$: u is Δ-fixed, $Q^Gu\in\mathbf{N}_1$ (Step 0), $\mathbf{N}(\Phi)(u) = \ell^{r+\kappa}w$, and $(\gamma_g-1)(u)\in\mathbf{N}_{1,c}$.

Step 5: $u\in I_c^1$. Let $\bar M = D_1(G)/\mathbf{N}_{1,c}^\Delta$. Multiplication by q^G identifies $q^{-G}\mathbf{N}_{1,c}/\mathbf{N}_{1,c}$ with $\mathbf{N}_{1,c}/q^G\mathbf{N}_{1,c}\cong (A_c/Q^GA_c)^d$ (d the rank; $q^G = Q^Gw_\Delta^G$), a free $\mathcal{O}_L$-module of finite rank by Weierstrass division by the distinguished polynomial Q^G; the γ_δ act on it, taking Δ-invariants is exact (averaging by $|\Delta|^{-1}\sum_\delta\gamma_\delta$), and $\bar M = (q^{-G}\mathbf{N}_{1,c}/\mathbf{N}_{1,c})^\Delta$ is the image of this projector, a direct summand, hence free of finite rank N over $\mathcal{O}_L$. Each γ_s ($s\in\Gamma_K$) preserves $D_1(G)$ and $\mathbf{N}_{1,c}^\Delta$ (Step 1) and acts $\mathcal{O}_L$-linearly on $\bar M$; $\rho(a) = \gamma_{g^a}$ defines a homomorphism $\rho\colon\mathbb{Z}_\ell\to\mathrm{GL}(\bar M)\cong\mathrm{GL}_N(\mathcal{O}_L)$ (Wm3). It is continuous: let ℓ^e be the exact power of ℓ dividing $g_0 = |\mathrm{GL}_N(\mathcal{O}_L/\ell\mathcal{O}_L)|$ and $K_i = 1+\ell^iM_N(\mathcal{O}_L)$; for $a\in\ell^{i+e}\mathbb{Z}_\ell$ write $a = g_0\ell^ib$ with $b\in\mathbb{Z}_\ell$; then $\rho(b)^{g_0}\in K_1$ and $\rho(a) = (\rho(b)^{g_0})^{\ell^i}\in K_{1+i}$, since $(1+\ell^kA)^\ell\in K_{k+1}$ for $k\ge 1$. The class $[u]\in\bar M$ is fixed by $\rho(1)$ (Step 4), so its stabiliser, a closed subgroup of $\mathbb{Z}_\ell$ containing $\mathbb{Z}$, is $\mathbb{Z}_\ell$. As $1+\ell\mathbb{Z}_\ell = g^{\mathbb{Z}_\ell}$ (ℓ odd) and $\Gamma_K = \Delta\cdot g^{\mathbb{Z}_\ell}$ (Step 0), every $s\in\Gamma_K$ is δg^a, and $(\gamma_s-1)(u) = \gamma_\delta((\gamma_{g^a}-1)(u)) + (\gamma_\delta-1)(u) = \gamma_\delta((\gamma_{g^a}-1)(u))\in\mathbf{N}_{1,c}$. By Step 1, also $(\gamma_s-1)(u) = Xz'$ with $q^Gz'\in\mathbf{N}_{1,c}$. In coordinates for an A_c-basis of $\mathbf{N}_{1,c}$, each coordinate f of z' has $Xf\in A_c$ and $q^Gf\in A_c$; writing $f = a/X$ with $a\in A_c$, X divides q^Ga in the unique factorisation domain $A_c\cong\mathcal{O}_L[[X]]$ and not q (Step 0), so X divides a and $f\in A_c$. Hence $(\gamma_s-1)(u)\in X\mathbf{N}_1$ for every $s\in\Gamma_K$, and $u\in I_c^1$.

Remark. Compared with Lemma 24.7 (the case $K=F$), the operator $\pi_0^{-1}(\gamma_g-1)$ is replaced by γ_g and the pole killer by Lemma 24.19; the price is 1 per index of J' on top of $v_\ell(x)$. With $J\subseteq[-A,B]$ and $G=A$, $J'\subseteq[-(A-1),A+B]\setminus\{0\}$, so $|J'|\le 2A+B$ and $\kappa\le(2A+B)+v_\ell((A-1)!)+v_\ell((A+B)!)$.

Level s. Let the data be as in the paragraph Level s of the statement; $\mathbf{N}_\nu = \mathbf{N}_s(T_\nu)$, $A_c = e_c\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$, $q = Q_{s-1}$, $Y = X_{s-1}$, and (Ex1), (Ex3), (Wm1), (Wm3') are taken at level s. Here Δ_K is trivial and $\Gamma_K = 1+\ell^s\mathbb{Z}_\ell$ (Definition 23.2, paragraph Level s), so (Wm3') gives $(\gamma_v-1)(\mathbf{N}_\nu)\subseteq Y\mathbf{N}_\nu$ for every $v\in\Gamma_K$. *Step 0.* Y and q are coprime in the unique factorisation domains $\mathbb{Z}_\ell[[X]]$ and A_c: neither is divisible by a uniformiser ($Y\equiv X^{\ell^{s-1}}$, $q\equiv X^{\ell^{s-1}(\ell-1)}$ modulo ℓ), and a common prime factor would be a distinguished polynomial with a common root, while the roots of Y are the $\zeta-1$ with $\zeta^{\ell^{s-1}}=1$ and those of q the $\zeta-1$ with ζ of exact order ℓ^s (Lemma 23.8(3)). For $v\in\Gamma_K$, $\gamma_v(q) = h_vq$ with $h_v\in\mathbb{Z}_\ell[[X]]^\times$ (Lemma 23.8(2)); since $q = \Phi_\ell(1+Y)$ and $\gamma_v(1+Y) = (1+Y)^v\in(1+Y)+Y\mathbb{Z}_\ell[[X]]$,

$\gamma_v(q) - q \in Y\mathbb{Z}_\ell[[X]] \cap q\mathbb{Z}_\ell[[X]] = Yq\,\mathbb{Z}_\ell[[X]]$, so $h_v \in 1 + Y\mathbb{Z}_\ell[[X]]$. *Step 1.* With $D_\nu(H) = \{z \in e_c\mathbf{N}_\nu[1/\lambda_\infty] :\ q^H z \in \mathbf{N}_\nu\}$, the computation of Step 1 gives, for $z \in D_\nu(H)$ and $n = q^H z$, $q^H(\gamma_v - 1)(z) = (h_v^{-H} - 1)\gamma_v(n) + (\gamma_v - 1)(n) \in Y\mathbf{N}_{\nu,c}$; so $(\gamma_v - 1)(z) = Yz'$ with $q^H z' \in \mathbf{N}_{\nu,c}$, γ_v preserves $D_\nu(H)$ and $\mathbf{N}_{\nu,c}$, and $\mathbf{N}_s(\Phi)$ maps $D_1(H)$ into $D_2(H)$. *Step 2* is void (no averaging is needed). *Step 3* carries over with $g = u_s = 1 + \ell^s$, Q replaced by q, invariance under Δ dropped, and Lemma 24.19 (paragraph Level s; $u = g \in 1 + \ell^s\mathbb{Z}_\ell$, $Y = G$) in (b); in (c), $(\gamma_g - 1)(w) \in Y\mathbf{N}_2 \cap e_c\mathbf{N}_2[1/\lambda_\infty] \subseteq \mathbf{N}_{2,c}$. It gives $u_2 \in D_1(G)$ with $\mathbf{N}_s(\Phi)(u_2) = \ell^r R(1)w$ and $(\gamma_g - 1)(u_2) \in \mathbf{N}_{1,c}$. *Step 4.* By item 1 of Lemma 23.22 ($p = \ell$, $m = s$, allowed as $s \geq 2$ if $\ell = 2$), $v_\ell(1 - g^{-x}) = s + v_\ell(x)$ for $x \in J'$, so $v_\ell(R(1)) = \kappa^{(s)}$, and $u = (\ell^{\kappa^{(s)}}/R(1))\,u_2 \in D_1(G)$ has $Q_{s-1}^G u \in \mathbf{N}_1$, $\mathbf{N}_s(\Phi)(u) = \ell^{r+\kappa^{(s)}}w$ and $(\gamma_g - 1)(u) \in \mathbf{N}_{1,c}$. *Step 5.* $\bar{M} = D_1(G)/\mathbf{N}_{1,c} \cong \mathbf{N}_{1,c}/q^G\mathbf{N}_{1,c}$ is free of finite rank over $\mathcal{O}_L$ (Weierstrass division by the distinguished polynomial q^G); the continuity argument for $\rho(a) = \gamma_{g^a}$ carries over unchanged, so $[u]$ is fixed by $\rho(\mathbb{Z}_\ell)$, and $\Gamma_K = g^{\mathbb{Z}_\ell}$ ($1+\ell^s\mathbb{Z}_\ell$ is procyclic with generator $1+\ell^s$, $\ell^s \neq 2$). Hence $(\gamma_v - 1)(u) \in \mathbf{N}_{1,c}$ for every $v \in \Gamma_K$; by Step 1 also $(\gamma_v - 1)(u) = Yz'$ with $q^G z' \in \mathbf{N}_{1,c}$. In coordinates, each coordinate f of z' has $Yf \in A_c$ and $q^G f \in A_c$; as Y and q are coprime in the unique factorisation domain A_c (Step 0), $f \in A_c$. So $(\gamma_v - 1)(u) \in Y\mathbf{N}_1$ for every $v \in \Gamma_K$, and $u \in I_c^{1,s}$. □

Lemma 24.19. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ be as in Proposition 23.7, (V,T) a pair over K, $\mathbf{N} = \mathbf{N}(T)$, $c \in \mathbb{Z}/n$, and $J \subset \mathbb{Z}$ a finite set containing every Hodge jump of V at every embedding of K over τ_c. Let $u \in 1 + \ell\mathbb{Z}_\ell$, $Y \geq 0$ an integer, and $x_1, \ldots, x_m$ an enumeration, without repetition, of the finite set $Z = \{j + k :\ j \in J,\ 1 \leq k \leq Y\}$. Let $y_0 \in e_c\mathbf{N}[1/\lambda_\infty]$ with $Q^Y y_0 \in \mathbf{N}$, and put*

$$y_i = \gamma_u(y_{i-1}) - u^{-x_i}\,y_{i-1} \qquad (1 \leq i \leq m).$$

Then $y_m \in \mathbf{N}_c$.

Level s. *Let ℓ be any prime, $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, L, K ($F \subseteq K \subseteq F(\mu_{\ell^s})$) and a pair (V,T) over K as in (Ex4) of Proposition 23.7, $\mathbf{N} = \mathbf{N}_s(T)$, and c, J, Y, Z, $x_1, \ldots, x_m$ as above. Let $u \in 1 + \ell^s\mathbb{Z}_\ell$ and $y_0 \in e_c\mathbf{N}[1/\lambda_\infty]$ with $Q_{s-1}^Y y_0 \in \mathbf{N}$, and define y_i as above. Then $y_m \in \mathbf{N}_c$. For $s = 1$ and ℓ odd this is the statement above with $u \in 1 + \ell\mathbb{Z}_\ell$.*

Proof. **Step 1: the level-0 recursion.** $y_0 \in W$, and W is an $\mathcal{O}_L$-submodule of $e_c\mathbf{N}[1/\lambda_\infty]$ (if $Q^Y w, Q^{Y'}w' \in \mathbf{N}$ then $Q^{\max(Y,Y')}(w + w') \in \mathbf{N}$) stable under γ_u (Lz2); as $u^{-x_i} \in \mathbb{Z}_\ell$, all y_i lie in W. Put $f_i = \mathrm{lv}(y_i) \in \mathcal{F}((t))^r$. By (Lz2) and the $\mathcal{O}_L$-linearity of lv,

$$f_i = (\gamma_u^{(0)} - u^{-x_i})(f_{i-1}) \qquad (1 \leq i \leq m),$$

so $f_m = \Omega(f_0)$ with $\Omega = \prod_{x\in Z}(\gamma_u^{(0)} - u^{-x})$, the factors being commuting $\mathbb{Z}_\ell$-linear operators. Since $u \in 1 + \ell\mathbb{Z}_\ell$, σ_u is the identity, so $\gamma_u^{(0)}(g\,v) = g(ut)\,v$ for $g \in \mathcal{F}((t))$ and $v \in \mathcal{F}^r$, where $g(ut) = \sum_i u^i a_i t^i$ for $g = \sum_i a_i t^i$.

Step 2: the integral vectors. By (Lz4), for each embedding τ of K over τ_c the filtration $\epsilon_\tau\mathrm{Fil}$ of $\epsilon_\tau\mathcal{F}_K^r = L^r$ is decreasing, equal to L^r for $j \ll 0$ and to 0 for $j \gg 0$; choose an L-basis $(v_{\tau,b})_{b\leq r}$ of L^r adapted to it: integers $j_{\tau,b}$ with $\epsilon_\tau\mathrm{Fil}(j) = \bigoplus_{b:\ j_{\tau,b}\geq j} Lv_{\tau,b}$ for every j (for each j choose a complement of $\epsilon_\tau\mathrm{Fil}(j+1)$ in $\epsilon_\tau\mathrm{Fil}(j)$, and put $j_{\tau,b} = j$ on a basis of it). Each $j_{\tau,b}$ satisfies $\epsilon_\tau\mathrm{Fil}(j_{\tau,b}+1) \neq \epsilon_\tau\mathrm{Fil}(j_{\tau,b})$, so it is a Hodge jump of V at τ (Lz4), and $j_{\tau,b} \in J$. As $\mathrm{Fil}(j)$ is an $\mathcal{F}_K$-submodule and $\mathcal{F}_K = \prod_\tau L\epsilon_\tau$, $\mathrm{Fil}(j) = \bigoplus_\tau \epsilon_\tau\mathrm{Fil}(j)$; and $\mathcal{F}$ is flat over the product of fields $\mathcal{F}_K$, so $\mathcal{F} \otimes_{\mathcal{F}_K} \mathrm{Fil}(j)$ is the $\mathcal{F}$-span of $\mathrm{Fil}(j)$ in $\mathcal{F}^r$, namely $\bigoplus_\tau \bigoplus_{b:\ j_{\tau,b}\geq j} \epsilon_\tau\mathcal{F}\,v_{\tau,b}$ (here $v_{\tau,b}$ is viewed in $\epsilon_\tau\mathcal{F}_K^r$). Every $f \in \mathcal{F}((t))^r$ is uniquely $f = \sum_{\tau,b} g_{\tau,b}v_{\tau,b}$ with $g_{\tau,b} \in \epsilon_\tau\mathcal{F}((t))$, and the t^i-coefficient of f lies in $\mathcal{F} \otimes_{\mathcal{F}_K} \mathrm{Fil}(-i)$ for every i if and only if $g_{\tau,b} \in t^{-j_{\tau,b}}\epsilon_\tau\mathcal{F}[[t]]$ for all τ, b.

So the set of f satisfying the condition of (Lz3) is

$$\Lambda = \bigoplus_{\tau,b} t^{-j_{\tau,b}}\,\epsilon_\tau \mathcal{F}[[t]]\,v_{\tau,b},$$

an $\mathcal{F}[[t]]$-submodule of $\mathcal{F}((t))^r$.

Step 3: the start. $Q^Y y_0 \in \mathbf{N} \cap e_c\mathbf{N}[1/\lambda_\infty] = \mathbf{N}_c$ and $Q^Y y_0 \in W$, so $\mathrm{lv}(Q^Y y_0) \in \Lambda$ by (Lz3). By (Lz1), $\mathrm{lv}(Q^Y y_0) = \lambda(e_cQ)^Y f_0 = t^Y \eta^Y f_0$ with $\eta \in \mathcal{F}[[t]]^\times$; hence $f_0 \in t^{-Y}\Lambda$, that is $f_0 = \sum_{\tau,b} g_{\tau,b} v_{\tau,b}$ with $g_{\tau,b} \in t^{-j_{\tau,b}-Y}\epsilon_\tau\mathcal{F}[[t]]$.

Step 4: one factor. Let $x \in \mathbb{Z}$ and $q \in \mathbb{Z}$. The operator $g \mapsto g(ut) - u^{-x}g$ maps $t^q\epsilon_\tau\mathcal{F}[[t]]$ into itself, and maps $t^{-x}\epsilon_\tau\mathcal{F}[[t]]$ into $t^{-x+1}\epsilon_\tau\mathcal{F}[[t]]$.

Step 5: conclusion. Fix (τ, b) and $j = j_{\tau,b} \in J$. The Y integers $j+1, \dots, j+Y$ lie in Z, so Ω is the product of $\prod_{k=1}^{Y}(\gamma_u^{(0)} - u^{-(j+k)})$ and of the factors with $x \in Z\setminus\{j+1, \dots, j+Y\}$. By Step 1, $\Omega(g_{\tau,b}v_{\tau,b}) = \Omega_1(g_{\tau,b})\,v_{\tau,b}$, where Ω_1 is the same product of the operators $g \mapsto g(ut) - u^{-x}g$. Applying Step 4 for $x = j+Y, j+Y-1, \dots, j+1$ in turn,

$$\prod_{k=1}^{Y} \left(g \mapsto g(ut) - u^{-(j+k)}g\right)(g_{\tau,b}) \in t^{-j}\epsilon_\tau\mathcal{F}[[t]],$$

and the remaining factors preserve $t^{-j}\epsilon_\tau\mathcal{F}[[t]]$ (Step 4). Hence $\Omega_1(g_{\tau,b}) \in t^{-j_{\tau,b}}\epsilon_\tau\mathcal{F}[[t]]$ for all (τ, b), and $f_m = \Omega(f_0) \in \Lambda$. As $y_m \in W$ (Step 1), (Lz3) gives $y_m \in \mathbf{N}_c$. (For $Y = 0$, $Z = \emptyset$, $m = 0$ and $y_0 \in \mathbf{N} \cap e_c\mathbf{N}[1/\lambda_\infty] = \mathbf{N}_c$ directly.)

Remark. Each factor costs $v_\ell(1-u^{-x}) = v_\ell(u-1) + v_\ell(x)$ when it is turned into a lift: with $v_\ell(u-1) = 1$ that is $1 + v_\ell(x)$ per index. The eigenvalue u^{-x} is the same at every embedding τ over τ_c, which is why one product serves all of them; this is where the plain operator $\gamma_u - u^{-x}$ is used instead of $\pi_0^{-1}(\gamma_u - 1)$ of Lemma 24.8, whose eigenvalues at the points over different τ differ when $K \neq F$.

Level s. Use Lemma 24.20, paragraph Level s (with $\zeta = \zeta_{\ell^s}$, W defined by Q_{s-1}-poles), in place of Lemma 24.20. Step 1 applies without change: W is an $\mathcal{O}_L$-module stable under γ_u ((Lz2); $u \in 1 + \ell^s\mathbb{Z}_\ell \subseteq \Gamma_K$), and σ_u is the identity because $\zeta_{\ell^s}^u = \zeta_{\ell^s}$, so $\gamma_u^{(0)}(g\,v) = g(ut)\,v$. Step 2 applies without change ((Lz3), (Lz4)). Step 3: $\mathrm{lv}(Q_{s-1}^Y y_0) = \lambda(e_cQ_{s-1})^Y f_0 = t^Y\eta^Y f_0$ with $\eta \in \mathcal{F}[[t]]^\times$ by (Lz1) of level s, so $f_0 \in t^{-Y}\Lambda$. Steps 4 and 5 apply without change. □

Lemma 24.20. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ be as in Proposition 23.7, (V,T) a pair over K, $\mathbf{N} = \mathbf{N}(T)$, $r = \dim_L V$, and $c \in \mathbb{Z}/n$. Let $\zeta = \zeta_\ell \in \overline{\mathbb{Q}}_\ell$ be the primitive ℓ-th root of unity of the compatible system $\underline{\zeta}$ fixed in Section 13 (the one defining t), so that $F(\zeta) = F(\mu_\ell) \supseteq K$. Let $\epsilon \in F \otimes_{\mathbb{Q}_\ell} L$ be the idempotent of τ_c (the one with $(x \otimes b)\epsilon = \tau_c(x)b\,\epsilon$), and put*

$$\mathcal{F} = \epsilon\big(F(\zeta) \otimes_{\mathbb{Q}_\ell} L\big) \;\supseteq\; \mathcal{F}_K = \epsilon\big(K \otimes_{\mathbb{Q}_\ell} L\big) = \prod_\tau L\,\epsilon_\tau,$$

the product over the embeddings τ of K over τ_c, ϵ_τ the idempotent of τ. For $u \in \Gamma_K$ let σ_u be the automorphism of $\mathcal{F}$ that is the identity on F and L and sends ζ to ζ^u (it fixes $\mathcal{F}_K$, and is the identity if $u \in 1 + \ell\mathbb{Z}_\ell$), and on $\mathcal{F}((t))^r$ let $\gamma_u^{(0)}(\sum_i a_i t^i) = \sum_i u^i\sigma_u(a_i)\,t^i$, coordinatewise. Let

$$W = \{w \in e_c\mathbf{N}[1/\lambda_\infty] :\; Q^Y w \in \mathbf{N} \text{ for some integer } Y \geq 0\}.$$

Then there are a ring homomorphism $\lambda\colon e_c\mathbf{A}_{F,L} \to \mathcal{F}[[t]]$, an $\mathcal{O}_L$-linear map $\mathrm{lv}\colon W \to \mathcal{F}((t))^r$ and a decreasing filtration $(\mathrm{Fil}(j))_{j\in\mathbb{Z}}$ of $\mathcal{F}_K^r$ by $\mathcal{F}_K$-submodules such that:

(Lz1) Ring $\lambda(e_c(x\otimes b))=\epsilon(x\otimes b)$ *for* $x\in\mathcal{O}_F$, $b\in\mathcal{O}_L$, $\lambda(e_cX)=\epsilon\,(\zeta e^{t/\ell}-1)$, $\lambda(e_cQ)\in t\,\mathcal{F}[[t]]^\times$, *and* $\mathrm{lv}(gw)=\lambda(g)\,\mathrm{lv}(w)$ *for* $g\in e_c\mathbf{A}_{F,L}$ *and* $w\in W$; *moreover* λ *is the substitution* $\lambda(e_c\sum_i b_iX^i)=\sum_i\epsilon\,b_i\,(\zeta e^{t/\ell}-1)^i$ *(*$b_i\in\mathcal{O}_L$, *under* $e_c\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$*), the sum converging coefficientwise in* $\mathcal{F}[[t]]$; *in particular* λ *does not depend on* (V,T);

(Lz2) Gamma *for* $u\in\Gamma_K$: $\gamma_u(W)\subseteq W$ *and* $\mathrm{lv}(\gamma_u w)=\gamma_u^{(0)}(\mathrm{lv}(w))$ *for* $w\in W$;

(Lz3) Membership *for* $w\in W$: $w\in\mathbf{N}_c$ *if and only if, for every* $i\in\mathbb{Z}$, *the* t^i*-coefficient of* $\mathrm{lv}(w)$ *lies in* $\mathcal{F}\otimes_{\mathcal{F}_K}\mathrm{Fil}(-i)$;

(Lz4) Hodge filtrations *for every embedding* τ *of* K *over* τ_c *there is an* L*-linear isomorphism* $\epsilon_\tau\mathcal{F}_K^r=L^r\to D_{\mathrm{dR},\tau}(V)$ *carrying* $\epsilon_\tau\mathrm{Fil}(j)$ *onto* $\mathrm{Fil}^jD_{\mathrm{dR},\tau}(V)$ *for every* j; *in particular* $\epsilon_\tau\mathrm{Fil}(j)=L^r$ *for* $j\ll0$, $=0$ *for* $j\gg0$, *and the integers* j *with* $\epsilon_\tau\mathrm{Fil}(j+1)\neq\epsilon_\tau\mathrm{Fil}(j)$ *are the Hodge jumps of* V *at* τ;

Level s. *Let* ℓ *be any prime,* $s\geq1$ *an integer with* $s\geq2$ *if* $\ell=2$, L, K *(*$F\subseteq K\subseteq F(\mu_{\ell^s})$*) and a pair* (V,T) *over* K *as in (Ex4) of Proposition 23.7,* $\mathbf{N}=\mathbf{N}_s(T)$, $r=\dim_L V$, $c\in\mathbb{Z}/n$. *Let* $\zeta=\zeta_{\ell^s}$ *be the primitive* ℓ^s*-th root of unity of the compatible system* $\underline{\zeta}$, *and define* ϵ, $\mathcal{F}=\epsilon(F(\zeta)\otimes_{\mathbb{Q}_\ell}L)\supseteq\mathcal{F}_K=\prod_\tau L\epsilon_\tau$, σ_u *(*$u\in\Gamma_K$; $\zeta\mapsto\zeta^u$*),* $\gamma_u^{(0)}$ *as above with this* ζ, *and* $W=\{w\in e_c\mathbf{N}[1/\lambda_\infty]:\ Q_{s-1}^Yw\in\mathbf{N}$ *for some* $Y\geq0\}$. *Then there are* λ, lv *and* Fil *with (Lz1)–(Lz4), where in (Lz1)* λ *is the substitution* $X\mapsto\zeta e^{t/\ell^s}-1$, *i.e.* $\lambda(e_cX)=\epsilon(\zeta e^{t/\ell^s}-1)$, *and* $\lambda(e_cQ_{s-1})\in t\,\mathcal{F}[[t]]^\times$ *in place of* $\lambda(e_cQ)\in t\,\mathcal{F}[[t]]^\times$. *(*$\sigma_u$ *is the identity for* $u\in1+\ell^s\mathbb{Z}_\ell$, *in particular for every* $u\in\Gamma_K$ *when* $K=F(\mu_{\ell^s})$*.) For* $s=1$ *and* ℓ *odd these are (Lz1)–(Lz4) above.*

Proof. Write $B=B_{\mathrm{dR}}^+$, $\mu=\mu_\varepsilon=q^\ell-1$, $\mu'=q-1$, and φ also for $\varphi\otimes1$ on $W(\mathbb{C}_\ell^\flat)\otimes_{\mathbb{Z}_\ell}T$. Put $R^+=\epsilon(B\otimes_{\mathbb{Q}_\ell}L)$ and $R=R^+[1/t]=\epsilon(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}L)$; here $F\subset\overline{\mathbb{Q}}_\ell\subset B$ by (Ai3), so $\epsilon\in F\otimes L\subset B\otimes L$.

Step 0: identities in B**.** By (Ai3), $tB=\xi_0B=\ker(\theta)$, B is a complete discrete valuation ring and $\overline{\mathbb{Q}}_\ell\subset B$ compatibly with θ; $t=\log(q^\ell)$, so $q^\ell=\exp(t)$. The elements $x=\zeta^{-1}q$ and $y=\exp(t/\ell)$ lie in $1+tB$ ($\theta(q)=\zeta_\ell=\theta(\zeta)$) and $x^\ell=q^\ell=y^\ell$; so $x/y\in1+tB$ is an ℓ-th root of unity of the domain B. The ℓ elements of $\mu_\ell\subset\overline{\mathbb{Q}}_\ell\subset B$ are all its ℓ-th roots of unity, and only 1 among them has θ-value 1; so $x=y$:

$$q=\zeta e^{t/\ell},\qquad\mu'=\zeta e^{t/\ell}-1,\qquad\mu=e^t-1\in tB^\times,\qquad\xi_0=\frac{\mu}{\mu'}=\frac{e^t-1}{\zeta e^{t/\ell}-1}\in tB^\times,$$

μ' being a unit ($\theta(\mu')=\zeta-1\neq0$). Also $\varphi^{-1}(\tilde{\xi})=\xi_0$ ($\tilde{\xi}=\varphi(\mu)/\mu$, Theorem B.41).

Step 1: the algebraic model. θ is injective on $\mathcal{F}$: $F(\zeta)\to\mathbb{C}_\ell$ is injective and L is flat over $\mathbb{Q}_\ell$. R^+ is a direct summand of the free B-module $B\otimes_{\mathbb{Q}_\ell}L$, hence t-torsion free and t-adically complete. So $\sum_{i\geq i_0}a_it^i\mapsto$ its sum is a ring homomorphism $\mathcal{F}((t))\to R$, injective (if a sum with $a_{i_0}\neq0$ vanished, θ of t^{-i_0} times it would give $a_{i_0}=0$); we identify $\mathcal{F}((t))$ with its image, and the same argument gives $\mathcal{F}((t))\cap t^mR^+=t^m\mathcal{F}[[t]]$ for $m\in\mathbb{Z}$.

Step 2: the ring map λ**.** Let $\lambda=\varphi^{-1}\circ(\iota\otimes\mathrm{id})$ on $e_c\mathbf{A}_{F,L}$, with values in $A_{\mathrm{inf}}\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L\subset B\otimes\mathcal{O}_L$. By Lemma 23.8(4), $\iota|_{\mathcal{O}_F}=\varphi\circ w$ and $\iota(X)=\mu$, so $\lambda(x\otimes b)=w(x)\otimes b$ and $\lambda(X)=\mu'$. The element $w(x)\in B$ is a root of the minimal polynomial of x over $\mathbb{Q}_\ell$ with $\theta(w(x))=x$ (Lemma 23.8(4): $\tilde{\theta}\circ\iota|_{\mathcal{O}_F}=\theta\circ w$ is the inclusion), so it is $x\in\overline{\mathbb{Q}}_\ell\subset B$ (the roots of that separable

polynomial in the domain B are its roots in $\overline{\mathbb{Q}}_\ell$, with distinct θ-values). Hence $\lambda(e_c)=\epsilon$ and $\lambda(e_c(x\otimes b))=\epsilon(x\otimes b)$. Now let $g=\sum_i b_iX^i\in e_c\mathbf{A}_{F,L}\cong\mathcal{O}_L[[X]]$ and put $g^{\mathrm{al}}=\sum_i \epsilon b_i(\zeta e^{t/\ell}-1)^i$. This converges coefficientwise in $\mathcal{F}[[t]]$: modulo t^m, $(\zeta e^{t/\ell}-1)^i=\sum_{j<m}\binom{i}{j}(\zeta-1)^{i-j}\zeta^j(e^{t/\ell}-1)^j$ lies in $(\zeta-1)^{i-m}\ell^{-C_m}\mathcal{O}[t]$ with $\mathcal{O}=\epsilon(\mathcal{O}_{F(\zeta)}\otimes\mathcal{O}_L)$ and C_m independent of i, and $v_\ell(\zeta-1)>0$. We claim $\lambda(g)=g^{\mathrm{al}}$. Fix $m\geq 1$. By (Ai3) and (Ai1), $B/t^mB=A_{\mathrm{inf}}[1/\ell]/\xi_0^m$ contains $\bar{A}=A_{\mathrm{inf}}/\xi_0^mA_{\mathrm{inf}}$ ($\bar{A}$ is ℓ-torsion free, an iterated extension of copies of $A_{\mathrm{inf}}/\xi_0\cong\mathcal{O}_{\mathbb{C}_\ell}$), and $\bar{A}\otimes\mathcal{O}_L$ is ℓ-adically separated (an extension of ℓ-torsion free ℓ-adically separated modules is such). Since $\theta(\mu')^{\ell-1}=(\zeta-1)^{\ell-1}\in\ell\mathcal{O}_{\mathbb{C}_\ell}$, $\mu'^{\ell-1}\in\ell A_{\mathrm{inf}}+\xi_0A_{\mathrm{inf}}$, hence $\mu'^N\in\ell^kA_{\mathrm{inf}}+\xi_0^mA_{\mathrm{inf}}$ for $N\geq(\ell-1)(m+k)$. With $S_N=\sum_{i<N}\epsilon b_i\mu'^i$: $\lambda(g)-S_N=\mu'^N\lambda(g_N)$ with $g_N\in e_c\mathbf{A}_{F,L}$ (μ' is topologically nilpotent in A_{inf}, its reduction lying in the maximal ideal of $\mathcal{O}_{\mathbb{C}_\ell^\flat}$), so its image modulo t^m lies in $\ell^k(\bar{A}\otimes\mathcal{O}_L)$ for N large. On the other side S_N is also the partial sum of g^{al} ($\mu'=\zeta e^{t/\ell}-1$ by Step 0), and $g^{\mathrm{al}}-S_N$ modulo t^m lies in $(\zeta-1)^{N-m}\ell^{-C_m}\mathcal{O}[t]$; the images in B/t^m of $\mathcal{O}_{F(\zeta)}=\mathcal{O}_F[\zeta]$ and of t lie in $\ell^{-C'_m}\bar{A}$ ($\zeta=q\,e^{-t/\ell}$, and $t=\log(1+\mu)\equiv\sum_{n<m}(-1)^{n+1}\mu^n/n$ modulo ξ_0^m, as $\mu=\xi_0\mu'$). So $\lambda(g)-g^{\mathrm{al}}$ modulo t^m lies in $\bigcap_k\ell^{k-C}(\bar{A}\otimes\mathcal{O}_L)=0$ for a constant C; as m is arbitrary and R^+ is t-adically separated, $\lambda(g)=g^{\mathrm{al}}\in\mathcal{F}[[t]]$. Finally $\lambda(e_cQ)=\epsilon\varphi^{-1}(\tilde{\xi})=\epsilon\xi_0=\epsilon(e^t-1)/(\zeta e^{t/\ell}-1)\in t\mathcal{F}[[t]]^\times$ ($e^t-1\in t\mathbb{Q}[[t]]^\times$, and $\zeta e^{t/\ell}-1$ has constant term $\zeta-1\neq 0$). So λ is a ring homomorphism $e_c\mathbf{A}_{F,L}\to\mathcal{F}[[t]]$ with the properties of (Lz1) on λ, and extends to $e_c\mathbf{A}_{F,L}[1/Q]\to\mathcal{F}((t))$.

Step 3: the horizontal level frame. By (Ex1) and (Wm1), $\mathbf{N}_{c-1}$ has an $e_{c-1}\mathbf{A}_{F,L}$-basis $(n_j)_{j\leq r}$; let $H_k=\sum_j h_{kj}n_j$ be the horizontal sections of (Hf2) over K through n_k, $\mathbf{h}=(h_{kj})\in M_r(e_{c-1}E[[X]])$, $\mathbf{h}\equiv 1 \bmod X$, and $\gamma_u(H_k)=H_k$ for $u\in\Gamma_K$. For $f=\sum_i a_iX^i\in e_{c-1}E[[X]]$ put $\mathrm{ev}(f)=\sum_i\iota_\Lambda(a_i)\mu^i$, $\iota_\Lambda=(\iota|_{\mathcal{O}_F}\otimes\mathrm{id})[1/\ell]$; $\iota_\Lambda(e_{c-1})=(w\otimes\mathrm{id})(\varphi(e_{c-1}))=\epsilon$ and $\mu=e^t-1\in t\mathbb{Q}_\ell[[t]]$, so the series converges t-adically in $\epsilon(F\otimes L)[[t]]=L[[t]]\epsilon\subseteq\mathcal{F}[[t]]$ and ev is a ring homomorphism. For $f\in e_{c-1}\mathbf{A}_{F,L}$, $\mathrm{ev}(f)=(\iota\otimes\mathrm{id})(f)$ (the tails of the second series lie in $\mu^bA_{\mathrm{inf}}\otimes\mathcal{O}_L\subseteq t^bB\otimes\mathcal{O}_L$). For $\sigma\in G_K$ and $u=\chi_{\mathrm{cyc}}(\sigma)\in\Gamma_K$: σ fixes $F\supseteq$ the coefficients, $\sigma(\mu)=(1+\mu)^u-1=h_u(\mu)$, and σ is t-adically continuous ($\sigma(t)=ut$), so $\sigma(\mathrm{ev}(f))=\mathrm{ev}(f\circ h_u)$. Put

$$D_k=\sum_j\mathrm{ev}(h_{kj})\,\iota_T(n_j)\in B_{\mathrm{dR}}\otimes_{\mathbb{Z}_\ell}T\qquad(k\leq r),$$

($\iota_T(n_j)\in A_{\mathrm{inf}}[1/\mu]\otimes T$, and $\mu\in tB^\times$ is a unit of B_{dR}). (a) *Basis.* By (Ex2), $A_{\mathrm{inf}}[1/\mu]\cdot\iota_T(\mathbf{N})=A_{\mathrm{inf}}[1/\mu]\otimes T$, and $\iota_T(e_bx)=(\iota\otimes\mathrm{id})(e_b)\iota_T(x)$ with $(\iota\otimes\mathrm{id})(e_{c-1})=\epsilon$; so $\epsilon(A_{\mathrm{inf}}[1/\mu]\otimes T)$ is generated over $A_{\mathrm{inf}}[1/\mu]\otimes\mathcal{O}_L$ by $\iota_T(\mathbf{N}_{c-1})$, hence by the r elements $\iota_T(n_j)$; it is free of rank r over $\epsilon(A_{\mathrm{inf}}[1/\mu]\otimes\mathcal{O}_L)$ (T is free of rank r over $\mathcal{O}_L$), so they form a basis, and after base change $(\iota_T(n_j))_j$ is an R-basis of $\epsilon(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)$. As $\mathrm{ev}(\mathbf{h})\equiv 1 \bmod t$ is invertible over $L[[t]]$, $(D_k)_k$ is an R-basis of $\epsilon(B_{\mathrm{dR}}\otimes V)$, and $\iota_T(n_j)=\sum_k\mathrm{ev}((\mathbf{h}^{-1})_{jk})D_k$. (b) *Invariance.* Let $\sigma\in G_K$, $u=\chi_{\mathrm{cyc}}(\sigma)$, and $\gamma_u(n_j)=\sum_l(G_u)_{lj}n_l$ with $G_u\in M_r(e_{c-1}\mathbf{A}_{F,L})$. By (Ex2), $\sigma(\iota_T(n_j))=\iota_T(\gamma_un_j)=\sum_l\mathrm{ev}((G_u)_{lj})\iota_T(n_l)$, so $\sigma(D_k)=\sum_l\mathrm{ev}(\sum_j(h_{kj}\circ h_u)(G_u)_{lj})\iota_T(n_l)$; the inner sum is the n_l-coordinate of $\gamma_u(H_k)=H_k$, i.e. h_{kl}. So $\sigma(D_k)=D_k$, and $D_k\in\epsilon D_{\mathrm{dR}}(V)$, $D_{\mathrm{dR}}(V)=(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)^{G_K}$. (c) *De Rham basis.* If $v\in\epsilon D_{\mathrm{dR}}(V)$, $v=\sum_k c_kD_k$ with unique $c_k\in R$ by (a), and σ-invariance and uniqueness give $c_k\in R^{G_K}=\epsilon(B_{\mathrm{dR}}^{G_K}\otimes_{\mathbb{Q}_\ell}L)=\epsilon(K\otimes_{\mathbb{Q}_\ell}L)=\mathcal{F}_K$, by $B_{\mathrm{dR}}^{G_K}=K$ [94]. So (D_k) is an $\mathcal{F}_K$-basis of $\epsilon D_{\mathrm{dR}}(V)$, and $(\epsilon_\tau D_k)_k$ an L-basis of $\epsilon_\tau D_{\mathrm{dR}}(V)=D_{\mathrm{dR},\tau}(V)$ for each τ over τ_c (Definition 13.7: $D_{\mathrm{dR},\tau}(V)=L\otimes_{K\otimes L,\tau\otimes\mathrm{id}}D_{\mathrm{dR}}(V)$ is the ϵ_τ-component).

Step 4: the level map. Extend ι_T and the γ_u to $\mathbf{N}[1/\lambda_\infty]$ as in (Gc0) over K, and put $\Lambda=\varphi^{-1}\circ\iota_T$ on $e_c\mathbf{N}[1/Q]$. Let $w\in W$, $Q^Yw\in\mathbf{N}$; then $Q^Yw\in\mathbf{N}_c$. Fix integers $M_a,h_a\geq 0$ bounding the Hodge jumps as in (Ex1); by (Wm2), $Q^{h_c}\mathbf{N}_c\subseteq\mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-1})$, so

$Q^{Y+h_c}w = \sum_j g_j\varphi(n_j)$ with $g_j \in e_c\mathbf{A}_{F,L}$. By (Ex2) and Steps 2–3,

$$\Lambda(w) = \lambda(e_cQ)^{-(Y+h_c)}\sum_j \lambda(g_j)\,\iota_T(n_j) = \sum_k \Big(\lambda(e_cQ)^{-(Y+h_c)}\sum_j \lambda(g_j)\,\mathrm{ev}((\mathbf{h}^{-1})_{jk})\Big)D_k,$$

with coefficients in $\mathcal{F}((t))$. Define $\mathrm{lv}(w) \in \mathcal{F}((t))^r$ as the coordinate vector of $\Lambda(w)$ in the R-basis (D_k); it depends only on w, and lv is $\mathcal{O}_L$-linear. For $g \in e_c\mathbf{A}_{F,L}$, $gw \in W$ and $\Lambda(gw) = \lambda(g)\Lambda(w)$ ((Ex2)), so $\mathrm{lv}(gw) = \lambda(g)\mathrm{lv}(w)$. This completes (Lz1).

Step 5: (Lz2). Let $u \in \Gamma_K$, $w \in W$. By Lemma 23.8(2), $\gamma_u(Q) \in Q\,\mathbb{Z}_\ell[[X]]^\times$, so $Q^Y\gamma_u(w) = (Q/\gamma_u(Q))^Y\gamma_u(Q^Yw) \in \mathbf{N}$, and $\gamma_u(e_c) = e_c$: $\gamma_u(w) \in W$. Choose $\sigma \in G_K$ with $\chi_{\mathrm{cyc}}(\sigma) = u$; by (Gc0), $\iota_T(\gamma_u w) = \sigma(\iota_T(w))$, and σ commutes with φ, so $\Lambda(\gamma_u w) = \sigma(\Lambda(w)) = \sum_k \sigma(\mathrm{lv}(w)_k)D_k$ by Step 3(b). On $\mathcal{F}((t))$, σ is the identity on F and L, sends ζ to ζ^u and t to ut (Ai3), and is t-adically continuous; so $\sigma(\sum_i a_it^i) = \sum_i u^i\sigma_u(a_i)t^i$, and $\mathrm{lv}(\gamma_u w) = \gamma_u^{(0)}(\mathrm{lv}(w))$ by uniqueness of coordinates. (σ_u fixes $\mathcal{F}_K$, as σ fixes K; for $u \in 1+\ell\mathbb{Z}_\ell$, $\zeta^u = \zeta$.)

Step 6: the filtration and (Lz4). V is crystalline, hence de Rham [94]. Put $\mathrm{Fil}(j) = \{v \in \mathcal{F}_K^r : \sum_k v_kD_k \in \mathrm{Fil}^j D_{\mathrm{dR}}(V)\}$, an $\mathcal{F}_K$-submodule, decreasing in j, since $\mathrm{Fil}^j D_{\mathrm{dR}}(V)$ is a decreasing family of $K\otimes L$-submodules (Definition 13.7). For τ over τ_c, $v \mapsto \sum_k v_k\epsilon_\tau D_k$ is an L-isomorphism $\epsilon_\tau\mathcal{F}_K^r = L^r \to D_{\mathrm{dR},\tau}(V)$ (Step 3(c)) carrying $\epsilon_\tau\mathrm{Fil}(j)$ onto $\epsilon_\tau\mathrm{Fil}^j D_{\mathrm{dR}}(V) = \mathrm{Fil}^j D_{\mathrm{dR},\tau}(V)$. The filtration of the finite-dimensional space $D_{\mathrm{dR},\tau}(V)$ is exhaustive and separated ($\bigcup_j t^jB = B_{\mathrm{dR}}$, $\bigcap_j t^jB = 0$), which gives the remaining assertions of (Lz4).

Step 7: de Rham integrality in coordinates. Claim: for $f \in \mathcal{F}((t))^r$, $\sum_k f_kD_k \in \epsilon(B\otimes_{\mathbb{Q}_\ell} V)$ if and only if the t^i-coefficient $f^{(i)}$ lies in $\mathcal{F}\otimes_{\mathcal{F}_K}\mathrm{Fil}(-i)$ for every i. Both sides decompose along the idempotents ϵ_τ ($\epsilon = \sum_\tau\epsilon_\tau$ in $K\otimes L$; $\mathcal{F} = \prod_\tau \epsilon_\tau\mathcal{F}$, $\epsilon_\tau\mathcal{F} = F(\zeta)\otimes_{K,\tau} L$). Fix τ, put $R_\tau^+ = \epsilon_\tau(B\otimes_{\mathbb{Q}_\ell} L)$ and choose an L-basis (D_i^{ad}) of $D_{\mathrm{dR},\tau}(V)$ with $D_i^{\mathrm{ad}} \in \mathrm{Fil}^{u_i}$ such that each $\mathrm{Fil}^j D_{\mathrm{dR},\tau}(V)$ is spanned by the D_i^{ad} with $u_i \ge j$. Applying ϵ_τ to (Ai4) for K and V with $k=0$ (the comparison map is $K\otimes L$-linear),

$$\epsilon_\tau(B\otimes_{\mathbb{Q}_\ell} V) = \sum_j t^{-j}R_\tau^+ \otimes_L \mathrm{Fil}^j D_{\mathrm{dR},\tau}(V) = \bigoplus_i t^{-u_i}R_\tau^+ D_i^{\mathrm{ad}},$$

a direct sum because (D_i^{ad}) is a basis of $\epsilon_\tau(B_{\mathrm{dR}}\otimes V)$ over $R_\tau^+[1/t]$ ((Ai4) again). Write $\epsilon_\tau D_k = \sum_i W_{ki}D_i^{\mathrm{ad}}$ ($W \in GL_r(L)$) and $\phi_i = \sum_k \epsilon_\tau f_k W_{ki} \in \epsilon_\tau\mathcal{F}((t))$. The ϵ_τ-component of $\sum_k f_kD_k$ lies in $\epsilon_\tau(B\otimes V)$ iff $\phi_i \in t^{-u_i}R_\tau^+$ for all i, iff (Step 1, with $\epsilon_\tau\mathcal{F}$) $\phi_i \in t^{-u_i}\epsilon_\tau\mathcal{F}[[t]]$, iff for every m the t^m-coefficients vanish when $u_i < -m$, iff $\sum_i \phi_i^{(m)}D_i^{\mathrm{ad}} \in \epsilon_\tau\mathcal{F}\otimes_L \mathrm{Fil}^{-m}D_{\mathrm{dR},\tau}(V)$ for every m; as $\sum_i \phi_i^{(m)}D_i^{\mathrm{ad}} = \sum_k \epsilon_\tau f_k^{(m)}\epsilon_\tau D_k$, Step 6 turns this into $\epsilon_\tau f^{(m)} \in \epsilon_\tau\mathcal{F}\otimes_L \epsilon_\tau\mathrm{Fil}(-m)$. Taking all τ gives the claim.

Step 8: (Lz3). Let $(n'_j)_{j\le r}$ be an $e_c\mathbf{A}_{F,L}$-basis of $\mathbf{N}_c$. (a) $(\Lambda(n'_j))_j$ is an R^+-basis of $\epsilon(B\otimes_{\mathbb{Z}_\ell} T) = \epsilon(B\otimes_{\mathbb{Q}_\ell} V)$: φ^{-1} maps $A_{\mathrm{inf}}[1/\mu]$ into $A_{\mathrm{inf}}[1/\mu'] \subseteq B$, so $\Lambda(\mathbf{N}) \subseteq B\otimes T$ and, by (Ex2), $B\cdot\Lambda(\mathbf{N}) \supseteq \varphi^{-1}(A_{\mathrm{inf}}[1/\mu]\otimes T) \supseteq 1\otimes T$, i.e. $B\cdot\Lambda(\mathbf{N}) = B\otimes T$; multiplying by $\epsilon = \lambda(e_c)$ and using $\Lambda(e_bx) = \lambda(e_b)\Lambda(x)$, $\epsilon(B\otimes T) = \sum_j R^+\Lambda(n'_j)$, a free R^+-module of rank r generated by r elements. (b) For $g \in Q^{-Y}e_c\mathbf{A}_{F,L}$: $g \in e_c\mathbf{A}_{F,L}$ iff $\lambda(g) \in R^+$. Indeed, if $Y \ge 1$, $g = Q^{-Y}g'$ and $\lambda(g) \in R^+$, then $\lambda(g') \in \xi_0^Y R^+ \subseteq tR^+$, so $\theta(\lambda(g')) = 0$; under $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $\theta\circ\lambda$ is $g' \mapsto \epsilon\,g'(\zeta-1)$ (Step 2), and $\epsilon(F(\zeta)\otimes L) \cong L[X]/(Q)$ via $X \mapsto \zeta - 1$ ($Q = \Phi_\ell(1+X)$ is irreducible over the unramified F); so g' vanishes at every root of Q and $Q \mid g'$ in $\mathcal{O}_L[[X]]$ (Lemma 23.8(3)); induction on Y. The converse is clear. (c) Let $w \in W$ and write $w = \sum_j g_jn'_j$, $g_j \in Q^{-Y}e_c\mathbf{A}_{F,L}$. Then $\Lambda(w) = \sum_j \lambda(g_j)\Lambda(n'_j)$, and by (a) (a basis of $\epsilon(B\otimes V)$ is a basis of $\epsilon(B_{\mathrm{dR}}\otimes V)$) and (b): $w \in \mathbf{N}_c$ iff all $g_j \in e_c\mathbf{A}_{F,L}$ iff $\Lambda(w) \in \epsilon(B\otimes V)$. Since $\Lambda(w) = \sum_k \mathrm{lv}(w)_kD_k$, Step 7 turns this into the condition of (Lz3).

Step 9: (Lz5). Let (n_j), $\mathbf{h}$, ev and (D_k) be as in Step 3, and $x = \sum_j a_jn_j \in \mathbf{N}_{c-1}$ with $a_j \in e_{c-1}\mathbf{A}_{F,L}$. By (Wm2) for the window of Step 4, $Q^{M_c}\varphi(x) \in \mathbf{N}$, and $\varphi(x) = e_c\varphi(x)$ as

$\varphi(e_{c-1}) = e_c$; so $\varphi(x) \in W$. By (Ex2), $\iota_T(\varphi(x)) = \varphi(\iota_T(x))$, hence $\Lambda(\varphi(x)) = \iota_T(x)$. Since $e_{c-1}\mathbf{A}_{F,L} = \mathcal{O}_F[[X]] \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ ($\mathcal{O}_L$ is finite free over $\mathbb{Z}_\ell$), each a_j is a finite sum $\sum f \otimes b$ with $f \in \mathbf{A}_F$, $b \in \mathcal{O}_L$, and (Ex2) gives $\iota_T(a_j n_j) = (\iota \otimes \mathrm{id})(a_j)\, \iota_T(n_j) = \mathrm{ev}(a_j)\, \iota_T(n_j)$ (Step 3). With Step 3(a),

$$\Lambda(\varphi(x)) = \sum_k \Big(\sum_j \mathrm{ev}(a_j)\, \mathrm{ev}((\mathbf{h}^{-1})_{jk}) \Big) D_k,$$

so $\mathrm{lv}(\varphi(x))_k = \sum_j \mathrm{ev}(a_j)\mathrm{ev}((\mathbf{h}^{-1})_{jk}) \in L[[t]]\epsilon \subseteq \mathcal{F}[[t]]$. Under $e_{c-1}\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ write $a_j(0) \in \mathcal{O}_L$ for the constant term; as $\mu = e^t - 1 \in t\mathbb{Q}_\ell[[t]]$ and $\iota_\Lambda(e_{c-1}) = \epsilon$, $\mathrm{ev}(a_j) \equiv \epsilon\, a_j(0)$ modulo t, and $\mathrm{ev}(\mathbf{h}^{-1}) \equiv \epsilon\, I$ modulo t ($\mathbf{h} \equiv 1$ modulo X). Hence $\mathrm{lv}(\varphi(x))_k \equiv \epsilon\, a_k(0)$ modulo t. Put $\mathrm{val}(x) = (a_k(0))_k$: it is $\mathcal{O}_L$-linear, surjective (take $x = bn_k$), and its kernel is $\{x :\ a_k(0) = 0 \text{ for all } k\} = X\mathbf{N}_{c-1}$.

Level s. Let the data be as in the paragraph Level s of the statement; every cited clause is taken in its level-s form ((Ex1), (Ex2) of (Ex4) of Proposition 23.7, (Wm1), (Wm2) of level s, (Gc0) of Lemma 23.29 and (Hf2) of Lemma 23.9, paragraphs Level s), and ι_s, $\mu_{\varepsilon,s} = [\varepsilon^{1/\ell^{s-1}}] - 1$ are as in Lemma 23.8(6). *Step 0.* Put $q_s = [\varepsilon^{1/\ell^s}]$, so $\theta(q_s) = \zeta$ and $q_s^{\ell^s} = [\varepsilon] = e^t$. The argument of Step 0 with $x = \zeta^{-1}q_s$, $y = e^{t/\ell^s}$ ($x^{\ell^s} = y^{\ell^s}$, $x/y \in 1 + tB$ an ℓ^s-th root of unity, and only $1 \in \mu_{\ell^s}$ has θ-value 1) gives $q_s = \zeta e^{t/\ell^s}$, and $\mu_s' := q_s - 1$ is a unit of B ($\theta(\mu_s') = \zeta - 1 \neq 0$); $\xi_0 = \varphi^{-1}(\tilde{\xi}) \in tB^\times$ as there. *Step 1* carries over with the new $\mathcal{F}$. *Step 2.* Let $\lambda = \varphi^{-1} \circ (\iota_s \otimes \mathrm{id})$ on $e_c\mathbf{A}_{F,L}$. As $\iota_s = \varphi \circ w$ on $\mathcal{O}_F$ and $\varphi^{-1}(\mu_{\varepsilon,s}) = q_s - 1 = \mu_s'$, $\lambda(x \otimes b) = w(x) \otimes b = x \otimes b$ and $\lambda(X) = \mu_s'$; the proof that $\lambda(g) = \sum_i \epsilon b_i (\zeta e^{t/\ell^s} - 1)^i$ carries over with μ_s' for μ' and $(\zeta - 1)^{\varphi(\ell^s)} \in \ell\mathcal{O}_{\mathbb{C}_\ell}$ for $(\zeta - 1)^{\ell - 1} \in \ell\mathcal{O}_{\mathbb{C}_\ell}$ (μ_s' is topologically nilpotent in A_{inf}, its reduction $\varepsilon^{1/\ell^s} - 1$ lying in the maximal ideal; $\zeta = q_s e^{-t/\ell^s}$). Finally $\lambda(e_c Q_{s-1}) = \epsilon\varphi^{-1}(\iota_s(Q_{s-1})) = \epsilon\varphi^{-1}(\tilde{\xi}) = \epsilon\xi_0 \in t\mathcal{F}[[t]]^\times$, and for $i \geq 1$, $\lambda(e_c Q_{s-1+i}) = \epsilon\, \Phi_{\ell^{s+i}}(\zeta e^{t/\ell^s})$ has constant term $\epsilon\Phi_{\ell^{s+i}}(\zeta) \neq 0$, so is a unit of $\mathcal{F}[[t]]$. *Step 3 (the frame, moved $s-1$ sites back).* This is the only substantial change: $\iota_s(X) = \mu_{\varepsilon,s}$ has $\theta(\mu_{\varepsilon,s}) = \zeta_{\ell^{s-1}} - 1$, which is non-zero for $s \geq 2$, so the series ev of Step 3 would not converge; we apply φ^{s-1}, which sends $\mu_{\varepsilon,s}$ to $\mu = e^t - 1 \in tB$. Let $(n_j)_{j \leq r}$ be an $e_{c-s}\mathbf{A}_{F,L}$-basis of $\mathbf{N}_{c-s}$ and $H_k = \sum_j h_{kj} n_j$ the horizontal sections of (Hf2) through n_k, $\mathbf{h} \equiv 1 \bmod X$. For $f = \sum_i a_i X^i \in e_{c-s}E[[X]]$ put $\mathrm{ev}_s(f) = \sum_i \varphi^{s-1}(\iota_\Lambda(a_i))\mu^i$, t-adically convergent; $\varphi^{s-1}(\iota_\Lambda(e_{c-s})) = (w \otimes \mathrm{id})(e_c) = \epsilon$ (as $(\varphi \otimes \mathrm{id})(e_b) = e_{b+1}$ and $w(x) = x$ in B), and $\mathrm{ev}_s(f) = \varphi^{s-1}((\iota_s \otimes \mathrm{id})(f))$ for $f \in e_{c-s}\mathbf{A}_{F,L}$ ($\varphi^{s-1}(\mu_{\varepsilon,s}) = \mu$). Put $D_k = \sum_j \mathrm{ev}_s(h_{kj})\, \varphi^{s-1}(\iota_{s,T}(n_j)) \in B_{\mathrm{dR}} \otimes T$. (a) By (Ex2), $A_{\mathrm{inf}}[1/\mu]\iota_{s,T}(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu] \otimes T$; applying the automorphism φ^{s-1} of $W(\mathbb{C}_\ell^\flat) \otimes T$, $A_{\mathrm{inf}}[1/\varphi^{s-1}(\mu)] \cdot \varphi^{s-1}\iota_{s,T}(\mathbf{N}) = A_{\mathrm{inf}}[1/\varphi^{s-1}(\mu)] \otimes T$, and $\varphi^{s-1}(\mu) = \mu \prod_{i<s-1} \varphi^i(\tilde{\xi})$ is a unit of B_{dR} ($\mu \in tB^\times$, and $\theta(\varphi^i(\tilde{\xi})) = \ell \neq 0$ since $\theta([\varepsilon^{\ell^i}]) = 1$). With $\iota_{s,T}(e_b x) = (\iota_s \otimes \mathrm{id})(e_b)\iota_{s,T}(x)$ and $\varphi^{s-1}((\iota_s \otimes \mathrm{id})(e_{c-s})) = \epsilon$, the $\varphi^{s-1}\iota_{s,T}(n_j)$ form an R-basis of $\epsilon(B_{\mathrm{dR}} \otimes V)$, hence so do the D_k, and $\varphi^{s-1}\iota_{s,T}(n_j) = \sum_k \mathrm{ev}_s((\mathbf{h}^{-1})_{jk})D_k$. (b) For $\sigma \in G_K$, $u = \chi_{\mathrm{cyc}}(\sigma)$: $\sigma(\varphi^{s-1}\iota_{s,T}(n_j)) = \varphi^{s-1}\iota_{s,T}(\gamma_u n_j)$ by (Ex2), $\sigma(\mathrm{ev}_s(f)) = \mathrm{ev}_s(f \circ h_u)$ (σ fixes the coefficients, $\sigma(\mu) = (1+\mu)^u - 1$), and horizontality gives $\sigma(D_k) = D_k$ exactly as in Step 3(b). (c) carries over unchanged. *Step 4.* For $w \in W$ with $Q_{s-1}^Y w \in \mathbf{N}_c$, iterating (Wm2) of level s along $c, c-1, \ldots, c-s+1$ (and $\varphi(Q_{s-1+i}) = Q_{s+i}$) gives $P\, Q_{s-1}^Y w = \sum_j g_j \varphi^s(n_j)$ with $g_j \in e_c\mathbf{A}_{F,L}$ and $P = \prod_{i=0}^{s-1} Q_{s-1+i}^{h_{c-i}}$. With $\Lambda = \varphi^{-1} \circ \iota_{s,T}$ and $\Lambda(\varphi^s(n_j)) = \varphi^{s-1}(\iota_{s,T}(n_j))$ ((Ex2)),

$$\Lambda(w) = \sum_k \Big(\lambda(e_c P Q_{s-1}^Y)^{-1} \sum_j \lambda(g_j)\, \mathrm{ev}_s((\mathbf{h}^{-1})_{jk}) \Big) D_k,$$

with coefficients in $\mathcal{F}((t))$ by Step 2; $\mathrm{lv}(w)$ is the coordinate vector, and (Lz1) follows as before. *Step 5* carries over with Q_{s-1} ($\gamma_u(Q_{s-1}) \in Q_{s-1}\mathbb{Z}_\ell[[X]]^\times$, Lemma 23.8(2)) and $\sigma(\zeta) = \zeta^u$ for $\zeta = \zeta_{\ell^s}$. *Steps 6 and 7* carry over unchanged. *Step 8.* (a) carries over unchanged ($\varphi^{-1}(\mu) = [\varepsilon^{1/\ell}] - 1$ is a unit of B). (b) For $g \in Q_{s-1}^{-Y} e_c \mathbf{A}_{F,L}$: if $\lambda(g) \in R^+$ and $g = Q_{s-1}^{-Y} g'$, $Y \geq 1$, then $\lambda(g') \in \xi_0^Y R^+ \subseteq tR^+$, so $\epsilon\, g'(\zeta - 1) = \theta(\lambda(g')) = 0$; as $\epsilon(F(\zeta) \otimes L) \cong L[X]/(Q_{s-1})$ via $X \mapsto \zeta - 1$

($Q_{s-1} = \Phi_{\ell^s}(1+X)$ is irreducible over the unramified F), g' vanishes at every root of Q_{s-1} and $Q_{s-1} \mid g'$ (Lemma 23.8(3)); induction on Y. (c) carries over unchanged. This proves (Lz1)–(Lz4) at level s. □

Lemma 24.21. *Let ℓ be an odd prime, F, L, K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Lemma 24.14, $\Delta = \Delta_K$, $\mathbf{N}$ a Wach module over K with coefficients L (any window), $a \in \mathbb{Z}/n$, $u \in \Gamma_K$ with $v_\ell(u-1) = 1$, and $M \geq 1$ an integer. If $y \in \pi_\Delta \mathbf{N}_a^\Delta$ and $(\gamma_u - 1)(y) \in \pi_\Delta^M \mathbf{N}_a^\Delta$, then $y \in \pi_\Delta^M \mathbf{N}_a^\Delta$.*

Proof. Write $\pi = \pi_\Delta$, $q = q_\Delta$ and $R = e_a \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$. By (Dm1), $\mathbf{N}_a^\Delta$ is free over $R^\Delta = \mathcal{O}_L[[\pi]]$, with a basis $(n_k)_k$ of Δ-fixed vectors.

Step 1: the constant. By (Rr7), $\Gamma_K = \Gamma_\Delta$, so (Rr6) applies to u: $\gamma_u(\pi) = \pi(1 + t_u q)$ with $t_u \in \mathbb{Z}_\ell[[X]]^\times$ Δ-invariant (as $v_\ell(u-1) = 1$). The element $t_u q \in \mathbb{Z}_\ell[[X]]$ is Δ-invariant, so by (Rr2) (for the coefficient field $\mathbb{Q}_\ell$) $t_u q = g(\pi)$ with $g \in \mathbb{Z}_\ell[[T]]$, and $g(0)$ is the value of $t_u q$ at $X = 0$ (as π has no constant term, (Rr2) and (Rr1) of Lemma 23.24). Put $b = g(0) = t_u(0)\, E_\Delta(0)$: here $q(0) = E_\Delta(\pi(0)) = E_\Delta(0)$, $t_u(0) \in \mathbb{Z}_\ell^\times$ since t_u is a unit, and $v_\ell(E_\Delta(0)) = 1$ since E_Δ is Eisenstein (Rr3). So $v_\ell(b) = 1$, $c = 1 + b \in 1 + \ell\mathbb{Z}_\ell$ and $c \neq 1$; as $1 + \ell\mathbb{Z}_\ell$ is torsion free (ℓ odd), $c^j \neq 1$ for every $j \geq 1$. Moreover $(1 + t_u q)^j = (1 + g(\pi))^j \equiv c^j \pmod{\pi \mathbb{Z}_\ell[[\pi]]}$.

Step 2: one step of the induction. Let $1 \leq j < M$ and $y \in \pi^j \mathbf{N}_a^\Delta$ with $(\gamma_u - 1)(y) \in \pi^M \mathbf{N}_a^\Delta$; write $y = \pi^j y'$ with $y' \in \mathbf{N}_a^\Delta$. Since γ_u is γ_u-semilinear,

$$(\gamma_u - 1)(y) = \gamma_u(\pi)^j \gamma_u(y') - \pi^j y' = \pi^j \Big((1+t_u q)^j (\gamma_u(y') - y') + ((1+t_u q)^j - c^j) y' + (c^j - 1)\, y' \Big).$$

By (Dm3), $\gamma_u(y') - y' \in \pi \mathbf{N}_a^\Delta$, and $(1+t_u q)^j \in \mathbb{Z}_\ell[[\pi]] \subseteq R^\Delta$; by Step 1, $(1+t_u q)^j - c^j \in \pi \mathbb{Z}_\ell[[\pi]]$. Hence the first two terms in the bracket lie in $\pi \mathbf{N}_a^\Delta$, and as $(\gamma_u - 1)(y) \in \pi^M \mathbf{N}_a^\Delta \subseteq \pi^{j+1} \mathbf{N}_a^\Delta$,

$$\pi^j (c^j - 1)\, y' \in \pi^{j+1} \mathbf{N}_a^\Delta.$$

In the basis (n_k), with $y' = \sum_k f_k n_k$, $f_k \in \mathcal{O}_L[[\pi]]$, this says $\pi^j (c^j - 1) f_k \in \pi^{j+1} \mathcal{O}_L[[\pi]]$ for every k; as $\mathcal{O}_L[[\pi]]$ is a domain, $(c^j - 1) f_k \in \pi \mathcal{O}_L[[\pi]]$, that is $(c^j - 1) f_k(0) = 0$ in $\mathcal{O}_L$, and since $c^j - 1 \neq 0$, $f_k(0) = 0$. So $y' \in \pi \mathbf{N}_a^\Delta$ and $y \in \pi^{j+1} \mathbf{N}_a^\Delta$.

Step 3: conclusion. Starting from $y \in \pi \mathbf{N}_a^\Delta$ and applying Step 2 for $j = 1, 2, \ldots, M-1$ (the hypothesis on $(\gamma_u - 1)(y)$ does not change), $y \in \pi^M \mathbf{N}_a^\Delta$. For $M = 1$ there is nothing to prove. □

25 Losses at the places above ℓ

This section converts lifting exponents into the local losses $\lambda_k(v)$ of Galois Ribet data at the places v above ℓ, and into the global losses κ_k where the module of extensions is enlarged. Its outputs are Theorem 25.1, used at the primes of split type and of small type, Corollary 25.39, the explicit losses at unramified places that the budget uses at the split and inert primes, and Corollary 25.6, used at the inert and ramified primes (Sections 26 and 27). The local condition is the Bloch–Kato condition (Ll2), and the points of the determinant algebra are crystalline at v (Ll1).

There are two ways to bound the loss at v, and Theorem 25.1 uses both. At a *row place* the loss is counted: a lifting exponent bounds the exponent of the Bloch–Kato defect, and the dual count Lemma 25.5, an exact formula from local Tate duality and the Bloch–Kato dimension formula [34], turns an exponent into a length (Theorem 25.3, Theorem 25.7). At a *column place* the module of extensions is replaced by its column-enlargement (Definition 22.3), which

makes every Ribet class satisfy the local condition at v; the price is paid in the global losses κ_k (Theorem 25.2). The constituent block 0 is treated with the lifting exponents of Section 24. For the character blocks $k \geq 1$, where the classes are pushed into negative Tate twists, the section proves a separate exponent, built from the ℓ-adic valuations of the differences between the Hodge jumps and the twist (Proposition 25.8); Subsections 25.2 and 25.3 contain its proof.

25.1 Column places and row places above ℓ

The subsection states the main result of the section, Theorem 25.1, and proves it from four ingredients: the column-enlarged module at the column places (Theorem 25.2), local losses from lifting exponents (Theorem 25.3), the push of integral Bloch–Kato classes into a torsion quotient (Lemma 25.4), and the dual count (Lemma 25.5), which gives the exact length of a Bloch–Kato defect of bounded exponent. Corollary 25.6 combines the lifting exponent for block 0 with the weight-logarithmic exponent of Proposition 25.8 for the character blocks, and Theorem 25.7 is the general form of the dual count for Galois Ribet data.

Theorem 25.1. *Let E be a number field, ℓ an odd prime, $K = \mathcal{O}[\ell^{-1}]$, column data with column places $C \subseteq S_\ell$ for items $\mathbf{r}, \chi_1, \mathcal{E}, \delta$, and Galois Ribet data over E on $(\mathcal{R}, \pi', \mathcal{N}^{\mathrm{col}})$ with these items, $\iota = \iota^{\mathrm{col}}$ and $t+1$ blocks, having (Gd1) and (Gd2); write $n_0 = n_{\mathcal{R},0}$, $D_v = G_{E_v}$ and $n_v = [E_v : \mathbb{Q}_\ell]$. Let $M_0, h_0 \geq 0$ be integers. Suppose that at every $v \in S_\ell$: $E_v \subseteq E_{v,0}(\mu_\ell)$, $E_{v,0}$ the maximal unramified subextension of $E_v/\mathbb{Q}_\ell$; K contains $\sigma(E_{v,0}(\mu_\ell))$ for every $\mathbb{Q}_\ell$-embedding σ of $E_{v,0}(\mu_\ell)$ into $\overline{\mathbb{Q}}_\ell$; (Ll1) and (Ll2) hold; and all Hodge jumps of $V_{\mathcal{N}}$, W_0 and W_0' lie in $[-M_0, h_0]$. Suppose moreover:*

(Lr1) Column places *at every $v \in C$ the column data have the column properties; $H^0(D_v, W_0) = 0$; W_0 has at most $\mu_\tau^-(v)$ Hodge jumps $a < 0$ at each τ, counted with multiplicity; and 0 is not a Hodge jump of W_0 at some embedding τ_v;*

(Lr2) Row places *at every $v \in S_\ell \setminus C$: $e_0(v) \geq 0$ is an integer with $\ell^{e_0(v)} H^1_f(D_v, \mathcal{N}_\mathcal{E}) \subseteq \mathrm{pr}_{1*} H^1_f(D_v, \widetilde{T}_\psi)$ for every $\mathcal{O}$-linear D_v-equivariant $\psi\colon \mathcal{N}_\mathcal{E} \to \mathrm{Cs}_0(u)$; $H^0(D_v, W_0') = 0$; W_0 has at most $\mu_\tau^+(v)$ Hodge jumps $a \geq 0$ at each τ, counted with multiplicity; and 0 is not a Hodge jump of W_0' at some embedding τ_v.*

Then (Gd7) holds at every $v \in S_\ell$ and (Gd6) holds with

$$\lambda_k(v) = 0 \quad (v \in C,\ 0 \leq k \leq t),$$
$$\lambda_0(v) = e_0(v) \sum_\tau \mu_\tau^+(v) + n_0\, c_{\mathrm{inv}}(W_0', \tau_v), \quad \lambda_k(v) = c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)\, n_v + w_k(v) \quad (v \notin C,\ k \geq 1),$$
$$\kappa_0 = \sum_{v \in C} \Big((e_v' + \nu(\delta)) \sum_\tau \mu_\tau^-(v) + n_0 \big(c_{\mathrm{inv}}(W_0, \tau_v) + \nu(\delta) \big) \Big),$$
$$\kappa_1 = \sum_{v \in C} \big(2\nu(\delta) + b_v \big), \qquad \kappa_k = \sum_{v \in C} \big(\nu(\delta) + w_{k-1}(v) \big)\ (k \geq 2).$$

In particular $\sum_{k=0}^t \kappa_k + \sum_{v \in S_\ell} \sum_{k=0}^t \lambda_k(v) = \Lambda_\ell$ with

$$\Lambda_\ell = \sum_{v \in C} \Big((e_v' + \nu(\delta)) \sum_\tau \mu_\tau^-(v) + n_0\, c_{\mathrm{inv}}(W_0, \tau_v) + (n_0 + t + 1)\nu(\delta) + b_v + \sum_{i=1}^{t-1} w_i(v) \Big)$$
$$+ \sum_{v \in S_\ell \setminus C} \Big(e_0(v) \sum_\tau \mu_\tau^+(v) + n_0\, c_{\mathrm{inv}}(W_0', \tau_v) + \sum_{k=1}^{t} \big(c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)\, n_v + w_k(v) \big) \Big).$$

Level s. *More generally, let ℓ be a prime and $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, and replace the two field conditions above by: at every $v \in S_\ell$, $E_v \subseteq E_{v,0}(\mu_{\ell^s})$, and K contains $\sigma(E_{v,0}(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ of $E_{v,0}(\mu_{\ell^s})$ into $\overline{\mathbb{Q}}_\ell$; keep the other hypotheses. Then all assertions above hold with $c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$ replaced by $c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1)$ of Proposition 25.8 (paragraph Level s, $p = \ell$) and $c_{\mathrm{inv}}(\cdot, \tau_v)$ by $c_{\mathrm{inv},s}(\cdot, \tau_v)$ of Proposition 25.35 (formed with $p = \ell$ and M_0, h_0), in $\lambda_0(v)$, $\lambda_k(v)$, κ_0 and Λ_ℓ. For $s = 1$ and ℓ odd this is the statement above.* ***Descent.*** *Let ℓ be a prime, $N \geq 1$ an integer with $4 \mid N$ if $\ell = 2$, $s = \max(1, v_\ell(N))$ and $N_\ell = \mathrm{lcm}(\ell, N)$, and replace the two field conditions by: at every $v \in S_\ell$, E_v is $\mathbb{Q}_\ell$-isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_{N_\ell})$, and K contains a primitive N_ℓ-th root of unity; keep the other hypotheses. Then all assertions of the paragraph Level s hold (with this s) with $c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1)$ replaced by $c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1) + s - 1$.*

Proof. We prove the first assertion and the assertion of the paragraph Level s together. In the first case put $s = 1$, $c_k^{\mathrm{B}} = c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$ and $c^{\mathrm{inv}}(\cdot, \tau) = c_{\mathrm{inv}}(\cdot, \tau) = c_{\mathrm{inv},1}(\cdot, \tau)$; in the second put $c_k^{\mathrm{B}} = c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1)$ and $c^{\mathrm{inv}}(\cdot, \tau) = c_{\mathrm{inv},s}(\cdot, \tau)$. In both cases $s \geq 2$ if $\ell = 2$, and at every $v \in S_\ell$, $E_v \subseteq E_{v,0}(\mu_{\ell^s})$ and K contains every $\sigma(E_{v,0}(\mu_{\ell^s}))$; in particular every embedding τ of E_v extends to an embedding σ of $E_{v,0}(\mu_{\ell^s})$, so $\tau(E_v) \subseteq \sigma(E_{v,0}(\mu_{\ell^s})) \subseteq K$.

Step 1: the column places. Let $v \in C$. By Theorem 25.3 ((Ll1), (Gd1), (Gd2)) W_0 is crystalline, and Λ_0 is a D_v-stable lattice with $W_0/\Lambda_0 = \mathrm{Cs}_0(u)$, $\dim_K W_0 = n_0$. By Lemma 25.34(1) (at our level s, with $W = W_0$, $\Lambda = \Lambda_0$, $\tau = \tau_v$ and the window $[-M_0, h_0]$; its field conditions are ours), $h^{\mathrm{c}}(v) = \mathrm{nl}\, H^0(D_v, \mathrm{Cs}_0(u)) \leq n_0\, c^{\mathrm{inv}}(W_0, \tau_v)$. By Theorem 25.2(4), with $K \supseteq \tau(E_v)$ for all τ and $H^0(D_v, W_0) = 0$, $j_v \leq \sum_\tau \mu_\tau^-(v)$. By Theorem 25.2(2) ((Ll2) at v), (Gd7) holds at v with $\lambda_k(v) = 0$; by Theorem 25.2(3) and the two bounds just proved (and $e'_v + \nu(\delta) \geq 0$), (Gd6) holds with the stated κ_k (with c^{inv} in κ_0).

Step 2: the row places. Let $v \in S_\ell \setminus C$. All hypotheses of Corollary 25.6 (in the second case of its paragraph Level s, with this s) hold at v: the prime ℓ (odd in the first case), the two field conditions, (Ll1), (Ll2), $H^0(D_v, W_0') = 0$, the integer $e_0 = e_0(v)$ of (Lr2), and $J(V_{\mathcal{N}}) \subseteq [-M_0, h_0]$. It gives (Gd7) at v with $\lambda_0(v) = e_0(v)\, d^0(W_0) + h_0(v)$, $h_0(v) = \mathrm{nl}\, H^0(D_v, W_0'/\Lambda_0')$, and $\lambda_k(v) = c_k^{\mathrm{B}} n_v + w_k(v)$ for $k \geq 1$. By Theorem 25.7(4), $d^0(W_0) \leq \sum_\tau \mu_\tau^+(v)$. W_0 is crystalline (Step 1), so by Lemma 25.34(2) W_0' is crystalline of K-dimension n_0 with the D_v-stable lattice Λ_0', and by Lemma 25.34(1) (at our level s, with $\tau = \tau_v$ and the window $[-M_0, h_0]$) $h_0(v) \leq n_0\, c^{\mathrm{inv}}(W_0', \tau_v)$. So (Gd7) holds at v with the stated $\lambda_0(v)$.

Step 3: the sum. Adding the stated κ_k and $\lambda_k(v)$: for $v \in C$ the contributions of $\kappa_1, \ldots, \kappa_t$ are $2\nu(\delta) + b_v + \sum_{k=2}^t (\nu(\delta) + w_{k-1}(v)) = (t+1)\nu(\delta) + b_v + \sum_{i=1}^{t-1} w_i(v)$, and that of κ_0 is $(e'_v + \nu(\delta)) \sum_\tau \mu_\tau^-(v) + n_0 c^{\mathrm{inv}}(W_0, \tau_v) + n_0 \nu(\delta)$; for $v \notin C$ the contribution is $\sum_{k=0}^t \lambda_k(v)$. This is Λ_ℓ (with c_k^{B} and c^{inv} in place of $c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$ and c_{inv}).

Descent. Put $c_k^{\mathrm{B}} = c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1) + s - 1$ and $c^{\mathrm{inv}} = c_{\mathrm{inv},s}$. As $\mathbb{Q}_\ell(\mu_{N_\ell})$ is Galois over $\mathbb{Q}_\ell$, every E_v ($v \in S_\ell$) lies in $\mathbb{Q}_\ell(\mu_{N_\ell})$, and every $\mathbb{Q}_\ell$-embedding τ of E_v has $\tau(E_v) \subseteq \mathbb{Q}_\ell(\mu_{N_\ell}) \subseteq K$. Steps 1–3 apply unchanged, with Lemma 25.34 and Corollary 25.6 in their paragraphs Descent (whose field conditions are ours) in place of their level-s forms; Theorem 25.2(4) needs only $K \supseteq \tau(E_v)$ for all τ. □

Theorem 25.2. *Let E be a number field, ℓ a prime and $K = \mathcal{O}[\ell^{-1}]$. Let column data $(C, e_1, (j_v, \alpha_{v,a}, \alpha_v^0)_{v \in C})$ be given for items $\mathbf{r}, \chi_1, \mathcal{E}, \delta$, and let Galois Ribet data over E on $(\mathcal{R}, \pi', \mathcal{N}^{\mathrm{col}})$ with these items, with $\iota = \iota^{\mathrm{col}}$ and $t+1$ blocks, have (Gd1) and (Gd2). Suppose that the column data have the column properties at every $v \in C$. For $v \in C$ put $h^{\mathrm{c}}(v) = \mathrm{nl}\, H^0(G_{E_v}, \mathrm{Cs}_0(u)) \in [0, \infty]$, and for an integer $i \geq 1$ let $w_i(v)$ be the largest integer $w \geq 0$ with $\chi_{\mathrm{cyc}}(g)^i \equiv 1 \bmod \ell^w$ for all $g \in G_{E_v}$. Then:*

1. *if $\mathcal{N}_{\mathcal{E}}$ is a finitely generated $\mathcal{R}$-module, so is $\mathcal{N}^{\mathrm{col}}$;*

2. *for every $v \in C$ at which (Ll2) holds and every $0 \le k \le t$, the image of X_k in*

$$H^1(G_{E_v}, \mathrm{Cs}_k(u))/F_k(v)$$

is zero; so (Gd7) holds at v with $\lambda_k(v) = 0$ for $0 \le k \le t$;

3. *(Gd6) holds whenever*

$$\begin{aligned}
\kappa_0 &\ge \sum_{v\in C} \Big(j_v\big(e'_v + \nu(\delta)\big) + h^{\mathrm{c}}(v) + n_{\mathcal{R},0}\,\nu(\delta) \Big), \\
\kappa_1 &\ge \sum_{v\in C} \big(2\nu(\delta) + b_v\big), \\
\kappa_k &\ge \sum_{v\in C} \big(\nu(\delta) + w_{k-1}(v)\big) \quad (2 \le k \le t);
\end{aligned}$$

4. *if $v \in C$ is a place at which (Ll1) holds, K contains $\tau(E_v)$ for every $\mathbb{Q}_\ell$-embedding τ of E_v into $\overline{\mathbb{Q}}_\ell$, and W_0 has at each such τ at most μ_τ^- Hodge jumps $a < 0$ counted with multiplicity, then*

$$j_v \le \dim_K H^0(G_{E_v}, W_0) + \sum_\tau \mu_\tau^-.$$

Proof. **Step 0: homomorphisms out of $\mathcal{N}^{\mathrm{col}}$.** Let $0 \le k \le t$. An $\mathcal{R}$-linear map $\varphi\colon \mathcal{N}^{\mathrm{col}} \to \mathrm{Cs}_k$ is the same as an $\mathcal{R}$-linear map $\tilde\varphi\colon \mathcal{N}_{\mathcal{E}} \oplus \mathcal{F} \to \mathrm{Cs}_k$ vanishing on Rel, i.e. on its generators. As $\mathcal{F}$ is free on the symbols, $\tilde\varphi$ is determined by $\psi = \tilde\varphi|_{\mathcal{N}_{\mathcal{E}}} = \varphi \circ \iota^{\mathrm{col}}$ and the values $m_v = \tilde\varphi(\epsilon_v)$, $s_{v,a} = \tilde\varphi(\epsilon_{v,a})$, $s_v^0 = \tilde\varphi(\epsilon_v^0)$, which may be any elements of Cs_k subject to: for all $v \in C$, a and $g \in G_{E_v}$,

$$\begin{aligned}
&\text{(i) } \rho_k(\mathcal{E})m_v = 0, \qquad \text{(ii) } \rho_k(e_1)s_{v,a} = s_{v,a}, \qquad \text{(iii) } (\delta - \rho_k(\mathcal{E}))s_v^0 = 0, \\
&\text{(iv) } \psi(y(g)) = -\big(\rho_k(u(g)) - 1\big)m_v + \delta \sum_a \rho_k(\alpha_{v,a}(g))\, s_{v,a} + \delta\, \rho_k(\alpha_v^0(g))\, s_v^0.
\end{aligned}$$

Since $c_\varphi(g) = \varphi(\iota^{\mathrm{col}}(y(g))) = \psi(y(g))$, (iv) says that on G_{E_v} the cocycle c_φ is the coboundary of $-m_v$ plus

$$c'_{\varphi,v}(g) = \delta \sum_a \rho_k(\alpha_{v,a}(g))\, s_{v,a} + \delta\, \rho_k(\alpha_v^0(g))\, s_v^0. \tag{25.1}$$

Three facts on the blocks are used repeatedly. (a) For $k \ge 1$, (Cm1) and (ii) give $s_{v,a} = \rho_k(e_1)s_{v,a} = 0$. (b) For $k \ne 1$, $\rho_k(\mathcal{E}) = 0$ by (Gd2), and as $\alpha_v^0(g) = r\mathcal{E}$ for some $r \in \mathcal{R}$, $\rho_k(\alpha_v^0(g)) = \rho_k(r)\rho_k(\mathcal{E}) = 0$. (c) For $k = 0$, by (ii) and (Cm1) $s_{v,a} = x_a z_1$ with $x_a \in K/\mathcal{O}$; for a lift $\tilde x_a$ and $g \in G_{E_v}$, as $\rho_0(\alpha_{v,a}(g))$ has entries in $\mathcal{O}$ and preserves Λ_0, (Cm2) gives

$$\delta\, \rho_0(\alpha_{v,a}(g))\, s_{v,a} = \delta \tilde x_a\, \rho_0(\alpha_{v,a}(g)) z_1 + \Lambda_0 = \delta \ell^{e'_v} \tilde x_a\, \beta_{v,a}(g) + \Lambda_0.$$

Item 1. $C \subseteq S_\ell$ is finite, so $\mathcal{N}^{\mathrm{col}}$ is generated by the image of a finite generating set of $\mathcal{N}_{\mathcal{E}}$ and the images of the finitely many symbols.

Item 2. Let $v \in C$ satisfy (Ll2), $0 \le k \le t$, and $x \in X_k$ the class of a continuous cocycle c_φ. By Step 0, $x|_{G_{E_v}}$ is the class of the continuous cocycle $c'_{\varphi,v}$ of (25.1) (a cocycle minus a coboundary). $k = 0$. By (b) and (c), $c'_{\varphi,v}(g) = b(g) + \Lambda_0$ with $b(g) = \sum_a \delta \ell^{e'_v} \tilde x_a \beta_{v,a}(g) \in W_0$. By (Cm2) b is a continuous W_0-valued 1-cocycle, and its class $\sum_a \delta \ell^{e'_v} \tilde x_a [\beta_{v,a}]$ lies in $H^1_f(G_{E_v}, W_0)$ by (Cm3), because $H^1_f(G_{E_v}, W_0)$ is a K-subspace of $H^1(G_{E_v}, W_0)$ (the kernel of the map to $H^1(G_{E_v}, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} W_0)$, which is K-linear for K acting through W_0). So $x|_{G_{E_v}}$ is the image of

a class of $H^1_f(G_{E_v}, W_0)$ in $H^1(G_{E_v}, W_0/\Lambda_0)$, i.e. it lies in $H^1_f(G_{E_v}, \mathrm{Cs}_0(u))$, which is $F_0(v)$ by (Ll2). $k = 1$. By (Gd1) $n_{\mathcal{R},1} = 1$ and $\rho_1(u(g)) = \chi_1(g)^{-1}\chi_1(g) = 1$, so $\mathrm{Cs}_1(u) = K/\mathcal{O}$ with trivial action, and by (a) $c'_{\varphi,v}(g) = \delta\rho_1(\alpha^0_v(g))s^0_v$. A cocycle with values in a trivial module is a homomorphism; this one vanishes on I_v by (Cm5). So $x|_{G_{E_v}}$ restricts to 0 on I_v: $x|_{G_{E_v}} \in H^1_{\mathrm{ur}}(E_v, \mathrm{Cs}_1(u)) = F_1(v)$. $k \geq 2$. By (a) and (b), $c'_{\varphi,v} = 0$, so $x|_{G_{E_v}} = 0 \in F_k(v)$. In all cases the image of X_k in $H^1(G_{E_v}, \mathrm{Cs}_k(u))/F_k(v)$ is 0, which is (Gd7) at v with $\lambda_k(v) = 0$.

Item 3: the kernel splits over the column places. By Step 0, φ lies in the kernel $\mathcal{K}_k$ of $\varphi \mapsto \varphi \circ \iota^{\mathrm{col}}$ if and only if $\psi = 0$, and then φ is determined by the tuple $(m_v, (s_{v,a})_a, s^0_v)_{v\in C}$, which satisfies (i)–(iv) with $\psi = 0$; conversely every such tuple defines an element of $\mathcal{K}_k$. The correspondence is $\mathcal{O}$-linear and the conditions involve each v separately, so $\mathcal{K}_k \cong \prod_{v\in C} \mathcal{K}_{k,v}$ with

$$\mathcal{K}_{k,v} = \Big\{(m, (s_a)_a, s^0) \in \mathrm{Cs}_k^{j_v+2} : \text{ (i)–(iii) hold and } (\rho_k(u(g)) - 1)m = \delta\sum_a \rho_k(\alpha_{v,a}(g))s_a + \delta\rho_k(\alpha^0_v(g))s^0 \ \ \forall g \in G_{E_v}\Big\},$$

and $\mathrm{nl}\,\mathcal{K}_k = \sum_v \mathrm{nl}\,\mathcal{K}_{k,v}$. For a submodule P of a product, $\mathrm{nl}P \leq \mathrm{nl}(\ker p|_P) + \mathrm{nl}(p(P))$ for every projection p; we use this with $p(m, s, s^0) = (s, s^0)$.

$k = 0$. The kernel of p on $\mathcal{K}_{0,v}$ consists of the m with $(\rho_0(u(g)) - 1)m = 0$ for all $g \in G_{E_v}$ ((i) holds as $\rho_0(\mathcal{E}) = 0$), i.e. of $H^0(G_{E_v}, \mathrm{Cs}_0(u))$, of normalised length $h^{\mathrm{c}}(v)$. In the image, $s^0 \in \mathrm{Cs}_0[\delta]$ by (iii) and $\rho_0(\mathcal{E}) = 0$, of normalised length $n_{\mathcal{R},0}\nu(\delta)$. For the s_a: by (b), (c) the last condition says that $g \mapsto \sum_a x'_a\beta_{v,a}(g)$, with $x'_a = \delta\ell^{e'_v}x_a \in K/\mathcal{O}$, is the coboundary of m; by (Cm4), $\delta\ell^{e'_v}x_a = 0$. So each s_a lies in the image of $(K/\mathcal{O})[\delta\ell^{e'_v}]$ under the $\mathcal{O}$-linear map $x \mapsto xz_1$, of normalised length at most $\nu(\delta\ell^{e'_v}) = \nu(\delta)+e'_v$. Hence $\mathrm{nl}\,\mathcal{K}_{0,v} \leq h^{\mathrm{c}}(v)+j_v(e'_v+\nu(\delta))+n_{\mathcal{R},0}\nu(\delta)$.

$k = 1$. Here $\mathrm{Cs}_1 = K/\mathcal{O}$, $\rho_1(\mathcal{E}) = \delta$ (Gd2), $\rho_1(u(g)) = 1$ and $s_a = 0$ by (a). So $\mathcal{K}_{1,v}$ consists of the $(m, 0, s^0)$ with $\delta m = 0$ (by (i)) and $\delta\rho_1(\alpha^0_v(g))s^0 = 0$ for all $g \in G_{E_v}$ ((iii) is automatic). Taking $g = g_v$ and using (Cm5), $s^0 \in (K/\mathcal{O})[\delta\rho_1(\alpha^0_v(g_v))]$, of normalised length $\nu(\delta) + \nu(\rho_1(\alpha^0_v(g_v))) \leq \nu(\delta) + b_v$ ($\delta \neq 0$ and $\rho_1(\alpha^0_v(g_v)) \neq 0$ in $\mathcal{O}$). So $\mathrm{nl}\,\mathcal{K}_{1,v} \leq 2\nu(\delta) + b_v$.

$2 \leq k \leq t$. Here $\mathrm{Cs}_k = K/\mathcal{O}$, $s_a = 0$ by (a), $\rho_k(\mathcal{E}) = 0$ and $\rho_k(\alpha^0_v(g)) = 0$ by (b), and $\rho_k(u(g)) = \chi_1(g)^{-1}\chi_k(g) = \chi_{\mathrm{cyc}}(g)^{1-k}$ by (Gd1). So $\mathcal{K}_{k,v}$ consists of the $(m, 0, s^0)$ with $\delta s^0 = 0$ and $(\chi_{\mathrm{cyc}}(g)^{1-k} - 1)m = 0$ for $g \in G_{E_v}$. As $\chi_{\mathrm{cyc}}(g)^{1-k} - 1 = -\chi_{\mathrm{cyc}}(g)^{1-k}(\chi_{\mathrm{cyc}}(g)^{k-1} - 1)$ with $\chi_{\mathrm{cyc}}(g)^{1-k} \in \mathbb{Z}_\ell^\times$, these elements generate the ideal $\ell^w\mathbb{Z}_\ell$ of $\mathbb{Z}_\ell$, $w = w_{k-1}(v)$; w is finite because $\chi_{\mathrm{cyc}}(G_{E_v})$ is an open subgroup of $\mathbb{Z}_\ell^\times$ and so contains an element of infinite order. So $m \in (K/\mathcal{O})[\ell^w]$, and $\mathrm{nl}\,\mathcal{K}_{k,v} \leq w_{k-1}(v) + \nu(\delta)$.

Summing over $v \in C$, $\mathrm{nl}\,\mathcal{K}_k$ is at most the stated lower bound for κ_k; this is (Gd6).

Item 4. *The classes $[\beta_{v,a}] \in H^1(G_{E_v}, W_0)$ are K-linearly independent.* Suppose $\sum_a c_a[\beta_{v,a}] = 0$ with $c \in K^{j_v}$ not zero; multiplying by a power of ϖ we may take all $c_a \in \mathcal{O}$ and some $c_{a_0} \in \mathcal{O}^\times$. Then $\sum_a c_a\beta_{v,a}(g) = (\rho_0(u(g)) - 1)w$ for some $w \in W_0$ and all $g \in G_{E_v}$, so with $x_a = \varpi^{-1}c_a + \mathcal{O}$ the function $g \mapsto \sum_a x_a\beta_{v,a}(g)$ is the coboundary of $\varpi^{-1}w + \Lambda_0$. By (Cm4) all $x_a = 0$, but $x_{a_0} \neq 0$ since c_{a_0} is a unit: a contradiction. By (Cm3) these classes lie in $H^1_f(G_{E_v}, W_0)$, so $j_v \leq \dim_K H^1_f(G_{E_v}, W_0)$. *The dimension.* By Theorem 25.3 ((Ll1), (Gd1), (Gd2)), W_0 is crystalline, hence de Rham [52]. By Theorem B.43, $\dim_{\mathbb{Q}_\ell} H^1_f = \dim_{\mathbb{Q}_\ell} H^0 + \dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(W_0) - \dim_{\mathbb{Q}_\ell} \mathrm{Fil}^0 D_{\mathrm{dR}}(W_0)$; all four are K-vector spaces (K acts through W_0), and $\dim_{E_v} D_{\mathrm{dR}}(W_0) = \dim_{\mathbb{Q}_\ell} W_0$, so $\dim_K D_{\mathrm{dR}}(W_0) = n_v n_{\mathcal{R},0}$, $n_v = [E_v : \mathbb{Q}_\ell]$. Hence

$$\dim_K H^1_f(G_{E_v}, W_0) = \dim_K H^0(G_{E_v}, W_0) + n_v n_{\mathcal{R},0} - d^0(W_0), \qquad d^0(W_0) = \dim_K \mathrm{Fil}^0 D_{\mathrm{dR}}(W_0).$$

The jump count. As K contains every $\tau(E_v)$, $E_v \otimes_{\mathbb{Q}_\ell} K \cong \prod_\tau K$, and with the idempotents e_τ, $D_{\mathrm{dR}}(W_0) = \bigoplus_\tau D_{\mathrm{dR},\tau}(W_0)$ compatibly with the filtrations, so $\sum_\tau \dim_K D_{\mathrm{dR},\tau}(W_0) =$

$n_v n_{\mathcal{R},0}$. On each $D_{\mathrm{dR},\tau}(W_0)$ the filtration is decreasing, equal to the whole space for $a \ll 0$ (every element lies in $t^a B_{\mathrm{dR}}^+ \otimes W_0$ for some a, and the space is finite-dimensional) and 0 for $a \gg 0$; so $\dim_K D_{\mathrm{dR},\tau}(W_0) = \sum_{a\in\mathbb{Z}} \dim_K \mathrm{gr}^a$. By Lemma 25.5(3), $d^0(W_0) = \sum_\tau \sum_{a\geq 0} \dim_K \mathrm{gr}^a D_{\mathrm{dR},\tau}(W_0)$. Therefore $n_v n_{\mathcal{R},0} - d^0(W_0) = \sum_\tau \sum_{a<0} \dim_K \mathrm{gr}^a D_{\mathrm{dR},\tau}(W_0) \leq \sum_\tau \mu_\tau^-$, which with the two previous displays gives item 4. □

Theorem 25.3. *Let E be a number field, ℓ a prime, and let Galois Ribet data over E on $(\mathcal{R}, \pi', \mathcal{N})$, with $t+1$ blocks of sizes $n_{\mathcal{R},0}, \dots, n_{\mathcal{R},t}$ over the Hecke lattice $(\mathcal{O}, \mathcal{Z}, \mathbb{T}, M)$, have (Gd1) and (Gd2); put $K = \mathcal{O}[\ell^{-1}]$. Let $V_{\mathcal{N}} = K\mathcal{N}_{\mathcal{E}} \subseteq \prod_{x'\in\mathcal{Z}'} \mathrm{M}_{n_{\mathcal{R}}}(K)$, on which $g \in G_E$ acts by left multiplication by $u(g)$, and for $0 \leq k \leq t$ let $W_k = K^{n_{\mathcal{R},k}}$, on which g acts by $\rho_k(u(g))$, with the lattice $\Lambda_k = \mathcal{O}^{n_{\mathcal{R},k}}$, so that $\mathrm{Cs}_k(u) = W_k/\Lambda_k$. Let v be a place of E above ℓ, $D = G_{E_v}$, and suppose:*

(Ll1) Crystalline points *for every $x' \in \mathcal{Z}'$ the representation $g \mapsto \mathbf{r}(g)(x')$ of D on $K^{n_{\mathcal{R}}}$ is crystalline;*

(Ll1') Potentially crystalline points *there is a finite Galois extension K' of E_v inside $\overline{E_v}$ such that, with $D_{K'} \subseteq D$ the image of $\mathrm{Gal}(\overline{E_v}/K')$ (an open normal subgroup of index $[K' : E_v]$, identified with $G_{K'}$), for every $x' \in \mathcal{Z}'$ the restriction of $g \mapsto \mathbf{r}(g)(x')$ to $D_{K'}$ is a crystalline representation of $G_{K'}$ (for $K' = E_v$ this is (Ll1));*

(Ll2) Bloch–Kato condition *$F_0(v) = H^1_f(D, \mathrm{Cs}_0(u))$;*

(Ll3) Lifting exponents *$e_0, \dots, e_t \geq 0$ are integers such that for every $0 \leq k \leq t$ and every $\mathcal{O}$-linear D-equivariant $\psi\colon \mathcal{N}_{\mathcal{E}} \to \mathrm{Cs}_k(u)$,*

$$\ell^{e_k}\, H^1_f(D, \mathcal{N}_{\mathcal{E}}) \subseteq \mathrm{pr}_{1*}\, H^1_f(D, \widetilde{T}_\psi), \qquad \widetilde{T}_\psi \subseteq V_{\mathcal{N}} \oplus W_k.$$

Then, under (Ll1) alone, $V_{\mathcal{N}}$ and every W_k are crystalline representations of D; under (Ll1') alone, their restrictions to $D_{K'}$ are crystalline representations of $G_{K'}$; under either of (Ll1), (Ll1'), $\mathcal{N}_{\mathcal{E}}$ is a D-stable lattice in $V_{\mathcal{N}}$ and the restriction of y to D has class in $H^1_f(D, \mathcal{N}_{\mathcal{E}})$; and, under (Ll1) or (Ll1') together with (Ll2) and (Ll3), for $0 \leq k \leq t$ the image of X_k in $H^1(G_{E_v}, \mathrm{Cs}_k(u))/F_k(v)$ has normalised length at most

$$\lambda_k(v) = \left([E_v : \mathbb{Q}_\ell] + 2\right) n_{\mathcal{R},k}\, e_k;$$

that is, (Gd7) holds at v with these local losses. If moreover $\mathcal{N} = \mathcal{N}_{\mathcal{E}}$ and ι is the identity, (Gd6) holds with $\kappa_k = 0$ for all k.

Proof. **Step 0: crystalline objects.** Fix $x' \in \mathcal{Z}'$ and write $r_{x'}$ for $g \mapsto \mathbf{r}(g)(x')$ on $K^{n_{\mathcal{R}}}$; $r_{\pi'}$ is the case $x' = \pi'$. By (Bf1) of Definition 13.11 every $r_{\pi'}(g)$ is block upper triangular, so the spans of the coordinates in the first $k+1$ blocks form a D-stable flag of $K^{n_{\mathcal{R}}}$, and the k-th graded piece is K^{n_k} with g acting by the diagonal block $\rho_k(\mathbf{r}(g))$. By (Ll1) and Theorem B.45 (subquotients), these pieces are crystalline; for $k = 1$, $n_1 = 1$ and the piece is $K(\chi_1)$ by (Gd1). Hence $K(\chi_1^{-1})$ is crystalline (dual), and so are $K(\chi_1^{-1}) \otimes_K r_{x'}$ for every x' (a quotient of the tensor product over $\mathbb{Q}_\ell$) and $W_k = K(\chi_1^{-1}) \otimes_K$ (k-th piece), on which g acts by $\chi_1(g)^{-1}\rho_k(\mathbf{r}(g)) = \rho_k(u(g))$ (ρ_k is $\mathcal{O}$-linear). The representation A with g acting by left multiplication by $u(g)$ is the direct sum over x' and over the $n_{\mathcal{R}}$ columns of copies of $K(\chi_1^{-1}) \otimes_K r_{x'}$, so it is crystalline, and so is every D-stable subspace of it. Under (Ll1') the same argument, applied to the restrictions to $D_{K'} \cong G_{K'}$ with Theorem B.45 for the finite extension K' of $\mathbb{Q}_\ell$, shows that the restrictions to $D_{K'}$ of the graded pieces, of $K(\chi_1^{\pm 1})$, of every W_k, of A and of every D-stable subspace of A are crystalline representations of $G_{K'}$. The algebra $\mathcal{R}$ is a finitely generated free $\mathcal{O}$-module: for each

x' the set $\mathbf{r}(G_E)(x')$ is compact, hence contained in $\varpi^{-a}\mathrm{M}_{n_\mathcal{R}}(\mathcal{O})$ for some a (ϖ a uniformiser of $\mathcal{O}$); $\mathcal{Z}'$ is finite, and the component at x' of an element $\sum_h f_h\mathbf{r}(h)$ of $\mathcal{R}$ (f_h in the coefficient algebra of Definition 17.2, whose elements are $\mathcal{O}$-valued) is an $\mathcal{O}$-combination of the $\mathbf{r}(h)(x')$; so $\mathcal{R}$ is a submodule of the finitely generated free module $\varpi^{-a}\prod_{x'}\mathrm{M}_{n_\mathcal{R}}(\mathcal{O})$ over the discrete valuation ring $\mathcal{O}$, hence finitely generated and free, and so is its submodule $\mathcal{N}_\mathcal{E}$; as $u(g)\in\mathcal{R}$ and $\mathcal{N}_\mathcal{E}$ is a left ideal, $\mathcal{N}_\mathcal{E}$ is $u(D)$-stable, and it spans $V_\mathcal{N}$. So $V_\mathcal{N}$ is crystalline and $\mathcal{N}_\mathcal{E}$ is a D-stable lattice in it; the action is continuous since $g\mapsto u(g)$ is continuous into $\mathcal{R}$ (each $g\mapsto\mathbf{r}(g)(x')$ and χ_1 is continuous, and the ϖ-adic topology of the lattice $\mathcal{R}$ is induced from the finite-dimensional K-space A).

Step 1: the Ribet cocycle is crystalline at v. The map $\rho_1\colon\mathcal{R}\to\mathrm{M}_1(\mathcal{O})=\mathcal{O}$ is a homomorphism of $\mathcal{O}$-algebras (Definition 13.11); it extends K-linearly to $K\mathcal{R}=K\otimes_\mathcal{O}\mathcal{R}\subseteq A$. By (Gd1) and (Gd2), $\rho_1(y(g))=(\rho_1(u(g))-1)\rho_1(\mathcal{E})=(\chi_1(g)^{-1}\chi_1(g)-1)\delta=0$, so $\rho_1(ay(g))=\rho_1(a)\cdot 0=0$ for $a\in\mathcal{R}$, i.e. $\rho_1(V_\mathcal{N})=0$; and $\rho_1(\mathcal{E})=\delta\neq 0$. Let $V_P=V_\mathcal{N}+K\mathcal{E}\subseteq A$. Then $\mathcal{E}\notin V_\mathcal{N}$, $V_P=V_\mathcal{N}\oplus K\mathcal{E}$, and V_P is D-stable because $u(g)\mathcal{E}=\mathcal{E}+y(g)$ with $y(g)\in\mathcal{N}_\mathcal{E}$. The map $\beta=\delta^{-1}\rho_1\colon V_P\to K$ is K-linear, surjective, with kernel $V_\mathcal{N}$ (compare dimensions), and D-equivariant for the trivial action on K: $\beta(u(g)z)=\delta^{-1}\rho_1(u(g))\rho_1(z)=\beta(z)$. So $0\to V_\mathcal{N}\to V_P\xrightarrow{\beta}K\to 0$ is an exact sequence of crystalline representations of D (Step 0; K trivial is crystalline). Write $D_\mathrm{cris}(X)=(X\otimes_{\mathbb{Q}_\ell}B_\mathrm{cris})^D$; it is left exact in X ($\otimes_{\mathbb{Q}_\ell}B_\mathrm{cris}$ is exact, invariants are left exact) and $\dim_{E_{v,0}}D_\mathrm{cris}(X)=\dim_{\mathbb{Q}_\ell}X$ for crystalline X. Hence the image of $D_\mathrm{cris}(V_P)$ in $D_\mathrm{cris}(K)$ has dimension $\dim_{\mathbb{Q}_\ell}V_P-\dim_{\mathbb{Q}_\ell}V_\mathcal{N}=\dim_{\mathbb{Q}_\ell}K=\dim D_\mathrm{cris}(K)$, and $D_\mathrm{cris}(V_P)\to D_\mathrm{cris}(K)$ is onto. Choose $z\in D_\mathrm{cris}(V_P)$ mapping to the invariant element $1\otimes 1$. Then $\mathcal{E}\otimes 1-z$ lies in the kernel of $V_P\otimes B_\mathrm{cris}\to K\otimes B_\mathrm{cris}$, which is $V_\mathcal{N}\otimes B_\mathrm{cris}$, and for $g\in D$

$$g(\mathcal{E}\otimes 1-z)-(\mathcal{E}\otimes 1-z)=(u(g)\mathcal{E}-\mathcal{E})\otimes 1=y(g)\otimes 1.$$

So $y|_D$ is a cocycle with values in $V_\mathcal{N}$ whose class lies in $H^1_f(D,V_\mathcal{N})$ (Definition 22.2); it takes values in $\mathcal{N}_\mathcal{E}$ and is continuous (each component of $y(g)=(u(g)-1)\mathcal{E}$ is continuous in g, as $g\mapsto\mathbf{r}(g)(x')$ and χ_1 are, and the ϖ-adic topology of the lattice $\mathcal{N}_\mathcal{E}$ is the topology induced from the finite-dimensional K-space $V_\mathcal{N}$). Hence $[y|_D]\in H^1_f(D,\mathcal{N}_\mathcal{E})$.

Under (Ll1'). The subspaces $V_\mathcal{N}\subset V_P$, the map β and the identity $u(g)\mathcal{E}=\mathcal{E}+y(g)$ do not depend on (Ll1), and by Step 0 the restriction of $0\to V_\mathcal{N}\to V_P\to K\to 0$ to $D_{K'}$ is an exact sequence of crystalline representations of $G_{K'}$. Put $D_{\mathrm{cris},K'}(X)=(X\otimes_{\mathbb{Q}_\ell}B_\mathrm{cris})^{D_{K'}}$, a vector space over $B_\mathrm{cris}^{D_{K'}}=K'_0$, the maximal unramified subextension of $K'/\mathbb{Q}_\ell$; it is left exact in X and of dimension $\dim_{\mathbb{Q}_\ell}X$ for X crystalline over K'. The dimension count above, with $D_{K'}$ in place of D, gives $z'\in D_{\mathrm{cris},K'}(V_P)$ mapping to $1\otimes 1$, and $m_0=\mathcal{E}\otimes 1-z'$ lies in $M=V_\mathcal{N}\otimes_{\mathbb{Q}_\ell}B_\mathrm{cris}$ with $y(h)\otimes 1=hm_0-m_0$ for $h\in D_{K'}$. We descend to D. The map $c(g)=y(g)\otimes 1-(gm_0-m_0)$ is a 1-cocycle $D\to M$ vanishing on $D_{K'}$. For $g\in D$ and $h\in D_{K'}$, $c(gh)=c(g)+gc(h)=c(g)$, and $c(hg)=c(h)+hc(g)=hc(g)$ while $hg=g(g^{-1}hg)$ with $g^{-1}hg\in D_{K'}$ (normality), so $c(hg)=c(g)$. Hence c takes values in $M^{D_{K'}}$ and is constant on the cosets of $D_{K'}$; write $\Gamma=D/D_{K'}$, of order $m=[K':E_v]$, and $c(\gamma)$ for its value on a coset. Summing $c(g\gamma)=c(g)+gc(\gamma)$ over $\gamma\in\Gamma$ and reindexing gives $\sum_\gamma c(\gamma)=m\,c(g)+g\sum_\gamma c(\gamma)$. Since M is a $\mathbb{Q}_\ell$-vector space we may put $m_1=-m^{-1}\sum_{\gamma\in\Gamma}c(\gamma)\in M$, and then $c(g)=gm_1-m_1$ for every $g\in D$. So $y(g)\otimes 1=g(m_0+m_1)-(m_0+m_1)$ for all $g\in D$ with $m_0+m_1\in M$, that is, the class of $y|_D$ in $H^1(D,V_\mathcal{N})$ lies in $H^1_f(D,V_\mathcal{N})$ (Definition 22.2), and as before $[y|_D]\in H^1_f(D,\mathcal{N}_\mathcal{E})$. The division by $m=[K':E_v]$ happens in the rational space M: membership in $H^1_f(D,\mathcal{N}_\mathcal{E})$ is the condition on the rational class, so no power of ℓ is lost and the exponents e_k and the losses $\lambda_k(v)$ below are the same under (Ll1) and (Ll1'). Steps 0 and 1 use only (Ll1) or (Ll1'), together with (Gd1) and (Gd2); Steps 2–5 do not use (Ll1).

Step 2: the local conditions contain the Bloch–Kato images and are divisible.

Put $F'_k = H^1_f(D, \mathrm{Cs}_k(u))$, the image of $H^1_f(D, W_k)$. We show $F'_k \subseteq F_k(v)$ and that $F_k(v)$ is divisible.

- $k = 0$: $F_0(v) = F'_0$ by (Ll2), divisible by Lemma 25.4(3).
- $k = 1$: $\rho_1(u(g)) = 1$, so $W_1 = K$ with trivial action and $H^1(D, K) = \mathrm{Hom}_{\mathrm{cont}}(D, K)$. Choosing a $\mathbb{Q}_\ell$-basis of K writes K as a sum of copies of $\mathbb{Q}_\ell$, and the condition of Definition 22.2 is componentwise; by Theorem B.44, $H^1_f(D, K)$ consists of the homomorphisms vanishing on I_v. Their images in $\mathrm{Hom}_{\mathrm{cont}}(D, K/\mathcal{O}) = H^1(D, K/\mathcal{O})$ vanish on I_v, so $F'_1 \subseteq H^1_{\mathrm{ur}}(E_v, K/\mathcal{O}) = F_1(v)$. The latter is the group of continuous homomorphisms $D/I_v \to K/\mathcal{O}$; $D/I_v \cong \widehat{\mathbb{Z}}$ is topologically generated by a Frobenius element, so evaluation at it is injective, and it is onto because every element of $K/\mathcal{O}$ has finite ℓ-power order ℓ^s and $\widehat{\mathbb{Z}} \to \mathbb{Z}/\ell^s$ is continuous. So $F_1(v) \cong K/\mathcal{O}$ is divisible.
- $k \geq 2$: by (Gd1), $\rho_k(u(g)) = \chi_1(g)^{-1}\chi_k(g) = \chi_{\mathrm{cyc}}(g)^{1-k}$, so as a $\mathbb{Q}_\ell$-representation W_k is a sum of copies of $\mathbb{Q}_\ell(s)$, $s = 1-k \leq -1$, the line on which g acts by $\chi_{\mathrm{cyc}}(g)^s$. For $V = \mathbb{Q}_\ell(s)$ with basis ϵ: $H^0(D, V) = 0$, since $\chi_{\mathrm{cyc}}(D)$ is infinite; an element $b \otimes \epsilon$ of $B_{\mathrm{dR}} \otimes V$ is D-invariant if and only if $g(b) = \chi_{\mathrm{cyc}}(g)^{-s} b$, i.e. if and only if $bt^s \in B_{\mathrm{dR}}^D = E_v$ (t is invertible in the field B_{dR} and $g(t) = \chi_{\mathrm{cyc}}(g)t$); so $D_{\mathrm{dR}}(V) = E_v\, t^{-s} \otimes \epsilon$, of dimension 1 over E_v, and V is de Rham; as $t^{-s} \in \mathrm{Fil}^{-s} B_{\mathrm{dR}} \subseteq \mathrm{Fil}^0 B_{\mathrm{dR}}$, $\mathrm{Fil}^0 D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V)$. By Theorem B.43, $H^1_f(D, \mathbb{Q}_\ell(s)) = 0$, hence $H^1_f(D, W_k) = 0$ (componentwise), and $F'_k = 0 = F_k(v)$, which is divisible.

Step 3: the Ribet classes at v. Let $\varphi \in \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k)$ with c_φ a continuous cocycle, and $\psi = \varphi \circ \iota \colon \mathcal{N}_{\mathcal{E}} \to \mathrm{Cs}_k$. Since ψ is $\mathcal{R}$-linear and $\mathcal{R}$ acts on Cs_k through ρ_k, $\psi(u(g)n) = \rho_k(u(g))\psi(n)$: ψ is $\mathcal{O}$-linear and D-equivariant into $\mathrm{Cs}_k(u) = W_k/\Lambda_k$. As $c_\varphi = \psi \circ y$, the restriction of $[c_\varphi]$ to D is $\psi_*[y|_D]$ with $[y|_D] \in H^1_f(D, \mathcal{N}_{\mathcal{E}})$ (Step 1). By (Ll3) the hypothesis of Lemma 25.4(2) holds for $F = E$, v, D, the coefficient field K, $V = V_{\mathcal{N}}$, $T = \mathcal{N}_{\mathcal{E}}$, $W = W_k$, $\Lambda = \Lambda_k$, ψ and $e = e_k$; it gives $\ell^{e_k}\,[c_\varphi|_D] \in F'_k \subseteq F_k(v)$ (Step 2). As $\ell^{e_k} = \varpi^{e_k e_{\mathcal{O}}} w$ with $w \in \mathcal{O}^\times$ and $F_k(v)$ is an $\mathcal{O}$-module, $\varpi^{e_k e_{\mathcal{O}}}[c_\varphi|_D] \in F_k(v)$.

Step 4: the length. By Step 3 the image of X_k under restriction lies in $Y_k = \{z \in H^1(D, \mathrm{Cs}_k(u)) : \varpi^{e_k e_{\mathcal{O}}} z \in F_k(v)\}$, so its image in $H^1(D, \mathrm{Cs}_k(u))/F_k(v)$ is a submodule of $Y_k/F_k(v)$. By Lemma 25.4(3), with the divisible submodule $F' = F_k(v)$ (Step 2), $a = e_k e_{\mathcal{O}}$ and $\dim_K W_k = n_k$, $\mathrm{nl}(Y_k/F_k(v)) \leq ([E_v : \mathbb{Q}_\ell] + 2)\, n_k\, e_k = \lambda_k(v)$. A submodule has at most the length of the module; this is (Gd7) at v.

Step 5: no column loss. If $\mathcal{N} = \mathcal{N}_{\mathcal{E}}$ and $\iota = \mathrm{id}$, the map $\varphi \mapsto \varphi \circ \iota$ of (Gd6) is the identity, with kernel 0; so (Gd6) holds with $\kappa_k = 0$. □

Lemma 25.4. *Let F be a number field, ℓ a prime, v a place of F above ℓ and $D \subseteq G_F$ a decomposition group at v. Let K be a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$, uniformiser ϖ and $e_{\mathcal{O}} = v_\varpi(\ell)$. Let V and W be finite-dimensional K-vector spaces with continuous K-linear actions of D, and $T \subset V$, $\Lambda \subset W$ D-stable $\mathcal{O}$-lattices (finitely generated $\mathcal{O}$-submodules spanning V, W over K). For a D-stable $\mathcal{O}$-lattice T' in such a representation V' let $H^1_f(D, T')$ be the inverse image of $H^1_f(D, V')$ under $H^1(D, T') \to H^1(D, V')$, and put*

$$H^1_f(D, W/\Lambda) = \mathrm{Im}\big(H^1_f(D, W) \to H^1(D, W/\Lambda)\big),$$

W/Λ carrying the discrete topology. Let $\psi \colon T \to W/\Lambda$ be an $\mathcal{O}$-linear D-equivariant map. Then:

1. *$\widetilde{T}_\psi = \{(t, w) \in T \oplus W : \psi(t) = w + \Lambda\}$ is a D-stable $\mathcal{O}$-lattice in $V \oplus W$, and the first projection pr_1 maps it onto T;*

2. *ψ is continuous, and if $e \geq 0$ is an integer with $\ell^e H^1_f(D,T) \subseteq \mathrm{pr}_{1*} H^1_f(D,\widetilde{T}_\psi)$, then $\ell^e \psi_*(x) \in H^1_f(D,W/\Lambda)$ for every $x \in H^1_f(D,T)$;*

3. *let $F' \subseteq H^1(D,W/\Lambda)$ be a divisible $\mathcal{O}$-submodule and $a \geq 0$ an integer; then*

$$\mathrm{nl}\Big(\{z \in H^1(D,W/\Lambda) :\ \varpi^a z \in F'\}/F'\Big) \leq \big([F_v:\mathbb{Q}_\ell]+2\big)\,\dim_K W\,\frac{a}{e_{\mathcal{O}}};$$

and $H^1_f(D,W/\Lambda)$ is divisible.

Proof. **Item 1.** $\widetilde{T}_\psi$ is an $\mathcal{O}$-submodule because ψ is $\mathcal{O}$-linear, and it is D-stable because $\psi(gt) = g\psi(t) = gw+\Lambda$ when $\psi(t) = w+\Lambda$ (Λ is D-stable). The image $\psi(T)$ is a finitely generated $\mathcal{O}$-submodule of the torsion module W/Λ, so it is killed by ϖ^b for some $b \geq 0$, i.e. $\psi(T) \subseteq \varpi^{-b}\Lambda/\Lambda$. Hence

$$\varpi^b T \oplus \Lambda \ \subseteq\ \widetilde{T}_\psi \ \subseteq\ T \oplus \varpi^{-b}\Lambda :$$

for the left inclusion, $\psi(\varpi^b t) = \varpi^b\psi(t) = 0 = 0+\Lambda$ and $\psi(0) = 0 = \lambda+\Lambda$ for $\lambda \in \Lambda$; for the right one, $w+\Lambda = \psi(t) \in \varpi^{-b}\Lambda/\Lambda$ gives $w \in \varpi^{-b}\Lambda$. The right side is finitely generated over the noetherian ring $\mathcal{O}$, so $\widetilde{T}_\psi$ is finitely generated (and free, being torsion-free over a discrete valuation ring), and the left side spans $V \oplus W$ over K. So $\widetilde{T}_\psi$ is a D-stable lattice. For $t \in T$ choose $w \in W$ with $w+\Lambda = \psi(t)$; then $(t,w) \in \widetilde{T}_\psi$, so $\mathrm{pr}_1(\widetilde{T}_\psi) = T$.

Item 2. ψ vanishes on the open subgroup $\varpi^b T$ of T, so it is continuous for the ϖ-adic topology of T and the discrete topology of W/Λ; hence $\psi \circ c$ is a continuous cocycle for every continuous cocycle $c\colon D \to T$, and ψ_* is defined on $H^1(D,T)$. Let $x = [c] \in H^1_f(D,T)$. By hypothesis there is a continuous cocycle $\tilde{c} = (c_1,c_2)\colon D \to \widetilde{T}_\psi$ whose class in $H^1(D,V\oplus W)$ lies in $H^1_f(D,V\oplus W)$ and with $\ell^e x = \mathrm{pr}_{1*}[\tilde{c}] = [c_1]$; so there is $t_0 \in T$ with $\ell^e c(g) = c_1(g) + gt_0 - t_0$ for all $g \in D$. Since $\tilde{c}(g) \in \widetilde{T}_\psi$, $\psi(c_1(g)) = c_2(g)+\Lambda$. The map $c_2\colon D \to W$ is a continuous cocycle (the second component of one), and its class lies in $H^1_f(D,W)$: there is $y \in (V\oplus W)\otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}} = (V\otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}) \oplus (W \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}})$ with $\tilde{c}(g)\otimes 1 = gy - y$, and the second component y_2 of y satisfies $c_2(g)\otimes 1 = gy_2 - y_2$, the action being componentwise. Therefore, for $g \in D$,

$$\psi(\ell^e c(g)) = \psi(c_1(g)) + \psi(gt_0 - t_0) = \big(c_2(g)+\Lambda\big) + \big(g\psi(t_0) - \psi(t_0)\big),$$

so $\ell^e\psi_*(x)$ is the image of $[c_2] \in H^1_f(D,W)$ in $H^1(D,W/\Lambda)$, the second term being a coboundary of the discrete module W/Λ. This is the claim.

Item 3. Write $\mathrm{Cs} = W/\Lambda$, $d = \dim_K W$, $H = H^1(D,\mathrm{Cs})$ and $Y = \{z \in H : \varpi^a z \in F'\}$. $Y = H[\varpi^a] + F'$. If $z \in Y$, then $\varpi^a z \in F' = \varpi^a F'$ (F' is divisible), say $\varpi^a z = \varpi^a f'$ with $f' \in F'$, and $z - f' \in H[\varpi^a]$; the other inclusion is clear. So Y/F' is a quotient of $H[\varpi^a]$. *$H[\varpi^a]$ is a quotient of $H^1(D,M)$, $M = \mathrm{Cs}[\varpi^a]$.* Multiplication by ϖ^a on Cs is surjective ($w+\Lambda = \varpi^a(\varpi^{-a}w+\Lambda)$) with kernel $M = \varpi^{-a}\Lambda/\Lambda$; the long exact cohomology sequence of $0 \to M \to \mathrm{Cs} \xrightarrow{\varpi^a} \mathrm{Cs} \to 0$ (discrete D-modules) contains $H^1(D,M) \to H \xrightarrow{\varpi^a} H$, so the image of the first map is $H[\varpi^a]$. *The size of $H^1(D,M)$.* $M \cong \Lambda/\varpi^a\Lambda \cong (\mathcal{O}/\varpi^a)^d$ is a finite $\mathcal{O}$-module of length ad, killed by ℓ^r for $r = \lceil a/e_{\mathcal{O}}\rceil$, with a continuous action of $D = G_{F_v}$. By Theorem B.29(4) ($v \mid \ell$), $\#H^1(D,M) = \#H^0(D,M)\,\#H^2(D,M)\,(\#M)^{[F_v:\mathbb{Q}_\ell]}$. Here $\#H^0(D,M) \leq \#M$, and by Theorem B.29(2) with $i=2$ the pairing $H^2(D,M)\times H^0(D,M^\vee) \to \mathbb{Z}/\ell^r$ is perfect, so $\#H^2(D,M) = \#H^0(D,M^\vee) \leq \#M^\vee = \#M$. Hence $\#H^1(D,M) \leq (\#M)^{[F_v:\mathbb{Q}_\ell]+2}$. All these groups are finite $\mathcal{O}$-modules, and a finite $\mathcal{O}$-module X has $\#X = q^{\mathrm{length}_{\mathcal{O}}X}$; so $\mathrm{length}_{\mathcal{O}} H^1(D,M) \leq ([F_v:\mathbb{Q}_\ell]+2)\,a\,d$. Lengths do not increase under quotients, and dividing by $e_{\mathcal{O}}$ gives the bound. Finally $H^1_f(D,W)$ is a K-subspace of $H^1(D,W)$, hence divisible, and its image under the $\mathcal{O}$-linear map $H^1(D,W) \to H^1(D,W/\Lambda)$ is divisible. □

Lemma 25.5. *Let F be a number field, ℓ a prime, v a place of F above ℓ, $D \subseteq G_F$ a decomposition group at v, and $n_v = [F_v : \mathbb{Q}_\ell]$. Let K be a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$ and uniformiser ϖ, W a K-vector space of finite dimension d with a continuous K-linear action of D which is de Rham as a $\mathbb{Q}_\ell$-representation, $\Lambda \subset W$ a D-stable $\mathcal{O}$-lattice, $\mathrm{Cs} = W/\Lambda$, $H = H^1(D, \mathrm{Cs})$ and $F' = H^1_f(D, \mathrm{Cs})$. Put*

$$d^0(W) = \dim_K \mathrm{Fil}^0 D_{\mathrm{dR}}(W), \qquad D_{\mathrm{dR}}(W) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} W)^D,$$

K acting through W. Let $W' = \mathrm{Hom}_{\mathbb{Q}_\ell}(W, \mathbb{Q}_\ell(1))$ and $\Lambda' = \mathrm{Hom}_{\mathbb{Z}_\ell}(\Lambda, \mathbb{Z}_\ell(1))$, with D acting by $(gf)(w) = g\, f(g^{-1}w)$ and $\mathcal{O}$ by $(\alpha f)(w) = f(\alpha w)$, and $A' = W'/\Lambda'$. For an integer $a \geq 0$ let $Y_a = \{z \in H : \varpi^a z \in F'\}$. Then:

1. $\mathrm{nl}(Y_a/F') = \dfrac{a}{e_{\mathcal{O}}}\, d^0(W) + \mathrm{nl}\big(H^2(D, \Lambda/\varpi^a\Lambda)\big)$;
2. $\mathrm{nl}\big(H^2(D, \Lambda/\varpi^a\Lambda)\big) = \mathrm{nl}\big(H^0(D, A')[\varpi^a]\big) \leq \mathrm{nl}\big(H^0(D, A')\big)$, *and $H^0(D, A')$ is finite if $H^0(D, W') = 0$;*
3. $d^0(W) \leq n_v\, d$; *and if K contains $\tau(F_v)$ for every $\mathbb{Q}_\ell$-embedding τ of F_v into $\overline{\mathbb{Q}}_\ell$, then $d^0(W) = \sum_\tau \sum_{a \geq 0} \dim_K\big(\mathrm{Fil}^a D_{\mathrm{dR},\tau}(W)/\mathrm{Fil}^{a+1} D_{\mathrm{dR},\tau}(W)\big)$, the number of Hodge jumps $a \geq 0$ of W counted with multiplicity over all τ.*

Proof. **Step 0: two facts on torsion modules.** (i) A torsion $\mathcal{O}$-module X with $X[\varpi]$ finite is isomorphic to $(K/\mathcal{O})^c \oplus X_0$ with X_0 finite (dual form of the structure theorem for finitely generated $\mathcal{O}$-modules); c is the *corank* of X, and it is the corank of any divisible submodule X_1 with X/X_1 finite (the image of X_1 in $X/(K/\mathcal{O})^c \cong X_0$ is divisible and finite, hence 0, so $X_1 \subseteq (K/\mathcal{O})^c$ with finite divisible quotient, hence $X_1 = (K/\mathcal{O})^c$). Every $\mathcal{O}$-submodule of $\mathrm{Cs} \cong (K/\mathcal{O})^d$ satisfies the hypothesis. (ii) For such X and $a \geq 0$,

$$\mathrm{length}\, X[\varpi^a] - \mathrm{length}\, X/\varpi^a X = a\, c,$$

because on $(K/\mathcal{O})^c$ multiplication by ϖ^a is onto with kernel of length ac, and on the finite X_0 its kernel and cokernel have equal length.

Step 1: $F' \cong (K/\mathcal{O})^{c_f}$ with $c_f = \dim_K H^1_f(D, W)$. The long exact sequence of $0 \to \Lambda \to W \to \mathrm{Cs} \to 0$ (a set-theoretic section of $W \to \mathrm{Cs}$ is continuous, Cs being discrete) shows that the kernel of $H^1_f(D, W) \to H$ is $L = \iota(H^1(D, \Lambda)) \cap H^1_f(D, W)$, $\iota\colon H^1(D, \Lambda) \to H^1(D, W)$. By Theorem B.30, $H^1(D, \Lambda)$ is finitely generated, so L is finitely generated, and torsion-free as a submodule of a K-vector space, hence free. L spans $H^1_f(D, W)$: if $x = [c] \in H^1_f(D, W)$, the image $c(D)$ of the compact group D is compact, hence contained in $\varpi^{-s}\Lambda$ for some s (the open sets $\varpi^{-s}\Lambda$ increase and cover W), so $\varpi^s c$ is a continuous cocycle with values in Λ and $\varpi^s x \in L$ ($H^1_f(D, W)$ is a K-subspace). Thus L is a lattice in $H^1_f(D, W)$ and $F' \cong H^1_f(D, W)/L \cong (K/\mathcal{O})^{c_f}$. In particular F' is divisible and $\mathrm{length}\, F'[\varpi^a] = a\, c_f$.

Step 2: $X = H^0(D, \mathrm{Cs})$ has corank $h^0 = \dim_K H^0(D, W)$. In $0 \to H^0(D, \Lambda) \to H^0(D, W) \to X \xrightarrow{\partial} H^1(D, \Lambda)$, $H^0(D, \Lambda) = \Lambda \cap H^0(D, W)$ is a lattice in $H^0(D, W)$ (finitely generated as a submodule of Λ; it spans, since $\varpi^s w \in \Lambda$ for $w \in W$ and large s), so the image of $H^0(D, W)$ in X is $\cong (K/\mathcal{O})^{h^0}$. The image of ∂ consists of torsion elements of the finitely generated module $H^1(D, \Lambda)$ (Theorem B.30), so it is finite. By Step 0(i), X has corank h^0.

Step 3: the length of Y_a/F'. Since F' is divisible, $Y_a = H[\varpi^a] + F'$: if $\varpi^a z = \varpi^a f'$ with $f' \in F'$, then $z - f' \in H[\varpi^a]$. Hence $Y_a/F' \cong H[\varpi^a]/(H[\varpi^a] \cap F') = H[\varpi^a]/F'[\varpi^a]$, and by Step 1

$$\mathrm{length}(Y_a/F') = \mathrm{length}\, H[\varpi^a] - a\, c_f.$$

Let $M = \mathrm{Cs}[\varpi^a] = \varpi^{-a}\Lambda/\Lambda \cong \Lambda/\varpi^a\Lambda$, a finite $\mathcal{O}$-module of length ad killed by ℓ^r, $r = \lceil a/e_{\mathcal{O}} \rceil$. The sequence $0 \to M \to \mathrm{Cs} \xrightarrow{\varpi^a} \mathrm{Cs} \to 0$ is exact (Cs is divisible) and gives the exact sequence

$$0 \to X/\varpi^a X \to H^1(D, M) \to H[\varpi^a] \to 0,$$

and $H^0(D, M) = X[\varpi^a]$. By Theorem B.29(4),

$$\operatorname{length} H^1(D, M) = \operatorname{length} H^0(D, M) + \operatorname{length} H^2(D, M) + n_v\, a\, d.$$

With Step 0(ii) and Step 2,

$$\begin{aligned} \operatorname{length} H[\varpi^a] &= \big(\operatorname{length} X[\varpi^a] - \operatorname{length} X/\varpi^a X\big) + \operatorname{length} H^2(D, M) + n_v ad \\ &= a\, h^0 + \operatorname{length} H^2(D, M) + n_v ad, \end{aligned}$$

so $\operatorname{length}(Y_a/F') = a\,(h^0 + n_v d - c_f) + \operatorname{length} H^2(D, M)$.

Step 4: the dimension count. W is de Rham as a $\mathbb{Q}_\ell$-representation, so by Theorem B.43

$$\dim_{\mathbb{Q}_\ell} H^1_f(D, W) = \dim_{\mathbb{Q}_\ell} H^0(D, W) + \dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(W) - \dim_{\mathbb{Q}_\ell} \mathrm{Fil}^0 D_{\mathrm{dR}}(W).$$

All four spaces are K-vector spaces (K acts through W, commuting with D and preserving $\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes W$, and Definition 22.2 defines H^1_f by a K-linear condition), so we may divide by $[K : \mathbb{Q}_\ell]$. Being de Rham, $\dim_{F_v} D_{\mathrm{dR}}(W) = \dim_{\mathbb{Q}_\ell} W = d[K : \mathbb{Q}_\ell]$ ($B^D_{\mathrm{dR}} = F_v$), so $\dim_K D_{\mathrm{dR}}(W) = n_v d$. Hence $c_f = h^0 + n_v d - d^0(W)$, and Step 3 gives $\operatorname{length}(Y_a/F') = a\, d^0(W) + \operatorname{length} H^2(D, M)$. Dividing by $e_{\mathcal{O}}$ gives item 1.

Item 2. By Theorem B.29(2) with $i = 2$, $\#H^2(D, M) = \#H^0(D, M^\vee)$. Since Λ is free over $\mathbb{Z}_\ell$, $\mathrm{Hom}_{\mathbb{Z}_\ell}(\Lambda, \mathbb{Q}_\ell/\mathbb{Z}_\ell(1)) = W'/\Lambda' = A'$, and $M^\vee = \mathrm{Hom}(\Lambda/\varpi^a\Lambda, \mu_{\ell^r})$ is the submodule of homomorphisms vanishing on $\varpi^a\Lambda$, i.e. $A'[\varpi^a]$ for the $\mathcal{O}$-structure of the statement; the identification is D-equivariant. So $H^0(D, M^\vee) = H^0(D, A')[\varpi^a]$; both $H^2(D, M)$ and this group are finite $\mathcal{O}$-modules ($M^\vee$ is an $\mathcal{O}$-module through M), and equal orders give equal lengths. If $H^0(D, W') = 0$, the sequence $0 = H^0(D, W') \to H^0(D, A') \xrightarrow{\partial} H^1(D, \Lambda')$ of $0 \to \Lambda' \to W' \to A' \to 0$ embeds the torsion module $H^0(D, A')$ into the torsion of $H^1(D, \Lambda')$, which is finite by Theorem B.30 (Λ' is a finitely generated $\mathcal{O}$-module with continuous action).

Item 3. $d^0(W) \le \dim_K D_{\mathrm{dR}}(W) = n_v d$ (Step 4). If K contains every $\tau(F_v)$, then $F_v \otimes_{\mathbb{Q}_\ell} K \cong \prod_\tau K$ ($F_v/\mathbb{Q}_\ell$ is separable), with idempotents e_τ; $D_{\mathrm{dR}}(W)$ and each $\mathrm{Fil}^a D_{\mathrm{dR}}(W)$ are $F_v \otimes K$-modules, so $\mathrm{Fil}^a D_{\mathrm{dR}}(W) = \bigoplus_\tau e_\tau \mathrm{Fil}^a D_{\mathrm{dR}}(W)$ and $e_\tau \mathrm{Fil}^a D_{\mathrm{dR}}(W) = \mathrm{Fil}^a D_{\mathrm{dR},\tau}(W)$. The filtration of the finite-dimensional space $D_{\mathrm{dR},\tau}(W)$ is decreasing, with $\mathrm{Fil}^a = 0$ for large a (as $\bigcap_a t^a B^+_{\mathrm{dR}} = 0$), so $\dim_K \mathrm{Fil}^0 D_{\mathrm{dR},\tau}(W) = \sum_{a \ge 0} \dim_K(\mathrm{Fil}^a/\mathrm{Fil}^{a+1})$, and summing over τ gives the formula. □

Corollary 25.6. *Let E be a number field, ℓ an odd prime, Galois Ribet data over E with $t+1$ blocks having (Gd1) and (Gd2), $K = \mathcal{O}[\ell^{-1}]$, and v a place of E above ℓ, $D = G_{E_v}$, $n_v = [E_v : \mathbb{Q}_\ell]$, such that: $E_v \subseteq E_{v,0}(\mu_\ell)$, $E_{v,0}$ the maximal unramified subextension of $E_v/\mathbb{Q}_\ell$; K contains $\sigma(E_{v,0}(\mu_\ell))$ for every $\mathbb{Q}_\ell$-embedding σ of $E_{v,0}(\mu_\ell)$ into $\overline{\mathbb{Q}}_\ell$; (Ll1) and (Ll2) hold; and $M_0, h_0 \ge 0$ are integers with $J(V_{\mathcal{N}}) \subseteq [-M_0, h_0]$. Then for $1 \le k \le t$ and every $x \in X_k$,*

$$\ell^{\,c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)}\, x|_D \in H^1_f(D, \mathrm{Cs}_k(u)),$$

and the image of X_k in $H^1(D, \mathrm{Cs}_k(u))/F_k(v)$ has normalised length at most $c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)\, n_v + w_k(v)$. If moreover $H^0(D, W_0') = 0$ and $e_0 \ge 0$ is an integer with $\ell^{e_0} H^1_f(D, \mathcal{N}_{\mathcal{E}}) \subseteq \mathrm{pr}_{1*} H^1_f(D, \widetilde{T}_\psi)$ for every $\mathcal{O}$-linear D-equivariant $\psi\colon \mathcal{N}_{\mathcal{E}} \to \mathrm{Cs}_0(u)$, then (Gd7) holds at v with

$$\lambda_0(v) = e_0\, d^0(W_0) + h_0(v), \qquad \lambda_k(v) = c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)\, n_v + w_k(v) \quad (1 \le k \le t).$$

Level s. *More generally, let ℓ be a prime and $s \geq 1$ an integer with $s \geq 2$ if $\ell = 2$, and replace the two field conditions above by: $E_v \subseteq E_{v,0}(\mu_{\ell^s})$, and K contains $\sigma(E_{v,0}(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ of $E_{v,0}(\mu_{\ell^s})$ into $\overline{\mathbb{Q}}_\ell$; keep the other hypotheses. Then all assertions above hold with $c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$ replaced by $c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1)$ of Proposition 25.8 (paragraph Level s, with $p = \ell$). For $s = 1$ and ℓ odd this is the statement above.* ***Descent.*** *Let ℓ be a prime, $N \geq 1$ an integer with $4 \mid N$ if $\ell = 2$, $s = \max(1, v_\ell(N))$ and $N_\ell = \mathrm{lcm}(\ell, N)$, and replace the two field conditions by: E_v is $\mathbb{Q}_\ell$-isomorphic to a subfield of $\mathbb{Q}_\ell(\mu_{N_\ell})$, and K contains a primitive N_ℓ-th root of unity; keep the other hypotheses. Then all assertions above hold with $c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$ replaced by $c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1) + s - 1$.*

Proof. We prove the first assertion and the assertion of the paragraph Level s together. In the first case put $s = 1$ and $c_k = c_{\mathrm{B}}(V_{\mathcal{N}}, k-1)$; in the second put $c_k = c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1)$ $(1 \leq k \leq t)$. In both cases $s \geq 2$ if $\ell = 2$, $E_v \subseteq E_{v,0}(\mu_{\ell^s})$ and K contains $\sigma(E_{v,0}(\mu_{\ell^s}))$ for every $\mathbb{Q}_\ell$-embedding σ; only Step 2 uses these conditions, and no step uses that ℓ is odd otherwise.

Step 1: the crystalline extension carrying the Ribet cocycle. By Theorem 25.3 ((Ll1), (Gd1), (Gd2)), $V_{\mathcal{N}}$ is crystalline, $\mathcal{N}_{\mathcal{E}}$ is a D-stable lattice in it, and $[y|_D] \in H^1_f(D, \mathcal{N}_{\mathcal{E}})$, i.e. the class of $y|_D$ in $H^1(D, V_{\mathcal{N}})$ lies in $H^1_f(D, V_{\mathcal{N}})$: there is $y_B \in V_{\mathcal{N}} \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g) \otimes 1 = g y_B - y_B$ for $g \in D$. Let $Y = V_{\mathcal{N}} \oplus K$ with $g(n, a) = (u(g)n + a\, y(g), a)$; as y is a cocycle for the action $n \mapsto u(g)n$ $(y(gh) = (u(gh) - 1)\mathcal{E} = u(g)y(h) + y(g))$, this is a continuous K-linear action, $T_Y = \mathcal{N}_{\mathcal{E}} \oplus \mathcal{O}$ is a D-stable lattice $(y(g) \in \mathcal{N}_{\mathcal{E}})$, $\beta(n, a) = a$ is an invariant form with $\beta(T_Y) = \mathcal{O}$, $\ker \beta = V_{\mathcal{N}} \oplus 0$ with $T_Y \cap \ker \beta = \mathcal{N}_{\mathcal{E}} \oplus 0$, and $y_0 = (0, 1)$ has $\beta(y_0) = 1$ and $g y_0 - y_0 = (y(g), 0)$. *Y is crystalline.* For $\alpha \in K$, $z_\alpha = (-\alpha y_B, \alpha \otimes 1) \in Y \otimes B_{\mathrm{cris}}$ satisfies $g z_\alpha = (-\alpha\, g y_B + \alpha\, y(g) \otimes 1, \alpha \otimes 1) = z_\alpha$. Write $D_{\mathrm{cris}}(X) = (X \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}})^D$, left exact in X. The second projection $D_{\mathrm{cris}}(Y) \to D_{\mathrm{cris}}(K) = K \otimes_{\mathbb{Q}_\ell} E_{v,0}$ has kernel $D_{\mathrm{cris}}(V_{\mathcal{N}})$ and its image contains every $\alpha \otimes 1$, hence is onto (an $E_{v,0}$-linear map). So $\dim_{E_{v,0}} D_{\mathrm{cris}}(Y) = \dim_{\mathbb{Q}_\ell} V_{\mathcal{N}} + [K : \mathbb{Q}_\ell] = \dim_{\mathbb{Q}_\ell} Y$.

Step 2: the character blocks. Let $1 \leq k \leq t$, $x \in X_k$ the class of c_φ, and $\psi = \varphi \circ \iota$. As in Definition 17.2, ψ is $\mathcal{O}$-linear with $\psi(u(g)n) = \rho_k(u(g))\psi(n) = \chi_{\mathrm{cyc}}(g)^{1-k}\psi(n)$ by (Gd1) (φ, ι are $\mathcal{R}$-linear and $\mathcal{R}$ acts on Cs_k through ρ_k), and $\mathrm{Cs}_k(u) = K/\mathcal{O}$ with this action is $L(-e)/\mathcal{O}_L(-e)$ for $L = K$, $e = k - 1$. Apply Proposition 25.8 (in the second case its paragraph Level s, with this s) with $p = \ell$, its K equal to E_v (so its K_0 is $E_{v,0}$; the inclusion into $E_{v,0}(\mu_{\ell^s})$ and the condition on $L = K$ are hypotheses here), Y, T_Y, β, y_0 of Step 1, $V = V_{\mathcal{N}}$ (de Rham, being crystalline), $T = \mathcal{N}_{\mathcal{E}}$, M_0, h_0, $e = k - 1$ and φ replaced by ψ (on T, gx is $u(g)x$). Since $\psi(g y_0 - y_0) = \psi(y(g)) = c_\varphi(g)$ for $g \in D$, it gives $\ell^{c_k} x|_D \in H^1_f(D, \mathrm{Cs}_k(u))$.

Step 3: block 0, under the additional hypotheses on $H^0(D, W_0')$ and e_0. For $x \in X_0$ the class of c_φ and $\psi = \varphi \circ \iota$, ψ is $\mathcal{O}$-linear and D-equivariant into $\mathrm{Cs}_0(u) = W_0/\Lambda_0$ and $x|_D = \psi_*[y|_D]$ with $[y|_D] \in H^1_f(D, \mathcal{N}_{\mathcal{E}})$ (Step 1); the hypothesis on e_0 is that of Lemma 25.4(2) for $T = \mathcal{N}_{\mathcal{E}}$, $W = W_0$, $\Lambda = \Lambda_0$, ψ, $e = e_0$, which gives $\ell^{e_0} x|_D \in H^1_f(D, \mathrm{Cs}_0(u))$.

Step 4: the losses. For $1 \leq k \leq t$, Step 2 is the hypothesis of Theorem 25.7(1) for the block k with this c_k, and by Theorem 25.7(3), $d^0(W_k) = n_v$ and $h_k(v) = w_k(v) < \infty$; so Theorem 25.7(1) bounds the normalised length of the image of X_k by $c_k n_v + w_k(v)$. Under the additional hypotheses, Step 3 is the hypothesis of Theorem 25.7(1) for the block 0 with $c_0 = e_0$, and $h_0(v) < \infty$ by Theorem 25.7(4) as $H^0(D, W_0') = 0$; so Theorem 25.7(1) bounds the image of X_0 by $e_0 d^0(W_0) + h_0(v)$, and (Gd7) holds at v with the stated $\lambda_k(v)$, $0 \leq k \leq t$.

Descent. Put $c_k = c_{\mathrm{B},s}(V_{\mathcal{N}}, k-1) + s - 1$. As $\mathbb{Q}_\ell(\mu_{N_\ell})$ is Galois over $\mathbb{Q}_\ell$, $E_v \subseteq \mathbb{Q}_\ell(\mu_{N_\ell})$ inside $\overline{\mathbb{Q}}_\ell$. Steps 1, 3 and 4 do not use the field conditions. In Step 2 apply the paragraph Descent of Proposition 25.8 (with $p = \ell$, this N, its K equal to E_v and its L equal to our K, which contains a primitive N_ℓ-th root of unity) instead of its paragraph Level s; with the same

data it gives $\ell^{c_k} x|_D \in H^1_f(D, \mathrm{Cs}_k(u))$, and Step 4 then gives the bound $c_k n_v + w_k(v)$ and (Gd7) with $\lambda_k(v) = c_k n_v + w_k(v)$ for $k \geq 1$. □

Theorem 25.7. *Let E be a number field, ℓ a prime, and Galois Ribet data over E with $t+1$ blocks having (Gd1) and (Gd2); put $K = \mathcal{O}[\ell^{-1}]$. Let v be a place of E above ℓ, $D = G_{E_v}$, $n_v = [E_v : \mathbb{Q}_\ell]$, and suppose (Ll1) and (Ll2). For $0 \leq k \leq t$ put*

$$h_k(v) = \mathrm{nl}\big(H^0(D, W_k'/\Lambda_k')\big) \in [0, \infty].$$

1. *Let $0 \leq k \leq t$ and let $c_k \geq 0$ be an integer such that $\ell^{c_k} x|_D \in H^1_f(D, \mathrm{Cs}_k(u))$ for every $x \in X_k$. If $h_k(v) < \infty$, then the image of X_k in $H^1(G_{E_v}, \mathrm{Cs}_k(u))/F_k(v)$ has normalised length at most*
$$\lambda_k(v) = c_k\, d^0(W_k) + h_k(v);$$
so (Gd7) holds at v with these local losses when such integers $c_0, \dots, c_t$ are given and all $h_k(v)$ are finite.

2. *If (Ll3) holds with integers $e_0, \dots, e_t$, the hypothesis of item 1 holds for every k with $c_k = e_k$.*

3. *For $1 \leq k \leq t$: $d^0(W_k) = n_v$, and $h_k(v) = w_k(v)$, where $w_k(v) \geq 0$ is the largest integer w with $\chi_{\mathrm{cyc}}(g)^k \equiv 1 \bmod \ell^w$ for all $g \in D$ (finite).*

4. *For $k = 0$: $d^0(W_0) \leq n_v\, n_{\mathcal{R},0}$; if K contains $\tau(E_v)$ for every $\mathbb{Q}_\ell$-embedding τ of E_v into $\overline{\mathbb{Q}}_\ell$ and, for each τ, at most μ_τ Hodge jumps $a \geq 0$ of W_0 at τ counted with multiplicity occur, then $d^0(W_0) \leq \sum_\tau \mu_\tau$; and $h_0(v) < \infty$ if $H^0(D, W_0') = 0$.*

In particular, under (Ll1)–(Ll3), $H^0(D, W_0') = 0$ and the jump condition of item 4, (Gd7) holds at v with $\lambda_0(v) = e_0 \sum_\tau \mu_\tau + h_0(v)$ and $\lambda_k(v) = e_k\, n_v + w_k(v)$ for $1 \leq k \leq t$.

Proof. **Step 1: the blocks are de Rham, and $F_k' = H^1_f(D, \mathrm{Cs}_k(u)) \subseteq F_k(v)$.** By Theorem 25.3, under (Ll1) and (Gd1), (Gd2) every W_k is a crystalline representation of D, hence de Rham, and Λ_k is a D-stable lattice with $W_k/\Lambda_k = \mathrm{Cs}_k(u)$. For $k = 0$, $F_0' = F_0(v)$ by (Ll2). For $k = 1$, $\rho_1(u(g)) = \chi_1(g)^{-1}\chi_1(g) = 1$ by (Gd1), so $W_1 = K$ with trivial action; in a $\mathbb{Q}_\ell$-basis of K the condition of Definition 22.2 is componentwise, and by Theorem B.44 $H^1_f(D, K)$ consists of the homomorphisms $D \to K$ vanishing on the inertia group; their images in $H^1(D, K/\mathcal{O})$ vanish on inertia, so $F_1' \subseteq H^1_{\mathrm{ur}}(E_v, \mathrm{Cs}_1(u)) = F_1(v)$. For $k \geq 2$, $\rho_k(u(g)) = \chi_{\mathrm{cyc}}(g)^{1-k}$ by (Gd1), so W_k is a sum of copies of $\mathbb{Q}_\ell(s)$, $s = 1-k \leq -1$; for this line $H^0(D, \mathbb{Q}_\ell(s)) = 0$ ($\chi_{\mathrm{cyc}}(D)$ is infinite) and $D_{\mathrm{dR}}(\mathbb{Q}_\ell(s)) = E_v\, t^{-s} \otimes \epsilon$ (ϵ a basis; $b \otimes \epsilon$ is invariant if and only if $bt^s \in B_{\mathrm{dR}}^D = E_v$), which lies in $\mathrm{Fil}^{-s} \subseteq \mathrm{Fil}^0$; so Theorem B.43 gives $H^1_f(D, \mathbb{Q}_\ell(s)) = 0$, hence $F_k' = 0 = F_k(v)$.

Step 2: item 1. Fix k with $h_k(v) < \infty$ and put $a = c_k e_{\mathcal{O}}$. Since $\ell^{c_k} = \varpi^a w$ with $w \in \mathcal{O}^\times$ and F_k' is an $\mathcal{O}$-module, the hypothesis gives $\varpi^a x|_D \in F_k'$, i.e. $x|_D \in Y_a$ for every $x \in X_k$, with Y_a formed for $W = W_k$, $\Lambda = \Lambda_k$. The image of X_k in $H^1(D, \mathrm{Cs}_k(u))/F_k'$ is therefore a submodule of Y_a/F_k', and its image in $H^1(D, \mathrm{Cs}_k(u))/F_k(v)$ is a quotient of it, because $F_k' \subseteq F_k(v)$ (Step 1). By Lemma 25.5(1),(2), applied with $F = E$, v, D, the coefficient field K, $W = W_k$ (de Rham, Step 1) and $\Lambda = \Lambda_k$,

$$\mathrm{nl}(Y_a/F_k') \leq \frac{a}{e_{\mathcal{O}}}\, d^0(W_k) + \mathrm{nl}\big(H^0(D, W_k'/\Lambda_k')\big) = c_k\, d^0(W_k) + h_k(v).$$

Lengths do not increase under passage to submodules and quotients; this is the bound.

Step 3: item 2. Let $x \in X_k$ be the class of c_φ, $\varphi \in \mathrm{Hom}_{\mathcal{R}}(\mathcal{N}, \mathrm{Cs}_k)$, and $\psi = \varphi \circ \iota \colon \mathcal{N}_{\mathcal{E}} \to \mathrm{Cs}_k$. Both maps are $\mathcal{R}$-linear and $\mathcal{R}$ acts on Cs_k through ρ_k, so $\psi(u(g)n) = \rho_k(u(g))\psi(n)$: ψ

is $\mathcal{O}$-linear and D-equivariant into $\mathrm{Cs}_k(u) = W_k/\Lambda_k$, and $c_\varphi = \psi \circ y$, so $x|_D = \psi_*[y|_D]$. By Theorem 25.3 (which uses (Ll1), (Gd1), (Gd2)), $V_{\mathcal{N}}$ is crystalline, $\mathcal{N}_{\mathcal{E}}$ is a D-stable lattice in it and $[y|_D] \in H^1_f(D, \mathcal{N}_{\mathcal{E}})$. (Ll3) is the hypothesis of Lemma 25.4(2) for $T = \mathcal{N}_{\mathcal{E}} \subset V = V_{\mathcal{N}}$, $\Lambda = \Lambda_k \subset W = W_k$, ψ and $e = e_k$; it gives $\ell^{e_k}\psi_*[y|_D] \in H^1_f(D, \mathrm{Cs}_k(u))$.

Step 4: item 3. Let $1 \le k \le t$. $W_k = K$ with g acting by $\chi_{\mathrm{cyc}}(g)^{1-k}$ (Step 1). $D_{\mathrm{dR}}(W_k) = D_{\mathrm{dR}}(\mathbb{Q}_\ell(1-k)) \otimes_{\mathbb{Q}_\ell} K$ has K-dimension n_v and lies in Fil^0 (Step 1, also for $k = 1$: $D_{\mathrm{dR}}(K) = E_v \otimes K \subseteq \mathrm{Fil}^0$), so $d^0(W_k) = n_v$. For $f \in \Lambda'_k = \mathrm{Hom}_{\mathbb{Z}_\ell}(\mathcal{O}, \mathbb{Z}_\ell(1))$ and $g \in D$, $(gf)(x) = \chi_{\mathrm{cyc}}(g)\, f(\chi_{\mathrm{cyc}}(g)^{k-1}x) = \chi_{\mathrm{cyc}}(g)^k f(x)$, as f is $\mathbb{Z}_\ell$-linear; so $W'_k/\Lambda'_k \cong (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^{[K:\mathbb{Q}_\ell]}$ as a group, with g acting by the scalar $\chi_{\mathrm{cyc}}(g)^k$. An element is invariant if and only if each coordinate is killed by $\chi_{\mathrm{cyc}}(g)^k - 1$ for all $g \in D$, i.e. by ℓ^w, $w = w_k(v)$; $w_k(v)$ is finite since $\chi_{\mathrm{cyc}}(D)$ is an open subgroup of $\mathbb{Z}_\ell^\times$, which contains elements χ with $\chi^k \ne 1$. Hence $\#H^0(D, W'_k/\Lambda'_k) = \ell^{w[K:\mathbb{Q}_\ell]} = q^{w\, e_{\mathcal{O}}}$ with $q = \ell^{[K:\mathbb{Q}_\ell]/e_{\mathcal{O}}}$ the order of the residue field, so its length is $w\, e_{\mathcal{O}}$ and $h_k(v) = w_k(v)$.

Step 5: item 4. W_0 has dimension $n_{\mathcal{R},0}$; Lemma 25.5(3) gives $d^0(W_0) \le n_v n_{\mathcal{R},0}$ and, under the condition on K, $d^0(W_0) = \sum_\tau$(number of Hodge jumps $a \ge 0$ at τ with multiplicity) $\le \sum_\tau \mu_\tau$; Lemma 25.5(2) gives finiteness of $h_0(v)$ when $H^0(D, W'_0) = 0$. The final sentence combines items 1–4. □

25.2 Torsion classes with coefficients in truncations of A_{inf}

The first step towards Proposition 25.8 is Proposition 25.10: if a cocycle of $G_{K_0(\mu_\ell)}$ with values in $T \otimes \xi^a A_{\mathrm{inf}}/\xi^b A_{\mathrm{inf}}$, ξ a generator of $\ker\theta$, becomes a coboundary after multiplication by some power of ℓ, then it does so after multiplication by $\ell^{c_{\mathrm{LL}}(V;a,b)}$, an explicit power determined by the Hodge jumps. The proof decompletes: a crystalline lattice has an integral Sen frame at the level fixed by its Hodge window (Proposition 25.11, built from the Wach lattice of Proposition 25.12), and the twisted cohomology of a Sen frame has bounded torsion (Proposition 25.17), an integral form of the Tate–Sen method. The graded pieces of the truncations are Tate twists of $\mathcal{O}_{\mathbb{C}_\ell}$ (Lemma 25.21). The remaining lemmas are integral versions of standard facts: Frobenius integrality in $W(\mathbb{C}_\ell^\flat)$, Frobenius heights of the Breuil–Kisin–Fargues module, the normalised trace on the cyclotomic tower, and the almost vanishing of its first cohomology.

Proposition 25.8. *Let p be an odd prime, K a finite extension of $\mathbb{Q}_p$ with maximal unramified subextension K_0 such that $K \subseteq K_0(\mu_p)$, and L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_0(\mu_p))$ for every $\mathbb{Q}_p$-embedding σ of $K_0(\mu_p)$ into $\overline{\mathbb{Q}}_p$, with ring of integers $\mathcal{O}_L$. For a finite-dimensional continuous L-linear representation V of G_K, de Rham over $\mathbb{Q}_p$, let $J(V)$ be the set of integers a with $\mathrm{Fil}^{a+1}D_{\mathrm{dR}}(V) \ne \mathrm{Fil}^a D_{\mathrm{dR}}(V)$, $D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}$.*

Let Y be a crystalline L-linear representation of G_K with a G_K-stable $\mathcal{O}_L$-lattice T_Y, let $\beta\colon Y \to L$ be a G_K-invariant L-linear form with $\beta(T_Y) \subseteq \mathcal{O}_L$, $V = \ker\beta$ and $T = T_Y \cap V$, and let $y_0 \in T_Y$ with $\beta(y_0) = 1$. Let $M_0, h_0 \ge 0$ be integers with $J(V) \subseteq [-M_0, h_0]$, put $H = M_0 + h_0$, $n_0 = \min\{n \ge 0 :\ H \le p^n(p-1)\}$ and $m_N = n_0 + 3$. Let $e \ge 0$ be an integer, $\mathcal{O}_L(-e)$ the lattice $\mathcal{O}_L$ in $L(-e) = L$ with g acting by $\chi_{\mathrm{cyc}}(g)^{-e}$, and $\varphi\colon T \to L/\mathcal{O}_L$ an $\mathcal{O}_L$-linear map with $\varphi(gx) = \chi_{\mathrm{cyc}}(g)^{-e}\varphi(x)$ for $g \in G_K$, $x \in T$. Put

$$r_i = \sum_{u \in J(V),\, u \ne i} (m_N + v_p(u-i)) \quad (0 \le i \le e),$$

$$c_{\mathrm{B}}(V,e) = (m_N - 1) + \sum_{i=0}^{e}(2 + \max(1, r_i)) + (e+2) + v_p(e) + \Big\lfloor \frac{e}{p-1} \Big\rfloor + 2 + v_p(e+1).$$

Then $g \mapsto \varphi(gy_0 - y_0)$ is a continuous 1-cocycle of G_K with values in $L(-e)/\mathcal{O}_L(-e)$, and

$$p^{\,c_{\mathrm{B}}(V,e)}\,[g \mapsto \varphi(gy_0 - y_0)] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e)).$$

Level s. *More generally, let p be a prime, $s \geq 1$ an integer with $s \geq 2$ if $p = 2$, K a finite extension of $\mathbb{Q}_p$ with maximal unramified subextension K_0 such that $K \subseteq K_s := K_0(\mu_{p^s})$, and L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_s)$ for every $\mathbb{Q}_p$-embedding σ of K_s, with ring of integers $\mathcal{O}_L$; let Y, T_Y, β, V, T, y_0, M_0, h_0, H, n_0, e and φ be as above, and put $m_{N,s} = 2s + n_0 + 1$,*

$$r_i^{(s)} = \sum_{u \in J(V),\, u \neq i} (m_{N,s} + v_p(u-i)) \quad (0 \leq i \leq e),$$

$$c_{\mathrm{B},s}(V,e) = (m_{N,s} - s) + \sum_{i=0}^{e} (2 + \max(1, r_i^{(s)})) + s(e+4) + v_p(e) + \Big\lfloor \frac{e}{p-1} \Big\rfloor + v_p(e+1).$$

Then $g \mapsto \varphi(gy_0 - y_0)$ is a continuous 1-cocycle of G_K with values in $L(-e)/\mathcal{O}_L(-e)$, and $p^{c_{\mathrm{B},s}(V,e)}[g \mapsto \varphi(gy_0 - y_0)] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$. For $s = 1$ and p odd, $m_{N,1} = m_N$, $r_i^{(1)} = r_i$, $c_{\mathrm{B},1} = c_{\mathrm{B}}$, and this is the statement above.

Descent. *Let p be a prime, $N \geq 1$ an integer with $4 \mid N$ if $p = 2$, $s = \max(1, v_p(N))$, $N_p = \mathrm{lcm}(p, N)$, K a field with $\mathbb{Q}_p \subseteq K \subseteq \mathbb{Q}_p(\mu_{N_p})$ inside $\overline{\mathbb{Q}}_p$, and L a finite extension of $\mathbb{Q}_p$ containing a primitive N_p-th root of unity, with ring of integers $\mathcal{O}_L$; let Y, T_Y, β, V, T, y_0, M_0, h_0, e and φ be as above, for G_K. Then $p^{c_{\mathrm{B},s}(V,e)+s-1}[g \mapsto \varphi(gy_0 - y_0)] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$.*

Proof. We prove the assertion of the paragraph Level s; the first assertion is its case $s = 1$, p odd (the hypotheses agree with $K_1 = K_0(\mu_p)$, and $c_{\mathrm{B},1}(V,e) = (m_N - 1) + \sum_{i=0}^{e}(2 + \max(1, r_i)) + (e+4) + v_p(e) + \lfloor e/(p-1) \rfloor + v_p(e+1) = c_{\mathrm{B}}(V,e)$). So let p, s, $K \subseteq K_s$, L and the data be as there.

The cocycle. As β is G_K-invariant, $\beta(gy_0 - y_0) = 0$, so $f(g) := gy_0 - y_0$ lies in $T_Y \cap V = T$; $f(gh) = g(hy_0 - y_0) + (gy_0 - y_0) = f(g) + gf(h)$, and f is continuous because G_K acts continuously on the finite free $\mathbb{Z}_p$-module T_Y. The image of φ is a finitely generated submodule of $L/\mathcal{O}_L$, hence killed by some p^n, so φ factors through T/p^nT and is continuous; with $\varphi(gx) = \chi_{\mathrm{cyc}}(g)^{-e}\varphi(x)$ this shows that $g \mapsto \varphi(f(g))$ is a continuous 1-cocycle with values in $L(-e)/\mathcal{O}_L(-e)$. Also $T = T_Y \cap V$ is a G_K-stable $\mathcal{O}_L$-lattice in V, and V is crystalline by Theorem B.45 (a G_K-stable subspace of the crystalline Y).

The class is torsion modulo ξ^{e+1}. Put $b = e + 1$ and $Q = A_{\mathrm{inf}}/\xi^b A_{\mathrm{inf}}$. The maximal unramified subfield of K_s is K_0 (K_s/K_0 is totally ramified), so $\dim_{K_0}(B_{\mathrm{cris}} \otimes Y)^{G_{K_s}} \geq \dim_{K_0}(B_{\mathrm{cris}} \otimes Y)^{G_K} = \dim_{\mathbb{Q}_p} Y$, and Y is crystalline, hence de Rham [52], as a representation of G_{K_s}; so is the trivial representation L. On de Rham representations $\mathrm{Fil}^0 D_{\mathrm{dR}}$ is exact [52], so the map $(Y \otimes_{\mathbb{Q}_p} B^+_{\mathrm{dR}})^{G_{K_s}} \to (L \otimes_{\mathbb{Q}_p} B^+_{\mathrm{dR}})^{G_{K_s}}$ induced by β is onto; choose y^+ mapping to $1 \otimes 1$ and let $\bar{y}^+$ be its image modulo ξ^b. Since $B^+_{\mathrm{dR}}/\xi^b B^+_{\mathrm{dR}} = Q[1/p]$, the element $m = y_0 \otimes 1 - \bar{y}^+$ of $Y \otimes_{\mathbb{Q}_p} Q[1/p]$ lies in the kernel $V \otimes_{\mathbb{Q}_p} Q[1/p]$ of $\beta \otimes 1$, and $(g-1)m = f(g) \otimes 1$ for $g \in G_{K_s}$, as $\bar{y}^+$ is invariant. Now Q has no p-torsion (it is filtered by the $\xi^i A_{\mathrm{inf}}/\xi^{i+1} A_{\mathrm{inf}} \cong \mathcal{O}_{\mathbb{C}_p}$, ξ being a non-zero-divisor and θ inducing $A_{\mathrm{inf}}/\xi \cong \mathcal{O}_{\mathbb{C}_p}$ [52]), and T is free over $\mathbb{Z}_p$, so $T \otimes_{\mathbb{Z}_p} Q$ embeds into $V \otimes_{\mathbb{Q}_p} Q[1/p]$; m is a finite sum of tensors, so $p^k m \in T \otimes_{\mathbb{Z}_p} Q$ for some $k \geq 0$, and $p^k(f(g) \otimes 1) = (g-1)(p^k m)$ in $T \otimes_{\mathbb{Z}_p} Q$. Thus $z = f|_{G_{K_s}} \otimes 1$, a continuous 1-cocycle of G_{K_s} with values in $T \otimes_{\mathbb{Z}_p} Q$, has $p^k z$ a coboundary.

The two exponents. By Proposition 25.10, paragraph Level s (with V, T, M_0, h_0, $a = 0$, $b = e + 1$; its hypotheses are ours), $p^N z$ is a coboundary for $N = c_{\mathrm{LL},s}(V; 0, e+1) = (m_{N,s} - s) + \sum_{i=0}^{e}(2 + \max(1, r_i^{(s)}))$. By Proposition 25.23, paragraph Level s (with $K \subseteq K_s$, L, T, e, φ, f and this N),

$$p^{N + s(e+4) + v_p(e) + \lfloor e/(p-1) \rfloor + v_p(e+1)}[g \mapsto \varphi(f(g))] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e)),$$

and the exponent is $c_{\mathrm{B},s}(V,e)$.

Descent. Let the data be as in the paragraph Descent of the statement, and $K' = K(\mu_{p^s})$. By Lemma 25.32, $K' = K'_0(\mu_{p^s})$ with K'_0 the maximal unramified subextension of $K'/\mathbb{Q}_p$, $v_p([K' : K]) \le s-1$, and $s \ge 2$ if $p = 2$; and L contains $\sigma(K')$ for every $\mathbb{Q}_p$-embedding σ of K', because $\sigma(K') \subseteq \mathbb{Q}_p(\mu_{N_p}) \subseteq L$ ($\mathbb{Q}_p(\mu_{N_p})$ is Galois over $\mathbb{Q}_p$). Restrict all data to $G_{K'}$: Y is crystalline over K', β is $G_{K'}$-invariant, $\varphi(gx) = \chi_{\mathrm{cyc}}(g)^{-e}\varphi(x)$ for $g \in G_{K'}$, and $J(V|_{G_{K'}}) = J(V)$: for the de Rham representation V the natural map $K' \otimes_K D_{\mathrm{dR},K}(V) \to D_{\mathrm{dR},K'}(V)$ is an isomorphism of filtered K'-vector spaces [94], and K' is faithfully flat over K, so $\mathrm{Fil}^{a+1} \ne \mathrm{Fil}^a$ over K if and only if over K'. So M_0, h_0, H, n_0 and $c_{\mathrm{B},s}(V,e)$ are the same over K', and the paragraph Level s over K' (with K', K'_0 in the roles of K, K_0) gives $p^c\,\mathrm{res}(x) \in H^1_f(G_{K'}, L(-e)/\mathcal{O}_L(-e))$, where x is the class of $g \mapsto \varphi(gy_0 - y_0)$ on G_K, $\mathrm{res}(x)$ the class of its restriction, and $c = c_{\mathrm{B},s}(V,e)$. By item 1 of Lemma 25.33 (for $E = K$, K', $V = L(-e)$, $T = \mathcal{O}_L(-e)$; the group $H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$ is the image of $H^1_f(G_K, L(-e))$, as in Lemma 25.4), $[K' : K]\,p^c x = \mathrm{cor}(p^c \mathrm{res}(x)) \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$. Write $[K' : K] = p^v u$ with $v \le s-1$ and u prime to p; $H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$ is an $\mathcal{O}_L$-submodule, so $p^{c+v}x$, and hence $p^{c+s-1}x$, lies in it. □

Definition 25.9. Let p be a prime and $K_0 \subset \overline{\mathbb{Q}}_p$ a finite unramified extension of $\mathbb{Q}_p$. Write $\mathcal{O}_{\mathbb{C}_p}$ for the valuation ring of $\mathbb{C}_p$, $|\cdot|$ for its absolute value with $|p| = p^{-1}$, $\mathcal{O}_F$ for the valuation ring of a subfield $F \subseteq \mathbb{C}_p$, $K_0(\mu_{p^\infty}) = \bigcup_{n\ge 0} K_0(\mu_{p^n})$ and $H_{K_0} = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K_0(\mu_{p^\infty}))$. A Galois group acts on $\mathbb{C}_p^r$ and on matrices over $\mathbb{C}_p$ entrywise.

Let $m \ge 1$ and $r \ge 0$ be integers, with $m \ge 2$ if $p = 2$, and $J \subset \mathbb{Z}$ a finite set. A **Sen frame** of level m and rank r over K_0 with weights in J is a pair (U, g) of a map $U\colon G_{K_0(\mu_{p^m})} \to M_r(\mathcal{O}_{K_0(\mu_{p^m})})$ and an element $g \in G_{K_0(\mu_{p^m})}$ such that:

(Sf1) U is continuous, $U(\sigma\tau) = U(\sigma)U(\tau)$ for $\sigma, \tau \in G_{K_0(\mu_{p^m})}$, and $U(h) = 1$ for $h \in H_{K_0}$;

(Sf2) $v_p(\chi_{\mathrm{cyc}}(g) - 1) = m$, and $|U(g)_{ab} - \delta_{ab}| < p^{-1/(p-1)}$ for all entries;

(Sf3) there are a $\mathbb{C}_p$-basis $e_1, \dots, e_r$ of $\mathbb{C}_p^r$ and integers $u_1, \dots, u_r \in J$ with

$$\chi_{\mathrm{cyc}}(\sigma)^{u_k}\, U(\sigma)\, \sigma(e_k) = e_k \qquad (\sigma \in G_{K_0(\mu_{p^m})},\ 1 \le k \le r).$$

For $i \in \mathbb{Z}$, the **i-twisted action** of $G_{K_0(\mu_{p^m})}$ on $\mathbb{C}_p^r$ attached to U is

$$\sigma *_i y = \chi_{\mathrm{cyc}}(\sigma)^i\, U(\sigma)\, \sigma(y) \qquad (\sigma \in G_{K_0(\mu_{p^m})},\ y \in \mathbb{C}_p^r). \tag{25.2}$$

Proposition 25.10. *Let p be an odd prime, K a finite extension of $\mathbb{Q}_p$ with maximal unramified subextension K_0 such that $K \subseteq K_1 := K_0(\mu_p)$, and L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_1)$ for every $\mathbb{Q}_p$-embedding σ of K_1, with ring of integers $\mathcal{O}_L$. Let V be a crystalline L-linear representation of G_K with a G_K-stable $\mathcal{O}_L$-lattice T, and $M_0, h_0 \ge 0$ integers with $J(V) \subseteq [-M_0, h_0]$; let m_N and r_i ($i \in \mathbb{Z}$) be formed as in Proposition 25.8. Let ξ be a generator of $\ker\theta$, $0 \le a < b$ integers, and $Q_{a,b} = \xi^a A_{\mathrm{inf}}/\xi^b A_{\mathrm{inf}}$, with the action of G_K induced from A_{inf}; give $T \otimes_{\mathbb{Z}_p} Q_{a,b}$ the diagonal action of G_{K_1} and the p-adic topology. Put*

$$c_{\mathrm{LL}}(V; a, b) = (m_N - 1) + \sum_{i=a}^{b-1} \bigl(2 + \max(1, r_i)\bigr).$$

If z is a continuous 1-cocycle of G_{K_1} with values in $T \otimes_{\mathbb{Z}_p} Q_{a,b}$ and $p^k z$ is a coboundary for some $k \ge 0$, then $p^{c_{\mathrm{LL}}(V;a,b)} z$ is a coboundary. ***Level s.*** *More generally, let p be a prime,*

$s \geq 1$ an integer with $s \geq 2$ if $p = 2$, K a finite extension of $\mathbb{Q}_p$ with maximal unramified subextension K_0 such that $K \subseteq K_s := K_0(\mu_{p^s})$, L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_s)$ for every $\mathbb{Q}_p$-embedding σ of K_s, and V, T, M_0, h_0, ξ, $0 \leq a < b$, $Q_{a,b}$ as above. Let $m_{N,s}$ be as in Proposition 25.36 and put

$$r_i^{(s)} = \sum_{u \in J(V),\, u \neq i} (m_{N,s} + v_p(u-i)) \quad (i \in \mathbb{Z}), \qquad c_{\mathrm{LL},s}(V; a, b) = (m_{N,s} - s) + \sum_{i=a}^{b-1} (2 + \max(1, r_i^{(s)})).$$

If z is a continuous 1-cocycle of G_{K_s} with values in $T \otimes_{\mathbb{Z}_p} Q_{a,b}$ (diagonal action, p-adic topology) and $p^k z$ is a coboundary for some $k \geq 0$, then $p^{c_{\mathrm{LL},s}(V;a,b)} z$ is a coboundary. For $s = 1$ and p odd, $m_{N,1} = m_N$, $r_i^{(1)} = r_i$, $c_{\mathrm{LL},1} = c_{\mathrm{LL}}$, and this is the statement above.

Proof. We prove the assertion of the paragraph Level s; the first assertion is its case $s = 1$, p odd (the hypotheses agree, and $m_{N,1} = n_0 + 3 = m_N$, so $r_i^{(1)} = r_i$ and $c_{\mathrm{LL},1} = c_{\mathrm{LL}}$). So let p, s, $K \subseteq K_s$, L, V, T, $a < b$ be as there. Write $m = m_{N,s} = 2s + n_0 + 1$, $K_n = K_0(\mu_{p^n})$ and $G_n = G_{K_n}$; thus $m \geq s$ and $G_m \subseteq G_s \subseteq G_K$, and $m \geq 3$ ($m \geq 5$ if $p = 2$). T is free of finite rank over $\mathbb{Z}_p$ (free over $\mathcal{O}_L$, which is free over $\mathbb{Z}_p$); fix a $\mathbb{Z}_p$-basis $b_1, \ldots, b_d$ and let $M(\sigma) \in \mathrm{GL}_d(\mathbb{Z}_p)$ be the matrix of $\sigma \in G_K$. Put $X_{a,b} = T \otimes_{\mathbb{Z}_p} Q_{a,b}$; in coordinates $X_{a,b} = Q_{a,b}^d$ with σ acting by $y \mapsto M(\sigma)\sigma(y)$, and the p-adic topology is the product topology. For a closed subgroup $G' \subseteq G_K$ and $c \geq 0$ we say that $X_{a,b}$ *has exponent c over G'* if for every continuous 1-cocycle $f\colon G' \to X_{a,b}$ such that $p^k f$ is a coboundary for some k, $p^c f$ is a coboundary; δx denotes the coboundary $\sigma \mapsto \sigma x - x$. By Lemma 25.21(2) applied coordinatewise and continuity of M, $\sigma \mapsto \sigma x$ is continuous for every $x \in X_{a,b}$, so coboundaries are continuous. Moreover V is crystalline, hence de Rham [52], as a representation of G_m: the maximal unramified subfield of K_m is K_0 and $\dim_{K_0}(B_{\mathrm{cris}} \otimes V)^{G_m} \geq \dim_{K_0}(B_{\mathrm{cris}} \otimes V)^{G_K} = \dim_{\mathbb{Q}_p} V$. We show that $X_{a,b}$ has exponent $c_{\mathrm{LL},s}(V; a, b)$ over G_s, which is the claim.

Step 1: the graded pieces have exponent $c_i = 2 + \max(1, r_i^{(s)})$ over G_m. Let $i \geq 0$. The map $\Theta = \vartheta_i^{\oplus d}\colon X_{i,i+1} \to \mathcal{O}_{\mathbb{C}_p}^d$ is an additive bijection with $\Theta(p^n x) = p^n \Theta(x)$, hence a homeomorphism for the p-adic topologies, and since $G_m \subseteq G_{\mathbb{Q}_p(\mu_p)}$ and $M(\sigma)$ has entries in $\mathbb{Z}_p$, Lemma 25.21(3) gives $\Theta(\sigma x) = \chi_{\mathrm{cyc}}(\sigma)^i M(\sigma)\sigma(\Theta(x))$ for $\sigma \in G_m$. So it suffices to treat continuous cocycles $f\colon G_m \to \mathcal{O}_{\mathbb{C}_p}^d$ for the action $\sigma \cdot y = \chi_{\mathrm{cyc}}(\sigma)^i M(\sigma)\sigma(y)$ with $p^k f = \delta x$, $x \in \mathcal{O}_{\mathbb{C}_p}^d$. Take D and the Sen frame (U, g) of level $m = m_{N,s}$ and rank d with weights in $J(V)$ from Proposition 25.11 (its hypotheses are ours: p, s, $K \subseteq K_s$, L, V, T, M_0, h_0). For $y \in \mathbb{C}_p^d$ and $\sigma \in G_m$,

$$\chi_{\mathrm{cyc}}(\sigma)^i M(\sigma)\sigma(Dy) = \chi_{\mathrm{cyc}}(\sigma)^i D\, U(\sigma)\sigma(y) = D\,(\sigma *_i y).$$

Hence $f' = pD^{-1}f$ is a continuous map into $\mathcal{O}_{\mathbb{C}_p}^d$ (pD^{-1} is integral) with $f'(\sigma\tau) = f'(\sigma) + pD^{-1}D(\sigma *_i (D^{-1}f(\tau))) = f'(\sigma) + \sigma *_i f'(\tau)$, a cocycle for $*_i$, and $p^k f'$ is the coboundary for $*_i$ of $pD^{-1}x \in \mathcal{O}_{\mathbb{C}_p}^d$. By Proposition 25.17(1) (level m; $m \geq 2$ if $p = 2$), $p^{1+N} f'$ is the $*_i$-coboundary of some $z \in \mathcal{O}_{\mathbb{C}_p}^d$, where $N = N_{J(V),m}(i) = \max(1, r_i^{(s)})$. Applying D: $p^{2+N} f(\sigma) = D(\sigma *_i z - z) = \sigma \cdot (Dz) - Dz$ with $Dz \in \mathcal{O}_{\mathbb{C}_p}^d$ (D is integral).

Step 2: $X_{a,b}$ has exponent $\sum_{i=a}^{b-1} c_i$ over G_m. By induction on $b - a$; $b = a + 1$ is Step 1. Assume it for $X_{a,b}$ and put $A = X_{b,b+1}$, $B = X_{a,b+1}$, $C = X_{a,b}$, $c_C = \sum_{i=a}^{b-1} c_i$. By Lemma 25.21(1) and freeness of T, $0 \to A \to B \xrightarrow{\pi} C \to 0$ is exact and equivariant, and $p^n B \cap A = p^n A$, so A carries the subspace topology. Let $f\colon G_m \to B$ be a continuous cocycle with $p^k f = \delta x$. Then πf is a continuous cocycle with $p^k \pi f = \delta(\pi x)$, so $p^{c_C} \pi f = \delta y$ for some $y \in C$; lift y to $\tilde{y} \in B$. The cocycle $f_1 = p^{c_C} f - \delta\tilde{y}$ is continuous and has $\pi f_1 = 0$, so it is a continuous cocycle with values in A. Next, $p^k f_1 = \delta w$ with $w = p^{c_C} x - p^k \tilde{y} \in B$, and $z = \pi(w)$

satisfies $\sigma z - z = \pi(p^k f_1(\sigma)) = 0$; by Lemma 25.22 (for $F = K_m$, the de Rham representation V of G_m, the lattice T and $a \le b \le b+1$) there are $k' \ge 0$ and $x' \in B$ fixed by G_m with $\pi(x') = p^{k'} z$. Then $a_0 = p^{k'} w - x' \in \ker \pi = A$ and $\delta a_0 = p^{k'} \delta w = p^{k+k'} f_1$. By Step 1 for A, $p^{c_b} f_1 = \delta a_1$ with $a_1 \in A$, and

$$p^{c_b + c_C} f = p^{c_b}(f_1 + \delta \tilde{y}) = \delta(a_1 + p^{c_b} \tilde{y}).$$

Step 3: descent from G_m to G_s. Since K_n/K_0 has degree $p^{n-1}(p-1)$ for $n \ge 1$ ($\Phi_{p^n}(X+1)$ is Eisenstein over $\mathcal{O}_{K_0}$, for every prime p), G_m is a normal subgroup of G_s of index $n_1 = [K_m : K_s] = p^{m-s}$; let S be a set of representatives of G_s/G_m. Let $f\colon G_s \to X_{a,b}$ be a continuous cocycle with $p^k f = \delta x$, and $c = \sum_{i=a}^{b-1} c_i$. By Step 2 applied to $f|_{G_m}$, $F = p^c f$ satisfies $F(h) = hy - y$ for $h \in G_m$, with $y \in X_{a,b}$. For $\sigma \in G_s$ and $s' \in S$ write $\sigma s' = s'' h$ with $s'' \in S$, $h \in G_m$; as s' runs through S so does s''. From $F(\sigma s') = F(\sigma) + \sigma F(s')$ and $F(s''h) = F(s'') + s''hy - s''y = F(s'') + \sigma s' y - s'' y$, summing over $s' \in S$,

$$n_1 F(\sigma) = \sum_{s''} F(s'') - \sigma \sum_{s'} F(s') + \sigma \sum_{s'} s'y - \sum_{s''} s''y = \sigma w - w, \qquad w = \sum_{s' \in S} \bigl(s'y - F(s')\bigr) \in X_{a,b}.$$

So $p^{(m-s)+c} f = n_1 F$ is a coboundary, and $(m-s) + c = (m_{N,s} - s) + \sum_{i=a}^{b-1} (2 + \max(1, r_i^{(s)})) = c_{\mathrm{LL},s}(V; a, b)$. □

Proposition 25.11. *Let p, s, $K \subseteq K_0(\mu_{p^s})$, L, V, T, M_0, h_0 and $m_{N,s}$ be as in Proposition 25.36, let $b_1, \dots, b_d$ be a $\mathbb{Z}_p$-basis of T and $M(\sigma) \in \mathrm{GL}_d(\mathbb{Z}_p)$ the matrix of $\sigma \in G_K$ in it. Then $J(V)$ is finite, and there are a matrix $D \in \mathrm{GL}_d(\mathbb{C}_p)$ such that D and pD^{-1} have all entries in $\mathcal{O}_{\mathbb{C}_p}$, and a Sen frame (U, g) of level $m_{N,s}$ and rank d over K_0 with weights in $J(V)$, such that*

$$D\,U(\sigma) = M(\sigma)\,\sigma(D) \qquad \text{for all } \sigma \in G_{K_0(\mu_{p^{m_{N,s}}})}.$$

Proof. Put $H = M_0 + h_0$, $n = n_0 + 1$, $n' = n + s - 1 = n_0 + s$ and $m = m_{N,s} = 2s + n_0 + 1 = n' + s + 1$. Since $J(V) \subseteq [-M_0, h_0]$, $J(V)$ is finite. Elements of $\mathcal{O} \otimes_{\mathbb{Z}_p} T$ and of $\mathbb{C}_p \otimes_{\mathbb{Z}_p} T$ are written in the coordinates of $b_\bullet$, so that $\sigma \in G_K$ acts by $y \mapsto M(\sigma)\sigma(y)$. Let $n_1, \dots, n_d$ be as in Proposition 25.12 at level s (whose hypotheses are ours: $K \subseteq K_s$ and L contains $\sigma(K_s)$ for every embedding σ).

Step 1: the specialisation θ_n. The ring $\mathcal{O}_{\mathbb{C}_p^\flat}$ is perfect of characteristic p, so the Witt vector Frobenius φ of A_{inf} is a ring automorphism with $\varphi([x]) = [x^p]$, commuting with $G_{\mathbb{Q}_p}$ (functoriality of Witt vectors). Put $\theta_n = \theta \circ \varphi^{-n}$, a surjective $G_{\mathbb{Q}_p}$-equivariant ring homomorphism $A_{\mathrm{inf}} \to \mathcal{O}$ by (Ai1), and $c = \theta_n(\mu_\varepsilon) = \theta([\varepsilon^{1/p^n}]) - 1 = \zeta_{p^n} - 1$. As $\varphi^{-n}(I) \subseteq (p, [(p^\flat)^{1/p^n}])$ and θ maps this ideal into $p^{1/p^n}\mathcal{O}$, θ_n is continuous for the I-adic and p-adic topologies. On the image of $W(k)$, θ_n maps $\sum_i p^i [s(a_i)]$ (s the lift $k \to \mathcal{O}_{\mathbb{C}_p^\flat}$, $a_i \in k$) to $\sum_i p^i\, \omega(a_i^{1/p^n}) \in \mathcal{O}_{K_0}$, ω the Teichmüller representatives of k in $\mathcal{O}_{K_0}$, since $s(a)^\sharp = \omega(a)$ [52]. Hence, by continuity, $\theta_n(\sum_k a_k \mu_\varepsilon^k) = \sum_k \theta_n(a_k) c^k$ and

$$\theta_n(\mathbf{A}^+_{K_0}) \subseteq \mathcal{O}_{K_n},$$

because $\mathcal{O}_{K_n} = \mathcal{O}_{K_0}[c]$ is complete: $\Phi_{p^n}(X+1)$ is Eisenstein over $\mathcal{O}_{K_0}$, so K_n/K_0 is totally ramified of degree $e = p^{n-1}(p-1)$ with uniformiser c, and $p \in c^e \mathcal{O}^\times_{K_n}$. In the same way $c' = \theta_n(\mu_{\varepsilon,s}) = \theta([\varepsilon^{1/p^{n'}}]) - 1 = \zeta_{p^{n'}} - 1$ is a uniformiser of $K_{n'}$, $p \in c'^{e'} \mathcal{O}^\times_{K_{n'}}$ with $e' = p^{n'-1}(p-1)$, $\theta_n(\mathbf{A}^+_{K_0,s}) \subseteq \mathcal{O}_{K_{n'}} = \mathcal{O}_{K_0}[c']$, and $c = (1+c')^{p^{s-1}} - 1 \in c' \mathcal{O}_{K_{n'}}$; for $s = 1$, $c' = c$. Finally, for

$\sigma \in G_{K_s}$, $\sigma(\mu_\varepsilon) = \mu_\varepsilon w_\sigma$ with

$$w_\sigma = \sum_{k\geq 1} \binom{\chi_{\mathrm{cyc}}(\sigma)}{k} \mu_\varepsilon^{k-1} \in \mathbf{A}_{K_0}^+ :$$

the binomial series $[\varepsilon]^\beta = \sum_k \binom{\beta}{k} \mu_\varepsilon^k$ converges for $\beta \in \mathbb{Z}_p$ by (Ai2) ($\mu_\varepsilon \equiv [\varepsilon - 1]$ modulo p and $\varepsilon - 1$ has positive valuation, so a power of μ_ε lies in I), is continuous in β and is the usual power for $\beta \in \mathbb{Z}_{\geq 0}$; if integers $\alpha_j \geq 0$ tend to $\chi_{\mathrm{cyc}}(\sigma)$, then $\varepsilon^{\alpha_j} \to \sigma(\varepsilon)$ componentwise, so $\sigma([\varepsilon]) = [\sigma(\varepsilon)] = \lim_j [\varepsilon]^{\alpha_j} = [\varepsilon]^{\chi_{\mathrm{cyc}}(\sigma)}$ by continuity of $[\cdot]$ (Ai2). As $\chi_{\mathrm{cyc}}(\sigma) \in 1 + p\mathbb{Z}_p$ and $p \in c\mathcal{O}_{K_n}$, $\theta_n(w_\sigma) \equiv \chi_{\mathrm{cyc}}(\sigma) \equiv 1$ modulo $c\mathcal{O}_{K_n}$.

Step 2: the matrix D and the sandwich. By (Wl1), $d_j = (\theta_n \otimes 1)(\mu_\varepsilon^{M_0} n_j) \in \mathcal{O}^d$; let $D \in M_d(\mathcal{O})$ have columns $d_1, \ldots, d_d$. The map $\theta_n \otimes 1 \colon A_{\mathrm{inf}} \otimes T \to \mathcal{O} \otimes T$ is additive, θ_n-semilinear and G_K-equivariant. Multiplying (Wl2) by $\mu_\varepsilon^{M_0}$ and applying $\theta_n \otimes 1$ gives, for $t = b_a$, $c^H f_a \in \sum_j \mathcal{O}\, d_j$ (f_a the standard basis), i.e. $DX = c^H \cdot 1$ for some $X \in M_d(\mathcal{O})$. As $c \neq 0$, D is invertible with $D^{-1} = c^{-H} X$. By the definition of n_0, $H \leq p^{n_0}(p-1) = e$, so $v_p(c^H) = H/e \leq 1$, $p/c^H \in \mathcal{O}$, and $pD^{-1} = (p/c^H)X$ has entries in $\mathcal{O}$.

Step 3: the cocycle U. For $\sigma \in G_{K_s}$ put $U(\sigma) = D^{-1} M(\sigma) \sigma(D)$. By (Wl4), $\sigma(\mu_\varepsilon^{M_0} n_j) = w_\sigma^{M_0} \sum_i a(\sigma)_{ij}\, \mu_\varepsilon^{M_0} n_i$, and applying $\theta_n \otimes 1$,

$$M(\sigma)\, \sigma(D) = D\, U(\sigma), \qquad U(\sigma) = \theta_n(w_\sigma)^{M_0}\, \theta_n(a(\sigma)) \in M_d(\mathcal{O}_{K_{n'}}), \qquad U(\sigma) \equiv 1 \bmod c'\, \mathcal{O}_{K_{n'}},$$

using Step 1 ($\theta_n(w_\sigma) \equiv 1$ modulo $c\mathcal{O}_{K_n} \subseteq c'\mathcal{O}_{K_{n'}}$) and $a(\sigma) - 1 \in M_d(\mu_{\varepsilon,s} \mathbf{A}_{K_0,s}^+)$, $\theta_n(\mu_{\varepsilon,s}) = c'$. Since $M(\tau)$ has rational entries and M is multiplicative,

$$U(\sigma\tau) = D^{-1} M(\sigma) \sigma(D)\, \sigma(D^{-1} M(\tau) \tau(D)) = U(\sigma)\, \sigma(U(\tau)).$$

For $h \in H_{K_0} \subseteq G_{K_s}$, $h([\varepsilon]) = [\varepsilon]$ (as $\chi_{\mathrm{cyc}}(h) = 1$) and $h(n_j) = n_j$ by (Wl3), so $M(h) h(d_j) = d_j$ and $U(h) = 1$. The cocycle U is continuous, as M and $\sigma \mapsto \sigma(D)$ are.

Step 4: (Sf1) at level m. As $m \geq n' \geq s$, $G_m \subseteq G_{K_{n'}} \subseteq G_{K_s}$ and G_m fixes $\mathcal{O}_{K_{n'}}$, so on G_m the cocycle relation reads $U(\sigma\tau) = U(\sigma)U(\tau)$; the entries of $U(\sigma)$ lie in $\mathcal{O}_{K_{n'}} \subseteq \mathcal{O}_{K_m}$; with Step 3 this is (Sf1) for the restriction of U to G_m.

Step 5: the element g and (Sf2). As $K_0/\mathbb{Q}_p$ is unramified and $\mathbb{Q}_p(\mu_{p^\infty})/\mathbb{Q}_p$ is totally ramified, χ_{cyc} maps G_{K_0} onto $\mathbb{Z}_p^\times$, hence G_{K_s} onto $1 + p^s\mathbb{Z}_p$; choose $g_1 \in G_{K_s}$ with $v_p(\chi_{\mathrm{cyc}}(g_1) - 1) = s$ and put $g = g_1^{p^{m-s}}$. Since $s \geq 1$, and $s \geq 2$ if $p = 2$, $v_p(x^p - 1) = v_p(x-1) + 1$ for $x \in 1 + p^s\mathbb{Z}_p$, so $v_p(\chi_{\mathrm{cyc}}(g) - 1) = s + (m - s) = m$; so g fixes μ_{p^m} and K_0, i.e. $g \in G_m$. Apply Lemma 25.15 to $R = \mathcal{O}_{K_{n'}}$, $\varpi = c'$, $e' = p^{n'-1}(p-1)$ in place of e, $\gamma = g_1|_{K_{n'}}$ and $Y(x) = U(g_1)\, g_1(x)$ on R^d. Its hypotheses: γ fixes $\mathcal{O}_{K_0}$ and $\gamma(c') - c' = \zeta_{p^{n'}}(\zeta_{p^{n'}}^{\chi_{\mathrm{cyc}}(g_1)-1} - 1)$, where $\zeta_{p^{n'}}^{\chi_{\mathrm{cyc}}(g_1)-1}$ is a $p^{n'-s}$-th root of unity (as p^s divides $\chi_{\mathrm{cyc}}(g_1) - 1$), so $\gamma(c') - c'$ is 0 (if $n' = s$) or has valuation at least $v_p(\zeta_{p^{n'-s}} - 1) = p^s v_p(c') \geq 2 v_p(c')$; hence $\gamma(c') - c' \in c'^2 R$, $\gamma(y) - y \in c'R$ for $y \in R = \mathcal{O}_{K_0}[c']$, and for $x = c'^j y$, $\gamma(x) - x = \gamma(c')^j(\gamma(y) - y) + (\gamma(c')^j - c'^j)y \in c'^{j+1}R$; Y is additive and γ-semilinear, and $Y(x) - x = (U(g_1) - 1)g_1(x) + (g_1(x) - x) \in c'R^d$ by Step 3. By the cocycle relation $Y^k(x) = U(g_1^k)\, g_1^k(x)$. Since $m - s = n' + 1 \geq n'$, the lemma (its last clause with n' in place of n) gives $(U(g) - 1)f_a = Y^{p^{m-s}}(f_a) - f_a \in c'^{p^{n'}} R^d$, and $v_p(c'^{p^{n'}}) = p^{n'}/e' = p/(p-1) > 1/(p-1)$; so $|U(g)_{ab} - \delta_{ab}| < \rho$. With $v_p(\chi_{\mathrm{cyc}}(g) - 1) = m$ this is (Sf2).

Step 6: (Sf3) with weights in $J(V)$. The representation V is crystalline, hence de Rham [52], and L contains the image of every embedding of $K \subseteq K_s$; let $e_1, \ldots, e_d$ and $u_k \in J(V)$ be as in Lemma 25.16(2). The vectors $D^{-1}e_k$ form a $\mathbb{C}_p$-basis, and for $\sigma \in G_m$,

$$\chi_{\mathrm{cyc}}(\sigma)^{u_k}\, U(\sigma)\, \sigma(D^{-1}e_k) = D^{-1}\big(\chi_{\mathrm{cyc}}(\sigma)^{u_k} M(\sigma)\sigma(e_k)\big) = D^{-1}e_k.$$

So $(U|_{G_m}, g)$ is a Sen frame of level $m = m_{N,s}$ and rank d over K_0 with weights in $J(V)$, D and pD^{-1} are integral (Step 2), and $DU(\sigma) = M(\sigma)\sigma(D)$ for $\sigma \in G_m$ (Step 3). □

Proposition 25.12. *Let p be a prime, $s \geq 1$ an integer, K_0 a finite unramified extension of $\mathbb{Q}_p$ with residue field k, K a field with $K_0 \subseteq K \subseteq K_s = K_0(\mu_{p^s})$, and L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_s)$ for every $\mathbb{Q}_p$-embedding σ of K_s. Let V be a crystalline L-linear representation of G_K with a G_K-stable $\mathcal{O}_L$-lattice T, $d = \operatorname{rank}_{\mathbb{Z}_p} T$, and $M_0, h_0 \geq 0$ integers with $J(V) \subseteq [-M_0, h_0]$. Put $\mu_\varepsilon = [\varepsilon] - 1$ and $\mu_{\varepsilon,s} = [\varepsilon^{1/p^{s-1}}] - 1$ in A_{inf}, where $\varepsilon^{1/p^{s-1}}$ is the unique p^{s-1}-th root of ε in the perfect ring $\mathcal{O}_{\mathbb{C}_p^\flat}$ (so $\mu_{\varepsilon,1} = \mu_\varepsilon$); let $W(k) \to A_{\mathrm{inf}}$ be the map of Witt vectors induced by the unique ring homomorphism $k \to \mathcal{O}_{\mathbb{C}_p^\flat}$ lifting the inclusion of k into the residue field, and $\mathbf{A}^+_{K_0,s} \subset A_{\mathrm{inf}}$ the image of $W(k)[[X]]$ under $X \mapsto \mu_{\varepsilon,s}$; write $\mathbf{A}^+_{K_0} = \mathbf{A}^+_{K_0,1}$. Let G_K act on $A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_p} T$ diagonally. Then there are $n_1, \dots, n_d \in A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_p} T$ such that:*

(Wl1) $\mu_\varepsilon^{M_0} n_j \in A_{\mathrm{inf}} \otimes_{\mathbb{Z}_p} T$ *for every j;*

(Wl2) $\mu_\varepsilon^{h_0}(1 \otimes t) \in \sum_{j=1}^d A_{\mathrm{inf}}\, n_j$ *for every $t \in T$;*

(Wl3) $h(n_j) = n_j$ *for every $h \in H_{K_0}$ and every j;*

(Wl4) *for every $\sigma \in G_{K_s}$ there is a matrix $a(\sigma) \in M_d(\mathbf{A}^+_{K_0,s})$ with $\sigma(n_j) = \sum_i a(\sigma)_{ij}\, n_i$ for all j and $a(\sigma) - 1 \in M_d(\mu_{\varepsilon,s}\mathbf{A}^+_{K_0,s})$.*

Proof. Forgetting the $\mathcal{O}_L$-structure, T is a free $\mathbb{Z}_p$-module of rank d with a continuous action of G_K, and $T[1/p] = V$ is crystalline. Let $\mathcal{E}$ be a datum attached to T by Theorem B.41, $M = \mathcal{E}(A_{\mathrm{inf}})$, and $c\colon M \otimes_{A_{\mathrm{inf}}} W(\mathbb{C}_p^\flat) \to T \otimes_{\mathbb{Z}_p} W(\mathbb{C}_p^\flat)$ the isomorphism of (Bs3), which maps M into $A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_p} T$. Write σ_0 for the Frobenius of $W(k)$ and $w\colon W(k) \to A_{\mathrm{inf}}$ for the map of the statement.

The cyclotomic prism is an object over $\mathcal{O}_K$. Let $A = W(k)[[X]]$ with the ring endomorphism φ_A equal to σ_0 on $W(k)$ and $X \mapsto (1+X)^p - 1$. It lifts the Frobenius modulo p and A has no p-torsion, so A is a δ-ring with $\delta(a) = (\varphi_A(a) - a^p)/p$. Put $d = \Phi_{p^s}(1+X) = \sum_{k=0}^{p-1}(1+X)^{kp^{s-1}}$, with Φ_{p^s} the p^s-th cyclotomic polynomial (for $s = 1$, $d = ((1+X)^p - 1)/X$). Since $(1+X)^{p^{s-1}} \equiv 1 + X^{p^{s-1}} \bmod p$, we have $d \equiv X^{p^{s-1}(p-1)} \bmod p$, so the ideals (p, d) and (p, X) have the same radical, so A is (p,d)-adically complete. The map $\mathrm{red}\colon A \to W(k)$, $X \mapsto 0$, is a homomorphism of δ-rings (it commutes with the Frobenius lifts, as $\varphi_A(X) \mapsto 0$) and sends d to p; as $\delta(p) = 1 - p^{p-1}$ is a unit of $W(k)$, $\delta(d)$ is not in the maximal ideal (p, X) of the local ring A, hence is a unit: d is distinguished. The polynomial $\Phi_{p^s}(X+1)$ is Eisenstein over $W(k)$ (it is congruent to $X^{p^{s-1}(p-1)}$ modulo p and its constant term is $\Phi_{p^s}(1) = p$), so $X \mapsto \zeta_{p^s} - 1$ induces $A/dA \cong W(k)[\zeta_{p^s}] = \mathcal{O}_{K_s}$, which has no p-torsion. So (A, dA) is a bounded prism, and $\mathcal{O}_K \subseteq \mathcal{O}_{K_s} = A/dA$ makes it an object over $\mathcal{O}_K$; this is where $K \subseteq K_s$ is used. Likewise $(W(k), pW(k))$ with $\mathcal{O}_K \to \mathcal{O}_{K_s} \to \mathcal{O}_{K_s}/(\zeta_{p^s} - 1) = k$ is an object over $\mathcal{O}_K$, and red is a morphism over $\mathcal{O}_K$ (it maps d to p and induces the reduction $\mathcal{O}_{K_s} \to k$).

The map to Fontaine's ring. Let $\iota\colon A \to A_{\mathrm{inf}}$ be $a \mapsto \varphi(w(a))$ on $W(k)$ and $X \mapsto \mu_{\varepsilon,s}$; it is well defined because $\mu_{\varepsilon,s}$ is topologically nilpotent for the topology of (Ai2) ($\mu_{\varepsilon,s} \bmod p = \varepsilon^{1/p^{s-1}} - 1$ has positive valuation). It commutes with the Frobenius lifts (w is Frobenius-equivariant and $\varphi(\mu_{\varepsilon,s}) = [\varepsilon^{1/p^{s-1}}]^p - 1 = (1+\mu_{\varepsilon,s})^p - 1$, as $\varphi([x]) = [x^p]$), and $\iota(d) = \sum_{k<p}[\varepsilon^{1/p^{s-1}}]^{kp^{s-1}} = \sum_{k<p}[\varepsilon]^k = \tilde{\xi}$. On the quotients it induces $\mathcal{O}_{K_s} \to \mathcal{O}_{\mathbb{C}_p}$, $\zeta_{p^s} - 1 \mapsto \tilde{\theta}(\mu_{\varepsilon,s}) = \theta([\varepsilon^{1/p^s}]) - 1 = \zeta_{p^s} - 1$, and on $W(k)$ the map $\tilde{\theta} \circ \varphi \circ w = \theta \circ w$, the inclusion $W(k) = \mathcal{O}_{K_0} \subset \mathcal{O}_{\mathbb{C}_p}$; so ι is a morphism $(A, dA) \to (A_{\mathrm{inf}}, \tilde{\xi} A_{\mathrm{inf}})$ over $\mathcal{O}_K$. Its image is $w(W(k))[[\mu_{\varepsilon,s}]] = \mathbf{A}^+_{K_0,s}$, because $\varphi \circ w = w \circ \sigma_0$ and σ_0 is bijective.

The elements n_j. As A is local, the finite projective module $\mathcal{E}(A)$ is free; let $e_1,\dots,e_d$ be a basis. By (Bs2) the elements $m_j=\mathcal{E}(\iota)(e_j)$ form an $A_{\inf}$-basis of M. Put $n_j=c(m_j)\in A_{\inf}[1/\mu_\varepsilon]\otimes_{\mathbb{Z}_p}T$.

(Wl3). Let $h\in H_{K_0}$. Then $h\in G_{K_s}\subseteq G_K$, h fixes every ζ_{p^n}, hence ε, its p-power roots and $\mu_{\varepsilon,s}$, and h fixes $w(W(k))$ (it acts trivially on k). So $h\circ\iota=\iota$ as morphisms over $\mathcal{O}_K$, and by (Bs2) $\mathcal{E}(h)\circ\mathcal{E}(\iota)=\mathcal{E}(\iota)$. By the G_K-equivariance of c, $h(n_j)=c(\mathcal{E}(h)(m_j))=c(m_j)=n_j$.

(Wl4), for every $\sigma\in G_K$. Let $\gamma_\sigma\colon A\to A$ be the identity on $W(k)$ and $X\mapsto(1+X)^{\chi_{\mathrm{cyc}}(\sigma)}-1=\sum_{k\geq1}\binom{\chi_{\mathrm{cyc}}(\sigma)}{k}X^k$. It commutes with φ_A (both composites send X to $(1+X)^{p\chi_{\mathrm{cyc}}(\sigma)}-1$). In $A/dA=\mathcal{O}_{K_s}$ the image of $\gamma_\sigma(d)=\sum_{k<p}(1+X)^{kp^{s-1}\chi_{\mathrm{cyc}}(\sigma)}$ is $\sum_{k<p}\zeta_{p^s}^{kp^{s-1}\chi_{\mathrm{cyc}}(\sigma)}=\sum_{k<p}\zeta_p^{k\chi_{\mathrm{cyc}}(\sigma)}=0$, since $\zeta_{p^s}^{p^{s-1}}=\zeta_p$ and $\zeta_p^{\chi_{\mathrm{cyc}}(\sigma)}$ is a primitive p-th root of unity; so $\gamma_\sigma(dA)\subseteq dA$, and the induced automorphism of $\mathcal{O}_{K_s}$ is $\zeta_{p^s}\mapsto\zeta_{p^s}^{\chi_{\mathrm{cyc}}(\sigma)}$, trivial on $W(k)$, i.e. the restriction of σ, which fixes $\mathcal{O}_K$. Hence γ_σ is a morphism over $\mathcal{O}_K$. Moreover $\sigma\circ\iota=\iota\circ\gamma_\sigma$: both are trivial on $W(k)$-parts ($\sigma\in G_{K_0}$), and $\sigma(\mu_{\varepsilon,s})=[(\varepsilon^{1/p^{s-1}})^{\chi_{\mathrm{cyc}}(\sigma)}]-1=(1+\mu_{\varepsilon,s})^{\chi_{\mathrm{cyc}}(\sigma)}-1$ (as σ raises every ζ_{p^n} to the power $\chi_{\mathrm{cyc}}(\sigma)$, it maps $\varepsilon^{1/p^{s-1}}$ to its $\chi_{\mathrm{cyc}}(\sigma)$-th power) by multiplicativity and continuity of the Teichmüller map. Write $\mathcal{E}(\gamma_\sigma)(e_j)=\sum_i\alpha_{ij}e_i$ with $\alpha=\alpha(\sigma)\in M_d(A)$. By (Bs2) and the equivariance of c,

$$\sigma(n_j)=c(\mathcal{E}(\sigma)\mathcal{E}(\iota)e_j)=c(\mathcal{E}(\iota)\mathcal{E}(\gamma_\sigma)e_j)=\sum_i\iota(\alpha_{ij})\,n_i,$$

so $a(\sigma)=\iota(\alpha)\in M_d(\mathbf{A}^+_{K_0,s})$. Finally $\mathrm{red}\circ\gamma_\sigma=\mathrm{red}$ (as $\gamma_\sigma(X)\in XA$), so $\mathcal{E}(\mathrm{red})\circ\mathcal{E}(\gamma_\sigma)=\mathcal{E}(\mathrm{red})$, i.e. $\sum_i\mathrm{red}(\alpha_{ij})\,\mathcal{E}(\mathrm{red})(e_i)=\mathcal{E}(\mathrm{red})(e_j)$. The $\mathcal{E}(\mathrm{red})(e_i)$ form a $W(k)$-basis of $\mathcal{E}(W(k))$ by (Bs2), so $\mathrm{red}(\alpha)=1$, i.e. $\alpha-1\in M_d(XA)$ and $a(\sigma)-1\in M_d(\mu_{\varepsilon,s}\mathbf{A}^+_{K_0,s})$. In particular (Wl4) holds for $\sigma\in G_{K_s}$.

(Wl1) and (Wl2). Fix a $\mathbb{Z}_p$-basis $t_1,\dots,t_d$ of T and write $n_j=\sum_k Z_{jk}\,t_k$ with $Z\in M_d(W(\mathbb{C}_p^\flat))$; since the m_j form a basis of M and c is an isomorphism after $\otimes W(\mathbb{C}_p^\flat)$, Z is invertible; let $U=Z^{-1}$, so $t_k=\sum_j U_{kj}n_j$. The element $\tilde\xi$ is a unit of $W(\mathbb{C}_p^\flat)$ (its reduction $(\varepsilon-1)^{p-1}$ is non-zero), so c extends to $M[1/\tilde\xi]$, and since c carries $\varphi_M\otimes\varphi$ to $1\otimes\varphi$, $c(\varphi_M(1\otimes m_j))=\sum_k\varphi(Z_{jk})t_k$. By Proposition 25.14 there are $P,R\in M_d(A_{\inf})$ with $\tilde\xi^{M_0}\varphi_M(1\otimes m_j)=\sum_i P_{ji}m_i$ and $\tilde\xi^{h_0}m_j=\sum_i R_{ji}\varphi_M(1\otimes m_i)$; applying c,

$$\tilde\xi^{M_0}\varphi(Z)=PZ,\qquad \tilde\xi^{h_0}Z=R\,\varphi(Z).$$

Recall $\varphi(\mu_\varepsilon)=\mu_\varepsilon\tilde\xi$. For (Wl1) put $Y=\mu_\varepsilon^{M_0}Z$: then $\varphi(Y)=\mu_\varepsilon^{M_0}\tilde\xi^{M_0}\varphi(Z)=PY$, so Y has entries in $A_{\inf}$ by Lemma 25.13 (with $S=P$, $S'=1$ and zero constant term), i.e. $\mu_\varepsilon^{M_0}n_j=\sum_k Y_{jk}t_k\in A_{\inf}\otimes_{\mathbb{Z}_p}T$. For (Wl2), multiplying $\tilde\xi^{h_0}Z=R\varphi(Z)$ by U on the left and by $\varphi(U)=\varphi(Z)^{-1}$ on the right gives $\tilde\xi^{h_0}\varphi(U)=UR$; with $Y'=\mu_\varepsilon^{h_0}U$ this is $\varphi(Y')=Y'R$, so Y' has entries in $A_{\inf}$ by Lemma 25.13 (with $S=1$, $S'=R$), and $\mu_\varepsilon^{h_0}(1\otimes t_k)=\sum_j Y'_{kj}n_j$. Since every $t\in T$ is a $\mathbb{Z}_p$-combination of the t_k, (Wl2) follows. □

Lemma 25.13. *Let p be a prime, $W(\mathbb{C}_p^\flat)$ the ring of Witt vectors of the perfect field $\mathbb{C}_p^\flat$, containing $A_{\inf}$ by functoriality of Witt vectors, and φ its Frobenius (the functorial extension of $x\mapsto x^p$, which restricts to the Frobenius of $A_{\inf}$), applied to matrices entrywise. Let $r,s\geq1$, $S\in M_r(A_{\inf})$, $S'\in M_s(A_{\inf})$, $Y\in M_{r\times s}(A_{\inf})$ and $Z\in M_{r\times s}(W(\mathbb{C}_p^\flat))$ with*

$$\varphi(Z)=S\,Z\,S'+Y.$$

Then $Z\in M_{r\times s}(A_{\inf})$.

Proof. We use the classical facts on Witt vectors of a perfect ring R of characteristic p: every element of $W(R)$ has a unique expansion $\sum_{i\geq 0} p^i[x_i]$ with $x_i \in R$; $W(R)/pW(R) = R$ via $x \mapsto x_0$; the Teichmüller map is multiplicative and $\varphi(\sum p^i[x_i]) = \sum p^i[x_i^p]$. Applied to $R = \mathcal{O}_{\mathbb{C}_p^\flat} \subset \mathbb{C}_p^\flat$, an element of $W(\mathbb{C}_p^\flat)$ lies in A_{inf} if and only if all its coordinates x_i lie in $\mathcal{O}_{\mathbb{C}_p^\flat}$; in particular $A_{\mathrm{inf}} \cap pW(\mathbb{C}_p^\flat) = pA_{\mathrm{inf}}$ (an element of A_{inf} with $x_0 = 0$ is $p\sum_{i\geq 1} p^{i-1}[x_i]$). Write v for the valuation of $\mathbb{C}_p^\flat$ and $\bar{X}$ for the entrywise reduction modulo p of a matrix X over $W(\mathbb{C}_p^\flat)$.

The first coordinates are integral. Reducing the equation modulo p gives $\bar{Z}^{(p)} = \bar{S}\,\bar{Z}\,\bar{S}' + \bar{Y}$ in $M_{r\times s}(\mathbb{C}_p^\flat)$, where $\bar{Z}^{(p)}$ is the entrywise p-th power and $\bar{S}, \bar{S}', \bar{Y}$ have entries in $\mathcal{O}_{\mathbb{C}_p^\flat}$. Suppose $\bar{Z} \neq 0$ and let m be the minimum of the valuations of its entries, attained at the entry (a, b). The (a, b)-entry of the left side has valuation pm; every entry of $\bar{S}\bar{Z}\bar{S}'$ is a sum of products of an entry of $\bar{Z}$ with two integral elements, so it has valuation at least m, and the entries of $\bar{Y}$ have valuation at least 0. Hence $pm \geq \min(m, 0)$. If $m < 0$ this reads $pm \geq m$, i.e. $(p-1)m \geq 0$, a contradiction. So $m \geq 0$: the entries of $\bar{Z}$ lie in $\mathcal{O}_{\mathbb{C}_p^\flat}$.

Induction on the coordinates. Let $z = \bar{Z}$ (entries in $\mathcal{O}_{\mathbb{C}_p^\flat}$) and $[z]$ its entrywise Teichmüller lift, a matrix over A_{inf}. Then $Z - [z] \in pM_{r\times s}(W(\mathbb{C}_p^\flat))$; write $Z = [z] + pZ_1$, where the coordinates of each entry of Z_1 are those of Z shifted by one. Since $\varphi([z]) = [z^{(p)}]$ is over A_{inf},

$$pY_1 := S[z]S' + Y - \varphi([z]) = p(\varphi(Z_1) - SZ_1S')$$

lies in $M_{r\times s}(A_{\mathrm{inf}}) \cap pM_{r\times s}(W(\mathbb{C}_p^\flat)) = pM_{r\times s}(A_{\mathrm{inf}})$, and as $W(\mathbb{C}_p^\flat)$ has no p-torsion, $\varphi(Z_1) = SZ_1S' + Y_1$ with Y_1 over A_{inf}. This is an equation of the same form, so by the first step the coordinate x_1 of every entry of Z is integral. Repeating, the coordinate x_k of every entry of Z is the coordinate x_0 of the corresponding entry of a matrix Z_k satisfying an equation $\varphi(Z_k) = SZ_kS' + Y_k$ with Y_k over A_{inf}, hence lies in $\mathcal{O}_{\mathbb{C}_p^\flat}$. All coordinates being integral, Z has entries in A_{inf}. □

Proposition 25.14. *Let p be a prime, K a finite extension of $\mathbb{Q}_p$, T a finite free $\mathbb{Z}_p$-module with a continuous action of G_K such that $V = T[1/p]$ is crystalline, $\mathcal{E}$ a datum attached to T as in Theorem B.41, $M = \mathcal{E}(A_{\mathrm{inf}})$, and $\varphi(M) \subseteq M[1/\tilde{\xi}]$ the A_{inf}-submodule generated by the elements $\varphi_M(1 \otimes m)$, $m \in M$. Let $D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}$ with the filtration of (Ai4), and let $M_0, h_0 \geq 0$ be integers such that every integer a with $\mathrm{Fil}^{a+1} D_{\mathrm{dR}}(V) \neq \mathrm{Fil}^a D_{\mathrm{dR}}(V)$ satisfies $-M_0 \leq a \leq h_0$. Then*

$$\tilde{\xi}^{M_0}\,\varphi(M) \subseteq M \qquad \text{and} \qquad \tilde{\xi}^{h_0}\,M \subseteq \varphi(M).$$

Proof. If $V = 0$ there is nothing to prove; let $V \neq 0$.

The Frobenius identifies Fontaine's B_{dR}^+ with B'^+. The Witt vector Frobenius φ is a ring automorphism of A_{inf} commuting with G_K, and $\varphi(q) = [\varepsilon]$, so $\varphi(\xi_0) = \sum_{k=0}^{p-1}[\varepsilon]^k = \tilde{\xi}$. Hence φ induces isomorphisms $A_{\mathrm{inf}}[1/p]/\xi_0^b \to A_{\mathrm{inf}}[1/p]/\tilde{\xi}^b$ compatible in b. By (Ai3) the source is $B_{\mathrm{dR}}^+/\xi_0^b B_{\mathrm{dR}}^+$, and B_{dR}^+, a complete discrete valuation ring with uniformiser ξ_0, is the inverse limit of these quotients. Passing to the limit gives a G_K-equivariant ring isomorphism $\Phi\colon B_{\mathrm{dR}}^+ \to B'^+$ with $\Phi(\xi_0) = \tilde{\xi}$, extending φ on the image of $A_{\mathrm{inf}}[1/p]$. Consequently B'^+ is a discrete valuation ring with uniformiser $\tilde{\xi}$, $B'^+/\tilde{\xi}B'^+ = A_{\mathrm{inf}}[1/p]/\tilde{\xi}A_{\mathrm{inf}}[1/p]$, and Φ extends to an isomorphism $B_{\mathrm{dR}} \to B'_{\mathrm{dR}}$ with $\Phi(t^j B_{\mathrm{dR}}^+) = \tilde{\xi}^j B'^+$ for every $j \in \mathbb{Z}$, because $tB_{\mathrm{dR}}^+ = \xi_0 B_{\mathrm{dR}}^+$ by (Ai3).

The Hodge window in $V \otimes_{\mathbb{Q}_p} B'_{\mathrm{dR}}$. Let $D = D_{\mathrm{dR}}(V)$ with $\mathrm{Fil}^j D$ as in (Ai4), $F = K$. The filtration is decreasing, exhaustive ($B_{\mathrm{dR}} \otimes V = \bigcup_N t^{-N} B_{\mathrm{dR}}^+ \otimes V$ and D is finite-dimensional) and

separated ($\bigcap_j t^j B^+_{\mathrm{dR}} \otimes V = 0$). So $a_0 = \max\{a : \mathrm{Fil}^a D = D\}$ and $a_1 = \max\{a : \mathrm{Fil}^a D \neq 0\}$ exist, and both are jumps ($\mathrm{Fil}^{a_0+1} D \neq \mathrm{Fil}^{a_0} D$, $\mathrm{Fil}^{a_1+1} D = 0 \neq \mathrm{Fil}^{a_1} D$). By hypothesis $a_0 \geq -M_0$ and $a_1 \leq h_0$, hence

$$\mathrm{Fil}^{-M_0} D = D, \qquad \mathrm{Fil}^{h_0+1} D = 0.$$

The map $1 \otimes \Phi \colon V \otimes B_{\mathrm{dR}} \to V \otimes B'_{\mathrm{dR}}$ is a G_K-equivariant bijection, Φ-semilinear; so $D' = (1 \otimes \Phi)(D)$ equals $(V \otimes B'_{\mathrm{dR}})^{G_K}$, and with $\mathrm{Fil}'^j = (1 \otimes \Phi)(\mathrm{Fil}^j D)$ the case $k = 0$ of (Ai4) becomes

$$\sum_{j \in \mathbb{Z}} \tilde{\xi}^{-j} B'^{+} \, \mathrm{Fil}'^j = V \otimes_{\mathbb{Q}_p} B'^{+} = T \otimes_{\mathbb{Z}_p} B'^{+},$$

where $\tilde{\xi}^{-j} B'^{+} \mathrm{Fil}'^j$ is the B'^{+}-submodule generated by $\tilde{\xi}^{-j} \mathrm{Fil}'^j$ (the image under $1 \otimes \Phi$ of the B^+_{dR}-submodule generated by $t^{-j} \mathrm{Fil}^j D$). Let $\Lambda_{\mathrm{dR}} = B'^{+} D'$. The term $j = -M_0$ gives $\tilde{\xi}^{M_0} \Lambda_{\mathrm{dR}} \subseteq T \otimes B'^{+}$; and since only $j \leq h_0$ contribute and $\tilde{\xi}^{-j} \in \tilde{\xi}^{-h_0} B'^{+}$ for $j \leq h_0$, also $T \otimes B'^{+} \subseteq \tilde{\xi}^{-h_0} \Lambda_{\mathrm{dR}}$.

The two lattices of M. Inside $M \otimes_{A_{\mathrm{inf}}} B'_{\mathrm{dR}} \cong T \otimes B'_{\mathrm{dR}}$ let Λ_0 be the image of $M \otimes B'^{+}$ and Λ_1 the B'^{+}-submodule generated by the images of the $\varphi_M(1 \otimes m)$. By (Bs4), $\Lambda_0 = T \otimes B'^{+}$ and $\Lambda_1 = \Lambda_{\mathrm{dR}}$. By the previous paragraph,

$$\tilde{\xi}^{M_0} \Lambda_1 \subseteq \Lambda_0, \qquad \tilde{\xi}^{h_0} \Lambda_0 \subseteq \Lambda_1. \tag{$*$}$$

Descent from B'^{+} to A_{inf}. First, $\iota^{-1}(\tilde{\xi}^k B'^{+}) = \tilde{\xi}^k A_{\mathrm{inf}}$ for $k \geq 0$. For $k = 1$: if $\iota(a) \in \tilde{\xi} B'^{+}$, then the image of a in $B'^{+}/\tilde{\xi} = A_{\mathrm{inf}}[1/p]/\tilde{\xi} A_{\mathrm{inf}}[1/p]$ vanishes, so $p^n a \in \tilde{\xi} A_{\mathrm{inf}} = \ker \tilde{\theta}$ for some n, hence $p^n \tilde{\theta}(a) = 0$ in $\mathcal{O}_{\mathbb{C}_p}$ and $a \in \ker \tilde{\theta} = \tilde{\xi} A_{\mathrm{inf}}$. For $k \geq 2$, write $a = \tilde{\xi} a_1$; then $\tilde{\xi}\, \iota(a_1) \in \tilde{\xi}^k B'^{+}$ and, B'^{+} being a domain, $\iota(a_1) \in \tilde{\xi}^{k-1} B'^{+}$; induct. Second, let N be a finite projective A_{inf}-module and $x \in N[1/\tilde{\xi}]$ an element whose image in $N \otimes B'_{\mathrm{dR}}$ lies in the image of $N \otimes B'^{+}$; then $x \in N$. Indeed, for $N = A_{\mathrm{inf}}^r$ write $x = \tilde{\xi}^{-k}(a_1, \ldots, a_r)$; the hypothesis says $\iota(a_i) \in \tilde{\xi}^k B'^{+}$, so $a_i \in \tilde{\xi}^k A_{\mathrm{inf}}$ and $x \in A_{\mathrm{inf}}^r$. In general $N \oplus P = A_{\mathrm{inf}}^r$ for some P; all the base changes respect the decomposition, so $x \in A_{\mathrm{inf}}^r$, and its component in P is 0 because $\tilde{\xi}^k x \in N$ for some k and P is $\tilde{\xi}$-torsion free (A_{inf} is a domain by (Ai1)); so $x \in N$.

Conclusion. For $m \in M$ the element $x = \tilde{\xi}^{M_0} \varphi_M(1 \otimes m)$ lies in $M[1/\tilde{\xi}]$ and, by $(*)$, its image lies in Λ_0; by the descent with $N = M$, $x \in M$. These elements generate $\tilde{\xi}^{M_0} \varphi(M)$, so $\tilde{\xi}^{M_0} \varphi(M) \subseteq M$. For the second inclusion, $\varphi^* M = A_{\mathrm{inf}} \otimes_{\varphi, A_{\mathrm{inf}}} M$ is finite projective, hence $\tilde{\xi}$-torsion free, and φ_M is an isomorphism after inverting $\tilde{\xi}$; so $\varphi(M)$, the image of $\varphi^* M$ in $M[1/\tilde{\xi}]$, is isomorphic to $\varphi^* M$ (finite projective) and $\varphi(M)[1/\tilde{\xi}] = M[1/\tilde{\xi}]$. Thus $\varphi(M) \otimes B'_{\mathrm{dR}} = M \otimes B'_{\mathrm{dR}}$, and the image of $\varphi(M) \otimes B'^{+}$ there is Λ_1. For $m \in M$ the element $\tilde{\xi}^{h_0} m \in \varphi(M)[1/\tilde{\xi}]$ has image in $\tilde{\xi}^{h_0} \Lambda_0 \subseteq \Lambda_1$ by $(*)$, so $\tilde{\xi}^{h_0} m \in \varphi(M)$ by the descent with $N = \varphi(M)$. Hence $\tilde{\xi}^{h_0} M \subseteq \varphi(M)$. $\square$

Lemma 25.15. *Let p be a prime, R a discrete valuation ring with uniformiser ϖ and $p \in \varpi^e R^\times$ for an integer $e \geq 1$, and $d \geq 1$. Let γ be a ring automorphism of R with $\gamma(x) - x \in \varpi^{j+1} R$ for all $j \geq 0$ and $x \in \varpi^j R$, and $Y \colon R^d \to R^d$ an additive map with $Y(\lambda x) = \gamma(\lambda) Y(x)$ ($\lambda \in R$, $x \in R^d$) and $Y(x) - x \in \varpi R^d$ for all x. Put $c_0 = 1$ and $c_{b+1} = \min(c_b + e, p c_b)$. Then*

$$Y^{p^b}(x) - x \in \varpi^{c_b} R^d \qquad (x \in R^d,\ b \geq 0).$$

If $e = p^{n-1}(p-1)$ for an integer $n \geq 1$, then $c_b \geq p^n$ for all $b \geq n$.

Proof. Say that an additive map Z of $R^{d'}$ ($d' \geq 1$) has *level* c if $Z(\varpi^j R^{d'}) \subseteq \varpi^{j+c} R^{d'}$ for all $j \geq 0$.

Semilinear maps congruent to 1. Let γ' be a ring automorphism of R such that $\gamma' - 1$ has level $c \geq 1$ on R, and Z an additive γ'-semilinear map of $R^{d'}$ with $(Z - 1) R^{d'} \subseteq \varpi^c R^{d'}$. Then $Z - 1$ has level c: for $x = \varpi^j y$,

$$Z(x) - x = \gamma'(\varpi^j)(Z(y) - y) + (\gamma'(\varpi^j) - \varpi^j) y,$$

where $\gamma'(\varpi^j) \in \varpi^j R$ (an automorphism of R preserves its maximal ideal), $Z(y) - y \in \varpi^c R^{d'}$ and $\gamma'(\varpi^j) - \varpi^j \in \varpi^{j+c} R$.

p-th powers. If Z is additive and $\delta = Z - 1$ has level $c \geq 1$, then $Z^p - 1$ has level $\min(c+e, pc)$: indeed $Z^p - 1 = \sum_{k=1}^{p-1} \binom{p}{k} \delta^k + \delta^p$, where δ^k has level $kc \geq c$, $p \mid \binom{p}{k}$ for $1 \leq k \leq p-1$ and multiplication by p maps $\varpi^i R^{d'}$ into $\varpi^{i+e} R^{d'}$, while δ^p has level pc.

Induction. We show that $\gamma^{p^b} - 1$ has level c_b on R and $Y^{p^b} - 1$ has level c_b on R^d. For $b = 0$ the first is the hypothesis on γ, and the second follows from the first paragraph with $\gamma' = \gamma$, $Z = Y$, $c = 1$. If both hold for b, the second paragraph applied to $Z = \gamma^{p^b}$ on R ($d' = 1$) and to $Z = Y^{p^b}$ on R^d gives both for $b+1$, since $c_{b+1} = \min(c_b + e, pc_b)$. Level c_b for $j = 0$ is the claim.

The case $e = p^{n-1}(p-1)$. The sequence (c_b) is non-decreasing, as $c_b + e > c_b$ and $pc_b > c_b$. If $c_b \leq p^{n-1}$ then $(p-1)c_b \leq e$, i.e. $pc_b \leq c_b + e$, so $c_{b+1} = pc_b$; by induction $c_b = p^b$ for $0 \leq b \leq n$. Hence $c_b \geq c_n = p^n$ for $b \geq n$. □

Lemma 25.16. *Let p be a prime, $K \subset \overline{\mathbb{Q}}_p$ a finite extension of $\mathbb{Q}_p$, and $L \subset \overline{\mathbb{Q}}_p$ a finite extension of $\mathbb{Q}_p$ containing $\sigma(K)$ for every $\mathbb{Q}_p$-embedding $\sigma\colon K \to \overline{\mathbb{Q}}_p$. Let V be a finite-dimensional L-vector space with a continuous L-linear action of G_K, de Rham as a $\mathbb{Q}_p$-representation, $b_1, \dots, b_d$ a $\mathbb{Q}_p$-basis of V, $M(\sigma) \in \mathrm{GL}_d(\mathbb{Q}_p)$ the matrix of $\sigma \in G_K$ and $B(y) \in M_d(\mathbb{Q}_p)$ the matrix of multiplication by $y \in L$ in it.*

1. *The map $K \otimes_{\mathbb{Q}_p} L \to \prod_\tau L$, $x \otimes y \mapsto (\tau(x)y)_\tau$, the product over the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$, is a ring isomorphism. Let $\epsilon_\tau \in K \otimes_{\mathbb{Q}_p} L$ be the element with components 1 at τ and 0 elsewhere, write $\epsilon_\tau = \sum_j x_j \otimes y_j$, and put $E_\tau = \sum_j x_j B(y_j) \in M_d(K)$. Then E_τ does not depend on the choice of the x_j, y_j, $E_\tau^2 = E_\tau$, $E_\tau E_{\tau'} = 0$ for $\tau \neq \tau'$, $\sum_\tau E_\tau = 1$, $\sigma(E_\tau) = E_\tau$ and $E_\tau M(\sigma) = M(\sigma) E_\tau$ for $\sigma \in G_K$.*

2. *There are a $\mathbb{C}_p$-basis $e_1, \dots, e_d$ of $\mathbb{C}_p^d$, integers $u_1, \dots, u_d$ and embeddings $\tau_1, \dots, \tau_d\colon K \to L$ such that, for all k: $\chi_{\mathrm{cyc}}(\sigma)^{u_k} M(\sigma) \sigma(e_k) = e_k$ for $\sigma \in G_K$; u_k is a Hodge jump of V at τ_k, and $u_k \in J(V)$; and $E_\tau e_k = e_k$ if $\tau = \tau_k$, $E_\tau e_k = 0$ if $\tau \neq \tau_k$.*

Proof. **Item 1.** Let $K = \mathbb{Q}_p(\alpha)$ with minimal polynomial f of degree $n = [K : \mathbb{Q}_p]$. The n embeddings of K into $\overline{\mathbb{Q}}_p$ take values in L by hypothesis, so $f = \prod_\tau (X - \tau(\alpha))$ in $L[X]$ with distinct roots ($K/\mathbb{Q}_p$ is separable). By the Chinese remainder theorem $K \otimes_{\mathbb{Q}_p} L = L[X]/(f) \to \prod_\tau L[X]/(X - \tau(\alpha)) = \prod_\tau L$ is an isomorphism; it is the stated map, since $\alpha \otimes 1 \mapsto (\tau(\alpha))_\tau$. The ring $K \otimes_{\mathbb{Q}_p} L$ acts $\mathbb{C}_p$-linearly on $\mathbb{C}_p \otimes_{\mathbb{Q}_p} V$ by $(x \otimes y)(c \otimes v) = xc \otimes yv$ ($K \subset \overline{\mathbb{Q}}_p \subset \mathbb{C}_p$); in the coordinates of the basis $b_\bullet$, $x \otimes y$ acts by the matrix $x\,B(y)$, so E_τ is the matrix of the action of ϵ_τ and does not depend on the chosen expression. The relations $\epsilon_\tau^2 = \epsilon_\tau$, $\epsilon_\tau \epsilon_{\tau'} = 0$ ($\tau \neq \tau'$), $\sum_\tau \epsilon_\tau = 1$ give the corresponding ones for E_τ. The entries of E_τ lie in K, hence are fixed by G_K; and $B(y)M(\sigma) = M(\sigma)B(y)$ because G_K acts L-linearly.

Item 2: the adapted basis of D_{dR}. Let $D = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}$ with $\mathrm{Fil}^j D = D \cap (t^j B_{\mathrm{dR}}^+ \otimes_{\mathbb{Q}_p} V)$; $\dim_K D = d$ as V is de Rham. The ring $K \otimes_{\mathbb{Q}_p} L$ acts on $B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V$ by $K \subset \overline{\mathbb{Q}}_p \subset B_{\mathrm{dR}}^+$ (Ai3) on the first factor and L on V; both commute with G_K (K is fixed by G_K, G_K acts L-linearly) and preserve $t^j B_{\mathrm{dR}}^+ \otimes V$, so they preserve D and every $\mathrm{Fil}^j D$. Hence $D = \bigoplus_\tau \epsilon_\tau D$ and $\mathrm{Fil}^j D = \bigoplus_\tau \epsilon_\tau \mathrm{Fil}^j D$ with $\epsilon_\tau \mathrm{Fil}^j D = \mathrm{Fil}^j D \cap \epsilon_\tau D$. The quotient map $D \to D_{\mathrm{dR},\tau}(V) = L \otimes_{K \otimes L, \tau \otimes \mathrm{id}} D$ is the projection onto $\epsilon_\tau D$, compatibly with the induced filtrations; so an integer a is a Hodge jump of V at τ exactly when $\epsilon_\tau \mathrm{Fil}^{a+1} D \neq \epsilon_\tau \mathrm{Fil}^a D$. On the finite-dimensional K-space $\epsilon_\tau D$ the filtration $(\epsilon_\tau \mathrm{Fil}^j D)_j$ is decreasing, equal to $\epsilon_\tau D$ for j small (a basis of D lies in $t^{-N} B_{\mathrm{dR}}^+ \otimes V$ for some N) and 0 for j large ($\bigcap_j t^j B_{\mathrm{dR}}^+ = 0$); so it has an adapted K-basis: elements d with integers u such that $\epsilon_\tau \mathrm{Fil}^j D$ is spanned by those d with $u \geq j$. Each such d lies in $\epsilon_\tau \mathrm{Fil}^u D \setminus \epsilon_\tau \mathrm{Fil}^{u+1} D$, so u is a Hodge jump of V at τ, and $\mathrm{Fil}^u D \neq \mathrm{Fil}^{u+1} D$,

so $u \in J(V)$. Taking the union over τ we get a K-basis $d_1, \dots, d_d$ of D, embeddings τ_k with $d_k \in \epsilon_{\tau_k} D$ and integers u_k with $\mathrm{Fil}^j D = \bigoplus_{u_k \ge j} K d_k$ for all j.

Item 2: the Hodge–Tate basis. Put $w_k = t^{-u_k} d_k \in B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V$. Then $\sum_j t^{-j} B_{\mathrm{dR}}^+ \otimes_K \mathrm{Fil}^j D = \bigoplus_k t^{-u_k} B_{\mathrm{dR}}^+ d_k$, so by (Ai4) (with $k=0$) the w_k generate $B_{\mathrm{dR}}^+ \otimes_{\mathbb{Q}_p} V$ over B_{dR}^+, and they are linearly independent over B_{dR} because $B_{\mathrm{dR}} \otimes_K D \to B_{\mathrm{dR}} \otimes V$ is an isomorphism; so they form a B_{dR}^+-basis. As $\theta\colon B_{\mathrm{dR}}^+ \to \mathbb{C}_p$ is onto with kernel tB_{dR}^+ (Ai3), the images $e_k = (\theta \otimes 1)(w_k)$ form a $\mathbb{C}_p$-basis of $\mathbb{C}_p \otimes_{\mathbb{Q}_p} V$; we identify $\mathbb{C}_p \otimes V$ with $\mathbb{C}_p^d$ by the basis $b_\bullet$, so that σ acts by $y \mapsto M(\sigma)\sigma(y)$. Since $\sigma(t) = \chi_{\mathrm{cyc}}(\sigma) t$ (Ai3) and $\sigma(d_k) = d_k$, $\sigma(w_k) = \chi_{\mathrm{cyc}}(\sigma)^{-u_k} w_k$, and $\theta \otimes 1$ is G_K-equivariant; so $M(\sigma)\sigma(e_k) = \chi_{\mathrm{cyc}}(\sigma)^{-u_k} e_k$. Finally $\theta \otimes 1$ commutes with the action of $K \otimes_{\mathbb{Q}_p} L$ (θ restricts to the inclusion on $K \subset \overline{\mathbb{Q}}_p$ by (Ai3), and is $\mathbb{Q}_p$-linear), and multiplication by t^{-u_k} commutes with it too; as $\epsilon_\tau d_k = \epsilon_\tau \epsilon_{\tau_k} d_k$ is d_k for $\tau = \tau_k$ and 0 otherwise, $E_\tau e_k = (\theta \otimes 1)(t^{-u_k} \epsilon_\tau d_k)$ is e_k for $\tau = \tau_k$ and 0 otherwise. □

Proposition 25.17. *Let p be a prime, K_0 a finite unramified extension of $\mathbb{Q}_p$, $m \ge 1$ with $m \ge 2$ if $p = 2$, $J \subset \mathbb{Z}$ finite, (U, g) a Sen frame of level m and rank r over K_0 with weights in J, and $G_m = G_{K_0(\mu_{p^m})}$. For $i \in \mathbb{Z}$ put*

$$N_{J,m}(i) = \max\Big(1, \sum_{u \in J,\ u \ne i} \big(m + v_p(u-i)\big)\Big).$$

A cocycle for $*_i$ *is a continuous map $c\colon G_m \to \mathbb{C}_p^r$ with $c(\sigma\tau) = c(\sigma) + \sigma *_i c(\tau)$; the* coboundary *of $x \in \mathbb{C}_p^r$ is $\sigma \mapsto \sigma *_i x - x$.*

1. *If c is a cocycle for $*_i$ with values in $\mathcal{O}_{\mathbb{C}_p}^r$ and $p^k c$ is the coboundary of an element of $\mathcal{O}_{\mathbb{C}_p}^r$ for some $k \ge 0$, then $p^{1+N_{J,m}(i)} c$ is the coboundary of an element of $\mathcal{O}_{\mathbb{C}_p}^r$.*
2. *If $i \notin J$, $M \subseteq \mathbb{C}_p^r$ is an additive subgroup with $\mathcal{O}_{\mathbb{C}_p}^r \subseteq M$ and $pM \subseteq \mathcal{O}_{\mathbb{C}_p}^r$, and $y \in \mathbb{C}_p^r$ satisfies $\sigma *_i y - y \in M$ for all $\sigma \in G_m$, then $p^{2+N_{J,m}(i)} y \in M$.*

Proof. For $r = 0$ both items are trivial; let $r \ge 1$, write $N = N_{J,m}(i)$, $H = H_{K_0}$, δx for the coboundary of x, and ζ_p for a primitive p-th root of unity.

The twisted action. For $\sigma, \tau \in G_m$ and $y \in \mathbb{C}_p^r$, $\sigma *_i (\tau *_i y) = \chi_{\mathrm{cyc}}(\sigma\tau)^i U(\sigma) U(\tau)\, \sigma\tau(y) = (\sigma\tau) *_i y$, since σ fixes $\chi_{\mathrm{cyc}}(\tau)^i \in \mathbb{Q}_p$ and the entries of $U(\tau)$, which lie in K_m, and U is multiplicative (Sf1). So $*_i$ is an action, additive, with $\sigma *_i (\lambda y) = \sigma(\lambda)\, \sigma *_i y$; $\sigma \mapsto \sigma *_i x$ is continuous (χ_{cyc}, U and the Galois action on $\mathbb{C}_p$ are continuous), so coboundaries are cocycles; $\sigma *_i$ preserves $\mathcal{O}_{\mathbb{C}_p}^r$ because $U(\sigma) \in M_r(\mathcal{O}_{K_m})$; and for $h \in H$, $h *_i y = h(y)$, as $U(h) = 1$ and $\chi_{\mathrm{cyc}}(h) = 1$. The group H is normal in G_m.

Step 1: killing the cocycle on H. Let c be as in item 1 and $p^k c = \delta x_0$ with $x_0 \in \mathcal{O}_{\mathbb{C}_p}^r$. On H, c is a continuous cocycle for the Galois action with values in $\mathcal{O}_{\mathbb{C}_p}^r$; by Lemma 25.19 with $F = K_0$ and $a = p \in K_\infty$ there is $x_1 \in \mathcal{O}_{\mathbb{C}_p}^r$ with $p\, c(h) = h(x_1) - x_1$ for $h \in H$. Put $c_1 = p\, c - \delta x_1$, a cocycle for $*_i$ with values in $\mathcal{O}_{\mathbb{C}_p}^r$ and $c_1|_H = 0$.

Step 2: its values are fixed by H. For $h \in H$ and $\sigma \in G_m$, $c_1(h\sigma) = c_1(h) + h(c_1(\sigma)) = h(c_1(\sigma))$ and $c_1(h\sigma) = c_1(\sigma \cdot \sigma^{-1} h \sigma) = c_1(\sigma) + \sigma *_i c_1(\sigma^{-1} h \sigma) = c_1(\sigma)$. So the entries of $c_1(\sigma)$ are fixed by H and lie in $\widehat{K}_\infty \cap \mathcal{O}_{\mathbb{C}_p} = \mathcal{O}_{\widehat{K}_\infty}$ by Theorem B.42(1). Moreover $p^k c_1 = p^{k+1} c - p^k \delta x_1 = \delta x_2$ with $x_2 = p\, x_0 - p^k x_1 \in \mathcal{O}_{\mathbb{C}_p}^r$, and for $h \in H$, $0 = p^k c_1(h) = h(x_2) - x_2$; so $x_2 \in \mathcal{O}_{\widehat{K}_\infty}^r$ by Theorem B.42(1).

Step 3: the coinvariant equation at g. Put $w = c_1(g) \in \mathcal{O}_{\widehat{K}_\infty}^r$, so $g *_i x_2 - x_2 = p^k w$. *There is $y \in \mathcal{O}_{\widehat{K}_\infty}^r$ with $g *_i y - y = p^N w$.* Decompose coordinatewise (Lemma 25.18(1)):

$w = w_0 + w_X$, $x_2 = v_0 + v_X$ with $w_0, v_0 \in \mathcal{O}_{K_m}^r$ and $w_X, v_X \in X_m^r$. The map $g*_i$ sends $\mathcal{O}_{K_m}^r$ into itself (there $g *_i v = \chi_{\mathrm{cyc}}(g)^i U(g)v$, as g fixes K_m) and X_m^r into itself (X_m is a G_{K_0}-stable $\mathcal{O}_{K_m}$-module). By uniqueness of the decomposition, $\chi_{\mathrm{cyc}}(g)^i U(g)v_0 - v_0 = p^k w_0$. Put $f_u = \chi_{\mathrm{cyc}}(g)^{-u} \in \mathbb{Z}_p^\times$ for $u \in \mathbb{Z}$; then

$$(U(g) - f_i)v_0 = f_i\, p^k w_0.$$

The part over K_m. Let $Q(X) = \prod_{u\in J,\, u\neq i}(X - f_u) \in \mathbb{Z}_p[X]$ and $Q(X) - Q(f_i) = (X - f_i)Q_1(X)$ with $Q_1 \in \mathbb{Z}_p[X]$ (Lemma 23.22(3)). The polynomial $Q(X)(X - f_i)$ is $\prod_{u\in J}(X - f_u)$ if $i \in J$ and a multiple of it if $i \notin J$, so $Q(U(g))(U(g) - f_i) = 0$ by Lemma 25.20(1). Applied to v_0: $f_i p^k Q(U(g))w_0 = 0$, so $Q(U(g))w_0 = 0$ and

$$\beta\, w_0 = -(U(g) - f_i)Q_1(U(g))\, w_0, \qquad \beta = Q(f_i) = \prod_{u\in J,\, u\neq i}(f_i - f_u).$$

Since $v_p(\chi_{\mathrm{cyc}}(g) - 1) = m$ (Sf2), with $m \geq 2$ if $p = 2$, $v_p(\chi_{\mathrm{cyc}}(g)^n - 1) = m + v_p(n)$ for $n \neq 0$ by Lemma 23.22(1); as $f_i - f_u = f_u(\chi_{\mathrm{cyc}}(g)^{u-i} - 1)$, $v_p(\beta) = \sum_{u\in J, u\neq i}(m + v_p(u - i)) \leq N$, so $t = p^N/\beta \in \mathbb{Z}_p$. The vector $z_0 = -t\, f_i\, Q_1(U(g))w_0 \in \mathcal{O}_{K_m}^r$ satisfies

$$g *_i z_0 - z_0 = \chi_{\mathrm{cyc}}(g)^i(U(g) - f_i)z_0 = -t(U(g) - f_i)Q_1(U(g))w_0 = t\beta\, w_0 = p^N w_0.$$

The part in X_m. As $N \geq 1 \geq 1/(p-1)$, $v_p(p^N/(\zeta_p - 1)) = N - 1/(p-1) \geq 0$ and $p^N/(\zeta_p - 1) \in \mathcal{O}_{K_1} \subseteq \mathcal{O}_{K_m}$, so $x' = p^N(\zeta_p - 1)^{-1}w_X \in X_m^r$. The matrix $A = \chi_{\mathrm{cyc}}(g)^i U(g) \in M_r(\mathcal{O}_{K_m})$ has $|A_{ab} - \delta_{ab}| < p^{-1/(p-1)}$ (write $A - 1 = \chi_{\mathrm{cyc}}(g)^i(U(g) - 1) + (\chi_{\mathrm{cyc}}(g)^i - 1)$ with $|\chi_{\mathrm{cyc}}(g)^i| = 1$: the entries of $U(g) - 1$ have absolute value $< p^{-1/(p-1)}$ by (Sf2), and $|\chi_{\mathrm{cyc}}(g)^i - 1| \leq p^{-m} < p^{-1/(p-1)}$, as $m \geq 1$, and $m \geq 2$ if $p = 2$), and $g \in G_{K_m}$ has $v_p(\chi_{\mathrm{cyc}}(g) - 1) = m$; by Lemma 25.18(2) there is $y_X \in X_m^r$ with $g *_i y_X - y_X = A\, g(y_X) - y_X = (\zeta_p - 1)x' = p^N w_X$. So $y = z_0 + y_X \in \mathcal{O}_{\widehat{K}_\infty}^r$ satisfies $g *_i y - y = p^N w$.

Step 4: the cocycle $p^N c_1 - \delta y$ vanishes. Let $d = p^N c_1 - \delta y$, a cocycle for $*_i$. For $h \in H$, $d(h) = 0 - (h(y) - y) = 0$ by Step 2 and $y \in \mathcal{O}_{\widehat{K}_\infty}^r$ (fixed by H); and $d(g) = p^N w - (g *_i y - y) = 0$. For $\sigma \in G_m$, $h \in H$: $d(\sigma h) = d(\sigma) + \sigma *_i d(h) = d(\sigma)$, so d factors through a continuous map $\bar{d}$ on $\Gamma_m = G_m/H = \mathrm{Gal}(K_\infty/K_m)$. Since K_n/K_0 has degree $p^{n-1}(p-1)$ ($\Phi_{p^n}(X+1)$ is Eisenstein over $\mathcal{O}_{K_0}$), χ_{cyc} identifies Γ_m with $1 + p^m\mathbb{Z}_p$, and $\chi_{\mathrm{cyc}}(g)$ is a topological generator of $1 + p^m\mathbb{Z}_p$; as $n \mapsto \chi_{\mathrm{cyc}}(g)^n$ extends to a homeomorphism $\mathbb{Z}_p \to 1 + p^m\mathbb{Z}_p$ and the positive integers are dense in $\mathbb{Z}_p$, the images of g^n, $n \geq 1$, are dense in Γ_m. By the cocycle relation $d(g^n) = \sum_{k=0}^{n-1} g^k *_i d(g) = 0$ for $n \geq 1$. So $\bar{d}$ vanishes on a dense subset, and $d = 0$.

Item 1. By Step 4, $p^N c_1 = \delta y$, hence $p^{N+1}c = p^N c_1 + p^N \delta x_1 = \delta(y + p^N x_1)$ with $y + p^N x_1 \in \mathcal{O}_{\mathbb{C}_p}^r$.

Item 2. Let $c(\sigma) = p\,(\sigma *_i y - y)$. It is the coboundary of py, hence a cocycle for $*_i$, and takes values in $pM \subseteq \mathcal{O}_{\mathbb{C}_p}^r$. Choose $k \geq 0$ with $p^{k+1}y \in \mathcal{O}_{\mathbb{C}_p}^r$; then $p^k c = \delta(p^{k+1}y)$. By item 1, $p^{1+N}c = \delta z$ for some $z \in \mathcal{O}_{\mathbb{C}_p}^r$. Since $p^{1+N}c = \delta(p^{2+N}y)$, the vector $p^{2+N}y - z$ is fixed by $\sigma*_i$ for every $\sigma \in G_m$, and as $i \notin J$, Lemma 25.20(2) gives $p^{2+N}y = z \in \mathcal{O}_{\mathbb{C}_p}^r \subseteq M$. □

Lemma 25.18. *Let p be a prime, $K_0 \subset \overline{\mathbb{Q}}_p$ a finite unramified extension of $\mathbb{Q}_p$, $K_n = K_0(\mu_{p^n})$ for $n \geq 0$, $K_\infty = \bigcup_n K_n$, $\widehat{K}_\infty$ the closure of K_∞ in $\mathbb{C}_p$, ζ_p a primitive p-th root of unity, and $m \geq 1$ an integer, with $m \geq 2$ if $p = 2$.*

1. *There is a unique continuous K_m-linear map $R_m \colon \widehat{K}_\infty \to K_m$ with*

$$R_m(x) = p^{m-n}\,\mathrm{Tr}_{K_n/K_m}(x) \qquad (x \in K_n,\ n \geq m).$$

It satisfies $R_m(\mathcal{O}_{\widehat{K}_\infty}) \subseteq \mathcal{O}_{K_m}$ *and* $R_m(\sigma x) = \sigma R_m(x)$ *for* $\sigma \in G_{K_0}$, $x \in \widehat{K}_\infty$. *Put* $X_m = \{x \in \mathcal{O}_{\widehat{K}_\infty} : R_m(x) = 0\}$. *Every* $z \in \mathcal{O}_{\widehat{K}_\infty}$ *can be written uniquely as* $z = z_0 + z_X$ *with* $z_0 \in \mathcal{O}_{K_m}$ *and* $z_X \in X_m$. *The set* X_m *is closed in* $\mathbb{C}_p$, $\mathcal{O}_{K_m} X_m \subseteq X_m$, *and* $\sigma(X_m) \subseteq X_m$ *for* $\sigma \in G_{K_0}$.

2. *Let* $g \in G_{K_m}$ *with* $v_p(\chi_{\mathrm{cyc}}(g) - 1) = m$, *let* $r \geq 1$, *and let* $A \in M_r(\mathcal{O}_{K_m})$ *with* $|A_{ab} - \delta_{ab}| < p^{-1/(p-1)}$ *for all entries. For every* $x \in X_m^r$ *there is exactly one* $y \in X_m^r$ *with*

$$A\, g(y) - y = (\zeta_p - 1)\, x.$$

Proof. Fix a compatible system $(\zeta_{p^n})_{n\geq 1}$ of primitive p^n-th roots of unity with $\zeta_{p^1} = \zeta_p$ and $\zeta_{p^n}^p = \zeta_{p^{n-1}}$; v is the valuation of $\mathbb{C}_p$ with $v(p) = 1$, and ϖ a uniformiser of K_m.

The layers. For $n \geq 1$ the polynomial $\Phi_{p^n}(X+1)$ is Eisenstein over $\mathcal{O}_{K_0}$, because p is a uniformiser of the unramified field K_0; so K_n/K_0 is totally ramified of degree $p^{n-1}(p-1)$ with uniformiser $\zeta_{p^n} - 1$. For $n \geq 2$, $[K_n : K_{n-1}] = p$, so $X^p - \zeta_{p^{n-1}}$ is the minimal polynomial of ζ_{p^n} over K_{n-1}, with roots $\zeta_{p^n}\zeta_p^a$ $(0 \leq a < p)$; and as K_n/K_{n-1} is totally ramified with uniformiser $\zeta_{p^n} - 1$, $\mathcal{O}_{K_n} = \mathcal{O}_{K_{n-1}}[\zeta_{p^n} - 1] = \mathcal{O}_{K_{n-1}}[\zeta_{p^n}]$ is free over $\mathcal{O}_{K_{n-1}}$ with basis $1, \zeta_{p^n}, \ldots, \zeta_{p^n}^{p-1}$ (Serre, *Local fields*, I, §6, Prop. 18).

One step of the trace. For $n \geq 2$ put $\rho_n = p^{-1}\mathrm{Tr}_{K_n/K_{n-1}}$. For $1 \leq j \leq p-1$, $\mathrm{Tr}_{K_n/K_{n-1}}(\zeta_{p^n}^j) = \zeta_{p^n}^j \sum_{a=0}^{p-1} \zeta_p^{aj} = 0$, so

$$\rho_n\Big(\sum_{j=0}^{p-1} y_j \zeta_{p^n}^j\Big) = y_0 \qquad (y_j \in K_{n-1}).$$

Hence ρ_n is the identity on K_{n-1}, $\rho_n(\mathcal{O}_{K_n}) \subseteq \mathcal{O}_{K_{n-1}}$, $\ker \rho_n = X^{(n)} := \bigoplus_{j=1}^{p-1} K_{n-1}\zeta_{p^n}^j$ and $X^{(n)} \cap \mathcal{O}_{K_n} = \bigoplus_{j=1}^{p-1} \mathcal{O}_{K_{n-1}}\zeta_{p^n}^j$. Every $\sigma \in G_{K_0}$ preserves K_n and K_{n-1} and normalises $\mathrm{Gal}(K_n/K_{n-1})$ (the group $\mathrm{Gal}(K_n/K_0)$ is abelian), so $\rho_n \circ \sigma = \sigma \circ \rho_n$ on K_n, and $\sigma(X^{(n)}) = X^{(n)}$.

Item 1. For $n \geq m$ let $R_{m,n} = \rho_{m+1} \circ \cdots \circ \rho_n \colon K_n \to K_m$ (the identity for $n = m$); by transitivity of traces $R_{m,n} = p^{m-n}\mathrm{Tr}_{K_n/K_m}$, and $R_{m,n+1}|_{K_n} = R_{m,n}$ as ρ_{n+1} is the identity on K_n. So the $R_{m,n}$ define a K_m-linear map R_m on K_∞, the identity on K_m, commuting with G_{K_0} and with $R_m(\mathcal{O}_{K_\infty}) \subseteq \mathcal{O}_{K_m}$. If $x \in K_\infty$ and $v(x) \geq k \in \mathbb{Z}_{\geq 0}$, then $p^{-k}x \in \mathcal{O}_{K_\infty}$, so $v(R_m(x)) \geq k$: R_m is uniformly continuous, and since K_m is complete and K_∞ is dense in $\widehat{K}_\infty$ it extends uniquely to a continuous map R_m on $\widehat{K}_\infty$; by continuity it is K_m-linear, maps the closure $\mathcal{O}_{\widehat{K}_\infty}$ of $\mathcal{O}_{K_\infty}$ into the closed set $\mathcal{O}_{K_m}$, and commutes with each $\sigma \in G_{K_0}$ (an isometry of $\mathbb{C}_p$ preserving K_∞). Uniqueness of R_m follows from continuity and density. As R_m is the identity on K_m, $R_m \circ R_m = R_m$; for $z \in \mathcal{O}_{\widehat{K}_\infty}$ put $z_0 = R_m(z) \in \mathcal{O}_{K_m}$ and $z_X = z - z_0$, which lies in $\mathcal{O}_{\widehat{K}_\infty}$ and has $R_m(z_X) = 0$. If $z_0 + z_X = z_0' + z_X'$ are two such decompositions, then $z_0 - z_0' \in K_m \cap \ker R_m = 0$. X_m is closed (a continuous preimage intersected with the closed $\mathcal{O}_{\widehat{K}_\infty}$), an $\mathcal{O}_{K_m}$-module by linearity, and G_{K_0}-stable by equivariance.

The kernel layer by layer. For $n > m$ and $x \in K_n$, $x = \rho_n(x) + (x - \rho_n(x))$ with $x - \rho_n(x) \in X^{(n)}$, $\rho_n(x) \in K_{n-1}$, and R_m vanishes on $X^{(n)}$ (on K_n it is $R_{m,n-1} \circ \rho_n$). By induction on n,

$$K_n = K_m \oplus X^{(m+1)} \oplus \cdots \oplus X^{(n)}, \qquad X_m \cap \mathcal{O}_{K_n} = \bigoplus_{k=m+1}^{n} (X^{(k)} \cap \mathcal{O}_{K_k}),$$

with R_m the projection to K_m; the integral form holds because each ρ_k maps $\mathcal{O}_{K_k}$ into $\mathcal{O}_{K_{k-1}}$, so the components of an integral element are integral. Moreover X_m is the closure of $X_m \cap \mathcal{O}_{K_\infty}$: if $z \in X_m$ and $z_j \in \mathcal{O}_{K_\infty}$ tend to z, then $z_j - R_m(z_j) \in X_m \cap \mathcal{O}_{K_\infty}$ tend to $z - R_m(z) = z$.

Inverting $g-1$ on one layer. Let g be as in item 2 and $n \geq m+1$, and put $h_n = g^{p^{n-1-m}}$. We have $v_p(a^p-1) = v_p(a-1)+1$ for $a \in 1+p\mathbb{Z}_p$ if p is odd, and for $a \in 1+4\mathbb{Z}_2$ if $p=2$ (then $a^2-1=(a-1)(a+1)$ with $v_2(a+1)=1$); as $v_p(\chi_{\mathrm{cyc}}(g)-1)=m$, with $m \geq 2$ if $p=2$, and the valuations only increase along the powers, it follows that $v_p(\chi_{\mathrm{cyc}}(h_n)-1) = n-1$: h_n fixes $\mu_{p^{n-1}}$ and K_0, hence K_{n-1}, and $h_n(\zeta_{p^n}) = \zeta_{p^n}\zeta_p^w$ for an integer w prime to p. So $h_n(y\zeta_{p^n}^j) = \zeta_p^{jw} y \zeta_{p^n}^j$ for $y \in K_{n-1}$, and $h_n - 1$ acts on the summand $K_{n-1}\zeta_{p^n}^j$ of $X^{(n)}$ as multiplication by $\zeta_p^{jw}-1 \neq 0$. The numbers $\varepsilon_j = (\zeta_p-1)/(\zeta_p^{jw}-1)$, $1 \leq j \leq p-1$, are units of $\mathbb{Z}_p[\zeta_p] \subseteq \mathcal{O}_{K_{n-1}}$ (both ζ_p-1 and $\zeta_p^{jw}-1$ are uniformisers of $\mathbb{Q}_p(\zeta_p)$). So $S_n = (\zeta_p-1)(h_n-1)^{-1}$, $S_n(\sum_j y_j\zeta_{p^n}^j) = \sum_j \varepsilon_j y_j \zeta_{p^n}^j$, is a K_{n-1}-linear bijection of $X^{(n)}$ preserving $X^{(n)} \cap \mathcal{O}_{K_n}$. The element g preserves K_n, $X^{(n)}$ and $\mathcal{O}_{K_n}$, is K_m-linear on K_n and commutes with h_n, hence with S_n. With $N_n = \sum_{k=0}^{p^{n-1-m}-1} g^k$ we have $(g-1)N_n = N_n(g-1) = h_n - 1$; so $T_n = N_n S_n$ is a K_m-linear endomorphism of $X^{(n)}$ commuting with g, preserving $X^{(n)} \cap \mathcal{O}_{K_n}$, with

$$(g-1)\,T_n = T_n\,(g-1) = (h_n-1)S_n = \zeta_p - 1 \qquad \text{on } X^{(n)}.$$

The operator T on X_m. On $X_m \cap K_\infty = \bigoplus_{n>m} X^{(n)}$ let $T = \bigoplus_n T_n$. It is K_m-linear, commutes with g, satisfies $(g-1)T = T(g-1) = \zeta_p - 1$, and maps $X_m \cap \mathcal{O}_{K_\infty}$ into itself by the integral decomposition above. If $x, x' \in X_m \cap \mathcal{O}_{K_\infty}$ and $v(x-x') \geq k \geq 0$, then $p^{-k}(x-x') \in X_m \cap \mathcal{O}_{K_\infty}$ and $v(T(x)-T(x')) \geq k$; so T extends by continuity to X_m (the closure of $X_m \cap \mathcal{O}_{K_\infty}$, and closed), with values in X_m, and by continuity it is $\mathcal{O}_{K_m}$-linear, commutes with g, and $(g-1)T = T(g-1) = (\zeta_p-1)\,\mathrm{id}$ on X_m. Let g and T act on X_m^r coordinatewise; then $T(Cw) = C\,T(w)$ for $C \in M_r(\mathcal{O}_{K_m})$, $w \in X_m^r$, and $T(\varpi^k X_m^r) \subseteq \varpi^k X_m^r$.

Item 2. Put $B = (\zeta_p-1)^{-1}(A-1) \in M_r(K_m)$. Its entries have absolute value <1 (as $|\zeta_p - 1| = p^{-1/(p-1)}$), so they lie in $\varpi\mathcal{O}_{K_m}$. The map $\Phi(z) = B\,g(T(z))$ satisfies $\Phi(\varpi^k X_m^r) \subseteq \varpi^{k+1} X_m^r$ for $k \geq 0$. *Existence.* The series $z = \sum_{j\geq 0}(-\Phi)^j(x)$ has its j-th term in $\varpi^j X_m^r \subseteq \varpi^j \mathcal{O}_{\mathbb{C}_p}^r$, so it converges, and its sum lies in the closed set X_m^r and satisfies $z + \Phi(z) = x$ (Φ is continuous, being additive with $\Phi(\varpi^k X_m^r) \subseteq \varpi^k X_m^r$). Put $y = T(z) \in X_m^r$. Then

$$A\,g(y) - y = (g-1)T(z) + (A-1)\,g(T(z)) = (\zeta_p-1)\big(z + \Phi(z)\big) = (\zeta_p-1)x.$$

Uniqueness. If y, y' are two solutions, $d = y - y' \in X_m^r$ satisfies $A\,g(d) = d$, so $(g-1)d = -(A-1)g(d)$; applying T gives $(\zeta_p-1)d = -(A-1)T(g(d))$, i.e. $d = -B\,T(g(d))$. If $d \in \varpi^k X_m^r$ then $-B\,T(g(d)) \in \varpi^{k+1} X_m^r$; so $d \in \bigcap_k \varpi^k \mathcal{O}_{\mathbb{C}_p}^r = 0$. □

Lemma 25.19. *Let p be a prime, F a finite extension of $\mathbb{Q}_p$, $r \geq 1$, and $c\colon H_F \to \mathcal{O}_{\mathbb{C}_p}^r$ a continuous map with $c(\sigma\tau) = c(\sigma) + \sigma\big(c(\tau)\big)$ for $\sigma, \tau \in H_F$. Then for every $a \in F_\infty$ with $|a| < 1$ there is $x \in \mathcal{O}_{\mathbb{C}_p}^r$ with $a\,c(\sigma) = \sigma(x) - x$ for all $\sigma \in H_F$.*

Proof. The action is coordinatewise, so it suffices to treat $r=1$; for $a=0$ take $x=0$. Let $a \neq 0$, and fix an integer $n \geq 1$ with $|p|^n < |a|$; put $b = p^n/a \in F_\infty$, so $|b|<1$, and every $\sigma \in H_F$ fixes a and b. Write δx for the map $\sigma \mapsto \sigma(x) - x$.

One approximation. *For every continuous $c'\colon H_F \to \mathcal{O}_{\mathbb{C}_p}$ with $c'(\sigma\tau) = c'(\sigma) + \sigma c'(\tau)$ there is $x \in \mathcal{O}_{\mathbb{C}_p}$ with $a\,c'(\sigma) - (\sigma x - x) \in p^n\mathcal{O}_{\mathbb{C}_p}$ for all $\sigma \in H_F$.* The set $V = \{\sigma \in H_F :\ c'(\sigma) \in p^n\mathcal{O}_{\mathbb{C}_p}\}$ is open (continuity) and a subgroup: $c'(\sigma\tau) = c'(\sigma) + \sigma c'(\tau)$ and $c'(\sigma^{-1}) = -\sigma^{-1}c'(\sigma)$, and H_F preserves $p^n\mathcal{O}_{\mathbb{C}_p}$. So V contains an open normal subgroup N of the profinite group H_F, and $N = \mathrm{Gal}(\overline{\mathbb{Q}}_p/L)$ for a finite Galois extension L of F_∞. By Theorem B.42(3) there is $\alpha \in \mathcal{O}_L$ with $\mathrm{Tr}_{L/F_\infty}(\alpha) = a$. Let $S \subset H_F$ be a set of representatives of H_F/N and $x = -\sum_{s\in S} s(\alpha)\,c'(s) \in \mathcal{O}_{\mathbb{C}_p}$. For $\sigma \in H_F$,

$$\sigma x = -\sum_{s\in S} \sigma s(\alpha)\big(c'(\sigma s) - c'(\sigma)\big) = -\sum_{s\in S} \sigma s(\alpha)\,c'(\sigma s) + c'(\sigma)\sum_{s\in S}\sigma s(\alpha).$$

As s runs through S, σs runs through a set of representatives of $H_F/N = \mathrm{Gal}(L/F_\infty)$; so $\sum_s \sigma s(\alpha) = \mathrm{Tr}_{L/F_\infty}(\alpha) = a$. Writing $\sigma s = s'\nu$ with $s' \in S$, $\nu \in N$, we have $\sigma s(\alpha) = s'(\alpha)$ and $c'(\sigma s) = c'(s') + s'c'(\nu) \in c'(s') + p^n\mathcal{O}_{\mathbb{C}_p}$; since $|s'(\alpha)| \le 1$, $\sum_s \sigma s(\alpha) c'(\sigma s) \equiv \sum_{s'} s'(\alpha) c'(s') = -x$ modulo $p^n\mathcal{O}_{\mathbb{C}_p}$. Hence $\sigma x - x \equiv a\, c'(\sigma)$ modulo $p^n\mathcal{O}_{\mathbb{C}_p}$.

Iteration. Put $c_0 = c$. Given a continuous cocycle $c_j\colon H_F \to \mathcal{O}_{\mathbb{C}_p}$, choose x_j by the approximation and put $c_{j+1} = p^{-n}(a\, c_j - \delta x_j)$, again a continuous cocycle with values in $\mathcal{O}_{\mathbb{C}_p}$. By induction on $J \ge 0$,

$$a\, c = \delta\Big(\sum_{j<J} b^j x_j\Big) + b^J a\, c_J,$$

since $b^J a\, c_J = b^J(\delta x_J + p^n c_{J+1}) = \delta(b^J x_J) + b^{J+1} a\, c_{J+1}$ (b is fixed by H_F). As $|b| < 1$ and $|c_J(\sigma)| \le 1$, letting $J \to \infty$ gives $a\, c = \delta x$ with $x = \sum_{j\ge 0} b^j x_j \in \mathcal{O}_{\mathbb{C}_p}$. □

Lemma 25.20. *Let p be a prime, K_0 a finite unramified extension of $\mathbb{Q}_p$, $m \ge 1$ with $m \ge 2$ if $p = 2$, $J \subset \mathbb{Z}$ finite, and (U, g) a Sen frame of level m and rank r over K_0 with weights in J.*

1. *$\prod_{u\in J}(U(g) - \chi_{\mathrm{cyc}}(g)^{-u}\cdot 1) = 0$ in $M_r(K_0(\mu_{p^m}))$.*
2. *If $i \in \mathbb{Z}\setminus J$ and $w \in \mathbb{C}_p^r$ satisfies $\sigma *_i w = w$ for all $\sigma \in G_{K_0(\mu_{p^m})}$, then $w = 0$.*

Proof. For $r = 0$ there is nothing to prove; let $r \ge 1$. Let $E \in \mathrm{GL}_r(\mathbb{C}_p)$ be the matrix with columns $e_1, \dots, e_r$ of (Sf3) and $D(\sigma) = \mathrm{diag}(\chi_{\mathrm{cyc}}(\sigma)^{-u_1}, \dots, \chi_{\mathrm{cyc}}(\sigma)^{-u_r})$. Then (Sf3) reads

$$U(\sigma)\,\sigma(E) = E\, D(\sigma) \qquad (\sigma \in G_{K_m}).$$

Item 2. Write $w = Ea$ with $a \in \mathbb{C}_p^r$. Then

$$\sigma *_i w = \chi_{\mathrm{cyc}}(\sigma)^i U(\sigma)\sigma(E)\sigma(a) = E\big(\chi_{\mathrm{cyc}}(\sigma)^i D(\sigma)\sigma(a)\big).$$

Since E is invertible, $\sigma *_i w = w$ for all σ means $\chi_{\mathrm{cyc}}(\sigma)^{i-u_k}\sigma(a_k) = a_k$ for all $\sigma \in G_{K_m}$ and all k. Since $u_k \in J$ and $i \notin J$, $i - u_k \ne 0$, and Theorem B.42(2) for the finite extension K_m of $\mathbb{Q}_p$ gives $a_k = 0$. So $w = 0$.

E has entries in $\widehat{K}_\infty$. For $h \in H_{K_0} \subseteq G_{K_m}$, $U(h) = 1$ by (Sf1) and $\chi_{\mathrm{cyc}}(h) = 1$ (h fixes μ_{p^∞}), so $h(E) = E$, and by Theorem B.42(1) for $F = K_0$ the entries of E lie in $\widehat{K}_\infty$. Choose $s \ge 0$ with $p^s E \in M_r(\mathcal{O}_{\widehat{K}_\infty})$ and decompose entrywise by Lemma 25.18(1): $p^s E = E_0 + E_X$ with $E_0 \in M_r(\mathcal{O}_{K_m})$ and $E_X \in M_r(X_m)$.

The kernel part vanishes. Multiply the displayed relation at $\sigma = g$ by p^s: $U(g)\, g(E_0) + U(g)\, g(E_X) = E_0 D(g) + E_X D(g)$. Here $g(E_0) = E_0$ (g fixes K_m), so $U(g)g(E_0)$ and $E_0 D(g)$ have entries in $\mathcal{O}_{K_m}$, while $U(g)g(E_X)$ and $E_X D(g)$ have entries in X_m (X_m is a G_{K_0}-stable $\mathcal{O}_{K_m}$-module, $U(g) \in M_r(\mathcal{O}_{K_m})$, $D(g) \in M_r(\mathbb{Z}_p)$). By uniqueness of the decomposition, $U(g)E_0 = E_0 D(g)$ and $U(g)g(E_X) = E_X D(g)$. So the k-th column $x_k \in X_m^r$ of E_X satisfies $A_k g(x_k) - x_k = 0$ with $A_k = \chi_{\mathrm{cyc}}(g)^{u_k} U(g) \in M_r(\mathcal{O}_{K_m})$. Now $A_k - 1 = \chi_{\mathrm{cyc}}(g)^{u_k}(U(g) - 1) + (\chi_{\mathrm{cyc}}(g)^{u_k} - 1)\cdot 1$, where $|\chi_{\mathrm{cyc}}(g)^{u_k}| = 1$, the entries of $U(g) - 1$ have absolute value $< p^{-1/(p-1)}$ by (Sf2), and $|\chi_{\mathrm{cyc}}(g)^{u_k} - 1| \le p^{-m} < p^{-1/(p-1)}$ because $\chi_{\mathrm{cyc}}(g) \in 1 + p^m\mathbb{Z}_p$ and $m > 1/(p-1)$ ($m \ge 1$ and $p \ge 3$, or $m \ge 2$ and $p = 2$). So A_k satisfies the hypothesis of Lemma 25.18(2), whose uniqueness (with $x = 0$, of which $y = 0$ is a solution) gives $x_k = 0$. Hence $E_X = 0$ and $p^s E = E_0$.

Item 1. So $E \in M_r(K_m) \cap \mathrm{GL}_r(\mathbb{C}_p) = \mathrm{GL}_r(K_m)$, and the relation at $\sigma = g$ becomes $U(g) = E\, D(g)\, E^{-1}$. Therefore

$$\prod_{u\in J}(U(g) - \chi_{\mathrm{cyc}}(g)^{-u}) = E\Big(\prod_{u\in J}(D(g) - \chi_{\mathrm{cyc}}(g)^{-u})\Big)E^{-1} = 0,$$

since the product in the middle is diagonal with k-th entry $\prod_{u\in J}(\chi_{\mathrm{cyc}}(g)^{-u_k}-\chi_{\mathrm{cyc}}(g)^{-u})$, which contains the factor $u=u_k\in J$. □

Lemma 25.21. *Let p be a prime and ξ a generator of $\ker\theta$. For integers $0\le a\le b$ let $Q_{a,b}=\xi^aA_{\mathrm{inf}}/\xi^bA_{\mathrm{inf}}$, with the action of $G_{\mathbb{Q}_p}$ induced from A_{inf} and the p-adic topology.*

1. *For $a\le e\le b$ the sequence $0\to Q_{e,b}\to Q_{a,b}\to Q_{a,e}\to 0$ of inclusion and projection is exact and $G_{\mathbb{Q}_p}$-equivariant; $Q_{a,b}$ has no p-torsion; and $p^nQ_{a,b}\cap Q_{e,b}=p^nQ_{e,b}$ for $n\ge 0$.*
2. *For every $x\in Q_{a,b}$ the map $G_{\mathbb{Q}_p}\to Q_{a,b}$, $\sigma\mapsto\sigma x$, is continuous.*
3. *For every $i\ge 0$ there is a bijective additive map $\vartheta_i\colon Q_{i,i+1}\to\mathcal{O}_{\mathbb{C}_p}$ with $\vartheta_i(p^nx)=p^n\vartheta_i(x)$ for $n\ge 0$ and $\vartheta_i(\sigma x)=\chi_{\mathrm{cyc}}(\sigma)^i\,\sigma(\vartheta_i(x))$ for $\sigma\in G_{\mathbb{Q}_p(\mu_p)}$.*

Proof. Write $A=A_{\mathrm{inf}}$ and $I=(p,\xi_0)=(p,[p^\flat])$ (Ai1). As ξ and ξ_0 generate the same ideal of the domain A (Ai1), $\xi=v\xi_0$ with $v\in A^\times$, so $\xi^jA=\xi_0^jA$ for all j and we may take $\xi=\xi_0$. Since θ is $G_{\mathbb{Q}_p}$-equivariant, $\sigma(\xi_0)\in\ker\theta=\xi_0A$, so every σ preserves the ideals ξ_0^jA and acts on the $Q_{a,b}$.

Item 3 without the Galois action, and item 1. Multiplication by ξ_0^i is injective on the domain A and induces an isomorphism $A/\xi_0A\to\xi_0^iA/\xi_0^{i+1}A$; with $A/\xi_0A\cong\mathcal{O}_{\mathbb{C}_p}$ via θ (Ai1), $\vartheta_i(\xi_0^i\lambda \bmod \xi_0^{i+1})=\theta(\lambda)$ is a well-defined additive bijection $Q_{i,i+1}\to\mathcal{O}_{\mathbb{C}_p}$, and $\vartheta_i(p^nx)=p^n\vartheta_i(x)$. The sequence of item 1 is exact by the isomorphism $(\xi_0^aA/\xi_0^bA)/(\xi_0^eA/\xi_0^bA)\cong\xi_0^aA/\xi_0^eA$, and equivariant. By induction on $b-a$, using the sequences $0\to Q_{b-1,b}\to Q_{a,b}\to Q_{a,b-1}\to 0$ and $Q_{b-1,b}\cong\mathcal{O}_{\mathbb{C}_p}$, every $Q_{a,b}$ has no p-torsion. If $x\in Q_{a,b}$ and $p^nx\in Q_{e,b}$, the image of x in $Q_{a,e}$ is killed by p^n, hence zero, so $x\in Q_{e,b}$: this gives $p^nQ_{a,b}\cap Q_{e,b}=p^nQ_{e,b}$.

Item 2. Let $x\in Q_{a,b}$ with a lift $\tilde x\in\xi_0^aA$, let $n\ge 0$ and $N=n+b-1$. Every generator $p^j\xi_0^{N-j}$ of I^N has $j\ge n$ or $N-j\ge b$, so $I^N\subseteq p^nA+\xi_0^bA$. By (Ai2) the set $U=\{\sigma:\ \sigma\tilde x-\tilde x\in I^N\}$ is open. For $\sigma\in U$, $y=\sigma\tilde x-\tilde x\in\xi_0^aA$ is $p^ns+\xi_0^bs'$ with $s,s'\in A$; then $p^ns\in\xi_0^aA$, and since $A/\xi_0^aA=Q_{0,a}$ has no p-torsion, $s\in\xi_0^aA$. So $\sigma x-x\in p^nQ_{a,b}$ for $\sigma\in U$, and for any τ, $\sigma x-\tau x=\tau(\tau^{-1}\sigma x-x)\in p^nQ_{a,b}$ for $\sigma\in\tau U$. Hence $\sigma\mapsto\sigma x$ is continuous.

The cocycle of ξ_0. Let $\sigma\in G_{\mathbb{Q}_p(\mu_p)}$ and $\alpha=\chi_{\mathrm{cyc}}(\sigma)\in 1+p\mathbb{Z}_p$. Modulo p, $q-1\equiv[\varepsilon^{1/p}-1]$ and $\varepsilon^{1/p}-1$ has positive valuation, so $(q-1)^M\in I$ for some $M\ge 1$ and $(q-1)^k\to 0$ for the I-adic topology. By (Ai2) the series $q^\beta=\sum_{k\ge 0}\binom{\beta}{k}(q-1)^k$ converges for $\beta\in\mathbb{Z}_p$, depends continuously on β, and is the usual power for $\beta\in\mathbb{Z}_{\ge 0}$. The element $\varepsilon^{1/p}$ has p-power-compatible components $\zeta_{p^{k+1}}$ $(k\ge 0)$, and σ raises them to the power α; so if integers $\alpha_j\ge 0$ tend to α, the components of $(\varepsilon^{1/p})^{\alpha_j}$ converge to those of $\sigma(\varepsilon^{1/p})$, and by continuity of the Teichmüller map (Ai2) $\sigma(q)=[\sigma(\varepsilon^{1/p})]=\lim_j q^{\alpha_j}=q^\alpha$; hence $\sigma(q^p)=q^{p\alpha}=(q^p)^\alpha$, the last power taken by the binomial series in q^p-1 (both sides are continuous in α and agree on $\mathbb{Z}_{\ge 0}$). Put $S=\sum_{k\ge 1}\binom{\alpha}{k}(q-1)^{k-1}$ and $S'=\sum_{k\ge 1}\binom{\alpha}{k}(q^p-1)^{k-1}$, so $\sigma(q)-1=(q-1)S$ and $\sigma(q^p)-1=(q^p-1)S'$. Since $\theta(I)\subseteq p\mathcal{O}_{\mathbb{C}_p}$, θ is continuous; with $\theta(q)=\zeta_p$ and $\theta(q^p)=\theta([\varepsilon])=1$ (Ai1),

$$\theta(S)=\sum_{k\ge 1}\binom{\alpha}{k}(\zeta_p-1)^{k-1}=\frac{\zeta_p^\alpha-1}{\zeta_p-1}=1,\qquad \theta(S')=\alpha,$$

because $\alpha\equiv 1 \bmod p$. Now $\xi_0(q-1)=q^p-1$; applying σ, $\sigma(\xi_0)(q-1)S=(q^p-1)S'=\xi_0(q-1)S'$, and as A is a domain and $q-1\ne 0$ $(\theta(q-1)=\zeta_p-1\ne 0)$, $\sigma(\xi_0)S=\xi_0S'$. Writing $\sigma(\xi_0)=\xi_0c_\sigma$ with $c_\sigma\in A$ and cancelling ξ_0, $c_\sigma S=S'$, so $\theta(c_\sigma)=\alpha$.

Item 3. For $x=\xi_0^i\lambda \bmod \xi_0^{i+1}$ and $\sigma\in G_{\mathbb{Q}_p(\mu_p)}$, $\sigma x=\xi_0^ic_\sigma^i\sigma(\lambda) \bmod \xi_0^{i+1}$, so $\vartheta_i(\sigma x)=\theta(c_\sigma)^i\theta(\sigma\lambda)=\chi_{\mathrm{cyc}}(\sigma)^i\sigma(\vartheta_i(x))$ by equivariance of θ. □

Lemma 25.22. *Let p be a prime, F a finite extension of $\mathbb{Q}_p$, V a de Rham representation of G_F on a finite-dimensional $\mathbb{Q}_p$-vector space, $T \subset V$ a G_F-stable $\mathbb{Z}_p$-lattice, ξ a generator of $\ker\theta$ and $0 \le a \le e \le b$ integers; give $T \otimes_{\mathbb{Z}_p} Q_{a,b}$ the diagonal action of G_F. If $z \in T \otimes_{\mathbb{Z}_p} Q_{a,e}$ is fixed by G_F, there are $k \ge 0$ and $x \in T \otimes_{\mathbb{Z}_p} Q_{a,b}$ fixed by G_F whose image in $T \otimes_{\mathbb{Z}_p} Q_{a,e}$ is $p^k z$.*

Proof. Write $A = A_{\mathrm{inf}}$, $B = B_{\mathrm{dR}}^+$; as $\xi A = \xi_0 A$ we may take $\xi = \xi_0$, and $\xi_0 B = tB$ by (Ai3).

Rationalisation. By (Ai3) the natural map $A[1/p]/\xi_0^b A[1/p] \to B/t^b B$ is a $G_{\mathbb{Q}_p}$-equivariant isomorphism; it maps $\xi_0^a A[1/p]/\xi_0^b A[1/p] = Q_{a,b}[1/p]$ onto $\xi_0^a(B/t^bB) = t^aB/t^bB$. Put $W_{a,b} = V \otimes_{\mathbb{Q}_p} t^aB/t^bB$. As T is free over $\mathbb{Z}_p$ and $Q_{a,b}$ has no p-torsion (Lemma 25.21(1)), $T \otimes Q_{a,b} \to W_{a,b}$ is injective and G_F-equivariant, every element of $W_{a,b}$ has a p-power multiple in its image, and these maps commute with the projections to $W_{a,e}$, $T \otimes Q_{a,e}$. So it suffices to show that $W_{a,b}^{G_F} \to W_{a,e}^{G_F}$ is onto: if $x' \in W_{a,b}^{G_F}$ maps to the image of z, choose k with $p^k x'$ in the image of $T \otimes Q_{a,b}$; its preimage x is fixed by G_F (injectivity and equivariance) and maps to $p^k z$ (injectivity of $T \otimes Q_{a,e} \to W_{a,e}$).

An adapted basis. Let $D = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_F}$ with $\mathrm{Fil}^j D = D \cap (t^j B \otimes V)$; V being de Rham, $\dim_F D = \dim_{\mathbb{Q}_p} V$. The $\mathrm{Fil}^j D$ form a decreasing filtration by F-subspaces, equal to D for j small (a basis of D lies in $t^{-N}B \otimes V$ for some N) and to 0 for j large ($\bigcap_j t^j B = 0$). Choose an F-basis $d_1, \dots, d_n$ of D and integers $h_1, \dots, h_n$ with $\mathrm{Fil}^j D = \bigoplus_{h_k \ge j} F d_k$. Then $\sum_j t^{a-j}B \otimes_F \mathrm{Fil}^j D = \bigoplus_k t^{a-h_k} B\, d_k$, and by (Ai4) for $k = a$ and $k = b$,

$$W_{a,b} \cong \bigoplus_{k=1}^{n} (t^{a-h_k}B/t^{b-h_k}B)\, d_k,$$

G_F-equivariantly (G_F fixes the d_k) and compatibly with the projection to $W_{a,e}$.

Invariants of $t^cB/t^{c'}B$. Let $c \le c'$ be integers. B is a discrete valuation ring with uniformiser t and $\theta\colon B/tB \cong \mathbb{C}_p$ (Ai3), so $y \mapsto \theta(t^{-j}y)$ identifies $t^jB/t^{j+1}B$ with $\mathbb{C}_p$ on which σ acts by $\chi_{\mathrm{cyc}}(\sigma)^j\sigma$ (as $\sigma t = \chi_{\mathrm{cyc}}(\sigma)t$). Its G_F-invariants are 0 for $j \ne 0$ by Theorem B.42(2) and F for $j = 0$ by Theorem B.42(1). By left exactness of invariants and induction on $c' - c$, $(t^cB/t^{c'}B)^{G_F}$ is an F-space of dimension at most 1, and 0 unless $c \le 0 < c'$. If $c \le 0 < c'$, the image of $F \subset \overline{\mathbb{Q}}_p \subset B$ (Ai3) lies in it and is non-zero (θ is injective on F), so the invariants are exactly the image of F.

Conclusion. Hence $W_{a,b}^{G_F} = \bigoplus_{k:\, a \le h_k < b} F\,\bar{d}_k$ and $W_{a,e}^{G_F} = \bigoplus_{k:\, a \le h_k < e} F\,\bar{d}_k$, where $\bar{d}_k$ is the image of $1 \cdot d_k$; the projection maps $\bar{d}_k$ to $\bar{d}_k$, so $W_{a,b}^{G_F} \to W_{a,e}^{G_F}$ is onto. □

25.3 The Bloch–Kato condition in negative Tate twists; lengths of invariants

The second step towards Proposition 25.8 is Proposition 25.23: if a cocycle becomes, after multiplication by ℓ^N, a coboundary with values in $T \otimes A_{\mathrm{inf}}/\xi^{e+1}A_{\mathrm{inf}}$, then its push into the negative Tate twist $L(-e)/\mathcal{O}_L(-e)$ lies in H^1_f after multiplication by $\ell^{N+e+4+\lfloor e/(\ell-1)\rfloor + v_\ell(e) + v_\ell(e+1)}$. The proof uses an integral form of the dual exponential at a finite cyclotomic level (Definition 25.25, Proposition 25.26), whose image is controlled by values of ψ-invariant series and twisted Frobenius power sums. Two descent lemmas move lifting exponents between a subfield of a cyclotomic field and a cyclotomic layer over its unramified part (Lemma 25.32, Lemma 25.33), and Lemma 25.34 bounds the length of the invariants of a crystalline lattice quotient, a term in Theorem 25.1. The subsection ends with Corollary 25.39, the explicit local losses at unramified places that the budget reads at the split and inert primes.

Proposition 25.23. *Let p, K, $K_1 = K_0(\mu_p) \supseteq K$ and $L \supseteq \mathcal{O}_L$ be as in Proposition 25.10, ξ a generator of $\ker\theta$. Let T be a G_K-stable $\mathcal{O}_L$-lattice in a finite-dimensional continuous L-linear representation of G_K, $e \geq 0$ an integer, $\varphi\colon T \to L/\mathcal{O}_L$ an $\mathcal{O}_L$-linear map with $\varphi(gx) = \chi_{\mathrm{cyc}}(g)^{-e}\varphi(x)$ ($g \in G_K$, $x \in T$), and $f\colon G_K \to T$ a continuous 1-cocycle. Let $N \geq 0$ be an integer such that $g \mapsto p^N(f(g)\otimes 1)$ is a coboundary of G_{K_1} with values in $T \otimes_{\mathbb{Z}_p} A_{\mathrm{inf}}/\xi^{e+1}A_{\mathrm{inf}}$ (diagonal action, p-adic topology). Then*

$$p^{\,N+(e+2)+v_p(e)+\lfloor e/(p-1)\rfloor+2+v_p(e+1)}\,[g \mapsto \varphi(f(g))] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e)).$$

Level s. *More generally, let p be a prime, $s \geq 1$ an integer with $s \geq 2$ if $p = 2$, K a finite extension of $\mathbb{Q}_p$ with maximal unramified subextension K_0 such that $K \subseteq K_s := K_0(\mu_{p^s})$, and L a finite extension of $\mathbb{Q}_p$ containing $\sigma(K_s)$ for every $\mathbb{Q}_p$-embedding σ of K_s, with ring of integers $\mathcal{O}_L$. Let ξ, T, e, φ and f be as above, and let $N \geq 0$ be an integer such that $g \mapsto p^N(f(g)\otimes 1)$ is a coboundary of G_{K_s} with values in $T \otimes_{\mathbb{Z}_p} A_{\mathrm{inf}}/\xi^{e+1}A_{\mathrm{inf}}$. Then*

$$p^{\,N+s(e+4)+v_p(e)+\lfloor e/(p-1)\rfloor+v_p(e+1)}\,[g \mapsto \varphi(f(g))] \in H^1_f(G_K, L(-e)/\mathcal{O}_L(-e)).$$

For $s = 1$ and p odd the exponent is $N + (e+2) + v_p(e) + \lfloor e/(p-1)\rfloor + 2 + v_p(e+1)$ and this is the statement above.

Proof. We prove the assertion of the paragraph Level s; the first assertion is its case $s = 1$, p odd (the hypotheses there, with $K_1 = K_0(\mu_p)$, are those of the case $s = 1$, and the exponents agree: $s(e+4) = e+4 = (e+2)+2$). So let p, s, $K \subseteq K_s$, L, T, e, φ, f and N be as in Level s. Write $W = L(-e)$, $\Lambda = \mathcal{O}_L(-e)$, $\chi = \chi_{\mathrm{cyc}}$, $Q = A_{\mathrm{inf}}/\xi^{e+1}A_{\mathrm{inf}} = Q_{0,e+1}$, $\kappa = s + v_p(e+1)$ and $M' = N + a_{e,s} + \kappa$. Since $\xi A_{\mathrm{inf}} = \xi_0 A_{\mathrm{inf}}$ and $\xi_0 B^+_{\mathrm{dR}} = tB^+_{\mathrm{dR}}$, (Ai3) gives a $G_{\mathbb{Q}_p}$-equivariant isomorphism $Q[1/p] \cong B^+_{\mathrm{dR}}/t^{e+1}B^+_{\mathrm{dR}}$ compatible with the maps from A_{inf}, and $Q \subset Q[1/p]$ as Q has no p-torsion (Lemma 25.21(1)). As $K_0/\mathbb{Q}_p$ is unramified, $[K_0(\mu_{p^j}) : K_0] = (p-1)p^{j-1}$ for $j \geq 1$, so χ maps G_{K_0} onto $\mathbb{Z}_p^\times$ and G_{K_s} onto $1 + p^s\mathbb{Z}_p$; so some $g \in G_{K_s}$ has $v_p(\chi(g) - 1) = s$.

Step 1: coordinates. $\varphi(T)$ is a finitely generated submodule of $L/\mathcal{O}_L$, hence killed by some p^r, so φ factors through T/p^rT and $g \mapsto \varphi(f(g))$ is a continuous cocycle. Let $w_1, \ldots, w_n$ be a $\mathbb{Z}_p$-basis of $\mathcal{O}_L$. As T is free over $\mathbb{Z}_p$, φ has a $\mathbb{Z}_p$-linear lift $\Phi\colon T \to p^{-r}\mathcal{O}_L$; write $\Phi(y) = \sum_i \psi_i(y)w_i$ with $\mathbb{Z}_p$-linear $\psi_i\colon T \to p^{-r}\mathbb{Z}_p$. Since $\Phi(gy)$ and $\chi(g)^{-e}\Phi(y)$ both lift $\varphi(gy)$, $\varepsilon_{g,i}(y) = \psi_i(gy) - \chi(g)^{-e}\psi_i(y) \in \mathbb{Z}_p$ for $g \in G_K$, $y \in T$. Put $c_i(\sigma) = \psi_i(f(\sigma))$. Then $c_i(\sigma\tau) - c_i(\sigma) - \chi(\sigma)^{-e}c_i(\tau) = \varepsilon_{\sigma,i}(f(\tau)) \in \mathbb{Z}_p$; and as f is continuous, every σ has a neighbourhood U with $f(\tau) - f(\sigma) \in p^rT$, hence $c_i(\tau) - c_i(\sigma) \in \mathbb{Z}_p$, for $\tau \in U$.

Step 2: genuine cocycles over K_s. By Lemma 25.24 (for $F = K_s$, this s and g, the restriction of c_i to G_{K_s}; for $p = 2$ its last sentence, as $s \geq 2$) there are continuous $z_i\colon G_{K_s} \to \mathbb{Q}_p$ with $z_i(\sigma\tau) = z_i(\sigma) + \chi(\sigma)^{-e}z_i(\tau)$ and $z_i - p^\kappa c_i$ with values in $\mathbb{Z}_p$.

Step 3: the trivialisation modulo t^{e+1} pushed to the coordinates. By hypothesis there is $X \in T \otimes_{\mathbb{Z}_p} Q$ with $p^N f(\sigma)\otimes 1 = \sigma X - X$ for $\sigma \in G_{K_s}$. The additive map $\Psi_i = \psi_i \otimes 1\colon T \otimes_{\mathbb{Z}_p} Q \to \mathbb{Q}_p \otimes_{\mathbb{Z}_p} Q = Q[1/p]$ satisfies, for $y \in T$, $a \in Q$, $\sigma \in G_K$,

$$\Psi_i(\sigma(y\otimes a)) = \psi_i(\sigma y)\,\sigma(a) = \chi(\sigma)^{-e}\sigma\big(\Psi_i(y\otimes a)\big) + \varepsilon_{\sigma,i}(y)\,\sigma(a),$$

so $\Psi_i(\sigma x) - \chi(\sigma)^{-e}\sigma(\Psi_i(x)) \in Q$ for all $x \in T \otimes Q$. With $\beta_i = \Psi_i(X)$ this gives $p^N c_i(\sigma) \equiv \chi(\sigma)^{-e}\sigma(\beta_i) - \beta_i$ modulo Q, and hence, by Step 2,

$$p^N z_i(\sigma) = p^{N+\kappa}c_i(\sigma) + p^N\big(z_i(\sigma) - p^\kappa c_i(\sigma)\big) \equiv \chi(\sigma)^{-e}\sigma(p^\kappa\beta_i) - p^\kappa\beta_i \pmod{Q} \qquad (\sigma \in G_{K_s}).$$

Transporting by $Q[1/p] \cong B^+_{\mathrm{dR}}/t^{e+1}B^+_{\mathrm{dR}}$, choose $b_i \in B^+_{\mathrm{dR}}$ lifting the image of $p^\kappa\beta_i$ and, for each σ, $a_{\sigma,i} \in A_{\mathrm{inf}}$ lifting the element of Q above; then $p^N z_i(\sigma) - (\chi(\sigma)^{-e}\sigma(b_i) - b_i) - a_{\sigma,i} \in t^{e+1}B^+_{\mathrm{dR}}$.

Step 4: the integral dual exponential. By Proposition 25.26 (paragraph Level s) applied to $p^N z_i$ there are continuous cocycles $z_{1,i}\colon G_{K_s} \to \mathbb{Z}_p$ (for χ^{-e}) and $b_{1,i} \in B_{\mathrm{dR}}^+$ such that $y_i = p^{N+a_{e,s}} z_i - z_{1,i}$ satisfies $\omega_i(\sigma) = y_i(\sigma) - (\chi(\sigma)^{-e}\sigma(b_{1,i}) - b_{1,i}) \in t^{e+1}B_{\mathrm{dR}}^+$ for $\sigma \in G_{K_s}$.

Step 5: the classes y_i are crystalline. Let $V_e = \mathbb{Q}_p(-e)$, the representation of G_{K_s} on $\mathbb{Q}_p$ by χ^{-e}, so that $B_{\mathrm{dR}}^+ \otimes V_e$ is B_{dR}^+ with $\sigma * x = \chi(\sigma)^{-e}\sigma(x)$. Then y_i is a continuous cocycle with values in V_e, and ω_i is a continuous cocycle for $*$ with values in $t^{e+1}B_{\mathrm{dR}}^+$ (the difference of y_i and a coboundary; $\sigma \mapsto \sigma(b_{1,i})$ is continuous). Multiplication by t^{-e} is an isomorphism of $(t^{e+1}B_{\mathrm{dR}}^+, *)$ onto tB_{dR}^+ with its Galois action, since $\sigma(t) = \chi(\sigma)t$. By Theorem B.46(1) for $F = K_s$, $\omega_i(\sigma) = \sigma * x_i - x_i$ for some $x_i \in t^{e+1}B_{\mathrm{dR}}^+$, so y_i is the coboundary of $b_{1,i} + x_i$ in $B_{\mathrm{dR}}^+ \otimes V_e \subset B_{\mathrm{dR}} \otimes V_e$, and $[y_i] \in H^1_g(K_s, V_e)$. Now $V_e^*(1) = \mathbb{Q}_p(1+e)$, the maximal unramified subfield of K_s is K_0 (K_s/K_0 is totally ramified), and $D_{\mathrm{cris}}(\mathbb{Q}_p(1+e))$ is the K_0-line spanned by t^{-1-e} times a basis vector, on which φ acts by $a\,t^{-1-e} \mapsto \varphi(a)p^{-1-e}t^{-1-e}$ ($\varphi(t) = pt$) [52]; as φ is an isometry of K_0, $\varphi(a)p^{-1-e} = a$ forces $a = 0$. By Theorem B.46(2), $H^1_g(K_s, V_e) = H^1_f(K_s, V_e)$, so $[y_i] \in H^1_f(K_s, V_e)$.

Step 6: the class over K_s. As a representation of G_{K_s} over $\mathbb{Q}_p$, $W = \bigoplus_i \mathbb{Q}_p w_i \cong V_e^{\oplus n}$, so $Y(\sigma) = \sum_i y_i(\sigma)w_i$ is a continuous cocycle with $[Y] \in H^1_f(K_s, W)$ (a coboundary in $B_{\mathrm{cris}} \otimes V_e$ in each coordinate). For $\sigma \in G_{K_s}$,

$$Y(\sigma) - p^{M'}\Phi(f(\sigma)) = \sum_i \Big(p^{N+a_{e,s}}\big(z_i(\sigma) - p^{\kappa}c_i(\sigma)\big) - z_{1,i}(\sigma)\Big)w_i \in \mathcal{O}_L,$$

so the image of $[Y]$ in $H^1(G_{K_s}, W/\Lambda)$ is the restriction of $p^{M'}[\varphi \circ f]$.

Step 7: descent to K. The degree $m = [K_s : K]$ divides $[K_s : K_0] = (p-1)p^{s-1}$, so $m = p^v u$ with $v \le s-1$ and $p \nmid u$. Corestriction $\mathrm{cor}\colon H^1(G_{K_s}, -) \to H^1(G_K, -)$ is natural in the coefficient module and $\mathrm{cor} \circ \mathrm{res}$ is multiplication by m (continuous cochains; Serre, *Cohomologie galoisienne*, I.2.4). Naturality for $W \to B_{\mathrm{cris}} \otimes W$ gives $\mathrm{cor}(H^1_f(K_s, W)) \subseteq H^1_f(K, W)$, and naturality for $W \to W/\Lambda$ gives

$$m\,p^{M'}[\varphi \circ f] = \mathrm{cor}\big(\mathrm{res}\,p^{M'}[\varphi \circ f]\big) = \text{image of } \mathrm{cor}[Y] \in H^1_f(G_K, W/\Lambda).$$

Every continuous cocycle of G_K with values in the discrete torsion module W/Λ has finite image, hence is killed by a power of p; so $H^1(G_K, W/\Lambda)$ is a $\mathbb{Z}_p$-module on which u acts invertibly, and $H^1_f(G_K, W/\Lambda)$, the image of an L-subspace under a $\mathbb{Z}_p$-linear map, is a $\mathbb{Z}_p$-submodule. Hence $p^{M'+v}[\varphi \circ f]$ and $p^{M'+s-1}[\varphi \circ f]$ lie in $H^1_f(G_K, L(-e)/\mathcal{O}_L(-e))$, and

$$\begin{aligned} M' + s - 1 &= N + s(e+2) + v_p(e) + \Big\lfloor \frac{e}{p-1} \Big\rfloor + 1 + s + v_p(e+1) + s - 1 \\ &= N + s(e+4) + v_p(e) + \Big\lfloor \frac{e}{p-1} \Big\rfloor + v_p(e+1). \end{aligned}$$

□
