2. *its finite part $G[\mathfrak{P}]^f$ is a finite locally free $\mathcal{O}_E$-stable subgroup scheme, equal to $G[p]^f \cap G[\mathfrak{P}]$, and isomorphic, $\mathcal{O}_E$-equivariantly, to $\widetilde{G}[\mathfrak{P}] = \bigcap_{a\in\mathfrak{P}} \ker(\iota(a)|_{\widetilde{G}})$;*
3. *$\omega_{G[\mathfrak{P}]^f} = \omega_{G[\mathfrak{P}]} \cong \omega_G \otimes_{\mathcal{O}_E} \mathbb{F}_{\mathfrak{P}} = \omega_G/\mathfrak{P}\omega_G$ as $R \otimes \mathcal{O}_E$-modules.*

Proof. We use the following standard facts: (i) a scheme quasi-finite and separated over a henselian local scheme S is the disjoint union of an open and closed subscheme finite over S (the largest one) and one with empty closed fibre (EGA IV, 18.5.11); a morphism to it from a scheme finite over S factors through the finite part; (ii) for a semiabelian scheme $[p]$ is quasi-finite and flat (SGA 7, Exp. IX, §2); (iii) for a smooth commutative group scheme P over S and $M \geq 1$, $\omega_{P[M]} = \omega_P/M\omega_P$, since the ideal of $P[M]$ near the unit section s_0 is generated by the $f \circ [M]$ with f in the ideal of s_0 and $s_0^*d(h \cdot f \circ [M]) = h(s_0)\, M\, s_0^*df$.

(1) As p is unramified in E, $\mathcal{O}_E/p = \prod_{\mathfrak{P}'|p} \mathbb{F}_{\mathfrak{P}'}$, with orthogonal idempotents $\epsilon_{\mathfrak{P}'}$ summing to 1. By (ii) $G[p]$ is closed, quasi-finite and flat over S, and $\mathcal{O}_E/p$ acts on it; the endomorphisms $\epsilon_{\mathfrak{P}'}$ of $G[p]$ are orthogonal idempotents with sum the identity, so $G[p] = \prod_{\mathfrak{P}'} \epsilon_{\mathfrak{P}'}G[p]$. For $a \in \mathfrak{P}$, a acts on $\epsilon_{\mathfrak{P}}G[p]$ by $a\epsilon_{\mathfrak{P}} = 0$; conversely, on $\epsilon_{\mathfrak{P}'}G[p]$ with $\mathfrak{P}' \neq \mathfrak{P}$ an element $a \in \mathfrak{P} \setminus \mathfrak{P}'$ acts invertibly (its image in $\mathbb{F}_{\mathfrak{P}'}$ is a unit), and $G[\mathfrak{P}] \subseteq G[p]$ as $p \in \mathfrak{P}$; hence $G[\mathfrak{P}] = \epsilon_{\mathfrak{P}}G[p]$. A direct factor of a flat quasi-finite group scheme is flat and quasi-finite, it is closed, $\mathcal{O}_E$-stable, and $\mathcal{O}_E$ acts on it through $\mathcal{O}_E/\mathfrak{P}$.

(2) S is complete, hence henselian, so by (i) $G[p]^f$ and $G[\mathfrak{P}]^f$ exist. For $a \in \mathcal{O}_E$ the image of $G[p]^f$ under $\iota(a)$ is finite over S, so lies in $G[p]^f$ by (i); thus $G[p]^f$ is $\mathcal{O}_E$-stable and $G[p]^f = \prod_{\mathfrak{P}'}(G[p]^f \cap G[\mathfrak{P}'])$, each factor open and closed in $G[\mathfrak{P}']$ and finite over S. A finite open and closed subscheme of $G[\mathfrak{P}]$ is finite over S inside $G[p]$, hence lies in $G[p]^f$ by (i); so $G[\mathfrak{P}]^f = G[p]^f \cap G[\mathfrak{P}] = \epsilon_{\mathfrak{P}}G[p]^f$. It is open and closed in the flat $G[\mathfrak{P}]$, so flat, and finite over the noetherian S, so finite locally free. By Theorem B.119 (1) there is an isomorphism $G[p]^f \cong \widetilde{G}[p]$, characterised on formal completions by $G^{\mathrm{for}} \cong \widetilde{G}^{\mathrm{for}}$; the endomorphisms $\iota(a)$ of G and their extensions to $\widetilde{G}$ (the Raynaud extension is unique up to unique isomorphism, Theorem B.109

(1), so endomorphisms of G extend uniquely and compatibly with $G^{\mathrm{for}} \cong \widetilde{G}^{\mathrm{for}}$) correspond on formal completions, and a morphism of schemes finite over the complete noetherian local ring R is determined by its formal completion. So the isomorphism is $\mathcal{O}_E$-equivariant and carries $\epsilon_{\mathfrak{P}} G[p]^f$ to $\epsilon_{\mathfrak{P}} \widetilde{G}[p] = \widetilde{G}[\mathfrak{P}]$ (the argument of (1) applies to $\widetilde{G}[p]$).

(3) $G[\mathfrak{P}]^f$ is an open subscheme of $G[\mathfrak{P}]$ containing the unit section, so $\omega_{G[\mathfrak{P}]^f} = \omega_{G[\mathfrak{P}]}$. For a product $H = H_1 \times H_2$ of group schemes, $\omega_H = \omega_{H_1} \oplus \omega_{H_2}$, and the idempotent endomorphism of H projecting onto H_1 acts on ω_H by the projection onto ω_{H_1}. With (1) and (iii), $\omega_{G[p]} = \omega_G / p\,\omega_G$ and

$$\omega_{G[\mathfrak{P}]} = \epsilon_{\mathfrak{P}}^*(\omega_G/p\,\omega_G) = (\omega_G/p\,\omega_G) \otimes_{\mathcal{O}_E/p} \mathbb{F}_{\mathfrak{P}} = \omega_G \otimes_{\mathcal{O}_E} \mathbb{F}_{\mathfrak{P}} = \omega_G/\mathfrak{P}\omega_G,$$

compatibly with the actions of R and $\mathcal{O}_E$. □

Lemma 35.31. *Let $\mathcal{X}$ be a joint model of the stages (B_0, c) and (B, c) of a root tower with a good origin over an integral model $\mathcal{Y}$, with function field Ω, let $p \in S(B_0, B)$ and let $R = R(p)$ be the integer at p of the root origin of $\mathcal{X}_{B,c}$. Let $\mathcal{X}'$ be a normal integral noetherian scheme with function field Ω' and $\pi\colon \mathcal{X}' \to \mathcal{X}$ a dominant morphism with $[\Omega' : \Omega] < \infty$, such that every prime $\ell \neq p$ is a unit on $\mathcal{X}'$; put $G' = \pi^* G_{\mathcal{X}}$, $\mathrm{Li} = \mathrm{Lie}(G'_{\Omega'})$, and for a point x let $V_{s,x} = \mathrm{HT}_{s,x}(p^R)$ if x lies over p and $V_{s,x} = \mathrm{dR}_{s,x}$ otherwise. Then:*

1. *$\mathcal{X}'$ with $f_0 \circ \mathrm{pr}_0 \circ \pi = f_1 \circ \mathrm{pr}_1 \circ \pi$ is a cover of $\mathcal{Y}$ in which every p^R-torsion point of G' over an algebraic closure of Ω' is defined over Ω', and at every point x over p the module ht_x is free of rank $\dim_{\Omega'} \mathrm{Li}$;*
2. *for every label s and every Ω'-basis $\beta = (\beta_1, \dots, \beta_r)$ of Li_s, the subsheaves $L, W \subseteq \Omega'^r$ with*

$$L(U) = \{c : \textstyle\sum_k c_k \beta_k \in \mathrm{dR}_{s,x}\ \forall x \in U\}, \qquad W(U) = \{c : \textstyle\sum_k c_k \beta_k \in V_{s,x}\ \forall x \in U\}$$

   are locally free of rank r with stalks $L_x = \{c : \sum_k c_k \beta_k \in \mathrm{dR}_{s,x}\}$ and $W_x = \{c : \sum_k c_k \beta_k \in V_{s,x}\}$; and their dual lattices $L^\vee$, $W^\vee$ (formed as in (Hf2) of Definition 35.22) are locally free of rank r, with stalks the dual lattices of L_x, W_x in Ω'^r for the dot product;
3. *if $w \in \Gamma(\mathcal{X}', \mathcal{O}_{\mathcal{X}'})$ satisfies $w^{p-1} = u\,p$ with u a unit on $\mathcal{X}'$, then $L \subseteq W \subseteq w^{-1}L$ and $W^\vee \subseteq L^\vee \subseteq w^{-1}W^\vee$.*

Proof. **Step 1: cover and torsion.** $\mathcal{X}'$ is normal, integral and noetherian; $f_0 \circ \mathrm{pr}_0 = f_1 \circ \mathrm{pr}_1$ by (Jm1), and $\mathrm{pr}_1 \circ \pi$ is dominant, so the generic point of $\mathcal{X}'$ maps to that of $\mathcal{X}_{B,c}$, hence by (Go3)(1) to the generic point of the component $\mathcal{Y}_c$, which meets $j(\mathrm{Sh}_F)$; and Ω', finite over Ω, is finitely generated over the residue field of that point. So $\mathcal{X}'$ is a cover with $G_{\mathcal{X}'} = G'$. Since $p \in S_B$, (Go3)(2) for $\mathcal{X}_1 = \mathcal{X}_{B,c}$ says that every p^R-torsion point of $G_{\mathcal{X}_1}$ is rational over Ω_1 and that ht_{x_1} is free of rank $g = \dim \mathrm{Li}$ at every point x_1 of $\mathcal{X}_1$ over p. By Lemma 31.30(2) for the dominant morphism $\mathrm{pr}_1 \circ \pi$, every p^R-torsion point of G' is rational over Ω', and $\mathrm{ht}_x = \mathcal{O}_x \cdot \mathrm{ht}_{x_1}$ for x over p, x_1 its image (which lies over p). So ht_x is generated by g elements. By Lemma 31.30(1), $p^R \omega_x \subseteq \mathrm{ht}_x$, so these g elements span the g-dimensional space $\mathrm{Li}^\vee$ and are linearly independent; ht_x is free of rank g. This is (1).

Step 2: W. Apply Lemma 31.29(1) to $\phi = \mathrm{pr}_1 \circ \pi\colon \mathcal{X}' \to \mathcal{X}_1$ with $S = S_B$ and the integers $R(\ell)$ of the root origin of $\mathcal{X}_1$: S_B contains the primes dividing $\mathrm{disc}(E)$; (Hp1) and (Hp2) are (Go3)(2) for $\mathcal{X}_1$. Hence the Hodge lattices of $\mathcal{X}'$ at (S_B, R) form a Hodge bundle $\mathcal{V}'_s \subseteq \mathrm{Li}_s$, locally free of rank $\mathrm{rk}(s) = r$ with stalks the Hodge lattices. A point of $\mathcal{X}'$ lies over a prime $\ell \in S_B$ only if $\ell = p$, all other primes being units; so the Hodge lattice of $\mathcal{X}'$ at (S_B, R) at x is $\mathrm{HT}_{s,x}(p^{R(p)}) = V_{s,x}$ if x lies over p and $\mathrm{dR}_{s,x} = V_{s,x}$ otherwise. As $\mathcal{V}'_s$ is a subsheaf of the constant sheaf Li_s, a vector lies in $\mathcal{V}'_s(U)$ iff it lies in $V_{s,x}$ for every $x \in U$. Therefore W is the

image of $\mathcal{V}'_s$ under the isomorphism $\mathrm{Li}_s \to \Omega'^r$ of coordinates in β: locally free of rank r, with stalks W_x as stated.

Step 3: L. Apply Lemma 31.29(1) to $\phi = \mathrm{pr}_0 \circ \pi \colon \mathcal{X}' \to \mathcal{X}_0 = \mathcal{X}_{B_0,c}$ with $S = S_{B_0}$ and the integers of the root origin of $\mathcal{X}_0$; its hypotheses hold as in Step 2 by (Go3)(1), (2) for $\mathcal{X}_0$, and $f_0 \circ \mathrm{pr}_0 \circ \pi$ is the structure map of the cover $\mathcal{X}'$. No point of $\mathcal{X}'$ lies over a prime of S_{B_0} (the only prime that is not a unit is $p \notin S_{B_0}$), so the Hodge lattices of $\mathcal{X}'$ at (S_{B_0}, R) are the $\mathrm{dR}_{s,x}$, and they form a Hodge bundle. As in Step 2, L is locally free of rank r with stalks L_x.

Step 4: the duals. Let $M \in \{L, W\}$ and U an open on which M is free with basis $c^{(1)}, \dots, c^{(r)}$; they form a basis of Ω'^r. For $e \in \Omega'^r$: if $e \in M^\vee(U)$ then $e{\cdot}c^{(k)} \in \mathcal{O}(U)$; conversely, if $e{\cdot}c^{(k)} \in \mathcal{O}(U)$ for all k, then $e{\cdot}c' \in \mathcal{O}(U')$ for every open $U' \subseteq U$ and $c' \in M(U') = \sum_k \mathcal{O}(U')c^{(k)}$. So $M^\vee(U)$ is free on the dual basis, and the same holds on every open of U; hence $M^\vee$ is locally free of rank r with stalk at x the span of the dual basis, which is the dual lattice of $M_x = \sum_k \mathcal{O}_x c^{(k)}$. This is (2).

Step 5: the inclusions (3). By Lemma 35.32, Ω' contains a primitive p-th root of unity ζ_p, and at every point x over p the element $\varpi_p = \zeta_p - 1$ lies in $\mathcal{O}_x$; as $\varpi_p^{p-1} \in p\,\mathbb{Z}[\zeta_p]^\times$ and $w^{p-1} = up$, the element w/ϖ_p has a unit $(p-1)$-th power, so $w\mathcal{O}_x = \varpi_p \mathcal{O}_x$ ($\mathcal{O}_x$ is normal). Let x lie over p. By Step 1, ht_x is free of rank $\dim \mathrm{Li}$, so Lemma 35.32(3) gives $\mathrm{dR}_{s,x} \subseteq \mathrm{HT}_{s,x}(p^R)$ and $\varpi_p \sigma_s(d)\,\mathrm{HT}_{s,x}(p^R) \subseteq \mathrm{dR}_{s,x}$ for every $d \in \mathfrak{d}_E$ (for $s = (\tau, -)$ even with $\sigma_s(d)$ omitted). As p is unramified in E, $\mathfrak{d}_E + p\mathcal{O}_E = \mathcal{O}_E$; choosing $d \in \mathfrak{d}_E$ with $d - 1 \in p\mathcal{O}_E$, $\sigma_s(d) \in 1 + p\mathcal{O}_x$ is a unit ($\sigma_s(\mathcal{O}_E)$ consists of algebraic integers, which lie in the normal ring $\mathcal{O}_x$). Hence $\mathrm{dR}_{s,x} \subseteq V_{s,x} \subseteq w^{-1}\mathrm{dR}_{s,x}$, that is $L_x \subseteq W_x \subseteq w^{-1}L_x$. If x does not lie over p, then $V_{s,x} = \mathrm{dR}_{s,x}$ and w is a unit at x, so the same chain holds. Since L, W are defined pointwise, $L \subseteq W \subseteq w^{-1}L$. Dualising (the dual lattice reverses inclusions and $(w^{-1}L)^\vee = wL^\vee$) gives $W^\vee \subseteq L^\vee$ and $wL^\vee \subseteq W^\vee$, that is $L^\vee \subseteq w^{-1}W^\vee$. □

Lemma 35.32. *Let $\mathcal{X}$ be a locally noetherian cover of an integral model of a unitary Shimura datum, with function field Ω, and put $g = \dim_\Omega \mathrm{Li}$. Let p be a prime and $R \geq 1$ an integer such that every p^R-torsion point of $G_\mathcal{X}$ over an algebraic closure of Ω is defined over Ω. Then Ω contains a primitive p-th root of unity ζ; put*

$$\varpi_p = 4 \quad (p = 2), \qquad \varpi_p = \zeta - 1 \quad (p \text{ odd}).$$

Let x be a point of $\mathcal{X}$ over p such that ht_x is a free $\mathcal{O}_x$-module of rank g. Then $\varpi_p \in \mathcal{O}_x$, and:

1. *$\varpi_p\, \omega_x \subseteq \mathrm{ht}_x \subseteq \omega_x$;*
2. *for every label s: $\mathrm{dR}_{s,x} \subseteq \mathrm{HT}'_{s,x}$ and $\varpi_p\, \mathrm{HT}'_{s,x} \subseteq \mathrm{dR}_{s,x}$;*
3. *for every label s: $\mathrm{dR}_{s,x} \subseteq \mathrm{HT}_{s,x}(p^R)$; and $\varpi_p\, \mathrm{HT}_{s,x}(p^R) \subseteq \mathrm{dR}_{s,x}$ if $s = (\tau, -)$, while $\varpi_p\, \sigma_s(d)\, \mathrm{HT}_{s,x}(p^R) \subseteq \mathrm{dR}_{s,x}$ for every $d \in \mathfrak{d}_E$ if $s = (\tau, +)$.*

In particular, if $\mathcal{X} = \mathcal{X}_{B,c}$ carries a root origin, all of this holds at every point x over every $\ell \in S_B$, with $p = \ell$ and $R = R(\ell)$.

Proof. Write $N = p^R$, $G = G_\mathcal{X}$ and $T = G(\Omega)[N]$; by hypothesis T is the whole group of N-torsion points over an algebraic closure $\overline{\Omega}$, so $T \cong (\mathbb{Z}/N)^{2g}$, and $g \geq 1$.

Step 0: roots of unity. The Weil pairing $e_N \colon T \times T \to \mu_N(\overline{\Omega})$ of the principal polarisation is perfect, hence surjective onto $\mu_N(\overline{\Omega})$, and it commutes with $\mathrm{Gal}(\overline{\Omega}/\Omega)$, which fixes T pointwise; so $\mu_N(\overline{\Omega}) \subseteq \Omega$, and ζ exists. Roots of unity are integral over $\mathbb{Z}$ and every local ring $\mathcal{O}_x$ of the normal scheme $\mathcal{X}$ is integrally closed in Ω, so $\mu_N \subseteq \mathcal{O}_x$ and $\varpi_p \in \mathcal{O}_x$. For every valuation v on

an extension of Ω with $v(p)=1$ we have $v(\varpi_p)\geq\frac{1}{p-1}$: $v(4)=2$ for $p=2$, and $v(\zeta-1)=\frac{1}{p-1}$ for p odd.

Step 1: Hodge–Tate spans localise. Let x be any point over p and q a generisation of x that lies over p; then $\mathcal{O}_q$ is a localisation of $\mathcal{O}_x$, $\omega_q=\mathcal{O}_q\omega_x$ and $\mathrm{Lie}_q=\mathcal{O}_q\mathrm{Lie}_x$. We claim $\mathrm{ht}_q=\mathcal{O}_q\,\mathrm{ht}_x$. By Lemma 31.30(1), $\mathrm{ht}_x=\sum_{y\in T}\mathcal{O}_x w_y+N\omega_x$, where w_y is a Hodge–Tate value of y at x with a function ϕ_y on an open set U_y containing the unit point $\epsilon(x)$. The unit section is continuous, so $\epsilon(q)$ is a generisation of $\epsilon(x)$ and lies in U_y; and $w_y-\epsilon^*d\phi_y\in N\omega_x\subseteq N\omega_q$. So w_y is a Hodge–Tate value of y at q, and Lemma 31.30(1) at q gives $\mathrm{ht}_q=\sum_y\mathcal{O}_q w_y+N\omega_q=\mathcal{O}_q\mathrm{ht}_x$.

Step 2: the lower inclusion at a point of codimension one over p. Let q be a point over p with $\mathcal{O}_q$ of dimension one; it is a noetherian normal local domain of dimension one, i.e. a discrete valuation ring, with p in its maximal ideal. We show $\varpi_p\omega_q\subseteq\mathrm{ht}_q$. (a) Let $\widehat{\mathcal{O}}$ be the completion of $\mathcal{O}_q$, K its fraction field, $v=\mathrm{ord}_q/\mathrm{ord}_q(p)$, so that K is complete with $v(p)=1$; let $\overline{K}$ be an algebraic closure and $\mathcal{O}_{\overline{K}}$ its valuation ring. Put $\omega=\omega_q\otimes\widehat{\mathcal{O}}$ and $\omega_{\overline{K}}=\omega_q\otimes_{\mathcal{O}_q}\mathcal{O}_{\overline{K}}$, free of rank g. (b) The torsion group scheme. Over $\mathcal{O}_q$, G is semiabelian; on each fibre $[N]$ is an isogeny of smooth connected groups, hence flat, so $[N]$ is flat by the fibrewise criterion and quasi-finite. Hence $\Gamma=G[N]=[N]^{-1}(\epsilon)$ is a closed subgroup scheme, flat, quasi-finite and separated of finite type, and its ideal near the unit section is generated by the functions $f\circ[N]$ with f in the ideal J of ϵ. Its generic fibre is finite étale of order N^{2g} with all N^{2g} points rational over Ω: the constant group T. Over the complete, hence henselian, local ring $\widehat{\mathcal{O}}$, $\Gamma_{\widehat{\mathcal{O}}}$ is the disjoint union of a finite part, which is a finite disjoint union of local schemes, one for each point of the closed fibre, and an open part with empty closed fibre (EGA IV 18.5.11). Let $\Gamma^0=\operatorname{Spec}\Lambda$ be the local piece at the unit point e' of the closed fibre: it is open in $\Gamma_{\widehat{\mathcal{O}}}$, so flat, and finite of finite presentation, so Λ is a free $\widehat{\mathcal{O}}$-module of finite rank; it consists of the generisations of e'. It is a subgroup scheme: $\Lambda\otimes_{\widehat{\mathcal{O}}}\Lambda$ is finite over $\widehat{\mathcal{O}}$ with local closed fibre (since e' has residue field that of $\widehat{\mathcal{O}}$), hence local (Tag 04GG (10)), so every point of $\Gamma^0\times\Gamma^0$ is a generisation of (e',e') and multiplication sends it to a generisation of e'; likewise for the inverse and the unit. So Γ^0 is a commutative finite flat group scheme over $\widehat{\mathcal{O}}$, whose generic fibre is the constant group of a subgroup $T^0\subseteq T$; its order $|T^0|$ is a power of p. Its module of invariant differentials is

$$\omega_{\Gamma^0}=\epsilon^*\Omega^1_{\Gamma^0}=\omega/N\omega,$$

since Γ^0 is open in $\Gamma_{\widehat{\mathcal{O}}}$, $\epsilon^*d\big(h\cdot(f\circ[N])\big)=h(\epsilon)\,N\,\epsilon^*df$ for $f\in J$ ($[N]$ induces multiplication by N on invariant differentials and $f\circ[N]\circ\epsilon=0$), and the ϵ^*df, $f\in J$, span ω. (c) Characters are Hodge–Tate values. Let $\chi\in\mathrm{Hom}(\Gamma^0_{\mathcal{O}_{\overline{K}}},\mathbb{G}_m)$, i.e. a unit $u\in\Lambda\otimes\mathcal{O}_{\overline{K}}$ with $u\otimes u$ as comultiplication and $u(\epsilon)=1$; then $\chi^*\frac{dT}{T}=\epsilon^*du$. On the generic fibre χ is a homomorphism $\chi_0\colon T^0\to\mu_N\subseteq\Omega$. As $\mu_N\cong\mathbb{Z}/N$ is an injective $\mathbb{Z}/N$-module, χ_0 extends to a homomorphism $T\to\mu_N$, which by perfectness is $e_N(y,\cdot)$ for some $y\in T$. Let w_y be a Hodge–Tate value of y at q with function ϕ on an open $U\ni\epsilon(q)$ (it exists by Lemma 31.30(1)). The preimage of U in $G_{\widehat{\mathcal{O}}}$ is open and contains e' (which maps to $\epsilon(q)$), hence contains all generisations of e', i.e. Γ^0; so ϕ restricts to $\phi^0\in\Lambda$. Since Λ is free, $\Lambda\otimes\mathcal{O}_{\overline{K}}\subseteq\Lambda\otimes\overline{K}=\overline{K}^{T^0}$, and at every $t\in T^0$ both $\phi^0\otimes1$ and u take the value $e_N(y,t)$; hence $u=\phi^0\otimes1$ and $\chi^*\frac{dT}{T}$ is the image of $\epsilon^*d\phi\equiv w_y\pmod{N\omega_q}$ in $\omega_{\overline{K}}/N\omega_{\overline{K}}=\omega_{\Gamma^0}\otimes\mathcal{O}_{\overline{K}}$. (d) Fargues. Apply Theorem B.53 to K, v and the Cartier dual $(\Gamma^0)^D$ (commutative, finite flat of order $|T^0|$), whose points over $\mathcal{O}_{\overline{K}}$ are the characters χ of (c), whose dual is Γ^0 and whose Hodge–Tate map is $\chi\mapsto\chi^*\frac{dT}{T}$; with $a=\varpi_p$ (Step 0) it gives $\varpi_p(\omega_{\overline{K}}/N\omega_{\overline{K}})\subseteq$ the $\mathcal{O}_{\overline{K}}$-span of these values. By (c) the span lies in the image of $H=\mathrm{ht}_q\otimes\mathcal{O}_{\overline{K}}$, so $\varpi_p\omega_{\overline{K}}\subseteq H+N\omega_{\overline{K}}=H$, as $N\omega_q\subseteq\mathrm{ht}_q$. Here $H\to\omega_{\overline{K}}$ is injective because $\mathcal{O}_q\to\mathcal{O}_{\overline{K}}$ is flat ($\mathcal{O}_{\overline{K}}$ is torsion free over the discrete valuation ring $\mathcal{O}_q$). (e) Descent. $\mathcal{O}_q\to\mathcal{O}_{\overline{K}}$ is a flat local homomorphism, hence faithfully flat. The module $Q=(\varpi_p\omega_q+\mathrm{ht}_q)/\mathrm{ht}_q$ satisfies $Q\otimes\mathcal{O}_{\overline{K}}=(\varpi_p\omega_{\overline{K}}+H)/H=0$, hence $Q=0$.

Step 3: item 1. $\mathrm{ht}_x \subseteq \omega_x$ by definition. The $\mathcal{O}_x$-modules ht_x and ω_x are free, so by Matsumura 11.5 applied coordinatewise $\mathrm{ht}_x = \bigcap_{\mathfrak{q}} (\mathrm{ht}_x)_{\mathfrak{q}}$ over the primes $\mathfrak{q}$ of height one of the noetherian normal domain $\mathcal{O}_x$. Let $w \in \omega_x$ and $\mathfrak{q}$ such a prime. If $p \in \mathfrak{q}$, then $(\mathcal{O}_x)_{\mathfrak{q}} = \mathcal{O}_q$ for a generisation q of x over p of codimension one, and $\varpi_p w \in \mathrm{ht}_q = (\mathrm{ht}_x)_{\mathfrak{q}}$ by Steps 2 and 1. If $p \notin \mathfrak{q}$, then N is a unit in $(\mathcal{O}_x)_{\mathfrak{q}}$ and $(\mathrm{ht}_x)_{\mathfrak{q}} \supseteq N(\omega_x)_{\mathfrak{q}} = (\omega_x)_{\mathfrak{q}} \ni \varpi_p w$. Hence $\varpi_p w \in \mathrm{ht}_x$.

Step 4: items 2 and 3. As Lie_x is free and ω_x is its dual, $\mathrm{Lie}_x = \{e \in \mathrm{Li} : \ w(e) \in \mathcal{O}_x \text{ for all } w \in \omega_x\}$. If $e \in \mathrm{dR}_{s,x} = \mathrm{Lie}_x \cap \mathrm{Li}_s$, then $w(e) \in \mathcal{O}_x$ for $w \in \mathrm{ht}_x \subseteq \omega_x$, so $e \in \mathrm{HT}'_{s,x}$. If $e \in \mathrm{HT}'_{s,x}$ and $w \in \omega_x$, then $\varpi_p w \in \mathrm{ht}_x$ by item 1, so $w(\varpi_p e) \in \mathcal{O}_x$; hence $\varpi_p e \in \mathrm{Lie}_x \cap \mathrm{Li}_s$. This is item 2. For $s = (\tau, -)$, $\mathrm{HT}_{s,x}(p^R) = \mathrm{HT}'_{s,x}$ and item 3 is item 2. For $s = (\tau, +)$ and $d \in \mathfrak{d}_E \subseteq \mathcal{O}_E$, $\sigma_s(d) \in \mathcal{O}_F$, whose image lies in $\mathcal{O}_x$ ($\mathcal{X}$ maps to $\mathcal{Y}$ over $\mathcal{O}_F$). If $e \in \mathrm{dR}_{s,x}$, then $\sigma_s(d)e \in \mathrm{dR}_{s,x} \subseteq \mathrm{HT}'_{s,x}$ for all d, so $e \in \mathrm{HT}_{s,x}(p^R)$; if $e \in \mathrm{HT}_{s,x}(p^R)$, then $\sigma_s(d)e \in \mathrm{HT}'_{s,x}$ and $\varpi_p \sigma_s(d) e \in \mathrm{dR}_{s,x}$ by item 2.

Root origins. $\mathcal{X}_{B,c}$ is a closed subscheme of a multiprojective space over $\mathbb{Z}$, hence noetherian, and a cover by (Go3)(1); by (Go3)(2), for $\ell \in S_B$ the $\ell^{R(\ell)}$-torsion is rational over Ω and ht_x is free of rank $\dim \mathrm{Li}$ at every point x over ℓ. □

Lemma 35.33. *Let $\mathfrak{T}$, p, R, w, a, $s = (a, +)$, $\bar{s}$, m, $\beta, \bar{\beta}$ and g be as in Lemma 35.34, and let $y = (y_1, \dots, y_m)$ be points for $(\mathfrak{T}, s)$. Then there is a Hodge–Tate atlas $(U_\nu, \iota_\nu, h_\nu)_\nu$ for $(\mathfrak{T}, s, \beta, \bar{\beta})$ with points y whose charts are Weil-adjoint: with forms η_j^ν,*

$$\sum_{l=1}^{m} \iota_\nu(c)_l \, g_{lj} = \eta_j^\nu \Big(\sum_k c_k \beta_k \Big) \qquad \text{for all } \nu, \ c \in V_L, \ 1 \le j \le m.$$

Proof. **Step 1: a chart around every point over p.** Let x be a point over p. By Lemma 31.30(1) each y_i has a Hodge–Tate value at x: by the definition of a Hodge–Tate value there is a regular function ϕ_i on an open neighbourhood N_i of the unit point $e(x)$ in G' with $\phi_i(g') = e_{p^R}(y_i, g')$ for every algebraically closed field $k \supseteq \Omega'$ and every $g' \in G'(k)[p^R]$. Put $N = \bigcap_i N_i$ and $U_x = e^{-1}(N)$, an open neighbourhood of x in $\mathcal{X}'$. Then $e^* d\phi_i$ is a section of $\omega_{G'}$ over U_x; let η_i be the linear form on Li given by its generic fibre. For every point $x' \in U_x$ over p, the function ϕ_i is regular on the neighbourhood N of $e(x')$ and has the Weil-pairing property, and $\eta_i(v) = d\phi_i(v)$ for $v \in \mathrm{Lie}_{x'}$; so $\eta_i|_{\mathrm{Lie}_{x'}}$ lies in $\omega_{x'}$ (the stalk of $\omega_{G'}$) and is a Hodge–Tate value at x' of y_i. Let $h_x \colon V_H \to V_\omega$ be the linear map with $h_x(e_i) = (\eta_i(\bar{\beta}_k))_k$. Then $(0, h_x)$ is a Hodge–Tate chart over U_x with points y and forms η_i, and by Lemma 35.34(1) so is (ι_x, h_x) with $\iota_x(c)_l = \sum_j \eta_j(\sum_k c_k \beta_k)(g^{-1})_{jl}$, which satisfies $\sum_l \iota_x(c)_l g_{lj} = \eta_j(\sum_k c_k \beta_k)$.

Step 2: finitely many charts cover. The points over p form the closed subset $Z = V(p)$ of the noetherian scheme $\mathcal{X}'$, which is quasi-compact; choose finitely many points $x_1, \dots, x_r$ over p with $Z \subseteq U_{x_1} \cup \dots \cup U_{x_r}$. On $U_0 = \mathcal{X}' \setminus Z$ no point lies over p, so $(0, 0)$ (forms $\eta_i = 0$) is a Hodge–Tate chart over U_0 with points y, and it is Weil-adjoint ($0 = 0$). The family consisting of $(U_0, 0, 0)$ and $(U_{x_k}, \iota_{x_k}, h_{x_k})$, $1 \le k \le r$, is a Hodge–Tate atlas with points y whose charts are Weil-adjoint. □

Lemma 35.34. *Let $\mathfrak{T} = (\mathcal{O}', \mathcal{X}', \pi, (\mathcal{A}_{\mathfrak{P}}, \theta))$ be a pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ with p odd and unramified in E, Ω' the function field of $\mathcal{X}'$, $G' = \pi^* G_{\mathcal{X}}$ with its principal polarisation, $R \ge 1$ as in Definition 35.22, and $w \in \mathcal{O}'$ with $w^{p-1} = u\,p$, $u \in \mathcal{O}'^{\times}$. Let $a \in \Phi$, $s = (a, +)$, $\bar{s} = (a, -)$, $\kappa = \mathrm{rk}(s)$, $m = m_{\mathfrak{P}_s}$, bases $\beta, \bar{\beta}$ as in Definition 35.22, and let (ι, h) be a Hodge–Tate chart over an open $U \subseteq \mathcal{X}'$ for $(\mathfrak{T}, s, \beta, \bar{\beta})$ with points $y_1, \dots, y_m$ and forms $\eta_1, \dots, \eta_m$. Let $\zeta \in \Omega'$ be a primitive p^R-th root of unity, $e_{p^R}(y, y') = \zeta^{\varepsilon(y, y')}$ the Weil pairing of the polarisation on $G'(\Omega')[p^R]$ with $\varepsilon(y, y') \in \{0, \dots, p^R - 1\}$, (ϖ_k) a $\mathbb{Z}$-basis of $\mathcal{O}_E$ with dual basis (ϖ_k^*) for the trace form, and $g_{lj} = \sum_k \sigma_s(\varpi_k^*)\, \varepsilon(\varpi_k y_l, y_j)$.*

1. *$g = (g_{lj}) \in \mathrm{GL}_m(\mathcal{O}')$. Define $\iota_0 \colon V_L \to V_H$ by $\iota_0(c)_l = \sum_j \eta_j(\sum_k c_k\beta_k)(g^{-1})_{jl}$. Then (ι_0, h) is a Hodge–Tate chart over U for $(\mathfrak{T}, s, \beta, \bar\beta)$ with the same y_i, η_i, and $\sum_l \iota_0(c)_l g_{lj} = \eta_j(\sum_k c_k\beta_k)$ for every $c \in V_L$ and every j.*

2. *Let x be a point of U over p at which ht_x is a free $\mathcal{O}_x$-module of rank $\dim_{\Omega'} \mathrm{Lie}(G'_{\Omega'})$. Put $W^x = \{c \in V_L : \sum_k c_k\beta_k \in V_{s,x}\}$, $\bar W^x = \{c \in V_\omega : \sum_k c_k\bar\beta_k \in V_{\bar s,x}\}$ and $\omega'^x = \{c \in V_\omega : c \cdot c' \in \mathcal{O}_x \ \forall c' \in \bar W^x\}$. Then W^x and ω'^x are free $\mathcal{O}_x$-modules of ranks κ and $\dim V_\omega$, and*

$$\iota_0(W^x) \subseteq \mathcal{O}_x^m, \qquad W^x \cap \iota_0^{-1}(w\,\mathcal{O}_x^m) = w\,W^x, \qquad h(\mathcal{O}_x^m) \subseteq \omega'^x, \qquad h(\mathcal{O}_x^m) + w\,\omega'^x = \omega'^x.$$

Proof. **Step 1: g is invertible.** For $y, y' \in M = G'(\Omega')[p^R]$ the map $b \mapsto \varepsilon(by, y') \bmod p^R$ is a $\mathbb{Z}$-linear form on $\mathcal{O}_E$ with values in $\mathbb{Z}/p^R$, represented under the trace form by $\langle y, y'\rangle = \sum_k \varpi_k^* \varepsilon(\varpi_k y, y') \in \mathfrak{d}_E^{-1}/p^R\mathfrak{d}_E^{-1}$; since $p \nmid \mathrm{disc}(E)$, $\mathfrak{d}_E^{-1} \otimes \mathbb{Z}_{(p)} = \mathcal{O}_E \otimes \mathbb{Z}_{(p)}$, so $\langle y, y'\rangle \in \mathcal{O}_E/p^R$. Then $\langle cy, y'\rangle = c\langle y, y'\rangle$ for $c \in \mathcal{O}_E$ (replace b by bc), and by the Rosati condition $\varepsilon(by, cy') = \varepsilon(\bar c by, y')$, so $\langle y, cy'\rangle = \bar c\langle y, y'\rangle$. The polarisation is principal and Ω' has characteristic 0, so e_{p^R} is perfect on M; by the adjunction $\mathrm{Hom}_{\mathbb{Z}}(M, \mathbb{Z}/p^R) \cong \mathrm{Hom}_{\mathcal{O}_E}(M, \mathrm{Hom}_{\mathbb{Z}}(\mathcal{O}_E, \mathbb{Z}/p^R))$ and $\mathrm{Hom}_{\mathbb{Z}}(\mathcal{O}_E, \mathbb{Z}/p^R) \cong \mathcal{O}_E/p^R$ (trace form, p unramified), the map $y' \mapsto \langle \cdot, y'\rangle$ is a bijection $M \to \mathrm{Hom}_{\mathcal{O}_E}(M, \mathcal{O}_E/p^R)$. With the basis (y_l), the composite $y' \mapsto (\langle y_l, y'\rangle)_l$ is a bijection $M \to (\mathcal{O}_E/p^R)^m$; it equals $\Gamma_0 \circ \mathrm{conj}$ in coordinates, $\Gamma_0 = (\langle y_l, y_j\rangle)_{l,j}$, conj the coordinate-wise complex conjugation (a bijection). Hence Γ_0 is bijective and $\det\Gamma_0 \in (\mathcal{O}_E/p^R)^\times$. Now $\sigma_s(\varpi_k^*) \in \sigma_s(\mathfrak{d}_E^{-1}) \subseteq \mathcal{O}'$ ($\mathfrak{d}_E$ is prime to p, and $\mathcal{O}' \supseteq \mathcal{O}_{F_{\Omega,\lambda}}$ inverts the elements of $\mathcal{O}_F$ outside λ), so $g \in M_m(\mathcal{O}')$, and $g \equiv \sigma_s(\Gamma_0) \bmod p^R\mathcal{O}'$ entrywise, $\sigma_s \colon \mathcal{O}_E/p^R \to \mathcal{O}'/p^R\mathcal{O}'$ being a ring homomorphism. So $\det g \equiv \sigma_s(\det\Gamma_0)$ is a unit modulo $p^R\mathcal{O}' \subseteq \mathfrak{m}_{\mathcal{O}'}$, and $\det g \in \mathcal{O}'^\times$.

Step 2: part (1). By Step 1, ι_0 is a well-defined Ω'-linear map, and $\sum_l \iota_0(c)_l g_{lj} = \sum_{j'} \eta_{j'}(\sum_k c_k\beta_k)(g^{-1}g)_{j'j} = \eta_j(\sum_k c_k\beta_k)$. The definition of a Hodge–Tate chart in Definition 35.22(Hf4) constrains only h, the y_i and the η_i (the latter at the points of U over p); so (ι_0, h) is a Hodge–Tate chart over U.

Step 3: the decomposition at x. Since $p \nmid \mathrm{disc}(E)$ and every prime that is not a unit in $\mathcal{O}_x$ is p ($\mathcal{O}_x$ is a local ring containing $\mathcal{O}_{F_{\Omega,\lambda}}$), $\mathcal{O}_E \otimes_{\mathbb{Z}} \mathcal{O}_x \to \prod_t \mathcal{O}_x$, $b \otimes z \mapsto (\sigma_t(b)z)_t$, is an isomorphism; its idempotents ϵ_t act on Lie_x and on ω_x, so $\mathrm{dR}_{t,x} = \epsilon_t\mathrm{Lie}_x$ and $\rho_t(\omega_x)$ is the dual lattice of $\mathrm{dR}_{t,x}$ in $\mathrm{Lie}_t(G'_{\Omega'})^\vee$. Also $\sigma_s(\mathfrak{d}_E)\mathcal{O}_x = \mathcal{O}_x$, so $V_{s,x} = \mathrm{HT}_{s,x}(p^R) = \mathrm{HT}'_{s,x}$ and $V_{\bar s,x} = \mathrm{HT}'_{\bar s,x}$. ht_x is stable under the action of $\mathcal{O}_E$ on ω_x: if ϕ is a function as in the definition of a Hodge–Tate value of y at x, then $\phi \circ \bar c$ (with $\bar c$ the endomorphism of G') is one for cy, because $e_{p^R}(cy, g') = e_{p^R}(y, \bar c g')$ (Rosati condition), and $d(\phi \circ \bar c) = \bar c^* d\phi$. Hence $\mathrm{ht}_x = \bigoplus_t \epsilon_t\mathrm{ht}_x$, and ρ_t restricted to $\epsilon_t\omega_x$ is injective, so $\rho_t(\mathrm{ht}_x) \cong \epsilon_t\mathrm{ht}_x$, a direct summand of the free module ht_x, hence free over the local ring $\mathcal{O}_x$, of rank $\mathrm{rk}(t)$ because $\varpi_p\omega_x \subseteq \mathrm{ht}_x \subseteq \omega_x$ by Lemma 35.32(1) (here $\varpi_p = \zeta_p - 1$, $\zeta_p = \zeta^{p^{R-1}}$, p odd). By Lemma 31.30(1), $\mathrm{ht}_x = \sum_y \mathcal{O}_x w_y + p^R\omega_x$, where w_y is a Hodge–Tate value of y. Hodge–Tate values are additive in y (if ϕ, ϕ' serve y, y', then $\phi\phi'$ serves $y + y'$ and $d(\phi\phi') = d\phi + d\phi'$ along the unit section, where $\phi = \phi' = 1$), and $w_{cy} = \bar c^* w_y$ as above. Writing $y = \sum_i c_i y_i$ ($c_i \in \mathcal{O}_E$) and using $\rho_t(\bar c^* v) = \sigma_t(\bar c)\rho_t(v)$ and that $\eta_i|_{\mathrm{Lie}_x}$ is a Hodge–Tate value of y_i at x (Definition 35.22(Hf4)):

$$\rho_t(\mathrm{ht}_x) = \sum_{i=1}^m \mathcal{O}_x\,\rho_t(\eta_i) + p^R\rho_t(\omega_x) \qquad (t = s, \bar s). \tag{$*$}$$

Finally $p^R\rho_t(\omega_x) \subseteq w\,\rho_t(\mathrm{ht}_x)$: by Lemma 35.32(1), $\varpi_p\rho_t(\omega_x) \subseteq \rho_t(\mathrm{ht}_x)$; $(w/\varpi_p)^{p-1} = up/\varpi_p^{p-1}$ is a unit of $\mathcal{O}_x$ ($\varpi_p^{p-1} \in p\,\mathbb{Z}[\zeta_p]^\times$), so w/ϖ_p and its inverse are integral over the normal ring $\mathcal{O}_x$, and $w\mathcal{O}_x = \varpi_p\mathcal{O}_x$; and $p^R/\varpi_p \in \varpi_p^{(p-1)R-1}\mathcal{O}_x^\times \subseteq \varpi_p\mathcal{O}_x$ since $(p-1)R - 1 \geq 1$. So

$p^R\rho_t(\omega_x) = (p^R/\varpi_p)\varpi_p\rho_t(\omega_x) \subseteq w\rho_t(\mathrm{ht}_x)$, and $(*)$ gives

$$\rho_t(\mathrm{ht}_x) = \sum_{i=1}^{m} \mathcal{O}_x\, \rho_t(\eta_i) + w\, \rho_t(\mathrm{ht}_x) \qquad (t = s, \bar{s}). \tag{$**$}$$

Step 4: coordinates. Let $N = \{(\lambda(\beta_k))_k : \lambda \in \rho_s(\mathrm{ht}_x)\} \subseteq V_L$ and $\bar{N} = \{(\lambda(\bar{\beta}_k))_k : \lambda \in \rho_{\bar{s}}(\mathrm{ht}_x)\} \subseteq V_\omega$, free of ranks κ, $\dim V_\omega$ (Step 3; $\beta, \bar{\beta}$ are bases). By definition of HT', $W^x = \{c : c \cdot n \in \mathcal{O}_x\ \forall n \in N\}$ is the dual lattice of N and $\bar{W}^x$ that of $\bar{N}$; duals of free lattices are free on the dual basis, and the dual of the dual is the lattice itself. Hence W^x is free of rank κ, N is the dual of W^x, and $\omega'^x = \bar{N}$ is free. Put $n_i = (\eta_i(\beta_k))_k \in N$; then $h(e_i) = (\eta_i(\bar{\beta}_k))_k \in \bar{N}$, and for $c \in V_L$, $c \cdot n_i = \eta_i(\sum_k c_k\beta_k)$.

Step 5: the four assertions. (a) For $c \in W^x$, $\eta_j(\sum_k c_k\beta_k) = c \cdot n_j \in \mathcal{O}_x$, so $\iota_0(c) = (c\cdot n_j)_j g^{-1} \in \mathcal{O}_x^m$, as $g^{-1} \in M_m(\mathcal{O}')$. (b) By (a), $wW^x \subseteq W^x \cap \iota_0^{-1}(w\mathcal{O}_x^m)$. Conversely let $c \in W^x$ with $\iota_0(c) \in w\mathcal{O}_x^m$. Then $(c \cdot n_j)_j = \iota_0(c)g \in w\mathcal{O}_x^m$. By $(**)$ for $t = s$, $N = \sum_i \mathcal{O}_x n_i + wN$, and $c\cdot(wN) \subseteq w\mathcal{O}_x$ since $c \in W^x$ is in the dual of N. So $c \cdot N \subseteq w\mathcal{O}_x$, that is $w^{-1}c \in W^x$, $c \in wW^x$. (c) $h(\mathcal{O}_x^m) = \sum_i \mathcal{O}_x h(e_i) \subseteq \bar{N} = \omega'^x$. (d) By $(**)$ for $t = \bar{s}$ in coordinates, $\bar{N} = \sum_i \mathcal{O}_x h(e_i) + w\bar{N}$, that is $h(\mathcal{O}_x^m) + w\omega'^x = \omega'^x$. □

Lemma 35.35. *Let $\mathfrak{T}$, p, R, w, a, $s = (a, +)$, $\bar{s} = (a, -)$, m, $\beta, \bar{\beta}$ and g be as in Lemma 35.34, and assume $R \geq 3$. Let (ι, h) and (ι', h') be Hodge–Tate charts for $(\mathfrak{T}, s, \beta, \bar{\beta})$ over opens U, U' of $\mathcal{X}'$, with the same points $y_1, \dots, y_m$ and with forms $\eta_1, \dots, \eta_m$ and $\eta'_1, \dots, \eta'_m$. Let $x \in U \cap U'$ be a point over p at which ht_x is a free $\mathcal{O}_x$-module of rank $\dim_{\Omega'} \mathrm{Lie}(G'_{\Omega'})$, and assume that for every $c \in W^x$ and every j*

$$\sum_{l=1}^{m} \iota(c)_l\, g_{lj} - \eta_j\Big(\sum_k c_k\beta_k\Big) \in p^{R-2}\mathcal{O}_x, \qquad \sum_{l=1}^{m} \iota'(c)_l\, g_{lj} - \eta'_j\Big(\sum_k c_k\beta_k\Big) \in p^{R-2}\mathcal{O}_x. \tag{35.1}$$

Then:

1. *$\iota(c) - \iota'(c) \in \mathcal{O}_x^m$ for every $c \in V_L$ with $wc \in W^x$;*
2. *$h(d) - h'(d) \in \omega'^x$ for every $d \in V_H$ with $wd \in \mathcal{O}_x^m$.*

Proof. **Step 1: the valuations at x.** By Lemma 35.32, Ω' contains a primitive p-th root of unity ζ_p and $\varpi_p = \zeta_p - 1 \in \mathcal{O}_x$ (p is odd). Since $p = \prod_{k=1}^{p-1}(1-\zeta_p^k)$ and each $(1-\zeta_p^k)/(1-\zeta_p)$ is a unit of $\mathbb{Z}[\zeta_p]$, $\varpi_p^{p-1} \in p\,\mathbb{Z}[\zeta_p]^\times$. With $w^{p-1} = u\,p$, $u \in \mathcal{O}'^\times$, the element $w/\varpi_p \in \Omega'$ has $(p-1)$-th power a unit of $\mathcal{O}_x$, so w/ϖ_p and its inverse are integral over the normal domain $\mathcal{O}_x$ and lie in it. Hence $w\mathcal{O}_x = \varpi_p\mathcal{O}_x$ and $p\mathcal{O}_x = \varpi_p^{p-1}\mathcal{O}_x$, and for integers a, b

$$p^a w^{-b}\mathcal{O}_x = \varpi_p^{(p-1)a-b}\mathcal{O}_x. \tag{$*$}$$

Step 2: every $\lambda \in \omega_x$ takes values in $\varpi_p^{-1}\mathcal{O}_x$ on $V_{s,x}$ and on $V_{\bar{s},x}$. As x lies over p, $V_{t,x} = \mathrm{HT}_{t,x}(p^R)$ for $t = s, \bar{s}$ (the Hodge lattice at $(\{p\}, R)$, Definition 35.22). Since ht_x is free of rank $\dim \mathrm{Li}$, Lemma 35.32(3) gives $\varpi_p\mathrm{HT}_{\bar{s},x}(p^R) \subseteq \mathrm{dR}_{\bar{s},x}$ and $\varpi_p\sigma_s(d)\mathrm{HT}_{s,x}(p^R) \subseteq \mathrm{dR}_{s,x}$ for every $d \in \mathfrak{d}_E$. As p is unramified in E, $\mathfrak{d}_E + p\mathcal{O}_E = \mathcal{O}_E$; choose $d \in \mathfrak{d}_E$ with $d - 1 \in p\mathcal{O}_E$. Then $\sigma_s(d) \in 1 + p\mathcal{O}_x \subseteq \mathcal{O}_x^\times$ ($\sigma_s(\mathcal{O}_E) \subseteq \mathcal{O}' \subseteq \mathcal{O}_x$ and p lies in the maximal ideal of $\mathcal{O}_x$). So $\varpi_p V_{t,x} \subseteq \mathrm{dR}_{t,x} = \mathrm{Lie}_x \cap \mathrm{Li}_t \subseteq \mathrm{Lie}_x$ for $t = s, \bar{s}$, and $\lambda(\mathrm{Lie}_x) \subseteq \mathcal{O}_x$ gives the claim.

Step 3: the forms of the two charts differ by p^R times forms in ω_x. Since $x \in U \cap U'$ lies over p, (Hf4) says that $\eta_j|_{\mathrm{Lie}_x}$ and $\eta'_j|_{\mathrm{Lie}_x}$ are Hodge–Tate values at x of the same point y_j.

By Lemma 31.30(1) the Hodge–Tate values of y_j at x form one coset of $p^R\omega_x$ in ω_x. Hence there is $\mu_j \in \omega_x$ with $\eta_j - \eta'_j = p^R\mu_j$ on Lie_x, and therefore on Li.

Step 4: part (1). Let $c \in V_L$ with $wc \in W^x$, and put $v = \sum_k c_k\beta_k \in \mathrm{Li}_s$, so that $wv \in V_{s,x}$. Applying (35.1) to wc and dividing by w, and using $(*)$ with $(p-1)(R-2)-1 \geq 1$ ($p \geq 3$, $R \geq 3$),

$$\sum_l \iota(c)_l g_{lj} - \eta_j(v) \in w^{-1}p^{R-2}\mathcal{O}_x \subseteq \mathcal{O}_x, \qquad \sum_l \iota'(c)_l g_{lj} - \eta'_j(v) \in \mathcal{O}_x.$$

By Step 3, $\eta_j(v) - \eta'_j(v) = p^R w^{-1}\mu_j(wv)$, and $\mu_j(wv) \in \varpi_p^{-1}\mathcal{O}_x$ by Step 2; by $(*)$, $p^R w^{-1}\varpi_p^{-1}\mathcal{O}_x = \varpi_p^{(p-1)R-2}\mathcal{O}_x \subseteq \mathcal{O}_x$. Subtracting, the row vector $(\iota(c) - \iota'(c))\, g$ has entries in $\mathcal{O}_x$. As $g \in \mathrm{GL}_m(\mathcal{O}')$ (Lemma 35.34(1)) and $\mathcal{O}' \subseteq \mathcal{O}_x$, $\iota(c) - \iota'(c) \in \mathcal{O}_x^m$.

Step 5: part (2). Let $d \in V_H$ with $wd \in \mathcal{O}_x^m$ and let $c' \in \bar{W}^x$, $u = \sum_k c'_k\bar{\beta}_k \in V_{\bar{s},x}$. By the definition of h, h' through the forms and Step 3,

$$(h(d) - h'(d)) \cdot c' = \sum_{i=1}^m d_i\,(\eta_i - \eta'_i)(u) = \sum_{i=1}^m d_i\, p^R\mu_i(u).$$

Here $d_i \in w^{-1}\mathcal{O}_x$ and $\mu_i(u) \in \varpi_p^{-1}\mathcal{O}_x$ (Step 2), so each term lies in $p^R w^{-1}\varpi_p^{-1}\mathcal{O}_x \subseteq \mathcal{O}_x$ by $(*)$. As $c' \in \bar{W}^x$ was arbitrary, $h(d) - h'(d)$ lies in ω'^x, the dual lattice of $\bar{W}^x$. □

Lemma 35.36. *Let $\mathfrak{T}$, p, R, w, a, $s = (a,+)$, $\bar{s} = (a,-)$, κ, m, $\beta, \bar{\beta}$ and g be as in Lemma 35.34, with $R \geq 3$, $\kappa = \mathrm{rk}(s)$, $\mathrm{rk}(\bar{s}) = n - \kappa$ and $m = n$. For every point x of $\mathcal{X}'$ put $W^x = \{c \in V_L : \sum_k c_k\beta_k \in V_{s,x}\}$, $\bar{W}^x = \{c \in V_\omega : \sum_k c_k\bar{\beta}_k \in V_{\bar{s},x}\}$ and $\omega'^x = \{c \in V_\omega : c \cdot c' \in \mathcal{O}_x\ \forall c' \in \bar{W}^x\}$. Let $(U_\nu, \iota_\nu, h_\nu)_\nu$ be a Hodge–Tate atlas for $(\mathfrak{T}, s, \beta, \bar{\beta})$ with points $y_1, \ldots, y_m$ and forms η_j^ν whose charts satisfy*

$$\sum_{l=1}^m \iota_\nu(c)_l\, g_{lj} = \eta_j^\nu\Big(\sum_k c_k\beta_k\Big) \qquad \text{for all } \nu,\ c \in V_L,\ 1 \leq j \leq m,$$

and let $(\mathrm{lie}, W, \omega, \omega', T, H, \Gamma, \Delta)$ be its Hodge–Tate lattice family for w. Assume:

(Sq1) *at every point x over p, ht_x is a free $\mathcal{O}_x$-module of rank $\dim_{\Omega'} \mathrm{Lie}(G'_{\Omega'})$;*

(Sq2) *W and ω' are locally free of ranks κ and $n - \kappa$, with stalks $W_x = W^x$ and $\omega'_x = \omega'^x$ at every point x;*

(Sq3) *for every point x over p and every ν with $x \in U_\nu$, the $\mathcal{O}_x$-module $\iota_\nu(W_x) + wT_x$ is free.*

Then:

1. *at every point x over p and for every ν with $x \in U_\nu$: $\iota_\nu(W_x) \subseteq T_x$, $h_\nu(T_x) \subseteq \omega'_x$, and the sequence of $\mathcal{O}_x$-modules*

$$0 \to W_x/wW_x \xrightarrow{\iota_\nu} T_x/wT_x \xrightarrow{h_\nu} \omega'_x/w\omega'_x \to 0$$

is exact;

2. *at every point x over p and for every ν with $x \in U_\nu$,*

$$\Gamma_x = \{(c,d) :\ wc \in W_x,\ d - \iota_\nu(c) \in T_x\}, \qquad \Delta_x = \{(d,e) :\ wd \in T_x,\ e - h_\nu(d) \in \omega'_x\};$$

3. *Γ and Δ satisfy (G1) and (G2) over every affine open of $\mathcal{X}'$.*

Proof. **Step 1: the inclusions and the two outer exactness assertions of (1).** Let x be a point over p and $x \in U_\nu$. By (Sq1), Lemma 35.34(2) applies at x to the chart (ι_ν, h_ν) over U_ν; with (Sq2) it gives $\iota_\nu(W_x) \subseteq T_x$, $W_x \cap \iota_\nu^{-1}(wT_x) = wW_x$, $h_\nu(T_x) \subseteq \omega'_x$ and $h_\nu(T_x) + w\omega'_x = \omega'_x$. So the maps of (1) are defined, the first is injective and the second surjective.

Step 2: $h_\nu(T_q) \subseteq \omega'_q$ at every generisation q of x, and $h_\nu\iota_\nu(W_x) \subseteq w\,\omega'_q$ at every generisation q of codimension one. Let q be a generisation of x; then $q \in U_\nu$. If q lies over p, (Sq1) holds at q and Step 1 at q gives $h_\nu(T_q) \subseteq \omega'_q$; if moreover q has codimension one, Lemma 35.38(1) gives $h_\nu(\iota_\nu(W^q)) \subseteq w\,\omega'^q$, and $W_x \subseteq W_q = W^q$, $\omega'^q = \omega'_q$ by (Sq2). If q does not lie over p, then $V_{\bar s,q} = \mathrm{dR}_{\bar s,q} \subseteq \mathrm{Lie}_q$, and $\eta_i^\nu(\mathrm{Lie}_q) = \mathcal{O}_q\,\eta_i^\nu(\mathrm{Lie}_x) \subseteq \mathcal{O}_q$ because $\eta_i^\nu|_{\mathrm{Lie}_x} \in \omega_x$ ((Hf4) at x). For $d \in \mathcal{O}_q^m$ and $c' \in \bar W^q$, $u = \sum_k c'_k\bar\beta_k \in V_{\bar s,q}$, we get $h_\nu(d)\cdot c' = \sum_i d_i\eta_i^\nu(u) \in \mathcal{O}_q$, so $h_\nu(T_q) \subseteq \omega'^q = \omega'_q$. As w is a unit at q and $\iota_\nu(W_x) \subseteq T_x \subseteq T_q$ (Step 1), $h_\nu\iota_\nu(W_x) \subseteq \omega'_q = w\,\omega'_q$.

Step 3: middle exactness in (1). Put $P_x = \iota_\nu(W_x) + wT_x$ and $P'_x = \{d \in T_x :\ h_\nu(d) \in w\,\omega'_x\}$, the kernel of the surjection $T_x \to \omega'_x/w\omega'_x$ of Step 1. Exactness at T_x/wT_x means $P_x = P'_x$. Since w is a non-zero non-unit of the domain $\mathcal{O}_x$ and ω'_x is free, $0 \to \omega'_x \xrightarrow{w} \omega'_x \to \omega'_x/w\omega'_x \to 0$ is a free resolution; by Schanuel's lemma $P'_x \oplus \omega'_x \cong T_x \oplus \omega'_x$, so P'_x is finitely generated projective over the local ring $\mathcal{O}_x$, hence free, of rank m (it contains wT_x). P_x is free by (Sq3), of rank m. For the normal noetherian domain $\mathcal{O}_x$, $\mathcal{O}_x = \bigcap_{\mathrm{ht}\,Q=1}(\mathcal{O}_x)_Q$ (Matsumura, Commutative Ring Theory, Thm. 11.5), hence $wF = \bigcap_Q wF_Q$ for every free submodule F of V_ω spanned by a basis of V_ω (compare coordinates in such a basis). So Step 2 gives $h_\nu\iota_\nu(W_x) \subseteq \bigcap_Q w\,\omega'_{q(Q)} = w\,\omega'_x$, where $q(Q)$ is the codimension-one generisation of x corresponding to the height-one prime Q of $\mathcal{O}_x$; so $P_x \subseteq P'_x$. At such $q = q(Q)$: if q lies over p, the localisations are $(P_x)_Q = \iota_\nu(W_q) + wT_q$ and $(P'_x)_Q = \{d \in T_q : h_\nu(d) \in w\omega'_q\}$, and these agree by the exactness of Lemma 35.38(2) at q (here $\kappa = \mathrm{rk}(s)$, $\mathrm{rk}(\bar s) = n - \kappa$, $m = n$, and $W^q = W_q$, $\omega'^q = \omega'_q$); if q does not lie over p, w is a unit at q and both localisations equal T_q. By Lemma 35.12(4) on the normal integral noetherian scheme $\mathrm{Spec}\,\mathcal{O}_x$, the free modules P_x and P'_x of rank m in V_H are equal. This proves (1).

Step 4: the stalks (2). The inclusions $\subseteq$ hold because the conditions defining $\Gamma(U)$, $\Delta(U)$ include those at x for the chart ν, and $W(U) \to W_x$, $T(U) \to T_x$. Conversely let $wc \in W_x$ and $d - \iota_\nu(c) \in T_x$. Choose an open neighbourhood $U \subseteq U_\nu$ of x on which W is free with a basis $c^{(1)}, \dots, c^{(\kappa)}$, with $wc \in W(U)$, $d - \iota_\nu(c) \in T(U)$ and $\iota_\nu(c^{(k)}) \in T(U)$ for all k (finitely many elements of V_H, V_L lying in the stalks at x, by Step 1, lie in the sections over a neighbourhood). Then $\iota_\nu(W(U')) \subseteq T(U')$ for every open $U' \subseteq U$. Let $y \in U$. If y lies over p and $y \in U_\mu$, then $d - \iota_\mu(c) = (d - \iota_\nu(c)) + (\iota_\nu(c) - \iota_\mu(c)) \in T_y$ by Lemma 35.35(1) at y (its hypotheses: (Sq1) at y, $R \geq 3$, $wc \in W_y \subseteq W^y$, and the adjointness congruence holds with value 0). If y does not lie over p, w is a unit at y, so $c \in W_y$, $\iota_\nu(c) \in T_y$ and $d \in T_y$. Hence $(c, d) \in \Gamma(U)$. For Δ, let $wd \in T_x$ and $e - h_\nu(d) \in \omega'_x$; choose $U \subseteq U_\nu$ with $wd \in T(U)$, $e - h_\nu(d) \in \omega'(U)$ and $h_\nu(e_i) \in \omega'(U)$ for the standard basis vectors e_i (by Step 1 and (Sq2)). For $y \in U$ over p and $y \in U_\mu$, $h_\nu(d) - h_\mu(d) \in \omega'^y = \omega'_y$ by Lemma 35.35(2), so $e - h_\mu(d) \in \omega'_y$; for y not over p, $d \in T_y$, so $h_\nu(d) \in \omega'_y$ and $e \in \omega'_y$. Hence $(d, e) \in \Delta(U)$.

Step 5: the conditions of (G1), (G2) that need no lifting. Let U be open and a, b, c sections over U of V_L, V_H, V_ω. By definition, $(0, b) \in \Gamma(U)$ if and only if $b \in T_y$ for all $y \in U$, if and only if $b \in T(U)$; and $(0, c) \in \Delta(U)$ if and only if $c \in \omega'(U)$, likewise. If $(a, 0) \in \Gamma(U)$, then $wa \in W(U)$, and at $y \in U$ over p (in U_ν) $\iota_\nu(wa) \in wT_y$, so $wa \in wW_y$ by Step 1, that is $a \in W^y$; at y not over p, $a = w^{-1}(wa) \in W^y$; so $a \in W(U)$, W being defined pointwise in (Hf2). Conversely if $a \in W(U)$ then $wa \in W(U)$ and $\iota_\nu(a) \in T_y$ for $y \in U \cap U_\nu$ over p (Step 1), so $(a, 0) \in \Gamma(U)$. If $(b', c) \in \Delta(U)$, then at y over p, $wc \in h_\nu(wb') + w\omega'_y \subseteq \omega'_y$ (Step 1), and at other y, $c \in \omega'_y$; so $wc \in \omega'(U)$. If $(a, b') \in \Gamma(U)$ then $wa \in W(U)$ by definition, and if $(b, c') \in \Delta(U)$ then $wb \in T(U)$. *The last clause of (G2) at stalks.* At x over p: $(b, 0) \in \Delta_x$ if and only if $wb \in T_x$ and $h_\nu(wb) \in w\omega'_x$ (Step 4), if and only if $wb \in P'_x = P_x$ (Step 3), if and

only if $wb = \iota_\nu(c_0) + wt$ with $c_0 \in W_x$, $t \in T_x$, if and only if $(w^{-1}c_0, b) \in \Gamma_x$ for some $c_0 \in W_x$ (Step 4), that is, if and only if $(a', b) \in \Gamma_x$ for some a' (any such a' has $wa' \in W_x$). At x not over p, using a neighbourhood on which p is invertible: $(b, 0) \in \Delta_x$ if and only if $b \in T_x$ if and only if $(a', b) \in \Gamma_x$ for some a' (take $a' = 0$).

Step 6: the lifting clauses over affine opens. The sequences of sheaves

$$0 \to T \xrightarrow{b\mapsto(0,b)} \Gamma \xrightarrow{\mathrm{pr}_1} w^{-1}W \to 0, \qquad 0 \to \omega' \xrightarrow{c\mapsto(0,c)} \Delta \xrightarrow{\mathrm{pr}_1} w^{-1}T \to 0$$

are exact: on the left by Step 5, in the middle by definition, and on the right on stalks by Step 4 at points over p (lifts $(a, \iota_\nu(a))$, $(d, h_\nu(d))$) and, at a point not over p, by the lifts $(a, 0)$, $(d, 0)$ on a neighbourhood where p is invertible and $wa \in W$, $wd \in T$. The outer sheaves are coherent. An extension of quasi-coherent sheaves is quasi-coherent (on an affine open V and $f \in \mathcal{O}(V)$, the sequences of sections over V and V_f are exact on the right because H^1 of a quasi-coherent sheaf on an affine scheme vanishes, and the five lemma compares the sections over V_f with the localisation at f of those over V). So Γ, Δ are quasi-coherent, and on an affine open U the maps $\Gamma(U) \to (w^{-1}W)(U)$ and $\Delta(U) \to (w^{-1}T)(U)$ are onto: this is the first clause of (G1) and of (G2). Next, $\mathrm{pr}_2 \colon \Delta \to w^{-1}\omega'$ is onto on stalks (at x over p: if $wc \in \omega'_x = h_\nu(T_x) + w\omega'_x$, write $wc = h_\nu(t) + we$, then $(w^{-1}t, c) \in \Delta_x$ by Step 4; at x not over p: $(0, c)$), with quasi-coherent kernel; so $\Delta(U) \to (w^{-1}\omega')(U)$ is onto for U affine, which with Step 5 is the second clause of (G2). Finally $\mathrm{pr}_2 \colon \Gamma \to V_H$ has kernel $\{(a, 0)\} \cong W$ (Step 5), so $0 \to W \to \Gamma \to Q \to 0$ is exact with $Q = \mathrm{pr}_2(\Gamma)$, and $\Gamma(U) \to Q(U)$ is onto for U affine. If $(b, 0) \in \Delta(U)$, then by the stalk form of the last clause of (G2) (Step 5) $b_x \in Q_x$ for every $x \in U$, so $b \in Q(U)$ and $(a', b) \in \Gamma(U)$ for some a'; conversely if $(a', b) \in \Gamma(U)$ then $(b, 0) \in \Delta_x$ for every $x \in U$ (Step 5), so $(b, 0) \in \Delta(U)$. With Step 5 this gives all of (G1) and (G2) over affine opens, which is (3). □

Definition 35.37. Let $\mathcal{X}$ be a cover of an integral model of a unitary Shimura datum, with function field Ω, an algebraic closure $\overline{\Omega}$, and $\iota \colon \mathcal{O}_E \to \mathrm{End}(G_{\mathcal{X}})$; let ℓ be a prime and $R \geq 1$ an integer such that every ℓ^R-torsion point of $G_{\mathcal{X}}$ over $\overline{\Omega}$ is defined over Ω, and $N = \ell^R$. Put $T_\ell = \varprojlim_k G_{\mathcal{X}}(\overline{\Omega})[\ell^k]$, with the Weil pairing $e \colon T_\ell \times T_\ell \to \mathbb{Z}_\ell$ of the polarisation, read through a fixed compatible system $(\zeta_{\ell^k})_k$ of primitive roots of unity; for $y \in T_\ell$ let $\bar{y} \in G_{\mathcal{X}}(\Omega)[N]$ be its image. Let q be a point of $\mathcal{X}$ over ℓ whose local ring $\mathcal{O}_q$ is a discrete valuation ring, $\widehat{\mathcal{O}}_q$ its completion, C the completion of an algebraic closure of the fraction field of $\widehat{\mathcal{O}}_q$, $\mathcal{O}_C$ its valuation ring, and fix an embedding $\overline{\Omega} \subseteq C$ over $\Omega \subseteq \widehat{\mathcal{O}}_q[1/\ell]$.

A **Hodge–Tate isotropic lift** at q is a $\mathbb{Z}_\ell$-linear map $\beta \colon T_\ell \to \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C$ with:

(Iz1) $\beta(\iota(a)y) = \iota(\bar{a})^*\beta(y)$ for all $a \in \mathcal{O}_E$ and $y \in T_\ell$, where $\iota(\bar{a})^*$ is the transpose of the action of $\iota(\bar{a})$ on Lie_q;

(Iz2) there is $\epsilon \in \{1, -1\}$ such that for every $y \in T_\ell$ and every Hodge–Tate value w of $\bar{y}$ at q,

$$\epsilon\,\beta(y) - w \in N\,(\omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C);$$

(Iz3) for a $\mathbb{Z}_\ell$-basis $(y_j)_j$ of T_ℓ and the basis $(y'_j)_j$ with $e(y_j, y'_k) = \delta_{jk}$,

$$\sum_j \beta(y_j) \otimes \beta(y'_j) = 0 \quad \text{in } (\omega_q \otimes_{\mathcal{O}_q} \omega_q) \otimes_{\mathcal{O}_q} \mathcal{O}_C.$$

The element $\sum_j y_j \otimes y'_j \in T_\ell \otimes T_\ell$ does not depend on the basis, nor, up to a unit of $\mathbb{Z}_\ell$, on the system (ζ_{ℓ^k}); so (Iz3) does not depend on these choices.

Lemma 35.38. *Let $\mathfrak{T}$, p, R, w, a, $s=(a,+)$, $\bar{s}=(a,-)$, κ, m, $\beta,\bar{\beta}$, the Hodge–Tate chart (ι,h) over the open U and ι_0 be as in Lemma 35.34, and let q be a point of U of codimension one in $\mathcal{X}'$ with $p\notin\mathcal{O}_q^\times$. Then:*

1. *$h(\iota_0(W^q))\subseteq w\,\omega'^q$;*
2. *if $\kappa=\mathrm{rk}(s)$, $\mathrm{rk}(\bar{s})=n-\kappa$ and $m=n$, the sequence of $\mathcal{O}_q$-modules*

$$0\to W^q/wW^q\xrightarrow{\iota_0}\mathcal{O}_q^m/w\mathcal{O}_q^m\xrightarrow{h}\omega'^q/w\omega'^q\to 0$$

is defined and exact.

Proof. **Step 0: the setting at q.** $\mathcal{O}_q$ is a discrete valuation ring ($\mathcal{X}'$ normal, q of codimension one), so ht_q, a finitely generated torsion-free $\mathcal{O}_q$-module, is free, of rank $\dim\mathrm{Lie}(G'_{\Omega'})$ (it lies between $\varpi_p\omega_q$ and ω_q, Lemma 35.32(1)); so Lemma 35.34(2) applies at $x=q$ (a point of U). As q lies over p, $V_{t,q}=\mathrm{HT}_{t,q}(p^R)$ for $t=s,\bar{s}$; this is $\mathrm{HT}'_{\bar{s},q}$ for $t=\bar{s}$ by definition, and for $t=s$ it is $\{e:\sigma_s(d)e\in\mathrm{HT}'_{s,q}\ \forall d\in\mathfrak{d}_E\}=\mathrm{HT}'_{s,q}$, because p is unramified in E, so $\mathfrak{d}_E+p\mathcal{O}_E=\mathcal{O}_E$ and some $d\in\mathfrak{d}_E$ with $d-1\in p\mathcal{O}_E$ has $\sigma_s(d)\in\mathcal{O}_q^\times$, while $\sigma_s(\mathfrak{d}_E)\subseteq\mathcal{O}_q$. So $V_{s,q}=\mathrm{HT}'_{s,q}$ and $V_{\bar{s},q}=\mathrm{HT}'_{\bar{s},q}$, the dual lattices of $\rho_s(\mathrm{ht}_q)$, $\rho_{\bar{s}}(\mathrm{ht}_q)$; since $\varpi_p\omega_q\subseteq\mathrm{ht}_q$, every $\lambda\in\omega_q$ takes values in $\varpi_p^{-1}\mathcal{O}_q$ on $\mathrm{HT}'_{s,q}$ and on $\mathrm{HT}'_{\bar{s},q}$, and every $\lambda\in\mathrm{ht}_q$ takes values in $\mathcal{O}_q$ there. The embedding $\Omega'\subseteq C$ satisfies $\mathcal{O}_C\cap\Omega'=\mathcal{O}_q$ (the valuation of C restricts to the q-adic one).

Step 1: reduction of (1) to a bilinear form. For $v\in\mathrm{Li}_s$, $u\in\mathrm{Li}_{\bar{s}}$ put $Q(v,u)=\sum_{j,l}(g^{-1})_{jl}\,\eta_j(v)\,\eta_l(u)$. For $c\in V_L$, $v_c=\sum_k c_k\beta_k$ and $c'\in V_\omega$, $u_{c'}=\sum_k c'_k\bar{\beta}_k$, the definitions of ι_0 and h give $h(\iota_0(c))\cdot c'=\sum_l\iota_0(c)_l\,\eta_l(u_{c'})=Q(v_c,u_{c'})$. Now $c\in W^q$ if and only if $v_c\in V_{s,q}$, $c'\in\bar{W}^q$ if and only if $u_{c'}\in V_{\bar{s},q}$, and ω'^q is the dual lattice of $\bar{W}^q$, so $w\omega'^q=\{e:e\cdot c'\in w\mathcal{O}_q\ \forall c'\in\bar{W}^q\}$. Hence (1) is equivalent to: $Q(v,u)\in w\mathcal{O}_q$ for all $v\in\mathrm{HT}'_{s,q}$, $u\in\mathrm{HT}'_{\bar{s},q}$.

Step 2: an isotropic lift. By Lemma 35.39 if $G'\times_{\mathcal{X}'}\operatorname{Spec}\mathcal{O}_q$ is an abelian scheme, and by Proposition 35.41 otherwise (both apply: $\mathcal{X}'$ is a cover, every p^R-torsion point is rational, $\mathcal{O}_q$ is a discrete valuation ring), there is a Hodge–Tate isotropic lift $\beta\colon T_p\to\omega_q\otimes\mathcal{O}_C$ at q, with sign ϵ. T_p is a module over $\mathcal{O}_E\otimes\mathbb{Z}_p$, a finite product of discrete valuation rings (p unramified), torsion-free, with $T_p/p^RT_p=G'(\Omega')[p^R]$ free of rank m over $\mathcal{O}_E/p^R$; so lifts $Y_1,\dots,Y_m\in T_p$ of $y_1,\dots,y_m$ form an $\mathcal{O}_E\otimes\mathbb{Z}_p$-basis (Nakayama over the semilocal complete ring, and comparison of $\mathbb{Z}_p$-ranks). Put $\beta_j=\epsilon\beta(Y_j)$. By (Iz2), $\beta_j-\eta_j\in p^R(\omega_q\otimes\mathcal{O}_C)$, $\eta_j|_{\mathrm{Lie}_q}$ being a Hodge–Tate value of y_j at q (Definition 35.22(Hf4)). By (Iz1), for $b\in\mathcal{O}_E\otimes\mathbb{Z}_p$, $\beta(bY)(v)=\sigma_s(\bar{b})\beta(Y)(v)$ for $v\in\mathrm{Li}_s$ and $\beta(bY)(u)=\sigma_s(b)\beta(Y)(u)$ for $u\in\mathrm{Li}_{\bar{s}}$ ($\iota(\bar{b})$ acts on Li_s by $\sigma_s(\bar{b})$ and on $\mathrm{Li}_{\bar{s}}$ by $\sigma_{\bar{s}}(\bar{b})=\sigma_s(b)$).

Step 3: the hermitian form on T_p. For $Y,Y'\in T_p$ put $\langle Y,Y'\rangle=\sum_k\varpi_k^*e(\varpi_kY,Y')\in\mathfrak{d}_E^{-1}\otimes\mathbb{Z}_p=\mathcal{O}_E\otimes\mathbb{Z}_p$ (p is unramified in E). Then $e(bY,Y')=\mathrm{Tr}(b\langle Y,Y'\rangle)$ for $b\in\mathcal{O}_E\otimes\mathbb{Z}_p$ (trace extended $\mathbb{Z}_p$-linearly): both sides are $\mathbb{Z}_p$-linear in b, and for $b=\varpi_l$ the right side is $\sum_k e(\varpi_kY,Y')\mathrm{Tr}(\varpi_l\varpi_k^*)=e(\varpi_lY,Y')$. Replacing b by bc gives $\langle cY,Y'\rangle=c\langle Y,Y'\rangle$, and the Rosati condition $e(bY,cY')=e(\bar{c}bY,Y')$ gives $\langle Y,cY'\rangle=\bar{c}\langle Y,Y'\rangle$; and since e is alternating, $\mathrm{Tr}(b\overline{\langle Y',Y\rangle})=e(bY',Y)=-e(Y,bY')=-e(\bar{b}Y,Y')=-\mathrm{Tr}(b\,\overline{\langle Y,Y'\rangle})$ for all b, so $\langle Y',Y\rangle=-\overline{\langle Y,Y'\rangle}$. Let $\Gamma_0=(\langle Y_l,Y_j\rangle)_{l,j}$; it is skew-hermitian, $\Gamma_0^{\mathsf{T}}=-\overline{\Gamma_0}$, and $g\equiv\sigma_s(\Gamma_0)\bmod p^RM_m(\mathcal{O}_C)$: the chosen roots of unity make $e(Y,Y')\equiv\varepsilon(\bar{Y},\bar{Y}')\bmod p^R$ for the images $\bar{Y},\bar{Y}'$ in $G'(\Omega')[p^R]$, and ϖ_kY_l has image ϖ_ky_l, so

$$\sigma_s(\Gamma_0)_{lj}=\sum_k\sigma_s(\varpi_k^*)\,e(\varpi_kY_l,Y_j)\equiv\sum_k\sigma_s(\varpi_k^*)\,\varepsilon(\varpi_ky_l,y_j)=g_{lj}$$

modulo $p^R\mathcal{O}_C$, as $\sigma_s(\varpi_k^*) \in \sigma_s(\mathfrak{d}_E^{-1}) \subseteq \mathcal{O}' \subseteq \mathcal{O}_C$ ($\mathfrak{d}_E$ is prime to p); as $\det g \in \mathcal{O}'^\times$, $\sigma_s(\Gamma_0) \in \mathrm{GL}_m(\mathcal{O}_C)$, Γ_0 is invertible, and $g^{-1} - \sigma_s(\Gamma_0)^{-1} = g^{-1}(\sigma_s(\Gamma_0) - g)\sigma_s(\Gamma_0)^{-1} \in p^R M_m(\mathcal{O}_C)$. Also $(\Gamma_0^{-1})^{\mathsf{T}} = -\overline{\Gamma_0^{-1}}$.

Step 4: the Casimir identity. The elements $\varpi_k Y_l$ form a $\mathbb{Z}_p$-basis of T_p. Its e-dual basis: $z_{kl} = \sum_j a_{kl,j} Y_j$ with $\bar{a}_{kl,j} = \varpi_k^*(\Gamma_0^{-1})_{jl}$; indeed $e(\varpi_{k'}Y_{l'}, z_{kl}) = \mathrm{Tr}\big(\varpi_{k'} \sum_j \bar{a}_{kl,j}(\Gamma_0)_{l'j}\big) = \mathrm{Tr}(\varpi_{k'}\varpi_k^*)\delta_{ll'} = \delta_{kk'}\delta_{ll'}$. By (Iz3) and Step 2, for $v \in \mathrm{Li}_s$, $u \in \mathrm{Li}_{\bar{s}}$:

$$0 = \sum_{k,l} \beta(\varpi_k Y_l)(v)\, \beta(z_{kl})(u) = \sum_{l,j} \Big(\sum_k \sigma_s(\overline{\varpi_k \varpi_k^*}) \Big) \sigma_s\big(\overline{(\Gamma_0^{-1})_{jl}}\big) \beta(Y_l)(v)\, \beta(Y_j)(u).$$

With $\sum_k \varpi_k \varpi_k^* = 1$ and $\overline{(\Gamma_0^{-1})_{jl}} = -(\Gamma_0^{-1})_{lj}$ (Step 3) this reads, after multiplying by $-\epsilon^2 = -1$,

$$Q_\beta(v,u) := \sum_{l,j} \sigma_s\big((\Gamma_0^{-1})_{lj}\big)\, \beta_l(v)\, \beta_j(u) = 0.$$

Step 5: (1). Let $v \in \mathrm{HT}'_{s,q}$, $u \in \mathrm{HT}'_{\bar{s},q}$. By Step 0, $\eta_j(v), \eta_l(u) \in \mathcal{O}_q$ and $(\beta_j - \eta_j)(v), (\beta_l - \eta_l)(u) \in p^R \varpi_p^{-1} \mathcal{O}_C \subseteq \mathcal{O}_C$ (as $p^R \varpi_p^{-1} \in \varpi_p^{(p-1)R-1}\mathcal{O}_q$ and $(p-1)R - 1 \geq 1$), so $\beta_j(v), \beta_l(u) \in \mathcal{O}_C$. Hence

$$\begin{aligned} Q(v,u) = Q(v,u) - Q_\beta(v,u) = \sum_{j,l} \big(g^{-1} - \sigma_s(\Gamma_0)^{-1}\big)_{jl} \eta_j(v) \eta_l(u) \\ + \sum_{j,l} \sigma_s(\Gamma_0^{-1})_{jl} \big((\eta_j - \beta_j)(v)\, \eta_l(u) + \beta_j(v)\, (\eta_l - \beta_l)(u) \big) \end{aligned}$$

lies in $p^R \varpi_p^{-1} \mathcal{O}_C$ (Step 3 for the first sum). As $Q(v,u) \in \Omega'$ and $\mathcal{O}_C \cap \Omega' = \mathcal{O}_q$, $Q(v,u) \in p^R \varpi_p^{-1} \mathcal{O}_q \subseteq \varpi_p \mathcal{O}_q = w\mathcal{O}_q$ ($w\mathcal{O}_q = \varpi_p \mathcal{O}_q$: $(w/\varpi_p)^{p-1} = up/\varpi_p^{p-1}$ is a unit, as $\varpi_p^{p-1} \in p\,\mathbb{Z}[\zeta_p]^\times$, so w/ϖ_p and its inverse are integral over the discrete valuation ring $\mathcal{O}_q$). By Step 1 this is (1).

Step 6: (2). By Lemma 35.34(2), $\iota_0(W^q) \subseteq \mathcal{O}_q^m$ and $h(\mathcal{O}_q^m) \subseteq \omega'^q$, so both maps are defined modulo w; the first is injective and the second surjective by the same lemma, and their composite is zero by (1). W^q, $\mathcal{O}_q^m$, ω'^q are free of ranks κ, m, $n-\kappa$, so with e the length of the artinian ring $\mathcal{O}_q/w\mathcal{O}_q$ (w is a non-zero non-unit of the discrete valuation ring $\mathcal{O}_q$), the three quotients have lengths κe, me, $(n-\kappa)e$. The image of the first map has length κe and the kernel of the second has length $(m - n + \kappa)e = \kappa e$ (as $m = n$); the image lies in the kernel, so they are equal, and the sequence is exact. □

Lemma 35.39. *Let $\mathcal{X}$, ℓ, R, N and q be as in Definition 35.37, and suppose that $G_{\mathcal{X}} \times_{\mathcal{X}} \mathrm{Spec}\,\mathcal{O}_q$ is an abelian scheme. Then there is a Hodge–Tate isotropic lift at q.*

Proof. Write $\widehat{\mathcal{O}} = \widehat{\mathcal{O}}_q$, K for its fraction field and $v = \mathrm{ord}_q/\mathrm{ord}_q(\ell)$; K is complete, of characteristic 0 (the generic point of $\mathcal{X}$ lies in characteristic 0), with $v(\ell) = 1$, and C is the completion of an algebraic closure of K. Let $A = G_{\mathcal{X}} \times_{\mathcal{X}} \mathrm{Spec}\,\widehat{\mathcal{O}}$, an abelian scheme with the principal polarisation $\lambda\colon A \to A^\vee$ of $\mathcal{L}$ and the action ι, and let s_0 be its unit section. Normalise the Weil pairing as $e_M(x,x') = \langle x, \lambda x' \rangle_M$, with $\langle\,,\rangle_M\colon A[M] \times A^\vee[M] \to \mu_M$ the Cartier pairing; for the opposite normalisation replace ϵ below by $-\epsilon$ and (y'_j) by $(-y'_j)$, which changes nothing.

Step 1: the ℓ-divisible group and its differentials. Let $H = A[\ell^\infty]$, an ℓ-divisible group over $\widehat{\mathcal{O}}$ with Cartier dual $H^D = A^\vee[\ell^\infty]$; λ induces an isomorphism $\lambda\colon H \to H^D$, and $\lambda^D = \pm\lambda$ under $H = H^{DD}$ by the symmetry of polarisations (the sign depends only on the biduality convention). Since A is proper and of characteristic 0 generically, $A(\mathcal{O}_C)[\ell^k] = A(C)[\ell^k] = G_{\mathcal{X}}(\overline{\Omega})[\ell^k]$, so $T_\ell H = T_\ell$, and e is $\langle\,,\lambda\,\rangle$ on $T_\ell H \times T_\ell H$. For $M = \ell^k$ the ideal of $A[M]$ near s_0 is generated by the $f \circ [M]$ with f in the ideal of s_0, and $s_0^* d(h \cdot f \circ [M]) = h(s_0)\, M\, s_0^* df$;

hence $\omega_{A[M]} = \omega_q \otimes \widehat{\mathcal{O}}/M$, and $\omega_H = \varprojlim_k \omega_{A[\ell^k]} = \omega_q \otimes_{\mathcal{O}_q} \widehat{\mathcal{O}}$, $\widehat{\mathcal{O}}$ being ℓ-adically complete. The Hodge–Tate map $\alpha_{H^D}\colon T_\ell(H^D) \to \omega_H \otimes \mathcal{O}_C$, $z \mapsto (z^D)^* \frac{dT}{T}$, is compatible with the levels: if $z_k \in H^D[\ell^k](\mathcal{O}_C) = \mathrm{Hom}(A[\ell^k]_{\mathcal{O}_C}, \mu_{\ell^k})$ is the image of z, then $\alpha_{H^D}(z) \bmod \ell^k = z_k^* \frac{dT}{T}$ in $\omega_{A[\ell^k]} \otimes \mathcal{O}_C$. For a homomorphism $f\colon H_1 \to H_2$ of ℓ-divisible groups and $x \in T_\ell H_1$, $(f \circ x)^D = x^D \circ f^D$ gives

$$\alpha_{H_2}(fx) = (f^D)^* \alpha_{H_1}(x). \tag{35.2}$$

Define

$$\beta = \alpha_{H^D} \circ \lambda\colon T_\ell \longrightarrow \omega_H \otimes_{\widehat{\mathcal{O}}} \mathcal{O}_C = \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C,$$

a $\mathbb{Z}_\ell$-linear map. We check (Iz1)–(Iz3).

Step 2: (Iz1). The Rosati involution of λ induces $a \mapsto \bar{a}$ on $\iota(\mathcal{O}_E)$, i.e. $\lambda \circ \iota(a) = \iota(\bar{a})^\vee \circ \lambda$. By (35.2) for the endomorphism $f = \iota(\bar{a})^\vee$ of H^D, whose Cartier dual is $\iota(\bar{a})$ on $H^{DD} = H$,

$$\beta(\iota(a)y) = \alpha_{H^D}\big(\iota(\bar{a})^\vee \lambda y\big) = \iota(\bar{a})^* \alpha_{H^D}(\lambda y) = \iota(\bar{a})^* \beta(y).$$

Step 3: (Iz2) with $\epsilon = -1$. Let $y \in T_\ell$ and $\chi = e_N(\bar{y}, \cdot)$, a character of the constant group $A[N]_K$. The image z_R of λy in $\mathrm{Hom}(A[N]_{\mathcal{O}_C}, \mu_N)$ is, on the generic fibre, $g \mapsto \langle g, \lambda\bar{y}\rangle_N = e_N(g, \bar{y}) = \chi(g)^{-1}$; so χ^{-1} extends to the homomorphism z_R over $\mathcal{O}_C$, hence so does χ, and $\beta(y) \bmod N = z_R^* \frac{dT}{T} = -\chi^* \frac{dT}{T}$. Let w be a Hodge–Tate value of $\bar{y}$ at q, with a function ϕ regular on an open $U \subseteq G_{\mathcal{X}}$ containing the unit point over q, $\phi(g) = e_N(\bar{y}, g)$ at the geometric N-torsion points g in U, and $w - s_0^* d\phi \in N\omega_q$. As $A[N]$ is finite over the complete local ring $\widehat{\mathcal{O}}$, it is a finite disjoint union of local schemes; let $\Gamma^0 = \operatorname{Spec} \Lambda_0$ be the one containing the unit point over the closed point. It is open and closed in $A[N]$, so flat, and Λ_0 is a free $\widehat{\mathcal{O}}$-module; its points are generisations of that unit point, which lies over the unit point of q, so Γ^0 lies in the preimage of U and ϕ restricts to $\phi_0 \in \Lambda_0$. The restriction of χ to $\Gamma^0_{\mathcal{O}_C}$ is a unit $u \in \Lambda_0 \otimes \mathcal{O}_C$ with $u(s_0) = 1$. Since $\Lambda_0 \otimes \mathcal{O}_C \subseteq \Lambda_0 \otimes C = C^{T^0}$, T^0 the set of generic points of Γ^0 (all rational), and $\phi_0 \otimes 1$ and u take the value $e_N(\bar{y}, t)$ at every $t \in T^0$, we get $u = \phi_0 \otimes 1$. As Γ^0 is an open neighbourhood of the unit section in $A[N]$, $\omega_{\Gamma^0} = \omega_{A[N]} = \omega_q \otimes \widehat{\mathcal{O}}/N$, and in it

$$\chi^* \tfrac{dT}{T} = s_0^* \tfrac{du}{u} = s_0^* du = s_0^* d\phi \equiv w \pmod{N(\omega_q \otimes \mathcal{O}_C)}.$$

Hence $-\beta(y) - w \in N(\omega_q \otimes \mathcal{O}_C)$: (Iz2) holds with $\epsilon = -1$.

Step 4: (Iz3). The isomorphism $\mu = \lambda\colon H \to H^D$ satisfies $\mu^D = \pm\mu$ (Step 1), $e = \langle\,\cdot\,, \lambda\,\cdot\,\rangle = e_\mu$ on $T_\ell H = T_\ell$, and $\beta = \alpha_{H^D} \circ \lambda = \beta_\mu$. So Lemma 35.40, applied to H over $\mathcal{O}_K = \widehat{\mathcal{O}}$ (complete and discretely valued, $v(\ell) = 1$), gives $\sum_j \beta(y_j) \otimes \beta(y_j') = 0$ for every $\mathbb{Z}_\ell$-basis (y_j) of T_ℓ and (y_j') with $e(y_j, y_k') = \delta_{jk}$, which is (Iz3). □

Lemma 35.40. *Let p, K, C and $\mathcal{O}_C$ be as in Theorem B.54, with K discretely valued, and fix a generator of $\mathbb{Z}_p(1)$, through which the Cartier pairing $\langle\,,\rangle\colon T_p(H) \times T_p(H^D) \to \mathbb{Z}_p(1)$ of a p-divisible group H over $\mathcal{O}_K$ takes values in $\mathbb{Z}_p$. Let $\mu\colon H \to H^D$ be an isomorphism of p-divisible groups with $\mu^D = \pm\mu$ under $H = H^{DD}$, put $e_\mu(x, x') = \langle x, \mu x'\rangle$ on $T_p(H)$ and*

$$\beta_\mu = \alpha_{H^D} \circ \mu\colon T_p(H) \longrightarrow \omega_H \otimes_{\mathcal{O}_K} \mathcal{O}_C.$$

Then e_μ is a perfect pairing, and for every $\mathbb{Z}_p$-basis $(x_j)_j$ of $T_p(H)$ and the basis $(x_j')_j$ with $e_\mu(x_j, x_k') = \delta_{jk}$,

$$\sum_j \beta_\mu(x_j) \otimes \beta_\mu(x_j') = 0 \quad \text{in } (\omega_H \otimes_{\mathcal{O}_K} \omega_H) \otimes_{\mathcal{O}_K} \mathcal{O}_C.$$

Proof. Naturality. For a homomorphism $f\colon H_1 \to H_2$ of p-divisible groups over $\mathcal{O}_K$ and $x \in T_p(H_1)$, the identity $(f \circ x)^D = x^D \circ f^D$ and the definition $\alpha_H(x) = (x^D)^* \frac{dT}{T}$ give

$$\alpha_{H_2}(fx) = (f^D)^* \alpha_{H_1}(x), \qquad (f^D)^*\colon \omega_{H_1^D} \to \omega_{H_2^D} \text{ (pull-back along } f^D\colon H_2^D \to H_1^D).$$

With $f = \mu\colon H \to H^D$ and $\mu^D = \pm\mu$ this reads $\beta_\mu(x) = \alpha_{H^D}(\mu x) = \pm\mu^* \alpha_H(x)$, with $\mu^*\colon \omega_{H^D} \to \omega_H$.

Perfectness. μ induces an isomorphism $T_p(H) \to T_p(H^D) = \operatorname{Hom}(T_p(H), \mathbb{Z}_p)$, $x' \mapsto \langle \cdot\,, \mu x' \rangle = e_\mu(\cdot, x')$; so e_μ is perfect and the basis (x'_j) exists and is unique. Moreover $(\mu x'_j)_j$ is the basis of $T_p(H^D)$ dual to $(x_j)_j$ under $\langle\,,\rangle$.

Isotropy. By Theorem B.54 applied to H, the composite of

$$\operatorname{Lie}(H) \otimes \mathcal{O}_C \xrightarrow{{}^t(\alpha_{H^D} \otimes 1)} T_p(H) \otimes_{\mathbb{Z}_p} \mathcal{O}_C \xrightarrow{\alpha_H \otimes 1} \omega_{H^D} \otimes \mathcal{O}_C$$

is zero (the Tate twist is trivialised by the fixed generator). In the bases (x_j) of $T_p(H)$ and $(\mu x'_j)$ of $T_p(H^D)$, which are dual, the transpose of $\alpha_{H^D} \otimes 1\colon T_p(H^D) \otimes \mathcal{O}_C \to \omega_H \otimes \mathcal{O}_C$ sends $v \in \operatorname{Lie}(H) \otimes \mathcal{O}_C$ to $\sum_j \langle \alpha_{H^D}(\mu x'_j), v \rangle\, x_j = \sum_j \langle \beta_\mu(x'_j), v \rangle\, x_j$. Hence $\sum_j \langle \beta_\mu(x'_j), v \rangle\, \alpha_H(x_j) = 0$ for every v. Since $\omega_H \otimes \mathcal{O}_C$ is free of finite rank with dual $\operatorname{Lie}(H) \otimes \mathcal{O}_C$, an element of $(\omega_{H^D} \otimes \mathcal{O}_C) \otimes_{\mathcal{O}_C} (\omega_H \otimes \mathcal{O}_C)$ all of whose contractions with elements v of $\operatorname{Lie}(H) \otimes \mathcal{O}_C$ in the second factor vanish is zero; so

$$\sum_j \alpha_H(x_j) \otimes \beta_\mu(x'_j) = 0 \quad \text{in } (\omega_{H^D} \otimes \omega_H) \otimes \mathcal{O}_C.$$

Applying $\mu^* \otimes 1$ and $\mu^* \alpha_H(x_j) = \pm\beta_\mu(x_j)$ gives $\sum_j \beta_\mu(x_j) \otimes \beta_\mu(x'_j) = 0$. □

Proposition 35.41. *Let $\mathcal{X}$, ℓ, R, N and q be as in Definition 35.37, and suppose that $G_{\mathcal{X}} \times_{\mathcal{X}} \operatorname{Spec} \mathcal{O}_q$ is not an abelian scheme. Then there is a Hodge–Tate isotropic lift at q.*

Proof. Throughout, v is the valuation with $v(\ell) = 1$, (ζ_{ℓ^k}) the fixed system of roots of unity, through which $\mathbb{Z}_\ell(1) = \mathbb{Z}_\ell$ and $\mu_{\ell^k}(C) = \mathbb{Z}/\ell^k$, and e_{ℓ^k} the reduction of e modulo ℓ^k, the Weil pairing on $T_\ell/\ell^k = G_{\mathcal{X}}(\overline{\Omega})[\ell^k]$. The hypothesis that the reduction is not abelian is not used: the argument below works for every torus rank.

Step 0: the base. Let κ be the residue field of $\widehat{\mathcal{O}}_q$, and G_κ the closed fibre of $G_{\mathcal{X}} \times_{\mathcal{X}} \operatorname{Spec} \widehat{\mathcal{O}}_q$, an extension of an abelian variety by a torus $\mathbb{T}_\kappa$. By (iii) there is a finite separable extension κ' of κ splitting $\mathbb{T}_\kappa$; choosing a primitive element and lifting its minimal polynomial gives a finite étale local $\widehat{\mathcal{O}}_q$-algebra $\mathcal{O}'$ with residue field κ', a complete discrete valuation ring with the uniformiser of $\widehat{\mathcal{O}}_q$; its fraction field K' is finite separable over the fraction field K of $\widehat{\mathcal{O}}_q$, and we fix a K-embedding $K' \subseteq C$, so $\mathcal{O}' \subseteq \mathcal{O}_C$ and C is the completion of an algebraic closure of K'. Put $S = \operatorname{Spec} \mathcal{O}'$ and $G = G_{\mathcal{X}} \times_{\mathcal{X}} S$, a semiabelian scheme with the action ι and the pull-back $\mathcal{L}_0$ of the rigidified symmetric cubical line bundle of the integral model (Definition 29.5, (Ud7)). The generic point of S maps to the generic point of $\mathcal{X}$, so $G_{K'}$ is the base change of $G_{\mathcal{X},\Omega}$, an abelian variety on which $\mathcal{L}_0$ is ample with principal polarisation $\phi_{\mathcal{L}_0}$, and e is the Weil pairing of $\phi_{\mathcal{L}_0}$ on $T_\ell = \varprojlim_k G(C)[\ell^k]$ (the ℓ^k-torsion is étale over Ω, so its $\overline{\Omega}$- and C-points agree). Finally $\omega_G = \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}'$, and a Hodge–Tate value w of $\bar{y}$ at q, given by a function ϕ regular on an open $U \subseteq G_{\mathcal{X}}$ containing the unit point over q, with $\phi(g) = e_N(\bar{y}, g)$ at the geometric N-torsion points g in U and $w - s_0^* d\phi \in N\omega_q$, pulls back to G with the same properties (s_0 the unit section).

Step 1: Raynaud extension and the abelian part. Apply Theorem B.109 (1) to $R = \mathcal{O}'$ with its maximal ideal: there is a Raynaud extension $0 \to \mathbb{T} \to \widetilde{G} \xrightarrow{\pi} B \to 0$ over S with $\widetilde{G}^{\mathrm{for}} \cong G^{\mathrm{for}}$; its torus $\mathbb{T}$ is split by (iii), as its closed fibre is $\mathbb{T}_\kappa \otimes \kappa'$, and ι induces an action of $\mathcal{O}_E$ on $\mathbb{T}$, $\widetilde{G}$

and B compatible with $\widetilde{G}^{\mathrm{for}} \cong G^{\mathrm{for}}$ (Theorem B.109 (3)). Tori over the field κ' are isotrivial, so the functor of Theorem B.109 (1) is an equivalence and $\mathcal{L}_0^{\mathrm{for}}$ lies in its essential image; $\mathcal{L}_0$ is rigidified, cubical and symmetric (Step 0), and $\mathcal{L}_{0,K'}$ is ample, hence nondegenerate, so $\mathcal{L}_0$ is ample over G by the ampleness criterion for symmetric sheaves in Theorem B.109 (2); hence $(G,\mathcal{L}_0) \in \mathrm{DEG}_{\mathrm{ample}}$; let $F_{\mathrm{ample}}(G,\mathcal{L}_0) = (B, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}_0, \tau, \psi)$. The character group X of the split torus is constant, and so is Y, which ϕ embeds in X. By Theorem B.110 (S is normal) $\widetilde{\mathcal{L}}_0 \cong \pi^*\mathcal{M}_0$ as cubical sheaves for a cubical $\mathcal{M}_0$ on B. By Theorem B.109 (4)(d), $1 = \deg \phi_{\mathcal{L}_0,K'} = [X:\phi(Y)]^2 \deg \lambda_B$ with $\lambda_B = \phi_{\mathcal{M}_0}$; hence λ_B is a principal polarisation of B, and its Weil pairing e_B on $T_\ell(B) = \varprojlim_k B(C)[\ell^k]$ is perfect. By Theorem B.109 (4)(c), for $n \geq 1$ the cubical sheaf of $F_{\mathrm{ample}}(G, \mathcal{L}_0^{\otimes n})$ is $\widetilde{\mathcal{L}}_0^{\otimes n} \cong \pi^*(\mathcal{M}_0^{\otimes n})$.

Step 2: finite parts and orthogonality at level $n = \ell^k$. Fix $k \geq 1$, $n = \ell^k$, and $\mathcal{L} = \mathcal{L}_0^{\otimes n}$, a cubical sheaf on G. By (v), $K(\mathcal{L}_{K'}) = G_{K'}[n]$ and $e^{\mathcal{L}_{K'}} = e_n$. By (iv) $G[n]$ is a closed subgroup quasi-finite and flat over S; flat over a discrete valuation ring, it is the schematic closure of its generic fibre $K(\mathcal{L}_{K'})$. So Theorem B.119 applies with $K_S = G[n]$ and the cubical extension $\mathcal{L}$, and (3) applies with $\mathcal{M} = \mathcal{M}_0^{\otimes n}$ by Step 1, $K(\mathcal{M}) = B[n]$ as λ_B is principal (by (v) over C). It gives: isomorphisms $G[n]^\mu \cong \mathbb{T}[n]$, $G[n]^f \cong \widetilde{G}[n]$, $G[n]^{ab} \cong B[n]$; $G[n]^f$ is the annihilator of $G[n]^\mu$ under the extension of e_n; the induced pairing on $G[n]^{ab} \cong B[n]$ is $e^{\mathcal{M}}$, which is the Weil pairing of λ_B by (v). The isomorphisms are characterised on formal completions; as multiplication by ℓ and the $\iota(a)$ commute with $\widetilde{G}^{\mathrm{for}} \cong G^{\mathrm{for}}$ and map finite parts into finite parts (i), (ii) shows that the isomorphisms for n and ℓn are compatible with $[\ell]$, with the inclusions $G[n]^\mu \subseteq G[n]^f$, $\mathbb{T}[n] \subseteq \widetilde{G}[n]$, with π, and with ι. The annihilator is the kernel of the homomorphism $G[n] \to (G[n]^\mu)^D$ given by the pairing, and kernels commute with base change; over C all these groups are constant. Writing $F_n = G[n]^f(C)$ and $T_n = G[n]^\mu(C)$, subgroups of $G(C)[n] = T_\ell/n$, we obtain

$$\begin{gathered} T_n \subseteq F_n = \{x \in T_\ell/n : \ e_n(x,t) = 1 \text{ for all } t \in T_n\}, \\ F_n/T_n \cong B(C)[n] \text{ isometrically for } e_n \text{ and } e_{B,n}, \end{gathered} \tag{35.3}$$

where $e_{B,n}$ is the Weil pairing of λ_B, and $T_n \cong \mathbb{T}(C)[n]$, $F_n \cong \widetilde{G}(C)[n]$.

Step 3: the lattices. Let $F = \varprojlim_k F_{\ell^k}$ and $T_t = \varprojlim_k T_{\ell^k}$, closed subgroups of T_ℓ with $T_t \subseteq F$. Multiplication by ℓ maps $T_{\ell^{k+1}} \cong \mathbb{T}(C)[\ell^{k+1}]$ onto T_{ℓ^k} ($\mathbb{T}(C) = (C^\times)^r$, r the rank of $\mathbb{T}$), and $F_{\ell^{k+1}}$ onto F_{ℓ^k} ($\widetilde{G}(C)$ is divisible, an extension of $B(C)$ by $(C^\times)^r$); so the projections $T_t \to T_{\ell^k}$, $F \to F_{\ell^k}$ are surjective. Hence: (a) $F/T_t \cong \varprojlim_k B(C)[\ell^k] = T_\ell(B)$ (inverse limits of finite groups are exact), and by (35.3), $e(f,f') = e_B(\bar f, \bar f')$ for $f, f' \in F$ with images $\bar f, \bar f'$; in particular F/T_t is free and the pairing it inherits is perfect. (b) $F = T_t^\perp = \{x \in T_\ell : e(x,t) = 0 \ \forall t \in T_t\}$: as $T_t \to T_{\ell^k}$ is onto, $e(x,T_t) = 0$ if and only if $e_{\ell^k}(x \bmod \ell^k, T_{\ell^k}) = 1$ for all k, that is, by (35.3), if and only if $x \bmod \ell^k \in F_{\ell^k}$ for all k, that is, if and only if $x \in F$. As e is alternating, also $e(T_t, F) = 0$. (c) The map $T_\ell/F \to \mathrm{Hom}(T_t, \mathbb{Z}_\ell)$, $y \mapsto e(y,\cdot)|_{T_t}$, is injective by (b), so T_ℓ/F is free; with (a), T_ℓ/T_t is free, T_t is a direct summand of T_ℓ, and as e is perfect on T_ℓ ($\phi_{\mathcal{L}_0}$ is principal) the map is also surjective. (d) By (iv), $\widetilde{H} = (\widetilde{G}[\ell^k])_k$ is an ℓ-divisible group over S, and the isomorphisms of Step 2 identify $T_\ell(\widetilde{H}) = \varprojlim_k \widetilde{G}(C)[\ell^k]$ with F, $\mathcal{O}_E$-equivariantly, carrying $T_\ell(\mathbb{T})$ to T_t and $T_\ell(\pi)\colon T_\ell(\widetilde{H}) \to T_\ell(B[\ell^\infty])$ to $F \to F/T_t$. For a smooth commutative group scheme P over S and $M \geq 1$ the ideal of $P[M]$ near s_0 is generated by the $f \circ [M]$, f in the ideal of s_0, and $s_0^* d(h \cdot f \circ [M]) = h(s_0)\, M\, s_0^* df$; so $\omega_{P[M]} = \omega_P/M$. As $G[\ell^k]^f$ is an open subscheme of $G[\ell^k]$ containing s_0, $\omega_{\widetilde{G}[\ell^k]} \cong \omega_{G[\ell^k]^f} = \omega_{G[\ell^k]} = \omega_G/\ell^k$, compatibly with k and ι, and

$$\omega_{\widetilde{H}} = \varprojlim_k \omega_{\widetilde{G}[\ell^k]} = \omega_G = \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}'.$$

Step 4: the lift. For $y \in T_\ell$ the functional $e(y,\cdot)|_F$ lies in $\mathrm{Hom}(F,\mathbb{Z}_\ell) = \mathrm{Hom}(T_\ell\widetilde{H},\mathbb{Z}_\ell(1)) = T_\ell(\widetilde{H}^D)$. Define

$$\beta(y) = \alpha_{\widetilde{H}^D}\big(e(y,\cdot)|_F\big) \in \omega_{\widetilde{H}} \otimes_{\mathcal{O}'} \mathcal{O}_C = \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C,$$

a $\mathbb{Z}_\ell$-linear map, with $\alpha_{\widetilde{H}^D}(z) = (z^D)^*\frac{dT}{T}$ the Hodge–Tate map of Theorem B.54. Two facts: if $z_k \in \widetilde{H}^D[\ell^k](\mathcal{O}_C) = \mathrm{Hom}(\widetilde{G}[\ell^k]_{\mathcal{O}_C},\mu_{\ell^k})$ is the image of z, then $\alpha_{\widetilde{H}^D}(z) \bmod \ell^k = z_k^*\frac{dT}{T}$ in $\omega_{\widetilde{G}[\ell^k]} \otimes \mathcal{O}_C$; and for a homomorphism $f\colon H_1 \to H_2$ of ℓ-divisible groups and $x \in T_\ell H_1$, (vi) gives

$$\alpha_{H_2}(fx) = (f^D)^*\alpha_{H_1}(x). \tag{35.4}$$

By Step 3 (b), $\beta(T_t) = 0$.

Step 5: (Iz1). The Rosati involution of $\phi_{\mathcal{L}_0}$ induces $a \mapsto \bar{a}$ on $\iota(\mathcal{O}_E)$ ((Ud4)), so $e(\iota(a)y,x) = e(y,\iota(\bar{a})x)$. For the endomorphism $f = \iota(\bar{a})$ of $\widetilde{H}$, f^D acts on $T_\ell(\widetilde{H}^D) = \mathrm{Hom}(F,\mathbb{Z}_\ell)$ by composition with $\iota(\bar{a})|_F$, and $f^{DD} = f$. So by (35.4)

$$\beta(\iota(a)y) = \alpha_{\widetilde{H}^D}\big(f^D(e(y,\cdot)|_F)\big) = \iota(\bar{a})^*\beta(y),$$

with $\iota(\bar{a})^*$ the pull-back on $\omega_{\widetilde{H}} = \omega_q \otimes \mathcal{O}'$, the transpose of $\iota(\bar{a})$ on Lie_q (Step 3 (d) is ι-equivariant).

Step 6: (Iz2) with $\epsilon = 1$. Let $y \in T_\ell$ and w, ϕ, U as in Step 0. The image z_R of $e(y,\cdot)|_F$ in $\mathrm{Hom}(G[N]^f_{\mathcal{O}_C},\mu_N)$ is the character χ with $\chi(g) = e_N(\bar{y},g)$ for $g \in F_N$, and $\beta(y) \bmod N = \chi^*\frac{dT}{T}$ in $\omega_{G[N]^f} \otimes \mathcal{O}_C$. As $G[N]^f$ is finite over the complete local ring $\mathcal{O}'$, it is a finite disjoint union of local schemes; let $\Gamma^0 = \operatorname{Spec}\Lambda_0$ be the one containing the unit point $s_0(\kappa')$ of the closed fibre. It is open and closed in $G[N]^f$, hence in $G[N]$, so Λ_0 is a free $\mathcal{O}'$-module and $\omega_{\Gamma^0} = \omega_{G[N]} = \omega_q \otimes \mathcal{O}'/N$ (Step 3 (d)). Every point of Γ^0 is a generisation of $s_0(\kappa')$, which lies in (the pull-back of) U; so $\Gamma^0 \subseteq U$ and ϕ restricts to $\phi_0 \in \Lambda_0$. The restriction of χ to $\Gamma^0_{\mathcal{O}_C}$ is a unit $u \in \Lambda_0 \otimes \mathcal{O}_C$ with $u(s_0) = 1$. Now $\Lambda_0 \otimes \mathcal{O}_C \subseteq \Lambda_0 \otimes C = C^{\Gamma^0(C)}$ ($\Gamma^0_{K'}$ is finite étale), and u and $\phi_0 \otimes 1$ both take the value $e_N(\bar{y},t)$ at each $t \in \Gamma^0(C) \subseteq F_N$, a geometric N-torsion point in U. Hence $u = \phi_0 \otimes 1$, and

$$\beta(y) \bmod N = \chi^*\tfrac{dT}{T} = s_0^*\tfrac{du}{u} = s_0^*du = s_0^*d\phi \equiv w \pmod{N(\omega_q \otimes \mathcal{O}_C)}.$$

So $\beta(y) - w \in N(\omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C)$: (Iz2) holds with $\epsilon = 1$.

Step 7: (Iz3). Choose a basis $t_1,\dots,t_r$ of T_t and a complement W of T_t in F with basis $w_1,\dots,w_s$; by Step 3 (a), $W \to F/T_t = T_\ell(B)$ is an isometry onto $(T_\ell(B),e_B)$, so $e|_W$ is perfect. By Step 3 (c) choose $z_1,\dots,z_r \in T_\ell$ with $e(z_m,t_i) = \delta_{mi}$; replacing z_m by $z_m - w$ for the $w \in W$ with $e(w,w') = e(z_m,w')$ for all $w' \in W$ (it exists as $e|_W$ is perfect; $e(W,T_t) = 0$ keeps $e(z_m,t_i) = \delta_{mi}$), we may assume $e(z_m,W) = 0$. Then (t,w,z) is a basis of T_ℓ ((t,w) is a basis of F and the z_m map to the basis of $T_\ell/F \cong \mathrm{Hom}(T_t,\mathbb{Z}_\ell)$ dual to (t_i)), with Gram matrix $E = (e(y_j,y_k))$ and inverse, in blocks for (t,w,z),

$$E = \begin{pmatrix} 0 & 0 & -I \\ 0 & \Phi & 0 \\ I & 0 & Z \end{pmatrix}, \qquad E^{-1} = \begin{pmatrix} Z & 0 & I \\ 0 & \Phi^{-1} & 0 \\ -I & 0 & 0 \end{pmatrix},$$

$\Phi = (e(w_j,w_k))$, $Z = (e(z_m,z_{m'}))$ (multiply out). The basis $y'_k = \sum_l (E^{-1})_{lk}y_l$ satisfies $e(y_j,y'_k) = \delta_{jk}$, so the element of (Iz3) is $c = \sum_k y_k \otimes y'_k = \sum_{k,l}(E^{-1})_{lk}\,y_k \otimes y_l$. Since $\beta(t_i) = 0$, and E^{-1} vanishes on the blocks (w,z), (z,w), (z,z),

$$(\beta\otimes\beta)(c) = \sum_{j,k}(\Phi^{-1})_{kj}\,\beta(w_j)\otimes\beta(w_k) = \sum_j \beta(w_j)\otimes\beta(w'_j), \qquad w'_j = \sum_k (\Phi^{-1})_{kj}w_k,$$

and (w'_j) is the basis of W with $e(w_i, w'_j) = \delta_{ij}$; so $b_j = \bar{w}_j$, $b'_j = \bar{w}'_j$ are dual bases of $T_\ell(B)$ for e_B. For $f \in F$, Step 3 (a) gives $e(f,\cdot)|_F = e_B(\bar{f},\cdot) \circ T_\ell(\pi) = \pi^D(e_B(\bar{f},\cdot))$, with $\pi^D\colon B[\ell^\infty]^D \to \widetilde{H}^D$, so by (35.4) and Step 3 (d)

$$\beta(f) = \pi^* \alpha_{B[\ell^\infty]^D}(e_B(\bar{f},\cdot)), \qquad \pi^*\colon \omega_{B[\ell^\infty]} \to \omega_{\widetilde{H}}.$$

Let $\mu_B\colon B[\ell^\infty] \to B^\vee[\ell^\infty] = B[\ell^\infty]^D$ be induced by λ_B; $\mu_B^D = \pm\mu_B$ by (vi), and $e_B = \sigma e_{\mu_B}$ for a sign σ fixed by the convention, $e_{\mu_B}(x,x') = \langle x, \mu_B x'\rangle$. Then $e_B(x,\cdot) = -e_B(\cdot,x) = -\sigma\mu_B x$ in $T_\ell(B[\ell^\infty]^D)$, so $\beta(f) = -\sigma\,\pi^*\beta_{\mu_B}(\bar{f})$ with $\beta_{\mu_B} = \alpha_{B[\ell^\infty]^D} \circ \mu_B$, and $(\sigma b'_j)$ is the e_{μ_B}-dual basis of (b_j). Hence

$$(\beta\otimes\beta)(c) = \sigma\,(\pi^*\otimes\pi^*)\Big(\sum_j \beta_{\mu_B}(b_j)\otimes\beta_{\mu_B}(\sigma b'_j)\Big) = 0$$

by Lemma 35.40, applied to $B[\ell^\infty]$ over $\mathcal{O}'$ (K' complete, discretely valued, $v(\ell)=1$) and μ_B. This is (Iz3), and β is a Hodge–Tate isotropic lift at q. □

35.4 Root lines, abelian factors and power sums of Hodge–Tate root classes

The last subsection supplies the remaining inputs of the local relations. On a joint model the de Rham and Hodge–Tate coordinate lattices carry the root lines of the two stages, related by the second roots (Lemma 35.42). The flag theorem for tight Hopf orders over $\mathcal{O}_C$ (Theorem 35.58) says that a tight Hopf order with the generation property along a flag satisfies the flag conditions for every fundamental character; its hypothesis is met for the p-torsion of principally polarised abelian schemes over $\mathcal{O}_C$, whose function modules are abelian factors with the generation property at every subgroup (Proposition 35.43): the p-torsion functions are generated by almost-additive functions (Proposition 35.46), by a count that uses the bound $g/(p-1)$ for the normalised length of the almost-additive quotient (Proposition 35.54), and subgroups are killed by homomorphisms to principally polarised abelian schemes, constructed with quotients by finite subgroup schemes and Zarhin's trick [273] (Proposition 35.44). Finally, modulo a prime of S_B the root lines are the graded pieces of a full flag of a trivial bundle (Proposition 35.66), from Hodge–Tate exactness modulo ℓ (Proposition 35.67); so the second-root lines on the components of the fibre are steps of such a flag and the power sums of the Hodge–Tate root classes vanish there (Proposition 35.65, Proposition 35.64). Proposition 35.66 is used again in Appendix D, for nefness at primes and for flat determinants.

Lemma 35.42. *Let $\mathcal{X}$, p, $\pi\colon \mathcal{X}' \to \mathcal{X}$ be as in Lemma 35.31, with $\mathcal{T}$ of type (Φ, n, κ), so that $\mathrm{rk}((a,+)) = \kappa$ and $\mathrm{rk}((a,-)) = n-\kappa$. Let $a \in \Phi$, β and $\bar{\beta}$ any Ω'-bases of $\mathrm{Li}_{(a,+)}$ and $\mathrm{Li}_{(a,-)}$, $\mathrm{lie} = L$, W the lattices of Lemma 35.31(2) for $((a,+),\beta)$, and $\omega = \bar{L}^\vee$, $\omega' = \bar{W}^\vee$ the duals of those for $((a,-),\bar{\beta})$. Then $\mathrm{lie}, W, \omega, \omega'$ satisfy (He4), with $\pi^*\mathcal{O}(e)$ the pull-back along π of the line bundles $\mathcal{O}(e)|_{\mathcal{X}}$.*

Proof. **Step 1: the pulled-back integral flags.** For $i = 0, 1$, (Go3)(3) gives an integral flag $(\mathcal{V}^i_{s,k})_k$ of the Hodge bundles $\mathcal{V}^i_s$ of $\mathcal{X}_i$ whose generic fibre is the image under g_i of the universal flag, and isomorphisms $\mathcal{O}(e^i_r)|_{\mathcal{X}_i} \to \mathcal{L}^i_r$, $P \mapsto \varrho^i_r P(y^i)$. By Lemma 31.29(1), (2) for ϕ_i (its hypotheses: $\mathcal{X}'$ is a locally noetherian cover with structure map $f_i \circ \phi_i$ by Lemma 35.31(1); S_{B_0} and S_B contain Bd, hence the primes dividing $\mathrm{disc}(E)$; (Hp1), (Hp2) are (Go3)(2) for $\mathcal{X}_i$), $\mathcal{V}'^i_s = \mathcal{O}_{\mathcal{X}'}\mathcal{V}^i_s$ is the Hodge bundle of $\mathcal{X}'$ at (S_{B_0}, R), resp. (S_B, R), which on $\mathcal{X}'$ has stalks $\mathrm{dR}_{s,x}$, resp. $V_{s,x}$; $(\mathcal{O}_{\mathcal{X}'}\mathcal{V}^i_{s,k})_k$ is an integral flag of it, with $\mathcal{O}_{\mathcal{X}'}\mathcal{V}^i_{s,k} = \mathcal{V}'^i_s \cap \Omega'\mathcal{V}^i_{s,k}$, and root lines $\mathcal{L}'^i_r = \mathcal{O}_{\mathcal{X}'}\mathcal{L}^i_r \cong \phi_i^*\mathcal{L}^i_r \cong \phi_i^*\mathcal{O}(e^i_r)$. By (Jm2), $\mathcal{O}(e_r)|_{\mathcal{X}} = \mathrm{pr}_0^*\mathcal{O}(e^0_r)$ and $\mathcal{O}(e'_r)|_{\mathcal{X}} = \mathrm{pr}_1^*\mathcal{O}(e^1_r)$, so $\mathcal{L}'^0_r \cong \pi^*\mathcal{O}(e_r)$ and $\mathcal{L}'^1_r \cong \pi^*\mathcal{O}(e'_r)$, through $P \mapsto \varrho^0_r P(\iota_0 y^0)$, resp. $P \mapsto \varrho^1_r P(\iota_1 y^1)$ (identifying Ω_i with its image in Ω').

Step 2: one generic flag. The generic fibres $\Omega'\mathcal{V}^0_{s,k}$ and $\Omega'\mathcal{V}^1_{s,k}$ are both obtained from the universal flag over Ω_c by extension of scalars along $\iota_0 g_0 = \iota_1 g_1$ (Jm1); call this common flag $(F_{s,k})_k$ of Li_s. Consequently $\mathcal{L}'^0_r$ and $\mathcal{L}'^1_r$ are two invertible subsheaves of the same generic line ℓ_r (the generic root line of r).

Step 3: the side of $(a,+)$. Let $s=(a,+)$ and $F_j = \{c \in V_L : \sum_k c_k\beta_k \in F_{s,j}\}$, a full flag of V_L. The coordinate isomorphism $c \mapsto \sum c_k\beta_k$ carries lie, W onto $\mathcal{V}'^0_s$, $\mathcal{V}'^1_s$ (Lemma 35.31(2) and Step 1), hence $\mathrm{lie}_j = \mathrm{lie} \cap F_j$ onto $\mathcal{V}'^0_s \cap F_{s,j} = \mathcal{O}_{\mathcal{X}'}\mathcal{V}^0_{s,j}$ and W_j onto $\mathcal{O}_{\mathcal{X}'}\mathcal{V}^1_{s,j}$: locally free with invertible graded pieces. For $j \le \kappa$ the root $r=(a,j)$ has label s, step j and sign 1 (Fh3), so $\mathrm{gr}_j\mathrm{lie} \cong \mathcal{L}'^0_r \cong \pi^*\mathcal{O}(e_{(a,j)})$ and $\mathrm{gr}_j W \cong \mathcal{L}'^1_r \cong \pi^*\mathcal{O}(e'_{(a,j)})$. The inclusion $\mathrm{gr}_j\mathrm{lie} \subseteq \mathrm{gr}_j W$ is the inclusion $\mathcal{L}'^0_r \subseteq \mathcal{L}'^1_r$ inside ℓ_r. For a local section P of $\pi^*\mathcal{O}(e_r)$, by (Jm3)

$$\varrho^0_r P(\iota_0 y^0) = \varrho^1_r \cdot \Big(P\,\frac{\varrho^0_r}{\varrho^1_r}\Big) = \varrho^1_r \cdot \Big(P\,\frac{g_r}{f_r}\Big)(\iota_0 y^0, \iota_1 y^1),$$

so, under the isomorphisms of Step 1, the inclusion is the pull-back of multiplication by g_r/f_r (of multidegree $e'_r - e_r$) from $\mathcal{O}(e_r)$ to $\mathcal{O}(e'_r)$.

Step 4: the side of $(a,-)$. Let $\bar s = (a,-)$, $q = n-\kappa$, $\bar F_k = \{c \in V_\omega : \sum c_k\bar\beta_k \in F_{\bar s,k}\}$; as in Step 3, $\bar L_k = \bar L \cap \bar F_k$ and $\bar W_k$ correspond to $\mathcal{O}_{\mathcal{X}'}\mathcal{V}^0_{\bar s,k}$, $\mathcal{O}_{\mathcal{X}'}\mathcal{V}^1_{\bar s,k}$, locally free with invertible graded pieces, and $\mathrm{gr}_k\bar L \cong (\mathcal{L}'^0_r)^{-1}$, $\mathrm{gr}_k\bar W \cong (\mathcal{L}'^1_r)^{-1}$ for the root r with label $\bar s$ and step k, namely $r=(a,n+1-k)$ (sign -1). Let $G_j \subseteq V_\omega$ be the annihilator of $\bar F_{q-j}$ for the dot product ($0 \le j \le q$), a full flag, and $\omega_j = \omega \cap G_j$, $\omega'_j = \omega' \cap G_j$. Since $\bar L_{q-j}$ spans $\bar F_{q-j}$, ω_j consists of the elements of $\omega = \bar L^\vee$ vanishing on $\bar L_{q-j}$, i.e. $\omega_j = (\bar L/\bar L_{q-j})^\vee$, locally free because $\bar L/\bar L_{q-j}$ is (successive invertible quotients), and $\omega_j/\omega_{j-1} \cong (\bar L_{q-j+1}/\bar L_{q-j})^\vee = (\mathrm{gr}_{q+1-j}\bar L)^\vee \cong \mathcal{L}'^0_r$ with $r = (a, n+1-(q+1-j)) = (a,\kappa+j)$; likewise $\omega'_j/\omega'_{j-1} \cong \mathcal{L}'^1_{(a,\kappa+j)}$. So $\mathrm{gr}_j\omega \cong \pi^*\mathcal{O}(e_{(a,\kappa+j)})$ and $\mathrm{gr}_j\omega' \cong \pi^*\mathcal{O}(e'_{(a,\kappa+j)})$. The inclusion $\mathrm{gr}_j\omega' \subseteq \mathrm{gr}_j\omega$ is restriction of functionals from $\mathrm{gr}\bar W$ to $\mathrm{gr}\bar L$, i.e. the inclusion $\mathcal{L}'^1_r \subseteq \mathcal{L}'^0_r$ inside ℓ_r; by (Jm3), $\varrho^1_r P(\iota_1 y^1) = \varrho^0_r \cdot (P\,f_r/g_r)(\iota_0 y^0, \iota_1 y^1)$, so it is the pull-back of multiplication by $f_r/g_r\colon \mathcal{O}(e'_r) \to \mathcal{O}(e_r)$. Steps 3 and 4 together give (He4). □

Proposition 35.43. *Let C and $\mathcal{O}_C$ be as in Definition 35.17, N a finite abelian group and $M \subseteq \mathrm{Map}(N,C)$ an abelian factor. Then M has the generation property at every subgroup $K \le N$.*

Proof. Write $\mathrm{alg}(S)$ for the $\mathcal{O}_C$-subalgebra of $\mathrm{Map}(\cdot,C)$ generated by a set S of functions, and $\mathrm{AA}(S)$ for the almost-additive elements of S. For a group homomorphism $h\colon N_1 \to N_2$ the pull-back $h^*\colon \mathrm{Map}(N_2,C) \to \mathrm{Map}(N_1,C)$, $g \mapsto g\circ h$, is a homomorphism of $\mathcal{O}_C$-algebras and maps almost-additive functions to almost-additive functions ($g(h(x+y)) - g(h(x)) - g(h(y)) = g(h(x)+h(y)) - g(h(x)) - g(h(y))$); hence $h^*\mathrm{alg}(S) = \mathrm{alg}(h^*S)$.

Step 1: the abelian scheme itself. Let A be an abelian scheme over $\mathcal{O}_C$ admitting a relatively ample line bundle and $K' \le N_A$. Take P and j from Proposition 35.44, so $M_A^{K'} = j^*M_P$. By Proposition 35.46, $M_P \subseteq \mathrm{alg}(\mathrm{AA}(M_P))$, so $M_A^{K'} = j^*M_P \subseteq \mathrm{alg}(j^*\mathrm{AA}(M_P))$. Each j^*g, $g \in \mathrm{AA}(M_P)$, is almost additive and lies in $j^*M_P = M_A^{K'}$. Hence $M_A^{K'} \subseteq \mathrm{alg}(\mathrm{AA}(M_A^{K'}))$: M_A has the generation property at K'.

Step 2: abelian factors. Let A, ι, ρ be as in (Af3) for M, let $K \le N$ and $K' = \iota(K) \le N_A$. Let $f \in M^K$, say $f = g\circ\iota$ with $g \in M_A$, and put $g' = f\circ\rho = g\circ\iota\circ\rho$, which lies in M_A by (Af3). For $y \in N_A$, $k \in K$: $g'(y+\iota(k)) = f(\rho(y)+\rho\iota(k)) = f(\rho(y)+k) = f(\rho(y)) = g'(y)$, so $g' \in M_A^{K'}$; and $g'\circ\iota = f\circ\rho\circ\iota = f$. By Step 1, $g' \in \mathrm{alg}(\mathrm{AA}(M_A^{K'}))$, so $f = \iota^*g' \in \mathrm{alg}(\iota^*\mathrm{AA}(M_A^{K'}))$. For $h \in \mathrm{AA}(M_A^{K'})$, ι^*h is almost additive, lies in $\iota^*M_A = M$, and is K-invariant: $h(\iota(x+k)) = h(\iota(x)+\iota(k)) = h(\iota(x))$. So $\iota^*\mathrm{AA}(M_A^{K'}) \subseteq \mathrm{AA}(M^K)$ and $f \in \mathrm{alg}(\mathrm{AA}(M^K))$. □

Proposition 35.44. *Let C and $\mathcal{O}_C$ be as in Definition 35.17, A an abelian scheme over $\mathcal{O}_C$ admitting a relatively ample line bundle, and $K' \leq N_A$ a subgroup. Then there are a principally polarised abelian scheme P over $\mathcal{O}_C$ and a homomorphism of group schemes $j\colon A \to P$ such that, writing j also for the induced homomorphism $N_A \to N_P$:*

1. *for $x, y \in N_A$, $j(x) = j(y)$ if and only if $x - y \in K'$;*
2. *$M_A^{K'} = \{g \circ j :\ g \in M_P\}$.*

Proof. Let $K' \leq N_A$. Write $\mathcal{O}(Y) = \Gamma(Y, \mathcal{O}_Y)$ for affine Y.

Step 1: the closure of K'. $A[p]$ is finite locally free over $\mathcal{O}_C$; its generic fibre is finite étale over the algebraically closed C (characteristic 0), hence constant, and $N_A = A[p](\mathcal{O}_C) = A[p](C)$ ($A[p]$ is finite). For a finite locally free $\mathcal{O}_C$-scheme Y with constant generic fibre, $\mathcal{O}(Y)$ is torsion free, so $\mathcal{O}(Y) \to \mathcal{O}(Y_C) = \operatorname{Map}(Y(C), C)$ is injective. Let $H \subseteq A[p]$ be the closed subscheme defined by the kernel of $\mathcal{O}(A[p]) \to \operatorname{Map}(K', C)$. Its ring is the image, a finitely generated torsion-free, hence free, $\mathcal{O}_C$-module, so H is finite locally free, with $H_C = K'$ and $H(\mathcal{O}_C) = K'$. $H \times H$ is flat with generic fibre $K' \times K'$, so it is the closure of $K' \times K'$ in $A[p] \times A[p]$; the group law and the inverse map $K' \times K'$ into K', hence $H \times H$ into H: H is a closed subgroup scheme of A, finite locally free over $\mathcal{O}_C$.

Step 2: the quotient, by spreading out. $\mathcal{O}_C$ is the filtered union of its finitely generated $\mathbb{Z}$-subalgebras R_α (noetherian). A, a relatively ample line bundle L on it, the group law, unit and inverse, and H with its closed immersion are of finite presentation over $\mathcal{O}_C$; by the limit theorems there are α, an abelian scheme A_α over R_α with a relatively ample line bundle and a closed subgroup scheme $H_\alpha \subseteq A_\alpha$, finite locally free over R_α, whose base changes to $\mathcal{O}_C$ are A, L, H (with their structures). By Theorem 35.45 over $S = \operatorname{Spec} R_\alpha$ there is a finite locally free surjective homomorphism $q_\alpha\colon A_\alpha \to A'_\alpha$ onto an abelian scheme with a relatively ample line bundle with $A_\alpha \times H_\alpha \cong A_\alpha \times_{A'_\alpha} A_\alpha$. Base change to $\mathcal{O}_C$ gives $q\colon A \to A'$, a finite locally free surjective homomorphism onto an abelian scheme A' over $\mathcal{O}_C$ with a relatively ample line bundle, and $A \times H \cong A \times_{A'} A$ via $(a, h) \mapsto (a, a + h)$.

Step 3: the principally polarised P. The abelian scheme A'_α carries a relatively ample line bundle $\mathcal{L}'_\alpha$ over the noetherian base $\operatorname{Spec} R_\alpha$, so its dual $A'^\vee_\alpha$ exists and $\phi_{\mathcal{L}'_\alpha}\colon A'_\alpha \to A'^\vee_\alpha$ is a polarisation. By Theorem B.120, $P_\alpha = (A'_\alpha \times_{R_\alpha} A'^\vee_\alpha)^4$ admits a principal polarisation $\lambda_\alpha\colon P_\alpha \to P_\alpha^\vee$. Let $i_\alpha\colon A'_\alpha \to P_\alpha$ be the inclusion of the first factor A'_α and $r_\alpha\colon P_\alpha \to A'_\alpha$ the projection onto it, so that $r_\alpha \circ i_\alpha = \mathrm{id}$. Let P, $i\colon A' \to P$, $r\colon P \to A'$ and λ be the base changes to $\mathcal{O}_C$ (recall that A' is the base change of A'_α). Since the dual commutes with base change, $\lambda\colon P \to P^\vee$ is an isomorphism, and it is a polarisation because every geometric point of $\operatorname{Spec} \mathcal{O}_C$ lies over a geometric point of $\operatorname{Spec} R_\alpha$ and the homomorphism ϕ of an ample line bundle is compatible with extension of the algebraically closed field. So P is a principally polarised abelian scheme over $\mathcal{O}_C$, $r \circ i = \mathrm{id}$, and i is a closed immersion (a section of the separated r). Put $j = i \circ q$.

Step 4: assertion (1). For $x, y \in N_A$: $j(x) = j(y)$ if and only if $q(x - y) = 0$ (i is injective on points), i.e. $x - y \in \ker q(\mathcal{O}_C) = H(\mathcal{O}_C) = K'$.

Step 5: assertion (2). If $g \in M_P$ is the function of $b \in \mathcal{O}(P[p])$, then $g \circ j$ is the function of $j^*b \in \mathcal{O}(A[p])$ (j maps $A[p]$ into $P[p]$), so $g \circ j \in M_A$, and it is K'-invariant by (1). Conversely let $f \in M_A^{K'}$ be the function of $a \in \mathcal{O}(A[p])$. The two pull-backs of a to $A[p] \times H$ (by the projection and by the action $(x, h) \mapsto x + h$) have the same values on $(A[p] \times H)(C) = N_A \times K'$, so they are equal (Step 1, injectivity for $A[p] \times H$). The closed subscheme $A[p] \subseteq A$ is stable under H; since q is an fppf H-torsor, it descends to a closed subscheme $Z \subseteq A'$ with $q^{-1}(Z) = A[p]$, $A[p] \to Z$ is an H-torsor, and by descent of functions $a = q^*a'$ for some $a' \in \mathcal{O}(Z)$. As $[p] \circ q = q \circ [p]$ and $q^{-1}(Z) = A[p]$, $[p]$ kills Z after the faithfully flat base change $A[p] \to Z$, so $Z \subseteq A'[p]$,

a closed subscheme of the affine $A'[p]$. Since i restricts to a closed immersion $A'[p] \to P[p]$, $\mathcal{O}(P[p]) \to \mathcal{O}(Z)$ is surjective: $a' = b|_Z$ for some $b \in \mathcal{O}(P[p])$, and $a = j^*b$. Hence $f = g \circ j$ with $g \in M_P$ the function of b. □

Theorem 35.45. *Let S be a noetherian scheme, A an abelian scheme over S admitting a relatively ample line bundle, and $H \subseteq A$ a closed subgroup scheme, finite and locally free over S. Then there are an abelian scheme A' over S admitting a relatively ample line bundle and a homomorphism $q\colon A \to A'$ which is finite, locally free and surjective, such that $A \times_S H \to A \times_{A'} A$, $(a, h) \mapsto (a, a + h)$, is an isomorphism; in particular* $\ker q = H$.

Proof. Let $\mathcal{L}$ be a relatively ample line bundle on A, and let H act on A by $\alpha(h, a) = a + h$.

Step 1: the quotient. The morphism $H \times_S A \to A \times_S A$, $(h, a) \mapsto (a + h, a)$, is the closed immersion $H \times_S A \to A \times_S A$ followed by the automorphism $(b, a) \mapsto (a + b, a)$ of $A \times_S A$; so it is a closed immersion, in particular a monomorphism, and the action is free. Let $x \in A$ lie over $s \in S$ and let $V \subseteq S$ be an affine open neighbourhood of s. As H is finite over S, the image of $H \times_S \operatorname{Spec} \kappa(x) \to A$ is a finite set of points of A_V. Since V is affine and $A_V \to V$ is of finite type, $\mathcal{L}|_{A_V}$ is an ample line bundle on the quasi-compact scheme A_V, so every finite subset of A_V lies in an affine open subscheme of A_V [81], §§4.5–4.6, which is an affine open subscheme of A. By Theorem B.152 there is a finite, locally free, surjective S-morphism $q\colon A \to A'$ with $q(a + h) = q(a)$ such that $H \times_S A \to A \times_{A'} A$, $(h, a) \mapsto (a + h, a)$, is an isomorphism; composing with the exchange of factors on both sides, $A \times_S H \to A \times_{A'} A$, $(a, h) \mapsto (a, a + h)$, is an isomorphism.

Step 2: group structure and uniqueness. For the fppf topology on S-schemes, q is a covering, so the sheaf $h_{A'}$ represented by A' is the coequaliser of the two projections $h_{A \times_{A'} A} \rightrightarrows h_A$ [226], Exp. IV. By Step 1 these are the maps $h_H \times h_A \rightrightarrows h_A$, $(h, a) \mapsto a + h$ and $(h, a) \mapsto a$, whose coequaliser is the quotient sheaf of commutative groups h_A/h_H. Hence A' is a commutative S-group scheme, q is a homomorphism, and pulling back the isomorphism of Step 1 along the unit section in the first factor gives $H \cong S \times_{A'} A = \ker q$. The same argument over an S-scheme T shows: if $p\colon A_T \to Y$ is a finite, locally free, surjective morphism of T-schemes such that $H_T \times_T A_T \to A_T \times_Y A_T$, $(h, a) \mapsto (a + h, a)$, is an isomorphism, then Y and A'_T both represent h_{A_T}/h_{H_T} (the properties of q and the isomorphism of Step 1 are stable under base change), so $Y \cong A'_T$.

Step 3: $A' \to S$ is of finite type, flat and proper. $A' \to S$ is quasi-compact, because $A \to S$ is and q is surjective. Let $\operatorname{Spec} C \subseteq A'$ be an affine open lying over an affine open $\operatorname{Spec} R \subseteq S$. As q is finite, its preimage is $\operatorname{Spec} B$ with B finite over C; B is a finitely generated R-algebra; and $C \to B$ is injective because q is faithfully flat. As R is noetherian, C is a finitely generated R-algebra [12], Prop. 7.8. Flatness: let $y \in A'$, $x \in A$ with $q(x) = y$, and s their image in S; $\mathcal{O}_{A',y} \to \mathcal{O}_{A,x}$ is faithfully flat and $\mathcal{O}_{S,s} \to \mathcal{O}_{A,x}$ is flat, so for an injection $M' \to M$ of $\mathcal{O}_{S,s}$-modules the map $M' \otimes \mathcal{O}_{A',y} \to M \otimes \mathcal{O}_{A',y}$ is injective after $\otimes_{\mathcal{O}_{A',y}} \mathcal{O}_{A,x}$, hence injective. Separatedness: the base change of the diagonal $A' \to A' \times_S A'$ along the fppf covering $q \times q\colon A \times_S A \to A' \times_S A'$ is $A \times_{A'} A \to A \times_S A$, which by Step 1 is identified with the closed immersion $H \times_S A \to A \times_S A$, $(h, a) \mapsto (a + h, a)$; closed immersions descend along fpqc coverings [83], (2.7.1), so the diagonal is a closed immersion. Universal closedness: for $S' \to S$, $q_{S'}$ is surjective, so the image in S' of a closed subset $Z \subseteq A'_{S'}$ is the image of the closed subset $q_{S'}^{-1}(Z)$ under the closed map $A_{S'} \to S'$. So $A' \to S$ is proper.

Step 4: A' is an abelian scheme. Let $s \in S$ and $\bar{s} = \operatorname{Spec} \bar{k}$ for an algebraic closure $\bar{k}$ of $\kappa(s)$. Then $A_{\bar{s}}$ is an abelian variety over $\bar{k}$ and $H_{\bar{s}} \subseteq A_{\bar{s}}$ a finite subgroup scheme; Theorem B.121 gives an abelian variety Y and a finite, flat, surjective $p\colon A_{\bar{s}} \to Y$ with $H_{\bar{s}} \times A_{\bar{s}} \cong A_{\bar{s}} \times_Y A_{\bar{s}}$, and Step 2 with $T = \bar{s}$ gives $A'_{\bar{s}} \cong Y$. So A'_s is smooth and geometrically connected over $\kappa(s)$.

Since $A' \to S$ is flat and of finite presentation (S noetherian) with smooth fibres, it is smooth [84], (17.5.1). Thus A' is a smooth proper commutative group scheme over S with geometrically connected fibres, an abelian scheme.

Step 5: a relatively ample line bundle on A'. Apply Theorem B.153 with $Y = S$, $X = A'$, $X' = A$, $f\colon A' \to S$ (quasi-compact by Step 3), $g = q$ (finite and surjective, with $q_*\mathcal{O}_A$ locally free as q is finite and locally free) and $\mathcal{L}' = \mathcal{L}$ (ample relative to $f \circ q$): $\mathrm{N}_{A/A'}(\mathcal{L})$ is ample relative to $A' \to S$. □

Proposition 35.46. *Let C and $\mathcal{O}_C$ be as in Definition 35.17 and P a principally polarised abelian scheme over $\mathcal{O}_C$. Then M_P has the generation property at the trivial subgroup: M_P is contained in the $\mathcal{O}_C$-subalgebra of* $\mathrm{Map}(N_P, C)$ *generated by the almost-additive elements of M_P.*

Proof. Let g be the relative dimension of P and $B = M_P$.

Step 1 (B is a Hopf order on N_P). The ring $\Gamma(P[p], \mathcal{O})$ is finite locally free over the local ring $\mathcal{O}_C$, hence free of rank p^{2g}; its generic fibre is the constant group scheme N_P, so evaluation at the points identifies $\Gamma(P[p], \mathcal{O}) \otimes C$ with $\mathrm{Map}(N_P, C)$, and evaluation is injective on the torsion-free $\Gamma(P[p], \mathcal{O})$. So B is spanned by the columns of a matrix in $\mathrm{GL}_{N_P}(C)$; it contains 1, is closed under products, and the group law and inverse of $P[p]$ give the comultiplication and antipode axioms of Definition 35.18(Ho2).

Step 2 (cotangent length). The augmentation ideal I_B is the ideal of the unit section, so $I_B/I_B^2 = \omega_{P[p]} \cong (\mathcal{O}_C/p)^g$, of normalised length g.

Step 3. By Lemma 35.47, Proposition 35.54, Step 2 and Lemma 35.49,

$$2\,\mathrm{colen}(B) \le (p-1)|N_P|\,\mathrm{len}_C(Q_B) \le |N_P|\,g = |N_P|\,\mathrm{len}_C(I_B/I_B^2) \le 2\,\mathrm{colen}(B).$$

So all are equalities; in particular $2\,\mathrm{colen}(B) = (p-1)|N_P|\,\mathrm{len}_C(Q_B)$, and Lemma 35.47 shows that B is spanned by products of its almost-additive elements: M_P has the generation property at the trivial subgroup. (The two equalities also show that M_P is tight in the sense of Definition 35.18(Ho3).) □

Lemma 35.47. *Let N be a finite abelian group with $pN = 0$, $n = \dim_{\mathbb{F}_p} N$, and $B \subseteq \mathrm{Map}(N, C)$ an $\mathcal{O}_C$-submodule spanned by the columns of a matrix in $\mathrm{GL}_N(C)$, containing 1 and closed under products (for instance a Hopf order on N). Let $V = \mathrm{Lin}(N)/p\,\mathrm{Map}(N, \mathcal{O}_C)$, the $\mathcal{O}_C/p$-module of additive maps $N \to \mathcal{O}_C/p$. Then Q_B has a normalised length and*

$$2\,\mathrm{colen}(B) \le (p-1)\,|N|\,\mathrm{len}_C(Q_B).$$

Moreover there are $g_1, \dots, g_n \in \mathrm{AF}(B)$ and $\varepsilon_1, \dots, \varepsilon_n \in \mathcal{O}_C$ with $\varepsilon_j \mid p$ such that:

(i) $g_j = \varepsilon_j \tilde{\lambda}_j$ with $\tilde{\lambda}_j \in \mathrm{Map}(N, \mathcal{O}_C)$, and the p^n functions $\tilde{\lambda}^d = \prod_j \tilde{\lambda}_j^{d_j}$, $d \in \{0, \dots, p-1\}^n$, form an $\mathcal{O}_C$-basis of $\mathrm{Map}(N, \mathcal{O}_C)$*;*

(ii) the reductions λ_j of the $\tilde{\lambda}_j$ modulo p form an $\mathcal{O}_C/p$-basis of V, the image of $\mathrm{AF}(B)$ *in V is $\bigoplus_j \bar{\varepsilon}_j(\mathcal{O}_C/p)\lambda_j$, and $\mathrm{len}_C(Q_B) = \sum_j v(\varepsilon_j)$;*

(iii) if equality holds in the inequality above, the products $g^d = \prod_j g_j^{d_j}$, $d \in \{0, \dots, p-1\}^n$, form an $\mathcal{O}_C$-basis of B.

In particular, if equality holds, B is the $\mathcal{O}_C$-span of products of almost-additive elements of B, and B has the generation property at the trivial subgroup.

Proof. B is spanned by the $|N|$ columns of a matrix, contains 1 and is closed under products, so its elements take values in $\mathcal{O}_C$ by Lemma 35.48, and $\mathrm{AF}(B) \subseteq \mathrm{Lin}(N)$. The module V is free of rank n over $\mathcal{O}_C/p$ with basis the coordinate functions $x_1, \dots, x_n$ for an $\mathbb{F}_p$-basis of N (reduction modulo p maps $\mathrm{Lin}(N)$ onto the additive maps $N \to \mathcal{O}_C/p$, since any lift of an additive map is almost additive, with kernel $\mathrm{Lin}(N) \cap p\,\mathrm{Map}(N, \mathcal{O}_C) = p\,\mathrm{Map}(N, \mathcal{O}_C)$). Let M be the image of $\mathrm{AF}(B)$, so $Q_B \cong V/M$. M is finitely generated: $\mathrm{AF}(B)$ is the kernel of the $\mathcal{O}_C$-linear map $B \to \mathrm{Map}(N \times N, \mathcal{O}_C/p)$, $g \mapsto \overline{g(x+y) - g(x) - g(y)}$, from the free module B of rank $|N|$ (its spanning columns are C-linearly independent) to a finitely presented module, and over the coherent ring $\mathcal{O}_C$ (a valuation ring: finitely generated ideals are principal) such a kernel is finitely generated. The preimage of M in $\mathcal{O}_C^n$ (coordinates in the basis x_k) is finitely generated and contains $p\,\mathcal{O}_C^n$; an adapted basis gives an $\mathcal{O}_C/p$-basis $\lambda_1, \dots, \lambda_n$ of V and $\varepsilon_j \in \mathcal{O}_C$ with $\varepsilon_j \mid p$ (so $\varepsilon_j \neq 0$) and $M = \bigoplus_j \bar{\varepsilon}_j(\mathcal{O}_C/p)\lambda_j$. Hence $Q_B \cong \bigoplus_j (\mathcal{O}_C/p)/\bar{\varepsilon}_j(\mathcal{O}_C/p) \cong \bigoplus_j \mathcal{O}_C/\varepsilon_j$ has normalised length $\sum_j v(\varepsilon_j)$.

Choose $g_j \in \mathrm{AF}(B)$ with $\bar{g}_j = \bar{\varepsilon}_j\lambda_j$; then $g_j = \varepsilon_j\tilde{\lambda}_j$ with $\tilde{\lambda}_j = g_j/\varepsilon_j \in \mathrm{Map}(N, \mathcal{O}_C)$ a lift of λ_j (write $g_j = \varepsilon_j\ell + ph$ for a lift ℓ and use $\varepsilon_j \mid p$). This gives (ii). *Claim (this is (i)): the p^n functions $\tilde{\lambda}^d = \prod_j \tilde{\lambda}_j^{d_j}$, $0 \le d_j \le p-1$, form a basis of* $\mathrm{Map}(N, \mathcal{O}_C)$. Modulo p, $\mathrm{Map}(N, \mathcal{O}_C/p) = (\mathcal{O}_C/p)[x_1, \dots, x_n]/(x_k^p - x_k)$; filter by degree. The associated graded ring is $(\mathcal{O}_C/p)[x]/(x_1^p, \dots, x_n^p)$. Write $\lambda = Ux$ with $U \in \mathrm{GL}_n(\mathcal{O}_C/p)$; in characteristic p, $\lambda_j^p = \sum_k u_{jk}^p x_k^p$ and $U^{(p)} = (u_{jk}^p)$ is invertible, so the ideals (x_k^p) and (λ_j^p) coincide and the graded ring is $(\mathcal{O}_C/p)[\lambda]/(\lambda_j^p)$, with basis the monomials λ^d, $d_j < p$. The reduction of $\tilde{\lambda}^d$ is λ^d, of degree $\sum_j d_j$ with symbol the monomial λ^d of the graded ring; a family whose symbols in the associated graded form a basis is a basis of the filtered free module, so the λ^d form a basis of $\mathrm{Map}(N, \mathcal{O}_C/p)$, and the claim follows by the fact quoted above.

Let Λ be the $\mathcal{O}_C$-span of the products $g^d = \prod_j g_j^{d_j} = (\prod_j \varepsilon_j^{d_j})\tilde{\lambda}^d$, $0 \le d_j < p$. Then $\Lambda \subseteq \mathcal{O}_C[\mathrm{AF}(B)] \subseteq B$. Since the $\tilde{\lambda}^d$ form a basis (claim) and the scalars $\prod_j \varepsilon_j^{d_j}$ are non-zero, the g^d form a basis of Λ, and $\mathrm{colen}(\Lambda) = \sum_d \sum_j d_j v(\varepsilon_j) = \sum_j v(\varepsilon_j) \cdot p^{n-1}\frac{p(p-1)}{2} = \frac{(p-1)|N|}{2}\mathrm{len}_C(Q_B)$. If T is the matrix expressing the basis $(g^d)_d$ of Λ in a basis of B, then T has entries in $\mathcal{O}_C$ and $\mathrm{colen}(\Lambda) = \mathrm{colen}(B) + v(\det T) \ge \mathrm{colen}(B)$, which is the inequality. If equality holds, $v(\det T) = 0$, so $T \in \mathrm{GL}(\mathcal{O}_C)$ and $B = \Lambda$; thus the g^d form a basis of B, which is (iii), and B is the span of products of the almost-additive elements g_j of B (the constant 1 is the empty product). □

Lemma 35.48. *Let X be a finite set and $B \subseteq \mathrm{Map}(X, C)$ a finitely generated $\mathcal{O}_C$-submodule that contains the constant function 1 and is closed under products. Then $B \subseteq \mathrm{Map}(X, \mathcal{O}_C)$. In particular every Hopf order on a finite-dimensional $\mathbb{F}$-vector space N consists of functions $N \to \mathcal{O}_C$.*

Proof. Let $b_1, \dots, b_r$ generate B and let $g \in B$. Since B is closed under products, $g\,b_j = \sum_k a_{jk}b_k$ with $a_{jk} \in \mathcal{O}_C$. Put $A = (a_{jk})$ and $P(T) = \det(T \cdot \mathbf{1}_r - A) \in \mathcal{O}_C[T]$, a monic polynomial. In the commutative ring $\mathrm{Map}(X, C)$ the vector $b = (b_1, \dots, b_r)^{\mathsf{T}}$ satisfies $(g\mathbf{1}_r - A)\,b = 0$; multiplying by the adjugate of $g\mathbf{1}_r - A$ gives $P(g)\,b_k = 0$ for every k. Writing $1 = \sum_k c_k b_k$ with $c_k \in \mathcal{O}_C$ ($1 \in B$), $P(g) = P(g) \cdot 1 = \sum_k c_k P(g) b_k = 0$. Evaluating at $x \in X$ (a ring homomorphism $\mathrm{Map}(X, C) \to C$), $P(g(x)) = 0$, so $g(x)$ is integral over $\mathcal{O}_C$. A valuation ring is integrally closed in its field of fractions, so $g(x) \in \mathcal{O}_C$.

A Hopf order on N is by (Ho2) the $\mathcal{O}_C$-span of the $|N|$ columns of a matrix (hence finitely generated), contains 1 and is closed under products, so the first part applies with $X = N$. □

Lemma 35.49. *Let N be a finite abelian group with $pN = 0$ and B a Hopf order on N. Then*

I_B/I_B^2 has a normalised length and $|N|\operatorname{len}_C(I_B/I_B^2) \le 2\operatorname{colen}(B)$.

Proof. Regard N as a vector space over $\mathbb{F} = \mathbb{F}_p$ ($f = 1$, $q = p$). B is $\mathbb{F}_p$-stable: for $g \in B$, $x \mapsto g(0)$ lies in $\mathcal{O}_C 1 \subseteq B$, and for $k \ge 1$, $x \mapsto g(kx)$ is obtained from $(x_1, \dots, x_k) \mapsto g(x_1 + \cdots + x_k)$, which lies in the span of products $g_1(x_1) \cdots g_k(x_k)$ with $g_i \in B$ (iterate the comultiplication axiom), by restriction to the diagonal, so it lies in B (closure under products). The Teichmüller character $\chi\colon \mathbb{F}_p \to \mathcal{O}_C$ ($\chi(a) \in \mu_{p-1}$, $\chi(a) \equiv a$ modulo $\mathfrak{m}_C$, values in $\mathbb{Z}_p$, so $\chi(a+b) - \chi(a) - \chi(b) \in p\mathbb{Z}_p$) is fundamental. Choose a basis of N and let $S_1, \dots, S_m$ be the step orders, as in Lemma 35.50. By Lemma 35.50(3), iterated from B_0, I_B/I_B^2 has the normalised length $\sum_\psi \operatorname{len}\operatorname{co}_\psi(B) \le \sum_\psi \sum_j \operatorname{len}\operatorname{co}_\psi(S_j) = \sum_j \operatorname{len}_C(I_{S_j}/I_{S_j}^2)$. By Lemma 35.52(4),(5) with $f = 1$, $\operatorname{len}_C(I_{S_j}/I_{S_j}^2) = v(\delta_j) = (p-1)v(c_j) = 2\operatorname{colen}(S_j)/p$, where c_j generates $\operatorname{Xr}_\chi(S_j)$. By Lemma 35.50(2), $\sum_j 2\operatorname{colen}(S_j)/p = 2\operatorname{colen}(B)/|N|$. □

Lemma 35.50. *Let B be an $\mathbb{F}$-stable Hopf order on N, $b_1, \dots, b_m$ a basis of N, $N_j = \mathbb{F}b_1 \oplus \cdots \oplus \mathbb{F}b_j$, $B_j = B|_{N_j}$ ($B_0 = \mathcal{O}_C$, $B_m = B$) and $S_j = B_{N_{j-1}, b_j}$ the step order ($1 \le j \le m$). Then:*

1. *each B_j is an $\mathbb{F}$-stable Hopf order on N_j, and each S_j is an $\mathbb{F}$-stable Hopf order on $\mathbb{F}$; for every character ψ, $\operatorname{Xr}_{\psi,j}(B) = \operatorname{Xv}_{\psi,j}(B) = \operatorname{Xr}_\psi(S_j)$;*
2. *$\operatorname{colen}(B)/|N| = \sum_{j=1}^m \operatorname{colen}(S_j)/q$;*
3. *for every character ψ the modules $\operatorname{co}_\psi(B_j)$, $\operatorname{co}_\psi(S_j)$ have normalised lengths, I_B/I_B^2 has normalised length $\sum_\psi \operatorname{len}_C \operatorname{co}_\psi(B)$ (sum over the $q-1$ characters), and $\operatorname{len}_C \operatorname{co}_\psi(B_j) \le \operatorname{len}_C \operatorname{co}_\psi(B_{j-1}) + \operatorname{len}_C \operatorname{co}_\psi(S_j)$ for $1 \le j \le m$;*
4. *if ψ is a character with*
$$\operatorname{len}_C \operatorname{co}_\psi(B) = \sum_{j=1}^m \operatorname{len}_C \operatorname{co}_\psi(S_j),$$
then $\operatorname{len}_C \operatorname{co}_\psi(B_j) = \sum_{i \le j} \operatorname{len}_C \operatorname{co}_\psi(S_i)$ for $0 \le j \le m$.

Proof. **Step 0 (group schemes).** For a Hopf order B' on a finite group N', $B' \otimes_{\mathcal{O}_C} B' \to \operatorname{Map}(N' \times N', C)$ is injective (a basis goes to a linearly independent family), so the axioms of Definition 35.18(Ho2) make $G' = \operatorname{Spec} B'$ a finite flat commutative group scheme over $\mathcal{O}_C$ with G'_C the constant group N'. For a subgroup $N'' \le N'$ the restriction $B' \to B'|_{N''}$ is surjective, $B'|_{N''}$ is finitely generated and torsion-free, hence free, spans $\operatorname{Map}(N'', C)$, and inherits the Hopf axioms; it is a Hopf order on N'', and $\operatorname{Spec} B'|_{N''}$ is a closed flat subgroup scheme of G'. If B' is $\mathbb{F}$-stable and N'' is an $\mathbb{F}$-subspace, $B'|_{N''}$ is $\mathbb{F}$-stable. For $K \le N'$ and $H = \operatorname{Spec} B'|_K$, the coaction $B' \to B' \otimes B'|_K$ is $g \mapsto ((x,k) \mapsto g(x+k))$, so by (a) $\mathcal{O}(G'/H) = B'^K = \{g \in B' : g(x+k) = g(x)\}$, and by flat base change $B'^K \otimes C = \operatorname{Map}(N'/K, C)$: B'^K is a Hopf order on N'/K.

Step 1 (part (1)). The first claim is Step 0. Let $G_j = \operatorname{Spec} B_j$ and $H = \operatorname{Spec} B_{j-1} \subseteq G_j \subseteq G$. The morphism $G_j/H \to G/H$ induced by $G_j \subseteq G$ is a monomorphism of fppf sheaves (two sections of G_j/H with the same image differ locally by a section of H), finite and of finite presentation, hence a closed immersion by (b). So restriction $B^{N_{j-1}} \to (B_j)^{N_{j-1}}$ is surjective: $(B^{N_{j-1}})|_{N_j} = (B_j)^{N_{j-1}}$. Composition with $\mathbb{F} \cong N_j/N_{j-1}$, $a \mapsto ab_j$, maps $(B_j)^{N_{j-1}}$ isomorphically and $\mathbb{F}$-equivariantly onto S_j (by definition of S_j and the previous equality); so S_j is an $\mathbb{F}$-stable Hopf order on $\mathbb{F}$ (Step 0). For $c \in C$, the function $h(ab_j + k) = c\psi(a)$ on N_j is N_{j-1}-invariant; $c \in \operatorname{Xr}_{\psi,j}(B)$ iff $h \in B_j$, iff $h \in (B_j)^{N_{j-1}} = (B^{N_{j-1}})|_{N_j}$, iff some $g \in B^{N_{j-1}}$ has $g(ab_j) = c\psi(a)$, i.e. $c \in \operatorname{Xv}_{\psi,j}(B) = \operatorname{Xr}_\psi(S_j)$.

Step 2 (part (2)). For a Hopf order B' on N' the trace of multiplication by g on $B' \otimes C = \mathrm{Map}(N', C)$ is $\sum_x g(x)$; if M is the matrix of a basis of B' in the basis of indicator functions, the Gram matrix of the trace form is $M^{\mathsf{T}}M$, so $v(\mathfrak{d}(B'/\mathcal{O}_C)) = 2\,\mathrm{colen}(B')$. Apply (d) to $\mathcal{O}_C \to A = (B_j)^{N_{j-1}} \to B_j$: B_j is finite locally free of rank q^{j-1} over the semilocal ring A (by (a)), hence free. The torsor isomorphism $G_j \times H \cong G_j \times_{G_j/H} G_j$, $(x,h) \mapsto (x, x+h)$, gives $B_j \otimes_A B_j \cong B_j \otimes_{\mathcal{O}_C} B_{j-1}$ as B_j-algebras, so $\mathfrak{d}(B_j/A)B_j = \mathfrak{d}(B_{j-1}/\mathcal{O}_C)B_j$, hence $\mathfrak{d}(B_j/A) = \mathfrak{d}(B_{j-1}/\mathcal{O}_C)A$ ($A \to B_j$ faithfully flat), whose norm is $\mathfrak{d}(B_{j-1}/\mathcal{O}_C)^q$. With $A \cong S_j$ (Step 1): $2\mathrm{colen}(B_j) = q \cdot 2\mathrm{colen}(B_{j-1}) + q^{j-1} \cdot 2\mathrm{colen}(S_j)$, i.e. $\mathrm{colen}(B_j)/q^j = \mathrm{colen}(B_{j-1})/q^{j-1} + \mathrm{colen}(S_j)/q$. Summing over j gives (2) ($\mathrm{colen}(B_0) = 0$).

Step 3 (part (3)). For an $\mathbb{F}$-stable Hopf order B' the projectors

$$\pi_\psi g = \frac{1}{q-1} \sum_{a \in \mathbb{F}^\times} \psi(a)^{-1} g(a\,\cdot)$$

preserve $I_{B'}$ and $I_{B'}^2$ and $\sum_\psi \pi_\psi = \mathrm{id}$, so $I_{B'}/I_{B'}^2 = \bigoplus_\psi \mathrm{co}_\psi(B')$. $I_{B'}^2$ is finitely generated, so $I_{B'}/I_{B'}^2$ is finitely presented, and it is torsion because the augmentation ideal of $\mathrm{Map}(N', C)$ equals its square (it is spanned by idempotents). By (c) it and its direct summands have normalised lengths, additive over the decomposition. Restriction $I_{B_j} \to I_{B_{j-1}}$ is surjective and maps $I_{B_j}^2$ onto $I_{B_{j-1}}^2$, so $\mathrm{co}_\psi(B_j) \to \mathrm{co}_\psi(B_{j-1})$ is surjective, with kernel the image of the ψ-part of $\{g \in I_{B_j} : \ g|_{N_{j-1}} = 0\}$. By Lemma 35.51 (for B_j on N_j and $N' = N_{j-1}$) every such g is $h + r$ with $h \in I_{B_j} \cap (B_j)^{N_{j-1}}$ and $r \in I_{B_j}^2$; projecting with π_ψ, the kernel is the image of $\mathrm{co}_\psi((B_j)^{N_{j-1}}) \cong \mathrm{co}_\psi(S_j)$ (Step 1; the isomorphism is $\mathbb{F}$-equivariant and preserves augmentation ideals). So $\mathrm{co}_\psi(S_j) \to \mathrm{co}_\psi(B_j) \to \mathrm{co}_\psi(B_{j-1}) \to 0$ is exact; the kernel U of the first map is finitely presented by coherence, and additivity gives $\mathrm{len}\,\mathrm{co}_\psi(B_j) = \mathrm{len}\,\mathrm{co}_\psi(B_{j-1}) + \mathrm{len}\,\mathrm{co}_\psi(S_j) - \mathrm{len}\,U$.

Step 4 (part (4)). Put $e_j = \mathrm{len}\,\mathrm{co}_\psi(B_j) - \sum_{i \le j} \mathrm{len}\,\mathrm{co}_\psi(S_i)$. By (3), $e_j \le e_{j-1}$, and $e_0 = 0$ ($I_{B_0} = 0$). The hypothesis is $e_m = 0$, so $e_j = 0$ for all j. □

Lemma 35.51. *Let p, C, $\mathcal{O}_C$, $\mathbb{F}$ and N be as in Definition 35.18, B a Hopf order on N and $N' \subseteq N$ a subgroup. Then every $g \in B$ vanishing on N' can be written $g = h + r$ with $h \in I_B$, $h(x+k) = h(x)$ for all $x \in N$, $k \in N'$, and $r \in I_B^2$.*

Proof. Being finite over $\mathcal{O}_C$, B consists of functions with values in $\mathcal{O}_C$. A basis of B is a C-basis of $\mathrm{Map}(N, C)$, so $B \otimes B \to \mathrm{Map}(N \times N, C)$ is injective and $G = \mathrm{Spec}\,B$ is a finite locally free commutative group scheme over $\mathcal{O}_C$ with $G(C) = N$, the comultiplication being $g \mapsto ((x,y) \mapsto g(x+y))$. Let $J = \ker(B \to B|_{N'})$ and $H = \mathrm{Spec}(B/J)$. $B/J \cong B|_{N'}$ is finitely generated and torsion free, hence free, so H is finite locally free; $H \times H$ is flat with generic fibre $N' \times N'$, hence equal to the closure of $N' \times N'$ in $G \times G$, which the group law maps into H: H is a closed subgroup scheme. By SGA 3, V, 4.1 the quotient $\varpi\colon G \to G/H$ exists, is an fppf H-torsor, and $\mathcal{O}(G/H)$ consists of the $f \in B$ whose two pull-backs to $G \times H$ agree; as $\mathcal{O}(G \times H) = B \otimes B/J$ embeds in $\mathrm{Map}(N \times N', C)$, $\mathcal{O}(G/H) = \{f \in B : \ f(x+k) = f(x)\ \forall x \in N,\ k \in N'\}$. The fibre of ϖ over the unit section is H (from $G \times_{G/H} G \cong G \times H$), so $J = I'B$ with $I' = \{f \in \mathcal{O}(G/H) : \ f(0) = 0\}$. Write $g = \sum_k f_k b_k$ with $f_k \in I'$, $b_k \in B$; then $h = \sum_k b_k(0) f_k \in I' \subseteq I_B$ is N'-invariant and $r = g - h = \sum_k f_k\,(b_k - b_k(0)) \in I_B^2$. □

Lemma 35.52. *Let S be an $\mathbb{F}$-stable Hopf order on the one-dimensional $\mathbb{F}$-vector space $\mathbb{F}$ and χ a fundamental character; put $\chi_s = \chi^{p^s}$. Then:*

1. *$S \subseteq \mathrm{Map}(\mathbb{F}, \mathcal{O}_C)$, and for every $m \in \{1, \dots, q-1\}$, $\mathrm{Xr}_{\chi^m}(S) = c(m)\mathcal{O}_C$ for some $c(m) \in \mathcal{O}_C \smallsetminus \{0\}$, and $S = \mathcal{O}_C \cdot 1 \oplus \bigoplus_{m=1}^{q-1} c(m)\mathcal{O}_C\,\chi^m$;*

2. *with* $c_s = c(p^{s \bmod f})$*: if* $m = \sum_{t<f} d_t p^t$ *with digits* $0 \le d_t \le p-1$*, then* $c(m)\mathcal{O}_C = \prod_t c_t^{d_t}\mathcal{O}_C$*; hence the monomials* $X^d = \prod_{t<f} X_t^{d_t}$ *in* $X_t = c_t\chi_t$ *(*$0 \le d_t \le p-1$*) form an* $\mathcal{O}_C$*-basis of* S*;*

3. $\delta_s := c_s^p/c_{s+1}$ *lies in* $\mathcal{O}_C$*, and* $\mathcal{O}_C[Y_0,\dots,Y_{f-1}]/(Y_t^p - \delta_t Y_{t+1} : t < f) \to S$*,* $Y_t \mapsto X_t$ *(indices modulo* f*), is an isomorphism;*

4. $I_S/I_S^2 \cong \bigoplus_{s<f} \mathcal{O}_C/\delta_s\mathcal{O}_C$*, the* s*-th summand spanned by the class of* X_{s+1}*; so* $\mathrm{co}_{\chi_{s+1}}(S)$ *has normalised length* $v(\delta_s)$*, and* $\mathrm{co}_\psi(S) = 0$ *for every character* $\psi \notin \{\chi_0,\dots,\chi_{f-1}\}$*;*

5. $\mathrm{colen}(S) = \frac{q(p-1)}{2}\sum_{s<f} v(c_s)$*, and* $\sum_{s<f} v(\delta_s) = (p-1)\sum_{s<f} v(c_s)$*.*

Proof. (1) S is a finite $\mathcal{O}_C$-algebra, so every $g \in S$ is integral over $\mathcal{O}_C$, and so is each value $g(x)$ (evaluation is a ring homomorphism); $\mathcal{O}_C$ is integrally closed, so $g(x) \in \mathcal{O}_C$. By Lemma 35.53(1) the functions $1, \chi, \dots, \chi^{q-1}$ form a basis of $\mathrm{Map}(\mathbb{F}, C)$; for $1 \le m \le q-2$ the χ^m-eigenspace of $\mathbb{F}^\times$ acting by $g \mapsto g(a\,\cdot)$ is $C\chi^m$, and the eigenspace of the trivial character is $C1 \oplus C\chi^{q-1}$. As $S = \bigoplus_\psi \pi_\psi S$, $\pi_{\chi^m} S = S \cap C\chi^m = \mathrm{Xr}_{\chi^m}(S)\chi^m$ for $m \le q-2$; for the trivial part, $g = \alpha 1 + \beta\chi^{q-1} \in S$ gives $\alpha = g(0) \in \mathcal{O}_C$ and $\beta\chi^{q-1} = g - \alpha 1 \in S$ (as $1 \in S$), so $\pi_{\mathrm{triv}} S = \mathcal{O}_C 1 \oplus \mathrm{Xr}_{\chi^{q-1}}(S)\chi^{q-1}$. Each $\mathrm{Xr}_{\chi^m}(S)$ is isomorphic to a direct summand of the finitely generated module S, nonzero because S spans $\mathrm{Map}(\mathbb{F}, C)$; it is a finitely generated $\mathcal{O}_C$-submodule of C, hence $c(m)\mathcal{O}_C$ with $c(m) \ne 0$, and $c(m) \in \mathcal{O}_C$ by the first sentence.

(2) Closure under products: $c(j)c(k)\chi^{j+k} \in S$, so $c(j)c(k) \in c(j+k)\mathcal{O}_C$ whenever $j + k \le q-1$. Conversely let m have digit sum at least 2; pick t with $d_t \ge 1$ and put $j = p^t$, $k = m - p^t$, so $1 \le j, k \le q-2$ and $j + k = m$ without carry. Let $\Delta g(x,y) = g(x+y)$; by definition of a Hopf order $\Delta(c(m)\chi^m)$ lies in $S \otimes S$, the $\mathcal{O}_C$-span of the functions $g_1(x)g_2(y)$ in $\mathrm{Map}(\mathbb{F}^2, C)$. The bi-projector $P = \pi_{\chi^j} \otimes \pi_{\chi^k}$ maps $S \otimes S$ onto $c(j)c(k)\mathcal{O}_C\,\chi^j \otimes \chi^k$, and $P\Delta\chi^m = \kappa\,\chi^j \otimes \chi^k$ with

$$\kappa = P\Delta\chi^m(1,1) = \frac{1}{(q-1)^2}\sum_{a,b\in\mathbb{F}^\times} \chi^{-j}(a)\chi^{-k}(b)\chi^m(a+b) = \frac{1}{q-1}\sum_{z\in\mathbb{F}^\times} \chi^{-k}(z)\chi^m(1+z)$$

(substitute $b = az$ and use $m = j + k$). Reduce modulo $\mathfrak{m}_C$ and identify $\mathbb{F}$ with $\bar\chi(\mathbb{F}) \subseteq k_C$ (Lemma 35.53(1)): $\bar\kappa = -\sum_{y\in\mathbb{F}}(1+y)^m y^{q-1-k} = -\sum_{i=0}^m \binom{m}{i}\sum_{y\in\mathbb{F}} y^{i+q-1-k}$ (the term $y = 0$ vanishes as $q-1-k \ge 1$). Since $\sum_{y\in\mathbb{F}} y^e = -1$ if $e \ge 1$ and $(q-1) \mid e$, and 0 otherwise, and the only multiple of $q-1$ in $[q-1-k,\, q-1-k+m]$ is $q-1$ (as $2(q-1) - (q-1-k) > m$ because $j \le q-2$), we get $\bar\kappa = \binom{m}{k} \bmod p$, nonzero by Lucas' theorem since $k + j = m$ has no carry. So $\kappa \in \mathcal{O}_C^\times$, and $c(m)\kappa \in c(j)c(k)\mathcal{O}_C$ gives $c(m)\mathcal{O}_C = c(j)c(k)\mathcal{O}_C = c_t\,c(k)\mathcal{O}_C$. Induction on the digit sum gives $c(m)\mathcal{O}_C = \prod_t c_t^{d_t}\mathcal{O}_C$. As $d \mapsto \sum_t d_t p^t$ is a bijection from $\{0,\dots,p-1\}^f$ onto $\{0,\dots,q-1\}$ and $X^d = \prod_t c_t^{d_t}\,\chi^{\sum d_t p^t}$ (the empty product being the constant 1), (1) shows that the X^d form a basis of S.

(3) $X_s^p = c_s^p\chi_{s+1} \in S$, so $c_s^p \in c_{s+1}\mathcal{O}_C$ and $X_s^p = \delta_s X_{s+1}$. The map of the statement is therefore defined and surjective by (2). Using the relations, every monomial with some exponent $\ge p$ is δ_t times a monomial of smaller total degree, so the source is generated as an $\mathcal{O}_C$-module by the q monomials with exponents $< p$; a surjection from a module generated by q elements onto the free module S of rank q composed with $\mathcal{O}_C^q \to$ source is a surjective endomorphism of $\mathcal{O}_C^q$, hence bijective, so the map is an isomorphism.

(4) The X_t vanish at 0, so I_S is the image of $J = (Y_0,\dots,Y_{f-1})$ and $I_S/I_S^2 = J/(J^2 + R)$, R the ideal of relations, $R \subseteq J$. Modulo J^2, $h\cdot(Y_t^p - \delta_t Y_{t+1}) \equiv -h(0)\,\delta_t Y_{t+1}$ because $p \ge 2$. Hence $I_S/I_S^2 = \bigoplus_t \mathcal{O}_C Y_{t+1}/\delta_t\mathcal{O}_C Y_{t+1}$. The class of X_{t+1} is χ_{t+1}-eigen, and $\chi_1,\dots,\chi_f$ are

pairwise distinct (Lemma 35.53(2)); since $I_S/I_S^2 = \bigoplus_\psi \mathrm{co}_\psi(S)$ (the projectors preserve I_S and I_S^2), $\mathrm{co}_{\chi_{s+1}}(S) \cong \mathcal{O}_C/\delta_s$ and the other $\mathrm{co}_\psi(S)$ vanish.

(5) The basis $1, \chi, \dots, \chi^{q-1}$ of $\mathrm{Map}(\mathbb{F}, \mathcal{O}_C)$ differs from the basis of indicator functions by a matrix in $\mathrm{GL}_q(\mathcal{O}_C)$ (Lemma 35.53(1)); in it the basis X^d of S is diagonal with entries $\prod_t c_t^{d_t}$, whose product is $\prod_t c_t^N$ with $N = \sum_d d_t = (q/p) \cdot p(p-1)/2$. So $\mathrm{colen}(S) = \frac{q(p-1)}{2} \sum_t v(c_t)$. Finally $\sum_{s<f} v(\delta_s) = p \sum_s v(c_s) - \sum_s v(c_{s+1}) = (p-1) \sum_s v(c_s)$ by periodicity. □

Lemma 35.53. *Let p, C, $\mathcal{O}_C$, v and $\mathbb{F}$ be as in Definition 35.18, $q = |\mathbb{F}| = p^f$, k_C the residue field of $\mathcal{O}_C$, and $\chi\colon \mathbb{F} \to \mathcal{O}_C$ a fundamental character. Put $\chi_s = \chi^{p^s}$ for $s \geq 0$ (with $\chi_s(0) = 0$). Then:*

1. *the reduction $\bar\chi\colon \mathbb{F} \to k_C$ of χ is an injective ring homomorphism; $\chi(a) - \chi(b) \in \mathcal{O}_C^\times$ for $a \neq b$; $\chi|_{\mathbb{F}^\times}$ has order $q-1$, so every character is χ^m for a unique $m \in \{1, \dots, q-1\}$, and $\{1, \chi, \chi^2, \dots, \chi^{q-1}\}$ is an $\mathcal{O}_C$-basis of $\mathrm{Map}(\mathbb{F}, \mathcal{O}_C)$;*
2. *every χ_s is a fundamental character, $\chi_{s+f} = \chi_s$, and $\chi_0, \dots, \chi_{f-1}$ are pairwise distinct on $\mathbb{F}^\times$; in particular $\sum_{a \in \mathbb{F}^\times} \chi_s(a)^{-1} \chi_{s'}(a) = 0$ for $s \not\equiv s' \pmod f$;*
3. *every additive map $\varphi\colon \mathbb{F} \to \mathcal{O}_C/p\mathcal{O}_C$ is $\varphi = \sum_{s=0}^{f-1} r_s\, (\chi_s \bmod p)$ for unique $r_0, \dots, r_{f-1} \in \mathcal{O}_C/p\mathcal{O}_C$.*

Proof. (1) Since $p \in \mathfrak{m}_C$, $\bar\chi$ is additive; it is multiplicative on $\mathbb{F}^\times$, $\bar\chi(0) = 0$ and $\bar\chi(1) = 1$ ($\chi|_{\mathbb{F}^\times}$ is a homomorphism). So $\bar\chi$ is a ring homomorphism from a field, hence injective. For $a \neq b$, $\overline{\chi(a) - \chi(b)} = \bar\chi(a-b) \neq 0$, so $\chi(a) - \chi(b)$ is a unit. Injectivity of $\bar\chi$ on $\mathbb{F}^\times$ makes $\chi|_{\mathbb{F}^\times}$ injective, of order $q-1 = |\mathbb{F}^\times|$; the character group of the cyclic group $\mathbb{F}^\times$ (values in $\mu_{q-1}(C)$) is cyclic of order $q-1$, so χ generates it, and the convention $\psi(0) = 0$ for every character gives $\psi = \chi^m$ with a unique $m \in \{1, \dots, q-1\}$ (χ^{q-1} is the indicator function of $\mathbb{F}^\times$). For $a, x \in \mathbb{F}^\times$, $\sum_{m=1}^{q-1} \chi(a)^{-m} \chi(x)^m = (q-1)[x = a]$, and all χ^m vanish at 0; since $q - 1 \in \mathcal{O}_C^\times$, the indicator $1_{\{a\}}$ ($a \neq 0$) lies in the $\mathcal{O}_C$-span of $\chi, \dots, \chi^{q-1}$, and $1_{\{0\}} = 1 - \sum_{a \neq 0} 1_{\{a\}}$. Thus these q functions span the free module $\mathrm{Map}(\mathbb{F}, \mathcal{O}_C)$ of rank q, hence form a basis.

(2) χ_s is a character. Write $\chi(a+b) = \chi(a) + \chi(b) + pe$ with $e \in \mathcal{O}_C$. For $u, e \in \mathcal{O}_C$, $(u+pe)^p \equiv u^p \pmod{p\mathcal{O}_C}$ and $(u+w)^p \equiv u^p + w^p \pmod{p\mathcal{O}_C}$ (the middle binomial coefficients are divisible by p); by induction on s, $\chi_s(a+b) \equiv \chi_s(a) + \chi_s(b) \pmod{p\mathcal{O}_C}$, so χ_s is fundamental. $\chi_{s+f} = \chi_s$ because $a^q = a$ in $\mathbb{F}$. The reduction of χ_s is $\mathrm{Frob}^s \circ \bar\chi$; for $0 \leq s < s' < f$ these two embeddings $\mathbb{F} \to k_C$ differ (their images of a generator α of $\mathbb{F}$ over $\mathbb{F}_p$ are the distinct conjugates $\bar\chi(\alpha^{p^s}) \neq \bar\chi(\alpha^{p^{s'}})$), so $\chi_s \neq \chi_{s'}$ on $\mathbb{F}^\times$, and the orthogonality relation is the vanishing of the sum of the nontrivial character $\chi_s^{-1}\chi_{s'}$ over the group $\mathbb{F}^\times$.

(3) By (2) each $\chi_s \bmod p$ is additive, hence so is $\sum r_s \chi_s$. An additive map $\mathbb{F} \to \mathcal{O}_C/p$ is $\mathbb{F}_p$-linear, so is determined by its values at the $\mathbb{F}_p$-basis $1, \alpha, \dots, \alpha^{f-1}$, which can be arbitrary. The equations $\sum_s r_s \chi_s(\alpha^i) = \sum_s r_s \chi_s(\alpha)^i = \varphi(\alpha^i)$ ($0 \leq i < f$) have the Vandermonde matrix $(\chi_s(\alpha)^i)_{i,s}$, whose determinant $\prod_{s<s'} (\chi(\alpha^{p^{s'}}) - \chi(\alpha^{p^s}))$ is a unit by (1), since α^{p^s}, $0 \leq s < f$, are pairwise distinct. So the system has a unique solution modulo p. □

Proposition 35.54. *Let C, $\mathcal{O}_C$ and v be as in Definition 35.18 and P a principally polarised abelian scheme over $\mathcal{O}_C$ of relative dimension g. Then $Q_{M_P} = \mathrm{Lin}(N_P)/(\mathrm{AF}(M_P) + p\,\mathrm{Map}(N_P, \mathcal{O}_C))$ has normalised length at most $g/(p-1)$.*

Proof. If $g = 0$, then $N_P = 0$, $\mathrm{Lin}(N_P) = p\,\mathrm{Map}(N_P, \mathcal{O}_C)$ (an almost-additive f has $f(0) \in p\mathcal{O}_C$) and $Q_{M_P} = 0$. Let $g \geq 1$ and let $x_1, \dots, x_{2g}$, H, B, J and c be as given by Proposition 35.55,

and let $L \in M_{2g}(\mathcal{O}_C)$ be the matrix whose rows are the g rows of H followed by the g rows of B.

Step 1: $v(\det L) = g/(p-1)$. With $\Omega = \begin{pmatrix} 0 & I_g \\ -I_g & 0 \end{pmatrix}$ ($\det\Omega = 1$), $L^{\mathsf{T}}\Omega L = H^{\mathsf{T}}B - B^{\mathsf{T}}H = -c\,J$. Taking determinants, $(\det L)^2 = c^{2g}\det J$, and $\det J$ is a unit, so $v(\det L) = g\,v(c) = g/(p-1)$.

Step 2: almost-additive elements. For a row r of L let $f_r \in M_P$ be as in Proposition 35.55 and $\ell_r = \sum_j r_j x_j$. Since $x_j(y+y') - x_j(y) - x_j(y') \in p\mathbb{Z}$, ℓ_r is almost additive, hence so is $f_r \equiv \ell_r$ modulo $p\,\mathcal{O}_C$: $f_r \in \mathrm{AF}(M_P)$.

Step 3: the bound. Let $b_1, \dots, b_{2g}$ be the basis of N_P dual to the x_j. An almost-additive f satisfies $f(y) \equiv \sum_j x_j(y) f(b_j)$ modulo $p\,\mathcal{O}_C$ (induction on $\sum_j x_j(y)$, using $f(0) \in p\mathcal{O}_C$), and $\sum_j a_j x_j$ is almost additive for every $a \in \mathcal{O}_C^{2g}$; so $f \mapsto (f(b_j))_j$ induces an isomorphism $\mathrm{Lin}(N_P)/p\,\mathrm{Map}(N_P, \mathcal{O}_C) \cong (\mathcal{O}_C/p)^{2g}$, under which $Q_{M_P} \cong \mathcal{O}_C^{2g}/U$, U the set of a with $\sum_j a_j x_j \in \mathrm{AF}(M_P) + p\,\mathrm{Map}(N_P, \mathcal{O}_C)$. By Step 2, U contains every row of L ($f_r(b_j) \equiv r_j$). Hence Q_{M_P} is a quotient of $Q_0 = \mathcal{O}_C^{2g}/(\text{span of the rows of } L) \cong \bigoplus_i \mathcal{O}_C/d_i$ with $\sum_i v(d_i) = v(\det L) = g/(p-1)$ (Step 1). By Lemma 35.47, $Q_{M_P} \cong \bigoplus_k \mathcal{O}_C/e_k$ has a normalised length; as the span of the rows of L lies in U, $(\prod_i d_i) = \mathrm{Fitt}_0(Q_0) \subseteq \mathrm{Fitt}_0(Q_{M_P}) = (\prod_k e_k)$, so $\mathrm{len}_C(Q_{M_P}) = \sum_k v(e_k) \le \sum_i v(d_i) = g/(p-1)$. □

Proposition 35.55. *Let C, $\mathcal{O}_C$ and v be as in Definition 35.18 and P a principally polarised abelian scheme over $\mathcal{O}_C$ of relative dimension $g \ge 1$. Then there are an $\mathbb{F}_p$-basis of N_P, with coordinate functions $x_1, \dots, x_{2g} \colon N_P \to \{0, 1, \dots, p-1\} \subseteq \mathbb{Z}$, matrices $H, B \in M_{g\times 2g}(\mathcal{O}_C)$, an alternating matrix $J \in M_{2g}(\mathbb{Z}_p)$ with $\det J \in \mathbb{Z}_p^\times$ and $c \in \mathcal{O}_C$ with $v(c) = 1/(p-1)$, such that*

$$B^{\mathsf{T}}H - H^{\mathsf{T}}B = c\,J,$$

and for every row $(r_1, \dots, r_{2g})$ of H or of B there is $f \in M_P$ with $f(y) - \sum_j r_j x_j(y) \in p\,\mathcal{O}_C$ for all $y \in N_P$.

Proof. We use the following classical facts: for an abelian scheme P over $\mathcal{O}_C$ the Cartier dual of $P[p^n]$ is $P^\vee[p^n]$, so the Cartier dual of the p-divisible group $\mathcal{G} = P[p^\infty]$ is $\mathcal{G}^D = P^\vee[p^\infty]$ and $\omega_{\mathcal{G}^D} = \omega_{P^\vee}$ is free of rank g; the Weil pairing of the principal polarisation $\varphi \colon P \to P^\vee$ is perfect and alternating (Mumford, Abelian varieties, §§20, 23; Oda for abelian schemes); for a commutative finite flat group scheme $\Gamma = \mathrm{Spec}\,R_\Gamma$ over $\mathcal{O}_C$ with Cartier dual $\Gamma^D = \mathrm{Spec}\,R_\Gamma^\vee$, a point $y \in \Gamma(\mathcal{O}_C)$ corresponds to a group-like element $\chi_y \in R_\Gamma^\vee$ (the character $\Gamma^D \to \mathbb{G}_m$ attached to y), and $f(y) = \chi_y(f)$ for $f \in R_\Gamma$ (Cartier duality); over the valuation ring $\mathcal{O}_C$ a finitely generated torsion-free module is free, so a submodule of a free module of finite rank with torsion-free quotient is a direct summand.

Step 0: set-up. Put $\mathcal{G} = P[p^\infty]$ and $T = T_p(\mathcal{G})$, a free $\mathbb{Z}_p$-module of rank $2g$. Since C is algebraically closed of characteristic 0 and $P[p^n]$ is finite over $\mathcal{O}_C$, $P[p^n](\mathcal{O}_C) = P[p^n](C) \cong (\mathbb{Z}/p^n)^{2g}$ and multiplication by p maps $P[p^{n+1}](C)$ onto $P[p^n](C)$; hence $T/pT = N_P$. Fix a compatible system of primitive p^n-th roots of unity in C, which identifies $\mathbb{Z}_p(1)$ with $\mathbb{Z}_p$; let ζ be its primitive p-th root of unity, and let $\langle\ ,\ \rangle \colon T \times T \to \mathbb{Z}_p$ be the Weil pairing of φ (the Cartier pairing of t with $\varphi(t') \in T_p(\mathcal{G}^D)$), extended $\mathcal{O}_C$-bilinearly. Choose a $\mathbb{Z}_p$-basis $b_1, \dots, b_{2g}$ of T and let $J = (\langle b_i, b_j\rangle) \in M_{2g}(\mathbb{Z}_p)$: it is alternating, and $\det J \in \mathbb{Z}_p^\times$ since the pairing is perfect. The images of the b_j form an $\mathbb{F}_p$-basis of N_P; let $x_j \colon N_P \to \{0, \dots, p-1\}$ be its coordinate functions, so that $\tilde{y} = \sum_j x_j(y) b_j \in T$ lifts y. Fix $c \in \mathcal{O}_C$ with $v(c) = \frac{1}{p-1}$ (C is algebraically closed). Let $u_1, \dots, u_g$ be an $\mathcal{O}_C$-basis of $\omega = \omega_{\mathcal{G}^D} \otimes \mathcal{O}_C$ and $\lambda_1, \dots, \lambda_g$ the coordinate forms.

Step 1: the kernel of the Hodge–Tate map is Lagrangian. Put $T^\circ = T \otimes_{\mathbb{Z}_p} \mathcal{O}_C$ and $\alpha = \alpha_{\mathcal{G}} \otimes 1 \colon T^\circ \to \omega$. By Lemma 35.57, $\Lambda = \ker \alpha$ is a direct summand of T°, free of rank g, with $\langle \Lambda, \Lambda \rangle = 0$; and by Theorem B.54 (with $K = C$, applied to $\mathcal{G}$), (a) $c\,\omega \subseteq \alpha(T^\circ)$.

Step 2: the matrices. Choose an $\mathcal{O}_C$-basis $v_1, \dots, v_g$ of Λ and $v'_1, \dots, v'_g$ of a complement Λ', and let $S \in \mathrm{GL}_{2g}(\mathcal{O}_C)$ express (v, v') in the basis (b_j). The Gram matrix of the pairing in the basis (v, v') is $J' = S^{\mathsf{T}} J S = \begin{pmatrix} 0 & D \\ -D^{\mathsf{T}} & Q \end{pmatrix}$ with Q alternating (Step 1 and the pairing alternating). The matrix of α in the bases (v, v') and (u_k) is $H' = (0 \mid A)$ with $A \in M_g(\mathcal{O}_C)$. Since $\alpha(T^\circ) = \alpha(\Lambda') = A\,\mathcal{O}_C^g$ contains $c\,\mathcal{O}_C^g$ by (a), A is invertible over C and $cA^{-1} \in M_g(\mathcal{O}_C)$. Write $Q = U - U^{\mathsf{T}}$ with U strictly upper triangular, and put

$$B' = (c\,A^{-\mathsf{T}} D^{\mathsf{T}} \mid c\,A^{-\mathsf{T}} U^{\mathsf{T}}) \in M_{g \times 2g}(\mathcal{O}_C).$$

So $B'^{\mathsf{T}} H' - H'^{\mathsf{T}} B' = c\,J'$. Put $H = H'S^{-1}$ and $B = B'S^{-1}$ in $M_{g\times 2g}(\mathcal{O}_C)$; then $B^{\mathsf{T}} H - H^{\mathsf{T}} B = S^{-\mathsf{T}}(cJ')S^{-1} = c\,J$. Moreover H is the matrix of α in the bases (b_j), (u_k), so $H_{kj} = \lambda_k(\alpha(b_j))$; and every row of B is $c\,(n_1, \dots, n_{2g})$ with $n_j \in \mathcal{O}_C$, since $c^{-1}B'$ and S^{-1} are integral.

Step 3: the rows of B lie in M_P. Since $v(c) = v(\zeta - 1) = \frac{1}{p-1}$, $c\,\mathcal{O}_C = (\zeta - 1)\mathcal{O}_C$, and Lemma 35.56 (with $K = C$, $\mathcal{O} = \mathcal{O}_C$ and $w = c$) gives $d_0, \dots, d_{p-1} \in \mathcal{O}_C$ with

$$\sum_{i=0}^{p-1} d_i\,\zeta^{ir} = c\,r \qquad (0 \le r \le p-1).$$

Since the Weil pairing e_p of φ on N_P is perfect, there is for each j a point $z_j \in N_P$ with $e_p(y, z_j) = \zeta^{x_j(y)}$ for all $y \in N_P$; and $y \mapsto e_p(y, z_j)$ is a homomorphism of group schemes $P[p] \to \mu_p$ over $\mathcal{O}_C$ (the Weil pairing restricted to the section z_j), so $\psi_j(y) = \zeta^{x_j(y)}$ is an element of M_P, as are its powers. Hence $c\,x_j = \sum_i d_i \psi_j^i \in M_P$, and for every row $c\,(n_j)$ of B the function $f = \sum_j c n_j x_j$ lies in M_P and has $f(y) - \sum_j c n_j x_j(y) = 0$.

Step 4: the rows of H are congruent to elements of M_P. Let $\Gamma = P[p] = \operatorname{Spec} R_\Gamma$, so $\Gamma^D = \mathcal{G}^D[p]$ and $\omega_{\Gamma^D} = \omega/p\omega$ (the cokernel of p on $\omega_{\mathcal{G}^D}$). For $x \in T$ with image $y \in N_P$, $\alpha_{\mathcal{G}}(x) \bmod p = \alpha_\Gamma(y)$, the class of $\chi_y - 1$ in $I/I^2 = \omega_{\Gamma^D}$, I the augmentation ideal of $R_\Gamma^\vee = \mathcal{O}(\Gamma^D)$. The composite $\phi_k \colon R_\Gamma^\vee \to I \to I/I^2 = \omega/p\omega \xrightarrow{\lambda_k} \mathcal{O}_C/p$ (the first map $a \mapsto a - \epsilon(a)$, ϵ the counit) is $\mathcal{O}_C$-linear; as $R_\Gamma^\vee$ is free of finite rank, it lifts to an $\mathcal{O}_C$-linear $\Phi_k \colon R_\Gamma^\vee \to \mathcal{O}_C$, an element of $R_\Gamma^{\vee\vee} = R_\Gamma$. By Cartier duality, for $y \in N_P$, $\Phi_k(y) = \Phi_k(\chi_y) \equiv \phi_k(\chi_y) = \lambda_k(\alpha_\Gamma(y))$ modulo p (note $\epsilon(\chi_y) = 1$), and $\lambda_k(\alpha_\Gamma(y)) \equiv \lambda_k(\alpha(\tilde{y})) = \sum_j H_{kj} x_j(y)$ modulo p. So the element f of M_P given by Φ_k satisfies $f(y) - \sum_j H_{kj} x_j(y) \in p\,\mathcal{O}_C$ for all $y \in N_P$.

Steps 0–4 give the basis, the x_j, H, B, J and c with all the stated properties. □

Lemma 35.56. *Let p be an odd prime, K a field of characteristic 0 with a valuation ring $\mathcal{O}$, $\zeta \in K$ a primitive p-th root of unity, and $w \in \mathcal{O}$ with $w\mathcal{O} = (\zeta - 1)\mathcal{O}$. For $t \in \mathbb{Z}/p$ let $\tilde{t} \in \{0, \dots, p-1\}$ be its representative. Then for every $t \in \mathbb{Z}/p$*

$$w\,\tilde{t} = \sum_{j=0}^{p-1} c_j\,\zeta^{jt}, \qquad c_0 = w\,\frac{p-1}{2}, \quad c_j = \frac{w}{\zeta^{-j} - 1}\ (1 \le j \le p-1),$$

and all c_j lie in $\mathcal{O}$.

Proof. **The Fourier coefficients of $t \mapsto \tilde{t}$.** For $x \in K$ with $x^p = 1$, $x \ne 1$, put $S(x) = \sum_{u=0}^{p-1} u x^u$. Then

$$xS(x) - S(x) = \sum_{u=1}^{p} (u-1)x^u - \sum_{u=1}^{p-1} u x^u = (p-1)x^p - \sum_{u=1}^{p-1} x^u = (p-1) + 1 = p,$$

using $x^p = 1$ and $\sum_{u=0}^{p-1} x^u = 0$; so $S(x) = p/(x-1)$. Put $a_j = \frac{1}{p}\sum_{u=0}^{p-1} u\,\zeta^{-ju}$; then $a_0 = \frac{p-1}{2}$ and $a_j = 1/(\zeta^{-j}-1)$ for $1 \le j \le p-1$. By orthogonality of characters ($\sum_{j=0}^{p-1}\zeta^{j(t-u)} = p$ if $t = u$ in $\mathbb{Z}/p$ and 0 otherwise),

$$\sum_j a_j \zeta^{jt} = \frac{1}{p}\sum_{u=0}^{p-1} u \sum_j \zeta^{j(t-u)} = \tilde{t}.$$

Multiplying by w gives the identity with $c_j = w a_j$. **Integrality.** $c_0 \in \mathcal{O}$ since $(p-1)/2 \in \mathbb{Z}$. For $1 \le j \le p-1$, $(\zeta^{-j}-1)/(\zeta-1) = -\zeta^{-j}(1+\zeta+\cdots+\zeta^{j-1})$ lies in $\mathbb{Z}[\zeta]$, and so does its inverse (exchange the roles of ζ and ζ^{-j}, both primitive), so $(\zeta^{-j}-1)\mathcal{O} = (\zeta-1)\mathcal{O} = w\mathcal{O}$ and $c_j = w/(\zeta^{-j}-1) \in \mathcal{O}^\times$. □

Lemma 35.57. *Let C, $\mathcal{O}_C$, v be as in Definition 35.18 and P a principally polarised abelian scheme over $\mathcal{O}_C$ of relative dimension $g \ge 1$, with p-divisible group $\mathcal{G} = P[p^\infty]$, Tate module $T = T_p(\mathcal{G})$ (free of rank $2g$ over $\mathbb{Z}_p$), and $\langle\ ,\ \rangle\colon T \times T \to \mathbb{Z}_p$ the Weil pairing of the principal polarisation (after fixing a compatible system of p-power roots of unity in C), extended $\mathcal{O}_C$-bilinearly to $T^\circ = T \otimes_{\mathbb{Z}_p} \mathcal{O}_C$. Let $\omega = \omega_{\mathcal{G}^D} \otimes \mathcal{O}_C$ and $\alpha = \alpha_{\mathcal{G}} \otimes 1\colon T^\circ \to \omega$. Then $\Lambda = \ker\alpha$ is a direct summand of T°, free of rank g, with $\langle\Lambda,\Lambda\rangle = 0$, and $\Lambda \otimes C = \ker(\alpha \otimes C)$ is its own orthogonal in $T \otimes C$. Equivalently, if $J \in M_{2g}(\mathbb{Z}_p)$ is the Gram matrix of $\langle\ ,\ \rangle$ in a $\mathbb{Z}_p$-basis of T and $H \in M_{g\times 2g}(\mathcal{O}_C)$ the matrix of α in that basis and an $\mathcal{O}_C$-basis of ω, then $H\,J^{-1}H^{\mathsf{T}} = 0$ and $\operatorname{rk} H = g$.*

Proof. Fix $c \in \mathcal{O}_C$ with $v(c) = \frac{1}{p-1}$. Apply Theorem B.54 with $K = C$ to $\mathcal{G}$ and to $\mathcal{G}^D$: (a) $c\,\omega \subseteq \alpha(T^\circ)$; (b) the map $\kappa = {}^t(\alpha_{\mathcal{G}^D} \otimes 1)(1)\colon \mathrm{Lie}(\mathcal{G}) \otimes \mathcal{O}_C(1) \to T^\circ$ is injective and $\alpha \circ \kappa = 0$; (c) $\alpha_{\mathcal{G}^D} \otimes C$ is onto, of rank g. By definition of the transpose, $\kappa(\nu)$ is the element t whose Cartier pairing with every $x' \in T_p(\mathcal{G}^D)$ is $\nu(\alpha_{\mathcal{G}^D}(x'))$; so $\mathrm{im}(\kappa) \otimes C$ lies in the annihilator (for the Cartier pairing) of $\ker(\alpha_{\mathcal{G}^D} \otimes C)$, and both have dimension g by (b), (c), so they are equal. The polarisation maps $\ker(\alpha \otimes C)$ onto $\ker(\alpha_{\mathcal{G}^D} \otimes C)$ (functoriality of the Hodge–Tate map: $\alpha_{\mathcal{G}^D}(\varphi x) = (\varphi^D)^* \alpha_{\mathcal{G}}(x)$, with φ^D an isomorphism). Hence, with $L = \ker(\alpha \otimes C)$, of dimension $2g - g = g$ by (a), $\mathrm{im}(\kappa) \otimes C = \{t :\ \langle t, s\rangle = 0\ \forall s \in L\} = L^\perp$ and $\mathrm{im}(\kappa) \otimes C \subseteq L$ ($\alpha \circ \kappa = 0$); comparing dimensions, $L = L^\perp$. Put $\Lambda = L \cap T^\circ = \ker\alpha$. As $T^\circ/\Lambda \cong \alpha(T^\circ) \subseteq \omega$ is torsion free, Λ is a direct summand of T°, free of rank g, $\Lambda \otimes C = L$, and $\langle\Lambda,\Lambda\rangle = 0$.

Matrix form. Write $\langle t, s\rangle = t^{\mathsf{T}} J s$ in the chosen basis. The rows $h_1, \dots, h_g$ of H are the coordinate forms of $\alpha \otimes C$; they span the g-dimensional space of linear forms vanishing on L (rank g by (a)). Every form vanishing on $L = L^\perp$ is $t \mapsto \langle t, s\rangle$ for some $s \in L$ (perfectness), i.e. $h_k = -s_k^{\mathsf{T}} J$ with $s_k \in L$ ($J^{\mathsf{T}} = -J$). Then $h_k J^{-1} h_l^{\mathsf{T}} = s_k^{\mathsf{T}} J\, J^{-1} J^{\mathsf{T}} s_l = -s_k^{\mathsf{T}} J s_l = -\langle s_k, s_l\rangle = 0$, so $H J^{-1} H^{\mathsf{T}} = 0$. Conversely, $H J^{-1} H^{\mathsf{T}} = 0$ with $\operatorname{rk} H = g$ says that $\{J^{-1} h_k^{\mathsf{T}}\}$, which span $\{s :\ \langle\cdot, s\rangle$ vanishes on $L\} = L^\perp$, lie in $\ker H = L$; so the two formulations are equivalent. □

Theorem 35.58. *Let p, C, $\mathcal{O}_C$, $\mathbb{F}$ and N be as in Definition 35.18, B an $\mathbb{F}$-stable tight Hopf order on N and $b_1, \dots, b_m$ a basis of N such that B has the generation property at $N_i = \mathbb{F}b_1 \oplus \cdots \oplus \mathbb{F}b_i$ for $0 \le i \le m-1$. Then $(B, (b_i))$ satisfies the flag conditions for every fundamental character $\chi\colon \mathbb{F} \to \mathcal{O}_C$.*

Proof. Fix a fundamental character χ, put $\chi_s = \chi^{p^s}$, $q = |\mathbb{F}| = p^f$, and let $B_j = B|_{N_j}$ and $S_j = B_{N_{j-1}, b_j}$ ($1 \le j \le m$) as in Lemma 35.50.

Step 1 (rank-one data). By Lemma 35.50(1), S_j is an $\mathbb{F}$-stable Hopf order on $\mathbb{F}$ and $\mathrm{Xr}_{\chi_s,j}(B) = \mathrm{Xv}_{\chi_s,j}(B) = \mathrm{Xr}_{\chi_s}(S_j)$. By Lemma 35.52 applied to S_j there are $c_{j,s} \in \mathcal{O}_C \smallsetminus \{0\}$, depending only on s modulo f, with $\mathrm{Xr}_{\chi_s}(S_j) = c_{j,s}\mathcal{O}_C$; $\delta_{j,s} = c_{j,s}^p / c_{j,s+1} \in \mathcal{O}_C$; $\mathrm{co}_{\chi_{s+1}}(S_j)$ has nor-

malised length $v(\delta_{j,s})$ and $\mathrm{co}_\psi(S_j) = 0$ for $\psi \notin \{\chi_0, \dots, \chi_{f-1}\}$; $2\,\mathrm{colen}(S_j) = q(p-1)\sum_{s<f} v(c_{j,s})$ and $\sum_{s<f} v(\delta_{j,s}) = (p-1)\sum_{s<f} v(c_{j,s})$. Put $X = \sum_{j=1}^{m}\sum_{s=0}^{f-1} v(c_{j,s}) < \infty$.

Step 2 (colength). By Lemma 35.50(2), $2\,\mathrm{colen}(B)/|N| = \sum_j 2\,\mathrm{colen}(S_j)/q = (p-1)X$.

Step 3 (flag condition (1)). By Lemma 35.59, $\mathrm{Ad}_{\chi_s,j}(B) = d_{j,s}\mathcal{O}_C$ with $v(d_{j,s}) \le 1$ and $\mathrm{len}_C(Q_B) = \sum_{j\le m}\sum_{s<f} v(d_{j,s})$. By the generation property at N_{j-1} and Lemma 35.60, $c_{j,s} \in \mathrm{Xv}_{\chi_s,j}(B) \subseteq d_{j,s}\mathcal{O}_C$, so $v(c_{j,s}) \ge v(d_{j,s})$. Tightness and Step 2 give $|N|(p-1)\,\mathrm{len}_C(Q_B) = 2\,\mathrm{colen}(B) = |N|(p-1)X$, so $\sum_{j,s} v(d_{j,s}) = \sum_{j,s} v(c_{j,s})$, all terms finite; hence $v(c_{j,s}) = v(d_{j,s})$ for all j and $s < f$, and $c_{j,s} \in d_{j,s}\mathcal{O}_C$ with equal valuations gives $c_{j,s}\mathcal{O}_C = d_{j,s}\mathcal{O}_C$. So $\mathrm{Xr}_{\chi_s,j}(B) = \mathrm{Xv}_{\chi_s,j}(B) = \mathrm{Ad}_{\chi_s,j}(B) = c_{j,s}\mathcal{O}_C$ for $s < f$, and for all $s \ge 0$ since the three modules and $c_{j,s}$ depend only on χ_s, which has period f in s (Lemma 35.53(2)).

Step 4 (flag condition (2)). $c_{j,s}^{p} = \delta_{j,s} c_{j,s+1}$ with $\delta_{j,s} \in \mathcal{O}_C$ by Step 1.

Step 5 (flag condition (3)). By Lemma 35.50(3), $\mathrm{len}_C(I_B/I_B^2) = \sum_\psi \mathrm{len}_C \mathrm{co}_\psi(B)$ and, iterating the inequality from B_0 (where $I_{B_0} = 0$), $\mathrm{len}_C \mathrm{co}_\psi(B) \le \sum_j \mathrm{len}_C \mathrm{co}_\psi(S_j)$ for each character ψ. As $\chi_1, \dots, \chi_f$ are pairwise distinct (Lemma 35.53(2)), Step 1 gives $\sum_\psi \sum_j \mathrm{len}_C \mathrm{co}_\psi(S_j) = \sum_j \sum_{s<f} v(\delta_{j,s}) = (p-1)X$. Tightness and Step 2 give $|N|\,\mathrm{len}_C(I_B/I_B^2) = 2\,\mathrm{colen}(B) = |N|(p-1)X$. So the sum of the termwise inequalities is an equality, and $\mathrm{len}_C \mathrm{co}_\psi(B) = \sum_j \mathrm{len}_C \mathrm{co}_\psi(S_j)$ for every ψ. For $\psi = \chi_{s+1}$, Lemma 35.50(4) gives that $\mathrm{co}_{\chi_{s+1}}(B|_{N_j})$ has normalised length $\sum_{i\le j} v(\delta_{i,s})$ for $0 \le j \le m$, first for $s < f$ and then for all $s \ge 0$ by periodicity. □

Lemma 35.59. *Let B be an $\mathbb{F}$-stable Hopf order on N, $b_1, \dots, b_m$ a basis of N and χ a fundamental character, $\chi_s = \chi^{p^s}$. Then for $1 \le i \le m$ and $s \ge 0$ there is $d_{i,s} \in \mathcal{O}_C$ with $0 \le v(d_{i,s}) \le 1$, depending only on s modulo f, such that $\mathrm{Ad}_{\chi_s,i}(B) = d_{i,s}\mathcal{O}_C$; and Q_B has normalised length*

$$\mathrm{len}_C(Q_B) = \sum_{i=1}^{m}\sum_{s=0}^{f-1} v(d_{i,s}).$$

Proof. By Lemma 35.48 $B \subseteq \mathrm{Map}(N, \mathcal{O}_C)$, so $\mathrm{AF}(B) \subseteq \mathrm{Lin}(N)$; also $p\,\mathrm{Map}(N, \mathcal{O}_C) \subseteq \mathrm{Lin}(N)$, and reduction modulo p identifies $V = \mathrm{Lin}(N)/p\,\mathrm{Map}(N, \mathcal{O}_C)$ with the additive maps $N \to \mathcal{O}_C/p$ (every additive map lifts). Write $x = \sum_i a_i(x) b_i$. An additive map φ is $\sum_i \varphi(\cdot\, b_i) \circ a_i$, so by Lemma 35.53(3) V is free over $\mathcal{O}_C/p$ with basis $e_{i,s} = \bar{\chi}_s \circ a_i$ ($i \le m$, $s < f$; bars denote reduction mod p). Let $M \subseteq V$ be the image of $\mathrm{AF}(B)$, so $Q_B \cong V/M$. $\mathrm{AF}(B)$ is the kernel of $B \to \mathrm{Map}(N \times N, \mathcal{O}_C/p)$, $g \mapsto \overline{g(x+y) - g(x) - g(y)}$, hence finitely generated (coherence), and M is finitely generated.

The projectors $\pi_s g = \frac{1}{q-1}\sum_{a\in\mathbb{F}^\times} \chi_s(a)^{-1} g(a\,\cdot)$ preserve B ($\mathbb{F}$-stability), almost additivity and $p\,\mathrm{Map}(N, \mathcal{O}_C)$; on V, $e_{i,s'}$ is $\bar{\chi}_{s'}$-eigen, so $\pi_s e_{i,s'} = [s = s']\, e_{i,s'}$ (Lemma 35.53(2)). Hence $M = \bigoplus_s M_s$ with $M_s = \pi_s M \subseteq V_s = \bigoplus_i (\mathcal{O}_C/p) e_{i,s}$, and $Q_B \cong \bigoplus_{s<f} V_s/M_s$.

Fix s and write $r \in V_s$ as $\sum_i r_i e_{i,s}$. Let $M_s^{(i)} = \{r \in M_s : r_j = 0\ (j < i)\}$. *Claim:* $\mathrm{Ad}_{\chi_s,i}(B)/p\mathcal{O}_C = \{r_i : r \in M_s^{(i)}\}$. If $r \in M_s^{(i)}$, lift it to $g \in \mathrm{AF}(B)$ and replace g by $\pi_s g$ (still a lift, as $\pi_s r = r$): then $g(ax) = \chi_s(a) g(x)$ for $a \ne 0$, $g(0) \in p\mathcal{O}_C$ (almost additivity), $\bar{g}|_{N_{i-1}} = \sum_{j<i} r_j \bar{\chi}_s \circ a_j = 0$ and $\bar{g}(b_i) = r_i$, so a lift of r_i lies in $\mathrm{Ad}_{\chi_s,i}(B)$. Conversely, if $c \in \mathrm{Ad}_{\chi_s,i}(B)$ and g is as in the definition of $\mathrm{Ad}_{\chi_s,i}(B)$ for c, then $\bar{g} \in M$ is $\bar{\chi}_s$-eigen, so $\bar{g} = \pi_s \bar{g} \in M_s$; $\bar{g}(ab_j) = r_j \bar{\chi}_s(a) = 0$ for $j < i$ and all a gives $r_j = 0$, and $r_i = \bar{g}(b_i) = \bar{c}$. Since $\mathcal{O}_C/p$ is coherent, $M_s^{(i)}$ (a kernel of a map from the finitely presented M_s to $(\mathcal{O}_C/p)^{i-1}$) is finitely generated, so $\mathrm{Ad}_{\chi_s,i}(B)$ is a finitely generated ideal containing p: it is $d_{i,s}\mathcal{O}_C$ with $v(d_{i,s}) \le 1$. It depends only on χ_s, hence on s modulo f.

Let $V^{(i)} = \{r \in V_s : r_j = 0\ (j < i)\}$ and $F^{(i)} = (V^{(i)} + M_s)/M_s$, so $F^{(1)} = V_s/M_s$,

$F^{(m+1)}=0$. By the modular law, $F^{(i)}/F^{(i+1)}\cong V^{(i)}/(V^{(i+1)}+M_s^{(i)})$, which the i-th coordinate maps isomorphically onto $(\mathcal{O}_C/p)/(d_{i,s}\mathcal{O}_C/p)\cong\mathcal{O}_C/d_{i,s}\mathcal{O}_C$, of normalised length $v(d_{i,s})$. All these modules are finitely presented and torsion, so additivity gives $\mathrm{len}_C(V_s/M_s)=\sum_i v(d_{i,s})$, and summing over $s<f$ gives the formula. □

Lemma 35.60. *Let B be an $\mathbb{F}$-stable Hopf order on N, $b_1,\dots,b_m$ a basis of N, $1\le i\le m$, and suppose B has the generation property at N_{i-1}. Let χ be a fundamental character and $\chi_s=\chi^{p^s}$. Then $\mathrm{Xv}_{\chi_s,i}(B)\subseteq\mathrm{Ad}_{\chi_s,i}(B)$ for every $s\ge 0$.*

Proof. Put $K=N_{i-1}$ and, by Lemma 35.59, $\mathrm{Ad}_{\chi_{s'},i}(B)=d_{s'}\mathcal{O}_C$ with $u_{s'}=v(d_{s'})\in[0,1]$, indices modulo f; recall $B\subseteq\mathrm{Map}(N,\mathcal{O}_C)$ (Lemma 35.48) and bars denote reduction modulo p.

Step 1: $u_{s'+1}\le p\,u_{s'}$. Choose g as in the definition of $\mathrm{Ad}_{\chi_{s'},i}(B)$ for $c=d_{s'}$, and put $h=g^p\in B$. Since $(u+pe)^p\equiv u^p$ and $(u+w)^p\equiv u^p+w^p$ modulo $p\mathcal{O}_C$, h is almost additive, $h(ax)\equiv\chi_{s'}(a)^p h(x)=\chi_{s'+1}(a)h(x)$, $h(K)\subseteq p\mathcal{O}_C$ and $h(b_i)\equiv d_{s'}^p$. So $d_{s'}^p\in d_{s'+1}\mathcal{O}_C$.

Step 2: if $s'_1,\dots,s'_n$ ($n\ge 1$) satisfy $\sum_j p^{s'_j}\equiv p^s\pmod{q-1}$, then $\prod_j d_{s'_j}\in d_s\mathcal{O}_C$. Let $\kappa_j\in\{0,\dots,f-1\}$ with $s'_j\equiv s-\kappa_j\pmod f$. Step 1 iterated gives $u_s\le p^{\kappa_j}u_{s'_j}$. Since $p^f\equiv 1\pmod{q-1}$, $\sum_j p^{f-\kappa_j}\equiv p^{f-s}\sum_j p^{s'_j}\equiv p^f\equiv 1\pmod{q-1}$; each term is at least $p\ge 2$, and an integer ≥ 2 congruent to 1 modulo $q-1$ is at least q. So $\sum_j p^{-\kappa_j}\ge 1$ and $\sum_j u_{s'_j}\ge\sum_j p^{-\kappa_j}u_s\ge u_s$.

Step 3. Let $c\in\mathrm{Xv}_{\chi_s,i}(B)$, and choose $g\in B^K$ with $g(ab_i)=c\chi_s(a)$. By the generation property $g=P(h_1,\dots,h_r)$ with $P\in\mathcal{O}_C[Y_1,\dots,Y_r]$ and h_k almost-additive elements of B^K. Each $h_k(0)\in p\mathcal{O}_C$ ($h_k(0)\equiv 2h_k(0)$), and $h_k-h_k(0)$ is again an almost-additive element of B^K; replacing h_k by it and P by $P(Y+h(0))$, we may assume $h_k(0)=0$, so $h_k(K)=0$. The map $a\mapsto\bar h_k(ab_i)$ is additive, so by Lemma 35.53(3) $\bar h_k(ab_i)=\sum_{s'<f}\bar e_{k,s'}\bar\chi_{s'}(a)$. *Each $e_{k,s'}$ may be taken in $d_{s'}\mathcal{O}_C$:* $h'=\frac{1}{q-1}\sum_{a\in\mathbb{F}^\times}\chi_{s'}(a)^{-1}h_k(a\,\cdot)$ lies in B, is almost additive, vanishes on K and at 0, satisfies $h'(ax)=\chi_{s'}(a)h'(x)$, and by Lemma 35.53(2) $\bar h'(b_i)=\bar e_{k,s'}$; so $\bar e_{k,s'}$ is the residue of an element of $\mathrm{Ad}_{\chi_{s'},i}(B)$.

Reducing $g=P(h)$ on the line $\mathbb{F}b_i$ modulo p: $\bar c\,\bar\chi_s=\sum_\alpha\bar a_\alpha\prod_k\bigl(\sum_{s'}\bar e_{k,s'}\bar\chi_{s'}\bigr)^{\alpha_k}$. Expanding, every term is a product of coefficients $\bar a_\alpha\prod_j\bar e_{k_j,s'_j}$ times $\prod_j\bar\chi_{s'_j}=\bar\chi^M$ with $M=\sum_j p^{s'_j}$ (the constant 1 if the product is empty). As functions on $\mathbb{F}$, $\bar\chi^M=\bar\chi^{M'}$ for $M\ge 1$, where $M'\in\{1,\dots,q-1\}$ and $M'\equiv M\pmod{q-1}$. The reductions of $1,\chi,\dots,\chi^{q-1}$ form a basis of $\mathrm{Map}(\mathbb{F},\mathcal{O}_C/p)$ (Lemma 35.53(1)), so comparing coefficients of $\bar\chi^{p^s}=\bar\chi_s$: $\bar c$ is a sum of terms $\bar a_\alpha\prod_j\bar e_{k_j,s'_j}$ with $n\ge 1$ and $\sum_j p^{s'_j}\equiv p^s\pmod{q-1}$. By Step 2 each lies in the image of $d_s\mathcal{O}_C$, so $c\in d_s\mathcal{O}_C+p\mathcal{O}_C=\mathrm{Ad}_{\chi_s,i}(B)$. □

Lemma 35.61. *Let $\mathfrak{T}$ be a pre-admissible torsion system and $(\mathfrak{q},C,\iota)$ a test point of $\mathfrak{T}$ at which (Ox3) holds and, for every label u, $(\mathcal{A}_{\mathfrak{P}_u,C},(b_i))$ satisfies the flag conditions for the character χ_u (with values in $\mathcal{O}_C$ through ι). Then (Ox4) holds at $(\mathfrak{q},C,\iota)$.*

Proof. Fix s, $t=\varphi_p s$, $\mathfrak{P}=\mathfrak{P}_s$, $1\le i\le m=m_{\mathfrak{P}}$, and write $B=\mathcal{A}_{\mathfrak{P},C}$, $I=\mathcal{I}_{\mathfrak{P},C}$, $N=\Gamma_{\mathfrak{P}}$, $N_j=\Gamma_{\mathfrak{P},j}$, $\mathbb{F}=\mathbb{F}_{\mathfrak{P}}$, $\theta=\theta_{t,C}$. By (Ox3), B is an $\mathbb{F}$-stable Hopf order on N. Being finite over $\mathcal{O}_C$, B consists of functions with values in $\mathcal{O}_C$; $B\otimes B\to\mathrm{Map}(N\times N,C)$ is injective (a basis of B is a C-basis of $\mathrm{Map}(N,C)$), so $G=\mathrm{Spec}\,B$ is a finite locally free commutative group scheme over $\mathcal{O}_C$ with $G(C)=N$, the group law being given by $g\mapsto((x,y)\mapsto g(x+y))$.

Step 1: functions vanishing on N_{i-1}. By Lemma 35.51, every $g\in B$ vanishing on N_{i-1} is $g=h+r$ with $h\in I$ invariant under translation by N_{i-1} and r in the $\mathcal{O}_C$-span I^2 of products of two elements of I.

Step 2: the first identity of (Ox4). $\mathcal{S}_{t,i,C} \subseteq \mathcal{I}_{\mathfrak{P},i-1,C}$, as $\xi_{t,i}$ vanishes on N_{i-1}. Conversely let $g \in \mathcal{I}_{\mathfrak{P},i-1,C}$ and $g = h + r$ as in Step 1; $\theta(r) = 0$ by (Ox3). Put $Q = |\mathbb{F}|$ (a power of p, so $Q - 1 \in \mathcal{O}_C^\times$) and

$$h' = (Q-1)^{-1} \sum_{a \in \mathbb{F}^\times} \chi_t(a)^{-1}\, h(a\,\cdot) \in I$$

($\mathbb{F}$-stability). By the equivariance in (Ox3), $\theta(h') = \theta(h) = \theta(g)$. h' is invariant under N_{i-1} (an $\mathbb{F}$-subspace) and $h'(bx) = \chi_t(b)h'(x)$ for $b \in \mathbb{F}^\times$. Hence for $x = \sum_{j \le i} x_j b_j \in N_i$: $h'(x) = h'(x_i b_i) = \chi_t(x_i) h'(b_i)$ (for $x_i = 0$ both sides vanish). So $h'|_{N_i} = h'(b_i)\,\xi_{t,i}$, $h' \in \mathcal{S}_{t,i,C}$, and $\theta(g) \in \theta(\mathcal{S}_{t,i,C})$.

Step 3: the second identity of (Ox4). Let ϵ generate $\mathcal{O}(\mathrm{Ec}_{s,i})_{\mathfrak{q}}$. The inclusion of the left side in $\mathcal{O}_C \epsilon^p$ is Lemma 35.62. Conversely, by (Ts5) $\epsilon\,\xi_{s,i} = g_0|_{N_i}$ for some $g_0 \in \mathcal{A}_{\mathfrak{P},\mathfrak{q}} \subseteq B$, and $g_0(0) = \epsilon\chi_s(0) = 0$, so $g_0 \in I$. For $r \in \mathcal{O}_C$, $g = r\, g_0^p \in I^2$, so $\theta(g) = 0$ (Ox3), and $g|_{N_i} = r\,\epsilon^p \xi_{s,i}^p = r\,\epsilon^p \xi_{t,i}$ since $\chi_s^p = \chi_t$. So $\mathcal{O}_C \epsilon^p$ lies in the left side. □

Lemma 35.62. *Let $\mathfrak{T}$ be a pre-admissible torsion system and $(\mathfrak{q}, C, \iota)$ a test point of $\mathfrak{T}$ at which (Ox3) holds and, for every label u, $(\mathcal{A}_{\mathfrak{P}_u,C}, (b_i))$ satisfies the flag conditions for χ_u. Let s be a label, $t = \varphi_p s$, $\mathfrak{P} = \mathfrak{P}_s$, $1 \le i \le m_{\mathfrak{P}}$, and let ϵ generate $\mathcal{O}(\mathrm{Ec}_{s,i})_{\mathfrak{q}}$. If $g \in \mathcal{A}_{\mathfrak{P},C}$ and $c \in C$ satisfy $g|_{\Gamma_{\mathfrak{P},i}} = c\,\xi_{t,i}$ and $\theta_{t,C}(g) = 0$, then $c \in \mathcal{O}_C\,\epsilon^p$.*

Proof. Write $B = \mathcal{A}_{\mathfrak{P},C}$, $I = \mathcal{I}_{\mathfrak{P},C} = I_B$, $N_j = \Gamma_{\mathfrak{P},j}$, $B_j = B|_{N_j}$, $\chi = \chi_t$, $\xi = \xi_{t,i}$, $Q = |\mathbb{F}_{\mathfrak{P}}|$ ($Q - 1 \in \mathcal{O}_C^\times$), and for $f \in B$ let $\mathrm{pr}(f) = (Q-1)^{-1} \sum_{a \in \mathbb{F}_{\mathfrak{P}}^\times} \chi(a)^{-1} f(a\,\cdot)$, which lies in B ($\mathbb{F}_{\mathfrak{P}}$-stability, (Ox3)), satisfies $\mathrm{pr}(f)(bx) = \chi(b)\mathrm{pr}(f)(x)$, agrees with f on every $\mathbb{F}_{\mathfrak{P}}$-subspace on which f is a χ-eigenfunction, maps I to I and I^2 to I^2, and satisfies $\theta_{t,C}(\mathrm{pr}(f)) = \theta_{t,C}(f)$ for $f \in I$ (equivariance in (Ox3)). Restriction to N_j maps I onto I_{B_j} (a lift of a function vanishing at 0 vanishes at 0) and I^2 onto $I_{B_j}^2$.

Step 0: the ideals. B_i is the $\mathcal{O}_C$-span of $\mathcal{A}_{\mathfrak{P},i,\mathfrak{q}}$, which is free over $R_{\mathfrak{q}}$ with a basis that is a C-basis of $\mathrm{Map}(N_i, C)$; writing $\xi_{u,i} = \sum_k \xi_k e_k$ in it, $c\,\xi_{u,i} \in B_i$ if and only if $v(c) \ge \max_k(-v(\xi_k))$, and the same over Ω' defines $\mathcal{O}(\mathrm{Ec}_{u,i})_{\mathfrak{q}}$ (Ts5), the valuation of C restricting to one with ring $R_{\mathfrak{q}}$. Since $\mathrm{Xr}_{\chi_u,i}(B) = \{c : \ c\,\xi_{u,i} \in B_i\}$, $\mathrm{Xr}_{\chi_s,i}(B) = \mathcal{O}_C\epsilon$. Take the flag conditions for the fundamental character χ_s, with exponent 0 and 1 ($\chi_s^p = \chi$): $\mathrm{Xr}_{\chi_s,i}(B) = c_0\mathcal{O}_C$, $\mathrm{Xr}_{\chi,i}(B) = c_1\mathcal{O}_C$, $c_0^p = \delta c_1$, and $\mathrm{len}_C(\mathrm{co}_\chi(B_j)) = \sum_{l \le j} v(\delta_l)$ with $\delta_i = \delta$. Hence

$$\mathrm{len}_C(\mathrm{co}_\chi(B_i)) - \mathrm{len}_C(\mathrm{co}_\chi(B_{i-1})) = v(\delta), \qquad c_0\mathcal{O}_C = \epsilon\,\mathcal{O}_C. \tag{1}$$

Step 1: the restriction map. Restriction maps $I_{B_i,\chi}$ into $I_{B_{i-1},\chi}$ and $I_{B_i}^2$ into $I_{B_{i-1}}^2$, so it induces $\rho\colon \mathrm{co}_\chi(B_i) \to \mathrm{co}_\chi(B_{i-1})$. It is onto: for $h \in I_{B_{i-1},\chi}$ take $f \in I$ with $f|_{N_{i-1}} = h$; then $\mathrm{pr}(f)|_{N_i} \in I_{B_i,\chi}$ restricts to h.

Step 2: the kernel of ρ is $\mathcal{O}_C[a_1]$, $a_1 = c_1\xi \in I_{B_i,\chi}$. $[a_1] \in \ker\rho$ as ξ vanishes on N_{i-1}. Let $z \in I_{B_i,\chi}$ with $z|_{N_{i-1}} \in I_{B_{i-1}}^2$; choose $g \in I$ with $g|_{N_i} = z$ and $w \in I^2$ with $w|_{N_{i-1}} = z|_{N_{i-1}}$. By Lemma 35.51, $g - w = h + r$ with $h \in I$ invariant under N_{i-1} and $r \in I^2$. Then $\mathrm{pr}(h)$ is N_{i-1}-invariant and a χ-eigenfunction, so $\mathrm{pr}(h)|_{N_i} = \lambda\,\xi$ with $\lambda = \mathrm{pr}(h)(b_i)$, and $\lambda \in \mathrm{Xr}_{\chi,i}(B) = c_1\mathcal{O}_C$, say $\lambda = r_0 c_1$. As z is a χ-eigenfunction on N_i, $z = \mathrm{pr}(g)|_{N_i} = r_0 a_1 + \mathrm{pr}(r+w)|_{N_i}$ with $\mathrm{pr}(r+w)|_{N_i} \in I_{B_i}^2$. So $[z] = r_0[a_1]$.

Step 3: $k[a_1] = 0$. By hypothesis $c\,\xi \in B_i$, so $c \in c_1\mathcal{O}_C$, $c = kc_1$. $g(0) = c\,\chi(0) = 0$, so $g \in I$, and $\theta_{t,C}(\mathrm{pr}(g)) = \theta_{t,C}(g) = 0$; $\mathrm{pr}(g)$ is a χ-eigenfunction, so $\mathrm{pr}(g) \in I^2$ by (Ox3). Restricting, $k\,a_1 = c\,\xi = g|_{N_i} = \mathrm{pr}(g)|_{N_i} \in I_{B_i}^2$.

Step 4: the length estimate. $\mathrm{co}_\chi(B_i)$ and $\mathrm{co}_\chi(B_{i-1})$ have normalised lengths (flag condition (3)): write $\mathrm{co}_\chi(B_{i-1}) \cong \bigoplus_{j=1}^{n'} \mathcal{O}_C/d_j$ with basis classes η_j, lift $\eta_j = \rho(\beta_j)$; $d_j\beta_j \in \ker\rho$, so

$d_j\beta_j = y_j[a_1]$ with $y_j \in \mathcal{O}_C$ (Step 2). The map $\mathcal{O}_C^{1+n'} \to \mathrm{co}_\chi(B_i)$, $(u_0, u) \mapsto u_0[a_1] + \sum_j u_j\beta_j$, is onto (Steps 1, 2) and kills the columns of

$$X = \begin{pmatrix} k & -y_1 & \cdots & -y_{n'} \\ 0 & d_1 & & \\ & & \ddots & \\ 0 & & & d_{n'} \end{pmatrix}$$

(Step 3), so $\mathrm{co}_\chi(B_i)$ is a quotient of $\operatorname{coker} X$. If $k = 0$, then $c = 0$ and there is nothing to prove. If $k \neq 0$, then

$$\mathrm{len}_C(\mathrm{co}_\chi(B_i)) \leq v(\det X) = v(k) + \mathrm{len}_C(\mathrm{co}_\chi(B_{i-1})).$$

With (1), $v(k) \geq v(\delta)$, so $c = kc_1 \in \delta c_1\mathcal{O}_C = c_0^p\mathcal{O}_C = \epsilon^p\mathcal{O}_C$. □

Lemma 35.63. *Let $\mathfrak{T} = (\mathcal{O}', \mathcal{X}', \pi, (\mathcal{A}_\mathfrak{P}, \theta))$ be a pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ such that*

1. *for every label t, with $m = m_{\mathfrak{P}_t}$, the step sheaves $\mathcal{U}_{t,j}$ $(0 \leq j \leq m)$ and $\mathcal{U}^{\mathrm{st}}_{t,i}$ $(1 \leq i \leq m)$ are locally free;*
2. *every point of $\mathcal{X}'$ of codimension one at which p is not a unit is the first entry of a test point at which (Ox4) holds.*

Then $\mathfrak{T}$ satisfies (Ts6); it is an admissible torsion system.

Proof. Fix a label s, put $t = \varphi_p s$, $\mathfrak{P} = \mathfrak{P}_s = \mathfrak{P}_t$, $m = m_\mathfrak{P}$, $1 \leq i \leq m$, and write $\mathcal{A} = \mathcal{A}_\mathfrak{P}$, $\mathcal{A}_j = \mathcal{A}_{\mathfrak{P},j}$, $\mathcal{I}_j = \mathcal{I}_{\mathfrak{P},j}$, $\Gamma_j = \Gamma_{\mathfrak{P},j}$, $\xi = \xi_{t,i}$. $\mathcal{X}'$ is integral, normal and noetherian (Ts2), so its local ring $R_\mathfrak{q}$ at a point $\mathfrak{q}$ of codimension one is a discrete valuation ring.

Step 0: two reflexivity facts. (a) If $\mathcal{V} \subseteq \mathcal{V}'$ are locally free of finite rank, $\mathcal{V}'$ locally free, a local section of $\mathcal{V}' \otimes \Omega'$ over an open W that lies in $\mathcal{V}_\mathfrak{q}$ for every point $\mathfrak{q} \in W$ of codimension one lies in $\mathcal{V}(W)$: in a local basis of $\mathcal{V}$ its coordinates lie in every $R_\mathfrak{q}$, hence in the local ring (intersection of the height-one localisations). The same holds for an invertible subsheaf of the constant sheaf Ω'. (b) Let $\mathcal{V} \subseteq \mathcal{V}'$ be locally free of the same rank and $\mathcal{Q} = \mathcal{V}'/\mathcal{V}$ with $\mathcal{Q}_\eta = 0$ at the generic point. At a point x of codimension ≥ 2, $\mathcal{Q}_x$ has projective dimension ≤ 1 and $\operatorname{depth} \mathcal{O}_{\mathcal{X}',x} \geq 2$, so $\operatorname{depth} \mathcal{Q}_x \geq 1$ if $\mathcal{Q}_x \neq 0$ (Auslander–Buchsbaum): $\mathcal{Q}$ has no associated point of codimension ≥ 2. A local section of $\mathcal{Q}$ vanishing at every point of codimension ≤ 1 has a support whose generic points are associated points of $\mathcal{Q}$, so it is 0.

Step 1: base change to a test point. Let $(\mathfrak{q}, C, \iota)$ be a test point, $R = R_\mathfrak{q}$; $\mathcal{O}_C$ is flat over R. Let v be an additive valuation of C defining its absolute value; its restriction to Ω' has valuation ring R. $\mathcal{A}_{j,\mathfrak{q}}$ is free over R (Ts4) with an R-basis that is an Ω'-basis of $\mathrm{Map}(\Gamma_j, \Omega')$, so $\mathcal{O}_C \otimes_R \mathcal{A}_{j,\mathfrak{q}}$ is the $\mathcal{O}_C$-span $\mathcal{A}_C|_{\Gamma_j}$ of $\mathcal{A}_{j,\mathfrak{q}}$ in $\mathrm{Map}(\Gamma_j, C)$, where $\mathcal{A}_C = \mathcal{A}_{\mathfrak{P},C}$. Writing $\xi = \sum_k \xi_k e_k$ in an R-basis (e_k) of $\mathcal{A}_{i,\mathfrak{q}}$, an element c of C (resp. of Ω') has $c\,\xi \in \mathcal{A}_C|_{\Gamma_i}$ (resp. $\in \mathcal{A}_{i,\mathfrak{q}}$) if and only if $v(c) \geq \max_k(-v(\xi_k))$; so with ϵ_t a generator of $\mathcal{O}(\mathrm{Ec}_{t,i})_\mathfrak{q}$ (Ts5),

$$\{c \in C :\ c\,\xi \in \mathcal{A}_C|_{\Gamma_i}\} = \mathcal{O}_C\,\epsilon_t. \tag{1}$$

By flatness, kernels and images commute with $\mathcal{O}_C \otimes_R -$. Hence $\mathcal{O}_C \otimes \mathcal{I}_{j,\mathfrak{q}} = \mathcal{I}_{\mathfrak{P},j,C}$ (kernel of restriction to Γ_j), $\mathcal{O}_C \otimes \mathcal{S}_{t,i,\mathfrak{q}} = \mathcal{S}_{t,i,C}$ ($\mathcal{S}_{t,i,\mathfrak{q}}$ is the kernel of $\mathcal{A}_\mathfrak{q} \to \mathcal{A}_{i,\mathfrak{q}}/R\epsilon_t\xi$, and (1)), and, as the step sheaves contain $p\,\omega_t$ and $\theta_{t,C} = \mathcal{O}_C \otimes \theta_{t,\mathfrak{q}}$, the $\mathcal{O}_C$-span of $\mathcal{U}_{t,j,\mathfrak{q}}$ (resp. $\mathcal{U}^{\mathrm{st}}_{t,i,\mathfrak{q}}$) in $\mathcal{O}_C \otimes \omega_{t,\mathfrak{q}}$ is the preimage of $\theta_{t,C}(\mathcal{I}_{\mathfrak{P},j,C})$ (resp. $\theta_{t,C}(\mathcal{S}_{t,i,C})$). Finally, (2): for a free R-submodule V of full rank of a finite free R-module F, $V = (\mathcal{O}_C \otimes V) \cap (F \otimes \Omega')$, since in a basis of V the coordinates of an element of the right side lie in $\mathcal{O}_C \cap \Omega' = R$.

Step 2: (onto). Let $\mathfrak{q}$ have codimension one. If p is a unit at $\mathfrak{q}$, $(\omega_t/p\,\omega_t)_{\mathfrak{q}} = 0$ and $\mathcal{U}_{t,i-1,\mathfrak{q}} = \mathcal{U}^{\mathrm{st}}_{t,i,\mathfrak{q}} = \omega_{t,\mathfrak{q}}$. Otherwise take a test point with (Ox4); by Step 1 the first identity of (Ox4) says that $\mathcal{U}_{t,i-1,\mathfrak{q}}$ and $\mathcal{U}^{\mathrm{st}}_{t,i,\mathfrak{q}}$ have the same $\mathcal{O}_C$-span, and both are free of full rank in $\omega_{t,\mathfrak{q}}$ (hypothesis 1; they contain $p\,\omega_{t,\mathfrak{q}}$), so they are equal by (2). By Step 0(a), $\mathcal{U}_{t,i-1} = \mathcal{U}^{\mathrm{st}}_{t,i}$; as both contain $p\,\omega_t$, $\theta_t(\mathcal{I}_{i-1}) = \theta_t(\mathcal{S}_{t,i})$, which is (onto).

Step 3: the step map. For a local section c of $\mathcal{O}(\mathrm{Ec}_{t,i})$, $c\,\xi$ is a local section of $\mathcal{A}_i$ (Ts5), so locally $c\,\xi = g|_{\Gamma_i}$ with $g \in \mathcal{A}$; $g \in \mathcal{I}_{i-1}$ as ξ vanishes on Γ_{i-1}; two choices differ by a section of $\mathcal{I}_i$. So $\psi(c) = \theta_t(g) \bmod \theta_t(\mathcal{I}_i)$ defines an $\mathcal{O}_{\mathcal{X}'}$-linear map $\psi\colon \mathcal{O}(\mathrm{Ec}_{t,i}) \to \mathcal{Q} := \mathcal{U}_{t,i-1}/\mathcal{U}_{t,i} \cong \theta_t(\mathcal{I}_{i-1})/\theta_t(\mathcal{I}_i)$. Let $\mathcal{K}$ be the subsheaf of Ω' of (inj) for (s,i). If $g|_{\Gamma_i} = c\,\xi$ with $g \in \mathcal{A}$, then $c \in \mathcal{O}(\mathrm{Ec}_{t,i})$ by (Ts5); and $\psi(c) = 0$ if and only if $\theta_t(g) = \theta_t(h)$ for some $h \in \mathcal{I}_i$, i.e. if and only if $g - h$ restricts to $c\,\xi$ and lies in $\ker\theta_t$. So $\mathcal{K} = \ker\psi$. The same argument over $\mathcal{O}_C$ at a test point, with (1), shows that $\mathcal{O}_C \otimes \psi_{\mathfrak{q}}\colon \mathcal{O}_C\epsilon_t \to \theta_{t,C}(\mathcal{I}_{\mathfrak{P},i-1,C})/\theta_{t,C}(\mathcal{I}_{\mathfrak{P},i,C})$ has kernel the left side of the second identity of (Ox4).

Step 4: (inj). $\mathcal{Q}$ is a quotient of locally free sheaves of the same rank (hypothesis 1) killed by p, so $\mathcal{Q}_\eta = 0$. Let c be a local section of Ω' over W with $c \in \mathcal{K}_{\mathfrak{q}}$ for all $\mathfrak{q} \in W$ of codimension one. By Step 0(a), $c \in \mathcal{O}(\mathrm{Ec}_{t,i})(W)$; $\psi(c)$ vanishes at every point of codimension ≤ 1, so $\psi(c) = 0$ by Step 0(b), and $c \in \mathcal{K}(W)$. As $\mathcal{O}(p\,\mathrm{Ec}_{s,i})$ (locally generated by ϵ_s^p, ϵ_s a local generator of $\mathcal{O}(\mathrm{Ec}_{s,i})$; it is the sheaf generated by the p-th powers of sections of $\mathcal{O}(\mathrm{Ec}_{s,i})$) is invertible, it suffices to show $\mathcal{K}_{\mathfrak{q}} = R_{\mathfrak{q}}\epsilon_s^p$ at every $\mathfrak{q}$ of codimension one. If p is a unit at $\mathfrak{q}$, $\mathcal{Q}_{\mathfrak{q}} = 0$ and $\mathcal{K}_{\mathfrak{q}} = \mathcal{O}(\mathrm{Ec}_{t,i})_{\mathfrak{q}} = R_{\mathfrak{q}} = \mathcal{O}(p\,\mathrm{Ec}_{s,i})_{\mathfrak{q}}$, the eigen-coordinate divisors being supported in $\mathcal{X}'_{\mathfrak{s}}$. Otherwise take a test point with (Ox4): by flatness and Step 3, $\mathcal{O}_C \otimes \mathcal{K}_{\mathfrak{q}} = \ker(\mathcal{O}_C \otimes \psi_{\mathfrak{q}}) = \mathcal{O}_C\epsilon_s^p \neq 0$. So $\mathcal{K}_{\mathfrak{q}} \subseteq R\epsilon_t$ is free of rank one, $\mathcal{K}_{\mathfrak{q}} = Rx$, and $x/\epsilon_s^p \in \mathcal{O}_C^\times \cap \Omega' = R^\times$. Hence $\mathcal{K} = \mathcal{O}(p\,\mathrm{Ec}_{s,i})$: (inj). □

Proposition 35.64. *Let $\mathcal{T}$ be a root tower of type (Φ, n, p_0) with a geometric realisation and a good origin immersive at level four over an integral model $\mathcal{Y}$ of a unitary Shimura datum $\mathfrak{u} = (E, \mathsf{H}, \dots)$, $\Phi = \Phi_{\mathsf{H}}$, with E Galois over $\mathbb{Q}$ with abelian Galois group. Let $c \in \mathrm{Cp}$, $2 \le B_0 \le B$, $\mathcal{X} \subseteq \mathbb{P} = \prod_{k\in K}\mathbb{P}(\mathbb{Z}^{I_k})$ a joint model of the stages (B_0, c) and (B, c), $p \in S(B_0, B)$, and $x'_r = c_1(\mathcal{O}(e'_r))$ the second-root classes on $\mathcal{X}$. Then for every irreducible component W of $\mathcal{X}_{\mathbb{F}_p}$, every $a \in \Phi$, every integer k with $1 \le k \le D$ and all $e_1, \dots, e_{D-k} \in \mathbb{Z}^K$,*

$$\deg\Big(\sum_{i=1}^{n} x'^{k}_{a,i} \cdot c_1(\mathcal{O}(e_1)) \cdots c_1(\mathcal{O}(e_{D-k})) \cap [W]\Big) = 0$$

(degree over $\mathbb{F}_p$ on the projective $\mathbb{F}_p$-scheme W of dimension D).

Proof. Fix W, a, k and $e_1, \dots, e_{D-k}$, and put $M = c_1(\mathcal{O}(e_1)) \cdots c_1(\mathcal{O}(e_{D-k}))$. By Proposition 35.65 there are a full flag $0 = \mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n = \mathcal{O}_W^n$ by subbundles and a permutation ϱ with $\mathcal{E}_i/\mathcal{E}_{i-1} \cong L_i := \mathcal{O}(e'_{(a,\varrho(i))})|_W$. The Chern character is additive along the exact sequences $0 \to \mathcal{E}_{i-1} \to \mathcal{E}_i \to L_i \to 0$, so as operators on $A_*(W)_{\mathbb{Q}}$

$$\mathrm{ch}(\mathcal{O}_W^n) = \sum_{i=1}^{n} \mathrm{ch}(L_i) = \sum_{i=1}^{n} e^{c_1(L_i)}.$$

The trivial bundle has total Chern class 1, so $\mathrm{ch}(\mathcal{O}_W^n) = n$, and comparing the parts of degree $k \ge 1$ gives $\sum_{i=1}^n c_1(L_i)^k = 0$. Since ϱ is a permutation and $c_1(L_i) \cap \alpha = c_1(\mathcal{O}(e'_{(a,\varrho(i))})) \cap \alpha$ for classes α on W,

$$\sum_{i=1}^{n} x'^{k}_{a,i} \cdot M \cap [W] = M \cap \Big(\sum_{i=1}^{n} c_1(L_i)^k \cap [W]\Big) = 0$$

in $A_0(W)_{\mathbb{Q}}$, and its degree vanishes. □

Proposition 35.65. *Let $\mathcal{T}$ be a root tower of type (Φ, n, p_0) with a geometric realisation and a good origin immersive at level four over an integral model $\mathcal{Y}$ of a unitary Shimura datum $\mathfrak{u} = (E, \mathsf{H}, \dots)$, $\Phi = \Phi_{\mathsf{H}}$, with E Galois over $\mathbb{Q}$ with abelian Galois group. Let $c \in \mathrm{Cp}$, $2 \le B_0 \le B$, $\mathcal{X} \subseteq \mathbb{P} = \prod_{k \in K} \mathbb{P}(\mathbb{Z}^{I_k})$ a joint model of the stages (B_0, c) and (B, c), and $p \in S(B_0, B)$. Then for every irreducible component W of $\mathcal{X}_{\mathbb{F}_p}$, with its reduced structure, and every $a \in \Phi$, there are a full flag $0 = \mathcal{E}_0 \subset \mathcal{E}_1 \subset \cdots \subset \mathcal{E}_n = \mathcal{O}_W^n$ of the trivial bundle of rank n on W by subbundles and a permutation ϱ of $\{1, \dots, n\}$ with*

$$\mathcal{E}_i / \mathcal{E}_{i-1} \cong \mathcal{O}(e'_{(a,\varrho(i))})\big|_W \qquad (1 \le i \le n).$$

Proof. A good origin is a tower origin, so $\mathcal{X}_1 = \mathcal{X}_{B,c}$ carries a root origin on the fixed data at c; and $p \in S(B_0, B)$ gives $p \le B$, so $p \in S_B$. Hence Proposition 35.66, applied to $\mathcal{X}_1$ with $\ell = p$ and $\tau = a$, gives a chain $0 = \mathcal{U}_{a,0} \subset \cdots \subset \mathcal{U}_{a,n} = \mathcal{O}^n_{\mathcal{X}_{1,p}}$ of locally free submodules with locally free quotients and $\mathcal{U}_{a,i}/\mathcal{U}_{a,i-1} \cong \mathcal{O}(e^1_{(a,i)})|_{\mathcal{X}_{1,p}}$, where $\mathcal{X}_{1,p} = \mathcal{X}_1 \times \operatorname{Spec} \mathbb{F}_p$. The projection pr_1 is the restriction of a projection of products of projective spaces over $\mathbb{Z}$, so it maps the reduced component W of $\mathcal{X}_{\mathbb{F}_p}$ into $\mathcal{X}_{1,p}$; let $h \colon W \to \mathcal{X}_{1,p}$ be the induced morphism. A chain of locally free submodules with locally free quotients is locally split, so its pull-back is again such a chain, with the pulled-back quotients: put $\mathcal{E}_i = h^* \mathcal{U}_{a,i}$. Then $\mathcal{E}_n = \mathcal{O}_W^n$ and

$$\mathcal{E}_i / \mathcal{E}_{i-1} \cong h^* \mathcal{O}(e^1_{(a,i)}) = \mathcal{O}(e'_{(a,i)})\big|_W,$$

because $\mathcal{O}(e'_r)$ is the pull-back of $\mathcal{O}(e^1_r)$ under the projection onto the factor $\mathbb{P}_1$ (Jm2). This is the assertion with $\varrho = \mathrm{id}$. □

Proposition 35.66. *Let $\mathfrak{u}$ be a unitary Shimura datum, $\mathcal{Y}$ an integral model of* Sh *over $\mathcal{O}_F$, and $\mathcal{T}$ a root tower of type (Φ, n, p) with a geometric realisation. Let $B \ge 2$ and $c \in \mathrm{Cp}$ be such that $\mathcal{X} = \mathcal{X}_{B,c}$ carries a root origin on fixed data at c. Let $\ell \in S_B$ and $\mathcal{X}_\ell = \mathcal{X} \times_{\operatorname{Spec} \mathbb{Z}} \operatorname{Spec} \mathbb{F}_\ell$. Then for every $\tau \in \Phi$ there is a chain*

$$0 = \mathcal{U}_{\tau,0} \subset \mathcal{U}_{\tau,1} \subset \cdots \subset \mathcal{U}_{\tau,n} = \mathcal{O}^n_{\mathcal{X}_\ell}$$

of locally free $\mathcal{O}_{\mathcal{X}_\ell}$-submodules with locally free quotients, and isomorphisms

$$\mathcal{U}_{\tau,i}/\mathcal{U}_{\tau,i-1} \cong \mathcal{O}(e_{(\tau,i)})|_{\mathcal{X}_\ell} \qquad (1 \le i \le n).$$

Proof. Let Ω, $R = R(\ell) \ge 4$, $T = G_{\mathcal{X}}(\Omega)[\ell^R]$, ω, $\rho_s \colon \mathrm{Li}^\vee \to \mathrm{Li}^\vee_s$ (restriction) and ϖ_ℓ ($= \zeta_\ell - 1$, or 4 if $\ell = 2$) be as in Proposition 35.67 and Lemma 35.32. In both cases ϖ_ℓ divides ℓ^2 in $\mathcal{O}_x$ ($\ell = \mathrm{unit} \cdot \varpi_\ell^{\ell-1}$ for odd ℓ).

Step 1: T is free of rank n over $\mathcal{O}_E/\ell^R$. The generic point of $\mathcal{X}$ lies in the abelian locus. At a complex point z of the abelian locus, $T \cong \Lambda_z/\ell^R\Lambda_z$ as $\mathcal{O}_E$-modules (all ℓ^R-torsion is rational over Ω by (Go3)(2)), and Λ_z is an $\mathcal{O}_E$-lattice with $\Lambda_z \otimes \mathbb{Q}$ an E-space of dimension $2g/[E:\mathbb{Q}] = 2|\Phi|n/(2|\Phi|) = n$. The ring $\mathcal{O}_E \otimes \mathbb{Z}_\ell$ is a finite product of discrete valuation rings and $\Lambda_z \otimes \mathbb{Z}_\ell$ is finitely generated and torsion-free over it, of rank n on every factor; so it is free of rank n, and so is T over $\mathcal{O}_E/\ell^R$. A basis gives $T \otimes_{\mathcal{O}_E,\tau} \mathcal{O}_{\mathcal{X}_\ell} \cong \mathcal{O}^n_{\mathcal{X}_\ell}$.

Step 2: the map α_τ is well defined. (i) For $y \in T$ and a point x over ℓ, a Hodge–Tate value at x (it exists, Lemma 31.30(1)) is the differential along the unit section of a regular function φ on a neighbourhood $\mathcal{W}$ of the unit point over x with $\varphi(h) = e_{\ell^R}(y, h)$ for all geometric ℓ^R-torsion

points h; the condition does not depend on x, so $d\varphi$ is a section of ω near x whose germ at every nearby point over ℓ is a Hodge–Tate value. By the uniqueness modulo $\ell^R\omega_x$ in Lemma 31.30(1) these local sections glue in $\omega/\ell^R\omega$ (which vanishes off the fibre over ℓ) to $\bar w_y$; $y\mapsto\bar w_y$ is additive ($e_{\ell^R}(y+y',\cdot)=e_{\ell^R}(y,\cdot)e_{\ell^R}(y',\cdot)$ and $d(\varphi\varphi')/(\varphi\varphi')=d\varphi/\varphi+d\varphi'/\varphi'$ along the unit section, where $\varphi=\varphi'=1$). (ii) By (Go3)(2), ht_x is free of rank g at every x over ℓ, so Lemma 35.32(1) gives $\varpi_\ell\omega_x\subseteq\mathrm{ht}_x$, hence $\ell^R\rho_s(\omega_x)\subseteq\ell^{R-2}\rho_s(\mathrm{ht}_x)$. By (Go3)(2) again $\rho_{(\tau,-)}(\mathrm{ht}_x)$ is free of rank q, and $\mathcal V_{(\tau,-),x}=\mathrm{HT}'_{(\tau,-),x}$ is its dual, so $\rho_{(\tau,-)}(\mathrm{ht}_x)=\mathcal V^\vee_{(\tau,-),x}$. Hence $\rho_{(\tau,-)}(\bar w_y)$ is a well-defined section of $\mathcal V^\vee_{(\tau,-)}/\ell^{R-2}\mathcal V^\vee_{(\tau,-)}$ near $\mathcal X_\ell$, and its class modulo ℓ is a section of $\mathcal V^\vee_{(\tau,-)}|_{\mathcal X_\ell}$ ($R-2\ge1$). (iii) τ-linearity: by the Rosati condition $e_{\ell^R}(\iota(a)y,h)=e_{\ell^R}(y,\iota(\bar a)h)$, so $\varphi_{\iota(a)y}=\varphi_y\circ\iota(\bar a)$ and $\bar w_{\iota(a)y}=\iota(\bar a)^*\bar w_y$, where $\iota(\bar a)^*$ is the transpose of the action on Lie. On $\mathrm{Li}_{(\tau,-)}$, $\bar a$ acts by $\sigma_{(\tau,-)}(\bar a)=\bar\tau(\bar a)=\tau(a)$; so $\rho_{(\tau,-)}(\bar w_{\iota(a)y})=\tau(a)\rho_{(\tau,-)}(\bar w_y)$, and $y\otimes1\mapsto\rho_{(\tau,-)}(\bar w_y)\bmod\ell$ extends to an $\mathcal O_{\mathcal X_\ell}$-linear map $\alpha_\tau\colon T\otimes_{\mathcal O_E,\tau}\mathcal O_{\mathcal X_\ell}\to\mathcal V^\vee_{(\tau,-)}|_{\mathcal X_\ell}$.

Step 3: α_τ is surjective, with locally free kernel of rank p. At x over ℓ, $\mathrm{ht}_x=\sum_y\mathcal O_x w_y+\ell^R\omega_x$ (Lemma 31.30(1)), so

$$\rho_{(\tau,-)}(\mathrm{ht}_x)=\sum_y\mathcal O_x\rho_{(\tau,-)}(w_y)+\ell^R\rho_{(\tau,-)}(\omega_x)\subseteq\sum_y\mathcal O_x\rho_{(\tau,-)}(w_y)+\ell\,\rho_{(\tau,-)}(\mathrm{ht}_x)$$

by Step 2(ii); modulo ℓ the classes of the $\rho_{(\tau,-)}(w_y)$ generate. So α_τ is a surjection from a free $\mathcal O_{\mathcal X_\ell}$-module of rank n (Step 1) onto a locally free one of rank q; locally it splits, and its kernel $\mathcal K_\tau$ is locally free of rank $n-q=p$ with

$$0\to\mathcal K_\tau\to\mathcal O^n_{\mathcal X_\ell}\xrightarrow{\alpha_\tau}\mathcal V^\vee_{(\tau,-)}|_{\mathcal X_\ell}\to0$$

exact and locally split. By Proposition 35.67, $\mathcal K_\tau\cong\mathcal V_{(\tau,+)}|_{\mathcal X_\ell}$.

Step 4: the flag. Let $(\mathcal V_{s,k})_k$ be the integral flag of (Go3)(3); its step quotients are invertible, so the filtrations are locally split and restrict to full flags of $\mathcal V_s|_{\mathcal X_\ell}$ with step quotients $(\mathcal V_{s,k}/\mathcal V_{s,k-1})|_{\mathcal X_\ell}$. Fix an isomorphism $\theta\colon\mathcal V_{(\tau,+)}|_{\mathcal X_\ell}\to\mathcal K_\tau$. Put $\mathcal U_{\tau,i}=\theta(\mathcal V_{(\tau,+),i}|_{\mathcal X_\ell})$ for $0\le i\le p$, and for $p<i\le n$, with $j=i-p$, let $\mathcal U_{\tau,i}$ be the preimage under α_τ of $\big(\mathcal V_{(\tau,-)}/\mathcal V_{(\tau,-),q-j}\big)^\vee|_{\mathcal X_\ell}\subseteq\mathcal V^\vee_{(\tau,-)}|_{\mathcal X_\ell}$ (the dual flag). Then $\mathcal U_{\tau,p}=\mathcal K_\tau$, $\mathcal U_{\tau,n}=\mathcal O^n$, all $\mathcal U_{\tau,i}$ are locally free with locally free quotients (extensions of locally split filtrations), and

$$\mathcal U_{\tau,i}/\mathcal U_{\tau,i-1}\cong\begin{cases}(\mathcal V_{(\tau,+),i}/\mathcal V_{(\tau,+),i-1})|_{\mathcal X_\ell}, & i\le p,\\ \big(\mathcal V_{(\tau,-),q+1-j}/\mathcal V_{(\tau,-),q-j}\big)^\vee|_{\mathcal X_\ell}, & i=p+j>p.\end{cases}$$

For $i\le p$ the root (τ,i) has label $(\tau,+)$, step i, sign 1; for $i=p+j>p$ it has label $(\tau,-)$, step $n+1-i=q+1-j$, sign -1 (Fh3). So in both cases $\mathcal U_{\tau,i}/\mathcal U_{\tau,i-1}\cong\mathcal L_{(\tau,i)}|_{\mathcal X_\ell}$, and the root sections of (Go3)(3) give $\mathcal L_{(\tau,i)}\cong\mathcal O(e_{(\tau,i)})|_{\mathcal X}$. This is the asserted chain. □

Proposition 35.67. *Let $\mathfrak u$, $\mathcal Y$, $\mathcal T$, B, c and $\mathcal X=\mathcal X_{B,c}$ with a root origin on fixed data at c be as in Proposition 35.66; let Ω be the function field of $\mathcal X$, $\ell\in S_B$, $R=R(\ell)$, $T=G_{\mathcal X}(\Omega)[\ell^R]$ (an $\mathcal O_E/\ell^R$-module through ι), $\mathcal X_\ell=\mathcal X\times\operatorname{Spec}\mathbb F_\ell$, and $\tau\in\Phi$. For $y\in T$ let $\bar w_y$ be the global section of $\omega/\ell^R\omega$ (ω the dual of $\mathrm{Lie}(G_{\mathcal X})$) whose germ at every point over ℓ is the class of the Hodge–Tate values of y, and let $\alpha_\tau\colon T\otimes_{\mathcal O_E,\tau}\mathcal O_{\mathcal X_\ell}\to\mathcal V^\vee_{(\tau,-)}|_{\mathcal X_\ell}$ be the $\mathcal O_{\mathcal X_\ell}$-linear map $y\otimes1\mapsto$ the class of the restriction of $\bar w_y$ to $\mathrm{Li}_{(\tau,-)}$. Then the kernel of α_τ is isomorphic, as an $\mathcal O_{\mathcal X_\ell}$-module, to $\mathcal V_{(\tau,+)}|_{\mathcal X_\ell}$.*

Proof. Write $N=\ell^R$, $\varpi=\varpi_\ell$, $s_\pm=(\tau,\pm)$, $\langle w,f\rangle=w(f)$ for $w\in\mathrm{Li}^\vee$, $f\in\mathrm{Li}$, and $\mathcal V_\pm=\mathcal V_{s_\pm}$. Let $\mathcal S=\mathbb Z\smallsetminus\ell\mathbb Z$; every $s\in\mathcal S$ is a unit in $\mathcal O_x$ for x over ℓ ($as+b\ell=1$), so τ and $\bar\tau$ map $\mathcal S^{-1}\mathcal O_E$ into $\mathcal O_x$. By $\bar w_{\iota(a)y}=\iota(\bar a)^*\bar w_y$ (if ϕ is a function for y, then $\phi\circ\iota(\bar a)$ is one for $\iota(a)y$, by

the Rosati condition) and since $\iota(\bar a)$ acts on Li_{s_+} by $\tau(\bar a)=\bar\tau(a)$ and on Li_{s_-} by $\bar\tau(\bar a)=\tau(a)$: $\rho_{s_-}(\bar w_{\iota(a)y})=\tau(a)\rho_{s_-}(\bar w_y)$ and $\rho_{s_+}(\bar w_{\iota(a)y})=\bar\tau(a)\rho_{s_+}(\bar w_y)$.

Step 1: lattices at a point x over ℓ. (a) $\mathrm{HT}'_{s,x}=\{f\in\mathrm{Li}_s:\langle\rho_s(\mathrm{ht}_x),f\rangle\subseteq\mathcal{O}_x\}$ is the dual of the free module $\rho_s(\mathrm{ht}_x)$, so $\rho_s(\mathrm{ht}_x)=(\mathrm{HT}'_{s,x})^\vee$; in particular $\rho_{s_-}(\mathrm{ht}_x)=\mathcal{V}^\vee_{-,x}$. (b) By Lemma 35.32(1),(2): $\varpi\omega_x\subseteq\mathrm{ht}_x$ and $\varpi\mathrm{HT}'_{s,x}\subseteq\mathrm{dR}_{s,x}\subseteq\mathrm{Lie}_x$, so $\langle\omega_x,\mathrm{HT}'_{s,x}\rangle\subseteq\varpi^{-1}\mathcal{O}_x$ and $\rho_s(\omega_x)\subseteq\varpi^{-1}\rho_s(\mathrm{ht}_x)$. Since $R\geq 4$ and $\varpi\mid\ell^2$, $N\varpi^{-1}\in\ell^{R-2}\mathcal{O}_x\subseteq\ell\mathcal{O}_x$. (c) $\mathcal{S}^{-1}\mathcal{O}_E$ is a semilocal Dedekind domain, hence a principal ideal domain; choose $\delta_0\in\mathfrak{d}_E$ with $\delta_0\mathcal{S}^{-1}\mathcal{O}_E=\mathfrak{d}_E\mathcal{S}^{-1}\mathcal{O}_E$. Then $\mathcal{V}_{+,x}=\tau(\delta_0)^{-1}\mathrm{HT}'_{s_+,x}$: if $f\in\mathcal{V}_{+,x}$ then $\tau(\delta_0)f\in\mathrm{HT}'_{s_+,x}$ as $\delta_0\in\mathfrak{d}_E$; if $\tau(\delta_0)f\in\mathrm{HT}'_{s_+,x}$ and $d\in\mathfrak{d}_E$, then $d=\delta_0 a$ with $a\in\mathcal{S}^{-1}\mathcal{O}_E$ and $\tau(d)f=\tau(a)\tau(\delta_0)f\in\mathrm{HT}'_{s_+,x}$. So multiplication by $\tau(\delta_0)$ is an isomorphism $\mu\colon\mathcal{V}_{+,x}\to\mathrm{HT}'_{s_+,x}$.

Step 2: the normalised hermitian pairing. Let (ε_m) be a $\mathbb{Z}$-basis of $\mathcal{O}_E$ and $(\varepsilon_m^\vee)$ the trace-dual basis of $\mathfrak{d}_E^{-1}$. For every embedding σ of E, $\sum_m\sigma(\varepsilon_m)\sigma'(\varepsilon_m^\vee)=\delta_{\sigma\sigma'}$ (the matrices $(\sigma(\varepsilon_m))_{\sigma,m}$ and $(\sigma(\varepsilon_m^\vee))_{\sigma,m}$ satisfy $X^tY=1$, hence $YX^t=1$); so $\sum_m\varepsilon_m\varepsilon_m^\vee=1$. Let M be T_ℓ with e, or T with e_N read in $\mathbb{Z}/N$ through ζ_{ℓ^R} (the reduction of e); $A'=\mathbb{Z}_\ell$, resp. $\mathbb{Z}/N$. (i) M is free of rank n over $\mathcal{O}_E\otimes A'$: $H_1(G_{\mathcal{X}}(\mathbb{C}),\mathbb{Q})$ is an E-vector space of dimension $2g/[E:\mathbb{Q}]=n$, so $T_\ell\otimes\mathbb{Q}$ is free of rank n over $E\otimes\mathbb{Q}_\ell$; T_ℓ is finitely generated and torsion free over $\mathcal{O}_E\otimes\mathbb{Z}_\ell$, a finite product of discrete valuation rings, hence free of rank n; and $T=T_\ell/N$. (ii) Put $\langle y,y'\rangle_E=\sum_m e(\varepsilon_m y,y')\varepsilon_m^\vee\in\mathfrak{d}_E^{-1}\otimes A'$. As $z=\sum_m\mathrm{Tr}(z\varepsilon_m)\varepsilon_m^\vee$ for $z\in\mathfrak{d}_E^{-1}$, $\langle y,y'\rangle_E$ is the unique element with $\mathrm{Tr}(a\langle y,y'\rangle_E)=e(ay,y')$ for all $a\in\mathcal{O}_E$; with the Rosati condition this gives $\langle ay,y'\rangle_E=a\langle y,y'\rangle_E$, $\langle y,ay'\rangle_E=\bar a\langle y,y'\rangle_E$, and $\mathrm{Tr}\langle y,y'\rangle_E=e(y,y')$. Since $\delta_0\mathfrak{d}_E^{-1}\subseteq\mathcal{S}^{-1}\mathcal{O}_E$ and $\mathcal{S}^{-1}\mathcal{O}_E\otimes A'=\mathcal{O}_E\otimes A'$, $\delta_0\langle y,y'\rangle_E\in\mathcal{O}_E\otimes A'$. (iii) For an $\mathcal{O}_E\otimes A'$-basis (u_k) of M the matrix $\Gamma=(\delta_0\langle u_j,u_k\rangle_E)_{j,k}$ is invertible. Modulo ℓ: if $y'\in M$ satisfies $\delta_0\langle y,y'\rangle_E\in\ell(\mathcal{O}_E\otimes A')$ for all y, then $\langle y,y'\rangle_E\in\ell\mathfrak{d}_E^{-1}\otimes A'$, so $e(y,y')\in\ell A'$ for all y, and $y'\in\ell M$ because the Weil pairing on $M/\ell M=G_{\mathcal{X}}(\Omega)[\ell]$ is perfect. So the injective map $c\mapsto\Gamma c$ on $(\mathcal{O}_E/\ell)^n$ (in coordinates $y'=\sum c_ku_k$ the functional is $\Gamma\bar c$) is bijective, $\det\Gamma$ is a unit modulo ℓ, hence a unit of $\mathcal{O}_E\otimes A'$. Hence there are $u_k^\#\in M$ with $\delta_0\langle u_j,u_k^\#\rangle_E=\delta_{jk}$. (iv) Let Λ be a ring with a homomorphism $\mathcal{S}^{-1}\mathcal{O}_F\to\Lambda$ (an A'-algebra), $M_\tau=M\otimes_{\mathcal{O}_E,\tau}\Lambda$, $M_{\bar\tau}=M\otimes_{\mathcal{O}_E,\bar\tau}\Lambda$, and $P_\tau(y\otimes a,y'\otimes a')=aa'\tau(\delta_0\langle y,y'\rangle_E)$, a well-defined Λ-bilinear pairing $M_\tau\times M_{\bar\tau}\to\Lambda$ by (ii) ($\tau(\bar b)=\bar\tau(b)$). The $u_k\otimes 1$ form a basis of M_τ, and $t'\mapsto(P_\tau(u_j\otimes 1,t'))_j$ is a surjection $M_{\bar\tau}\to\Lambda^n$ (it sends $u_k^\#\otimes 1$ to the k-th unit vector) between free modules of rank n, hence bijective: P_τ is perfect and $(u_k^\#\otimes 1)$ is the dual basis. Let (y_j) be an A'-basis of M and (y_j') the basis with $e(y_j,y_k')=\delta_{jk}$. Then in $M_\tau\otimes_\Lambda M_{\bar\tau}$

$$\sum_j(y_j\otimes 1)\otimes(y_j'\otimes 1)=\tau(\delta_0)\sum_k(u_k\otimes 1)\otimes(u_k^\#\otimes 1).\tag{35.5}$$

Indeed $L(t\otimes t')(t'')=P_\tau(t'',t')\,t$ defines an isomorphism $L\colon M_\tau\otimes M_{\bar\tau}\to\mathrm{End}_\Lambda(M_\tau)$ (it sends $(u_k\otimes 1)\otimes(u_i^\#\otimes 1)$ to a matrix unit), L of the right side is $\tau(\delta_0)\,\mathrm{id}$, and for $y\in M$, using $z=\sum_j e(z,y_j')y_j$,

$$L\Big(\sum_j y_j\otimes y_j'\Big)(y\otimes 1)=\sum_m\tau(\delta_0\varepsilon_m^\vee)\sum_j e(\varepsilon_m y,y_j')(y_j\otimes 1)=\sum_m\tau(\delta_0\varepsilon_m^\vee\varepsilon_m)(y\otimes 1)=\tau(\delta_0)(y\otimes 1).$$

Fix an $\mathcal{O}_E\otimes\mathbb{Z}_\ell$-basis (u_k) of T_ℓ with $(u_k^\#)$ as in (iii), and let $b_k,b_k^\#\in T$ be their images; they are as in (iii) for T.

Step 3: the map θ. For x over ℓ and $f\in\mathcal{V}_{+,x}$ put

$$\theta(f)=\sum_k\langle w_{b_k^\#},\tau(\delta_0)f\rangle\,(b_k\otimes 1)\bmod\ell\ \in T\otimes_{\mathcal{O}_E,\tau}\mathcal{O}_x/\ell,$$

with w_y a Hodge–Tate value of y at x. The coefficient lies in $\mathcal{O}_x$ ($w_y \in \mathrm{ht}_x$, $\tau(\delta_0)f \in \mathrm{HT}'_{s_+,x}$) and does not depend modulo ℓ on the choice of w_y (Lemma 31.30(1): another choice differs by $N\omega_x$, and $\langle N\omega_x, \mathrm{HT}'_{s_+,x}\rangle \subseteq N\varpi^{-1}\mathcal{O}_x \subseteq \ell\mathcal{O}_x$ by Step 1(b)). On an open set on which the sections $\bar{w}_y$ lift to sections of ω, the lifts are Hodge–Tate values at all points over ℓ, and the formula is $\mathcal{O}$-linear in f; so θ is a morphism of $\mathcal{O}_{\mathcal{X}_\ell}$-modules $\mathcal{V}_+|_{\mathcal{X}_\ell} \to T \otimes_{\mathcal{O}_E,\tau} \mathcal{O}_{\mathcal{X}_\ell}$. It is a locally split injection: let $\alpha^+ \colon T \otimes_{\mathcal{O}_E,\bar{\tau}} \mathcal{O}_{\mathcal{X}_\ell} \to (\mathrm{HT}'_{s_+})^\vee|_{\mathcal{X}_\ell}$, $y \otimes 1 \mapsto \rho_{s_+}(w_y) \bmod \ell$ (well defined by the semilinearity above and $N\rho_{s_+}(\omega_x) \subseteq \ell\rho_{s_+}(\mathrm{ht}_x)$, Step 1); it is surjective, as $\rho_{s_+}(\mathrm{ht}_x) = \sum_y \mathcal{O}_x\rho_{s_+}(w_y) + N\rho_{s_+}(\omega_x)$ (Lemma 31.30(1)), so it is a locally split surjection of locally free modules and its transpose is a locally split injection. Both sides of $P_\tau(\theta(f), y' \otimes 1) = \langle w_{y'}, \tau(\delta_0)f\rangle \bmod \ell$ are $\bar{\tau}$-semilinear in $y' \in T$ and agree at $y' = b_j^\#$; so $P_\tau(\theta(\cdot),\cdot) = {}^t\alpha^+ \circ \mu$, and θ is the composite of the isomorphism μ (Step 1(c)), the transpose of α^+, and the inverse of the isomorphism $T_\tau \to (T_{\bar{\tau}})^\vee$ given by P_τ over $\Lambda = \mathcal{O}_{\mathcal{X}_\ell}$ (Step 2(iv)). Its image is locally a direct summand of rank p.

Step 4: $\alpha_\tau \circ \theta = 0$. For x over ℓ and $f \in \mathcal{V}_{+,x}$, $\alpha_\tau(\theta(f))$ is the class modulo ℓ of

$$c_x(f) = \sum_k \langle w_{b_k^\#}, \tau(\delta_0)f\rangle\, \rho_{s_-}(w_{b_k}) \in \rho_{s_-}(\mathrm{ht}_x) = \mathcal{V}^\vee_{-,x}.$$

We show $c_x(f) \in \ell\mathcal{V}^\vee_{-,x}$. As $\mathcal{V}^\vee_{-,x}$ is free and $\ell\mathcal{O}_x = \bigcap_{\mathfrak{q}} \ell(\mathcal{O}_x)_{\mathfrak{q}}$ over the primes of height one (Matsumura 11.5 applied to c/ℓ), it suffices to check this in $(\mathcal{O}_x)_{\mathfrak{q}}$; if $\ell \notin \mathfrak{q}$ there is nothing to show. If $\ell \in \mathfrak{q}$, then $(\mathcal{O}_x)_{\mathfrak{q}} = \mathcal{O}_q$ for a point q of codimension one over ℓ generising x, a discrete valuation ring ($\mathcal{X}$ is normal); $\mathcal{V}_{+,x} \subseteq \mathcal{V}_{+,q}$, $(\mathcal{V}^\vee_{-,x})_{\mathfrak{q}} = \mathcal{V}^\vee_{-,q}$, and a Hodge–Tate value at x is one at q (the same function, and $N\omega_x \subseteq N\omega_q$). So $c_x(f) = c_q(f)$ computed at q, and it suffices to show $c_q(f) \in \ell\mathcal{V}^\vee_{-,q}$ for $f \in \mathcal{V}_{+,q}$. By Lemma 35.39 if $G_{\mathcal{X}} \times \operatorname{Spec}\mathcal{O}_q$ is an abelian scheme, and by Proposition 35.41 otherwise, there is a Hodge–Tate isotropic lift β at q, with sign ϵ. By (Iz1) and the action of $\iota(\bar{a})^*$ on $\mathrm{Li}^\vee_{s_\pm}$, $(y \otimes a) \otimes (y' \otimes a') \mapsto aa'\rho_{s_-}(\beta y) \otimes \rho_{s_+}(\beta y')$ is a well-defined map on $(T_\ell)_\tau \otimes (T_\ell)_{\bar{\tau}}$ ($\Lambda = \mathcal{O}_C$) to $\rho_{s_-}(\omega_q) \otimes_{\mathcal{O}_q} \rho_{s_+}(\omega_q) \otimes_{\mathcal{O}_q} \mathcal{O}_C$, a free $\mathcal{O}_C$-module. Applied to (35.5) for $M = T_\ell$ it gives, by (Iz3), $0 = \tau(\delta_0)\sum_k \rho_{s_-}(\beta u_k) \otimes \rho_{s_+}(\beta u_k^\#)$, hence, as $\tau(\delta_0) \neq 0$,

$$\sum_k \rho_{s_-}(\beta u_k) \otimes \rho_{s_+}(\beta u_k^\#) = 0. \tag{35.6}$$

By (Iz2), $w_{b_k} = \epsilon\beta(u_k) + N\eta_k$ and $w_{b_k^\#} = \epsilon\beta(u_k^\#) + N\eta'_k$ with $\eta_k, \eta'_k \in \omega_q \otimes \mathcal{O}_C$; in particular $\beta(u_k) \in \mathrm{ht}_q \otimes \mathcal{O}_C$. Put $f' = \tau(\delta_0)f \in \mathrm{HT}'_{s_+,q}$. Contracting (35.6) with f' in the second factor,

$$c_q(f) = N\sum_k \Big(\epsilon\langle\eta'_k, f'\rangle\, \rho_{s_-}(\beta u_k) + \langle w_{b_k^\#}, f'\rangle\, \rho_{s_-}(\eta_k)\Big).$$

By Step 1(b), $\langle\eta'_k, f'\rangle \in \varpi^{-1}\mathcal{O}_C$, $\rho_{s_-}(\beta u_k) \in \rho_{s_-}(\mathrm{ht}_q) \otimes \mathcal{O}_C$, $\langle w_{b_k^\#}, f'\rangle \in \mathcal{O}_q$ and $\rho_{s_-}(\eta_k) \in \varpi^{-1}\rho_{s_-}(\mathrm{ht}_q) \otimes \mathcal{O}_C$. So $c_q(f) \in N\varpi^{-1}(\mathcal{V}^\vee_{-,q} \otimes \mathcal{O}_C) \cap \mathcal{V}^\vee_{-,q} = N\varpi^{-1}\mathcal{V}^\vee_{-,q}$ ($\mathcal{O}_q \to \mathcal{O}_C$ is faithfully flat and $N\varpi^{-1} \in \mathcal{O}_q$), which lies in $\ell\mathcal{V}^\vee_{-,q}$ by Step 1(b).

Step 5: the kernel. The module $T \otimes_{\mathcal{O}_E,\tau} \mathcal{O}_{\mathcal{X}_\ell}$ is free of rank n (Step 2(i)), and α_τ is surjective onto the locally free module $\mathcal{V}^\vee_-|_{\mathcal{X}_\ell}$ of rank q, since $\rho_{s_-}(\mathrm{ht}_x) = \sum_y \mathcal{O}_x\rho_{s_-}(w_y) + N\rho_{s_-}(\omega_x)$ and $N\rho_{s_-}(\omega_x) \subseteq \ell\rho_{s_-}(\mathrm{ht}_x)$. So $\mathcal{K}_\tau = \ker\alpha_\tau$ is locally a direct summand, locally free of rank $n-q = p$. By Steps 3 and 4, $\theta(\mathcal{V}_+|_{\mathcal{X}_\ell}) \subseteq \mathcal{K}_\tau$, and it is locally a direct summand of $T \otimes_\tau \mathcal{O}_{\mathcal{X}_\ell}$, hence of $\mathcal{K}_\tau$ (if $F' = A_1 \oplus C_1$ and $A_1 \subseteq K_1 \subseteq F'$ then $K_1 = A_1 \oplus (K_1 \cap C_1)$), with a complement that is locally free of rank $p - p = 0$, hence zero by Nakayama. So $\theta \colon \mathcal{V}_{(\tau,+)}|_{\mathcal{X}_\ell} \to \ker\alpha_\tau$ is an isomorphism. □

Part VII
The window Sha bound

Part VII proves the window Sha bound, Theorem 36.4: every primitive character satisfies the bound of Definition 7.1 with exponent 401. It is the second of the three inputs of Part I and is used once, in the proof of the existence theorem Proposition 7.8, through the supply of hosts Proposition 9.1. At a scale x it makes the field E of the chosen host satisfy $\mathrm{V}(E; \lfloor x^{401} \rfloor, \exp(x^{\varepsilon}/2))$: the lengths of the Tate–Shafarevich groups $\mathrm{Sha}^1_\ell(E,k)$ of the Tate twists, weighted by $\log \ell$ and summed over all primes ℓ and all $1 \le k < \lfloor x^{401} \rfloor$, are at most $\exp(x^{\varepsilon}/2)$. These lengths bound the defects of the lattices in the divisor package (Theorem 13.2). For the classes in $H^1(\mathfrak{o}_E[1/\ell], \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))$ that could not be removed by twisting, Alpöge asks for "a significant weakening of Vandiver" [4]. The theorem bounds lengths and asserts no vanishing; the comparison with Vandiver's conjecture is the note's, and nothing below uses it.

The bound is proved, as it is needed, on windows only: for every window pair at a large scale the theorem provides one range $[Y, Y^2]$ of scales. The restriction comes from the prime 2 and the finitely many primes of the bad set B_ψ. There the group at the twist k is small unless k is ℓ-adically close to one of finitely many exceptional points, and at those twists only a doubly exponential bound is available; Y is chosen so that the exceptional twists that occur are small (Section 39).

For odd ℓ and a CM field E, complex conjugation splits $\mathrm{Sha}^1_\ell(E,k)$ into a plus and a minus part (Definition 36.1), and each part is bounded by the strict Tate–Shafarevich groups $\mathrm{Sha}^1_{\ell N}(\chi, k)$ of the twisted characters $\chi\chi^k_{\mathrm{cyc}}$, with χ running over the Dirichlet characters of E of one parity (Lemma 36.8); here we follow the exposition of [2]. On the minus part, $\chi(-1) = (-1)^{k+1}$, the generalised Bernoulli numbers $B_{k+1,\chi}$ are non-zero and control the groups. On the plus part they vanish, and the groups are bounded by Eisenstein congruences, whose one-character form is proved in Part VIII. The characters of the plus part are sorted, with the prime ℓ, into the cases (I)–(V) and (Z) of Definition 36.3.

Section 36 states the theorem and proves it from four bounds. Section 37 bounds the minus parts by Kolyvagin systems of Gauss sums. Section 38 proves the counts for the plus parts from the one-character bounds and from congruence numbers. Section 39 supplies the windows at 2 and at the bad primes, and Section 40 the bound for second cohomology of Tate twists, uniform in the twist, on which the windows and one count rest.

36 The window Sha bound: characters and cases

This section states the window Sha bound, Theorem 36.4, and proves it from four bounds for the field E of a Sha-host $\mathfrak{h} = (a, q, d)$ at a scale x. A Sha-host records the arithmetic part of a host: its field is a CM field contained in $\mathbb{Q}(\zeta_{N_\mathfrak{h}})$, of degree dividing $2^{a+2} o_\psi$ (Lemma 36.6). The four bounds are the bound at the prime 2 (item 1 of Proposition 39.2); the bound for the minus parts (Proposition 37.2); the bound for the plus parts at the odd primes outside the bad set B_ψ (Proposition 36.5); and the bound for the plus parts at the primes of B_ψ (Proposition 36.10), which takes as input the layer bound of item 2 of Proposition 39.2. The bounds at odd primes are polynomial in $N_\mathfrak{h} t$, apart from a multiple of $\exp(x^{4\varepsilon/5})$ at the bad primes, and the bound at 2 is $\exp(x^{4\varepsilon/5})$. At the scale x one has $\log(N_\mathfrak{h} t) \le 2x^{\varepsilon/4}$, because $\log(qd) \le x^{\varepsilon/4}$ for a window pair and $t = \lfloor x^{401} \rfloor$, so the total is at most $\exp(x^{\varepsilon}/2)$.

The plus parts are reduced to characters by Lemma 36.7: the characters are those of $X_\mathfrak{h}(\mathcal{O}, k)$, trivial on $H_\mathfrak{h}$ with $\chi(-1) = (-1)^k$, and the reduction is exact for $\ell \notin B_\psi$, because every odd

prime dividing $[E:\mathbb{Q}]$ lies in B_ψ. The bad set consists of 3 and the odd prime factors of five integers attached to ψ, so it is finite and independent of the host. Each pair (ℓ,χ) falls into one of the cases of Definition 36.3. Case (I), $\ell \notin B_\psi$ and $(\ell-1)\nmid 2e$, is the main case. A prime $\ell \notin B_\psi$ outside case (I) satisfies $\ell \le 2e+1 < \min(q,d)$, since the host is big at t, and its characters are in case (Z) if trivial, where the group vanishes (Proposition 36.9), in case (II) if of even order and in case (III) if of odd order. At the primes of B_ψ the characters are in case (II), (IV) or (V). Accordingly Proposition 36.5 combines Count I with Counts II and III and the vanishing in case (Z), and Proposition 36.10 combines Counts II, IV and V; the counts are proved in Section 38.

Definition 36.1. Let E be a CM field with maximal totally real subfield E^+ and complex conjugation $c \in \mathrm{Gal}(E/E^+)$, let ℓ be an odd prime and $k \in \mathbb{Z}$. Let E_{S_ℓ} be the maximal extension of E unramified outside the places above ℓ, so that $G_{E,S_\ell} = \mathrm{Gal}(E_{S_\ell}/E)$; it is Galois over E^+. A **lift** of c is an element $\tilde{c} \in \mathrm{Gal}(E_{S_\ell}/E^+)$ restricting to c on E. A lift acts on continuous cocycles $f\colon G_{E,S_\ell} \to \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)$ by

$$(\tilde{c}\cdot f)(g) = \chi_{\mathrm{cyc}}(\tilde{c})^{-k}\, f(\tilde{c}^{-1}g\tilde{c}),$$

and hence on $H^1(G_{E,S_\ell},\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))$. The **plus part** and the **minus part** of $\mathrm{Sha}^1_\ell(E,k)$ are

$$\mathrm{Sha}^{\pm}_\ell(E,k) = \{x \in \mathrm{Sha}^1_\ell(E,k) \;:\; \tilde{c}\cdot x = \pm(-1)^k x \text{ for every lift } \tilde{c} \text{ of } c\},$$

and $\mathrm{len}^{\pm}_\ell(E,k) \in \mathbb{N}\cup\{\infty\}$ are their lengths as $\mathbb{Z}_\ell$-modules.

For an integer $t \ge 1$ and $B \in \mathbb{R}$, the CM field E satisfies the **plus Sha bound** $\mathrm{V}^+(E;t,B)$ if $\mathrm{len}^+_\ell(E,k) < \infty$ for every odd prime ℓ and every $1 \le k < t$, and

$$\sum_{\ell \text{ odd}} \log \ell \sum_{k=1}^{t-1} \mathrm{len}^+_\ell(E,k) \le B;$$

the **minus Sha bound** $\mathrm{V}^-(E;t,B)$ is defined in the same way with len^-_ℓ. For a number field L, a prime ℓ (here $\ell = 2$ is allowed), $t \ge 1$ and $B \in \mathbb{R}$, the field L satisfies the **Sha bound at** ℓ, $\mathrm{V}_\ell(L;t,B)$, if $\mathrm{len}_\ell(L,k) < \infty$ for every $1 \le k < t$ and

$$\sum_{k=1}^{t-1} \mathrm{len}_\ell(L,k) \le B.$$

Definition 36.2. Let ℓ be a prime, $\mathcal{O}$ a coefficient ring, $N \ge 1$, χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$ (viewed as a character of $G_\mathbb{Q}$), $e \ge 0$ and $n \ge 1$ integers. Put $\Psi_{\chi,e} = \chi\,\chi^e_{\mathrm{cyc}}$. The **strict Tate–Shafarevich group** of (χ,e) away from n is

$$\mathrm{Sha}^1_n(\chi,e) = \ker\Big(H^1(\mathbb{Q},\mathcal{O}^\vee(\Psi^{-1}_{\chi,e})) \longrightarrow \prod_{p\mid n} H^1(\mathbb{Q}_p,\mathcal{O}^\vee(\Psi^{-1}_{\chi,e})) \times \prod_{p} H^1(I_p,\mathcal{O}^\vee(\Psi^{-1}_{\chi,e}))\Big),$$

the classes that are unramified at every prime and locally trivial at the primes dividing n. Its **length** is $\mathrm{length}_\mathcal{O}\,\mathrm{Sha}^1_n(\chi,e) \in \mathbb{N}\cup\{\infty\}$, and the **normalised length**

$$\nu_\mathcal{O}(\chi,e) = \mathrm{length}_\mathcal{O}\,\mathrm{Sha}^1_{\ell N}(\chi,e)\,/\,e_\mathcal{O}$$

(taken with ℓN, and meaningful when the length is finite). For a subgroup $H \le (\mathbb{Z}/N\mathbb{Z})^\times$, $\mathcal{X}_\mathcal{O}(N,H)$ is the finite set of Dirichlet characters modulo N with values in $\mathcal{O}^\times$ whose kernel is exactly H.

Definition 36.3. Let $\psi \in \mathcal{P}$ have modulus N_ψ and order o_ψ. Its **auxiliary primes** are: $p_K(\psi)$, the least prime $p \geq 7$ with $p \equiv 3 \pmod 4$ and $\gcd(p, N_\psi) = 1$; $h^*(\psi)$, the class number of $\mathbb{Q}(\sqrt{-p_K(\psi)})$; and $p_1(\psi)$, the least prime p that is congruent to 1 modulo the odd part of o_ψ and prime to $2N_\psi\, p_K(\psi)$. The **bad set** B_ψ consists of 3 and the odd prime factors of $o_\psi N_\psi\, p_K(\psi)\, h^*(\psi)\, p_1(\psi)$.

A **Sha-host** of ψ is a triple $\mathfrak{h} = (a, q, d)$ with $a \geq 2$ and primes $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$, $\gcd(qd, N_\psi) = 1$. Its conductor is $N_\mathfrak{h} = \operatorname{lcm}(2^{a+2}, N_\psi)\, qd$, and $H_\mathfrak{h} \leq (\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times$ is the subgroup of the u with $u \equiv \pm 1 \pmod{2^{a+2}}$, $\psi(u) = 1$, and u a square modulo q and modulo d. The host is **big at** an integer $t \geq 1$ if $2t + 1 < \min(q, d)$ and each of $N_\psi, o_\psi, p_K(\psi), h^*(\psi), p_1(\psi)$ is smaller than $\min(q, d)$. For a coefficient ring $\mathcal{O}$ and $e \geq 0$, $X_\mathfrak{h}(\mathcal{O}, e)$ is the finite set of Dirichlet characters χ modulo $N_\mathfrak{h}$ with values in $\mathcal{O}^\times$ such that $H_\mathfrak{h} \subseteq \ker \chi$ and $\chi(-1) = (-1)^e$.

For a prime ℓ, write $\chi^{(\ell)}$ for the product of the part of χ of order prime to ℓ with the inverse of its ℓ-component. For $e \geq 1$ and $\chi \in X_\mathfrak{h}(\mathcal{O}, e)$ the **cases** are:

(I) $\ell \notin B_\psi$ and $(\ell - 1) \nmid 2e$;

(II) $e \geq 2$, the order of $\chi^{(\ell)}$ is even, and $\ell \in B_\psi$ or $(\ell - 1) \mid 2e$;

(III) $\ell \notin B_\psi$, $(\ell - 1) \mid 2e$, $\chi \neq 1$ and the order of χ is odd;

(IV) $\ell \in B_\psi$, $e \geq 2$ and the order of $\chi^{(\ell)}$ is odd;

(V) $\ell \in B_\psi$ and $e = 1$;

(Z) $\ell \notin B_\psi$, $(\ell - 1) \mid 2e$ and $\chi = 1$.

Case (V) is split by the quantity $R_1(\ell, \chi) = 16\, o_\psi(\ell N_\psi)^2\, 4^{n_0(\ell,\chi)}$ against $2^{c_2(\chi)}$, where $c_2(\chi)$ is the exponent of 2 in the conductor of the 2-component of χ, and $n_0(\ell, \chi)$ is the 2-adic valuation of $\ell^f - 1$ for f the order of ℓ modulo $\operatorname{lcm}(4, \operatorname{ord}\vartheta)$, with ϑ the part of χ of order prime to ℓ multiplied by the inverse of its 2-component.

Theorem 36.4. *Every $\psi \in \mathcal{P}$ satisfies the window Sha bound with exponent* 401.

Proof. Fix $\psi \in \mathcal{P}$, $\varepsilon \in (0, 1/52)$ and a page function e_ε. We find $J \geq 1$ and X_0 as required by the window Sha bound with exponent 401.

Plus and minus parts. Let E be a CM field, ℓ an odd prime and $k \in \mathbb{Z}$; we show $\operatorname{len}_\ell(E, k) = \operatorname{len}_\ell^+(E, k) + \operatorname{len}_\ell^-(E, k)$. The formula of Definition 36.1 defines an action of $\operatorname{Gal}(E_{S_\ell}/E^+)$ on $H^1(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))$, and the subgroup G_{E,S_ℓ} acts trivially, since conjugation by an element of a profinite group acts trivially on its cohomology (Serre, *Local fields*, Ch. VII, §5). Hence all lifts of c induce one automorphism ι, and $\iota^2 = 1$ because the square of a lift lies in G_{E,S_ℓ}. The lift $\tilde{c}$ permutes the places of E above ℓ and carries the decomposition group of a place w of E_{S_ℓ} to that of $\tilde{c}(w)$; so ι maps classes that are locally trivial at all places above ℓ to such classes and preserves $\operatorname{Sha}^1_\ell(E, k)$. Thus $\operatorname{Sha}^\pm_\ell(E, k)$ are the eigenspaces of ι on $\operatorname{Sha}^1_\ell(E, k)$ for $\pm(-1)^k$. Since ℓ is odd, 2 is invertible on the ℓ-primary group $\operatorname{Sha}^1_\ell(E, k)$; writing $x = \frac{1}{2}(x + (-1)^k \iota x) + \frac{1}{2}(x - (-1)^k \iota x)$ and noting that $\iota x = (-1)^k x = -(-1)^k x$ forces $2x = 0$, we get $\operatorname{Sha}^1_\ell(E, k) = \operatorname{Sha}^+_\ell(E, k) \oplus \operatorname{Sha}^-_\ell(E, k)$, and lengths add.

Constants. All the following depend only on $(\psi, \varepsilon, e_\varepsilon)$.

- $J \geq 1$, X_1 and integers $j_\ell \geq 0$ ($\ell \in B_\psi$): given by Proposition 39.2 for $(\psi, \varepsilon, e_\varepsilon)$.
- C_-: given by Proposition 37.2 for ψ; put $K_- = 3 + |C_-| \sum_{\ell \mid o_\psi} \ell^3$.

- C_0, r_1, r_2: given by Proposition 36.5 for ψ; and for $\ell \in B_\psi$, C_ℓ: given by Proposition 36.10 for (ψ, ℓ, j_ℓ). Put $D = \max(C_0, \max_{\ell \in B_\psi} C_\ell)$ and $b = |B_\psi|$.
- $P = \max\bigl(N_\psi, o_\psi, p_K(\psi), h^*(\psi), p_1(\psi), r_1, r_2\bigr)$.
- $Y_0 \geq e$ such that $Y^{\varepsilon/5}(1+\log^2 Y) \leq Y^{\varepsilon/4}$ for $Y \geq Y_0$ (possible since $\log^2 Y = o(Y^{\varepsilon/20})$).
- $x_0 \geq 2$ such that for $x \geq x_0$: $\log(8N_\psi)+404\log x \leq x^{\varepsilon/4}$, and each of $(\log 2+bD)\exp(x^{4\varepsilon/5})$, $K_-\exp(8x^{\varepsilon/4})$, $(b+1)\exp(2Dx^{\varepsilon/4})$ is at most $\frac{1}{3}\exp(x^\varepsilon/2)$. This is possible because $\varepsilon/4 < 4\varepsilon/5 < \varepsilon$, so $x^\varepsilon/2 - x^{4\varepsilon/5} \to \infty$ and $x^\varepsilon/2 - \max(8,2D)x^{\varepsilon/4} \to \infty$.
- $X_0 \geq \max(X_1, 1)$ such that for $X \geq X_0$: $X^{1/J} \geq \max(Y_0, x_0)$ and $\exp\bigl(\frac{1}{2}X^{\varepsilon/(5J)}\bigr) > \max\bigl(2X^{401}+1,\ P\bigr)$.

The scale Y. Let $X \geq X_0$ and let (q,d) be a window pair at scale $W = X^{1/J}$. By definition $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$ are primes; $\log q > \frac{1}{2}W^{\varepsilon/5}$ and $\log d > \frac{1}{2}W^{\varepsilon/5}\log^2 W \geq \frac{1}{2}W^{\varepsilon/5}$ (as $W \geq e$), so $\min(q,d) > \max(2X^{401}+1, P)$; in particular $q, d > N_\psi$ and $\gcd(qd, N_\psi) = 1$. Also $\log(qd) \leq W^{\varepsilon/5}(1+\log^2 W) \leq W^{\varepsilon/4} = X^{\varepsilon/(4J)}$ since $W \geq Y_0$. So Proposition 39.2 gives Y with $X^{1/J} \leq Y$, $Y^2 \leq X$ and its items 1, 2 for every $x \in [Y, Y^2]$. We show that this Y has the required property.

The host at a scale x. Let $x \in [Y, Y^2]$, put $a = e_\varepsilon(x)$, $t = \lfloor x^{401} \rfloor$, $B = \exp(x^{4\varepsilon/5})$, and let E be a (ψ, a, q, d)-field. Then $x \geq W \geq x_0 \geq 2$, so $t \geq 2$ and $2^a \geq x^{2+8\varepsilon} \geq 4$, whence $a \geq 2$; therefore $\mathfrak{h} = (a, q, d)$ is a Sha-host of ψ. It is big at t: $2t+1 \leq 2x^{401}+1 \leq 2X^{401}+1 < \min(q,d)$ because $x \leq Y^2 \leq X$, and $N_\psi, o_\psi, p_K(\psi), h^*(\psi), p_1(\psi) \leq P < \min(q,d)$; moreover $r_1, r_2 < \min(q,d)$. By Lemma 36.6, E is a CM field, embeds into $\mathbb{Q}(\zeta_{N_\mathfrak{h}})$ and $n = [E:\mathbb{Q}] \leq N_\mathfrak{h}$; hence $\mathrm{cond}(E) \leq N_\mathfrak{h}$.

The four bounds.

1. The prime 2: by item 1 of Proposition 39.2, $\mathrm{V}_2(E; t, B)$.
2. Minus parts: by Proposition 37.2 ($a \geq 2$, $t \geq 2$, E CM), $\mathrm{V}^-(E; t, \beta)$ with
$$\beta = 3nt^2\log(t\,\mathrm{cond}(E)) + C_- \sum_{\ell \mid o_\psi,\ \ell \text{ odd}} \ell n^2 t^2 \log^2(t\ell\,\mathrm{cond}(E)).$$
3. Plus parts outside B_ψ: by Proposition 36.5, for every finite set S of odd primes not in B_ψ, $\mathrm{len}^+_\ell(E,k) < \infty$ ($\ell \in S$, $1 \leq k < t$) and $\sum_{\ell\in S}\log\ell\sum_{k<t}\mathrm{len}^+_\ell(E,k) \leq (N_\mathfrak{h}t)^{C_0}$.
4. Plus parts at $\ell \in B_\psi$: by item 2 of Proposition 39.2, $\mathrm{V}_\ell(\mathbb{Q}(\zeta_{\ell^{j_\ell+1}N_\psi}); t, B)$ with $B \geq 0$; so Proposition 36.10 gives $\mathrm{len}^+_\ell(E,k) < \infty$ for $1 \leq k < t$ and $\log\ell\sum_{k<t}\mathrm{len}^+_\ell(E,k) \leq (N_\mathfrak{h}t)^{C_\ell} + C_\ell B$.

By the splitting above, $\mathrm{len}_\ell(E,k) < \infty$ for every prime ℓ and $1 \leq k < t$, and for every finite set S of primes, with $U = N_\mathfrak{h}t \geq 2$,

$$\sum_{\ell\in S}\log\ell\sum_{k=1}^{t-1}\mathrm{len}_\ell(E,k) \leq B\log 2 + \beta + U^{C_0} + \sum_{\ell\in B_\psi}\bigl(U^{C_\ell} + C_\ell B\bigr) \leq (\log 2 + bD)B + \beta + (b+1)U^D.$$

As the terms are non-negative, the same bound holds for the sum over all primes.

Estimates at the scale x. Since $2^a \leq 2x^{2+8\varepsilon} \leq 2x^3$, $N_\mathfrak{h} \leq 2^{a+2}N_\psi qd$, $t \leq x^{401}$, and $\log(qd) \leq W^{\varepsilon/4} \leq x^{\varepsilon/4}$,
$$\log U \leq \log(8N_\psi) + 3\log x + \log(qd) + 401\log x \leq 2x^{\varepsilon/4},$$

by the choice of x_0. Put $w = x^{\varepsilon/4}$, so $U \le e^{2w}$. As $n \le N_{\mathfrak{h}}$, $\operatorname{cond}(E) \le N_{\mathfrak{h}}$ and $\log y \le y$ for $y \ge 1$:

$$\beta \le K_- \exp(8x^{\varepsilon/4}) \quad \text{and} \quad U^D \le \exp(2Dx^{\varepsilon/4}).$$

By the choice of x_0 the total is at most $\exp(x^{\varepsilon}/2)$. Hence E satisfies $\mathrm{V}(E; \lfloor x^{401} \rfloor, \exp(x^{\varepsilon}/2))$, for every $x \in [Y, Y^2]$ and every $(\psi, e_\varepsilon(x), q, d)$-field E. This is the window Sha bound with exponent 401 for ψ, with the constants J and X_0. □

Proposition 36.5. *Let $\psi \in \mathcal{P}$. There are an integer $C \ge 0$ and primes r_1, r_2 such that for every Sha-host $\mathfrak{h} = (a, q, d)$ of ψ with $r_1, r_2 < \min(q, d)$, every integer $t \ge 2$ at which $\mathfrak{h}$ is big, every (ψ, a, q, d)-field E and every finite set S of odd primes not in B_ψ: $\operatorname{len}_\ell^+(E, k) < \infty$ for all $\ell \in S$ and $1 \le k < t$, and*

$$\sum_{\ell \in S} \log \ell \sum_{k=1}^{t-1} \operatorname{len}_\ell^+(E, k) \le (N_{\mathfrak{h}} t)^C.$$

Proof. Let C_1, r_1, r_2 be given by Proposition 38.2 for ψ and K by Proposition 38.26 for ψ. Put $C = C_1 + 3K + 4$. Fix $\mathfrak{h}$, t, E, S as in the statement, write $N = N_{\mathfrak{h}}$, $H = H_{\mathfrak{h}}$ and $M = Nt$. Since $16 \mid N$ and $t \ge 2$, we have $M \ge 2$, $t \le M$ and $N \le M$. By Lemma 36.6, E is a CM field isomorphic to the fixed field of H in $\mathbb{Q}(\zeta_N)$, and $[E : \mathbb{Q}]$ divides $2^{a+2} o_\psi$. Since every odd prime factor of o_ψ lies in B_ψ, every $\ell \in S$ satisfies $\ell \nmid [E : \mathbb{Q}]$, and likewise ℓ does not divide the exponent of $(\mathbb{Z}/N\mathbb{Z})^\times / H$, so $\ell \nmid \operatorname{ord} \chi$ for every character χ with $H \subseteq \ker \chi$.

Reduction to characters. For each $\ell \in S$ let $\mathcal{O}_\ell$ be the ring of integers of $\mathbb{Q}_\ell(\zeta_{\varphi(N)})$ (a coefficient ring containing a primitive $\varphi(N)$-th root of unity); for the other primes choose any coefficient ring. For $\ell \in S$ and $1 \le k < t$, Lemma 36.7 (second inequality; $N \ge 2$, E is CM, $\ell \nmid [E : \mathbb{Q}]$) gives, since its set X is $X_{\mathfrak{h}}(\mathcal{O}_\ell, k)$,

$$\operatorname{len}_\ell^+(E, k) \le \sum_{\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, k)} \nu_{\mathcal{O}_\ell}(\chi, k), \tag{36.1}$$

as soon as every term on the right is finite. We show that every term is finite and bound the right-hand side summed over ℓ.

The primes outside case (I). Let $1 \le e < t$, let $\ell \in S$ be not in case (I) for e, and let $\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)$. Since $\ell \notin B_\psi$, we have $(\ell - 1) \mid 2e$, so $\ell \le 2e + 1 < 2t$; as $\mathfrak{h}$ is big at t, $\ell < 2t + 1 < \min(q, d)$, so $\ell \ne q, d$, and $\ell \nmid N_\psi$ (the odd prime factors of N_ψ lie in B_ψ); hence $\ell \nmid N$. Also $e \ge 2$: otherwise $(\ell - 1) \mid 2$ forces $\ell = 3 \in B_\psi$. We show that χ is in case (Z), (II) or (III).

- If $\chi = \mathbf{1}$, then χ is in case (Z); $\chi(-1) = 1 = (-1)^e$, so e is even, and $\ell \ge 5$ since $3 \in B_\psi$. Every class of $\mathrm{Sha}^1_{\ell N}(\mathbf{1}, e)$ satisfies the conditions defining $\mathrm{Sha}^1_\ell(\mathbf{1}, e)$ (the trivial character modulo N and modulo 1 give the same Galois character), so $\mathrm{Sha}^1_{\ell N}(\mathbf{1}, e) \subseteq \mathrm{Sha}^1_\ell(\mathbf{1}, e) = 0$ by Proposition 36.9, and $\nu_{\mathcal{O}_\ell}(\chi, e) = 0$.
- If $\chi \ne \mathbf{1}$ has odd order, χ is in case (III).
- If χ has even order: since $\ell \nmid \operatorname{ord} \chi$, the part of χ of order prime to ℓ is χ, and since $\ell \nmid N$ its component at ℓ is trivial; so $\chi^{(\ell)} = \chi$ has even order and χ is in case (II).

In cases (II) and (III), Proposition 38.26 gives that $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length and $\nu_{\mathcal{O}_\ell}(\chi, e) \log \ell \le (\ell N e)^K$. Since $1 \le \ell N e \le 2t \cdot N \cdot t = 2Mt \le M^3$ (as $2 \le M$ and $t \le M$), in all three cases

$$\nu_{\mathcal{O}_\ell}(\chi, e) \log \ell \le M^{3K}. \tag{36.2}$$

The sum for one e. Fix $1 \le e < t$ and split $S = \Lambda_e \cup \Lambda_e'$, with Λ_e the primes of S in case (I) for e. Since $r_1, r_2 < \min(q,d)$ and $\mathfrak{h}$ is big at t, Proposition 38.2 applied to Λ_e and the rings $\mathcal{O}_\ell$ gives finiteness of $\mathrm{Sha}^1_{\ell N}(\chi, e)$ for $\ell \in \Lambda_e$, $\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)$, and

$$\sum_{\ell \in \Lambda_e} \log \ell \sum_{\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)} \nu_{\mathcal{O}_\ell}(\chi, e) \le M^{C_1}.$$

The primes of Λ_e' are at most $2t$ in number (each is $< 2t$, as shown above), and each $X_{\mathfrak{h}}(\mathcal{O}_\ell, e)$ has at most $\varphi(N) \le N$ elements (a finite abelian group G has at most $|G|$ homomorphisms into the unit group of a domain). With (36.2),

$$\sum_{\ell \in \Lambda_e'} \log \ell \sum_{\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)} \nu_{\mathcal{O}_\ell}(\chi, e) \le 2t \cdot N \cdot M^{3K} = 2M^{3K+1}.$$

Conclusion. All terms on the right of (36.1) are finite, so $\mathrm{len}^+_\ell(E,k) < \infty$ for $\ell \in S$, $1 \le k < t$. Multiplying (36.1) by $\log \ell \ge 0$, summing over $\ell \in S$ and $1 \le k < t$, and exchanging the two finite sums,

$$\sum_{\ell \in S} \log \ell \sum_{k=1}^{t-1} \mathrm{len}^+_\ell(E,k) \le \sum_{e=1}^{t-1} (M^{C_1} + 2M^{3K+1}) \le t(M^{C_1} + 2M^{3K+1}) \le M^{C_1+3K+4}.$$

This is the claim, since $M^C = (N_{\mathfrak{h}} t)^C$. □

Lemma 36.6. *Let $\psi \in \mathcal{P}$, let $\mathfrak{h} = (a,q,d)$ be a Sha-host of ψ and let E be a (ψ, a, q, d)-field. Then:*

1. *E is isomorphic to the subfield of $\mathbb{Q}(\zeta_{N_{\mathfrak{h}}})$ fixed by the automorphisms $\zeta_{N_{\mathfrak{h}}} \mapsto \zeta_{N_{\mathfrak{h}}}^u$, $u \in H_{\mathfrak{h}}$; in particular E embeds into $\mathbb{Q}(\zeta_{N_{\mathfrak{h}}})$;*
2. *E is a CM field;*
3. *$[E:\mathbb{Q}] = [(\mathbb{Z}/N_{\mathfrak{h}}\mathbb{Z})^\times : H_{\mathfrak{h}}]$, this index divides $2^{a+2} o_\psi$, and $[E:\mathbb{Q}] \le N_{\mathfrak{h}}$; the exponent of $(\mathbb{Z}/N_{\mathfrak{h}}\mathbb{Z})^\times / H_{\mathfrak{h}}$ divides $2^{a+2} o_\psi$ as well.*

Proof. Put $N = N_{\mathfrak{h}} = \mathrm{lcm}(2^{a+2}, N_\psi)\, qd$ and $H = H_{\mathfrak{h}}$. Since $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod 8$, the primes q, d are distinct and odd, and $\gcd(qd, N_\psi) = 1$; hence $N = \mathrm{lcm}(2^{a+2}, N_\psi, q, d)$.

Item 1. By definition there are N' divisible by 2^{a+2}, N_ψ, q, d (hence by N) and an embedding $j\colon E \hookrightarrow \mathbb{Q}(\zeta_{N'})$ whose image is the fixed field of the set Σ of σ_b, $b \in (\mathbb{Z}/N'\mathbb{Z})^\times$, with $b \equiv \pm 1 \pmod{2^{a+2}}$, $\psi(b) = 1$ and $(b/q) = (b/d) = 1$. Each of these four conditions depends only on b modulo 2^{a+2}, N_ψ, q, d respectively, hence only on $b \bmod N$. In particular Σ is a subgroup and contains $\mathrm{Gal}(\mathbb{Q}(\zeta_{N'})/\mathbb{Q}(\zeta_N)) = \{\sigma_b : b \equiv 1 \ (N)\}$, so $j(E) \subseteq \mathbb{Q}(\zeta_N)$, and $j(E)$ is the fixed field in $\mathbb{Q}(\zeta_N)$ of the image of Σ, which is $\{\sigma_u : u \in (\mathbb{Z}/N\mathbb{Z})^\times,\ u \equiv \pm 1 \ (2^{a+2}),\ \psi(u) = 1,\ (u/q) = (u/d) = 1\}$. For the odd primes q, d the condition $(u/q) = 1$ says that u is a square modulo q (and likewise for d), so this group is $\{\sigma_u : u \in H\}$.

Item 3. By item 1 and Galois theory, $[E:\mathbb{Q}] = [(\mathbb{Z}/N\mathbb{Z})^\times : H] \le \varphi(N) \le N$. The homomorphism

$$(\mathbb{Z}/N\mathbb{Z})^\times \to (\mathbb{Z}/2^{a+2}\mathbb{Z})^\times / \{\pm 1\} \times \psi((\mathbb{Z}/N_\psi\mathbb{Z})^\times) \times \{\pm 1\} \times \{\pm 1\}, \qquad u \mapsto \big(u,\ \psi(u),\ (u/q),\ (u/d)\big),$$

has kernel H, and its target is a finite abelian group of order $2^a \cdot o_\psi \cdot 4$ and exponent dividing $2^a \cdot o_\psi \cdot 2$ (the image of ψ is cyclic of order o_ψ). So $(\mathbb{Z}/N\mathbb{Z})^\times / H$ embeds into it, and its order and its exponent divide $2^{a+2} o_\psi$.

Item 2. Identify E with $j(E) \subseteq \mathbb{Q}(\zeta_N)$. For every embedding $\mathbb{Q}(\zeta_N) \hookrightarrow \mathbb{C}$, complex conjugation induces σ_{-1}, which is central in the abelian group $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$; hence it restricts to the same automorphism $c = \sigma_{-1}|_E$ of E for every embedding of E. Since $q \equiv 3 \pmod 4$, $(-1/q) = -1$, so $-1 \notin H$ and, by item 1 and Galois theory, $c \neq \mathrm{id}_E$. The fixed field $E^+ = E^{\langle c \rangle}$ is contained in $\mathbb{Q}(\zeta_N)^{\langle \sigma_{-1} \rangle} = \mathbb{Q}(\zeta_N + \zeta_N^{-1})$, which is totally real, so E^+ is totally real; $[E : E^+] = 2$; and no embedding of E into $\mathbb{C}$ is real, since complex conjugation acts on its image as $c \neq \mathrm{id}$. Thus E is a totally imaginary quadratic extension of a totally real field, that is, a CM field. □

Lemma 36.7. *Let $N \geq 2$, let $H \leq (\mathbb{Z}/N\mathbb{Z})^\times$ be a subgroup and let E be a number field isomorphic to the subfield of $\mathbb{Q}(\zeta_N)$ fixed by the automorphisms $\zeta_N \mapsto \zeta_N^a$, $a \in H$; assume that E is a CM field. Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring containing a primitive $\varphi(N)$-th root of unity, and $k \geq 1$. Let X be the set of Dirichlet characters χ modulo N with values in $\mathcal{O}^\times$ such that $H \subseteq \ker \chi$ and $\chi(-1) = (-1)^k$. Then, in $\mathbb{N} \cup \{\infty\}$,*

$$e_{\mathcal{O}} \operatorname{len}_\ell^+(E,k) \leq \sum_{\chi \in X} \Big(\operatorname{length}_{\mathcal{O}} \operatorname{Sha}^1_{\ell N}(\chi, k) + e_{\mathcal{O}}(Nk)^6 \Big),$$

and if $\ell \nmid [E : \mathbb{Q}]$, then

$$e_{\mathcal{O}} \operatorname{len}_\ell^+(E,k) \leq \sum_{\chi \in X} \operatorname{length}_{\mathcal{O}} \operatorname{Sha}^1_{\ell N}(\chi, k).$$

Proof. This is the case of the sign $+$ in Lemma 36.8: the hypotheses are the same, and the set X is the set X^+ of that lemma, the characters χ modulo N with values in $\mathcal{O}^\times$, $H \subseteq \ker \chi$ and $\chi(-1) = (-1)^k$. □

Lemma 36.8. *Let $N \geq 2$, let $H \leq (\mathbb{Z}/N\mathbb{Z})^\times$ be a subgroup and let E be a number field isomorphic to the subfield of $\mathbb{Q}(\zeta_N)$ fixed by the automorphisms $\zeta_N \mapsto \zeta_N^a$, $a \in H$; assume that E is a CM field. Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring containing a primitive $\varphi(N)$-th root of unity, $k \geq 1$, and fix a sign $\pm$. Let $X^\pm$ be the set of Dirichlet characters χ modulo N with values in $\mathcal{O}^\times$ such that $H \subseteq \ker \chi$ and $\chi(-1) = \pm(-1)^k$. Then, in $\mathbb{N} \cup \{\infty\}$,*

$$e_{\mathcal{O}} \operatorname{len}_\ell^\pm(E,k) \leq \sum_{\chi \in X^\pm} \Big(\operatorname{length}_{\mathcal{O}} \operatorname{Sha}^1_{\ell N}(\chi, k) + e_{\mathcal{O}}(Nk)^6 \Big),$$

and if $\ell \nmid [E : \mathbb{Q}]$, then

$$e_{\mathcal{O}} \operatorname{len}_\ell^\pm(E,k) \leq \sum_{\chi \in X^\pm} \operatorname{length}_{\mathcal{O}} \operatorname{Sha}^1_{\ell N}(\chi, k).$$

Proof. Set-up. Both sides are unchanged if E is replaced by an isomorphic field, so let $E \subseteq \mathbb{Q}(\zeta_N)$ be the fixed field of $\{\sigma_u : u \in H\}$, $\sigma_u(\zeta_N) = \zeta_N^u$. Put $G = G_{\mathbb{Q}}$, let $G_E \subseteq G$ be the open normal subgroup fixing E, $\Delta = G/G_E \cong (\mathbb{Z}/N\mathbb{Z})^\times/H$ and $n = |\Delta| = [E : \mathbb{Q}] \leq \varphi(N) \leq N$. The exponent of Δ divides $\varphi(N)$, so every character of Δ takes values in the $\varphi(N)$-th roots of unity, which lie in $\mathcal{O}$ and are distinct. A Dirichlet character χ modulo N with $H \subseteq \ker \chi$ gives a character of G trivial on G_E, hence a character θ_χ of Δ; $\chi \mapsto \theta_\chi$ is a bijection onto the characters of Δ with values in $\mathcal{O}^\times$, and $\theta_\chi(c) = \chi(-1)$ for a complex conjugation $c \in G$, which acts on $\mathbb{Q}(\zeta_N)$ as σ_{-1}. Put $M = \mathcal{O}^\vee(\chi_{\mathrm{cyc}}^{-k}) = \mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)$ and, for such χ, $M_\chi = \mathcal{O}^\vee(\Psi_{\chi,k}^{-1})$: the same group, on which σ acts by $\chi(\sigma)^{-1}\chi_{\mathrm{cyc}}(\sigma)^{-k}$. On G_E the two actions agree. Both modules are divisible.

Step 1: the plus and minus parts as eigenspaces. The group G acts on $H^1(G_E, M)$ by $(\sigma \star f)(g) = \sigma\, f(\sigma^{-1} g \sigma)$ (action of σ on M); G_E acts trivially (inner automorphisms act trivially on cohomology), so this is an $\mathcal{O}$-linear action of Δ. Let $\mathrm{Sha}_{\mathcal{O}} \subseteq H^1(G_E, M)$ be the classes unramified at every place of E and trivial at every place above ℓ; $\star$ preserves it, since σ permutes the inertia and decomposition groups of G_E. Inflation from G_{E,S_ℓ} is injective with image the classes unramified outside the places above ℓ (the kernel of $G_E \to G_{E,S_\ell}$ is generated as a closed normal subgroup by the inertia groups at the other places, on which M is trivial), so $\mathrm{Sha}_{\mathcal{O}} \cong \mathrm{Sha}^1_\ell(E,k) \otimes_{\mathbb{Z}_\ell} \mathcal{O}$ ($\mathcal{O}$ is free of finite rank over $\mathbb{Z}_\ell$), compatibly with the action of a lift of complex conjugation of Definition 36.1, which is $\star$ for $\sigma = c$. Put $s = \pm(-1)^k$. Since $\mathcal{O}$ is flat, $\mathrm{Sha}^{\pm}_\ell(E,k) \otimes \mathcal{O} = \ker(c \star -s)$ on $\mathrm{Sha}_{\mathcal{O}}$, and a $\mathbb{Z}_\ell$-module P of length $\lambda \in \mathbb{N} \cup \{\infty\}$ gives $\mathrm{length}_{\mathcal{O}}(P \otimes \mathcal{O}) = e_{\mathcal{O}} \lambda$. Hence

$$e_{\mathcal{O}}\, \mathrm{len}^{\pm}_\ell(E,k) = \mathrm{length}_{\mathcal{O}} \ker(c \star -s)\big|_{\mathrm{Sha}_{\mathcal{O}}}. \tag{36.3}$$

Step 2: splitting into eigenspaces. For a character θ of Δ let $\mathrm{Sha}^{(\theta)}_{\mathcal{O}} = \{x \in \mathrm{Sha}_{\mathcal{O}} : \sigma \star x = \theta(\sigma) x \ \forall \sigma\}$. Write $\Delta = \langle a_1 \rangle \times \cdots \times \langle a_r \rangle$ with a_i of order n_i. For an $\mathcal{O}[\Delta]$-module P, $\prod_{\zeta \in \mu_{n_1}} (a_1 - \zeta) = a_1^{n_1} - 1 = 0$ on P, so $\mathrm{length}\, P \le \sum_\zeta \mathrm{length} \ker(a_1 - \zeta)$; each $\ker(a_1 - \zeta)$ is stable under Δ (abelian). Repeating with $a_2, \dots, a_r$ gives $\mathrm{length}\, P \le \sum_\theta \mathrm{length}\, P^{(\theta)}$, the sum over all characters θ of Δ. Apply this to $P = \ker(c \star -s)$: if $\theta(c) \ne s$, then on $P^{(\theta)}$ we have $(\theta(c) - s)x = 0$ with $\theta(c) - s = \pm 2$ a unit (ℓ odd), so $P^{(\theta)} = 0$; if $\theta(c) = s$, then $P^{(\theta)} = \mathrm{Sha}^{(\theta)}_{\mathcal{O}}$. With (36.3) and the bijection $\chi \mapsto \theta_\chi$,

$$e_{\mathcal{O}}\, \mathrm{len}^{\pm}_\ell(E,k) \le \sum_{\chi \in X^{\pm}} \mathrm{length}_{\mathcal{O}}\, \mathrm{Sha}^{(\theta_\chi)}_{\mathcal{O}}. \tag{36.4}$$

Step 3: one eigenspace against the strict Tate–Shafarevich group. Fix $\chi \in X^{\pm}$ and write $\theta = \theta_\chi$. For a cocycle on G_E, the action $\star_\chi$ defined with M_χ in place of M is $\sigma \star_\chi = \chi(\sigma)^{-1} \sigma \star$; so the invariants of $H^1(G_E, M_\chi)$ under $\star_\chi$ are the θ-eigenspace of $H^1(G_E, M)$. The inflation–restriction sequence

$$0 \to H^1(\Delta, M_\chi^{G_E}) \to H^1(G, M_\chi) \xrightarrow{R} H^1(G_E, M)^{(\theta)} \to H^2(\Delta, M_\chi^{G_E})$$

is exact. Let $\widetilde{\mathrm{Sha}}_\chi = R^{-1}(\mathrm{Sha}^{(\theta)}_{\mathcal{O}})$ and $S_\chi = \mathrm{Sha}^1_{\ell N}(\chi, k) \subseteq H^1(G, M_\chi)$. Then $\mathrm{Sha}^{(\theta)}_{\mathcal{O}} / R(\widetilde{\mathrm{Sha}}_\chi)$ embeds in $H^2(\Delta, M_\chi^{G_E})$. For each prime p fix a decomposition group $D_p \subseteq G$ at p with inertia group I_p, and let $\phi_p \colon \widetilde{\mathrm{Sha}}_\chi \to H^1(D_p, M_\chi)$ be the restriction. Let $y \in \widetilde{\mathrm{Sha}}_\chi$. If $p \nmid \ell N$, then $E/\mathbb{Q}$ is unramified at p (as $E \subseteq \mathbb{Q}(\zeta_N)$), so $I_p \subseteq G_E$ and $y|_{I_p} = R(y)|_{I_p} = 0$. A class of $H^1(G, M_\chi)$ restricting to zero on one inertia (decomposition) group at p restricts to zero on all of them, since conjugation acts trivially on $H^1(G, M_\chi)$. So $y \in S_\chi$ as soon as $\phi_p(y) = 0$ for every $p \mid \ell N$ (local triviality implies unramifiedness), and

$$\mathrm{length}\, \widetilde{\mathrm{Sha}}_\chi / (\widetilde{\mathrm{Sha}}_\chi \cap S_\chi) \le \sum_{p \mid \ell N} \mathrm{length}\, \phi_p(\widetilde{\mathrm{Sha}}_\chi).$$

Since $R(\widetilde{\mathrm{Sha}}_\chi)$ contains $R(\widetilde{\mathrm{Sha}}_\chi \cap S_\chi)$, of length at most $\mathrm{length}\, S_\chi$, with quotient a quotient of $\widetilde{\mathrm{Sha}}_\chi / (\widetilde{\mathrm{Sha}}_\chi \cap S_\chi)$, we obtain

$$\mathrm{length}\, \mathrm{Sha}^{(\theta)}_{\mathcal{O}} \le \mathrm{length}\, S_\chi + \mathrm{length}\, H^2(\Delta, M_\chi^{G_E}) + \sum_{p \mid \ell N} \mathrm{length}\, \phi_p(\widetilde{\mathrm{Sha}}_\chi). \tag{36.5}$$

Step 4: the error terms. Three facts are used. (F1) For a finite group Γ and a finite $\mathcal{O}[\Gamma]$-module A, evaluation embeds the i-cocycles into $A^{|\Gamma|^i}$, so $\mathrm{length}\, H^i(\Gamma, A) \le |\Gamma|^i\, \mathrm{length}\, A$; and

$H^i(\Gamma, A) = 0$ for $i \geq 1$ if $\ell \nmid |\Gamma|$, as it is then killed by $|\Gamma|$ and by a power of ℓ. (F2) For a root of unity $\zeta \neq 1$ in $\mathcal{O}$, $1-\zeta$ is a unit unless ζ has ℓ-power order, and then $v_\ell(1-\zeta) \leq 1$; so length $M[1-\zeta] = e_{\mathcal{O}} v_\ell(1-\zeta) \leq e_{\mathcal{O}}$, and $M[1-\zeta] = 0$ if the order of ζ is prime to ℓ. (F3) There is $g_0 \in I_\ell \cap G_{\mathbb{Q}(\zeta_N)}$ with $\chi_{\mathrm{cyc}}(g_0) = 1 + \ell N$: by total ramification, $\chi_{\mathrm{cyc}}(I_\ell) = \mathbb{Z}_\ell^\times$, elements of I_ℓ fix the roots of unity of order prime to ℓ, and $1 + \ell N$ fixes $\zeta_{\ell^{v_\ell(N)}}$.

(a) *The modules of invariants.* With g_0 from (F3), $g_0 \in D_\ell \cap G_E$ and g_0 acts on M_χ by $(1+\ell N)^{-k}$. The integer $u_1 = (1+\ell N)^k - 1 \geq 1$ satisfies $(1+\ell N)^{-k} - 1 = -(1+\ell N)^{-k} u_1$; if $\ell^{b_1} \| u_1$, then $M_\chi^{G_E} \subseteq M_\chi^{D_\ell \cap G_E} \subseteq M[\ell^{b_1}]$, of length $b_1 e_{\mathcal{O}}$, and $b_1 \leq \log_\ell u_1 < k \log_\ell(2\ell N) \leq k(2 + \log_2 N) \leq 3kN$.

(b) H^2. By (F1) and (a), length $H^2(\Delta, M_\chi^{G_E}) \leq n^2 \cdot 3kN e_{\mathcal{O}}$.

(c) *At ℓ.* $R(y)$ is trivial at the places of E above ℓ, so $\phi_\ell(y)$ restricts to zero on $D_\ell \cap G_E$, and $\phi_\ell(\widetilde{\mathrm{Sha}}_\chi) \subseteq H^1(D_\ell/(D_\ell \cap G_E), M_\chi^{D_\ell \cap G_E})$ (inflation–restriction). The group $D_\ell/(D_\ell \cap G_E)$ embeds in Δ; by (F1) and (a) the length is at most $n \cdot 3kN e_{\mathcal{O}}$.

(d) *At $p \mid N$, $p \neq \ell$.* Put $W_p = I_p \cap G_E$, normal in D_p, acting trivially on M_χ (χ is trivial on G_E, χ_{cyc} on I_p). As $R(y)$ is unramified above p, $\phi_p(y)$ restricts to zero on W_p, so $\phi_p(\widetilde{\mathrm{Sha}}_\chi) \subseteq H^1(D_p/W_p, M_\chi)$, and inflation–restriction for $I_p/W_p \subseteq D_p/W_p$ gives length $H^1(D_p/W_p, M_\chi) \leq$ length $H^1(D_p/I_p, M_\chi^{I_p}) +$ length $H^1(J_p, M_\chi)$, where $J_p = I_p/W_p$ is a finite abelian group (it embeds in Δ) of order dividing n, acting through χ. Here D_p/I_p is procyclic, generated by a Frobenius F_p, and $H^1(D_p/I_p, M_\chi^{I_p}) = M_\chi^{I_p}/(F_p - 1)M_\chi^{I_p}$. If χ is trivial on I_p, then $M_\chi^{I_p} = M_\chi$ and F_p acts by $\zeta p^{\mp k}$ with ζ a root of unity, which is $\neq 1$ as $k \geq 1$; multiplication by the nonzero element $\zeta p^{\mp k} - 1$ is surjective on the divisible module M_χ, so this term is 0; and $H^1(J_p, M_\chi) = \mathrm{Hom}(J_p, M)$ has length $e_{\mathcal{O}} \log_\ell |J_p|_\ell \leq e_{\mathcal{O}} \log_\ell n$, which is 0 if $\ell \nmid n$. If $\chi(j_1) = \zeta \neq 1$ for some $j_1 \in I_p$, then $M_\chi^{I_p} \subseteq M[\zeta - 1]$, so the first term has length at most $e_{\mathcal{O}}$ by (F2); for $J_1 = \langle j_1 \rangle \subseteq J_p$, $H^1(J_1, M_\chi) = \ker(\mathrm{norm})/(\zeta-1)M_\chi = 0$ (the norm is $\sum_i \zeta^i = 0$, and $(\zeta - 1)M_\chi = M_\chi$), so $H^1(J_p, M_\chi) \cong H^1(J_p/J_1, M[\zeta - 1])$ has length at most $n e_{\mathcal{O}}$ by (F1), (F2). The order of ζ divides the exponent of Δ, which divides n; so if $\ell \nmid n$, both terms vanish by (F2). In all cases length $\phi_p(\widetilde{\mathrm{Sha}}_\chi) \leq (n+1)e_{\mathcal{O}}$.

Conclusion. N has at most $\log_2 N \leq N$ prime factors. By (36.5) and (b)–(d), with $n \leq N$, $N \geq 2$, $k \geq 1$,

$$\text{length}\, \mathrm{Sha}_{\mathcal{O}}^{(\theta_\chi)} \leq \text{length}\, S_\chi + e_{\mathcal{O}}\big(3kN^3 + 3kN^2 + N(N+1)\big) \leq \text{length}\, S_\chi + e_{\mathcal{O}}(Nk)^6,$$

and (36.4) gives the first inequality. If $\ell \nmid n = [E : \mathbb{Q}]$, the terms (b), (c) vanish by (F1), and (d) vanishes as shown, so length $\mathrm{Sha}_{\mathcal{O}}^{(\theta_\chi)} \leq$ length S_χ and (36.4) gives the second inequality. □

Proposition 36.9. *Let $\ell \geq 5$ be a prime, $\mathcal{O}$ a coefficient ring and $e \geq 2$ an even integer with $(\ell - 1) \mid 2e$. Then* $\mathrm{Sha}_\ell^1(\mathbf{1}, e) = 0$.

Proof. Put $M = \mathcal{O}^\vee(\Psi_{\mathbf{1},e}^{-1}) = \mathcal{O}^\vee(\chi_{\mathrm{cyc}}^{-e})$, the group $\mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$ on which $g \in G_{\mathbb{Q}}$ acts by multiplication by $\chi_{\mathrm{cyc}}(g)^{-e} \in \mathbb{Z}_\ell^\times$. For $m \in M$ let ∂m be the coboundary $g \mapsto (\chi_{\mathrm{cyc}}(g)^{-e} - 1)m$, and let $M[\ell]$ be the subgroup killed by ℓ. A class of $\mathrm{Sha}_\ell^1(\mathbf{1}, e)$ restricts to zero in $H^1(I_p, M)$ for an inertia subgroup I_p at every prime p (the local triviality at ℓ will not be used). Conjugation by an element of $G_{\mathbb{Q}}$ induces the identity on $H^1(\mathbb{Q}, M)$ and carries restriction to I_p to restriction to the conjugate subgroup, so such a class restricts to zero on every inertia subgroup at every prime. We use three classical facts on cyclotomic fields [266]:

(a) $\chi_{\mathrm{cyc}}(I') = \mathbb{Z}_\ell^\times$ for every inertia subgroup I' at ℓ, since $\mathbb{Q}_\ell(\mu_{\ell^n})/\mathbb{Q}_\ell$ is totally ramified of degree $\varphi(\ell^n)$ for every n;

(b) χ_{cyc} is trivial on every inertia subgroup at a prime $p \neq \ell$;

(c) (Kronecker–Weber) every finite abelian extension of $\mathbb{Q}$ unramified at all primes $p \neq \ell$ is contained in $\mathbb{Q}(\mu_{\ell^n})$ for some n.

Reduction to classes killed by ℓ. A class in $H^1(\mathbb{Q}, M)$ is represented by a continuous cocycle on the compact group $G_\mathbb{Q}$ with values in the discrete torsion group M; it takes finitely many values and is therefore killed by a power of ℓ. If $\mathrm{Sha}^1_\ell(\mathbf{1}, e)$ contained a nonzero class $[z_1]$, with $n \geq 1$ minimal such that $\ell^n[z_1] = 0$, then $\ell^{n-1}[z_1]$ would be a nonzero class of the submodule $\mathrm{Sha}^1_\ell(\mathbf{1}, e)$ killed by ℓ. It therefore suffices to show that every class $[z] \in \mathrm{Sha}^1_\ell(\mathbf{1}, e)$ with $\ell[z] = 0$ is zero.

Fix such a class. Since ℓz is a coboundary, $\ell z = \partial m$ for some $m \in M$. The group M is divisible (a finite direct sum of copies of $\mathbb{Q}_\ell/\mathbb{Z}_\ell$), so $m = \ell m'$ with $m' \in M$, and $z' = z - \partial m'$ is a continuous cocycle representing $[z]$ with $\ell z'(g) = \ell z(g) - \partial m(g) = 0$ for all g. Thus z' takes values in $M[\ell]$, on which g acts by $\chi_{\mathrm{cyc}}(g)^{-e} \bmod \ell$. The local conditions give:

(i) if $p \neq \ell$ and I' is an inertia subgroup at p, then $z'|_{I'} = \partial m_{I'}|_{I'}$ for some $m_{I'} \in M$, and $\partial m_{I'}$ vanishes on I' by (b); so z' vanishes on I';

(ii) if I' is an inertia subgroup at ℓ, there is $m_{I'} \in M$ with $z'(g) = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)m_{I'}$ for all $g \in I'$.

Since $(\ell - 1) \mid 2e$, either $(\ell - 1) \mid e$, or $\frac{\ell-1}{2} \mid e$ with $e/\frac{\ell-1}{2}$ odd.

Case $(\ell - 1) \mid e$. For $u \in \mathbb{Z}_\ell^\times$ we have $u^{\ell-1} \equiv 1 \pmod{\ell}$, so $G_\mathbb{Q}$ acts trivially on $M[\ell]$ and $z' \colon G_\mathbb{Q} \to M[\ell]$ is a continuous homomorphism. By (i) it vanishes on every inertia subgroup at every prime $p \neq \ell$, so the fixed field of its kernel is a finite abelian extension of $\mathbb{Q}$ unramified outside ℓ, contained in some $\mathbb{Q}(\mu_{\ell^n})$ by (c). Hence z' is trivial on $\ker \chi_{\mathrm{cyc}}$, i.e. $z'(g)$ depends only on $\chi_{\mathrm{cyc}}(g)$. Fix an inertia subgroup I' at ℓ and $m_{I'}$ as in (ii). For $g \in G_\mathbb{Q}$ choose by (a) an element $g' \in I'$ with $\chi_{\mathrm{cyc}}(g') = \chi_{\mathrm{cyc}}(g)$; then

$$z'(g) = z'(g') = (\chi_{\mathrm{cyc}}(g')^{-e} - 1)m_{I'} = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)m_{I'}.$$

So $z' = \partial m_{I'}$ is a coboundary and $[z] = 0$.

Case $(\ell - 1) \nmid e$: the quadratic character. Here $\frac{\ell-1}{2} \mid e$ with $r = e/\frac{\ell-1}{2}$ odd; as e is even, $\frac{\ell-1}{2}$ is even, i.e. $\ell \equiv 1 \pmod 4$, and $\ell \geq 5$. Let $\eta_\ell \colon G_\mathbb{Q} \to \{\pm 1\}$ be the character of $\mathbb{Q}(\sqrt{\ell})$, $g(\sqrt{\ell}) = \eta_\ell(g)\sqrt{\ell}$. Since $\ell \equiv 1 \pmod 4$, $\sqrt{\ell} = \pm\sum_{a=1}^{\ell-1}(\frac{a}{\ell})\zeta_\ell^a$ (quadratic Gauss sum), so $\eta_\ell(g) = (\frac{u}{\ell})$ with $u = \chi_{\mathrm{cyc}}(g)$. By Euler's criterion $u^{(\ell-1)/2} \equiv (\frac{u}{\ell}) \pmod{\ell}$, hence, $-r$ being odd,

$$\chi_{\mathrm{cyc}}(g)^{-e} = \big(u^{(\ell-1)/2}\big)^{-r} \equiv \Big(\frac{u}{\ell}\Big)^{-r} = \eta_\ell(g) \pmod{\ell} \qquad (g \in G_\mathbb{Q}). \tag{36.6}$$

So g acts on $M[\ell]$ by $\eta_\ell(g)$. Let $G' = \ker \eta_\ell = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell}))$; it acts trivially on $M[\ell]$, so $f = z'|_{G'} \colon G' \to M[\ell]$ is a continuous homomorphism.

f is unramified everywhere. The inertia groups of G' at the finite places are the groups $I' \cap G'$ with I' an inertia subgroup of $G_\mathbb{Q}$. For I' at $p \neq \ell$, f vanishes on $I' \cap G'$ by (i). Let I' be at ℓ, with $m_{I'}$ as in (ii). By (a) choose $t \in I'$ such that $\chi_{\mathrm{cyc}}(t) \bmod \ell$ generates $\mathbb{F}_\ell^\times$; by (36.6), $\chi_{\mathrm{cyc}}(t)^{-e} \equiv (\frac{\chi_{\mathrm{cyc}}(t)}{\ell}) = -1 \pmod{\ell}$, so $\chi_{\mathrm{cyc}}(t)^{-e} - 1 \equiv -2$ is a unit of $\mathbb{Z}_\ell$. From $0 = \ell z'(t) = (\chi_{\mathrm{cyc}}(t)^{-e} - 1)\,\ell m_{I'}$ we get $\ell m_{I'} = 0$. For $g \in I' \cap G'$, (36.6) gives $\chi_{\mathrm{cyc}}(g)^{-e} - 1 \in \ell\mathbb{Z}_\ell$,

hence $f(g) = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)m_{I'} = 0$. Finally $\mathbb{Q}(\sqrt{\ell})$ is real; for a complex conjugation $\tau \in G'$ we have $2f(\tau) = f(\tau^2) = 0$ and $\ell f(\tau) = 0$, so $f(\tau) = 0$. Hence the fixed field of $\ker f$ is a finite abelian extension of $\mathbb{Q}(\sqrt{\ell})$ unramified at all places, with Galois group isomorphic to $f(G')$. By class field theory it lies in the Hilbert class field, so $|f(G')|$ divides the class number h of $\mathbb{Q}(\sqrt{\ell})$ [190]; and $|f(G')|$ is a power of ℓ, since $f(G') \subseteq M[\ell]$.

$\ell \nmid h$. The discriminant of $\mathbb{Q}(\sqrt{\ell})$ is ℓ, so by Minkowski's bound every ideal class contains an integral ideal of norm at most $\frac{2!}{2^2}\sqrt{\ell} = \frac{\sqrt{\ell}}{2}$ [190]. Integral ideals factor uniquely into prime ideals; above a rational prime p lie either two prime ideals of norm p, or one of norm p, or one of norm p^2; so the number of integral ideals of norm p^a is at most $a+1$, and the number of integral ideals of norm n is at most the number of divisors of n, hence at most n. Therefore

$$h \le \sum_{1 \le n \le \sqrt{\ell}/2} n \le \Big(\frac{\sqrt{\ell}}{2}\Big)^2 = \frac{\ell}{4} < \ell,$$

and $\ell \nmid h$ because ℓ is prime. So $f(G') = 0$, that is, z' vanishes on G'.

z' is a coboundary. Choose $g_0 \in G_{\mathbb{Q}}$ with $\eta_\ell(g_0) = -1$, put $m_0 = z'(g_0) \in M[\ell]$ and $m'' = \frac{\ell-1}{2} m_0 \in M[\ell]$, so that $-2m'' = m_0$. As $m'' \in M[\ell]$, $\partial m''(g) = (\eta_\ell(g) - 1)m''$ by (36.6): it vanishes on G', and equals $-2m'' = m_0$ on $g_0 G'$. On the other hand, for $h \in G'$, $z'(h) = 0$ and $z'(g_0 h) = z'(g_0) + g_0\, z'(h) = m_0$. Since $G_{\mathbb{Q}} = G' \cup g_0 G'$, we get $z' = \partial m''$ and $[z] = 0$.

In both cases every class of $\mathrm{Sha}^1_\ell(\mathbf{1}, e)$ killed by ℓ vanishes, so $\mathrm{Sha}^1_\ell(\mathbf{1}, e) = 0$. The argument uses of ℓ only that it is odd, and does not use the local triviality at ℓ. □

Proposition 36.10. *Let $\psi \in \mathcal{P}$, $\ell \in B_\psi$ and let $j \ge 0$ be an integer. There is an integer $C \ge 0$ such that for every Sha-host $\mathfrak{h} = (a, q, d)$ of ψ, every integer $t \ge 2$ at which $\mathfrak{h}$ is big, every real $B \ge 0$ such that $\mathrm{V}_\ell(\mathbb{Q}(\zeta_{\ell^{j+1}N_\psi}); t, B)$ holds, and every (ψ, a, q, d)-field E: $\mathrm{len}^+_\ell(E, k) < \infty$ for $1 \le k < t$, and*

$$\log \ell \sum_{k=1}^{t-1} \mathrm{len}^+_\ell(E, k) \le (N_{\mathfrak{h}} t)^C + C\, B.$$

Proof. Let K, C_5, C_6 be the constants of Proposition 38.26, Proposition 38.32, Proposition 38.35 for ψ, and C_4 that of Proposition 38.38 for (ψ, ℓ, j). Put $C_m = \max(K, C_5, C_6)$ and $C = C_4 + 2C_m + 9 + \ell N_\psi$. Fix $\mathfrak{h}$, t, B, E as in the statement and write $N = N_{\mathfrak{h}}$, $H = H_{\mathfrak{h}}$, $M = Nt$, $L = \log \ell$. As $16 \mid N$ and $t \ge 2$: $M \ge 3$, $t \le M$, $N \le M$, and $N_\psi \le N$.

Position of ℓ. The set B_ψ consists of odd primes, so ℓ is odd. Either $\ell = 3 < \min(q, d)$ (since $q, d > 2t + 1 \ge 5$), or ℓ divides one of $o_\psi, N_\psi, p_K(\psi), h^*(\psi), p_1(\psi)$, all smaller than $\min(q, d)$ because $\mathfrak{h}$ is big at t. Hence $\ell < \min(q, d)$, so $\ell \ne q, d$ and $\ell \le N$; and $L \le \ell$.

Characters with $\chi^{(\ell)}$ of odd order. Let $\mathcal{O}$ be the ring of integers of $\mathbb{Q}_\ell(\zeta_{\varphi(N)})$, a coefficient ring containing a primitive $\varphi(N)$-th root of unity, and let Θ be the set of Dirichlet characters χ modulo N with values in $\mathcal{O}^\times$, $H \subseteq \ker \chi$ and $\chi^{(\ell)}$ of odd order. We show $|\Theta| \le N_\psi$. Write $\chi = \prod_{p \mid N} \chi_p$ with χ_p a character of $(\mathbb{Z}/p^{v_p(N)}\mathbb{Z})^\times$. Since $v_q(N) = 1$, every $u \equiv 1 \pmod{N/q}$ that is a square modulo q lies in H (it is $\equiv 1$ modulo 2^{a+2} and N_ψ and a square modulo q and d); so χ_q is trivial on the squares and has order at most 2; likewise χ_d. Every character of $(\mathbb{Z}/2^m\mathbb{Z})^\times$ has 2-power order, so χ_2 has 2-power order. For $p \in \{2, q, d\}$ (all different from ℓ), the component at p of the part of χ of order prime to ℓ is χ_p (its order is a power of 2, prime to ℓ), and the component at p of the component of χ at ℓ is trivial; hence the component of $\chi^{(\ell)}$ at p is χ_p. As $\chi^{(\ell)}$ has odd order, so has χ_p, and therefore $\chi_2 = \chi_q = \chi_d = \mathbf{1}$. For the odd primes $p \mid N$ with $p \ne q, d$ we have $p \mid N_\psi$ and $v_p(N) = v_p(N_\psi)$. Hence χ is trivial on the units $\equiv 1$

(mod N_ψ), that is, χ is the composite of $(\mathbb{Z}/N\mathbb{Z})^\times \to (\mathbb{Z}/N_\psi\mathbb{Z})^\times$ with a character modulo N_ψ, which it determines. So $|\Theta|$ is at most the number of characters of $(\mathbb{Z}/N_\psi\mathbb{Z})^\times$ with values in the domain $\mathcal{O}$, at most $\varphi(N_\psi) \le N_\psi$.

For $\chi \in \Theta$, Proposition 38.38 (with the given j and B; $\mathfrak{h}$ is big at $t \ge 2$) gives that $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length for $1 \le e < t$ and

$$\sum_{e=1}^{t-1} \nu_{\mathcal{O}}(\chi, e) \le B + M^{C_4}. \tag{36.7}$$

The other characters. Let $1 \le e < t$ and $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e) \setminus \Theta$. If $e = 1$, then (ℓ, e) is in case (V), and Proposition 38.32 (if $R_1(\ell, \chi) \le 2^{c_2(\chi)}$) or Proposition 38.35 (otherwise) applies. If $e \ge 2$, then $\chi^{(\ell)}$ has even order and $\ell \in B_\psi$, so χ is in case (II), and Proposition 38.26 applies. In each case $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length and $\nu_{\mathcal{O}}(\chi, e)L \le (\ell N e)^{C_m} \le M^{2C_m}$, since $1 \le \ell N e \le N \cdot Nt = NM \le M^2$.

Reduction and summation. By Lemma 36.6, E is a CM field isomorphic to the fixed field of H in $\mathbb{Q}(\zeta_N)$. By the first inequality of Lemma 36.7 (with $N \ge 2$, its set X being $X_{\mathfrak{h}}(\mathcal{O}, k)$) and the finiteness just shown, for $1 \le k < t$, dividing by $e_{\mathcal{O}}$,

$$\mathrm{len}^+_\ell(E, k) \le \sum_{\chi \in X_{\mathfrak{h}}(\mathcal{O}, k)} \nu_{\mathcal{O}}(\chi, k) + |X_{\mathfrak{h}}(\mathcal{O}, k)|\,(Nk)^6 < \infty.$$

Here $|X_{\mathfrak{h}}(\mathcal{O}, k)| \le \varphi(N) \le N$ and $(Nk)^6 \le M^6$. Summing over k, splitting each $X_{\mathfrak{h}}(\mathcal{O}, k)$ into its part in Θ and the rest, and using that every pair (χ, k) with $\chi \in \Theta$ occurs at most once,

$$L \sum_{k=1}^{t-1} \mathrm{len}^+_\ell(E, k) \le L \sum_{\chi \in \Theta} \sum_{k=1}^{t-1} \nu_{\mathcal{O}}(\chi, k) + \sum_{k=1}^{t-1} N\, M^{2C_m} + L\, t\, N\, M^6.$$

By (36.7) and $|\Theta| \le N_\psi$ the first term is at most $LN_\psi(B + M^{C_4})$. Hence, with $L \le \ell \le M$, $N_\psi \le M$, $tN = M$ and $B \ge 0$,

$$L \sum_{k=1}^{t-1} \mathrm{len}^+_\ell(E, k) \le \ell N_\psi B + M^{C_4+2} + M^{2C_m+1} + M^8 \le C\, B + M^C.$$

This is the claim. □

37 The minus part

This section proves Proposition 37.2, the minus Sha bound for the (ψ, e, q, d)-fields that are CM fields, which gives the minus parts in the proof of Theorem 36.4. The bound is $3nt^2 \log(t \operatorname{cond}(E))$ plus a term from the finitely many odd primes dividing o_ψ, so it is polynomial in the degree n, the conductor and t. For an odd prime $\ell \nmid [E : \mathbb{Q}]$, the minus part at the twist k is the sum of the strict Tate–Shafarevich groups of the characters χ of E with $\chi(-1) = (-1)^{k+1}$ (Lemma 36.8). The length of each is at most the valuation of the normalised Bernoulli number $\mathrm{Ber}_{k+1}(\chi)$ (Proposition 37.4). These numbers are non-zero, and their valuations, weighted by $\log \ell$ and summed over all primes, are at most $|\mathcal{X}| \log(16N^{k+2}(k+1)!)$ for the set $\mathcal{X}$ of characters involved (Proposition 37.9). The odd primes dividing the degree are treated separately: twisted Stickelberger elements annihilate the Tate–Shafarevich groups of a cyclotomic subfield (Lemma 37.25), which gives Proposition 37.24.

The heart of the section is the Bernoulli bound Proposition 37.4, an upper bound of the kind given by the main conjecture for abelian fields [169], obtained here by the Euler system method [209] applied to Gauss sums. The Gauss sums of the primes of cyclotomic fields form an Euler system (Proposition 37.15); its Kolyvagin derivatives give Kolyvagin systems (Proposition 37.14); a Kolyvagin system bounds the normalised strict cocycles by the valuation of a twisted Stickelberger value (Proposition 37.11); and at a suitable Kolyvagin level that value is the Bernoulli number $B_{e+1,\psi}$ divided by $e+1$, up to a unit (Lemma 37.7). Stickelberger's factorisation of Gauss sums [266] enters through the norm and congruence relations of the Gauss-sum elements. The Chebotarev selection of Kolyvagin primes, the reciprocity at a Kolyvagin prime and the comparison of finite and singular parts are the usual steps of the method.

Definition 37.1. Let Ω be a field of characteristic 0, $N \geq 1$ an integer and χ a Dirichlet character modulo N with values in $\Omega^\times$ (a homomorphism $(\mathbb{Z}/N\mathbb{Z})^\times \to \Omega^\times$, extended by 0 to the non-units). Let χ^* be the primitive character inducing χ and $f \mid N$ its conductor. For an integer $k \geq 1$ the **generalised Bernoulli number** of χ^* is

$$B_{k,\chi^*} = f^{\,k-1} \sum_{a=1}^{f} \chi^*(a)\, B_k\Big(\frac{a}{f}\Big) \in \Omega,$$

where $B_k(X) \in \mathbb{Q}[X]$ is the k-th Bernoulli polynomial, and the **normalised Bernoulli number** of χ is

$$\mathrm{Ber}_k(\chi) = N \cdot (k+1)\# \cdot B_{k,\chi^*} \in \Omega, \qquad (k+1)\# = \prod_{p \leq k+1,\ p \text{ prime}} p. \tag{37.1}$$

It depends on the modulus N with which χ is given.

Proposition 37.2. *Let $\psi \in \mathcal{P}$. There is a real C such that for all integers $e \geq 2$ and $t \geq 2$, all primes $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$ with $\gcd(qd, N_\psi) = 1$, and every (ψ, e, q, d)-field E that is a CM field, with $n = [E:\mathbb{Q}]$ and $\mathrm{cond}(E)$ the least integer $N \geq 1$ such that E embeds into $\mathbb{Q}(\zeta_N)$,*

$$\mathrm{V}^-\Big(E;\ t,\ 3nt^2 \log\big(t\,\mathrm{cond}(E)\big) + C \sum_{\substack{\ell \mid o_\psi \\ \ell \text{ odd prime}}} \ell\, n^2 t^2 \log^2\big(t\ell\,\mathrm{cond}(E)\big)\Big)$$

holds.

Proof. Let $C \geq 0$ be the constant of Proposition 37.24. Fix e, t, q, d and E as in the statement, write $n = [E:\mathbb{Q}]$ and $F = \mathrm{cond}(E)$.

The field. The triple $\mathfrak{h} = (e, q, d)$ is a Sha-host of ψ ($e \geq 2$, $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$, $\gcd(qd, N_\psi) = 1$). By Lemma 36.6, E embeds into $\mathbb{Q}(\zeta_{N_\mathfrak{h}})$, so F exists, and n divides $2^{e+2} o_\psi$; hence every odd prime dividing n divides o_ψ. As E is CM, $E \neq \mathbb{Q}$ and $F \geq 3$. Fix an embedding $E \hookrightarrow \mathbb{Q}(\zeta_F)$; by Galois theory its image is the fixed field of $\{\zeta_F \mapsto \zeta_F^u : u \in H\}$ for a subgroup $H \leq (\mathbb{Z}/F\mathbb{Z})^\times$ of index n, and the exponent of $(\mathbb{Z}/F\mathbb{Z})^\times/H$ divides n.

Odd primes not dividing n. Let $\ell \nmid n$ be an odd prime and $1 \leq k < t$; let $\mathcal{O}$ be the ring of integers of $\mathbb{Q}_\ell(\zeta_{\varphi(F)})$. By the second inequality of Lemma 36.8 for the sign $-$ ($F \geq 2$, E CM, $\ell \nmid n$),

$$e_\mathcal{O}\, \mathrm{len}_\ell^-(E,k) \leq \sum_{\chi \in X^-} \mathrm{length}_\mathcal{O}\, \mathrm{Sha}^1_{\ell F}(\chi, k),$$

where X^- is the set of Dirichlet characters χ modulo F with values in $\mathcal{O}^\times$, $H \subseteq \ker\chi$ and $\chi(-1) = (-1)^{k+1}$. Every character of $(\mathbb{Z}/F\mathbb{Z})^\times/H$ with values in $\overline{\mathbb{Q}}_\ell^\times$ takes values in the $\varphi(F)$-th roots of unity, which lie in $\mathcal{O}$; so X^- is the set $\mathcal{X}_{\overline{\mathbb{Q}}_\ell}$ of Proposition 37.9 for $(F, k+1, H)$. Let

$\chi \in X^-$. The group $\mathrm{Sha}^1_{\ell F}(\chi,k)$ is contained in $\mathrm{Sha}^1_\ell(\chi,k)$ (it satisfies more local conditions). The order of χ divides the exponent of $(\mathbb{Z}/F\mathbb{Z})^\times/H$, hence n, so it is prime to ℓ. By item 1 of Proposition 37.9, $\mathrm{Ber}_{k+1}(\chi)$ is nonzero and integral over $\mathbb{Z}_\ell$; it lies in the fraction field of $\mathcal{O}$ (it is a $\mathbb{Q}$-linear combination of values of χ), hence in $\mathcal{O}$, which is integrally closed. So Proposition 37.4 applies (e there is $k \geq 1$, $\chi(-1) = (-1)^{k+1}$):

$$\mathrm{length}_{\mathcal{O}} \mathrm{Sha}^1_{\ell F}(\chi,k) \leq \mathrm{length}_{\mathcal{O}} \mathrm{Sha}^1_{\ell}(\chi,k) \leq v_{\mathcal{O}}(\mathrm{Ber}_{k+1}(\chi)) = e_{\mathcal{O}} v_\ell(\mathrm{Ber}_{k+1}(\chi)) < \infty.$$

Hence $\mathrm{len}^-_\ell(E,k) < \infty$, and with the integers $w^{(k)}_\ell$ of item 2 of Proposition 37.9 for $(F, k+1, H)$,

$$\mathrm{len}^-_\ell(E,k) \leq \sum_{\chi \in X^-} v_\ell(\mathrm{Ber}_{k+1}(\chi)) \leq w^{(k)}_\ell.$$

The complex characters of $(\mathbb{Z}/F\mathbb{Z})^\times/H$ number n, so for every finite set S of odd primes not dividing n,

$$\sum_{\ell \in S} \log \ell \, \mathrm{len}^-_\ell(E,k) \leq \sum_{\ell \in S} w^{(k)}_\ell \log \ell \leq n \log\bigl(16 F^{k+2}(k+1)!\bigr) \leq n\,(2t+5)\log(tF).$$

Summing over $1 \leq k < t$ and using $(t-1)(2t+5) = 2t^2+3t-5 \leq 3t^2$,

$$\sum_{\ell \in S} \log \ell \sum_{k=1}^{t-1} \mathrm{len}^-_\ell(E,k) \leq 3nt^2 \log(tF). \tag{37.2}$$

Odd primes dividing n. Let ℓ be an odd prime dividing n; then $\ell \mid o_\psi$. For $1 \leq k < t$, Proposition 37.24 (with $N = F$; E is CM and embeds into $\mathbb{Q}(\zeta_F)$) gives $\mathrm{len}^-_\ell(E,k) < \infty$ and, as $k+1 \leq t$, $1 \leq k\ell F \leq t\ell F$ and $C \geq 0$,

$$\mathrm{len}^-_\ell(E,k) \log \ell \leq C\,\ell\, n^2 (k+1) \log^2(k\ell F) \leq C\,\ell\, n^2\, t\, \log^2(t\ell F).$$

Summing over the $t-1 < t$ values of k, $\log \ell \sum_{k<t} \mathrm{len}^-_\ell(E,k) \leq C\ell n^2 t^2 \log^2(t\ell F)$.

Conclusion. For every odd prime ℓ and $1 \leq k < t$, $\mathrm{len}^-_\ell(E,k) < \infty$. For a finite set S of odd primes, split S into the primes not dividing n and those dividing n; by (37.2), the bound just shown, and since the odd primes dividing n divide o_ψ and all terms are non-negative,

$$\sum_{\ell \in S} \log \ell \sum_{k=1}^{t-1} \mathrm{len}^-_\ell(E,k) \leq 3nt^2 \log(tF) + C \sum_{\substack{\ell \mid o_\psi \\ \ell \text{ odd prime}}} \ell\, n^2 t^2 \log^2(t\ell F).$$

The right-hand side does not depend on S, so the same bound holds for the sum over all odd primes. This is $\mathrm{V}^-(E;t,\beta)$ with the β of the statement, since $F = \mathrm{cond}(E)$. □

Definition 37.3. Let ℓ be an odd prime and $\mathcal{O}$ a coefficient ring, with maximal ideal $\mathfrak{m}$ and normalised valuation $v_{\mathcal{O}}$ ($v_{\mathcal{O}}$ of a uniformiser is 1), extended to the fraction field of $\mathcal{O}$. Write $\mathcal{O}^\vee = \mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$, a discrete $\mathcal{O}$-module. Fix an algebraic closure $\overline{\mathbb{Q}}$, so $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$; for $N \geq 1$ let $\mu_N \subset \overline{\mathbb{Q}}$ be the N-th roots of unity and $U_N = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\mu_N))$. A **decomposition group** at a prime p is the stabiliser $D \subseteq G_{\mathbb{Q}}$ of a place of $\overline{\mathbb{Q}}$ above p; $I(D) \subseteq D$ is its inertia group, and a **Frobenius** of D is an element of D inducing $x \mapsto x^p$ on the residue field of that place. Let $\theta\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ be a continuous character, and let $\check{\theta} = \chi_{\mathrm{cyc}}\theta^{-1}$ be its **dual character** (χ_{cyc} takes values in $\mathbb{Z}_\ell^\times \subseteq \mathcal{O}^\times$).

Kolyvagin levels. A **Kolyvagin level** of θ is a pair (N_0, m) of integers with $m \geq 1$, $N_0 \geq 1$ and $\ell \nmid N_0$ such that, with $N = N_0\ell^m$ (the **modulus** of the level),

(Kv1) $\theta(u)-1\in\ell^m\mathcal{O}$ for every $u\in U_N$;

(Kv2) $\theta(g)+1\in\ell^m\mathcal{O}$ for every $g\in G_{\mathbb{Q}}$ with $g(\zeta)=\zeta^{-1}$ for all $\zeta\in\mu_N$;

(Kv3) there is $g_1\in G_{\mathbb{Q}}$ with $\theta(g_1)-\chi_{\mathrm{cyc}}(g_1)\in\mathcal{O}^\times$.

A **normaliser** for θ is an element $\delta\in G_{\mathbb{Q}}$ with $\theta(\delta)-1\in\mathcal{O}^\times$.

Normalised strict cocycles. Let δ be a normaliser for θ, Σ a finite set of primes, $a\in\mathcal{O}\backslash\{0\}$ and $n\geq 1$ an integer. Then $\mathrm{Z}_{\theta,\delta}(\Sigma,a;n)$ is the set of continuous maps $z\colon G_{\mathbb{Q}}\to\mathcal{O}^\vee$ such that

(Kd1) $z(gh)=z(g)+\theta(g)z(h)$ for all $g,h\in G_{\mathbb{Q}}$, and $z(\delta)=0$;

(Kd2) $a\,z(g)=0$ for all $g\in G_{\mathbb{Q}}$;

(Kd3) $z(g)=0$ for every g in an inertia group at a prime $p\notin\Sigma$;

(Kd4) for every prime $p\in\Sigma$ and every decomposition group D at p there is $y\in\mathcal{O}^\vee$ with $ay=0$ and $z(g)=\theta(g)y-y$ for all $g\in D$;

(Kd5) $z(g)=0$ for every g in a decomposition group at a prime dividing n.

It is an $\mathcal{O}$-submodule of the module of all maps $G_{\mathbb{Q}}\to\mathcal{O}^\vee$; we put $\mathrm{Z}_{\theta,\delta}(\Sigma,a)=\mathrm{Z}_{\theta,\delta}(\Sigma,a;1)$, and lengths are $\mathcal{O}$-lengths in $\mathbb{N}\cup\{\infty\}$.

Twisted Stickelberger values. Let $N\geq 2$ and b be integers. For $t\in(\mathbb{Z}/N\mathbb{Z})^\times$ let $\tilde{t}\in\{1,\dots,N-1\}$ be its representative and

$$h_N(b,t)=\Big\lfloor\frac{\tilde{t}\,b}{N}\Big\rfloor-\Big\lfloor\frac{(N-\tilde{t})\,b}{N}\Big\rfloor\in\mathbb{Z}.$$

A **family of lifts** modulo N is a family $\sigma=(\sigma_t)_{t\in(\mathbb{Z}/N\mathbb{Z})^\times}$ of elements of $G_{\mathbb{Q}}$ with $\sigma_t(\zeta)=\zeta^{\tilde{t}}$ for all $\zeta\in\mu_N$. The **twisted Stickelberger value** is

$$\mathrm{st}_{N,b}(\theta,\sigma)=\sum_{t\in(\mathbb{Z}/N\mathbb{Z})^\times}h_N(b,t)\,\theta(\sigma_t)^{-1}\in\mathcal{O}. \tag{37.3}$$

Proposition 37.4. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $N\geq 1$, χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$ whose order is prime to ℓ, and $e\geq 1$ an integer with $\chi(-1)=(-1)^{e+1}$. If $\mathrm{Ber}_{e+1}(\chi)\in\mathcal{O}$, then*

$$\mathrm{length}_{\mathcal{O}}\,\mathrm{Sha}^1_\ell(\chi,e)\leq v_{\mathcal{O}}(\mathrm{Ber}_{e+1}(\chi)).$$

Proof. Step 0: reduction to the primitive character. Let $\psi=\chi^*$ be the primitive character inducing χ and $f\mid N$ its conductor. If $g\in G_{\mathbb{Q}}$ acts on μ_N by $\zeta\mapsto\zeta^a$, then $\chi(g)=\chi(a)=\psi(a)=\psi(g)$; so χ and ψ are the same character of $G_{\mathbb{Q}}$, $\Psi_{\chi,e}=\Psi_{\psi,e}$, and $\mathrm{Sha}^1_\ell(\chi,e)=\mathrm{Sha}^1_\ell(\psi,e)$. Reduction $(\mathbb{Z}/N\mathbb{Z})^\times\to(\mathbb{Z}/f\mathbb{Z})^\times$ is surjective, so ψ takes values in $\mathcal{O}^\times$, its order is that of χ, prime to ℓ, and $\psi(-1)=\chi(-1)=(-1)^{e+1}$. Put $\theta=\Psi_{\psi,e}^{-1}=\psi^{-1}\chi_{\mathrm{cyc}}^{-e}$. By definition, $\mathrm{Sha}^1_\ell(\chi,e)$ is the module of classes in $H^1(G_{\mathbb{Q}},\mathcal{O}^\vee(\theta))$ that are trivial on a decomposition group at ℓ and on every inertia group, i.e. Sha_θ. By (37.1), $\mathrm{Ber}_{e+1}(\chi)=N\,(e+2)\#\,B_{e+1,\psi}$, so

$$v_{\mathcal{O}}(\mathrm{Ber}_{e+1}(\chi))=v_{\mathcal{O}}(N)+v_{\mathcal{O}}((e+2)\#)+v_{\mathcal{O}}(B_{e+1,\psi})\geq v_{\mathcal{O}}(B_{e+1,\psi}). \tag{37.4}$$

We use the following fact. (R) If $\zeta \neq 1$ is a root of unity in $\mathcal{O}$ of order n prime to ℓ, then $\zeta - 1 \in \mathcal{O}^\times$, because $X^n - 1$ is separable modulo $\mathfrak{m}$, so reduction is injective on μ_n. The values of ψ are roots of unity of order dividing the order of ψ.

Case A: $\theta(g) - \chi_{\mathrm{cyc}}(g) \in \mathfrak{m}$ for all $g \in G_{\mathbb{Q}}$. Let g lie in an inertia group at a prime $p \neq \ell$. Then $\chi_{\mathrm{cyc}}(g) = 1$, so $\psi(g)^{-1} = \theta(g) \equiv 1 \pmod{\mathfrak{m}}$, and $\psi(g) = 1$ by (R); hence $\theta(g) = 1$. By Lemma 37.6, $\mathrm{Sha}_\theta = 0$, and the bound holds because $\mathrm{Ber}_{e+1}(\chi) \in \mathcal{O}$ has $v_{\mathcal{O}} \geq 0$.

Case B: $\theta(g_1) - \chi_{\mathrm{cyc}}(g_1) \in \mathcal{O}^\times$ for some g_1. Let Σ be the set of primes dividing $f\ell$, and let $c \in G_{\mathbb{Q}}$ be a complex conjugation; it acts on every root of unity by inversion, so $\theta(c) = \psi(-1)^{-1}(-1)^{-e} = -1$ and $\theta(c) - 1 = -2$ is a unit: c is a normaliser. The hypotheses of Lemma 37.5 hold for (θ, c, Σ):

(1) for g in an inertia group at $p \notin \Sigma$: $\psi(g) = 1$, since ψ factors through $\mathrm{Gal}(\mathbb{Q}(\mu_f)/\mathbb{Q})$ and $p \nmid f$, and $\chi_{\mathrm{cyc}}(g) = 1$ as $p \neq \ell$; so $\theta(g) = 1$;

(2) let $p \in \Sigma$, $p \neq \ell$, so $p \mid f$; write $f = p^k f'$ with $p \nmid f'$ and $\psi = \psi_p \psi'$ with ψ_p modulo p^k and ψ' modulo f'; ψ_p is nontrivial since ψ is primitive. An inertia group I at p maps onto the subgroup of $(\mathbb{Z}/f\mathbb{Z})^\times \cong (\mathbb{Z}/p^k\mathbb{Z})^\times \times (\mathbb{Z}/f'\mathbb{Z})^\times$ of the classes $\equiv 1 \pmod{f'}$ (p is totally ramified in $\mathbb{Q}(\mu_{p^k})$ and unramified in $\mathbb{Q}(\mu_{f'})$); so some $g \in I$ has $\psi(g) = \psi_p(g) \neq 1$. Then $\theta(g) = \psi(g)^{-1}$ and $\theta(g) - 1 = -\psi(g)^{-1}(\psi(g) - 1)$ is a unit by (R).

Hence $\mathrm{length}_{\mathcal{O}} \mathrm{Sha}^1_\ell(\chi, e) \leq \sup_{a_0 \neq 0} \mathrm{length}_{\mathcal{O}} \mathrm{Z}_{\theta,c}(\Sigma, a_0)$. Fix $a_0 \in \mathcal{O} \setminus \{0\}$. By Lemma 37.7 (applied to ψ, e, g_1, a_0) there are $m \geq \max(1, v_\ell(f))$ and $0 \leq b < N' = N_0 \ell^m$ with $\gcd(b, N') = 1$, with N_0 the prime-to-ℓ part of f, such that (N_0, m) is a Kolyvagin level of θ; choose a family of lifts σ modulo N' (every class in $(\mathbb{Z}/N'\mathbb{Z})^\times$ is induced by an element of $G_{\mathbb{Q}}$) and write $\mathrm{st} = \mathrm{st}_{N',b}(\theta, \sigma)$; then $a_0 \,\mathrm{st} \mid \ell^m$ and $v_{\mathcal{O}}(\mathrm{st}) = v_{\mathcal{O}}(B_{e+1,\psi}) - v_{\mathcal{O}}(e+1)$. The primes dividing N' are exactly those of Σ. So Proposition 37.11 applies and gives, with (37.4),

$$\mathrm{length}_{\mathcal{O}} \mathrm{Z}_{\theta,c}(\Sigma, a_0) \leq v_{\mathcal{O}}(\mathrm{st}) \leq v_{\mathcal{O}}(B_{e+1,\psi}) \leq v_{\mathcal{O}}(\mathrm{Ber}_{e+1}(\chi)).$$

Taking the supremum over a_0 proves the proposition. □

Lemma 37.5. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $\theta\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a continuous character, δ a normaliser for θ and Σ a finite set of primes containing ℓ, such that*

1. *$\theta(g) = 1$ for every g in an inertia group at a prime $p \notin \Sigma$, and*
2. *for every prime $p \in \Sigma \setminus \{\ell\}$ and every inertia group I at p there is $g \in I$ with $\theta(g) - 1 \in \mathcal{O}^\times$.*

Let $\mathrm{Sha}_\theta \subseteq H^1(G_{\mathbb{Q}}, \mathcal{O}^\vee(\theta))$ be the submodule of classes whose restriction to every inertia group (at every prime) and to a decomposition group at ℓ is zero. Then, in $\mathbb{N} \cup \{\infty\}$,

$$\mathrm{length}_{\mathcal{O}} \mathrm{Sha}_\theta \leq \sup_{a \in \mathcal{O} \setminus \{0\}} \mathrm{length}_{\mathcal{O}} \mathrm{Z}_{\theta,\delta}(\Sigma, a).$$

Proof. For $y \in \mathcal{O}^\vee$ write ∂y for the coboundary $g \mapsto \theta(g)y - y$.

Step 1: normalised representatives. Every continuous cocycle z (for the action θ) is cohomologous to exactly one cocycle vanishing at δ: $z - \partial y$ vanishes at δ for $y = (\theta(\delta) - 1)^{-1} z(\delta)$, and a coboundary ∂y with $\partial y(\delta) = (\theta(\delta) - 1)y = 0$ has $y = 0$. So $c \mapsto z_c$, the representative of c with $z_c(\delta) = 0$, is an injective $\mathcal{O}$-linear map from $H^1(G_{\mathbb{Q}}, \mathcal{O}^\vee(\theta))$ to the module of maps $G_{\mathbb{Q}} \to \mathcal{O}^\vee$.

Step 2: each z_c, $c \in \mathrm{Sha}_\theta$, lies in some $\mathrm{Z}_{\theta,\delta}(\Sigma, a)$. Let $z = z_c$. Restriction to conjugate subgroups corresponds under conjugation, and conjugation by an element of $G_\mathbb{Q}$ acts trivially on $H^1(G_\mathbb{Q}, \mathcal{O}^\vee(\theta))$; so z restricts to a coboundary on every inertia group and on one decomposition group D_ℓ at ℓ: $z|_{D_\ell} = \partial y_\ell$. The set $z(G_\mathbb{Q})$ is finite (z is continuous into a discrete module and $G_\mathbb{Q}$ is compact), and every element of $\mathcal{O}^\vee$ is killed by a power of ℓ; let $a \neq 0$ kill y_ℓ and all values of z. Then (Kd1) and (Kd2) hold, and (Kd5) is empty for $n = 1$.

(Kd3) Let I be an inertia group at $p \notin \Sigma$. Then $z|_I = \partial y$ for some y, and $\partial y|_I = 0$ as $\theta(I) = 1$; so $z|_I = 0$.

(Kd4) at ℓ A decomposition group at ℓ is $\sigma D_\ell \sigma^{-1}$ for some $\sigma \in G_\mathbb{Q}$, and for $g \in D_\ell$, $h = \sigma g \sigma^{-1}$, one has $z(h) = \theta(h)y' - y'$ with $y' = \theta(\sigma)y_\ell - z(\sigma)$, and $ay' = 0$.

Kd4) at $p \in \Sigma$, $p \neq \ell$ Let D be a decomposition group at p and $I = I(D)$; choose $g_0 \in I$ with $\theta(g_0) - 1$ a unit (hypothesis 2). As $z|_I = \partial y$ for some y, $y = (\theta(g_0) - 1)^{-1} z(g_0)$, so $ay = 0$. For $d \in D$, $d^{-1} g_0 d \in I$ and $\theta(d^{-1} g_0 d) = \theta(g_0)$, so $z(d^{-1} g_0 d) = (\theta(g_0) - 1)y$; expanding the left side with the cocycle relation gives $(\theta(g_0) - 1)(z(d) + y) = \theta(d)(\theta(g_0) - 1)y$, hence $z(d) = \theta(d)y - y$ for all $d \in D$.

So $z \in \mathrm{Z}_{\theta,\delta}(\Sigma, a)$.

Step 3: lengths. Let π be a uniformiser. For $a = u\pi^k$ with u a unit, $\mathrm{Z}_{\theta,\delta}(\Sigma, a) = \mathrm{Z}_{\theta,\delta}(\Sigma, \pi^k)$, and these modules increase with k. By Steps 1 and 2, Sha_θ is isomorphic to its image V under $c \mapsto z_c$, and $V = \bigcup_k V_k$ with $V_k = V \cap \mathrm{Z}_{\theta,\delta}(\Sigma, \pi^k)$ increasing, $\operatorname{length} V_k \leq s$, where s is the supremum in the statement. If $s = \infty$ there is nothing to prove. Otherwise a strictly increasing chain of submodules $0 = V^{(0)} \subsetneq \cdots \subsetneq V^{(t)}$ of V gives, choosing $x_i \in V^{(i)} \setminus V^{(i-1)}$, a strictly increasing chain of the same length in the submodule generated by $x_1, \ldots, x_t$, which lies in some V_k; so $t \leq s$, and $\operatorname{length} \mathrm{Sha}_\theta = \operatorname{length} V \leq s$. □

Lemma 37.6. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring with maximal ideal $\mathfrak{m}$, and $\theta\colon G_\mathbb{Q} \to \mathcal{O}^\times$ a continuous character such that $\theta(g) - \chi_{\mathrm{cyc}}(g) \in \mathfrak{m}$ for every $g \in G_\mathbb{Q}$ and $\theta(g) = 1$ for every g in an inertia group at a prime $p \neq \ell$. Then $\mathrm{Sha}_\theta = 0$.*

Proof. A normaliser at ℓ. Let D_0 be a decomposition group at ℓ. As $\mathbb{Q}_\ell(\mu_\ell)/\mathbb{Q}_\ell$ is totally ramified of degree $\ell - 1$, $I(D_0)$ maps onto $\mathrm{Gal}(\mathbb{Q}(\mu_\ell)/\mathbb{Q})$; choose $t \in I(D_0)$ with $t(\zeta) = \zeta^{-1}$ for $\zeta \in \mu_\ell$. Then $\chi_{\mathrm{cyc}}(t) \equiv -1 \pmod{\ell}$, so $\theta(t) \equiv -1 \pmod{\mathfrak{m}}$ and $\theta(t) - 1$ is a unit (ℓ odd): t is a normaliser. By Lemma 37.5 with $\Sigma = \{\ell\}$ and $\delta = t$ (hypothesis 1 is assumed, hypothesis 2 is empty), it suffices to show $\mathrm{Z}_{\theta,t}(\{\ell\}, a) = 0$ for every $a \neq 0$.

Reduction to π-torsion. Let π be a uniformiser and $\mathrm{Z} = \mathrm{Z}_{\theta,t}(\{\ell\}, a)$, an $\mathcal{O}$-module killed by a, hence by π^k for $k = v_\mathcal{O}(a)$. It suffices to show: if $z \in \mathrm{Z}$ and $\pi z = 0$, then $z = 0$; for then $z \in \mathrm{Z}$ with $\pi^j z = 0$ gives $\pi^{j-1} z \in \mathrm{Z}$ with $\pi(\pi^{j-1} z) = 0$, so $\pi^{j-1} z = 0$, and by descending induction $z = 0$.

Kummer theory. Let $z \in \mathrm{Z}$ with $\pi z = 0$. Its values lie in $V = \{x \in \mathcal{O}^\vee : \pi x = 0\}$, a finite-dimensional vector space over $\mathcal{O}/\mathfrak{m}$, hence over $\mathbb{F}_\ell$. For $g \in G_\mathbb{Q}$ let $n_g \in \mathbb{Z}$ with $n_g \equiv \chi_{\mathrm{cyc}}(g) \pmod{\ell}$; as $\theta(g) - n_g \in \mathfrak{m}$, $\theta(g)x = n_g x$ for $x \in V$. Fix a primitive ℓ-th root of unity ζ and an $\mathbb{F}_\ell$-linear map $f\colon V \to \mathbb{F}_\ell$, and put $\psi_f(g) = \zeta^{f(z(g))}$. Since $g(\zeta) = \zeta^{n_g}$, (Kd1) gives $\psi_f(gh) = \psi_f(g)\, g(\psi_f(h))$, so ψ_f is a continuous 1-cocycle with values in $\mu_\ell \subset \overline{\mathbb{Q}}^\times$. By Hilbert's Theorem 90 there is $\beta \in \overline{\mathbb{Q}}^\times$ with $\psi_f(g) = g(\beta)/\beta$ for all g; then $A = \beta^\ell$ is fixed by $G_\mathbb{Q}$, so $A \in \mathbb{Q}^\times$.

Local conditions. By (Kd3), z vanishes on the inertia groups at every prime $p \neq \ell$. By (Kd4), $z|_{D_0} = \theta y - y$ for some y; by (Kd1), $0 = z(t) = (\theta(t) - 1)y$, so $y = 0$ and z vanishes on D_0. So for

every prime p some inertia group I at p fixes β; then β lies in the maximal unramified extension of $\mathbb{Q}_p$ inside the completion of $\overline{\mathbb{Q}}$ at the corresponding place, whose normalised valuation extends v_p with value group $\mathbb{Z}$, and $v_p(A) = \ell\, v(\beta) \in \ell\mathbb{Z}$. Hence $A = \pm C^\ell$ with $C \in \mathbb{Q}^\times$, and since ℓ is odd, $A = (\pm C)^\ell$: replacing C by $\pm C$, $A = C^\ell$. Then $\beta = \zeta^j C$ for some integer j, and $\psi_f(g) = \zeta^{j(n_g-1)}$, i.e. $f(z(g)) = j(n_g-1)$ in $\mathbb{F}_\ell$. At $g = t$: $0 = j(n_t-1)$ with $n_t - 1 \equiv -2 \not\equiv 0 \pmod{\ell}$, so $j \equiv 0$ and $f \circ z = 0$. As f was arbitrary, $z = 0$. $\square$

Lemma 37.7. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $f \geq 1$, ψ a primitive Dirichlet character modulo f with values in $\mathcal{O}^\times$, and $e \geq 1$ an integer with $\psi(-1) = (-1)^{e+1}$. Put $\theta = \psi^{-1}\chi_{\mathrm{cyc}}^{-e}$ and assume that $\theta(g_1) - \chi_{\mathrm{cyc}}(g_1) \in \mathcal{O}^\times$ for some $g_1 \in G_{\mathbb{Q}}$. Let N_0 be the prime-to-ℓ part of f. Then for every $a_0 \in \mathcal{O} \setminus \{0\}$ there are integers $m \geq \max(1, v_\ell(f))$ and b with $0 \leq b < N = N_0\ell^m$ and $\gcd(b, N) = 1$ such that (N_0, m) is a Kolyvagin level of θ and, for every family of lifts σ modulo N,*

$$v_{\mathcal{O}}\big(\mathrm{st}_{N,b}(\theta,\sigma)\big) + v_{\mathcal{O}}(e+1) = v_{\mathcal{O}}(B_{e+1,\psi}) \qquad \text{and} \qquad a_0\,\mathrm{st}_{N,b}(\theta,\sigma) \mid \ell^m \text{ in } \mathcal{O}.$$

Proof. Put $m_1 = \max(1, v_\ell(f))$ and $F = N_0\ell^{m_1}$; then $f \mid F$, $\ell \mid F$, and F and $f\ell$ have the same prime divisors. For $m \geq m_1$ put $N = N_0\ell^m = F\ell^j$ with $j = m - m_1$, and let χ be the character modulo N induced by ψ ($\chi(t) = \psi(t)$ if $\gcd(t,N) = 1$, $\chi(t) = 0$ otherwise); $\chi(t)$ depends only on t modulo F, and χ_F denotes the same character modulo F. Put $B_i^{(F)} = F^{\,i-1}\sum_{c=1}^{F}\chi_F(c)B_i(c/F)$.

Step 1: Kolyvagin levels. Let $m \geq m_1$. For $u \in U_N$: $\psi(u) = 1$ as $f \mid N$, and $\chi_{\mathrm{cyc}}(u) \equiv 1 \pmod{\ell^m}$, so $\theta(u) \equiv 1$: (Kv1). If g acts on μ_N by inversion, $\psi(g) = \psi(-1) = (-1)^{e+1}$ and $\chi_{\mathrm{cyc}}(g) \equiv -1 \pmod{\ell^m}$, so $\theta(g) \equiv (-1)^{e+1}(-1)^e = -1$: (Kv2). (Kv3) is the hypothesis. So (N_0, m) is a Kolyvagin level.

Step 2: the choice of b. Let $b \in \{1, \dots, N-1\}$ with $g_1(\zeta) = \zeta^b$ for $\zeta \in \mu_N$; $\gcd(b,N) = 1$. Then $\psi(g_1) = \psi(b)$, $\chi_{\mathrm{cyc}}(g_1) \equiv b \pmod{\ell^m}$, and $\theta(g_1) - \chi_{\mathrm{cyc}}(g_1) \equiv \psi(b)^{-1}b^{-e}(1 - \psi(b)b^{e+1}) \pmod{\ell^m}$; as $m \geq 1$, $u_b = \psi(b)b^{e+1} - 1$ is a unit.

Step 3: reduction to a Stickelberger sum. Let σ be a family of lifts modulo N. Since σ_t acts on μ_f by $\tilde{t}$ and $\chi_{\mathrm{cyc}}(\sigma_t) \equiv \tilde{t} \pmod{\ell^m}$, $\theta(\sigma_t)^{-1} = \psi(\sigma_t)\chi_{\mathrm{cyc}}(\sigma_t)^e \equiv \chi(\tilde{t})\tilde{t}^{\,e}$. As $\gcd(\tilde{t}b, N) = 1$ and $N \geq 2$, $\tilde{t}b/N \notin \mathbb{Z}$, so $\lfloor (N-\tilde{t})b/N \rfloor = b - 1 - \lfloor \tilde{t}b/N \rfloor$ and $h_N(b,t) = 2\lfloor \tilde{t}b/N \rfloor - (b-1)$. Hence, with sums over $0 \leq t < N$,

$$\mathrm{st}_{N,b}(\theta,\sigma) \equiv 2T' - (b-1)P_e \pmod{\ell^m\mathcal{O}}, \qquad T' = \sum_t \Big\lfloor \frac{bt}{N} \Big\rfloor \chi(t)t^e, \quad P_k = \sum_t \chi(t)t^k.$$

Substituting $t \mapsto N - t$ and using $\chi(-1) = (-1)^{e+1}$, $(N-t)^e \equiv (-1)^e t^e \pmod{N}$, gives $P_e \equiv -P_e \pmod{N\mathcal{O}}$; as ℓ is odd and $v_\ell(N) = m$, $v_\ell(P_e) \geq m$. So $v_\ell(\mathrm{st}_{N,b}(\theta,\sigma) - 2T') \geq m$.

Step 4: an exact identity. For $0 \leq t < N$ let $\iota(t) = \lfloor bt/N \rfloor$ and $\rho(t) = bt - N\iota(t) \in [0, N)$. Then $t \mapsto \rho(t)$ is a bijection of $\{0, \dots, N-1\}$ and $\chi(\rho(t)) = \chi(b)\chi(t)$. Expanding $\rho(t)^{e+1} = b^{e+1}t^{e+1} - (e+1)b^e t^e N\iota(t) + N^2 y_t$ with $y_t \in \mathbb{Z}$,

$$P_{e+1} = \sum_t \chi(\rho(t))\rho(t)^{e+1} = \chi(b)b^{e+1}P_{e+1} - (e+1)\chi(b)b^e N\,T' + N^2 Y, \qquad Y \in \mathcal{O},$$

so that

$$(e+1)\chi(b)b^e\,T' = u_b\,\frac{P_{e+1}}{N} + NY, \qquad u_b = \chi(b)b^{e+1} - 1. \tag{37.5}$$

Step 5: the power sum. Write $t = c + Fu$ with $1 \leq c \leq F$ and $0 \leq u < \ell^j$ (the terms $t = 0$ and $t = N$ vanish). From $\sum_{u=0}^{L-1}(X+u)^{e+1} = \frac{1}{e+2}(B_{e+2}(X+L) - B_{e+2}(X)) =$

$\frac{1}{e+2}\sum_{i=0}^{e+1}\binom{e+2}{i}B_i(X)L^{e+2-i}$ with $X = c/F$, $L = \ell^j$, multiplied by $\chi_F(c)F^{e+1}$ and summed over c,

$$\frac{P_{e+1}}{N} = B_{e+1}^{(F)} + \sum_{i=0}^{e}\frac{\binom{e+2}{i}}{e+2}N^{\,e+1-i}B_i^{(F)}.$$

For $0 \le i \le e+1$, $F^iB_i(c/F) = \sum_{r\le i}\binom{i}{r}B_rc^{i-r}F^r$ and $(i+1)\#\,B_r \in \mathbb{Z}$ for $r \le i$ by Theorem B.19 ($(i+1)\#$ the product of the primes $\le i+1$), so $F(i+1)\#B_i^{(F)}$ is integral and $v_\ell(B_i^{(F)}) \ge -v_\ell(F)-1$. Hence each term of the sum has $v_\ell \ge (j+v_\ell(F))-v_\ell(F)-1-v_\ell(e+2) = j-1-v_\ell(e+2)$, and with (37.5), as $v_\ell(N) = m \ge j$,

$$v_\ell\Big((e+1)\chi(b)b^eT' - u_bB_{e+1}^{(F)}\Big) \ge j-1-v_\ell(e+2). \tag{37.6}$$

Step 6: the Bernoulli number. By item 1 of Lemma 37.8 (for χ_F, with $\chi_F^* = \psi$), $B_{e+1}^{(F)} = B_{e+1,\psi}\prod_{p|F}(1-\psi(p)p^e)$; for $p \mid f$, $\psi(p) = 0$, and the only other prime dividing F is ℓ (if $\ell \nmid f$), with $v_\ell(\psi(\ell)\ell^e) = e \ge 1$. So $v_\ell(B_{e+1}^{(F)}) = v_\ell(B_{e+1,\psi}) =: \beta$. By item 1 of Proposition 37.9 (modulus f, $k = e+1$, H trivial), $f(e+2)\#B_{e+1,\psi} \ne 0$, so $\beta < \infty$.

Step 7: choice of m and conclusion. Choose $m \ge m_1$ so large that $j = m - m_1$ satisfies $j-1-v_\ell(e+2) > \beta$ and $e_{\mathcal{O}}m \ge v_{\mathcal{O}}(a_0) + e_{\mathcal{O}}\beta$, and let b be as in Step 2 for this m; in particular $\gcd(b,N) = 1$. As $\chi(b) = \psi(b)$ and b are units and u_b is a unit, $v_\ell(u_bB_{e+1}^{(F)}) = \beta$, and (37.6) gives $v_\ell((e+1)T') = \beta$, i.e. $v_\ell(T') = \beta - v_\ell(e+1)$. By Step 3 and $m > \beta$, $v_\ell(\mathrm{st}_{N,b}(\theta,\sigma)) = v_\ell(2T') = \beta - v_\ell(e+1)$, which is the first claim after multiplying by $e_{\mathcal{O}}$. Then $v_{\mathcal{O}}(a_0\,\mathrm{st}_{N,b}(\theta,\sigma)) \le v_{\mathcal{O}}(a_0) + e_{\mathcal{O}}\beta \le e_{\mathcal{O}}m = v_{\mathcal{O}}(\ell^m)$, so $a_0\,\mathrm{st}_{N,b}(\theta,\sigma) \mid \ell^m$ in the discrete valuation ring $\mathcal{O}$. □

Lemma 37.8. *Let ℓ be a prime, $F \ge 2$ an integer divisible by ℓ, $e \ge 1$ an integer, and χ a Dirichlet character modulo F with values in $\overline{\mathbb{Q}}_\ell^\times$ (extended by 0 to the integers not prime to F). Put $a = 1+F$, $Q_j = F\ell^j$ for $j \ge 0$,*

$$T_j(\chi) = \sum_{1\le b<Q_j}\Big\lfloor\frac{ab}{Q_j}\Big\rfloor b^e\chi(b), \qquad B_{k,\chi}^{(F)} = F^{\,k-1}\sum_{b=1}^{F}\chi(b)\,B_k\Big(\frac{b}{F}\Big) \quad (k \ge 0).$$

Then:

1. *for every $k \ge 1$, $B_{k,\chi}^{(F)} = B_{k,\chi^*}\prod_{p|F}(1-\chi^*(p)\,p^{k-1})$, the product over the primes dividing F;*
2. *for every $j \ge 0$,*

$$v_\ell\Big((e+1)\,a^e\,T_j(\chi) - (a^{e+1}-1)\,B_{e+1,\chi}^{(F)}\Big) \ge j - v_\ell(e+2) - 1.$$

Proof. Three identities follow from the generating function: $B_n(X+Y) = \sum_{i=0}^{n}\binom{n}{i}B_i(X)Y^{n-i}$ (multiply by e^{Yt}); $B_n(X+1) - B_n(X) = nX^{n-1}$ (the difference of the generating functions is te^{Xt}); and, for an integer $h \ge 1$, $\sum_{u=0}^{h-1}B_n(\frac{X+u}{h}) = h^{1-n}B_n(X)$.

Item 1. Let $f \mid F$ be the conductor of χ and $R = \prod_{p|F}p$. For $1 \le b \le F$, $\chi(b) = \chi^*(b)$ if $\gcd(b,F) = 1$ and $\chi(b) = 0$ otherwise; since $\chi^*(b) = 0$ when $\gcd(b,f) > 1$, in all cases $\chi(b) = \chi^*(b)\sum_{g|\gcd(b,R)}\mu(g)$. Hence, writing $b = gb'$,

$$B_{k,\chi}^{(F)} = \sum_{g|R}\mu(g)\chi^*(g)\,F^{\,k-1}\sum_{b'=1}^{F/g}\chi^*(b')\,B_k\Big(\frac{b'}{F/g}\Big).$$

If $\chi^*(g) \neq 0$ then $\gcd(g,f)=1$, so $f \mid F/g$; write $F/g = fh$. Grouping $b' = r + fu$ ($1 \le r \le f$, $0 \le u < h$) and using the last identity with $X = r/f$, $(F/g)^{k-1}\sum_{b'} \chi^*(b')B_k(b'/(F/g)) = (fh)^{k-1}h^{1-k}\sum_{r=1}^{f}\chi^*(r)B_k(r/f) = B_{k,\chi^*}$. With $F^{k-1} = g^{k-1}(F/g)^{k-1}$ this gives $B_{k,\chi}^{(F)} = B_{k,\chi^*}\sum_{g\mid R}\mu(g)\chi^*(g)g^{k-1} = B_{k,\chi^*}\prod_{p\mid F}(1-\chi^*(p)p^{k-1})$.

Integrality. For $0 \le i \le e+1$, $F^{\,i}B_i(b/F) = \sum_{r=0}^{i}\binom{i}{r}B_r\, b^{i-r}F^{\,r}$, and $(i+1)\#\,B_r \in \mathbb{Z}$ for $r \le i$ by Theorem B.19 (the denominator of B_r is a product of distinct primes $p \le r+1$), with $(i+1)\# = \prod_{p\le i+1} p$. So $F\,(i+1)\#\,B_{i,\chi}^{(F)}$ is integral over $\mathbb{Z}$, and, as ℓ divides $(i+1)\#$ at most once,

$$v_\ell(B_{i,\chi}^{(F)}) \ge -v_\ell(F) - 1 \qquad (0 \le i \le e+1). \tag{37.7}$$

Item 2: an exact identity. Fix j and write $Q = Q_j$. Every prime dividing Q divides F and $a \equiv 1 \pmod F$, so $\gcd(a,Q)=1$. For $0 \le b < Q$ put $\iota(b) = \lfloor ab/Q \rfloor$ and $\rho(b) = ab - Q\,\iota(b) \in [0,Q)$. Then $b \mapsto \rho(b)$ is a bijection of $\{0,\dots,Q-1\}$ (multiplication by a modulo Q), and $\rho(b) \equiv ab \equiv b \pmod F$, so $\chi(\rho(b)) = \chi(b)$. Put $P_k = \sum_{b=0}^{Q-1}\chi(b)b^k$; then $T_j(\chi) = \sum_{b=0}^{Q-1}\iota(b)\chi(b)b^e$ as $\chi(0)=0$. Let $\mathcal{O}_\chi$ be the ring generated over $\mathbb{Z}$ by the values of χ; the Y_i below lie in $\mathcal{O}_\chi$.

(i) From $ab = \rho(b) + Q\iota(b)$: $aP_{e+1} = Y_0 + QT_j(\chi)$ with $Y_0 = \sum_b \chi(b)b^e\rho(b)$.

(ii) From $(ab)^e = (\rho(b)+Q\iota(b))^e = \rho(b)^e + eQ\iota(b)\rho(b)^{e-1} + Q^2y_b$ with $y_b \in \mathbb{Z}$, multiplied by $\chi(\rho(b))\rho(b)$ and summed, using the bijection: $a^eY_0 = P_{e+1} + eQ\sum_b \chi(b)\iota(b)\rho(b)^e + Q^2Y_1$.

(iii) As $\rho(b) \equiv ab \pmod Q$, $\rho(b)^e \equiv a^eb^e \pmod Q$, so $\sum_b \chi(b)\iota(b)\rho(b)^e = a^eT_j(\chi) + QY_2$.

Multiplying (i) by a^e and inserting (ii), (iii):

$$a^{e+1}P_{e+1} = P_{e+1} + (e+1)Q\,a^eT_j(\chi) + Q^2Y_3, \qquad \text{so} \qquad (e+1)\,a^eT_j(\chi) = (a^{e+1}-1)\frac{P_{e+1}}{Q} - QY_3.$$

Item 2: the power sum. Write $b = c + Fu$ with $1 \le c \le F$ and $0 \le u < L = Q/F$ (the term $b=0$ and the terms with $c = F$ vanish, as $\chi(0) = \chi(F) = 0$). By the first two identities, $\sum_{u=0}^{L-1}(c/F+u)^{e+1} = \frac{1}{e+2}\big(B_{e+2}(c/F+L) - B_{e+2}(c/F)\big) = \frac{1}{e+2}\sum_{i=0}^{e+1}\binom{e+2}{i}B_i(c/F)L^{e+2-i}$. Multiplying by $\chi(c)F^{e+1}$ and summing over c,

$$\frac{P_{e+1}}{Q} = \frac{1}{e+2}\sum_{i=0}^{e+1}\binom{e+2}{i}Q^{\,e+1-i}B_{i,\chi}^{(F)} = B_{e+1,\chi}^{(F)} + \sum_{i=0}^{e}\frac{\binom{e+2}{i}}{e+2}\,Q^{\,e+1-i}B_{i,\chi}^{(F)}.$$

Item 2: valuations. Hence

$$(e+1)a^eT_j(\chi) - (a^{e+1}-1)B_{e+1,\chi}^{(F)} = (a^{e+1}-1)\sum_{i=0}^{e}\frac{\binom{e+2}{i}}{e+2}Q^{e+1-i}B_{i,\chi}^{(F)} - QY_3.$$

Here $v_\ell(Q) = j + v_\ell(F) \ge j+1$, so $v_\ell(QY_3) \ge j+1$; $v_\ell(a^{e+1}-1) \ge 0$; and for $0 \le i \le e$, by (37.7), $v_\ell\big(\binom{e+2}{i}Q^{e+1-i}B_{i,\chi}^{(F)}/(e+2)\big) \ge (j+v_\ell(F)) - v_\ell(F) - 1 - v_\ell(e+2) = j - 1 - v_\ell(e+2)$. This proves item 2. □

Proposition 37.9. *Let $N \ge 1$ and $k \ge 1$ be integers and $H \le (\mathbb{Z}/N\mathbb{Z})^\times$ a subgroup. For a field Ω of characteristic 0 let $\mathcal{X}_\Omega$ be the set of Dirichlet characters χ modulo N with values in $\Omega^\times$ such that $H \subseteq \ker\chi$ and $\chi(-1) = (-1)^k$. Then:*

1. *for every prime ℓ and every $\chi \in \mathcal{X}_{\overline{\mathbb{Q}}_\ell}$, $\mathrm{Ber}_k(\chi)$ is nonzero and integral over $\mathbb{Z}_\ell$;*

2. *there are integers $w_\ell \geq 0$, one for each prime ℓ, such that $\sum_{\ell\in S} w_\ell \log \ell \leq |\mathcal{X}_{\mathbb{C}}| \log(16N^{k+1}k!)$ for every finite set S of primes, and $\sum_{\chi\in\mathcal{X}_{\overline{\mathbb{Q}}_\ell}} v_\ell(\mathrm{Ber}_k(\chi)) \leq w_\ell$ for every prime ℓ.*

Proof. Put $m = \varphi(N)$; the exponent of $(\mathbb{Z}/N\mathbb{Z})^\times$ divides m, so a character of it with values in a field Ω of characteristic 0 takes values in the group $\mu_m(\Omega)$ of m-th roots of unity.

Transport of characters. By (37.1),

$$\mathrm{Ber}_k(\chi) = N\,(k+1)\#\,f^{\,k-1}\sum_{a=1}^{f}\chi^*(a)\,B_k\Big(\frac{a}{f}\Big), \tag{37.8}$$

a linear combination with rational coefficients of the values of χ^*, where f is the conductor of χ. Let Ω, Ω' be fields of characteristic 0 and $j\colon \Omega \to \Omega'$ a field embedding. For a character χ modulo N with values in $\Omega^\times$, $j\circ\chi$ has the same kernel and the same value at -1; the conductor depends only on the kernel, and $(j\circ\chi)^* = j\circ\chi^*$. Hence $\mathrm{Ber}_k(j\circ\chi) = j(\mathrm{Ber}_k(\chi))$. If $\mu_m(\Omega)$ and $\mu_m(\Omega')$ both have m elements, j maps the first bijectively onto the second, so $\chi \mapsto j\circ\chi$ is a bijection $\mathcal{X}_\Omega \to \mathcal{X}_{\Omega'}$. This applies to $\overline{\mathbb{Q}} \subseteq \mathbb{C}$ (so $\mathcal{X}_{\mathbb{C}} = \mathcal{X}_{\overline{\mathbb{Q}}}$), to every automorphism σ of $\overline{\mathbb{Q}}$, and to a fixed embedding $j_\ell\colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ (which exists because $\overline{\mathbb{Q}}_\ell$ is algebraically closed of characteristic 0).

Integrality. Let $\chi \in \mathcal{X}_{\overline{\mathbb{Q}}}$ with conductor f. Multiplying the generating functions $t/(e^t-1)$ and e^{Xt} gives $B_k(X) = \sum_{i=0}^{k}\binom{k}{i}B_i X^{k-i}$, so

$$f\,B_{k,\chi^*} = \sum_{a=1}^{f}\chi^*(a)\,a^k + \sum_{i=1}^{k}\binom{k}{i}B_i\,f^{\,i}\sum_{a=1}^{f}\chi^*(a)\,a^{k-i}.$$

By Theorem B.19, for $0 \leq i \leq k$ the denominator of B_i is a product of distinct primes p with $(p-1) \mid i$ or $p = 2$, hence $p \leq i+1 \leq k+1$; so $(k+1)\#\,B_i \in \mathbb{Z}$. The values of χ^* are roots of unity. Hence $f\,(k+1)\#\,B_{k,\chi^*}$ is an algebraic integer, and so is $\mathrm{Ber}_k(\chi) = (N/f)\cdot f\,(k+1)\#\,B_{k,\chi^*}$, as $f \mid N$.

Absolute values. We show: for $\chi \in \mathcal{X}_{\mathbb{C}}$, $\mathrm{Ber}_k(\chi) \neq 0$ and

$$|\mathrm{Ber}_k(\chi)| \leq 16\,N^{k+1}k!. \tag{37.9}$$

Let f be the conductor; $\chi^*(-1) = \chi(-1) = (-1)^k$. There is no primitive character modulo 2, so $f = 1$ or $f \geq 3$. Let $a \in \{0,1\}$ with $a \equiv k \pmod 2$ and $i = (k-a)/2 \in \mathbb{Z}_{\geq 0}$.

Case $f \geq 3$. Then χ^* is primitive modulo f with $\chi^*(-1) = (-1)^a$, and Theorem B.12 at $s = 1-k$ gives $|\xi(1-k,\chi^*)| = |\xi(k,\overline{\chi^*})|$. At $s = 1-k$ the Gamma factor is $\Gamma(\frac12 - i)$, finite and nonzero; at $s = k$ it is $\Gamma(i+a) = (i+a-1)!$, as $i + a \geq 1$ ($a = 0$ forces $k \geq 2$). Hence

$$|L(1-k,\chi^*)| = \Big(\frac{f}{\pi}\Big)^{k-\frac12}\frac{(i+a-1)!}{|\Gamma(\frac12 - i)|}\,|L(k,\overline{\chi^*})| = \frac{2\,(k-1)!\,f^{\,k-\frac12}}{(2\pi)^k}\,|L(k,\overline{\chi^*})|.$$

By Theorem B.11, $|B_{k,\chi^*}| = k\,|L(1-k,\chi^*)|$, so

$$|B_{k,\chi^*}| = \frac{2\,k!\,f^{\,k-\frac12}}{(2\pi)^k}\,|L(k,\overline{\chi^*})|. \tag{37.10}$$

The character $\overline{\chi^*}$ is primitive modulo $f \geq 3$, hence not principal. If $k \geq 2$, the Euler product of $L(k,\overline{\chi^*})$ converges absolutely and has no vanishing factor, so $L(k,\overline{\chi^*}) \neq 0$, and $|L(k,\overline{\chi^*})| \leq$

$\zeta(2)=\pi^2/6$. If $k=1$, $L(1,\overline{\chi^*})\neq 0$ by Theorem B.2. So $B_{k,\chi^*}\neq 0$ and $\mathrm{Ber}_k(\chi)\neq 0$. For $k\geq 2$, by (37.10), $(k+1)\#<4^{k+1}$ (Lemma B.3) and $f\leq N$,

$$|\mathrm{Ber}_k(\chi)|<N\,4^{k+1}\,\frac{2\,k!\,f^{\,k-\frac12}}{(2\pi)^k}\,\frac{\pi^2}{6}=\frac{4\pi^2}{3}\Big(\frac{2}{\pi}\Big)^k N\,f^{\,k-\frac12}\,k!\leq\frac{16}{3}\,N^{k+\frac12}\,k!,$$

using $(2/\pi)^k\leq 4/\pi^2$. For $k=1$, $B_1(X)=X-\frac12$ and $\sum_{a=1}^f\chi^*(a)=0$, so $B_{1,\chi^*}=\frac1f\sum_{a=1}^f\chi^*(a)\,a$ and $|B_{1,\chi^*}|\leq\frac{f+1}{2}$; with $(1+1)\#=2$, $|\mathrm{Ber}_1(\chi)|\leq N(f+1)\leq 2N^2$. Both bounds imply (37.9).

Case $f=1$. Then $\chi^*=\chi_{0,1}$, $(-1)^k=\chi(-1)=1$, so $k\geq 2$ is even, $a=0$, and $B_{k,\chi^*}=B_k(1)$. Theorem B.4 at $s=1-k\notin\{0,1\}$ gives $\pi^{-(1-k)/2}|\Gamma(\frac{1-k}{2})\zeta(1-k)|=\pi^{-k/2}\Gamma(\frac{k}{2})\zeta(k)$, which is the computation above with $f=1$, $a=0$; with Theorem B.11, $|B_k(1)|=2\,k!\,\zeta(k)/(2\pi)^k$, which is nonzero and at most $2\,k!\,\zeta(2)/(2\pi)^k$. As in the previous case $|\mathrm{Ber}_k(\chi)|\leq\frac{16}{3}N\,k!$, and (37.9) holds.

The product. Let $P=\prod_{\chi\in\mathcal{X}_{\overline{\mathbb{Q}}}}\mathrm{Ber}_k(\chi)$ (the empty product is 1). For an automorphism σ of $\overline{\mathbb{Q}}$, $\sigma(P)=\prod_\chi\mathrm{Ber}_k(\sigma\circ\chi)=P$, because $\chi\mapsto\sigma\circ\chi$ permutes $\mathcal{X}_{\overline{\mathbb{Q}}}$. So $P\in\mathbb{Q}$; it is a nonzero algebraic integer, hence $P\in\mathbb{Z}\setminus\{0\}$. Put $w_\ell=v_\ell(P)\geq 0$. For a finite set S of primes, by (37.9),

$$\sum_{\ell\in S}w_\ell\log\ell\leq\sum_\ell v_\ell(P)\log\ell=\log|P|=\sum_{\chi\in\mathcal{X}_{\mathbb{C}}}\log|\mathrm{Ber}_k(\chi)|\leq|\mathcal{X}_{\mathbb{C}}|\log(16N^{k+1}k!).$$

The prime ℓ. Every $\chi\in\mathcal{X}_{\overline{\mathbb{Q}}_\ell}$ is $j_\ell\circ\chi_0$ for a unique $\chi_0\in\mathcal{X}_{\overline{\mathbb{Q}}}$, and $\mathrm{Ber}_k(\chi)=j_\ell(\mathrm{Ber}_k(\chi_0))$ is nonzero and integral over $\mathbb{Z}$, hence over $\mathbb{Z}_\ell$: this is item 1. Moreover

$$\sum_{\chi\in\mathcal{X}_{\overline{\mathbb{Q}}_\ell}}v_\ell(\mathrm{Ber}_k(\chi))=v_\ell\Big(j_\ell\Big(\prod_{\chi_0\in\mathcal{X}_{\overline{\mathbb{Q}}}}\mathrm{Ber}_k(\chi_0)\Big)\Big)=v_\ell(P)=w_\ell,$$

as $j_\ell(P)=P\in\mathbb{Z}$; this, with the previous display, is item 2. □

Definition 37.10. Let $\theta\colon G_{\mathbb{Q}}\to\mathcal{O}^\times$ be a continuous character with a Kolyvagin level (N_0,m) of modulus $N=N_0\ell^m$, and let r be a prime with $r\equiv 1\pmod N$.

A **Kolyvagin prime** for (N,r) is a prime p with $p\equiv 1\pmod N$, $p\neq r$, and $\ell\nmid\mathrm{ord}_p(r)$, where $\mathrm{ord}_p(r)$ is the order of r in $(\mathbb{Z}/p\mathbb{Z})^\times$. Let $\mathcal{L}(N,r)$ be the set of finite sequences $L=(p_1,\dots,p_k)$, $k\geq 0$, of pairwise distinct Kolyvagin primes for (N,r); put $|L|=p_1\cdots p_k$ ($|L|=1$ for the empty sequence $\emptyset$), and for a Kolyvagin prime p not occurring in L put $(p,L)=(p,p_1,\dots,p_k)\in\mathcal{L}(N,r)$.

Let D_0 be a decomposition group at r and $w\in\mathcal{O}^\vee$. A **Kolyvagin system** for (θ,N_0,m,r,D_0,w) is a family $(\kappa_L)_{L\in\mathcal{L}(N,r)}$ of continuous maps $\kappa_L\colon U_N\to\mathcal{O}^\vee$ such that for every $L\in\mathcal{L}(N,r)$:

(Ks1) $\kappa_L(uv)=\kappa_L(u)+\kappa_L(v)$ and $\ell^m\kappa_L(u)=0$ for all $u,v\in U_N$;

(Ks2) $\kappa_L(gug^{-1})=\check\theta(g)\,\kappa_L(u)$ for all $g\in G_{\mathbb{Q}}$ and $u\in U_N$;

(Ks3) $\kappa_L(u)=0$ for every $u\in U_N$ lying in an inertia group at a prime not dividing $Nr|L|$;

(Ks4) for every Kolyvagin prime p for (N,r) not occurring in L, every decomposition group D at p and every Frobenius φ of D, there are $\tau\in I(D)$ and $u\in\mathcal{O}^\times$ with $\kappa_{(p,L)}(\tau)=u\,\kappa_L(\varphi)$;

(Ks5) there are $\tau_0\in I(D_0)$ and $u_0\in\mathcal{O}^\times$ with $\kappa_\emptyset(\tau_0)=u_0\,w$.

In (Ks4) and (Ks5) the elements φ,τ,τ_0 lie in U_N: a prime $p\equiv 1\pmod N$ is unramified in $\mathbb{Q}(\mu_N)$ with residue degree 1, so D acts trivially on μ_N; the same holds for r and D_0.

Proposition 37.11. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring and $\theta\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a continuous character with a Kolyvagin level (N_0, m) of modulus N; let Σ be the set of primes dividing N, δ a normaliser for θ, b an integer with $0 \le b < N$ and $\gcd(b, N) = 1$, σ a family of lifts modulo N, and $a_0 \in \mathcal{O} \setminus \{0\}$ with $a_0 \operatorname{st}_{N,b}(\theta, \sigma) \mid \ell^m$ in $\mathcal{O}$. Then*

$$\operatorname{length}_{\mathcal{O}} \mathrm{Z}_{\theta,\delta}(\Sigma, a_0) \le v_{\mathcal{O}}\big(\operatorname{st}_{N,b}(\theta, \sigma)\big).$$

Proof. Write $\mathrm{st} = \operatorname{st}_{N,b}(\theta, \sigma)$ and $\mathrm{Z}(n) = \mathrm{Z}_{\theta,\delta}(\Sigma, a_0; n)$, so that $\mathrm{Z}(n) \supseteq \mathrm{Z}(nn')$. As $\mathcal{O}$ is free of finite rank over $\mathbb{Z}_\ell$, $\mathcal{O}^\vee = K/\mathcal{O}$ with K the fraction field of $\mathcal{O}$. Hence: every $x \in \mathcal{O}^\vee$ has annihilator $c\mathcal{O}$ for some $c \ne 0$; for $c \ne 0$ there is $w \in \mathcal{O}^\vee$ with annihilator $c\mathcal{O}$, and then $\{x : cx = 0\} = \mathcal{O}w$, of length $v_{\mathcal{O}}(c)$; so for an $\mathcal{O}$-linear map $f\colon P \to \mathcal{O}^\vee$ and $e \ne 0$ with $ef = 0$, $\operatorname{length} P \le \operatorname{length} \ker f + v_{\mathcal{O}}(e)$. For a map $\lambda\colon U_N \to \mathcal{O}^\vee$ with $\ell^m\lambda = 0$, the ideal $\{y \in \mathcal{O} : y\lambda(u) = 0 \ \forall u \in U_N\}$ contains ℓ^m; a generator of it is called an *annihilator of* λ; it divides ℓ^m.

Step 1: properties of normalised strict cocycles. Let $z \in \mathrm{Z}(n)$ for some $n \ge 1$; its values are killed by a_0, which divides ℓ^m. For $u \in U_N$, $\theta(u) - 1 \in \ell^m\mathcal{O}$ by (Kv1), so $\theta(u)$ acts trivially on the values of z.

(L1) $z|_{U_N}$ is a homomorphism with $\ell^m z = 0$, and $z(gug^{-1}) = \theta(g)z(u)$ for $g \in G_{\mathbb{Q}}$, $u \in U_N$.

(L2) If $z|_{U_N} = 0$ then $z = 0$: for $g \in G_{\mathbb{Q}}$ the commutator $k = g\delta g^{-1}\delta^{-1}$ lies in U_N ($G_{\mathbb{Q}}/U_N$ is abelian), and by (Kd1) $z(g) = z(g\delta) = z(k\delta g) = z(\delta g) = \theta(\delta)z(g)$; as $\theta(\delta) - 1$ is a unit, $z(g) = 0$.

(L3) Let $p \equiv 1 \pmod N$ be a prime, D a decomposition group at p and φ a Frobenius of D with $z(\varphi) = 0$. Then z vanishes on every decomposition group at p. Indeed $D \subseteq U_N$ (p is unramified in $\mathbb{Q}(\mu_N)$ and φ acts on μ_N by $\zeta \mapsto \zeta^p = \zeta$), $z|_D$ is a continuous homomorphism vanishing on $I(D)$ by (Kd3) ($p \notin \Sigma$) and at φ; its kernel is open, hence closed, and contains $I(D)$ and φ, while $D/I(D)$ is topologically generated by the image of φ; so $z|_D = 0$. The other decomposition groups at p are gDg^{-1}, on which z vanishes by (L1).

Step 2: one step of the descent. Let $n \ge 1$, p a prime with $p \equiv 1 \pmod N$ and $p \nmid n$, and $\lambda\colon U_N \to \mathcal{O}^\vee$ a continuous homomorphism with $\ell^m\lambda = 0$ and $\lambda(gug^{-1}) = \breve{\theta}(g)\lambda(u)$, vanishing on $U_N \cap I$ for every inertia group I at a prime not dividing Nnp. Let D be a decomposition group at p, φ a Frobenius of D and $\tau \in I(D)$ ($\subseteq U_N$); let a generate the annihilator of $\lambda(\tau)$ and a' be an annihilator of λ, and assume $a_0 \mid a$. We claim: $a \mid a'$, and writing $a' = ae$,

$$e\,z(\varphi) = 0 \text{ for all } z \in \mathrm{Z}(n), \qquad \operatorname{length} \mathrm{Z}(n) \le \operatorname{length} \mathrm{Z}(np) + v_{\mathcal{O}}(e). \tag{37.11}$$

As $a'\lambda(\tau) = 0$, $a \mid a'$; so $a_0 \mid a \mid a' \mid \ell^m$. Choose $w_0 \in \mathcal{O}^\vee$ with annihilator $a'\mathcal{O}$; then $\lambda(\tau) = y\,w_0$ for some $y \in \mathcal{O}$, and Lemma 37.22 gives $y\,z(\varphi) = 0$ for every $z \in \mathrm{Z}(n)$. If $v_{\mathcal{O}}(y) \le v_{\mathcal{O}}(a')$, write $a' = yt$; then $t\lambda(\tau) = a'w_0 = 0$, so $t = as$ for some $s \in \mathcal{O}$, $ae = a' = yas$, $e = ys$ and $e\,z(\varphi) = s\,y\,z(\varphi) = 0$. If $v_{\mathcal{O}}(y) > v_{\mathcal{O}}(a')$, then $\lambda(\tau) = 0$, a is a unit, so is a_0, and $\mathrm{Z}(n) = 0$ by (Kd2). This proves the first part. The $\mathcal{O}$-linear map $z \mapsto z(\varphi)$ on $\mathrm{Z}(n)$ is killed by $e \ne 0$, and by (L3) its kernel lies in $\mathrm{Z}(np)$ (condition (Kd5) at p); this gives the inequality.

Step 3: the Kolyvagin system. Since $a_0 \operatorname{st} \mid \ell^m \ne 0$, $\mathrm{st} \ne 0$; write $\ell^m = \mathrm{st} \cdot k$ with $k \in \mathcal{O}$; then $a_0 \mid k$. Choose $w' \in \mathcal{O}^\vee$ with annihilator $\ell^m\mathcal{O}$, a prime $r \equiv 1 \pmod N$ (there are infinitely many, by Dirichlet's theorem), a decomposition group D_0 at r and a Frobenius φ_0 of D_0. By Proposition 37.14 there is a Kolyvagin system $(\kappa_L)_{L \in \mathcal{L}(N,r)}$ for $(\theta, N_0, m, r, D_0, \operatorname{st} w')$. For

$L \in \mathcal{L}(N,r)$ let a_L be an annihilator of κ_L (by (Ks1)) and $j(L) = v_{\mathcal{O}}(a_L) \le J := v_{\mathcal{O}}(\ell^m)$, and put $\mathrm{Z}_L = \mathrm{Z}(r|L|)$.

Step 4: the base step. By (Ks5), $\kappa_\emptyset(\tau_0) = u_0 \,\mathrm{st}\, w'$ with $\tau_0 \in I(D_0)$ and u_0 a unit; its annihilator is $\{y : \ell^m \mid y\,\mathrm{st}\} = k\mathcal{O}$. Step 2 with $n=1$, $p=r$, $\lambda = \kappa_\emptyset$ ((Ks1)–(Ks3)), D_0, φ_0, τ_0, $a = k$, $a' = a_\emptyset$ gives $a_\emptyset = ke_0$ and

$$\operatorname{length} \mathrm{Z}(1) \le \operatorname{length} \mathrm{Z}_\emptyset + v_{\mathcal{O}}(e_0). \tag{37.12}$$

Step 5: the induction. Let $\mathcal{T} = \{L \in \mathcal{L}(N,r) : a_0 \mid a_L\}$. We show $\operatorname{length} \mathrm{Z}_L + j(L) \le J$ for every $L \in \mathcal{T}$, by induction on $J - j(L)$. If $\mathrm{Z}_L = 0$ this holds. Otherwise let $z \in \mathrm{Z}_L$, $z \neq 0$. By (L2) and (L1), $z|_{U_N}$ is a nonzero continuous homomorphism with $\ell^m z = 0$ and $z(gug^{-1}) = \theta(g)z(u)$; κ_L satisfies the hypotheses on λ of Lemma 37.23 by (Ks1), (Ks2). That lemma, with $T = Nr|L|$, gives a Kolyvagin prime $p \nmid Nr|L|$ for (N,r), a decomposition group D at p and a Frobenius $\varphi \in U_N$ of D with $z(\varphi) \neq 0$ and $\kappa_L(U_N) \subseteq \mathcal{O}\kappa_L(\varphi)$. Then p does not occur in L, $L' = (p, L) \in \mathcal{L}(N,r)$, and by (Ks4) there are $\tau \in I(D)$ and a unit u with $\kappa_{L'}(\tau) = u\,\kappa_L(\varphi)$; so $\kappa_{L'}(\tau)$ has annihilator $a_L\mathcal{O}$, since $\kappa_L(\varphi)$ is a value of κ_L of which all values are multiples. Step 2 with $n = r|L|$, p, $\lambda = \kappa_{L'}$ (which vanishes on the inertia groups at the primes not dividing $Nr|L'| = Nnp$ by (Ks3)), D, φ, τ, $a = a_L$, $a' = a_{L'}$ (here $a_0 \mid a_L$ as $L \in \mathcal{T}$) gives $a_{L'} = a_L e$ with $e\,z(\varphi) = 0$, and $\operatorname{length} \mathrm{Z}_L \le \operatorname{length} \mathrm{Z}_{L'} + v_{\mathcal{O}}(e)$. As $z(\varphi) \neq 0$, e is not a unit, so $j(L') = j(L) + v_{\mathcal{O}}(e) > j(L)$; also $a_0 \mid a_L \mid a_{L'}$, so $L' \in \mathcal{T}$. By induction $\operatorname{length} \mathrm{Z}_{L'} + j(L') \le J$, hence $\operatorname{length} \mathrm{Z}_L + j(L) \le \operatorname{length} \mathrm{Z}_{L'} + j(L') \le J$.

Conclusion. As $a_0 \mid k \mid a_\emptyset$, $\emptyset \in \mathcal{T}$, so $\operatorname{length} \mathrm{Z}_\emptyset + v_{\mathcal{O}}(k) + v_{\mathcal{O}}(e_0) \le J = v_{\mathcal{O}}(\mathrm{st}) + v_{\mathcal{O}}(k)$. With (37.12) and $\mathrm{Z}(1) = \mathrm{Z}_{\theta,\delta}(\Sigma, a_0)$,

$$\operatorname{length} \mathrm{Z}_{\theta,\delta}(\Sigma, a_0) \le \operatorname{length} \mathrm{Z}_\emptyset + v_{\mathcal{O}}(e_0) \le v_{\mathcal{O}}(\mathrm{st}).$$

□

Definition 37.12. Let $m \ge 2$ be an integer and $K_m = \mathbb{Q}(\mu_m) \subset \overline{\mathbb{Q}}$. For $t \in (\mathbb{Z}/m\mathbb{Z})^\times$, $\sigma_{m,t} \in \mathrm{Gal}(K_m/\mathbb{Q})$ is the automorphism with $\sigma_{m,t}(\zeta) = \zeta^{\tilde{t}}$ for $\zeta \in \mu_m$; $t \mapsto \sigma_{m,t}$ is an isomorphism $(\mathbb{Z}/m\mathbb{Z})^\times \to \mathrm{Gal}(K_m/\mathbb{Q})$.

Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_{K_m}$ not dividing m, p its residue characteristic and $k_\mathfrak{p} = \mathcal{O}_{K_m}/\mathfrak{p}$, a field with $|k_\mathfrak{p}| \equiv 1 \pmod m$. The **$m$-th power residue character** of $\mathfrak{p}$ is $\chi_\mathfrak{p} \colon k_\mathfrak{p}^\times \to \mu_m$, where $\chi_\mathfrak{p}(x \bmod \mathfrak{p})$ is the element of μ_m congruent to $x^{(|k_\mathfrak{p}|-1)/m}$ modulo $\mathfrak{p}$ ($x \in \mathcal{O}_{K_m} \setminus \mathfrak{p}$). For a primitive p-th root of unity $\zeta_p \in \overline{\mathbb{Q}}$ and $j \in \mathbb{Z}$, the **Gauss sums** of $\mathfrak{p}$ are

$$\mathrm{g}_\mathfrak{p}(j) = \sum_{c \in k_\mathfrak{p}^\times} \chi_\mathfrak{p}(c)^{-j}\, \zeta_p^{\mathrm{Tr}_{k_\mathfrak{p}/\mathbb{F}_p}(c)} \in \mathbb{Q}(\mu_{mp}); \tag{37.13}$$

for $m \nmid j$ they are nonzero, since $\mathrm{g}_\mathfrak{p}(j)\mathrm{g}_\mathfrak{p}(-j) = \chi_\mathfrak{p}(-1)^j |k_\mathfrak{p}|$ [266]. For an integer b with $1 \le b < m$, the **Stickelberger quotient** and the **Gauss-sum element** of $(m, b, \mathfrak{p})$ are

$$\mathrm{J}_{m,b}(\mathfrak{p}) = \frac{\mathrm{g}_\mathfrak{p}(1)^b}{\mathrm{g}_\mathfrak{p}(b)}, \qquad \mathrm{R}_{m,b}(\mathfrak{p}) = \frac{\mathrm{g}_\mathfrak{p}(1)^b\, \mathrm{g}_\mathfrak{p}(-b)}{\mathrm{g}_\mathfrak{p}(b)\, \mathrm{g}_\mathfrak{p}(-1)^b}, \tag{37.14}$$

formed with the same ζ_p.

Definition 37.13. Let ℓ be an odd prime, $N_0 \ge 1$ and $m \ge 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, and r a prime with $r \equiv 1 \pmod N$. A **Kolyvagin integer** for (N,r) is an integer $|L|$ with $L \in \mathcal{L}(N,r)$, i.e. 1 or a product of distinct Kolyvagin primes for (N,r). Put $\mathbb{Q}(\mu_\infty) = \bigcup_{n \ge 1} K_n$.

For a place w of $\overline{\mathbb{Q}}$ above a prime p, v_w is its valuation with $v_w(p)=1$; z is a w-unit if $v_w(z)=0$, and for w-units z,z' we write $z\equiv z'\pmod{w}$ if $v_w(z-z')>0$.

Euler systems. An **Euler system for** (N,r) is a family (α_d), indexed by the Kolyvagin integers d for (N,r), with $\alpha_d\in K_{Nd}^{\times}$, together with integers $e_{d,p}$, indexed by the pairs of a Kolyvagin integer d and a Kolyvagin prime $p\nmid d$, such that for all such d and p:

(Eu1) α_d is a w-unit for every place w of $\overline{\mathbb{Q}}$ not above r;

(Eu2) $\ell\nmid e_{d,p}$, and for every $\tau\in G_{\mathbb{Q}}$ that fixes μ_{Nd} pointwise and acts on μ_p by $\zeta\mapsto\zeta^g$ with g a generator of $(\mathbb{Z}/p\mathbb{Z})^{\times}$, and every $\varphi\in G_{\mathbb{Q}}$ with $\varphi(\zeta)=\zeta^p$ for $\zeta\in\mu_{Nd}$,

$$\prod_{i=0}^{p-2}\tau^i(\alpha_{pd})=\Big(\frac{\alpha_d}{\varphi^{-1}(\alpha_d)}\Big)^{e_{d,p}};$$

(Eu3) for every φ as in (Eu2) and every place w of $\overline{\mathbb{Q}}$ above p, $\alpha_{pd}\equiv\varphi^{-1}(\alpha_d)^{e_{d,p}}\pmod{w}$.

Kolyvagin derivatives. A **choice of generators** for (N,r) is a family (τ_p), indexed by the Kolyvagin primes p, of elements $\tau_p\in G_{\mathbb{Q}}$ that fix every root of unity of order prime to p and act on μ_p by $\zeta\mapsto\zeta^{g_p}$ with g_p a generator of $(\mathbb{Z}/p\mathbb{Z})^{\times}$. The **Kolyvagin derivatives** are the maps $\overline{\mathbb{Q}}^{\times}\to\overline{\mathbb{Q}}^{\times}$

$$\mathrm{Der}_p(z)=\prod_{i=0}^{p-2}\tau_p^i(z)^i,\qquad \mathrm{Der}_L=\mathrm{Der}_{p_1}\circ\cdots\circ\mathrm{Der}_{p_k}\quad(L=(p_1,\dots,p_k)\in\mathcal{L}(N,r)),\tag{37.15}$$

with $\mathrm{Der}_{\emptyset}$ the identity.

Descended Kummer characters. Let $\delta\in G_{\mathbb{Q}}$ and $a\in\mathbb{Z}$ with $\delta(\zeta)=\zeta^a$ for $\zeta\in\mu_{\ell^m}$, and put $\mathrm{P}_{\delta,a}(z)=\delta(z)\,z^{-a}$ for $z\in\overline{\mathbb{Q}}^{\times}$. Fix a primitive ℓ^m-th root of unity ζ_{ℓ^m}. An element $y\in\mathbb{Q}(\mu_\infty)^{\times}$ is **ℓ^m-invariant over** K_N if for every $g\in U_N$ the element $g(y)/y$ is an ℓ^m-th power in $\mathbb{Q}(\mu_\infty)^{\times}$. For such y and $g\in U_N$, let $Q_y(g)$ be the set of the quotients

$$\frac{g(\mathrm{P}_{\delta,a}(Y))}{\mathrm{P}_{\delta,a}(Y)\,\mathrm{P}_{\delta,a}(z)},\qquad Y\in\overline{\mathbb{Q}},\ Y^{\ell^m}=y,\qquad z\in\mathbb{Q}(\mu_\infty),\ z^{\ell^m}=g(y)/y.$$

If $Q_y(g)=\{\zeta_{\ell^m}^k\}$ for a class $k\in\mathbb{Z}/\ell^m\mathbb{Z}$, the **descended Kummer character** of y takes the value $\mathrm{k}_y(g)=k$ at g; it depends on $(\delta,a,\zeta_{\ell^m})$, which are fixed wherever it is used.

Proposition 37.14. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring and $\theta\colon G_{\mathbb{Q}}\to\mathcal{O}^{\times}$ a continuous character with a Kolyvagin level (N_0,m) of modulus $N=N_0\ell^m$. Let r be a prime with $r\equiv1\pmod{N}$, D_0 a decomposition group at r, b an integer with $0\le b<N$ and $\gcd(b,N)=1$, σ a family of lifts modulo N, and $w\in\mathcal{O}^{\vee}$ with $\ell^m w=0$. Then there is a Kolyvagin system for $(\theta,N_0,m,r,D_0,\mathrm{st}_{N,b}(\theta,\sigma)\,w)$.*

Proof. Write $M=\ell^m$, $\mathrm{st}=\mathrm{st}_{N,b}(\theta,\sigma)$, and let $\bar{\mathfrak{r}}$ be the place stabilised by D_0. As $N\ge3$ and $\gcd(b,N)=1$, $1\le b<N$. For $j\in\mathbb{Z}/M\mathbb{Z}$ and $v\in\mathcal{O}^{\vee}$ with $Mv=0$, $j\,v$ means $\tilde{j}v$ for any integer $\tilde{j}$ in the class j. For $h\in U_N$, $\chi_{\mathrm{cyc}}(h)\equiv1$ and, by (Kv1), $\theta(h)\equiv1$ modulo $M\mathcal{O}$; hence $\check{\theta}(h)\equiv1$, and $\check{\theta}(gh)v=\check{\theta}(g)v$, $\theta(gh)^{-1}v=\theta(g)^{-1}v$ for $g\in G_{\mathbb{Q}}$ and $Mv=0$.

Step 1: construction. By (Kv3) choose $\delta\in G_{\mathbb{Q}}$ with $\theta(\delta)-\chi_{\mathrm{cyc}}(\delta)\in\mathcal{O}^{\times}$, an integer a with $\delta(\zeta)=\zeta^a$ for $\zeta\in\mu_M$ (so $\chi_{\mathrm{cyc}}(\delta)\equiv a\pmod{M}$), and let $t_\delta\in(\mathbb{Z}/N\mathbb{Z})^{\times}$ be the class of the action of δ on μ_N. For each Kolyvagin prime p let τ_p be an element of an inertia group at p acting on μ_p by a generator of $(\mathbb{Z}/p\mathbb{Z})^{\times}$; it exists because p is totally ramified in $\mathbb{Q}(\mu_p)$, and

it fixes every root of unity ζ' of order prime to p (as $\tau_p(\zeta') \equiv \zeta'$ modulo the place, and such roots of unity are pairwise incongruent there). So (τ_p) is a choice of generators for (N, r). Fix a primitive M-th root of unity ζ_{ℓ^m}, so that k_y is formed with $(\delta, a, \zeta_{\ell^m})$, and $\rho \in \overline{\mathbb{Q}}$ with $\rho^M = r$. By Proposition 37.15, applied to $(\ell, N_0, m, r, \bar{\mathfrak{r}}, b, \delta, a)$, there is an Euler system $((\alpha_d), (e_{d,p}))$ for (N, r) with

$$v_{\bar{\mathfrak{r}}}(g(\alpha_1)) = 2N_0\big(h_N(b, t\,t_\delta) - a\,h_N(b,t)\big) \quad \text{if } g \in G_{\mathbb{Q}} \text{ acts on } \mu_N \text{ by } t. \tag{37.16}$$

For $L \in \mathcal{L}(N,r)$ let $y_L = \mathrm{Der}_L(\alpha_{|L|})$; by Lemma 37.19 it lies in $K^\times_{N|L|}$, is a w'-unit for every place w' not above r, and is ℓ^m-invariant over K_N, so by item 1 of Lemma 37.20 $\mathrm{k}_L = \mathrm{k}_{y_L} \colon U_N \to \mathbb{Z}/M\mathbb{Z}$ is a continuous homomorphism. Put

$$\kappa_L(u) = \sum_{t \in (\mathbb{Z}/N\mathbb{Z})^\times} \mathrm{k}_L(\sigma_t^{-1} u \sigma_t)\, \check{\theta}(\sigma_t)\, w \qquad (u \in U_N),$$

which makes sense as U_N is normal in $G_{\mathbb{Q}}$. We check (Ks1)–(Ks5) for $(\kappa_L)_{L \in \mathcal{L}(N,r)}$.

Step 2: (Ks1). Each $u \mapsto \mathrm{k}_L(\sigma_t^{-1} u \sigma_t)$ is a continuous homomorphism into $\mathbb{Z}/M\mathbb{Z}$, so κ_L is continuous, additive, and killed by M.

Step 3: (Ks2). Let $g \in G_{\mathbb{Q}}$. For $t \in (\mathbb{Z}/N\mathbb{Z})^\times$ let t' be the class of the action of $g^{-1}\sigma_t$ on μ_N and $h_t = \sigma_{t'}^{-1} g^{-1} \sigma_t \in U_N$; $t \mapsto t'$ is a bijection. Then $\sigma_t^{-1}(gug^{-1})\sigma_t = h_t^{-1}(\sigma_{t'}^{-1} u \sigma_{t'}) h_t$, whose image under the homomorphism k_L into an abelian group is $\mathrm{k}_L(\sigma_{t'}^{-1} u \sigma_{t'})$, and $\check{\theta}(\sigma_t)w = \check{\theta}(g)\check{\theta}(\sigma_{t'})\check{\theta}(h_t)w = \check{\theta}(g)\check{\theta}(\sigma_{t'})w$. Summing, $\kappa_L(gug^{-1}) = \check{\theta}(g)\kappa_L(u)$.

Step 4: (Ks3). Let $u \in U_N$ lie in an inertia group I at a prime $p' \nmid Nr|L|$. For each t, $h = \sigma_t^{-1} u \sigma_t$ lies in the inertia group $\sigma_t^{-1} I \sigma_t$ at p'; it fixes the roots of unity of order prime to p' (as in Step 1), hence $K_{N|L|}$ and y_L. As $p' \neq \ell$ ($\ell \mid N$) and y_L is a unit at the places above $p' \neq r$, item 3 of Lemma 37.20 gives $\mathrm{k}_L(h) = 0$. So $\kappa_L(u) = 0$.

Step 5: (Ks4). Let $L \in \mathcal{L}(N,r)$, p a Kolyvagin prime not in L, D a decomposition group at p and φ a Frobenius of D. As p is totally ramified in $\mathbb{Q}(\mu_p)$, $I(D)$ maps onto $\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$; choose $\tau \in I(D)$ agreeing with τ_p on μ_p. For $t \in (\mathbb{Z}/N\mathbb{Z})^\times$, $\sigma_t^{-1} D \sigma_t$ is a decomposition group at p, $\sigma_t^{-1}\tau\sigma_t$ lies in its inertia group and agrees with τ_p on μ_p ($\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$ is abelian), and $\sigma_t^{-1}\varphi\sigma_t$ is a Frobenius of it. Since $y_{(p,L)} = \mathrm{Der}_p(\mathrm{Der}_L(\alpha_{p|L|}))$, Lemma 37.21 gives $\mathrm{k}_{(p,L)}(\sigma_t^{-1}\tau\sigma_t) = -e\,\mathrm{k}_L(\sigma_t^{-1}\varphi\sigma_t)$ with $e = e_{|L|,p}$. Summing over t, $\kappa_{(p,L)}(\tau) = (-e)\,\kappa_L(\varphi)$, and $-e \in \mathcal{O}^\times$ as $\ell \nmid e$ by (Eu2).

Step 6: (Ks5). By item 4 of Lemma 37.20 there is $\tau_0 \in I(D_0)$ with $\tau_0(\rho) = \zeta_{\ell^m}\rho$. Let $t \in (\mathbb{Z}/N\mathbb{Z})^\times$; σ_t acts on $\mu_M \subseteq \mu_N$ by $\tilde{t}$, and $y_\emptyset = \alpha_1 \in K_N^\times$. Item 4 of Lemma 37.20 and (37.16), applied to $\sigma_t\delta$ (acting on μ_N by $t\,t_\delta$) and to σ_t, give in $\mathbb{Z}/M\mathbb{Z}$

$$\tilde{t}\,\mathrm{k}_\emptyset(\sigma_t^{-1}\tau_0\sigma_t) = v_{\bar{\mathfrak{r}}}(\sigma_t\delta(\alpha_1)) - a\,v_{\bar{\mathfrak{r}}}(\sigma_t(\alpha_1)) = H(t) := 2N_0\big(h_N(b, t\,t_\delta^2) - 2a\,h_N(b, t\,t_\delta) + a^2 h_N(b,t)\big).$$

As $\chi_{\mathrm{cyc}}(\sigma_t) \equiv \tilde{t} \pmod M$, $\check{\theta}(\sigma_t)w = \tilde{t}\,\theta(\sigma_t)^{-1}w$, so $\kappa_\emptyset(\tau_0) = \sum_t H(t)\,\theta(\sigma_t)^{-1}w$. For $j \geq 0$, substituting $t = t''t_\delta^{-j}$ and using that $\sigma_{t''t_\delta^{-j}}$ and $\sigma_{t''}\delta^{-j}$ agree on μ_N, hence differ by an element of U_N,

$$\sum_t h_N(b, t\,t_\delta^j)\,\theta(\sigma_t)^{-1}w = \sum_{t''} h_N(b,t'')\,\theta(\sigma_{t''})^{-1}\theta(\delta)^j w = \theta(\delta)^j\,\mathrm{st}\,w$$

by (37.3). Hence $\kappa_\emptyset(\tau_0) = u_0\,\mathrm{st}\,w$ with $u_0 = 2N_0(\theta(\delta)^2 - 2a\theta(\delta) + a^2) = 2N_0(\theta(\delta) - a)^2$. Here $\ell \nmid 2N_0$, and $\theta(\delta) - a = (\theta(\delta) - \chi_{\mathrm{cyc}}(\delta)) + (\chi_{\mathrm{cyc}}(\delta) - a)$ is a unit plus an element of $M\mathcal{O} \subseteq \mathfrak{m}$ ($m \geq 1$), hence a unit; so $u_0 \in \mathcal{O}^\times$.

Hence $(\kappa_L)_{L \in \mathcal{L}(N,r)}$ is a Kolyvagin system for $(\theta, N_0, m, r, D_0, \mathrm{st}\,w)$. □

Proposition 37.15. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod N$, $\bar{\mathfrak{r}}$ a place of $\overline{\mathbb{Q}}$ above r, and b an integer with $1 \leq b < N$ and $\gcd(b, N) = 1$. Let $\delta \in G_{\mathbb{Q}}$ and $a \in \mathbb{Z}$ with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_{\ell^m}$, and let $t_\delta \in (\mathbb{Z}/N\mathbb{Z})^\times$ be the class with $\delta(\zeta) = \zeta^{\tilde{t}_\delta}$ for $\zeta \in \mu_N$. Then there is an Euler system $((\alpha_d), (e_{d,p}))$ for (N, r) such that, for every $t \in (\mathbb{Z}/N\mathbb{Z})^\times$ and every $\sigma \in G_{\mathbb{Q}}$ with $\sigma(\zeta) = \zeta^{\tilde{t}}$ for $\zeta \in \mu_N$,*

$$v_{\bar{\mathfrak{r}}}(\sigma(\alpha_1)) = 2N_0\big(h_N(b, t\,t_\delta) - a\,h_N(b, t)\big).$$

Proof. We use two classical facts on cyclotomic fields: (C1) for $n \geq 1$ and a prime $p \nmid n$, p is unramified in K_n with residue degree the order of p in $(\mathbb{Z}/n\mathbb{Z})^\times$; (C2) every root of unity in K_n lies in μ_{2n}. Write $\mathrm{P} = \mathrm{P}_{\delta,a}$. It is an endomorphism of the group $\overline{\mathbb{Q}}^\times$, it is trivial on μ_{ℓ^m}, and $g(\mathrm{P}(z)) = \mathrm{P}(g(z))$ for $g \in G_{\mathbb{Q}}$ and $z \in \mathbb{Q}(\mu_\infty)$, since $\mathrm{Gal}(\mathbb{Q}(\mu_\infty)/\mathbb{Q})$ is abelian.

Construction. Let d be a Kolyvagin integer. Its prime factors are $\equiv 1 \pmod N$, hence $> N > b$, so $\gcd(b, Nd) = 1$; also $r \nmid Nd$, as $r \equiv 1 \pmod N$ and Kolyvagin primes differ from r. Let $\mathfrak{r}_d = \{z \in \mathcal{O}_{K_{Nd}} : v_{\bar{\mathfrak{r}}}(z) > 0\}$, a prime of K_{Nd} above r, and put

$$\mathrm{R}_d = \mathrm{R}_{Nd,b}(\mathfrak{r}_d) \in K_{Nd}^\times, \qquad \alpha_d = \mathrm{P}(\mathrm{R}_d)^{2N_0 d} = \big(\delta(\mathrm{R}_d)\,\mathrm{R}_d^{-a}\big)^{2N_0 d} \in K_{Nd}^\times,$$

using item 1 of Lemma 37.16 ($Nd \geq N \geq 3$) and that $K_{Nd}/\mathbb{Q}$ is Galois. For a Kolyvagin prime $p \nmid d$ let $s_{d,p} = [k_{\mathfrak{r}_{pd}} : k_{\mathfrak{r}_d}]$ and $e_{d,p} = p\,s_{d,p}$.

Step 1: $\ell \nmid e_{d,p}$. $p \neq \ell$, as $\ell \mid N$ and $p \equiv 1 \pmod N$. By (C1), $s_{d,p} = f_{pd}/f_d$ with f_n the order of r modulo Nn. As $(\mathbb{Z}/Npd\mathbb{Z})^\times \cong (\mathbb{Z}/p\mathbb{Z})^\times \times (\mathbb{Z}/Nd\mathbb{Z})^\times$, $f_{pd} = \mathrm{lcm}(\mathrm{ord}_p(r), f_d)$, so $s_{d,p}$ divides $\mathrm{ord}_p(r)$, which is prime to ℓ because p is a Kolyvagin prime.

Step 2: (Eu1). By item 2 of Lemma 37.16, R_d is a unit at every prime of K_{Nd} not above r. Let w be a place of $\overline{\mathbb{Q}}$ not above r; then $v_w(\mathrm{R}_d) = 0$, and $v_w(\delta(\mathrm{R}_d)) = v_{w'}(\mathrm{R}_d) = 0$ for the place $w' = w \circ \delta$, again not above r. So α_d is a w-unit.

Step 3: (Eu2). Let τ and φ be as in (Eu2). As $p \nmid Nd$, $\mathrm{Gal}(K_{Npd}/K_{Nd})$ is cyclic of order $p-1$ and is generated by the restriction of τ; so $\prod_{i=0}^{p-2} \tau^i(z) = \mathrm{N}_{K_{Npd}/K_{Nd}}(z)$ for $z \in K_{Npd}$. Lemma 37.17 (with $m := Nd$, $q := p$, $\mathfrak{p}' := \mathfrak{r}_{pd}$, $\mathfrak{p} = \mathfrak{r}_d$; $b < p$, $\gcd(b, Nd) = 1$, $\mathfrak{r}_{pd} \nmid pNd$) gives a root of unity $\eta \in K_{Nd}$ with $\mathrm{N}_{K_{Npd}/K_{Nd}}(\mathrm{R}_{pd}) = \eta\,(\mathrm{R}_d/\varphi^{-1}(\mathrm{R}_d))^{s_{d,p}}$. As P commutes with the norm and with φ^{-1} on K_{Npd},

$$\begin{aligned}\prod_{i=0}^{p-2} \tau^i(\alpha_{pd}) &= \mathrm{N}_{K_{Npd}/K_{Nd}}\big(\mathrm{P}(\mathrm{R}_{pd})\big)^{2N_0 pd} = \mathrm{P}\big(\eta^{2N_0 pd}\big)\Big(\frac{\mathrm{P}(\mathrm{R}_d)}{\varphi^{-1}(\mathrm{P}(\mathrm{R}_d))}\Big)^{2N_0 pd\,s_{d,p}} \\ &= \mathrm{P}\big(\eta^{2N_0 pd}\big)\Big(\frac{\alpha_d}{\varphi^{-1}(\alpha_d)}\Big)^{e_{d,p}}.\end{aligned}$$

By (C2), $\eta^{2Nd} = 1$, so $\eta^{2N_0 d} \in \mu_{\ell^m}$ and $\mathrm{P}(\eta^{2N_0 pd}) = \mathrm{P}(\eta^{2N_0 d})^p = 1$.

Step 4: (Eu3). Let φ be as in (Eu2) and w a place above p; put $\mathfrak{Q} = \{z \in \mathcal{O}_{K_{Npd}} : v_w(z) > 0\}$. By Lemma 37.18 (same data as in Step 3), R_{pd} and $\varphi^{-1}(\mathrm{R}_d)$ are w-units and $\mathrm{R}_{pd} \equiv \varphi^{-1}(\mathrm{R}_d)^{s_{d,p}} \pmod w$. The same holds at the place $w \circ \delta$, also above p; since $v_w(\delta(z) - \delta(z')) = v_{w\circ\delta}(z - z')$ and $\delta\varphi^{-1} = \varphi^{-1}\delta$ on K_{Nd}, this gives $\delta(\mathrm{R}_{pd}) \equiv \varphi^{-1}(\delta(\mathrm{R}_d))^{s_{d,p}} \pmod w$. Congruences between w-units are compatible with products and inverses, so $\mathrm{P}(\mathrm{R}_{pd}) \equiv \varphi^{-1}(\mathrm{P}(\mathrm{R}_d))^{s_{d,p}} \pmod w$, and raising to the power $2N_0 pd$ gives $\alpha_{pd} \equiv \varphi^{-1}(\alpha_d)^{e_{d,p}} \pmod w$.

Step 5: the valuations of α_1. By (C1), $r \equiv 1 \pmod N$ splits completely in K_N: the primes $\sigma_{N,t}^{-1}(\mathfrak{r}_1)$, $t \in (\mathbb{Z}/N\mathbb{Z})^\times$, are pairwise distinct, and $v_{\bar{\mathfrak{r}}}$ restricts to the $\mathfrak{r}_1$-adic valuation $\mathrm{ord}_{\mathfrak{r}_1}$ on K_N. By item 2 of Lemma 37.16, $\mathrm{ord}_{\sigma_{N,t}^{-1}(\mathfrak{r}_1)}(\mathrm{R}_1) = h_N(b, t)$. If σ acts on μ_N by t, then

$\sigma|_{K_N} = \sigma_{N,t}$ and $v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{R}_1)) = \mathrm{ord}_{\mathfrak{r}_1}(\sigma_{N,t}(\mathrm{R}_1)) = \mathrm{ord}_{\sigma_{N,t}^{-1}(\mathfrak{r}_1)}(\mathrm{R}_1) = h_N(b,t)$. As $\sigma\delta$ acts on μ_N by $t\,t_\delta$,

$$v_{\bar{\mathfrak{r}}}(\sigma(\alpha_1)) = 2N_0\big(v_{\bar{\mathfrak{r}}}(\sigma\delta(\mathrm{R}_1)) - a\,v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{R}_1))\big) = 2N_0\big(h_N(b,t\,t_\delta) - a\,h_N(b,t)\big).$$

□

Lemma 37.16. *Let $m \geq 2$, let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_{K_m}$ not dividing m, with residue characteristic p, and let b be an integer with $1 \leq b < m$ and $\gcd(b,m) = 1$. Then:*

1. *$\mathrm{J}_{m,b}(\mathfrak{p})$ and $\mathrm{R}_{m,b}(\mathfrak{p})$ lie in $K_m^\times$ and do not depend on the choice of ζ_p;*

$$\mathrm{R}_{m,b}(\mathfrak{p})\,\sigma_{m,-1}(\mathrm{R}_{m,b}(\mathfrak{p})) = 1,$$

   and $|\iota(\mathrm{R}_{m,b}(\mathfrak{p}))| = 1$ for every field embedding $\iota\colon K_m \to \mathbb{C}$;

2. *as fractional ideals of K_m,*

$$\mathrm{R}_{m,b}(\mathfrak{p})\,\mathcal{O}_{K_m} = \prod_{t\in(\mathbb{Z}/m\mathbb{Z})^\times} \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,t)};$$

   in particular $\mathrm{R}_{m,b}(\mathfrak{p})$ is a unit at every prime of K_m not above p.

Proof. Write $\mathrm{g}(j) = \mathrm{g}_{\mathfrak{p}}(j)$, $\chi = \chi_{\mathfrak{p}}$, $k = k_{\mathfrak{p}}$, $\mathrm{J} = \mathrm{J}_{m,b}(\mathfrak{p})$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$ and $L = K_m(\zeta_p) = \mathbb{Q}(\mu_{mp})$. As $p \nmid m$, restriction gives $\mathrm{Gal}(L/\mathbb{Q}) \cong \mathrm{Gal}(K_m/\mathbb{Q}) \times \mathrm{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$. For $c \in \mathbb{F}_p^\times$ let $\rho_c \in \mathrm{Gal}(L/K_m)$ be the element with $\rho_c(\zeta_p) = \zeta_p^c$ (these are all the elements of $\mathrm{Gal}(L/K_m)$), and for $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ let $\tilde{\sigma}_t \in \mathrm{Gal}(L/\mathbb{Q}(\zeta_p))$ be the element restricting to $\sigma_{m,t}$. The Gauss sum $\mathrm{g}(j)$ depends only on j modulo m, as χ takes values in μ_m.

Step 1: Galois action on Gauss sums. For $c \in \mathbb{F}_p^\times \subseteq k^\times$ we have $c\,\mathrm{Tr}_{k/\mathbb{F}_p}(x) = \mathrm{Tr}_{k/\mathbb{F}_p}(cx)$, so substituting $x \mapsto c^{-1}x$,

$$\rho_c(\mathrm{g}(j)) = \sum_{x\in k^\times} \chi(x)^{-j}\zeta_p^{\mathrm{Tr}(cx)} = \chi(c)^j\,\mathrm{g}(j). \tag{37.17}$$

As $\tilde{\sigma}_t$ fixes ζ_p and raises elements of μ_m to the power $\tilde{t}$, $\tilde{\sigma}_t(\mathrm{g}(j)) = \mathrm{g}(j\tilde{t})$. By item 1 of Theorem B.20, $\mathrm{g}(j) \neq 0$ for $m \nmid j$; this applies to $j = \pm 1, \pm b$, since $1 \leq b < m$.

Step 2: item 1. By (37.17), $\rho_c(\mathrm{J}) = \chi(c)^b\mathrm{g}(1)^b/(\chi(c)^b\mathrm{g}(b)) = \mathrm{J}$ for all c, so $\mathrm{J} \in L^{\mathrm{Gal}(L/K_m)} = K_m$, and $\mathrm{J} \neq 0$. By Step 1, $\tilde{\sigma}_{-1}(\mathrm{J}) = \mathrm{g}(-1)^b/\mathrm{g}(-b)$, so $\mathrm{R} = \mathrm{J}/\tilde{\sigma}_{-1}(\mathrm{J}) = \mathrm{J}/\sigma_{m,-1}(\mathrm{J}) \in K_m^\times$. Replacing ζ_p by ζ_p^c replaces each $\mathrm{g}(j)$ by $\rho_c(\mathrm{g}(j))$ (ρ_c fixes the values of χ), hence J by $\rho_c(\mathrm{J}) = \mathrm{J}$ and R by R. Since $\sigma_{m,-1}^2 = 1$, $\mathrm{R}\,\sigma_{m,-1}(\mathrm{R}) = \frac{\mathrm{J}}{\sigma_{m,-1}(\mathrm{J})} \cdot \frac{\sigma_{m,-1}(\mathrm{J})}{\mathrm{J}} = 1$. For an embedding $\iota\colon K_m \to \mathbb{C}$, $\iota\circ\sigma_{m,-1}$ and $\bar{\iota}$ agree on μ_m (both send ζ to $\iota(\zeta)^{-1} = \overline{\iota(\zeta)}$), hence on $K_m = \mathbb{Q}(\mu_m)$; so $|\iota(\mathrm{R})|^2 = \iota(\mathrm{R})\,\overline{\iota(\mathrm{R})} = \iota(\mathrm{R}\,\sigma_{m,-1}(\mathrm{R})) = 1$.

Step 3: item 2. By item 2 of Theorem B.20, $\mathrm{g}(1)^m \in K_m$ generates $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\tilde{t}}$. As $\gcd(b,m) = 1$, $\mathrm{g}(b)^m = \tilde{\sigma}_b(\mathrm{g}(1)^m) = \sigma_{m,b}(\mathrm{g}(1)^m)$ generates

$$\prod_t \sigma_{m,b}\sigma_{m,t}^{-1}(\mathfrak{p})^{\tilde{t}} = \prod_{t'} \sigma_{m,t'}^{-1}(\mathfrak{p})^{\widetilde{bt'}} \qquad (t = bt').$$

Hence $\mathrm{J}^m = \mathrm{g}(1)^{bm}/\mathrm{g}(b)^m$ generates $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{b\tilde{t}-\widetilde{bt}}$, and $b\tilde{t} - \widetilde{bt} = m\lfloor b\tilde{t}/m\rfloor$, because $b\tilde{t} \equiv \widetilde{bt} \pmod m$ and $0 < \widetilde{bt} < m$. The group of fractional ideals of K_m is free abelian, so

$$\mathrm{J}\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor b\tilde{t}/m\rfloor}, \qquad \sigma_{m,-1}(\mathrm{J})\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,-t}^{-1}(\mathfrak{p})^{\lfloor b\tilde{t}/m\rfloor} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor b(m-\tilde{t})/m\rfloor},$$

and $\mathrm{R}\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor \tilde{t}b/m\rfloor - \lfloor (m-\tilde{t})b/m\rfloor} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,t)}$. All the primes $\sigma_{m,t}^{-1}(\mathfrak{p})$ lie above p. □

Lemma 37.17. *Let $m \geq 2$, let q be a prime with $q \nmid m$, and let b be an integer with $1 \leq b < m$, $b < q$ and $\gcd(b, m) = 1$. Let $\mathfrak{p}'$ be a prime ideal of $\mathcal{O}_{K_{qm}}$ not dividing qm, $\mathfrak{p} = \mathfrak{p}' \cap \mathcal{O}_{K_m}$, and $s = [k_{\mathfrak{p}'} : k_{\mathfrak{p}}]$. Let $\varphi \in G_{\mathbb{Q}}$ satisfy $\varphi(\zeta) = \zeta^q$ for $\zeta \in \mu_m$. Then there is a root of unity $\eta \in K_m$ with*

$$\mathrm{N}_{K_{qm}/K_m}(\mathrm{R}_{qm,b}(\mathfrak{p}')) = \eta \Big(\frac{\mathrm{R}_{m,b}(\mathfrak{p})}{\varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))} \Big)^s .$$

Proof. Put $n = qm$, $\mathrm{R}' = \mathrm{R}_{n,b}(\mathfrak{p}')$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$, and let $u \in (\mathbb{Z}/m\mathbb{Z})^\times$ be the class of q, so that $\varphi|_{K_m} = \sigma_{m,u}$. For $t' \in (\mathbb{Z}/n\mathbb{Z})^\times$ with image $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ (written $t' \mapsto t$), $\sigma_{n,t'}|_{K_m} = \sigma_{m,t}$. As $1 \leq b < q$, $\gcd(b, n) = 1$, so Lemma 37.16 applies at both levels.

Step 1: a distribution identity. We show, for every $t \in (\mathbb{Z}/m\mathbb{Z})^\times$,

$$\sum_{t' \mapsto t} h_n(b, t') = h_m(b, t) - h_m(b, u^{-1}t). \tag{37.18}$$

The integers in $[1, n-1]$ congruent to $\tilde{t}$ modulo m are $\tilde{t} + mj$, $0 \leq j \leq q-1$; they are prime to m, and since m is invertible modulo q exactly one of them, for $j = j_0$, is divisible by q. So the representatives $\tilde{t}'$ of the classes $t' \mapsto t$ are the $\tilde{t} + mj$ with $j \neq j_0$. Write $\tilde{t} + mj_0 = qt_1$; then $1 \leq t_1 \leq m-1$ and $qt_1 \equiv \tilde{t} \pmod m$, so $t_1 = \widetilde{u^{-1}t}$. Write $bj = qa_j + i_j$ with $0 \leq i_j < q$; as $\gcd(b, q) = 1$, $j \mapsto i_j$ permutes $\{0, \dots, q-1\}$. With $z = b\tilde{t}/m$ and Hermite's identity $\sum_{i=0}^{q-1} \lfloor (z+i)/q \rfloor = \lfloor z \rfloor$,

$$\sum_{j=0}^{q-1} \Big\lfloor \frac{b(\tilde{t} + mj)}{n} \Big\rfloor = \sum_{j=0}^{q-1} \Big(a_j + \Big\lfloor \frac{z + i_j}{q} \Big\rfloor \Big) = C_b + \Big\lfloor \frac{b\tilde{t}}{m} \Big\rfloor, \qquad C_b = \sum_{j=0}^{q-1} \Big\lfloor \frac{bj}{q} \Big\rfloor,$$

and the term $j = j_0$ is $\lfloor bqt_1/n \rfloor = \lfloor bt_1/m \rfloor$. Hence $A(t) := \sum_{t' \mapsto t} \lfloor b\tilde{t}'/n \rfloor = \lfloor b\tilde{t}/m \rfloor + C_b - \lfloor b\,\widetilde{u^{-1}t}/m \rfloor$. Since $n - \tilde{t}' = \widetilde{-t'}$ and $t' \mapsto t$ if and only if $-t' \mapsto -t$, $\sum_{t' \mapsto t} \lfloor b(n - \tilde{t}')/n \rfloor = A(-t) = \lfloor b(m - \tilde{t})/m \rfloor + C_b - \lfloor b(m - \widetilde{u^{-1}t})/m \rfloor$. Subtracting gives (37.18).

Step 2: ideals. The ideal norm $\mathrm{N} = \mathrm{N}_{K_n/K_m}$ on fractional ideals is multiplicative, satisfies $\mathrm{N}(\mathfrak{p}') = \mathfrak{p}^s$, $\mathrm{N}(x\mathcal{O}_{K_n}) = \mathrm{N}_{K_n/K_m}(x)\mathcal{O}_{K_m}$, and $\mathrm{N}(\sigma(\mathfrak{a})) = \sigma|_{K_m}(\mathrm{N}(\mathfrak{a}))$ for $\sigma \in \mathrm{Gal}(K_n/\mathbb{Q})$ ($K_n/\mathbb{Q}$ is abelian). By item 2 of Lemma 37.16 at level n and (37.18),

$$\mathrm{N}_{K_n/K_m}(\mathrm{R}')\mathcal{O}_{K_m} = \prod_{t'} \sigma_{m,t}^{-1}(\mathfrak{p})^{s\,h_n(b,t')} = \prod_{t} \sigma_{m,t}^{-1}(\mathfrak{p})^{s\,(h_m(b,t) - h_m(b,u^{-1}t))}.$$

Substituting $t = ut_1$, $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,u^{-1}t)} = \sigma_{m,u}^{-1}\big(\prod_{t_1} \sigma_{m,t_1}^{-1}(\mathfrak{p})^{h_m(b,t_1)}\big) = \varphi^{-1}(\mathrm{R})\mathcal{O}_{K_m}$ by item 2 of Lemma 37.16 at level m. Hence $\mathrm{N}_{K_n/K_m}(\mathrm{R}')$ and $(\mathrm{R}/\varphi^{-1}(\mathrm{R}))^s$ generate the same fractional ideal.

Step 3: the unit is a root of unity. So $\beta = \mathrm{N}_{K_n/K_m}(\mathrm{R}')\,(\varphi^{-1}(\mathrm{R})/\mathrm{R})^s$ is a unit of $\mathcal{O}_{K_m}$. Let $\iota\colon K_m \to \mathbb{C}$ be an embedding and ι' an extension to K_n. Then $\iota(\mathrm{N}_{K_n/K_m}(\mathrm{R}')) = \prod_{\rho \in \mathrm{Gal}(K_n/K_m)} (\iota' \circ \rho)(\mathrm{R}')$ has absolute value 1, and so do $\iota(\mathrm{R})$ and $\iota(\varphi^{-1}(\mathrm{R})) = (\iota \circ \varphi^{-1}|_{K_m})(\mathrm{R})$, by item 1 of Lemma 37.16 applied to the embeddings $\iota' \circ \rho$, ι, $\iota \circ \varphi^{-1}|_{K_m}$. So every conjugate of the algebraic integer β has absolute value 1, and β is a root of unity by Kronecker's theorem [266]. Put $\eta = \beta^{-1}$. □

Lemma 37.18. *Let $m \geq 2$, let q be a prime with $q \nmid m$, and let b be an integer with $1 \leq b < m$, $b < q$ and $\gcd(b, m) = 1$. Let $\mathfrak{p}'$ be a prime ideal of $\mathcal{O}_{K_{qm}}$ not dividing qm, $\mathfrak{p} = \mathfrak{p}' \cap \mathcal{O}_{K_m}$, $s = [k_{\mathfrak{p}'} : k_{\mathfrak{p}}]$, and let $\varphi \in G_{\mathbb{Q}}$ satisfy $\varphi(\zeta) = \zeta^q$ for $\zeta \in \mu_m$. Then for every prime ideal $\mathfrak{Q}$ of $\mathcal{O}_{K_{qm}}$ above q, the elements $\mathrm{R}_{qm,b}(\mathfrak{p}')$ and $\varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))$ are $\mathfrak{Q}$-adic units and*

$$\mathrm{R}_{qm,b}(\mathfrak{p}') \equiv \varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))^s \pmod{\mathfrak{Q}}.$$

Proof. Put $n = qm$, $\mathrm{R}' = \mathrm{R}_{n,b}(\mathfrak{p}')$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$; let p be the residue characteristic of $\mathfrak{p}'$, so $p \neq q$; $k = k_{\mathfrak{p}} \subseteq k' = k_{\mathfrak{p}'}$ (via $\mathcal{O}_{K_m}/\mathfrak{p} \to \mathcal{O}_{K_n}/\mathfrak{p}'$), $\chi = \chi_{\mathfrak{p}}$, $\chi' = \chi_{\mathfrak{p}'}$, and $\mathrm{g}(j) = \mathrm{g}_{\mathfrak{p}}(j)$, $\mathrm{g}'(j) = \mathrm{g}_{\mathfrak{p}'}(j)$, formed with the same ζ_p. As $1 \le b < q$, $\gcd(b,n) = 1$. Let $L = \mathbb{Q}(\mu_{np})$.

Step 1: the residue characters. For $c \in k'^{\times}$, $\chi'(c)^q = \chi(\mathrm{N}_{k'/k}(c))$. Indeed, let $x \in \mathcal{O}_{K_n}$ lift c and $y \in \mathcal{O}_{K_m}$ lift $\mathrm{N}_{k'/k}(c) = c^{(|k'|-1)/(|k|-1)}$. Modulo $\mathfrak{p}'$, $\chi'(c)^q \equiv x^{(|k'|-1)/m}$ and $\chi(\mathrm{N}_{k'/k}(c)) \equiv y^{(|k|-1)/m} \equiv x^{(|k'|-1)/m}$; both sides lie in μ_n, whose elements are pairwise incongruent modulo $\mathfrak{p}'$ as $p \nmid n$.

Step 2: q-th powers of Gauss sums. Let $j \in \{\pm 1, \pm b\}$; then $m \nmid j$ and χ^{-j} is a nontrivial character of $k^{\times}$. In a commutative ring $(a_1 + \cdots + a_r)^q \equiv a_1^q + \cdots + a_r^q$ modulo q. Hence, in $\mathcal{O}_L$ modulo q, using $q \operatorname{Tr}_{k'/\mathbb{F}_p}(c) = \operatorname{Tr}_{k'/\mathbb{F}_p}(qc)$, the substitution $c \mapsto q^{-1}c$ in $k'^{\times}$ ($q \in \mathbb{F}_p^{\times}$), Step 1, and Theorem B.21 for $\alpha = \chi^{-j}$:

$$\begin{aligned} \mathrm{g}'(j)^q &\equiv \sum_{c \in k'^{\times}} \chi'(c)^{-jq} \zeta_p^{\operatorname{Tr}(qc)} = \chi'(q)^{jq} \sum_{c \in k'^{\times}} \chi\big(\mathrm{N}_{k'/k}(c)\big)^{-j} \zeta_p^{\operatorname{Tr}(c)} \\ &= \chi'(q)^{jq}\, \mathrm{g}_{k'}(\chi^{-j} \circ \mathrm{N}_{k'/k}) = \chi'(q)^{jq} (-1)^{s-1} \mathrm{g}(j)^s. \end{aligned} \tag{37.19}$$

Step 3: $\mathrm{R}'^q \equiv \mathrm{R}^s$ modulo $\mathfrak{Q}$. By item 1 of Theorem B.20, $\mathrm{g}(j)\mathrm{g}(-j) = \pm|k|$ and $\mathrm{g}'(j)\mathrm{g}'(-j) = \pm|k'|$ are powers of p up to sign, so these Gauss sums are units at every prime of L above q. Let $\widetilde{\mathfrak{Q}}$ be a prime of $\mathcal{O}_L$ above $\mathfrak{Q}$. Dividing the congruences (37.19) according to (37.14) in the local ring at $\widetilde{\mathfrak{Q}}$, the factors $\chi'(q)^{\pm q}$, $\chi'(q)^{\pm bq}$ and the signs cancel:

$$\mathrm{R}'^q = \frac{\mathrm{g}'(1)^{qb}\, \mathrm{g}'(-b)^q}{\mathrm{g}'(b)^q\, \mathrm{g}'(-1)^{qb}} \equiv \frac{\chi'(q)^{qb}\chi'(q)^{-bq}}{\chi'(q)^{bq}\chi'(q)^{-qb}} \cdot \frac{(-1)^{(s-1)(b+1)}}{(-1)^{(s-1)(1+b)}} \cdot \mathrm{R}^s = \mathrm{R}^s.$$

Both sides lie in K_n, so $\mathrm{R}'^q \equiv \mathrm{R}^s$ modulo $\mathfrak{Q} = \widetilde{\mathfrak{Q}} \cap \mathcal{O}_{K_n}$.

Step 4: Frobenius. Since $q \nmid m$, q is unramified in K_m and the Frobenius of every prime $\mathfrak{q}$ of K_m above q is $\sigma_{m,u} = \varphi|_{K_m}$, u the class of q; so $\varphi(z) \equiv z^q$ modulo $\mathfrak{q}$ for z in the local ring at $\mathfrak{q}$. By item 2 of Lemma 37.16, R, $\varphi^{-1}(\mathrm{R})$ and R' are units at every prime not above p, in particular at $\mathfrak{q} = \mathfrak{Q} \cap \mathcal{O}_{K_m}$ and at $\mathfrak{Q}$. Applied to $z = \varphi^{-1}(\mathrm{R})$ this gives $\mathrm{R} \equiv \varphi^{-1}(\mathrm{R})^q$ modulo $\mathfrak{q}$, hence $\mathrm{R}'^q \equiv \big(\varphi^{-1}(\mathrm{R})^s\big)^q$ modulo $\mathfrak{Q}$.

Step 5: conclusion. In the residue field $\mathcal{O}_{K_n}/\mathfrak{Q}$, of characteristic q, the images of R' and $\varphi^{-1}(\mathrm{R})^s$ have the same q-th power; as $x \mapsto x^q$ is injective on a field of characteristic q, they are equal. □

Lemma 37.19. *Let ℓ be an odd prime, $N_0 \ge 1$ and $m \ge 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod N$, $((\alpha_d),(e_{d,p}))$ an Euler system for (N,r) and (τ_p) a choice of generators for (N,r). For $L \in \mathcal{L}(N,r)$ put $y_L = \mathrm{Der}_L(\alpha_{|L|})$. Then $y_L \in K_{N|L|}^{\times}$, y_L does not change when the primes of L are permuted, y_L is a w-unit for every place w of $\overline{\mathbb{Q}}$ not above r, and for every $g \in U_N$ there is $z \in K_{N|L|}^{\times}$ with*

$$z^{\ell^m} = g(y_L)/y_L.$$

In particular y_L is ℓ^m-invariant over K_N.

Proof. Write $M = \ell^m$ in this proof. For a Kolyvagin prime p put $\mathrm{N}_p(z) = \prod_{i=0}^{p-2} \tau_p^i(z)$.

Step 1: elementary properties. Let n be a Kolyvagin integer. Every element of $G_{\mathbb{Q}}$ maps K_{Nn} onto itself, and elements of $G_{\mathbb{Q}}$ commute on K_{Nn} ($K_{Nn}/\mathbb{Q}$ is abelian). Hence each Der_p

is an endomorphism of the group $K_{Nn}^\times$, $\mathrm{Der}_p \circ \mathrm{Der}_{p'} = \mathrm{Der}_{p'} \circ \mathrm{Der}_p$ on $K_{Nn}^\times$, and $g(\mathrm{Der}_p(z)) = \mathrm{Der}_p(g(z))$, $g(\mathrm{N}_p(z)) = \mathrm{N}_p(g(z))$ for $g \in G_\mathbb{Q}$ and $z \in K_{Nn}^\times$. So $y_L \in K_{N|L|}^\times$ and y_L depends only on the set of primes of L. If z is a w-unit for every place w not above r, so is $g(z)$, as $v_w(g(z)) = v_{w\circ g}(z)$; with (Eu1) this shows that y_L is such a unit.

Step 2: telescoping. Let $p \mid n$. Then τ_p^{p-1} fixes K_{Nn}: it fixes the roots of unity of order prime to p and acts on μ_p by $g_p^{p-1} = 1$. For $z \in K_{Nn}^\times$,

$$\frac{\tau_p(\mathrm{Der}_p(z))}{\mathrm{Der}_p(z)} = \frac{z^{p-1}}{\mathrm{N}_p(z)}. \tag{37.20}$$

Step 3: induction on the length of L. If $L = \emptyset$, $y_L = \alpha_1 \in K_N$ is fixed by U_N and $z = 1$ works. Let L have length $k \geq 1$ and assume the claim for sequences of length $k-1$. Put $n = |L|$ and let S be the set of $g \in U_N$ for which some $z \in K_{Nn}^\times$ has $z^M = g(y_L)/y_L$.

(a) $U_{Nn} \subseteq S$, with $z = 1$, since $y_L \in K_{Nn}$.

(b) S is closed under products: if z_g, z_h serve for g, h, then $g(z_h)z_g \in K_{Nn}^\times$ and $(g(z_h)z_g)^M = g(h(y_L)/y_L) \cdot g(y_L)/y_L = gh(y_L)/y_L$.

(c) $\tau_p \in S$ for every prime p of L. First $\tau_p \in U_N$, as $p \nmid N$. By Step 1 we may write $L = (p, L_0)$ with $L_0 \in \mathcal{L}(N, r)$ of length $k-1$; put $n_0 = |L_0|$, so $n = pn_0$, and $w_0 = \mathrm{Der}_{L_0}(\alpha_n)$, so $y_L = \mathrm{Der}_p(w_0)$. Choose $\varphi \in G_\mathbb{Q}$ with $\varphi(\zeta) = \zeta^p$ for $\zeta \in \mu_{Nn_0}$ (possible as $p \nmid Nn_0$); as $p \equiv 1 \pmod N$, $\varphi \in U_N$. Since τ_p fixes μ_{Nn_0} and acts on μ_p by a generator, (Eu2) for $d = n_0$ gives $\mathrm{N}_p(\alpha_n) = (\alpha_{n_0}/\varphi^{-1}(\alpha_{n_0}))^e$ with $e = e_{n_0,p}$. Applying Der_{L_0}, which commutes with N_p on $K_{Nn}^\times$ and with φ^{-1} on $K_{Nn_0}^\times$ (Step 1), $\mathrm{N}_p(w_0) = (y_{L_0}/\varphi^{-1}(y_{L_0}))^e$. By the induction hypothesis, applied to L_0 and $\varphi^{-1} \in U_N$, there is $z_0 \in K_{Nn_0}^\times$ with $z_0^M = \varphi^{-1}(y_{L_0})/y_{L_0}$. By (37.20), and as $M \mid N \mid p-1$,

$$\frac{\tau_p(y_L)}{y_L} = \frac{w_0^{p-1}}{\mathrm{N}_p(w_0)} = w_0^{p-1}\Big(\frac{\varphi^{-1}(y_{L_0})}{y_{L_0}}\Big)^e = (w_0^{(p-1)/M} z_0^e)^M,$$

with $w_0^{(p-1)/M} z_0^e \in K_{Nn}^\times$.

(d) $S = U_N$. Restriction maps U_N onto $\mathrm{Gal}(K_{Nn}/K_N)$ with kernel U_{Nn}, and $\mathrm{Gal}(K_{Nn}/K_N) \cong (\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_{p|n}(\mathbb{Z}/p\mathbb{Z})^\times$ through the action on μ_n; the image of τ_p is a generator of the factor at p and trivial at the other factors. So every element of this finite group is a product of nonnegative powers of the images of the τ_p, every $g \in U_N$ is of the form $\tau_{p_1}^{c_1} \cdots \tau_{p_k}^{c_k} h$ with $c_i \geq 0$ and $h \in U_{Nn}$, and $g \in S$ by (a)–(c).

Finally, $K_{N|L|} \subseteq \mathbb{Q}(\mu_\infty)$, so y_L is ℓ^m-invariant over K_N. □

Lemma 37.20. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, $\delta \in G_\mathbb{Q}$ and $a \in \mathbb{Z}$ with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_{\ell^m}$, ζ_{ℓ^m} a primitive ℓ^m-th root of unity, and $y \in \mathbb{Q}(\mu_\infty)^\times$ ℓ^m-invariant over K_N. Write $\mathrm{P} = \mathrm{P}_{\delta,a}$.*

1. *For every $g \in U_N$, $Q_y(g)$ consists of one ℓ^m-th root of unity; the map $\mathrm{k}_y \colon U_N \to \mathbb{Z}/\ell^m\mathbb{Z}$ so defined is a continuous homomorphism.*

2. *If $g \in U_N$ fixes y, then $\zeta_{\ell^m}^{\mathrm{k}_y(g)} = g(\mathrm{P}(Y))/\mathrm{P}(Y)$ for every $Y \in \overline{\mathbb{Q}}$ with $Y^{\ell^m} = y$.*

3. *Let $p' \neq \ell$ be a prime such that y is a w-unit for every place w of $\overline{\mathbb{Q}}$ above p', and let $g \in U_N$ fix y and lie in an inertia group $I(D)$ at p'. Then $\mathrm{k}_y(g) = 0$.*

4. *Let r be a prime with $r \equiv 1 \pmod N$, D_0 a decomposition group at r, the stabiliser of the place $\bar{\mathfrak{r}}$, and $\rho \in \overline{\mathbb{Q}}$ with $\rho^{\ell^m} = r$. There is $t_0 \in I(D_0)$ with $t_0(\rho) = \zeta_{\ell^m}\rho$. If moreover $y \in K_N^\times$, then for every $\sigma \in G_\mathbb{Q}$, with $c \in \mathbb{Z}$ such that $\sigma(\zeta) = \zeta^c$ for $\zeta \in \mu_{\ell^m}$, one has $\sigma^{-1}t_0\sigma \in U_N$ and*

$$c \cdot \mathrm{k}_y(\sigma^{-1}t_0\sigma) = v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{P}(y))) \quad \text{in } \mathbb{Z}/\ell^m\mathbb{Z}.$$

Proof. Write $M = \ell^m$ and $\zeta = \zeta_{\ell^m}$. The map P is an endomorphism of $\overline{\mathbb{Q}}^\times$, trivial on μ_M, and $g(\mathrm{P}(x)) = \mathrm{P}(g(x))$ for $g \in G_\mathbb{Q}$ and $x \in \mathbb{Q}(\mu_\infty)$, as $\mathrm{Gal}(\mathbb{Q}(\mu_\infty)/\mathbb{Q})$ is abelian. Elements of U_N fix $\mu_M \subseteq \mu_N$.

Item 1. Let $g \in U_N$, $Y^M = y$, and $z \in \mathbb{Q}(\mu_\infty)$ with $z^M = g(y)/y$ (it exists by invariance). Then $\mathrm{P}(Y)^M = \mathrm{P}(y)$, $g(\mathrm{P}(Y))^M = g(\mathrm{P}(y)) = \mathrm{P}(g(y))$ and $\mathrm{P}(z)^M = \mathrm{P}(g(y))/\mathrm{P}(y)$, so the quotient $g(\mathrm{P}(Y))/(\mathrm{P}(Y)\mathrm{P}(z))$ lies in μ_M. Any other choices are ξY and $\xi' z$ with $\xi, \xi' \in \mu_M$, and $\mathrm{P}(\xi Y) = \mathrm{P}(Y)$, $\mathrm{P}(\xi' z) = \mathrm{P}(z)$; so $Q_y(g)$ is one element $\zeta^{\mathrm{k}_y(g)}$. For $g, h \in U_N$ with z_g, z_h as above, $z = g(z_h)z_g \in \mathbb{Q}(\mu_\infty)$ satisfies $z^M = gh(y)/y$ and $\mathrm{P}(z) = g(\mathrm{P}(z_h))\mathrm{P}(z_g)$, so

$$\frac{gh(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z)} = g\Big(\frac{h(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z_h)}\Big) \cdot \frac{g(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z_g)} = g\big(\zeta^{\mathrm{k}_y(h)}\big)\zeta^{\mathrm{k}_y(g)} = \zeta^{\mathrm{k}_y(h)+\mathrm{k}_y(g)},$$

and k_y is a homomorphism. The subgroup U' of the $h \in U_N$ fixing y and $\mathrm{P}(Y)$ is open; for $h \in U'$ one may take $z = 1$, so $\zeta^{\mathrm{k}_y(h)} = h(\mathrm{P}(Y))/\mathrm{P}(Y) = 1$. A homomorphism into a finite group that vanishes on an open subgroup is continuous.

Item 2. Take $z = 1$ in the definition.

Item 3. Let w be the place of which D is the stabiliser, and $V = \mathrm{P}(Y)$, so $V^M = \mathrm{P}(y) = \delta(y)y^{-a}$. As $v_w(\delta(y)) = v_{w\circ\delta}(y) = 0$, $\mathrm{P}(y)$ and hence V are w-units. Since $g \in I(D)$ acts trivially on the residue field of w, $g(V)/V \equiv 1 \pmod w$; it lies in μ_M, whose elements are pairwise incongruent modulo w as $p' \nmid M$. So $g(V)/V = 1$, and $\mathrm{k}_y(g) = 0$ by item 2.

Item 4: the element t_0. Let $E = K_N(\rho)$; it contains μ_M and all the roots $\xi\rho$ of $X^M - r$, so $E/\mathbb{Q}$ is Galois. As $r \equiv 1 \pmod N$, r splits completely in K_N, so the completion of K_N at $\bar{\mathfrak{r}}$ is $\mathbb{Q}_r$; there $X^M - r$ is an Eisenstein polynomial, so the completion of E is totally ramified of degree M over $\mathbb{Q}_r$. Hence $[E : K_N] = M$, $X^M - r$ is irreducible over K_N, and the inertia group of $E/\mathbb{Q}$ at $\bar{\mathfrak{r}}$, which lies in $\mathrm{Gal}(E/K_N)$ (K_N is unramified at r) and has order M, is all of $\mathrm{Gal}(E/K_N)$. It contains the automorphism $\rho \mapsto \zeta\rho$. Since $I(D_0)$ maps onto the inertia group of E at $\bar{\mathfrak{r}}$, some $t_0 \in I(D_0)$ satisfies $t_0(\rho) = \zeta\rho$.

Item 4: the value. As $r \nmid N$, inertia groups at r fix K_N, so $t_0 \in U_N$ and $h = \sigma^{-1}t_0\sigma \in U_N$; h fixes $y \in K_N$. Let $Y^M = y$, $V = \sigma(\mathrm{P}(Y))$ and $u = \sigma(\mathrm{P}(y)) = V^M \in K_N^\times$. By item 2, $\zeta^{\mathrm{k}_y(h)} = h(\mathrm{P}(Y))/\mathrm{P}(Y) = \sigma^{-1}(t_0(V)/V)$. Let $v = v_{\bar{\mathfrak{r}}}(u) \in \mathbb{Z}$ (K_N is unramified at r) and $V_0 = V\rho^{-v}$; then $V_0^M = ur^{-v}$ is a $\bar{\mathfrak{r}}$-unit, hence so is V_0, and as in item 3 ($r \nmid M$) $t_0(V_0) = V_0$. So $t_0(V)/V = (t_0(\rho)/\rho)^v = \zeta^v$, and $\zeta^{\mathrm{k}_y(h)} = \sigma^{-1}(\zeta^v) = \zeta^{vc'}$ with $cc' \equiv 1 \pmod M$. Hence $c\,\mathrm{k}_y(h) = v$ in $\mathbb{Z}/M\mathbb{Z}$. □

Lemma 37.21. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod N$, $((\alpha_d), (e_{d,p}))$ an Euler system for (N, r), (τ_p) a choice of generators, and δ, a, ζ_{ℓ^m} as in the definition of k_y. For $L \in \mathcal{L}(N, r)$ put $y_L = \mathrm{Der}_L(\alpha_{|L|})$. Let $L \in \mathcal{L}(N, r)$, p a Kolyvagin prime for (N, r) not occurring in L, D a decomposition group at p, φ a Frobenius of D, and $t \in I(D)$ with $t(\zeta) = \tau_p(\zeta)$ for $\zeta \in \mu_p$. Then $\varphi, t \in U_N$ and*

$$\mathrm{k}_{y_{(p,L)}}(t) = -\,e_{|L|,p}\,\mathrm{k}_{y_L}(\varphi) \quad \text{in } \mathbb{Z}/\ell^m\mathbb{Z}.$$

Proof. Write $M=\ell^m$, $\zeta=\zeta_{\ell^m}$, $\mathrm{P}=\mathrm{P}_{\delta,a}$, $n=|L|$, $e=e_{n,p}$, $k'=(p-1)/M\in\mathbb{Z}$ ($M\mid N\mid p-1$), $\mathrm{N}_p(z)=\prod_{i=0}^{p-2}\tau_p^i(z)$, and let w be the place stabilised by D. Put $y=y_L\in K_{Nn}^\times$, $w_0=\mathrm{Der}_L(\alpha_{pn})\in K_{Npn}^\times$ and $y'=y_{(p,L)}=\mathrm{Der}_p(w_0)$. Elements of $G_\mathbb{Q}$ commute on the abelian field K_{Npn}, so Der_L, Der_p, N_p and P commute with them there.

Step 1: t and φ. For $\zeta'\in\mu_{Nn}$ we have $t(\zeta')\equiv\zeta'$ and $\varphi(\zeta')\equiv\zeta'^p$ modulo w; both sides lie in μ_{Nn}, whose elements are pairwise incongruent modulo w as $p\nmid Nn$; so t fixes μ_{Nn} and $\varphi(\zeta')=\zeta'^p$. As $p\equiv1\pmod N$, $t,\varphi\in U_N$. Since τ_p also fixes μ_{Nn} and agrees with t on μ_p, t and τ_p agree on K_{Npn}.

Step 2: a root of $t(y')/y'$. As τ_p^{p-1} fixes K_{Npn}, $\tau_p(\mathrm{Der}_p(w_0))/\mathrm{Der}_p(w_0)=w_0^{p-1}/\mathrm{N}_p(w_0)$.

By (Eu2) for $d=n$, with τ_p (which fixes μ_{Nn} and acts on μ_p by a generator) and φ, and as Der_L is multiplicative and commutes with N_p and φ^{-1}, $\mathrm{N}_p(w_0)=\mathrm{Der}_L(\mathrm{N}_p(\alpha_{pn}))=(y/\varphi^{-1}(y))^e$. By Lemma 37.19 applied to $\varphi^{-1}\in U_N$, there is $z'\in K_{Nn}^\times$ with $z'^M=\varphi^{-1}(y)/y$. Then $z=w_0^{k'}z'^e\in K_{Npn}^\times$ satisfies

$$z^M=w_0^{p-1}\Big(\frac{\varphi^{-1}(y)}{y}\Big)^e=\frac{\tau_p(y')}{y'}=\frac{t(y')}{y'}.$$

Step 3: an identity. Choose $Y,Y'\in\overline{\mathbb{Q}}$ with $Y^M=y'$ and $Y'^M=y$, and put $c=w_0/\varphi^{-1}(y)^e\in K_{Npn}^\times$. By the definition of k, $\zeta^{\mathrm{k}_{y'}(t)}=t(\mathrm{P}(Y))/(\mathrm{P}(Y)\mathrm{P}(z))$ and $\zeta^{\mathrm{k}_y(\varphi^{-1})}=\varphi^{-1}(\mathrm{P}(Y'))/(\mathrm{P}(Y')\mathrm{P}(z'))$. Hence

$$\zeta^{\mathrm{k}_{y'}(t)-e\,\mathrm{k}_y(\varphi^{-1})}=\frac{t(\mathrm{P}(Y))}{\mathrm{P}(Y)}\cdot\Big(\frac{\mathrm{P}(Y')}{\varphi^{-1}(\mathrm{P}(Y'))^p}\Big)^e\cdot\mathrm{P}(c)^{-k'}.\tag{37.21}$$

Step 4: each factor is $\equiv1\pmod w$. The elements y, y', w_0 are products of integer powers of Galois conjugates of α_n, α_{pn}, hence w-units by (Eu1) ($p\neq r$); so are $\mathrm{P}(y)$, $\mathrm{P}(y')$ ($v_w\circ\delta=v_{w\circ\delta}$), hence $\mathrm{P}(Y)$, $\mathrm{P}(Y')$, and $x=\varphi^{-1}(\mathrm{P}(Y'))$ (φ stabilises w). As $t\in I(D)$ acts trivially on the residue field of w, $t(\mathrm{P}(Y))\equiv\mathrm{P}(Y)$. As φ is a Frobenius of D, $\mathrm{P}(Y')=\varphi(x)\equiv x^p$. Finally, by (Eu3) for $d=n$, $\alpha_{pn}/\varphi^{-1}(\alpha_n)^e\equiv1$ modulo every place above p; $c=\mathrm{Der}_L(\alpha_{pn}/\varphi^{-1}(\alpha_n)^e)$ is a product of integer powers of its conjugates $g(\cdot)$, $g\in G_\mathbb{Q}$, and $v_{w'}(g(x')-1)=v_{w'\circ g}(x'-1)$; so $c\equiv1$ modulo every place above p, hence $\delta(c)\equiv1$, $c^{-a}\equiv1$ and $\mathrm{P}(c)\equiv1\pmod w$.

Step 5: conclusion. By (37.21) and Step 4, the M-th root of unity $\zeta^{\mathrm{k}_{y'}(t)-e\mathrm{k}_y(\varphi^{-1})}$ is $\equiv1\pmod w$; as $p\nmid M$ it equals 1. So $\mathrm{k}_{y'}(t)=e\,\mathrm{k}_y(\varphi^{-1})=-e\,\mathrm{k}_y(\varphi)$, k_y being a homomorphism. □

Lemma 37.22. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $\theta\colon G_\mathbb{Q}\to\mathcal{O}^\times$ a continuous character with a Kolyvagin level (N_0,m) of modulus N, Σ the set of primes dividing N, and δ a normaliser for θ. Let $n\geq1$ be an integer, p a prime with $p\equiv1\pmod N$ and $p\nmid n$, and $\lambda\colon U_N\to\mathcal{O}^\vee$ a continuous homomorphism with $\lambda(gug^{-1})=\check\theta(g)\lambda(u)$ for $g\in G_\mathbb{Q}$, $u\in U_N$, vanishing on $U_N\cap I$ for every inertia group I at a prime not dividing Nnp. Let $a_0,a'\in\mathcal{O}$ with $a_0\neq0$, $a_0\mid a'\mid\ell^m$ and $a'\lambda=0$, and let $w_0\in\mathcal{O}^\vee$ have annihilator $a'\mathcal{O}$. Let $z\in\mathrm{Z}_{\theta,\delta}(\Sigma,a_0;n)$, let D be a decomposition group at p, $g\in D$, $\tau\in I(D)$, and $y\in\mathcal{O}$ with $\lambda(\tau)=y\,w_0$. Then $y\,z(g)=0$.*

Proof. Let K be the fraction field of $\mathcal{O}$. As $\mathcal{O}$ is free of finite rank over $\mathbb{Z}_\ell$, $\mathcal{O}^\vee=(\mathcal{O}\otimes\mathbb{Q}_\ell)/\mathcal{O}=K/\mathcal{O}$. Put $M=\{x\in\mathcal{O}^\vee:a'x=0\}=a'^{-1}\mathcal{O}/\mathcal{O}$; then $M=\mathcal{O}w_0$ and $x\mapsto xw_0$ identifies $\mathcal{O}/a'\mathcal{O}$ with M. Let $\beta\colon M\times M\to M$, $\beta(xw_0,x'w_0)=xx'w_0$, the $\mathcal{O}$-bilinear product transported from the ring $\mathcal{O}/a'\mathcal{O}$. Since $a_0\mid a'$, z takes values in M; so does λ.

Step 1: the actions on M. For $u\in U_N$, $\theta(u)\equiv1$ by (Kv1) and $\chi_{\mathrm{cyc}}(u)\equiv1$ modulo ℓ^m (u fixes $\mu_{\ell^m}\subseteq\mu_N$), hence also $\check\theta(u)\equiv1$; as $a'\mid\ell^m$, $\theta(u)$, $\check\theta(u)$ and $\chi_{\mathrm{cyc}}(u)$ act trivially on M, and $\chi_{\mathrm{cyc}}(u)$ acts trivially on μ_{ℓ^m}. An inertia group at a prime $p'\nmid N$ lies in U_N, since $\mathbb{Q}(\mu_N)$ is

unramified at p'; the decomposition group D lies in U_N, since $p \nmid N$ and its Frobenius elements act on μ_N by $\zeta \mapsto \zeta^p = \zeta$, while $I(D)$ acts trivially on μ_N.

Step 2: λ extends to a cocycle on $G_{\mathbb{Q}}$. Let $\Gamma = G_{\mathbb{Q}}/U_N$, a finite abelian group acting on M through $\check{\theta}$ (Step 1). Let g_1 be as in (Kv3) and $s = \check{\theta}(g_1)$; then $s-1 = \theta(g_1)^{-1}(\chi_{\mathrm{cyc}}(g_1)-\theta(g_1)) \in \mathcal{O}^\times$. For an element γ of a finite group, conjugation by γ together with $x \mapsto \gamma x$ on the coefficients induces the identity on cohomology ([221, VII.5]); for the central element $\gamma_1 = g_1 U_N$ of Γ this map is multiplication by s. Hence $s-1$ kills the $\mathcal{O}$-module $H^2(\Gamma, M)$, so $H^2(\Gamma, M) = 0$. In the inflation–restriction sequence $H^1(G_{\mathbb{Q}}, M) \to H^1(U_N, M)^\Gamma \to H^2(\Gamma, M)$ [222], $H^1(U_N, M) = \mathrm{Hom}_{\mathrm{cont}}(U_N, M)$ (Step 1), and λ is Γ-invariant: $\check{\theta}(g)\lambda(g^{-1}ug) = \check{\theta}(g)\check{\theta}(g)^{-1}\lambda(u) = \lambda(u)$. So there is a continuous cocycle $\tilde{\lambda}\colon G_{\mathbb{Q}} \to M$ for the action $\check{\theta}$ whose restriction to U_N differs from λ by a coboundary $u \mapsto \check{\theta}(u)x - x$, which is 0 by Step 1: $\tilde{\lambda}|_{U_N} = \lambda$. In particular $\tilde{\lambda}$ vanishes on every inertia group at a prime not dividing Nnp, and $\tilde{\lambda}(\tau) = \lambda(\tau)$.

Step 3: a global class. Let $\Lambda\colon M \to \mathbb{Z}/\ell^m\mathbb{Z}$ be any homomorphism of abelian groups ($\ell^m M = 0$), and give $\mathbb{Z}/\ell^m\mathbb{Z}$ the action $g \cdot k = \chi_{\mathrm{cyc}}(g)k$, which is μ_{ℓ^m} after fixing a primitive root of unity. The map $(x, x') \mapsto \Lambda(\beta(x, x'))$ from $M(\theta) \times M(\check{\theta})$ is biadditive and $G_{\mathbb{Q}}$-equivariant, since $\beta(\theta(g)x, \check{\theta}(g)x') = \chi_{\mathrm{cyc}}(g)\beta(x, x')$ and Λ commutes with multiplication by $\chi_{\mathrm{cyc}}(g) \in \mathbb{Z}_\ell$. So the cup product

$$w_\Lambda(g, h) = \Lambda(\beta(z(g), \check{\theta}(g)\tilde{\lambda}(h)))$$

is a continuous 2-cocycle on $G_{\mathbb{Q}}$ with values in μ_{ℓ^m}; let $\xi_\Lambda \in H^2(G_{\mathbb{Q}}, \mu_{\ell^m})$ be its class.

Step 4: ξ_Λ is locally trivial at every place $v \neq p$. Let D_v be a decomposition group at v.

(a) $v = \infty$: $H^2(G_{\mathbb{R}}, \mu_{\ell^m}) = 0$ by item 1 of Theorem B.22.

(b) $v = p' \in \Sigma$: by (Kd4) there is $x \in M$ with $z(g) = \theta(g)x - x$ on D_v. With $b(h) = \Lambda(\beta(x, \tilde{\lambda}(h)))$, for $g, h \in D_v$,

$$\begin{aligned}\chi_{\mathrm{cyc}}(g)b(h) - b(gh) + b(g) &= \Lambda(\beta(x, (\chi_{\mathrm{cyc}}(g) - \check{\theta}(g))\tilde{\lambda}(h))) \\ &= \Lambda(\beta((\theta(g) - 1)x, \check{\theta}(g)\tilde{\lambda}(h))) = w_\Lambda(g, h),\end{aligned}$$

so $w_\Lambda|_{D_v}$ is a coboundary.

(c) $v = p' \mid n$: $z = 0$ on D_v by (Kd5), so $w_\Lambda = 0$ on $D_v \times D_v$.

(d) $v = p' \notin \Sigma$, $p' \nmid np$: z vanishes on $I(D_v)$ by (Kd3), $\tilde{\lambda}$ by Step 2, and $I(D_v) \subseteq U_N$ acts trivially on M (Step 1); hence $z(gi) = z(g)$, $\tilde{\lambda}(hi') = \tilde{\lambda}(h)$ and $\check{\theta}(gi)x = \check{\theta}(g)x$ on M for $i, i' \in I(D_v)$, and $w_\Lambda|_{D_v}$ is inflated from a continuous 2-cocycle of $D_v/I(D_v) \cong \widehat{\mathbb{Z}}$ with values in a finite module. Since $\widehat{\mathbb{Z}}$ has cohomological dimension 1 [222], it is a coboundary.

Restriction to conjugate decomposition groups at the same place corresponds under conjugation, so $\mathrm{res}_v \xi_\Lambda = 0$ for every $v \neq p$. By Theorem B.22, $\mathrm{res}_p \xi_\Lambda = 0$: there is a continuous $b_p\colon D \to \mathbb{Z}/\ell^m\mathbb{Z}$ with $w_\Lambda(g, h) = \chi_{\mathrm{cyc}}(g)b_p(h) - b_p(gh) + b_p(g)$ for $g, h \in D$.

Step 5: the local computation at p. By Step 1, $D \subseteq U_N$ acts trivially on M and on μ_{ℓ^m}; so on D, z and $\tilde{\lambda}$ are continuous homomorphisms into M, z vanishes on $I(D)$ by (Kd3) ($p \notin \Sigma$), and $w_\Lambda(g, h) = \Lambda(\beta(z(g), \tilde{\lambda}(h))) = b_p(h) - b_p(gh) + b_p(g)$ on D. Fix a Frobenius φ of D. We use:

(F) a continuous homomorphism f from D to a discrete abelian group that vanishes on $I(D)$ and at φ is 0: its kernel is an open, hence closed, subgroup containing $I(D)$ and φ, and $D/I(D)$ is procyclic, topologically generated by the image of φ.

Let $y_\Lambda\colon D \to \mathbb{Z}/\ell^m\mathbb{Z} = \mu_{\ell^m}$, $y_\Lambda(h) = \Lambda(\beta(z(\varphi), \tilde{\lambda}(h)))$, a continuous homomorphism, i.e. a class in $H^1(D, \mu_{\ell^m})$. Let $x\colon D \to \mathbb{Z}/\ell^m\mathbb{Z}$ be a continuous homomorphism vanishing on $I(D)$, i.e. a class in $H^1_{\mathrm{ur}}(D, \mathbb{Z}/\ell^m\mathbb{Z})$. By (F) applied to $g \mapsto x(g)z(\varphi) - x(\varphi)z(g)$, we have $x(g)z(\varphi) = x(\varphi)z(g)$ for $g \in D$, hence

$$x(g)\, y_\Lambda(h) = \Lambda\big(\beta(x(\varphi)z(g), \tilde{\lambda}(h))\big) = x(\varphi)\big(b_p(h) - b_p(gh) + b_p(g)\big),$$

so the cup product $x \cup y_\Lambda$ is 0 in $H^2(D, \mu_{\ell^m})$. By item 3 of Theorem B.29 (applied to $\mathbb{Q}_p$, $p \neq \ell$, and the module $\mathbb{Z}/\ell^m\mathbb{Z}$ with trivial action, whose dual is μ_{ℓ^m}), $y_\Lambda \in H^1_{\mathrm{ur}}(D, \mu_{\ell^m})$; as D acts trivially on μ_{ℓ^m}, this means y_Λ vanishes on $I(D)$. In particular $\Lambda(\beta(z(\varphi), \tilde{\lambda}(\tau))) = 0$. The finite group M is killed by ℓ^m, so the homomorphisms $\Lambda\colon M \to \mathbb{Z}/\ell^m\mathbb{Z}$ separate its points; hence $\beta(z(\varphi), \lambda(\tau)) = 0$. Writing $z(\varphi) = \hat{z}w_0$ with $\hat{z} \in \mathcal{O}$, this says $\hat{z}\, y\, w_0 = 0$, i.e. $y\, z(\varphi) = 0$. Finally $g \mapsto y\, z(g)$ is a continuous homomorphism on D vanishing on $I(D)$ and at φ, so $y\, z(g) = 0$ for every $g \in D$ by (F). □

Lemma 37.23. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $\theta\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a continuous character with a Kolyvagin level (N_0, m) of modulus N, r a prime with $r \equiv 1 \pmod N$, and $T \geq 1$ an integer. Let $\lambda, z\colon U_N \to \mathcal{O}^\vee$ be continuous homomorphisms with $\ell^m\lambda = \ell^m z = 0$ and*

$$\lambda(gug^{-1}) = \check{\theta}(g)\lambda(u), \qquad z(gug^{-1}) = \theta(g)z(u) \qquad (g \in G_{\mathbb{Q}},\ u \in U_N),$$

and assume $z \neq 0$. Then there are a Kolyvagin prime p for (N, r) with $p \nmid T$, a decomposition group D at p and a Frobenius φ of D such that $\varphi \in U_N$, $z(\varphi) \neq 0$ and $\lambda(U_N) \subseteq \mathcal{O}\lambda(\varphi)$.

Proof. Let $\mathfrak{m}$ be the maximal ideal of $\mathcal{O}$; recall $\mathcal{O}^\vee \cong K/\mathcal{O}$ for the fraction field K of $\mathcal{O}$, so its $\mathcal{O}$-submodules are 0, $\pi^{-k}\mathcal{O}/\mathcal{O}$ (π a uniformiser) and $\mathcal{O}^\vee$, totally ordered by inclusion. Fix $\rho \in \overline{\mathbb{Q}}$ with $\rho^{\ell^m} = r$ and let $H = \{u \in U_N : u(\rho) = \rho\} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\mu_N, \rho))$; the field $\mathbb{Q}(\mu_N, \rho)$ contains all $\zeta\rho$ with $\zeta \in \mu_{\ell^m} \subseteq \mu_N$, so it is Galois over $\mathbb{Q}$ and H is open and normal in $G_{\mathbb{Q}}$. For $u \in U_N$ put $\epsilon(u) = u(\rho)/\rho \in \mu_{\ell^m}$; since u fixes μ_{ℓ^m}, ϵ is a continuous homomorphism with kernel H, and $\epsilon(gug^{-1}) = g(\epsilon(u)) = \epsilon(u)^k$ for $g \in G_{\mathbb{Q}}$ and any integer $k \equiv \chi_{\mathrm{cyc}}(g) \pmod{\ell^m}$.

Step 1: a Kummer constraint. Let A be an $\mathcal{O}$-module with $\ell^m A = 0$, $\gamma\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a character and $f\colon U_N \to A$ a homomorphism with $f(gug^{-1}) = \gamma(g)f(u)$, vanishing on H. Then $(\gamma(g) - \chi_{\mathrm{cyc}}(g))f(u) = 0$ for all $g \in G_{\mathbb{Q}}$, $u \in U_N$. Indeed, for $k \equiv \chi_{\mathrm{cyc}}(g) \pmod{\ell^m}$, $\epsilon(gug^{-1}) = \epsilon(u^k)$, so $gug^{-1} \in u^k H$ and $\gamma(g)f(u) = f(gug^{-1}) = kf(u) = \chi_{\mathrm{cyc}}(g)f(u)$.

Step 2: three open normal subgroups not containing H.

(a) $B = \ker z$ is open (z is continuous into a discrete module) and normal (equivariance). If $H \subseteq B$, Step 1 with $\gamma = \theta$ and $g = g_1$ from (Kv3) gives $z = 0$, as $\theta(g_1) - \chi_{\mathrm{cyc}}(g_1)$ is a unit; so $H \not\subseteq B$.

(b) The set $\lambda(U_N)$ is finite (U_N is compact, λ locally constant), so there is $u_0 \in U_N$ with $\mathcal{O}\lambda(u) \subseteq \mathcal{O}\lambda(u_0)$ for all u. If $\lambda(u_0) = 0$ put $K_\lambda = B$. Otherwise let $P = \mathfrak{m}\lambda(u_0)$ and $K_\lambda = \{u \in U_N : \lambda(u) \in P\}$, an open normal subgroup. If $H \subseteq K_\lambda$, Step 1 applied to $u \mapsto \lambda(u) + P \in \mathcal{O}^\vee/P$ with $\gamma = \check{\theta}$ and an element $c \in G_{\mathbb{Q}}$ acting on μ_N by $\zeta \mapsto \zeta^{-1}$ gives $(\check{\theta}(c) - \chi_{\mathrm{cyc}}(c))\lambda(u_0) \in P$; here $\check{\theta}(c) - \chi_{\mathrm{cyc}}(c) = \check{\theta}(c)(1 - \theta(c))$ and $1 - \theta(c) \equiv 2 \pmod{\mathfrak{m}}$ by (Kv2), a unit as ℓ is odd. So $\lambda(u_0) = y\lambda(u_0)$ with $y \in \mathfrak{m}$, and $(1-y)\lambda(u_0) = 0$ forces $\lambda(u_0) = 0$, a contradiction. Hence $H \not\subseteq K_\lambda$. In both cases, every $\varphi \in U_N \setminus K_\lambda$ satisfies $\lambda(U_N) \subseteq \mathcal{O}\lambda(\varphi)$: if $\lambda(u_0) \neq 0$, $\lambda(\varphi) = y\lambda(u_0)$ with $y \notin \mathfrak{m}$, so $\mathcal{O}\lambda(\varphi) = \mathcal{O}\lambda(u_0)$; if $\lambda(u_0) = 0$, $\lambda = 0$.

(c) $C = U_{N\ell}$. Let $u \in G_{\mathbb{Q}}$ act on $\mu_{N\ell}$ by $\zeta \mapsto \zeta^{1+N}$ ($1+N$ is prime to $N\ell$ as $\ell \mid N$), so $u \in U_N$, and let $c' \in G_{\mathbb{Q}}$ act on $\mu_{N\ell}$ by inversion. Then $h = c'uc'^{-1}u \in U_N$ and $\epsilon(h) = \epsilon(u)^{-1}\epsilon(u) = 1$, since $\chi_{\mathrm{cyc}}(c') \equiv -1 \pmod{\ell^m}$; so $h \in H$. As $\mathrm{Gal}(\mathbb{Q}(\mu_{N\ell})/\mathbb{Q})$ is abelian, h acts on $\mu_{N\ell}$ by $\zeta \mapsto \zeta^{(1+N)^2}$, and $(1+N)^2 - 1 = N(N+2)$ is not divisible by $N\ell$ because $\ell \nmid N+2$. So $h \notin C$ and $H \not\subseteq C$.

Moreover $x^{\ell^m} \in B$ for every $x \in H$, since $z(x^{\ell^m}) = \ell^m z(x) = 0$.

Step 3: an element of H outside the three subgroups. First, if A, A' are subgroups with $H \not\subseteq A$, $H \not\subseteq A'$, there is $x \in H$ outside $A \cup A'$: take $a \in H \setminus A$ and $b \in H \setminus A'$; if $a \notin A'$ or $b \notin A$ we are done; otherwise $ab \notin A$ and $ab \notin A'$. Suppose now $H \subseteq K_\lambda \cup B \cup C$. Choose $x \in H \setminus (B \cup C)$ and $y \in H \setminus (K_\lambda \cup C)$; then $x \in K_\lambda$ and $y \in B$. The element xy lies neither in K_λ (else $y \in K_\lambda$) nor in B (else $x \in B$), so $xy \in C$. The element $x^2y = x \cdot xy$ lies neither in K_λ (else $xy \in K_\lambda$, so $y \in K_\lambda$) nor in C (else $x \in C$); so $x^2y \in B$ and $x^2 \in B$. Writing $\ell^m = 2j+1$, $x = x^{\ell^m}(x^2)^{-j} \in B$, a contradiction. So there is $x \in H$ with $x \notin K_\lambda \cup B \cup C$.

Step 4: Chebotarev. Let $W = K_\lambda \cap B \cap C \cap H$, an open normal subgroup of $G_{\mathbb{Q}}$ with finite Galois fixed field L. By Theorem B.18, applied to the conjugacy class of the image of x in $\mathrm{Gal}(L/\mathbb{Q})$, infinitely many primes are unramified in L and have this class as Frobenius class; choose such a prime p with $p \nmid TNr$, a prime of L above p whose Frobenius is the image of x, a place of $\overline{\mathbb{Q}}$ above it with decomposition group D, and a Frobenius φ of D. Then φ maps to the image of x in $\mathrm{Gal}(L/\mathbb{Q})$, i.e. $\varphi \in xW$. Since W lies in each of K_λ, B, C and x in none, $\varphi \notin K_\lambda \cup B \cup C$; and $\varphi \in H \subseteq U_N$. So $z(\varphi) \neq 0$ by (a) and $\lambda(U_N) \subseteq \mathcal{O}\lambda(\varphi)$ by (b).

Step 5: p is a Kolyvagin prime for (N, r). As $p \nmid N\ell$, φ acts on $\mu_{N\ell}$ by $\zeta \mapsto \zeta^p$. From $\varphi \in U_N$, $p \equiv 1 \pmod{N}$; from $\varphi \notin U_{N\ell}$, $p \not\equiv 1 \pmod{N\ell}$; as $N_0 \mid p-1$ and $\ell \nmid N_0$, this gives $v_\ell(p-1) = m$. Since $p \neq r$, ρ is a unit at the chosen place, and $\varphi(\rho) = \rho$ with $\varphi(\rho) \equiv \rho^p$ modulo that place gives $\rho^{p-1} \equiv 1$; so the integer $r^{(p-1)/\ell^m} - 1 = \rho^{p-1} - 1$ is divisible by p, and $\mathrm{ord}_p(r)$ divides $(p-1)/\ell^m$, which is prime to ℓ. Finally $p \neq r$ and $p \nmid T$. □

Proposition 37.24. *There is a real number $C \geq 0$ such that for every integer $N \geq 1$, every CM field E that embeds into $\mathbb{Q}(\zeta_N)$, every odd prime ℓ dividing $n = [E : \mathbb{Q}]$ and every integer $e \geq 1$: $\mathrm{len}_\ell^-(E, e) < \infty$ and*

$$\mathrm{len}_\ell^-(E, e)\, \log \ell \leq C\, \ell\, n^2\, (e+1)\, \log^2(e\ell N).$$

Proof. We show the claim with $C = 44$. Fix N, E, ℓ, e as in the statement; the hypothesis $\ell \mid n$ is not used. The lengths do not change when E is replaced by an isomorphic field, so let $E \subseteq \mathbb{Q}(\zeta_N)$. Let $N_1 = 4N\ell$, Δ, π, $a = 1 + N_1$, Q_j, ξ_j and the action $\star$ be as in Lemma 37.25, and put $D_E = \varphi(N_1)/n$. Let $c = \pi(-1) \in \Delta$: it is the restriction of $\zeta \mapsto \zeta^{-1}$, which is complex conjugation for every embedding of $\mathbb{Q}(\zeta_{N_1})$ into $\mathbb{C}$, so c is the complex conjugation of the CM field E, and $c \neq 1$. A lift of c to $\mathrm{Gal}(E_{S_\ell}/\mathbb{Q})$ lies in $\mathrm{Gal}(E_{S_\ell}/E^+)$, and $c\star$ is the action of Definition 36.1; so, with $\varsigma = (-1)^{e+1}$,

$$\mathrm{Sha}_\ell^-(E, e) = \{x \in \mathrm{Sha}_\ell^1(E, e) : c \star x = \varsigma x\}.$$

Characters. Let X_ς be the set of characters $\vartheta \colon \Delta \to \overline{\mathbb{Q}}_\ell^\times$ with $\vartheta(c) = \varsigma$. As Δ is abelian of order n and $c \neq 1$, $\vartheta \mapsto \vartheta(c)$ is a surjective homomorphism from the n characters of Δ onto $\{\pm 1\}$, so $|X_\varsigma| = n/2$. For $\vartheta \in X_\varsigma$, $\chi_\vartheta = \vartheta \circ \pi$ is a Dirichlet character modulo N_1 with $\ker \pi \subseteq \ker \chi_\vartheta$ and $\chi_\vartheta(-1) = (-1)^{e+1}$, and $\vartheta \mapsto \chi_\vartheta$ is a bijection of X_ς onto the set $\mathcal{X}_{\overline{\mathbb{Q}}_\ell}$ of Proposition 37.9 for $(N_1, e+1, \ker \pi)$; the corresponding set $\mathcal{X}_{\mathbb{C}}$ also has $n/2$ elements.

The ring A_-. Let $A_- = \mathbb{Z}_\ell[\Delta]/(c-\varsigma)$. As $\mathbb{Z}_\ell[\Delta]$ is free over $\mathbb{Z}_\ell[\langle c\rangle]$ on a set of representatives of $\Delta/\langle c\rangle$, A_- is free of rank $n/2$ over $\mathbb{Z}_\ell$. For $\xi \in \mathbb{Z}_\ell[\Delta]$ let $\mathrm{Nm}(\xi) \in \mathbb{Z}_\ell$ be the determinant of multiplication by ξ on A_-. Then:

(a) $\mathrm{Nm}(\xi) = \prod_{\vartheta \in X_\varsigma} \vartheta(\xi)$. Indeed $\xi \mapsto (\vartheta(\xi))_\vartheta$, over all n characters, is an isomorphism $\overline{\mathbb{Q}}_\ell[\Delta] \to \overline{\mathbb{Q}}_\ell^{\,n}$ (the characters are linearly independent); it carries $c-\varsigma$ to the vector with entries $\vartheta(c)-\varsigma$, which vanish exactly for $\vartheta \in X_\varsigma$ and are -2ς otherwise. So $A_- \otimes \overline{\mathbb{Q}}_\ell \cong \overline{\mathbb{Q}}_\ell^{\,X_\varsigma}$, on which ξ acts diagonally with entries $\vartheta(\xi)$.

(b) $\mathrm{Nm}(\xi) \in \xi A_-$: by the Cayley–Hamilton theorem the characteristic polynomial $T^{n/2} + \cdots \pm \mathrm{Nm}(\xi)$ of multiplication by ξ vanishes at ξ in A_-.

An exponent for the minus part. For $\vartheta \in X_\varsigma$ let χ_ϑ^* be the primitive character inducing χ_ϑ and

$$y_\vartheta = (a^{e+1}-1)\, B_{e+1,\chi_\vartheta^*} \prod_{p \mid N_1} (1 - \chi_\vartheta^*(p) p^e).$$

It is nonzero: $a^{e+1} \neq 1$; $B_{e+1,\chi_\vartheta^*} \neq 0$ because $\mathrm{Ber}_{e+1}(\chi_\vartheta) = N_1(e+2)\# B_{e+1,\chi_\vartheta^*} \neq 0$ by item 1 of Proposition 37.9; and $1 - \chi_\vartheta^*(p)p^e \neq 0$, as $p^e > 1$ is not a root of unity. For every j, $\vartheta(\xi_j) = \sum_{1 \le b < Q_j} \lfloor ab/Q_j \rfloor b^e \chi_\vartheta(b)$ (the terms with $\gcd(b, N_1) > 1$ vanish), which is $T_j(\chi_\vartheta)$ of Lemma 37.8 for $F = N_1$ (here $\ell \mid N_1$, $a = 1 + N_1$); by item 1 there, $(a^{e+1}-1) B_{e+1,\chi_\vartheta}^{(N_1)} = y_\vartheta$. Let $j_1 = \max_\vartheta v_\ell(y_\vartheta) + v_\ell(e+2) + 2$. For $j \ge j_1$, item 2 there gives $v_\ell\big((e+1)a^e\vartheta(\xi_j) - y_\vartheta\big) > v_\ell(y_\vartheta)$, hence $v_\ell((e+1)a^e\vartheta(\xi_j)) = v_\ell(y_\vartheta)$, and as $a \equiv 1 \pmod{\ell}$ is a unit,

$$v_\ell\big(\vartheta(\xi_j)\big) = v_\ell(y_\vartheta) - v_\ell(e+1) \qquad (j \ge j_1). \tag{37.22}$$

Put $r_0 = \sum_{\vartheta \in X_\varsigma} \big(v_\ell(y_\vartheta) - v_\ell(e+1)\big)$ and $r = r_0 + v_\ell(D_E)$. Let $x \in \mathrm{Sha}_\ell^-(E,e)$ and $z = D_E x$. By Lemma 37.25 there is j_0 with $\xi_j \star z = D_E(\xi_j \star x) = 0$ for $j \ge j_0$. Fix $j \ge \max(j_0, j_1)$. As $(c-\varsigma)\star z = 0$, the action of $\mathbb{Z}_\ell[\Delta]$ on the submodule it generates from z factors through A_-, and by (b), $\mathrm{Nm}(\xi_j)\, z = 0$. By (a) and (37.22), $\mathrm{Nm}(\xi_j) \in \mathbb{Z}_\ell$ has valuation r_0, so it is ℓ^{r_0} times a unit, and $\ell^{r_0} D_E x = 0$. Hence ℓ^r kills $\mathrm{Sha}_\ell^-(E,e)$.

The size of r. For $\vartheta \in X_\varsigma$ and a prime $p \mid N_1$,

$$v_\ell(y_\vartheta) - v_\ell(e+1) \le v_\ell(a^{e+1}-1) + v_\ell\big(\mathrm{Ber}_{e+1}(\chi_\vartheta)\big) + \sum_{p \mid N_1} v_\ell(1 - \chi_\vartheta^*(p)p^e),$$

as $v_\ell(N_1(e+2)\#) \ge 0$. We bound the three sums over ϑ.

(i) $a^{e+1}-1$ is a positive integer, so $v_\ell(a^{e+1}-1)\log\ell \le (e+1)\log(1+N_1)$.

(ii) By item 2 of Proposition 37.9 for $(N_1, e+1, \ker\pi)$ and $S = \{\ell\}$: $\sum_\vartheta v_\ell(\mathrm{Ber}_{e+1}(\chi_\vartheta))\log\ell \le w_\ell \log\ell \le \frac{n}{2}\log(16 N_1^{e+2}(e+1)!)$.

(iii) Fix $p \mid N_1$ and an embedding $j_\ell\colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$. Every χ_ϑ is $j_\ell \circ \chi_0$ for a unique character χ_0 in the set $\mathcal{X}_{\overline{\mathbb{Q}}} = \mathcal{X}_{\mathbb{C}}$, and then $\chi_\vartheta^* = j_\ell \circ \chi_0^*$ (the conductor depends only on the kernel). The set $\mathcal{X}_{\overline{\mathbb{Q}}}$ is permuted by the automorphisms σ of $\overline{\mathbb{Q}}$, with $(\sigma\circ\chi_0)^* = \sigma \circ \chi_0^*$, so $P_p = \prod_{\chi_0 \in \mathcal{X}_{\overline{\mathbb{Q}}}} (1 - \chi_0^*(p)p^e)$ is a rational algebraic integer, nonzero, with $|P_p| \le (1+p^e)^{n/2}$. Hence $\sum_\vartheta v_\ell(1-\chi_\vartheta^*(p)p^e)\log\ell = v_\ell(P_p)\log\ell \le \log|P_p| \le \frac{n}{2}\log(1+p^e) \le \frac{n}{2}(e\log p + \log 2)$, and summing over the primes $p \mid N_1$ gives at most $\frac{n}{2}(e+1)\log N_1$.

Let $L=\log(eN_1)$; as $N_1\ge 12$: $\log(1+N_1)\le 2L$, $\log 16\le 2L$, $\log(e+1)\le L$, so $\log(16N_1^{e+2}(e+1)!)\le(2e+5)L\le 4(e+1)L$. With $v_\ell(D_E)\log\ell\le\log N_1\le L$ and $n\ge 2$,

$$r\log\ell\le\frac{n}{2}(2(e+1)+4(e+1)+(e+1))L+L\le 4n(e+1)L\le 12\,n(e+1)\log(e\ell N),$$

since $4eN\ell\le(e\ell N)^3$.

Length. Let $P=\mathrm{Sha}^-_\ell(E,e)\subseteq H^1(G_{E,S_\ell},\mathbb{Q}_\ell/\mathbb{Z}_\ell(-e))$; it is killed by ℓ^r. For $0\le i<r$, multiplication by ℓ^i maps $P[\ell^{i+1}]$ into $P[\ell]$ with kernel $P[\ell^i]$; so

$$\operatorname{length}P=\sum_{i<r}\operatorname{length}(P[\ell^{i+1}]/P[\ell^i])\le r\operatorname{length}P[\ell].$$

By Lemma 37.26 (E has no real place), $P[\ell]$ is finite of length at most $4\ell n\log(\ell N)/\log\ell$. Hence $\mathrm{len}^-_\ell(E,e)<\infty$ and, with $\log\ell\ge\log 3$,

$$\mathrm{len}^-_\ell(E,e)\log\ell\le(r\log\ell)\cdot\frac{4\ell n\log(\ell N)}{\log\ell}\le\frac{48}{\log 3}\,\ell\,n^2(e+1)\log^2(e\ell N)\le 44\,\ell\,n^2(e+1)\log^2(e\ell N).$$

□

Lemma 37.25. *Let $N\ge 1$, let $E\subseteq\mathbb{Q}(\zeta_N)$ be a subfield with $n=[E:\mathbb{Q}]$, let ℓ be an odd prime and $e\ge 1$ an integer. Put $N_1=4N\ell$, $\Delta=\mathrm{Gal}(E/\mathbb{Q})$, and for b prime to N_1 let $\pi(b)\in\Delta$ be the restriction to E of the automorphism $\zeta_{N_1}\mapsto\zeta_{N_1}^b$ of $\mathbb{Q}(\zeta_{N_1})$. Let E_{S_ℓ} be the maximal extension of E unramified outside the places above ℓ, so that $G_{E,S_\ell}=\mathrm{Gal}(E_{S_\ell}/E)$. The group Δ acts on $H^1(G_{E,S_\ell},\mathbb{Q}_\ell/\mathbb{Z}_\ell(-e))$ by*

$$\delta\star[f]=[g\mapsto\chi_{\mathrm{cyc}}(\tilde\delta)^{-e}f(\tilde\delta^{-1}g\tilde\delta)],$$

with $\tilde\delta\in\mathrm{Gal}(E_{S_\ell}/\mathbb{Q})$ any element restricting to δ; this action preserves $\mathrm{Sha}^1_\ell(E,e)$ and is extended linearly to $\mathbb{Z}[\Delta]$. Put $a=1+N_1$ and, for $j\ge 0$, $Q_j=N_1\ell^j$ and

$$\xi_j=\sum_{\substack{1\le b<Q_j\\ \gcd(b,N_1)=1}}\Big\lfloor\frac{ab}{Q_j}\Big\rfloor\,b^e\,\pi(b)\in\mathbb{Z}[\Delta].$$

Then for every $x\in\mathrm{Sha}^1_\ell(E,e)$ there is $j_0\ge 0$ such that $\frac{\varphi(N_1)}{n}(\xi_j\star x)=0$ for every $j\ge j_0$.

Proof. Write $M=\mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$, a $G_\mathbb{Q}$-module through χ_{cyc}^{-e}; for $r\ge 0$ let $M[\ell^r]$ be its ℓ^r-torsion. The field E is Galois over $\mathbb{Q}$, so E_{S_ℓ} is Galois over $\mathbb{Q}$, and it contains $E(\mu_{\ell^\infty})$; so χ_{cyc} is defined on $\mathrm{Gal}(E_{S_\ell}/\mathbb{Q})$.

The action. On $H^1(G_E,M)$ put $\delta\star[f]=[g\mapsto\tilde\delta f(\tilde\delta^{-1}g\tilde\delta)]$ with $\tilde\delta\in G_\mathbb{Q}$ restricting to δ. Two lifts differ by an element of G_E, and inner automorphisms act trivially on cohomology, so this is well defined; it is an action of Δ. Inflation from G_{E,S_ℓ} to G_E is injective with image the classes unramified at the places not above ℓ (the kernel of $G_E\to G_{E,S_\ell}$ is the closed normal subgroup generated by the inertia groups at those places, which act trivially on M), and it carries the action of the statement to this one. Conjugation by $\tilde\delta$ permutes the inertia groups and the decomposition groups of G_E; so $\star$ preserves the classes that are unramified everywhere and trivial on every decomposition group above ℓ, which is the image of $\mathrm{Sha}^1_\ell(E,e)$. We work in $H^1(G_E,M)$ from now on.

Step 1: a cocycle with bounded local data. Let $x\in\mathrm{Sha}^1_\ell(E,e)$. It has finite order, say $\ell^r x=0$. As M is divisible, $0\to M[\ell^r]\to M\xrightarrow{\ell^r}M\to 0$ is exact, so x is the image of a class of $H^1(G_E,M[\ell^r])$: choose a continuous cocycle $f\colon G_E\to M[\ell^r]$ representing x.

(a) If $I \subseteq G_E$ is the inertia group at a place not above ℓ, then I acts trivially on M and $f|_I$ is a coboundary, so $f|_I = 0$.

(b) For each of the finitely many places v of E above ℓ fix a decomposition group $D_v \subseteq G_E$; as x is trivial at v there is $m_v \in M$ with $f(g) = (g-1)m_v$ for $g \in D_v$. Choose $r_1 \geq r$ with $\ell^{r_1} m_v = 0$ for all v. Every decomposition group of G_E at a place above ℓ is $\sigma D_v \sigma^{-1}$ for some v and $\sigma \in G_E$, and for $g \in D_v$ and $h = \sigma g \sigma^{-1}$,

$$f(h) = (h-1)\bigl(\sigma m_v - f(\sigma)\bigr),$$

with $\ell^{r_1}(\sigma m_v - f(\sigma)) = 0$. So on every decomposition group D at a place above ℓ, $f(h) = (h-1)m_D$ for some $m_D \in M[\ell^{r_1}]$.

Put $j_0 = r_1$.

Step 2: restriction to a cyclotomic field. Fix $j \geq j_0$, let $K_j = \mathbb{Q}(\zeta_{Q_j})$, which contains E as $N \mid Q_j$, and $U_j = G_{K_j}$, a closed normal subgroup of $G_{\mathbb{Q}}$ contained in G_E. As $\ell^{j+1} \mid Q_j$, $\chi_{\mathrm{cyc}}(U_j) \subseteq 1 + \ell^{j+1}\mathbb{Z}_\ell$, so U_j acts trivially on $M[\ell^{j+1}] \supseteq M[\ell^{r_1}]$. Hence $\psi = f|_{U_j}$ is a continuous homomorphism $U_j \to M[\ell^r]$. By (a), ψ vanishes on the inertia groups of U_j at the places not above ℓ, which are the intersections of those of G_E with U_j; by (b), it vanishes on the decomposition groups of U_j at the places above ℓ, as $(h-1)m_D = 0$ for $h \in U_j$. Since K_j has no real place, the fixed field of $\ker\psi$ is an abelian extension of K_j unramified at every place, hence contained in the Hilbert class field H_j of K_j. Let $\mathrm{Art}_j \colon \mathrm{Cl}(K_j) \to \mathrm{Gal}(H_j/K_j)$ be the Artin isomorphism; there is a homomorphism $\bar\psi \colon \mathrm{Cl}(K_j) \to M[\ell^r]$ with $\psi(u) = \bar\psi(\mathfrak{c})$ whenever $u|_{H_j} = \mathrm{Art}_j(\mathfrak{c})$. The field H_j is Galois over $\mathbb{Q}$, and $\mathrm{Art}_j(\tau(\mathfrak{c})) = \tau\,\mathrm{Art}_j(\mathfrak{c})\,\tau^{-1}$ for $\tau \in G_{\mathbb{Q}}$ (Frobenius elements are conjugated in this way). Hence, for $u \in U_j$ with $u|_{H_j} = \mathrm{Art}_j(\mathfrak{c})$ and $\tau \in G_{\mathbb{Q}}$,

$$\psi(\tau^{-1}u\tau) = \bar\psi(\tau^{-1}(\mathfrak{c})). \tag{37.23}$$

Step 3: the Stickelberger relation. For $1 \leq b < Q_j$ prime to N_1 (equivalently, to Q_j) choose $\tau_b \in G_{\mathbb{Q}}$ with $\tau_b(\zeta_{Q_j}) = \zeta_{Q_j}^b$; then $\tau_b|_{K_j} = \sigma_b$ in the notation of Theorem B.23, and $\tau_b|_E = \pi(b)$. As $\ell^{j+1} \mid Q_j$, $\chi_{\mathrm{cyc}}(\tau_b) \equiv b \pmod{\ell^{j+1}}$, so $b^e\chi_{\mathrm{cyc}}(\tau_b)^{-e} \equiv 1 \pmod{\ell^{j+1}}$ and $b^e\tau_b$ acts as the identity on $M[\ell^{j+1}] \supseteq M[\ell^r]$. The cocycle

$$F = \sum_b \Bigl\lfloor \frac{ab}{Q_j} \Bigr\rfloor b^e\,(\tau_b \cdot f), \qquad (\tau \cdot f)(g) = \tau f(\tau^{-1}g\tau),$$

represents $\xi_j \star x$. Let $u \in U_j$ with $u|_{H_j} = \mathrm{Art}_j(\mathfrak{c})$. Then $\tau_b^{-1}u\tau_b \in U_j$, so $f(\tau_b^{-1}u\tau_b) = \psi(\tau_b^{-1}u\tau_b) \in M[\ell^r]$, and by (37.23)

$$F(u) = \sum_b \Bigl\lfloor \frac{ab}{Q_j} \Bigr\rfloor \bar\psi(\sigma_b^{-1}(\mathfrak{c})) = \bar\psi(\beta\,\mathfrak{c}), \qquad \beta = \sum_b \Bigl\lfloor \frac{ab}{Q_j} \Bigr\rfloor \sigma_b^{-1} \in \mathbb{Z}[\mathrm{Gal}(K_j/\mathbb{Q})].$$

Here $\beta = (a - \sigma_a)\theta_{Q_j}$.

As $Q_j \geq 3$, $4 \mid Q_j$ and $\gcd(a, Q_j) = 1$ (every prime dividing Q_j divides N_1, and $a \equiv 1 \pmod{N_1}$), Theorem B.23 shows that β annihilates $\mathrm{Cl}(K_j)$. So $F(u) = 0$: F vanishes on U_j.

Step 4: descent from the cyclotomic tower. Let $K_\infty = \bigcup_j K_j$ and $U = G_{K_\infty} \subseteq U_j$; as $\mu_{\ell^\infty} \subset K_\infty$, U acts trivially on M. Since F vanishes on U, $F(gu) = F(g) + gF(u) = F(g)$ and $F(ug) = F(u) + uF(g) = F(g)$ for $g \in G_E$, $u \in U$; so F is the inflation of a continuous cocycle $\bar F$ on the abelian group $W = G_E/U = \mathrm{Gal}(K_\infty/E)$. Write $N_1 = N_0\ell^t$ with $\ell \nmid N_0$, $t \geq 1$, and let $K_0 = \mathbb{Q}(\zeta_{N_1})$ and $W_0 = \mathrm{Gal}(K_\infty/K_0) \subseteq W$. As $K_\infty = K_0(\mu_{\ell^\infty})$, χ_{cyc} maps W_0 isomorphically

onto $1+\ell^t\mathbb{Z}_\ell$; let $\gamma_0 \in W_0$ with $\chi_{\mathrm{cyc}}(\gamma_0) = 1+\ell^t$, which generates a dense subgroup of W_0 (ℓ odd). It acts on M by the scalar $u_0 = (1+\ell^t)^{-e}$, and $u_0 - 1 \neq 0$ as $e \geq 1$; multiplication by $u_0 - 1$ is surjective on the divisible module M, so there is $y_0 \in M$ with $(\gamma_0 - 1)y_0 = \bar{F}(\gamma_0)$. The cocycle $F' = \bar{F} - \partial y_0$, $\partial y_0(w) = (w-1)y_0$, vanishes at γ_0, hence on the group generated by γ_0, hence on W_0, because $\{w : F'(w) = 0\}$ is closed (F' is continuous and M is discrete). For $w \in W$ and $w_0 \in W_0$, $F'(ww_0) = F'(w)$ and $F'(w_0 w) = w_0 F'(w)$, so, W being abelian, F' is constant on the cosets of W_0 and takes values in M^{W_0}: it is inflated from a cocycle on $W/W_0 = \mathrm{Gal}(K_0/E)$, a group of order $D_E = \varphi(N_1)/n$. With $y_1 = \sum_{w' \in W/W_0} F'(w')$, summing $F'(ww') = F'(w) + wF'(w')$ over w' gives $y_1 = D_E F'(w) + wy_1$, that is $D_E F' = \partial(-y_1)$. Hence $D_E \bar{F} = \partial(D_E y_0 - y_1)$, $D_E F$ is a coboundary on G_E, and $D_E\,(\xi_j \star x) = 0$. This holds for every $j \geq j_0$. □

Lemma 37.26. *Let $N \geq 1$, let $E \subseteq \mathbb{Q}(\zeta_N)$ be a subfield with no real place, $n = [E:\mathbb{Q}]$, let ℓ be an odd prime and $e \in \mathbb{Z}$. Then the ℓ-torsion subgroup $H^1(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e))[\ell]$ is finite and*

$$\mathrm{length}_{\mathbb{Z}_\ell} H^1(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e))[\ell] \leq \frac{4\,\ell\, n \log(\ell N)}{\log \ell}.$$

Proof. Write $M = \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$, $A = M[\ell]$ (the group $\mathbb{Z}/\ell\mathbb{Z}$ with G_E acting through χ_{cyc}^{-e}) and $G = G_{E,S_\ell}$.

Reduction to a homomorphism group. As M is divisible, $0 \to A \to M \xrightarrow{\ell} M \to 0$ is exact, and $H^1(G,A) \to H^1(G,M)[\ell]$ is surjective; so it suffices to bound $\dim_{\mathbb{F}_\ell} H^1(G,A)$. Let $F = E(\mu_\ell) \subseteq \mathbb{Q}(\zeta_{\ell N})$ and $m = [F:\mathbb{Q}]$; then $[F:E]$ divides $\ell - 1$, $m \leq (\ell-1)n$, and F has no real place, so $m \geq 2$. The extension F/E is unramified outside ℓ, so the maximal extension of E unramified outside the places above ℓ is also that of F, and G_{F,S_ℓ} is an open subgroup of G of index $[F:E]$. Corestriction after restriction is multiplication by $[F:E]$, which is invertible on $H^1(G,A)$ (killed by ℓ); so restriction $H^1(G,A) \to H^1(G_{F,S_\ell}, A)$ is injective. As $\mu_\ell \subset F$, G_{F,S_ℓ} acts trivially on A, and $H^1(G_{F,S_\ell}, A) = \mathrm{Hom}_{\mathrm{cts}}(G_{F,S_\ell}, \mathbb{Z}/\ell\mathbb{Z})$.

Kummer theory. Fix a primitive ℓ-th root of unity in F. Kummer theory gives an isomorphism

$$\mathrm{Hom}_{\mathrm{cts}}(G_F, \mathbb{Z}/\ell\mathbb{Z}) \cong F^\times/F^{\times\ell},$$

the class of α corresponding to a character cutting out $F(\alpha^{1/\ell})$; it factors through G_{F,S_ℓ} if and only if $F(\alpha^{1/\ell})/F$ is unramified at every finite place not above ℓ (F has no real place), and at a prime $\mathfrak{p} \nmid \ell$ this holds if and only if $\ell \mid v_\mathfrak{p}(\alpha)$ [190]. Hence $\mathrm{Hom}_{\mathrm{cts}}(G_{F,S_\ell}, \mathbb{Z}/\ell\mathbb{Z}) \cong \mathcal{B} = \{\alpha \in F^\times : \ell \mid v_\mathfrak{p}(\alpha) \text{ for all } \mathfrak{p} \nmid \ell\}/F^{\times\ell}$. Let S be the set of primes of F above ℓ, so $\#S \leq m$, $\mathcal{O}_S^\times$ the S-units and $\mathrm{Cl}' = \mathrm{Cl}(F)/\langle[\mathfrak{p}] : \mathfrak{p} \in S\rangle$. For α representing a class in $\mathcal{B}$ write $(\alpha) = \mathfrak{a}^\ell\mathfrak{s}$ with $\mathfrak{a} = \prod_{\mathfrak{p}\notin S} \mathfrak{p}^{v_\mathfrak{p}(\alpha)/\ell}$ and $\mathfrak{s}$ supported on S; the class of $\mathfrak{a}$ in Cl' is killed by ℓ and does not change when α is multiplied by an ℓ-th power. This defines a homomorphism $\mathcal{B} \to \mathrm{Cl}'[\ell]$. If α is in its kernel, then $\mathfrak{a} = (\beta)\mathfrak{s}'$ with $\mathfrak{s}'$ supported on S, so $\alpha\beta^{-\ell} \in \mathcal{O}_S^\times$: the kernel is the image of $\mathcal{O}_S^\times$. By the S-unit theorem, $\mathcal{O}_S^\times$ is the product of the cyclic group of roots of unity of F, whose order is divisible by ℓ, and a free group of rank $m/2 - 1 + \#S$ [190]. Since Cl' is a quotient of $\mathrm{Cl}(F)$, $\dim \mathrm{Cl}'[\ell] = \dim \mathrm{Cl}'/\ell\mathrm{Cl}' \leq \dim \mathrm{Cl}(F)/\ell\mathrm{Cl}(F) \leq \log_\ell h(F)$. Hence

$$\dim_{\mathbb{F}_\ell} H^1(G,A) \leq \Big(\frac{m}{2} + \#S\Big) + \log_\ell h(F) \leq \frac{3m}{2} + \frac{\log h(F)}{\log \ell}. \tag{37.24}$$

The class number. By Minkowski's theorem every ideal class of F contains an integral ideal of norm at most $\frac{m!}{m^m}(\frac{4}{\pi})^{m/2}|d_F|^{1/2} \leq |d_F|^{1/2}$ [190]. The number of integral ideals of norm k is

at most $d_m(k) = \#\{(k_1,\dots,k_m) \in \mathbb{N}^m : k_1 \cdots k_m = k\}$: both counts are multiplicative in k, and if p has g primes above it with residue degrees $f_1,\dots,f_g$ ($\sum f_i \le m$), the ideals of norm p^c correspond to the tuples $(c_1,\dots,c_g)$ with $\sum f_i c_i = c$, which inject into the m-tuples of non-negative integers with sum c (repeat c_i exactly f_i times and pad with zeros), whose number is $d_m(p^c)$. By induction on m, $\sum_{k\le X} d_m(k) \le X(1+\log X)^{m-1}$ for $X \ge 1$: $\sum_{k\le X} d_m(k) = \sum_{k_1\le X}\sum_{k'\le X/k_1} d_{m-1}(k') \le X(1+\log X)^{m-2}\sum_{k_1\le X} k_1^{-1}$ and $\sum_{k_1\le X} k_1^{-1} \le 1+\log X$. By the conductor–discriminant formula, $|d_F|$ is the product of the conductors of the m characters of $\mathrm{Gal}(F/\mathbb{Q})$, each dividing ℓN [266]; so $|d_F| \le (\ell N)^m$ and

$$\log h(F) \le \frac{m}{2}\log(\ell N) + (m-1)\log\Big(1+\frac{m}{2}\log(\ell N)\Big) \le \frac{5m}{2}\log(\ell N).$$

Conclusion. With (37.24), $\log(\ell N) \ge \log \ell$ and $m \le (\ell-1)n$,

$$\dim_{\mathbb{F}_\ell} H^1(G,A) \le \frac{3m}{2}\frac{\log(\ell N)}{\log \ell} + \frac{5m}{2}\frac{\log(\ell N)}{\log \ell} \le \frac{4\,\ell\, n\log(\ell N)}{\log \ell},$$

and the surjection of the first step gives the claim, finiteness included. □

38 The plus part: the counts and congruence numbers

This section proves the counts for the plus parts: bounds for the normalised lengths $\nu_{\mathcal{O}}(\chi, e)$ of the strict Tate–Shafarevich groups of the characters of a Sha-host, weighted by $\log \ell$, that are polynomial in $N_{\mathfrak{h}}$, t and, outside case (I), ℓ. They are used in Proposition 36.5 and Proposition 36.10. The method is that of Eisenstein congruences. It goes back to Ribet's construction of unramified extensions of $\mathbb{Q}(\mu_p)$ from cusp forms congruent to Eisenstein series [208], and was developed for Selmer groups of characters by Mazur and Wiles [169], by Wiles [271] and, on U(3), by Bellaïche and Chenevier [22]. There the congruences produce Selmer classes; here they bound the strict Tate–Shafarevich group from above.

Part VIII proves the one-character bounds (Proposition 42.2, Proposition 44.3, Proposition 46.2): the length for one character and one prime ℓ is at most twice the sum of the ℓ-adic valuations of the differences between an Eisenstein trace and the Frobenius traces of finitely many admissible automorphic Galois representations. This section makes these bounds effective and uniform in ℓ. At a fixed place w above an auxiliary prime p, the Frobenius traces of all admissible representations lie in one finite set of algebraic numbers, stable under $\mathrm{Aut}(\mathbb{C})$, independent of ℓ, of size polynomial in $N(e+1)$ and of absolute value at most $\sqrt{q_w}+2$ (Proposition 38.9; Proposition 38.29 is its counterpart on GSp_4). On the unitary group the Eisenstein traces $q_w^{-e}z + 1 + q_w^e z^{-1}$, with z a root of unity, are larger in absolute value. So every difference is non-zero, and a product of norms of the differences is one non-zero integer M with $\log|M|$ polynomial in $N(e+1)$, whose ℓ-adic valuation dominates the congruences for every prime $\ell \ne p$ at once (Lemma 38.7, Proposition 38.6). In Count I two auxiliary primes r_1, r_2 are used, so that every ℓ differs from one of them.

Subsection 38.1 proves Count I, the main case, on the unitary group in three variables. Subsection 38.2 proves the counts in the cases (II)–(V): on GSp_4, on the unitary group attached to $\mathbb{Q}(i)$, and, where no congruence is needed, from the bounds of Sections 39 and 40.

38.1 The first count and congruence numbers

This subsection proves Count I, Proposition 38.2: in case (I) the normalised lengths, weighted by $\log \ell$ and summed over the primes ℓ and over the characters of the host, are at most $(N_{\mathfrak{h}}t)^C$.

The congruences are formed on the unitary group in three variables attached to the fixed field $K = \mathbb{Q}(\sqrt{-p_K(\psi)})$: every character in case (I) gives a unitary Eisenstein datum (Lemma 38.3), and Proposition 38.5 bounds the sum over all characters with a given kernel H by $2v_\ell(M)$ for one integer M, by combining the one-character bound Proposition 42.2 with the congruence numbers Proposition 38.6. The second hypothesis of the one-character bound, the vanishing of the Bloch–Kato Selmer groups of the representations attached to newforms of weight $2e+1$ and of their quadratic twist by K, comes from Kato's Euler system [141] (Lemma 38.23).

The rest of the subsection counts. The admissible representations of stable type come from conjugate self-dual cuspidal representations of $\mathrm{GL}_3(\mathbb{A}_K)$ of weight e and level N; their number is polynomial in $N(e+1)$, and $\mathrm{Aut}(\mathbb{C})$ permutes them (Proposition 38.15). Those of endoscopic type come from newforms of weight $2e+1$ whose level divides the square of the level of the representation (Proposition 38.21), and these are counted by Lemma 38.22. Local–global compatibility fixes the weight and the level of the cuspidal representation attached to an admissible one, and the integrality of the Satake parameters gives the integrality of q_w^e times the Frobenius traces that Lemma 38.7 requires.

Definition 38.1. Let $N \geq 1$, let $\mathcal{O}$ be a coefficient ring and let χ be a Dirichlet character modulo N with values in $\mathcal{O}^\times$. For a prime p write $N = p^a N'$ with $p \nmid N'$; the **p-component** of χ is the character χ_p of $(\mathbb{Z}/p^a\mathbb{Z})^\times$ given by $\chi_p(u) = \chi(\tilde{u})$, where $\tilde{u} \equiv u \pmod{p^a}$ and $\tilde{u} \equiv 1 \pmod{N'}$ (so $\chi_p = \mathbf{1}$ if $p \nmid N$, and $\chi = \prod_{p \mid N} \chi_p$).

Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field with discriminant d_K and class number h_K, let ℓ be a prime and $e \geq 1$ an integer, and let $L_{\ell,\chi} \subset \overline{\mathbb{Q}}$ be the fixed field of the subgroup of $G_{\mathbb{Q}}$ of the elements that act trivially on the ℓ-th roots of unity and lie in the kernel of $\chi^{(\ell)}$. The tuple (K, ℓ, e, N, χ) is a **unitary Eisenstein datum** if

(Ue1) ℓ is odd;

(Ue2) N is even;

(Ue3) ℓ does not divide the order of χ;

(Ue4) $\chi_\ell^2 = \mathbf{1}$;

(Ue5) $\chi(-1) = (-1)^e$;

(Ue6) $\ell \nmid d_K h_K$;

(Ue7) $\gcd(d_K, N) = 1$;

(Ue8) $K \not\subseteq L_{\ell,\chi}$;

(Ue9) $(\ell - 1) \nmid 2e$.

These are the data for which the Eisenstein congruences on the unitary group in three variables attached to $K/\mathbb{Q}$ are used to bound $\mathrm{Sha}^1_{\ell N}(\chi, e)$.

Proposition 38.2. *Let $\psi \in \mathcal{P}$. There are an integer $C \geq 0$ and primes r_1, r_2 such that the following holds for every Sha-host $\mathfrak{h} = (a, q, d)$ of ψ with $r_1 < \min(q, d)$ and $r_2 < \min(q, d)$, every integer $t \geq 1$ at which $\mathfrak{h}$ is big, every integer e with $0 < e < t$, every choice of a coefficient ring $\mathcal{O}_\ell$ for each prime ℓ, and every finite set Λ of odd primes ℓ that are in case (I) for e. For every $\ell \in \Lambda$ and every $\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)$ the group $\mathrm{Sha}^1_{\ell N_{\mathfrak{h}}}(\chi, e)$ has finite length, and*

$$\sum_{\ell \in \Lambda} \log \ell \sum_{\chi \in X_{\mathfrak{h}}(\mathcal{O}_\ell, e)} \nu_{\mathcal{O}_\ell}(\chi, e) \leq (N_{\mathfrak{h}} t)^C.$$

Proof. Let $\psi \in \mathcal{P}$, write $p_K = p_K(\psi)$ and $K = \mathbb{Q}(\sqrt{-p_K})$. By Lemma 38.3, K is imaginary quadratic with $d_K = -p_K$. Let $c, A \geq 0$ be the integers given by Proposition 38.5 for K. Choose primes $r_1 > 30 N_\psi p_K$ and $r_2 > r_1$, and an integer $k \geq 0$ with $2c(\log r_1 + \log r_2) \leq 16^k$. Put $C = k + 1 + A$. We show that C, r_1, r_2 have the stated property.

Fix $\mathfrak{h} = (a, q, d)$ with $r_1, r_2 < \min(q, d)$, an integer $t \geq 1$ at which $\mathfrak{h}$ is big, $0 < e < t$, coefficient rings $\mathcal{O}_\ell$ and a finite set Λ of odd primes in case (I) for e. Write $N = N_\mathfrak{h}$ and $G = (\mathbb{Z}/N\mathbb{Z})^\times$. Since $a \geq 2$, $16 \mid N$, so $N \geq 16$.

Step 1: the auxiliary primes are admissible. Let $i \in \{1, 2\}$. As $r_i > 30 N_\psi p_K \geq 210$, $r_i \nmid 30$ and $r_i \neq p_K$, so $r_i \nmid d_K = -p_K$. A prime factor of $N = \operatorname{lcm}(2^{a+2}, N_\psi) q d$ is 2, a prime factor of N_ψ (hence at most $N_\psi < r_i$), q or d (both larger than r_i); so $r_i \nmid N$. Thus $r_i \nmid 30 N d_K$.

Step 2: one kernel. Let $\mathcal{T}$ be the finite set of subgroups $\ker\chi$ with $\ell \in \Lambda$ and $\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)$, and for $H' \in \mathcal{T}$ let $\Lambda(H')$ be the set of $\ell \in \Lambda$ for which some $\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)$ has kernel H'. Fix $H' \in \mathcal{T}$. By Step 1 and $e, N \geq 1$, Proposition 38.5 applies to (e, N, H', r_i) and gives nonzero integers M_1, M_2 (for $p = r_1$, $p = r_2$) with

$$\log|M_i| \leq c\,\varphi([G : H'])\big(N(e+1)\big)^A \log r_i \qquad (i = 1, 2).$$

Let $\ell \in \Lambda(H')$ and choose $\chi_0 \in X_\mathfrak{h}(\mathcal{O}_\ell, e)$ with $\ker\chi_0 = H'$; then $\chi_0 \in \mathcal{X}_{\mathcal{O}_\ell}(N, H')$, and (K, ℓ, e, N, χ_0) is a unitary Eisenstein datum by Lemma 38.3 (ℓ is odd and in case (I) for e, $\mathfrak{h}$ is big at t, $0 < e < t$). Choose i with $\ell \neq r_i$ (possible as $r_1 \neq r_2$). By Proposition 38.5 for $p = r_i$, every $\chi \in \mathcal{X}_{\mathcal{O}_\ell}(N, H')$ has $\mathrm{Sha}^1_{\ell N}(\chi, e)$ of finite length, and

$$\sum_{\chi \in \mathcal{X}_{\mathcal{O}_\ell}(N, H')} \nu_{\mathcal{O}_\ell}(\chi, e) \leq 2 v_\ell(M_i) \leq 2 v_\ell(M_1) + 2 v_\ell(M_2).$$

Multiplying by $\log\ell \geq 0$ and summing over $\ell \in \Lambda(H')$,

$$\begin{aligned} \sum_{\ell \in \Lambda(H')} \log\ell \sum_{\chi \in \mathcal{X}_{\mathcal{O}_\ell}(N, H')} \nu_{\mathcal{O}_\ell}(\chi, e) &\leq 2\big(\log|M_1| + \log|M_2|\big) \\ &\leq 2c\,\varphi([G : H'])\big(N(e+1)\big)^A (\log r_1 + \log r_2), \end{aligned} \tag{38.1}$$

where the integers M_1, M_2 depend on H' but not on ℓ: this is where one integer serves all primes.

Step 3: finiteness. Let $\ell \in \Lambda$ and $\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)$. Then $H' = \ker\chi \in \mathcal{T}$, $\ell \in \Lambda(H')$ and $\chi \in \mathcal{X}_{\mathcal{O}_\ell}(N, H')$, so $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length by Step 2.

Step 4: summing over the kernels. By Step 3 every pair (ℓ, χ) with $\ell \in \Lambda$, $\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)$ occurs on the left of (38.1) for $H' = \ker\chi$; since all $\nu_{\mathcal{O}_\ell}(\chi, e) \geq 0$,

$$\sum_{\ell \in \Lambda} \log\ell \sum_{\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)} \nu_{\mathcal{O}_\ell}(\chi, e) \leq 2c(\log r_1 + \log r_2)\big(N(e+1)\big)^A \sum_{H' \in \mathcal{T}} \varphi([G : H']).$$

Each $H' \in \mathcal{T}$ is the kernel of a homomorphism from G to the unit group of a field, so G/H' is cyclic (a finite subgroup of the multiplicative group of a field is cyclic), and a cyclic group of order m has exactly $\varphi(m)$ injective homomorphisms to $\mathbb{C}^\times$. Hence exactly $\varphi([G : H'])$ homomorphisms $G \to \mathbb{C}^\times$ have kernel H'; these sets are disjoint for distinct H', and G has $|G| = \varphi(N) \leq N$ homomorphisms to $\mathbb{C}^\times$. So $\sum_{H' \in \mathcal{T}} \varphi([G : H']) \leq N$, and with $2c(\log r_1 + \log r_2) \leq 16^k$,

$$\sum_{\ell \in \Lambda} \log\ell \sum_{\chi \in X_\mathfrak{h}(\mathcal{O}_\ell, e)} \nu_{\mathcal{O}_\ell}(\chi, e) \leq 16^k\, N\,\big(N(e+1)\big)^A \leq (Nt)^{k+1+A} = (N_\mathfrak{h} t)^C.$$

□

Lemma 38.3. *Let $\psi \in \mathcal{P}$ and let $K = \mathbb{Q}(\sqrt{-p_K(\psi)}) \subset \overline{\mathbb{Q}}$. Then K is an imaginary quadratic field with $d_K = -p_K(\psi)$. Let $\mathfrak{h} = (a, q, d)$ be a Sha-host of ψ that is big at an integer $t \geq 1$, let $0 < e < t$, let ℓ be an odd prime in case (I) for e, let $\mathcal{O}$ be a coefficient ring and $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$. Then $(K, \ell, e, N_{\mathfrak{h}}, \chi)$ is a unitary Eisenstein datum.*

Proof. Write $p_K = p_K(\psi)$, $N = N_{\mathfrak{h}}$, $G = (\mathbb{Z}/N\mathbb{Z})^\times$, and recall that ℓ in case (I) means $\ell \notin B_\psi$ and $(\ell-1) \nmid 2e$. By definition p_K is a prime with $p_K \geq 7$, $p_K \equiv 3 \pmod 4$ and $\gcd(p_K, N_\psi) = 1$.

The field K. Since $p_K \equiv 3 \pmod 4$, the integer $-p_K$ is squarefree and $\equiv 1 \pmod 4$, so $K = \mathbb{Q}(\sqrt{-p_K})$ is an imaginary quadratic field of discriminant $d_K = -p_K$; in particular p_K ramifies in K. Its class number is $h_K = h^*(\psi)$ by definition.

Facts on ℓ and N. The prime p_K is odd and is a prime factor of p_K, so $p_K \in B_\psi$; every odd prime factor of o_ψ, of N_ψ and of $h_K = h^*(\psi)$ lies in B_ψ. As ℓ is odd and $\ell \notin B_\psi$:

$$\ell \neq p_K, \qquad \ell \nmid h_K, \qquad \ell \nmid o_\psi, \qquad \ell \nmid N_\psi. \tag{38.2}$$

Since $\mathfrak{h}$ is big at t, $p_K < \min(q, d)$, so $p_K \notin \{q, d\}$; with $\gcd(p_K, N_\psi) = 1$ and p_K odd this gives $p_K \nmid N = \operatorname{lcm}(2^{a+2}, N_\psi)qd$.

(Ue1), (Ue2), (Ue5), (Ue9). The prime ℓ is odd by hypothesis; $2 \mid 2^{a+2} \mid N$; $\chi(-1) = (-1)^e$ is part of the definition of $X_{\mathfrak{h}}(\mathcal{O}, e)$; $(\ell - 1) \nmid 2e$ is part of case (I).

(Ue3). The map $\Phi\colon G \to \big((\mathbb{Z}/2^{a+2}\mathbb{Z})^\times/\{\pm 1\}\big) \times \psi\big((\mathbb{Z}/N_\psi\mathbb{Z})^\times\big) \times \{\pm 1\} \times \{\pm 1\}$, $u \mapsto \big(\pm u \bmod 2^{a+2},\ \psi(u),\ (\frac{u}{q}),\ (\frac{u}{d})\big)$, is a homomorphism (note $2^{a+2} \mid N$, $N_\psi \mid N$, $q, d \mid N$) with kernel $H_{\mathfrak{h}}$. The first factor has order 2^a and the second is cyclic of order o_ψ, so $[G : H_{\mathfrak{h}}]$ divides $2^{a+2}o_\psi$. Since $H_{\mathfrak{h}} \subseteq \ker \chi$, the order of χ divides $[G : H_{\mathfrak{h}}]$, hence $2^{a+2}o_\psi$, and $\ell \nmid \operatorname{ord} \chi$ by (38.2) and ℓ odd.

(Ue4). If $\ell \nmid N$, then $\chi_\ell = \mathbf{1}$. Let $\ell \mid N$. As ℓ is odd and $\ell \nmid N_\psi$, $\ell \in \{q, d\}$; say $\ell = r$ with $\{r, r'\} = \{q, d\}$. The primes q, d are distinct ($q \equiv 3$, $d \equiv 7 \pmod 8$), odd and prime to N_ψ, so $N = rN'$ with $N' = \operatorname{lcm}(2^{a+2}, N_\psi)r'$ prime to r. Let $u \in (\mathbb{Z}/r\mathbb{Z})^\times$ be a square and $\tilde{u} \in G$ with $\tilde{u} \equiv u \pmod r$, $\tilde{u} \equiv 1 \pmod{N'}$. Then $\tilde{u} \equiv 1 \pmod{2^{a+2}}$, $\psi(\tilde{u}) = \psi(1) = 1$ (as $N_\psi \mid N'$), $(\frac{\tilde{u}}{r'}) = 1$ (as $r' \mid N'$) and $(\frac{\tilde{u}}{r}) = (\frac{u}{r}) = 1$; so $\tilde{u} \in H_{\mathfrak{h}} \subseteq \ker \chi$ and $\chi_r(u) = \chi(\tilde{u}) = 1$. Thus χ_ℓ is trivial on the squares, and $\chi_\ell(u)^2 = \chi_\ell(u^2) = 1$ for every u.

(Ue6). By (38.2), $\ell \nmid p_K h_K = |d_K| h_K$.

(Ue7). As shown above, $\gcd(d_K, N) = \gcd(p_K, N) = 1$.

(Ue8). The character $\chi^{(\ell)}$ is a Dirichlet character modulo N (a product of a power of χ and of the inverse of a component of that power), so it is trivial on $G_{\mathbb{Q}(\zeta_N)}$, and $G_{\mathbb{Q}(\zeta_{\ell N})}$ acts trivially on the ℓ-th roots of unity. Hence $G_{\mathbb{Q}(\zeta_{\ell N})}$ is contained in the subgroup defining $L_{\ell,\chi}$, and $L_{\ell,\chi} \subseteq \mathbb{Q}(\zeta_{\ell N})$. Since $p_K \neq \ell$ and $p_K \nmid N$, the prime p_K is unramified in $\mathbb{Q}(\zeta_{\ell N})$, hence in every subfield. As p_K ramifies in K, $K \not\subseteq L_{\ell,\chi}$. □

Definition 38.4. Number fields are subfields of a fixed algebraic closure $\overline{\mathbb{Q}}$; ℓ is a prime and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. For a number field F and a place $\bar{v}$ of $\overline{\mathbb{Q}}$ above a finite place v of F, $D_{\bar{v}} \supseteq I_{\bar{v}}$ are the decomposition and inertia subgroups of G_F at $\bar{v}$, and an **arithmetic Frobenius at** $\bar{v}$ is an element of $D_{\bar{v}}$ acting on the residue field of $\bar{v}$ as $x \mapsto x^{q_v}$. We write χ_{cyc} also for its restriction to G_F, with values in $\mathbb{Z}_\ell^\times \subset \overline{\mathbb{Q}}_\ell^\times$. For $M \geq 1$, a character of G_F is **of level** M if it is trivial on $G_{F(\mu_M)}$. For a subgroup $D \subseteq G_F$ and characters $\kappa_1, \ldots, \kappa_n\colon D \to \overline{\mathbb{Q}}_\ell^\times$, a representation $r\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ is **triangular on** D **with diagonal** $(\kappa_1, \ldots, \kappa_n)$ if there is $g \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that, for every $s \in D$, $g\, r(s)\, g^{-1}$ is upper triangular with diagonal entries $\kappa_1(s), \ldots, \kappa_n(s)$.

Level and weights. Let $n, M \geq 1$ and $m = (m_1, \ldots, m_n) \in \mathbb{Z}^n$. A continuous $r\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ has **level** M **and weights** m if

(Lw1) for every finite place $v \nmid \ell$ of F there are a place $\bar{v} \mid v$ and characters $\chi_1, \dots, \chi_n$ of G_F of level M such that $r|_{I_{\bar{v}}}$ is conjugate to $s \mapsto \mathrm{diag}(\chi_1(s), \dots, \chi_n(s))$;

(Lw2) for every place $v \mid \ell$ of F there are a place $\bar{v} \mid v$, characters $\chi_1, \dots, \chi_n$ of G_F of level M and characters $\kappa_1, \dots, \kappa_n$ of $D_{\bar{v}}$ such that r is triangular on $D_{\bar{v}}$ with diagonal $(\kappa_1, \dots, \kappa_n)$, $\kappa_i(s) = \chi_{\mathrm{cyc}}(s)^{m_i}\chi_i(s)$ for all i and $s \in I_{\bar{v}}$, and either $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j, or $r|_{D_{\bar{v}}}$ is potentially crystalline.

It is **generic ordinary of level** M **and weights** m if for every place $v \mid \ell$ of F there are $\bar{v}$, χ_i and κ_i as in (Lw2) with $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j.

Witness conditions. Let F be a CM field and $r\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a representation. For a place $v \mid \ell$ of F, r is **generic at** v if for every place $\bar{v} \mid v$ it is triangular on $D_{\bar{v}}$ with some diagonal (κ_i) such that $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j; it is **potentially generic at** v if for every $\bar{v} \mid v$ it is triangular on $D_{\bar{v}}$ with some diagonal (κ_i) such that $\kappa_i^a \neq (\kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}})^a$ for all i, j and all integers $a \geq 1$. The representation r satisfies the **witness conditions** if

(Wc1) r is potentially generic at every place $v \mid \ell$ at which it is generic;

(Wc2) for every regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_F)$ such that r is semisimple and $r \leftrightarrow_\iota \pi$, there is a real number τ_π such that at every finite place v of F with $v \nmid \ell$, or with $v \mid \ell$ and r potentially generic at v, the local component π_v has a cuspidal support consisting of characters of $F_v^\times$, and every character ξ occurring in a cuspidal support of π_v satisfies $q_v^{\tau_\pi - 1/2} < |\xi(\varpi_v)| < q_v^{\tau_\pi + 1/2}$.

(The number $|\xi(\varpi_v)|$ does not depend on the uniformiser, since ξ has finite image on $\mathcal{O}_{F_v}^\times$.) A representation W of $G_\mathbb{Q}$ satisfies the **witness conditions over imaginary quadratic fields** if $W|_{G_{K'}}$ satisfies the witness conditions for every imaginary quadratic field K' such that $W|_{G_{K'}}$ is irreducible.

Admissible representations. Let K be an imaginary quadratic field with discriminant d_K and let $e, N \geq 1$ be integers. A representation $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is **admissible of stable type** for (ι, e, N) if

(Sb1) ρ is irreducible;

(Sb2) $\rho \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type and satisfies the witness conditions;

(Sb3) ρ has level N and weights $(e, 0, -e)$;

(Sb4) ρ is generic ordinary of level N and weights $(e, 0, -e)$.

For $M \geq 1$, ρ is **admissible of endoscopic type** for (ι, e, M) if there is a representation $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that

(Eo1) W is irreducible and satisfies the witness conditions over imaginary quadratic fields;

(Eo2) $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple, and there is a normalised newform $f = \sum_{n \geq 1} a_n q^n$ of weight $2e + 1$, some level and Nebentypus ε_f such that for all but finitely many primes p and every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p, $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is trivial on $I_{\bar{p}}$ and $\iota(\det(X - (W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1}))) = X^2 - a_p X + \varepsilon_f(p)p^{2e}$ for every arithmetic Frobenius σ at $\bar{p}$;

(Eo3) W has level M and weights $(e, -e)$, and $\det W$ is a character of level M' for some $M' \geq 1$;

(Eo4) ρ is conjugate to $s \mapsto \begin{pmatrix} a(s) & 0 & b(s) \\ 0 & 1 & 0 \\ c(s) & 0 & d(s) \end{pmatrix}$, where $W(s) = \begin{pmatrix} a(s) & b(s) \\ c(s) & d(s) \end{pmatrix}$ for $s \in G_K \subseteq G_{\mathbb{Q}}$.

A representation $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is **admissible of weight** e **and level** N (for K and ι) if it is admissible of stable type for (ι, e, N) or admissible of endoscopic type for $(\iota, e, N|d_K|)$.

Proposition 38.5. *Let K be an imaginary quadratic field with discriminant d_K. There are integers $c, A \geq 0$ with the following property. For all integers $e \geq 1$ and $N \geq 1$, every subgroup $H \leq (\mathbb{Z}/N\mathbb{Z})^\times$ and every prime p with $p \nmid 30Nd_K$ there is a nonzero integer M with*

$$\log|M| \leq c\,\varphi\big([(\mathbb{Z}/N\mathbb{Z})^\times : H]\big)\,\big(N(e+1)\big)^A \log p$$

such that for every prime $\ell \neq p$ and every coefficient ring $\mathcal{O}$ (at ℓ) the following holds: if (K, ℓ, e, N, χ_0) is a unitary Eisenstein datum for some $\chi_0 \in \mathcal{X}_{\mathcal{O}}(N, H)$, then $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length for every $\chi \in \mathcal{X}_{\mathcal{O}}(N, H)$, and

$$\sum_{\chi \in \mathcal{X}_{\mathcal{O}}(N,H)} \nu_{\mathcal{O}}(\chi, e) \leq 2\, v_\ell(M).$$

Proof. Let $c, A \geq 0$ be the integers given by Proposition 38.6 for K. Fix $e, N \geq 1$, a subgroup $H \leq G = (\mathbb{Z}/N\mathbb{Z})^\times$ and a prime $p \nmid 30Nd_K$; put $m = [G : H]$. Since $p \nmid 30$, $p \geq 7$. Choose a prime w of K above p and write $q = q_w$, a power of p; as $p \nmid N$, q is prime to N. Put $\mathrm{Eis}(z) = q^{-e}z + 1 + q^e z^{-1}$.

Step 1: the integer M. Let Z be the set of homomorphisms $\xi\colon G \to \mathbb{C}^\times$ with kernel exactly H, and $z(\xi) = \xi(q)^{-1}$, a root of unity. For $\sigma \in \mathrm{Aut}(\mathbb{C})$, $\sigma \circ \xi$ has kernel H (σ is injective) and $z(\sigma \circ \xi) = \sigma(z(\xi))$; the map $\xi \mapsto \sigma \circ \xi$ is a bijection of Z with inverse $\xi \mapsto \sigma^{-1} \circ \xi$. If $Z \neq \emptyset$, the image of any $\xi_0 \in Z$ is a finite subgroup of $\mathbb{C}^\times$, so G/H is cyclic of order m, and the elements of Z are the ξ_0^j with $j \in (\mathbb{Z}/m\mathbb{Z})^\times$; hence $|Z| \leq \varphi(m)$. By Proposition 38.6 applied to (e, N, p, w, Z, z) (note $p \geq 7$, $p \nmid Nd_K$) there is a nonzero integer M with

$$\log|M| \leq c\,|Z|\,\big(N(e+1)\big)^A \log p \leq c\,\varphi(m)\big(N(e+1)\big)^A \log p,$$

and M depends only on (K, e, N, H, p) and the choice of w.

Step 2: setting up at a prime ℓ. Let $\ell \neq p$ be a prime, $\mathcal{O}$ a coefficient ring and $\chi_0 \in \mathcal{X}_{\mathcal{O}}(N, H)$ such that (K, ℓ, e, N, χ_0) is a unitary Eisenstein datum. Then ℓ is odd by (Ue1). Choose an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ (both fields are algebraically closed of characteristic 0 and of the cardinality of the continuum), a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w and an arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$ (the decomposition group maps onto the Galois group of the residue field extension). Since $p \nmid \ell N$, reduction modulo $\bar{w}$ is injective on the roots of unity of order dividing $\ell^k N$ for every k, and σ acts on the residue field as $x \mapsto x^q$; hence $\sigma(\zeta) = \zeta^q$ for these roots of unity, so that

$$\chi(\sigma) = \chi(q) \quad \text{for every Dirichlet character } \chi \text{ modulo } N, \qquad \chi_{\mathrm{cyc}}(\sigma) = q. \tag{38.3}$$

Step 3: the characters with kernel H. Every $\chi \in \mathcal{X}_{\mathcal{O}}(N, H)$ has kernel H, so $\chi = \chi_0^j$ for some j prime to m (Step 1 applied to the cyclic group G/H and the injective characters it induces), and conversely every such χ_0^j lies in $\mathcal{X}_{\mathcal{O}}(N, H)$. So $\chi \mapsto \iota \circ \chi$ is a bijection $\mathcal{X}_{\mathcal{O}}(N, H) \to Z$ (injective as ι is). Moreover, for $\chi = \chi_0^j$ with $\gcd(j, m) = 1$, (K, ℓ, e, N, χ) is a unitary Eisenstein datum:

- (Ue1), (Ue2), (Ue6), (Ue7), (Ue9) do not involve the character;

- (Ue3): χ and χ_0 both have order m;
- (Ue4): p-components are multiplicative in the character $((\chi\chi')_r(u) = \chi(\tilde{u})\chi'(\tilde{u}))$, so $\chi_\ell = (\chi_0)_\ell^j$ and $\chi_\ell^2 = ((\chi_0)_\ell^2)^j = \mathbf{1}$;
- (Ue5): if e is odd, $\chi_0(-1) = -1$, so m is even and j odd, and $\chi(-1) = (-1)^j = -1$; if e is even, $\chi(-1) = \chi_0(-1)^j = 1$;
- (Ue8): the part of order prime to ℓ and the ℓ-component of χ are the j-th powers of those of χ_0, so $\chi^{(\ell)} = (\chi_0^{(\ell)})^j$; both factors of $\chi_0^{(\ell)}$ have order dividing m and commute, so $\chi_0^{(\ell)}$ has order dividing m, and as $\gcd(j, m) = 1$, $\ker \chi^{(\ell)} = \ker \chi_0^{(\ell)}$. Hence $L_{\ell,\chi} = L_{\ell,\chi_0}$, which does not contain K.

Step 4: the Eisenstein traces. For $\chi \in \mathcal{X}_{\mathcal{O}}(N, H)$ put $t_\chi = \Psi_{\chi,e}(\sigma^{-1}) + 1 + \Psi_{\chi,e}(\sigma^{-1})^{-1}$. By (38.3), $\Psi_{\chi,e}(\sigma) = \chi(q)q^e$, so

$$t_\chi = q^{-e}\chi(q)^{-1} + 1 + q^e\chi(q) = \iota^{-1}\big(\mathrm{Eis}(z(\iota \circ \chi))\big),$$

since $z(\iota \circ \chi) = \iota(\chi(q))^{-1}$ and ι^{-1} is a field isomorphism fixing q.

Step 5: the one-character bound for each χ. Let $\chi \in \mathcal{X}_{\mathcal{O}}(N, H)$. We apply Proposition 42.2 to the unitary Eisenstein datum (K, ℓ, e, N, χ) (Step 3), to ι and to the element $\sigma^{-1} \in G_K$, whose Eisenstein trace is t_χ. Its hypothesis 1: for an admissible ρ of weight e and level N, Proposition 38.6, item 1, for the family with $X_{\iota\circ\chi} = \{\rho\}$ and all other members empty gives $\operatorname{tr}\rho(\sigma^{-1}) \neq \iota^{-1}(\mathrm{Eis}(z(\iota \circ \chi))) = t_\chi$ (here ℓ is odd, $\ell \neq p$). Its hypothesis 2: for W as there, Lemma 38.23 with $\theta = \mathbf{1}$ gives $H^1_f(\mathbb{Q}, W) = 0$, and with $\theta = \eta_K$ (continuous, of order 2, factoring through $\mathrm{Gal}(K/\mathbb{Q})$) gives $H^1_f(\mathbb{Q}, W \otimes \eta_K) = 0$; the hypotheses of Lemma 38.23 are exactly those imposed on W in hypothesis 2. Hence $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length, which is the first assertion, and there is a finite set X_χ of pairwise non-isomorphic admissible representations of weight e and level N with

$$\nu_{\mathcal{O}}(\chi, e) \leq 2 \sum_{\rho \in X_\chi} v_\ell(\operatorname{tr}\rho(\sigma^{-1}) - t_\chi). \tag{38.4}$$

Step 6: one integer for the whole kernel. Apply Proposition 38.6, item 2, to $\ell, \iota, \bar{\imath}, \sigma$ and the family $(X_\xi)_{\xi \in Z}$ with $X_{\iota\circ\chi} = X_\chi$ (well defined by the bijection of Step 3). With Step 4,

$$v_\ell(M) \geq \sum_{\chi \in \mathcal{X}_{\mathcal{O}}(N,H)} \sum_{\rho \in X_\chi} v_\ell(\operatorname{tr}\rho(\sigma^{-1}) - t_\chi),$$

and summing (38.4) over χ,

$$\sum_{\chi \in \mathcal{X}_{\mathcal{O}}(N,H)} \nu_{\mathcal{O}}(\chi, e) \leq 2\, v_\ell(M).$$

Here M is the integer of Step 1, which does not depend on ℓ, $\mathcal{O}$ or χ_0. □

Proposition 38.6. *Let K be an imaginary quadratic field with discriminant d_K. There are integers $c, A \geq 0$ with the following property. Let $e, N \geq 1$ be integers, $p \geq 7$ a prime with $p \nmid N d_K$, w a prime of K above p, and put $\mathrm{Eis}(z) = q_w^{-e}z + 1 + q_w^e z^{-1}$ for $z \in \mathbb{C}^\times$. Let Z be a finite set and $z\colon Z \to \mathbb{C}$ a map such that every $z(o)$ is a root of unity and for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ there is a bijection u_σ of Z with $z(u_\sigma(o)) = \sigma(z(o))$ for all $o \in Z$. Then there is a nonzero integer M with*

$$\log|M| \leq c\,|Z|\,\big(N(e+1)\big)^A \log p$$

such that for every odd prime $\ell \neq p$, every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w, every arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$ and every family $(X_o)_{o\in Z}$ of finite sets of pairwise non-isomorphic representations $G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ admissible of weight e and level N (for K and ι):

1. $\operatorname{tr}\rho(\sigma^{-1}) \neq \iota^{-1}\big(\mathrm{Eis}(z(o))\big)$ *for every $o \in Z$ and $\rho \in X_o$;*
2. $v_\ell(M) \geq \displaystyle\sum_{o\in Z}\sum_{\rho\in X_o} v_\ell\Big(\operatorname{tr}\rho(\sigma^{-1}) - \iota^{-1}\big(\mathrm{Eis}(z(o))\big)\Big)$.

Proof. Let c_0, A_0 be the integers given by Proposition 38.9 for K, and put $c = 5c_0$, $A = A_0 + 1$. Fix e, N, p, w, Z, z as in the statement and write $q = q_w$, so that $\mathrm{Eis} = \mathrm{Eis}_{q,e}$. Since K is quadratic, $q = p^f$ with $f \in \{1, 2\}$; in particular $q \geq p \geq 7$ and $\log q \leq 2\log p$.

The integer M. As $p \nmid N d_K$, Proposition 38.9 gives a finite set S and $t\colon S \to \mathbb{C}$ with (Ft1)–(Ft4) for (e, N, p, w). By (Ft1) and (Ft2), Lemma 38.7 applies to (q, e, S, t, Z, z) and gives a nonzero integer M with $\log|M| \leq |Z|\,|S|\,(2e\log q + 1)$. Since $\log p \geq \log 7 > 1$,

$$2e\log q + 1 \leq 4e\log p + \log p \leq 5(e+1)\log p \leq 5N(e+1)\log p,$$

and with (Ft3),

$$\log|M| \leq |Z| \cdot c_0\big(N(e+1)\big)^{A_0} \cdot 5N(e+1)\log p \leq c\,|Z|\,\big(N(e+1)\big)^{A}\log p.$$

The two properties. Let $\ell \neq p$ be an odd prime, ι, $\bar{w}$ and σ as in the statement, and $(X_o)_{o\in Z}$ a family of finite sets of pairwise non-isomorphic admissible representations of weight e and level N. Let λ be the map given by (Ft4) for $(\ell, \iota, \bar{w}, \sigma)$; then $\operatorname{tr}\rho(\sigma^{-1}) = \iota^{-1}(t(\lambda(\rho)))$ for each admissible ρ. By Lemma 38.7, $t(s) \neq \mathrm{Eis}(z(o))$ for all s, o; applying the injective map ι^{-1} gives item 1. For each o, the restriction of λ to X_o is injective: if $\lambda(\rho) = \lambda(\rho')$ with $\rho, \rho' \in X_o$, then $\rho \cong \rho'$ by (Ft4), hence $\rho = \rho'$ since the members of X_o are pairwise non-isomorphic. Put $Y_o = \lambda(X_o) \subseteq S$. As q is a power of p and $\ell \neq p$, $\ell \nmid q$, and Lemma 38.7 gives

$$v_\ell(M) \geq \sum_{o\in Z}\sum_{s\in Y_o} v_\ell(\iota^{-1}(t(s)) - \iota^{-1}(\mathrm{Eis}(z(o)))) = \sum_{o\in Z}\sum_{\rho\in X_o} v_\ell(\operatorname{tr}\rho(\sigma^{-1}) - \iota^{-1}(\mathrm{Eis}(z(o)))),$$

the equality by reindexing along the bijection $\lambda\colon X_o \to Y_o$. This is item 2. □

Lemma 38.7. *Let $q \geq 7$ and $e \geq 1$ be integers, and for $z \in \mathbb{C}^\times$ put $\mathrm{Eis}_{q,e}(z) = q^{-e}z + 1 + q^e z^{-1}$. Let S be a finite set and $t\colon S \to \mathbb{C}$ a map such that*

- *for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ there is a bijection u_σ of S with $t(u_\sigma(s)) = \sigma(t(s))$ for all $s \in S$;*
- *for every $s \in S$, $|t(s)| \leq \sqrt{q} + 2$ and $q^e t(s)$ is an algebraic integer.*

Let Z be a finite set and $z\colon Z \to \mathbb{C}$ a map such that every $z(o)$ is a root of unity and for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ there is a bijection u'_σ of Z with $z(u'_\sigma(o)) = \sigma(z(o))$ for all $o \in Z$. Then $t(s) \neq \mathrm{Eis}_{q,e}(z(o))$ for all $s \in S$, $o \in Z$, and there is a nonzero integer M with

$$\log|M| \leq |Z|\,|S|\,(2e\log q + 1)$$

such that for every prime $\ell \nmid q$, every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ and every family $(Y_o)_{o\in Z}$ of subsets of S,

$$v_\ell(M) \geq \sum_{o\in Z}\sum_{s\in Y_o} v_\ell\Big(\iota^{-1}(t(s)) - \iota^{-1}\big(\mathrm{Eis}_{q,e}(z(o))\big)\Big).$$

Proof. For $o \in Z$ and $s \in S$ put

$$F(o,s) = q^e\big(t(s) - \mathrm{Eis}_{q,e}(z(o))\big) = q^e t(s) - z(o) - q^e - q^{2e} z(o)^{-1}.$$

Step 1: $t(s) \neq \mathrm{Eis}_{q,e}(z(o))$. As $z(o)$ is a root of unity, $|z(o)| = 1$, so $|\mathrm{Eis}_{q,e}(z(o))| \geq q^e - 1 - q^{-e} \geq q - \frac{8}{7}$, using $q^e \geq q$ and $q^{-e} \leq \frac{1}{7}$. On the other hand $|t(s)| \leq \sqrt{q} + 2$, and $q - \sqrt{q} \geq 7 - \sqrt{7} > 4 > 2 + \frac{8}{7}$ since $x \mapsto x - \sqrt{x}$ is increasing for $x \geq \frac{1}{4}$. Hence $|t(s)| < |\mathrm{Eis}_{q,e}(z(o))|$, and in particular $F(o,s) \neq 0$.

Step 2: integrality and size of $F(o,s)$. By hypothesis, $q^e t(s)$ is an algebraic integer, and $z(o)$, $z(o)^{-1}$ are roots of unity; so $F(o,s)$ is a sum of algebraic integers and is an algebraic integer. Moreover

$$|F(o,s)| \leq q^e\big(\sqrt{q} + 2 + q^{-e} + 1 + q^e\big) = q^{2e}\Big(1 + \frac{\sqrt{q}+3}{q^e} + \frac{1}{q^{2e}}\Big) < 2q^{2e},$$

so $\log|F(o,s)| < \log 2 + 2e\log q \leq 2e\log q + 1$.

Step 3: the product is a rational integer. Let $P = \prod_{(o,s)\in Z\times S} F(o,s)$. For $\sigma \in \mathrm{Aut}(\mathbb{C})$, σ fixes q, so $\sigma(\mathrm{Eis}_{q,e}(w)) = \mathrm{Eis}_{q,e}(\sigma(w))$ for $w \in \mathbb{C}^\times$, and therefore $\sigma(F(o,s)) = F(u'_\sigma(o), u_\sigma(s))$. Since $(o,s) \mapsto (u'_\sigma(o), u_\sigma(s))$ is a bijection of $Z \times S$, $\sigma(P) = P$. Every element of $\mathbb{C}$ outside $\mathbb{Q}$ is moved by some automorphism of $\mathbb{C}$, so $P \in \mathbb{Q}$; as P is an algebraic integer (Step 2), $P \in \mathbb{Z}$, and $P \neq 0$ by Step 1. Put $M = P$. By Step 2,

$$\log|M| = \sum_{(o,s)\in Z\times S} \log|F(o,s)| \leq |Z|\,|S|\,(2e\log q + 1)$$

(if $Z \times S$ is empty, $M = 1$ and both sides are 0).

Step 4: the ℓ-adic inequality. Let $\ell \nmid q$ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and $(Y_o)_{o\in Z}$ subsets of S. The ring isomorphism ι^{-1} fixes $\mathbb{Z}$, so $\iota^{-1}(M) = M$ and

$$v_\ell(M) = \sum_{(o,s)\in Z\times S} v_\ell\big(\iota^{-1}(F(o,s))\big).$$

Each $y = \iota^{-1}(F(o,s))$ is a root of a monic polynomial $X^n + a_{n-1}X^{n-1} + \cdots + a_0$ with $a_i \in \mathbb{Z}$; if $v_\ell(y) < 0$, then $v_\ell(y^n) < v_\ell(a_i y^i)$ for all $i < n$, which contradicts $y^n = -\sum_{i<n} a_i y^i$. So every term is ≥ 0, and dropping the terms with $s \notin Y_o$ gives

$$v_\ell(M) \geq \sum_{o\in Z}\sum_{s\in Y_o} v_\ell\big(\iota^{-1}(F(o,s))\big) = \sum_{o\in Z}\sum_{s\in Y_o}\Big(e\,v_\ell(q) + v_\ell\big(\iota^{-1}(t(s)) - \iota^{-1}(\mathrm{Eis}_{q,e}(z(o)))\big)\Big),$$

and $v_\ell(q) = 0$ because $\ell \nmid q$. Each difference on the right is nonzero by Step 1, so every term is finite. □

Definition 38.8. Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field with ring of integers $\mathcal{O}_K$, let $\widehat{\mathcal{O}}_K = \prod_{v\nmid\infty} \mathcal{O}_{K_v} \subset \mathbb{A}_{K,f}$, and for an integer $N \geq 1$ let

$$\mathrm{K}(N) = \ker\Big(\mathrm{GL}_3(\widehat{\mathcal{O}}_K) \to \mathrm{GL}_3\big(\widehat{\mathcal{O}}_K/N\widehat{\mathcal{O}}_K\big)\Big) = \prod_{v\nmid\infty} \mathrm{K}(N)_v$$

be the principal congruence subgroup of level N; for a finite place $v \nmid N$ of K, $\mathrm{K}(N)_v = \mathrm{GL}_3(\mathcal{O}_{K_v})$. For a cuspidal automorphic representation $\pi = \pi_\infty \otimes \pi_f$ of $\mathrm{GL}_3(\mathbb{A}_K)$ and an embedding $\tau\colon K \to \mathbb{C}$, the **infinitesimal character of π at τ** is the multiset of three complex numbers attached to τ by the infinitesimal character of π_∞, a representation of $\mathrm{GL}_3(K \otimes_{\mathbb{Q}} \mathbb{R}) \cong \mathrm{GL}_3(\mathbb{C})$,

in the normalisation of [68] (in which π is regular algebraic exactly when, for every τ, these are three distinct integers).

For integers $e, N \geq 1$, $\mathrm{Cusp}_K(e,N)$ is the set of isomorphism classes of cuspidal automorphic representations π of $\mathrm{GL}_3(\mathbb{A}_K)$ such that

(Cs1) for both embeddings $\tau\colon K \to \mathbb{C}$, the infinitesimal character of π at τ is $\{e, 0, -e\}$;

(Cs2) π is conjugate self-dual: $\pi^\vee \cong \pi^c$;

(Cs3) π_f has a nonzero vector fixed by $\mathrm{K}(N)$.

Its members are the **conjugate self-dual cuspidal representations of** GL_3 **over** K **of weight** e **and level** N. By (Cs1) they are regular algebraic. For a finite place $v \nmid N$ of K, (Cs3) and the factorisation $\pi_f \cong \bigotimes'_v \pi_v$ give $\pi_v^{\mathrm{GL}_3(\mathcal{O}_{K_v})} \neq 0$, so π_v is unramified; its multiset of Satake parameters is written $\mathrm{Sat}_v(\pi) = \{\alpha_1, \alpha_2, \alpha_3\} \subset \mathbb{C}^\times$ and depends only on the isomorphism class of π.

Proposition 38.9. *Let K be an imaginary quadratic field with discriminant d_K. There are integers $c, A \geq 0$ with the following property. For all integers $e, N \geq 1$, every prime p with $p \nmid N d_K$ and every prime w of K above p there are a finite set S and a map $t\colon S \to \mathbb{C}$ such that*

(Ft1) *for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ there is a bijection u_σ of S with $t(u_\sigma(s)) = \sigma(t(s))$ for all $s \in S$;*

(Ft2) *for every $s \in S$, $|t(s)| \leq \sqrt{q_w} + 2$ and $q_w^e\, t(s)$ is an algebraic integer;*

(Ft3) $|S| \leq c\,(N(e+1))^A$;

(Ft4) *for every odd prime $\ell \neq p$, every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w and every arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$, there is a map λ from the set of representations $G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ that are admissible of weight e and level N (for K and ι) to S such that $\lambda(\rho) = \lambda(\rho')$ implies $\rho \cong \rho'$, and $\iota(\mathrm{tr}\,\rho(\sigma^{-1})) = t(\lambda(\rho))$ for every such ρ.*

Proof. Let c_1, A_1 be the integers given by Proposition 38.15 for K, and put $c = c_1 + d_K^4$, $A = \max(A_1, 4)$. Fix $e, N \geq 1$, a prime $p \nmid N d_K$ and a prime w of K above p. Write $q = q_w = p^\delta$ with $\delta \in \{1, 2\}$ the residue degree, and put $L = (N|d_K|)^2$; then $p \nmid L$.

Step 1: the set S and the map t. Let S be the disjoint union of $\mathrm{Cusp}_K(e,N)$ and $\mathrm{New}_{2e+1}(L)$; both are finite, by (Cc1) and by Lemma 38.22. For $\pi \in \mathrm{Cusp}_K(e,N)$, $w \nmid N$, so π_w is unramified with $\mathrm{Sat}_w(\pi) = \{\alpha_1, \alpha_2, \alpha_3\}$, and we put $t(\pi) = \alpha_1 + \alpha_2 + \alpha_3$. For $g \in \mathrm{New}_{2e+1}(L)$ with coefficients $a_n(g)$, level $L_g \mid L$ and character ε_g, let $\beta_1(g), \beta_2(g)$ be the roots of

$$P_g(X) = X^2 - a_p(g)X + \varepsilon_g(p)p^{2e},$$

and put $t(g) = 1 + q^{-e}(\beta_1(g)^\delta + \beta_2(g)^\delta)$, which does not depend on the order of the roots.

Step 2: (Ft3). By (Cc1) and Lemma 38.22 with $k = 2e+1$,

$$\begin{aligned} |S| &\leq c_1(N(e+1))^{A_1} + 1 + \frac{(2e+1)L^2}{12} \leq c_1(N(e+1))^{A_1} + (e+1)L^2 \\ &\leq c_1(N(e+1))^{A_1} + d_K^4(N(e+1))^4 \leq c\,(N(e+1))^A, \end{aligned}$$

Step 3: (Ft2) on $\mathrm{Cusp}_K(e,N)$. Let $\pi \in \mathrm{Cusp}_K(e,N)$ with central character ω. By (Cs2), $\omega^{-1} = \omega \circ c$. The continuous homomorphism $|\omega|\colon \mathbb{A}_K^\times / K^\times \to \mathbb{R}_{>0}$ is trivial on the compact

subgroup $\mathbb{A}_K^1/K^\times$, and $\mathbb{A}_K^\times = \mathbb{A}_K^1 \cdot \mathbb{R}_{>0}$ ($\mathbb{R}_{>0}$ embedded at the archimedean place), so $|\omega| = |\cdot|_{\mathbb{A}}^s$ for some real s. As $|x^c|_{\mathbb{A}} = |x|_{\mathbb{A}}$, $|\cdot|_{\mathbb{A}}^{-s} = |\omega^{-1}| = |\omega \circ c| = |\cdot|_{\mathbb{A}}^s$, so $s = 0$ and ω is unitary. By (Js2) of [136], $q^{-1/2} < |\alpha_i| < q^{1/2}$ for $i = 1, 2, 3$. Moreover π_w lies in the normalised induction of unramified characters μ_1, μ_2, μ_3 with $\mu_i(\varpi_w) = \alpha_i$, on which the centre acts by $\mu_1\mu_2\mu_3$; so $\alpha_1\alpha_2\alpha_3 = \omega_w(\varpi_w)$ has absolute value 1. Put $x_i = \log|\alpha_i|/\log q \in (-\frac{1}{2}, \frac{1}{2})$, ordered $x_1 \geq x_2 \geq x_3$, so $x_1 + x_2 + x_3 = 0$, and $\phi(x) = q^x$, convex and increasing. For $a, b \geq 0$, $\phi(a+b) - \phi(b) \geq \phi(a) - \phi(0)$, and for $a, b \leq 0$, $\phi(0) - \phi(a) \geq \phi(b) - \phi(a+b)$; in both cases $\phi(a) + \phi(b) \leq \phi(a+b) + 1$. If $x_2 \geq 0$, apply this to (x_1, x_2), whose sum is $-x_3$; if $x_2 \leq 0$, to (x_2, x_3), whose sum is $-x_1$. In both cases there is $y \in (-\frac{1}{2}, \frac{1}{2})$ with

$$|t(\pi)| \leq \sum_i |\alpha_i| = \sum_i \phi(x_i) \leq \phi(y) + \phi(-y) + 1 < q^{1/2} + q^{-1/2} + 1 \leq \sqrt{q} + 2,$$

since $y \mapsto \phi(y) + \phi(-y)$ is even and increasing on $[0, \infty)$. By Proposition 38.17 (applicable as $p \nmid Nd_K$), each $q^e\alpha_i$ is an algebraic integer, hence so is $q^e t(\pi)$.

Step 4: (Ft2) on $\mathrm{New}_{2e+1}(L)$. Let $g \in \mathrm{New}_{2e+1}(L)$; $p \nmid L_g$. By (Dg2) of [77] (weight $k = 2e+1 \geq 3$), $|\beta_j(g)| = p^e$, so $|q^{-e}\beta_j(g)^\delta| = 1$ and $|t(g)| \leq 3 \leq \sqrt{q} + 2$. By (Nw2) of [229], $a_p(g)$ is an algebraic integer, and $\varepsilon_g(p)$ is a root of unity; so P_g is monic with algebraic integer coefficients, $\beta_1(g), \beta_2(g)$ are algebraic integers, and so is $q^e t(g) = q^e + \beta_1(g)^\delta + \beta_2(g)^\delta$.

Step 5: (Ft1). Let $\theta \in \mathrm{Aut}(\mathbb{C})$. On $\mathrm{Cusp}_K(e, N)$: by (Cc2) choose for each π some $u_\theta(\pi) \in \mathrm{Cusp}_K(e, N)$ with $\mathrm{Sat}_v(u_\theta(\pi)) = \theta(\mathrm{Sat}_v(\pi))$ for all finite $v \nmid N$. If $u_\theta(\pi_1) = u_\theta(\pi_2)$, then $\mathrm{Sat}_v(\pi_1) = \mathrm{Sat}_v(\pi_2)$ for all finite $v \nmid N$ (θ is injective); an unramified irreducible representation of $\mathrm{GL}_3(K_v)$ is determined up to isomorphism by its Satake parameters, being the unique unramified irreducible subquotient of the corresponding normalised induction ([60]), so $\pi_{1,v} \cong \pi_{2,v}$ for all but finitely many v, and $\pi_1 \cong \pi_2$ by (Js1) of [136]. So u_θ is an injective, hence bijective, self-map of the finite set $\mathrm{Cusp}_K(e, N)$, and $t(u_\theta(\pi)) = \sum_i \theta(\alpha_i) = \theta(t(\pi))$. On $\mathrm{New}_{2e+1}(L)$: put $u_\theta(g) = g^\theta$, a normalised newform of weight $2e+1$, level L_g and character $\theta \circ \varepsilon_g$ by (Nw3) of [229]; so u_θ maps $\mathrm{New}_{2e+1}(L)$ to itself, with inverse $u_{\theta^{-1}}$. Since $a_p(g^\theta) = \theta(a_p(g))$ and θ fixes p^{2e}, P_{g^θ} is P_g with θ applied to its coefficients, its roots are $\theta(\beta_1(g)), \theta(\beta_2(g))$, and $t(g^\theta) = \theta(t(g))$ as θ fixes q^{-e}. The two maps together are a bijection u_θ of S with $t \circ u_\theta = \theta \circ t$.

Step 6: setting up (Ft4). Fix an odd prime $\ell \neq p$, an isomorphism ι, a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w and an arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$. Since $\ell \neq p$, reduction modulo $\bar{w}$ is injective on the roots of unity of ℓ-power order, and σ acts on the residue field as $x \mapsto x^q$; hence $\sigma(\zeta) = \zeta^q$ for these roots of unity and $\chi_{\mathrm{cyc}}(\sigma) = q$. We use twice the following consequence of the Chebotarev density theorem and the Brauer–Nesbitt theorem ([220], Chapter I, 2.2): if F is a number field and $r_1, r_2 \colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ are continuous semisimple representations such that, for all finite places v outside a finite set, both are unramified at v and $\det(X - r_1(\mathrm{Frob}_v^{-1})) = \det(X - r_2(\mathrm{Frob}_v^{-1}))$, then $r_1 \cong r_2$ (the Frobenius elements at these places are dense in the quotient of G_F through which $r_1 \oplus r_2$ factors, so $\mathrm{tr}\, r_1 = \mathrm{tr}\, r_2$). (T)

Step 7: stable points. Let ρ be admissible of stable type for (ι, e, N) and $r = \rho \otimes \chi_{\mathrm{cyc}}^{-1}$; r is irreducible by (Sb1), hence semisimple. By (Sb2) choose a regular algebraic conjugate self-dual cuspidal π_ρ with $r \leftrightarrow_\iota \pi_\rho$; by Proposition 38.11 ($\ell$ odd) the class of π_ρ lies in $\mathrm{Cusp}_K(e, N)$, and we put $\lambda(\rho) = \pi_\rho \in S$. The representation $r_0 = r_{\ell,\iota}(\pi_\rho)$ of [231], [67] (with $E = K$, $n = 3$) is continuous, semisimple and satisfies $r_0 \leftrightarrow_\iota \pi_\rho$; by (T), $r \cong r_0$. Now $w \nmid \ell$ and $\pi_{\rho,w}$ is unramified ($w \nmid N$), so the compatibility of r_0 at w gives $\iota(\det(X - r(\sigma^{-1}))) = \prod_i (X - q\alpha_i)$ with $\{\alpha_i\} = \mathrm{Sat}_w(\pi_\rho)$. As $\rho(\sigma^{-1}) = \chi_{\mathrm{cyc}}(\sigma)^{-1} r(\sigma^{-1}) = q^{-1} r(\sigma^{-1})$,

$$\iota(\mathrm{tr}\, \rho(\sigma^{-1})) = q^{-1} \sum_i q\alpha_i = t(\lambda(\rho)).$$

If ρ' is another such representation with $\lambda(\rho') = \lambda(\rho)$, then $\pi_{\rho'} \cong \pi_\rho$ have the same Satake

parameters at all unramified places, so $r' = \rho' \otimes \chi_{\mathrm{cyc}}^{-1}$ and r (both irreducible) have the same characteristic polynomials of Frob_v^{-1} at almost all v; by (T), $r \cong r'$, hence $\rho \cong \rho'$.

Step 8: endoscopic points. Let ρ be admissible of endoscopic type for (ι, e, M), $M = N|d_K|$; choose $W = W_\rho$ with (Eo1)–(Eo4) and a normalised newform $g = g_\rho$ of weight $2e+1$ as in (Eo2), and put $W' = W \otimes \chi_{\mathrm{cyc}}^{-e}$. By (Eo3), W has level M and weights $(e, -e)$, so Proposition 38.21 (ℓ odd) gives $L_g \mid M^2 = L$; thus $g \in \mathrm{New}_{2e+1}(L)$ and we put $\lambda(\rho) = g \in S$. Let ρ_g^{ss} be the semisimplification of $\rho_{g,\iota}$ of (Dg1) of [76]; it has the same characteristic polynomials and is trivial on every inertia group on which $\rho_{g,\iota}$ is. W' is semisimple by (Eo2), and W' and ρ_g^{ss} are unramified with characteristic polynomial $P_{g,p'}(X) = X^2 - a_{p'}(g)X + \varepsilon_g(p')p'^{2e}$ of geometric Frobenius at all primes p' outside a finite set (by (Eo2) and (Dg1)); by (T), $W' \cong \rho_g^{\mathrm{ss}}$. Since $p \nmid \ell L_g$, W' is trivial on the inertia group I' of $\bar{w}$ in $G_{\mathbb{Q}}$, and $\iota(\det(X - W'(\tau^{-1}))) = P_g(X)$ for an arithmetic Frobenius $\tau \in G_{\mathbb{Q}}$ at $\bar{w}$ (which exists: the decomposition group of $\bar{w}$ in $G_{\mathbb{Q}}$ maps onto the Galois group of the residue field extension). The element $\sigma \in G_K \subseteq G_{\mathbb{Q}}$ lies in that decomposition group and acts on the residue field as $x \mapsto x^{p^\delta}$, so $\tau^\delta \sigma^{-1} \in I'$ and $W'(\sigma^{-1}) = W'(\tau^{-1})^\delta$, with eigenvalues $\iota^{-1}(\beta_1(g)^\delta), \iota^{-1}(\beta_2(g)^\delta)$. By (Eo4), ρ is conjugate to $s \mapsto j(W(s))$ on G_K, where $j\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & 0 & b \\ 0 & 1 & 0 \\ c & 0 & d \end{pmatrix}$ is a group homomorphism $\mathrm{GL}_2 \to \mathrm{GL}_3$; so $\operatorname{tr}\rho(\sigma^{-1}) = \operatorname{tr} W(\sigma^{-1}) + 1$ and, as $W(\sigma^{-1}) = \chi_{\mathrm{cyc}}(\sigma)^{-e} W'(\sigma^{-1}) = q^{-e} W'(\sigma^{-1})$,

$$\iota(\operatorname{tr}\rho(\sigma^{-1})) = 1 + q^{-e}\big(\beta_1(g)^\delta + \beta_2(g)^\delta\big) = t(\lambda(\rho)).$$

If ρ' is another such representation with $\lambda(\rho') = g$, then $W_{\rho'} \otimes \chi_{\mathrm{cyc}}^{-e} \cong \rho_g^{\mathrm{ss}} \cong W'$, so $W_{\rho'} = hW_\rho h^{-1}$ for some $h \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$, and ρ' is conjugate to $j \circ W_{\rho'}|_{G_K} = j(h)\,(j \circ W_\rho|_{G_K})\,j(h)^{-1}$, hence to ρ.

Step 9: (Ft4). A representation admissible of weight e and level N is of stable type for (ι, e, N) or of endoscopic type for $(\iota, e, N|d_K|)$, and not both: a stable one is irreducible by (Sb1), while an endoscopic one is conjugate to $j \circ W|_{G_K}$, which fixes the second basis vector. So Steps 7 and 8 define a map λ from the admissible representations of weight e and level N to S, sending the stable ones to $\mathrm{Cusp}_K(e, N)$ and the endoscopic ones to $\mathrm{New}_{2e+1}(L)$, with $\iota(\operatorname{tr}\rho(\sigma^{-1})) = t(\lambda(\rho))$; and $\lambda(\rho) = \lambda(\rho')$ forces ρ, ρ' to be of the same type, hence $\rho \cong \rho'$ by Step 7 or Step 8. The set S and the map t of Step 1 do not depend on ℓ, ι, $\bar{w}$ or σ. □

Definition 38.10. Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field with a fixed embedding $\tau\colon K \to \mathbb{C}$, $\bar{\tau} = \overline{\tau(\cdot)}$ the other one, and $n \geq 1$. Put $G_\infty = \mathrm{GL}_n(K \otimes_{\mathbb{Q}} \mathbb{R})$, identified with $\mathrm{GL}_n(\mathbb{C})$ through τ; $K_\infty = \mathrm{U}(n) \cdot \mathbb{R}_{>0} \subset G_\infty$ ($\mathbb{R}_{>0}$ as scalar matrices); $\mathfrak{g} = \mathrm{Lie}(G_\infty) \otimes_{\mathbb{R}} \mathbb{C} \cong \mathfrak{gl}_n(\mathbb{C}) \times \mathfrak{gl}_n(\mathbb{C})$, the two factors corresponding to τ and $\bar{\tau}$. For $N \geq 1$, $\mathrm{K}_n(N) \subset \mathrm{GL}_n(\widehat{\mathcal{O}}_K)$ is the kernel of reduction modulo N (so $\mathrm{K}_3(N) = \mathrm{K}(N)$).

Infinitesimal characters. For a cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_K)$, the **infinitesimal character of π at τ** (resp. at $\bar{\tau}$) is the multiset of n complex numbers given by the τ- (resp. $\bar{\tau}$-) factor of the infinitesimal character of π_∞, in the normalisation of [68], in which the trivial representation has infinitesimal character $\{\frac{n-1}{2}, \frac{n-3}{2}, \dots, -\frac{n-1}{2}\}$ at both embeddings (for $n = 3$ this is the infinitesimal character of Definition 38.8).

Coefficient systems. For $\mu \in \mathbb{Z}^n$ with $\mu_1 \geq \cdots \geq \mu_n$ let (ρ_μ, V_μ) be the irreducible algebraic representation of $\mathrm{GL}_n(\mathbb{C})$ of highest weight μ; its infinitesimal character is $\{\mu_i + \frac{n+1}{2} - i : 1 \leq i \leq n\}$ and that of its dual is $\{-\mu_i - \frac{n+1}{2} + i\}$. For two such μ, μ', $V_{\mu,\mu'} = V_\mu \otimes_{\mathbb{C}} V_{\mu'}$ with $g \in G_\infty$ acting by $\rho_\mu(g) \otimes \rho_{\mu'}(\bar{g})$; $\mathrm{GL}_n(K) \subset G_\infty$ acts by restriction. For a cuspidal π, $H^*(\mathfrak{g}, K_\infty; \pi_\infty \otimes V_{\mu,\mu'})$ is the relative Lie algebra cohomology of the $(\mathfrak{g}, K_\infty)$-module of K_∞-finite vectors of π_∞ tensored with $V_{\mu,\mu'}$; π is **cohomological for** $V_{\mu,\mu'}$ if it is nonzero in some degree.

Arithmetic groups of a level. For an open compact subgroup $U \subseteq \mathrm{GL}_n(\mathbb{A}_{K,f})$ the double

coset space $\mathrm{GL}_n(K)\backslash\mathrm{GL}_n(\mathbb{A}_{K,f})/U$ is finite ([38]); for representatives $g_1,\dots,g_h$ put $\Gamma_j(U) = \mathrm{GL}_n(K)\cap g_jUg_j^{-1}$, acting on $V_{\mu,\mu'}$ through $\mathrm{GL}_n(K)\subset G_\infty$, and

$$h^*(U,V_{\mu,\mu'}) = \sum_{j=1}^{h}\sum_{q\geq 0}\dim_{\mathbb{C}} H^q(\Gamma_j(U),V_{\mu,\mu'}) \in \mathbb{Z}_{\geq 0}\cup\{\infty\},$$

which does not depend on the representatives (replacing g_j by $\gamma g_j u$ with $\gamma\in\mathrm{GL}_n(K)$, $u\in U$ conjugates $\Gamma_j(U)$ by γ, compatibly with the action on $V_{\mu,\mu'}$). It is the total dimension of the cohomology of the locally symmetric space of level U with coefficients in $V_{\mu,\mu'}$.

Proposition 38.11. *Let K be an imaginary quadratic field, $e,N\geq 1$ integers, ℓ an odd prime, $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism and $\rho\colon G_K\to\mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ a representation admissible of stable type for (ι,e,N). Let π be a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_3(\mathbb{A}_K)$ with $\rho\otimes\chi_{\mathrm{cyc}}^{-1}\leftrightarrow_\iota\pi$. Then the isomorphism class of π lies in $\mathrm{Cusp}_K(e,N)$.*

Proof. Put $r=\rho\otimes\chi_{\mathrm{cyc}}^{-1}$ and $m=(e-1,-1,-e-1)$. We check the hypotheses of Proposition 38.13 for $n=3$, $M=N$, r and π.

- r is irreducible, as ρ is by (Sb1) and twisting by a character preserves invariant subspaces.
- r has level N and weights m. By (Sb3), ρ has level N and weights $(e,0,-e)$. For a finite place $v\nmid\ell$, χ_{cyc} is trivial on $I_{\bar v}$, so (Lw1) for ρ is (Lw1) for r with the same characters. For $v\mid\ell$, if ρ is triangular on $D_{\bar v}$ with diagonal (κ_i), $\kappa_i=\chi_{\mathrm{cyc}}^{m_i'}\chi_i$ on $I_{\bar v}$ ($m'=(e,0,-e)$), then r is triangular on $D_{\bar v}$ (same g) with diagonal $(\kappa_i\chi_{\mathrm{cyc}}^{-1})$, equal to $\chi_{\mathrm{cyc}}^{m_i'-1}\chi_i=\chi_{\mathrm{cyc}}^{m_i}\chi_i$ on $I_{\bar v}$; the alternative in (Lw2) is preserved, since $\kappa_i\neq\kappa_j\chi_{\mathrm{cyc}}$ is invariant under twisting all κ_i by one character, and twisting by the crystalline character χ_{cyc}^{-1} preserves potential crystallinity.
- π is polarizable: it is conjugate self-dual, $\pi^c\cong\pi^\vee=\pi^\vee\otimes(\mathbf{1}\circ\mathrm{N}_{K/\mathbb{Q}}\circ\det)$.
- By (Sb2), r satisfies the witness conditions, in particular (Wc2).
- r is potentially generic at every place $v\mid\ell$ of K. By (Sb4) and the twist computation above, for each $v\mid\ell$ there is $\bar v\mid v$ such that r is triangular on $D_{\bar v}$ with some diagonal (κ_i) satisfying $\kappa_i\neq\kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar v}}$ for all i,j. Every other place above v is $g\bar v$ with $g\in G_K$, $D_{g\bar v}=gD_{\bar v}g^{-1}$, and $r(gsg^{-1})=r(g)r(s)r(g)^{-1}$; so r is triangular on $D_{g\bar v}$ with diagonal $(s\mapsto\kappa_i(g^{-1}sg))$, and these satisfy the same inequalities because $\chi_{\mathrm{cyc}}(g^{-1}sg)=\chi_{\mathrm{cyc}}(s)$. So r is generic at v, hence potentially generic at v by (Wc1).

By Proposition 38.13: (Wl2) gives the infinitesimal character $\{m_i+1\}=\{e,0,-e\}$ at both embeddings, which is (Cs1); (Wl3) gives a nonzero vector of π_f fixed by $\mathrm{K}_3(N)=\mathrm{K}(N)$, which is (Cs3); and (Cs2) is the hypothesis that π is conjugate self-dual. So the isomorphism class of π lies in $\mathrm{Cusp}_K(e,N)$. (The hypothesis that ℓ is odd is not used.) □

Definition 38.12. Let v and ℓ be primes and $I_v\subset G_{\mathbb{Q}_v}$ the inertia subgroup. For w in the Weil group $W_{\mathbb{Q}_v}\subseteq G_{\mathbb{Q}_v}$ let $n(w)\in\mathbb{Z}$ be the integer with $w(x)=x^{v^{n(w)}}$ on the residue field of $\overline{\mathbb{Q}}_v$.

A **Weil–Deligne representation** of $W_{\mathbb{Q}_v}$ over $\overline{\mathbb{Q}}_\ell$ is a triple $D=(V,\rho,N)$ of a finite-dimensional $\overline{\mathbb{Q}}_\ell$-vector space V, a homomorphism $\rho\colon W_{\mathbb{Q}_v}\to\mathrm{GL}(V)$ trivial on an open subgroup of I_v, and a nilpotent endomorphism N of V (the **monodromy**) with

$$\rho(w)\,N\,\rho(w)^{-1}=v^{n(w)}N\qquad(w\in W_{\mathbb{Q}_v}).\tag{38.5}$$

Its **conductor exponent** is

$$\mathrm{a}(D) = \mathrm{a}\big(\rho|_{I_v}\big) + \dim V^{I_v} - \dim\big(\ker N\big)^{I_v},$$

where, for a finite-dimensional representation θ of I_v trivial on an open subgroup, $\mathrm{a}(\theta)$ is its Artin conductor ([221], Chapter VI, §2: the sum of the codimension of the invariants and the Swan conductor, computed on any finite quotient of I_v through which θ factors).

For a continuous representation $r\colon G_{\mathbb{Q}_v} \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, the **Weil–Deligne representation** $\mathrm{WD}(r)$ is defined when $v \neq \ell$, or when $v = \ell$ and r is potentially semistable:

(Wd1) if $v \neq \ell$: by Grothendieck's monodromy theorem there are a unique nilpotent N and an open subgroup $J \subseteq I_v$ with $r(\sigma) = \exp(t_\ell(\sigma)N)$ for $\sigma \in J$, where $t_\ell\colon I_v \to \mathbb{Z}_\ell$ is a nonzero homomorphism (a choice of tame character); $\mathrm{WD}(r) = (\overline{\mathbb{Q}}_\ell^{\,n}, \rho, N)$ with $\rho(\Phi^m\sigma) = r(\Phi^m\sigma)\exp(-t_\ell(\sigma)N)$ for a fixed $\Phi \in W_{\mathbb{Q}_v}$ with $n(\Phi) = -1$, $m \in \mathbb{Z}$ and $\sigma \in I_v$;

(Wd2) if $v = \ell$ and r is potentially semistable: $\mathrm{WD}(r)$ is the Weil–Deligne representation attached by Fontaine to the filtered $(\varphi, N, G_{\mathbb{Q}_\ell})$-module $D_{\mathrm{pst}}(r)$ ([95]).

Both are well defined up to isomorphism (independent of the choices), and the **conductor exponent of** r is $\mathrm{a}(r) = \mathrm{a}(\mathrm{WD}(r))$.

Frobenius-semisimplification. Let $D = (V, \rho, N)$ be a Weil–Deligne representation and $\Phi \in W_{\mathbb{Q}_v}$ an element with $n(\Phi) = -1$ (a lift of geometric Frobenius). Write $\rho(\Phi) = \rho(\Phi)_s\rho(\Phi)_u$ for the Jordan decomposition into commuting semisimple and unipotent parts. The **Frobenius-semisimplification** of D is $D^{F\text{-}ss} = (V, \rho_s, N)$, where $\rho_s(\Phi^m\sigma) = \rho(\Phi)_s^m\rho(\sigma)$ for $m \in \mathbb{Z}$ and $\sigma \in I_v$. It is a Weil–Deligne representation, independent of Φ up to isomorphism, and D is **Frobenius-semisimple** if $D \cong D^{F\text{-}ss}$, i.e. if $\rho(\Phi)$ is semisimple.

All of the above applies without change to a finite extension K of $\mathbb{Q}_v$ in place of $\mathbb{Q}_v$, with $W_K \supseteq I_K$, and the cardinality q_K of the residue field of K in place of v in the definition of $n(\cdot)$ and in (38.5).

Proposition 38.13. *Let K be an imaginary quadratic field, $n, M \geq 1$ integers, $m = (m_1, \dots, m_n) \in \mathbb{Z}^n$, ℓ a prime and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Let $r\colon G_K \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ be an irreducible continuous representation satisfying (Lw1) and the following part of (Lw2): for every place $v \mid \ell$ of K there are a place $\bar v \mid v$, characters $\chi_1, \dots, \chi_n$ of G_K of level M and characters $\kappa_1, \dots, \kappa_n$ of $D_{\bar v}$ such that r is triangular on $D_{\bar v}$ with diagonal (κ_i) and $\kappa_i(s) = \chi_{\mathrm{cyc}}(s)^{m_i}\chi_i(s)$ for $s \in I_{\bar v}$ (so every representation of level M and weights m qualifies); and let π be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_K)$ with $r \leftrightarrow_\iota \pi$ which is polarizable: $\pi^c \cong \pi^\vee \otimes (\chi \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det)$ for some continuous character $\chi\colon \mathbb{A}_{\mathbb{Q}}^\times/\mathbb{Q}^\times \to \mathbb{C}^\times$. Assume that r satisfies (Wc2), and that r is potentially generic at every place $v \mid \ell$ of K with $v \nmid M$. Then:*

(Wl1) *for every finite place $w \nmid \ell$ of K at which π_w is unramified, every place $\bar w$ of $\overline{\mathbb{Q}}$ above w and every arithmetic Frobenius $\sigma \in G_K$ at $\bar w$, r is trivial on $I_{\bar w}$ and $\iota\big(\det(X - r(\sigma^{-1}))\big) = \prod_\alpha (X - q_w^{(n-1)/2}\alpha)$, α running over the Satake parameters of π_w with multiplicity;*

(Wl2) *at both embeddings $K \to \mathbb{C}$ the infinitesimal character of π is $\{m_1 + \frac{n-1}{2}, \dots, m_n + \frac{n-1}{2}\}$;*

(Wl3) *π_f has a nonzero vector fixed by $\mathrm{K}_n(M)$.*

Proof. Step 1: $r \cong r_{\ell,\iota}(\pi)$. K is a CM field with $K^+ = \mathbb{Q}$, so the condition on $\chi_v(-1)$ in Theorem B.62 is empty and $r_0 = r_{\ell,\iota}(\pi)$ exists. Both r (irreducible) and r_0 are semisimple, and

by $r \leftrightarrow_\iota \pi$ and (Bg1) both are unramified with the same characteristic polynomial of Frob_w^{-1} at all finite places w outside a finite set. By the Chebotarev density theorem and the Brauer–Nesbitt theorem ([220], Chapter I, 2.2), $r \cong r_0$. As isomorphic representations have the same restrictions up to conjugation, (Bg1) gives (Wl1), and (Bg2), (Bg3) hold for r in place of r_0.

Step 2: a character of level M is trivial on $\mathrm{Art}_{K_v}(U_k)$. Let v be a finite place of K above the prime p, $k \geq 0$ the exponent with $M\mathcal{O}_v = \varpi_v^k \mathcal{O}_v$, and ψ a character of G_K of level M. Write $M = p^a M'$ with $p \nmid M'$; then $p^a \mathcal{O}_v = \varpi_v^k \mathcal{O}_v$. The restriction of ψ to a decomposition group $D_{\bar{v}} \cong G_{K_v}$ factors through $\mathrm{Gal}(K_v(\mu_M)/K_v)$, so it suffices that U_k lies in the norm group of $K_v(\mu_M) = K_v(\mu_{M'}) \cdot K_v(\mu_{p^a})$, which is the intersection of the two norm groups. $K_v(\mu_{M'})/K_v$ is unramified, so its norm group contains $\mathcal{O}_v^\times \supseteq U_k$. The norm group of $K_v(\mu_{p^a}) = K_v \cdot \mathbb{Q}_p(\mu_{p^a})$ is the preimage under $\mathrm{N}_{K_v/\mathbb{Q}_p}$ of the norm group $p^{\mathbb{Z}} \times (1 + p^a\mathbb{Z}_p)$ of $\mathbb{Q}_p(\mu_{p^a})/\mathbb{Q}_p$ ([190], Chapter V, Proposition 6.2 and Theorem 1.10 with Corollary 6.4 there; for $a = 0$ there is nothing to show). For $u \in U_k = 1 + p^a\mathcal{O}_v$ (if $a \geq 1$; $k \geq 1$ in that case), each conjugate of u in a Galois closure lies in $1 + p^a\mathcal{O}$, so $\mathrm{N}_{K_v/\mathbb{Q}_p}(u) \in (1 + p^a\mathcal{O}) \cap \mathbb{Q}_p = 1 + p^a\mathbb{Z}_p$. Hence $\psi(\mathrm{Art}_{K_v}(u)) = 1$ for all $u \in U_k$.

Step 3: the inertial part of $\mathrm{WD}(r_{\bar{v}})$. Keep v, k. We find characters $\Psi_1, \ldots, \Psi_n$ of the Weil group $W_{\bar{v}}$, trivial on $\mathrm{Art}_{K_v}(U_k)$, with $\mathrm{WD}(r_{\bar{v}})^{\mathrm{ss}}|_{I_{\bar{v}}} \cong \bigoplus_i \Psi_i|_{I_{\bar{v}}}$, for some place $\bar{v} \mid v$. If $v \nmid \ell$: by (Lw1) there are $\bar{v}$ and characters $\chi_1, \ldots, \chi_n$ of G_K of level M with $r|_{I_{\bar{v}}}$ conjugate to $\mathrm{diag}(\chi_i)$; then $r(I_{\bar{v}})$ is finite, so in (Wd1) $\exp(t_\ell(\sigma)N)$ has finite order for σ in an open subgroup of $I_{\bar{v}}$, which for a unipotent matrix forces $\exp(t_\ell(\sigma)N) = 1$, and $N = 0$ as t_ℓ is nonzero on every open subgroup; thus $\rho|_{I_{\bar{v}}} = r|_{I_{\bar{v}}}$, and $\Psi_i = \chi_i|_{W_{\bar{v}}}$ works by Step 2. If $v \mid \ell$: by (Lw2) there are $\bar{v}$, characters χ_i of level M and characters κ_i of $D_{\bar{v}}$ with r triangular on $D_{\bar{v}}$ with diagonal (κ_i) and $\kappa_i = \chi_{\mathrm{cyc}}^{m_i}\chi_i$ on $I_{\bar{v}}$. The character $\kappa_i' = \kappa_i\chi_{\mathrm{cyc}}^{-m_i}$ agrees on $I_{\bar{v}}$ with χ_i, of finite order; so for the finite extension L/K_v cut out by $\ker\chi_i \cap D_{\bar{v}}$, κ_i' is unramified on G_L, hence crystalline over L with Hodge–Tate weight 0. Thus κ_i is potentially semistable, de Rham with Hodge–Tate weight m_i at every embedding. By (Bg2), $r_{\bar{v}}$ is de Rham, hence potentially semistable; its triangular filtration has graded pieces κ_i, and Fontaine's functor D_{pst} is exact and compatible with tensor products on potentially semistable representations ([95]), so $\mathrm{WD}(r_{\bar{v}})^{\mathrm{ss}} \cong \bigoplus_i \mathrm{WD}(\kappa_i)$ and $\mathrm{WD}(\kappa_i) = \mathrm{WD}(\chi_{\mathrm{cyc}}^{m_i}) \otimes \mathrm{WD}(\kappa_i')$. Here $\mathrm{WD}(\chi_{\mathrm{cyc}}^{m_i})$ is unramified ($\chi_{\mathrm{cyc}}^{m_i}$ is crystalline), and $\mathrm{WD}(\kappa_i')$ is a character of $W_{\bar{v}}$ whose restriction to $I_{\bar{v}}$ is ${\kappa_i'}^{\epsilon}|_{I_{\bar{v}}} = \chi_i^{\epsilon}|_{I_{\bar{v}}}$, with $\epsilon \in \{\pm 1\}$ fixed by the normalisation of Fontaine's construction (κ_i' becomes unramified over L, and the Weil group acts on D_{pst} through the action of $I_{\bar{v}}/I_L$ on the line). So $\Psi_i = \mathrm{WD}(\kappa_i)$ works: $\mathrm{Art}_{K_v}(U_k)$ lies in the image of inertia, where $\Psi_i = \chi_i^{\epsilon}$ is trivial by Step 2.

The same reading of (Lw2) gives the Hodge–Tate weights: at every place $v \mid \ell$ and every embedding $\tau\colon K_v \to \overline{\mathbb{Q}}_\ell$, the τ-Hodge–Tate weights of $r_{\bar{v}}$ are $m_1, \ldots, m_n$, since D_{dR} is exact on de Rham representations, so the Hodge–Tate multiset of $r_{\bar{v}}$ is the union of those of the κ_i (and it does not depend on the choice of $\bar{v} \mid v$, the decomposition groups being conjugate).

Step 4: (Wl2). Every embedding $\phi\colon K \to \mathbb{C}$ is $\iota \circ \tau|_K$ for the embedding $\tau = \iota^{-1} \circ \phi$, which extends continuously to the completion K_v at the place $v \mid \ell$ it defines. By (Bg2) and Step 3, $\{z - \frac{n-1}{2} : z \text{ in the infinitesimal character of } \pi \text{ at } \phi\} = \{m_1, \ldots, m_n\}$, which is (Wl2).

Step 5: local fixed vectors. Let v be a finite place of K and k as in Step 2. By Step 3 and (Bg3) with $U = U_k$, π_v is isomorphic to an irreducible subquotient of $I(\xi_1, \ldots, \xi_n)$ with characters ξ_i trivial on U_k. If $k \geq 1$, Lemma 38.14 gives $\pi_v^{\mathrm{K}_v(k)} \neq 0$. If $k = 0$, then $v \nmid M$; if $v \mid \ell$, r is potentially generic at v by hypothesis. In both cases (Wc2) (applicable: r is semisimple and $r \leftrightarrow_\iota \pi$) gives a real τ_π with $q_v^{\tau_\pi - 1/2} < |\xi_i(\varpi_v)| < q_v^{\tau_\pi + 1/2}$ for all i, (ξ_i) being a cuspidal support of π_v; hence $q_v^{-1} < |\xi_i\xi_j^{-1}(\varpi_v)| < q_v$, while $|\varpi_v|_v = q_v^{-1}$, so $\xi_i\xi_j^{-1} \neq |\cdot|_v$ for $i \neq j$, and Lemma 38.14 gives $\pi_v^{\mathrm{GL}_n(\mathcal{O}_v)} \neq 0$.

Step 6: (Wl3). $\mathrm{K}_n(M) = \prod_{v \nmid \infty} \mathrm{K}_v(k_v)$ with k_v the exponent of Step 2 at v ($k_v = 0$ for $v \nmid M$).

Write $\pi_f \cong \bigotimes'_v \pi_v$ ([91]), the restricted tensor product with respect to vectors $x_v^0 \in \pi_v^{\mathrm{GL}_n(\mathcal{O}_v)}$ given for all v outside a finite set $S \supseteq \{v \mid M\}$. For $v \notin S$ take $x_v = x_v^0$, and for $v \in S$ a nonzero $x_v \in \pi_v^{\mathrm{K}_v(k_v)}$ (Step 5). Then $\bigotimes_v x_v$ is a nonzero vector of π_f fixed by $\mathrm{K}_n(M)$. □

Lemma 38.14. *Let F_v be a non-archimedean local field with ring of integers $\mathcal{O}_v$, $n \geq 1$ and $k \geq 0$ integers. Put $U_k = 1 + \varpi_v^k \mathcal{O}_v$ for $k \geq 1$ and $U_0 = \mathcal{O}_v^\times$, and let $\mathrm{K}_v(k)$ be the kernel of $\mathrm{GL}_n(\mathcal{O}_v) \to \mathrm{GL}_n(\mathcal{O}_v/\varpi_v^k\mathcal{O}_v)$ (so $\mathrm{K}_v(0) = \mathrm{GL}_n(\mathcal{O}_v)$). Let $\xi_1, \dots, \xi_n$ be characters of $F_v^\times$ trivial on U_k and π an irreducible smooth representation of $\mathrm{GL}_n(F_v)$ isomorphic to a subquotient of $I(\xi_1, \dots, \xi_n)$. If $k \geq 1$, or if $\xi_i\xi_j^{-1} \neq |\cdot|_v$ for all $i \neq j$, then π has a nonzero vector fixed by $\mathrm{K}_v(k)$.*

Proof. Write $\mathrm{K} = \mathrm{K}_v(k)$ and $T_k = \{\mathrm{diag}(t_1, \dots, t_n) : t_i \in U_k\}$. Every element of K has diagonal entries in U_k (for $k = 0$: an element of $B \cap \mathrm{GL}_n(\mathcal{O}_v)$ has unit diagonal entries, its determinant being a unit), so $B \cap \mathrm{K} \subseteq T_k N$; and δ_B is trivial on $T_0 \supseteq T_k$, since $|u|_v = 1$ for units u.

Case 1: $\xi_i\xi_j^{-1} \neq |\cdot|_v$ for all $i \neq j$. By (Ps2) of Theorem B.161, $I = I(\xi_1, \dots, \xi_n)$ is irreducible, so $\pi \cong I$. Let $\eta(\mathrm{diag}(t_i)) = \delta_B^{1/2}(\mathrm{diag}(t_i)) \prod_i \xi_i(t_i)$, a character of T trivial on T_k. Define $f\colon G \to \mathbb{C}$ by $f(tu\kappa) = \eta(t)$ for $t \in T$, $u \in N$, $\kappa \in \mathrm{K}$, and $f = 0$ outside $B\mathrm{K}$. It is well defined: if $tu\kappa = t'u'\kappa'$, then $(t'u')^{-1}tu = \kappa'\kappa^{-1} \in B \cap \mathrm{K} \subseteq T_k N$, so $t'^{-1}t \in T_k$ and $\eta(t) = \eta(t')$. The set $B\mathrm{K}$ is open and closed (its complement is a union of open double cosets $Bg\mathrm{K}$), f is right K-invariant, hence locally constant, and $f(tux) = \eta(t)f(x)$ for all $x \in G$. So f is a nonzero ($f(1) = 1$) element of I^{K}.

Case 2: $k \geq 1$. By (Ps1) of Theorem B.161 there is a permutation s with $\pi \hookrightarrow I(\xi_{s(1)}, \dots, \xi_{s(n)})$. By Frobenius reciprocity for normalised parabolic induction ([27], Proposition 2.3),

$$\mathrm{Hom}_G(\pi, I(\xi_{s(1)}, \dots, \xi_{s(n)})) \cong \mathrm{Hom}_T(\pi_N, \eta_s)$$

with $\eta_s(\mathrm{diag}(t_i)) = \delta_B^{1/2}(\mathrm{diag}(t_i)) \prod_i \xi_{s(i)}(t_i)$, so there is a nonzero, hence surjective, T-equivariant $\lambda\colon \pi_N \to \mathbb{C}$ on which T acts by η_s; the character η_s is trivial on T_k. The representation π is admissible (irreducible smooth representations of $\mathrm{GL}_n(F_v)$ are admissible, [27]), and π_N is a smooth representation of T. Choose $x \in \pi_N$ with $\lambda(x) = 1$ and let $x_0 = \int_{T_k} t \cdot x \, dt$ (Haar probability measure on the compact open subgroup T_k; a finite average, as x is fixed by an open subgroup of T_k). Then $x_0 \in (\pi_N)^{T_k}$ and $\lambda(x_0) = \int_{T_k} \eta_s(t)\, dt \cdot \lambda(x) = 1$, so $(\pi_N)^{T_k} \neq 0$. Finally $\mathrm{K} = (\mathrm{K} \cap \bar{N})(\mathrm{K} \cap T)(\mathrm{K} \cap N)$ with $\mathrm{K} \cap T = T_k$: for $g \in \mathrm{K}$ every leading principal minor of g lies in $1 + \varpi_v^k\mathcal{O}_v$, a unit, so $g = LDU$ with $L \in \bar{N}$, $D \in T$, $U \in N$ whose entries are quotients of minors of g by leading principal minors, hence in $\mathcal{O}_v$; reducing modulo ϖ_v^k, the decomposition $1 = \bar{L}\bar{D}\bar{U}$ is unique, so L, D, U are congruent to 1 and lie in K. By (Ps3) of Theorem B.161, π^{K} maps onto $(\pi_N)^{T_k} \neq 0$, so $\pi^{\mathrm{K}} \neq 0$. □

Proposition 38.15. *Let K be an imaginary quadratic field. There are integers $c, A \geq 0$ such that for all integers $e, N \geq 1$:*

(Cc1) *$\mathrm{Cusp}_K(e, N)$ is finite and $|\mathrm{Cusp}_K(e, N)| \leq c\,(N(e+1))^A$;*

(Cc2) *for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ and every $\pi \in \mathrm{Cusp}_K(e, N)$ there is $\pi' \in \mathrm{Cusp}_K(e, N)$ with $\mathrm{Sat}_v(\pi') = \{\sigma(\alpha) : \alpha \in \mathrm{Sat}_v(\pi)\}$ (as multisets) for every finite place $v \nmid N$ of K.*

Proof. Fix an embedding $\tau\colon K \to \mathbb{C}$ and let c, A be the integers of Lemma 38.16 for K and $n = 3$.

(Cc1). Let $e, N \geq 1$. A member π of $\mathrm{Cusp}_K(e,N)$ is a cuspidal automorphic representation of $\mathrm{GL}_3(\mathbb{A}_K)$ with infinitesimal character $\{e,0,-e\}$ at both embeddings (Cs1), a multiset of three distinct elements of $\frac{3-1}{2}+\mathbb{Z}=\mathbb{Z}$ of absolute value at most e, and with $\pi_f^{\mathrm{K}_3(N)} \neq 0$ (Cs3). So $\mathrm{Cusp}_K(e,N)$ is contained in the set of Lemma 38.16 for $Z=Z'=\{e,0,-e\}$ and $H=e$, and is finite with $|\mathrm{Cusp}_K(e,N)| \leq c\,(N(e+1))^A$.

(Cc2), the representation π'. Let $\sigma \in \mathrm{Aut}(\mathbb{C})$ and $\pi \in \mathrm{Cusp}_K(e,N)$; π is regular algebraic by (Cs1). By [68] (Theorem B.63) there is a regular algebraic cuspidal π' with $\pi'_f \cong {}^\sigma\pi_f$ whose infinitesimal character at $\sigma\circ\phi$ is that of π at ϕ; as $\phi \mapsto \sigma\circ\phi$ permutes the two embeddings and π has $\{e,0,-e\}$ at both, so does π': (Cs1). The σ-semilinear bijection $\pi_f \to {}^\sigma\pi_f$, $x \mapsto x\otimes 1$, commutes with the action of $\mathrm{GL}_3(\mathbb{A}_{K,f})$, so ${}^\sigma\pi_f^{\mathrm{K}(N)} \neq 0$: (Cs3). For (Cs2): twisting by σ commutes with smooth contragredients of admissible representations and with the conjugation $g \mapsto g^c$ of $\mathrm{GL}_3(\mathbb{A}_{K,f})$; hence $(\pi'^\vee)_f \cong {}^\sigma(\pi_f^\vee) \cong {}^\sigma((\pi^c)_f) = ({}^\sigma\pi_f)^c \cong (\pi'^c)_f$, using $\pi^\vee \cong \pi^c$. The cuspidal representations $\pi'^\vee$ and π'^c are therefore isomorphic at every finite place, and $\pi'^\vee \cong \pi'^c$ by (Js1) of [136]. So $\pi' \in \mathrm{Cusp}_K(e,N)$.

(Cc2), the Satake parameters. Let $v \nmid N$ be a finite place, $\mathrm{Sat}_v(\pi)=\{\alpha_1,\alpha_2,\alpha_3\}$, and B the upper triangular Borel subgroup of $\mathrm{GL}_3(K_v)$ with modulus character δ_B. π_v is the unique unramified irreducible subquotient ([60]) of the normalised induction $i(\chi)=\mathrm{Ind}_B^{\mathrm{GL}_3(K_v)}(\chi\delta_B^{1/2})$ of the unramified character χ of the torus with $\chi_j(\varpi_v)=\alpha_j$. Here $\delta_B^{1/2}(\mathrm{diag}(t_1,t_2,t_3)) = |t_1|_v\,|t_3|_v^{-1}$ takes values in $q_v^{\mathbb{Z}}$, which σ fixes, and for every character θ of B the map $f \mapsto \sigma\circ f$ identifies ${}^\sigma\mathrm{Ind}_B(\theta)$ with $\mathrm{Ind}_B(\sigma\circ\theta)$; so ${}^\sigma i(\chi) \cong i(\sigma\circ\chi)$. Since $\pi'_f \cong {}^\sigma\pi_f \cong \bigotimes'_v {}^\sigma\pi_v$, $\pi'_v \cong {}^\sigma\pi_v$, which is unramified (its $\mathrm{GL}_3(\mathcal{O}_{K_v})$-invariants are the twist of those of π_v) and a subquotient of ${}^\sigma i(\chi) \cong i(\sigma\circ\chi)$. Hence $\mathrm{Sat}_v(\pi')=\{\sigma(\alpha_1),\sigma(\alpha_2),\sigma(\alpha_3)\}$. □

Lemma 38.16. *Let K be an imaginary quadratic field with embeddings $\tau,\bar\tau$, and $n\geq 1$. There are integers $c, A \geq 0$ such that for all integers $N\geq 1$, $H\geq 0$ and all multisets Z, Z', each consisting of n pairwise distinct elements of $\frac{n-1}{2}+\mathbb{Z}$ of absolute value at most H, the set of isomorphism classes of cuspidal automorphic representations π of $\mathrm{GL}_n(\mathbb{A}_K)$ with infinitesimal character Z at τ and Z' at $\bar\tau$ and with $\pi_f^{\mathrm{K}_n(N)} \neq 0$ is finite and has at most $c\,(N(H+1))^A$ elements.*

Proof. Let $U_0=\mathrm{K}_n(3)$, fix representatives $g_1,\dots,g_h$ of $\mathrm{GL}_n(K)\backslash\mathrm{GL}_n(\mathbb{A}_{K,f})/U_0$ and put $\Gamma_i^0 = \Gamma_i(U_0) = \mathrm{GL}_n(K)\cap g_iU_0g_i^{-1}$. These depend only on K and n.

Step 1: every subgroup of $\mathrm{GL}_n(K)$ contained in gU_0g^{-1} for some $g\in\mathrm{GL}_n(\mathbb{A}_{K,f})$ is torsion-free. Let γ be such an element of finite order, v a place of K above 3 and $x=(g^{-1}\gamma g)_v \in 1+3\,\mathrm{M}_n(\mathcal{O}_{K_v})$. Then x is conjugate to γ in $\mathrm{GL}_n(K_v)$ and has finite order. Write $x=1+3y$. In a finite extension L of K_v containing the eigenvalues, every eigenvalue of x is $\zeta=1+3\beta$ with β an eigenvalue of y, integral over $\mathcal{O}_{K_v}$; and ζ is a root of unity. If $\zeta\neq 1$, some power $\zeta'=\zeta^k$ has prime order r, and still $\zeta'\in 1+3\mathcal{O}_L$. If $r\neq 3$, $\prod_{0<i<r}(1-\zeta'^i)=r$ is a unit at 3, so $1-\zeta'$ is a unit, a contradiction. If $r=3$, $(1-\zeta')^2=-3\zeta'$, so $v_L(1-\zeta')=\frac12 v_L(3)<v_L(3)$, a contradiction. Hence all eigenvalues of x are 1; an element of finite order is diagonalisable in characteristic 0, so $x=1$ and $\gamma=1$.

Step 2: the coefficient system. Fix N,H,Z,Z'. Write $\{-z : z\in Z\}=\{c_1>\cdots>c_n\}$ and put $\mu_i = c_i - \frac{n+1}{2}+i$. As $c_i\in\frac{n-1}{2}+\mathbb{Z}$ and the c_i are distinct, $\mu_i\in\mathbb{Z}$ and $\mu_i-\mu_{i+1} = c_i-c_{i+1}-1\geq 0$; the infinitesimal character of the dual of V_μ is $\{-c_i\}=Z$. Define μ' from Z' in the same way, and put $V=V_{\mu,\mu'}$. By Weyl's dimension formula ([99], §24.1),

$$\dim V_\mu = \prod_{i<j}\frac{\mu_i-\mu_j+j-i}{j-i} = \prod_{i<j}\frac{c_i-c_j}{j-i} \leq (2H)^{n(n-1)/2},$$

as $0 < c_i - c_j \le 2H$; so $\dim V \le (2H+1)^{n(n-1)}$. By [68] (Theorem B.65) every π in the set of the statement is cohomological for V.

Step 3: the level. Put $U = \mathrm{K}_n(3N)$, the kernel of $\mathrm{GL}_n(\widehat{\mathcal{O}}_K) \to \mathrm{GL}_n(\mathcal{O}_K/3N\mathcal{O}_K)$; it is normal in $\mathrm{GL}_n(\widehat{\mathcal{O}}_K)$ and contained in U_0 and in $\mathrm{K}_n(N)$. So $\pi_f^U \supseteq \pi_f^{\mathrm{K}_n(N)} \neq 0$ for every π in the set, and $[U_0 : U] \le |\mathrm{GL}_n(\mathcal{O}_K/3N)| \le |\mathcal{O}_K/3N|^{n^2} = (3N)^{2n^2}$.

Step 4: the double cosets of level U. Fix i. The group Γ_i^0 acts on the finite set U_0/U by $\gamma \cdot uU = (g_i^{-1}\gamma g_i)uU$, and $uU \mapsto \mathrm{GL}_n(K)g_iuU$ induces a bijection from the orbits onto the U-double cosets contained in $\mathrm{GL}_n(K)g_iU_0$: it is surjective, and if $\gamma g_i u U = g_i u' U$ with $\gamma \in \mathrm{GL}_n(K)$, then $g_i^{-1}\gamma g_i \in u'Uu^{-1} \subseteq U_0$, so $\gamma \in \Gamma_i^0$ and $u'U = \gamma \cdot uU$. The stabiliser of uU is $\{\gamma \in \Gamma_i^0 : g_i^{-1}\gamma g_i \in uUu^{-1} = U\} = \Gamma_i'$, where $\Gamma_i' = \mathrm{GL}_n(K) \cap g_i U g_i^{-1}$ (U is normal in U_0); this is also the group $\mathrm{GL}_n(K) \cap (g_iu)U(g_iu)^{-1}$ attached to the representative g_iu. So there are $[U_0 : U]/[\Gamma_i^0 : \Gamma_i']$ double cosets, each with group Γ_i', and

$$h^*(U, V) = \sum_{i=1}^{h} \frac{[U_0 : U]}{[\Gamma_i^0 : \Gamma_i']} \sum_{q \ge 0} \dim H^q(\Gamma_i', V).$$

Step 5: cohomology of the finite-index subgroups. By Step 1, the group Γ_i^0 is torsion-free; it is commensurable with $\mathrm{GL}_n(\mathcal{O}_K) = \mathrm{GL}_n(K) \cap \mathrm{GL}_n(\widehat{\mathcal{O}}_K)$, since the open compact groups $g_iU_0g_i^{-1}$ and $\mathrm{GL}_n(\widehat{\mathcal{O}}_K)$ are commensurable. By [43] (Theorem B.162) there is a resolution $F_\bullet \to \mathbb{C}$ by free $\mathbb{C}[\Gamma_i^0]$-modules F_q of finite ranks $r_q^{(i)}$, zero for large q. Let $m = [\Gamma_i^0 : \Gamma_i']$. As $\mathbb{C}[\Gamma_i^0]$ is a free $\mathbb{C}[\Gamma_i']$-module of rank m (on coset representatives), $F_\bullet$ is a resolution of $\mathbb{C}$ by free $\mathbb{C}[\Gamma_i']$-modules of ranks $mr_q^{(i)}$; so $H^q(\Gamma_i', V) = \mathrm{Ext}^q_{\mathbb{C}[\Gamma_i']}(\mathbb{C}, V)$ is a subquotient of $\mathrm{Hom}_{\mathbb{C}[\Gamma_i']}(F_q, V) \cong V^{mr_q^{(i)}}$, and $\dim H^q(\Gamma_i', V) \le m\, r_q^{(i)} \dim V$. With Step 4 and $C_0 = \sum_i \sum_q r_q^{(i)}$ (depending only on K, n),

$$h^*(U, V) \le [U_0 : U]\, C_0 \dim V \le (3N)^{2n^2} C_0 (2H+1)^{n(n-1)}.$$

Step 6: conclusion. Every finite subset S of the set of the statement consists of pairwise non-isomorphic cuspidal representations, cohomological for V (Step 2) with $\pi_f^U \neq 0$ (Step 3); by [40] (Theorem B.64) and Step 5, $|S| \le (3N)^{2n^2} C_0 (2H+1)^{n(n-1)}$. Hence the set is finite with at most this many elements, and with $A = 2n^2$, $c = 3^{2n^2} 2^{n^2} C_0$, using $2H+1 \le 2(H+1)$, $n(n-1) \le n^2 \le 2n^2$ and $N, H+1 \ge 1$,

$$(3N)^{2n^2} C_0 (2H+1)^{n(n-1)} \le c\,\big(N(H+1)\big)^A.$$

□

Proposition 38.17. *Let K be an imaginary quadratic field with discriminant d_K, $e, N \ge 1$ integers, p a prime with $p \nmid N d_K$, w a prime of K above p and $\pi \in \mathrm{Cusp}_K(e, N)$. Then for every $\alpha \in \mathrm{Sat}_w(\pi)$ the numbers $q_w^e\alpha$ and $q_w^e\alpha^{-1}$ are algebraic integers.*

Proof. Let π represent the class in $\mathrm{Cusp}_K(e, N)$. By (Cs2), $\pi^c \cong \pi^\vee = \pi^\vee \otimes (\mathbf{1} \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det)$, so π is polarizable; by (Cs3), $\pi_f^{\mathrm{K}_3(N)} \neq 0$; by (Cs1), its infinitesimal character at both embeddings is $Z = \{e, 0, -e\}$, three distinct integers ($e \ge 1$), i.e. elements of $\frac{3-1}{2} + \mathbb{Z}$, with $z - 1 \in [-e-1, e-1]$ for $z \in Z$. As $p \nmid N d_K$, Proposition 38.18 applies with $n = 3$, $M = N$, $a = -e-1$, $b = e-1$: for $\alpha \in \mathrm{Sat}_w(\pi)$ and $\beta = q_w\alpha$, the numbers

$$q_w^{e-1}\beta = q_w^e\alpha \qquad \text{and} \qquad q_w^{e+1}\beta^{-1} = q_w^e\alpha^{-1}$$

are algebraic integers. □

Proposition 38.18. *Let K be an imaginary quadratic field with discriminant d_K, $n, M \geq 1$ and $a \leq b$ integers, and π a polarizable cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_K)$ with $\pi_f^{\mathrm{K}_n(M)} \neq 0$ whose infinitesimal character at both embeddings $K \to \mathbb{C}$ is one multiset Z of n pairwise distinct elements of $\frac{n-1}{2} + \mathbb{Z}$ with $a \leq z - \frac{n-1}{2} \leq b$ for all $z \in Z$. Let p be a prime with $p \nmid M d_K$ and w a prime of K above p. Then for every Satake parameter α of π_w, the number $\beta = q_w^{(n-1)/2}\alpha$ is algebraic, and $q_w^b\beta$ and $q_w^{-a}\beta^{-1}$ are algebraic integers.*

Proof. As $w \nmid M$, π_w is unramified, and π is regular algebraic (Z consists of distinct elements of $\frac{n-1}{2} + \mathbb{Z}$). By (Cj2) of Lemma 38.19, every $\beta \in B_w(\pi)$ is algebraic; let $F_\beta = \mathbb{Q}(\beta)$. An algebraic number is an algebraic integer if its valuation is nonnegative at every finite place of the number field it generates, so it suffices to show: β is a unit at every place of F_β above a prime $\ell \neq p$, and $-bf \leq v_p(\beta) \leq -af$ at every place above p, where $q_w = p^f$ and v_p is normalised by $v_p(p) = 1$; then $q_w^b\beta$ and $q_w^{-a}\beta^{-1}$ have nonnegative valuation everywhere (q_w being a unit away from p).

Every place arises from some ι. Let ℓ be any prime and $j\colon F_\beta \to \overline{\mathbb{Q}}_\ell$ a field embedding, defining a place of F_β above ℓ. Extend j to $\overline{\mathbb{Q}}$ and then to an isomorphism $\mathbb{C} \to \overline{\mathbb{Q}}_\ell$ (both fields are algebraically closed of characteristic 0 and of the same uncountable cardinality, hence of the same transcendence degree over $\overline{\mathbb{Q}}$); its inverse ι satisfies $\iota^{-1}|_{F_\beta} = j$.

Places above $\ell \neq p$. With ι as above, $r = r_{\ell,\iota}(\pi)$ exists (K is CM with $K^+ = \mathbb{Q}$), and by (Bg1) at $w \nmid \ell$, for an arithmetic Frobenius σ at a place above w, $\iota(\det(X - r(\sigma^{-1}))) = \prod_{\beta' \in B_w(\pi)}(X - \beta')$; so $j(\beta) = \iota^{-1}(\beta)$ is an eigenvalue of $r(\sigma^{-1})$. A continuous representation of the compact group G_K in $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ takes values in $\mathrm{GL}_n(E)$ for a finite extension $E/\mathbb{Q}_\ell$ (Baire category: G_K is the countable union of the closed subgroups $r^{-1}(\mathrm{GL}_n(E'))$), and then preserves an $\mathcal{O}_E$-lattice (the $\mathcal{O}_E$-span of the orbit of $\mathcal{O}_E^n$ under the compact image, which is bounded). So the characteristic polynomial of $r(\sigma^{-1})$ is monic in $\mathcal{O}_E[X]$ with unit constant term, and its roots are units: $j(\beta)$ is a unit.

Places above p. Take $\ell = p$ and ι as above, and $r = r_{p,\iota}(\pi)$, $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above w. By (Bg4), $r_{\bar{w}}$ is crystalline, and the eigenvalues of $\rho(\Phi)$ on $\mathrm{WD}(r_{\bar{w}})$ for a geometric Frobenius Φ are the $\iota^{-1}(\beta')$, $\beta' \in B_w(\pi)$. As $p \nmid d_K$, $L = K_w$ is unramified over $\mathbb{Q}_p$ of degree f. Choose a finite $E/\mathbb{Q}_p$ in $\overline{\mathbb{Q}}_p$ containing the images of all embeddings of L such that $r_{\bar{w}}$ takes values in $\mathrm{GL}_n(E)$ (as above), and let $V = E^n$. By (Bg2), for every embedding $\tau\colon L \to E$, the τ-Hodge–Tate weights of V are the $z - \frac{n-1}{2}$, $z \in Z$, all in $[a, b]$. In Fontaine's construction of WD for crystalline representations ([95]), $D_{\mathrm{pst}}(V) = D_{\mathrm{cris}}(V) \otimes_L \mathbb{Q}_p^{\mathrm{nr}}$, $N = 0$, inertia acts trivially, and Φ acts on $\mathrm{WD}(V)$ through the E-linear map φ^f on any D_τ, extended to $\overline{\mathbb{Q}}_p$. This is the normalisation of (Bg4): for $n = 1$ and the polarizable regular algebraic character $\pi_1 = |\cdot|_{\mathbb{A}_K}$ (infinitesimal character 1 at both embeddings; $\pi_1^c = \pi_1 = \pi_1^\vee \otimes (|\cdot|^2_{\mathbb{A}_\mathbb{Q}} \circ \mathrm{N}_{K/\mathbb{Q}})$), (Bg1) gives $r_{p,\iota}(\pi_1)(\sigma^{-1}) = q_v^{-1}$ at all $v \nmid p$, so $r_{p,\iota}(\pi_1) = \chi_{\mathrm{cyc}}$ by the Chebotarev density theorem, and (Bg4) gives $\rho(\Phi) = q_w^{-1}$, which is the eigenvalue of φ^f on $D_{\mathrm{cris}}(\chi_{\mathrm{cyc}}) = \mathbb{Q}_p t^{-1} \otimes e$ ($\varphi(t^{-1}) = p^{-1}t^{-1}$), not its inverse. So the $\iota^{-1}(\beta')$ are the roots of the characteristic polynomial P of φ^f on D_τ, and Lemma 38.20 gives $-bf \leq v_p(\iota^{-1}(\beta)) \leq -af$, i.e. the claimed bounds at the place of F_β defined by $j = \iota^{-1}|_{F_\beta}$. □

Lemma 38.19. *Let K be an imaginary quadratic field, $n, M \geq 1$ integers, Z a multiset of n pairwise distinct elements of $\frac{n-1}{2} + \mathbb{Z}$, and π a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_K)$ with infinitesimal character Z at both embeddings $K \to \mathbb{C}$ and $\pi_f^{\mathrm{K}_n(M)} \neq 0$. For a finite place $w \nmid M$ of K (at which π_w is unramified) let $B_w(\pi)$ be the multiset of the numbers $q_w^{(n-1)/2}\alpha$, α running over the Satake parameters of π_w with multiplicity ($q_w^{1/2} > 0$). Then:*

(Cj1) *for every $\theta \in \mathrm{Aut}(\mathbb{C})$ there is a cuspidal automorphic representation π' of $\mathrm{GL}_n(\mathbb{A}_K)$ with infinitesimal character Z at both embeddings and $\pi'_f \cong {}^\theta\pi_f$ (so $\pi_f'^{\mathrm{K}_n(M)} \neq 0$), and every*

such π' satisfies $B_w(\pi') = \theta(B_w(\pi))$ for every finite place $w \nmid M$;

(Cj2) *every element of $B_w(\pi)$, $w \nmid M$, is an algebraic number.*

Proof. (Cj1). As Z consists of n distinct elements of $\frac{n-1}{2} + \mathbb{Z}$ at both embeddings, π is regular algebraic, and Theorem B.63 gives a regular algebraic cuspidal π' with $\pi'_f \cong {}^\theta\pi_f$ whose infinitesimal character at $\theta \circ \phi$ equals that of π at ϕ, i.e. Z at both embeddings. A nonzero $\mathrm{K}_n(M)$-fixed vector of π_f is one of ${}^\theta\pi_f = \pi_f \otimes_{\mathbb{C},\theta} \mathbb{C}$. Now let π' be any cuspidal representation with $\pi'_f \cong {}^\theta\pi_f$, and $w \nmid M$. Since ${}^\theta(\bigotimes'_v \pi_v) \cong \bigotimes'_v {}^\theta\pi_v$ and the local factors of a restricted tensor product are determined up to isomorphism ([91]), $\pi'_w \cong {}^\theta\pi_w$. Let π_w be the unramified irreducible subquotient of $I(\mu_1, \dots, \mu_n)$ with unramified μ_i, $\mu_i(\varpi_w) = \alpha_i$. The map $f \mapsto \theta \circ f$ is a θ-semilinear G-equivariant bijection from $I(\mu_1, \dots, \mu_n)$ onto the space of smooth f' with $f'(tug) = \theta(\delta_B^{1/2}(t) \prod_i \mu_i(t_i)) f'(g)$, which is $I(\eta_1, \dots, \eta_n)$ for the characters with $\prod_i \eta_i(t_i) = \delta_B^{-1/2}(t)\, \theta(\delta_B^{1/2}(t)) \prod_i \theta(\mu_i(t_i))$. For $t = \mathrm{diag}(\varpi_w^{a_1} u_1, \dots, \varpi_w^{a_n} u_n)$ with units u_i, $\delta_B^{1/2}(t) = (\sqrt{q_w})^{-\sum_i (n+1-2i)a_i}$; with $\epsilon = \theta(\sqrt{q_w})/\sqrt{q_w} \in \{\pm 1\}$,

$$\delta_B^{-1/2}(t)\, \theta(\delta_B^{1/2}(t)) = \epsilon^{\sum_i (n+1-2i)a_i} = \epsilon^{(n-1)\sum_i a_i},$$

so $\eta_i = (\theta \circ \mu_i)\nu$ with ν unramified, $\nu(\varpi_w) = \epsilon^{n-1}$, and $\eta_i(\varpi_w) = \epsilon^{n-1}\theta(\alpha_i)$. The bijection carries $\mathrm{GL}_n(\mathcal{O}_w)$-fixed vectors to fixed vectors and subquotients to subquotients, so ${}^\theta\pi_w$ is the unramified irreducible subquotient of $I(\eta_1, \dots, \eta_n)$, and its Satake parameters are the $\epsilon^{n-1}\theta(\alpha_i)$ (an unramified irreducible representation determines its unramified characters up to permutation, [60]). Hence

$$B_w(\pi') = \{q_w^{(n-1)/2} \epsilon^{n-1} \theta(\alpha_i)\} = \{\theta(\sqrt{q_w})^{n-1} \theta(\alpha_i)\} = \theta(B_w(\pi)).$$

(Cj2). Let $H = \max_{z \in Z} |z|$ and Π the set of isomorphism classes of cuspidal π'' with infinitesimal character Z at both embeddings and $\pi''^{\mathrm{K}_n(M)}_f \neq 0$; Π is finite by Lemma 38.16, applied with $N = M$, $Z' = Z$ and this H. By (Cj1), for every $\theta \in \mathrm{Aut}(\mathbb{C})$ the multiset $\theta(B_w(\pi))$ equals $B_w(\pi')$ for some $\pi' \in \Pi$ (B_w depends only on the isomorphism class). So each elementary symmetric function s of $B_w(\pi)$ has a finite orbit under $\mathrm{Aut}(\mathbb{C})$. A transcendental complex number has an infinite orbit (for transcendental x, y the isomorphism $\mathbb{Q}(x) \to \mathbb{Q}(y)$, $x \mapsto y$, extends to an automorphism of $\mathbb{C}$), so every s is algebraic, and the elements of $B_w(\pi)$, roots of $\prod_{\beta \in B_w(\pi)} (X - \beta)$, whose coefficients are $\pm s$, are algebraic. □

Lemma 38.20. *Let L be an unramified extension of $\mathbb{Q}_p$ of degree f, $E \subset \overline{\mathbb{Q}}_p$ a finite extension of $\mathbb{Q}_p$ containing the images of all embeddings $L \to \overline{\mathbb{Q}}_p$, and V an n-dimensional E-vector space with a continuous E-linear action of G_L that is crystalline (as a representation on a $\mathbb{Q}_p$-vector space). The E-action makes $D = D_{\mathrm{cris}}(V)$ a module over $L \otimes_{\mathbb{Q}_p} E \cong \prod_\tau E$ (τ running over the embeddings $L \to E$, $x \otimes y \mapsto (\tau(x)y)_\tau$); write $D = \bigoplus_\tau D_\tau$ accordingly, with the induced filtrations $\mathrm{Fil}^i D_\tau$. The τ-**Hodge–Tate weights** of V are the integers h, counted $\dim_E(\mathrm{Fil}^{-h} D_\tau / \mathrm{Fil}^{1-h} D_\tau)$ times. Suppose that for integers $a \leq b$ all τ-Hodge–Tate weights of V, for all τ, lie in $[a, b]$. Then each D_τ has E-dimension n, φ^f restricts to an E-linear endomorphism of each D_τ whose characteristic polynomial $P(X) \in E[X]$ does not depend on τ, and every root $\beta \in \overline{\mathbb{Q}}_p$ of P satisfies*

$$-bf \leq v_p(\beta) \leq -af \qquad (v_p(p) = 1).$$

Proof. Structure. The action of E on V commutes with G_L, so E acts on D and on $\mathrm{Fil}^i D$, commuting with φ; with L acting through B_{cris}, D and each $\mathrm{Fil}^i D$ are $L \otimes_{\mathbb{Q}_p} E$-modules, hence $\mathrm{Fil}^i D = \bigoplus_\tau \mathrm{Fil}^i D_\tau$ with $\mathrm{Fil}^i D_\tau = e_\tau \mathrm{Fil}^i D$ for the idempotents e_τ. As φ is σ-semilinear for L and E-linear, $\varphi(x \otimes y)$-equivariance gives $\varphi(D_\tau) \subseteq D_{\tau\circ\sigma^{-1}}$, with equality since φ is bijective; so all D_τ have the same E-dimension d, and φ^f ($\sigma^f = 1$) is E-linear on each D_τ, with $\varphi \circ \varphi^f|_{D_\tau} = \varphi^f|_{D_{\tau\sigma^{-1}}} \circ \varphi$, so the characteristic polynomials on all D_τ agree. An E-vector space of dimension d on which L acts through τ has L-dimension $d[E : L]$, so $\dim_{\mathbb{Q}_p} V = \dim_L D = f\, d\, [E : L] = d[E : \mathbb{Q}_p]$ (Theorem B.55) gives $d = n$.

The two invariants on E-stable subobjects. Let $D' = \bigoplus_\tau D'_\tau$ be a φ-stable $L \otimes E$-submodule, $d' = \dim_E D'_\tau$ (independent of τ as above), and $P_{D'}$ the characteristic polynomial of φ^f on D'_τ. (i) If A is the matrix of $\varphi|_{D'}$ in an L-basis, $\varphi^f|_{D'}$ is L-linear with matrix $A\sigma(A)\cdots\sigma^{f-1}(A)$, so $f\, t_N(D') = v_p(\det_L(\varphi^f|_{D'})) = \sum_\tau v_p(\mathrm{N}_{E/\tau(L)} \det_E(\varphi^f|_{D'_\tau})) = f\,[E : L] \sum_\beta v_p(\beta)$, the last sum over the roots of $P_{D'}$ with multiplicity (for an E-linear map of an E-space regarded as a $\tau(L)$-space, the determinant is the norm of the E-determinant, and $v_p(\mathrm{N}_{E/\tau(L)} x) = [E : L] v_p(x)$). So $t_N(D') = [E : L] \sum_\beta v_p(\beta)$. (ii) With the induced filtration, $\mathrm{Fil}^i D'_\tau / \mathrm{Fil}^{i+1} D'_\tau$ injects into $\mathrm{Fil}^i D_\tau / \mathrm{Fil}^{i+1} D_\tau$, which vanishes unless $-b \le i \le -a$ by hypothesis; and $\dim_L$ of a graded piece of D' is $[E : L]$ times the sum over τ of the E-dimensions. Hence $-b\, f\, d'[E : L] \le t_H(D')$. Dually, for the quotient D/D' with the quotient filtration, each graded piece is a quotient of the corresponding graded piece of D, so $t_H(D/D') \le -a\, f\, (n - d')[E : L]$, and $t_H(D) = t_H(D') + t_H(D/D')$ (dimensions of graded pieces are additive for a subspace with induced and a quotient with quotient filtration).

Subobjects by slope. For a real s, let P_s be the product of $(X - \beta)$ over the roots β of P (with multiplicity) with $v_p(\beta) < s$. This set of roots is stable under $\mathrm{Gal}(\overline{\mathbb{Q}}_p/E)$, so $P_s \in E[X]$, and $D^{(s)} = \bigoplus_\tau \ker P_s(\varphi^f|_{D_\tau})$ is an $L \otimes E$-submodule (sum of generalised eigenspaces) with $\varphi(D^{(s)}) \subseteq D^{(s)}$, as φ is E-linear and commutes with φ^f; the roots of $P_{D^{(s)}}$ are those of P_s.

Lower bound. Let λ be the least valuation of a root of P and choose $s > \lambda$ below every larger valuation; then $D' = D^{(s)}$ has $d' \ge 1$ and all roots of $P_{D'}$ of valuation λ. By Theorem B.55, $-bfd'[E : L] \le t_H(D') \le t_N(D') = [E : L]d'\lambda$, so $\lambda \ge -bf$.

Upper bound. Let μ be the largest valuation of a root and $D' = D^{(\mu)}$ (roots of valuation $< \mu$); then $n - d' \ge 1$ roots of P have valuation μ, so $t_N(D) - t_N(D') = [E : L](n - d')\mu$. By Theorem B.55, $t_N(D) = t_H(D)$ and $t_H(D') \le t_N(D')$, so $[E : L](n - d')\mu \le t_H(D) - t_H(D') = t_H(D/D') \le -af(n - d')[E : L]$, and $\mu \le -af$. □

Proposition 38.21. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $e, M \ge 1$ integers and $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ a continuous representation of level M and weights $(e, -e)$. Let g be a normalised newform of weight $2e+1$, level L_g and character ε_g such that W satisfies (Eo2) with $f = g$: $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple and, for all but finitely many primes p and every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p, $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is trivial on $I_{\bar{p}}$ and $\iota(\det(X - (W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1}))) = X^2 - a_p(g)X + \varepsilon_g(p)p^{2e}$ for every arithmetic Frobenius σ at $\bar{p}$. Then L_g divides M^2.*

Proof. Put $W' = W \otimes \chi_{\mathrm{cyc}}^{-e}$. By hypothesis W' is continuous and semisimple, and its Frobenius characteristic polynomials are those of g of weight $k = 2e + 1$ (so $p^{k-1} = p^{2e}$); hence (Lc1) and (Lc2) of [59], [213] apply to $\rho = W'$. Restrictions to the decomposition groups of two places above the same prime are conjugate, so $\mathrm{a}(W'_v)$ may be computed at any place above v. We show $v_v(L_g) \le 2v_v(M)$ for every prime v, which gives $L_g \mid M^2$.

Step 1: characters of level M have conductor exponent at most $v_v(M)$ at v. Let χ be a character of $G_{\mathbb{Q}}$ of level M, v a prime, $a = v_v(M)$, $M = v^a M'$, and $\bar{v}$ a place above v. Then $\chi|_{D_{\bar{v}}}$ factors through $\mathrm{Gal}(\mathbb{Q}_v(\mu_M)/\mathbb{Q}_v)$, and $\mathbb{Q}_v(\mu_M)$ is the compositum of $\mathbb{Q}_v(\mu_{v^a})$ with the

unramified extension $\mathbb{Q}_v(\mu_{M'})$. Hence $\chi|_{I_{\bar v}}$ factors through the inertia group of $\mathbb{Q}_v(\mu_{v^a})/\mathbb{Q}_v$ (in particular it is trivial on an open subgroup), whose upper ramification groups G^u are trivial for $u > a-1$ ([221], Chapter IV, §4). The Artin conductor of a character θ of inertia is the least integer $f \geq 0$ with $\theta(G^f) = 1$ ([221], Chapter VI, §2), so $\mathrm{a}(\chi|_{I_{\bar v}}) \leq a$. The same holds for χ^{-1}, which also has level M.

Step 2: primes $v \neq \ell$. By (Lw1) there are a place $\bar v \mid v$ and characters χ_1, χ_2 of level M with $W|_{I_{\bar v}}$ conjugate to $\mathrm{diag}(\chi_1, \chi_2)$. As $v \neq \ell$, $\mathbb{Q}(\mu_{\ell^\infty})$ is unramified at v, so χ_{cyc} is trivial on $I_{\bar v}$ and $W'|_{I_{\bar v}}$ is conjugate to $\mathrm{diag}(\chi_1, \chi_2)|_{I_{\bar v}}$. By Step 1 this is trivial on an open subgroup J of $I_{\bar v}$. In (Wd1), take σ in the open subgroup $J \cap J_0$, J_0 the subgroup given there: $\exp(t_\ell(\sigma)N) = 1$, and since $t_\ell(\sigma)N$ is nilpotent, $t_\ell(\sigma)N = \log\exp(t_\ell(\sigma)N) = 0$. The continuous nonzero homomorphism t_ℓ is nonzero on the finite-index subgroup $J \cap J_0$, so $N = 0$, and then $\rho|_{I_{\bar v}} = W'|_{I_{\bar v}}$. Hence, the Artin conductor being additive on direct sums,

$$v_v(L_g) = \mathrm{a}(W'_v) = \mathrm{a}(\chi_1|_{I_{\bar v}}) + \mathrm{a}(\chi_2|_{I_{\bar v}}) \leq 2v_v(M)$$

by (Lc1) and Step 1.

Step 3: the prime ℓ: the diagonal characters. By (Lw2) there are a place $\bar\ell \mid \ell$, characters χ_1, χ_2 of $G_{\mathbb{Q}}$ of level M and characters κ_1, κ_2 of $D = D_{\bar\ell} \cong G_{\mathbb{Q}_\ell}$ such that W is triangular on D with diagonal (κ_1, κ_2) and $\kappa_1 = \chi_{\mathrm{cyc}}^e\chi_1$, $\kappa_2 = \chi_{\mathrm{cyc}}^{-e}\chi_2$ on $I_{\bar\ell}$; the κ_i are continuous, being diagonal entries of a continuous triangular representation. Then W' is triangular on D with diagonal $(\kappa'_1, \kappa'_2) = (\kappa_1\chi_{\mathrm{cyc}}^{-e}, \kappa_2\chi_{\mathrm{cyc}}^{-e})$. Put $\psi_i = \chi_i|_D$, characters of finite order, and

$$\lambda_1 = \kappa'_1\psi_1^{-1}, \qquad \lambda_2 = \kappa'_2\chi_{\mathrm{cyc}}^{2e}\psi_2^{-1}.$$

Both are trivial on $I_{\bar\ell}$, i.e. unramified, and continuous; the image of the compact group D under a continuous character lies in a compact subgroup of $E^\times$ for a finite extension $E/\mathbb{Q}_\ell$, hence in $\mathcal{O}_E^\times$, so the λ_i take unit values. Thus

$$\kappa'_1 = \psi_1\lambda_1, \qquad \kappa'_2 = \chi_{\mathrm{cyc}}^{-2e}\psi_2\lambda_2.$$

Step 4: the prime ℓ: the Weil–Deligne representation. By (Lc2), $W'_\ell = W'|_D$ is potentially semistable. We use the following standard properties of Fontaine's construction ([95], with the period rings of [94]): subrepresentations and quotients of potentially semistable representations are potentially semistable; $r \mapsto \mathrm{WD}(r)$ is exact on them and compatible with tensor products; for a character $\psi\lambda$ with ψ of finite order and λ unramified with unit values, $\mathrm{WD}(\psi\lambda)$ is one-dimensional with $N = 0$, I_ℓ acting through $\psi^\epsilon|_{I_\ell}$ and every w with $n(w) = 1$ acting by a unit, where $\epsilon \in \{\pm 1\}$ is fixed by the conventions of loc. cit.; and $\mathrm{WD}(\chi_{\mathrm{cyc}})$ is unramified with $N = 0$, an element w acting by $\ell^{\epsilon' n(w)}$ for a sign $\epsilon' \in \{\pm 1\}$ fixed by the conventions. Let $\mathrm{WD}(W'_\ell) = (V, \rho, N)$. By exactness there is a line $V_1 \subset V$, stable under ρ and N, with $V_1 \cong \mathrm{WD}(\kappa'_1)$ and $V/V_1 \cong \mathrm{WD}(\kappa'_2)$. Fix $w \in W_{\mathbb{Q}_\ell}$ with $n(w) = 1$. By Step 3 and the properties above, the eigenvalues of $\rho(w)$ are a unit u_1 (on V_1) and $u_2 = \ell^{-2e\epsilon'}u'_2$ with u'_2 a unit (on V/V_1), so

$$v_\ell(u_1) = 0, \qquad v_\ell(u_2) = -2e\epsilon' \in \{2e, -2e\}.$$

As $e \geq 1$ these differ, so V is the direct sum of the two eigenspaces of $\rho(w)$. By (38.5), $\rho(w)N = \ell N\rho(w)$, so N maps the α-eigenspace into the $\ell\alpha$-eigenspace. Since $v_\ell(\ell u_1) = 1$ and $v_\ell(\ell u_2) = 1 - 2e\epsilon'$, and neither 1 nor $1 \pm 2e$ lies in $\{0, 2e\epsilon'\}$ (as $2e \geq 2$), ℓu_1 and ℓu_2 are not eigenvalues, and $N = 0$. The restriction $\rho|_{I_\ell}$ is trivial on an open subgroup, so it factors through a finite group and is semisimple; its constituents are those of V_1 and V/V_1, namely $\psi_1^\epsilon|_{I_\ell}$ and $\psi_2^\epsilon|_{I_\ell}$ (the factors λ_i and $\chi_{\mathrm{cyc}}^{-2e}$ contribute unramified Weil–Deligne characters). Hence, with $N = 0$,

$$v_\ell(L_g) = \mathrm{a}(W'_\ell) = \mathrm{a}\big(\chi_1^\epsilon|_{I_{\bar\ell}}\big) + \mathrm{a}\big(\chi_2^\epsilon|_{I_{\bar\ell}}\big) \leq 2v_\ell(M)$$

by (Lc2) and Step 1 (applied to χ_i^{ϵ}).

Conclusion. By Steps 2 and 4, $v_v(L_g) \le v_v(M^2)$ for every prime v, so $L_g \mid M^2$. □

Lemma 38.22. *Let $k \ge 2$ and $L \ge 1$ be integers. The set $\mathrm{New}_k(L)$ of normalised newforms of weight k (of any character) whose level divides L is finite, and*

$$|\mathrm{New}_k(L)| \le 1 + \frac{kL^2}{12}.$$

Proof. Write $M_k(\Gamma_1(L)) \supseteq S_k(\Gamma_1(L))$ for the spaces of modular and cusp forms of weight k for $\Gamma_1(L)$, and $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \Gamma_1(L)$; every $f \in M_k(\Gamma_1(L))$ satisfies $f(z+1) = f(z)$ and has an expansion $f = \sum_{n \ge 0} a_n(f) q^n$, $q = e^{2\pi i z}$. Put $B = \lfloor kL^2/12 \rfloor$.

The map $f \mapsto (a_0(f), \dots, a_B(f))$ from $M_k(\Gamma_1(L))$ to $\mathbb{C}^{B+1}$ is injective. Let $\Gamma = \Gamma_1(L) \cup (-\Gamma_1(L))$, a subgroup of $\mathrm{SL}_2(\mathbb{Z})$ containing -1 and T, of index

$$m = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma] \le [\mathrm{SL}_2(\mathbb{Z}) : \Gamma_1(L)] = L^2 \prod_{p \mid L} (1 - p^{-2}) \le L^2$$

(the classical index formula, [229], Section 1.6). Let f be in the kernel and $F = f^2$. For $\alpha \in \mathrm{SL}_2(\mathbb{Z})$, $F|_{2k}\alpha = (f|_k\alpha)^2$; so $F|_{2k}\gamma = F$ for $\gamma \in \Gamma_1(L)$, $F|_{2k}(-\gamma) = (-1)^{2k} F|_{2k}\gamma = F$, and F is holomorphic on $\mathfrak{H}$ and at every cusp because f is. Thus F is a modular form of the even weight $2k$ for Γ. Since $a_n(f) = 0$ for $n \le B$, $f = q^{B+1} h$ with h a power series in q, so $F = q^{2B+2} h^2$ and its coefficients b_n vanish for $n \le 2B+1$. As $B + 1 > kL^2/12$,

$$\frac{2k\, m}{12} \le \frac{2kL^2}{12} < 2B + 2,$$

so $b_n = 0$ for every integer n with $0 \le n \le 2km/12$. The valence bound [229], applied to Γ, the weight $2k$ and F, gives $F = 0$; hence $f = 0$.

Conclusion. By this injectivity, $\dim M_k(\Gamma_1(L)) \le B + 1 \le 1 + kL^2/12$. A normalised newform of level $L' \mid L$ lies in $S_k(\Gamma_1(L')) \subseteq S_k(\Gamma_1(L)) \subseteq M_k(\Gamma_1(L))$, and by (Nw1) of [13], [161] distinct such newforms are linearly independent. So $\mathrm{New}_k(L)$ is finite with $|\mathrm{New}_k(L)| \le \dim M_k(\Gamma_1(L)) \le 1 + kL^2/12$. □

Lemma 38.23. *Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $e \ge 1$ an integer and $f = \sum_{n \ge 1} a_n q^n$ a normalised newform of weight $2e+1$, level M_f and Nebentypus ε_f. Let $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ be a continuous representation such that $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple and, for all but finitely many primes p, is unramified at p and satisfies*

$$\iota\Big(\det\big(X - (W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1})\big)\Big) = X^2 - a_p X + \varepsilon_f(p) p^{2e}$$

for every arithmetic Frobenius element σ at p. Let $\theta\colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell^{\times}$ be a continuous character of finite order. Then

$$H^1_f(\mathbb{Q}, W \otimes \theta) = 0;$$

in particular ($\theta = \mathbf{1}$) $H^1_f(\mathbb{Q}, W) = 0$.

Proof. Write $k = 2e+1$ and $F_f = \mathbb{Q}(a_n : n \geq 1)$. The embedding $\iota^{-1}|_{F_f} \colon F_f \to \overline{\mathbb{Q}}_\ell$ determines a finite place λ of F_f above ℓ and identifies F_λ with a finite extension of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$; write $V_\lambda = V_{F_\lambda}(f)$.

Step 1: $W \otimes \chi_{\mathrm{cyc}}^{-e} \cong V_\lambda \otimes_{F_\lambda} \overline{\mathbb{Q}}_\ell$. Let S be the finite set of primes dividing $M_f \ell$ together with the exceptional primes of the hypothesis. For $p \notin S$ and an arithmetic Frobenius σ at p, Theorem B.32(1) gives $\det(1 - \sigma^{-1}u \mid V_\lambda) = 1 - \iota^{-1}(a_p)u + \iota^{-1}(\varepsilon_f(p))p^{k-1}u^2$, so $\mathrm{tr}(\sigma^{-1} \mid V_\lambda) = \iota^{-1}(a_p) = \mathrm{tr}((W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1}))$ by the hypothesis. By Chebotarev's density theorem, for every finite Galois extension $L/\mathbb{Q}$ every element of $\mathrm{Gal}(L/\mathbb{Q})$ is the image of an arithmetic Frobenius at some $p \notin S$; hence the inverses of the arithmetic Frobenius elements at primes $p \notin S$ form a dense subset of $G_\mathbb{Q}$. Both traces are continuous on $G_\mathbb{Q}$, so they agree everywhere. The representation V_λ is irreducible (Ribet, *Galois representations attached to eigenforms with Nebentypus*, 1977, Theorem 2.3), so $V_\lambda \otimes_{F_\lambda} \overline{\mathbb{Q}}_\ell$ is semisimple (characteristic 0); $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple by hypothesis. Two finite-dimensional semisimple representations of a group over a field of characteristic 0 with the same trace are isomorphic, so $W \otimes \chi_{\mathrm{cyc}}^{-e} \cong V_\lambda \otimes_{F_\lambda} \overline{\mathbb{Q}}_\ell$ and

$$W \otimes \theta \cong V_\lambda(e) \otimes_{F_\lambda} \overline{\mathbb{Q}}_\ell \otimes \theta.$$

Step 2: a finite coefficient field. Let n be the order of θ and $E = F_\lambda(\mu_n) \subset \overline{\mathbb{Q}}_\ell$, a finite extension of F_λ. Let U be the E-vector space $V_\lambda(e) \otimes_{F_\lambda} E$ with g acting by $\theta(g)$ times its action on $V_\lambda(e)$; it is continuous and E-linear, and $W \otimes \theta \cong U \otimes_E \overline{\mathbb{Q}}_\ell$. An isomorphism of representations is a continuous linear $G_\mathbb{Q}$-equivariant bijection and carries Bloch–Kato cocycles and coboundaries to Bloch–Kato cocycles and coboundaries (tensored with B_{cris} at the places above ℓ), so it suffices to show $H^1_f(\mathbb{Q}, U \otimes_E \overline{\mathbb{Q}}_\ell) = 0$.

Step 3: descent to a finite extension. Let c be a Bloch–Kato cocycle with values in $U \otimes_E \overline{\mathbb{Q}}_\ell$.

(a) *c takes values in $U \otimes_E E'$ for a finite extension E'/E in $\overline{\mathbb{Q}}_\ell$.* For $d \geq 1$ let E_d be the compositum of the finitely many extensions of E of degree at most d in $\overline{\mathbb{Q}}_\ell$ (Krasner); E_d is finite over E and $\overline{\mathbb{Q}}_\ell = \bigcup_d E_d$. Each $U \otimes_E E_d$ is a finite-dimensional space over the complete field E_d, hence closed in $U \otimes_E \overline{\mathbb{Q}}_\ell$, and $G_\mathbb{Q}$-stable. So $G_\mathbb{Q} = \bigcup_d c^{-1}(U \otimes_E E_d)$ is a countable union of closed sets; $G_\mathbb{Q}$ is compact Hausdorff, so by Baire's theorem one of them, say for d, contains a coset gH of an open normal subgroup H. For $h \in H$, $c(h) = g^{-1}(c(gh) - c(g)) \in U \otimes_E E_d$. Let $g_1, \ldots, g_s$ represent $G_\mathbb{Q}/H$ and let $E' \supseteq E_d$ be a finite extension containing the coordinates of $c(g_1), \ldots, c(g_s)$ in an E-basis of U. Then $c(g_i h) = c(g_i) + g_i c(h) \in U \otimes_E E'$ for all i and $h \in H$.

(b) *c is a Bloch–Kato cocycle of $U' = U \otimes_E E'$.* Choose an E'-linear map $\pi \colon \overline{\mathbb{Q}}_\ell \to E'$ with $\pi|_{E'} = \mathrm{id}$, and let $P = \mathrm{id}_U \otimes \pi \colon U \otimes_E \overline{\mathbb{Q}}_\ell \to U'$; P is $G_\mathbb{Q}$-equivariant (the group acts on U only) and is the identity on U'. If $c(g) = gx - x$ on an inertia group, then $c(g) = P(c(g)) = gP(x) - P(x)$ there; at ℓ, the $\mathbb{Q}_\ell$-linear and equivariant map $P \otimes \mathrm{id}$ to $U' \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ fixes $c(g) \otimes 1$ and carries a y with $c(g) \otimes 1 = gy - y$ to such an element for U'; at the archimedean place, $c|_D = gx - x$ gives $c|_D = gP(x) - P(x)$. The topology of U' is the subspace topology, so c is continuous into U'.

Hence it suffices to show $H^1_f(\mathbb{Q}, U') = 0$ for every finite extension E' of E in $\overline{\mathbb{Q}}_\ell$: then $c = gz - z$ with $z \in U'$.

Step 4: restriction to the field of θ. Let $K \subset \overline{\mathbb{Q}}$ be the fixed field of $\ker\theta$; as θ is continuous of finite order, $K/\mathbb{Q}$ is finite and abelian. Let c be a Bloch–Kato cocycle of U' with $c|_{G_K} = (g \mapsto gx - x)$ for some $x \in U'$. Then $c' = c - (g \mapsto gx - x)$ vanishes on G_K, so $c'(gh) = c'(g)$ and $c'(hg) = hc'(g)$ for $h \in G_K$; since $hg = g(g^{-1}hg)$ with $g^{-1}hg \in G_K$, also $c'(hg) = c'(g)$, so c' takes values in U'^{G_K} and factors through $\Gamma = \mathrm{Gal}(K/\mathbb{Q})$. With $s = |\Gamma|$ and $x' = s^{-1}\sum_{\gamma\in\Gamma} c'(\gamma)$,

summing $c'(g\gamma) = c'(g) + gc'(\gamma)$ over γ gives $c'(g) = x' - gx'$. So restriction $H^1(\mathbb{Q}, U') \to H^1(K, U')$ is injective. It maps Bloch–Kato cocycles to Bloch–Kato cocycles: an embedding j over K is an embedding over $\mathbb{Q}$, the decomposition and inertia groups of K for j are contained in those of $\mathbb{Q}$ for j, and the elements x, y of Definition 22.2 for $\mathbb{Q}$ serve for K (with the same B_{cris}); at archimedean places the zero class restricts to zero. Hence $H^1_f(\mathbb{Q}, U')$ embeds in $H^1_f(K, U')$.

Step 5: Kato's theorem. On G_K the character θ is trivial, so $U'|_{G_K} = V_\lambda(e) \otimes_{F_\lambda} E'$. An F_λ-basis $b_1, \dots, b_m$ of E' gives a G_K-equivariant F_λ-linear homeomorphism $U' \cong V_\lambda(e)^m$; the conditions of Definition 22.2 do not depend on the coefficient field and are compatible with the inclusions and projections of a finite direct sum, so $H^1_f(K, U') \cong H^1_f(K, V_\lambda(e))^m$. Choose a $G_{\mathbb{Q}}$-stable $\mathcal{O}_\lambda$-lattice $T \subset V_\lambda(e)$ (for a lattice T_0 the stabiliser is open, and $T = \sum_g gT_0$ over representatives of the finitely many cosets is stable). Since $k = 2e + 1$, the twist $r = e$ satisfies $1 \le r \le k - 1$ and $r \ne k/2$; so $\mathrm{Sel}(K, T)$ is finite by Theorem B.32(2), and $H^1_f(K, V_\lambda(e)) = 0$ by Lemma 38.24 (with $F = K$, $L = F_\lambda$). By Steps 4 and 2–3, $H^1_f(\mathbb{Q}, U') = 0$ and $H^1_f(\mathbb{Q}, W \otimes \theta) = 0$. □

Lemma 38.24. *Let $F \subset \overline{\mathbb{Q}}$ be a number field, ℓ a prime, $L \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$, V a finite-dimensional L-vector space with a continuous L-linear action of G_F, and $T \subset V$ a G_F-stable $\mathcal{O}_L$-lattice. If $\mathrm{Sel}(F, T)$ is finite, then $H^1_f(F, V) = 0$.*

Proof. Let $m = |\mathrm{Sel}(F, T)|$ and let c be a Bloch–Kato cocycle. We show that c is a coboundary. Fix an $\mathcal{O}_L$-basis of T and the sup norm $\|\cdot\|$ on V in this basis, so that T is the closed unit ball; for $n \ge 0$ put $T_n = \ell^n m^{-1} T$, whose elements have norm at most $\ell^{-n}|m|_\ell^{-1}$.

Step 1: the reductions of $\ell^{-n}c$ lie in $\mathrm{Sel}(F, T)$. Let $n \ge 0$. The map $c_n \colon g \mapsto \ell^{-n}c(g) \bmod T$ is a continuous cocycle with values in the discrete module V/T (T is open in V). For a place v and a decomposition group D at v, the class of $\ell^{-n}c|_D$ lies in $H^1_f(D, V)$: the conditions of Definition 22.2 are preserved by multiplication by ℓ^{-n} (replace x by $\ell^{-n}x$, y by $\ell^{-n}y$; at archimedean v the class of $c|_D$ is 0, hence so is that of $\ell^{-n}c|_D$). The class of $c_n|_D$ is its image in $H^1(D, V/T)$. Hence the class of c_n lies in $\mathrm{Sel}(F, T)$ and is killed by m.

Step 2: approximate primitives. By Step 1 there is $z_n \in V/T$ with $m\ell^{-n}c(g) - (g-1)\hat{z}_n \in T$ for all $g \in G_F$, where $\hat{z}_n \in V$ lifts z_n. With $w_n = \ell^n m^{-1}\hat{z}_n$,

$$c(g) - (g-1)w_n \in T_n \qquad (g \in G_F,\ n \ge 0). \tag{38.6}$$

Step 3: convergence. Let $V_0 = V^{G_F} = \bigcap_g \ker(g-1)$. As V is finite-dimensional, there are $g_1, \dots, g_s \in G_F$ with $V_0 = \bigcap_i \ker(g_i - 1)$, so $[w] \mapsto ((g_i - 1)w)_i$ is an injective L-linear map $V/V_0 \to V^s$. Give V/V_0 the quotient norm; all norms on a finite-dimensional L-space are equivalent, so there is $\kappa > 0$ with $\|[w]\| \le \kappa \max_i \|(g_i - 1)w\|$ for all $w \in V$. For $n \le n'$, (38.6) gives $(g-1)(w_n - w_{n'}) \in T_n + T_{n'} = T_n$ for every g, hence $\|[w_n - w_{n'}]\| \le \kappa\ell^{-n}|m|_\ell^{-1}$. So $([w_n])_n$ is a Cauchy sequence in the complete space V/V_0; let $[w]$ be its limit. For each g the map $[u] \mapsto (g-1)u$ is a well-defined continuous linear map $V/V_0 \to V$, so $(g-1)w_n \to (g-1)w$, while $\|c(g) - (g-1)w_n\| \le \ell^{-n}|m|_\ell^{-1} \to 0$ by (38.6). Hence $c(g) = (g-1)w$ for all $g \in G_F$, and the class of c is 0. □

38.2 The counts in the remaining cases

This subsection proves the counts in the cases (II)–(V), each for one character, with a bound polynomial in $\ell N_{\mathfrak{h}} e$. In cases (II) and (III) the congruences are formed on GSp_4 over $\mathbb{Q}$. The Eisenstein trace is $(1 + \Psi)(1 + \Psi_{\mathrm{aux}})$, with $\Psi = \chi\chi_{\mathrm{cyc}}^e$ and an auxiliary character $\Psi_{\mathrm{aux}} = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ whose 2-power part χ_{dy} has a large conductor, and the congruence numbers of

Proposition 38.28 turn the symplectic one-character bound Proposition 44.3 into Counts II and III (Proposition 38.26). In case (V), when the 2-component of χ has a large conductor, $R_1(\ell,\chi) \le 2^{c_2(\chi)}$, the character gives a dyadic Eisenstein datum (Lemma 38.33), and the congruences are formed on the unitary group in three variables attached to $\mathbb{Q}(i)$, with the congruence numbers of Proposition 38.6 for $K=\mathbb{Q}(i)$ (Proposition 46.2, Proposition 38.32).

The other characters at the bad primes need no congruences. In the rest of case (V) the twist is $e=1$ and the order of χ is bounded in terms of ψ, so χ factors through an abelian field of bounded degree containing μ_ℓ; the strict Tate–Shafarevich group of χ is bounded through that of this field (Lemma 38.37), and the bound for second cohomology of Section 40, at the single twist $e=1$, is polynomial in the conductor (Proposition 38.35). A character with $\chi^{(\ell)}$ of odd order, in particular every character of case (IV), factors through $(\mathbb{Z}/N_\psi\mathbb{Z})^\times$ (Lemma 38.34), and its groups, summed over the twists $1 \le e < t$, are bounded through those of the cyclotomic field $\mathbb{Q}(\zeta_{\ell^{j+1}N_\psi})$, for which Section 39 supplies the layer bound (Proposition 38.38).

Definition 38.25. Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism of fields, and $e, M \ge 1$ integers. A continuous representation $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ is **admissible symplectic of weight e and level M** (for ι) if

(Sy1) r is irreducible;

(Sy2) for every imaginary quadratic field $K \subset \overline{\mathbb{Q}}$ such that $r|_{G_K}$ is irreducible, $r|_{G_K} \leftrightarrow_\iota \pi$ for some regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_4(\mathbb{A}_K)$; and r satisfies the witness conditions over imaginary quadratic fields;

(Sy3) r has level M and weights $(e+1, e, 1, 0)$;

(Sy4) there are an integer $M' \ge 1$, a character χ' of $G_{\mathbb{Q}}$ of level M' and a matrix $P \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ such that
$$ {}^t r(s)\, P\, r(s) = \chi_{\mathrm{cyc}}(s)^{e+1}\chi'(s)\, P \qquad \text{for all } s \in G_{\mathbb{Q}};$$

(Sy5) $\ell \mid M$, and for every place $\bar\ell$ of $\overline{\mathbb{Q}}$ above ℓ the representation r is triangular on $D_{\bar\ell}$ with some diagonal $(\kappa_1,\dots,\kappa_4)$ such that $\kappa_i \ne \kappa_j\, \chi_{\mathrm{cyc}}|_{D_{\bar\ell}}$ for all i,j.

Condition (Sy4) says that r preserves a non-degenerate bilinear form up to the similitude character $\chi_{\mathrm{cyc}}^{e+1}\chi'$. These are the representations whose Eisenstein congruences on GSp_4 bound the strict Tate–Shafarevich groups of the characters in cases (II) and (III).

Proposition 38.26. *Let $\psi \in \mathcal{P}$. There is an integer $C \ge 0$ such that for every Sha-host $\mathfrak{h}$ of ψ, every integer $t \ge 1$ at which $\mathfrak{h}$ is big, every odd prime ℓ, every coefficient ring $\mathcal{O}$, every integer e with $0 < e < t$ and every $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$ that is in case (II) or in case (III) for (ℓ, e), the group $\mathrm{Sha}^1_{\ell N_{\mathfrak{h}}}(\chi, e)$ has finite length and*
$$\nu_{\mathcal{O}}(\chi, e)\log \ell \le (\ell N_{\mathfrak{h}} e)^C.$$

Proof. Let $\psi \in \mathcal{P}$ and write $p_1 = p_1(\psi)$. Let $c, A \ge 0$ be the integers given by Proposition 38.28, put $K_\psi = 12c\,(128p_1^2)^{A+2}$, choose an integer $j \ge 0$ with $K_\psi \le 96^j$, and put $C = 12 + 7A + j$; C depends only on ψ. Fix $\mathfrak{h} = (a,q,d)$, t, ℓ, $\mathcal{O}$, e and χ as in the statement, write $N = N_{\mathfrak{h}}$ and $X_0 = \ell N e$.

Step 1: $e \ge 2$ and $X_0 \ge 96$. In case (II), $e \ge 2$ by definition. In case (III), $\ell \notin B_\psi$, so $\ell \ne 3$ (as $3 \in B_\psi$) and $\ell \ge 5$; then $4 \le \ell - 1$ divides $2e$, so $e \ge 2$. Since $a \ge 2$, $16 \mid 2^{a+2} \mid N$; with $\ell \ge 3$, $X_0 \ge 3 \cdot 16 \cdot 2 = 96$.

Step 2: size of the level. Let n', p', m and $M = \ell 2^{n'} N p'$ be as in Proposition 44.3. We show

$$M \le 128\, p_1^2 X_0^6. \tag{38.7}$$

First, $4^{n_0(\ell,\chi)} \le 16\ell^4 N^2$. Indeed, let χ' be the part of χ of order prime to ℓ; the 2-component of χ' is the image of χ' under a group homomorphism, so its order divides that of χ', and $\vartheta = \chi'(\chi_2')^{-1}$ has order dividing $\operatorname{ord}\chi'$, which is prime to ℓ and divides the exponent of $(\mathbb{Z}/N\mathbb{Z})^\times$, at most N. So ℓ is prime to $L = \operatorname{lcm}(4, \operatorname{ord}\vartheta) \le 4N$, and the order f of ℓ modulo L satisfies $1 \le f < L \le 4N$. Write $f = 2^s u$ with u odd. For odd integers y and u, $(y^u - 1)/(y-1) = 1 + y + \cdots + y^{u-1}$ is a sum of u odd numbers, hence odd, so $v_2(y^u - 1) = v_2(y-1)$. If $s = 0$, $v_2(\ell^f - 1) = v_2(\ell - 1)$ and $2^{v_2(\ell^f-1)} \le \ell$. If $s \ge 1$, put $y = \ell^u$; then $\ell^f - 1 = (y^2-1)\prod_{i=1}^{s-1}(y^{2^i}+1)$, each y^{2^i} $(i \ge 1)$ is an odd square, hence $\equiv 1 \pmod 8$, so $v_2(y^{2^i}+1) = 1$, and $v_2(y^2-1) = v_2((\ell^2)^u - 1) = v_2(\ell^2 - 1)$; hence $2^{v_2(\ell^f-1)} = 2^{v_2(\ell^2-1)} 2^{s-1} \le \ell^2 f$. In both cases $2^{n_0(\ell,\chi)} \le \ell^2 f \le 4\ell^2 N$, which gives the claim. Next, $2^{c_2(\chi)} \le N$, since the conductor of the 2-component of χ divides the 2-part of N; and $o_\psi \le N_\psi \le N$, as o_ψ divides $\varphi(N_\psi)$ and $N_\psi \mid N$. For an integer $Y \ge 1$, the least $n \ge 0$ with $2^n \ge Y$ satisfies $2^n < 2Y$. In case (II), $\ell N 4^{n_0(\ell,\chi)} \le 16\ell^5 N^3$ and $2^{c_2(\chi)+6} o_\psi \ell^3 N_\psi^2 \le 64\ell^3 N^4$, so $2^{n'} < 128\ell^5 N^4$. In case (III), $\ell N_\psi p_1 4^{n_0(\ell,\chi)} \le 16\ell^5 N^3 p_1$ and $8\ell^2 \le 16\ell^5 N^3 p_1$, so $2^{n'} < 32\ell^5 N^3 p_1$. In both cases $2^{n'} \le 128 p_1 \ell^5 N^4$ and $p' \le p_1$, so $M \le 128 p_1^2 \ell^6 N^5 \le 128 p_1^2 X_0^6$.

Step 3: enlarging the coefficient ring. Let L_0 be the fraction field of $\mathcal{O}$, $\zeta \in \overline{\mathbb{Q}}_\ell$ a primitive $2^{n'}$-th root of unity and $\mathcal{O}'$ the ring of integers of the finite extension $L_0(\zeta)$ of $\mathbb{Q}_\ell$; it is a coefficient ring containing $\mathcal{O}$ and ζ. Viewed with values in $\mathcal{O}'^\times$, χ lies in $X_\mathfrak{h}(\mathcal{O}', e)$ (the conditions $H_\mathfrak{h} \subseteq \ker\chi$ and $\chi(-1) = (-1)^e$ do not involve the ring), and it is in the same case with the same $n_0(\ell,\chi)$, $c_2(\chi)$ and orders, all of which depend only on χ as a $\overline{\mathbb{Q}}_\ell^\times$-valued character. By Lemma 38.27, item 2, applied to $\mathcal{O}$ and $\mathcal{O}'$, $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length over $\mathcal{O}$ if and only if it has over $\mathcal{O}'$, and then $\nu_{\mathcal{O}}(\chi, e) = \nu_{\mathcal{O}'}(\chi, e)$. Hence it suffices to prove the claim with $\mathcal{O}'$ in place of $\mathcal{O}$, and we assume from now on that $\mathcal{O}$ contains a primitive $2^{n'}$-th root of unity.

Step 4: the symplectic datum. By Proposition 44.3, applied to $\psi, \mathfrak{h}, t, \ell, e, \mathcal{O}, \chi$, there are χ_{dy} (primitive modulo $2^{n'}$), χ_{pr} (modulo p', of order m) and ι with the property stated there; let $\Psi = \Psi_{\chi,e}$, Ψ_{aux} and T_{Eis} be as there.

Step 5: an auxiliary prime and its Frobenius. Let p_0 be a prime factor of $6M - 1 \ge 5$. Then $p_0 \nmid 6M$; so $p_0 \ge 5$, $p_0 \nmid M$, and p_0 divides none of $\ell, N, 2^{n'}, p'$, which divide M; also $p_0 \le 6M$. Choose a place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p_0 and an arithmetic Frobenius $\sigma \in G_\mathbb{Q}$ at $\bar{p}$. Reduction modulo $\bar{p}$ is injective on the roots of unity of order prime to p_0, and σ acts on the residue field as $x \mapsto x^{p_0}$; hence $\sigma(\zeta') = \zeta'^{p_0}$ for every root of unity ζ' of order prime to p_0. Therefore $\chi_{\mathrm{cyc}}(\sigma) = p_0$, and $\phi(\sigma) = \phi(p_0)$ for every Dirichlet character ϕ whose modulus divides M; and $w = \omega_\ell(\sigma)$ satisfies $w^{\ell-1} = 1$. Put

$$y_2 = \chi(p_0), \qquad y_3 = w^{-1}\chi_{\mathrm{dy}}(p_0)\chi_{\mathrm{pr}}(p_0), \qquad y_1 = y_2 y_3.$$

Then $\Psi(\sigma) = p_0^e y_2$, $\Psi_{\mathrm{aux}}(\sigma) = p_0 y_3$, and

$$T_{\mathrm{Eis}}(\sigma) = 1 + \Psi(\sigma) + \Psi_{\mathrm{aux}}(\sigma) + \Psi(\sigma)\Psi_{\mathrm{aux}}(\sigma) = p_0^{e+1} y_1 + p_0^e y_2 + p_0 y_3 + 1.$$

Let $k = \varphi(N)\varphi(2^{n'})\varphi(p')(\ell - 1)$. The values of a Dirichlet character modulo n_1 are $\varphi(n_1)$-th roots of unity, so $y_1^k = y_2^k = y_3^k = 1$; and $1 \le k \le N 2^{n'} p' \ell = M$. Put $z_i = \iota(y_i)$; then $z_i^k = 1$ and, ι being a field isomorphism fixing $\mathbb{Z}$, $E = p_0^{e+1} z_1 + p_0^e z_2 + p_0 z_3 + 1$ satisfies $\iota^{-1}(E) = T_{\mathrm{Eis}}(\sigma)$.

Step 6: congruences. Apply Proposition 38.28 to $(e, M, p_0, k, z_1, z_2, z_3)$ (here $e \ge 2$ by Step 1, $p_0 \ge 5$, $p_0 \nmid M$); it gives a nonzero integer R with $\log|R| \le c\varphi(k)(M(e+1))^A \log p_0$. Let r be admissible symplectic of weight e and level M for ι. Item 1 of Proposition 38.28 for $X = \{r\}$ (ℓ is odd and $\ell \ne p_0$) gives $\operatorname{tr} r(\sigma) \ne \iota^{-1}(E) = T_{\mathrm{Eis}}(\sigma)$. So σ satisfies the hypothesis of the property in Proposition 44.3: $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length, which is the first assertion, and there is a finite

set X of pairwise non-isomorphic admissible symplectic representations of weight e and level M with $\nu_{\mathcal{O}}(\chi,e) \le 2\sum_{r\in X} v_\ell(\operatorname{tr} r(\sigma) - T_{\mathrm{Eis}}(\sigma))$. Item 2 of Proposition 38.28 for this X gives

$$\nu_{\mathcal{O}}(\chi,e) \le 2\, v_\ell(R).$$

Step 7: the estimate. As $\ell^{v_\ell(R)}$ divides R, $v_\ell(R)\log\ell \le \log|R|$. With $\varphi(k) \le k \le M$, $\log p_0 \le p_0 \le 6M$, $e+1 \le X_0$ and (38.7),

$$\nu_{\mathcal{O}}(\chi,e)\log\ell \le 2c\, M\big(M(e+1)\big)^A 6M \le 12c\,(128p_1^2)^{A+2}X_0^{12+7A} = K_\psi X_0^{12+7A} \le X_0^C = (\ell N_{\mathfrak{h}} e)^C,$$

using $M(e+1) \le 128p_1^2X_0^7$, $M^2 \le (128p_1^2)^2X_0^{12}$ and $K_\psi \le 96^j \le X_0^j$ (Step 1). This is the claim. □

Lemma 38.27. *Let ℓ be a prime, $N, n \ge 1$ and $e \ge 0$ integers, and χ a Dirichlet character modulo N with values in $\overline{\mathbb{Q}}_\ell^\times$.*

1. *If the order of χ is prime to ℓ, there is a coefficient ring $\mathcal{O}'$ with $e_{\mathcal{O}'} = 1$ containing all values of χ.*
2. *If $\mathcal{O}_1, \mathcal{O}_2$ are coefficient rings containing all values of χ, then $\mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}_1}$ has finite length if and only if $\mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}_2}$ has, and in that case, for $n = \ell N$, $\nu_{\mathcal{O}_1}(\chi,e) = \nu_{\mathcal{O}_2}(\chi,e)$; more precisely $\operatorname{length}_{\mathcal{O}_1} \mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}_1}/e_{\mathcal{O}_1} = \operatorname{length}_{\mathcal{O}_2} \mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}_2}/e_{\mathcal{O}_2}$ in $[0,\infty]$.*

Proof. Item 1. Let m be the order of χ; its values are m-th roots of unity. Since $\ell \nmid m$, $X^m - 1$ is separable modulo ℓ, so $\mathbb{Q}_\ell(\mu_m) \subset \overline{\mathbb{Q}}_\ell$ is unramified over $\mathbb{Q}_\ell$ and its ring of integers $\mathcal{O}' = \mathbb{Z}_\ell[\mu_m]$ is a discrete valuation ring, finite over $\mathbb{Z}_\ell$, in which ℓ is a uniformiser; so $e_{\mathcal{O}'} = 1$ and $\mathcal{O}'$ contains the values of χ.

Reduction for item 2. Let L_i be the fraction field of $\mathcal{O}_i$ and $\mathcal{O}''$ the ring of integers of the compositum $L_1L_2 \subset \overline{\mathbb{Q}}_\ell$, a coefficient ring containing $\mathcal{O}_1$ and $\mathcal{O}_2$. It suffices to prove, for a coefficient ring $\mathcal{O}$ containing the values of χ and a coefficient ring $\mathcal{O}'' \supseteq \mathcal{O}$, that $\operatorname{length}_{\mathcal{O}''} \mathrm{Sha}''/e_{\mathcal{O}''} = \operatorname{length}_{\mathcal{O}} \mathrm{Sha}/e_{\mathcal{O}}$ in $[0,\infty]$, where $\mathrm{Sha} = \mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}}$ and $\mathrm{Sha}'' = \mathrm{Sha}^1_n(\chi,e)_{\mathcal{O}''}$; both lengths are then finite or infinite together.

The modules. Let e'' be the ramification index and f'' the residue degree of $\mathcal{O}''$ over $\mathcal{O}$, so that $\mathcal{O}''$ is a free $\mathcal{O}$-module of rank $\mathrm{e}''\mathrm{f}''$, and $e_{\mathcal{O}''} = \mathrm{e}'' e_{\mathcal{O}}$ (if ϖ, ϖ'' are uniformisers, ℓ is $\varpi^{e_{\mathcal{O}}}$ times a unit and ϖ is $\varpi''^{\mathrm{e}''}$ times a unit). Put $\theta = \Psi_{\chi,e}^{-1}$, with values in $\mathcal{O}^\times$. A basis of $\mathcal{O}''$ over $\mathcal{O}$ gives an isomorphism of $\mathcal{O}$-modules $\mathcal{O}'' \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell \cong (\mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell)^{\mathrm{e}''\mathrm{f}''}$, which commutes with multiplication by elements of $\mathcal{O}$ and hence with the action of $G_{\mathbb{Q}}$ through θ: $\mathcal{O}''^\vee(\theta) \cong \mathcal{O}^\vee(\theta)^{\mathrm{e}''\mathrm{f}''}$ as $\mathcal{O}[G_{\mathbb{Q}}]$-modules. Continuous cohomology with discrete coefficients commutes with finite direct sums, compatibly with restriction to $G_{\mathbb{Q}_p}$ and to I_p; therefore the kernels defining the strict Tate–Shafarevich groups correspond, and $\mathrm{Sha}'' \cong \mathrm{Sha}^{\mathrm{e}''\mathrm{f}''}$ as $\mathcal{O}$-modules. Hence $\operatorname{length}_{\mathcal{O}} \mathrm{Sha}'' = \mathrm{e}''\mathrm{f}'' \cdot \operatorname{length}_{\mathcal{O}} \mathrm{Sha}$ in $[0,\infty]$.

Lengths over $\mathcal{O}$ and $\mathcal{O}''$. The simple $\mathcal{O}''$-module $\mathcal{O}''/\varpi''\mathcal{O}''$ has $\mathcal{O}$-length f''; so an $\mathcal{O}''$-module of finite $\mathcal{O}''$-length λ has $\mathcal{O}$-length $\mathrm{f}''\lambda$ (along a composition series), and an $\mathcal{O}''$-module of infinite $\mathcal{O}''$-length has infinite $\mathcal{O}$-length (it has $\mathcal{O}''$-submodule chains of every finite length). Thus $\operatorname{length}_{\mathcal{O}''} \mathrm{Sha}'' = \operatorname{length}_{\mathcal{O}} \mathrm{Sha}''/\mathrm{f}'' = \mathrm{e}'' \operatorname{length}_{\mathcal{O}} \mathrm{Sha}$, and

$$\frac{\operatorname{length}_{\mathcal{O}''} \mathrm{Sha}''}{e_{\mathcal{O}''}} = \frac{\mathrm{e}'' \operatorname{length}_{\mathcal{O}} \mathrm{Sha}}{\mathrm{e}'' e_{\mathcal{O}}} = \frac{\operatorname{length}_{\mathcal{O}} \mathrm{Sha}}{e_{\mathcal{O}}}.$$

□

Proposition 38.28. *There are integers $c, A \geq 0$ with the following property. Let $e \geq 2$ and $M \geq 1$ be integers, $p \geq 5$ a prime with $p \nmid M$, $k \geq 1$ an integer and $z_1, z_2, z_3 \in \mathbb{C}$ with $z_1^k = z_2^k = z_3^k = 1$, and put*

$$E = p^{e+1} z_1 + p^e z_2 + p\, z_3 + 1.$$

Then there is a nonzero integer R with

$$\log |R| \leq c\, \varphi(k)\, \big(M(e+1)\big)^A \log p$$

such that for every odd prime $\ell \neq p$, every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p, every arithmetic Frobenius $\sigma \in G_{\mathbb{Q}}$ at $\bar{p}$ and every finite set X of pairwise non-isomorphic representations $G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ admissible symplectic of weight e and level M (for ι):

1. *$\operatorname{tr} r(\sigma) \neq \iota^{-1}(E)$ for every $r \in X$;*
2. *$v_\ell(R) \geq \displaystyle\sum_{r \in X} v_\ell\big(\operatorname{tr} r(\sigma) - \iota^{-1}(E)\big)$.*

Proof. Let c_0, A_0 be the integers given by Proposition 38.29, and put $c = 2^{A_0+1} c_0$, $A = A_0 + 1$. Fix $e, M, p, k, z_1, z_2, z_3$ as in the statement. As $p \nmid M$, Proposition 38.29 gives a finite set S and $t\colon S \to \mathbb{C}$ with (Tr1)–(Tr4) for (e, M, p). Let $U = (\mathbb{Z}/k\mathbb{Z})^\times$; for $j \in U$ and a k-th root of unity y the power y^j is well defined. For $j \in U$ and $s \in S$ put

$$E_j = p^{e+1} z_1^j + p^e z_2^j + p\, z_3^j + 1, \qquad F(s, j) = t(s) - E_j,$$

so that $E_1 = E$.

Step 1: size of $F(s, j)$. Put $x = p^{(e+1)/2}$. As $e \geq 2$ and $p \geq 5$, $x \geq p^{3/2} \geq \sqrt{5}\, p \geq 2p \geq p + 1$ and $x \geq 5\sqrt{5} > 25/4$; also $p^e = x^2/p \leq x^2/5$. Since $|z_i^j| = 1$,

$$|E_j| \geq p^{e+1} - p^e - p - 1 \geq x^2 - \tfrac{1}{5}x^2 - x = \tfrac{4}{5}x^2 - x > (2\sqrt{p} + 2)x \geq |t(s)|$$

by (Tr2); the strict inequality holds because $\frac{4}{5}x \geq \frac{4}{5}p\sqrt{p} \geq 4\sqrt{p} \geq 2\sqrt{p} + 2\sqrt{5} > 2\sqrt{p} + 3$. Hence $F(s, j) \neq 0$. Moreover $|F(s, j)| \leq (2\sqrt{p} + 2)x + x^2 + \frac{1}{5}x^2 + x < \frac{6}{5}x^2 + \frac{4}{5}x^2 = 2x^2 = 2p^{e+1}$, since $(2\sqrt{p} + 3)x < \frac{4}{5}x^2$; so $\log |F(s, j)| \leq \log 2 + (e+1)\log p \leq 2(e+1)\log p$.

Step 2: integrality. By (Tr2) $t(s)$ is an algebraic integer, and z_i^j are roots of unity; so $F(s, j)$ is an algebraic integer.

Step 3: the integer R. Let $\sigma' \in \mathrm{Aut}(\mathbb{C})$. It maps the cyclic group μ_k of k-th roots of unity onto itself by a group automorphism, so there is $b \in U$ with $\sigma'(y) = y^b$ for all $y \in \mu_k$; as σ' fixes p, $\sigma'(E_j) = E_{bj}$, and with $u_{\sigma'}$ from (Tr1), $\sigma'(F(s, j)) = t(u_{\sigma'}(s)) - E_{bj} = F(u_{\sigma'}(s), bj)$. Since $(s, j) \mapsto (u_{\sigma'}(s), bj)$ is a bijection of $S \times U$, the product

$$R = \prod_{(s,j) \in S \times U} F(s, j)$$

satisfies $\sigma'(R) = R$. A complex number fixed by every automorphism of $\mathbb{C}$ is rational; R is an algebraic integer (Step 2), hence $R \in \mathbb{Z}$, and $R \neq 0$ by Step 1 ($R = 1$ if $S \times U$ is empty). By Step 1, (Tr3) and $|U| = \varphi(k)$,

$$\log |R| \leq |S|\, \varphi(k)\, 2(e+1)\log p \leq c_0 \big(M(e+2)\big)^{A_0} \varphi(k)\, 2(e+1)\log p \leq c\, \varphi(k) \big(M(e+1)\big)^A \log p.$$

Step 4: the two properties. Let $\ell \neq p$ be an odd prime, ι, $\bar{p}$, σ and X as in the statement, and λ the map given by (Tr4) for $(\ell, \iota, \bar{p}, \sigma)$. For $r \in X$, $\iota(\operatorname{tr} r(\sigma)) = t(\lambda(r))$, so, ι^{-1} being a field isomorphism,

$$\operatorname{tr} r(\sigma) - \iota^{-1}(E) = \iota^{-1}\big(t(\lambda(r)) - E_1\big) = \iota^{-1}\big(F(\lambda(r), 1)\big),$$

which is non-zero by Step 1. This proves item 1. If $\lambda(r) = \lambda(r')$ for $r, r' \in X$, then $r \cong r'$ by (Tr4), so $r = r'$; thus $r \mapsto (\lambda(r), 1)$ is injective on X. Since ι^{-1} fixes $\mathbb{Z}$,

$$v_\ell(R) = \sum_{(s,j)\in S\times U} v_\ell\big(\iota^{-1}(F(s,j))\big).$$

Each $y = \iota^{-1}(F(s,j))$ is a root of a monic polynomial $X^n + a_{n-1}X^{n-1} + \cdots + a_0$ with $a_i \in \mathbb{Z}$ (Step 2), so $v_\ell(y) \geq 0$: otherwise $v_\ell(y^n) < v_\ell(a_i y^i)$ for all $i < n$, which contradicts $y^n = -\sum_{i<n} a_i y^i$. Dropping the terms with (s,j) outside the image of $r \mapsto (\lambda(r), 1)$,

$$v_\ell(R) \geq \sum_{r\in X} v_\ell\big(\iota^{-1}(F(\lambda(r),1))\big) = \sum_{r\in X} v_\ell\big(\operatorname{tr} r(\sigma) - \iota^{-1}(E)\big),$$

which is item 2. □

Proposition 38.29. *There are integers $c, A \geq 0$ with the following property. For all integers $e \geq 2$ and $M \geq 1$ and every prime p with $p \nmid M$ there are a finite set S and a map $t\colon S \to \mathbb{C}$ such that*

(Tr1) *for every $\sigma \in \operatorname{Aut}(\mathbb{C})$ there is a bijection u_σ of S with $t(u_\sigma(s)) = \sigma(t(s))$ for all $s \in S$;*

(Tr2) *for every $s \in S$, $t(s)$ is an algebraic integer and $|t(s)| \leq (2\sqrt{p} + 2)\, p^{(e+1)/2}$;*

(Tr3) *$|S| \leq c\,(M(e+2))^A$;*

(Tr4) *for every odd prime $\ell \neq p$, every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p and every arithmetic Frobenius $\sigma \in G_{\mathbb{Q}}$ at $\bar{p}$, there is a map λ from the set of representations $G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ that are admissible symplectic of weight e and level M (for ι) to S such that $\lambda(r) = \lambda(r')$ implies $r \cong r'$, and $\iota\big(\operatorname{tr} r(\sigma)\big) = t(\lambda(r))$ for every such r.*

Proof. Step 0: auxiliary fields and constants. Let $p_1 < \cdots < p_{18}$ be the first eighteen primes $\equiv 3 \pmod 4$ and $K_j = \mathbb{Q}(\sqrt{-p_j})$, with discriminant $-p_j$; the discriminants are pairwise coprime. Let $\delta_j\colon G_{\mathbb{Q}} \to \{\pm 1\}$ be the character with kernel G_{K_j}; the δ_j are pairwise distinct. Let c_j, A_j be the integers of Lemma 38.16 for K_j and $n = 4$, and put $c_0 = \sum_j c_j$, $A = \max_j A_j$, $c = 64 \cdot 2^A c_0$. For $e \geq 1$ let $Z_e = \{e + \frac{5}{2}, e + \frac{3}{2}, \frac{5}{2}, \frac{3}{2}\}$. We use: (T) if F is a number field and r_1, r_2 are continuous semisimple representations of G_F over $\overline{\mathbb{Q}}_\ell$ that are unramified with equal characteristic polynomials of Frobenius at all finite places outside a finite set, then $r_1 \cong r_2$ (Chebotarev density and Brauer–Nesbitt, [220], Chapter I, 2.2).

Step 1: the set S and the map t. Fix $e \geq 2$, $M \geq 1$ and a prime $p \nmid M$. Let J be the set of j with $p \nmid p_j$; $|J| \geq 17$. For $j \in J$, p is unramified in K_j; let W_j be the set of primes of K_j above p and $f_j \in \{1, 2\}$ their residue degree. For $w \in W_j$ let $\Pi_j(w)$ be the set of isomorphism classes of cuspidal automorphic representations π of $\mathrm{GL}_4(\mathbb{A}_{K_j})$ with infinitesimal character Z_e at both embeddings and $\pi_f^{\mathrm{K}_4(M)} \neq 0$ (so π_w is unramified, as $w \nmid M$), such that, with

$$\beta(\pi, w) = \big\{(q_w^{3/2}\alpha)^{-1} : \alpha \text{ a Satake parameter of } \pi_w\big\} \quad \text{(a multiset of four numbers)},$$

(Pi1) every element of $\beta(\pi, w)$ is an algebraic integer, and (Pi2) $q_w^{-(2e+2)} \prod_{x\in\beta(\pi,w)} x$ is a root of unity. Let $R(\pi, w)$ be the set of multisets B of four complex numbers with $\{x^{f_j} : x \in B\} =$

$\beta(\pi,w)$; each element $y\neq 0$ of $\beta(\pi,w)$ has exactly f_j roots of $X^{f_j}=y$, so $|R(\pi,w)|\le f_j^4\le 16$. Put

$$S=\{(j,w,\pi,B,b): j\in J,\ w\in W_j,\ \pi\in\Pi_j(w),\ B\in R(\pi,w),\ b\in\{0,1\}\},$$
$$t(j,w,\pi,B,b)=\sum_{x\in B}x.$$

The set S and the map t depend only on (e,M,p).

Step 2: (Tr3). The set Z_e consists of four distinct elements of $\frac{3}{2}+\mathbb{Z}=\frac{4-1}{2}+\mathbb{Z}$ of absolute value at most $e+3$, so by Lemma 38.16 with $H=e+3$, $\Pi_j(w)$ is finite with $|\Pi_j(w)|\le c_j(M(e+4))^{A_j}\le c_j2^A(M(e+2))^A$. As $|W_j|\le 2$, $|S|\le\sum_j 2\cdot 16\cdot 2\cdot c_j2^A(M(e+2))^A=c\,(M(e+2))^A$.

Step 3: (Tr2). Let $s=(j,w,\pi,B,b)\in S$ and $q=q_w=p^{f_j}$. Each $x\in B$ satisfies $x^{f_j}\in\beta(\pi,w)$, an algebraic integer by (Pi1); so x and $t(s)$ are algebraic integers. For the size, let ω be the central character of π. The continuous homomorphism $|\omega|\colon \mathbb{A}_{K_j}^\times/K_j^\times\to\mathbb{R}_{>0}$ is trivial on the compact group $\mathbb{A}^1_{K_j}/K_j^\times$, and $\mathbb{A}^\times_{K_j}=\mathbb{A}^1_{K_j}\cdot\mathbb{R}_{>0}$, so $|\omega|=|\cdot|_{\mathbb{A}}^{s_0}$ for a real s_0. Then $\pi\otimes|\det|^{-s_0/4}$ is cuspidal with unitary central character and Satake parameters $\alpha q^{s_0/4}$ at w, so by (Js2) of [136] the numbers $y_\alpha=\log|\alpha q^{s_0/4}|/\log q$ lie in $(-\frac12,\frac12)$; and $\prod_\alpha\alpha=\omega_w(\varpi_w)$ has absolute value q^{-s_0}, so $\sum_\alpha y_\alpha=0$. By (Pi2), $q^{2e+2}=\prod_{x\in\beta}|x|=q^{-6}\prod_\alpha|\alpha|^{-1}=q^{-6+s_0}$, so $s_0=2e+8$ and $|(q^{3/2}\alpha)^{-1}|=q^{(e+1)/2-y_\alpha}$. Hence the elements of B have absolute values $p^{(e+1)/2}p^{z_i}$ $(i=1,\dots,4)$ with $z=(z_i)$ in the polytope $P=\{z\in[-\frac12,\frac12]^4:\sum_i z_i=0\}$. The function $z\mapsto\sum_i p^{z_i}$ is convex, so its maximum on P is attained at an extreme point. A point of P with two coordinates in $(-\frac12,\frac12)$ is not extreme (it is the midpoint of two points of P obtained by moving these two coordinates in opposite directions); at a point with at most one such coordinate, the other three are $\pm\frac12$ and the sum condition forces the fourth to be $\pm\frac12$ as well. So the extreme points have two coordinates $\frac12$ and two $-\frac12$, and

$$|t(s)|\le p^{(e+1)/2}\sum_i p^{z_i}\le p^{(e+1)/2}(2\sqrt{p}+2/\sqrt{p})\le(2\sqrt{p}+2)\,p^{(e+1)/2}.$$

Step 4: (Tr1). Let $\theta\in\mathrm{Aut}(\mathbb{C})$, $j\in J$, $w\in W_j$, $\pi\in\Pi_j(w)$ and $q=q_w$. Since Z_e consists of four distinct elements of $\frac{4-1}{2}+\mathbb{Z}$, π is regular algebraic, and [68] (Theorem B.63) gives a cuspidal π' with $\pi'_f\cong{}^\theta\pi_f$ and infinitesimal character Z_e at both embeddings; moreover, ${}^\theta\pi_f$ has nonzero $\mathrm{K}_4(M)$-invariants. Satake parameters: let B_4 be the upper triangular Borel subgroup of $\mathrm{GL}_4(K_{j,w})$ and δ its modulus character; π_w is the unramified subquotient of $\mathrm{Ind}_{B_4}(\chi\delta^{1/2})$ with $\chi_k(\varpi_w)=\alpha_k$. As $\delta^{1/2}(\mathrm{diag}(\varpi_w^{a_1},\dots,\varpi_w^{a_4})u)=q^{-(3a_1+a_2-a_3-3a_4)/2}$ for diagonal units u, we get $\theta\circ\delta^{1/2}=\delta^{1/2}\nu$ with $\nu=\varepsilon^{a_1+a_2+a_3+a_4}$, $\varepsilon=\theta(\sqrt{q})/\sqrt{q}\in\{\pm1\}$; since $f\mapsto\theta\circ f$ identifies ${}^\theta\mathrm{Ind}_{B_4}(\eta)$ with $\mathrm{Ind}_{B_4}(\theta\circ\eta)$, $\pi'_w\cong{}^\theta\pi_w$ is the unramified subquotient of $\mathrm{Ind}_{B_4}((\theta\circ\chi)\nu\,\delta^{1/2})$ ([60]), and its Satake parameters are the $\varepsilon\,\theta(\alpha_k)$. As $\theta(q^{3/2})=\varepsilon q^{3/2}$, $q^{3/2}\varepsilon\theta(\alpha_k)=\theta(q^{3/2}\alpha_k)$, so $\beta(\pi',w)=\theta(\beta(\pi,w))$. Hence (Pi1), (Pi2) hold for π' (θ maps algebraic integers and roots of unity to such and fixes q), and $\pi'\in\Pi_j(w)$. Choose such a $\pi'=:v_\theta(\pi)$ for each π. If $v_\theta(\pi_1)=v_\theta(\pi_2)$, then ${}^\theta\pi_{1,f}\cong{}^\theta\pi_{2,f}$, hence $\pi_{1,f}\cong\pi_{2,f}$ (twist by θ^{-1}), and $\pi_1\cong\pi_2$ by (Js1) of [136]; so v_θ is a bijection of the finite set $\Pi_j(w)$. For $B\in R(\pi,w)$, $\theta(B)\in R(v_\theta(\pi),w)$, since $\theta(x)^{f_j}=\theta(x^{f_j})$. The map $u_\theta(j,w,\pi,B,b)=(j,w,v_\theta(\pi),\theta(B),b)$ is an injective, hence bijective, self-map of S with $t\circ u_\theta=\theta\circ t$.

Step 5: setting up (Tr4). Fix an odd prime $\ell\neq p$, ι, a place $\bar p\mid p$ and an arithmetic Frobenius $\sigma\in G_{\mathbb{Q}}$ at $\bar p$. Let r be admissible symplectic of weight e and level M, on $V=\overline{\mathbb{Q}}_\ell^4$. (a) *Some $j\in J$ has $r\not\cong r\otimes\delta_j$.* Otherwise for each $j\in J$ there is $\phi_j\neq 0$ in $\mathrm{End}(V)$ with $r(g)\phi_j r(g)^{-1}=\delta_j(g)\phi_j$ for all g; eigenvectors of the conjugation action for pairwise distinct characters are linearly independent, giving $|J|\ge 17$ independent elements of the 16-dimensional

space $\mathrm{End}(V)$. Let $j = j(r)$ be the least such index; it depends only on the isomorphism class of r. Write $K = K_j$, $\delta = \delta_j$, $f = f_j$. (b) *$r|_{G_K}$ is irreducible.* Otherwise let $V_1 \subsetneq V$ be a nonzero irreducible G_K-subrepresentation and $\gamma \in G_{\mathbb{Q}} \smallsetminus G_K$; $V_2 = r(\gamma)V_1$ is G_K-stable, $V_1 + V_2$ and $V_1 \cap V_2$ are $G_{\mathbb{Q}}$-stable (as $\gamma^2 \in G_K$), so by (Sy1) $V = V_1 \oplus V_2$, and every $g \notin G_K$ exchanges V_1 and V_2. Then $\phi = \mathrm{id}_{V_1} \oplus (-\mathrm{id}_{V_2})$ satisfies $\phi\, r(g) = \delta(g)\, r(g)\, \phi$, i.e. $r \cong r \otimes \delta$, a contradiction. (c) *The automorphic data.* By (Sy2) there is a regular algebraic cuspidal π of $\mathrm{GL}_4(\mathbb{A}_K)$ with $r|_{G_K} \leftrightarrow_\iota \pi$; its class is determined by the class of r (two such have the same Satake parameters at almost all places, hence are isomorphic by [60] and (Js1)). Let w be the prime of K below $\bar{p}$; $w \in W_j$. The image of σ in $\mathrm{Gal}(K/\mathbb{Q})$ generates the decomposition group of w, of order f, so $\sigma^f \in G_K$ is an arithmetic Frobenius at $\bar{p}$ for K. By Proposition 38.30, (Ls1) and (Ls2), π has infinitesimal character Z_e at both embeddings and $\pi_f^{\mathrm{K}_4(M)} \neq 0$; π_w is unramified and $w \nmid \ell$, so by (Ls3) the eigenvalues of $r(\sigma^f)$ are ι^{-1} of the elements of $\beta(\pi, w)$. (Pi1) is (Ls4) ($p \nmid Mp_j$). For (Pi2): (Sy4) and $\det P \neq 0$ give $(\det r)^2 = (\chi_{\mathrm{cyc}}^{e+1}\chi')^4$, so $\det r = \eta\, \chi_{\mathrm{cyc}}^{2e+2}\chi'^2$ with $\eta^2 = 1$; as $\ell \neq p$, $\chi_{\mathrm{cyc}}(\sigma^f) = q_w$, and η, χ' have finite order, so $\prod_{x \in \beta(\pi,w)} x = \iota(\det r(\sigma^f))$ is q_w^{2e+2} times a root of unity. So $\pi \in \Pi_j(w)$. Let $B_r = \iota(\text{multiset of eigenvalues of } r(\sigma))$; then $\{x^f : x \in B_r\} = \beta(\pi, w)$, i.e. $B_r \in R(\pi, w)$, and $\sum_{x \in B_r} x = \iota(\mathrm{tr}\, r(\sigma))$.

Step 6: (Tr4). Let $\lambda_0(r) = (j(r), w, \pi, B_r)$; it depends only on the class of r. If $\lambda_0(r) = \lambda_0(r')$, then $r|_{G_K}$ and $r'|_{G_K}$ are irreducible and attached to the same π, so $r|_{G_K} \cong r'|_{G_K}$ by (T). The space $\mathrm{Hom}_{G_K}(r, r')$ is one-dimensional (Schur) and $G_{\mathbb{Q}}$ acts on it by $g \cdot \phi = r'(g)\phi\, r(g)^{-1}$ through $G_{\mathbb{Q}}/G_K$, by a character equal to $\mathbf{1}$ or δ; so $r' \cong r$ or $r' \cong r \otimes \delta$. Hence each fibre of λ_0 consists of at most two isomorphism classes, and we choose for each fibre an injection of its set of classes into $\{0, 1\}$, writing $b(r)$ for the value at the class of r. Put $\lambda(r) = (\lambda_0(r), b(r)) \in S$. If $\lambda(r) = \lambda(r')$, then r and r' lie in one fibre with the same bit, so $r \cong r'$; and $\iota(\mathrm{tr}\, r(\sigma)) = \sum_{x \in B_r} x = t(\lambda(r))$ by Step 5. The set S and the map t of Step 1 do not depend on ℓ, ι, $\bar{p}$ or σ. □

Proposition 38.30. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $e \geq 2$ and $M \geq 1$ integers, $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ admissible symplectic of weight e and level M, K an imaginary quadratic field with discriminant d_K such that $r|_{G_K}$ is irreducible, and π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_4(\mathbb{A}_K)$ with $r|_{G_K} \leftrightarrow_\iota \pi$. Then:*

(Ls1) *at both embeddings of K the infinitesimal character of π is $\{e + \frac{5}{2}, e + \frac{3}{2}, \frac{5}{2}, \frac{3}{2}\}$;*

(Ls2) *π_f has a nonzero vector fixed by $\mathrm{K}_4(M)$;*

(Ls3) *for every finite place $w \nmid \ell$ of K at which π_w is unramified, every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w and every arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$: $r|_{G_K}$ is trivial on $I_{\bar{w}}$ and $\iota(\det(X - r(\sigma^{-1}))) = \prod_\alpha (X - q_w^{3/2}\alpha)$, α running over the Satake parameters of π_w with multiplicity;*

(Ls4) *for every prime $p \nmid Md_K$, every prime w of K above p and every Satake parameter α of π_w, $(q_w^{3/2}\alpha)^{-1}$ is an algebraic integer.*

Proof. Write $s = r|_{G_K}$, $\mu = \chi_{\mathrm{cyc}}^{e+1}\chi'$ with χ', P as in (Sy4), and fix a complex conjugation $c \in G_{\mathbb{Q}}$.

Step 1: π is polarizable. Let S be a finite set of finite places of K, stable under c, containing those above ℓ, M, M' (the level of χ') and those where π is ramified, and outside of which s is unramified with $\iota(\det(X - s(\sigma^{-1}))) = \prod_\alpha (X - q_w^{3/2}\alpha)$ for arithmetic Frobenius elements σ at places above w (possible by $s \leftrightarrow_\iota \pi$). Let $w \notin S$, $\sigma \in G_K$ an arithmetic Frobenius at a place $\bar{w} \mid w$, $q = q_w$, and A_w the multiset of Satake parameters of π_w. (a) $c\sigma c^{-1} \in G_K$ is an arithmetic Frobenius at $c(\bar{w})$, which lies above w^c, and $s(c\sigma^{-1}c^{-1}) = r(c)s(\sigma^{-1})r(c)^{-1}$; so $A_{w^c} = A_w$. The local component of π^c at w is π_{w^c} transported by $c\colon K_w \to K_{w^c}$, unramified

with Satake parameters $A_{w^c} = A_w$. Unramified irreducible representations are determined by their Satake parameters ([60]), so $(\pi^c)_w \cong \pi_w$ for all $w \notin S$, and $\pi^c \cong \pi$ by (Js1). (b) By (Sy4) and $\det P \neq 0$, $r(g) = \mu(g)\, P^{-1}\, {}^t r(g)^{-1} P$, so $r \cong r^\vee \otimes \mu$ and the eigenvalues of $s(\sigma^{-1})$ are the $\mu(\sigma^{-1})b^{-1}$, b running over them. As $w \nmid \ell M'$, $\chi_{\mathrm{cyc}}(\sigma) = q$ (as $w \nmid \ell$, reduction modulo $\bar{w}$ is injective on the ℓ-power roots of unity, and σ acts on the residue field as $x \mapsto x^q$) and $\mu(\sigma^{-1}) = q^{-(e+1)}\chi'(\sigma)^{-1}$. Applying ι: $\{q^{3/2}\alpha\} = \{q^{-(e+1)}\iota(\chi'(\sigma))^{-1} q^{-3/2}\alpha^{-1}\}$, that is

$$A_w = \{q^{-(e+4)}\, \iota(\chi'(\sigma))^{-1}\alpha^{-1} : \alpha \in A_w\}.$$

Let $\omega = \iota \circ \chi'^{-1} \circ \mathrm{Art}_{\mathbb{Q}}$, a finite-order character of $\mathbb{A}_{\mathbb{Q}}^\times/\mathbb{Q}^\times$, unramified at primes $p \nmid M'$ with $\omega_p(p) = \iota(\chi'(\mathrm{Frob}_p))^{-1}$, and $\psi = |\cdot|_{\mathbb{A}_{\mathbb{Q}}}^{e+4}\omega$, a continuous character of $\mathbb{A}_{\mathbb{Q}}^\times/\mathbb{Q}^\times$. For $w \mid p$, $w \notin S$, $K_w/\mathbb{Q}_p$ is unramified of degree f ($p \nmid d_K$ as ramified primes may be put into S), $\mathrm{N}_{K_w/\mathbb{Q}_p}(\varpi_w) \in p^f\mathbb{Z}_p^\times$, and σ restricts to Frob_p^f on the abelian extension cut out by χ'; so $\psi_p(\mathrm{N}_{K_w/\mathbb{Q}_p}\varpi_w) = q^{-(e+4)}\iota(\chi'(\sigma))^{-1}$, and the right side of the display is the Satake multiset of $(\pi^\vee \otimes (\psi \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det))_w$ (the contragredient inverts the Satake parameters, the twist multiplies them by the value of the unramified character at ϖ_w). As in (a), (Js1) gives $\pi \cong \pi^\vee \otimes (\psi \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det)$, both sides being cuspidal. With (a), $\pi^c \cong \pi^\vee \otimes (\psi \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det)$: π is polarizable (the condition on $\psi_\infty(-1)$ is empty, $\mathbb{Q}$ having one infinite place). In particular every π attached to s is polarizable; no choice of representative is involved.

Step 2: s satisfies the hypotheses of Proposition 38.13 for $n = 4$, M, $m = (e+1, e, 1, 0)$. s is irreducible by hypothesis. (Lw1) and the triangular part of (Lw2) for s: by (Sy3), for a prime p of $\mathbb{Q}$ there is a place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p with the properties of (Lw1) (if $p \neq \ell$) or (Lw2) (if $p = \ell$) for r, with characters χ_i of $G_{\mathbb{Q}}$ of level M. Given a place $v \mid p$ of K, choose $g \in G_{\mathbb{Q}}$ with $g\bar{p}$ above v ($G_{\mathbb{Q}}$ permutes the places above p transitively). Then $I_{g\bar{p}} = gI_{\bar{p}}g^{-1}$, $D_{g\bar{p}} = gD_{\bar{p}}g^{-1}$ and $r(gxg^{-1}) = r(g)r(x)r(g)^{-1}$; since χ_i and χ_{cyc} are invariant under conjugation, r restricted to $I_{g\bar{p}}$ is diagonalisable with the characters χ_i (for $p \neq \ell$), resp. triangular on $D_{g\bar{p}}$ with diagonal $(x \mapsto \kappa_i(g^{-1}xg))$, equal to $\chi_{\mathrm{cyc}}^{m_i}\chi_i$ on $I_{g\bar{p}}$ (for $p = \ell$). Restricting to the inertia and decomposition groups $I_{g\bar{p}} \cap G_K$, $D_{g\bar{p}} \cap G_K$ of $g\bar{p}$ in G_K, and the χ_i to G_K (still of level M: trivial on $G_{K(\mu_M)} \subseteq G_{\mathbb{Q}(\mu_M)}$), gives (Lw1) and the triangular part of (Lw2) for s. Polarizability is Step 1. By (Sy2), r satisfies the witness conditions over imaginary quadratic fields, and $s = r|_{G_K}$ is irreducible, so s satisfies the witness conditions, in particular (Wc2). By (Sy5), $\ell \mid M$, so every place $v \mid \ell$ of K divides M and the genericity hypothesis is empty.

Step 3: (Ls1)–(Ls3). By Proposition 38.13: (Wl2) gives the infinitesimal character $\{m_i + \frac{3}{2}\} = \{e + \frac{5}{2}, e + \frac{3}{2}, \frac{5}{2}, \frac{3}{2}\}$ at both embeddings, (Ls1); (Wl3) is (Ls2); (Wl1) is (Ls3).

Step 4: (Ls4). Let $p \nmid Md_K$ and $w \mid p$. By Step 1, (Ls1), (Ls2), Proposition 38.18 applies with $n = 4$, $Z = \{e + \frac{5}{2}, e + \frac{3}{2}, \frac{5}{2}, \frac{3}{2}\}$ (four distinct elements of $\frac{3}{2} + \mathbb{Z}$, as $e \geq 2$), $z - \frac{3}{2} \in \{e+1, e, 1, 0\} \subseteq [0, e+1]$, so $a = 0$, $b = e + 1$: for every Satake parameter α of π_w, $q_w^{-a}\beta^{-1} = (q_w^{3/2}\alpha)^{-1}$ is an algebraic integer. (The hypothesis that ℓ is odd is not used.) □

Definition 38.31. Let ℓ be a prime, $\mathcal{O}$ a coefficient ring, $N \geq 1$ an integer and χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$. Write $\chi = \chi'\chi''$ with χ' of order prime to ℓ and χ'' of ℓ-power order (both are powers of χ). Let $S_\ell(\chi)$ be the set of primes $p \mid N$ with $p \neq \ell$ and $\chi''_p \neq \mathbf{1}$, and put $T_\ell(\chi) = \{\ell\} \cup S_\ell(\chi)$. Recall that $c_2(\chi)$ is the exponent of 2 in the conductor of χ_2, that $\vartheta = \chi'(\chi'_2)^{-1}$, and that $n_0(\ell, \chi)$ is the 2-adic valuation of $\ell^f - 1$ for f the order of ℓ modulo $\mathrm{lcm}(4, \mathrm{ord}\,\vartheta)$.

For integers $e \geq 1$, $o \geq 1$ and $m \geq 1$, the tuple (ℓ, e, N, χ, o, m) is a **dyadic Eisenstein datum** if

(Dy1) ℓ is odd;

(Dy2) N is even;

(Dy3) $\chi(-1) = (-1)^e$;

(Dy4) $(\chi'_r)^{2o} = \mathbf{1}$ for every odd prime r;

(Dy5) $8\,o\,v^2 < 2^{c_2(\chi)}$ for every $v \in T_\ell(\chi)$;

(Dy6) $c_2(\chi) \geq 4$;

(Dy7) the conductor of ϑ^2 divides m, and $2\,\ell\,m\,4^{n_0(\ell,\chi)} \leq 2^{c_2(\chi)}$.

In words: the 2-component of χ has a conductor that is large compared with ℓ, with the primes of $S_\ell(\chi)$, with the order bound o of the odd components and with the conductor of ϑ^2. These are the data for which the Eisenstein congruences on the unitary group in three variables attached to $\mathbb{Q}(i)/\mathbb{Q}$ are used to bound $\mathrm{Sha}^1_{\ell N}(\chi, e)$.

Proposition 38.32. *Let $\psi \in \mathcal{P}$. There is an integer $C \geq 0$ such that for every Sha-host $\mathfrak{h}$ of ψ, every integer $t \geq 1$ at which $\mathfrak{h}$ is big, every odd prime ℓ, every coefficient ring $\mathcal{O}$, every integer e with $0 < e < t$ and every $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$ such that (ℓ, e) is in case (V) and $R_1(\ell, \chi) \leq 2^{c_2(\chi)}$, the group $\mathrm{Sha}^1_{\ell N_{\mathfrak{h}}}(\chi, e)$ has finite length and*

$$\nu_{\mathcal{O}}(\chi, e) \log \ell \leq (\ell N_{\mathfrak{h}} e)^C.$$

Proof. Let $K = \mathbb{Q}(i)$, an imaginary quadratic field with discriminant $d_K = -4$, and let $c, A \geq 0$ be the integers given by Proposition 38.6 for K. Choose an integer $k \geq 0$ with $60c \leq 48^k$ and put $C = A + k + 2$. Then C does not depend on ψ; we show that it has the stated property. Fix $\mathfrak{h}$, t, ℓ, $\mathcal{O}$, e and χ as in the statement and write $N = N_{\mathfrak{h}}$, $X_0 = \ell N e$. Only the facts that ℓ is odd, $e \geq 1$, $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$ and $R_1(\ell, \chi) \leq 2^{c_2(\chi)}$ are used. Since $16 \mid N$ and $\ell \geq 3$, $X_0 \geq 48$.

Step 1: the datum. By Lemma 38.33, $(\ell, e, N, \chi, o_\psi, N_\psi)$ is a dyadic Eisenstein datum.

Step 2: an auxiliary prime. Let p be a prime factor of $30\ell N - 1 \geq 2$. Then $p \nmid 30\ell N$; hence $p \geq 7$, $p \nmid N d_K$ (as p is odd), $p \neq \ell$, and $p \leq 30\ell N$. Choose a prime w of K above p and put $q = q_w$, a power of p, hence prime to ℓN; put $\mathrm{Eis}(z) = q^{-e} z + 1 + q^e z^{-1}$ for $z \in \mathbb{C}^\times$.

Step 3: the congruence integer. Let $n = \varphi(N)$, let $Z \subset \mathbb{C}^\times$ be the group of n-th roots of unity and $z\colon Z \to \mathbb{C}$ the inclusion. Every $\sigma \in \mathrm{Aut}(\mathbb{C})$ maps Z bijectively onto itself, so $u_\sigma = \sigma|_Z$ satisfies $z(u_\sigma(o)) = \sigma(z(o))$. By Proposition 38.6 applied to (e, N, p, w, Z, z) there is a nonzero integer M with

$$\log |M| \leq c\, n\, \big(N(e+1)\big)^A \log p$$

such that items 1 and 2 of Proposition 38.6 hold for every odd prime $\neq p$, in particular for ℓ.

Step 4: a Frobenius element and the Eisenstein trace. Choose an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ (both fields are algebraically closed of characteristic 0 and of the cardinality of the continuum), a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above w and an arithmetic Frobenius $\sigma \in G_K$ at $\bar{w}$ (the decomposition group maps onto the Galois group of the residue field extension). As $p \nmid \ell N$, reduction modulo $\bar{w}$ is injective on the roots of unity of order dividing $\ell^j N$ for every $j \geq 1$, and σ acts on the residue field as $x \mapsto x^q$; hence $\sigma(\zeta) = \zeta^q$ for all these roots of unity, so $\chi(\sigma) = \chi(q)$, $\chi_{\mathrm{cyc}}(\sigma) = q$ and $\Psi_{\chi,e}(\sigma) = \chi(q) q^e$. Put $\tau = \sigma^{-1} \in G_K$ and

$$t = \Psi_{\chi,e}(\tau) + 1 + \Psi_{\chi,e}(\tau)^{-1} = q^{-e}\chi(q)^{-1} + 1 + q^e \chi(q).$$

Since $\chi(q)$ is a value of a character of $(\mathbb{Z}/N\mathbb{Z})^\times$, $\chi(q)^n = 1$, so $z_0 = \iota(\chi(q))^{-1}$ lies in Z, and $\iota^{-1}(\mathrm{Eis}(z_0)) = t$ because ι^{-1} is a field isomorphism fixing q.

Step 5: the hypothesis of the one-character bound. Let $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ be admissible of stable type for (ι, e, N); then it is admissible of weight e and level N. Item 1 of Proposition 38.6 for the family with $X_{z_0} = \{\rho\}$ and $X_o = \emptyset$ for $o \neq z_0$ gives $\mathrm{tr}\,\rho(\tau) \neq \iota^{-1}(\mathrm{Eis}(z_0)) = t$.

Step 6: one character. By Steps 1 and 5, Proposition 46.2 applies to the datum of Step 1, to K, ι and τ: the group $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length, which is the first assertion, and there is a finite set X of pairwise non-isomorphic representations admissible of stable type for (ι, e, N), hence of weight e and level N, with

$$\nu_{\mathcal{O}}(\chi, e) \leq 2 \sum_{\rho \in X} v_\ell\big(\mathrm{tr}\,\rho(\tau) - t\big).$$

Item 2 of Proposition 38.6 for the family with $X_{z_0} = X$ and $X_o = \emptyset$ for $o \neq z_0$ gives $v_\ell(M) \geq \sum_{\rho\in X} v_\ell(\mathrm{tr}\,\rho(\tau) - t)$, so $\nu_{\mathcal{O}}(\chi, e) \leq 2v_\ell(M)$.

Step 7: the estimate. As $\ell^{v_\ell(M)}$ divides M, $v_\ell(M)\log\ell \leq \log|M|$. With Step 3,

$$\nu_{\mathcal{O}}(\chi, e)\log\ell \leq 2\log|M| \leq 2c\,n\,\big(N(e+1)\big)^A \log p \leq 60c\,X_0^{A+2} \leq X_0^C = (\ell N_{\mathfrak{h}} e)^C.$$

This is the claim. □

Lemma 38.33. *Let $\psi \in \mathcal{P}$, let $\mathfrak{h}$ be a Sha-host of ψ, let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring and $e \geq 1$ an integer, and let $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$ with $R_1(\ell, \chi) \leq 2^{c_2(\chi)}$. Then $(\ell, e, N_{\mathfrak{h}}, \chi, o_\psi, N_\psi)$ is a dyadic Eisenstein datum.*

Proof. Write $\mathfrak{h} = (a, q, d)$ and $N = N_{\mathfrak{h}} = \mathrm{lcm}(2^{a+2}, N_\psi)\,qd$. The primes q, d are odd, distinct and prime to N_ψ; hence the odd prime factors of N are q, d and the odd prime factors of N_ψ, and $v_r(N) = v_r(N_\psi)$ for every odd prime $r \mid N_\psi$. Taking p-components is multiplicative, so for every prime p the components χ'_p and χ''_p are powers of χ_p. By Lemma 38.34, items 1 and 2, χ_2 has 2-power order, $\chi_q^2 = \chi_d^2 = \mathbf{1}$, and $\chi_r^{o_\psi} = \mathbf{1}$ for every odd prime $r \mid N_\psi$ (the r-component of $\chi_{\mathrm{od}}^{o_\psi} = \mathbf{1}$ is $\chi_r^{o_\psi}$). Put $R = R_1(\ell, \chi)$; since $o_\psi, N_\psi \geq 1$ and $\ell \geq 3$,

$$16\,o_\psi\,\ell^2 N_\psi^2 \leq R \leq 2^{c_2(\chi)}. \tag{38.8}$$

(Dy1)–(Dy3). The prime ℓ is odd by hypothesis; $16 \mid N$ since $a \geq 2$; and $\chi(-1) = (-1)^e$ because $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$.

(Dy4). Let r be an odd prime. If $r \nmid N$, then $\chi'_r = \mathbf{1}$. If $r \in \{q, d\}$, then χ'_r is a power of χ_r and $(\chi'_r)^2 = \mathbf{1}$. Otherwise $r \mid N_\psi$, and χ'_r is a power of χ_r, so $(\chi'_r)^{o_\psi} = \mathbf{1}$. In all cases $(\chi'_r)^{2o_\psi} = \mathbf{1}$.

(Dy5). For $v = \ell$ we have $8o_\psi\ell^2 < 16o_\psi\ell^2N_\psi^2 \leq 2^{c_2(\chi)}$ by (38.8). Let $v \in S_\ell(\chi)$. The component χ''_v is a power of χ_v and has ℓ-power order with ℓ odd. If $v = 2$, it also has 2-power order; if $v \in \{q, d\}$, its square is trivial; in both cases $\chi''_v = \mathbf{1}$, which is excluded. So v is an odd prime factor of N other than q, d, hence $v \mid N_\psi$ and $v \leq N_\psi$, and $8o_\psi v^2 \leq 8o_\psi N_\psi^2 < 16o_\psi\ell^2N_\psi^2 \leq 2^{c_2(\chi)}$.

(Dy6). By (38.8), $2^{c_2(\chi)} \geq 16 \cdot 9 > 2^4$, so $c_2(\chi) \geq 4$.

(Dy7). By definition $\vartheta = \prod_r \chi'_r$, the product over the odd primes $r \mid N$, so $\vartheta^2 = \prod_r (\chi'_r)^2$. The factors at $r \in \{q, d\}$ are trivial (proof of (Dy4)), so $\vartheta^2 = \prod_r (\chi'_r)^2$ over the odd primes $r \mid N_\psi$, and χ'_r is a character of $(\mathbb{Z}/r^{v_r(N_\psi)}\mathbb{Z})^\times$ since $v_r(N) = v_r(N_\psi)$. Hence $\vartheta^2(u) = 1$ for every

$u \in (\mathbb{Z}/N\mathbb{Z})^\times$ with $u \equiv 1 \pmod{N_\psi}$, that is, ϑ^2 is induced from a character modulo N_ψ, and its conductor divides N_ψ [266]. Finally, by (38.8),

$$2\,\ell\,N_\psi\,4^{n_0(\ell,\chi)} \le 16\,o_\psi\,\ell^2 N_\psi^2\,4^{n_0(\ell,\chi)} = R \le 2^{c_2(\chi)}.$$

So (Dy7) holds with $m = N_\psi$, and $(\ell, e, N, \chi, o_\psi, N_\psi)$ is a dyadic Eisenstein datum. □

Lemma 38.34. *Let $\psi \in \mathcal{P}$, let $\mathfrak{h} = (a, q, d)$ be a Sha-host of ψ, let $\mathcal{O}$ be a coefficient ring and let χ be a Dirichlet character modulo $N_\mathfrak{h}$ with values in $\mathcal{O}^\times$ such that $H_\mathfrak{h} \subseteq \ker\chi$. Write $\chi = \prod_{p|N_\mathfrak{h}} \chi_p$, with χ_p a character of $(\mathbb{Z}/p^{v_p(N_\mathfrak{h})}\mathbb{Z})^\times$ (the component of χ at p), and let $\chi_{\mathrm{od}} = \prod_{p|N_\psi,\ p \text{ odd}} \chi_p$. Then:*

1. *χ_2 has 2-power order, and $\chi_q^2 = \chi_d^2 = \mathbf{1}$;*
2. *$\chi_{\mathrm{od}}^{o_\psi} = \mathbf{1}$;*
3. *if ℓ is an odd prime with $\ell \notin \{q, d\}$ and $\chi^{(\ell)}$ has odd order, then $\chi(u) = 1$ for every $u \in (\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times$ with $u \equiv 1 \pmod{N_\psi}$; that is, χ is the composite of the reduction $(\mathbb{Z}/N_\mathfrak{h}\mathbb{Z})^\times \to (\mathbb{Z}/N_\psi\mathbb{Z})^\times$ with a Dirichlet character modulo N_ψ.*

Proof. Write $N = N_\mathfrak{h} = \mathrm{lcm}(2^{a+2}, N_\psi)\,qd$. The primes $q \equiv 3 \pmod 8$ and $d \equiv 7 \pmod{16}$ are distinct, odd and prime to N_ψ, so $v_q(N) = v_d(N) = 1$, the odd primes dividing N other than q, d are those dividing N_ψ, and $v_p(N) = v_p(N_\psi)$ for them. The decomposition $\chi = \prod_p \chi_p$ is that of the Chinese remainder theorem; taking components is multiplicative.

Item 1. The group $(\mathbb{Z}/2^{v_2(N)}\mathbb{Z})^\times$ is a 2-group, so χ_2 has 2-power order. Let v be a square in $(\mathbb{Z}/q\mathbb{Z})^\times$ and let $u \in (\mathbb{Z}/N\mathbb{Z})^\times$ with $u \equiv 1 \pmod{N/q}$ and $u \equiv v \pmod q$. Since 2^{a+2}, N_ψ and d divide N/q, we have $u \equiv 1 \pmod{2^{a+2}}$, $\psi(u) = 1$, u is a square modulo d, and u is a square modulo q; so $u \in H_\mathfrak{h}$ and $\chi_q(v) = \chi(u) = 1$. Thus χ_q is trivial on the subgroup of squares, which has index 2, and $\chi_q^2 = \mathbf{1}$. In the same way $\chi_d^2 = \mathbf{1}$.

Item 2. Let U be the subgroup of $u \in (\mathbb{Z}/N\mathbb{Z})^\times$ with $u \equiv 1$ modulo $2^{v_2(N)}qd$; on U all components other than those at the odd primes dividing N_ψ are trivial, so $\chi|_U = \chi_{\mathrm{od}}|_U$, and χ_{od} is determined by $\chi_{\mathrm{od}}|_U$ (Chinese remainder theorem). An element $u \in U$ satisfies $u \equiv 1 \pmod{2^{a+2}}$ and is a square modulo q and d, so $u \in H_\mathfrak{h}$ if and only if $\psi(u) = 1$. Hence $\chi_{\mathrm{od}}|_U$ is trivial on $U \cap \ker\psi$ and factors through $\psi(U)$, a subgroup of the cyclic group of order o_ψ; so $\chi_{\mathrm{od}}(u)^{o_\psi} = 1$ for $u \in U$, and $\chi_{\mathrm{od}}^{o_\psi} = \mathbf{1}$.

Item 3. Write $\chi = \chi'\chi''$ with χ' of order prime to ℓ and χ'' of ℓ-power order; both are powers of χ. By definition $\chi^{(\ell)} = \chi' \cdot (\chi'_\ell)^{-1}$, where χ'_ℓ is the component of χ' at ℓ (trivial if $\ell \nmid N$). Let $p \in \{2, q, d\}$; then $p \ne \ell$, as ℓ is odd and $\ell \notin \{q, d\}$. The component χ''_p is a power of χ_p, so its order divides the 2-power order of χ_p (item 1), and it has ℓ-power order with ℓ odd; hence $\chi''_p = \mathbf{1}$ and $\chi'_p = \chi_p$. The component of $(\chi'_\ell)^{-1}$ at $p \ne \ell$ is trivial, so the component of $\chi^{(\ell)}$ at p is χ_p. As $\chi^{(\ell)}$ has odd order, so has χ_p; having also 2-power order, $\chi_p = \mathbf{1}$. Now let $u \equiv 1 \pmod{N_\psi}$. For every odd prime $p \mid N_\psi$, $u \equiv 1 \pmod{p^{v_p(N)}}$, so $\chi_p(u) = 1$; and $\chi_2(u) = \chi_q(u) = \chi_d(u) = 1$. Hence $\chi(u) = 1$. The reduction map $(\mathbb{Z}/N\mathbb{Z})^\times \to (\mathbb{Z}/N_\psi\mathbb{Z})^\times$ is surjective with kernel the classes $u \equiv 1 \pmod{N_\psi}$, so χ factors through it. □

Proposition 38.35. *Let $\psi \in \mathcal{P}$. There is an integer $C \ge 0$ such that for every Sha-host $\mathfrak{h}$ of ψ, every integer $t \ge 1$ at which $\mathfrak{h}$ is big, every odd prime ℓ, every coefficient ring $\mathcal{O}$, every integer e with $0 < e < t$ and every $\chi \in X_\mathfrak{h}(\mathcal{O}, e)$ such that (ℓ, e) is in case (V) and $2^{c_2(\chi)} < R_1(\ell, \chi)$, the group $\mathrm{Sha}^1_{\ell N_\mathfrak{h}}(\chi, e)$ has finite length and*

$$\nu_\mathcal{O}(\chi, e)\log\ell \le (\ell N_\mathfrak{h} e)^C.$$

Proof. Constants. Let $r_\psi = \max B_\psi$ (B_ψ is finite and contains 3). For $\ell \in B_\psi$ let $c_\ell \ge 1$ be the constant of Theorem 40.1 for ℓ, and $c_B = \max_{\ell \in B_\psi} c_\ell$. Put

$$D_1 = 32\, o_\psi^2\, (r_\psi N_\psi)^2\, r_\psi^{2\varphi(4o_\psi)}, \qquad D_2 = r_\psi D_1, \qquad D_3 = (D_2+1)(2D_2)^{c_B}, \qquad C = D_3 + D_2 + 3.$$

These depend only on ψ. Fix $\mathfrak{h} = (a,q,d)$, t, ℓ, $\mathcal{O}$, e and χ as in the statement and write $N = N_\mathfrak{h}$. Case (V) means $\ell \in B_\psi$ and $e = 1$. Since $\mathfrak{h}$ is big at $t \ge 1$, $\min(q,d) > 2t+1 \ge 3$ and $\min(q,d)$ exceeds each of $o_\psi, N_\psi, p_K(\psi), h^*(\psi), p_1(\psi)$; as ℓ is 3 or a prime factor of their product, $\ell < \min(q,d)$, so $\ell \notin \{q,d\}$, and $3 \le \ell \le r_\psi$.

The order of χ. Write $\chi = \prod_{p \mid N} \chi_p$ and χ_{od} as in Lemma 38.34, so that $\chi = \chi_2\, \chi_{\mathrm{od}}\, \chi_q\, \chi_d$. By definition $2^{c_2(\chi)}$ is the conductor of χ_2, so χ_2 factors through $(\mathbb{Z}/2^{c_2(\chi)}\mathbb{Z})^\times$, a group of order at most $2^{c_2(\chi)}$. By items 1 and 2 of Lemma 38.34, $\chi_q^2 = \chi_d^2 = \mathbf{1}$ and $\chi_{\mathrm{od}}^{o_\psi} = \mathbf{1}$. The components commute, so the order of χ divides $\operatorname{lcm}(\operatorname{ord}\chi_2, o_\psi, 2)$ and

$$\operatorname{ord}\chi \le 2\, o_\psi\, 2^{c_2(\chi)} < 2\, o_\psi\, R_1(\ell,\chi).$$

Next we bound $n_0(\ell,\chi)$. Let χ' be the part of χ of order prime to ℓ and $\vartheta = \chi'(\chi_2')^{-1}$, the product of the components of χ' at the odd primes. Since χ' is a power of χ, each component χ_p' is a power of χ_p; so $\vartheta^{2o_\psi} = \mathbf{1}$, the order of ϑ divides $2o_\psi$ and is prime to ℓ, and $L_0 = \operatorname{lcm}(4, \operatorname{ord}\vartheta)$ divides $4o_\psi$ and is prime to ℓ. The order f of ℓ modulo L_0 satisfies $f \le \varphi(L_0) \le \varphi(4o_\psi)$ (Euler; $\varphi(L_0) \le \varphi(4o_\psi)$ as $L_0 \mid 4o_\psi$). As $2^{n_0(\ell,\chi)}$ divides $\ell^f - 1 < \ell^f$, we get $4^{n_0(\ell,\chi)} < \ell^{2f} \le \ell^{2\varphi(4o_\psi)}$. With $\ell \le r_\psi$,

$$\operatorname{ord}\chi < 2\, o_\psi \cdot 16\, o_\psi (\ell N_\psi)^2 \ell^{2\varphi(4o_\psi)} \le D_1.$$

An auxiliary field. Put $m = \ell N$ and let H' be the subgroup of $u \in (\mathbb{Z}/m\mathbb{Z})^\times$ with $u \equiv 1 \pmod{\ell}$ and $\chi(\bar u) = 1$, where $\bar u$ is the image of u in $(\mathbb{Z}/N\mathbb{Z})^\times$. Let $L \subseteq \mathbb{Q}(\zeta_m)$ be the fixed field of $\{\zeta_m \mapsto \zeta_m^u : u \in H'\}$. Then:

- $[L:\mathbb{Q}] = [(\mathbb{Z}/m\mathbb{Z})^\times : H'] \le (\ell-1)\operatorname{ord}\chi < \ell D_1 \le D_2$, since H' is the kernel of $u \mapsto (u \bmod \ell,\ \chi(\bar u))$, whose image has at most $(\ell-1)\operatorname{ord}\chi$ elements;
- $\zeta_\ell = \zeta_m^N \in L$, because ζ_m^N is fixed by $\zeta_m \mapsto \zeta_m^u$ when $u \equiv 1 \pmod{\ell}$; as $\ell \ge 3$, $L \supseteq \mathbb{Q}(\zeta_\ell)$ is totally complex;
- χ is trivial on G_L: an element of G_L acts on $\mathbb{Q}(\zeta_m)$ as $\zeta_m \mapsto \zeta_m^u$ with $u \in H'$, so on $\mathbb{Q}(\zeta_N)$ as $\zeta_N \mapsto \zeta_N^{\bar u}$ with $\chi(\bar u) = 1$;
- $|d_L| \le m^{[L:\mathbb{Q}]}$, by the conductor–discriminant formula, $|d_L|$ being the product of the conductors of the $[L:\mathbb{Q}]$ characters of $\operatorname{Gal}(L/\mathbb{Q})$, each dividing m [266].

The Tate–Shafarevich group of L. By Proposition 38.36 (L totally complex, ℓ odd, $e = 1$) and Theorem 40.1 (L totally complex with $\zeta_\ell \in L$, $e = 1$), $H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(2))$ is finite and

$$\operatorname{len}_\ell(L,1)\log\ell \le \log \#H^2\big(G_{L,S_\ell}, \mathbb{Z}_\ell(2)\big) \le (2|d_L|)^{(2[L:\mathbb{Q}])^{c_\ell}} \le \big(2m^{D_2}\big)^{(2D_2)^{c_B}} \le m^{D_3},$$

using $\operatorname{length}_{\mathbb{Z}_\ell} = \log_\ell \#$, $c_\ell \le c_B$, $2|d_L| \ge 2$, $[L:\mathbb{Q}] \le D_2$ and $2 \le m$. In particular $\operatorname{len}_\ell(L,1) < \infty$.

Conclusion. The group $\mathrm{Sha}^1_{\ell N}(\chi,1)$ is contained in $\mathrm{Sha}^1_\ell(\chi,1)$. By Lemma 38.37 ($L \subseteq \mathbb{Q}(\zeta_m)$, χ trivial on G_L, $e = 1$), $\mathrm{Sha}^1_{\ell N}(\chi,1)$ has finite length and $\nu_\mathcal{O}(\chi,1) \le \operatorname{len}_\ell(L,1) + m\,[L:\mathbb{Q}]$. Hence, with $\log\ell \le \ell \le m$ and $m \ge 48$,

$$\nu_\mathcal{O}(\chi,1)\log\ell \le m^{D_3} + D_2\, m^2 \le m^{D_3+D_2+3} = (\ell N_\mathfrak{h} e)^C,$$

which is the claim. □

Proposition 38.36. *Let L be a totally complex number field, ℓ an odd prime and $e \geq 1$ an integer. Then, in $\mathbb{N} \cup \{\infty\}$,*

$$\operatorname{len}_\ell(L, e) \leq \operatorname{length}_{\mathbb{Z}_\ell} H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(e+1)).$$

Proof. Write $G = G_{L,S_\ell}$, $T = \mathbb{Z}_\ell(e+1)$ and $h = \operatorname{length}_{\mathbb{Z}_\ell} H^2(G, T)$. If $h = \infty$ there is nothing to prove, so let $h < \infty$. The extension $L(\mu_{\ell^\infty})/L$ is unramified outside the places above ℓ and the archimedean places, which are complex; so χ_{cyc} factors through G. For $n \geq 1$ let A_n be $\mathbb{Z}/\ell^n\mathbb{Z}$ with G acting through χ_{cyc}^{-e}, and $T_n = T/\ell^n T$; both are finite discrete G-modules with continuous action.

The places. Let S be the set of places above ℓ together with the archimedean places. A complex place does not ramify in any extension, so $G_{L,S} = G$; and for a complex place v the group G_{L_v} is trivial, so $H^i(L_v, M) = 0$ for $i \geq 1$ and every module M. Hence, for $i = 1, 2$ and every discrete G-module M,

$$\operatorname{Sha}^i_S(L, M) = \ker\Big(H^i(G, M) \to \prod_{v \mid \ell} H^i(L_v, M)\Big),$$

and in particular $\operatorname{Sha}^1_\ell(L, e) = \operatorname{Sha}^1_S(L, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e))$.

Duality at finite level. The Cartier dual $A_n^\vee = \operatorname{Hom}(A_n, \mu_{\ell^n})$ is $\mathbb{Z}/\ell^n\mathbb{Z}$ with G acting through $\chi_{\mathrm{cyc}} \cdot \chi_{\mathrm{cyc}}^{e}$, that is, $A_n^\vee \cong T_n$. By Theorem B.34 (L has no real place, S contains the places above ℓ and the archimedean places, A_n is a finite $\mathbb{Z}/\ell^n\mathbb{Z}$-module with continuous action of $G_{L,S} = G$), $\operatorname{Sha}^1_S(L, A_n)$ and $\operatorname{Sha}^2_S(L, T_n)$ are finite of the same order, so

$$\operatorname{length} \operatorname{Sha}^1_S(L, A_n) = \operatorname{length} \operatorname{Sha}^2_S(L, T_n) \leq \operatorname{length} H^2(G, T_n). \tag{38.9}$$

$H^2(G, T_n)$ is a quotient of $H^2(G, T)$. The reductions $T_{m+1} \to T_m$ are surjective and $\varprojlim_m T_m = T$ with its ℓ-adic topology. Each $H^1(G, T_m)$ is finite by Theorem B.34, so by Lemma B.33 (with $i = 2$) the map $\pi\colon H^2(G, T) \to \varprojlim_m H^2(G, T_m)$ induced by the projections is an isomorphism. For $m \geq 1$ the sequence $0 \to T_1 \to T_{m+1} \to T_m \to 0$, whose first map is $x \bmod \ell \mapsto \ell^m x \bmod \ell^{m+1}$, is an exact sequence of finite discrete G-modules; its cohomology sequence gives the exact sequence $H^2(G, T_{m+1}) \to H^2(G, T_m) \to H^3(G, T_1)$, and $H^3(G, T_1) = 0$ by Theorem B.34. So the transition maps of $(H^2(G, T_m))_m$ are surjective, and so is the projection $\varprojlim_m H^2(G, T_m) \to H^2(G, T_n)$: an element y_n extends to a compatible family by choosing preimages $y_{n+1}, y_{n+2}, \ldots$ successively and taking images for $m < n$. The composite of π with this projection is the map induced by $T \to T_n$. Hence $H^2(G, T_n)$ is a quotient of $H^2(G, T)$, and with (38.9)

$$\operatorname{length} \operatorname{Sha}^1_S(L, A_n) \leq h \qquad (n \geq 1). \tag{38.10}$$

Passage to $\mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$. The G-equivariant maps $\iota_n\colon A_n \to \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$, $a \bmod \ell^n \mapsto a/\ell^n$, are injective, compatible with the inclusions $A_n \to A_{n+1}$ given by multiplication by ℓ, and their images exhaust $\mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$. For a profinite group, the cohomology with coefficients in a direct limit of discrete modules is the direct limit of the cohomology groups [222] (Chapter I, Section 2.2, Proposition 8); this applies to G and to each G_{L_v}. Let $P \subseteq \operatorname{Sha}^1_\ell(L, e)$ be the submodule generated by finitely many elements $x_1, \ldots, x_r$. There are n and $y_j \in H^1(G, A_n)$ with $\iota_{n*}(y_j) = x_j$. For each of the finitely many places $v \mid \ell$, the restriction of y_j to $H^1(L_v, A_n)$ maps to the restriction of x_j, which is 0, in $H^1(L_v, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)) = \varinjlim_m H^1(L_v, A_m)$; so it maps

to 0 in $H^1(L_v, A_m)$ for some $m \geq n$. Taking one m for all j and v, the images y_j' of the y_j in $H^1(G, A_m)$ lie in $\mathrm{Sha}^1_S(L, A_m)$, and $\iota_{m*}(y_j') = x_j$. So P is the image under ι_{m*} of a submodule of $\mathrm{Sha}^1_S(L, A_m)$, and length $P \leq h$ by (38.10).

Conclusion. Suppose $\mathrm{len}_\ell(L, e) > h$. Then $\mathrm{Sha}^1_\ell(L, e)$ has a chain of submodules $P_0 \subsetneq P_1 \subsetneq \cdots \subsetneq P_{h+1}$; choose $x_i \in P_i \setminus P_{i-1}$ for $1 \leq i \leq h+1$. As $x_i \notin P_{i-1} \supseteq \langle x_1, \ldots, x_{i-1}\rangle$, the submodules $\langle x_1, \ldots, x_i\rangle$, $0 \leq i \leq h+1$, form a strictly increasing chain in $\langle x_1, \ldots, x_{h+1}\rangle$, which therefore has length at least $h+1$, contradicting the previous step. Hence $\mathrm{len}_\ell(L, e) \leq h$. □

Lemma 38.37. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring, $m \geq 1$ an integer, $L \subseteq \mathbb{Q}(\zeta_m)$ a subfield, $N \geq 1$, χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$ that is trivial on G_L, and $e \geq 1$. If $\mathrm{len}_\ell(L, e) < \infty$, then $\mathrm{Sha}^1_\ell(\chi, e)$ has finite length and*

$$\mathrm{length}_{\mathcal{O}} \mathrm{Sha}^1_\ell(\chi, e) \leq e_{\mathcal{O}}(\mathrm{len}_\ell(L, e) + e\, m\, [L : \mathbb{Q}]).$$

Proof. Put $M = \mathcal{O}^\vee(\Psi_{\chi,e}^{-1})$. As χ is trivial on G_L, the group G_L acts on M through χ_{cyc}^{-e}, so as a G_L-module $M = \mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$. The field L is Galois over $\mathbb{Q}$, as a subfield of the abelian field $\mathbb{Q}(\zeta_m)$. Let res: $H^1(\mathbb{Q}, M) \to H^1(L, M)$ be the restriction.

The kernel. By inflation–restriction, $\ker(\mathrm{res}) \cong H^1(\mathrm{Gal}(L/\mathbb{Q}), M^{G_L})$. Choose $g_0 \in G_{\mathbb{Q}(\zeta_m)} \subseteq G_L$ with $\chi_{\mathrm{cyc}}(g_0) = 1 + m$: the compatible system $(1 + m \bmod m\ell^n)_{n\geq 1}$ is an element of $\varprojlim_n (\mathbb{Z}/m\ell^n\mathbb{Z})^\times = \mathrm{Gal}(\mathbb{Q}(\zeta_m, \mu_{\ell^\infty})/\mathbb{Q})$ fixing ζ_m; take any lift to $G_\mathbb{Q}$. For $m_1 \in M^{G_L}$ we get $((1+m)^{-e} - 1)m_1 = 0$. The integer $u_1 = (1+m)^e - 1 \geq 1$ satisfies $(1+m)^{-e} - 1 = -(1+m)^{-e}u_1$ with $(1+m)^{-e} \in \mathbb{Z}_\ell^\times$; writing $u_1 = \ell^{b_1}u'$ with $\ell \nmid u'$, we get $\ell^{b_1}m_1 = 0$. So $M^{G_L} \subseteq M[\ell^{b_1}] \cong \mathcal{O}/\ell^{b_1}\mathcal{O}$, of length $b_1 e_{\mathcal{O}} \leq e\, m\, e_{\mathcal{O}}$.

For a finite group Γ and a finite $\mathcal{O}[\Gamma]$-module A, evaluation $z \mapsto (z(\gamma))_{\gamma\in\Gamma}$ embeds the cocycles $\mathcal{O}$-linearly into $A^{|\Gamma|}$, so length $H^1(\Gamma, A) \leq |\Gamma|$ length A. Hence $\mathrm{length}_{\mathcal{O}} \ker(\mathrm{res}) \leq [L : \mathbb{Q}]\, e\, m\, e_{\mathcal{O}}$.

The image. Let $[z] \in \mathrm{Sha}^1_\ell(\chi, e)$. Conjugation by $G_\mathbb{Q}$ acts trivially on $H^1(\mathbb{Q}, M)$, so $[z]$ restricts to zero on every inertia subgroup of $G_\mathbb{Q}$ and on every decomposition subgroup at ℓ. The inertia and decomposition groups of G_L are the intersections of those of $G_\mathbb{Q}$ with G_L; so res$[z]$ is unramified at every place of L and trivial at the places above ℓ. Let L_{S_ℓ} be the maximal extension of L unramified outside the places above ℓ; M is unramified outside ℓ as a G_L-module, and $\mathrm{Gal}(\overline{\mathbb{Q}}/L_{S_\ell})$ is the closed normal subgroup of G_L generated by the inertia groups at the places not above ℓ. Restricted to it, res$[z]$ is a homomorphism vanishing on these generators, hence zero; so res$[z]$ is the inflation of a unique class of $H^1(G_{L,S_\ell}, M)$, locally trivial at the places above ℓ. Thus res maps $\mathrm{Sha}^1_\ell(\chi, e)$ $\mathcal{O}$-linearly into

$$\mathrm{Sha}_{\mathcal{O}} = \ker\Big(H^1(G_{L,S_\ell}, M) \to \prod_{v|\ell} H^1(L_v, M)\Big) \cong \mathrm{Sha}^1_\ell(L, e) \otimes_{\mathbb{Z}_\ell} \mathcal{O},$$

the isomorphism because $\mathcal{O}$ is free of rank $r = [\mathcal{O} : \mathbb{Z}_\ell]$ over $\mathbb{Z}_\ell$ and cohomology commutes with finite direct sums. As $\mathrm{len}_\ell(L, e) < \infty$, $\mathrm{Sha}^1_\ell(L, e)$ has order $\ell^{\mathrm{len}_\ell(L,e)}$, $\mathrm{Sha}_{\mathcal{O}}$ has order $\ell^{r\,\mathrm{len}_\ell(L,e)}$, and $\mathrm{length}_{\mathcal{O}} \mathrm{Sha}_{\mathcal{O}} = r\,\mathrm{len}_\ell(L, e)/f_{\mathcal{O}} = e_{\mathcal{O}}\,\mathrm{len}_\ell(L, e)$.

Conclusion. From the exact sequence $0 \to \ker(\mathrm{res}) \cap \mathrm{Sha}^1_\ell(\chi, e) \to \mathrm{Sha}^1_\ell(\chi, e) \to \mathrm{Sha}_{\mathcal{O}}$, the group $\mathrm{Sha}^1_\ell(\chi, e)$ has finite length, at most $[L : \mathbb{Q}]\, e\, m\, e_{\mathcal{O}} + e_{\mathcal{O}}\,\mathrm{len}_\ell(L, e)$. □

Proposition 38.38. *Let $\psi \in \mathcal{P}$, $\ell \in B_\psi$ and let $j \geq 0$ be an integer. There is an integer $C \geq 0$ such that the following holds for every Sha-host $\mathfrak{h}$ of ψ, every integer $t \geq 2$ at which $\mathfrak{h}$ is big, and every real B such that $\mathrm{V}_\ell(\mathbb{Q}(\zeta_{\ell^{j+1}N_\psi}); t, B)$ holds. For every coefficient ring $\mathcal{O}$ and every*

Dirichlet character χ modulo $N_{\mathfrak{h}}$ with values in $\mathcal{O}^{\times}$ such that $H_{\mathfrak{h}} \subseteq \ker \chi$ and $\chi^{(\ell)}$ has odd order, the groups $\mathrm{Sha}^1_{\ell N_{\mathfrak{h}}}(\chi, e)$ with $1 \le e < t$ have finite length and

$$\sum_{e=1}^{t-1} \nu_{\mathcal{O}}(\chi, e) \le B + (N_{\mathfrak{h}} t)^C.$$

Proof. Put $m = \ell^{j+1} N_\psi$, $L = \mathbb{Q}(\zeta_m)$ and $C = 2m + 2$; these depend only on (ψ, ℓ, j). Fix $\mathfrak{h} = (a, q, d)$, t, B, $\mathcal{O}$ and χ as in the statement, and write $N = N_{\mathfrak{h}}$.

The character is trivial on G_L. The set B_ψ consists of odd primes: 3, and prime factors of $o_\psi N_\psi\, p_K(\psi)\, h^*(\psi)\, p_1(\psi)$. Since $\mathfrak{h}$ is big at $t \ge 2$, $\min(q, d) > 2t + 1 \ge 5$ and $\min(q, d)$ exceeds each of $o_\psi, N_\psi, p_K(\psi), h^*(\psi), p_1(\psi)$; so $\ell < \min(q, d)$, and ℓ is odd with $\ell \notin \{q, d\}$. By item 3 of Lemma 38.34, $\chi(u) = 1$ whenever $u \equiv 1 \pmod{N_\psi}$. As a character of $G_{\mathbb{Q}}$, χ factors through $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q}) \cong (\mathbb{Z}/N\mathbb{Z})^{\times}$, $\sigma_u \colon \zeta_N \mapsto \zeta_N^u$; an element of G_L fixes ζ_{N_ψ}, so it acts on $\mathbb{Q}(\zeta_N)$ as some σ_u with $u \equiv 1 \pmod{N_\psi}$. Hence χ is trivial on G_L.

One twist. Let $1 \le e < t$. By hypothesis $\mathrm{V}_\ell(L; t, B)$ holds, so $\mathrm{len}_\ell(L, e) < \infty$. The group $\mathrm{Sha}^1_{\ell N}(\chi, e)$ is contained in $\mathrm{Sha}^1_{\ell}(\chi, e)$ (it satisfies more local conditions). By Lemma 38.37 (for $L = \mathbb{Q}(\zeta_m)$, $[L : \mathbb{Q}] = \varphi(m) \le m$), $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length and

$$\nu_{\mathcal{O}}(\chi, e) = \frac{\mathrm{length}_{\mathcal{O}} \mathrm{Sha}^1_{\ell N}(\chi, e)}{e_{\mathcal{O}}} \le \mathrm{len}_\ell(L, e) + e\, m^2.$$

Summation. Summing over $1 \le e < t$ and using $\sum_{e=1}^{t-1} \mathrm{len}_\ell(L, e) \le B$,

$$\sum_{e=1}^{t-1} \nu_{\mathcal{O}}(\chi, e) \le B + m^2 \sum_{e=1}^{t-1} e \le B + m^2 t^2 \le B + (Nt)^C.$$

This is the claim, with the integer $C = 2m + 2 \ge 0$ depending only on (ψ, ℓ, j). □

39 The prime 2 and the bad primes on windows

This section proves Proposition 39.2. For every pair of primes (q, d) of the shape of a window pair with $\log(qd) \le X^{\varepsilon/(4J)}$ it gives a range $[Y, Y^2]$ inside $[X^{1/J}, X^{1/2}]$ on which, for every x in the range and $t = \lfloor x^{401} \rfloor$, the Tate–Shafarevich groups at 2 of the fields of the Sha-hosts, and at each bad prime ℓ those of one cyclotomic field $\mathbb{Q}(\zeta_{\ell^{j\ell+1} N_\psi})$, have total length at most $\exp(x^{4\varepsilon/5})$ over the twists $1 \le k < t$. It is used in the proof of Theorem 36.4, directly at the prime 2 and through Proposition 36.10 at the bad primes, and it is the reason why the window Sha bound holds on windows.

The tool is twist control (Definition 39.1). A field has twist control at ℓ with rank R if over every cyclotomic ℓ-layer the length of the group at the twist e grows at most linearly in the index of the layer and in D, as long as e keeps an ℓ-adic distance at least ℓ^{-D} from at most R fixed ℓ-adic numbers (Tw1), and is bounded in general by second cohomology at one fixed layer (Tw2). Twist control follows from a bounded rank of the unramified characters of the cyclotomic ℓ-tower (Proposition 39.8), through the structure of a finitely generated $\mathbb{Z}_\ell$-module with an endomorphism that is unipotent modulo ℓ (Lemma 39.9). The bounded rank comes from the bounded ℓ-rank of class groups along the cyclotomic tower of an abelian field, a consequence of the theorem of Ferrero and Washington [90] (Lemma 39.5, Lemma 39.7). At 2 the control must be uniform in the window pair. The fields of the pair lie in a cyclotomic

2-layer over $\mathbb{Q}(\zeta_{N_\psi})^\psi(i,\sqrt{-q},\sqrt{-d})$ (Lemma 39.4), and the 2-rank of the unramified characters of its cyclotomic tower is bounded independently of (q,d) (Lemma 39.12, Proposition 39.11).

The windows come from the exceptional twists. Below X^{401} at most R twists, the total rank over 2 and the bad primes, lie ℓ-adically close to one of the fixed points, and at them only the bound of Section 40 is available, doubly exponential in the twist. A lemma on separation of scales (Lemma 39.3) chooses Y so that every exceptional twist below x^{401}, for $x \in [Y, Y^2]$, lies below a small power $x^{\varepsilon_{\mathrm{H}}}$, where that bound is still at most $\exp(O(x^{3\varepsilon/4}))$. The argument produces one such range inside every $[X^{1/J}, X^{1/2}]$, not a bound at every large scale; this is why the bound is stated on windows.

Definition 39.1. Let ℓ be a prime and L a number field. For an integer $m \geq 0$, a **cyclotomic ℓ-layer of degree ℓ^m over L** is a field extension L'/L such that $L' = L(\zeta)$ for some $k \geq 0$ and some primitive ℓ^k-th root of unity $\zeta \in L'$, and $[L' : L] = \ell^m$. For an integer $R \geq 1$ put

$$j_\ell(R) = \lfloor \log_\ell R \rfloor + 3.$$

For $n \in \mathbb{Z}$, $\mathbb{Z}_\ell(n)$ is $\mathbb{Z}_\ell$ with G_{L,S_ℓ} acting through χ_{cyc}^n (the cyclotomic character factors through G_{L,S_ℓ}), and $H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(n))$ is continuous cohomology; its length as a $\mathbb{Z}_\ell$-module lies in $\mathbb{N} \cup \{\infty\}$, with $\infty + n = \infty$.

Let $R \geq 1$ be an integer. The field L has **twist control at ℓ with rank R** if the following two conditions hold.

(Tw1) *Roots.* There are a field $K \supseteq \mathbb{Q}_\ell$ with an ultrametric absolute value $|\cdot|$ extending the ℓ-adic absolute value, an integer $c_\mu \geq 0$ such that L contains a primitive ℓ^{c_μ}-th root of unity, an integer R' with $0 \leq R' \leq R$ and elements $s_1, \dots, s_{R'} \in K$, such that for all integers $e \geq 1$, $m \geq 0$, $D \geq 0$ with

$$|s_i - e| \geq \ell^{-D} \qquad (1 \leq i \leq R')$$

and every cyclotomic ℓ-layer L' of degree ℓ^m over L,

$$\mathrm{len}_\ell(L', e) \leq R'\big(\max(m, j_\ell(R)) + c_\mu + D\big).$$

(Tw2) *Second bound.* For all integers $e \geq 1$ and $m \geq 0$, every cyclotomic ℓ-layer L' of degree ℓ^m over L and every cyclotomic ℓ-layer L'' of degree $\ell^{j_\ell(R)}$ over L,

$$\mathrm{len}_\ell(L', e) \leq \mathrm{length}_{\mathbb{Z}_\ell} H^2\big(G_{L'',S_\ell}, \mathbb{Z}_\ell(e+1)\big) + R\max\big(m - j_\ell(R), 0\big).$$

Proposition 39.2. *Let $\psi \in \mathcal{P}$, $\varepsilon \in (0, 1/52)$ and let e_ε be a page function. There are a real $J \geq 1$, a real X_0 and integers $j_\ell \geq 0$ for $\ell \in B_\psi$ such that for every $X \geq X_0$ and every pair of primes (q,d) with*

$$q \equiv 3 \pmod 8, \qquad d \equiv 7 \pmod{16}, \qquad \gcd(qd, N_\psi) = 1, \qquad \log(qd) \leq X^{\varepsilon/(4J)},$$

there is a real Y with $X^{1/J} \leq Y$ and $Y^2 \leq X$ such that for every $x \in [Y, Y^2]$, with $t = \lfloor x^{401} \rfloor$ and $B = \exp(x^{4\varepsilon/5})$:

1. *every $(\psi, e_\varepsilon(x), q, d)$-field E satisfies $\mathrm{V}_2(E; t, B)$;*
2. *for every $\ell \in B_\psi$ the cyclotomic field $\mathbb{Q}(\zeta_{\ell^{j_\ell+1}N_\psi})$ satisfies $\mathrm{V}_\ell\big(\mathbb{Q}(\zeta_{\ell^{j_\ell+1}N_\psi}); t, B\big)$.*

Proof. Fix $\psi \in \mathcal{P}$, $\varepsilon \in (0, 1/52)$ and a page function e_ε. We first outline the argument. At a prime $\ell \in \{2\} \cup B_\psi$ the Tate–Shafarevich group at the twist k is small, of size $O(\log x)$, unless k is ℓ-adically close to one of at most R fixed ℓ-adic numbers (the points of (Tw1)); in $[1, X^{401}]$ there are at most R such exceptional twists, and the scale Y is chosen so that every exceptional twist below x^{401} is in fact below $x^{\varepsilon_{\mathrm{H}}}$ for a small exponent ε_{H}, where the crude bound Theorem 40.1 suffices.

Step 1: the inputs and the constants.

- For $\ell \in B_\psi$ the field $\mathbb{Q}(\zeta_{\ell N_\psi})$ is abelian over $\mathbb{Q}$ and contains a primitive ℓ-th root of unity. By Lemma 39.5 it satisfies the hypothesis of Proposition 39.6, which gives an integer $R_\ell \geq 1$ such that $\mathbb{Q}(\zeta_{\ell N_\psi})$ has twist control at ℓ with rank R_ℓ. Put $j_\ell = j_\ell(R_\ell) \geq 3$; these are the integers of the statement.

- The field $\mathbb{Q}(\zeta_{N_\psi})^\psi(i)$, with $\mathbb{Q}(\zeta_{N_\psi})^\psi$ as in Proposition 39.11, lies in $\mathbb{Q}(\zeta_{\mathrm{lcm}(4,N_\psi)})$, so it is abelian over $\mathbb{Q}$, and it contains i. By Lemma 39.5 for $\ell = 2$ it satisfies the hypothesis of Proposition 39.11, which gives an integer $R_2 \geq 1$ such that for every pair of primes (q, d) with $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$, $\gcd(qd, N_\psi) = 1$ the field $L_{q,d} = \mathbb{Q}(\zeta_{N_\psi})^\psi(i, \sqrt{-q}, \sqrt{-d})$ has twist control at 2 with rank R_2. Put $j_2 = j_2(R_2)$.

- For $\ell \in \{2\} \cup B_\psi$ let $C_\ell \geq 1$ be the constant of Theorem 40.1 and $C_{\mathrm{H}} = \max_\ell C_\ell$. The bound of Theorem 40.1 holds with C_{H} in place of C_ℓ, because $2|d_L| > 1$ and $2e[L : \mathbb{Q}] \geq 1$ make $(2|d_L|)^{(2e[L:\mathbb{Q}])^C}$ increasing in C.

- Put $R = R_2 + \sum_{\ell \in B_\psi} R_\ell$, $\varepsilon_{\mathrm{H}} = \varepsilon/(2C_{\mathrm{H}})$, $\beta = 401/\varepsilon_{\mathrm{H}} = 802C_{\mathrm{H}}/\varepsilon \geq 1$ and $J = 2^{R+2}\beta^R \geq 1$.

Step 2: the fields at the odd primes. Let $\ell \in B_\psi$, write $N_\psi = \ell^v N'$ with $\ell \nmid N'$, and put $L_\ell = \mathbb{Q}(\zeta_{\ell^{j_\ell+1} N_\psi})$. Adjoining a primitive ℓ^{v+1+j_ℓ}-th root of unity to $\mathbb{Q}(\zeta_{\ell N_\psi}) = \mathbb{Q}(\zeta_{\ell^{v+1}N'})$ gives L_ℓ, of degree $\varphi(\ell^{v+1+j_\ell})/\varphi(\ell^{v+1}) = \ell^{j_\ell}$ over it; so L_ℓ is a cyclotomic ℓ-layer of degree ℓ^{j_ℓ} over $\mathbb{Q}(\zeta_{\ell N_\psi})$. It contains a primitive ℓ-th root of unity and, as $\ell \geq 3$, has no real embedding. Put $n_\ell = [L_\ell : \mathbb{Q}]$ and $\delta_\ell = \log(2|d_{L_\ell}|) > 0$. Let $c_{\mu,\ell}$, $R'_\ell \leq R_\ell$ and the points $s_{\ell,1}, \dots, s_{\ell,R'_\ell}$ be the data of (Tw1) for $\mathbb{Q}(\zeta_{\ell N_\psi})$.

Step 3: the fields at 2. Let (q, d) be a pair as in the statement and $L = L_{q,d}$. By item 1 of Lemma 39.4, $i \in L$, $[L : \mathbb{Q}] \leq 8o_\psi$ and $L \subseteq \mathbb{Q}(\zeta_{4N_\psi qd})$. If L contains a primitive 2^c-th root of unity with $c \geq 1$, then $2^{c-1} = \varphi(2^c) \leq [L : \mathbb{Q}]$, so $c \leq 2^c \leq 16o_\psi$. Let $c_{\max}$ be the largest integer with $\mu_{2^{c_{\max}}} \subseteq L$; then $2 \leq c_{\max} \leq 16o_\psi$. The cyclotomic character identifies $\mathrm{Gal}(L(\mu_{2^\infty})/L)$ with a closed subgroup of $1 + 2^{c_{\max}}\mathbb{Z}_2$ not contained in $1 + 2^{c_{\max}+1}\mathbb{Z}_2$; as $c_{\max} \geq 2$, the closed subgroups of $1 + 2^{c_{\max}}\mathbb{Z}_2 \cong \mathbb{Z}_2$ are $\{1\}$ and the $1 + 2^k\mathbb{Z}_2$ with $k \geq c_{\max}$, so the image is all of $1 + 2^{c_{\max}}\mathbb{Z}_2$, and $L'' = L(\zeta_{2^{c_{\max}+j_2}})$ has degree 2^{j_2} over L: it is a cyclotomic 2-layer of degree 2^{j_2} over L. It contains i, so it has no real embedding. Its degree is $n'' \leq n_2 := 2^{j_2} \cdot 8o_\psi$, and $L'' \subseteq \mathbb{Q}(\zeta_{N_*})$ with $N_* = 2^{c_{\max}+j_2} \cdot 4N_\psi qd$. For a subfield L° of $\mathbb{Q}(\zeta_{N_*})$ the tower formula for discriminants gives $|d_{L^\circ}|^{[\mathbb{Q}(\zeta_{N_*}):L^\circ]} \leq |d_{\mathbb{Q}(\zeta_{N_*})}| \leq N_*^{\varphi(N_*)}$ ([266], Chapter 2), so $|d_{L^\circ}| \leq N_*^{[L^\circ:\mathbb{Q}]}$. Hence

$$\log(2|d_{L''}|) \leq \gamma_2 + n_2 \log(qd), \qquad \gamma_2 = \log 2 + n_2\big((16o_\psi + j_2 + 2)\log 2 + \log N_\psi\big). \tag{39.1}$$

Let c_μ, $R' \leq R_2$ and the points $s_1, \dots, s_{R'}$ be the data of (Tw1) for L; by the above, $c_\mu \leq 16o_\psi$.

Step 4: exceptional twists at a scale X. Let $X \geq X_0$, with $X_0 \geq 2$ fixed in Step 7, let (q, d) be as in the statement, and put $Z = \lfloor X^{401} \rfloor \geq 1$. For $\ell \in B_\psi$ (base field $\mathbb{Q}(\zeta_{\ell N_\psi})$, points $s_{\ell,i}$) and for $\ell = 2$ (base field $L_{q,d}$, points s_i) let Exc_ℓ be the set of integers $k \in [1, Z]$ with $|s - k| < \ell^{-b_\ell(Z)}$ for one of the points s at ℓ.

1. $|\mathrm{Exc}_\ell| \le R_\ell$. Let s be one of the points and let $k \ne k'$ in $[1,Z]$ satisfy $|s-k|, |s-k'| < \ell^{-b}$, $b = b_\ell(Z)$. By the ultrametric inequality $|k-k'| < \ell^{-b}$; the absolute value of the nonzero integer $k-k'$ is $\ell^{-v_\ell(k-k')}$, so $\ell^{b+1} \mid k-k'$. But the ordinary absolute value of $k-k'$ is positive and less than $Z < \ell^{b+1}$ by the maximality of b, a contradiction. So each point accounts for at most one element of Exc_ℓ, and there are at most R_ℓ points.

2. For an integer $k \in [1,Z] \setminus \mathrm{Exc}_\ell$, every $m \ge 0$ and every cyclotomic ℓ-layer L' of degree ℓ^m over the base field, (Tw1) applied with $e = k$ and $D = b_\ell(Z)$ gives $\mathrm{len}_\ell(L',k) \le R_\ell\big(\max(m, j_\ell) + c_{\mu,\ell} + b_\ell(Z)\big)$, with $c_{\mu,\ell}$ replaced by c_μ when $\ell = 2$.

Put $\mathrm{Exc} = \mathrm{Exc}_2 \cup \bigcup_{\ell \in B_\psi} \mathrm{Exc}_\ell$; then $|\mathrm{Exc}| \le R$.

Step 5: the choice of Y. Apply Lemma 39.3 to R, β, $U = \log X > 0$ and the set $\{(\log k)/401 : k \in \mathrm{Exc}\}$ of at most R reals. It gives y with $U/J \le y$ and $2y \le U$; put $Y = \exp(y)$, so that $X^{1/J} \le Y$ and $Y^2 \le X$. Let $x \in [Y, Y^2]$ and $k \in \mathrm{Exc}$ with $k \le x^{401}$. Then $u = \log x \in [y, 2y]$ and $(\log k)/401 \le u$, so $\beta(\log k)/401 \le u$, that is $(\log k)/\varepsilon_{\mathrm{H}} \le \log x$:

$$k \in \mathrm{Exc},\ k \le x^{401} \implies k \le x^{\varepsilon_{\mathrm{H}}} \qquad (x \in [Y, Y^2]). \tag{39.2}$$

Step 6: the bound at one twist. Let $x \in [Y, Y^2]$, $t = \lfloor x^{401} \rfloor \ge 1$ and $1 \le k < t$. Since $x \le Y^2 \le X$, $k \le x^{401} \le X^{401}$, so $k \le Z$. Since $X^{1/J} \le x$, $\log X \le J \log x$ and $b_\ell(Z) \le \log Z / \log 2 \le (401/\log 2)\, J \log x \le 579 J \log x$; also $\log(qd) \le X^{\varepsilon/(4J)} \le x^{\varepsilon/4}$. If $k \in \mathrm{Exc}_\ell$ then $k \le x^{\varepsilon_{\mathrm{H}}}$ by (39.2), so $(2kn)^{C_{\mathrm{H}}} \le (2n)^{C_{\mathrm{H}}} x^{\varepsilon/2}$ for every $n \ge 1$. For a finite $\mathbb{Z}_\ell$-module H, $\#H = \ell^{\mathrm{length}\, H}$, so $\mathrm{length}\, H = \log \#H / \log \ell \le 2 \log \#H$.

1. $\ell \in B_\psi$. If $k \notin \mathrm{Exc}_\ell$, Step 4 for $L' = L_\ell$, $m = j_\ell$, gives $\mathrm{len}_\ell(L_\ell, k) \le R_\ell(j_\ell + c_{\mu,\ell} + 579 J \log x)$. If $k \in \mathrm{Exc}_\ell$, (Tw2) with $L' = L'' = L_\ell$ ($m = j_\ell$) and Theorem 40.1 for L_ℓ give

$$\mathrm{len}_\ell(L_\ell, k) \le \mathrm{length}\, H^2\big(G_{L_\ell, S_\ell}, \mathbb{Z}_\ell(k+1)\big) \le 2\exp\big((2kn_\ell)^{C_{\mathrm{H}}} \delta_\ell\big) \le 2\exp\big((2n_\ell)^{C_{\mathrm{H}}} \delta_\ell\, x^{\varepsilon/2}\big).$$

2. $\ell = 2$. Let $a = e_\varepsilon(x)$ and let E be a (ψ, a, q, d)-field. As $x \ge 2$, $2^a \ge x^{2+8\varepsilon} \ge 4$, so $a \ge 2$, and $2^a \le 2x^{2+8\varepsilon} \le 2x^3$, so $a \le 1 + 5\log x$. By item 2 of Lemma 39.4 there is a cyclotomic 2-layer L' of degree 2^m over $L_{q,d}$, $m \le a$, with $\mathrm{len}_2(E,k) \le 1 + \mathrm{len}_2(L',k)$. If $k \notin \mathrm{Exc}_2$, Step 4 gives

$$\mathrm{len}_2(L',k) \le R_2(m + j_2 + c_\mu + 579 J \log x) \le R_2(1 + j_2 + 16 o_\psi) + R_2(5 + 579J)\log x.$$

If $k \in \mathrm{Exc}_2$, (Tw2) with the layer L'' of Step 3, Theorem 40.1 for L'' (no real embedding, $i \in L''$), (39.1) and $\log(qd) \le x^{\varepsilon/4}$ give

$$\begin{aligned}\mathrm{len}_2(L',k) &\le 2\exp\big((2kn'')^{C_{\mathrm{H}}} \log(2|d_{L''}|)\big) + R_2 m \\ &\le 2\exp\big((2n_2)^{C_{\mathrm{H}}} (\gamma_2 + n_2)\, x^{3\varepsilon/4}\big) + R_2(1 + 5\log x).\end{aligned}$$

Put

$$C_{\mathrm{lin}} = \max\big(R_2(6 + j_2 + 16 o_\psi + 579J),\ \max_{\ell \in B_\psi} R_\ell(j_\ell + c_{\mu,\ell} + 579J)\big),$$
$$C_{\mathrm{exp}} = \max\big((2n_2)^{C_{\mathrm{H}}}(\gamma_2 + n_2),\ \max_{\ell \in B_\psi} (2n_\ell)^{C_{\mathrm{H}}} \delta_\ell\big);$$

these depend only on (ψ, ε) (the bounds $c_\mu \le 16 o_\psi$ and $n'' \le n_2$ are uniform in (q,d)). Since $x \ge 1$, $x^{\varepsilon/2} \le x^{3\varepsilon/4}$, and in every case above, for $1 \le k < t$,

$$\mathrm{len}_\ell(L_\ell, k)\ (\ell \in B_\psi),\ \ \mathrm{len}_2(E,k) \ \le\ \Upsilon(x) := 1 + C_{\mathrm{lin}}(1 + \log x) + 2\exp\big(C_{\mathrm{exp}} x^{3\varepsilon/4}\big);$$

in particular all these lengths are finite.

Step 7: the threshold. As $\exp(C_{\exp}x^{3\varepsilon/4}) \geq 1$, $\Upsilon(x) \leq (3 + C_{\lin}(1 + \log x))\exp(C_{\exp}x^{3\varepsilon/4})$, so $\log(x^{401}\Upsilon(x)) \leq 401\log x + \log(3 + C_{\lin}(1 + \log x)) + C_{\exp}x^{3\varepsilon/4}$, which is at most $x^{4\varepsilon/5}$ for all large x because $\log x = o(x^{3\varepsilon/4})$ and $x^{3\varepsilon/4} = o(x^{4\varepsilon/5})$. Choose $x_0 \geq 2$ with $x^{401}\Upsilon(x) \leq \exp(x^{4\varepsilon/5})$ for $x \geq x_0$, and put $X_0 = \max(2, x_0^J)$. For $X \geq X_0$ every $x \in [Y, Y^2]$ satisfies $x \geq X^{1/J} \geq x_0 \geq 2$, as used in Step 6.

Conclusion. Let $X \geq X_0$, (q, d) as in the statement, Y as in Step 5, $x \in [Y, Y^2]$, $t = \lfloor x^{401} \rfloor$ and $B = \exp(x^{4\varepsilon/5})$. By Step 6, for every $(\psi, e_\varepsilon(x), q, d)$-field E,

$$\sum_{k=1}^{t-1} \len_2(E, k) \leq (t-1)\,\Upsilon(x) \leq x^{401}\Upsilon(x) \leq B,$$

with every term finite, which is $\mathrm{V}_2(E; t, B)$, item 1; and for $\ell \in B_\psi$ the same computation with $L_\ell = \mathbb{Q}(\zeta_{\ell^{j_\ell+1}N_\psi})$ gives $\mathrm{V}_\ell(L_\ell; t, B)$, item 2. The constants $J \geq 1$, X_0 and j_ℓ depend only on (ψ, ε). □

Lemma 39.3. *Let $R \geq 0$ be an integer, let $\beta \geq 1$ and $U > 0$ be real numbers, and let $T \subset \mathbb{R}$ be a finite set with $|T| \leq R$. There is a real number y with*

$$\frac{U}{2^{R+2}\beta^R} \leq y, \qquad 2y \leq U,$$

such that for every $a \in T$ and every $u \in [y, 2y]$ with $a \leq u$ we have $\beta a \leq u$.

Proof. We argue by induction on R, for all β, U and T at once.

If $R = 0$ then $T = \emptyset$, and $y = U/2$ works: $U/4 \leq U/2$ and $2y = U$.

Let $R \geq 0$, assume the claim for R, and let $|T| \leq R + 1$. Two cases.

Some $a_0 \in T$ satisfies $U/(2\beta) < a_0 \leq U$. Put $U' = U/(2\beta) > 0$ and $T' = T \setminus \{a_0\}$, so $|T'| \leq R$. The induction hypothesis for (β, U', T') gives y with $U'/(2^{R+2}\beta^R) \leq y$ and $2y \leq U'$, such that $a \leq u$ implies $\beta a \leq u$ for $a \in T'$ and $u \in [y, 2y]$. Then

$$\frac{U}{2^{R+3}\beta^{R+1}} = \frac{U'}{2^{R+2}\beta^R} \leq y, \qquad 2y \leq U' \leq U$$

(as $\beta \geq 1$). Let $a \in T$ and $u \in [y, 2y]$ with $a \leq u$. If $a = a_0$, then $a_0 \leq u \leq 2y \leq U' < a_0$, which is impossible; so $a \in T'$ and $\beta a \leq u$.

Every $a \in T$ satisfies $a \leq U/(2\beta)$ or $a > U$. Take $y = U/2$. Then $U/(2^{R+3}\beta^{R+1}) \leq U/2$ because $2^{R+3}\beta^{R+1} \geq 2$, and $2y = U$. Let $a \in T$ and $u \in [U/2, U]$ with $a \leq u$. Then $a \leq U$, so $a \leq U/(2\beta)$ and $\beta a \leq U/2 \leq u$.

In both cases y has the required properties for $R + 1$. □

Lemma 39.4. *Let $\psi \in \mathcal{P}$ and let q, d be primes with $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$ and $\gcd(qd, N_\psi) = 1$. Let $\mathbb{Q}(\zeta_{N_\psi})^\psi \subset \mathbb{C}$ be the subfield of $\mathbb{Q}(\zeta_{N_\psi})$ fixed by the automorphisms $\zeta \mapsto \zeta^u$ with $\psi(u) = 1$, and put*

$$L_{q,d} = \mathbb{Q}(\zeta_{N_\psi})^\psi(i, \sqrt{-q}, \sqrt{-d}) \subset \mathbb{C}.$$

1. *$i \in L_{q,d}$, $[L_{q,d} : \mathbb{Q}] \leq 8o_\psi$, and $L_{q,d} \subseteq \mathbb{Q}(\zeta_{4N_\psi qd})$.*
2. *For every integer $a \geq 2$ and every (ψ, a, q, d)-field E there are an integer $0 \leq m \leq a$ and a cyclotomic 2-layer L' of degree 2^m over $L_{q,d}$ such that $\len_2(E, k) \leq 1 + \len_2(L', k)$ for every $k \in \mathbb{Z}$.*

Proof. Item 1. Since $q \equiv 3 \pmod 4$, the Gauss sum $g_q = \sum_{x \bmod q}(x/q)\zeta_q^x$ satisfies $g_q^2 = (-1/q)\,q = -q$, so $\sqrt{-q} \in \mathbb{Q}(\zeta_q)$; likewise $\sqrt{-d} \in \mathbb{Q}(\zeta_d)$, as $d \equiv 3 \pmod 4$. With $i \in \mathbb{Q}(\zeta_4)$ and $\mathbb{Q}(\zeta_{N_\psi})^\psi \subseteq \mathbb{Q}(\zeta_{N_\psi})$ this gives $L_{q,d} \subseteq \mathbb{Q}(\zeta_{\mathrm{lcm}(4,N_\psi)qd}) \subseteq \mathbb{Q}(\zeta_{4N_\psi qd})$. By Galois theory $\mathrm{Gal}(\mathbb{Q}(\zeta_{N_\psi})^\psi/\mathbb{Q}) \cong (\mathbb{Z}/N_\psi\mathbb{Z})^\times/\ker\psi$, which is isomorphic to the image of ψ, of order o_ψ; adjoining three square roots multiplies the degree by at most 8. Finally, $i \in L_{q,d}$ by construction.

The layer. Let $a \geq 2$ and put $N = \mathrm{lcm}(2^{a+2}, N_\psi)\,qd$; then $\mathfrak{h} = (a, q, d)$ is a Sha-host of ψ with $N_\mathfrak{h} = N$. All fields below are subfields of $\mathbb{Q}(\zeta_N) \subset \mathbb{C}$, and we identify $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$ with $(\mathbb{Z}/N\mathbb{Z})^\times$. The fixing groups of $\mathbb{Q}(\zeta_{2^{a+2}})$, $\mathbb{Q}(\zeta_{N_\psi})^\psi$, $\mathbb{Q}(\sqrt{-q})$ and $\mathbb{Q}(\sqrt{-d})$ are, respectively, the u with $u \equiv 1 \pmod{2^{a+2}}$, with $\psi(u) = 1$, with u a square modulo q, and with u a square modulo d; for the last two because $\mathbb{Q}(\sqrt{-q})$ is the unique quadratic subfield of the cyclic extension $\mathbb{Q}(\zeta_q)/\mathbb{Q}$, fixed by the squares of $(\mathbb{Z}/q\mathbb{Z})^\times$, and likewise for d. Let H_1 be the intersection of these four groups and L' its fixed field, the compositum of the four fields. As $i \in \mathbb{Q}(\zeta_{2^{a+2}})$, $L' = L_{q,d}(\zeta_{2^{a+2}})$; and $[L' : L_{q,d}]$ divides $[\mathbb{Q}(\zeta_{2^{a+2}}) : \mathbb{Q}(i)] = 2^a$, because L' is the compositum of $L_{q,d}$ and the Galois extension $\mathbb{Q}(\zeta_{2^{a+2}})$ of $\mathbb{Q}$, whose intersection with $L_{q,d}$ contains $\mathbb{Q}(i)$. So L' is a cyclotomic 2-layer of degree 2^m over $L_{q,d}$ with $0 \leq m \leq a$.

E inside the layer. Let E be a (ψ, a, q, d)-field. By item 1 of Lemma 36.6, E is isomorphic to the fixed field E_0 of $H_\mathfrak{h}$, and E_0 is a CM field by item 2 of Lemma 36.6. Lengths of Sha groups are invariant under isomorphisms of fields, so it suffices to treat E_0. By definition $H_1 = \{u \in H_\mathfrak{h} : u \equiv 1 \pmod{2^{a+2}}\}$, so $E_0 \subseteq L'$, and $H_\mathfrak{h}/H_1$ embeds into $\{\pm 1\} \subset (\mathbb{Z}/2^{a+2}\mathbb{Z})^\times$; hence $[L' : E_0] \leq 2$. The extension L'/E_0 is unramified at every prime $p \neq 2$: the inertia group of p in $(\mathbb{Z}/N\mathbb{Z})^\times$ is $I_p = \{u : u \equiv 1 \pmod{N/p^{v_p(N)}}\}$, and the inertia groups of L'/E_0 above p are the image of $I_p \cap H_\mathfrak{h}$ in $H_\mathfrak{h}/H_1$; an element of I_p is $\equiv 1 \pmod{2^{a+2}}$, since $2^{a+2} \mid N/p^{v_p(N)}$, so $I_p \cap H_\mathfrak{h} \subseteq H_1$. As E_0 is totally imaginary, no infinite place ramifies. Hence L' lies in the maximal extension E_{0,S_2} of E_0 unramified outside the places above 2, and E_{0,S_2} is also the maximal such extension of L'. So $G = G_{E_0,S_2}$ contains $H = G_{L',S_2}$ as an open normal subgroup with $|G/H| = [L' : E_0] \leq 2$.

Comparison of Sha. Let $k \in \mathbb{Z}$ and $M = \mathbb{Q}_2/\mathbb{Z}_2(-k)$, a discrete G-module. Inflation and restriction give an exact sequence

$$0 \to H^1(G/H, M^H) \to H^1(G, M) \xrightarrow{\mathrm{res}} H^1(H, M).$$

The group $H^1(G/H, M^H)$ has order at most 2: it is 0 if $G = H$; otherwise $G/H = \{1, \sigma\}$ and $H^1(G/H, M^H) = \ker(1+\sigma)/(\sigma - 1)M^H$ is a subquotient of the subgroup M^H of $M \cong \mathbb{Q}_2/\mathbb{Z}_2$ that is killed by $|G/H| = 2$; every subgroup of $\mathbb{Q}_2/\mathbb{Z}_2$ is finite cyclic or all of $\mathbb{Q}_2/\mathbb{Z}_2$, so every subquotient is finite cyclic or isomorphic to $\mathbb{Q}_2/\mathbb{Z}_2$, and such a group killed by 2 has order at most 2. Restriction maps $\mathrm{Sha}^1_2(E_0, k)$ into $\mathrm{Sha}^1_2(L', k)$: for a place w of L' above 2, lying over the place v of E_0, the composite of res with the localisation at w is the localisation at v followed by restriction from $E_{0,v}$ to L'_w, because both are induced by the inclusions $G_{L'_w} \subseteq G_{E_{0,v}}$ and $H \subseteq G$ (with compatible choices of decomposition groups); so a class trivial at every $v \mid 2$ restricts to a class trivial at every $w \mid 2$. The kernel of res on $\mathrm{Sha}^1_2(E_0, k)$ lies in $H^1(G/H, M^H)$, of length at most 1, and its image lies in $\mathrm{Sha}^1_2(L', k)$. By additivity of length,

$$\mathrm{len}_2(E, k) = \mathrm{len}_2(E_0, k) \leq 1 + \mathrm{len}_2(L', k)$$

in $\mathbb{N} \cup \{\infty\}$. □

Lemma 39.5. *Let ℓ be a prime and K a finite abelian extension of $\mathbb{Q}$ containing a primitive ℓ-th root of unity if ℓ is odd, a primitive fourth root of unity if $\ell = 2$. There is an integer $r \geq 0$ such that for every $n \geq 0$ and every field K' generated over K by a primitive ℓ^n-th root of unity,*

$$\#(\mathrm{Cl}(K')/\mathrm{Cl}(K')^\ell) \leq \ell^r.$$

Proof. The fields K' are layers of the cyclotomic $\mathbb{Z}_\ell$-extension. Fix an algebraic closure $\overline{K}$; each K' is K-isomorphic to $K(\mu_{\ell^n}) \subseteq \overline{K}$, and class groups are invariant under isomorphism, so we may take $K' = K(\mu_{\ell^n})$. Let c be the largest integer with $\mu_{\ell^c} \subseteq K$; it exists since K is a number field, and $c \geq 1$, with $c \geq 2$ if $\ell = 2$. Put $K(\mu_{\ell^\infty}) = \bigcup_n K(\mu_{\ell^n})$ and $U_k = 1 + \ell^k\mathbb{Z}_\ell$. The cyclotomic character identifies $\Gamma' = \mathrm{Gal}(K(\mu_{\ell^\infty})/K)$ with a closed subgroup of U_c, and $\mu_{\ell^k} \subseteq K$ holds exactly when $\Gamma' \subseteq U_k$. As $c \geq 1$ ($c \geq 2$ if $\ell = 2$), the ℓ-adic logarithm is an isomorphism $U_c \cong \ell^c\mathbb{Z}_\ell \cong \mathbb{Z}_\ell$ of topological groups, whose closed subgroups are $\{1\}$ and the U_k, $k \geq c$. The group Γ' is infinite, because $[K(\mu_{\ell^n}) : \mathbb{Q}] \geq [\mathbb{Q}(\mu_{\ell^n}) : \mathbb{Q}] \to \infty$; so $\Gamma' = U_k$ for some $k \geq c$, and $k = c$ by the maximality of c. Thus $K(\mu_{\ell^\infty})/K$ is a $\mathbb{Z}_\ell$-extension. It contains $K\mathbb{Q}_\infty$, where $\mathbb{Q}_\infty \subseteq \mathbb{Q}(\mu_{\ell^\infty})$ is the $\mathbb{Z}_\ell$-extension of $\mathbb{Q}$, which is itself a $\mathbb{Z}_\ell$-extension of K; since a quotient of $\mathbb{Z}_\ell$ by a nonzero closed subgroup is finite, $K\mathbb{Q}_\infty = K(\mu_{\ell^\infty})$, so this is the cyclotomic $\mathbb{Z}_\ell$-extension K_∞. Its layer K_j of degree ℓ^j is the fixed field of U_{c+j}, and $K(\mu_{\ell^n})$ is the fixed field of $U_{\max(n,c)}$; hence $K(\mu_{\ell^n}) = K_{\max(n-c,0)}$.

From $\mu = 0$ to bounded rank. By Theorem B.35 (applicable as $K/\mathbb{Q}$ is finite abelian), the μ-invariant of K_∞/K is 0. Let A_j be the ℓ-Sylow subgroup of $\mathrm{Cl}(K_j)$ and $X = \varprojlim A_j$ (limit along the norm maps), a module over $\Lambda = \mathbb{Z}_\ell[[T]]$. We use three facts of Iwasawa's theory ([266], Chapter 13): X is a finitely generated torsion Λ-module; there is a pseudo-isomorphism, that is a homomorphism with finite kernel and cokernel, from X to $\bigoplus_i \Lambda/(\ell^{m_i}) \oplus \bigoplus_j \Lambda/(f_j^{n_j})$ with $m_i, n_j \geq 1$ and distinguished polynomials f_j, and $\mu = \sum_i m_i$; and there are $e \geq 0$ and a Λ-submodule $Y_e \subseteq X$ with $A_j \cong X/\nu_{j,e}Y_e$ for all $j \geq e$, where $\nu_{j,e} \in \Lambda$. As $\mu = 0$ there are no summands $\Lambda/(\ell^{m_i})$, and each $\Lambda/(f_j^{n_j})$ is a free $\mathbb{Z}_\ell$-module of rank $n_j \deg f_j$ by division by the distinguished polynomial $f_j^{n_j}$. So X is an extension of a $\mathbb{Z}_\ell$-submodule of a finitely generated free $\mathbb{Z}_\ell$-module by a finite group, hence a finitely generated $\mathbb{Z}_\ell$-module, and $\delta = \dim_{\mathbb{F}_\ell} X/\ell X$ is finite. For $j \geq e$, A_j is a quotient of X, so $A_j/\ell A_j$ is a quotient of $X/\ell X$ and $\#(A_j/\ell A_j) \leq \ell^\delta$. Let r be the maximum of δ and of $\dim_{\mathbb{F}_\ell} A_j/\ell A_j$ for $j < e$.

Conclusion. For a finite abelian group C with ℓ-Sylow subgroup A, $C/C^\ell \cong A/\ell A$, since the prime-to-ℓ part is ℓ-divisible. Hence $\#(\mathrm{Cl}(K(\mu_{\ell^n}))/\mathrm{Cl}(K(\mu_{\ell^n}))^\ell) = \#(A_j/\ell A_j) \leq \ell^r$ with $j = \max(n-c, 0)$. □

Proposition 39.6. *Let ℓ be an odd prime and L a finite abelian extension of $\mathbb{Q}$ containing a primitive ℓ-th root of unity. Suppose there is an integer $r \geq 0$ such that $\#(\mathrm{Cl}(L')/\mathrm{Cl}(L')^\ell) \leq \ell^r$ for every $n \geq 0$ and every field L' generated over L by a primitive ℓ^n-th root of unity. Then there is an integer $R \geq 1$ such that L has twist control at ℓ with rank R.*

Proof. Let r be as in the statement, fix an algebraic closure $\overline{L}$ and let $L(\mu_{\ell^\infty}) \subseteq \overline{L}$ be generated over L by the roots of unity of ℓ-power order. For each $n \geq 0$ the field $L(\mu_{\ell^n}) \subseteq \overline{L}$ is generated over L by a primitive ℓ^n-th root of unity, so the hypothesis of Lemma 39.7 holds for L, which contains a primitive ℓ-th root of unity: the continuous homomorphisms $G_{L(\mu_{\ell^\infty})} \to \mathbb{Z}/\ell\mathbb{Z}$ that vanish on the inertia groups of all places above finite places form a space of dimension at most r. Put $R = \max(r, 1)$. As ℓ is odd and L contains a primitive ℓ-th root of unity, Proposition 39.8 applies with this R, and L has twist control at ℓ with rank R. (The hypothesis that L is abelian over $\mathbb{Q}$ is not used.) □

Lemma 39.7. *Let ℓ be a prime and L a number field containing a primitive ℓ-th root of unity, and a primitive fourth root of unity if $\ell = 2$; fix an algebraic closure $\overline{L}$ and let $L(\mu_{\ell^\infty}) \subseteq \overline{L}$ be the field generated over L by all roots of unity of ℓ-power order. Suppose there is an integer $r \geq 0$ such that $\#(\mathrm{Cl}(L')/\mathrm{Cl}(L')^\ell) \leq \ell^r$ for every $n \geq 0$ and every field L' generated over L by a primitive ℓ^n-th root of unity. Then the $\mathbb{F}_\ell$-vector space of continuous homomorphisms*

$G_{L(\mu_{\ell^\infty})} \to \mathbb{Z}/\ell\mathbb{Z}$ that vanish on the inertia group of every place of $\overline{L}$ above a finite place has dimension at most r.

Proof. Put $L_n = L(\mu_{\ell^n}) \subseteq \overline{L}$ for $n \geq 0$, $L_\infty = L(\mu_{\ell^\infty}) = \bigcup_n L_n$ and $\Gamma_n = \mathrm{Gal}(L_\infty/L_n)$. Each L_n is generated over L by a primitive ℓ^n-th root of unity, so $\dim_{\mathbb{F}_\ell} \mathrm{Cl}(L_n)/\mathrm{Cl}(L_n)^\ell \leq r$; and L_n has no real place, because it contains a primitive ℓ-th root of unity with ℓ odd, or i. The Γ_n are open subgroups of the profinite group Γ_0 with trivial intersection; by compactness they form a basis of neighbourhoods of 1 in Γ_0, and in each Γ_n. Call a continuous homomorphism unramified if it vanishes on the inertia groups at all places above finite places.

Descent of one character. Let $\chi\colon G_{L_\infty} \to \mathbb{Z}/\ell\mathbb{Z}$ be a nonzero unramified continuous homomorphism, and F the fixed field of its kernel, a cyclic extension of degree ℓ of L_∞, unramified at every finite place. We show that for all large n there is an unramified continuous homomorphism $\chi_n\colon G_{L_n} \to \mathbb{Z}/\ell\mathbb{Z}$ whose restriction to G_{L_∞} is χ. By Kummer theory $F = L_\infty(\alpha)$ with $\alpha^\ell = a \in L_\infty^\times$; fix n_0 with $a \in L_{n_0}$. For $n \geq n_0$ put $F_n = L_n(\alpha)$. As $[F : L_\infty] = \ell$ and $F = F_n L_\infty$, $[F_n : L_n] = \ell$; since $\mu_\ell \subseteq L_n$, F_n/L_n is cyclic, and F_n and L_∞ are linearly disjoint over L_n. Restriction gives isomorphisms $\mathrm{Gal}(F/L_n) \cong \mathrm{Gal}(F_n/L_n) \times \Gamma_n$ and $\mathrm{Gal}(F/L_\infty) \cong \mathrm{Gal}(F_n/L_n)$; under the first, $\mathrm{Gal}(F/L_{n'})$ corresponds to $\mathrm{Gal}(F_{n_0}/L_{n_0}) \times \Gamma_{n'}$ for $n' \geq n_0$ (taking $n = n_0$), and restriction to $F_{n'} = F_{n_0}L_{n'}$ is the first projection.

Let v be a finite place of L_{n_0} and $I_v \subseteq \mathrm{Gal}(F/L_{n_0})$ the inertia group of a place of F above v; it depends only on v, as $\mathrm{Gal}(F/L_{n_0})$ is abelian. Its intersection with $\mathrm{Gal}(F/L_\infty) = \mathrm{Gal}(F_{n_0}/L_{n_0}) \times 1$ is the inertia group of F/L_∞, which is trivial. So the second projection is injective on I_v; as I_v is compact, it is a homeomorphism onto a closed subgroup $B_v \subseteq \Gamma_{n_0}$, and $I_v = \{(\beta_v(b), b) : b \in B_v\}$ for a continuous homomorphism $\beta_v\colon B_v \to \mathrm{Gal}(F_{n_0}/L_{n_0})$. If $v \nmid \ell$, then B_v, the inertia group of L_∞/L_{n_0} at v, is trivial, so $I_v = 1$. For each of the finitely many $v \mid \ell$, $\ker \beta_v$ is open in B_v, so there is $n_v \geq n_0$ with $B_v \cap \Gamma_{n_v} \subseteq \ker \beta_v$. Let $n_1 = \max_{v|\ell} n_v$ and $n \geq n_1$. For every finite place, the inertia group of F/L_n there is $I_v \cap (\mathrm{Gal}(F_{n_0}/L_{n_0}) \times \Gamma_n) = \{(\beta_v(b), b) : b \in B_v \cap \Gamma_n\} \subseteq 1 \times \Gamma_n$, so its image in $\mathrm{Gal}(F_n/L_n)$, the inertia group of F_n/L_n, is trivial. Thus F_n/L_n is unramified at every finite place. Let χ_n be the composite of $G_{L_n} \to \mathrm{Gal}(F_n/L_n)$, the inverse of the restriction isomorphism $\mathrm{Gal}(F/L_\infty) \to \mathrm{Gal}(F_n/L_n)$, and the map $\mathrm{Gal}(F/L_\infty) \to \mathbb{Z}/\ell\mathbb{Z}$ induced by χ. It is continuous, unramified (it factors through $\mathrm{Gal}(F_n/L_n)$), and for $g \in G_{L_\infty}$, $\chi_n(g) = \chi(g)$, because the restrictions of g to F and to F_n correspond.

Conclusion. Let $\chi^{(1)}, \ldots, \chi^{(t)}$ be linearly independent unramified continuous homomorphisms $G_{L_\infty} \to \mathbb{Z}/\ell\mathbb{Z}$. Choose n so large that each of them has an unramified extension $\chi_n^{(i)}$ to G_{L_n}. A linear relation among the $\chi_n^{(i)}$ restricts to the same relation among the $\chi^{(i)}$, so the $\chi_n^{(i)}$ are linearly independent. By the Hilbert class field, $t \leq \dim_{\mathbb{F}_\ell} \mathrm{Cl}(L_n)/\mathrm{Cl}(L_n)^\ell \leq r$. □

Proposition 39.8. *Let ℓ be a prime, $R \geq 1$ an integer and L a number field containing a primitive ℓ-th root of unity, and a primitive fourth root of unity if $\ell = 2$. Fix an algebraic closure $\overline{L}$ and let $L(\mu_{\ell^\infty}) \subseteq \overline{L}$ be the field generated over L by all roots of unity of ℓ-power order. Suppose that the $\mathbb{F}_\ell$-vector space of continuous homomorphisms $G_{L(\mu_{\ell^\infty})} \to \mathbb{Z}/\ell\mathbb{Z}$ that vanish on the inertia group of every place of $\overline{L}$ above a finite place has dimension at most R. Then L has twist control at ℓ with rank R. Moreover, in (Tw1) one can take $K = \mathbb{Q}_\ell$, $R' = R$, $s_1, \ldots, s_R \in \mathbb{Z}_\ell$, and c_μ the largest integer c such that L contains a primitive ℓ^c-th root of unity.*

Proof. Put $j = j_\ell(R)$, $L_n = L(\mu_{\ell^n}) \subseteq \overline{L}$ for $n \geq 0$, $L_\infty = L(\mu_{\ell^\infty})$ and $\Gamma = \mathrm{Gal}(L_\infty/L)$. As L contains a primitive ℓ-th root of unity with ℓ odd, or i, it has no real place, and neither has any extension of it.

Step 1: the cyclotomic tower. Since $\varphi(\ell^k) \le [L:\mathbb{Q}]$ whenever $\mu_{\ell^k} \subseteq L$, the largest integer c with $\mu_{\ell^c} \subseteq L$ exists, and $c \ge 1$, with $c \ge 2$ if $\ell = 2$. The cyclotomic character $\chi_{\mathrm{cyc}}\colon \Gamma \to \mathbb{Z}_\ell^\times$ is continuous and injective (as L_∞ is generated by μ_{ℓ^∞}), and $\tau \in \Gamma$ fixes μ_{ℓ^n} if and only if $\chi_{\mathrm{cyc}}(\tau) \in U_n$ $(n \ge 1)$. So its image is a closed subgroup of U_c; it is infinite, because $[L_n : L] \ge \varphi(\ell^n)/[L:\mathbb{Q}] \to \infty$; hence it is some U_k with $k \ge c$, and $k = c$, because the image lies in U_{c+1} only if $\mu_{\ell^{c+1}} \subseteq L$. Thus $\chi_{\mathrm{cyc}}\colon \Gamma \to U_c$ is an isomorphism of topological groups, and for $m \ge 0$ the subgroup $\Gamma_m = \chi_{\mathrm{cyc}}^{-1}(U_{c+m})$ is $\mathrm{Gal}(L_\infty/L_{c+m})$, so $[L_{c+m} : L] = [U_c : U_{c+m}] = \ell^m$. Let $\sigma \in \Gamma$ with $u := \chi_{\mathrm{cyc}}(\sigma) = 1 + \ell^c$; then $v(u-1) = c$, $v(u^{\ell^m} - 1) = c + m$, and Γ_m is the closure of $\langle \sigma^{\ell^m} \rangle$. The Γ_m form a basis of neighbourhoods of 1 in Γ.

Every cyclotomic ℓ-layer L' of degree ℓ^m over L is L-isomorphic to L_{c+m}: write $L' = L(\zeta)$ with ζ a primitive ℓ^k-th root of unity and choose an L-embedding $\iota\colon L' \to \overline{L}$; then $\iota(\zeta)$ is a primitive ℓ^k-th root of unity, whose powers are all of μ_{ℓ^k}, so $\iota(L') = L_k$; if $k \le c$ then $L_k = L = L_c$ and $m = 0$, and if $k > c$ then $[L_k : L] = \ell^{k-c}$ forces $k = c + m$. Lengths of Tate–Shafarevich groups and of cohomology groups are invariant under isomorphisms of fields, so in (Tw1) and (Tw2) it suffices to treat $L' = L_{c+m}$ and $L'' = L_{c+j}$.

Step 2: the split Iwasawa module. Let $M' \subseteq \overline{L}$ be the compositum of all finite abelian extensions of L_∞ of ℓ-power degree that are unramified at every finite place and in which every place above ℓ splits completely, and put $\mathrm{Iw}^{\mathrm{sp}}(L) = \mathrm{Gal}(M'/L_\infty)$, an abelian pro-$\ell$ group, hence a compact $\mathbb{Z}_\ell$-module. As these conditions are preserved by automorphisms of $\overline{L}$ that preserve L_∞, M' is Galois over L. For $\tau \in \Gamma$ and $x \in \mathrm{Iw}^{\mathrm{sp}}(L)$ put $\tau \cdot x = \tilde{\tau} x \tilde{\tau}^{-1}$ for any lift $\tilde{\tau} \in \mathrm{Gal}(M'/L)$ of τ; this is independent of the lift because $\mathrm{Iw}^{\mathrm{sp}}(L)$ is abelian, it is a continuous automorphism, hence $\mathbb{Z}_\ell$-linear, and $\tau \mapsto \tau \cdot x$ is continuous (it factors the continuous map $\tilde{\tau} \mapsto \tilde{\tau} x \tilde{\tau}^{-1}$ through the open quotient map $\mathrm{Gal}(M'/L) \to \Gamma$). Let ϕ be the action of σ.

Generation by R elements. A continuous homomorphism $\mathrm{Iw}^{\mathrm{sp}}(L) \to \mathbb{Z}/\ell\mathbb{Z}$, composed with the surjection $G_{L_\infty} \to \mathrm{Iw}^{\mathrm{sp}}(L)$, vanishes on all inertia groups at finite places, since M'/L_∞ is unramified there; and different homomorphisms give different composites. By hypothesis the continuous homomorphisms $\overline{W} \to \mathbb{F}_\ell$ of the profinite $\mathbb{F}_\ell$-vector space $\overline{W} = \mathrm{Iw}^{\mathrm{sp}}(L)/\ell\,\mathrm{Iw}^{\mathrm{sp}}(L)$ span a space of dimension $d \le R$. They separate points (for $x \ne 0$ choose an open subgroup $U \not\ni x$ and a linear form on the finite space $\overline{W}/U$ not vanishing at the class of x), so a basis of them gives an injection $\overline{W} \to \mathbb{F}_\ell^d$ and $\dim \overline{W} \le R$. Lift a basis of $\overline{W}$ to $x_1, \dots, x_{d'} \in \mathrm{Iw}^{\mathrm{sp}}(L)$, $d' \le R$. The image Y of the continuous map $\mathbb{Z}_\ell^{d'} \to \mathrm{Iw}^{\mathrm{sp}}(L)$, $a \mapsto \sum a_i x_i$, is compact, hence closed, and $Y + \ell\,\mathrm{Iw}^{\mathrm{sp}}(L) = \mathrm{Iw}^{\mathrm{sp}}(L)$. The quotient $\mathrm{Iw}^{\mathrm{sp}}(L)/Y$ is an abelian pro-ℓ group equal to ℓ times itself; each of its finite quotients is a finite ℓ-group Q with $\ell Q = Q$, hence 0, so $\mathrm{Iw}^{\mathrm{sp}}(L) = Y$. So $\mathrm{Iw}^{\mathrm{sp}}(L)$ is generated over $\mathbb{Z}_\ell$ by R elements (add zeros).

Unipotence modulo ℓ. The fixed field F_1 of $\ell\,\mathrm{Iw}^{\mathrm{sp}}(L)$ is finite over L_∞ and Galois over L, and Γ acts on $\overline{W} = \mathrm{Gal}(F_1/L_\infty)$ through conjugation in $\mathrm{Gal}(F_1/L)$. For $x \in \overline{W}$ the map $\tilde{\tau} \mapsto \tilde{\tau} x \tilde{\tau}^{-1}$ is continuous with values in the finite, hence discrete, subgroup $\overline{W}$, so the centraliser of x is open; hence the kernel of the action of Γ on the finite set $\overline{W}$ is open and contains some Γ_n. Then σ^{ℓ^n} acts trivially on $\overline{W}$, and in characteristic ℓ the induced endomorphism $\bar{\phi}$ satisfies $(\bar{\phi} - 1)^{\ell^n} = \bar{\phi}^{\ell^n} - 1 = 0$. So $(\phi - 1)^{\ell^n}\mathrm{Iw}^{\mathrm{sp}}(L) \subseteq \ell\,\mathrm{Iw}^{\mathrm{sp}}(L)$.

Step 3: the Tate–Shafarevich groups of the layers. Let $e \ge 1$ and $m \ge 0$; put $L' = L_{c+m}$ and $T_{e,m} = (u^e\phi)^{\ell^m} - 1$, an endomorphism of $\mathrm{Iw}^{\mathrm{sp}}(L)$. We show

$$\mathrm{len}_\ell(L_{c+m}, e) = \mathrm{length}_{\mathbb{Z}_\ell}\Big(\mathrm{Iw}^{\mathrm{sp}}(L)/T_{e,m}\,\mathrm{Iw}^{\mathrm{sp}}(L)\Big) = \mathrm{tl}(e,m), \tag{39.3}$$

where tl is formed as in Lemma 39.9 with $M = \mathrm{Iw}^{\mathrm{sp}}(L)$, ϕ and u. Let $\Omega \subseteq \overline{L}$ be the maximal extension of L' unramified outside the places above ℓ, $G = \mathrm{Gal}(\Omega/L') = G_{L',S_\ell}$ and $A = \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$. The field L_∞ is unramified over L' outside ℓ, and M' is unramified over L_∞, so

$L_\infty \subseteq M' \subseteq \Omega$. Let $H = \mathrm{Gal}(\Omega/L_\infty)$, a closed normal subgroup with $G/H = \Gamma_m$; H acts trivially on A.

(a) *Inflation and restriction.* $\Gamma_m \cong U_{c+m} \cong \mathbb{Z}_\ell$ with topological generator σ^{ℓ^m}, which acts on A as multiplication by $u^{-e\ell^m}$. By the lifting-the-exponent rule $v(u^{-e\ell^m}-1) = c+m+v(e) < \infty$, so $u^{-e\ell^m}-1$ is a nonzero element of $\mathbb{Z}_\ell$, and multiplication by it is surjective on the divisible group A: hence $H^1(\Gamma_m, A) = 0$; and $H^2(\Gamma_m, A) = 0$. The inflation–restriction sequence therefore gives an isomorphism $H^1(G, A) \to H^1(H, A)^{\Gamma_m} = \mathrm{Hom}_{\mathrm{cont}}(H, A)^{\Gamma_m}$, where $\tau \in \Gamma_m$ acts by $(\tau f)(h) = \chi_{\mathrm{cyc}}(\tau)^{-e} f(\tilde\tau^{-1} h \tilde\tau)$.

(b) *Local conditions.* Let v be a place of L' above ℓ, w a place of Ω above v and $D_w \subseteq G$ its decomposition group. Localisation at v is restriction to D_w followed by inflation along the surjection $G_{L'_v} \to D_w$, and inflation is injective on H^1; so a class $y \in H^1(G, A)$ is trivial at v if and only if $y|_{D_w} = 0$. The group $D_w \cap H$ is normal in D_w, and $D_w/(D_w \cap H)$ is the decomposition group of L_∞/L' at the place below w, a closed subgroup of Γ_m; it is not trivial, because the ramification index of $L'(\mu_{\ell^n})/L'$ at v is at least $\varphi(\ell^n)/[L' : \mathbb{Q}]$ ($\mathbb{Q}(\mu_{\ell^n})/\mathbb{Q}$ is totally ramified at ℓ), which tends to infinity. So it is isomorphic to $\mathbb{Z}_\ell$, with a generator acting on A by $\chi_{\mathrm{cyc}}^{-e} \neq 1$, and as in (a) its H^1 with coefficients in A vanishes. By inflation–restriction for $D_w \cap H \subseteq D_w$, $y|_{D_w} = 0$ if and only if the homomorphism $f = y|_H$ vanishes on $D_w \cap H$. The decomposition groups of the places of Ω above v are the G-conjugates of D_w, and $f(\tilde\tau h \tilde\tau^{-1}) = \chi_{\mathrm{cyc}}(\tau)^{-e} f(h)$ for Γ_m-invariant f. Hence restriction identifies $\mathrm{Sha}^1_\ell(L', e)$ with the group of Γ_m-invariant $f \in \mathrm{Hom}_{\mathrm{cont}}(H, A)$ that vanish on $D_w \cap H$ for every place w of Ω above ℓ.

(c) *Passage to the split module.* Let f be such a homomorphism. Its image is finite (compact in the discrete A), an ℓ-group, and the fixed field of $\ker f$ is a finite abelian extension of L_∞ of ℓ-power degree inside Ω, unramified outside ℓ and with every place above ℓ split completely (the decomposition groups $D_w \cap H$ lie in $\ker f$); so it is unramified at every finite place, lies in M', and f factors through the surjection $H \to \mathrm{Iw}^{\mathrm{sp}}(L)$. Conversely, a continuous homomorphism $\mathrm{Iw}^{\mathrm{sp}}(L) \to A$, composed with this surjection, vanishes on every $D_w \cap H$, whose image is a decomposition group of M'/L_∞ at a place above ℓ, hence trivial. The surjection is compatible with the conjugation actions of Γ_m. So $\mathrm{Sha}^1_\ell(L', e)$ is isomorphic to the group of continuous homomorphisms $f\colon \mathrm{Iw}^{\mathrm{sp}}(L) \to A$ with $f(\tau \cdot x) = \chi_{\mathrm{cyc}}(\tau)^{-e} f(x)$ for all $\tau \in \Gamma_m$ and x.

(d) *The cokernel.* For a continuous f the set of $\tau \in \Gamma_m$ satisfying this identity for all x is a subgroup, and it is closed, since for fixed x the map $\tau \mapsto f(\tau \cdot x) - \chi_{\mathrm{cyc}}(\tau)^{-e} f(x)$ is continuous with values in the discrete A. As Γ_m is the closure of $\langle \sigma^{\ell^m} \rangle$, the identity holds on Γ_m if and only if it holds for $\tau = \sigma^{\ell^m}$, that is $f(\phi^{\ell^m} x) = u^{-e\ell^m} f(x)$ for all x; as f is $\mathbb{Z}_\ell$-linear and $(u^e\phi)^{\ell^m} = u^{e\ell^m}\phi^{\ell^m}$, this says that f vanishes on $T_{e,m}\mathrm{Iw}^{\mathrm{sp}}(L)$. This submodule is closed (compact), so $\mathrm{Sha}^1_\ell(L', e)$ is isomorphic to the group of continuous homomorphisms $C \to \mathbb{Q}_\ell/\mathbb{Z}_\ell$ with $C = \mathrm{Iw}^{\mathrm{sp}}(L)/T_{e,m}\mathrm{Iw}^{\mathrm{sp}}(L)$. By Step 2, C is a finitely generated $\mathbb{Z}_\ell$-module, $C \cong \mathbb{Z}_\ell^a \oplus C_0$ with C_0 finite; its group of continuous homomorphisms to $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ is $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^a \oplus \mathrm{Hom}(C_0, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$, of length ∞ if $a > 0$ and length C_0 if $a = 0$, which is length C in both cases. This is (39.3).

Step 4: (Tw1) and (Tw2). By Step 2 the hypotheses of Lemma 39.9 hold for $M = \mathrm{Iw}^{\mathrm{sp}}(L)$, ϕ, $N = \ell^n$ and u with $v(u-1) = c$; let $s_1, \dots, s_R \in \mathbb{Z}_\ell$ be the elements of its item 1. Let $e \geq 1$ and $m \geq 0$. By (39.3) and items 2 and 1 of Lemma 39.9,

$$\mathrm{len}_\ell(L_{c+m}, e) = \mathrm{tl}(e, m) \leq \mathrm{tl}(e, j) + R\max(m-j, 0) \leq \sum_{i=1}^{R} (j + c + v(s_i - e)) + R\max(m-j, 0). \tag{39.4}$$

For (Tw1) take $K = \mathbb{Q}_\ell$ with its absolute value, $c_\mu = c$ (admissible, as $\mu_{\ell^c} \subseteq L$), $R' = R$ and the points $s_1, \dots, s_R$. If $D \geq 0$ and $|s_i - e| \geq \ell^{-D}$ for all i, then $v(s_i - e) \leq D$, and (39.4) gives $\mathrm{len}_\ell(L_{c+m}, e) \leq R(j + c + D) + R\max(m-j, 0) = R(\max(m, j) + c + D)$; by Step 1 this is (Tw1)

for every cyclotomic ℓ-layer of degree ℓ^m. For (Tw2), the first inequality of (39.4) and (39.3) for $m = j$ give $\mathrm{len}_\ell(L_{c+m}, e) \le \mathrm{len}_\ell(L_{c+j}, e) + R\max(m-j, 0)$, and by Lemma 39.10 for the field L_{c+j}, which has no real place, $\mathrm{len}_\ell(L_{c+j}, e) \le \mathrm{length}_{\mathbb{Z}_\ell} H^2(G_{L_{c+j},S_\ell}, \mathbb{Z}_\ell(e+1))$. By Step 1 this is (Tw2) for all layers L' of degree ℓ^m and L'' of degree ℓ^j. So L has twist control at ℓ with rank R. □

Lemma 39.9. *Let ℓ be a prime, $R \ge 1$ an integer and $j = j_\ell(R)$. Let M be a $\mathbb{Z}_\ell$-module generated by R elements, ϕ a $\mathbb{Z}_\ell$-linear endomorphism of M such that $(\phi-1)^N M \subseteq \ell M$ for some integer $N \ge 0$, and $u \in \mathbb{Z}_\ell$ with $v(u-1) = c$, where $c \ge 1$, and $c \ge 2$ if $\ell = 2$. For integers $e, m \ge 0$ put*

$$\mathrm{tl}(e,m) = \mathrm{length}_{\mathbb{Z}_\ell}\Big(M/\big((u^e\phi)^{\ell^m} - 1\big)M\Big) \in \mathbb{N} \cup \{\infty\}.$$

1. *There are $s_1, \dots, s_R \in \mathbb{Z}_\ell$ such that for every integer $e \ge 0$*

$$\mathrm{tl}(e,j) \le \sum_{i=1}^{R} \big(j + c + v(s_i - e)\big).$$

2. *For all integers $e, m \ge 0$, $\mathrm{tl}(e,m) \le \mathrm{tl}(e,j) + R\max(m-j,0)$.*

Proof. Item 1, reduction to a determinant. Let $x_1, \dots, x_R$ generate M and let $\pi\colon \mathbb{Z}_\ell^R \to M$, $\pi(a) = \sum_i a_i x_i$. Put $\phi_1 = \phi^{\ell^j}$ and choose $S = (S_{ik}) \in M_R(\mathbb{Z}_\ell)$ with $\phi_1(x_k) = \sum_i S_{ik} x_i$ for each k; then $\pi \circ S = \phi_1 \circ \pi$. For $a \in \mathbb{Z}_\ell$ this gives $\pi \circ (aS - 1) = (a\phi_1 - 1) \circ \pi$, so π maps $(aS-1)\mathbb{Z}_\ell^R$ into $(a\phi_1 - 1)M$ and induces a surjection $\mathbb{Z}_\ell^R/(aS-1)\mathbb{Z}_\ell^R \to M/(a\phi_1 - 1)M$. As the scalar u^e commutes with ϕ, $(u^e\phi)^{\ell^j} = a_e\phi_1$ with $a_e = u^{e\ell^j}$. Hence

$$\mathrm{tl}(e,j) \le v\big(\det(a_e S - 1)\big) \qquad (e \ge 0). \tag{39.5}$$

Item 1, the eigenvalues. Let K be a finite extension of $\mathbb{Q}_\ell$ containing the roots $z_1, \dots, z_R$ (with multiplicity) of the characteristic polynomial of S, with the absolute value $|\cdot|$ extending the ℓ-adic one ($|\ell| = \ell^{-1}$), and extend $v = -\log_\ell|\cdot|$ to K. Over K the matrix S is conjugate to an upper triangular matrix with diagonal $z_1, \dots, z_R$; so for $a \in \mathbb{Z}_\ell$ the matrix $aS - 1$ is conjugate to an upper triangular one with diagonal $az_i - 1$, and $\det(aS-1) = \prod_{i=1}^R (az_i - 1)$.

Item 1, one centre for each eigenvalue. Fix $z \in K$; we show that there is $s \in \mathbb{Z}_\ell$ with

$$v(a_e z - 1) \le j + c + v(s - e) \qquad \text{for every integer } e \ge 0. \tag{39.6}$$

Put $r(e) = \ell^{j+c}|a_e z - 1| \ge 0$. Let $e, e' \ge 0$. The a_e are units, and by the lifting-the-exponent rule $|a_e - a_{e'}| = |u^{(e-e')\ell^j} - 1| = \ell^{-(j+c)}|e - e'|$ (also when $e = e'$). Moreover $|a_e - a_{e'}| \le \max(|a_e z - 1|, |a_{e'} z - 1|)$: if $|z| \ge 1$, then $|a_e - a_{e'}| \le |a_e - a_{e'}|\,|z| = |(a_e z - 1) - (a_{e'} z - 1)|$ and the ultrametric inequality applies; if $|z| < 1$, then $|a_e z| < 1$, so $|a_e z - 1| = 1 \ge |a_e - a_{e'}|$. Together,

$$|e - e'| \le \max\big(r(e), r(e')\big) \qquad (e, e' \ge 0).$$

The sets $B(e) = \{y \in \mathbb{Z}_\ell : |y - e| \le r(e)\}$ are closed in $\mathbb{Z}_\ell$. Every finite nonempty family of them has a common point: if e^* minimises r over the finite set E of indices, then $|e^* - e| \le \max(r(e^*), r(e)) = r(e)$, that is $e^* \in B(e)$, for every $e \in E$. As $\mathbb{Z}_\ell$ is compact, there is $s \in \bigcap_{e \ge 0} B(e)$. Then $|s - e| \le \ell^{j+c}|a_e z - 1|$ for all e, which is (39.6) (if $a_e z = 1$, then $r(e) = 0$, $s = e$ and both sides are ∞).

Item 1, conclusion. Choose s_i as in (39.6) for $z = z_i$. By (39.5) and the product formula for the determinant,

$$\mathrm{tl}(e,j) \le v\Big(\prod_{i=1}^{R}(a_e z_i - 1)\Big) = \sum_{i=1}^{R} v(a_e z_i - 1) \le \sum_{i=1}^{R}\big(j + c + v(s_i - e)\big).$$

Item 2, unipotence modulo ℓ survives the twist. Fix $e \ge 0$ and put $\phi_e = u^e\phi$ and $\overline{M} = M/\ell M$, an $\mathbb{F}_\ell$-vector space of dimension at most R. As $u^e \equiv 1 \pmod{\ell}$, ϕ_e and ϕ induce the same endomorphism $\bar\phi$ of $\overline{M}$, and $(\bar\phi - 1)^N = 0$ by hypothesis. A nilpotent endomorphism of a vector space of dimension at most R has R-th power 0. Let $k = \lfloor \log_\ell R \rfloor + 1$, so that $\ell^k > R$ and $j = k+2$. Then $(\bar\phi - 1)^{\ell^k} = 0$, and since $\binom{\ell^k}{i} \equiv 0 \pmod{\ell}$ for $0 < i < \ell^k$, $\bar\phi^{\ell^k} - 1 = (\bar\phi - 1)^{\ell^k} = 0$. Hence $(\phi_e^{\ell^k} - 1)M \subseteq \ell M$.

Item 2, raising to the power ℓ gains a factor ℓ. Let ϕ' be an endomorphism of M with $(\phi' - 1)M \subseteq \ell^t M$ for some $t \ge 1$. By induction $(\phi' - 1)^i M \subseteq \ell^{ti} M$, since $(\phi' - 1)(\ell^{t(i-1)}y) = \ell^{t(i-1)}(\phi' - 1)y$. In $\phi'^\ell - 1 = \sum_{i=1}^{\ell}\binom{\ell}{i}(\phi' - 1)^i$ the terms with $1 \le i < \ell$ map M into $\ell^{1+ti}M \subseteq \ell^{t+1}M$, because $\ell \mid \binom{\ell}{i}$, and the term $i = \ell$ maps M into $\ell^{t\ell}M \subseteq \ell^{t+1}M$, because $t\ell \ge 2t \ge t+1$. So $(\phi'^\ell - 1)M \subseteq \ell^{t+1}M$. Applied to $\phi' = \phi_e^{\ell^k}$ with $t = 1$ this gives $(\phi_e^{\ell^{k+1}} - 1)M \subseteq \ell^2 M$; and for $n \ge k+1$, $\phi_e^{\ell^n} - 1 = (\phi_e^{\ell^{k+1}} - 1) \circ \sum_{0 \le i < \ell^{n-k-1}} \phi_e^{i\ell^{k+1}}$, so

$$(\phi_e^{\ell^n} - 1)M \subseteq \ell^2 M \qquad (n \ge k+1). \tag{39.7}$$

Item 2, one step costs at most R. Let ϕ' be an endomorphism of M with $(\phi' - 1)M \subseteq \ell^2 M$, and put $\mathrm{Nm} = \sum_{i=0}^{\ell-1}\phi'^i$, so that $\phi'^\ell - 1 = \mathrm{Nm} \circ (\phi' - 1)$. For endomorphisms A, B of M the projection $M/ABM \to M/AM$ is surjective with kernel AM/ABM, which is the image of M/BM under the map induced by A; so $\mathrm{length}(M/ABM) \le \mathrm{length}(M/AM) + \mathrm{length}(M/BM)$. With $A = \mathrm{Nm}$ and $B = \phi' - 1$,

$$\mathrm{length}\big(M/(\phi'^\ell - 1)M\big) \le \mathrm{length}\big(M/\mathrm{Nm}(M)\big) + \mathrm{length}\big(M/(\phi' - 1)M\big).$$

For every $i \ge 0$ and $x \in M$, $\phi'^i x - x \in \ell^2 M$, because $\phi'^i - 1 = \sum_{h<i}\phi'^h \circ (\phi' - 1)$ and $\phi'^h(\ell^2 y) = \ell^2 \phi'^h y$. Hence $\mathrm{Nm}(x) - \ell x \in \ell^2 M$, so $\ell M \subseteq \mathrm{Nm}(M) + \ell(\ell M)$. The module $Q = (\ell M + \mathrm{Nm}(M))/\mathrm{Nm}(M)$ is finitely generated over $\mathbb{Z}_\ell$ and satisfies $Q = \ell Q$, so $Q = 0$ by Nakayama's lemma, that is $\ell M \subseteq \mathrm{Nm}(M)$. Therefore $M/\mathrm{Nm}(M)$ is a quotient of $M/\ell M$ and has length at most $\dim_{\mathbb{F}_\ell} M/\ell M \le R$. So

$$\mathrm{length}\big(M/(\phi'^\ell - 1)M\big) \le \mathrm{length}\big(M/(\phi' - 1)M\big) + R.$$

Item 2, conclusion. For $n \ge k+1$, (39.7) allows the last bound with $\phi' = \phi_e^{\ell^n}$, and $\phi'^\ell = \phi_e^{\ell^{n+1}}$: so $\mathrm{tl}(e, n+1) \le \mathrm{tl}(e,n) + R$. As $j = k+2 \ge k+1$, induction on m gives $\mathrm{tl}(e,m) \le \mathrm{tl}(e,j) + R(m-j)$ for $m \ge j$. For $m < j$, $\phi_e^{\ell^j} - 1 = (\phi_e^{\ell^m} - 1) \circ \sum_{0 \le i < \ell^{j-m}} \phi_e^{i\ell^m}$, so $(\phi_e^{\ell^j} - 1)M \subseteq (\phi_e^{\ell^m} - 1)M$ and $M/(\phi_e^{\ell^m} - 1)M$ is a quotient of $M/(\phi_e^{\ell^j} - 1)M$; hence $\mathrm{tl}(e,m) \le \mathrm{tl}(e,j)$. Both cases together are item 2. □

Lemma 39.10. *Let ℓ be a prime, L a number field with no real place and $k \in \mathbb{Z}$. Then, in $\mathbb{N} \cup \{\infty\}$,*

$$\mathrm{len}_\ell(L,k) \le \mathrm{length}_{\mathbb{Z}_\ell} H^2\big(G_{L,S_\ell}, \mathbb{Z}_\ell(k+1)\big).$$

Proof. Let h be the length of $H^2(G_{L,S_\ell},\mathbb{Z}_\ell(k+1))$; if $h=\infty$ there is nothing to prove, so let $h<\infty$. Let S be the set of places of L above ℓ or ∞. The archimedean places are complex, so an extension of L is unramified outside S_ℓ if and only if it is unramified outside S; thus $G_{L,S_\ell}=G_{L,S}$, and $H^i(L_v,\cdot)=0$ for $i\geq 1$ at the complex places v. Hence $\mathrm{Sha}^1_\ell(L,k)=\mathrm{Sha}^1_S(L,\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))$, and $\mathrm{Sha}^i_S(L,\cdot)$ is the kernel of localisation at the places above ℓ. For $n\geq 1$ put $M_n=\ell^{-n}\mathbb{Z}_\ell/\mathbb{Z}_\ell(-k)\subseteq\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)$, a $\mathbb{Z}/\ell^n\mathbb{Z}$-module of order ℓ^n, and $T=\mathbb{Z}_\ell(k+1)$, $T_n=T/\ell^nT$. The Cartier dual of M_n is $M_n^\vee=\mathrm{Hom}(M_n,\mu_{\ell^n})\cong T_n$ as $G_{L,S}$-modules, since the twists by χ_{cyc}^{-k} and χ_{cyc} combine to $\chi_{\mathrm{cyc}}^{k+1}$.

Finite levels. By item 2 of Theorem B.34,

$$\#\mathrm{Sha}^1_S(L,M_n)=\#\mathrm{Sha}^2_S(L,T_n)\leq\#H^2(G_{L,S},T_n)\qquad(n\geq 1).\tag{39.8}$$

The finite levels are quotients of $H^2(G_{L,S},T)$. For $n\geq 1$ the sequence $0\to\ell^nT/\ell^{n+1}T\to T_{n+1}\to T_n\to 0$ is exact, and its long exact cohomology sequence continues $H^2(G_{L,S},T_{n+1})\to H^2(G_{L,S},T_n)\to H^3(G_{L,S},\ell^nT/\ell^{n+1}T)$, whose last term is 0 by item 3 of Theorem B.34. So the maps $H^2(G_{L,S},T_{n+1})\to H^2(G_{L,S},T_n)$ are surjective; as all these groups are finite (item 1 of Theorem B.34), compatible preimages can be chosen step by step, so each projection

$$\varprojlim_m H^2(G_{L,S},T_m)\to H^2(G_{L,S},T_n)$$

is surjective. The groups $H^1(G_{L,S},T_n)$ are finite (item 1 of Theorem B.34), so by Theorem B.31 with $i=2$ the natural map $H^2(G_{L,S},T)\to\varprojlim_m H^2(G_{L,S},T_m)$ is an isomorphism. Hence $H^2(G_{L,S},T)\to H^2(G_{L,S},T_n)$ is a surjective $\mathbb{Z}_\ell$-linear map, and

$$\#H^2(G_{L,S},T_n)\leq\ell^h\qquad(n\geq 1).\tag{39.9}$$

Finite subgroups of the Sha group come from a finite level. Let $A\subseteq\mathrm{Sha}^1_\ell(L,k)$ be a finite subgroup. Since $H^1(G_{L,S},\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))=\varinjlim_n H^1(G_{L,S},M_n)$, and likewise $H^1(L_v,\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))=\varinjlim_n H^1(L_v,M_n)$ for $v\mid\ell$, every $x\in A$ is the image of some $y_x\in H^1(G_{L,S},M_{n_x})$. For $v\mid\ell$ the localisation of y_x maps to the localisation of x, which is 0, so it becomes 0 in $H^1(L_v,M_{n'})$ for some $n'\geq n_x$. As A and the set of places above ℓ are finite, there is one n such that, for every $x\in A$, the image y'_x of y_x in $H^1(G_{L,S},M_n)$ is locally trivial at every place above ℓ (localisation commutes with the maps induced by $M_{n_x}\subseteq M_n$); then $y'_x\in\mathrm{Sha}^1_S(L,M_n)$ and y'_x maps to x. So A is the image of a subset of $\mathrm{Sha}^1_S(L,M_n)$, and by (39.8) and (39.9), $\#A\leq\ell^h$.

Conclusion. The group $H^1(G_{L,S},\mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))=\varinjlim_n H^1(G_{L,S},M_n)$ is ℓ-primary torsion, and so is $\mathrm{Sha}^1_\ell(L,k)$. Suppose its length were $>h$. Then it has a chain of submodules $0=N_0\subsetneq N_1\subsetneq\cdots\subsetneq N_{h+1}$; choosing $x_i\in N_i\setminus N_{i-1}$, the submodule A generated by $x_1,\dots,x_{h+1}$ contains the strictly increasing chain of the submodules generated by $x_1,\dots,x_i$ ($x_i\notin N_{i-1}$), so length $A\geq h+1$; and A, being finitely generated and ℓ-primary torsion, is finite, so $\#A=\ell^{\mathrm{length}\,A}\geq\ell^{h+1}$. This contradicts $\#A\leq\ell^h$. Hence $\mathrm{len}_\ell(L,k)\leq h$. □

Proposition 39.11. *Let $\psi\in\mathcal{P}$ and let $\mathbb{Q}(\zeta_{N_\psi})^\psi\subset\mathbb{C}$ be the subfield of $\mathbb{Q}(\zeta_{N_\psi})$ fixed by the automorphisms $\zeta\mapsto\zeta^u$ with $\psi(u)=1$. Suppose there is an integer $r\geq 0$ such that $\#(\mathrm{Cl}(L')/\mathrm{Cl}(L')^2)\leq 2^r$ for every $n\geq 0$ and every field L' generated over $\mathbb{Q}(\zeta_{N_\psi})^\psi(i)$ by a primitive 2^n-th root of unity. Then there is an integer $R\geq 1$ such that for every pair of primes (q,d) with $q\equiv 3\pmod 8$, $d\equiv 7\pmod{16}$ and $\gcd(qd,N_\psi)=1$, the field $\mathbb{Q}(\zeta_{N_\psi})^\psi(i,\sqrt{-q},\sqrt{-d})$ has twist control at 2 with rank R.*

Proof. Let r be as in the statement, $\overline{\mathbb{Q}}$ the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$, $F_0=\mathbb{Q}(\zeta_{N_\psi})^\psi$, and for a subfield $F\subseteq\overline{\mathbb{Q}}$ let $F(\mu_{2^\infty})$ be generated over F by the roots of unity of 2-power order; call

a continuous homomorphism $G_F \to \mathbb{Z}/2\mathbb{Z}$ unramified if it vanishes on the inertia groups of all places above prime numbers.

The base field. The field $F_0(i)$ contains a primitive fourth root of unity, and for every $n \geq 0$ the field $F_0(i)(\mu_{2^n}) \subseteq \overline{\mathbb{Q}}$ is generated over $F_0(i)$ by a primitive 2^n-th root of unity; so by the hypothesis and Lemma 39.7 (with $\ell = 2$, $L = F_0(i)$, $\overline{L} = \overline{\mathbb{Q}}$), the unramified continuous homomorphisms $G_{F_0(i)(\mu_{2^\infty})} \to \mathbb{Z}/2\mathbb{Z}$ form a space of dimension at most r. As $i \in \mu_{2^\infty}$, $F_0(i)(\mu_{2^\infty}) = F_0(\mu_{2^\infty})$.

Uniformity. By Lemma 39.12 with $g = r$, for every pair of primes (q, d) with $q \equiv 3 \pmod 8$, $d \equiv 7 \pmod{16}$ and $\gcd(qd, N_\psi) = 1$, the unramified continuous homomorphisms $G_{L_{q,d}(\mu_{2^\infty})} \to \mathbb{Z}/2\mathbb{Z}$, where $L_{q,d} = F_0(i, \sqrt{-q}, \sqrt{-d})$, form a space of dimension at most $R := 4(r + 6o_\psi)$. This integer satisfies $R \geq 24 \geq 1$ and does not depend on (q, d).

Twist control. Let (q, d) be such a pair. The field $L_{q,d}$ contains i, so Proposition 39.8 applies with $\ell = 2$, $L = L_{q,d}$, $\overline{L} = \overline{\mathbb{Q}}$ and the rank R; hence $L_{q,d}$ has twist control at 2 with rank R, for every pair (q, d) as in the statement. □

Lemma 39.12. *Let $\psi \in \mathcal{P}$, let $\overline{\mathbb{Q}}$ be the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$, and let $\mathbb{Q}(\zeta_{N_\psi})^\psi \subset \overline{\mathbb{Q}}$ be the subfield of $\mathbb{Q}(\zeta_{N_\psi})$ fixed by the automorphisms $\zeta \mapsto \zeta^u$ with $\psi(u) = 1$. For a subfield $F \subseteq \overline{\mathbb{Q}}$ write $F(\mu_{2^\infty})$ for the field generated over F by all roots of unity of 2-power order, and call a continuous homomorphism $G_F \to \mathbb{Z}/2\mathbb{Z}$ unramified if it vanishes on the inertia group of every place of $\overline{\mathbb{Q}}$ above a prime number. Let $g \geq 0$ be an integer such that the unramified continuous homomorphisms $G_{\mathbb{Q}(\zeta_{N_\psi})^\psi(\mu_{2^\infty})} \to \mathbb{Z}/2\mathbb{Z}$ form an $\mathbb{F}_2$-vector space of dimension at most g. Then for every pair of primes (q, d) with*

$$q \equiv 3 \pmod 8, \qquad d \equiv 7 \pmod{16}, \qquad \gcd(qd, N_\psi) = 1,$$

the unramified continuous homomorphisms $G_{L_{q,d}(\mu_{2^\infty})} \to \mathbb{Z}/2\mathbb{Z}$, where

$$L_{q,d} = \mathbb{Q}(\zeta_{N_\psi})^\psi(i, \sqrt{-q}, \sqrt{-d}),$$

form an $\mathbb{F}_2$-vector space of dimension at most $4(g + 6o_\psi)$.

Proof. Put $F_0 = \mathbb{Q}(\zeta_{N_\psi})^\psi$ and $F_\infty = F_0(\mu_{2^\infty})$. By Galois theory $\mathrm{Gal}(F_0/\mathbb{Q}) \cong (\mathbb{Z}/N_\psi\mathbb{Z})^\times / \ker\psi$, which is isomorphic to the image of ψ, so $[F_0 : \mathbb{Q}] = o_\psi$. For a finite set P of odd primes and a subfield $F \supseteq F_\infty$ of $\overline{\mathbb{Q}}$, let $\mathrm{Ur}_P(F)$ be the $\mathbb{F}_2$-space of continuous homomorphisms $G_F \to \mathbb{Z}/2\mathbb{Z}$ that vanish on the inertia group of every place of $\overline{\mathbb{Q}}$ above a prime not in P; so $\mathrm{Ur}_\emptyset(F)$ is the space of unramified ones, and $\dim \mathrm{Ur}_\emptyset(F_\infty) \leq g$. Fix (q, d) as in the statement; $q \neq d$, as $q \equiv 3$ and $d \equiv 7 \pmod 8$, and both are odd and prime to N_ψ.

Step 1: few places above q and d. The field $F_\infty \subseteq \mathbb{Q}(\zeta_{N_\psi}, \mu_{2^\infty})$ is abelian over $\mathbb{Q}$ and unramified at every odd prime $p \nmid N_\psi$. Let $\mathcal{G} = \mathrm{Gal}(F_\infty/\mathbb{Q})$, and for such p let $D_p \subseteq \mathcal{G}$ be its decomposition group (the same for all places above p, as $\mathcal{G}$ is abelian) and $t_p = [\mathcal{G} : D_p]$ the number of places of F_∞ above p. Restriction $\rho\colon \mathcal{G} \to \mathrm{Gal}(\mathbb{Q}(\mu_{2^\infty})/\mathbb{Q}) \cong \mathbb{Z}_2^\times$ (through χ_{cyc}) is surjective, and its kernel $\mathcal{K} = \mathrm{Gal}(F_\infty/\mathbb{Q}(\mu_{2^\infty}))$ embeds into $\mathrm{Gal}(F_0/\mathbb{Q})$ by restriction, since $F_\infty = F_0\,\mathbb{Q}(\mu_{2^\infty})$; so $\#\mathcal{K} \leq o_\psi$. The image $\rho(D_p)$ is closed and contains $\rho(\mathrm{Frob}_p) = p$. Hence

$$t_p = [\mathcal{G} : D_p\mathcal{K}]\,[D_p\mathcal{K} : D_p] \leq [\mathbb{Z}_2^\times : \rho(D_p)]\,[\mathcal{K} : \mathcal{K} \cap D_p] \leq [\mathbb{Z}_2^\times : \overline{\langle p \rangle}]\; o_\psi.$$

For $q \equiv 3 \pmod 8$, $v(q-1) = 1$ and $v(q+1) = 2$, so $v(q^2-1) = 3$ and $\overline{\langle q^2 \rangle} = U_3$, of index 4 in $\mathbb{Z}_2^\times$; as $q \notin U_3$ and $\overline{\langle q \rangle} = \overline{\langle q^2 \rangle} \cup q\,\overline{\langle q^2 \rangle}$, $[\overline{\langle q \rangle} : U_3] = 2$ and $[\mathbb{Z}_2^\times : \overline{\langle q \rangle}] = 2$. For $d \equiv 7 \pmod{16}$, $v(d-1) = 1$ and $v(d+1) = 3$, so $v(d^2-1) = 4$, $\overline{\langle d^2 \rangle} = U_4$ of index 8, $d \notin U_4$, and $[\mathbb{Z}_2^\times : \overline{\langle d \rangle}] = 4$. Therefore

$$t_q \leq 2o_\psi, \qquad t_d \leq 4o_\psi. \tag{39.10}$$

Step 2: allowing ramification at one more prime. Let P be a finite set of odd primes and $p \notin P$ an odd prime with $p \nmid N_\psi$. We show $\dim \mathrm{Ur}_{P\cup\{p\}}(F_\infty) \le \dim \mathrm{Ur}_P(F_\infty) + t_p$. For each of the t_p places w of F_∞ above p fix a place $\bar w$ of $\overline{\mathbb{Q}}$ above w, with inertia group $I_{\bar w} \subseteq G_{F_\infty}$; as $F_\infty/\mathbb{Q}$ is unramified at p, $I_{\bar w}$ is the inertia group of $\bar w$ in $G_\mathbb{Q}$, isomorphic to the inertia group of $\overline{\mathbb{Q}}_p/\mathbb{Q}_p$. A continuous homomorphism $I_{\bar w} \to \mathbb{Z}/2\mathbb{Z}$ factors through the maximal pro-2 quotient of $I_{\bar w}$, which is procyclic; so there is $\tau_w \in I_{\bar w}$ such that every continuous homomorphism $I_{\bar w} \to \mathbb{Z}/2\mathbb{Z}$ vanishing at τ_w vanishes. Consider the linear map $\mathrm{Ur}_{P\cup\{p\}}(F_\infty) \to (\mathbb{Z}/2\mathbb{Z})^{t_p}$, $\chi \mapsto (\chi(\tau_w))_w$. If χ is in its kernel, χ vanishes on each $I_{\bar w}$; every place of $\overline{\mathbb{Q}}$ above p is $h\bar w$ for one of the chosen $\bar w$ and some $h \in G_{F_\infty}$, with inertia group $hI_{\bar w}h^{-1}$, on which χ vanishes because $\chi(hxh^{-1}) = \chi(x)$. So the kernel is $\mathrm{Ur}_P(F_\infty)$, and the claim follows.

Step 3: a quadratic step at most doubles the dimension. Let P be a finite set of odd primes, $p \in P$ with $p \equiv 3 \pmod 4$, $F \supseteq F_\infty$ a subfield of $\overline{\mathbb{Q}}$ with $\dim \mathrm{Ur}_P(F) < \infty$, and $F' = F(\sqrt{-p})$. We show $\dim \mathrm{Ur}_P(F') \le 2 \dim \mathrm{Ur}_P(F)$. The field $\mathbb{Q}(\sqrt{-p})$ has discriminant $-p$, so it is unramified at every prime $p' \ne p$; hence so is $F' = F\,\mathbb{Q}(\sqrt{-p})$ over F, and the inertia group $I \subseteq G_F$ of a place of $\overline{\mathbb{Q}}$ above a prime not in P lies in $G_{F'}$ and is its inertia group there. If $F' = F$ there is nothing to show. Otherwise $V = G_F$ contains $V' = G_{F'}$ with index 2, and the homomorphism $\rho_0 \colon V \to \mathbb{Z}/2\mathbb{Z}$ with kernel V' lies in $\mathrm{Ur}_P(F)$ and is nonzero. The group V acts on the continuous homomorphisms $V' \to \mathbb{Z}/2\mathbb{Z}$ by $(h\chi)(x) = \chi(h^{-1}xh)$; V' acts trivially, and $\mathrm{Ur}_P(F')$ is stable, because $h^{-1}Ih$ is the inertia group of a place above the same prime. Fix $s \in V \setminus V'$ and let θ be its action on $W = \mathrm{Ur}_P(F')$; then $\theta^2 = 1$, so in characteristic 2, $(\theta-1)^2 = \theta^2 - 1 = 0$ and $(\theta-1)W \subseteq W^V$, the subspace of V-invariants. By the five-term sequence $0 \to \mathrm{Hom}(V/V', \mathbb{Z}/2) \to \mathrm{Hom}(V, \mathbb{Z}/2) \to \mathrm{Hom}(V', \mathbb{Z}/2)^V \to H^2(V/V', \mathbb{Z}/2) \cong \mathbb{Z}/2$ (continuous homomorphisms), the subspace $W_0 = W^V \cap \mathrm{res}(\mathrm{Hom}(V, \mathbb{Z}/2))$ has codimension at most 1 in W^V. If $\chi' = \mathrm{res}\,\chi \in W_0$, then χ vanishes on every inertia group I as above, since $I \subseteq V'$ and $\chi|_I = \chi'|_I = 0$; so $\chi \in \mathrm{Ur}_P(F)$, and $W_0 \subseteq \mathrm{res}(\mathrm{Ur}_P(F))$, which has dimension at most $\dim \mathrm{Ur}_P(F) - 1$ because the nonzero $\rho_0 \in \mathrm{Ur}_P(F)$ restricts to 0. Hence $\dim W^V \le \dim \mathrm{Ur}_P(F)$. Finally $W/\ker(\theta-1) \cong (\theta-1)W \subseteq W^V = \ker(\theta-1)$, so $\dim W \le 2 \dim W^V \le 2 \dim \mathrm{Ur}_P(F)$.

Step 4: assembly. By Step 2 with $P = \emptyset$, $p = q$, and then with $P = \{q\}$, $p = d$, and by (39.10),

$$\dim \mathrm{Ur}_{\{q,d\}}(F_\infty) \le \dim \mathrm{Ur}_\emptyset(F_\infty) + t_q + t_d \le g + 6o_\psi.$$

Since $q \equiv d \equiv 3 \pmod 4$, Step 3 applies with $P = \{q, d\}$, first to $F = F_\infty$, $p = q$, and then to $F = F_\infty(\sqrt{-q})$, $p = d$:

$$\dim \mathrm{Ur}_{\{q,d\}}\big(F_\infty(\sqrt{-q}, \sqrt{-d})\big) \le 4(g + 6o_\psi).$$

As $i \in \mu_{2^\infty}$, $F_\infty(\sqrt{-q}, \sqrt{-d}) = L_{q,d}(\mu_{2^\infty})$, and the unramified homomorphisms form the subspace $\mathrm{Ur}_\emptyset$ of $\mathrm{Ur}_{\{q,d\}}$. This proves the bound. □

40 Second cohomology of Tate twists

This section proves Theorem 40.1: for a totally complex field L containing the ℓ-th roots of unity (the fourth roots if $\ell = 2$) and every $e \ge 1$, the group $H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(e+1))$ is finite and $\log \# H^2 \le (2|d_L|)^{(2e[L:\mathbb{Q}])^C}$. The bound is uniform in the twist but doubly exponential, and it is used where only a few twists or a fixed field occur: at the exceptional twists of Section 39 (Proposition 39.2) and at the twist $e = 1$ in the remaining part of case (V) (Proposition 38.35). Its form for Tate–Shafarevich groups, Proposition 40.3, gives the finiteness of the strict groups of Tate twists that Part VIII needs to show that certain cocycles are rational coboundaries (Proposition 43.32, Lemma 45.31, Proposition 46.14). The groups $H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(e+1))$ are

those that Soulé relates to the K-theory of $\mathcal{O}_L$ [237], and the bound is of the type of his bound for the torsion in that K-theory [238]; here it is proved for the Galois cohomology directly.

The proof first bounds the Tate–Shafarevich group (Proposition 40.3) and then passes to H^2 by Poitou–Tate and local Tate duality. After an extension that adds enough roots of unity without loss (Proposition 40.4), the Tate–Shafarevich group is bounded by the eigencharacters of the class groups of cyclotomic Kummer layers (Proposition 40.27), and these are counted by twisted Kummer classes (Proposition 40.24). The key step is Theorem 40.7: twisted Kummer classes are detected by the integral homology of $\mathrm{GL}_N(\mathcal{O}_L)$ with $N = 4e + 10$, through cycles built from the standard cycle of a cyclic group and evaluated by additive families over finite fields (Theorem 40.22). The torsion in that homology is polynomial in the discriminant (Theorem 40.29), by a complex of perfect forms in the manner of Soulé: the perfect-cone nerve built from the Ryshkov polyhedron is acyclic, its simplices have finite stabilisers, and the number of their orbits is polynomial in the discriminant. The construction of cycles occupies most of the section; the duality steps are routine.

Theorem 40.1. *Let ℓ be a prime. There is a real number $C \geq 1$ such that for every totally complex number field L containing a primitive ℓ-th root of unity (a primitive fourth root of unity if $\ell = 2$) and every integer $e \geq 1$, the group $H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(e+1))$ is finite and*

$$\log \#H^2(G_{L,S_\ell}, \mathbb{Z}_\ell(e+1)) \leq \left(2|d_L|\right)^{(2e[L:\mathbb{Q}])^C}.$$

Proof. Fix ℓ and let $C_0 \geq 0$ be the constant of Proposition 40.3 for ℓ; put $C = \max(C_0, 2)+3 \geq 1$. Let L and $e \geq 1$ be as in the statement, $n = [L:\mathbb{Q}]$, $s = \mathrm{len}_\ell(L, e)$, finite by Proposition 40.3, S the set of places of L above ℓ or ∞, and $G = G_{L,S_\ell}$. The archimedean places are complex, so $G = G_{L,S}$ and $H^i(L_v, \cdot) = 0$ $(i \geq 1)$ at them. Put $T = \mathbb{Z}_\ell(e+1)$, $T_r = T/\ell^r T$, $A = \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$ and $A_r = A[\ell^r]$ for $r \geq 1$, a free $\mathbb{Z}/\ell^r\mathbb{Z}$-module of rank one on which G acts through χ_{cyc}^{-e}. Its Cartier dual $A_r^\vee = \mathrm{Hom}(A_r, \mu_{\ell^r})$ is $\mathbb{Z}/\ell^r\mathbb{Z}$ with action through $\chi_{\mathrm{cyc}}^{e+1}$, so $A_r^\vee \cong T_r$ and dually $T_r^\vee \cong A_r$.

Step 1: the local invariants are small. Let v be a place of L above ℓ and $U_v = \chi_{\mathrm{cyc}}(G_{L_v}) \subseteq \mathbb{Z}_\ell^\times$. As G_{L_v} is a subgroup of index $[L_v : \mathbb{Q}_\ell] \leq n$ of $G_{\mathbb{Q}_\ell}$ and χ_{cyc} is surjective on $G_{\mathbb{Q}_\ell}$, the index $k = [\mathbb{Z}_\ell^\times : U_v]$ is at most n, and $u = (1+\ell^2)^k \in U_v$. By the lifting-the-exponent rule, $v_\ell(u^e - 1) = 2 + v_\ell(ke)$. If $x \in H^0(L_v, A)$ and $g \in G_{L_v}$ has $\chi_{\mathrm{cyc}}(g) = u$, then $x = gx = u^{-e}x$, so $(u^{-e} - 1)x = 0$; as $u^{-e} - 1 = -u^{-e}(u^e - 1)$ is $\ell^{2+v_\ell(ke)}$ times a unit of $\mathbb{Z}_\ell$, $\ell^{2+v_\ell(ke)}x = 0$. The ℓ^a-torsion of $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ has ℓ^a elements, so

$$\#H^0(L_v, A) \leq \ell^{2+v_\ell(k)+v_\ell(e)} \leq \ell^2 ne. \tag{40.1}$$

The action of G_{L_v} on A factors through its image in G, so $H^0(G, A) \subseteq H^0(L_v, A)$, and $\#H^0(G, A) \leq \ell^2 ne$; there is at least one place above ℓ.

Step 2: a uniform bound at finite level. Let $r \geq 1$. By definition of Sha^2_S and the vanishing at the complex places, the sequence $0 \to \mathrm{Sha}^2_S(L, T_r) \to H^2(G, T_r) \to \prod_{v|\ell} H^2(L_v, T_r)$ is exact. By item 2 of Theorem B.29 for $M = T_r$, $H^2(L_v, T_r)$ is dual to $H^0(L_v, T_r^\vee) \cong H^0(L_v, A_r) \subseteq H^0(L_v, A)$. By item 2 of Theorem B.34 for $M = A_r$ (L has no real place, S contains the places above ℓ and ∞), $\#\mathrm{Sha}^2_S(L, T_r) = \#\mathrm{Sha}^1_S(L, A_r)$. To bound the latter, let $\iota\colon H^1(G, A_r) \to H^1(G, A)$ be induced by the inclusion. The cohomology sequence of $0 \to A_r \to A \xrightarrow{\ell^r} A \to 0$ (exact, as A is divisible) shows that $\ker\iota$ is the image of $H^0(G, A)$ under the connecting map, so $\#\ker\iota \leq \#H^0(G, A)$. Localisation at each $v \mid \ell$ commutes with ι, so ι maps $\mathrm{Sha}^1_S(L, A_r)$ into $\mathrm{Sha}^1_\ell(L, e)$; the image P is finite, because $H^1(G, A_r)$ is finite (item 1 of Theorem B.34), so

$\#P = \ell^{\operatorname{length} P} \le \ell^s$. Hence $\#\mathrm{Sha}^1_S(L, A_r) \le \#H^0(G,A)\,\ell^s$. Since L has at most n places above ℓ, Step 1 gives

$$\#H^2(G,T_r) \le \#H^0(G,A)\,\ell^s \prod_{v\mid\ell} \#H^0(L_v,A) \le \ell^s\big(\ell^2 ne\big)^{n+1} =: B \qquad (r \ge 1). \tag{40.2}$$

Step 3: passage to $\mathbb{Z}_\ell$-coefficients. The groups $H^1(G,T_r)$ are finite (item 1 of Theorem B.34), so by Theorem B.31 with $i=2$ the map $H^2(G,T) \to \varprojlim_r H^2(G,T_r)$ is an isomorphism. An inverse limit of finite sets of cardinality at most B has at most B elements: finitely many distinct elements of the limit are already distinct in one component, which has at most B elements. So $H^2(G,T)$ is finite and $\log \#H^2(G,T) \le s\log\ell + (n+1)\log(\ell^2 ne)$.

Step 4: the shape of the bound. If ℓ is odd, $\mathbb{Q}(\zeta_\ell) \subseteq L$ gives $\ell - 1 \le n$; if $\ell = 2$, $\ell \le n+1$ trivially. So $\log\ell \le \log(n+1) \le n$, and $(n+1)\log(\ell^2 ne) \le (n+1)(2n+n+e) \le 8n^2 e$. Put $u = 2en \ge 2$ and $Y = \log(2|d_L|) \ge \log 2 > 1/2$; then $8n^2 e \le 2u^2 \le 4u^2 Y$. With Proposition 40.3, $s\log\ell \le \exp(u^{C_0}Y)$, and since $\exp(a)+b \le \exp(a+b)$ for $a,b \ge 0$,

$$\log\#H^2(G,T) \le \exp\big(u^{C_0}Y + 4u^2Y\big) \le \exp\big(5u^{\max(C_0,2)}Y\big) \le \exp\big(u^C Y\big) = \big(2|d_L|\big)^{(2e[L:\mathbb{Q}])^C},$$

which is the claim, with C depending only on ℓ. □

Definition 40.2. Let ℓ be a prime, L a number field, and c, ν integers with $1 \le c \le \nu$, and $c \ge 2$ if $\ell = 2$. A **cyclotomic Kummer layer of level (c,ν) over L** is a triple (F,γ,ζ) where F/L is a finite Galois extension of number fields, γ is a generator of $\mathrm{Gal}(F/L)$ of order $\ell^{\nu-c}$, and $\zeta \in \mathcal{O}_F^\times$ is a primitive ℓ^ν-th root of unity with

$$\gamma(\zeta) = \zeta^{1+\ell^c}. \tag{40.3}$$

Let (F,γ,ζ) be such a layer and let $a \ge 0$, $q \ge 1$, $s \ge 0$ be integers.

(Ky1) The **(γ,a)-eigencharacters of level q** are the homomorphisms $\varphi\colon \mathrm{Cl}(F) \to \mathbb{Z}/q\mathbb{Z}$ with $\varphi([\gamma^{-1}(\mathfrak{a})]) = a\,\varphi([\mathfrak{a}])$ for every fractional ideal $\mathfrak{a}$ of F. They form a group, written $\mathrm{Hom}(\mathrm{Cl}(F),\mathbb{Z}/q\mathbb{Z})^{(\gamma,a)}$.

(Ky2) An element $\alpha \in F^\times$ is a **(γ,a)-Kummer element** if $(\alpha) = \gamma^{-1}(\mathfrak{d})\,\mathfrak{d}^{-a}$ for some fractional ideal $\mathfrak{d}$ of F.

(Ky3) The **twisted norm** of $\alpha \in F^\times$ is

$$\mathrm{N}_{\gamma,a}(\alpha) = \prod_{j=0}^{\ell^{\nu-c}-1} \gamma^j(\alpha)^{a^j} \in F^\times.$$

(Ky4) The set of **twisted Kummer classes** $\mathrm{Ku}_{s,q}(F,\gamma,a) \subseteq F^\times/F^{\times q}$ is the set of classes of $\mathrm{N}_{\gamma,a}(\alpha)^s$, where α runs over the (γ,a)-Kummer elements.

Proposition 40.3. *Let ℓ be a prime. There is a real number $C_0 \ge 0$ such that for every totally complex number field L containing a primitive ℓ-th root of unity (a primitive fourth root of unity if $\ell = 2$) and every integer $e \ge 1$, $\mathrm{len}_\ell(L,e)$ is finite and*

$$\mathrm{len}_\ell(L,e)\,\log\ell \le \big(2|d_L|\big)^{(2e[L:\mathbb{Q}])^{C_0}}.$$

Proof. Let $C_{\mathrm{T}} \geq 0$ be the constant of Theorem 40.29; put $C_1 = \max(C_{\mathrm{T}}, 4)$, $C_2 = C_1 + 5$ and $C_0 = 5C_2 + 11$. Fix ℓ, a totally complex number field L containing a primitive ℓ-th root of unity (fourth if $\ell = 2$) and $e \geq 1$; put $n = [L : \mathbb{Q}]$, $Y = \log(2|d_L|)$, $U = 2en \geq 2$ and $s = \mathrm{len}_\ell(L, e)$.

Step 1: the auxiliary field. By Proposition 40.4 there are a totally complex field L' and integers $c \geq 1$ ($c \geq 2$ if $\ell = 2$), $d \geq 1$ with: $\mu_{\ell^c} \subseteq L'$, $\mu_{\ell^{c+1}} \not\subseteq L'$; $2e + 1 < \ell^c \leq 2n'$, where $n' = [L' : \mathbb{Q}] = dn$; $d \leq (n+1)(4e+4)$ and $|d_{L'}| \leq |d_L|^d (\ell^c)^{n'}$; and $s \leq \mathrm{len}_\ell(L', e)$. Put $Y' = \log(2|d_{L'}|) \geq \log 2 > 1/2$ and $u' = 2en'$; as $n' \geq 2$, $u' \geq 4e \geq 4$.

Step 2: one bound for the eigencharacters of all layers over L'. Let t_1, t_2 be the orders of $H_{2e+1}(\mathrm{GL}_{4e+6}(\mathcal{O}_{L'}), \mathbb{Z})_{\mathrm{tors}}$ and $H_{2e}(\mathrm{GL}_{4e+6}(\mathcal{O}_{L'}), \mathbb{Z})_{\mathrm{tors}}$, finite by Theorem 40.29 (L' totally complex, $m = 2e+1$ and $m = 2e$, both $\leq 2e+1$), and put $b = 2e + (2e+1)(c + 2e + 1)$, $g' = 2n' + \lfloor \log_2 h_{L'} \rfloor + 2$ and $X = (b + v_\ell(e))g' + c + v_\ell(e)$. Let $\nu \geq c$ and let (F, γ, ζ) be a cyclotomic Kummer layer of level (c, ν) over L'; put $a = (1 + \ell^c)^e$. Theorem 40.7, applied to L' and $e - 1 \geq 0$ (its hypotheses read: L' totally complex and $2e + 1 < \ell^c$; its N is $4e + 6$ and its b_{e-1} is b), gives $\#\mathrm{Ku}_{\ell^b, \ell^\nu}(F, \gamma, a) \leq \ell^{\nu r_2(L')} t_1 t_2$. Then Proposition 40.24, applied to L' with $B = \ell^{\nu r_2(L')} t_1 t_2$, shows that $\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma, a)}$ is finite with $\#\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)} \cdot \ell^{\nu r_2(L')} \leq \ell^{\nu r_2(L')} t_1 t_2\, \ell^X$, that is

$$\#\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)} \leq t_1 t_2\, \ell^X, \tag{40.4}$$

a bound independent of ν and of the layer.

Step 3: the Tate–Shafarevich group. By (40.4) the hypothesis of Proposition 40.27 holds for L', c, e and $B = t_1 t_2 \ell^X$. So $\mathrm{len}_\ell(L', e)$ is finite and $\ell^{\mathrm{len}_\ell(L', e)} \leq t_1 t_2 \ell^X$; with $s \leq \mathrm{len}_\ell(L', e)$, s is finite and

$$s \log \ell \leq \log t_1 + \log t_2 + X \log \ell. \tag{40.5}$$

Step 4: the class number of L'. By Minkowski's bound and the count of ideals, $h_{L'} \leq \sum_{k \leq \sqrt{|d_{L'}|}} k^{n'} \leq |d_{L'}|^{(n'+1)/2}$, so $\lfloor \log_2 h_{L'} \rfloor \leq \frac{n'+1}{2 \log 2} \log |d_{L'}| \leq 2n'Y'$ and $g' \leq 2n' + 2n'Y' + 2$.

Step 5: the bound in terms of L'. Since $e \geq 1$ and $n' \geq 2$: $2e + 1 \leq u'$; $c < \ell^c \leq 2n' \leq u'$; $\log \ell \leq \ell \leq u'$; $v_\ell(e) \leq \log_2 e < e \leq u'$. Hence $b + v_\ell(e) \leq u' + u' \cdot 2u' + u' \leq 4u'^2$, $g' \leq 2u' + u'Y' \leq 5u'Y'$ (using $2 \leq u'$, $2n' \leq u'$, $1 < 2Y'$), and

$$X \log \ell \leq (4u'^2 \cdot 5u'Y' + 2u')u' \leq 24u'^4 Y'.$$

By Theorem 40.29 for L', $\log t_i \leq \exp(u'^{C_{\mathrm{T}}} Y')$. With (40.5) and $2\exp(x) + y \leq \exp(x + 1 + y)$ for $x, y \geq 0$,

$$s \log \ell \leq \exp\bigl(u'^{C_{\mathrm{T}}} Y' + 1 + 24u'^4 Y'\bigr) \leq \exp\bigl(27u'^{C_1} Y'\bigr) \leq \exp\bigl(u'^{C_2} Y'\bigr).$$

Step 6: back to L. From $d \leq (n+1)(4e+4) \leq 16en = 8U$ and $n' = dn \leq 16en^2 \leq 4U^2$ we get $u' = 2en' \leq 32e^2n^2 = 8U^2 \leq U^5$. From $|d_{L'}| \leq |d_L|^d (\ell^c)^{n'}$, $d \geq 1$ and $\ell^c \leq 2n'$,

$$Y' \leq \log 2 + d \log |d_L| + n' \log(2n') \leq dY + 2n'^2 \leq 8UY + 32U^4 \leq 72U^4 Y \leq U^{11} Y,$$

using $Y > 1/2$ and $72 \leq U^7$. Hence $u'^{C_2} Y' \leq U^{5C_2 + 11} Y = U^{C_0} Y$, and by Step 5

$$\mathrm{len}_\ell(L, e) \log \ell = s \log \ell \leq \exp\bigl(U^{C_0} Y\bigr) = \bigl(2|d_L|\bigr)^{(2e[L:\mathbb{Q}])^{C_0}}.$$

The constant $C_0 \geq 0$ does not depend on L or e (nor on ℓ). □

Proposition 40.4. *Let ℓ be a prime, L a number field containing a primitive ℓ-th root of unity (a primitive fourth root of unity if $\ell = 2$), and $e \geq 1$ an integer. There are a totally complex number field L' and integers $c \geq 1$ ($c \geq 2$ if $\ell = 2$) and $d \geq 1$ such that:*

1. *L' contains a primitive ℓ^c-th root of unity and no primitive ℓ^{c+1}-th root of unity;*
2. *$2e+1 < \ell^c \le 2[L':\mathbb{Q}]$;*
3. *$[L':\mathbb{Q}] = d\,[L:\mathbb{Q}]$, $d \le ([L:\mathbb{Q}]+1)(4e+4)$, and $|d_{L'}| \le |d_L|^d\,(\ell^c)^{[L':\mathbb{Q}]}$;*
4. *$\mathrm{len}_\ell(L,e) \le \mathrm{len}_\ell(L',e)$.*

Proof. Let $n = [L:\mathbb{Q}]$; as L contains a primitive ℓ-th root of unity with ℓ odd, or i, it has no real place and $n \ge 2$, and $\ell \le n+1$ ($\ell - 1 = \varphi(\ell) \le n$ for ℓ odd). Let c_0 be the largest integer with $\mu_{\ell^{c_0}} \subseteq L$ (it exists as $\varphi(\ell^k) \le n$ when $\mu_{\ell^k} \subseteq L$); $c_0 \ge 1$, and $c_0 \ge 2$ if $\ell = 2$. Let $m \ge 0$ be the least integer with $\ell^{c_0+m} > 2e+1$. Fix an algebraic closure $\overline{L}$, put $L_k = L(\mu_{\ell^k}) \subseteq \overline{L}$, $L' = L_{c_0+m}$, $d = \ell^m$, and let c be the largest integer with $\mu_{\ell^c} \subseteq L'$.

Step 1: the cyclotomic tower. The cyclotomic character embeds $\Gamma = \mathrm{Gal}(L(\mu_{\ell^\infty})/L)$ as a closed subgroup of U_{c_0}, and $\tau \in \Gamma$ fixes μ_{ℓ^k} ($k \ge 1$) exactly when $\chi_{\mathrm{cyc}}(\tau) \in U_k$. The image is infinite, since $[L_k : L] \ge \varphi(\ell^k)/n \to \infty$, so it is U_{k_1} for some $k_1 \ge c_0$, and $k_1 = c_0$ because the image lies in U_{c_0+1} only if $\mu_{\ell^{c_0+1}} \subseteq L$. Hence $\chi_{\mathrm{cyc}}\colon \Gamma \to U_{c_0}$ is an isomorphism, $\mathrm{Gal}(L(\mu_{\ell^\infty})/L')$ maps onto U_{c_0+m}, and $[L':L] = [U_{c_0} : U_{c_0+m}] = \ell^m = d$. Let $\sigma \in \mathrm{Gal}(L'/L)$ be the restriction of an element of Γ with χ_{cyc}-value $u = 1+\ell^{c_0}$; it generates the cyclic group $\mathrm{Gal}(L'/L) \cong U_{c_0}/U_{c_0+m}$ of order ℓ^m.

Step 2: items 1 to 3. L' contains L, so it has no real place; $c \ge c_0 + m \ge c_0$ gives the conditions on c, and item 1 holds by the choice of c. $[L':\mathbb{Q}] = dn$. If $m = 0$, then $d = 1$. If $m \ge 1$, the minimality of m gives $\ell^{c_0+m-1} \le 2e+1$, and as $c_0 \ge 1$, $d = \ell^m \le \ell \cdot \ell^{c_0+m-1} \le \ell(2e+1) \le (n+1)(4e+4)$. Further $\ell^c \ge \ell^{c_0+m} > 2e+1$; $\mathbb{Q}(\mu_{\ell^c}) \subseteq L'$ gives $\ell^c/2 \le \ell^{c-1}(\ell-1) = \varphi(\ell^c) \le [L':\mathbb{Q}]$. For the discriminant, $L' = L(\zeta)$ with ζ a primitive M-th root of unity, $M = \ell^{c_0+m}$; its minimal polynomial f over L divides $X^M - 1$ in $\mathcal{O}_L[X]$, say $X^M - 1 = fg$, so $M\zeta^{M-1} = f'(\zeta)g(\zeta)$ and, ζ being a unit, $\mathfrak{D}_{L'/L}$ divides $f'(\zeta)$, which divides M. Hence $\mathrm{N}_{L'/\mathbb{Q}}(\mathfrak{D}_{L'/L}) \le M^{[L':\mathbb{Q}]} \le (\ell^c)^{[L':\mathbb{Q}]}$ and $|d_{L'}| \le |d_L|^d(\ell^c)^{[L':\mathbb{Q}]}$.

Step 3: restriction is injective on H^1. Let $\Omega \subseteq \overline{L}$ be the maximal extension of L unramified outside the places above ℓ, $G = \mathrm{Gal}(\Omega/L) = G_{L,S_\ell}$ and $A = \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$. As L'/L is unramified outside ℓ, $L' \subseteq \Omega$, Ω is also the maximal extension of L' unramified outside the places above ℓ, and $H = \mathrm{Gal}(\Omega/L') = G_{L',S_\ell}$ is normal in G with $G/H = \mathrm{Gal}(L'/L)$. By Step 1, $\chi_{\mathrm{cyc}}(H) = U_{c_0+m}$, so A^H is the set of $x \in A$ with $(y^{-e}-1)x = 0$ for all $y \in U_{c_0+m}$; by the lifting-the-exponent rule the least valuation of $y^{-e}-1$ is $a := c_0 + m + v(e)$, attained at $y = (1+\ell^{c_0})^{\ell^m}$, so $A^H = A[\ell^a]$, cyclic of order ℓ^a. On it σ acts by $\beta = u^{-e}$ with $v(\beta-1) = c_0 + v(e)$. Thus $(\sigma-1)A^H = \ell^{c_0+v(e)}A[\ell^a]$ has order $\ell^{a-c_0-v(e)} = \ell^m$; and $\mathrm{Nm} = \sum_{i<\ell^m}\beta^i = (\beta^{\ell^m}-1)/(\beta-1)$ has valuation m, so $\ker \mathrm{Nm} = A[\ell^m]$ also has order ℓ^m ($a \ge m$). In a cyclic group the subgroup of a given order is unique, so $\ker \mathrm{Nm} = (\sigma-1)A^H$ and $H^1(\mathrm{Gal}(L'/L), A^H) = 0$. By inflation–restriction, $\mathrm{res}\colon H^1(G,A) \to H^1(H,A)$ is injective.

Step 4: item 4. Let $x \in \mathrm{Sha}^1_\ell(L,e)$ and let w be a place of L' above ℓ, over the place v of L. The localisation of $\mathrm{res}(x)$ at w is the restriction of the localisation of x at v along $G_{L'_w} \subseteq G_{L_v}$, hence 0. So res maps $\mathrm{Sha}^1_\ell(L,e)$ injectively and $\mathbb{Z}_\ell$-linearly into $\mathrm{Sha}^1_\ell(L',e)$, and lengths are monotone under injective maps: $\mathrm{len}_\ell(L,e) \le \mathrm{len}_\ell(L',e)$ in $\mathbb{N} \cup \{\infty\}$. □

Definition 40.5. Let G be a group and A a commutative ring. For $m \ge 0$, $\mathrm{Bar}_m(G;A)$ is the free A-module on the set of tuples $[g_1|\dots|g_m] \in G^m$, and the **bar differential** $\partial\colon \mathrm{Bar}_{m+1}(G;A) \to \mathrm{Bar}_m(G;A)$ is the A-linear map

$$\partial[g_0|\dots|g_m] = [g_1|\dots|g_m] + \sum_{j=0}^{m-1}(-1)^{j+1}[g_0|\dots|g_jg_{j+1}|\dots|g_m] + (-1)^{m+1}[g_0|\dots|g_{m-1}],$$

so that $(\mathrm{Bar}_\bullet(G;A),\partial)$ is the bar complex computing $H_\bullet(G;A)$ with trivial coefficients. An element $z\in\mathrm{Bar}_m(G;A)$, $m\ge 1$, is a **cycle** if $\partial z=0$ and a **boundary** if $z\in\partial\,\mathrm{Bar}_{m+1}(G;A)$. A homomorphism $f\colon G\to H$ induces $f_*[g_1|\dots|g_m]=[f(g_1)|\dots|f(g_m)]$. For $k\in G$ the **prism operator** $\mathrm{Pr}_k\colon \mathrm{Bar}_m(G;A)\to\mathrm{Bar}_{m+1}(G;A)$ is

$$\mathrm{Pr}_k[g_0|\dots|g_{m-1}]=\sum_{i=0}^{m}(-1)^i\,[g_0|\dots|g_{i-1}|k|k^{-1}g_ik|\dots|k^{-1}g_{m-1}k].$$

For integers $q\ge 1$ and $e\ge 0$ let $C_q=\langle\tau\rangle$ be the cyclic group of order q with a fixed generator τ; the **standard cycle** is

$$\mathbf{z}_{q,e}=\sum_{(j_0,\dots,j_e)\in(\mathbb{Z}/q\mathbb{Z})^{e+1}}[\tau^{j_0}|\tau|\tau^{j_1}|\tau|\dots|\tau^{j_e}|\tau]\in\mathrm{Bar}_{2e+2}(C_q;\mathbb{Z}/q\mathbb{Z}).$$

Let R be a commutative ring and $n\ge 0$. For $n\le n'$ the **stabilisation** $\mathrm{stab}_{n,n'}\colon \mathrm{GL}_n(R)\to\mathrm{GL}_{n'}(R)$ is $g\mapsto\begin{pmatrix}g&0\\0&1\end{pmatrix}$, and for $d\ge 1$ the **block-diagonal map** $\mathrm{blk}_{d,n}\colon\mathrm{GL}_n(R)\to\mathrm{GL}_{dn}(R)$ is $g\mapsto\mathrm{diag}(g,\dots,g)$ (d blocks). For a ring homomorphism $r\colon R\to k$ to a field, $\mathrm{red}_{r,n}\colon\mathrm{GL}_n(R)\to\mathrm{GL}(k^n)$ applies r to the entries.

Definition 40.6. Let k be a finite field, A a commutative ring and $m\ge 1$. An **additive family of degree m over k with values in A** is a family $\theta=(\theta_V)_V$ of A-linear maps $\theta_V\colon\mathrm{Bar}_m(\mathrm{GL}(V);A)\to A$, one for each finite-dimensional k-vector space V, such that:

(Fa1) θ_V vanishes on boundaries;

(Fa2) for every k-linear isomorphism $\varphi\colon V\to W$ and every cycle $z\in\mathrm{Bar}_m(\mathrm{GL}(V);A)$,

$$\theta_W((c_\varphi)_*z)=\theta_V(z),$$

where $c_\varphi(g)=\varphi g\varphi^{-1}$;

(Fa3) for every group G, all homomorphisms $\rho\colon G\to\mathrm{GL}(V)$, $\sigma\colon G\to\mathrm{GL}(W)$ and every cycle $z\in\mathrm{Bar}_m(G;A)$, $\theta_{V\oplus W}((\rho\oplus\sigma)_*z)=\theta_V(\rho_*z)+\theta_W(\sigma_*z)$, where $(\rho\oplus\sigma)(g)=\rho(g)\oplus\sigma(g)$.

Let $q\ge 1$ and $e\ge 0$ be integers, $\zeta\in k^\times$ with $\zeta^q=1$, and $v\colon k^\times\to\mathbb{Z}/q\mathbb{Z}$ a homomorphism. An additive family θ of degree $2e+3$ over k with values in $\mathbb{Z}/q\mathbb{Z}$ has the **value property for** (q,e,ζ,v) if

(Fa4) for every V, every integer $x\ge 0$ and every $g\in\mathrm{GL}(V)$,

$$\theta_V\Big(\mathrm{Pr}_g\big((s_V\circ\chi_x)_*\mathbf{z}_{q,e}\big)\Big)=x^{e+1}\,v(\det g),$$

where $\chi_x\colon C_q\to k^\times$ is $\tau^j\mapsto\zeta^{xj}$ and $s_V\colon k^\times\to\mathrm{GL}(V)$ sends λ to multiplication by λ.

Let R and A be commutative rings, B an A-module and $m\ge 1$. A **primitive family of degree m over R with values in B** is a family $\Phi=(\Phi_n)_{n\ge0}$ of A-linear maps $\Phi_n\colon\mathrm{Bar}_m(\mathrm{GL}_n(R);A)\to B$ such that:

(Pm1) Φ_n vanishes on boundaries;

(Pm2) $\Phi_{n'}((\mathrm{stab}_{n,n'})_*z)=\Phi_n(z)$ for $n\le n'$ and every cycle z;

(Pm3) $\Phi_{dn}((\mathrm{blk}_{d,n})_* z) = d\,\Phi_n(z)$ for $d \geq 1$ and every cycle z.

Theorem 40.7. *Let L be a totally complex number field, ℓ a prime, (F, γ, ζ) a cyclotomic Kummer layer of level (c, ν) over L, and $e \geq 0$ an integer with $2e + 3 < \ell^c$. Put $N = 4e + 10$ and $b_e = 2e + 2 + (2e + 3)(c + 2e + 3)$. If the torsion subgroups $H_{2e+3}(\mathrm{GL}_N(\mathcal{O}_L), \mathbb{Z})_{\mathrm{tors}}$ and $H_{2e+2}(\mathrm{GL}_N(\mathcal{O}_L), \mathbb{Z})_{\mathrm{tors}}$ are finite, of orders t_1 and t_2, then*

$$\#\mathrm{Ku}_{\ell^{b_e}, \ell^\nu}\big(F, \gamma, (1 + \ell^c)^{e+1}\big) \leq \ell^{\nu\, r_2(L)}\, t_1\, t_2.$$

Proof. Put $q = \ell^\nu$, $\kappa = 1 + \ell^c$, $a = \kappa^{e+1}$, $M = 2e + 3$, $s = \ell^{b_e}$ (so $b_e = (2e + 2) + M(c + M)$), $\mathrm{N} = \mathrm{N}_{\gamma,a}$, and let p_e be the integer of Proposition 40.9.

Step 1: p_e divides $\ell^{M(c+M)}$ in $\mathbb{Z}/q\mathbb{Z}$. For $0 \leq j < M$, $j \neq e + 1$, put $d = |e + 1 - j|$, so $1 \leq d \leq e + 1 < M$; then $\kappa^{e+1} - \kappa^j = \pm\kappa^{\min(e+1,j)}(\kappa^d - 1)$, and κ is prime to ℓ, so $v_\ell(\kappa^{e+1} - \kappa^j) = c + v_\ell(d) < c + M$. Hence $p_e = \ell^w u_0$ with $\ell \nmid u_0$ and $w < M(c + M)$, and $\ell^{M(c+M)} = p_e \cdot u_0^{-1} \ell^{M(c+M)-w}$ in $\mathbb{Z}/q\mathbb{Z}$, u_0 being invertible there. Consequently, for $X \in \mathbb{Z}/q\mathbb{Z}$,

$$p_e\, X = 0 \implies \ell^{M(c+M)} X = 0. \tag{40.6}$$

Step 2: data at the degree-one primes. Let $T \subseteq \mathrm{Ku}_{s,q}(F, \gamma, a)$ be finite. For each $t \in T$ choose a (γ, a)-Kummer element α_t whose class $\mathrm{N}(\alpha_t)^s F^{\times q}$ is t, and let $S = \{\alpha_t : t \in T\}$, so $\#S = \#T$ and distinct elements of S have distinct classes. For $\alpha \in S$ let N_α, y_α, b_α be given by Proposition 40.9 (its hypothesis $2e + 3 < \ell^c$ holds). Put $b = \ell \prod_{\alpha \in S} b_\alpha \neq 0$ and let I be the set of nonzero primes $\mathfrak{P}$ of $\mathcal{O}_F$ with $b \notin \mathfrak{P}$ for which $\mathcal{O}_L \to \mathcal{O}_F/\mathfrak{P}$ is surjective. For $\mathfrak{P} \in I$ let $k_\mathfrak{P} = \mathcal{O}_F/\mathfrak{P}$, $r_\mathfrak{P} \colon \mathcal{O}_F \to k_\mathfrak{P}$ the projection and $r_{\mathfrak{P},L}$ its restriction to $\mathcal{O}_L$. As $\ell \notin \mathfrak{P}$, $r_\mathfrak{P}(\zeta)$ is a primitive q-th root of unity, so q divides the order of the cyclic group $k_\mathfrak{P}^\times$; let $v_\mathfrak{P} \colon k_\mathfrak{P}^\times \to \mathbb{Z}/q\mathbb{Z}$ be a surjective homomorphism, whose kernel is $(k_\mathfrak{P}^\times)^q$. By Proposition 40.17 there is an additive family $\theta^\mathfrak{P}$ of degree M over $k_\mathfrak{P}$ with values in $\mathbb{Z}/q\mathbb{Z}$ having the value property for $(q, e, r_\mathfrak{P}(\zeta), v_\mathfrak{P})$, and by Lemma 40.20 $\Phi_n^\mathfrak{P} = \theta^\mathfrak{P}_{k_\mathfrak{P}^n} \circ (\mathrm{red}_{r_{\mathfrak{P},L},n})_*$ is a primitive family of degree M over $\mathcal{O}_L$ with values in $\mathbb{Z}/q\mathbb{Z}$.

Step 3: separation at one prime. Let $\mathfrak{P} \in I$ and $\alpha, \alpha' \in S$ with $\ell^{2e+2}\Phi^\mathfrak{P}_{N_\alpha}(y_\alpha) = \ell^{2e+2}\Phi^\mathfrak{P}_{N_{\alpha'}}(y_{\alpha'})$. As $r_\mathfrak{P}(b_\alpha) \neq 0 \neq r_\mathfrak{P}(b_{\alpha'})$, Proposition 40.9 shows that $\mathrm{N}(\alpha)$ and $\mathrm{N}(\alpha')$ are units at $\mathfrak{P}$, with residues u, u', and $\Phi^\mathfrak{P}_{N_\alpha}(y_\alpha) = p_e\, v_\mathfrak{P}(u)$, $\Phi^\mathfrak{P}_{N_{\alpha'}}(y_{\alpha'}) = p_e\, v_\mathfrak{P}(u')$. So $p_e \cdot \ell^{2e+2}(v_\mathfrak{P}(u) - v_\mathfrak{P}(u')) = 0$, and by (40.6) $v_\mathfrak{P}(u^s u'^{-s}) = \ell^{b_e}(v_\mathfrak{P}(u) - v_\mathfrak{P}(u')) = 0$. Hence the residue $u^s u'^{-s}$ of $\mathrm{N}(\alpha)^s \mathrm{N}(\alpha')^{-s}$ at $\mathfrak{P}$ is a q-th power in $k_\mathfrak{P}^\times$.

Step 4: injectivity. Let $B = \prod_{\mathfrak{P} \in I} \mathbb{Z}/q\mathbb{Z}$ and $\Phi_n = (\Phi_n^\mathfrak{P})_{\mathfrak{P} \in I}$; since (Pm1)–(Pm3) hold in each coordinate, Φ is a primitive family of degree M over $\mathcal{O}_L$ with values in the $\mathbb{Z}/q\mathbb{Z}$-module B. Let $f \colon S \to B$, $f(\alpha) = \ell^{2e+2}\Phi_{N_\alpha}(y_\alpha)$. If $f(\alpha) = f(\alpha')$, then by Step 3 the element $\beta = \mathrm{N}(\alpha)^s \mathrm{N}(\alpha')^{-s}$ is a unit with q-th power residue at every $\mathfrak{P} \in I$; F contains the primitive q-th root of unity ζ, so Lemma 40.21 gives $\beta \in F^{\times q}$. Thus α and α' have the same class, and $\alpha = \alpha'$: f is injective.

Step 5: the count. Apply Theorem 40.22 with $k = 2e + 2$, which is even, to Φ (L is totally complex); its $N_0 = 2k + 6$ is $4e + 10 = N$, and its t_{k+1}, t_k are t_1, t_2. Each $f(\alpha)$ is of the form $\ell^k \Phi_n(y)$ with y a cycle, so $\#T = \#S = \#f(S) \leq \ell^{\nu r_2(L)} t_1 t_2$. As this holds for every finite $T \subseteq \mathrm{Ku}_{s,q}(F, \gamma, a)$, the set is finite and $\#\mathrm{Ku}_{\ell^{b_e}, \ell^\nu}(F, \gamma, (1 + \ell^c)^{e+1}) \leq \ell^{\nu r_2(L)} t_1 t_2$. □

Definition 40.8. Let $L \subseteq F$ be number fields with F/L Galois, and J a finite set; F^J is the F-vector space of maps $J \to F$, regarded also as an L-vector space.

(Lt1) For a family $\mathfrak{b} = (\mathfrak{b}_j)_{j\in J}$ of fractional ideals of F, $M(\mathfrak{b}) = \{x \in F^J : x_j \in \mathfrak{b}_j \text{ for all } j\}$; so $M((\mathcal{O}_F)_j) = \mathcal{O}_F^J$. For $b \in \mathcal{O}_L \smallsetminus \{0\}$, $M_b = \mathcal{O}_F[1/b]^J$, and $\mathrm{Aut}_b(F^J)$ is the group of L-linear automorphisms g of F^J with $g(M_b) = M_b$. Similarly, $\mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J)$ is the group of L-linear automorphisms g of F^J with $g(\mathcal{O}_F^J) = \mathcal{O}_F^J$; it is contained in every $\mathrm{Aut}_b(F^J)$, as $M_b = \mathcal{O}_L[1/b]\cdot\mathcal{O}_F^J$.

(Lt2) Let $q \geq 1$ and $\zeta \in \mathcal{O}_F^\times$ of order q. For $\sigma \in \mathrm{Gal}(F/L)$, $\kappa_\zeta(\sigma) \in (\mathbb{Z}/q\mathbb{Z})^\times$ is defined by $\sigma(\zeta) = \zeta^{\kappa_\zeta(\sigma)}$. For a map $h\colon J \to \mathbb{Z}/q\mathbb{Z}$, the **diagonal action** $\mathrm{D}_h\colon C_q \to \mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J)$ is $(\mathrm{D}_h(\tau^c)x)_j = \zeta^{c\,h(j)}x_j$.

(Lt3) Let $h\colon J \to \mathbb{Z}/q\mathbb{Z}$, $\mathfrak{b}$ a family of fractional ideals indexed by J and $\delta\colon \mathbb{Z}/q\mathbb{Z} \to F^\times$. An L-linear automorphism g of F^J is **adapted to** $(h, \mathfrak{b}, \delta)$ if $g(\mathcal{O}_F^J) = M(\mathfrak{b})$ and there are a map $s\colon J \to \mathrm{Gal}(F/L)$ and, writing $J_x = \{j \in J : \kappa_\zeta(s_j)h(j) = x\}$ for $x \in \mathbb{Z}/q\mathbb{Z}$ and $w^s = (s_i(w_i))_{i\in J}$ for $w \in F^J$, F-linear automorphisms g'_x of F^{J_x} with $\det g'_x = \delta(x)$ (the determinant of the automorphism of the zero space being 1), such that

$$s_j((gw)_j) = \big(g'_x(w^s|_{J_x})\big)_j \qquad \text{for all } w \in F^J,\ x \in \mathbb{Z}/q\mathbb{Z},\ j \in J_x.$$

(Lt4) Let k be a finite field and $r\colon \mathcal{O}_F \to k$ a ring homomorphism whose restriction r_L to $\mathcal{O}_L$ is surjective. The homomorphism r is **split in** F/L if the map $\mathcal{O}_F \to k^{\mathrm{Gal}(F/L)}$, $a \mapsto (r(\sigma(a)))_\sigma$, is surjective with kernel $\mathfrak{p}\mathcal{O}_F$, where $\mathfrak{p} = \ker r_L$. If $r(b) \neq 0$, r extends uniquely to $\mathcal{O}_F[1/b]$, and the **reduction** $\mathrm{rd}_r\colon M_b \to k^{\mathrm{Gal}(F/L)\times J}$ is $\mathrm{rd}_r(x) = \big(r(\sigma(x_j))\big)_{(\sigma,j)}$.

Proposition 40.9. *Let L be a number field, ℓ a prime, (F, γ, ζ) a cyclotomic Kummer layer of level (c, ν) over L, and $e \geq 0$ an integer with $2e + 3 < \ell^c$. Put $q = \ell^\nu$, $\kappa = 1 + \ell^c$, $a = \kappa^{e+1}$ and*

$$p_e = \prod_{0\leq j<2e+3,\ j\neq e+1} (\kappa^{e+1} - \kappa^j) \in \mathbb{Z}.$$

For every (γ, a)-Kummer element $\alpha \in F^\times$ there are an integer $N \geq 1$, a cycle

$$y \in \mathrm{Bar}_{2e+3}(\mathrm{GL}_N(\mathcal{O}_L); \mathbb{Z}/q\mathbb{Z})$$

and $b \in \mathcal{O}_F \smallsetminus \{0\}$ with the following property. Let k be a finite field and $r\colon \mathcal{O}_F \to k$ a ring homomorphism whose restriction r_L to $\mathcal{O}_L$ is surjective and with $r(b) \neq 0$; let $v\colon k^\times \to \mathbb{Z}/q\mathbb{Z}$ be a homomorphism and θ an additive family of degree $2e + 3$ over k with values in $\mathbb{Z}/q\mathbb{Z}$ having the value property for $(q, e, r(\zeta), v)$. Then $\mathrm{N}_{\gamma,a}(\alpha)$ is a unit at the prime $\ker r$, and its residue $u \in k^\times$ satisfies

$$\theta_{k^N}\big((\mathrm{red}_{r_L,N})_*\, y\big) = p_e \cdot v(u).$$

Proof. Put $q = \ell^\nu$, $\kappa = 1 + \ell^c$, $a = \kappa^{e+1}$, $M = 2e + 3$, $\Gamma = \mathrm{Gal}(F/L) = \{\gamma^j : 0 \leq j < \ell^{\nu-c}\}$, $J = (\mathbb{Z}/q\mathbb{Z})^2$, $T = \{0, \dots, M\}$ and $\chi_t(j) = j_1 + tj_2$ for $t \in T$. By (40.3), $\kappa_\zeta(\gamma^j) = \kappa^j$. By the lifting-the-exponent rule $\kappa^{\ell^{\nu-c}} \equiv 1 \pmod q$. Let α be a (γ, a)-Kummer element, $(\alpha) = \gamma^{-1}(\mathfrak{d})\,\mathfrak{d}^{-a}$.

Step 1: the combinatorial data. By Lemma 40.10 ($q = \ell^\nu$, $2e + 3 = M$) there are $n_t \in \mathbb{Z}/q\mathbb{Z}$ ($t \in T$) and $t_0 \in T$ with n_{t_0} a unit such that $\sum_t n_t(d_t)_*\mathbf{z}_{q,e}$ is a boundary, $d_t(c) = (c, c^t)$; and $\mathbf{z}_{q,e}$ is a cycle. Write $P(Y) = \prod_{j<M}(Y - \kappa^j) = \sum_{i=0}^M p_i Y^i$. As $M < \ell^c$ and $1 \leq c \leq \nu$, Lemma 40.11 gives $\eta\colon J \to \mathbb{Z}$ with $\sum_{\chi_t(j)=y}\eta(j) = 0$ for $t \in T \smallsetminus \{t_0\}$ and $\sum_{\chi_{t_0}(j)=y}\eta(j) = \sum_{i\leq M,\,\kappa^i\equiv y} p_i$, for all y.

Step 2: the element β. Let $P_e(Y) = \prod_{j<M,\, j\neq e+1}(Y-\kappa^j) = \sum_i \pi_i Y^i$; then $(Y-a)P_e(Y) = P(Y)$ and $P_e(a) = p_e$. Put $\beta = \prod_i \gamma^{-i}(\alpha)^{\pi_i}$. Let $\mathbb{Z}[Y]$ act on the group of fractional ideals by $f\cdot\mathfrak{a} = \prod_i \gamma^{-i}(\mathfrak{a})^{f_i}$; this is a module structure, as γ^{-1} is an automorphism. Then $(\alpha) = (Y-a)\cdot\mathfrak{d}$ and

$$(\beta) = P_e\cdot(\alpha) = P\cdot\mathfrak{d} = \prod_{i=0}^{M}\gamma^{-i}(\mathfrak{d})^{p_i}.$$

Step 3: adapted automorphisms. Let $\mathfrak{b} = (\mathfrak{d}^{\eta(j)})_{j\in J}$. For $t\neq t_0$, (Ca1) of Proposition 40.12 with $h=\chi_t$ gives g_t adapted to $(\chi_t,\mathfrak{b},1)$; put $\delta_t = 1$. For t_0: $\chi_{t_0}(1,0)=1$, the line sums are as required by Step 1 and (β) by Step 2, so (Ca2) gives g_{t_0} adapted to $(\chi_{t_0},\mathfrak{b},\delta_{t_0})$ with $\delta_{t_0}(1)=\beta$ and $\delta_{t_0}(x)=1$ for $x\neq 1$.

Step 4: the element b. Let b_0 be as in (Re1) of Proposition 40.14, and $b = b_0\prod_{\mathfrak{P}} p_{\mathfrak{P}} \in \mathcal{O}_L\smallsetminus\{0\}$, the product over the primes $\mathfrak{P}$ in the support of $\mathfrak{d}$, $p_{\mathfrak{P}}$ the rational prime below $\mathfrak{P}$. Every prime in the support of $\mathfrak{d}$, hence (as $b\in L$) of every $\sigma(\mathfrak{d})$, contains b. Consequently $\mathfrak{d}^{\eta(j)}\mathcal{O}_F[1/b] = \mathcal{O}_F[1/b]$, so $\mathcal{O}_L[1/b]M(\mathfrak{b}) = M_b$ and $g_t(M_b) = \mathcal{O}_L[1/b]\,g_t(\mathcal{O}_F^J) = M_b$: each $g_t\in \mathrm{Aut}_b(F^J)$. Also α, β and their conjugates lie in $U = \mathcal{O}_F[1/b]^\times$, a Γ-stable group, by Step 2.

Step 5: the cycle. Let $G = \mathrm{Aut}_b(F^J)$, $H = \mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J)\leq G$ and $\rho\colon C_q\times C_q\to H$, $(\rho(\tau^{c_1},\tau^{c_2})x)_j = \zeta^{c_1 j_1 + c_2 j_2}x_j$; then $\rho\circ d_t = \mathrm{D}_{\chi_t}$. The hypotheses of Lemma 40.13 hold: g_t commutes with $\mathrm{D}_{\chi_t}(C_q)$ by Proposition 40.15; ρ takes values in H; $\rho(x)$ is diagonal with unit entries, so it preserves $M(\mathfrak{b})$ and $g_{t_0}^{-1}\rho(x)g_{t_0}$ preserves $g_{t_0}^{-1}M(\mathfrak{b}) = \mathcal{O}_F^J$; and $g_t^{-1}g_{t_0}$ maps $\mathcal{O}_F^J$ onto $g_t^{-1}M(\mathfrak{b}) = \mathcal{O}_F^J$. With $A=\mathbb{Z}/q\mathbb{Z}$, $m = 2e{+}1$ and $z = \mathbf{z}_{q,e}$, it gives a cycle $y_0\in \mathrm{Bar}_{2e+3}(H;\mathbb{Z}/q\mathbb{Z})$ with

$$\iota_* y_0 - \sum_{t\in T} n_t\,\mathrm{Pr}_{g_t}\big((\mathrm{D}_{\chi_t})_*\mathbf{z}_{q,e}\big) \text{ a boundary in } G. \tag{40.7}$$

Let N and λ be as in (Re3) and put $y = n_{t_0}^{-1}\lambda_* y_0 \in \mathrm{Bar}_{2e+3}(\mathrm{GL}_N(\mathcal{O}_L);\mathbb{Z}/q\mathbb{Z})$, a cycle. These are the N, y and b of the statement.

Step 6: the value. Let k, r, v, θ be as in the statement. As $b_0\mid b$, $r(b_0)\neq 0$, so r is split by (Re1), and Rd_r exists by (Re2). As r extends to $\mathcal{O}_F[1/b]$, $f = v\circ r$ is a homomorphism $U\to\mathbb{Z}/q\mathbb{Z}$; $\mathrm{N}_{\gamma,a}(\alpha)\in U$ is a unit at $\ker r$, with residue $u = r(\mathrm{N}_{\gamma,a}(\alpha))$. By (Re3), then (40.7) with (Fa1), push-forward along Rd_r and Proposition 40.15,

$$\theta_{k^N}\big((\mathrm{red}_{r_L,N}\circ\lambda)_* y_0\big) = \theta_{k^{\Gamma\times J}}\big((\mathrm{Rd}_r)_*\iota_* y_0\big) = \sum_{t\in T} n_t \sum_{\sigma\in\Gamma}\sum_x (\kappa_\zeta(\sigma)x)^{e+1} f(\sigma(\delta_t(x))).$$

Since $f(1)=0$, only $t=t_0$ and $x=1$ contribute, and with $\sigma=\gamma^j$, using $\kappa^{j(e+1)} = a^j$ and $a^{\ell^{\nu-c}}\equiv 1 \pmod q$ to substitute $j'\equiv j-i \pmod{\ell^{\nu-c}}$,

$$\begin{aligned}\sum_j a^j f(\gamma^j\beta) &= \sum_i \pi_i \sum_j a^j f(\gamma^{j-i}\alpha) = \sum_i \pi_i a^i \sum_{j'=0}^{\ell^{\nu-c}-1} a^{j'} f(\gamma^{j'}\alpha)\\ &= P_e(a)\, f\Big(\prod_{j'}\gamma^{j'}(\alpha)^{a^{j'}}\Big) = p_e\, v(u).\end{aligned}$$

Hence $\theta_{k^N}((\mathrm{red}_{r_L,N})_* y) = n_{t_0}^{-1}\, n_{t_0}\, p_e\, v(u) = p_e\cdot v(u)$. □

Lemma 40.10. *Let $q\geq 1$ and $e\geq 0$ be integers. Then $\mathbf{z}_{q,e}$ is a cycle. If moreover q is a power of a prime ℓ, and $d_t\colon C_q\to C_q\times C_q$ is $c\mapsto(c,c^t)$ for $0\leq t\leq 2e+3$, then there are $n_0,\dots,n_{2e+3}\in\mathbb{Z}/q\mathbb{Z}$ and $t_0\in\{0,\dots,2e+3\}$ with n_{t_0} a unit such that $\sum_{t=0}^{2e+3} n_t\,(d_t)_*\mathbf{z}_{q,e}$ is a boundary in $\mathrm{Bar}_{2e+2}(C_q\times C_q;\mathbb{Z}/q\mathbb{Z})$.*

Proof. Step 1: $\mathbf{z}_{q,e}$ is a cycle. Write $\mathbf{z}_{q,e} = \sum_{a \in C_q^{e+1}} \sigma_a$ with $\sigma_a = [a_0|\tau|a_1|\tau|\dots|a_e|\tau]$, of length $n = 2e+2$, and apply ∂ face by face, summing over a. The first face $[\tau|a_1|\tau|\dots|a_e|\tau]$ does not depend on a_0, so it occurs q times and vanishes in $\mathbb{Z}/q\mathbb{Z}$. For $0 \le i < e$, the face merging a_i with the following τ (sign $(-1)^{2i+1}$) and the face merging that τ with a_{i+1} (sign $(-1)^{2i+2}$) give, after summing over a_i and a_{i+1} and substituting $a_i\tau \mapsto a_i$, respectively $\tau a_{i+1} \mapsto a_{i+1}$, the same sum over all $(a_0,\dots,a_e)$ of $[a_0|\tau|\dots|a_i|a_{i+1}|\tau|\dots|a_e|\tau]$; they cancel. The face merging a_e with the last τ (sign $(-1)^{2e+1}$) gives, after $a_e\tau \mapsto a_e$, the sum of $[a_0|\tau|\dots|a_{e-1}|\tau|a_e]$, and the last face, which drops the final τ (sign $(-1)^{2e+2}$), gives the same sum; they cancel. Hence $\partial \mathbf{z}_{q,e} = 0$.

Step 2: $H_{2e+2}(C_q \times C_q; \mathbb{Z}/q\mathbb{Z}) \cong (\mathbb{Z}/q\mathbb{Z})^{2e+3}$. The complex $W \otimes_{\mathbb{Z}} W$ is a free resolution of $\mathbb{Z}$ over $\mathbb{Z}[C_q \times C_q]$ with $(W \otimes W)_n$ free of rank $n+1$. After $\mathbb{Z}/q\mathbb{Z} \otimes_{\mathbb{Z}[C_q \times C_q]} -$, each differential becomes a sum of tensor products of the induced differentials of W, which are multiplication by 0 (from $\tau - 1$) and by $q = 0$ (from the norm element); so all differentials vanish and $H_n(C_q \times C_q; \mathbb{Z}/q\mathbb{Z}) \cong (\mathbb{Z}/q\mathbb{Z})^{n+1}$.

Step 3: the relation. Let $q = \ell^\nu$ and $r = 2e+3$. The classes $[(d_t)_*\mathbf{z}_{q,e}]$, $0 \le t \le r$, are $r+1$ elements of $H_{2e+2}(C_q \times C_q; \mathbb{Z}/q\mathbb{Z}) \cong (\mathbb{Z}/q\mathbb{Z})^r$ (Steps 1, 2). Lift their coordinates to an integer $r \times (r+1)$ matrix Φ. Over $\mathbb{Q}$, Φ has a nonzero kernel, so there is $x \in \mathbb{Z}^{r+1}$ with $\Phi x = 0$ and coprime coordinates; some x_{t_0} is prime to ℓ. Put $n_t = x_t \bmod q$. Then n_{t_0} is a unit and $\sum_t n_t[(d_t)_*\mathbf{z}_{q,e}] = 0$, i.e. the cycle $\sum_t n_t (d_t)_*\mathbf{z}_{q,e}$ is a boundary. □

Lemma 40.11. *Let ℓ be a prime, $c \ge 1$ and $\nu \ge 1$ integers, $q = \ell^\nu$, $\kappa = 1 + \ell^c$, $M \ge 0$ an integer with $M < \ell^c$, and $t_0 \in \{0,\dots,M\}$. Write $\prod_{j=0}^{M-1}(Y - \kappa^j) = \sum_{i=0}^{M} p_i Y^i \in \mathbb{Z}[Y]$. There is a map $\eta\colon (\mathbb{Z}/q\mathbb{Z})^2 \to \mathbb{Z}$ such that, for every $y \in \mathbb{Z}/q\mathbb{Z}$,*

$$\sum_{x_1 + t x_2 = y} \eta(x_1,x_2) = 0 \quad (t \in \{0,\dots,M\},\ t \ne t_0), \qquad \sum_{x_1 + t_0 x_2 = y} \eta(x_1,x_2) = \sum_{0 \le i \le M,\ \kappa^i \equiv y \pmod q} p_i.$$

Proof. Identify a map $\phi\colon B \to \mathbb{Z}$ on a finite abelian group B with the element $\sum_b \phi(b)[b]$ of the group ring $\mathbb{Z}[B]$. For a homomorphism $\psi\colon B \to B'$, the map $\phi \mapsto (y \mapsto \sum_{\psi(b)=y} \phi(b))$ is then the ring homomorphism $\psi_*\colon \mathbb{Z}[B] \to \mathbb{Z}[B']$ induced by ψ. Let $R = \mathbb{Z}[\mathbb{Z}/q\mathbb{Z}]$ and $T = [1] \in R$, so $[y] = T^y$; and for $t \in \mathbb{Z}$ let $\chi_t\colon (\mathbb{Z}/q\mathbb{Z})^2 \to \mathbb{Z}/q\mathbb{Z}$, $(x_1,x_2) \mapsto x_1 + t x_2$. We must find $\eta \in \mathbb{Z}[(\mathbb{Z}/q\mathbb{Z})^2]$ with $(\chi_t)_*\eta = 0$ for $t \in \{0,\dots,M\} \smallsetminus \{t_0\}$ and $(\chi_{t_0})_*\eta = \Theta$, where $\Theta = \sum_{i=0}^{M} p_i T^{\kappa^i}$.

Step 1: $(X^w - 1)^M$ divides $P = \sum_i p_i X^{(1+w)^i}$ in $\mathbb{Z}[X]$, where $w = \ell^c$. Let $\mathcal{E}$ be the ring endomorphism $X \mapsto X^{1+w}$ of $\mathbb{Z}[X]$; then $\mathcal{E}^i(X) = X^{(1+w)^i}$, so $P = \prod_{j<M}(\mathcal{E} - (1+w)^j)(X)$, the factors being commuting $\mathbb{Z}$-linear operators. We show: if $(X^w-1)^j \mid f$, then $(X^w-1)^{j+1} \mid \mathcal{E}(f) - (1+w)^j f$; applying this to $f = X$ and the factors $j = 0, 1, \dots, M-1$ in turn gives the claim. Write $f = (X^w-1)^j g$ and $S = \sum_{i=0}^{w} X^{wi}$, so that $\mathcal{E}(X^w - 1) = X^{w(1+w)} - 1 = (X^w - 1)S$. Then

$$\mathcal{E}(f) - (1+w)^j f = (X^w-1)^j \Big((S^j - (1+w)^j)\mathcal{E}(g) + (1+w)^j (\mathcal{E}(g) - g) \Big).$$

The polynomial $X^w - 1$ divides $S - (1+w) = \sum_i (X^{wi} - 1)$, hence $S^j - (1+w)^j$; and it divides $\mathcal{E}(g) - g$, as $X^{n(1+w)} - X^n = X^n(X^{nw} - 1)$ for each monomial.

Step 2: $T^s - 1$ divides $T^w - 1$ in R for every integer s with $1 \le |s| < w$. Write $s = \ell^a u$ with $\ell \nmid u$; as $|s| < \ell^c$, $a < c$. Choose an integer $u' \ge 1$ with $uu' \equiv 1 \pmod q$ and put $m = \ell^{c-a} u' \ge 1$. Then $sm \equiv \ell^c \pmod q$, so $T^w - 1 = (T^s)^m - 1$, which is divisible by $T^s - 1$.

Step 3: construction. The ring homomorphism $\mathbb{Z}[X] \to R$, $X \mapsto T$, maps P to Θ, since $(1+w)^i = \kappa^i$. By Step 1, $\Theta = (T^w - 1)^M u_1$ for some $u_1 \in R$. The set $\{0,\dots,M\} \smallsetminus \{t_0\}$ has M elements, and for each such t, $1 \le |t_0 - t| \le M < w$; by Step 2, $T^w - 1 = (T^{t_0 - t} - 1)v_t$ with $v_t \in R$. Hence $\Theta = u_2 \prod_{t \ne t_0}(T^{t_0 - t} - 1)$ with $u_2 = u_1 \prod_{t \ne t_0} v_t$. Let $\iota_1\colon \mathbb{Z}/q\mathbb{Z} \to (\mathbb{Z}/q\mathbb{Z})^2$,

$y \mapsto (y,0)$, so $\chi_t \circ \iota_1 = \mathrm{id}$ for all t, and for $t \neq t_0$ let $\epsilon_t = [(-t,1)] - [(0,0)]$, so $(\chi_{t'})_* \epsilon_t = T^{t'-t} - 1$. Put

$$\eta = (\iota_1)_*(u_2) \cdot \prod_{t \in \{0,\dots,M\},\, t \neq t_0} \epsilon_t.$$

For $t' \neq t_0$ in $\{0,\dots,M\}$, $(\chi_{t'})_*\eta$ contains the factor $(\chi_{t'})_*\epsilon_{t'} = T^0 - 1 = 0$; and $(\chi_{t_0})_*\eta = u_2 \prod_{t \neq t_0}(T^{t_0-t} - 1) = \Theta$. □

Proposition 40.12. *Let $L \subseteq F$ be number fields with F/L Galois, $q \geq 1$, $\zeta \in \mathcal{O}_F^\times$ of order q, J a finite set, $h\colon J \to \mathbb{Z}/q\mathbb{Z}$, $\eta\colon J \to \mathbb{Z}$, $\mathfrak{d}$ a fractional ideal of F, and $\mathfrak{b} = (\mathfrak{d}^{\eta(j)})_{j \in J}$.*

(Ca1) *If $\sum_{j:h(j)=y} \eta(j) = 0$ for every $y \in \mathbb{Z}/q\mathbb{Z}$, there is an L-linear automorphism of F^J adapted to $(h, \mathfrak{b}, 1)$, where 1 is the constant map.*

(Ca2) *Let (F, γ, ζ) be a cyclotomic Kummer layer of level (c,ν) over L for a prime ℓ (so $q = \ell^\nu$), $\kappa = 1 + \ell^c$, $M \geq 0$, $p_0, \dots, p_M \in \mathbb{Z}$ and $\beta \in F^\times$ with $(\beta) = \prod_{i=0}^M \gamma^{-i}(\mathfrak{d})^{p_i}$. If $h(j_0) = 1$ for some $j_0 \in J$ and $\sum_{j:h(j)=y} \eta(j) = \sum_{0 \leq i \leq M,\ \kappa^i \equiv y} p_i$ for every $y \in \mathbb{Z}/q\mathbb{Z}$, there is an L-linear automorphism of F^J adapted to $(h, \mathfrak{b}, \delta_\beta)$, where $\delta_\beta(1) = \beta$ and $\delta_\beta(x) = 1$ for $x \neq 1$.*

Proof. Step 0: Steinitz with a prescribed determinant. Let I be a finite set, $\mathfrak{a} = (\mathfrak{a}_i)_{i \in I}$, $\mathfrak{c} = (\mathfrak{c}_i)_{i \in I}$ families of nonzero fractional ideals and $\beta' \in F^\times$ with $(\beta') = \prod_i \mathfrak{c}_i \prod_i \mathfrak{a}_i^{-1}$; if $I = \varnothing$ assume $\beta' = 1$. Then there is an F-linear automorphism g' of F^I with $g'(M(\mathfrak{a})) = M(\mathfrak{c})$ and $\det g' = \beta'$. For $I = \varnothing$ take the identity. Otherwise $\prod \mathfrak{a}_i$ and $\prod \mathfrak{c}_i$ have the same class, so by Theorem B.24 there is an $\mathcal{O}_F$-isomorphism $M(\mathfrak{a}) \to M(\mathfrak{c})$; it extends to an F-linear automorphism g_1 of $F^I = F \cdot M(\mathfrak{a})$. Expanding determinants, the $\mathcal{O}_F$-submodule of $\Lambda_F^n F^I = F e_I$ spanned by the wedge products of n elements of $M(\mathfrak{a})$ is $(\prod_i \mathfrak{a}_i)e_I$, and likewise for $\mathfrak{c}$; g_1 maps the one onto the other and acts by $\det g_1$, so $(\det g_1)\prod \mathfrak{a}_i = \prod \mathfrak{c}_i$ and $\det g_1 = \beta' u$ with $u \in \mathcal{O}_F^\times$. Fix $i_1 \in I$, let d_u multiply the coordinate i_1 by u^{-1} (so $d_u(M(\mathfrak{a})) = M(\mathfrak{a})$), and put $g' = g_1 d_u$.

Step 1: gluing blocks. Let $s\colon J \to \mathrm{Gal}(F/L)$, $J_x = \{j : \kappa_\zeta(s_j) h(j) = x\}$, and for each x let g'_x be an F-linear automorphism of F^{J_x} with $g'_x(\mathcal{O}_F^{J_x}) = M((s_j(\mathfrak{b}_j))_{j \in J_x})$ and $\det g'_x = \delta(x)$. Let $S(w) = w^s = (s_j(w_j))_j$, an L-linear bijection of F^J with $S(\mathcal{O}_F^J) = \mathcal{O}_F^J$ and $S^{-1}(M((s_j(\mathfrak{b}_j))_j)) = M(\mathfrak{b})$, and let $g = S^{-1} \circ (\bigoplus_x g'_x) \circ S$, the middle map acting blockwise on $F^J = \bigoplus_x F^{J_x}$. Then g is an L-linear automorphism, $s_j((gw)_j) = (g'_x(w^s|_{J_x}))_j$ for $j \in J_x$, and $g(\mathcal{O}_F^J) = S^{-1}(\bigoplus_x g'_x(\mathcal{O}_F^{J_x})) = M(\mathfrak{b})$. So g is adapted to $(h, \mathfrak{b}, \delta)$.

(Ca1). Take $s_j = 1$, so $J_x = h^{-1}(x)$. For each x, $\prod_{j \in J_x} \mathfrak{d}^{\eta(j)} = \mathfrak{d}^0 = (1)$, and Step 0 with $\mathfrak{a} = (\mathcal{O}_F)$, $\mathfrak{c} = (\mathfrak{d}^{\eta(j)})_{j \in J_x}$, $\beta' = 1$ gives g'_x; Step 1 gives g.

(Ca2). Let $K = \{\kappa^i \bmod q : 0 \leq i \leq M\}$ and for $y \in K$ fix $i(y) \in \{0,\dots,M\}$ with $\kappa^{i(y)} \equiv y$. Put $s_j = \gamma^{-i(h(j))}$ if $h(j) \in K$ and $s_j = 1$ otherwise. By (40.3), $\kappa_\zeta(\gamma) = \kappa$, so $\kappa_\zeta(s_j)h(j) = 1$ if $h(j) \in K$; hence $J_1 = h^{-1}(K) \ni j_0$, $J_x = h^{-1}(x)$ for $x \notin K$, and $J_x = \varnothing$ for $x \in K \smallsetminus \{1\}$. For $x \notin K$ the hypothesis gives $\sum_{j \in J_x} \eta(j) = 0$, and Step 0 gives g'_x with determinant 1 as in (Ca1). For $x = 1$:

$$\prod_{j \in J_1} s_j(\mathfrak{d})^{\eta(j)} = \prod_{y \in K} (\gamma^{-i(y)}\mathfrak{d})^{\sum_{h(j)=y} \eta(j)} = \prod_{y \in K} \prod_{i:\kappa^i \equiv y} (\gamma^{-i(y)}\mathfrak{d})^{p_i} = \prod_{i=0}^{M} (\gamma^{-i}\mathfrak{d})^{p_i} = (\beta),$$

where the third equality holds because $\kappa^i \equiv \kappa^{i(y)} \pmod{\ell^\nu}$ forces $i \equiv i(y) \pmod{\ell^{\nu-c}}$ by the lifting-the-exponent rule, and γ has order $\ell^{\nu-c}$. Step 0 with $I = J_1 \neq \varnothing$, $\mathfrak{a} = (\mathcal{O}_F)$, $\mathfrak{c} = (s_j(\mathfrak{d})^{\eta(j)})_{j \in J_1}$ and $\beta' = \beta$ gives g'_1; for $x \in K \smallsetminus \{1\}$ take the identity of the zero space. Step 1 gives g, adapted to $(h, \mathfrak{b}, \delta_\beta)$. □

Lemma 40.13. *Let A be a commutative ring, $m \geq 0$, C, D, G groups, $H \leq G$ a subgroup with inclusion ι, T a finite set with an element t_0, $\rho\colon D \to G$ and $d_t\colon C \to D$ ($t \in T$) homomorphisms, $n_t \in A$ ($t \in T$), and $z \in \mathrm{Bar}_{m+1}(C;A)$ a cycle such that $\sum_t n_t\,(d_t)_* z$ is a boundary. Let $g_t \in G$ ($t \in T$) be such that g_t commutes with $\rho(d_t(c))$ for all $c \in C$, $\rho(D) \subseteq H$, $g_{t_0}^{-1}\rho(D)g_{t_0} \subseteq H$, and $g_t^{-1}g_{t_0} \in H$ for all t. Then there is a cycle $y \in \mathrm{Bar}_{m+2}(H;A)$ such that*

$$\iota_* y - \sum_{t\in T} n_t \,\mathrm{Pr}_{g_t}\big((\rho\circ d_t)_* z\big)$$

is a boundary in $\mathrm{Bar}_{m+2}(G;A)$.

Proof. For $k \in \Gamma$ let $\kappa_k(\gamma) = k^{-1}\gamma k$.

Step 1: the prism formula and multiplicativity of prisms. On $P_\bullet$ let $R_k(\gamma_0,\dots,\gamma_n) = (\gamma_0 k,\dots,\gamma_n k)$ and $h_k(\gamma_0,\dots,\gamma_n) = \sum_{i=0}^{n}(-1)^i(\gamma_0,\dots,\gamma_i,\gamma_i k,\dots,\gamma_n k)$. Both are Γ-equivariant, R_k is a chain map, and $\partial h_k + h_k\partial = R_k - \mathrm{id}$ (the prism formula for the simplicial homotopy from id to R_k). Under the identification above, R_k induces $(\kappa_k)_*$, since $(k, g_1 k,\dots) = k\cdot(1, k^{-1}g_1 k, k^{-1}g_1 g_2 k,\dots)$, and h_k induces Pr_k. Hence, for $w \in \mathrm{Bar}_n(\Gamma;A)$, $n \geq 1$,

$$\partial\,\mathrm{Pr}_k(w) + \mathrm{Pr}_k(\partial w) = (\kappa_k)_* w - w. \tag{40.8}$$

Now let $k, k' \in \Gamma$ and $E = h_{kk'} - h_k - h_{k'}R_k$. It is equivariant of degree 1, and $\partial E + E\partial = (R_{kk'} - 1) - (R_k - 1) - (R_{k'} - 1)R_k = 0$ because $R_{k'}R_k = R_{kk'}$. We construct equivariant $F_n\colon P_n \to P_{n+2}$ with $E_n = \partial F_n - F_{n-1}\partial$ ($F_{-1} = 0$). For $n = 0$: $\partial E_0 = 0$, so E_0 takes values in the cycles of P_1, which are boundaries, and P_0 is free, so $E_0 = \partial F_0$ for some equivariant F_0. If $F_0,\dots,F_{n-1}$ are constructed, then $\partial(E_n + F_{n-1}\partial) = -E_{n-1}\partial + (E_{n-1} + F_{n-2}\partial)\partial = 0$, so $E_n + F_{n-1}\partial$ takes values in the cycles of P_{n+1}, which are boundaries, and since P_n is free it equals ∂F_n for some equivariant F_n. Passing to $A \otimes_{A[\Gamma]} -$, E induces $\mathrm{Pr}_{kk'} - \mathrm{Pr}_k - \mathrm{Pr}_{k'}\circ(\kappa_k)_*$ and F a map $\bar F$ with $\mathrm{Pr}_{kk'} - \mathrm{Pr}_k - \mathrm{Pr}_{k'}(\kappa_k)_* = \partial\bar F - \bar F\partial$. Hence, for every cycle $x \in \mathrm{Bar}_n(\Gamma;A)$, $n \geq 1$,

$$\mathrm{Pr}_{kk'}(x) - \mathrm{Pr}_k(x) - \mathrm{Pr}_{k'}\big((\kappa_k)_* x\big) \text{ is a boundary.} \tag{40.9}$$

Step 2: the cycle. For $t \in T$ put $x_t = (\rho\circ d_t)_* z \in \mathrm{Bar}_{m+1}(G;A)$, a cycle all of whose entries lie in $\rho(D)$, and $h_t = g_t^{-1}g_{t_0} \in H$, so $g_t = g_{t_0}h_t^{-1}$. Each $\mathrm{Pr}_{g_t}(x_t)$ is a cycle: by (40.8), $\partial\,\mathrm{Pr}_{g_t}(x_t) = (\kappa_{g_t})_* x_t - x_t = 0$, as g_t commutes with the entries of x_t. By (40.9) with $k = g_{t_0}$, $k' = h_t^{-1}$, modulo boundaries of G,

$$\mathrm{Pr}_{g_t}(x_t) \equiv \mathrm{Pr}_{g_{t_0}}(x_t) + \mathrm{Pr}_{h_t^{-1}}\big((\kappa_{g_{t_0}})_* x_t\big).$$

Choose $w \in \mathrm{Bar}_{m+2}(D;A)$ with $\partial w = \sum_t n_t (d_t)_* z$; then $\sum_t n_t x_t = \partial\rho_* w$, and by (40.8)

$$\mathrm{Pr}_{g_{t_0}}(\partial\rho_* w) = (\kappa_{g_{t_0}})_*\rho_* w - \rho_* w - \partial\,\mathrm{Pr}_{g_{t_0}}(\rho_* w).$$

Therefore $\sum_t n_t \mathrm{Pr}_{g_t}(x_t) \equiv y'$ modulo boundaries, where

$$y' = (\kappa_{g_{t_0}})_*\rho_* w - \rho_* w + \sum_t n_t\,\mathrm{Pr}_{h_t^{-1}}\big((\kappa_{g_{t_0}})_* x_t\big).$$

Every entry of every basis element in y' lies in H: the entries of $\rho_* w$ lie in $\rho(D) \subseteq H$, those of $(\kappa_{g_{t_0}})_*\rho_* w$ and $(\kappa_{g_{t_0}})_* x_t$ in $g_{t_0}^{-1}\rho(D)g_{t_0} \subseteq H$, and the prism by $h_t^{-1} \in H$ only adds the entry h_t^{-1} and conjugates by h_t^{-1}. As ι_* is injective on chains, $y' = \iota_* y$ for a unique $y \in \mathrm{Bar}_{m+2}(H;A)$. Finally $\iota_*\partial y = \partial y'$ is the boundary of a cycle minus the boundary of a boundary, i.e. 0, so $\partial y = 0$. □

Proposition 40.14. *Let $L \subseteq F$ be number fields with F/L Galois, $\Gamma = \mathrm{Gal}(F/L)$, and J a finite set. For a finite field k and a ring homomorphism $r\colon \mathcal{O}_F \to k$ we write $r_L = r|_{\mathcal{O}_L}$.*

(Re1) *There is $b_0 \in \mathcal{O}_L \smallsetminus \{0\}$ such that every r with r_L surjective and $r(b_0) \neq 0$ is split in F/L.*

(Re2) *Let $b \in \mathcal{O}_L \smallsetminus \{0\}$ and let r be split in F/L, with r_L surjective and $r(b) \neq 0$. There is a unique homomorphism $\mathrm{Rd}_r\colon \mathrm{Aut}_b(F^J) \to \mathrm{GL}(k^{\Gamma\times J})$ with $\mathrm{Rd}_r(g)(\mathrm{rd}_r(x)) = \mathrm{rd}_r(gx)$ for all g and all $x \in M_b$.*

(Re3) *There are $N \geq 1$ and a homomorphism $\lambda\colon \mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J) \to \mathrm{GL}_N(\mathcal{O}_L)$ such that for all b and r as in (Re2), every commutative ring A, every $m \geq 1$, every additive family θ of degree m over k with values in A and every cycle $y \in \mathrm{Bar}_m(\mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J); A)$,*

$$\theta_{k^N}\big((\mathrm{red}_{r_L,N} \circ \lambda)_* y\big) = \theta_{k^{\Gamma\times J}}\big((\mathrm{Rd}_r|_{\mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J)})_* y\big).$$

Proof. (Re1). Let b_0 be a nonzero element of $\mathcal{O}_L$ in the relative discriminant of F/L. Let r be as in (Re1); as r_L is surjective, so is r, and $P = \ker r$ is a prime of $\mathcal{O}_F$ over $\mathfrak{p} = \ker r_L$ with $\mathcal{O}_L/\mathfrak{p} \to \mathcal{O}_F/P \cong k$ surjective, i.e. of residue degree 1. As $b_0 \notin \mathfrak{p}$, $\mathfrak{p}$ is unramified, so $e = f = 1$ and $\mathfrak{p}$ has $\#\Gamma$ primes above it, which are the $\sigma^{-1}(P) = \ker(r \circ \sigma)$, $\sigma \in \Gamma$, pairwise distinct. By the Chinese remainder theorem $\mathcal{O}_F \to \prod_\sigma \mathcal{O}_F/\sigma^{-1}(P) \cong k^\Gamma$, $a \mapsto (r(\sigma a))_\sigma$, is surjective with kernel $\prod_\sigma \sigma^{-1}(P) = \mathfrak{p}\mathcal{O}_F$.

(Re2). As r is split, rd_r is surjective; its kernel is $\mathfrak{p}M_b$: if $\mathrm{rd}_r(x) = 0$, write $x_j = a_j/b^n$ with $a_j \in \mathcal{O}_F$; then $r(\sigma a_j) = 0$ for all σ, so $a_j \in \mathfrak{p}\mathcal{O}_F$. For $a \in \mathcal{O}_L[1/b]$, $\mathrm{rd}_r(ax) = r(a)\,\mathrm{rd}_r(x)$, as $\sigma(a) = a$. An element $g \in \mathrm{Aut}_b(F^J)$ is L-linear with $g(M_b) = M_b$, so $g(\mathfrak{p}M_b) = \mathfrak{p}M_b$; hence $\mathrm{rd}_r(x) \mapsto \mathrm{rd}_r(gx)$ is a well-defined bijection of $k^{\Gamma\times J}$, k-linear because r_L is surjective. Uniqueness follows from the surjectivity of rd_r, and the homomorphism property from uniqueness.

(Re3). Let $Q = \mathcal{O}_F^J$, a finitely generated torsion-free, hence projective, $\mathcal{O}_L$-module; choose an $\mathcal{O}_L$-module P' and an isomorphism $\psi\colon Q \oplus P' \to \mathcal{O}_L^N$, and put $\lambda(g) = \psi \circ (g|_Q \oplus \mathrm{id}_{P'}) \circ \psi^{-1}$, a homomorphism to $\mathrm{GL}_N(\mathcal{O}_L)$. Let b, r be as in (Re2) and $\mathfrak{p} = \ker r_L$. As in (Re2), rd_r restricts to a surjection $Q \to k^{\Gamma\times J}$ with kernel $\mathfrak{p}Q$, and $\mathrm{Rd}_r(g)$ is the map induced by g on $Q/\mathfrak{p}Q$ for $g \in \mathrm{Aut}_{\mathcal{O}_L}(\mathcal{O}_F^J)$. Identifying $\mathcal{O}_L/\mathfrak{p} = k$ through r_L, ψ induces a k-isomorphism $\varphi\colon k^{\Gamma\times J} \oplus P'/\mathfrak{p}P' \to k^N$, and since $\mathrm{red}_{r_L,N}$ of a matrix is the map it induces on $\mathcal{O}_L^N/\mathfrak{p}\mathcal{O}_L^N$,

$$\mathrm{red}_{r_L,N}(\lambda(g)) = \varphi \circ \big(\mathrm{Rd}_r(g) \oplus \mathrm{id}\big) \circ \varphi^{-1} = c_\varphi\big(\mathrm{Rd}_r(g) \oplus \mathbf{1}(g)\big),$$

with $\mathbf{1}$ the trivial homomorphism to $\mathrm{GL}(P'/\mathfrak{p}P')$. For a cycle y, (Fa2) and (Fa3) give $\theta_{k^N}((\mathrm{red}_{r_L,N} \circ \lambda)_* y) = \theta_{k^{\Gamma\times J}}((\mathrm{Rd}_r)_* y) + \theta_{P'/\mathfrak{p}P'}(\mathbf{1}_* y)$. Finally $\mathbf{1}_* y$ is a boundary, so the last term vanishes by (Fa1): $\mathbf{1}$ factors through the trivial group E, and in $\mathrm{Bar}_\bullet(E; A)$, with $e_n = [1|\ldots|1]$, $\partial e_{n+1} = e_n$ for n odd and $\partial e_{n+1} = 0$ for $n \geq 2$ even; so every element of degree n odd is a boundary and the only cycle of even degree $n \geq 2$ is 0. □

Proposition 40.15. *Let $L \subseteq F$ be number fields with F/L Galois, $\Gamma = \mathrm{Gal}(F/L)$, $q \geq 1$, $\zeta \in \mathcal{O}_F^\times$ of order q, J a finite set and $b \in \mathcal{O}_L \smallsetminus \{0\}$. Let k be a finite field, $r\colon \mathcal{O}_F \to k$ split in F/L with r_L surjective and $r(b) \neq 0$, $e \geq 0$, $v\colon k^\times \to \mathbb{Z}/q\mathbb{Z}$ a homomorphism, and θ an additive family of degree $2e+3$ over k with values in $\mathbb{Z}/q\mathbb{Z}$ having the value property for $(q, e, r(\zeta), v)$. Let $h\colon J \to \mathbb{Z}/q\mathbb{Z}$, $\mathfrak{b}$ a family of fractional ideals indexed by J, $\delta\colon \mathbb{Z}/q\mathbb{Z} \to F^\times$, and $g \in \mathrm{Aut}_b(F^J)$ adapted to $(h, \mathfrak{b}, \delta)$. Then $\mathrm{D}_h(C_q) \subseteq \mathrm{Aut}_b(F^J)$, g commutes with $\mathrm{D}_h(C_q)$, every $\delta(x)$ is a unit at every prime of F not containing b, and*

$$\theta_{k^{\Gamma\times J}}\Big(\mathrm{Pr}_{\mathrm{Rd}_r(g)}\big((\mathrm{Rd}_r \circ \mathrm{D}_h)_* \mathbf{z}_{q,e}\big)\Big) = \sum_{\sigma\in\Gamma} \sum_{x\in\mathbb{Z}/q\mathbb{Z}} \big(\kappa_\zeta(\sigma)\, x\big)^{e+1}\, v\big(r(\sigma(\delta(x)))\big).$$

Proof. Let $s\colon J \to \Gamma$, J_x and g'_x be as in the definition of adapted automorphisms, and $w^s = (s_j(w_j))_j$. Write $\bar\zeta = r(\zeta)$ and, for an integer $y \geq 0$, $\chi_y\colon C_q \to k^\times$, $\tau^c \mapsto \bar\zeta^{yc}$.

Step 1: the first three assertions. $\mathrm{D}_h(\tau^c)$ multiplies coordinates by units, so it preserves M_b. For $w \in F^J$ and $j \in J_x$, using the F-linearity of g'_x and $s_i(\zeta^{ch(i)}) = \zeta^{c\kappa_\zeta(s_i)h(i)} = \zeta^{cx}$ for $i \in J_x$,

$$s_j\big((g\,\mathrm{D}_h(\tau^c)w)_j\big) = \big(g'_x((\zeta^{cx}s_i(w_i))_{i\in J_x})\big)_j = \zeta^{cx}s_j((gw)_j) = s_j(\zeta^{ch(j)}(gw)_j),$$

so $g\,\mathrm{D}_h(\tau^c) = \mathrm{D}_h(\tau^c)\,g$. Since $w \mapsto w^s$ preserves M_b ($b \in L$), so does $\bigoplus_x g'_x$, hence each g'_x and its inverse preserve $\mathcal{O}_F[1/b]^{J_x}$; their matrices have entries in $\mathcal{O}_F[1/b]$, and $\delta(x) = \det g'_x \in \mathcal{O}_F[1/b]^\times$.

Step 2: the block decomposition of the reduction. For $j \in J$, $\sigma \mapsto \sigma s_j$ is a bijection of Γ; so $\Gamma \times J$ is the disjoint union of the sets $B_{\sigma,x} = \{(\sigma s_j, j) : j \in J_x\}$, $\sigma \in \Gamma$, $x \in \mathbb{Z}/q\mathbb{Z}$, each identified with J_x by $(\sigma s_j, j) \mapsto j$; let $V_{\sigma,x} = k^{B_{\sigma,x}} \cong k^{J_x}$, so $k^{\Gamma\times J} = \bigoplus_{\sigma,x} V_{\sigma,x}$. For $w \in M_b$ and $j \in J_x$,

$$\mathrm{rd}_r(gw)_{(\sigma s_j,j)} = r\big(\sigma s_j((gw)_j)\big) = r\Big(\big(\sigma(g'_x)\,(\sigma s_i(w_i))_{i\in J_x}\big)_j\Big),$$

where $\sigma(g'_x)$ is the matrix of g'_x with σ applied to the entries (in $\mathcal{O}_F[1/b]$ by Step 1), and $r(\sigma s_i(w_i)) = \mathrm{rd}_r(w)_{(\sigma s_i,i)}$. Hence $\mathrm{Rd}_r(g)$ preserves each $V_{\sigma,x}$ and acts there by $\bar g_{\sigma,x} = r(\sigma(g'_x))$, with $\det \bar g_{\sigma,x} = r(\sigma(\delta(x)))$. Likewise $\mathrm{Rd}_r(\mathrm{D}_h(\tau^c))$ multiplies the coordinate $(\sigma s_j, j)$ by

$$r(\sigma s_j(\zeta^{ch(j)})) = \bar\zeta^{c\kappa_\zeta(\sigma)x},$$

so on $V_{\sigma,x}$ it is the scalar $\chi_{y_{\sigma,x}}(\tau^c)$, where $y_{\sigma,x} \geq 0$ represents $\kappa_\zeta(\sigma)x$.

Step 3: the value. Let $G' = \prod_{\sigma,x} \mathrm{GL}(V_{\sigma,x})$, $\iota\colon G' \to \mathrm{GL}(k^{\Gamma\times J})$ the block-diagonal embedding, $\phi\colon C_q \to G'$ with components $s_{V_{\sigma,x}} \circ \chi_{y_{\sigma,x}}$, and $\hat g = (\bar g_{\sigma,x}) \in G'$. By Step 2, $\mathrm{Rd}_r(g) = \iota(\hat g)$ and $\mathrm{Rd}_r \circ \mathrm{D}_h = \iota \circ \phi$, so the chain on the left of the assertion is $\iota_*\mathrm{Pr}_{\hat g}(\phi_*\mathbf{z}_{q,e})$. As $\phi(C_q)$ is central in G' and $\mathbf{z}_{q,e}$ is a cycle, $u = \mathrm{Pr}_{\hat g}(\phi_*\mathbf{z}_{q,e})$ is a cycle of G'. Up to the coordinate isomorphism $\bigoplus V_{\sigma,x} \cong k^{\Gamma\times J}$, ι is the direct sum of the projections $\pi_{\sigma,x}\colon G' \to \mathrm{GL}(V_{\sigma,x})$; by (Fa2) and (Fa3), applied block by block,

$$\theta_{k^{\Gamma\times J}}(\iota_*u) = \sum_{\sigma,x} \theta_{V_{\sigma,x}}\big((\pi_{\sigma,x})_*u\big) = \sum_{\sigma,x} \theta_{V_{\sigma,x}}\Big(\mathrm{Pr}_{\bar g_{\sigma,x}}\big((s_{V_{\sigma,x}} \circ \chi_{y_{\sigma,x}})_*\mathbf{z}_{q,e}\big)\Big).$$

By (Fa4) the (σ,x) term is $y_{\sigma,x}^{e+1}v(\det \bar g_{\sigma,x}) = (\kappa_\zeta(\sigma)x)^{e+1}v(r(\sigma(\delta(x))))$; for $J_x = \varnothing$ both are 0, as $\delta(x) = 1$ there. □

Definition 40.16. Let G be a group, X a finite set with a right action of G, written $x \cdot g$ (so $x \cdot 1 = x$ and $x \cdot (gh) = (x \cdot g) \cdot h$), and M an abelian group, written multiplicatively. A **monomial cocycle** of G on X with values in M is a map $c\colon G \times X \to M$ with

$$c(gh, x) = c(g, x)\,c(h, x \cdot g) \qquad (g, h \in G,\ x \in X). \tag{40.10}$$

Two monomial cocycles c, c' of G on X are **cohomologous** if there is a map $b\colon X \to M$ with $c'(g,x) = b(x)^{-1}c(g,x)\,b(x\cdot g)$ for all $g \in G$, $x \in X$. For a commutative ring A and $m \geq 0$, the **monomial transfer** of (X,c) is the A-linear map $\mathrm{Tf}_{X,c}\colon \mathrm{Bar}_m(G;A) \to \mathrm{Bar}_m(M;A)$ given on basis elements by

$$\mathrm{Tf}_{X,c}[g_1|\dots|g_m] = \sum_{x\in X} \big[c(g_1,x_0)\,\big|\,c(g_2,x_1)\,\big|\,\dots\,\big|\,c(g_m,x_{m-1})\big], \qquad x_0 = x,\ x_i = x_{i-1}\cdot g_i.$$

Proposition 40.17. *Let k be a finite field, $q \geq 1$ and $e \geq 0$ integers, $\zeta \in k^\times$ a primitive q-th root of unity and $v\colon k^\times \to \mathbb{Z}/q\mathbb{Z}$ a homomorphism. There is an additive family of degree $2e+3$ over k with values in $\mathbb{Z}/q\mathbb{Z}$ that has the value property for (q, e, ζ, v).*

Proof. Put $A = \mathbb{Z}/q\mathbb{Z}$ and $m = 2e + 3$. If $q = 1$, then $A = 0$ and the family of zero maps has all the properties; assume $q \geq 2$. As ζ has order q in $k^\times$, q divides $\#k - 1$, so $\#k = 1$ in A and $\#W = (\#k)^{\dim W} = 1$ in A for every finite-dimensional k-vector space W; and $\zeta \notin \{0, 1\}$, so $\#k \geq 3$. Let $t\colon \mathrm{Bar}_m(k^\times; A) \to A$ be the map of Lemma 40.19 for the cyclic group $K = k^\times$, the element ζ of order q, the homomorphism v and e.

Step 1: line cocycles. For a finite-dimensional k-vector space V let $\mathbb{P}(V)$ be its finite set of lines, with the right action $\ell \cdot g = g^{-1}\ell$ of $\mathrm{GL}(V)$. A *homogeneous function* on V is a map $\lambda\colon V \smallsetminus \{0\} \to k^\times$ with $\lambda(aw) = a\lambda(w)$ for $a \in k^\times$; one exists (fix a nonzero vector w_ℓ in each line and put $\lambda(aw_\ell) = a$). For such λ put $c_\lambda(g, \ell) = \lambda(w)/\lambda(g^{-1}w)$ for any $w \in \ell \smallsetminus \{0\}$; by homogeneity it does not depend on w. It is a monomial cocycle of $\mathrm{GL}(V)$ on $\mathbb{P}(V)$ with values in $k^\times$: as $g^{-1}w$ spans $\ell \cdot g$,

$$c_\lambda(gh, \ell) = \frac{\lambda(w)}{\lambda(g^{-1}w)} \cdot \frac{\lambda(g^{-1}w)}{\lambda(h^{-1}g^{-1}w)} = c_\lambda(g, \ell)\, c_\lambda(h, \ell \cdot g).$$

For two homogeneous functions λ, λ' on V, $b(\ell) = \lambda(w)/\lambda'(w)$ ($w \in \ell \smallsetminus \{0\}$) is well defined and $c_{\lambda'}(g, \ell) = b(\ell)^{-1} c_\lambda(g, \ell) b(\ell \cdot g)$, so c_λ and $c_{\lambda'}$ are cohomologous. For a homomorphism $\pi\colon G \to \mathrm{GL}(V)$ we write $\pi^* c_\lambda$ for the monomial cocycle $(g, \ell) \mapsto c_\lambda(\pi(g), \ell)$ of G on $\mathbb{P}(V)$, G acting through π; pull-backs of cohomologous cocycles are cohomologous (with the same b), and (Mt2) with $p = \mathrm{id}$ gives $\mathrm{Tf}_{\mathbb{P}(V), c_\lambda} \circ \pi_* = \mathrm{Tf}_{\mathbb{P}(V), \pi^* c_\lambda}$. Fix a homogeneous function λ_V on each V and define

$$\theta_V = t \circ \mathrm{Tf}_{\mathbb{P}(V), c_{\lambda_V}} : \mathrm{Bar}_m(\mathrm{GL}(V); A) \to A.$$

Step 2: (Fa1). Tf maps boundaries to boundaries by (Mt1), and t vanishes on boundaries.

Step 3: (Fa2). Let $\varphi\colon V \to W$ be an isomorphism, $f = c_\varphi\colon \mathrm{GL}(V) \to \mathrm{GL}(W)$, and z a cycle of $\mathrm{GL}(V)$. The bijection $p\colon \mathbb{P}(V) \to \mathbb{P}(W)$, $\ell \mapsto \varphi(\ell)$, satisfies $p(\ell \cdot g) = \varphi g^{-1} \ell = (\varphi g \varphi^{-1})^{-1} \varphi(\ell) = p(\ell) \cdot f(g)$, and $c_{\lambda_W}(f(g), p(\ell)) = \lambda_W(\varphi w)/\lambda_W(\varphi g^{-1} w) = c_{\lambda_W \circ \varphi}(g, \ell)$, where $\lambda_W \circ \varphi$ is a homogeneous function on V. By (Mt2), $\mathrm{Tf}_{\mathbb{P}(W), c_{\lambda_W}}(f_* z) = \mathrm{Tf}_{\mathbb{P}(V), c_{\lambda_W \circ \varphi}}(z)$, which by Step 1 and (Mt4) differs from $\mathrm{Tf}_{\mathbb{P}(V), c_{\lambda_V}}(z)$ by a boundary. Applying t gives $\theta_W(f_* z) = \theta_V(z)$.

Step 4: (Fa3). Let $\rho\colon G \to \mathrm{GL}(V)$, $\sigma\colon G \to \mathrm{GL}(W)$, $U = V \oplus W$, $\pi = \rho \oplus \sigma$ and $z \in \mathrm{Bar}_m(G; A)$ a cycle. The map $\lambda'(w_1, w_2) = \lambda_V(w_1)$ if $w_1 \neq 0$, $\lambda'(0, w_2) = \lambda_W(w_2)$, is a homogeneous function on U; by Step 1 and (Mt4),

$$\theta_U(\pi_* z) = t\big(\mathrm{Tf}_{\mathbb{P}(U), \pi^* c_{\lambda_U}}(z)\big) = t\big(\mathrm{Tf}_{\mathbb{P}(U), \pi^* c_{\lambda'}}(z)\big).$$

Let $\mathrm{pr}\colon \mathbb{P}(U) \to \mathbb{P}(V) \sqcup \mathbb{P}(W)$ send the line of (w_1, w_2) to the line of w_1 if $w_1 \neq 0$ and to the line of w_2 if $w_1 = 0$. Since $\pi(g)^{-1}(w_1, w_2) = (\rho(g)^{-1} w_1, \sigma(g)^{-1} w_2)$, pr is equivariant for the actions of G through π, ρ and σ, and for $w_1 \neq 0$, $c_{\lambda'}(\pi(g), [(w_1, w_2)]) = \lambda_V(w_1)/\lambda_V(\rho(g)^{-1} w_1) = c_{\lambda_V}(\rho(g), [w_1])$, and likewise for $w_1 = 0$ with λ_W and σ. The fibre of pr over the line of $w_1 \neq 0$ consists of the lines of (w_1, w_2), $w_2 \in W$, pairwise distinct, so it has $\#W = 1$ (in A) elements; the fibre over the line of w_2 is the line of $(0, w_2)$. By (Mt2) with $f = \mathrm{id}_G$, then (Mt3) and Step 1,

$$\mathrm{Tf}_{\mathbb{P}(U), \pi^* c_{\lambda'}}(z) = \mathrm{Tf}_{\mathbb{P}(V), \rho^* c_{\lambda_V}}(z) + \mathrm{Tf}_{\mathbb{P}(W), \sigma^* c_{\lambda_W}}(z) = \mathrm{Tf}_{\mathbb{P}(V), c_{\lambda_V}}(\rho_* z) + \mathrm{Tf}_{\mathbb{P}(W), c_{\lambda_W}}(\sigma_* z).$$

Applying t gives $\theta_U(\pi_* z) = \theta_V(\rho_* z) + \theta_W(\sigma_* z)$.

Step 5: the transfer of a prism of scalars. Let $V \neq 0$, $g \in \mathrm{GL}(V)$, $\lambda = \lambda_V$ and $\gamma(\ell) = c_\lambda(g, \ell)$. For a scalar $h = s_V(a)$ and every line ℓ', $\ell' \cdot h = \ell'$ and $c_\lambda(h, \ell') = \lambda(w)/\lambda(a^{-1}w) = a$. Scalars are central, so for $a_1, \ldots, a_n \in k^\times$ and $h_i = s_V(a_i)$,

$$\mathrm{Pr}_g[h_1 | \ldots | h_n] = \sum_{i=0}^{n} (-1)^i [h_1 | \ldots | h_i | g | h_{i+1} | \ldots | h_n],$$

and the term of ℓ in the i-th summand is $[a_1|\dots|a_i|\gamma(\ell)|a_{i+1}|\dots|a_n]$, the point at the entry g being $\ell\cdot(h_1\cdots h_i)=\ell$. Since $k^\times$ is abelian, the prism there is

$$\mathrm{Pr}_b[a_1|\dots|a_n]=\sum_i(-1)^i[a_1|\dots|a_i|b|a_{i+1}|\dots|a_n];$$

by linearity

$$\mathrm{Tf}_{\mathbb{P}(V),c_\lambda}\big(\mathrm{Pr}_g((s_V)_*y)\big)=\sum_{\ell\in\mathbb{P}(V)}\mathrm{Pr}_{\gamma(\ell)}(y)\qquad(y\in\mathrm{Bar}_{m-1}(k^\times;A)).$$

With $y=(\chi_x)_*\mathbf{z}_{q,e}$, so that $(s_V)_*y=(s_V\circ\chi_x)_*\mathbf{z}_{q,e}$, Lemma 40.19 gives

$$\theta_V\Big(\mathrm{Pr}_g\big((s_V\circ\chi_x)_*\mathbf{z}_{q,e}\big)\Big)=\sum_\ell x^{e+1}v(\gamma(\ell))=x^{e+1}\,v(D(g)),\qquad D(g)=\prod_{\ell\in\mathbb{P}(V)}c_\lambda(g,\ell).\tag{40.11}$$

Step 6: $D=\det$, hence (Fa4). By (40.10) and since $\ell\mapsto\ell\cdot g$ permutes $\mathbb{P}(V)$, $D(gh)=\prod_\ell c_\lambda(g,\ell)c_\lambda(h,\ell\cdot g)=D(g)D(h)$: $D\colon\mathrm{GL}(V)\to k^\times$ is a homomorphism. Replacing λ by another homogeneous function multiplies $D(g)$ by $\prod_\ell b(\ell)^{-1}b(\ell\cdot g)=1$ (Step 1), so D does not depend on λ. Fix a basis $e_1,\dots,e_n$ of V. If $ge_i=a_ie_i$ for all i, take $\lambda(w)=w_{i(w)}$, the coordinate of w at the smallest index $i(w)$ with $w_{i(w)}\neq0$; $g^{-1}w$ has the same support and coordinate $a_{i(w)}^{-1}w_{i(w)}$ there, so $c_\lambda(g,[w])=a_{i(w)}$. There are $(\#k)^{n-i}$ lines with $i(w)=i$, so $D(g)=\prod_i a_i^{(\#k)^{n-i}}=\prod_i a_i=\det g$, as $a^{\#k}=a$. For an elementary transvection $T_{ij}(c)$ let d be the diagonal matrix with entry ζ at i and 1 elsewhere; then $dT_{ij}(y)d^{-1}=T_{ij}(\zeta y)$, and with $y=c/(\zeta-1)$ we get $T_{ij}(c)=T_{ij}(\zeta y)T_{ij}(-y)=dT_{ij}(y)d^{-1}T_{ij}(y)^{-1}$, a commutator; so $D(T_{ij}(c))=1=\det T_{ij}(c)$. As these elements generate $\mathrm{GL}(V)$, $D=\det$, and (40.11) is (Fa4). For $V=0$ both sides of (Fa4) are 0 ($\mathbb{P}(0)=\varnothing$, $v(1)=0$). Hence $\theta=(\theta_V)_V$ is an additive family of degree $2e+3$ over k with values in $\mathbb{Z}/q\mathbb{Z}$ having the value property for (q,e,ζ,v). □

Lemma 40.18. *Let G be a group, X a finite set with a right action of G, M an abelian group, c a monomial cocycle of G on X with values in M, and A a commutative ring.*

(Mt1) *$\partial\circ\mathrm{Tf}_{X,c}=\mathrm{Tf}_{X,c}\circ\partial$ on $\mathrm{Bar}_{m+1}(G;A)$ for every $m\geq0$; hence $\mathrm{Tf}_{X,c}$ maps cycles to cycles and boundaries to boundaries.*

(Mt2) *Let H be a group, Y a finite set with a right action of H, c' a monomial cocycle of H on Y with values in M, $f\colon G\to H$ a homomorphism and $p\colon X\to Y$ a map with $p(x\cdot g)=p(x)\cdot f(g)$ and $c(g,x)=c'(f(g),p(x))$ for all g, x. If for every $y\in Y$ the number of $x\in X$ with $p(x)=y$ equals 1 in A, then $\mathrm{Tf}_{X,c}=\mathrm{Tf}_{Y,c'}\circ f_*$ on $\mathrm{Bar}_m(G;A)$ for every $m\geq0$.*

(Mt3) *If $X=X_1\sqcup X_2$ with X_1,X_2 stable under G, and c_i is the restriction of c to $G\times X_i$, then $\mathrm{Tf}_{X,c}=\mathrm{Tf}_{X_1,c_1}+\mathrm{Tf}_{X_2,c_2}$.*

(Mt4) *If c' is a monomial cocycle of G on X cohomologous to c, then $\mathrm{Tf}_{X,c'}(z)-\mathrm{Tf}_{X,c}(z)$ is a boundary for every cycle $z\in\mathrm{Bar}_m(G;A)$, $m\geq1$.*

Proof. For a basis element $\sigma=[g_1|\dots|g_m]$ and $x\in X$ put $x_0=x$, $x_i=x_{i-1}\cdot g_i$, and call $\tau_x(\sigma)=[c(g_1,x_0)|\dots|c(g_m,x_{m-1})]$ the term of x; so $\mathrm{Tf}_{X,c}\sigma=\sum_{x\in X}\tau_x(\sigma)$.

(Mt1). Let $\sigma=[g_0|\dots|g_m]\in\mathrm{Bar}_{m+1}(G;A)$, $x\in X$, $x_0=x$ and $x_{i+1}=x_i\cdot g_i$, so that $\tau_x(\sigma)=[c(g_0,x_0)|\dots|c(g_m,x_m)]$. We compare the faces of $\tau_x(\sigma)$ with the terms of the faces of σ.

The first face $[c(g_1,x_1)|\dots|c(g_m,x_m)]$ is the term of $x\cdot g_0$ in $[g_1|\dots|g_m]$. For $0\le j<m$ the j-th inner face has the entry $c(g_j,x_j)c(g_{j+1},x_{j+1})=c(g_jg_{j+1},x_j)$ by (40.10), and $x_{j+2}=x_j\cdot(g_jg_{j+1})$; so it is the term of x in $[g_0|\dots|g_jg_{j+1}|\dots|g_m]$. The last face is the term of x in $[g_0|\dots|g_{m-1}]$. Summing over $x\in X$, and using that $x\mapsto x\cdot g_0$ is a bijection of X for the first face, gives $\partial\,\mathrm{Tf}_{X,c}\sigma=\mathrm{Tf}_{X,c}\,\partial\sigma$. Linearity gives (Mt1).

(Mt2). Let $\sigma=[g_1|\dots|g_m]$, $x\in X$ and $y=p(x)$, with $y_0=y$, $y_i=y_{i-1}\cdot f(g_i)$. By induction $p(x_i)=y_i$, hence $c(g_i,x_{i-1})=c'(f(g_i),y_{i-1})$, and the term of x in σ equals the term of $p(x)$ in $f_*\sigma=[f(g_1)|\dots|f(g_m)]$. Grouping the points x by $p(x)$,

$$\mathrm{Tf}_{X,c}\sigma=\sum_{y\in Y}\#\{x:p(x)=y\}\cdot\tau_y(f_*\sigma)=\sum_{y\in Y}\tau_y(f_*\sigma)=\mathrm{Tf}_{Y,c'}(f_*\sigma),$$

as each of these numbers is 1 in A.

(Mt3). The points x_i attached to $x\in X_j$ stay in X_j, so the sum over X splits into the sums over X_1 and X_2.

(Mt4). Let W be the set of pairs (h,g) with $h\colon X\to M$ a map and $g\in G$, with the product $(h,g)(h',g')=(h*_g h',gg')$, where $(h*_g h')(x)=h(x)h'(x\cdot g)$. It is a group: both bracketings of a triple product give $(x\mapsto h(x)h'(x\cdot g)h''(x\cdot gg'),gg'g'')$, the neutral element is $(1,1)$, and $(x\mapsto h(x\cdot g^{-1})^{-1},g^{-1})$ is inverse to (h,g). The group W acts on X on the right by $x\cdot(h,g)=x\cdot g$, and $c_W((h,g),x)=h(x)$ is a monomial cocycle of W on X, since $c_W((h,g)(h',g'),x)=h(x)h'(x\cdot g)$. For a monomial cocycle d of G on X the map $\rho_d\colon G\to W$, $g\mapsto(d(g,\cdot),g)$, is a homomorphism by (40.10), and (Mt2), with $f=\rho_d$ and $p=\mathrm{id}_X$, gives

$$\mathrm{Tf}_{X,d}=\mathrm{Tf}^W_{X,c_W}\circ(\rho_d)_*,\tag{40.12}$$

where Tf^W_{X,c_W} is the monomial transfer of the group W. Now let $c'(g,x)=b(x)^{-1}c(g,x)b(x\cdot g)$ and $\beta=(b,1)\in W$. Then $\beta^{-1}=(b^{-1},1)$ and

$$\beta^{-1}\rho_c(g)\beta=(x\mapsto b(x)^{-1}c(g,x),\,g)\,(b,1)=(x\mapsto b(x)^{-1}c(g,x)b(x\cdot g),\,g)=\rho_{c'}(g),$$

so $\rho_{c'}=\kappa_\beta\circ\rho_c$. Let $z\in\mathrm{Bar}_m(G;A)$, $m\ge1$, be a cycle and $w=(\rho_c)_*z$, a cycle of W. By the prism formula, $(\kappa_\beta)_*w-w=\partial\,\mathrm{Pr}_\beta(w)$. By (40.12) for $d=c$ and $d=c'$ and by (Mt1) for W,

$$\mathrm{Tf}_{X,c'}(z)-\mathrm{Tf}_{X,c}(z)=\mathrm{Tf}^W_{X,c_W}\big((\kappa_\beta)_*w-w\big)=\partial\,\mathrm{Tf}^W_{X,c_W}\big(\mathrm{Pr}_\beta(w)\big),$$

a boundary. □

Lemma 40.19. *Let K be a finite cyclic group, $q\ge1$ and $e\ge0$ integers, $\zeta\in K$ an element of order q, and $v\colon K\to\mathbb{Z}/q\mathbb{Z}$ a homomorphism. For an integer $x\ge0$ let $\chi_x\colon C_q\to K$ be the homomorphism $\tau^j\mapsto\zeta^{xj}$. There is a $\mathbb{Z}/q\mathbb{Z}$-linear map $t\colon\mathrm{Bar}_{2e+3}(K;\mathbb{Z}/q\mathbb{Z})\to\mathbb{Z}/q\mathbb{Z}$ that vanishes on boundaries and satisfies*

$$t\Big(\mathrm{Pr}_a\big((\chi_x)_*\mathbf{z}_{q,e}\big)\Big)=x^{e+1}\,v(a)\qquad\text{for all integers } x\ge0 \text{ and all } a\in K.$$

Proof. Step 1: a normalised logarithm. Let $Q=\#K$; $q\mid Q$ as ζ has order q; put $r=Q/q$. Let $L_0\colon K\to\mathbb{Z}/Q\mathbb{Z}$ be an isomorphism. The element $L_0(\zeta)$ has order q, so $L_0(\zeta)=rc$ with c prime to q; choose $\tilde c\in\mathbb{Z}$ prime to Q with $\tilde c\,c\equiv1\pmod q$. Then $L=\tilde cL_0$ is an isomorphism with $L(\zeta)=r\tilde cc=r$, since $r(\tilde cc-1)\equiv0\pmod{rq}$. Let $\lg(a)\in\{0,\dots,Q-1\}$ represent $L(a)$, and

$$U(a,b)=\big(\lg(a)+\lg(b)-\lg(ab)\big)/Q\in\mathbb{Z}\qquad(a,b\in K),$$

an integer because L is a homomorphism. The function U is symmetric, K being abelian, and expanding the four terms gives $U(b,c')-U(ab,c')+U(a,bc')-U(a,b)=0$. So $u=U \bmod q \in C^2$ satisfies $\delta u=0$; also $\delta v=0$, as $(\delta v)(a,b)=v(b)-v(ab)+v(a)$.

Step 2: the cocycle. Define $F_n \in C^n$ by $F_0=1$, $F_1=v$ and $F_{n+2}(g_1,\dots,g_{n+2}) = u(g_1,g_2)\,F_n(g_3,\dots,g_{n+2})$, i.e. $F_{n+2}=u\cup F_n$. By induction and the Leibniz rule (the degree of u is even), $\delta F_n=0$ for $n\geq 1$. Let t be the linear extension of F_{2e+3} to $\mathrm{Bar}_{2e+3}(K;\mathbb{Z}/q\mathbb{Z})$; then $t(\partial\sigma)=(\delta F_{2e+3})(\sigma)=0$, so t vanishes on boundaries.

Step 3: insertion of one entry. For $E\geq 0$, $h=(h_1,\dots,h_{2E})\in K^{2E}$ and $a\in K$,

$$\sum_{i=0}^{2E}(-1)^i F_{2E+1}(h_1,\dots,h_i,a,h_{i+1},\dots,h_{2E}) = F_{2E}(h)\,v(a). \tag{40.13}$$

For $E=0$ both sides are $v(a)$. For $E+1$, the terms $i=0$ and $i=1$ are $u(a,h_1)F_{2E+1}(h_2,\dots)$ and $-u(h_1,a)F_{2E+1}(h_2,\dots)$ and cancel by symmetry of u; for $i\geq 2$ the term is

$$(-1)^i u(h_1,h_2)F_{2E+1}(a \text{ inserted at place } i-2 \text{ of } h_3,\dots,h_{2E+2}),$$

so by induction these sum to $u(h_1,h_2)F_{2E}(h_3,\dots,h_{2E+2})v(a)=F_{2E+2}(h)v(a)$.

Step 4: the value. As K is abelian,

$$\mathrm{Pr}_a[h_1|\dots|h_n]=\sum_{i=0}^{n}(-1)^i[h_1|\dots|h_i|a|h_{i+1}|\dots|h_n],$$

so by (40.13) $t(\mathrm{Pr}_a[h_1|\dots|h_{2e+2}])=F_{2e+2}(h)v(a)$. With

$$(\chi_x)_*\mathbf{z}_{q,e}=\sum_{j\in(\mathbb{Z}/q\mathbb{Z})^{e+1}}[\zeta^{xj_0}|\zeta^x|\zeta^{xj_1}|\zeta^x|\dots|\zeta^{xj_e}|\zeta^x]$$

we obtain

$$t\Big(\mathrm{Pr}_a\big((\chi_x)_*\mathbf{z}_{q,e}\big)\Big)=\sum_{j\in(\mathbb{Z}/q\mathbb{Z})^{e+1}}\prod_{s=0}^{e}u(\zeta^{xj_s},\zeta^x)\cdot v(a)=\Big(\sum_{j=0}^{q-1}u(\zeta^{xj},\zeta^x)\Big)^{e+1}v(a).$$

Finally, the sum telescopes:

$$\sum_{j=0}^{q-1}U(\zeta^{xj},\zeta^x)=\frac{1}{Q}\Big(q\lg(\zeta^x)+\lg(\zeta^0)-\lg(\zeta^{xq})\Big)=\frac{q\lg(\zeta^x)}{Q},$$

and $\lg(\zeta^x)=xr+Qm$ for some $m\in\mathbb{Z}$ because $L(\zeta^x)=xr$; so the sum is $x+qm\equiv x \pmod q$, and the value is $x^{e+1}v(a)$. □

Lemma 40.20. *Let k be a finite field, A a commutative ring, $m\geq 1$, θ an additive family of degree m over k with values in A, R a commutative ring and $r\colon R\to k$ a ring homomorphism. Then $\Phi_n=\theta_{k^n}\circ(\mathrm{red}_{r,n})_*$ $(n\geq 0)$ is a primitive family of degree m over R with values in A.*

Proof. Push-forward along a homomorphism commutes with the bar differential, so it maps cycles to cycles and boundaries to boundaries.

Cycles of the trivial group are boundaries. Let $E=\{1\}$ and $m'\geq 1$. Then $\mathrm{Bar}_{m'}(E;A)=A\,e_{m'}$ with $e_{m'}=[1|\dots|1]$, and $\partial e_{m'+1}=(\sum_{i=0}^{m'+1}(-1)^i)e_{m'}$, which is $e_{m'}$ if m' is odd and 0 if m' is even. If m' is odd, every element of $\mathrm{Bar}_{m'}(E;A)$ is a boundary. If m' is even, $\partial e_{m'}=e_{m'-1}$, so the only cycle is 0. Hence, for every group G and every homomorphism $\rho\colon G\to\mathrm{GL}(W)$ that is

trivial, ρ factors through E, $\rho_* z$ is a boundary for every cycle $z \in \mathrm{Bar}_m(G;A)$, and $\theta_W(\rho_* z) = 0$ by (Fa1).

(Pm1). If z is a boundary, so is $(\mathrm{red}_{r,n})_* z$, and $\Phi_n(z) = 0$ by (Fa1).

(Pm2). Let $n \le n'$ and z a cycle. Let $\varphi\colon k^n \oplus k^{n'-n} \to k^{n'}$ be the isomorphism of coordinates. Then $\mathrm{red}_{r,n'} \circ \mathrm{stab}_{n,n'} = c_\varphi \circ (\mathrm{red}_{r,n} \oplus \mathbf{1})$, where $\mathbf{1}\colon \mathrm{GL}_n(R) \to \mathrm{GL}(k^{n'-n})$ is trivial. By (Fa2), (Fa3) and the previous paragraph,

$$\Phi_{n'}((\mathrm{stab}_{n,n'})_* z) = \theta_{k^n \oplus k^{n'-n}}((\mathrm{red}_{r,n} \oplus \mathbf{1})_* z) = \theta_{k^n}((\mathrm{red}_{r,n})_* z) + \theta_{k^{n'-n}}(\mathbf{1}_* z) = \Phi_n(z).$$

(Pm3). Let $d \ge 1$ and z a cycle. Let $\varphi_d\colon (k^n)^{\oplus d} \to k^{dn}$ be the isomorphism that places the i-th summand in the i-th block of n consecutive coordinates. Then $\mathrm{red}_{r,dn} \circ \mathrm{blk}_{d,n} = c_{\varphi_d} \circ (\mathrm{red}_{r,n} \oplus \cdots \oplus \mathrm{red}_{r,n})$. By (Fa2), $\Phi_{dn}((\mathrm{blk}_{d,n})_* z) = \theta_{(k^n)^{\oplus d}}((\mathrm{red}_{r,n}^{\oplus d})_* z)$, and by (Fa3) applied $d-1$ times, with $(k^n)^{\oplus j} = k^n \oplus (k^n)^{\oplus (j-1)}$ (each push-forward of z is a cycle), this equals $d\,\theta_{k^n}((\mathrm{red}_{r,n})_* z) = d\,\Phi_n(z)$. □

Lemma 40.21. *Let $L \subseteq F$ be number fields, $q \ge 1$ an integer such that F contains a primitive q-th root of unity, $\beta \in F^\times$ and $b \in \mathcal{O}_F \smallsetminus \{0\}$. Suppose that for every nonzero prime $\mathfrak{P}$ of $\mathcal{O}_F$ with $b \notin \mathfrak{P}$ for which $\mathcal{O}_L \to \mathcal{O}_F/\mathfrak{P}$ is surjective, β is a unit at $\mathfrak{P}$ and its residue is a q-th power in $(\mathcal{O}_F/\mathfrak{P})^\times$. Then $\beta \in F^{\times q}$.*

Proof. Fix an algebraic closure of F, an element η with $\eta^q = \beta$, and $K = F(\eta)$. Since F contains μ_q, all roots of $X^q - \beta$ are $\eta\zeta'$ with $\zeta' \in \mu_q \subseteq F$, so K/F is Galois. Let Σ be the set of nonzero primes $\mathfrak{P}$ of $\mathcal{O}_F$ of absolute residue degree one with $\mathfrak{P} \nmid qb$; it differs from the set of all primes of absolute degree one by finitely many primes, so it has Dirichlet density one. For $\mathfrak{P} \in \Sigma$ the residue field is $\mathbb{F}_p$, the image of $\mathbb{Z} \subseteq \mathcal{O}_L$, so $\mathcal{O}_L \to \mathcal{O}_F/\mathfrak{P}$ is surjective; by hypothesis β is a unit at $\mathfrak{P}$ with residue s^q for some $s \in (\mathcal{O}_F/\mathfrak{P})^\times$. Since $\mathfrak{P} \nmid q$, the reduction of a primitive q-th root of unity is a primitive q-th root of unity, so $X^q - \bar\beta = \prod_{\zeta' \in \mu_q}(X - \bar\zeta' s)$ has q distinct roots in $\mathcal{O}_F/\mathfrak{P}$. The element η is integral at $\mathfrak{P}$ (a root of the monic $\mathfrak{P}$-integral polynomial $X^q - \beta$), and its minimal polynomial divides $X^q - \beta$, so it is separable and splits into linear factors modulo $\mathfrak{P}$; hence $\mathfrak{P}$ splits completely in K. So the set of primes of F splitting completely in K contains Σ and has Dirichlet density one. By Chebotarev's density theorem with $C = \{1\} \subseteq \mathrm{Gal}(K/F)$ this density is $1/[K:F]$; hence $K = F$, $\eta \in F^\times$ and $\beta = \eta^q \in F^{\times q}$. □

Theorem 40.22. *Let L be a totally complex number field, $k \ge 0$ an even integer, ℓ a prime, $\nu \ge 0$ an integer, B a $\mathbb{Z}/\ell^\nu\mathbb{Z}$-module and Φ a primitive family of degree $k+1$ over $\mathcal{O}_L$ with values in B (with $A = \mathbb{Z}/\ell^\nu\mathbb{Z}$). Put $N_0 = 2k+6$ and suppose that $H_{k+1}(\mathrm{GL}_{N_0}(\mathcal{O}_L), \mathbb{Z})_{\mathrm{tors}}$ and $H_k(\mathrm{GL}_{N_0}(\mathcal{O}_L), \mathbb{Z})_{\mathrm{tors}}$ are finite, of orders t_{k+1} and t_k. Then the set*

$$\{\ell^k\,\Phi_n(y) :\ n \ge 0,\ y \in \mathrm{Bar}_{k+1}(\mathrm{GL}_n(\mathcal{O}_L); \mathbb{Z}/\ell^\nu\mathbb{Z}) \text{ a cycle}\} \subseteq B$$

is finite with at most $\ell^{\nu r_2(L)}\, t_{k+1}\, t_k$ elements.

Proof. Put $q = \ell^\nu$, $R = \mathcal{O}_L$ and $r = r_2(L)$; then $qB = 0$. Let $\rho\colon \mathrm{Bar}_m(G;\mathbb{Z}) \to \mathrm{Bar}_m(G;\mathbb{Z}/q\mathbb{Z})$ be reduction of coefficients. It is surjective with kernel $q\,\mathrm{Bar}_m(G;\mathbb{Z})$, and it commutes with ∂ and with every f_*; $\mathrm{Bar}_m(G;\mathbb{Z})$ is free abelian, hence torsion-free.

Step 1: Φ induces maps on integral homology. For $n \ge 0$ define $\varphi_n\colon H_{k+1}(\mathrm{GL}_n(R), \mathbb{Z}) \to B$ by $\varphi_n([z]) = \Phi_n(\rho z)$ for integral cycles z. Here ρz is a cycle, and if $z = \partial w$ then $\rho z = \partial \rho w$ is a boundary and $\Phi_n(\rho z) = 0$ by (Pm1); so φ_n is a well-defined homomorphism. Since $(\mathrm{stab}_{n,n'})_* \rho z = \rho(\mathrm{stab}_{n,n'})_* z$ and $(\mathrm{blk}_{d,n})_* \rho z = \rho(\mathrm{blk}_{d,n})_* z$, (Pm2) and (Pm3) give, for every $x \in H_{k+1}(\mathrm{GL}_n(R), \mathbb{Z})$,

$$\varphi_{n'}((\mathrm{stab}_{n,n'})_* x) = \varphi_n(x) \quad (n \le n'), \qquad \varphi_{dn}((\mathrm{blk}_{d,n})_* x) = d\,\varphi_n(x) \quad (d \ge 1). \tag{40.14}$$

Step 2: $\ell^k\varphi_n$ factors through z_k. Let $n \geq 0$, $x \in H_{k+1}(\mathrm{GL}_n(R), \mathbb{Z})$ and let $z_t(x) \in H_{k+1}(\mathrm{GL}_{\ell^t n}(R), \mathbb{Z})$ be the sequence of Lemma 40.23: $z_0(x) = x$, $z_{t+1}(x) = (\mathrm{blk}_{\ell,\ell^t n})_* z_t(x) - \ell^{t+2}(\mathrm{stab}_{\ell^t n,\ell^{t+1} n})_* z_t(x)$. By (40.14), $\varphi_{\ell^{t+1}n}(z_{t+1}(x)) = \ell(1-\ell^{t+1})\,\varphi_{\ell^t n}(z_t(x))$, so by induction

$$\varphi_{\ell^k n}(z_k(x)) = \ell^k w\, \varphi_n(x), \qquad w = \prod_{t=0}^{k-1}(1-\ell^{t+1}).$$

As $w \equiv 1 \pmod{\ell}$, there is $u \in \mathbb{Z}$ with $uw \equiv 1 \pmod{q}$, and since $qB = 0$,

$$\ell^k \varphi_n(x) = \varphi_{\ell^k n}(u\, z_k(x)) \qquad \text{for all } x \in H_{k+1}(\mathrm{GL}_n(R), \mathbb{Z}). \tag{40.15}$$

Step 3: the torsion is stable from N_0 on. Let $m \in \{k, k+1\}$ and $n \geq N_0$. R has stable rank at most 2, so by Theorem B.163 with $s = 2$ and $i = m$ the maps $H_m(\mathrm{GL}_N(R), \mathbb{Z}) \to H_m(\mathrm{GL}_{N+1}(R), \mathbb{Z})$ induced by $\mathrm{stab}_{N,N+1}$ are isomorphisms for all $N \geq 2m+4$, in particular for all $N \geq N_0 = 2k+6$. Their composite is an isomorphism $H_m(\mathrm{GL}_{N_0}(R), \mathbb{Z}) \to H_m(\mathrm{GL}_n(R), \mathbb{Z})$, which maps the torsion subgroup onto the torsion subgroup. Hence $H_m(\mathrm{GL}_n(R), \mathbb{Z})_{\mathrm{tors}}$ is finite of order t_m.

Step 4: the Bockstein homomorphism. Fix $n \geq N_0$. Let $Y \subseteq \mathrm{Bar}_{k+1}(\mathrm{GL}_n(R); \mathbb{Z}/q\mathbb{Z})$ be the group of cycles and $T = H_k(\mathrm{GL}_n(R), \mathbb{Z})_{\mathrm{tors}}$, of order t_k by Step 3. For $y \in Y$ choose $\tilde{y} \in \mathrm{Bar}_{k+1}(\mathrm{GL}_n(R); \mathbb{Z})$ with $\rho\tilde{y} = y$. Then $\rho\,\partial\tilde{y} = \partial y = 0$, so $\partial\tilde{y} = q\,w_{\tilde{y}}$ for a unique $w_{\tilde{y}} \in \mathrm{Bar}_k(\mathrm{GL}_n(R); \mathbb{Z})$. If $k = 0$, then $\partial[g] = [\,] - [\,] = 0$ on Bar_1, so $w_{\tilde{y}} = 0$. If $k \geq 1$, then $q\,\partial w_{\tilde{y}} = \partial\partial\tilde{y} = 0$, so $w_{\tilde{y}}$ is a cycle. Put $\beta(y) = [w_{\tilde{y}}] \in H_k(\mathrm{GL}_n(R), \mathbb{Z})$. It lies in T, as $q[w_{\tilde{y}}] = [\partial\tilde{y}] = 0$. It does not depend on the lift: another lift is $\tilde{y} + qv$, and $w_{\tilde{y}+qv} = w_{\tilde{y}} + \partial v$. The sum of two lifts is a lift of the sum, so $\beta\colon Y \to T$ is a homomorphism. Finally, if $\beta(y) = 0$, then $w_{\tilde{y}} = \partial v$ for some v, and $\tilde{y} - qv$ is an integral cycle with $\rho(\tilde{y} - qv) = y$. Hence

$$\ker\beta = \{\rho z :\ z \in \mathrm{Bar}_{k+1}(\mathrm{GL}_n(R); \mathbb{Z}) \text{ a cycle}\}. \tag{40.16}$$

Step 5: the values on Y for fixed $n \geq N_0$. Let $g\colon Y \to B$ be the homomorphism $g(y) = \ell^k\Phi_n(y)$. Let $H' = H_{k+1}(\mathrm{GL}_{\ell^k n}(R), \mathbb{Z})$, let $J \subseteq H'$ be the subgroup generated by the $z_k(x)$, $x \in H_{k+1}(\mathrm{GL}_n(R), \mathbb{Z})$, and $f = \varphi_{\ell^k n}|_J$.

- $g(\ker\beta) \subseteq f(J)$. By (40.16) an element of $\ker\beta$ is ρz with z an integral cycle, and by (40.15) $g(\rho z) = \ell^k\varphi_n([z]) = f(u\,z_k([z]))$.
- $\#f(J) \leq q^r t_{k+1}$. As $f(qJ) = qf(J) = 0$, $f(J)$ is a quotient of J/qJ. The torsion subgroup J_{t} of J lies in H'_{tors}, which has order t_{k+1} by Step 3 ($\ell^k n \geq N_0$). Let $D = J/J_{\mathrm{t}}$, a torsion-free group of rank at most r by Lemma 40.23 (applicable since L is totally complex, k is even and $n \geq 2k+6$). The sequence $J_{\mathrm{t}} \to J/qJ \to D/qD \to 0$ is exact, so $\#(J/qJ) \leq t_{k+1}\,\#(D/qD)$. Next, $\dim_{\mathbb{F}_\ell} D/\ell D \leq r$: if $d_1, \dots, d_s \in D$ have linearly independent images in $D/\ell D$, the subgroup D' they generate is finitely generated and torsion-free of rank at most r, hence free of rank at most r, and a relation $\sum a_i d_i \in \ell D' \subseteq \ell D$ forces $\ell \mid a_i$; so the images in $D'/\ell D'$ are independent and $s \leq r$. Each quotient $\ell^i D/\ell^{i+1}D$ is the image of $D/\ell D$ under multiplication by ℓ^i, so $\#(D/qD) = \prod_{i=0}^{\nu-1}\#(\ell^i D/\ell^{i+1}D) \leq \ell^{r\nu} = q^r$.
- $\#g(Y) \leq \#T \cdot \#g(\ker\beta)$. For each $\tau \in \beta(Y)$ fix $y_\tau \in Y$ with $\beta(y_\tau) = \tau$. If $\beta(y) = \tau$, then $y - y_\tau \in \ker\beta$ and $g(y) \in g(y_\tau) + g(\ker\beta)$. So $g(Y)$ is covered by at most $\#T$ translates of $g(\ker\beta)$.

Together, $\#g(Y) \leq t_k\, q^r\, t_{k+1}$.

Step 6: all n. Let S be a finite subset of the set in the statement, each $s \in S$ written as $s = \ell^k \Phi_{n_s}(y_s)$ with y_s a cycle, and let $n = \max(N_0, \max_{s\in S} n_s)$. Then $(\mathrm{stab}_{n_s,n})_* y_s$ is a cycle and, by (Pm2), $s = \ell^k \Phi_n((\mathrm{stab}_{n_s,n})_* y_s)$, so $S \subseteq g(Y)$ for this n. By Step 5, $\#S \le \ell^{\nu r} t_{k+1} t_k$. As this holds for every finite subset, the set is finite with at most $\ell^{\nu r_2(L)} t_{k+1} t_k$ elements. □

Lemma 40.23. *Let L be a totally complex number field, $k \ge 0$ an even integer, $\ell \ge 1$ an integer and $n \ge 2k+6$. For $x \in H_{k+1}(\mathrm{GL}_n(\mathcal{O}_L), \mathbb{Z})$ define $z_t(x) \in H_{k+1}(\mathrm{GL}_{\ell^t n}(\mathcal{O}_L), \mathbb{Z})$ by $z_0(x) = x$ and*

$$z_{t+1}(x) = (\mathrm{blk}_{\ell,\ell^t n})_*\, z_t(x) - \ell^{t+2}\, (\mathrm{stab}_{\ell^t n,\ell^{t+1} n})_*\, z_t(x) \qquad (t \ge 0).$$

Then the subgroup of $H_{k+1}(\mathrm{GL}_{\ell^k n}(\mathcal{O}_L), \mathbb{Z})$ generated by the $z_k(x)$, $x \in H_{k+1}(\mathrm{GL}_n(\mathcal{O}_L), \mathbb{Z})$, has rank at most $r_2(L)$.

Proof. Let $R = \mathcal{O}_L$, $\mathcal{H}$, ι_N, μ, Δ and $\mathcal{P}$ as in Theorem B.164, and write x also for the image of x in rational homology.

Step 1: stability. R has stable rank at most 2, so by Theorem B.163 with $s = 2$ and $i = k+1$ the maps $H_{k+1}(\mathrm{GL}_N(R), \mathbb{Z}) \to H_{k+1}(\mathrm{GL}_{N+1}(R), \mathbb{Z})$ are isomorphisms for $N \ge 2k+6$. Tensoring with $\mathbb{Q}$ and passing to the colimit, $\iota_N \colon H_{k+1}(\mathrm{GL}_N(R); \mathbb{Q}) \to \mathcal{H}_{k+1}$ is an isomorphism for every $N \ge 2k+6$, in particular for $N = \ell^k n$.

Step 2: weights. By Theorem B.164, $\mathcal{H} = \bigoplus_{j\ge 0} \mathcal{H}_{(j)}$, where $\mathcal{H}_{(j)}$ is the span of the products of j primitive elements; since $\mathcal{P}$ lives in degrees ≥ 1, the degree-$(k+1)$ part of $\mathcal{H}_{(j)}$ is 0 for $j = 0$ and for $j > k+1$, and $\mathcal{H}_{(1)} = \mathcal{P}$. For $d \ge 1$ let $[d] = \mu^{(d)} \circ \Delta^{(d)} \colon \mathcal{H} \to \mathcal{H}$ (iterated coproduct, then iterated product). As $\mathcal{H}$ is commutative and cocommutative, $\mu^{(d)}$ and $\Delta^{(d)}$ are algebra homomorphisms, hence so is $[d]$; for $p \in \mathcal{P}$, $\Delta^{(d)}(p) = \sum_{i=1}^{d} 1 \otimes \cdots \otimes p \otimes \cdots \otimes 1$ and $[d]p = dp$. Hence $[d]$ acts on $\mathcal{H}_{(j)}$ as multiplication by d^j.

Step 3: the block-diagonal map is $[d]$. The map $\mathrm{blk}_{d,N}$ is the composite of the diagonal $\mathrm{GL}_N(R) \to \mathrm{GL}_N(R)^d$ and the d-fold block sum $\mathrm{GL}_N(R)^d \to \mathrm{GL}_{dN}(R)$. On rational homology the first induces $\Delta^{(d)}$ (with the Künneth isomorphism), and by the defining property of μ in Theorem B.164 the second, followed by ι_{dN}, is $\mu^{(d)} \circ \iota_N^{\otimes d}$. Hence $\iota_{dN} \circ (\mathrm{blk}_{d,N})_* = [d] \circ \iota_N$. Also $\iota_{N'} \circ (\mathrm{stab}_{N,N'})_* = \iota_N$.

Step 4: $z_k(x)$ is primitive in the stable range. By Step 3, $\iota_{\ell^{t+1} n}(z_{t+1}(x)) = ([\ell] - \ell^{t+2})\, \iota_{\ell^t n}(z_t(x))$, so $\iota_{\ell^k n}(z_k(x)) = \prod_{t=0}^{k-1} ([\ell] - \ell^{t+2})\, \iota_n(x)$. Write $\iota_n(x) = \sum_{j=1}^{k+1} x_j$ with x_j in the degree-$(k+1)$ part of $\mathcal{H}_{(j)}$ (Step 2). By Step 2,

$$\iota_{\ell^k n}(z_k(x)) = \sum_{j=1}^{k+1} \prod_{t=0}^{k-1} (\ell^j - \ell^{t+2}) x_j = \prod_{t=0}^{k-1} (\ell - \ell^{t+2})\, x_1 \in \mathcal{P}_{k+1},$$

because for $2 \le j \le k+1$ the factor with $t = j-2 \in \{0, \dots, k-1\}$ vanishes.

Step 5: the rank. By Steps 1 and 4, $\iota_{\ell^k n}$ maps the $\mathbb{Q}$-span of the $z_k(x)$ in $H_{k+1}(\mathrm{GL}_{\ell^k n}(R); \mathbb{Q})$ injectively into $\mathcal{P}_{k+1} \cong K_{k+1}(R) \otimes \mathbb{Q}$. As $k+1$ is odd and $r_1(L) = 0$, Theorem B.25 gives $\dim K_{k+1}(R) \otimes \mathbb{Q} = r_2(L)$ if $k+1 \ge 3$, and $\dim K_1(R) \otimes \mathbb{Q} = r_2(L) - 1$ if $k = 0$. So the rank of the subgroup generated by the $z_k(x)$ is at most $r_2(L)$. □

Proposition 40.24. *Let L be a totally complex number field, ℓ a prime, (F, γ, ζ) a cyclotomic Kummer layer of level (c, ν) over L, and $e \ge 1$, $b \ge 0$, $B \ge 0$ integers; put $a = (1+\ell^c)^e$ and $g(L) = 2[L:\mathbb{Q}] + \lfloor \log_2 h_L \rfloor + 2$. If $\#\mathrm{Ku}_{\ell^b,\ell^\nu}(F, \gamma, a) \le B$, then $\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)}$ is finite and*

$$\#\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)} \cdot \ell^{\nu\, r_2(L)} \le B \cdot \ell^{(b+v_\ell(e))\, g(L) + c + v_\ell(e)}.$$

Proof. All groups below are written multiplicatively. Put $\sigma = \gamma^{-1}$, $n = \ell^{\nu-c}$ (the order of γ), $r = r_2(L)$, $q = \ell^\nu$, $s = \ell^b$, $g = g(L)$, $\mu = \mu(F)$, $E = \mathcal{O}_F^\times$, and let I_F be the group of fractional ideals and $\mathrm{Cl} = \mathrm{Cl}(F)$. On $F^\times$, on I_F and on Cl let $\delta(x) = \sigma(x)\,x^{-a}$; these are endomorphisms, compatible with $y \mapsto (y)$ and $\mathfrak{d} \mapsto [\mathfrak{d}]$, and they commute with γ. Write $\mathrm{N} = \mathrm{N}_{\gamma,a}$ as in (Ky3).

Step 1: arithmetic of a. Since $v_\ell(\ell^c) = c \geq 1$ (≥ 2 if $\ell = 2$), the lifting-the-exponent rule gives $v_\ell(a-1) = c + v_\ell(e)$ and $v_\ell(a^n - 1) = c + v_\ell(e) + (\nu - c) = \nu + v_\ell(e)$; also $a \geq 3$. So $a^n - 1 = qu$ with $u = \ell^{v_\ell(e)}m$ and $\ell \nmid m$, and $\ell \mid a - 1$.

Step 2: δ is injective on I_F and on $F^\times/\mu$. If $\delta(x) = 1$ in I_F, then $\sigma(x) = x^a$, and $x = \sigma^n(x) = x^{a^n}$; as I_F is torsion free and $a^n \neq 1$, $x = 1$. If $\delta(y) \in \mu$ for $y \in F^\times$, then $\sigma(y) = y^a t$ with $t \in \mu$, and inductively $\sigma^k(y) \in y^{a^k}\mu$; for $k = n$ this gives $y^{a^n-1} \in \mu$, so $y \in \mu$.

Step 3: the Kummer group and its order. Let $U \subseteq F^\times$ be the group of (γ, a)-Kummer elements, that is, of α with $(\alpha) \in \delta(I_F)$ (Ky2), and $W = U/\delta(F^\times)\mu$; indeed $\delta(F^\times)\mu \subseteq U$. For $\alpha \in U$ let $\mathfrak{d}_\alpha \in I_F$ be the unique ideal with $\delta(\mathfrak{d}_\alpha) = (\alpha)$ (Step 2). The map $\alpha \mapsto [\mathfrak{d}_\alpha]$ is a homomorphism from U to $\mathrm{Cl}[\delta] = \ker(\delta|_{\mathrm{Cl}})$, as $\delta([\mathfrak{d}_\alpha]) = [(\alpha)] = 1$. It is surjective: if $\delta([\mathfrak{d}]) = 1$, then $\delta(\mathfrak{d}) = (\alpha)$ for some α, which lies in U with $\mathfrak{d}_\alpha = \mathfrak{d}$. Its kernel is $\delta(F^\times)E$: if $\mathfrak{d}_\alpha = (\beta)$, then $(\alpha) = (\delta(\beta))$ and $\alpha\delta(\beta)^{-1} \in E$; conversely $\mathfrak{d}_{\delta(\beta)} = (\beta)$ and $\mathfrak{d}_\varepsilon = 1$ for $\varepsilon \in E$. Moreover $E \cap \delta(F^\times)\mu = \delta(E)\mu$: if $\varepsilon = \delta(z)t$ with $t \in \mu$, then $\delta((z)) = (\varepsilon) = 1$, so $(z) = 1$ and $z \in E$. Hence the sequence

$$1 \to E/\delta(E)\mu \to W \to \mathrm{Cl}[\delta] \to 1$$

is exact. By Lemma 40.25 (L totally complex, F/L cyclic of degree n generated by γ, $a \geq 2$), $E/\delta(E)\mu$ is finite of order $(a^n-1)^r/(a-1)$; Cl is finite, and $\#\mathrm{Cl}[\delta] = \#(\mathrm{Cl}/\delta(\mathrm{Cl}))$. So W is finite and, by Step 1,

$$v_\ell(\#W) = r(\nu + v_\ell(e)) - (c + v_\ell(e)) + v_\ell\big(\#(\mathrm{Cl}/\delta(\mathrm{Cl}))\big). \tag{40.17}$$

Step 4: the eigencharacters. A homomorphism $\varphi\colon \mathrm{Cl} \to \mathbb{Z}/q\mathbb{Z}$ satisfies (Ky1) exactly when $\varphi(\sigma(x)x^{-a}) = 0$ for all $x \in \mathrm{Cl}$, that is, when it factors through $\mathrm{Cl}/\delta(\mathrm{Cl})$. So $\mathrm{Hom}(\mathrm{Cl}, \mathbb{Z}/q\mathbb{Z})^{(\gamma,a)} \cong \mathrm{Hom}(\mathrm{Cl}/\delta(\mathrm{Cl}), \mathbb{Z}/q\mathbb{Z})$ is finite of order at most $\ell^{v_\ell(\#(\mathrm{Cl}/\delta(\mathrm{Cl})))}$.

Step 5: the map to twisted Kummer classes. Since $\gamma^n = 1$ and $\gamma^{n-1} = \sigma$, a telescoping product gives

$$\mathrm{N}(\delta(y)) = \sigma(y)^{1-a^n} = \sigma(y)^{-qu} \qquad (y \in F^\times), \tag{40.18}$$

and N is a homomorphism commuting with δ and mapping μ into μ. Let $f\colon W \to F^\times/F^{\times q}\mu$ send the class of $\alpha \in U$ to the class of $\mathrm{N}(\alpha)^s$; by (40.18) it kills $\delta(F^\times)\mu$, so it is a well-defined homomorphism. Its image is the image of $\mathrm{Ku}_{s,q}(F,\gamma,a)$ under the projection $F^\times/F^{\times q} \to F^\times/F^{\times q}\mu$ (Ky4), so $\#f(W) \leq \#\mathrm{Ku}_{s,q}(F,\gamma,a) \leq B$. Its kernel is killed by su: if $\mathrm{N}(\alpha)^s = \beta^q t$ with $t \in \mu$, put $y = \alpha^s$; applying δ and (40.18), $\sigma(y)^{-qu} = \mathrm{N}(\delta(y)) = \delta(\mathrm{N}(y)) = \delta(\beta)^q\delta(t)$, so $(\sigma(y)^u\delta(\beta))^q \in \mu$, hence $\sigma(y)^u \in \delta(F^\times)\mu$, and applying γ, which preserves $\delta(F^\times)\mu$, $\alpha^{su} = y^u \in \delta(F^\times)\mu$.

Step 6: the ℓ-torsion of W. Let $\mathcal{S} \subseteq F^\times/F^{\times\ell}\mu$ be the set of Lemma 40.26. Let $[\alpha] \in W$ with $[\alpha]^\ell = 1$, so $\alpha^\ell = \delta(\beta)t$ with $\beta \in F^\times$, $t \in \mu$; by Step 2, β is determined by α up to μ. We claim that $[\alpha] \mapsto$ (class of β) is a well-defined injective homomorphism $W[\ell] \to \mathcal{S}$. First, $\delta((\beta)) = (\alpha)^\ell = \delta(\mathfrak{d}_\alpha^\ell)$, so $(\beta) = \mathfrak{d}_\alpha^\ell$ by Step 2, and ℓ divides every valuation of β; and $\sigma(\beta)\beta^{-1} = \alpha^\ell\beta^{a-1}t^{-1} \in F^{\times\ell}\mu$ since $\ell \mid a-1$, whence $\gamma(\beta)\beta^{-1} = \gamma\big((\sigma(\beta)\beta^{-1})^{-1}\big) \in F^{\times\ell}\mu$. So the class of β lies in $\mathcal{S}$. Replacing α by $\alpha\delta(z)t_1$ ($t_1 \in \mu$) replaces β by βz^ℓ up to μ, so the map is well defined, and it is a homomorphism. If $\beta = z^\ell t_2$ with $t_2 \in \mu$, then $(\alpha\delta(z)^{-1})^\ell = \delta(t_2)t \in \mu$, so $\alpha\delta(z)^{-1} \in \mu$ and $[\alpha] = 1$. By Lemma 40.26, $\#W[\ell] \leq \#\mathcal{S} \leq \ell^{2[L:\mathbb{Q}]+\lfloor \log_2 h_L \rfloor + 2} = \ell^g$.

Step 7: the ℓ-part of W. Let W_ℓ be the ℓ-Sylow subgroup of W and $K = \ker f \cap W_\ell$. By Step 5, K is killed by $su = \ell^{b+v_\ell(e)}m$, and as $\ell \nmid m$, by $\ell^{b+v_\ell(e)}$. K is a sum of $\dim_{\mathbb{F}_\ell} K[\ell] \leq$

$\dim_{\mathbb{F}_\ell} W[\ell] \le g$ cyclic groups (Step 6), each of order at most $\ell^{b+v_\ell(e)}$, so $\#K \le \ell^{(b+v_\ell(e))g}$. Hence

$$\ell^{v_\ell(\#W)} = \#W_\ell = \#f(W_\ell)\,\#K \le \#f(W)\,\ell^{(b+v_\ell(e))g} \le B\,\ell^{(b+v_\ell(e))g}.$$

Step 8: conclusion. By Step 4, $\nu r \le r(\nu + v_\ell(e))$, (40.17) and Step 7,

$$\#\mathrm{Hom}(\mathrm{Cl}, \mathbb{Z}/q\mathbb{Z})^{(\gamma,a)} \cdot \ell^{\nu r} \le \ell^{v_\ell(\#(\mathrm{Cl}/\delta(\mathrm{Cl})))+r(\nu+v_\ell(e))} = \ell^{v_\ell(\#W)}\,\ell^{c+v_\ell(e)} \le B\,\ell^{(b+v_\ell(e))g(L)+c+v_\ell(e)}.$$

□

Lemma 40.25. *Let L be a totally complex number field, F/L a cyclic extension of degree n, γ a generator of $\mathrm{Gal}(F/L)$, and $a \ge 2$ an integer. The endomorphism $u \mapsto \gamma^{-1}(u)\,u^{-a}$ of the group $\mathcal{O}_F^\times/\mu(F)$ is injective, and its cokernel is finite of order*

$$\frac{(a^n-1)^{r_2(L)}}{a-1}.$$

Proof. Write the group $\bar{E} = \mathcal{O}_F^\times/\mu(F)$ additively, put $r = r_2(L)$, $\sigma = \gamma^{-1}$, and $\delta = \sigma - a$ on $\bar{E}$, so that δ is the endomorphism of the statement. Since L is totally complex, so is F, and $r_2(F) = nr$.

The logarithmic embedding. Let S be the set of archimedean places of F and, for $w \in S$, $|\cdot|_w$ the absolute value of $\mathbb{C}$ composed with an embedding representing w. Let $\Lambda\colon \mathcal{O}_F^\times \to \mathbb{R}^S$, $\Lambda(u)_w = \log|u|_w$. By Dirichlet's unit theorem, $\ker\Lambda = \mu(F)$ and $\Lambda(\mathcal{O}_F^\times)$ is a lattice of rank $nr-1$ spanning the hyperplane $H_0 = \{x \in \mathbb{R}^S : \sum_w x_w = 0\}$; so $\bar{E}$ is free of rank $nr-1$ and Λ maps a $\mathbb{Z}$-basis of $\bar{E}$ to an $\mathbb{R}$-basis of H_0. For $\tau \in \mathrm{Gal}(F/L)$ and $w \in S$ let τw be the place with $|x|_{\tau w} = |\tau^{-1}x|_w$, and let τ act on $\mathbb{R}^S$ by $(\tau x)_{\tau w} = x_w$. Then $\Lambda(\tau u)_{\tau w} = \log|u|_w$, that is, $\Lambda(\tau u) = \tau\Lambda(u)$; and H_0 and the line $\mathbb{R}\mathbf{1}$ spanned by $\mathbf{1} = (1)_{w\in S}$ are stable, with $\mathbb{R}^S = H_0 \oplus \mathbb{R}\mathbf{1}$ and $\tau\mathbf{1} = \mathbf{1}$.

The characteristic polynomial. Let v be an archimedean place of L; it is complex, so $L_v = \mathbb{C}$ and $[F_w : L_v] = 1$ for every $w \mid v$. Hence exactly n places of F lie above v; $\mathrm{Gal}(F/L)$, of order n, permutes them transitively, hence simply transitively, and its generator σ permutes them in one cycle of length n. So S is the disjoint union of r orbits of length n, on each of which σ acts on the coordinates as a cyclic permutation, and the characteristic polynomial of σ on $\mathbb{R}^S$ is $(X^n-1)^r$. Removing the factor $X-1$ of the line $\mathbb{R}\mathbf{1}$, the characteristic polynomial of σ on H_0 is

$$P(X) = \frac{(X^n-1)^r}{X-1} = (X^n-1)^{r-1}\,(1 + X + \cdots + X^{n-1}).$$

In a $\mathbb{Z}$-basis of $\bar{E}$, σ has an integer matrix M, which is also the matrix of σ on H_0 in the image basis; so $\det(X - M) = P(X)$.

The index. The matrix of δ is $M - a$, and $\det(M-a) = (-1)^{nr-1}P(a)$. As $a \ge 2$, $P(a) = (a^n-1)^r/(a-1) > 0$, so δ is injective, and $\#(\bar{E}/\delta\bar{E}) = |\det(M-a)| = (a^n-1)^r/(a-1)$. (If $nr = 1$, then $\bar{E} = 0$ and $P = 1$, and the formula reads $1 = 1$.) □

Lemma 40.26. *Let L be a number field, ℓ a prime and (F, γ, ζ) a cyclotomic Kummer layer of level (c, ν) over L. Let $\mathcal{S} \subseteq F^\times/F^{\times\ell}\mu(F)$ be the set of classes of the elements $y \in F^\times$ such that $\ell \mid \mathrm{ord}_{\mathfrak{P}}(y)$ for every nonzero prime $\mathfrak{P}$ of $\mathcal{O}_F$ and $\gamma(y)\,y^{-1} \in F^{\times\ell}\mu(F)$. Then $\mathcal{S}$ is finite and*

$$\#\mathcal{S} \le \ell^{\,2[L:\mathbb{Q}]+\lfloor\log_2 h_L\rfloor+2}.$$

Proof. Let $n = [L : \mathbb{Q}]$ and $\mathrm{N} = \mathrm{N}_{F/L}$.

Step 1: $F = L(\zeta)$, and F/L is unramified at every prime not above ℓ. For an integer k, $\gamma^k(\zeta) = \zeta^{(1+\ell^c)^k}$ by (40.3), and by the lifting-the-exponent rule $(1+\ell^c)^k \equiv 1 \pmod{\ell^\nu}$ holds only if $\ell^{\nu-c} \mid k$, that is, only if $\gamma^k = 1$. So the only element of $\mathrm{Gal}(F/L) = \langle\gamma\rangle$ fixing $L(\zeta)$ is the identity, and $F = L(\zeta)$. Hence a prime of L not above ℓ is unramified in F.

Step 2: the Selmer group of L. Let $\mathrm{Sel}_L \subseteq L^\times/L^{\times\ell}$ be the subgroup of classes of the $x \in L^\times$ with $\ell \mid \mathrm{ord}_\mathfrak{p}(x)$ for every prime $\mathfrak{p}$ of L not above ℓ (a condition on the class). We show $\#\mathrm{Sel}_L \le \ell^{2n+\lfloor \log_2 h_L \rfloor}$. Let T be the set of primes of L above ℓ, so $\#T \le n$, and Cl_T the quotient of $\mathrm{Cl}(L)$ by the subgroup generated by the classes of the primes in T. For $x \in L^\times$ as above write $(x) = \mathfrak{a}^\ell\mathfrak{b}$ with $\mathfrak{a} = \prod_{\mathfrak{p}\notin T} \mathfrak{p}^{\mathrm{ord}_\mathfrak{p}(x)/\ell}$ and $\mathfrak{b}$ supported on T, and send the class of x to the class of $\mathfrak{a}$ in Cl_T. Replacing x by xz^ℓ multiplies $\mathfrak{a}$ by (z) times an ideal supported on T, so this is a well-defined homomorphism $\pi\colon \mathrm{Sel}_L \to \mathrm{Cl}_T$, with values in $\mathrm{Cl}_T[\ell]$ because $\mathfrak{a}^\ell = (x)\mathfrak{b}^{-1}$. If π kills the class of x, then $\mathfrak{a} = (w)\mathfrak{c}$ with $\mathfrak{c}$ supported on T, so $(xw^{-\ell}) = \mathfrak{c}^\ell\mathfrak{b}$ is supported on T and $xw^{-\ell} \in \mathcal{O}_{L,T}^\times$. So $\ker\pi$ is the image of $\mathcal{O}_{L,T}^\times$, a quotient of $\mathcal{O}_{L,T}^\times/\mathcal{O}_{L,T}^{\times\ell}$, which by the T-unit theorem has order at most $\ell^{1+(r_1+r_2-1+\#T)} \le \ell^{2n}$. The ℓ-rank of $\mathrm{Cl}(L)$ is an integer k with $\ell^k \le h_L$, so $k \le \lfloor \log_2 h_L \rfloor$, and $\#\mathrm{Cl}_T[\ell] \le \#\mathrm{Cl}(L)[\ell] = \ell^k$. Hence $\#\mathrm{Sel}_L \le \ell^{2n+\lfloor \log_2 h_L \rfloor}$.

Step 3: types. Let ρ generate the cyclic group $\mu(F)$. For each $x \in \mathcal{S}$ fix y as in the statement; then $\gamma(y) = y\,v^\ell\rho^k$ for some $v \in F^\times$ and $k \in \mathbb{Z}$, and writing $k = \ell q + r$ with $0 \le r < \ell$ and replacing v by $v\rho^q$ we may take $k = r$. Taking norms, $\mathrm{N}(\gamma(y)) = \mathrm{N}(y)$ gives $\mathrm{N}(v)^\ell = \mathrm{N}(\rho)^{-r}$. Call $(r, \mathrm{N}(v))$ the type of x (for the fixed choices). Types lie in $\Theta = \{(r,\lambda) : 0 \le r < \ell,\ \lambda \in L,\ \lambda^\ell = \mathrm{N}(\rho)^{-r}\}$, and $\#\Theta \le \ell\cdot\ell$, as $X^\ell - \mathrm{N}(\rho)^{-r}$ has at most ℓ roots in L.

Step 4: elements of one type differ by a class from L. Let $x, x' \in \mathcal{S}$ have the same type (r,λ), with the fixed y, v and y', v'. Put $\beta = y/y'$ and $w = v/v'$; then $\gamma(\beta) = \beta w^\ell$ and $\mathrm{N}(w) = \lambda/\lambda = 1$. By Hilbert's Theorem 90, $w = \gamma(z)z^{-1}$ with $z \in F^\times$, so $\gamma(\beta z^{-\ell}) = \beta w^\ell \gamma(z)^{-\ell} = \beta z^{-\ell}$, and $x_0 = \beta z^{-\ell}$ lies in $L^\times$, as γ generates $\mathrm{Gal}(F/L)$. For a prime $\mathfrak{p}$ of L not above ℓ and a prime $\mathfrak{P}$ of F above it, $\mathfrak{P}$ is unramified over $\mathfrak{p}$ (Step 1), so $\mathrm{ord}_\mathfrak{p}(x_0) = \mathrm{ord}_\mathfrak{P}(x_0) = \mathrm{ord}_\mathfrak{P}(y) - \mathrm{ord}_\mathfrak{P}(y') - \ell\,\mathrm{ord}_\mathfrak{P}(z) \equiv 0 \pmod{\ell}$. So the class of x_0 lies in Sel_L, and $x = x'\,\iota(x_0)$, where $\iota\colon L^\times/L^{\times\ell} \to F^\times/F^{\times\ell}\mu(F)$ is induced by the inclusion.

Step 5: the count. For each type $\theta \in \Theta$ that occurs, fix $x_\theta \in \mathcal{S}$ of type θ. By Step 4 every $x \in \mathcal{S}$ lies in $x_\theta\,\iota(\mathrm{Sel}_L)$ for its type θ. Hence $\mathcal{S}$ is finite and, by Steps 2 and 3, $\#\mathcal{S} \le \#\Theta\cdot\#\mathrm{Sel}_L \le \ell^2\,.\,\ell^{2n+\lfloor \log_2 h_L \rfloor}$. □

Proposition 40.27. *Let L be a totally complex number field, ℓ a prime and $c \ge 1$ an integer ($c \ge 2$ if $\ell = 2$) such that L contains a primitive ℓ^c-th root of unity and no primitive ℓ^{c+1}-th root of unity. Let $e \ge 1$ and $B \ge 0$ be integers. Suppose that for every integer $\nu \ge c$ and every cyclotomic Kummer layer (F,γ,ζ) of level (c,ν) over L, the group $\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,(1+\ell^c)^e)}$ is finite of order at most B. Then $\mathrm{len}_\ell(L,e)$ is finite and $\ell^{\mathrm{len}_\ell(L,e)} \le B$.*

Proof. Put $a = (1+\ell^c)^e$. Fix an algebraic closure $\overline{L}$ of L, let $\Omega \subseteq \overline{L}$ be the maximal extension of L unramified outside the places above ℓ, $G = \mathrm{Gal}(\Omega/L) = G_{L,S_\ell}$, and $A = \mathbb{Q}_\ell/\mathbb{Z}_\ell(-e)$, on which $g \in G$ acts as multiplication by $\chi_{\mathrm{cyc}}(g)^{-e}$. For $1 \le k \le \infty$ let $L_k \subseteq \overline{L}$ be the field generated over L by the roots of unity of order dividing ℓ^k (all ℓ-power orders if $k = \infty$). The extension L_k/L is unramified outside the places above ℓ, and L has no real place, so $L_k \subseteq \Omega$; put $H_k = \mathrm{Gal}(\Omega/L_k)$, a closed normal subgroup of G. For each place v of L above ℓ let $D_v \subseteq G$ be the image of G_{L_v} under the map that defines the localisation $H^1(G,A) \to H^1(L_v,A)$; it is the decomposition group of a place of Ω above v, so the decomposition groups in G of the places of Ω above v are the gD_vg^{-1}, $g \in G$.

Step 1: the cyclotomic tower. Since $\mu_{\ell^c} \subseteq L$, χ_{cyc} maps G into U_c, and $g \in G$ fixes μ_{ℓ^k}

$(k \geq 1)$ exactly when $\chi_{\mathrm{cyc}}(g) \in U_k$. So χ_{cyc} induces an injective continuous homomorphism from $\Gamma = \mathrm{Gal}(L_\infty/L)$ to U_c, whose image is closed. The image is infinite, because $[L_k : L] \geq \varphi(\ell^k)/[L : \mathbb{Q}]$ tends to infinity; so it is U_{k_1} for some $k_1 \geq c$. If $k_1 \geq c+1$, then G fixes $\mu_{\ell^{c+1}}$, that is, L contains a primitive ℓ^{c+1}-th root of unity, which is excluded. Hence $\chi_{\mathrm{cyc}} \colon \Gamma \to U_c$ is an isomorphism, and for $\nu \geq c$ it induces an isomorphism $\mathrm{Gal}(L_\nu/L) \cong U_c/U_\nu$, a cyclic group of order $\ell^{\nu-c}$ generated by the class of $1+\ell^c$. Fix $g_0 \in G$ with $\chi_{\mathrm{cyc}}(g_0) = 1+\ell^c$ (restriction $G \to \Gamma$ is surjective), and let $\gamma_0 \in \Gamma$ be its restriction; the powers γ_0^k, $k \in \mathbb{Z}$, are dense in Γ.

Step 2: restriction to H_∞ is injective. The group H_∞ acts trivially on A, because $\chi_{\mathrm{cyc}}(H_\infty) = 1$. By inflation–restriction the sequence

$$0 \to H^1(\Gamma, A) \to H^1(G, A) \xrightarrow{\mathrm{res}} \mathrm{Hom}_{\mathrm{cts}}(H_\infty, A)$$

is exact, where res sends the class of a cocycle f to the homomorphism $f|_{H_\infty}$ (coboundaries vanish on H_∞). We show $H^1(\Gamma, A) = 0$. The element γ_0 acts on A as multiplication by $\beta = (1+\ell^c)^{-e}$, and $\beta \neq 1$ because U_c is torsion free and $e \geq 1$. Multiplication by the nonzero element $\beta - 1$ of $\mathbb{Z}_\ell$, a power of ℓ times a unit, is surjective on the divisible group A. Let $f \colon \Gamma \to A$ be a continuous cocycle and choose $y \in A$ with $(\beta-1)y = f(\gamma_0)$; then $f'(\sigma) = f(\sigma) - (\sigma - 1)y$ is a cocycle cohomologous to f with $f'(\gamma_0) = 0$. From $f'(\sigma\tau) = f'(\sigma) + \sigma f'(\tau)$ we get $f'(\gamma_0^k) = 0$ for $k \geq 0$ by induction, and $f'(\gamma_0^{-k}) = -\gamma_0^{-k} f'(\gamma_0^k) = 0$. The zero set of the continuous map f' to the discrete group A is closed and contains a dense subset, so $f' = 0$. Hence $H^1(\Gamma, A) = 0$ and res is injective.

Step 3: a Tate–Shafarevich class restricted to a finite level. For a continuous cocycle $f \colon G \to A$ and $g, d \in G$, the cocycle identity gives

$$f(gdg^{-1}) = g\, f(d) + (1 - gdg^{-1}) f(g). \tag{40.19}$$

Let $x \in \mathrm{Sha}^1_\ell(L, e)$ and let f be a continuous cocycle representing x. Its image is finite, so $f(G) \subseteq A[\ell^r]$ for some $r \geq 0$. For each $v \mid \ell$ the localisation of x at v is 0, so there is $a_v \in A$ with $f(d) = (d-1)a_v$ for all $d \in D_v$. As there are finitely many such v, there is $R \geq r$ with $\ell^R a_v = 0$ for all $v \mid \ell$. Let $\nu \geq \max(c, R)$ and $\psi = f|_{H_\nu}$. We claim: ψ is a continuous homomorphism $H_\nu \to A[\ell^\nu]$ and

1. $\psi(ghg^{-1}) = \chi_{\mathrm{cyc}}(g)^{-e}\, \psi(h)$ for $g \in G$ and $h \in H_\nu$;
2. ψ vanishes on $gD_vg^{-1} \cap H_\nu$ for every $v \mid \ell$ and $g \in G$;
3. $\psi|_{H_\infty} = \mathrm{res}(x)$.

An element $h \in H_\nu$ fixes μ_{ℓ^ν}, so $\chi_{\mathrm{cyc}}(h) \in U_\nu$ and $\chi_{\mathrm{cyc}}(h)^{-e} \equiv 1 \pmod{\ell^\nu}$: H_ν acts trivially on $A[\ell^\nu]$, which contains $f(G)$ as $r \leq \nu$. Hence $\psi(hh') = f(h) + h\, f(h') = \psi(h) + \psi(h')$, and ψ takes values in $A[\ell^\nu]$. For item 1, H_ν is normal, so $ghg^{-1} \in H_\nu$ fixes $f(g)$, and (40.19) gives $\psi(ghg^{-1}) = g\, f(h) = \chi_{\mathrm{cyc}}(g)^{-e}\psi(h)$. For item 2, let $d \in D_v$ with $d' = gdg^{-1} \in H_\nu$. By (40.19) and $f(d) = (d-1)a_v$,

$$f(d') = g(d-1)a_v + (1-d')f(g) = (d'-1)(g\, a_v - f(g)).$$

The element $g\, a_v - f(g)$ is killed by ℓ^ν (as g acts by a unit, $\ell^R a_v = 0$ and $f(g) \in A[\ell^r]$), and $d' \in H_\nu$ acts trivially on $A[\ell^\nu]$; so $f(d') = 0$. Item 3 holds because $H_\infty \subseteq H_\nu$.

Step 4: from such a homomorphism to an eigencharacter. Let $\nu \geq c$, $F = L_\nu$, and let $\psi \colon H_\nu \to A[\ell^\nu]$ be a continuous homomorphism with items 1 and 2 of Step 3. By Step 1, F/L is Galois with $\mathrm{Gal}(F/L)$ cyclic of order $\ell^{\nu-c}$, generated by $\gamma = g_0|_F$; let $\zeta \in F$ be a primitive ℓ^ν-th

root of unity, a unit of $\mathcal{O}_F$, with $\gamma(\zeta) = \zeta^{\chi_{\mathrm{cyc}}(g_0)} = \zeta^{1+\ell^c}$. So (F, γ, ζ) is a cyclotomic Kummer layer of level (c, ν) over L. Let $K \subseteq \Omega$ be the fixed field of $\ker\psi$, an abelian extension of F. It is unramified at the finite places of F not above ℓ, because Ω/L is; at a place of F above ℓ, the decomposition group in $H_\nu = \mathrm{Gal}(\Omega/F)$ of a place of Ω above it is some $gD_vg^{-1} \cap H_\nu$, which lies in $\ker\psi$ by item 2, so the place splits completely in K. As $F \supseteq L$ has no real place, $K \subseteq H_F$. Further H_F/L is unramified outside the places above ℓ (as H_F/F is unramified and F/L is unramified outside them), so $H_F \subseteq \Omega$, and ψ vanishes on $\mathrm{Gal}(\Omega/H_F) \subseteq \mathrm{Gal}(\Omega/K)$: $\psi = \bar\psi \circ \rho$ with $\rho\colon H_\nu \to \mathrm{Gal}(H_F/F)$ the (surjective) restriction and $\bar\psi$ a homomorphism. Let $\iota\colon \mathbb{Z}/\ell^\nu\mathbb{Z} \to A[\ell^\nu]$ be the group isomorphism $k \mapsto k\ell^{-\nu} + \mathbb{Z}_\ell$, and put

$$\theta_\psi = \iota^{-1} \circ \bar\psi \circ \mathrm{Art}\colon \mathrm{Cl}(F) \to \mathbb{Z}/\ell^\nu\mathbb{Z},$$

where $\mathrm{Art}\colon \mathrm{Cl}(F) \to \mathrm{Gal}(H_F/F)$ is the Artin isomorphism. Let $\mathfrak{p}$ be a nonzero prime of $\mathcal{O}_F$ and $\tilde g = g_0|_{H_F}$, which restricts to γ; then $\tilde g^{-1}$ restricts to γ^{-1}, and $\mathrm{Frob}_{\gamma^{-1}(\mathfrak{p})} = \tilde g^{-1}\,\mathrm{Frob}_{\mathfrak{p}}\,\tilde g$. Choose $h \in H_\nu$ with $\rho(h) = \mathrm{Frob}_{\mathfrak{p}}$; then $\rho(g_0^{-1}hg_0) = \mathrm{Frob}_{\gamma^{-1}(\mathfrak{p})}$, and item 1 with $g = g_0^{-1}$ gives

$$\bar\psi(\mathrm{Frob}_{\gamma^{-1}(\mathfrak{p})}) = \psi(g_0^{-1}hg_0) = \chi_{\mathrm{cyc}}(g_0)^e\,\psi(h) = a\,\bar\psi(\mathrm{Frob}_{\mathfrak{p}}).$$

So $\theta_\psi([\gamma^{-1}(\mathfrak{p})]) = a\,\theta_\psi([\mathfrak{p}])$; both sides are additive in the ideal, and every fractional ideal is a product of prime powers, so the relation of (Ky1) holds for every fractional ideal: $\theta_\psi \in \mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)}$. The assignment $\psi \mapsto \theta_\psi$ is injective, since ρ is surjective and Art and ι are bijective.

Step 5: the count. Let $T \subseteq \mathrm{Sha}^1_\ell(L, e)$ be finite. For each $x \in T$ choose f_x and R_x as in Step 3, and let $\nu = \max(c, \max_{x\in T} R_x)$, $F = L_\nu$, and (F, γ, ζ) the layer of Step 4. By Step 3, each $\psi_x = f_x|_{H_\nu}$ is a continuous homomorphism to $A[\ell^\nu]$ with items 1 to 3. If $x \neq x'$ in T, then $\psi_x|_{H_\infty} = \mathrm{res}(x) \neq \mathrm{res}(x') = \psi_{x'}|_{H_\infty}$ by Step 2, so $\psi_x \neq \psi_{x'}$ and, by Step 4, $\theta_{\psi_x} \neq \theta_{\psi_{x'}}$. Hence $x \mapsto \theta_{\psi_x}$ maps T injectively into $\mathrm{Hom}(\mathrm{Cl}(F), \mathbb{Z}/\ell^\nu\mathbb{Z})^{(\gamma,a)}$, which by hypothesis ($\nu \geq c$) has at most B elements; so $\#T \leq B$. As every finite subset of $\mathrm{Sha}^1_\ell(L, e)$ has at most B elements, $\mathrm{Sha}^1_\ell(L, e)$ is finite of order at most B. It is a $\mathbb{Z}_\ell$-submodule of $H^1(G, A)$; being finite, it has finite length $\mathrm{len}_\ell(L, e)$, and $\ell^{\mathrm{len}_\ell(L,e)} = \#\mathrm{Sha}^1_\ell(L, e) \leq B$. □

Definition 40.28. Let L be a totally complex number field, $n = [L : \mathbb{Q}]$, $S_\infty(L)$ its set of complex places (it has $r_2 = n/2$ elements), and fix for every $w \in S_\infty(L)$ an embedding $\sigma_w\colon L \to \mathbb{C}$ inducing w. Let $N \geq 1$ be an integer.

(Vn1) Forms. $V_{L,N}$ is the real vector space of tuples $h = (h_w)_{w\in S_\infty(L)}$ of hermitian complex $N \times N$ matrices; $\dim_{\mathbb{R}} V_{L,N} = r_2N^2$. For $h \in V_{L,N}$ and $y \in L^N$,

$$h[y] = \sum_{w\in S_\infty(L)} \sigma_w(y)^*\,h_w\,\sigma_w(y) \in \mathbb{R}. \tag{40.20}$$

Further, $V^{\geq 0}_{L,N}$ is the closed cone of the h with every h_w positive semidefinite, $V^*_{L,N}$ the dual space of $V_{L,N}$, and

$$\Omega_{L,N} = \{x \in V^*_{L,N} :\ x(k) > 0 \text{ for every } k \in V^{\geq 0}_{L,N} \setminus \{0\}\}.$$

(Vn2) Ryshkov polyhedron and perfect forms. The **Ryshkov polyhedron** is

$$\mathcal{R}_{L,N} = \{h \in V_{L,N} :\ h[y] \geq 1 \text{ for every } y \in \mathcal{O}_L^N \setminus \{0\}\}.$$

For $h \in \mathcal{R}_{L,N}$ the set of **minimal vectors** is $\mathrm{Min}(h) = \{y \in \mathcal{O}_L^N \setminus \{0\} :\ h[y] = 1\}$. A **perfect form** is an $h \in \mathcal{R}_{L,N}$ such that the only $k \in V_{L,N}$ with $k[y] = 0$ for all $y \in \mathrm{Min}(h)$ is $k = 0$. The set of perfect forms is denoted $\mathrm{Perf}_{L,N}$.

(Vn3) Normal cones. For $v \in \mathrm{Perf}_{L,N}$ the **normal cone** is the closed convex cone

$$\mathrm{Nc}(v) = \{x \in V_{L,N}^* : \ x(v) \le x(h) \text{ for every } h \in \mathcal{R}_{L,N}\}.$$

(Vn4) The perfect-cone nerve. For an integer $p \ge 0$, $\mathcal{N}_p(L,N)$ is the set of $(p+1)$-tuples $t = (t_0, \dots, t_p)$ of perfect forms, repetitions allowed, with

$$\Omega_{L,N} \cap \mathrm{Nc}(t_0) \cap \cdots \cap \mathrm{Nc}(t_p) \neq \emptyset;$$

a point of this intersection is a **witness** of t. For $p \ge 1$ and $0 \le i \le p$ the face $\partial_i t \in \mathcal{N}_{p-1}(L,N)$ is t with the entry t_i omitted (a witness of t is one of $\partial_i t$). The **augmented chain complex of the perfect-cone nerve** is

$$\cdots \xrightarrow{d_2} \mathbb{Z}[\mathcal{N}_1(L,N)] \xrightarrow{d_1} \mathbb{Z}[\mathcal{N}_0(L,N)] \xrightarrow{\mathrm{aug}} \mathbb{Z} \to 0,$$

where $\mathbb{Z}[X]$ is the free abelian group on a set X with basis $[x]$ ($x \in X$), $d_p[t] = \sum_{i=0}^{p} (-1)^i [\partial_i t]$ and $\mathrm{aug}[t] = 1$.

(Vn5) Action. $\mathrm{GL}_N(\mathcal{O}_L)$ acts on $V_{L,N}$ by $(g \cdot h)_w = \sigma_w(g^{-1})^* \, h_w \, \sigma_w(g^{-1})$, so that $(g \cdot h)[y] = h[g^{-1}y]$; on $V_{L,N}^*$ by $(g \cdot x)(h) = x(g^{-1} \cdot h)$; and on tuples of elements of $V_{L,N}$ entry by entry.

Theorem 40.29. *There is a real number $C_{\mathrm{T}} \ge 0$ such that for every totally complex number field L, every integer $e \ge 1$ and every integer m with $0 \le m \le 2e+1$, the group $H_m(\mathrm{GL}_{4e+6}(\mathcal{O}_L), \mathbb{Z})_{\mathrm{tors}}$ is finite and*

$$\log \# H_m\big(\mathrm{GL}_{4e+6}(\mathcal{O}_L), \mathbb{Z}\big)_{\mathrm{tors}} \le \big(2|d_L|\big)^{(2e[L:\mathbb{Q}])^{C_{\mathrm{T}}}}.$$

Proof. We prove the statement with $C_{\mathrm{T}} = 12$. Let L, $e \ge 1$ and $0 \le m \le 2e+1$ be as in the statement; put $n = [L : \mathbb{Q}]$ (even, so $n \ge 2$), $r_2 = n/2$, $N = 4e+6$, $\Gamma = \mathrm{GL}_N(\mathcal{O}_L)$, $R_0 = R_0(L,N) \ge 1$, $Y = \log(2|d_L|)$ and $u = 2en$.

Step 1: the torsion lemma applies. Take $X_p = \mathcal{N}_p(L,N)$ for $0 \le p \le m+1$, $M = \mathbb{Z}$ with the trivial action, $\alpha = \mathrm{aug}$ and the boundary maps d_p of the perfect-cone nerve. These maps are Γ-equivariant by item 5 of Lemma 40.32, and the sequence is exact at $\mathbb{Z}$ and at every $\mathbb{Z}[X_p]$ by Lemma 40.31. For $p \le m$ the number of orbits on X_p is at most $A_p(L,N) \le A_m(L,N)$ (Lemma 40.35; A_p increases with p), and every stabiliser has order at most $T = 3^{nN^2}$ (Lemma 40.34). For $t \in X_{m+1}$, $d_{m+1}[t]$ is a signed sum of $m+2$ basis elements, so $\|d_{m+1}[t]\|_1 \le m+2$. By Lemma 40.30 with $A = A_m(L,N)$, T and $b = m+2$, the group $H_m(\Gamma, \mathbb{Z})_{\mathrm{tors}}$ is finite and

$$\# H_m(\Gamma, \mathbb{Z})_{\mathrm{tors}} \le (m+2)^A \, T^{\,mAT^m}.$$

Step 2: a doubly exponential form. Since $\log(m+2) \le m+1 \le (m+1)T^{m+1}$ and $\log T \le T$,

$$\begin{aligned} \log \# H_m(\Gamma, \mathbb{Z})_{\mathrm{tors}} &\le A \log(m+2) + mAT^m \log T \le (2m+1)AT^{m+1} \\ &= \exp\big(\log A + (m+1)\log T + \log(2m+1)\big). \end{aligned}$$

Step 3: the exponent. From $e \ge 1$ and $n \ge 2$: $u \ge 4$, $e \le u/4$, $N \le 10e \le 5u/2$, $nN \le 10en = 5u$, $nN^2 = 2r_2N^2 \le 25u^2/2$, $m+1 \le 2e+2 \le 4e \le u$; and $Y \ge \log 2 > 1/2$,

$\log|d_L| \le Y$, $\log 3 \le 2Y$. As $R_0 \ge 1$, $A \le (3R_0)^{(nN)^2+1+nN\cdot r_2N^2\cdot(m+1)}$, with exponent at most $(25u^2+1)+5u\cdot\frac{25u^2}{4}\cdot u \le 58u^4$, and

$$\log(3R_0) = \log 3 + \tfrac{nN}{2}\log(nN) + \tfrac{N}{2}\log|d_L| \le 2Y + \tfrac{5u}{2}\cdot 5u + \tfrac{5u}{4}Y \le (2+25u^2+2u)Y \le 29u^2Y.$$

So $\log A \le 1682u^6Y$. Further $(m+1)\log T = (m+1)nN^2\log 3 \le u\cdot\frac{25u^2}{2}\cdot\frac{11}{10} \le 14u^3 \le 28u^3Y$, and $\log(2m+1) \le 2m \le 2u \le 4uY$. Hence

$$\log A + (m+1)\log T + \log(2m+1) \le (1682u^6 + 28u^3 + 4u)\,Y \le 1714u^6Y \le u^{12}Y,$$

and by Step 2

$$\log \#H_m\big(\mathrm{GL}_{4e+6}(\mathcal{O}_L),\mathbb{Z}\big)_{\mathrm{tors}} \le \exp\big(u^{12}Y\big) = \big(2|d_L|\big)^{(2e[L:\mathbb{Q}])^{12}}.$$

This is the statement with $C_{\mathrm{T}} = 12$. □

Lemma 40.30. *Let Γ be a group, $m \ge 0$ an integer and $A, T, b \ge 1$ integers. Let $X_0, \dots, X_{m+1}$ be Γ-sets, M a $\mathbb{Z}[\Gamma]$-module, and*

$$\mathbb{Z}[X_{m+1}] \xrightarrow{d_{m+1}} \mathbb{Z}[X_m] \xrightarrow{d_m} \cdots \xrightarrow{d_1} \mathbb{Z}[X_0] \xrightarrow{\alpha} M \to 0$$

a sequence of Γ-equivariant homomorphisms that is exact at M and at $\mathbb{Z}[X_p]$ for $0 \le p \le m$. Suppose that for $0 \le p \le m$ the set X_p has at most A orbits and every stabiliser Γ_x, $x \in X_p$, is finite of order at most T, and that $\|d_{m+1}[y]\|_1 \le b$ for every $y \in X_{m+1}$. Then $H_m(\Gamma, M)_{\mathrm{tors}}$ is finite and

$$\#H_m(\Gamma, M)_{\mathrm{tors}} \le b^A\, T^{\,mAT^m}.$$

Proof. Step 1: torsion of a cokernel. Let $k \ge 0$ and $\Lambda \subseteq \mathbb{Z}^k$ be generated by a set Z of vectors with $\|z\|_1 \le b$. Then $(\mathbb{Z}^k/\Lambda)_{\mathrm{tors}}$ has at most b^k elements. Indeed, it is $\Lambda^{\mathrm{sat}}/\Lambda$ with $\Lambda^{\mathrm{sat}} = \mathbb{Z}^k \cap \mathbb{Q}\Lambda$, a free group of the rank $r \le k$ of Λ. As Z spans $\mathbb{Q}\Lambda$, it contains linearly independent $z_1, \dots, z_r$; they span $\Lambda' \subseteq \Lambda \subseteq \Lambda^{\mathrm{sat}}$. The Gram determinant of a basis of Λ^{sat} is a positive integer, so $\mathrm{vol}(\Lambda^{\mathrm{sat}}) \ge 1$, and

$$[\Lambda^{\mathrm{sat}} : \Lambda] \le [\Lambda^{\mathrm{sat}} : \Lambda'] = \frac{\mathrm{vol}(\Lambda')}{\mathrm{vol}(\Lambda^{\mathrm{sat}})} \le \prod_{i=1}^{r} \|z_i\|_2 \le \prod_{i=1}^{r} \|z_i\|_1 \le b^r \le b^k.$$

Step 2: finite groups. If H is finite with $|H| \le T$ and $q \ge 1$, then $\#H_q(H,\mathbb{Z}) \le T^{T^q}$. Indeed $H_q(H,\mathbb{Z}) = Z_q/B_q$ with Z_q a subgroup of the q-th term of the bar complex, hence free of rank at most $|H|^q$, and it is annihilated by $|H|$, so it is a quotient of $Z_q/|H|Z_q$, of order at most $|H|^{|H|^q} \le T^{T^q}$.

Step 3: permutation modules. If a Γ-set X has at most A orbits and stabilisers of order at most T, then for $q \ge 1$, by Shapiro's lemma and Step 2,

$$\#H_q(\Gamma, \mathbb{Z}[X]) = \prod_{\Gamma x \in X/\Gamma} \#H_q(\Gamma_x, \mathbb{Z}) \le T^{AT^q}.$$

Step 4: torsion along an exact sequence. If $U \xrightarrow{f} V \xrightarrow{g} W$ is exact, U is finite and W_{tors} is finite, then V_{tors} is finite and $\#V_{\mathrm{tors}} \le \#U \cdot \#W_{\mathrm{tors}}$: g maps V_{tors} into W_{tors} with kernel inside $\ker g = f(U)$.

Step 5: induction on m. We prove the lemma for all Γ, M, X_p and maps with the given A, T, b, by induction on m.

$m = 0$. By right exactness, $\mathbb{Z}[X_1]_\Gamma \to \mathbb{Z}[X_0]_\Gamma \to M_\Gamma \to 0$ is exact. The map $\pi\colon [x] \mapsto [\Gamma x]$ identifies $\mathbb{Z}[X_0]_\Gamma$ with $\mathbb{Z}^k$, $k = \#(X_0/\Gamma) \le A$, and does not increase $\|\cdot\|_1$. So $H_0(\Gamma, M) = M_\Gamma \cong \mathbb{Z}^k/\Lambda$, where Λ is generated by the $\pi(d_1[y])$, $y \in X_1$, of ℓ^1-norm at most b. Step 1 gives $\#H_0(\Gamma, M)_{\mathrm{tors}} \le b^k \le b^A = b^A T^0$.

$m \to m+1$. Assume the lemma for m, and let data for $m+1$ be given. Let $K = \ker\alpha = d_1(\mathbb{Z}[X_1])$, a $\mathbb{Z}[\Gamma]$-submodule of $\mathbb{Z}[X_0]$. The sequence

$$\mathbb{Z}[X_{m+2}] \xrightarrow{d_{m+2}} \cdots \xrightarrow{d_2} \mathbb{Z}[X_1] \xrightarrow{d_1} K \to 0$$

is exact at K and at $\mathbb{Z}[X_p]$ for $1 \le p \le m+1$ (exactness at $\mathbb{Z}[X_1]$ because $K \subseteq \mathbb{Z}[X_0]$), the sets X_{p+1}, $0 \le p \le m$, satisfy the orbit and stabiliser bounds, and $\|d_{m+2}[y]\|_1 \le b$. By the case m, $\#H_m(\Gamma, K)_{\mathrm{tors}} \le b^A T^{mAT^m}$. The long exact sequence of $0 \to K \to \mathbb{Z}[X_0] \to M \to 0$ contains $H_{m+1}(\Gamma, \mathbb{Z}[X_0]) \to H_{m+1}(\Gamma, M) \to H_m(\Gamma, K)$, and by Step 3 (with $q = m+1$) the first group is finite of order at most $T^{AT^{m+1}}$. By Step 4, $H_{m+1}(\Gamma, M)_{\mathrm{tors}}$ is finite and

$$\#H_{m+1}(\Gamma, M)_{\mathrm{tors}} \le T^{AT^{m+1}} \cdot b^A T^{mAT^m} \le b^A T^{(m+1)AT^{m+1}},$$

since $mAT^m \le mAT^{m+1}$. □

Lemma 40.31. *Let L be a totally complex number field and $N \ge 1$. The augmented chain complex of the perfect-cone nerve is exact:* aug *is surjective,* $\ker(\mathrm{aug}) = d_1(\mathbb{Z}[\mathcal{N}_1(L,N)])$*, and* $\ker(d_p) = d_{p+1}(\mathbb{Z}[\mathcal{N}_{p+1}(L,N)])$ *for every $p \ge 1$.*

Proof. Write $\mathcal{N}_p = \mathcal{N}_p(L,N)$ and $\Omega = \Omega_{L,N}$; Ω is convex, as an intersection of open half-spaces of $V^*_{L,N}$.

Surjectivity of aug. By item 3 of Lemma 40.33 there is a perfect form v with $x_{\mathrm{tr}} \in \mathrm{Nc}(v)$, so $(v) \in \mathcal{N}_0$ with witness x_{tr}, and $\mathrm{aug}[(v)] = 1$.

Reduction to a finite nerve. Let $p \ge 0$ and $c \in \mathbb{Z}[\mathcal{N}_p]$ with $d_p c = 0$ if $p \ge 1$, $\mathrm{aug}(c) = 0$ if $p = 0$. Write $c = \sum_{i=1}^k a_i[t^{(i)}]$ with $t^{(i)} \in \mathcal{N}_p$, choose a witness x_i of $t^{(i)}$, and let $K \subseteq \Omega$ be the convex hull of $x_{\mathrm{tr}}, x_1, \dots, x_k$; it is compact and convex. By item 4 of Lemma 40.33 the perfect forms v with $\mathrm{Nc}(v) \cap K \ne \emptyset$ form a finite set $\{u_1, \dots, u_q\}$ (u_l distinct), and by item 3, $q \ge 1$ and $K = \bigcup_l K_l$ with $K_l = \mathrm{Nc}(u_l) \cap K$. Each K_l is nonempty, compact and convex ($\mathrm{Nc}(u_l)$ is closed and convex). Let $\mathcal{K}$ be the nerve of $(K_1, \dots, K_q)$. By Theorem B.174, $\mathcal{K}$ is homotopy equivalent to the convex set K, hence contractible; so its augmented oriented chain complex is exact, and by Munkres' comparison so is its augmented ordered chain complex $C'(\mathcal{K})$.

Comparison map. For a basis element $(l_0, \dots, l_p)$ of $C'_p(\mathcal{K})$, a point of $K_{l_0} \cap \cdots \cap K_{l_p}$ lies in Ω and in every $\mathrm{Nc}(u_{l_j})$, so $(u_{l_0}, \dots, u_{l_p}) \in \mathcal{N}_p$. The resulting homomorphisms $\iota\colon C'_p(\mathcal{K}) \to \mathbb{Z}[\mathcal{N}_p]$ commute with the boundaries and the augmentations (both are alternating sums of omissions, resp. 1 on vertices), and are injective because $l \mapsto u_l$ is injective. Each $t^{(i)}$ is in the image of a basis element: its entries $t^{(i)}_j$ satisfy $x_i \in \mathrm{Nc}(t^{(i)}_j) \cap K$, so $t^{(i)}_j = u_{l_j}$ for some l_j, and $x_i \in K_{l_0} \cap \cdots \cap K_{l_p}$. Hence $c = \iota(c')$ for some $c' \in C'_p(\mathcal{K})$, and $\iota(\partial c') = d_p c = 0$ (resp. ι preserves the augmentation), so c' is a cycle of the augmented complex by injectivity. By exactness of $C'(\mathcal{K})$, $c' = \partial b'$ with $b' \in C'_{p+1}(\mathcal{K})$, and $c = \iota(\partial b') = d_{p+1}\iota(b')$. This proves exactness at $\mathbb{Z}[\mathcal{N}_0]$ and at every $\mathbb{Z}[\mathcal{N}_p]$, $p \ge 1$. □

Lemma 40.32. *Let L be a totally complex number field of degree n and $N \ge 1$.*

1. *For every $h \in \mathcal{R}_{L,N}$ and every complex place w, the matrix h_w is positive definite.*

2. *The tuple $(I_N)_w$ of identity matrices lies in $\mathcal{R}_{L,N}$, and the functional $x_{\mathrm{tr}}(k) = \sum_w \mathrm{tr}(k_w)$ lies in $\Omega_{L,N}$.*

3. *For every $h \in \mathcal{R}_{L,N}$ and every real B there are a neighbourhood U of h in $V_{L,N}$ and a finite set $Y_0 \subseteq \mathcal{O}_L^N$ such that $k[y] > B$ for all $k \in U$ and all $y \in \mathcal{O}_L^N \setminus Y_0$.*

4. *For every $h \in \mathcal{R}_{L,N}$,*

$$\prod_w \det h_w \;\geq\; c_0(L,N) := (nN)^{-nN/2}\,|d_L|^{-N/2}. \tag{40.21}$$

5. *Every $g \in \mathrm{GL}_N(\mathcal{O}_L)$ maps $\mathcal{R}_{L,N}$, $\mathrm{Perf}_{L,N}$, $V_{L,N}^{\geq 0}$ and $\Omega_{L,N}$ onto themselves, $\mathrm{Min}(g\cdot h) = g\,\mathrm{Min}(h)$ and $\mathrm{Nc}(g\cdot v) = g\cdot \mathrm{Nc}(v)$. Hence g maps $\mathcal{N}_p(L,N)$ onto itself for every $p \geq 0$, $\partial_i(g\cdot t) = g\cdot \partial_i t$, and the maps d_p and* aug *are $\mathrm{GL}_N(\mathcal{O}_L)$-equivariant.*

Proof. Item 1. Let $h \in \mathcal{R}_{L,N}$ and suppose that for some place w_0 the matrix h_{w_0} is not positive definite. Then it has a unit eigenvector $\xi \in \mathbb{C}^N$ with eigenvalue $\mu \leq 0$. Put $c = \max(\|h\|, 1)$ and fix $\eta \in (0,1)$ with $r_2 c\eta^2 < 1$. For $T > 0$ let K_T be the set of $z = (z_w)_w \in \prod_w \mathbb{C}^N$ with $|\xi^* z_{w_0}| < T$, $\|z_{w_0} - (\xi^* z_{w_0})\xi\| < \eta$ and $\|z_w\| < \eta$ for $w \neq w_0$. It is convex and centrally symmetric, and its volume is πT^2 times a positive number independent of T; choose T so large that it exceeds 2^{nN} times the covolume of $j(\mathcal{O}_L^N)$. By Minkowski's theorem there is $y \in \mathcal{O}_L^N \setminus \{0\}$ with $j(y) \in K_T$. Write $\sigma_{w_0}(y) = a\xi + u$ with $a = \xi^*\sigma_{w_0}(y)$ and $\xi^* u = 0$. Since $\xi^* h_{w_0} u = (h_{w_0}\xi)^* u = \mu\,\xi^* u = 0$,

$$\sigma_{w_0}(y)^* h_{w_0} \sigma_{w_0}(y) = \mu|a|^2 + u^* h_{w_0} u \leq c\eta^2,$$

and $\sigma_w(y)^* h_w \sigma_w(y) \leq c\eta^2$ for $w \neq w_0$. So $h[y] \leq r_2 c\eta^2 < 1$, contradicting $h \in \mathcal{R}_{L,N}$.

Item 2. Let $y \in \mathcal{O}_L^N \setminus \{0\}$ and $y_a \neq 0$ a coordinate. Then

$$(I_N)_w[y] = \sum_w \|\sigma_w(y)\|^2 \geq \sum_w |\sigma_w(y_a)|^2 \geq r_2\Big(\prod_w |\sigma_w(y_a)|^2\Big)^{1/r_2} = r_2\,|\mathrm{N}_{L/\mathbb{Q}}(y_a)|^{1/r_2} \geq 1.$$

If $k \in V_{L,N}^{\geq 0} \setminus \{0\}$, some k_w is a nonzero positive semidefinite matrix, so $\mathrm{tr}(k_w) > 0$ and $\mathrm{tr}(k_{w'}) \geq 0$ for all w'; hence $x_{\mathrm{tr}}(k) > 0$.

Item 3. By item 1 the least eigenvalue λ of the matrices h_w, over all w, is positive. Let $U = \{k : \|k - h\| < \lambda/2\}$. For $k \in U$ every $k_w - (\lambda/2)I_N$ is positive semidefinite, so $k[y] \geq (\lambda/2)\|j(y)\|^2$. The set $Y_0 = \{y \in \mathcal{O}_L^N : \|j(y)\|^2 \leq 2|B|/\lambda\}$ is finite because $j(\mathcal{O}_L^N)$ is a lattice, and $k[y] > B$ for $k \in U$, $y \notin Y_0$.

Item 4. By item 1 each h_w is positive definite. The set $K = \{z \in \prod_w \mathbb{C}^N : \sum_w z_w^* h_w z_w < 1\}$ is convex and centrally symmetric; the substitution $z_w = h_w^{-1/2} u_w$ maps the unit ball of $\mathbb{R}^{nN}$ onto it with Jacobian $\prod_w \det(h_w)^{-1}$, so $\mathrm{vol}(K) = \beta_{nN} \prod_w \det(h_w)^{-1}$, where β_D is the volume of the unit ball of $\mathbb{R}^D$. As $h[y] \geq 1$ for $y \neq 0$, K contains no nonzero point of $j(\mathcal{O}_L^N)$, and Minkowski's theorem gives $\mathrm{vol}(K) \leq 2^{nN}(2^{-r_2}|d_L|^{1/2})^N = 2^{nN/2}|d_L|^{N/2}$. The cube of half-side $D^{-1/2}$ lies in the unit ball, so $\beta_D \geq (2D^{-1/2})^D$, and

$$\prod_w \det h_w \geq \frac{\beta_{nN}}{2^{nN/2}|d_L|^{N/2}} \geq \frac{2^{nN}(nN)^{-nN/2}}{2^{nN/2}|d_L|^{N/2}} \geq (nN)^{-nN/2}|d_L|^{-N/2}.$$

Item 5. The map $h \mapsto g\cdot h$ is a linear bijection of $V_{L,N}$ with inverse $h \mapsto g^{-1}\cdot h$, and $y \mapsto g^{-1}y$ is a bijection of $\mathcal{O}_L^N \setminus \{0\}$. Hence $(g\cdot h)[y] = h[g^{-1}y]$ shows $g\cdot\mathcal{R}_{L,N} = \mathcal{R}_{L,N}$ and $\mathrm{Min}(g\cdot h) = g\,\mathrm{Min}(h)$. If v is perfect and $k[y] = 0$ for all $y \in \mathrm{Min}(g\cdot v) = g\,\mathrm{Min}(v)$, then

$(g^{-1}\cdot k)[y'] = k[gy'] = 0$ for all $y' \in \mathrm{Min}(v)$, so $g^{-1}\cdot k = 0$ and $k = 0$: $g\cdot v$ is perfect. Congruence by $\sigma_w(g^{-1})$ preserves positive semidefiniteness, so $g\cdot V_{L,N}^{\geq 0} = V_{L,N}^{\geq 0}$, and then $(g\cdot x)(k) = x(g^{-1}\cdot k)$ shows $g\cdot\Omega_{L,N} = \Omega_{L,N}$. Finally $(g\cdot x)(g\cdot v) = x(v)$ and $(g\cdot x)(g\cdot h) = x(h)$ with $g\cdot\mathcal{R}_{L,N} = \mathcal{R}_{L,N}$ give $\mathrm{Nc}(g\cdot v) = g\cdot\mathrm{Nc}(v)$. So if x is a witness of t, then $g\cdot x$ is a witness of $g\cdot t$; omission of an entry commutes with the entrywise action, and d_p, aug are therefore equivariant. □

Lemma 40.33. *Let L be a totally complex number field with r_2 complex places and $N \geq 1$.*

1. *For every compact $K \subseteq \Omega_{L,N}$ there is $c_K > 0$ with $x(k) \geq c_K\|k\|$ for all $x \in K$ and $k \in V_{L,N}^{\geq 0}$.*
2. *Every bounded subset of $V_{L,N}$ contains only finitely many perfect forms.*
3. *For every $x \in \Omega_{L,N}$ there is $v \in \mathrm{Perf}_{L,N}$ with $x \in \mathrm{Nc}(v)$; that is, the normal cones of the perfect forms cover $\Omega_{L,N}$.*
4. *For every compact $K \subseteq \Omega_{L,N}$ only finitely many $v \in \mathrm{Perf}_{L,N}$ satisfy $\mathrm{Nc}(v) \cap K \neq \emptyset$.*
5. *For every $p \geq 0$ and $t = (t_0, \ldots, t_p) \in \mathcal{N}_p(L,N)$, the set $\mathrm{Min}(t_0) \cap \cdots \cap \mathrm{Min}(t_p)$ spans L^N over L.*
6. *For every $v \in \mathrm{Perf}_{L,N}$ there are $y_1, \ldots, y_r \in \mathrm{Min}(v)$, $r = r_2N^2$, such that v is the only $k \in V_{L,N}$ with $k[y_i] = 1$ for $1 \leq i \leq r$.*

Proof. The set $\mathcal{R}$ is closed and convex, as an intersection of closed half-spaces, and $\mathcal{R} \subseteq V_{L,N}^{\geq 0}$ by item 1 of Lemma 40.32.

Step 0: a perturbation principle. Let $h \in \mathcal{R}$ and $k \in V_{L,N}$ with $k[y] \geq 0$ for all $y \in \mathrm{Min}(h)$. Then $\mathrm{Min}(h)$ is finite and $h + \eta k \in \mathcal{R}$ for all sufficiently small $\eta > 0$. Indeed, item 3 of Lemma 40.32 with $B = 1$ gives a neighbourhood U of h and a finite Y_0 with $k'[y] > 1$ for $k' \in U$, $y \notin Y_0$; so $\mathrm{Min}(h) \subseteq Y_0$. For small η: $h + \eta k \in U$, so $(h+\eta k)[y] > 1$ for $y \notin Y_0$; $(h+\eta k)[y] > 1$ for the finitely many $y \in Y_0 \setminus (\mathrm{Min}(h) \cup \{0\})$, where $h[y] > 1$; and $(h+\eta k)[y] = 1 + \eta k[y] \geq 1$ for $y \in \mathrm{Min}(h)$.

Item 1. The set $S = \{k \in V_{L,N}^{\geq 0} : \|k\| = 1\}$ is compact and $(x,k) \mapsto x(k)$ is continuous and positive on $K \times S$ by the definition of $\Omega_{L,N}$; let $c_K > 0$ be its minimum. Homogeneity in k gives the claim.

Item 2. Two perfect forms v, v' with $\mathrm{Min}(v) = \mathrm{Min}(v')$ are equal: $k = v - v'$ satisfies $k[y] = 0$ on $\mathrm{Min}(v)$. Suppose a bounded set contains infinitely many perfect forms. They accumulate at some h, which lies in $\mathcal{R}$ as $\mathcal{R}$ is closed. Take U, Y_0 for h as in Step 0. Every perfect form $v \in U$ has $\mathrm{Min}(v) \subseteq Y_0$, so U contains at most $2^{|Y_0|}$ perfect forms, contradicting the choice of h.

Item 3. Let $x \in \Omega_{L,N}$ and $h_0 = (I_N)_w \in \mathcal{R}$ (item 2 of Lemma 40.32). By item 1 with $K = \{x\}$, the closed set $\{h \in \mathcal{R} : x(h) \leq x(h_0)\}$ lies in the ball of radius $x(h_0)/c_{\{x\}}$, so it is compact and nonempty, and x attains on it its minimum μ over $\mathcal{R}$. The set $F = \{h \in \mathcal{R} : x(h) = \mu\}$ is nonempty, compact and convex; let v be an extreme point of F. If $v = \frac{1}{2}(a+b)$ with $a, b \in \mathcal{R}$, then $x(a), x(b) \geq \mu$ and their mean is μ, so $a, b \in F$ and $a = b = v$: v is an extreme point of $\mathcal{R}$. If v were not perfect, there would be $k \neq 0$ with $k[y] = 0$ on $\mathrm{Min}(v)$; Step 0 for k and $-k$ gives $v \pm \eta k \in \mathcal{R}$ for a small $\eta > 0$, and v would be their midpoint. So $v \in \mathrm{Perf}_{L,N}$, and $x(v) = \mu \leq x(h)$ for all $h \in \mathcal{R}$, i.e. $x \in \mathrm{Nc}(v)$.

Item 4. Let c_K be as in item 1 and $M = \max_{x \in K} x(h_0)$. If $x \in K \cap \mathrm{Nc}(v)$, then $c_K\|v\| \leq x(v) \leq x(h_0) \leq M$. So these v lie in a ball, and by item 2 there are finitely many.

Item 5. Let x be a witness of t. Then $x(t_j) \le x(h)$ for all $h \in \mathcal{R}$ and all j, so all $x(t_j)$ equal $\mu = \min_{\mathcal{R}} x$. The barycentre $h^* = \frac{1}{p+1}\sum_j t_j$ lies in $\mathcal{R}$, $x(h^*) = \mu$, and since every $t_j[y] \ge 1$ for $y \ne 0$, $h^*[y] = 1$ exactly when $t_j[y] = 1$ for all j: $\mathrm{Min}(h^*) = \bigcap_j \mathrm{Min}(t_j)$. Suppose this set does not span L^N. Then there is $0 \ne \varphi \in L^N$ with $\varphi^T y = 0$ for all $y \in \mathrm{Min}(h^*)$. Put $k_w = \overline{\sigma_w(\varphi)}\,\sigma_w(\varphi)^T$, a hermitian positive semidefinite matrix with $\zeta^* k_w \zeta = |\sigma_w(\varphi)^T\zeta|^2$; so $k = (k_w)_w \in V_{L,N}^{\ge 0} \setminus \{0\}$ and $k[y] = \sum_w |\sigma_w(\varphi^T y)|^2 = 0$ for $y \in \mathrm{Min}(h^*)$. By Step 0 for k and $-k$, $h^* \pm \eta k \in \mathcal{R}$ for a small $\eta > 0$, so $x(h^* \pm \eta k) \ge \mu = x(h^*)$ and $x(k) = 0$, contradicting $x \in \Omega_{L,N}$.

Item 6. The linear forms $k \mapsto k[y]$, $y \in \mathrm{Min}(v)$, on $V_{L,N}$ have common kernel $\{0\}$ since v is perfect, so they span $V_{L,N}^*$, of dimension $r = r_2N^2$; choose $y_1, \dots, y_r$ among them giving a basis. If $k[y_i] = 1 = v[y_i]$ for all i, then $(k - v)[y_i] = 0$ for a basis of $V_{L,N}^*$, so $k = v$. □

Lemma 40.34. *Let L be a totally complex number field of degree n, $N \ge 1$ and $p \ge 0$. For every $t \in \mathcal{N}_p(L,N)$ the stabiliser of t in $\mathrm{GL}_N(\mathcal{O}_L)$ is finite, of order at most 3^{nN^2}.*

Proof. Reduction to a perfect form. An element fixing $t = (t_0, \dots, t_p)$ fixes $v = t_0 \in \mathrm{Perf}_{L,N} \subseteq \mathcal{R}_{L,N}$, so it suffices to bound the stabiliser G_v of v.

G_v is finite. Let $c = \max_a v[e_a]$. Item 3 of Lemma 40.32 at $h = v$ with $B = c$ gives a finite set Y_0 containing every $y \in \mathcal{O}_L^N$ with $v[y] \le c$. If $g \in G_v$, then $g^{-1} \cdot v = v$ and $v[ge_a] = (g^{-1} \cdot v)[e_a] = v[e_a] \le c$, so every column ge_a of g lies in Y_0. Hence $g \mapsto (ge_1, \dots, ge_N)$ embeds G_v into Y_0^N.

Minkowski's reduction modulo 3. Let $R = \mathrm{M}_N(\mathcal{O}_L)$, a ring that is a free $\mathbb{Z}$-module of rank nN^2, so $|R/3R| = 3^{nN^2}$, and $\mathrm{GL}_N(\mathcal{O}_L) = R^\times$. Let $H \subseteq R^\times$ be a finite subgroup and $\rho\colon R \to R/3R$ the reduction, a ring homomorphism. We show that $\rho|_H$ is injective; then $|H| \le |(R/3R)^\times| < 3^{nN^2}$, and $H = G_v$ gives the claim. Suppose $1 \ne g \in H$ with $\rho(g) = 1$. Some power g' of g has prime order p', and $\rho(g') = 1$. As R is free of finite rank, $\bigcap_k 3^k R = 0$, so there are $k \ge 1$ and $X \in R \setminus 3R$ with $g' = 1 + 3^k X$. Then

$$0 = g'^{p'} - 1 = \sum_{i=1}^{p'} \binom{p'}{i} 3^{ik} X^i.$$

If $p' \ne 3$, the right side is $3^k(p'X + 3^k Y)$ with $Y \in R$; since R is torsion free, $p'X = -3^k Y \in 3R$, and as p' is invertible modulo 3, $X \in 3R$, a contradiction. If $p' = 3$, the right side is $3^{k+1}(X + 3^k X^2 + 3^{2k-1}X^3)$, so $X = -3^k X^2 - 3^{2k-1}X^3 \in 3R$ as $k \ge 1$, again a contradiction. □

Lemma 40.35. *Let L be a totally complex number field of degree n, $N \ge 1$, and*

$$R_0(L,N) = (nN)^{nN/2}\,|d_L|^{N/2}.$$

For every $p \ge 0$ the set of $\mathrm{GL}_N(\mathcal{O}_L)$-orbits in $\mathcal{N}_p(L,N)$ is finite, with at most

$$A_p(L,N) = R_0(L,N)^{(nN)^2+1}\left(2R_0(L,N)+1\right)^{nN\cdot r_2N^2\cdot(p+1)} \tag{40.22}$$

elements.

Proof. Step 1: algebraic integers with bounded conjugates. For real $R \ge 0$ the set $I_R = \{\alpha \in \mathcal{O}_L : |\sigma_w(\alpha)| \le R \text{ for all } w\}$ has at most $(2R+1)^n$ elements. For $\alpha \in I_R$ let $P(\alpha) \subseteq \mathbb{C}^{r_2}$ be the product of the open discs of radius $\frac{1}{2}$ about the $\sigma_w(\alpha)$. If $P(\alpha) \cap P(\beta) \ne \emptyset$ for $\alpha \ne \beta$, then $|\sigma_w(\alpha - \beta)| < 1$ for all w and $|\mathrm{N}(\alpha - \beta)| < 1$, impossible. So the $P(\alpha)$ are disjoint, of volume $(\pi/4)^{r_2}$, and lie in the product of the discs of radius $R + \frac{1}{2}$ about 0, of volume $(\pi(R+\frac{1}{2})^2)^{r_2}$. Hence $|I_R| \le (2R+1)^{2r_2} = (2R+1)^n$.

Step 2: matrices of minimal vectors. Let $A \in \mathrm{M}_N(\mathcal{O}_L)$ with $\det A \neq 0$, $\delta_A = |\mathrm{N}(\det A)| \geq 1$ and $B = \delta_A A^{-1}$. Then $B = \pm(\mathrm{N}(\det A)/\det A)\,\mathrm{adj}(A) \in \mathrm{M}_N(\mathcal{O}_L)$. Suppose moreover that $h \in \mathcal{R}_{L,N}$ satisfies $h[Ae_a] = 1$ for all a. We show: $\delta_A \leq R_0$, and every coordinate of By lies in I_{R_0} for every $y \in \mathcal{O}_L^N$ with $h[y] = 1$. Let $G_w = \sigma_w(A)^* h_w \sigma_w(A)$, positive definite by item 1 of Lemma 40.32. Its diagonal entries $\sigma_w(Ae_a)^* h_w \sigma_w(Ae_a)$ are at most $h[Ae_a] = 1$, all terms of the sum defining $h[y]$ in (Vn1) being non-negative; so $\det G_w \leq 1$ and every principal minor of G_w is at most 1 (Hadamard). By item 4 of Lemma 40.32,

$$\prod_w \det G_w = \prod_w |\sigma_w(\det A)|^2 \prod_w \det h_w = \delta_A \prod_w \det h_w \geq \delta_A c_0.$$

Hence $\delta_A \leq c_0^{-1} = R_0$, and $\det G_w \geq \prod_{w'} \det G_{w'} \geq \delta_A c_0$ for each w. Now let $h[y] = 1$, $z = A^{-1}y$ and $\zeta = \sigma_w(z)$. Then $\zeta^* G_w \zeta = \sigma_w(y)^* h_w \sigma_w(y) \leq h[y] = 1$. By the Cauchy–Schwarz inequality for $\langle u, u' \rangle = u^* G_w u'$ and $\zeta_a = \langle G_w^{-1} e_a, \zeta \rangle$,

$$|\zeta_a|^2 \leq (e_a^* G_w^{-1} e_a)(\zeta^* G_w \zeta) \leq \frac{\det G_w^{(a)}}{\det G_w} \leq \frac{1}{\delta_A c_0},$$

where $G_w^{(a)}$ is the principal submatrix without row and column a. Since $By = \delta_A z$, $|\sigma_w((By)_a)|^2 \leq \delta_A / c_0 \leq c_0^{-2}$, i.e. $|\sigma_w((By)_a)| \leq R_0$, and $(By)_a \in \mathcal{O}_L$ as B is integral.

Step 3: perfect forms with prescribed minimal vectors. For A with $\det A \neq 0$ let $\mathrm{Perf}(A)$ be the set of perfect forms v with $v[Ae_a] = 1$ for all a, and $Y(A)$ the set of $y \in \mathcal{O}_L^N$ such that $h[y] = 1$ for some $h \in \mathcal{R}_{L,N}$ with $h[Ae_a] = 1$ for all a. By Step 2 the injective map $y \mapsto By$ sends $Y(A)$ into $I_{R_0}^N$, so $|Y(A)| \leq (2R_0 + 1)^{nN}$ by Step 1. For $v \in \mathrm{Perf}(A)$, $\mathrm{Min}(v) \subseteq Y(A)$; choosing $y_1, \ldots, y_r \in \mathrm{Min}(v)$ as in item 6 of Lemma 40.33 defines an injective map $\mathrm{Perf}(A) \to Y(A)^r$, since v is the only form with $k[y_i] = 1$ for all i. So $|\mathrm{Perf}(A)| \leq (2R_0 + 1)^{nNr}$.

Step 4: orbits of matrices. Let $\mathcal{A}$ be the set of $A \in \mathrm{M}_N(\mathcal{O}_L)$ with $\det A \neq 0$ and $\delta_A \leq R_0$; $\mathrm{GL}_N(\mathcal{O}_L)$ acts on it by left multiplication. Put $M_A = A^{-1}\mathcal{O}_L^N \subseteq L^N$. Then $M_{gA} = M_A$; and if $M_A = M_{A'}$, then $g = A'A^{-1}$ satisfies $g\mathcal{O}_L^N = A' M_{A'} = \mathcal{O}_L^N$, so g and g^{-1} have entries in $\mathcal{O}_L$ (they map each e_a into $\mathcal{O}_L^N$), $g \in \mathrm{GL}_N(\mathcal{O}_L)$ and $A' = gA$. Thus $A \mapsto M_A$ is injective on orbits. As $A\mathcal{O}_L^N \subseteq \mathcal{O}_L^N$ and $\delta_A M_A = B\mathcal{O}_L^N \subseteq \mathcal{O}_L^N$, we have $\mathcal{O}_L^N \subseteq M_A \subseteq \delta_A^{-1}\mathcal{O}_L^N$, so M_A is determined by δ_A and the subgroup $M_A/\mathcal{O}_L^N$ of $\delta_A^{-1}\mathcal{O}_L^N/\mathcal{O}_L^N \cong (\mathbb{Z}/\delta_A\mathbb{Z})^{nN}$. That group has at most $(\delta_A^{nN})^{nN}$ subgroups, each being generated by nN elements. Summing over $1 \leq \delta \leq R_0$, the number of orbits on $\mathcal{A}$ is at most $R_0 \cdot R_0^{(nN)^2}$.

Step 5: orbits of simplices. Fix a set S of representatives of the orbits on $\mathcal{A}$. Let $t \in \mathcal{N}_p(L, N)$. By item 5 of Lemma 40.33, $\bigcap_j \mathrm{Min}(t_j)$ contains an L-basis $y_1, \ldots, y_N$ of L^N; let A be the matrix with columns y_a. Then $\det A \neq 0$, and Step 2 with $h = t_0$ gives $\delta_A \leq R_0$, so $A \in \mathcal{A}$ and $gA \in S$ for some $g \in \mathrm{GL}_N(\mathcal{O}_L)$. By item 5 of Lemma 40.32, $g \cdot t \in \mathcal{N}_p(L, N)$ lies in the orbit of t, and each entry $g \cdot t_j$ is perfect with $(g \cdot t_j)[gAe_a] = t_j[Ae_a] = 1$: $g \cdot t \in \mathrm{Perf}(gA)^{p+1}$. Choosing one such element in each orbit gives an injective map from the set of orbits into $\bigcup_{A' \in S} \mathrm{Perf}(A')^{p+1}$, whose cardinality is at most $R_0^{(nN)^2+1}(2R_0 + 1)^{nNr(p+1)} = A_p(L, N)$ by Steps 3 and 4. □

Part VIII
Eisenstein congruences: the one-character bounds

Part VIII proves the three one-character bounds. For one character χ, one twist e and one prime ℓ, each bounds the normalised length of the strict Tate–Shafarevich group $\mathrm{Sha}^1_{\ell N}(\chi, e)$ by twice the sum of the ℓ-adic valuations of the differences between an Eisenstein trace and the Frobenius traces of finitely many admissible automorphic Galois representations. They are Proposition 42.2, on the unitary group in three variables attached to an imaginary quadratic field, for case (I); Proposition 44.3, on GSp_4, for cases (II) and (III); and Proposition 46.2, on the unitary group attached to $\mathbb{Q}(i)$, for case (V). Section 38 uses them in Proposition 38.5, Proposition 38.26 and Proposition 38.32. In return Part VIII takes from Part IX the three automorphy theorems 47.1, Theorem 51.1 and Theorem 47.16, and from Part VII the finiteness of the Tate–Shafarevich groups of Tate twists (Proposition 40.3).

The method is Ribet's [208], in the language of deformation rings. The Eisenstein representation, $\Psi \oplus \mathbf{1} \oplus \Psi^{-1}$ on G_K with $\Psi = \chi\chi_{\mathrm{cyc}}^{e}$ in the unitary case, is fixed by a torus $\mathrm{T}(t) = \mathrm{diag}(t, 1, t^{-1})$, and the torus grades its deformation ring by the weights of the matrix entries. A class in the Tate–Shafarevich group is a first-order deformation in weight -1, so the group embeds into the derivations of degree -1 of a graded model of the ring (clause (Mo7) of Proposition 43.3). An Euler-characteristic count gives the model one more equation than tangent directions in degree -1, and the graded numerical criterion Lemma 41.2 turns this excess into a bound: the cotangent length in degree -1 is at most twice the valuations of a weight-zero function at the two-signed points, the points that are neither upper nor lower triangular. The function is a trace difference, and Part IX shows that the two-signed points are automorphic, which identifies its valuations with Eisenstein congruences.

Section 41 proves the criterion, which is commutative algebra. Sections 42 and 43 prove the unitary bound and construct its graded model; Sections 44 and 45 do the same on GSp_4; Section 46 treats the dyadic case, bound and model together.

41 The graded numerical criterion

This section proves the graded numerical criterion, Lemma 41.2, on which the three one-character bounds rest (Proposition 42.2, Proposition 44.3, Proposition 46.2). It is commutative algebra and uses no Galois representations. The data are a $\mathbb{Z}$-graded $\mathcal{O}$-algebra A with a fixed point φ_0, smooth with given tangent dimensions in degrees $-2, \dots, 2$, a system u of homogeneous equations and a function a of weight zero (Definition 41.1). The conditions (Gc1)–(Gc5) ask that u have one more equation than tangent directions in degree -1, one fewer in degrees 1 and 2, and as many in degrees -2 and 0; that the weight-zero part of $A/I(u)$ be finite over $\mathcal{O}$; that no point other than φ_0 lie, in weight zero, under both a point that vanishes in all negative degrees but not in all positive ones and a point with the roles of the signs exchanged; that the tangent spaces at the two-signed points be at most one-dimensional; and that a vanish at φ_0 and at no two-signed point. The conclusion bounds the cotangent length of u in degree -1 by twice the sum of the valuations of a over a set of representatives of the two-signed points up to the torus. In the applications A is a graded model of an Eisenstein deformation ring, the cotangent length bounds the Tate–Shafarevich group, and a is a trace difference.

The proof is an intersection count on the Rees algebra of the equations. After a reduction to

an injective chart in weights -1, 1, 2 with equations in Smith form (Lemma 41.4, Lemma 41.7), a Koszul Euler characteristic of the equations and of a is computed in large degree in two ways. At the fixed point it is bounded below by the cotangent length (Proposition 41.13); at the two-signed points it is bounded above by Herbrand quotients of a, where the weight pieces have local length at most one (Proposition 41.21, Proposition 41.23). These two bounds carry the argument; the lemmas on Koszul complexes over standard multigraded algebras and on Rees algebras between them are standard commutative algebra.

Definition 41.1. Let $\mathcal{O}$ be a coefficient ring with fraction field $\mathcal{O}[\ell^{-1}]$, and put $v_{\mathcal{O}} = e_{\mathcal{O}}\, v_\ell$ on $\overline{\mathbb{Q}}_\ell$, so that $v_{\mathcal{O}}$ is 1 on a uniformiser of $\mathcal{O}$. All algebras are commutative.

Graded algebras with a fixed point. A **graded $\mathcal{O}$-algebra with a fixed point** is a pair (A, φ_0) of a $\mathbb{Z}$-graded $\mathcal{O}$-algebra $A = \bigoplus_{j\in\mathbb{Z}} A_j$ (so $A_i A_j \subseteq A_{i+j}$ and $\mathcal{O} \to A_0$) and an $\mathcal{O}$-algebra homomorphism $\varphi_0 \colon A \to \mathcal{O}$ such that

- A_0 is a complete Noetherian local ring, and $\mathcal{O} \to A_0$ is a local homomorphism inducing an isomorphism of residue fields;
- A is generated as an $\mathcal{O}$-algebra by A_0 and finitely many homogeneous elements of degrees in $\{-2, -1, 1, 2\}$;
- $\varphi_0(A_j) = 0$ for every $j \neq 0$.

Cotangent lengths. Put $\mathfrak{m}_0 = \ker \varphi_0$ and let $\mathrm{Sq}(\varphi_0) = \{f \in A : \ cf \in \mathfrak{m}_0^2 \text{ for some } c \in \mathcal{O} \setminus \{0\}\}$, an $\mathcal{O}$-submodule of A. For $j \in \mathbb{Z}$ the **cotangent lattice in degree j** is the image Cot_j of $A_j \cap \mathfrak{m}_0$ in $A/\mathrm{Sq}(\varphi_0)$. For a finite family $u = (u_i)_{i\in I}$ of elements of A, $\mathrm{Cot}(u)$ is the $\mathcal{O}$-span of the images of the u_i in $A/\mathrm{Sq}(\varphi_0)$. The family u **spans rationally in degree j** if for every $p \in \mathrm{Cot}_j$ there is $c \in \mathcal{O} \setminus \{0\}$ with $cp \in \mathrm{Cot}(u)$, and its **cotangent length in degree j** is

$$\mathrm{ct}_j(u) = \mathrm{length}_{\mathcal{O}}\big(\mathrm{Cot}_j / (\mathrm{Cot}_j \cap \mathrm{Cot}(u))\big) \in \mathbb{N} \cup \{\infty\} \tag{41.1}$$

(the dependence on (A, φ_0) is not written).

Charts. For a finite set J with a map $\mathrm{wt} \colon J \to \mathbb{Z}$, a power series in $\mathcal{O}[\ell^{-1}][[X_i : i \in J]]$ has **weight j** if every monomial $\prod_i X_i^{n_i}$ occurring in it has $\sum_i n_i \mathrm{wt}(i) = j$. For a function $\mathrm{td} \colon \mathbb{Z} \to \mathbb{N}$ with finite support, (A, φ_0) is **smooth with tangent dimensions** td if there are such (J, wt) with $\#\mathrm{wt}^{-1}(j) = \mathrm{td}(j)$ for every j, and an $\mathcal{O}$-algebra homomorphism $\phi \colon A \to \mathcal{O}[\ell^{-1}][[X_i : i \in J]]$ (a **chart**) such that

(Sm1) $\phi(f)$ has weight j for every $f \in A_j$;

(Sm2) the constant term of $\phi(f)$ is $\varphi_0(f)$ for every $f \in A$;

(Sm3) for every $i \in J$ there is $f \in A$ such that in $\phi(f)$ the coefficient of X_i is non-zero and the coefficient of $X_{i'}$ is zero for every $i' \neq i$;

(Sm4) if $\varphi_0(f) = 0$ and all coefficients of degree one of $\phi(f)$ vanish, then $f \in \mathrm{Sq}(\varphi_0)$.

Equations and points. A **system of equations** for (A, φ_0) with counts ne, where $\mathrm{ne} \colon \{-2, -1, 0, 1, 2\} \to \mathbb{N}$, is a family $u = (u_{j,i})$, $-2 \le j \le 2$, $1 \le i \le \mathrm{ne}(j)$, with $u_{j,i} \in A_j$ and $\varphi_0(u_{0,i}) = 0$; $u_j = (u_{j,i})_i$ is its **part in degree j**, and $I(u)$ is the ideal of A generated by all $u_{j,i}$. A **point** is an $\mathcal{O}$-algebra homomorphism $\varphi \colon A \to \overline{\mathbb{Q}}_\ell$; it lies **on** u if $\varphi(I(u)) = 0$. The fixed point φ_0 is a point through $\mathcal{O} \subset \overline{\mathbb{Q}}_\ell$. For $t \in \overline{\mathbb{Q}}_\ell^{\times}$ the **torus translate** $t \cdot \varphi$ is the point with $(t \cdot \varphi)(f) = t^j \varphi(f)$ for $f \in A_j$; it lies on u if and only if φ does, since $I(u)$ is generated by homogeneous elements. A point φ is **negative-vanishing** if $\varphi(A_j) = 0$ for all $j < 0$,

positive-vanishing if $\varphi(A_j) = 0$ for all $j > 0$, and **two-signed** if it is neither. An **orbit cover** of u is a finite set Σ of two-signed points on u such that every two-signed point on u is a torus translate of a member of Σ. For a point φ, a **φ-derivation** is an $\mathcal{O}$-linear map $D\colon A \to \overline{\mathbb{Q}}_\ell$ with $D(fg) = \varphi(f)D(g) + \varphi(g)D(f)$ for all f, g.

The conditions of the graded numerical criterion. Let (A, φ_0) be a graded $\mathcal{O}$-algebra with a fixed point, u a system of equations with counts ne, and $a \in A$. The tuple (A, φ_0, u, a) satisfies the **conditions of the graded numerical criterion** if

(Gc1) there is td with $\mathrm{td}(j) = 0$ for $|j| > 2$ such that (A, φ_0) is smooth with tangent dimensions td and

$$\mathrm{ne}(-1) = \mathrm{td}(-1) + 1, \quad \mathrm{ne}(-2) = \mathrm{td}(-2), \quad \mathrm{ne}(0) = \mathrm{td}(0),$$
$$\mathrm{ne}(1) = \mathrm{td}(1) - 1, \quad \mathrm{ne}(2) = \mathrm{td}(2) - 1;$$

and u_{-1}, u_{-2}, u_0 span rationally in degrees -1, -2, 0 respectively;

(Gc2) the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module;

(Gc3) for every point $\varphi_1 \neq \varphi_0$ on u that is both negative-vanishing and positive-vanishing, either no point on u that is negative-vanishing but not positive-vanishing agrees with φ_1 on A_0, or no point on u that is positive-vanishing but not negative-vanishing agrees with φ_1 on A_0;

(Gc4) for every two-signed point φ on u, any two φ-derivations that vanish on $I(u)$ are linearly dependent over $\overline{\mathbb{Q}}_\ell$;

(Gc5) $a \in A_0$, $\varphi_0(a) = 0$, and $\varphi(a) \neq 0$ for every two-signed point φ on u.

Lemma 41.2. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point, u a system of equations for (A, φ_0) and $a \in A$, such that (A, φ_0, u, a) satisfies (Gc1)–(Gc5). Then u has an orbit cover, the cotangent length $\mathrm{ct}_{-1}(u_{-1})$ is finite, and for every orbit cover Σ of u,*

$$\mathrm{ct}_{-1}(u_{-1}) \leq 2 \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a)).$$

Proof. Let td be as in (Gc1), $n_j = \mathrm{td}(j)$ for $j \in \{-1, 1, 2\}$, $K_0 = \mathcal{O}[\ell^{-1}]$ and ϖ a uniformiser of $\mathcal{O}$. Since $\mathrm{ne}(1) = \mathrm{td}(1) - 1$ and $\mathrm{ne}(2) = \mathrm{td}(2) - 1$ are natural numbers, $n_1, n_2 \geq 1$.

Step 1: orbit covers exist. By (Gc2) and Lemma 41.3, item 4, u has an orbit cover. For every orbit cover Σ and $\varphi \in \Sigma$, $\varphi(a) \neq 0$ by (Gc5), so $v_{\mathcal{O}}(\varphi(a))$ is defined, and it is ≥ 0 by Lemma 41.3, item 1, as $a \in A_0$.

The case $n_{-1} = 0$. Let ϕ be a chart with tangent dimensions td; no variable has weight -1. For $f \in A_{-1}$, $\phi(f)$ has weight -1 by (Sm1), so its coefficients of degree one, which are coefficients of variables of weight -1, vanish; and $\varphi_0(f) = 0$. By (Sm4), $f \in \mathrm{Sq}(\varphi_0)$. Hence $\mathrm{Cot}_{-1} = 0$, $\mathrm{ct}_{-1}(u_{-1}) = 0$, and the inequality holds for every orbit cover by Step 1. From now on $n_{-1} \geq 1$.

Step 2: reduction. Let J' be a finite set with $\mathrm{wt}'\colon J' \to \{-1, 1, 2\}$ and $\#\mathrm{wt}'^{-1}(j) = \mathrm{td}(j)$, and $P' = K_0[[X_i : i \in J']]$. By Lemma 41.4 there are $A' \subseteq P'$ and a surjection $\pi\colon A \to A'$ with (Rc1)–(Rc3); let φ_0' and u' be as there. For $g \in P'$ write $g^{(1)}$ for its linear part. For $b \in A_0'$ and $g \in A_{-1}'$, $(bg)^{(1)} = \varphi_0'(b)g^{(1)}$, since g has zero constant term; and an element of $\mathrm{Sq}(\varphi_0')$ has zero linear part (if $cg \in \mathfrak{m}_0'^2$, $\mathfrak{m}_0' = \ker \varphi_0'$, then $cg^{(1)} = 0$, as the linear part of a product of two series

without constant term is 0). By (Sm4) for the inclusion, the map sending the class of g to $g^{(1)}$ is therefore an isomorphism of Cot'_{-1} (the cotangent lattice of (A', φ'_0) in degree -1) onto

$$\mathrm{Lp}_{-1} = \{g^{(1)} : g \in A'_{-1}\},$$

and it maps $\mathrm{Cot}(u'_{-1})$ onto the $\mathcal{O}$-span $\mathrm{Lp}(u'_{-1})$ of the $u'^{(1)}_{-1,k}$, $1 \le k \le n_{-1}+1$; as $u'_{-1,k} \in A'_{-1}$, $\mathrm{Cot}'_{-1} \cap \mathrm{Cot}(u'_{-1}) = \mathrm{Cot}(u'_{-1})$. By (Rc2), $\mathrm{ct}_{-1}(u_{-1}) = \mathrm{length}_{\mathcal{O}}(\mathrm{Lp}_{-1}/\mathrm{Lp}(u'_{-1}))$.

Step 3: Lp_{-1} and $\mathrm{Lp}(u'_{-1})$ are free of rank n_{-1}. By (Rc1), A' is generated as an $\mathcal{O}$-algebra by A'_0 and finitely many homogeneous elements $s_1, \dots, s_q$ of non-zero degrees $d_1, \dots, d_q$; so A'_{-1} is spanned over A'_0 by the monomials $s^n = \prod_k s_k^{n_k}$ with $n \in \mathcal{E}_{-1} = \{n \in \mathbb{N}^q : \sum_k n_k d_k = -1\}$. By Dickson's lemma, $\mathcal{E}_{-1}$ has finitely many minimal elements for the componentwise order; for $n \in \mathcal{E}_{-1}$ choose a minimal $n' \le n$; then $\sum_k (n_k - n'_k)d_k = 0$, so $s^n = s^{n'}s^{n-n'} \in s^{n'}A'_0$. Hence A'_{-1} is a finitely generated A'_0-module, and by the product rule Lp_{-1} is the $\mathcal{O}$-span of the linear parts of finitely many generators: a finitely generated $\mathcal{O}$-submodule of the K_0-span V of $\{X_i : \mathrm{wt}'(i) = -1\}$, which has dimension n_{-1}. Being torsion free, Lp_{-1} is free. For i with $\mathrm{wt}'(i) = -1$, (Sm3) gives $f \in A'$ with $f^{(1)} = cX_i$, $c \ne 0$, and the weight -1 part $f_{-1} \in A'_{-1}$ of f has $f^{(1)}_{-1} = cX_i$ (linear terms of weight -1 come from the weight -1 part); so Lp_{-1} spans V and has rank n_{-1}. By (Rc2), u'_{-1} spans rationally in degree -1, so for every $\mathbf{v} \in \mathrm{Lp}_{-1}$ some $c\mathbf{v}$, $c \ne 0$, lies in $\mathrm{Lp}(u'_{-1})$; thus $\mathrm{Lp}(u'_{-1})$ has rank n_{-1} as well.

Step 4: Smith form; finiteness of ct_{-1}. By the elementary divisor theorem over the principal ideal domain $\mathcal{O}$ there are a basis $\mathbf{v}_1, \dots, \mathbf{v}_{n_{-1}}$ of Lp_{-1} and integers $c_1, \dots, c_{n_{-1}} \ge 0$ such that $\varpi^{c_1}\mathbf{v}_1, \dots, \varpi^{c_{n_{-1}}}\mathbf{v}_{n_{-1}}$ is a basis of $\mathrm{Lp}(u'_{-1})$. Then $\mathrm{Lp}_{-1}/\mathrm{Lp}(u'_{-1}) \cong \bigoplus_i \mathcal{O}/\varpi^{c_i}\mathcal{O}$, so

$$\mathrm{ct}_{-1}(u_{-1}) = \sum_{i=1}^{n_{-1}} c_i < \infty.$$

The $\mathcal{O}$-linear map $\mathrm{ev}\colon \mathcal{O}^{n_{-1}+1} \to \mathrm{Lp}(u'_{-1})$, $\mathbf{e}_k \mapsto u'^{(1)}_{-1,k}$ (standard basis $\mathbf{e}_k$), is onto. Choose $w_i \in \mathcal{O}^{n_{-1}+1}$ with $\mathrm{ev}(w_i) = \varpi^{c_i}\mathbf{v}_i$ ($1 \le i \le n_{-1}$); the w_i span a submodule mapped isomorphically onto $\mathrm{Lp}(u'_{-1})$, so $\mathcal{O}^{n_{-1}+1} = \bigoplus_{i \le n_{-1}} \mathcal{O}w_i \oplus \ker \mathrm{ev}$, and $\ker \mathrm{ev}$ is free of rank 1; let $w_{n_{-1}+1}$ be a generator. Then $w_1, \dots, w_{n_{-1}+1}$ is a basis of $\mathcal{O}^{n_{-1}+1}$. Put $\tilde{u}_{-1,i} = \sum_k (w_i)_k u'_{-1,k} \in A'_{-1}$, and let $\tilde{u}$ be u' with u'_{-1} replaced by $\tilde{u}_{-1}$. The $\mathcal{O}$-spans of $\tilde{u}_{-1}$ and u'_{-1} agree, the matrix with columns w_i being invertible; hence $I(\tilde{u}) = I(u')$, $\mathrm{Cot}(\tilde{u}_{-1}) = \mathrm{Cot}(u'_{-1})$, $\tilde{u}_{-1}$ spans rationally in degree -1, and u' and $\tilde{u}$ have the same points, two-signed points and orbit covers; so $(A', \varphi'_0, \tilde{u}, \pi(a))$ satisfies (Gc2)–(Gc5) by (Rc2). Choose $y_i \in A'_{-1}$ with $y_i^{(1)} = \mathbf{v}_i$. Then $\tilde{u}_{-1,i} - \varpi^{c_i} y_i$ ($i \le n_{-1}$) and $\tilde{u}_{-1,n_{-1}+1}$ have zero linear part, as $\tilde{u}^{(1)}_{-1,i} = \mathrm{ev}(w_i)$, and zero constant term (degree -1); by (Sm4) they lie in $\mathrm{Sq}(\varphi'_0)$.

Step 5: the weight-zero element. If $\pi(a) \ne 0$, put $a' = \pi(a)$. If $\pi(a) = 0$, then by (Gc5) for $(A', \varphi'_0, u', \pi(a))$ there is no two-signed point on u'. In that case choose i_0 with $\mathrm{wt}'(i_0) = 1$ and, by (Sm3), $f \in A'$ with $f^{(1)} = cX_{i_0}$, $c \ne 0$; its weight-one part $g \in A'_1$ is non-zero. Also $\tilde{u}_{-1,1} \ne 0$, its linear part being $\varpi^{c_1}\mathbf{v}_1 \ne 0$. Put $a' = \tilde{u}_{-1,1}g \in A'_0$; it is non-zero ($P'$ is a domain), $\varphi'_0(a') = 0$, and (Gc5) holds for a' because there are no two-signed points on $\tilde{u}$. In both cases $a' \ne 0$, $(A', \varphi'_0, \tilde{u}, a')$ satisfies (Gc2)–(Gc5), and $\varphi'(a') = \varphi'(\pi(a))$ for every two-signed point φ' on $\tilde{u}$ (there are none in the second case).

Step 6: the count. The data $(A' \subseteq P', \tilde{u}, a', y, c)$ satisfy the hypotheses of Lemma 41.7: $A' = \bigoplus_j A'_j$ is a graded $\mathcal{O}$-algebra with a fixed point and the inclusion satisfies (Sm1)–(Sm4) by (Rc1); $\#\mathrm{wt}'^{-1}(j) = n_j \ge 1$ for $j \in \{-1, 1, 2\}$; the counts of $\tilde{u}$ are $n_{-1}+1$, $n_1 - 1$, $n_2 - 1$ in degrees -1, 1, 2 and 0 in degrees -2, 0; $\tilde{u}_{-1}$ spans rationally in degree -1; and Steps 4 and 5 give the rest. Let Σ be an orbit cover of u. By (Rc3), $\Sigma' = \{\varphi' : \varphi' \circ \pi \in \Sigma\}$ is an orbit cover of

u', hence of $\tilde{u}$. By Steps 4 and 5 above, Lemma 41.7 and (Rc3),

$$\mathrm{ct}_{-1}(u_{-1}) = \sum_{i=1}^{n_{-1}} c_i \le 2 \sum_{\varphi' \in \Sigma'} v_{\mathcal{O}}(\varphi'(a')) = 2 \sum_{\varphi' \in \Sigma'} v_{\mathcal{O}}(\varphi'(\pi(a))) \le 2 \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a)).$$

With Steps 1 and 4 this proves the three assertions. □

Lemma 41.3. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point and u a system of equations for (A, φ_0) such that the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module (condition (Gc2)). Then:*

1. *for every point φ on u and every $b \in A_0$, $\varphi(b)$ is integral over $\mathcal{O}$; in particular $v_{\mathcal{O}}(\varphi(b)) \ge 0$ if $\varphi(b) \neq 0$;*
2. *the set of restrictions $\varphi|_{A_0}$ of the points φ on u is finite;*
3. *if φ, φ' are two-signed points with $\varphi|_{A_0} = \varphi'|_{A_0}$, then $\varphi' = t \cdot \varphi$ for some $t \in \overline{\mathbb{Q}}_\ell^\times$;*
4. *u has an orbit cover.*

Proof. Let B be the image of A_0 in $A/I(u)$, and write $\bar{b} \in B$ for the image of $b \in A_0$. A point φ on u vanishes on $I(u)$, so it induces an $\mathcal{O}$-algebra homomorphism $\bar{\varphi}\colon B \to \overline{\mathbb{Q}}_\ell$ with $\varphi(b) = \bar{\varphi}(\bar{b})$ for $b \in A_0$. By hypothesis B is a finitely generated $\mathcal{O}$-module.

Item 1. Let $b \in A_0$ and let $g_1, \dots, g_n$ generate B as an $\mathcal{O}$-module. Write $\bar{b} g_k = \sum_l o_{kl} g_l$ with $o_{kl} \in \mathcal{O}$; with the matrix $\mathbf{M} = (o_{kl})$, the determinant trick (multiply the system $\sum_l (\bar{b}\delta_{kl} - o_{kl}) g_l = 0$ by the adjugate of $\bar{b} \cdot 1 - \mathbf{M}$) gives $\det(\bar{b} \cdot 1 - \mathbf{M}) g_l = 0$ for all l, hence $\det(\bar{b} \cdot 1 - \mathbf{M}) = 0$ in B, since $1 \in B$ is an $\mathcal{O}$-combination of the g_l. So $\bar{b}$ is a root of the monic polynomial $\det(T \cdot 1 - \mathbf{M}) \in \mathcal{O}[T]$, and so is $\varphi(b) = \bar{\varphi}(\bar{b})$. If $z = \varphi(b) \neq 0$ satisfied $v_{\mathcal{O}}(z) < 0$, then in $z^n + o'_{n-1} z^{n-1} + \cdots + o'_0 = 0$ ($o'_k \in \mathcal{O}$) the term z^n would have valuation $n v_{\mathcal{O}}(z)$, strictly smaller than that of every other non-zero term, which is impossible for a vanishing sum. Hence $v_{\mathcal{O}}(\varphi(b)) \ge 0$.

Item 2. The fraction field of $\mathcal{O}$ is $\mathcal{O}[\ell^{-1}]$, and $B[\ell^{-1}] = B \otimes_{\mathcal{O}} \mathcal{O}[\ell^{-1}]$ is a commutative $\mathcal{O}[\ell^{-1}]$-algebra of dimension at most n. If $c \in \mathcal{O} \setminus \{0\}$ and $cg = 0$ for some $g \in B$, then $c\bar{\varphi}(g) = 0$, so $\bar{\varphi}(g) = 0$; hence $\bar{\varphi}$ is the composite of $B \to B[\ell^{-1}]$ with the $\mathcal{O}[\ell^{-1}]$-linear extension $\bar{\varphi}'\colon B[\ell^{-1}] \to \overline{\mathbb{Q}}_\ell$, an algebra homomorphism, and $\bar{\varphi}$ is determined by $\bar{\varphi}'$. Distinct algebra homomorphisms $B[\ell^{-1}] \to \overline{\mathbb{Q}}_\ell$ are distinct multiplicative maps sending 1 to 1, hence linearly independent over $\overline{\mathbb{Q}}_\ell$ (Dedekind's argument: in a shortest non-trivial relation $\sum_k c_k \vartheta_k = 0$, choose g with $\vartheta_1(g) \neq \vartheta_2(g)$ and subtract $\vartheta_1(g)$ times the relation from the relation evaluated at gg', g' variable, to get a shorter one); they lie in $\mathrm{Hom}_{\mathcal{O}[\ell^{-1}]}(B[\ell^{-1}], \overline{\mathbb{Q}}_\ell)$, a $\overline{\mathbb{Q}}_\ell$-vector space of dimension at most n. So there are at most n of them, and the restrictions $\varphi|_{A_0}$ of the points on u, which are determined by $\bar{\varphi}$, form a set with at most n elements.

Item 3. For a point φ put $S_\varphi = \{m \in \mathbb{Z} : \varphi(A_m) \neq 0\}$. Let φ be two-signed. Then $0 \in S_\varphi$ ($\varphi(1) = 1$), and S_φ is closed under addition: if $f \in A_m$, $g \in A_{m'}$ with $\varphi(f)\varphi(g) \neq 0$, then $fg \in A_{m+m'}$ and $\varphi(fg) \neq 0$. Since φ is neither negative- nor positive-vanishing, S_φ contains some $m_- < 0$ and some $m_+ > 0$. For $m \in S_\varphi$ with $m > 0$,

$$-m = (-m_- - 1)\, m + m\, m_-$$

is a sum of $-m_- - 1 \ge 0$ copies of m and $m \ge 1$ copies of m_-, so $-m \in S_\varphi$; symmetrically, using m_+, $-m \in S_\varphi$ for $m < 0$. Hence S_φ is a subgroup of $\mathbb{Z}$, say $S_\varphi = d\mathbb{Z}$ with $d \ge 1$.

Now let φ, φ' be two-signed with the same restriction to A_0. Let $m \in S_\varphi$; choose $f_m \in A_m$ and $g_m \in A_{-m}$ with $\varphi(f_m) \neq 0 \neq \varphi(g_m)$. For every $f \in A_m$, $fg_m \in A_0$, so $\varphi'(f)\varphi'(g_m) = \varphi(f)\varphi(g_m)$. For $f = f_m$ the right side is non-zero, so $\varphi'(g_m) \neq 0$, and with $z_m = \varphi(g_m)/\varphi'(g_m) \in \overline{\mathbb{Q}}_\ell^\times$,

$$\varphi'(f) = z_m\, \varphi(f) \qquad (f \in A_m).$$

In particular $\varphi'(A_m) \neq 0$, so $S_\varphi \subseteq S_{\varphi'}$, and by symmetry $S_{\varphi'} = S_\varphi$. The number z_m does not depend on the choice of g_m, being $\varphi'(f_m)/\varphi(f_m)$. For $m, m' \in S_\varphi$, applying the display to $f_m f_{m'} \in A_{m+m'}$ gives $z_{m+m'}\varphi(f_m)\varphi(f_{m'}) = \varphi'(f_m)\varphi'(f_{m'}) = z_m z_{m'}\varphi(f_m)\varphi(f_{m'})$, so $z_{m+m'} = z_m z_{m'}$ and $z_{kd} = z_d^k$ for all $k \in \mathbb{Z}$. Since $\overline{\mathbb{Q}}_\ell$ is algebraically closed, choose t with $t^d = z_d$; then $z_m = t^m$ for $m \in S_\varphi$. Hence $\varphi'(f) = t^m\varphi(f)$ for $f \in A_m$, $m \in S_\varphi$, and for $m \notin S_\varphi = S_{\varphi'}$ both $\varphi'(f)$ and $t^m\varphi(f)$ vanish. As $A = \bigoplus_m A_m$ and both sides are additive, $\varphi' = t \cdot \varphi$.

Item 4. By item 2 the set P_0 of restrictions $\varphi|_{A_0}$ of two-signed points φ on u is finite. Choose a set Σ of two-signed points on u containing, for each member of P_0, exactly one point with that restriction; Σ is finite. If φ is a two-signed point on u, then $\varphi|_{A_0} \in P_0$, so some $\varphi_1 \in \Sigma$ has $\varphi_1|_{A_0} = \varphi|_{A_0}$, and by item 3, $\varphi = t \cdot \varphi_1$ for some t. So Σ is an orbit cover of u. □

Lemma 41.4. *Let $\mathcal{O}$ be a coefficient ring and (A, φ_0, u, a) a tuple satisfying (Gc1)–(Gc5), with tangent dimensions* td *as in (Gc1). Let J' be a finite set with a map* $\mathrm{wt}'\colon J' \to \{-1, 1, 2\}$ *such that* $\#\mathrm{wt}'^{-1}(j) = \mathrm{td}(j)$ *for $j \in \{-1, 1, 2\}$, and $P' = \mathcal{O}[\ell^{-1}][[X_i : i \in J']]$ with the weights of power series defined by* wt'. *Then there are an $\mathcal{O}$-subalgebra $A' \subseteq P'$ and a surjective $\mathcal{O}$-algebra homomorphism $\pi\colon A \to A'$ with the following properties, where A'_j is the set of elements of A' of weight j, $\varphi'_0\colon A' \to \mathcal{O}[\ell^{-1}]$ is the constant term, and u' is the system of equations for (A', φ'_0) with $u'_j = (\pi(u_{j,i}))_i$ for $j \in \{-1, 1, 2\}$ and no equations of degrees -2 and 0:*

(Rc1) *$\pi(A_j) = A'_j$ for all j, $A' = \bigoplus_j A'_j$, $\varphi'_0 \circ \pi = \varphi_0$, (A', φ'_0) is a graded $\mathcal{O}$-algebra with a fixed point, and the inclusion $A' \to P'$ is a chart for (A', φ'_0), i.e. satisfies (Sm1)–(Sm4);*

(Rc2) *$I(u') = \pi(I(u))$, the tuple $(A', \varphi'_0, u', \pi(a))$ satisfies (Gc1)–(Gc5), and the cotangent length of u'_{-1} in degree -1 computed in (A', φ'_0) equals* $\mathrm{ct}_{-1}(u_{-1})$*;*

(Rc3) *for every orbit cover Σ of u, the set Σ' of points φ' of A' with $\varphi' \circ \pi \in \Sigma$ is an orbit cover of u', and*

$$\sum_{\varphi' \in \Sigma'} v_{\mathcal{O}}(\varphi'(\pi(a))) \leq \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a)).$$

Proof. Write $K_0 = \mathcal{O}[\ell^{-1}]$ for the fraction field of $\mathcal{O}$ and $\mathfrak{m}_0 = \ker \varphi_0$. By (Gc1) there are a finite set J, $\mathrm{wt}\colon J \to \mathbb{Z}$ with $\#\mathrm{wt}^{-1}(j) = \mathrm{td}(j)$, and a chart $\phi\colon A \to P = K_0[[X_i : i \in J]]$; as $\mathrm{td}(j) = 0$ for $|j| > 2$, wt takes values in $\{-2, \ldots, 2\}$. Replacing J' by a set in bijection with it, we take $J' = \mathrm{wt}^{-1}(\{-1, 1, 2\}) \subseteq J$ with $\mathrm{wt}' = \mathrm{wt}|_{J'}$, so that $P' \subseteq P$; put $J_e = J \setminus J' = \mathrm{wt}^{-1}(\{0, -2\})$. For $g \in P$ let $g^{(1)}$ be its linear part (the sum of its terms of total degree one), and for $f \in A$ write $f^{(1)} = \phi(f)^{(1)}$.

Step 1: linear parts. (a) For $f, g \in A$, by (Sm2), $(fg)^{(1)} = \varphi_0(f)g^{(1)} + \varphi_0(g)f^{(1)}$; so $f^{(1)} = 0$ for $f \in \mathfrak{m}_0^2$, and for $f \in \mathrm{Sq}(\varphi_0)$, $cf \in \mathfrak{m}_0^2$ with $c \neq 0$ gives $cf^{(1)} = 0$, so $f^{(1)} = 0$. (b) If $f \in A_j$, $\phi(f)$ has weight j by (Sm1), so $f^{(1)}$ is a K_0-combination of the X_i with $\mathrm{wt}(i) = j$. (c) For each j, the map $\mathrm{Cot}_j \to P$, class of $f \mapsto f^{(1)}$, is well defined by (a) and injective by (Sm4); hence for $f \in A_j \cap \mathfrak{m}_0$ and a family w in A, the class of f lies in $\mathrm{Cot}(w)$ if and only if $f^{(1)}$ lies in the $\mathcal{O}$-span of the $w_k^{(1)}$. (d) For $j \in \{0, -2\}$ the linear parts of the members of u_j form a basis of the K_0-span V_j of $\{X_i : \mathrm{wt}(i) = j\}$. Indeed, let $\mathrm{wt}(i) = j$. By (Sm3) there is $f \in A$ with $f^{(1)} = cX_i$, $c \neq 0$. Writing $f = \sum_m f_m$ with $f_m \in A_m$, $\phi(f_m)$ is the weight-m part of $\phi(f)$, so by (b) $f_j^{(1)} = cX_i$;

put $f' = f_j - \varphi_0(f_j) \in A_j \cap \mathfrak{m}_0$ (for $j \neq 0$, $\varphi_0(f_j) = 0$), with $f'^{(1)} = cX_i$ as $1^{(1)} = 0$. Since u_j spans rationally in degree j, by (c) some $c'X_i$, $c' \neq 0$, is an $\mathcal{O}$-combination of the $u_{j,k}^{(1)}$. Thus these linear parts, which lie in V_j by (b), span V_j; there are $\mathrm{ne}(j) = \mathrm{td}(j) = \dim V_j$ of them.

Step 2: elimination of the variables of weight 0 *and* -2. Let $f_1, \dots, f_n$ be the elements $\phi(u_{0,k})$ and $\phi(u_{-2,k})$, so $n = \#J_e$; each f_k has a weight $w_k \in \{0, -2\}$, zero constant term (by (Sm2), as $\varphi_0(u_{0,k}) = 0$ and $\varphi_0(A_{-2}) = 0$), and by (b) and (d) $f_k^{(1)} = \sum_{i \in J_e} m_{ki} X_i$ with $\mathbf{M} = (m_{ki})$ invertible and $m_{ki} = 0$ unless $\mathrm{wt}(i) = w_k$, i.e. $\mathbf{M}$ is block diagonal for the weights. Write $f_k = f_k^{(1)} + R_k$, where R_k has only terms of total degree at least 2 and weight w_k. We claim there are unique $p_i \in P'$ ($i \in J_e$) with zero constant term and $f_k(X_{J'}, p) = 0$ for all k, where $(X_{J'}, p)$ means the substitution $X_i \mapsto p_i$ for $i \in J_e$; and p_i has weight $\mathrm{wt}(i)$. The equations are equivalent to $p = -\mathbf{M}^{-1} R(X_{J'}, p)$. Write $p_i = \sum_{d \geq 1} p_i^{[d]}$ with $p_i^{[d]}$ homogeneous of total degree d. Every term of R_k has total degree at least 2, and each p_i has no constant term, so the part of total degree d of $R_k(X_{J'}, p)$ depends only on $p^{[1]}, \dots, p^{[d-1]}$; hence the equations determine $p^{[d]}$ recursively, $p^{[d]} = -\mathbf{M}^{-1}(\text{part of degree } d \text{ of } R(X_{J'}, p^{[1]} + \cdots + p^{[d-1]}))$, which proves existence and uniqueness. By induction on d, if $p^{[1]}, \dots, p^{[d-1]}$ have the weights $\mathrm{wt}(i)$, then $R_k(X_{J'}, p^{[<d]})$ has weight w_k (each monomial of weight w_k becomes a product of homogeneous series of total weight w_k), and so has its part of degree d; as $\mathbf{M}^{-1}$ is block diagonal, $p_i^{[d]}$ is a combination of such parts with $w_k = \mathrm{wt}(i)$ and has weight $\mathrm{wt}(i)$. Since no variable of J' has weight 0 or -2, $p_i^{(1)} = 0$.

Let $\mathrm{Sb}\colon P \to P'$ be the substitution homomorphism $X_i \mapsto X_i$ ($i \in J'$), $X_i \mapsto p_i$ ($i \in J_e$), well defined and continuous as the p_i have no constant term. It preserves weights, kills $f_1, \dots, f_n$, and for $g \in P$ the constant term of $\mathrm{Sb}(g)$ is that of g and $\mathrm{Sb}(g)^{(1)}$ is $g^{(1)}$ with the terms in X_i, $i \in J_e$, deleted (terms of degree at least 2 and the p_i contribute no linear terms). Put $A' = \mathrm{Sb}(\phi(A)) \subseteq P'$ and let $\pi\colon A \to A'$ be the surjection $f \mapsto \mathrm{Sb}(\phi(f))$. Then $\pi(u_{0,k}) = \pi(u_{-2,k}) = 0$, and for $f \in A$, $\pi(f)$ has the same constant term as $\phi(f)$ and the linear part $f^{(1)}$ with the J_e-terms deleted.

Step 3: (Rc1). Each $\pi(A_j)$ consists of series of weight j; as weight components of a series are unique, $A' = \sum_j \pi(A_j)$ is direct and $A' \cap \{\text{weight } j\} = \pi(A_j)$, so $A'_j = \pi(A_j)$. The constant term gives $\varphi'_0 \circ \pi = \varphi_0$ by (Sm2), so φ'_0 takes values in $\mathcal{O}$ and kills A'_j for $j \neq 0$. The ring $A'_0 = \pi(A_0)$ is a quotient of the complete Noetherian local ring A_0, hence complete Noetherian local, with maximal ideal the image of that of A_0 and the same residue field, so $\mathcal{O} \to A'_0$ is local and induces an isomorphism of residue fields; A' is generated by A'_0 and the images of the homogeneous generators of A. So (A', φ'_0) is a graded $\mathcal{O}$-algebra with a fixed point. For the inclusion $A' \to P'$: (Sm1) holds by $A'_j = \pi(A_j)$; (Sm2) by definition of φ'_0; (Sm3): for $i \in J'$, take f from (Sm3) for ϕ; then $\pi(f)^{(1)} = cX_i$. (Sm4): let $g = \pi(f) \in A'$ with $\varphi'_0(g) = 0$ and $g^{(1)} = 0$, $f = \sum_m f_m$, $f_m \in A_m$; the weight-m part $\pi(f_m)$ of g has zero linear part. For $m \notin \{0, -2\}$, $f_m^{(1)}$ involves only variables of weight m, all in J', so $f_m^{(1)} = \pi(f_m)^{(1)} = 0$, $\varphi_0(f_m) = 0$, and $f_m \in \mathrm{Sq}(\varphi_0)$ by (Sm4) for ϕ. Also $\varphi_0(f_0) = \varphi'_0(g) = 0$, so $f_0 \in A_0 \cap \mathfrak{m}_0$, and $f_{-2} \in A_{-2} \cap \mathfrak{m}_0$; as u_0, u_{-2} span rationally, there are $c \in \mathcal{O} \setminus \{0\}$ and $o_{m,k} \in \mathcal{O}$ with $cf_m - \sum_k o_{m,k} u_{m,k} \in \mathrm{Sq}(\varphi_0)$ for $m = 0, -2$. Hence $cf \in \mathrm{Sq}(\varphi_0) + \sum_{m \in \{0,-2\}, k} \mathcal{O} u_{m,k}$. Since $\pi(\mathfrak{m}_0) \subseteq \mathfrak{m}'_0 = \ker \varphi'_0$, $\pi(\mathrm{Sq}(\varphi_0)) \subseteq \mathrm{Sq}(\varphi'_0)$, and $\pi(u_{m,k}) = 0$; so $cg \in \mathrm{Sq}(\varphi'_0)$, i.e. $c'cg \in \mathfrak{m}'^2_0$ for some $c' \neq 0$, and $g \in \mathrm{Sq}(\varphi'_0)$.

Step 4: (Rc2). The set $\pi(I(u))$ is the ideal of A' generated by the $\pi(u_{j,i})$ (π is surjective), and the generators of degrees 0 and -2 map to 0; so $\pi(I(u)) = I(u')$. (Gc1): the inclusion is a chart with tangent dimensions td', $\mathrm{td}'(j) = \mathrm{td}(j)$ for $j \in \{-1, 1, 2\}$ and 0 otherwise; the counts of u' are $\mathrm{ne}(j)$ for $j \in \{-1, 1, 2\}$ and 0 for $j \in \{-2, 0\}$, which are the required ones. No variable of J' has weight 0 or -2, so every element of $A'_0 \cap \mathfrak{m}'_0$ or of A'_{-2} has zero linear part

and lies in $\mathrm{Sq}(\varphi'_0)$ by (Sm4): $\mathrm{Cot}'_0 = \mathrm{Cot}'_{-2} = 0$, and the empty families span rationally. For $f \in A_{-1}$, all variables of weight -1 lie in J', so $\pi(f)^{(1)} = f^{(1)}$. By (c), applied to ϕ and to the inclusion of A', the maps sending the class of f to $f^{(1)}$ identify Cot_{-1} and Cot'_{-1} with the same $\mathcal{O}$-module $\mathrm{Lp}_{-1} = \{f^{(1)} : f \in A_{-1}\}$, and $\mathrm{Cot}(u_{-1})$, $\mathrm{Cot}(u'_{-1})$ with the same submodule, the $\mathcal{O}$-span of the $u^{(1)}_{-1,i}$ (as $u_{-1,i} \in A_{-1} \subseteq \mathfrak{m}_0$, $\mathrm{Cot}_{-1} \cap \mathrm{Cot}(u_{-1}) = \mathrm{Cot}(u_{-1})$, and likewise for u'). Hence u'_{-1} spans rationally in degree -1 and the two cotangent lengths in degree -1 are equal. (Gc2): $A'/I(u') \cong A/(I(u) + \ker\pi)$, so the image of A'_0 in it is a quotient of the image of A_0 in $A/I(u)$, a finitely generated $\mathcal{O}$-module. For the remaining conditions, $\varphi' \mapsto \varphi' \circ \pi$ is an injection of the points of A' into the points of A; since $\pi(A_j) = A'_j$, $\varphi' \circ \pi$ is negative-vanishing, positive-vanishing or two-signed exactly when φ' is, it lies on u exactly when φ' lies on u' (as $\pi(I(u)) = I(u')$), and two points of A' agree on A'_0 exactly when their composites with π agree on A_0. (Gc3): if $\varphi'_1 \neq \varphi'_0$ is a point on u' that is negative- and positive-vanishing, then $\varphi'_1 \circ \pi \neq \varphi_0$ is such a point of A on u; (Gc3) for A excludes one of the two kinds of points agreeing with it on A_0, and composing with π shows that the same kind is excluded for φ'_1. (Gc4): if D, D' are φ'-derivations of A' vanishing on $I(u')$ at a two-signed point φ' on u', then $D \circ \pi$, $D' \circ \pi$ are $(\varphi' \circ \pi)$-derivations of A vanishing on $I(u)$; by (Gc4) for A, $c_1 D \circ \pi + c_2 D' \circ \pi = 0$ with $(c_1, c_2) \neq (0, 0)$ in $\overline{\mathbb{Q}}_\ell$, and $c_1 D + c_2 D' = 0$ as π is onto. (Gc5): $\pi(a) \in A'_0$, $\varphi'_0(\pi(a)) = \varphi_0(a) = 0$, and $\varphi'(\pi(a)) = (\varphi' \circ \pi)(a) \neq 0$ at every two-signed point φ' on u'.

Step 5: (Rc3). By Step 4 the members of Σ' are two-signed points on u', and Σ' is finite since $\varphi' \mapsto \varphi' \circ \pi$ is injective. Let φ' be a two-signed point on u'. Then $\varphi' \circ \pi = t \cdot \varphi$ with $\varphi \in \Sigma$. The ideal $\ker\pi$ is spanned by homogeneous elements: if $\pi(f) = 0$, each weight part $\pi(f_m)$ of $\pi(f)$ vanishes. For homogeneous $f \in A_m \cap \ker\pi$, $\varphi(f) = t^{-m}(t \cdot \varphi)(f) = t^{-m}\varphi'(\pi(f)) = 0$; so φ vanishes on $\ker\pi$, and $\varphi = \varphi'' \circ \pi$ for a point φ'' of A', which lies in Σ'. For $f \in A_m$, $\varphi'(\pi(f)) = t^m\varphi(f) = t^m\varphi''(\pi(f))$, and $\pi(A_m) = A'_m$, so $\varphi' = t \cdot \varphi''$. Thus Σ' is an orbit cover of u'. Finally $\varphi' \mapsto \varphi' \circ \pi$ maps Σ' injectively into Σ with $\varphi'(\pi(a)) = (\varphi' \circ \pi)(a)$, and every term $v_{\mathcal{O}}(\varphi(a))$, $\varphi \in \Sigma$, is defined ($\varphi(a) \neq 0$ by (Gc5)) and non-negative by Lemma 41.3, item 1, which applies by (Gc2); this gives the inequality. □

Definition 41.5. Let B be a Noetherian local ring with maximal ideal $\mathfrak{m}_B$, and let $k \geq 1$. On $\mathbb{Z}^k$ we use the componentwise partial order, and $e_0, \ldots, e_{k-1}$ are the unit vectors. A property of $m \in \mathbb{Z}^k$ holds **in large degree** if there is $m_0 \in \mathbb{Z}^k$ such that it holds for every $m \geq m_0$; finitely many properties that hold in large degree hold simultaneously in large degree (take the componentwise maximum of the thresholds). All rings are commutative.

Standard algebras. A **standard $\mathbb{N}^k$-graded B-algebra** is a B-algebra $S = \bigoplus_{\mu \in \mathbb{N}^k} S_\mu$ with $S_\mu S_{\mu'} \subseteq S_{\mu+\mu'}$ such that

- the structure map $B \to S$ maps B onto S_0;
- each S_{e_i} is a finitely generated B-module;
- $S_{\mu+e_i} = S_\mu S_{e_i}$ (the B-span of the products) for all $\mu \in \mathbb{N}^k$ and $0 \leq i < k$.

Its **irrelevant ideal** is $\mathrm{Irr}(S) = \prod_{i=0}^{k-1}(S_{e_i}S)$, the product of the ideals generated by the S_{e_i}.

Graded modules. A graded S-module is an S-module $F = \bigoplus_{m \in \mathbb{Z}^k} F_m$ with $S_\mu F_m \subseteq F_{\mu+m}$; each F_m is a B-module. For $d \in \mathbb{Z}^k$, $F(-d)$ is F with $F(-d)_m = F_{m-d}$. For a homogeneous ideal I of S, S/I is a graded S-module.

Koszul complexes. A **sequence of homogeneous elements** is a finite sequence $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_q)$ with $\sigma_j \in S_{d_j}$ for given degrees $d_j \in \mathbb{N}^k$ (the degrees are part of the data; $q = 0$ is allowed). Write $(\boldsymbol{\sigma})$ for the ideal it generates and, for $J \subseteq \{1, \ldots, q\}$, $d_J = \sum_{j \in J} d_j$. The

Koszul complex $\mathrm{Kos}_\bullet(\boldsymbol{\sigma}; F)$ of a graded S-module F is the complex of graded S-modules with

$$\mathrm{Kos}_p(\boldsymbol{\sigma}; F) = \bigoplus_{J\subseteq\{1,\dots,q\},\ \#J=p} F(-d_J)\,\epsilon_J,$$

$$\partial(f\,\epsilon_J) = \sum_{t=1}^{p}(-1)^{t+1}\sigma_{j_t} f\,\epsilon_{J\setminus\{j_t\}} \quad (J=\{j_1<\cdots<j_p\}),$$

whose differential preserves degrees. Its degree-m part $\mathrm{Kos}_\bullet(\boldsymbol{\sigma}; F)_m$ is a complex of B-modules, with homology $H_p(\boldsymbol{\sigma}; F)_m$. For $\boldsymbol{\sigma}$ and an element a of degree d, $(\boldsymbol{\sigma}, a)$ and $(a, \boldsymbol{\sigma})$ are the sequences with a appended at the end, respectively at the beginning.

Euler characteristics. The **Euler characteristic** of $\boldsymbol{\sigma}$ on F in degree m is

$$\mathrm{eu}(\boldsymbol{\sigma}; F)(m) = \sum_{p=0}^{q}(-1)^p \operatorname{length}_B H_p(\boldsymbol{\sigma}; F)_m, \tag{41.2}$$

and it is **defined** if all the lengths in (41.2) are finite. For $q=0$, $\mathrm{eu}(();F)(m) = \operatorname{length}_B F_m$. For a single element $a\in S_0$ (degree 0), $\mathrm{Kos}_\bullet((a);F)_m$ is $F_m \xrightarrow{a} F_m$, so

$$\mathrm{eu}((a);F)(m) = \operatorname{length}_B(F_m/aF_m) - \operatorname{length}_B(0:_{F_m} a),$$

the Herbrand quotient of a on F_m, defined if both lengths are finite.

Definition 41.6. Let $\mathcal{O}$ be a coefficient ring, (A,φ_0) a graded $\mathcal{O}$-algebra with a fixed point, and u a system of equations for (A,φ_0) with counts ne such that $\mathrm{ne}(-2)=\mathrm{ne}(0)=0$ and $\mathrm{ne}(-1)=n+1$ with $n\ge 1$. The **excess equation** of u is $w=u_{-1,n+1}$, the last member of u_{-1}. Each A_j is an A_0-submodule of A, as $A_0A_j\subseteq A_j$. Put

$$N_0 = A_{-2}, \qquad N_1 = A_2, \qquad N_2 = A_0w^2 + A_{-2}A_{-2}A_2,$$

A_0-submodules of A (products of submodules are A_0-spans of products; $N_2\subseteq A_{-2}$). For $\mu=(\mu_0,\mu_1,\mu_2)\in\mathbb{N}^3$ let $N^\mu = N_0^{\mu_0}N_1^{\mu_1}N_2^{\mu_2}$, with $N_i^0=A_0$. The **Rees algebra** of u is the A_0-subalgebra

$$\mathrm{Rs}(u) = \bigoplus_{\mu\in\mathbb{N}^3} N^\mu\, T_0^{\mu_0}T_1^{\mu_1}T_2^{\mu_2} \ \subseteq\ A[T_0,T_1,T_2]$$

of the polynomial ring in three variables over A, graded by $\mathbb{N}^3$ with $\mathrm{Rs}(u)_\mu = N^\mu T^\mu$; an element $b\in A_0$ is identified with $bT^0\in\mathrm{Rs}(u)_0$. The **sections** of u form the sequence of homogeneous elements $\boldsymbol{\sigma}(u)$ of $\mathrm{Rs}(u)$ consisting, in this order, of

- $u_{-1,i}^2T_0$ for $1\le i\le n$, of degree e_0 (as $u_{-1,i}^2\in A_{-2}=N_0$);
- $u_{1,i}^2T_1$ for $1\le i\le \mathrm{ne}(1)$, of degree e_1 (as $u_{1,i}^2\in A_2=N_1$);
- $u_{2,i}T_1$ for $1\le i\le \mathrm{ne}(2)$, of degree e_1;
- w^2T_2, of degree e_2 (as $w^2\in N_2$).

It has $n+\mathrm{ne}(1)+\mathrm{ne}(2)+1$ members.

Lemma 41.7. *Let $\mathcal{O}$ be a coefficient ring with uniformiser ϖ, J a finite set with a map* $\mathrm{wt}\colon J\to\{-1,1,2\}$ *such that $n_j=\#\mathrm{wt}^{-1}(j)\ge 1$ for $j\in\{-1,1,2\}$, and $P=\mathcal{O}[\ell^{-1}][[X_i : i\in J]]$ with the weights defined by* wt. *Let $A\subseteq P$ be an $\mathcal{O}$-subalgebra such that, with A_j the set of elements of A of weight j and φ_0 the constant term, $A=\bigoplus_j A_j$, (A,φ_0) is a graded $\mathcal{O}$-algebra with a*

fixed point, and the inclusion $A \to P$ satisfies (Sm1)–(Sm4). Let u be a system of equations for (A, φ_0) with counts $\mathrm{ne}(-1) = n_{-1}+1$, $\mathrm{ne}(1) = n_1 - 1$, $\mathrm{ne}(2) = n_2 - 1$, $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$, such that u_{-1} spans rationally in degree -1, and let $a \in A$ with $a \neq 0$ such that (A, φ_0, u, a) satisfies (Gc2)–(Gc5). Assume that there are $y_1, \dots, y_{n_{-1}} \in A_{-1}$ and integers $c_1, \dots, c_{n_{-1}} \geq 0$ with

$$u_{-1,i} - \varpi^{c_i} y_i \in \mathrm{Sq}(\varphi_0) \quad (1 \leq i \leq n_{-1}), \qquad u_{-1,n_{-1}+1} \in \mathrm{Sq}(\varphi_0).$$

Then for every orbit cover Σ of u,

$$\sum_{i=1}^{n_{-1}} c_i \leq 2 \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a)).$$

Proof. Write $n = n_{-1}$, $\mathrm{Rs} = \mathrm{Rs}(u)$ and $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$; the definition applies since $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$ and $\mathrm{ne}(-1) = n+1$ with $n \geq 1$, and $\boldsymbol{\sigma}$ has $n + (n_1 - 1) + (n_2 - 1) + 1$ members. Let Σ be an orbit cover of u. Every term $v_{\mathcal{O}}(\varphi(a))$, $\varphi \in \Sigma$, is defined, as $\varphi(a) \neq 0$ by (Gc5).

Step 1: the setting. By Lemma 41.8, item 2, Rs is a standard $\mathbb{N}^3$-graded algebra over the Noetherian local ring A_0. The power series ring P over the field $\mathcal{O}[\ell^{-1}]$ is a domain, hence so is $A \subseteq P$, and by Lemma 41.8, item 3, the non-zero element $a \in A_0$ is a non-zerodivisor on Rs. Moreover $A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$: for $f \in A_{-2}$, $\varphi_0(f) = 0$, and f has weight -2 by (Sm1) while no variable has weight -2, so all coefficients of degree one of f vanish and (Sm4) applies.

Step 2: admissibility. The hypotheses of Proposition 41.9 hold: the counts, rational spanning of u_{-1}, $A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$ (Step 1), and (Gc2), (Gc3), (Gc5). So there is $N \geq 1$ with $(\mathfrak{m}_{A_0}\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs}))^N \subseteq (\boldsymbol{\sigma}, a)$.

Step 3: the lower bound at the fixed point. The hypotheses of Proposition 41.13 hold: $A \subseteq P$ with the inclusion satisfying (Sm1)–(Sm3), the counts, the elements y_i and exponents c_i, $a \in A_0$ with $\varphi_0(a) = 0$ (Gc5), and the inclusion of Step 2. Hence in large degree $m \in \mathbb{Z}^3$, $\mathrm{eu}(\boldsymbol{\sigma}; \mathrm{Rs}/(a))(m)$ is defined and at least $2^{n+n_1-1} \sum_{i=1}^{n} c_i$.

Step 4: moving a to the end. Let $C = \mathrm{Kos}_\bullet(\boldsymbol{\sigma}; \mathrm{Rs})$. As a has degree 0, $\mathrm{Kos}_\bullet((a, \boldsymbol{\sigma}); \mathrm{Rs})$ is the mapping cone of multiplication by a on C (split ϵ_J according to whether J contains the index of a). Each C_p is a direct sum of shifted copies of Rs, on which a is injective (Step 1), with cokernel $\mathrm{Kos}_p(\boldsymbol{\sigma}; \mathrm{Rs}/(a))$. For an injective chain map, the long exact homology sequence of the short exact sequence $0 \to C \xrightarrow{a} C \to C/aC \to 0$ and that of the cone identify the homology of the cone with that of C/aC; all maps preserve degrees. Hence $H_p((a, \boldsymbol{\sigma}); \mathrm{Rs})_m \cong H_p(\boldsymbol{\sigma}; \mathrm{Rs}/(a))_m$ for all p and m (the classical fact that a regular element may be divided out of a Koszul complex; [55, Cor. 1.6.13]). Further, a Koszul complex is the tensor product over Rs of the complexes of its single elements, tensored with the module, and the tensor product of complexes is symmetric up to isomorphism (with the usual signs); so permuting the sequence does not change the homology. Therefore, for every m, $\mathrm{eu}((\boldsymbol{\sigma}, a); \mathrm{Rs})(m)$ is defined if and only if $\mathrm{eu}(\boldsymbol{\sigma}; \mathrm{Rs}/(a))(m)$ is, and then

$$\mathrm{eu}((\boldsymbol{\sigma}, a); \mathrm{Rs})(m) = \mathrm{eu}((a, \boldsymbol{\sigma}); \mathrm{Rs})(m) = \mathrm{eu}(\boldsymbol{\sigma}; \mathrm{Rs}/(a))(m).$$

Step 5: the Serre-type inequality. By Proposition 41.20, applied to $B = A_0$, $S = \mathrm{Rs}$, the sequence $\boldsymbol{\sigma}$ and $a \in \mathrm{Rs}_0$, with the inclusion of Step 2, in large degree $\mathrm{eu}((\boldsymbol{\sigma}, a); \mathrm{Rs})(m) \leq \mathrm{eu}((a); \mathrm{Rs}/(\boldsymbol{\sigma}))(m)$, both defined.

Step 6: the upper bound at the two-signed points. The hypotheses of Proposition 41.21 hold: the counts, rational spanning of u_{-1}, $A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$, (Gc2)–(Gc5) and the orbit cover Σ. As $\mathrm{ne}(1) = n_1 - 1$, in large degree $\mathrm{eu}((a); \mathrm{Rs}/(\boldsymbol{\sigma}))(m)$ is defined and at most $2^{n+n_1} \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a))$.

Step 7: conclusion. Choose $m \in \mathbb{Z}^3$ in large degree for Steps 3, 5 and 6 at once. Then by Steps 3–6

$$2^{n+n_1-1}\sum_{i=1}^{n} c_i \le \mathrm{eu}(\boldsymbol{\sigma};\mathrm{Rs}/(a))(m) = \mathrm{eu}((\boldsymbol{\sigma},a);\mathrm{Rs})(m)$$
$$\le \mathrm{eu}((a);\mathrm{Rs}/(\boldsymbol{\sigma}))(m) \le 2^{n+n_1}\sum_{\varphi\in\Sigma} v_{\mathcal{O}}(\varphi(a)),$$

and dividing by 2^{n+n_1-1} gives the assertion. The factor 2 is the ratio of the two powers of 2: the excess equation $w = u_{-1,n+1}$ lies in $\mathrm{Sq}(\varphi_0)$ and contributes nothing at the fixed point, while its square w^2T_2 is a section and contributes a factor 2 at the two-signed points. □

Lemma 41.8. *Let $\mathcal{O}$ be a coefficient ring and (A,φ_0) a graded $\mathcal{O}$-algebra with a fixed point. Then:*

1. *every A_j, $j\in\mathbb{Z}$, is a finitely generated A_0-module;*
2. *for every system of equations u for (A,φ_0) as in Definition 41.6, $\mathrm{Rs}(u)$ is a standard $\mathbb{N}^3$-graded A_0-algebra over the Noetherian local ring A_0;*
3. *if moreover A is a domain, so is $\mathrm{Rs}(u)$; in particular every non-zero $b\in A_0$ is a non-zerodivisor on $\mathrm{Rs}(u)$.*

Proof. Item 1. By definition, A is generated as an $\mathcal{O}$-algebra by A_0 and finitely many homogeneous elements $s_1,\dots,s_q$ of non-zero degrees $d_1,\dots,d_q$. Hence every element of A is a finite sum of products $b\,s^\nu$ with $b\in A_0$, $\nu\in\mathbb{N}^q$ and $s^\nu=\prod_k s_k^{\nu_k}$ (the $\mathcal{O}$-multiples and products of elements of A_0 lie in A_0); such a product is homogeneous of degree $\sum_k \nu_k d_k$. Taking the component of degree j of such a sum, A_j is the A_0-span of the s^ν with $\nu\in\mathcal{E}_j=\{\nu\in\mathbb{N}^q : \sum_k\nu_k d_k = j\}$. By Dickson's lemma, $\mathcal{E}_j$ has finitely many minimal elements for the componentwise order, and every $\nu\in\mathcal{E}_j$ satisfies $\nu\ge\nu'$ for one of them. Then $\nu-\nu'\in\mathcal{E}_0$, so $s^\nu = s^{\nu'}s^{\nu-\nu'}\in s^{\nu'}A_0$. Hence A_j is generated over A_0 by the finitely many $s^{\nu'}$, ν' minimal in $\mathcal{E}_j$.

Item 2. By the definition of a graded algebra with a fixed point, A_0 is a complete Noetherian local ring. Let N_0,N_1,N_2 be as in Definition 41.6. The piece $\mathrm{Rs}(u)_0 = N^0T^0 = A_0$ is the image of the structure map. By item 1, $N_0=A_{-2}$ and $N_1=A_2$ are finitely generated A_0-modules, say by $g_1,\dots,g_a$ and $h_1,\dots,h_b$; then $N_2 = A_0w^2 + A_{-2}A_{-2}A_2$ is generated by w^2 and the $g_ig_{i'}h_l$. So each $\mathrm{Rs}(u)_{e_i}=N_iT_i$ is finitely generated. Finally, for $\mu\in\mathbb{N}^3$, $N^{\mu+e_i}=N^\mu N_i$ by the definition of N^μ (products of submodules are associative and commutative), so $\mathrm{Rs}(u)_{\mu+e_i} = N^\mu N_i T^\mu T_i = \mathrm{Rs}(u)_\mu \mathrm{Rs}(u)_{e_i}$.

Item 3. The ring $\mathrm{Rs}(u)$ is a subring of the polynomial ring $A[T_0,T_1,T_2]$, which is a domain if A is. A non-zero $b\in A_0$ is a non-zero element bT^0 of this domain, hence a non-zerodivisor on it. □

Proposition 41.9. *Let $\mathcal{O}$ be a coefficient ring, (A,φ_0) a graded $\mathcal{O}$-algebra with a fixed point, $\mathfrak{m}_{A_0}$ the maximal ideal of A_0, and u a system of equations for (A,φ_0) with $\mathrm{ne}(-2)=\mathrm{ne}(0)=0$ and $\mathrm{ne}(-1)=n+1$, $n\ge1$, such that u_{-1} spans rationally in degree -1 and $A_{-2}\subseteq\mathrm{Sq}(\varphi_0)$. Let $a\in A$ be such that (A,φ_0,u,a) satisfies (Gc2), (Gc3) and (Gc5). Then there is $N\ge1$ with*

$$\left(\mathfrak{m}_{A_0}\mathrm{Rs}(u)\cdot\mathrm{Irr}(\mathrm{Rs}(u))\right)^N \subseteq (\boldsymbol{\sigma}(u),a).$$

Proof. Write $\mathrm{Rs} = \mathrm{Rs}(u)$, $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$ and $I_{\mathrm{ex}} = \mathfrak{m}_{A_0}\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs})$. By (Gc5), $a \in A_0 = \mathrm{Rs}_0$.

Reduction to prime ideals. By Lemma 41.8, item 2, Rs is standard over A_0; it is generated as an A_0-algebra by the finitely generated A_0-modules $\mathrm{Rs}_{e_0}, \mathrm{Rs}_{e_1}, \mathrm{Rs}_{e_2}$, hence is Noetherian by Hilbert's basis theorem, A_0 being Noetherian. Suppose that every prime ideal $\mathfrak{P}$ of Rs containing $(\boldsymbol{\sigma}, a)$ contains I_{ex}. Then I_{ex} lies in the radical of $(\boldsymbol{\sigma}, a)$, the intersection of these primes. Let $g_1, \dots, g_t$ generate I_{ex} and $g_i^{e_i} \in (\boldsymbol{\sigma}, a)$; with $N = 1 + \sum_i (e_i - 1)$, every product of N generators contains some g_i at least e_i times, so $I_{\mathrm{ex}}^N \subseteq (\boldsymbol{\sigma}, a)$.

The primes. Let $\mathfrak{P} \supseteq (\boldsymbol{\sigma}, a)$ be prime and $\mathfrak{p} = \mathfrak{P} \cap A_0$, which contains a. If $\mathrm{Irr}(\mathrm{Rs}) \subseteq \mathfrak{P}$, then $I_{\mathrm{ex}} \subseteq \mathfrak{P}$. Otherwise Lemma 41.10 applies (the counts, rational spanning of u_{-1}, $A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$, (Gc2) and (Gc3) are hypotheses here), and by its item 2 either $\mathfrak{p} = \mathfrak{m}_{A_0}$, so that $I_{\mathrm{ex}} \subseteq \mathfrak{m}_{A_0}\mathrm{Rs} \subseteq \mathfrak{P}$, or $\mathfrak{p} = \ker(\varphi|_{A_0})$ for a two-signed point φ on u. In the second case $\varphi(a) = 0$ as $a \in \mathfrak{p}$, against (Gc5). Hence every such prime contains I_{ex}, which proves the supposition. □

Lemma 41.10. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point, $\mathfrak{m}_{A_0}$ the maximal ideal of A_0, and u a system of equations for (A, φ_0) with $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$ and $\mathrm{ne}(-1) = n + 1$, $n \geq 1$, such that u_{-1} spans rationally in degree -1, $A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$, and (Gc2) and (Gc3) hold (these two conditions do not involve the element a). Let $\mathfrak{P}$ be a prime ideal of $\mathrm{Rs}(u)$ that contains every member of $\boldsymbol{\sigma}(u)$ and does not contain $\mathrm{Irr}(\mathrm{Rs}(u))$, and let $\mathfrak{p} = \mathfrak{P} \cap A_0$. Then:*

1. *$I(u) \cap A_0 \subseteq \mathfrak{p}$;*
2. *either $\mathfrak{p} = \mathfrak{m}_{A_0}$, or there is a two-signed point φ on u with $\mathfrak{p} = \ker(\varphi|_{A_0})$.*

Proof. Write $\mathrm{Rs} = \mathrm{Rs}(u)$, $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$, $w = u_{-1,n+1}$, $\mathfrak{m}_0 = \ker \varphi_0$ and $I_0 = I(u) \cap A_0$. As $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$, the equations are the $u_{-1,i}$ $(i \leq n+1)$, $u_{1,i}$, $u_{2,i}$, and $\boldsymbol{\sigma}$ consists of the $u_{-1,i}^2 T_0$ $(i \leq n)$, $u_{1,i}^2 T_1$, $u_{2,i} T_1$ and $w^2 T_2$. For $k \geq 1$, $A_{-2k} = A_{-2}^k = N_0^k$ and $A_{2k} = A_2^k = N_1^k$ by Lemma 41.11; hence $x T_0^k \in \mathrm{Rs}$ for $x \in A_{-2k}$ and $x T_1^k \in \mathrm{Rs}$ for $x \in A_{2k}$, $k \geq 0$.

Step 1: three elements outside $\mathfrak{P}$. As $\mathrm{Irr}(\mathrm{Rs}) \subseteq \mathrm{Rs}_{e_i}\mathrm{Rs}$ for each i, no $\mathrm{Rs}_{e_i} = N_i T_i$ lies in $\mathfrak{P}$. Choose $h_0 \in A_{-2}$, $h_1 \in A_2$, $h_2 \in N_2$ with $h_i T_i \notin \mathfrak{P}$.

Step 2: $u_{-1,i}^2 T_0 \in \mathfrak{P}$ for $1 \leq i \leq n+1$. For $i \leq n$ this is a section. Since $N_2 \subseteq A_{-2} = N_0$ and $w^2 \in N_0 \cap N_2$, the elements $w^2 T_0$, $h_2 T_0$ lie in Rs_{e_0} and $(w^2 T_0)(h_2 T_2) = (h_2 T_0)(w^2 T_2) \in \mathfrak{P}$, as $w^2 T_2$ is a section; since $h_2 T_2 \notin \mathfrak{P}$, $w^2 T_0 \in \mathfrak{P}$.

Step 3: item 1. Put $U = (h_0 T_0)(h_1 T_1) = h_0 h_1 T_0 T_1 \notin \mathfrak{P}$. Let v be an equation of degree d and $c \in A_{-d}$; then $cv \in \mathfrak{p}$:

- $d = -1$: $c^2 h_0 h_1 \in A_2 = N_1$ and $(cv)^2 U = (v^2 T_0)(c^2 h_0 h_1 T_1) \in \mathfrak{P}$ by Step 2;
- $d = 1$: $c^2 h_0 h_1 \in A_{-2} = N_0$ and $(cv)^2 U = (c^2 h_0 h_1 T_0)(v^2 T_1) \in \mathfrak{P}$, $v^2 T_1$ being a section;
- $d = 2$: $c h_0 h_1 \in A_{-2}$ and $(cv) U = (c h_0 h_1 T_0)(v T_1) \in \mathfrak{P}$, $v T_1$ being a section;

as $U \notin \mathfrak{P}$ and $\mathfrak{P}$ is prime, $cv \in \mathfrak{P}$. Now let $b \in I_0$, $b = \sum_k \alpha_k v_k$ with $\alpha_k \in A$ and equations v_k of degrees d_k. Comparing components of degree 0, $b = \sum_k (\alpha_k)_{-d_k} v_k \in \mathfrak{p}$.

Step 4: a homomorphism with kernel $\mathfrak{p}$. By (Gc2) and Step 3, $D_0 = A_0/\mathfrak{p}$ is a quotient of the finitely generated $\mathcal{O}$-module A_0/I_0, and a domain. If $\varpi \in \mathfrak{p}$, D_0 is a domain of finite dimension over the field $\mathcal{O}/\varpi\mathcal{O}$, hence a field, and $\mathfrak{p} = \mathfrak{m}_{A_0}$. Assume from now on that $\varpi \notin \mathfrak{p}$. Every non-zero $c \in \mathcal{O}$ is a unit times a power of ϖ, so D_0 is torsion free and embeds into $D_0[\varpi^{-1}]$, a domain of finite dimension over $\mathcal{O}[\ell^{-1}] = \mathcal{O}[\varpi^{-1}]$, hence a finite field extension of it, which

embeds into the algebraically closed field $\overline{\mathbb{Q}}_\ell \supseteq \mathcal{O}[\ell^{-1}]$. The composite $\beta\colon A_0 \to D_0 \to \overline{\mathbb{Q}}_\ell$ is an $\mathcal{O}$-algebra homomorphism with $\ker\beta = \mathfrak{p}$.

Step 5: points over β that kill $I(u)$. The ideal $\mathfrak{a}_0 = I(u) + \mathfrak{p}A$ is generated by homogeneous elements, so its elements of degree 0 form $I_0 + \mathfrak{p} = \mathfrak{p}$ (Step 3); hence $\mathfrak{a}_0$ and the element 1 satisfy (Lf1), (Lf2) of Lemma 41.12 for β (A is finitely generated as an A_0-algebra by the definition of a graded algebra with a fixed point), and there is a point φ on u with $\varphi|_{A_0} = \beta$. If $\beta(fg) \neq 0$ for some $f \in A_{-2}$ and $g \in A_2$, then $\varphi(f) \neq 0 \neq \varphi(g)$, so φ is two-signed and item 2 holds. It remains to show that $\beta(fg) = 0$ for all $f \in A_{-2}$, $g \in A_2$ is impossible; assume it, for a contradiction, in Steps 6 to 10.

Step 6: $\beta(A_{-j}A_j) = 0$ for $j \geq 1$. Let $x \in A_{-j}$, $y \in A_j$. By Lemma 41.11, $x^2 \in A_{-2}^j$ and $y^2 \in A_2^j$, so $(xy)^2$ is an A_0-linear combination of products $f_1g_1\cdots f_jg_j$ with $f_l \in A_{-2}$, $g_l \in A_2$, each $f_lg_l \in A_0$; hence $\beta((xy)^2) = 0$ and $\beta(xy) = 0$.

Step 7: a point over β vanishing in all non-zero degrees. Define $\varphi_\star(x) = \beta(x_0)$. It is $\mathcal{O}$-linear with $\varphi_\star(1) = 1$; for $x, y \in A$, $(xy)_0 = \sum_j x_jy_{-j}$ and $\beta(x_jy_{-j}) = 0$ for $j \neq 0$ (Step 6), so $\varphi_\star(xy) = \varphi_\star(x)\varphi_\star(y)$. Thus $\varphi_\star$ is a point, negative-vanishing and positive-vanishing, with $\varphi_\star|_{A_0} = \beta$, and it lies on u, since $x \in I(u)$ has $x_0 \in I_0 \subseteq \ker\beta$.

Step 8: a positive-vanishing point over β that is not negative-vanishing. Let

$$\mathfrak{a}_- = \{x \in A :\ (hx)_{-2k}T_0^k \in \mathfrak{P} \text{ for all } h \in A \text{ and } k \geq 0\},$$

an ideal of A, since components are additive and $(h(yx))_{-2k} = ((hy)x)_{-2k}$. For x homogeneous of degree j, $(hx)_{-2k} = h_{-2k-j}x$, so

$$x \in \mathfrak{a}_- \iff hxT_0^k \in \mathfrak{P} \text{ for all } k \geq 0 \text{ and } h \in A_{-2k-j}. \qquad (*)$$

For homogeneous x of degree j, $k \geq 0$ and $h \in A_{-2k-j}$:

(a) if $x^2 \in \mathfrak{a}_-$ then $x \in \mathfrak{a}_-$: $h^2 \in A_{-2(2k)-2j}$, so $(hxT_0^k)^2 = h^2x^2T_0^{2k} \in \mathfrak{P}$ by $(*)$ for x^2;

(b) if $h_0x \in \mathfrak{a}_-$ then $x \in \mathfrak{a}_-$: $h \in A_{-2(k+1)-(j-2)}$, so $(h_0T_0)(hxT_0^k) = hh_0xT_0^{k+1} \in \mathfrak{P}$, and $h_0T_0 \notin \mathfrak{P}$;

(c) $\mathfrak{p} \subseteq \mathfrak{a}_-$: for $b \in \mathfrak{p}$ and $h \in A_{-2k}$, $hbT_0^k = b \cdot hT_0^k \in \mathfrak{P}$;

(d) if $x \in A_{-2}$ and $xT_0 \in \mathfrak{P}$ then $x \in \mathfrak{a}_-$: for $h \in A_{-2k+2}$, $h_0h \in A_{-2k}$ and $(h_0T_0)(hxT_0^k) = (h_0hT_0^k)(xT_0) \in \mathfrak{P}$;

(e) if $b \in A_0$ with $\beta(b) \neq 0$ and $k \geq 0$, then $bh_0^k \notin \mathfrak{a}_-$: otherwise, with $h = 1$, $b(h_0T_0)^k \in \mathfrak{P}$, while $b \notin \mathfrak{p}$ and $h_0T_0 \notin \mathfrak{P}$.

For $g \in A_2$, $h_0g \in \ker\beta = \mathfrak{p}$ by the assumption of Step 5, so $g \in \mathfrak{a}_-$ by (c) and (b). For $j \geq 1$ and $g \in A_j$, $g^2 \in A_{2j} = A_2^j \subseteq \mathfrak{a}_-$, so $g \in \mathfrak{a}_-$ by (a). For $i \leq n+1$, $u_{-1,i}^2T_0 \in \mathfrak{P}$ (Step 2), so $u_{-1,i} \in \mathfrak{a}_-$ by (d) and (a); the $u_{1,i}$, $u_{2,i}$ have positive degree. Hence $I(u) \subseteq \mathfrak{a}_-$ and $A_j \subseteq \mathfrak{a}_-$ for $j > 0$. By (c) and (e), Lemma 41.12 applies to $\mathfrak{a}_-$ and h_0 and gives a point φ_- on u with $\varphi_-|_{A_0} = \beta$, positive-vanishing, and not negative-vanishing since $\varphi_-(h_0) \neq 0$.

Step 9: a negative-vanishing point over β that is not positive-vanishing. Let $\mathfrak{a}_+ = \{x \in A :\ (hx)_{2k}T_1^k \in \mathfrak{P} \text{ for all } h \in A,\ k \geq 0\}$. With T_1, h_1, $A_{2k} = N_1^k$ and all degrees negated, the arguments of Step 8 show that $\mathfrak{a}_+$ is an ideal with the properties (a), (c), (b) for h_1, (d) for $x \in A_2$ with $xT_1 \in \mathfrak{P}$, and (e) for bh_1^k. For $g \in A_{-2}$, $h_1g \in \mathfrak{p}$, so $g \in \mathfrak{a}_+$; for $j \geq 1$ and $g \in A_{-j}$, $g^2 \in A_{-2}^j \subseteq \mathfrak{a}_+$, so $g \in \mathfrak{a}_+$. As $u_{1,i}^2T_1$ and $u_{2,i}T_1$ are sections, $u_{1,i}^2, u_{2,i} \in \mathfrak{a}_+$ by (d), so

$u_{1,i} \in \mathfrak{a}_+$ by (a); the $u_{-1,i}$ have negative degree. By Lemma 41.12 there is a point φ_+ on u with $\varphi_+|_{A_0} = \beta$, negative-vanishing, and not positive-vanishing since $\varphi_+(h_1) \neq 0$.

Step 10: the contradiction. If $\beta \neq \varphi_0|_{A_0}$, then $\varphi_\star \neq \varphi_0$ is a point on u that is negative-vanishing and positive-vanishing, and φ_+ (negative-vanishing, not positive-vanishing) and φ_- (positive-vanishing, not negative-vanishing) are points on u agreeing with $\varphi_\star$ on A_0, against (Gc3). If $\beta = \varphi_0|_{A_0}$, we show $\varphi_-(A_{-2}) = 0$, against $\varphi_-(h_0) \neq 0$. First, $\varphi_-(x) = 0$ for $x \in A_e \cap \mathfrak{m}_0$ with $e \geq 0$: for $e > 0$ as φ_- is positive-vanishing, for $e = 0$ as $\varphi_-(x) = \beta(x) = \varphi_0(x)$. Second, let $d \in \{-1, -2\}$ and $z \in A_d \cap \mathfrak{m}_0^2$, $z = \sum_k p_k q_k$ with $p_k, q_k \in \mathfrak{m}_0$. All components of an element of $\mathfrak{m}_0$ lie in $\mathfrak{m}_0$, as φ_0 vanishes in non-zero degrees, and

$$z = z_d = \sum_k \sum_{e \in \mathbb{Z}} (p_k)_e \, (q_k)_{d-e}.$$

A term with $e \geq 0$ or $d - e \geq 0$ is killed by φ_-; the others have $d < e < 0$, impossible for $d = -1$ and forcing $e = -1$ for $d = -2$. Hence $\varphi_-(z) = 0$ for $d = -1$, and for $d = -2$ once $\varphi_-(A_{-1}) = 0$. Let $x \in A_{-1}$; then $x \in \mathfrak{m}_0$, and as u_{-1} spans rationally in degree -1 there are $c \in \mathcal{O} \setminus \{0\}$, $o_i \in \mathcal{O}$ and $c' \in \mathcal{O} \setminus \{0\}$ with $z = c'(cx - \sum_i o_i u_{-1,i}) \in A_{-1} \cap \mathfrak{m}_0^2$. As $\varphi_-(z) = 0 = \varphi_-(u_{-1,i})$ and $c'c \neq 0$ in $\mathcal{O} \subseteq \overline{\mathbb{Q}}_\ell$, $\varphi_-(x) = 0$. Finally, for $x \in A_{-2} \subseteq \mathrm{Sq}(\varphi_0)$ there is $c' \neq 0$ with $c'x \in A_{-2} \cap \mathfrak{m}_0^2$, so $\varphi_-(x) = 0$. □

Lemma 41.11. *Let $\mathcal{O}$ be a coefficient ring and (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point. For $n \geq 1$ let A_{-2}^n and A_2^n be the A_0-submodules of A spanned by the products of n elements of A_{-2}, respectively of A_2. Then for every $n \geq 1$*

$$A_{-2n} = A_{-2}^n, \qquad A_{2n} = A_2^n.$$

Proof. The inclusions $A_{-2}^n \subseteq A_{-2n}$ and $A_2^n \subseteq A_{2n}$ hold because $A_i A_j \subseteq A_{i+j}$ and $A_0 A_j \subseteq A_j$. For the converse, by the definition of a graded $\mathcal{O}$-algebra with a fixed point, A is generated as an $\mathcal{O}$-algebra by A_0 and finitely many homogeneous elements $s_1, \ldots, s_q$ with degrees $d_1, \ldots, d_q \in \{-2, -1, 1, 2\}$. Every element of A is therefore a finite sum of products $b\, s_{k_1} \cdots s_{k_r}$ with $b \in A_0$ and $r \geq 0$ (the $\mathcal{O}$-multiples and products of elements of A_0 lie in A_0), and such a product is homogeneous of degree $d_{k_1} + \cdots + d_{k_r}$. Taking the component of degree j, A_j is the A_0-span of the products $s_{k_1} \cdots s_{k_r}$ with $d_{k_1} + \cdots + d_{k_r} = j$.

A combinatorial claim. Let $\delta_1, \ldots, \delta_r \in \{-2, -1, 1, 2\}$ with $\sum_{i=1}^r \delta_i = -2n$, $n \geq 1$. Then there are pairwise disjoint subsets $T_1, \ldots, T_n$ of $\{1, \ldots, r\}$ with $\sum_{i \in T_l} \delta_i = -2$ for each l. Induction on n: since the sum is negative, some δ_i is negative. If some $\delta_i = -2$, put $T_n = \{i\}$; otherwise, if two indices $i \neq i'$ have $\delta_i = \delta_{i'} = -1$, put $T_n = \{i, i'\}$. In the remaining case at most one δ_i is negative and it equals -1, so $\sum_i \delta_i \geq -1 > -2n$, which is impossible. The indices outside T_n have sum $-2(n-1)$; for $n \geq 2$ the induction hypothesis applied to them gives $T_1, \ldots, T_{n-1}$, disjoint from T_n.

The case $-2n$. Let $s_{k_1} \cdots s_{k_r}$ be a product of degree $-2n$ and apply the claim to $\delta_i = d_{k_i}$. With $T_0 = \{1, \ldots, r\} \setminus (T_1 \cup \cdots \cup T_n)$,

$$s_{k_1} \cdots s_{k_r} = \Big(\prod_{i \in T_0} s_{k_i} \Big) \prod_{l=1}^{n} \Big(\prod_{i \in T_l} s_{k_i} \Big),$$

where each $\prod_{i \in T_l} s_{k_i}$, $l \geq 1$, lies in A_{-2}, and $\prod_{i \in T_0} s_{k_i}$ has degree $-2n - n(-2) = 0$, so lies in A_0 (the empty product is $1 \in A_0$). As $A_0 A_{-2} \subseteq A_{-2}$, the product lies in A_{-2}^n; hence $A_{-2n} \subseteq A_{-2}^n$.

The case $2n$. The same argument applied to $\delta_i = -d_{k_i}$ for a product of degree $2n$ gives disjoint $T_1, \dots, T_n$ with $\sum_{i \in T_l} d_{k_i} = 2$, so each $\prod_{i \in T_l} s_{k_i}$ lies in A_2 and the rest in A_0; hence $A_{2n} \subseteq A_2^n$. □

Lemma 41.12. *Let A be a commutative ring and $A_0 \subseteq A$ a subring such that A is finitely generated as an A_0-algebra. Let $\beta\colon A_0 \to \overline{\mathbb{Q}}_\ell$ be a ring homomorphism, $\mathfrak{a}$ an ideal of A and $f \in A$ such that*

(Lf1) $\ker\beta \subseteq \mathfrak{a}$*;*

(Lf2) $b\,f^n \notin \mathfrak{a}$ *for every $b \in A_0$ with $\beta(b) \neq 0$ and every $n \geq 0$.*

Then there is a ring homomorphism $\varphi\colon A \to \overline{\mathbb{Q}}_\ell$ with $\varphi|_{A_0} = \beta$, $\varphi(\mathfrak{a}) = 0$ and $\varphi(f) \neq 0$. If A_0 is an algebra over a coefficient ring $\mathcal{O}$ and β is an $\mathcal{O}$-algebra homomorphism, then φ is an $\mathcal{O}$-algebra homomorphism for the induced structure on A.

Proof. A prime ideal. Let $S = \{b\,f^n : b \in A_0,\ \beta(b) \neq 0,\ n \geq 0\}$. It contains 1 and is multiplicative, since $\beta(bb') = \beta(b)\beta(b') \neq 0$ in the field $\overline{\mathbb{Q}}_\ell$. By (Lf2), $S \cap \mathfrak{a} = \emptyset$, so no element of S maps to 0 in $A/\mathfrak{a}$ and the localisation $S^{-1}(A/\mathfrak{a})$ is a non-zero ring. The inverse image in A of a maximal ideal of it is a prime ideal $\mathfrak{q}$ with $\mathfrak{a} \subseteq \mathfrak{q}$ and $\mathfrak{q} \cap S = \emptyset$. Then $\mathfrak{q} \cap A_0 = \ker\beta$: the inclusion $\supseteq$ holds by (Lf1), and an element $b \in \mathfrak{q} \cap A_0$ with $\beta(b) \neq 0$ would be the element bf^0 of $S \cap \mathfrak{q}$. Also $f = 1 \cdot f^1 \in S$, so $f \notin \mathfrak{q}$.

A finitely generated algebra over a field. Let $D = A/\mathfrak{q}$, a domain, and $\bar{f} \neq 0$ the image of f. As $\mathfrak{q} \cap A_0 = \ker\beta$, the map $A_0 \to D$ induces an injection of $R = \beta(A_0) \cong A_0/\ker\beta$ into D, through which we regard R as a subring of D. Let $L \subseteq \overline{\mathbb{Q}}_\ell$ be the fraction field of R; the inclusion $R \subseteq D$ extends uniquely to an embedding of L into the fraction field of D. Let E be the subring of the fraction field of D generated by D, $\bar{f}^{-1}$ and L. It is a non-zero L-algebra, generated as an L-algebra by $\bar{f}^{-1}$ and the images of finitely many elements that generate A as an A_0-algebra (the image of A_0 is $R \subseteq L$). Let $\mathfrak{n}$ be a maximal ideal of E. The field $E/\mathfrak{n}$ contains L and is finitely generated as an L-algebra, so by Zariski's lemma (the weak Nullstellensatz; Atiyah–Macdonald, *Introduction to commutative algebra*, Cor. 5.24) it is a finite extension of L. Since $\overline{\mathbb{Q}}_\ell$ is algebraically closed and contains L, there is a field embedding $\iota\colon E/\mathfrak{n} \to \overline{\mathbb{Q}}_\ell$ restricting to the inclusion on L.

The homomorphism. Let φ be the composite $A \to D \to E \to E/\mathfrak{n} \xrightarrow{\iota} \overline{\mathbb{Q}}_\ell$. For $b \in A_0$ the image of b in D is $\beta(b) \in R \subseteq L$, so $\varphi(b) = \iota(\beta(b)) = \beta(b)$. As $\mathfrak{a} \subseteq \mathfrak{q}$, $\varphi(\mathfrak{a}) = 0$. The image of f in E is the unit $\bar{f}$, so its image in the field $E/\mathfrak{n}$ is non-zero and $\varphi(f) \neq 0$, ι being injective. Finally, if $\mathcal{O} \to A_0$ is the structure map and β is $\mathcal{O}$-linear, then for $c \in \mathcal{O}$ the image of c in A lies in A_0 and $\varphi(c \cdot 1) = \beta(c \cdot 1)$, so φ is an $\mathcal{O}$-algebra homomorphism. □

Proposition 41.13. *Let $\mathcal{O}$ be a coefficient ring with uniformiser ϖ, J a finite set with a map* $\mathrm{wt}\colon J \to \{-1, 1, 2\}$ *such that $n = \#\mathrm{wt}^{-1}(-1)$, $n_1 = \#\mathrm{wt}^{-1}(1)$ and $n_2 = \#\mathrm{wt}^{-1}(2)$ are ≥ 1, and $P = \mathcal{O}[\ell^{-1}][[X_i : i \in J]]$ with the weights defined by* wt*. Let $A \subseteq P$ be an $\mathcal{O}$-subalgebra such that, with A_j the set of elements of A of weight j and φ_0 the constant term, $A = \bigoplus_j A_j$, (A, φ_0) is a graded $\mathcal{O}$-algebra with a fixed point, and the inclusion $A \to P$ satisfies (Sm1)–(Sm3). Let u be a system of equations for (A, φ_0) with counts* $\mathrm{ne}(-1) = n+1$, $\mathrm{ne}(1) = n_1 - 1$, $\mathrm{ne}(2) = n_2 - 1$, $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$*, let $y_1, \dots, y_n \in A_{-1}$ and $c_1, \dots, c_n \geq 0$ be integers with*

$$u_{-1,i} - \varpi^{c_i} y_i \in \mathrm{Sq}(\varphi_0) \quad (1 \leq i \leq n), \qquad u_{-1,n+1} \in \mathrm{Sq}(\varphi_0),$$

and let $a \in A_0$ with $\varphi_0(a) = 0$. Assume that there is $N \geq 1$ with

$$\left(\mathfrak{m}_{A_0}\mathrm{Rs}(u) \cdot \mathrm{Irr}(\mathrm{Rs}(u))\right)^N \subseteq (\boldsymbol{\sigma}(u), a),$$

$\mathfrak{m}_{A_0}$ *the maximal ideal of* A_0*. Then in large degree* $m \in \mathbb{Z}^3$*,* $\mathrm{eu}(\boldsymbol{\sigma}(u); \mathrm{Rs}(u)/(a))(m)$ *is defined and*

$$\mathrm{eu}(\boldsymbol{\sigma}(u); \mathrm{Rs}(u)/(a))(m) \;\geq\; 2^{n+n_1-1} \sum_{i=1}^{n} c_i.$$

Proof. Write $\mathrm{Rs} = \mathrm{Rs}(u)$, $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$, $\mathfrak{m} = \mathfrak{m}_{A_0}$ and $M = n_1 + n_2 - 2$. As $\mathrm{ne}(1) = n_1 - 1$ and $\mathrm{ne}(2) = n_2 - 1$, $\boldsymbol{\sigma}$ consists of n elements $u_{-1,i}^2 T_0$ of degree e_0, M elements of degree e_1 and $w^2 T_2$ of degree e_2. By Lemma 41.8, item 2, Rs is a standard $\mathbb{N}^3$-graded algebra over the Noetherian local ring A_0, and it is Noetherian (Lemma 41.14, item 1). A sequence $\boldsymbol{x}$ of homogeneous elements is called *admissible for* a finitely generated graded Rs-module G if $(\mathfrak{m}\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs}))^{N'} \subseteq \mathrm{Ann}_{\mathrm{Rs}}(G) + (\boldsymbol{x})$ for some $N' \geq 1$; then $\mathrm{eu}(\boldsymbol{x}; G)(m)$ is defined in large degree (Lemma 41.14, item 2).

Step 1: the leading-form quotient. The hypotheses of Lemma 41.17 hold ($A \subseteq P$ with (Sm1)–(Sm3), $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$, $\mathrm{ne}(-1) = n + 1$, $w \in \mathrm{Sq}(\varphi_0)$). Let $\mathfrak{q}$ be the homogeneous prime ideal it provides and $F = \mathrm{Rs}/\mathfrak{q}$, so $\mathrm{Ann}_{\mathrm{Rs}}(F) = \mathfrak{q}$. By its item 2, $a \in \mathfrak{q}$, as $\varphi_0(a) = 0$.

Step 2: passing from $\mathrm{Rs}/(a)$ *to* F*.* By hypothesis $\boldsymbol{\sigma}$ is admissible for $\mathrm{Rs}/(a)$, whose annihilator is (a). As $a \in \mathfrak{q}$, there is an exact sequence $0 \to \mathfrak{q}/(a) \to \mathrm{Rs}/(a) \to F \to 0$ of finitely generated graded modules with degree-preserving maps. By Lemma 41.14, item 3, in large degree $\mathrm{eu}(\boldsymbol{\sigma}; \mathrm{Rs}/(a))(m) = \mathrm{eu}(\boldsymbol{\sigma}; \mathfrak{q}/(a))(m) + \mathrm{eu}(\boldsymbol{\sigma}; F)(m)$, all three defined; $\boldsymbol{\sigma}$ is admissible for $\mathfrak{q}/(a)$, whose annihilator contains (a), so $\mathrm{eu}(\boldsymbol{\sigma}; \mathfrak{q}/(a))(m) \geq 0$ in large degree by Lemma 41.15. Hence in large degree

$$\mathrm{eu}(\boldsymbol{\sigma}; \mathrm{Rs}/(a))(m) \geq \mathrm{eu}(\boldsymbol{\sigma}; F)(m).$$

Step 3: replacing $u_{-1,i}$ *by* $\varpi^{c_i} y_i$ *on* F*.* Let $\boldsymbol{\sigma}'$ be $\boldsymbol{\sigma}$ with $u_{-1,i}^2 T_0$ replaced by $\varpi^{2c_i} y_i^2 T_0 = (\varpi^{c_i} y_i)^2 T_0$ for $1 \leq i \leq n$ (of degree e_0, as $y_i^2 \in A_{-2}$). Since $u_{-1,i} - \varpi^{c_i} y_i \in \mathrm{Sq}(\varphi_0)$ with both terms in A_{-1}, item 3 of Lemma 41.17 gives $u_{-1,i}^2 T_0 - \varpi^{2c_i} y_i^2 T_0 \in \mathfrak{q}$. So corresponding members of $\boldsymbol{\sigma}$ and $\boldsymbol{\sigma}'$ have the same degree and act in the same way on F; as the terms of a Koszul complex depend only on the degrees and its differentials only on the action of the elements on the module, $\mathrm{Kos}_\bullet(\boldsymbol{\sigma}; F) = \mathrm{Kos}_\bullet(\boldsymbol{\sigma}'; F)$ and $\mathrm{eu}(\boldsymbol{\sigma}; F) = \mathrm{eu}(\boldsymbol{\sigma}'; F)$. Moreover $\mathfrak{q} + (\boldsymbol{\sigma}') = \mathfrak{q} + (\boldsymbol{\sigma}) \supseteq (\boldsymbol{\sigma}, a)$, so $\boldsymbol{\sigma}'$, and every sequence generating an ideal containing $(\boldsymbol{\sigma}')$, is admissible for F.

Step 4: peeling the powers of ϖ*.* For $0 \leq k \leq n$ let $\boldsymbol{\sigma}^{[k]}$ be $\boldsymbol{\sigma}'$ with $\varpi^{2c_i} y_i^2 T_0$ replaced by $y_i^2 T_0$ for $i \leq k$; so $\boldsymbol{\sigma}^{[0]} = \boldsymbol{\sigma}'$, and each $(\boldsymbol{\sigma}^{[k]})$ contains $(\boldsymbol{\sigma}')$. Let $\boldsymbol{\rho}_k$ be $\boldsymbol{\sigma}^{[k]}$ with its k-th member removed. If $c_k \geq 1$, Lemma 41.18, applied to $S = \mathrm{Rs}$, the homogeneous prime $\mathfrak{q}$, $\beta = \varpi \notin \mathfrak{q}$ (item 1 of Lemma 41.17), the sequence $\boldsymbol{\sigma}^{[k]}$, its k-th member and $c = 2c_k$ (so that the modified sequence is $\boldsymbol{\sigma}^{[k-1]}$, admissible for F by Step 3), gives in large degree

$$\mathrm{eu}(\boldsymbol{\sigma}^{[k-1]}; F)(m) = \mathrm{eu}(\boldsymbol{\sigma}^{[k]}; F)(m) + 2c_k \,\mathrm{eu}(\boldsymbol{\rho}_k; F/\varpi F)(m);$$

if $c_k = 0$, then $\boldsymbol{\sigma}^{[k-1]} = \boldsymbol{\sigma}^{[k]}$ and the same identity holds. Adding over k,

$$\mathrm{eu}(\boldsymbol{\sigma}'; F)(m) = \mathrm{eu}(\boldsymbol{\sigma}^{[n]}; F)(m) + \sum_{k=1}^{n} 2c_k \,\mathrm{eu}(\boldsymbol{\rho}_k; F/\varpi F)(m)$$

in large degree, and $\mathrm{eu}(\boldsymbol{\sigma}^{[n]}; F)(m) \geq 0$ in large degree by Lemma 41.15, $\boldsymbol{\sigma}^{[n]}$ being admissible for F.

Step 5: the Euler characteristics modulo ϖ*.* By item 4 of Lemma 41.17, every piece $(F/\varpi F)_\mu$ has finite length $h(\mu)$, with h as there for $\mu \in \mathbb{N}^3$, and $(F/\varpi F)_\mu = 0$ for $\mu \notin \mathbb{N}^3$. For a sequence $\boldsymbol{\rho}$ with degrees d_j, $\mathrm{Kos}_p(\boldsymbol{\rho}; F/\varpi F)_m = \bigoplus_{\#J=p} (F/\varpi F)_{m-d_J}$ has finite length, and the alternating sum of the lengths of the homology of a finite complex of modules of finite length equals that

of its terms (additivity of length on $0 \to Z_p \to C_p \to B_{p-1} \to 0$ and $0 \to B_p \to Z_p \to H_p \to 0$). Each $\boldsymbol{\rho}_k$ consists of $n-1$ elements of degree e_0, M of degree e_1 and one of degree e_2; the subsets J containing i of the first kind, j of the second and ε of the third number $\binom{n-1}{i}\binom{M}{j}$. Hence for $m \in \mathbb{N}^3$ with $m \geq (n-1, M, 1)$, where all $m - d_J$ lie in $\mathbb{N}^3$,

$$\operatorname{eu}(\boldsymbol{\rho}_k; F/\varpi F)(m) = \sum_{i=0}^{n-1}\sum_{j=0}^{M}\sum_{\varepsilon=0}^{1}(-1)^{i+j+\varepsilon}\binom{n-1}{i}\binom{M}{j}h(m - ie_0 - je_1 - \varepsilon e_2) = 2^{\,n+n_1-2}$$

by Lemma 41.19 (with $n, n_1, n_2 \geq 1$).

Step 6: conclusion. Choosing m in large degree for Steps 2, 4 and 5 at once, Steps 2–5 give that $\operatorname{eu}(\boldsymbol{\sigma}; \operatorname{Rs}/(a))(m)$ is defined and

$$\operatorname{eu}(\boldsymbol{\sigma}; \operatorname{Rs}/(a))(m) \geq \operatorname{eu}(\boldsymbol{\sigma}'; F)(m) \geq \sum_{k=1}^{n} 2c_k \cdot 2^{\,n+n_1-2} = 2^{\,n+n_1-1}\sum_{i=1}^{n} c_i.$$

□

Lemma 41.14. *Let B be a Noetherian local ring with maximal ideal $\mathfrak{m}_B$, S a standard $\mathbb{N}^k$-graded B-algebra and F a finitely generated graded S-module. Then:*

1. *S is Noetherian, and every S_μ and every F_m is a finitely generated B-module. If F is annihilated by an ideal $\mathfrak{b}$ of S with $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \mathfrak{b}$ for some $N \geq 1$, then F_m has finite length for m in large degree.*

2. *For every sequence $\boldsymbol{x}$ of homogeneous elements and every p, $H_p(\boldsymbol{x}; F) = \bigoplus_m H_p(\boldsymbol{x}; F)_m$ is a finitely generated graded S-module annihilated by $\operatorname{Ann}_S(F) + (\boldsymbol{x})$. Consequently, if*

$$(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(F) + (\boldsymbol{x}) \quad \text{for some } N \geq 1, \tag{41.3}$$

   then $\operatorname{eu}(\boldsymbol{x}; F)(m)$ is defined in large degree.

3. *Let $0 \to F' \to F \to F'' \to 0$ be an exact sequence of finitely generated graded S-modules with degree-preserving maps, and let $\boldsymbol{x}$ satisfy (41.3) for F. Then (41.3) holds for F' and F'', and in large degree*

$$\operatorname{eu}(\boldsymbol{x}; F)(m) = \operatorname{eu}(\boldsymbol{x}; F')(m) + \operatorname{eu}(\boldsymbol{x}; F'')(m).$$

4. *For $\delta \in \mathbb{Z}^k$ and all m, $\operatorname{eu}(\boldsymbol{x}; F(-\delta))(m)$ is defined if and only if $\operatorname{eu}(\boldsymbol{x}; F)(m - \delta)$ is, and then they are equal.*

Proof. Item 1. By the definition of a standard algebra, $S_\mu = S_{e_0}^{\mu_0} \cdots S_{e_{k-1}}^{\mu_{k-1}}$ (the B-span of products) by induction on μ, so each S_μ is a finitely generated B-module, the S_{e_i} being finitely generated; and S is generated as a B-algebra by finitely many generators of the S_{e_i}, hence Noetherian by Hilbert's basis theorem. The homogeneous components of a finite generating set of F give homogeneous generators $f_1, \ldots, f_t$ of degrees $\delta_1, \ldots, \delta_t \in \mathbb{Z}^k$, and $F_m = \sum_j S_{m-\delta_j} f_j$ (with $S_\mu = 0$ for $\mu \notin \mathbb{N}^k$), a finitely generated B-module. Now let $\mathfrak{b}F = 0$ with $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \mathfrak{b}$, and let $m \geq \delta_j + N\not\Vdash$ for all j. Since $S_{\not\Vdash} = S_{e_0} \cdots S_{e_{k-1}} \subseteq \operatorname{Irr}(S)$, we have $S_{m-\delta_j} = S_{\not\Vdash}^N S_{m-\delta_j - N\not\Vdash} \subseteq \operatorname{Irr}(S)^N$, so $F_m \subseteq \operatorname{Irr}(S)^N F$ and

$$\mathfrak{m}_B^N F_m \subseteq (\mathfrak{m}_B S)^N \operatorname{Irr}(S)^N F = (\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N F \subseteq \mathfrak{b}F = 0.$$

A finitely generated module over the Artinian ring $B/\mathfrak{m}_B^N$ has finite length.

Item 2. Each $\mathrm{Kos}_p(\boldsymbol{x}; F)$ is a finite direct sum of shifts of F, a finitely generated graded S-module, and the differential preserves degrees; so its kernels and images are graded submodules and, S being Noetherian, $H_p(\boldsymbol{x}; F)$ is finitely generated and graded. It is annihilated by $\mathrm{Ann}_S(F)$, which annihilates every term of the complex, and by every member x_j of $\boldsymbol{x}$, since multiplication by x_j on a Koszul complex is null-homotopic ([55, Prop. 1.6.5]). If (41.3) holds, item 1 with $\mathfrak{b} = \mathrm{Ann}_S(F) + (\boldsymbol{x})$, applied to the finitely many non-zero modules $H_p(\boldsymbol{x}; F)$, $0 \le p \le q$ (q the length of $\boldsymbol{x}$), shows that all lengths in (41.2) are finite in large degree.

Item 3. The ideal $\mathrm{Ann}_S(F)$ annihilates F' and F'', so (41.3) passes to them. As $\mathrm{Kos}_p(\boldsymbol{x}; -)$ is a finite direct sum of shifts, $0 \to \mathrm{Kos}_\bullet(\boldsymbol{x}; F') \to \mathrm{Kos}_\bullet(\boldsymbol{x}; F) \to \mathrm{Kos}_\bullet(\boldsymbol{x}; F'') \to 0$ is an exact sequence of complexes, in each degree m. Its long exact homology sequence in degree m is a finite exact sequence of B-modules, which by item 2 (for F, F', F'') consists of modules of finite length in large degree; the alternating sum of the lengths in such a sequence is 0, which is the assertion.

Item 4. We have $\mathrm{Kos}_\bullet(\boldsymbol{x}; F(-\delta))_m = \mathrm{Kos}_\bullet(\boldsymbol{x}; F)_{m-\delta}$ as complexes of B-modules. □

Lemma 41.15. *Let B be a Noetherian local ring with maximal ideal $\mathfrak{m}_B$, S a standard $\mathbb{N}^k$-graded B-algebra, F a finitely generated graded S-module and $\boldsymbol{x}$ a sequence of homogeneous elements of S with $(\mathfrak{m}_B S \cdot \mathrm{Irr}(S))^N \subseteq \mathrm{Ann}_S(F) + (\boldsymbol{x})$ for some $N \ge 1$. Then in large degree $m \in \mathbb{Z}^k$, $\mathrm{eu}(\boldsymbol{x}; F)(m)$ is defined and*

$$\mathrm{eu}(\boldsymbol{x}; F)(m) \ge 0.$$

Proof. In this proof, a sequence $\boldsymbol{x}$ of homogeneous elements is *admissible for* a finitely generated graded S-module M if $(\mathfrak{m}_B S \cdot \mathrm{Irr}(S))^N \subseteq \mathrm{Ann}_S(M) + (\boldsymbol{x})$ for some $N \ge 1$. By Lemma 41.14, item 2, $\mathrm{eu}(\boldsymbol{x}; F)(m)$ is defined in large degree. We prove the inequality by induction on the length q of $\boldsymbol{x}$, for all F at once. If $\boldsymbol{x}$ is admissible for M, it is admissible for every module whose annihilator contains $\mathrm{Ann}_S(M)$, in particular for submodules and quotients of M.

Step 1: a filtration with prime quotients. We show: there are graded submodules $0 = F_0 \subset F_1 \subset \cdots \subset F_t = F$ and degree-preserving isomorphisms $F_i/F_{i-1} \cong (S/\mathfrak{q}_i)(-\delta_i)$ with homogeneous prime ideals $\mathfrak{q}_i$ and $\delta_i \in \mathbb{Z}^k$. Let $M \ne 0$ be a finitely generated graded S-module. As S is Noetherian (Lemma 41.14, item 1), among the annihilators $\mathrm{Ann}_S(f)$ of non-zero homogeneous $f \in M$ there is a maximal one, $\mathfrak{q} = \mathrm{Ann}_S(f) \ne S$. It is homogeneous: if $af = 0$, the products $a_\mu f$ of the components of a lie in distinct degrees, so all vanish. For homogeneous a, b with $ab \in \mathfrak{q}$ and $b \notin \mathfrak{q}$, $bf \ne 0$ is homogeneous and $\mathrm{Ann}_S(bf) \supseteq \mathfrak{q}$, so equality holds by maximality and $a \in \mathfrak{q}$. For arbitrary $a, b \notin \mathfrak{q}$ with $ab \in \mathfrak{q}$: removing from a and b their components lying in $\mathfrak{q}$ changes neither a, b modulo $\mathfrak{q}$ nor $ab \in \mathfrak{q}$, so we may assume that no component of a or b lies in $\mathfrak{q}$. Order $\mathbb{Z}^k$ lexicographically, a total order compatible with addition, and let a^*, b^* be the components of largest degree. The component of ab of degree $\deg a^* + \deg b^*$ is $a^* b^*$, every other pair of components having a smaller degree sum; as $\mathfrak{q}$ is homogeneous, $a^* b^* \in \mathfrak{q}$, so a^* or b^* lies in $\mathfrak{q}$, a contradiction. Hence $\mathfrak{q}$ is prime and $Sf \cong (S/\mathfrak{q})(-\deg f)$, $1 \mapsto f$. Starting with $M = F$ and continuing with F/F_i (lifting the submodule found), we obtain a strictly increasing chain of graded submodules, which stops at F because F is a Noetherian module.

Step 2: reduction to $S/\mathfrak{q}$. $\boldsymbol{x}$ is admissible for each F_i and each F_i/F_{i-1}. By Lemma 41.14, items 3 and 4, in large degree

$$\mathrm{eu}(\boldsymbol{x}; F)(m) = \sum_{i=1}^{t} \mathrm{eu}(\boldsymbol{x}; S/\mathfrak{q}_i)(m - \delta_i),$$

and $\boldsymbol{x}$ is admissible for $S/\mathfrak{q}_i$, whose annihilator is $\mathfrak{q}_i \supseteq \operatorname{Ann}_S(F)$. As $m - \delta_i$ is in large degree when m is, it suffices to prove $\operatorname{eu}(\boldsymbol{x}; D)(m) \geq 0$ in large degree for $D = S/\mathfrak{q}$, $\mathfrak{q}$ a homogeneous prime ideal with $\boldsymbol{x}$ admissible for D.

Step 3: $q = 0$. Then $\operatorname{eu}((); D)(m) = \operatorname{length}_B D_m \geq 0$.

Step 4: $q \geq 1$. Write $\boldsymbol{x} = (s, \boldsymbol{x}')$ with $s \in S_d$; the induction hypothesis applies to $\boldsymbol{x}'$. D is a domain.

- If $s \notin \mathfrak{q}$, then $0 :_D s = 0$, and by Lemma 41.16, in large degree

$$\operatorname{eu}(\boldsymbol{x}; D)(m) = \operatorname{eu}(\boldsymbol{x}'; D/sD)(m),$$

  as $\operatorname{eu}(\boldsymbol{x}'; 0) = 0$. Since $\operatorname{Ann}_S(D/sD) \supseteq \mathfrak{q} + (s)$, $\boldsymbol{x}'$ is admissible for D/sD, and the induction hypothesis gives $\operatorname{eu}(\boldsymbol{x}; D)(m) \geq 0$ in large degree.

- If $s \in \mathfrak{q}$ and $S_d \subseteq \mathfrak{q}$, then $d \neq 0$, as $1 \in S_0$. Since $S_d = S_{e_0}^{d_0} \cdots S_{e_{k-1}}^{d_{k-1}}$ and $\mathfrak{q}$ is prime, $S_{e_i} \subseteq \mathfrak{q}$ for some i with $d_i \geq 1$ (otherwise a product of elements $y_i \in S_{e_i} \setminus \mathfrak{q}$ lies in $S_d \setminus \mathfrak{q}$). Then $S_\mu = S_{\mu - e_i} S_{e_i} \subseteq \mathfrak{q}$, so $D_\mu = 0$, for every $\mu \in \mathbb{N}^k$ with $\mu_i \geq 1$, and $D_\mu = 0$ for $\mu \notin \mathbb{N}^k$. Every term D_{m-d_J} of $\operatorname{Kos}_\bullet(\boldsymbol{x}; D)_m$ vanishes once m_i exceeds the i-th coordinates of all d_J; so $\operatorname{eu}(\boldsymbol{x}; D)(m) = 0$ in large degree.

- If $s \in \mathfrak{q}$ and there is $\tau \in S_d \setminus \mathfrak{q}$: then $sD = 0$ and $0 :_D s = D$, and $\boldsymbol{x}'$ is admissible for D, since $\mathfrak{q} + (s, \boldsymbol{x}') = \mathfrak{q} + (\boldsymbol{x}')$. By Lemma 41.16, in large degree $\operatorname{eu}(\boldsymbol{x}; D)(m) = \operatorname{eu}(\boldsymbol{x}'; D)(m) - \operatorname{eu}(\boldsymbol{x}'; D)(m-d)$. Multiplication by τ is injective on the domain D, so $0 \to D(-d) \xrightarrow{\tau} D \to D/\tau D \to 0$ is exact with degree-preserving maps, and by Lemma 41.14, items 3 and 4, in large degree $\operatorname{eu}(\boldsymbol{x}'; D/\tau D)(m) = \operatorname{eu}(\boldsymbol{x}'; D)(m) - \operatorname{eu}(\boldsymbol{x}'; D)(m-d)$. Hence $\operatorname{eu}(\boldsymbol{x}; D)(m) = \operatorname{eu}(\boldsymbol{x}'; D/\tau D)(m)$ in large degree; $\boldsymbol{x}'$ is admissible for $D/\tau D$, and the induction hypothesis gives $\operatorname{eu}(\boldsymbol{x}; D)(m) \geq 0$.

Finitely many conditions in large degree hold simultaneously in large degree, which completes the induction. □

Lemma 41.16. *Let B be a Noetherian local ring with maximal ideal $\mathfrak{m}_B$, S a standard $\mathbb{N}^k$-graded B-algebra and F a finitely generated graded S-module. Let $s \in S_d$, let $\boldsymbol{x}'$ be a sequence of homogeneous elements, write $(s, \boldsymbol{x}')$ for s followed by $\boldsymbol{x}'$, and assume $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(F) + (s, \boldsymbol{x}')$ for some $N \geq 1$. Let $0 :_F s = \{f \in F : sf = 0\}$. Then in large degree $m \in \mathbb{Z}^k$ the Euler characteristics below are defined and*

$$\operatorname{eu}((s, \boldsymbol{x}'); F)(m) = \operatorname{eu}(\boldsymbol{x}'; F/sF)(m) - \operatorname{eu}(\boldsymbol{x}'; 0 :_F s)(m - d).$$

Proof. Write $Y = \operatorname{Kos}_\bullet((s, \boldsymbol{x}'); F)$ and $K(M) = \operatorname{Kos}_\bullet(\boldsymbol{x}'; M)$ with differential ∂', for graded S-modules M; let $Z = 0 :_F s$, a graded submodule as s is homogeneous. All maps below preserve degrees.

The cone description. Give s the index 1 and the members of $\boldsymbol{x}'$ the indices $2, 3, \ldots$. Sorting the basis elements ϵ_J of Y according to whether $1 \in J$ identifies $Y_p = K_p(F) \oplus K_{p-1}(F)(-d)$, the second summand corresponding to the $\epsilon_{\{1\} \cup J'}$. For $J = \{1\} \cup J'$, the term $t = 1$ of the differential is $sf\epsilon_{J'}$, and the terms $t \geq 2$ are those of $\partial'(f\epsilon_{J'})$ with the opposite sign, since the position of each j_t in J' is $t - 1$. Hence

$$\partial(y, z) = (\partial' y + sz,\ -\partial' z).$$

A subcomplex and its quotient. The submodules $Y'_p = 0 \oplus K_{p-1}(Z)(-d)$ form a subcomplex, since $\partial(0,z) = (sz, -\partial' z) = (0, -\partial' z)$ for z with coefficients in Z; it is $K(Z)(-d)$ shifted by one place with differential $-\partial'$, so $H_p(Y') \cong H_{p-1}(\boldsymbol{x}'; Z)(-d)$. The quotient $Y'' = Y/Y'$ has $Y''_p = K_p(F) \oplus K_{p-1}(F/Z)(-d)$ and $\partial(y, \bar{z}) = (\partial' y + sz, -\partial' \bar{z})$, well defined as $sZ = 0$. Let $\Phi\colon Y'' \to K(F/sF)$, $(y, \bar{z}) \mapsto \bar{y}$. It is a surjective map of complexes, since sz has coefficients in sF. Its kernel W consists of the $(y, \bar{z})$ with $y \in K_p(sF)$, and W is acyclic: let $(y, \bar{z}) \in W$ be a cycle, so $\partial' y = -sz$ and $\partial' \bar{z} = 0$. Write $y = sv$ with $v \in K_p(F)$. Then $s(\partial' v + z) = \partial' y + sz = 0$, so $\partial' \bar{v} = -\bar{z}$ in $K(F/Z)$, and $\partial(0, \bar{v}) = (sv, -\partial' \bar{v}) = (y, \bar{z})$. By the long exact sequence of $0 \to W \to Y'' \to K(F/sF) \to 0$, Φ induces isomorphisms $H_p(Y'') \cong H_p(\boldsymbol{x}'; F/sF)$.

Lengths. The long exact sequence of $0 \to Y' \to Y \to Y'' \to 0$ in degree m reads

$$\cdots \to H_{p-1}(\boldsymbol{x}'; Z)_{m-d} \to H_p((s, \boldsymbol{x}'); F)_m \to H_p(\boldsymbol{x}'; F/sF)_m \to H_{p-2}(\boldsymbol{x}'; Z)_{m-d} \to \cdots,$$

a finite exact sequence. Since $\operatorname{Ann}_S(F/sF)$ and $\operatorname{Ann}_S(Z)$ contain $\operatorname{Ann}_S(F) + (s)$, the hypothesis gives $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(M) + (\boldsymbol{x}')$ for $M = F/sF$ and $M = Z$, and $\subseteq \operatorname{Ann}_S(F) + (s, \boldsymbol{x}')$ for F. By Lemma 41.14, items 1 and 2 (Z and F/sF are finitely generated, S being Noetherian), the three Euler characteristics are defined in large degree, in the variable $m-d$ for Z, which is in large degree when m is. Taking the alternating sum of lengths, with $H_p(Y')_m \cong H_{p-1}(\boldsymbol{x}'; Z)_{m-d}$ contributing with the sign $(-1)^p = -(-1)^{p-1}$, gives the formula. □

Lemma 41.17. *Let $\mathcal{O}$ be a coefficient ring with uniformiser ϖ, J a finite set with a map* $\mathrm{wt}\colon J \to \{-1, 1, 2\}$ *such that $n = \#\mathrm{wt}^{-1}(-1)$, $n_1 = \#\mathrm{wt}^{-1}(1)$ and $n_2 = \#\mathrm{wt}^{-1}(2)$ are ≥ 1, and $P = \mathcal{O}[\ell^{-1}][[X_i : i \in J]]$ with the weights defined by* wt. *Let $A \subseteq P$ be an $\mathcal{O}$-subalgebra such that, with A_j the set of elements of A of weight j and φ_0 the constant term, $A = \bigoplus_j A_j$, (A, φ_0) is a graded $\mathcal{O}$-algebra with a fixed point, and the inclusion $A \to P$ satisfies (Sm1)–(Sm3). Let u be a system of equations for (A, φ_0) with $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$ and $\mathrm{ne}(-1) = n + 1$ such that $u_{-1,n+1} \in \mathrm{Sq}(\varphi_0)$. Then there is a homogeneous prime ideal $\mathfrak{q}$ of $\mathrm{Rs}(u)$ such that the graded $\mathrm{Rs}(u)$-module $F = \mathrm{Rs}(u)/\mathfrak{q}$ has the following properties:*

1. *$\varpi \notin \mathfrak{q}$;*
2. *every $b \in A_0$ with $\varphi_0(b) = 0$ lies in $\mathfrak{q}$, and $bF \subseteq \varpi F$ for every b in the maximal ideal of A_0;*
3. *$f^2 T_0 - g^2 T_0 \in \mathfrak{q}$ for all $f, g \in A_{-1}$ with $f - g \in \mathrm{Sq}(\varphi_0)$;*
4. *for every $\mu \in \mathbb{N}^3$, the A_0-module $(F/\varpi F)_\mu$ has length*

$$h(\mu) = \binom{2\mu_0 + 4\mu_2 + n - 1}{n - 1} p(2\mu_1 + 2\mu_2),$$

where $p(k)$ is the number of pairs $(\beta, \gamma) \in \mathbb{N}^{n_1} \times \mathbb{N}^{n_2}$ with $|\beta| + 2|\gamma| = k$, $|\beta|$ the sum of the entries.

Proof. Write $K_0 = \mathcal{O}[\ell^{-1}]$, $\mathrm{Rs} = \mathrm{Rs}(u)$, $\mathfrak{m}_0 = \ker \varphi_0$. For a monomial $X^\alpha = \prod_i X_i^{\alpha_i}$ let $\mathrm{xd}(\alpha) = \sum_{\mathrm{wt}(i)=-1} \alpha_i$ (its *x-degree*) and $\mathrm{pw}(\alpha) = \sum_{\mathrm{wt}(i)=1} \alpha_i + 2\sum_{\mathrm{wt}(i)=2} \alpha_i$; its weight is $\mathrm{pw}(\alpha) - \mathrm{xd}(\alpha)$. For $g \in P$ and $k \in \mathbb{N}$ let $g_{[k]}$ be the sum of the terms of g of x-degree k, and $\mathrm{Fil}_k = \{g \in P : g_{[k']} = 0 \text{ for } k' < k\}$. Since x-degrees add under multiplication of monomials and each coefficient of a product is a finite sum of products of coefficients, $\mathrm{Fil}_k \mathrm{Fil}_{k'} \subseteq \mathrm{Fil}_{k+k'}$ and $(gg')_{[k+k']} = g_{[k]} g'_{[k']}$ for $g \in \mathrm{Fil}_k$, $g' \in \mathrm{Fil}_{k'}$. Put $\theta(\mu) = 2\mu_0 + 4\mu_2$ for $\mu \in \mathbb{N}^3$. For $g \in P$, $g^{(1)}$ is its linear part (the terms of total degree one).

Step 1: $N^\mu \subseteq \mathrm{Fil}_{\theta(\mu)} \cap A_{-2\mu_0+2\mu_1-2\mu_2}$. A monomial of weight -2 has x-degree $\mathrm{pw}+2 \geq 2$, so $A_{-2} \subseteq \mathrm{Fil}_2$; trivially $A_2 \subseteq \mathrm{Fil}_0$. Elements of $\mathfrak{m}_0$ have zero constant term, so elements of $\mathfrak{m}_0^2$ have zero linear part; hence an element f of $\mathrm{Sq}(\varphi_0)$ has $f^{(1)} = 0$ ($cf \in \mathfrak{m}_0^2$ with $c \neq 0$). A monomial of weight -1 has x-degree $\mathrm{pw}+1 \geq 1$, with equality only for a single variable of weight -1, a linear term. So $w \in \mathrm{Fil}_2$, as $w \in A_{-1} \cap \mathrm{Sq}(\varphi_0)$, and $N_2 \subseteq \mathrm{Fil}_4$, since Fil_k is an ideal of P. As $N_0, N_2 \subseteq A_{-2}$ and $N_1 = A_2$, the claim follows by multiplying.

For $x \in N^\mu$ the polynomial $x_{[\theta(\mu)]}$ is therefore a K_0-combination of monomials X^α with $\mathrm{xd}(\alpha) = \theta(\mu)$ and $\mathrm{pw}(\alpha) = 2\mu_1 + 2\mu_2$ (the weight plus the x-degree). Let G_μ be the K_0-span of these finitely many monomials. A monomial is the product of a monomial in the n variables of weight -1 and one in the variables of weights $1, 2$, so $\dim_{K_0} G_\mu = \binom{\theta(\mu)+n-1}{n-1} p(2\mu_1+2\mu_2) = h(\mu)$.

Step 2: the leading-form homomorphism and $\mathfrak{q}$. Define $\Lambda\colon \mathrm{Rs} \to K_0[X_i : i \in J][T_0, T_1, T_2]$ by $\Lambda(xT^\mu) = x_{[\theta(\mu)]}T^\mu$ for $x \in N^\mu$, additively on $\mathrm{Rs} = \bigoplus_\mu N^\mu T^\mu$. For $x \in N^\mu$, $x' \in N^{\mu'}$, Step 1 and the product rule give $(xx')_{[\theta(\mu+\mu')]} = x_{[\theta(\mu)]}x'_{[\theta(\mu')]}$, as θ is additive; and $\Lambda(1) = 1$. So Λ is a ring homomorphism mapping Rs_μ into $G_\mu T^\mu$. Let $\mathfrak{q} = \ker\Lambda$: it is homogeneous, Λ preserving degrees, and prime, the target being a domain. So $F \cong \Lambda(\mathrm{Rs}) = \bigoplus_\mu \Lambda_\mu T^\mu$ with $\Lambda_\mu = \{x_{[\theta(\mu)]} : x \in N^\mu\} \subseteq G_\mu$. For $b \in A_0 = N^0$, $b_{[0]}$ consists of the terms of weight 0 and x-degree 0, hence of positive weight 0: it is the constant term, $\Lambda(b) = \varphi_0(b)$. So $b \in A_0$ acts on $F \cong \Lambda(\mathrm{Rs})$ as multiplication by $\varphi_0(b) \in \mathcal{O}$.

Items 1–3. We have $\Lambda(\varpi) = \varpi \neq 0$. If $\varphi_0(b) = 0$, then $\Lambda(b) = 0$. If b lies in the maximal ideal of A_0, then $\varphi_0(b) \in \varpi\mathcal{O}$: otherwise $\varphi_0(b)$ is a unit of $\mathcal{O}$, and $\varphi_0(b) = b - (b - \varphi_0(b))$ lies in the maximal ideal, as $b - \varphi_0(b) \in \ker(\varphi_0|_{A_0})$, a proper ideal; so $bF = \varphi_0(b)F \subseteq \varpi F$. For $f \in A_{-1}$, $f \in \mathrm{Fil}_1$ and $f_{[1]}$ consists of the terms of x-degree 1 and positive weight 0, i.e. $f_{[1]} = f^{(1)}$; so $\Lambda(f^2T_0) = (f^{(1)})^2T_0$. If $f - g \in \mathrm{Sq}(\varphi_0)$, then $f^{(1)} = g^{(1)}$ (Step 1), hence $\Lambda(f^2T_0) = \Lambda(g^2T_0)$.

Step 3: $K_0\Lambda_\mu = G_\mu$. For $i \in J$, (Sm3) gives $f \in A$ with $f^{(1)} = c_iX_i$, $c_i \neq 0$. Writing $f = \sum_m f_m$ with $f_m \in A_m$, the terms of weight m of f are those of f_m, so $f_i = f_{\mathrm{wt}(i)} \in A_{\mathrm{wt}(i)}$ has $f_i^{(1)} = c_iX_i$. If $\mathrm{wt}(i) = -1$, $(f_i)_{[1]} = c_iX_i$ (Items 1–3); if $\mathrm{wt}(i) = 1$, $(f_i)_{[0]}$ consists of the terms of x-degree 0 and positive weight 1, so $(f_i)_{[0]} = c_iX_i$; if $\mathrm{wt}(i) = 2$, $(f_i)_{[0]}$ consists of the terms of x-degree 0 and positive weight 2, so it is c_iX_i plus a quadratic form in the variables of weight 1. Hence:

- for $\mathrm{wt}(a) = \mathrm{wt}(b) = -1$, $f_af_b \in A_{-2}$ and $(f_af_b)_{[2]} = c_ac_bX_aX_b$; so $K_0\Lambda_{e_0} = G_{e_0}$, the span of the quadratic monomials in the variables of weight -1;
- for $\mathrm{wt}(a) = \mathrm{wt}(b) = 1$, $f_af_b \in A_2$ and $(f_af_b)_{[0]} = c_ac_bX_aX_b$; with the f_i, $\mathrm{wt}(i) = 2$, this gives $K_0\Lambda_{e_1} = G_{e_1}$, the span of the X_aX_b ($\mathrm{wt}(a) = \mathrm{wt}(b) = 1$) and the X_i ($\mathrm{wt}(i) = 2$);
- for $f, f' \in A_{-2}$, $g \in A_2$, $ff'g \in N_2$ and $(ff'g)_{[4]} = f_{[2]}f'_{[2]}g_{[0]}$; so $K_0\Lambda_{e_2} \supseteq G_{e_0}G_{e_0}G_{e_1} = G_{e_2}$.

Since Rs is standard (Lemma 41.8, item 2), $\mathrm{Rs}_\mu = \mathrm{Rs}_{e_0}^{\mu_0}\mathrm{Rs}_{e_1}^{\mu_1}\mathrm{Rs}_{e_2}^{\mu_2}$, so $K_0\Lambda_\mu \supseteq G_{e_0}^{\mu_0}G_{e_1}^{\mu_1}G_{e_2}^{\mu_2}$. Every monomial X^α spanning G_μ lies in the right side: its factor in the variables of weight -1 has degree $2(\mu_0 + 2\mu_2)$, a product of $\mu_0 + 2\mu_2$ quadratic monomials; its factor in the variables of weights $1, 2$ has positive weight $2(\mu_1 + \mu_2)$, so contains an even number of variables of weight 1, and is a product of $\mu_1 + \mu_2$ monomials of positive weight 2 (pairs of variables of weight 1, single variables of weight 2); grouping two quadratic factors with one factor of positive weight 2 exactly μ_2 times gives a factorisation of type $G_{e_0}^{\mu_0}G_{e_1}^{\mu_1}G_{e_2}^{\mu_2}$. Hence $K_0\Lambda_\mu = G_\mu$.

Item 4. By Lemma 41.8, item 2, and Lemma 41.14, item 1, N^μ is a finitely generated A_0-module; as $\Lambda(bx) = \varphi_0(b)\Lambda(x)$ for $b \in A_0$, Λ_μ is the $\mathcal{O}$-span of the images of finitely many generators. It is torsion free, lying in a K_0-vector space, hence free over the discrete valuation ring

$\mathcal{O}$, of rank $\dim_{K_0} K_0\Lambda_\mu = h(\mu)$ by Steps 1 and 3. Thus $(F/\varpi F)_\mu \cong \Lambda_\mu/\varpi\Lambda_\mu \cong (\mathcal{O}/\varpi\mathcal{O})^{h(\mu)}$, on which A_0 acts through φ_0; its A_0-submodules are its $\mathcal{O}$-submodules, and its length is $h(\mu)$. $\square$

Lemma 41.18. *Let B be a Noetherian local ring with maximal ideal $\mathfrak{m}_B$, S a standard $\mathbb{N}^k$-graded B-algebra, $\mathfrak{q}$ a homogeneous prime ideal of S and $D = S/\mathfrak{q}$. Let $\beta \in B$ be such that its image in S_0 does not lie in $\mathfrak{q}$. Let $\boldsymbol{x} = (x_1, \dots, x_q)$ be a sequence of homogeneous elements of S, $1 \le i \le q$ and $c \ge 1$ an integer; let $\boldsymbol{x}^{(c)}$ be the sequence $\boldsymbol{x}$ with x_i replaced by $\beta^c x_i$ (of the same degree), and $\hat{\boldsymbol{x}}$ the sequence $\boldsymbol{x}$ with x_i removed. Assume that*

$$\big(\mathfrak{m}_B S \cdot \operatorname{Irr}(S)\big)^N \subseteq \mathfrak{q} + (\boldsymbol{x}^{(c)}) \quad \text{for some } N \ge 1.$$

Then in large degree $m \in \mathbb{Z}^k$ the Euler characteristics below are defined and

$$\operatorname{eu}(\boldsymbol{x}^{(c)}; D)(m) = \operatorname{eu}(\boldsymbol{x}; D)(m) + c \cdot \operatorname{eu}(\hat{\boldsymbol{x}}; D/\beta D)(m).$$

Proof. In this proof a sequence $\boldsymbol{y}$ of homogeneous elements is *admissible for* a finitely generated graded S-module M if $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^{N'} \subseteq \operatorname{Ann}_S(M) + (\boldsymbol{y})$ for some $N' \ge 1$; then $\operatorname{eu}(\boldsymbol{y}; M)(m)$ is defined in large degree by Lemma 41.14, item 2. The ring D is a domain with $\operatorname{Ann}_S(D) = \mathfrak{q}$, and β acts on D injectively, as $\beta \notin \mathfrak{q}$; all modules below are cyclic or quotients of cyclic modules, hence finitely generated, and β has degree 0, so multiplication by β preserves degrees.

Step 1: the order of the sequence does not matter. Let $E = \bigoplus_j S(-d_j)\epsilon_j$ ($d_j = \deg x_j$). Then $\operatorname{Kos}_p(\boldsymbol{x}; F) = \bigwedge^p E \otimes_S F$ with $\epsilon_J = \epsilon_{j_1} \wedge \cdots \wedge \epsilon_{j_p}$, and the differential of Definition 41.5 is $\partial(\epsilon_{l_1} \wedge \cdots \wedge \epsilon_{l_p} \otimes f) = \sum_t (-1)^{t+1} \epsilon_{l_1} \wedge \dots \widehat{\epsilon_{l_t}} \cdots \wedge \epsilon_{l_p} \otimes x_{l_t} f$ for $l_1 < \cdots < l_p$; both sides are alternating in $(l_1, \dots, l_p)$, so the same formula holds for every ordering of distinct indices. Hence renumbering the ϵ_j by a permutation identifies the Koszul complex of the permuted sequence with $\operatorname{Kos}_\bullet(\boldsymbol{x}; F)$, degree by degree; in particular eu is unchanged by permuting a sequence. We may therefore assume $i = 1$ and write $\boldsymbol{x} = (y, \hat{\boldsymbol{x}})$, $\boldsymbol{x}^{(c')} = (\beta^{c'} y, \hat{\boldsymbol{x}})$.

Step 2: admissibility. For $0 \le c' \le c$, $(\boldsymbol{x}^{(c')}) \supseteq (\boldsymbol{x}^{(c)})$, so $\boldsymbol{x}^{(c')}$ is admissible for D. As $\beta^c y \in \beta S \subseteq \operatorname{Ann}_S(D/\beta D)$ and $\mathfrak{q} \subseteq \operatorname{Ann}_S(D/\beta D)$, $\hat{\boldsymbol{x}}$ is admissible for $D/\beta D$. So all Euler characteristics in the assertion are defined in large degree.

Step 3: one factor of β. Let $1 \le c' \le c$ and $z = \beta^{c'-1} y$, of degree $d = \deg y$. We show that in large degree

$$\operatorname{eu}((\beta z, \hat{\boldsymbol{x}}); D)(m) = \operatorname{eu}((z, \hat{\boldsymbol{x}}); D)(m) + \operatorname{eu}(\hat{\boldsymbol{x}}; D/\beta D)(m).$$

- If $z \notin \mathfrak{q}$, then $\beta z \notin \mathfrak{q}$, $\mathfrak{q}$ being prime; so $0 :_D z = 0 :_D \beta z = 0$, and Lemma 41.16 (admissibility by Step 2) gives in large degree $\operatorname{eu}((z, \hat{\boldsymbol{x}}); D)(m) = \operatorname{eu}(\hat{\boldsymbol{x}}; D/zD)(m)$ and $\operatorname{eu}((\beta z, \hat{\boldsymbol{x}}); D)(m) = \operatorname{eu}(\hat{\boldsymbol{x}}; D/\beta z D)(m)$, the Euler characteristic on the zero module being 0. The sequence
$$0 \to D/zD \xrightarrow{\beta} D/\beta z D \to D/\beta D \to 0$$
is exact with degree-preserving maps: the first map is well defined; it is injective, since $\beta v = \beta z v'$ implies $v = z v'$ (β is injective on D); and the kernel of the second map is $\beta D/\beta z D$, the image of the first. Since $\operatorname{Ann}_S(D/\beta z D) \supseteq \mathfrak{q} + (\beta z)$, $\hat{\boldsymbol{x}}$ is admissible for $D/\beta z D$, and Lemma 41.14, item 3, gives $\operatorname{eu}(\hat{\boldsymbol{x}}; D/\beta z D)(m) = \operatorname{eu}(\hat{\boldsymbol{x}}; D/zD)(m) + \operatorname{eu}(\hat{\boldsymbol{x}}; D/\beta D)(m)$ in large degree.

- If $z \in \mathfrak{q}$, then z and βz both act as 0 on D and have the same degree, so $\operatorname{Kos}_\bullet((z, \hat{\boldsymbol{x}}); D) = \operatorname{Kos}_\bullet((\beta z, \hat{\boldsymbol{x}}); D)$ (the terms depend only on the degrees, the differentials only on the action

of the elements on D), and the two Euler characteristics agree. Moreover $\mathfrak{q}+(\beta z,\hat{\boldsymbol{x}})=\mathfrak{q}+(\hat{\boldsymbol{x}})$, so $\hat{\boldsymbol{x}}$ is admissible for D, and Lemma 41.14, item 3, applied to $0\to D\xrightarrow{\beta}D\to D/\beta D\to 0$ gives $\mathrm{eu}(\hat{\boldsymbol{x}};D)(m)=\mathrm{eu}(\hat{\boldsymbol{x}};D)(m)+\mathrm{eu}(\hat{\boldsymbol{x}};D/\beta D)(m)$, i.e. $\mathrm{eu}(\hat{\boldsymbol{x}};D/\beta D)(m)=0$, in large degree.

Step 4: conclusion. Adding the identities of Step 3 for $c'=1,\dots,c$, which hold simultaneously in large degree, the terms $\mathrm{eu}(\boldsymbol{x}^{(c')};D)(m)$ with $1\le c'<c$ cancel, and $\mathrm{eu}(\boldsymbol{x}^{(c)};D)(m)=\mathrm{eu}(\boldsymbol{x}^{(0)};D)(m)+c\cdot\mathrm{eu}(\hat{\boldsymbol{x}};D/\beta D)(m)$ with $\boldsymbol{x}^{(0)}=\boldsymbol{x}$. □

Lemma 41.19. *Let $n,n_1,n_2\ge 1$ be integers. For $k\in\mathbb{Z}$ let $p(k)$ be the number of pairs $(\beta,\gamma)\in\mathbb{N}^{n_1}\times\mathbb{N}^{n_2}$ with $|\beta|+2|\gamma|=k$, where $|\beta|$ is the sum of the entries, and for $\mu=(\mu_0,\mu_1,\mu_2)\in\mathbb{N}^3$ put*

$$h(\mu)=\binom{2\mu_0+4\mu_2+n-1}{n-1}\,p(2\mu_1+2\mu_2).$$

Let e_0,e_1,e_2 be the unit vectors of $\mathbb{Z}^3$ and $M=n_1+n_2-2$. Then for every $\mu\in\mathbb{N}^3$ with $\mu_0\ge n-1$, $\mu_1\ge M$ and $\mu_2\ge 1$,

$$\sum_{i=0}^{n-1}\sum_{j=0}^{M}\sum_{\varepsilon=0}^{1}(-1)^{i+j+\varepsilon}\binom{n-1}{i}\binom{M}{j}\,h(\mu-ie_0-je_1-\varepsilon e_2)=2^{\,n+n_1-2}.$$

Proof. All points $\mu-ie_0-je_1-\varepsilon e_2$ in the sum lie in $\mathbb{N}^3$, by the bounds on μ. Let $a(N)=\binom{N+n-1}{n-1}$ for $N\ge 0$, $a(N)=0$ for $N<0$, and $b(l)=p(2l)$ for $l\in\mathbb{Z}$; then $h(\mu')=a(2\mu_0'+4\mu_2')\,b(\mu_1'+\mu_2')$ for $\mu'\in\mathbb{N}^3$. In the ring of formal power series,

$$\sum_{N\ge0}a(N)t^N=(1-t)^{-n},\qquad \sum_{k\ge0}p(k)t^k=(1-t)^{-n_1}(1-t^2)^{-n_2}=(1+t)^{n_1}(1-t^2)^{-(n_1+n_2)},$$

the second because each variable of weight 1, respectively 2, contributes a factor $\sum_r t^r$, respectively $\sum_r t^{2r}$. Keeping the terms of even degree and substituting $s=t^2$,

$$\sum_{l\ge0}b(l)s^l=E(s)(1-s)^{-(n_1+n_2)},\qquad E(s)=\sum_{r\ge0}\binom{n_1}{2r}s^r.$$

For a power series $\sum_N c_N t^N$ and a polynomial $\sum_i\gamma_i t^i$, the coefficient of t^N in their product is $\sum_i\gamma_i c_{N-i}$, with $c_{N'}=0$ for $N'<0$.

The sum over i. Fix j,ε and put $N=2\mu_0+4(\mu_2-\varepsilon)\ge 2\mu_0\ge n-1$. Then $\sum_i(-1)^i\binom{n-1}{i}a(N-2i)$ is the coefficient of t^N in $(1-t^2)^{n-1}(1-t)^{-n}=(1+t)^{n-1}(1-t)^{-1}$, which is $\sum_{r=0}^{\min(N,n-1)}\binom{n-1}{r}=2^{n-1}$.

The sum over j and ε. Hence the left side equals $2^{n-1}\sum_{j,\varepsilon}(-1)^{j+\varepsilon}\binom{M}{j}b(L-j-\varepsilon)$ with $L=\mu_1+\mu_2$. As $\sum_{j,\varepsilon}(-1)^{j+\varepsilon}\binom{M}{j}s^{j+\varepsilon}=(1-s)^{M+1}$ and $M+2=n_1+n_2$, this sum is the coefficient of s^L in

$$(1-s)^{M+1}E(s)(1-s)^{-(M+2)}=E(s)(1-s)^{-1},$$

namely $\sum_{r\le L}\binom{n_1}{2r}$. Since $L\ge M+1\ge n_1$, this is $\sum_{r\ge0}\binom{n_1}{2r}=\frac12\big((1+1)^{n_1}+(1-1)^{n_1}\big)=2^{n_1-1}$, as $n_1\ge1$. The left side is therefore $2^{n-1}\cdot2^{n_1-1}=2^{n+n_1-2}$. □

Proposition 41.20. *Let B be a Noetherian local ring, S a standard $\mathbb{N}^k$-graded B-algebra, $\boldsymbol{\sigma} = (\sigma_1, \dots, \sigma_q)$ a sequence of homogeneous elements of S, and $a \in S_0$, regarded as an element of degree 0. Assume that there is $N \geq 1$ with*

$$\big(\mathfrak{m}_B S \cdot \operatorname{Irr}(S)\big)^N \subseteq (\sigma_1, \dots, \sigma_q, a).$$

Then in large degree $m \in \mathbb{Z}^k$ the Euler characteristics $\operatorname{eu}((\boldsymbol{\sigma}, a); S)(m)$ and $\operatorname{eu}((a); S/(\boldsymbol{\sigma}))(m)$ are defined and

$$\operatorname{eu}((\boldsymbol{\sigma}, a); S)(m) \leq \operatorname{eu}((a); S/(\boldsymbol{\sigma}))(m).$$

Proof. We prove, by induction on q, the following more general claim: *for every finitely generated graded S-module F with $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(F) + (\boldsymbol{\sigma}, a)$ for some $N \geq 1$, in large degree $\operatorname{eu}((\boldsymbol{\sigma}, a); F)(m)$ and $\operatorname{eu}((a); F/(\boldsymbol{\sigma})F)(m)$ are defined and $\operatorname{eu}((\boldsymbol{\sigma}, a); F)(m) \leq \operatorname{eu}((a); F/(\boldsymbol{\sigma})F)(m)$.* The proposition is the case $F = S$, as $\operatorname{Ann}_S(S) = 0$.

Definedness. By Lemma 41.14, item 2, $\operatorname{eu}((\boldsymbol{\sigma}, a); F)(m)$ is defined in large degree. As $\operatorname{Ann}_S(F) + (\boldsymbol{\sigma})$ is contained in $\operatorname{Ann}_S(F/(\boldsymbol{\sigma})F)$, the hypothesis gives

$$(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(F/(\boldsymbol{\sigma})F) + (a),$$

and the same item shows that $\operatorname{eu}((a); F/(\boldsymbol{\sigma})F)(m)$ is defined in large degree.

The case $q = 0$. Both sides are $\operatorname{eu}((a); F)(m)$.

The induction step. Let $q \geq 1$ and write $\boldsymbol{\sigma} = (s, \boldsymbol{\sigma}')$ with $s = \sigma_1 \in S_d$, so that $(\boldsymbol{\sigma}, a) = (s, (\boldsymbol{\sigma}', a))$. By Lemma 41.16, applied to s and the sequence $(\boldsymbol{\sigma}', a)$, in large degree

$$\operatorname{eu}((\boldsymbol{\sigma}, a); F)(m) = \operatorname{eu}((\boldsymbol{\sigma}', a); F/sF)(m) - \operatorname{eu}((\boldsymbol{\sigma}', a); 0 :_F s)(m - d).$$

The modules F/sF and $0 :_F s$ are finitely generated and graded, and their annihilators contain $\operatorname{Ann}_S(F) + (s)$, so $(\mathfrak{m}_B S \cdot \operatorname{Irr}(S))^N \subseteq \operatorname{Ann}_S(M) + (\boldsymbol{\sigma}', a)$ for $M = F/sF$ and $M = 0 :_F s$. By the induction hypothesis for F/sF and the sequence $\boldsymbol{\sigma}'$ of length $q - 1$, in large degree

$$\operatorname{eu}((\boldsymbol{\sigma}', a); F/sF)(m) \leq \operatorname{eu}\big((a); (F/sF)/(\boldsymbol{\sigma}')(F/sF)\big)(m) = \operatorname{eu}((a); F/(\boldsymbol{\sigma})F)(m),$$

since $(F/sF)/(\boldsymbol{\sigma}')(F/sF) = F/(\boldsymbol{\sigma})F$. By Lemma 41.15 for $0 :_F s$ and the sequence $(\boldsymbol{\sigma}', a)$, $\operatorname{eu}((\boldsymbol{\sigma}', a); 0 :_F s)(m') \geq 0$ for m' in large degree, hence for $m' = m - d$ when m is in large degree. Combining the three statements, which hold simultaneously in large degree, gives $\operatorname{eu}((\boldsymbol{\sigma}, a); F)(m) \leq \operatorname{eu}((a); F/(\boldsymbol{\sigma})F)(m)$. □

Proposition 41.21. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point and u a system of equations for (A, φ_0) with $\operatorname{ne}(-2) = \operatorname{ne}(0) = 0$ and $\operatorname{ne}(-1) = n + 1$, $n \geq 1$, such that u_{-1} spans rationally in degree -1 and $A_{-2} \subseteq \operatorname{Sq}(\varphi_0)$. Let $a \in A$ be such that (A, φ_0, u, a) satisfies (Gc2)–(Gc5), and let Σ be an orbit cover of u. Then in large degree $m \in \mathbb{Z}^3$, $\operatorname{eu}\big((a); \operatorname{Rs}(u)/(\boldsymbol{\sigma}(u))\big)(m)$ is defined and*

$$\operatorname{eu}\big((a); \operatorname{Rs}(u)/(\boldsymbol{\sigma}(u))\big)(m) \;\leq\; 2^{\,n+1+\operatorname{ne}(1)} \sum_{\varphi \in \Sigma} v_{\mathcal{O}}(\varphi(a)).$$

Proof. Write $\operatorname{Rs} = \operatorname{Rs}(u)$, $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$, $M = \operatorname{Rs}/(\boldsymbol{\sigma})$, $I_0 = I(u) \cap A_0$, $\mathfrak{d}$ for the ideal of A_0 generated by the products fg with $f \in A_{-2}$, $g \in A_2$, and $C = 2^{\,n+1+\operatorname{ne}(1)}$. By (Gc5), $a \in A_0$. By Lemma 41.8, item 2, and Lemma 41.14, item 1, Rs is a Noetherian standard $\mathbb{N}^3$-graded algebra

over A_0 and each M_d is a finitely generated A_0-module. In a Noetherian ring a finitely generated ideal contained in the radical of an ideal J has a power contained in J; we use this twice.

Step 1: a two-signed point is non-zero on some $f \in A_{-2}$ and some $g \in A_2$. If φ is two-signed, there are $j > 0$ and $x \in A_{-j}$ with $\varphi(x) \neq 0$; then $x^2 \in A_{-2}^{\,j}$ by Lemma 41.11, so $\varphi(f) \neq 0$ for some $f \in A_{-2}$; likewise $\varphi(g) \neq 0$ for some $g \in A_2$. In particular $\varphi(\mathfrak{d}) \neq 0$.

Step 2: two inclusions in Rs. Let $\mathfrak{P}$ be a prime of Rs containing $(\boldsymbol{\sigma})$. If $\mathrm{Irr}(\mathrm{Rs}) \not\subseteq \mathfrak{P}$, then Lemma 41.10 applies (its hypotheses are among ours) and gives $I_0 \subseteq \mathfrak{P}$; and if moreover $\mathfrak{d} \subseteq \mathfrak{P}$, its item 2 gives $\mathfrak{P} \cap A_0 = \mathfrak{m}_{A_0}$, since the other alternative, $\mathfrak{P} \cap A_0 = \ker(\varphi|_{A_0})$ for a two-signed point φ, would contradict Step 1. Hence every prime containing $(\boldsymbol{\sigma})$ contains $I_0\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs})$, and every prime containing $(\boldsymbol{\sigma}) + \mathfrak{d}\mathrm{Rs}$ contains $\mathfrak{m}_{A_0}\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs})$. So there is $N \geq 1$ with

$$(I_0\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs}))^N \subseteq (\boldsymbol{\sigma}), \qquad (\mathfrak{m}_{A_0}\mathrm{Rs} \cdot \mathrm{Irr}(\mathrm{Rs}))^N \subseteq (\boldsymbol{\sigma}) + \mathfrak{d}\mathrm{Rs}.$$

Step 3: the pieces in large degree. For $d \geq N\mathbb{1}$, $\mathrm{Rs}_d = \mathrm{Rs}_{\mathbb{1}}^N \mathrm{Rs}_{d-N\mathbb{1}} \subseteq \mathrm{Irr}(\mathrm{Rs})^N$, so $I_0^N \mathrm{Rs}_d \subseteq (\boldsymbol{\sigma})$ and $I_0^N M_d = 0$. By the second inclusion and Lemma 41.14, item 1, applied to $M/\mathfrak{d}M$, there is $d_0 \geq N\mathbb{1}$ such that $M_d/\mathfrak{d}M_d$ has finite length for $d \geq d_0$. Fix $d \geq d_0$. Then:

- $A_0/\mathrm{Ann}_{A_0}(M_d)$ is a quotient of A_0/I_0^N, which is a finitely generated $\mathcal{O}$-module: A_0/I_0 is one by (Gc2), and each I_0^j/I_0^{j+1} is a finitely generated A_0/I_0-module, A_0 being Noetherian.
- Let $\beta\colon A_0 \to \overline{\mathbb{Q}}_\ell$ be an $\mathcal{O}$-algebra homomorphism with $(M_d)_\mathfrak{p} \neq 0$, $\mathfrak{p} = \ker\beta$. Then $I_0^N \subseteq \mathrm{Ann}(M_d) \subseteq \mathfrak{p}$, so $I_0 \subseteq \mathfrak{p}$. If $\mathfrak{d} \subseteq \mathfrak{p}$, then $(M_d/\mathfrak{d}M_d)_\mathfrak{p} = 0$, as a module of finite length vanishes at the non-maximal prime $\mathfrak{p}$ ($\beta(\varpi) \neq 0$), so $(M_d)_\mathfrak{p} = \mathfrak{d}(M_d)_\mathfrak{p} \subseteq \mathfrak{p}(M_d)_\mathfrak{p}$, and $(M_d)_\mathfrak{p} = 0$ by Nakayama's lemma, a contradiction. So $\beta(fg) \neq 0$ for some $f \in A_{-2}$, $g \in A_2$. The ideal $I(u) + \mathfrak{p}A$ is generated by homogeneous elements and its elements of degree 0 form $I_0 + \mathfrak{p} = \mathfrak{p}$; by Lemma 41.12 (with the element 1) there is a point φ' on u with $\varphi'|_{A_0} = \beta$, and $\varphi'(f)\varphi'(g) \neq 0$, so φ' is two-signed. As Σ is an orbit cover, $\varphi' = t \cdot \varphi$ for some $\varphi \in \Sigma$ and $t \in \overline{\mathbb{Q}}_\ell^{\times}$, and torus translation does not change the restriction to A_0; so $\beta \in \Sigma_0 = \{\varphi|_{A_0} : \varphi \in \Sigma\}$.

Step 4: the Herbrand bound. Apply Lemma 41.26 to $B = A_0$ (local, with the residue field of $\mathcal{O}$, by the definition of a graded algebra with a fixed point), the module M_d, the element a, the finite set Σ_0 and C. The finiteness hypothesis on $A_0/\mathrm{Ann}(M_d)$ and (Hq2) hold by Step 3. For (Hq1), let $\beta = \varphi|_{A_0}$ with $\varphi \in \Sigma$, a two-signed point on u, and $\mathfrak{p} = \ker\beta$: $\beta(a) = \varphi(a) \neq 0$ by (Gc5); $\varphi(A_0)$ is the image of A_0/I_0, a finitely generated $\mathcal{O}$-module, so $\varphi(a)$ is integral over $\mathcal{O}$ and $v_\mathcal{O}(\beta(a)) \geq 0$; and by Proposition 41.23 ((Gc2), (Gc4)) the weight pieces of $A/I(u)$ have local length at most 1 at $\mathfrak{p}$, so Lemma 41.22 with $L = 1$ gives $\mathrm{length}((M_d)_\mathfrak{p}) \leq C$, as $d \geq \mathbb{1}$. Hence M_d/aM_d and $0 :_{M_d} a$ have finite length, so $\mathrm{eu}((a); M)(d)$ is defined, and since the map $\Sigma \to \Sigma_0$ is onto and all terms are ≥ 0,

$$\mathrm{eu}((a); M)(d) = \mathrm{length}(M_d/aM_d) - \mathrm{length}(0 :_{M_d} a) \leq C \sum_{\beta \in \Sigma_0} v_\mathcal{O}(\beta(a)) \leq C \sum_{\varphi \in \Sigma} v_\mathcal{O}(\varphi(a)).$$

This holds for all $d \geq d_0$, which is the assertion. □

Lemma 41.22. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point, and u a system of equations for (A, φ_0) with $\mathrm{ne}(-2) = \mathrm{ne}(0) = 0$ and $\mathrm{ne}(-1) = n + 1$, $n \geq 1$. Let φ be a two-signed point, $\mathfrak{p} = \ker(\varphi|_{A_0})$ and $R = (A_0)_\mathfrak{p}$, and assume that there is an integer $L \geq 0$ with $\mathrm{length}_R((A/I(u))_{w,\mathfrak{p}}) \leq L$ for every $w \in \mathbb{Z}$. Then for every $d \in \mathbb{N}^3$ with $d \geq (1,1,1)$,*

$$\mathrm{length}_R\Big(\big(\mathrm{Rs}(u)/(\boldsymbol{\sigma}(u))\big)_{d,\mathfrak{p}}\Big) \leq 2^{\,n+1+\mathrm{ne}(1)}\, L.$$

Proof. Write $\mathrm{Rs} = \mathrm{Rs}(u)$, $\boldsymbol{\sigma} = \boldsymbol{\sigma}(u)$, $w = u_{-1,n+1}$, and $A_{\mathfrak{p}}$, $\mathrm{Rs}_{\mathfrak{p}}$ for the localisations at $A_0 \setminus \mathfrak{p}$.

Step 1: units of degree ± 2. As φ is not positive-vanishing, there are $j > 0$ and $y \in A_j$ with $\varphi(y) \neq 0$; then $y^2 \in A_{2j} = A_2^j$ by Lemma 41.11, so some product of elements of A_2 is not killed by φ, and there is $g \in A_2$ with $\varphi(g) \neq 0$. Likewise there is $f \in A_{-2}$ with $\varphi(f) \neq 0$. Then $\tau = fg \in A_0 \setminus \mathfrak{p}$ is a unit of R. Every $x \in A_{-2}$ satisfies $x = \tau^{-1}(xg)f$ in $A_{\mathfrak{p}}$ with $xg \in A_0$, and every $y \in A_2$ satisfies $y = \tau^{-1}(fy)g$; hence $(A_{-2})_{\mathfrak{p}} = Rf$ and $(A_2)_{\mathfrak{p}} = Rg$. As $N_2 \subseteq A_{-2}$ and $f \cdot fg = \tau f \in A_{-2}A_{-2}A_2 \subseteq N_2$, also $(N_2)_{\mathfrak{p}} = Rf$. Hence for $\mu \in \mathbb{N}^3$, $(\mathrm{Rs}_\mu)_{\mathfrak{p}} = R\,\epsilon_\mu$ with $\epsilon_\mu = f^{\mu_0+\mu_2} g^{\mu_1} T^\mu$, and $\epsilon_\mu \epsilon_{\mu'} = \epsilon_{\mu+\mu'}$.

Step 2: the localised piece is a quotient of a weight-zero piece. In $A_{\mathfrak{p}}$, $u_{-1,i}^2 = \tau^{-1}(u_{-1,i}^2 g)f$, $w^2 = \tau^{-1}(w^2 g)f$, $u_{1,i}^2 = \tau^{-1}(f u_{1,i}^2)g$ and $u_{2,i} = \tau^{-1}(f u_{2,i})g$. So the sections are R-multiples of ϵ_{e_0}, ϵ_{e_1}, ϵ_{e_2} with coefficients generating the ideal

$$\mathfrak{c} = (u_{-1,i}^2 g \ (i \le n),\ w^2 g,\ f u_{1,i}^2,\ f u_{2,i})R.$$

For $d \geq (1,1,1)$, the degree-d part of $(\boldsymbol{\sigma})$ is the sum of the $s\,\mathrm{Rs}_{d-\deg s}$ over the sections s, so its localisation is $\mathfrak{c}\,\epsilon_d$, and $(\mathrm{Rs}/(\boldsymbol{\sigma}))_{d,\mathfrak{p}} = R\epsilon_d/\mathfrak{c}\epsilon_d$ is a quotient of $R/\mathfrak{c}$. Let I_2 be the ideal of A generated by the $u_{-1,i}^2$ $(i \le n)$, w^2, $u_{1,i}^2$ and $u_{2,i}$. Its degree-0 part is the sum of the $A_{-\deg v} v$ over these generators v; since $(A_{\pm 2})_{\mathfrak{p}}$ are Rf, Rg, its localisation is $\mathfrak{c}$. Hence

$$\mathrm{length}_R\big((\mathrm{Rs}/(\boldsymbol{\sigma}))_{d,\mathfrak{p}}\big) \le \mathrm{length}_R(R/\mathfrak{c}) = \mathrm{length}_R\big((A/I_2)_{0,\mathfrak{p}}\big).$$

Step 3: removing the squares. Let $v_1, \dots, v_r$, $r = n + 1 + \mathrm{ne}(1)$, be the elements $u_{-1,i}$ $(i \le n+1)$ and $u_{1,i}$, and let J_s be the ideal generated by I_2 and $v_1, \dots, v_s$; so $J_0 = I_2$, $J_r = I(u)$, and $v_{s+1}^2 \in J_s$. The map $A \to J_{s+1}/J_s$, $x \mapsto x v_{s+1}$, is surjective and kills J_{s+1} (as $J_s v_{s+1} \subseteq J_s$ and $v_{s+1}^2 \in J_s$); it shifts degrees by $\delta = \deg v_{s+1}$. From $0 \to J_{s+1}/J_s \to A/J_s \to A/J_{s+1} \to 0$, in each weight w and after localisation,

$$\mathrm{length}_R\big((A/J_s)_{w,\mathfrak{p}}\big) \le \mathrm{length}_R\big((A/J_{s+1})_{w,\mathfrak{p}}\big) + \mathrm{length}_R\big((A/J_{s+1})_{w-\delta,\mathfrak{p}}\big).$$

Since all weight pieces of $A/J_r = A/I(u)$ have local length at most L, downward induction on s gives $\mathrm{length}_R((A/J_s)_{w,\mathfrak{p}}) \le 2^{r-s}L$ for all w. For $s = 0$, $w = 0$ and Step 2 this is the assertion. □

Proposition 41.23. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point and u a system of equations for (A, φ_0) such that (Gc2) and (Gc4) hold (they do not involve the element a). Let φ be a two-signed point on u, $\mathfrak{p} = \ker(\varphi|_{A_0})$ and $R = (A_0)_{\mathfrak{p}}$. Then for every $w \in \mathbb{Z}$,*

$$\mathrm{length}_R\big((A/I(u))_{w,\mathfrak{p}}\big) \le 1.$$

Proof. Write $I = I(u)$, $\sigma = \varphi|_{A_0}$, so $\mathfrak{p} = \ker\sigma$, a prime ideal of A_0. Since I is generated by homogeneous elements, $(A/I)_w = A_w/(I \cap A_w)$ for every w.

Step 1: a unit of degree zero. As φ is not negative-vanishing, there are $j > 0$ and $x \in A_{-j}$ with $\varphi(x) \neq 0$; by Lemma 41.11, $x^2 \in A_{-2j} = A_{-2}^j$, so $\varphi(f) \neq 0$ for some $f \in A_{-2}$. Likewise $\varphi(g) \neq 0$ for some $g \in A_2$. Put $\tau = fg \in A_0$; then $\sigma(\tau) \neq 0$.

Step 2: elements of $\mathfrak{p}$ are nilpotent modulo I up to a unit at $\mathfrak{p}$. Let $p \in \mathfrak{p}$. By (Gc2) the image $\bar{A}_0$ of A_0 in A/I, a subring, is a finitely generated $\mathcal{O}$-module, so the image $\bar{p}$ of p is integral over $\mathcal{O}$ (Atiyah–Macdonald, Prop. 5.1): $Q(\bar{p}) = 0$ for a monic $Q \in \mathcal{O}[X]$. Write $Q = X^r Q_1$ with $Q_1(0) \neq 0$ and put $b = Q_1(p) \in A_0$. Then $bp^r = Q(p) \in I$, and $\sigma(b) = Q_1(\sigma(p)) = Q_1(0) \neq 0$, as $\mathcal{O} \to \overline{\mathbb{Q}}_\ell$ is injective. So: *for every $p \in \mathfrak{p}$ there are $b \in A_0 \setminus \mathfrak{p}$ and $r \geq 0$ with $bp^r \in I$.*

Step 3: removing powers. Let $h \in A_j$ be homogeneous, $b \in A_0 \setminus \mathfrak{p}$ and $r \geq 0$ with $bh^r \in I$. We show that $b'h \in I$ for some $b' \in A_0 \setminus \mathfrak{p}$. Every two-signed point ξ on u kills I, so $\xi(b)\xi(h)^r = 0$ and hence $\xi(bh) = 0$. As $bh \in A_j$, Lemma 41.24 (with f, g of Step 1; (Gc2), (Gc4) hold) gives $c \in \mathcal{O} \setminus \{0\}$ and $N, m \geq 0$ with $cf^m g^N bh \in I$. Put $b' = c\tau^{N+m} b \in A_0$. Then $b'h = (f^N g^m)(cf^m g^N bh) \in I$ and $\sigma(b') = c\,\sigma(\tau)^{N+m}\sigma(b) \neq 0$.

Step 4: $\mathfrak{p}$ kills the weight pieces at $\mathfrak{p}$. Let $w \in \mathbb{Z}$, $p \in \mathfrak{p}$ and $h \in A_w$. By Step 2 there are $b \in A_0 \setminus \mathfrak{p}$ and r with $bp^r \in I$, so $b(ph)^r \in I$, and Step 3 applied to $ph \in A_w$ gives $b' \in A_0 \setminus \mathfrak{p}$ with $b'ph \in I$.

Step 5: the weight pieces are cyclic at $\mathfrak{p}$. Let $w \in \mathbb{Z}$ and $k = |w|$; put $e = f^k$, $e' = g^k$ if $w \geq 0$, and $e = g^k$, $e' = f^k$ if $w < 0$. Then $e \in A_{-2w}$ and $ee' = \tau^k$, so $hh'e \in A_0$ for $h, h' \in A_w$. We find $h_0 \in A_w$ such that for every $h \in A_w$ there are $b \in A_0 \setminus \mathfrak{p}$ and $a \in A_0$ with $bh - ah_0 \in I$.

- If $h_0^2 e \notin \mathfrak{p}$ for some $h_0 \in A_w$: for $h \in A_w$ take $b = h_0^2 e$ and $a = hh_0 e$; then $bh - ah_0 = 0$.
- If $h^2 e \in \mathfrak{p}$ for every $h \in A_w$: take $h_0 = 0$. For $h \in A_w$, Step 2 for $p = h^2 e$ gives $b \in A_0 \setminus \mathfrak{p}$ and r with $b(h^2 e)^r \in I$; then $(b\tau^{kr})h^{2r} = e'^r\, b(h^2 e)^r \in I$ with $b\tau^{kr} \notin \mathfrak{p}$, and Step 3 gives $b' \in A_0 \setminus \mathfrak{p}$ with $b'h \in I$; take $a = 0$.

Step 6: conclusion. Let $M = (A/I)_w$, an A_0-module whose elements are the classes $\bar{h}$ of $h \in A_w$, and $M_\mathfrak{p}$ its localisation, a module over the local ring R with maximal ideal $\mathfrak{p}R$. By Step 5, $b\bar{h} = a\bar{h}_0$ with $b \notin \mathfrak{p}$, so $\bar{h}/s = (a/(bs))\,\bar{h}_0/1$ for $s \in A_0 \setminus \mathfrak{p}$: $M_\mathfrak{p}$ is generated by $\bar{h}_0/1$. By Step 4, $(p/1)(\bar{h}_0/1) = b'p\bar{h}_0/b' = 0$ for $p \in \mathfrak{p}$. Hence $M_\mathfrak{p}$ is a quotient of $R/\mathfrak{p}R$, a field, and $\operatorname{length}_R(M_\mathfrak{p}) \leq 1$. □

Lemma 41.24. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point and u a system of equations for (A, φ_0) such that (Gc2) and (Gc4) hold. Let $f \in A_{-2}$, $g \in A_2$, $j \in \mathbb{Z}$ and $h \in A_j$ be such that $\xi(h) = 0$ for every two-signed point ξ on u with $\xi(f) = 1$ and $\xi(g) \neq 0$. Then there are $c \in \mathcal{O} \setminus \{0\}$ and $N, m \in \mathbb{N}$ with*

$$c\, f^m g^N h \in I(u).$$

Proof. Write $I = I(u)$; it is generated by homogeneous elements, so A/I is graded and the components of an element of I lie in I. Let $J = I + (f-1)A$, $s \in A/J$ the image of ϖg, $C = (A/J)[s^{-1}]$ and $\pi\colon A \to C$ the canonical map.

Step 1: C is a finitely generated K_0-algebra. By the definition of a graded algebra with a fixed point, A is generated as an $\mathcal{O}$-algebra by A_0 and finitely many homogeneous $s_1, \ldots, s_q$; so every element of A is a polynomial in the s_k with coefficients in A_0. By (Gc2) the image of A_0 in A/I is spanned over $\mathcal{O}$ by the images of finitely many $b_1, \ldots, b_r \in A_0$. Hence A/I, and its quotient A/J, are generated as $\mathcal{O}$-algebras by the images of the b_i and s_k. In C the element $\pi(\varpi)\pi(g) = s$ is a unit, so $\pi(\varpi)$ is a unit and C is a K_0-algebra, generated by the images of the b_i, the s_k and s^{-1}.

Step 2: the points of C give two-signed points on u. Let $\psi\colon C \to \overline{\mathbb{Q}}_\ell$ be a K_0-algebra homomorphism and $\xi = \psi \circ \pi$, an $\mathcal{O}$-algebra homomorphism $A \to \overline{\mathbb{Q}}_\ell$, i.e. a point. It kills $I \subseteq J$, so it lies on u; $\xi(f) = 1$ as $f - 1 \in J$; and $\xi(\varpi)\xi(g) = \psi(s) \neq 0$, s being a unit, so $\xi(g) \neq 0$. As $f \in A_{-2}$ and $g \in A_2$, ξ is neither negative-vanishing nor positive-vanishing: it is two-signed.

Step 3: C has no non-zero derivations at its points. Let ψ, ξ be as in Step 2 and D a ψ-derivation of C. Then $D' = D \circ \pi\colon A \to \overline{\mathbb{Q}}_\ell$ is $\mathcal{O}$-linear and a ξ-derivation, and it vanishes on I. Define the Euler derivation $E\colon A \to \overline{\mathbb{Q}}_\ell$ by $E(x) = \sum_{i \in \mathbb{Z}} i\,\xi(x_i)$, where x_i is the component of

x of degree i. It is $\mathcal{O}$-linear; for $x \in A_i$, $y \in A_{i'}$, $E(xy) = (i+i')\xi(x)\xi(y) = \xi(x)E(y)+\xi(y)E(x)$, and by bilinearity E is a ξ-derivation. It vanishes on I, since the components of an element of I lie in I, which ξ kills. By (Gc4) at the two-signed point ξ on u, there are $(c_1, c_2) \neq (0,0)$ in $\overline{\mathbb{Q}}_\ell$ with $c_1 D' + c_2 E = 0$. Now $D(1) = D(1 \cdot 1) = 2D(1)$ gives $D(1) = 0$, so $D'(f) = D(\pi(f)) = D(1) = 0$, while $E(f) = -2\xi(f) = -2$. Evaluating at f gives $-2c_2 = 0$, so $c_2 = 0$, $c_1 \neq 0$ and $D' = 0$: D vanishes on $\pi(A)$. Every element of C has the form $z = \pi(x)s^{-k}$; then $0 = D(\pi(x)) = D(zs^k) = \psi(s)^k D(z) + \psi(z)D(s^k)$ and $D(s^k) = D(\pi(\varpi^k g^k)) = 0$, so $D(z) = 0$ as $\psi(s) \neq 0$. Thus every ψ-derivation of C is zero.

Step 4: the image of h in C vanishes. For every K_0-algebra homomorphism $\psi\colon C \to \overline{\mathbb{Q}}_\ell$, $\psi(\pi(h)) = \xi(h) = 0$ by the hypothesis on h and Step 2. By Steps 1 and 3, Lemma 41.25 applies to $k = K_0 \subseteq \Omega = \overline{\mathbb{Q}}_\ell$ (characteristic 0) and C, and gives $\pi(h) = 0$. By the definition of the localisation, $s^N h \in J$ in A/J for some $N \geq 0$, that is,

$$h' = \varpi^N g^N h \in I + (f-1)A, \qquad h' \in A_w,\ w = 2N + j.$$

Step 5: dehomogenisation. Write $h' = x + v(f-1)$ with $x \in I$, $v \in A$, and pass to the graded ring $\bar{A} = A/I$, writing $\bar{y}$ for images and $\bar{v}_e$ for the component of $\bar{v}$ of degree e, non-zero for only finitely many e. Since $\bar{f}$ has degree -2, the component of $\bar{v}\bar{f}$ of degree e is $\bar{v}_{e+2}\bar{f}$, and comparing components of degree e in $\bar{h}' = \bar{v}\bar{f} - \bar{v}$ gives

$$\bar{v}_e = \bar{v}_{e+2}\bar{f} \quad (e \neq w), \qquad \bar{v}_w = \bar{v}_{w+2}\bar{f} - \bar{h}'.$$

By the first relation, $\bar{v}_{w+2} = \bar{v}_{w+2+2k}\bar{f}^{\,k}$ for all $k \geq 0$, which is 0 for k large; so $\bar{v}_w = -\bar{h}'$. Again by the first relation, $\bar{v}_{w-2k} = \bar{v}_w \bar{f}^{\,k} = -\bar{f}^{\,k}\bar{h}'$ for $k \geq 0$, which is 0 for k large. So $f^m h' \in I$ for some m, i.e. $\varpi^N f^m g^N h \in I$, and $c = \varpi^N \neq 0$. □

Lemma 41.25. *Let $k \subseteq \Omega$ be fields of characteristic 0 with Ω algebraically closed, and let C be a finitely generated k-algebra. For a k-algebra homomorphism $\psi\colon C \to \Omega$, a ψ-**derivation** is a k-linear map $D\colon C \to \Omega$ with $D(xy) = \psi(x)D(y) + \psi(y)D(x)$ for all $x, y \in C$. Assume that for every k-algebra homomorphism $\psi\colon C \to \Omega$ every ψ-derivation is zero. Then every $z \in C$ with $\psi(z) = 0$ for all k-algebra homomorphisms $\psi\colon C \to \Omega$ is zero.*

Proof. Step 1: every maximal ideal is the kernel of a point. Let $\mathfrak{n}$ be a maximal ideal of C. The field $\kappa = C/\mathfrak{n}$ is a finitely generated k-algebra, hence a finite extension of k by Zariski's lemma (Atiyah–Macdonald, *Introduction to commutative algebra*, Cor. 5.24). As Ω is algebraically closed, there is a k-embedding $\iota\colon \kappa \to \Omega$, and $\psi_{\mathfrak{n}} = \iota \circ (C \to \kappa)$ is a k-algebra homomorphism with kernel $\mathfrak{n}$.

Step 2: $\mathfrak{n} = \mathfrak{n}^2$ for every maximal ideal $\mathfrak{n}$. Suppose $\mathfrak{n} \neq \mathfrak{n}^2$, and let κ, ι be as in Step 1. Put $\bar{C} = C/\mathfrak{n}^2$ and $\bar{\mathfrak{n}} = \mathfrak{n}/\mathfrak{n}^2 \neq 0$; then $\bar{C}$ is local with maximal ideal $\bar{\mathfrak{n}}$, $\bar{\mathfrak{n}}^2 = 0$, and $\bar{\mathfrak{n}}$ is a $\kappa = \bar{C}/\bar{\mathfrak{n}}$-vector space. Since κ/k is finite and separable (characteristic 0), $\kappa = k(\theta)$ with minimal polynomial $Q \in k[X]$ and $Q'(\theta) \neq 0$. Let $t \in \bar{C}$ lift θ; then $Q(t) \in \bar{\mathfrak{n}}$ and $Q'(t)$ is a unit, its image $Q'(\theta)$ being non-zero. Put $\varepsilon = -Q(t)Q'(t)^{-1} \in \bar{\mathfrak{n}}$ and $t' = t + \varepsilon$. By Taylor expansion, $Q(t') = Q(t) + Q'(t)\varepsilon + \varepsilon^2 r = 0$ for some $r \in \bar{C}$, as $\varepsilon^2 = 0$. Hence $X \mapsto t'$ defines a k-algebra homomorphism $k[X]/(Q) \to \bar{C}$; its composite with $\bar{C} \to \kappa$ maps X to θ and is an isomorphism, so its image κ' is a subring of $\bar{C}$ mapped isomorphically onto κ, and $\bar{C} = \kappa' \oplus \bar{\mathfrak{n}}$ as k-vector spaces. For $x \in C$ write $x + \mathfrak{n}^2 = s(x) + \nu(x)$ with $s(x) \in \kappa'$, $\nu(x) \in \bar{\mathfrak{n}}$; the image of $s(x)$ in κ is $x + \mathfrak{n}$, and $\nu(x) = x + \mathfrak{n}^2$ for $x \in \mathfrak{n}$. From $\bar{\mathfrak{n}}^2 = 0$,

$$(x + \mathfrak{n}^2)(y + \mathfrak{n}^2) = s(x)s(y) + \big(s(x)\nu(y) + s(y)\nu(x)\big), \qquad s(x)s(y) \in \kappa',$$

so $\nu(xy) = s(x)\nu(y) + s(y)\nu(x)$, where $s(x)$ acts on $\bar{\mathfrak{n}}$ as $x + \mathfrak{n} \in \kappa$. Choose a non-zero κ-linear map $\lambda\colon \bar{\mathfrak{n}} \to \kappa$ (the κ-vector space $\bar{\mathfrak{n}}$ is non-zero) and put $D = \iota \circ \lambda \circ \nu\colon C \to \Omega$. It is k-linear,

and $D(xy) = \psi_{\mathfrak{n}}(x)D(y) + \psi_{\mathfrak{n}}(y)D(x)$; it is non-zero, as ν maps $\mathfrak{n}$ onto $\bar{\mathfrak{n}}$ and ι is injective. This contradicts the hypothesis for $\psi_{\mathfrak{n}}$.

Step 3: every localisation at a maximal ideal is a field. C is Noetherian by Hilbert's basis theorem. For a maximal ideal $\mathfrak{n}$, the finitely generated ideal $\mathfrak{n}C_{\mathfrak{n}}$ of the local ring $C_{\mathfrak{n}}$ satisfies $\mathfrak{n}C_{\mathfrak{n}} = (\mathfrak{n}C_{\mathfrak{n}})^2$ by Step 2, so $\mathfrak{n}C_{\mathfrak{n}} = 0$ by Nakayama's lemma, and $C_{\mathfrak{n}}$ is a field.

Step 4: conclusion. Let $z \in C$ with $\psi(z) = 0$ for all ψ. By Step 1, z lies in every maximal ideal. Then z is nilpotent: otherwise $C[z^{-1}]$ is a non-zero finitely generated k-algebra; for a maximal ideal $\mathfrak{m}'$ of it, $L = C[z^{-1}]/\mathfrak{m}'$ is a finite extension of k by Zariski's lemma, the image of C in L is a domain of finite dimension over k, hence a field, so the kernel $\mathfrak{n}'$ of $C \to L$ is a maximal ideal of C; and $z \notin \mathfrak{n}'$, as z is a unit in $C[z^{-1}]$. This contradicts the fact that z lies in every maximal ideal. So z is nilpotent, and its image in each field $C_{\mathfrak{n}}$ (Step 3) is nilpotent, hence zero. An element of C whose images in all localisations at maximal ideals vanish is zero (Atiyah–Macdonald, Prop. 3.8), so $z = 0$. □

Lemma 41.26. *Let $\mathcal{O}$ be a coefficient ring, B a local $\mathcal{O}$-algebra with maximal ideal $\mathfrak{m}_B$ such that $\mathcal{O} \to B$ is a local homomorphism inducing an isomorphism of residue fields, and M a finitely generated B-module such that $B/\mathrm{Ann}_B(M)$ is a finitely generated $\mathcal{O}$-module. Let $a \in B$, $C \geq 0$ an integer, and Σ_0 a finite set of $\mathcal{O}$-algebra homomorphisms $B \to \overline{\mathbb{Q}}_\ell$ such that*

(Hq1) *for every $\beta \in \Sigma_0$: $\beta(a) \neq 0$, $v_{\mathcal{O}}(\beta(a)) \geq 0$, and $\mathrm{length}_{B_{\ker\beta}}(M_{\ker\beta}) \leq C$;*

(Hq2) *$M_{\ker\beta} = 0$ for every $\mathcal{O}$-algebra homomorphism $\beta\colon B \to \overline{\mathbb{Q}}_\ell$ with $\beta \notin \Sigma_0$.*

Then M/aM and $0 :_M a = \{x \in M : ax = 0\}$ have finite length and

$$\mathrm{length}_B(M/aM) - \mathrm{length}_B(0 :_M a) \leq C \sum_{\beta\in\Sigma_0} v_{\mathcal{O}}(\beta(a)).$$

Proof. Step 1: lengths over B and over $\mathcal{O}$. The ring $R = B/\mathrm{Ann}_B(M)$ is a finitely generated $\mathcal{O}$-module and a local ring with residue field $\mathcal{O}/\varpi\mathcal{O}$; M is a finitely generated R-module, hence a finitely generated $\mathcal{O}$-module, and so are its B-submodules and quotients. For such a B-module X of finite $\mathcal{O}$-length, every chain of B-submodules is a chain of $\mathcal{O}$-submodules, so X has finite B-length; its B-composition factors are $\cong B/\mathfrak{m}_B \cong \mathcal{O}/\varpi\mathcal{O}$, of $\mathcal{O}$-length 1. Hence $\mathrm{length}_B(X) = \mathrm{length}_{\mathcal{O}}(X)$, and below all lengths are over $\mathcal{O}$.

Step 2: the torsion part. Let M_t be the $\mathcal{O}$-torsion submodule of M, a B-submodule of finite length, and $M' = M/M_t$, a free $\mathcal{O}$-module of finite rank. For the endomorphism a of M_t, $\mathrm{length}(M_t/aM_t) = \mathrm{length}(0 :_{M_t} a)$. The snake lemma for multiplication by a on $0 \to M_t \to M \to M' \to 0$ gives the exact sequence

$$0 \to 0 :_{M_t} a \to 0 :_M a \to 0 :_{M'} a \to M_t/aM_t \to M/aM \to M'/aM' \to 0.$$

Step 3: the determinant of a. Let $V = M \otimes_{\mathcal{O}} K_0 = M' \otimes_{\mathcal{O}} K_0$, a finite-dimensional K_0-vector space with an action of the finite-dimensional K_0-algebra $R' = R \otimes_{\mathcal{O}} K_0$. As R' is Artinian, $V = \bigoplus_{\mathfrak{p}} V_{\mathfrak{p}}$ over the finitely many primes $\mathfrak{p}$ of R with $\varpi \notin \mathfrak{p}$, where $V_{\mathfrak{p}} = M_{\mathfrak{p}}$ (ϖ is a unit in $R_{\mathfrak{p}}$). For such $\mathfrak{p}$, $R/\mathfrak{p}$ is a torsion-free domain finite over $\mathcal{O}$, so $\kappa(\mathfrak{p}) = (R/\mathfrak{p})[\varpi^{-1}]$ is a finite extension of K_0, and $M_{\mathfrak{p}}$, a module of finite length over the Artinian local ring $R_{\mathfrak{p}}$, has a filtration by $R_{\mathfrak{p}}$-submodules with $\lambda_{\mathfrak{p}} = \mathrm{length}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}})$ factors, each isomorphic to $\kappa(\mathfrak{p})$. The determinant of multiplication by a on the K_0-vector space $\kappa(\mathfrak{p})$ is the norm $N_{\kappa(\mathfrak{p})/K_0}(\bar{a}) = \prod_\iota \iota(\bar{a})$ over the $[\kappa(\mathfrak{p}) : K_0]$ embeddings ι of $\kappa(\mathfrak{p})$ into $\overline{\mathbb{Q}}_\ell$ over K_0 (characteristic 0). The composites $B \to R/\mathfrak{p} \to$

$\kappa(\mathfrak{p}) \xrightarrow{\iota} \overline{\mathbb{Q}}_\ell$ are exactly the $\mathcal{O}$-algebra homomorphisms $\beta\colon B \to \overline{\mathbb{Q}}_\ell$ with $\ker\beta = \mathfrak{p}_B$, the inverse image of $\mathfrak{p}$ in B: such a β factors through the domain $B/\mathfrak{p}_B = R/\mathfrak{p}$ and extends uniquely to its fraction field. Moreover $M_\mathfrak{p} = M_{\mathfrak{p}_B}$ and $\lambda_\mathfrak{p} = \mathrm{length}_{B_{\mathfrak{p}_B}}(M_{\mathfrak{p}_B})$. By multiplicativity of determinants along filtrations,

$$\det(a \mid V) = \prod_{\mathfrak{p}} \prod_{\beta\colon\ \ker\beta = \mathfrak{p}_B} \beta(a)^{\lambda_\mathfrak{p}}.$$

If $\lambda_\mathfrak{p} > 0$, every β with $\ker\beta = \mathfrak{p}_B$ lies in Σ_0 by (Hq2), so $\beta(a) \neq 0$ by (Hq1). Hence $\det(a \mid V) \neq 0$: a is injective on V, hence on $M' \subseteq V$, and choosing bases in which the matrix of a on M' is in Smith normal form over the discrete valuation ring $\mathcal{O}$,

$$\mathrm{length}(M'/aM') = v_\mathcal{O}(\det(a \mid M')) = \sum_{\mathfrak{p}} \lambda_\mathfrak{p} \sum_{\beta\colon\ \ker\beta = \mathfrak{p}_B} v_\mathcal{O}(\beta(a)).$$

Step 4: conclusion. As $0 :_{M'} a = 0$, the sequence of Step 2 shows that $0 :_M a = 0 :_{M_t} a$ and M/aM have finite length and $\mathrm{length}(M/aM) - \mathrm{length}(0 :_M a) = \mathrm{length}(M_t/aM_t) + \mathrm{length}(M'/aM') - \mathrm{length}(0 :_{M_t} a) = \mathrm{length}(M'/aM')$. In the last sum of Step 3 only primes with $\lambda_\mathfrak{p} > 0$ contribute; each β occurring then lies in Σ_0, distinct primes give distinct β, and $\lambda_\mathfrak{p} \leq C$ by (Hq1). Since $v_\mathcal{O}(\beta(a)) \geq 0$ for every $\beta \in \Sigma_0$, the sum is at most $C \sum_{\beta\in\Sigma_0} v_\mathcal{O}(\beta(a))$. □

42 The one-character bound on $\mathrm{U}(3)$

This section proves Proposition 42.2, the one-character bound for a unitary Eisenstein datum (K, ℓ, e, N, χ), which Proposition 38.5 uses for Count I. The conditions (Ue1)–(Ue9) of Definition 38.1 are those that a character of a Sha-host satisfies in case (I) for $K = \mathbb{Q}(\sqrt{-p_K(\psi)})$. The deformation problem is set up in Definition 42.1. The Eisenstein representation takes values in $\mathrm{GL}_3 \rtimes \{\pm 1\}$, the group through which conjugate self-dual representations of G_K extend to $G_\mathbb{Q}$ [69]; its restriction to G_K is $\Psi \oplus \mathbf{1} \oplus \Psi^{-1}$. A normalised ordinary lift is normalised at complex conjugation and at a marking (Ed1), trivial on the inertia away from ℓ that the residual representation kills (Ed2), and ordinary at ℓ (Ed3); the ring R represents these lifts, and R^0 is its subalgebra of weight zero.

The proof assembles four inputs. The graded model of Section 43 (Proposition 43.3) embeds the Tate–Shafarevich group into derivations of degree -1, whose length is bounded by the cotangent length (Lemma 42.12). Part IX (Theorem 47.1) gives the finiteness of R^0 and shows that the two-signed points, which are of type I (irreducible) or of type II (endoscopic) by Lemma 42.3, are admissible. Rigidity, Theorem 42.5, is the vanishing of the adjoint Bloch–Kato Selmer group at every two-signed point, which gives (Gc4). At points of type I it is the theorem of Newton and Thorne [192] (Proposition 42.6); at points of type II the adjoint decomposes (Lemma 42.9), and the pieces are handled by the second hypothesis of the bound, by the theorem of Newton and Thorne for newforms, by the vanishing for the quadratic character of K (Lemma 42.10) and by a separate argument for CM newforms (Proposition 42.11). The first hypothesis, that no admissible representation has the Eisenstein trace at σ, gives (Gc5) for the trace difference at σ, and the graded numerical criterion Lemma 41.2 concludes.

Definition 42.1. Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum (Definition 38.1) with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with residue field $\mathbb{F}_\mathcal{O}$; put $\Psi = \Psi_{\chi,e}\colon G_\mathbb{Q} \to \mathcal{O}^\times$, let $\eta_K\colon G_\mathbb{Q} \to \{\pm 1\}$ be the character with kernel G_K, and let χ_ℓ be the ℓ-component of χ (Definition 38.1), viewed as a character of $G_\mathbb{Q}$. $\mathrm{CNL}_\mathcal{O}$ is the category of complete Noetherian local $\mathcal{O}$-algebras A for which $\mathcal{O} \to A$ is local and induces an isomorphism $\mathbb{F}_\mathcal{O} \cong A/\mathfrak{m}_A$; its

morphisms are the local $\mathcal{O}$-algebra homomorphisms. Decomposition and inertia groups $D_{\bar v} \supseteq I_{\bar v}$ at places $\bar v$ of $\overline{\mathbb{Q}}$ are as in Definition 38.4. Fix a complex conjugation $c \in G_{\mathbb{Q}}$ and a place $\bar\ell$ of $\overline{\mathbb{Q}}$ above ℓ, and write $D_\ell = D_{\bar\ell} \supseteq I_\ell = I_{\bar\ell}$.

The group and the torus. For a commutative ring B let $J \in \mathrm{GL}_3(B)$ be the antidiagonal matrix with all antidiagonal entries 1, put $\theta(g) = J\,{}^t g^{-1} J$ for $g \in \mathrm{GL}_3(B)$, and let $\mathcal{G}_3(B) = \mathrm{GL}_3(B) \rtimes \{\pm 1\}$, with -1 acting by θ. For an element (g, ς) of $\mathcal{G}_3(B)$, g is its **GL-part** and ς its **sign**; for a homomorphism r into $\mathcal{G}_3(B)$, $\underline{r}$ denotes its GL-part. For $t \in B^\times$ put $\mathrm{T}(t) = \mathrm{diag}(t, 1, t^{-1})$; then $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$. The **weight** of a matrix entry (a, b), $1 \le a, b \le 3$, is $\mathrm{wt}(a, b) = b - a$; conjugation $X \mapsto \mathrm{T}(t) X \mathrm{T}(t)^{-1}$ multiplies the (a, b) entry by $t^{\mathrm{wt}(a,b)}$.

The Eisenstein representation. $r_0 \colon G_{\mathbb{Q}} \to \mathcal{G}_3(\mathcal{O})$, $r_0(g) = (\mathrm{T}(\Psi(g)), \eta_K(g))$; it is a homomorphism because $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$, and its GL-part on G_K is $\Psi \oplus \mathbf{1} \oplus \Psi^{-1}$. Its reduction is $\bar r_0 \colon G_{\mathbb{Q}} \to \mathcal{G}_3(\mathbb{F}_{\mathcal{O}})$. For $1 \le a \le 3$ and $g \in G_{\mathbb{Q}}$ put $\psi_a(g) = \Psi(g)^{2-a}$, the diagonal entries of $\underline{r_0}(g)$.

Lifts. Let G be $G_{\mathbb{Q}}$ or D_ℓ. For $A \in \mathrm{CNL}_{\mathcal{O}}$, a **lift** of $\bar r_0|_G$ to A is a homomorphism $r \colon G \to \mathcal{G}_3(A)$ whose reduction modulo $\mathfrak{m}_A$ is $\bar r_0|_G$ (so its sign is η_K) and whose GL-part has entries that are continuous for the $\mathfrak{m}_A$-adic topology; for a morphism $f \colon A \to A'$, $f \circ r$ is a lift to A'. A **base point** of a lift r to A is an $\mathcal{O}$-algebra homomorphism $\beta \colon A \to \mathcal{O}$ with $\beta \circ r = r_0|_G$. Let $(R^{\square}_\ell, r^{\square}_\ell)$ be the universal lift of $\bar r_0|_{D_\ell}$, which exists by Mazur's representability theorem (D_ℓ satisfies the ℓ-finiteness condition).

The ordinary condition at ℓ. Let $D^\circ_\ell = \{g \in D_\ell : \ \eta_K(g) = 1,\ \chi_\ell(g) = 1\}$. Fix $\sigma_0 \in D^\circ_\ell \cap I_\ell$ with $\chi_{\mathrm{cyc}}(\sigma_0)$ of infinite order, and $\sigma_\ell \in D^\circ_\ell$ such that D°_ℓ is the closed subgroup generated by $D^\circ_\ell \cap I_\ell$ and σ_ℓ, and $\sigma_\ell \in \mathrm{Fr}^n I_\ell$ for an arithmetic Frobenius $\mathrm{Fr} \in D_\ell$ and an integer $n \ge 1$. For a lift r of $\bar r_0|_{D_\ell}$ to A, the **ordinary ideal** $I^{\mathrm{ord}}(r) \subseteq A$ is generated by the coefficients of $\det(X - \underline{r}(g)) - \prod_{a=1}^3 (X - \psi_a(g))$ for $g \in D^\circ_\ell \cap I_\ell$ and by the entries of the product $(\underline{r}(g_1) - \psi_1(g_1))(\underline{r}(g_2) - \psi_2(g_2))(\underline{r}(g_3) - \psi_3(g_3))$ for $g_1, g_2, g_3 \in D^\circ_\ell \cap I_\ell$. With indices of ψ read modulo 3 in $\{1, 2, 3\}$ put

$$\mathrm{gp}_a = (\psi_a(\sigma_0) - \psi_{a+1}(\sigma_0))(\psi_a(\sigma_0) - \psi_{a+2}(\sigma_0)),$$
$$\mathrm{tq}_a(r) = \mathrm{tr}\Big((\underline{r}(\sigma_0) - \psi_{a+1}(\sigma_0))(\underline{r}(\sigma_0) - \psi_{a+2}(\sigma_0))\underline{r}(\sigma_\ell)\Big),$$

$\mathrm{dt}_a(r) = \mathrm{gp}_{a+1}\mathrm{tq}_a(r) - \chi_{\mathrm{cyc}}(\sigma_\ell)\,\mathrm{gp}_a\mathrm{tq}_{a+1}(r)$ and $\mathrm{gd}(r) = \ell\,\mathrm{dt}_1(r)\mathrm{dt}_2(r) \in A$. Let $I^{\mathrm{cr}} \subseteq R^{\square}_\ell$ be the radical of $\{y : \ \mathrm{gd}(r^{\square}_\ell)^n y \in I^{\mathrm{ord}}(r^{\square}_\ell)$ for some $n \ge 0\}$, and let I^{ord}_ℓ be the intersection of the minimal primes $\mathfrak{P}$ of I^{cr} such that $\mathfrak{P} \subseteq \ker\beta$ for every base point β of $r^{\square}_\ell$ (the components through the Eisenstein point of the closure of the generic ordinary lifts with diagonal characters ψ_1, ψ_2, ψ_3 on $D^\circ_\ell \cap I_\ell$).

Normalised ordinary lifts. An element $g_\star \in G_{\mathbb{Q}}$ is a **marking** if $\eta_K(g_\star) = 1$ and $\Psi(g_\star)^2 - 1 \in \mathcal{O}^\times$ (moreover $c^2 = 1$, $\eta_K(c) = -1$, and $\Psi(c) = 1$ by (Ue5)). For a marking $g_\star$, a lift r of $\bar r_0$ to $A \in \mathrm{CNL}_{\mathcal{O}}$ is a **normalised ordinary lift** if

(Ed1) $\underline{r}(c) = 1$, and the entries $(1,2)$ and $(2,1)$ of $\underline{r}(g_\star) - \underline{r}(cg_\star^{-1}c)$ vanish;

(Ed2) $r(g) = 1$ for every $g \in I_{\bar v}$, $\bar v$ a place of $\overline{\mathbb{Q}}$ not above ℓ, with $\bar r_0(g) = 1$;

(Ed3) $r|_{D_\ell} = f \circ r^{\square}_\ell$ for a morphism $f \colon R^{\square}_\ell \to A$ with $f(I^{\mathrm{ord}}_\ell) = 0$.

A **normalised ordinary Eisenstein deformation ring** for $g_\star$ is a pair (R, r) of $R \in \mathrm{CNL}_{\mathcal{O}}$ and a normalised ordinary lift r to R such that $f \circ r$ is a normalised ordinary lift for every morphism $f \colon R \to A$, and for every normalised ordinary lift r' to some A there is exactly one morphism $f \colon R \to A$ with $f \circ r = r'$. Its **weight-zero subalgebra** R^0 is the $\mathcal{O}$-subalgebra generated by the products $\prod_k \underline{r}(g_k)_{a_k b_k}$ with $\sum_k \mathrm{wt}(a_k, b_k) = 0$; a base point of r is written φ_{Eis}.

Points. A **point** of (R,r) is an $\mathcal{O}$-algebra homomorphism $\varphi\colon R\to\overline{\mathbb{Q}}_\ell$ with $|\varphi(y)|_\ell<1$ for all $y\in\mathfrak{m}_R$; $r_\varphi=\varphi\circ r\colon G_{\mathbb{Q}}\to\mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$, and $\rho_\varphi\colon G_K\to\mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is the restriction of r_φ to G_K (both are continuous, $\mathfrak{m}_R$ being finitely generated). The point is **upper** if for all $g\in G_K$ the entries of $\rho_\varphi(g)$ of negative weight vanish, **lower** if those of positive weight vanish, and **two-signed** if it is neither. It is **of type I** if ρ_φ is irreducible, and **of type II** if for all $g\in G_K$ the entries of $\rho_\varphi(g)$ of odd weight vanish and $g\mapsto\bigl(\rho_\varphi(g)_{ab}\bigr)_{a,b\in\{1,3\}}$ is an irreducible representation of G_K on $\overline{\mathbb{Q}}_\ell^2$. For $t\in\overline{\mathbb{Q}}_\ell^\times$ the **torus conjugate** $\mathrm{T}(t)\cdot r_\varphi$ is $g\mapsto(\mathrm{T}(t),1)\,r_\varphi(g)\,(\mathrm{T}(t),1)^{-1}$. For $\sigma\in G_K$ the **trace difference** of φ at σ is $\operatorname{tr}\rho_\varphi(\sigma)-\bigl(\Psi(\sigma)+1+\Psi(\sigma)^{-1}\bigr)$. The **adjoint representation** $\operatorname{ad} r_\varphi$ is $\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ on which $g\in G_{\mathbb{Q}}$ with $r_\varphi(g)=(P,\varsigma)$ acts by $X\mapsto PXP^{-1}$ if $\varsigma=1$ and by $X\mapsto -P\,J\,{}^tX\,J\,P^{-1}$ if $\varsigma=-1$; $H^1_f(\mathbb{Q},\operatorname{ad} r_\varphi)$ is its Bloch–Kato Selmer group.

Proposition 42.2. *Let (K,ℓ,e,N,χ) be a unitary Eisenstein datum, with χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $\eta_K\colon G_{\mathbb{Q}}\to\{\pm1\}\subset\overline{\mathbb{Q}}_\ell^\times$ be the character with kernel G_K. Let $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ be an isomorphism, $\sigma\in G_K$, and*

$$t=\Psi_{\chi,e}(\sigma)+1+\Psi_{\chi,e}(\sigma)^{-1}\in\mathcal{O}.$$

Assume:

1. *$\operatorname{tr}\rho(\sigma)\neq t$ for every representation $\rho\colon G_K\to\mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ admissible of weight e and level N (for K and ι);*
2. *for every continuous $W\colon G_{\mathbb{Q}}\to\mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that $W\otimes\chi_{\mathrm{cyc}}^{-e}$ is semisimple and there is a normalised newform $f=\sum_{n\geq1}a_nq^n$ of weight $2e+1$ and Nebentypus ε_f with the property that for all but finitely many primes p, $W\otimes\chi_{\mathrm{cyc}}^{-e}$ is unramified at p and $\iota\bigl(\det(X-(W\otimes\chi_{\mathrm{cyc}}^{-e})(\sigma'^{-1}))\bigr)=X^2-a_pX+\varepsilon_f(p)p^{2e}$ for every arithmetic Frobenius σ' at a place above p, one has $H^1_f(\mathbb{Q},W)=0$ and $H^1_f(\mathbb{Q},W\otimes\eta_K)=0$.*

Then $\mathrm{Sha}^1_{\ell N}(\chi,e)$ has finite length, and there is a finite set X of pairwise non-isomorphic representations $G_K\to\mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ admissible of weight e and level N such that

$$\nu_{\mathcal{O}}(\chi,e)\leq2\sum_{\rho\in X}v_\ell\bigl(\operatorname{tr}\rho(\sigma)-t\bigr).$$

Proof. Step 0: we may assume $e_{\mathcal{O}}=1$. By (Ue3) the order of χ is prime to ℓ, so by Lemma 38.27, item 1, there is a coefficient ring $\mathcal{O}'$ with $e_{\mathcal{O}'}=1$ containing the values of χ. The conditions (Ue1)–(Ue9) and the element $t\in\overline{\mathbb{Q}}_\ell$ depend only on χ as a $\overline{\mathbb{Q}}_\ell^\times$-valued character, and the two hypotheses and the conclusion other than $\nu_{\mathcal{O}}(\chi,e)$ do not involve $\mathcal{O}$; by Lemma 38.27, item 2, $\mathrm{Sha}^1_{\ell N}(\chi,e)$ has finite length over $\mathcal{O}$ if and only if it has over $\mathcal{O}'$, with the same normalised length. So we may and do replace $\mathcal{O}$ by $\mathcal{O}'$. Then $v_{\mathcal{O}}=v_\ell$ and $\nu_{\mathcal{O}}(\chi,e)=\operatorname{length}_{\mathcal{O}}\mathrm{Sha}^1_{\ell N}(\chi,e)$.

Step 1: the ring and its graded model. By Theorem 47.1, applied to the datum, $\mathcal{O}$ and ι, there is a marking $g_\star$ such that (Au1)–(Au3) hold for every normalised ordinary Eisenstein deformation ring for $g_\star$. By Proposition 43.3, applied with $g_\star$, there are such a ring (R,r) with its base point φ_{Eis}, and (A,φ_0,u,q) with (Mo3)–(Mo7). For a point φ of (R,r), $\varphi\circ q$ is a point of A on u, because $I(u)=\ker q$.

Step 2: every two-signed point of (R,r) is admissible and rigid. Let φ be a two-signed point. By Lemma 42.3 it is of type I or of type II. If it is of type I, ρ_φ is admissible of stable type for (ι,e,N) and irreducible on every open subgroup of G_K by (Au2); by (Sb2), $\rho_\varphi\otimes\chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type, so Theorem 42.5, case (Ri1), gives $H^1_f(\mathbb{Q},\operatorname{ad} r_\varphi)=0$. If

it is of type II, ρ_φ is admissible of endoscopic type for $(\iota, e, N|d_K|)$ by (Au3), and every continuous $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ restricting on G_K to the corner $\left(\rho_\varphi(g)_{ab}\right)_{a,b\in\{1,3\}}$ with $\operatorname{tr} W(c) = 0$ satisfies the witness conditions over imaginary quadratic fields and (Eo2). Condition (Eo2) says exactly that W satisfies the assumptions made on W in hypothesis 2 ($W \otimes \chi_{\mathrm{cyc}}^{-e}$ semisimple, attached to a normalised newform of weight $2e+1$ at almost all primes, being trivial on inertia at all places above a prime meaning unramified there); so hypothesis 2 gives $H^1_f(\mathbb{Q}, W) = H^1_f(\mathbb{Q}, W \otimes \eta_K) = 0$ for every such W, and Theorem 42.5, case (Ri2) (whose remaining hypothesis, endoscopic admissibility of ρ_φ, is (Au3)), gives $H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi) = 0$. In both cases ρ_φ is admissible of weight e and level N. With (Au1), the hypotheses of (Mo6) hold, so (A, φ_0, u) satisfies (Gc1)–(Gc4); in particular (Gc2) holds, and (Mo5) applies.

Step 3: points on u. Let ψ' be a two-signed point of A on u. By (Mo5), $\psi' = t \cdot (\varphi \circ q)$ for a point φ of (R, r) and some t. Since $(t \cdot \varphi \circ q)(f) = t^j \varphi(q(f))$ on A_j and $t \neq 0$, $\varphi \circ q$ is two-signed, so by (Mo4) φ is neither upper nor lower: φ is a two-signed point of (R, r). Conversely, for a two-signed point φ of (R, r), $\varphi \circ q$ is a two-signed point on u by (Mo4) and Step 1.

Step 4: the weight-zero element. By (Mo3) choose $h_1, h_2, h_3 \in A_0$ with $q(h_i) = \underline{r}(\sigma)_{ii}$ (the diagonal entries have weight 0), and put $a_\sigma = h_1 + h_2 + h_3 - t \in A_0$, with $t \in \mathcal{O}$. Then $q(a_\sigma) = \operatorname{tr} \underline{r}(\sigma) - t$, so for every point φ of (R, r), as $\sigma \in G_K$,

$$\varphi(q(a_\sigma)) = \operatorname{tr} \rho_\varphi(\sigma) - t.$$

Since $\varphi_{\mathrm{Eis}} \circ r = r_0$, $\varphi_0(a_\sigma) = \varphi_{\mathrm{Eis}}(q(a_\sigma)) = \operatorname{tr} \mathrm{T}(\Psi(\sigma)) - t = 0$. For a two-signed point $\psi' = t' \cdot (\varphi \circ q)$ on u as in Step 3, $\psi'(a_\sigma) = \varphi(q(a_\sigma)) = \operatorname{tr} \rho_\varphi(\sigma) - t$ (degree 0), which is non-zero by hypothesis 1, ρ_φ being admissible of weight e and level N by Step 2. So (Gc5) holds for a_σ, and $(A, \varphi_0, u, a_\sigma)$ satisfies (Gc1)–(Gc5).

Step 5: the graded numerical criterion. By Lemma 41.2, u has an orbit cover Σ_0, $C := \mathrm{ct}_{-1}(u_{-1})$ is finite, and $C \leq 2 \sum_{\psi' \in \Sigma} v_\ell(\psi'(a_\sigma))$ for every orbit cover Σ (recall $v_\mathcal{O} = v_\ell$).

Step 6: the Sha group has length at most C. Let $b \in \mathcal{O} \setminus \{0\}$ and $\mathrm{Sha}[b]$ the b-torsion of $\mathrm{Sha}^1_{\ell N}(\chi, e)$. The map D of (Mo7) satisfies the hypotheses of Lemma 42.12 for $j = -1$, the family u_{-1}, $c = b$ and $M = \mathrm{Sha}[b]$; hence $\operatorname{length}_\mathcal{O} \mathrm{Sha}[b] \leq C$. Every class in $H^1(\mathbb{Q}, \mathcal{O}^\vee(\Psi^{-1}))$ is represented by a continuous cocycle on the compact group $G_\mathbb{Q}$ with values in a discrete module, which has finite image; every element of $\mathcal{O}^\vee = \mathcal{O} \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$ is killed by a power of ℓ; so every class is killed by some ℓ^k, and $\mathrm{Sha}^1_{\ell N}(\chi, e) = \bigcup_k \mathrm{Sha}[\ell^k]$, an increasing union. If $\mathrm{Sha}^1_{\ell N}(\chi, e)$ contained a strictly increasing chain $M_0 \subsetneq M_1 \subsetneq \cdots \subsetneq M_{C+1}$ of submodules, choose $x_i \in M_i \setminus M_{i-1}$; the submodule generated by $x_1, \ldots, x_{C+1}$ lies in some $\mathrm{Sha}[\ell^k]$ and contains the strictly increasing chain of the submodules generated by $x_1, \ldots, x_i$ (the i-th lies in M_i and contains $x_i \notin M_{i-1}$), so it has length at least $C+1$, a contradiction. Hence $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length and $\nu_\mathcal{O}(\chi, e) \leq C$.

Step 7: from an orbit cover to representations. For two-signed points φ, φ' of (R, r) write $\varphi \sim \varphi'$ if $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ for some $t \in \overline{\mathbb{Q}}_\ell^\times$; since $t \mapsto (\mathrm{T}(t), 1)$ is a homomorphism, $\sim$ is an equivalence relation. For each $\psi' \in \Sigma_0$ choose, by Step 3, a two-signed point $\varphi_{\psi'}$ and $t_{\psi'}$ with $\psi' = t_{\psi'} \cdot (\varphi_{\psi'} \circ q)$. Every two-signed point φ of (R, r) is equivalent to some $\varphi_{\psi'}$: by Step 3 and the definition of an orbit cover, $\varphi \circ q = t \cdot \psi' = (t t_{\psi'}) \cdot (\varphi_{\psi'} \circ q)$ for some $\psi' \in \Sigma_0$ and t, and (Mo4) gives $r_\varphi = \mathrm{T}(t t_{\psi'}) \cdot r_{\varphi_{\psi'}}$. Let P be a set containing exactly one member of each equivalence class that meets $\{\varphi_{\psi'} : \psi' \in \Sigma_0\}$; P is finite, its members are pairwise inequivalent, and every two-signed point is equivalent to a member of P. Then $\Sigma = \{\varphi \circ q : \varphi \in P\}$ is an orbit cover: its members are two-signed points on u (Step 3); a two-signed point ψ'' on u is $t'' \cdot (\varphi'' \circ q)$ with φ'' two-signed (Step 3), $\varphi'' \sim \varphi \in P$, say $r_{\varphi''} = \mathrm{T}(s) \cdot r_\varphi$, so $\varphi'' \circ q = s \cdot (\varphi \circ q)$ by (Mo4) and $\psi'' = (t''s) \cdot (\varphi \circ q)$. The map $\varphi \mapsto \varphi \circ q$ is injective on P: if $\varphi \circ q = \varphi' \circ q$, then $r_{\varphi'} = \mathrm{T}(1) \cdot r_\varphi$

by (Mo4), so $\varphi \sim \varphi'$ and $\varphi = \varphi'$. With Steps 4 and 5,

$$C \le 2 \sum_{\varphi \in P} v_\ell(\varphi(q(a_\sigma))) = 2 \sum_{\varphi \in P} v_\ell(\operatorname{tr} \rho_\varphi(\sigma) - t).$$

Put $X = \{\rho_\varphi : \varphi \in P\}$. Its members are admissible of weight e and level N (Step 2). If $\varphi, \varphi' \in P$ and $\rho_\varphi \cong \rho_{\varphi'}$, then Lemma 42.3 gives $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ for some t, so $\varphi \sim \varphi'$ and $\varphi = \varphi'$. Hence the members of X are pairwise non-isomorphic, $\varphi \mapsto \rho_\varphi$ is a bijection $P \to X$, and with Step 6

$$\nu_{\mathcal{O}}(\chi, e) \le C \le 2 \sum_{\rho \in X} v_\ell(\operatorname{tr} \rho(\sigma) - t).$$

□

Lemma 42.3. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking and (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$. Let φ be a two-signed point of (R, r). Then φ is of type I or of type II, and for every point φ' of (R, r) with $\rho_{\varphi'} \cong \rho_\varphi$ there is $t \in \overline{\mathbb{Q}}_\ell^\times$ with $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$.*

Proof. Let φ be a two-signed point and φ' a point of (R, r) with $\rho_{\varphi'} \cong \rho_\varphi$.

Step 1: r_φ and $r_{\varphi'}$ satisfy (Ns1)–(Ns3) of Lemma 42.4 for K, c and $g_\star$, and $\delta_\star(r_\varphi) + \delta_\star(r_{\varphi'}) \neq 0$. Let $\phi \in \{\varphi, \varphi'\}$. Applying the ring homomorphism ϕ to the entries of GL-parts is a homomorphism $\mathcal{G}_3(R) \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$ (it commutes with products, inverses, transposes and hence with θ), so $r_\phi = \phi \circ r$ is a homomorphism $G_\mathbb{Q} \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$. The sign of $r(g)$ is $\eta_K(g)$, r being a lift of $\bar{r}_0$, and (Ed1) says that $\underline{r}(c) = 1$ and that the entries $(1,2)$, $(2,1)$ of $\underline{r}(g_\star) - \underline{r}(cg_\star^{-1}c)$ vanish; applying ϕ gives (Ns1) and (Ns2) for r_ϕ. The marking satisfies $\eta_K(g_\star) = 1$, so $g_\star \in G_K$. Put $u = \Psi(g_\star) - \Psi(g_\star)^{-1} = \Psi(g_\star)^{-1}(\Psi(g_\star)^2 - 1)$, a unit of $\mathcal{O}$ because $g_\star$ is a marking. Since r reduces to $\bar{r}_0$ modulo $\mathfrak{m}_R$ and $\underline{r_0}(g_\star) = \mathrm{T}(\Psi(g_\star))$, the element $y = \underline{r}(g_\star)_{11} - \underline{r}(g_\star)_{33} - u$ lies in $\mathfrak{m}_R$. As ϕ is an $\mathcal{O}$-algebra homomorphism, $\delta_\star(r_\phi) = u + \phi(y)$ with $|u|_\ell = 1$ and $|\phi(y)|_\ell < 1$ (definition of a point); by the ultrametric inequality $|\delta_\star(r_\phi)|_\ell = 1$, so (Ns3) holds. Likewise $\delta_\star(r_\varphi) + \delta_\star(r_{\varphi'}) = 2u + \varphi(y) + \varphi'(y)$, where $|2u|_\ell = 1$ because ℓ is odd (Ue1) and $|\varphi(y) + \varphi'(y)|_\ell < 1$; so it is non-zero.

Step 2: φ is of type I or of type II. Apply Lemma 42.4, item 1, to r_φ; the restriction of $\underline{r_\varphi}$ to G_K is ρ_φ. Since φ is two-signed, it is neither upper nor lower: the entries of negative weight of $\rho_\varphi(g)$ do not vanish for all $g \in G_K$, nor do those of positive weight. So ρ_φ is irreducible, i.e. φ is of type I, or the entries of odd weight of $\rho_\varphi(g)$ vanish for all $g \in G_K$ and the corner $g \mapsto (\rho_\varphi(g)_{ab})_{a,b \in \{1,3\}}$ is irreducible, i.e. φ is of type II.

Step 3: torus conjugacy. By Step 1 and $\rho_{\varphi'} \cong \rho_\varphi$, Lemma 42.4, item 2, applied to $r = r_\varphi$ and $r' = r_{\varphi'}$, gives $t \in \overline{\mathbb{Q}}_\ell^\times$ with $r_{\varphi'}(g) = (\mathrm{T}(t), 1)\, r_\varphi(g)\, (\mathrm{T}(t), 1)^{-1}$ for all g, that is $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$. □

Lemma 42.4. *Let ℓ be a prime, $K \subset \overline{\mathbb{Q}}$ an imaginary quadratic field, $\eta_K \colon G_\mathbb{Q} \to \{\pm 1\}$ the character with kernel G_K, $c \in G_\mathbb{Q}$ a complex conjugation and $g_\star \in G_K$. Let k be a field of characteristic not 2 (for instance $\overline{\mathbb{Q}}_\ell$) and $r, r' \colon G_\mathbb{Q} \to \mathcal{G}_3(k)$ homomorphisms such that each $s \in \{r, r'\}$ satisfies*

(Ns1) *the sign of $s(g)$ is $\eta_K(g)$ for every $g \in G_\mathbb{Q}$, and $\underline{s}(c) = 1$;*

(Ns2) *the entries $(1,2)$ and $(2,1)$ of $\underline{s}(g_\star) - \underline{s}(cg_\star^{-1}c)$ vanish;*

(Ns3) $\delta_\star(s) := \underline{s}(g_\star)_{11} - \underline{s}(g_\star)_{33} \neq 0$.

Let $\rho, \rho' \colon G_K \to \mathrm{GL}_3(k)$ be the restrictions of $\underline{r}$, $\underline{r'}$ to G_K. Then:

1. *at least one of the following holds: ρ is irreducible; for every $g \in G_K$ the entries of $\rho(g)$ of negative weight vanish; for every $g \in G_K$ the entries of $\rho(g)$ of positive weight vanish; for every $g \in G_K$ the entries of $\rho(g)$ of odd weight vanish and $g \mapsto \left(\rho(g)_{ab}\right)_{a,b\in\{1,3\}}$ is an irreducible representation of G_K on k^2;*

2. *if k is algebraically closed, $\rho' \cong \rho$ (conjugate in $\mathrm{GL}_3(k)$) and $\delta_\star(r) + \delta_\star(r') \neq 0$, there is $t \in k^\times$ with $r'(g) = (\mathrm{T}(t), 1)\, r(g)\, (\mathrm{T}(t), 1)^{-1}$ for every $g \in G_{\mathbb{Q}}$.*

Proof. For $a \in \{1,2,3\}$ put $\bar{a} = 4 - a$, and for a 3×3 matrix X put $X^\tau = J\,{}^t\!X\,J$, so that $(X^\tau)_{ab} = X_{\bar{b}\bar{a}}$; note $\mathrm{wt}(\bar{b}, \bar{a}) = \mathrm{wt}(a, b)$. For $g \in G_{\mathbb{Q}}$ put $g^* = cg^{-1}c$; if $g \in G_K$ then $g^* \in G_K$, since $\eta_K(g^*) = \eta_K(c)^2\eta_K(g)^{-1}$. Write e_1, e_2, e_3 for the standard basis of k^3.

Step 1: for $s \in \{r, r'\}$ and $g \in G_K$, $\underline{s}(g^*) = \underline{s}(g)^\tau$. By (Ns1), $s(c) = (1, -1)$ and $s(g) = (P, 1)$ with $P = \underline{s}(g)$, so $s(g^{-1}) = (P^{-1}, 1)$. By the multiplication rule, $s(c)s(g^{-1}) = (\theta(P^{-1}), -1)$ and $(\theta(P^{-1}), -1)(1, -1) = (\theta(P^{-1})\theta(1), 1) = (\theta(P^{-1}), 1)$. Since $\theta(P^{-1}) = J\,{}^t\!P\,J = P^\tau$, this is the claim.

Step 2: $\underline{s}(g_\star) - \underline{s}(g_\star^*) = \mathrm{diag}(\delta_\star(s), 0, -\delta_\star(s))$ for $s \in \{r, r'\}$. Put $P = \underline{s}(g_\star)$. By Step 1 the (a, b) entry of the difference is $P_{ab} - P_{\bar{b}\bar{a}}$.

The entries $(1, 2)$ and $(2, 1)$ vanish by (Ns2), hence so do $(2, 3)$ and $(3, 2)$, their negatives. Write $D_s = \mathrm{diag}(d_1, d_2, d_3)$ for this matrix, $d = (\delta_\star(s), 0, -\delta_\star(s))$. By (Ns3) and since k has characteristic not 2, d_1, d_2, d_3 are pairwise distinct.

Step 3: mirror symmetry of vanishing entries. For $a, b \in \{1, 2, 3\}$ write $Z(a, b)$ for the property $\rho(g)_{ab} = 0$ for all $g \in G_K$. Then $Z(a, b)$ implies $Z(\bar{b}, \bar{a})$: for $g \in G_K$, Step 1 gives $\rho(g)_{\bar{b}\bar{a}} = (\rho(g)^\tau)_{ab} = \rho(g^*)_{ab} = 0$.

Step 4: stable subspaces are coordinate subspaces. Let $W \subseteq k^3$ be stable under $\rho(G_K)$. As $g_\star, g_\star^* \in G_K$, W is stable under $D_r = \rho(g_\star) - \rho(g_\star^*)$. For $w = \sum_i w_i e_i \in W$ and each i, the polynomial $L_i(X) = \prod_{j\neq i}(X - d_j)/(d_i - d_j)$ (defined by Step 2) satisfies $L_i(D_r)w = w_i e_i \in W$. Hence W is spanned by the e_i it contains: $W = \bigoplus_{i\in S} ke_i$ with $S = \{i : e_i \in W\}$. The same argument with $\mathrm{diag}(d_1, d_3)$ shows that a line in $ke_1 \oplus ke_3$ stable under $\mathrm{diag}(d_1, d_3)$ is ke_1 or ke_3.

Step 5: item 1. Suppose ρ is reducible, and let W be a stable subspace with $0 \neq W \neq k^3$; by Step 4, $W = \bigoplus_{i\in S} ke_i$ with $\emptyset \neq S \subsetneq \{1, 2, 3\}$. For $j \in S$ and $g \in G_K$, $\rho(g)e_j \in W$, so $Z(i, j)$ holds whenever $i \notin S$ and $j \in S$. The entries of negative weight are $(2, 1), (3, 1), (3, 2)$, those of positive weight $(1, 2), (1, 3), (2, 3)$, those of odd weight $(1, 2), (2, 1), (2, 3), (3, 2)$.

- $1 \in S$, $3 \notin S$. Then $Z(3, 1)$. If $2 \in S$, then $Z(3, 2)$, and $Z(2, 1)$ by Step 3 ($\bar{2} = 2$, $\bar{3} = 1$). If $2 \notin S$, then $Z(2, 1)$, and $Z(3, 2)$ by Step 3. So the entries of negative weight vanish on G_K.

- $3 \in S$, $1 \notin S$. Then $Z(1, 3)$. If $2 \in S$, then $Z(1, 2)$ and, by Step 3, $Z(2, 3)$; if $2 \notin S$, then $Z(2, 3)$ and, by Step 3, $Z(1, 2)$. So the entries of positive weight vanish on G_K.

- Otherwise S contains both or neither of $1, 3$, so $S = \{1, 3\}$ or $S = \{2\}$. If $S = \{1, 3\}$: $Z(2, 1)$, $Z(2, 3)$, and by Step 3 $Z(3, 2)$, $Z(1, 2)$. If $S = \{2\}$: $Z(1, 2)$, $Z(3, 2)$, and by Step 3 $Z(2, 3)$, $Z(2, 1)$. In both cases the entries of odd weight vanish on G_K. Then $\rho(g)$ preserves $U = ke_1 \oplus ke_3$, and $\tau(g) = (\rho(g)_{ab})_{a,b\in\{1,3\}}$ is the matrix of $\rho(g)|_U$, so τ is a representation of G_K. If τ is irreducible, the fourth alternative holds. If not, some line of U is $\tau(G_K)$-stable, hence stable under $\tau(g_\star) - \tau(g_\star^*) = \mathrm{diag}(d_1, d_3)$, so by Step 4 it is ke_1 or ke_3. If it is ke_1, then $Z(3, 1)$, and with the vanishing of $(2, 1)$ and $(3, 2)$ all entries of negative weight vanish on G_K; if it is ke_3, then $Z(1, 3)$ and all entries of positive weight vanish on G_K.

So if ρ is not irreducible, one of the other three alternatives holds.

Step 6: item 2 on G_K. Let $M \in \mathrm{GL}_3(k)$ with $M\rho(g) = \rho'(g)M$ for all $g \in G_K$. Applying this to $g_\star$ and $g_\star^*$ and subtracting gives $MD_r = D_{r'}M$ (Step 2). Write $D_r = \mathrm{diag}(d_1, d_2, d_3)$, $D_{r'} = \mathrm{diag}(d_1', d_2', d_3')$ and $\delta = \delta_\star(r)$, $\delta' = \delta_\star(r')$. The (a,b) entry gives $M_{ab}(d_b - d_a') = 0$.

By (Ns3) and the hypothesis $\delta + \delta' \neq 0$ these are all non-zero, so $M = \mathrm{diag}(m_1, m_2, m_3)$, and $m_1 m_2 m_3 = \det M \neq 0$. Hence, for all $g \in G_K$ and all a, b,

$$m_a\, \rho(g)_{ab} = \rho'(g)_{ab}\, m_b. \tag{42.1}$$

Applying (42.1) to g^* and using Step 1 for r and r' gives $m_a \rho(g)_{\bar b \bar a} = \rho'(g)_{\bar b \bar a} m_b$; renaming (a,b) as $(\bar b, \bar a)$, $m_{\bar b}\rho(g)_{ab} = \rho'(g)_{ab} m_{\bar a}$. Multiplying this by m_b, (42.1) by $m_{\bar a}$, and subtracting,

$$(m_a m_{\bar a} - m_b m_{\bar b})\, \rho(g)_{ab} = 0 \qquad (g \in G_K), \tag{42.2}$$

where $m_a m_{\bar a}$ is $m_1 m_3$ if $a \in \{1,3\}$ and m_2^2 if $a = 2$. Recall that $\mathrm{T}(t) X \mathrm{T}(t)^{-1}$ has (a,b) entry $t^{b-a} X_{ab}$.

- If $m_1 m_3 = m_2^2$, put $t = m_1/m_2$. Then $m_3 = m_2 t^{-1}$, so $m_a = m_2 t^{2-a}$ for all a, and (42.1) gives $\rho'(g)_{ab} = t^{b-a}\rho(g)_{ab}$.
- If $m_1 m_3 \neq m_2^2$, then by (42.2) $\rho(g)_{ab} = 0$ whenever exactly one of a, b is 2, and then $\rho'(g)_{ab} = 0$ by (42.1). Choose $t \in k^\times$ with $t^2 = m_1/m_3$ (k is algebraically closed). For $a, b \in \{1,3\}$ or $a = b = 2$, m_a/m_b is 1, t^2 or t^{-2} according as $b - a$ is 0, 2 or -2, so (42.1) gives $\rho'(g)_{ab} = t^{b-a}\rho(g)_{ab}$; for the remaining entries both sides vanish.

In both cases $\rho'(g) = \mathrm{T}(t)\rho(g)\mathrm{T}(t)^{-1}$ for all $g \in G_K$.

Step 7: item 2 on $G_\mathbb{Q}$. Let ι_t be the automorphism $x \mapsto (\mathrm{T}(t), 1)\, x\, (\mathrm{T}(t), 1)^{-1}$ of $\mathcal{G}_3(k)$. By the multiplication rule and $\theta(\mathrm{T}(t)^{-1}) = \mathrm{T}(t)^{-1}$, $\iota_t(P, \varsigma) = (\mathrm{T}(t) P \mathrm{T}(t)^{-1}, \varsigma)$ for both signs. By Step 6 and (Ns1), $r'(g) = \iota_t(r(g))$ for $g \in G_K$, and $r'(c) = (1, -1) = \iota_t(r(c))$. For $g \notin G_K$, $gc \in G_K$ and $g = (gc)c$ since $c^2 = 1$, so $r'(g) = r'(gc)r'(c) = \iota_t(r(gc))\iota_t(r(c)) = \iota_t(r(g))$. □

Theorem 42.5. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, d_K the discriminant of K, $g_\star$ a marking, (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and φ a two-signed point of (R, r). Then $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$ in each of the following cases:*

(Ri1) *φ is of type I, ρ_φ is irreducible on every open subgroup of G_K, and $\rho_\varphi \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type (for ι);*

(Ri2) *φ is of type II, ρ_φ is admissible of endoscopic type for $(\iota, e, N|d_K|)$, every continuous $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $W(g) = (\rho_\varphi(g)_{ab})_{a,b\in\{1,3\}}$ for all $g \in G_K$ and $\mathrm{tr}\, W(c) = 0$ satisfies the witness conditions over imaginary quadratic fields and (Eo2) (for ι, with some normalised newform of weight $2e+1$), and every such W has $H^1_f(\mathbb{Q}, W) = 0$ and $H^1_f(\mathbb{Q}, W \otimes \eta_K) = 0$.*

Proof. The homomorphism $r_\varphi = \varphi \circ r\colon G_\mathbb{Q} \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$ has sign η_K (the sign of a lift is that of $\bar r_0$) and continuous GL-part, whose restriction to G_K is ρ_φ; by (Ed1), $r_\varphi(c) = (1, -1)$. The module $\mathrm{ad}\, r_\varphi$ of Definition 42.1 is the module $\mathrm{ad}\, r_\varphi$ of Proposition 42.6 (same formulas). Bloch–Kato Selmer groups are additive in finite direct sums and invariant under isomorphisms of continuous representations.

Case (Ri1). The hypotheses of Proposition 42.6 hold for r_φ: assumption 1 is the irreducibility on open subgroups, and assumption 2 is the automorphy. Hence $H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi) = 0$.

Case (Ri2), Step 1: the shape of ρ_φ. Write $W'(g) = (\rho_\varphi(g)_{ab})_{a,b\in\{1,3\}}$ and $\chi_2(g) = \rho_\varphi(g)_{22}$ for $g \in G_K$. As φ is of type II, the entries of odd weight of $\rho_\varphi(g)$ vanish, so $\rho_\varphi \cong W' \oplus \chi_2$, with W' irreducible. By (Eo4) there is $W_0 \colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with (Eo1)–(Eo4) and $\rho_\varphi \cong W_0|_{G_K} \oplus \mathbf{1}$. Comparing Jordan–Hölder factors, the irreducible 2-dimensional factor W' is a factor of $W_0|_{G_K}$, which is therefore irreducible and isomorphic to W', and $\chi_2 = \mathbf{1}$. Choose $h \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $W' = hW_0|_{G_K}h^{-1}$ and put $W = hW_0h^{-1}$, a continuous representation of $G_\mathbb{Q}$ with $W|_{G_K} = W'$. So the GL-part of $r_\varphi(g)$ is $j(W(g))$ for $g \in G_K$.

Step 2: $\operatorname{tr} W(c) = 0$, and the newform. By (Eo2) for W_0 there is a normalised newform $f = \sum a_n q^n$ of weight $2e+1$ and character ε_f such that $V := W_0 \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple and, for almost all primes p, V is unramified at p with $\iota(\det(X - V(\sigma^{-1}))) = X^2 - a_pX + \varepsilon_f(p)p^{2e}$ for every arithmetic Frobenius σ at p. Taking constant terms and using $\chi_{\mathrm{cyc}}(\sigma) = p$, we obtain $\det W_0(\sigma) = \iota^{-1}(\varepsilon_f(p))^{-1}$ for such σ; arithmetic Frobenius elements at almost all primes are dense in $G_\mathbb{Q}$ (Chebotarev) and both sides are continuous characters, so $\det W_0 = \varepsilon_f^{-1}$ as characters of $G_\mathbb{Q}$. A newform of odd weight has odd character, so $\det W(c) = \varepsilon_f(-1)^{-1} = -1$; as $W(c)^2 = W(c^2) = 1$, $W(c)$ is diagonalisable with eigenvalues $1, -1$, and $\operatorname{tr} W(c) = 0$. By the hypotheses of (Ri2), $H^1_f(\mathbb{Q}, W) = H^1_f(\mathbb{Q}, W \otimes \eta_K) = 0$.

Step 3: $\det W' = 1$. For $g \in G_K$, $r_\varphi(cgc) = (1,-1)(j(W'(g)),1)(1,-1) = (J\,{}^t j(W'(g))^{-1}J, 1)$, so $W'(cgc) = J_2\,{}^tW'(g)^{-1}J_2$ with $J_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$; also $W'(cgc) = W(c)W'(g)W(c)^{-1}$. Hence $W' \cong W'^\vee$, and $W'^\vee \cong W' \otimes \mu$ with $\mu = (\det W')^{-1}$ (for $B \in \mathrm{GL}_2$, ${}^tB^{-1} = (\det B)^{-1}SBS^{-1}$, $S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$). Taking determinants in $W' \cong W' \otimes \mu$ gives $\mu^2 = 1$, so $\det W'(g) \in \{\pm 1\}$ for $g \in G_K$. On the other hand $\det W'(g) = \det j(W'(g)) = \det \rho_\varphi(g) = \varphi(\det \underline{r}(g))$ (Step 1), and $\det \underline{r}(g) \equiv \det \mathrm{T}(\Psi(g)) = 1$ modulo $\mathfrak{m}_R$ because r lifts $\bar{r}_0$; as $|\varphi(y)|_\ell < 1$ for $y \in \mathfrak{m}_R$, $|\det W'(g) - 1|_\ell < 1$. Since ℓ is odd (Ue1), $|-1-1|_\ell = 1$; hence $\det W(g) = \det W'(g) = 1$ for $g \in G_K$.

Step 4: the decomposition. By Steps 1 and 3, r_φ and W satisfy the hypotheses of Lemma 42.9, so

$$H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi) \cong H^1_f(\mathbb{Q}, \overline{\mathbb{Q}}_\ell(\eta_K))^2 \oplus H^1_f(\mathbb{Q}, \operatorname{ad}^0 W) \oplus H^1_f(\mathbb{Q}, W) \oplus H^1_f(\mathbb{Q}, W \otimes \eta_K).$$

The first term vanishes by Lemma 42.10, the last two by Step 2.

Step 5: $H^1_f(\mathbb{Q}, \operatorname{ad}^0 W) = 0$. Conjugation by h and the twist by the character χ_{cyc}^{-e} do not change the adjoint action, so $\operatorname{ad}^0 W \cong \operatorname{ad}^0 V$, a direct summand of $\operatorname{ad} V = \mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$ (the scalars being the other one). By Lemma 42.8, item 1, V takes values in $\mathrm{GL}_2(E)$ for a finite extension E of $\mathbb{Q}_\ell$. If f is without complex multiplication (no quadratic Dirichlet character η' has $\eta'(p)a_p = a_p$ for almost all p), Newton–Thorne's theorem for non-CM forms [192], Theorem B(1), with $k = 2e+1$ and $\varepsilon = \varepsilon_f$, gives $H^1_f(\mathbb{Q}, \operatorname{ad}_E V) = 0$. If f has complex multiplication, we check the inertia hypothesis of Proposition 42.11 for $I = I_\ell$ and $U = D_\ell^\circ \cap I_\ell$, an open subgroup of I_ℓ contained in G_K. By (Ed3), $r|_{D_\ell} = \lambda_\ell \circ r_\ell^\square$ for a morphism $\lambda_\ell \colon R_\ell^\square \to R$ with $\lambda_\ell(I_\ell^{\mathrm{ord}}) = 0$, and $I^{\mathrm{ord}}(r_\ell^\square) \subseteq I^{\mathrm{cr}} \subseteq I_\ell^{\mathrm{ord}}$ (each prime containing I^{cr} contains $I^{\mathrm{ord}}(r_\ell^\square)$). So for $x \in U$ the coefficients of $\det(X - \underline{r}(x)) - \prod_{a=1}^3 (X - \psi_a(x))$ vanish, and applying φ, $\det(X - \rho_\varphi(x)) = \prod_{a=1}^3 (X - \psi_a(x)) = (X - \Psi(x))(X-1)(X - \Psi(x)^{-1})$. As $\rho_\varphi(x) = j(W(x))$, $\det(X - \rho_\varphi(x)) = (X-1)\det(X - W(x))$, so $\det(X - W(x)) = (X - \Psi(x))(X - \Psi(x)^{-1})$. For $x \in U$, $\chi_\ell(x) = 1$ and the p-components of χ for $p \neq \ell$ are unramified at ℓ, so $\Psi(x) = \chi_{\mathrm{cyc}}(x)^e$, and the eigenvalues of $V(x) = \chi_{\mathrm{cyc}}(x)^{-e}h^{-1}W(x)h$ are 1 and $\chi_{\mathrm{cyc}}(x)^{-2e}$. Hence Proposition 42.11 gives $H^1_f(\mathbb{Q}, \operatorname{ad}_E V) = 0$. In both cases Lemma 42.8, item 2, gives $H^1_f(\mathbb{Q}, \operatorname{ad} V) = 0$. So

$H^1_f(\mathbb{Q}, \mathrm{ad}^0 W) = 0$, and by Step 4, $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$. □

Proposition 42.6. *Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, $\eta_K \colon G_\mathbb{Q} \to \{\pm 1\}$ the character with kernel G_K, ℓ a prime and $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Let $r \colon G_\mathbb{Q} \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$ be a homomorphism with sign η_K and continuous GL-part, and let $\rho \colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ be the restriction of its GL-part to G_K. Assume:*

1. *$\rho|_U$ is irreducible for every open subgroup $U \subseteq G_K$;*
2. *$\rho \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type for ι.*

Let $\mathrm{ad}\, r$ be $\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ on which $g \in G_\mathbb{Q}$ with $r(g) = (P, \varsigma)$ acts by $X \mapsto PXP^{-1}$ if $\varsigma = 1$ and by $X \mapsto -P\, J\, {}^t X\, J\, P^{-1}$ if $\varsigma = -1$. Then

$$H^1_f(\mathbb{Q}, \mathrm{ad}\, r) = 0.$$

Proof. Fix a complex conjugation $c \in G_\mathbb{Q}$; then $c^2 = 1$, $\eta_K(c) = -1$ and $G_\mathbb{Q} = G_K \sqcup cG_K$. Write $r(g) = (P_g, \eta_K(g))$, so $P_g = \rho(g)$ for $g \in G_K$.

Step 1: a finite coefficient field. By Lemma 42.8, item 1, applied to ρ on the profinite group G_K, there is a finite extension $E_0 \subset \overline{\mathbb{Q}}_\ell$ of $\mathbb{Q}_\ell$ with $\rho(G_K) \subseteq \mathrm{GL}_3(E_0)$. Let E be the compositum of a finite extension of E_0 containing the entries of P_c with all extensions of it of degree at most 3 in $\overline{\mathbb{Q}}_\ell$; there are finitely many (Krasner), so E is finite over $\mathbb{Q}_\ell$, and every element of $\mathrm{GL}_3(E_0)$, in particular of $\rho(G_K)$, has its eigenvalues (roots of a cubic over E_0) in E. For $g \in G_K$, $r(cg) = (P_c, -1)(\rho(g), 1) = (P_c\, \theta(\rho(g)), -1)$, whose GL-part has entries in E. Hence the formulas defining $\mathrm{ad}\, r$ preserve $\mathrm{M}_3(E)$; call this $E[G_\mathbb{Q}]$-module $\mathrm{ad}_E\, r$, so that $\mathrm{ad}\, r = \mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell$.

Step 2: the polarisation. Put $\mathbf{A} = P_c J \in \mathrm{GL}_3(E)$. In $\mathcal{G}_3$, $(P_c, -1)^{-1} = (\theta(P_c^{-1}), -1)$ (as θ is an involution), so for $g \in G_K$

$$r(cgc) = r(c)r(g)r(c)^{-1} = (P_c\, \theta(\rho(g))\, P_c^{-1}, 1),$$

that is,

$$\rho(cgc) = P_c J\, {}^t\rho(g)^{-1} J P_c^{-1} = \mathbf{A}\, {}^t\rho(g)^{-1} \mathbf{A}^{-1},$$

using $J^{-1} = J$. The element c acts on $\mathrm{ad}_E\, r$ by $X \mapsto -P_c J\, {}^t X J P_c^{-1} = -\mathbf{A}\, {}^t X \mathbf{A}^{-1}$, and $g \in G_K$ by $X \mapsto \rho(g) X \rho(g)^{-1}$.

Step 3: the cuspidal representation. Let $r_1 = \rho \otimes \chi_{\mathrm{cyc}}^{-1} \colon G_K \to \mathrm{GL}_3(E)$ (χ_{cyc} takes values in $\mathbb{Z}_\ell^\times \subset E^\times$). By assumption 2 there is a regular algebraic conjugate self-dual cuspidal automorphic representation π of $\mathrm{GL}_3(\mathbb{A}_K)$ with $r_1 \leftrightarrow_\iota \pi$; r_1 is absolutely irreducible by assumption 1 with $U = G_K$. Since χ_{cyc} is a character of $G_\mathbb{Q}$, $\chi_{\mathrm{cyc}}(cgc) = \chi_{\mathrm{cyc}}(g)$, and Step 2 gives, for $g \in G_K$,

$$r_1(cgc) = \chi_{\mathrm{cyc}}(g)^{-1} \mathbf{A}\, {}^t(\chi_{\mathrm{cyc}}(g) r_1(g))^{-1} \mathbf{A}^{-1} = \chi_{\mathrm{cyc}}(g)^{1-3}\, \mathbf{A}\, {}^t r_1(g)^{-1} \mathbf{A}^{-1}.$$

So r_1, π, E and $\mathbf{P} = \mathbf{A}$ satisfy the hypotheses of Theorem B.70 with $n = 3$, apart from the image condition. The module $\mathrm{ad}_E\, r_1$ of that theorem coincides with $\mathrm{ad}_E\, r$: on G_K, conjugation by $r_1(g)$ equals conjugation by $\rho(g)$ (the scalar cancels), and c acts by $X \mapsto -\mathbf{A}\, {}^t X \mathbf{A}^{-1}$ in both; two actions of $G_\mathbb{Q}$ agreeing on G_K and on c agree.

Step 4: the image condition. Every element of $r_1(G_K)$ has its eigenvalues in E: those of $r_1(g)$ are $\chi_{\mathrm{cyc}}(g)^{-1}$ times those of $\rho(g)$ (Step 1). On $G_{K(\mu_{\ell^\infty})}$ the character χ_{cyc} is trivial, so r_1

and ρ agree there and have the same Zariski closure $\mathbf{Z}$ of the image of $G_{K(\mu_{\ell^\infty})}$. By Lemma 42.7 (with $F = K$, using assumption 1), $\mathbf{Z}^\circ$ acts absolutely irreducibly on E^3 and $\mathbf{Z}^\circ(\overline{\mathbb{Q}}_\ell)$ contains an element with three distinct eigenvalues.

Step 5: conclusion. By Theorem B.70, $H^1_f(\mathbb{Q}, \mathrm{ad}_E\, r) = H^1_f(\mathbb{Q}, \mathrm{ad}_E\, r_1) = 0$, and by Lemma 42.8, item 2 (with $F = \mathbb{Q}$, $V = \mathrm{ad}_E\, r$), $H^1_f(\mathbb{Q}, \mathrm{ad}\, r) = 0$. □

Lemma 42.7. *Let $F \subset \overline{\mathbb{Q}}$ be a number field, ℓ a prime, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and $\rho\colon G_F \to \mathrm{GL}_3(E)$ a continuous representation such that $\rho|_U$ is irreducible on $\overline{\mathbb{Q}}_\ell^3$ for every open subgroup $U \subseteq G_F$. Let $\mathbf{Z} \subseteq \mathrm{GL}_{3,E}$ be the Zariski closure of $\rho(G_{F(\mu_{\ell^\infty})})$ and $\mathbf{Z}^\circ$ its identity component. Then $\mathbf{Z}^\circ$ acts absolutely irreducibly on E^3, and $\mathbf{Z}^\circ(\overline{\mathbb{Q}}_\ell)$ contains an element with three distinct eigenvalues.*

Proof. Facts on linear algebraic groups over the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic 0 are used from A. Borel, *Linear algebraic groups*, 2nd ed., 1991. The vanishing ideal in $\overline{\mathbb{Q}}_\ell[x]$ of a set of E-points is spanned by polynomials over E (vanishing is an E-linear condition on the coefficients), so Zariski closures of subsets of $\mathrm{GL}_3(E)$ and their identity components commute with extension of scalars to $\overline{\mathbb{Q}}_\ell$; absolute irreducibility is irreducibility over $\overline{\mathbb{Q}}_\ell$. We therefore work over $\overline{\mathbb{Q}}_\ell$, with $V = \overline{\mathbb{Q}}_\ell^3$, $\Gamma = \rho(G_F)$, $H = \rho(G_{F(\mu_{\ell^\infty})})$, and G, G' the Zariski closures of Γ, H in GL_3; so $\mathbf{Z}^\circ$ becomes G'°.

Step 1: G° acts irreducibly on V. G° is Zariski closed of finite index in G, so $U = \rho^{-1}(G^\circ)$ is a subgroup of G_F of finite index (it is the preimage of the finite-index subgroup $\Gamma \cap G^\circ$ of Γ), and closed (Zariski-closed sets are closed for the ℓ-adic topology); a closed subgroup of finite index of a profinite group is open. Every G°-stable subspace of V is $\rho(U)$-stable, and $\rho|_U$ is irreducible by hypothesis.

Step 2: G° is reductive, and its derived group $S = [G^\circ, G^\circ]$ is non-trivial and acts irreducibly on V. The unipotent radical R of G° fixes a non-zero vector (Kolchin), and V^R is G°-stable because R is normal; by Step 1, $V^R = V$, so R acts trivially, and $R = 1$ since $G^\circ \subseteq \mathrm{GL}(V)$. So G° is reductive and $G^\circ = Z^\circ \cdot S$ with Z° the identity component of its centre and S semisimple and connected. The centre commutes with the irreducible action of G°, so acts by scalars (Schur); hence every S-stable subspace is G°-stable, and S acts irreducibly. If $S = 1$, $G^\circ = Z^\circ$ acts by scalars, and every line would be stable, contradicting irreducibility on the 3-dimensional V.

Step 3: $S \subseteq G'^\circ$. H is normal in Γ and Γ/H is a quotient of $\mathrm{Gal}(F(\mu_{\ell^\infty})/F)$, which embeds in $\mathbb{Z}_\ell^\times$ and is abelian; so all commutators of Γ lie in H. For $\gamma \in \Gamma$, $\gamma G' \gamma^{-1}$ is the Zariski closure of $\gamma H \gamma^{-1} = H$, so the normaliser of G', a closed subgroup, contains Γ and hence G; thus G' is normal in G, and the quotient $q\colon G \to G/G'$ is a morphism of affine algebraic groups. The morphism $G \times G \to G/G'$, $(x, y) \mapsto q(xyx^{-1}y^{-1})$, is trivial on $\Gamma \times \Gamma$, which is Zariski dense in $G \times G$, so it is trivial: $[G, G] \subseteq G'$. The connected group $S \subseteq [G, G]$ therefore lies in G'°.

Step 4: S contains an element with three distinct eigenvalues. Let $T \subseteq S$ be a maximal torus; $\dim T \geq 1$ since S is non-trivial semisimple. T acts on V diagonalisably with a multiset of weights $\{\chi_1, \chi_2, \chi_3\}$ in the character group $X(T)$; $\chi_1 + \chi_2 + \chi_3 = 0$ because the semisimple group S has no non-trivial characters, so $\det|_S = 1$; and the weights span $X(T) \otimes \mathbb{Q}$ because T acts faithfully. The Weyl group $W = N_S(T)/T$ permutes the weights with their multiplicities ($n \in N_S(T)$ maps the χ-weight space to the $n \cdot \chi$-weight space). Suppose two weights coincide, say $\chi_1 = \chi_2 = a$; then $\chi_3 = -2a$, the span of the weights is $\mathbb{Q}a$, so T has rank 1 and $a \neq 0$; then W has order 2 and acts on $X(T) \otimes \mathbb{Q}$ by -1, so $-a$ is a weight, i.e. $-a \in \{a, -2a\}$, which forces $a = 0$, a contradiction. Hence χ_1, χ_2, χ_3 are pairwise distinct, the subgroups $\ker(\chi_i - \chi_j)$, $i \neq j$, are proper closed subsets of the irreducible variety T, and any $t \in T$ outside their union has the three distinct eigenvalues $\chi_1(t), \chi_2(t), \chi_3(t)$.

By Steps 2–4, $G'^{\circ} \supseteq S$ acts irreducibly on V and contains an element of $S \subseteq G'^{\circ}(\overline{\mathbb{Q}}_\ell)$ with three distinct eigenvalues. □

Lemma 42.8. *Let ℓ be a prime.*

1. *Let Γ be a profinite group and $\rho\colon \Gamma \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a continuous homomorphism. There is a finite extension $E \subset \overline{\mathbb{Q}}_\ell$ of $\mathbb{Q}_\ell$ with $\rho(\Gamma) \subseteq \mathrm{GL}_n(E)$.*
2. *Let $F \subset \overline{\mathbb{Q}}$ be a number field, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and V a finite-dimensional E-vector space with a continuous E-linear action of G_F. If $H^1_f(F, V) = 0$, then $H^1_f(F, V \otimes_E \overline{\mathbb{Q}}_\ell) = 0$.*
3. *Let Γ be a profinite group, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and V a finite-dimensional E-vector space with a continuous E-linear action of Γ. Every continuous 1-cocycle $c\colon \Gamma \to V \otimes_E \overline{\mathbb{Q}}_\ell$ takes values in $V \otimes_E E'$ for some finite extension $E' \subset \overline{\mathbb{Q}}_\ell$ of E.*

Proof. For $d \geq 1$ let $E_d \subset \overline{\mathbb{Q}}_\ell$ be the compositum of the finitely many extensions of $\mathbb{Q}_\ell$ of degree at most d (Krasner); E_d is finite over $\mathbb{Q}_\ell$, hence complete and closed in $\overline{\mathbb{Q}}_\ell$, and $\overline{\mathbb{Q}}_\ell = \bigcup_d E_d$. The same holds with $\mathbb{Q}_\ell$ replaced by any finite extension E (write E_d for the compositum of E with the extensions of E of degree at most d).

Item 1. Each $\mathrm{GL}_n(E_d) = \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell) \cap \mathrm{M}_n(E_d)$ is a closed subgroup, so $\Gamma = \bigcup_d \rho^{-1}(\mathrm{GL}_n(E_d))$ is a countable union of closed subgroups. Γ is compact Hausdorff, so by Baire's theorem one of them, U say, has non-empty interior; a subgroup with non-empty interior is open. Let $g_1, \dots, g_s$ represent Γ/U and let $E \supseteq E_d$ be a finite extension containing the entries of $\rho(g_1), \dots, \rho(g_s)$. Then $\rho(g_i u) = \rho(g_i)\rho(u) \in \mathrm{GL}_n(E)$ for all i and $u \in U$.

Item 3. Put $V' = V \otimes_E \overline{\mathbb{Q}}_\ell$. Each $V \otimes_E E_d$ is a finite-dimensional space over the complete field E_d, hence closed in V', and is Γ-stable. So $\Gamma = \bigcup_d c^{-1}(V \otimes_E E_d)$, and by Baire's theorem one of these closed sets, say for d, contains a coset gH of an open normal subgroup H (open normal subgroups form a basis of neighbourhoods of 1 in a profinite group). For $h \in H$, $c(h) = g^{-1}(c(gh) - c(g)) \in V \otimes_E E_d$. Let $g_1, \dots, g_s$ represent Γ/H and $E' \supseteq E_d$ finite containing the coordinates of $c(g_1), \dots, c(g_s)$ in an E-basis of V; then $c(g_i h) = c(g_i) + g_i c(h) \in V \otimes_E E'$.

Item 2. Put $V' = V \otimes_E \overline{\mathbb{Q}}_\ell$ and let c be a Bloch–Kato cocycle of V'.

(a) By item 3 (with $\Gamma = G_F$), c takes values in $V \otimes_E E'$ for a finite extension E'/E.

(b) *c is a Bloch–Kato cocycle of $V \otimes_E E'$.* Choose an E'-linear $\varpi\colon \overline{\mathbb{Q}}_\ell \to E'$ with $\varpi|_{E'} = \mathrm{id}$ and put $\Pi = \mathrm{id}_V \otimes \varpi\colon V' \to V \otimes_E E'$, which is G_F-equivariant and the identity on $V \otimes_E E'$. If $c(g) = gx - x$ on an inertia group (or on an archimedean decomposition group), then $c(g) = \Pi(c(g)) = g\Pi(x) - \Pi(x)$ there; at a place above ℓ, the $\mathbb{Q}_\ell$-linear equivariant map $\Pi \otimes \mathrm{id}$ into $(V \otimes_E E') \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ fixes $c(g) \otimes 1$ and carries y with $c(g) \otimes 1 = gy - y$ to such an element. The topology of $V \otimes_E E'$ is the subspace topology, so c is continuous into it.

(c) *Conclusion.* An E-basis $b_1, \dots, b_m$ of E' gives a G_F-equivariant E-linear homeomorphism $V \otimes_E E' \cong V^m$. The conditions of Definition 22.2 depend only on the underlying topological $\mathbb{Q}_\ell[G_F]$-module and are compatible with the inclusions and projections of a finite direct sum; hence $H^1_f(F, V \otimes_E E') \cong H^1_f(F, V)^m = 0$, and $c(g) = gz - z$ for some $z \in V \otimes_E E' \subseteq V'$. So $H^1_f(F, V') = 0$. □

Lemma 42.9. *Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, η_K the character of $G_{\mathbb{Q}}$ with kernel G_K, $c \in G_{\mathbb{Q}}$ a complex conjugation and ℓ a prime. For $B = \begin{pmatrix} a & b \\ c' & d \end{pmatrix} \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ put $j(B) =$*

$\begin{pmatrix} a & 0 & b \\ 0 & 1 & 0 \\ c' & 0 & d \end{pmatrix}$. *Let* $r\colon G_{\mathbb{Q}} \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$ *be a homomorphism with sign* η_K *and continuous GL-part, and* $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ *a continuous representation, such that*

1. $r(c) = (1,-1)$*, and the GL-part of* $r(g)$ *is* $j(W(g))$ *for every* $g \in G_K$*;*
2. $W|_{G_K}$ *is irreducible and* $\det W(g) = 1$ *for every* $g \in G_K$*.*

Let $\mathrm{ad}^0 W$ *be the space of trace-zero matrices in* $\mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$ *with* g *acting by* $X \mapsto W(g)XW(g)^{-1}$*, and* $W \otimes \eta_K$ *the space* $\overline{\mathbb{Q}}_\ell^2$ *with* g *acting by* $\eta_K(g)W(g)$*. Then there is an isomorphism of continuous representations of* $G_{\mathbb{Q}}$

$$\mathrm{ad}\, r \;\cong\; \overline{\mathbb{Q}}_\ell(\eta_K)^{\oplus 2} \oplus \mathrm{ad}^0 W \oplus W \oplus (W \otimes \eta_K).$$

Proof. All maps below are linear maps of finite-dimensional spaces, hence continuous; two actions of $G_{\mathbb{Q}}$ that agree on G_K and on c agree, as $G_{\mathbb{Q}} = G_K \sqcup cG_K$. Put $J_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$.

Step 1: blocks. For $X \in \mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ write $X_C = (X_{ab})_{a,b\in\{1,3\}} \in \mathrm{M}_2$, $x_M = X_{22}$, $u_X = {}^t(X_{12}, X_{32})$ and $v_X = (X_{21}, X_{23})$. For $g \in G_K$, g acts by conjugation with $j(W(g))$, which gives

$$(g\cdot X)_C = W(g)X_C W(g)^{-1}, \quad (g\cdot X)_M = x_M, \quad u_{g\cdot X} = W(g)u_X, \quad v_{g\cdot X} = v_X W(g)^{-1}.$$

The element c acts by $X \mapsto -J\,{}^t\!X\,J$ (by item 1), and $(J\,{}^t\!X\,J)_{ab} = X_{4-b,4-a}$; hence

$$(c\cdot X)_C = -J_2\,{}^t\!X_C\,J_2, \quad (c\cdot X)_M = -x_M, \quad u_{c\cdot X} = -J_2\,{}^t\!v_X, \quad v_{c\cdot X} = -{}^t\!u_X\,J_2.$$

So the subspaces $V_C = \{X : X_{ab} = 0 \text{ unless } a,b \in \{1,3\}\}$, $V_M = \overline{\mathbb{Q}}_\ell E_{22}$ and $V_\times = \{X : X_C = 0,\ x_M = 0\}$ are $G_{\mathbb{Q}}$-stable and $\mathrm{ad}\, r = V_C \oplus V_M \oplus V_\times$. On V_M, G_K acts trivially and c by -1: $V_M \cong \overline{\mathbb{Q}}_\ell(\eta_K)$.

Step 2: the matrix $W(c)$*.* For $g \in G_K$, $r(cgc) = r(c)r(g)r(c)^{-1} = (1,-1)(j(W(g)),1)(1,-1) = (\theta(j(W(g))),1)$. Since j is a homomorphism commuting with transposition and $J\,j(B)\,J = j(J_2 B J_2)$, this reads $j(W(cgc)) = j(J_2\,{}^t\!W(g)^{-1}J_2)$. For $B \in \mathrm{SL}_2$, ${}^t\!B^{-1} = SBS^{-1}$, so by item 2

$$W(c)W(g)W(c)^{-1} = W(cgc) = (J_2 S)\,W(g)\,(J_2 S)^{-1} \qquad (g \in G_K).$$

Thus $(J_2S)^{-1}W(c)$ commutes with $W(G_K)$, and by Schur's lemma ($W|_{G_K}$ is irreducible over the algebraically closed field $\overline{\mathbb{Q}}_\ell$) $W(c) = \lambda J_2 S$ for some $\lambda \in \overline{\mathbb{Q}}_\ell^\times$.

Step 3: $V_C \cong \overline{\mathbb{Q}}_\ell(\eta_K) \oplus \mathrm{ad}^0 W$*.* Identify V_C with M_2 via $X \mapsto X_C$. The scalars are fixed by G_K and negated by c ($-J_2\,{}^t\!1\,J_2 = -1$): a copy of $\overline{\mathbb{Q}}_\ell(\eta_K)$. The trace-zero matrices form a $G_{\mathbb{Q}}$-stable complement (both formulas preserve the trace up to sign). For trace-zero Y, ${}^t\!Y = -SYS^{-1}$, so c acts by $Y \mapsto J_2 S Y S^{-1} J_2 = W(c)YW(c)^{-1}$ by Step 2 ($J_2^{-1} = J_2$, the scalar λ cancels); and $g \in G_K$ acts by $Y \mapsto W(g)YW(g)^{-1}$. Hence the trace-zero part is $\mathrm{ad}^0 W$.

Step 4: $V_\times \cong W \oplus (W \otimes \eta_K)$*.* Let $V_1 = \{X \in V_\times : v_X = 0\}$ and $V_2 = \{X \in V_\times : u_X = 0\}$; for $u \in \overline{\mathbb{Q}}_\ell^2$ let $[u] \in V_1$ be the element with $u_X = u$. By Step 1, $g\cdot[u] = [W(g)u]$ for $g \in G_K$, and c maps V_1 into V_2 and V_2 into V_1, injectively. For $\epsilon \in \{1, \eta_K\}$ define $\iota_\epsilon(u) = [u] + \epsilon(c)\,c\cdot[W(c)u]$. For $g \in G_K$, using $cgc \in G_K$ and $W(cgc)W(c) = W(c)W(g)$,

$$g\cdot\iota_\epsilon(u) = [W(g)u] + \epsilon(c)\,c\cdot((cgc)\cdot[W(c)u]) = [W(g)u] + \epsilon(c)\,c\cdot[W(c)W(g)u] = \iota_\epsilon(W(g)u),$$

and, using $c^2 = 1$, $W(c)^2 = 1$, $\epsilon(c)^2 = 1$,

$$c \cdot \iota_\epsilon(u) = c \cdot [u] + \epsilon(c)[W(c)u] = \iota_\epsilon(\epsilon(c)W(c)u).$$

So $\iota_1 \colon W \to V_\times$ and $\iota_{\eta_K} \colon W \otimes \eta_K \to V_\times$ are $G_\mathbb{Q}$-equivariant. If $\iota_1(u) + \iota_{\eta_K}(u') = 0$, the V_1-component gives $u + u' = 0$ and the V_2-component gives $c \cdot [W(c)(u - u')] = 0$, so $u = u' = 0$. Hence $\iota_1 \oplus \iota_{\eta_K}$ is injective, and an isomorphism since both sides have dimension 4.

Steps 1, 3 and 4 give the stated decomposition. □

Lemma 42.10. *Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, $\eta_K \colon G_\mathbb{Q} \to \{\pm 1\}$ the character with kernel G_K, ℓ a prime, and $\overline{\mathbb{Q}}_\ell(\eta_K)$ the line $\overline{\mathbb{Q}}_\ell$ on which g acts by $\eta_K(g)$. Then $H^1_f(\mathbb{Q}, \overline{\mathbb{Q}}_\ell(\eta_K)) = 0$.*

Proof. By Lemma 42.8, item 2 (with $F = \mathbb{Q}$, $E = \mathbb{Q}_\ell$), it suffices to show $H^1_f(\mathbb{Q}, \mathbb{Q}_\ell(\eta_K)) = 0$. Let x be a Bloch–Kato cocycle with values in $\mathbb{Q}_\ell(\eta_K)$, and let $\psi = x|_{G_K}$; as G_K acts trivially, $\psi \colon G_K \to \mathbb{Q}_\ell$ is a continuous homomorphism.

Step 1: ψ is unramified at every finite place of K. Let w be a finite place of K, v the prime below it and $j \colon \overline{\mathbb{Q}} \to \overline{K_w}$ an embedding over K; it is also an embedding over $\mathbb{Q}$, and the decomposition and inertia groups $D_j^K \supseteq I_j^K$ of K at w are contained in those $D_j \supseteq I_j$ of $\mathbb{Q}$ at v. If $v \neq \ell$, there is z with $x(g) = \eta_K(g)z - z$ for $g \in I_j$, so $\psi(g) = 0$ for $g \in I_j^K \subseteq G_K$. If $v = \ell$, there is $y \in \mathbb{Q}_\ell(\eta_K) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $x(g) \otimes 1 = gy - y$ for $g \in D_j$; restricting to $D_j^K \cong G_{K_w}$, on which $\mathbb{Q}_\ell(\eta_K)$ is the trivial representation, the class of $\psi|_{D_j^K}$ lies in $H^1_f(G_{K_w}, \mathbb{Q}_\ell)$, so ψ vanishes on I_j^K by Theorem B.44.

Step 2: $\psi = 0$. By Step 1, ψ factors through the Galois group of the maximal abelian extension of K unramified at all finite places; since K has no real places, this is the Hilbert class field of K, which is finite over K by class field theory. So $\psi(G_K)$ is a finite subgroup of the torsion-free group $\mathbb{Q}_\ell$, and $\psi = 0$.

Step 3: x is a coboundary. Fix $c \in G_\mathbb{Q} \setminus G_K$ and put $a = x(c)$, $z = -a/2$. For $h \in G_K$, $x(ch) = x(c) + \eta_K(c)x(h) = a$ and $x(h) = 0$; on the other hand $\eta_K(ch)z - z = -2z = a$ and $\eta_K(h)z - z = 0$. As $G_\mathbb{Q} = G_K \sqcup cG_K$, $x(g) = \eta_K(g)z - z$ for all g. □

Proposition 42.11. *Let ℓ be a prime, $e \geq 1$ an integer, $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $f = \sum_{n \geq 1} a_n q^n$ a normalised newform of weight $2e+1$ and character ε_f with complex multiplication: there is a quadratic Dirichlet character η' with $\eta'(p)a_p = a_p$ for all but finitely many primes p. Let $E \subset \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ and $V \colon G_\mathbb{Q} \to \mathrm{GL}_2(E)$ a continuous representation, semisimple over $\overline{\mathbb{Q}}_\ell$, such that for all but finitely many primes p, V is unramified at p and $\iota(\det(X - V(\sigma^{-1}))) = X^2 - a_p X + \varepsilon_f(p)p^{2e}$ for every arithmetic Frobenius σ at p. Assume that there are an inertia group I of $G_\mathbb{Q}$ at a place above ℓ and an open subgroup $U \subseteq I$ such that, for every $h \in U$, the eigenvalues of $V(h)$ are 1 and $\chi_{\mathrm{cyc}}(h)^{-2e}$. Then $H^1_f(\mathbb{Q}, \mathrm{ad}_E V) = 0$, where $\mathrm{ad}_E V$ is $\mathrm{M}_2(E)$ with g acting by $X \mapsto V(g)XV(g)^{-1}$.*

Proof. Step 1: $V \cong V \otimes \eta'$ over $\overline{\mathbb{Q}}_\ell$. For all but finitely many p and every arithmetic Frobenius σ at p, $\eta'(\sigma^{-1}) = \eta'(p)^{\pm 1} = \eta'(p)$, so $\operatorname{tr} V(\sigma^{-1}) = \iota^{-1}(a_p) = \iota^{-1}(\eta'(p)a_p) = \operatorname{tr}(V \otimes \eta')(\sigma^{-1})$. These elements σ^{-1} are dense in $G_\mathbb{Q}$ (Chebotarev) and traces are continuous, so V and $V \otimes \eta'$ have the same trace everywhere; both are semisimple, hence isomorphic ([220], I.2.2).

Step 2: η' is trivial on I. Let $U_0 \subseteq U$ be an open subgroup normal in I (the intersection of the finitely many I-conjugates of U) and $s = [I : U_0]$, so $h^s \in U_0$ for every $h \in I$. Suppose that $C = \{h \in I : \eta'(h) = -1\}$ is non-empty. For $h \in C$, Step 1 gives $\operatorname{tr} V(h) = -\operatorname{tr} V(h)$, so the eigenvalues of $V(h)$ are $\lambda, -\lambda$ for some λ; the eigenvalues of $V(h^s) = V(h)^s$ are then $\lambda^s, (-\lambda)^s$,

and also $1, \chi_{\mathrm{cyc}}(h)^{-2es}$. If s is even the two eigenvalues coincide, so $\chi_{\mathrm{cyc}}(h)^{-2es} = 1$; if s is odd they are $\lambda^s, -\lambda^s$, so $\chi_{\mathrm{cyc}}(h)^{-2es} = -1$. In both cases $\chi_{\mathrm{cyc}}(h)^{4es} = 1$ for all $h \in C$. But χ_{cyc} maps I onto $\mathbb{Z}_\ell^\times$ ($\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ is totally ramified with group $\mathbb{Z}_\ell^\times$), C is a coset of the subgroup $\ker(\eta'|_I)$ of index 2, so $\chi_{\mathrm{cyc}}(C)$ is a coset of a subgroup of index at most 2 of $\mathbb{Z}_\ell^\times$ and is infinite, while $x^{4es} = 1$ has finitely many solutions ($e, s \geq 1$). So C is empty.

Step 3: $K' \not\subseteq \mathbb{Q}(\mu_{\ell^\infty})$, where $G_{K'} = \ker \eta'$. By Step 2, K' is unramified at ℓ. Every subfield $F \neq \mathbb{Q}$ of $\mathbb{Q}(\mu_{\ell^\infty})$ is ramified at ℓ, because each $\mathbb{Q}(\mu_{\ell^n})/\mathbb{Q}$ is totally ramified at ℓ, so an inertia group at ℓ surjects onto $\mathrm{Gal}(F/\mathbb{Q}) \neq 1$. As $K' \neq \mathbb{Q}$, $K' \not\subseteq \mathbb{Q}(\mu_{\ell^\infty})$.

Step 4: conclusion. By Newton–Thorne's theorem for CM newforms [192], Theorem 5.4(2), applied with $k = 2e+1$, $\varepsilon = \varepsilon_f$ and the field K' of Step 3, $H^1_f(\mathbb{Q}, \mathrm{ad}_E V) = 0$. □

Lemma 42.12. *Let $\mathcal{O}$ be a coefficient ring, (A, φ_0) a graded $\mathcal{O}$-algebra with a fixed point, $j \neq 0$ an integer, $u = (u_i)_{i \in I}$ a finite family of elements of A_j, $c \in \mathcal{O} \setminus \{0\}$, M an $\mathcal{O}$-module and $D\colon M \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/c\mathcal{O})$ an injective additive map such that*

1. *$D(\mu)(u_i) = 0$ for all $\mu \in M$ and $i \in I$;*
2. *for every $\mu \in M$ there is an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_i) = 0$ for all $i \neq j$, such that $D(\mu)(f)$ is the class of $D'(f)$ for every $f \in A$.*

Then $\mathrm{length}_{\mathcal{O}}(M) \leq \mathrm{ct}_j(u)$.

Proof. Let k be the residue field of $\mathcal{O}$ and $q = \#k$, which is finite because $\mathcal{O}$ is finite over $\mathbb{Z}_\ell$; let ϖ be a uniformiser and $\mathfrak{m}_0 = \ker \varphi_0$. If $\mathrm{ct}_j(u) = \infty$ there is nothing to prove, so assume $\mathrm{ct}_j(u) = n < \infty$.

Step 1: the derivations factor through the cotangent lattice. Let D' be as in item 2 for some μ. For $f, g \in \mathfrak{m}_0$, $D'(fg) = 0$; by additivity $D'(\mathfrak{m}_0^2) = 0$. Also $D'(1) = D'(1 \cdot 1) = 2D'(1)$, so $D'(1) = 0$. If $f \in \mathrm{Sq}(\varphi_0)$, choose $c' \neq 0$ with $c'f \in \mathfrak{m}_0^2$; then $c'D'(f) = D'(c'f) = 0$, and $D'(f) = 0$ because $\mathcal{O}$ is a domain. Hence D' induces an $\mathcal{O}$-linear map $\lambda\colon A/\mathrm{Sq}(\varphi_0) \to \mathcal{O}$, and the reduction of λ modulo c sends the class of f to $D(\mu)(f)$. In particular the map $\bar{\lambda}_\mu\colon \mathrm{Cot}_j \to \mathcal{O}/c\mathcal{O}$, the class of $f \in A_j$ going to $D(\mu)(f)$, is well defined and $\mathcal{O}$-linear; it depends only on μ.

Step 2: the quotient C. Since $j \neq 0$, $\varphi_0(A_j) = 0$, so $A_j \subseteq \mathfrak{m}_0$ and Cot_j is the image of A_j. Each u_i lies in A_j, so $\mathrm{Cot}(u) \subseteq \mathrm{Cot}_j$ and $\mathrm{Cot}_j \cap \mathrm{Cot}(u) = \mathrm{Cot}(u)$. Put $C = \mathrm{Cot}_j/\mathrm{Cot}(u)$, an $\mathcal{O}$-module of length n. By item 1 and linearity, $\bar{\lambda}_\mu$ vanishes on $\mathrm{Cot}(u)$, so it induces $\Phi(\mu) \in \mathrm{Hom}_{\mathcal{O}}(C, \mathcal{O}/c\mathcal{O})$ with $\Phi(\mu)(\text{class of } f) = D(\mu)(f)$ for $f \in A_j$. As D is additive, so is $\Phi\colon M \to \mathrm{Hom}_{\mathcal{O}}(C, \mathcal{O}/c\mathcal{O})$.

Step 3: Φ is injective. Let $\Phi(\mu) = 0$, so $D(\mu)(f) = 0$ for every $f \in A_j$. For $f \in A_i$ with $i \neq j$, $D(\mu)(f)$ is the class of $D'(f) = 0$. Every element of A is a finite sum of homogeneous elements and $D(\mu)$ is additive, so $D(\mu) = 0$, and $\mu = 0$ since D is injective.

Step 4: counting. A module of finite length over the discrete valuation ring $\mathcal{O}$ is finitely generated and torsion, so $C \cong \bigoplus_{k=1}^{s} \mathcal{O}/\varpi^{a_k}\mathcal{O}$ with $\sum_k a_k = n$. For $a \geq 0$, $\mathrm{Hom}_{\mathcal{O}}(\mathcal{O}/\varpi^a\mathcal{O}, \mathcal{O}/c\mathcal{O})$ is isomorphic to the submodule of $\mathcal{O}/c\mathcal{O}$ killed by ϖ^a, which is cyclic of length $\min(a, v(c)) \leq a$, where v is the normalised valuation of $\mathcal{O}$; so it has at most q^a elements, and $\#\mathrm{Hom}_{\mathcal{O}}(C, \mathcal{O}/c\mathcal{O}) \leq q^n$. By Step 3, M is finite with $\#M \leq q^n$. A finite $\mathcal{O}$-module has finite length, and its composition factors are all isomorphic to k, so $\#M = q^{\mathrm{length}_{\mathcal{O}}(M)}$. Hence $\mathrm{length}_{\mathcal{O}}(M) \leq n = \mathrm{ct}_j(u)$. □

43 The graded model of the Eisenstein deformation ring on $\mathrm{U}(3)$

This section proves Proposition 43.3, the graded model of the normalised ordinary Eisenstein deformation ring, which is the algebraic input of Proposition 42.2. The model is a graded algebra A with a system of equations u and a map $q\colon A \to R$ with kernel $I(u)$, such that the matrix entries of weight j come from A_j, the points of R correspond to the points of A on u up to the torus, the conditions (Gc1)–(Gc4) hold once R^0 is finite and the adjoint Selmer groups vanish at the two-signed points, and the Tate–Shafarevich group embeds into the derivations of degree -1 (clauses (Mo1)–(Mo7)). Its construction is the deformation theory of Mazur [167] made equivariant for the torus: a presentation of R over the ordinary local lifting ring at ℓ, with the framed Selmer cocycles of each weight as variables and the obstruction groups as relations, is made homogeneous and then replaced by a smooth graded algebra built from a chart of the local ring.

The numbers that make the criterion apply come from one count. In each weight j between -2 and 2, the obstruction group of the residual adjoint exceeds the framed Selmer cocycles by 1 for $j \in \{-1, 0, 1\}$ and by 0 for $j = \pm 2$ (Lemma 43.34); together with the tangent dimensions $1, 2, 3, 4, 2$ of the local chart at ℓ and the normalisations, it gives the numbers of equations that (Gc1) requires (clause (Pq6) of Proposition 43.4), in particular the one excess equation in degree -1. Subsection 43.1 constructs the model, Subsection 43.2 the chart of the local ring at ℓ, and Subsection 43.3 proves the rigidity clause and the count.

43.1 The graded model and the presentation of the deformation ring

This subsection constructs the model. The central statement is Proposition 43.4: a presentation of R that is equivariant for the torus, with clauses (Pq1)–(Pq8), in which the numbers of variables and relations in each weight are controlled by the framed Selmer cocycles and the obstruction groups of the weight pieces $\mathfrak{g}_j$ of the residual adjoint (Definition 43.2). It is obtained in three steps. The ring R is the quotient of the ring of global ordinary lifts by eight homogeneous normalisation equations (Proposition 43.5); that ring has a presentation relative to the ordinary local lifting ring at ℓ, with framed Selmer cocycles as variables and obstruction groups as relations (Proposition 43.9); and the kernel of a presentation equivariant for a formal torus action is homogeneous (Lemma 43.8, Lemma 43.10). The relative graded model (Definition 43.11, Proposition 43.12) then replaces the local ring by its graded chart (Proposition 43.13) and carries the Tate–Shafarevich classes into the tangent space of weight -1. The two lemmas on homogeneity are used again for the symplectic and dyadic models and in Part IX.

Definition 43.1. Let ℓ be a prime, $\mathbb{F}$ a finite field of characteristic ℓ, S a finite set of places of $\mathbb{Q}$ containing ℓ and ∞, $G_S = G_{\mathbb{Q},S}$, and M a finite-dimensional $\mathbb{F}$-vector space with a continuous $\mathbb{F}$-linear action of G_S (M discrete). For every prime $p \in S$ fix a decomposition group $D_p \subseteq G_{\mathbb{Q}}$ at p, acting on M through $G_{\mathbb{Q}} \to G_S$. For a profinite group G acting on M (namely G_S or D_p), $C^i(G, M) \supseteq Z^i(G, M) \supseteq B^i(G, M)$ are the continuous i-cochains, cocycles and coboundaries and d is the differential; res_p is the restriction of cochains of G_S to D_p.

A **family of local conditions** for M is a family $\mathcal{L} = (L_p)_p$, indexed by the primes $p \in S$, of $\mathbb{F}$-subspaces $L_p \subseteq Z^1(D_p, M)$. The **Selmer cocycles** are the $z \in Z^1(G_S, M)$ with $\mathrm{res}_p z \in L_p$ for every prime $p \in S$; the **Selmer group** $H^1_{\mathcal{L}}(M)$ is their quotient by the coboundaries $B^1(G_S, M)$ among them. The **obstruction group** $H^2_{\mathcal{L}}(M)$ is the quotient of

$$Z^2_{\mathcal{L}}(M) = \Big\{ (z, (y_p)_p) : \ z \in Z^2(G_S, M),\ y_p \in C^1(D_p, M),\ dy_p = \mathrm{res}_p z \text{ for every prime } p \in S \Big\}$$

by its subspace

$$B^2_{\mathcal{L}}(M) = \Big\{(dw, (\mathrm{res}_p w)_p) :\ w \in C^1(G_S, M)\Big\} + \Big\{(0, (\lambda_p)_p) :\ \lambda_p \in L_p\Big\}.$$

Both are $\mathbb{F}$-vector spaces; dim is $\dim_{\mathbb{F}}$. (They are H^1 and H^2 of the Selmer complex of M with the local conditions $\mathcal{L}$.)

Definition 43.2. Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with residue field $\mathbb{F}_{\mathcal{O}}$, and let $\bar\Psi\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^\times$ be the reduction of Ψ. In this definition and in the results citing it the datum and $\mathcal{O}$ are fixed and not written in the notation.

Weight pieces. For $j \in \mathbb{Z}$ let $\mathfrak{g}_j \subseteq \mathrm{M}_3(\mathbb{F}_{\mathcal{O}})$ be the subspace of matrices X with $X_{ab} = 0$ whenever $\mathrm{wt}(a,b) \neq j$. The group $G_{\mathbb{Q}}$ acts on $\mathrm{M}_3(\mathbb{F}_{\mathcal{O}})$ through $\bar r_0$: if $\bar r_0(g) = (P, \varsigma)$, then g acts by $X \mapsto PXP^{-1}$ if $\varsigma = 1$ and by $X \mapsto -PJ\,{}^tX\,JP^{-1}$ if $\varsigma = -1$. Each $\mathfrak{g}_j$ is stable ($P = \mathrm{T}(\bar\Psi(g))$ is diagonal, and the (a,b) entry of $J\,{}^tXJ$ is $X_{4-b,4-a}$, of the same weight), and $\mathfrak{g}_j$ with this action is the **weight j piece** of the residual adjoint representation. Let S be the set of places of $\mathbb{Q}$ consisting of ∞ and the primes dividing $\ell N d_K$, and $G_S = G_{\mathbb{Q},S}$; the action on $\mathfrak{g}_j$ factors through G_S, because it is trivial on $G_K \cap \ker\bar\Psi$, whose fixed field lies in $K(\mu_{\ell N})$. For every prime $p \in S$ fix a place $\bar p$ of $\overline{\mathbb{Q}}$ above p, the place $\bar\ell$ for $p = \ell$, and put $D_p = D_{\bar p} \supseteq I_p = I_{\bar p}$ and

$$N_{\bar p} = \{g \in I_{\bar p} :\ \eta_K(g) = 1,\ \bar\Psi(g) = 1\} = \{g \in I_{\bar p} :\ \bar r_0(g) = 1\}.$$

Local conditions. For a prime $p \in S$ and $j \in \mathbb{Z}$ the **local condition** $L^{\mathrm{u}}_{p,j} \subseteq Z^1(D_p, \mathfrak{g}_j)$ is the space of cocycles vanishing on $N_{\bar p}$ if $p \neq \ell$, and $B^1(D_\ell, \mathfrak{g}_j)$ if $p = \ell$.

Selmer and obstruction groups; framed Selmer cocycles. $H^1_{\mathrm{u}}(\mathfrak{g}_j)$ and $H^2_{\mathrm{u}}(\mathfrak{g}_j)$ are the Selmer group and the obstruction group (Definition 43.1) of $M = \mathfrak{g}_j$, for $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, the set S, the decomposition groups D_p and the family of local conditions $(L^{\mathrm{u}}_{p,j})_p$. The space of **framed Selmer cocycles** is

$$Z^1_{\mathrm{u}}(\mathfrak{g}_j) = \{z \in Z^1(G_S, \mathfrak{g}_j) :\ \mathrm{res}_\ell z = 0,\ \mathrm{res}_p z \in L^{\mathrm{u}}_{p,j} \text{ for every prime } p \in S,\ p \neq \ell\};$$

it is the weight j part of the tangent space of the global lifts relative to their restriction to D_ℓ.

Proposition 43.3. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking. Then:*

(Mo1) *there is a normalised ordinary Eisenstein deformation ring (R, r) for $g_\star$, and r has exactly one base point φ_{Eis};*

(Mo2) *there are a graded $\mathcal{O}$-algebra with a fixed point (A, φ_0), a system of equations u for it and an $\mathcal{O}$-algebra homomorphism $q\colon A \to R$ with $\ker q = I(u)$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$, such that (Mo3)–(Mo7) hold;*

(Mo3) *for all $g \in G_{\mathbb{Q}}$ and $1 \le a, b \le 3$, $\underline{r}(g)_{ab} \in q\big(A_{\mathrm{wt}(a,b)}\big)$;*

(Mo4) *for points φ, φ' of (R, r) and $t \in \overline{\mathbb{Q}}_\ell^\times$: $\varphi \circ q$ is negative-vanishing if and only if φ is upper; $\varphi \circ q$ is positive-vanishing if and only if φ is lower; and $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ if and only if $\varphi' \circ q = t \cdot (\varphi \circ q)$;*

(Mo5) *if the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module, then every point of A on u is a torus translate of $\varphi \circ q$ for some point φ of (R, r);*

(Mo6) *if R^0 is a finitely generated $\mathcal{O}$-module and $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$ for every two-signed point φ of (R, r), then (A, φ_0, u) satisfies (Gc1)–(Gc4);*

(Mo7) *for every $b \in \mathcal{O} \setminus \{0\}$, writing* $\mathrm{Sha}[b]$ *for the submodule of* $\mathrm{Sha}^1_{\ell^N}(\chi, e)$ *killed by b, there is an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/b\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo b of an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_j) = 0$ for all $j \neq -1$.*

Proof. Step 1: the presentation. By Proposition 43.4 there are (R, r) with (Pq1), which is (Mo1), and $(A, \varphi_0, u, q, \mathrm{td})$ with (Pq2)–(Pq8); let ne be the counts of u.

Step 2: padding the equations. For $-2 \le j \le 2$ put $d(j) = \mathrm{td}_\ell(j) - \mathrm{nc}(j) - b(j)$, so that $d(-2) = 0$, $d(-1) = -1$, $d(0) = 0$, $d(1) = d(2) = 1$, and put $\mathrm{ne}'(j) = \mathrm{td}(j) - d(j)$, that is

$$\mathrm{ne}'(-1) = \mathrm{td}(-1) + 1, \quad \mathrm{ne}'(-2) = \mathrm{td}(-2), \quad \mathrm{ne}'(0) = \mathrm{td}(0),$$
$$\mathrm{ne}'(1) = \mathrm{td}(1) - 1, \quad \mathrm{ne}'(2) = \mathrm{td}(2) - 1.$$

By (Pq6) and Lemma 43.34 (the dimensions there are finite),

$$\mathrm{ne}(j) \le \mathrm{td}(j) + \dim H^2_{\mathrm{u}}(\mathfrak{g}_j) - \dim Z^1_{\mathrm{u}}(\mathfrak{g}_j) + \mathrm{nc}(j) - \mathrm{td}_\ell(j) = \mathrm{td}(j) + b(j) + \mathrm{nc}(j) - \mathrm{td}_\ell(j) = \mathrm{ne}'(j);$$

in particular $\mathrm{ne}'(j) \ge 0$. Let u' be the family with $u'_{j,i} = u_{j,i}$ for $i \le \mathrm{ne}(j)$ and $u'_{j,i} = 0 \in A_j$ for $\mathrm{ne}(j) < i \le \mathrm{ne}'(j)$. It is a system of equations for (A, φ_0) with counts ne' ($\varphi_0(0) = 0$), and since only zeros were added, $I(u') = I(u)$, the points on u' are those on u, and $\mathrm{Cot}(u'_j) = \mathrm{Cot}(u_j)$ for every j.

Step 3: (Mo2)–(Mo5) and (Mo7) for (A, φ_0, u', q). $\ker q = I(u) = I(u')$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$ (Pq2); (Mo3) and (Mo4) are (Pq3) and (Pq4), which do not involve the equations; (Mo5) is (Pq5), since $A/I(u') = A/I(u)$ and the points on u' and on u coincide; (Mo7) is (Pq8), since $D(\mu)(0) = 0$ for the added equations of degree -1.

Step 4: (Mo6). Assume that R^0 is a finitely generated $\mathcal{O}$-module and that $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$ for every two-signed point φ of (R, r). (Gc1): by (Pq6), (A, φ_0) is smooth with tangent dimensions td, where $\mathrm{td}(j) = 0$ for $|j| > 2$ (Pq2); the counts of u' satisfy the five equalities of (Gc1) by the definition of ne′; and u'_{-1}, u'_{-2}, u'_0 span rationally in degrees -1, -2, 0 because u_{-1}, u_{-2}, u_0 do (Pq7) and $\mathrm{Cot}(u'_j) = \mathrm{Cot}(u_j)$. (Gc2)–(Gc4) hold for u by (Pq7), and they depend on u only through $I(u)$ and the points on u (the image of A_0 in $A/I(u)$; points on u; derivations vanishing on $I(u)$), so they hold for u'. Hence (A, φ_0, u') satisfies (Gc1)–(Gc4). □

Proposition 43.4. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking. Put*

$$\big(\mathrm{td}_\ell(j)\big)_{j=-2}^{2} = (1, 2, 3, 4, 2), \qquad \big(\mathrm{nc}(j)\big)_{j=-2}^{2} = (1, 2, 2, 2, 1).$$

Then:

(Pq1) *there is a normalised ordinary Eisenstein deformation ring (R, r) for $g_\star$, and r has exactly one base point φ_{Eis};*

(Pq2) *there are a graded $\mathcal{O}$-algebra with a fixed point (A, φ_0), a system of equations u for it with counts* ne*, an $\mathcal{O}$-algebra homomorphism $q\colon A \to R$ with $\ker q = I(u)$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$, and a function* $\mathrm{td}\colon \mathbb{Z} \to \mathbb{N}$ *with $\mathrm{td}(j) = 0$ for $|j| > 2$, such that (Pq3)–(Pq8) hold;*

(Pq3) *for all $g \in G_{\mathbb{Q}}$ and $1 \le a, b \le 3$, $\underline{r}(g)_{ab} \in q\big(A_{\mathrm{wt}(a,b)}\big)$;*

(Pq4) *for points φ, φ' of (R, r) and $t \in \overline{\mathbb{Q}}_\ell^\times$: $\varphi \circ q$ is negative-vanishing if and only if φ is upper; $\varphi \circ q$ is positive-vanishing if and only if φ is lower; and $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ if and only if $\varphi' \circ q = t \cdot (\varphi \circ q)$;*

(Pq5) *if the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module, then every point of A on u is a torus translate of $\varphi \circ q$ for some point φ of (R, r);*

(Pq6) *(A, φ_0) is smooth with tangent dimensions* td*, and for $-2 \le j \le 2$*

$$\mathrm{ne}(j) + \mathrm{td}_\ell(j) + \dim Z^1_{\mathrm{u}}(\mathfrak{g}_j) \le \mathrm{td}(j) + \dim H^2_{\mathrm{u}}(\mathfrak{g}_j) + \mathrm{nc}(j);$$

(Pq7) *if R^0 is a finitely generated $\mathcal{O}$-module and $H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi) = 0$ for every two-signed point φ of (R, r), then u_{-1}, u_{-2}, u_0 span rationally in degrees -1, -2, 0 respectively, and (A, φ_0, u) satisfies (Gc2)–(Gc4);*

(Pq8) *for every $b \in \mathcal{O} \setminus \{0\}$, writing* $\mathrm{Sha}[b]$ *for the submodule of* $\mathrm{Sha}^1_{\ell N}(\chi, e)$ *killed by b, there is an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/b\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo b of an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_j) = 0$ for all $j \ne -1$.*

Proof. (Pq1). By (Bx1) let (B, r_B) be the ring of lifts of $\bar{r}_0$ satisfying (Ed2), (Ed3), and by (Bx3) let $(R, r) = (B/\mathfrak{n}, r)$: a normalised ordinary Eisenstein deformation ring for $g_\star$ whose lift r has exactly one base point φ_{Eis}.

(Pq2)–(Pq6), (Pq8). Choose a weighted presentation $(\sigma_\ell, \mathrm{wt}, \pi_\ell)$ of R^{ord}_ℓ as in (Ol3), then τ, P, π and the family f of Proposition 43.9, and then lifts $\tilde{n}_k$ and the system u as in Proposition 43.12. Let $(A, \varphi_0, \bar{u}, q)$ be the relative graded model of $(\sigma_\ell \sqcup \tau, \mathrm{wt}, \pi_R)$ modulo $\mathfrak{a}$ with equations u, and $\mathrm{td}(j) = \mathrm{td}_\ell(j) + \#\{t \in \tau : \mathrm{wt}(t) = j\}$. By (Mp1), (A, φ_0) is a graded $\mathcal{O}$-algebra with a fixed point, $\bar{u}$ is a system of equations for it with counts ne, $q\colon A \to R$ is an $\mathcal{O}$-algebra homomorphism with $\ker q = I(\bar{u})$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$, and $\mathrm{td}(j) = 0$ for $|j| > 2$: so (Pq2) holds with $\bar{u}$ as the system of equations, once (Pq3)–(Pq8) are checked for it. By (Mp2), (Pq3), (Pq4), (Pq5), (Pq6) and (Pq8) hold.

(Pq7). By Proposition 43.29, applied to these objects: if R^0 is a finitely generated $\mathcal{O}$-module and $H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi) = 0$ for every two-signed point φ, then $\bar{u}_{-1}$, $\bar{u}_{-2}$, $\bar{u}_0$ span rationally in degrees -1, -2, 0, and $(A, \varphi_0, \bar{u})$ satisfies (Gc2)–(Gc4). □

Proposition 43.5. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and $g_\star$ a marking.*

(Bx1) *There are $B \in \mathrm{CNL}_{\mathcal{O}}$ and a lift r_B of $\bar{r}_0$ to B satisfying (Ed2) and (Ed3) such that for every lift r' of $\bar{r}_0$ to some $A \in \mathrm{CNL}_{\mathcal{O}}$ satisfying (Ed2) and (Ed3) there is exactly one morphism $f\colon B \to A$ with $f \circ r_B = r'$, and $f \circ r_B$ satisfies (Ed2), (Ed3) for every morphism f out of B. There is exactly one morphism $i_B\colon R^{\mathrm{ord}}_\ell \to B$ with $i_B \circ r^{\mathrm{ord}}_\ell = r_B|_{D_\ell}$, and r_B has exactly one base point.*

(Bx2) *For $A \in \mathrm{CNL}_{\mathcal{O}}$, $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \bmod \mathfrak{m}_A$ and a lift r' to A satisfying (Ed2), (Ed3), the lift $(h, 1)r'(h, 1)^{-1}$ satisfies (Ed2), (Ed3). The family $y_{g,a,b} = \underline{r_B}(g)_{ab} - \underline{r_0}(g)_{ab}$ ($g \in G_{\mathbb{Q}}$, $1 \le a, b \le 3$) with weights $\mathrm{wt}(a, b)$ satisfies (Tc1) and (Tc2) for B, with $\rho_B \circ r_B = (\mathrm{T}(1+T), 1)\, r_B\, (\mathrm{T}(1+T), 1)^{-1}$; every entry $\underline{r_B}(g)_{ab}$ has torus weight $\mathrm{wt}(a, b)$; $i_B(x_{g,a,b}) = y_{g,a,b}$ for $g \in D_\ell$; and $\rho_B \circ i_B = i_B[[T]] \circ \rho_\ell$, so that i_B maps elements of torus weight j to elements of torus weight j.*

(Bx3) *Let $\Delta = \underline{r_B}(g_\star) - \underline{r_B}(cg_\star^{-1}c)$, $P = \underline{r_B}(c)$, and let $\mathfrak{n} \subseteq B$ be the ideal generated by*

$$n_1 = P_{11} - 1,\ n_2 = P_{22} - 1,\ n_3 = P_{12},\ n_4 = P_{21},\ n_5 = P_{13},\ n_6 = P_{31},\ n_7 = \Delta_{12},\ n_8 = \Delta_{21},$$

which have torus weights $0,0,1,-1,2,-2,1,-1$. *Then* $R = B/\mathfrak{n}$ *with the image* r *of* r_B *is a normalised ordinary Eisenstein deformation ring for* $g_\star$, *and* r *has exactly one base point.*

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$. Let S consist of ∞ and the primes dividing $\ell N d_K$, $G_S = G_{\mathbb{Q},S}$, and $\Gamma \subseteq G_S$ the image of G_K; K is unramified outside d_K, so $\Gamma = G_{K,S_K}$ (S_K the places of K above S) has index 2, and $G_S = \Gamma \sqcup \Gamma c$. Recall $\Psi(c) = 1$, so $\bar{r}_0(c) = (1,-1)$.

Step 1: lifts satisfying (Ed2) factor through G_S. For $\bar{v}$ above a prime $p \notin S$, η_K and $\bar{\Psi}$ are unramified at p, so $I_{\bar{v}} \subseteq \ker \bar{r}_0$ and (Ed2) makes the lift trivial on $I_{\bar{v}}$; hence on the closed normal subgroup generated by these groups, the kernel of $G_{\mathbb{Q}} \to G_S$.

Step 2: lifts on G_S. Let $\bar{\rho} = \underline{\bar{r}_0}|_\Gamma = \mathrm{T}(\bar{\Psi})$ and $(R^\square_\Gamma, \rho^\square)$ its universal lift (Theorem B.71; Γ satisfies Φ_ℓ by item 2). For a lift r' of $\bar{r}_0$ through G_S, $\rho = \underline{r'}|_\Gamma$ is a lift of $\bar{\rho}$ and $r'(c) = (Q,-1)$ with $Q \equiv 1$; the relations $r'(c)^2 = 1$ and $r'(cgc) = r'(c)r'(g)r'(c)$ ($g \in \Gamma$) read

$$Q\,\theta(Q) = 1, \qquad \rho(cgc) = Q\,\theta(\rho(g))\,\theta(Q) \qquad (g \in \Gamma),$$

since $(Q,-1)(M,1)(Q,-1) = (Q\theta(M)\theta(Q),1)$. Conversely a lift ρ of $\bar{\rho}$ and $Q \equiv 1$ with these relations define the homomorphism $r'(g) = (\rho(g),1)$, $r'(gc) = (\rho(g)Q,-1)$ ($g \in \Gamma$) of $\Gamma \rtimes \langle c\rangle = G_S$, continuous as ρ is. Hence lifts of $\bar{r}_0$ through G_S are represented by $R_S = R^\square_\Gamma[[Z_{ab}]]/\mathfrak{a}$, with $Q = 1 + (Z_{ab})$ and $\mathfrak{a}$ generated by the entries of the two relations, and the universal lift r_S.

Step 3: (Ed2), (Ed3) are cut out by ideals. For a morphism $f\colon R_S \to A$: $f \circ r_S$ satisfies (Ed2) if and only if f kills the entries of $\underline{r_S}(g) - 1$ for $g \in N = \bigcup_{\bar{v}\nmid\ell}(I_{\bar{v}} \cap \ker \bar{r}_0)$ (such g have sign 1; Step 1 covers $p \notin S$ automatically). The restriction $r_S|_{D_\ell}$ is classified by a morphism $f_S\colon R^\square_\ell \to R_S$, and $f \circ r_S|_{D_\ell}$ by $f \circ f_S$; so $f \circ r_S$ satisfies (Ed3) if and only if f kills $f_S(I^{\mathrm{ord}}_\ell)$. Let B be the quotient of R_S by these elements and r_B the image of r_S. Then r_B and all $f \circ r_B$ satisfy (Ed2), (Ed3), and a lift r' to A satisfying them factors through G_S (Step 1), so $r' = f \circ r_S$ for exactly one f (Step 2), which kills the generators, i.e. factors uniquely through B.

Step 4: $B \neq 0$ *and the base point.* r_0 satisfies (Ed2): for $g \in I_{\bar{v}} \cap \ker \bar{r}_0$ with $\bar{v} \nmid \ell$, $\eta_K(g) = 1$ and $\Psi(g) = \chi(g)$ (χ_{cyc} is unramified at $\bar{v}$) is a root of unity of order dividing the order of χ, prime to ℓ by (Ue3), with residue 1; so $\Psi(g) = 1$ and $r_0(g) = 1$. It satisfies (Ed3) by (Ol1): $r_0|_{D_\ell} = \beta_\ell \circ r^\square_\ell$ and $\beta_\ell(I^{\mathrm{ord}}_\ell) = 0$. So $r_0 = \varphi \circ r_B$ for one morphism $\varphi\colon B \to \mathcal{O}$; in particular $B \neq 0$, $B \in \mathrm{CNL}_{\mathcal{O}}$. An $\mathcal{O}$-algebra homomorphism $B \to \mathcal{O}$ is local (for $y \in \mathfrak{m}_B$, $u \in \mathcal{O}^\times$, $y - u$ is a unit), so the base points of r_B are the morphisms classifying r_0: φ is the only one. By (Ed3) for r_B, $r_B|_{D_\ell} = f_B \circ r^\square_\ell$ with $f_B(I^{\mathrm{ord}}_\ell) = 0$ (f_B is unique by universality), so f_B induces i_B, unique because $R^\square_\ell \to R^{\mathrm{ord}}_\ell$ is onto. This proves (Bx1).

Step 5: (Bx2). Conjugation by $(h,1)$ keeps the reduction, continuity and the value 1 on elements with $r'(g) = 1$, so (Ed2) is kept; (Ed3) is kept by (Ol2). (Tc1): morphisms f, f' out of B agreeing on all $y_{g,a,b}$ give lifts with equal GL-parts and equal signs η_K, hence $f = f'$ by (Bx1). (Tc2): by the first part with $A = B[[T]]$ and $h = \mathrm{T}(1+T)$ there is ρ_B with $\rho_B \circ r_B = (\mathrm{T}(1+T),1)r_B(\mathrm{T}(1+T),1)^{-1}$; since $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$, the GL-part of the right side at g is $\mathrm{T}(1+T)\underline{r_B}(g)\mathrm{T}(1+T)^{-1}$ for both signs, which multiplies the entry (a,b) by $(1+T)^{\mathrm{wt}(a,b)}$; as $\underline{r_0}(g)$ is diagonal, $\rho_B(y_{g,a,b}) = (1+T)^{\mathrm{wt}(a,b)}y_{g,a,b}$. The identity $i_B(x_{g,a,b}) = y_{g,a,b}$ for $g \in D_\ell$ is $i_B \circ r^{\mathrm{ord}}_\ell = r_B|_{D_\ell}$. Finally $\rho_B \circ i_B$ and $i_B[[T]] \circ \rho_\ell$ are morphisms $R^{\mathrm{ord}}_\ell \to B[[T]]$ carrying r^{ord}_ℓ to the same lift $(\mathrm{T}(1+T),1)r_B|_{D_\ell}(\mathrm{T}(1+T),1)^{-1}$; composed with the surjection $R^\square_\ell \to R^{\mathrm{ord}}_\ell$ they classify the same lift of $\bar{r}_0|_{D_\ell}$, so they are equal. If $\rho_\ell(z) = (1+T)^j z$, then $\rho_B(i_B(z)) = i_B[[T]]((1+T)^j z) = (1+T)^j i_B(z)$.

Step 6: (Bx3). The torus weights of $n_1,\dots,n_8$ follow from (Bx2) (1 has weight 0, and the entries $(1,2)$, $(2,1)$ of both terms of Δ have weights 1, -1). Let $f\colon B \to A$ and $Q = f(P)$.

Since $c^2 = 1$ and c has sign -1, $(Q,-1)^2 = (Q\theta(Q),1) = 1$, i.e. $QJ\,{}^tQ^{-1}J = 1$, i.e. $QJ = J\,{}^tQ = {}^t(QJ)$: the matrix QJ, with entries $(QJ)_{ab} = Q_{a,4-b}$, is symmetric. Its symmetry gives $Q_{33} = Q_{11}$, $Q_{23} = Q_{12}$, $Q_{32} = Q_{21}$. Hence $Q = 1$ if and only if $f(n_1) = \cdots = f(n_6) = 0$, and $f \circ r_B$ satisfies (Ed1) if and only if $f(\mathfrak{n}) = 0$. So the lifts to A satisfying (Ed1)–(Ed3) are exactly the $f \circ r_B$ with $f(\mathfrak{n}) = 0$, each for exactly one f, i.e. the $\bar{f} \circ r$ for exactly one $\bar{f}\colon B/\mathfrak{n} \to A$, and every $\bar{f} \circ r$ satisfies (Ed1)–(Ed3). r_0 satisfies (Ed1): $\underline{r_0}(c) = \mathrm{T}(\Psi(c)) = 1$, and $\underline{r_0}(g_\star) = \mathrm{T}(\Psi(g_\star))$ and $\underline{r_0}(cg_\star^{-1}c) = \theta(\mathrm{T}(\Psi(g_\star))^{-1}) = \mathrm{T}(\Psi(g_\star))^{-1}$ are diagonal. So $\varphi(\mathfrak{n}) = 0$, $R = B/\mathfrak{n} \neq 0$ lies in $\mathrm{CNL}_{\mathcal{O}}$, (R, r) is a normalised ordinary Eisenstein deformation ring for $g_\star$, and as in Step 4 its only base point is induced by φ. □

Definition 43.6. Let $\mathcal{O}$ be a coefficient ring and $R \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_R$. For a finite set σ with a map $\mathrm{wt}\colon \sigma \to \mathbb{Z}$, the **weight** of a monomial $X^n = \prod_s X_s^{n_s}$ in $\mathcal{O}[[X_s : s \in \sigma]]$ is $\sum_s n_s \mathrm{wt}(s)$; the **weight j component** $f_{(j)}$ of a power series f is the power series formed by the terms of f whose monomials have weight j, and $\mathcal{O}[[X_\sigma]]_j$ is the set of power series f with $f = f_{(j)}$.

Weighted presentations. A **weighted presentation** of R is a triple $(\sigma, \mathrm{wt}, \pi)$ of a finite set σ, a map $\mathrm{wt}\colon \sigma \to \{-2,-1,0,1,2\}$ and a surjective $\mathcal{O}$-algebra homomorphism $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to R$ with $\pi(X_s) \in \mathfrak{m}_R$ for every s. A **homogeneous generating system** of its kernel with counts $\mathrm{ne}\colon \{-2,\dots,2\} \to \mathbb{N}$ is a family $u = (u_{j,i})$, $-2 \le j \le 2$, $1 \le i \le \mathrm{ne}(j)$, with $u_{j,i} \in \ker\pi \cap \mathcal{O}[[X_\sigma]]_j$, which generates the ideal $\ker\pi$.

The graded model. For a weighted presentation $(\sigma, \mathrm{wt}, \pi)$ of R and an $\mathcal{O}$-algebra homomorphism $\beta\colon R \to \mathcal{O}$ with $\beta(\pi(X_s)) = 0$ for every s, the **graded model** is the tuple $(A_\pi, \varphi_\beta, q_\pi)$, where

$$A_\pi = \sum_{j \in \mathbb{Z}} \mathcal{O}[[X_\sigma]]_j \subseteq \mathcal{O}[[X_s : s \in \sigma]]$$

(the set of finite sums of power series of single weights), graded by $(A_\pi)_j = \mathcal{O}[[X_\sigma]]_j$, q_π is the restriction of π to A_π, and $\varphi_\beta = \beta \circ q_\pi$. With a homogeneous generating system u of $\ker\pi$, the tuple $(A_\pi, \varphi_\beta, u, q_\pi)$ is the **graded model with equations** u.

Lemma 43.7. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. Put $R_\ell^{\mathrm{ord}} = R_\ell^{\square}/I_\ell^{\mathrm{ord}}$ and let r_ℓ^{ord} be the image of $r_\ell^{\square}$ in $\mathcal{G}_3(R_\ell^{\mathrm{ord}})$. Then:*

(Ol1) *$r_\ell^{\square}$ has exactly one base point β_ℓ, and $I_\ell^{\mathrm{ord}} \subseteq \ker\beta_\ell$; hence $R_\ell^{\mathrm{ord}} \in \mathrm{CNL}_{\mathcal{O}}$, and r_ℓ^{ord} has exactly one base point.*

(Ol2) *Let $A \in \mathrm{CNL}_{\mathcal{O}}$, $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \bmod \mathfrak{m}_A$, and $f\colon R_\ell^{\square} \to A$ a morphism with $f(I_\ell^{\mathrm{ord}}) = 0$. Then $(h,1)\,(f \circ r_\ell^{\square})\,(h,1)^{-1} = f' \circ r_\ell^{\square}$ for a morphism f' with $f'(I_\ell^{\mathrm{ord}}) = 0$.*

(Ol3) *The family $x_{g,a,b} = \underline{r_\ell^{\mathrm{ord}}}(g)_{ab} - \underline{r_0}(g)_{ab}$ ($g \in D_\ell$, $1 \le a,b \le 3$) with $w(g,a,b) = \mathrm{wt}(a,b)$ satisfies (Tc1) and (Tc2) for $R = R_\ell^{\mathrm{ord}}$, with $\rho \circ r_\ell^{\mathrm{ord}} = (\mathrm{T}(1+T),1)\,r_\ell^{\mathrm{ord}}\,(\mathrm{T}(1+T),1)^{-1}$, and every entry $\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}$ has torus weight $\mathrm{wt}(a,b)$. Consequently there is a weighted presentation $(\sigma_\ell, \mathrm{wt}, \pi_\ell)$ of R_ℓ^{ord} with $\pi_\ell(X_s) = x_s$ for a finite set σ_ℓ of triples $s = (g_s, a_s, b_s)$ and $\mathrm{wt}(s) = \mathrm{wt}(a_s, b_s)$, satisfying (Tp1)–(Tp3), and $\underline{r_\ell^{\mathrm{ord}}}(g)_{ab} \in \pi_\ell\big(\mathcal{O}[[X_{\sigma_\ell}]]_{\mathrm{wt}(a,b)}\big)$ for all $g \in D_\ell$ and a,b.*

Proof. Write $R = R_\ell^{\square}$, $J = I^{\mathrm{ord}}(r_\ell^{\square})$ and $\gamma = \mathrm{gd}(r_\ell^{\square})$. Two remarks are used throughout. (a) For a morphism $f\colon R \to A$, $I^{\mathrm{ord}}(f \circ r_\ell^{\square})$ is the ideal generated by $f(J)$, and $\mathrm{gd}(f \circ r_\ell^{\square}) = f(\gamma)$, since the generators and gd are polynomials in the entries. (b) An $\mathcal{O}$-algebra homomorphism β from a ring $B \in \mathrm{CNL}_{\mathcal{O}}$ to $\mathcal{O}$ is local (for $y \in \mathfrak{m}_B$ and $u \in \mathcal{O}^\times$, $y - u$ is a unit, so $\beta(y) \neq u$), hence a morphism of $\mathrm{CNL}_{\mathcal{O}}$.

(Ol1). By (b) and universality, the base points of $r_\ell^\square$ are the morphisms $R \to \mathcal{O}$ classifying the lift $r_0|_{D_\ell}$; there is exactly one, β_ℓ. We exhibit a minimal prime of I^{cr} inside $\ker \beta_\ell$. Let $B = \mathcal{O}[[u]]$, a domain. The group $1+\mathfrak{m}_B$ is pro-ℓ ($\mathbb{F}_\mathcal{O}$ is finite), so there is a continuous unramified character $\lambda\colon D_\ell \to B^\times$, trivial on I_ℓ, with $\lambda(\mathrm{Fr}) = 1+u$. Since $(\mathrm{T}(s),\varsigma)(\mathrm{T}(s'),\varsigma') = (\mathrm{T}(ss'),\varsigma\varsigma')$ (θ fixes $\mathrm{T}(s')$), $r_u(g) = (\mathrm{T}(\Psi(g)\lambda(g)), \eta_K(g))$ is a lift of $\bar r_0|_{D_\ell}$ to B; let $F\colon R \to B$ classify it, so that β_ℓ is F followed by $u \mapsto 0$. On $D_\ell^\circ \cap I_\ell$, $\underline{r_u} = \mathrm{diag}(\psi_1,\psi_2,\psi_3)$, so the characteristic polynomials agree with $\prod_a (X-\psi_a)$, and the product $\prod_{k=1}^3 (\underline{r_u}(g_k) - \psi_k(g_k))$ is a product of diagonal matrices whose k-th factor has (k,k) entry 0; so $F(J) = 0$ by (a). Next, $\Psi(\sigma_0) = \chi_{\mathrm{cyc}}(\sigma_0)^e$ (on $D_\ell^\circ \cap I_\ell$ both χ_ℓ and the unramified part of χ are trivial) has infinite order, so $\psi_1(\sigma_0), \psi_2(\sigma_0), \psi_3(\sigma_0)$ are distinct and $\mathrm{gp}_a \neq 0$. With $\mu = \lambda(\sigma_\ell) = (1+u)^n$ one has $\underline{r_u}(\sigma_\ell) = \mathrm{diag}(\psi_b(\sigma_\ell)\mu^{2-b})_b$, and only $b = a$ contributes to the trace in tq_a:

$$F(\gamma) = \mathrm{gd}(r_u) = \ell\,\mathrm{gp}_1\mathrm{gp}_2^2\mathrm{gp}_3\,\psi_2\psi_3(\sigma_\ell)\,\mu^{-1}\big(\Psi(\sigma_\ell)(1+u)^n - \chi_{\mathrm{cyc}}(\sigma_\ell)\big)^2.$$

The last factor is a power series with coefficient $n\Psi(\sigma_\ell) \neq 0$ at u, so $F(\gamma) \neq 0$. As B is a domain, $\gamma^k y \in J$ implies $F(y) = 0$, and $\ker F$ is a prime ideal containing the saturation of J, hence I^{cr}. So $\ker F$ contains a minimal prime $\mathfrak{P}$ of I^{cr}, and $\mathfrak{P} \subseteq \ker F \subseteq \ker \beta_\ell$. Hence $\mathfrak{P}$ is one of the primes intersected in I_ℓ^{ord}, $I_\ell^{\mathrm{ord}} \subseteq \mathfrak{P} \subseteq \ker\beta_\ell$, R_ℓ^{ord} is a non-zero quotient of R and lies in $\mathrm{CNL}_\mathcal{O}$, β_ℓ factors through it, and by (b) and universality it is the only base point of r_ℓ^{ord}.

(Ol2), Step 1: the universal conjugation. Let $R' = R[[Z_{ab} : 1 \le a,b \le 3]] \in \mathrm{CNL}_\mathcal{O}$, $\iota\colon R \to R'$ the inclusion and $H = 1 + (Z_{ab}) \in \mathrm{GL}_3(R')$. The lifts $(H^{\pm1},1)(\iota\circ r_\ell^\square)(H^{\pm1},1)^{-1}$ are classified by morphisms $\Theta_0^\pm\colon R \to R'$; let $\Theta^\pm\colon R' \to R'$ be the continuous extensions with $\Theta^\pm(Z_{ab}) = Z_{ab}$. Then $\Theta^-\circ\Theta_0^+$ classifies $(H,1)(H,1)^{-1}(\iota\circ r_\ell^\square)(H,1)(H,1)^{-1} = \iota\circ r_\ell^\square$, so it is ι; thus $\Theta^-\Theta^+$ is the identity on $\iota(R)$ and on the Z_{ab}, hence on R', and likewise $\Theta^+\Theta^-$. Write $\Theta = \Theta^+$, an automorphism. Modulo (Z), $H \equiv 1$, so $\Theta_0 \equiv \iota \bmod (Z)R'$ (both reductions classify $r_\ell^\square$), and Θ induces the identity on $R'/(Z)R' = R$.

Step 2: Θ preserves JR' and fixes γ. For $g \in D_\ell^\circ$ (sign 1) the GL-part of the conjugate is $H\underline{r_\ell^\square}(g)H^{-1}$: it has the same characteristic polynomial and traces of products, and the entries of HMH^{-1} generate the same ideal as those of M. So I^{ord} of the conjugate is JR' and its gd is γ. By (a) they are also $\Theta(J)R' = \Theta(JR')$ and $\Theta(\gamma)$.

Step 3: Θ preserves $I_\ell^{\mathrm{ord}}R'$. R' is flat over the Noetherian ring R, so for ideals $\mathfrak{a},\mathfrak{b}$ of R: $(\mathfrak{a}R' :_{R'} \gamma^k) = (\mathfrak{a} :_R \gamma^k)R'$ and $(\mathfrak{a}\cap\mathfrak{b})R' = \mathfrak{a}R' \cap \mathfrak{b}R'$ (Matsumura, Theorem 7.4). The saturation $\mathrm{Sat}(J) = (J : \gamma^k)$ for k large (ascending chain), so $\mathrm{Sat}(JR') = \mathrm{Sat}(J)R'$, and Θ preserves it by Step 2. For a radical ideal $\mathfrak{r}$ of R with minimal primes $\mathfrak{P}_1,\dots,\mathfrak{P}_m$, $R'/\mathfrak{P}_iR' = (R/\mathfrak{P}_i)[[Z]]$ is a domain and $R'/\mathfrak{r}R' = (R/\mathfrak{r})[[Z]]$ embeds coefficientwise in $\prod_i (R/\mathfrak{P}_i)[[Z]]$, hence is reduced; so $\mathrm{rad}(\mathfrak{a}R') = \mathrm{rad}(\mathfrak{a})R'$ for every ideal $\mathfrak{a}$, and $I^{\mathrm{cr}}R' = \mathrm{rad}(\mathrm{Sat}(JR'))$ is Θ-stable. With $\mathfrak{r} = I^{\mathrm{cr}}$: $I^{\mathrm{cr}}R' = \bigcap_i \mathfrak{P}_iR'$ with primes $\mathfrak{P}_iR'$, and $\mathfrak{P}_iR' \cap R = \mathfrak{P}_i$ (reduce modulo (Z)), so they are pairwise incomparable and are exactly the minimal primes of $I^{\mathrm{cr}}R'$. Θ permutes them, and if $\Theta(\mathfrak{P}_iR') = \mathfrak{P}_jR'$, reducing modulo (Z), where Θ induces the identity, gives $\mathfrak{P}_i = \mathfrak{P}_j$. So Θ fixes every $\mathfrak{P}_iR'$ and preserves $I_\ell^{\mathrm{ord}}R' = \bigcap_{\mathfrak{P}_i \subseteq \ker\beta_\ell} \mathfrak{P}_iR'$.

Step 4: (Ol2). Let $\Phi\colon R' \to A$ be the continuous extension of f with $\Phi(Z_{ab}) = (h-1)_{ab} \in \mathfrak{m}_A$. Then $\Phi(H) = h$ and $\Phi\circ\Theta_0$ classifies $(h,1)(f\circ r_\ell^\square)(h,1)^{-1}$; put $f' = \Phi\circ\Theta_0$. By Step 3, $f'(I_\ell^{\mathrm{ord}}) \subseteq \Phi(I_\ell^{\mathrm{ord}}R') = f(I_\ell^{\mathrm{ord}})A = 0$.

(Ol3). Each $x_{g,a,b}$ lies in $\mathfrak{m}_{R_\ell^{\mathrm{ord}}}$, since r_ℓ^{ord} and r_0 have the same reduction. (Tc1): if morphisms f, f' out of R_ℓ^{ord} agree on all $x_{g,a,b}$, the two lifts $f\circ r_\ell^{\mathrm{ord}}$, $f'\circ r_\ell^{\mathrm{ord}}$ have equal GL-parts and equal signs η_K, so by universality f and f' agree after composition with the surjection $R \to R_\ell^{\mathrm{ord}}$, hence are equal. (Tc2): apply (Ol2) to $A = R_\ell^{\mathrm{ord}}[[T]]$, f the composite $R \to R_\ell^{\mathrm{ord}} \subseteq A$ and $h = \mathrm{T}(1+T) \equiv 1$; the morphism f' kills I_ℓ^{ord} and induces $\rho\colon R_\ell^{\mathrm{ord}} \to A$ with

$\rho \circ r_\ell^{\mathrm{ord}} = (\mathrm{T}(1+T),1) r_\ell^{\mathrm{ord}} (\mathrm{T}(1+T),1)^{-1}$. For g of sign 1 the GL-part of the right side is $\mathrm{T}(1+T)\underline{r_\ell^{\mathrm{ord}}}(g)\mathrm{T}(1+T)^{-1}$; for g of sign -1 it is $\mathrm{T}(1+T)\underline{r_\ell^{\mathrm{ord}}}(g)\theta(\mathrm{T}(1+T))^{-1}$, the same matrix as $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$. Conjugation by $\mathrm{T}(t)$ multiplies the entry (a,b) by $t^{\mathrm{wt}(a,b)}$, so every entry $\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}$ has torus weight $\mathrm{wt}(a,b)$, and as $\underline{r_0}(g)$ is diagonal and $\mathrm{wt}(a,a)=0$, $\rho(x_{g,a,b}) = (1+T)^{\mathrm{wt}(a,b)} x_{g,a,b}$. Lemma 43.8 now gives σ_ℓ, wt, π_ℓ with (Tp1)–(Tp3), and (Tp3) applied to the entries gives the last assertion. □

Lemma 43.8. *Let $\mathcal{O}$ be a coefficient ring, $R \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_R$, S a set, $(x_s)_{s\in S}$ a family of elements of $\mathfrak{m}_R$ and $w\colon S \to \{-2,-1,0,1,2\}$ a map. Let $R[[T]]$ be the power series ring in one variable over R, an object of $\mathrm{CNL}_{\mathcal{O}}$. Assume:*

(Tc1) *any two morphisms $f, f'\colon R \to B$ in $\mathrm{CNL}_{\mathcal{O}}$ with $f(x_s) = f'(x_s)$ for all $s \in S$ are equal;*

(Tc2) *there is a morphism $\rho\colon R \to R[[T]]$ in $\mathrm{CNL}_{\mathcal{O}}$ with $\rho(x_s) = (1+T)^{w(s)} x_s$ for every $s \in S$.*

An element $y \in R$ has torus weight $j \in \mathbb{Z}$ *if $\rho(y) = (1+T)^j y$. Then there is a finite subset $\sigma \subseteq S$ such that, with $\mathrm{wt} = w|_\sigma$ and $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to R$ the continuous $\mathcal{O}$-algebra homomorphism with $\pi(X_s) = x_s$:*

(Tp1) *$(\sigma, \mathrm{wt}, \pi)$ is a weighted presentation of R, and the images of the x_s, $s \in \sigma$, form a basis of the $\mathbb{F}_{\mathcal{O}}$-vector space $\mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_{\mathcal{O}} R)$;*

(Tp2) *for every $f \in \ker\pi$ and $j \in \mathbb{Z}$, $f_{(j)} \in \ker\pi$; and every element of $\ker\pi$ has all its coefficients of degree one in $\mathfrak{m}_{\mathcal{O}}$;*

(Tp3) *every $y \in R$ of torus weight j lies in $\pi(\mathcal{O}[[X_\sigma]]_j)$.*

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $t^* = \mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_{\mathcal{O}} R)$ and $\bar y$ for the image in t^* of $y \in \mathfrak{m}_R$. For $i \in \mathbb{Z}$ and $k \geq 0$ let $\binom{i}{k} = i(i-1)\cdots(i-k+1)/k! \in \mathbb{Z}$, so that $(1+T)^i = \sum_{k\geq 0} \binom{i}{k} T^k$ in $\mathbb{Z}[[T]]$.

Step 1: the $\bar x_s$ span t^*. Otherwise there is a non-zero linear form $\lambda\colon t^* \to \mathbb{F}$ with $\lambda(\bar x_s) = 0$ for all s. Let $f\colon R \to \mathbb{F}[\epsilon]$ be the residue map and put $f'(y) = f(y) + \epsilon\,\lambda(\overline{y-c})$, where $c \in \mathcal{O}$ is any element with $y - c \in \mathfrak{m}_R$ (it exists as $R/\mathfrak{m}_R = \mathbb{F}$; another choice changes $y-c$ by an element of $\mathfrak{m}_{\mathcal{O}} R$, which maps to 0 in t^*). For $y, z \in R$ with $y-c, z-d \in \mathfrak{m}_R$ one has $yz - cd = c(z-d) + d(y-c) + (y-c)(z-d)$, so $\lambda(\overline{yz-cd}) = \bar c\lambda(\overline{z-d}) + \bar d\lambda(\overline{y-c})$, and f' is an $\mathcal{O}$-algebra homomorphism, local, hence a morphism of $\mathrm{CNL}_{\mathcal{O}}$. Then $f(x_s) = 0 = f'(x_s)$ for all s and $f \neq f'$, contradicting (Tc1). As $\mathfrak{m}_R$ is finitely generated, t^* is finite-dimensional; choose a finite $\sigma \subseteq S$ such that $(\bar x_s)_{s\in\sigma}$ is a basis.

Step 2: (Tp1). Put $P = \mathcal{O}[[X_s : s \in \sigma]]$ with maximal ideal $\mathfrak{m}_P = (\mathfrak{m}_{\mathcal{O}}, X_s)$. As $x_s \in \mathfrak{m}_R$ and R is complete, π exists and is continuous. By Step 1, $\mathfrak{m}_R = \pi(\mathfrak{m}_P)R + \mathfrak{m}_R^2$, so $\mathfrak{m}_R = \pi(\mathfrak{m}_P)R$ by Nakayama's lemma. Regard R as a P-module through π: it is separated for the $\mathfrak{m}_P R = \mathfrak{m}_R$-adic topology (Krull), P is $\mathfrak{m}_P$-adically complete, and $R/\mathfrak{m}_P R = \mathbb{F}$ is generated by 1; by the complete Nakayama lemma [166, Thm. 8.4], $R = P \cdot 1$, i.e. π is surjective. With $\pi(X_s) \in \mathfrak{m}_R$ and $\mathrm{wt}(\sigma) \subseteq \{-2,\dots,2\}$, $(\sigma, \mathrm{wt}, \pi)$ is a weighted presentation.

Step 3: degree-one coefficients of the kernel. Let $J = \ker\pi$ and $f = c + \sum_s a_s X_s + f_2 \in J$ with $c, a_s \in \mathcal{O}$ and $f_2 \in (X_s)^2$. Then $c = -\pi(\sum_s a_s X_s + f_2) \in \mathfrak{m}_R$, so $c \in \mathfrak{m}_{\mathcal{O}}$ ($\mathcal{O} \to R$ is local), and in t^* we get $\sum_s \bar a_s \bar x_s = 0$; by the basis property every $a_s \in \mathfrak{m}_{\mathcal{O}}$.

Step 4: the divided Euler operators. For $n \in \mathbb{N}^\sigma$ write $X^n = \prod_s X_s^{n_s}$, $|n| = \sum_s n_s$ and $\mathrm{wt}(n) = \sum_s n_s \mathrm{wt}(s)$; note $|\mathrm{wt}(n)| \leq 2|n|$. For $k \geq 0$ let $E_k\colon P \to P$ be the $\mathcal{O}$-linear map

$\sum_n c_n X^n \mapsto \sum_n \binom{\mathrm{wt}(n)}{k} c_n X^n$. Let $\rho_P\colon P \to P[[T]]$ be the continuous $\mathcal{O}$-algebra homomorphism with $\rho_P(X_s) = (1+T)^{\mathrm{wt}(s)} X_s$; then $\rho_P(X^n) = (1+T)^{\mathrm{wt}(n)} X^n$ and, comparing coefficients,

$$\rho_P(f) = \sum_{k \ge 0} E_k(f)\, T^k \qquad (f \in P). \tag{43.1}$$

Let $\pi_T\colon P[[T]] \to R[[T]]$ apply π to the coefficients. The maps $\rho \circ \pi$ and $\pi_T \circ \rho_P$ are continuous $\mathcal{O}$-algebra homomorphisms $P \to R[[T]]$ (morphisms of $\mathrm{CNL}_{\mathcal{O}}$ are continuous) which agree on every X_s by (Tc2); since polynomials are dense in P, they are equal. Hence, by (43.1), $\rho(\pi(f)) = \sum_k \pi(E_k f) T^k$ for all $f \in P$. Consequently $E_k(J) \subseteq J$ for all k; and if $y = \pi(f)$ has torus weight j, then comparing with $(1+T)^j y$ gives $\pi(E_k f) = \binom{j}{k} y$ for all k.

Step 5: projectors onto one weight, up to high degree. Fix $j \in \mathbb{Z}$ and an integer $M \ge |j|$, and let

$$L(x) = \prod_{\substack{-2M \le i \le 2M \\ i \ne j}} \frac{x-i}{j-i} = \binom{x+2M}{j+2M}\binom{2M-x}{2M-j}$$

(the two factors are the products over $i < j$ and over $i > j$). Both binomial polynomials take integer values at integers, so L is an integer-valued polynomial of degree $4M$, and therefore $L(x) = \sum_{k=0}^{4M} a_k \binom{x}{k}$ with $a_k \in \mathbb{Z}$ (Newton interpolation: a_k is the k-th finite difference of L at 0). Moreover $L(j) = 1$ and $L(i) = 0$ for $|i| \le 2M$, $i \ne j$. Put $\Pi = \sum_k a_k E_k$. For $f = \sum_n c_n X^n$,

$$\Pi(f) = \sum_n L(\mathrm{wt}(n)) c_n X^n = f_{(j)} + r, \qquad r = \sum_{|\mathrm{wt}(n)| > 2M} L(\mathrm{wt}(n)) c_n X^n,$$

and every monomial of r has $|n| \ge |\mathrm{wt}(n)|/2 > M$, so $r \in (X_s)^{M+1} \subseteq \mathfrak{m}_P^{M+1}$.

Step 6: (Tp2). Let $f \in J$. By Step 4, $\Pi(f) \in J$, so by Step 5 $f_{(j)} \in J + \mathfrak{m}_P^{M+1}$ for every $M \ge |j|$. By Krull's intersection theorem in P/J, $\bigcap_M (J + \mathfrak{m}_P^{M+1}) = J$; so $f_{(j)} \in J$. With Step 3 this is (Tp2).

Step 7: (Tp3). Let $y \in R$ have torus weight j and choose $f \in P$ with $\pi(f) = y$ (Step 2). By Step 4, $\pi(\Pi f) = \sum_k a_k \binom{j}{k} y = L(j) y = y$, so by Step 5 $y - \pi(f_{(j)}) = \pi(r) \in \mathfrak{m}_R^{M+1}$ for every $M \ge |j|$. Hence $y = \pi(f_{(j)})$ with $f_{(j)} \in \mathcal{O}[[X_\sigma]]_j$. □

Proposition 43.9. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, let (B, r_B) and i_B be as in (Bx1), and let $(\sigma_\ell, \mathrm{wt}, \pi_\ell)$ be a weighted presentation of R_ℓ^{ord} as in (Ol3). Then there is a finite set τ of triples $t = (g_t, a_t, b_t)$ with $g_t \in G_{\mathbb{Q}}$ such that, with $\mathrm{wt}(t) = \mathrm{wt}(a_t, b_t)$, $P = \mathcal{O}[[X_s : s \in \sigma_\ell \sqcup \tau]]$, $P_\ell = \mathcal{O}[[X_s : s \in \sigma_\ell]] \subseteq P$ and $\pi\colon P \to B$ the continuous $\mathcal{O}$-algebra homomorphism with $\pi(X_s) = i_B(\pi_\ell(X_s))$ for $s \in \sigma_\ell$ and $\pi(X_t) = y_{g_t, a_t, b_t}$ for $t \in \tau$:*

(Rp1) *$(\sigma_\ell \sqcup \tau, \mathrm{wt}, \pi)$ is a weighted presentation of B, $\pi|_{P_\ell} = i_B \circ \pi_\ell$, and $\#\{t \in \tau : \mathrm{wt}(t) = j\} = \dim Z^1_{\mathrm{u}}(\mathfrak{g}_j)$ for every $j \in \mathbb{Z}$;*

(Rp2) *$f_{(j)} \in \ker \pi$ for every $f \in \ker \pi$ and $j \in \mathbb{Z}$; every element of B of torus weight j lies in $\pi(\mathcal{O}[[X]]_j)$, where $\mathcal{O}[[X]]_j$ is the set of elements of P of weight j; in particular $\underline{r_B}(g)_{ab} \in \pi(\mathcal{O}[[X]]_{\mathrm{wt}(a,b)})$ for all $g \in G_{\mathbb{Q}}$ and a, b;*

(Rp3) *there is a family $f = (f_{j,i})$, $-2 \le j \le 2$, $1 \le i \le \mathrm{nf}(j)$, with $f_{j,i} \in \ker \pi \cap \mathcal{O}[[X]]_j$, such that $\ker \pi = (\ker \pi_\ell)P + (f_{j,i})_{j,i}$ and $\mathrm{nf}(j) \le \dim H^2_{\mathrm{u}}(\mathfrak{g}_j)$ for every j.*

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $\mathfrak{m}_\ell = \mathfrak{m}_{R_\ell^{\mathrm{ord}}}$, $\bar{y}$ for residues, and for $X \in \mathrm{M}_3(A)$ with entries in an ideal of square zero killed by $\mathfrak{m}_A$, $g \cdot X$ for the action of g through its residue (so $(P,\varsigma)(1+X,1)(P,\varsigma)^{-1} = (1+g\cdot X,1)$ for (P,ς) reducing to $\bar{r}_0(g)$). For a ring $C = \bigoplus_j C_j$ graded by finitely many weights, a matrix is *graded* if its entry (a,b) lies in $C_{\mathrm{wt}(a,b)}$; graded matrices form the degree-zero part of $\mathrm{M}_3(C)$ for $\deg E_{ab} = \mathrm{wt}(a,b)$, a subring closed under inverses, and θ preserves them (the entry (a,b) of $J\,{}^tMJ$ is $M_{4-b,4-a}$, of the same weight); an element of $\mathcal{G}_3(C)$ is graded if its GL-part is. (F)

Step 1: the relative tangent space. Let $t^*_{\mathrm{rel}} = \mathfrak{m}_B/(\mathfrak{m}_B^2 + \mathfrak{m}_{\mathcal{O}}B + i_B(\mathfrak{m}_\ell)B)$, finite-dimensional. An $\mathbb{F}$-linear form λ on t^*_{rel} defines $f_\lambda(y) = \bar{y} + \epsilon\lambda(\overline{y-c})$ ($c \in \mathcal{O}$ with $y - c \in \mathfrak{m}_B$; another choice changes $y-c$ by an element of $\mathfrak{m}_{\mathcal{O}}B$), an $\mathcal{O}$-algebra homomorphism $B \to \mathbb{F}[\epsilon]$ because $yz - cd = c(z-d) + d(y-c) + (y-c)(z-d)$, local, and killing $i_B(\mathfrak{m}_\ell)$. Conversely a morphism $f\colon B \to \mathbb{F}[\epsilon]$ is $\bar{y} + \epsilon\lambda'(y)$ with λ' vanishing on $\mathfrak{m}_B^2$ and $\mathfrak{m}_{\mathcal{O}}B$; if it kills $i_B(\mathfrak{m}_\ell)$, then $f = f_\lambda$ for the form λ induced by λ'. So the f_λ are exactly the morphisms $B \to \mathbb{F}[\epsilon]$ killing $i_B(\mathfrak{m}_\ell)$. By (Bx1) they correspond to the lifts r' to $\mathbb{F}[\epsilon]$ satisfying (Ed2), (Ed3) with $r'|_{D_\ell}$ classified by the residue map of R_ℓ^{ord}, i.e. $r'|_{D_\ell} = \bar{r}_0|_{D_\ell}$. Write $r'(g) = (1 + \epsilon z(g), 1)\bar{r}_0(g)$: r' is a homomorphism if and only if $z \in Z^1(G_{\mathbb{Q}}, \mathrm{M}_3(\mathbb{F}))$; (Ed2) holds if and only if z vanishes on every $N_{\bar{v}}$, $\bar{v} \nmid \ell$ (for $\bar{v}$ above $p \notin S$, $N_{\bar{v}} = I_{\bar{v}}$, so z factors through G_S; for $p \in S$, $N_{g\bar{p}} = gN_{\bar{p}}g^{-1}$ and $z(gng^{-1}) = g \cdot z(n)$ for n acting trivially, so vanishing on $N_{\bar{p}}$ suffices); (Ed3) holds as $\bar{r}_0|_{D_\ell}$ is classified by the residue of β_ℓ, which kills I_ℓ^{ord} (Ol1); and $r'|_{D_\ell} = \bar{r}_0|_{D_\ell}$ means $\mathrm{res}_\ell z = 0$. Decomposing $z = \sum_j z_j$ along $\mathrm{M}_3(\mathbb{F}) = \bigoplus_j \mathfrak{g}_j$ we get a linear isomorphism $\bigoplus_j Z^1_{\mathrm{u}}(\mathfrak{g}_j) \cong (t^*_{\mathrm{rel}})^\vee$, $z \mapsto \lambda_z$, with

$$\lambda_z(\bar{y}_{g,a,b}) = \big(z(g)\,\mathrm{T}(\bar{\Psi}(g))\big)_{ab},$$

which vanishes for $z \in Z^1_{\mathrm{u}}(\mathfrak{g}_i)$ unless $\mathrm{wt}(a,b) = i$. The $\bar{y}_{g,a,b}$ span t^*_{rel}: otherwise a non-zero λ kills them, and f_λ and f_0 are distinct morphisms agreeing on all $y_{g,a,b}$, against (Tc1) in (Bx2). Let V_j be the span of the $\bar{y}_{g,a,b}$ with $\mathrm{wt}(a,b) = j$. If $z \in Z^1_{\mathrm{u}}(\mathfrak{g}_j)$ and λ_z kills V_j, it kills every V_i, so $\lambda_z = 0$ and $z = 0$; and if $v \in V_j \cap \sum_{i\neq j} V_i$, every λ_z kills v, so $v = 0$. Hence $t^*_{\mathrm{rel}} = \bigoplus_j V_j$, and every form on V_j, extended by 0, is λ_z with $z = \sum_i z_i$ and $\lambda_{z_i}|_{V_i} = 0$ for $i \neq j$, i.e. $z \in Z^1_{\mathrm{u}}(\mathfrak{g}_j)$. So $V_j^\vee \cong Z^1_{\mathrm{u}}(\mathfrak{g}_j)$. Choose τ as the disjoint union over j of sets of triples of weight j whose $\bar{y}$ form a basis of V_j; this gives the count in (Rp1).

Step 2: (Rp1), (Rp2). By (Ol3) the x_s with $\mathfrak{m}_{\mathcal{O}}$ generate $\mathfrak{m}_\ell$ (π_ℓ is onto), so the images of $y_s = i_B(x_s)$ ($s \in \sigma_\ell$) and $\mathfrak{m}_{\mathcal{O}}$ span the image of $i_B(\mathfrak{m}_\ell)B$ in $\mathfrak{m}_B/\mathfrak{m}_B^2$, and with Step 1 the $\pi(X_s)$, $s \in \sigma_\ell \sqcup \tau$, and $\mathfrak{m}_{\mathcal{O}}$ span $\mathfrak{m}_B/\mathfrak{m}_B^2$. By Nakayama's lemma and the complete Nakayama lemma [166, Thm. 8.4] π is onto. Weights lie in $\{-2,\dots,2\}$, $\pi(X_s) \in \mathfrak{m}_B$, and $\pi|_{P_\ell} = i_B \circ \pi_\ell$ since both are continuous and agree on the X_s: (Rp1). Each $\pi(X_s)$ has torus weight $\mathrm{wt}(s)$ for ρ_B ((Bx2): i_B preserves torus weights and x_s has weight $\mathrm{wt}(s)$; y_t has weight $\mathrm{wt}(t)$), so (Rp2) is Lemma 43.10, items 1 and 2, with (Bx2) for the entries.

Step 3: relative minimality. Let $f \in \ker\pi$ and let $a_t(f) \in \mathcal{O}$ be the coefficient of X_t ($t \in \tau$). Then $a_t(f) \in \mathfrak{m}_{\mathcal{O}}$: write $f = c_0 + \sum_{s\in\sigma_\ell} a_s X_s + \sum_t a_t(f)X_t + f_2$ with $f_2 \in (X)^2$; $\pi(f) = 0$ gives $c_0 \in \mathfrak{m}_{\mathcal{O}}$ ($\mathcal{O} \to B$ is local), and in t^*_{rel}, where the y_s ($s \in \sigma_\ell$), c_0 and $\pi(f_2)$ vanish, $\sum_t \bar{a}_t(f)\bar{y}_t = 0$, so $\bar{a}_t(f) = 0$ by the basis property.

Step 4: the graded space of relations. Let $\mathcal{J} = \ker\pi$, $\mathcal{J}_\ell = \ker\pi_\ell$ and $\mathfrak{m} = \mathfrak{m}_P$. By Lemma 43.10, item 3, applied to π_ℓ (the x_s have torus weight $\mathrm{wt}(s)$ for ρ_ℓ), $\mathcal{J}_\ell$ is generated by finitely many elements of single weights, so $\mathcal{J}_\ell P$ is homogeneous (contains the weight components of its elements: $(gh)_{(m)} = g_{(m-k)}h$ for h of weight k); so is $\mathfrak{m}\mathcal{J}$ ($\mathfrak{m}$ is generated by ϖ and the X_s), and $\mathcal{J}_\ell P \subseteq \mathcal{J}$. By Artin–Rees choose $N_0 \geq 1$ with $\mathcal{J} \cap \mathfrak{m}^{N_0} \subseteq \mathfrak{m}\mathcal{J}$. Put $V = \mathcal{J}/(\mathcal{J}_\ell P + \mathfrak{m}\mathcal{J})$ and V_j^{rel} the image of $\mathcal{J} \cap \mathcal{O}[[X]]_j$. For $f \in \mathcal{J}$, $f - \sum_{|i|\leq 2N_0} f_{(i)}$ lies in $\mathcal{J} \cap \mathfrak{m}^{N_0+1} \subseteq \mathfrak{m}\mathcal{J}$ (its monomials have degree $> N_0$) with $f_{(i)} \in \mathcal{J}$ (Rp2), so the V_j^{rel} span V; and a relation $\sum_i f_i \in \mathcal{J}_\ell P + \mathfrak{m}\mathcal{J}$ with $f_i \in \mathcal{J} \cap \mathcal{O}[[X]]_i$ forces each f_i, a weight component of an element of

this homogeneous ideal, to lie in it. So $V = \bigoplus_j V_j^{\mathrm{rel}}$. Choose $f_{j,1}, \dots, f_{j,\mathrm{nf}(j)} \in \mathcal{J} \cap \mathcal{O}[[X]]_j$ lifting a basis of V_j^{rel}; by Nakayama's lemma applied to $\mathcal{J}/(\mathcal{J}_\ell P + (f))$, $\mathcal{J} = \mathcal{J}_\ell P + (f_{j,i})$. It remains to prove $\mathrm{nf}(j) = \dim V_j^{\mathrm{rel}} \le \dim H^2_{\mathrm{u}}(\mathfrak{g}_j)$; for $|j| > 2$ this forces $V_j^{\mathrm{rel}} = 0$ ($\mathfrak{g}_j = 0$).

Step 5: the graded small extension of weight j. Fix j and let $\mathcal{W} \subseteq \mathcal{J}$ be the preimage of $\bigoplus_{i \ne j} V_i^{\mathrm{rel}}$, a homogeneous ideal containing $\mathcal{J}_\ell P + \mathfrak{m}\mathcal{J}$ (for $f \in \mathcal{W}$, $f_{(j)}$ maps to the j-component of $\bar f$, which is 0). Put $C = P/(\mathcal{W} + \mathfrak{m}^{N_0})$ and $\bar C = P/(\mathcal{J} + \mathfrak{m}^{N_0}) = B/\mathfrak{m}_B^{N_0}$, finite local $\mathcal{O}$-algebras graded by the images of the $\mathcal{O}[[X]]_i$, $|i| \le 2N_0$. The projection $\mathrm{pr}\colon C \to \bar C$ has kernel I, the image of $\mathcal{J} \cap \mathcal{O}[[X]]_j$, so $I \subseteq C_j$, $\mathfrak{m}_C I = 0$ and $I \cong \mathcal{J}/\mathcal{W} \cong V_j^{\mathrm{rel}}$. As $\mathcal{J}_\ell \subseteq \mathcal{W}$, $P_\ell \to C$ induces $i_C\colon R_\ell^{\mathrm{ord}} \to C$, and $\mathrm{pr} \circ i_C$ is i_B followed by $B \to \bar C$. Let $\bar r$ be r_B reduced to $\bar C$, graded by (Rp2), and $\rho_C = i_C \circ r_\ell^{\mathrm{ord}}\colon D_\ell \to \mathcal{G}_3(C)$, a graded continuous homomorphism (Ol3) lifting $\bar r|_{D_\ell}$.

Step 6: graded local lifts away from ℓ. Let $p \in S$, $p \ne \ell$. $N_{\bar p}$ is normal in D_p, $I_p/N_{\bar p}$ embeds in the image of $\bar r_0$, of order prime to ℓ ($\bar\Psi$ has values in $\mathbb{F}^\times$, signs in $\{\pm 1\}$, ℓ odd), and $D_p/I_p \cong \widehat{\mathbb{Z}}$; by the Hochschild–Serre spectral sequence $H^2(D_p/N_{\bar p}, M) = 0$ for every finite ℓ-primary discrete module M. $\bar r|_{D_p}$ is trivial on $N_{\bar p}$ (Ed2); a graded set-theoretic lift of it through $D_p/N_{\bar p}$ (lift entries weight by weight) has obstruction 2-cocycle in $\mathrm{M}_3(I)$, graded, hence with values in $\mathfrak{g}_j \otimes I$; it is a coboundary $d\omega$, and correcting the lift by $(1 - \omega)$ gives a graded continuous homomorphism $\rho_p\colon D_p \to \mathcal{G}_3(C)$ lifting $\bar r|_{D_p}$ and trivial on $N_{\bar p}$.

Step 7: the obstruction class. $\bar r$ factors through a finite quotient of G_S; choose a continuous graded set-theoretic lift $s\colon G_S \to \mathcal{G}_3(C)$ of $\bar r$ with $s(1) = 1$. Then $s(g)s(g')s(gg')^{-1} = (1 + k(g,g'), 1)$ with k graded with entries in I, hence $k \in Z^2(G_S, \mathfrak{g}_j \otimes I)$. For each prime $p \in S$ write $s(g) = (1 + y_p(g), 1)\rho_p(g)$ on D_p (with $\rho_\ell = \rho_C$), $y_p \in C^1(D_p, \mathfrak{g}_j \otimes I)$; expanding $s(g)s(g')$ in two ways gives $dy_p = \mathrm{res}_p k$. For $\phi \in I^\vee$, $(\phi \circ k, (\phi \circ y_p)_p) \in Z^2_{\mathcal{L}}(\mathfrak{g}_j)$ for the local conditions $L^{\mathrm{u}}_{p,j}$, and its class $o(\phi) \in H^2_{\mathrm{u}}(\mathfrak{g}_j)$ is linear in ϕ.

Step 8: a vanishing class gives a lift framed at ℓ. Suppose $\dim V_j^{\mathrm{rel}} > \dim H^2_{\mathrm{u}}(\mathfrak{g}_j)$. As $\dim I^\vee = \dim V_j^{\mathrm{rel}}$, some $\phi \ne 0$ has $o(\phi) = 0$: $\phi \circ k = dw$ and $\phi \circ y_p = \mathrm{res}_p w + \lambda_p$, with $w \in C^1(G_S, \mathfrak{g}_j)$, $\lambda_p \in L^{\mathrm{u}}_{p,j}$, in particular $\lambda_\ell = dX$ for some $X \in \mathfrak{g}_j$. Let $I' = \ker\phi$ (a homogeneous ideal), $C' = C/I'$, identify I/I' with $\mathbb{F}$ through ϕ, and regard w, X as matrices with entries in I/I'. Over C', $s'(g) = (1 - w(g), 1)s(g)$ satisfies $s'(g)s'(g')s'(gg')^{-1} = 1 + \phi k(g,g') - dw(g,g') = 1$ (all cross terms lie in $\mathrm{M}_3(I/I')^2 = 0$), so s' is a continuous graded homomorphism lifting $\bar r$. On D_p, $p \ne \ell$, $s' = (1 + \lambda_p, 1)\rho_p$ is trivial on $N_{\bar p}$, hence on all $N_{g\bar p} = gN_{\bar p}g^{-1}$; for $\bar v$ above $p \notin S$, s' factors through G_S; so s' satisfies (Ed2). On D_ℓ, $s'(g) = (1 + g\cdot X - X, 1)\rho_C(g) = (h, 1)\rho_C(g)(h, 1)^{-1}$ with $h = 1 - X \equiv 1$. Put $s'' = (h,1)^{-1}s'(h,1)$: a graded continuous homomorphism lifting $\bar r$, satisfying (Ed2), with $s''|_{D_\ell} = i_{C'} \circ r_\ell^{\mathrm{ord}}$, where $i_{C'}$ is i_C followed by $C \to C'$; so $s''|_{D_\ell}$ is classified by a morphism killing I_ℓ^{ord}, and s'' satisfies (Ed3).

Step 9: contradiction. By (Bx1), $s'' = F \circ r_B$ for a morphism $F\colon B \to C'$; $F \circ i_B = i_{C'}$, both carrying r_ℓ^{ord} to $s''|_{D_\ell}$ (universality of $R_\ell^\square$ and surjectivity of $R_\ell^\square \to R_\ell^{\mathrm{ord}}$); and F followed by $C' \to \bar C$ is the projection $B \to \bar C$, both classifying $\bar r$ ($h \equiv 1$ and $s' \equiv s$ modulo I/I'). Let $\alpha\colon P \to C'$ be the projection and $\beta = F \circ \pi$. Then $\alpha \equiv \beta$ modulo I/I', which $\mathfrak{m}_{C'}$ kills, so $\delta = \alpha - \beta$ satisfies $\delta(xy) = \delta(x)\bar y + \bar x\delta(y)$; and $\alpha|_{P_\ell} = i_{C'} \circ \pi_\ell = F \circ i_B \circ \pi_\ell = \beta|_{P_\ell}$. For $f \in P$ write $f = f_0 + \sum_t X_t g_t$ with $f_0 \in P_\ell$ (assign each term containing some X_t to the first such t); the constant term of g_t is $a_t(f)$, and $\delta(f) = \sum_t \delta(X_t)\,\bar a_t(f)$ since $\delta(P_\ell) = 0$ and $\bar X_t = 0$. By Step 3, $\delta(\mathcal{J}) = 0$; and $\beta(\mathcal{J}) = 0$. Hence $\alpha(\mathcal{J}) = 0$; but $\alpha(\mathcal{J})$ is the image $I/I' \ne 0$ of $\mathcal{J}$ in C'. So $\dim V_j^{\mathrm{rel}} \le \dim H^2_{\mathrm{u}}(\mathfrak{g}_j)$, which completes (Rp3). □

Lemma 43.10. *Let $\mathcal{O}$ be a coefficient ring, $R \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_R$, and $\rho\colon R \to R[[T]]$ a morphism of $\mathrm{CNL}_{\mathcal{O}}$; an element $y \in R$ has* torus weight $j \in \mathbb{Z}$ *if $\rho(y) = (1 + T)^j y$. Let σ be a finite set,* $\mathrm{wt}\colon \sigma \to \mathbb{Z}$ *a map, and $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to R$ a surjective continuous $\mathcal{O}$-algebra homomorphism such that each $\pi(X_s)$ lies in $\mathfrak{m}_R$ and has torus weight $\mathrm{wt}(s)$. Then:*

1. *for every* $f \in \ker\pi$ *and* $j \in \mathbb{Z}$, $f_{(j)} \in \ker\pi$*;*

2. *every* $y \in R$ *of torus weight* j *lies in* $\pi(\mathcal{O}[[X_\sigma]]_j)$*;*

3. $\ker\pi$ *is generated by finitely many elements each lying in some* $\mathcal{O}[[X_\sigma]]_j$*.*

Proof. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$, $\mathfrak{m}_P = (\mathfrak{m}_\mathcal{O}, X_s)$, $J = \ker\pi$, and for $n \in \mathbb{N}^\sigma$, $X^n = \prod_s X_s^{n_s}$, $|n| = \sum_s n_s$, $\mathrm{wt}(n) = \sum_s n_s \mathrm{wt}(s)$. Let $W = \max(1, \max_s |\mathrm{wt}(s)|)$, so $|\mathrm{wt}(n)| \le W|n|$. For $i \in \mathbb{Z}$ and $k \ge 0$, $\binom{i}{k} = i(i-1)\cdots(i-k+1)/k! \in \mathbb{Z}$, and $(1+T)^i = \sum_k \binom{i}{k} T^k$ in $\mathbb{Z}[[T]]$.

Step 1: divided Euler operators. Let $E_k \colon P \to P$ be the $\mathcal{O}$-linear map

$$\sum_n c_n X^n \mapsto \sum_n \binom{\mathrm{wt}(n)}{k} c_n X^n,$$

and $\rho_P \colon P \to P[[T]]$ the continuous $\mathcal{O}$-algebra homomorphism with $\rho_P(X_s) = (1+T)^{\mathrm{wt}(s)} X_s$. Then $\rho_P(X^n) = (1+T)^{\mathrm{wt}(n)} X^n$, so $\rho_P(f) = \sum_k E_k(f) T^k$. Let $\pi_T \colon P[[T]] \to R[[T]]$ apply π to coefficients. The continuous $\mathcal{O}$-algebra homomorphisms $\rho \circ \pi$ and $\pi_T \circ \rho_P$ (morphisms of $\mathrm{CNL}_\mathcal{O}$ are continuous) agree on the X_s, by the hypothesis on torus weights, hence on the dense subring of polynomials, hence on P:

$$\rho(\pi(f)) = \sum_{k \ge 0} \pi(E_k f)\, T^k \qquad (f \in P).$$

So $E_k(J) \subseteq J$ for all k, and if $\pi(f) = y$ has torus weight j, then $\pi(E_k f) = \binom{j}{k} y$ for all k.

Step 2: approximate projectors. Fix j and $M \ge |j|$, and let

$$L(x) = \prod_{\substack{-WM \le i \le WM \\ i \ne j}} \frac{x-i}{j-i} = \binom{x+WM}{j+WM}\binom{WM-x}{WM-j},$$

an integer-valued polynomial (both factors are), so $L(x) = \sum_{k \le 2WM} a_k \binom{x}{k}$ with $a_k \in \mathbb{Z}$ (Newton interpolation), $L(j) = 1$ and $L(i) = 0$ for $|i| \le WM$, $i \ne j$. Put $\Pi = \sum_k a_k E_k$. For $f = \sum_n c_n X^n$, $\Pi(f) = f_{(j)} + r$ with $r = \sum_{|\mathrm{wt}(n)| > WM} L(\mathrm{wt}(n)) c_n X^n$, and each monomial of r has $|n| \ge |\mathrm{wt}(n)|/W > M$, so $r \in \mathfrak{m}_P^{M+1}$.

Step 3: items 1 and 2. If $f \in J$, then $\Pi(f) \in J$ (Step 1), so $f_{(j)} \in J + \mathfrak{m}_P^{M+1}$ for every $M \ge |j|$; by Krull's intersection theorem in P/J, $f_{(j)} \in J$. If y has torus weight j and $\pi(f) = y$, then $\pi(\Pi f) = \sum_k a_k \binom{j}{k} y = L(j) y = y$, so $y - \pi(f_{(j)}) = \pi(r) \in \mathfrak{m}_R^{M+1}$ for every M, and $y = \pi(f_{(j)})$ by Krull's intersection theorem in R.

Step 4: item 3. J is generated by the set of all $f_{(j)}$, $f \in J$, $j \in \mathbb{Z}$: these lie in J by item 1, and every $f \in J$ is the $\mathfrak{m}_P$-adic limit of the finite sums $\sum_{|j| \le WM} f_{(j)}$ (the remaining terms lie in $\mathfrak{m}_P^{M+1}$), while the ideal generated by any finitely many elements of J is closed. As P is Noetherian, finitely many of the $f_{(j)}$ generate J. □

Definition 43.11. Let $\mathcal{O}$ be a coefficient ring, $R \in \mathrm{CNL}_\mathcal{O}$, $(\sigma, \mathrm{wt}, \pi)$ a weighted presentation of R, $\beta \colon R \to \mathcal{O}$ an $\mathcal{O}$-algebra homomorphism with $\beta(\pi(X_s)) = 0$ for every $s \in \sigma$, and $\mathfrak{a} \subseteq \ker\pi$ an ideal of $\mathcal{O}[[X_s : s \in \sigma]]$ generated by finitely many elements each of which lies in some $\mathcal{O}[[X_\sigma]]_j$.

A **homogeneous generating system of** $\ker\pi$ **modulo** $\mathfrak{a}$ with counts $\mathrm{ne} \colon \{-2, \dots, 2\} \to \mathbb{N}$ is a family $u = (u_{j,i})$, $-2 \le j \le 2$, $1 \le i \le \mathrm{ne}(j)$, with $u_{j,i} \in \ker\pi \cap \mathcal{O}[[X_\sigma]]_j$ and $\ker\pi = \mathfrak{a} + (u_{j,i})_{j,i}$.

The **relative graded model** of $(\sigma, \mathrm{wt}, \pi)$ modulo $\mathfrak{a}$ with equations u is the tuple $(A, \varphi_0, \bar{u}, q)$, where $A = A_\pi/(\mathfrak{a} \cap A_\pi)$ with the subgroups A_j, the images of $(A_\pi)_j$; $q \colon A \to R$ is induced by q_π (which kills $\mathfrak{a} \cap A_\pi \subseteq \ker\pi$); $\varphi_0 = \beta \circ q$; and $\bar{u}_{j,i}$ is the image of $u_{j,i}$ in A_j.

Proposition 43.12. *Let (K,ℓ,e,N,χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking, (B,r_B) and (R,r) as in (Bx1), (Bx3), φ_{Eis} the base point of r, $p\colon B\to R$ the projection, $(\sigma_\ell,\mathrm{wt},\pi_\ell)$ as in (Ol3), and τ, P, π, f as in Proposition 43.9. Put $\sigma=\sigma_\ell\sqcup\tau$, $\pi_R=p\circ\pi$, $\mathfrak{a}=(\ker\pi_\ell)P$, $(\mathrm{nw}(k))_{k=1}^8=(0,0,1,-1,2,-2,1,-1)$, and choose $\tilde n_k\in\mathcal{O}[[X_\sigma]]_{\mathrm{nw}(k)}$ with $\pi(\tilde n_k)=n_k$. Let u be the family consisting of the $f_{j,i}$ and of the $\tilde n_k$ (placed in degree $\mathrm{nw}(k)$), with counts $\mathrm{ne}(j)=\mathrm{nf}(j)+\mathrm{nc}(j)$, $(\mathrm{nc}(j))_{j=-2}^2=(1,2,2,2,1)$, and $\mathrm{td}(j)=\mathrm{td}_\ell(j)+\#\{t\in\tau:\mathrm{wt}(t)=j\}$. Then the $\tilde n_k$ exist; $(\sigma,\mathrm{wt},\pi_R)$ is a weighted presentation of R with $\varphi_{\mathrm{Eis}}(\pi_R(X_s))=0$ for all s; $\mathfrak{a}\subseteq\ker\pi_R$ is generated by finitely many elements of single weights; u is a homogeneous generating system of $\ker\pi_R$ modulo $\mathfrak{a}$; and the relative graded model $(A,\varphi_0,\bar u,q)$ of $(\sigma,\mathrm{wt},\pi_R)$ modulo $\mathfrak{a}$ with equations u (for $\beta=\varphi_{\mathrm{Eis}}$) satisfies:*

(Mp1) *(A,φ_0) is a graded $\mathcal{O}$-algebra with a fixed point, $A=\bigoplus_j A_j$, $\bar u$ is a system of equations for it with counts* ne, *$\ker q=I(\bar u)$, $\varphi_{\mathrm{Eis}}\circ q=\varphi_0$, and $\mathrm{td}(j)=0$ for $|j|>2$;*

(Mp2) *(Pq3), (Pq4), (Pq5), (Pq6) and (Pq8) hold for (A,φ_0), $\bar u$, q and* td.

Proof. Write $\mathbb{F}=\mathbb{F}_{\mathcal{O}}$, $E_{\mathcal{O}}=\mathcal{O}[\ell^{-1}]$, $P_j=\mathcal{O}[[X_\sigma]]_j$, $a_s(h)$ for the coefficient of X_s in $h\in P$, and $E_j\subseteq\mathbb{N}^\sigma$ for the exponents of weight j.

Step 0: the presentation. The $\tilde n_k$ exist by (Rp2), as n_k has torus weight $\mathrm{nw}(k)$ (Bx3). π_R is onto with $\pi_R(X_s)\in\mathfrak{m}_R$, weights in $\{-2,\dots,2\}$; $\pi_R(X_s)$ is the image of y_{g_s,a_s,b_s}, so $\varphi_{\mathrm{Eis}}(\pi_R(X_s))=0$ as $\varphi_{\mathrm{Eis}}\circ r=r_0$, and $\varphi_{\mathrm{Eis}}(\pi_R(h))$ is the constant term of h ($h-h(0)=\sum_s X_s g_s$). By Lemma 43.10, item 3, applied to π_ℓ and ρ_ℓ (Ol3), $\mathfrak{a}$ is generated by elements $v_1,\dots,v_m\in P_\ell$ of weights ω_i, and $\mathfrak{a}\subseteq\ker\pi\subseteq\ker\pi_R$ ($\pi|_{P_\ell}=i_B\circ\pi_\ell$). As $\ker p=\mathfrak{n}=\pi((\tilde n_k)_k)B$ and $\ker\pi=\mathfrak{a}+(f)$ by (Rp3), $\ker\pi_R=\mathfrak{a}+(f)+(\tilde n)$, so u is a homogeneous generating system modulo $\mathfrak{a}$. For $g\in P_k$ and $h\in P$, $(hg)_{(m)}=h_{(m-k)}g$; hence for an ideal $\mathfrak{b}$ generated by elements $w_1,\dots,w_r$ of weights κ_i, $h\in\mathfrak{b}$ implies $h_{(j)}=\sum_i(c_i)_{(j-\kappa_i)}w_i$ for $h=\sum_i c_iw_i$, so $h_{(j)}\in\mathfrak{b}\cap P_j=\sum_i P_{j-\kappa_i}w_i$. (C)

Step 1: (Mp1). By Lemma 43.28, item 1, for the weighted presentation $(\sigma,\mathrm{wt},\mathrm{id}_P)$ of P, the constant term, and the empty system (the graded model A_π depends only on (σ,wt)), $A_\pi=\bigoplus_j P_j\subseteq P$ and $(A_\pi,\text{constant term})$ is a graded $\mathcal{O}$-algebra with a fixed point. By (C) for $\mathfrak{b}=\mathfrak{a}$, $\mathfrak{a}\cap A_\pi=\bigoplus_j(\mathfrak{a}\cap P_j)$; so $A=\bigoplus_j A_j$ with $A_j=P_j/(\mathfrak{a}\cap P_j)$, $A_iA_k\subseteq A_{i+k}$. Elements of $\mathfrak{a}$ have constant term $\varphi_{\mathrm{Eis}}(\pi_R(h))=0$, so $A_0=P_0/(\mathfrak{a}\cap P_0)$ is a complete Noetherian local ring with residue field $\mathbb{F}$, A is generated by A_0 and the images of finitely many homogeneous elements of degrees in $\{-2,-1,1,2\}$, and $\varphi_0=\varphi_{\mathrm{Eis}}\circ q$ is induced by the constant term, hence kills A_j for $j\neq0$: (A,φ_0) is a graded $\mathcal{O}$-algebra with a fixed point, and $\bar u$ a system of equations ($\varphi_0(\bar u_{0,i})=\varphi_{\mathrm{Eis}}(\pi_R(u_{0,i}))=0$). Moreover, $I(\bar u)\subseteq\ker q$. If $h=\sum_k h_k\in A_\pi$ ($h_k\in P_k$) has $\pi_R(h)=0$, then $h_k=h_{(k)}\in\ker\pi_R\cap P_k$, which by (C) for the generators v, f, $\tilde n$ of $\ker\pi_R$ is a sum of multiples of them by elements of A_π; its image in A lies in $I(\bar u)$. So $\ker q=I(\bar u)$. $\mathrm{td}(j)=0$ for $|j|>2$ since td_ℓ and wt are supported in $[-2,2]$.

Step 2: (Pq3). By (Rp2), $\underline{r_B}(g)_{ab}\in\pi(P_{\mathrm{wt}(a,b)})$; apply p: $\underline{r}(g)_{ab}\in\pi_R(P_{\mathrm{wt}(a,b)})=q(A_{\mathrm{wt}(a,b)})$.

Step 3: (Pq6). Let $\Lambda=E_{\mathcal{O}}[[Y_i,X_t:i\in\tau_\ell,t\in\tau]]$, with Y_i of weight $w(i)$ and X_t of weight $\mathrm{wt}(t)$. By (Lc2), $\phi_\ell(x_s)$ ($s\in\sigma_\ell$) has no constant term, so there is a continuous $\mathcal{O}$-algebra homomorphism $\tilde\Phi\colon P\to\Lambda$ with $\tilde\Phi(X_s)=\phi_\ell(x_s)$ ($s\in\sigma_\ell$) and $\tilde\Phi(X_t)=X_t$; X^n goes to $(Y,X_\tau)^{|n|}$. On P_ℓ, $\tilde\Phi=\phi_\ell\circ\pi_\ell$: both agree on polynomials, and for $h\in P_\ell$ both send $h-h_{<M}\in(X)^MP_\ell$ into $(Y)^M$ ($\phi_\ell(\pi_\ell(X^ng))=\phi_\ell(x)^n\phi_\ell(\pi_\ell g)$). Hence $\tilde\Phi(\mathfrak{a})=0$ and $\tilde\Phi$ induces $\Phi\colon A\to\Lambda$. By (Lc1), $\phi_\ell(x_s)=\phi_\ell(\underline{r_\ell^{\mathrm{ord}}}(g_s)_{a_sb_s})-\underline{r_0}(g_s)_{a_sb_s}$ has weight $\mathrm{wt}(s)$ (the constant is 0 off the diagonal), so $\tilde\Phi$ maps monomials of weight j, and by continuity all of P_j, to series of weight j, and $\tilde\Phi(h_{(j)})=\tilde\Phi(h)_{(j)}$ for $h\in P$. (Sm1) follows. (Sm2): the constant term of $\tilde\Phi(h)$ is that of h, i.e. $\varphi_0(\bar h)$. (Sm3): $\Phi(\bar X_t)=X_t$; for $i\in\tau_\ell$ take f from (Lc3), $f=\pi_\ell(h)$ with $h\in P_\ell$; then

$h_{(w(i))} \in A_\pi$ and the linear part of $\tilde\Phi(h_{(w(i))}) = \phi_\ell(f)_{(w(i))}$ is the weight-$w(i)$ part of that of $\phi_\ell(f)$, a non-zero multiple of Y_i. (Sm4): let $\bar h \in A$ with $\varphi_0(\bar h) = 0$ and all degree-one coefficients of $\Phi(\bar h)$ zero; as the variables have single weights, every component $h_k \in P_k$ has the same property, so let $h \in P_k$. Write $h = h_\ell + \sum_t X_t g_t$ with $h_\ell \in P_\ell$ (each term containing some X_t assigned to the first such t); taking weight-k components, $h = (h_\ell)_{(k)} + \sum_t X_t (g_t)_{(k-\mathrm{wt}(t))}$. The coefficient of X_t in $\tilde\Phi(h)$ is the constant term of $(g_t)_{(k-\mathrm{wt}(t))}$, so it vanishes and $X_t(g_t)_{(k-\mathrm{wt}(t))}$ maps into $\mathfrak{m}_0^2$, $\mathfrak{m}_0 = \ker\varphi_0$. Let $a = \pi_\ell((h_\ell)_{(k)})$: $\beta_\ell(a) = 0$ and all Y-coefficients of degree one of $\phi_\ell(a)$ vanish, so by (Lc4) $ca \in (\ker\beta_\ell)^2 = \pi_\ell((X_s : s \in \sigma_\ell)^2)$ with $c \neq 0$: $c(h_\ell)_{(k)} - \sum_{s,s'} X_s X_{s'} b_{ss'} \in \ker\pi_\ell$ for some $b_{ss'} \in P_\ell$. Its weight-k component $c(h_\ell)_{(k)} - \sum X_s X_{s'} (b_{ss'})_{(k-\mathrm{wt}(s)-\mathrm{wt}(s'))}$ lies in $\ker\pi_\ell$ (Lemma 43.10, item 1), hence in $\mathfrak{a} \cap A_\pi$; so c times the image of $(h_\ell)_{(k)}$ lies in $\mathfrak{m}_0^2$. Thus $c\bar h \in \mathfrak{m}_0^2$ and $\bar h \in \mathrm{Sq}(\varphi_0)$. So Φ is a chart and (A, φ_0) is smooth with tangent dimensions td. The inequality of (Pq6): $\mathrm{ne}(j)+\mathrm{td}_\ell(j)+\dim Z^1_{\mathrm{u}}(\mathfrak{g}_j) = \mathrm{nf}(j)+\mathrm{nc}(j)+\mathrm{td}(j) \leq \dim H^2_{\mathrm{u}}(\mathfrak{g}_j)+\mathrm{nc}(j)+\mathrm{td}(j)$ by (Rp1), (Rp3).

Step 4: points of A_π are evaluations. Let $z \in \overline{\mathbb{Q}}_\ell^\sigma$ with $|z_s|_\ell < 1$ (in a finite extension) and $\psi\colon A_\pi \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}$-algebra homomorphism with $\psi(X_s) = z_s$ and $|\psi| \leq 1$ on P_0. Then $\psi = \mathrm{ev}_z$ on A_π. By Dickson's lemma the minimal elements $m_1, \ldots, m_k$ of $E_0 \setminus \{0\}$ are finitely many and every $n \in E_0$ is a sum of them, so $\theta\colon \mathcal{O}[[Y_1, \ldots, Y_k]] \to P_0$, $Y_i \mapsto X^{m_i}$, is onto (send $\sum_n c_n X^n$ to $\sum_n c_n Y^{e(n)}$ with $\sum_i e(n)_i m_i = n$; $n \mapsto e(n)$ is injective). For $g = g_{<M} + \sum_{|e|=M} Y^e g_e$, $|\psi(\theta g) - \mathrm{ev}_z(\theta g_{<M})| \leq \max_i |z^{m_i}|^M \to 0$, so $\psi = \mathrm{ev}_z$ on P_0. For $j \neq 0$ the minimal elements Min_j of E_j are finitely many and $P_j = \sum_{m \in \mathrm{Min}_j} X^m P_0$; so $\psi = \mathrm{ev}_z$ on P_j.

Step 5: (Pq4). A point φ of (R, r) is continuous ($\mathfrak{m}_R$ is finitely generated and $|\varphi| < 1$ on it), so $\varphi \circ \pi_R = \mathrm{ev}_z$ with $z_s = \varphi(\pi_R(X_s))$, and $\varphi \circ q$ is induced by $\mathrm{ev}_z|_{A_\pi}$. If $\varphi \circ q$ is negative-vanishing, φ kills the entries of negative weight by (Pq3): φ is upper. If φ is upper, the negative-weight entries of $\underline{r_\varphi}(g)$ vanish for $g \in G_K$, and for $g \notin G_K$ too, since $r(c) = (1, -1)$ by (Ed1) gives $\underline{r}(g) = \underline{r}(gc)$; as $\underline{r_0}$ is diagonal, $z_s = 0$ whenever $\mathrm{wt}(s) < 0$, and every monomial of negative weight contains such a variable, so $\mathrm{ev}_z(P_j) = 0$ for $j < 0$. The same holds for positive weights and lower points. If $\varphi' \circ q = t \cdot (\varphi \circ q)$, then by (Pq3) $\varphi'(\underline{r}(g)_{ab}) = t^{\mathrm{wt}(a,b)} \varphi(\underline{r}(g)_{ab})$ for all g, i.e. $\underline{r_{\varphi'}}(g) = \mathrm{T}(t)\underline{r_\varphi}(g)\mathrm{T}(t)^{-1}$, and since $(\mathrm{T}(t), 1)(M, \varsigma)(\mathrm{T}(t), 1)^{-1} = (\mathrm{T}(t)M\mathrm{T}(t)^{-1}, \varsigma)$, $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$. Conversely, this gives $\varphi'(\pi_R(X_s)) = t^{\mathrm{wt}(s)} \varphi(\pi_R(X_s))$, and evaluating a series of weight j at $(t^{\mathrm{wt}(s)} z_s)$ multiplies its value by t^j.

Step 6: (Pq5). Let ψ be a point of A on $\bar u$ and suppose the image $\bar A_0$ of A_0 in $A/I(\bar u)$ is a finitely generated $\mathcal{O}$-module. It is a non-zero quotient of the local ring A_0, hence a finite local $\mathcal{O}$-algebra through which $\psi|_{A_0}$ factors; so $|\psi| \leq 1$ on A_0 and $|\psi| < 1$ on $\mathfrak{m}_{A_0}$ ($\mathfrak{m}_{\bar A_0}^M \subseteq \varpi \bar A_0$ for some M). Put $\alpha_s = |\psi(\bar X_s)|$. If $\mathrm{wt}(s) = 0$, $\bar X_s \in \mathfrak{m}_{A_0}$ and $\alpha_s < 1$; if $\mathrm{wt}(s) = v > 0 > -v' = \mathrm{wt}(s')$, then $X_s^{v'} X_{s'}^{v} \in \mathfrak{m}_{A_0}$ and $\alpha_s^{1/v} < \alpha_{s'}^{-1/v'}$. As $|\overline{\mathbb{Q}}_\ell^\times|$ is dense in $\mathbb{R}_{>0}$, there is t with $\alpha_s^{1/\mathrm{wt}(s)} < |t|$ for $\mathrm{wt}(s) > 0$ and $|t| < \alpha_s^{-1/|\mathrm{wt}(s)|}$ for $\mathrm{wt}(s) < 0$. Then $\psi' = t^{-1} \cdot \psi$ lies on $\bar u$, agrees with ψ on A_0, and $|\psi'(\bar X_s)| < 1$ for all s. By Step 4 the composite of ψ' with $A_\pi \to A$ is $\mathrm{ev}_z|_{A_\pi}$, $z_s = \psi'(\bar X_s)$; it kills v and u, so ev_z kills $\ker\pi_R$, and $\mathrm{ev}_z = \varphi \circ \pi_R$ for an $\mathcal{O}$-algebra homomorphism $\varphi\colon R \to \overline{\mathbb{Q}}_\ell$ with $|\varphi| < 1$ on $\mathfrak{m}_R = \pi_R(\mathfrak{m}_P)$: a point of (R, r), with $\psi = t \cdot (\varphi \circ q)$.

Step 7: (Pq8). Let $b \in \mathcal{O} \setminus \{0\}$, $\mu \in \mathrm{Sha}[b]$, $X_0 = E_{21} - E_{32}$; $c \cdot X_0 = X_0$ and $G_{\mathbb{Q}}$ acts on X_0 by Ψ^{-1}. By (Ue9), $\bar\Psi^2 = \bar\chi_{\mathrm{cyc}}^{2e} \neq 1$ on I_ℓ ((Ue4): $\chi_\ell^2 = \mathbf{1}$), so $H^0(D_\ell, \mathcal{O}^\vee(\Psi^{-1})) = 0 = H^0(\mathbb{Q}, \mathcal{O}^\vee(\Psi^{-1}))$, and $0 \to \mathcal{O}/b \to \mathcal{O}^\vee \xrightarrow{b} \mathcal{O}^\vee \to 0$ identifies $\mathrm{Sha}[b]$ with a subgroup of $H^1(\mathbb{Q}, (\mathcal{O}/b)(\Psi^{-1}))$. Let $\tilde z$ represent μ. For $\bar v$ above $p \nmid \ell N$, Ψ is unramified at p and μ is unramified, so the homomorphism $\tilde z|_{I_{\bar v}}$ vanishes. For $p \mid N$, $p \neq \ell$, $\tilde z = dy_p$ on $D_{\bar p}$; on $N_{\bar p} = I_{\bar p} \cap \ker\bar r_0$, $\Psi = \chi$ has values in roots of unity of order prime to ℓ (Ue3) with residue 1, so $\Psi = 1$ there and $\tilde z(N_{\bar p}) = 0$, and then $\tilde z(N_{g\bar p}) = 0$ by the cocycle relation. At ℓ, $\tilde z = dm_\ell$ on D_ℓ with $m_\ell \in \mathcal{O}^\vee$ and bm_ℓ invariant, so $m_\ell \in \mathcal{O}/b$. As $\Psi(g_\star)^{-1} - 1$ is a unit, there is

a unique $z_\mu = \tilde{z} + dm$ ($m \in \mathcal{O}/b$) with $z_\mu(g_\star) = 0$, and $z_\mu(c) = 0$ ($2z_\mu(c) = z_\mu(c^2) = 0$); $\mu \mapsto z_\mu$ is additive and injective, and $z_\mu = d(m_\ell + m)$ on D_ℓ. Over $A_b = \mathcal{O}[\epsilon]/(\epsilon^2, b\epsilon)$ put $r_\mu(g) = (1+\epsilon z_\mu(g)X_0, 1)\, r_0(g)$. It is a lift of $\bar{r}_0$; (Ed1) holds as $r_\mu(c) = r_0(c)$ and $r_\mu(g_\star) = r_0(g_\star)$; (Ed2) holds by the vanishing above and because $r_0 = \varphi_{\mathrm{Eis}} \circ r$ satisfies (Ed2) ((Bx3): every $f \circ r$ does); on D_ℓ, r_μ is the conjugate of $r_0|_{D_\ell} = \beta_\ell \circ r_\ell^{\square}$ by $(1 - \epsilon(m_\ell + m)X_0, 1)$, so (Ed3) holds by (Ol1), (Ol2). Hence $r_\mu = F_\mu \circ r$, $F_\mu = \varphi_{\mathrm{Eis}} + \epsilon\delta_\mu$ with $\delta_\mu \colon R \to \mathcal{O}/b$ a φ_{Eis}-derivation. Put $D(\mu) = \delta_\mu \circ q$. As $\delta_\mu \circ \pi_R$ kills $\mathcal{O}$ and $(X)^2$, $D(\mu)(\bar{h}) = \sum_s a_s(h)\, \delta_\mu(\pi_R(X_s))$, where $\delta_\mu(\pi_R(X_s))$ is the entry (a_s, b_s) of $z_\mu(g_s)X_0\underline{r_0}(g_s)$, zero unless $\mathrm{wt}(s) = -1$. So D is additive, $D(\mu)(\bar{u}_{-1,i}) = \delta_\mu(\pi_R(u_{-1,i})) = 0$, and $D(\mu)(\bar{A}_j) = 0$ for $j \neq -1$. Lift: let $\tilde{m} \in \mathcal{O}$ lift $m_\ell + m$; $(1 - \epsilon\tilde{m}X_0, 1)\, r_0|_{D_\ell}\, (1 - \epsilon\tilde{m}X_0, 1)^{-1}$ over $\mathcal{O}[\epsilon]/(\epsilon^2)$ is classified, by (Ol2), by $\beta_\ell + \epsilon D_1$ with D_1 a β_ℓ-derivation $R_\ell^{\mathrm{ord}} \to \mathcal{O}$, and $D_1(x_s)$ is the entry (a_s, b_s) of $\tilde{m}(g_s \cdot X_0 - X_0)\underline{r_0}(g_s)$, which reduces to $\delta_\mu(\pi_R(X_s))$ modulo b for $s \in \sigma_\ell$. Put $D'(X_s) = D_1(x_s)$ for $s \in \sigma_\ell$, $D'(X_t)$ a lift of $\delta_\mu(\pi_R(X_t))$ if $\mathrm{wt}(t) = -1$ and 0 otherwise, and $D'(h) = \sum_s a_s(h)D'(X_s)$ on P, a derivation at the constant term. On P_ℓ, $D' = D_1 \circ \pi_\ell$ (both kill $\mathcal{O}$ and $(X)^2$ and agree on the X_s), so for $h = \sum_i k_i p_i \in \mathfrak{a}$ with $k_i \in \ker \pi_\ell$ (no constant term), $D'(h) = \sum_i \bar{p}_i(0)D_1(\pi_\ell(k_i)) = 0$. Hence D' induces an $\mathcal{O}$-linear map $A \to \mathcal{O}$ with $D'(xy) = \varphi_0(x)D'(y) + \varphi_0(y)D'(x)$, vanishing on A_j for $j \neq -1$ (all $D'(X_s)$ with $\mathrm{wt}(s) \neq -1$ vanish), and reducing to $D(\mu)$ modulo b. If $D(\mu) = 0$, then $\delta_\mu(\pi_R(X_s)) = 0$ for all s, so $\delta_\mu \circ \pi_R = 0$, $\delta_\mu = 0$, $r_\mu = r_0$, $z_\mu = 0$ and $\mu = 0$: D is injective. $\square$

Proposition 43.13. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and put $(\mathrm{td}_\ell(j))_{j=-2}^2 = (1, 2, 3, 4, 2)$ and $\mathrm{td}_\ell(j) = 0$ for $|j| > 2$. There are a finite set τ_ℓ, a map $w \colon \tau_\ell \to \mathbb{Z}$ with $\#w^{-1}(j) = \mathrm{td}_\ell(j)$ for every j, and an $\mathcal{O}$-algebra homomorphism $\phi_\ell \colon R_\ell^{\mathrm{ord}} \to \mathcal{O}[\ell^{-1}][[Y_i : i \in \tau_\ell]]$, where Y_i has weight $w(i)$, such that:*

(Lc1) *$\phi_\ell(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab})$ has weight $\mathrm{wt}(a, b)$ for all $g \in D_\ell$ and $1 \leq a, b \leq 3$;*

(Lc2) *the constant term of $\phi_\ell(f)$ is $\beta_\ell(f)$ for every $f \in R_\ell^{\mathrm{ord}}$;*

(Lc3) *for every $i \in \tau_\ell$ there is $f \in R_\ell^{\mathrm{ord}}$ such that in $\phi_\ell(f)$ the coefficient of Y_i is non-zero and the coefficient of $Y_{i'}$ is zero for every $i' \neq i$;*

(Lc4) *if $f \in R_\ell^{\mathrm{ord}}$, $\beta_\ell(f) = 0$ and all coefficients of degree one of $\phi_\ell(f)$ vanish, then $cf \in (\ker \beta_\ell)^2$ for some $c \in \mathcal{O} \setminus \{0\}$.*

Proof. Write $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$, $\Lambda = E_\mathcal{O}[[Y_1, \ldots, Y_{12}]]$, $L \colon \Lambda \to E_\mathcal{O}^{12}$ for the vector of coefficients of $Y_1, \ldots, Y_{12}$, $\beta = \beta_\ell$, $R = R_\ell^{\mathrm{ord}}$, and $x_s = x_{g_s, a_s, b_s}$ for $s \in \sigma_\ell$; $\beta(x_s) = 0$ as $\beta \circ r_\ell^{\mathrm{ord}} = r_0$.

Step 0: $\ker \beta = (x_s : s \in \sigma_\ell)$. β is local (for y in the maximal ideal and $u \in \mathcal{O}^\times$, $y - u$ is a unit, so $\beta(y) \neq u$), hence continuous, so $\beta \circ \pi_\ell$ and the constant term agree on $\mathcal{O}[[X]]$ (both continuous, equal on the X_s); as π_ℓ is onto, $\ker \beta = \pi_\ell((X_s)_s) = (x_s)_s$. Also $R = \mathcal{O} + \ker \beta$, and the maximal ideal of R is $\mathfrak{m}_\mathcal{O} R + \ker \beta$.

Step 1: a torus endomorphism. Let $t = 1 + \ell \in \mathcal{O}^\times$; $t \equiv 1 \bmod \mathfrak{m}_\mathcal{O}$ and $t^k \neq 1$ for $k \neq 0$ ($v_\ell(t^k - 1) = 1 + v_\ell(k)$, ℓ odd). By (Ol2) for $A = R$, $h = \mathrm{T}(t)$ and f the projection $R_\ell^{\square} \to R$, there is a morphism f' killing I_ℓ^{ord} with $f' \circ r_\ell^{\square} = (\mathrm{T}(t), 1)(f \circ r_\ell^{\square})(\mathrm{T}(t), 1)^{-1}$; it induces an $\mathcal{O}$-algebra endomorphism ϑ of R with $\vartheta \circ r_\ell^{\mathrm{ord}} = (\mathrm{T}(t), 1)r_\ell^{\mathrm{ord}}(\mathrm{T}(t), 1)^{-1}$. Since $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$, the GL-part of the right side is $\mathrm{T}(t)\underline{r_\ell^{\mathrm{ord}}}(g)\mathrm{T}(t)^{-1}$ for both signs, so $\vartheta(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}) = t^{\mathrm{wt}(a,b)}\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}$ and $\vartheta(x_s) = t^{\mathrm{wt}(s)}x_s$ (the constant is 0 off the diagonal). Moreover $\beta \circ \vartheta = \beta$: $\beta \circ \vartheta$ carries r_ℓ^{ord} to $(\mathrm{T}(t), 1)r_0(\mathrm{T}(t), 1)^{-1} = r_0$, and r_ℓ^{ord} has exactly one base point (Ol1).

Step 2: equivariance of a chart. Let $\phi \colon R \to \Lambda$ be an $\mathcal{O}$-algebra homomorphism with (Cp1) and (Cp3), and $z_1, \ldots, z_{12} \in R$, $w_1, \ldots, w_{12} \in \mathbb{Z}$ with $\phi(z_i) = Y_i$ and $\vartheta(z_i) = t^{w_i}z_i$. Let ρ be the continuous $E_\mathcal{O}$-algebra automorphism of Λ with $\rho(Y_i) = t^{w_i}Y_i$. Then $\phi \circ \vartheta = \rho \circ \phi$.

Indeed $\psi_1 = \phi \circ \vartheta$ and $\psi_2 = \rho \circ \phi$ are $\mathcal{O}$-algebra homomorphisms with constant term β ((Cp1), $\beta \circ \vartheta = \beta$, ρ preserves constant terms), so $\psi_k((\ker\beta)^N) \subseteq \mathfrak{m}_Y^N$, and $\psi_1(z_i) = t^{w_i} Y_i = \psi_2(z_i)$. Given $a \in R$ and $N \geq 1$, let p be the polynomial formed by the terms of degree $< N$ of $\phi(a)$, $d \in \mathcal{O} \setminus \{0\}$ with $dp \in \mathcal{O}[Y]$, and $b = (dp)(z_1, \dots, z_{12}) \in R$. Then $\phi(da - b) = d(\phi(a) - p) \in \mathfrak{m}_Y^N$, so $c(da - b) \in (\ker\beta)^N$ for some $c \neq 0$ by (Cp3); and $\psi_1(b) = (dp)(t^{w_1} Y_1, \dots) = \psi_2(b)$. Hence $cd(\psi_1(a) - \psi_2(a)) = \psi_1(c(da-b)) - \psi_2(c(da-b)) \in \mathfrak{m}_Y^N$; cd is a unit of $E_{\mathcal{O}}$, so $\psi_1(a) - \psi_2(a) \in \bigcap_N \mathfrak{m}_Y^N = 0$. Consequently, if $\vartheta(a) = t^j a$, then $\rho(\phi(a)) = t^j \phi(a)$; as ρ multiplies the coefficient of Y^n by $t^{\sum_i n_i w_i}$ and $k \mapsto t^k$ is injective, $\phi(a)$ has weight j for the weights w_i of the Y_i.

Step 3: coordinates among the entries. Let ϕ_0 be as in Proposition 43.14. Since $L(gh) = \mathrm{const}(g)L(h) + \mathrm{const}(h)L(g)$, $\delta = \lambda \circ L \circ \phi_0$ is a β-derivation of R for every linear form λ on $E_{\mathcal{O}}^{12}$. If the $L(\phi_0(x_s))$, $s \in \sigma_\ell$, did not span, some $\lambda \neq 0$ would kill them; then $\delta(x_s) = 0$, so $\delta(\sum_s x_s r_s) = \sum_s \delta(x_s)\beta(r_s) = 0$, $\delta(\ker\beta) = 0$ and $\delta = 0$ (Step 0). By (Cp2) with $h = Y_i$ there are f, $c \neq 0$ with $L(\phi_0(f)) = c\, e_i$, so $\lambda(e_i) = c^{-1}\delta(f) = 0$ for all i, a contradiction. Choose $s_1, \dots, s_{12} \in \sigma_\ell$ with $L(\phi_0(x_{s_i}))$ a basis, and put $z_i = x_{s_i}$, $w_i = \mathrm{wt}(s_i) \in \{-2, \dots, 2\}$. Let α be the continuous $E_{\mathcal{O}}$-algebra endomorphism of Λ with $\alpha(Y_i) = \phi_0(z_i) \in \mathfrak{m}_Y$ (constant term $\beta(z_i) = 0$); its matrix of linear parts is invertible, so α is an automorphism, mapping $\mathfrak{m}_Y^N$ onto itself and preserving constant terms. Put $\phi_\ell = \alpha^{-1} \circ \phi_0$, $\tau_\ell = \{1, \dots, 12\}$, $w(i) = w_i$. Then $\phi_\ell(z_i) = Y_i$, ϕ_ℓ satisfies (Cp1), and (Cp3) (if $\phi_\ell(f) \in \mathfrak{m}_Y^N$ then $\phi_0(f) = \alpha(\phi_\ell(f)) \in \mathfrak{m}_Y^N$); and $\vartheta(z_i) = t^{w_i} z_i$ (Step 1).

Step 4: (Lc1)–(Lc4). (Lc1): by Step 1, $\vartheta(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}) = t^{\mathrm{wt}(a,b)} \underline{r_\ell^{\mathrm{ord}}}(g)_{ab}$, so Step 2 gives weight $\mathrm{wt}(a,b)$. (Lc2) is (Cp1). (Lc3): take $f = z_i$. (Lc4): if $\beta(f) = 0$ and all degree-one coefficients of $\phi_\ell(f)$ vanish, $\phi_\ell(f) \in \mathfrak{m}_Y^2$, and (Cp3) with $N = 2$ gives $c \neq 0$ with $cf \in (\ker\beta)^2$.

Step 5: the counts $\#w^{-1}(j) = \mathrm{td}_\ell(j)$. For $i \in \tau_\ell$ let $F_i \colon R \to E_{\mathcal{O}}[\epsilon]$ send f to the constant term of $\phi_\ell(f)$ plus ϵ times its coefficient of Y_i; it is an $\mathcal{O}$-algebra homomorphism (the jet $\Lambda \to E_{\mathcal{O}}[\epsilon]$ is), with reduction β, local. It kills $(\ker\beta)^2$, and $F_i(\ker\beta) = \sum_s \mathcal{O} F_i(x_s)$ is bounded ($F_i(x_s r) = F_i(x_s)\beta(r)$); as the maximal ideal of R is $\mathfrak{m}_{\mathcal{O}} R + \ker\beta$, F_i maps its N-th power into ϖ^{N-1} times a bounded set: F_i is continuous, and so is $g \mapsto F_i(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab})$. By Lemma 43.22 (with $E = E_{\mathcal{O}}$ and $\rho_0 = \underline{r_0}|_{D_\ell}$) the map y_i with $F_i(\underline{r_\ell^{\mathrm{ord}}}(g)) = (1 + \epsilon y_i(g))\underline{r_0}(g)$ is a continuous cocycle with a primitive $Y \in \mathrm{M}_3(E_{\mathcal{O}}) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$. Its entry (a,b) is the coefficient of Y_i in $\phi_\ell(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab})$ times $\psi_b(g)^{-1}$, which vanishes unless $\mathrm{wt}(a,b) = w_i$ by (Lc1); so $y_i \in Z_{w_i}$ (Lemma 43.23). For fixed j the y_i with $w_i = j$ are linearly independent: at $g = g_{s_k}$ the entry (a_{s_k}, b_{s_k}) of y_i is the coefficient of Y_i in $\phi_\ell(z_k) + \mathrm{const} = Y_k + \mathrm{const}$, times a unit, which is non-zero exactly for $i = k$. Hence $\#w^{-1}(j) \leq \dim Z_j = \mathrm{td}_\ell(j)$ for every j (Lemma 43.23). As all w_i lie in $\{-2, \dots, 2\}$, $\sum_j \#w^{-1}(j) = 12 = 1 + 2 + 3 + 4 + 2 = \sum_j \mathrm{td}_\ell(j)$, so equality holds for every j. □

43.2 The ordinary local lifting ring at the Eisenstein point

This subsection proves that the ordinary local lifting ring at ℓ is smooth at the Eisenstein point after inverting ℓ: its rational completion there is a power series ring in twelve variables (Proposition 43.14). This gives the graded chart Proposition 43.13, with weight multiplicities $1, 2, 3, 4, 2$, which the model of Subsection 43.1 uses. The upper bound for the tangent space is the core. Points of the ordinary ideal are triangular on the open subgroup D_ℓ° (Lemma 43.17, Lemma 43.19), triangular representations with cyclotomic inertial weights and finite adjacent extension classes are crystalline (Lemma 43.21), and so the tangent cocycles are Bloch–Kato classes (Proposition 43.15, Lemma 43.22), whose dimensions in the five weights are $1, 2, 3, 4, 2$ (Lemma 43.23). The lower bound comes from an explicit twelve-parameter family of triangular ordinary lifts through the Eisenstein point (Lemma 43.25, Proposition 43.24). The remaining lemmas, on lifting cocycles over power series rings and on weighted presentations, are routine

deformation theory. This subsection also introduces the triangular lifts (Definition 43.16), which Part IX uses to describe the points of the deformation ring.

Proposition 43.14. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $\mathfrak{m}_Y$ be the maximal ideal of $\mathcal{O}[\ell^{-1}][[Y_1, \dots, Y_{12}]]$. There is an $\mathcal{O}$-algebra homomorphism $\phi\colon R_\ell^{\mathrm{ord}} \to \mathcal{O}[\ell^{-1}][[Y_1, \dots, Y_{12}]]$ such that:*

(Cp1) *the constant term of $\phi(f)$ is $\beta_\ell(f)$ for every $f \in R_\ell^{\mathrm{ord}}$;*

(Cp2) *for every $h \in \mathcal{O}[\ell^{-1}][[Y_1, \dots, Y_{12}]]$ there are $f \in R_\ell^{\mathrm{ord}}$ and $c \in \mathcal{O}\backslash\{0\}$ with $ch - \phi(f) \in \mathfrak{m}_Y^2$;*

(Cp3) *for every $N \geq 1$ and $f \in R_\ell^{\mathrm{ord}}$ with $\phi(f) \in \mathfrak{m}_Y^N$ there is $c \in \mathcal{O} \setminus \{0\}$ with $cf \in (\ker \beta_\ell)^N$.*

Proof. Write $A = R_\ell^{\mathrm{ord}}$, $\beta = \beta_\ell$, $\mathfrak{q} = \ker \beta$ (a prime ideal, $A/\mathfrak{q} \cong \mathcal{O}$), $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$, the fraction field of $\mathcal{O}$, and $\Lambda = E_\mathcal{O}[[Y_1, \dots, Y_{12}]]$.

Step 1: $\mathfrak{q} = \sum_s x_s A$ and $A = \mathcal{O} + \mathfrak{q}$. $\beta(x_s) = 0$, as $\beta \circ r_\ell^{\mathrm{ord}} = r_0$. Every $P \in \mathcal{O}[[X_\sigma]]$ satisfies $P - P(0) = \sum_s X_s P_s$ for some power series P_s; as π_ℓ is onto, every $a \in A$ is $o + t$ with $o \in \mathcal{O}$ and $t \in \sum_s x_s A$. If $a \in \mathfrak{q}$, then $0 = \beta(a) = o$, so $a \in \sum_s x_s A$.

Step 2: the local ring $A_\mathfrak{q}$ and its cotangent space. Elements of $\mathcal{O} \setminus \{0\}$ lie outside $\mathfrak{q}$, so $A_\mathfrak{q}$ is a Noetherian local $E_\mathcal{O}$-algebra, with residue field $E_\mathcal{O}$, the composite $E_\mathcal{O} \to A_\mathfrak{q} \to E_\mathcal{O}$ being the identity. Let $T = \mathfrak{q}A_\mathfrak{q}/\mathfrak{q}^2 A_\mathfrak{q}$. For $a \in A$ and $s \notin \mathfrak{q}$ one has $\beta(s) \neq 0$ and $a/s - a/\beta(s) = a(\beta(s) - s)/(s\beta(s))$; so for $a \in \mathfrak{q}$ the classes of a/s and $\beta(s)^{-1}a$ in T agree, and T is spanned over $E_\mathcal{O}$ by the classes of the x_s (Step 1, and $x_s r \equiv \beta(r) x_s$ modulo $\mathfrak{q}^2$).

Step 3: $\dim_{E_\mathcal{O}} T \leq 12$. Let $\lambda\colon T \to E_\mathcal{O}$ be $E_\mathcal{O}$-linear, and define $F_\lambda\colon A \to E_\mathcal{O}[\epsilon]$ by $F_\lambda(a) = \beta(a) + \epsilon\,\lambda(a - \beta(a))$ (here $a - \beta(a) \in \mathfrak{q}$ by Step 1). From $ab - \beta(a)\beta(b) = (a - \beta(a))(b - \beta(b)) + \beta(a)(b - \beta(b)) + \beta(b)(a - \beta(a))$, F_λ is an $\mathcal{O}$-algebra homomorphism; its reduction modulo ϵ is β, which maps the maximal ideal $\mathfrak{m}_\mathcal{O} A + \mathfrak{q}$ of A into $\mathfrak{m}_\mathcal{O}$, so the first hypothesis of Proposition 43.15 holds with $E = E_\mathcal{O}$. For the second: $F_\lambda(\mathfrak{q}) \subseteq L = \sum_s \mathcal{O}\lambda(x_s)$, a bounded set, F_λ kills $\mathfrak{q}^2$, and $(\mathfrak{m}_\mathcal{O} A + \mathfrak{q})^N \subseteq \mathfrak{m}_\mathcal{O}^N A + \mathfrak{m}_\mathcal{O}^{N-1}\mathfrak{q} + \mathfrak{q}^2$, so F_λ maps the N-th power of the maximal ideal into $\mathfrak{m}_\mathcal{O}^N + \epsilon\,\mathfrak{m}_\mathcal{O}^{N-1} L$; hence F_λ is continuous, and so is $g \mapsto F_\lambda(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab})$, the lift r_ℓ^{ord} having continuous entries. By Lemma 43.22 for $f = F_\lambda$ (whose ρ_0 is $\underline{r_0}|_{D_\ell}$), the map $y_\lambda\colon D_\ell \to \mathrm{M}_3(E_\mathcal{O})$ with $F_\lambda(\underline{r_\ell^{\mathrm{ord}}}(g)) = (1 + \epsilon y_\lambda(g))\underline{r_0}(g)$ is a continuous cocycle with a primitive $Y_\lambda \in \mathrm{M}_3(E_\mathcal{O}) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$. The action of D_ℓ through r_0 preserves the weight of every entry ($\underline{r_0}(g)$ is diagonal, and $J\,{}^t X J$ has entry (a, b) equal to $X_{4-b,4-a}$, of the same weight), so the projection p_j to the entries of weight j is equivariant; then $p_j \circ y_\lambda$ is a cocycle with primitive $(p_j \otimes 1)(Y_\lambda)$, i.e. $p_j \circ y_\lambda \in Z_j$ (formed with $E = E_\mathcal{O}$). The map $\lambda \mapsto (p_j \circ y_\lambda)_j \in \bigoplus_j Z_j$ is $E_\mathcal{O}$-linear and injective: if $y_\lambda = 0$, then $F_\lambda(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}) = \underline{r_0}(g)_{ab}$, so $\lambda(x_s) = 0$ for all s, and $\lambda = 0$ by Step 2. By Lemma 43.23, $\dim T = \dim \overline{T}^* \leq 1 + 2 + 3 + 4 + 2 = 12$.

Step 4: $A_\mathfrak{q}$ is regular of dimension 12, and the map ϕ. By Proposition 43.24, $\dim A_\mathfrak{q} \geq 12 \geq \dim T$; so $A_\mathfrak{q}$ is regular of dimension 12 and $\dim T = 12$. Its completion $\widehat{A}$ is a complete regular local ring of dimension 12 with coefficient field $E_\mathcal{O}$; choosing $y_1, \dots, y_{12} \in \mathfrak{q}A_\mathfrak{q}$ whose classes form a basis of T, Cohen's theorem gives an isomorphism $\Lambda \cong \widehat{A}$, $Y_i \mapsto y_i$, under which $\mathfrak{m}_Y^N$ corresponds to $\mathfrak{q}^N \widehat{A}$ and $\Lambda/\mathfrak{m}_Y^N \cong A_\mathfrak{q}/\mathfrak{q}^N A_\mathfrak{q}$. Let $\phi\colon A \to A_\mathfrak{q} \to \widehat{A} \cong \Lambda$, an $\mathcal{O}$-algebra homomorphism.

Step 5: (Cp1)–(Cp3). (Cp1): the constant term of $\phi(f)$ is the image of f in the residue field $A_\mathfrak{q}/\mathfrak{q}A_\mathfrak{q} = E_\mathcal{O}$, i.e. $\beta(f)$. (Cp2): given $h \in \Lambda$, since $A_\mathfrak{q} \to \Lambda/\mathfrak{m}_Y^2$ is onto, $h \equiv \phi(a)\phi(s)^{-1}$ modulo $\mathfrak{m}_Y^2$ for some $a \in A$, $s \notin \mathfrak{q}$. Multiplying by $\phi(s) = \beta(s) + (\phi(s) - \beta(s))$, where $\phi(s) - \beta(s) \in \mathfrak{m}_Y$ by (Cp1), gives $\beta(s)h - \phi(a) \equiv -(\phi(s) - \beta(s))h \equiv -(\phi(s) - \beta(s))h_0$ modulo $\mathfrak{m}_Y^2$, with $h_0 \in E_\mathcal{O}$ the constant term of h. Choose $c_0 \in \mathcal{O} \setminus \{0\}$ with $c_0 h_0 \in \mathcal{O}$; then $f = c_0 a - c_0 h_0 (s - \beta(s)) \in A$

and $c = c_0\beta(s) \in \mathcal{O} \setminus \{0\}$ satisfy $ch - \phi(f) \in \mathfrak{m}_Y^2$. (Cp3): let $\phi(f) \in \mathfrak{m}_Y^N$. Then $f \in \mathfrak{q}^N A_{\mathfrak{q}}$. Put $A' = A[\ell^{-1}]$ and $\mathfrak{n} = \mathfrak{q}A'$, a maximal ideal ($A'/\mathfrak{n} = E_{\mathcal{O}}$); $A_{\mathfrak{q}} = A'_{\mathfrak{n}}$ as $\ell \notin \mathfrak{q}$, and $\mathfrak{n}^N$ is $\mathfrak{n}$-primary, so $\mathfrak{n}^N A'_{\mathfrak{n}} \cap A' = \mathfrak{n}^N = \mathfrak{q}^N A'$. Hence $f = g\ell^{-k}$ in A' with $g \in \mathfrak{q}^N$, i.e. $\ell^m(\ell^k f - g) = 0$ in A for some m, and $c = \ell^{m+k}$ satisfies $cf = \ell^m g \in \mathfrak{q}^N$. □

Proposition 43.15. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. Fix an embedding $\mathrm{emb}_\ell\colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}$ inducing the place $\bar{\ell}$, and identify D_ℓ with $\mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ through it; then D_ℓ°, an open subgroup, is the absolute Galois group of a finite extension of $\mathbb{Q}_\ell$. Let $E \subseteq \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ containing $\mathcal{O}$, let $E[\epsilon] = E[X]/(X^2)$, and let $f\colon R_\ell^{\mathrm{ord}} \to E[\epsilon]$ be an $\mathcal{O}$-algebra homomorphism such that*

- *its reduction f_0 modulo ϵ satisfies $|f_0(y)|_\ell < 1$ for every y in the maximal ideal of R_ℓ^{ord}, and*
- *for $1 \le a, b \le 3$ the map $g \mapsto f(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab})$ from D_ℓ to $E[\epsilon]$ is continuous.*

Then the representation $g \mapsto f(\underline{r_\ell^{\mathrm{ord}}}(g))$ of D_ℓ° on $E[\epsilon]^3$, regarded as a finite-dimensional $\mathbb{Q}_\ell$-vector space, is crystalline.

Proof. Write $B = E[\epsilon]$, a local $E_{\mathcal{O}}$-algebra of finite dimension, $H = D_\ell^\circ$, and $\tilde{f}\colon R_\ell^\square \to B$ for f composed with the projection $R_\ell^\square \to R_\ell^{\mathrm{ord}}$. Through emb_ℓ, H is the absolute Galois group G_M of a finite extension M of $\mathbb{Q}_\ell$, with inertia subgroup $I_M = H \cap I_\ell$, and $\chi_{\mathrm{cyc}}|_H$ is the cyclotomic character of M. The representation in question is $\rho_B(g) = \tilde{f}(\underline{r_\ell^\square}(g))$, $g \in H$; it is a homomorphism, lifts having sign η_K, trivial on H. As in Lemma 43.19, χ is trivial on I_M ($\chi = \chi_\ell(\chi_{\mathrm{cyc}} \bmod \ell^b)$ on I_ℓ and $\chi_\ell|_H = 1$), so $\psi_a = \chi_{\mathrm{cyc}}^{e(2-a)}$ on I_M.

Step 1: the saturated ideal. Let $\mathrm{Sat} = \{y \in R_\ell^\square : \ \mathrm{gd}(r_\ell^\square)^n y \in I^{\mathrm{ord}}(r_\ell^\square) \text{ for some } n \ge 0\}$. Then $\mathrm{gd}(r_\ell^\square)\, y \in \mathrm{Sat}$ implies $y \in \mathrm{Sat}$, and $I^{\mathrm{ord}}(r_\ell^\square) \subseteq \mathrm{Sat} \subseteq I^{\mathrm{cr}}$, which is contained in every minimal prime of I^{cr}, hence in I_ℓ^{ord}; so $\tilde{f}(\mathrm{Sat}) = 0$. Let $R = R_\ell^\square[\ell^{-1}]$, a Noetherian $E_{\mathcal{O}}$-algebra, $\mathfrak{s} = \mathrm{Sat}\, R$ and d the image of $\mathrm{gd}(r_\ell^\square)$. If $d \cdot y\ell^{-k} \in \mathfrak{s}$ with $y \in R_\ell^\square$, then $\ell^m \mathrm{gd}(r_\ell^\square) y \in \mathrm{Sat}$ for some m, so $\ell^m y \in \mathrm{Sat}$ and $y\ell^{-k} \in \mathfrak{s}$. As $\tilde{f}(\ell)$ is a unit, $\tilde{f}$ extends to an $E_{\mathcal{O}}$-algebra homomorphism $R \to B$ killing $\mathfrak{s}$.

Step 2: a lift with small annihilator. By Lemma 43.18 (with $k = E_{\mathcal{O}}$) there are $n \ge 1$, the local $E_{\mathcal{O}}$-algebra $B' = R/(\mathfrak{s} + \mathfrak{M}^n)$ of finite dimension, $\mathfrak{M}$ the preimage of ϵB, the projection $\pi\colon R \to B'$ and $q\colon B' \to B$ with $\tilde{f} = q \circ \pi$ on $R_\ell^\square$, such that $q(b) = 0$ whenever $\pi(d)b = 0$. Let $f'\colon R_\ell^\square \to B'$ be the restriction of π, an $\mathcal{O}$-algebra homomorphism killing $\mathrm{Sat} \supseteq I^{\mathrm{ord}}(r_\ell^\square)$.

Step 3: continuity of $f' \circ r_\ell^\square$. Let $\mathfrak{M}_0 = \mathfrak{M} \cap R_\ell^\square$, the kernel of $\varphi = f_0 \circ (R_\ell^\square \to R_\ell^{\mathrm{ord}})$; $\mathfrak{M} = \mathfrak{M}_0 R$. The maximal ideal of $R_\ell^\square$ maps into that of R_ℓ^{ord}, so $|\varphi(y)|_\ell < 1$ on it (first hypothesis), and (Ol1) gives an integral test ring A with $\varphi(R_\ell^\square) \subseteq A$. So $R_\ell^\square/\mathfrak{M}_0 \cong \varphi(R_\ell^\square)$ is a submodule of the finitely generated $\mathcal{O}$-module A, hence finitely generated; each $\mathfrak{M}_0^i/\mathfrak{M}_0^{i+1}$ is a finitely generated module over it, so $Q = R_\ell^\square/\mathfrak{M}_0^n$ is a finitely generated $\mathcal{O}$-module and a local ring. Then $Q/\ell Q$ is a finite local ring, its maximal ideal is nilpotent, and the $\mathfrak{m}_{R_\ell^\square}$-adic topology maps continuously onto the ℓ-adic topology of Q. f' factors through $Q \to Q[\ell^{-1}] = R/\mathfrak{M}^n \to B'$, the last two maps being continuous ($\mathbb{Q}_\ell$-linear between finite-dimensional spaces, and the inclusion of the lattice image). The entries of $r_\ell^\square$ are continuous for the $\mathfrak{m}_{R_\ell^\square}$-adic topology, so the entries of $\rho'(g) = f'(\underline{r_\ell^\square}(g))$, $g \in H$, are continuous.

Step 4: triangular form over B'. By Lemma 43.19 for $x = f'$ there are $h' \in \mathrm{GL}_3(B')$ and continuous homomorphisms $\kappa'_a\colon H \to B'^\times$ such that $T'(g) = h'^{-1}\rho'(g)h'$ is upper triangular with

diagonal $(\kappa'_a(g))_a$, $\kappa'_a = \psi_a = \chi_{\mathrm{cyc}}^{e(2-a)}$ on I_M, and, with $\lambda'_a = \kappa'_a\kappa'^{-1}_{a+1}$ and $\delta_a = \lambda'_a(\sigma_\ell) - \chi_{\mathrm{cyc}}(\sigma_\ell)$,

$$\pi(d) = f'(\mathrm{gd}(r_\ell^{\square})) = \ell \prod_{a=1}^{2} \mathrm{gp}_a \mathrm{gp}_{a+1} \kappa'_{a+1}(\sigma_\ell)\, \delta_a = u\, \delta_1\delta_2, \qquad u \in B'^{\times}.$$

Hence for $a = 1, 2$: if $\delta_a b = 0$, then $\pi(d)b = 0$ and $q(b) = 0$.

Step 5: the pushed cocycles are finite. $\lambda'_a = \chi_{\mathrm{cyc}}^{e}$ on I_M, and $c'_a(g) = T'(g)_{a,a+1}\kappa'_{a+1}(g)^{-1}$ is a continuous cocycle of $B'(\lambda'_a)$ (the $(a, a+1)$ entry of $T'(gh) = T'(g)T'(h)$). H is the closed subgroup generated by I_M and σ_ℓ, so the image of σ_ℓ topologically generates G_M/I_M. By Lemma 43.20 (with $F = \sigma_\ell$, $w = e$, $\lambda = \lambda'_a$ and Step 4), $q \circ c'_a$ has class in $H^1_f(G_M, B(q\lambda'_a))$, for $a = 1, 2$.

Step 6: conclusion. Put $h = q(h') \in \mathrm{GL}_3(B)$. Since $\tilde{f} = q \circ f'$, $h^{-1}\rho_B(g)h = q(T'(g))$ for $g \in H$: upper triangular, continuous, with diagonal $q \circ \kappa'_a$, equal to $\chi_{\mathrm{cyc}}^{e(2-a)}$ on I_M, and with adjacent cocycles $q \circ c'_a$ (in the notation of Lemma 43.21). By Lemma 43.21 with $w = e$, $g \mapsto q(T'(g))$ is crystalline on B^3, and $v \mapsto hv$ is a $\mathbb{Q}_\ell$-linear H-isomorphism from it to ρ_B. So ρ_B is crystalline.

Remark. Nothing above uses $B = E[\epsilon]$ beyond its being a local $E_{\mathcal{O}}$-algebra of finite dimension with residue field E; the same proof gives the conclusion for every such B and every f with the two hypotheses (the first for the reduction modulo the maximal ideal of B). □

Definition 43.16. Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, $\eta_K \colon G_{\mathbb{Q}} \to \{\pm 1\}$ the character with kernel G_K, $\mathcal{O}$ a coefficient ring with maximal ideal $\mathfrak{m}_{\mathcal{O}}$ and residue field $\mathbb{F}_{\mathcal{O}}$, $c \in G_{\mathbb{Q}}$ a complex conjugation and $\Psi \colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a continuous character with $\Psi(c) = 1$. The group $\mathcal{G}_3$, the representation $r_0(g) = (\mathrm{T}(\Psi(g)), \eta_K(g))$, its reduction $\bar{r}_0$, the characters $\psi_a = \Psi^{2-a}$ $(a = 1, 2, 3)$, markings $g_\star$ and condition (Ed1) are those of Definition 42.1 formed with K, $\mathcal{O}$, Ψ and c (their definitions there use only these data and $\Psi(c) = 1$). Fix a place $\bar{\ell}$ of $\overline{\mathbb{Q}}$ above ℓ and write $D_\ell \supseteq I_\ell$ for $D_{\bar{\ell}} \supseteq I_{\bar{\ell}}$.

Test rings. A **test ring** is a complete discrete valuation ring A with finite residue field, with maximal ideal $\mathfrak{m}_A$, together with a ring homomorphism $\mathcal{O} \to A$ mapping $\mathfrak{m}_{\mathcal{O}}$ into $\mathfrak{m}_A$. It is **integral** if A is a subring of $\overline{\mathbb{Q}}_\ell$ containing $\mathcal{O}$ and finitely generated as an $\mathcal{O}$-module (the homomorphism being the inclusion), and **of characteristic** ℓ if $\ell = 0$ in A (then $\mathfrak{m}_{\mathcal{O}}$ maps to 0).

Triangular lifts. Let $g_\star$ be a marking and A a test ring. A **triangular lift** (for $g_\star$) to A is a homomorphism $r \colon G_{\mathbb{Q}} \to \mathcal{G}_3(A)$ such that

(Tl1) the sign of r is η_K, every entry of $\underline{r}(g) - \underline{r_0}(g)$ (the latter mapped to A) lies in $\mathfrak{m}_A$ for every g, and for every $n \geq 1$ the map $g \mapsto \underline{r}(g) \bmod \mathfrak{m}_A^n$ is locally constant;

(Tl2) r satisfies (Ed1) for $g_\star$: $\underline{r}(c) = 1$, and the entries $(1,2)$ and $(2,1)$ of $\underline{r}(g_\star) - \underline{r}(cg_\star^{-1}c)$ vanish;

(Tl3) $r(g) = 1$ for every $g \in I_{\bar{v}}$ with $\eta_K(g) = 1$ and $\Psi(g) = 1$, for every place $\bar{v}$ of $\overline{\mathbb{Q}}$ not above ℓ;

(Tl4) there is $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \pmod{\mathfrak{m}_A}$ such that for every $g \in D_\ell \cap G_K$ the matrix $h^{-1}\underline{r}(g)h$ is upper triangular (its entries of negative weight vanish), with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_\ell$.

For a triangular lift r to an integral test ring, $\rho_r \colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is the restriction of $\underline{r}$ to G_K; r is **of type I** or **of type II** if ρ_r satisfies the condition of the same name in Definition 42.1 (stated there for ρ_φ). The **corner** of r is $g \mapsto (\rho_r(g)_{ab})_{a,b\in\{1,3\}}$ on G_K.

Lemma 43.17. (Ol1) *Let $\mathcal{O}$ be a coefficient ring, $R \in \mathrm{CNL}_{\mathcal{O}}$ and $\varphi\colon R \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}$-algebra homomorphism with $|\varphi(y)|_\ell < 1$ for $y \in \mathfrak{m}_R$. There is an integral test ring A with $\varphi(R) \subseteq A$ and $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$.*

(Ol2) *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$. Let A be a test ring (integral or of characteristic ℓ) and $x\colon R_\ell^{\square} \to A$ a homomorphism of $\mathcal{O}$-algebras (for the structure map $\mathcal{O} \to A$) with $x(\mathfrak{m}_{R_\ell^{\square}}) \subseteq \mathfrak{m}_A$ and $x(I_\ell^{\mathrm{ord}}) = 0$, and let ρ be the GL-part of $x \circ r_\ell^{\square}$. There is $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \pmod{\mathfrak{m}_A}$ such that for every $g \in D_\ell \cap G_K$ the matrix $h^{-1}\rho(g)h$ is upper triangular, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ (mapped to A) when moreover $g \in I_\ell$.*

Proof. (Ol1). Since R is local with residue field $\mathbb{F}_{\mathcal{O}}$, $R = \mathcal{O} + \mathfrak{m}_R$, so $|\varphi(y)|_\ell \leq 1$ for all $y \in R$. Choose generators $x_1, \dots, x_n$ of $\mathfrak{m}_R$ and the surjection $\pi\colon \mathcal{O}[[X_1, \dots, X_n]] \to R$, $X_i \mapsto x_i$ (Cohen); put $a_i = \varphi(x_i)$, let $E \subset \overline{\mathbb{Q}}_\ell$ be the finite extension of the fraction field of $\mathcal{O}$ generated by the a_i, and A its valuation ring, an integral test ring. For $f \in \mathcal{O}[[X]]$ and $k \geq 1$ write $f = P_k + \sum_{|\alpha|=k} X^\alpha g_\alpha$ with P_k a polynomial; then $|\varphi(\pi f) - P_k(a)|_\ell \leq \max_i |a_i|_\ell^k \to 0$, so $\varphi(\pi f) = \lim_k P_k(a) \in A$, A being closed. Thus $\varphi(R) \subseteq A$, and $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$ as $|\varphi(y)|_\ell < 1$ there.

(Ol2), notation. Put $I^\circ = D_\ell^\circ \cap I_\ell$ and $D' = D_\ell \cap G_K$. By (Ue6), $\ell \nmid d_K$, so $I_\ell \subseteq G_K$, $I_\ell \subseteq D'$ and η_K is trivial on I_ℓ; by (Ue4), $\chi_\ell^2 = \mathbf{1}$, so $[I_\ell : I^\circ] \leq 2$ and $g^2 \in I^\circ$ for every $g \in I_\ell$. Write $N = \ell^a N'$ with $\ell \nmid N'$; an element of I_ℓ fixes $\mu_{N'}$, so $\chi = \chi_\ell(\chi_{\mathrm{cyc}} \bmod \ell^a)$ on I_ℓ. Hence $\chi(\sigma_0) = \chi_\ell(\sigma_0) = 1$, $\Psi(\sigma_0) = \chi_{\mathrm{cyc}}(\sigma_0)^e$ has infinite order, and $\psi_1(\sigma_0), \psi_2(\sigma_0), \psi_3(\sigma_0)$ are pairwise distinct. For a commutative $\mathcal{O}$-algebra B, a homomorphism $\rho'\colon D_\ell \to \mathrm{GL}_3(B)$, $s \in I_\ell$ and $\nu \in \{1, -1\}$ put

$$\begin{aligned} Z_1 &= (\rho'(\sigma_0) - \psi_2(\sigma_0))(\rho'(\sigma_0) - \psi_3(\sigma_0)), \qquad Z_2 = \rho'(\sigma_0) - \psi_3(\sigma_0), \\ Y_1 &= (\rho'(s) - \nu\psi_1(s))Z_1, \qquad Y_2 = (\rho'(\sigma_0) - \psi_1(\sigma_0))(\rho'(s) - \nu\psi_2(s))Z_2, \\ Y_3 &= (\rho'(\sigma_0) - \psi_1(\sigma_0))(\rho'(\sigma_0) - \psi_2(\sigma_0))(\rho'(s) - \nu\psi_3(s)), \end{aligned} \tag{43.2}$$

written $Z_i(\rho')$, $Y_a(\rho', s, \nu)$; their entries are polynomials in the entries of $\rho'(\sigma_0)$, $\rho'(s)$, so they commute with ring homomorphisms $B \to B'$.

(Ol2), a flag over a field. Let k' be a field of characteristic 0 with an injective $\mathcal{O}$-algebra map $\mathcal{O} \to k'$, and $\rho'\colon D_\ell \to \mathrm{GL}_3(k')$ a homomorphism such that, for $g, g_1, g_2, g_3 \in I^\circ$,

$$\det(X - \rho'(g)) = \prod_{a=1}^{3}(X - \psi_a(g)), \qquad (\rho'(g_1) - \psi_1(g_1))(\rho'(g_2) - \psi_2(g_2))(\rho'(g_3) - \psi_3(g_3)) = 0. \tag{43.3}$$

We show: (i) $F_1 = \operatorname{im} Z_1(\rho')$ and $F_2 = \operatorname{im} Z_2(\rho')$ form a $\rho'(D')$-stable flag of dimensions $1, 2$ on whose graded pieces F_1, F_2/F_1, k'^3/F_2 the group I° acts by ψ_1, ψ_2, ψ_3; (ii) for $s \in I_\ell$, $\rho'(s)$ acts on the a-th graded piece by a scalar $\kappa_a(s)$ with $\kappa_a(s)^2 = \psi_a(s)^2$, and $Y_a(\rho', s, \nu) = 0$ if and only if $\kappa_a(s) = \nu\psi_a(s)$. By (43.3) with $g = \sigma_0$, $\rho'(\sigma_0)$ has the distinct eigenvalues $\psi_a(\sigma_0)$, hence eigenlines E_1, E_2, E_3, and $\operatorname{im} Z_1 = E_1$, $\operatorname{im} Z_2 = E_1 \oplus E_2$. Let F_1' be the span of the images of $(\rho'(g_2) - \psi_2(g_2))(\rho'(g_3) - \psi_3(g_3))$ and F_2' the span of the images of $\rho'(g_3) - \psi_3(g_3)$, over $g_2, g_3 \in I^\circ$. By (43.3), $\rho'(g) - \psi_1(g)$ kills F_1' for all $g \in I^\circ$; with $g = \sigma_0$, $F_1' \subseteq E_1$, and $F_1' \supseteq \operatorname{im} Z_1 = E_1$; so $F_1' = F_1 = E_1$ and I° acts on F_1 by ψ_1. Likewise $(\rho'(\sigma_0) - \psi_1(\sigma_0))(\rho'(\sigma_0) - \psi_2(\sigma_0))$ kills $F_2' \supseteq \operatorname{im} Z_2$, so $F_2' = F_2 = E_1 \oplus E_2$. For $u \in F_2$ and $g \in I^\circ$, $(\rho'(g) - \psi_2(g))u$ is killed by every $\rho'(g_1) - \psi_1(g_1)$, hence lies in $\ker(\rho'(\sigma_0) - \psi_1(\sigma_0)) = F_1$: I° acts on F_2/F_1 by ψ_2, and on k'^3/F_2 by ψ_3, the characteristic polynomial being the product of those of the graded pieces. Let $d \in D'$; it normalises I° (the intersection of the normal subgroup I_ℓ of D_ℓ with kernels of characters of D_ℓ),

and $\psi_a(d^{-1}gd) = \psi_a(g)$. For $u \in F_1$ and $g \in I^\circ$, $\rho'(g)\rho'(d)u = \rho'(d)\rho'(d^{-1}gd)u = \psi_1(g)\rho'(d)u$, so $\rho'(d)u \in \ker(\rho'(\sigma_0) - \psi_1(\sigma_0)) = F_1$. For $u \in F_2$, $(\rho'(g) - \psi_2(g))\rho'(d)u = \rho'(d)(\rho'(d^{-1}gd) - \psi_2(d^{-1}gd))u \in \rho'(d)F_1 = F_1$; with $g = \sigma_0$, $(\rho'(\sigma_0) - \psi_1(\sigma_0))(\rho'(\sigma_0) - \psi_2(\sigma_0))\rho'(d)u = 0$, so $\rho'(d)u \in E_1 \oplus E_2 = F_2$. This is (i). For (ii), $s \in I_\ell \subseteq D'$ preserves the flag and acts on each graded piece, of dimension 1, by a scalar $\kappa_a(s)$; $g \mapsto \kappa_a(g)$ is a character of D', and $s^2 \in I^\circ$ gives $\kappa_a(s)^2 = \psi_a(s^2) = \psi_a(s)^2$. On $\operatorname{im} Z_1 = F_1$, $\rho'(s) - \nu\psi_1(s)$ is multiplication by $\kappa_1(s) - \nu\psi_1(s)$. The map $\rho'(s) - \nu\psi_2(s)$ sends $F_2 = \operatorname{im} Z_2$ into F_2, inducing multiplication by $\kappa_2(s) - \nu\psi_2(s)$ on F_2/F_1, and the kernel of $\rho'(\sigma_0) - \psi_1(\sigma_0)$ on $F_2 = E_1 \oplus E_2$ is F_1; so $Y_2 = 0$ if and only if $\kappa_2(s) = \nu\psi_2(s)$. The map $\rho'(s) - \nu\psi_3(s)$ induces multiplication by $\kappa_3(s) - \nu\psi_3(s)$ on k'^3/F_2, and $(\rho'(\sigma_0) - \psi_1(\sigma_0))(\rho'(\sigma_0) - \psi_2(\sigma_0))$ has kernel F_2; so $Y_3 = 0$ if and only if $\kappa_3(s) = \nu\psi_3(s)$. This is (ii).

(Ol2), a component through the Eisenstein point. By universality there is exactly one base point $\beta\colon R_\ell^\square \to \mathcal{O}$ of $r_\ell^\square$. I_ℓ^{ord} is the intersection of the minimal primes $\mathfrak{P}$ of I^{cr} with $\mathfrak{P} \subseteq \ker\beta$; they are finitely many ($R_\ell^\square$ is Noetherian), and there is at least one, since otherwise $I_\ell^{\mathrm{ord}} = R_\ell^\square$ and $x(1) = 0$. As A is a domain, $\ker x$ is a prime ideal containing their product, hence one of them, $\mathfrak{P}$. Put $J = \{y :\ \mathrm{gd}(r_\ell^\square)^n y \in I^{\mathrm{ord}}(r_\ell^\square) \text{ for some } n\}$, so $I^{\mathrm{cr}} = \sqrt{J}$ and $\mathfrak{P}$ is minimal over J. Then $\mathrm{gd} = \mathrm{gd}(r_\ell^\square) \notin \mathfrak{P}$: otherwise, $JR_{\ell,\mathfrak{P}}^\square$ being primary to the maximal ideal, $\mathrm{gd}^n \in JR_{\ell,\mathfrak{P}}^\square$ for some n, so $t\,\mathrm{gd}^n \in J$ for some $t \notin \mathfrak{P}$, whence $t \in J \subseteq \mathfrak{P}$ (J is stable under division by gd), a contradiction. As $\mathrm{gd} = \ell\,\mathrm{dt}_1\mathrm{dt}_2$, $\ell \notin \mathfrak{P}$. So $A_{\mathfrak{P}} = R_\ell^\square/\mathfrak{P}$ is a domain in which $\ell \neq 0$, $\mathcal{O} \to A_{\mathfrak{P}}$ is injective (its kernel is a prime of $\mathcal{O}$ not containing ℓ), and $k' = \mathrm{Frac}(A_{\mathfrak{P}})$ has characteristic 0. Let $\rho^{\mathrm{g}}\colon D_\ell \to \mathrm{GL}_3(k')$ be the image of the GL-part of $r_\ell^\square$. Since $I^{\mathrm{ord}}(r_\ell^\square) \subseteq J \subseteq \mathfrak{P}$ and the generators of I^{ord} are polynomials in the entries, ρ^{g} satisfies (43.3). Let $s \in I_\ell$ and $a \in \{1,2,3\}$. By (ii) for ρ^{g} there is $\nu \in \{1,-1\}$ with $Y_a(\rho^{\mathrm{g}}, s, \nu) = 0$, i.e. the entries of $Y_a(\underline{r_\ell^\square}, s, \nu)$ lie in $\mathfrak{P} \subseteq \ker\beta$. Now $\beta \circ \underline{r_\ell^\square} = \mathrm{T}(\Psi)$ on D_ℓ, so $Y_a(\mathrm{T}(\Psi), s, \nu) = 0$; this matrix is diagonal with (a,a) entry

$$\begin{gathered}\big(\Psi(s) - \nu\Psi(s)\big)\big(\Psi(\sigma_0) - 1\big)\big(\Psi(\sigma_0) - \Psi(\sigma_0)^{-1}\big),\\ \big(1 - \Psi(\sigma_0)\big)(1 - \nu)\big(1 - \Psi(\sigma_0)^{-1}\big),\\ \big(\Psi(\sigma_0)^{-1} - \Psi(\sigma_0)\big)\big(\Psi(\sigma_0)^{-1} - 1\big)\big(\Psi(s)^{-1} - \nu\Psi(s)^{-1}\big)\end{gathered}$$

for $a = 1,2,3$. The factors involving only σ_0 are non-zero ($\Psi(\sigma_0)$ has infinite order), $\Psi(s) \neq 0$, and $\mathcal{O}$ has characteristic 0; so $\nu = 1$. Hence $Y_a(\rho^{\mathrm{g}}, s, 1) = 0$, and by (ii) $\rho^{\mathrm{g}}(s)$ acts on the a-th graded piece of the flag (i) of ρ^{g} by $\psi_a(s)$, for every $s \in I_\ell$ and every a. So for $g, g_1, g_2, g_3 \in I_\ell$ we get $\det(X - \rho^{\mathrm{g}}(g)) = \prod_a (X - \psi_a(g))$ and $(\rho^{\mathrm{g}}(g_1) - \psi_1(g_1))(\rho^{\mathrm{g}}(g_2) - \psi_2(g_2))(\rho^{\mathrm{g}}(g_3) - \psi_3(g_3)) = 0$: the last factor maps k'^3 into F_2, the middle one maps F_2 into F_1, the first kills F_1. These are polynomial identities in the entries, so the corresponding coefficients and entries formed with $\underline{r_\ell^\square}$ lie in $\mathfrak{P} \subseteq \ker x$, and ρ satisfies, for $g, g_1, g_2, g_3 \in I_\ell$ (with ψ_a mapped to A),

$$\det(X - \rho(g)) = \prod_{a=1}^{3} (X - \psi_a(g)), \qquad \big(\rho(g_1) - \psi_1(g_1)\big)\big(\rho(g_2) - \psi_2(g_2)\big)\big(\rho(g_3) - \psi_3(g_3)\big) = 0. \tag{43.4}$$

(Ol2), a separating element in I_ℓ. On I_ℓ, $\chi^2 = \chi_\ell^2(\chi_{\mathrm{cyc}} \bmod \ell^a) = 1$, so $\Psi^2 = \chi_{\mathrm{cyc}}^{2e}$, whose reduction is ω^{2e} for ω the reduction of χ_{cyc}, which maps I_ℓ onto the cyclic group $\mathbb{F}_\ell^\times$ of order $\ell - 1$. By (Ue9), $\omega^{2e} \neq 1$; from now on s denotes a fixed element of I_ℓ with $\Psi(s)^2 \not\equiv 1 \pmod{\mathfrak{m}_{\mathcal{O}}}$. The images $\lambda_a \in A$ of $\psi_a(s) = \Psi(s)^{2-a}$ reduce to the pairwise distinct elements $\bar\Psi(s), 1, \bar\Psi(s)^{-1}$ of $A/\mathfrak{m}_A$, so they are pairwise distinct.

(Ol2), the flag at x. Let $E = \mathrm{Frac}(A)$ (of characteristic 0 or ℓ). By (43.4) with $g = s$, $\rho(s)$ has the distinct eigenvalues λ_a, with eigenlines E_1, E_2, E_3 in E^3. Put $F_1 = \operatorname{im}(\rho(s) - \lambda_2)(\rho(s) - \lambda_3) = E_1$ and $F_2 = \operatorname{im}(\rho(s) - \lambda_3) = E_1 \oplus E_2$. By (43.4) with $g_2 = g_3 = s$, $\rho(g) - \psi_1(g)$ kills F_1

for every $g \in I_\ell$. For $u \in F_2$ and $g \in I_\ell$, $(\rho(g) - \psi_2(g))u$ is killed by every $\rho(g_1) - \psi_1(g_1)$ ((43.4) with $g_3 = s$), in particular by $\rho(s) - \lambda_1$, so it lies in $E_1 = F_1$; and on E^3/F_2, I_ℓ acts by ψ_3, by the determinant in (43.4). Let $d \in D'$; it normalises I_ℓ, and $\psi_a(d^{-1}sd) = \psi_a(s)$. For $u \in F_1$, $\rho(s)\rho(d)u = \rho(d)\rho(d^{-1}sd)u = \lambda_1\rho(d)u$, so $\rho(d)u \in E_1 = F_1$. For $u \in F_2$, $(\rho(s)-\lambda_2)\rho(d)u = \rho(d)(\rho(d^{-1}sd)-\psi_2(d^{-1}sd))u \in \rho(d)F_1 = F_1$, so $(\rho(s)-\lambda_1)(\rho(s)-\lambda_2)\rho(d)u = 0$ and $\rho(d)u \in E_1 \oplus E_2 = F_2$. So $F_1 \subset F_2$ is a $\rho(D')$-stable flag whose graded pieces carry characters $\kappa_1, \kappa_2, \kappa_3$ of D' with $\kappa_a = \psi_a$ on I_ℓ.

(Ol2), an integral basis. Let $\Lambda = A^3$, $\Lambda_i = F_i \cap \Lambda$ $(i = 1, 2)$, saturated $\rho(D')$-stable submodules of ranks $1, 2$, and $\bar\Lambda_i$ their images in k^3, $k = A/\mathfrak{m}_A$ (of dimensions $1, 2$, by saturation). Since $r_\ell^\square$ lifts $\bar r_0|_{D_\ell}$ and $x(\mathfrak{m}_{R_\ell^\square}) \subseteq \mathfrak{m}_A$, $\rho(g) \equiv \mathrm{T}(\Psi(g))$ (mod $\mathfrak{m}_A$) for $g \in D'$. The reduction of $\rho(s)$ is $\mathrm{diag}(\bar\Psi(s), 1, \bar\Psi(s)^{-1})$ with pairwise distinct entries, as $\bar\Psi(s)^2 \neq 1$; a subspace stable under such a matrix is spanned by the coordinate vectors it contains (Lagrange interpolation). On Λ_1, $\rho(s)$ acts by $\kappa_1(s) = \psi_1(s) = \Psi(s)$, so $\bar\Lambda_1 = ke_1$; on Λ_2/Λ_1 it acts by $\kappa_2(s) = \psi_2(s) = 1$, so $\bar\Lambda_2 = ke_1 \oplus ke_2$. Choose $f_1 \in \Lambda_1$ reducing to e_1 (rescale a generator by a unit), $f_2 \in \Lambda_2$ reducing to e_2 ($\Lambda_2 \to \bar\Lambda_2$ is onto) and $f_3 = e_3$, and let $h = (f_1\, f_2\, f_3)$. Then $h \equiv 1$ (mod $\mathfrak{m}_A$), f_1 spans F_1 and f_1, f_2 span F_2 (their reductions are independent), so for $g \in D'$ the matrix $h^{-1}\rho(g)h$ is upper triangular with diagonal entries $\kappa_1(g), \kappa_2(g), \kappa_3(g)$, and these are $\psi_1(g), \psi_2(g), \psi_3(g)$ for $g \in I_\ell$. □

Lemma 43.18. *Let k be a field, R a Noetherian k-algebra, $\mathfrak{s} \subseteq R$ an ideal and $d \in R$ such that $da \in \mathfrak{s}$ implies $a \in \mathfrak{s}$ for every $a \in R$. Let B be a local k-algebra of finite dimension over k, with maximal ideal $\mathfrak{m}_B$, and $f\colon R \to B$ a homomorphism of k-algebras with $f(\mathfrak{s}) = 0$; put $\mathfrak{M} = f^{-1}(\mathfrak{m}_B)$. Then $\mathfrak{M}$ is a maximal ideal of R, and there is an integer $n \geq 1$ with the following properties: $B' = R/(\mathfrak{s} + \mathfrak{M}^n)$ is a local k-algebra of finite dimension over k; $f = q \circ \pi$ for the projection $\pi\colon R \to B'$ and a homomorphism of k-algebras $q\colon B' \to B$; and $q(b) = 0$ for every $b \in B'$ with $\pi(d)\, b = 0$.*

Proof. $\mathfrak{M}$ is maximal. f induces an injective k-algebra map $R/\mathfrak{M} \to B/\mathfrak{m}_B$, so $R/\mathfrak{M}$ is a domain of finite dimension over k, hence a field.

Choice of n. B is Artinian local, so $\mathfrak{m}_B^N = 0$ for some $N \geq 1$; then $f(\mathfrak{M}^N) \subseteq \mathfrak{m}_B^N = 0$. Put $C = R/\mathfrak{s}$, a Noetherian ring, and $\mathfrak{m} = \mathfrak{M}C$, a maximal ideal of C. The hypothesis on d says that the image of d is not a zero divisor in C; as localisation is exact, it is not a zero divisor in the Noetherian local ring $C_\mathfrak{m}$. By the Artin–Rees lemma for the ideal $dC_\mathfrak{m}$ there is $c \geq 0$ with $\mathfrak{m}^j C_\mathfrak{m} \cap dC_\mathfrak{m} = \mathfrak{m}^{j-c}(\mathfrak{m}^c C_\mathfrak{m} \cap dC_\mathfrak{m}) \subseteq d\,\mathfrak{m}^{j-c}C_\mathfrak{m}$ for all $j \geq c$. Put $n = N + c$.

B' is local and finite over k. $B' = C/\mathfrak{m}^n$. A maximal ideal of C containing $\mathfrak{m}^n$ contains $\mathfrak{m}$, hence equals it, so B' is local with maximal ideal $\mathfrak{m}/\mathfrak{m}^n$. Each $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ is a finitely generated module over $C/\mathfrak{m} = R/\mathfrak{M}$, which is finite over k; so B' has finite dimension over k.

The factorisation. f kills $\mathfrak{s}$ and $\mathfrak{M}^n \subseteq \mathfrak{M}^N$, so it factors as $f = q \circ \pi$ with $q\colon B' \to B$ a k-algebra homomorphism.

Annihilator of $\pi(d)$. Let $b \in B'$ with $\pi(d)b = 0$, and let $a \in C$ map to b; then $da \in \mathfrak{m}^n$. In $C_\mathfrak{m}$, $da \in \mathfrak{m}^n C_\mathfrak{m} \cap dC_\mathfrak{m} \subseteq d\,\mathfrak{m}^N C_\mathfrak{m}$, so $da = da'$ with $a' \in \mathfrak{m}^N C_\mathfrak{m}$, and $a = a'$ in $C_\mathfrak{m}$ since d is not a zero divisor there. Hence $a \in \mathfrak{m}^N C_\mathfrak{m} \cap C = \mathfrak{m}^N$, the last equality because $\mathfrak{m}^N$ is $\mathfrak{m}$-primary ($\mathfrak{m}$ is maximal). Therefore $q(b)$ is the image of an element of $\mathfrak{M}^N$ under f, which is 0. □

Lemma 43.19. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with fraction field $E_\mathcal{O}$. Let B be a local ring which is an $E_\mathcal{O}$-algebra, $x\colon R_\ell^\square \to B$ a homomorphism of $\mathcal{O}$-algebras with $x(I^{\mathrm{ord}}(r_\ell^\square)) = 0$, and $\rho\colon D_\ell^\circ \to \mathrm{GL}_3(B)$ the restriction to D_ℓ° of the GL-part of $x \circ r_\ell^\square$. Then there are $h \in \mathrm{GL}_3(B)$ and homomorphisms $\kappa_1, \kappa_2, \kappa_3\colon D_\ell^\circ \to B^\times$ such that:*

1. *for every $g \in D_\ell^\circ$ the matrix $h^{-1}\rho(g)h$ is upper triangular with diagonal entries $\kappa_1(g)$, $\kappa_2(g), \kappa_3(g)$, and $\kappa_a(g) = \psi_a(g)$ for $g \in D_\ell^\circ \cap I_\ell$ and $a = 1, 2, 3$;*

2. *for $a = 1, 2$,*

$$x\big(\mathrm{dt}_a(r_\ell^{\square})\big) = \mathrm{gp}_a\,\mathrm{gp}_{a+1}\,\kappa_{a+1}(\sigma_\ell)\Big(\kappa_a(\sigma_\ell)\kappa_{a+1}(\sigma_\ell)^{-1} - \chi_{\mathrm{cyc}}(\sigma_\ell)\Big).$$

If moreover B has finite dimension over $\mathbb{Q}_\ell$ and the entries of ρ are continuous for its natural topology, then $\kappa_1, \kappa_2, \kappa_3$ are continuous.

Proof. Notation and the defining equations. Put $I^\circ = D_\ell^\circ \cap I_\ell$. Lifts have sign η_K, which is trivial on D_ℓ°, so ρ is a homomorphism. The generators of $I^{\mathrm{ord}}(r_\ell^{\square})$ are polynomials in the entries of $\underline{r_\ell^{\square}}$, and x is a ring homomorphism; so for $g, g_1, g_2, g_3 \in I^\circ$,

$$\det(X - \rho(g)) = \prod_{a=1}^{3}(X - \psi_a(g)), \qquad (\rho(g_1) - \psi_1(g_1))(\rho(g_2) - \psi_2(g_2))(\rho(g_3) - \psi_3(g_3)) = 0. \tag{43.5}$$

Write $N = \ell^b N'$ with $\ell \nmid N'$. An element of I_ℓ fixes the N'-th roots of unity, so $\chi = \chi_\ell\,(\chi_{\mathrm{cyc}} \bmod \ell^b)$ on I_ℓ, which is trivial on I° as χ_ℓ is trivial on D_ℓ°; hence $\Psi = \chi_{\mathrm{cyc}}^e$ on I°. In particular $u_a = \psi_a(\sigma_0) = \chi_{\mathrm{cyc}}(\sigma_0)^{e(2-a)}$ $(a = 1, 2, 3)$ are pairwise distinct elements of $\mathcal{O}$, $\chi_{\mathrm{cyc}}(\sigma_0)$ having infinite order. Non-zero elements of the field $E_\mathcal{O}$ are units in B, so the $u_a - u_b$ $(a \neq b)$ and the gp_a are units of B. Let $k = B/\mathfrak{m}_B$, a field containing $E_\mathcal{O}$.

The eigenlines of $S = \rho(\sigma_0)$. By (43.5) and Cayley–Hamilton, $\prod_a(S - u_a) = 0$. Put $\varepsilon_a = \prod_{b\neq a}(S - u_b)(u_a - u_b)^{-1}$. The Lagrange identity $\sum_a \prod_{b\neq a}(X - u_b)/(u_a - u_b) = 1$ gives $\sum_a \varepsilon_a = 1$; for $a \neq b$ the product $\varepsilon_a\varepsilon_b$ is divisible by $\prod_c(S - u_c)$, so $\varepsilon_a\varepsilon_b = 0$, $\varepsilon_a^2 = \varepsilon_a$ and $(S - u_a)\varepsilon_a = 0$. Hence $B^3 = L_1 \oplus L_2 \oplus L_3$ with $L_a = \varepsilon_a B^3$, S acting on L_a by u_a. Each L_a is a finitely generated projective module over the local ring B, hence free, of rank $\dim_k(L_a \otimes_B k)$, the dimension of the $\bar{u}_a$-eigenspace of the reduction $\bar{S}$; as $\bar{S}$ has the three distinct eigenvalues $\bar{u}_a$ in k, every L_a is free of rank 1. Since $S - u_a$ acts on L_b $(b \neq a)$ by the unit $u_b - u_a$, $\ker(S - u_a) = L_a$, $\ker\big((S - u_1)(S - u_2)\big) = L_1 \oplus L_2$, and $\mathrm{im}(S - u_3) = L_1 \oplus L_2$, $\mathrm{im}\big((S - u_2)(S - u_3)\big) = L_1$.

The flag on I°. Put $F_1 = L_1$ and $F_2 = L_1 \oplus L_2$. Let $g \in I^\circ$. By (43.5) with $(g_1, g_2, g_3) = (g, \sigma_0, \sigma_0)$, $\rho(g) - \psi_1(g)$ kills $\mathrm{im}\big((S - u_2)(S - u_3)\big) = F_1$. By (43.5) with $(g_1, g_2, g_3) = (\sigma_0, g, \sigma_0)$, $(S - u_1)(\rho(g) - \psi_2(g))$ kills $\mathrm{im}(S - u_3) = F_2$, so $(\rho(g) - \psi_2(g))F_2 \subseteq \ker(S - u_1) = F_1$. In particular $\rho(g)F_1 \subseteq F_1$ and $\rho(g)F_2 \subseteq F_2$.

The flag is stable under D_ℓ°. I° is normal in D_ℓ (I_ℓ is, and D_ℓ° is the kernel of homomorphisms to abelian groups), and $\psi_a(d^{-1}gd) = \psi_a(g)$. Let $d \in D_\ell^\circ$ and $\sigma' = d^{-1}\sigma_0 d \in I^\circ$. For $v \in F_1$, $(S - u_1)\rho(d)v = \rho(d)(\rho(\sigma') - \psi_1(\sigma'))v = 0$ by the previous step, so $\rho(d)v \in F_1$. For $v \in F_2$, $(S - u_2)\rho(d)v = \rho(d)(\rho(\sigma') - \psi_2(\sigma'))v \in \rho(d)F_1 = F_1$, so $(S - u_1)(S - u_2)\rho(d)v = 0$ and $\rho(d)v \in F_2$.

The basis and (i). Let f_a generate L_a and $h = (f_1\, f_2\, f_3) \in \mathrm{GL}_3(B)$. For $g \in D_\ell^\circ$, $\rho(g)$ preserves Bf_1 and $Bf_1 \oplus Bf_2$, so $h^{-1}\rho(g)h$ is upper triangular; let $\kappa_a(g)$ be its diagonal entries. They are units (their product is $\det\rho(g)$), and κ_a is a homomorphism because the diagonal of a product of upper triangular matrices is the product of the diagonals. For $g \in I^\circ$, the flag step gives $\kappa_1(g) = \psi_1(g)$ and $\kappa_2(g) = \psi_2(g)$; then $\det(X - \rho(g)) = (X - \psi_1(g))(X - \psi_2(g))(X - \kappa_3(g))$, and comparing with (43.5), the monic polynomial $(X - \psi_1(g))(X - \psi_2(g))$ being a non-zero-divisor in $B[X]$, $\kappa_3(g) = \psi_3(g)$.

(ii). f_a is an eigenvector of S, so $h^{-1}Sh = \mathrm{diag}(u_1, u_2, u_3)$ and $h^{-1}(S - u_{a+1})(S - u_{a+2})h = \mathrm{gp}_a E_{aa}$, with E_{aa} the matrix unit. As $\sigma_0, \sigma_\ell \in D_\ell^\circ$ and tq_a is a polynomial in the entries of

$\underline{r_\ell^\square}(\sigma_0)$, $\underline{r_\ell^\square}(\sigma_\ell)$, the trace being invariant under conjugation,

$$x(\mathrm{tq}_a(r_\ell^\square)) = \mathrm{tr}\big(\mathrm{gp}_a E_{aa}\, h^{-1}\rho(\sigma_\ell)h\big) = \mathrm{gp}_a\, \kappa_a(\sigma_\ell).$$

Hence $x(\mathrm{dt}_a(r_\ell^\square)) = \mathrm{gp}_{a+1}\mathrm{gp}_a\kappa_a(\sigma_\ell) - \chi_{\mathrm{cyc}}(\sigma_\ell)\mathrm{gp}_a\mathrm{gp}_{a+1}\kappa_{a+1}(\sigma_\ell)$, which is (ii).

Continuity. $\kappa_a(g)$ is an entry of $h^{-1}\rho(g)h$, a polynomial in the entries of $\rho(g)$ with fixed coefficients; multiplication is continuous on the finite-dimensional $\mathbb{Q}_\ell$-algebra B. □

Lemma 43.20. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M and inertia subgroup I_M, and $F \in G_M$ an element whose image topologically generates G_M/I_M. Let B' and B be commutative $\mathbb{Q}_\ell$-algebras of finite dimension, with their natural topologies, $q\colon B' \to B$ a homomorphism of $\mathbb{Q}_\ell$-algebras, $w \geq 1$ an integer and $\lambda\colon G_M \to B'^\times$ a continuous homomorphism with $\lambda(g) = \chi_{\mathrm{cyc}}(g)^w$ for $g \in I_M$; put $\delta = \lambda(F) - \chi_{\mathrm{cyc}}(F) \in B'$. Write $B'(\lambda)$ for B' with $g \in G_M$ acting by multiplication by $\lambda(g)$, and $B(q\lambda)$ likewise. Assume that $w \geq 2$, or that $q(b) = 0$ for every $b \in B'$ with $\delta b = 0$. Then for every continuous 1-cocycle $c\colon G_M \to B'(\lambda)$ the cocycle $q \circ c$ of $B(q\lambda)$ has its class in $H^1_f(G_M, B(q\lambda))$.*

Proof. Put $V = B(q\lambda)$ and $\mu = (q\lambda)\chi_{\mathrm{cyc}}^{-w}\colon G_M \to B^\times$, a continuous homomorphism trivial on I_M.

V is crystalline, hence de Rham. The map $b\otimes 1 \mapsto b$ is a G_M-isomorphism $B(\mu)\otimes_{\mathbb{Q}_\ell}\mathbb{Q}_\ell(w) \to V$; $B(\mu)$ is unramified, hence crystalline, $\mathbb{Q}_\ell(w)$ is crystalline, and so is their tensor product (Theorem B.45).

The dual. Let $B^\vee = \mathrm{Hom}_{\mathbb{Q}_\ell}(B, \mathbb{Q}_\ell)$. Then $U = V^*(1)$ is the space $B^\vee$ with the action $(g\varphi)(b) = \chi_{\mathrm{cyc}}(g)\varphi(q\lambda(g)^{-1}b)$; on I_M, g acts by the scalar $\chi_{\mathrm{cyc}}(g)^{1-w}$. The representation $U \cong B^\vee(\mu^{-1}) \otimes \mathbb{Q}_\ell(1-w)$ is crystalline with all Hodge–Tate weights $1 - w \leq 0$, so $\mathrm{Fil}^0 D_{\mathrm{dR}}(U) = D_{\mathrm{dR}}(U)$ and Theorem B.56 gives $\dim_{\mathbb{Q}_\ell} H^1_f(G_M, U) = h^0(U)$. Likewise $U' = B'(\lambda)^*(1)$ is $B'^\vee$ with $(g\varphi)(b) = \chi_{\mathrm{cyc}}(g)\varphi(\lambda(g)^{-1}b)$, and $q^t\colon U \to U'$, $\varphi \mapsto \varphi \circ q$, is G_M-equivariant, since $q(\lambda(g)^{-1}b) = q\lambda(g)^{-1}q(b)$.

Reduction to $q^t_* H^1_f(G_M, U) = 0$. The map $q\colon B'(\lambda) \to V$ is $\mathbb{Q}_\ell$-linear and G_M-equivariant, and for $v' \in B'$, $\varphi \in B^\vee$ the evaluation satisfies $\varphi(q(v')) = (q^t\varphi)(v')$. Hence, on cochains, the cup products satisfy $\langle q\circ c, y\rangle = \langle c, q^t \circ y\rangle'$ for cocycles y of U, with $\langle\ ,\ \rangle'$ the pairing of $B'(\lambda)$. If $q^t \circ y$ is a coboundary for every y with class in $H^1_f(G_M, U)$, then $\langle q\circ c, y\rangle = 0$ for all such y, and Theorem B.49 for the de Rham representation V gives that the class of $q \circ c$ lies in $H^1_f(G_M, V)$.

The case $w \geq 2$. Since $\chi_{\mathrm{cyc}}(I_M)$ is open in $\mathbb{Z}_\ell^\times$, there is $g \in I_M$ with $\chi_{\mathrm{cyc}}(g)^{1-w} \neq 1$, so $h^0(U) = 0$ and $H^1_f(G_M, U) = 0$; the reduction applies.

The case $w = 1$: $H^1_f(G_M, U)$ is unramified. Now I_M acts trivially on U. By inflation–restriction, inflation identifies $H^1(\Gamma, U)$ with $H^1_{\mathrm{ur}} = \ker\big(H^1(G_M, U) \to H^1(I_M, U)\big)$, of dimension $\dim U/(\bar F - 1)U = \dim\ker(\bar F - 1) = h^0(U)$ (the fixed vectors of $\bar F$ are fixed by its closure Γ). Every class in H^1_{ur} lies in $H^1_f(G_M, U)$: for a cocycle z vanishing on I_M, let $X = U \oplus \mathbb{Q}_\ell e$ with $g(u + te) = gu + tz(g) + te$, an unramified, hence crystalline, representation; by left exactness of invariants, $0 \to D_{\mathrm{cris}}(U) \to D_{\mathrm{cris}}(X) \to D_{\mathrm{cris}}(\mathbb{Q}_\ell) = M_0$ is exact, and $\dim_{M_0} D_{\mathrm{cris}}(X) = \dim U + 1 = \dim_{M_0} D_{\mathrm{cris}}(U) + 1$, so there is an invariant $1 \otimes e - b$ with $b \in B_{\mathrm{cris}} \otimes U$; invariance says $1 \otimes z(g) = gb - b$. As both spaces have dimension $h^0(U)$, $H^1_f(G_M, U) = H^1_{\mathrm{ur}}$.

The case $w = 1$: q^t kills it. Let y have class in $H^1_f(G_M, U)$; by the previous step we may take y inflated from a cocycle $\tilde y$ of Γ. Put $\nu = \lambda\chi_{\mathrm{cyc}}^{-1}$, trivial on I_M; F acts on U' by $\varphi \mapsto \varphi \circ m_{\nu(F)^{-1}}$, m_β denoting multiplication by β on B', and $\nu(F)^{-1} - 1 = -\lambda(F)^{-1}\delta$, so $(F-1)U' = \{\psi \circ m_\delta : \psi \in B'^\vee\}$, the image of the transpose of m_δ. Its dimension is $\dim B' - \dim\ker m_\delta$, and it

is contained in the annihilator of $\ker m_\delta = \{b : \delta b = 0\}$, which has the same dimension; so $(F-1)U'$ is the space of linear forms vanishing on $\ker m_\delta$. By hypothesis $\ker m_\delta \subseteq \ker q$, so $q^t(U) \subseteq (F-1)U'$. Hence $(q^t \circ \tilde{y})(\bar{F}) = (\bar{F}-1)u'$ for some $u' \in U'$, and $q^t \circ \tilde{y} - du'$ is a cocycle of Γ vanishing at $\bar{F}$; by the cocycle identity it vanishes on the subgroup generated by $\bar{F}$, hence on Γ by continuity. So $q^t \circ y$ is a coboundary, and the reduction applies. □

Lemma 43.21. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M and inertia subgroup I_M, B a commutative $\mathbb{Q}_\ell$-algebra of finite dimension with its natural topology, and $w \geq 1$ an integer. Let $\rho\colon G_M \to \mathrm{GL}_3(B)$ be a continuous homomorphism with values in the upper triangular matrices, with diagonal entries $\kappa_1, \kappa_2, \kappa_3\colon G_M \to B^\times$ such that $\kappa_a(g) = \chi_{\mathrm{cyc}}(g)^{w(2-a)}$ for $g \in I_M$ and $a = 1, 2, 3$. For $a = 1, 2$ let $B(\kappa_a\kappa_{a+1}^{-1})$ be B with g acting by multiplication by $\kappa_a(g)\kappa_{a+1}(g)^{-1}$, and $c_a(g) = \rho(g)_{a,a+1}\,\kappa_{a+1}(g)^{-1}$, a continuous 1-cocycle with values in it. If the classes of c_1 and c_2 lie in $H^1_f(G_M, B(\kappa_1\kappa_2^{-1}))$ and $H^1_f(G_M, B(\kappa_2\kappa_3^{-1}))$, then the representation ρ on B^3, regarded as a $\mathbb{Q}_\ell$-vector space, is crystalline.*

Proof. That c_a is a cocycle follows from the $(a, a+1)$ entry of $\rho(gh) = \rho(g)\rho(h)$: $\rho(gh)_{a,a+1} = \kappa_a(g)\rho(h)_{a,a+1} + \rho(g)_{a,a+1}\kappa_{a+1}(h)$. Let e_1, e_2, e_3 be the standard basis of $X = B^3$.

Characters. If $\kappa\colon G_M \to B^\times$ is continuous and $\kappa\chi_{\mathrm{cyc}}^{-m}$ is trivial on I_M, then $B(\kappa)$ is crystalline: it is isomorphic to $B(\kappa\chi_{\mathrm{cyc}}^{-m}) \otimes_{\mathbb{Q}_\ell} \mathbb{Q}_\ell(m)$, the first factor unramified (Theorem B.45); for $m \geq 1$ its Hodge–Tate weights are all m, so $\mathrm{Fil}^0 D_{\mathrm{dR}} = 0$; and if $m \neq 0$ then $h^0(B(\kappa)) = 0$, as some $g \in I_M$ has $\chi_{\mathrm{cyc}}(g)^m \neq 1$ ($\chi_{\mathrm{cyc}}(I_M)$ is open in $\mathbb{Z}_\ell^\times$).

Claim: extensions of a trivial representation with finite classes. Let Y be a finite-dimensional continuous $\mathbb{Q}_\ell$-representation of G_M and $U \subseteq Y$ a crystalline subrepresentation such that G_M acts trivially on Y/U and, for every $y \in Y$, the cocycle $g \mapsto gy - y$ (with values in U) has class in $H^1_f(G_M, U)$. Then Y is crystalline. Indeed, for $y \in Y$ choose $b_y \in B_{\mathrm{cris}} \otimes U$ with $1 \otimes (gy - y) = gb_y - b_y$; then $1 \otimes y - b_y \in D_{\mathrm{cris}}(Y)$ maps to $1 \otimes \bar{y}$ in $D_{\mathrm{cris}}(Y/U) = M_0 \otimes_{\mathbb{Q}_\ell} (Y/U)$. So the map $D_{\mathrm{cris}}(Y) \to D_{\mathrm{cris}}(Y/U)$, M_0-linear, is onto; its kernel is $D_{\mathrm{cris}}(U)$ (invariants are left exact), and $\dim_{M_0} D_{\mathrm{cris}}(Y) = \dim U + \dim Y/U = \dim Y$.

Twists. If $\kappa\colon G_M \to B^\times$ is a continuous homomorphism and $X' \subseteq X$ a B-submodule stable under ρ, write $X'\langle\kappa\rangle$ for X' with g acting by $\kappa(g)\rho(g)$. The map $X'\langle\kappa^{-1}\rangle \otimes_{\mathbb{Q}_\ell} B(\kappa) \to X'$, $y \otimes b \mapsto by$, is G_M-equivariant and onto; so if $X'\langle\kappa^{-1}\rangle$ is crystalline, so is X' (Theorem B.45 and the characters step). Also H^1_f is stable under multiplication by elements of B on $B(\kappa)$, and H^1_f is functorial for G_M-maps.

$X_2 = Be_1 \oplus Be_2$ is crystalline. In $Y_1 = X_2\langle\kappa_2^{-1}\rangle$, $U_1 = Be_1 \cong B(\kappa_1\kappa_2^{-1})$ is crystalline, and G_M acts trivially on Y_1/U_1. For $y = b_1e_1 + b_2e_2$, $gy - y = ((\kappa_1\kappa_2^{-1})(g)b_1 - b_1)e_1 + b_2c_1(g)e_1$, a coboundary plus b_2c_1; its class lies in H^1_f. By the claim Y_1 is crystalline, and so is X_2.

X is crystalline. Let $Y = X\langle\kappa_3^{-1}\rangle \supseteq U = X_2\langle\kappa_3^{-1}\rangle \supseteq U_2 = Be_1$. Then U is crystalline (twists step, as X_2 is), $U_2 \cong B(\kappa_1\kappa_3^{-1})$, $U'' = U/U_2 \cong B(\kappa_2\kappa_3^{-1})$ by $e_2 \mapsto 1$, and G_M acts trivially on Y/U. On I_M the characters of U_2 and U'' are χ_{cyc}^{2w} and χ_{cyc}^{w}.

- $H^1(G_M, U_2) = H^1_f(G_M, U_2)$: by the characters step $h^0(U_2) = 0$, $\mathrm{Fil}^0 D_{\mathrm{dR}}(U_2) = 0$, and $h^0(U_2^*(1)) = 0$ since I_M acts on $U_2^*(1)$ by $\chi_{\mathrm{cyc}}^{1-2w}$ and $1 - 2w \neq 0$. By Theorem B.36, $h^1(U_2) = d \dim U_2$, and by Theorem B.56, $\dim H^1_f(G_M, U_2) = d \dim U_2$.

- The map $H^1_f(G_M, U) \to H^1_f(G_M, U'')$ is onto. Indeed, $h^0(U) = 0$ (its graded pieces have none) and the Hodge–Tate weights of U are $2w$ and w, so $\dim H^1_f(G_M, U) = d \dim U$ and $\dim H^1_f(G_M, U'') = d \dim U''$ by Theorem B.56. In the long exact sequence of $0 \to U_2 \to U \to U'' \to 0$, $H^1(G_M, U_2) \to H^1(G_M, U)$ is injective ($h^0(U'') = 0$), with image the kernel

of $H^1(G_M,U)\to H^1(G_M,U'')$, contained in $H^1_f(G_M,U)$ by the first item and functoriality. So the image of $H^1_f(G_M,U)$ in $H^1_f(G_M,U'')$ has dimension $d\dim U - d\dim U_2 = d\dim U''$.

- For $y=b_1e_1+b_2e_2+b_3e_3$, the class of $z_y(g)=gy-y$ lies in $H^1_f(G_M,U)$: since $ge_3-e_3=\rho(g)_{13}\kappa_3(g)^{-1}e_1+c_2(g)e_2$, the image of z_y in U'' is a coboundary plus b_3c_2, whose class lies in $H^1_f(G_M,U'')$. By the second item there is $\zeta\in H^1_f(G_M,U)$ with the same image, and $[z_y]-\zeta$ lies in the kernel of $H^1(G_M,U)\to H^1(G_M,U'')$, contained in $H^1_f(G_M,U)$.

By the claim Y is crystalline, and so is X (twists step). □

Lemma 43.22. *Let (K,ℓ,e,N,χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let emb_ℓ, E and $f\colon R^{\mathrm{ord}}_\ell\to E[\epsilon]$ be as in Proposition 43.15, with reduction f_0 modulo ϵ. Put $\rho_0(g)=f_0(\underline{r^{\mathrm{ord}}_\ell}(g))\in \mathrm{GL}_3(E)$ and define $y\colon D_\ell\to \mathrm{M}_3(E)$ by*

$$f(\underline{r^{\mathrm{ord}}_\ell}(g))=(1+\epsilon\, y(g))\rho_0(g)\qquad (g\in D_\ell).$$

Let D_ℓ act on $\mathrm{M}_3(E)$ by $g\cdot X=\rho_0(g)X\rho_0(g)^{-1}$ if $\eta_K(g)=1$ and $g\cdot X=-\rho_0(g)J\,{}^tXJ\rho_0(g)^{-1}$ if $\eta_K(g)=-1$, and on $\mathrm{M}_3(E)\otimes_{\mathbb{Q}_\ell}B_{\mathrm{cris}}$ diagonally, through emb_ℓ on B_{cris}. Then y is a continuous 1-cocycle, $y(gh)=y(g)+g\cdot y(h)$, and there is $Y\in \mathrm{M}_3(E)\otimes_{\mathbb{Q}_\ell}B_{\mathrm{cris}}$ with $y(g)\otimes 1=g\cdot Y-Y$ for every $g\in D_\ell$.

Proof. Write $P_g=\rho_0(g)$ and $\varsigma_g=\eta_K(g)$ for the sign of $f\circ r^{\mathrm{ord}}_\ell$ at g; $f\circ r^{\mathrm{ord}}_\ell\colon D_\ell\to\mathcal{G}_3(E[\epsilon])$ is a homomorphism, and its reduction modulo ϵ is $g\mapsto(P_g,\varsigma_g)$, also a homomorphism.

Step 1: y is a continuous cocycle. In $\mathcal{G}_3$, $(A,\varsigma)(B,\tau)=(A\,\theta^\varsigma(B),\varsigma\tau)$ with $\theta^1=\mathrm{id}$ and $\theta^{-1}=\theta$. For $Y'\in\mathrm{M}_3(E)$ and $P\in\mathrm{GL}_3(E)$, $((1+\epsilon Y')P)^{-1}=P^{-1}(1-\epsilon Y')$, so, using $J^2=1$,

$$\theta((1+\epsilon Y')P)=J(1-\epsilon\,{}^tY')\,{}^tP^{-1}J=(1-\epsilon JY'\,{}^tJ)\,\theta(P).$$

Hence the GL-part of $f(r^{\mathrm{ord}}_\ell(g))f(r^{\mathrm{ord}}_\ell(h))$ is $(1+\epsilon y(g))P_g(1+\epsilon Z)\theta^{\varsigma_g}(P_h)$ with $Z=y(h)$ if $\varsigma_g=1$ and $Z=-Jy(h)^tJ$ if $\varsigma_g=-1$, that is $(1+\epsilon(y(g)+g\cdot y(h)))P_g\theta^{\varsigma_g}(P_h)$, since $P_gZP_g^{-1}=g\cdot y(h)$. As $P_{gh}=P_g\theta^{\varsigma_g}(P_h)$ and $1+\epsilon X$ determines X, $y(gh)=y(g)+g\cdot y(h)$. The entries of P_g and of the ϵ-part of $f(\underline{r^{\mathrm{ord}}_\ell}(g))$ are continuous in g (second hypothesis of Proposition 43.15), so are those of P_g^{-1} (adjugate over determinant), and $y(g)$ is the ϵ-part times P_g^{-1}.

Step 2: a primitive on D°_ℓ. Put $H=D^\circ_\ell$; its elements have sign 1. Let $V=E^3$ with $h\mapsto P_h$ and $V_\epsilon=E[\epsilon]^3$ with $h\mapsto f(\underline{r^{\mathrm{ord}}_\ell}(h))$, continuous representations of H on finite-dimensional $\mathbb{Q}_\ell$-vector spaces. By Proposition 43.15, V_ϵ is crystalline. Reduction modulo ϵ is an H-equivariant surjection $V_\epsilon\to V$ with kernel ϵV_ϵ, so V is crystalline (quotient, Theorem B.45). Let $W=\mathrm{Hom}_E(V,V_\epsilon)$ with $h\cdot\phi=f(\underline{r^{\mathrm{ord}}_\ell}(h))\circ\phi\circ P_h^{-1}$; it is an H-stable subspace of $\mathrm{Hom}_{\mathbb{Q}_\ell}(V,V_\epsilon)\cong V^*\otimes_{\mathbb{Q}_\ell}V_\epsilon$, which is crystalline (dual and tensor product), so W is crystalline. Writing $E[\epsilon]^3=E^3\oplus\epsilon E^3$, every $\phi\in W$ is $v\mapsto Av+\epsilon Bv$ for unique $A,B\in\mathrm{M}_3(E)$, written $A+\epsilon B$, and

$$h\cdot(A+\epsilon B)=P_hAP_h^{-1}+\epsilon(P_hBP_h^{-1}+y(h)P_hAP_h^{-1}).$$

So $V_P=\{\lambda+\epsilon B:\lambda\in E,\ B\in\mathrm{M}_3(E)\}$ and $W_0=\{\epsilon B\}$ are H-stable, $h\cdot\epsilon B=\epsilon\,(h\cdot B)$, and $\mathrm{pr}\colon V_P\to E$, $\lambda+\epsilon B\mapsto\lambda$, is surjective, H-equivariant for the trivial action on E, with kernel W_0. All three are crystalline ($V_P,W_0\subseteq W$; the trivial representation is crystalline). By left exactness of D_{cris} ($\otimes_{\mathbb{Q}_\ell}B_{\mathrm{cris}}$ is exact and invariants are left exact), the image of $D_{\mathrm{cris}}(V_P)$ in $D_{\mathrm{cris}}(E)$ has dimension $\dim_{\mathbb{Q}_\ell}V_P-\dim_{\mathbb{Q}_\ell}W_0=\dim_{\mathbb{Q}_\ell}E=\dim D_{\mathrm{cris}}(E)$, so $D_{\mathrm{cris}}(V_P)\to D_{\mathrm{cris}}(E)$ is onto. Choose $w_0\in D_{\mathrm{cris}}(V_P)$ with $(\mathrm{pr}\otimes 1)(w_0)=1\otimes 1$, and put $e_0=1+\epsilon 0\in V_P$. Then $e_0\otimes 1-w_0$ lies in $\ker(\mathrm{pr}\otimes 1)=W_0\otimes_{\mathbb{Q}_\ell}B_{\mathrm{cris}}$, and for $h\in H$, as w_0 is invariant,

$$h(e_0\otimes 1-w_0)-(e_0\otimes 1-w_0)=(h\cdot e_0-e_0)\otimes 1=\epsilon\, y(h)\otimes 1.$$

Identifying W_0 with $\mathrm{M}_3(E)$ by $\epsilon B \mapsto B$ (an H-isomorphism), we get $Y_H \in \mathrm{M}_3(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(h) \otimes 1 = h \cdot Y_H - Y_H$ for $h \in H$.

Step 3: averaging to D_ℓ. H is the kernel of $g \mapsto (\eta_K(g), \chi_\ell(g))$ on D_ℓ, a normal subgroup of finite index n (χ_ℓ has finite order). Put $M = \mathrm{M}_3(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with the diagonal action, a $\mathbb{Q}_\ell$-vector space. By Step 1, $c(g) = y(g) \otimes 1$ satisfies $c(gh) = c(g) + g \cdot c(h)$ (the element $1 \in B_{\mathrm{cris}}$ is invariant), and so does $z(g) = c(g) - (g \cdot Y_H - Y_H)$, which vanishes on H by Step 2. Then $z(gh) = z(g) + g \cdot z(h) = z(g)$ for $h \in H$. Let $\mathcal{T}$ be a set of representatives of D_ℓ/H; for $g \in D_\ell$, $g\mathcal{T}$ is another one, so with $W' = \sum_{\tau \in \mathcal{T}} z(\tau)$,

$$W' = \sum_{\tau \in \mathcal{T}} z(g\tau) = \sum_{\tau \in \mathcal{T}} \bigl(z(g) + g \cdot z(\tau)\bigr) = n\, z(g) + g \cdot W'.$$

Hence $z(g) = g \cdot (-n^{-1}W') - (-n^{-1}W')$, and $Y = Y_H - n^{-1}W'$ satisfies $y(g) \otimes 1 = g \cdot Y - Y$ for all $g \in D_\ell$. □

Lemma 43.23. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, emb_ℓ as in Proposition 43.15, and $E \subseteq \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ containing $\mathcal{O}$. Let D_ℓ act on $\mathrm{M}_3(E)$ through r_0 (if $r_0(g) = (P, \varsigma)$: $X \mapsto PXP^{-1}$ for $\varsigma = 1$, $X \mapsto -PJ\,{}^tXJP^{-1}$ for $\varsigma = -1$) and on $\mathrm{M}_3(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ diagonally, through emb_ℓ on B_{cris}; let $\mathfrak{g}_j(E)$ be the matrices supported in the positions of weight j. For $j \in \mathbb{Z}$ let Z_j be the E-vector space of continuous 1-cocycles $y\colon D_\ell \to \mathfrak{g}_j(E)$ for which there is $Y \in \mathrm{M}_3(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g) \otimes 1 = g \cdot Y - Y$ for all $g \in D_\ell$. Then $\dim_E Z_j$ is $1, 2, 3, 4, 2$ for $j = -2, -1, 0, 1, 2$ respectively, and 0 for $|j| > 2$.*

Proof. For $|j| > 2$, $\mathfrak{g}_j(E) = 0$ and $Z_j = 0$. Let $|j| \le 2$ and $V = \mathfrak{g}_j(E)$, of E-dimension $3 - |j|$ and $\mathbb{Q}_\ell$-dimension $m = (3 - |j|)[E : \mathbb{Q}_\ell]$; it is D_ℓ-stable (P is diagonal, and $J\,{}^tXJ$ has entry (a, b) equal to $X_{4-b,4-a}$, of the same weight), and the projection $p_j\colon \mathrm{M}_3(E) \to V$ to the entries of weight j is D_ℓ-equivariant and E-linear.

Step 1: Z_j is the preimage of H^1_f. If $y \in Z_j$ with Y, then $(p_j \otimes 1)(Y) \in V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ serves as well; so Z_j is the set of continuous cocycles $D_\ell \to V$ whose class lies in $H^1_f(D_\ell, V)$. It contains the coboundaries ($Y = X \otimes 1$), so $\dim_{\mathbb{Q}_\ell} Z_j = \dim B^1(D_\ell, V) + \dim H^1_f(D_\ell, V) = m - \dim H^0(D_\ell, V) + \dim H^1_f(D_\ell, V)$.

Step 2: V is de Rham, and $\dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 D_{\mathrm{dR}}(V)$ is m if $j \ge 1$ and 0 if $j \le 0$. Let $H'' = \{g \in D_\ell : \eta_K(g) = 1,\ \chi(g) = 1\}$, an open normal subgroup (η_K and χ have finite image), $H'' = G_{F''}$ with $F''/\mathbb{Q}_\ell$ finite Galois. On H'', $r_0(g) = (\mathrm{T}(\chi_{\mathrm{cyc}}(g)^e), 1)$, so g acts on V by the scalar $\chi_{\mathrm{cyc}}(g)^n$, $n = ej$: as a representation of H'', $V \cong \mathbb{Q}_\ell(n)^m$. An element $b \otimes 1$ of $B_{\mathrm{dR}} \otimes \mathbb{Q}_\ell(n)$ is H''-invariant if and only if $g(b) = \chi_{\mathrm{cyc}}(g)^{-n} b$, i.e. if and only if $bt^n \in B_{\mathrm{dR}}^{H''} = F''$ (t is a unit of the field B_{dR} with $g(t) = \chi_{\mathrm{cyc}}(g)t$); so the invariants are $F''t^{-n}$, of dimension 1 over F'', and $\mathbb{Q}_\ell(n)$ is de Rham over F''. Since t generates the maximal ideal of $B_{\mathrm{dR}}^+ = \mathrm{Fil}^0 B_{\mathrm{dR}}$ and $F'' \subseteq (B_{\mathrm{dR}}^+)^\times$, $at^{-n} \in \mathrm{Fil}^0$ for $a \in F'' \setminus \{0\}$ if and only if $n \le 0$; so Fil^0 of the invariants is everything if $n \le 0$ and 0 if $n \ge 1$. By Galois descent, V is de Rham as a representation of D_ℓ, $\dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(V) = m$, and $\dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 = \dim_{F''}$ of the corresponding quotient over F'', which is m if $n \ge 1$ and 0 if $n \le 0$. As $e \ge 1$, $n \ge 1$ if and only if $j \ge 1$.

Step 3: the count. By Theorem B.43 for $D_\ell \cong G_{\mathbb{Q}_\ell}$ and V, $\dim_{\mathbb{Q}_\ell} H^1_f(D_\ell, V) = \dim H^0(D_\ell, V) + \dim D_{\mathrm{dR}}(V)/\mathrm{Fil}^0$. With Steps 1 and 2, $\dim_{\mathbb{Q}_\ell} Z_j = m$ for $j \le 0$ and $2m$ for $j \ge 1$. Dividing by $[E : \mathbb{Q}_\ell]$, $\dim_E Z_j = 3 - |j|$ for $-2 \le j \le 0$ and $2(3 - j)$ for $j = 1, 2$: the values $1, 2, 3, 4, 2$. □

Proposition 43.24. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$*

for a coefficient ring $\mathcal{O}$. The localisation of R_ℓ^{ord} at the prime ideal $\ker\beta_\ell$ has Krull dimension at least 12.

Proof. Write $R = R_\ell^{\square}$, $\mathfrak{J} = I^{\mathrm{ord}}(r_\ell^{\square})$, $\gamma = \mathrm{gd}(r_\ell^{\square})$, $\mathfrak{q} = \ker\beta_\ell \subset R$, $E = E_{\mathcal{O}}$, ϖ a uniformiser of $\mathcal{O}$, and $E_k = E[[T]]/\mathfrak{m}_T^k$ ($k \geq 1$), a finite-dimensional local E-algebra with its natural topology. Let r_T be as in Lemma 43.25.

Step 1: a ring homomorphism $F\colon R \to E[[T]]$ with $F(\underline{r_\ell^{\square}}(g)_{ab}) = \underline{r_T}(g)_{ab}$ whose constant term is β_ℓ. Fix $k \geq 1$ and let $r_k\colon D_\ell \to \mathcal{G}_3(E_k)$ be the reduction of r_T; its entries are continuous by (Fa). Let $S_k \subset \mathfrak{m}_T E_k$ be the set of entries of $\underline{r_k}(g)\underline{r_0}(g)^{-1} - 1$, $g \in D_\ell$ (in $\mathfrak{m}_T E_k$ by (Fa)); it is compact, hence bounded. Products of k elements of $\mathfrak{m}_T E_k$ vanish. Let A_k^+ be the $\mathcal{O}$-span of the products $s_1 \cdots s_j$ with $1 \leq j < k$ and $s_i \in S_k$; these products form bounded sets, and the $\mathcal{O}$-span of a bounded subset of a finite-dimensional E-vector space lies in a finitely generated $\mathcal{O}$-module, so A_k^+ is a finitely generated $\mathcal{O}$-module, closed under multiplication and nilpotent. Put $A_k = \mathcal{O} + A_k^+$, an $\mathcal{O}$-subalgebra of E_k, finitely generated and torsion free over $\mathcal{O}$. As $\mathcal{O} \cap \mathfrak{m}_T E_k = 0$, $A_k/A_k^+ \cong \mathcal{O}$, so A_k is local with maximal ideal $\mathfrak{m}_{\mathcal{O}} + A_k^+$ and residue field $\mathbb{F}_{\mathcal{O}}$; being finite over $\mathcal{O}$ it is Noetherian and complete, and $A_k \in \mathrm{CNL}_{\mathcal{O}}$. Since $(A_k^+)^k = 0$, $(\mathfrak{m}_{\mathcal{O}} + A_k^+)^m \subseteq \varpi^{m-k}A_k$ for $m \geq k$, so its maximal-ideal-adic topology is the ϖ-adic one, which is the topology of A_k as a lattice in its E-span, i.e. the subspace topology from E_k. The entries of $\underline{r_k}(g) = (1+s)\underline{r_0}(g)$ lie in A_k ($\underline{r_0}$ has entries in $\mathcal{O}$), and its determinant lies in $\mathcal{O}^\times + A_k^+ \subseteq A_k^\times$; so r_k is a homomorphism $D_\ell \to \mathcal{G}_3(A_k)$ with continuous entries and reduction $\bar{r}_0|_{D_\ell}$, i.e. a lift of $\bar{r}_0|_{D_\ell}$ to A_k. Let $x_k\colon R \to A_k$ be the unique morphism with $x_k \circ r_\ell^{\square} = r_k$ and $F_k\colon R \to E_k$ its composite with the inclusion. The projection $\pi_k\colon E_{k+1} \to E_k$ maps S_{k+1} onto S_k, and products of k elements vanish in E_k, so $\pi_k(A_{k+1}) = A_k$ and $\pi_k\colon A_{k+1} \to A_k$ is a morphism of $\mathrm{CNL}_{\mathcal{O}}$; $\pi_k \circ x_{k+1}$ classifies $\pi_k \circ r_{k+1} = r_k$, so $\pi_k \circ x_{k+1} = x_k$ by uniqueness. Hence the F_k define an $\mathcal{O}$-algebra homomorphism $F\colon R \to \varprojlim_k E_k = E[[T]]$ with $F(\underline{r_\ell^{\square}}(g)_{ab}) = \underline{r_T}(g)_{ab}$. For $k = 1$, $E_1 = E$, $r_1 = r_0|_{D_\ell}$ and $A_1 = \mathcal{O}$, so x_1 is a base point of $r_\ell^{\square}$, which is β_ℓ by (Ol1): the constant term of $F(y)$ is $\beta_\ell(y)$.

Step 2: F factors through R_ℓ^{ord}. The generators of $\mathfrak{J}$ are polynomials with coefficients in $\mathcal{O}$ in the entries of $\underline{r_\ell^{\square}}(g)$, $g \in D_\ell^\circ \cap I_\ell$; F maps them to the same polynomials in the entries of $\underline{r_T}(g)$, which vanish by (Fb). So $F(\mathfrak{J}) = 0$; likewise $F(\gamma) = \mathrm{gd}(r_T) \neq 0$ by (Fc). As $E[[T]]$ is a domain, $\ker F$ is prime, and $\gamma^m y \in \mathfrak{J}$ implies $F(\gamma)^m F(y) = 0$, $F(y) = 0$; so $\ker F$ contains the saturation of $\mathfrak{J}$ and its radical I^{cr}. By Step 1, $\ker F \subseteq \mathfrak{q}$. As R is Noetherian, $\ker F$ contains a minimal prime $\mathfrak{P}$ of I^{cr}; $\mathfrak{P} \subseteq \mathfrak{q}$, the kernel of the only base point (Ol1), so $\mathfrak{P}$ is one of the primes intersected in I_ℓ^{ord}, and $I_\ell^{\mathrm{ord}} \subseteq \mathfrak{P} \subseteq \ker F$. So $F = \bar{F} \circ (R \to R_\ell^{\mathrm{ord}})$ for an $\mathcal{O}$-algebra homomorphism $\bar{F}$.

Step 3: twelve coordinates. Let $\mathrm{L}\colon E[[T]] \to E^{12}$ give the coefficients of $T_1, \ldots, T_{12}$. For $g \in D_\ell$ and $1 \leq a, b \leq 3$, $x_{g,a,b} = \underline{r_\ell^{\square}}(g)_{ab} - \underline{r_0}(g)_{ab}$ lies in $\mathfrak{q}$ ($\beta_\ell \circ r_\ell^{\square} = r_0|_{D_\ell}$), and $\mathrm{L}(F(x_{g,a,b}))$ is the vector of (a,b) entries of $\underline{y_i}(g)\underline{r_0}(g)$, $i = 1, \ldots, 12$. If these vectors spanned a proper subspace, some $(\mu_i) \neq 0$ would satisfy $\sum_i \mu_i y_i(g)\underline{r_0}(g) = 0$ for all g, so $\sum_i \mu_i y_i = 0$, against (Fd). Choose $z_1, \ldots, z_{12}$ among the $x_{g,a,b}$ with $\mathrm{L}(F(z_1)), \ldots, \mathrm{L}(F(z_{12}))$ a basis of E^{12}.

Step 4: the dimension. Let $A = R_\ell^{\mathrm{ord}}$, $\mathfrak{q}_A = \ker\beta_\ell \subset A$ and $\bar{z}_i$ the image of z_i. For $s \in A \setminus \mathfrak{q}_A$, $\bar{F}(s)$ has constant term $\beta_\ell(s) \neq 0$ and is a unit; so $\bar{F}$ extends to $\Phi\colon A_{\mathfrak{q}_A} \to E[[T]]$, with $\Phi(\mathfrak{q}_A A_{\mathfrak{q}_A}) \subseteq \mathfrak{m}_T$ and hence $\Phi((\mathfrak{q}_A A_{\mathfrak{q}_A})^N) \subseteq \mathfrak{m}_T^N$. $A_{\mathfrak{q}_A}$ is a Noetherian local ring containing E (β_ℓ is the identity on $\mathcal{O}$, so non-zero elements of $\mathcal{O}$ are units). Let $\widehat{A}$ be its completion, with maximal ideal $\widehat{\mathfrak{n}}$; the maps $A_{\mathfrak{q}_A}/(\mathfrak{q}_A A_{\mathfrak{q}_A})^N \to E[[T]]/\mathfrak{m}_T^N$ induced by Φ define an E-algebra homomorphism $\widehat{\Phi}\colon \widehat{A} \to E[[T]]$ with $\widehat{\Phi}(\widehat{\mathfrak{n}}^N) \subseteq \mathfrak{m}_T^N$. Let $\iota\colon E[[Y_1, \ldots, Y_{12}]] \to \widehat{A}$ be the continuous E-algebra homomorphism with $\iota(Y_i) = \bar{z}_i \in \widehat{\mathfrak{n}}$; as $\widehat{\mathfrak{n}}^N$ is closed, ι maps $(Y)^N$ into $\widehat{\mathfrak{n}}^N$. So $\psi = \widehat{\Phi} \circ \iota$ maps $(Y)^N$ into $\mathfrak{m}_T^N$ and agrees with the substitution $Y_i \mapsto F(z_i)$ on polynomials; as every power

series differs from a polynomial by an element of $(Y)^N$, for every N, ψ is that substitution. Its matrix of linear parts, with rows $\mathrm{L}(F(z_i))$, is invertible (Step 3), so ψ is an automorphism and $\widehat{\Phi}$ is onto. Hence $E[[T]]$ is a quotient of $\widehat{A}$, $\dim \widehat{A} \geq 12$, and $\dim A_{\mathfrak{q}_A} = \dim \widehat{A} \geq 12$. $\square$

Lemma 43.25. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with fraction field $E_\mathcal{O}$, and let $E_\mathcal{O}[[T]] = E_\mathcal{O}[[T_1, \dots, T_{12}]]$, with maximal ideal $\mathfrak{m}_T$. There is a homomorphism $r_T \colon D_\ell \to \mathcal{G}_3(E_\mathcal{O}[[T]])$ such that:*

(Fa) *the sign of $r_T(g)$ is $\eta_K(g)$; every coefficient of every entry of $\underline{r_T}(g)$ is a continuous function of $g \in D_\ell$; and $\underline{r_T}(g) - \underline{r_0}(g)$ has its entries in $\mathfrak{m}_T$ for every $g \in D_\ell$;*

(Fb) *for all $g, g_1, g_2, g_3 \in D_\ell^\circ \cap I_\ell$, $\det\bigl(X - \underline{r_T}(g)\bigr) = \prod_{a=1}^{3}(X - \psi_a(g))$ and*

$$\bigl(\underline{r_T}(g_1) - \psi_1(g_1)\bigr)\bigl(\underline{r_T}(g_2) - \psi_2(g_2)\bigr)\bigl(\underline{r_T}(g_3) - \psi_3(g_3)\bigr) = 0;$$

(Fc) $\mathrm{gd}(r_T) \neq 0$ *in $E_\mathcal{O}[[T]]$;*

(Fd) *the maps $y_1, \dots, y_{12} \colon D_\ell \to \mathrm{M}_3(E_\mathcal{O})$, where $y_i(g)$ is the coefficient of T_i in $\underline{r_T}(g)\,\underline{r_0}(g)^{-1}$, are linearly independent over $E_\mathcal{O}$.*

Proof. Write $E = E_\mathcal{O}$, a finite extension of $\mathbb{Q}_\ell$ inside $\overline{\mathbb{Q}}_\ell$ containing $\mathcal{O}$, and $\eta = \eta_K|_{D_\ell}$. Through emb_ℓ, $D_\ell = \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ with inertia I_ℓ. A map to $E[[T]]$ (or to matrices over it) is called continuous if all its coefficients are; sums, products, and inverses of matrices with unit determinant (adjugate over determinant; the inverse of a unit power series has coefficients polynomial in its coefficients and the inverse of its constant term) of continuous maps are continuous. Case (S): $\eta = 1$; case (N): $\eta \neq 1$. Let $\mathrm{fr} \colon D_\ell \to \widehat{\mathbb{Z}} \to \mathbb{Z}_\ell$ be the continuous homomorphism, trivial on I_ℓ, with $\mathrm{fr}(\mathrm{Fr}) = 1$; then $\mathrm{fr}(\sigma_\ell) = n$. Put $\lambda_i(g) = (1+T_i)^{\mathrm{fr}(g)}$, a continuous character $D_\ell \to E[[T]]^\times$, trivial on I_ℓ, with $\lambda_i(g) \equiv 1 + \mathrm{fr}(g) T_i$ modulo $\mathfrak{m}_T^2$. On $D_\ell^\circ \cap I_\ell$ the prime-to-ℓ part of χ is trivial (it is unramified at ℓ) and so is χ_ℓ; hence $\Psi = \chi\chi_{\mathrm{cyc}}^e = \chi_{\mathrm{cyc}}^e$ there, the $u_a = \psi_a(\sigma_0) = \chi_{\mathrm{cyc}}(\sigma_0)^{e(2-a)}$ are pairwise distinct, $\mathrm{gp}_a \neq 0$, and $\Psi(\sigma_0)^j \neq 1$ for $j \neq 0$.

Step 1: a diagonal family. Define $D(g)$ by $\mathrm{diag}(\psi_1\lambda_1\lambda_3,\ \psi_2\lambda_3,\ \psi_3\lambda_2^{-1}\lambda_3)(g)$ in case (S) and $\mathrm{T}(\Psi(g)\lambda_1(g))$ in case (N), with diagonal entries $\kappa_1, \kappa_2, \kappa_3$. Then $d(g) = (D(g), \eta(g))$ is a homomorphism $D_\ell \to \mathcal{G}_3(E[[T]])$ (in case (S) the signs are 1; in case (N), $\mathrm{T}(t)\mathrm{T}(t') = \mathrm{T}(tt')$ and $\theta(\mathrm{T}(t')) = \mathrm{T}(t')$). The κ_a are continuous characters with $\kappa_a = \psi_a$ on I_ℓ, $D(g) \equiv \mathrm{T}(\Psi(g)) = \underline{r_0}(g)$ modulo $\mathfrak{m}_T$, and $\kappa_1\kappa_2^{-1} = \Psi\lambda_1$, $\kappa_2\kappa_3^{-1} = \Psi\lambda_2$ in case (S), $\kappa_1\kappa_2^{-1} = \kappa_2\kappa_3^{-1} = \Psi\lambda_1$ in case (N).

Step 2: upper triangular elements. Put $\mathrm{n}(x, y, z) = 1 + xE_{12} + yE_{23} + zE_{13}$ (E_{ab} the matrix units) for $x, y, z \in E[[T]]$, and $\mathrm{n}_2(z) = (\mathrm{n}(0, 0, z), 1) \in \mathcal{G}_3(E[[T]])$.

For $g \in D_\ell$ let $\alpha_g(u) = D(g)\theta^{\eta(g)}(u)D(g)^{-1}$ ($\theta^1 = \mathrm{id}$, $\theta^{-1} = \theta$) for unipotent upper triangular u. As $D(g)\theta^{\eta(g)}(D(h)) = D(gh)$,

$$(uD(g), \eta(g))\,(u'D(h), \eta(h)) = \bigl(u\,\alpha_g(u')\,D(gh),\ \eta(gh)\bigr). \tag{43.6}$$

By the side calculation,

$$\alpha_g(\mathrm{n}(x, y, z)) = \begin{cases} \mathrm{n}(\kappa_{12}x, \kappa_{23}y, \kappa_{13}z) & \text{if } \eta(g) = 1, \\ \mathrm{n}(-\kappa' y, -\kappa' x, \kappa_{13}(xy - z)) & \text{if } \eta(g) = -1 \text{ (case (N))}, \end{cases}$$

where $\kappa_{ab} = \kappa_a\kappa_b^{-1}(g)$ and $\kappa' = \Psi\lambda_1(g)$. So the first two coordinates of $\alpha_g(\mathrm{n}(x, y, z))$ are $A_g(x, y)$, with $A_g(x, y) = (\Psi\lambda_1(g)x, \Psi\lambda_2(g)y)$ in case (S) and $A_g = \Psi\lambda_1(g)\, s_g$ in case (N), $s_g = \mathrm{id}$ if $\eta(g) = 1$ and $s_g(x, y) = (-y, -x)$ otherwise; and $\alpha_g(\mathrm{n}(0, 0, z)) = \mathrm{n}(0, 0, \chi_2(g)z)$

with $\chi_2 = \eta\kappa_1\kappa_3^{-1}$. $g \mapsto A_g$ and $g \mapsto \chi_2(g)$ are continuous actions on $E[[T]]^2$ and $E[[T]]$ (s is a homomorphism, $s_g^2 = \mathrm{id}$). Identifying $\mathfrak{g}_1(E)$ with E^2 by $xE_{12} + yE_{23} \leftrightarrow (x, y)$ and $\mathfrak{g}_2(E)$ with E by $zE_{13} \leftrightarrow z$, the action of Lemma 43.23 through r_0 is A_g, resp. $\chi_2(g)$, at $T = 0$: for sign 1 conjugation by $\mathrm{T}(\Psi(g))$ multiplies weight j entries by $\Psi(g)^j$; for sign -1, $-J\,{}^t(xE_{12} + yE_{23})J = -yE_{12} - xE_{23}$ and $-J\,{}^t(zE_{13})J = -zE_{13}$.

Step 3: base cocycles. For $j = 1, 2$ the projection $\mathrm{M}_3(E) \to \mathfrak{g}_j(E)$ is equivariant, so a cocycle in Z_j has a primitive in $\mathfrak{g}_j(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ and its class lies in $H^1_f(D_\ell, \mathfrak{g}_j(E))$. The coboundaries $B_j = \{g \mapsto X - g \cdot X : X \in \mathfrak{g}_j(E)\}$ lie in Z_j (primitive $X \otimes 1$), and $X \mapsto (g \mapsto X - g \cdot X)$ is injective, since $\sigma_0 \cdot X = \Psi(\sigma_0)^j X$. By Lemma 43.23, $\dim Z_1 = 4$, $\dim B_1 = 2$, $\dim Z_2 = 2$, $\dim B_2 = 1$. Choose $c_0'' \in Z_2 \setminus B_2$ and $c_0^{(1)}, c_0^{(2)} \in Z_1$ linearly independent modulo B_1; in case (S) choose them with $c_0^{(1)}$ valued in $E \times 0$ and $c_0^{(2)}$ in $0 \times E$: there the two coordinate projections of E^2 are equivariant ($A_g = \Psi(g)$ at $T = 0$), so Z_1 and B_1 split into the cocycles valued in $E \times 0$ and in $0 \times E$, the coordinate swap is an equivariant automorphism exchanging the two parts, and each part of Z_1 has dimension 2 and contains the corresponding one-dimensional part of B_1.

Step 4: a criterion for the characters met. Let $\varphi\colon D_\ell \to E^\times$ be a continuous character and $E(\varphi)$ the $\mathbb{Q}_\ell$-representation E with g acting by $\varphi(g)$. If $\varphi = \chi_{\mathrm{cyc}}$ on D_ℓ, a $\mathbb{Q}_\ell$-basis of E gives $E(\varphi) \cong \mathbb{Q}_\ell(1)^{[E:\mathbb{Q}_\ell]}$. Otherwise $H^2(D_\ell, E(\varphi)) = 0$: by Theorem B.36 its dimension is that of the invariant linear forms $f\colon E \to \mathbb{Q}_\ell$ with $f(x) = \chi_{\mathrm{cyc}}(g) f(\varphi(g)^{-1}x)$; for g with $\beta = \chi_{\mathrm{cyc}}(g)\varphi(g)^{-1} \neq 1$ this gives $f((\beta - 1)x) = 0$ for all x, so $f = 0$.

Step 5: the families of cocycles. Weight 1, case (S): apply Lemma 43.26 to $V_0 = E(\Psi)$, the variable T_1 and the first coordinate of $c_0^{(1)}$ (its class is finite, the projection being equivariant); by Step 4, $V' = V_0$, $V'' = 0$ if $\Psi = \chi_{\mathrm{cyc}}$ on D_ℓ, and $V' = 0$, $V'' = V_0$ otherwise. This gives $c^{(1)}\colon D_\ell \to E[[T_1]]$ with $c^{(1)}(gh) = c^{(1)}(g) + \Psi\lambda_1(g)c^{(1)}(h)$ and constant term that coordinate; likewise $c^{(2)}$ with T_2, $\Psi\lambda_2$ and the second coordinate of $c_0^{(2)}$. Put $a(g) = (T_4 c^{(1)}(g), T_5 c^{(2)}(g))$. Case (N): $E^2 = E(1,-1) \oplus E(1,1)$ with g acting at $T = 0$ by $\Psi(g)$ and $\Psi(g)\eta(g)$, since $s_g(1,-1) = (1,-1)$ and $s_g(1,1) = \eta(g)(1,1)$; by Step 4 each summand is a sum of copies of $\mathbb{Q}_\ell(1)$ or has vanishing H^2, and not both are of the first kind ($\Psi = \chi_{\mathrm{cyc}} = \Psi\eta$ would force $\eta = 1$). As $A_g = \lambda_1(g) \cdot A_g|_{T=0}$, Lemma 43.26 with the variable T_1 gives cocycles $c^{(i)}\colon D_\ell \to E[[T_1]]^2$ of A with constant terms $c_0^{(i)}$; put $a = T_4 c^{(1)} + T_5 c^{(2)}$. In both cases a is continuous, $a(gh) = a(g) + A_g a(h)$, a has values in $\mathfrak{m}_T E[[T]]^2$, and $a \equiv T_4 c_0^{(1)} + T_5 c_0^{(2)}$ modulo $\mathfrak{m}_T^2$. Weight 2: $\chi_2 \equiv \eta\Psi^2$ modulo $\mathfrak{m}_T$, and $\eta\Psi^2(\sigma_0) = \chi_{\mathrm{cyc}}(\sigma_0)^{2e} \neq \chi_{\mathrm{cyc}}(\sigma_0)$ ($2e \neq 1$), so $H^2(D_\ell, E(\eta\Psi^2)) = 0$ by Step 4, and Lemma 43.27 (ii) gives a continuous $c''\colon D_\ell \to E[[T]]$ with $c''(gh) = c''(g) + \chi_2(g)c''(h)$ and constant term c_0''.

Step 6: the triangular homomorphism. Write $a = (a_1, a_2)$ and

$$\tilde{\rho}(g) = (\mathrm{n}(a_1(g), a_2(g), 0) D(g), \eta(g)).$$

As $\mathrm{n}(x, y, z) \mapsto (x, y)$ is a homomorphism with central kernel $\{\mathrm{n}(0, 0, z)\}$, (43.6) and the cocycle identity of a give $\tilde{\rho}(g)\tilde{\rho}(h) = \mathrm{n}_2(o(g,h))\tilde{\rho}(gh)$, where $o(g,h)$ is the $(1,3)$ coordinate of $\mathrm{n}(a(g), 0)\alpha_g(\mathrm{n}(a(h), 0))$ (by the side calculation, $\mathrm{n}(X,Y,Z)\mathrm{n}(X,Y,0)^{-1} = \mathrm{n}(0,0,Z)$): explicitly $o(g,h) = a_1(g)\kappa_{23}a_2(h)$ if $\eta(g) = 1$ and $o(g,h) = \kappa_{13}a_1(h)a_2(h) - a_1(g)\kappa' a_1(h)$ otherwise. So o is continuous with values in $\mathfrak{m}_T^2$. By (43.6) with $u' = \mathrm{n}(0,0,z)$, $\tilde{\rho}(g)\mathrm{n}_2(z) = \mathrm{n}_2(\chi_2(g)z)\tilde{\rho}(g)$. Comparing $(\tilde{\rho}(g)\tilde{\rho}(h))\tilde{\rho}(k) = \mathrm{n}_2(o(g,h) + o(gh,k))\tilde{\rho}(ghk)$ with $\tilde{\rho}(g)(\tilde{\rho}(h)\tilde{\rho}(k)) = \mathrm{n}_2(\chi_2(g)o(h,k) + o(g,hk))\tilde{\rho}(ghk)$ shows that o is a 2-cocycle for χ_2. By Lemma 43.27 (i) (with $V_0 = E(\eta\Psi^2)$ and $j = 2$) there is a continuous $b\colon D_\ell \to \mathfrak{m}_T^2$ with $o(g,h) = \chi_2(g)b(h) - b(gh) + b(g)$. Put $t(g) = \mathrm{n}_2(T_6 c''(g) - b(g))\tilde{\rho}(g)$. Then

$$t(g)t(h) = \mathrm{n}_2(T_6 c''(g) - b(g) + \chi_2(g)(T_6 c''(h) - b(h)) + o(g,h))\tilde{\rho}(gh) = t(gh),$$

so t is a homomorphism, with sign $\eta(g)$ and GL-part $\mathrm{n}(a_1(g), a_2(g), T_6c''(g) - b(g))D(g)$, upper triangular with diagonal $(\kappa_a(g))_a$.

Step 7: conjugation; (Fa) and (Fb). Let $h = (1 + T_7E_{21} + T_8E_{32} + T_9E_{31})\,\Delta\,\mathrm{n}(T_{10}, T_{11}, T_{12})$ with $\Delta = 1$ in case (S) and $\Delta = \mathrm{diag}(1 + T_2, 1 + T_3, 1)$ in case (N); $h \in \mathrm{GL}_3(E[[T]])$ and $h \equiv 1$ modulo $\mathfrak{m}_T$. Put $r_T(g) = (h, 1)t(g)(h, 1)^{-1}$, a homomorphism with sign $\eta(g)$ and GL-part $h\,\underline{t}(g)\,\theta^{\eta(g)}(h)^{-1}$. (Fa): continuity follows from that of a, b, c'', D; modulo $\mathfrak{m}_T$, a, b, T_6c'' vanish, $D(g) \equiv \underline{r_0}(g)$ and $h \equiv 1$. (Fb): for $g \in D_\ell^\circ \cap I_\ell$, $\eta(g) = 1$ and $\underline{r_T}(g) = hU(g)h^{-1}$ with $U(g)$ upper triangular with diagonal $(\psi_a(g))_a$ (λ_i trivial on I_ℓ); this gives the characteristic polynomial, and the product equals $h\prod_k(U(g_k) - \psi_k(g_k))h^{-1}$, where the k-th factor is upper triangular with (k, k) entry 0: the third maps $E[[T]]^3$ into $\langle e_1, e_2\rangle$, the second maps $\langle e_1, e_2\rangle$ into $\langle e_1\rangle$, the first kills e_1, so the product is 0.

Step 8: (Fc). $\sigma_0, \sigma_\ell \in D_\ell^\circ$ have sign 1, so $\underline{r_T}(\sigma_0) = hU_0h^{-1}$, $\underline{r_T}(\sigma_\ell) = hU_\ell h^{-1}$ with U_0, U_ℓ upper triangular with diagonals $(u_b)_b$ and $(\kappa_b(\sigma_\ell))_b$. The trace being invariant under conjugation and the diagonal of a product of upper triangular matrices being the product of the diagonals,

$$\mathrm{tq}_a(r_T) = \sum_b (u_b - u_{a+1})(u_b - u_{a+2})\kappa_b(\sigma_\ell) = \mathrm{gp}_a\kappa_a(\sigma_\ell),$$
$$\mathrm{dt}_a(r_T) = \mathrm{gp}_a\mathrm{gp}_{a+1}\kappa_{a+1}(\sigma_\ell)\big(\kappa_a\kappa_{a+1}^{-1}(\sigma_\ell) - \chi_{\mathrm{cyc}}(\sigma_\ell)\big).$$

For $a = 1, 2$, $\kappa_a\kappa_{a+1}^{-1}(\sigma_\ell) = \Psi(\sigma_\ell)(1 + T_i)^n$ with $i = a$ in case (S) and $i = 1$ in case (N) (Step 1), and $\Psi(\sigma_\ell)(1 + T_i)^n - \chi_{\mathrm{cyc}}(\sigma_\ell)$ has coefficient $n\Psi(\sigma_\ell) \neq 0$ at T_i. As $\mathrm{gp}_a \neq 0$, the $\kappa_b(\sigma_\ell)$ are units and $E[[T]]$ is a domain, $\mathrm{gd}(r_T) = \ell\,\mathrm{dt}_1(r_T)\mathrm{dt}_2(r_T) \neq 0$.

Step 9: (Fd). Write $P_0 = \underline{r_0}(g)$ and $H_1 = \sum_i T_iX_i$ for the part of degree one of h: $X_7 = E_{21}$, $X_8 = E_{32}$, $X_9 = E_{31}$, $X_{10} = E_{12}$, $X_{11} = E_{23}$, $X_{12} = E_{13}$, and in case (N) also $X_2 = E_{11}$, $X_3 = E_{22}$. Modulo $\mathfrak{m}_T^2$: $\underline{t}(g)P_0^{-1} \equiv 1 + \Delta_1(g) + T_4c_0^{(1)}(g) + T_5c_0^{(2)}(g) + T_6c_0''(g)$, read in $\mathrm{M}_3(E)$ through the identifications of Step 2, where $\Delta_1(g) = \mathrm{fr}(g)(T_1E_{11} - T_2E_{33} + T_3 1)$ in case (S) and $\mathrm{fr}(g)T_1(E_{11} - E_{33})$ in case (N) (as $b \in \mathfrak{m}_T^2$, $a \equiv T_4c_0^{(1)} + T_5c_0^{(2)}$, $c'' \equiv c_0''$ modulo $\mathfrak{m}_T$, and $D(g)P_0^{-1}$ is the diagonal matrix of the λ-factors); $h \equiv 1 + H_1$; and $P_0\theta^{\eta(g)}(h)^{-1}P_0^{-1} \equiv 1 - g \cdot H_1$, since $h^{-1} \equiv 1 - H_1$ and $\theta(h)^{-1} = \theta(h^{-1}) \equiv 1 + J\,{}^tH_1J$. Hence $\underline{r_T}(g)P_0^{-1} \equiv 1 + \Delta_1(g) + T_4c_0^{(1)}(g) + T_5c_0^{(2)}(g) + T_6c_0''(g) + H_1 - g \cdot H_1$, and

- $y_i(g) = X_i - g \cdot X_i$ for $i \in \{7, \dots, 12\}$, and for $i \in \{2, 3\}$ in case (N);
- $y_1 = \mathrm{fr}\,E_{11}$, $y_2 = -\mathrm{fr}\,E_{33}$, $y_3 = \mathrm{fr} \cdot 1$ in case (S); $y_1 = \mathrm{fr}\,(E_{11} - E_{33})$ in case (N);
- $y_4 = c_0^{(1)}$, $y_5 = c_0^{(2)}$ (weight 1), $y_6 = c_0''E_{13}$ (weight 2).

Each y_i takes values in one $\mathfrak{g}_j(E)$, so a linear relation splits by weight. Weight -2: $y_9(\sigma_0) = (1 - \Psi(\sigma_0)^{-2})E_{31} \neq 0$. Weight -1: $y_7(\sigma_0), y_8(\sigma_0)$ are $(1 - \Psi(\sigma_0)^{-1})E_{21}$, $(1 - \Psi(\sigma_0)^{-1})E_{32}$, independent. Weight 1: if $\mu_4y_4 + \mu_5y_5 + \mu_{10}y_{10} + \mu_{11}y_{11} = 0$, then $\mu_4c_0^{(1)} + \mu_5c_0^{(2)} \in B_1$, so $\mu_4 = \mu_5 = 0$, and evaluating at σ_0 gives $(1 - \Psi(\sigma_0))(\mu_{10}E_{12} + \mu_{11}E_{23}) = 0$. Weight 2: $\mu_6c_0'' \in B_2$ forces $\mu_6 = 0$, then $\mu_{12} = 0$ as for weight 1. Weight 0, case (S): $\mathrm{fr}(\mathrm{Fr}) = 1$, and $E_{11}, -E_{33}, 1$ are independent. Weight 0, case (N): elements of sign 1 fix diagonal matrices, so y_2, y_3 vanish on $\ker\eta$ while $y_1(\mathrm{Fr}^2) = 2(E_{11} - E_{33})$ with $\mathrm{Fr}^2 \in \ker\eta$, forcing the coefficient of y_1 to vanish; for g of sign -1, $g \cdot X = -JXJ$ for diagonal X, so $y_2(g) = E_{11} + E_{33}$ and $y_3(g) = 2E_{22}$, independent. Hence $y_1, \dots, y_{12}$ are linearly independent. □

Lemma 43.26. *Let ℓ be a prime, $G = \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ with inertia subgroup I, and $\mathrm{fr}\colon G \to \mathbb{Z}_\ell$ a continuous homomorphism which is trivial on I and not identically zero. For $a \in \mathbb{Z}_\ell$ put $(1 + T)^a = \sum_{k\geq 0}\binom{a}{k}T^k \in \mathbb{Z}_\ell[[T]]$. Let V_0 be a finite-dimensional $\mathbb{Q}_\ell$-vector space with a*

continuous linear action of G, and assume $V_0 = V' \oplus V''$ with G-stable subspaces such that V' is G-isomorphic to a direct sum of copies of $\mathbb{Q}_\ell(1)$ (possibly none) and $H^2(G, V'') = 0$. Let $V_0[[T]]$ be the set of power series $\sum_k x_k T^k$ with $x_k \in V_0$, with G acting by

$$g \cdot \sum_k x_k T^k = (1+T)^{\mathrm{fr}(g)} \sum_k (g x_k) T^k.$$

Then for every continuous 1-cocycle $c_0 \colon G \to V_0$ whose class lies in $H^1_f(G, V_0)$ there is a map $c \colon G \to V_0[[T]]$ with continuous coefficients, satisfying $c(gh) = c(g) + g \cdot c(h)$ for all $g, h \in G$, whose constant term is c_0.

Proof. Since $\binom{a+b}{k} = \sum_i \binom{a}{i}\binom{b}{k-i}$ holds for integers, hence by continuity for $a, b \in \mathbb{Z}_\ell$, $(1+T)^{a+b} = (1+T)^a(1+T)^b$, so the formula defines an action, and $g \mapsto \binom{\mathrm{fr}(g)}{k}$ is continuous. Cochains below are continuous, with $(db)(g,h) = g \cdot b(h) - b(gh) + b(g)$. For $k \geq 1$ let $M_k = V_0[[T]]/T^k V_0[[T]]$, a finite-dimensional representation; as $(1+T)^a \equiv 1$ modulo T, the map $\iota_k \colon V_0 \to T^k M_{k+1}$, $x \mapsto xT^k$, is a G-isomorphism. For $z \in Z^1(G, V_0)$ let $\delta(z) \in H^2(G, V_0)$ be the class of the 2-cocycle $(g,h) \mapsto \mathrm{fr}(g)\, g\, z(h)$; it depends only on the class of z (it is the connecting map of Step 4), and it is compatible with G-maps $V_0 \to V_1$ and with direct sums.

Step 1: the obstruction. Let $k \geq 1$ and $c \in Z^1(G, M_k)$, and let $\tilde{c} \colon G \to M_{k+1}$ be its lift with zero coefficient of T^k. Then $d\tilde{c}$ reduces to $dc = 0$, so it has values in $T^k M_{k+1}$, and $d(d\tilde{c}) = 0$; let $\mathrm{ob}(c) \in H^2(G, V_0)$ be its class through ι_k. If $\mathrm{ob}(c) = 0$, i.e. $d\tilde{c} = d(\iota_k \circ b)$ for some $b \colon G \to V_0$, then $\tilde{c} - \iota_k \circ b \in Z^1(G, M_{k+1})$ lifts c.

Step 2: changing the top coefficient. Let $k \geq 1$, $c \in Z^1(G, M_k)$ and $z \in Z^1(G, V_0)$. Since $T^{k-1} M_k \cong V_0$ equivariantly, $c' = c + zT^{k-1}$ lies in $Z^1(G, M_k)$, its lift with zero top coefficient is $\tilde{c} + zT^{k-1}$, and in M_{k+1}

$$d(zT^{k-1})(g,h) = \big((1+T)^{\mathrm{fr}(g)} g\, z(h) - z(gh) + z(g)\big) T^{k-1} = \mathrm{fr}(g)\, g\, z(h)\, T^k,$$

using $(1+T)^a \equiv 1 + aT$ modulo T^2 and the cocycle identity of z. Hence $\mathrm{ob}(c') = \mathrm{ob}(c) + \delta(z)$. For $k = 1$ and $c = 0$ (whose obstruction is 0) this gives $\mathrm{ob}(z) = \delta(z)$ for $z \in Z^1(G, V_0) = Z^1(G, M_1)$.

Step 3: δ vanishes on finite classes. Fix a G-isomorphism $V' \cong \mathbb{Q}_\ell(1)^a$ and let $p_i \colon V_0 \to \mathbb{Q}_\ell(1)$ $(1 \leq i \leq a)$ be the projection to V' along V'' followed by the i-th coordinate. As cohomology commutes with finite direct sums and $H^2(G, V'') = 0$, $(p_{i*})_i \colon H^2(G, V_0) \to H^2(G, \mathbb{Q}_\ell(1))^a$ is an isomorphism, and $p_{i*}\delta(c_0) = \delta(p_i \circ c_0)$. If $c_0(g) \otimes 1 = gy - y$ with $y \in V_0 \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$, then $(p_i \otimes 1)(y)$ is a primitive of $p_i \circ c_0$; so $x_i = p_i \circ c_0$ has class in $H^1_f(G, \mathbb{Q}_\ell(1))$. The homomorphism fr is a cocycle of the trivial representation $\mathbb{Q}_\ell$, and its class lies in $H^1_f(G, \mathbb{Q}_\ell)$: on $X = \mathbb{Q}_\ell e_0 \oplus \mathbb{Q}_\ell e_1$ with $ge_0 = e_0$, $ge_1 = e_1 + \mathrm{fr}(g) e_0$, an unramified, hence crystalline, representation, the sequence $0 \to D_{\mathrm{cris}}(\mathbb{Q}_\ell e_0) \to D_{\mathrm{cris}}(X) \to D_{\mathrm{cris}}(X/\mathbb{Q}_\ell e_0)$ is exact (left exactness of invariants) and the dimensions $1, 2, 1$ force the last map to be onto, so some invariant has the form $1 \otimes e_1 + b \otimes e_0$, and invariance reads $\mathrm{fr}(g) = g(-b) - (-b)$. Now $\mathbb{Q}_\ell(1)$ is de Rham and $\mathbb{Q}_\ell(1)^*(1)$ is the trivial representation, so Theorem B.49 (with $M = \mathbb{Q}_\ell$) gives $\langle [x_i], [\mathrm{fr}] \rangle = 0$: the 2-cocycle $(g,h) \mapsto \mathrm{fr}(h) x_i(g)$ is a coboundary. For $f(g) = \mathrm{fr}(g) x_i(g)$,

so $(g,h) \mapsto \mathrm{fr}(g) g x_i(h)$ is a coboundary as well, i.e. $\delta(x_i) = 0$. Hence $\delta(c_0) = 0$.

Step 4: δ is onto $H^2(G, V_0)$. With $s_i \colon \mathbb{Q}_\ell(1) \to V_0$ the inclusion of the i-th summand of V', $p_{j*}\delta(s_i \circ z) = \delta(p_j s_i \circ z)$ is $\delta(z)$ for $j = i$ and 0 otherwise; by Step 3's isomorphism it suffices that $\delta \colon H^1(G, \mathbb{Q}_\ell(1)) \to H^2(G, \mathbb{Q}_\ell(1))$ is onto. Take $V_0 = \mathbb{Q}_\ell(1)$ and $W = M_2$, with basis $w_0 = 1$, $w_1 = T$: $gw_0 = \chi_{\mathrm{cyc}}(g)(w_0 + \mathrm{fr}(g) w_1)$, $gw_1 = \chi_{\mathrm{cyc}}(g) w_1$. By Step 2 (lift z with zero top coefficient), δ is the connecting map of $0 \to TM_2 \to W \to \mathbb{Q}_\ell(1) \to 0$, $TM_2 \cong \mathbb{Q}_\ell(1)$ by ι_1; the long exact sequence and $H^3 = 0$ (Theorem B.36) give the exact sequence

$$H^1(G, \mathbb{Q}_\ell(1)) \xrightarrow{\delta} H^2(G, \mathbb{Q}_\ell(1)) \longrightarrow H^2(G, W) \longrightarrow H^2(G, \mathbb{Q}_\ell(1)) \longrightarrow 0.$$

By Theorem B.36, $h^2(\mathbb{Q}_\ell(1)) = h^0(\mathbb{Q}_\ell) = 1$ and $h^2(W) = h^0(W^*(1))$. A linear form φ on W is invariant in $W^*(1)$ iff $\varphi(w) = \chi_{\mathrm{cyc}}(g)\varphi(g^{-1}w)$ for all g, w; as $g^{-1}w_0 = \chi_{\mathrm{cyc}}(g)^{-1}(w_0 - \mathrm{fr}(g)w_1)$ and $g^{-1}w_1 = \chi_{\mathrm{cyc}}(g)^{-1}w_1$, this says $\mathrm{fr}(g)\varphi(w_1) = 0$ for all g, i.e. $\varphi(w_1) = 0$. So $h^2(W) = 1$, the map $H^2(G, W) \to H^2(G, \mathbb{Q}_\ell(1))$ is an onto map of one-dimensional spaces, hence injective, the map before it is zero, and δ is onto.

Step 5: construction. We construct $c^{(k)} \in Z^1(G, M_{k+1})$, $k \geq 1$, with $c^{(1)} \equiv c_0$ modulo T and $c^{(k+1)} \equiv c^{(k)}$ modulo T^k. By Steps 2 and 3, $\mathrm{ob}(c_0) = \delta(c_0) = 0$, so Step 1 gives $c^{(1)}$. Given $c^{(k)}$ ($k \geq 1$), choose by Step 4 a cocycle z with $\delta(z) = -\mathrm{ob}(c^{(k)})$; by Step 2 (with $k+1$ for k), $c' = c^{(k)} + zT^k$ has $\mathrm{ob}(c') = 0$ and $c' \equiv c^{(k)}$ modulo T^k; let $c^{(k+1)}$ be a lift of c' (Step 1). Define c by letting its coefficient of T^j be that of $c^{(k)}$ for any $k \geq j+1$; this does not depend on k, and it is continuous. For every j, c modulo T^{j+1} is the reduction of $c^{(j+1)}$, a cocycle of M_{j+1}; so $c(gh) - c(g) - g \cdot c(h)$ has all coefficients zero, and the constant term of c is that of $c^{(1)}$, namely c_0. □

Lemma 43.27. *Let G be a profinite group, E a finite extension of $\mathbb{Q}_\ell$ for a prime ℓ, $E[[T]] = E[[T_1, \dots, T_m]]$ with maximal ideal $\mathfrak{m}_T$, and V_0 a finite-dimensional E-vector space. Put $M = V_0 \otimes_E E[[T]]$, the power series in $T_1, \dots, T_m$ with coefficients in V_0; a map from a topological space to M is* coefficientwise continuous *if each of its coefficients is continuous for the natural topology of V_0. Let G act on M by $E[[T]]$-linear automorphisms $\rho(g)$ such that, in an E-basis of V_0, every coefficient of every entry of the matrix of $\rho(g)$ is a continuous function of g, and such that $\rho(g)$ reduces modulo $\mathfrak{m}_T$ to a continuous action ρ_0 of G on V_0. For cochains use $(db)(g,h) = \rho(g)b(h) - b(gh) + b(g)$ and $(dw)(g,h,k) = \rho(g)w(h,k) - w(gh,k) + w(g,hk) - w(g,h)$. Assume $H^2(G, V_0) = 0$. Then:*

(i) for every $j \geq 1$ and every coefficientwise continuous $w\colon G \times G \to \mathfrak{m}_T^j M$ with $dw = 0$ there is a coefficientwise continuous $b\colon G \to \mathfrak{m}_T^j M$ with $db = w$;

(ii) every continuous 1-cocycle $c_0\colon G \to V_0$ of ρ_0 is the constant term of a coefficientwise continuous $c\colon G \to M$ with $dc = 0$.

Proof. Truncations. For $k \geq 1$ let $M_k = M/\mathfrak{m}_T^k M$, a finite-dimensional E-vector space (the coefficients of the monomials of degree $< k$) on which ρ induces a continuous action; a coefficientwise continuous map to M is the same as a family of continuous maps to the M_k, compatible under the projections. Coboundaries and the relation $d \circ d = 0$ for inhomogeneous cochains hold in every M_k and in every G-stable subspace of it.

Step 1: the graded pieces have no second cohomology. Let $k \geq 1$. For $x \in V_0$ and a monomial t of degree k, $\rho(g)(x \otimes t) = t\,\rho(g)(x \otimes 1) \equiv \rho_0(g)x \otimes t$ modulo $\mathfrak{m}_T^{k+1}M$, since $\rho(g)(x \otimes 1) - \rho_0(g)x \otimes 1 \in \mathfrak{m}_T M$. So $\mathfrak{m}_T^k M/\mathfrak{m}_T^{k+1}M$ is G-isomorphic to a finite direct sum of copies of (V_0, ρ_0), one for each monomial of degree k, and its H^2 is a direct sum of copies of $H^2(G, V_0) = 0$.

Step 2: (i). We construct continuous $b_k\colon G \to \mathfrak{m}_T^j M_k$, $k \geq j$, with $db_k \equiv w$ modulo $\mathfrak{m}_T^k$ and $b_{k+1} \equiv b_k$ modulo $\mathfrak{m}_T^k$. For $k = j$ take $b_j = 0$: w has values in $\mathfrak{m}_T^j M$. Given b_k, let $\tilde{b}\colon G \to \mathfrak{m}_T^j M_{k+1}$ have the coefficients of b_k in degrees $< k$ and zero coefficients in degree k; it is continuous. The 2-cochain $w' = w - d\tilde{b}$ of M_{k+1} is continuous, vanishes modulo $\mathfrak{m}_T^k$ (as $d\tilde{b} \equiv db_k \equiv w$), so has values in $\mathfrak{m}_T^k M/\mathfrak{m}_T^{k+1}M$, and $dw' = dw - d(d\tilde{b}) = 0$. By Step 1, $w' = db'$ for a continuous $b'\colon G \to \mathfrak{m}_T^k M/\mathfrak{m}_T^{k+1}M$; then $b_{k+1} = \tilde{b} + b'$ has the required properties ($k \geq j$). The b_k define a coefficientwise continuous $b\colon G \to \mathfrak{m}_T^j M$ with $db \equiv w$ modulo $\mathfrak{m}_T^k$ for every k, that is $db = w$.

Step 3: (ii). Let $\tilde{c}(g) = c_0(g) \otimes 1 \in M$, coefficientwise continuous. Then $w = d\tilde{c}$ satisfies $dw = 0$, and modulo $\mathfrak{m}_T$ it is the coboundary of c_0 for ρ_0, which vanishes; so w has values in

$\mathfrak{m}_T M$. By (i) with $j = 1$, $w = db$ with b valued in $\mathfrak{m}_T M$, and $c = \tilde{c} - b$ satisfies $dc = 0$ and has constant term c_0. □

Lemma 43.28. *Let $\mathcal{O}$ be a coefficient ring, $R \in \mathrm{CNL}_{\mathcal{O}}$, $(\sigma, \mathrm{wt}, \pi)$ a weighted presentation of R, $\beta\colon R \to \mathcal{O}$ an $\mathcal{O}$-algebra homomorphism with $\beta(\pi(X_s)) = 0$ for every $s \in \sigma$, u a homogeneous generating system of* $\ker \pi$ *with counts* ne*, and $(A_\pi, \varphi_\beta, q_\pi)$ the graded model. Then:*

1. *A_π is an $\mathcal{O}$-subalgebra of $\mathcal{O}[[X_s : s \in \sigma]]$, $A_\pi = \bigoplus_j (A_\pi)_j$, $\varphi_\beta(f)$ is the constant term of f, and (A_π, φ_β) is a graded $\mathcal{O}$-algebra with a fixed point;*
2. *u is a system of equations for (A_π, φ_β) with counts* ne*, and* $\ker q_\pi = I(u)$*;*
3. *(A_π, φ_β) is smooth with tangent dimensions* $\mathrm{td}(j) = \#\mathrm{wt}^{-1}(j)$*; in particular* $\mathrm{td}(j) = 0$ *for $|j| > 2$.*

Proof. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$, $P_j = \mathcal{O}[[X_\sigma]]_j$, $A = A_\pi$, $A_j = (A_\pi)_j = P_j$, $|n| = \sum_s n_s$ for $n \in \mathbb{N}^\sigma$, and $E_j = \{n \in \mathbb{N}^\sigma : \sum_s n_s \mathrm{wt}(s) = j\}$, so that P_j consists of the series $\sum_{n \in E_j} c_n X^n$.

Step 0: weight components. Monomials of distinct weights are distinct, and the weight of a product of monomials is the sum of their weights. Hence $P_i P_k \subseteq P_{i+k}$, and for $f \in P$ and $g \in P_k$,

$$(fg)_{(m)} = f_{(m-k)}\, g \qquad (m \in \mathbb{Z}), \tag{43.7}$$

since every term of fg of weight m comes from a term of f of weight $m - k$.

Step 1: A is a graded subalgebra. A is closed under addition by definition and under multiplication since $P_i P_k \subseteq P_{i+k}$; it contains $\mathcal{O} \subseteq P_0$. If $\sum_j f_j = 0$ with $f_j \in P_j$ (finitely many), taking the weight k component gives $f_k = 0$; so the sum $A = \sum_j P_j$ is direct, and $A_i A_k \subseteq A_{i+k}$.

Step 2: A_0 is a complete Noetherian local ring with residue field that of $\mathcal{O}$. E_0 is a submonoid of $\mathbb{N}^\sigma$. By Dickson's lemma the set $\{m_1, \dots, m_k\}$ of minimal elements of $E_0 \setminus \{0\}$ (componentwise order) is finite. Every $n \in E_0$ is a sum of m_i's, by induction on $|n|$: if $n \neq 0$, the finite non-empty set of $m \in E_0 \setminus \{0\}$ with $m \leq n$ has a minimal element, which is some m_i, and $n - m_i \in E_0$ with $|n - m_i| < |n|$. Let $\theta\colon \mathcal{O}[[Y_1, \dots, Y_k]] \to P$ be the $\mathcal{O}$-algebra homomorphism substituting $Y_i \mapsto X^{m_i}$ (an element of the maximal ideal of the complete ring P, as $m_i \neq 0$); explicitly $\theta(\sum_e c_e Y^e) = \sum_e c_e X^{\sum_i e_i m_i}$, the coefficient of each X^n being a finite sum since $|\sum_i e_i m_i| \geq |e|$. So θ takes values in P_0. It is onto P_0: for $f = \sum_{n \in E_0} c_n X^n$ choose $e(n) \in \mathbb{N}^k$ with $\sum_i e(n)_i m_i = n$; $n \mapsto e(n)$ is injective, so $g = \sum_n c_n Y^{e(n)}$ is a power series, and $\theta(g) = f$. The constant coefficient of $\theta(g)$ is that of g, so $\ker \theta$ lies in the maximal ideal $(\mathfrak{m}_{\mathcal{O}}, Y)$. Hence $A_0 = P_0 \cong \mathcal{O}[[Y]]/\ker\theta$ is a complete Noetherian local ring, $\mathcal{O} \to A_0$ is local, and the residue fields agree.

Step 3: generation, and φ_β. Let $j \in \mathbb{Z}$. By Dickson's lemma the set Min_j of minimal elements of E_j is finite; choose for every $n \in E_j$ some $\mu(n) \in \mathrm{Min}_j$ with $\mu(n) \leq n$; then $n - \mu(n) \in E_0$. For $f = \sum_{n \in E_j} c_n X^n \in P_j$,

$$f = \sum_{m \in \mathrm{Min}_j} X^m h_m, \qquad h_m = \sum_{\mu(n) = m} c_n X^{n-m} \in P_0,$$

coefficientwise ($n \mapsto n - m$ is injective). Each X^m is a product of variables X_s, which lie in A_0 if $\mathrm{wt}(s) = 0$ and are homogeneous of degree $\mathrm{wt}(s) \in \{-2, -1, 1, 2\}$ otherwise. So A is generated as an $\mathcal{O}$-algebra by A_0 and the finitely many X_s with $\mathrm{wt}(s) \neq 0$. A series $f \in P$ with constant term c satisfies $f - c = \sum_s X_s g_s$ for some $g_s \in P$ (assign each non-constant term to the first variable, in a fixed order of σ, occurring in it); as $\beta \circ \pi$ is an $\mathcal{O}$-algebra homomorphism killing every X_s,

$\beta(\pi(f)) = c$. So $\varphi_\beta(f)$ is the constant term of f, and $\varphi_\beta(A_j) = 0$ for $j \neq 0$, a monomial of weight $j \neq 0$ being non-constant. With Steps 1 and 2 this proves item 1.

Step 4: item 2. Each $u_{j,i}$ lies in A_j, and $\varphi_\beta(u_{0,i}) = \beta(\pi(u_{0,i})) = 0$; so u is a system of equations with counts ne. As $u_{j,i} \in \ker\pi$, $I(u) \subseteq \ker q_\pi$. Conversely, an element f of $\ker\pi$ is $\sum_{j,i} g_{j,i}u_{j,i}$ with $g_{j,i} \in P$, so by (43.7)

$$f_{(k)} = \sum_{j,i} (g_{j,i})_{(k-j)}\, u_{j,i} \qquad (k \in \mathbb{Z}),$$

which lies in $\ker\pi$, and, when $f_{(k)}$ is regarded as an element of A, in $I(u)$, since $(g_{j,i})_{(k-j)} \in A_{k-j}$. Let $f \in \ker q_\pi$ and write $f = \sum_k f_k$ with $f_k \in A_k$. Then $f_k = f_{(k)}$, so $f_k \in I(u)$ for every k, and $f \in I(u)$.

Step 5: item 3. Let $\phi\colon A \to \mathcal{O}[\ell^{-1}][[X_s : s \in \sigma]]$ be the inclusion, with the weights wt on the variables; $\#\mathrm{wt}^{-1}(j) = \mathrm{td}(j)$. (Sm1): elements of $A_j = P_j$ have weight j. (Sm2): the constant term of $\phi(f)$ is $\varphi_\beta(f)$ by Step 3. (Sm3): for $s \in \sigma$, $X_s \in A_{\mathrm{wt}(s)}$ has coefficient 1 at X_s and 0 at every other variable. (Sm4): let $f \in A$ with $\varphi_\beta(f) = 0$ and all coefficients of degree one zero, and write $f = \sum_k f_k$, $f_k \in A_k$. The constant term and the coefficient of X_s in f are those of f_0 and of $f_{\mathrm{wt}(s)}$, and the other components have none; so every monomial of every f_k has degree at least 2. Assigning each term of f_k to the first variable occurring in it gives $f_k = \sum_s X_s h_s$ with $h_s \in A_{k-\mathrm{wt}(s)}$ without constant term. Both X_s and h_s lie in $\mathfrak{m}_0 = \ker\varphi_\beta$ (Step 3), so $f_k \in \mathfrak{m}_0^2$ and $f \in \mathfrak{m}_0^2 \subseteq \mathrm{Sq}(\varphi_\beta)$. Hence ϕ is a chart and (A, φ_β) is smooth with tangent dimensions td; $\mathrm{td}(j) = 0$ for $|j| > 2$ because wt takes values in $\{-2, \dots, 2\}$. □

43.3 Rigidity and the Euler-characteristic count

This subsection proves the two facts that make the model satisfy the criterion. The first is the rigidity clause Proposition 43.29: if R^0 is finite over $\mathcal{O}$ and the adjoint Bloch–Kato Selmer groups vanish at the two-signed points, the equations span rationally in weights -2, -1, 0, and (Gc2)–(Gc4) hold. Its main input is Proposition 43.32: the Bloch–Kato cocycles of the Eisenstein adjoint of weights -2, -1 and 0 are coboundaries. Here Part VII enters: a cocycle of a Tate twist that is a coboundary locally above ℓ is a rational coboundary when the strict Tate–Shafarevich group has finite length (Lemma 43.33), and that finiteness is Proposition 40.3. The second fact is the count Lemma 43.34 of obstructions against framed Selmer cocycles in each weight, which follows from an Euler-characteristic formula for Selmer complexes over $\mathbb{Q}$ with tame local conditions (Lemma 43.35, Lemma 43.36). The formula Lemma 43.35 is used again in the dyadic case and, for auxiliary fields, in Part IX.

Proposition 43.29. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking, and (R, r) and $(A, \varphi_0, \bar{u}, q)$ as in Proposition 43.12, for some choice of the objects there. If R^0 is a finitely generated $\mathcal{O}$-module and $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$ for every two-signed point φ of (R, r), then $\bar{u}_{-1}$, $\bar{u}_{-2}$, $\bar{u}_0$ span rationally in degrees -1, -2, 0 respectively, and $(A, \varphi_0, \bar{u})$ satisfies (Gc2), (Gc3) and (Gc4).*

Proof. Write $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$, $a_s(h)$ for the coefficient of X_s in $h \in P$, $\bar{h}$ for the image of $h \in A_\pi$ in A, $t_\star = \Psi(g_\star)$, and $e_s = \pi_R(X_s)$; since $\pi(X_s) = y_{g_s, a_s, b_s}$ (Proposition 43.9, (Ol3) of Lemma 43.7 and (Bx2) of Proposition 43.5) and $\pi_R = p \circ \pi$, $e_s = \underline{r}(g_s)_{a_s b_s} - \underline{r_0}(g_s)_{a_s b_s}$, the second term a constant, zero unless $a_s = b_s$. The ideal $\ker\pi_R$ is generated by elements $v_1, \dots, v_m$ of $\mathfrak{a} \cap A_\pi$ of single weights and the entries of u (Proposition 43.12); $\ker q = I(\bar{u})$ by (Mp1), and $\bar{v}_i = 0$. For $h = \sum_i c_i v_i \in \mathfrak{a}$, $h_{(j)} = \sum_i (c_i)_{(j-\kappa_i)} v_i \in \mathfrak{a}$ (κ_i the weight of v_i).

Step 0: points and evaluation. Let φ be a point of (R,r) and $z_s=\varphi(e_s)$. Since $r'\mapsto\varphi(r')$ maps $\mathcal{O}+\mathfrak{m}_R$ into the closed unit disc and $\mathfrak{m}_R$ is finitely generated with $|\varphi|<1$ on it, $|\varphi(\mathfrak{m}_R^N)|_\ell\le\kappa^N$ for some $\kappa<1$; so φ is continuous, and $\varphi\circ\pi_R$ and ev_z (evaluation at z, $|z_s|<1$) are continuous homomorphisms agreeing on polynomials: $\varphi\circ\pi_R=\mathrm{ev}_z$. In particular $\varphi(R)$ lies in the integers of the finite extension $E_\varphi=E_{\mathcal{O}}(z_s:s\in\sigma)$, and $\varphi\circ q$ is induced by $\mathrm{ev}_z|_{A_\pi}$; for $\varphi=\varphi_{\mathrm{Eis}}$, $z=0$ and $\varphi_0(\bar h)$ is the constant term of h. For $f\in P_j$ the Euler identity $\sum_s\mathrm{wt}(s)X_s\partial_s f=jf$ holds monomial by monomial.

Step 1: (Gc2). R^0 is a finitely generated $\mathcal{O}$-module, so compact in its ϖ-adic topology; the inclusion into R is continuous ($\varpi R^0\subseteq\mathfrak{m}_R$), so R^0 is compact, hence closed, in R. For a monomial of weight 0, $\pi_R(X^n)=\prod_s e_s^{n_s}$; expanding, each term is a constant times a product of entries whose weights add up to 0 (the constants sit on the diagonal), so π_R maps the weight-0 polynomials into R^0. As P_0 is the closure of its polynomials and π_R is continuous, $q(A_0)=\pi_R(P_0)\subseteq R^0$, a finitely generated $\mathcal{O}$-module ($\mathcal{O}$ is Noetherian). Since $\ker q=I(\bar u)$, $q(A_0)$ is isomorphic to the image of A_0 in $A/I(\bar u)$: (Gc2) holds, and (Pq5) applies to every point on $\bar u$.

Step 2: the only point of (R,r) that is upper and lower is φ_{Eis}. Let φ be such a point and $E=E_\varphi$. For $g\in G_K$ the entries of non-zero weight of $\rho_\varphi(g)$ vanish, so $\rho_\varphi=\mathrm{diag}(\chi_1,\chi_2,\chi_3)$ with continuous characters $\chi_a\colon G_K\to\mathcal{O}_E^\times$, $\chi_a\equiv\psi_a \bmod \mathfrak{m}_E$ (entries of $\underline{r}(g)-\underline{r_0}(g)$ lie in $\mathfrak{m}_R$). Put $\lambda_a=\chi_a\psi_a^{-1}\colon G_K\to 1+\mathfrak{m}_E$. (i) At ℓ: $\ell\nmid d_K$ (Ue6), so $I_\ell\subseteq G_K$. By (Ed3), $r|_{D_\ell}=f_R\circ r_\ell^\square$ with f_R a morphism killing I_ℓ^{ord}. By Lemma 43.17 (Ol1) there is an integral test ring $A'\supseteq\varphi(R)$ with $\varphi(\mathfrak{m}_R)\subseteq\mathfrak{m}_{A'}$, and (Ol2) applied to $x=\varphi\circ f_R$ shows that for $g\in I_\ell$ the matrix $\mathrm{diag}(\chi_a(g))$ is conjugate to an upper triangular matrix with diagonal $\psi_1(g),\psi_2(g),\psi_3(g)$; so for each a there is k with $\chi_a(g)=\psi_k(g)$, and then $\Psi(g)^{a-k}=\psi_k(g)/\psi_a(g)\equiv 1$. On I_ℓ, $\Psi=\chi_\ell\chi_{\mathrm{cyc}}^e$ (the other components of χ are unramified at ℓ), so $\bar\Psi^2=\bar\chi_{\mathrm{cyc}}^{2e}$ by (Ue4); $\bar\chi_{\mathrm{cyc}}(I_\ell)=\mathbb{F}_\ell^\times$, so by (Ue9) there is $s_0\in I_\ell$ with $\bar\Psi(s_0)^2\ne 1$. If $\bar\Psi(g)^2\ne 1$, then $k=a$ ($a-k\in\{\pm1,\pm2\}$ would give $\bar\Psi(g)^2=1$); if $\bar\Psi(g)^2=1$, then $\bar\Psi(gs_0)^2\ne 1$ and $\chi_a(g)=\chi_a(gs_0)/\chi_a(s_0)=\psi_a(g)$. So $\lambda_a=1$ on I_ℓ. (ii) Away from ℓ: for a place $\bar v\nmid\ell$, (Ed2) gives $r(g)=1$ on $N'=\{g\in I_{\bar v}:\bar r_0(g)=1\}\subseteq G_K$, and so does (Ed2) for $r_0=\varphi_{\mathrm{Eis}}\circ r$ ((Bx3)); hence $\lambda_a(N')=1$, and $\lambda_a|_{I_{\bar v}\cap G_K}$ factors through $(I_{\bar v}\cap G_K)/N'$, which embeds in the image of $\bar r_0$, a finite group of order prime to ℓ (it divides $2(\#\mathbb{F}_{\mathcal{O}}-1)$, ℓ odd); a homomorphism from it to the pro-ℓ group $1+\mathfrak{m}_E$ is trivial. (iii) The places $g\bar\ell$: $I_{g\bar\ell}=gI_\ell g^{-1}$. If $g\in G_K$, $\lambda_a(gxg^{-1})=\lambda_a(x)$. As $r(c)=(1,-1)$ by (Ed1), $\rho_\varphi(cxc)=\theta(\rho_\varphi(x))$ and $\theta(\mathrm{diag}(\alpha_1,\alpha_2,\alpha_3))=\mathrm{diag}(\alpha_3^{-1},\alpha_2^{-1},\alpha_1^{-1})$, so $\chi_a(cxc)=\chi_{4-a}(x)^{-1}$, likewise $\psi_a(cxc)=\psi_{4-a}(x)^{-1}$ ($\Psi(c)=1$), and $\lambda_a(cxc)=\lambda_{4-a}(x)^{-1}$. Every $g\in G_{\mathbb{Q}}$ lies in $G_K\sqcup G_Kc$, so $\lambda_a=1$ on every $I_{g\bar\ell}$. So λ_a is trivial on the inertia groups of K at all finite places (K has no real place), hence factors through the Galois group of the Hilbert class field of K, of order h_K, prime to ℓ by (Ue6), into the pro-ℓ group $1+\mathfrak{m}_E$: $\lambda_a=1$. Hence $r_\varphi=r_0$ on G_K, and at c both are $(1,-1)$, so $r_\varphi=r_0$ on $G_K\sqcup G_Kc=G_{\mathbb{Q}}$. Then $z_s=0$ for all s, $\varphi\circ\pi_R=\mathrm{ev}_0=\varphi_{\mathrm{Eis}}\circ\pi_R$ (Step 0), and $\varphi=\varphi_{\mathrm{Eis}}$ as π_R is onto.

Step 3: (Gc3). Let ψ be a point on $\bar u$ that is negative- and positive-vanishing. By (Pq5), $\psi=t\cdot(\varphi\circ q)$ for a point φ of (R,r); $\varphi\circ q$ is again negative- and positive-vanishing, so φ is upper and lower by (Pq4), $\varphi=\varphi_{\mathrm{Eis}}$ by Step 2, and $\psi=t\cdot\varphi_0=\varphi_0$ ($\varphi_0(A_j)=0$ for $j\ne 0$). So no point $\varphi_1\ne\varphi_0$ as in (Gc3) exists, and (Gc3) holds.

Step 4: the normalisation of a tangent coboundary. Let φ be a point, $E\supseteq E_\varphi$ finite, $F\colon R\to E[\epsilon]$ an $\mathcal{O}$-algebra homomorphism lifting φ with $F(\mathfrak{m}_R^N)\to 0$ (so F is continuous), y the cocycle of Lemma 43.31, and suppose $y=dX$ for some $X\in\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ (action of $\mathrm{ad}\,r_\varphi$, $P_g=\underline{r_\varphi}(g)$). Then $X=x\,\mathrm{diag}(1,0,-1)$ for some x. Indeed $\underline{r}(c)=1$ gives $y(c)=0$, i.e. $c\cdot X=X$, i.e. $X_{ab}=-X_{4-b,4-a}$ ($P_c=1$). Let $Q=P_{g_\star}$; then $\underline{r_\varphi}(cg_\star^{-1}c)=\theta(Q^{-1})=JQ^tJ$, and the GL-parts of $F(r(g_\star))$ and $F(r(cg_\star^{-1}c))$ are $Q+\epsilon[Q,X]$ (as $y(g_\star)Q=QX-XQ$) and

$J^t(Q+\epsilon[Q,X])J = Q' + \epsilon[Q',X]$, $Q' = JQ^tJ$, using $JX^tJ = -X$. By (Ed1) the entries $(1,2)$, $(2,1)$ of $\Delta = Q - Q'$ and of $[\Delta, X]$ vanish. Since $\Delta_{ab} = Q_{ab} - Q_{4-b,4-a}$, also $\Delta_{23} = -\Delta_{12} = 0$, $\Delta_{32} = 0$, $\Delta_{13} = \Delta_{31} = \Delta_{22} = 0$: $\Delta = \mathrm{diag}(d_\star, 0, -d_\star)$ with $d_\star \equiv t_\star - t_\star^{-1}$ modulo the maximal ideal of $\mathcal{O}_E$, a unit as $t_\star^2 - 1 \in \mathcal{O}^\times$. So $d_\star X_{12} = -d_\star X_{21} = 0$, and with $X_{ab} = -X_{4-b,4-a}$ all off-diagonal entries and X_{22} vanish and $X_{33} = -X_{11}$. For such X, $JX^tJ = -X$, so $g\cdot X = P_g X P_g^{-1}$ for both signs, and

$$F(\underline{r}(g)_{ab}) - \varphi(\underline{r}(g)_{ab}) = \epsilon\,(P_gX - XP_g)_{ab} = -\epsilon\, x\,\mathrm{wt}(a,b)\,\varphi(\underline{r}(g)_{ab}).$$

Step 5: (Gc4). Let ψ be a two-signed point on $\bar{u}$ and D a ψ-derivation vanishing on $I(\bar{u})$. By (Pq5), $\psi = t\cdot(\varphi\circ q)$ with φ a point of (R,r); $D'(f) = t^{-j}D(f)$ $(f\in A_j)$ is a $(\varphi\circ q)$-derivation vanishing on $I(\bar{u})$ (which is spanned by its homogeneous elements), and $D\mapsto D'$ is linear and injective; so it suffices to treat $t=1$. $\varphi\circ q$ is two-signed, so φ is two-signed by (Pq4). By Step 0 and Lemma 43.30 (for $h\mapsto D(\bar{h})$ on A_π), $D(\bar{h}) = \tilde{D}(h)$ for $h\in A_\pi$, where $\tilde{D}(h) = \sum_s(\partial_s h)(z)w_s$, $w_s = D(\bar{X}_s)$, is an ev_z-derivation of P. $\tilde{D}$ kills the v_i $(\bar{v}_i = 0)$ and the entries of u, which ev_z also kills; so $\tilde{D}(\ker\pi_R) = 0$ and $\tilde{D} = \delta\circ\pi_R$ for a φ-derivation δ of R with values in $E = E_\varphi(w_s : s\in\sigma)$. Since $|\tilde{D}(h)|_\ell \le \max_s|w_s|\,\kappa^{N-1}$ for $h\in\mathfrak{m}_P^N$ $(\kappa = \max(|\varpi|,|z_s|))$, and $\pi_R(\mathfrak{m}_P^N) = \mathfrak{m}_R^N$, $F = \varphi + \epsilon\delta\colon R\to E[\epsilon]$ is an $\mathcal{O}$-algebra homomorphism with $F(\mathfrak{m}_R^N)\to 0$; so $g\mapsto F(\underline{r}(g)_{ab})$ is continuous. By Lemma 43.31 its cocycle y has class in $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$, so $y = dX$, and Step 4 gives x with $\delta(\underline{r}(g)_{ab}) = -x\,\mathrm{wt}(a,b)\varphi(\underline{r}(g)_{ab})$. Hence $w_s = \delta(e_s) = -x\,\mathrm{wt}(s)z_s$ (for $\mathrm{wt}(s)=0$ both sides vanish, for $\mathrm{wt}(s)\neq 0$ the constant in e_s is 0), and for $h\in P_j\cap A_\pi$, by the Euler identity,

$$D(\bar{h}) = -x\sum_s \mathrm{wt}(s)z_s(\partial_s h)(z) = -x\,j\,h(z) = -x\,\mathrm{Eu}_\varphi(\bar{h}),\qquad \mathrm{Eu}_\varphi(\bar{f}) = j\,\varphi(q(\bar{f}))\ \ (\bar{f}\in A_j).$$

So every such D is a multiple of the fixed map Eu_φ, and any two are linearly dependent over $\overline{\mathbb{Q}}_\ell$: (Gc4).

Step 6: rational spanning in degree $j\in\{-2,-1,0\}$. (a) For $\bar{f}\in A_j\cap\mathfrak{m}_0$ with $f\in P_j$, f has no constant term and its linear terms are in the variables of weight j; $f - \sum_{\mathrm{wt}(s)=j}a_s(f)X_s = \sum_s X_s h_s$ with $h_s\in P_{j-\mathrm{wt}(s)}$ without constant term (assign each monomial to its first variable, take weight components), whose image lies in $\mathfrak{m}_0^2\subseteq\mathrm{Sq}(\varphi_0)$. So Cot_j is spanned over $\mathcal{O}$ by the images of the $\bar{X}_s$, $\mathrm{wt}(s) = j$. (b) Let $\Lambda\subseteq E_{\mathcal{O}}^{\mathrm{wt}^{-1}(j)}$ be the span of the vectors $(a_s(h))_{\mathrm{wt}(s)=j}$ for h an entry $u_{j,i}$ of u or $h\in\mathfrak{a}\cap P_j$. If Λ is everything, then for each s of weight j there are $c_s\in\mathcal{O}\setminus\{0\}$, $b_i\in\mathcal{O}$ and $h\in\mathfrak{a}\cap P_j$ such that $c_sX_s - \sum_i b_iu_{j,i} - h\in P_j$ has no constant and no linear term; by (a) its image $c_s\bar{X}_s - \sum_i b_i\bar{u}_{j,i}$ $(\bar{h}=0)$ lies in $\mathrm{Sq}(\varphi_0)$, so c_s times the class of $\bar{X}_s$ lies in $\mathrm{Cot}(\bar{u}_j)$, and with (a), $\bar{u}_j$ spans rationally in degree j. (c) Suppose $\Lambda\neq E_{\mathcal{O}}^{\mathrm{wt}^{-1}(j)}$: there are $\lambda_s\in\mathcal{O}$ $(\mathrm{wt}(s)=j)$, not all 0, with $\sum_s\lambda_s a_s(h) = 0$ for those h. Put $\tilde{D}(h) = \sum_{\mathrm{wt}(s)=j}\lambda_s a_s(h)$ on P, an $\mathcal{O}$-linear derivation at the constant term ev_0. It kills the $u_{j',i}$ for $j'\neq j$ (no linear terms in variables of weight j), the $u_{j,i}$, and every $h\in\mathfrak{a}$ (its linear terms in weight-j variables are those of $h_{(j)}\in\mathfrak{a}\cap P_j$); as ev_0 kills $\ker\pi_R$, $\tilde{D}(\ker\pi_R) = 0$ and $\tilde{D} = \delta\circ\pi_R$ with $\delta\colon R\to\mathcal{O}$ a φ_{Eis}-derivation. Then $F = \varphi_{\mathrm{Eis}} + \epsilon\delta\colon R\to\mathcal{O}[\epsilon]$ is a morphism of $\mathrm{CNL}_{\mathcal{O}}$, so $F\circ r$ satisfies (Ed1); $F(\mathfrak{m}_R^N)\subseteq\varpi^{N-1}\mathcal{O}[\epsilon]$, and φ_{Eis} is a point with $r_{\varphi_{\mathrm{Eis}}} = r_0$. By Lemma 43.31 (with $E = E_{\mathcal{O}}$), the cocycle y, $F(\underline{r}(g)) = (1+\epsilon y(g))\underline{r_0}(g)$, is a Bloch–Kato cocycle for $\mathrm{ad}\, r_0$. By (Pq3), $\underline{r}(g)_{ab} = \pi_R(h)$ with $h\in P_{\mathrm{wt}(a,b)}$, so $\delta(\underline{r}(g)_{ab}) = \tilde{D}(h) = 0$ unless $\mathrm{wt}(a,b) = j$; as $\underline{r_0}(g)$ is diagonal, y takes values in $\mathfrak{g}_j(E_{\mathcal{O}})$. By Proposition 43.32, $y = dX$ with $X\in\mathfrak{g}_j(E_{\mathcal{O}})$, and $y(c) = 0$ gives $c\cdot X = X$. If $j=-2$: $c\cdot E_{31} = -E_{31}$, so $X = 0$. If $j=0$: G_K acts trivially on $\mathfrak{g}_0$ and c fixes X, so $dX = 0$. If $j=-1$: $c\cdot(\alpha E_{21} + \beta E_{32}) = -(\alpha E_{32} + \beta E_{21})$, so $X = b(E_{21} - E_{32})$, $y(g_\star) = (t_\star^{-1} - 1)X$, and the ϵ-part of the entry $(2,1)$ of $\underline{Fr}(g_\star) - \underline{Fr}(cg_\star^{-1}c)$, which is $y(g_\star)\mathrm{T}(t_\star) - \mathrm{T}(t_\star)^{-1}Jy(g_\star)^tJ$, equals $(t_\star+1)y(g_\star)_{21} = (t_\star+1)(t_\star^{-1}-1)b$; it vanishes

by (Ed1), and $(t_\star+1)(t_\star^{-1}-1) = -t_\star^{-1}(t_\star^2-1) \neq 0$, so $b=0$. In all cases $y=0$, so δ kills all entries, $\lambda_s = \tilde{D}(X_s) = \delta(e_s) = 0$ for all s: a contradiction. Hence $\Lambda = E_{\mathcal{O}}^{\mathrm{wt}^{-1}(j)}$ and $\bar{u}_j$ spans rationally in degree j, for $j = -1, -2, 0$. □

Lemma 43.30. *Let $\mathcal{O}$ be a coefficient ring, σ a finite set,* $\mathrm{wt}\colon \sigma \to \mathbb{Z}$ *a map, $P = \mathcal{O}[[X_s : s \in \sigma]]$ and $A_\pi = \sum_{j\in\mathbb{Z}} \mathcal{O}[[X_\sigma]]_j \subseteq P$. Let $z = (z_s) \in \overline{\mathbb{Q}}_\ell^{\,\sigma}$ with $|z_s|_\ell < 1$ for every s, and* $\mathrm{ev}_z\colon P \to \overline{\mathbb{Q}}_\ell$ *the evaluation $f \mapsto f(z)$. If $D\colon A_\pi \to \overline{\mathbb{Q}}_\ell$ is $\mathcal{O}$-linear with $D(fg) = \mathrm{ev}_z(f)D(g) + \mathrm{ev}_z(g)D(f)$ for all $f, g \in A_\pi$, then*

$$D(f) = \sum_{s\in\sigma} (\partial_s f)(z)\, D(X_s) \qquad (f \in A_\pi),$$

where ∂_s is the formal partial derivative.

Proof. The z_s lie in a finite extension E' of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_{E'} \supseteq \mathcal{O}$, complete, so ev_z is defined (each z^n has $|z^n|_\ell \leq \max_s |z_s|_\ell^{|n|}$), and it is an $\mathcal{O}$-algebra homomorphism. Write $P_j = \mathcal{O}[[X_\sigma]]_j$ and $E_j = \{n \in \mathbb{N}^\sigma : \sum_s n_s \mathrm{wt}(s) = j\}$, ordered componentwise.

Step 1: generators of the weight pieces. By Dickson's lemma the set Min_j of minimal elements of E_j is finite. Every $n \in E_j$ dominates some $m \in \mathrm{Min}_j$, and $n - m \in E_0$; choosing one such $m(n)$ for each n, every $f = \sum_n c_n X^n \in P_j$ is $\sum_{m\in\mathrm{Min}_j} X^m h_m$ with $h_m = \sum_{m(n)=m} c_n X^{n-m} \in P_0$. Let $m_1, \ldots, m_k$ be the minimal elements of $E_0 \setminus \{0\}$; by induction on $|n|$ every $n \in E_0$ is $\sum_i e(n)_i m_i$ for some $e(n) \in \mathbb{N}^k$, and $n \mapsto e(n)$ (one choice for each n) is injective. So the continuous homomorphism $\theta\colon \mathcal{O}[[Y_1, \ldots, Y_k]] \to P$, $Y_i \mapsto X^{m_i}$, maps $\sum_n c_n Y^{e(n)}$ to $\sum_n c_n X^n$, and θ is onto P_0; likewise $\theta' = \mathcal{O}_{E'} \otimes \theta$ maps $\mathcal{O}_{E'}[[Y]] = \mathcal{O}_{E'} \otimes_{\mathcal{O}} \mathcal{O}[[Y]]$ onto $\mathcal{O}_{E'} \otimes_{\mathcal{O}} P_0$ ($\mathcal{O}_{E'}$ is free of finite rank over $\mathcal{O}$).

Step 2: the difference is a derivation vanishing on the variables. The map given by $\tilde{D}(f) = \sum_s (\partial_s f)(z) D(X_s)$ is an $\mathcal{O}$-linear ev_z-derivation of P (Leibniz rule for ∂_s; ev_z is multiplicative), and $\tilde{D}(X_s) = D(X_s)$. So $\Delta = D - \tilde{D}|_{A_\pi}$ is an $\mathcal{O}$-linear ev_z-derivation of A_π with $\Delta(X_s) = 0$ for every s; by the Leibniz rule $\Delta(X^n) = 0$ for every monomial, and $\Delta(1) = 0$. Extend Δ and ev_z to $\mathcal{O}_{E'} \otimes_{\mathcal{O}} A_\pi$ by $\Delta(\lambda \otimes f) = \lambda\Delta(f)$, $\mathrm{ev}_z(\lambda \otimes f) = \lambda\, \mathrm{ev}_z(f)$: a ring homomorphism and a derivation at it, killing $\mathcal{O}_{E'} \otimes 1$.

Step 3: $\Delta = 0$ on P_0. Let $g \in \mathcal{O}[[Y]]$ and $y^* = (z^{m_i})_i$, with $|y_i^*|_\ell < 1$. The substitution $Y \mapsto Y' + y^*$ is an automorphism of $\mathcal{O}_{E'}[[Y]]$, so $g(Y) - g(y^*) = \sum_i (Y_i - y_i^*) g_i(Y)$ with $g_i \in \mathcal{O}_{E'}[[Y]]$ (expand $g(Y' + y^*)$, remove the constant term $g(y^*)$, assign each remaining monomial to its first variable, and substitute back). Applying the ring homomorphism θ',

$$\theta(g) - g(y^*) = \sum_{i=1}^{k} (X^{m_i} - y_i^*)\, \theta'(g_i) \quad \text{in } \mathcal{O}_{E'} \otimes_{\mathcal{O}} P_0,$$

and applying Δ: $\Delta(\theta(g)) = \sum_i (\Delta(X^{m_i})\, \mathrm{ev}_z(\theta'(g_i)) + (z^{m_i} - y_i^*)\Delta(\theta'(g_i))) = 0$. As θ is onto P_0, $\Delta(P_0) = 0$.

Step 4: $\Delta = 0$ on A_π. For $f \in P_j$ write $f = \sum_{m\in\mathrm{Min}_j} X^m h_m$ (Step 1); then $\Delta(f) = \sum_m (\Delta(X^m)\mathrm{ev}_z(h_m) + \mathrm{ev}_z(X^m)\Delta(h_m)) = 0$ by Steps 2 and 3. Every element of A_π is a finite sum of elements of the P_j. □

Lemma 43.31. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking and (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$. Let $E \subseteq \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ containing $\mathcal{O}$, $E[\epsilon] = E[X]/(X^2)$, and $F\colon R \to E[\epsilon]$ an $\mathcal{O}$-algebra homomorphism whose reduction φ modulo ϵ is a point of (R, r) and such that $g \mapsto F(\underline{r}(g)_{ab})$ is continuous on $G_\mathbb{Q}$ for $1 \leq a, b \leq 3$. Define $y\colon G_\mathbb{Q} \to \mathrm{M}_3(E)$ by*

$$F(\underline{r}(g)) = (1 + \epsilon\, y(g))\, \underline{r_\varphi}(g) \qquad (g \in G_\mathbb{Q}).$$

Then y is a continuous 1-cocycle of $G_{\mathbb{Q}}$ with values in $\operatorname{ad} r_\varphi$, and it is a Bloch–Kato cocycle; in particular its class lies in $H^1_f(\mathbb{Q}, \operatorname{ad} r_\varphi)$.

Proof. Write $P_g = \underline{r_\varphi}(g)$, $\varsigma_g = \eta_K(g)$ and $g \cdot X$ for the action of $\operatorname{ad} r_\varphi$; $F \circ r \colon G_{\mathbb{Q}} \to \mathcal{G}_3(E[\epsilon])$ is a homomorphism with reduction r_φ.

Step 1: cocycle and continuity. For $Y' \in \mathrm{M}_3(E)$ and $P \in \mathrm{GL}_3(E)$, $\theta((1+\epsilon Y')P) = J(1 - \epsilon\, {}^tY')\, {}^tP^{-1}J = (1 - \epsilon JY'\, {}^tJ)\theta(P)$ ($J^2 = 1$). Multiplying in $\mathcal{G}_3$, $(A,\varsigma)(B,\tau) = (A\theta^{\varsigma}(B), \varsigma\tau)$, the GL-part of $F(r(g))F(r(h))$ is $(1+\epsilon y(g))P_g(1+\epsilon Z)\theta^{\varsigma_g}(P_h)$ with $Z = y(h)$ if $\varsigma_g = 1$, $Z = -Jy(h)^tJ$ if $\varsigma_g = -1$; since $P_g Z P_g^{-1} = g \cdot y(h)$ and $P_{gh} = P_g\theta^{\varsigma_g}(P_h)$, this gives $y(gh) = y(g) + g \cdot y(h)$. Continuity: $y(g)$ is the ϵ-part of $F(\underline{r}(g))$ times P_g^{-1}, and both are continuous by hypothesis (the inverse through the adjugate).

Step 2: averaging. If a 1-cocycle z of a profinite group Γ with values in a $\mathbb{Q}$-vector space M (with Γ acting linearly) vanishes on an open normal subgroup Γ' of index n, then $z = dW$ with $W \in M$: indeed $z(gh) = z(g) + g \cdot z(h) = z(g)$ for $h \in \Gamma'$, and summing $z(g\tau) = z(g) + g \cdot z(\tau)$ over a set $\mathcal{T}$ of representatives of Γ/Γ' (so is $g\mathcal{T}$) gives $W' = nz(g) + g \cdot W'$ for $W' = \sum_{\tau\in\mathcal{T}} z(\tau)$, so $z(g) = g \cdot W - W$ with $W = -n^{-1}W'$.

Step 3: places $v \nmid \ell$. Archimedean: a decomposition group at ∞ is $\{1, c'\}$ with c' a complex conjugation, of order 2; by Step 2 with $\Gamma' = \{1\}$, $y|_{\{1,c'\}}$ is a coboundary, so its class is 0, as Definition 22.2 requires. Finite $v = p \neq \ell$: let $D = D_j$ be a decomposition group at p, with inertia $I_j = I_{\bar v}$ for the place $\bar v$ of $\overline{\mathbb{Q}}$ induced by j. By (Ed2) for r, $r(g) = 1$ for $g \in N' = \{g \in I_{\bar v} : \bar r_0(g) = 1\}$, so $F(\underline{r}(g)) = 1 = P_g$ and $y(g) = 0$ there. The group N' is the kernel of the continuous homomorphism $\bar r_0|_{I_{\bar v}}$ to a finite group, an open normal subgroup of $I_{\bar v}$; by Step 2 applied to $y|_{I_{\bar v}}$ there is $x \in \mathrm{M}_3(E)$ with $y(g) = g \cdot x - x$ for $g \in I_j$, the condition of Definition 22.2 at v.

Step 4: the decomposition group D_ℓ. By (Ed3), $r|_{D_\ell} = f_R \circ r_\ell^{\square}$ for a morphism $f_R \colon R_\ell^{\square} \to R$ killing I_ℓ^{ord}; it induces $i \colon R_\ell^{\mathrm{ord}} \to R$ with $\underline{r}(g) = i(\underline{r_\ell^{\mathrm{ord}}}(g))$ for $g \in D_\ell$, a local homomorphism. Let $f = F \circ i \colon R_\ell^{\mathrm{ord}} \to E[\epsilon]$ and fix an embedding $\mathrm{emb}_\ell \colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ inducing $\bar\ell$. The reduction of f is $\varphi \circ i$, and $|\varphi(i(y'))|_\ell < 1$ for y' in the maximal ideal of R_ℓ^{ord}, because $i(y') \in \mathfrak{m}_R$ and φ is a point; $g \mapsto f(\underline{r_\ell^{\mathrm{ord}}}(g)_{ab}) = F(\underline{r}(g)_{ab})$ is continuous. So Lemma 43.22 applies to f; its ρ_0 is P_g, its action on $\overline{\mathrm{M}_3(E)}$ is that of $\operatorname{ad} r_\varphi$ restricted to D_ℓ, and its y is our $y|_{D_\ell}$. It gives $Y \in \mathrm{M}_3(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}} \subseteq \operatorname{ad} r_\varphi \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(k) \otimes 1 = k \cdot Y - Y$ for $k \in D_\ell = D_{\mathrm{emb}_\ell}$, B_{cris} acted on through emb_ℓ.

Step 5: the other decomposition groups above ℓ. Every embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}$ is $j = \mathrm{emb}_\ell \circ \alpha$ with $\alpha \in G_{\mathbb{Q}}$ (both have image the algebraic closure of $\mathbb{Q}$ in $\overline{\mathbb{Q}}_\ell$). Put $g = \alpha^{-1}$. If $\hat h \in \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ restricts along j to h, i.e. $\hat h \circ j = j \circ h$, then $\hat h \circ \mathrm{emb}_\ell = \mathrm{emb}_\ell \circ (\alpha h \alpha^{-1})$; so $D_j = gD_\ell g^{-1}$, and $h = gkg^{-1} \in D_j$ acts on B_{cris} as $k \in D_\ell$ does through emb_ℓ. The $\mathbb{Q}_\ell$-linear map $\Phi(X \otimes b) = (g \cdot X) \otimes b$ satisfies $\Phi(k \cdot w) = h \cdot \Phi(w)$ for $h = gkg^{-1}$, the left side for D_{emb_ℓ}, the right side for D_j. By Step 1 and $y(g^{-1}) = -g^{-1} \cdot y(g)$, $y(h) = y(g) + g \cdot y(k) - h \cdot y(g)$. With $Y' = \Phi(Y) - y(g) \otimes 1$ and Step 4,

$$y(h) \otimes 1 = \Phi(k \cdot Y - Y) - \big(h \cdot (y(g) \otimes 1) - y(g) \otimes 1\big) = h \cdot Y' - Y' \qquad (h \in D_j).$$

So the condition of Definition 22.2 holds at every decomposition group above ℓ, and with Step 3 at every place: y is a Bloch–Kato cocycle. □

Proposition 43.32. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $E \subseteq \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ containing $\mathcal{O}$. Let $G_{\mathbb{Q}}$ act on $\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ through r_0: if $r_0(g) = (P, \varsigma)$, by $X \mapsto PXP^{-1}$ if $\varsigma = 1$ and by $X \mapsto -PJ\, {}^tXJP^{-1}$ if $\varsigma = -1$; for $j \in \mathbb{Z}$ let $\mathfrak{g}_j(E) \subseteq \mathrm{M}_3(E)$ be the matrices supported in the positions of weight j. Let*

$j \in \{-2,-1,0\}$ *and let* $y\colon G_{\mathbb{Q}} \to \mathfrak{g}_j(E)$ *be a continuous* 1*-cocycle which is a Bloch–Kato cocycle for this representation on* $\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$*. Then there is* $X \in \mathfrak{g}_j(E)$ *with* $y(g) = g \cdot X - X$ *for every* $g \in G_{\mathbb{Q}}$*.*

Proof. Write $g \cdot X$ for the action and dX for $g \mapsto g \cdot X - X$. Let $L = K(\zeta_{\ell N}) \subset \overline{\mathbb{Q}}$; it is Galois over $\mathbb{Q}$ of some degree n, totally complex, contains K and a primitive ℓ-th root of unity, and χ, which factors through $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$, is trivial on G_L. So for $g \in G_L \subseteq G_K$ (sign 1), $r_0(g) = (\mathrm{T}(\chi_{\mathrm{cyc}}(g)^e), 1)$ and g multiplies the entry (a,b) by $\chi_{\mathrm{cyc}}(g)^{e\,\mathrm{wt}(a,b)}$; on $\mathfrak{g}_j(\overline{\mathbb{Q}}_\ell)$, G_L acts by the scalar $\chi_{\mathrm{cyc}}(g)^{-k}$ with $k = -ej \geq 0$. Put $V' = \mathfrak{g}_j(E)$, a finite-dimensional $\mathbb{Q}_\ell$-vector space.

Step 1: averaging. If a 1-cocycle z of $G_{\mathbb{Q}}$ with values in a $G_{\mathbb{Q}}$-stable $\mathbb{Q}_\ell$-subspace M vanishes on an open normal subgroup Γ' of index m, then $z = dW$ with $W \in M$: $z(gh) = z(g)$ for $h \in \Gamma'$, and summing $z(g\tau) = z(g) + g \cdot z(\tau)$ over representatives τ of $G_{\mathbb{Q}}/\Gamma'$ gives $W' = mz(g) + g \cdot W'$ with $W' = \sum_\tau z(\tau)$, so $W = -m^{-1}W'$. V' is $G_{\mathbb{Q}}$-stable (the action is diagonal on G_K, and c maps the entry (a,b) to $(4-b, 4-a)$, of the same weight).

Step 2: local behaviour of $y|_{G_L}$*.* (a) Let $\bar{v}$ be a place of $\overline{\mathbb{Q}}$ above a prime $p \neq \ell$. By the Bloch–Kato condition at p (for the decomposition group of an embedding inducing $\bar{v}$), $y(g) = g \cdot x - x$ for $g \in I_{\bar{v}}$, some $x \in \mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$. On $I_{\bar{v}} \cap G_L$, χ_{cyc} is trivial ($p \neq \ell$), so $G_L \cap I_{\bar{v}}$ acts trivially on $\mathrm{M}_3(\overline{\mathbb{Q}}_\ell)$ and $y = 0$ there. (b) Let $D = D_{j'}$ be a decomposition group at ℓ for an embedding j', $D' = D \cap G_L$, the decomposition group of L for j' at the place w it induces, identified with G_{L_w}, and $I' = I_{j'} \cap G_L$ its inertia. The Bloch–Kato condition gives $Y \in \mathrm{M}_3(\overline{\mathbb{Q}}_\ell) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g) \otimes 1 = g \cdot Y - Y$ on D. Let $p_j\colon \mathrm{M}_3(\overline{\mathbb{Q}}_\ell) \to \mathfrak{g}_j(\overline{\mathbb{Q}}_\ell)$ be the projection to the entries of weight j and $\pi\colon \overline{\mathbb{Q}}_\ell \to E$ a $\mathbb{Q}_\ell$-linear map with $\pi|_E = \mathrm{id}$ (a complement of E exists); $p = \pi \circ p_j$ (entrywise) is $\mathbb{Q}_\ell$-linear, is the identity on V', and commutes with the action of G_L, which acts on entries by elements of $\mathbb{Q}_\ell^\times$. Applying $p \otimes 1$, $y(g) \otimes 1 = g \cdot Y' - Y'$ for $g \in D'$, with $Y' = (p \otimes 1)(Y) \in V' \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$: the class of $y|_{D'}$ lies in $H^1_f(D', V')$ (Definition 22.2). As a representation of D', V' is a direct sum of copies of $\mathbb{Q}_\ell(-k)$ (a $\mathbb{Q}_\ell$-basis of V'), and the condition of Definition 22.2 is componentwise. If $k \geq 1$: $H^0(D', \mathbb{Q}_\ell(-k)) = 0$ since $\chi_{\mathrm{cyc}}(D')$ is infinite; an element $b \otimes 1$ of $B_{\mathrm{dR}} \otimes \mathbb{Q}_\ell(-k)$ is invariant iff $g(b) = \chi_{\mathrm{cyc}}(g)^k b$, i.e. iff $bt^{-k} \in B_{\mathrm{dR}}^{D'} = L_w$, so $D_{\mathrm{dR}} = L_w t^k$ is one-dimensional over L_w, $\mathbb{Q}_\ell(-k)$ is de Rham, and $t^k \in \mathrm{Fil}^0 B_{\mathrm{dR}}$ gives $\mathrm{Fil}^0 D_{\mathrm{dR}} = D_{\mathrm{dR}}$; by Theorem B.43, $H^1_f(D', \mathbb{Q}_\ell(-k)) = 0$. Hence $y|_{D'} = dW_w$ for some $W_w \in V'$. If $k = 0$: D' acts trivially on V' and by Theorem B.44 (componentwise) $y|_{D'}$ is a homomorphism vanishing on I'.

Step 3: $y|_{G_L}$ *factors through* G_{L,S_ℓ}*.* Let H be the kernel of $G_L \to G_{L,S_\ell}$, the closed normal subgroup generated by the groups $I_{\bar{v}} \cap G_L$ for the places $\bar{v}$ not above ℓ (the infinite places of L are complex); this family is stable under conjugation by G_L. χ_{cyc} is trivial on H (the field of ℓ-power roots of unity over L is unramified outside ℓ), so $y|_H$ is a continuous homomorphism, vanishing on these generators by Step 2(a); hence $y|_H = 0$, $y(gh) = y(g)$ for $g \in G_L$, $h \in H$, and $y|_{G_L} = \tilde{y} \circ (G_L \to G_{L,S_\ell})$ for a continuous cocycle $\tilde{y}$ of G_{L,S_ℓ} in V' with the scalar action χ_{cyc}^{-k}.

Step 4: weights -2*,* -1 *(*$k = -ej \geq 1$*).* Let $b_1, \ldots, b_m$ be a $\mathbb{Q}_\ell$-basis of V' and $\lambda_1, \ldots, \lambda_m$ the dual coordinates. Each $\lambda_i \circ \tilde{y}\colon G_{L,S_\ell} \to \mathbb{Q}_\ell$ is continuous with $\lambda_i\tilde{y}(gh) = \lambda_i\tilde{y}(g) + \chi_{\mathrm{cyc}}(g)^{-k}\lambda_i\tilde{y}(h)$, and for $v \in S_\ell$ the restriction to L_v in the definition of $\mathrm{Sha}^1_\ell(L,k)$ is taken through the image of a decomposition group D' as in Step 2(b), on which $\lambda_i\tilde{y}$ is the coboundary of $\lambda_i(W_v)$. Its image is compact, so for some $s \geq 0$ all $\ell^s\lambda_i \circ \tilde{y}$ and all $\ell^s\lambda_i(W_v)$ ($v \in S_\ell$, finitely many) are $\mathbb{Z}_\ell$-valued. By Proposition 40.3 (with its e equal to k), $\mathrm{len}_\ell(L,k) < \infty$, and Lemma 43.33 (with $E = L$) gives $x_i \in \mathbb{Q}_\ell$ with $\ell^s\lambda_i(\tilde{y}(g)) = (\chi_{\mathrm{cyc}}(g)^{-k} - 1)x_i$. With $X_L = \sum_i \ell^{-s} x_i b_i \in V'$, $y = dX_L$ on G_L.

Step 5: weight 0 *(*$k = 0$*).* Here $y|_{G_L}$ is a continuous homomorphism $G_L \to V'$; by Steps 2 and 3 it vanishes on every inertia group of L at a finite place. Its kernel is a closed normal subgroup with abelian quotient, whose fixed field is an abelian extension of L unramified at all places,

hence finite; so $y(G_L)$ is a finite subgroup of the torsion-free group V', and $y|_{G_L} = 0 = dX_L$ with $X_L = 0$.

Step 6: conclusion. In all cases $y - dX_L$ is a cocycle with values in V' vanishing on the open normal subgroup G_L of index n; by Step 1, $y - dX_L = dX'$ with $X' \in V'$, and $X = X_L + X'$. □

Lemma 43.33. *Let E be a number field, ℓ a prime and $k \geq 1$ an integer with $\mathrm{len}_\ell(E,k) < \infty$. For $v \in S_\ell$ let $\iota_v \colon G_{E_v} \to G_{E,S_\ell}$ be the homomorphism through which the restriction to E_v in the definition of $\mathrm{Sha}^1_\ell(E,k)$ is taken. Let $z \colon G_{E,S_\ell} \to \mathbb{Z}_\ell$ be a continuous map with*

$$z(gh) = z(g) + \chi_{\mathrm{cyc}}(g)^{-k} z(h) \qquad (g, h \in G_{E,S_\ell}),$$

such that for every $v \in S_\ell$ there is $W_v \in \mathbb{Z}_\ell$ with $z(\iota_v(g)) = (\chi_{\mathrm{cyc}}(\iota_v(g))^{-k} - 1)W_v$ for all $g \in G_{E_v}$. Then there is $x \in \mathbb{Q}_\ell$ with $z(g) = (\chi_{\mathrm{cyc}}(g)^{-k} - 1)x$ for all $g \in G_{E,S_\ell}$.

Proof. Write $\kappa(g) = \chi_{\mathrm{cyc}}(g)^{-k}$, $G = G_{E,S_\ell}$ and $s = \mathrm{len}_\ell(E,k)$.

The reductions of $\ell^{-m}z$ are locally trivial classes, hence trivial. For $m \geq 0$ let $z_m \colon G \to \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)$ be $g \mapsto \ell^{-m} z(g) \bmod \mathbb{Z}_\ell$. It takes values in the finite group $\ell^{-m}\mathbb{Z}_\ell/\mathbb{Z}_\ell$ and is the composite of the continuous map z with a locally constant map, so it is a continuous 1-cocycle; let c_m be its class in $H^1(G, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))$. For $v \in S_\ell$, $z_m \circ \iota_v$ is the coboundary of $\ell^{-m}W_v \bmod \mathbb{Z}_\ell$, so the restriction of c_m to E_v vanishes and $c_m \in \mathrm{Sha}^1_\ell(E,k)$. A $\mathbb{Z}_\ell$-module of finite length s has a composition series of length s with quotients $\mathbb{Z}/\ell\mathbb{Z}$, hence is killed by ℓ^s. Since $\ell^s z_{m+s} = z_m$ as cocycles, $c_m = \ell^s c_{m+s} = 0$ for every $m \geq 0$.

Approximate primitives. By $c_m = 0$ there is $w_m \in \mathbb{Q}_\ell$ with $\ell^{-m}z(g) - (\kappa(g) - 1)w_m \in \mathbb{Z}_\ell$ for all $g \in G$; with $x_m = \ell^m w_m$,

$$z(g) - (\kappa(g) - 1)x_m \in \ell^m \mathbb{Z}_\ell \qquad (g \in G,\ m \geq 0). \tag{43.8}$$

An element on which κ is not 1. The image of G_E in $\mathrm{Gal}(\mathbb{Q}(\mu_{\ell^\infty})/\mathbb{Q}) \cong \mathbb{Z}_\ell^\times$ is $\mathrm{Gal}(\mathbb{Q}(\mu_{\ell^\infty})/E \cap \mathbb{Q}(\mu_{\ell^\infty}))$, a closed subgroup of index at most $[E : \mathbb{Q}]$, hence open; so $\chi_{\mathrm{cyc}}(G)$ contains $1 + \ell^r\mathbb{Z}_\ell$ for some $r \geq 2$. This group is torsion-free (the ℓ-adic logarithm is injective on it), so $u = 1 + \ell^r$ satisfies $u^{-k} \neq 1$, and there is $g_0 \in G$ with $\kappa(g_0) = u^{-k} \neq 1$.

Passage to the limit. By (43.8) at g_0, $|(\kappa(g_0) - 1)x_m - z(g_0)|_\ell \leq \ell^{-m}$, so $x_m \to x := z(g_0)/(\kappa(g_0) - 1)$ in $\mathbb{Q}_\ell$. For $g \in G$, $z(g) - (\kappa(g) - 1)x$ is the limit of $z(g) - (\kappa(g) - 1)x_m$, which lies in $\ell^m\mathbb{Z}_\ell$ by (43.8); hence it is 0. □

Lemma 43.34. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. For every integer j with $-2 \leq j \leq 2$, the spaces $Z^1_{\mathrm{u}}(\mathfrak{g}_j)$ and $H^2_{\mathrm{u}}(\mathfrak{g}_j)$ are finite-dimensional over $\mathbb{F}_\mathcal{O}$ and*

$$\dim H^2_{\mathrm{u}}(\mathfrak{g}_j) - \dim Z^1_{\mathrm{u}}(\mathfrak{g}_j) = b(j), \qquad b(-2) = b(2) = 0, \quad b(-1) = b(0) = b(1) = 1.$$

Proof. Write $\mathbb{F} = \mathbb{F}_\mathcal{O}$, $q = \#\mathbb{F}$ (a power of ℓ), $\dim = \dim_\mathbb{F}$, and fix $j \in \{-2, \dots, 2\}$.

Step 1: the action. If $g \in G_K$ then $\bar{r}_0(g) = (\mathrm{T}(\bar{\Psi}(g)), 1)$, and $\mathrm{T}(t)X\mathrm{T}(t)^{-1}$ has entries $t^{b-a}X_{ab}$, so g acts on $\mathfrak{g}_j$ by the scalar $\bar{\Psi}(g)^j$; in particular $G_K \cap \ker\bar{\Psi}$, and hence every $N_{\bar{p}}$, acts trivially. As $\Psi(c) = 1$, $\bar{r}_0(c) = (1, -1)$ and c acts by $X \mapsto -J\,{}^tXJ$, whose (a,b) entry is $-X_{4-b,4-a}$.

Hence $\dim \mathfrak{g}_j^{c=1} = b(j)$.

Step 2: $H^0(G_S, \mathfrak{g}_j^\vee) = 0$. Let $H \subseteq G_\mathbb{Q}$ be the closed subgroup of the elements acting trivially on μ_ℓ and lying in $\ker\chi^{(\ell)}$, so that $L_{\ell,\chi}$ is its fixed field and $G_{L_{\ell,\chi}} = H$. By (Ue8), $K \not\subseteq L_{\ell,\chi}$,

so $H \not\subseteq G_K$: choose $h \in H$ with $\eta_K(h) = -1$. By (Ue3) the part of χ of order prime to ℓ is χ, so $\chi^{(\ell)} = \chi\chi_\ell^{-1}$ and $\chi(h) = \chi_\ell(h)$. If $\ell \nmid N$, $\chi_\ell = \mathbf{1}$. If $\ell^a \parallel N$ with $a \geq 1$, χ_ℓ is a character of $(\mathbb{Z}/\ell^a\mathbb{Z})^\times$ whose order divides that of χ, hence is prime to ℓ; so it is trivial on the kernel of reduction to $(\mathbb{Z}/\ell\mathbb{Z})^\times$, of order ℓ^{a-1}, and $\chi_\ell(h) = \chi_\ell(b)$ with $b \equiv 1 \pmod{\ell}$ because h fixes μ_ℓ; so $\chi_\ell(h) = 1$. Moreover $\chi_{\mathrm{cyc}}(h) \equiv 1 \pmod{\ell}$. Hence $\bar\Psi(h) = 1$. Put $g = ch$. Then $\eta_K(g) = (-1)(-1) = 1$, $\bar\Psi(g) = \bar\Psi(c)\bar\Psi(h) = 1$, and g acts on μ_ℓ as c does, by $\zeta \mapsto \zeta^{-1}$. By Step 1, g acts trivially on $\mathfrak{g}_j$. If $f \in \mathfrak{g}_j^\vee$ is G_S-invariant, then $f(X) = g(f(g^{-1}X)) = g(f(X)) = f(X)^{-1}$ for every X, so $f(X)^2 = 1$ and $f(X) = 1$ (ℓ odd): f is trivial.

Step 3: the local conditions. Let $p \in S$ be a prime, $p \neq \ell$. The map $D_p \to \{\pm 1\} \times \mathbb{F}^\times$, $g \mapsto (\eta_K(g), \bar\Psi(g))$, is a homomorphism, and $N_{\bar p}$ is the intersection of its kernel with the normal subgroup I_p of D_p; so $N_{\bar p}$ is normal in D_p, $[I_p : N_{\bar p}]$ divides $2(q-1)$ and is prime to ℓ, and $N_{\bar p}$ acts trivially on $\mathfrak{g}_j$ (Step 1). By Lemma 43.35, item 1, applied with $N' = N_{\bar p}$, $L^{\mathrm{u}}_{p,j} \supseteq B^1(D_p, \mathfrak{g}_j)$ and $\dim L^{\mathrm{u}}_{p,j} = \dim \mathfrak{g}_j$. At ℓ, $L^{\mathrm{u}}_{\ell,j} = B^1(D_\ell, \mathfrak{g}_j)$ by definition.

Step 4: the count. By Steps 2 and 3 and (Ue1), Lemma 43.36 applies to $M = \mathfrak{g}_j$, $\mathbb{F}$, S, $(D_p)_p$ and $(L^{\mathrm{u}}_{p,j})_p$; its space Z_0 is $Z^1_{\mathrm{u}}(\mathfrak{g}_j)$ by definition. It gives finite dimensions and

$$\dim H^2_{\mathrm{u}}(\mathfrak{g}_j) - \dim Z^1_{\mathrm{u}}(\mathfrak{g}_j) = \dim \mathfrak{g}_j^{c=1} + \sum_{p \neq \ell} (\dim \mathfrak{g}_j - \dim L^{\mathrm{u}}_{p,j}) = b(j) + 0,$$

by Steps 1 and 3. □

Lemma 43.35. *Let ℓ be an odd prime and let $\mathbb{F}$, S, G_S, M and $(D_p)_p$ be as in Definition 43.1; let $c \in G_{\mathbb{Q}}$ be a complex conjugation and $M^{c=1}$ the subspace of M fixed by c.*

1. *Let $p \in S$ be a prime and $N' \subseteq I_p$ a normal subgroup of D_p with $[I_p : N']$ finite and prime to ℓ, acting trivially on M. Then $\{z \in Z^1(D_p, M) : z|_{N'} = 0\}$ contains $B^1(D_p, M)$ and has dimension $\dim M$.*

2. *Let $\mathcal{L} = (L_p)_p$ be a family of local conditions for M with $B^1(D_p, M) \subseteq L_p$ for every prime $p \in S$, and assume $H^0(G_S, M^\vee) = 0$. Then $H^1_{\mathcal{L}}(M)$ and $H^2_{\mathcal{L}}(M)$ are finite-dimensional and*

$$\dim H^1_{\mathcal{L}}(M) - \dim H^2_{\mathcal{L}}(M) = \dim H^0(G_S, M) - \dim M^{c=1} + \sum_{p \in S \text{ prime}} (\dim L_p - \dim M).$$

Proof. Item 1. Coboundaries $g \mapsto gx - x$ vanish on N', which acts trivially. Let W be the space in question, $z \in W$ and $n = [I_p : N']$. Then $z|_{I_p}$ is a cocycle of the finite group I_p/N'; summing $z(gh) = z(g) + gz(h)$ over $h \in I_p/N'$ gives $z(g) = gx - x$ for $g \in I_p$, with $x = -n^{-1}\sum_h z(h)$. So restriction maps W onto $B^1(I_p, M)$ (onto, because $B^1(D_p, M) \subseteq W$), of dimension $\dim M - \dim M^{I_p}$. The kernel consists of the $z \in Z^1(D_p, M)$ vanishing on I_p. For such z and $h \in I_p$, $z(hg) = hz(g)$ and $z(hg) = z(g \cdot g^{-1}hg) = z(g)$, so z takes values in M^{I_p} and is a cocycle of D_p/I_p, which is topologically generated by a Frobenius ϕ. The map $z \mapsto z(\phi)$ is injective (a continuous cocycle vanishing on I_p and at ϕ vanishes on a dense subgroup) and onto M^{I_p}: for $x \in M^{I_p}$, if ϕ acts on M^{I_p} with order n', then $k \mapsto \sum_{i<k} \phi^i x$ depends only on k modulo $n'\ell$ (the sum of $n'\ell$ terms is $\ell \sum_{i<n'} \phi^i x = 0$), hence defines a continuous cocycle of D_p/I_p. So $\dim W = \dim M^{I_p} + \dim M - \dim M^{I_p} = \dim M$.

Item 2, the exact sequences. Write $h^i = \dim H^i(G_S, M)$, finite by Theorem B.37, item 1, and $h^i_p = \dim H^i(D_p, M)$, finite by Theorem B.29, item 1. Then $Z^1(G_S, M)$ and $Z^1(D_p, M)$ are finite, of dimensions $h^1 + \dim M - h^0$ and $h^1_p + \dim M - h^0_p$. Let $Z_{\mathcal{L}}$ be the Selmer cocycles; since $L_p \supseteq B^1(D_p, M)$, $Z_{\mathcal{L}} \supseteq B^1(G_S, M)$ and $\dim H^1_{\mathcal{L}}(M) = \dim Z_{\mathcal{L}} - \dim M + h^0$. Let $\alpha\colon H^2_{\mathcal{L}}(M) \to$

$H^2(G_S, M)$ send the class of $(z, (y_p))$ to the class of z; it is well defined since $B^2_{\mathcal{L}}(M)$ maps to coboundaries.

- The image of α is the kernel $\mathcal{K}$ of $H^2(G_S, M) \to \bigoplus_p H^2(D_p, M)$: if $dy_p = \mathrm{res}_p z$ the restrictions vanish, and conversely one chooses such y_p. By Theorem B.37, item 3, and $H^0(G_S, M^\vee) = 0$ the restriction map is onto, so $\dim \mathcal{K} = h^2 - \sum_p h^2_p$.
- The kernel of α is the image of $\bigoplus_p Z^1(D_p, M)$, $(y_p) \mapsto$ class of $(0, (y_p))$: if $z = dw$ then $(z, (y_p)) \equiv (0, (y_p - \mathrm{res}_p w))$ modulo $B^2_{\mathcal{L}}(M)$, and $d(y_p - \mathrm{res}_p w) = 0$. A family $(0, (y_p))$ with $y_p \in Z^1(D_p, M)$ lies in $B^2_{\mathcal{L}}(M)$ if and only if $y_p = \mathrm{res}_p w + \lambda_p$ with $dw = 0$ and $\lambda_p \in L_p$. So $\ker \alpha$ is the cokernel of $\rho\colon Z^1(G_S, M) \to \bigoplus_p Z^1(D_p, M)/L_p$, $w \mapsto (\mathrm{res}_p w)_p$, whose kernel is $Z_{\mathcal{L}}$.

Hence $H^2_{\mathcal{L}}(M)$ is finite-dimensional, $\dim \ker \alpha = \sum_p (h^1_p + \dim M - h^0_p - \dim L_p) - (h^1 + \dim M - h^0) + \dim Z_{\mathcal{L}}$, and

$$\begin{aligned}\dim H^1_{\mathcal{L}}(M) - \dim H^2_{\mathcal{L}}(M) &= \dim H^1_{\mathcal{L}}(M) - \dim \ker \alpha - \dim \mathcal{K} \\ &= h^1 - h^2 + \sum_p (h^0_p - h^1_p + h^2_p - \dim M + \dim L_p).\end{aligned}$$

Item 2, the Euler characteristics. By Theorem B.29, item 4, $h^0_p - h^1_p + h^2_p$ is 0 for $p \neq \ell$ and $-\dim M$ for $p = \ell$ ($[\mathbb{Q}_\ell : \mathbb{Q}_\ell] = 1$). By Theorem B.37, item 2, for $F = \mathbb{Q}$ (one real place ∞, with $|\#M|_\infty = \#M$ and $H^0(\mathbb{R}, M)$ the fixed space of a complex conjugation, of the same dimension as $M^{c=1}$ since all complex conjugations are conjugate in $G_\mathbb{Q}$), $h^0 - h^1 + h^2 = \dim M^{c=1} - \dim M$. Substituting,

$$\dim H^1_{\mathcal{L}}(M) - \dim H^2_{\mathcal{L}}(M) = (h^0 - \dim M^{c=1} + \dim M) - \dim M + \sum_p (\dim L_p - \dim M),$$

which is the assertion. □

Lemma 43.36. *Let ℓ be an odd prime and let $\mathbb{F}$, S, G_S, M and $(D_p)_p$ be as in Definition 43.1; let $c \in G_\mathbb{Q}$ be a complex conjugation and $M^{c=1}$ the subspace of M fixed by c. Let $\mathcal{L} = (L_p)_p$ be a family of local conditions for M with $L_\ell = B^1(D_\ell, M)$ and $B^1(D_p, M) \subseteq L_p$ for every prime $p \in S$, and assume $H^0(G_S, M^\vee) = 0$. Let*

$$Z_0 = \{z \in Z^1(G_S, M) :\ \mathrm{res}_\ell z = 0,\ \mathrm{res}_p z \in L_p \text{ for every prime } p \in S\}.$$

Then Z_0 and $H^2_{\mathcal{L}}(M)$ are finite-dimensional and

$$\dim H^2_{\mathcal{L}}(M) - \dim Z_0 = \dim M^{c=1} + \sum_{p \in S \text{ prime},\ p \neq \ell} (\dim M - \dim L_p).$$

Proof. Let $Z_{\mathcal{L}}$ be the space of Selmer cocycles, so that $Z_0 \subseteq Z_{\mathcal{L}}$ ($0 \in L_\ell$). By Lemma 43.35, item 2 (its hypotheses are those made here), $H^1_{\mathcal{L}}(M)$ and $H^2_{\mathcal{L}}(M)$ are finite-dimensional and

$$\dim H^1_{\mathcal{L}}(M) - \dim H^2_{\mathcal{L}}(M) = h^0 - \dim M^{c=1} + \sum_{p \in S \text{ prime}} (\dim L_p - \dim M), \qquad h^0 = \dim H^0(G_S, M). \tag{43.9}$$

Step 1: $\dim Z_{\mathcal{L}} = \dim H^1_{\mathcal{L}}(M) + \dim M - h^0$. For $x \in M$ the coboundary $b_x\colon g \mapsto gx - x$ restricts at every prime $p \in S$ to an element of $B^1(D_p, M) \subseteq L_p$, so $B^1(G_S, M) \subseteq Z_{\mathcal{L}}$, and

$H^1_{\mathcal{L}}(M) = Z_{\mathcal{L}}/B^1(G_S, M)$. The map $x \mapsto b_x$ from M onto $B^1(G_S, M)$ has kernel $H^0(G_S, M)$, so $\dim B^1(G_S, M) = \dim M - h^0$.

Step 2: $\dim Z_0 = \dim Z_{\mathcal{L}} - \dim M + h^0_\ell$, *where* $h^0_\ell = \dim H^0(D_\ell, M)$. The restriction $z \mapsto \mathrm{res}_\ell z$ maps $Z_{\mathcal{L}}$ into $L_\ell = B^1(D_\ell, M)$, and its kernel is Z_0. It is onto: an element of $B^1(D_\ell, M)$ is $\mathrm{res}_\ell b_x$ for some $x \in M$, and $b_x \in Z_{\mathcal{L}}$ by Step 1. As in Step 1, $\dim B^1(D_\ell, M) = \dim M - h^0_\ell$. In particular Z_0 is finite-dimensional.

Step 3: the count. By Steps 1 and 2, $\dim Z_0 = \dim H^1_{\mathcal{L}}(M) - h^0 + h^0_\ell$. In (43.9) the term of $p = \ell$ is $\dim L_\ell - \dim M = -h^0_\ell$. Hence

$$\dim H^2_{\mathcal{L}}(M) - \dim Z_0 = \dim H^2_{\mathcal{L}}(M) - \dim H^1_{\mathcal{L}}(M) + h^0 - h^0_\ell = \dim M^{c=1} - \sum_{p \neq \ell} (\dim L_p - \dim M),$$

which is the assertion. □

44 The symplectic one-character bound

This section proves Proposition 44.3, the one-character bound for the characters in cases (II) and (III), which Proposition 38.26 uses. These are characters for which $(\ell - 1) \mid 2e$ or ℓ lies in the bad set, and the unitary construction of Section 42 is replaced by one on GSp_4 over $\mathbb{Q}$. The Eisenstein representation is built from $\Psi = \chi\chi^e_{\mathrm{cyc}}$ and an auxiliary character $\alpha = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\xi$, with similitude $\theta = \alpha\Psi$, and its trace is $(1 + \Psi)(1 + \alpha)$ (Definition 44.1). The character ξ, of large 2-power conductor and in case (III) with a factor modulo $p_1(\psi)$, is chosen so that the residual Selmer cocycles of α, $\beta = \Psi\alpha^{-1}$, θ and their inverses are coboundaries (Sg6). This is Lemma 44.5; it rests on the fact that the first Bernoulli number of an odd character with a large 2-power conductor is an ℓ-adic unit (Lemma 44.6), together with a vanishing of Herbrand type for unramified cocycles (Lemma 44.7); the existence of an attached datum is Proposition 44.4.

The proof follows that of Proposition 42.2. The graded model is Proposition 45.2 (Section 45); Part IX gives finiteness in weight zero, the absence of endoscopic points and the automorphy of the irreducible points (Theorem 51.1). Rigidity at the irreducible automorphic points, Theorem 44.8, follows from Thorne's vanishing theorem for adjoint Bloch–Kato Selmer groups [257], after a character twist over an imaginary quadratic field makes the representation conjugate self-dual (Proposition 44.13) and after checking that it stays irreducible over the cyclotomic tower (Lemma 44.9). Finally the irreducible automorphic points are admissible symplectic of weight e and level M (Proposition 44.15), and isomorphic points are torus conjugate (Lemma 44.16), so the orbit cover of the criterion is a set of pairwise non-isomorphic admissible representations.

Definition 44.1. Let ℓ be an odd prime and $\mathcal{O}$ a coefficient ring with maximal ideal $\mathfrak{m}_{\mathcal{O}}$ and residue field $\mathbb{F}_{\mathcal{O}}$; for a character $\gamma\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ write $\bar\gamma$ for its reduction modulo $\mathfrak{m}_{\mathcal{O}}$. The **Teichmüller character** $\omega_\ell\colon G_{\mathbb{Q}} \to \mathbb{Z}_\ell^\times \subseteq \mathcal{O}^\times$ is the character with $\omega_\ell^{\ell-1} = \mathbf{1}$ and $\bar\omega_\ell = \bar\chi_{\mathrm{cyc}}$. Fix a complex conjugation $c \in G_{\mathbb{Q}}$ and, for every prime p, a place $\bar p$ of $\overline{\mathbb{Q}}$ above p; write $D_p \supseteq I_p$ for $D_{\bar p} \supseteq I_{\bar p}$.

Symplectic Eisenstein data. Let $e \geq 2$ and $N \geq 1$ be integers with N even, χ a Dirichlet character modulo N and ξ a Dirichlet character, both with values in $\mathcal{O}^\times$ and viewed as characters of $G_{\mathbb{Q}}$, ξ of order prime to ℓ, and S a finite set of primes. Put $\Psi = \Psi_{\chi,e} = \chi\chi^e_{\mathrm{cyc}}$, $T = T_\ell(\chi)$ and

$$\alpha = \chi_{\mathrm{cyc}}\,\omega_\ell^{-1}\,\xi, \qquad \theta = \alpha\Psi, \qquad \beta = \Psi\alpha^{-1}. \tag{44.1}$$

For $\gamma\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ a **residual Selmer cocycle** for γ is a locally constant map $z\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}$ with $z(gh) = z(g) + \bar\gamma(g)z(h)$ for all g, h, such that $z(g) = 0$ for every $g \in I_{\bar w}$ with $\bar\theta(g) = \bar\Psi(g) =$

$\bar\alpha(g)=1$ and every place $\bar w$ of $\overline{\mathbb{Q}}$ above a prime not in T, and such that for every $v\in T$ there is $y\in\mathbb{F}_{\mathcal O}$ with $z(g)=\bar\gamma(g)y-y$ for all $g\in D_v$. A tuple $\mathfrak D=(\ell,\mathcal O,e,N,\chi,\xi,S,(\sigma_v)_{v\in T},\phi,g_0,s_0)$ with $\sigma_v,\phi,g_0,s_0\in G_{\mathbb Q}$ is a **symplectic Eisenstein datum** if

(Sg1) S contains 2, ℓ and every prime dividing N; ξ is unramified at every prime not in S and at every prime of T; $\xi(c)=-1$ and $\Psi(c)=1$;

(Sg2) for every $v\in T$, $\sigma_v\in D_v$ is an arithmetic Frobenius element at $\bar v$; $\chi_{\mathrm{cyc}}(\sigma_\ell)=1$; and $\overline{\xi\Psi^i}(\sigma_v)\neq 1$ for every $v\in T$ and every $i\in\mathbb{Z}$;

(Sg3) the sequence $\sigma_\ell^{\ell^{n!}}$ converges to ϕ as $n\to\infty$;

(Sg4) $\bar\alpha(g_0)\neq 1$ and $\bar\Psi(g_0)\neq 1$;

(Sg5) $s_0\in I_\ell$, $\chi(s_0)=\omega_\ell(s_0)=1$, and $\chi_{\mathrm{cyc}}(s_0)$ has infinite order;

(Sg6) for every $\gamma\in\{\alpha,\beta,\theta,\alpha^{-1},\beta^{-1},\theta^{-1}\}$, every residual Selmer cocycle for γ is a coboundary, that is of the form $g\mapsto\bar\gamma(g)y-y$ with $y\in\mathbb{F}_{\mathcal O}$.

The characters (44.1) and the sets T, S are those **of the datum**.

Data attached to a host character. Let $\psi\in\mathcal P$, let $\mathfrak h$ be a Sha-host of ψ big at an integer $t\geq 1$, $0<e<t$, and $\chi\in X_{\mathfrak h}(\mathcal O,e)$ in case (II) or in case (III) for (ℓ,e). Define integers $n',p',m\geq 1$: in case (II), n' is the least integer $n\geq 0$ with $2^n\geq\max\bigl(\ell N_{\mathfrak h}4^{n_0(\ell,\chi)},\ 2^{c_2(\chi)+6}o_\psi\ell^3N_\psi^2\bigr)$ and $p'=m=1$; in case (III), n' is the least integer $n\geq 0$ with $2^n\geq\max\bigl(\ell N_\psi\,p_1(\psi)\,4^{n_0(\ell,\chi)},\ 8\ell^2\bigr)$, $p'=p_1(\psi)$ and m is the order of χ. A symplectic Eisenstein datum $\mathfrak D=(\ell,\mathcal O,e',N,\chi',\xi,S,\dots)$ is **attached to** $(\psi,\mathfrak h,t,\chi)$ if $e'=e$, $N=N_{\mathfrak h}$, $\chi'=\chi$, S is the set of primes dividing $2\ell N_{\mathfrak h}p'$, and $\xi=\chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ for a primitive Dirichlet character χ_{dy} modulo $2^{n'}$ with $\chi_{\mathrm{dy}}(-1)=-1$ and a Dirichlet character χ_{pr} modulo p' of order m, both with values in $\mathcal O^\times$; the integer

$$M=\ell\,2^{n'}N_{\mathfrak h}\,p' \tag{44.2}$$

is its **level**. These are the data on which the Eisenstein congruences on GSp_4 bound the strict Tate–Shafarevich groups of the characters in cases (II) and (III).

Definition 44.2. Let $\mathfrak D=(\ell,\mathcal O,e,N,\chi,\xi,S,(\sigma_v),\phi,g_0,s_0)$ be a symplectic Eisenstein datum, with characters Ψ,α,θ, the set T, maximal ideal $\mathfrak m_{\mathcal O}$ and residue field $\mathbb{F}_{\mathcal O}$. Indices i,j run over $\{1,2,3,4\}$.

The group and the torus. Let J_4 be the 4×4 matrix with $(J_4)_{14}=(J_4)_{23}=1$, $(J_4)_{32}=(J_4)_{41}=-1$ and all other entries 0, so that ${}^tJ_4=-J_4$. For a commutative ring B and $\nu\in B$, a matrix $X\in\mathrm M_4(B)$ **has similitude** ν if ${}^tX\,J_4\,X=\nu J_4$; and $\mathfrak{sp}_4(B)=\{X\in\mathrm M_4(B):{}^tXJ_4+J_4X=0\}$. Put $\boldsymbol\lambda=(1,0,1,0)$, $\boldsymbol\mu=(1,1,0,0)$, the **weight** of the entry (i,j)

$$\mathrm{wt}_4(i,j)=(\lambda_i-\lambda_j,\ \mu_i-\mu_j)\in\mathbb{Z}^2,$$

and, for units t_1,t_2 of B, $\mathrm T_4(t_1,t_2)=\mathrm{diag}(t_1t_2,t_2,t_1,1)$; then $\mathrm T_4(t_1,t_2)\,X\,\mathrm T_4(t_1,t_2)^{-1}$ has entries $t_1^{\lambda_i-\lambda_j}t_2^{\mu_i-\mu_j}X_{ij}$. A matrix is **block diagonal** if its entries (i,j) with $\lambda_i\neq\lambda_j$ vanish (blocks $\{1,3\}$ and $\{2,4\}$). The **Eisenstein representation** is

$$r_0=\mathrm{diag}(\theta,\Psi,\alpha,\mathbf 1)\colon G_{\mathbb Q}\to\mathrm{GL}_4(\mathcal O),$$

with similitude θ at every g, and $\bar r_0$ is its reduction modulo $\mathfrak m_{\mathcal O}$; write $(\kappa_1,\kappa_2,\kappa_3,\kappa_4)=(\theta,\Psi,\alpha,\mathbf 1)$.

Lifts and the local conditions. For $A \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_A$, a **lift** to A is a continuous homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(A)$ with $r \equiv \bar{r}_0 \pmod{\mathfrak{m}_A}$; a lift of $\bar{r}_0|_{D_v}$ is defined in the same way. For B a commutative $\mathcal{O}$-algebra and $\rho\colon D_\ell \to \mathrm{GL}_4(B)$, put $\Pi_i = \prod_{j\neq i}(\rho(s_0) - \kappa_j(s_0))$; ρ is **ordinary** if the characteristic polynomial of $\rho(s_0)$ is $\prod_j(X - \kappa_j(s_0))$, $\Pi_j\rho(g)\Pi_i = 0$ for all $g \in D_\ell$ and $i < j$, and $\Pi_i(\rho(s) - \kappa_i(s))\Pi_i = 0$ for all $s \in I_\ell$ and all i. For $v \in T$, a lift ρ of $\bar{r}_0|_{D_v}$ to $B \in \mathrm{CNL}_{\mathcal{O}}$ **satisfies the local condition at** v if $\rho(g)$ has similitude $\theta(g)$ for all $g \in D_v$ and, for $v = \ell$, ρ is ordinary, for $v \neq \ell$, $\rho(g) = 1$ for all $g \in I_v$ with $\chi(g) = 1$. A lift r to A is a **symplectic Eisenstein lift** if

(Se1) $r(g)$ has similitude $\theta(g)$ for every $g \in G_{\mathbb{Q}}$;

(Se2) $r(g) = 1$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$ and every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a prime not in T;

(Se3) $r(\phi)$ is block diagonal, and the matrix $h(r) = r(g_0) + \theta(g_0)\, r(g_0^{-1})$ has $h(r)_{13} = h(r)_{31} = 0$;

(Se4) for every $v \in T$, $r|_{D_v}$ lies on a component through the Eisenstein point: there are a domain $B \in \mathrm{CNL}_{\mathcal{O}}$, a lift ρ_B of $\bar{r}_0|_{D_v}$ to B satisfying the local condition at v, and $\mathcal{O}$-algebra homomorphisms $x\colon B \to \mathcal{O}$ and $y\colon B \to A$ with $x \circ \rho_B = r_0|_{D_v}$ and $y \circ \rho_B = r|_{D_v}$.

Points. Let B be $\overline{\mathbb{Q}}_\ell$ or the dual numbers $\overline{\mathbb{Q}}_\ell[\epsilon]$ ($\epsilon^2 = 0$). A **point** of $\mathfrak{D}$ with values in B is a homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(B)$ of the form $g \mapsto f(r_A(g))$ for a symplectic Eisenstein lift r_A to some $A \in \mathrm{CNL}_{\mathcal{O}}$ and an $\mathcal{O}$-algebra homomorphism $f\colon A \to B$; a point means a point with values in $\overline{\mathbb{Q}}_\ell$. A point r is **irreducible** if the $\overline{\mathbb{Q}}_\ell$-span of $r(G_{\mathbb{Q}})$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$; its **torus conjugates** are the points $\mathrm{T}_4(t_1,t_2)\, r\, \mathrm{T}_4(t_1,t_2)^{-1}$, $t_1, t_2 \in \overline{\mathbb{Q}}_\ell^{\times}$. A point r is **rigid** if every point r' with values in $\overline{\mathbb{Q}}_\ell[\epsilon]$ whose reduction modulo ϵ is r has the form $r'(g) = r(g) + \epsilon\big(Xr(g) - r(g)X\big)$ for some $X \in \mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell)$. For an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, a point is **automorphic** for ι if it satisfies (Sy2) for ι.

Two global properties. $\mathfrak{D}$ is **finite in weight zero** if for every symplectic Eisenstein lift r_A to some $A \in \mathrm{CNL}_{\mathcal{O}}$ the $\mathcal{O}$-subalgebra of A generated by the products $r_A(g_1)_{i_1j_1} \cdots r_A(g_k)_{i_kj_k}$ ($k \geq 0$) with $\sum_s \mathrm{wt}_4(i_s, j_s) = (0,0)$ is a finitely generated $\mathcal{O}$-module. $\mathfrak{D}$ has **no endoscopic points** if there is no point r such that every $r(g)$ is block diagonal and the matrices $\big(r(g)_{ab}\big)_{a,b\in\{1,3\}}$, $g \in G_{\mathbb{Q}}$, span $\mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$.

Proposition 44.3. *Let $\psi \in \mathcal{P}$, let $\mathfrak{h}$ be a Sha-host of ψ that is big at an integer $t \geq 1$, let ℓ be an odd prime, e an integer with $0 < e < t$, $\mathcal{O}$ a coefficient ring and $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$ in case (II) or in case (III) for (ℓ, e); write $N = N_{\mathfrak{h}}$. (The two cases exclude each other: in case (III) χ has odd order, hence so has $\chi^{(\ell)}$, a product of powers of χ.) Define integers $n', p', m \geq 1$ as follows:*

- *in case (II), n' is the least integer $n \geq 0$ with $2^n \geq \max\big(\ell N 4^{n_0(\ell,\chi)},\ 2^{c_2(\chi)+6} o_\psi \ell^3 N_\psi^2\big)$, and $p' = m = 1$;*
- *in case (III), n' is the least integer $n \geq 0$ with $2^n \geq \max\big(\ell N_\psi\, p_1(\psi)\, 4^{n_0(\ell,\chi)},\ 8\ell^2\big)$, $p' = p_1(\psi)$ and m is the order of χ.*

Assume that $\mathcal{O}$ contains a primitive $2^{n'}$-th root of unity. Put $M = \ell\, 2^{n'} N\, p'$, and let $\omega_\ell\colon G_{\mathbb{Q}} \to \mathbb{Z}_\ell^{\times} \subseteq \mathcal{O}^{\times}$ be the Teichmüller character, the character with $\omega_\ell^{\ell-1} = \mathbf{1}$ and $\omega_\ell \equiv \chi_{\mathrm{cyc}} \pmod{\ell}$. Then there are Dirichlet characters χ_{dy} modulo $2^{n'}$ and χ_{pr} modulo p' with values in $\mathcal{O}^{\times}$, χ_{dy} primitive with $\chi_{\mathrm{dy}}(-1) = -1$ and χ_{pr} of order m, and an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, with the following property. Put $\Psi = \Psi_{\chi,e}$, $\Psi_{\mathrm{aux}} = \chi_{\mathrm{cyc}}\, \omega_\ell^{-1} \chi_{\mathrm{dy}} \chi_{\mathrm{pr}}$ and, for $\sigma \in G_{\mathbb{Q}}$,

$$T_{\mathrm{Eis}}(\sigma) = \big(1 + \Psi(\sigma)\big)\big(1 + \Psi_{\mathrm{aux}}(\sigma)\big) \in \mathcal{O}.$$

For every $\sigma \in G_{\mathbb{Q}}$ such that $\operatorname{tr} r(\sigma) \neq T_{\mathrm{Eis}}(\sigma)$ for every representation $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ admissible symplectic of weight e and level M (for ι), the group $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length, and there is a finite set X of pairwise non-isomorphic representations $G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$, each admissible symplectic of weight e and level M (for ι), such that

$$\nu_{\mathcal{O}}(\chi, e) \leq 2 \sum_{r \in X} v_\ell(\operatorname{tr} r(\sigma) - T_{\mathrm{Eis}}(\sigma)).$$

Proof. Let $\psi, \mathfrak{h}, t, \ell, e, \mathcal{O}, \chi$, $N = N_{\mathfrak{h}}$, n', p', m and $M = \ell 2^{n'} N p'$ be as in the statement.

Step 1: the datum and its Eisenstein trace. Since $\mathcal{O}$ contains a primitive $2^{n'}$-th root of unity, Proposition 44.4 gives a symplectic Eisenstein datum $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, (\sigma_v), \phi, g_0, s_0)$ attached to $(\psi, \mathfrak{h}, t, \chi)$: S is the set of primes dividing $2\ell N p'$, and $\xi = \chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ with χ_{dy} primitive modulo $2^{n'}$, $\chi_{\mathrm{dy}}(-1) = -1$, and χ_{pr} modulo p' of order m, both with values in $\mathcal{O}^\times$. These are the characters $\chi_{\mathrm{dy}}, \chi_{\mathrm{pr}}$ of the statement. The level of $\mathfrak{D}$ is M. The characters of the datum are $\alpha = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\xi = \Psi_{\mathrm{aux}}$ and $\theta = \alpha\Psi = \Psi\Psi_{\mathrm{aux}}$, so $r_0 = \operatorname{diag}(\Psi\Psi_{\mathrm{aux}}, \Psi, \Psi_{\mathrm{aux}}, \mathbf{1})$ and, for every $g \in G_{\mathbb{Q}}$,

$$\operatorname{tr} r_0(g) = \Psi(g)\Psi_{\mathrm{aux}}(g) + \Psi(g) + \Psi_{\mathrm{aux}}(g) + 1 = T_{\mathrm{Eis}}(g). \tag{44.3}$$

Step 2: automorphy, rigidity and admissibility of the irreducible points. By Theorem 51.1, $\mathfrak{D}$ is finite in weight zero (Sa1), has no endoscopic points (Sa2), and there is an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ for which every irreducible point of $\mathfrak{D}$ is automorphic (Sa3); this is the ι of the statement. By Theorem 44.8 every irreducible point of $\mathfrak{D}$ is rigid, and by Proposition 44.15 every irreducible point of $\mathfrak{D}$ is admissible symplectic of weight e and level M for ι.

Step 3: the graded model satisfies (Gc1)–(Gc4). Let (A, φ_0), u, $(a_g)_{g \in G_{\mathbb{Q}}}$ be as in Proposition 45.2, and, $\mathfrak{D}$ being finite in weight zero, let $x \mapsto r_x$ be a map with (Gs3)–(Gs6). By (Gs1), (Gs5) and (Gs6), which applies since $\mathfrak{D}$ has no endoscopic points and all its irreducible points are rigid (Step 2), the triple (A, φ_0, u) satisfies (Gc1)–(Gc4), and r_x is an irreducible point of $\mathfrak{D}$ for every two-signed point x of A on u.

Step 4: the weight-zero function, (Gc5). Let $\sigma \in G_{\mathbb{Q}}$ be as in the statement and $a = a_\sigma \in A_0$; then $\varphi_0(a) = 0$. Let x be a two-signed point of A on u. By Step 3 r_x is an irreducible point, hence admissible symplectic of weight e and level M for ι (Step 2), so $\operatorname{tr} r_x(\sigma) \neq T_{\mathrm{Eis}}(\sigma)$ by the hypothesis on σ. By (Gs3) and (44.3),

$$x(a) = \operatorname{tr} r_x(\sigma) - T_{\mathrm{Eis}}(\sigma) \neq 0. \tag{44.4}$$

So (A, φ_0, u, a) satisfies (Gc1)–(Gc5).

Step 5: the graded numerical criterion. By Lemma 41.2, u has an orbit cover, $\mathrm{ct}_{-1}(u_{-1})$ is finite, and $\mathrm{ct}_{-1}(u_{-1}) \leq 2\sum_{x \in \Sigma} v_{\mathcal{O}}(x(a))$ for every orbit cover Σ of u.

Step 6: $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length at most $\mathrm{ct}_{-1}(u_{-1})$. Put $n_S = \prod_{p \in S} p$ and $V = \mathcal{O}^\vee(\Psi^{-1})$. First, $\mathrm{Sha}^1_{\ell N}(\chi, e) = \mathrm{Sha}^1_{n_S}(\chi, e)$. Since N is even, the primes dividing n_S are those dividing ℓN together with p' when $p' > 1$; so $\mathrm{Sha}^1_{n_S}(\chi, e) \subseteq \mathrm{Sha}^1_{\ell N}(\chi, e)$, with equality when $p' = 1$. Let $p' > 1$, so we are in case (III) and $p' = p_1(\psi)$, an odd prime prime to N_ψ. Then $p' \nmid N$: $p' \nmid 2N_\psi$, and $p' < \min(q, d)$ by bigness, where $\mathfrak{h} = (a', q, d)$ and $N = \mathrm{lcm}(2^{a'+2}, N_\psi)qd$. Also $p' \neq \ell$, since $p' \in B_\psi$ and $\ell \notin B_\psi$ in case (III). Let $c' \in \mathrm{Sha}^1_{\ell N}(\chi, e)$. Since $p' \nmid \ell N$, Ψ is unramified at p' and $I_{p'}$ acts trivially on V; the class c' is unramified at p', so by inflation–restriction its restriction to $D_{p'}$ is inflated from $H^1(D_{p'}/I_{p'}, V)$. The group $D_{p'}/I_{p'}$ is procyclic, topologically generated by the image F of an arithmetic Frobenius, and for the discrete torsion module V one has $H^1(D_{p'}/I_{p'}, V) \cong V/(F-1)V$. Here F acts on V as multiplication by $\Psi(F)^{-1} = (\chi(p')p'^e)^{-1}$, and $\Psi(F) \neq 1$, since otherwise the integer $p'^e > 1$ would be a root of unity. As V is a divisible

$\mathcal{O}$-module (the Pontryagin dual of the injective multiplication by $\Psi(F)^{-1}-1\neq 0$ on $\mathcal{O}$ is surjective), $(F-1)V=V$, the restriction of c' to $D_{p'}$ vanishes, and $c'\in \mathrm{Sha}^1_{n_S}(\chi,e)$.

Now let $b\in\mathcal{O}\setminus\{0\}$ and $\mathrm{Sha}[b]$ the submodule of $\mathrm{Sha}^1_{n_S}(\chi,e)$ killed by b. Let $a\in b\mathcal{O}\setminus\{0\}$ and D be as in (Gs2); then D satisfies the hypotheses of Lemma 42.12 for $j=-1$, the family u_{-1}, $c=a$ and the module $\mathrm{Sha}[b]$; hence $\mathrm{length}_{\mathcal{O}}\mathrm{Sha}[b]\le \mathrm{ct}_{-1}(u_{-1})$. Every class of $H^1(\mathbb{Q},V)$ is represented by a continuous cocycle on the compact group $G_{\mathbb{Q}}$ with values in the discrete module V, which has finite image; every element of V is killed by a power of ℓ; so every class is killed by some ℓ^k and $\mathrm{Sha}^1_{n_S}(\chi,e)=\bigcup_k \mathrm{Sha}[\ell^k]$, an increasing union. If $\mathrm{Sha}^1_{n_S}(\chi,e)$ contained a strictly increasing chain $M_0\subsetneq M_1\subsetneq\cdots\subsetneq M_L$ of submodules with $L=\mathrm{ct}_{-1}(u_{-1})+1$, choose $y_i\in M_i\setminus M_{i-1}$; the submodule generated by $y_1,\dots,y_L$ lies in some $\mathrm{Sha}[\ell^k]$ and contains the strictly increasing chain of the submodules generated by $y_1,\dots,y_i$ $(1\le i\le L)$, so it has length at least L, a contradiction. Hence $\mathrm{Sha}^1_{\ell N}(\chi,e)=\mathrm{Sha}^1_{n_S}(\chi,e)$ has finite length, at most $\mathrm{ct}_{-1}(u_{-1})$.

Step 7: from a minimal orbit cover to representations. By Step 5 orbit covers exist; let Σ be one of least cardinality. Let $x\neq x'$ in Σ and suppose $r_{x'}\cong r_x$. Since x is two-signed, r_x is an irreducible point (Step 3), so by Lemma 44.16 $r_{x'}$ is a torus conjugate of r_x, and by (Gs4) $x'=t\cdot x$ for some $t\in\overline{\mathbb{Q}}_\ell^\times$. Then $\Sigma\setminus\{x'\}$ is an orbit cover: a two-signed point y on u is $s\cdot z$ with $z\in\Sigma$ and $s\in\overline{\mathbb{Q}}_\ell^\times$, and if $z=x'$ then $y=(st)\cdot x$, because $(s\cdot(t\cdot x))(f)=s^jt^jx(f)$ for $f\in A_j$. This contradicts the minimality of Σ. Hence the representations r_x, $x\in\Sigma$, are pairwise non-isomorphic, in particular pairwise distinct. Put $X=\{r_x:\ x\in\Sigma\}$, a finite set of pairwise non-isomorphic representations $G_{\mathbb{Q}}\to\mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$, each admissible symplectic of weight e and level M for ι (Steps 2 and 3). With Steps 6, 5, (44.4) and $v_{\mathcal{O}}=e_{\mathcal{O}}v_\ell$,

$$\nu_{\mathcal{O}}(\chi,e)=\frac{\mathrm{length}_{\mathcal{O}}\mathrm{Sha}^1_{\ell N}(\chi,e)}{e_{\mathcal{O}}}\le\frac{\mathrm{ct}_{-1}(u_{-1})}{e_{\mathcal{O}}}\le\frac{2}{e_{\mathcal{O}}}\sum_{x\in\Sigma}v_{\mathcal{O}}(x(a))=2\sum_{r\in X}v_\ell(\mathrm{tr}\,r(\sigma)-T_{\mathrm{Eis}}(\sigma)).$$

□

Proposition 44.4. *Let $\psi\in\mathcal{P}$, let $\mathfrak{h}$ be a Sha-host of ψ big at an integer $t\ge 1$, ℓ an odd prime, e an integer with $0<e<t$, $\mathcal{O}$ a coefficient ring and $\chi\in X_{\mathfrak{h}}(\mathcal{O},e)$ in case (II) or in case (III) for (ℓ,e). Let n' be the integer of the case. If $\mathcal{O}$ contains a primitive $2^{n'}$-th root of unity, then there is a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ attached to $(\psi,\mathfrak{h},t,\chi)$.*

Proof. Write $\mathfrak{h}=(a,q,d)$, $N=N_{\mathfrak{h}}=\mathrm{lcm}(2^{a+2},N_\psi)qd$, $T=T_\ell(\chi)$; reduction modulo $\mathfrak{m}_{\mathcal{O}}$ is written with a bar and is injective on roots of unity of order prime to ℓ. Recall $(\mathbb{Z}/2^k\mathbb{Z})^\times=\{\pm1\}\times\langle 5\rangle$ with 5 of order 2^{k-2} for $k\ge 3$ [266].

Step 1: the characters χ_{dy}, χ_{pr} and ξ. By the definition of n', $2^{n'}\ge 2^{c_2(\chi)+6}\ge 2^6$ in case (II) and $2^{n'}\ge 8\ell^2>8$ in case (III), so $n'\ge 3$. Let $\zeta\in\mathcal{O}$ be a primitive $2^{n'}$-th root of unity and define χ_{dy} on $(\mathbb{Z}/2^{n'}\mathbb{Z})^\times$ by $\chi_{\mathrm{dy}}(-1)=-1$, $\chi_{\mathrm{dy}}(5)=\zeta^4$, a primitive $2^{n'-2}$-th root of unity. It is non-trivial on $\{u\equiv 1\pmod{2^{n'-1}}\}=\langle 5^{2^{n'-3}}\rangle$, hence primitive modulo $2^{n'}$, and $\chi_{\mathrm{dy}}(-1)=-1$. In case (II), $p'=m=1$ and $\chi_{\mathrm{pr}}=\mathbf{1}$. In case (III), m is the order of χ; χ has odd order, so by Lemma 38.34, items 1 and 2, χ is a product of components at odd primes dividing N_ψ and $m\mid o_\psi$; m is odd, so it divides the odd part of o_ψ, hence $p'-1$, by the definition of $p'=p_1(\psi)$. As $(\mathbb{Z}/p'\mathbb{Z})^\times$ is cyclic of order $p'-1$ and $\mathcal{O}$ contains the values of χ, among them a primitive m-th root of unity, there is a Dirichlet character χ_{pr} modulo p' of order m with values in $\mathcal{O}^\times$. Put $\xi=\chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ and let α,β,θ,Ψ be the characters (44.1). By Lemma 44.5, $e\ge 2$ and ξ has order prime to ℓ; N is even since $a\ge 2$. Let S be the set of primes dividing $2\ell Np'$.

Step 2: the primes of T. Let $v\in S_\ell(\chi)$. The component χ''_v is a power of χ_v of ℓ-power order, ℓ odd, and non-trivial. If $v=2$ it would also have 2-power order; if $v\in\{q,d\}$ its square would be trivial (Lemma 38.34, item 1); both are excluded. So v is an odd prime dividing N_ψ,

$v \le N_\psi$, and $\ell \mid v-1$, because χ''_v is a non-trivial character of ℓ-power order of $(\mathbb{Z}/v^k\mathbb{Z})^\times$, of order $v^{k-1}(v-1)$, with $v \ne \ell$. In case (III), χ has order prime to ℓ (Lemma 44.5), so $\chi'' = \mathbf{1}$ and $T = \{\ell\}$. In all cases every $v \in T$ is odd, and $p' \notin T$ when $p' > 1$: in case (III) $T = \{\ell\}$ and $p' \in B_\psi \not\ni \ell$.

Step 3: (Sg1). The set S contains 2, ℓ and the primes dividing N. The conductor of ξ divides $2^{n'}p'$, so ξ is unramified at every prime $p \nmid 2p'$, in particular outside S and, by Step 2, at the primes of T. For the fixed complex conjugation c, $\xi(c) = \chi_{\mathrm{dy}}(-1)\chi_{\mathrm{pr}}(-1) = -1$, since χ_{pr} has odd order and so $\chi_{\mathrm{pr}}(-1) = 1$; and $\Psi(c) = \chi(-1)\chi_{\mathrm{cyc}}(c)^e = (-1)^e(-1)^e = 1$ as $\chi \in X_{\mathfrak{h}}(\mathcal{O}, e)$.

Step 4: the Frobenius elements, and (Sg2). For $v \in T \setminus \{\ell\}$ let $\sigma_v \in D_v$ be any arithmetic Frobenius element at $\bar{v}$. At ℓ: the maximal unramified extension $\mathbb{Q}_\ell^{\mathrm{ur}}$ and $\mathbb{Q}_\ell(\mu_{\ell^\infty})$ (totally ramified) of $\mathbb{Q}_\ell$, inside the completion of $\overline{\mathbb{Q}}$ at $\bar{\ell}$, are linearly disjoint, so the Galois group of their composite is the product of their Galois groups, and there is $\sigma_\ell \in D_\ell$ acting as the Frobenius on $\mathbb{Q}_\ell^{\mathrm{ur}}$ and trivially on μ_{ℓ^∞}: an arithmetic Frobenius element at $\bar{\ell}$ with $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$. For $v \in T$ we have $\bar{\chi}_{\mathrm{cyc}}(\sigma_v) = 1$: for $v = \ell$ by the choice, for $v \ne \ell$ because $\chi_{\mathrm{cyc}}(\sigma_v) = v \equiv 1 \pmod{\ell}$ (Step 2).

We choose $a_0 \ge 0$ and an odd $u \ge 1$ with $\chi^{2^{a_0}u} = \chi_{\mathrm{pr}}^{2^{a_0}u} = \mathbf{1}$ and $v^2 2^{a_0} \le 2^{n'}$ for all $v \in T$. In case (III) take $a_0 = 0$, $u = m$; then $T = \{\ell\}$ and $\ell^2 < 8\ell^2 \le 2^{n'}$. In case (II), $\chi_{\mathrm{pr}} = \mathbf{1}$; by Lemma 38.34, χ_2 is induced from $(\mathbb{Z}/2^{c_2(\chi)}\mathbb{Z})^\times$, of order dividing $2^{c_2(\chi)}$, $\chi_q^2 = \chi_d^2 = \mathbf{1}$ and the product of the odd components at primes dividing N_ψ is killed by o_ψ; so $\chi^K = \mathbf{1}$ for $K = 2^{c_2(\chi)+1}o_\psi = 2^{a_0}u$ with u odd, and $2^{a_0} \le 2^{c_2(\chi)+1}o_\psi$. For $v \in T$, $v \le \max(\ell, N_\psi) \le \ell N_\psi$ (Step 2), so $v^2 2^{a_0} \le 2^{c_2(\chi)+1}o_\psi \ell^2 N_\psi^2 < 2^{c_2(\chi)+6}o_\psi \ell^3 N_\psi^2 \le 2^{n'}$.

Now let $v \in T$ and $i \in \mathbb{Z}$, and suppose $\overline{\xi\Psi^i}(\sigma_v) = 1$. Since $\bar{\chi}'' = \mathbf{1}$, $\bar{\Psi} = \bar{\chi}\,\bar{\chi}_{\mathrm{cyc}}^e$ and $\bar{\chi}_{\mathrm{cyc}}(\sigma_v) = 1$, this says $\bar{\xi}(\sigma_v)\bar{\chi}(\sigma_v)^i = 1$. Raising to the power $2^{a_0}u$ kills $\bar{\chi}$ and $\bar{\chi}_{\mathrm{pr}}$, so $\bar{\chi}_{\mathrm{dy}}(\sigma_v)^{2^{a_0}u} = 1$; as $\chi_{\mathrm{dy}}(\sigma_v)$ is a root of unity of 2-power order, $\chi_{\mathrm{dy}}(\sigma_v)^{2^{a_0}u} = 1$, hence $\chi_{\mathrm{dy}}(\sigma_v)^{2^{a_0}} = 1$ (u odd). Since v is odd, $\chi_{\mathrm{dy}}(\sigma_v) = \chi_{\mathrm{dy}}(v)$, so $x = v^{2^{a_0+1}}$ lies in $\ker\chi_{\mathrm{dy}}$. Now $x \equiv 1 \pmod 8$, so $x \in \langle 5\rangle$, a cyclic 2-group on which χ_{dy} is injective (its kernel there is a subgroup not containing the unique subgroup $\langle 5^{2^{n'-3}}\rangle$ of order 2). Hence $x \equiv 1 \pmod{2^{n'}}$. But

$$v^{2^{a_0+1}} - 1 = (v^2-1)\prod_{j=1}^{a_0}(v^{2^j}+1), \qquad v^{2^j}+1 \equiv 2 \pmod 4\ (j \ge 1),$$

so the exponent of 2 in $x-1$ is that of v^2-1 plus a_0, and $2^{n'} \le (v^2-1)2^{a_0} < v^2 2^{a_0} \le 2^{n'}$, a contradiction. So $\overline{\xi\Psi^i}(\sigma_v) \ne 1$ for all $v \in T$, $i \in \mathbb{Z}$, which with the choice of σ_ℓ is (Sg2).

Step 5: the element ϕ, (Sg3). Let U be an open normal subgroup of $G_\mathbb{Q}$ and write the order of $G_\mathbb{Q}/U$ as $\ell^s k'$ with $\ell \nmid k'$. For $n \ge \max(s, k')$ we have $\ell^s \mid \ell^{n!}$ and, the order of ℓ modulo k' being at most $k' \le n$, $\ell^{n!} \equiv 1 \pmod{k'}$; so the residue of $\ell^{n!}$ modulo $\ell^s k'$ does not depend on $n \ge \max(s, k')$, and the image of $\sigma_\ell^{\ell^{n!}}$ in $G_\mathbb{Q}/U$ is eventually constant. As $G_\mathbb{Q}$ is profinite, the sequence $\sigma_\ell^{\ell^{n!}}$ converges; let ϕ be its limit.

Step 6: the element g_0, (Sg4). The character $\bar{\alpha} = \bar{\xi}$ (as $\bar{\chi}_{\mathrm{cyc}} = \bar{\omega}_\ell$) is non-trivial: for g with $g(\zeta') = \zeta'^b$ on the roots of unity of order dividing $2^{n'}p'$, where $b \equiv 5 \pmod{2^{n'}}$ and $b \equiv 1 \pmod{p'}$, $\xi(g) = \chi_{\mathrm{dy}}(5)$ has order $2^{n'-2} \ge 2$, so $\bar{\xi}(g) \ne 1$. The character $\bar{\Psi}$ is non-trivial: otherwise $\chi'\omega_\ell^e$, of order prime to ℓ with trivial reduction (as $\bar{\Psi} = \bar{\chi}'\bar{\omega}_\ell^e$), would be trivial, so $\chi' = \omega_\ell^{-e}$ and χ' would be induced from a character modulo ℓ. In case (II) this gives $\chi' = \chi'_\ell$, so $\chi^{(\ell)} = \mathbf{1}$ has odd order, contrary to (II). In case (III), $\chi = \chi'$ is induced from a character modulo N_ψ (Lemma 44.5) with $\ell \nmid N_\psi$ (the odd prime factors of N_ψ lie in $B_\psi \not\ni \ell$), so its conductor divides $\gcd(\ell, N_\psi) = 1$ and $\chi = \mathbf{1}$, contrary to (III). The kernels of $\bar{\alpha}$ and $\bar{\Psi}$ are proper subgroups, and a group is not the union of two proper subgroups; so there is g_0 with $\bar{\alpha}(g_0) \ne 1$ and $\bar{\Psi}(g_0) \ne 1$.

Step 7: the element s_0, (Sg5). The subgroup $H = I_\ell \cap \ker\chi \cap \ker\omega_\ell$ is open in I_ℓ, as χ and ω_ℓ are continuous with finite image. Since $\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ is totally ramified with group $\mathbb{Z}_\ell^\times$, $\chi_{\mathrm{cyc}}(I_\ell) = \mathbb{Z}_\ell^\times$, so $\chi_{\mathrm{cyc}}(H)$ has finite index in $\mathbb{Z}_\ell^\times$ and contains $1+\ell^j\mathbb{Z}_\ell$ for some $j \geq 1$. Choose $s_0 \in H$ with $\chi_{\mathrm{cyc}}(s_0) = 1+\ell^j$, which has infinite order.

Step 8: (Sg6) and conclusion. By Lemma 44.5, every residual Selmer cocycle for $\gamma \in \{\alpha, \beta, \theta, \alpha^{-1}, \beta^{-1}, \theta^{-1}\}$ is a coboundary. By Steps 1–8, $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, (\sigma_v)_{v\in T}, \phi, g_0, s_0)$ is a symplectic Eisenstein datum; by construction $e' = e$, $N = N_\mathfrak{h}$, $\chi' = \chi$ in the notation of the definition, S is the set of primes dividing $2\ell N_\mathfrak{h} p'$ and $\xi = \chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ with χ_{dy} primitive modulo $2^{n'}$, $\chi_{\mathrm{dy}}(-1) = -1$, and χ_{pr} modulo p' of order m, both with values in $\mathcal{O}^\times$. So $\mathfrak{D}$ is attached to $(\psi, \mathfrak{h}, t, \chi)$. □

Lemma 44.5. *Let $\psi \in \mathcal{P}$, let $\mathfrak{h}$ be a Sha-host of ψ big at an integer $t \geq 1$, ℓ an odd prime, e an integer with $0 < e < t$, $\mathcal{O}$ a coefficient ring and $\chi \in X_\mathfrak{h}(\mathcal{O}, e)$ in case (II) or in case (III) for (ℓ, e), with integers n', p', m of the case. Let χ_{dy} be a primitive Dirichlet character modulo $2^{n'}$ with $\chi_{\mathrm{dy}}(-1) = -1$ and χ_{pr} a Dirichlet character modulo p' whose order divides m, both with values in $\mathcal{O}^\times$; put $\xi = \chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$, $N = N_\mathfrak{h}$, and let α, β, θ be the characters (44.1) for $(\ell, \mathcal{O}, e, N, \chi, \xi)$ and $T = T_\ell(\chi)$. Then $e \geq 2$, $n' \geq 3$, $c_2(\chi) < n'$ and ξ has order prime to ℓ; in case (III), χ has order prime to ℓ and is induced from a Dirichlet character modulo N_ψ; and for every $\gamma \in \{\alpha, \beta, \theta, \alpha^{-1}, \beta^{-1}, \theta^{-1}\}$ every residual Selmer cocycle for γ is a coboundary.*

Proof. Write $\mathfrak{h} = (a, q, d)$. Reduction modulo $\mathfrak{m}_\mathcal{O}$ is written with a bar; it is injective on roots of unity of order prime to ℓ. The Teichmüller character ω_ℓ is the Dirichlet character modulo ℓ sending b to the $(\ell-1)$-th root of unity in $\mathbb{Z}_\ell$ congruent to b; so $\bar\omega_\ell = \bar\chi_{\mathrm{cyc}}$ and $\omega_\ell(-1) = -1$.

Step 0: preliminaries on χ, e and ξ. By Lemma 38.34, items 1 and 2, χ_2 has 2-power order, $\chi_q^2 = \chi_d^2 = \mathbf{1}$ and $\chi_r^{o_\psi} = \mathbf{1}$ for every odd prime $r \mid N_\psi$. The 2-component of χ'' has ℓ-power and 2-power order, so it is trivial and $\chi_2' = \chi_2$; hence $\chi' = \chi_2\vartheta$ with ϑ a product of components at odd primes. The values of χ'' are roots of unity of ℓ-power order, so $\bar\chi'' = \mathbf{1}$ and $\chi''(-1) = 1$; thus $\chi'(-1) = \chi(-1) = (-1)^e$. In case (II), $e \geq 2$, $p' = m = 1$ and $\chi_{\mathrm{pr}} = \mathbf{1}$. In case (III), $\ell \notin B_\psi \ni 3$ forces $\ell \geq 5$, and $(\ell-1) \mid 2e$ gives $e \geq 2$; χ has odd order m, so $\chi_2 = \chi_q = \chi_d = \mathbf{1}$ and $\chi = \prod_r \chi_r$ over the odd primes $r \mid N_\psi$; as $v_r(N) = v_r(N_\psi)$ for these r (q, d are prime to N_ψ), χ is induced from a character modulo N_ψ, and $m \mid o_\psi$. Since $\ell \notin B_\psi$, $\ell \nmid o_\psi$, so m is prime to ℓ, $\chi'' = \mathbf{1}$, $\chi' = \vartheta = \chi$ and $c_2(\chi) = 0$. In both cases χ_{pr} has odd order dividing m, so $\chi_{\mathrm{pr}}(-1) = 1$ and ξ has order dividing $2^{n'}m$, prime to ℓ. Finally $c_2(\chi) < n'$ and $n' \geq 3$: in case (II), $2^{n'} \geq 2^{c_2(\chi)+6}$; in case (III), $c_2(\chi) = 0$ and $2^{n'} \geq 8\ell^2 > 8$.

Step 1: the residual characters are reductions of Dirichlet characters. Put

$$\chi_\alpha = \chi_{\mathrm{dy}} \cdot \chi_{\mathrm{pr}}, \qquad \chi_\theta = (\chi_2\chi_{\mathrm{dy}}) \cdot (\vartheta\,\omega_\ell^e\chi_{\mathrm{pr}}), \qquad \chi_\beta = (\chi_2\chi_{\mathrm{dy}}^{-1}) \cdot (\vartheta\,\omega_\ell^e\chi_{\mathrm{pr}}^{-1}),$$

and for $\gamma \in \{\alpha, \theta, \beta\}$ let $\chi_{\gamma,2}$ and $\chi_{\gamma,\mathrm{od}}$ be the first and second factor. Since $\bar\chi_{\mathrm{cyc}}\bar\omega_\ell^{-1} = \mathbf{1}$, $\bar\alpha = \bar\xi$; since $\bar\Psi = \bar\chi'\bar\omega_\ell^e$ and $\chi' = \chi_2\vartheta$, $\bar\theta = \bar\alpha\bar\Psi$ and $\bar\beta = \bar\Psi\bar\alpha^{-1}$, we get $\bar\gamma = \bar\chi_\gamma$ for $\gamma \in \{\alpha, \theta, \beta\}$, and $\overline{\gamma^{-1}} = \overline{\chi_\gamma^{-1}}$. Each χ_γ has order prime to ℓ (χ', ω_ℓ and ξ have).

Step 2: the 2-parts are primitive modulo $2^{n'}$. Let $U = \{u \in (\mathbb{Z}/2^{n'}\mathbb{Z})^\times : u \equiv 1 \pmod{2^{n'-1}}\}$. The character χ_2 is induced from a character modulo $2^{c_2(\chi)}$, and $c_2(\chi) \leq n'-1$ (Step 0), so χ_2 is trivial on U; $\chi_{\mathrm{dy}}^{\pm1}$ is not, being primitive. Hence $\chi_{\gamma,2}$ is non-trivial on U; as its conductor is a power of 2 dividing $2^{n'}$ and every proper such divisor divides $2^{n'-1}$, $\chi_{\gamma,2}$ is primitive modulo $2^{n'}$. Classically $(\mathbb{Z}/2^{n'}\mathbb{Z})^\times = \{\pm1\} \times \langle 5\rangle$ with 5 of order $2^{n'-2}$ and $U = \langle 5^{2^{n'-3}}\rangle$ [266]; a character non-trivial on U is therefore injective on $\langle 5\rangle$, and $\chi_{\gamma,2}(5)$ has order $2^{n'-2} \geq 2$.

Step 3: the odd parts. Let $\chi_{\gamma,\mathrm{od}}^*$ be the primitive character inducing $\chi_{\gamma,\mathrm{od}}$, of conductor f_γ. The conductor of a product divides the least common multiple of the conductors [266];

ϑ has odd conductor, ω_ℓ^e conductor dividing ℓ, χ_{pr} conductor dividing p'; so f_γ is odd and $f_\gamma \le \ell\,\mathrm{cond}(\vartheta)\,p'$. In case (II), $p'=1$ and $\mathrm{cond}(\vartheta)\le N$, since ϑ is a character modulo N; in case (III), $\mathrm{cond}(\vartheta)=\mathrm{cond}(\chi)\le N_\psi$ by Step 0 and $p'=p_1(\psi)$. By the definition of n',

$$f_\gamma\, 4^{n_0(\ell,\chi)} \le 2^{n'} \qquad (\gamma\in\{\alpha,\theta,\beta\}).$$

Let f_ℓ be the order of ℓ modulo $\mathrm{lcm}(4,\mathrm{ord}\,\vartheta)$, so that $4\mid \ell^{f_\ell}-1$, $n_0(\ell,\chi)$ is the exponent of 2 in $\ell^{f_\ell}-1$, $\mathrm{ord}\,\vartheta \mid \ell^{f_\ell}-1$ and $(\ell-1)\mid \ell^{f_\ell}-1$. The order of $\chi_{\gamma,\mathrm{od}}$ divides $\mathrm{lcm}(\mathrm{ord}\,\vartheta,\ell-1,m)$, and $m\mid \ell^{f_\ell}-1$ (in case (III), $m=\mathrm{ord}\,\chi=\mathrm{ord}\,\vartheta$). So $\chi_{\gamma,\mathrm{od}}^*(b)^{\ell^{f_\ell}-1}=1$ for b prime to f_γ. Finally, with Step 0, $\chi_\gamma(-1)=-1$:

$$\begin{aligned}
\chi_\alpha(-1) &= \chi_{\mathrm{dy}}(-1)\chi_{\mathrm{pr}}(-1) = -1,\\
\chi_\theta(-1) &= \chi_\alpha(-1)\,\chi'(-1)\,\omega_\ell(-1)^e = -1,\\
\chi_\beta(-1) &= \chi'(-1)\,\omega_\ell(-1)^e\,\chi_\alpha(-1)^{-1} = -1.
\end{aligned}$$

Step 4: Bernoulli units. Let $\varepsilon\in\{1,-1\}$. The hypotheses of Lemma 44.6 hold for ℓ, the exponent f_ℓ (in place of m), $a=n_0(\ell,\chi)$, $f=f_\gamma$, $n=n'$, and the characters $(\chi_{\gamma,\mathrm{od}}^*)^\varepsilon$ (primitive modulo f_γ) and $\chi_{\gamma,2}^\varepsilon$ (primitive modulo $2^{n'}$, Step 2): Step 3 gives the order condition, the bound and $(\chi_{\gamma,\mathrm{od}}^*)^\varepsilon(-1)\chi_{\gamma,2}^\varepsilon(-1)=\chi_\gamma(-1)^\varepsilon=-1$. Hence $\chi_\gamma^{*,\varepsilon}:=(\chi_{\gamma,\mathrm{od}}^*\chi_{\gamma,2})^\varepsilon$ is primitive modulo $f_\gamma 2^{n'}$ and $|B_{1,\chi_\gamma^{*,\varepsilon}}|_\ell=1$. As characters of $G_\mathbb{Q}$, $\chi_\gamma^{*,\varepsilon}=\chi_\gamma^\varepsilon$: the two Dirichlet characters agree on integers prime to $2\ell N p'$.

Step 5: the hypotheses of Lemma 44.7 on the character. Fix $\gamma_0\in\{\alpha,\theta,\beta\}$ and ε, put $\gamma=\gamma_0^\varepsilon$ and $\chi_{\mathrm{H}}=\chi_{\gamma_0}^{*,\varepsilon}$. Then χ_{H} is primitive, of order prime to ℓ (Step 1), $\bar\chi_{\mathrm{H}}=\bar\gamma$ (Steps 1 and 4) and $|B_{1,\chi_{\mathrm{H}}^{-1}}|_\ell=1$ (Step 4 with $-\varepsilon$). Choose an integer $b\equiv 1 \pmod{\ell f_{\gamma_0}}$ with $b\equiv 5 \pmod{2^{n'}}$ and $g\in G_\mathbb{Q}$ with $g(\zeta)=\zeta^b$ for all roots of unity of order dividing $\ell f_{\gamma_0}2^{n'}$. Then $\bar\chi_{\mathrm{cyc}}(g)=\bar b=1$, while $\chi_{\mathrm{H}}(g)=\chi_{\gamma_0,2}(5)^\varepsilon$ is a root of unity of order $2^{n'-2}\ge 2$ (Step 2), whose reduction is not 1 as ℓ is odd. So $\chi_{\mathrm{H}}\ne\mathbf{1}$ and $\bar\chi_{\mathrm{H}}\ne\bar\chi_{\mathrm{cyc}}$, the reduction of χ_{cyc} modulo ℓ.

Step 6: a residual Selmer cocycle for γ vanishes on $I_{\bar v}\cap\ker\bar\gamma$ at every place. Let z be a residual Selmer cocycle for γ. On $\ker\bar\gamma$ the cocycle relation makes z a homomorphism to $(\mathbb{F}_\mathcal{O},+)$. Let $\bar w$ be a place above a prime not in T, and $N_{\bar w}=\{g\in I_{\bar w}:\bar\theta(g)=\bar\Psi(g)=\bar\alpha(g)=1\}$; as γ is a product of powers of θ,Ψ,α, $N_{\bar w}\subseteq I_{\bar w}\cap\ker\bar\gamma$, a normal subgroup with quotient embedded in $(\mathbb{F}_\mathcal{O}^\times)^3$, of order prime to ℓ. Since z vanishes on $N_{\bar w}$, it induces a homomorphism from a group of order prime to ℓ to a group of exponent ℓ, which is trivial: $z=0$ on $I_{\bar w}\cap\ker\bar\gamma$. Let $v\in T$. On D_v, $z(g)=\bar\gamma(g)y-y$ for some y, which vanishes on $I_v\cap\ker\bar\gamma$, at the fixed place $\bar v$. A place above v is $g_1\bar v$ with $g_1\in G_\mathbb{Q}$, with inertia group $g_1 I_v g_1^{-1}$; for $h\in I_v\cap\ker\bar\gamma$,

$$z(g_1hg_1^{-1}) = z(g_1)+\bar\gamma(g_1)\big(z(h)+\bar\gamma(h)z(g_1^{-1})\big) = z(g_1)+\bar\gamma(g_1)z(g_1^{-1}) = z(1)=0.$$

So $z(g)=0$ for every place $\bar p$ above a prime and every $g\in I_{\bar p}$ with $\bar\chi_{\mathrm{H}}(g)=\bar\gamma(g)=1$.

Step 7: conclusion. By Steps 5 and 6, Lemma 44.7 applies to χ_{H}, the field $k=\mathbb{F}_\mathcal{O}$ and z (locally constant by definition): there is $\mu\in\mathbb{F}_\mathcal{O}$ with $z(g)=\mu(\bar\gamma(g)-1)=\bar\gamma(g)\mu-\mu$ for all g. As γ_0 and ε were arbitrary, this proves the claim for the six characters. □

Lemma 44.6. *Let ℓ be an odd prime and $m\ge 1$ an integer with $4\mid\ell^m-1$, and let a be the exponent of 2 in ℓ^m-1. Let $f\ge 1$ be odd, $n\ge 1$, α a primitive Dirichlet character modulo f and β a primitive Dirichlet character modulo 2^n, both with values in $\overline{\mathbb{Q}}_\ell^\times$, such that*

$$\alpha(b)^{\ell^m-1}=1 \text{ for all } b \text{ prime to } f, \qquad f\cdot 4^a\le 2^n, \qquad \alpha(-1)\beta(-1)=-1.$$

Then $\alpha\beta$ is a primitive Dirichlet character modulo $f2^n$ and $|B_{1,\alpha\beta}|_\ell=1$.

Proof. Step 0: sizes and the Bernoulli number as a sum. Since $f \ge 1$, $2^{2a} \le f4^a \le 2^n$, so $n \ge 2a \ge 4$. Put $n_1 = n - a \ge a \ge 2$ and $\varkappa = f2^a$; then $\varkappa \cdot 2^a = f4^a \le 2^n$, so $4 \le \varkappa \le 2^{n_1}$. A product of primitive characters of coprime conductors is primitive modulo the product of the conductors [266], so $\alpha\beta$ is primitive modulo $F = f2^n$; it is odd, hence non-trivial, so $\sum_{c=1}^{F} \alpha\beta(c) = 0$ and, as $\alpha\beta(F) = 0$,

$$B_{1,\alpha\beta} = \sum_{c=1}^{F} \alpha\beta(c)\Big(\frac{c}{F} - \frac{1}{2}\Big) = \frac{1}{F}\sum_{c=0}^{F-1} \alpha(c)\beta(c)\, c. \tag{44.5}$$

Step 1: three facts on 2-power residues. (i) Put $v = 1 + 2^{n-1}$. Since $n \ge 2$, $v^2 \equiv 1 \pmod{2^n}$, and $\{1, v\}$ is the kernel of $(\mathbb{Z}/2^n\mathbb{Z})^\times \to (\mathbb{Z}/2^{n-1}\mathbb{Z})^\times$. If $\beta(v) = 1$, β would be induced from a character modulo 2^{n-1}, against primitivity; as $\beta(v)^2 = \beta(v^2) = 1$, $\beta(v) = -1$. (ii) Recall that for $n \ge 3$, $(\mathbb{Z}/2^n\mathbb{Z})^\times = \{\pm 1\} \times \langle 5\rangle$ with 5 of order 2^{n-2}, and $5^{2^i} \equiv 1 + 2^{i+2} \pmod{2^{i+3}}$ for $i \ge 0$ [266]; hence $5^{2^{n-3}} \equiv v$ and $\langle 5^{2^i}\rangle = \{u : u \equiv 1 \pmod{2^{i+2}}\}$ for $0 \le i \le n-2$. By (i), $\beta(5)^{2^{n-3}} = -1$, so $\beta(5)$ has order exactly 2^{n-2}. Let $u = \pm 5^j$ be a unit with $\beta(u)^{2^a} = 1$. As $\beta(-1)^2 = 1$ and $a \ge 1$, $\beta(5)^{j2^a} = 1$, so $2^{n-2} \mid j2^a$, that is $2^{n-2-a} \mid j$ (note $n-2-a \ge a-2 \ge 0$), and $5^j \in \langle 5^{2^{n-2-a}}\rangle$, so $5^j \equiv 1 \pmod{2^{n_1}}$. Hence

$$\beta(u)^{2^a} = 1 \implies u \equiv 1 \text{ or } u \equiv -1 \pmod{2^{n_1}}, \tag{44.6}$$

and not both, as $n_1 \ge 2$. (iii) Write $\ell^m = 1 + 2^a o$ with o odd. If $y = 1 + 2^b o'$ with $b \ge 2$ and o' odd, then $y^2 = 1 + 2^{b+1}(o' + 2^{b-1}o'^2)$ with $o' + 2^{b-1}o'^2$ odd. By induction $\ell^{m2^i} - 1$ has 2-adic valuation exactly $a + i$, so the class of ℓ^m in $(\mathbb{Z}/2^n\mathbb{Z})^\times$ has order 2^{n-a}, and its powers ℓ^{mi}, $0 \le i < 2^{n-a}$, are pairwise distinct modulo 2^n and $\equiv 1 \pmod{2^a}$. As there are exactly 2^{n-a} classes $\equiv 1 \pmod{2^a}$ modulo 2^n,

$$\{\ell^{mi} \bmod 2^n : 0 \le i < 2^{n-a}\} = \{1 + 2^a j \bmod 2^n : 0 \le j < 2^{n-a}\}. \tag{44.7}$$

Step 2: partial sums along residue classes modulo 2^n. For $u \in \mathbb{Z}/2^n\mathbb{Z}$ put

$$\tau(u) = \frac{1}{F}\sum_{\substack{0 \le c < F \\ c \equiv u \ (2^n)}} \alpha(c)\, c, \qquad \delta_\alpha = \sum_{c=0}^{f-1} \alpha(c) \in \{0, 1\}$$

($\delta_\alpha = 1$ if $f = 1$ and 0 otherwise). Since f is odd, by the Chinese remainder theorem the integers $c \equiv u \pmod{2^n}$ in any interval of F consecutive integers run over all residues modulo f exactly once; so their α-values sum to δ_α. Grouping (44.5) by classes modulo 2^n gives

$$B_{1,\alpha\beta} = \sum_{u \in \mathbb{Z}/2^n\mathbb{Z}} \beta(u)\, \tau(u). \tag{44.8}$$

Let $t \ge 0$ be an integer with $ft \le F$ and $u \in \mathbb{Z}/2^n\mathbb{Z}$. Substituting $c = c' - ft$ (so $\alpha(c) = \alpha(c')$, as $f \mid ft$) and splitting the range $ft \le c' < F + ft$ at F, where $c' = F + c''$ with $0 \le c'' < ft$, $\alpha(c') = \alpha(c'')$ and $c' \equiv c'' \pmod{2^n}$:

$$F\tau(u - ft) = \sum_{\substack{ft \le c' < F + ft \\ c' \equiv u}} \alpha(c')(c' - ft) = F\tau(u) - \sum_{\substack{0 \le c'' < ft \\ c'' \equiv u}} \alpha(c'')c'' + \sum_{\substack{0 \le c'' < ft \\ c'' \equiv u}} \alpha(c'')(F + c'') - ft\,\delta_\alpha.$$

Hence

$$\tau(u) - \tau(u - ft) = \frac{t\,\delta_\alpha}{2^n} - \sum_{\substack{0 \le c < ft \\ c \equiv u \ (2^n)}} \alpha(c). \tag{44.9}$$

Put $g_0(u) = \tau(u) - \tau(0)$. Given u, choose $0 \le t < 2^n$ with $ft \equiv u \pmod{2^n}$ (f is a unit modulo 2^n); then $ft \le F$ and (44.9) reads $g_0(u) = t\delta_\alpha/2^n - \sum_{0\le c<ft,\, c\equiv u} \alpha(c)$. Since ℓ is odd and every non-zero value of α is a root of unity ζ with $\zeta^{\ell^m} = \zeta$, we get $g_0(u) \in \overline{\mathbb{Z}}_\ell$ and

$$\overline{g_0(u)}^{\,\ell^m} = \overline{g_0(u)} \qquad (u \in \mathbb{Z}/2^n\mathbb{Z}), \tag{44.10}$$

because $y \mapsto y^{\ell^m}$ is a ring endomorphism of $\overline{\mathbb{F}}_\ell$ fixing $\mathbb{F}_\ell$. As $\beta \ne \mathbf{1}$ by Step 1(i), $\sum_u \beta(u) = 0$, so (44.8) gives $B_{1,\alpha\beta} = \sum_u \beta(u) g_0(u) \in \overline{\mathbb{Z}}_\ell$. Finally, (44.9) with $t = 2^a$ (allowed, as $\varkappa \le 2^n \le F$), where the only c with $0 \le c < \varkappa \le 2^n$ and $c \equiv u$ is $c = u_0$ if $u_0 < \varkappa$, gives for every u, with $\delta' = 2^a\delta_\alpha/2^n \in \overline{\mathbb{Z}}_\ell$,

$$g_0(u) - g_0(u - \varkappa) = \delta' - [u_0 < \varkappa]\, \alpha(u_0), \tag{44.11}$$

where $[P]$ is 1 if P holds and 0 otherwise.

Step 3: if $B_{1,\alpha\beta} \in \mathfrak{m}_\ell$, the sum localises at U. Suppose $|B_{1,\alpha\beta}|_\ell < 1$, that is $\sum_u \bar\beta(u)\bar g_0(u) = 0$ in $\overline{\mathbb{F}}_\ell$. Let U be the set of units u modulo 2^n with $\beta(u)^{2^a} = 1$. We claim that for every unit y modulo 2^n

$$\sum_{u\in U} \bar\beta(u)\, \bar g_0(uy) = 0. \tag{44.12}$$

Substituting $u \mapsto uy^{-1}$, $\sum_u \bar\beta(u)\bar g_0(uy) = \bar\beta(y)^{-1}\sum_u \bar\beta(u)\bar g_0(u) = 0$. Applying the ring endomorphism $y' \mapsto y'^{\ell^{mi}}$ of $\overline{\mathbb{F}}_\ell$ and (44.10) gives $\sum_u \bar\beta(u)^{\ell^{mi}} \bar g_0(uy) = 0$ for all $i \ge 0$; summing over $0 \le i < 2^{n-a}$,

$$\sum_u \Big(\sum_{i=0}^{2^{n-a}-1} \bar\beta(u)^{\ell^{mi}} \Big) \bar g_0(uy) = 0.$$

The terms with u even vanish. For a unit u, $\beta(u)$ is a root of unity of order dividing 2^{n-1}, so $\bar\zeta = \bar\beta(u)$ satisfies $\bar\zeta^{2^n} = 1$, and by (44.7) the inner sum is $\bar\zeta \sum_{j=0}^{2^{n-a}-1} (\bar\zeta^{2^a})^j$, which is $2^{n-a}\bar\zeta$ if $\bar\zeta^{2^a} = 1$ and 0 otherwise ($\bar\zeta^{2^a}$ has order dividing 2^{n-a}). Reduction is injective on roots of unity of order prime to ℓ, so $\bar\zeta^{2^a} = 1$ exactly when $u \in U$. As $2^{n-a} \ne 0$ in $\overline{\mathbb{F}}_\ell$, (44.12) follows.

Step 4: the contradiction. The element $1 - \varkappa$ is odd, so (44.12) for $y = 1$ and $y = 1 - \varkappa$ gives

$$\sum_{u\in U} \bar\beta(u)(\bar g_0(u) - \bar g_0(u(1-\varkappa))) = 0.$$

By (44.6) each $u \in U$ satisfies exactly one of $u \equiv 1$, $u \equiv -1 \pmod{2^{n_1}}$; put $\mathrm{sg}(u) = 1$, respectively -1. Since $2^a \mid \varkappa$ and $n_1 + a = n$:

- if $u \equiv 1 \pmod{2^{n_1}}$, then $(u-1)\varkappa \equiv 0 \pmod{2^n}$, so $u(1-\varkappa) = u - \varkappa$, and by (44.11) $g_0(u) - g_0(u-\varkappa) = \delta' - [u_0 < \varkappa]\alpha(u_0)$; as $u_0 \equiv 1 \pmod{2^{n_1}}$ and $\varkappa \le 2^{n_1}$, $u_0 < \varkappa$ holds exactly when $u_0 = 1$ (note $\varkappa \ge 4$), that is $u = 1$, and $\alpha(1) = 1$;
- if $u \equiv -1 \pmod{2^{n_1}}$, then $(u+1)\varkappa \equiv 0 \pmod{2^n}$, so $u(1-\varkappa) = u + \varkappa$, and (44.11) at $u + \varkappa$ gives $g_0(u) - g_0(u+\varkappa) = -\delta' + [(u+\varkappa)_0 < \varkappa]\alpha((u+\varkappa)_0)$; as $(u+\varkappa)_0 \equiv \varkappa - 1 \pmod{2^{n_1}}$ with $0 \le \varkappa - 1 < 2^{n_1}$, $(u+\varkappa)_0 < \varkappa$ holds exactly when $(u+\varkappa)_0 = \varkappa - 1$, that is $u = -1$, and $\alpha(\varkappa - 1) = \alpha(-1)$ since $f \mid \varkappa$.

Both 1 and -1 lie in U. Summing, and using $\alpha(-1)\beta(-1) = -1$,

$$0 = \bar\delta' \sum_{u\in U} \mathrm{sg}(u)\bar\beta(u) - \bar\beta(1) + \bar\beta(-1)\bar\alpha(-1) = \bar\delta' \sum_{u\in U} \mathrm{sg}(u)\bar\beta(u) - 2.$$

The element $v = 1 + 2^{n-1}$ lies in U ($\beta(v)^{2^a} = 1$ by Step 1(i)) and $v \equiv 1 \pmod{2^{n_1}}$ since $n - 1 \ge n_1$. Multiplication by v permutes U, preserves sg (as $vu \equiv u \pmod{2^{n_1}}$) and multiplies $\bar\beta$ by $\bar\beta(v) = -1$; so $\Sigma = \sum_{u\in U} \mathrm{sg}(u)\bar\beta(u)$ satisfies $\Sigma = -\Sigma$, hence $\Sigma = 0$ as $\ell \ne 2$. Therefore $2 = 0$ in $\overline{\mathbb{F}}_\ell$, which is false as ℓ is odd. So $|B_{1,\alpha\beta}|_\ell \ge 1$, and with $B_{1,\alpha\beta} \in \overline{\mathbb{Z}}_\ell$ (Step 2), $|B_{1,\alpha\beta}|_\ell = 1$. $\square$

Lemma 44.7. *Let ℓ be an odd prime and $\chi \neq \mathbf{1}$ a primitive Dirichlet character modulo Q with values in $\overline{\mathbb{Q}}_\ell^\times$ and of order prime to ℓ. View χ as the character of $G_{\mathbb{Q}}$ with $\chi(g) = \chi(b)$ whenever $g(\zeta) = \zeta^b$ for all Q-th roots of unity ζ, let $\bar\chi\colon G_{\mathbb{Q}} \to \overline{\mathbb{F}}_\ell^\times$ be its reduction ($\overline{\mathbb{F}}_\ell$ the residue field of the integral closure of $\mathbb{Z}_\ell$ in $\overline{\mathbb{Q}}_\ell$) and $\bar\omega\colon G_{\mathbb{Q}} \to \mathbb{F}_\ell^\times$ the reduction of χ_{cyc} modulo ℓ. Assume*

$$\bar\chi \neq \bar\omega \qquad \text{and} \qquad |B_{1,\chi^{-1}}|_\ell = 1.$$

Let $k \subseteq \overline{\mathbb{F}}_\ell$ be a subfield containing the values of $\bar\chi$, and $z\colon G_{\mathbb{Q}} \to k$ a locally constant map with $z(gh) = z(g) + \bar\chi(g)z(h)$ for all $g, h \in G_{\mathbb{Q}}$, such that $z(g) = 0$ for every place $\bar p$ of $\overline{\mathbb{Q}}$ above a prime and every $g \in I_{\bar p}$ with $\bar\chi(g) = 1$. Then there is $\mu \in k$ with $z(g) = \mu\,(\bar\chi(g) - 1)$ for all $g \in G_{\mathbb{Q}}$.

Proof. Since $\chi \neq \mathbf{1}$ is primitive, $Q \geq 3$, and $Q \not\equiv 2 \pmod 4$ (a character modulo $2Q'$ with Q' odd is induced from one modulo Q'). Let $K_Q = \mathbb{Q}(\zeta_Q)$, $G = \mathrm{Gal}(K_Q/\mathbb{Q})$, $\sigma_b \in G$ with $\sigma_b(\zeta_Q) = \zeta_Q^b$, and $H_Q = G_{K_Q} \subseteq G_{\mathbb{Q}}$; χ is trivial on H_Q. As χ has order prime to ℓ and reduction is injective on roots of unity of order prime to ℓ, $\bar\chi \neq \mathbf{1}$. From $z(1) = z(1) + z(1)$ we get $z(1) = 0$, and then $z(g^{-1}) = -\bar\chi(g)^{-1} z(g)$.

Step 1: z gives a homomorphism on the class group of K_Q. On H_Q, $z(hh') = z(h) + z(h')$, so $z|_{H_Q}$ is a locally constant homomorphism to the additive group of k; its kernel is an open normal subgroup of H_Q, with fixed field L a finite abelian extension of K_Q. For a place $\bar p$ of $\overline{\mathbb{Q}}$ above a prime, the inertia group of L/K_Q at $\bar p$ is the image of $I_{\bar p} \cap H_Q$, on which z vanishes by hypothesis (as $\bar\chi = 1$ there); so L/K_Q is unramified at all finite places, and at the archimedean places since K_Q is totally complex. Hence L lies in the Hilbert class field H of K_Q and $z|_{H_Q}$ factors through $\mathrm{Gal}(H/K_Q)$ [190]. Composing with the Artin isomorphism $\mathrm{Art}\colon \mathrm{Cl}(K_Q) \to \mathrm{Gal}(H/K_Q)$ gives an additive map $\tilde z\colon \mathrm{Cl}(K_Q) \to k$, $\tilde z(\mathfrak{a}) = z(h)$ for any $h \in H_Q$ restricting to $\mathrm{Art}(\mathfrak{a})$ on H.

Step 2: equivariance. For $g \in G_{\mathbb{Q}}$ and $h \in H_Q$, since $\bar\chi(h) = 1$,

$$z(ghg^{-1}) = z(g) + \bar\chi(g)\big(z(h) + z(g^{-1})\big) = \bar\chi(g)\, z(h).$$

The field H is Galois over $\mathbb{Q}$, and if $g|_{K_Q} = \sigma_b$ then $\mathrm{Art}(\sigma_b\mathfrak{a}) = g\,\mathrm{Art}(\mathfrak{a})\,g^{-1}$ on H (functoriality of the Artin map). Hence $\tilde z(\sigma_b\mathfrak{a}) = \bar\chi(b)\,\tilde z(\mathfrak{a})$ for all b prime to Q and all $\mathfrak{a}$.

Step 3: z vanishes on H_Q. Choose an integer c prime to Q with $\bar c \neq \bar\chi(c)$ in $\overline{\mathbb{F}}_\ell$: if $\ell \nmid Q$, $c = \ell$ works ($\bar c = 0 \neq \bar\chi(\ell)$); if $\ell \mid Q$, then $\mu_\ell \subset K_Q$ and $\bar\omega(g) = \bar b$ for $g|_{K_Q} = \sigma_b$, so if $\bar\chi(c) = \bar c$ for all c prime to Q we would have $\bar\chi = \bar\omega$, which is excluded. By Theorem B.23, $\beta = (c - \sigma_c)\theta_Q$ lies in $\mathbb{Z}[G]$ and annihilates $\mathrm{Cl}(K_Q)$; write $\beta = \sum_b n_b\sigma_b$ with $n_b \in \mathbb{Z}$. Let $\chi_*\colon \mathbb{Q}[G] \to \overline{\mathbb{Q}}_\ell$ be the $\mathbb{Q}$-linear ring homomorphism with $\chi_*(\sigma_b) = \chi(b)$. By Step 2, for every class $\mathfrak{a}$,

$$0 = \tilde z(\beta\mathfrak{a}) = \sum_b n_b\,\tilde z(\sigma_b\mathfrak{a}) = \Big(\sum_b n_b\bar\chi(b)\Big)\tilde z(\mathfrak{a}),$$

and $\sum_b n_b\bar\chi(b)$ is the reduction of $\chi_*(\beta) = (c - \chi(c))\,\chi_*(\theta_Q)$. Since χ^{-1} is primitive modulo Q and non-trivial,

$$\chi_*(\theta_Q) = \sum_{\substack{1\leq b\leq Q\\ \gcd(b,Q)=1}} \Big\{\frac{b}{Q}\Big\}\chi^{-1}(b) = \sum_{b=1}^{Q} \chi^{-1}(b)\Big(\frac{b}{Q} - \frac12\Big) = B_{1,\chi^{-1}}$$

($\chi^{-1}(b) = 0$ for b not prime to Q, $\{b/Q\} = b/Q$ for $1 \leq b < Q$, and $\sum_b \chi^{-1}(b) = 0$). By the choice of c and the hypothesis $|B_{1,\chi^{-1}}|_\ell = 1$, the reduction $(\bar c - \bar\chi(c))\overline{B_{1,\chi^{-1}}}$ is non-zero. Hence $\tilde z = 0$, and z vanishes on H_Q.

Step 4: z is a coboundary. For $g \in G_{\mathbb{Q}}$ and $h \in H_Q$, $z(gh) = z(g) + \bar\chi(g)z(h) = z(g)$; so $z(g)$ depends only on the image of g in G. As G is abelian, gg' and $g'g$ have the same image, so $z(g) + \bar\chi(g)z(g') = z(gg') = z(g'g) = z(g') + \bar\chi(g')z(g)$ for all g, g'. Choose g_1 with $\bar\chi(g_1) \neq 1$ and put $\mu = z(g_1)/(\bar\chi(g_1) - 1) \in k$. Taking $g' = g_1$ gives $z(g)(1 - \bar\chi(g_1)) = z(g_1)(1 - \bar\chi(g))$, that is $z(g) = \mu(\bar\chi(g) - 1)$. □

Theorem 44.8. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to some $(\psi, \mathfrak{h}, t, \chi)$, with odd prime ℓ, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. Every irreducible point of $\mathfrak{D}$ that is automorphic for ι is rigid.*

Proof. Let r be an irreducible point of $\mathfrak{D}$, automorphic for ι, and r'' a point with values in $\overline{\mathbb{Q}}_\ell[\epsilon]$ reducing to r modulo ϵ; write $r''(g) = r(g) + \epsilon r_1(g)$. We must find $X \in \mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell)$ with $r_1(g) = Xr(g) - r(g)X$ for all g.

Step 1: the tangent cocycle is continuous with values in $\mathfrak{sp}_4$. Write $r'' = f'' \circ r_A$ for a symplectic Eisenstein lift r_A to $A \in \mathrm{CNL}_{\mathcal{O}}$ and an $\mathcal{O}$-algebra homomorphism $f'' = f + \epsilon f_1\colon A \to \overline{\mathbb{Q}}_\ell[\epsilon]$; then $r = f \circ r_A$, and f_1 is $\mathcal{O}$-linear with $f_1(ab) = f(a)f_1(b) + f(b)f_1(a)$. Let $P = \ker f$. The domain $A/P \cong f(A) \subseteq \overline{\mathbb{Q}}_\ell$ is complete Noetherian local and contains $\mathcal{O}$, so by Cohen's structure theorem it is finite over a subring $\mathcal{O}[[Y_1, \dots, Y_d]]$; if $d \geq 1$, $f(Y_1)$ is algebraic over the fraction field of $\mathcal{O}$, so $Q(Y_1) = 0$ in A/P for some non-zero $Q \in \mathcal{O}[Y]$, which is impossible in $\mathcal{O}[[Y_1, \dots, Y_d]]$. So A/P is a finite $\mathcal{O}$-module, and so is A/P^2 (P/P^2 is finitely generated over A/P). As f_1 vanishes on P^2, it factors through A/P^2, on which an $\mathcal{O}$-linear map to $\overline{\mathbb{Q}}_\ell$ is ℓ-adically continuous; $(A/P^2)/\ell$ is a finite local ring, so the image of $\mathfrak{m}_A^N$ lies in $\ell(A/P^2)$ for some N, and f_1 is continuous on A. Together with (Sq1), it follows that f'', and hence r'' and r_1, are continuous. Put $z(g) = r_1(g)r(g)^{-1}$. From $r''(gh) = r''(g)r''(h)$ we get $z(gh) = z(g) + r(g)z(h)r(g)^{-1}$; thus z is a continuous 1-cocycle for the action $\mathrm{Ad}\, r$ on $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$. By (Se1), ${}^t r''(g) J_4 r''(g) = \theta(g) J_4$; the ϵ-part gives ${}^t r_1 J_4 r + {}^t r J_4 r_1 = 0$, that is ${}^t r(g)({}^t z(g) J_4 + J_4 z(g)) r(g) = 0$, so $z(g) \in \mathfrak{sp}_4$.

Step 2: local conditions away from ℓ. Let $p \neq \ell$ be a prime and I the inertia group at a place $\bar w$ above p. If $p \notin T$, (Se2) gives $r''(g) = 1$ for $g \in N = I \cap \ker \bar r_0$. If $p \in T$, the local condition in (Se4) gives $\rho_B(g) = 1$ on $I_p \cap \ker\chi$, so $r''(g) = 1$ there; for $\bar w = h\bar p$, $I = hI_p h^{-1}$ and $r''(hgh^{-1}) = r''(h)r''(g)r''(h)^{-1} = 1$, so $r'' = 1$ on $N = I \cap \ker\chi$. In both cases N is normal of finite index in I and $r''|_N = 1$, so $r|_N = 1$, $z|_N = 0$, and $z|_I$ is inflated from a cocycle of the finite group I/N on a $\overline{\mathbb{Q}}_\ell$-vector space, which is a coboundary (average over I/N). So $z|_D \in H^1_f(D, \cdot)$ for every decomposition group D at p. At the archimedean place the decomposition group has order at most 2 and H^1 vanishes.

Step 3: the local condition at ℓ. By (Se4) at ℓ, $r''|_{D_\ell} = F'' \circ \rho_B$ for an ordinary lift ρ_B to a domain B and an $\mathcal{O}$-algebra homomorphism $F''\colon B \to \overline{\mathbb{Q}}_\ell[\epsilon]$; as the ordinary conditions are polynomial identities with coefficients in $\mathcal{O}$, $\rho'' = r''|_{D_\ell}$ is ordinary over $\overline{\mathbb{Q}}_\ell[\epsilon]$. The c_j are distinct, so d_i is a unit and $E_i = d_i^{-1}\Pi_i(\rho'')$ satisfy $E_iE_j = 0$ ($i \neq j$, by Cayley–Hamilton, the characteristic polynomial of $\rho''(s_0)$ being $\prod_j(X - c_j)$) and $\sum_i E_i = 1$ (Lagrange interpolation); they are orthogonal idempotents with $\rho''(s_0)E_i = c_iE_i$. Each $E_i\overline{\mathbb{Q}}_\ell[\epsilon]^4$ is a direct summand, hence free over the local ring $\overline{\mathbb{Q}}_\ell[\epsilon]$, of rank 1 (its reduction is the c_i-eigenline of $r(s_0)$); choosing generators gives $P'' \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell[\epsilon])$ with $P''^{-1}\Pi_i(\rho'')P'' = d_i\, e_{ii}$. As in the field case, $\Pi_j\rho''(g)\Pi_i = 0$ for $i < j$ makes $T''(g) = P''^{-1}\rho''(g)P''$ upper triangular, and $\Pi_i(\rho''(s) - \kappa_i(s))\Pi_i = 0$ gives $T''(s)_{ii} = \kappa_i(s)$ for $s \in I_\ell$. Write $P'' = P(1 + \epsilon M)$ with $P \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$; then $T(g) = P^{-1}r(g)P$ is upper triangular with diagonal $(\delta_i(g))$, the characters of (Zt2) (both are the diagonal characters of $r|_{D_\ell}$ in the eigenbasis of $r(s_0)$ for $c_1, \dots, c_4$), and with $T'' = T + \epsilon T_1$ a direct computation gives

$$z_T(g) := T_1(g)T(g)^{-1} = P^{-1}z(g)P + (T(g)MT(g)^{-1} - M) \qquad (g \in D_\ell).$$

So z_T is a cocycle of $\operatorname{Ad} T$ cohomologous to $P^{-1}zP$; it takes upper triangular values, and its diagonal entries $T_1(g)_{ii}/\delta_i(g)$ vanish on I_ℓ, as $T''(s)_{ii} = \kappa_i(s) = \delta_i(s)$ there. By Lemma 42.8, items 1 and 3, T and z_T take values in $\mathrm{M}_4(E)$ for a finite extension E of $\mathbb{Q}_\ell$. The hypotheses of Lemma 44.14 hold for $\rho = T|_{D_\ell}$ (with $D_\ell \cong \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$), the integers $m_1 > m_2 > m_3 > m_4$ and $u = z_T$, by (Zt3). So the class of z_T, and hence (transporting by $X \mapsto PXP^{-1}$) that of $z|_{D_\ell}$, lies in H^1_f. For another place $h\bar{\ell}$ above ℓ, $z(hyh^{-1}) = r(h)z(y)r(h)^{-1} + (1 - \operatorname{Ad} r(hyh^{-1}))z(h)$ for $y \in D_\ell$, so the class at $hD_\ell h^{-1}$ is the transport of the class at D_ℓ by h and lies in H^1_f as well. By Steps 2 and 3, z is a Bloch–Kato cocycle for $(\mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell), \operatorname{Ad} r)$.

Step 4: Thorne's theorem for a conjugate self-dual twist. Let $K = \mathbb{Q}(i)$, in which the odd prime ℓ is unramified. By Lemma 44.9 the restriction of r to $G_{K(\mu_{\ell^\infty})}$ is irreducible; in particular $r|_{G_K}$ is irreducible, so by (Sy2) $r|_{G_K} \leftrightarrow_\iota \pi$ for a regular algebraic cuspidal π of $\mathrm{GL}_4(\mathbb{A}_K)$. By (Sq2), $r(g)$ has similitude $\theta(g) = \chi_{\mathrm{cyc}}(g)^{e+1}\nu(g)$, $\nu = \omega_\ell^{-1}\xi\chi$ of finite order. By Proposition 44.13 there are ψ and a regular algebraic conjugate self-dual cuspidal π' with $\psi(cgc)\psi(g)\theta(g) = \chi_{\mathrm{cyc}}(g)^{-3}$ on G_K and $r' = (r|_{G_K}) \otimes \psi \leftrightarrow_\iota \pi'$. From ${}^t r(g)J_4 r(g) = \theta(g)J_4$ we get $r(g) = \theta(g)J_4^{-1}\,{}^t r(g)^{-1}J_4$, hence with $\mathbf{P} = r(c)J_4^{-1}$,

$$\begin{aligned} r'(cgc) &= \psi(cgc)\, r(c)r(g)r(c)^{-1} = \psi(cgc)\psi(g)\theta(g)\, \mathbf{P}\,{}^t r'(g)^{-1}\mathbf{P}^{-1} \\ &= \chi_{\mathrm{cyc}}(g)^{1-4}\, \mathbf{P}\,{}^t r'(g)^{-1}\mathbf{P}^{-1} \qquad (g \in G_K). \end{aligned}$$

By Lemma 42.8, item 1, $r'(G_K) \subseteq \mathrm{GL}_4(E)$ for a finite extension E; as a local field has only finitely many extensions of degree at most 4 in $\overline{\mathbb{Q}}_\ell$, enlarging E we may assume that the entries of $\mathbf{P}$ lie in E. The restriction of r' to $G_{K(\mu_{\ell^\infty})}$ is irreducible, since twisting by a character does not change invariant subspaces. So Theorem B.72 applies to K, c, $n = 4$, π', E, r', $\mathbf{P}$, and gives $H^1_f(\mathbb{Q}, \operatorname{ad}_E r' \otimes_E \overline{\mathbb{Q}}_\ell) = 0$.

Step 5: $\mathfrak{sp}_4$ is a direct summand. Let $\tau(X) = J_4^{-1}\,{}^t X J_4$, an involution of M_4 with (-1)-eigenspace $\mathfrak{sp}_4$ and $(+1)$-eigenspace $\mathfrak{c}$, so $\mathrm{M}_4 = \mathfrak{sp}_4 \oplus \mathfrak{c}$. For $g \in G_K$, g acts on $\operatorname{ad} r'$ by $\operatorname{Ad} r(g)$, and Ad of a matrix with a similitude commutes with τ. The element c acts by $X \mapsto -\mathbf{P}\,{}^t X \mathbf{P}^{-1} = -r(c)J_4^{-1}\,{}^t X J_4 r(c)^{-1} = -r(c)\tau(X)r(c)^{-1}$, which is $\operatorname{Ad} r(c)$ on $\mathfrak{sp}_4$ and $-\operatorname{Ad} r(c)$ on $\mathfrak{c}$. As $G_\mathbb{Q}$ is generated by G_K and c, both summands are $G_\mathbb{Q}$-stable and $\mathfrak{sp}_4 \subseteq \operatorname{ad} r' \otimes \overline{\mathbb{Q}}_\ell$ is the representation $(\mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell), \operatorname{Ad} r)$. Local conditions are compatible with direct sums, so $H^1_f(\mathbb{Q}, \mathfrak{sp}_4)$ is a direct summand of $H^1_f(\mathbb{Q}, \operatorname{ad} r' \otimes \overline{\mathbb{Q}}_\ell) = 0$.

Step 6: conclusion. By Steps 3 and 5 the Bloch–Kato cocycle z is a coboundary: $z(g) = r(g)X_0 r(g)^{-1} - X_0$ with $X_0 \in \mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell)$. Then $r_1(g) = z(g)r(g) = r(g)X_0 - X_0 r(g) = Xr(g) - r(g)X$ with $X = -X_0 \in \mathfrak{sp}_4(\overline{\mathbb{Q}}_\ell)$, so $r''(g) = r(g) + \epsilon(Xr(g) - r(g)X)$ and r is rigid. □

Lemma 44.9. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with odd prime ℓ, let r be an irreducible point of $\mathfrak{D}$, and let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field in which ℓ is unramified. Then the restriction of r to $G_{K(\mu_{\ell^\infty})}$ is irreducible on $\overline{\mathbb{Q}}_\ell^4$.*

Proof. Put $V = \overline{\mathbb{Q}}_\ell^4$ and $H = G_{K(\mu_{\ell^\infty})}$, a closed normal subgroup of $G_\mathbb{Q}$ with $G_\mathbb{Q}/H \cong \mathrm{Gal}(K(\mu_{\ell^\infty})/\mathbb{Q})$ abelian. So every subgroup of $G_\mathbb{Q}$ containing H is normal, and $gyg^{-1}y^{-1} \in H$ for all $g, y \in G_\mathbb{Q}$. By (Sq5), r is continuous.

Step 1: the only closed subgroup of index 2 of $G_\mathbb{Q}$ containing H and I_ℓ is G_K. The only quadratic subfield of $\mathbb{Q}(\mu_{\ell^\infty})$ is $\mathbb{Q}(\sqrt{\ell^*})$, $\ell^* = (-1)^{(\ell-1)/2}\ell$, which is ramified at ℓ, whereas K is not; so $K \cap \mathbb{Q}(\mu_{\ell^\infty}) = \mathbb{Q}$ and restriction gives $\mathrm{Gal}(K(\mu_{\ell^\infty})/\mathbb{Q}) \cong \mathrm{Gal}(K/\mathbb{Q}) \times \mathbb{Z}_\ell^\times$, the second factor through χ_{cyc}. A closed subgroup of index 2 containing H is the kernel of a continuous character of order 2 of this group. As $\mathbb{Z}_\ell^\times \cong \mu_{\ell-1} \times (1 + \ell\mathbb{Z}_\ell)$ with $1 + \ell\mathbb{Z}_\ell$ pro-ℓ and ℓ odd, the characters of order 2 are ε_K (the character of K), η and $\varepsilon_K\eta$, where $\eta(g)$ is the Legendre symbol of $\chi_{\mathrm{cyc}}(g)$ modulo ℓ. Since $\chi_{\mathrm{cyc}}(I_\ell) = \mathbb{Z}_\ell^\times$, η is non-trivial on I_ℓ, and ε_K is trivial on I_ℓ as ℓ is

unramified in K; so η and $\varepsilon_K\eta$ are non-trivial on I_ℓ, and the only such kernel containing I_ℓ is $\ker\varepsilon_K = G_K$.

Step 2: no closed normal subgroup G' of finite index with $H \subseteq G'$ has $r|_{G'}$ reducible. Suppose it does. G' is open, so by Lemma 44.10 (second assertion, with $V_0 = G'$), $\bar\Psi$ has order 2, $\bar\Psi|_{D_\ell} = \mathbf{1}$ and $G' \subseteq \ker\bar\Psi$. Then $\ker\bar\Psi$ is a closed subgroup of index 2 containing H and $I_\ell \subseteq D_\ell$, so $\ker\bar\Psi = G_K$ by Step 1. A complex conjugation c is not in G_K, K being imaginary, so $\bar\Psi(c) \neq 1$; but $\Psi(c) = 1$ by (Sg1) (for every complex conjugation, as they are conjugate in $G_\mathbb{Q}$). This is a contradiction.

Step 3: $r|_H$ is isotypic. Let $V' \subseteq V$ be the sum of all $r(H)$-stable subspaces on which H acts irreducibly. It is non-zero, and $r(g)V' = V'$ for $g \in G_\mathbb{Q}$, since $r(g)$ maps an H-irreducible subspace onto one (H is normal); as r is irreducible, $V' = V$, so $r|_H$ is semisimple. Let $V = U_1 \oplus \cdots \oplus U_k$ be its decomposition into isotypic components. Each $r(g)$ maps isotypic components onto isotypic components, and the sum of the components in one orbit is $r(G_\mathbb{Q})$-stable, so $G_\mathbb{Q}$ permutes them transitively. The stabiliser $G' = \{g :\ r(g)U_1 = U_1\}$ is closed (r is continuous), of index k, contains H, and is therefore normal. If $k \geq 2$, U_1 is a proper non-zero $r(G')$-stable subspace, contradicting Step 2. So $k = 1$: there are an irreducible representation of H on a space W of dimension d and an H-isomorphism $V \cong W \otimes \overline{\mathbb{Q}}_\ell^m$ (H acting on the first factor), with $md = 4$.

Step 4: an element with four distinct eigenvalues. The group $I_\ell \cap \ker\chi \cap \ker\omega_\ell$ is open in I_ℓ and $\chi_{\mathrm{cyc}}(I_\ell) = \mathbb{Z}_\ell^\times$, so it contains u with $c_u = \chi_{\mathrm{cyc}}(u)$ of infinite order. As ξ is unramified at ℓ (Sg1), $\kappa_i(u) = c_u^{m_i}$, pairwise distinct. By (Zt2), $r(u)$ is conjugate to an upper triangular matrix with diagonal $(\kappa_i(u))$, so it has four distinct eigenvalues; let $L_1, \ldots, L_4$ be its eigenlines. For $g \in G_\mathbb{Q}$ put $h_g = gug^{-1}u^{-1} \in H$.

Step 5: $d \neq 1$. If $d = 1$, every $r(h)$, $h \in H$, is a scalar $w(h)$, and $r(g)r(u)r(g)^{-1} = r(h_g)r(u) = w(h_g)r(u)$; so $r(g)$ maps each eigenline of $r(u)$ onto an eigenline, and $G_\mathbb{Q}$ permutes $\{L_1, \ldots, L_4\}$. The kernel V_1 of this permutation action is normal of finite index and closed (the conditions $r(g)L_i = L_i$ are closed), hence open, and L_1 is $r(V_1)$-stable. This contradicts Lemma 44.10 (second assertion: no $r(V_1)$-stable line).

Step 6: $d \neq 2$. Let $d = m = 2$ and identify $V = W \otimes \overline{\mathbb{Q}}_\ell^2$. By Burnside's theorem the span of $r(H)$ is $\mathcal{A} = \mathrm{End}(W) \otimes 1$, whose commutant in $\mathrm{End}(V) = \mathrm{End}(W) \otimes \mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$ is $\mathcal{C} = 1 \otimes \mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$, and the commutant of $\mathcal{C}$ is $\mathcal{A}$. For $g \in G_\mathbb{Q}$, conjugation by $r(g)$ preserves $r(H)$, hence $\mathcal{A}$ and $\mathcal{C}$; on $\mathcal{C} \cong \mathrm{M}_2$ it is an algebra automorphism, hence inner (Skolem–Noether): there is $m_g \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$, unique up to a scalar, with $r(g)(1 \otimes X)r(g)^{-1} = 1 \otimes m_g X m_g^{-1}$. Then $r(g)(1 \otimes m_g)^{-1}$ commutes with $\mathcal{C}$, so lies in $\mathcal{A}$, and $r(g) = w_g \otimes m_g$ with $w_g \in \mathrm{GL}(W)$. The map $g \mapsto \mathrm{Ad}(m_g)$ is a homomorphism, and m_h is a scalar for $h \in H$ (as $r(h) \in \mathcal{A}$ commutes with $\mathcal{C}$). Applied to h_g: $m_g m_u m_g^{-1} = \lambda_g m_u$ with $\lambda_g \in \overline{\mathbb{Q}}_\ell^\times$. The eigenvalues of $r(u) = w_u \otimes m_u$ are the products $a_i b_j$ of those of w_u and m_u; they are distinct (Step 4), so m_u has two distinct eigenvalues, with eigenlines $M_1, M_2 \subset \overline{\mathbb{Q}}_\ell^2$, and every m_g permutes $\{M_1, M_2\}$. Put $X_1 = W \otimes M_1$ and $X_2 = W \otimes M_2$; then $r(g)X_1 = w_g W \otimes m_g M_1 \in \{X_1, X_2\}$. The stabiliser $G'' = \{g :\ r(g)X_1 = X_1\}$ is closed, of index at most 2, contains H (m_h is a scalar), and is different from $G_\mathbb{Q}$ because r is irreducible; so it has index 2, is normal, and X_1 is a proper non-zero $r(G'')$-stable subspace. This contradicts Step 2.

By Steps 3, 5 and 6, $d = 4$ and $m = 1$: $r|_H$ is irreducible. □

Lemma 44.10. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and character Ψ, let $\bar\Psi$ be the reduction of Ψ modulo $\mathfrak{m}_\mathcal{O}$, and let r be an irreducible point of $\mathfrak{D}$. If there is an open subgroup $U \subseteq G_\mathbb{Q}$ such that $r|_U$ is reducible, then $\bar\Psi$ has order exactly 2 and $\bar\Psi|_{D_\ell} = \mathbf{1}$. Moreover, if $V_0 \subseteq G_\mathbb{Q}$ is an open normal subgroup such that $r|_{V_0}$ is reducible, then $V_0 \subseteq \ker\bar\Psi$,*

and every non-zero $r(V_0)$-stable subspace of $\overline{\mathbb{Q}}_\ell^4$ has dimension at least 2.

Proof. Assume $r|_U$ is reducible. Bars denote residues in $\overline{\mathbb{F}}_\ell$ (for elements of $\overline{\mathbb{Z}}_\ell$, the integral closure of $\mathbb{Z}_\ell$ in $\overline{\mathbb{Q}}_\ell$); ℓ is odd, so $1 \neq -1$ in $\overline{\mathbb{F}}_\ell$.

Step 1: a normal open subgroup. $V_0 = \bigcap_{g \in G_\mathbb{Q}} gUg^{-1}$ is a finite intersection (U has finite index), hence an open normal subgroup contained in U; $r|_{V_0}$ is reducible. For the second assertion let instead V_0 be the given open normal subgroup with $r|_{V_0}$ reducible. Steps 2–7 use only that V_0 is open and normal and that $r|_{V_0}$ is reducible.

Step 2: an adapted basis. By (Zt2) there is $P_1 \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $P_1^{-1} r(y) P_1$ upper triangular with diagonal $(\delta_1(y), \dots, \delta_4(y))$ for $y \in D_\ell$, and $\delta_i = \kappa_i$ on I_ℓ. The group $V_0 \cap I_\ell \cap \ker\chi \cap \ker\omega_\ell$ is open in I_ℓ and $\chi_{\mathrm{cyc}}(I_\ell) = \mathbb{Z}_\ell^\times$, so it contains u with $c = \chi_{\mathrm{cyc}}(u)$ of infinite order; as ξ is unramified at ℓ (Sg1), $\kappa_i(u) = c^{m_i}$ with $(m_1, \dots, m_4) = (e{+}1, e, 1, 0)$, pairwise distinct. An upper triangular matrix with distinct diagonal entries is diagonalised by an upper triangular matrix; so there is P (a product of P_1 and an upper triangular matrix) such that $r'(g) = P^{-1} r(g) P$ satisfies: $r'(u)$ is diagonal with distinct entries, and $r'(y)$ is upper triangular with diagonal $(\delta_i(y))$ for $y \in D_\ell$. Irreducibility of r, $r|_{V_0}$ is that of r', $r'|_{V_0}$.

Step 3: $r'(V_0)$-stable subspaces are coordinate subspaces. If W is $r'(V_0)$-stable and $w = \sum_i w_i e_i \in W$, then with the Lagrange polynomials L_i of the distinct eigenvalues of $r'(u)$, $L_i(r'(u))w = w_i e_i \in W$; so $W = V_S$ with $S = \{i : e_i \in W\}$.

Step 4: a system of imprimitivity. Let $W \neq 0$ be an $r'(V_0)$-stable subspace of least dimension; as $r'|_{V_0}$ is reducible, $W \neq V$, and $W = V_S$ with $\emptyset \neq S \subsetneq \{1, \dots, 4\}$. For $g \in G_\mathbb{Q}$, $r'(g)W$ is $r'(V_0)$-stable (V_0 is normal) of the same dimension, hence $r'(g)W = V_{S_g}$ with $|S_g| = |S|$ by Step 3. For g, h with $S_g \neq S_h$, $V_{S_g} \cap V_{S_h} = V_{S_g \cap S_h}$ is $r'(V_0)$-stable of smaller dimension, so $S_g \cap S_h = \emptyset$. The sum of the V_{S_g} is $r'(G_\mathbb{Q})$-stable and non-zero, hence V as r' is irreducible. So the distinct sets S_g form a partition $S_1, \dots, S_k$ of $\{1, \dots, 4\}$ into $k \geq 2$ blocks of equal size, $k \in \{2, 4\}$, permuted by $G_\mathbb{Q}$: $r'(g) V_{S_a} = V_{S_{\pi_g(a)}}$ with a homomorphism $g \mapsto \pi_g$ to the symmetric group on the blocks, whose image Γ is transitive.

Step 5: D_ℓ fixes every block. Let $y \in D_\ell$ and $i = \max S_a$. Since $r'(y)$ is upper triangular with diagonal entry $\delta_i(y) \neq 0$ at (i,i), $r'(y)e_i$ has non-zero e_i-coordinate, and it lies in $V_{S_{\pi_y(a)}}$; so $i \in S_{\pi_y(a)}$, and $\pi_y(a) = a$.

Step 6: elements with fixed-point-free block permutation. Let $g \in G_\mathbb{Q}$ with π_g fixed-point-free. For $y \in D_\ell$, $\pi_{gy} = \pi_g$ (Step 5), so $r'(gy)$ maps each V_{S_a} into some V_{S_b} with $b \neq a$, its diagonal entries vanish, and $\operatorname{tr} r(gy) = 0$. By (Sq4) the entries of $r(gy)$ are congruent to those of $r_0(gy)$ modulo the maximal ideal, so

$$\sum_{i=1}^{4} \bar\kappa_i(g)\, \bar\kappa_i(y) = 0 \qquad (y \in D_\ell).$$

Group the indices i by the character $\bar\kappa_i|_{D_\ell} \colon D_\ell \to \overline{\mathbb{F}}_\ell^\times$; distinct characters are linearly independent (Artin), so for each class C the sum $\sum_{i \in C} \bar\kappa_i(g)$ vanishes, and as each $\bar\kappa_i(g) \neq 0$, every class has at least two elements. If $\lambda_i \neq \lambda_j$, then $\bar\kappa_i(\sigma_\ell) \neq \bar\kappa_j(\sigma_\ell)$: since $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$ (Sg2) and $\bar\omega_\ell = \bar\chi_{\mathrm{cyc}}$, $\bar\alpha(\sigma_\ell) = \bar\xi(\sigma_\ell)$, and the ratios κ_i/κ_j for the pairs $(1,2), (1,4), (3,2), (3,4)$ are $\alpha, \alpha\Psi, \alpha\Psi^{-1}, \alpha$, with residues $\bar\xi, \overline{\xi\Psi}, \overline{\xi\Psi^{-1}}, \bar\xi$ at σ_ℓ, none equal to 1 by (Sg2) at $\ell \in T$. Hence the classes are $\{1,3\}$ and $\{2,4\}$: $\bar\theta = \bar\alpha$ and $\bar\Psi = \mathbf{1}$ on D_ℓ, and $\bar\kappa_2(g) + \bar\kappa_4(g) = \bar\Psi(g) + 1 = 0$. So

$$\bar\Psi|_{D_\ell} = \mathbf{1}, \qquad \bar\Psi(g) = -1 \ \text{ whenever } \pi_g \text{ is fixed-point-free.} \tag{44.13}$$

Fixed-point-free elements exist: in a transitive group on $k \geq 2$ points the average number of fixed points is 1 (Burnside), and the identity fixes $k \geq 2$.

Step 7: the block structure. If $k = 4$, Γ is a transitive subgroup of the symmetric group on four letters, so it contains a 4-cycle or the three double transpositions. If π_g is a 4-cycle, π_g and π_{g^2} are fixed-point-free, and (44.13) gives $-1 = \bar\Psi(g^2) = \bar\Psi(g)^2 = 1$. If π_g, π_h, π_{gh} are the three double transpositions, (44.13) gives $-1 = \bar\Psi(gh) = \bar\Psi(g)\bar\Psi(h) = 1$. Both are impossible, so $k = 2$ and $\Gamma = \{1, \tau\}$ with τ the transposition of the two blocks. Fix g_1 with $\pi_{g_1} = \tau$. For h with $\pi_h = 1$, $\pi_{g_1 h} = \tau$, so $\bar\Psi(g_1 h) = \bar\Psi(g_1) = -1$ and $\bar\Psi(h) = 1$. Hence $\bar\Psi(g) = 1$ if $\pi_g = 1$ and $\bar\Psi(g) = -1$ if $\pi_g = \tau$: $\bar\Psi$ has order exactly 2, and $\bar\Psi|_{D_\ell} = \mathbf{1}$ by (44.13).

Step 8: $V_0 \subseteq \ker\bar\Psi$, and no stable lines. By Step 7, $k = 2$, so the minimal $r'(V_0)$-stable subspace $W = V_S$ of Step 4 has $\dim W = |S| = 2$. Every non-zero $r'(V_0)$-stable subspace contains one of least dimension, hence has dimension at least 2; the $r(V_0)$-stable subspaces are the images under P of the $r'(V_0)$-stable ones, so the same holds for them. For $g \in V_0$, $r'(g)W = W$, so π_g fixes the block of W; as $k = 2$, $\pi_g = 1$, and $\bar\Psi(g) = 1$ by Step 7. □

Lemma 44.11. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, and put $\overline{\mathbb{Z}}_\ell = \{y \in \overline{\mathbb{Q}}_\ell : |y|_\ell \le 1\}$ and $\mathfrak{m}_\ell = \{y \in \overline{\mathbb{Q}}_\ell : |y|_\ell < 1\}$.*

(Sq1) *For every local $\mathcal{O}$-algebra A with maximal ideal $\mathfrak{m}_A$ and every $\mathcal{O}$-algebra homomorphism $f\colon A \to \overline{\mathbb{Q}}_\ell$ one has $f(\mathfrak{m}_A) \subseteq \mathfrak{m}_\ell$; if moreover $A \in \mathrm{CNL}_\mathcal{O}$, then $f(A) \subseteq \overline{\mathbb{Z}}_\ell$ and f is continuous for the $\mathfrak{m}_A$-adic topology on A.*

Let $r\colon G_\mathbb{Q} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ be a point of $\mathfrak{D}$. Then:

(Sq2) *$r(g)$ has similitude $\theta(g)$ for every $g \in G_\mathbb{Q}$;*

(Sq3) *$r(\phi)$ is block diagonal, and $h(r) = r(g_0) + \theta(g_0)\,r(g_0^{-1})$ satisfies $h(r)_{13} = h(r)_{31} = 0$;*

(Sq4) *for all $g \in G_\mathbb{Q}$ and all i, j, $r(g)_{ij} \in \overline{\mathbb{Z}}_\ell$ and $r(g)_{ij} - r_0(g)_{ij} \in \mathfrak{m}_\ell$;*

(Sq5) *r is continuous.*

Proof. Step 1: $f(\mathfrak{m}_A) \subseteq \mathfrak{m}_\ell$ for every local $\mathcal{O}$-algebra A. Let $x \in \mathfrak{m}_A$ and $y = f(x)$, and suppose $|y|_\ell \ge 1$. The element y is algebraic over K, so $L = K(y)$ is a finite extension of the complete discretely valued field K; its valuation ring $\{z \in L : |z|_\ell \le 1\}$ is the integral closure of $\mathcal{O}$ in L. As $|y^{-1}|_\ell \le 1$, y^{-1} is integral over $\mathcal{O}$: there are $d \ge 1$ and $b_0, \dots, b_{d-1} \in \mathcal{O}$ with $y^{-d} + b_{d-1}y^{-(d-1)} + \cdots + b_0 = 0$. Multiplying by y^d,

$$Q(y) = 0, \qquad Q(X) = 1 + b_{d-1}X + b_{d-2}X^2 + \cdots + b_0X^d \in \mathcal{O}[X].$$

Now $Q(x) \in 1 + \mathfrak{m}_A$ is a unit of the local ring A, so $f(Q(x))$ is a unit of $\overline{\mathbb{Q}}_\ell$; but $f(Q(x)) = Q(f(x)) = Q(y) = 0$ because f is an $\mathcal{O}$-algebra homomorphism. This contradiction shows $|f(x)|_\ell < 1$.

Step 2: $f(A) \subseteq \overline{\mathbb{Z}}_\ell$ and continuity for $A \in \mathrm{CNL}_\mathcal{O}$; this completes (Sq1). Let $a \in A$. Since $\mathcal{O} \to A/\mathfrak{m}_A$ is surjective, $a = \lambda + x$ with $\lambda \in \mathcal{O}$ and $x \in \mathfrak{m}_A$, so $f(a) = \lambda + f(x)$ has $|f(a)|_\ell \le \max(|\lambda|_\ell, |f(x)|_\ell) \le 1$. As A is Noetherian, $\mathfrak{m}_A = (x_1, \dots, x_k)$; put $c = \max_i |f(x_i)|_\ell$, so $c < 1$ by Step 1. Every element of $\mathfrak{m}_A^n$ is a finite sum of terms $a' x_{i_1} \cdots x_{i_n}$ with $a' \in A$, so by the ultrametric inequality and $|f(a')|_\ell \le 1$, $|f(z)|_\ell \le c^n$ for $z \in \mathfrak{m}_A^n$. Hence $|f(a) - f(a')|_\ell \le c^n$ whenever $a - a' \in \mathfrak{m}_A^n$, and f is continuous.

Step 3: (Sq2)–(Sq5). By definition $r(g) = f(r_A(g))$ (entrywise) for a symplectic Eisenstein lift r_A to some $A \in \mathrm{CNL}_\mathcal{O}$ and an $\mathcal{O}$-algebra homomorphism $f\colon A \to \overline{\mathbb{Q}}_\ell$. Applying the ring homomorphism f entrywise to ${}^t r_A(g) J_4 r_A(g) = \theta(g) J_4$ (that is (Se1)), and using $f(\theta(g)\cdot 1_A) = \theta(g)$, gives (Sq2). By (Se3) the entries (i, j) of $r_A(\phi)$ with $\lambda_i \ne \lambda_j$ vanish, and $h(r_A)_{13} = h(r_A)_{31} = 0$;

since f applied entrywise to $h(r_A) = r_A(g_0) + \theta(g_0) r_A(g_0^{-1})$ gives $r(g_0) + \theta(g_0) r(g_0^{-1}) = h(r)$, (Sq3) follows. Since r_A is a lift, $r_A(g) \equiv \bar{r}_0(g) \pmod{\mathfrak{m}_A}$, that is $r_A(g)_{ij} - r_0(g)_{ij} \cdot 1_A \in \mathfrak{m}_A$ (the identification $\mathbb{F}_{\mathcal{O}} \cong A/\mathfrak{m}_A$ is induced by $\mathcal{O} \to A$); applying f and Steps 1 and 2 gives $r(g)_{ij} \in \overline{\mathbb{Z}}_\ell$ and $r(g)_{ij} - r_0(g)_{ij} = f(r_A(g)_{ij} - r_0(g)_{ij} \cdot 1_A) \in \mathfrak{m}_\ell$, which is (Sq4). Finally r_A is continuous for the $\mathfrak{m}_A$-adic topology and f is continuous by (Sq1), so each entry $g \mapsto r(g)_{ij}$ is continuous, which is (Sq5). $\square$

Lemma 44.12. *Let $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, \dots)$ be a symplectic Eisenstein datum with set T, and let r be a point of $\mathfrak{D}$. Then:*

(Zt1) *for every $v \in T$ with $v \neq \ell$, $r(g) = 1$ for every $g \in I_v$ with $\chi(g) = 1$;*

(Zt2) *there are continuous characters $\delta_1, \dots, \delta_4 \colon D_\ell \to \overline{\mathbb{Q}}_\ell^\times$ such that r is triangular on D_ℓ with diagonal $(\delta_1, \dots, \delta_4)$, $\delta_i(s) = \kappa_i(s)$ for all $s \in I_\ell$, and $\delta_i(g) - \kappa_i(g) \in \mathfrak{m}_\ell$ for all $g \in D_\ell$ $(i = 1, \dots, 4)$;*

(Zt3) *the characters of (Zt2) satisfy $\delta_i \neq \delta_j \, \chi_{\mathrm{cyc}}|_{D_\ell}$ for all i, j, and $\delta_i \chi_{\mathrm{cyc}}^{-m_i}$ has finite image on I_ℓ, where $(m_1, m_2, m_3, m_4) = (e+1, e, 1, 0)$.*

Proof. Write $r = f \circ r_A$ for a symplectic Eisenstein lift r_A to $A \in \mathrm{CNL}_{\mathcal{O}}$ and an $\mathcal{O}$-algebra homomorphism $f \colon A \to \overline{\mathbb{Q}}_\ell$. Let $v \in T$. By (Se4) there are a domain $B \in \mathrm{CNL}_{\mathcal{O}}$, a lift ρ_B of $\bar{r}_0|_{D_v}$ to B satisfying the local condition at v, and $\mathcal{O}$-algebra homomorphisms $x \colon B \to \mathcal{O}$, $y \colon B \to A$ with $x \circ \rho_B = r_0|_{D_v}$ and $y \circ \rho_B = r_A|_{D_v}$; put $F = f \circ y \colon B \to \overline{\mathbb{Q}}_\ell$, so that $r|_{D_v} = F \circ \rho_B$ (entrywise). Since x is an $\mathcal{O}$-algebra homomorphism to $\mathcal{O}$, the structure map $\mathcal{O} \to B$ is injective.

Step 1: (Zt1). For $v \neq \ell$ the local condition gives $\rho_B(g) = 1$ for $g \in I_v$ with $\chi(g) = 1$; applying F gives $r(g) = 1$.

From now on $v = \ell$. Put $c = \chi_{\mathrm{cyc}}(s_0)$ and $c_j = \kappa_j(s_0)$. By (Sg5), $\chi(s_0) = \omega_\ell(s_0) = 1$, and $\xi(s_0) = 1$ because ξ is unramified at $\ell \in T$ (Sg1); so $(c_1, c_2, c_3, c_4) = (c^{e+1}, c^e, c, 1)$, which are pairwise distinct because c has infinite order and $e \geq 2$. Put $d_i = \prod_{j \neq i} (c_i - c_j) \in \mathcal{O} \setminus \{0\}$.

Step 2: ordinary representations over a field. Let E be a field containing $\mathcal{O}$ and $\rho \colon D_\ell \to \mathrm{GL}_4(E)$ an ordinary homomorphism, with $\Pi_i = \prod_{j \neq i} (\rho(s_0) - c_j)$. The characteristic polynomial of $\rho(s_0)$ is $\prod_j (X - c_j)$ with distinct roots, so E^4 has a basis $w_1, \dots, w_4$ with $\rho(s_0) w_k = c_k w_k$; let P be the matrix with columns w_k and E_i the projection onto $E w_i$ along the other w_k. Then $\Pi_i w_k = \prod_{j \neq i} (c_k - c_j) w_k$, so $\Pi_i = d_i E_i$. The condition $\Pi_j \rho(g) \Pi_i = 0$ for $i < j$ gives $E_j \rho(g) E_i = 0$, that is, $P^{-1} \rho(g) P$ is upper triangular for every $g \in D_\ell$; its diagonal entries $\delta_i^E(g)$ are characters of D_ℓ (the diagonal of a product of upper triangular matrices is the product of the diagonals), and

$$\mathrm{tr}\big(\Pi_i \, \rho(g)\big) = d_i \, \mathrm{tr}\big(E_i \rho(g)\big) = d_i \, \delta_i^E(g). \tag{44.14}$$

For $s \in I_\ell$, $\Pi_i (\rho(s) - \kappa_i(s)) \Pi_i = 0$ gives $d_i^2 (\delta_i^E(s) - \kappa_i(s)) E_i = 0$, so $\delta_i^E(s) = \kappa_i(s)$. Finally, the ordinary conditions are polynomial identities in the entries of $\rho(s_0)$, $\rho(g)$ with coefficients in $\mathcal{O}$, so for a ring homomorphism h of $\mathcal{O}$-algebras, $h \circ \rho$ is ordinary whenever ρ is.

Step 3: the characters δ_i. By the local condition at ℓ, ρ_B is ordinary, hence so is $r|_{D_\ell} = F \circ \rho_B$ (Step 2). Step 2 with $E = \overline{\mathbb{Q}}_\ell$ gives characters $\delta_i = \delta_i^{\overline{\mathbb{Q}}_\ell}$ such that r is triangular on D_ℓ with diagonal $(\delta_1, \dots, \delta_4)$ (conjugate by P^{-1}) and $\delta_i = \kappa_i$ on I_ℓ. By (44.14), $\delta_i(g) = d_i^{-1} \, \mathrm{tr}(\Pi_i \, r(g))$ is a polynomial in the entries of $r(s_0)$ and $r(g)$, hence continuous in g by (Sq5).

Step 4: $\delta_i(g) \equiv \kappa_i(g)$ modulo $\mathfrak{m}_\ell$. Fix i and $g \in D_\ell$. Let K be the fraction field of B; ρ_B is ordinary over K, and Step 2 gives $\delta_i^K(g) \in K$ with $t = \mathrm{tr}(\Pi_i(\rho_B) \, \rho_B(g)) = d_i \delta_i^K(g)$, where

$t \in B$. Applying x and F to t and using (44.14) for $r_0|_{D_\ell}$ (where $\Pi_i(r_0)$ is diagonal with the single non-zero entry d_i at (i,i)) and for $r|_{D_\ell}$,

$$x(t) = d_i\,\kappa_i(g), \qquad F(t) = d_i\,\delta_i(g).$$

Put $w = \delta_i^K(g) - \kappa_i(g) \in K$. As a diagonal entry of a triangular conjugate of $\rho_B(g)$, $\delta_i^K(g)$ is a root of the characteristic polynomial of $\rho_B(g)$, which is monic with coefficients in B; so w is integral over B, and $C = B[w] \subseteq K$ is a domain, finite over B. A complete Noetherian local ring is Henselian, and a finite algebra over a Henselian local ring is a finite product of local rings; as C is a domain, C is local, with maximal ideal $\mathfrak{m}_C$. Since C is integral over B, the lying-over theorem gives primes Q_x, Q_F of C lying over $\ker x$ and $\ker F$. The domain C/Q_x is integral over $B/\ker x \cong \mathcal{O}$, so its fraction field is algebraic over that of $\mathcal{O}$ and embeds into $\overline{\mathbb{Q}}_\ell$ over it; this gives an $\mathcal{O}$-algebra homomorphism $\tilde{x}\colon C \to \overline{\mathbb{Q}}_\ell$ extending x. In the same way, C/Q_F is integral over $B/\ker F \cong F(B) \subseteq \overline{\mathbb{Q}}_\ell$, and as $\overline{\mathbb{Q}}_\ell$ is algebraically closed there is $\tilde{F}\colon C \to \overline{\mathbb{Q}}_\ell$ extending F. Now $d_i w = t - d_i\kappa_i(g) \in B$, so

$$d_i\,\tilde{x}(w) = x(t) - d_i\kappa_i(g) = 0, \qquad d_i\,\tilde{F}(w) = F(t) - d_i\kappa_i(g) = d_i\big(\delta_i(g) - \kappa_i(g)\big).$$

As $d_i \neq 0$, $\tilde{x}(w) = 0$; hence w is not a unit of C, that is, $w \in \mathfrak{m}_C$. By (Sq1) for the local $\mathcal{O}$-algebra C, $\tilde{F}(w) \in \mathfrak{m}_\ell$, and therefore $\delta_i(g) - \kappa_i(g) = \tilde{F}(w) \in \mathfrak{m}_\ell$.

Step 5: (Zt3). On I_ℓ, $\delta_i = \kappa_i$, and $\kappa_i\chi_{\mathrm{cyc}}^{-m_i}$ is $\omega_\ell^{-1}\xi\chi$, χ, $\omega_\ell^{-1}\xi$, $\mathbf{1}$ for $i = 1,2,3,4$, of finite image. Suppose $\delta_i = \delta_j\chi_{\mathrm{cyc}}$ on D_ℓ. If $\lambda_i \neq \lambda_j$ ($\boldsymbol{\lambda} = (1,0,1,0)$), evaluate at σ_ℓ: as $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$ (Sg2), $\delta_i(\sigma_\ell) = \delta_j(\sigma_\ell)$, so by Step 4 $\kappa_i(\sigma_\ell) - \kappa_j(\sigma_\ell) \in \mathfrak{m}_\ell \cap \mathcal{O} = \mathfrak{m}_\mathcal{O}$; but $\bar{\alpha}(\sigma_\ell) = \bar{\xi}(\sigma_\ell)$ (as $\bar{\omega}_\ell = \bar{\chi}_{\mathrm{cyc}}$), and for the pairs $(1,2),(1,4),(3,2),(3,4)$ the ratio κ_i/κ_j is $\alpha, \alpha\Psi, \alpha\Psi^{-1}, \alpha$, with residue $\bar{\xi}, \overline{\xi\Psi}, \overline{\xi\Psi^{-1}}, \bar{\xi}$ at σ_ℓ, never 1 by (Sg2) at $\ell \in T$. If $\lambda_i = \lambda_j$, evaluate at s_0: $c^{m_i} = c^{m_j+1}$, so $m_i = m_j + 1$, which fails for $i = j$ and for $\{i,j\} = \{1,3\}$ or $\{2,4\}$ (there $m_i - m_j - 1 \in \{e-1, -e-1\}$ and $e \geq 2$). □

Proposition 44.13. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $c \in G_\mathbb{Q}$ a complex conjugation, w an integer and $\nu\colon G_\mathbb{Q} \to \overline{\mathbb{Q}}_\ell^\times$ a character of finite order. Let $r\colon G_\mathbb{Q} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ be continuous such that $r(g)$ has similitude $\theta(g) = \chi_{\mathrm{cyc}}(g)^w\nu(g)$ for every g, let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field in which ℓ is unramified, and let π be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_4(\mathbb{A}_K)$ with $r|_{G_K} \leftrightarrow_\iota \pi$. Then there are a continuous character $\psi\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$ with*

$$\psi(cgc)\,\psi(g)\,\theta(g) = \chi_{\mathrm{cyc}}(g)^{-3} \qquad (g \in G_K)$$

and a regular algebraic conjugate self-dual cuspidal automorphic representation π' of $\mathrm{GL}_4(\mathbb{A}_K)$ with $(r|_{G_K}) \otimes \psi \leftrightarrow_\iota \pi'$.

Proof. Put $\chi' = \chi_{\mathrm{cyc}}^{-3}\theta^{-1} = \chi_{\mathrm{cyc}}^{-3-w}\nu^{-1}$, a continuous character of $G_\mathbb{Q}$; we need ψ with $\psi(g)\psi(cgc) = \chi'(g)$ on G_K. Write $\chi'_\ell = \chi' \circ \mathrm{Art}_{\mathbb{Q}_\ell}$ for its restriction to a decomposition group at ℓ; since $\chi_{\mathrm{cyc}} \circ \mathrm{Art}_{\mathbb{Q}_\ell}(x) = x^{\pm 1}$ on $\mathbb{Z}_\ell^\times$ and ν has finite order, there are $k \in \mathbb{Z}$ and a character λ of $\mathbb{Z}_\ell^\times$ of finite order with $\chi'_\ell(x) = x^k\lambda(x)$ for $x \in \mathbb{Z}_\ell^\times$.

Step 1: local characters at ℓ. Let S be the set of places of K above ℓ; $S^c = S$, and every $v \in S$ is unramified over $\mathbb{Q}$. Choose $\bar{v}$ as in Lemma B.26. By local class field theory a character of G_{K_v} is a character of $K_v^\times$, the inertia group corresponds to $\mathcal{O}_{K_v}^\times$, restriction from $G_{\mathbb{Q}_\ell}$ corresponds to composition with $\mathrm{N}_{K_v/\mathbb{Q}_\ell}$, and conjugation by an element acting on K_v as an automorphism σ corresponds to composition with σ. If ℓ splits in K, $S = \{v, v^c\}$ with $K_v = K_{v^c} = \mathbb{Q}_\ell$; put $\psi_v = \chi'|_{G_{K_v}}$ and $\psi_{v^c} = \mathbf{1}$. Then $\psi_v(g)\psi_{v^c}(cgc) = \chi'(g)$ for $g \in G_{K_v}$, and $\psi_{v^c}(g)\psi_v(cgc) = \chi'(cgc) = \chi'(g)$ for $g \in G_{K_{v^c}}$, since χ' is a character of $G_\mathbb{Q}$. If ℓ is inert, $S = \{v\}$, K_v is the unramified quadratic extension of $\mathbb{Q}_\ell$ with non-trivial automorphism σ, and

$\mathrm{N} = \mathrm{N}_{K_v/\mathbb{Q}_\ell}$ maps $\mathcal{O}_{K_v}^\times$ onto $\mathbb{Z}_\ell^\times$. Fix an embedding $\tau\colon K_v \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}_\ell$. The finite-order character λ factors through $\mathbb{Z}_\ell^\times/(1+\ell^a\mathbb{Z}_\ell)$ for some a, a subgroup of the finite abelian group $\mathcal{O}_{K_v}^\times/(1+\ell^a\mathcal{O}_{K_v})$, so it extends to a finite-order character μ of $\mathcal{O}_{K_v}^\times$. Let ψ_v be the character of $K_v^\times = \ell^{\mathbb{Z}} \times \mathcal{O}_{K_v}^\times$ with $\psi_v(\ell) = 1$ and $\psi_v(x) = \tau(x)^k\mu(x)$ on units. For $x \in \mathcal{O}_{K_v}^\times$, as ψ_v is multiplicative and $x\,\sigma(x) = \mathrm{N}x \in \mathbb{Z}_\ell^\times$,

$$\psi_v(x)\,\psi_v(\sigma x) = \psi_v(\mathrm{N}x) = (\mathrm{N}x)^k\lambda(\mathrm{N}x) = \chi'_\ell(\mathrm{N}x),$$

which is $(\psi_v\psi_{v^c}^c)|_{I_{K_v}} = \chi'|_{I_{K_v}}$ in the notation of Lemma B.26 (the element s there acts on K_v as σ). In both cases each ψ_v agrees on an open subgroup of $\mathcal{O}_{K_v}^\times$ with an algebraic character $x \mapsto \prod_{\tau'}\tau'(x)^{n_{\tau'}}$ (τ' over the embeddings of K_v), so it is locally algebraic and hence de Rham [220].

Step 2: the global character. The character χ' takes the same value on all complex conjugations ($\mathbb{Q}$ has one infinite place). By Lemma B.26 for $F = K$, $F^+ = \mathbb{Q}$, S, χ' and the ψ_v of Step 1, there is a continuous $\psi\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$ with $\psi(g)\psi(cgc) = \chi'(g)$, that is $\psi(cgc)\psi(g)\theta(g) = \chi_{\mathrm{cyc}}(g)^{-3}$, for $g \in G_K$, and $\psi|_{I_{K_v}} = \psi_v|_{I_{K_v}}$ for $v \in S$. So $\psi \circ \mathrm{Art}_K$ agrees on an open subgroup of $\prod_{v|\ell}\mathcal{O}_{K_v}^\times$ with an algebraic character: ψ is locally algebraic at ℓ, and by the correspondence between locally algebraic ℓ-adic characters and algebraic Hecke characters [220] there is an algebraic Hecke character ϕ of K with $\psi \leftrightarrow_\iota \phi$: for almost all finite places w, ψ and ϕ are unramified at w and $\iota\,\psi(\mathrm{Frob}_w^{-1}) = \phi_w(\varpi_w)$.

Step 3: the twisted automorphic representation. Put $\pi' = \pi \otimes (\phi \circ \det)$ and $r' = (r|_{G_K}) \otimes \psi$. The representation π' is cuspidal; it is regular algebraic, since twisting by an algebraic Hecke character shifts the infinitesimal character at each complex place by an integral scalar, which preserves integrality and regularity. At every finite w at which π, ϕ, r and ψ are unramified and the defining identities of $r|_{G_K} \leftrightarrow_\iota \pi$ and $\psi \leftrightarrow_\iota \phi$ hold (all but finitely many), the Satake parameters of π'_w are $\alpha\,\phi_w(\varpi_w)$, α those of π_w, and the eigenvalues of $\iota\,r'(\mathrm{Frob}_w^{-1})$ are $\mathrm{N}w^{3/2}\alpha \cdot \phi_w(\varpi_w)$; so $r' \leftrightarrow_\iota \pi'$.

Step 4: r' is conjugate self-dual. From ${}^t r(g)J_4 r(g) = \theta(g)J_4$, $r(g) = \theta(g)J_4^{-1}\,{}^t r(g)^{-1}J_4$ for $g \in G_{\mathbb{Q}}$; with $\mathbf{P} = r(c)J_4^{-1}$ and $g \in G_K$,

$$\begin{aligned} r'(cgc) &= \psi(cgc)\,r(c)r(g)r(c)^{-1} = \psi(cgc)\theta(g)\,\mathbf{P}\,{}^t r(g)^{-1}\mathbf{P}^{-1} \\ &= \psi(cgc)\psi(g)\theta(g)\,\mathbf{P}\,{}^t r'(g)^{-1}\mathbf{P}^{-1} \\ &= \chi_{\mathrm{cyc}}(g)^{-3}\,\mathbf{P}\,{}^t r'(g)^{-1}\mathbf{P}^{-1}. \end{aligned}$$

So for almost all w the characteristic polynomials of

$$r'(\mathrm{Frob}_{cw}^{-1}) = r'(c\,\mathrm{Frob}_w^{-1}c) \quad \text{and of} \quad \chi_{\mathrm{cyc}}(\mathrm{Frob}_w)^3\,{}^t r'(\mathrm{Frob}_w^{-1})^{-1}$$

agree (choosing $\mathrm{Frob}_{cw} = c\,\mathrm{Frob}_w c$). With $\chi_{\mathrm{cyc}}(\mathrm{Frob}_w) = \mathrm{N}w$ and Step 3, the multiset $\{\mathrm{N}w^{3/2}\alpha'\}$, α' over the Satake parameters of $\pi'_{cw} = (\pi'^c)_w$, equals $\{\mathrm{N}w^3(\mathrm{N}w^{3/2}\alpha)^{-1}\} = \{\mathrm{N}w^{3/2}\alpha^{-1}\}$, α over those of π'_w; the α^{-1} are the Satake parameters of $(\pi'^\vee)_w$. Unramified irreducible representations with the same Satake parameters are isomorphic, so $(\pi'^c)_w \cong (\pi'^\vee)_w$ for almost all w; both are cuspidal, and by (Js1) of Theorem B.60, $\pi'^c \cong \pi'^\vee$. Hence π' is regular algebraic, conjugate self-dual and cuspidal, and $(r|_{G_K}) \otimes \psi \leftrightarrow_\iota \pi'$. □

Lemma 44.14. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M and inertia subgroup I_M, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$, $n \geq 1$, and $\rho\colon G_M \to \mathrm{GL}_n(E)$ a continuous homomorphism with values in the upper triangular matrices; let $\kappa_1, \dots, \kappa_n\colon G_M \to E^\times$ be its diagonal entries. Assume that there are integers $m_1 > m_2 > \cdots > m_n$ such that $\kappa_a\chi_{\mathrm{cyc}}^{-m_a}$ has finite image on I_M for every a, and that $\kappa_a \neq \kappa_b\chi_{\mathrm{cyc}}$ for all $a < b$. Let $\mathrm{ad}\,\rho$ be $\mathrm{M}_n(E)$*

with g acting by $X \mapsto \rho(g)X\rho(g)^{-1}$, $\mathfrak{b} \subseteq \operatorname{ad}\rho$ the subspace of upper triangular matrices, and $u\colon G_M \to \mathfrak{b}$ a continuous 1-cocycle of $\operatorname{ad}\rho$ whose diagonal entries vanish on I_M. Then there is $Y \in \operatorname{ad}\rho \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with

$$u(g) \otimes 1 = gY - Y \qquad (g \in G_M),$$

G_M acting diagonally; that is, the class of u lies in $H^1_f(G_M, \operatorname{ad}\rho)$.

Proof. All representations below are finite-dimensional E-vector spaces U with a continuous E-linear action of G_M, regarded as $\mathbb{Q}_\ell$-representations. Dimensions are over $\mathbb{Q}_\ell$. We write $h^i(U) = \dim H^i(G_M, U)$ and $d = [M : \mathbb{Q}_\ell]$, and $H^1_f(U)$ is the kernel of $H^1(G_M, U) \to H^1(G_M, U \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}})$; it is functorial in U. For a character $\delta\colon G_M \to E^\times$, $E(\delta)$ is E with g acting by $\delta(g)$. We use the following standard facts of p-adic Hodge theory [94], [52]: (P1) subquotients, direct sums, tensor products over E and E-duals of de Rham representations are de Rham; (P2) for U de Rham, $\dim_M D_{\mathrm{dR}}(U) = \dim U$, $\dim_M \operatorname{Fil}^0 D_{\mathrm{dR}}(U)$ is the number of Hodge–Tate weights of U that are ≤ 0 (with multiplicity), and the multiset of Hodge–Tate weights is additive in short exact sequences; (P3) if $\delta\chi_{\mathrm{cyc}}^{-k}$ has finite image on I_M, then $E(\delta)$ is de Rham with all Hodge–Tate weights equal to k (it is crystalline with weight k over a finite extension of M on whose inertia $\delta\chi_{\mathrm{cyc}}^{-k}$ is trivial, and the de Rham property descends). By (P3), $E(\kappa_a\kappa_b^{-1})$ is de Rham with all weights $m_a - m_b$, which is ≥ 1 when $a < b$.

Step 1: three cohomological facts. (i) If $\delta \ne \chi_{\mathrm{cyc}}$, then $H^2(G_M, E(\delta)) = 0$: by Theorem B.36 $h^2(E(\delta)) = h^0(E(\delta)^*(1))$, and the trace pairing $(x, y) \mapsto \operatorname{tr}_{E/\mathbb{Q}_\ell}(xy)$ identifies $E(\delta)^*(1)$ with $E(\delta^{-1}\chi_{\mathrm{cyc}})$, whose invariants vanish as $\delta^{-1}\chi_{\mathrm{cyc}} \ne 1$. (ii) If $0 \to U' \to U \to U'' \to 0$ is exact and $H^2(G_M, U') = H^2(G_M, U'') = 0$, then $H^2(G_M, U) = 0$ (long exact sequence). (iii) If U is de Rham with all Hodge–Tate weights ≥ 1 and $H^2(G_M, U) = 0$, then $H^1_f(U) = H^1(G_M, U)$: by (P2) $\operatorname{Fil}^0 D_{\mathrm{dR}}(U) = 0$, so $\dim H^1_f(U) = h^0(U) + d\dim U$ by Theorem B.56, and $h^1(U) = h^0(U) + d\dim U$ by Theorem B.36.

Step 2: filtrations. For $k \ge 0$ let $\mathfrak{n}_{\ge k} \subseteq \mathrm{M}_n(E)$ be the span of the elementary matrices E_{ab} with $b - a \ge k$; so $\mathfrak{n}_{\ge 0} = \mathfrak{b}$, and put $\mathfrak{n} = \mathfrak{n}_{\ge 1}$. Write $\rho(g) = D_g(1 + N_g)$ with D_g diagonal and N_g strictly upper triangular. For $X \in \mathfrak{n}_{\ge k}$, $N_g X$ and $X N_g$ lie in $\mathfrak{n}_{\ge k+1}$, so $\rho(g)X\rho(g)^{-1} \equiv D_g X D_g^{-1} \pmod{\mathfrak{n}_{\ge k+1}}$. Hence each $\mathfrak{n}_{\ge k}$ is stable, $\mathfrak{n}_{\ge k}/\mathfrak{n}_{\ge k+1} \cong \bigoplus_{b-a=k} E(\kappa_a\kappa_b^{-1})$ for $k \ge 1$, and $\mathfrak{t} := \mathfrak{b}/\mathfrak{n}$ is E^n with trivial action, the quotient map taking the diagonal part.

Step 3: ρ is de Rham. Let $L_k \subseteq E^n$ be the span of the first k standard basis vectors; it is stable, and $L_k/L_{k-1} \cong E(\kappa_k)$. $L_1 = E(\kappa_1)$ is de Rham by (P3). Let $k \ge 2$ with L_{k-1} de Rham, and put $W = \operatorname{Hom}_E(E(\kappa_k), L_{k-1})$ with g acting by $f \mapsto g \circ f \circ g^{-1}$. $W \cong L_{k-1} \otimes_E E(\kappa_k^{-1})$ is de Rham (P1), with a filtration whose graded pieces are $E(\kappa_a\kappa_k^{-1})$, $a < k$; so its weights are ≥ 1 (P2), $H^2(G_M, W) = 0$ by (i) and (ii) (as $\kappa_a\kappa_k^{-1} \ne \chi_{\mathrm{cyc}}$), and $H^1_f(W) = H^1(G_M, W)$ by (iii). Choose an E-linear section $s\colon E(\kappa_k) \to L_k$ of the quotient map; $\xi(g) = g \circ s \circ g^{-1} - s$ is a cocycle with values in W, so there is $\Phi \in W \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}} \subseteq W \otimes_{\mathbb{Q}_\ell} B_{\mathrm{dR}}$ with $\xi(g) \otimes 1 = g\Phi - \Phi$. Viewing $W \otimes_{\mathbb{Q}_\ell} B_{\mathrm{dR}}$ inside $\operatorname{Hom}_{B_{\mathrm{dR}}}(E(\kappa_k) \otimes B_{\mathrm{dR}}, L_{k-1} \otimes B_{\mathrm{dR}})$, the map $s' = s \otimes 1 - \Phi$ is a B_{dR}-linear section of $L_k \otimes B_{\mathrm{dR}} \to E(\kappa_k) \otimes B_{\mathrm{dR}}$ with $g \circ s' \circ g^{-1} = s \otimes 1 + \xi(g) \otimes 1 - \Phi - \xi(g) \otimes 1 = s'$. So $L_k \otimes B_{\mathrm{dR}} \cong (L_{k-1} \otimes B_{\mathrm{dR}}) \oplus (E(\kappa_k) \otimes B_{\mathrm{dR}})$ equivariantly, and taking invariants, $\dim_M D_{\mathrm{dR}}(L_k) = \dim L_{k-1} + \dim E(\kappa_k) = \dim L_k$: L_k is de Rham. Hence $\rho = L_n$ is de Rham, and by (P1) so are $\operatorname{ad}\rho \cong E^n \otimes_E (E^n)^\vee$, $\mathfrak{b}$, $\mathfrak{n}$ and $\mathfrak{t}$.

Step 4: $H^2(G_M, \mathfrak{n}) = 0$ and $H^1_f(\mathfrak{n}) = H^1(G_M, \mathfrak{n})$. By Step 2, $\mathfrak{n}$ has a filtration with graded pieces $E(\kappa_a\kappa_b^{-1})$, $a < b$; by (i) and (ii), $H^2(G_M, \mathfrak{n}) = 0$; its weights are $m_a - m_b \ge 1$ (P2, P3); and (iii) applies.

Step 5: $H^1_f(\mathfrak{b}) \to H^1_f(\mathfrak{t})$ is surjective. Put $\sigma = \dim \mathfrak{n}$ and $\tau = \dim \mathfrak{t} = h^0(\mathfrak{t})$. The cohomology

sequence of $0 \to \mathfrak{n} \to \mathfrak{b} \to \mathfrak{t} \to 0$ is exact:

$$0 \to H^0(\mathfrak{n}) \to H^0(\mathfrak{b}) \to H^0(\mathfrak{t}) \to H^1(\mathfrak{n}) \to H^1(\mathfrak{b}) \to H^1(\mathfrak{t}) \to H^2(\mathfrak{n}) = 0.$$

By Theorem B.36 and Step 4, $h^1(\mathfrak{n}) = h^0(\mathfrak{n}) + d\sigma$, so the image J of $H^1(\mathfrak{n})$ in $H^1(\mathfrak{b})$ has dimension $h^1(\mathfrak{n}) - (\tau - h^0(\mathfrak{b}) + h^0(\mathfrak{n})) = d\sigma - \tau + h^0(\mathfrak{b})$, and $J \subseteq H^1_f(\mathfrak{b})$ by Step 4 and functoriality. The weights of $\mathfrak{b}$ are those of $\mathfrak{n}$ (all ≥ 1) and those of $\mathfrak{t}$ (all 0), so $\dim_M \big(D_{\mathrm{dR}}(\mathfrak{b})/\mathrm{Fil}^0\big) = (\sigma+\tau) - \tau = \sigma$ by (P2), and $\dim H^1_f(\mathfrak{b}) = h^0(\mathfrak{b}) + d\sigma$ by Theorem B.56. The map $H^1_f(\mathfrak{b}) \to H^1(\mathfrak{t})$ has kernel $H^1_f(\mathfrak{b}) \cap J = J$ and lands in $H^1_f(\mathfrak{t})$, so its image has dimension $h^0(\mathfrak{b}) + d\sigma - (d\sigma - \tau + h^0(\mathfrak{b})) = \tau$. On the other hand $\mathfrak{t} \cong \mathbb{Q}_\ell^\tau$ is trivial, so by Theorem B.44, applied to each coordinate, $H^1_f(\mathfrak{t})$ is the space of homomorphisms $G_M \to \mathfrak{t}$ trivial on I_M, of dimension τ (G_M/I_M is topologically generated by a Frobenius element). Hence the map is onto $H^1_f(\mathfrak{t})$.

Step 6: conclusion. The image of the class of u in $H^1(G_M, \mathfrak{t}) = \mathrm{Hom}_{\mathrm{cont}}(G_M, \mathfrak{t})$ is $g \mapsto$ (diagonal part of $u(g)$), which vanishes on I_M and so lies in $H^1_f(\mathfrak{t})$. By Step 5 there is $x \in H^1_f(\mathfrak{b})$ with the same image; then $[u] - x$ lies in the kernel of $H^1(\mathfrak{b}) \to H^1(\mathfrak{t})$, which is $J \subseteq H^1_f(\mathfrak{b})$. So $[u] \in H^1_f(\mathfrak{b})$, and by functoriality along $\mathfrak{b} \subseteq \mathrm{ad}\,\rho$, $[u] \in H^1_f(\mathrm{ad}\,\rho)$, which is the assertion. □

Proposition 44.15. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to some $(\psi, \mathfrak{h}, t, \chi)$, with odd prime ℓ, weight e and level M, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. Every irreducible point of $\mathfrak{D}$ that is automorphic for ι is admissible symplectic of weight e and level M for ι.*

Proof. Let r be an irreducible point of $\mathfrak{D}$, automorphic for ι. Reduction modulo $\mathfrak{m}_{\mathcal{O}}$ is written with a bar; write $\chi = \chi'\chi''$ with χ' of order prime to ℓ and χ'' of ℓ-power order, so $\bar{\chi}'' = \mathbf{1}$. Since $\mathfrak{D}$ is attached, χ is a character modulo N and ξ one modulo $2^{n'}p'$, and ω_ℓ is one modulo ℓ; all three are characters of level M. Recall $\theta = \alpha\Psi$, $\alpha = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\xi$, $\Psi = \chi\chi_{\mathrm{cyc}}^e$, and $\bar{\omega}_\ell = \bar{\chi}_{\mathrm{cyc}}$.

(Sy1), (Sy2), (Sy4) and continuity. The point r is continuous by (Sq5). If $W \subseteq \overline{\mathbb{Q}}_\ell^4$ is stable under $r(G_{\mathbb{Q}})$, it is stable under its span $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$, so $W = 0$ or $W = \overline{\mathbb{Q}}_\ell^4$: (Sy1). (Sy2) is the definition of an automorphic point. By (Sq2), ${}^t r(s) J_4 r(s) = \theta(s) J_4$ for all s, and $\theta = \chi_{\mathrm{cyc}}^{e+1}\,\omega_\ell^{-1}\xi\chi$ with $\omega_\ell^{-1}\xi\chi$ of level M; this is (Sy4) with $M' = M$ and $P = J_4$.

(Lw1) at primes $v \notin T$, $v \neq \ell$. Let $I = I_{\bar{v}}$ for the fixed place $\bar{v}$. By (Se2) for the lift underlying r and an application of the homomorphism to $\overline{\mathbb{Q}}_\ell$, $r(g) = 1$ for $g \in I$ with $\bar{r}_0(g) = 1$. Hence $r|_I = R \circ \bar{r}_0|_I$ for a homomorphism R from the finite abelian group $H = \bar{r}_0(I)$ to $\mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$; $R(H)$ consists of commuting matrices of finite order, which are simultaneously diagonalisable, so $r|_I$ is conjugate to $\mathrm{diag}(\varepsilon_1 \circ \bar{r}_0, \dots, \varepsilon_4 \circ \bar{r}_0)$ with characters ε_k of H. The map $\bar{r}_0(g) \mapsto (\bar{\theta}(g), \bar{\Psi}(g), \bar{\alpha}(g))$ embeds H into $(\mathbb{F}_{\mathcal{O}}^\times)^3$; every character of a subgroup of a finite abelian group extends to the group, and the characters of $(\mathbb{F}_{\mathcal{O}}^\times)^3$ with values in $\overline{\mathbb{Q}}_\ell^\times$ are $(a,b,c) \mapsto [a]^i[b]^j[c]^k$, where $[\cdot]\colon \mathbb{F}_{\mathcal{O}}^\times \to \mathcal{O}^\times$ is the Teichmüller lift, a faithful character of a cyclic group. So $\varepsilon_k \circ \bar{r}_0 = [\bar{\theta}]^i[\bar{\Psi}]^j[\bar{\alpha}]^k$ on I. Now $\bar{\alpha} = \bar{\xi}$ and $\bar{\Psi} = \overline{\chi'\omega_\ell^e}$, and a character of order prime to ℓ with values in $\mathcal{O}^\times$ is the Teichmüller lift of its reduction (reduction is injective on the roots of unity of order prime to ℓ in $\mathcal{O}$); ξ has order prime to ℓ, so $[\bar{\alpha}] = \xi$, $[\bar{\Psi}] = \chi'\omega_\ell^e$ and $[\bar{\theta}] = \xi\chi'\omega_\ell^e$, characters of level M (χ' is a power of χ). Hence (Lw1) holds at v.

(Lw1) at $v \in T$, $v \neq \ell$. By (Zt1), $r(g) = 1$ for $g \in I_v$ with $\chi(g) = 1$, so $r|_{I_v} = R \circ \chi|_{I_v}$ for a homomorphism R from the finite cyclic group $\chi(I_v) \subset \overline{\mathbb{Q}}_\ell^\times$; as before R is diagonalisable with characters of $\chi(I_v)$, which are powers of the inclusion. So $r|_{I_v}$ is conjugate to $\mathrm{diag}(\chi^{a_1}, \dots, \chi^{a_4})|_{I_v}$, with χ^{a_k} of level M.

(Lw2) at ℓ, and genericity. Let $\delta_1, \dots, \delta_4$ be the characters of (Zt2): r is triangular on D_ℓ with diagonal (δ_i), and on I_ℓ, with $m = (e+1, e, 1, 0)$,

$$\delta_i = \kappa_i = \chi_{\mathrm{cyc}}^{m_i}\chi_i, \qquad (\chi_1, \chi_2, \chi_3, \chi_4) = (\omega_\ell^{-1}\xi\chi,\ \chi,\ \omega_\ell^{-1}\xi,\ \mathbf{1}),$$

characters of level M; and $\delta_i \neq \delta_j\chi_{\mathrm{cyc}}|_{D_\ell}$ for all i,j by (Zt3). Hence (Lw2) holds at ℓ (with its first alternative), and r has level M and weights $(e+1,e,1,0)$: (Sy3).

(Sy5). First, $\ell \mid M$. A place of $\overline{\mathbb{Q}}$ above ℓ is $h\bar{\ell}$ with $h \in G_{\mathbb{Q}}$, with $D_{h\bar{\ell}} = hD_\ell h^{-1}$. If $u\,r(s)\,u^{-1}$ is upper triangular with diagonal $(\delta_i(s))$ for $s \in D_\ell$, then for $s' = hsh^{-1}$ the matrix $u\,r(h)^{-1}\,r(s')\,r(h)\,u^{-1} = u\,r(s)\,u^{-1}$ is upper triangular with diagonal $\delta'_i(s') = \delta_i(h^{-1}s'h)$. If $\delta'_i = \delta'_j\chi_{\mathrm{cyc}}$ on $D_{h\bar{\ell}}$, then, since $\chi_{\mathrm{cyc}}(h^{-1}s'h) = \chi_{\mathrm{cyc}}(s')$, $\delta_i = \delta_j\chi_{\mathrm{cyc}}$ on D_ℓ, which was excluded. So r is triangular on $D_{h\bar{\ell}}$ with a diagonal (δ'_i) satisfying $\delta'_i \neq \delta'_j\chi_{\mathrm{cyc}}|_{D_{h\bar{\ell}}}$ for all i,j: (Sy5).

So r is admissible symplectic of weight e and level M for ι. □

Lemma 44.16. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and r, r' points of $\mathfrak{D}$ with r irreducible. If $r' \cong r$, that is $r'(g) = u\,r(g)\,u^{-1}$ for all $g \in G_{\mathbb{Q}}$ and some $u \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$, then there are $t_1, t_2 \in \overline{\mathbb{Q}}_\ell^\times$ with $r'(g) = \mathrm{T}_4(t_1,t_2)\,r(g)\,\mathrm{T}_4(t_1,t_2)^{-1}$ for all $g \in G_{\mathbb{Q}}$.*

Proof. Let $u \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $u\,r(g) = r'(g)\,u$ for all $g \in G_{\mathbb{Q}}$. Write $E = \{(i,j) : \lambda_i \neq \lambda_j\}$; a matrix is block diagonal when its entries in E vanish. For $y \in \mathcal{O}$ write $\bar{y}$ for its residue in $\mathbb{F}_{\mathcal{O}}$; an element $y \in \mathcal{O}$ with $\bar{y} \neq 0$ is a unit, so $|y|_\ell = 1$, and $y + z \neq 0$ for every $z \in \mathfrak{m}_\ell$.

Step 1: the diagonal entries $d_i = \kappa_i(\phi) \in \mathcal{O}^\times$ of $r_0(\phi)$ satisfy $|d_i - d_j|_\ell = 1$ for $(i,j) \in E$. Let $q = \#\mathbb{F}_{\mathcal{O}}$. For a character $\kappa\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$, $\bar{\kappa}$ takes values in $\mathbb{F}_{\mathcal{O}}^\times$, of order $q-1$, and is locally constant. Since q is a power of ℓ, ℓ is prime to $q-1$; its multiplicative order δ modulo $q-1$ satisfies $\delta \leq q-1$, so for $n \geq q-1$ we have $\delta \mid n!$, hence $\ell^{n!} \equiv 1 \pmod{q-1}$ and $\bar{\kappa}(\sigma_\ell^{\ell^{n!}}) = \bar{\kappa}(\sigma_\ell)$; by (Sg3) and local constancy, $\bar{\kappa}(\phi) = \bar{\kappa}(\sigma_\ell)$. By (Sg2), $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$, so $\bar{\omega}_\ell(\sigma_\ell) = \bar{\chi}_{\mathrm{cyc}}(\sigma_\ell) = 1$ and $\bar{\alpha}(\sigma_\ell) = \bar{\xi}(\sigma_\ell)$. The pairs in E are, up to order, $(1,2),(1,4),(3,2),(3,4)$, and

$$\frac{\bar{\kappa}_1}{\bar{\kappa}_2}(\sigma_\ell) = \bar{\alpha}(\sigma_\ell) = \bar{\xi}(\sigma_\ell), \quad \frac{\bar{\kappa}_1}{\bar{\kappa}_4}(\sigma_\ell) = \overline{\xi\Psi}(\sigma_\ell), \quad \frac{\bar{\kappa}_3}{\bar{\kappa}_2}(\sigma_\ell) = \overline{\xi\Psi^{-1}}(\sigma_\ell), \quad \frac{\bar{\kappa}_3}{\bar{\kappa}_4}(\sigma_\ell) = \bar{\xi}(\sigma_\ell),$$

using $\theta = \alpha\Psi$. Since $\ell \in T$, (Sg2) with $i = 0, 1, -1$ says that none of these is 1. Hence $\bar{d}_i \neq \bar{d}_j$ for $(i,j) \in E$, and $d_i - d_j$ is a unit of $\mathcal{O}$.

Step 2: u is block diagonal. Put $X = r(\phi)$, $X' = r'(\phi)$, $D = r_0(\phi) = \mathrm{diag}(d_1,\dots,d_4)$, $Y = X - D$, $Y' = X' - D$. By (Sq3) X and X' are block diagonal, and by (Sq4) every entry of Y and Y' lies in $\mathfrak{m}_\ell$. Suppose some entry of u in E is non-zero, and choose $(i,j) \in E$ with $m = |u_{ij}|_\ell$ maximal among the entries of u in E; so $m > 0$. From $uX = X'u$, $X = D + Y$, $X' = D + Y'$ and the (i,j) entry,

$$(d_i - d_j)\,u_{ij} = (uY)_{ij} - (Y'u)_{ij}.$$

In $(uY)_{ij} = \sum_k u_{ik}Y_{kj}$: if $\lambda_k \neq \lambda_j$, then $k \neq j$ and $Y_{kj} = X_{kj} = 0$; if $\lambda_k = \lambda_j$, then $\lambda_i \neq \lambda_k$, so $|u_{ik}|_\ell \leq m$ and $|u_{ik}Y_{kj}|_\ell < m$. In $(Y'u)_{ij} = \sum_k Y'_{ik}u_{kj}$: if $\lambda_i \neq \lambda_k$, then $Y'_{ik} = X'_{ik} = 0$; if $\lambda_i = \lambda_k$, then $(k,j) \in E$, so $|Y'_{ik}u_{kj}|_\ell < m$. By the ultrametric inequality the right-hand side has absolute value $< m$, while the left-hand side has absolute value $|d_i - d_j|_\ell\, m = m$ by Step 1. This contradiction shows that u is block diagonal: $u_{ij} = 0$ for $(i,j) \in E$.

Step 3: $u_{13} = u_{31} = 0$. Put $H = h(r)$, $H' = h(r')$. From $u\,r(g_0) = r'(g_0)\,u$ and $u\,r(g_0^{-1}) = r'(g_0^{-1})\,u$ we get $uH = H'u$. By (Sq4), $r(g)_{ii} - \kappa_i(g)$ and $r'(g)_{ii} - \kappa_i(g)$ lie in $\mathfrak{m}_\ell$ for $g = g_0^{\pm 1}$; as $\theta(g_0) \in \mathcal{O}$ and $\theta = \alpha\Psi$, the entries H_{11}, H'_{11} differ from $\theta(g_0) + 1$, and H_{33}, H'_{33} differ from $\alpha(g_0) + \Psi(g_0)$, by elements of $\mathfrak{m}_\ell$. Hence $H_{33} - H'_{11}$ and $H_{11} - H'_{33}$ differ from $\mp y_0$, where

$$y_0 = \theta(g_0) + 1 - \alpha(g_0) - \Psi(g_0) = \big(\alpha(g_0) - 1\big)\big(\Psi(g_0) - 1\big) \in \mathcal{O},$$

by elements of $\mathfrak{m}_\ell$. By (Sg4) $\bar{y}_0 \neq 0$, so $H_{33} \neq H'_{11}$ and $H_{11} \neq H'_{33}$. By Step 2, $u_{12} = u_{14} = u_{32} = u_{34} = 0$ and $u_{21} = u_{23} = u_{41} = u_{43} = 0$; by (Sq3), $H_{13} = H_{31} = H'_{13} = H'_{31} = 0$. The entries $(1,3)$ and $(3,1)$ of $uH = H'u$ are therefore

$$u_{13}H_{33} = H'_{11}u_{13}, \qquad u_{31}H_{11} = H'_{33}u_{31},$$

so $u_{13} = u_{31} = 0$.

Step 4: u has a similitude. For $Z \in \mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$ put $Z^* = J_4^{-1}\,{}^t\!Z\,J_4$; then $(ZZ')^* = Z'^*Z^*$, and Z has similitude ν if and only if $Z^*Z = \nu \cdot 1$. By (Sq2), $r(g)^*r(g) = \theta(g) \cdot 1$ with $\theta(g) \neq 0$, so $r(g)^* = \theta(g)\,r(g)^{-1}$, and likewise $r'(g)^* = \theta(g)\,r'(g)^{-1}$. Applying * to $u\,r(g) = r'(g)\,u$ gives $r(g)^*u^* = u^*r'(g)^*$, that is $r(g)^{-1}u^* = u^*r'(g)^{-1}$, so $u^*r'(g) = r(g)\,u^*$. For $C = u^*u$ this gives

$$C\,r(g) = u^*r'(g)\,u = r(g)\,u^*u = r(g)\,C \qquad (g \in G_{\mathbb{Q}}).$$

As r is irreducible, the span of $r(G_{\mathbb{Q}})$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$, so C is central in $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$: $C = a \cdot 1$ with $a \in \overline{\mathbb{Q}}_\ell$, and $a \neq 0$ because $\det u^* = \det u \neq 0$. Multiplying by J_4 on the left, ${}^t\!u\,J_4\,u = a\,J_4$.

Step 5: u is a scalar multiple of $\mathrm{T}_4(t_1, t_2)$. Since $(J_4u)_{kj}$ is $u_{4j}, u_{3j}, -u_{2j}, -u_{1j}$ for $k = 1, 2, 3, 4$,

$$({}^t\!u\,J_4\,u)_{ij} = u_{1i}u_{4j} + u_{2i}u_{3j} - u_{3i}u_{2j} - u_{4i}u_{1j}.$$

By Steps 2 and 3 the only entries of u that may be non-zero are $u_{11}, u_{33}, u_{22}, u_{24}, u_{42}, u_{44}$. Rows 1 and 3 of u are $(u_{11}, 0, 0, 0)$ and $(0, 0, u_{33}, 0)$, so $u_{11}u_{33} \neq 0$ as u is invertible. The entries $(1, 2)$ and $(3, 4)$ of ${}^t\!u\,J_4\,u = aJ_4$ give $u_{11}u_{42} = 0$ and $-u_{33}u_{24} = 0$, hence $u_{42} = u_{24} = 0$ and $u = \mathrm{diag}(u_{11}, u_{22}, u_{33}, u_{44})$ with all diagonal entries non-zero. The entries $(1, 4)$ and $(2, 3)$ give $u_{11}u_{44} = a = u_{22}u_{33}$. Put $t_1 = u_{33}/u_{44}$ and $t_2 = u_{22}/u_{44}$; then $t_1t_2 = u_{22}u_{33}/u_{44}^2 = u_{11}/u_{44}$, so $u = u_{44}\,\mathrm{T}_4(t_1, t_2)$. Since the scalar u_{44} cancels in conjugation, $r'(g) = u\,r(g)\,u^{-1} = \mathrm{T}_4(t_1, t_2)\,r(g)\,\mathrm{T}_4(t_1, t_2)^{-1}$ for all $g \in G_{\mathbb{Q}}$. □

45 The graded model of the symplectic Eisenstein deformation problem

This section proves Proposition 45.2, the graded model of the symplectic Eisenstein deformation problem, which is the algebraic input of Proposition 44.3. Its clauses (Gs1)–(Gs6) are those of the unitary model: the conditions of the criterion, the embedding of the Tate–Shafarevich group into derivations of degree -1, trace elements a_g whose values at points are trace differences, and the correspondence between points. The construction follows Section 43 with two changes. The torus that acts has rank two, so the model is graded by $\mathbb{Z} \times \mathbb{Z}$, and the criterion is applied to its part of λ-weight zero, which is graded by the remaining weight (Definition 45.1, Lemma 45.29). And the deformation problem is framed at all primes of the set T, not only at ℓ, so the model is assembled from local charts at each of them (Definition 45.3).

Subsection 45.1 constructs the local charts; Subsection 45.2 the graded relative presentation with its Euler-characteristic count and the assembly of the model; Subsection 45.3 checks the conditions of the criterion and the Tate–Shafarevich classes on the part of weight zero; and Subsection 45.4 analyses the reducible points, which gives the separation condition (Gc3) and, at the two-signed points, irreducibility and one-dimensional tangent spaces (Gc4).

45.1 Symplectic weighted models and symplectic local bases

This subsection defines symplectic weighted models (Definition 45.1) and symplectic local bases (Definition 45.3), states the existence of a model (Proposition 45.4), and constructs the local charts from which it is built. At ℓ the ordinary symplectic lifting ring has a weighted chart at the Eisenstein point (Proposition 45.6). As in Subsection 43.2, the tangent vectors are crystalline (Proposition 45.7, Lemma 45.8) and are counted by weight (Lemma 45.14), and an explicit fourteen-parameter family of ordinary symplectic lifts gives the dimension from below (Lemma 45.10, Proposition 45.9). At the other primes of T there is a weighted chart of the local

lifting ring (Proposition 45.16), and the completed tensor product of the local rings is smooth with the summed tangent dimensions (Proposition 45.17). The lemmas on finite subalgebras and power series rings that turn families into charts are routine.

Definition 45.1. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, and let $\mathcal{W}_4 = \{\mathrm{wt}_4(i,j) : 1 \le i,j \le 4\} = \{(0,0), \pm(1,0), \pm(-1,1), \pm(1,1), \pm(0,1)\} \subset \mathbb{Z}^2$.

$\mathbb{Z}^2$-weighted quotients. For a finite set σ and $\mathrm{wt}\colon \sigma \to \mathbb{Z}^2$, weights of monomials, weight components $f_{(w)}$ and the sets $\mathcal{O}[[X_\sigma]]_w$ ($w \in \mathbb{Z}^2$) are formed as in Definition 43.6 with $\mathbb{Z}^2$ in place of $\mathbb{Z}$. An ideal $\mathfrak{a}$ of $\mathcal{O}[[X_s : s \in \sigma]]$ is **homogeneous** if $f_{(w)} \in \mathfrak{a}$ for every $f \in \mathfrak{a}$ and every w. If $\mathfrak{a}$ is homogeneous and every element of $\mathfrak{a}$ has constant term 0, put $R = \mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$, let R_w be the image of $\mathcal{O}[[X_\sigma]]_w$, let $x_R\colon R \to \mathcal{O}$ be the homomorphism induced by the constant term (its **origin**), and let $R^{\mathrm{gr}} = \sum_{w \in \mathbb{Z}^2} R_w \subseteq R$ be the $\mathcal{O}$-subalgebra of finite sums of elements of single weights. For $t\colon \mathbb{Z}^2 \to \mathbb{N}$ of finite support, R is **smooth at the origin with tangent dimensions** t if (Sm1)–(Sm4) hold for $(R^{\mathrm{gr}}, x_R|_{R^{\mathrm{gr}}})$, read with $\mathbb{Z}^2$-valued weights, R_w in place of A_j, and Sq formed in R^{gr} with $\mathfrak{m}_0 = \ker x_R \cap R^{\mathrm{gr}}$, for some chart $\phi\colon R^{\mathrm{gr}} \to \mathcal{O}[\ell^{-1}][[Y_i : i \in J]]$ and weights $\mathrm{wt}_J\colon J \to \mathbb{Z}^2$ with $\#\mathrm{wt}_J^{-1}(w) = t(w)$ for all w. For integers $r, r', m \ge 0$ let $t_{r,r',m}$ take the value 1 at $(1,0)$, $(-1,1)$ and $(1,1)$, r' at $(0,1)$, r at $(0,-1)$, m at $(0,0)$, and 0 elsewhere.

Normalised Sha cocycles. For $a \in \mathcal{O} \setminus \{0\}$, a **normalised Sha cocycle modulo** a for $\mathfrak{D}$ is a locally constant map $z\colon G_{\mathbb{Q}} \to \mathcal{O}/a\mathcal{O}$ such that $z(gh) = z(g) + \Psi^{-1}(g)z(h)$ for all g, h; $z(g) = 0$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$ and every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a prime not in T; $z(g_0) = 0$; and for every $v \in T$ there is $y \in \mathcal{O}/a\mathcal{O}$ with $z(g) = \Psi^{-1}(g)y - y$ for all $g \in D_v$.

Symplectic weighted models. A **symplectic weighted model** of $\mathfrak{D}$ is a tuple $M = (\sigma, \mathrm{wt}, \mathfrak{a}, r, r', m, F, E, Z, S, q, r_S)$ of a finite set σ, a map $\mathrm{wt}\colon \sigma \to \mathcal{W}_4$, a homogeneous ideal $\mathfrak{a}$ of $\mathcal{O}[[X_s : s \in \sigma]]$ all of whose elements have constant term 0, with $R = \mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$, R_w and x_R as above, integers $r, r', m \ge 0$, families $F = (F_1, \dots, F_{r+1})$, $E = (E_1, \dots, E_{r'})$, $Z = (Z_1, \dots, Z_m)$ of elements of R, a ring $S \in \mathrm{CNL}_{\mathcal{O}}$, an $\mathcal{O}$-algebra homomorphism $q\colon R \to S$ and a lift $r_S\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(S)$, such that

(Wm1) R is a domain and is smooth at the origin with tangent dimensions $t_{r,r',m}$;

(Wm2) $F_i \in R_{(0,-1)}$, $E_i \in R_{(0,1)}$, $Z_i \in R_{(0,0)}$ and $x_R(Z_i) = 0$ for all i;

(Wm3) q is surjective and $\ker q$ is the ideal generated by the F_i, E_i and Z_i;

(Wm4) r_S is a symplectic Eisenstein lift to S, and it generates S: if $f, f'\colon S \to S'$ are $\mathcal{O}$-algebra homomorphisms to some $S' \in \mathrm{CNL}_{\mathcal{O}}$ with $f \circ r_S = f' \circ r_S$, then $f = f'$;

(Wm5) for all $g \in G_{\mathbb{Q}}$ and $1 \le i,j \le 4$ there is $f \in R_{\mathrm{wt}_4(i,j)}$ with $q(f) = r_S(g)_{ij}$, and $x_R(f) = r_0(g)_{ij}$ for every $f \in R$ with $q(f) = r_S(g)_{ij}$;

(Wm6) for every $a \in \mathcal{O} \setminus \{0\}$ and every normalised Sha cocycle z modulo a there is an $\mathcal{O}$-linear map $\delta\colon R \to \mathcal{O}$ with $\delta(fh) = x_R(f)\delta(h) + x_R(h)\delta(f)$ for all $f, h \in R$, $\delta(R_w) = 0$ for every $w \ne (0,-1)$, $\delta(\ker q) \subseteq a\mathcal{O}$, and, for all $g \in G_{\mathbb{Q}}$ and $f \in R$, $\delta(f) \equiv \theta(g)z(g)$ modulo a if $q(f) = r_S(g)_{31}$, and $\delta(f) \equiv \Psi(g)z(g)$ modulo a if $q(f) = r_S(g)_{42}$.

The graded algebra of a model. For a symplectic weighted model M put

$$A_M = \sum_{n \in \mathbb{Z}} R_{(0,n)} \subseteq R, \qquad (A_M)_n = R_{(0,n)}, \qquad x_M = x_R|_{A_M},$$

the finite sums of elements of λ-weight 0, and let u_M be the system of equations with parts $u_{-1} = F$, $u_1 = E$, $u_0 = Z$ and u_{-2}, u_2 empty, so with counts $(0, r+1, m, r', 0)$ in degrees $-2, \dots, 2$.

Proposition 45.2. *Let $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, \dots)$ be a symplectic Eisenstein datum and $n_S = \prod_{p\in S} p$. There are a graded $\mathcal{O}$-algebra with a fixed point (A, φ_0), a system of equations u for it and elements $a_g \in A_0$ with $\varphi_0(a_g) = 0$ ($g \in G_{\mathbb{Q}}$) such that:*

(Gs1) *(A, φ_0, u) satisfies (Gc1);*

(Gs2) *for every $b \in \mathcal{O} \setminus \{0\}$, writing $\mathrm{Sha}[b]$ for the submodule of $\mathrm{Sha}^1_{n_S}(\chi, e)$ killed by b, there are $a \in b\mathcal{O} \setminus \{0\}$ and an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/a\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo a of an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_j) = 0$ for all $j \neq -1$;*

and, if $\mathfrak{D}$ is finite in weight zero, there is a map $x \mapsto r_x$ from the points of A on u to the points of $\mathfrak{D}$ such that:

(Gs3) *$x(a_g) = \mathrm{tr}\, r_x(g) - \mathrm{tr}\, r_0(g)$ for every point x of A on u and every $g \in G_{\mathbb{Q}}$;*

(Gs4) *for points x, x' of A on u, if $r_{x'}$ is a torus conjugate of r_x, then x' is a torus translate of x;*

(Gs5) *(A, φ_0, u) satisfies (Gc2) and (Gc3);*

(Gs6) *if $\mathfrak{D}$ has no endoscopic points, then r_x is irreducible for every two-signed point x of A on u; if moreover every irreducible point of $\mathfrak{D}$ is rigid, then (A, φ_0, u) satisfies (Gc4).*

Proof. By Proposition 45.4, $\mathfrak{D}$ has a symplectic weighted model M, with integers r, r', m. Put $(A, \varphi_0) = (A_M, x_M)$ and $u = u_M$, and let $(a_g)_{g\in G_{\mathbb{Q}}}$ be elements as in Proposition 45.28 for M; so $a_g \in A_0$ and $\varphi_0(a_g) = 0$.

u is a system of equations. By (Wm2), $F_i \in R_{(0,-1)} = A_{-1}$, $E_i \in R_{(0,1)} = A_1$, $Z_i \in R_{(0,0)} = A_0$ and $\varphi_0(Z_i) = x_R(Z_i) = 0$; so u is a system of equations for (A, φ_0), with counts $\mathrm{ne}(-2), \dots, \mathrm{ne}(2)$ equal to $0, r+1, m, r', 0$ (by (Mc1), (A, φ_0) is a graded $\mathcal{O}$-algebra with a fixed point).

(Gs1). By (Mc1), (A, φ_0) is smooth with tangent dimensions td, $\mathrm{td}(j) = 0$ for $|j| > 2$ and $\mathrm{td}(-2), \dots, \mathrm{td}(2)$ equal to $0, r, m, r'+1, 1$. Hence

$$\mathrm{ne}(-1) = r+1 = \mathrm{td}(-1)+1, \quad \mathrm{ne}(-2) = 0 = \mathrm{td}(-2), \quad \mathrm{ne}(0) = m = \mathrm{td}(0),$$
$$\mathrm{ne}(1) = r' = \mathrm{td}(1) - 1, \quad \mathrm{ne}(2) = 0 = \mathrm{td}(2) - 1,$$

and by (Mc2) u_{-1}, u_{-2}, u_0 span rationally in degrees -1, -2, 0. This is (Gc1).

(Gs2) is (Mc3) of Proposition 45.28 for M.

(Gs3)–(Gs6). Let $\mathfrak{D}$ be finite in weight zero, and let $x \mapsto r_x$ be the map of Proposition 45.28. Then (Gs3) and (Gs4) are the two assertions of (Mc4), and (Gs5) and (Gs6) are the assertions of (Mc5). □

Definition 45.3. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and set $T \ni \ell$. Let $d_\ell, d_p\colon \mathbb{Z}^2 \to \mathbb{N}$ be: $d_\ell(w) = 2$ for $w \in \{(1,0), (-1,1), (0,1), (1,1), (0,0)\}$, $d_\ell(w) = 1$ for $w \in \{(-1,0), (1,-1), (0,-1), (-1,-1)\}$; $d_p(0,0) = 2$, $d_p(w) = 1$ for $w \in \mathcal{W}_4 \setminus \{(0,0)\}$; both 0 elsewhere.

Symplectic local bases. A **symplectic local base** of $\mathfrak{D}$ is a tuple $L = (\sigma_L, \mathrm{wt}_L, \mathfrak{a}_L, (\rho_v)_{v\in T})$ of a finite set σ_L, a map $\mathrm{wt}_L\colon \sigma_L \to \mathcal{W}_4$ and a homogeneous ideal $\mathfrak{a}_L$ of $\mathcal{O}[[X_s : s \in \sigma_L]]$ all of whose elements have constant term 0, with $B_L = \mathcal{O}[[X_s : s \in \sigma_L]]/\mathfrak{a}_L$, its parts $(B_L)_w$, projection π_L and origin x_L, and for each $v \in T$ a lift $\rho_v\colon D_v \to \mathrm{GL}_4(B_L)$ of $\bar{r}_0|_{D_v}$ satisfying the local condition at v, such that

(Bq1) for every $A \in \mathrm{CNL}_{\mathcal{O}}$ and every family $(\rho'_v)_{v\in T}$ of lifts of the $\bar r_0|_{D_v}$ to A satisfying the local conditions there is exactly one $\mathcal{O}$-algebra homomorphism $f\colon B_L \to A$ with $f\circ\rho_v = \rho'_v$ for all $v \in T$;

(Bq2) $\rho_v(g)_{ij} \in (B_L)_{\mathrm{wt}_4(i,j)}$ and $x_L(\rho_v(g)_{ij}) = r_0(g)_{ij}$ for all $v \in T$, $g \in D_v$ and i, j;

(Bq3) B_L is smooth at the origin with tangent dimensions $d_\ell + \#(T \setminus \{\ell\})\, d_p$.

Framed lifts. For a symplectic local base L, a **framed lift** over L is a tuple $(A, \iota, r, (\alpha_v)_{v\in T})$ of $A \in \mathrm{CNL}_{\mathcal{O}}$, an $\mathcal{O}$-algebra homomorphism $\iota\colon B_L \to A$, a lift r of $\bar r_0$ to A and matrices $\alpha_v \in \mathrm{M}_4(A)$ such that

(Fw1) $r(g)$ has similitude $\theta(g)$ for every $g \in G_{\mathbb{Q}}$, and r satisfies (Se2);

(Fw2) every α_v has similitude 1 and is congruent to 1 modulo $\mathfrak{m}_A$, and $\alpha_\ell = 1$;

(Fw3) $r(g)\,\alpha_v = \alpha_v\,\iota(\rho_v(g))$ for all $v \in T$ and $g \in D_v$ (ι applied entrywise).

Framed relative presentations. A **framed relative presentation** over L is a tuple $(U, \iota, r_U, (\alpha_v)_{v\in T}, \tau, \mathrm{wt}_\tau, (y_t)_{t\in\tau}, \kappa, (f_k)_{k\in\kappa}, \mathrm{wf})$ of a framed lift $(U, \iota, r_U, (\alpha_v))$ over L, finite sets τ, κ, maps $\mathrm{wt}_\tau\colon \tau \to \mathcal{W}_4$, $\mathrm{wf}\colon \kappa \to \mathbb{Z}^2$, elements $y_t \in U$ and power series f_k in $P_U = \mathcal{O}[[X_s : s \in \sigma_L \sqcup \tau]]$ (weights wt_L on σ_L, wt_τ on τ) such that

(Fv1) for every framed lift $(A, \iota', r', (\alpha'_v))$ over L there is exactly one $\mathcal{O}$-algebra homomorphism $y\colon U \to A$ with $y\circ\iota = \iota'$, $y\circ r_U = r'$ and $y(\alpha_v) = \alpha'_v$ for all v;

(Fv2) the continuous $\mathcal{O}$-algebra homomorphism $\Pi_U\colon P_U \to U$ with $\Pi_U(X_s) = \iota(\pi_L(X_s))$ ($s \in \sigma_L$) and $\Pi_U(X_t) = y_t$ ($t \in \tau$) is surjective, $f_k \in \mathcal{O}[[X]]_{\mathrm{wf}(k)}$ has constant term 0, $\ker\Pi_U = \mathfrak{a}_L P_U + (f_k)_{k\in\kappa}$, and for each $t \in \tau$ there are a, b with $\mathrm{wt}_\tau(t) = \mathrm{wt}_4(a, b)$ and either $y_t = r_U(g)_{ab} - r_0(g)_{ab}$ for some $g \in G_{\mathbb{Q}}$ or $y_t = (\alpha_v - 1)_{ab}$ for some $v \in T$;

(Fv3) writing $U_w = \Pi_U(\mathcal{O}[[X]]_w)$ and x_U for the homomorphism induced by the constant term: $r_U(g)_{ab} \in U_{\mathrm{wt}_4(a,b)}$, $(\alpha_v)_{ab} \in U_{\mathrm{wt}_4(a,b)}$, $x_U(r_U(g)_{ab}) = r_0(g)_{ab}$, $x_U(\alpha_v) = 1$ and $x_U\circ\iota = x_L$;

(Fv4) $\#\mathrm{wt}_\tau^{-1}(w) = 0$ for $w \notin \{(0,0), (0,1), (0,-1)\}$, and $\#\mathrm{wf}^{-1}(w) = \#\mathrm{wt}_\tau^{-1}(w) + c(w)$ for all w, where $c(0,0) = 2$, $c(0,\pm1) = 1$ and $c(w) = 0$ otherwise.

Proposition 45.4. *Every symplectic Eisenstein datum has a symplectic weighted model.*

Proof. Let $\mathfrak{D}$ be a symplectic Eisenstein datum. By Proposition 45.5, $\mathfrak{D}$ has a symplectic local base L. By Proposition 45.20, there is a framed relative presentation over L. By Proposition 45.23, applied to $\mathfrak{D}$, L and this presentation, $\mathfrak{D}$ has a symplectic weighted model. □

Proposition 45.5. *Every symplectic Eisenstein datum has a symplectic local base.*

Proof. Step 1: the local rings. For $v \in T$ the local condition at v is the vanishing of finitely many families of polynomial expressions in the entries of a lift (the entries of ${}^t\rho(g)J_4\rho(g) - \theta(g)J_4$; for $v = \ell$ the coefficients of the characteristic polynomial of $\rho(s_0)$ minus those of $\prod_j(X - \kappa_j(s_0))$ and the entries of $\Pi_j\rho(g)\Pi_i$ and $\Pi_i(\rho(s) - \kappa_i(s))\Pi_i$; for $v \neq \ell$ the entries of $\rho(g) - 1$, $g \in I_v$, $\chi(g) = 1$). So the quotient of Mazur's universal lifting ring of $\bar r_0|_{D_v}$ by the closed ideal they generate is a universal pair (R_v, ρ_v) for the lifts satisfying the local condition at v; let x_v classify $r_0|_{D_v}$, which satisfies it. For $t_1, t_2 \in A^\times$ congruent to 1 modulo $\mathfrak{m}_A$, conjugation by $\mathrm{T}_4(t_1, t_2)$ (a

similitude, congruent to 1) carries lifts satisfying the local condition at v to such lifts: it preserves similitudes, it fixes 1, and it conjugates $\rho(s_0)$, each Π_i and each identity of the ordinary condition.

Step 2: the coproduct, (Bq1). Let $B = \widehat{\bigotimes}_{v\in T} R_v$ and regard each ρ_v as a lift to B. For $A \in \mathrm{CNL}_{\mathcal{O}}$ and lifts $(\rho'_v)_v$ satisfying the local conditions, the homomorphisms $R_v \to A$ classifying the ρ'_v induce exactly one $f\colon B \to A$ with $f \circ \rho_v = \rho'_v$ for all v. In particular two homomorphisms $B \to A$ agreeing on the entries of all ρ_v are equal, and $x_B = \bigotimes_v x_v\colon B \to \mathcal{O}$ classifies $(r_0|_{D_v})_v$.

Step 3: the weighted presentation, (Bq2). By Step 2, two morphisms $B \to A$ of $\mathrm{CNL}_{\mathcal{O}}$ that agree on the entries of all ρ_v are equal; so Lemma 45.15, item 1, applied to these entries with $c_e = r_0(g)_{ab}$ for $e = \rho_v(g)_{ab}$, shows that the classes of the elements $\rho_v(g)_{ab} - r_0(g)_{ab}$ ($v \in T$, $g \in D_v$; they lie in $\mathfrak{m}_B$ as r_0 is diagonal) span $\mathfrak{m}_B/(\mathfrak{m}_B^2 + \mathfrak{m}_{\mathcal{O}} B)$. Choose a finite set σ_L of triples $s = (v_s, g_s, (a_s, b_s))$ whose classes span, put $\mathrm{wt}_L(s) = \mathrm{wt}_4(a_s, b_s) \in \mathcal{W}_4$, and let $\pi\colon P = \mathcal{O}[[X_s : s \in \sigma_L]] \to B$, $X_s \mapsto \rho_{v_s}(g_s)_{a_s b_s} - r_0(g_s)_{a_s b_s}$; it is onto by Lemma 45.15, item 2. By Step 1 and (Bq1) for $A = B[[T_1, T_2]]$, there is a morphism $\rho_T\colon B \to B[[T_1, T_2]]$ of $\mathrm{CNL}_{\mathcal{O}}$ with $\rho_T \circ \rho_v = \mathrm{T}_4(1 + T_1, 1 + T_2)\, \rho_v\, \mathrm{T}_4(1 + T_1, 1 + T_2)^{-1}$ for all v, so that $\rho_v(g)_{ab}$ has torus weight $\mathrm{wt}_4(a, b)$ in the sense of Lemma 45.18 ($d = 2$), and so has $\pi(X_s)$, of weight $\mathrm{wt}_L(s)$ (on the diagonal the constant has weight 0). By Lemma 45.18, $\mathfrak{a}_L = \ker \pi$ is homogeneous and $\rho_v(g)_{ab} \in \pi(\mathcal{O}[[X_{\sigma_L}]]_{\mathrm{wt}_4(a,b)}) = (B_L)_{\mathrm{wt}_4(a,b)}$ with $B_L = P/\mathfrak{a}_L \cong B$. As $x_B \circ \pi$ is the constant term (both continuous, equal on the X_s), every element of $\mathfrak{a}_L$ has constant term 0, the origin x_L is x_B, and $x_L(\rho_v(g)_{ab}) = r_0(g)_{ab}$: (Bq2).

Step 4: (Bq3). Proposition 45.6 gives a chart of R_ℓ with (Yc1)–(Yc4) and counts d_ℓ, and Proposition 45.16 one of R_p with counts d_p for each $p \in T \setminus \{\ell\}$. By Proposition 45.17, applied to σ_L and π (onto, with homogeneous kernel and constant terms 0 by Step 3), B_L is smooth at the origin with tangent dimensions $d_\ell + \#(T \setminus \{\ell\})\, d_p$.

Hence $L = (\sigma_L, \mathrm{wt}_L, \mathfrak{a}_L, (\rho_v)_{v\in T})$ is a symplectic local base of $\mathfrak{D}$. □

Proposition 45.6. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, (R_ℓ, ρ_ℓ) universal for the lifts of $\bar{r}_0|_{D_\ell}$ satisfying the local condition at ℓ, and x_ℓ as in Proposition 45.7. There are a finite set τ_ℓ, a map $w\colon \tau_\ell \to \mathbb{Z}^2$ with $\#w^{-1}(v) = d_\ell(v)$ for every $v \in \mathbb{Z}^2$, and an $\mathcal{O}$-algebra homomorphism $\phi_\ell\colon R_\ell \to \mathcal{O}[\ell^{-1}][[Y_i : i \in \tau_\ell]]$, where Y_i has weight $w(i)$, such that, with $\mathfrak{m}_Y$ the maximal ideal of the target:*

(Yc1) *$\phi_\ell(\rho_\ell(g)_{ab})$ has weight $\mathrm{wt}_4(a, b)$ for all $g \in D_\ell$ and $1 \le a, b \le 4$;*

(Yc2) *the constant term of $\phi_\ell(f)$ is $x_\ell(f)$ for every $f \in R_\ell$;*

(Yc3) *for every $i \in \tau_\ell$ there is $f \in \ker x_\ell$ with $\phi_\ell(f) \equiv Y_i$ modulo $\mathfrak{m}_Y^2$;*

(Yc4) *for every $N \ge 1$ and $f \in R_\ell$ with $\phi_\ell(f) \in \mathfrak{m}_Y^N$ there is $c \in \mathcal{O} \setminus \{0\}$ with $cf \in (\ker x_\ell)^N$;*

(Yc5) *the localisation of R_ℓ at the prime ideal $\ker x_\ell$ is a regular local ring of dimension 14; in particular R_ℓ has exactly one minimal prime ideal contained in $\ker x_\ell$.*

Proof. Write $R = R_\ell$, $x = x_\ell$, $\mathfrak{q} = \ker x$, $E = \mathcal{O}[\ell^{-1}]$, $\Lambda = E[[Y_1, \dots, Y_{14}]]$, $L\colon \Lambda \to E^{14}$ for the vector of coefficients of $Y_1, \dots, Y_{14}$, and $x_{g,a,b} = \rho_\ell(g)_{ab} - r_0(g)_{ab}$.

Step 1: generators. For $u \in \mathcal{O}^\times$ and y in the maximal ideal of R, $y - u$ is a unit, so x is local and continuous. By universality, two $\mathcal{O}$-algebra homomorphisms from R to some $A \in \mathrm{CNL}_{\mathcal{O}}$ that agree on the entries of ρ_ℓ are equal. Since r_0 is diagonal with entries in $\mathcal{O}$ and ρ_ℓ lifts $\bar{r}_0|_{D_\ell}$, every $x_{g,a,b}$ lies in the maximal ideal; so Lemma 45.15, item 1, applied to the entries of ρ_ℓ with $c_e = r_0(g)_{ab}$ for $e = \rho_\ell(g)_{ab}$, shows that the classes of the $x_{g,a,b}$ span $\mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_{\mathcal{O}} R)$; choose finitely many triples $s = (g_s, a_s, b_s)$, $s \in \sigma$, whose classes span, and put $x_s = x_{g_s,a_s,b_s}$.

By Lemma 45.15, item 2, $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to R$, $X_s \mapsto x_s$, is onto; $x \circ \pi$ is the constant term (both continuous, equal on the X_s, as $x(x_s) = 0$). Hence $\mathfrak{q} = (x_s)_{s\in\sigma}$ and $R = \mathcal{O} + \mathfrak{q}$.

Step 2: the local ring at $\mathfrak{q}$. The ring $A = R_{\mathfrak{q}}$ is a Noetherian local E-algebra with residue field E; its cotangent space $T = \mathfrak{q}A/\mathfrak{q}^2A$ is spanned over E by the classes of the x_s (for $a \in \mathfrak{q}$ and $s' \notin \mathfrak{q}$, $a/s' \equiv x(s')^{-1}a$ modulo $\mathfrak{q}^2A$, and $x_s r \equiv x(r)x_s$ modulo $\mathfrak{q}^2$).

Step 3: $\dim_E T \le 14$. For an E-linear $\lambda\colon T \to E$ let $F_\lambda(a) = x(a) + \epsilon\lambda(a - x(a))$, an $\mathcal{O}$-algebra homomorphism $R \to E[\epsilon]$ with reduction x (as $ab - x(a)x(b) = (a - x(a))(b - x(b)) + x(a)(b - x(b)) + x(b)(a - x(a))$). It is continuous: it kills $\mathfrak{q}^2$, maps $\mathfrak{q}$ into ϵL_0 with $L_0 = \sum_s \mathcal{O}\lambda(x_s)$ bounded, and the N-th power of the maximal ideal $\mathfrak{m}_{\mathcal{O}}R+\mathfrak{q}$ into $\mathfrak{m}_{\mathcal{O}}^N+\epsilon\mathfrak{m}_{\mathcal{O}}^{N-1}L_0$; so $g \mapsto F_\lambda(\rho_\ell(g)_{ab})$ is continuous. By Proposition 45.7, the map y_λ with $F_\lambda(\rho_\ell(g)) = (1 + \epsilon y_\lambda(g))r_0(g)$ has a primitive in $\mathrm{M}_4(E) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$. Both $F_\lambda(\rho_\ell(g))$ and $r_0(g)$ have similitude $\theta(g)$, so ${}^t(1+\epsilon y_\lambda)J_4(1+\epsilon y_\lambda) = J_4$ and $y_\lambda(g) \in \mathfrak{sp}_4(E)$. The projection of $\mathrm{M}_4(E)$ to the entries of weight w is equivariant, since $r_0(g) = \mathrm{diag}(\kappa_i(g))$ acts on the entry (a, b) by the scalar $\kappa_a(g)\kappa_b(g)^{-1}$; and it preserves $\mathfrak{sp}_4(E)$, since $X \in \mathfrak{sp}_4(E)$ means that J_4X is symmetric, i.e. $X_{ab} = \pm X_{5-b,5-a}$ for all a, b, and $\mathrm{wt}_4(5 - b, 5 - a) = \mathrm{wt}_4(a, b)$ as $\lambda_{5-i} = 1 - \lambda_i$, $\mu_{5-i} = 1 - \mu_i$. So the weight-w part $y_{\lambda,w}$ of y_λ has the weight-w part of the primitive as a primitive, and $y_{\lambda,w} \in Z_w$. The linear map $\lambda \mapsto (y_{\lambda,w})_w \in \bigoplus_w Z_w$ is injective: if all $y_{\lambda,w}$ vanish, $y_\lambda = 0$, so $F_\lambda(x_s) = 0$, $\lambda(x_s) = 0$ for all s, and $\lambda = 0$ by Step 2. By Lemma 45.14, $\dim_E T \le \sum_w d_\ell(w) = 14$.

Step 4: the completion. By Proposition 45.9, $\dim A \ge 14 \ge \dim_E T$, so A is regular of dimension 14 and $\dim_E T = 14$; a regular local ring is a domain, so A has exactly one minimal prime, and the minimal primes of R contained in $\mathfrak{q}$ correspond to those of A: this is (Yc5). Choosing $y_1, \dots, y_{14} \in \mathfrak{q}A$ with classes a basis of T, Cohen's theorem gives $\widehat{A} \cong \Lambda$, $y_i \mapsto Y_i$, under which $\mathfrak{q}^N\widehat{A}$ corresponds to $\mathfrak{m}_Y^N$; let $\phi_0\colon R \to A \to \widehat{A} \cong \Lambda$. The constant term of $\phi_0(f)$ is the image of f in $A/\mathfrak{q}A = E$, i.e. $x(f)$. If $\phi_0(f) \in \mathfrak{m}_Y^N$, then $f \in \mathfrak{q}^N A$; with $A' = R[\ell^{-1}]$ and $\mathfrak{n} = \mathfrak{q}A'$, a maximal ideal with $A = A'_{\mathfrak{n}}$, the $\mathfrak{n}$-primary ideal $\mathfrak{n}^N$ satisfies $\mathfrak{n}^N A \cap A' = \mathfrak{n}^N$, so $\ell^k f \in \mathfrak{q}^N + \ker(R \to A')$ and $cf \in \mathfrak{q}^N$ for some $c = \ell^{k'}$. The map $L \circ \phi_0$ induces the isomorphism $T \cong \mathfrak{m}_Y/\mathfrak{m}_Y^2 \cong E^{14}$, so the vectors $L(\phi_0(x_s))$ span E^{14} (Step 2).

Step 5: torus endomorphisms. Let $t = 1 + \ell \in \mathcal{O}^\times$, so $t^k \ne 1$ for $k \ne 0$, and $h_1 = \mathrm{T}_4(t, 1)$, $h_2 = \mathrm{T}_4(1, t)$, congruent to 1 modulo $\mathfrak{m}_{\mathcal{O}}$ and of similitudes t, t. For $k = 1, 2$, $h_k\rho_\ell h_k^{-1}$ is a lift of $\bar{r}_0|_{D_\ell}$ satisfying the local condition at ℓ: conjugation by a similitude preserves the similitude of each $\rho_\ell(g)$, and it preserves the characteristic polynomial of $\rho_\ell(s_0)$ and conjugates each Π_i and each identity of the ordinary condition. By universality there is $\vartheta_k\colon R \to R$ with $\vartheta_k \circ \rho_\ell = h_k\rho_\ell h_k^{-1}$, i.e. $\vartheta_k(\rho_\ell(g)_{ab}) = t^{\mathrm{wt}_4(a,b)_k}\rho_\ell(g)_{ab}$, so $\vartheta_k(x_s) = t^{\mathrm{wt}(s)_k}x_s$ with $\mathrm{wt}(s) = \mathrm{wt}_4(a_s, b_s)$; and $x \circ \vartheta_k = x$, both classifying $h_k r_0 h_k^{-1} = r_0|_{D_\ell}$.

Step 6: coordinates among the entries. Choose $s_1, \dots, s_{14}$ with $L(\phi_0(x_{s_i}))$ a basis (Step 4), and put $z_i = x_{s_i}$, $w(i) = \mathrm{wt}(s_i)$, $\tau_\ell = \{1, \dots, 14\}$. The continuous E-algebra endomorphism α of Λ with $\alpha(Y_i) = \phi_0(z_i) \in \mathfrak{m}_Y$ has invertible linear part, hence is an automorphism preserving constant terms and each $\mathfrak{m}_Y^N$; put $\phi_\ell = \alpha^{-1} \circ \phi_0$. Then $\phi_\ell(z_i) = Y_i$, the constant term of $\phi_\ell(f)$ is $x(f)$ (Yc2), (Yc3) holds with $f = z_i$, and (Yc4) holds by Step 4.

Step 7: equivariance, (Yc1). Fix k and let ϱ_k be the continuous E-algebra automorphism of Λ with $\varrho_k(Y_i) = t^{w(i)_k}Y_i$. Then $\phi_\ell \circ \vartheta_k = \varrho_k \circ \phi_\ell$: $\psi_1 = \phi_\ell \circ \vartheta_k$ and $\psi_2 = \varrho_k \circ \phi_\ell$ have constant term x, so map $\mathfrak{q}^N$ into $\mathfrak{m}_Y^N$, and agree on the z_i. Given $a \in R$ and N, let p be the truncation of $\phi_\ell(a)$ in degrees $< N$, $d \in \mathcal{O} \setminus \{0\}$ with $dp \in \mathcal{O}[Y]$ and $b = (dp)(z_1, \dots, z_{14})$; then $\phi_\ell(da - b) \in \mathfrak{m}_Y^N$, so $c(da - b) \in \mathfrak{q}^N$ for some $c \ne 0$ (Yc4), $\psi_1(b) = \psi_2(b)$, and $cd(\psi_1(a) - \psi_2(a)) \in \mathfrak{m}_Y^N$ for all N; so $\psi_1(a) = \psi_2(a)$. If $\vartheta_k(a) = t^j a$, then $\varrho_k(\phi_\ell(a)) = t^j\phi_\ell(a)$, and since ϱ_k multiplies the coefficient of Y^n by $t^{\sum_i n_i w(i)_k}$, every monomial of $\phi_\ell(a)$ has k-th weight coordinate j. Applied to $a = \rho_\ell(g)_{ab}$ for $k = 1, 2$ (Step 5), this is (Yc1).

Step 8: the counts. For $i \in \tau_\ell$ let $F_i(f)$ be the constant term of $\phi_\ell(f)$ plus ϵ times its coefficient

of Y_i: an $\mathcal{O}$-algebra homomorphism $R \to E[\epsilon]$ with reduction x, killing $\mathfrak{q}^2$ and continuous as in Step 3. By Proposition 45.7 and as in Step 3, the map y_i with $F_i(\rho_\ell(g)) = (1+\epsilon y_i(g))r_0(g)$ is $\mathfrak{sp}_4(E)$-valued with a crystalline primitive; its entry (a,b) is the coefficient of Y_i in $\phi_\ell(\rho_\ell(g)_{ab})$ times $\kappa_b(g)^{-1}$, which vanishes unless $\mathrm{wt}_4(a,b) = w(i)$ by (Yc1). So $y_i \in Z_{w(i)}$. For fixed v the y_i with $w(i) = v$ are linearly independent: at $g = g_{s_k}$ the entry (a_{s_k}, b_{s_k}) of y_i is the coefficient of Y_i in Y_k (plus a constant), times a unit. Hence $\#w^{-1}(v) \le \dim Z_v = d_\ell(v)$ by Lemma 45.14; as $\sum_v \#w^{-1}(v) = 14 = \sum_v d_\ell(v)$, equality holds for every v. □

Proposition 45.7. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$, $E_\mathcal{O}[\epsilon] = E_\mathcal{O}[X]/(X^2)$, and $\mathrm{emb}_\ell\colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ an embedding inducing $\bar\ell$. Let $R_\ell \in \mathrm{CNL}_\mathcal{O}$ and ρ_ℓ a lift of $\bar r_0|_{D_\ell}$ to R_ℓ satisfying the local condition at ℓ which is universal: for every $A \in \mathrm{CNL}_\mathcal{O}$ and every lift ρ of $\bar r_0|_{D_\ell}$ to A satisfying the local condition at ℓ there is exactly one $\mathcal{O}$-algebra homomorphism $f\colon R_\ell \to A$ with $f\circ\rho_\ell = \rho$. Let $x_\ell\colon R_\ell \to \mathcal{O}$ be the homomorphism with $x_\ell \circ \rho_\ell = r_0|_{D_\ell}$. Let $f\colon R_\ell \to E_\mathcal{O}[\epsilon]$ be an $\mathcal{O}$-algebra homomorphism whose reduction modulo ϵ is x_ℓ and such that $g \mapsto f(\rho_\ell(g)_{ab})$ is continuous for all a,b, and define $y\colon D_\ell \to \mathrm{M}_4(E_\mathcal{O})$ by $f(\rho_\ell(g)) = (1+\epsilon\, y(g))\, r_0(g)$. Let D_ℓ act on $\mathrm{M}_4(E_\mathcal{O})$ by $g\cdot X = r_0(g) X r_0(g)^{-1}$, on B_cris through emb_ℓ and on $\mathrm{M}_4(E_\mathcal{O}) \otimes_{\mathbb{Q}_\ell} B_\mathrm{cris}$ diagonally. Then there is $Y \in \mathrm{M}_4(E_\mathcal{O}) \otimes_{\mathbb{Q}_\ell} B_\mathrm{cris}$ with $y(g)\otimes 1 = g\cdot Y - Y$ for all $g \in D_\ell$.*

Proof. Write $E = E_\mathcal{O}$, a finite extension of $\mathbb{Q}_\ell$, $B = E[\epsilon]$, $\rho(g) = f(\rho_\ell(g)) \in \mathrm{GL}_4(B)$ and $u_i = \kappa_i(s_0)$. Through emb_ℓ, $D_\ell = \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ with inertia I_ℓ. For a continuous character $\gamma\colon D_\ell \to E^\times$ let $E(\gamma)$ be the $\mathbb{Q}_\ell$-representation E with g acting by $\gamma(g)$; a continuous cocycle c of $E(\gamma)$ has a *crystalline primitive* if $c(g)\otimes 1 = \gamma(g)\, g(Y) - Y$ for some $Y \in E \otimes_{\mathbb{Q}_\ell} B_\mathrm{cris}$ and all g, i.e. its class lies in $H^1_f(D_\ell, E(\gamma))$.

Step 1: the characters. By Lemma 45.8, $u_1,\dots,u_4$ are pairwise distinct elements of $\mathcal{O}$. For $a<b$ put $\gamma_{ab} = \kappa_a\kappa_b^{-1}$.

Step 2: for $a<b$, every continuous cocycle of $E(\gamma_{ab})$ has a crystalline primitive, since $H^1(D_\ell, E(\gamma_{ab})) = H^1_f(D_\ell, E(\gamma_{ab}))$ by Lemma 45.8.

Step 3: unramified homomorphisms have crystalline primitives. Let $z\colon D_\ell \to E$ be a continuous homomorphism vanishing on I_ℓ. On $X = E \oplus \mathbb{Q}_\ell e$ let $g(x+te) = x + tz(g) + te$; this is a continuous representation on which I_ℓ acts trivially, hence crystalline. Invariants being left exact, $0 \to D_\mathrm{cris}(E) \to D_\mathrm{cris}(X) \to D_\mathrm{cris}(\mathbb{Q}_\ell e) = \mathbb{Q}_\ell(1\otimes e)$ is exact, and $\dim D_\mathrm{cris}(X) = \dim_{\mathbb{Q}_\ell} E + 1 = \dim D_\mathrm{cris}(E) + 1$; so there is an invariant element $1\otimes e - Y$ with $Y \in B_\mathrm{cris}\otimes E$, and invariance says $z(g)\otimes 1 = g(Y) - Y$.

Step 4: a triangular basis. The identities of the ordinary condition and of the characteristic polynomial are polynomial identities with coefficients in $\mathcal{O}$ in the entries of ρ_ℓ, so they hold for ρ. By Cayley–Hamilton, $S = \rho(s_0)$ satisfies $\prod_i (S - u_i) = 0$. The differences $u_i - u_j$ $(i \ne j)$ are non-zero elements of E, hence units of B; put $c_i = \prod_{j\ne i}(u_i - u_j)$ and $\varepsilon_i = c_i^{-1}\Pi_i$. The Lagrange identity $\sum_i \prod_{j\ne i}(X-u_j)/(u_i-u_j) = 1$ in $E[X]$ gives $\sum_i \varepsilon_i = 1$; for $i \ne j$, $\varepsilon_i\varepsilon_j$ is a multiple of $\prod_k (S-u_k) = 0$; so the ε_i are orthogonal idempotents with sum 1. Modulo ϵ, $S \equiv r_0(s_0) = \mathrm{diag}(u_1,\dots,u_4)$, so $\varepsilon_i \equiv E_{ii}$ (E_{ij} the matrix units) and $f_i = \varepsilon_i e_i \equiv e_i$. Hence $h = (f_1\, f_2\, f_3\, f_4) = 1 + \epsilon H$ with $H \in \mathrm{M}_4(E)$ is invertible, and $\varepsilon_i f_j = \delta_{ij} f_j$, so $\varepsilon_i v$ is the f_i-component of v in the basis (f_j). The ordinary condition gives $\varepsilon_j \rho(g) \varepsilon_i = 0$ for $i<j$ and $g \in D_\ell$, and $\varepsilon_i(\rho(s) - \kappa_i(s))\varepsilon_i = 0$ for $s \in I_\ell$. Therefore $\mathcal{T}(g) = h^{-1}\rho(g)h$ is upper triangular for every $g \in D_\ell$ (the f_j-component of $\rho(g)f_i$ is $\varepsilon_j\rho(g)\varepsilon_i f_i = 0$ for $j>i$), and $\mathcal{T}(s)_{ii} = \kappa_i(s)$ for $s \in I_\ell$.

Step 5: change of cocycle. As $h \equiv 1$ and $\rho \equiv r_0$ modulo ϵ, $\mathcal{T}(g) = (1+\epsilon y_\mathcal{T}(g))r_0(g)$ with

$$y_\mathcal{T}(g) = y(g) - H + g\cdot H,$$

because $(1-\epsilon H)(1+\epsilon y(g))r_0(g)(1+\epsilon H) = \big(1+\epsilon(y(g)-H+r_0(g)Hr_0(g)^{-1})\big)r_0(g)$. So $y_{\mathcal{T}}$ is continuous, upper triangular, and a cocycle ($\mathcal{T}$ is a homomorphism). Since $r_0(g) = \operatorname{diag}(\kappa_i(g))$, $(g\cdot X)_{ab} = \gamma_{ab}(g)X_{ab}$ with $\gamma_{ab} = \kappa_a\kappa_b^{-1}$, so each entry $y_{\mathcal{T},ab}$ is a continuous cocycle of $E(\gamma_{ab})$. For $a = b$ the action is trivial, $y_{\mathcal{T},aa}$ is a homomorphism, and it vanishes on I_ℓ, because $\mathcal{T}(s)_{aa} = (1+\epsilon y_{\mathcal{T}}(s)_{aa})\kappa_a(s)$ equals $\kappa_a(s)$ there. For $a > b$, $y_{\mathcal{T},ab} = 0$.

Step 6: conclusion. By Step 3 for $a = b$ and Step 2 for $a < b$, there are $Y_{ab} \in E \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y_{\mathcal{T},ab}(g)\otimes 1 = \gamma_{ab}(g)g(Y_{ab}) - Y_{ab}$ (and $Y_{ab} = 0$ for $a > b$). As D_ℓ acts on $\mathrm{M}_4(E)\otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ entrywise through γ_{ab}, $Y_{\mathcal{T}} = \sum_{a,b} E_{ab}\otimes Y_{ab}$ satisfies $y_{\mathcal{T}}(g)\otimes 1 = g\cdot Y_{\mathcal{T}} - Y_{\mathcal{T}}$, and $Y = Y_{\mathcal{T}} + H\otimes 1$ satisfies $y(g)\otimes 1 = g\cdot Y - Y$ by Step 5. □

Lemma 45.8. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and integer e, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, and identify D_ℓ with $\mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ through an embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ inducing $\bar\ell$. Put $(n_1,n_2,n_3,n_4) = (e+1, e, 1, 0)$. Then $\kappa_a(s_0) = \chi_{\mathrm{cyc}}(s_0)^{n_a}$ for $a = 1,\dots,4$, and these four elements of $\mathcal{O}$ are pairwise distinct. For $1 \le a < b \le 4$ let $\gamma_{ab} = \kappa_a\kappa_b^{-1}$ and V_{ab} the $\mathbb{Q}_\ell$-representation of D_ℓ on $E_{\mathcal{O}}$ in which g acts by multiplication by $\gamma_{ab}(g)$. Then*

$$H^0(D_\ell, V_{ab}) = 0, \qquad H^2(D_\ell, V_{ab}) = 0,$$
$$H^1(D_\ell, V_{ab}) = H^1_f(D_\ell, V_{ab}), \qquad \dim_{\mathbb{Q}_\ell} H^1(D_\ell, V_{ab}) = [E_{\mathcal{O}} : \mathbb{Q}_\ell].$$

Proof. Write $E = E_{\mathcal{O}}$, $V = V_{ab}$ and $n = n_a - n_b \ge 1$.

The values at s_0 and σ_ℓ. $\ell \in T$, so ξ is unramified at ℓ (Sg1) and $\xi(s_0) = 1$ ($s_0 \in I_\ell$); $\chi(s_0) = \omega_\ell(s_0) = 1$ (Sg5). From $\alpha = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\xi$, $\Psi = \chi\chi_{\mathrm{cyc}}^e$, $\theta = \alpha\Psi$ we get $\kappa_a(s_0) = \chi_{\mathrm{cyc}}(s_0)^{n_a}$; these are pairwise distinct as $\chi_{\mathrm{cyc}}(s_0)$ has infinite order (Sg5), and $\gamma_{ab}(s_0) = \chi_{\mathrm{cyc}}(s_0)^n$. Each of χ, ξ, ω_ℓ has finite order, so $\gamma_{ab} = \chi_{\mathrm{cyc}}^n\nu$ with ν of finite order. Explicitly $\gamma_{12} = \gamma_{34} = \alpha$ ($n = 1$), $\gamma_{23} = \beta = \Psi\alpha^{-1}$ ($n = e-1$), $\gamma_{13} = \gamma_{24} = \Psi$ ($n = e$) and $\gamma_{14} = \theta$ ($n = e+1$). By (Sg2), $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$; $\omega_\ell(\sigma_\ell)$ is a root of unity of order dividing $\ell - 1$ with reduction $\bar\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$, and reduction modulo $\mathfrak{m}_{\mathcal{O}}$ is injective on such roots of unity, so $\omega_\ell(\sigma_\ell) = 1$. Hence $\alpha(\sigma_\ell) = \xi(\sigma_\ell)$ and $\beta(\sigma_\ell) = (\xi\Psi^{-1})(\sigma_\ell)^{-1}$, and by (Sg2) for $v = \ell$ and $i = 0$, $i = -1$, neither is congruent to 1 modulo $\mathfrak{m}_{\mathcal{O}}$; so $\alpha(\sigma_\ell) \ne 1$ and $\beta(\sigma_\ell) \ne 1$.

An element where γ_{ab} and χ_{cyc} differ. If $n \ge 2$, $\gamma_{ab}(s_0) = \chi_{\mathrm{cyc}}(s_0)^n \ne \chi_{\mathrm{cyc}}(s_0)$. If $n = 1$, then $\gamma_{ab} = \alpha$, or $\gamma_{ab} = \beta$ and $e = 2$; in both cases $\gamma_{ab}(\sigma_\ell) \ne 1 = \chi_{\mathrm{cyc}}(\sigma_\ell)$.

H^0 and H^2. $s_0 - 1$ acts on V as multiplication by $\chi_{\mathrm{cyc}}(s_0)^n - 1$, a non-zero element of the field E, hence injectively; so $H^0(D_\ell, V) = 0$. The dual $V^*(1)$ is $\mathrm{Hom}_{\mathbb{Q}_\ell}(E, \mathbb{Q}_\ell)$ with $(g\varphi)(x) = \chi_{\mathrm{cyc}}(g)\varphi(\gamma_{ab}(g)^{-1}x)$; an invariant φ satisfies $\varphi((\gamma_{ab}(g) - \chi_{\mathrm{cyc}}(g))x) = 0$ for all g and x (replace x by $\gamma_{ab}(g)x$), so $\varphi = 0$ by the previous step. By Theorem B.36 ($M = \mathbb{Q}_\ell$), $\dim H^2(D_\ell, V) = \dim H^0(D_\ell, V^*(1)) = 0$, and $\dim_{\mathbb{Q}_\ell} H^1(D_\ell, V) = \dim_{\mathbb{Q}_\ell} V = [E : \mathbb{Q}_\ell]$.

H^1_f. V is de Rham with all Hodge–Tate weights $n \ge 1$, so $\dim_{\mathbb{Q}_\ell}(D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 D_{\mathrm{dR}}(V)) = \dim_{\mathbb{Q}_\ell} V$, and Theorem B.43 ($K = \mathbb{Q}_\ell$) gives $\dim H^1_f(D_\ell, V) = 0 + \dim_{\mathbb{Q}_\ell} V = \dim H^1(D_\ell, V)$. As $H^1_f \subseteq H^1$, they are equal. □

Proposition 45.9. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, and let (R_ℓ, ρ_ℓ) be universal for the lifts of $\bar r_0|_{D_\ell}$ satisfying the local condition at ℓ, with $x_\ell\colon R_\ell \to \mathcal{O}$ the homomorphism with $x_\ell \circ \rho_\ell = r_0|_{D_\ell}$, as in Proposition 45.7. Then the localisation of R_ℓ at the prime ideal $\ker x_\ell$ has Krull dimension at least 14.*

Proof. By Lemma 45.10 there is a homomorphism $r_T\colon D_\ell \to \mathrm{GL}_4(E_{\mathcal{O}}[[T_1,\dots,T_{14}]])$ satisfying (Fm1)–(Fm3) for $v = \ell$ and $n = 14$: its coefficients are continuous, $r_T \equiv r_0$ modulo the maximal

ideal, $r_T(g)$ has similitude $\theta(g)$, r_T is ordinary, and the fourteen maps y_i are linearly independent. Since (R_ℓ, ρ_ℓ) is universal for the lifts of $\bar{r}_0|_{D_\ell}$ satisfying the local condition at ℓ, Lemma 45.11 gives an $\mathcal{O}$-algebra homomorphism $F\colon R_\ell \to E_\mathcal{O}[[T_1, \dots, T_{14}]]$ with $F(f) - x_\ell(f)$ in the maximal ideal for every f, and such that the vectors of linear coefficients of the $F(f)$, $f \in \ker x_\ell$, span $E_\mathcal{O}^{14}$. By Lemma 45.13 (1) with $R = R_\ell$, $x = x_\ell$ and $n = 14$, the localisation of R_ℓ at $\ker x_\ell$ has Krull dimension at least 14. □

Lemma 45.10. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$, and $\mathfrak{m}_T$ the maximal ideal of $E_\mathcal{O}[[T]] = E_\mathcal{O}[[T_1, \dots, T_{14}]]$. There is a homomorphism $r_T\colon D_\ell \to \mathrm{GL}_4(E_\mathcal{O}[[T]])$ such that every coefficient of every entry of $r_T(g)$ is a continuous function of $g \in D_\ell$; $r_T(g) - r_0(g)$ has its entries in $\mathfrak{m}_T$ and $r_T(g)$ has similitude $\theta(g)$ for every $g \in D_\ell$; r_T is ordinary; and the maps $y_1, \dots, y_{14}\colon D_\ell \to \mathrm{M}_4(E_\mathcal{O})$, $y_i(g)$ the coefficient of T_i in $r_T(g)\, r_0(g)^{-1}$, are linearly independent over $E_\mathcal{O}$.*

Proof. Write $E = E_\mathcal{O}$, $E_k = E[[T]]/\mathfrak{m}_T^k$, E_{ab} for the matrix units and $g \cdot X = r_0(g) X r_0(g)^{-1}$ for $X \in \mathrm{M}_4(E)$. A map from D_ℓ to $E[[T]]$, to E_k or to matrices over them is called continuous if all its coefficients are; sums and products of continuous maps are continuous, and so are inverses of matrices with unit determinant (adjugate over determinant; the inverse of a unit power series has coefficients polynomial in its coefficients and the inverse of its constant term). Let $\Phi^+ = \{(1,0), (-1,1), (0,1), (1,1)\}$ and

$$X_{(1,0)} = E_{12} - E_{34}, \quad X_{(-1,1)} = E_{23}, \quad X_{(0,1)} = E_{13} + E_{24}, \quad X_{(1,1)} = E_{14}, \qquad X_{-w} = {}^t X_w,$$

with characters $\gamma_{(1,0)} = \gamma_{12} = \gamma_{34}$, $\gamma_{(-1,1)} = \gamma_{23}$, $\gamma_{(0,1)} = \gamma_{13} = \gamma_{24}$, $\gamma_{(1,1)} = \gamma_{14}$, so that $g \cdot X_{\pm w} = \gamma_w(g)^{\pm 1} X_{\pm w}$; the entries of $X_{\pm w}$ have weight $\pm w$, and the eight matrices $X_{\pm w}$ are supported on pairwise disjoint sets of off-diagonal positions.

Step 1: unramified twists. Let $\mathrm{fr}\colon D_\ell \to \widehat{\mathbb{Z}} \to \mathbb{Z}_\ell$ be the continuous homomorphism, trivial on I_ℓ, with $\mathrm{fr}(\sigma_\ell) = 1$. For $x \in \mathbb{Z}_\ell$ put $(1+T_i)^x = \sum_{j \geq 0} \binom{x}{j} T_i^j$; the binomial coefficients are polynomials in x with values in $\mathbb{Z}_\ell$ on $\mathbb{Z}_\ell$ (by continuity, from $\mathbb{N}$), and $(1+T_i)^{x+x'} = (1+T_i)^x (1+T_i)^{x'}$ (Vandermonde's identity, a polynomial identity true on $\mathbb{N}^2$). So $\lambda_i(g) = (1+T_i)^{\mathrm{fr}(g)}$ $(i = 1, 2)$ is a continuous character $D_\ell \to E[[T]]^\times$, trivial on I_ℓ, with $\lambda_i(g) \equiv 1 + \mathrm{fr}(g) T_i$ modulo $\mathfrak{m}_T^2$. Put

$$d(g) = \mathrm{diag}(\kappa_1\lambda_1,\ \kappa_2\lambda_2,\ \kappa_3\lambda_2^{-1},\ \kappa_4\lambda_1^{-1})(g),$$

a continuous homomorphism with $d(g) \equiv r_0(g)$ modulo $\mathfrak{m}_T$, $d(s) = r_0(s)$ for $s \in I_\ell$, and similitude $\theta(g)$ (a diagonal matrix has similitude ν if and only if $d_{11}d_{44} = d_{22}d_{33} = \nu$, and $\kappa_1\kappa_4 = \kappa_2\kappa_3 = \theta$); modulo $\mathfrak{m}_T^2$, $d(g) r_0(g)^{-1} \equiv 1 + \Delta(g)$ with $\Delta(g) = \mathrm{fr}(g)(T_1(E_{11} - E_{44}) + T_2(E_{22} - E_{33}))$.

Step 2: the unipotent radical. For a commutative ring A let $U(A)$ be the group of upper unitriangular $u \in \mathrm{GL}_4(A)$ with similitude 1.

So $u \mapsto (u_{12}, u_{23}, u_{24}, u_{14})$ is a bijection $U(A) \to A^4$ whose inverse is given by polynomials, and the strictly upper triangular elements of $\mathfrak{sp}_4(E)$ form $\mathfrak{n} = \bigoplus_{w \in \Phi^+} E X_w$. For $A = E[[T]]$ or E_k let $U^1(A) = \{u \in U(A) : u \equiv 1 \bmod \mathfrak{m}_T\}$, a subgroup. Conjugation by a diagonal matrix with a similitude preserves upper unitriangularity and similitude 1, so $\alpha_g(u) = d(g) u d(g)^{-1}$ is an action of D_ℓ on $U^1(A)$ by group automorphisms (d is a homomorphism).

Step 3: the kernels. Let $k \geq 2$ and K_k the kernel of the reduction $U^1(E_{k+1}) \to U^1(E_k)$. By the coordinates, $u \in K_k$ if and only if $u = 1 + A$ with $A_{12}, A_{23}, A_{24}, A_{14} \in \mathfrak{m}_T^k E_{k+1}$, $A_{34} = -A_{12}$, $A_{13} = A_{24} + A_{12}A_{23} = A_{24}$ (as $\mathfrak{m}_T^{2k} E_{k+1} = 0$); that is, $K_k = \{1 + A : A \in \mathfrak{n} \otimes_E \mathfrak{m}_T^k E_{k+1}\}$. For such A, A' and $v = 1 + B \in U^1(E_{k+1})$, $AA' = AB = BA = 0$, so $(1+A)(1+A') = 1 + A + A'$ and K_k is central in $U^1(E_{k+1})$; and $\alpha_g(1+A) = 1 + r_0(g) A r_0(g)^{-1}$ since $d(g) \equiv r_0(g)$ modulo

$\mathfrak{m}_T$. Hence K_k, written additively, is the continuous representation $\mathfrak{n} \otimes_E (\mathfrak{m}_T^k/\mathfrak{m}_T^{k+1})$, a finite direct sum of copies of the $E(\gamma_w)$, $w \in \Phi^+$, and $H^2(D_\ell, K_k) = 0$ by Lemma 45.8.

Step 4: a crossed homomorphism. By Lemma 45.8, $H^1(D_\ell, E(\gamma_w)) \neq 0$; choose continuous cocycles $c_w \colon D_\ell \to E$ of $E(\gamma_w)$ that are not coboundaries, and number the variables T_3, T_4, T_5, T_6 as T_w for $w = (1,0), (-1,1), (0,1), (1,1)$. We construct continuous $u_k \colon D_\ell \to U^1(E_k)$, $k \geq 2$, with

$$u_k(gh) = u_k(g)\,\alpha_g(u_k(h)) \qquad (g, h \in D_\ell)$$

and $u_{k+1} \equiv u_k$ modulo $\mathfrak{m}_T^k$. For $k = 2$ let $u_2(g) = 1 + \sum_w T_w c_w(g) X_w$: it lies in $U^1(E_2)$ (the coordinate conditions hold as products of two elements of $\mathfrak{m}_T$ vanish in E_2), and $u_2(g)\alpha_g(u_2(h)) = 1 + \sum_w T_w(c_w(g) + \gamma_w(g)c_w(h))X_w = u_2(gh)$. Given u_k, let $\tilde{u}(g) \in U^1(E_{k+1})$ be the element whose four coordinates are those of $u_k(g)$ with their coefficients of degree $< k$ and zero coefficients of degree k; $\tilde{u}$ is continuous and reduces to u_k. Then $o(g,h) = \tilde{u}(g)\alpha_g(\tilde{u}(h))\tilde{u}(gh)^{-1}$ reduces to 1, so $o(g,h) = 1 + \omega(g,h)$ with ω continuous with values in K_k. Using that K_k is central and the α_g are automorphisms with $\alpha_g\alpha_h = \alpha_{gh}$,

$$\tilde{u}(g)\alpha_g(\tilde{u}(h))\alpha_{gh}(\tilde{u}(k')) = o(g,h)\,o(gh,k')\,\tilde{u}(ghk'),$$
$$\tilde{u}(g)\alpha_g(\tilde{u}(h)\alpha_h(\tilde{u}(k'))) = \alpha_g(o(h,k'))\,o(g,hk')\,\tilde{u}(ghk'),$$

so $g \cdot \omega(h,k') - \omega(gh,k') + \omega(g,hk') - \omega(g,h) = 0$: ω is a continuous 2-cocycle of K_k. As $H^2(D_\ell, K_k) = 0$ there is a continuous $b \colon D_\ell \to K_k$ with $\omega(g,h) = g \cdot b(h) - b(gh) + b(g)$. Put $u_{k+1}(g) = (1 - b(g))\tilde{u}(g)$. Then

$$u_{k+1}(g)\alpha_g(u_{k+1}(h)) = \big(1 - b(g) - g \cdot b(h) + \omega(g,h)\big)\tilde{u}(gh) = (1 - b(gh))\tilde{u}(gh) = u_{k+1}(gh),$$

and $u_{k+1} \equiv u_k$ modulo $\mathfrak{m}_T^k$. The u_k define a continuous $u \colon D_\ell \to \mathrm{GL}_4(E[[T]])$, upper unitriangular, of similitude 1 and congruent to 1 modulo $\mathfrak{m}_T$ (these identities hold modulo every $\mathfrak{m}_T^k$), with $u(gh) = u(g)d(g)u(h)d(g)^{-1}$ and $u(g) \equiv 1 + \sum_w T_w c_w(g) X_w$ modulo $\mathfrak{m}_T^2$.

Step 5: the triangular homomorphism. $t(g) = u(g)d(g)$ is a homomorphism: $t(g)t(h) = u(g)(d(g)u(h)d(g)^{-1})d(g)d(h) = u(gh)d(gh)$. It is continuous, upper triangular with diagonal $d(g)$, of similitude $\theta(g)$, and $t(g) \equiv r_0(g)$ modulo $\mathfrak{m}_T$.

Step 6: conjugation, and the conditions other than independence. Number $T_7, \ldots, T_{10}$ as T'_w and $T_{11}, \ldots, T_{14}$ as T''_w ($w \in \Phi^+$ in the order above), and let

$$h = \prod_{w \in \Phi^+} (1 + T'_w X_{-w}) \prod_{w \in \Phi^+} (1 + T''_w X_w), \qquad r_T(g) = h\,t(g)\,h^{-1}.$$

By the first side calculation h has similitude 1, and $h \equiv 1$ modulo $\mathfrak{m}_T$. So r_T is a continuous homomorphism, $r_T(g)$ has similitude $\theta(g)$, and $r_T(g) \equiv r_0(g)$ modulo $\mathfrak{m}_T$. Ordinarity: let $u_i = \kappa_i(s_0)$, pairwise distinct with differences units of $E[[T]]$ (Lemma 45.8), $S = t(s_0)$, upper triangular with diagonal (u_i) ($\lambda_i(s_0) = 1$), and $F_i = \bigoplus_{j \leq i} E[[T]]e_j$, preserved by every upper triangular matrix. $S - u_m$ maps F_m into F_{m-1}. Hence $\Pi'_i = \prod_{j \neq i}(S - u_j)$ maps $E[[T]]^4$ into F_i (through the factors $j > i$) and kills F_{i-1} (through the factors $j < i$); the characteristic polynomial of S is $\prod_j (X - u_j)$. For $i < j$ and $g \in D_\ell$, $\Pi'_j t(g) \Pi'_i = 0$, since $t(g)F_i \subseteq F_i \subseteq F_{j-1}$. For $s \in I_\ell$, $t(s)$ has diagonal $(\kappa_i(s))$, so $t(s) - \kappa_i(s)$ maps F_i into F_{i-1} and $\Pi'_i(t(s) - \kappa_i(s))\Pi'_i = 0$. Conjugating by h: $r_T(s_0) = hSh^{-1}$ has characteristic polynomial $\prod_j (X - \kappa_j(s_0))$, the matrices Π_i formed from r_T are $h\Pi'_i h^{-1}$, and the identities transfer. So r_T is ordinary.

Step 7: independence. Write $H_1 = \sum_w (T'_w X_{-w} + T''_w X_w)$, so that, modulo $\mathfrak{m}_T^2$,

$$h \equiv 1 + H_1, \qquad h^{-1} \equiv 1 - H_1, \qquad r_0(g) h^{-1} r_0(g)^{-1} \equiv 1 - g \cdot H_1.$$

From $r_T(g)r_0(g)^{-1} = h\,u(g)\,(d(g)r_0(g)^{-1})(r_0(g)h^{-1}r_0(g)^{-1})$ and Steps 1 and 4,

$$r_T(g)r_0(g)^{-1} \equiv 1 + \Delta(g) + \sum_w T_w c_w(g) X_w + H_1 - g\cdot H_1 \pmod{\mathfrak{m}_T^2}.$$

So $y_1 = \mathrm{fr}\,(E_{11}-E_{44})$, $y_2 = \mathrm{fr}\,(E_{22}-E_{33})$, the y_i for T_w are $c_w X_w$, those for T'_w are $(1-\gamma_w^{-1})X_{-w}$, and those for T''_w are $(1-\gamma_w)X_w$. As the diagonal and the eight supports of the $X_{\pm w}$ are disjoint, a linear relation $\sum_i \mu_i y_i = 0$ splits into: $\mathrm{fr}(g)(\mu_1(E_{11}-E_{44}) + \mu_2(E_{22}-E_{33})) = 0$, which at $g = \sigma_\ell$ gives $\mu_1 = \mu_2 = 0$; for each w, $\mu'_w(1-\gamma_w(g)^{-1}) = 0$, which at $g = s_0$ gives $\mu'_w = 0$ as $\gamma_w(s_0) \neq 1$ (Lemma 45.8); and $\mu_w c_w(g) + \mu''_w(1-\gamma_w(g)) = 0$ for all g. In the last, $\mu_w \neq 0$ would make c_w the coboundary $g \mapsto \gamma_w(g)x - x$ with $x = \mu''_w/\mu_w$; so $\mu_w = 0$, and then $\mu''_w = 0$ at $g = s_0$. Hence $y_1, \dots, y_{14}$ are linearly independent. □

Lemma 45.11. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $E_\mathcal{O} = \mathcal{O}[\ell^{-1}]$ and $v \in T$. Let $R_v \in \mathrm{CNL}_\mathcal{O}$ and ρ_v a lift of $\bar{r}_0|_{D_v}$ to R_v satisfying the local condition at v such that for every $A \in \mathrm{CNL}_\mathcal{O}$ and every lift ρ of $\bar{r}_0|_{D_v}$ to A satisfying the local condition at v there is exactly one $\mathcal{O}$-algebra homomorphism $f\colon R_v \to A$ with $f\circ\rho_v = \rho$; let $x_v\colon R_v \to \mathcal{O}$ be the one with $x_v\circ\rho_v = r_0|_{D_v}$ and $\mathfrak{q}_v = \ker x_v$. Let $n \geq 0$, $\mathfrak{m}_T$ the maximal ideal of $E_\mathcal{O}[[T_1,\dots,T_n]]$, and $r_T\colon D_v \to \mathrm{GL}_4(E_\mathcal{O}[[T_1,\dots,T_n]])$ a homomorphism such that*

(Fm1) *every coefficient of every entry of $r_T(g)$ is a continuous function of $g \in D_v$, and $r_T(g) - r_0(g)$ has its entries in $\mathfrak{m}_T$ for every $g \in D_v$;*

(Fm2) *$r_T(g)$ has similitude $\theta(g)$ for every $g \in D_v$; if $v = \ell$, r_T is ordinary; if $v \neq \ell$, $r_T(g) = 1$ for every $g \in I_v$ with $\chi(g) = 1$;*

(Fm3) *the maps $y_1,\dots,y_n\colon D_v \to \mathrm{M}_4(E_\mathcal{O})$, $y_i(g)$ the coefficient of T_i in $r_T(g)\,r_0(g)^{-1}$, are linearly independent over $E_\mathcal{O}$.*

Then there is an $\mathcal{O}$-algebra homomorphism $F\colon R_v \to E_\mathcal{O}[[T_1,\dots,T_n]]$ with $F(\rho_v(g)_{ab}) = r_T(g)_{ab}$ for all $g \in D_v$ and $1 \leq a,b \leq 4$, such that $F(f) - x_v(f) \in \mathfrak{m}_T$ for every $f \in R_v$, and such that the vectors of coefficients of $T_1,\dots,T_n$ of the $F(f)$, where f runs over the elements $\rho_v(g)_{ab} - r_0(g)_{ab}$ of $\mathfrak{q}_v$ ($g \in D_v$, $1 \leq a,b \leq 4$), span $E_\mathcal{O}^n$.

Proof. Write $E = E_\mathcal{O}$, $E[[T]] = E[[T_1,\dots,T_n]]$, $E_k = E[[T]]/\mathfrak{m}_T^k$ ($k \geq 1$) and r_k for the reduction of r_T modulo $\mathfrak{m}_T^k$.

Step 1: lifts to finite $\mathcal{O}$-algebras. Fix k. Since $r_0(g) = \mathrm{diag}(\kappa_i(g))$ has entries in $\mathcal{O}$ and inverse with entries in $\mathcal{O}$, the entries of $r_k(g)r_0(g)^{-1} - 1$ are continuous functions of g with values in $\mathfrak{m}_T E_k$ (Fm1); let S_k be the set of all of them, a compact subset of $\mathfrak{m}_T E_k$ (D_v is compact). For $1 \leq j < k$ the set of products of j elements of S_k is compact, as the image of S_k^j under the continuous multiplication; so the union of these sets is compact and lies in $\varpi^{-N}\Lambda$ for an $\mathcal{O}$-lattice Λ of E_k and some N. Let A_k be the $\mathcal{O}$-span of 1 and these products. It is a submodule of the finitely generated $\mathcal{O}$-module $\mathcal{O} + \varpi^{-N}\Lambda$, hence finitely generated; it is closed under multiplication (products of k or more elements of $\mathfrak{m}_T E_k$ vanish), contains $\mathcal{O}$ and lies in $\mathcal{O}+\mathfrak{m}_T E_k$. By Lemma 45.12, $A_k \in \mathrm{CNL}_\mathcal{O}$, with maximal ideal $\mathfrak{m}_\mathcal{O} + A_k^+$ and the subspace topology. The entries of $r_k(g) = (r_k(g)r_0(g)^{-1})r_0(g)$ lie in A_k, and $\det r_k(g) \in \det r_0(g) + A_k^+ \subseteq \mathcal{O}^\times + A_k^+$ is a unit of A_k; so r_k is a continuous homomorphism $D_v \to \mathrm{GL}_4(A_k)$, and $r_k(g) - r_0(g)$ has entries in A_k^+, so $r_k \equiv \bar{r}_0$ modulo $\mathfrak{m}_{A_k}$. The identities of (Fm2) are identities between polynomial expressions with coefficients in $\mathcal{O}$ in the entries of r_T (for $v = \ell$, those of the ordinary condition, with the $\kappa_j(s_0)$, $\kappa_i(s)$ as coefficients); they hold in $E[[T]]$, hence in E_k and in its subring A_k. So r_k is a lift of $\bar{r}_0|_{D_v}$ to A_k satisfying the local condition at v; let $x_k\colon R_v \to A_k$ be the $\mathcal{O}$-algebra homomorphism with $x_k\circ\rho_v = r_k$.

Step 2: the limit. Let $\pi_k\colon E_{k+1} \to E_k$ be the projection. It maps S_{k+1} onto S_k, and products of k elements of $\mathfrak{m}_T E_k$ vanish, so $\pi_k(A_{k+1}) \subseteq A_k$; $\pi_k\colon A_{k+1} \to A_k$ is an $\mathcal{O}$-algebra homomorphism and $\pi_k \circ x_{k+1}$ classifies $\pi_k \circ r_{k+1} = r_k$, so $\pi_k \circ x_{k+1} = x_k$ by uniqueness. Hence $F(f) = (x_k(f))_k \in \varprojlim_k E_k = E[[T]]$ defines an $\mathcal{O}$-algebra homomorphism with $F(\rho_v(g)_{ab}) = r_T(g)_{ab}$. For $k = 1$, $E_1 = E$, $S_1 = \{0\}$, $A_1 = \mathcal{O}$ and $r_1 = r_0|_{D_v}$, so $x_1 = x_v$ by uniqueness: the constant term of $F(f)$ is $x_v(f)$.

Step 3: spanning. Let $\mathrm{L}\colon E[[T]] \to E^n$ give the coefficients of $T_1, \dots, T_n$. For $g \in D_v$ and $1 \le a, b \le 4$ the element $x_{g,a,b} = \rho_v(g)_{ab} - r_0(g)_{ab}$ lies in $\mathfrak{q}_v$, and $\mathrm{L}(F(x_{g,a,b}))$ is the vector of the (a,b) entries of $y_i(g) r_0(g)$, $i = 1, \dots, n$. If these vectors spanned a proper subspace of E^n, there would be $(\mu_i) \neq 0$ with $\sum_i \mu_i y_i(g) r_0(g) = 0$, hence $\sum_i \mu_i y_i(g) = 0$, for all g, against (Fm3). □

Lemma 45.12. *Let $\mathcal{O}$ be a coefficient ring, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, $n \ge 0$ and $k \ge 1$ integers, $\mathfrak{m}_T$ the maximal ideal of $E_{\mathcal{O}}[[T_1, \dots, T_n]]$, and $E_k = E_{\mathcal{O}}[[T_1, \dots, T_n]]/\mathfrak{m}_T^k$, a finite-dimensional $E_{\mathcal{O}}$-vector space with its natural topology. Let $A \subseteq E_k$ be a subring containing $\mathcal{O}$ which is a finitely generated $\mathcal{O}$-module and is contained in $\mathcal{O} + \mathfrak{m}_T E_k$. Then $A \in \mathrm{CNL}_{\mathcal{O}}$, its maximal ideal is $\mathfrak{m}_{\mathcal{O}} + A^+$ with $A^+ = A \cap \mathfrak{m}_T E_k$, and its topology as a complete local ring is the subspace topology from E_k. Moreover every $\mathcal{O}$-algebra homomorphism from a ring of $\mathrm{CNL}_{\mathcal{O}}$ to A is local.*

Proof. Decomposition. Elements of $\mathcal{O} + \mathfrak{m}_T E_k$ decompose uniquely as $c + a^+$ with $c \in \mathcal{O}$ and $a^+ \in \mathfrak{m}_T E_k$ (the constant term), and if $c + a^+ \in A$ then $a^+ \in A$ since $\mathcal{O} \subseteq A$. So $A = \mathcal{O} \oplus A^+$, A^+ is an ideal of A (as $\mathfrak{m}_T E_k$ is an ideal of E_k), and $(A^+)^k \subseteq \mathfrak{m}_T^k E_k = 0$.

Local ring. The map $A \to \mathbb{F}_{\mathcal{O}}$, $c + a^+ \mapsto c \bmod \mathfrak{m}_{\mathcal{O}}$, is a surjective ring homomorphism with kernel $\mathfrak{m}_A = \mathfrak{m}_{\mathcal{O}} + A^+$. An element $c + a^+$ with $c \in \mathcal{O}^\times$ is a unit of A: its inverse is $c^{-1} \sum_{j=0}^{k-1} (-c^{-1}a^+)^j \in A$. So A is local with maximal ideal $\mathfrak{m}_A$ and residue field $\mathbb{F}_{\mathcal{O}}$, and $\mathcal{O} \to A$ is local and induces an isomorphism of residue fields. A is a finitely generated module over the Noetherian ring $\mathcal{O}$, hence a Noetherian ring; it is torsion free (E_k is an $E_{\mathcal{O}}$-vector space), hence free of finite rank over the discrete valuation ring $\mathcal{O}$, and an $\mathcal{O}$-basis of A is linearly independent over $E_{\mathcal{O}}$ (clear denominators).

Topology and completeness. For $m \ge k$, $\mathfrak{m}_A^m = \sum_{j=0}^m \mathfrak{m}_{\mathcal{O}}^{m-j} (A^+)^j$, where only $j \le k-1$ contribute, so $\mathfrak{m}_A^m \subseteq \varpi^{m-k+1} A$; and $\varpi^m A \subseteq \mathfrak{m}_A^m$. Hence the $\mathfrak{m}_A$-adic topology is the ϖ-adic topology, for which the free module A of finite rank is complete; so $A \in \mathrm{CNL}_{\mathcal{O}}$. With an $\mathcal{O}$-basis $a_1, \dots, a_r$ of A, the sets $\varpi^m A = \sum_i \varpi^m \mathcal{O} a_i$ form a basis of neighbourhoods of 0 for the natural topology of the $E_{\mathcal{O}}$-space $\bigoplus_i E_{\mathcal{O}} a_i \subseteq E_k$, which is the subspace topology (a finite-dimensional $E_{\mathcal{O}}$-vector space carries a unique Hausdorff vector space topology).

Local homomorphisms. Let $R \in \mathrm{CNL}_{\mathcal{O}}$, $f\colon R \to A$ an $\mathcal{O}$-algebra homomorphism and $y \in \mathfrak{m}_R$. If $f(y) \notin \mathfrak{m}_A$, choose $u \in \mathcal{O}^\times$ with $f(y) \equiv u$ modulo $\mathfrak{m}_A$; then $y - u \notin \mathfrak{m}_R$ ($\mathcal{O} \to R$ is local), so $y - u$ is a unit and so is $f(y) - u \in \mathfrak{m}_A$, a contradiction. So $f(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$. □

Lemma 45.13. *Let $\mathcal{O}$ be a coefficient ring, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, $R \in \mathrm{CNL}_{\mathcal{O}}$, $x\colon R \to \mathcal{O}$ an $\mathcal{O}$-algebra homomorphism and $\mathfrak{q} = \ker x$. Let $n \ge 0$, $\mathfrak{m}_T$ the maximal ideal of $E_{\mathcal{O}}[[T_1, \dots, T_n]]$, and $F\colon R \to E_{\mathcal{O}}[[T_1, \dots, T_n]]$ an $\mathcal{O}$-algebra homomorphism such that $F(f) - x(f) \in \mathfrak{m}_T$ for every $f \in R$ and such that the vectors of coefficients of $T_1, \dots, T_n$ of the $F(f)$, $f \in \mathfrak{q}$, span $E_{\mathcal{O}}^n$. Then:*

1. *the localisation $R_{\mathfrak{q}}$ has Krull dimension at least n;*
2. *if moreover $\dim_{E_{\mathcal{O}}}(\mathfrak{q}R_{\mathfrak{q}}/\mathfrak{q}^2 R_{\mathfrak{q}}) \le n$, then $R_{\mathfrak{q}}$ is a regular local ring of dimension n, R has exactly one minimal prime ideal contained in $\mathfrak{q}$, and for every $N \ge 1$ and every $f \in R$ with $F(f) \in \mathfrak{m}_T^N$ there is $c \in \mathcal{O} \setminus \{0\}$ with $cf \in \mathfrak{q}^N$.*

Proof. Write $E = E_{\mathcal{O}}$, $E[[T]] = E[[T_1, \dots, T_n]]$ and $\mathrm{L}\colon E[[T]] \to E^n$ for the coefficients of $T_1, \dots, T_n$.

Step 1: the local ring. x is the identity on $\mathcal{O}$, so it is onto, $R/\mathfrak{q} \cong \mathcal{O}$ is a domain and $\mathfrak{q}$ is prime; non-zero elements of $\mathcal{O}$ lie outside $\mathfrak{q}$. So $A = R_{\mathfrak{q}}$ is a Noetherian local E-algebra with maximal ideal $\mathfrak{n} = \mathfrak{q}A$ and residue field E. For $s \notin \mathfrak{q}$, $F(s)$ has constant term $x(s) \neq 0$ and is a unit; so F extends to $\Phi\colon A \to E[[T]]$ with $\Phi(\mathfrak{n}^N) \subseteq \mathfrak{m}_T^N$. Let $\widehat{A}$ be the $\mathfrak{n}$-adic completion, with maximal ideal $\widehat{\mathfrak{n}}$; the maps $A/\mathfrak{n}^N \to E[[T]]/\mathfrak{m}_T^N$ induced by Φ define an E-algebra homomorphism $\widehat{\Phi}\colon \widehat{A} \to E[[T]]$ with $\widehat{\Phi}(\widehat{\mathfrak{n}}^N) \subseteq \mathfrak{m}_T^N$, extending Φ.

Step 2: $\widehat{\Phi}$ is onto; (1). Choose $z_1, \dots, z_n \in \mathfrak{q}$ with $\mathrm{L}(F(z_1)), \dots, \mathrm{L}(F(z_n))$ a basis of E^n. Let $\iota\colon E[[Y_1, \dots, Y_n]] \to \widehat{A}$ be the continuous E-algebra homomorphism with $\iota(Y_i) = z_i \in \widehat{\mathfrak{n}}$; as $\widehat{\mathfrak{n}}^N$ is closed, ι maps $(Y)^N$ into $\widehat{\mathfrak{n}}^N$. So $\psi = \widehat{\Phi} \circ \iota$ maps $(Y)^N$ into $\mathfrak{m}_T^N$ and agrees with the substitution $Y_i \mapsto F(z_i)$ on polynomials; every power series differs from a polynomial by an element of $(Y)^N$, for every N, so ψ is that substitution. Its matrix of linear parts has rows $\mathrm{L}(F(z_i))$ and is invertible, so ψ is an automorphism and $\widehat{\Phi}$ is onto. Hence $\dim A = \dim \widehat{A} \geq \dim E[[T]] = n$.

Step 3: (2). Now $\dim A \geq n \geq \dim_E \mathfrak{n}/\mathfrak{n}^2$, so A is regular of dimension n, and so is $\widehat{A}$, a domain. The kernel $\mathfrak{P}$ of $\widehat{\Phi}$ is prime and $\dim \widehat{A}/\mathfrak{P} = n = \dim \widehat{A}$; a non-zero prime of the n-dimensional local domain $\widehat{A}$ has height ≥ 1 and quotient of dimension $\leq n-1$, so $\mathfrak{P} = 0$ and $\widehat{\Phi}$ is an isomorphism of local rings, with $\widehat{\Phi}(\widehat{\mathfrak{n}}^N) = \mathfrak{m}_T^N$. The minimal primes of R contained in $\mathfrak{q}$ correspond to those of the domain A, so there is exactly one. Let $f \in R$ with $F(f) \in \mathfrak{m}_T^N$. Then $\widehat{\Phi}(f) \in \mathfrak{m}_T^N$, so $f \in \widehat{\mathfrak{n}}^N \cap A = \mathfrak{n}^N$ ($A/\mathfrak{n}^N \to \widehat{A}/\widehat{\mathfrak{n}}^N$ is an isomorphism). Let $A' = R[\ell^{-1}]$ and $\mathfrak{n}' = \mathfrak{q}A'$, a maximal ideal ($A'/\mathfrak{n}' \cong E$) with $A = A'_{\mathfrak{n}'}$. As $\mathfrak{n}'^N$ is $\mathfrak{n}'$-primary, $\mathfrak{n}'^N A \cap A' = \mathfrak{n}'^N$, so the image of f in A' is $h\ell^{-k}$ with $h \in \mathfrak{q}^N$; then $\ell^{k'}(\ell^k f - h) = 0$ in R for some k', and $c = \ell^{k+k'}$ satisfies $cf = \ell^{k'}h \in \mathfrak{q}^N$. □

Lemma 45.14. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, and fix an embedding $\mathrm{emb}_\ell\colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ inducing $\bar{\ell}$. Let D_ℓ act on $\mathrm{M}_4(E_{\mathcal{O}})$ by $g \cdot X = r_0(g) X r_0(g)^{-1}$, on B_{cris} through emb_ℓ, and on $\mathrm{M}_4(E_{\mathcal{O}}) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ diagonally. For $w \in \mathbb{Z}^2$ let $\mathfrak{sp}_{4,w}$ be the space of $X \in \mathfrak{sp}_4(E_{\mathcal{O}})$ with $X_{ij} = 0$ whenever $\mathrm{wt}_4(i,j) \neq w$, and Z_w the $E_{\mathcal{O}}$-space of continuous maps $y\colon D_\ell \to \mathfrak{sp}_{4,w}$ with $y(gh) = y(g) + g \cdot y(h)$ for which there is $Y \in \mathrm{M}_4(E_{\mathcal{O}}) \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g) \otimes 1 = g \cdot Y - Y$ for all $g \in D_\ell$. Then $\dim_{E_{\mathcal{O}}} Z_w = d_\ell(w)$ for every $w \in \mathbb{Z}^2$.*

Proof. Write $E = E_{\mathcal{O}}$, $i^* = 5 - i$, and $\iota(X) = -J_4^{-1}\,{}^t X J_4$, an involution of $\mathrm{M}_4(E)$ with fixed space $\mathfrak{sp}_4(E)$ (as ${}^t J_4 = -J_4$).

Step 1: equivariant projections. If u has similitude ν, then ${}^t u = \nu J_4 u^{-1} J_4^{-1}$, and a direct computation gives $\iota(uXu^{-1}) = u\,\iota(X)\,u^{-1}$; $r_0(g)$ has similitude $\theta(g)$, so ι commutes with the action. The entry (a,b) of $\iota(X)$ is $\pm X_{b^*a^*}$, and $\mathrm{wt}_4(b^*,a^*) = \mathrm{wt}_4(a,b)$ ($\lambda_{i^*} = 1-\lambda_i$, $\mu_{i^*} = 1-\mu_i$); the action multiplies the entry (a,b) by $\kappa_a\kappa_b^{-1}$, so it preserves weights. Hence p_w, the projection to the entries of weight w followed by $X \mapsto \frac{1}{2}(X + \iota(X))$, is an equivariant projection of $\mathrm{M}_4(E)$ onto $\mathfrak{sp}_{4,w}$ (ℓ is odd). For $y \in Z_w$ with primitive Y, $(p_w \otimes 1)(Y)$ is a primitive in $\mathfrak{sp}_{4,w} \otimes B_{\mathrm{cris}}$. So, with $V_w = \mathfrak{sp}_{4,w}$, Z_w is the space of continuous cocycles whose class lies in $H^1_f(D_\ell, V_w)$, and

$$\dim_E Z_w = \dim_E H^1_f(D_\ell, V_w) + \dim_E V_w - \dim_E V_w^{D_\ell}.$$

Step 2: the pieces V_w. $X \in \mathfrak{sp}_4$ if and only if $X = \iota(X)$, which relates X_{ab} to $X_{b^*a^*}$ and gives $X_{ii} = -X_{i^*i^*}$. So $V_{(0,0)} = \{\mathrm{diag}(x_1, x_2, -x_2, -x_1)\}$, of dimension 2 with trivial action; for each $w \in \mathcal{W}_4 \setminus \{(0,0)\}$ the entries of weight w form one pair $\{(a,b),(b^*,a^*)\}$ or one entry with $(a,b) = (b^*,a^*)$, so $\dim V_w = 1$, with D_ℓ acting by $\gamma_w = \kappa_a\kappa_b^{-1}$ (well defined, as $\kappa_i\kappa_{i^*} = \theta$); and $V_w = 0$ for $w \notin \mathcal{W}_4$. Explicitly $\gamma_w = \alpha, \Psi, \theta, \beta$ for $w = (1,0), (0,1), (1,1), (-1,1)$ (entries $(1,2)$, $(1,3)$, $(1,4)$, $(2,3)$), and $\gamma_{-w} = \gamma_w^{-1}$.

Step 3: Hodge–Tate weights. ξ is unramified at $\ell \in T$ (Sg1), and χ, ω_ℓ have finite order; so on I_ℓ, $\alpha = \chi_{\mathrm{cyc}}\eta_1$, $\Psi = \chi_{\mathrm{cyc}}^{e}\eta_2$, $\theta = \chi_{\mathrm{cyc}}^{e+1}\eta_3$, $\beta = \chi_{\mathrm{cyc}}^{e-1}\eta_4$ with η_k of finite order. Hence V_w is de Rham with all Hodge–Tate weights n_w, where $n_w = 1, e, e+1, e-1$ for the four weights of Step 2, $n_{-w} = -n_w$, and $n_{(0,0)} = 0$; as $e \geq 2$, $n_w \geq 1$ for the four positive roots and $n_w \leq -1$ for their negatives.

Step 4: the count. By Theorem B.43 with $K = \mathbb{Q}_\ell$ ($D_\ell \cong \mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ through emb_ℓ), dividing $\mathbb{Q}_\ell$-dimensions by $[E:\mathbb{Q}_\ell]$, $\dim_E H^1_f(D_\ell, V_w) = \dim_E V_w^{D_\ell} + \delta_w \dim_E V_w$ with $\delta_w = 1$ if $n_w \geq 1$ and 0 otherwise. With Step 1, $\dim_E Z_w = (1+\delta_w)\dim_E V_w$: this is 2 for $w = (0,0)$, 2 for the positive roots $(1,0), (0,1), (1,1), (-1,1)$, 1 for their negatives, and 0 for $w \notin \mathcal{W}_4$, i.e. $d_\ell(w)$. □

Lemma 45.15. *Let $\mathcal{O}$ be a coefficient ring, $S \in \mathrm{CNL}_\mathcal{O}$ with maximal ideal $\mathfrak{m}_S$, and $\mathcal{E} \subseteq S$ a subset such that any two morphisms $S \to A$ of $\mathrm{CNL}_\mathcal{O}$ that agree on $\mathcal{E}$ are equal. For each $e \in \mathcal{E}$ let $c_e \in \mathcal{O}$ with $e - c_e \in \mathfrak{m}_S$. Then:*

1. *the classes of the elements $e - c_e$ ($e \in \mathcal{E}$) span the $\mathbb{F}_\mathcal{O}$-vector space $\mathfrak{m}_S/(\mathfrak{m}_S^2 + \mathfrak{m}_\mathcal{O} S)$, which is finite-dimensional;*
2. *if $e_1, \dots, e_k \in \mathcal{E}$ are such that the classes of $e_i - c_{e_i}$ span this space, the continuous $\mathcal{O}$-algebra homomorphism $\mathcal{O}[[X_1, \dots, X_k]] \to S$, $X_i \mapsto e_i - c_{e_i}$, is surjective.*

Proof. Put $t^* = \mathfrak{m}_S/(\mathfrak{m}_S^2 + \mathfrak{m}_\mathcal{O} S)$. As S is Noetherian, $\mathfrak{m}_S$ is finitely generated, so t^* is a finite-dimensional vector space over $S/\mathfrak{m}_S = \mathbb{F}_\mathcal{O}$. For $y \in S$ choose $c \in \mathcal{O}$ with $y - c \in \mathfrak{m}_S$ (possible since $\mathcal{O} \to S/\mathfrak{m}_S$ is onto) and write $\langle y \rangle \in t^*$ for the class of $y - c$; another choice of c changes $y - c$ by an element of $\mathfrak{m}_\mathcal{O} \subseteq \mathfrak{m}_\mathcal{O} S$, so $\langle y \rangle$ is well defined. The map $y \mapsto \langle y \rangle$ is $\mathcal{O}$-linear, kills $\mathcal{O}$, and satisfies $\langle yz \rangle = \bar{y}\langle z \rangle + \bar{z}\langle y \rangle$, where $\bar{y}, \bar{z} \in \mathbb{F}_\mathcal{O}$ are the residues: with $c, d \in \mathcal{O}$ for y, z,

$$yz - cd = c(z-d) + d(y-c) + (y-c)(z-d),$$

the last term lies in $\mathfrak{m}_S^2$, and $c(z-d) \equiv \bar{y}(z-d)$ in t^* because $\mathfrak{m}_\mathcal{O}$ acts on t^* by zero.

Item 1. Suppose the classes $\langle e \rangle$ ($e \in \mathcal{E}$), which are the classes of the $e - c_e$, do not span t^*. Then there is a non-zero $\mathbb{F}_\mathcal{O}$-linear form λ on t^* vanishing on all of them. Consider the ring $\mathbb{F}_\mathcal{O}[\epsilon]$ with $\epsilon^2 = 0$, an object of $\mathrm{CNL}_\mathcal{O}$, and put $f_\lambda(y) = \bar{y} + \epsilon\lambda(\langle y \rangle)$. By the properties of $\langle \cdot \rangle$, f_λ is an $\mathcal{O}$-algebra homomorphism $S \to \mathbb{F}_\mathcal{O}[\epsilon]$: it is $\mathcal{O}$-linear, $f_\lambda(1) = 1$, and $f_\lambda(yz) = \bar{y}\bar{z} + \epsilon(\bar{y}\lambda\langle z \rangle + \bar{z}\lambda\langle y \rangle) = f_\lambda(y) f_\lambda(z)$. It maps $\mathfrak{m}_S$ into $\epsilon\mathbb{F}_\mathcal{O}$, so it is local, a morphism of $\mathrm{CNL}_\mathcal{O}$. The same holds for f_0 (reduction modulo $\mathfrak{m}_S$). For $e \in \mathcal{E}$, $f_\lambda(e) = \bar{e} = f_0(e)$ since $\lambda\langle e \rangle = 0$. By the hypothesis on $\mathcal{E}$, $f_\lambda = f_0$, so $\lambda(\langle y \rangle) = 0$ for all $y \in S$; as every element of t^* is $\langle y \rangle$ for some $y \in \mathfrak{m}_S$, $\lambda = 0$, a contradiction.

Item 2. Let $P = \mathcal{O}[[X_1, \dots, X_k]]$ and $\pi\colon P \to S$ the homomorphism of the statement; it exists and is continuous because $e_i - c_{e_i} \in \mathfrak{m}_S$ and S is complete, and it is local. Let $I = \sum_i (e_i - c_{e_i})S + \mathfrak{m}_\mathcal{O} S$. By assumption $\mathfrak{m}_S = I + \mathfrak{m}_S^2$, so $\mathfrak{m}_S = I$ by Nakayama's lemma applied to the finitely generated S-module $\mathfrak{m}_S/I$. Hence $\mathfrak{m}_P S = I = \mathfrak{m}_S$, and $S/\mathfrak{m}_P S = \mathbb{F}_\mathcal{O}$ is generated by the image of 1 as a P-module. By Krull's intersection theorem, S is separated for the $\mathfrak{m}_P S = \mathfrak{m}_S$-adic topology, and P is complete; so the complete Nakayama lemma [166, Thm. 8.4] shows that S is generated by 1 as a P-module, that is, π is surjective. □

Proposition 45.16. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $p \in T$ with $p \neq \ell$, $R_p \in \mathrm{CNL}_\mathcal{O}$ and ρ_p a lift of $\bar{r}_0|_{D_p}$ to R_p satisfying the local condition at p which is universal for such lifts (to rings in $\mathrm{CNL}_\mathcal{O}$), and $x_p\colon R_p \to \mathcal{O}$ the homomorphism with $x_p \circ \rho_p = r_0|_{D_p}$. Then there are a finite set τ_p, $w\colon \tau_p \to \mathbb{Z}^2$ with $\#w^{-1}(v) = d_p(v)$ for every v, and an $\mathcal{O}$-algebra*

homomorphism $\phi_p\colon R_p \to \mathcal{O}[\ell^{-1}][[Y_i : i \in \tau_p]]$ *(*Y_i *of weight* $w(i)$*) satisfying (Yc1)–(Yc4) read with* $p, D_p, \rho_p, x_p, \phi_p$ *in place of* $\ell, D_\ell, \rho_\ell, x_\ell, \phi_\ell$*, and (Yc5) with* 10 *in place of* 14*.*

Proof. Write $E = \mathcal{O}[\ell^{-1}]$, $R = R_p$, $x = x_p$, $\mathfrak{q} = \ker x$, $T_R = \mathfrak{q}R_\mathfrak{q}/\mathfrak{q}^2R_\mathfrak{q}$, $g \cdot X = r_0(g)Xr_0(g)^{-1}$, E_{ab} for the matrix units, and $\gamma_{ab} = \kappa_a\kappa_b^{-1}$. Let $\Phi^+ = \{(1,0),(-1,1),(0,1),(1,1)\}$, $X_{(1,0)} = E_{12} - E_{34}$, $X_{(-1,1)} = E_{23}$, $X_{(0,1)} = E_{13} + E_{24}$, $X_{(1,1)} = E_{14}$, $X_{-w} = {}^tX_w$; the entries of $X_{\pm w}$ have weight $\pm w$, and $g \cdot X_{\pm w} = \gamma_w(g)^{\pm 1}X_{\pm w}$ with $\gamma_{(1,0)} = \gamma_{12} = \gamma_{34}$, $\gamma_{(-1,1)} = \gamma_{23}$, $\gamma_{(0,1)} = \gamma_{13} = \gamma_{24}$, $\gamma_{(1,1)} = \gamma_{14}$. Each $X_{\pm w}$ lies in $\mathfrak{sp}_4(E)$ and has square 0, so $1 + aX_{\pm w}$ has similitude 1 for every a in a commutative E-algebra.

With $\operatorname{diag}(x_1, x_2, -x_2, -x_1)$ these give ten linearly independent elements of $\mathfrak{sp}_4(E)$, hence a basis, each supported on entries of one weight; so $\mathfrak{sp}_4(E) = \bigoplus_{w \in \mathcal{W}_4} V_w$ with $V_{(0,0)}$ the diagonal part (trivial action) and $V_{\pm w} = EX_{\pm w}$, and the projection onto V_w (the entries of weight w) is equivariant.

Step 1: the characters at p. From $\alpha = \chi_{\mathrm{cyc}}\omega_\ell^{-1}\xi$, $\Psi = \chi\chi_{\mathrm{cyc}}^e$, $\theta = \alpha\Psi$: $\kappa_a = \chi_{\mathrm{cyc}}^{n_a}\nu_a$ with $(n_a) = (e+1, e, 1, 0)$ and ν_a of finite order. On I_p, χ_{cyc}, ω_ℓ and ξ are trivial (ξ is unramified at $p \in T$ by (Sg1)), so $\alpha = 1$ and $\Psi = \theta = \chi$ there; hence $r_0(g) = 1$ on the closed normal subgroup $N = \{g \in I_p : \chi(g) = 1\}$ of D_p, and I_p/N is finite. For $a \neq b$, $\gamma_{ab}(\sigma_p) = p^{n_a - n_b}\zeta$ with ζ a root of unity, which is $\neq 1$: otherwise $\zeta = p^{n_b - n_a}$ would be a rational root of unity, i.e. ± 1. So $\gamma_w(\sigma_p) \neq 1$ for $w \in \Phi^+$.

Step 2: cocycles vanishing on N. For $w \in \mathcal{W}_4$ let Z_w be the space of continuous cocycles $y\colon D_p \to V_w$ vanishing on N. Then $\dim_E Z_{(0,0)} \leq 2$ and $\dim_E Z_{\pm w} \leq 1$ for $w \in \Phi^+$. For $w = (0,0)$, y is a continuous homomorphism to $V_{(0,0)} \cong E^2$; it kills the finite group I_p/N (E is torsion free), hence I_p, and is determined by $y(\sigma_p)$, since I_p and σ_p generate a dense subgroup. For $V = V_{\pm w} \cong E(\gamma)$, $\gamma = \gamma_w^{\pm 1}$, let $y \in Z_{\pm w}$; we show y is a coboundary, so $Z_{\pm w} \subseteq \{g \mapsto \gamma(g)z - z : z \in V\}$. As y vanishes on N and $\gamma(N) = 1$, y factors through D_p/N; on the finite group I_p/N, with $z_0 = |I_p/N|^{-1}\sum_{h \in I_p/N} y(h)$, the cocycle identity gives $y(g) = \gamma(g)(-z_0) - (-z_0)$. Replacing y by $y - (g \mapsto \gamma(g)(-z_0) + z_0)$, which still vanishes on N, we may assume $y|_{I_p} = 0$. For $g \in D_p$ and $i \in I_p$, $y(gi) = y(g)$ and $y(gig^{-1} \cdot g) = \gamma(gig^{-1})y(g)$, so $y(g) = \gamma(i')y(g)$ for all $i' \in I_p$. If $\gamma|_{I_p} \neq 1$, $y = 0$. Otherwise, with $z_1 = (\gamma(\sigma_p) - 1)^{-1}y(\sigma_p)$ (Step 1), $y' = y - (g \mapsto \gamma(g)z_1 - z_1)$ vanishes on I_p and at σ_p, hence on the subgroup they generate (cocycle identity), hence everywhere by continuity. In both cases y is a coboundary.

Step 3: $\dim_E T_R \leq 10$. Let $\lambda\colon T_R \to E$ be E-linear and $F_\lambda(a) = x(a) + \epsilon\lambda(a - x(a))$, $a \in R$, with values in $E[\epsilon] = E[X]/(X^2)$; it is an $\mathcal{O}$-algebra homomorphism, as $ab - x(a)x(b) \equiv x(a)(b - x(b)) + x(b)(a - x(a))$ modulo $\mathfrak{q}^2$. If $\mathfrak{q} = \sum_j Rz_j$ (finitely many z_j, R Noetherian), then $\lambda(\mathfrak{q}) = \sum_j \mathcal{O}\lambda(z_j)$, since $rz_j \equiv x(r)z_j$ modulo $\mathfrak{q}^2$; so $F_\lambda(R) \subseteq A_\lambda = \mathcal{O} + \epsilon\sum_j \mathcal{O}\lambda(z_j)$, which lies in $\mathrm{CNL}_\mathcal{O}$ by Lemma 45.12 ($n = 1$, $k = 2$), and $F_\lambda\colon R \to A_\lambda$ is local, hence continuous. So $F_\lambda \circ \rho_p$ is a lift of $\bar{r}_0|_{D_p}$ to A_λ satisfying the local condition at p, and $F_\lambda(\rho_p(g)) = (1 + \epsilon y_\lambda(g))r_0(g)$ defines a continuous cocycle y_λ, linear in λ. Both $F_\lambda(\rho_p(g))$ and $r_0(g)$ have similitude $\theta(g)$, so ${}^ty_\lambda(g)J_4 + J_4y_\lambda(g) = 0$ and y_λ is $\mathfrak{sp}_4(E)$-valued; it vanishes on N, where ρ_p and r_0 are 1. So its weight-w parts lie in Z_w. If they all vanish, $F_\lambda \circ \rho_p = r_0|_{D_p} = F_0 \circ \rho_p$, and the uniqueness in the universal property (with $A = A_\lambda$) gives $F_\lambda = F_0$, i.e. $\lambda = 0$. By Step 2, $\dim_E T_R \leq 2 + 8 = 10$.

Step 4: a weighted ten-parameter family. Let $\mathrm{fr}\colon D_p \to \widehat{\mathbb{Z}} \to \mathbb{Z}_\ell$ be the continuous homomorphism trivial on I_p with $\mathrm{fr}(\sigma_p) = 1$, and $\lambda_i(g) = (1 + T_i)^{\mathrm{fr}(g)} = \sum_j \binom{\mathrm{fr}(g)}{j} T_i^j$ ($i = 1, 2$), continuous characters $D_p \to E[[T_1, \ldots, T_{10}]]^\times$, trivial on I_p, congruent to $1 + \mathrm{fr}(g)T_i$ modulo degree 2 (the binomial coefficients are $\mathbb{Z}_\ell$-valued polynomials and satisfy Vandermonde's identity). Put $d(g) = \operatorname{diag}(\kappa_1\lambda_1, \kappa_2\lambda_2, \kappa_3\lambda_2^{-1}, \kappa_4\lambda_1^{-1})(g)$, of similitude $\theta(g)$ ($\kappa_1\kappa_4 = \kappa_2\kappa_3 = \theta$). Number $T_3, \ldots, T_6$ as T'_w and $T_7, \ldots, T_{10}$ as T''_w, $w \in \Phi^+$, and let $h = \prod_w (1 + T'_wX_{-w}) \prod_w (1 + T''_wX_w)$, of similitude 1 and $\equiv 1$ modulo the maximal ideal, and $r_T(g) = h\,d(g)\,h^{-1}$. (Fm1) holds;

(Fm2): $r_T(g)$ has similitude $\theta(g)$, and for $g \in N$, $d(g) = r_0(g) = 1$, so $r_T(g) = 1$. (Fm3): modulo degree 2, $r_T(g)r_0(g)^{-1} \equiv 1 + \mathrm{fr}(g)(T_1(E_{11} - E_{44}) + T_2(E_{22} - E_{33})) + H_1 - g \cdot H_1$ with $H_1 = \sum_w (T'_w X_{-w} + T''_w X_w)$; so $y_1, y_2 = \mathrm{fr}\,(E_{11} - E_{44}), \mathrm{fr}\,(E_{22} - E_{33})$, the y of T'_w is $(1 - \gamma_w^{-1})X_{-w}$ and that of T''_w is $(1 - \gamma_w)X_w$. The supports being disjoint, evaluation at σ_p ($\mathrm{fr}(\sigma_p) = 1$, $\gamma_w(\sigma_p) \neq 1$) shows that they are linearly independent. By Lemma 45.11 there is $F\colon R \to E[[T_1, \ldots, T_{10}]]$ with $F(\rho_p(g)_{ab}) = r_T(g)_{ab}$, $F(f) - x(f)$ in the maximal ideal, and the linear parts of the $F(\rho_p(g)_{ab} - r_0(g)_{ab})$ spanning E^{10}. By Step 3 and Lemma 45.13 (2), $R_{\mathfrak{q}}$ is regular of dimension 10, R has exactly one minimal prime inside $\mathfrak{q}$, and $F(f) \in \mathfrak{m}_T^N$ implies $cf \in \mathfrak{q}^N$ for some $c \in \mathcal{O} \setminus \{0\}$.

Step 5: weights. Give T_1, T_2 weight $(0,0)$, T'_w weight $-w$ and T''_w weight w. For $t = (t_1, t_2) \in (\mathcal{O}^\times)^2$ let ς_t be the continuous E-automorphism of $E[[T]]$ multiplying each variable of weight u by $t^u = t_1^{u_1} t_2^{u_2}$. Since $\mathrm{T}_4(t_1,t_2)X_{\pm w}\mathrm{T}_4(t_1,t_2)^{-1} = t^{\pm w}X_{\pm w}$ and $d(g)$ is diagonal, $\varsigma_t(r_T(g)) = \mathrm{T}_4(t_1,t_2)r_T(g)\mathrm{T}_4(t_1,t_2)^{-1}$, so $\varsigma_t(r_T(g)_{ab}) = t^{\mathrm{wt}_4(a,b)} r_T(g)_{ab}$. As ς_t multiplies the coefficient of a monomial of weight u by t^u, taking $t = (1+\ell, 1)$ and $(1, 1+\ell)$ shows that $r_T(g)_{ab}$ has weight $\mathrm{wt}_4(a,b)$, and so has $F(\rho_p(g)_{ab} - r_0(g)_{ab})$ ($r_0(g)_{ab} = 0$ for $a \neq b$). Hence the linear part of $F(\rho_p(g)_{ab} - r_0(g)_{ab})$ involves only variables of weight $\mathrm{wt}_4(a,b)$, and for each weight u the linear parts of those of weight u span the coordinates of weight u. Choose $f_1, \ldots, f_{10}$ among these elements, with $F(f_i)$ of the weight of T_i and $\mathrm{L}(F(f_i))$ a basis of E^{10} (L the linear coefficients).

Step 6: the chart. The continuous E-algebra endomorphism ϑ of $E[[T]]$ with $\vartheta(T_i) = F(f_i)$ has invertible linear part, so it is an automorphism; it maps series of weight u to series of weight u, hence so does ϑ^{-1} (decompose into weight components), and both preserve constant terms and each power of the maximal ideal. Put $\tau_p = \{1, \ldots, 10\}$, $Y_i = T_i$ with its weight $w(i)$, and $\phi_p = \vartheta^{-1} \circ F$. Then $\#w^{-1}(u) = 2$ for $u = (0,0)$, 1 for $u \in \mathcal{W}_4 \setminus \{(0,0)\}$ and 0 otherwise, i.e. $d_p(u)$. (Yc1): $\phi_p(\rho_p(g)_{ab}) = \vartheta^{-1}(r_T(g)_{ab})$ has weight $\mathrm{wt}_4(a,b)$. (Yc2): the constant term of $\phi_p(f)$ is that of $F(f)$, i.e. $x(f)$. (Yc3): $f_i \in \mathfrak{q}$ and $\phi_p(f_i) = Y_i$. (Yc4): $\phi_p(f) \in \mathfrak{m}_Y^N$ iff $F(f) \in \mathfrak{m}_Y^N$, and Step 4 applies. (Yc5) with 10: Step 4. □

Proposition 45.17. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$. For each $v \in T$ let (R_v, ρ_v) be universal for the lifts of $\bar{r}_0|_{D_v}$ satisfying the local condition at v, x_v its homomorphism with $x_v \circ \rho_v = r_0|_{D_v}$, and (τ_v, w_v, ϕ_v) data satisfying (Yc1)–(Yc4) read at v. Let $B = \widehat{\bigotimes}_{v\in T} R_v$ (completed tensor product over $\mathcal{O}$), σ a finite set of triples $s = (v_s, g_s, (a_s, b_s))$ with $g_s \in D_{v_s}$, $\mathrm{wt}(s) = \mathrm{wt}_4(a_s, b_s)$, and $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to B$ the continuous $\mathcal{O}$-algebra homomorphism with $\pi(X_s) = \rho_{v_s}(g_s)_{a_s b_s} - r_0(g_s)_{a_s b_s}$; suppose that π is surjective and $\mathfrak{a} = \ker\pi$ is homogeneous with constant terms 0. Then $B = \mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$ is smooth at the origin with tangent dimensions $\sum_{v\in T} t_v$, where $t_v(u) = \#w_v^{-1}(u)$.*

Proof. Write $E = \mathcal{O}[\ell^{-1}]$, $\iota_v\colon R_v \to B$ for the canonical maps (the lifts ρ_v to B being $\iota_v \circ \rho_v$), $\mathfrak{q}_v = \ker x_v$, $P = \mathcal{O}[[X_s : s \in \sigma]]$ with the weights wt, $J = \bigsqcup_v \tau_v$ with weights $w(i) = w_v(i)$ for $i \in \tau_v$, $n = \#J$, $E[[Y]] = E[[Y_i : i \in J]] \supseteq E[[Y_i : i \in \tau_v]]$ with maximal ideal $\mathfrak{m}_Y$, $E_k = E[[Y]]/\mathfrak{m}_Y^k$, and L for the vector of coefficients of the Y_i.

Step 1: the base point. Let $x_B\colon B \to \mathcal{O}$ be the morphism with $x_B \circ \iota_v = x_v$ for all v. Then $x_B(\pi(X_s)) = x_{v_s}(\rho_{v_s}(g_s)_{a_s b_s}) - r_0(g_s)_{a_s b_s} = 0$, so $x_B \circ \pi$ and the constant term are continuous homomorphisms $P \to \mathcal{O}$ agreeing on the X_s, hence equal: x_B is the origin x_R of $B = P/\mathfrak{a}$. Its kernel is $\mathfrak{q} = \pi((X_s)_s) = \sum_s B\,\pi(X_s)$, and $\iota_v(\mathfrak{q}_v) \subseteq \mathfrak{q}$.

Step 2: the charts assemble into $F\colon B \to E[[Y]]$. Fix $k \geq 1$. By (Yc2), $\phi_v(\mathfrak{q}_v^k) \subseteq \mathfrak{m}_Y^k$, so the image $A_{v,k}$ of R_v in E_k is a quotient of $R_v/\mathfrak{q}_v^k$, a finitely generated $\mathcal{O}$-module ($R_v/\mathfrak{q}_v \cong \mathcal{O}$, and each $\mathfrak{q}_v^j/\mathfrak{q}_v^{j+1}$ is a finitely generated $R_v/\mathfrak{q}_v$-module); it contains $\mathcal{O}$ and lies in $\mathcal{O} + \mathfrak{m}_Y E_k$ (Yc2). The $\mathcal{O}$-span A_k of the products $\prod_v a_v$, $a_v \in A_{v,k}$, is a subring of E_k with the same three

properties. By Lemma 45.12, $A_k \in \mathrm{CNL}_{\mathcal{O}}$ and the maps $R_v \to A_k$ induced by ϕ_v are morphisms; let $F_k\colon B \to A_k$ be the morphism with $F_k \circ \iota_v = \phi_v \bmod \mathfrak{m}_Y^k$ for all v. The projection $E_{k+1} \to E_k$ maps A_{k+1} into A_k, and its composite with F_{k+1} has the defining property of F_k, so equals F_k. Hence the F_k define an $\mathcal{O}$-algebra homomorphism $F\colon B \to E[[Y]]$ with $F \circ \iota_v = \phi_v$. For $k = 1$, $A_1 = \mathcal{O}$ and $F_1 \circ \iota_v = x_v$, so $F_1 = x_B$: the constant term of $F(f)$ is $x_B(f)$, $F(\mathfrak{q}) \subseteq \mathfrak{m}_Y$ and $F(\mathfrak{q}^N) \subseteq \mathfrak{m}_Y^N$.

Step 3: $F \circ \pi$ is a substitution and respects weights. The element $F(\pi(X_s)) = \phi_{v_s}(\rho_{v_s}(g_s)_{a_s b_s}) - r_0(g_s)_{a_s b_s}$ lies in $\mathfrak{m}_Y$ and has weight $\mathrm{wt}(s)$ by (Yc1) (the constant $r_0(g_s)_{a_s b_s}$ is non-zero only when $a_s = b_s$, of weight $(0,0)$). For $h \in P$ and $N \geq 1$ write $h = h_N + h'_N$ with h_N a polynomial and $h'_N \in (X)^N$; then $\pi(h'_N) \in \mathfrak{q}^N$, so $F(\pi(h)) \equiv F(\pi(h_N))$ modulo $\mathfrak{m}_Y^N$, which is the substitution $X_s \mapsto F(\pi(X_s))$ applied to h_N, hence to h, modulo $\mathfrak{m}_Y^N$. So $F \circ \pi$ is that substitution; it maps series of weight u to series of weight u, and $F(\pi(h)) = \sum_u F(\pi(h_{(u)}))$ with $F(\pi(h_{(u)}))$ the weight-u component of $F(\pi(h))$.

Step 4: the cotangent space of B at $\mathfrak{q}$ has dimension $\leq n$. For $v \in T$ let $T_v = \mathfrak{q}_v R_{v,\mathfrak{q}_v} / \mathfrak{q}_v^2 R_{v,\mathfrak{q}_v}$. The map ϕ_v extends to $R_{v,\mathfrak{q}_v}$ (elements outside $\mathfrak{q}_v$ go to units, by (Yc2)) and induces an E-linear map $T_v \to \mathfrak{m}_Y/\mathfrak{m}_Y^2$, $f \mapsto \mathrm{L}(\phi_v(f))$, onto E^{τ_v} by (Yc3) and injective by (Yc4) (if $f \in \mathfrak{q}_v$ and $\phi_v(f) \in \mathfrak{m}_Y^2$ then $cf \in \mathfrak{q}_v^2$ with $c \neq 0$ invertible in $R_{v,\mathfrak{q}_v}$); so $\dim_E T_v = \#\tau_v$. Let $\lambda\colon \mathfrak{q}B_{\mathfrak{q}}/\mathfrak{q}^2 B_{\mathfrak{q}} \to E$ be E-linear and $D(f) = \lambda(f - x_B(f))$; then D is $\mathcal{O}$-linear with $D(fh) = x_B(f)D(h) + x_B(h)D(f)$, and so is $D \circ \iota_v$ for x_v; it kills $\mathfrak{q}_v^2$ and $\mathcal{O}$, so it is given by an E-linear form λ_v on T_v. If all λ_v vanish, D vanishes on the generators $\pi(X_s) \in \iota_{v_s}(\mathfrak{q}_{v_s})$ of $\mathfrak{q}$, hence on $\mathfrak{q}$ ($D(bz) = x_B(b)D(z)$ for $z \in \mathfrak{q}$), and $\lambda = 0$. So $\lambda \mapsto (\lambda_v)_v$ is injective and $\dim_E \mathfrak{q}B_{\mathfrak{q}}/\mathfrak{q}^2 B_{\mathfrak{q}} \leq \sum_v \#\tau_v = n$.

Step 5: regularity. For $i \in \tau_v$, (Yc3) gives $f \in \mathfrak{q}_v$ with $\phi_v(f) \equiv Y_i$ modulo $\mathfrak{m}_Y^2$; then $\iota_v(f) \in \mathfrak{q}$ and $F(\iota_v(f)) \equiv Y_i$. So the linear parts of $F(\mathfrak{q})$ span E^n, and by Steps 2 and 4 and Lemma 45.13 (2), for every N and every $f \in B$ with $F(f) \in \mathfrak{m}_Y^N$ there is $c \in \mathcal{O} \setminus \{0\}$ with $cf \in \mathfrak{q}^N$.

Step 6: the chart. Let ϕ be the restriction of F to B^{gr}, with variables Y_i of weights $w(i)$; $\#w^{-1}(u) = \sum_v t_v(u)$. (Sm1): for $f = \pi(h) \in B_u$ with $h \in P_u$, $\phi(f)$ has weight u by Step 3. (Sm2): Steps 1 and 2. (Sm3): for $i \in \tau_v$ take f as in Step 5 and $h \in P$ with $\pi(h) = \iota_v(f)$; by Step 3, $F(\pi(h_{(w(i))}))$ is the weight-$w(i)$ component of $F(\iota_v(f)) \equiv Y_i$ modulo $\mathfrak{m}_Y^2$, so it is $\equiv Y_i$, and $\pi(h_{(w(i))}) \in B_{w(i)} \subseteq B^{\mathrm{gr}}$. (Sm4): let $f = \sum_u f_u \in B^{\mathrm{gr}}$ ($f_u \in B_u$, finitely many) with $x_B(f) = 0$ and all coefficients of degree one of $\phi(f)$ zero. By (Sm1) the $\phi(f_u)$ are the weight components of $\phi(f)$, so each has no linear terms, and no constant term (for $u \neq (0,0)$ by weight, for $u = (0,0)$ as $x_B(f) = 0$); so $\phi(f_u) \in \mathfrak{m}_Y^2$, and by Step 5 there is $c_u \neq 0$ with $c_u f_u \in \mathfrak{q}^2 = \pi((X)^2)$. Write $f_u = \pi(h)$ with $h \in P_u$ and $c_u f_u = \pi(q)$ with $q \in (X)^2$; then $c_u h - q \in \mathfrak{a}$, and as $\mathfrak{a}$ is homogeneous, $c_u h - q_{(u)} \in \mathfrak{a}$, so $c_u f_u = \pi(q_{(u)})$ with $q_{(u)} \in (X)^2 \cap P_u$. Fixing an order on σ and assigning each monomial of $q_{(u)}$ to its two smallest variables gives $q_{(u)} = \sum_{s \leq s'} X_s X_{s'} q_{ss'}$ with $q_{ss'} \in P_{u - \mathrm{wt}(s) - \mathrm{wt}(s')}$. Hence $c_u f_u = \sum_{s \leq s'} \pi(X_s) \cdot \pi(X_{s'}) \pi(q_{ss'})$, a sum of products of two elements of $\mathfrak{m}_0 = \ker x_B \cap B^{\mathrm{gr}}$, and $cf \in \mathfrak{m}_0^2$ for $c = \prod_u c_u$: $f \in \mathrm{Sq}$.

So $B = P/\mathfrak{a}$ is smooth at the origin with tangent dimensions $\sum_v t_v$. □

Lemma 45.18. *Let $\mathcal{O}$ be a coefficient ring, $d \geq 1$, $R \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_R$, and $\rho\colon R \to R[[T_1, \ldots, T_d]]$ a morphism of $\mathrm{CNL}_{\mathcal{O}}$; an element $y \in R$ has* torus weight $w = (w_1, \ldots, w_d) \in \mathbb{Z}^d$ *if $\rho(y) = \prod_{k=1}^d (1 + T_k)^{w_k} y$. Let σ be a finite set,* $\mathrm{wt}\colon \sigma \to \mathbb{Z}^d$ *a map, and $\pi\colon \mathcal{O}[[X_s : s \in \sigma]] \to R$ a surjective continuous $\mathcal{O}$-algebra homomorphism such that each $\pi(X_s)$ lies in $\mathfrak{m}_R$ and has torus weight $\mathrm{wt}(s)$. Then:*

1. *for every $f \in \ker \pi$ and $w \in \mathbb{Z}^d$, $f_{(w)} \in \ker \pi$;*
2. *every $y \in R$ of torus weight w lies in $\pi(\mathcal{O}[[X_\sigma]]_w)$;*
3. *$\ker \pi$ is generated by finitely many elements each lying in some $\mathcal{O}[[X_\sigma]]_w$.*

Proof. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$, $\mathfrak{m}_P = (\mathfrak{m}_\mathcal{O}, X_s)$, $J = \ker \pi$, and for $n \in \mathbb{N}^\sigma$, $X^n = \prod_s X_s^{n_s}$, $|n| = \sum_s n_s$, $\mathrm{wt}(n) = \sum_s n_s \mathrm{wt}(s) \in \mathbb{Z}^d$; for $v \in \mathbb{Z}^d$ let $|v|_\infty = \max_k |v_k|$. Let $W = \max(1, \max_s |\mathrm{wt}(s)|_\infty)$, so $|\mathrm{wt}(n)|_\infty \le W|n|$. For $k = (k_1, \dots, k_d) \in \mathbb{N}^d$ and $v \in \mathbb{Z}^d$ put $\binom{v}{k} = \prod_i \binom{v_i}{k_i} \in \mathbb{Z}$ and $T^k = \prod_i T_i^{k_i}$, so that $\prod_i (1+T_i)^{v_i} = \sum_k \binom{v}{k} T^k$ in $\mathbb{Z}[[T_1, \dots, T_d]]$.

Step 1: divided Euler operators. Let $E_k \colon P \to P$ be the $\mathcal{O}$-linear map

$$\sum_n c_n X^n \mapsto \sum_n \binom{\mathrm{wt}(n)}{k} c_n X^n,$$

and $\rho_P \colon P \to P[[T_1, \dots, T_d]]$ the continuous $\mathcal{O}$-algebra homomorphism with $\rho_P(X_s) = \prod_i (1+T_i)^{\mathrm{wt}(s)_i} X_s$. Then $\rho_P(f) = \sum_k E_k(f) T^k$. With π_T applying π to coefficients, the continuous homomorphisms $\rho \circ \pi$ and $\pi_T \circ \rho_P$ agree on the X_s, hence on P:

$$\rho(\pi(f)) = \sum_{k \in \mathbb{N}^d} \pi(E_k f)\, T^k \qquad (f \in P).$$

So $E_k(J) \subseteq J$, and if $\pi(f) = y$ has torus weight w, then $\pi(E_k f) = \binom{w}{k} y$.

Step 2: approximate projectors. Fix w and $M \ge |w|_\infty$, put $Q = WM$ and, for each i, $L_i(x) = \prod_{-Q \le m \le Q,\, m \ne w_i} \frac{x-m}{w_i - m} = \binom{x+Q}{w_i+Q}\binom{Q-x}{Q-w_i}$, an integer-valued polynomial, so $L_i(x) = \sum_{k \le 2Q} a_{i,k} \binom{x}{k}$ with $a_{i,k} \in \mathbb{Z}$. Then $L(v) = \prod_i L_i(v_i) = \sum_k a_k \binom{v}{k}$ with $a_k = \prod_i a_{i,k_i}$, $L(w) = 1$, and $L(v) = 0$ for $v \ne w$ with $|v|_\infty \le Q$. Put $\Pi = \sum_k a_k E_k$. For $f = \sum_n c_n X^n$, $\Pi(f) = f_{(w)} + r$ with $r = \sum_{|\mathrm{wt}(n)|_\infty > Q} L(\mathrm{wt}(n)) c_n X^n$, and every monomial of r has $|n| \ge |\mathrm{wt}(n)|_\infty / W > M$, so $r \in \mathfrak{m}_P^{M+1}$.

Step 3: items 1 and 2. If $f \in J$, then $\Pi(f) \in J$, so $f_{(w)} \in J + \mathfrak{m}_P^{M+1}$ for every $M \ge |w|_\infty$, and $f_{(w)} \in J$ by Krull's intersection theorem in P/J. If y has torus weight w and $\pi(f) = y$, then $\pi(\Pi f) = \sum_k a_k \binom{w}{k} y = L(w) y = y$, so $y - \pi(f_{(w)}) = \pi(r) \in \mathfrak{m}_R^{M+1}$ for every M, and $y = \pi(f_{(w)})$.

Step 4: item 3. Every $f \in J$ is the $\mathfrak{m}_P$-adic limit of the finite sums $\sum_{|v|_\infty \le WM} f_{(v)}$, whose terms lie in J by item 1, and ideals of the Noetherian ring P are closed; so J is generated by the $f_{(v)}$, $f \in J$, and finitely many of them suffice. □

45.2 Graded relative presentations and the assembly of weighted models

This subsection proves that every symplectic local base carries a graded framed relative presentation with Euler-characteristic counts (Proposition 45.20), and that such a presentation gives a symplectic weighted model (Proposition 45.23). The presentation is the graded form of Mazur's: over the completed tensor product of the local rings, the framed Selmer cocycles of each weight are the variables and the framed obstruction groups bound the relations (Definition 45.19, Proposition 45.21). The count that replaces Lemma 43.34 is Lemma 45.22: the dimension of the framed obstruction group exceeds that of the framed Selmer cocycles by the dimensions of the invariants of complex conjugation and of the global invariants of the dual module. The assembly cuts a smooth weighted cover by weighted elements with independent point derivations (Proposition 45.24). The subsection also defines the ordinary test representations (Definition 45.26), the representations over valuation rings through which Part IX describes the points of a symplectic datum.

Definition 45.19. Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring with residue field $\mathbb{F} = \mathbb{F}_\mathcal{O}$ of characteristic ℓ, and $d, n \ge 1$ integers; indices a, b run over $\{1, \dots, n\}$.

Graded form data. A **graded form datum** of rank n with weights in $\mathbb{Z}^d$ is a tuple $\Phi = (J, K, \beta, s, w, c_\Phi)$ of a matrix $J \in \mathrm{GL}_n(\mathcal{O})$ with ${}^tJ = J$ or ${}^tJ = -J$, a finite set K (the

blocks) with a map $\beta\colon \{1,\dots,n\} \to K$ and an involution s of K, a map $w\colon \{1,\dots,n\} \to \mathbb{Z}^d$ (the *weights*) and an element $c_\Phi \in \mathbb{Z}^d$, such that

$$J_{ab} \neq 0 \implies \beta(b) = s(\beta(a)) \quad \text{and} \quad w(a) + w(b) = c_\Phi.$$

For a commutative $\mathcal{O}$-algebra A, a matrix $X \in \mathrm{M}_n(A)$ **has similitude** $\nu \in A$ if ${}^tXJX = \nu J$; it is **block diagonal** if $X_{ab} = 0$ whenever $\beta(a) \neq \beta(b)$, and **weight diagonal** if $X_{ab} = 0$ whenever $w(a) \neq w(b)$. Put

$$\mathfrak{g}_\Phi(A) = \{Y \in \mathrm{M}_n(A) \text{ block diagonal} : \ {}^tYJ + JY = 0\},$$
$$\mathfrak{g}_{\Phi,j}(A) = \{Y \in \mathfrak{g}_\Phi(A) : \ Y_{ab} = 0 \text{ unless } w(a) - w(b) = j\} \quad (j \in \mathbb{Z}^d),$$

and, for $A \in \mathrm{CNL}_\mathcal{O}$ with maximal ideal $\mathfrak{m}_A$, let $\mathrm{H}_\Phi(A)$ be the set of block diagonal $h \in \mathrm{M}_n(A)$ of similitude 1 with $h \equiv 1 \pmod{\mathfrak{m}_A}$.

Graded framed deformation problems. A **graded framed deformation problem** over $\mathcal{O}$ is a tuple

$$\mathfrak{P} = \big(\Phi, \Gamma, \bar{r}, r_0, T, v_0, (\Gamma_v, \varphi_v)_{v\in T}, Q, (\Gamma_q, \psi_q, N_q)_{q\in Q}\big)$$

of a graded form datum Φ of rank n with weights in $\mathbb{Z}^d$, a profinite group Γ, continuous homomorphisms $\bar{r}\colon \Gamma \to \mathrm{GL}_n(\mathbb{F})$ and $r_0\colon \Gamma \to \mathrm{GL}_n(\mathcal{O})$ with $r_0 \equiv \bar{r} \pmod{\mathfrak{m}_\mathcal{O}}$, finite sets T and Q with $v_0 \in T$, profinite groups Γ_v ($v \in T$) and Γ_q ($q \in Q$), continuous homomorphisms $\varphi_v\colon \Gamma_v \to \Gamma$ and $\psi_q\colon \Gamma_q \to \Gamma$, and closed normal subgroups $N_q \subseteq \Gamma_q$, such that

(Gq1) $\mathrm{Hom}_{\mathrm{cont}}(\Gamma', \mathbb{F}_\ell)$ is finite for every open subgroup $\Gamma' \subseteq \Gamma$;

(Gq2) there is a homomorphism $g \mapsto \pi_g$ from Γ to the group of permutations of K such that for every $g \in \Gamma$ the matrix $r_0(g)$ is weight diagonal, has a similitude in $\mathcal{O}^\times$, and $r_0(g)_{ab} \neq 0$ implies $\beta(a) = \pi_g(\beta(b))$;

(Gq3) for every $q \in Q$, $r_0(\psi_q(x)) = 1$ for all $x \in N_q$, and $H^2(\Gamma_q/N_q, M) = 0$ for every finite-dimensional $\mathbb{F}$-vector space M with a continuous $\mathbb{F}$-linear action of Γ_q/N_q (M discrete).

Bases and framed lifts. A **base** for $\mathfrak{P}$ is a pair $(B, (\rho_v)_{v\in T})$ of $B \in \mathrm{CNL}_\mathcal{O}$ and continuous homomorphisms $\rho_v\colon \Gamma_v \to \mathrm{GL}_n(B)$ with $\rho_v(g)\, r_0(\varphi_v(g))^{-1} \in \mathrm{H}_\Phi(B)$ for all $v \in T$ and $g \in \Gamma_v$. A **framed lift** over the base $(B, (\rho_v))$ to $A \in \mathrm{CNL}_\mathcal{O}$ is a triple $(\iota, r, (\alpha_v)_{v\in T})$ of a morphism $\iota\colon B \to A$ of $\mathrm{CNL}_\mathcal{O}$, a continuous homomorphism $r\colon \Gamma \to \mathrm{GL}_n(A)$ and matrices $\alpha_v \in \mathrm{M}_n(A)$ such that

(Gq4) $r(g)\, r_0(g)^{-1} \in \mathrm{H}_\Phi(A)$ for every $g \in \Gamma$;

(Gq5) $r(\psi_q(x)) = 1$ for every $q \in Q$ and $x \in N_q$;

(Gq6) $\alpha_v \in \mathrm{H}_\Phi(A)$ for every $v \in T$, $\alpha_{v_0} = 1$, and $r(\varphi_v(g))\, \alpha_v = \alpha_v\, \iota(\rho_v(g))$ for all $v \in T$ and $g \in \Gamma_v$.

Here $r_0(g)$ is read in $\mathrm{GL}_n(A)$ through $\mathcal{O} \to A$, and ι is applied entrywise.

Framed Selmer cocycles and framed obstruction groups. Let M be a finite-dimensional $\mathbb{F}$-vector space with a continuous $\mathbb{F}$-linear action of Γ (M discrete) on which $\psi_q(N_q)$ acts trivially for every $q \in Q$; Γ_v and Γ_q act on M through φ_v and ψ_q, φ_v^* and ψ_q^* denote the

pull-back of cochains, and for $y \in M$, $dy \in C^1(\Gamma_v, M)$ is $g \mapsto gy - y$. The **framed Selmer cocycles** of M form the $\mathbb{F}$-vector space

$$Z^1_{\mathrm{fr}}(M) = \{(x, (x_v)_{v\in T}) \in Z^1(\Gamma, M) \times M^T : \\ x(\psi_q(y)) = 0 \ (q \in Q,\ y \in N_q),\ \varphi_v^* x = dx_v \ (v \in T),\ x_{v_0} = 0\}.$$

The **framed obstruction group** $\mathrm{Ob}_{\mathrm{fr}}(M)$ is the quotient of

$$Z^2_{\mathrm{fr}}(M) = \{(k, (k_v)_{v\in T}, (k_q)_{q\in Q}) :\ k \in Z^2(\Gamma, M),\ k_v \in C^1(\Gamma_v, M), \\ k_q \in C^1(\Gamma_q, M),\ \varphi_v^* k = dk_v,\ \psi_q^* k = dk_q\}$$

by its subspace

$$B^2_{\mathrm{fr}}(M) = \{(dh, (\varphi_v^* h - dy_v)_{v\in T}, (\psi_q^* h - e_q)_{q\in Q}) :\ h \in C^1(\Gamma, M), \\ y_v \in M,\ e_q \in Z^1(\Gamma_q, M),\ e_q(N_q) = 0\};$$

dim denotes $\dim_{\mathbb{F}} \in \mathbb{N} \cup \{\infty\}$.

Proposition 45.20. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and L a symplectic local base of $\mathfrak{D}$. Then there is a framed relative presentation over L.*

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $G_S = G_{\mathbb{Q},S}$ (ramification allowed at S and ∞), $Q = S \setminus T$ ($T \subseteq S$ since $T = \{\ell\} \cup S_\ell(\chi)$ and the primes of $S_\ell(\chi)$ divide N), $\bar r_0$ the reduction of r_0, and for $q \in Q$ let $N_q = I_q \cap \ker \bar r_0$, a closed normal subgroup of D_q.

Step 1: the problem. The representation r_0 is unramified outside S ((Sg1): ξ is, χ has modulus N, χ_{cyc} and ω_ℓ ramify only at ℓ), so r_0 and $\bar r_0$ factor through G_S. Let $\Phi = (J_4, \{*\}, \beta, \mathrm{id}, w, (1,1))$ with $w(a) = (\lambda_a, \mu_a)$, i.e. $w(1) = (1,1)$, $w(2) = (0,1)$, $w(3) = (1,0)$, $w(4) = (0,0)$: ${}^t J_4 = -J_4$, and $(J_4)_{ab} \neq 0$ only for $\{a,b\} = \{1,4\}, \{2,3\}$, where $w(a) + w(b) = (1,1)$; so Φ is a graded form datum with one block, and $w(a) - w(b) = \mathrm{wt}_4(a,b)$. Let $\mathfrak{P} = (\Phi, G_S, \bar r_0, r_0, T, \ell, (D_v)_{v\in T}, Q, (D_q, N_q)_{q\in Q})$, the groups mapping to G_S through $G_{\mathbb{Q}}$. (Gq1) is Theorem B.71, item 2. (Gq2): $r_0(g)$ is diagonal of similitude $\theta(g) \in \mathcal{O}^\times$. (Gq3): let $q \in Q$. Then $q \neq \ell$, and $\alpha|_{I_q} = \xi|_{I_q}$ (χ_{cyc}, ω_ℓ are unramified at q) has order prime to ℓ; $\Psi|_{I_q} = \chi|_{I_q} = \chi'|_{I_q}$ because $q \notin S_\ell(\chi)$ (either $q \nmid N$, or the q-component of χ'' is trivial), of order prime to ℓ; hence each diagonal entry of $r_0|_{I_q}$ ($\theta = \alpha\Psi$) has values in the roots of unity of order prime to ℓ of $\mathcal{O}^\times$, which inject into $\mathbb{F}^\times$, and r_0 is trivial on N_q. The same injectivity shows $I_q/N_q \hookrightarrow \bar r_0(I_q)$, a group of diagonal matrices over $\mathbb{F}$, finite of order prime to ℓ; as $D_q/I_q \cong \widehat{\mathbb{Z}}$ has cohomological dimension 1 on finite ℓ-primary modules, the Hochschild–Serre spectral sequence gives $H^2(D_q/N_q, M) \cong H^2(D_q/I_q, M^{I_q}) = 0$ for every finite-dimensional $\mathbb{F}$-vector space M with a continuous action [191]. So $\mathfrak{P}$ is a graded framed deformation problem.

Step 2: the base and the framed lifts. Let $L = (\sigma_L, \mathrm{wt}_L, \mathfrak{a}_L, (\rho_v))$. Each ρ_v is a continuous homomorphism $D_v \to \mathrm{GL}_4(B_L)$ lifting $\bar r_0|_{D_v}$ with $\rho_v(g)$ of similitude $\theta(g)$ (local condition at v), so $\rho_v(g) r_0(g)^{-1}$ has similitude 1 (similitudes multiply: ${}^t(XY) J_4 XY = \nu_X \nu_Y J_4$) and is $\equiv 1$: it lies in $\mathrm{H}_\Phi(B_L)$, and $(B_L, (\rho_v))$ is a base. The ideal $\mathfrak{a}_L$ is homogeneous with constant terms 0, $\rho_v(g)_{ab} \in (B_L)_{\mathrm{wt}_4(a,b)}$ and $x_L(\rho_v(g)) = r_0(g)$ by (Bq2). For $A \in \mathrm{CNL}_{\mathcal{O}}$, $(A, \iota, r, (\alpha_v))$ is a framed lift over L in the sense of Definition 45.3 if and only if r factors through G_S and $(\iota, r, (\alpha_v))$ is a framed lift over $(B_L, (\rho_v))$ for $\mathfrak{P}$. Indeed: (Gq4) says that $r(g)$ has similitude $\theta(g)$ and $r \equiv \bar r_0$ (one block); (Fw2) together with the last clause of (Fw3) is (Gq6) with $v_0 = \ell$; and (Se2) is equivalent to: r is trivial on the inertia groups at places above primes $p \notin S$ (there $\bar r_0$ is unramified, so $I_{\bar w} \subseteq \ker \bar r_0$), i.e. r factors through G_S, and $r(N_q) = 1$ for $q \in Q$, which is (Gq5)

(for another place $g\bar{q}$ above q, $I_{g\bar{q}} \cap \ker \bar{r}_0 = gN_qg^{-1}$). Continuity is the same on $G_{\mathbb{Q}}$ and on its quotient G_S. An $\mathcal{O}$-algebra homomorphism between objects of $\mathrm{CNL}_{\mathcal{O}}$ is local (its composite with the residue map has kernel the maximal ideal), so (Fv1) is the universal property (Pz1).

Step 3: the weight pieces. A matrix Y lies in $\mathfrak{sp}_4(\mathbb{F})$ if and only if J_4Y is symmetric; as $(J_4Y)_{ab} = \epsilon_a Y_{5-a,b}$ with $\epsilon = (1,1,-1,-1)$, this says $Y_{5-b,5-i} = \pm Y_{ib}$ for all i,b, and the entries (i,b) and $(5-b,5-i)$ have the same weight. Hence $\mathfrak{g}_w := \mathfrak{g}_{\Phi,w}(\mathbb{F})$ has dimension 2 for $w=(0,0)$ (entries $\{(1,1),(4,4)\}$, $\{(2,2),(3,3)\}$), 1 for $w \in \mathcal{W}_4 \setminus \{(0,0)\}$ (one orbit: $\{(1,2),(3,4)\}$, $\{(1,3),(2,4)\}$, $\{(1,4)\}$, $\{(2,3)\}$ and their transposes), and 0 for $w \notin \mathcal{W}_4$. Since the a-th diagonal entry of r_0 is $\alpha^{\lambda_a}\Psi^{\mu_a}$, $g \in G_S$ acts on $\mathfrak{g}_w$ by the scalar $\bar{\gamma}_w(g)$, $\gamma_w = \alpha^{w_1}\Psi^{w_2}$. Now $\alpha(c) = \chi_{\mathrm{cyc}}(c)\omega_\ell(c)^{-1}\xi(c) = -1$ and $\Psi(c) = 1$ ((Sg1); $\omega_\ell(c) = -1$ as $\omega_\ell(c)^2 = 1$ and $\omega_\ell(c) \equiv -1$, ℓ odd), so $\dim \mathfrak{g}_w^{c=1}$ is 2 at $(0,0)$, 1 at $(0,\pm 1)$, and 0 at the six weights $w \in \mathcal{W}_4$ with w_1 odd; this is $c(w)$ of (Fv4). For w_1 odd, $\gamma_w \in \{\alpha^{\pm 1}, \theta^{\pm 1}, \beta^{\pm 1}\}$ and, as $\bar{\alpha} = \bar{\xi}$ ($\bar{\chi}_{\mathrm{cyc}} = \bar{\omega}_\ell$), $\bar{\gamma}_w$ is $(\overline{\xi\Psi^i})^{\pm 1}$ with $i \in \{0,1,-1\}$; so $\bar{\gamma}_w(\sigma_v) \neq 1$ for every $v \in T$ by (Sg2).

Step 4: the framed Selmer cocycles. Let w_1 be odd and $(x,(x_v)) \in Z^1_{\mathrm{fr}}(\mathfrak{g}_w)$; write $x = zY_w$, $x_v = y_vY_w$ for a basis vector Y_w. Inflated to $G_{\mathbb{Q}}$, z is a residual Selmer cocycle for γ_w: the cocycle rule holds with $\bar{\gamma}_w$; z vanishes on inertia above primes outside S (it factors through G_S), and above $q \in Q$ on gN_qg^{-1} by the cocycle rule ($z(gng^{-1}) = z(g) + \bar{\gamma}_w(g)z(g^{-1}) = 0$ for $n \in N_q$, $\bar{\gamma}_w(n) = 1$); and $z(g) = \bar{\gamma}_w(g)y_v - y_v$ on D_v. By (Sg6), $z(g) = \bar{\gamma}_w(g)y - y$ for some $y \in \mathbb{F}$; then $(\bar{\gamma}_w(g) - 1)(y - y_v) = 0$ on D_v, and $g = \sigma_v$ gives $y_v = y$; $y_\ell = 0$ gives $y = 0$. So $Z^1_{\mathrm{fr}}(\mathfrak{g}_w) = 0$ for w_1 odd, and trivially for $w \notin \mathcal{W}_4$.

Step 5: the obstruction groups. For every w, $H^0(G_S, \mathfrak{g}_w^\vee) = 0$: G_S acts on $\mathfrak{g}_w^\vee = \mathrm{Hom}(\mathfrak{g}_w, \mu_\ell)$ by $\bar{\chi}_{\mathrm{cyc}}\bar{\gamma}_w^{-1}$, and $\bar{\chi}_{\mathrm{cyc}} \neq \bar{\gamma}_w$: at c for w_1 even ($\chi_{\mathrm{cyc}}(c) = -1 \neq 1 = \gamma_w(c)$), at σ_ℓ for w_1 odd ($\chi_{\mathrm{cyc}}(\sigma_\ell) = 1 \neq \bar{\gamma}_w(\sigma_\ell)$ by (Sg2) and Step 3). The hypotheses of Lemma 45.22 hold (Step 1: $N_q \subseteq I_q$, I_q/N_q finite of order prime to ℓ, N_q acts trivially on $\mathfrak{g}_w$ by (Pz0)), so

$$\dim \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_w) = \dim Z^1_{\mathrm{fr}}(\mathfrak{g}_w) + c(w) \qquad (w \in \mathbb{Z}^2),$$

with c as in (Fv4) (Step 3; both sides vanish for $w \notin \mathcal{W}_4$).

Step 6: the presentation. Apply Proposition 45.21 to $\mathfrak{P}$ and the base $(B_L, (\rho_v))$ with $\sigma_B = \sigma_L$, $\mathrm{wt}_B = \mathrm{wt}_L$, $\mathfrak{a}_B = \mathfrak{a}_L$. Let $U = R$, $\iota = \iota_R$, r_U the inflation of r_R to $G_{\mathbb{Q}}$, $\alpha_v = \alpha_{R,v}$, and $\tau, \mathrm{wt}_\tau, (y_t)$, $\Pi_U = \Pi$, $\kappa_0, \mathrm{wf}_0, (f_k)$ as in (Pz2)–(Pz4). Pad the relations: for each w add $\dim Z^1_{\mathrm{fr}}(\mathfrak{g}_w) + c(w) - \#\mathrm{wf}_0^{-1}(w) \geq 0$ indices k of weight w with $f_k = 0$ (non-negative by (Pz4) and Step 5; only finitely many w are involved), giving $\kappa \supseteq \kappa_0$ and wf. Then: (Fv1) by Step 2. (Fv2): Π_U is onto with $\Pi_U(X_s) = \iota(\pi_L(X_s))$ and $\Pi_U(X_t) = y_t$ (Pz3); $\ker \Pi_U = \mathfrak{a}_L P_U + (f_k)_{k\in\kappa}$ (Pz4; zero series add nothing); $f_k \in \mathcal{O}[[X]]_{\mathrm{wf}(k)}$ with constant term 0 (Pz5, its hypothesis by (Bq2)); each y_t is $r_U(g)_{ab} - r_0(g)_{ab}$ (with $g \in G_{\mathbb{Q}}$ lifting the element of G_S) or $(\alpha_v - 1)_{ab}$, with $\mathrm{wt}_\tau(t) = \mathrm{wt}_4(a,b) \in \mathcal{W}_4$ (Pz2). (Fv3): the entries lie in $U_{\mathrm{wt}_4(a,b)}$ (Pz3), and the homomorphism x_U induced by the constant term is x_R of (Pz5), so $x_U(r_U(g)_{ab}) = r_0(g)_{ab}$, $x_U(\alpha_v) = 1$, $x_U \circ \iota = x_L$. (Fv4): $\#\mathrm{wt}_\tau^{-1}(w) = \dim Z^1_{\mathrm{fr}}(\mathfrak{g}_w)$ (Pz2), which is 0 unless $w \in \{(0,0),(0,1),(0,-1)\}$ (Step 4), and $\#\mathrm{wf}^{-1}(w) = \#\mathrm{wt}_\tau^{-1}(w) + c(w)$ by the padding. So $(U, \iota, r_U, (\alpha_v), \tau, \mathrm{wt}_\tau, (y_t), \kappa, (f_k), \mathrm{wf})$ is a framed relative presentation over L. □

Proposition 45.21. *Let $\mathfrak{P} = (\Phi, \Gamma, \bar{r}, r_0, T, v_0, (\Gamma_v, \varphi_v), Q, (\Gamma_q, \psi_q, N_q))$ be a graded framed deformation problem over a coefficient ring $\mathcal{O}$ with residue field $\mathbb{F}$, Φ of rank n with weights w in $\mathbb{Z}^d$. Let $(B, (\rho_v)_{v\in T})$ be a base for $\mathfrak{P}$ with $B = \mathcal{O}[[X_s : s \in \sigma_B]]/\mathfrak{a}_B$, where σ_B is a finite set with a map $\mathrm{wt}_B \colon \sigma_B \to \mathbb{Z}^d$ and $\mathfrak{a}_B$ is an ideal all of whose elements have constant term 0 and which is homogeneous ($f_{(u)} \in \mathfrak{a}_B$ for all $f \in \mathfrak{a}_B$, $u \in \mathbb{Z}^d$); write π_B for the projection, $B_u = \pi_B(\mathcal{O}[[X_{\sigma_B}]]_u)$, $x_B \colon B \to \mathcal{O}$ for the homomorphism induced by the constant term, and assume $\rho_v(g)_{ab} \in B_{w(a)-w(b)}$ for all $v \in T$, $g \in \Gamma_v$ and a,b. Proof. Write $\mathbb{F}$ for the residue field, ϖ for a uniformiser of $\mathcal{O}$, $V_k \subseteq \mathbb{F}^n$ (or A^n) for the span of the basis vectors e_a with $\beta(a) = k$, and $u^i = \prod_m u_m^{i_m}$ for units $u_1, \dots, u_d$ and $i \in \mathbb{Z}^d$.

Step 0: facts on the form datum. (F1) $(J^{-1})_{ab} \neq 0$ implies $\beta(b) = s(\beta(a))$ and $w(a)+w(b) = c_\Phi$. Indeed $J(V_k) \subseteq V_{s(k)}$ and J is injective, so, s being a bijection, $J(V_k) = V_{s(k)}$ for every k and $J^{-1}(V_{s(k)}) = V_k$; and over $A = \mathcal{O}[u_1^{\pm1}, \dots, u_d^{\pm1}]$ the matrix $t_u = \mathrm{diag}(u^{w(1)}, \dots, u^{w(n)})$ satisfies ${}^t t_u J t_u = u^{c_\Phi} J$ (entry (a,b) is $u^{w(a)+w(b)}J_{ab}$), hence $t_u^{-1}J^{-1}t_u^{-1} = u^{-c_\Phi}J^{-1}$, whose entry (a,b) reads $u^{-w(a)-w(b)}(J^{-1})_{ab} = u^{-c_\Phi}(J^{-1})_{ab}$. (F2) Let A be a commutative $\mathcal{O}$-algebra and $g \in \Gamma$, and read $X = r_0(g)$ in $\mathrm{GL}_n(A)$, of similitude $\nu \in A^\times$ (Gq2). Then $Y \mapsto XYX^{-1}$ preserves $\mathfrak{g}_{\Phi,j}(A)$ and the set of block diagonal matrices of similitude 1, and, for $A \in \mathrm{CNL}_{\mathcal{O}}$, $\mathrm{H}_\Phi(A)$. Indeed ${}^t X J = \nu J X^{-1}$ and $JX = \nu\, {}^t X^{-1} J$, so ${}^t(XYX^{-1})J + JXYX^{-1} = \nu\, {}^t X^{-1}({}^t YJ + JY)X^{-1}$ and ${}^t(XhX^{-1})J(XhX^{-1}) = \nu\, {}^t X^{-1}\, {}^t h J h\, X^{-1} = \nu\, {}^t X^{-1} J X^{-1} = J$ if ${}^t hJh = J$. For the entries: $X^{-1} = r_0(g^{-1})$, so a non-zero term $X_{ac}Y_{cd}(X^{-1})_{db}$ needs $w(a) = w(c)$, $w(d) = w(b)$, $\beta(a) = \pi_g(\beta(c))$, $\beta(d) = \pi_g^{-1}(\beta(b))$; for block diagonal Y ($\beta(c) = \beta(d)$) this gives $\beta(a) = \beta(b)$, and $Y_{cd} \neq 0 \Rightarrow w(c) - w(d) = j$ gives $w(a) - w(b) = j$. (F3) Let $A \in \mathrm{CNL}_{\mathcal{O}}$ and $I \subseteq \mathfrak{m}_A$ an ideal with $I^2 = 0$. For $Y \in \mathrm{M}_n(I)$ block diagonal, $1+Y \in \mathrm{H}_\Phi(A)$ if and only if $Y \in \mathfrak{g}_\Phi(I)$ (since ${}^t(1+Y)J(1+Y) = J + {}^t YJ + JY$), and then $(1+Y)^{-1} = 1-Y$. $\mathrm{H}_\Phi(A)$ is a group: block diagonal matrices of similitude 1 are closed under products, invertible (${}^t hJh = J$ forces $\det h = \pm 1$), and $h^{-1} = J^{-1}\, {}^t h J$ is block diagonal by (F1). (F4) $\mathfrak{g}_\Phi(A) = \bigoplus_j \mathfrak{g}_{\Phi,j}(A)$: for $Y \in \mathfrak{g}_\Phi(A)$ let $Y^{(j)}$ keep the entries (a,b) with $w(a) - w(b) = j$; by the weight condition on J, the entry (a,b) of ${}^t Y^{(j)}J + JY^{(j)}$ is that of ${}^t YJ + JY$ if $c_\Phi - w(a) - w(b) = j$ and 0 otherwise. (F5) For units $u_m \equiv 1$ of $A \in \mathrm{CNL}_{\mathcal{O}}$, $t_u = \mathrm{diag}(u^{w(a)})$ has similitude u^{c_Φ}, $(t_u M t_u^{-1})_{ab} = u^{w(a)-w(b)}M_{ab}$, t_u commutes with every weight diagonal matrix, and conjugation by t_u preserves $\mathrm{H}_\Phi(A)$ (as in (F2) with $\nu = u^{c_\Phi}$; t_u is diagonal and $\equiv 1$).

(Pz0). By (F2) over $\mathbb{F}$, conjugation by $\bar r(g)$ (the image of $r_0(g)$) preserves $\mathfrak{g}_j$; it is an action, continuous since $\bar r$ is; and $\bar r(\psi_q(N_q)) = 1$ by (Gq3).

Step 1: graded lifting. Let $C \in \mathrm{CNL}_{\mathcal{O}}$ be of finite length with a decomposition $C = \bigoplus_{i\in\mathbb{Z}^d} C_i$ of $\mathcal{O}$-modules, finitely many $C_i \neq 0$, $C_iC_k \subseteq C_{i+k}$ and $\mathcal{O}\cdot 1 \subseteq C_0$; call $X \in \mathrm{M}_n(C)$ *graded* if $X_{ab} \in C_{w(a)-w(b)}$. Graded matrices form a subring containing every $r_0(g)$ (weight diagonal with entries in $\mathcal{O}$), and the inverse of an invertible graded matrix is graded.

Claim (L). Let $\mathrm{pr}\colon C \to \bar C$ be a surjective $\mathcal{O}$-algebra homomorphism onto another such algebra with $\mathrm{pr}(C_i) = \bar C_i$ for all i, whose kernel I satisfies $I \subseteq C_j$ for one j and $\mathfrak{m}_C I = 0$. Then every graded $\bar h \in \mathrm{H}_\Phi(\bar C)$ is $\mathrm{pr}(h)$ for a graded $h \in \mathrm{H}_\Phi(C)$, with $h = 1$ if $\bar h = 1$. *Proof of (L).* Lift each entry $\bar h_{ab}$ with $\beta(a) = \beta(b)$ to an element of $C_{w(a)-w(b)}$ and put 0 elsewhere: a graded block diagonal h' with $\mathrm{pr}(h') = \bar h$, $h' \equiv 1 \pmod{\mathfrak{m}_C}$. $E = {}^t h' J h' - J$ has entries in I, satisfies ${}^tE = \pm E$ (with ${}^tJ = \pm J$), maps V_k into $V_{s(k)}$, and $E_{ab} \in C_{c_\Phi - w(a) - w(b)}$ (a term $h'_{ca}J_{cd}h'_{db}$ with $J_{cd} \neq 0$ has weight $w(c) - w(a) + w(d) - w(b) = c_\Phi - w(a) - w(b)$, and $J_{ab} \neq 0$ only if $c_\Phi = w(a) + w(b)$). Put $Y = -\frac{1}{2}J^{-1}E$ (ℓ odd). By (F1), Y is block diagonal and $Y_{ab} = -\frac{1}{2}\sum_c (J^{-1})_{ac}E_{cb} \in C_{w(a)-w(b)} \cap I$. Since ${}^t(J^{-1}) = \pm J^{-1}$ with the same sign, ${}^tYJ = -\frac{1}{2}E$ and $JY = -\frac{1}{2}E$. As $\mathfrak{m}_C I = 0$ and $h' \equiv 1$, ${}^t(h'+Y)J(h'+Y) = J + E + {}^tYJ + JY = J$. So $h = h' + Y$ works; if $\bar h = 1$, $h' = 1$ and $E = 0$.

Step 2: (Pz1). By (Gq1) and Theorem B.71, item 1, there is Mazur's universal lift $(R^\square, r^\square)$ of $\bar r$. Let $\tilde A$ be the completed tensor product over $\mathcal{O}$ of $R^\square$, B and $\mathcal{O}[[Z_{v,ab} : v \in T \setminus \{v_0\},\ 1 \le a, b \le n]]$, the coproduct in $\mathrm{CNL}_{\mathcal{O}}$: morphisms $\tilde A \to A$ are triples (a morphism $R^\square \to A$, a morphism $B \to A$, elements $z_{v,ab} \in \mathfrak{m}_A$). Let $\tilde r$, $\tilde\iota$ be the images of $r^\square$ and the identity of B, $\tilde\alpha_v = 1 + (Z_{v,ab})_{a,b}$ for $v \neq v_0$ and $\tilde\alpha_{v_0} = 1$, and $\tilde h_g = \tilde r(g) r_0(g)^{-1}$. Let $\mathfrak{a} \subseteq \tilde A$ be generated by the entries of ${}^t\tilde h_g J \tilde h_g - J$ and the entries $(\tilde h_g)_{ab}$ with $\beta(a) \neq \beta(b)$ ($g \in \Gamma$); of $\tilde r(\psi_q(x)) - 1$ ($q \in Q$, $x \in N_q$); of ${}^t\tilde\alpha_v J \tilde\alpha_v - J$ and $(\tilde\alpha_v)_{ab}$ with $\beta(a) \neq \beta(b)$; and of $\tilde r(\varphi_v(g))\tilde\alpha_v - \tilde\alpha_v \tilde\iota(\rho_v(g))$ ($v \in T$, $g \in \Gamma_v$). A morphism $f\colon \tilde A \to A$ kills $\mathfrak{a}$ if and only if $(f\circ\tilde\iota, f\circ\tilde r, (f(\tilde\alpha_v)))$ satisfies (Gq4)–(Gq6) (the congruences $\equiv 1$ hold automatically: $\tilde r$ lifts $\bar r = r_0 \bmod \mathfrak{m}_{\mathcal{O}}$, and $Z_{v,ab} \in \mathfrak{m}$). Conversely every framed lift $(\iota, r, (\alpha_v))$ to A is of this form for exactly one f: r is a lift of $\bar r$ (by (Gq4)), so it comes from exactly one morphism $R^\square \to A$, and $(\alpha_v - 1)_{ab} \in \mathfrak{m}_A$. The framed lift (residue map $B \to \mathbb{F}$, $\bar r$, $\alpha_v = 1$) to $\mathbb{F}$ satisfies (Gq4)–(Gq6) ($\bar r(\psi_q(N_q)) = 1$ by (Gq3); $\rho_v \equiv r_0 \circ \varphi_v \equiv \bar r \circ \varphi_v$ as $\rho_v(g) r_0(\varphi_v(g))^{-1} \in \mathrm{H}_\Phi(B)$), so $\mathfrak{a} \subseteq \mathfrak{m}_{\tilde A}$ and $R = \tilde A/\mathfrak{a} \in \mathrm{CNL}_{\mathcal{O}}$ with the images $(\iota_R, r_R, (\alpha_{R,v}))$ has the property (Pz1). (By this property, any R as in (Pz1) is isomorphic to this one by a unique isomorphism compatible with the framed lifts, so it suffices to prove (Pz2)–(Pz5) for one.)

Step 3: the torus coaction. Write $u_m = 1 + T_m$ in $A[[T_1, \dots, T_d]]$. On $P_B = \mathcal{O}[[X_{\sigma_B}]]$ let ρ_P be the continuous homomorphism to $P_B[[T_1, \dots, T_d]]$ with $\rho_P(X_s) = u^{\mathrm{wt}_B(s)} X_s$. As $u^i = \sum_{k\in\mathbb{N}^d} \binom{i}{k} T^k$ ($\binom{i}{k} = \prod_m \binom{i_m}{k_m}$), $\rho_P(f) = \sum_k E_k(f) T^k$ with $E_k(f) = \sum_u \binom{u}{k} f_{(u)}$, the $\mathfrak{m}$-adic limit of its finite partial sums over $|u|_\infty \le M$ (the remaining monomials have degree $> M/\max(1, |\mathrm{wt}_B|_\infty)$). As $\mathfrak{a}_B$ is homogeneous and closed, $E_k(\mathfrak{a}_B) \subseteq \mathfrak{a}_B$, so ρ_P induces a morphism $\rho_B\colon B \to B[[T_1, \dots, T_d]]$ of $\mathrm{CNL}_{\mathcal{O}}$ with $\rho_B(y) = u^i y$ for $y \in B_i$. Over $A = R[[T_1, \dots, T_d]]$ let $t = t_u$ as in (F5), $\iota' = \iota_{R,T} \circ \rho_B$ ($\iota_{R,T}$ applies ι_R to coefficients), $r'(g) = t\, r_R(g)\, t^{-1}$ and $\alpha'_v = t\, \alpha_{R,v}\, t^{-1}$. This is a framed lift: $r'(g) r_0(g)^{-1} = t(r_R(g) r_0(g)^{-1}) t^{-1} \in \mathrm{H}_\Phi(A)$ by (F5) ($r_0(g)$ is weight diagonal); (Gq5) and $\alpha'_{v_0} = 1$ are clear; $\alpha'_v \in \mathrm{H}_\Phi(A)$ by (F5); and $t\, \iota_R(\rho_v(g))\, t^{-1} = \iota'(\rho_v(g))$ entrywise, because $\rho_v(g)_{ab} \in B_{w(a)-w(b)}$, which gives the intertwining relation. By (Pz1) there is a morphism $\rho_R\colon R \to R[[T_1, \dots, T_d]]$ of $\mathrm{CNL}_{\mathcal{O}}$ with $\rho_R \circ \iota_R = \iota'$, $\rho_R \circ r_R = r'$, $\rho_R(\alpha_{R,v}) = \alpha'_v$. In the terminology of Lemma 45.18 for ρ_R: $r_R(g)_{ab}$, $(\alpha_{R,v})_{ab}$ and $r_R(g)_{ab} - r_0(g)_{ab}$ have torus weight $w(a) - w(b)$ (constants have weight 0, and $r_0(g)_{ab} \neq 0$ only if $w(a) = w(b)$), and $\iota_R(\pi_B(X_s))$ has torus weight $\mathrm{wt}_B(s)$. Likewise $\pi_B(X_s) \in \mathfrak{m}_B$ has torus weight $\mathrm{wt}_B(s)$ for ρ_B, so by Lemma 45.18, item 3, $\mathfrak{a}_B$ is generated by finitely many elements of single weights.

Step 4: the relative tangent space, and (Pz2). Let $\mathfrak{m} = \mathfrak{m}_R$ and $t^*_{\mathrm{rel}} = \mathfrak{m}/(\mathfrak{m}^2 + \mathfrak{m}_{\mathcal{O}}R + \iota_R(\mathfrak{m}_B)R)$, finite-dimensional. A linear form λ on t^*_{rel} defines $f_\lambda(y) = \bar{y} + \epsilon\lambda(\overline{y-c})$, where $c \in \mathcal{O}$ with $y - c \in \mathfrak{m}$ (another choice changes $y - c$ by an element of $\mathfrak{m}_{\mathcal{O}}$); it is a local $\mathcal{O}$-algebra homomorphism $R \to \mathbb{F}[\epsilon]$, as $yz - cc' = c(z-c') + c'(y-c) + (y-c)(z-c')$, and it kills $\iota_R(\mathfrak{m}_B)$. Conversely a morphism $f\colon R \to \mathbb{F}[\epsilon]$ is $y \mapsto \bar{y} + \epsilon\lambda'(y)$ with λ' additive, vanishing on $\mathcal{O}$, $\mathfrak{m}^2$ and $\mathfrak{m}_{\mathcal{O}}R$; if f kills $\iota_R(\mathfrak{m}_B)$, then λ' vanishes on $\iota_R(\mathfrak{m}_B)R$ and $f = f_\lambda$ for the form induced by λ'. So $\lambda \mapsto f_\lambda$ is a bijection onto the morphisms killing $\iota_R(\mathfrak{m}_B)$. By (Pz1) they correspond to the framed lifts to $\mathbb{F}[\epsilon]$ whose first entry is $B \to \mathbb{F} \subseteq \mathbb{F}[\epsilon]$. Write such a lift as $r(g) = (1 + \epsilon z(g))\bar{r}(g)$, $\alpha_v = 1 - \epsilon x_v$. Then, using (F3) with $I = \epsilon\mathbb{F}$ and $\iota(\rho_v(g)) = \bar{r}(\varphi_v(g))$: (Gq4) says $z(g) \in \mathfrak{g}_\Phi(\mathbb{F})$; r is a continuous homomorphism if and only if $z \in Z^1(\Gamma, \mathfrak{g}_\Phi(\mathbb{F}))$; (Gq5) says $z(\psi_q(N_q)) = 0$; and (Gq6) says $x_v \in \mathfrak{g}_\Phi(\mathbb{F})$, $x_{v_0} = 0$ and

$$(1 + \epsilon z(\varphi_v(g)))\bar{r}(\varphi_v(g))(1 - \epsilon x_v) = (1 - \epsilon x_v)\bar{r}(\varphi_v(g)), \quad \text{i.e.} \quad z(\varphi_v(g)) = g \cdot x_v - x_v.$$

By (F4) and (Pz0), these $(z, (x_v))$ form $\bigoplus_j Z^1_{\mathrm{fr}}(\mathfrak{g}_j)$. Let $\Theta(z, x)$ be the form λ of the corresponding morphism. For $y_{g,ab} = r_R(g)_{ab} - r_0(g)_{ab}$ and $y'_{v,ab} = (\alpha_{R,v} - 1)_{ab}$, elements of $\mathfrak{m}$, comparing f_λ with the lift gives

$$\Theta(z, x)(\bar{y}_{g,ab}) = \big(z(g)\bar{r}(g)\big)_{ab}, \qquad \Theta(z, x)(\bar{y}'_{v,ab}) = -(x_v)_{ab}.$$

The classes $\bar{y}_{g,ab}$, $\bar{y}'_{v,ab}$ span t^*_{rel}: a non-zero λ killing them gives $f_\lambda \neq f_0$ classifying the same framed lift (ι residual, $r = \bar{r}$, $\alpha_v = 1$), against the uniqueness in (Pz1). Hence Θ, a bijection given on a spanning set by expressions linear in (z, x), is a linear isomorphism $\bigoplus_j Z^1_{\mathrm{fr}}(\mathfrak{g}_j) \cong (t^*_{\mathrm{rel}})^\vee$; in particular each $Z^1_{\mathrm{fr}}(\mathfrak{g}_j)$ is finite-dimensional and almost all vanish. Let $V_j \subseteq t^*_{\mathrm{rel}}$ be spanned by the $\bar{y}_{g,ab}$, $\bar{y}'_{v,ab}$ with $w(a) - w(b) = j$. For $(z, x) \in Z^1_{\mathrm{fr}}(\mathfrak{g}_i)$, $\Theta(z, x)$ vanishes on V_j for $j \neq i$ ($\bar{r}(g)$ is weight diagonal). Hence: if $\Theta(z, x)$ with $(z, x) \in Z^1_{\mathrm{fr}}(\mathfrak{g}_j)$ kills V_j, it kills every V_i, hence $t^*_{\mathrm{rel}} = \sum_i V_i$, so $(z, x) = 0$. An element of $V_j \cap \sum_{i \neq j} V_i$ is killed by every form $\Theta(\sum_i \zeta_i)$, $\zeta_i \in Z^1_{\mathrm{fr}}(\mathfrak{g}_i)$ ($\Theta(\zeta_j)$ kills $\sum_{i \neq j} V_i$, and $\Theta(\zeta_i)$, $i \neq j$, kills V_j), so it is 0; thus $t^*_{\mathrm{rel}} = \bigoplus_j V_j$. A form on V_j, extended by 0 on the other V_i, is $\Theta(\sum_i \zeta_i)$ with $\Theta(\zeta_i)$ zero on V_i for $i \neq j$, hence $\zeta_i = 0$ for $i \neq j$; so restriction is an isomorphism $Z^1_{\mathrm{fr}}(\mathfrak{g}_j) \cong V_j^\vee$. Choose $\tau = \bigsqcup_j \tau_j$, where τ_j indexes elements y_t among the $y_{g,ab}$, $y'_{v,ab}$ with $w(a) - w(b) = j$ whose classes form a basis of V_j, and $\mathrm{wt}_\tau(t) = j$ for $t \in \tau_j$. This is (Pz2).

Step 5: (Pz3). $R = \mathcal{O} + \mathfrak{m}$, so $\iota_R(\mathfrak{m}_B)R \subseteq \iota_R(\mathfrak{m}_B) + \mathfrak{m}^2$, and $\mathfrak{m}_B$ is generated by ϖ and the $\pi_B(X_s)$ (constant terms of $\mathfrak{a}_B$ vanish). With Step 4, $\mathfrak{m}/\mathfrak{m}^2$ is spanned by the images of ϖ and the $\Pi(X_s)$, $s \in \sigma_B \sqcup \tau$, all of which lie in $\mathfrak{m}$. By Nakayama's lemma and the complete Nakayama lemma [166, Thm. 8.4], Π is surjective. $\Pi|_{\mathcal{O}[[X_{\sigma_B}]]} = \iota_R \circ \pi_B$ (continuous, equal on the X_s). By Step 3 each $\Pi(X_s)$ has torus weight equal to its weight, so Lemma 45.18, items 1 and 2, give the homogeneity of $\ker\Pi$ and, with the torus weights of Step 3, the entries in $\Pi(\mathcal{O}[[X]]_{w(a)-w(b)})$.

Step 6: relative minimality. For $f \in \mathcal{J} = \ker\Pi$ the coefficient $a_t(f)$ of X_t ($t \in \tau$) lies in $\mathfrak{m}_{\mathcal{O}}$: write $f = c_0 + \sum_{s \in \sigma_B} a_s X_s + \sum_t a_t(f) X_t + f_2$ with $f_2 \in (X)^2$; $\Pi(f) = 0$ gives $c_0 \in \mathfrak{m}_{\mathcal{O}}$, and in t^*_{rel}, where the images of c_0, $\Pi(a_s X_s) \in \iota_R(\mathfrak{m}_B)R$ and $\Pi(f_2) \in \mathfrak{m}^2$ vanish, $\sum_t \bar{a}_t(f)\bar{y}_t = 0$, so $\bar{a}_t(f) = 0$.

Step 7: the graded space of relations. Let $\mathcal{J}_B = \mathfrak{a}_B P \subseteq \mathcal{J}$ and $\mathfrak{n} = \mathfrak{m}_P$. An ideal generated by elements of single weights is homogeneous ($(gh)_{(u)} = g\,h_{(u-i)}$ for g of weight i); so $\mathcal{J}_B$ (Step 3), $\mathfrak{n}^N$ (generated by the monomials $\varpi^e X^m$) and $\mathfrak{n}\mathcal{J}$ (Lemma 45.18, item 3, for Π) are homogeneous, and so are their sums. By Artin–Rees choose $N_0 \geq 1$ with $\mathcal{J} \cap \mathfrak{n}^{N_0} \subseteq \mathfrak{n}\mathcal{J}$; let $W = \max(1, \max_s |\mathrm{wt}(s)|_\infty)$, so that monomials of weight u with $|u|_\infty > WN_0$ have degree $> N_0$. Put $\mathcal{V} = \mathcal{J}/(\mathcal{J}_B + \mathfrak{n}\mathcal{J})$, finite-dimensional over $\mathbb{F}$, and $\mathcal{V}_j$ the image of $\mathcal{J} \cap \mathcal{O}[[X]]_j$. For $f \in \mathcal{J}$, $f - \sum_{|u|_\infty \leq WN_0} f_{(u)} \in \mathcal{J} \cap \mathfrak{n}^{N_0} \subseteq \mathfrak{n}\mathcal{J}$ with $f_{(u)} \in \mathcal{J}$ (Pz3), so the $\mathcal{V}_j$ span $\mathcal{V}$; and if $\sum_u f_u \in \mathcal{J}_B + \mathfrak{n}\mathcal{J}$ with $f_u \in \mathcal{J} \cap \mathcal{O}[[X]]_u$, each f_u is a weight component of an element of

this homogeneous ideal and lies in it. So $\mathcal{V} = \bigoplus_j \mathcal{V}_j$. Choose $f_{j,1}, \dots, f_{j,\mathrm{nf}(j)} \in \mathcal{J} \cap \mathcal{O}[[X]]_j$ lifting a basis of $\mathcal{V}_j$; by Nakayama's lemma applied to $\mathcal{J}/(\mathcal{J}_B + (f_{j,i}))$, $\mathcal{J} = \mathcal{J}_B + (f_{j,i})_{j,i}$. With $\kappa = \{(j,i)\}$ and $\mathrm{wf}(j,i) = j$, it remains for (Pz4) to show $\dim \mathcal{V}_j \le \dim \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_j)$; fix j and assume $\dim \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_j) < \dim \mathcal{V}_j$.

Step 8: the graded small extension of weight j. Let $\mathcal{W} \subseteq \mathcal{J}$ be the preimage of $\bigoplus_{i \neq j} \mathcal{V}_i$. It is a homogeneous ideal containing $\mathcal{J}_B + \mathfrak{n}\mathcal{J}$: for $f \in \mathcal{W}$ the images of the $f_{(u)} \in \mathcal{J}$ are the components of $\bar{f}$ (Step 7), so $f_{(j)} \in \mathcal{J}_B + \mathfrak{n}\mathcal{J}$ and $f_{(u)} \in \mathcal{W}$ for $u \neq j$. Put $C = P/(\mathcal{W} + \mathfrak{n}^{N_0})$ and $\bar{C} = P/(\mathcal{J} + \mathfrak{n}^{N_0}) = R/\mathfrak{m}^{N_0}$, of finite length, graded by the images C_i, $\bar{C}_i$ of the $\mathcal{O}[[X]]_i$ (direct sums with $|i|_\infty \le WN_0$, the ideals being homogeneous), so that $\mathrm{pr}\colon C \to \bar{C}$ satisfies the hypotheses of Claim (L): its kernel I is the image of $\mathcal{J} = (\mathcal{J} \cap \mathcal{O}[[X]]_j) + \mathcal{W}$, so $I \subseteq C_j$; $\mathfrak{m}_C I = 0$ as $\mathfrak{n}\mathcal{J} \subseteq \mathcal{W}$; and $I \cong \mathcal{J}/\mathcal{W} \cong \mathcal{V}_j$ (as $\mathcal{J} \cap \mathfrak{n}^{N_0} \subseteq \mathcal{W}$). Both are $\mathcal{O}/\varpi^{N_0}$-algebras. As $\mathfrak{a}_B \subseteq \mathcal{W}$, $\mathcal{O}[[X_{\sigma_B}]] \to C$ induces $\iota_C\colon B \to C$, mapping B_i into C_i, and $\mathrm{pr} \circ \iota_C = \iota_{\bar{C}}$, where $\iota_{\bar{C}}$, $\bar{r}$ (abusing notation only inside Steps 8–12) and $\bar{\alpha}_v$ denote ι_R, r_R, $\alpha_{R,v}$ followed by $R \to \bar{C}$: a framed lift to $\bar{C}$ whose matrices are graded by (Pz3). I is an $\mathbb{F}$-vector space, $\mathfrak{g}_{\Phi,j}(I) = \mathfrak{g}_j \otimes_{\mathbb{F}} I$, and for $X \in \mathrm{M}_n(I)$ and $Z \in \mathrm{GL}_n(C)$ reducing to $\bar{r}_0(g)$ modulo $\mathfrak{m}_C$, $ZXZ^{-1} = g \cdot X$. A graded matrix with entries in I has its non-zero entries in positions of weight j ($I \cap C_i = 0$ for $i \neq j$).

Step 9: graded local homomorphisms. For $v \in T$ choose by (L) a graded $\tilde{\alpha}_v \in \mathrm{H}_\Phi(C)$ lifting $\bar{\alpha}_v$, with $\tilde{\alpha}_{v_0} = 1$, and put $\rho'_v(g) = \tilde{\alpha}_v\, \iota_C(\rho_v(g))\, \tilde{\alpha}_v^{-1}$: a continuous graded homomorphism $\Gamma_v \to \mathrm{GL}_n(C)$ lifting $\bar{r} \circ \varphi_v$ (by (Gq6) over $\bar{C}$), with

$$\rho'_v(g) r_0(\varphi_v(g))^{-1} = \tilde{\alpha}_v\, \iota_C(\rho_v(g) r_0(\varphi_v(g))^{-1}) (r_0(\varphi_v(g)) \tilde{\alpha}_v^{-1} r_0(\varphi_v(g))^{-1}) \in \mathrm{H}_\Phi(C)$$

by (F2), (F3). For $q \in Q$: $\bar{h}_g = \bar{r}(\psi_q(g)) r_0(\psi_q(g))^{-1} \in \mathrm{H}_\Phi(\bar{C})$ is graded, depends only on gN_q (both factors kill N_q by (Gq3), (Gq5)), and is constant on the cosets of the open normal subgroup $U_q \supseteq N_q$ on which $\bar{r} \circ \psi_q$ and $r_0 \circ \psi_q \bmod \varpi^{N_0}$ are trivial. Choosing by (L) graded lifts $h_g \in \mathrm{H}_\Phi(C)$ on representatives of Γ_q/U_q ($h = 1$ at the trivial coset), $\sigma_q(g) = h_g r_0(\psi_q(g))$ is a continuous graded map on Γ_q/N_q lifting $\bar{r} \circ \psi_q$, with $\sigma_q(1) = 1$. Then $\sigma_q(g)\sigma_q(g')\sigma_q(gg')^{-1} = h_g (r_0(\psi_q(g)) h_{g'} r_0(\psi_q(g))^{-1}) h_{gg'}^{-1}$ lies in $\mathrm{H}_\Phi(C)$, is graded and reduces to 1, so by (F3) and Step 8 it is $1 + k_q^\circ(g,g')$ with k_q° a continuous 2-cocycle of Γ_q/N_q in $\mathfrak{g}_j \otimes I$. By (Gq3), $k_q^\circ = d\omega_q$, and $\rho'_q(g) = (1 - \omega_q(g))\sigma_q(g)$ is a continuous graded homomorphism $\Gamma_q \to \mathrm{GL}_n(C)$, trivial on N_q, lifting $\bar{r} \circ \psi_q$, with $\rho'_q(g) r_0(\psi_q(g))^{-1} \in \mathrm{H}_\Phi(C)$.

Step 10: the obstruction class. As in Step 9 (with Γ, an open normal subgroup on which $\bar{r}$ and $r_0 \bmod \varpi^{N_0}$ are trivial, and (L)), choose a continuous graded map $\sigma\colon \Gamma \to \mathrm{GL}_n(C)$ lifting $\bar{r}$ with $\sigma(1) = 1$ and $\sigma(g) r_0(g)^{-1} \in \mathrm{H}_\Phi(C)$. Then $\sigma(g)\sigma(g')\sigma(gg')^{-1} = 1 + k(g,g')$ with $k \in Z^2(\Gamma, \mathfrak{g}_j \otimes I)$, and $\sigma(\varphi_v(g)) = (1 + k_v(g))\rho'_v(g)$, $\sigma(\psi_q(g)) = (1 + k_q(g))\rho'_q(g)$ with $k_v \in C^1(\Gamma_v, \mathfrak{g}_j \otimes I)$, $k_q \in C^1(\Gamma_q, \mathfrak{g}_j \otimes I)$ (Step 8, (F3)). Expanding $\sigma(\varphi_v(g))\sigma(\varphi_v(g'))$ in two ways gives $\varphi_v^* k = dk_v$, and likewise $\psi_q^* k = dk_q$. For $\phi \in I^\vee = \mathrm{Hom}_{\mathbb{F}}(I, \mathbb{F})$ the triple $(\phi \circ k, (\phi \circ k_v), (\phi \circ k_q))$ lies in $Z^2_{\mathrm{fr}}(\mathfrak{g}_j)$, and its class $o(\phi) \in \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_j)$ is linear in ϕ.

Step 11: a vanishing class gives a framed lift. Since $\dim I^\vee = \dim \mathcal{V}_j > \dim \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_j)$, some $\phi \neq 0$ has $o(\phi) = 0$: $\phi k = dh$, $\phi k_v = \varphi_v^* h - dy_v$, $\phi k_q = \psi_q^* h - e_q$ with $h \in C^1(\Gamma, \mathfrak{g}_j)$, $y_v \in \mathfrak{g}_j$, $e_q \in Z^1(\Gamma_q, \mathfrak{g}_j)$, $e_q(N_q) = 0$. Let $I' = \ker \phi$, an ideal of C (as $\mathfrak{m}_C I = 0$), $C' = C/I'$, graded with $C'_j \supseteq I/I' \cong \mathbb{F}$ via ϕ, and read $h(g)$, y_v, $e_q(g)$ as elements of $\mathfrak{g}_{\Phi,j}(I/I')$, graded matrices. Over C' put $\sigma'(g) = (1 - h(g))\sigma(g)$; then $\sigma'(g)\sigma'(g')\sigma'(gg')^{-1} = 1 + \phi k(g,g') - dh(g,g') = 1$, so σ' is a continuous graded homomorphism lifting $\bar{r}$, and $\sigma'(g) r_0(g)^{-1} \in \mathrm{H}_\Phi(C')$. For $v \in T$,

$$\sigma'(\varphi_v(g)) = (1 + \phi k_v(g) - h(\varphi_v(g)))\rho'_v(g) = (1 - (g \cdot y_v - y_v))\rho'_v(g) = (1 + y_v)\rho'_v(g)(1 + y_v)^{-1};$$

for $q \in Q$, $\sigma'(\psi_q(g)) = (1 - e_q(g))\rho'_q(g)$, which is 1 on N_q. Put $c = 1 + y_{v_0}$, $s''(g) = c^{-1}\sigma'(g)c$ and $\alpha''_v = c^{-1}(1 + y_v)\tilde{\alpha}_v$. Then $\alpha''_{v_0} = 1$, $\alpha''_v \in \mathrm{H}_\Phi(C')$ (F3), s'' satisfies (Gq4) by (F2), (F3) and

(Gq5), and $s''(\varphi_v(g))\alpha''_v = c^{-1}(1+y_v)\rho'_v(g)\tilde{\alpha}_v = \alpha''_v\,\iota_{C'}(\rho_v(g))$ with $\iota_{C'} = (C \to C') \circ \iota_C$. So $(\iota_{C'}, s'', (\alpha''_v))$ is a framed lift to C'.

Step 12: contradiction, and (Pz4). By (Pz1) there is $F\colon R \to C'$ with $F \circ \iota_R = \iota_{C'}$, $F \circ r_R = s''$, $F(\alpha_{R,v}) = \alpha''_v$. F followed by $C' \to \bar{C}$ is the projection $R \to \bar{C}$: both classify the framed lift $(\iota_{\bar{C}}, \bar{r}, (\bar{\alpha}_v))$, since s'', α''_v reduce to $\bar{r}$, $\bar{\alpha}_v$ (c, $1+y_v$, $1-h$ reduce to 1). Let $\alpha\colon P \to C'$ be the projection and $\beta = F \circ \Pi$. Then $\delta = \alpha - \beta$ takes values in I/I', which $\mathfrak{m}_{C'}$ kills, so $\delta(fg) = \bar{f}\delta(g) + \bar{g}\delta(f)$ with residues $\bar{f}, \bar{g} \in \mathbb{F}$, and $\delta = 0$ on $\mathcal{O}[[X_{\sigma_B}]]$ (there $\alpha = \iota_{C'} \circ \pi_B = F \circ \iota_R \circ \pi_B = \beta$, by continuity). For $f \in P$ write $f = f_0 + \sum_t X_t g_t$ with $f_0 \in \mathcal{O}[[X_{\sigma_B}]]$, each term containing some X_t assigned to the first such t; the constant term of g_t is $a_t(f)$ and $\delta(f) = \sum_t \bar{a}_t(f)\delta(X_t)$. By Step 6, $\delta(\mathcal{J}) = 0$; and $\beta(\mathcal{J}) = 0$. Hence $\alpha(\mathcal{J}) = 0$; but $\alpha(\mathcal{J})$ is the image $I/I' \neq 0$ of $\mathcal{J}$ in C'. This contradiction proves $\dim \mathcal{V}_j \leq \dim \mathrm{Ob}_{\mathrm{fr}}(\mathfrak{g}_j)$, hence (Pz4).

Step 13: (Pz5). Under the hypothesis, $(x_B, r_0, (1)_v)$ is a framed lift to $\mathcal{O}$ ((Gq4) trivially, (Gq5) by (Gq3), (Gq6) by the hypothesis), so (Pz1) gives x_R. $x_R \circ \Pi$ is a continuous $\mathcal{O}$-algebra homomorphism $P \to \mathcal{O}$ killing every X_s: $x_R(\iota_R(\pi_B(X_s))) = x_B(\pi_B(X_s)) = 0$, $x_R(r_R(g)_{ab} - r_0(g)_{ab}) = 0$, $x_R((\alpha_{R,v}-1)_{ab}) = 0$. So it is the constant-term homomorphism, and $\ker\Pi$ lies in its kernel. □

Lemma 45.22. *Let ℓ be an odd prime, $\mathbb{F}$ a finite field of characteristic ℓ, S a finite set of primes with $\ell \in S$, $G_S = G_{\mathbb{Q},S}$ (ramification allowed at S and ∞), $c \in G_S$ the image of a complex conjugation, and for every $p \in S$ a decomposition group $D_p \supseteq I_p$ at p with its map to G_S. Let $T \subseteq S$ with $\ell \in T$, $Q = S \setminus T$, and for $q \in Q$ let $N_q \subseteq I_q$ be a closed normal subgroup of D_q with I_q/N_q finite of order prime to ℓ. Let M be a finite-dimensional $\mathbb{F}$-vector space with a continuous $\mathbb{F}$-linear action of G_S on which every N_q acts trivially, and form $Z^1_{\mathrm{fr}}(M)$ and $\mathrm{Ob}_{\mathrm{fr}}(M)$ for $\Gamma = G_S$, the set T with $v_0 = \ell$ and $\Gamma_v = D_v$, and the set Q with $\Gamma_q = D_q$ and N_q. Then $\mathrm{Ob}_{\mathrm{fr}}(M)$ is finite-dimensional and*

$$\dim_{\mathbb{F}} \mathrm{Ob}_{\mathrm{fr}}(M) = \dim_{\mathbb{F}} Z^1_{\mathrm{fr}}(M) + \dim_{\mathbb{F}} M^{c=1} + \dim_{\mathbb{F}} H^0(G_S, M^\vee).$$

Proof. All cohomology groups below are $\mathbb{F}$-vector spaces, finite by Theorem B.37, item 1, and Theorem B.29, item 1; $\dim = \dim_{\mathbb{F}}$, which is $\log_{\#\mathbb{F}}$ of the cardinality (also for $M^\vee$, an $\mathbb{F}$-space through M). Write $h^i = \dim H^i(G_S, M)$, $h^i_p = \dim H^i(D_p, M)$, and for $q \in Q$ let $L_q \subseteq H^1(D_q, M)$ be the classes of cocycles vanishing on N_q (a coboundary $g \mapsto gm - m$ vanishes on N_q, so this is a condition on classes). Let

$$\mathrm{res}^1\colon H^1(G_S, M) \to \bigoplus_{v\in T} H^1(D_v, M) \oplus \bigoplus_{q\in Q} H^1(D_q, M)/L_q,$$
$$\mathrm{res}^2\colon H^2(G_S, M) \to \bigoplus_{p\in S} H^2(D_p, M)$$

be the restrictions, and $\mathrm{Sel} = \ker \mathrm{res}^1$.

Step 1: $\dim Z^1_{\mathrm{fr}}(M) = \dim \mathrm{Sel} + \sum_{v\in T} h^0_v - h^0$. The map $(x, (x_v)) \mapsto [x]$ sends $Z^1_{\mathrm{fr}}(M)$ into Sel ($x|_{D_v} = dx_v$; x vanishes on N_q). It is onto: for a class in Sel choose a cocycle x and $m_v \in M$ with $x|_{D_v} = dm_v$; x vanishes on N_q (its restriction to D_q is a cocycle vanishing on N_q plus a coboundary, and coboundaries vanish on N_q); then $(x - dm_\ell, (m_v - m_\ell)_v) \in Z^1_{\mathrm{fr}}(M)$. Its kernel consists of the $(dm, (m+a_v)_v)$ with $m \in M$, $a_v \in M^{D_v}$ and $m + a_\ell = 0$; the parameters $(m, (a_v))$ with $a_\ell = -m$ form a space of dimension $\sum_{v\in T} h^0_v$ (choose $a_\ell \in M^{D_\ell}$ and a_v, $v \neq \ell$, freely), and the parameter map has kernel $\{(m, (-m)_v) :\ m \in M^{G_S}\}$, of dimension h^0.

Step 2: $\dim \mathrm{Ob}_{\mathrm{fr}}(M) = \dim \operatorname{coker} \mathrm{res}^1 + \dim \ker \mathrm{res}^2$. The map $\kappa\colon \mathrm{Ob}_{\mathrm{fr}}(M) \to H^2(G_S, M)$, $[(k, (k_v), (k_q))] \mapsto [k]$, is well defined ($B^2_{\mathrm{fr}}$ has first entries dh) and has image $\ker \mathrm{res}^2$: $k|_{D_p} = dk_p$ gives $\mathrm{res}^2[k] = 0$, and conversely such k_p exist if $\mathrm{res}^2[k] = 0$. If $[k] = 0$, then $k = dh$, and subtracting $(dh, (h|_{D_v}), (h|_{D_q})) \in B^2_{\mathrm{fr}}(M)$ leaves $(0, (a_v), (a_q))$ with $a_p \in Z^1(D_p, M)$. So $\ker \kappa$ is the image of $\partial\colon \bigoplus_v Z^1(D_v, M) \oplus \bigoplus_q Z^1(D_q, M) \to \mathrm{Ob}_{\mathrm{fr}}(M)$, $(a_p) \mapsto [(0, (a_p))]$, and $(0, (a_p)) \in B^2_{\mathrm{fr}}(M)$ exactly when $a_v = h|_{D_v} - dy_v$ and $a_q = h|_{D_q} - e_q$ with $h \in Z^1(G_S, M)$, $y_v \in M$ and e_q cocycles vanishing on N_q. Hence $\ker \kappa \cong \operatorname{coker} \mathrm{res}^1$.

Step 3: the local terms. For $v \in T$, $h^1_v - h^0_v - h^2_v$ is $\dim M$ if $v = \ell$ and 0 otherwise (Theorem B.29, item 4). For $q \in Q$, L_q is the image of the inflation $H^1(D_q/N_q, M) \to H^1(D_q, M)$, which is injective; as I_q/N_q is finite of order prime to ℓ, inflation-restriction gives $H^1(D_q/N_q, M) \cong H^1(D_q/I_q, M^{I_q})$, and for the procyclic group $D_q/I_q \cong \widehat{\mathbb{Z}}$, topologically generated by a Frobenius Fr, $H^1(D_q/I_q, V) \cong V/(\mathrm{Fr} - 1)V$, of the same dimension as $V^{\mathrm{Fr}=1}$ [191]. So $\dim L_q = \dim M^{D_q} = h^0_q$, and $h^1_q - h^2_q - \dim L_q = 0$ (Theorem B.29, item 4, $q \neq \ell$).

Step 4: the count. By Steps 1–2, with $\dim \operatorname{coker} \mathrm{res}^1 = \sum_v h^1_v + \sum_q (h^1_q - \dim L_q) - h^1 + \dim \mathrm{Sel}$ and, by Theorem B.37, item 3, $\dim \ker \mathrm{res}^2 = h^2 - \sum_{p \in S} h^2_p + \dim H^0(G_S, M^\vee)$,

$$\dim \mathrm{Ob}_{\mathrm{fr}}(M) - \dim Z^1_{\mathrm{fr}}(M) = \sum_{v \in T} (h^1_v - h^0_v - h^2_v) + \sum_{q \in Q} (h^1_q - h^2_q - \dim L_q) + (h^0 - h^1 + h^2) + \dim H^0(G_S, M^\vee).$$

By Step 3 the first two sums are $\dim M$. By Theorem B.37, item 2, for $\mathbb{Q}$ (one archimedean place, $H^0(\mathbb{R}, M) = M^{c=1}$, $|\#M|_\infty = \#M$), $h^0 - h^1 + h^2 = \dim M^{c=1} - \dim M$. This gives the formula. □

Proposition 45.23. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, L a symplectic local base of $\mathfrak{D}$, and suppose there is a framed relative presentation over L. Then $\mathfrak{D}$ has a symplectic weighted model.*

Proof. Let $(U, \iota, r_U, (\alpha_v), \tau, \mathrm{wt}_\tau, (y_t), \kappa, (f_k), \mathrm{wf})$ be a framed relative presentation over L, $P = \mathcal{O}[[X_s : s \in \sigma_L \sqcup \tau]]$ with $\Pi_U\colon P \to U$, $\tau_w = \#\mathrm{wt}_\tau^{-1}(w)$, $b = \#(T \setminus \{\ell\})$, $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, and κ_a the a-th diagonal entry of r_0. By (Fv3), $x_U(\Pi_U(f)) = f(0)$, the constant term, for $f \in P$.

Step 1: preliminaries. (a) Similitude, (Se2) and the local conditions are polynomial identities in the entries, so they pass to images under ring homomorphisms and to conjugates by matrices of similitude 1 (for the ordinary condition: the characteristic polynomial and the products of the $\rho(s_0) - \kappa_j(s_0)$ are conjugation equivariant). Hence $r_0 = x_U \circ r_U$ satisfies (Se1), (Se2), and $r_0|_{D_v} = x_L \circ \rho_v$ (Bq2) satisfies the local condition at v. (b) Put $X^{(1)} = E_{12} - E_{34}$, $X^{(2)} = E_{14}$, $X^{(3)} = E_{32}$, $X^{(4)} = E_{21} - E_{43}$, $X^{(5)} = E_{41}$, $X^{(6)} = E_{23}$, and let $p(e)$ be the position $(1,2), (1,4), (3,2), (2,1), (4,1), (2,3)$ for $e = 1, \dots, 6$; their weights are the six elements of $\mathcal{W}_4$ with odd first coordinate, $\lambda_a \neq \lambda_b$ at $p(e) = (a, b)$, and $X^{(e)}$ has entry 1 at $p(e)$ and 0 at $p(e')$, $e' \neq e$. Put $X_m = E_{31} + E_{42}$, of weight $(0, -1)$, with $r_0(g) X_m r_0(g)^{-1} = \Psi(g)^{-1} X_m$. These seven matrices lie in $\mathfrak{sp}_4(\mathcal{O})$.

(c) (Six blocks.) Let A be a local ring and $X \in \mathrm{M}_4(A)$ of similitude $\nu \in A^\times$ with off-diagonal entries in $\mathfrak{m}_A$ and $X_{12} = X_{14} = X_{32} = X_{21} = X_{41} = X_{23} = 0$. Then X is block diagonal; if moreover $\nu = 1$, $X_{13} = X_{31} = 0$ and $X_{11} = X_{22} = 1$, then $X = 1$. Indeed $\det X$ is a unit, so the diagonal entries are units; the entry (a, b) of ${}^t X J_4 X$ is $X_{1a}X_{4b} + X_{2a}X_{3b} - X_{3a}X_{2b} - X_{4a}X_{1b}$, and at $(2,4)$ and $(3,1)$ it equals $X_{22}X_{34}$ and $-X_{43}X_{11}$, which must vanish; under the further hypotheses the entries $(1,4)$, $(2,3)$, $(3,4)$, $(1,2)$ give $X_{44} = 1$, $X_{33} = 1$, $X_{24} = 0$, $X_{42} = 0$. (d) (Dual numbers.) Let $\Lambda = \mathcal{O}$ or $\mathcal{O}/a\mathcal{O}$ with $a \in \mathfrak{m}_{\mathcal{O}} \setminus \{0\}$, so $\Lambda[\epsilon] \in \mathrm{CNL}_{\mathcal{O}}$. If $(\Lambda[\epsilon], \iota', r', (\alpha'_v))$ is a framed lift over L reducing modulo ϵ to $(x_L, r_0, (1))$ (read modulo a), the morphism $y\colon U \to \Lambda[\epsilon]$

of (Fv1) is $x_U + \epsilon D$ (modulo a) with $D\colon U \to \Lambda$ $\mathcal{O}$-linear, $D(fh) = x_U(f)D(h) + x_U(h)D(f)$, and D applied to $r_U(g)$, α_v, ι gives the ϵ-parts of $r'(g)$, α'_v, ι': y followed by $\epsilon \mapsto 0$ and x_U both classify $(x_L, r_0, (1))$ (by (Fv3)), so they agree by (Fv1). By (Bq1) and (Bq2), a family of lifts ρ'_v of $\bar{r}_0|_{D_v}$ to $\Lambda[\epsilon]$ satisfying the local conditions and reducing to $r_0|_{D_v}$ is $\iota' \circ \rho_v$ for exactly one ι', and ι' reduces to x_L.

Step 2: independent derivations of the framing entries. For $v \in T$ and $1 \le e \le 6$ put $t_{v,e} = r_U(\phi)_{p(e)}$ if $v = \ell$ and $t_{v,e} = (\alpha_v)_{p(e)}$ if $v \ne \ell$; $t_{v,e} \in U_{w_e}$ with $w_e = \mathrm{wt}_4(p(e))$ (Fv3), and $x_U(t_{v,e}) = 0$. Over $\mathcal{O}[\epsilon]$: for $v = \ell$ take $r' = (1 + \epsilon X^{(e)})r_0(1 - \epsilon X^{(e)})$, all $\alpha'_{v'} = 1$, and ι' classifying the local lifts $r'|_{D_{v'}}$; for $v \ne \ell$ take $r' = r_0$, $\alpha'_v = 1 + \epsilon X^{(e)}$, $\alpha'_{v'} = 1$ for $v' \ne v$, and ι' classifying $(1 - \epsilon X^{(e)})r_0|_{D_v}(1 + \epsilon X^{(e)})$ at v and $r_0|_{D_{v'}}$ at $v' \ne v$. By Step 1(a),(b) these local lifts satisfy the local conditions and the triples are framed lifts ((Fw3) at v: $r_0(1 + \epsilon X) = (1 + \epsilon X)(1 - \epsilon X)r_0(1 + \epsilon X)$). Step 1(d) gives point derivations $D_{v,e}$ of U with

$$D_{\ell,e}(t_{\ell,e'}) = X^{(e)}_{ab}(\kappa_b(\phi) - \kappa_a(\phi)) \quad ((a,b) = p(e')),$$
$$D_{\ell,e}(t_{v',e'}) = 0 \ (v' \ne \ell), \qquad D_{v,e}(t_{v',e'}) = [v' = v][e' = e] \ (v \ne \ell).$$

By (Ae1), $\bar{\kappa}_a(\phi) \ne \bar{\kappa}_b(\phi)$ when $\lambda_a \ne \lambda_b$, so $D_{\ell,e}(t_{\ell,e}) \ne 0$ and $D_{\ell,e}(t_{\ell,e'}) = 0$ for $e' \ne e$. Choose $g_{v,e} \in \mathcal{O}[[X]]_{w_e}$ with $\Pi_U(g_{v,e}) = t_{v,e}$ (Fv3); its constant term is $x_U(t_{v,e}) = 0$. The maps $\delta_{v,e} = D_{v,e} \circ \Pi_U$ vanish on $\mathfrak{a}_L P \subseteq \ker \Pi_U$, satisfy $\delta(fh) = f(0)\delta(h) + h(0)\delta(f)$, and $\delta_{v,e}(g_{v',e'}) \ne 0$ if and only if $(v', e') = (v, e)$.

Step 3: the cut. By (Bq3), $\mathcal{O}[[X_{\sigma_L}]]/\mathfrak{a}_L$ is smooth at the origin with tangent dimensions $d_\ell + b\,d_p$. Proposition 45.24, applied with $\sigma = \sigma_L$, τ, $\mathfrak{a} = \mathfrak{a}_L$ and the $6(b+1)$ elements $g_{v,e}$, gives a homogeneous ideal $\mathfrak{b} \supseteq \mathfrak{a}_L P + (g_{v,e})$ with constant terms 0 such that $R = P/\mathfrak{b}$ (weights wt_L, wt_τ, with values in $\mathcal{W}_4$) is a domain, smooth at the origin with tangent dimensions $d_\ell(w) + b\,d_p(w) + \tau_w - (b+1)[w \in \{w_1, \dots, w_6\}]$. With

$$r = 1 + b + \tau_{(0,-1)}, \qquad r' = 2 + b + \tau_{(0,1)}, \qquad m = 2 + 2b + \tau_{(0,0)},$$

this function is $t_{r,r',m}$ ($\tau_w = 0$ outside $\{(0,0),(0,\pm 1)\}$ by (Fv4)), so (Wm1) holds.

Step 4: the equations. The elements $s \in U$: for $v \in T \setminus \{\ell\}$, $(\alpha_v)_{13}$, $(\alpha_v)_{31}$, $(\alpha_v)_{11} - 1$, $(\alpha_v)_{22} - 1$, of weights $(0,1), (0,-1), (0,0), (0,0)$; and $h(r_U)_{13}$, $h(r_U)_{31}$, of weights $(0,1), (0,-1)$. Each lies in U_w for its weight w (Fv3; $1 \in U_{(0,0)}$) and has $x_U(s) = 0$ ($x_U(\alpha_v) = 1$, $x_U(r_U(g)_{13}) = r_0(g)_{13} = 0$); choose lifts $\tilde{s} \in \mathcal{O}[[X]]_w$, of constant term 0. By (Fv4), every $\mathrm{wf}(k)$ lies in $\{(0,0),(0,\pm 1)\}$, with $\tau_w + c(w)$ relations of weight w. Let F, E, Z list the images in R of the f_k and $\tilde{s}$ of weights $(0,-1)$, $(0,1)$, $(0,0)$: they have $(\tau_{(0,-1)}+1)+b+1 = r+1$, $(\tau_{(0,1)}+1)+b+1 = r'$ and $(\tau_{(0,0)} + 2) + 2b = m$ members, and (Wm2) holds. Let $\mathfrak{c} = \mathfrak{b} + (f_k)_k + (\tilde{s})_s$, a proper ideal (constant terms 0), $S = P/\mathfrak{c} \in \mathrm{CNL}_\mathcal{O}$, and $q\colon R \to S$ the projection: surjective with kernel generated by F, E, Z (Wm3). As $\mathfrak{c} \supseteq \mathfrak{a}_L P + (f_k) = \ker \Pi_U$ (Fv2), there is a surjective $\mathcal{O}$-algebra homomorphism $\sigma_S\colon U \to S$ with $\sigma_S \circ \Pi_U$ the projection; it kills every $t_{v,e}$ and every s.

Step 5: the lift $r_S = \sigma_S \circ r_U$, (Wm4), (Wm5). By Step 1(c), $\sigma_S(\alpha_v)$ has similitude 1, is $\equiv 1$ and has the ten listed entries, so $\sigma_S(\alpha_v) = 1$ for $v \ne \ell$, and $\alpha_\ell = 1$ by (Fw2); and $r_S(\phi)$, of unit similitude $\theta(\phi)$, with off-diagonal entries reducing to those of $\bar{r}_0(\phi)$, which vanish, is block diagonal. So r_S is a symplectic Eisenstein lift: (Se1), (Se2) from (Fw1); (Se3) as just shown, with $h(r_S)_{13} = \sigma_S(h(r_U)_{13}) = 0$ and likewise at $(3,1)$; (Se4): for $v \in T$ let $i_R\colon B_L \to R$ be induced by $\mathcal{O}[[X_{\sigma_L}]] \to P \to R$ (it kills $\mathfrak{a}_L$); R is a domain in $\mathrm{CNL}_\mathcal{O}$, $\rho_B = i_R \circ \rho_v$ satisfies the local condition at v (Step 1(a)), $x_R \circ \rho_B = x_L \circ \rho_v = r_0|_{D_v}$, and $q \circ i_R = \sigma_S \circ \iota$ (both are induced by $\mathcal{O}[[X_{\sigma_L}]] \to P \to S$, by (Fv2)), so $q \circ \rho_B = \sigma_S(\alpha_v^{-1} r_U \alpha_v)|_{D_v} = r_S|_{D_v}$ by (Fw3). Generation: if $f, f'\colon S \to S'$ agree on r_S, then $f \circ \sigma_S$ and $f' \circ \sigma_S$ carry the framed lift to framed lifts with the same global lift and frames 1, and $f \circ \sigma_S \circ \iota$, $f' \circ \sigma_S \circ \iota$ both classify the local lifts

$f \circ r_S|_{D_v}$, so they agree by (Bq1); by (Fv1) $f \circ \sigma_S = f' \circ \sigma_S$, and $f = f'$ as σ_S is onto. This is (Wm4). (Wm5): $r_U(g)_{ij} = \Pi_U(\tilde{f})$ with $\tilde{f} \in \mathcal{O}[[X]]_{\mathrm{wt}_4(i,j)}$ (Fv3), whose image f in $R_{\mathrm{wt}_4(i,j)}$ has $q(f) = r_S(g)_{ij}$; x_R (induced by the constant term) kills $\ker q$, so every f' with $q(f') = r_S(g)_{ij}$ has $x_R(f') = \tilde{f}(0) = x_U(r_U(g)_{ij}) = r_0(g)_{ij}$.

Step 6: (Wm6). Let $a \in \mathcal{O} \setminus \{0\}$ and z a normalised Sha cocycle modulo a; if a is a unit, $\delta = 0$ works, so let $a \in \mathfrak{m}_\mathcal{O}$. Choose $\tilde{y}_v \in \mathcal{O}$ ($v \in T$) with $z(g) = \Psi^{-1}(g)\tilde{y}_v - \tilde{y}_v$ modulo a on D_v. (i) Over $\mathcal{O}[\epsilon]$ the local lifts $(1 - \epsilon\tilde{y}_v X_m) r_0|_{D_v} (1 + \epsilon\tilde{y}_v X_m)$ satisfy the local conditions (Step 1(a),(b)), so by Step 1(d) they are classified by $x_L + \epsilon D_B$ with $D_B \colon B_L \to \mathcal{O}$ a point derivation at x_L. The derivation D_B vanishes on $(B_L)_w$ for $w \neq (0,-1)$: as $\mathfrak{a}_L$ is homogeneous and closed, $X_s \mapsto u^{\mathrm{wt}_L(s)} X_s$ ($u^w = (1+T_1)^{w_1}(1+T_2)^{w_2}$) induces a morphism $\rho_B \colon B_L \to B_L[[T_1, T_2]]$ with $\rho_B(f) = u^w f$ for $f \in (B_L)_w$; with $t_u = \mathrm{diag}(u^{(1,1)}, u^{(0,1)}, u^{(1,0)}, 1)$, $t_u r_0 t_u^{-1} = r_0$ and $t_u X_m t_u^{-1} = u^{(0,-1)} X_m$, both $(x_L + \epsilon D_B) \circ \rho_B$ (coefficientwise) and $x_L + \epsilon u^{(0,-1)} D_B$ are morphisms $B_L \to \mathcal{O}[\epsilon][[T_1, T_2]]$ classifying the local lifts $t_u(1 - \epsilon\tilde{y}_v X_m) r_0 (1 + \epsilon\tilde{y}_v X_m) t_u^{-1}$, as $\rho_v(g)_{ab} \in (B_L)_{\mathrm{wt}_4(a,b)}$; by (Bq1) they are equal, and for $f \in (B_L)_w$ this reads $u^w D_B(f) = u^{(0,-1)} D_B(f)$. (ii) Over $(\mathcal{O}/a)[\epsilon]$ let $r'(g) = (1 + \epsilon z(g) X_m) r_0(g)$, $\alpha'_v = 1$ and $\iota' = (x_L + \epsilon D_B) \bmod a$. The map r' is a continuous homomorphism (cocycle rule and $r_0 X_m r_0^{-1} = \Psi^{-1} X_m$), of similitude θ ($X_m \in \mathfrak{sp}_4$), satisfies (Se2) (z vanishes on residually trivial inertia outside T, and Step 1(a)), and on D_v, $(1 - \epsilon\tilde{y}_v X_m) r_0 (1 + \epsilon\tilde{y}_v X_m) = (1 + \epsilon(\Psi^{-1} - 1)\tilde{y}_v X_m) r_0 = r'$ (with $\tilde{y}_v$ read modulo a): (Fw3) holds with $\alpha'_v = 1$. Step 1(d) gives $D \colon U \to \mathcal{O}/a$ with $D(r_U(g)) = z(g) X_m r_0(g)$, $D(\alpha_v) = 0$, $D \circ \iota = D_B \bmod a$. In particular $D(r_U(g)_{31}) = \theta(g) z(g)$, $D(r_U(g)_{42}) = \Psi(g) z(g)$, and $D(r_U(g)_{ab}) = 0$ unless $\mathrm{wt}_4(a,b) = (0,-1)$. (iii) Let $\delta_P \colon P \to \mathcal{O}$ be the point derivation at the constant term, $\delta_P(f) = \sum_s \frac{\partial f}{\partial X_s}(0)\, \delta_P(X_s)$, with $\delta_P(X_s) = D_B(\pi_L(X_s))$ for $s \in \sigma_L$, $\delta_P(X_t)$ a lift of $D(y_t)$ if $\mathrm{wt}_\tau(t) = (0,-1)$, and $\delta_P(X_t) = 0$ otherwise. A point derivation of a power series ring at the constant term is determined by its values on the variables (it kills $(X)^2$); hence $\delta_P = D_B \circ \pi_L$ on $\mathcal{O}[[X_{\sigma_L}]]$, so $\delta_P(\mathfrak{a}_L P) = 0$ (product rule, constant terms 0); $\delta_P \equiv D \circ \Pi_U \pmod a$, as both agree on the variables ($D(y_t) = 0$ for $\mathrm{wt}_\tau(t) \neq (0,-1)$ by (ii) and $D(\alpha_v) = 0$); and $\delta_P(\mathcal{O}[[X]]_w) = 0$ for $w \neq (0,-1)$ (only linear terms count, and $\delta_P(X_s) = 0$ for $\mathrm{wt}(s) \neq (0,-1)$ by (i)). So $\delta_P(g_{v,e}) = 0$, and by Proposition 45.24, item 2, δ_P induces $\delta \colon R \to \mathcal{O}$ with $\delta(fh) = x_R(f)\delta(h) + x_R(h)\delta(f)$ and $\delta(R_w) = 0$ for $w \neq (0,-1)$. Moreover, $\delta(\ker q) \subseteq a\mathcal{O}$: on the generators, $\delta_P(f_k) \equiv D(\Pi_U(f_k)) = 0$; the $\tilde{s}$ of weight $\neq (0,-1)$ give 0; $\delta_P(\tilde{s}) \equiv D((\alpha_v)_{31}) = 0$ and $\delta_P(\tilde{s}) \equiv D(h(r_U)_{31}) = \theta(g_0) z(g_0) + z(g_0^{-1}) = 0$, since $z(g_0) = 0$ and $0 = z(g_0^{-1} g_0) = z(g_0^{-1}) + \Psi^{-1}(g_0^{-1}) z(g_0)$; and $\delta(\sum c_i e_i) = \sum x_R(c_i)\delta(e_i)$ for generators e_i ($x_R(e_i) = 0$). Finally, if $q(f) = r_S(g)_{31}$, then f differs by an element of $\ker q$ from the image of a lift $\tilde{f} \in \mathcal{O}[[X]]_{(0,-1)}$ of $r_U(g)_{31}$, so $\delta(f) \equiv \delta_P(\tilde{f}) \equiv D(r_U(g)_{31}) = \theta(g) z(g)$ modulo a; likewise $\delta(f) \equiv \Psi(g) z(g)$ if $q(f) = r_S(g)_{42}$. This is (Wm6), and $(\sigma_L \sqcup \tau, \mathrm{wt}_L \sqcup \mathrm{wt}_\tau, \mathfrak{b}, r, r', m, F, E, Z, S, q, r_S)$ is a symplectic weighted model of $\mathfrak{D}$. □

Proposition 45.24. *Let $\mathcal{O}$ be a coefficient ring, σ and τ disjoint finite sets with a map $\mathrm{wt} \colon \sigma \sqcup \tau \to \mathbb{Z}^2$, $P = \mathcal{O}[[X_s : s \in \sigma \sqcup \tau]]$, and $\mathfrak{a}$ a homogeneous ideal of $\mathcal{O}[[X_s : s \in \sigma]]$ all of whose elements have constant term 0, such that $\mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$ is smooth at the origin with tangent dimensions t_0. Let $g_1, \dots, g_N \in P$ with $g_i \in \mathcal{O}[[X]]_{w_i}$ of constant term 0, and suppose that for every i there is an $\mathcal{O}$-linear map $\delta_i \colon P \to \mathcal{O}$ with $\delta_i(\mathfrak{a}P) = 0$, $\delta_i(fh) = f(0)\delta_i(h) + h(0)\delta_i(f)$ for all $f, h \in P$ ($f(0)$ the constant term), $\delta_i(g_i) \neq 0$ and $\delta_i(g_j) = 0$ for $j \neq i$. Then there is a homogeneous ideal $\mathfrak{b} \subseteq P$, all of whose elements have constant term 0, with $\mathfrak{a}P + (g_1, \dots, g_N) \subseteq \mathfrak{b}$, such that:*

1. *$P/\mathfrak{b}$ is a domain and is smooth at the origin with tangent dimensions $w \mapsto t_0(w) + \#\{t \in \tau : \mathrm{wt}(t) = w\} - \#\{i : \ w_i = w\}$;*
2. *every $\mathcal{O}$-linear $\delta \colon P \to \mathcal{O}$ with $\delta(\mathfrak{a}P) = 0$, $\delta(fh) = f(0)\delta(h) + h(0)\delta(f)$ for all f, h, and*

$\delta(g_i) = 0$ *for all* i*, vanishes on* $\mathfrak{b}$.

Proof. Write $E = \mathcal{O}[\ell^{-1}]$ (the fraction field of $\mathcal{O}$), $P_\sigma = \mathcal{O}[[X_s : s \in \sigma]] \subseteq P$, $P^{\mathrm{gr}} = \sum_w P_w$ (finite sums of elements of single weights), $f(0)$ for the constant term, and for a series F over E with variables indexed by a set K, $\mathrm{lin}(F) \in E^K$ for the vector of its coefficients of degree one. For $N \geq 1$ let U_N be the finite set of weights of monomials in the X_s ($s \in \sigma \sqcup \tau$) of degree $< N$; for every $f \in P$, $f - \sum_{w \in U_N} f_{(w)}$ has only monomials of degree $\geq N$. By hypothesis there are J, wt_J with $\#\mathrm{wt}_J^{-1}(w) = t_0(w)$ and a chart ϕ_0 of $R_0 = P_\sigma/\mathfrak{a}$ into $E[[Y_i : i \in J]]$ with (Sm1)–(Sm4); let $\Phi_0 \colon P_\sigma \to E[[Y_J]]$ be its substitution homomorphism (Lemma 45.25).

Step 1: the cover $R_1 = P/\mathfrak{a}P$ *is smooth with tangent dimensions* $t_0 + \tau$*-counts.* $\mathfrak{a}$ is generated by its elements of single weight (every $f \in \mathfrak{a}$ is the limit of the partial sums $\sum_{w \in U_N} f_{(w)}$, which lie in the ideal generated by them, and that ideal is closed), hence by finitely many $a_1, \dots, a_k$ of single weights. So $\mathfrak{a}P = (a_1, \dots, a_k)P$ is homogeneous ($(\sum_i a_i p_i)_{(w)} = \sum_i a_i p_{i,(w - \mathrm{wt}(a_i))}$) with constant terms 0, and R_1 is a $\mathbb{Z}^2$-weighted quotient. Let $K = J \sqcup \tau$ with $\mathrm{wt}_K = \mathrm{wt}_J \sqcup \mathrm{wt}|_\tau$, and $\Phi_1 \colon P \to E[[Y_K]]$ the substitution $X_s \mapsto \Phi_0(X_s)$ ($s \in \sigma$), $X_t \mapsto Y_t$ ($t \in \tau$). Then $\Phi_1|_{P_\sigma} = \Phi_0$, $\Phi_1(\mathfrak{a}P) = 0$ by (Wx1), $\Phi_1(P_w)$ consists of series of weight w (Wx2), the constant term of $\Phi_1(f)$ is $f(0)$, and $\Phi_1(X^m P) \subseteq (Y)^{|m|}$. So Φ_1 induces a chart ϕ_1 of R_1 satisfying (Sm1), (Sm2). (Sm3): for $i \in J$ take a lift in P_σ^{gr} of the element given by (Sm3) for ϕ_0 (its image involves no Y_t); for $t \in \tau$ take X_t. (Sm4): let $f \in P^{\mathrm{gr}}$ with $f(0) = 0$ and $\mathrm{lin}(\Phi_1(f)) = 0$. Splitting the monomials of each single-weight part by their degree in the X_t ($t \in \tau$) gives $f = f_0 + \sum_t X_t f_t + \sum_{t \leq t'} X_t X_{t'} q_{tt'}$ with $f_0, f_t \in P_\sigma^{\mathrm{gr}}$, $q_{tt'} \in P^{\mathrm{gr}}$. Then $\mathrm{lin}(\Phi_1(f)) = \mathrm{lin}(\Phi_0(f_0)) + \sum_t f_t(0)\, e_t$, so $f_t(0) = 0$ for all t, and $f_0(0) = 0$, $\mathrm{lin}(\Phi_0(f_0)) = 0$; by (Sm4) for ϕ_0 there is $c \in \mathcal{O} \setminus \{0\}$ with cf_0 congruent modulo $\mathfrak{a}$ to an element of $\mathfrak{m}_0(R_0)^2$. As X_t, f_t have constant term 0, the image of cf in R_1^{gr} lies in $\mathfrak{m}_0(R_1)^2$, i.e. $f \in \mathrm{Sq}$. So R_1 is smooth at the origin with tangent dimensions $w \mapsto t_0(w) + \#\{t \in \tau : \mathrm{wt}(t) = w\} = \#\mathrm{wt}_K^{-1}(w)$.

Step 2: the cotangent map and derivations. Let $\mathfrak{m}_0 = \mathfrak{m}_0(R_1)$ and $\mathrm{lin}(f) = \mathrm{lin}(\phi_1(f))$ for $f \in \mathfrak{m}_0$. (a) $\mathrm{lin}(\mathfrak{m}_0)$ spans E^K by (Sm3) (subtract constant terms). (b) The kernel of lin on $\mathfrak{m}_0$ is $\mathrm{Sq} \cap \mathfrak{m}_0$: one inclusion is (Sm4); conversely if $cf \in \mathfrak{m}_0^2$ then $c\,\mathrm{lin}(f) = 0$, since a product of two series without constant term has no linear part. (c) Let $\delta \colon P \to \mathcal{O}$ be $\mathcal{O}$-linear with $\delta(fh) = f(0)\delta(h) + h(0)\delta(f)$ and $\delta(\mathfrak{a}P) = 0$. It induces $\bar{\delta}$ on R_1 with the same rule for x_{R_1}; $\bar{\delta}(\mathfrak{m}_0^2) = 0$, hence $\bar{\delta}(\mathrm{Sq} \cap \mathfrak{m}_0) = 0$ ($\mathcal{O}$ is torsion free). By (a), (b) there is a unique E-linear $\lambda_\delta \colon E^K \to E$ with $\bar{\delta}(f) = \lambda_\delta(\mathrm{lin}(f))$ for $f \in \mathfrak{m}_0$ (define it on the $\mathcal{O}$-module $\mathrm{lin}(\mathfrak{m}_0) \cong \mathfrak{m}_0/(\mathrm{Sq} \cap \mathfrak{m}_0)$ and extend E-linearly; this is well defined after clearing denominators, as $\mathcal{O}$ is torsion free). In particular $\delta(f) = \lambda_\delta(\mathrm{lin}(\Phi_1(f)))$ for $f \in P^{\mathrm{gr}}$ with $f(0) = 0$.

Step 3: independence of the g_i *and the formal cut.* Put $G_i = \Phi_1(g_i)$, of weight w_i without constant term. By Step 2 (c), $\lambda_{\delta_i}(\mathrm{lin}(G_j)) = \delta_i(g_j)$, which is non-zero exactly for $j = i$; so $\mathrm{lin}(G_1), \dots, \mathrm{lin}(G_N)$ are linearly independent, and $\mathrm{lin}(G_i)$ is supported on $K_{w_i} = \mathrm{wt}_K^{-1}(w_i)$. For each weight w choose $K_w^1 \subseteq K_w$ with $\#K_w^1 = \#\{i : w_i = w\}$ such that the coefficients of the Y_k, $k \in K_w^1$, in the $\mathrm{lin}(G_i)$ with $w_i = w$ form an invertible matrix; let $K^1 = \bigsqcup_w K_w^1$, $K^2 = K \setminus K^1$, and $i \mapsto k_i$ a bijection $\{1, \dots, N\} \to K^1$ with $\mathrm{wt}_K(k_i) = w_i$. The continuous E-algebra endomorphism α of $E[[Y_K]]$ with $\alpha(Y_{k_i}) = G_i$ and $\alpha(Y_k) = Y_k$ ($k \in K^2$) has invertible linear part (block triangular, with the identity on K^2 and the block-diagonal-by-weight Jacobian $(\partial G_i/\partial Y_{k_j}(0))$ on K^1), so it is an automorphism. For $u \in (E^\times)^2$ let s_u be the automorphism $Y_k \mapsto u^{\mathrm{wt}_K(k)} Y_k$ ($u^{(a,b)} = u_1^a u_2^b$); a series F has weight w iff $s_u(F) = u^w F$ for all u (E is infinite). As G_i has weight $w_i = \mathrm{wt}_K(k_i)$, $\alpha \circ s_u = s_u \circ \alpha$ (equal on the variables), so α^{-1} preserves weights. Let $\varepsilon \colon E[[Y_K]] \to E[[Y_{K^2}]]$ kill the Y_k, $k \in K^1$, and $\psi = \varepsilon \circ \alpha^{-1}$. Then ψ preserves weights and constant terms, maps (Y_K) into (Y_{K^2}), fixes Y_k for $k \in K^2$, and

$$\ker \psi = \alpha((Y_k : k \in K^1)) = (G_1, \dots, G_N).$$

On linear parts ψ induces a linear map $\Lambda\colon E^K \to E^{K^2}$, $\mathrm{lin}(\psi(F)) = \Lambda(\mathrm{lin}(F))$; Λ is the identity on E^{K^2}, hence onto, and kills the N independent vectors $\mathrm{lin}(G_i)$, so $\ker\Lambda = \sum_i E\,\mathrm{lin}(G_i)$.

Step 4: the ideal $\mathfrak{b}$. Let $\Phi_2 = \psi \circ \Phi_1\colon P \to E[[Y_{K^2}]]$ and $\mathfrak{b} = \ker\Phi_2$. It is a prime ideal (the target is a domain), contains $\mathfrak{a}P$ and the g_i, and its elements have constant term 0 (the constant term of $\Phi_2(f)$ is $f(0)$). It is homogeneous: Φ_2 maps P_w to series of weight w and X^mP into $(Y)^{|m|}$, so for $f \in \mathfrak{b}$, $w \in \mathbb{Z}^2$ and a monomial Y^m of weight w, choosing $N > |m|$ with $w \in U_N$ (if w lies in no U_N then $f_{(w)} = 0$), the coefficient of Y^m in $\Phi_2(f_{(w)})$ equals that in $\sum_{w' \in U_N} \Phi_2(f_{(w')}) \equiv \Phi_2(f) = 0$ modulo $(Y)^N$; so $\Phi_2(f_{(w)}) = 0$. Hence $P/\mathfrak{b}$ is a $\mathbb{Z}^2$-weighted quotient and a domain.

Step 5: (1), smoothness of $P/\mathfrak{b}$. Φ_2 induces a chart ϕ_2 of $P/\mathfrak{b}$ into $E[[Y_{K^2}]]$ with the weights $\mathrm{wt}_K|_{K^2}$, and $\#(K^2 \cap \mathrm{wt}_K^{-1}(w)) = t_0(w) + \#\{t \in \tau : \mathrm{wt}(t) = w\} - \#\{i : w_i = w\}$. (Sm1), (Sm2) hold as for Φ_1. (Sm3): for $k \in K^2$ take f from (Sm3) for ϕ_1 with $\mathrm{lin}(\Phi_1(f)) = c\,e_k$; then $\mathrm{lin}(\Phi_2(f)) = \Lambda(c\,e_k) = c\,e_k$. (Sm4): let $f \in P^{\mathrm{gr}}$ with $f(0) = 0$ and $\mathrm{lin}(\Phi_2(f)) = 0$. Then $\mathrm{lin}(\Phi_1(f)) \in \ker\Lambda$, so $\mathrm{lin}(\Phi_1(f)) = \sum_i e_i\,\mathrm{lin}(G_i)$ with $e_i \in E$; take $c \in \mathcal{O} \setminus \{0\}$ with all $ce_i \in \mathcal{O}$. The element $f' = cf - \sum_i (ce_i)g_i \in P^{\mathrm{gr}}$ has $f'(0) = 0$ and $\mathrm{lin}(\Phi_1(f')) = 0$, so by Step 1 some $c'f'$ maps into $\mathfrak{m}_0(R_1)^2$. Under $R_1 \to P/\mathfrak{b}$ (which maps R_1^{gr} onto $(P/\mathfrak{b})^{\mathrm{gr}}$, $\mathfrak{m}_0$ into $\mathfrak{m}_0$, and kills the g_i), $c'cf$ maps into $\mathfrak{m}_0(P/\mathfrak{b})^2$: $f \in \mathrm{Sq}$. This proves (1).

Step 6: (2), derivations descend. Let δ be as in (2) and λ_δ as in Step 2 (c); then $\lambda_\delta(\mathrm{lin}(G_i)) = \delta(g_i) = 0$. Let $h \in \mathfrak{b} \cap P_w$ with $h(0) = 0$. Then $\Phi_1(h) \in \ker\psi = (G_1, \dots, G_N)$, say $\Phi_1(h) = \sum_i b_i G_i$, so $\mathrm{lin}(\Phi_1(h)) = \sum_i b_i(0)\,\mathrm{lin}(G_i)$ and $\delta(h) = \lambda_\delta(\mathrm{lin}(\Phi_1(h))) = 0$. Now let $f \in \mathfrak{b}$; then $f(0) = 0$ and all $f_{(w)} \in \mathfrak{b}$ (Step 4), with $f_{(w)}(0) = 0$. Since δ kills $\mathcal{O}$ and every $X_sX_{s'}p$ (both constant terms vanish), $\delta(f) = \sum_s c_s\delta(X_s)$ for $f = \sum_s c_sX_s +$ (terms of degree ≥ 2), and likewise $\delta(f_{(w)}) = \sum_{\mathrm{wt}(s)=w} c_s\delta(X_s)$. Summing over the finitely many weights of the variables, $\delta(f) = \sum_w \delta(f_{(w)}) = 0$. This proves (2). □

Lemma 45.25. *Let $\mathcal{O}$ be a coefficient ring, σ a finite set with $\mathrm{wt}\colon \sigma \to \mathbb{Z}^2$, $\mathfrak{a}$ a homogeneous ideal of $\mathcal{O}[[X_s : s \in \sigma]]$ all of whose elements have constant term 0, $R = \mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$ with projection π, J a finite set, and $\phi\colon R^{\mathrm{gr}} \to \mathcal{O}[\ell^{-1}][[Y_i : i \in J]]$ an $\mathcal{O}$-algebra homomorphism satisfying (Sm2) (the constant term of $\phi(f)$ is $x_R(f)$). Let $\Phi\colon \mathcal{O}[[X_s : s \in \sigma]] \to \mathcal{O}[\ell^{-1}][[Y_i : i \in J]]$ be the substitution homomorphism $f \mapsto f((\phi(\pi(X_s)))_{s\in\sigma})$ (each $\phi(\pi(X_s))$ has constant term 0). Then:*

(Wx1) *$\Phi(f) = \phi(\pi(f))$ for every $f \in \mathcal{O}[[X_\sigma]]$ that is a finite sum of elements of single weights, and $\Phi(\mathfrak{a}) = 0$; so Φ induces a homomorphism $R \to \mathcal{O}[\ell^{-1}][[Y_J]]$ extending ϕ;*

(Wx2) *if $\mathrm{wt}_J\colon J \to \mathbb{Z}^2$ is given and ϕ satisfies (Sm1), then $\Phi(f)$ has weight w for every $f \in \mathcal{O}[[X_\sigma]]_w$.*

Proof. Write $P = \mathcal{O}[[X_\sigma]]$, $Q = \mathcal{O}[\ell^{-1}][[Y_J]]$ and $\mathfrak{y}$ for the ideal of Q of series without constant term. Since $\phi(\pi(X_s)) \in \mathfrak{y}$, the substitution $\Phi(\sum_m c_mX^m) = \sum_m c_m \prod_s \phi(\pi(X_s))^{m_s}$ converges coefficientwise ($\prod_s \phi(\pi(X_s))^{m_s} \in \mathfrak{y}^{|m|}$) and is an $\mathcal{O}$-algebra homomorphism with $\Phi(X^mP) \subseteq \mathfrak{y}^{|m|}$.

(Wx1). Let $f = \sum_m c_mX^m \in P_v$ and $N \geq 1$. Assigning each monomial of degree $\geq N$ to one of its divisors X^μ of degree N gives

$$f = \sum_{|m|<N} c_mX^m + \sum_{|\mu|=N} X^\mu r_\mu, \qquad r_\mu \in P_{v-\mathrm{wt}(\mu)},$$

a finite sum. Each $\pi(X_s)$ lies in $R_{\mathrm{wt}(s)}$ and each $\pi(r_\mu)$ in $R_{v-\mathrm{wt}(\mu)}$, so all these terms lie in R^{gr} and, ϕ being a ring homomorphism on R^{gr},

$$\phi(\pi(f)) = \sum_{|m|<N} c_m \prod_s \phi(\pi(X_s))^{m_s} + \sum_{|\mu|=N} \Big(\prod_s \phi(\pi(X_s))^{\mu_s}\Big)\phi(\pi(r_\mu)) \equiv \Phi(f) \pmod{\mathfrak{y}^N},$$

as both $\phi(\pi(f))$ and $\Phi(f)$ differ from the first sum by an element of $\mathfrak{y}^N$. As N is arbitrary, $\phi(\pi(f)) = \Phi(f)$; by additivity this holds for finite sums of elements of single weights. Let $f \in \mathfrak{a}$. Every $f_{(w)}$ lies in $\mathfrak{a}$, so $\Phi(f_{(w)}) = \phi(\pi(f_{(w)})) = 0$. For $N \geq 1$ let U_N be the finite set of weights of monomials of degree $< N$; all monomials of $f - \sum_{w\in U_N} f_{(w)}$ have degree $\geq N$, so $\Phi(f) \equiv \sum_{w\in U_N} \Phi(f_{(w)}) = 0$ modulo $\mathfrak{y}^N$ for every N, and $\Phi(f) = 0$. Hence Φ factors through R, and the induced map agrees with ϕ on $R^{\mathrm{gr}} = \pi(\sum_w P_w)$.

(Wx2). By (Sm1), $\phi(\pi(X_s))$ has weight $\mathrm{wt}(s)$; a product of series of weights u, u' has weight $u+u'$, so $\prod_s \phi(\pi(X_s))^{m_s}$ has weight $\sum_s m_s \mathrm{wt}(s)$, which is w for every monomial X^m of $f \in P_w$; and a coefficientwise convergent sum of series of weight w has weight w. □

Definition 45.26. Let ℓ be an odd prime, $\overline{\mathbb{Z}}_\ell = \{y \in \overline{\mathbb{Q}}_\ell : |y|_\ell \leq 1\}$ and $\mathfrak{m}_\ell = \{y \in \overline{\mathbb{Q}}_\ell : |y|_\ell < 1\}$. Let $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, (\sigma_v), \phi, g_0, s_0)$ be a symplectic Eisenstein datum with characters θ, Ψ, α, set T and $r_0 = \mathrm{diag}(\kappa_1, \kappa_2, \kappa_3, \kappa_4) = \mathrm{diag}(\theta, \Psi, \alpha, \mathbf{1})$. Indices i, j run over $\{1, 2, 3, 4\}$.

Test fields. A **test field** is a triple (K, V, a) of an algebraically closed field K, a valuation ring $V \subseteq K$ of K with maximal ideal $\mathfrak{m}_V$, and a ring homomorphism $a\colon \overline{\mathbb{Z}}_\ell \to V$ with $a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$, such that every element of V is congruent modulo $\mathfrak{m}_V$ to an element of $a(\overline{\mathbb{Z}}_\ell)$. Its **characteristic** is that of K (0 or ℓ). The **standard test field** is $(\overline{\mathbb{Q}}_\ell, \overline{\mathbb{Z}}_\ell, \mathrm{id})$. For a matrix X with entries in $\mathcal{O} \subseteq \overline{\mathbb{Z}}_\ell$, $a(X)$ is formed entrywise.

Ordinary test representations. Let (K, V, a) be a test field. An **ordinary test representation** of $\mathfrak{D}$ with values in V is a pair (r, u) of a homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ and a matrix $u \in \mathrm{GL}_4(V)$ such that:

(Ot1) there are a complete discrete valuation ring Λ with finite residue field and an injective local homomorphism $j\colon \Lambda \to V$ such that every element of K is algebraic over $j(\Lambda)$, the entries of u and of every $r(g)$ lie in $j(\Lambda)$, and $g \mapsto j^{-1}(r(g)_{ij})$ is continuous for the $\mathfrak{m}_\Lambda$-adic topology on Λ, for all i, j;

(Ot2) for every $g \in G_{\mathbb{Q}}$, the entries of $r(g) - a(r_0(g))$ lie in $\mathfrak{m}_V$, and $r(g)$ has similitude $a(\theta(g))$;

(Ot3) $r(g) = 1$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$ and every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a prime not in T; and for every $v \in T$ with $v \neq \ell$, $r(g) = 1$ for every $g \in I_v$ with $\chi(g) = 1$;

(Ot4) u has similitude 1, and for every $s \in D_\ell$ the matrix $u^{-1}r(s)u$ is upper triangular with diagonal entries $d_1(s), \ldots, d_4(s)$ such that $d_i(s) - a(\kappa_i(s)) \in \mathfrak{m}_V$, and $d_i(s) = a(\kappa_i(s))$ if $s \in I_\ell$.

Points with values in V. A **point of $\mathfrak{D}$ with values in** V is a homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ of the form $g \mapsto f(r_A(g))$ (entrywise) for a symplectic Eisenstein lift r_A to some $A \in \mathrm{CNL}_{\mathcal{O}}$ and a ring homomorphism $f\colon A \to V$ that restricts to a on $\mathcal{O}$ and satisfies $f(\mathfrak{m}_A) \subseteq \mathfrak{m}_V$, such that the pair $(r, 1)$ satisfies (Ot1).

Shapes. Let (K, V, a) be a test field and $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ a homomorphism. The entry (i, j) of r is **active** if $r(g)_{ij} \neq 0$ for some $g \in G_{\mathbb{Q}}$. The representation r is

- **irreducible** if the K-span of $r(G_{\mathbb{Q}})$ is $\mathrm{M}_4(K)$;
- **of diagonal type** if there are no $i \neq j$ such that both (i, j) and (j, i) are active;

- a **non-split block extension** if (i) $r(g)_{ij} = 0$ for all g whenever $i \in \{1,3\}$ and $j \in \{2,4\}$; (ii) the K-span of the matrices $(r(g)_{ab})_{a,b\in\{2,4\}}$, $g \in G_{\mathbb{Q}}$, is $\mathrm{M}_2(K)$; and (iii) there is no $Y \in \mathrm{M}_4(K)$ with $Y_{ij} = 0$ unless $i \in \{2,4\}$ and $j \in \{1,3\}$ such that $(1-Y)\,r(g)\,(1+Y)$ is block diagonal for every g;
- **essential** if it is irreducible or a non-split block extension.

Weak purity. Let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. A homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ is **weakly pure** for ι if there are an open subgroup $H \subseteq G_{\mathbb{Q}}$ and an integer $M \geq 1$ such that for every prime $p \nmid M$, every place $\bar{p}'$ of $\overline{\mathbb{Q}}$ above p, every integer $f \geq 1$ and every $\sigma \in H$ that is an arithmetic Frobenius element for p^f at $\bar{p}'$, any two eigenvalues x, y of $r(\sigma)$ with $y \neq 0$ satisfy

$$|\iota(x)| < p^f\,|\iota(y)|. \tag{45.1}$$

Weak purity depends only on the characteristic polynomials of the $r(\sigma)$.

Lemma 45.27. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and residue field $\mathbb{F}_{\mathcal{O}}$; write $\bar{\kappa}_i\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^{\times}$ for the reduction of κ_i, E_{ij} for the matrix units and $i^* = 5 - i$.*

(Ae1) *If $\lambda_i \neq \lambda_j$, then $\bar{\kappa}_i(\sigma_\ell) \neq \bar{\kappa}_j(\sigma_\ell)$; and $\bar{\kappa}_i(\phi) = \bar{\kappa}_i(\sigma_\ell)$ for every i.*

(Ae2) *For every symplectic Eisenstein lift r_A to some $A \in \mathrm{CNL}_{\mathcal{O}}$ and every i, E_{ii} lies in the A-submodule of $\mathrm{M}_4(A)$ spanned by $r_A(G_{\mathbb{Q}})$.*

Let (K, V, a) be a test field and r a point of $\mathfrak{D}$ with values in V. Then:

(Ae3) *E_{ii} lies in the V-submodule of $\mathrm{M}_4(V)$ spanned by $r(G_{\mathbb{Q}})$, for every i;*

(Ae4) *every entry (i,i) is active; if (i,j) and (j,k) are active, so is (i,k); if (i,j) is active, so is (j^*, i^*);*

(Ae5) *r is irreducible if and only if every entry (i,j) is active.*

Proof. (Ae1). As $\bar{\omega}_\ell = \bar{\chi}_{\mathrm{cyc}}$, $\bar{\alpha} = \bar{\xi}$, $\bar{\theta} = \bar{\xi}\bar{\Psi}$. For the four pairs $(i,j) = (1,2), (1,4), (3,2), (3,4)$ with $\lambda_i \neq \lambda_j$ the ratio $\bar{\kappa}_i/\bar{\kappa}_j$ is $\bar{\alpha} = \bar{\xi}$, $\bar{\theta} = \bar{\xi}\bar{\Psi}$, $\bar{\alpha}\bar{\Psi}^{-1} = \bar{\xi}\bar{\Psi}^{-1}$, $\bar{\alpha} = \bar{\xi}$; by (Sg2) at $v = \ell$ (with $i = 0, 1, -1$) its value at σ_ℓ is not 1; the pairs with $i \in \{2,4\}$ follow by inversion. Let $q = \ell^f = \#\mathbb{F}_{\mathcal{O}}$. For $n \geq f$, $f \mid n!$, so $x^{\ell^{n!}} = x$ for $x \in \mathbb{F}_{\mathcal{O}}$ and $\bar{\kappa}_i(\sigma_\ell^{\ell^{n!}}) = \bar{\kappa}_i(\sigma_\ell)$. As $\bar{\kappa}_i$ is locally constant, (Sg3) gives $\bar{\kappa}_i(\phi) = \bar{\kappa}_i(\sigma_\ell^{\ell^{n!}})$ for large n, whence the second claim.

(Ae2). Let $S \subseteq \mathrm{M}_4(A)$ be the A-span of $r_A(G_{\mathbb{Q}})$. It contains 1 and is closed under products ($r_A(g)r_A(h) = r_A(gh)$). For $X \in \mathrm{M}_4(A)$ put $X^\natural = J_4^{-1}\,{}^t\!X\,J_4$, an A-linear map. If X has similitude ν, then $X^\natural X = \nu$; by (Se1), $r_A(g)^\natural = \theta(g) r_A(g^{-1}) \in S$, so $S^\natural \subseteq S$. As $J_4 e_b = \pm e_{b^*}$, $E_{kk}^\natural = E_{k^*k^*}$. Write $\bar{X}$ for reduction modulo $\mathfrak{m}_A$; as r_A is a lift, $\overline{r_A(g)} = \bar{r}_0(g)$. Let $X = r_A(\phi)$, block diagonal by (Se3), with blocks $X_{\mathrm{A}} = (X_{ab})_{a,b\in\{1,3\}}$ and $X_{\mathrm{B}} = (X_{ab})_{a,b\in\{2,4\}}$, and put $t = X_{22} + X_{44}$, $d = X_{22}X_{44} - X_{24}X_{42}$ and $Y = X^2 - tX + d\cdot 1 \in S$. By the Cayley–Hamilton theorem for X_{B}, Y is block diagonal with blocks $Y_{\mathrm{A}} = X_{\mathrm{A}}^2 - tX_{\mathrm{A}} + d$ and 0. Modulo $\mathfrak{m}_A$,

$$\overline{Y_{\mathrm{A}}} = \mathrm{diag}\Big((\bar{\kappa}_1 - \bar{\kappa}_2)(\bar{\kappa}_1 - \bar{\kappa}_4),\ (\bar{\kappa}_3 - \bar{\kappa}_2)(\bar{\kappa}_3 - \bar{\kappa}_4)\Big)(\phi),$$

whose determinant is non-zero by (Ae1); so $\det Y_{\mathrm{A}}$ is a unit of the local ring A. With $E_{\mathrm{A}} = E_{11} + E_{33}$, the Cayley–Hamilton theorem for Y_{A} gives $Y^2 - \mathrm{tr}(Y_{\mathrm{A}})Y + \det(Y_{\mathrm{A}})E_{\mathrm{A}} = 0$, so

$E_{\mathrm{A}} = \det(Y_{\mathrm{A}})^{-1}(\mathrm{tr}(Y_{\mathrm{A}})Y - Y^2) \in S$. Next $H = h(r_A) = r_A(g_0) + \theta(g_0)r_A(g_0^{-1}) \in S$ has $H_{13} = H_{31} = 0$ by (Se3), so $E_{\mathrm{A}}HE_{\mathrm{A}} = H_{11}E_{11} + H_{33}E_{33}$ and

$$E_{\mathrm{A}}HE_{\mathrm{A}} - H_{33}E_{\mathrm{A}} = (H_{11} - H_{33})E_{11}.$$

Modulo $\mathfrak{m}_A$, $H_{11} - H_{33} \equiv \theta(g_0) + 1 - \alpha(g_0) - \theta(g_0)\alpha(g_0)^{-1} = (\alpha(g_0) - 1)(\Psi(g_0) - 1)$, a unit by (Sg4). So $E_{11} \in S$, $E_{33} = E_{\mathrm{A}} - E_{11} \in S$, and $E_{44} = E_{11}^{\natural}$, $E_{22} = E_{33}^{\natural} \in S$.

(Ae3). Write $r = f \circ r_A$. If $E_{ii} = \sum_t a_t r_A(t)$ with $a_t \in A$, then $E_{ii} = f(E_{ii}) = \sum_t f(a_t)r(t)$.

(Ae4). $r(1) = 1$. Let S_V be the V-span of $r(G_{\mathbb{Q}})$, closed under products. If $r(g)_{ij} \neq 0$ and $r(h)_{jk} \neq 0$, then $E_{ii}r(g)E_{jj}r(h)E_{kk} \in S_V$ by (Ae3) has (i,k) entry $r(g)_{ij}r(h)_{jk} \neq 0$ (V is a domain), so $r(t)_{ik} \neq 0$ for some t. By (Se1), $r(g)$ has similitude $a(\theta(g)) \in V^{\times}$, so $r(g^{-1}) = a(\theta(g))^{-1}r(g)^{\natural}$, and $(X^{\natural})_{j^*i^*} = \pm X_{ij}$ (as $J_4 e_b = \pm e_{b^*}$); hence $r(g)_{ij} \neq 0$ implies $r(g^{-1})_{j^*i^*} \neq 0$.

(Ae5). If every entry is active, $E_{ii}r(g)E_{jj} = r(g)_{ij}E_{ij}$ with $r(g)_{ij} \neq 0$ for some g, so every E_{ij} lies in the K-span of $r(G_{\mathbb{Q}})$, which is therefore $\mathrm{M}_4(K)$. Conversely, if (i,j) is not active, every element of the K-span has entry (i,j) equal to 0, so the span is not $\mathrm{M}_4(K)$. □

45.3 Smoothness and points of the weight-zero algebra

This subsection proves Proposition 45.28: the part of λ-weight zero of a symplectic weighted model satisfies the conditions of the criterion, carries the Tate–Shafarevich classes and parametrises the points of the datum; the reducible points, which (Gc3) and (Gc4) concern, are analysed in Subsection 45.4. The part of weight zero is a smooth graded algebra with a fixed point, with explicit tangent dimensions (Lemma 45.29), and the tangent vectors of torus weights $(0,-1)$ and $(0,0)$ at the Eisenstein point vanish (Lemma 45.30). The Tate–Shafarevich classes enter through normalised cocycles (Lemma 45.32), and here again Part VII is used: the unramified classes of a finite-order character times a negative power of the cyclotomic character that are trivial at ℓ vanish (Lemma 45.31), which rests on Proposition 40.3. When the datum is finite in weight zero, the points of the algebra lift and scale to the deformation ring and the weight parts are spanned by monomials in the entries (Lemma 45.33, Lemma 45.34).

Proposition 45.28. *Let $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, \dots)$ be a symplectic Eisenstein datum, $n_S = \prod_{p \in S} p$, and M a symplectic weighted model of $\mathfrak{D}$ with integers r, r', m. Then there are elements $a_g \in (A_M)_0$ with $x_M(a_g) = 0$ ($g \in G_{\mathbb{Q}}$) such that:*

(Mc1) *(A_M, x_M) is a graded $\mathcal{O}$-algebra with a fixed point, smooth with tangent dimensions* td, *where* $\mathrm{td}(-2), \dots, \mathrm{td}(2)$ *are* $0, r, m, r'+1, 1$ *and* $\mathrm{td}(j) = 0$ *for* $|j| > 2$;

(Mc2) *the parts u_{-1}, u_{-2}, u_0 of u_M span rationally in degrees -1, -2, 0 respectively;*

(Mc3) *for every $b \in \mathcal{O} \setminus \{0\}$, writing* $\mathrm{Sha}[b]$ *for the submodule of* $\mathrm{Sha}^1_{n_S}(\chi, e)$ *killed by b, there are $a \in b\mathcal{O} \setminus \{0\}$ and an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A_M, \mathcal{O}/a\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo a of an $\mathcal{O}$-linear map $D'\colon A_M \to \mathcal{O}$ with $D'(fh) = x_M(f)D'(h) + x_M(h)D'(f)$ for all $f, h \in A_M$ and $D'((A_M)_j) = 0$ for all $j \neq -1$;*

and, if $\mathfrak{D}$ is finite in weight zero, there is a map $x \mapsto r_x$ from the points of A_M on u_M to the points of $\mathfrak{D}$ such that:

(Mc4) *$x(a_g) = \mathrm{tr}\, r_x(g) - \mathrm{tr}\, r_0(g)$ for every point x of A_M on u_M and every $g \in G_{\mathbb{Q}}$; and for points x, x' of A_M on u_M, if $r_{x'}$ is a torus conjugate of r_x, then x' is a torus translate of x;*

(Mc5) *(A_M, x_M, u_M) satisfies (Gc2) and (Gc3); if $\mathfrak{D}$ has no endoscopic points, then r_x is irreducible for every two-signed point x of A_M on u_M; if moreover every irreducible point of $\mathfrak{D}$ is rigid, then (A_M, x_M, u_M) satisfies (Gc4).*

Proof. Write $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, $P = \mathcal{O}[[X_s : s \in \sigma]]$, $\pi\colon P \to R$ the projection, $z_s = \pi(X_s)$, and $a_s(G)$ for the coefficient of X_s in $G \in P$. For $c \in \mathcal{O} \setminus \{0\}$ let $\mathcal{O}_c[\epsilon] = \mathcal{O}[\epsilon]/(\epsilon^2, c\epsilon)$ (for $c = 0$, $\mathcal{O}[\epsilon]/(\epsilon^2)$); these rings lie in $\mathrm{CNL}_{\mathcal{O}}$.

Step 0: preliminaries. (a) x_R kills $\ker q$: by (Wm5) for $g = 1$, $i = j = 1$ there is f_1 with $q(f_1) = 1$ and $x_R(f_1) = 1$; for $h \in \ker q$, $q(f_1 + h) = 1$, so $x_R(f_1 + h) = 1$ and $x_R(h) = 0$. Hence x_R induces an $\mathcal{O}$-algebra homomorphism $\bar{x}\colon S \to \mathcal{O}$ with $\bar{x} \circ q = x_R$, and $\bar{x}(r_S(g)) = r_0(g)$ by (Wm5). (b) *Uniqueness of derivations.* Let $c \in \mathcal{O}$ and $\Delta\colon R \to \mathcal{O}/c\mathcal{O}$ an $\mathcal{O}$-linear map with $\Delta(fh) = x_R(f)\Delta(h) + x_R(h)\Delta(f)$ and $\Delta(\ker q) = 0$, such that for all g, i, j some h with $q(h) = r_S(g)_{ij}$ has $\Delta(h) = 0$. Then $\Delta = 0$: the homomorphism $x_R + \epsilon\Delta\colon R \to \mathcal{O}_c[\epsilon]$ kills $\ker q$ (by (a)) and induces $F_\Delta\colon S \to \mathcal{O}_c[\epsilon]$ with $F_\Delta(r_S(g)_{ij}) = \bar{x}(r_S(g)_{ij})$; by (Wm4), $F_\Delta = \bar{x}$, so $\Delta = 0$. (c) *The elements a_g.* By (Wm5) choose $f_{g,i} \in R_{\mathrm{wt}_4(i,i)} = R_{(0,0)}$ with $q(f_{g,i}) = r_S(g)_{ii}$, and put $a_g = \sum_{i=1}^4 f_{g,i} - \operatorname{tr} r_0(g) \in (A_M)_0$; by (Wm5), $x_M(a_g) = \sum_i r_0(g)_{ii} - \operatorname{tr} r_0(g) = 0$.

(Mc1) is (La1) and (La2) of Lemma 45.29.

(Mc2). Let ϕ, J, J_w be a chart of R^{gr} as in (Wm1). In degree -2, $J_{(0,-2)} = \emptyset$ ($t_{r,r',m}$ vanishes at $(0,-2)$), so by (La3) the empty family u_{-2} spans rationally. Let $n \in \{-1, 0\}$; the elements of u_n have $x_M = 0$ (by (Wm2): x_R, induced by the constant term, kills $R_{(0,-1)}$, and $x_R(Z_i) = 0$). By (La3) it suffices to show that the vectors $(\mathrm{coeff}_{Y_i}\phi(u_{n,k}))_{i \in J_{(0,n)}}$ span $E_{\mathcal{O}}^{J_{(0,n)}}$. If not, there is $\lambda \in E_{\mathcal{O}}^{J_{(0,n)}} \setminus \{0\}$ with $\delta_0(u_{n,k}) = 0$ for all k, where $\delta_0(f) = \sum_{i \in J_{(0,n)}} \lambda_i \mathrm{coeff}_{Y_i}\phi(f)$ for $f \in R^{\mathrm{gr}}$. Then: δ_0 is $\mathcal{O}$-linear with $\delta_0(fh) = x_R(f)\delta_0(h) + x_R(h)\delta_0(f)$ (linear coefficients of a product of series, and (Sm2)); $\delta_0(R_v) = 0$ for $v \neq (0,n)$ (Sm1); so δ_0 kills every F_i, E_i, Z_i (those of weight $(0,n)$ by the choice of λ); and $\delta_0 \neq 0$, since by (Sm3) for ϕ some f has linear part a non-zero multiple of Y_i for an i with $\lambda_i \neq 0$. *Extension to R.* For $G \in \sum_w P_w$, write $G = G(0) + \sum_s a_s(G)X_s + \sum_s X_s G_s$ with $G_s \in \sum_w P_w$ without constant term (assign each monomial of degree ≥ 2 to the first variable occurring in it); as $x_R(z_s) = 0 = x_R(\pi(G_s))$ and $\delta_0(1) = 0$, $\delta_0(\pi(G)) = \sum_s a_s(G)v_s$ with $v_s = \delta_0(z_s) \in E_{\mathcal{O}}$. Choose $c \in \mathcal{O} \setminus \{0\}$ with all $cv_s \in \mathcal{O}$ and let $\tilde{\delta}\colon P \to \mathcal{O}$, $\tilde{\delta}(G) = \sum_s a_s(G)cv_s$; it satisfies $\tilde{\delta}(GH) = G(0)\tilde{\delta}(H) + H(0)\tilde{\delta}(G)$. For $G \in \mathfrak{a}$, $a_s(G) = a_s(G_{(\mathrm{wt}\, s)})$ and $G_{(\mathrm{wt}\, s)} \in \mathfrak{a}$, so $\tilde{\delta}(G) = \sum_v c\,\delta_0(\pi(G_{(v)})) = 0$ (sum over the weights v of variables). Hence $\tilde{\delta}$ induces an $\mathcal{O}$-linear $\delta\colon R \to \mathcal{O}$ with $\delta(fh) = x_R(f)\delta(h) + x_R(h)\delta(f)$ and $\delta|_{R^{\mathrm{gr}}} = c\,\delta_0$. It kills $\ker q = \sum_u Ru$ (u running over the F_i, E_i, Z_i): $\delta(hu) = x_R(h)\delta(u) + x_R(u)\delta(h) = 0$. So $x_R + \epsilon\delta$ induces $f_\delta\colon S \to \mathcal{O}[\epsilon]$ with $f_\delta(r_S(g)_{ij}) = r_0(g)_{ij} + \epsilon\, c\,\delta_0(h_{g,ij})$ for any $h_{g,ij} \in R_{\mathrm{wt}_4(i,j)}$ with $q(h_{g,ij}) = r_S(g)_{ij}$ (Wm5); the ϵ-part vanishes unless $\mathrm{wt}_4(i,j) = (0,n)$. By Lemma 45.30 (with $A = S$, $r_A = r_S$, $w = (0,n)$), all ϵ-parts vanish; by Step 0 (b) (with $c = 0$), $\delta = 0$, so $\delta_0 = 0$: a contradiction.

(Mc3). Let $b \in \mathcal{O} \setminus \{0\}$. By Lemma 45.32 there are $a \in b\mathcal{O} \setminus \{0\}$ and an injective additive map $\mu \mapsto z_\mu$ from $\mathrm{Sha}[b]$ to the normalised Sha cocycles modulo a. For each μ, (Wm6) gives an $\mathcal{O}$-linear $\delta_\mu\colon R \to \mathcal{O}$ with $\delta_\mu(fh) = x_R(f)\delta_\mu(h) + x_R(h)\delta_\mu(f)$, $\delta_\mu(R_w) = 0$ for $w \neq (0,-1)$, $\delta_\mu(\ker q) \subseteq a\mathcal{O}$, and $\delta_\mu(f) \equiv \theta(g)z_\mu(g)$, resp. $\Psi(g)z_\mu(g)$, modulo a whenever $q(f) = r_S(g)_{31}$, resp. $r_S(g)_{42}$. Let $D(\mu)\colon A_M \to \mathcal{O}/a\mathcal{O}$ be $\delta_\mu|_{A_M}$ followed by reduction, and $D' = \delta_\mu|_{A_M}$; then $D'(fh) = x_M(f)D'(h) + x_M(h)D'(f)$, $D'((A_M)_j) = \delta_\mu(R_{(0,j)}) = 0$ for $j \neq -1$, and $D(\mu)(F_i) = 0$ as $F_i \in \ker q$. *Additivity:* for μ, μ', apply Step 0 (b) with $c = a$ to $\Delta = \delta_{\mu+\mu'} - \delta_\mu - \delta_{\mu'}$ modulo a: it kills $\ker q$ modulo a; for the entries $(3,1)$, $(4,2)$ every h with $q(h) = r_S(g)_{ij}$ has $\Delta(h) = 0$, by additivity of $\mu \mapsto z_\mu$; for every other entry the element $h \in R_{\mathrm{wt}_4(i,j)}$ of (Wm5) has weight $\neq (0,-1)$, so $\Delta(h) = 0$. Hence $D(\mu+\mu') = D(\mu) + D(\mu')$. *Injectivity:* if $D(\mu) = 0$, then for every

g the element $h \in R_{\mathrm{wt}_4(3,1)} = R_{(0,-1)} \subseteq A_M$ with $q(h) = r_S(g)_{31}$ gives $0 = D(\mu)(h) = \theta(g) z_\mu(g)$, so $z_\mu = 0$ ($\theta(g)$ is a unit) and $\mu = 0$.

(Mc4). Let $\mathfrak{D}$ be finite in weight zero. For every point x of A_M on u_M choose $y_x \colon S \to \overline{\mathbb{Q}}_\ell$ and $t_x \in \overline{\mathbb{Q}}_\ell^\times$ as in (Pm2), and put $r_x(g) = y_x(r_S(g))$: a point of $\mathfrak{D}$, as r_S is a symplectic Eisenstein lift to $S \in \mathrm{CNL}_{\mathcal{O}}$ (Wm4). Since $f_{g,i} \in (A_M)_0$, $x(a_g) = \sum_i y_x(q(f_{g,i})) - \operatorname{tr} r_0(g) = \operatorname{tr} r_x(g) - \operatorname{tr} r_0(g)$. If $r_{x'}(g) = \mathrm{T}_4(s_1, s_2)\, r_x(g)\, \mathrm{T}_4(s_1, s_2)^{-1}$ for all g, then by (Pm3), for $f \in (A_M)_n = R_{(0,n)}$, $t_{x'}^n x'(f) = y_{x'}(q(f)) = s_2^n y_x(q(f)) = s_2^n t_x^n x(f)$; so $x' = \tau \cdot x$ with $\tau = s_2 t_x / t_{x'}$.

(Mc5). (Gc2) is (Pm1), and (Gc3) is (Mr1). Let $\mathfrak{D}$ have no endoscopic points and x be a two-signed point of A_M on u_M. By (Pm2), $y_x \circ q|_{A_M} = t_x \cdot x$, a torus translate of x; it lies on u_M and is two-signed ($t_x \neq 0$). By (Mr2), r_x is irreducible. If moreover every irreducible point of $\mathfrak{D}$ is rigid, (Gc4) is (Mr3). □

Lemma 45.29. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, M a symplectic weighted model of $\mathfrak{D}$ with integers r, r', m, and $\phi \colon R^{\mathrm{gr}} \to E_{\mathcal{O}}[[Y_i : i \in J]]$, $\mathrm{wt}_J \colon J \to \mathbb{Z}^2$ a chart as in (Wm1). For $w \in \mathbb{Z}^2$ put $J_w = \mathrm{wt}_J^{-1}(w)$. Then:*

(La1) *$A_M = \bigoplus_{n \in \mathbb{Z}} (A_M)_n$, (A_M, x_M) is a graded $\mathcal{O}$-algebra with a fixed point, and $\{f \in A_M : q(f) = 0\} = I(u_M)$;*

(La2) *(A_M, x_M) is smooth with tangent dimensions* td, *where* $\mathrm{td}(-2), \dots, \mathrm{td}(2)$ *are* $0, r, m, r'+1, 1$ *and* $\mathrm{td}(j) = 0$ *for $|j| > 2$; more precisely, there is a chart ψ of (A_M, x_M) whose variables of degree $n \leq 0$ are the Y_i, $i \in J_{(0,n)}$, such that for all $f \in A_M$ and $i \in J_{(0,n)}$, $n \leq 0$, the coefficient of Y_i in $\psi(f)$ is the coefficient of Y_i in $\phi(f)$;*

(La3) *for $n \leq 0$ and a finite family $u = (u_k)_k$ of elements of $(A_M)_n$ with $x_M(u_k) = 0$: u spans rationally in degree n if and only if the vectors $\big($coefficient of Y_i in $\phi(u_k)\big)_{i \in J_{(0,n)}}$ span the $E_{\mathcal{O}}$-vector space $E_{\mathcal{O}}^{J_{(0,n)}}$.*

Proof. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$, $\pi \colon P \to R$ for the projection, $z_s = \pi(X_s)$, $P_w = \mathcal{O}[[X_\sigma]]_w$, $A_P = \sum_w P_w$, $A_P^0 = \sum_n P_{(0,n)}$, $F(0)$ for the constant term of $F \in P$, $|n| = \sum_s n_s$ for $n \in \mathbb{N}^\sigma$, and $w = (\lambda(w), \mu(w))$ for $w \in \mathbb{Z}^2$. So $R_w = \pi(P_w)$, $R^{\mathrm{gr}} = \pi(A_P)$, $A_M = \pi(A_P^0)$. Put $\mathfrak{m}_R = \ker x_R \cap R^{\mathrm{gr}}$ and $\mathfrak{m}_A = \ker x_M$. As $\mathrm{wt}(\sigma) \subseteq \mathcal{W}_4$, every variable has λ-weight -1, 0 or 1; let $\sigma_0, \sigma_+, \sigma_-$ be the corresponding sets of indices, and call *generators* the monomials X_γ, $\gamma \in \Gamma = \sigma_0 \sqcup (\sigma_+ \times \sigma_-)$, namely X_s ($s \in \sigma_0$) and $X_p X_q$ ($p \in \sigma_+$, $q \in \sigma_-$); each has weight in $\{0\} \times \{-2, \dots, 2\}$, and $z_\gamma = \pi(X_\gamma)$.

Step 0: homogeneity. (i) Monomials of distinct weights are distinct and weights add under multiplication, so $P_v P_w \subseteq P_{v+w}$ and $(GH)_{(u)} = G_{(u-w)} H$ for $H \in P_w$. (ii) If $\pi(F) \in R_w$, say $\pi(F) = \pi(G)$ with $G \in P_w$, then $(F - G)_{(w)} = F_{(w)} - G \in \mathfrak{a}$ ($\mathfrak{a}$ is homogeneous), so $\pi(F) = \pi(F_{(w)})$. (iii) If $\sum_w y_w = 0$ with $y_w = \pi(G_w)$, $G_w \in P_w$ (finitely many), then $\sum_w G_w \in \mathfrak{a}$ and its components G_w lie in $\mathfrak{a}$; so $y_w = 0$ for all w. (iv) $x_R(\pi(F)) = F(0)$ by definition of the origin; hence $x_R(R_w) = 0$ for $w \neq 0$, and for $y \in R^{\mathrm{gr}}$ with components y_w, $x_R(y_0) = x_R(y)$. So every element of $\mathfrak{m}_R$ is a sum of homogeneous elements of $\mathfrak{m}_R$, every element of $\mathfrak{m}_R^k$ is a sum of products of k homogeneous elements of $\mathfrak{m}_R$, and a homogeneous $y \in \mathfrak{m}_R$ of weight w is $\pi(Y)$ with $Y \in P_w$, $Y(0) = 0$ (by (ii) and (iv)). (v) Let $\mathfrak{b} = \pi^{-1}(\ker q)$. By (Wm2), (Wm3) and (ii), $\mathfrak{b} = \mathfrak{a} + (\tilde{u}_k)_k P$ for lifts $\tilde{u}_k \in P_{(0,-1)}, P_{(0,1)}, P_{(0,0)}$ of the F_i, E_i, Z_i; for $H = a + \sum_k B_k \tilde{u}_k$ with $a \in \mathfrak{a}$, (i) gives $H_{(w)} = a_{(w)} + \sum_k (B_k)_{(w - \mathrm{wt}\tilde{u}_k)} \tilde{u}_k \in \mathfrak{b}$.

Step 1: monomials of λ-weight zero. A monomial X^n of λ-weight 0 contains as many factors from σ_+ as from σ_-; pairing them writes X^n as a product of g generators with $|n| \leq 2g$. Hence if $|n| \geq 3$, then $g \geq 2$; if $|n| = 2$, then X^n is $X_s X_{s'}$ with $s, s' \in \sigma_0$ ($g = 2$) or a single generator

X_pX_q. Given $F \in P_{(0,n)}$ with $F(0) = 0$, assign each monomial of F that is a product of at least two generators to one pair (γ, γ') of generators dividing it with λ-weight 0 quotient (finitely many pairs); grouping terms (the maps $n \mapsto n - n_\gamma - n_{\gamma'}$ are injective) gives

$$F = \sum_{\gamma\in\Gamma} c_\gamma X_\gamma + \sum_{(\gamma,\gamma')} X_\gamma X_{\gamma'} H_{\gamma\gamma'}, \qquad c_\gamma \in \mathcal{O},\ H_{\gamma\gamma'} \in A_P^0, \tag{45.2}$$

with c_γ the coefficient of the monomial X_γ in F, and all $c_\gamma = 0$ if every monomial of F has degree at least 3. As $z_\gamma \in \mathfrak{m}_A$ for every γ ($x_M(z_\gamma) = 0$ by (iv)), π of the second sum lies in $\mathfrak{m}_A^2$. Moreover, by Dickson's lemma the set $E_{(0,n)} \subseteq \mathbb{N}^\sigma$ of exponents of weight $(0, n)$ has finitely many minimal elements, every $n' \in E_{(0,n)}$ is $\geq$ one of them with difference in $E_{(0,0)}$, and so $P_{(0,n)} = \sum_m X^m P_{(0,0)}$ over the minimal m; for $n = 0$ the minimal elements $m_1, \dots, m_k$ of $E_{(0,0)} \setminus \{0\}$ generate the monoid $E_{(0,0)}$ (induction on $|n'|$), and $\mathcal{O}[[T_1, \dots, T_k]] \to P_{(0,0)}$, $T_i \mapsto X^{m_i}$, is onto (send $\sum c_{n'} X^{n'}$ to $\sum c_{n'} T^{e(n')}$ for a choice $e(n')$ with $\sum_i e(n')_i m_i = n'$; $n' \mapsto e(n')$ is injective), with kernel in $(\mathfrak{m}_\mathcal{O}, T)$ as constant terms are preserved. So $P_{(0,0)}$ is a complete Noetherian local ring with residue field $\mathbb{F}_\mathcal{O}$.

Step 2: (La1). By Step 0 (iii), the sum $A_M = \sum_n \pi(P_{(0,n)})$ is direct, and $(A_M)_m(A_M)_n \subseteq (A_M)_{m+n}$ by (i). $(A_M)_0 = \pi(P_{(0,0)}) \cong P_{(0,0)}/(\mathfrak{a} \cap P_{(0,0)})$ with $\mathfrak{a} \cap P_{(0,0)}$ inside the maximal ideal (elements of $\mathfrak{a}$ have constant term 0), so it is a complete Noetherian local ring, $\mathcal{O} \to (A_M)_0$ is local and the residue fields agree (Step 1). Each X^m in Step 1 is a product of generators, those of μ-weight 0 lying in $P_{(0,0)}$; so A_M is generated by $(A_M)_0$ and the finitely many z_γ with $\mu(\operatorname{wt}\gamma) \in \{\pm 1, \pm 2\}$. x_M kills $(A_M)_n$ for $n \neq 0$ by (iv). So (A_M, x_M) is a graded $\mathcal{O}$-algebra with a fixed point. The elements F_i, E_i, Z_i lie in $\ker q$ (Wm3), so $I(u_M) \subseteq \ker q$. Conversely let $f = \pi(G) \in A_M$, $G \in A_P^0$, with $q(f) = 0$; then $G \in \mathfrak{b}$, and by Step 0 (v) each component $G_{(0,n)} = a_{(0,n)} + \sum_k (B_k)_{(0,n)-\operatorname{wt}\tilde{u}_k} \tilde{u}_k$, with coefficients in A_P^0 since $\operatorname{wt}\tilde{u}_k$ has λ-weight 0; applying π, $f = \sum_n \pi(G_{(0,n)}) \in I(u_M)$.

Step 3: the chart. Let $i_\alpha, i_\beta, i_\theta$ be the unique elements of J of weights $(1, 0)$, $(-1, 1)$, $(1, 1)$, and $J_0 = J \setminus \{i_\alpha, i_\beta, i_\theta\}$, the indices of λ-weight 0 (counts: r' of weight $(0, 1)$, r of $(0, -1)$, m of $(0, 0)$). Let $\Lambda = E_\mathcal{O}[[Y_J]]$ and Λ^0 the series all of whose monomials have λ-weight 0; these monomials are $Y_{i_\alpha}^a Y_{i_\theta}^c Y_{i_\beta}^{a+c} Y^n$ with Y^n a monomial in the Y_i, $i \in J_0$. Let $\Lambda' = E_\mathcal{O}[[Y_i\,(i \in J_0), Y_{\alpha\beta}, Y_{\theta\beta}]]$ with μ-weights $\mu(\operatorname{wt}_J(i))$, 1, 2, and $\kappa\colon \Lambda^0 \to \Lambda'$ the coefficientwise map $Y_{i_\alpha}^a Y_{i_\theta}^c Y_{i_\beta}^{a+c} Y^n \mapsto Y_{\alpha\beta}^a Y_{\theta\beta}^c Y^n$: a bijection on monomials, multiplicative, hence a ring isomorphism; it preserves μ-weights ($c + (a + c) = a + 2c$), constant terms and the coefficients of the Y_i, $i \in J_0$, and it sends monomials of degree $2a + 2c + |n| \geq 3$ to monomials of degree $a + c + |n| \geq 2$. By (Sm1) for ϕ, $\phi(A_M) \subseteq \Lambda^0$; put $\psi = \kappa \circ \phi|_{A_M}$. The numbers of variables of μ-weight $-2, \dots, 2$ are $0, r, m, r' + 1, 1$, the variables of degree $n \leq 0$ are the Y_i, $i \in J_{(0,n)}$, and the coefficient assertion of (La2) holds. (Sm1) and (Sm2) for ψ follow from those for ϕ.

Step 4: (Sm3) for ψ. By (Sm3) for ϕ there are $f \in R^{\mathrm{gr}}$ whose linear part is a non-zero multiple c_iY_i of Y_i; replacing f by its component of weight $\operatorname{wt}_J(i)$ (whose image is the weight-$\operatorname{wt}_J(i)$ part of $\phi(f)$ by (Sm1)) and subtracting $x_R(f)$, we get $f_i \in R_{\operatorname{wt}_J(i)} \cap \mathfrak{m}_R$ with linear part c_iY_i, $c_i \neq 0$ ($i \in J$). Put $g_{\alpha\beta} = f_{i_\alpha} f_{i_\beta} \in R_{(0,1)}$ and $g_{\theta\beta} = f_{i_\theta} f_{i_\beta} \in R_{(0,2)}$, elements of A_M. Since $\phi(f_{i_\alpha}) = c_{i_\alpha} Y_{i_\alpha} + (\text{degree} \geq 2)$ and likewise for i_β, $\phi(g_{\alpha\beta}) = c_{i_\alpha} c_{i_\beta} Y_{i_\alpha} Y_{i_\beta} + (\text{degree} \geq 3)$, so $\psi(g_{\alpha\beta}) = c_{i_\alpha} c_{i_\beta} Y_{\alpha\beta} + (\text{degree} \geq 2)$; similarly $\psi(g_{\theta\beta}) = c_{i_\theta} c_{i_\beta} Y_{\theta\beta} + (\text{degree} \geq 2)$. For $i \in J_0$, $f_i \in A_M$ and $\psi(f_i)$ has linear part $c_iY_i + e_iY_{\alpha\beta} + e_i'Y_{\theta\beta}$ with $e_i, e_i' \in E_\mathcal{O}$; choose $k \geq 0$ with $o_i = \ell^k e_i/(c_{i_\alpha} c_{i_\beta})$ and $o_i' = \ell^k e_i'/(c_{i_\theta} c_{i_\beta})$ in $\mathcal{O}$; then $\ell^k f_i - o_i g_{\alpha\beta} - o_i' g_{\theta\beta} \in A_M$ has linear part $\ell^k c_i Y_i$. This is (Sm3).

Step 5: products in A_M. (a) If $y_1, y_2, y_3 \in \mathfrak{m}_R$ are homogeneous and $y_1y_2y_3 \in A_M$, then $y_1y_2y_3 \in \mathfrak{m}_A^2$: by Step 0 (iv) write $y_k = \pi(Y_k)$, $Y_k \in P_{w_k}$, $Y_k(0) = 0$; then $Y_1Y_2Y_3 \in P_{(0,n)}$ has only monomials of degree ≥ 3, and (45.2) with all $c_\gamma = 0$ gives the claim. (b) If $y_1, y_2 \in \mathfrak{m}_R$ are

homogeneous and $y_1y_2 \in A_M$, then in the same way $y_1y_2 \in \mathfrak{m}_A^2 + \sum_{p\in\sigma_+,q\in\sigma_-} \mathcal{O} z_pz_q$ (the only single generators of degree 2 are the X_pX_q). (c) By Step 0 (iv) and (iii) (compare components of weight $(0,n)$), every element of $\mathfrak{m}_R^3 \cap (A_M)_n$ lies in $\mathfrak{m}_A^2$ and every element of $\mathfrak{m}_R^2 \cap (A_M)_n$ in $\mathfrak{m}_A^2 + \sum \mathcal{O} z_pz_q$.

Step 6: the pairs. Let $p \in \sigma_+$, $q \in \sigma_-$. We show: there are $d \in \mathcal{O}\setminus\{0\}$ and $e, e' \in \mathcal{O}$ with $dz_pz_q - eg_{\alpha\beta} - e'g_{\theta\beta} \in \mathfrak{m}_A^2$. By (Sm1), the linear part of $\phi(z_p)$ involves only variables of weight $\mathrm{wt}(p) \in \{(1,0),(1,1),(1,-1)\}$: it is $L_pY_{i_\alpha}$, $L_pY_{i_\theta}$ or 0 with $L_p \in E_{\mathcal{O}}$. In the first case choose $d_p \in \mathcal{O}\setminus\{0\}$, $o_p \in \mathcal{O}$ with $d_pL_p = o_pc_{i_\alpha}$; then $h = d_pz_p - o_pf_{i_\alpha} \in R_{(1,0)} \cap \mathfrak{m}_R$ has zero linear part, so by (Sm4) for ϕ, $c\,h \in \mathfrak{m}_R^2$ for some $c \neq 0$: $cd_pz_p = co_pf_{i_\alpha} + k_p$ with $k_p \in \mathfrak{m}_R^2 \cap R_{(1,0)}$. The second case is the same with f_{i_θ}; in the third, $cz_p = k_p \in \mathfrak{m}_R^2$. Likewise $c'd_qz_q = c'o_qf_{i_\beta} + k_q$ if $\mathrm{wt}(q) = (-1,1)$, and $c'z_q = k_q \in \mathfrak{m}_R^2$ if $\mathrm{wt}(q) \in \{(-1,0),(-1,-1)\}$. Multiplying the two relations, the product of the constants times z_pz_q equals $o\,f_{i_*}f_{i_\beta}$ (when both first relations occur, $f_{i_*}f_{i_\beta} \in \{g_{\alpha\beta}, g_{\theta\beta}\}$) plus terms each of which is a product of a homogeneous element of $\mathfrak{m}_R$ and a homogeneous element of $\mathfrak{m}_R^2$, of total weight $\mathrm{wt}(p)+\mathrm{wt}(q)$, of λ-weight 0; these lie in $\mathfrak{m}_A^2$ by Step 5 (a), (c).

Step 7: (Sm4) for ψ. Let $f \in A_M$ with $x_M(f) = 0$ and all linear coefficients of $\psi(f)$ zero. By (Sm1) the components f_n have the same properties ($\psi(f_n)$ is the weight-n part of $\psi(f)$, and $x_M(f_0) = x_M(f)$), and $\mathrm{Sq}(x_M)$ is an $\mathcal{O}$-module; so let $f \in (A_M)_n$, $f = \pi(F)$ with $F \in P_{(0,n)}$, $F(0) = 0$. By (45.2), $f \equiv \sum_{s\in\sigma_0} c_sz_s + \sum_{p,q} c_{pq}z_pz_q$ modulo $\mathfrak{m}_A^2$. For $s \in \sigma_0$ of weight $(0,n)$ the linear part of $\phi(z_s)$ is $\sum_{i\in J_{(0,n)}} L_{si}Y_i$; choose $d_s \neq 0$, $o_{si} \in \mathcal{O}$ with $d_sL_{si} = o_{si}c_i$; then $d_sz_s - \sum_i o_{si}f_i \in R_{(0,n)} \cap \mathfrak{m}_R$ has zero linear part, so a non-zero multiple of it lies in $\mathfrak{m}_R^2 \cap (A_M)_n$, hence (Step 5 (c)) in $\mathfrak{m}_A^2 + \sum \mathcal{O} z_pz_q$. With Step 6, there are $c \in \mathcal{O}\setminus\{0\}$ and e_i $(i \in J_0), e_{\alpha\beta}, e_{\theta\beta} \in \mathcal{O}$ with

$$cf - \sum_{i\in J_0} e_if_i - e_{\alpha\beta}g_{\alpha\beta} - e_{\theta\beta}g_{\theta\beta} \in \mathfrak{m}_A^2.$$

Elements of $\mathfrak{m}_A^2$ have images without constant and linear terms ($\psi(\mathfrak{m}_A)$ has zero constant terms by (Sm2)). Comparing linear coefficients, using Step 4: at Y_i $(i \in J_0)$, $0 = e_ic_i$, so $e_i = 0$; then at $Y_{\alpha\beta}$ and $Y_{\theta\beta}$, $e_{\alpha\beta} = e_{\theta\beta} = 0$. So $cf \in \mathfrak{m}_A^2$ and $f \in \mathrm{Sq}(x_M)$. Hence ψ is a chart, which proves (La2).

Step 8: (La3). Let $n \leq 0$ and $\mathrm{Lin}(f) \in E_{\mathcal{O}}^{J_{(0,n)}}$ the vector of coefficients of the Y_i, $i \in J_{(0,n)}$, in $\psi(f)$, equivalently in $\phi(f)$; for $f \in (A_M)_n$ these are all the linear coefficients of $\psi(f)$ (Sm1), and Lin kills $\mathrm{Sq}(x_M)$. If the $\mathrm{Lin}(u_k)$ span, let $p \in \mathrm{Cot}_n$ be the class of $f \in (A_M)_n \cap \mathfrak{m}_A$, write $\mathrm{Lin}(f) = \sum_k e_k\mathrm{Lin}(u_k)$ and choose $c \neq 0$ with all $ce_k \in \mathcal{O}$; then $cf - \sum_k ce_ku_k$ has $x_M = 0$ and no linear terms, so it lies in $\mathrm{Sq}(x_M)$ (Sm4), and $cp \in \mathrm{Cot}(u)$. Conversely, if u spans rationally, then for $i \in J_{(0,n)}$ the degree-n component of the element of Step 4 for Y_i, minus its value under x_M, has Lin a non-zero multiple of the basis vector at i, and some non-zero multiple of its class lies in $\mathrm{Cot}(u)$; applying Lin, that basis vector lies in the span of the $\mathrm{Lin}(u_k)$. □

Lemma 45.30. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, and $\mathcal{O}[\epsilon] = \mathcal{O}[\epsilon]/(\epsilon^2)$. Let $A \in \mathrm{CNL}_{\mathcal{O}}$, r_A a symplectic Eisenstein lift to A and $f\colon A \to \mathcal{O}[\epsilon]$ an $\mathcal{O}$-algebra homomorphism with $f(r_A(g)_{ij}) = r_0(g)_{ij} + \epsilon\, y_{ij}(g)$, $y_{ij}(g) \in \mathcal{O}$, for all $g \in G_{\mathbb{Q}}$ and $1 \leq i,j \leq 4$. Let $w \in \{(0,-1),(0,0)\}$. If $y_{ij} = 0$ for every (i,j) with $\mathrm{wt}_4(i,j) \neq w$, then $y_{ij} = 0$ for all i,j.*

Proof. Write $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, $f = f_0 + \epsilon f_1$ with $f_0\colon A \to \mathcal{O}$ an $\mathcal{O}$-algebra homomorphism and f_1 an $\mathcal{O}$-linear map with $f_1(ab) = f_0(a)f_1(b) + f_0(b)f_1(a)$. Put $Y(g) = (y_{ij}(g))$ and $Z(g) = Y(g)\,r_0(g)^{-1}$, so $Z(g)_{ij} = y_{ij}(g)\kappa_j(g)^{-1}$ and $f(r_A(g)) = (1 + \epsilon Z(g))\,r_0(g)$; write $z_{ij} = Z_{ij}$. It suffices to show $Z = 0$.

Step 1: Z is a continuous $\mathfrak{sp}_4$-valued cocycle. f_0 is local (for $a \in \mathfrak{m}_A$ and $u \in \mathcal{O}^\times$, $a-u$ is a unit, so $f_0(a) \neq u$), and by induction $f_1(\mathfrak{m}_A^{N+1}) \subseteq \mathfrak{m}_\mathcal{O}^N$ (for $a \in \mathfrak{m}_A^N$, $b \in \mathfrak{m}_A$: $f_1(ab) = f_0(a)f_1(b) + f_0(b)f_1(a)$, $f_0(a) \in \mathfrak{m}_\mathcal{O}^N$, $f_0(b) \in \mathfrak{m}_\mathcal{O}$). As r_A is continuous, each y_{ij}, hence each z_{ij}, is continuous for the ℓ-adic topology. Comparing ϵ-parts in $f(r_A(gh)) = f(r_A(g))f(r_A(h))$ gives $Z(gh) = Z(g) + r_0(g)Z(h)r_0(g)^{-1}$, that is

$$z_{ij}(gh) = z_{ij}(g) + (\kappa_i/\kappa_j)(g)\, z_{ij}(h).$$

By (Se1), ${}^t f(r_A(g))\, J_4\, f(r_A(g)) = \theta(g)J_4$; its ϵ-part is ${}^t r_0(g)({}^t Z(g)J_4 + J_4 Z(g))r_0(g) = 0$, so $Z(g) \in \mathfrak{sp}_4(\mathcal{O})$. The entry $(1,2)$ of ${}^t Z J_4 + J_4 Z$ is $-z_{31} + z_{42}$ (J_4 has entries $(1,4),(2,3)$ equal to 1 and $(3,2),(4,1)$ equal to -1); hence $z_{42} = z_{31}$.

Step 2: two facts on cocycles. Let H be a group, $\kappa\colon H \to E_\mathcal{O}^\times$ a homomorphism and $z\colon H \to E_\mathcal{O}$ with $z(gh) = z(g) + \kappa(g)z(h)$. (a) If z vanishes on a subgroup U of finite index, there is $m \in E_\mathcal{O}$ with $z(g) = \kappa(g)m - m$ on H. Indeed, for $x \in \ker\kappa$ some x^n, $1 \leq n \leq [H:U]$, lies in U (two of the cosets $x^k U$, $0 \leq k \leq [H:U]$, coincide), and z is additive on $\ker\kappa$, so $nz(x) = 0$ and $z(x) = 0$. If $\kappa = 1$ take $m = 0$. Otherwise pick s with $\kappa(s) \neq 1$; for $g \in H$ the commutator $g^{-1}s^{-1}gs$ lies in $\ker\kappa$, so $z(gs) = z(sg)$, i.e. $z(g) + \kappa(g)z(s) = z(s) + \kappa(s)z(g)$, and $z(g) = \kappa(g)m - m$ with $m = z(s)/(\kappa(s)-1)$. (b) If $z(h) = \kappa(h)m - m$ for h in a subgroup H_1 and $t \in H$, then $z(x) = \kappa(x)m' - m'$ for $x \in tH_1t^{-1}$, with $m' = \kappa(t)m - z(t)$: for $x = tht^{-1}$, $z(x) + \kappa(x)z(t) = z(xt) = z(th) = z(t) + \kappa(t)(\kappa(h)m - m)$ and $\kappa(x) = \kappa(h)$.

Step 3: local behaviour. (i) Let $\bar{w}$ be a place above a prime $p \notin T$. By (Se2), $Z = 0$ on $I_{\bar{w}} \cap \ker\bar{r}_0$, a subgroup of finite index of $I_{\bar{w}}$ ($\bar{r}_0$ has finite image); by Step 2 (a), each z_{ij} is a coboundary on $I_{\bar{w}}$. (ii) Let $v \in T$, $v \neq \ell$. By (Se4) there are a domain $B \in \mathrm{CNL}_\mathcal{O}$, a lift ρ_B of $\bar{r}_0|_{D_v}$ satisfying the local condition at v and $y\colon B \to A$ with $y \circ \rho_B = r_A|_{D_v}$; so $f(r_A(g)) = 1$ for $g \in I_v \cap \ker\chi$, a subgroup of finite index of I_v (χ has finite order), and each z_{ij} is a coboundary on I_v, hence (Step 2 (b)) on $I_{\bar{w}} = tI_v t^{-1}$ for every place $\bar{w} = t\bar{v}$ above v. (iii) At ℓ, (Se4) gives B, ρ_B, y with ρ_B ordinary and $y \circ \rho_B = r_A|_{D_\ell}$. The conditions defining ordinary representations are polynomial identities in the entries of $\rho(s_0)$ and $\rho(g)$ with coefficients in $\mathcal{O}$, so $\rho' = f \circ r_A|_{D_\ell}$ is ordinary, as a homomorphism to $\mathrm{GL}_4(E_\mathcal{O}[\epsilon])$. Put $c = \chi_{\mathrm{cyc}}(s_0)$ and $c_k = \kappa_k(s_0)$; by (Sg5) and (Sg1) (ξ is unramified at $\ell \in T$), $(c_1,\dots,c_4) = (c^{e+1}, c^e, c, 1)$, pairwise distinct as c has infinite order and $e \geq 2$; put $d_i = \prod_{k\neq i}(c_i - c_k) \neq 0$, $D = \mathrm{diag}(c_1,\dots,c_4)$, and E_i the diagonal idempotent at i, so that $\prod_{k\neq i}(D - c_k) = d_i E_i$.

Step 4: the case $w = (0,0)$. Here $Z(g)$ is diagonal and each $z_i = z_{ii}$ is a continuous homomorphism $G_\mathbb{Q} \to \mathcal{O}$ ($\kappa_i/\kappa_i = 1$). At ℓ: $\rho'(s_0) = \mathrm{diag}(c_k(1+\epsilon z_k(s_0)))$, so $\Pi_i = \prod_{k\neq i}(\rho'(s_0) - c_k)$ is diagonal with entry (i,i) equal to $d_i + \epsilon(\cdot)$; for $s \in I_\ell$, $\rho'(s) - \kappa_i(s)$ is diagonal with entry (i,i) equal to $\epsilon\kappa_i(s)z_i(s)$; the entry (i,i) of $\Pi_i(\rho'(s) - \kappa_i(s))\Pi_i = 0$ is $\epsilon d_i^2 \kappa_i(s) z_i(s)$, so $z_i = 0$ on I_ℓ, hence on every $tI_\ell t^{-1}$. At $p \neq \ell$: by Step 3 (i), (ii) and Step 2 (a) with $\kappa = 1$, z_i vanishes on every inertia group. For $N \geq 1$ the reduction of z_i modulo $\ell^N\mathcal{O}$ is a continuous homomorphism with finite abelian image that kills every inertia group; its kernel cuts out a finite abelian extension of $\mathbb{Q}$ unramified at every prime, which is $\mathbb{Q}$ by Minkowski's theorem. So $z_i(G_\mathbb{Q}) \subseteq \bigcap_N \ell^N\mathcal{O} = 0$, and $Z = 0$.

Step 5: the case $w = (0,-1)$. The entries of weight $(0,-1)$ are $(3,1)$ and $(4,2)$, so $Z(g)$ has at most the entries $z_{31}(g)$ and $z_{42}(g) = z_{31}(g)$, and $z = z_{31}$ is a continuous cocycle for $\kappa_3/\kappa_1 = \alpha/\theta = \Psi^{-1}$. *At ℓ:* $\rho'(s_0) = D + \epsilon N D$ with $N = Z(s_0)$. Let X have entries $X_{31} = -N_{31}c_1/(c_3 - c_1)$, $X_{42} = -N_{42}c_2/(c_4 - c_2)$ and 0 elsewhere, and $P = 1 + \epsilon X$; then $(DX - XD)_{ak} = (c_a - c_k)X_{ak}$, so $P^{-1}\rho'(s_0)P = D + \epsilon(ND + DX - XD) = D$. Hence $\Pi_i = P\prod_{k\neq i}(D - c_k)P^{-1} = d_i P E_i P^{-1}$, and the ordinary condition $\Pi_j \rho'(g)\Pi_i = 0$ ($i < j$, $g \in D_\ell$) gives $E_j P^{-1}\rho'(g)P E_i = 0$: $P^{-1}\rho'(g)P$ is upper triangular. Its entry $(3,1)$ has ϵ-part $z(g)\kappa_1(g) - X_{31}\kappa_1(g) + \kappa_3(g)X_{31} = 0$, so $z(g) = \Psi^{-1}(g)m_\ell - m_\ell$ on D_ℓ with $m_\ell = -X_{31} \in E_\mathcal{O}$, and by Step 2 (b) z is a coboundary

on $D_{\bar w} = tD_\ell t^{-1}$ for every place $\bar w = t\bar\ell$ above ℓ. *Away from ℓ:* z is a coboundary on every $I_{\bar w}$, $\bar w \nmid \ell$, by Step 3 (i), (ii). Now $\Psi^{-1} = \chi^{-1}\chi_{\mathrm{cyc}}^{-e}$ with χ of finite order (open kernel) and $e \geq 2$; by Lemma 45.31 (with $\psi = \chi$), there is $m \in \overline{\mathbb{Q}}_\ell$ with $z(g) = \Psi^{-1}(g)m - m$ for all $g \in G_{\mathbb{Q}}$. *Normalisation*: by (Se3), $h(r_A)_{31} = 0$, hence the entry $(3,1)$ of $f(r_A(g_0)) + \theta(g_0)f(r_A(g_0^{-1}))$ vanishes; its ϵ-part is $z(g_0)\theta(g_0) + \theta(g_0)z(g_0^{-1})\theta(g_0)^{-1} = \theta(g_0)z(g_0) + z(g_0^{-1})$. Substituting,

$$0 = \theta(g_0)(\Psi^{-1}(g_0) - 1)m + (\Psi(g_0) - 1)m = (\Psi(g_0) - 1)(1 - \alpha(g_0))m,$$

using $\theta = \alpha\Psi$. By (Sg4) both factors are units of $\mathcal{O}$, so $m = 0$, $z = 0$, and $Z = 0$. □

Lemma 45.31. *Let ℓ be a prime, $\psi\colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell^\times$ a homomorphism with open kernel, $e \geq 1$ an integer and $\theta = \psi^{-1}\chi_{\mathrm{cyc}}^{-e}$. Let $z\colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ be continuous with $z(gh) = z(g) + \theta(g)z(h)$ for all g, h, such that for every place $\bar w$ of $\overline{\mathbb{Q}}$ above a prime $p \neq \ell$ there is $m_{\bar w}$ with $z(g) = \theta(g)m_{\bar w} - m_{\bar w}$ for $g \in I_{\bar w}$, and for every place $\bar w$ above ℓ there is $m_{\bar w}$ with $z(g) = \theta(g)m_{\bar w} - m_{\bar w}$ for $g \in D_{\bar w}$. Then there is $m \in \overline{\mathbb{Q}}_\ell$ with $z(g) = \theta(g)m - m$ for all $g \in G_{\mathbb{Q}}$.*

Proof. Step 1: a field. Let $L \subset \overline{\mathbb{Q}}$ be the compositum of the fixed field of $\ker\psi$ (finite and Galois over $\mathbb{Q}$, as $\ker\psi$ is open and normal), $\mathbb{Q}(i)$ and $\mathbb{Q}(\mu_\ell)$. L is a number field, Galois over $\mathbb{Q}$, totally complex, and contains a primitive ℓ-th and a primitive fourth root of unity. On G_L, $\psi = \mathbf{1}$ and $\theta = \chi_{\mathrm{cyc}}^{-e}$. Since $\chi_{\mathrm{cyc}}(D_{\bar w} \cap G_L)$ is an open, hence infinite, subgroup of $\mathbb{Z}_\ell^\times$ for $\bar w$ above ℓ, while $x^{-e} = 1$ has finitely many solutions, each $D_{\bar w} \cap G_L$ ($\bar w \mid \ell$) contains h with $\theta(h) \neq 1$.

Step 2: $z|_{G_L}$ factors through G_{L,S_ℓ}. Let $\bar w$ lie above a prime $p \neq \ell$. As χ_{cyc} is trivial on $I_{\bar w}$, $\theta = 1$ on $I_{\bar w} \cap G_L$, so $z = \theta m_{\bar w} - m_{\bar w} = 0$ there. On $H_0 = \ker\theta \cap G_L$ the cocycle relation makes z additive; the groups $I_{\bar w} \cap G_L$ ($\bar w$ above primes $\neq \ell$) lie in H_0 and are permuted by conjugation in G_L, so z vanishes on the closed normal subgroup $N \subseteq H_0$ of G_L they generate (z is continuous). For $g \in G_L$ and $n \in N$, $z(gn) = z(g) + \theta(g)z(n) = z(g)$, and $\theta|_{G_L} = \chi_{\mathrm{cyc}}^{-e}$ is trivial on N; since $G_L/N = G_{L,S_\ell}$ (L is totally complex), $z|_{G_L}$ is a continuous cocycle of G_{L,S_ℓ} for χ_{cyc}^{-e}.

Step 3: rational coordinates. By Lemma 42.8, item 3 (for $\Gamma = G_{\mathbb{Q}}$ acting on $\mathbb{Q}_\ell(\psi)$, enlarged to a finite extension containing the values of ψ by item 1), z takes values in a finite extension $E' \subset \overline{\mathbb{Q}}_\ell$ of $\mathbb{Q}_\ell$. For each place v of L above ℓ fix $\bar w_v$ above v, so that $G_{L_v} = D_{\bar w_v} \cap G_L$; with h as in Step 1, $m_{\bar w_v} = z(h)/(\theta(h) - 1) \in E'$. Choose a $\mathbb{Q}_\ell$-basis $b_1, \dots, b_d$ of E' and write $z = \sum_i z_i b_i$, $m_{\bar w_v} = \sum_i m_{v,i} b_i$ with $z_i\colon G_L \to \mathbb{Q}_\ell$ and $m_{v,i} \in \mathbb{Q}_\ell$. As $\theta|_{G_L}$ is $\mathbb{Z}_\ell^\times$-valued, each z_i is a continuous cocycle of G_{L,S_ℓ} for χ_{cyc}^{-e} with $z_i(g) = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)m_{v,i}$ on G_{L_v}. The images $z_i(G_L)$ are compact, so for some $n \geq 0$ all $\ell^n z_i$ take values in $\mathbb{Z}_\ell$ and all $\ell^n m_{v,i}$ lie in $\mathbb{Z}_\ell$ (finitely many v).

Step 4: z is a coboundary on G_L. By Proposition 40.3, $\mathrm{len}_\ell(L, e) < \infty$ (L is totally complex and contains a primitive ℓ-th root of unity, and a primitive fourth one if $\ell = 2$). By Lemma 43.33 for $E = L$, $k = e$, the cocycle $\ell^n z_i$ and $W_v = \ell^n m_{v,i}$, there is $x_i \in \mathbb{Q}_\ell$ with $\ell^n z_i(g) = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)x_i$ on G_L. With $x = \ell^{-n}\sum_i x_i b_i$, $z(g) = \theta(g)x - x$ for $g \in G_L$.

Step 5: z is a coboundary on $G_{\mathbb{Q}}$. $z'(g) = z(g) - (\theta(g)x - x)$ is a cocycle for θ vanishing on G_L. For $g \in G_{\mathbb{Q}}$ and $h \in G_L$, $z'(hg) = z'(h) + \theta(h)z'(g) = \theta(h)z'(g)$, and, G_L being normal, $z'(hg) = z'(g) + \theta(g)z'(g^{-1}hg) = z'(g)$. Taking $h \in G_L$ with $\theta(h) \neq 1$ (Step 1) gives $z'(g) = 0$. So $z(g) = \theta(g)m - m$ with $m = x$. □

Lemma 45.32. *Let $\mathfrak{D} = (\ell, \mathcal{O}, e, N, \chi, \xi, S, \dots)$ be a symplectic Eisenstein datum, $n_S = \prod_{p\in S} p$, $b \in \mathcal{O} \setminus \{0\}$, and $\mathrm{Sha}[b]$ the submodule of $\mathrm{Sha}^1_{n_S}(\chi, e)$ killed by b. There are $a \in b\mathcal{O} \setminus \{0\}$ and an injective additive map $\mu \mapsto z_\mu$ from $\mathrm{Sha}[b]$ to the group of maps $G_{\mathbb{Q}} \to \mathcal{O}/a\mathcal{O}$ such that every z_μ is a normalised Sha cocycle modulo a for $\mathfrak{D}$.*

Proof. Write $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$ and $V = \mathcal{O}^{\vee}(\Psi^{-1}) = E_{\mathcal{O}}/\mathcal{O}$ with g acting by $\Psi^{-1}(g)$; for $m \in V$ let dm be the coboundary $g \mapsto \Psi^{-1}(g)m - m$. For $a \in \mathcal{O} \setminus \{0\}$, $V[a] = a^{-1}\mathcal{O}/\mathcal{O}$, and $\iota_a \colon \mathcal{O}/a\mathcal{O} \to V[a]$, $y \mapsto a^{-1}y$, is an isomorphism of $\mathcal{O}$-modules compatible with the actions through Ψ^{-1}.

Step 1: local elements. For every $v \in T$ there is $s_v \in D_v$ with $\Psi(s_v) \neq 1$. For $v = \ell$ take $s_v = s_0$: $\chi(s_0) = 1$ by (Sg5), so $\Psi(s_0) = \chi_{\mathrm{cyc}}(s_0)^e \neq 1$, $\chi_{\mathrm{cyc}}(s_0)$ having infinite order. For $v \in S_\ell(\chi)$, χ'' is ramified at v; if χ were trivial on I_v, then $\chi''|_{I_v} = (\chi'|_{I_v})^{-1}$ would have order both a power of ℓ and prime to ℓ, hence be trivial; so there is $s_v \in I_v$ with $\chi(s_v) \neq 1$, and $\Psi(s_v) = \chi(s_v)$ as χ_{cyc} is trivial on I_v ($v \neq \ell$). Moreover, *if $p \notin T$ and $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$ for a place $\bar{w}$ above p, then* $\Psi(g) = 1$: $p \neq \ell$, so $\chi_{\mathrm{cyc}}(g) = 1$ and $\bar{\chi}(g) = \bar{\Psi}(g) = 1$; on $I_{\bar{w}}$, χ'' is trivial (as $p \notin S_\ell(\chi)$), so $\chi(g) = \chi'(g)$ is a root of unity of order prime to ℓ with residue 1, hence $\chi(g) = 1$.

Step 2: the modulus. Put $c_T = \prod_{v \in T}(\Psi^{-1}(s_v) - 1) \in \mathcal{O} \setminus \{0\}$ and $a = bc_T$.

Step 3: normalised representatives. By (Sg4), $u = \Psi^{-1}(g_0) - 1$ is a unit of $\mathcal{O}$. Every class $\mu \in H^1(\mathbb{Q}, V)$ has exactly one representative N_μ (a continuous cocycle $G_{\mathbb{Q}} \to V$) with $N_\mu(g_0) = 0$: if $\tilde{z}$ represents μ, then $\tilde{z} - d(u^{-1}\tilde{z}(g_0))$ vanishes at g_0, and two such representatives differ by some dm with $um = 0$, i.e. $m = 0$. Uniqueness gives $N_{\mu+\mu'} = N_\mu + N_{\mu'}$, and $N_\mu = 0$ only for $\mu = 0$. For $\mu \in \mathrm{Sha}[b]$, bN_μ is the normalised representative of $b\mu = 0$, so $bN_\mu = 0$: N_μ takes values in $V[b] \subseteq V[a]$. Put $z_\mu = \iota_a^{-1} \circ N_\mu \colon G_{\mathbb{Q}} \to \mathcal{O}/a\mathcal{O}$. Then $\mu \mapsto z_\mu$ is additive and injective, z_μ is locally constant (N_μ is continuous with values in the discrete module V), $z_\mu(gh) = z_\mu(g) + \Psi^{-1}(g)z_\mu(h)$ and $z_\mu(g_0) = 0$.

Step 4: away from T. Let $\bar{w} = t\bar{p}$ ($t \in G_{\mathbb{Q}}$) be a place above $p \notin T$ and $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$. As μ is unramified at p, $N_\mu = dm$ on $I_{\bar{p}}$ for some $m \in V$; for $x = tht^{-1}$ with $h \in I_{\bar{p}}$, $N_\mu(x) + \Psi^{-1}(x)N_\mu(t) = N_\mu(th) = N_\mu(t) + \Psi^{-1}(t)(\Psi^{-1}(h)m - m)$, so $N_\mu = dm'$ on $I_{\bar{w}} = tI_{\bar{p}}t^{-1}$ with $m' = \Psi^{-1}(t)m - N_\mu(t)$. By Step 1, $\Psi(g) = 1$, so $N_\mu(g) = 0$ and $z_\mu(g) = 0$.

Step 5: at T. Let $v \in T$. By (Sg1), $T \subseteq S$, so $v \mid n_S$ and μ is locally trivial at v: $N_\mu(g) = \Psi^{-1}(g)m_v - m_v$ for $g \in D_v$, with $m_v \in V$. Then $(\Psi^{-1}(s_v) - 1)m_v = N_\mu(s_v) \in V[b]$, so $am_v = \big(\prod_{v' \neq v}(\Psi^{-1}(s_{v'}) - 1)\big)\, b\,(\Psi^{-1}(s_v) - 1)m_v = 0$, $m_v \in V[a]$, and $y_v = \iota_a^{-1}(m_v)$ satisfies $z_\mu(g) = \Psi^{-1}(g)y_v - y_v$ for $g \in D_v$. Hence z_μ is a normalised Sha cocycle modulo a. □

Lemma 45.33. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ that is finite in weight zero, and M a symplectic weighted model of $\mathfrak{D}$. For $s = (s_1, s_2) \in (\overline{\mathbb{Q}}_\ell^{\times})^2$ and $w = (w_1, w_2) \in \mathbb{Z}^2$ write $s^w = s_1^{w_1}s_2^{w_2}$. Then:*

(Pm1) *the image of $(A_M)_0$ in $A_M/I(u_M)$ is a finitely generated $\mathcal{O}$-module;*

(Pm2) *for every point x of A_M on u_M there are an $\mathcal{O}$-algebra homomorphism $y \colon S \to \overline{\mathbb{Q}}_\ell$ and $t \in \overline{\mathbb{Q}}_\ell^{\times}$ with $y(q(f)) = t^n x(f)$ for all $n \in \mathbb{Z}$ and $f \in (A_M)_n$;*

(Pm3) *if $y, y' \colon S \to \overline{\mathbb{Q}}_\ell$ are $\mathcal{O}$-algebra homomorphisms and $s \in (\overline{\mathbb{Q}}_\ell^{\times})^2$ with*

$$y'(r_S(g)) = \mathrm{T}_4(s)\, y(r_S(g))\, \mathrm{T}_4(s)^{-1}$$

for all $g \in G_{\mathbb{Q}}$ (entrywise application), then $y'(q(f)) = s^w y(q(f))$ for all $w \in \mathbb{Z}^2$ and $f \in R_w$.

Proof. Write $K = \overline{\mathbb{Q}}_\ell$, $P = \mathcal{O}[[X_s : s \in \sigma]]$, $P_w = \mathcal{O}[[X_\sigma]]_w$, $p \colon P \to S$ for q composed with $P \to R$, $\mathfrak{b} = \ker p$, $S_w = p(P_w) = q(R_w)$, $\bar{z}_s = p(X_s)$, and $\zeta^n = \prod_s \zeta_s^{n_s}$ for $\zeta \in K^\sigma$, $n \in \mathbb{N}^\sigma$. For $w = (w_1, w_2)$ write $\lambda(w) = w_1$, $\mu(w) = w_2$.

Step 0: homogeneity. By (Wm2), (Wm3), $\mathfrak{b} = \mathfrak{a} + (\tilde{u}_k)_k P$ with $\tilde{u}_k \in P_{(0,-1)} \cup P_{(0,1)} \cup P_{(0,0)}$ lifting the F_i, E_i, Z_i; since $\mathfrak{a}$ is homogeneous and $(BH)_{(w)} = B_{(w-v)}H$ for $H \in P_v$, every weight

component of an element of $\mathfrak{b}$ lies in $\mathfrak{b}$. Hence a finite sum $\sum_w b_w$ with $b_w \in S_w$ vanishes only if every b_w does, and $S^{\mathrm{gr}} = \sum_w S_w = \bigoplus_w S_w$ is an $\mathcal{O}$-subalgebra with $S_v S_w \subseteq S_{v+w}$. By Dickson's lemma, for each w the set E_w of exponents of weight w has a finite set Min_w of minimal elements, every $n \in E_w$ satisfies $n - m \in E_{(0,0)}$ for some $m \in \mathrm{Min}_w$ with $m \le n$, and so every $H \in P_w$ is a finite sum $\sum_{m \in \mathrm{Min}_w} X^m h_m$ with $h_m \in P_{(0,0)}$; the minimal elements $m_1, \dots, m_k$ of $E_{(0,0)} \setminus \{0\}$ generate the monoid $E_{(0,0)}$, and $\theta\colon \mathcal{O}[[T_1, \dots, T_k]] \to P_{(0,0)}$, $T_i \mapsto X^{m_i}$, is onto.

Step 1: (Pm1). Let C_0 be the $\mathcal{O}$-span of the products $r_S(g_1)_{i_1 j_1} \cdots r_S(g_k)_{i_k j_k}$ of weight $(0,0)$; it is the $\mathcal{O}$-subalgebra of S they generate. As r_S is a symplectic Eisenstein lift to $S \in \mathrm{CNL}_{\mathcal{O}}$ (Wm4) and $\mathfrak{D}$ is finite in weight zero, C_0 is a finitely generated $\mathcal{O}$-module, and $S_{(0,0)} = C_0$ by Lemma 45.34. By (La1), $\{f \in A_M : q(f) = 0\} = I(u_M)$, so the image of $(A_M)_0$ in $A_M/I(u_M)$ is isomorphic to $q((A_M)_0) = S_{(0,0)} = C_0$.

Step 2: C_0 is local and points are bounded on it. C_0 is finite over $\mathcal{O}$, hence a finite product of local rings; it has no idempotents other than $0, 1$ (it is a subring of the local ring S), so it is local; its maximal ideal $\mathfrak{n}$ satisfies $\mathfrak{n}^N \subseteq \varpi C_0$ for some N ($C_0/\varpi C_0$ is a local Artinian ring; ϖ a uniformiser of $\mathcal{O}$), hence $\mathfrak{n} \subseteq \mathfrak{m}_S$, and $\mathfrak{n} = C_0 \cap \mathfrak{m}_S$. For an $\mathcal{O}$-algebra homomorphism $\xi\colon C_0 \to K$, every $\xi(c)$ is integral over $\mathcal{O}$, so $|\xi(c)|_\ell \le 1$; and for $c \in \mathfrak{n}$, $\xi(c)^N = \varpi \xi(c')$ with $c' \in C_0$, so $|\xi(c)|_\ell < 1$.

Step 3: lifting to S^{gr}. Let x be a point of A_M on u_M. By (La1), x kills the kernel of q on A_M, so $x = \bar{x} \circ q$ for an $\mathcal{O}$-algebra homomorphism $\bar{x}\colon C \to K$, $C = q(A_M) = \bigoplus_n S_{(0,n)}$. The map $\Pi\colon S^{\mathrm{gr}} \to C$, $\sum_w b_w \mapsto \sum_{\lambda(w)=0} b_w$, is C-linear ($C S_w \subseteq \sum_n S_{w+(0,n)}$) with $\Pi(1) = 1$. By Step 0, S^{gr} is generated as a C-algebra by the finitely many $\bar{z}_s$ ($S_{(0,0)} \subseteq C$). Let K be a C-algebra through $\bar{x}$ and $T = K \otimes_C S^{\mathrm{gr}}$, a K-algebra of finite type. The C-linear map $\bar{x} \circ \Pi$ induces a K-linear map $T \to K$ with $1 \otimes 1 \mapsto 1$, so $T \neq 0$, and by Hilbert's Nullstellensatz (K algebraically closed) there is a K-algebra homomorphism $T \to K$. Composed with $b \mapsto 1 \otimes b$ it is an $\mathcal{O}$-algebra homomorphism $\xi\colon S^{\mathrm{gr}} \to K$ with $\xi|_C = \bar{x}$.

Step 4: ξ is an evaluation. Put $\zeta_s = \xi(\bar{z}_s)$; these finitely many algebraic elements lie in a finite extension K_0 of $\mathbb{Q}_\ell$. By Steps 1 and 2 (for $\xi|_{C_0}$), $|\xi|_\ell \le 1$ on $S_{(0,0)}$, and $\rho = \max_i |\zeta^{m_i}|_\ell < 1$, as $p(X^{m_i}) \in \mathfrak{m}_S \cap C_0 = \mathfrak{n}$. For $H = \theta(h) \in P_{(0,0)}$, the series $H(\zeta)$ converges in K_0 (its terms are bounded by powers of ρ through θ), and writing $h = h_{<M} + \sum_{|e|=M} T^e h_e$, both $\xi(p(H))$ and $H(\zeta)$ differ from $h_{<M}(\zeta^{m_1}, \dots, \zeta^{m_k})$ by at most ρ^M (using $|\xi(p(\theta(h_e)))|_\ell \le 1$); so $\xi(p(H)) = H(\zeta)$. For $H = \sum_{m \in \mathrm{Min}_w} X^m h_m \in P_w$ (Step 0) this gives $\xi(p(H)) = \sum_m \zeta^m h_m(\zeta)$.

Step 5: scaling. Let $\sigma' = \{s : \zeta_s \neq 0\}$ and $a_s = \log |\zeta_s|_\ell$ for $s \in \sigma'$. We claim there is $u \in \mathbb{R}^2$ with $\lambda(\mathrm{wt}(s))u_1 + \mu(\mathrm{wt}(s))u_2 + a_s < 0$ for all $s \in \sigma'$. If not, the transposition theorem of Gordan and Motzkin for strict linear inequalities gives $c \in \mathbb{R}_{\ge 0}^{\sigma'} \setminus \{0\}$ with $\sum_s c_s \mathrm{wt}(s) = 0$ and $\sum_s c_s a_s \ge 0$. The cone $\{c \in \mathbb{R}_{\ge 0}^{\sigma'} : \sum_s c_s \mathrm{wt}(s) = 0\}$ is rational polyhedral, generated by finitely many integral vectors; a linear form that is non-negative at a non-zero point of it is non-negative at one of the generators, so we may take $c \in \mathbb{N}^{\sigma'} \setminus \{0\}$. Then X^c has weight $(0,0)$ and positive degree, $p(X^c) \in \mathfrak{n}$, and $|\zeta^c|_\ell = |\xi(p(X^c))|_\ell < 1$ by Step 2, i.e. $\sum_s c_s a_s < 0$: a contradiction. As $|K^\times|_\ell = \ell^{\mathbb{Q}}$ is dense in $\mathbb{R}_{>0}$ and the inequalities are strict, there is $t = (t_1, t_2) \in (K^\times)^2$ with $|t^{\mathrm{wt}(s)} \zeta_s|_\ell < 1$ for every $s \in \sigma$. Put $\zeta'_s = t^{\mathrm{wt}(s)} \zeta_s$.

Step 6: (Pm2). The evaluation $\mathrm{ev}\colon P \to K_0(t_1, t_2)$, $H \mapsto H(\zeta')$, is a continuous $\mathcal{O}$-algebra homomorphism. For $H \in P_w$ every monomial X^n of H has $\zeta'^n = t^w \zeta^n$, so by Step 4, $\mathrm{ev}(H) = t^w \xi(p(H))$. For $H \in \mathfrak{b}$, $H = \sum_w H_{(w)}$ converges in P (only finitely many weights occur in each degree), each $H_{(w)} \in \mathfrak{b}$ (Step 0), so $\mathrm{ev}(H) = \sum_w t^w \xi(p(H_{(w)})) = 0$. Hence ev induces an $\mathcal{O}$-algebra homomorphism $y\colon S = P/\mathfrak{b} \to K$ with $y(b) = t^w \xi(b)$ for $b \in S_w$. For $f \in (A_M)_n$, $q(f) \in S_{(0,n)} \subseteq C$, so $y(q(f)) = t_2^n \bar{x}(q(f)) = t_2^n x(f)$, which is (Pm2) with t_2 in place of t.

Step 7: (Pm3). By the definition of T_4, the entry (i,j) of $\mathrm{T}_4(s) X \mathrm{T}_4(s)^{-1}$ is $s^{\mathrm{wt}_4(i,j)} X_{ij}$, so

$y'(r_S(g)_{ij}) = s^{\mathrm{wt}_4(i,j)} y(r_S(g)_{ij})$, and by multiplicativity $y'(\pi_0) = s^w y(\pi_0)$ for every product π_0 of entries of weight w. By Lemma 45.34, $q(f)$ is an $\mathcal{O}$-linear combination of such products for $f \in R_w$; hence $y'(q(f)) = s^w y(q(f))$. □

Lemma 45.34. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ that is finite in weight zero, and M a symplectic weighted model of $\mathfrak{D}$. Then for every $w \in \mathbb{Z}^2$, $q(R_w)$ is the $\mathcal{O}$-linear span of the products $r_S(g_1)_{i_1 j_1} \cdots r_S(g_k)_{i_k j_k}$ ($k \geq 0$, $g_s \in G_{\mathbb{Q}}$) with $\sum_{s=1}^{k} \mathrm{wt}_4(i_s, j_s) = w$.*

Proof. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$ with the weights wt, P_w for its power series of weight w, $\pi\colon P \to R$ the projection, $\Pi = q \circ \pi\colon P \to S$, $S_w = \Pi(P_w) = q(R_w)$, $\mathfrak{m}_S$ the maximal ideal of S, and $\mathcal{M}_w$ for the $\mathcal{O}$-span of the products of entries of r_S of total weight w in the statement. Then $1 \in \mathcal{M}_{(0,0)}$ (the empty product) and $\mathcal{M}_v \mathcal{M}_{v'} \subseteq \mathcal{M}_{v+v'}$; so $C = \mathcal{M}_{(0,0)}$ is the $\mathcal{O}$-subalgebra of S generated by the products of weight $(0,0)$, and since r_S is a symplectic Eisenstein lift (Wm4) and $\mathfrak{D}$ is finite in weight zero, C is a finitely generated $\mathcal{O}$-module. For a power series f write $f_{(v)}$ for its weight-v component; since $P_v P_k \subseteq P_{v+k}$ and extraction of components is continuous coefficientwise, $(gh)_{(v)} = g_{(v-k)} h$ for $h \in P_k$.

Step 1: $\mathcal{M}_w \subseteq S_w$, and $J = \ker \Pi$ is homogeneous. By (Wm5) every entry $r_S(g)_{ij}$ lies in $S_{\mathrm{wt}_4(i,j)}$; $1 \in S_{(0,0)}$ and $S_v S_{v'} \subseteq S_{v+v'}$, so every product of entries of total weight w lies in S_w, an $\mathcal{O}$-module. Next, choose by (Wm2) and $R_v = \pi(P_v)$ elements $\tilde{F}_i \in P_{(0,-1)}$, $\tilde{E}_i \in P_{(0,1)}$, $\tilde{Z}_i \in P_{(0,0)}$ with images F_i, E_i, Z_i; by (Wm3), $J = \mathfrak{a} + (\tilde{F}_i, \tilde{E}_i, \tilde{Z}_i)_i$. If $f = a + \sum_i g_i h_i$ with $a \in \mathfrak{a}$ and $h_i \in P_{k_i}$ among these generators, then $f_{(v)} = a_{(v)} + \sum_i (g_i)_{(v-k_i)} h_i \in J$, as $\mathfrak{a}$ is homogeneous. So $f_{(v)} \in J$ for all $f \in J$ and all v.

Step 2: the entries span the cotangent space. For each triple $t = (g, a, b)$ ($g \in G_{\mathbb{Q}}$, $1 \leq a, b \leq 4$) put $z_t = r_S(g)_{ab}$ if $a \neq b$, and $z_t = r_S(g)_{aa} - c_t$ with $c_t \in \mathcal{O}$ such that $z_t \in \mathfrak{m}_S$ if $a = b$ (the residue field of S is $\mathbb{F}_{\mathcal{O}}$). As $\bar{r}_0$ is diagonal and r_S lifts it, $z_t \in \mathfrak{m}_S$ for all t; by Step 1 and $c_t \in \mathcal{M}_{(0,0)} \cap S_{(0,0)}$, $z_t \in S_{\mathrm{wt}_4(a,b)} \cap \mathcal{M}_{\mathrm{wt}_4(a,b)}$. Let $t^* = \mathfrak{m}_S / (\mathfrak{m}_S^2 + \mathfrak{m}_{\mathcal{O}} S)$, a finite-dimensional $\mathbb{F}_{\mathcal{O}}$-space. By (Wm4), two morphisms $S \to A$ of $\mathrm{CNL}_{\mathcal{O}}$ that agree on the entries of r_S are equal; so Lemma 45.15, item 1, applied to the set of these entries (with $c_e = 0$ off the diagonal and $c_e = c_t$ on it), shows that the classes $\bar{z}_t$ span t^*. Choose triples $t_1, \ldots, t_k$ such that the $\bar{z}_{t_i}$ span t^*, put $\mathrm{wt}'(i) = \mathrm{wt}_4(a_i, b_i)$ for $t_i = (g_i, a_i, b_i)$, $Q = \mathcal{O}[[Y_1, \ldots, Y_k]]$ with these weights, Q_v its series of weight v, and $\Pi'\colon Q \to S$ the continuous $\mathcal{O}$-algebra homomorphism with $\Pi'(Y_i) = z_{t_i}$. The images of the Y_i and $\mathfrak{m}_{\mathcal{O}}$ span $\mathfrak{m}_S / \mathfrak{m}_S^2$, so Π' is surjective by Lemma 45.15, item 2.

Step 3: $S_w = \Pi'(Q_w)$. As $z_{t_i} \in S_{\mathrm{wt}'(i)}$, choose $\kappa_i \in P_{\mathrm{wt}'(i)}$ with $\Pi(\kappa_i) = z_{t_i}$; its constant term lies in $\mathfrak{m}_{\mathcal{O}}$ (it is congruent to $z_{t_i} \in \mathfrak{m}_S$ modulo $\mathfrak{m}_S$), so $\kappa_i \in \mathfrak{m}_P$, and there is a continuous $\mathcal{O}$-algebra homomorphism $\Theta\colon Q \to P$ with $\Theta(Y_i) = \kappa_i$; $\Pi \circ \Theta = \Pi'$ (both continuous, equal on the Y_i). A monomial of weight v in the Y_i goes to a product of series of total weight v, and P_v is closed, so $\Theta(Q_v) \subseteq P_v$; hence $\Pi'(Q_w) \subseteq S_w$. Conversely let $f \in P_w$. By surjectivity $\Pi(f) = \Pi'(h) = \Pi(\Theta(h))$ for some $h \in Q$, so $f - \Theta(h) \in J$. Now $\Theta(h) = \sum_v \Theta(h_{(v)})$ (convergent) with $\Theta(h_{(v)}) \in P_v$, so $\Theta(h)_{(w)} = \Theta(h_{(w)})$, and by Step 1, $(f - \Theta(h))_{(w)} = f - \Theta(h_{(w)}) \in J$. Hence $\Pi(f) = \Pi'(h_{(w)}) \in \Pi'(Q_w)$.

Step 4: monomial generators. By Dickson's lemma let E_w be the finite set of minimal elements of $\{n \in \mathbb{N}^k : \sum_i n_i \mathrm{wt}'(i) = w\}$ and H that of $\{n \neq 0 : \sum_i n_i \mathrm{wt}'(i) = (0,0)\}$. Every exponent n of weight w dominates some $m \in E_w$, and $n - m$ has weight $(0,0)$; assigning each n to one such m gives, for $h \in Q_w$, $h = \sum_{m \in E_w} Y^m b_m$ with $b_m \in Q_{(0,0)}$. In the same way every $h \in Q_{(0,0)}$ is $h(0) + \sum_{m \in H} Y^m b_m$ with $b_m \in Q_{(0,0)}$. Put $y_m = \Pi'(Y^m) = \prod_i z_{t_i}^{m_i}$: by Step 2, $y_m \in \mathcal{M}_w$ for $m \in E_w$, and $y_m \in C \cap \mathfrak{m}_S$ for $m \in H$. With $B = S_{(0,0)} = \Pi'(Q_{(0,0)})$ (Step 3), an

$\mathcal{O}$-subalgebra of S containing C (Step 1):

$$S_w = \sum_{m \in E_w} B\, y_m, \qquad B = \mathcal{O} + \sum_{m \in H} y_m B. \tag{45.3}$$

Step 5: $B = C$. C is a module-finite $\mathcal{O}$-algebra, hence a finite product of local rings; it is a subring of the local ring S, whose only idempotents are $0, 1$, so C is local. Its maximal ideal is $\mathfrak{n} = C \cap \mathfrak{m}_S$, the kernel of the surjection $C \to S/\mathfrak{m}_S = \mathbb{F}_{\mathcal{O}}$. $C/\mathfrak{m}_{\mathcal{O}}C$ is a finite-dimensional local $\mathbb{F}_{\mathcal{O}}$-algebra, so its maximal ideal is nilpotent: there is N_1 with $\mathfrak{n}^{N_1} \subseteq \mathfrak{m}_{\mathcal{O}}C$. Let $I = \sum_{m \in H} y_m C \subseteq \mathfrak{n}$. By induction on j, $B \subseteq C + \mathfrak{m}_{\mathcal{O}}B + I^j B$: for $j = 0$ this is trivial, and if it holds for j, then for $b = c + \sum_m y_m b_m \in B$ as in (45.3), $c \in \mathcal{O} \subseteq C$ and $y_m b_m \in y_m C + \mathfrak{m}_{\mathcal{O}}B + I^{j+1}B$. With $j = N_1$, $I^{N_1}B \subseteq \mathfrak{m}_{\mathcal{O}}CB = \mathfrak{m}_{\mathcal{O}}B$, so $B = C + \mathfrak{m}_{\mathcal{O}}B$, and by induction $\mathfrak{m}_{\mathcal{O}}^n B = \mathfrak{m}_{\mathcal{O}}^n C + \mathfrak{m}_{\mathcal{O}}^{n+1}B$ for every n. Let $b \in B$; then $b = c_0 + c_1 + \cdots + c_n + \beta_{n+1}$ with $c_i \in \mathfrak{m}_{\mathcal{O}}^i C$ and $\beta_{n+1} \in \mathfrak{m}_{\mathcal{O}}^{n+1}B$, the c_i chosen successively. As C is a finitely generated module over the complete ring $\mathcal{O}$, $c = \sum_i c_i$ converges in C, and $\sum_{i>n} c_i \in \mathfrak{m}_{\mathcal{O}}^{n+1}C$ (a closed submodule). So $b - c \in \mathfrak{m}_{\mathcal{O}}^{n+1}B \subseteq \mathfrak{m}_S^{n+1}$ for every n, and $b = c \in C$ by Krull's intersection theorem in S. Hence $B = C$.

Step 6: conclusion. By (45.3) and Step 5, $S_w = \sum_{m \in E_w} C y_m \subseteq \mathcal{M}_{(0,0)}\mathcal{M}_w \subseteq \mathcal{M}_w$; with Step 1, $q(R_w) = S_w = \mathcal{M}_w$. □

45.4 Reducible points of a symplectic weighted model

This subsection proves Proposition 45.35: the reducible points of a symplectic weighted model satisfy the separation condition (Gc3), the two-signed points are irreducible, and the tangent spaces there are one-dimensional (Gc4). It works with points with values in a valuation ring, which are ordinary test representations carrying an ordinary symplectic flag at ℓ (Lemma 45.37, Lemma 45.41). Such a point is irreducible, of diagonal type or of block type (Proposition 45.36). For points of diagonal type the diagonal characters at ℓ are $(\theta, \Psi, \alpha, 1)$ or $(\alpha, 1, \theta, \Psi)$, and the non-zero entries respect that order (Lemma 45.40); the proof of (Gc3) and (Gc4) is a case analysis over these shapes. That case analysis is the core of the subsection; the lemmas on isotropic flags and on enlarging the valuation ring are routine.

Proposition 45.35. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum that is finite in weight zero, and M a symplectic weighted model of $\mathfrak{D}$.*

(Mr1) *(A_M, x_M, u_M) satisfies (Gc3).*

(Mr2) *If $\mathfrak{D}$ has no endoscopic points, then for every $\mathcal{O}$-algebra homomorphism $y\colon S \to \overline{\mathbb{Q}}_\ell$ such that $y \circ q|_{A_M}$ is a two-signed point of A_M on u_M, the point $g \mapsto y(r_S(g))$ of $\mathfrak{D}$ is irreducible.*

(Mr3) *If $\mathfrak{D}$ has no endoscopic points and every irreducible point of $\mathfrak{D}$ is rigid, then (A_M, x_M, u_M) satisfies (Gc4).*

Proof. Write $K = \overline{\mathbb{Q}}_\ell$, $P = \mathcal{O}[[X_s : s \in \sigma]]$, P_w its series of weight w, $\Pi\colon P \to S$ the composite of the projection to R and q, $S_w = \Pi(P_w) = q(R_w)$, $S^{\mathrm{gr}} = \sum_w S_w$, $\mathrm{A} = \{1, 3\}$, $\mathrm{B} = \{2, 4\}$. Since $\ker q$ is generated by the F_i, E_i, Z_i (Wm3), which are images of series of single weights (Wm2), and $\mathfrak{a}$ is homogeneous, every weight component of an element of $\ker \Pi$ lies in $\ker \Pi$: choose series $\tilde{F}_i \in P_{(0,-1)}$, $\tilde{E}_i \in P_{(0,1)}$, $\tilde{Z}_i \in P_{(0,0)}$ mapping to F_i, E_i, Z_i (Wm2), so that $\ker \Pi = \mathfrak{a} + (\tilde{F}_i, \tilde{E}_i, \tilde{Z}_i)_i$; for $F = a + \sum_i g_i h_i$ with $a \in \mathfrak{a}$ and $h_i \in P_{k_i}$ among these generators, the weight-v component is $F_{(v)} = a_{(v)} + \sum_i (g_i)_{(v-k_i)} h_i \in \ker \Pi$ (extraction of components is continuous coefficientwise and $P_v P_k \subseteq P_{v+k}$); hence $S^{\mathrm{gr}} = \bigoplus_w S_w$, a subalgebra with $S_v S_w \subseteq S_{v+w}$. By (Wm5) the entry (i, j) of r_S lies in $S_{\mathrm{wt}_4(i,j)}$, and $\mathrm{wt}_4(i, j) = (\lambda_i - \lambda_j, \mu_i - \mu_j)$. For an $\mathcal{O}$-algebra homomorphism

$y\colon S \to K$ put $r_y(g) = y(r_S(g))$, a point of $\mathfrak{D}$ (r_S is a symplectic Eisenstein lift, (Wm4)), hence a point with values in $\overline{\mathbb{Z}}_\ell$ for the standard test field (Lemma 45.41), and $x_y = y \circ q|_{A_M}$, a point of A_M on u_M. Put $\zeta_s = y(\Pi(X_s))$; these finitely many elements lie in a finite extension $K_0 \subseteq K$ of $\mathbb{Q}_\ell$, which is complete; by (Sq1), $|\zeta_s|_\ell < 1$ and $y \circ \Pi$ is continuous, so $y(\Pi(F)) = F(\zeta)$ (a convergent series in K_0) for $F \in P$.

Step 0: four facts for such y. (F1) If no entry (i,j) of r_y with $\mu_i < \mu_j$ is active, x_y is negative-vanishing; if none with $\mu_i > \mu_j$ is active, x_y is positive-vanishing. Indeed for $f \in (A_M)_n = R_{(0,n)}$, $q(f)$ is an $\mathcal{O}$-combination of products of entries of total weight $(0,n)$ (Lemma 45.34); if $n < 0$, each product has a factor (i,j) with $\mu_i < \mu_j$, which y kills; likewise for $n > 0$. (F2) If x_y is positive-vanishing, the entry $(1,3)$ of r_y is not active: $r_S(g)_{13} \in S_{(0,1)} = q((A_M)_1)$. (F3) If y, y' agree on $S_{(0,0)} = q((A_M)_0)$, then r_y, $r_{y'}$ have the same diagonal entries, and if r_y is of diagonal type so is $r_{y'}$: $r_S(g)_{ii}$ and $r_S(g)_{ij}r_S(h)_{ji}$ lie in $S_{(0,0)}$. (F4) A torus translate $t \cdot x$ ($t \neq 0$) of a point x agrees with x on $(A_M)_0$ and is negative-vanishing, positive-vanishing or two-signed exactly when x is.

(Mr1). Let φ_1 be a point on u_M that is negative- and positive-vanishing; by (Pm2) choose y_1, t_1 with $x_{y_1} = t_1 \cdot \varphi_1$, both-vanishing by (F4). By (Zr1), r_{y_1} is irreducible, of diagonal type or of block type; in the first and the last case the entry $(1,3)$ is active ((Ae5), resp. the definition of block type), against (F2). So r_{y_1} is of diagonal type, and by Lemma 45.40, $r_{y_1}(s_0)_{11} \in \{\theta(s_0), \alpha(s_0)\}$, two distinct values (by (Sg1) and (Sg5) of Definition 44.1, ξ is unramified at ℓ and $\chi(s_0) = \omega_\ell(s_0) = 1$, so $(\kappa_1, \dots, \kappa_4)(s_0) = (c^{e+1}, c^e, c, 1)$ with $c = \chi_{\mathrm{cyc}}(s_0)$ of infinite order; in particular $\kappa_1(s_0) \neq \kappa_3(s_0)$). Suppose $r_{y_1}(s_0)_{11} = \theta(s_0)$, and let φ be a point on u_M agreeing with φ_1 on $(A_M)_0$; choose y, t by (Pm2). Then y and y_1 agree on $S_{(0,0)}$ (both equal $\varphi = \varphi_1$ there, by (F4)), so by (F3) r_y is of diagonal type with $r_y(s_0)_{11} = \theta(s_0) \neq \alpha(s_0)$; by Lemma 45.40 its permutation is the identity and no entry with $\mu_i < \mu_j$ is active, so x_y, hence φ, is negative-vanishing ((F1), (F4)). So no point on u_M that is positive-vanishing but not negative-vanishing agrees with φ_1 on $(A_M)_0$. If $r_{y_1}(s_0)_{11} = \alpha(s_0)$, the same argument shows that every such φ is positive-vanishing. This is (Gc3).

(Mr2). Let y be such that x_y is two-signed, and $r = r_y$. If r were of diagonal type, the last assertion of Lemma 45.40 and (F1) would make x_y negative- or positive-vanishing. Suppose r is of block type, and let $\varepsilon = 1$ if no entry (i,j) with $i \in \mathrm{B}$, $j \in \mathrm{A}$ is active, $\varepsilon = -1$ otherwise (then none with $i \in \mathrm{A}$, $j \in \mathrm{B}$ is active), and $p(w) = \varepsilon w_1$. Then y kills every entry of r_S of weight w with $p(w) < 0$, hence by Lemma 45.34 every S_w with $p(w) < 0$ (each product of entries of such a weight has a factor with $p < 0$); in particular $\zeta_s = 0$ if $p(\mathrm{wt}(s)) < 0$. Let $\zeta^0_s = \zeta_s$ if $\mathrm{wt}(s)_1 = 0$ and $\zeta^0_s = 0$ otherwise, and $Y_0(F) = F(\zeta^0)$, a continuous $\mathcal{O}$-algebra homomorphism $P \to K$. For $F \in P_w$: if $w_1 \neq 0$, every monomial of F contains a variable with $\mathrm{wt}(s)_1 \neq 0$, so $Y_0(F) = 0$; if $w_1 = 0$, a monomial of F containing such a variable contains one with $p(\mathrm{wt}(s)) < 0$ (the values of p sum to 0), so it vanishes at ζ and at ζ^0, and $Y_0(F) = F(\zeta) = y(\Pi(F))$. For $F \in \ker\Pi$, $F = \sum_w F_{(w)}$ converges with $F_{(w)} \in \ker\Pi$, so $Y_0(F) = \sum_{w_1=0} y(\Pi(F_{(w)})) = 0$. Hence Y_0 induces $y_0\colon S \to K$ with $y_0 = y$ on S_w for $w_1 = 0$ and $y_0 = 0$ on S_w for $w_1 \neq 0$, so $r_{y_0}(g)_{ij} = r(g)_{ij}$ if $\lambda_i = \lambda_j$ and 0 otherwise: r_{y_0} is a point with block diagonal values. Let $\beta(g) = (r(g)_{ab})_{a,b\in\mathrm{A}}$, the A-block of $r_{y_0}(g)$. In $(r(g)r(h))_{ab} = \sum_k r(g)_{ak}r(h)_{kb}$ ($a, b \in \mathrm{A}$) the terms with $k \in \mathrm{B}$ vanish ($r(h)_{kb} = 0$ if $\varepsilon = 1$, $r(g)_{ak} = 0$ if $\varepsilon = -1$), so β is multiplicative and the K-span of $\beta(G_\mathbb{Q})$ is a subalgebra of $\mathrm{M}_2(K)$; it contains the two diagonal matrix units, images of E_{11}, E_{33}, which lie in the span of $r(G_\mathbb{Q})$ by (Ae3), under the linear map $Y \mapsto (Y_{ab})_{a,b\in\mathrm{A}}$; and, as $(1,3)$, $(3,1)$ are active (block type), multiplying $\beta(g)$ on both sides by these units gives both off-diagonal units. So r_{y_0} is an endoscopic point, which $\mathfrak{D}$ does not have. By (Zr1), r is irreducible.

(Mr3). Let x be a two-signed point on u_M and δ an x-derivation of A_M vanishing on $I(u_M)$. We show that $\delta(f) = b\,n\,x(f)$ for all n and $f \in (A_M)_n$, for some $b \in K$; then for two such

derivations δ,δ' with constants b,b', $b'\delta-b\delta'=0$, and $(1,0)$ works if $b=b'=0$ (then $\delta=0$): (Gc4).

(a) *The point.* By (Pm2) choose y, t with $y(q(f))=t^n x(f)$ for $f\in(A_M)_n$; $x_y=t\cdot x$ is two-signed, so $r=r_y$ is irreducible by (Mr2), hence rigid. By (Ae5) choose g_1,g_2 with $y(u)\neq 0\neq y(v)$ for $u=r_S(g_1)_{12}\in S_{(1,0)}$ and $v=r_S(g_2)_{21}\in S_{(-1,0)}$.

(b) *A derivation on $C=q(A_M)=\bigoplus_n S_{(0,n)}$.* By (La1), $\ker(q|_{A_M})=I(u_M)$, which δ kills; so $\delta_1(q(f))=t^n\delta(f)$ for $f\in(A_M)_n$, extended additively, is well defined on C, and $\delta_1(q(f)q(f'))=t^{n+n'}(x(f)\delta(f')+x(f')\delta(f))=y(q(f))\delta_1(q(f'))+y(q(f'))\delta_1(q(f))$. So $X=y+\epsilon\delta_1\colon C\to K[\epsilon]$ ($\epsilon^2=0$) is an $\mathcal{O}$-algebra homomorphism.

(c) *Extension to S^{gr}.* Put $U_0=y(u)$ and $V_0=X(uv)U_0^{-1}$, a unit of $K[\epsilon]$ with first component $y(v)$. For $c\in S_w$ let $p_w=\max(-w_1,0)$, $q_w=\max(w_1,0)$, so $cu^{p_w}v^{q_w}\in S_{(0,w_2)}\subseteq C$, and put $\Xi(c)=X(cu^{p_w}v^{q_w})U_0^{-p_w}V_0^{-q_w}$, extended additively to $S^{\mathrm{gr}}=\bigoplus_w S_w$. It is $\mathcal{O}$-linear, $\Xi(1)=1$ and $\Xi|_C=X$. For $c\in S_w$, $c'\in S_{w'}$ one has $(p_w+p_{w'},q_w+q_{w'})=(p_{w+w'}+d,q_{w+w'}+d)$ with $d\geq 0$, and $X(uv)=U_0V_0$, so $\Xi(c)\Xi(c')=X(cc'u^{p_{w+w'}}v^{q_{w+w'}})X(uv)^d(U_0V_0)^{-d}U_0^{-p_{w+w'}}V_0^{-q_{w+w'}}=\Xi(cc')$. Its first component is $y(cu^{p_w}v^{q_w})y(u)^{-p_w}y(v)^{-q_w}=y(c)$. So $\Xi=y+\epsilon D_{\mathrm{gr}}$ with D_{gr} a y-derivation of S^{gr} equal to δ_1 on C.

(d) *Extension to S.* Let $d_s=D_{\mathrm{gr}}(\Pi(X_s))$ (enlarge K_0 to contain them), $\rho=\max_s|\zeta_s|_\ell<1$, and $\Delta(F)=\sum_s(\partial F/\partial X_s)(\zeta)\,d_s$ for $F\in P$: it converges, $\Delta(FG)=F(\zeta)\Delta(G)+G(\zeta)\Delta(F)$, and $|\Delta(F)|_\ell\leq\Lambda_2\rho^{N-1}$ for $F\in\mathfrak{m}_P^N$, $\Lambda_2=\max_s|d_s|_\ell$ (the coefficients lie in $\mathcal{O}$). We claim $D_{\mathrm{gr}}(\Pi(F))=\Delta(F)$ for $F\in P_w$. Both are $y\circ\Pi$-derivations on the finite sums of monomials. The $\mathcal{O}$-module $S_{(0,0)}$ is finitely generated (Lemma 45.34 and finiteness in weight zero), so $|D_{\mathrm{gr}}|_\ell\leq\Lambda_0$ on it, and $|y|_\ell\leq 1$ on S (Sq1). Let $m_1,\dots,m_k$ be the minimal non-zero exponents of weight $(0,0)$ (Dickson); every $H\in P_{(0,0)}$ is $\vartheta(h)$ for some $h\in\mathcal{O}[[T_1,\dots,T_k]]$, $\vartheta(T_i)=X^{m_i}$. Write $h=h_{<L}+\sum_{|e|=L}T^e h_e$; then $H-\vartheta(h_{<L})=\sum_e X^{\sum_i e_i m_i}\vartheta(h_e)\in\mathfrak{m}_P^L$, $\Pi(\vartheta(h_e))\in S_{(0,0)}$, and with $\rho_0=\max_i|\zeta^{m_i}|_\ell<1$ and $\Lambda_1=\max_i|D_{\mathrm{gr}}(\Pi(X^{m_i}))|_\ell$, the Leibniz rule gives $|D_{\mathrm{gr}}(\Pi(H-\vartheta(h_{<L})))|_\ell\leq\max(\Lambda_1\rho_0^{L-1},\Lambda_0\rho_0^L)$, while $|\Delta(H-\vartheta(h_{<L}))|_\ell\leq\Lambda_2\rho^{L-1}$. Letting $L\to\infty$, $D_{\mathrm{gr}}(\Pi(H))=\Delta(H)$. Every $F\in P_w$ is $\sum_m X^m h_m$ over the finitely many minimal exponents m of weight w, with $h_m\in P_{(0,0)}$ (Dickson), which gives the claim by the Leibniz rule. For $F\in\ker\Pi$, $F=\sum_w F_{(w)}$ converges with $F_{(w)}\in\ker\Pi$, so $\Delta(F)=\sum_w D_{\mathrm{gr}}(\Pi(F_{(w)}))=0$. Hence Δ induces a y-derivation D of S with $D=D_{\mathrm{gr}}$ on S^{gr}, and $y+\epsilon D\colon S\to K[\epsilon]$ is an $\mathcal{O}$-algebra homomorphism.

(e) *Rigidity and the normalisation.* Put $r'(g)=(y+\epsilon D)(r_S(g))$; this is a point with values in $K[\epsilon]$ reducing to r; as r is rigid, $r'(g)=r(g)+\epsilon[X_0,r(g)]$ with $X_0\in\mathfrak{sp}_4(K)$. By (Se3) for r_S, $r'(\phi)$ is block diagonal and $h(r')_{13}=h(r')_{31}=0$, where $h(r')=r'(g_0)+\theta(g_0)r'(g_0^{-1})=h(r)+\epsilon[X_0,h(r)]$. So $[X_0,r(\phi)]$ is block diagonal and $[X_0,h(r)]_{13}=[X_0,h(r)]_{31}=0$. By (Sq3) $r(\phi)$ is block diagonal with blocks $R_{\mathrm{A}},R_{\mathrm{B}}$, whose eigenvalues are integral and reduce to $\bar\kappa_1(\phi),\bar\kappa_3(\phi)$, resp. $\bar\kappa_2(\phi),\bar\kappa_4(\phi)$ (Sq4), disjoint sets by (Ae1). The off-block part Y of X_0 satisfies $[Y,r(\phi)]=0$, i.e. $Y_{\mathrm{AB}}R_{\mathrm{B}}=R_{\mathrm{A}}Y_{\mathrm{AB}}$ and $Y_{\mathrm{BA}}R_{\mathrm{A}}=R_{\mathrm{B}}Y_{\mathrm{BA}}$; by Sylvester's theorem $Y=0$. With X_0 block diagonal and $h=h(r)$, $h_{13}=h_{31}=0$ (Sq3): $[X_0,h]_{13}=(X_0)_{13}(h_{33}-h_{11})$ and $[X_0,h]_{31}=(X_0)_{31}(h_{11}-h_{33})$. By (Sq4), $h_{11}-h_{33}\equiv\theta(g_0)+1-\alpha(g_0)-\Psi(g_0)=(\alpha(g_0)-1)(\Psi(g_0)-1)$ modulo $\mathfrak{m}_\ell$, a unit by (Sg4); so $(X_0)_{13}=(X_0)_{31}=0$. The condition ${}^tX_0J_4+J_4X_0=0$ reads $(X_0)_{j^*i}(J_4)_{j^*j}+(J_4)_{ii^*}(X_0)_{i^*j}=0$ ($i^*=5-i$); for $(i,j)=(3,4),(1,2),(i,i^*)$ it gives $(X_0)_{24}=\pm(X_0)_{13}=0$, $(X_0)_{42}=\pm(X_0)_{31}=0$ and $(X_0)_{ii}+(X_0)_{i^*i^*}=0$. So $X_0=\mathrm{diag}(x_1,x_2,-x_2,-x_1)$, and $(X_0)_{ii}-(X_0)_{jj}=a(\lambda_i-\lambda_j)+b(\mu_i-\mu_j)$ with $a=x_1-x_2$, $b=x_1+x_2$. Hence $D(r_S(g)_{ij})=(aw_1+bw_2)\,y(r_S(g)_{ij})$ for $w=\mathrm{wt}_4(i,j)$; by the Leibniz rule the same holds for every product of entries of total weight w, and by Lemma 45.34 $D(c)=(aw_1+bw_2)y(c)$ for every $c\in S_w$.

(f) *Conclusion.* For $f\in(A_M)_n$, $q(f)\in S_{(0,n)}\subseteq C$, so $t^n\delta(f)=\delta_1(q(f))=D(q(f))=b\,n\,y(q(f))=b\,n\,t^n x(f)$, and $\delta(f)=b\,n\,x(f)$. □

Proposition 45.36. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and (K,V,a) a test field. Say that a homomorphism $r\colon G_{\mathbb{Q}}\to \mathrm{GL}_4(V)$ is* of block type *if the entries $(1,3)$ and $(3,1)$ of r are active and either no entry (i,j) with $i\in\{2,4\}$, $j\in\{1,3\}$ is active, or no entry (i,j) with $i\in\{1,3\}$, $j\in\{2,4\}$ is active.*

(Zr1) *Every point r of $\mathfrak{D}$ with values in V is irreducible, or of diagonal type, or of block type.*

(Zr2) *Let (K,V,a) have characteristic ℓ, let r be a point of $\mathfrak{D}$ with values in V of diagonal type, and let u be such that (r,u) is an ordinary test representation. Then for every $k\ge 0$, all $g_1,\dots,g_k\in G_{\mathbb{Q}}$ and all indices with $\sum_{s=1}^{k}\mathrm{wt}_4(i_s,j_s)=(0,0)$, the product $x=r(g_1)_{i_1j_1}\cdots r(g_k)_{i_kj_k}$ satisfies $x^{\ell^n}=x$ for some $n\ge 1$.*

(Zr3) *Let r be a point of $\mathfrak{D}$ with values in V of block type and u such that (r,u) is an ordinary test representation. Then there is an ordinary test representation (r_1,u_1) of $\mathfrak{D}$ with values in V such that every $r_1(g)$ is block diagonal and the K-span of the matrices $(r_1(g)_{ab})_{a,b\in\{1,3\}}$, $g\in G_{\mathbb{Q}}$, is $\mathrm{M}_2(K)$.*

Proof. Fix a test field (K,V,a). For a point r of $\mathfrak{D}$ with values in V write $i\to j$ if the entry (i,j) of r is active, and $i\sim j$ if $i\to j$ and $j\to i$. By (Ae4), $\to$ is reflexive and transitive, so $\sim$ is an equivalence relation, and $i\to j$ implies $j^*\to i^*$, so $i\sim j$ implies $i^*\sim j^*$.

Step 1: if $s\sim t$ with $\lambda_s\neq\lambda_t$, then $k\sim s$ for some $k\notin\{s,t\}$. Let r be a point with values in V and, by Lemma 45.37, u such that (r,u) is an ordinary test representation. Suppose $s\sim t$, $\lambda_s\neq\lambda_t$, and no $k\notin\{s,t\}$ satisfies $k\sim s$.

(1a) For $k\notin\{s,t\}$ and all g,h, $r(g)_{sk}r(h)_{kt}=0$: otherwise $s\to k\to t\to s$, so $k\sim s$. The same holds with s,t exchanged. Hence

$$r(gh)_{st}=r(g)_{ss}\,r(h)_{st}+r(g)_{st}\,r(h)_{tt}\qquad(g,h\in G_{\mathbb{Q}}).\tag{45.4}$$

(1b) A common eigenvector at ℓ. Let $Q=\{k:k\to s\}\ni s,t$ and $W_Q=\langle e_k:k\in Q\rangle\subseteq K^4$. If $b\in Q$ and $r(g)_{ab}\neq 0$, then $a\to b\to s$, so $a\in Q$: W_Q is $r(G_{\mathbb{Q}})$-stable. For $k\in Q\setminus\{s,t\}$, $r(g)_{sk}=0$ (else $k\sim s$) and $r(g)_{tk}=0$ (else $s\to t\to k\to s$). By (Ot4), $G_n=\langle ue_1,\dots,ue_n\rangle$ is $r(D_\ell)$-stable and $g\in D_\ell$ acts on G_n/G_{n-1} by the diagonal entry $d_n(g)$ of $u^{-1}r(g)u$. Let n be minimal such that some $w\in W_Q\cap G_n$ has $(w_s,w_t)\neq(0,0)$ ($n\le 4$, as $e_s\in W_Q$). For $g\in D_\ell$, $r(g)w-d_n(g)w\in W_Q\cap G_{n-1}$, so its coordinates s,t vanish, and as $w_k=0$ for $k\notin Q$,

$$r(g)_{ss}w_s+r(g)_{st}w_t=d_n(g)w_s,\qquad r(g)_{ts}w_s+r(g)_{tt}w_t=d_n(g)w_t.$$

As V is a valuation ring, $w_s/w_t\in V$ (with $w_t\neq 0$) or $w_t/w_s\in V$ (with $w_s\neq 0$); the two displayed equations, (1a) and the hypotheses on s,t are symmetric in s and t, so after exchanging s and t we may assume the first, and put $y_0=w_s/w_t\in V$. Eliminating $d_n(g)$, for $g\in D_\ell$

$$r(g)_{st}=\bigl(r(g)_{tt}-r(g)_{ss}\bigr)y_0+r(g)_{ts}\,y_0^2.\tag{45.5}$$

(1c) The residual cocycle. Let (Λ,j) be as in (Ot1) and identify Λ with $j(\Lambda)\subseteq V$; as j is local, the residue field of Λ embeds into k_V. Let $k'\subseteq k_V$ be the finite field generated by it and by $\mathbb{F}_{\mathcal{O}}$. Put $\zeta(g)=r(g)_{st}\in\Lambda$, not identically 0 as $s\to t$; choose $\hat{g}$ with $\zeta(\hat{g})$ of minimal valuation in Λ, put $b=\zeta(\hat{g})\neq 0$ and $\eta(g)=\zeta(g)/b\in\Lambda$. Then $\eta(1)=0$ ($s\neq t$), $\eta(\hat{g})=1$, and $\bar{\eta}$ is locally constant by the continuity in (Ot1). By (Ot2), $\overline{r(g)_{ii}}=\bar{\kappa}_i(g)$ and $\overline{r(g)_{ij}}=0$ for $i\neq j$. Dividing (45.4) by b and reducing, $\bar{\eta}(gh)=\bar{\kappa}_s(g)\bar{\eta}(h)+\bar{\eta}(g)\bar{\kappa}_t(h)$. Let $\gamma=\kappa_s\kappa_t^{-1}$ and $z(g)=\bar{\eta}(g)\bar{\kappa}_t(g)^{-1}\in k'$; then z is locally constant and $z(gh)=z(g)+\bar{\gamma}(g)z(h)$. As $\lambda_s\neq\lambda_t$, γ is one of α $(1,2),(3,4)$, θ $(1,4)$, $\beta^{-1}=\alpha\Psi^{-1}$ $(3,2)$, or their inverses (pairs reversed).

(1d) Local conditions. (i) If g lies in the inertia group of a place of $\overline{\mathbb{Q}}$ above a prime not in T and $\bar\theta(g)=\bar\Psi(g)=\bar\alpha(g)=1$, then $\bar r_0(g)=1$, $r(g)=1$ by (Ot3), and $z(g)=0$. (ii) At ℓ: put $D(g)=r(g)_{tt}-r(g)_{ss}$ and $\epsilon(g)=r(g)_{ts}\in\mathfrak{m}_V$. By (45.5), $b\eta(g)=D(g)y_0+\epsilon(g)y_0^2$ for $g\in D_\ell$. For $g\in D_\ell$ and $\sigma=\sigma_\ell\in D_\ell$, multiplying out and substituting $D(\cdot)y_0=b\eta(\cdot)-\epsilon(\cdot)y_0^2$ twice,

$$\eta(g)D(\sigma)-\eta(\sigma)D(g)=y_0\big(\epsilon(g)\eta(\sigma)-\epsilon(\sigma)\eta(g)\big)\in\mathfrak{m}_V.$$

Reducing, $\bar\eta(g)\delta=\bar\eta(\sigma_\ell)(\bar\kappa_t(g)-\bar\kappa_s(g))$ with $\delta=\bar\kappa_t(\sigma_\ell)-\bar\kappa_s(\sigma_\ell)\neq0$ by (Ae1). With $y_1=-\bar\eta(\sigma_\ell)/\delta\in k'$ this says $\bar\eta(g)=(\bar\kappa_s(g)-\bar\kappa_t(g))y_1$, i.e. $z(g)=\bar\gamma(g)y_1-y_1$ for $g\in D_\ell$. (iii) At $v\in T$, $v\neq\ell$: then $v\in S_\ell(\chi)$, so the v-component of the ℓ-power order part of χ is a non-trivial character of $(\mathbb{Z}/v^m\mathbb{Z})^\times$ of ℓ-power order, whence $\ell\mid v-1$; χ_{cyc} is unramified at v with Frobenius value v, so $\bar\chi_{\mathrm{cyc}}$ is trivial on D_v. By (Sg2) and the list in (1c) ($\bar\alpha=\bar\xi$, $\bar\theta=\bar\xi\bar\Psi$, $\bar\beta^{-1}=\bar\xi\bar\Psi^{-1}$), $\bar\gamma(\sigma_v)\neq1$. Let $M=k'$ with $D_v\cong G_{\mathbb{Q}_v}$ acting by $\bar\gamma$, a finite $\mathbb{F}_\ell$-module. Then $H^0(\mathbb{Q}_v,M)=0$, since $\bar\gamma(\sigma_v)-1$ is invertible on M; and $M^\vee=\mathrm{Hom}(M,\mu_\ell)$ has σ_v acting by $\bar\gamma(\sigma_v)^{-1}\bar\chi_{\mathrm{cyc}}(\sigma_v)=\bar\gamma(\sigma_v)^{-1}\neq1$, so $H^0(\mathbb{Q}_v,M^\vee)=0$ and, by local duality, $H^2(\mathbb{Q}_v,M)=0$. By the local Euler characteristic formula for $v\nmid\ell$, $H^1(\mathbb{Q}_v,M)=0$ (Theorem B.29, items 2 and 4, [249]). So the continuous cocycle $z|_{D_v}$ is a coboundary.

(1e) z is a coboundary. For every $\mathbb{F}_{\mathcal{O}}$-linear $\pi\colon k'\to\mathbb{F}_{\mathcal{O}}$, $\pi\circ z$ is a residual Selmer cocycle for γ by (1c), (1d) ($\bar\gamma$ takes values in $\mathbb{F}_{\mathcal{O}}$), hence a coboundary by (Sg6). If $\bar\gamma=\mathbf{1}$, every $\pi\circ z$ vanishes, so $z=0$. Otherwise fix g' with $\bar\gamma(g')\neq1$ and put $y=z(g')/(\bar\gamma(g')-1)$; if $\pi\circ z(g)=\bar\gamma(g)y_\pi-y_\pi$, then $y_\pi=\pi(y)$, so $\pi(z(g)-\bar\gamma(g)y+y)=0$ for all π, and $z(g)=\bar\gamma(g)y-y$. In both cases $\bar\eta(g)=(\bar\kappa_s(g)-\bar\kappa_t(g))y$ for all g, for some $y\in k'$.

(1f) Contradiction. By (Ae3), $E_{ss}=\sum_m b_m r(h_m)$ for finitely many $b_m\in V$, $h_m\in G_{\mathbb{Q}}$. Then $\sum_m b_m r(h_mh)=E_{ss}r(h)$; its entries (s,t), (s,s), (t,t) give

$$\sum_m b_m\eta(h_mh)=\eta(h),\qquad \sum_m b_m r(h_mh)_{ss}=r(h)_{ss}\qquad\text{and}\qquad \sum_m b_m r(h_mh)_{tt}=0.$$

Reducing and using (1e),

$$\bar\eta(h)=y\sum_m\bar b_m\big(\bar\kappa_s(h_mh)-\bar\kappa_t(h_mh)\big)=y\,\bar\kappa_s(h).$$

At $h=1$ this gives $y=0$, and at $h=\hat g$ it gives $1=0$: a contradiction.

Step 2: (Zr1). Let r be a point with values in V. The map $i\mapsto i^*$ permutes the $\sim$-classes; it is a fixed-point-free involution of $\{1,2,3,4\}$. If some class C meets both blocks, then $|C|\geq3$ by Step 1, so C^* is a class of size ≥3 meeting C, $C^*=C$, and C is a union of orbits of $*$, so $|C|=4$: every entry is active and r is irreducible by (Ae5). Otherwise every class lies in one block. If all classes are singletons, there are no $i\neq j$ with $i\to j\to i$: r is of diagonal type. If not, $\{1,3\}$ or $\{2,4\}$ is a class, hence both are ($\{1,3\}^*=\{2,4\}$); in particular $(1,3)$ and $(3,1)$ are active. If $a\to b$ and $b'\to a'$ with $a,a'\in\mathrm{A}$ and $b,b'\in\mathrm{B}$, then $b\to b'\to a'\to a$ (as $b\sim b'$, $a\sim a'$), so $a\sim b$, which is excluded. So no entry (i,j) with $i\in\mathrm{B}$, $j\in\mathrm{A}$ is active, or none with $i\in\mathrm{A}$, $j\in\mathrm{B}$: r is of block type.

Step 3: (Zr2). Let K have characteristic ℓ, r of diagonal type and (r,u) an ordinary test representation. (3a) A functional. For i let $n(i)=\#\{k:i\to k\}$; if $i\to j$ with $i\neq j$, then $\{k:j\to k\}\subseteq\{k:i\to k\}$ and i lies only in the second set (diagonal type), so $n(j)<n(i)$; as also $j^*\to i^*$, $n(i^*)<n(j^*)$. Put $f(i)=n(i)-n(i^*)$, so $f(i)>f(j)$ whenever $i\to j$, $i\neq j$, and $f(i^*)=-f(i)$. The linear map $\Phi(x,y)=(f(1)-f(2))x+(f(1)+f(2))y$ on $\mathbb{Z}^2$ satisfies $\Phi(\mathrm{wt}_4(i,j))=f(i)-f(j)$ for all i,j.

(3b) Products of weight zero. Let $x=r(g_1)_{i_1j_1}\cdots r(g_m)_{i_mj_m}$ with $\sum_k\mathrm{wt}_4(i_k,j_k)=(0,0)$. If a factor is 0, then $x=0=x^\ell$. Otherwise every (i_k,j_k) is active, so $\Phi(\mathrm{wt}_4(i_k,j_k))\geq0$

with equality only if $i_k = j_k$; the sum being $\Phi(0) = 0$, all $i_k = j_k$ and $x = \prod_k \delta_{i_k}(g_k)$ with $\delta_i(g) = r(g)_{ii}$. Each δ_i is a character $G_{\mathbb{Q}} \to \Lambda^\times$: $r(gh)_{ii} = \sum_k r(g)_{ik} r(h)_{ki}$ and the terms $k \neq i$ vanish (diagonal type). (3c) Each δ_i has finite order. As K has characteristic ℓ, $\ker a$ is a non-zero prime of $\overline{\mathbb{Z}}_\ell$, hence $\mathfrak{m}_\ell$; so $a(\kappa_i(g)) = 1$ when $\bar{r}_0(g) = 1$. Let m_0 be the product of the order of the finite group $\bar{r}_0(G_{\mathbb{Q}})$ and the order of χ, and $N_0 = m_0 \ell^2$. Let I be an inertia group at a place above a prime p and $g \in I$. If $p \notin T$, $r(g^{m_0}) = 1$ by (Ot3). If $p \in T \setminus \{\ell\}$, then $\chi(g^{m_0}) = 1$ and $r(g^{m_0}) = 1$ by (Ot3) when $I = I_p$; δ_i being a character, $\delta_i^{m_0}$ is then trivial on every conjugate of I_p. If $p = \ell$ and $I = I_\ell$ (again it suffices to treat I_ℓ), then $g' = g^{m_0}$ has $\bar{r}_0(g') = 1$, so by (Ot4) $u^{-1} r(g') u$ is upper triangular with diagonal entries 1, $(r(g') - 1)^4 = 0$, and in characteristic ℓ, $r(g')^{\ell^2} - 1 = (r(g') - 1)^{\ell^2} = 0$. So $\delta_i^{N_0}$ is trivial on every inertia group. It is continuous by (Ot1), so the fixed field of its kernel is an abelian extension of $\mathbb{Q}$ unramified at every prime, hence $\mathbb{Q}$ (Minkowski), and $\delta_i^{N_0} = \mathbf{1}$. (3d) Hence x is a root of unity in K: $x^{M_0} = 1$ for some $M_0 = \ell^c M_1$ with $\ell \nmid M_1$; then $(x^{M_1} - 1)^{\ell^c} = 0$, $x^{M_1} = 1$, and with $n \geq 1$ the order of ℓ modulo M_1, $x^{\ell^n} = x$.

Step 4: (Zr3). Let r be of block type and (r, u) an ordinary test representation. For $Y \in \mathrm{M}_4(V)$ let $Y^\flat$ have entries Y_{ij} if $\lambda_i = \lambda_j$ and 0 otherwise, and $E_{\mathrm{A}} = E_{11} + E_{33}$; then $Y^\flat = E_{\mathrm{A}} Y E_{\mathrm{A}} + (1 - E_{\mathrm{A}}) Y (1 - E_{\mathrm{A}})$. By block type, in case (a) every $r(g)$ has vanishing entries (i, j) with $i \in \mathrm{B}$, $j \in \mathrm{A}$, in case (b) those with $i \in \mathrm{A}$, $j \in \mathrm{B}$. For two matrices Y, Y' of the same such shape, $(YY')^\flat = Y^\flat Y'^\flat$ (a product $Y_{ak} Y'_{kb}$ with a, b in one block and k in the other has a vanishing factor). So $r_1(g) = r(g)^\flat$ is a homomorphism $G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ with block diagonal values, and $u_1 = u$. (Ot1) holds with the same (Λ, j); (Ot3) holds since $r(g) = 1$ implies $r_1(g) = 1$; the congruence in (Ot2) holds since r_0 is diagonal. Similitude: in case (a), for $\tau \in K^\times$, $\mathrm{T}_4(\tau, 1)\, r(g)\, \mathrm{T}_4(\tau, 1)^{-1} = r_1(g) + \tau(r(g) - r_1(g))$; conjugation by $\mathrm{T}_4(\tau, 1) = \mathrm{diag}(\tau, 1, \tau, 1)$, of similitude τ, preserves the similitude $\nu = a(\theta(g))$, so ${}^t(r_1(g) + \tau Y_g) J_4 (r_1(g) + \tau Y_g) = \nu J_4$ with $Y_g = r(g) - r_1(g)$, for infinitely many τ; comparing constant terms of this polynomial identity in τ, $r_1(g)$ has similitude ν. Case (b) is the same with τ^{-1}. (Ot4): u has similitude 1. The matrix $X_\phi = r(\phi)$ is block diagonal by (Se3), and $\phi \in D_\ell$ (D_ℓ is closed and contains σ_ℓ; (Sg3)). The characteristic polynomials $p_{\mathrm{A}}, p_{\mathrm{B}}$ (with coefficients in V) of its two blocks have roots in V (V is integrally closed and K algebraically closed) reducing to $\bar{\kappa}_1(\phi), \bar{\kappa}_3(\phi)$ and $\bar{\kappa}_2(\phi), \bar{\kappa}_4(\phi)$ by (Ot2), distinct across the blocks by (Ae1). So $p_{\mathrm{A}}, p_{\mathrm{B}}$ are coprime polynomials over K: $q_{\mathrm{A}} p_{\mathrm{A}} + q_{\mathrm{B}} p_{\mathrm{B}} = 1$, and by the Cayley–Hamilton theorem $(q_{\mathrm{B}} p_{\mathrm{B}})(X_\phi) = E_{\mathrm{A}}$. Since $u^{-1} X_\phi u$ is upper triangular by (Ot4), so is the idempotent $\Pi = u^{-1} E_{\mathrm{A}} u = (q_{\mathrm{B}} p_{\mathrm{B}})(u^{-1} X_\phi u)$, whose diagonal entries c_i satisfy $c_i^2 = c_i$. For $g \in D_\ell$, with $R_g = u^{-1} r(g) u$, $u^{-1} r_1(g) u = \Pi R_g \Pi + (1 - \Pi) R_g (1 - \Pi)$ is upper triangular with diagonal entries $(c_i^2 + (1 - c_i)^2)(R_g)_{ii} = (R_g)_{ii}$. So (r_1, u) satisfies (Ot4) with the diagonal of (r, u), and is an ordinary test representation. Finally, by (Ae3) E_{11}, E_{33} lie in the V-span of $r(G_{\mathbb{Q}})$, hence ($Y \mapsto Y^\flat$ being linear and fixing them) in that of $r_1(G_{\mathbb{Q}})$; the entries $(1, 3)$, $(3, 1)$ of r_1 are those of r, hence active; so $E_{11} r_1(g) E_{33} = r_1(g)_{13} E_{13}$ and $E_{33} r_1(g') E_{11} = r_1(g')_{31} E_{31}$ give E_{13}, E_{31} in the K-span, and the matrices $(r_1(g)_{ab})_{a,b \in \{1,3\}}$ span $\mathrm{M}_2(K)$. □

Lemma 45.37. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, (K, V, a) a test field and r a point of $\mathfrak{D}$ with values in V. Then there is $u \in \mathrm{GL}_4(V)$ such that (r, u) is an ordinary test representation of $\mathfrak{D}$ with values in V.*

Proof. Write $r(g) = f(r_A(g))$ for a symplectic Eisenstein lift r_A to $A \in \mathrm{CNL}_{\mathcal{O}}$ and a ring homomorphism $f\colon A \to V$ restricting to a on $\mathcal{O}$ with $f(\mathfrak{m}_A) \subseteq \mathfrak{m}_V$, such that $(r, 1)$ satisfies (Ot1). By (Se4) at $v = \ell$ there are a domain $B \in \mathrm{CNL}_{\mathcal{O}}$, a lift ρ_B of $\bar{r}_0|_{D_\ell}$ to B satisfying the local condition at ℓ (similitude $\theta(g)$ on D_ℓ, and ordinary), and $\mathcal{O}$-algebra homomorphisms $x\colon B \to \mathcal{O}$, $y\colon B \to A$ with $x \circ \rho_B = r_0|_{D_\ell}$, $y \circ \rho_B = r_A|_{D_\ell}$. Put $F = f \circ y\colon B \to V$, so

$r|_{D_\ell} = F \circ \rho_B$ entrywise and F restricts to a on $\mathcal{O}$. The composite $B \to A \to A/\mathfrak{m}_A = \mathbb{F}_\mathcal{O}$ is an $\mathcal{O}$-algebra homomorphism onto a field, so its kernel is the maximal ideal $\mathfrak{m}_B$; hence $y(\mathfrak{m}_B) \subseteq \mathfrak{m}_A$ and $F(\mathfrak{m}_B) \subseteq \mathfrak{m}_V$.

Step 1: (Ot2) and (Ot3). Since r_A is a lift, $r_A(g)_{ij} - r_0(g)_{ij} \cdot 1_A \in \mathfrak{m}_A$; applying f gives $r(g)_{ij} - a(r_0(g)_{ij}) \in \mathfrak{m}_V$. Applying f to ${}^t r_A(g) J_4 r_A(g) = \theta(g) J_4$ (that is (Se1)) shows that $r(g)$ has similitude $a(\theta(g))$. This is (Ot2). The first half of (Ot3) is the image under f of (Se2). For $v \in T$, $v \neq \ell$, (Se4) gives B_v, ρ_{B_v} satisfying the local condition at v and $y_v \colon B_v \to A$ with $y_v \circ \rho_{B_v} = r_A|_{D_v}$; as $\rho_{B_v}(g) = 1$ for $g \in I_v$ with $\chi(g) = 1$, also $r(g) = f(y_v(\rho_{B_v}(g))) = 1$. This is the second half of (Ot3).

Step 2: the flag at the generic point of B. Since x is an $\mathcal{O}$-algebra homomorphism to $\mathcal{O}$, $\mathcal{O} \to B$ is injective, and $L = \mathrm{Frac}(B)$ has characteristic 0. Put $c = \chi_{\mathrm{cyc}}(s_0)$ and $c_j = \kappa_j(s_0)$. By (Sg5), $\chi(s_0) = \omega_\ell(s_0) = 1$, and $\xi(s_0) = 1$ since ξ is unramified at $\ell \in T$ (Sg1) and $s_0 \in I_\ell$; so $(c_1, c_2, c_3, c_4) = (c^{e+1}, c^e, c, 1)$, pairwise distinct as c has infinite order. Put $d_i = \prod_{j \neq i}(c_i - c_j) \in \mathcal{O} \backslash \{0\}$. As ρ_B is ordinary, the characteristic polynomial of $\rho_B(s_0)$ is $\prod_j (X - c_j)$, so L^4 has a basis $w_1, \ldots, w_4$ with $\rho_B(s_0) w_k = c_k w_k$; let E_i be the projection onto Lw_i along the other w_k. Then $\Pi_i = d_i E_i$, and $\Pi_j \rho_B(g) \Pi_i = 0$ for $i < j$ gives $E_j \rho_B(g) E_i = 0$: the subspaces $F_i^L = \langle w_1, \ldots, w_i \rangle$ are $\rho_B(D_\ell)$-stable. Let $\delta_i(g) \in L$ be the scalar by which $\rho_B(g)$ acts on F_i^L / F_{i-1}^L ($g \in D_\ell$); then $E_i \rho_B(g) E_i = \delta_i(g) E_i$, so

$$\mathrm{tr}(\Pi_i \, \rho_B(g)) = d_i \, \delta_i(g), \tag{45.6}$$

and for $s \in I_\ell$ the ordinary condition $\Pi_i(\rho_B(s) - \kappa_i(s))\Pi_i = 0$ gives $d_i^2(\delta_i(s) - \kappa_i(s))E_i = 0$, so $\delta_i(s) = \kappa_i(s)$. The flag is isotropic: by the local condition, $\langle \rho_B(s_0)v, \rho_B(s_0)v' \rangle = \theta(s_0)\langle v, v' \rangle$ for $\langle v, v' \rangle = {}^t v J_4 v'$, and $\theta(s_0) = \alpha(s_0)\Psi(s_0) = c^{e+1}$, so $(c_a c_b - c^{e+1})\langle w_a, w_b \rangle = 0$. With $(m_1, \ldots, m_4) = (e+1, e, 1, 0)$ we have $c_a c_b = c^{m_a + m_b}$, and $m_a + m_b = e+1$ only for $\{a, b\} = \{1, 4\}$ or $\{2, 3\}$ (the other sums are $2e+2, 2e, 2, 0, 2e+1, e+2, e, 1$, all $\neq e+1$ as $e \geq 2$). So $\langle w_a, w_b \rangle = 0$ unless $\{a, b\}$ is $\{1, 4\}$ or $\{2, 3\}$: the form vanishes on $F_2^L \times F_2^L$, and F_3^L is orthogonal to F_1^L, hence equal to its orthogonal, both having dimension 3.

Step 3: a valuation ring of L over $\ker F$. Let $\mathfrak{p} = \ker F$, a prime of B. By Chevalley's theorem there is a valuation ring W of L with $B_\mathfrak{p} \subseteq W$ and $\mathfrak{m}_W \cap B_\mathfrak{p} = \mathfrak{p} B_\mathfrak{p}$, so $\mathfrak{m}_W \cap B = \mathfrak{p}$. By Lemma 45.38 for W and the flag of Step 2, there is $k \in \mathrm{GL}_4(W)$ of similitude 1 such that for $g \in D_\ell$ the matrix $M(g) = k^{-1} \rho_B(g) k$ is upper triangular with diagonal $\delta_1(g), \ldots, \delta_4(g)$ (second consequence, with h the matrix of columns $w_1, \ldots, w_4$). The entries of $\rho_B(g)$ lie in $B \subseteq W$, so $M(g) \in \mathrm{M}_4(W)$ and $\delta_i(g) \in W$.

Step 4: transport to K. Let $\kappa_W = W/\mathfrak{m}_W$ and write $\bar{z}$ for residues in κ_W. Since $\mathfrak{m}_W \cap B = \mathfrak{p}$, $B/\mathfrak{p} \subseteq \kappa_W$; let $E = \mathrm{Frac}(B/\mathfrak{p}) \subseteq \kappa_W$. The map F induces an injective homomorphism $B/\mathfrak{p} \to V \subseteq K$, hence a field embedding $\varepsilon \colon E \to K$. Let $C \subseteq \kappa_W$ be the E-algebra generated by the entries of $\bar{k}$; as $k^{-1} = -J_4 \, {}^t k \, J_4$, it contains the entries of $\bar{k}^{-1}$. For a maximal ideal $\mathfrak{n}$ of C, $C/\mathfrak{n}$ is a finite extension of E (Zariski's lemma), so, K being algebraically closed, ε extends to $C/\mathfrak{n} \to K$; this gives a ring homomorphism $\varphi \colon C \to K$ with $\varphi(\bar{b}) = F(b)$ for $b \in B$. Put $h = \varphi(\bar{k})$. From ${}^t k J_4 k = J_4$, h has similitude 1 and $h^{-1} = \varphi(\bar{k}^{-1})$. For $g \in D_\ell$, $\varphi(\overline{\rho_B(g)}) = F(\rho_B(g)) = r(g)$, so

$$h^{-1} r(g) h = \varphi(\overline{M(g)})$$

is upper triangular with diagonal entries $d_i'(g) = \varphi(\overline{\delta_i(g)})$. For $s \in I_\ell$, $\delta_i(s) = \kappa_i(s) \in \mathcal{O} \subseteq B$, so $d_i'(s) = F(\kappa_i(s)) = a(\kappa_i(s))$.

Step 5: the diagonal is congruent to $a \circ \kappa_i$ on D_ℓ. Fix $g \in D_\ell$ and i, and put $w = \delta_i(g) - \kappa_i(g) \in W$. As a diagonal entry of a triangular conjugate of $\rho_B(g)$, $\delta_i(g)$ is a root of the characteristic polynomial of $\rho_B(g)$, which is monic over B; so w is integral over B and $C' = B[w] \subseteq L$ is a domain finite over B. As B is complete, hence Henselian, C' is a finite product of local rings,

hence local, with maximal ideal $\mathfrak{m}'$. Let $t = \operatorname{tr}(\Pi_i \rho_B(g)) \in B$. By (45.6), $d_i w = t - d_i\kappa_i(g)$. Applying x, and using that Π_i formed with r_0 is diagonal with the single non-zero entry d_i at (i,i), gives $x(t) = d_i\kappa_i(g)$. By the lying-over theorem there is a prime Q of C' over $\ker x$; C'/Q is integral over $B/\ker x \cong \mathcal{O}$, so its fraction field embeds into $\overline{\mathbb{Q}}_\ell$ over $\operatorname{Frac}(\mathcal{O})$, giving $\tilde{x}\colon C' \to \overline{\mathbb{Q}}_\ell$ extending x. Then $d_i\tilde{x}(w) = x(t) - d_i\kappa_i(g) = 0$, so $\tilde{x}(w) = 0$, and w lies in the proper ideal $\ker\tilde{x} \subseteq \mathfrak{m}'$. Every prime of C' containing $\mathfrak{m}_B C'$ lies over $\mathfrak{m}_B$, hence is maximal, hence equals $\mathfrak{m}'$; so $\mathfrak{m}' = \sqrt{\mathfrak{m}_B C'}$, and by Atiyah–Macdonald, Lemma 5.14, there are $n \geq 1$ and $b_1, \dots, b_n \in \mathfrak{m}_B$ with

$$w^n + b_1 w^{n-1} + \cdots + b_n = 0.$$

Reducing modulo $\mathfrak{m}_W$ and applying φ (note $\bar{w} = \overline{\delta_i(g)} - \overline{\kappa_i(g)} \in C$), the element $z = \varphi(\bar{w}) = d_i'(g) - a(\kappa_i(g))$ satisfies $z^n + F(b_1)z^{n-1} + \cdots + F(b_n) = 0$ with $F(b_k) \in \mathfrak{m}_V$. So z is integral over V, hence $z \in V$, and $z^n \in \mathfrak{m}_V$, hence $z \in \mathfrak{m}_V$.

Step 6: an integral flag, and (Ot4), (Ot1). The subspaces $G_i = \langle he_1, \dots, he_i\rangle \subseteq K^4$ ($i = 1,2,3$) form an isotropic flag with G_3 the orthogonal of G_1: as h has similitude 1, $\langle he_a, he_b\rangle = (J_4)_{ab}$, which vanishes for $a, b \in \{1,2\}$ and, for $a = 1$, unless $b = 4$. Since $h^{-1}r(g)h$ is upper triangular, $r(g)G_i \subseteq G_i$ for $g \in D_\ell$. By Lemma 45.38 for $V \subseteq K$ there is $u \in \mathrm{GL}_4(V)$ of similitude 1 such that $u^{-1}r(s)u$ is upper triangular with the diagonal entries $d_i'(s)$ of $h^{-1}r(s)h$, for every $s \in D_\ell$. By Steps 4 and 5, $d_i'(s) - a(\kappa_i(s)) \in \mathfrak{m}_V$, with equality $d_i'(s) = a(\kappa_i(s))$ for $s \in I_\ell$: this is (Ot4). Finally $(r,1)$ satisfies (Ot1), so (r,u) satisfies (Ot1) by Lemma 45.39. Together with Step 1, (r,u) is an ordinary test representation of $\mathfrak{D}$ with values in V. □

Lemma 45.38. *Let W be a valuation ring with fraction field L, and put $\langle x, y\rangle = {}^t x\, J_4\, y$ for $x, y \in L^4$. Let $F_1 \subset F_2 \subset F_3 \subset L^4$ be subspaces of dimensions $1,2,3$ such that $\langle x, y\rangle = 0$ for all $x, y \in F_2$ and $F_3 = \{y \in L^4 : \langle x, y\rangle = 0$ for all $x \in F_1\}$. Then there is $u \in \mathrm{GL}_4(W)$ of similitude 1 such that for $i = 1,2,3$ the columns $ue_1, \dots, ue_i$ span F_i. Consequently, if $X \in \mathrm{M}_4(L)$ satisfies $XF_i \subseteq F_i$ for $i = 1,2,3$, then $u^{-1}Xu$ is upper triangular; and if moreover $h \in \mathrm{GL}_4(L)$ is such that $he_1, \dots, he_i$ span F_i for $i = 1,2,3$, then $u^{-1}Xu$ and $h^{-1}Xh$ have the same diagonal entries.*

Proof. Call $f \in W^4$ *unimodular* if some coordinate of f is a unit of W.

Step 1: lines contain unimodular vectors, and unimodular vectors pair onto W. Let $0 \neq y \in L^4$. For non-zero $a, b \in L$, $a/b \in W$ or $b/a \in W$, so among the non-zero coordinates of y there is one, y_k, with $y_i/y_k \in W$ for all i; then $y/y_k \in W^4$ has k-th coordinate 1. The same holds for a free W-module of finite rank and a non-zero vector of its scalar extension to L, using coordinates in a basis. If $f \in W^4$ is unimodular, the W-linear map $W^4 \to W$, $z \mapsto \langle f, z\rangle$, is surjective: $\langle f, e_j\rangle = \sum_i f_i(J_4)_{ij}$ equals $\pm f_{\tau(j)}$ for the permutation τ exchanging $1 \leftrightarrow 4$, $2 \leftrightarrow 3$, so some $\langle f, e_j\rangle$ is a unit.

Step 2: the vectors f_1, f_4 and a splitting. By Step 1 choose a unimodular $f_1 \in W^4$ spanning F_1, and $f_4 \in W^4$ with $\langle f_1, f_4\rangle = 1$. For $z \in L^4$ put

$$\pi(z) = z - \langle f_1, z\rangle f_4 + \langle f_4, z\rangle f_1.$$

Then

$$\langle f_1, \pi(z)\rangle = \langle f_1, z\rangle - \langle f_1, z\rangle\langle f_1, f_4\rangle + \langle f_4, z\rangle\langle f_1, f_1\rangle = 0,$$
$$\langle f_4, \pi(z)\rangle = \langle f_4, z\rangle - \langle f_1, z\rangle\langle f_4, f_4\rangle + \langle f_4, z\rangle\langle f_4, f_1\rangle = 0,$$

as $\langle f_4, f_1\rangle = -1$. So π maps L^4 onto $H_L = \{z : \langle f_1, z\rangle = \langle f_4, z\rangle = 0\}$, is the identity there, and maps W^4 onto $H = H_L \cap W^4$. Hence $W^4 = Wf_1 \oplus Wf_4 \oplus H$ (if $af_1 + bf_4 + z = 0$ with $z \in H$, pairing with f_1 gives $b = 0$ and pairing with f_4 gives $a = 0$). As a direct summand of

W^4, H is projective, hence free over the local ring W, and $H \otimes_W L = H_L$ has dimension 2 ($\langle\cdot,\cdot\rangle$ is non-degenerate and f_1, f_4 are independent). In a basis (f_1, f_4, h_1, h_2) of W^4 with (h_1, h_2) a basis of H, the Gram matrix of $\langle\cdot,\cdot\rangle$ is the block sum of $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ and the Gram matrix G_H of H; its determinant is $\det(J_4) = 1$ times the square of a unit, so $\det G_H$ is a unit: the form is perfect on H.

Step 3: the vectors f_2, f_3. Since $\langle\cdot,\cdot\rangle$ vanishes on $F_2 \times F_2 \supseteq F_1 \times F_2$, we have $F_2 \subseteq F_3$. For $z \in F_3$ we have $\langle f_1, z\rangle = 0$, so $\pi(z) = z + \langle f_4, z\rangle f_1 \equiv z$ modulo Lf_1; and $\pi(f_1) = f_1 + \langle f_4, f_1\rangle f_1 = 0$. Hence $\ell_2 = \pi(F_2) \subseteq H_L$ is a line with $F_2 = Lf_1 \oplus \ell_2$. By Step 1, applied to H, choose $f_2 \in H \cap \ell_2$ spanning ℓ_2 and part of a basis (f_2, h') of H. Then $G_H = \begin{pmatrix} 0 & b \\ -b & 0 \end{pmatrix}$ with $b = \langle f_2, h'\rangle$, and $b^2 = \det G_H$ is a unit, so b is a unit; put $f_3 = b^{-1}h'$, so $\langle f_2, f_3\rangle = 1$.

Step 4: the matrix u. Let u have columns f_1, f_2, f_3, f_4. Its Gram matrix ${}^t u J_4 u = (\langle f_a, f_b\rangle)_{a,b}$ has $\langle f_1, f_4\rangle = \langle f_2, f_3\rangle = 1$, $\langle f_4, f_1\rangle = \langle f_3, f_2\rangle = -1$, and all other entries 0: $\langle f_a, f_a\rangle = 0$, $f_2, f_3 \in H$ are orthogonal to f_1 and f_4. So ${}^t u J_4 u = J_4$: u has similitude 1, $\det(u)^2 = 1$, and $u \in \mathrm{GL}_4(W)$. The column $ue_1 = f_1$ spans F_1; f_1, f_2 span $Lf_1 \oplus \ell_2 = F_2$; and f_1, f_2, f_3 are independent and orthogonal to f_1, so they span the 3-dimensional space F_3.

Step 5: the consequences. If $XF_i \subseteq F_i$, then $u^{-1}Xu$ maps $\langle e_1, \dots, e_i\rangle = u^{-1}F_i$ into itself for $i = 1, 2, 3$, so it is upper triangular. If h is as stated, $b' = u^{-1}h$ maps each $\langle e_1, \dots, e_i\rangle$ onto itself, so b' and b'^{-1} are upper triangular with $(b'^{-1})_{ii} = (b'_{ii})^{-1}$; and $h^{-1}Xh$ is upper triangular by the first consequence applied to h in place of u (the argument used only the spanning property). Then $u^{-1}Xu = b'(h^{-1}Xh)b'^{-1}$, and the diagonal of a product of upper triangular matrices is the product of the diagonals, so $(u^{-1}Xu)_{ii} = b'_{ii}(h^{-1}Xh)_{ii}(b'_{ii})^{-1} = (h^{-1}Xh)_{ii}$. □

Lemma 45.39. *Let K be a field, V a valuation ring of K with maximal ideal $\mathfrak{m}_V$, Λ a complete discrete valuation ring with finite residue field and $j\colon \Lambda \to V$ an injective local homomorphism such that every element of K is algebraic over $j(\Lambda)$. For every finite subset $Y \subseteq V$ there are a complete discrete valuation ring Λ' with finite residue field and an injective local homomorphism $j'\colon \Lambda' \to V$ such that $j(\Lambda) \cup Y \subseteq j'(\Lambda')$ and $\iota = j'^{-1} \circ j\colon \Lambda \to \Lambda'$ is a local homomorphism. In particular, if (K, V, a) is a test field, $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ a homomorphism such that $(r, 1)$ satisfies (Ot1), and $u \in \mathrm{GL}_4(V)$, then (r, u) satisfies (Ot1).*

Proof. Step 1: the ring Λ'. Let $E_0 \subseteq K$ be the fraction field of $j(\Lambda)$; it is complete for the discrete valuation with valuation ring $j(\Lambda) \cong \Lambda$. Every $y \in Y$ is algebraic over $j(\Lambda)$, so $E' = E_0(Y) \subseteq K$ is a finite extension of E_0. Let Λ' be the integral closure of $j(\Lambda)$ in E'. Since E_0 is complete, Λ' is a complete discrete valuation ring, finite over $j(\Lambda)$, whose residue field is a finite extension of that of Λ, hence finite (Serre, Local Fields, Ch. II, §2, Proposition 3); its fraction field is E'.

Step 2: $\Lambda' = V \cap E'$. The ring $V \cap E'$ is a valuation ring of E' (for $0 \neq x \in E'$, $x \in V$ or $x^{-1} \in V$) containing $j(\Lambda)$; valuation rings are integrally closed, so $\Lambda' \subseteq V \cap E'$. A ring between a discrete valuation ring and its fraction field is one of the two: if it contains an element $w\varpi'^{-k}$ with w a unit and $k \geq 1$ (ϖ' a uniformiser), it contains ϖ'^{-1} and hence all of E'. Let ϖ be a uniformiser of Λ; as j is local, $j(\varpi) \in \mathfrak{m}_V$, so $j(\varpi)^{-1} \in E' \setminus V$ and $V \cap E' \neq E'$. Hence $V \cap E' = \Lambda'$, and $Y \subseteq V \cap E' = \Lambda'$.

Step 3: j' and ι. Let $j'\colon \Lambda' \to V$ be the inclusion; it is injective, and $j(\Lambda) \cup Y \subseteq j'(\Lambda')$. It is local: if $x \in \Lambda'$ is not a unit of Λ', then $x^{-1} \in E' \setminus \Lambda' = E' \setminus V$ (or $x = 0$), so $x \in \mathfrak{m}_V$. Conversely a unit of Λ' is a unit of V, so $\mathfrak{m}_{\Lambda'} = \Lambda' \cap \mathfrak{m}_V$. The map $\iota\colon \Lambda \to \Lambda'$ sends $\mathfrak{m}_\Lambda$ into $\mathfrak{m}_V \cap \Lambda' = \mathfrak{m}_{\Lambda'}$, so it is local, $\iota(\mathfrak{m}_\Lambda^n) \subseteq \mathfrak{m}_{\Lambda'}^n$, and a map φ from a topological space to Λ whose reductions modulo every $\mathfrak{m}_\Lambda^n$ are locally constant has $\iota \circ \varphi$ with reductions modulo every $\mathfrak{m}_{\Lambda'}^n$ locally constant: ι

preserves continuity for the adic topologies.

Step 4: (Ot1) for (r,u). Let (Λ, j) be as in (Ot1) for $(r,1)$, and apply Steps 1–3 with Y the set of entries of u. Every element of K is algebraic over $j(\Lambda) \subseteq j'(\Lambda')$; the entries of u and of every $r(g)$ lie in $j'(\Lambda')$; and $g \mapsto j'^{-1}(r(g)_{ab}) = \iota(j^{-1}(r(g)_{ab}))$ is continuous for the $\mathfrak{m}_{\Lambda'}$-adic topology by Step 3. So (Ot1) holds for (r,u), with the pair (Λ', j'). □

Lemma 45.40. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and r a point of $\mathfrak{D}$ of diagonal type. Then there is a permutation m of $\{1,2,3,4\}$, either the identity or $m_\star = (1\,3)(2\,4)$, such that:*

(Dt1) *$r(s)_{ii} = \kappa_{m(i)}(s)$ for every $s \in I_\ell$ and every i;*

(Dt2) *if $i \neq j$ and the entry (i,j) of r is active, then $m(i) < m(j)$.*

In particular, if m is the identity, then $r(s_0)_{11} = \theta(s_0)$ and no entry (i,j) with $\mu_i < \mu_j$ is active; if $m = m_\star$, then $r(s_0)_{11} = \alpha(s_0)$ and no entry (i,j) with $\mu_i > \mu_j$ is active.

Proof. Write $K = \overline{\mathbb{Q}}_\ell$, $i^* = 5 - i$, $i \to j$ if the entry (i,j) is active, and $(n_1, n_2, n_3, n_4) = (e+1, e, 1, 0)$, strictly decreasing as $e \geq 2$. By Lemma 45.41, r is a point with values in $\overline{\mathbb{Z}}_\ell$ for the standard test field, so (Ae3), (Ae4) apply: $\to$ is reflexive and transitive, $i \to j$ implies $j^* \to i^*$, and, r being of diagonal type, $i \to j \to i$ implies $i = j$. Since ξ is unramified at $\ell \in T$ (Sg1) and $\chi(s_0) = \omega_\ell(s_0) = 1$ (Sg5), $(\kappa_1, \ldots, \kappa_4)(s_0) = (c^{e+1}, c^e, c, 1)$ with $c = \chi_{\mathrm{cyc}}(s_0)$ of infinite order: the four values are pairwise distinct.

Step 1: the diagonal entries are characters. For $g, h \in G_{\mathbb{Q}}$, $r(gh)_{ii} = \sum_k r(g)_{ik} r(h)_{ki}$, and a term with $k \neq i$ would give $i \to k \to i$; so $\delta_i(g) = r(g)_{ii}$ is multiplicative. Ordering $\{1, \ldots, 4\}$ by a linear order extending $\to$, every $r(g)$ is triangular in the reordered basis, so $\det r(g) = \prod_i \delta_i(g)$ and $\delta_i(g) \in K^\times$; each δ_i is continuous by (Sq5), and $\operatorname{tr} r(g) = \sum_i \delta_i(g)$.

Step 2: the permutation. Let $\delta'_1, \ldots, \delta'_4$ be the characters of (Zt2): r is triangular on D_ℓ with diagonal (δ'_k), $\delta'_k = \kappa_k$ on I_ℓ and $\delta'_k \equiv \kappa_k$ modulo $\mathfrak{m}_\ell$ on D_ℓ. They are pairwise distinct (their values at s_0 are). On D_ℓ, $\sum_i \delta_i = \operatorname{tr} r = \sum_k \delta'_k$; by Artin's independence of characters, each distinct character occurs with the same multiplicity on both sides, so there is a permutation m with $\delta_i|_{D_\ell} = \delta'_{m(i)}$. This gives (Dt1). By (Sq4) $\delta_i(\sigma_\ell) \equiv \kappa_i(\sigma_\ell)$ and by (Zt2) $\delta'_{m(i)}(\sigma_\ell) \equiv \kappa_{m(i)}(\sigma_\ell)$ modulo $\mathfrak{m}_\ell$ ($\sigma_\ell \in D_\ell$ by (Sg2)), so $\bar\kappa_i(\sigma_\ell) = \bar\kappa_{m(i)}(\sigma_\ell)$ and $\lambda_i = \lambda_{m(i)}$ by (Ae1). Next, by (Sq2) ${}^t r(g) J_4 r(g) = \theta(g) J_4$; the entry (i, i^*) is $\sum_a \epsilon_a r(g)_{ai} r(g)_{a^* i^*} = \theta(g)\epsilon_i$ with $\epsilon_a = (J_4)_{aa^*} = \pm 1$, and for $a \neq i$ a non-zero term would give $a \to i$ and $a^* \to i^*$, hence $i \to a$: excluded. So $\delta_i \delta_{i^*} = \theta$, and likewise $\kappa_k \kappa_{k^*} = \theta$. At s_0: $\kappa_{m(i)}(s_0)\kappa_{m(i^*)}(s_0) = \theta(s_0) = \kappa_{m(i)}(s_0)\kappa_{m(i)^*}(s_0)$, so $m(i^*) = m(i)^*$. A permutation preserving the blocks $\{1,3\}$, $\{2,4\}$ and commuting with $i \mapsto i^*$ is determined by $m(1) \in \{1,3\}$: $m(1) = 1$ gives $m(4) = 4$, $m(3) = 3$, $m(2) = 2$; $m(1) = 3$ gives $m(4) = 2$, $m(3) = 1$, $m(2) = 4$. So $m \in \{\mathrm{id}, m_\star\}$.

Step 3: $\eta_i = \delta_i \chi_{\mathrm{cyc}}^{-n_{m(i)}}$ has open kernel. η_i is a continuous character. Let N_1 be the product of the order of $\bar r_0(G_{\mathbb{Q}})$, the order of χ and the order of the finite group $\kappa_k \chi_{\mathrm{cyc}}^{-n_k}(I_\ell)$ over k ((Zt3) with $\delta'_k = \kappa_k$ on I_ℓ). For an inertia group I at a place above $p \notin T$ and $g \in I$, $\bar r_0(g^{N_1}) = 1$, so $r(g^{N_1}) = 1$ by (Se2) (applied to the lift of which r is an image) and $\chi_{\mathrm{cyc}}(g) = 1$ ($p \neq \ell$); for $p \in T \setminus \{\ell\}$ and $g \in I_p$, $\chi(g^{N_1}) = 1$, so $r(g^{N_1}) = 1$ by (Zt1); for $g \in I_\ell$, $\eta_i(g) = \kappa_{m(i)} \chi_{\mathrm{cyc}}^{-n_{m(i)}}(g)$ by (Dt1). As η_i is a character, triviality on $I_{\bar p}$ gives triviality on its conjugates. So $\eta_i^{N_1}$ is trivial on every inertia group. Every open subgroup $H \supseteq \ker \eta_i^{N_1}$ is normal with abelian quotient and contains every inertia group, so its fixed field is unramified everywhere and $H = G_{\mathbb{Q}}$ by Minkowski's theorem; the closed subgroup $\ker \eta_i^{N_1}$ is the intersection of such H, hence $\eta_i^{N_1} = \mathbf{1}$. So η_i has finite image, and its kernel, closed of finite index, is open.

Step 4: a minimal bad pair. Suppose (Dt2) fails, and call (i,j) bad if $i \neq j$, $i \to j$ and $m(j) < m(i)$. If (i,j) is bad and $i \to k \to j$ with $k \notin \{i,j\}$, then (i,k) is bad (if $m(k) < m(i)$)

or (k,j) is bad (if $m(k) > m(i) > m(j)$), and the set $\{k' : i \to k' \to k\}$, resp. $\{k' : k \to k' \to j\}$, is strictly smaller than $\{k' : i \to k' \to j\}$ (it misses j, resp. i, by antisymmetry). So there is a bad pair (i,j) with no $k \notin \{i,j\}$ such that $i \to k \to j$. Put $a = m(j) < b = m(i)$.

Step 5: the subquotient. Let U be the span of the e_k with $k \to j$ and U' that of the e_k with $k \to j$, $k \notin \{i,j\}$. Both are $r(G_{\mathbb{Q}})$-stable: if $r(g)_{ck} \neq 0$ with e_k in U', then $c \to k \to j$, $c \neq j$ (else $j \to k \to j$) and $c \neq i$ (else $i \to k \to j$). In $W = U/U'$ with basis $\bar{e}_i, \bar{e}_j$ one has $r(g)\bar{e}_i = \delta_i(g)\bar{e}_i$ (a component along e_j would give $j \to i$) and $r(g)\bar{e}_j = r(g)_{ij}\bar{e}_i + \delta_j(g)\bar{e}_j$. Hence, with $\gamma = \delta_i\delta_j^{-1}$, $z(g) = r(g)_{ij}\delta_j(g)^{-1}$ is a continuous map with $z(gh) = z(g) + \gamma(g)z(h)$.

Step 6: z is locally a coboundary. For a cocycle z and $g \in G_{\mathbb{Q}}$, if $z(h) = \gamma(h)m_0 - m_0$ on a subgroup H, then $z(h) = \gamma(h)m_1 - m_1$ on gHg^{-1} with $m_1 = \gamma(g)m_0 + z(g)$ (expand $z(ghg^{-1})$ by the cocycle rule; γ is a character); so it suffices to treat $I_{\bar{p}}$ and D_ℓ. (i) For $p \neq \ell$: on the open normal subgroup $I' = I_{\bar{p}} \cap \ker \bar{r}_0$ ($p \notin T$) or $I' = I_p \cap \ker \chi$ ($p \in T$) one has $r = 1$, so $z = 0$ and $\gamma = 1$ there; $z|_{I_{\bar{p}}}$ is inflated from the finite group $I_{\bar{p}}/I'$ with values in the $\mathbb{Q}$-vector space K, hence a coboundary. (ii) At ℓ: let u be as in (Zt2) and $F_n = u\langle e_1, \dots, e_n\rangle$, a D_ℓ-stable flag on whose graded pieces s_0 acts by the distinct scalars $\kappa_n(s_0)$; so $r(s_0)$ is diagonalisable with eigenlines L_k, $F_n = L_1 \oplus \cdots \oplus L_n$, and $r(g)L_k \subseteq F_k$ for $g \in D_\ell$. As U, U' are $r(s_0)$-stable, $U = \bigoplus_k (U \cap L_k)$ and likewise for U'. On W, s_0 has the eigenvalues $\kappa_b(s_0)$ (on $\bar{e}_i$) and $\kappa_a(s_0)$ (by (Dt1)); so $U \cap L_k \subseteq U'$ for $k \notin \{a,b\}$, and there is $w \in U \cap L_a$ with image $\bar{w} \neq 0$, $\bar{w} \notin K\bar{e}_i$. For $g \in D_\ell$, $r(g)w \in U \cap F_a = \bigoplus_{k \le a}(U \cap L_k)$, whose image in W is $K\bar{w}$ (as $b > a$). So $K\bar{w}$ is D_ℓ-stable, mapping isomorphically onto $W/K\bar{e}_i$, on which D_ℓ acts by δ_j. Scaling, $\bar{w} = \bar{e}_j + c\bar{e}_i$, and $r(g)\bar{w} = \delta_j(g)\bar{w}$ gives $r(g)_{ij} = c(\delta_j(g) - \delta_i(g))$, i.e. $z(g) = \gamma(g)(-c) - (-c)$ for $g \in D_\ell$.

Step 7: contradiction. $\gamma = \chi_{\mathrm{cyc}}^{n_b - n_a}\eta_i\eta_j^{-1} = \psi^{-1}\chi_{\mathrm{cyc}}^{-e'}$ with $e' = n_a - n_b \geq 1$ and $\psi = \eta_j\eta_i^{-1}$ of open kernel (Step 3). By Step 6 and Lemma 45.31, there is $c' \in K$ with $z(g) = \gamma(g)c' - c'$ for all g, i.e. $r(g)_{ij} = c'(r(g)_{ii} - r(g)_{jj})$. The linear form $X \mapsto X_{ij} - c'(X_{ii} - X_{jj})$ vanishes on $r(G_{\mathbb{Q}})$, hence on its span, which contains E_{ii} by (Ae3); so $c' = 0$ and $r(g)_{ij} = 0$ for all g, contradicting $i \to j$. This proves (Dt2).

The last assertion. $r(s_0)_{11} = \kappa_{m(1)}(s_0)$ by (Dt1), which is $\theta(s_0)$ or $\alpha(s_0)$. For $m = \mathrm{id}$, an active (i,j) with $i \neq j$ has $i < j$, so $\mu_i \geq \mu_j$ ($\boldsymbol{\mu} = (1,1,0,0)$). For $m = m_\star$, the pairs with $m(i) < m(j)$ are $(3,4),(3,1),(3,2),(4,1),(4,2),(1,2)$, all with $\mu_i \leq \mu_j$. □

Lemma 45.41. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ a point of $\mathfrak{D}$. Then r takes values in $\mathrm{GL}_4(\overline{\mathbb{Z}}_\ell)$ and is a point of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ for the standard test field.*

Proof. Write $r(g) = f(r_A(g))$ for a symplectic Eisenstein lift r_A to $A \in \mathrm{CNL}_{\mathcal{O}}$ and an $\mathcal{O}$-algebra homomorphism $f\colon A \to \overline{\mathbb{Q}}_\ell$. By (Sq1) of Lemma 44.11, $f(A) \subseteq \overline{\mathbb{Z}}_\ell$, $f(\mathfrak{m}_A) \subseteq \mathfrak{m}_\ell$ and f is continuous for the $\mathfrak{m}_A$-adic topology. So $f\colon A \to \overline{\mathbb{Z}}_\ell$ restricts to the inclusion $a = \mathrm{id}$ on $\mathcal{O}$ and maps $\mathfrak{m}_A$ into the maximal ideal $\mathfrak{m}_\ell$ of $V = \overline{\mathbb{Z}}_\ell$. The entries of every $r(g)$ lie in $\overline{\mathbb{Z}}_\ell$, and $\det r(g) = f(\det r_A(g))$ is the image of a unit of A, hence a unit of $\overline{\mathbb{Z}}_\ell$; so r takes values in $\mathrm{GL}_4(\overline{\mathbb{Z}}_\ell)$. It remains to check (Ot1) for the pair $(r,1)$.

The discrete valuation ring. As A is Noetherian, $\mathfrak{m}_A = (x_1, \dots, x_k)$. Each $f(x_i)$ is algebraic over $\mathbb{Q}_\ell$, and the fraction field of $\mathcal{O}$ is a finite extension of $\mathbb{Q}_\ell$, so $E = \mathrm{Frac}(\mathcal{O})(f(x_1), \dots, f(x_k)) \subseteq \overline{\mathbb{Q}}_\ell$ is a finite extension of $\mathbb{Q}_\ell$. Let $\Lambda = \{y \in E : |y|_\ell \leq 1\}$, a complete discrete valuation ring with finite residue field, and $j\colon \Lambda \to \overline{\mathbb{Z}}_\ell$ the inclusion. It is injective and local, since $\Lambda \cap \mathfrak{m}_\ell = \mathfrak{m}_\Lambda$. Every element of $\overline{\mathbb{Q}}_\ell$ is algebraic over $\mathbb{Q}_\ell$, hence a root of a nonzero polynomial with coefficients in $\mathbb{Z}_\ell \subseteq \Lambda$ (clear denominators).

The entries lie in Λ. Since A is complete and $\mathcal{O} \to A/\mathfrak{m}_A$ is surjective, every $b \in A$ is the limit, for the $\mathfrak{m}_A$-adic topology, of a sequence of polynomials in $x_1, \dots, x_k$ with coefficients in $\mathcal{O}$: write $b = \lambda_0 + b_1$ with $\lambda_0 \in \mathcal{O}$, $b_1 \in \mathfrak{m}_A$, write $b_1 = \sum_i x_i b_{1,i}$ and repeat with the $b_{1,i}$;

after n steps b is congruent modulo $\mathfrak{m}_A^n$ to a polynomial $P_n(x_1,\dots,x_k)$ with coefficients in $\mathcal{O}$. By continuity of f, $f(b)=\lim_n P_n(f(x_1),\dots,f(x_k))$ in $\overline{\mathbb{Q}}_\ell$. Each $P_n(f(x_1),\dots,f(x_k))$ lies in Λ (its coefficients are in $\mathcal{O}\subseteq\Lambda$ and $|f(x_i)|_\ell<1$), and Λ is closed in $\overline{\mathbb{Q}}_\ell$, being complete. Hence $f(A)\subseteq\Lambda$, and all entries of all $r(g)$, and of the matrix 1, lie in $j(\Lambda)$.

Continuity. The map $g\mapsto r_A(g)_{ab}$ is continuous for the $\mathfrak{m}_A$-adic topology, and $f\colon A\to\Lambda$ is continuous by (Sq1), the topology of Λ induced by $|\cdot|_\ell$ being its $\mathfrak{m}_\Lambda$-adic topology. So $g\mapsto r(g)_{ab}$ is continuous for the $\mathfrak{m}_\Lambda$-adic topology, for all a,b. Thus $(r,1)$ satisfies (Ot1), and r is a point of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$. □

46 The dyadic one-character bound

This section proves Proposition 46.2, the one-character bound for dyadic Eisenstein data, which Proposition 38.32 uses for the characters of case (V) whose 2-component has a large conductor. A dyadic Eisenstein datum (Definition 38.31) asks that the conductor $2^{c_2(\chi)}$ of the 2-component be large compared with ℓ, with the primes of $S_\ell(\chi)$, with the order bound of the odd components and with the conductor of ϑ^2 (conditions (Dy5)–(Dy7)). The congruences are formed on the unitary group in three variables attached to $\mathbb{Q}(i)$, with local conditions at the primes of $T_\ell(\chi)$ (Definition 46.1, Definition 46.10). The section proves bound and graded model together, Proposition 46.4 with clauses (Dm1)–(Dm7), and reuses from Sections 42 and 43 the homogeneity of presentations, the Euler-characteristic formula and the rationality of cocycles.

Two points differ from the unitary case of Section 42. First, only representations of stable type occur. The residual Selmer group of weight -2 vanishes (Lemma 46.15), because the first Bernoulli number of an odd character with a large 2-power conductor is an ℓ-adic unit (Lemma 44.6); hence the deformation ring has no endoscopic two-signed points (Lemma 46.17), and no hypothesis on newforms is needed. Second, the presentation counts are made with the dyadic local conditions: graded local lifts exist along small extensions (Lemma 46.12), the pieces of non-zero weight have no local invariants and no local H^2 at the primes of $T_\ell(\chi)$ (Lemma 46.13), and integral cocycles of weights -2, -1, 0 are torsion modulo coboundaries (Proposition 46.14), which uses Proposition 40.3 from Part VII. Rigidity at the automorphic points, Theorem 46.18, rests on the vanishing theorem of Newton and Thorne through Proposition 42.6 [192], and automorphy is Theorem 47.16 of Part IX.

Definition 46.1. Let (ℓ,e,N,χ,o,m) be a dyadic Eisenstein datum (Definition 38.31) with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with maximal ideal $\mathfrak{m}_\mathcal{O}$ and residue field $\mathbb{F}_\mathcal{O}$. Let $K=\mathbb{Q}(i)$, $\eta_K\colon G_\mathbb{Q}\to\{\pm1\}$ the character with kernel G_K, $\Psi=\Psi_{\chi,e}$ and $\bar\Psi\colon G_\mathbb{Q}\to\mathbb{F}_\mathcal{O}^\times$ its reduction. Fix a complex conjugation $c\in G_\mathbb{Q}$ and, for every prime p, a place $\bar p$ of $\overline{\mathbb{Q}}$ above p; write $D_p\supseteq I_p$ for $D_{\bar p}\supseteq I_{\bar p}$. For a place $\bar v$ of $\overline{\mathbb{Q}}$ above a prime put

$$N_{\bar v}=\{g\in I_{\bar v}:\ \eta_K(g)=1,\ \bar\Psi(g)=1\}.$$

The group, the Eisenstein representation, lifts and points. The group $\mathcal{G}_3(B)$ with J and θ, GL-parts $\underline{r}$ and signs, $\mathrm{T}(t)$, the weights $\mathrm{wt}(a,b)=b-a$, the Eisenstein representation $r_0(g)=(\mathrm{T}(\Psi(g)),\eta_K(g))$ and its reduction $\bar r_0$, the characters $\psi_a=\Psi^{2-a}$ $(a=1,2,3)$, the category $\mathrm{CNL}_\mathcal{O}$, lifts of $\bar r_0$ to $A\in\mathrm{CNL}_\mathcal{O}$, base points, markings $g_\star$ and condition (Ed1) are those of Definition 42.1, formed with the present K, $\mathcal{O}$, Ψ and c: of the unitary Eisenstein datum, their definitions there use only K, $\mathcal{O}$, Ψ and the identity $\Psi(c)=1$, which holds here since $\Psi(c)=\chi(-1)(-1)^e=1$ by (Dy3). For a pair (R,r) of $R\in\mathrm{CNL}_\mathcal{O}$ and a lift r of $\bar r_0$ to R, the weight-zero subalgebra R^0, points φ with r_φ and $\rho_\varphi\colon G_K\to\mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$, upper, lower and two-signed points, points of type I and of type II, torus conjugates $\mathrm{T}(t)\cdot r_\varphi$, trace differences and

the adjoint representation $\operatorname{ad} r_\varphi$ are defined as in Definition 42.1 under the headings *Normalised ordinary lifts* (last sentence) and *Points*, whose wording applies unchanged to such a pair.

Dyadic local conditions. Let $A \in \mathrm{CNL}_{\mathcal{O}}$ with maximal ideal $\mathfrak{m}_A$. A lift r of $\bar{r}_0$ to A satisfies the **dyadic local conditions** if

(Dd1) there is $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \pmod{\mathfrak{m}_A}$ such that for every $g \in D_\ell \cap G_K$ the matrix $h^{-1}\underline{r}(g)h$ is upper triangular (its entries of negative weight vanish), and its diagonal entries are $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_\ell$;

(Dd2) for every $p \in S_\ell(\chi)$ there is $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \pmod{\mathfrak{m}_A}$ such that for every $g \in D_p \cap G_K$ the matrix $h^{-1}\underline{r}(g)h$ is diagonal, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_p$;

(Dd3) $r(g) = 1$ for every $g \in N_{\bar{v}}$ and every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above a prime not in $T_\ell(\chi)$.

For a marking $g_\star$, a **dyadic Eisenstein deformation ring** for $g_\star$ is a pair (R, r) of $R \in \mathrm{CNL}_{\mathcal{O}}$ and a lift r of $\bar{r}_0$ to R satisfying (Ed1) for $g_\star$ and (Dd1)–(Dd3), such that for every lift r' of $\bar{r}_0$ to some $A \in \mathrm{CNL}_{\mathcal{O}}$ satisfying (Ed1) for $g_\star$ and (Dd1)–(Dd3) there is exactly one morphism $f\colon R \to A$ with $f \circ r = r'$. (For every morphism $f\colon R \to A$, $f \circ r$ again satisfies these conditions, f being local.)

Rigid points. Let φ be a point of a dyadic Eisenstein deformation ring and $\overline{\mathbb{Q}}_\ell[\epsilon]$ the dual numbers ($\epsilon^2 = 0$). For a continuous 1-cocycle y of $G_{\mathbb{Q}}$ with values in $\operatorname{ad} r_\varphi$, the map $r_y(g) = ((1 + \epsilon\, y(g))P_g, \varsigma_g)$, where $r_\varphi(g) = (P_g, \varsigma_g)$, is a homomorphism $G_{\mathbb{Q}} \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell[\epsilon])$. The cocycle y is a **dyadic tangent cocycle** at φ if

(Ty1) $y(g) = 0$ for every $g \in N_{\bar{v}}$ and every place $\bar{v}$ above a prime not in $T_\ell(\chi)$;

(Ty2) there is $h \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell[\epsilon])$ such that for every $g \in D_\ell \cap G_K$ the matrix $h^{-1}\underline{r_y}(g)h$ is upper triangular, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_\ell$;

(Ty3) for every $p \in S_\ell(\chi)$ there is $h \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell[\epsilon])$ such that for every $g \in D_p \cap G_K$ the matrix $h^{-1}\underline{r_y}(g)h$ is diagonal, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_p$.

The point φ is **rigid** if every dyadic tangent cocycle at φ is a coboundary, that is of the form $g \mapsto g \cdot X - X$ for some $X \in \operatorname{ad} r_\varphi$.

Automorphic points. For an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, a point φ is **Lie-irreducible automorphic** (for ι) if ρ_φ is irreducible on every open subgroup of G_K and on $G_{K(\mu_{\ell^\infty})}$, and $\rho_\varphi \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type (for ι).

The weight -2 residual Selmer group. Put $\gamma_{-2} = \eta_K \bar{\Psi}^{-2}\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^\times$; it is the character by which $G_{\mathbb{Q}}$ acts, through $\operatorname{ad} \bar{r}_0$, on the line of matrices supported on the entry $(3,1)$, the only entry of weight -2. Let Z_{-2} be the set of locally constant maps $z\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}$ with $z(gh) = z(g) + \gamma_{-2}(g)z(h)$ for all g, h, such that $z(g) = 0$ for every $g \in N_{\bar{v}}$ and every place $\bar{v}$ above a prime other than ℓ, and such that there is $y \in \mathbb{F}_{\mathcal{O}}$ with $z(g) = \gamma_{-2}(g)y - y$ for all $g \in D_\ell$. The **weight -2 residual Selmer group** $\mathrm{Sel}_{-2}(\chi, e)$ is the quotient of Z_{-2} by the coboundaries $g \mapsto \gamma_{-2}(g)y - y$, $y \in \mathbb{F}_{\mathcal{O}}$ (it depends on the whole datum and on $\mathcal{O}$; the subscript and the arguments separate it from $\mathrm{Sel}(F, T)$ of Definition 22.2).

Proposition 46.2. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum, with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. Let $K = \mathbb{Q}(i) \subset \overline{\mathbb{Q}}$, let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism, $\sigma \in G_K$, and*

$$t = \Psi_{\chi,e}(\sigma) + 1 + \Psi_{\chi,e}(\sigma)^{-1} \in \mathcal{O}.$$

Assume that $\operatorname{tr}\rho(\sigma) \neq t$ *for every representation* $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ *that is admissible of stable type for* (ι, e, N)*. Then* $\mathrm{Sha}^1_{\ell N}(\chi, e)$ *has finite length, and there is a finite set* X *of pairwise non-isomorphic representations* $G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$*, each admissible of stable type for* (ι, e, N)*, such that*

$$\nu_{\mathcal{O}}(\chi, e) \leq 2 \sum_{\rho \in X} v_\ell(\operatorname{tr}\rho(\sigma) - t).$$

Proof. Step 1: the ring and its graded model. By Theorem 47.16, applied to the datum, $\mathcal{O}$ and ι, there is a marking $g_\star$ such that (Da1) and (Da2) hold for every dyadic Eisenstein deformation ring for $g_\star$. By Proposition 46.4, applied with $g_\star$, there are such a ring (R, r) with its base point φ_{Eis}, and (A, φ_0, u, q) with (Dm3)–(Dm7). For a point φ of (R, r), $\varphi \circ q$ is a point of A on u, because $I(u) = \ker q$.

Step 2: every two-signed point of (R, r) *is of type I, stable admissible and rigid.* $\mathrm{Sel}_{-2}(\chi, e) = 0$ by Lemma 46.15, and R^0 is a finitely generated $\mathcal{O}$-module by (Da1). Let φ be a two-signed point. By Lemma 46.17 it is of type I. By (Da2) it is Lie-irreducible automorphic for ι and ρ_φ is admissible of stable type for (ι, e, N). By Theorem 46.18 (its finiteness hypothesis is (Da1); ρ_φ is generic ordinary of level N and weights $(e, 0, -e)$ by (Sb4) of its stable admissibility) φ is rigid. So the hypotheses of (Dm6) hold, (A, φ_0, u) satisfies (Gc1)–(Gc4); in particular (Gc2) holds, and (Dm5) applies.

Step 3: points on u*.* Let φ_A be a two-signed point of A on u. By (Dm5), $\varphi_A = t_1 \cdot (\varphi \circ q)$ for a point φ of (R, r) and some $t_1 \in \overline{\mathbb{Q}}_\ell^\times$. Since $(t_1 \cdot \varphi \circ q)(f) = t_1^j \varphi(q(f))$ for $f \in A_j$ and $t_1 \neq 0$, $\varphi \circ q$ is two-signed, so by (Dm4) φ is neither upper nor lower: φ is a two-signed point of (R, r). Conversely, for a two-signed point φ of (R, r), $\varphi \circ q$ is a two-signed point on u by (Dm4) and Step 1.

Step 4: the weight-zero element. By (Dm3) choose $w_1, w_2, w_3 \in A_0$ with $q(w_a) = \underline{r}(\sigma)_{aa}$ (diagonal entries have weight 0), and put $a_\sigma = w_1 + w_2 + w_3 - t \in A_0$, with $t \in \mathcal{O}$. Then $q(a_\sigma) = \operatorname{tr}\underline{r}(\sigma) - t$, so for every point φ of (R, r), as $\sigma \in G_K$,

$$\varphi(q(a_\sigma)) = \operatorname{tr}\rho_\varphi(\sigma) - t.$$

Since $\varphi_{\mathrm{Eis}} \circ r = r_0$, $\varphi_0(a_\sigma) = \varphi_{\mathrm{Eis}}(q(a_\sigma)) = \operatorname{tr}\mathrm{T}(\Psi(\sigma)) - t = 0$. For a two-signed point $\varphi_A = t_1 \cdot (\varphi \circ q)$ on u as in Step 3, $\varphi_A(a_\sigma) = \varphi(q(a_\sigma)) = \operatorname{tr}\rho_\varphi(\sigma) - t$ (degree 0), which is non-zero by hypothesis, since ρ_φ is admissible of stable type for (ι, e, N) by Step 2. So (Gc5) holds for a_σ, and $(A, \varphi_0, u, a_\sigma)$ satisfies (Gc1)–(Gc5).

Step 5: the graded numerical criterion. By Lemma 41.2, u has an orbit cover Σ_0, the cotangent length $\mathrm{ct}_{-1}(u_{-1})$ is finite, and $\mathrm{ct}_{-1}(u_{-1}) \leq 2\sum_{\varphi_A \in \Sigma} v_{\mathcal{O}}(\varphi_A(a_\sigma))$ for every orbit cover Σ.

Step 6: the Sha group has length at most $\mathrm{ct}_{-1}(u_{-1})$*.* Let $b \in \mathcal{O} \setminus \{0\}$ and $\mathrm{Sha}[b]$ the b-torsion of $\mathrm{Sha}^1_{\ell N}(\chi, e)$. The map D of (Dm7) satisfies the hypotheses of Lemma 42.12 for $j = -1$, the family u_{-1}, $c = b$ and $M = \mathrm{Sha}[b]$; hence $\operatorname{length}_{\mathcal{O}} \mathrm{Sha}[b] \leq \mathrm{ct}_{-1}(u_{-1})$. Every class in $H^1(\mathbb{Q}, \mathcal{O}^\vee(\Psi^{-1}))$ is represented by a continuous cocycle on the compact group $G_{\mathbb{Q}}$ with values in a discrete module, which has finite image; every element of $\mathcal{O}^\vee$ is killed by a power of ℓ; so every class is killed by some ℓ^k, and $\mathrm{Sha}^1_{\ell N}(\chi, e) = \bigcup_k \mathrm{Sha}[\ell^k]$, an increasing union. If $\mathrm{Sha}^1_{\ell N}(\chi, e)$ contained a strictly increasing chain $M_0 \subsetneq M_1 \subsetneq \cdots \subsetneq M_L$ of submodules with $L = \mathrm{ct}_{-1}(u_{-1}) + 1$, choose $x_i \in M_i \setminus M_{i-1}$; the submodule generated by $x_1, \ldots, x_L$ lies in some $\mathrm{Sha}[\ell^k]$ and contains the strictly increasing chain of the submodules generated by $x_1, \ldots, x_i$ (the i-th lies in M_i and contains $x_i \notin M_{i-1}$), so it has length at least L, a contradiction. Hence $\mathrm{Sha}^1_{\ell N}(\chi, e)$ has finite length, at most $\mathrm{ct}_{-1}(u_{-1})$.

Step 7: from an orbit cover to representations. For two-signed points φ, φ' of (R, r) write $\varphi \sim \varphi'$ if $r_{\varphi'} = \mathrm{T}(t_1) \cdot r_\varphi$ for some $t_1 \in \overline{\mathbb{Q}}_\ell^\times$; since $t_1 \mapsto (\mathrm{T}(t_1), 1)$ is a homomorphism, $\sim$ is an equivalence relation. For each $\varphi_A \in \Sigma_0$ choose, by Step 3, a two-signed point $\varphi_{[\varphi_A]}$ of (R, r) and t_{φ_A} with $\varphi_A = t_{\varphi_A} \cdot (\varphi_{[\varphi_A]} \circ q)$. Every two-signed point φ of (R, r) is equivalent to some $\varphi_{[\varphi_A]}$: by Step 3 and the definition of an orbit cover, $\varphi \circ q = t_2 \cdot \varphi_A = (t_2 t_{\varphi_A}) \cdot (\varphi_{[\varphi_A]} \circ q)$ for some $\varphi_A \in \Sigma_0$ and t_2, and (Dm4) gives $r_\varphi = \mathrm{T}(t_2 t_{\varphi_A}) \cdot r_{\varphi_{[\varphi_A]}}$. Let P be a set containing exactly one member of each equivalence class that meets $\{\varphi_{[\varphi_A]} : \varphi_A \in \Sigma_0\}$; P is finite, its members are pairwise inequivalent, and every two-signed point is equivalent to a member of P. Then $\Sigma = \{\varphi \circ q : \varphi \in P\}$ is an orbit cover: its members are two-signed points on u (Step 3); a two-signed point φ'_A on u is $t_2 \cdot (\varphi'' \circ q)$ with φ'' two-signed (Step 3), $\varphi'' \sim \varphi \in P$, say $r_{\varphi''} = \mathrm{T}(t_3) \cdot r_\varphi$, so $\varphi'' \circ q = t_3 \cdot (\varphi \circ q)$ by (Dm4) and $\varphi'_A = (t_2 t_3) \cdot (\varphi \circ q)$. The map $\varphi \mapsto \varphi \circ q$ is injective on P: if $\varphi \circ q = \varphi' \circ q$, then $r_{\varphi'} = \mathrm{T}(1) \cdot r_\varphi$ by (Dm4), so $\varphi \sim \varphi'$ and $\varphi = \varphi'$. With Steps 4 and 5, and $v_\mathcal{O} = e_\mathcal{O} v_\ell$,

$$\mathrm{ct}_{-1}(u_{-1}) \le 2 \sum_{\varphi \in P} v_\mathcal{O}(\varphi(q(a_\sigma))) = 2 e_\mathcal{O} \sum_{\varphi \in P} v_\ell(\mathrm{tr}\, \rho_\varphi(\sigma) - t).$$

Put $X = \{\rho_\varphi : \varphi \in P\}$. Its members are admissible of stable type for (ι, e, N) (Step 2). If $\varphi, \varphi' \in P$ and $\rho_\varphi \cong \rho_{\varphi'}$, then Lemma 46.17 gives $r_{\varphi'} = \mathrm{T}(t_1) \cdot r_\varphi$ for some t_1, so $\varphi \sim \varphi'$ and $\varphi = \varphi'$. Hence the members of X are pairwise non-isomorphic, $\varphi \mapsto \rho_\varphi$ is a bijection $P \to X$, and with Step 6

$$\nu_\mathcal{O}(\chi, e) = \frac{\mathrm{length}_\mathcal{O} \mathrm{Sha}^1_{\ell N}(\chi, e)}{e_\mathcal{O}} \le \frac{\mathrm{ct}_{-1}(u_{-1})}{e_\mathcal{O}} \le 2 \sum_{\rho \in X} v_\ell(\mathrm{tr}\, \rho(\sigma) - t).$$

□

Definition 46.3. Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with residue field $\mathbb{F}_\mathcal{O}$. In this definition and in the results citing it the datum and $\mathcal{O}$ are fixed and not written in the notation.

Weight pieces. For $j \in \mathbb{Z}$ let $\mathfrak{g}_j \subseteq \mathrm{M}_3(\mathbb{F}_\mathcal{O})$ be the subspace of matrices X with $X_{ab} = 0$ whenever $\mathrm{wt}(a, b) \ne j$. The group $G_\mathbb{Q}$ acts on $\mathrm{M}_3(\mathbb{F}_\mathcal{O})$ through $\bar{r}_0$: if $\bar{r}_0(g) = (P, \varsigma)$, then g acts by $X \mapsto PXP^{-1}$ if $\varsigma = 1$ and by $X \mapsto -PJ\,{}^t X\, JP^{-1}$ if $\varsigma = -1$. This action preserves each $\mathfrak{g}_j$, and $\mathfrak{g}_j$ with it is the **weight** j **piece** of the residual adjoint representation. Let S be the set of places of $\mathbb{Q}$ consisting of ∞ and the primes dividing ℓN, and $G_S = G_{\mathbb{Q},S}$; the action on $\mathfrak{g}_j$ factors through G_S. For the primes $p \in S$ the decomposition groups are the $D_p = D_{\bar{p}}$ at the fixed places.

Local conditions. For a prime $p \in S$ and $j \in \mathbb{Z}$ the **local condition** $L_{p,j} \subseteq Z^1(D_p, \mathfrak{g}_j)$ is

- for $p \ne \ell$: the cocycles vanishing on $N_{\bar{p}}$;
- for $p = \ell$: $B^1(D_\ell, \mathfrak{g}_j)$ if $j < 0$; the cocycles vanishing on I_ℓ if $j = 0$; all of $Z^1(D_\ell, \mathfrak{g}_j)$ if $j > 0$.

Selmer and obstruction groups. $H^1_\mathcal{L}(\mathfrak{g}_j)$ and $H^2_\mathcal{L}(\mathfrak{g}_j)$ are the Selmer group and the obstruction group (Definition 43.1) of $M = \mathfrak{g}_j$, for $\mathbb{F} = \mathbb{F}_\mathcal{O}$, the set S, the decomposition groups D_p and the family of local conditions $(L_{p,j})_p$.

Proposition 46.4. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking. Then:*

(Dm1) *there is a dyadic Eisenstein deformation ring (R, r) for $g_\star$, and r has exactly one base point φ_{Eis};*

(Dm2) *there are a graded $\mathcal{O}$-algebra with a fixed point (A, φ_0), a system of equations u for it and an $\mathcal{O}$-algebra homomorphism $q\colon A \to R$ with $\ker q = I(u)$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$, such that (Dm3)–(Dm7) hold;*

(Dm3) *for all $g \in G_{\mathbb{Q}}$ and $1 \le a, b \le 3$, $\underline{r}(g)_{ab} \in q\big(A_{\mathrm{wt}(a,b)}\big)$;*

(Dm4) *for points φ, φ' of (R, r) and $t \in \overline{\mathbb{Q}}_\ell^\times$: $\varphi \circ q$ is negative-vanishing if and only if φ is upper; $\varphi \circ q$ is positive-vanishing if and only if φ is lower; and $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ if and only if $\varphi' \circ q = t \cdot (\varphi \circ q)$;*

(Dm5) *if the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module, then every point of A on u is a torus translate of $\varphi \circ q$ for some point φ of (R, r);*

(Dm6) *if R^0 is a finitely generated $\mathcal{O}$-module and every two-signed point of (R, r) is rigid, then (A, φ_0, u) satisfies (Gc1)–(Gc4);*

(Dm7) *for every $b \in \mathcal{O} \setminus \{0\}$, writing $\mathrm{Sha}[b]$ for the submodule of $\mathrm{Sha}^1_{\ell N}(\chi, e)$ killed by b, there is an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/b\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo b of an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_j) = 0$ for all $j \ne -1$.*

Proof. Step 1: the presentation. By Proposition 46.5 there are (R, r) with (Dq1), which is (Dm1), and $(A, \varphi_0, u, q, \mathrm{td})$ with (Dq2)–(Dq8); let ne be the counts of u.

Step 2: padding the equations. For $-2 \le j \le 2$ put $\mathrm{ne}'(j) = \mathrm{td}(j) - d(j)$, that is

$$\mathrm{ne}'(-1) = \mathrm{td}(-1) + 1, \quad \mathrm{ne}'(-2) = \mathrm{td}(-2), \quad \mathrm{ne}'(0) = \mathrm{td}(0),$$
$$\mathrm{ne}'(1) = \mathrm{td}(1) - 1, \quad \mathrm{ne}'(2) = \mathrm{td}(2) - 1.$$

By (Dq6) and Lemma 46.16, $\mathrm{ne}(j) \le \mathrm{td}(j) + \dim H^2_{\mathcal{L}}(\mathfrak{g}_j) - \dim H^1_{\mathcal{L}}(\mathfrak{g}_j) = \mathrm{ne}'(j)$; in particular $\mathrm{ne}'(j) \ge 0$. Let u' be the family with $u'_{j,i} = u_{j,i}$ for $i \le \mathrm{ne}(j)$ and $u'_{j,i} = 0 \in A_j$ for $\mathrm{ne}(j) < i \le \mathrm{ne}'(j)$. It is a system of equations for (A, φ_0) with counts ne' ($\varphi_0(0) = 0$), and since only zeros were added, $I(u') = I(u)$, the points on u' are those on u, and $\mathrm{Cot}(u'_j) = \mathrm{Cot}(u_j)$ for every j.

Step 3: (Dm2)–(Dm5) and (Dm7) for (A, φ_0, u', q). $\ker q = I(u) = I(u')$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$ (Dq2); (Dm3) and (Dm4) are (Dq3) and (Dq4), which do not involve the equations; (Dm5) is (Dq5), since $A/I(u') = A/I(u)$ and the points on u' and on u coincide; (Dm7) is (Dq8), since $D(\mu)(0) = 0$ for the added equations of degree -1.

Step 4: (Dm6). Assume that R^0 is a finitely generated $\mathcal{O}$-module and that every two-signed point of (R, r) is rigid. (Gc1): by (Dq6), (A, φ_0) is smooth with tangent dimensions td, where $\mathrm{td}(j) = 0$ for $|j| > 2$ (Dq2); the counts of u' satisfy the five equalities of (Gc1) by the definition of ne′; and u'_{-1}, u'_{-2}, u'_0 span rationally in degrees -1, -2, 0 because u_{-1}, u_{-2}, u_0 do (Dq7) and $\mathrm{Cot}(u'_j) = \mathrm{Cot}(u_j)$. (Gc2)–(Gc4) hold for u by (Dq7), and they depend on u only through $I(u)$ and the points on u (the image of A_0 in $A/I(u)$; points on u; derivations vanishing on $I(u)$), so they hold for u'. Hence (A, φ_0, u') satisfies (Gc1)–(Gc4). □

Proposition 46.5. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking. Then:*

(Dq1) *there is a dyadic Eisenstein deformation ring (R, r) for $g_\star$, and r has exactly one base point φ_{Eis};*

(Dq2) *there are a graded $\mathcal{O}$-algebra with a fixed point (A, φ_0), a system of equations u for it with counts* ne*, an $\mathcal{O}$-algebra homomorphism $q\colon A \to R$ with $\ker q = I(u)$ and $\varphi_{\mathrm{Eis}} \circ q = \varphi_0$, and a function* $\mathrm{td}\colon \mathbb{Z} \to \mathbb{N}$ *with $\mathrm{td}(j) = 0$ for $|j| > 2$, such that (Dq3)–(Dq8) hold;*

(Dq3) *for all $g \in G_{\mathbb{Q}}$ and $1 \le a, b \le 3$, $\underline{r}(g)_{ab} \in q(A_{\mathrm{wt}(a,b)})$;*

(Dq4) *for points φ, φ' of (R, r) and $t \in \overline{\mathbb{Q}}_\ell^\times$: $\varphi \circ q$ is negative-vanishing if and only if φ is upper; $\varphi \circ q$ is positive-vanishing if and only if φ is lower; and $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$ if and only if $\varphi' \circ q = t \cdot (\varphi \circ q)$;*

(Dq5) *if the image of A_0 in $A/I(u)$ is a finitely generated $\mathcal{O}$-module, then every point of A on u is a torus translate of $\varphi \circ q$ for some point φ of (R, r);*

(Dq6) *(A, φ_0) is smooth with tangent dimensions* td*, and for $-2 \le j \le 2$*

$$\mathrm{ne}(j) + \dim H^1_{\mathcal{L}}(\mathfrak{g}_j) \le \mathrm{td}(j) + \dim H^2_{\mathcal{L}}(\mathfrak{g}_j);$$

(Dq7) *if R^0 is a finitely generated $\mathcal{O}$-module and every two-signed point of (R, r) is rigid, then u_{-1}, u_{-2}, u_0 span rationally in degrees -1, -2, 0 respectively, and (A, φ_0, u) satisfies (Gc2)–(Gc4);*

(Dq8) *for every $b \in \mathcal{O} \setminus \{0\}$, writing* $\mathrm{Sha}[b]$ *for the submodule of* $\mathrm{Sha}^1_{\ell^N}(\chi, e)$ *killed by b, there is an injective additive map $D\colon \mathrm{Sha}[b] \to \mathrm{Hom}_{\mathcal{O}}(A, \mathcal{O}/b\mathcal{O})$ such that $D(\mu)(u_{-1,i}) = 0$ for all μ and i, and every $D(\mu)$ is the reduction modulo b of an $\mathcal{O}$-linear map $D'\colon A \to \mathcal{O}$ with $D'(fg) = \varphi_0(f)D'(g) + \varphi_0(g)D'(f)$ for all $f, g \in A$ and $D'(A_j) = 0$ for all $j \ne -1$.*

Proof. By Proposition 46.6 there are (R, r) with exactly one base point φ_{Eis}, which is (Dq1), a weighted presentation $(\sigma, \mathrm{wt}, \pi)$ of R with $\varphi_{\mathrm{Eis}}(\pi(X_s)) = 0$ for all s, and a homogeneous generating system u of $\ker \pi$ with counts ne, satisfying (Dw1)–(Dw6) for the graded model (A, φ_0, q) with $\beta = \varphi_{\mathrm{Eis}}$. Put $\mathrm{td}(j) = \#\mathrm{wt}^{-1}(j)$.

(Dq2). $R \in \mathrm{CNL}_{\mathcal{O}}$ and $\beta = \varphi_{\mathrm{Eis}}\colon R \to \mathcal{O}$ is an $\mathcal{O}$-algebra homomorphism killing every $\pi(X_s)$, so Lemma 43.28 applies: (A, φ_0) is a graded $\mathcal{O}$-algebra with a fixed point (item 1), u is a system of equations for it with counts ne and $\ker q = I(u)$ (item 2), and $\mathrm{td}(j) = 0$ for $|j| > 2$ (item 3). By definition of the graded model, $\varphi_0 = \varphi_{\mathrm{Eis}} \circ q$, and q is an $\mathcal{O}$-algebra homomorphism $A \to R$.

(Dq3). By (Dw2), $\underline{r}(g)_{ab} = \pi(f)$ for some $f \in \mathcal{O}[[X_\sigma]]_{\mathrm{wt}(a,b)} = A_{\mathrm{wt}(a,b)}$, and $\pi(f) = q(f)$.

(Dq4), (Dq5), (Dq7), (Dq8) are (Dw3), (Dw4), (Dw5), (Dw6).

(Dq6). By Lemma 43.28, item 3, (A, φ_0) is smooth with tangent dimensions td. For $-2 \le j \le 2$, (Dw1) gives $\mathrm{ne}(j) \le \dim H^2_{\mathcal{L}}(\mathfrak{g}_j)$ and $\dim H^1_{\mathcal{L}}(\mathfrak{g}_j) \le \mathrm{td}(j)$; adding,

$$\mathrm{ne}(j) + \dim H^1_{\mathcal{L}}(\mathfrak{g}_j) \le \mathrm{td}(j) + \dim H^2_{\mathcal{L}}(\mathfrak{g}_j).$$

□

Proposition 46.6. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking. Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $E_{\mathcal{O}} = \mathcal{O}[\ell^{-1}]$, $P = \mathcal{O}[[X_s : s \in \sigma]]$, $P_j = \mathcal{O}[[X_\sigma]]_j$, and for $f \in P$ let $a_s(f)$ be the coefficient of X_s in f; $t_\star = \Psi(g_\star)$, so that $t_\star^2 - 1 \in \mathcal{O}^\times$.

Construction. By (Dr1) let (R, r) be a dyadic Eisenstein deformation ring for $g_\star$ with its unique base point $\beta = \varphi_{\mathrm{Eis}}$. By (Dr3) and Lemma 43.8 there is a weighted presentation $(\sigma, \mathrm{wt}, \pi)$ of R with $\pi(X_s) = x_s = x_{g_s, a_s, b_s}$, $\mathrm{wt}(s) = \mathrm{wt}(a_s, b_s)$, satisfying (Tp1)–(Tp3); $\beta(x_s) = 0$ as $\beta \circ r = r_0$. By (Oc2) let u be a homogeneous generating system of $\ker \pi$ with counts ne, $\mathrm{ne}(j) \le \dim H^2_{\mathcal{L}}(\mathfrak{g}_j)$. Let (A, φ_0, q) be the graded model; by Lemma 43.28, $\varphi_0(f)$ is the constant term of f, $\ker q = I(u)$, and A_0 is a complete local ring whose maximal ideal $\mathfrak{m}_{A_0}$ consists of the elements with constant term in $\mathfrak{m}_{\mathcal{O}}$.

(Dw1), (Dw2). (Dw1) is (Oc1) and (Oc2). By (Dr3), $\underline{r}(g)_{ab}$ has torus weight $\mathrm{wt}(a, b)$, so lies in $\pi(P_{\mathrm{wt}(a,b)})$ by (Tp3): this is (Dw2).

Three facts on A. (A1) By Dickson's lemma the set of minimal elements of $\{n \in \mathbb{N}^\sigma : \mathrm{wt}(n) = j\}$ is finite, and every $f \in A_j$ is $\sum_m X^m h_m$ over these minimal m, with $h_m \in A_0$ (assign each term X^n to a minimal $m \le n$; $n - m$ has weight 0). Likewise A_0 is the image of $\theta\colon \mathcal{O}[[Y_1, \dots, Y_k]] \to P$, $Y_i \mapsto X^{m_i}$, the m_i being the minimal non-zero elements of weight 0. (A2) Let $z \in \overline{\mathbb{Q}}_\ell^\sigma$ with $|z_s|_\ell < 1$ and let $\mathrm{ev}_z\colon P \to \overline{\mathbb{Q}}_\ell$ be evaluation (convergent: the z_s lie in a finite extension). If $\psi\colon A \to \overline{\mathbb{Q}}_\ell$ is an $\mathcal{O}$-algebra homomorphism with $\psi(X_s) = z_s$ and $|\psi(y)|_\ell \le 1$ for $y \in A_0$, then $\psi = \mathrm{ev}_z|_A$: for $g \in \mathcal{O}[[Y]]$ and $n \ge 1$, $g = g_{<n} + \sum_{|e|=n} Y^e g_e$ with $g_{<n}$ a polynomial, so $|\psi(\theta g) - \mathrm{ev}_z(\theta g_{<n})| \le \max_i |z^{m_i}|^n \to 0$, giving $\psi = \mathrm{ev}_z$ on A_0, and then on every A_j by (A1). (A3) A ψ-derivation D of A, for $\psi = \mathrm{ev}_z|_A$ as in (A2), is $D(f) = \sum_s (\partial_s f)(z)\, D(X_s)$. Indeed the right side $\tilde{D}$ is a ev_z-derivation of P. On A_0: let $\mathcal{O}_E$ be the integers of a finite extension containing the z_s, and extend $D, \tilde{D}$ $\mathcal{O}_E$-linearly to $\mathcal{O}_E \otimes_{\mathcal{O}} A_0$, the image of $\mathcal{O}_E[[Y]]$; for $g \in \mathcal{O}_E[[Y]]$ and $y^* = (z^{m_i})_i$, $g - g(y^*) = \sum_i (Y_i - y_i^*) g_i$ with $g_i \in \mathcal{O}_E[[Y]]$ (expand $g(Y' + y^*)$), so both derivations send $\theta(g)$ to $\sum_i \mathrm{ev}_z(\theta g_i)\, D(X^{m_i})$, and they agree on X^{m_i} by the Leibniz rule. Then they agree on every A_j by (A1).

(Dw3). Let φ be a point of (R, r). As $\mathfrak{m}_R$ is finitely generated and $|\varphi| < 1$ on it, φ is continuous and $\varphi \circ \pi = \mathrm{ev}_z$ with $z_s = \varphi(x_s)$. If $\varphi \circ q$ is negative-vanishing, φ kills the entries of negative weight, which lie in $\pi(P_j)$, $j < 0$, by (Dw2): φ is upper. If φ is upper, $z_s = 0$ whenever $\mathrm{wt}(s) < 0$ ($\underline{r_0}$ is diagonal), and every monomial of negative weight contains such a variable, so $\mathrm{ev}_z(P_j) = 0$ for $j < 0$. The same for positive weights. If $\varphi' \circ q = t \cdot (\varphi \circ q)$, then by (Dw2) $\varphi'(\underline{r}(g)_{ab}) = t^{\mathrm{wt}(a,b)} \varphi(\underline{r}(g)_{ab})$, i.e. $\underline{r_{\varphi'}}(g) = \mathrm{T}(t)\underline{r_\varphi}(g)\mathrm{T}(t)^{-1}$ for g of sign 1; both are $(1, -1)$

at c and $(\mathrm{T}(t),1)(1,-1)(\mathrm{T}(t),1)^{-1}=(1,-1)$, so $r_{\varphi'}=\mathrm{T}(t)\cdot r_\varphi$ on $G_K\sqcup G_Kc$. Conversely, if $r_{\varphi'}=\mathrm{T}(t)\cdot r_\varphi$ then $\varphi'(x_s)=t^{\mathrm{wt}(s)}\varphi(x_s)$, and evaluating a series of weight j at $(t^{\mathrm{wt}(s)}z_s)$ multiplies it by t^j.

(Dw4). Let ψ be a point of A on u and let $\bar{A}_0$, the image of A_0 in $A/I(u)$, be a finitely generated $\mathcal{O}$-module. $\bar{A}_0$ is a non-zero quotient of the local ring A_0, hence a finite local $\mathcal{O}$-algebra, and ψ factors through it; so $\psi(A_0)$ consists of elements integral over $\mathcal{O}$ ($|\psi|\le 1$ on A_0), and since $\mathfrak{m}_{\bar{A}_0}^n\subseteq\varpi\bar{A}_0$ for some n (ϖ a uniformiser), $|\psi(y)|<1$ for $y\in\mathfrak{m}_{A_0}$. Put $\alpha_s=|\psi(X_s)|$. If $\mathrm{wt}(s)=0$, $X_s\in\mathfrak{m}_{A_0}$ and $\alpha_s<1$. If $\mathrm{wt}(s)=w>0$ and $\mathrm{wt}(s')=-w'<0$, the monomial $X_s^{w'}X_{s'}^{w}$ lies in $\mathfrak{m}_{A_0}$, so $\alpha_s^{1/w}<\alpha_{s'}^{-1/w'}$. Hence there is $t\in\overline{\mathbb{Q}}_\ell^\times$ ($|\overline{\mathbb{Q}}_\ell^\times|$ is dense in $\mathbb{R}_{>0}$) with $\alpha_s^{1/\mathrm{wt}(s)}<|t|$ for $\mathrm{wt}(s)>0$ and $|t|<\alpha_s^{-1/|\mathrm{wt}(s)|}$ for $\mathrm{wt}(s)<0$. The point $\psi'=t^{-1}\cdot\psi$ lies on u ($I(u)$ is generated by homogeneous elements), agrees with ψ on A_0, and has $|\psi'(X_s)|<1$ for all s. By (A2), $\psi'=\mathrm{ev}_z|_A$ with $z_s=\psi'(X_s)$. Then ev_z kills the $u_{j,i}$, hence $\ker\pi$, so $\mathrm{ev}_z=\varphi\circ\pi$ for an $\mathcal{O}$-algebra homomorphism $\varphi\colon R\to\overline{\mathbb{Q}}_\ell$ with $|\varphi(\mathfrak{m}_R)|<1$ ($\mathfrak{m}_R=\pi(\mathfrak{m}_P)$), a point of (R,r); and $\psi=t\cdot(\varphi\circ q)$.

(Dw5). Assume R^0 is a finitely generated $\mathcal{O}$-module and every two-signed point of (R,r) is rigid.

(Gc2). For a monomial of weight 0, $\pi(X^n)=\prod_k(\underline{r}(g_k)_{a_kb_k}-\underline{r_0}(g_k)_{a_kb_k})$; expanding, each term is a constant times a product of entries whose weights add up to 0, because the constants are non-zero only on the diagonal; so π maps the weight-0 polynomials into R^0. R^0, a finitely generated $\mathcal{O}$-module, is compact, hence closed in R; as P_0 is the closure of its polynomials and π is continuous, $q(A_0)=\pi(P_0)\subseteq R^0$ is a finitely generated $\mathcal{O}$-module. Since $\ker q=I(u)$, it is the image of A_0 in $A/I(u)$. In particular (Dw4) applies to every point on u.

(Gc3). Let φ be a point of (R,r) that is upper and lower, so that $\underline{r_\varphi}|_{G_K}=\mathrm{diag}(\chi_1,\chi_2,\chi_3)$ with continuous characters χ_a of G_K, valued in the integers $\mathcal{O}_E$ of a finite extension ($\varphi(R)\subseteq\mathcal{O}_E$) and $\equiv\psi_a$ modulo $\mathfrak{m}_E$. At ℓ the image under φ of a matrix as in (Dd1) conjugates $\underline{r_\varphi}$ to upper triangular form on $D_\ell\cap G_K$ with diagonal ψ_a on I_ℓ; as $\underline{r_\varphi}(x)$, for $x\in D_\ell\cap G_K$ with $\bar{\Psi}(x)^2\ne1$ (Lemma 46.9), is already diagonal, its canonical diagonaliser is 1, and (Cd4) gives $\chi_a=\psi_a$ on I_ℓ; likewise on I_p for $p\in S_\ell(\chi)$. For $\bar{v}$ above $p\notin T_\ell(\chi)$, both χ_a and ψ_a are trivial on $N_{\bar{v}}$ ((Dd3); and $\Psi=1$ on $N_{\bar{v}}$: if $p\nmid\ell N$, Ψ is unramified at p; if $p\mid N$, then $p\ne\ell$ and $\chi_p''=\mathbf{1}$, so $\Psi(I_{\bar{v}})$ consists of roots of unity of order prime to ℓ, and such a root of unity with residue 1 is 1), so $\chi_a\psi_a^{-1}$ maps $I_{\bar{v}}$ through the finite group $I_{\bar{v}}/N_{\bar{v}}$ of order prime to ℓ into $1+\mathfrak{m}_E$, hence is trivial on $I_{\bar{v}}$; for $p\nmid\ell N$ both are unramified. Since $\underline{r_\varphi}(cgc)=\theta(\underline{r_\varphi}(g))$ gives $\chi_a(cgc)=\chi_{4-a}(g)^{-1}$, and the same for ψ_a, $\chi_a\psi_a^{-1}$ is trivial on the inertia groups at all places of K (every place of $\overline{\mathbb{Q}}$ is $g\bar{p}$ with $g\in G_K\sqcup G_Kc$). As $\mathbb{Q}(i)$ has class number one, class field theory makes every such character trivial: $\chi_a=\psi_a$. So $r_\varphi=r_0$ on G_K and at c, $\varphi(x_s)=0$ for all s, and $\varphi\circ\pi=\mathrm{ev}_0=\beta\circ\pi$: $\varphi=\beta$. Now let $\varphi_1\ne\varphi_0$ be a point on u, both negative- and positive-vanishing. By (Dw4), $\varphi_1=t\cdot(\varphi\circ q)$ for a point φ of (R,r), and $\varphi\circ q$ is negative- and positive-vanishing, so φ is upper and lower (Dw3), $\varphi=\beta$, and $\varphi_1=t\cdot\varphi_0=\varphi_0$ ($\varphi_0(A_j)=0$ for $j\ne0$): a contradiction. So (Gc3) holds vacuously.

(Gc4). Let ψ be a two-signed point on u and D a ψ-derivation vanishing on $I(u)$. By (Dw4), $\psi=t\cdot(\varphi\circ q)$; then $f\mapsto t^{-j}D(f)$ ($f\in A_j$) is a $(\varphi\circ q)$-derivation vanishing on $I(u)$, so we may assume $\psi=\varphi\circ q=\mathrm{ev}_z|_A$, $z_s=\varphi(x_s)$; φ is two-signed by (Dw3), hence rigid. By (A3), $D=\tilde{D}|_A$ with $\tilde{D}(f)=\sum_s(\partial_sf)(z)D(X_s)$; $\tilde{D}$ kills the $u_{j,i}$ and so $\ker\pi$ ($\mathrm{ev}_z(u_{j,i})=0$), hence $\tilde{D}=\delta\circ\pi$ for a continuous φ-derivation $\delta\colon R\to\overline{\mathbb{Q}}_\ell$. The $\mathcal{O}$-algebra homomorphism $\varphi+\epsilon\delta\colon R\to\overline{\mathbb{Q}}_\ell[\epsilon]$ carries r to r_y, $\underline{r_y}(g)=(1+\epsilon y(g))\underline{r_\varphi}(g)$, with y a continuous cocycle in $\mathrm{ad}\,r_\varphi$; y satisfies (Ty1) because $r=1$ on $N_{\bar{v}}$, and (Ty2), (Ty3) with the images of the matrices as in (Dd1), (Dd2). By rigidity $y(g)=g\cdot X-X$, so by (46.1) $\underline{r_y}=(1-\epsilon X)\underline{r_\varphi}(1+\epsilon X)$ on elements of sign 1. As $r_y(c)=(1,-1)$,

$c \cdot X = X$, i.e. $X_{ab} = -X_{4-b,4-a}$. For $Q = \underline{r_\varphi}(g_\star)$, $\underline{r_\varphi}(cg_\star^{-1}c) = JQ^{\mathrm{t}}J$, so $\Delta = Q - JQ^{\mathrm{t}}J$ has $\Delta_{ab} = Q_{ab} - Q_{4-b,4-a}$; (Ed1) gives $\Delta_{12} = \overline{\Delta_{21}} = 0$, hence $\Delta_{23} = \Delta_{32} = 0$, and $\Delta_{13} = \Delta_{31} = \Delta_{22} = 0$: $\Delta = \mathrm{diag}(\delta_\varphi, 0, -\delta_\varphi)$ with $\delta_\varphi \equiv t_\star - t_\star^{-1}$ a unit. The marking condition for r_y says that the entries $(1,2)$, $(2,1)$ of $[\Delta, X]$ vanish, i.e. $\delta_\varphi X_{12} = -\delta_\varphi X_{21} = 0$. With $X_{ab} = -X_{4-b,4-a}$ this leaves $X = x\,\mathrm{diag}(1,0,-1)$. Then $\delta(\underline{r}(g)_{ab}) = (\underline{r_\varphi}(g)X - X\underline{r_\varphi}(g))_{ab} = -x\,\mathrm{wt}(a,b)\,\varphi(\underline{r}(g)_{ab})$, so $D(X_s) = -x\,\mathrm{wt}(s)\,\varphi(x_s)$, and by (A3) $D = -x\,\overline{E_\varphi}$, where $\overline{E_\varphi}(f) = j\,\varphi(q(f))$ for $f \in A_j$ is a ψ-derivation. Any two such D are linearly dependent.

(Rational spanning in degrees $j \in \{-2,-1,0\}$.) For $f \in A_j \cap \mathfrak{m}_0$, $f - \sum_{\mathrm{wt}(s)=j} a_s(f)X_s$ has only monomials of degree ≥ 2, hence is $\sum_s X_s h_s$ with $h_s \in A_{j-\mathrm{wt}(s)}$ without constant term (assign each term to its first variable), and lies in $\mathfrak{m}_0^2 \subseteq \mathrm{Sq}(\varphi_0)$. So Cot_j is spanned by the images of the X_s with $\mathrm{wt}(s) = j$, and it suffices that the vectors $v_i = (a_s(u_{j,i}))_{\mathrm{wt}(s)=j}$ span $E_{\mathcal{O}}^{\mathrm{wt}^{-1}(j)}$: then for each such s some $c_s \neq 0$ has $c_s X_s - \sum_i b_i u_{j,i}$ with zero linear part, so $c_s\bar{X}_s \in \mathrm{Cot}(u)$. Suppose a linear form $\lambda = (\lambda_s)$ on $E_{\mathcal{O}}^{\mathrm{wt}^{-1}(j)}$, scaled into $\mathcal{O}$, kills all v_i. Then $\tilde{D}(f) = \sum_{\mathrm{wt}(s)=j} \lambda_s a_s(f)$ is a ev_0-derivation of P killing every $u_{j',i}$ (for $j' \neq j$, $u_{j',i} \in P_{j'}$ has no linear term in variables of weight j), hence $\ker\pi$; so $\tilde{D} = \delta \circ \pi$ with δ a β-derivation $R \to \mathcal{O}$. The morphism $\beta + \epsilon\delta\colon R \to \mathcal{O}[\epsilon]$ carries r to a lift r_δ satisfying (Ed1), (Dd1)–(Dd3), with $\underline{r_\delta}(g) = (1 + \epsilon y(g))\underline{r_0}(g)$, y a continuous cocycle $G_S \to \mathfrak{g}_j(\mathcal{O})$ (by (Dw2), $\delta(\underline{r}(g)_{ab}) = \tilde{D}(f)$ for some $f \in P_{\mathrm{wt}(a,b)}$, which is 0 unless $\mathrm{wt}(a,b) = j$). It satisfies (Vn1)–(Vn3): (Dd3) gives $y = 0$ on $N_{\bar{p}}$ for $p \notin T_\ell(\chi)$. If $h = h_0 + \epsilon h_1$ is a matrix as in (Dd1) for r_δ, then h_0 is one for r_0, so by (Cd3), the canonical diagonaliser of the diagonal matrix $\underline{r_0}(x)$ being 1, h_0 is upper triangular; then $h' = hh_0^{-1} = 1 + \epsilon Z$ is still a matrix as in (Dd1) (conjugation by the upper triangular h_0 preserves upper triangular matrices and their diagonals), and $h'^{-1}\underline{r_\delta}(g)h' = (1 + \epsilon(y(g) + g \cdot Z - Z))\underline{r_0}(g)$ on sign-1 elements; so, with Z_j the weight-j part of Z, $y(g) = g \cdot (-Z_j) - (-Z_j)$ on $D_\ell \cap G_K$ if $j < 0$, and y vanishes on I_ℓ if $j = 0$ ($I_\ell \subseteq G_K$ acts trivially on $\mathfrak{g}_0$). The same argument with (Dd2) at $p \in S_\ell(\chi)$ gives $y(g) = g \cdot (-Z_j) - (-Z_j)$ on $D_p \cap G_K \supseteq I_p \supseteq N_{\bar{p}}$ for $j \neq 0$, so $y = 0$ on $N_{\bar{p}}$, and $y = 0$ on I_p for $j = 0$. By Proposition 46.14, $a\,y = dX$ with $a \neq 0$, $X \in \mathfrak{g}_j(\mathcal{O})$. As $y(c) = 0$, $c \cdot X = X$. If $j = -2$, $X = 0$ (c acts by -1 on $\mathfrak{g}_{-2}$). If $j = 0$, X is fixed by c and by G_K, so $dX = 0$. If $j = -1$, $X = b(E_{21} - E_{32})$ and $dX(g_\star) = (t_\star^{-1} - 1)X$; since $\underline{r_\delta}(cg_\star^{-1}c) = J\,{}^t\underline{r_\delta}(g_\star)J$ and $\underline{r_\delta}(g_\star) = (1 + \epsilon Y)\mathrm{T}(t_\star)$ with $Y = y(g_\star)$, the ϵ-part of the marking difference is $Y\mathrm{T}(t_\star) - \mathrm{T}(t_\star)^{-1}J\,{}^tYJ$, whose entry $(2,1)$ is $t_\star Y_{21} - Y_{32}$; so the marking condition gives $t_\star y_{21}(g_\star) - y_{32}(g_\star) = 0$, and for $a\,y = dX$ it gives $(t_\star^{-1} - 1)(t_\star + 1)b = 0$, so $b = 0$. In all cases $a\,y = 0$, so $y = 0$, $\delta(x_s) = 0$ and $\lambda_s = \tilde{D}(X_s) = 0$. Hence the v_i span, and u_j spans rationally in degree j.

(Dw6). Let $b \in \mathcal{O} \setminus \{0\}$ and $\mu \in \mathrm{Sha}[b]$. Since $\bar{\Psi}(s) \neq 1$ for an element s of D_ℓ (Lemma 46.9), $H^0(\mathbb{Q}, \mathcal{O}^\vee(\Psi^{-1})) = 0$, and the sequence $0 \to \mathcal{O}/b \to \mathcal{O}^\vee \xrightarrow{b} \mathcal{O}^\vee \to 0$ (with $\mathcal{O}/b \cong b^{-1}\mathcal{O}/\mathcal{O}$) identifies $\mathrm{Sha}[b]$ with a subgroup of $H^1(\mathbb{Q}, (\mathcal{O}/b)(\Psi^{-1}))$. Let $\tilde{z}$ be a cocycle representing μ. For $\bar{v}$ above $p \notin S$, Ψ is unramified, $\tilde{z}|_{I_{\bar{v}}}$ is a homomorphism whose image in $\mathrm{Hom}(I_{\bar{v}}, \mathcal{O}^\vee)$ is 0, so $\tilde{z}$ vanishes on $I_{\bar{v}}$ and factors through G_S. For $p \mid \ell N$ the class is trivial in $H^1(\mathbb{Q}_p, \mathcal{O}^\vee(\Psi^{-1}))$, so $\tilde{z}(g) = g \cdot y_p - y_p$ on D_p with $y_p \in \mathcal{O}^\vee$; if $p \in T_\ell(\chi)$ then $H^0(D_p, \mathcal{O}^\vee(\Psi^{-1})) = 0$ (Lemma 46.9), and as by_p is D_p-invariant, $y_p \in \mathcal{O}/b$; if $p \notin T_\ell(\chi)$, $\Psi = 1$ on $N_{\bar{p}}$, so $\tilde{z} = 0$ on $N_{\bar{p}}$, and on $N_{g\bar{p}} = gN_{\bar{p}}g^{-1}$ by the cocycle relation. Since $\Psi(g_\star)^{-1} - 1$ is a unit, there is a unique $z_\mu = \tilde{z} + dm$ ($m \in \mathcal{O}/b$) with $z_\mu(g_\star) = 0$; then $z_\mu(c) = 0$ ($2z_\mu(c) = z_\mu(c^2) = 0$). The map $\mu \mapsto z_\mu$ is additive and injective. Let $X_0 = E_{21} - E_{32}$; $G_{\mathbb{Q}}$ acts on it by Ψ^{-1} ($c \cdot X_0 = X_0$). Over $A_b = \mathcal{O}[\epsilon]/(\epsilon^2, b\epsilon) \in \mathrm{CNL}_{\mathcal{O}}$, $r_\mu(g) = (1 + \epsilon z_\mu(g)X_0, 1)\,r_0(g)$ is a lift of $\bar{r}_0$: (Ed1) holds because $z_\mu(c) = z_\mu(g_\star) = 0$ gives $r_\mu(c) = r_0(c)$, $r_\mu(g_\star) = r_0(g_\star)$, hence $r_\mu(cg_\star^{-1}c) = r_0(cg_\star^{-1}c)$; (Dd3) holds as $r_0 = 1$ and $z_\mu = 0$ on the relevant $N_{\bar{v}}$; on D_p, $p \in T_\ell(\chi)$, $z_\mu X_0 = d(m_p X_0)$, so $r_\mu|_{D_p}$ is the conjugate of $r_0|_{D_p}$ by $1 - \epsilon m_p X_0 \equiv 1$ ((46.1)), which gives (Dd1), (Dd2). So $r_\mu = f_\mu \circ r$ with $f_\mu = \beta + \epsilon\delta_\mu$ (f_μ modulo ϵ classifies r_0), $\delta_\mu\colon R \to \mathcal{O}/b$ a β-derivation. Put $D(\mu) = \delta_\mu \circ q$. Since $\delta_\mu \circ \pi$ kills $\mathcal{O}$ and $(X_s)^2$,

$D(\mu)(f) = \sum_s a_s(f)\delta_\mu(x_s)$, with $\delta_\mu(x_s)$ the entry (a_s, b_s) of $z_\mu(g_s)X_0\underline{r_0}(g_s)$; so D is additive, $D(\mu)(u_{-1,i}) = \delta_\mu(\pi(u_{-1,i})) = 0$, and $\delta_\mu(x_s) = 0$ unless $\mathrm{wt}(s) = -1$, whence $D(\mu)(A_j) = 0$ for $j \neq -1$ ($f \in A_j$ has linear terms only in variables of weight j). With lifts $d_s \in \mathcal{O}$ of $\delta_\mu(x_s)$ for $\mathrm{wt}(s) = -1$, $D'(f) = \sum_{\mathrm{wt}(s)=-1} a_s(f)d_s$ is $\mathcal{O}$-linear, satisfies $D'(fg) = \varphi_0(f)D'(g)+\varphi_0(g)D'(f)$, vanishes on A_j for $j \neq -1$ and reduces to $D(\mu)$. If $D(\mu) = 0$ then $\delta_\mu(x_s) = D(\mu)(X_s) = 0$ for all s, so $\delta_\mu = 0$, $r_\mu = r_0$, $z_\mu = 0$ and $\mu = 0$: D is injective. □

Proposition 46.7. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $g_\star$ be a marking.*

(Dr1) *There is a dyadic Eisenstein deformation ring (R, r) for $g_\star$, and r has exactly one base point φ_{Eis}.*

(Dr2) *For $A \in \mathrm{CNL}_\mathcal{O}$, $t \in A^\times$ and a lift r' of $\bar{r}_0$ to A satisfying (Ed1) for $g_\star$ and (Dd1)–(Dd3), the torus conjugate $g \mapsto (\mathrm{T}(t), 1)\, r'(g)\, (\mathrm{T}(t), 1)^{-1}$ is a lift of $\bar{r}_0$ to A satisfying (Ed1) for $g_\star$ and (Dd1)–(Dd3).*

(Dr3) *For (R, r) as in (Dr1), the family $x_{g,a,b} = \underline{r}(g)_{ab} - \underline{r_0}(g)_{ab}$ ($g \in G_K$, $1 \le a, b \le 3$) with $w(g, a, b) = \mathrm{wt}(a, b)$ satisfies (Tc1) and (Tc2) of Lemma 43.8, where $\rho\colon R \to R[[T]]$ is the morphism with $\rho \circ r = (\mathrm{T}(1 + T), 1)\, r\, (\mathrm{T}(1 + T), 1)^{-1}$; and for every $g \in G_\mathbb{Q}$ and all a, b the entry $\underline{r}(g)_{ab}$ has torus weight $\mathrm{wt}(a, b)$.*

Proof. Write $\mathbb{F} = \mathbb{F}_\mathcal{O}$, $G_S = G_{\mathbb{Q},S}$ and $\Gamma \subseteq G_S$ for the image of G_K ($K = \mathbb{Q}(i)$ is unramified outside 2∞ and $2 \mid N$ by (Dy2), so K lies in the fixed field of $\ker(G_\mathbb{Q} \to G_S)$, and $\Gamma = G_{K,S_K}$ for S_K the places of K above S). Recall $\Psi(c) = 1$.

Step 1: every lift satisfying (Dd3) factors through G_S. Let $\bar{v}$ lie above a prime $p \notin S$. Then $p \nmid 2\ell N$, so η_K and $\bar{\Psi}$ are unramified at $\bar{v}$ and $N_{\bar{v}} = I_{\bar{v}}$; (Dd3) makes the lift trivial on every such $I_{\bar{v}}$, hence on the normal subgroup they generate, whose fixed field is the maximal extension unramified outside S.

Step 2: lifts normalised at c. Let $\bar{\rho}\colon \Gamma \to \mathrm{GL}_3(\mathbb{F})$, $g \mapsto \mathrm{T}(\bar{\Psi}(g))$, and let $(R^\square, \rho^\square)$ be its universal lift (Theorem B.71; Γ satisfies Φ_ℓ by item 2). As $G_S = \Gamma \sqcup \Gamma c$ and $c^2 = 1$, a lift r' of $\bar{r}_0$ through G_S with $\underline{r'}(c) = 1$ is the same as a continuous lift ρ' of $\bar{\rho}$ with $\rho'(cgc) = \theta(\rho'(g))$ for $g \in \Gamma$: given r' put $\rho' = \underline{r'}|_\Gamma$, and $(1, -1)(\rho'(g), 1)(1, -1) = (\theta(\rho'(g)), 1)$ gives the relation; given ρ', $r'(g) = (\rho'(g), 1)$, $r'(gc) = (\rho'(g), -1)$ ($g \in \Gamma$) is a homomorphism of $\Gamma \rtimes \langle c\rangle$. Hence such lifts are represented by $R_c = R^\square/\mathfrak{a}_c$, $\mathfrak{a}_c$ generated by the entries of $\rho^\square(cgc) - \theta(\rho^\square(g))$, $g \in \Gamma$; let r_c be the corresponding lift to R_c.

Step 3: the other conditions are cut out by ideals. For each condition below we give an ideal $\mathfrak{a} \subseteq R_c$ such that, for every morphism $f\colon R_c \to A$ in $\mathrm{CNL}_\mathcal{O}$, $f \circ r_c$ satisfies the condition if and only if $f(\mathfrak{a}) = 0$.

- The rest of (Ed1): the entries $(1, 2)$, $(2, 1)$ of $\underline{r_c}(g_\star) - \underline{r_c}(cg_\star^{-1}c)$.
- (Dd3): the entries of $\underline{r_c}(g) - 1$ for $g \in N_{\bar{v}}$, $\bar{v}$ above a prime of $S \setminus T_\ell(\chi)$ (by Step 1 nothing more is needed; $\eta_K = 1$ on $N_{\bar{v}}$, so the sign is 1 there).
- (Dd1): by Lemma 46.9 choose $x \in D_\ell \cap G_K$ with $\bar{\Psi}(x)^2 \neq 1$; then $M = \underline{r_c}(x)$ reduces to $\mathrm{T}(\bar{\Psi}(x))$, with pairwise distinct diagonal entries, so $h_c = h(M)$ exists (Cd1). Take the entries of negative weight of $h_c^{-1}\underline{r_c}(g)h_c$ for $g \in D_\ell \cap G_K$ and the elements $(h_c^{-1}\underline{r_c}(g)h_c)_{aa} - \psi_a(g)$ for $g \in I_\ell$. If f kills them, $f(h_c)$ is a matrix as in (Dd1) for $f \circ r_c$. Conversely, if some $k \equiv 1$ is a matrix as in (Dd1), then by (Cd4) so is $h(f(M))$, with the same diagonal entries, and $h(f(M)) = f(h_c)$ by (Cd2); so f kills the generators.

- (Dd2), for each $p \in S_\ell(\chi)$: in the same way, with $x \in D_p \cap G_K$ from Lemma 46.9, all off-diagonal entries of $h_c^{-1}\underline{r_c}(g)h_c$ for $g \in D_p \cap G_K$ and the diagonal ones minus $\psi_a(g)$ for $g \in I_p$.

Let R be the quotient of R_c by the sum of these ideals and r the image of r_c. It is non-zero: $\bar{r}_0$ itself, as a lift to $\mathbb{F}$, satisfies all conditions (Step 4 below, reduced modulo $\mathfrak{m}_\mathcal{O}$), so $R_c \to \mathbb{F}$ factors through R. Hence $R \in \mathrm{CNL}_\mathcal{O}$, r satisfies (Ed1) and (Dd1)–(Dd3) (with the matrices above), and a lift r' to A satisfying them factors through G_S (Step 1), has $\underline{r'}(c) = 1$, so $r' = f \circ r_c$ for exactly one $f\colon R_c \to A$ (Step 2), and f kills the ideals (Step 3), i.e. factors uniquely through R. So (R, r) is a dyadic Eisenstein deformation ring for $g_\star$.

Step 4: the base point. r_0 is a lift to $\mathcal{O}$ satisfying the conditions: $\underline{r_0}(c) = \mathrm{T}(\Psi(c)) = 1$; $\underline{r_0}(cg_\star^{-1}c) = \theta(\mathrm{T}(\Psi(g_\star))^{-1}) = \mathrm{T}(\Psi(g_\star))^{-1}$ is diagonal, as is $\underline{r_0}(g_\star)$; on G_K, $\underline{r_0} = \mathrm{diag}(\psi_1, \psi_2, \psi_3)$, so $h = 1$ is a matrix as in (Dd1), (Dd2); and for $g \in N_{\bar{v}}$ with $\bar{v}$ above $p \notin T_\ell(\chi)$, $\Psi(g) = 1$: if $p \nmid \ell N$, Ψ is unramified at p; if $p \mid N$, then $p \neq \ell$ and $\chi_p'' = \mathbf{1}$, so $\Psi|_{I_{\bar{v}}}$ takes values in roots of unity of order prime to ℓ, and such a root of unity with residue 1 equals 1. Hence $r_0(g) = (\mathrm{T}(1), 1) = 1$. By universality there is exactly one morphism $\varphi_{\mathrm{Eis}}\colon R \to \mathcal{O}$ with $\varphi_{\mathrm{Eis}} \circ r = r_0$. Every base point is such a morphism: an $\mathcal{O}$-algebra homomorphism $\beta\colon R \to \mathcal{O}$ is local, since for $y \in \mathfrak{m}_R$ and $u \in \mathcal{O}^\times$, $y - u$ is a unit of R and cannot lie in $\ker\beta$. This is (Dr1).

Step 5: (Dr2). Let $D = (\mathrm{T}(t), 1)$ and $r'' = Dr'D^{-1}$. It reduces to $\bar{r}_0$, because $\mathrm{T}(\bar{t})$ commutes with $\mathrm{T}(\bar{\Psi}(g))$ and $\theta(\mathrm{T}(s)) = \mathrm{T}(s)$. It is continuous. $\underline{r''}(c) = \mathrm{T}(t)\,\theta(\mathrm{T}(t)^{-1}) = 1$. On elements of sign 1, $\underline{r''} = \mathrm{T}(t)\,\underline{r'}\,\mathrm{T}(t)^{-1}$, which multiplies the entry (a, b) by $t^{\mathrm{wt}(a,b)}$; so the entries $(1, 2)$, $(2, 1)$ of $\underline{r''}(g_\star) - \underline{r''}(cg_\star^{-1}c)$ vanish. If h is a matrix as in (Dd1) or (Dd2) for r', then $\mathrm{T}(t)h\mathrm{T}(t)^{-1} \equiv 1$ is one for r'', since conjugation by $\mathrm{T}(t)$ preserves triangular and diagonal matrices and their diagonals. (Dd3) is preserved by conjugation.

Step 6: (Dr3). Each $x_{g,a,b}$ lies in $\mathfrak{m}_R$, as r and r_0 have the same reduction. (Tc1): if $f(x_{g,a,b}) = f'(x_{g,a,b})$ for all $g \in G_K$ and a, b, then $f \circ r$ and $f' \circ r$ agree on G_K, and at c both are $(1, -1)$ by (Ed1); as $G_\mathbb{Q} = G_K \sqcup G_K c$, $f \circ r = f' \circ r$, so $f = f'$ by universality. (Tc2): $R[[T]] \in \mathrm{CNL}_\mathcal{O}$; by (Dr2) for $A = R[[T]]$, $t = 1 + T$ and the push-forward of r along $R \subseteq R[[T]]$, there is a morphism ρ with $\rho \circ r = (\mathrm{T}(1 + T), 1)\, r\, (\mathrm{T}(1 + T), 1)^{-1}$. For g of sign 1, $\rho(\underline{r}(g)_{ab}) = (1 + T)^{\mathrm{wt}(a,b)}\underline{r}(g)_{ab}$; for g of sign -1, $r(g) = r(gc)\, r(c)$ with $\underline{r}(c) = 1$ gives $\underline{r}(g) = \underline{r}(gc)$, so the same holds. As $\underline{r_0}(g)_{ab} \in \mathcal{O}$ vanishes for $a \neq b$ and $\mathrm{wt}(a, a) = 0$, $\rho(x_{g,a,b}) = (1 + T)^{\mathrm{wt}(a,b)}x_{g,a,b}$. □

Lemma 46.8. *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}_B$, and call $M \in \mathrm{GL}_3(B)$* residually regular diagonal *if its off-diagonal entries lie in $\mathfrak{m}_B$ and its diagonal entries have pairwise distinct images in $B/\mathfrak{m}_B$.*

(Cd1) *For such M there is exactly one $h = h(M) \in \mathrm{GL}_3(B)$ with $h \equiv 1 \pmod{\mathfrak{m}_B}$, $h_{aa} = 1$ for $a = 1, 2, 3$, and $h^{-1}Mh$ diagonal (the* canonical diagonaliser*).*

(Cd2) *For every local homomorphism $f\colon B \to B'$ of complete Noetherian local rings, $f(M)$ is residually regular diagonal and $h(f(M)) = f(h(M))$; for every invertible diagonal $D \in \mathrm{GL}_3(B)$, $h(DMD^{-1}) = D\,h(M)\,D^{-1}$.*

(Cd3) *If $k \in \mathrm{GL}_3(B)$, $k \equiv 1 \pmod{\mathfrak{m}_B}$, and $k^{-1}Mk$ is upper triangular (resp. diagonal), then $k = h(M)\,b$ with b upper triangular (resp. diagonal) and $b \equiv 1 \pmod{\mathfrak{m}_B}$.*

(Cd4) *Let H be a group, $\rho\colon H \to \mathrm{GL}_3(B)$ a homomorphism and $x \in H$ with $\rho(x)$ residually regular diagonal. If some $k \equiv 1 \pmod{\mathfrak{m}_B}$ makes $k^{-1}\rho(g)k$ upper triangular (resp. diagonal) for all $g \in H$, then so does $h(\rho(x))$, and $h(\rho(x))^{-1}\rho(g)h(\rho(x))$ and $k^{-1}\rho(g)k$ have the same diagonal entries for every $g \in H$.*

(Cd5) *Let $B = \bigoplus_{i\in\mathbb{Z}} B_i$ be a finite local ring which is $\mathbb{Z}$-graded with only finitely many non-zero B_i, and let M be residually regular diagonal and* graded, *i.e. $M_{ab} \in B_{\mathrm{wt}(a,b)}$ for all a, b. Then $h(M)$ is graded.*

Proof. Write $\bar{y}$ for residues modulo $\mathfrak{m}_B$ and $d_a = M_{aa}$.

(Cd1), existence. The characteristic polynomial of M reduces to $\prod_a (X - \bar{d}_a)$, whose roots are simple; by Hensel's lemma in the complete local ring B it factors as $\prod_a (X - \lambda_a)$ with $\lambda_a \in B$, $\bar{\lambda}_a = \bar{d}_a$. Fix a and let w be the a-th column of the adjugate of $M - \lambda_a$. Since $(M - \lambda_a)\operatorname{adj}(M - \lambda_a) = \det(M - \lambda_a) \cdot 1 = 0$, we have $(M - \lambda_a)w = 0$. Modulo $\mathfrak{m}_B$, $M - \lambda_a$ is $\operatorname{diag}(\bar{d}_b - \bar{d}_a)_b$, whose adjugate is $\prod_{b\neq a}(\bar{d}_b - \bar{d}_a)E_{aa}$; so w_a is a unit and $w_b \in \mathfrak{m}_B$ for $b \neq a$. Put $v_a = w_a^{-1} w$ and let h have columns v_1, v_2, v_3. Then $h \equiv 1$, $h_{aa} = 1$, h is invertible, and $Mh = h \operatorname{diag}(\lambda_1, \lambda_2, \lambda_3)$.

(Cd1), uniqueness. Let h, h' both have the properties, $h^{-1}Mh = D$, $h'^{-1}Mh' = D'$ diagonal, and $g = h^{-1}h' \equiv 1$. Then $Dg = gD'$, i.e. $(D_{aa} - D'_{bb})g_{ab} = 0$; since $\bar{D}_{aa} = \bar{d}_a$ and $\bar{D}'_{bb} = \bar{d}_b$, $D_{aa} - D'_{bb}$ is a unit for $a \neq b$, so g is diagonal; and $1 = h'_{aa} = h_{aa} g_{aa} = g_{aa}$. So $h' = h$.

(Cd2). Since f is local, $f(M)$ is residually regular diagonal. The matrix $f(h(M))$ is $\equiv 1$ modulo $\mathfrak{m}_{B'}$, has diagonal entries 1, and $f(h(M))^{-1} f(M) f(h(M)) = f(h(M)^{-1} M h(M))$ is diagonal; by uniqueness it is $h(f(M))$. Likewise DMD^{-1} is residually regular diagonal, and $Dh(M)D^{-1}$ has entries $D_{aa} h(M)_{ab} D_{bb}^{-1}$, so it is $\equiv 1$ with diagonal entries 1, and conjugates DMD^{-1} to $D\,(h(M)^{-1} M h(M))\,D^{-1}$, which is diagonal; by uniqueness it is $h(DMD^{-1})$.

(Cd3). Let $U = k^{-1}Mk$, upper triangular, $U \equiv \bar{M}$. There is an upper unitriangular $n \equiv 1$ with $n^{-1}Un = \operatorname{diag}(U_{11}, U_{22}, U_{33})$: the equations $(Un)_{ab} = n_{ab} U_{bb}$ for $a < b$ read

$$n_{ab}(U_{bb} - U_{aa}) = \sum_{a<c\leq b} U_{ac} n_{cb} \qquad (n_{bb} = 1),$$

and are solved recursively in $b - a$, since $U_{bb} - U_{aa}$ is a unit; as $U_{ac} \in \mathfrak{m}_B$ for $a < c$, all $n_{ab} \in \mathfrak{m}_B$. If U is diagonal, $n = 1$. Let $\delta = \operatorname{diag}((kn)_{11}, (kn)_{22}, (kn)_{33})$, a diagonal matrix $\equiv 1$. Then $h' = kn\delta^{-1}$ is $\equiv 1$, has diagonal entries 1, and $h'^{-1}Mh' = \delta(n^{-1}Un)\delta^{-1}$ is diagonal; so $h' = h(M)$ by (Cd1), and $k = h(M)\,b$ with $b = \delta n^{-1}$ upper triangular (diagonal if U is), $b \equiv 1$.

(Cd4). Apply (Cd3) to $M = \rho(x)$: $k = h\,b$ with $h = h(\rho(x))$ and b upper triangular (resp. diagonal). Then $h^{-1}\rho(g)h = b\,(k^{-1}\rho(g)k)\,b^{-1}$ is upper triangular (resp. diagonal) for all g, and the diagonal of a product of upper triangular matrices is the product of their diagonals, which commute; so the diagonal entries of $b\,(k^{-1}\rho(g)k)\,b^{-1}$ are those of $k^{-1}\rho(g)k$.

(Cd5). Since B is finite and local, $B[[u]]$ is a complete Noetherian local ring. The map $\gamma\colon B \to B[[u]]$, $\gamma(y) = \sum_i (1+u)^i y_i$ for $y = \sum_i y_i$ with $y_i \in B_i$, is a ring homomorphism because $B_i B_k \subseteq B_{i+k}$; it is local, since $\gamma(y) \equiv y \pmod{u}$. For a graded matrix M, $\gamma(M)_{ab} = (1+u)^{\mathrm{wt}(a,b)} M_{ab}$, i.e. $\gamma(M) = \mathrm{T}(1+u)\,M\,\mathrm{T}(1+u)^{-1}$. By (Cd2), applied to γ, to the inclusion $B \to B[[u]]$, and to $D = \mathrm{T}(1+u)$ over $B[[u]]$,

$$\gamma(h(M)) = h(\gamma(M)) = h\big(\mathrm{T}(1+u)\,M\,\mathrm{T}(1+u)^{-1}\big) = \mathrm{T}(1+u)\,h(M)\,\mathrm{T}(1+u)^{-1}.$$

Hence, for $y = h(M)_{ab}$, we have $\sum_i (1+u)^i y_i = (1+u)^{\mathrm{wt}(a,b)} \sum_i y_i$. The powers $(1+u)^i$, $|i| \leq K$, are linearly independent over B: if $\sum_{|i|\leq K} (1+u)^i c_i = 0$, multiplying by $(1+u)^K$ gives a polynomial identity in $B[u]$ whose coefficient of u^{2K} is c_K, and descending induction gives $c_i = 0$ for all i. Comparing coefficients gives $y_i = 0$ for $i \neq \mathrm{wt}(a,b)$, so $h(M)$ is graded. □

Lemma 46.9. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. For every $p \in T_\ell(\chi)$ there is $s \in D_p \cap G_K$ with $\bar{\Psi}(s)^2 \neq 1$ that fixes the ℓ-th roots of unity.*

Proof. Fix $p \in T_\ell(\chi)$, write $N = p^a N'$ with $p \nmid N'$, and let $\mathbb{F}_{\mathcal{O}}$ be the residue field of $\mathcal{O}$.

Step 1: p is odd, and $p = \ell$ or $\ell \mid p-1$. If $p = \ell$, p is odd by (Dy1). Otherwise $p \in S_\ell(\chi)$: $p \neq \ell$, $p \mid N$ and $\chi_p'' \neq \mathbf{1}$. Since $(\chi_p'')^n = ((\chi'')^n)_p$, the order of χ_p'' divides the order of χ'', a power of ℓ; it is > 1 and divides $\#(\mathbb{Z}/p^a\mathbb{Z})^\times = p^{a-1}(p-1)$; as $p \neq \ell$, $\ell \mid p-1$, so $p > \ell \geq 3$ and p is odd. In particular $2 \mid N'$, because N is even (Dy2).

Step 2: an element $\sigma \in D_p$ acting as $\zeta \mapsto \zeta^p$ on the N'-th roots of unity and trivially on the ℓ-th roots of unity. If $p \neq \ell$, let $\sigma \in D_p$ be an arithmetic Frobenius at $\bar{p}$. For $\zeta^{N'\ell} = 1$, $\sigma(\zeta) \equiv \zeta^p$ modulo the maximal ideal of $\bar{p}$, and reduction modulo $\bar{p}$ is injective on the roots of unity of order prime to p; so $\sigma(\zeta) = \zeta^p$, and $\zeta^p = \zeta$ if $\zeta^\ell = 1$ since $\ell \mid p-1$. If $p = \ell$, identify D_ℓ with $\mathrm{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)$ through the place $\bar{\ell}$. The extension $\mathbb{Q}_\ell(\mu_{N'})/\mathbb{Q}_\ell$ is unramified and $\mathbb{Q}_\ell(\mu_\ell)/\mathbb{Q}_\ell$ is totally ramified, so they are linearly disjoint over $\mathbb{Q}_\ell$ and there is $\sigma \in D_\ell$ inducing the Frobenius automorphism on $\mathbb{Q}_\ell(\mu_{N'})$ (which acts on $\mu_{N'}$ by $\zeta \mapsto \zeta^\ell$) and the identity on $\mathbb{Q}_\ell(\mu_\ell)$.

Step 3: reduction to the 2-component. Put $s = \sigma^2 \in D_p$. Then $\eta_K(s) = \eta_K(\sigma)^2 = 1$, so $s \in D_p \cap G_K$; s fixes the ℓ-th roots of unity because σ does; and $\bar{\Psi}(s)^2 = \bar{\Psi}(\sigma)^4$. Since σ fixes the ℓ-th roots of unity, $\chi_{\mathrm{cyc}}(\sigma) \equiv 1 \pmod{\ell}$, so the residue of $\chi_{\mathrm{cyc}}(\sigma)$ is 1. Let $b \in (\mathbb{Z}/N\mathbb{Z})^\times$ be the class of σ, so $\chi(\sigma) = \chi(b)$ and $b \equiv p \pmod{N'}$ by Step 2. The values of χ'' are roots of unity of ℓ-power order, whose residues are 1 (in characteristic ℓ, $\bar{z}^{\ell^k} = 1$ forces $\bar{z} = 1$). Hence $\bar{\Psi}(s)^2$ is the residue of $\chi'(b)^4$. Now $\chi'(b) = \prod_r \chi_r'(b)$ over the primes $r \mid N$. The component χ_2'' has order dividing a power of ℓ and dividing $\#(\mathbb{Z}/2^{a_2}\mathbb{Z})^\times$, a power of 2 ($2^{a_2} \parallel N$), so $\chi_2'' = \mathbf{1}$ and $\chi_2' = \chi_2$; as $2^{a_2} \mid N'$ and $b \equiv p \pmod{N'}$, $\chi_2'(b) = \chi_2(p)$. For odd r, $\chi_r'(b)^{2o} = 1$ by (Dy4). So

$$\chi'(b)^4 = \chi_2(p)^4\,\omega^4, \qquad \omega = \prod_{r \mid N,\ r \text{ odd}} \chi_r'(b), \qquad \omega^{2o} = 1.$$

Step 4: $\chi_2(p)^{4o} \neq 1$. Let $c = c_2(\chi) \geq 4$ (Dy6) and let χ_2^* be the primitive character modulo 2^c inducing χ_2, so $\chi_2(p) = \chi_2^*(p)$. Classically $(\mathbb{Z}/2^c\mathbb{Z})^\times = \{\pm 1\} \times \langle 5 \rangle$, where $\langle 5 \rangle = \{u \equiv 1 \pmod 4\}$ is cyclic of order 2^{c-2} and $5^{2^{c-3}} \equiv 1 + 2^{c-1} \pmod{2^c}$. The kernel of reduction to $(\mathbb{Z}/2^{c-1}\mathbb{Z})^\times$ is $\{1, 1+2^{c-1}\}$, on which χ_2^* is non-trivial by primitivity; so $\chi_2^*(5)^{2^{c-3}} \neq 1$, $\chi_2^*(5)$ has order 2^{c-2}, and χ_2^* is injective on $\langle 5 \rangle$. Since p is odd, $p^{4o} \equiv 1 \pmod 4$, so if $\chi_2(p)^{4o} = 1$ then $p^{4o} \equiv 1 \pmod{2^c}$. But for odd x and even n, $v_2(x^n - 1) = v_2(x^2-1) + v_2(n) - 1$ (lifting the exponent), so

$$2^{v_2(p^{4o}-1)} = 2^{v_2(p^2-1)} \cdot 2^{v_2(o)+1} \leq 2o(p^2-1) < 2op^2 < 2^c/4$$

by (Dy5) ($8op^2 < 2^c$, $p \in T_\ell(\chi)$). So $2^c \nmid p^{4o} - 1$, and $\chi_2(p)^{4o} \neq 1$.

Step 5: conclusion. If $\chi'(b)^4 = 1$, then $\chi_2(p)^4 = \omega^{-4}$ and $\chi_2(p)^{4o} = (\omega^{2o})^{-2} = 1$, contradicting Step 4. So $\chi'(b)^4 \neq 1$. It is a root of unity of order n dividing the order of χ', which is prime to ℓ; the polynomial $X^n - 1$ is separable over $\mathbb{F}_{\mathcal{O}}$, so distinct n-th roots of unity in $\mathcal{O}$ have distinct residues, and the residue of $\chi'(b)^4$ is not 1. By Step 3, $\bar{\Psi}(s)^2 \neq 1$. □

Definition 46.10. Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and $p \in S$ a prime.

Local conditions. Let $A \in \mathrm{CNL}_{\mathcal{O}}$. A continuous homomorphism $\rho\colon D_p \to \mathcal{G}_3(A)$ reducing to $\bar{r}_0|_{D_p}$ **satisfies the dyadic local condition at** p if

(Lp1) for $p = \ell$: there is $h \in \mathrm{GL}_3(A)$, $h \equiv 1 \pmod{\mathfrak{m}_A}$, such that $h^{-1}\underline{\rho}(g)h$ is upper triangular for every $g \in D_\ell \cap G_K$, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_\ell$;

(Lp2) for $p \in S_\ell(\chi)$: there is $h \in \mathrm{GL}_3(A)$, $h \equiv 1 \pmod{\mathfrak{m}_A}$, such that $h^{-1}\underline{\rho}(g)h$ is diagonal for every $g \in D_p \cap G_K$, with diagonal entries $\psi_1(g), \psi_2(g), \psi_3(g)$ when moreover $g \in I_p$;

(Lp3) for $p \notin T_\ell(\chi)$: $\rho(g) = 1$ for every $g \in N_{\bar{p}}$.

Graded small extensions. A **graded finite $\mathcal{O}$-algebra** is an object B of $\mathrm{CNL}_\mathcal{O}$ which is a finite ring, together with a decomposition $B = \bigoplus_{i\in\mathbb{Z}} B_i$ into $\mathcal{O}$-submodules, only finitely many non-zero, with $B_iB_k \subseteq B_{i+k}$ and $\mathcal{O}\cdot 1 \subseteq B_0$. A matrix X over B is **graded** if $X_{ab} \in B_{\mathrm{wt}(a,b)}$ for all a, b; a homomorphism into $\mathcal{G}_3(B)$ is **graded** if the GL-parts of all its values are graded. For $j \in \mathbb{Z}$, a **graded small extension of weight** j is a surjective homomorphism $\mathrm{pr}\colon B \to \bar{B}$ of graded finite $\mathcal{O}$-algebras with $\mathrm{pr}(B_i) = \bar{B}_i$ for all i, whose kernel I satisfies $\mathfrak{m}_B I = 0$ and $I \subseteq B_j$.

Proposition 46.11. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking, (R, r) a dyadic Eisenstein deformation ring for $g_\star$, and $(\sigma, \mathrm{wt}, \pi)$ a weighted presentation of R given by Lemma 43.8 for the family $(x_{g,a,b})$ with the weights $\mathrm{wt}(a,b)$. Then:*

(Oc1) $\dim H^1_\mathcal{L}(\mathfrak{g}_j) \le \#\mathrm{wt}^{-1}(j)$ *for every $j \in \mathbb{Z}$;*

(Oc2) $\ker\pi$ *has a homogeneous generating system u with counts* ne *such that* $\mathrm{ne}(j) \le \dim H^2_\mathcal{L}(\mathfrak{g}_j)$ *for $-2 \le j \le 2$.*

Proof. Write $\mathbb{F} = \mathbb{F}_\mathcal{O}$, $P = \mathcal{O}[[X_s : s \in \sigma]]$, $\mathfrak{m} = \mathfrak{m}_P$, $\mathcal{J} = \ker\pi$, $P_j = \mathcal{O}[[X_\sigma]]_j$, $t^* = \mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_\mathcal{O}R)$, $t = \bar{\Psi}(g_\star)$ and $\delta = t - t^{-1}$; since $g_\star$ is a marking, $t^2 \ne 1$, so $t \pm 1$ and δ are non-zero. For $X \in \mathrm{M}_3$, $c\cdot X = -JX^{\mathrm{t}}J$, whose entry (a,b) is $-X_{4-b,4-a}$.

Step 0: normalisation of weight-j perturbations. Let $A \in \mathrm{CNL}_\mathcal{O}$, $I \subseteq A$ an ideal with $\mathfrak{m}_A I = 0$, and r_1 a lift of $\bar{r}_0$ to A such that $r_1 \bmod I$ satisfies (Ed1) for $g_\star$ and $\underline{r_1}(c)$, $\underline{r_1}(g_\star) - \underline{r_1}(cg_\star^{-1}c)$ differ from their values modulo I only in positions of weight j. Then there is $X \in \mathrm{M}_3(I)$ supported in weight j such that $(1+X,1)\,r_1\,(1+X,1)^{-1}$ satisfies (Ed1). Indeed, $\underline{r_1}(c) = 1+\gamma$ with $\gamma \in \mathrm{M}_3(I)$; $r_1(c)^2 = 1$ gives $(1+\gamma)\theta(1+\gamma) = 1+\gamma+c\cdot\gamma = 1$, so $c\cdot\gamma = -\gamma$, and by (46.1) conjugation by $1-\gamma/2$ makes $\underline{r_1}(c) = 1$. After that, conjugation by $1+X$ with $c\cdot X = X$ keeps $\underline{r_1}(c) = 1$ and replaces $\Delta = \underline{r_1}(g_\star) - \underline{r_1}(cg_\star^{-1}c)$ (two elements of sign 1) by $\Delta + [X, \bar{\Delta}]$, where $\bar{\Delta} = \mathrm{T}(t) - \mathrm{T}(t^{-1}) = \mathrm{diag}(\delta, 0, -\delta)$ is its residue. The entries $(1,2)$, $(2,1)$ of Δ lie in I and vanish unless $j = 1$, resp. $j = -1$. For $j = 1$ take $X = a(E_{12} - E_{23})$ (fixed by c): $[X, \bar{\Delta}]_{12} = -a\delta$, so a suitable $a \in I$ kills the entry $(1,2)$; for $j = -1$ take $X = a(E_{21} - E_{32})$, with $[X, \bar{\Delta}]_{21} = a\delta$.

Step 1: (Oc1). Fix j. Let $y \in Z^1(G_S, \mathfrak{g}_j)$ with $\mathrm{res}_p y \in L_{p,j}$ for every prime $p \in S$. Every $L_{p,j}$ contains $B^1(D_p, \mathfrak{g}_j)$ (for $p \ne \ell$ coboundaries vanish on $N_{\bar{p}}$, which acts trivially; at ℓ: $L_{\ell,j} = B^1$ for $j < 0$, $I_\ell \subseteq G_K$ acts trivially on $\mathfrak{g}_0$, $L_{\ell,j} = Z^1$ for $j > 0$). The lift $r_y(g) = (1 + \epsilon y(g), 1)\,\bar{r}_0(g)$ of $\bar{r}_0$ to $\mathbb{F}[\epsilon]$ is a homomorphism (cocycle relation) and satisfies the dyadic local condition at every $p \in S$ by (Ll2) (with $\rho = \bar{r}_0|_{D_p}$, which satisfies it with $h = 1$, and $\lambda = \epsilon y$); hence it satisfies (Dd1), (Dd2), and (Dd3): at the places above $p \in S \setminus T_\ell(\chi)$ by conjugation from $\bar{p}$ ($N_{g\bar{p}} = gN_{\bar{p}}g^{-1}$), at places above $p \notin S$ because y factors through G_S and $N_{\bar{v}} = I_{\bar{v}}$. Replacing y by $y + dX$ ($X \in \mathfrak{g}_j$) corresponds to conjugating r_y by $1 - \epsilon X$ ((46.1)); by Step 0 ($A = \mathbb{F}[\epsilon]$, $I = \epsilon\mathbb{F}$) every class in $H^1_\mathcal{L}(\mathfrak{g}_j)$ has a representative y with r_y satisfying (Ed1). This representative is unique: two of them differ by dX with $c\cdot X = X$ (from $y(c) = 0$), and $\mathfrak{g}_j^{c=1}$ is 0 for $j = \pm 2$, consists of $G_\mathbb{Q}$-invariants for $j = 0$ (G_K acts trivially on $\mathfrak{g}_0$), and for $j = \pm 1$ is the line of Step 0, on which the marking condition forces $a = 0$ ($\delta \ne 0$). So $y \mapsto r_y$ gives an injective map from $H^1_\mathcal{L}(\mathfrak{g}_j)$ to lifts satisfying (Ed1), (Dd1)–(Dd3), linear in y, and by universality to morphisms $f_y\colon R \to \mathbb{F}[\epsilon]$. Write $f_y(z) = \bar{z} + \epsilon\lambda_y(z)$; λ_y vanishes on $\mathfrak{m}_R^2 + \mathfrak{m}_\mathcal{O}R$ and on $\mathcal{O}$, and is a linear form on t^* depending linearly and injectively on the class of y (f_y determines r_y). Moreover $\lambda_y(x_{g,a,b})$ is the entry (a,b) of $y(g)\mathrm{T}(\bar{\Psi}(g))$, which vanishes unless $\mathrm{wt}(a,b) = j$. By

(Tp1), $(\bar{x}_s)_{s\in\sigma}$ is a basis of t^*, and the linear forms vanishing on the $\bar{x}_s$ with $\mathrm{wt}(s)\neq j$ form a space of dimension $\#\mathrm{wt}^{-1}(j)$. This proves (Oc1).

Step 2: a graded truncation. By the Artin–Rees lemma there is $N_0\geq 1$ with $\mathcal{J}\cap\mathfrak{m}^{N_0}\subseteq\mathfrak{m}\mathcal{J}$. The ideal $\mathfrak{m}^{N_0}$ is generated by the monomials $\varpi^a X^n$ with $a+|n|=N_0$ (ϖ a uniformiser, of weight 0), so it is homogeneous: the weight components of its elements lie in it (for $f=\sum_k g_k\mu_k$ with monomials μ_k, $f_{(i)}=\sum_k (g_k)_{(i-\mathrm{wt}(\mu_k))}\mu_k$); the same holds for $\mathcal{J}$ (Tp2) and hence for $\mathfrak{m}\mathcal{J}$. $P/\mathfrak{m}^{N_0}$ is finite, and graded by the images of the P_i: every element of P is congruent modulo $\mathfrak{m}^{N_0}$ to the sum of its finitely many components of weight $|i|\leq 2N_0$ (monomials of larger weight have degree $>N_0$), and the sum is direct by homogeneity of $\mathfrak{m}^{N_0}$. Quotients of $P/\mathfrak{m}^{N_0}$ by homogeneous ideals are graded finite $\mathcal{O}$-algebras.

Step 3: the space of minimal relations is graded. Let $V=\mathcal{J}/\mathfrak{m}\mathcal{J}$ and V_j the image of $\mathcal{J}\cap P_j$. For $f\in\mathcal{J}$, $f-\sum_{|i|\leq 2N_0} f_{(i)}\in\mathcal{J}\cap\mathfrak{m}^{N_0}\subseteq\mathfrak{m}\mathcal{J}$ with $f_{(i)}\in\mathcal{J}$ (Tp2), so the V_j span V; and if $\sum_i f_i\in\mathfrak{m}\mathcal{J}$ with $f_i\in\mathcal{J}\cap P_i$, each f_i is a weight component of an element of $\mathfrak{m}\mathcal{J}$, hence in $\mathfrak{m}\mathcal{J}$. So $V=\bigoplus_j V_j$. Choose $u_{j,1},\dots,u_{j,n_j}\in\mathcal{J}\cap P_j$ whose images form a basis of V_j; by Nakayama's lemma all the $u_{j,i}$ together generate $\mathcal{J}$. It remains to show $n_j=\dim V_j\leq\dim H^2_{\mathcal{L}}(\mathfrak{g}_j)$ for every j: then $V_j=0$ for $|j|>2$ ($\mathfrak{g}_j=0$), and $u=(u_{j,i})_{-2\leq j\leq 2}$ is the required system.

Step 4: the graded small extension of weight j. Fix j and let $\mathcal{W}\subseteq\mathcal{J}$ be the preimage of $\bigoplus_{i\neq j}V_i$; it is an ideal containing $\mathfrak{m}\mathcal{J}$, and homogeneous: for $f\in\mathcal{W}$ the components $f_{(i)}$ lie in $\mathcal{J}$, their images are the components of $\bar{f}$ in $V=\bigoplus V_i$ (Step 3), so $f_{(j)}\in\mathfrak{m}\mathcal{J}$. Put $B=P/(\mathcal{W}+\mathfrak{m}^{N_0})$ and $\bar{B}=P/(\mathcal{J}+\mathfrak{m}^{N_0})=R/\mathfrak{m}_R^{N_0}$. The projection $\mathrm{pr}\colon B\to\bar{B}$ is a graded small extension of weight j: its kernel I is the image of $\mathcal{J}=(\mathcal{J}\cap P_j)+\mathcal{W}$, so $I\subseteq B_j$; $\mathfrak{m}_B I=0$ as $\mathfrak{m}\mathcal{J}\subseteq\mathcal{W}$; and $I\cong\mathcal{J}/(\mathcal{W}+\mathcal{J}\cap\mathfrak{m}^{N_0})=\mathcal{J}/\mathcal{W}\cong V_j$. Let $\bar{r}$ be r reduced modulo $\mathfrak{m}_R^{N_0}$: it satisfies (Ed1), (Dd1)–(Dd3), and it is graded, since $\underline{r}(g)_{ab}$ has torus weight $\mathrm{wt}(a,b)$ ((Dr3)) and so lies in $\pi(P_{\mathrm{wt}(a,b)})$ (Tp3).

Step 5: the obstruction class. $\bar{r}$ factors through a finite quotient of G_S; choose a continuous graded set-theoretic lift $s\colon G_S\to\mathcal{G}_3(B)$ of $\bar{r}$ with $s(1)=1$ (F3). Then $s(g)s(g')s(gg')^{-1}=(1+k(g,g'),1)$ with $k(g,g')\in\mathrm{M}_3(I)$ graded, hence supported in weight j: k is a continuous 2-cocycle with values in $\mathfrak{g}_j\otimes_{\mathbb{F}} I$. For each prime $p\in S$, (Ll1) gives a continuous graded homomorphism $\rho_p\colon D_p\to\mathcal{G}_3(B)$ lifting $\bar{r}|_{D_p}$ and satisfying the dyadic local condition at p; write $s(g)=(1+y_p(g),1)\rho_p(g)$ for $g\in D_p$, with $y_p\in C^1(D_p,\mathfrak{g}_j\otimes I)$. Expanding $s(g)s(g')$ in two ways gives $dy_p=\mathrm{res}_p k$. Hence for every linear $\phi\colon I\to\mathbb{F}$, $(\phi\circ k,(\phi\circ y_p)_p)\in Z^2_{\mathcal{L}}(\mathfrak{g}_j)$, and its class $o(\phi)\in H^2_{\mathcal{L}}(\mathfrak{g}_j)$ depends linearly on ϕ.

Step 6: a vanishing class gives a lift. Suppose $\dim V_j>\dim H^2_{\mathcal{L}}(\mathfrak{g}_j)$. As $\dim I^\vee=\dim V_j$, some $\phi\neq 0$ has $o(\phi)=0$: $\phi\circ k=dw$ and $\phi\circ y_p=\mathrm{res}_p w+\lambda_p$ with $w\in C^1(G_S,\mathfrak{g}_j)$, $\lambda_p\in L_{p,j}$. Let $I'=\ker\phi$, an ideal of B as $\mathfrak{m}_B I=0$, homogeneous as $I'\subseteq B_j$, and $B'=B/I'$, so that $B'\to\bar{B}$ is a graded small extension of weight j with kernel $I/I'\cong\mathbb{F}$ via ϕ. Over B', $s'(g)=(1-w(g),1)\,s(g)$ satisfies $s'(g)s'(g')s'(gg')^{-1}=1+\phi k-dw=1$ (computation of (F2) in Lemma 46.12), so s' is a continuous graded homomorphism lifting $\bar{r}$. On D_p, $s'=(1+\phi y_p-w,1)\rho_p=(1+\lambda_p,1)\rho_p$, which satisfies the dyadic local condition at p by (Ll2). As in Step 1, s' then satisfies (Dd1)–(Dd3). By Step 0 ($A=B'$, $I=I/I'$; the relevant entries are graded and vanish modulo I/I', so they lie in $(I/I')\cap B'_{\mathrm{wt}}$, which is 0 outside weight j), a conjugate r' of s' by some $(1+X,1)$ with X supported in weight j satisfies (Ed1); conjugation by an element $\equiv 1$ keeps (Dd1)–(Dd3) and the reduction $\bar{r}$.

Step 7: contradiction with minimality. By universality $r'=f\circ r$ for a morphism $f\colon R\to B'$, and $R\to B'\to\bar{B}$ is the projection (both classify $\bar{r}$). Let $\alpha\colon P\to B'$ be the projection and $\beta=f\circ\pi$. Then $\alpha-\beta$ takes values in I/I', which $\mathfrak{m}_{B'}$ kills; so $(\alpha-\beta)(f_1f_2)=\bar{f}_1(\alpha-\beta)(f_2)+\bar{f}_2(\alpha-\beta)(f_1)$ with $\bar{f}_i$ the residues, i.e. $\alpha-\beta$ is a derivation over the residue map, vanishing on $\mathcal{O}$, on $\mathfrak{m}_{\mathcal{O}}P$ and on $(X_s)^2$. By (Tp2) every $f\in\mathcal{J}$ is $c_0+\sum_s a_s X_s+f_2$ with $c_0,a_s\in\mathfrak{m}_{\mathcal{O}}$ and

$f_2 \in (X_s)^2$, so $(\alpha-\beta)(f)=0$; and $\beta(\mathcal{J})=0$. Hence $\alpha(\mathcal{J})=0$, i.e. the image I/I' of $\mathcal{J}$ in B' is zero, contradicting $\phi\neq 0$. So $\dim V_j \le \dim H^2_{\mathcal{L}}(\mathfrak{g}_j)$. □

Lemma 46.12. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $p\in S$ a prime and $j\in\mathbb{Z}$.*

(Ll1) *Let* $\mathrm{pr}\colon B\to\bar B$ *be a graded small extension of weight j and $\bar\rho\colon D_p\to\mathcal{G}_3(\bar B)$ a continuous graded homomorphism reducing to $\bar r_0|_{D_p}$ and satisfying the dyadic local condition at p. Then there is a continuous graded homomorphism $\rho\colon D_p\to\mathcal{G}_3(B)$ with $\mathrm{pr}\circ\rho=\bar\rho$ satisfying the dyadic local condition at p.*

(Ll2) *Let $A\in\mathrm{CNL}_{\mathcal{O}}$, $I\subseteq A$ an ideal with $\mathfrak{m}_A I=0$, $\rho\colon D_p\to\mathcal{G}_3(A)$ a continuous homomorphism satisfying the dyadic local condition at p, and $\lambda\colon D_p\to \mathrm{M}_3(I)$ a continuous map whose values have non-zero entries only in positions of weight j, such that $\phi\circ\lambda\in L_{p,j}$ for every $\mathbb{F}_{\mathcal{O}}$-linear $\phi\colon I\to\mathbb{F}_{\mathcal{O}}$. Then $g\mapsto(1+\lambda(g),1)\,\rho(g)$ is a continuous homomorphism $D_p\to\mathcal{G}_3(A)$ satisfying the dyadic local condition at p.*

Proof. Write $\mathbb{F}=\mathbb{F}_{\mathcal{O}}$, $H=D_p\cap G_K$, and for g with $\eta_K(g)=-1$ let $\sigma_g=\theta$, otherwise $\sigma_g=\mathrm{id}$. For an ideal I with $\mathfrak{m}I=0$, $\mathrm{M}_3(I)=\mathrm{M}_3(\mathbb{F})\otimes_{\mathbb{F}} I$, $(1+X)(1+Y)=1+X+Y$ for $X,Y\in\mathrm{M}_3(I)$, and conjugation by an element of $\mathcal{G}_3(A)$ reducing to $\bar r_0(g)$ acts on $\{(1+X,1)\}$ through the action of g on $\mathrm{M}_3(\mathbb{F})$ of Definition 46.3. In particular, for $X\in\mathrm{M}_3(I)$ and $\rho(g)$ reducing to $\bar r_0(g)$,

$$(1+X,1)\,\rho(g)\,(1+X,1)^{-1}=(1+X-g\cdot X,1)\,\rho(g). \tag{46.1}$$

Three general facts are used. (F1) $D_p=I_p\rtimes Z$ for a closed subgroup Z mapping isomorphically onto $D_p/I_p\cong\hat{\mathbb{Z}}$ ($\hat{\mathbb{Z}}$ is free profinite on one generator, so the projection has a continuous section). (F2) If D is a profinite group, $\tilde Q\to\bar Q$ a surjective homomorphism of finite groups whose kernel V is abelian, written additively, and $\bar\rho\colon D\to\bar Q$ continuous, then V is a D-module by conjugation, and if $H^2(D,V)=0$ then $\bar\rho$ lifts to a continuous homomorphism $D\to\tilde Q$: take a set-theoretic lift s of $\bar\rho$ through a section of $\tilde Q\to\bar Q$ with $s(1)=1$, so that $c(g,g')=s(g)s(g')s(gg')^{-1}\in V$ is a continuous 2-cocycle; for a continuous 1-cochain w, $s_w(g)=w(g)s(g)$ satisfies $s_w(g)s_w(g')s_w(gg')^{-1}=c(g,g')+w(g)+g\cdot w(g')-w(gg')$, and w with $dw=-c$ makes s_w a homomorphism. (F3) For a graded finite $\mathcal{O}$-algebra B, the graded elements of $\mathcal{G}_3(B)$ form a subgroup $\mathcal{G}^{\mathrm{gr}}(B)$: products of graded matrices are graded as $\mathrm{wt}(a,c)+\mathrm{wt}(c,b)=\mathrm{wt}(a,b)$; the cofactor giving the entry (a,b) of the inverse has weight $\mathrm{wt}(a,b)$, and the determinant of a graded matrix has weight 0 and its inverse, a homogeneous unit's inverse, lies in B_0; and $\theta(g)_{ab}=(g^{-1})_{4-b,4-a}$ has weight $\mathrm{wt}(a,b)$. The same holds for the subgroups of graded upper triangular (resp. diagonal) GL-parts, which θ preserves (θ maps upper triangular matrices to upper triangular ones). For a graded small extension pr of weight j, pr maps $\mathcal{G}^{\mathrm{gr}}(B)$ onto $\mathcal{G}^{\mathrm{gr}}(\bar B)$ (lift entries homogeneously; a lift of an invertible matrix is invertible, B being local) with kernel $\{(1+X,1): X\in\mathrm{M}_3(I)\text{ supported in weight }j\}\cong\mathfrak{g}_j\otimes I$; and $\mathrm{pr}\colon B_i\to\bar B_i$ is bijective for $i\neq j$.

(Ll2). The map $\rho_\lambda(g)=(1+\lambda(g),1)\rho(g)$ is a homomorphism because λ is a cocycle for the action of g ($\phi\circ\lambda$ is one for every ϕ): $\rho_\lambda(g)\rho_\lambda(g')=(1+\lambda(g)+g\cdot\lambda(g'),1)\rho(gg')=\rho_\lambda(gg')$. Continuity is clear. The condition at p:

- $p\notin T_\ell(\chi)$: every $\phi\circ\lambda$ vanishes on $N_{\bar p}$, so $\lambda=0$ there and $\rho_\lambda=\rho=1$ on $N_{\bar p}$.
- $p=\ell$: let h be as in (Lp1) for ρ and $\beta=h^{-1}\underline{\rho}h$. As $h\equiv 1$ and $\mathfrak{m}I=0$, $h^{-1}(1+\lambda)\underline{\rho}\,h=(1+\lambda)\beta$. If $j>0$, the positions of weight j lie above the diagonal, so $(1+\lambda)\beta$ is upper triangular on H with the diagonal of β. If $j=0$, λ is diagonal and vanishes on I_ℓ (this is $L_{\ell,0}$), so $(1+\lambda)\beta$ is upper triangular on H with diagonal ψ_a on I_ℓ. If $j<0$, every $\phi\circ\lambda$ is

a coboundary; choosing a basis of I gives $X \in \mathrm{M}_3(I)$ with $\lambda(g) = g \cdot X - X$, and by (46.1) $\rho_\lambda = k\rho k^{-1}$ with $k = (1 - X, 1)$; then kh is a matrix as required in (Lp1).

- $p \in S_\ell(\chi)$: here p is odd (the 2-component of χ'' has both ℓ-power and 2-power order, so it is trivial), hence unramified in K and $I_p \subseteq H$. If $j \neq 0$, $H^1(D_p, \mathfrak{g}_j) = 0$ by Lemma 46.13, so as before ρ_λ is a conjugate of ρ by an element $\equiv 1$, and (Lp2) persists. If $j = 0$, λ is diagonal; on I_p, which acts trivially on $\mathfrak{g}_0$, each $\phi \circ \lambda$ is a homomorphism vanishing on $N_{\bar{p}}$, hence factors through $I_p/N_{\bar{p}}$, of order dividing $2(\#\mathbb{F} - 1)$, prime to ℓ, into a group of exponent ℓ; so $\lambda = 0$ on I_p, and with h as in (Lp2) for ρ, $h^{-1}\underline{\rho_\lambda}h = (1 + \lambda)\, h^{-1}\underline{\rho}h$ is diagonal on H with diagonal ψ_a on I_p.

(Ll1), $p \notin T_\ell(\chi)$. The group $N_{\bar{p}}$ is the kernel of $I_p \to \{\pm 1\} \times \mathbb{F}^\times$, $g \mapsto (\eta_K(g), \bar{\Psi}(g))$, the restriction of a homomorphism on D_p; so it is normal in D_p and $I_p/N_{\bar{p}}$ is finite of order prime to ℓ. As $\bar{\rho}$ is trivial on $N_{\bar{p}}$ it factors through $\Delta = D_p/N_{\bar{p}}$, and $N_{\bar{p}}$ acts trivially on $\mathfrak{g}_j$. By the Hochschild–Serre spectral sequence for the normal subgroup $I_p/N_{\bar{p}}$, whose cohomology in positive degrees with ℓ-torsion coefficients vanishes, $H^2(\Delta, \mathfrak{g}_j) = H^2(D_p/I_p, \mathfrak{g}_j^{I_p}) = 0$, since $\hat{\mathbb{Z}}$ has ℓ-cohomological dimension 1. By (F2) for $\mathcal{G}^{\mathrm{gr}}(B) \to \mathcal{G}^{\mathrm{gr}}(\bar{B})$ (F3) and the continuous map $\Delta \to \mathcal{G}^{\mathrm{gr}}(\bar{B})$ induced by $\bar{\rho}$, there is a graded lift ρ trivial on $N_{\bar{p}}$.

(Ll1), $p \in T_\ell(\chi)$: reduction to triangular form. By Lemma 46.9 there is $x \in H$ with $\bar{\Psi}(x)^2 \neq 1$; then $\bar{\Psi}(x), 1, \bar{\Psi}(x)^{-1}$ are pairwise distinct, and $\underline{\bar{\rho}}(x)$, which reduces to $\mathrm{T}(\bar{\Psi}(x))$, is residually regular diagonal. Let $\bar{h} = h(\underline{\bar{\rho}}(x))$: it is graded by (Cd5), and by (Cd4) $\bar{\beta} = \bar{h}^{-1}\bar{\rho}\bar{h}$ has GL-parts on H which are upper triangular, diagonal if $p \in S_\ell(\chi)$, with diagonal ψ_a on I_p. The same holds on all of D_p: for $g \in D_p \setminus H$ write $\bar{\beta}(g) = (P, -1)$; then $P\,\theta(U)\,P^{-1} = U'$ with $U = \underline{\bar{\beta}}(x)$, $U' = \underline{\bar{\beta}}(gxg^{-1})$, both upper triangular (diagonal), and $\theta(U)$ is upper triangular (diagonal) with residual diagonal $\mathrm{T}(\bar{\Psi}(x))$ ($\theta(\mathrm{T}(t)) = \mathrm{T}(t)$), as is U' ($\bar{\Psi}(gxg^{-1}) = \bar{\Psi}(x)$). For an upper triangular $V \in \mathrm{GL}_3(\bar{B})$ whose diagonal entries have pairwise distinct residues, the equations $(Vn)_{ab} = n_{ab}V_{bb}$ ($a < b$) for an upper unitriangular n read $n_{ab}(V_{bb} - V_{aa}) = \sum_{a<c\leq b} V_{ac}n_{cb}$ ($n_{bb} = 1$) and are solved recursively in $b - a$, $V_{bb} - V_{aa}$ being a unit; then $n^{-1}Vn = \mathrm{diag}(V_{11}, V_{22}, V_{33})$, and $n = 1$ if V is diagonal. Applied to $V = \theta(U)$ and $V = U'$ this gives upper unitriangular n, n' (equal to 1 in the diagonal case) with $n^{-1}\theta(U)n = \Lambda$, $n'^{-1}U'n' = \Lambda'$ diagonal. The matrix $Q = n'^{-1}Pn$ satisfies $Q\Lambda = \Lambda'Q$, i.e. $(\Lambda'_{aa} - \Lambda_{bb})Q_{ab} = 0$; as Λ, Λ' have the same pairwise distinct residual diagonal entries, $\Lambda'_{aa} - \Lambda_{bb}$ is a unit for $a \neq b$, so Q is diagonal; so $P = n'Qn^{-1}$ is upper triangular (diagonal). Write $\bar{\beta}(g) = (\bar{u}(g), 1)\,\bar{\tau}(g)$ with $\bar{u}(g)$ upper unitriangular and $\bar{\tau}(g)$ with diagonal GL-part; $\bar{\tau}$ is a continuous graded homomorphism (the torus quotient of the Borel is compatible with θ), with values in $\mathrm{diag}(\bar{B}_0^\times) \rtimes \{\pm 1\}$, and $\bar{\tau} = r_0$ on I_p ($I_p \subseteq H$ as p is odd).

The diagonal part. If $j \neq 0$, $\mathrm{pr}\colon B_0 \to \bar{B}_0$ is a ring isomorphism and $\tau = \mathrm{pr}^{-1} \circ \bar{\tau}$ is a graded continuous lift with $\tau = r_0$ on I_p. If $j = 0$, use (F1): $D_p = I_p \rtimes Z$. Let ϕ be a topological generator of Z and Δ_ϕ any graded lift of $\bar{\tau}(\phi)$ with diagonal GL-part. For $i \in I_p$, $\Delta_\phi r_0(i)\Delta_\phi^{-1} = (\sigma_\phi(\mathrm{T}(\Psi(i))), 1) = r_0(i) = r_0(\phi i \phi^{-1})$, because diagonal matrices commute, $\theta(\mathrm{T}(t)) = \mathrm{T}(t)$ and Ψ is a character. Hence $\tau(i\phi^a) = r_0(i)\Delta_\phi^a$ ($i \in I_p$, $a \in \hat{\mathbb{Z}}$, Δ_ϕ of finite order) is a well-defined continuous homomorphism lifting $\bar{\tau}$, graded, with $\tau = r_0$ on I_p.

The unipotent part. Let $U^{\mathrm{gr}}(B)$ be the group of graded upper unitriangular matrices; $\mathrm{pr}\colon U^{\mathrm{gr}}(B) \to U^{\mathrm{gr}}(\bar{B})$ is surjective with kernel $\{1 + X\}$, $X \in \mathrm{M}_3(I)$ supported in the positions of weight j above the diagonal; it is an isomorphism if $j \leq 0$. Conjugation by $\tau(g)$ preserves $U^{\mathrm{gr}}(B)$, and because the off-diagonal entries of $\bar{u}(g)$ lie in $\mathfrak{m}_{\bar{B}}$ and $\mathfrak{m}_B I = 0$, pr intertwines conjugation by $\tau(g)$ with conjugation by $\bar{\tau}(g)$.

- If $j \leq 0$ (or $p \in S_\ell(\chi)$, where $\bar{u} = 1$): put $\beta(g) = (\mathrm{pr}^{-1}(\bar{u}(g)), 1)\,\tau(g)$ (with $\bar{u} = 1$, $\beta = \tau$, in

the diagonal case). Since $\bar{u}(gg') = \bar{u}(g)\cdot(\bar{\tau}(g)\bar{u}(g')\bar{\tau}(g)^{-1})$ and pr^{-1} is a group isomorphism intertwining the conjugations, β is a continuous graded homomorphism lifting $\bar{\beta}$.

- If $j \geq 1$ and $p = \ell$: let $\tilde{Q}$ (resp. $\bar{Q}$) be the finite group of graded elements of $\mathcal{G}_3(B)$ (resp. $\mathcal{G}_3(\bar{B})$) with upper triangular GL-part (F3). As $B_0 \to \bar{B}_0$ is bijective, $\tilde{Q} \to \bar{Q}$ is surjective with kernel $\{(1+X, 1)\}$, $X \in \mathrm{M}_3(I)$ supported in the positions of weight j (which lie above the diagonal), a D_ℓ-module isomorphic to $\mathfrak{g}_j \otimes I$ (zero if $j \geq 3$). By Lemma 46.13, $H^2(D_\ell, \mathfrak{g}_j \otimes I) = H^2(D_\ell, \mathfrak{g}_j) \otimes I = 0$ for $j \in \{1, 2\}$, so by (F2) $\bar{\beta}$ lifts to a continuous graded $\beta\colon D_\ell \to \tilde{Q}$. Its diagonal part lifts $\bar{\tau}$ and so equals τ, the lift being unique as $B_0 \to \bar{B}_0$ is bijective.

In all cases β is graded, upper triangular (diagonal if $p \in S_\ell(\chi)$) on D_p, with diagonal ψ_a on I_p. Let h be a graded lift of $\bar{h}$ (it is $\equiv 1$, hence invertible) and $\rho = h\beta h^{-1}$. Then ρ is a continuous graded homomorphism lifting $\bar{\rho}$ (F3), and h is a matrix as required in (Lp1), resp. (Lp2). □

Lemma 46.13. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, let $p \in T_\ell(\chi)$ and $j \in \{-2, -1, 1, 2\}$. Then $H^0(D_p \cap G_K, \mathfrak{g}_j) = H^0(D_p \cap G_K, \mathfrak{g}_j^\vee) = 0$, $H^2(D_p, \mathfrak{g}_j) = 0$, and, if $p \in S_\ell(\chi)$, $H^1(D_p, \mathfrak{g}_j) = 0$.*

Proof. Write $\mathbb{F} = \mathbb{F}_\mathcal{O}$. An element $g \in G_K$ has $\bar{r}_0(g) = (\mathrm{T}(\bar{\Psi}(g)), 1)$ and acts on $\mathfrak{g}_j$ by conjugation with $\mathrm{T}(\bar{\Psi}(g))$, which multiplies the entry (a, b) by $\bar{\Psi}(g)^{b-a}$; so it acts on $\mathfrak{g}_j$ by the scalar $\bar{\Psi}(g)^j$. By Lemma 46.9 there is $s \in D_p \cap G_K$ with $\bar{\Psi}(s)^2 \neq 1$ that fixes μ_ℓ. Then $\alpha = \bar{\Psi}(s)^j \neq 1$: for $j = \pm 2$ directly, and for $j = \pm 1$ because $\bar{\Psi}(s)^{\pm 1} = 1$ would give $\bar{\Psi}(s)^2 = 1$.

Invariants. The element s acts on $\mathfrak{g}_j$ by $\alpha \neq 1$, so $H^0(D_p \cap G_K, \mathfrak{g}_j) \subseteq \{X : (\alpha - 1)X = 0\} = 0$. For $f \in \mathfrak{g}_j^\vee$, $(s \cdot f)(X) = s(f(s^{-1}X)) = f(\alpha^{-1}X)$, since s fixes μ_ℓ. If $s \cdot f = f$, then, f being a homomorphism from the additive group of $\mathfrak{g}_j$ to μ_ℓ, $f((\alpha^{-1} - 1)X) = f(\alpha^{-1}X)f(X)^{-1} = 1$ for all X, and $(\alpha^{-1} - 1)\mathfrak{g}_j = \mathfrak{g}_j$, so f is trivial. Hence $H^0(D_p \cap G_K, \mathfrak{g}_j^\vee) = 0$, and a fortiori $H^0(D_p, \mathfrak{g}_j) = H^0(D_p, \mathfrak{g}_j^\vee) = 0$.

H^2. The group D_p is the absolute Galois group of $\mathbb{Q}_p$ (through the completion at $\bar{p}$), and $\mathfrak{g}_j$ is a finite $\mathbb{Z}/\ell\mathbb{Z}$-module with continuous action. By Theorem B.29, item 2 ($r = 1$), $H^2(D_p, \mathfrak{g}_j)$ is dual to $H^0(D_p, \mathfrak{g}_j^\vee) = 0$.

H^1 at $S_\ell(\chi)$. If $p \in S_\ell(\chi)$ then $p \neq \ell$, and item 4 of Theorem B.29 gives $\#H^1(D_p, \mathfrak{g}_j) = \#H^0(D_p, \mathfrak{g}_j)\,\#H^2(D_p, \mathfrak{g}_j) = 1$. □

Proposition 46.14. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. Let $G_\mathbb{Q}$ act on $\mathrm{M}_3(\mathcal{O})$ through r_0: if $r_0(g) = (P, \varsigma)$, by $X \mapsto PXP^{-1}$ if $\varsigma = 1$ and by $X \mapsto -PJ\,{}^tXJP^{-1}$ if $\varsigma = -1$; let $j \in \{-2, -1, 0\}$ and let $\mathfrak{g}_j(\mathcal{O})$ be the matrices over $\mathcal{O}$ supported in the positions of weight j. Let $y\colon G_S \to \mathfrak{g}_j(\mathcal{O})$ be a continuous 1-cocycle such that*

(Vn1) *$y(g) = 0$ for every $g \in N_{\bar{p}}$ and every prime $p \in S$, $p \neq \ell$;*

(Vn2) *if $j = 0$: $y(g) = 0$ for every $g \in I_\ell$ and every $g \in I_p$, $p \in S_\ell(\chi)$;*

(Vn3) *if $j < 0$: there is $Z \in \mathfrak{g}_j(\mathcal{O})$ with $y(g) = g \cdot Z - Z$ for every $g \in D_\ell \cap G_K$.*

Then there are $a \in \mathcal{O} \setminus \{0\}$ and $X \in \mathfrak{g}_j(\mathcal{O})$ with $a\,y(g) = g \cdot X - X$ for every $g \in G_S$.

Proof. Write $\mathcal{M}_j = \mathfrak{g}_j(\mathcal{O})$, $g \cdot X$ for the action of $g \in G_\mathbb{Q}$ on $\mathrm{M}_3(\mathcal{O})$ through r_0, and dX for the coboundary $g \mapsto g \cdot X - X$; we write y also for the inflation of y to $G_\mathbb{Q}$, a continuous cocycle. Put $H_p = D_p \cap G_K$ for primes p. Let ϖ be a uniformiser of $\mathcal{O}$ and $\mathbb{F} = \mathbb{F}_\mathcal{O}$.

Preliminaries.

(P1) For $g \in G_K$, $r_0(g) = (\mathrm{T}(\Psi(g)), 1)$, so g acts on $\mathcal{M}_j$ by multiplication by $\Psi(g)^j$. Since $\Psi(c) = \chi(-1)(-1)^e = 1$ by (Dy3), $r_0(c) = (1, -1)$ and c acts by $X \mapsto -J\,{}^tXJ$; as J is antidiagonal with entries 1, $c \cdot E_{31} = -E_{31}$ and $c \cdot \mathrm{diag}(a_1, a_2, a_3) = -\mathrm{diag}(a_3, a_2, a_1)$. Hence $G_{\mathbb{Q}}$ acts on $\mathcal{M}_{-2} = \mathcal{O}E_{31}$ through the character $\gamma = \eta_K \Psi^{-2}$, whose reduction is γ_{-2}, and G_K acts trivially on $\mathcal{M}_0$.

(P2) Let Γ be a profinite group acting on an abelian group M, $\Gamma' \subseteq \Gamma$ an open normal subgroup of index n and z a 1-cocycle of Γ in M vanishing on Γ'. Then $z(gh) = z(g) + g \cdot z(h) = z(g)$ for $h \in \Gamma'$, so z is constant on cosets; summing $z(g\tau) = z(g) + g \cdot z(\tau)$ over a set $\mathcal{T}$ of coset representatives ($g\mathcal{T}$ is another one) gives $n\, z(g) = g \cdot (-W) - (-W)$ with $W = \sum_{\tau \in \mathcal{T}} z(\tau)$.

(P3) Let z be a cocycle of $G_{\mathbb{Q}}$, $g \in G_{\mathbb{Q}}$ and $D \subseteq G_{\mathbb{Q}}$ a subgroup. If $z(h) = 0$ and h acts trivially on the coefficients, then $z(ghg^{-1}) = z(g) + g \cdot z(h) + gh \cdot z(g^{-1}) = z(g) + g \cdot z(g^{-1}) = z(1) = 0$. If $z = dZ$ on D, then, using $z(g^{-1}) = -g^{-1} \cdot z(g)$, $z = d(g \cdot Z - z(g))$ on gDg^{-1}.

(P4) Every place of $\overline{\mathbb{Q}}$ above a prime p is $g\bar{p}$ with $g \in G_{\mathbb{Q}}$, and $I_{g\bar{p}} = gI_{\bar{p}}g^{-1}$, $N_{g\bar{p}} = gN_{\bar{p}}g^{-1}$. If $p \notin S$, $I_{g\bar{p}}$ lies in the kernel of $G_{\mathbb{Q}} \to G_S$, so $y = 0$ on it.

(P5) If $p \in S \setminus T_\ell(\chi)$ is a prime, then $\Psi = 1$ on $N_{\bar{p}}$. Indeed $p \neq \ell$, so $p \mid N$ and $\chi''_p = \mathbf{1}$; χ_{cyc} and the r-components of χ for $r \neq p$ are unramified at p, so $\Psi(I_{\bar{p}}) = \chi_p(I_{\bar{p}}) = \chi'_p(I_{\bar{p}})$ consists of roots of unity of order prime to ℓ, which reduce injectively into $\mathbb{F}^\times$; on $N_{\bar{p}}$ the reduction is 1. Moreover $2 \notin S_\ell(\chi)$, the 2-component of χ'' having order both a power of 2 and of ℓ, odd by (Dy1); so every $p \in S_\ell(\chi)$ is odd, unramified in K, and $I_p \subseteq H_p$.

Weight -2: y is a coboundary. Identify $\mathcal{M}_{-2}$ with $\mathcal{O}$ via E_{31}, so that $y(gh) = y(g) + \gamma(g)y(h)$ (P1). For $p \in T_\ell(\chi)$ let $s_p \in H_p$ be the element of Lemma 46.9; as $\eta_K(s_p) = 1$, $\bar{\gamma}(s_p) = \bar{\Psi}(s_p)^{-2} \neq 1$, so $\gamma(s_p) - 1 \in \mathcal{O}^\times$. Let $\mathcal{Z}$ be the set of continuous cocycles $z \colon G_S \to \mathcal{O}$ (for γ) such that

(Z1) for every $p \in T_\ell(\chi)$, $z = dW$ on H_p for some $W \in \mathcal{O}$;

(Z2) $z = 0$ on $N_{\bar{p}}$ for every prime $p \in S \setminus T_\ell(\chi)$.

Step 1: $y \in \mathcal{Z}$. (Z2) is (Vn1); (Z1) at $p = \ell$ is (Vn3). Let $p \in S_\ell(\chi)$. The group $N_{\bar{p}}$ is the kernel of $g \mapsto (\eta_K(g), \bar{\Psi}(g))$ on I_p, normal of index n_p dividing $2(\#\mathbb{F} - 1)$, prime to ℓ, and $y = 0$ on it by (Vn1); by (P2), $y = dW_1$ on I_p with $W_1 = -n_p^{-1} \sum_\tau y(\tau) \in \mathcal{O}$. The cocycle $y' = y - dW_1$ on H_p vanishes on I_p, which is normal in H_p; for $g \in H_p$ and $h \in I_p$, $y'(hg) = \gamma(h)y'(g)$ and $y'(hg) = y'(g \cdot g^{-1}hg) = y'(g)$. If γ is non-trivial on I_p, this forces $y' = 0$ ($\mathcal{O}$ is a domain). Otherwise γ factors through $\Gamma_p = H_p/I_p$, and so does y' ($y'(gh) = y'(g)$ for $h \in I_p$). Γ_p is open in D_p/I_p, hence procyclic, topologically generated by some ϕ; since $\bar{\gamma}$ is continuous, factors through Γ_p and $\bar{\gamma}(s_p) \neq 1$, $\bar{\gamma}(\phi) \neq 1$, so $\gamma(\phi) - 1$ is a unit. Put $W_2 = y'(\phi)/(\gamma(\phi) - 1)$. The set of $g \in \Gamma_p$ with $y'(g) = (dW_2)(g)$ is a closed subgroup (both are continuous cocycles) containing ϕ, hence is Γ_p. So $y = d(W_1 + W_2)$ on H_p: (Z1).

Step 2: $\mathcal{Z}$ is an $\mathcal{O}$-module containing the coboundaries. Clear for (Z1); for (Z2), $\gamma = \eta_K\Psi^{-2} = 1$ on $N_{\bar{p}}$ by (P5), so $(d\mu)(g) = (\gamma(g) - 1)\mu = 0$ there.

Step 3: the reduction of $z \in \mathcal{Z}$ lies in Z_{-2}. Let $\bar{z} \colon G_{\mathbb{Q}} \to \mathbb{F}$ be the reduction of (the inflation of) z: a locally constant cocycle for γ_{-2}. Let $\bar{v} = g\bar{p}$ be a place above a prime $p \neq \ell$. If $p \notin S$, $\bar{z} = 0$ on $N_{\bar{v}}$ by (P4). If $p \in S \setminus T_\ell(\chi)$, $z = 0$ on $N_{\bar{p}}$ by (Z2). If $p \in S_\ell(\chi)$, $z = dW$ on $H_p \supseteq N_{\bar{p}}$ by (Z1), and $\bar{\gamma} = 1$ on $N_{\bar{p}}$, so $\bar{z}(h) = (\bar{\gamma}(h) - 1)\bar{W} = 0$ for $h \in N_{\bar{p}}$. In both cases $\bar{z}$ vanishes on $N_{\bar{p}}$, on which γ_{-2} is trivial, so by (P3) it vanishes on $N_{g\bar{p}} = gN_{\bar{p}}g^{-1}$. At ℓ, $\bar{z} = d\bar{W}$ on H_ℓ, of index at most 2 in D_ℓ; the cocycle $\bar{z} - d\bar{W}$ of D_ℓ vanishes on H_ℓ, so by (P2) it is a coboundary on D_ℓ (2 times it is one, and 2 is invertible in $\mathbb{F}$). Hence $\bar{z} \in Z_{-2}$.

Step 4: saturation. If $z \in \mathcal{Z}$ takes values in $\varpi\mathcal{O}$, then $z_1 = \varpi^{-1}z \in \mathcal{Z}$: it is a continuous cocycle; (Z2) is clear; if $z = dW$ on H_p, $p \in T_\ell(\chi)$, then $(\gamma(s_p) - 1)W = z(s_p) \in \varpi\mathcal{O}$ with $\gamma(s_p) - 1$ a unit, so $W \in \varpi\mathcal{O}$ and $z_1 = d(\varpi^{-1}W)$ on H_p.

Step 5: descent. Put $y_0 = y \in \mathcal{Z}$ (Step 1). Given $y_k \in \mathcal{Z}$, Step 3 and $\mathrm{Sel}_{-2}(\chi, e) = 0$ (Lemma 46.15) give $\bar{\mu}_k \in \mathbb{F}$ with $\bar{y}_k = d\bar{\mu}_k$; for a lift $\mu_k \in \mathcal{O}$, $y_k - d\mu_k \in \mathcal{Z}$ (Step 2) has values in $\varpi\mathcal{O}$, and $y_{k+1} = \varpi^{-1}(y_k - d\mu_k) \in \mathcal{Z}$ (Step 4). By induction $y = d(\sum_{k<n} \varpi^k \mu_k) + \varpi^n y_n$ for all n. With $X = \sum_{k\geq 0} \varpi^k \mu_k \in \mathcal{O}$ (convergent, $\mathcal{O}$ being complete), $y(g) - (\gamma(g) - 1)X \in \varpi^n\mathcal{O}$ for all n, so $y = dX$: the claim holds with $a = 1$ and $XE_{31} \in \mathcal{M}_{-2}$.

Weight 0*: y is a coboundary.* By (P1), $y|_{G_K}$ is a continuous homomorphism $G_K \to \mathcal{M}_0 \cong \mathcal{O}^3$. It vanishes on $I_{\bar{v}} \cap G_K$ for every place $\bar{v}$ above a prime p: for $p \notin S$ by (P4); for $p = \ell$ by (Vn2); for $p \in S$, $p \neq \ell$, at $\bar{v} = \bar{p}$, because $y = 0$ on $N_{\bar{p}} \subseteq I_{\bar{p}} \cap G_K$ (Vn1), a subgroup of finite index ($\bar{\Psi}$ has finite image), so $y(I_{\bar{p}} \cap G_K)$ is a finite subgroup of the torsion-free group $\mathcal{O}^3$; and at $\bar{v} = g\bar{p}$ by (P3), since $I_{g\bar{p}} \cap G_K = g(I_{\bar{p}} \cap G_K)g^{-1}$ (G_K is normal) and G_K acts trivially on $\mathcal{M}_0$. So the fixed field of the closed normal subgroup $\ker(y|_{G_K})$ is an abelian extension of K unramified at every finite place, and at the one infinite place, which is complex. Since $K = \mathbb{Q}(i)$ has class number one, this extension is K, and $y = 0$ on G_K. Then $0 = y(c^2) = y(c) + c \cdot y(c)$; put $X = -\frac{1}{2}y(c) \in \mathcal{M}_0$ (ℓ is odd). Then $c \cdot X - X = y(c)$, and for $g \in G_K$: $y(g) = 0 = g \cdot X - X$ and $y(gc) = y(g) + g \cdot y(c) = y(c) = (gc) \cdot X - X$. So $y = dX$ on $G_K \sqcup G_K c = G_{\mathbb{Q}}$: the claim holds with $a = 1$.

Weight -1*: y is torsion modulo coboundaries.* Let $L = \mathbb{Q}(\zeta_{4\ell N}) \subset \overline{\mathbb{Q}}$, a totally complex abelian extension of $\mathbb{Q}$ containing i and a primitive ℓ-th root of unity, and $n = [L : \mathbb{Q}]$. The character χ factors through $\mathrm{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$, so $\Psi = \chi_{\mathrm{cyc}}^e$ on $G_L \subseteq G_K$, and by (P1) G_L acts on $\mathcal{M}_{-1}$ by the scalar χ_{cyc}^{-e}.

Step 1: $y|_{G_L}$ is unramified outside ℓ. Let $\bar{v} = g\bar{p}$ be a place above a prime $p \neq \ell$. The group $I_{\bar{p}} \cap G_L$ acts trivially on $\mathcal{M}_{-1}$ (χ_{cyc} is unramified at p), so y is a homomorphism on it; if $p \in S$ it vanishes on the finite-index subgroup $N_{\bar{p}} \cap G_L$ (Vn1), so its image is a finite subgroup of the torsion-free $\mathcal{M}_{-1}$, hence 0; if $p \notin S$, $y = 0$ on it by (P4). By (P3), $y = 0$ on $I_{g\bar{p}} \cap G_L = g(I_{\bar{p}} \cap G_L)g^{-1}$. The kernel H of $G_L \to G_{L,S_\ell}$ is the closed normal subgroup generated by these groups $I_{\bar{v}} \cap G_L$ (the infinite places of L are complex); χ_{cyc} is trivial on each of them, hence on H, so $y|_H$ is a continuous homomorphism vanishing on a set of topological generators: $y|_H = 0$. Hence $y(gh) = y(g)$ for $g \in G_L$, $h \in H$, and $y|_{G_L} = \tilde{y} \circ (G_L \to G_{L,S_\ell})$ for a continuous cocycle $\tilde{y}$ of G_{L,S_ℓ} in $\mathcal{M}_{-1}$ with the scalar action χ_{cyc}^{-e}.

Step 2: local triviality above ℓ. For a place w of L above ℓ, the restriction to L_w is taken through $D_{\bar{w}} \cap G_L$ for a place $\bar{w} = g\bar{\ell}$ of $\overline{\mathbb{Q}}$ above w. By (Vn3), $y = dZ$ on H_ℓ, so by (P3) $y = dZ_w$ with $Z_w = g \cdot Z - y(g) \in \mathcal{M}_{-1}$ on $gH_\ell g^{-1} = D_{\bar{w}} \cap G_K \supseteq D_{\bar{w}} \cap G_L$.

Step 3: a rational primitive over L. $\mathcal{M}_{-1}$ is a free $\mathbb{Z}_\ell$-module of finite rank ($\mathcal{O}$ is finite free over $\mathbb{Z}_\ell$); let $b_1, \ldots, b_m$ be a basis and $\lambda_1, \ldots, \lambda_m$ the dual coordinates. Since G_L acts by a scalar in $\mathbb{Z}_\ell^\times$, each $\lambda_i \circ \tilde{y}$: $G_{L,S_\ell} \to \mathbb{Z}_\ell$ satisfies the cocycle relation for χ_{cyc}^{-e}, and by Step 2 it is the coboundary of $\lambda_i(Z_w) \in \mathbb{Z}_\ell$ on the image of G_{L_w} for each $w \mid \ell$. By Proposition 40.3 (L totally complex, containing a primitive ℓ-th root of unity, $e \geq 1$), $\mathrm{len}_\ell(L, e) < \infty$, so Lemma 43.33 (with $E = L$, $k = e$) gives $x_i \in \mathbb{Q}_\ell$ with $\lambda_i(\tilde{y}(g)) = (\chi_{\mathrm{cyc}}(g)^{-e} - 1)x_i$. Choose $t \geq 0$ with $\ell^t x_i \in \mathbb{Z}_\ell$ for all i and put $X_L = \sum_i \ell^t x_i b_i \in \mathcal{M}_{-1}$; then $\ell^t y = dX_L$ on G_L.

Step 4: descent to $G_{\mathbb{Q}}$. The cocycle $\ell^t y - dX_L$ of $G_{\mathbb{Q}}$ vanishes on the open normal subgroup G_L of index n; by (P2), $n(\ell^t y - dX_L) = dX'$ for some $X' \in \mathcal{M}_{-1}$. So $a\,y = dX$ with $a = n\ell^t \neq 0$ and $X = nX_L + X' \in \mathcal{M}_{-1}$; all these maps factor through G_S, so the identity holds on G_S. □

Lemma 46.15. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. Then* $\mathrm{Sel}_{-2}(\chi, e) = 0$.

Proof. Let $z \in Z_{-2}$. We show that z is a coboundary.

Step 1: γ_{-2} is the reduction of a Dirichlet character. Let ω_ℓ be the Teichmüller character modulo ℓ ($\omega_\ell(b)$ is the $(\ell-1)$-th root of unity in $\mathbb{Z}_\ell$ congruent to b), so that χ_{cyc} and ω_ℓ have the same reduction, and let χ_4 be the character modulo 4 with $\chi_4(-1) = -1$, which as a character of $G_{\mathbb{Q}}$ is η_K. The values of χ'' are roots of unity of ℓ-power order, which reduce to 1; so $\bar{\Psi}^2\eta_K$ is the reduction of

$$\chi_{\mathrm{B}} = (\chi')^2\,\omega_\ell^{2e}\,\chi_4,$$

a Dirichlet character of order prime to ℓ, and $\gamma_{-2} = (\bar{\Psi}^2\eta_K)^{-1}$ is the reduction of χ_{B}^{-1}. The 2-component of χ'' has both ℓ-power and 2-power order, so it is trivial and $\chi_2' = \chi_2$. Hence $\chi_{\mathrm{B}} = \chi_{\mathrm{B,od}}\chi_{\mathrm{B},2}$ with $\chi_{\mathrm{B,od}} = \vartheta^2\omega_\ell^{2e}$, a product of characters of odd conductor, and $\chi_{\mathrm{B},2} = \chi_2^2\chi_4$.

Step 2: the two primitive characters. Let α be the primitive character inducing $\chi_{\mathrm{B,od}}$, of conductor f_α. The conductor of a product divides the least common multiple of the conductors [266]; ϑ^2 has trivial 2-component, so its conductor is odd and divides m by (Dy7). Hence f_α is odd and $f_\alpha \le \ell m$. Let f_ℓ be the order of ℓ modulo $\mathrm{lcm}(4, \operatorname{ord}\vartheta)$, so that $n_0(\ell,\chi)$ is the exponent of 2 in $\ell^{f_\ell} - 1$, $4 \mid \ell^{f_\ell} - 1$, $\operatorname{ord}\vartheta \mid \ell^{f_\ell} - 1$ and $(\ell-1) \mid \ell^{f_\ell} - 1$; the order of α divides $\mathrm{lcm}(\operatorname{ord}\vartheta, \ell-1)$, so $\alpha(b)^{\ell^{f_\ell}-1} = 1$ for b prime to f_α. Put $c = c_2(\chi) \ge 4$ (Dy6). Since χ_2 is primitive modulo 2^c, $\chi_2(5)$ has order exactly 2^{c-2} (classically $(\mathbb{Z}/2^c\mathbb{Z})^\times = \{\pm1\} \times \langle 5\rangle$ with 5 of order 2^{c-2} and $5^{2^{c-3}} \equiv 1 + 2^{c-1} \pmod{2^c}$ [266]; $\{1, 1+2^{c-1}\}$ is the kernel of reduction modulo 2^{c-1}, so primitivity gives $\chi_2(1+2^{c-1}) \ne 1$, and $(1+2^{c-1})^2 \equiv 1$, so $\chi_2(5)^{2^{c-3}} = -1$). As $\chi_4(5) = 1$, $\chi_{\mathrm{B},2}(5) = \chi_2(5)^2$ has order $2^{c-3} \ge 2$. The subgroup $\{u \equiv 1 \pmod{2^{c-1}}\}$ is $\langle 5^{2^{c-3}}\rangle$, on which $\chi_{\mathrm{B},2}$ is trivial, and $\{u \equiv 1 \pmod{2^{c-2}}\} = \langle 5^{2^{c-4}}\rangle$, on which it is not; so the primitive character β inducing $\chi_{\mathrm{B},2}$ has conductor 2^n with $n = c - 1 \ge 3$, and $\beta(5)$ has order 2^{n-2}.

Step 3: the Bernoulli number is a unit. The hypotheses of Lemma 44.6 hold for ℓ, the exponent f_ℓ (in place of m), $a = n_0(\ell,\chi)$, f_α, n, α and β: ℓ is odd by (Dy1); f_α is odd; $\alpha^{\ell^{f_\ell}-1} = 1$ (Step 2); by (Dy7), $f_\alpha 4^a \le \ell m 4^{n_0(\ell,\chi)} \le 2^{c-1} = 2^n$; and $\alpha(-1)\beta(-1) = \chi_{\mathrm{B}}(-1) = \chi'(-1)^2\omega_\ell(-1)^{2e}\chi_4(-1) = -1$. Hence $\alpha\beta$ is primitive modulo $f_\alpha 2^n$, it agrees with χ_{B} on integers prime to $2\ell N$, so it is χ_{B} as a character of $G_{\mathbb{Q}}$, and $|B_{1,\alpha\beta}|_\ell = 1$.

Step 4: the hypotheses of the Herbrand-type lemma. Let $\chi_{\mathrm{H}} = (\alpha\beta)^{-1}$: a non-trivial primitive character modulo $f_\alpha 2^n$ of order prime to ℓ, with $\bar{\chi}_{\mathrm{H}} = \gamma_{-2}$ (Steps 1 and 3) and $|B_{1,\chi_{\mathrm{H}}^{-1}}|_\ell = |B_{1,\alpha\beta}|_\ell = 1$. Choose an integer $b \equiv 1 \pmod{\ell f_\alpha}$ with $b \equiv 5 \pmod{2^n}$ and $g \in G_{\mathbb{Q}}$ with $g(\zeta) = \zeta^b$ for all roots of unity of order dividing $\ell f_\alpha 2^n$. Then $\bar{\omega}(g) = \bar{b} = 1$, while $\chi_{\mathrm{H}}(g) = \alpha(b)^{-1}\beta(5)^{-1} = \beta(5)^{-1}$ is a root of unity of order $2^{n-2} \ge 2$, whose reduction is $\ne 1$; so $\bar{\chi}_{\mathrm{H}} \ne \bar{\omega}$.

Step 5: z is unramified everywhere. Let $\bar{p}$ be a place above a prime $p \ne \ell$. On $I_{\bar{p}} \cap \ker\gamma_{-2}$ the map z is a homomorphism (as $\gamma_{-2} = 1$ there), and $N_{\bar{p}} \subseteq I_{\bar{p}} \cap \ker\gamma_{-2}$ is the kernel of $g \mapsto (\eta_K(g), \bar{\Psi}(g)) \in \{\pm1\} \times \mathbb{F}_{\mathcal{O}}^\times$ on it, a normal subgroup of index dividing $2(\#\mathbb{F}_{\mathcal{O}} - 1)$, prime to ℓ. Since z vanishes on $N_{\bar{p}}$, it induces a homomorphism from a finite group of order prime to ℓ to the additive group of $\mathbb{F}_{\mathcal{O}}$, of exponent ℓ; so $z = 0$ on $I_{\bar{p}} \cap \ker\gamma_{-2}$. At the fixed place $\bar{\ell}$, $z(g) = \gamma_{-2}(g)y - y$ on D_ℓ, which vanishes on $I_\ell \cap \ker\gamma_{-2}$. At another place $g_0\bar{\ell}$ ($g_0 \in G_{\mathbb{Q}}$), $I_{g_0\bar{\ell}} = g_0 I_\ell g_0^{-1}$, and for $h \in I_\ell \cap \ker\gamma_{-2}$ the cocycle relation gives $z(g_0 h g_0^{-1}) = \gamma_{-2}(g_0)z(h) = 0$ (expand $z(g_0 \cdot hg_0^{-1})$ and use $z(g_0^{-1}) = -\gamma_{-2}(g_0)^{-1}z(g_0)$). So $z(g) = 0$ for every place $\bar{p}$ above a prime and every $g \in I_{\bar{p}}$ with $\gamma_{-2}(g) = 1$.

Step 6: conclusion. By Steps 4 and 5, Lemma 44.7 applies to χ_{H}, the field $k = \mathbb{F}_{\mathcal{O}}$ (which contains the values of $\gamma_{-2} = \bar{\chi}_{\mathrm{H}}$) and z: there is $\mu \in \mathbb{F}_{\mathcal{O}}$ with $z(g) = \gamma_{-2}(g)\mu - \mu$ for all g. So every element of Z_{-2} is a coboundary, and $\mathrm{Sel}_{-2}(\chi, e) = 0$. □

Lemma 46.16. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$. For every integer j with $-2 \le j \le 2$, the spaces $H^1_{\mathcal{L}}(\mathfrak{g}_j)$ and $H^2_{\mathcal{L}}(\mathfrak{g}_j)$*

are finite-dimensional over $\mathbb{F}_{\mathcal{O}}$ *and*

$$\dim H^1_{\mathcal{L}}(\mathfrak{g}_j) - \dim H^2_{\mathcal{L}}(\mathfrak{g}_j) = d(j), \qquad d(-2)=0, \quad d(-1)=-1, \quad d(0)=0, \quad d(1)=d(2)=1.$$

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $q = \#\mathbb{F}$ (a power of ℓ), $\dim = \dim_{\mathbb{F}}$, and fix $j \in \{-2,\dots,2\}$. The entries of weight j are $(a, a+j)$, so $\dim \mathfrak{g}_j = 3 - |j|$. Finite $\mathbb{F}$-vector spaces X have $\#X = q^{\dim X}$, so the cardinality formulas of Theorem B.29 (with $r=1$) can be written additively in dimensions.

Step 1: the action. If $g \in G_K$ then $\bar{r}_0(g) = (\mathrm{T}(\bar{\Psi}(g)), 1)$ and $\mathrm{T}(t)X\mathrm{T}(t)^{-1}$ has entries $t^{b-a}X_{ab}$, so g acts on $\mathfrak{g}_j$ by the scalar $\bar{\Psi}(g)^j$. As $\Psi(c) = 1$, $\bar{r}_0(c) = (1,-1)$ and c acts by $X \mapsto -J\,{}^tXJ$, whose (a,b) entry is $-X_{4-b,4-a}$, of the same weight; every $g \notin G_K$ is $g'c$ with $g' \in G_K$. So $G_{\mathbb{Q}}$ preserves $\mathfrak{g}_j$, and the kernel of the action contains $G_K \cap \ker\bar{\Psi}$, whose fixed field lies in $\mathbb{Q}(i, \mu_{\ell N})$ ($\Psi = \chi\chi_{\mathrm{cyc}}^e$) and is unramified outside $2\ell N$; since $2 \mid N$ (Dy2), the action factors through G_S. The elements of $N_{\bar{p}}$ act trivially ($\eta_K = 1$, $\bar{\Psi} = 1$ there), and so do those of I_ℓ on $\mathfrak{g}_0$ (ℓ is odd, hence unramified in K, so $I_\ell \subseteq G_K$).

Hence $\dim \mathfrak{g}_j^{c=1}$ is $0,1,1,1,0$ for $j = -2,-1,0,1,2$.

Step 2: invariants. Let $s \in D_\ell \cap G_K$ be as in Lemma 46.9 for $p=\ell$: $\bar{\Psi}(s)^2 \neq 1$ and s fixes μ_ℓ. If $j \neq 0$, s acts on $\mathfrak{g}_j$ by $a = \bar{\Psi}(s)^j \neq 1$ ($a=1$ would give $\bar{\Psi}(s)^2 = 1$); an s-invariant $f \in \mathfrak{g}_j^\vee$ satisfies $f(sX) = s(f(X)) = f(X)$ (s fixes μ_ℓ), i.e. f vanishes on $(a-1)\mathfrak{g}_j = \mathfrak{g}_j$; so

$$H^0(D_\ell, \mathfrak{g}_j) = H^0(G_S, \mathfrak{g}_j) = 0, \qquad H^0(D_\ell, \mathfrak{g}_j^\vee) = H^0(G_S, \mathfrak{g}_j^\vee) = 0 \qquad (j \neq 0).$$

If $j = 0$, then G_K acts trivially on $\mathfrak{g}_0$, so $H^0(G_S, \mathfrak{g}_0) = \mathfrak{g}_0^{c=1}$, of dimension 1. Moreover $K \cap \mathbb{Q}(\mu_\ell) = \mathbb{Q}$ ($\mathbb{Q}(\mu_\ell)$ is unramified at 2, K is not), so some $\tau \in G_K$ acts non-trivially on μ_ℓ, hence fixes only $1 \in \mu_\ell$; as τ acts trivially on $\mathfrak{g}_0$, a τ-invariant $f \in \mathfrak{g}_0^\vee$ has $f(X) = \tau(f(X))$, so $f = 0$ and $H^0(G_S, \mathfrak{g}_0^\vee) = 0$.

Step 3: the local conditions. For a prime $p \in S$, $p \neq \ell$, $N_{\bar{p}}$ is the kernel of $I_p \to \{\pm 1\} \times \mathbb{F}^\times$, $g \mapsto (\eta_K(g), \bar{\Psi}(g))$, hence normal in D_p, of index in I_p dividing $2(q-1)$, prime to ℓ, and it acts trivially (Step 1); by Lemma 43.35, item 1, $L_{p,j} \supseteq B^1(D_p, \mathfrak{g}_j)$ and $\dim L_{p,j} = \dim \mathfrak{g}_j$. For $p = \ell$ and $j = 0$ the same item with $N' = I_\ell$ (Step 1) gives $L_{\ell,0} \supseteq B^1$ and $\dim L_{\ell,0} = \dim \mathfrak{g}_0$. If $j < 0$, $L_{\ell,j} = B^1(D_\ell, \mathfrak{g}_j)$ has dimension $\dim \mathfrak{g}_j - \dim H^0(D_\ell, \mathfrak{g}_j) = \dim \mathfrak{g}_j$ (Step 2). If $j > 0$, $L_{\ell,j} = Z^1(D_\ell, \mathfrak{g}_j)$ has dimension $h^1 + \dim \mathfrak{g}_j - h^0$ with $h^i = \dim H^i(D_\ell, \mathfrak{g}_j)$; by Theorem B.29, item 2, $h^2 = \dim H^0(D_\ell, \mathfrak{g}_j^\vee) = 0$, by item 4 ($[\mathbb{Q}_\ell : \mathbb{Q}_\ell] = 1$) $h^1 = h^0 + h^2 + \dim \mathfrak{g}_j$, and $h^0 = 0$ (Step 2); so $\dim L_{\ell,j} = 2\dim \mathfrak{g}_j$. In all cases $L_{p,j} \supseteq B^1(D_p, \mathfrak{g}_j)$ and

$$\sum_{p \in S \text{ prime}} (\dim L_{p,j} - \dim \mathfrak{g}_j) = \begin{cases} \dim \mathfrak{g}_j & j > 0, \\ 0 & j \leq 0. \end{cases} \tag{46.2}$$

Step 4: the count. By Steps 2 and 3 the hypotheses of Lemma 43.35, item 2, hold for $M = \mathfrak{g}_j$ and $(L_{p,j})_p$ (ℓ is odd by (Dy1)). So $H^1_{\mathcal{L}}(\mathfrak{g}_j)$ and $H^2_{\mathcal{L}}(\mathfrak{g}_j)$ are finite-dimensional and, by (46.2),

$$\dim H^1_{\mathcal{L}}(\mathfrak{g}_j) - \dim H^2_{\mathcal{L}}(\mathfrak{g}_j) = \dim H^0(G_S, \mathfrak{g}_j) - \dim \mathfrak{g}_j^{c=1} + \begin{cases} \dim \mathfrak{g}_j & j > 0, \\ 0 & j \leq 0. \end{cases}$$

By Steps 1 and 2: for $j=-2$, $0-0+0=0$; $j=-1$, $0-1+0=-1$; $j=0$, $1-1+0=0$; $j=1$, $0-1+2=1$; $j=2$, $0-0+1=1$. This is $d(j)$. □

Lemma 46.17. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking and (R, r) a dyadic Eisenstein deformation ring for $g_\star$. Assume that* $\mathrm{Sel}_{-2}(\chi, e) = 0$. *Then every two-signed point of (R, r) is of type I, and for points φ, φ' of (R, r) with $\rho_{\varphi'} \cong \rho_\varphi$ there is $t \in \overline{\mathbb{Q}}_\ell^\times$ with $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$.*

Proof. Let $\mathfrak{m}_R$ be the maximal ideal of R, $K_0 = \mathcal{O}[\ell^{-1}]$ and $\mathbb{F}_{\mathcal{O}}$ the residue field of $\mathcal{O}$.

Step 0: points are integral over a finite extension. Let φ be a point and $y_1, \dots, y_n$ generators of $\mathfrak{m}_R$. Let $L = K_0(\varphi(y_1), \dots, \varphi(y_n))$, a finite extension of K_0, with ring of integers $\mathcal{O}_L$ (a discrete valuation ring, closed in $\overline{\mathbb{Q}}_\ell$) and maximal ideal $\mathfrak{m}_L$, and put $\varrho = \max_i |\varphi(y_i)|_\ell < 1$. Since $R/\mathfrak{m}_R = \mathbb{F}_{\mathcal{O}}$, $R = \mathcal{O} + \mathfrak{m}_R$, so $|\varphi(f)|_\ell \le 1$ for every $f \in R$; and by induction $R = \sum_{|\alpha|<k} \mathcal{O} y^\alpha + \sum_{|\alpha|=k} y^\alpha R$ for every $k \ge 1$ (multi-indices α). Hence every $\varphi(f)$ lies within ϱ^k of $\mathcal{O}[\varphi(y_1), \dots, \varphi(y_n)] \subseteq \mathcal{O}_L$ for every k, so $\varphi(R) \subseteq \mathcal{O}_L$, and $|\varphi(f)|_\ell \le \varrho^k$ for $f \in \mathfrak{m}_R^k$. Consequently $P_g := \underline{r_\varphi}(g)$ has entries in $\mathcal{O}_L$, reduces modulo $\mathfrak{m}_L$ to $\mathrm{T}(\bar\Psi(g))$ (the entries of $\underline{r}(g) - \underline{r_0}(g)$ lie in $\mathfrak{m}_R$), so $\det P_g \in \mathcal{O}_L^\times$, and $g \mapsto P_g$ is continuous into $\mathrm{M}_3(\mathcal{O}_L)$ (the entries of $\underline{r}$ are $\mathfrak{m}_R$-adically continuous).

Step 1: r_φ satisfies (Ns1)–(Ns3) of Lemma 42.4 for K, c, $g_\star$, and $\delta_\star(r_\varphi)+\delta_\star(r_{\varphi'}) \neq 0$ for any two points. Applying a point ϕ to the entries of GL-parts is a homomorphism $\mathcal{G}_3(R) \to \mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$, so r_ϕ is a homomorphism; its signs are those of the lift r, i.e. η_K; and (Ed1) gives $\underline{r_\phi}(c) = 1$ and the vanishing of the entries $(1,2)$, $(2,1)$ of $\underline{r_\phi}(g_\star) - \underline{r_\phi}(c g_\star^{-1} c)$. So (Ns1), (Ns2) hold, and $g_\star \in G_K$ as $\eta_K(g_\star) = 1$. With $u = \Psi(g_\star) - \overline{\Psi(g_\star)}^{-1} = \overline{\Psi(g_\star)}^{-1}(\Psi(g_\star)^2 - 1) \in \mathcal{O}^\times$ (marking), $y = \underline{r}(g_\star)_{11} - \underline{r}(g_\star)_{33} - u \in \mathfrak{m}_R$, so $\delta_\star(r_\phi) = u + \phi(y)$ with $|u|_\ell = 1 > |\phi(y)|_\ell$, whence $|\delta_\star(r_\phi)|_\ell = 1$; and $\delta_\star(r_\varphi) + \delta_\star(r_{\varphi'}) = 2u + \varphi(y) + \varphi'(y)$ is non-zero because $|2u|_\ell = 1$ (ℓ odd, (Dy1)) and $|\varphi(y) + \varphi'(y)|_\ell < 1$.

Step 2: a two-signed point of type II would have a $(3,1)$-entry cocycle. Let φ be two-signed. By Lemma 42.4, item 1, and since φ is neither upper nor lower, φ is of type I or of type II. Suppose, for a contradiction, that it is of type II, and use the notation of Step 0. For $g \in G_K$ the entries of odd weight of P_g vanish, in particular $(P_g)_{32} = 0$. For $g \notin G_K$, $g = (gc)c$ and $r_\varphi(g) = r_\varphi(gc)(1,-1) = (P_{gc}, -1)$, so $P_g = P_{gc}$ and again $(P_g)_{32} = 0$. As φ is not upper, some entry of negative weight of some P_g, $g \in G_K$, is non-zero; the entries $(2,1)$, $(3,2)$ vanish, so $(P_g)_{31} \neq 0$ for some g. The valuations of the non-zero $(P_g)_{31}$ lie in a discrete subset of $[0,\infty)$; choose g_0 where the valuation is minimal, put $x = (P_{g_0})_{31} \neq 0$ and $b(g) = (P_g)_{31}/x \in \mathcal{O}_L$. Then $b(g_0) = 1$ and $b(c) = 0$ ($P_c = 1$). Let k_L be the residue field of $\mathcal{O}_L$ and $f \mapsto \bar f$ the reduction, and put

$$z(g) = \bar b(g)\, \bar\Psi(g)^{-1} \in k_L \qquad (g \in G_{\mathbb{Q}}).$$

z is locally constant: by continuity of $g \mapsto P_g$, $g \mapsto x b(g)$ modulo $x\mathfrak{m}_L$ is locally constant, and $x b(g) \equiv x b(g') \pmod{x\mathfrak{m}_L}$ if and only if $\bar b(g) = \bar b(g')$; $\bar\Psi$ is locally constant. $z(gh) = z(g) + \gamma_{-2}(g) z(h)$: for matrices X, Y with $X_{32} = 0$, $(XY)_{31} = X_{31}Y_{11} + X_{33}Y_{31}$. If $\eta_K(g) = 1$, $P_{gh} = P_g P_h$, so $b(gh) = b(g)(P_h)_{11} + (P_g)_{33} b(h)$; reducing, $\bar b(gh) = \bar b(g)\bar\Psi(h) + \bar\Psi(g)^{-1}\bar b(h)$, and multiplying by $\bar\Psi(gh)^{-1}$ gives $z(gh) = z(g) + \bar\Psi(g)^{-2} z(h)$, where $\bar\Psi(g)^{-2} = \gamma_{-2}(g)$. If $\eta_K(g) = -1$, $P_{gh} = P_g\, Y$ with $Y = J\, {}^t(P_h^{-1}) J$, so $Y_{11} = (P_h^{-1})_{33} = (\det P_h)^{-1}((P_h)_{11}(P_h)_{22} - (P_h)_{12}(P_h)_{21})$ and $Y_{31} = (P_h^{-1})_{31} = (\det P_h)^{-1}((P_h)_{21}(P_h)_{32} - (P_h)_{22}(P_h)_{31}) = -(\det P_h)^{-1}(P_h)_{22}\, x\, b(h)$ (cofactors). Hence $b(gh) = b(g) Y_{11} - (P_g)_{33}(\det P_h)^{-1}(P_h)_{22} b(h)$, and reducing ($\bar Y_{11} = \bar\Psi(h)$, $\overline{\det P_h} = 1$, $\overline{(P_h)_{22}} = 1$) $\bar b(gh) = \bar b(g)\bar\Psi(h) - \bar\Psi(g)^{-1}\bar b(h)$, i.e. $z(gh) = z(g) - \bar\Psi(g)^{-2} z(h) = z(g) + \gamma_{-2}(g) z(h)$.

Step 3: the shape at the primes of $T_\ell(\chi)$. Let $p \in T_\ell(\chi)$. We show that there is $w_p \in k_L$ with $z(g) = -w_p(\gamma_{-2}(g) - 1)$ for all $g \in D_p \cap G_K$. By (Dd1) if $p = \ell$ and (Dd2) if $p \in S_\ell(\chi)$ there is $h \in \mathrm{GL}_3(R)$, $h \equiv 1 \pmod{\mathfrak{m}_R}$, such that $h^{-1}\underline{r}(g) h$ is upper triangular for $g \in D_p \cap G_K$. Put $H = \varphi(h) \in \mathrm{GL}_3(\mathcal{O}_L)$, $H \equiv 1 \pmod{\mathfrak{m}_L}$, and $U_g = H^{-1} P_g H$, upper triangular. Comparing the entries $(1,1)$ and $(3,1)$ of $P_g H = H U_g$ and using $(P_g)_{32} = 0$: $(P_g H)_{11} = H_{11}(U_g)_{11}$ and $x b(g) H_{11} + (P_g)_{33} H_{31} = H_{31}(U_g)_{11}$. Multiplying the second by H_{11} and inserting the first,

$$x\, b(g)\, H_{11}^2 = H_{31} V_g, \qquad V_g = (P_g)_{11}H_{11} + (P_g)_{12}H_{21} + (P_g)_{13}H_{31} - (P_g)_{33}H_{11},$$

with $\bar V_g = \bar\Psi(g) - \bar\Psi(g)^{-1}$. By Lemma 46.9 choose $s_p \in D_p \cap G_K$ with $\bar\Psi(s_p)^2 \neq 1$; then

$\bar{V}_{s_p} \neq 0$, $V_{s_p} \in \mathcal{O}_L^\times$ and $H_{31} = xb(s_p)H_{11}^2 V_{s_p}^{-1}$. Substituting and cancelling $xH_{11}^2 \neq 0$ (H_{11} is a unit), $b(g) = b(s_p)V_g V_{s_p}^{-1}$, so $\bar{b}(g) = w_p(\bar{\Psi}(g) - \bar{\Psi}(g)^{-1})$ with $w_p = \bar{b}(s_p)\bar{V}_{s_p}^{-1}$, and $z(g) = w_p(1 - \bar{\Psi}(g)^{-2}) = -w_p(\gamma_{-2}(g) - 1)$ ($\eta_K(g) = 1$).

Step 4: z satisfies the local conditions of Z_{-2}. (a) Let $\bar{v}$ be a place above a prime $p \notin T_\ell(\chi)$ and $g \in N_{\bar{v}}$. By (Dd3), $r(g) = 1$, so $P_g = 1$, $b(g) = 0$ and $z(g) = 0$. (b) Let $p \in S_\ell(\chi)$. As $N_{\bar{p}} \subseteq I_{\bar{p}} \cap G_K \subseteq D_p \cap G_K$ and $\bar{\Psi} = 1$ on $N_{\bar{p}}$, Step 3 gives $z = 0$ on $N_{\bar{p}}$. Another place above p is $g_1\bar{p}$ with $g_1 \in G_\mathbb{Q}$, and $N_{g_1\bar{p}} = g_1 N_{\bar{p}} g_1^{-1}$ ($I_{g_1\bar{p}} = g_1 I_{\bar{p}} g_1^{-1}$, and η_K, $\bar{\Psi}$ are characters). For $h \in N_{\bar{p}}$, $\gamma_{-2}(h) = 1$ and $z(h) = 0$, so the cocycle relation gives $z(g_1 h g_1^{-1}) = z(g_1) + \gamma_{-2}(g_1)z(g_1^{-1}) = z(1) = 0$. (c) At ℓ: the map $a(g) = z(g) + w_\ell(\gamma_{-2}(g) - 1)$ on D_ℓ satisfies $a(gh) = a(g) + \gamma_{-2}(g)a(h)$ and vanishes on the normal subgroup $D_\ell \cap G_K$, of index at most 2, by Step 3. If $d \in D_\ell \setminus G_K$ and $h \in D_\ell \cap G_K$, then $a(hd) = \gamma_{-2}(h)a(d)$, while $hd = d(d^{-1}hd)$ gives $a(hd) = a(d)$; taking $h = s_\ell$, with $\gamma_{-2}(s_\ell) = \bar{\Psi}(s_\ell)^{-2} \neq 1$, gives $a(d) = 0$. So $a = 0$ on D_ℓ: $z(g) = \gamma_{-2}(g)y - y$ on D_ℓ with $y = -w_\ell$.

Step 5: contradiction. Choose an $\mathbb{F}_\mathcal{O}$-linear map $\lambda_0 \colon k_L \to \mathbb{F}_\mathcal{O}$ with $\lambda_0(1) = 1$. Since γ_{-2} takes values in $\mathbb{F}_\mathcal{O}^\times$, $\lambda_0 \circ z$ is locally constant, satisfies the cocycle relation for γ_{-2}, vanishes on $N_{\bar{v}}$ for every place $\bar{v}$ above a prime other than ℓ (Step 4 (a), (b); $T_\ell(\chi) \setminus \{\ell\} = S_\ell(\chi)$), and equals $\gamma_{-2}(g)\lambda_0(y) - \lambda_0(y)$ on D_ℓ: so $\lambda_0 \circ z \in Z_{-2}$. As $\mathrm{Sel}_{-2}(\chi, e) = 0$, there is $\mu \in \mathbb{F}_\mathcal{O}$ with $\lambda_0(z(g)) = \gamma_{-2}(g)\mu - \mu$ for all g. At $g = c$: $z(c) = 0$, and $\gamma_{-2}(c) = \eta_K(c)\bar{\Psi}(c)^{-2} = -1$ because $\Psi(c) = 1$; so $2\mu = 0$, $\mu = 0$ (ℓ odd) and $\lambda_0 \circ z = 0$. But $\lambda_0(z(g_0)) = \bar{\Psi}(g_0)^{-1}\lambda_0(1) \neq 0$. Hence φ is of type I.

Step 6: torus conjugacy. For points φ, φ' with $\rho_{\varphi'} \cong \rho_\varphi$, Step 1 and Lemma 42.4, item 2, give $t \in \overline{\mathbb{Q}}_\ell^\times$ with $r_{\varphi'}(g) = (\mathrm{T}(t), 1)r_\varphi(g)(\mathrm{T}(t), 1)^{-1}$ for all g, i.e. $r_{\varphi'} = \mathrm{T}(t) \cdot r_\varphi$. □

Theorem 46.18. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking, (R, r) a dyadic Eisenstein deformation ring for $g_\star$ such that its weight-zero subalgebra R^0 is a finitely generated $\mathcal{O}$-module, and $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Every point φ of (R, r) that is Lie-irreducible automorphic for ι and at which ρ_φ is generic ordinary of level N and weights $(e, 0, -e)$ is rigid.*

Proof. Let φ be a point that is Lie-irreducible automorphic for ι with ρ_φ generic ordinary of level N and weights $(e, 0, -e)$, and y a dyadic tangent cocycle at φ. We show that y is a Bloch–Kato cocycle of $\mathrm{ad}\, r_\varphi$; the finiteness of R^0 is not used. The decomposition and inertia groups of Definition 22.2 at a finite place v of $\mathbb{Q}$ are the groups $D_{\bar{v}} \supseteq I_{\bar{v}}$ of the places $\bar{v}$ of $\overline{\mathbb{Q}}$ above v. We write $g \cdot X$ for the action of $\mathrm{ad}\, r_\varphi$; on G_K it is $X \mapsto \rho_\varphi(g)X\rho_\varphi(g)^{-1}$.

Claim (C). Let I be a group acting linearly on a $\overline{\mathbb{Q}}_\ell$-vector space M, $I' \subseteq I$ a normal subgroup of finite index, and $z \colon I \to M$ a 1-cocycle whose restriction to I' is $g \mapsto g \cdot X - X$ for some $X \in M$. Then z is of this form on I. Indeed, $z' = z - (g \mapsto g \cdot X - X)$ vanishes on I'; so $z'(gh) = z'(g)$ and $z'(hg) = h \cdot z'(g)$ for $h \in I'$, and since $hg = g(g^{-1}hg)$ with $g^{-1}hg \in I'$, $z'(hg) = z'(g)$; hence z' takes values in $M^{I'}$ and factors through the finite group I/I'. Summing $z'(g\gamma) = z'(g) + g \cdot z'(\gamma)$ over representatives γ of I/I' and dividing by $s = [I : I']$ gives $z'(g) = X' - g \cdot X'$ with $X' = s^{-1}\sum_\gamma z'(\gamma)$.

Claim (D). If $y|_{I_{\bar{v}}}$ is a coboundary $g \mapsto g \cdot X - X$, then for every $\sigma \in G_\mathbb{Q}$, $y|_{I_{\sigma\bar{v}}}$ is a coboundary, as $I_{\sigma\bar{v}} = \sigma I_{\bar{v}} \sigma^{-1}$ and, for $g \in I_{\bar{v}}$ and $h = \sigma g \sigma^{-1}$, the cocycle relation gives $y(h) = y(\sigma) + \sigma \cdot y(g) - h \cdot y(\sigma) = h \cdot X'' - X''$ with $X'' = \sigma \cdot X - y(\sigma)$.

Step 1: places $v = p \notin T_\ell(\chi)$. For every place $\bar{v}$ above p, $N_{\bar{v}}$ is the kernel of the homomorphism $g \mapsto (\eta_K(g), \bar{\Psi}(g))$ on $I_{\bar{v}}$ with finite target, hence normal of finite index, and y vanishes on it by (Ty1). By (C), $y|_{I_{\bar{v}}}$ is a coboundary.

Step 2: places $v = p \in S_\ell(\chi)$. By (Ty3) there is $h = h_0 + \epsilon h_1 \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell[\epsilon])$ such that

$h^{-1}r_y(g)h = \Delta(g) := \mathrm{diag}(\psi_1(g),\psi_2(g),\psi_3(g))$ for $g \in I_p \cap G_K$ (the GL-part of r_y is meant). As $h^{-1} = h_0^{-1} - \epsilon h_0^{-1}h_1h_0^{-1}$, with $Z = h_1h_0^{-1}$,

$$r_y(g) = h\Delta(g)h^{-1} = h_0\Delta(g)h_0^{-1} + \epsilon(Zh_0\Delta(g)h_0^{-1} - h_0\Delta(g)h_0^{-1}Z).$$

Reducing modulo ϵ, $\rho_\varphi(g) = h_0\Delta(g)h_0^{-1}$; comparing with $r_y(g) = (1+\epsilon y(g))\rho_\varphi(g)$, $y(g)\rho_\varphi(g) = Z\rho_\varphi(g) - \rho_\varphi(g)Z$, i.e. $y(g) = g\cdot(-Z) - (-Z)$ for $g \in I_p \cap G_K$. The subgroup $I_p \cap G_K$ is the kernel of $\eta_K|_{I_p}$, normal of index at most 2; by (C), $y|_{I_p}$ is a coboundary, and by (D) so is $y|_{I_{\bar v}}$ for every place $\bar v$ above p.

Step 3: the place ℓ and the archimedean place. By Lemma 46.19 (its genericity hypothesis is assumed), the class of $y|_D$ lies in $H^1_f(D, \mathrm{ad}\, r_\varphi)$ for every decomposition group D at ℓ. An archimedean decomposition group D has order at most 2, and by (C) with $I' = 1$ every cocycle on it is a coboundary, so the class of $y|_D$ is $0 = H^1_f(D, \mathrm{ad}\, r_\varphi)$.

Step 4: conclusion. By Steps 1–3, y (continuous by definition) is a Bloch–Kato cocycle of $\mathrm{ad}\, r_\varphi$. The homomorphism r_φ has sign η_K, $K = \mathbb{Q}(i)$, and continuous GL-part restricting to ρ_φ on G_K; as φ is Lie-irreducible automorphic, ρ_φ is irreducible on every open subgroup of G_K and $\rho_\varphi \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type. The module $\mathrm{ad}\, r_\varphi$ is the module $\mathrm{ad}\, r_\varphi$ of Proposition 42.6 (same formulas), so $H^1_f(\mathbb{Q}, \mathrm{ad}\, r_\varphi) = 0$ by that proposition, and $y(g) = g\cdot X - X$ for some $X \in \mathrm{ad}\, r_\varphi$. Hence φ is rigid. □

Lemma 46.19. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking, (R, r) a dyadic Eisenstein deformation ring for $g_\star$, φ a point of (R, r) such that ρ_φ is generic ordinary of level N and weights $(e, 0, -e)$, and y a dyadic tangent cocycle at φ. Then for every decomposition group D of $G_\mathbb{Q}$ at ℓ, the class of $y|_D$ lies in $H^1_f(D, \mathrm{ad}\, r_\varphi)$.*

Proof. Write $K = \mathbb{Q}(i)$, $r_\varphi(g) = (P_g, \varsigma_g)$, and $g\cdot X$ for the action on $\mathrm{ad}\, r_\varphi$. As ℓ is odd (Dy1), it is unramified in K, so η_K is trivial on I_ℓ; put $D' = D_\ell \cap G_K$, a normal subgroup of D_ℓ of index 1 or 2 containing I_ℓ. Fix an embedding $j_0 \colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ inducing $\bar\ell$; then $D_\ell = D_{j_0}$ in the notation of Definition 22.2, and D' is identified with the absolute Galois group of the closure M of $j_0(K)$, with inertia subgroup I_ℓ.

Step 1: finite coefficients. By Lemma 42.8, item 1, there is a finite extension E_0 of $\mathbb{Q}_\ell$ with $\rho_\varphi(G_K) \subseteq \mathrm{GL}_3(E_0)$; by (Ed1), $P_c = 1$, so $P_{cg} = \theta(\rho_\varphi(g)) \in \mathrm{GL}_3(E_0)$ for $g \in G_K$, and $\mathrm{M}_3(E_0)$ is stable under $G_\mathbb{Q}$. By Lemma 42.8, item 3 (with $\Gamma = G_\mathbb{Q}$), y takes values in $\mathrm{M}_3(E_1)$ for a finite extension $E_1 \supseteq E_0$. Let $h = h_0 + \epsilon h_1$ be as in (Ty2), and let $E \supseteq E_1$ be finite containing the entries of h_0 and h_1. Put $V = \mathrm{M}_3(E)$ with the action of $\mathrm{ad}\, r_\varphi$; so $\mathrm{ad}\, r_\varphi = V \otimes_E \overline{\mathbb{Q}}_\ell$, y is a cocycle with values in V, and it suffices to find $Y \in V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g)\otimes 1 = gY - Y$ on D.

Step 2: triangular form on D'. As h is invertible, so is h_0. Reducing (Ty2) modulo ϵ, $\rho'(g) := h_0^{-1}\rho_\varphi(g)h_0 \in \mathrm{GL}_3(E)$ is upper triangular for $g \in D'$, with diagonal entries $\kappa_1(g), \kappa_2(g), \kappa_3(g)$, where the $\kappa_a \colon D' \to E^\times$ are continuous characters with $\kappa_a = \psi_a = \chi^{2-a}\chi_{\mathrm{cyc}}^{e(2-a)}$ on I_ℓ. As χ has finite order, $\kappa_a\chi_{\mathrm{cyc}}^{-m_a}$ has finite image on I_ℓ for $(m_1, m_2, m_3) = (e, 0, -e)$, and $m_1 > m_2 > m_3$ since $e \geq 1$.

Step 3: $\kappa_a \neq \kappa_b\chi_{\mathrm{cyc}}$ on D' for all a, b. Let v be the place of K below $\bar\ell$. As ρ_φ is generic ordinary, there are a place $\bar v$ of $\overline{\mathbb{Q}}$ above v and characters $\kappa'_1, \kappa'_2, \kappa'_3$ of $D_{\bar v} \subseteq G_K$ such that ρ_φ is triangular on $D_{\bar v}$ with diagonal (κ'_i) and $\kappa'_i \neq \kappa'_j\chi_{\mathrm{cyc}}$ for all i, j. Since G_K acts transitively on the places above v, $\bar v = \tau\bar\ell$ and $D_{\bar v} = \tau D'\tau^{-1}$ for some $\tau \in G_K$. For $g \in D'$, $\rho_\varphi(\tau g\tau^{-1}) = \rho_\varphi(\tau)\rho_\varphi(g)\rho_\varphi(\tau)^{-1}$, so $\rho_\varphi|_{D'}$ is also triangular with diagonal $(\kappa'_i(\tau\cdot\tau^{-1}))$. The diagonal characters of a triangular representation are its Jordan–Hölder factors, so $\{\kappa_a\} = \{\kappa'_i(\tau\cdot\tau^{-1})\}$ as multisets; as $\chi_{\mathrm{cyc}}(\tau g\tau^{-1}) = \chi_{\mathrm{cyc}}(g)$, the claim follows.

Step 4: $y|_{D'}$ is crystalline. Put $Z' = h_0^{-1}h_1$, $y'(g) = h_0^{-1}y(g)h_0$ and $u(g) = y'(g) + \rho'(g)Z'\rho'(g)^{-1} - Z'$ for $g \in D'$. The GL-part of $r_y(g)$ is $(1+\epsilon y(g))\rho_\varphi(g)$, and $h^{-1} = h_0^{-1} - \epsilon h_0^{-1}h_1h_0^{-1}$, so

$$h^{-1}(1+\epsilon y(g))\rho_\varphi(g)h = \rho'(g) + \epsilon(y'(g)\rho'(g) + \rho'(g)Z' - Z'\rho'(g)) = \rho'(g) + \epsilon\, u(g)\rho'(g).$$

By (Ty2) this matrix is upper triangular for $g \in D'$, with diagonal $\psi_a(g) \in \overline{\mathbb{Q}}_\ell$ for $g \in I_\ell$. Hence $u(g)\rho'(g)$, and so $u(g) = (u(g)\rho'(g))\rho'(g)^{-1}$, is upper triangular, and the diagonal of $u(g)\rho'(g)$, which is the diagonal of $u(g)$ times that of $\rho'(g)$, vanishes for $g \in I_\ell$. Conjugation $X \mapsto h_0^{-1}Xh_0$ is an isomorphism of $E[D']$-modules from $V|_{D'}$ to $\operatorname{ad}\rho'$ (notation of Lemma 44.14) carrying y to y', and $u = y' + (g \mapsto g\cdot Z' - Z')$ is a cocycle of $\operatorname{ad}\rho'$ with values in the upper triangular matrices whose diagonal vanishes on I_ℓ. By Steps 2 and 3, Lemma 44.14 applies (with M, $G_M = D'$, $I_M = I_\ell$, $n = 3$) and gives Y' with $u(g)\otimes 1 = gY' - Y'$; then $y'(g)\otimes 1 = g(Y' - Z'\otimes 1) - (Y' - Z'\otimes 1)$, and conjugating back by h_0 gives $Y_1 \in V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $y(g)\otimes 1 = gY_1 - Y_1$ for $g \in D'$.

Step 5: the group D_ℓ. If $D' \neq D_\ell$, let $z(g) = y(g)\otimes 1 - (gY_1 - Y_1)$ for $g \in D_\ell$, a cocycle with values in $V \otimes B_{\mathrm{cris}}$ vanishing on D'. For $h' \in D'$, $z(gh') = z(g)$ and $z(h'g) = h'z(g)$, while $h'g = g(g^{-1}h'g)$ with $g^{-1}h'g \in D'$ gives $z(h'g) = z(g)$; so z factors through $D_\ell/D' = \{1, \gamma D'\}$. Summing $z(g\gamma') = z(g) + gz(\gamma')$ over $\gamma' \in \{1, \gamma\}$, and using that $g\gamma'$ runs over both cosets, $z(g) = Y_2 - gY_2$ with $Y_2 = \frac{1}{2}(z(1) + z(\gamma))$. Hence $y(g)\otimes 1 = gY_0 - Y_0$ on D_ℓ with $Y_0 = Y_1 - Y_2$ (and $Y_0 = Y_1$ if $D' = D_\ell$).

Step 6: every decomposition group at ℓ. Every embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ is $j = j_0 \circ \sigma$ for some $\sigma \in G_{\mathbb{Q}}$, and then $D_j = \sigma^{-1}D_\ell\sigma$, the element $g = \sigma^{-1}g_0\sigma$ ($g_0 \in D_\ell$) acting on B_{cris} as g_0 does. The cocycle relation gives $y(g) = \sigma^{-1}\cdot y(g_0) + g\cdot w - w$ with $w = \sigma^{-1}\cdot y(\sigma)$. Put $Y = (\sigma^{-1}\otimes 1)Y_0 + w\otimes 1$; since g acts on V as $\sigma^{-1}g_0\sigma$ and on B_{cris} as g_0, $g(\sigma^{-1}\otimes 1)Y_0 = (\sigma^{-1}\otimes 1)(g_0Y_0)$, so $gY - Y = (\sigma^{-1}\cdot y(g_0) + g\cdot w - w)\otimes 1 = y(g)\otimes 1$. So the class of $y|_{D_j}$ lies in $H^1_f(D_j, V)$, and in $H^1_f(D_j, \operatorname{ad} r_\varphi)$ by extension of scalars. □

Part IX
Automorphy of Eisenstein deformations

Part IX proves the three automorphy theorems that Part VIII uses: Theorem 47.1 for the unitary Eisenstein deformation rings, used in Proposition 42.2; Theorem 51.1 for the symplectic data, used in Proposition 44.3; and Theorem 47.16 for the dyadic rings, used in Proposition 46.2. Each has the same two parts. The subalgebra of weight zero of the deformation ring is finite over $\mathcal{O}$, which is condition (Gc2) of the criterion. And the points that matter are automorphic: those of type I are admissible of stable type, those of type II come from newforms of weight $2e + 1$, and in the symplectic case there are no endoscopic points and every irreducible point is automorphic. This identifies the two-signed points of the criterion with automorphic Galois representations, whose Frobenius traces Section 38 counts.

The method is $R = T$ for residually reducible representations, in the line of Skinner and Wiles [236] and Thorne [256], with Hida theory and patching. Every point of an Eisenstein deformation ring is a triangular lift of the Eisenstein representation. Over an auxiliary abelian CM field L whose Selmer ranks are small compared with its degree, these lifts become polarised ordinary lifts for which an $R = T$ theorem is proved. Its Hecke side comes from Hida theory for ordinary forms on a definite unitary group [105] and from patching in the manner of Taylor and Wiles [254], which give a modular ideal in the deformation ring. Modularity is then propagated from seeds, ordinary newforms congruent to Eisenstein series, to every component: the components through the reducible locus are connected, and the reducible locus is small compared with their dimension. Automorphy finally descends from L to K. The symplectic case follows the same plan in rank four, with auxiliary totally real towers and chains of residual pairs.

Section 47 deduces the unitary and dyadic theorems from the automorphy of triangular lifts, which Section 48 reduces to an auxiliary field. Section 49 proves $R = T$ over the auxiliary field from seeds, from propagation and from the Hecke realisation, which Section 50 constructs; the Hida theory and the patching behind it are in Appendix E. Sections 51–53 prove the symplectic theorem: Section 51 reduces it to essential test representations, Section 52 connects those to seeds by chains, and Section 53 supplies the Hecke side and the propagation in rank four.

47 Automorphy at the points of the Eisenstein deformation rings

This section proves Theorem 47.1 and Theorem 47.16, the automorphy theorems used in Proposition 42.2 and Proposition 46.2, from the automorphy of triangular lifts, Theorem 48.1, which is proved in Section 48. The points of the normalised ordinary and of the dyadic deformation rings are triangular lifts of the Eisenstein representation (Lemma 47.3, Lemma 47.4). Finiteness in weight zero, (Au1) and (Da1), comes from a test in characteristic ℓ (Proposition 47.2). If the triangular lifts to test rings of characteristic ℓ have the residual characteristic polynomials on a subgroup of finite index, which is clause (Tp1) of Theorem 48.1, they are upper or lower triangular with the residual diagonal (Lemma 47.5), so the products of weight zero are constant at the points of characteristic ℓ, and this makes R^0 finite (Proposition 47.6). Automorphy, (Au2) and (Da2), comes from clause (Tp2): an irreducible triangular lift is Lie-irreducible (Lemma 47.8), and its level, weights and genericity at ℓ are read off from its local shape (Lemma 47.9, Proposition 47.11). In weight one with trivial ℓ-component, crystallinity and genericity at ℓ need separate arguments (Proposition 47.13, Proposition 47.12). The endoscopic clause (Au3) comes from clause (Tp3), which makes the corner of a lift of type II modular.

Theorem 47.1. *Let (K, ℓ, e, N, χ) be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with $e_\mathcal{O} = 1$, let d_K be the discriminant of K, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. There is a marking $g_\star$ such that for every normalised ordinary Eisenstein deformation ring (R, r) for $g_\star$:*

(Au1) *R^0 is a finitely generated $\mathcal{O}$-module;*

(Au2) *for every point φ of type I, ρ_φ is admissible of stable type for (ι, e, N) and irreducible on every open subgroup of G_K;*

(Au3) *for every point φ of type II, ρ_φ is admissible of endoscopic type for $(\iota, e, N|d_K|)$, and every continuous representation $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $W(g) = \left(\rho_\varphi(g)_{ab}\right)_{a,b\in\{1,3\}}$ for all $g \in G_K$ and $\operatorname{tr} W(c) = 0$ satisfies the witness conditions over imaginary quadratic fields and the condition (Eo2) (for some normalised newform of weight $2e + 1$).*

Proof. Choice of the marking. By Theorem 48.1, case (a), there is a marking $g_\star$ with (Tp1)–(Tp3). Let (R, r) be a normalised ordinary Eisenstein deformation ring for $g_\star$.

(Au1). By (Tp1) the hypothesis of Proposition 47.2, case (a), holds for $g_\star$, so R^0 is a finitely generated $\mathcal{O}$-module.

Torus conjugates. Let φ be a point of (R, r). By Lemma 47.3 (which does not use (Au1)) there are an integral test ring A, $t \in \overline{\mathbb{Q}}_\ell^\times$ and a triangular lift r' to A for $g_\star$ with $r' = \mathrm{T}(t) \cdot r_\varphi$. Since $(\mathrm{T}(t), 1)(X, 1)(\mathrm{T}(t), 1)^{-1} = (\mathrm{T}(t)X\mathrm{T}(t)^{-1}, 1)$, we have $\rho_{r'}(g) = \mathrm{T}(t)\rho_\varphi(g)\mathrm{T}(t)^{-1}$ for $g \in G_K$: the entry (a, b) is multiplied by t^{b-a}. Being irreducible on a subgroup, the attached-to relation, automorphy of conjugate self-dual type, level and weights, triangularity and genericity on decomposition groups, the witness conditions, condition (Eo2) and the witness conditions over imaginary quadratic fields depend only on the isomorphism class of the representation; we use this without further comment.

(Au2). Let φ be of type I. Then $\rho_{r'} \cong \rho_\varphi$ is irreducible, so by Lemma 47.8, (Li1), $\rho_{r'}$ and hence ρ_φ is irreducible on every open subgroup of G_K. By (Tp2), $\rho_{r'} \otimes \varepsilon^{-1}$, hence $\rho_\varphi \otimes \varepsilon^{-1}$, is automorphic of conjugate self-dual type for ι and satisfies the witness conditions: this is (Sb2). (Sb1) is the definition of type I. For (Sb3), (Sb4): if $e \geq 2$ or $\chi_\ell \neq \mathbf{1}$, Proposition 47.11, (Cv1), applied to r' shows that $\rho_{r'}$, hence ρ_φ, has level N and weights $(e, 0, -e)$ and is generic ordinary of level N and weights $(e, 0, -e)$. If $e = 1$ and $\chi_\ell = \mathbf{1}$, then by Proposition 47.12 (applied with ι; its hypothesis, automorphy of $\rho_\varphi \otimes \varepsilon^{-1}$ of conjugate self-dual type, was just shown), ρ_φ, hence $\rho_{r'}$, is generic at every place $v \mid \ell$ of K, and (Cv1) applied to r' gives the same conclusion. So ρ_φ is admissible of stable type for (ι, e, N).

(Au3). Let φ be of type II. Conjugation by $\mathrm{T}(t)$ keeps the vanishing of the entries of odd weight, leaves the entry $(2, 2)$ unchanged and replaces the corner by its conjugate under $D = \operatorname{diag}(t, t^{-1})$; so r' is of type II, and $\rho_\varphi(g)_{22} = \rho_{r'}(g)_{22} = 1$ for $g \in G_K$ by Proposition 47.11, (Cv2), applied to r'. Let $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ be continuous, equal to the corner of ρ_φ on G_K, with $\operatorname{tr} W(c) = 0$. Then $W' = DWD^{-1}$ is continuous, equal to the corner of r' on G_K, and $\operatorname{tr} W'(c) = 0$; by (Tp3) W', hence W, satisfies (Eo2) and the witness conditions over imaginary quadratic fields. This is the second assertion of (Au3). By (Cv2) for r' there is a continuous W_0 equal to the corner of r' on G_K with $\operatorname{tr} W_0(c) = 0$; then $D^{-1}W_0D$ is continuous, equal to the corner of ρ_φ on G_K, with trace 0 at c: such a W exists. For such a W we check (Eo1)–(Eo4) with $M = N|d_K|$. (Eo1): $W|_{G_K}$ is the corner, irreducible by the definition of type II, so W is irreducible, and it satisfies the witness conditions over imaginary quadratic fields. (Eo2) was just shown. (Eo3): by (Cv2) for r', $W' = DWD^{-1}$ has level $N|d_K|$ and weights $(e, -e)$, and $\det W' = \eta_K$ is a character of level $|d_K|$; these properties pass to the conjugate W, and

$\det W = \det W'$. (Eo4): for $s \in G_K$ the entries $(1,2),(2,1),(2,3),(3,2)$ of $\rho_\varphi(s)$ have odd weight and vanish, and the entry $(2,2)$ is 1, so $\rho_\varphi(s)$ is the matrix of (Eo4) built from $W(s)$, with the identity as conjugating matrix. So ρ_φ is admissible of endoscopic type for $(\iota, e, N|d_K|)$. □

Proposition 47.2. *Let $\mathcal{O}$ be a coefficient ring and assume (a) (K,ℓ,e,N,χ) is a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $e_\mathcal{O} = 1$, or (b) (ℓ,e,N,χ,o,m) is a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $K = \mathbb{Q}(i)$; form triangular lifts with K, $\mathcal{O}$ and $\Psi_{\chi,e}$. Let $g_\star$ be a marking, and let (R,r) be a normalised ordinary Eisenstein deformation ring for $g_\star$ in case (a), a dyadic Eisenstein deformation ring for $g_\star$ in case (b). Assume there is a subgroup U of finite index in $G_\mathbb{Q}$ such that for every test ring A of characteristic ℓ, every triangular lift r' to A for $g_\star$ and every $g \in U \cap G_K$, the characteristic polynomials of $\underline{r}'(g)$ and $\underline{r_0}(g)$ agree. Then R^0 is a finitely generated $\mathcal{O}$-module.*

Proof. We verify the hypothesis of Proposition 47.6, which then gives the claim. Let A be a test ring of characteristic ℓ whose structure map kills $\mathfrak{m}_\mathcal{O}$, $\varphi\colon R \to A$ a homomorphism of $\mathcal{O}$-algebras with $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, and $y = \prod_k \underline{r}(g_k)_{a_k b_k}$ with $g_k \in G_\mathbb{Q}$ and $\sum_k \mathrm{wt}(a_k,b_k) = 0$; write $\bar{x}$ for the image in A of $x \in \mathcal{O}$.

Step 1: $r' = \varphi \circ r$ is a triangular lift to A for $g_\star$. In case (a) this is Lemma 47.3 (its general form), in case (b) Lemma 47.4.

Step 2: the shape of r' on G_K. For $g \in U \cap G_K$, the hypothesis and $\underline{r_0}(g) = \mathrm{T}(\Psi(g))$ give $\det(X - \underline{r}'(g)) = \prod_a (X - \overline{\psi_a(g)})$. The prime ℓ is odd ((Ue9) excludes $\ell = 2$ in case (a); (Dy1) in case (b)), and $\Psi(c) = 1$ ((Ue5), resp. (Dy3)). So Lemma 47.5 applies to r': either the entries of negative weight of $\underline{r}'(g)$ vanish for all $g \in G_K$, or those of positive weight do, and $\underline{r}'(g)_{aa} = \overline{\psi_a(g)}$ for $g \in G_K$.

Step 3: $\varphi(y)$ is constant. By (Ed1), $r(c) = (1,-1)$. For $g \notin G_K$, $gc \in G_K$, $r(gc) = (P,1)$ with $P = \underline{r}(gc)$, and $r(g) = r(gc)r(c) = (P,1)(1,-1) = (P,-1)$, so $\underline{r}(g) = \underline{r}(gc)$. Replacing each $g_k \notin G_K$ by $g_k c$ we may assume all $g_k \in G_K$; then $\varphi(y) = \prod_k \underline{r}'(g_k)_{a_k b_k}$. Suppose the entries of negative weight vanish on G_K (the other case is symmetric). If some factor has $\mathrm{wt}(a_k,b_k) \neq 0$, then, the weights summing to 0, some factor has negative weight and vanishes, so $\varphi(y) = 0 = \bar{0}$. Otherwise $a_k = b_k$ for all k and $\varphi(y) = \prod_k \overline{\psi_{a_k}(g_k)} = \overline{\prod_k \psi_{a_k}(g_k)}$. In both cases $\varphi(y)$ lies in the image of $\mathcal{O}$. □

Lemma 47.3. *Let (K,ℓ,e,N,χ) be a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with $e_\mathcal{O} = 1$, let $g_\star$ be a marking and (R,r) a normalised ordinary Eisenstein deformation ring for $g_\star$. For every point φ of (R,r) there are an integral test ring A, an element $t \in \overline{\mathbb{Q}}_\ell^\times$ and a triangular lift r' to A for $g_\star$ such that $r'(g) = (\mathrm{T}(t) \cdot r_\varphi)(g)$ in $\mathcal{G}_3(\overline{\mathbb{Q}}_\ell)$ for all $g \in G_\mathbb{Q}$; one can take $t = 1$. More generally, for every test ring A (integral or of characteristic ℓ) and every homomorphism of $\mathcal{O}$-algebras $\varphi\colon R \to A$ with $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, $\varphi \circ r$ is a triangular lift to A for $g_\star$.*

Proof. If φ is a point, (Ol1) gives an integral test ring A with $\varphi(R) \subseteq A$ and $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, and with $t = 1$ the first assertion follows from the second, as $\varphi \circ r = r_\varphi = \mathrm{T}(1) \cdot r_\varphi$. So let A be a test ring and $\varphi\colon R \to A$ a homomorphism of $\mathcal{O}$-algebras with $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, and put $r' = \varphi \circ r\colon G_\mathbb{Q} \to \mathcal{G}_3(A)$. We check (Tl1)–(Tl4) for $g_\star$.

(Tl1): r is a lift of $\bar{r}_0$, so its sign is η_K, the entries of $\underline{r}(g) - \underline{r_0}(g)$ lie in $\mathfrak{m}_R$ and are mapped into $\mathfrak{m}_A$; the entries of $\underline{r}$ are continuous for the $\mathfrak{m}_R$-adic topology, hence locally constant modulo $\mathfrak{m}_R^n$, and $\varphi(\mathfrak{m}_R^n) \subseteq \mathfrak{m}_A^n$. (Tl2) is the image of (Ed1). (Tl3): let $\bar{v} \nmid \ell$ and $g \in I_{\bar{v}}$ with $\eta_K(g) = 1$ and $\Psi(g) = 1$; then $\bar{r}_0(g) = (\mathrm{T}(\bar{\Psi}(g)),1) = 1$, so $r(g) = 1$ by (Ed2) and $r'(g) = 1$. (Tl4): by (Ed3), $r|_{D_\ell} = f \circ r_\ell^\square$ for a morphism f of $\mathrm{CNL}_\mathcal{O}$ with $f(I_\ell^{\mathrm{ord}}) = 0$. Then $x = \varphi \circ f\colon R_\ell^\square \to A$ is

an $\mathcal{O}$-algebra homomorphism with $x(\mathfrak{m}_{R_\ell^\square}) \subseteq \varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$ and $x(I_\ell^{\mathrm{ord}}) = 0$, and the GL-part of $x \circ r_\ell^\square$ is $\underline{r}'|_{D_\ell}$. (Ol2) gives $h \in \mathrm{GL}_3(A)$, $h \equiv 1 \pmod{\mathfrak{m}_A}$, with $h^{-1}\underline{r}'(g)h$ upper triangular for $g \in D_\ell \cap G_K$ and diagonal $(\psi_1(g), \psi_2(g), \psi_3(g))$ for $g \in I_\ell$. This is (Tl4). □

Lemma 47.4. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, $g_\star$ a marking and (R, r) a dyadic Eisenstein deformation ring for $g_\star$. For every test ring A (integral or of characteristic ℓ) and every homomorphism of $\mathcal{O}$-algebras $\varphi\colon R \to A$ with $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, $\varphi \circ r$ is a triangular lift to A for $g_\star$.*

Proof. Put $r'' = \varphi \circ r\colon G_\mathbb{Q} \to \mathcal{G}_3(A)$. (Tl1): r is a lift of $\bar{r}_0$, so its sign is η_K and the entries of $\underline{r}(g) - \underline{r_0}(g)$ lie in $\mathfrak{m}_R$, which φ maps into $\mathfrak{m}_A$; the entries of $\underline{r}$ are continuous for the $\mathfrak{m}_R$-adic topology, hence locally constant modulo $\mathfrak{m}_R^n$, and $\varphi(\mathfrak{m}_R^n) \subseteq \mathfrak{m}_A^n$. (Tl2): r satisfies (Ed1) for $g_\star$, and so does its image. (Tl3): let $\bar{v}$ be a place of $\overline{\mathbb{Q}}$ above a prime $p \neq \ell$, and $g \in I_{\bar{v}}$ with $\eta_K(g) = \Psi(g) = 1$. If $p \notin T_\ell(\chi)$, then $g \in N_{\bar{v}}$ and $r(g) = 1$ by (Dd3). If $p \in S_\ell(\chi)$, write $\bar{v} = \gamma\bar{p}$ with $\gamma \in G_\mathbb{Q}$ and $g = \gamma g_0 \gamma^{-1}$ with $g_0 \in I_p$; then $\eta_K(g_0) = \Psi(g_0) = 1$, and by (Dd2) $h^{-1}\underline{r}(g_0)h$ is diagonal with entries $\psi_a(g_0) = \Psi(g_0)^{2-a} = 1$, so $r(g_0) = (1, 1)$ and $r(g) = 1$. As $T_\ell(\chi) = \{\ell\} \cup S_\ell(\chi)$, this covers all $p \neq \ell$, and $r''(g) = \varphi(r(g)) = 1$. (Tl4): apply φ to the matrix h of (Dd1); $\varphi(h) \equiv 1 \pmod{\mathfrak{m}_A}$, and $\varphi(h)^{-1}\underline{r''}(g)\varphi(h)$ is the image of $h^{-1}\underline{r}(g)h$, upper triangular for $g \in D_\ell \cap G_K$ with diagonal $\psi_1(g), \psi_2(g), \psi_3(g)$ (mapped to A) for $g \in I_\ell$. □

Lemma 47.5. *Let ℓ be an odd prime, $K \subset \overline{\mathbb{Q}}$ an imaginary quadratic field, $\mathcal{O}$ a coefficient ring with residue field $\mathbb{F}_\mathcal{O}$, $c \in G_\mathbb{Q}$ a complex conjugation and $\Psi\colon G_\mathbb{Q} \to \mathcal{O}^\times$ a continuous character with $\Psi(c) = 1$; form triangular lifts with K, $\mathcal{O}$ and Ψ, and let $g_\star$ be a marking. Let A be a test ring of characteristic ℓ whose structure map $\mathcal{O} \to A$ kills $\mathfrak{m}_\mathcal{O}$, write $\bar{x}$ for the image in A of $x \in \mathcal{O}$, and let r be a triangular lift to A for $g_\star$. Assume that there is a subgroup U of finite index in $G_\mathbb{Q}$ such that $\det(X - \underline{r}(g)) = \prod_{a=1}^3 (X - \overline{\psi_a(g)})$ for every $g \in U \cap G_K$. Then either the entries of negative weight of $\underline{r}(g)$ vanish for all $g \in G_K$, or the entries of positive weight of $\underline{r}(g)$ vanish for all $g \in G_K$; and $\underline{r}(g)_{aa} = \overline{\psi_a(g)}$ for all $g \in G_K$ and $a = 1, 2, 3$.*

Proof. Let $\rho\colon G_K \to \mathrm{GL}_3(A)$ be the restriction of $\underline{r}$, $\mathfrak{m}_A$ the maximal ideal of A, $k = A/\mathfrak{m}_A$ and $\bar{k}$ an algebraic closure of the fraction field of A, a field of characteristic $\ell \neq 2$. By (Tl1), $\rho(g) \equiv \mathrm{T}(\overline{\Psi(g)}) \pmod{\mathfrak{m}_A}$ for $g \in G_K$, and $\overline{\Psi(g)}$ is the image of the reduction of $\Psi(g)$ in $\mathbb{F}_\mathcal{O}^\times$, a root of unity of order prime to ℓ.

Step 1: the shape over $\bar{k}$. View r as a homomorphism into $\mathcal{G}_3(\bar{k})$. (Ns1) holds by (Tl1), (Tl2): the sign is η_K and $\underline{r}(c) = 1$; (Ns2) is part of (Tl2); and $g_\star \in G_K$. By (Tl1), $\underline{r}(g_\star)_{11} - \underline{r}(g_\star)_{33} \equiv \overline{\Psi(g_\star)} - \overline{\Psi(g_\star)}^{-1} \pmod{\mathfrak{m}_A}$, a unit because $\Psi(g_\star)^2 - 1 \in \mathcal{O}^\times$; so (Ns3) holds. By Lemma 42.4, item 1, over the field $\bar{k}$: ρ is irreducible over $\bar{k}$, or upper (entries of negative weight vanish on G_K), or lower (entries of positive weight vanish), or of type II: the entries of odd weight vanish on G_K and the corner $\tau(g) = (\rho(g)_{ab})_{a,b\in\{1,3\}}$ is irreducible over $\bar{k}$.

Step 2: a normal subgroup on which ρ is unipotent. Let V be the intersection of the conjugates of U in $G_\mathbb{Q}$ (finitely many, U having finite index), of G_K and of the kernel of the reduction $\bar{\Psi}\colon G_\mathbb{Q} \to \mathbb{F}_\mathcal{O}^\times$. It is a normal subgroup of finite index of $G_\mathbb{Q}$ contained in $U \cap G_K$, and $\overline{\psi_a(g)} = 1$ for $g \in V$. So $\det(X - \rho(g)) = (X - 1)^3$ for $g \in V$.

Step 3: ρ is not irreducible and not of type II. Suppose it is, and let W be ρ in the first case and τ in the second: an irreducible representation of G_K over $\bar{k}$ of dimension $d \in \{3, 2\}$ with matrices in $\mathrm{GL}_d(A)$, which modulo $\mathfrak{m}_A$ are diagonal with entries in $\overline{\Psi(G_K)}$. For $g \in V$, $\det(X - W(g)) = (X - 1)^d$ (in the second case $\rho(g)$ is the direct sum of $\tau(g)$ on $\bar{k}e_1 \oplus \bar{k}e_3$ and $\rho(g)_{22}$ on $\bar{k}e_2$, so $\det(X - \tau(g))$ divides $(X - 1)^3$). By Clifford's theorem ($V \cap G_K = V$ is normal of finite index in G_K), $W|_V$ is semisimple; it has the characteristic polynomials of the trivial

representation of dimension d, so by the Brauer–Nesbitt theorem it is trivial: $W(V) = 1$. Hence $G' = W(G_K)$ is a finite subgroup of $\mathrm{GL}_d(A)$. Let P be the kernel of reduction $G' \to \mathrm{GL}_d(k)$, a normal subgroup of G' inside $1 + \mathrm{M}_d(\mathfrak{m}_A)$. Every $y = 1 + Y \in P$ has ℓ-power order: if its order is $\ell^a m'$ with $\ell \nmid m'$, then $y^{\ell^a} = 1 + Y^{\ell^a}$ (characteristic ℓ) has order m', and $0 = (1+Y')^{m'} - 1 = Y'(m' + Y'Q)$ with $Y' = Y^{\ell^a}$ and Q a polynomial in Y'; $m' + Y'Q$ is invertible (its reduction is $m' \neq 0$ in k), so $Y' = 0$ and $m' = 1$. So P is a finite ℓ-group, and its fixed vectors in $\bar{k}^d$ form a non-zero subspace (a finite ℓ-group acting on a non-zero vector space in characteristic ℓ fixes a non-zero vector), stable under G' because P is normal. By irreducibility P acts trivially, so $P = 1$, and G' embeds into the group of diagonal matrices of $\mathrm{GL}_d(k)$ with entries in $\overline{\Psi(G_K)}$: G' is abelian of order prime to ℓ. Its representation on $\bar{k}^d$ is then semisimple (Maschke) and, $\bar{k}$ being algebraically closed, a sum of $d \geq 2$ characters, so reducible: a contradiction.

Step 4: the diagonal. By Steps 1 and 3, ρ is upper or lower. In either case the diagonal entry maps $\kappa_a(g) = \rho(g)_{aa}$ are homomorphisms $G_K \to A^\times$ (the diagonal of a product of triangular matrices is the product of the diagonals), with $\kappa_a(g) \equiv \overline{\psi_a(g)} \pmod{\mathfrak{m}_A}$ by (Tl1), and $\kappa_a(g) = 1$ for $g \in V$ by Step 2 (the eigenvalues of a triangular matrix are its diagonal entries). So $\mu_a = \kappa_a \cdot \overline{\psi_a}^{-1}$ is a homomorphism $G_K \to 1 + \mathfrak{m}_A$ trivial on V, hence of finite order. An element $1 + y$ of finite order $\ell^a m'$ ($\ell \nmid m'$) of $1 + \mathfrak{m}_A$ satisfies, as in Step 3 with $d = 1$, $y^{\ell^a} = 0$, so $y = 0$ (A is a domain). Hence $\mu_a = 1$ and $\kappa_a = \overline{\psi_a}$ on G_K. □

Proposition 47.6. *Let $\mathcal{O}$ be a coefficient ring and assume (a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $e_{\mathcal{O}} = 1$, or (b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$. Let $g_\star$ be a marking and (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$ in case (a), a dyadic Eisenstein deformation ring for $g_\star$ in case (b). Assume that for every test ring A of characteristic ℓ whose structure map $\mathcal{O} \to A$ kills $\mathfrak{m}_{\mathcal{O}}$, every homomorphism of $\mathcal{O}$-algebras $\varphi\colon R \to A$ with $\varphi(\mathfrak{m}_R) \subseteq \mathfrak{m}_A$, and every product $y = \prod_{k=1}^{n} \underline{r}(g_k)_{a_k b_k}$ with $g_k \in G_{\mathbb{Q}}$ and $\sum_k \mathrm{wt}(a_k, b_k) = 0$, the element $\varphi(y)$ lies in the image of $\mathcal{O}$ in A. Then R^0 is a finitely generated $\mathcal{O}$-module.*

Proof. Step 1: a presentation with homogeneous kernel in which every entry is homogeneous. In case (a), Proposition 43.12 (with (Bx3) of Proposition 43.5) gives a normalised ordinary Eisenstein deformation ring (R_1, r_1) for $g_\star$ and a weighted presentation $(\sigma, \mathrm{wt}, \pi_1)$ of R_1 with $\ker \pi_1 = \mathfrak{a} + (u_{j,i})$, where $\mathfrak{a}$ is generated by finitely many elements of single weights and $u_{j,i} \in P_j$; by (Pq3) (clause (Mp2) there), $\underline{r_1}(g)_{ab} \in q(A_{\mathrm{wt}(a,b)}) = \pi_1(P_{\mathrm{wt}(a,b)})$. In case (b), Proposition 46.6 gives a dyadic Eisenstein deformation ring (R_1, r_1) for $g_\star$ and a weighted presentation $(\sigma, \mathrm{wt}, \pi_1)$ whose kernel is generated by a homogeneous generating system, with $\underline{r_1}(g)_{ab} \in \pi_1(P_{\mathrm{wt}(a,b)})$ by (Dw2). By the universal properties there are morphisms $f\colon R_1 \to R$, $f_1\colon R \to R_1$ with $f \circ r_1 = r$, $f_1 \circ r = r_1$; then $(f \circ f_1) \circ r = r$, so $f \circ f_1 = \mathrm{id}$ by uniqueness, and likewise $f_1 \circ f = \mathrm{id}$. Put $\pi = f \circ \pi_1$. Then $\pi\colon P \to R$ is a surjective continuous $\mathcal{O}$-algebra homomorphism with $\pi(\mathfrak{m}_P) = \mathfrak{m}_R$ ($\pi(\mathfrak{m}_P)$ is an ideal with residue ring a quotient of $\mathbb{F}_{\mathcal{O}}$), $\ker \pi$ is generated by finitely many $h_1, \dots, h_m$ with $h_i \in P_{\kappa_i}$, and

$$\underline{r}(g)_{ab} \in \pi\big(P_{\mathrm{wt}(a,b)}\big) \qquad (g \in G_{\mathbb{Q}},\ 1 \leq a, b \leq 3). \tag{47.1}$$

Step 2: the weight-zero projection. For $f = \sum_i c_i h_i \in \ker \pi$, $f_{(0)} = \sum_i (c_i)_{(-\kappa_i)} h_i \in \ker \pi$, since h_i has the single weight κ_i. Hence $\mathrm{E}(\pi(f)) = \pi(f_{(0)})$ is a well-defined $\mathcal{O}$-linear map $\mathrm{E}\colon R \to R$ with image $C = \pi(P_0)$. For $p \in P_0$ and $f \in P$, $(pf)_{(0)} = p f_{(0)}$, so $\mathrm{E}(cy) = c\,\mathrm{E}(y)$ for $c \in C$, $y \in R$, and $\mathrm{E}(c) = c$. Consequently, for every ideal $\mathfrak{p}$ of C,

$$\mathfrak{p}R \cap C = \mathfrak{p}: \qquad \textstyle\sum_i a_i y_i \in C\ (a_i \in \mathfrak{p}) \ \Rightarrow\ \sum_i a_i y_i = \mathrm{E}\big(\sum_i a_i y_i\big) = \sum_i a_i \mathrm{E}(y_i) \in \mathfrak{p}. \tag{47.2}$$

A power series in $\mathfrak{m}_P^N$ has its coefficient of X^n in $\mathfrak{m}_{\mathcal{O}}^{\max(0,N-|n|)}$; $f_{(0)}$ keeps some of these coefficients, so $f_{(0)} \in \mathfrak{m}_P^N$, and with $\pi(\mathfrak{m}_P^N) = \mathfrak{m}_R^N$ we get $\mathrm{E}(\mathfrak{m}_R^N) \subseteq \mathfrak{m}_R^N$: E is continuous.

Step 3: C is a complete local Noetherian $\mathcal{O}$-algebra. The monoid $\{n \in \mathbb{N}^\sigma : \sum_s n_s \mathrm{wt}(s) = 0\}$ is generated by finitely many non-zero $n^{(1)}, \dots, n^{(k)}$ (Gordan). The continuous homomorphism $\mathcal{O}[[Y_1, \dots, Y_k]] \to P$, $Y_i \mapsto X^{n^{(i)}} \in \mathfrak{m}_P$, has image P_0: the image lies in the closed subring P_0; conversely, for $f = \sum_n c_n X^n \in P_0$ choose for each n some $\alpha(n) \in \mathbb{N}^k$ with $\sum_i \alpha(n)_i n^{(i)} = n$; $n \mapsto \alpha(n)$ is injective, and $\sum_n c_n Y^{\alpha(n)}$ maps to f. So $C = \pi(P_0)$ is a quotient of $\mathcal{O}[[Y_1, \dots, Y_k]]$: a complete local Noetherian ring, with residue field $\mathbb{F}_{\mathcal{O}}$, maximal ideal $\mathfrak{m}_C = C \cap \mathfrak{m}_R$, and $\mathcal{O} \to C$ local.

Step 4: $R^0 \subseteq C \subseteq \overline{R^0}$ (closure in R). A product $\prod_k \underline{r}(g_k)_{a_k b_k}$ with $\sum_k \mathrm{wt}(a_k, b_k) = j$ is, by (47.1), $\pi(\prod_k f_k)$ with $\prod_k f_k \in P_j$; so it lies in C if $j = 0$, and E maps it to itself if $j = 0$ and to 0 otherwise. Hence $R^0 \subseteq C$, and E maps the $\mathcal{O}$-subalgebra R_2 of R generated by all entries $\underline{r}(g)_{ab}$ into R^0. We show that R_2 is dense in R; then, E being continuous, $C = \mathrm{E}(R) \subseteq \overline{\mathrm{E}(R_2)} \subseteq \overline{R^0}$. Fix $N \geq 1$, let $Q = R/\mathfrak{m}_R^N$ (a finite local ring) and $S \subseteq Q$ the image of R_2. An element of S outside the maximal ideal of Q is a unit of finite order in Q, so its inverse is a power of it and lies in S; thus S is a finite local ring with residue field $\mathbb{F}_{\mathcal{O}}$, and so is $Q \otimes_S Q$ (its quotient by the nilpotent ideal generated by the two maximal ideals is $\mathbb{F}_{\mathcal{O}} \otimes_{\mathbb{F}_{\mathcal{O}}} \mathbb{F}_{\mathcal{O}}$). The two morphisms $R \to Q \rightrightarrows Q \otimes_S Q$, through $x \mapsto x \otimes 1$ and $x \mapsto 1 \otimes x$, agree on all entries of r (their images lie in S), hence carry r to the same lift, which is a normalised ordinary lift in case (a), a lift with (Ed1), (Dd1)–(Dd3) in case (b) (images of r under morphisms are such); by the uniqueness in the universal property they are equal, so $x \otimes 1 = 1 \otimes x$ for all $x \in Q$. Let $p\colon Q \to M = Q/S$ be the projection of S-modules. The map $Q \otimes_S Q \to Q \otimes_S M$, $x \otimes y \mapsto x \otimes p(y)$, sends $x \otimes 1$ to 0 and $1 \otimes x$ to $1 \otimes p(x)$, so $1 \otimes p(x) = 0$ for all x, and $Q \otimes_S M = 0$ (it is generated by the $q(1 \otimes p(x))$). Then $M \otimes_S \mathbb{F}_{\mathcal{O}} = (Q \otimes_S M) \otimes_Q \mathbb{F}_{\mathcal{O}} = 0$, and $M = 0$ by Nakayama's lemma (M is finite). So $S = Q$, i.e. $R_2 + \mathfrak{m}_R^N = R$ for every N.

Step 5: $C/\mathfrak{m}_{\mathcal{O}}C$ is Artinian. Suppose not. Let $\mathfrak{p}_0$ be a minimal prime of $\mathfrak{m}_{\mathcal{O}}C$ with $\dim C/\mathfrak{p}_0 \geq 1$ and $t_0 \in \mathfrak{m}_C \setminus \mathfrak{p}_0$; by Lemma 47.7 for the complete local domain $C/\mathfrak{p}_0$ there is a prime $\mathfrak{p} \supseteq \mathfrak{p}_0$ of C with $\dim C/\mathfrak{p} = 1$; choose $t \in \mathfrak{m}_C \setminus \mathfrak{p}$. By (47.2), $\mathfrak{p}R$ does not meet the multiplicative set $C \setminus \mathfrak{p}$; an ideal of R maximal among those containing $\mathfrak{p}R$ and disjoint from $C \setminus \mathfrak{p}$ is a prime $\mathfrak{Q}$ with $\mathfrak{Q} \cap C = \mathfrak{p}$. $R/\mathfrak{Q}$ is a complete local Noetherian domain of characteristic ℓ ($\ell \in \mathfrak{m}_{\mathcal{O}} \subseteq \mathfrak{p} \subseteq \mathfrak{Q}$) in which the image of t is a non-zero non-unit, so $\dim R/\mathfrak{Q} \geq 1$, and Lemma 47.7 gives a prime $\mathfrak{Q}' \supseteq \mathfrak{Q}$ with $t \notin \mathfrak{Q}'$ and $\dim R/\mathfrak{Q}' = 1$. The normalisation $\tilde{A}$ of $R/\mathfrak{Q}'$ is a complete discrete valuation ring with finite residue field, finite over $R/\mathfrak{Q}'$, of characteristic ℓ; with $\mathcal{O} \to R \to \tilde{A}$ it is a test ring of characteristic ℓ whose structure map kills $\mathfrak{m}_{\mathcal{O}}$, and $\psi\colon R \to R/\mathfrak{Q}' \to \tilde{A}$ is an $\mathcal{O}$-algebra homomorphism with $\psi(\mathfrak{m}_R) \subseteq \mathfrak{m}_{\tilde{A}}$. By hypothesis ψ maps every weight-zero product of entries, hence R^0, into the image F_0 of $\mathcal{O}$ in $\tilde{A}$, the image of $\mathbb{F}_{\mathcal{O}}$, a finite subfield. F_0 is finite, hence closed, and ψ is continuous ($\psi(\mathfrak{m}_R^N) \subseteq \mathfrak{m}_{\tilde{A}}^N$), so $\psi(\overline{R^0}) \subseteq F_0$, and $\psi(t) \in F_0$ by Step 4. But $\psi(t) \neq 0$ ($t \notin \mathfrak{Q}'$ and $R/\mathfrak{Q}' \to \tilde{A}$ is injective) and $\psi(t) \in \mathfrak{m}_{\tilde{A}}$, while the non-zero elements of F_0 are units: a contradiction.

Step 6: conclusion. $C/\mathfrak{m}_{\mathcal{O}}C$ is an Artinian local ring with finite residue field, hence finite, and its maximal ideal is nilpotent, so the $\mathfrak{m}_C$-adic and $\mathfrak{m}_{\mathcal{O}}$-adic topologies of C coincide; C is complete and separated, so by Nakayama's lemma for complete modules C is a finitely generated $\mathcal{O}$-module. $\mathcal{O}$ is Noetherian and $R^0 \subseteq C$ (Step 4), so R^0 is a finitely generated $\mathcal{O}$-module. □

Lemma 47.7. *Let C be a complete local Noetherian domain of dimension ≥ 1 and $f \in C$, $f \neq 0$. Then there is a prime ideal q of C with $f \notin q$ and $\dim C/q = 1$.*

Proof. By induction on $d = \dim C$. If $d = 1$, take $q = 0$. Let $d \geq 2$ and $\mathfrak{m}_C$ the maximal ideal. C has infinitely many primes of height one: if $q_1, \dots, q_s$ were all of them, then $\mathfrak{m}_C \not\subseteq q_i$

(its height is $d \geq 2$), so by prime avoidance there is $x \in \mathfrak{m}_C \setminus \bigcup_i q_i$; $x \neq 0$ is not a unit, and a minimal prime over xC has height one by Krull's principal ideal theorem and contains x, a contradiction. A prime of height one containing the non-zero element f is minimal over fC (the primes strictly inside it are 0), and there are finitely many such. So there is a prime q_1 of height one with $f \notin q_1$. The complete local ring C is catenary, so for the local domain C one has $\dim C/q_1 + \operatorname{ht} q_1 = \dim C$, i.e. $\dim C/q_1 = d - 1 \geq 1$. C/q_1 is a complete local Noetherian domain in which the image of f is non-zero; by induction there is a prime $q \supseteq q_1$ of C with $f \notin q$ and $\dim C/q = 1$. □

Lemma 47.8. *Let $\mathcal{O}$ be a coefficient ring and $g_\star$ a marking.*

(Li1) *If (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $e_{\mathcal{O}} = 1$, and r is a triangular lift for $g_\star$ (formed with K, $\mathcal{O}$, $\Psi_{\chi,e}$) to an integral test ring with ρ_r irreducible, then $\rho_r|_V$ is irreducible for every open subgroup $V \subseteq G_K$.*

(Li2) *If (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$, $K = \mathbb{Q}(i)$, and r is a triangular lift for $g_\star$ (formed with K, $\mathcal{O}$, $\Psi_{\chi,e}$) to an integral test ring with ρ_r irreducible, then $\rho_r|_V$ is irreducible for every open subgroup $V \subseteq G_K$.*

Proof. We treat both items together. Let r be as in (Li1) or (Li2), A its integral test ring with maximal ideal $\mathfrak{m}_A$, $\rho = \rho_r$ and $\Psi = \Psi_{\chi,e}$. The marking is not used.

Step 1: two elements of $D_{\bar\ell}$. There is $x \in D_{\bar\ell}$ with $\Psi(x)^2 - 1 \in \mathcal{O}^\times$: in case (Li1) by (Lo3) (with $x \in I_{\bar\ell}$), in case (Li2) by Lemma 47.10. Let $V \subseteq G_K$ be open and $V_0 = \bigcap_{g \in G_K} gVg^{-1}$; as V has finite index in the compact group G_K, this is a finite intersection, so V_0 is an open normal subgroup of G_K, and it suffices to show that $\rho|_{V_0}$ is irreducible. The group $V_0 \cap I_{\bar\ell} \cap \ker\chi$ is open in $I_{\bar\ell}$, and $\chi_{\mathrm{cyc}}(I_{\bar\ell}) = \mathbb{Z}_\ell^\times$ (ℓ is unramified in K), so its image under χ_{cyc} is open in $\mathbb{Z}_\ell^\times$ and contains $1+\ell^k$ for some $k \geq 1$. Choose u in it with $\chi_{\mathrm{cyc}}(u) = 1+\ell^k$; then $\Psi(u)^2 = (1+\ell^k)^{2e} \neq 1$, so $\Psi(u)$, 1, $\Psi(u)^{-1}$ are pairwise distinct.

Step 2: a basis. Take h as in (Lo2) at $\bar\ell$. Then $h^{-1}\rho(u)h$ and $h^{-1}\rho(x)h$ are upper triangular, and the diagonal of the first is $(\Psi(u), 1, \Psi(u)^{-1})$ by (Lo2). An upper triangular matrix with pairwise distinct diagonal entries is diagonalised by an upper triangular matrix (its eigenvectors, found successively, span the standard flag). So there is $P \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ such that $\rho'(g) = P^{-1}\rho(g)P$ satisfies: $\rho'(u) = \mathrm{diag}(d_1, d_2, d_3)$ with d_1, d_2, d_3 pairwise distinct, and $\rho'(x)$ is upper triangular. Irreducibility of ρ and of $\rho|_{V_0}$ is that of ρ' and $\rho'|_{V_0}$. Suppose, for a contradiction, that $\rho'|_{V_0}$ is reducible.

Step 3: V_0-stable subspaces are coordinate subspaces. Let W be $\rho'(V_0)$-stable. It is stable under $\rho'(u)$; for $w = \sum_i w_i e_i \in W$ and the Lagrange polynomial $L_i(X) = \prod_{j \neq i}(X - d_j)/(d_i - d_j)$, $L_i(\rho'(u))w = w_i e_i \in W$. So W is spanned by the e_i it contains.

Step 4: a V_0-stable coordinate line. Let W be a $\rho'(V_0)$-stable subspace with $0 \neq W \neq \overline{\mathbb{Q}}_\ell^3$; by Step 3, $W = \bigoplus_{i \in S} \overline{\mathbb{Q}}_\ell e_i$ with $\emptyset \neq S \subsetneq \{1,2,3\}$. If $|S| = 1$ we are done. If $|S| = 2$: as ρ' is irreducible, W is not $\rho'(G_K)$-stable, so $W' = \rho'(g)W \neq W$ for some $g \in G_K$. Since V_0 is normal in G_K, $\rho'(s)\rho'(g)W = \rho'(g)\rho'(g^{-1}sg)W = \rho'(g)W$ for $s \in V_0$, so W' is $\rho'(V_0)$-stable, hence $W' = \bigoplus_{i \in S'} \overline{\mathbb{Q}}_\ell e_i$ with $|S'| = 2$, $S' \neq S$; then $W \cap W'$ is $\rho'(V_0)$-stable and spanned by e_i for the single $i \in S \cap S'$.

Step 5: ρ' is monomial. Let $\overline{\mathbb{Q}}_\ell e_i$ be $\rho'(V_0)$-stable. For $g \in G_K$ the line $\rho'(g)\overline{\mathbb{Q}}_\ell e_i$ is $\rho'(V_0)$-stable (as in Step 4), hence a coordinate line by Step 3. The span of these lines for $g \in G_K$ is non-zero and $\rho'(G_K)$-stable, hence everything; so every coordinate line is $\rho'(g_j)\overline{\mathbb{Q}}_\ell e_i$ for some $g_j \in G_K$, and for every $g \in G_K$ and every j, $\rho'(g)\overline{\mathbb{Q}}_\ell e_j = \rho'(gg_j)\overline{\mathbb{Q}}_\ell e_i$ is a coordinate line. So $\rho'(g)e_j \in \overline{\mathbb{Q}}_\ell^\times e_{\pi_g(j)}$ for a permutation π_g of $\{1,2,3\}$, and $g \mapsto \pi_g$ is a homomorphism $G_K \to S_3$.

Step 6: a derangement. The image $\pi(G_K)$ is transitive on $\{1,2,3\}$: otherwise the span of the e_j over an orbit would be a proper non-zero $\rho'(G_K)$-stable subspace. A transitive subgroup of S_3 is A_3 or S_3 and contains a 3-cycle; let $g \in G_K$ with π_g a 3-cycle. The matrix $\rho'(x)$ is upper triangular and monomial, so $\pi_x(j) \le j$ for all j, whence $\pi_x = \mathrm{id}$. Hence $\pi_{gx^n} = \pi_g$ has no fixed point for every $n \ge 0$, so $\rho'(gx^n)$ has zero diagonal and

$$\operatorname{tr}\rho(gx^n) = \operatorname{tr}\rho'(gx^n) = 0 \qquad (n \ge 0).$$

Step 7: contradiction modulo $\mathfrak{m}_A$. By (Tl1), $\rho(y) \equiv \mathrm{T}(\Psi(y)) \pmod{\mathfrak{m}_A}$ for $y \in G_K$. Let a, b be the images of $\Psi(g)$, $\Psi(x)$ in the residue field of A and $t_n = ab^n$. Reducing Step 6, $t_n + 1 + t_n^{-1} = 0$, i.e. $t_n^2 + t_n + 1 = 0$, for $n = 0, 1, 2$. Suppose $b \ne 1$; then $t_0 \ne t_1$ are the two roots of $X^2 + X + 1$, and $t_2 = t_1 b$ is a root as well: $t_2 = t_1$ would give $b = 1$, so $t_2 = t_0$ and $b^2 = 1$. In all cases $b^2 = 1$, i.e. $\Psi(x)^2 \equiv 1 \pmod{\mathfrak{m}_A}$, contradicting $\Psi(x)^2 - 1 \in \mathcal{O}^\times$ (and $\mathfrak{m}_A \cap \mathcal{O} = \mathfrak{m}_{\mathcal{O}}$). So $\rho|_{V_0}$, and hence $\rho|_V$, is irreducible. □

Lemma 47.9. *Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, $\mathcal{O}$ a coefficient ring, $N \ge 1$, χ a Dirichlet character modulo N with values in $\mathcal{O}^\times$, $e \ge 1$, $\Psi = \Psi_{\chi,e}$ with $\Psi(c) = 1$, and form triangular lifts with K, $\mathcal{O}$ and Ψ. Let $g_\star$ be a marking, A an integral test ring with maximal ideal $\mathfrak{m}_A$, r a triangular lift to A for $g_\star$ and $\rho = \rho_r$.*

(Lo1) *For every place $\bar v$ of $\overline{\mathbb{Q}}$ not above ℓ, $\Psi(I_{\bar v})$ is finite, and there are $P \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ and integers a_1, a_2, a_3 with $\rho(g) = P\,\mathrm{diag}\big(\Psi(g)^{a_1}, \Psi(g)^{a_2}, \Psi(g)^{a_3}\big)P^{-1}$ for all $g \in I_{\bar v} \cap G_K$.*

(Lo2) *Every place of K above ℓ lies below $\bar\ell$ or below $c\bar\ell$. For $\bar v \in \{\bar\ell, c\bar\ell\}$, with $D_{\bar v} \supseteq I_{\bar v}$ the decomposition and inertia subgroups of G_K at $\bar v$, there are $h \in \mathrm{GL}_3(A)$ with $h \equiv 1 \pmod{\mathfrak{m}_A}$ and continuous characters $\kappa_1, \kappa_2, \kappa_3 \colon D_{\bar v} \to A^\times$ such that for every $g \in D_{\bar v}$ the matrix $h^{-1}\rho(g)h$ is upper triangular with diagonal entries $\kappa_1(g), \kappa_2(g), \kappa_3(g)$, and*

$$\kappa_a(g) \equiv \Psi(g)^{2-a} \pmod{\mathfrak{m}_A} \quad (g \in D_{\bar v}), \qquad \kappa_a(g) = \Psi(g)^{2-a} \quad (g \in I_{\bar v}), \qquad a = 1, 2, 3.$$

(Lo3) *If (K, ℓ, e, N, χ) is a unitary Eisenstein datum, then for every place $\bar v$ of $\overline{\mathbb{Q}}$ above ℓ the inertia group of $G_{\mathbb{Q}}$ at $\bar v$ lies in G_K and contains an element s with $\Psi(s)^2 - 1 \in \mathcal{O}^\times$.*

Proof. (Lo1). Let $\bar v$ lie above a prime $p \ne \ell$. The extension of $\mathbb{Q}$ generated by the ℓ-power roots of unity is unramified at p, so χ_{cyc} is trivial on $I_{\bar v}$ and $\Psi|_{I_{\bar v}} = \chi|_{I_{\bar v}}$, which takes values in the finite group of values of χ. Put $H = I_{\bar v} \cap G_K$ and $Z = \Psi(H)$, a finite subgroup of $\overline{\mathbb{Q}}_\ell^\times$, hence cyclic, say of order n with generator z_0. If $g, g' \in H$ and $\Psi(g) = \Psi(g')$, then $g^{-1}g' \in I_{\bar v}$ has $\eta_K(g^{-1}g') = 1$ and $\Psi(g^{-1}g') = 1$, so $r(g^{-1}g') = 1$ by (Tl3) and $\rho(g) = \rho(g')$. Hence $M(\Psi(g)) = \rho(g)$ defines a homomorphism $M \colon Z \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$. The matrix $M(z_0)$ satisfies $X^n = 1$, a polynomial with distinct roots in the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic 0, so $M(z_0) = P\,\mathrm{diag}(\lambda_1, \lambda_2, \lambda_3)P^{-1}$ with $\lambda_i^n = 1$; as Z consists of n distinct n-th roots of unity it contains all of them, so $\lambda_i = z_0^{a_i}$ for integers a_i. Then $M(z_0^k) = P\,\mathrm{diag}(z_0^{ka_i})P^{-1}$ for all k, which is (Lo1).

(Lo2), the places. Let v_0 be the place of K below $\bar\ell$. A place $v \mid \ell$ of K lies below $\gamma\bar\ell$ for some $\gamma \in G_{\mathbb{Q}}$ (the places of $\overline{\mathbb{Q}}$ above ℓ form one $G_{\mathbb{Q}}$-orbit); as $\mathrm{Gal}(K/\mathbb{Q}) = \{1, c|_K\}$, $v = \gamma|_K(v_0)$ is v_0 or $c|_K(v_0)$, the place below $c\bar\ell$.

(Lo2) at $\bar\ell$. The decomposition and inertia subgroups of G_K at $\bar\ell$ are $D_{\bar\ell} = D_\ell \cap G_K$ and $I_{\bar\ell} = I_\ell \cap G_K$, in the notation of Definition 43.16. Take h as in (Tl4) and put $Y(g) = h^{-1}\rho(g)h$ for $g \in D_{\bar\ell}$, upper triangular. The diagonal entries of a product of upper triangular matrices are the products of the diagonal entries, so $\kappa_a(g) = Y(g)_{aa}$ are homomorphisms $D_{\bar\ell} \to A^\times$, continuous

by (Tl1). By (Tl4), $\kappa_a(g) = \Psi(g)^{2-a}$ for $g \in I_{\bar\ell}$. By (Tl1) and $h \equiv 1$, $Y(g) \equiv \rho(g) \equiv \mathrm{T}(\Psi(g))$ (mod $\mathfrak{m}_A$), whose diagonal is $(\Psi(g), 1, \Psi(g)^{-1})$.

(Lo2) at $c\bar\ell$. By (Tl1), (Tl2), $r(c) = (1,-1)$, and $c^2 = 1$. For $g \in G_K$, $r(g) = (\rho(g), 1)$ and $r(cgc) = (1,-1)(\rho(g),1)(1,-1) = (\theta(\rho(g)),1)$, so $\rho(cgc) = \theta(\rho(g))$. The decomposition and inertia subgroups of G_K at $c\bar\ell$ are $cD_{\bar\ell}c$ and $cI_{\bar\ell}c$ (G_K is normal in $G_{\mathbb{Q}}$). Put $h' = \theta(h) = J\,{}^t h^{-1} J \in \mathrm{GL}_3(A)$; $h' \equiv 1 \pmod{\mathfrak{m}_A}$. For $g' = cgc$ with $g \in D_{\bar\ell}$, θ being a group automorphism of $\mathrm{GL}_3(A)$,

$$h'^{-1}\rho(g')h' = \theta\big(h^{-1}\rho(g)h\big) = J\,{}^t Y(g)^{-1} J.$$

$Y(g)^{-1}$ is upper triangular with diagonal $(\kappa_1(g)^{-1}, \kappa_2(g)^{-1}, \kappa_3(g)^{-1})$, its transpose is lower triangular, and conjugation by J sends the entry (a,b) to $(4-a, 4-b)$, so $J\,{}^t Y(g)^{-1} J$ is upper triangular with diagonal entries $\kappa'_a(g') = \kappa_{4-a}(cg'c)^{-1}$. These are continuous characters of $cD_{\bar\ell}c$. Since Ψ is a character of $G_{\mathbb{Q}}$ with $\Psi(c) = 1$, $\Psi(cg'c) = \Psi(g')$, so $\kappa'_a(g') = \Psi(g')^{-(2-(4-a))} = \Psi(g')^{2-a}$ for $g' \in cI_{\bar\ell}c$, and the same computation modulo $\mathfrak{m}_A$ gives $\kappa'_a(g') \equiv \Psi(g')^{2-a}$ on $cD_{\bar\ell}c$.

(Lo3). By (Ue6), ℓ is unramified in K, so the inertia group I of $G_{\mathbb{Q}}$ at $\bar v$ acts trivially on K: $I \subseteq G_K$. Write $N = \ell^a N'$ with $\ell \nmid N'$. An element $g \in I$ fixes $\mu_{N'}$ and acts on μ_{ℓ^a} through $\chi_{\mathrm{cyc}}(g)$, so $\chi(g) = \chi_\ell(\chi_{\mathrm{cyc}}(g) \bmod \ell^a)$, and $\chi(g)^2 = 1$ by (Ue4). Hence $\Psi(g)^2 \equiv \omega(g)^{2e} \pmod{\mathfrak{m}_{\mathcal{O}}}$, where $\omega\colon I \to \mathbb{F}_\ell^\times$ is the reduction of χ_{cyc}, which is surjective since $\chi_{\mathrm{cyc}}(I) = \mathbb{Z}_\ell^\times$. If ω^{2e} were trivial, $\mathbb{F}_\ell^\times$, cyclic of order $\ell - 1$, would have exponent dividing $2e$, contradicting (Ue9). So some $s \in I$ has $\omega(s)^{2e} \neq 1$, i.e. $\Psi(s)^2 \not\equiv 1$, i.e. $\Psi(s)^2 - 1 \in \mathcal{O}^\times$. □

Lemma 47.10. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, put $\Psi = \Psi_{\chi,e}$ and $K = \mathbb{Q}(i)$, and let $\bar\ell$ be a place of $\overline{\mathbb{Q}}$ above ℓ, with decomposition group $D_{\bar\ell} \subseteq G_{\mathbb{Q}}$. There is $x \in D_{\bar\ell} \cap G_K$ with $\chi_{\mathrm{cyc}}(x) = 1$ and $\Psi(x)^2 - 1 \in \mathcal{O}^\times$.*

Proof. Choice of x. Let $\sigma_0 \in D_{\bar\ell}$ be an arithmetic Frobenius. The roots of unity of order prime to ℓ reduce injectively to the residue field of $\bar\ell$, so $\sigma_0(\zeta) = \zeta^\ell$ for every root of unity ζ of order prime to ℓ. The restriction of χ_{cyc} to the inertia group $I_{\bar\ell} \subseteq D_{\bar\ell}$ is surjective onto $\mathbb{Z}_\ell^\times$ ($\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ is totally ramified with group $\mathbb{Z}_\ell^\times$), so there is $\tau \in I_{\bar\ell}$ with $\chi_{\mathrm{cyc}}(\tau) = \chi_{\mathrm{cyc}}(\sigma_0)^{-1}$; τ fixes the roots of unity of order prime to ℓ, which generate an extension unramified at ℓ. Put $\sigma = \sigma_0\tau$ and $x = \sigma^2$. Then $x \in D_{\bar\ell}$, $\eta_K(x) = \eta_K(\sigma)^2 = 1$ for the character η_K with kernel G_K, so $x \in G_K$, and $\chi_{\mathrm{cyc}}(x) = \chi_{\mathrm{cyc}}(\sigma)^2 = 1$.

Reduction to a statement on χ_2. Write $N = \ell^a N'$ with $\ell \nmid N'$. The element σ acts on μ_N by $\zeta \mapsto \zeta^u$ with $u \in (\mathbb{Z}/N\mathbb{Z})^\times$, $u \equiv \ell \pmod{N'}$ and $u \equiv 1 \pmod{\ell^a}$ (as $\chi_{\mathrm{cyc}}(\sigma) = 1$), so $\chi(\sigma) = \chi(u)$, and $\Psi(x)^2 = \chi(\sigma)^4\chi_{\mathrm{cyc}}(\sigma)^{4e} = \chi(u)^4$. Suppose, for a contradiction, that $\chi(u)^4 \equiv 1 \pmod{\mathfrak{m}_{\mathcal{O}}}$. The value $\chi''(u)$ is a root of unity of ℓ-power order ℓ^k, and $(\chi''(u)-1)^{\ell^k} \equiv \chi''(u)^{\ell^k} - 1 = 0 \pmod\ell$, so $\chi''(u) \equiv 1$; hence $\chi'(u)^4 \equiv 1$. As χ' has order n prime to ℓ and $X^n - 1$ has distinct roots modulo $\mathfrak{m}_{\mathcal{O}}$, the n-th roots of unity in $\mathcal{O}$ reduce injectively, and $\chi'(u)^4 = 1$. Write $\chi' = \prod_{p|N}\chi'_p$ as the product of its p-components; by (Dy4), $(\chi'_r)^{2o} = \mathbf{1}$ for every odd prime r, so $1 = \chi'(u)^{4o} = \chi'_2(u \bmod 2^{a_2})^{4o}$, where $2^{a_2} \parallel N$ ($a_2 \geq 1$ by (Dy2)). Taking 2-components is multiplicative, $\chi_2 = \chi'_2\chi''_2$, and χ''_2 is a character of the 2-group $(\mathbb{Z}/2^{a_2}\mathbb{Z})^\times$ whose order divides the ℓ-power order of χ''; as ℓ is odd (Dy1), $\chi''_2 = \mathbf{1}$ and $\chi_2 = \chi'_2$. Since $2^{a_2} \mid N'$, $u \equiv \ell \pmod{2^{a_2}}$. Hence

$$\chi_2(\ell)^{4o} = 1. \tag{47.3}$$

Contradiction with (Dy5). Write $o = 2^j o'$ with o' odd, and $\ell^2 = 1 + 2^s b$ with b odd; $s \geq 3$ since ℓ is odd. For $t \geq 2$ and b odd, $(1 + 2^t b)^2 = 1 + 2^{t+1}(b + 2^{t-1}b^2)$ with $b + 2^{t-1}b^2$ odd; by induction $y = \ell^{2^{j+2}} = (\ell^2)^{2^{j+1}} = 1 + 2^t b_0$ with $t = s + j + 1$ and b_0 odd, and the powers y^{2^i} are $\equiv 1 + 2^{t+i} \pmod{2^{t+i+1}}$. By (47.3), $\chi_2(y)^{o'} = \chi_2(\ell)^{4o} = 1$; χ_2 has 2-power order, so $\chi_2(y) = 1$. If $t < a_2$, the subgroup U_t of $(\mathbb{Z}/2^{a_2}\mathbb{Z})^\times$ of classes $\equiv 1 \pmod{2^t}$ has order 2^{a_2-t},

and y has order exactly 2^{a_2-t} in it by the congruences for y^{2^i}; so y generates U_t, χ_2 is trivial on U_t, and χ_2 factors through $(\mathbb{Z}/2^t\mathbb{Z})^\times$: $c_2(\chi) \le t$. If $t \ge a_2$, then $c_2(\chi) \le a_2 \le t$ as well. But $2^s \le 2^s b = \ell^2 - 1$ and $2^j \le o$, so

$$2^t = 2 \cdot 2^j \cdot 2^s \le 2o(\ell^2 - 1) < 8o\ell^2 < 2^{c_2(\chi)},$$

the last inequality by (Dy5) for $v = \ell \in T_\ell(\chi)$. Thus $t < c_2(\chi)$, a contradiction. Hence $\chi(u)^4 \not\equiv 1$, that is $\Psi(x)^2 - 1 \in \mathcal{O}^\times$. □

Proposition 47.11. *Let $\mathcal{O}$ be a coefficient ring, and assume (a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $e_\mathcal{O} = 1$, or (b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $K = \mathbb{Q}(i)$. Form triangular lifts with K, $\mathcal{O}$ and $\Psi = \Psi_{\chi,e}$, let $g_\star$ be a marking, r a triangular lift for $g_\star$ to an integral test ring and $\rho = \rho_r$.*

(Cv1) *ρ satisfies (Lw1) with $M = N$, and for every place $v \mid \ell$ of K there are a place $\bar v \mid v$, characters χ_1, χ_2, χ_3 of G_K of level N and characters $\kappa_1, \kappa_2, \kappa_3$ of $D_{\bar v}$ such that ρ is triangular on $D_{\bar v}$ with diagonal $(\kappa_1, \kappa_2, \kappa_3)$ and $\kappa_a(s) = \chi_{\mathrm{cyc}}(s)^{m_a}\chi_a(s)$ for $s \in I_{\bar v}$, where $(m_1, m_2, m_3) = (e, 0, -e)$. If moreover (b) holds, or (a) holds with $e \ge 2$ or $\chi_\ell \ne \mathbf{1}$, or ρ is generic at every place $v \mid \ell$ of K, then ρ has level N and weights $(e, 0, -e)$ and is generic ordinary of level N and weights $(e, 0, -e)$.*

(Cv2) *Assume (a), let d_K be the discriminant of K and η_K the character of $G_\mathbb{Q}$ with kernel G_K, and let r be of type II. Then $\rho(g)_{22} = 1$ for all $g \in G_K$; there is a continuous $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ whose restriction to G_K is the corner of r and with $\operatorname{tr} W(c) = 0$; and every such W has level $N|d_K|$ and weights $(e, -e)$, and $\det W = \eta_K$, a character of level $|d_K|$.*

Proof. Preliminaries. (i) ρ is continuous: A is a discrete valuation ring finite over $\mathcal{O}$ inside $\overline{\mathbb{Q}}_\ell$, so its $\mathfrak{m}_A$-adic topology is the ℓ-adic one, and (Tl1) gives local constancy modulo every $\mathfrak{m}_A^n$. (ii) ℓ is unramified in K ((Ue6) in case (a); $K = \mathbb{Q}(i)$ and ℓ odd in case (b)), so for $\bar v \mid \ell$ the inertia group of $G_\mathbb{Q}$ at $\bar v$ lies in G_K and equals $I_{\bar v}$, and $\chi_{\mathrm{cyc}}(I_{\bar v}) = \mathbb{Z}_\ell^\times$. Every open subgroup of $I_{\bar v}$ has an image under χ_{cyc} open in $\mathbb{Z}_\ell^\times$, hence containing some $1 + \ell^k\mathbb{Z}_\ell$, which has no non-trivial element of finite order; so χ_{cyc}^n is non-trivial on every open subgroup of $I_{\bar v}$ for $n \ne 0$. (iii) For $g \in I_{\bar v}$, $\bar v \mid \ell$, write $N = \ell^a N'$ with $\ell \nmid N'$: g fixes $\mu_{N'}$ and acts on μ_{ℓ^a} through $\chi_{\mathrm{cyc}}(g)$, so $\chi(g) = \chi_\ell(\chi_{\mathrm{cyc}}(g) \bmod \ell^a)$; hence $\chi|_{I_{\bar v}} = \mathbf{1}$ if and only if $\chi_\ell = \mathbf{1}$. (iv) In case (a), for $\bar v \mid \ell$, $\bar\Psi^2 \ne 1$ on $I_{\bar v}$, where $\bar\Psi$ is the reduction of Ψ: this is (Lo3). (v) If a representation of a group D on $\overline{\mathbb{Q}}_\ell^3$ is triangular on D with diagonals (κ_a) and (κ'_a), the two multisets coincide: each is the multiset of the one-dimensional composition factors of $\overline{\mathbb{Q}}_\ell^3$ as a D-module (Jordan–Hölder). (vi) A character of G_F of level M is of level MM' for every $M' \ge 1$, and products of characters of level M are of level M.

(Cv1), the clause (Lw1). Let $v \nmid \ell$ be a finite place of K and $\bar v \mid v$. By (Lo1) there are P and integers a_1, a_2, a_3 with $\rho(g) = P\,\mathrm{diag}(\Psi(g)^{a_i})P^{-1}$ for $g \in I_{\bar v}$. On $I_{\bar v}$, χ_{cyc} is trivial and $\Psi = \chi$; the characters $\chi^{a_i}|_{G_K}$ are trivial on $G_{K(\mu_N)} \subseteq G_{\mathbb{Q}(\mu_N)}$, so they are of level N, and $\rho|_{I_{\bar v}}$ is conjugate to $\mathrm{diag}(\chi^{a_1}, \chi^{a_2}, \chi^{a_3})$.

(Cv1), triangular form above ℓ. Let $v \mid \ell$. By (Lo2), v lies below some $\bar v \in \{\bar\ell, c\bar\ell\}$, and there are $h \equiv 1 \pmod{\mathfrak{m}_A}$ and characters κ_a of $D_{\bar v}$ with $h^{-1}\rho(g)h$ upper triangular with diagonal $(\kappa_a(g))$; so ρ is triangular on $D_{\bar v}$ with diagonal $(\kappa_1, \kappa_2, \kappa_3)$. For $s \in I_{\bar v}$, $\kappa_a(s) = \Psi(s)^{2-a} = \chi_{\mathrm{cyc}}(s)^{e(2-a)}\chi(s)^{2-a}$, and $e(2-a) = m_a$; put $\chi_a = \chi^{2-a}|_{G_K}$, of level N.

(Cv1), genericity. We show $\kappa_a \ne \kappa_b\chi_{\mathrm{cyc}}$ on $D_{\bar v}$ for all a, b under each of the three additional hypotheses. Then (Lw2) holds with the first alternative, so with (i) and (Lw1) ρ has level N

and weights $(e, 0, -e)$, and the same data show that ρ is generic ordinary of level N and weights $(e, 0, -e)$.

- For $a = b$: $\chi_{\mathrm{cyc}} \neq \mathbf{1}$ on $I_{\bar{v}}$ by (ii).
- Inertia. Let $a \neq b$ with $\kappa_a = \kappa_b \chi_{\mathrm{cyc}}$. On $I_{\bar{v}}$ this reads $\Psi^{b-a} = \chi_{\mathrm{cyc}}$, i.e. $\chi^{b-a} \chi_{\mathrm{cyc}}^{e(b-a)-1} = \mathbf{1}$. On the open subgroup $I_{\bar{v}} \cap \ker \chi$ this gives $\chi_{\mathrm{cyc}}^{e(b-a)-1} = \mathbf{1}$, so $e(b-a) = 1$ by (ii): $e = 1$ and $b = a+1$; then $\chi = \mathbf{1}$ on $I_{\bar{v}}$, i.e. $\chi_\ell = \mathbf{1}$ by (iii). So the claim holds if $e \geq 2$ or $\chi_\ell \neq \mathbf{1}$, in either case.
- Case (b). By Lemma 47.10 there is $x \in D_{\bar{\ell}}$ with $\chi_{\mathrm{cyc}}(x) = 1$ and $\Psi(x)^2 - 1 \in \mathcal{O}^\times$; put $y = x$ if $\bar{v} = \bar{\ell}$ and $y = cxc \in D_{c\bar{\ell}}$ if $\bar{v} = c\bar{\ell}$; as $\chi_{\mathrm{cyc}}(c)^2 = 1$ and $\Psi(c) = 1$, $\chi_{\mathrm{cyc}}(y) = 1$ and $\Psi(y) = \Psi(x)$. If $\kappa_a = \kappa_b \chi_{\mathrm{cyc}}$ with $a \neq b$, then $\kappa_a(y) = \kappa_b(y)$, and by (Lo2) $\Psi(y)^{2-a} \equiv \Psi(y)^{2-b}$, so $\Psi(y)^{b-a} \equiv 1 \pmod{\mathfrak{m}_A}$ with $b - a \in \{\pm 1, \pm 2\}$, whence $\Psi(y)^2 \equiv 1 \pmod{\mathfrak{m}_A}$. But $\Psi(y)^2 - 1$ is a unit of $\mathcal{O} \subseteq A$ and $\mathfrak{m}_A \cap \mathcal{O} = \mathfrak{m}_{\mathcal{O}}$: a contradiction.
- ρ generic at v. Then ρ is triangular on $D_{\bar{v}}$ with a diagonal (κ'_a) with $\kappa'_a \neq \kappa'_b \chi_{\mathrm{cyc}}$ for all a, b; by (v), $\{\kappa_a\} = \{\kappa'_a\}$ as multisets, and the claim follows.

(Cv2), a triviality criterion. Let $\lambda\colon G_K \to A^\times$ be a continuous character with $\lambda \equiv 1 \pmod{\mathfrak{m}_A}$ that is trivial on $I_{\bar{v}}$ for every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above a finite prime. Then $\lambda = \mathbf{1}$: by class field theory λ factors through the Galois group of the Hilbert class field of K (the maximal abelian extension unramified at all places; K has no real places), which has order h_K; so $\lambda^{h_K} = \mathbf{1}$, and $(\lambda - 1)(1 + \lambda + \cdots + \lambda^{h_K - 1}) = 0$ with the second factor $\equiv h_K \not\equiv 0 \pmod{\mathfrak{m}_A}$ by (Ue6), so $\lambda = 1$. It suffices to check triviality on $I_{\bar{v}}$ for one $\bar{v}$ above each place v of K: the others are $\gamma I_{\bar{v}} \gamma^{-1}$ with $\gamma \in G_K$, and λ is a class function.

(Cv2), the determinant and the middle entry. Let r be of type II. As the entries of odd weight vanish, $\rho(g)$ preserves $U = \overline{\mathbb{Q}}_\ell e_1 \oplus \overline{\mathbb{Q}}_\ell e_3$ and $L = \overline{\mathbb{Q}}_\ell e_2$, so $\rho = C \oplus \mu$ with C the corner and $\mu(g) = \rho(g)_{22}$ a continuous character. Put $\Delta = \det \rho = \det C \cdot \mu$. Both Δ and μ are $\equiv 1 \pmod{\mathfrak{m}_A}$, since $\rho(g) \equiv \mathrm{T}(\Psi(g))$ by (Tl1). Away from ℓ: for $g \in I_{\bar{v}}$, $\bar{v} \nmid \ell$, the eigenvalues of $\rho(g)$ are the $\Psi(g)^{a_i} = \chi(g)^{a_i}$ of (Lo1), roots of unity of order dividing the order of χ, prime to ℓ by (Ue3); $\Delta(g)$ is their product and $\mu(g)$ is one of them; a root of unity of order prime to ℓ that is $\equiv 1 \pmod{\mathfrak{m}_A}$ equals 1 ($X^n - 1$ is separable modulo $\mathfrak{m}_A$ for $\ell \nmid n$). So $\Delta(g) = \mu(g) = 1$. Above ℓ, for $\bar{v} \in \{\bar{\ell}, c\bar{\ell}\}$ and $g \in I_{\bar{v}}$, the eigenvalues of $\rho(g)$ are $\Psi(g), 1, \Psi(g)^{-1}$ by (Lo2), so $\Delta(g) = 1$, and $\mu(g)$ is one of them. By (iv) there is $s \in I_{\bar{v}}$ with $\bar{\Psi}(s) \neq 1$. If $\bar{\Psi}(g) \neq 1$, then $\Psi(g)^{\pm 1} \not\equiv 1$ while $\mu(g) \equiv 1$, so $\mu(g) = 1$; if $\bar{\Psi}(g) = 1$, then $\bar{\Psi}(gs) \neq 1$ and $\mu(g) = \mu(gs)\mu(s)^{-1} = 1$. By the criterion, $\Delta = \mu = \mathbf{1}$: $\rho(g)_{22} = 1$ and $\det C(g) = 1$ for $g \in G_K$.

(Cv2), existence of W. Put $D = \mathrm{diag}(1, -1)$. As in (Lo2), $r(c) = (1, -1)$ gives $\rho(cgc) = \theta(\rho(g))$ for $g \in G_K$. For $\rho(g) = C(g) \oplus 1$, the matrix $\theta(\rho(g)) = J\, {}^t\rho(g)^{-1} J$ has corner $w\, {}^tC(g)^{-1} w$ with $w = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, since J exchanges e_1 and e_3. For $C = \left(\begin{smallmatrix} \alpha & \beta \\ \gamma & \delta \end{smallmatrix}\right)$ of determinant 1, ${}^tC^{-1} = \left(\begin{smallmatrix} \delta & -\gamma \\ -\beta & \alpha \end{smallmatrix}\right)$ and $w\, {}^tC^{-1} w = \left(\begin{smallmatrix} \alpha & -\beta \\ -\gamma & \delta \end{smallmatrix}\right) = DCD$. Hence $C(cgc) = D\, C(g)\, D$ for $g \in G_K$. Every element of $G_{\mathbb{Q}} \setminus G_K$ is gc with a unique $g \in G_K$; define $W(g) = C(g)$ and $W(gc) = C(g)D$ for $g \in G_K$. Using $c^2 = 1$, $D^2 = 1$ and $DC(h) = C(chc)D$, for $g, h \in G_K$: $W(g)W(hc) = C(gh)D = W(ghc)$; $W(gc)W(h) = C(g)C(chc)D = W(g\, chc\, c) = W(gch)$; $W(gc)W(hc) = C(g)C(chc) = W(g\, chc) = W(gchc)$. So W is a homomorphism, continuous because C is and G_K is open, with $W|_{G_K} = C$ and $\mathrm{tr}\, W(c) = \mathrm{tr}\, D = 0$. Moreover $\det W = \eta_K$: $\det W(g) = \det C(g) = 1$ and $\det W(gc) = -1$.

(Cv2), every such W. Let W' be continuous with $W'|_{G_K} = C$ and $\mathrm{tr}\, W'(c) = 0$. For $g \in G_K$, $W'(c)C(g)W'(c)^{-1} = C(cgc) = DC(g)D$, so $DW'(c)$ commutes with $C(G_K)$; C is irreducible (type II), so $DW'(c)$ is a scalar λ (Schur's lemma over $\overline{\mathbb{Q}}_\ell$), and $W'(c)^2 = W'(c^2) = 1$ gives

$\lambda = \pm 1$. Hence $W' = W$ or $W' = W \otimes \eta_K$, and $\det W' = \det W = \eta_K$. The character η_K is of level $|d_K|$ ($K \subseteq \mathbb{Q}(\mu_{|d_K|})$), hence of level $N|d_K|$ by (vi). We check (Lw1), (Lw2) for W' over $F = \mathbb{Q}$ with $M = N|d_K|$ and weights $(e, -e)$; W' is continuous by assumption.

- (Lw1) at $p \neq \ell$ with $p \nmid d_K$, and $\bar{p} \mid p$: K is unramified at p, so $I_{\bar{p}} \subseteq G_K$ and $W'|_{I_{\bar{p}}} = C|_{I_{\bar{p}}}$. By (Lo1) the finite group $\rho(I_{\bar{p}})$ is diagonalisable with $\rho|_{I_{\bar{p}}} \cong \bigoplus_i \chi^{a_i}|_{I_{\bar{p}}}$; $C|_{I_{\bar{p}}}$ is a direct summand, so (representations of a finite group in characteristic 0 being semisimple, and the decomposition into characters unique) $C|_{I_{\bar{p}}}$ is conjugate to $\mathrm{diag}(\chi^{a_i}, \chi^{a_j})$ for some $i \neq j$; the χ^a are of level N, hence of level $N|d_K|$.

- (Lw1) at $p \mid d_K$: $p \neq \ell$ by (Ue6) and $p \nmid N$ by (Ue7). On $H = I_{\bar{p}} \cap G_K$, $\eta_K = 1$ and $\Psi = \chi\chi_{\mathrm{cyc}}^e = 1$ (χ is unramified at p), so $r = 1$ on H by (Tl3) and $W'|_H = 1$. As K is ramified at p, $[I_{\bar{p}} : H] = 2$; for $\tau \in I_{\bar{p}} \setminus H$, $W'(\tau)^2 = W'(\tau^2) = 1$ and $\det W'(\tau) = \eta_K(\tau) = -1$, so $W'(\tau)$ is conjugate to $\mathrm{diag}(1, -1)$ and $W'|_{I_{\bar{p}}}$ is conjugate to $\mathrm{diag}(\mathbf{1}, \eta_K)$, characters of level $|d_K|$, hence of level $N|d_K|$.

- (Lw2) at ℓ. Let $D_\ell \subseteq G_{\mathbb{Q}}$ be the decomposition group at $\bar{\ell}$ and $D' = D_\ell \cap G_K = D_{\bar{\ell}}$; $I_{\bar{\ell}} \subseteq D'$ by (ii). Take h, κ_a of (Lo2) at $\bar{\ell}$ and let V_1 be the line spanned by he_1, stable under $\rho(D')$ with character κ_1. The projection $U \oplus L \to L$ is D'-equivariant and D' acts on L trivially ($\mu = \mathbf{1}$); as $\kappa_1 = \Psi \neq \mathbf{1}$ on $I_{\bar{\ell}}$ by (iv), V_1 projects to 0, so $V_1 \subseteq U$, and D' acts on U/V_1 by $\kappa_1^{-1} \det C = \kappa_1^{-1}$. If $D' \neq D_\ell$, let $\tau \in D_\ell \setminus D'$; $W'(\tau)V_1 \subseteq U$ is D'-stable with character $g \mapsto \kappa_1(\tau^{-1}g\tau)$, equal to Ψ on the normal subgroup $I_{\bar{\ell}}$. If $W'(\tau)V_1 \neq V_1$, then $U = V_1 \oplus W'(\tau)V_1$ and $U/V_1 \cong W'(\tau)V_1$, so $\Psi^{-1} = \Psi$ on $I_{\bar{\ell}}$, contradicting (iv). So V_1 is $W'(D_\ell)$-stable and W' is triangular on D_ℓ with a diagonal (λ_1, λ_2) of characters of D_ℓ, with $\lambda_1 = \Psi = \chi_{\mathrm{cyc}}^e\chi$ and $\lambda_2 = \det W' \cdot \lambda_1^{-1} = \chi_{\mathrm{cyc}}^{-e}\chi^{-1}$ on $I_{\bar{\ell}} \subseteq G_K$; $\chi^{\pm 1}$ are of level N. Genericity: $\lambda_a \neq \lambda_a\chi_{\mathrm{cyc}}$ by (ii); $\lambda_1 = \lambda_2\chi_{\mathrm{cyc}}$ would give $\chi^2\chi_{\mathrm{cyc}}^{2e-1} = \mathbf{1}$ on $I_{\bar{\ell}}$, and $\lambda_2 = \lambda_1\chi_{\mathrm{cyc}}$ would give $\chi^{-2}\chi_{\mathrm{cyc}}^{-2e-1} = \mathbf{1}$; on $I_{\bar{\ell}} \cap \ker\chi$ both contradict (ii), as $2e \pm 1 \neq 0$.

So W' has level $N|d_K|$ and weights $(e, -e)$, and $\det W' = \eta_K$ is of level $|d_K|$. □

Proposition 47.12. *Let $(K, \ell, 1, N, \chi)$ be a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$ with $e_{\mathcal{O}} = 1$, assume $\chi_\ell = \mathbf{1}$, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. Let $g_\star$ be a marking and (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$. For every point φ of type I such that $\rho_\varphi \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type for ι, ρ_φ is generic at every place $v \mid \ell$ of K.*

Proof. Let φ be as in the statement and $\rho = \rho_\varphi$.

Step 1: the triangular forms. By Lemma 47.3, $\varphi \circ r$ is a triangular lift to an integral test ring A for $g_\star$, formed with K, $\mathcal{O}$, Ψ and $\bar{\ell}$, with $\rho_{\varphi\circ r} = \rho$; and $\Psi(c) = 1$ by (Ue5). Let $v \mid \ell$ be a place of K. By Lemma 47.9, (Lo2), v lies below some $\bar{w} \in \{\bar{\ell}, c\bar{\ell}\}$, and there are $h \in \mathrm{GL}_3(A)$ and characters $\kappa_1, \kappa_2, \kappa_3$ of the decomposition group $D = D_{\bar{w}}$ of G_K at $\bar{w}$ such that $h^{-1}\rho(g)h$ is upper triangular with diagonal $(\kappa_a(g))_a$ for $g \in D$, and $\kappa_a = \psi_a$ on the inertia group $I_{\bar{w}}$. Write $N = \ell^b N'$ with $\ell \nmid N'$; on $I_{\bar{w}}$, $\chi = \chi_\ell(\varepsilon \bmod \ell^b) = 1$, so $\Psi = \varepsilon$ and $(\kappa_1, \kappa_2, \kappa_3) = (\varepsilon, 1, \varepsilon^{-1})$ on $I_{\bar{w}}$.

Step 2: only two coincidences are possible. If $\kappa_i = \kappa_j\varepsilon$ on D, then $\varepsilon^{2-i} = \varepsilon^{3-j}$ on $I_{\bar{w}}$, where ε has infinite order; so $j = i + 1$. Hence the diagonal (κ_a) is generic unless $\kappa_1 = \kappa_2\varepsilon$ or $\kappa_2 = \kappa_3\varepsilon$ on D.

Step 3: $r' = \rho \otimes \varepsilon^{-1}$ is the representation attached to π. By hypothesis $r' \leftrightarrow_\iota \pi$ for a regular algebraic conjugate self-dual cuspidal π of $\mathrm{GL}_3(\mathbb{A}_K)$; π is polarizable with the trivial character,

and r' is irreducible (φ is of type I). By the Chebotarev density theorem and the Brauer–Nesbitt theorem, r' and the semisimple $r_{\ell,\iota}(\pi)$ of Theorem B.62, which agree in characteristic polynomials at almost all Frobenius elements by (Bg1), are isomorphic.

Step 4: r' is crystalline at $\bar{w}$. If $\bar{w} = \bar{\ell}$, $\rho|_D$ is crystalline by Proposition 47.13. If $\bar{w} = c\bar{\ell}$: by (Tl1), (Tl2), $r(c) = (1,-1)$ in $\mathcal{G}_3$, so $\rho(cgc) = \theta(\rho(g)) = J\,{}^t\rho(g)^{-1}J$ for $g \in G_K$; the decomposition group at $c\bar{\ell}$ is $c(D_\ell \cap G_K)c$, and $g \mapsto cgc$ is the isomorphism of decomposition groups induced by the isomorphism of completions given by c; so $\rho|_D$ is the transport along this isomorphism of the dual of the crystalline $\rho|_{D_\ell \cap G_K}$, hence crystalline. As ε is crystalline, so is $r'|_D$, and the monodromy of $\mathrm{WD}(r'|_D)$ vanishes.

Step 5: the Frobenius eigenvalues. $r'|_D$ is triangular with the crystalline diagonal characters $\kappa_a\varepsilon^{-1}$ (subquotients of a crystalline representation). Fontaine's functor D_{pst} is exact and compatible with tensor products, so $\mathrm{WD}(r'|_D)$ has the semisimplification $\bigoplus_a \mathrm{WD}(\kappa_a\varepsilon^{-1})$, and $\mathrm{WD}(\mu\mu') = \mathrm{WD}(\mu) \otimes \mathrm{WD}(\mu')$ for characters μ, μ' of D for which both sides are defined. $\mathrm{WD}(\varepsilon)$ is the unramified character on which a geometric Frobenius Φ ($n(\Phi) = -1$) acts by q_v^{-1} or by q_v, according to the normalisation of (Wd2) ($D_{\mathrm{cris}}(\varepsilon)$ is spanned by t^{-1}, on which the crystalline Frobenius acts by ℓ^{-1}, and q_v is a power ℓ^f); in either case its image β under ι has $|\beta| \neq 1$. Let α_a be the eigenvalue of Φ on $\mathrm{WD}(\kappa_a\varepsilon^{-1})$; the eigenvalues of Φ on $\mathrm{WD}(r'|_D)$ are $\alpha_1, \alpha_2, \alpha_3$. By Step 3, $\mathrm{WD}(r'|_D) \cong \mathrm{WD}(r_{\ell,\iota}(\pi)|_D)$, so by Theorem B.73 (with $F = K$, $n = 3$, the place v and $\bar{v} = \bar{w}$) $\mathrm{WD}(r'|_D) = (V, \rho', N)$ is pure of some weight k. By Step 4, $N = 0$; for every $i \geq 1$ the map $\mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$ induced by $N^i = 0$ is then both zero and an isomorphism (Pu2), so $\mathrm{gr}_j = 0$ for all $j \neq k$, and since the filtration is 0 for small and V for large indices, $V = \mathrm{gr}_k$. By (Pu1), $|\iota(\alpha_a)| = q_v^{k/2}$ for $a = 1,2,3$. If $\kappa_1 = \kappa_2\varepsilon$, then $\mathrm{WD}(\kappa_1\varepsilon^{-1}) = \mathrm{WD}(\kappa_2\varepsilon^{-1}) \otimes \mathrm{WD}(\varepsilon)$, so $\iota(\alpha_1) = \iota(\alpha_2)\beta$ and $|\iota(\alpha_1)| \neq |\iota(\alpha_2)|$, a contradiction; likewise $\kappa_2 = \kappa_3\varepsilon$ is impossible. By Step 2, the diagonal (κ_a) on $D_{\bar{w}}$ is generic.

Step 6: all places above v. Let $\bar{v} \mid v$. G_K acts transitively on the places of $\overline{\mathbb{Q}}$ above v, so $\bar{v} = \gamma\bar{w}$ with $\gamma \in G_K$ and $D_{\bar{v}} = \gamma D\gamma^{-1}$; for $g \in D$, $(\rho(\gamma)h)^{-1}\rho(\gamma g\gamma^{-1})\rho(\gamma)h = h^{-1}\rho(g)h$. So ρ is triangular on $D_{\bar{v}}$ with diagonal $\kappa_a(\gamma^{-1}\cdot\gamma)$, and since $\varepsilon(\gamma^{-1}g\gamma) = \varepsilon(g)$ the inequalities $\kappa_i \neq \kappa_j\varepsilon$ persist. So ρ is generic at v. □

Proposition 47.13. *Let $(K, \ell, 1, N, \chi)$ be a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and assume $\chi_\ell = \mathbf{1}$. Let $g_\star$ be a marking and (R, r) a normalised ordinary Eisenstein deformation ring for $g_\star$. For every point φ of (R, r), the restriction of ρ_φ to $D_\ell \cap G_K$ (the absolute Galois group of the completion of K at the place below $\bar{\ell}$) is crystalline.*

Proof. Setting. Put $D' = D_\ell \cap G_K$. By (Ue6), ℓ is unramified in K, so $I_\ell \subseteq D'$. Through an embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell$ inducing $\bar{\ell}$, D' is the absolute Galois group G_M of the completion M of K at the place below $\bar{\ell}$, $I_\ell = I_M$, and $\varepsilon|_{D'}$ is the cyclotomic character of M. As $\chi_\ell = \mathbf{1}$, $D_\ell^\circ = D_\ell \cap \ker \eta_K = D'$. Write $N = \ell^b N'$ with $\ell \nmid N'$; an element of I_ℓ fixes the N'-th roots of unity, so $\chi = \chi_\ell(\varepsilon \bmod \ell^b) = \mathbf{1}$ on I_ℓ, hence $\Psi = \varepsilon$ and $\psi_a = \varepsilon^{2-a}$ on I_ℓ. For an $\mathcal{O}$-algebra homomorphism $y\colon R_\ell^\square \to A$ write $\rho_y\colon D' \to \mathrm{GL}_3(A)$ for the restriction to D' of the GL-part of $y \circ r_\ell^\square$.

Step 1: the components. $R_\ell^\square$ is Noetherian, so I_ℓ^{ord} is the intersection of finitely many minimal primes $\mathfrak{P}$ of I^{cr} (those contained in the kernel of every base point). For each of them $\mathrm{gd} = \mathrm{gd}(r_\ell^\square) \notin \mathfrak{P}$ and $\ell \notin \mathfrak{P}$. Indeed, put $J = \{z : \mathrm{gd}^n z \in I^{\mathrm{ord}}(r_\ell^\square) \text{ for some } n\}$, so that $I^{\mathrm{cr}} = \sqrt{J}$ and $\mathfrak{P}$ is minimal over J; if $\mathrm{gd} \in \mathfrak{P}$, then, $JR_{\ell,\mathfrak{P}}^\square$ being primary to the maximal ideal, $\mathrm{gd}^n \in JR_{\ell,\mathfrak{P}}^\square$ for some n, i.e. $t\,\mathrm{gd}^n \in J$ for some $t \notin \mathfrak{P}$; then $t \in J \subseteq \mathfrak{P}$ (if $\mathrm{gd}^n t \in J$ then $\mathrm{gd}^{n+m}t \in I^{\mathrm{ord}}(r_\ell^\square)$ for some m), a contradiction. As $\mathrm{gd} = \ell\,\mathrm{dt}_1\mathrm{dt}_2$, also $\ell \notin \mathfrak{P}$.

Step 2: points with $\mathrm{gd} \neq 0$ are crystalline. Let $\mathfrak{P}$ be as in Step 1, A the valuation ring of a

finite extension of the fraction field of $\mathcal{O}$ in $\overline{\mathbb{Q}}_\ell$, and $y\colon R^{\square}_\ell \to A$ an $\mathcal{O}$-algebra homomorphism with $y(\mathfrak{m}_{R^{\square}_\ell}) \subseteq \mathfrak{m}_A$, $y(\mathfrak{P}) = 0$ and $y(\mathrm{gd}) \neq 0$. We show: ρ_y is crystalline with τ-Hodge–Tate weights $\{1, 0, -1\}$ for every embedding $\tau\colon M \to \overline{\mathbb{Q}}_\ell$. As $I_\ell^{\mathrm{ord}} \subseteq \mathfrak{P}$, $y(I_\ell^{\mathrm{ord}}) = 0$, and (Ol2) for the integral test ring A gives $h \in \mathrm{GL}_3(A)$ and characters $\kappa_1, \kappa_2, \kappa_3$ of D' such that $Y(g) = h^{-1}\rho_y(g)h$ is upper triangular with diagonal $(\kappa_a(g))_a$ for $g \in D'$, and $\kappa_a = \psi_a = \varepsilon^{2-a}$ on I_ℓ. The diagonal entries $\psi_b(\sigma_0) = \varepsilon(\sigma_0)^{2-b}$ of $Y(\sigma_0)$ are pairwise distinct ($\varepsilon(\sigma_0)$ has infinite order), so there is an upper triangular $Q \in \mathrm{GL}_3(\mathrm{Frac}\, A)$ (its columns are eigenvectors of $Y(\sigma_0)$, the b-th in the span of $e_1, \dots, e_b$) with $Q^{-1}Y(\sigma_0)Q = \mathrm{diag}(\psi_b(\sigma_0))_b$; then $Q^{-1}Y(\sigma_\ell)Q$ is upper triangular with diagonal $(\kappa_b(\sigma_\ell))_b$, since $\sigma_\ell \in D_\ell^\circ = D'$. The matrix $\big(\mathrm{diag}(\psi_b(\sigma_0)) - \psi_{a+1}(\sigma_0)\big)\big(\mathrm{diag}(\psi_b(\sigma_0)) - \psi_{a+2}(\sigma_0)\big)$ is gp_a times the matrix unit E_{aa}. The entries of $\mathrm{tq}_a(r^{\square}_\ell)$ are polynomials in the entries of $\underline{r^{\square}_\ell}(\sigma_0)$, $\underline{r^{\square}_\ell}(\sigma_\ell)$, and the trace is invariant under conjugation, so

$$y(\mathrm{tq}_a(r^{\square}_\ell)) = \mathrm{tr}\big(\mathrm{gp}_a E_{aa}\, Q^{-1}Y(\sigma_\ell)Q\big) = \mathrm{gp}_a\, \kappa_a(\sigma_\ell),$$
$$y(\mathrm{dt}_a(r^{\square}_\ell)) = \mathrm{gp}_a \mathrm{gp}_{a+1}\big(\kappa_a(\sigma_\ell) - \varepsilon(\sigma_\ell)\kappa_{a+1}(\sigma_\ell)\big).$$

As $y(\mathrm{gd}) = \ell\, y(\mathrm{dt}_1)y(\mathrm{dt}_2) \neq 0$, we get $\kappa_1 \neq \kappa_2\varepsilon$ and $\kappa_2 \neq \kappa_3\varepsilon$ on D'; and $\kappa_1 \neq \kappa_3\varepsilon$, since on I_ℓ, $\kappa_1\kappa_3^{-1} = \varepsilon^2 \neq \varepsilon$. By Lemma 47.14 (with M, $n = 3$, $(m_1, m_2, m_3) = (1, 0, -1)$ and the upper triangular Y), $\rho_y \cong Y$ is crystalline; its graded pieces $\kappa_a = \varepsilon^{2-a} \cdot$ (unramified) have τ-Hodge–Tate weight $2 - a$ for every τ, so its τ-Hodge–Tate weights are $\{1, 0, -1\}$.

Step 3: the crystalline ideal after enlarging the coefficients. Let $\mathcal{O}' \supseteq \mathcal{O}$ be the ring of integers of a finite extension of the fraction field of $\mathcal{O}$ in $\overline{\mathbb{Q}}_\ell$ containing the images of all embeddings $M \to \overline{\mathbb{Q}}_\ell$, with residue field $\mathbb{F}'$, and $R' = R^{\square}_\ell \otimes_{\mathcal{O}} \mathcal{O}'$. As $\mathcal{O}'$ is free of finite rank over $\mathcal{O}$, R' is a finite free $R^{\square}_\ell$-module, hence a complete Noetherian semi-local ring whose maximal ideals lie over $\mathfrak{m}_{R^{\square}_\ell}$; as $R'/\mathfrak{m}_{R^{\square}_\ell}R' = \mathcal{O}'/\mathfrak{m}_{\mathcal{O}}\mathcal{O}'$ is local with residue field $\mathbb{F}'$, R' is a complete local Noetherian $\mathcal{O}'$-algebra with residue field $\mathbb{F}'$, whose maximal ideal is generated by $\mathfrak{m}_{R^{\square}_\ell}$ and $\mathfrak{m}_{\mathcal{O}'}$. The homomorphism $\rho' = \rho_{\mathrm{id}} \otimes 1\colon D' \to \mathrm{GL}_3(R')$ is a continuous lift of $\bar\rho = \mathrm{T}(\bar\Psi)|_{D'}$ (with values in $\mathbb{F}_{\mathcal{O}} \subseteq \mathbb{F}'$). Let (S, ρ^S) be the universal lifting ring of $\bar\rho$ over $\mathcal{O}'$, $h_S\colon S \to R'$ the local homomorphism with $h_S \circ \rho^S = \rho'$, $\mathfrak{a} \subseteq S$ the ideal of Theorem B.57 for $H_\tau = \{1, 0, -1\}$ (all τ), and $\mathfrak{b} = h_S(\mathfrak{a})R'$. Let $y\colon R^{\square}_\ell \to A$ be an $\mathcal{O}$-algebra homomorphism into the valuation ring of a finite extension, with $y(\mathfrak{m}_{R^{\square}_\ell}) \subseteq \mathfrak{m}_A$; let A' be the valuation ring of the compositum of the fraction fields of A and $\mathcal{O}'$, and $y'\colon R' \to A'$, $z \otimes o \mapsto y(z)o$. Then y' maps the maximal ideal of R' into $\mathfrak{m}_{A'}$, and $y' \circ h_S$ is a local $\mathcal{O}'$-algebra homomorphism with $(y' \circ h_S) \circ \rho^S = y' \circ \rho' = \rho_y$. By Theorem B.57:

$$y'(\mathfrak{b}) = 0 \iff \rho_y \text{ is crystalline with } \tau\text{-Hodge–Tate weights } \{1, 0, -1\} \text{ for every } \tau. \tag{47.4}$$

Step 4: each component lies in the crystalline locus. Let $\mathfrak{P}$ be as in Step 1, $B = R^{\square}_\ell/\mathfrak{P}$ and $B' = B \otimes_{\mathcal{O}} \mathcal{O}' = R'/\mathfrak{P}R'$. We show that the image $\bar{\mathfrak{b}}$ of $\mathfrak{b}$ in B' is 0. B is a domain in which $\ell \neq 0$ (Step 1), so $\mathcal{O} \to B$ is injective and the fraction field k_B of B contains that of $\mathcal{O}$. B' is free over B, so $B' \subseteq k_B \otimes_{\mathcal{O}} \mathcal{O}'$, a finite separable algebra over the field k_B of characteristic 0, hence a product of fields; so B' is reduced, and ℓ and gd, non-zero in B, are not zero divisors in B'. B' is a quotient of R', hence complete local Noetherian with finite residue field $\mathbb{F}'$. Suppose $g \in \bar{\mathfrak{b}}$, $g \neq 0$; then $g\,\mathrm{gd} \neq 0$, and Lemma 47.15 (with $\mathcal{O}'$, $C = B'$, $f = g\,\mathrm{gd}$) gives the valuation ring A' of a finite extension and an $\mathcal{O}'$-algebra homomorphism $y_1\colon B' \to A'$ with $y_1(\mathfrak{m}_{B'}) \subseteq \mathfrak{m}_{A'}$, $y_1(g) \neq 0$ and $y_1(\mathrm{gd}) \neq 0$. Let $y\colon R^{\square}_\ell \to A'$ be the composite of $R^{\square}_\ell \to B \to B'$ with y_1: an $\mathcal{O}$-algebra homomorphism with $y(\mathfrak{m}_{R^{\square}_\ell}) \subseteq \mathfrak{m}_{A'}$, $y(\mathfrak{P}) = 0$, $y(\mathrm{gd}) \neq 0$. By Step 2, ρ_y is crystalline with τ-Hodge–Tate weights $\{1, 0, -1\}$, so by (47.4) $y'(\mathfrak{b}) = 0$. But y' and the composite $R' \to B' \xrightarrow{y_1} A'$ are $\mathcal{O}'$-linear and agree on $R^{\square}_\ell \otimes 1$, so they are equal, and $y_1(g) = 0$: a contradiction. Hence $\bar{\mathfrak{b}} = 0$, i.e. $\mathfrak{b} \subseteq \mathfrak{P}R'$.

Step 5: the points of (R,r). Let φ be a point of (R,r). By (Ol1) there is an integral test ring A with $\varphi(R)\subseteq A$ and $\varphi(\mathfrak{m}_R)\subseteq\mathfrak{m}_A$. By (Ed3), $r|_{D_\ell}=f\circ r_\ell^{\square}$ for a local homomorphism $f\colon R_\ell^{\square}\to R$ with $f(I_\ell^{\mathrm{ord}})=0$; put $x=\varphi\circ f$, so $x(\mathfrak{m}_{R_\ell^{\square}})\subseteq\mathfrak{m}_A$, $x(I_\ell^{\mathrm{ord}})=0$ and $\rho_x=\rho_\varphi|_{D'}$. The primes of Step 1 exist (otherwise $I_\ell^{\mathrm{ord}}=R_\ell^{\square}$ and $x(1)=0$), and the prime ideal $\ker x$ contains their product, hence one of them, $\mathfrak{P}$. Then $x'\colon R'\to A'$ factors through $B'=R'/\mathfrak{P}R'$, so $x'(\mathfrak{b})=0$ by Step 4, and by (47.4) $\rho_\varphi|_{D'}=\rho_x$ is crystalline. □

Lemma 47.14. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M and inertia subgroup I_M, $E\subset\overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$, $n\geq 1$, and $\rho\colon G_M\to\mathrm{GL}_n(E)$ a continuous homomorphism with values in the upper triangular matrices, with diagonal entries $\kappa_1,\dots,\kappa_n\colon G_M\to E^\times$. Assume that there are integers $m_1>m_2>\cdots>m_n$ such that $\kappa_a(g)=\chi_{\mathrm{cyc}}(g)^{m_a}$ for all $g\in I_M$ and all a, and that $\kappa_a\neq\kappa_b\chi_{\mathrm{cyc}}$ for all $a<b$. Then the representation ρ on E^n, regarded as a $\mathbb{Q}_\ell$-vector space, is crystalline.*

Proof. We use the classical facts of Fontaine's theory: crystalline representations are de Rham; they are stable under subrepresentations, quotients, tensor products and duals; χ_{cyc} and every unramified character are crystalline; for a crystalline (or de Rham) U, $\dim_{M_0}D_{\mathrm{cris}}(U)\leq\dim_{\mathbb{Q}_\ell}U$ always, with equality exactly when U is crystalline, and $\dim_M D_{\mathrm{dR}}(U)=\dim_{\mathbb{Q}_\ell}U$; in the normalisation fixed in Section 13, a de Rham U all of whose Hodge–Tate weights are ≥ 1 has $\mathrm{Fil}^0D_{\mathrm{dR}}(U)=0$, and the Hodge–Tate weights of a de Rham representation with a filtration by subrepresentations are those of its graded pieces.

The characters. Put $\mu_a=\kappa_a\chi_{\mathrm{cyc}}^{-m_a}$; by hypothesis μ_a is trivial on I_M, i.e. unramified, so $E(\kappa_a)=E(\chi_{\mathrm{cyc}}^{m_a})\otimes_E E(\mu_a)$ is crystalline with all Hodge–Tate weights equal to m_a. This is the case $n=1$. We argue by induction on $n\geq 2$.

The extension. Let $X=E^n$ with the action ρ and $X'\subset X$ the span of $e_1,\dots,e_{n-1}$, stable because ρ is upper triangular; the action on X' is upper triangular with diagonal $\kappa_1,\dots,\kappa_{n-1}$ and satisfies the hypotheses, so X' is crystalline by induction, and $X/X'\cong E(\kappa_n)$. Put $Y=X\otimes_E E(\kappa_n^{-1})$ and $U=X'\otimes_E E(\kappa_n^{-1})\subset Y$, so that $Y/U\cong E$ with trivial action. U is crystalline, and it has the filtration by the spans of $e_1,\dots,e_k$ $(k<n)$ with graded pieces $E(\kappa_a\kappa_n^{-1})$, $a<n$. Fix $y_0\in Y$ mapping to $1\in E$ and put $c(g)=gy_0-y_0\in U$, a continuous 1-cocycle.

$h^0(U)=0$ and $h^0(U^*(1))=0$. On I_M, $\kappa_a\kappa_n^{-1}=\chi_{\mathrm{cyc}}^{m_a-m_n}$ with $m_a-m_n\geq 1$, which is non-trivial because $\chi_{\mathrm{cyc}}(I_M)$ is open in $\mathbb{Z}_\ell^\times$, hence infinite; so every graded piece of U has no non-zero invariants, and by left exactness of invariants along the filtration $U^{G_M}=0$. Via the trace form of $E/\mathbb{Q}_\ell$, $U^*(1)\cong\mathrm{Hom}_E(U,E)\otimes\chi_{\mathrm{cyc}}$, which has a filtration with graded pieces $E(\kappa_n\kappa_a^{-1}\chi_{\mathrm{cyc}})$, $a<n$; these characters are non-trivial because $\kappa_a\neq\kappa_n\chi_{\mathrm{cyc}}$; so again $h^0(U^*(1))=0$.

$H^1_f(G_M,U)=H^1(G_M,U)$. By Theorem B.36, $h^1(U)=d\dim_{\mathbb{Q}_\ell}U+h^0(U)+h^0(U^*(1))=d\dim_{\mathbb{Q}_\ell}U$. The Hodge–Tate weights of U are the numbers $m_a-m_n\geq 1$, so $\mathrm{Fil}^0D_{\mathrm{dR}}(U)=0$ and $\dim_{\mathbb{Q}_\ell}D_{\mathrm{dR}}(U)=d\dim_M D_{\mathrm{dR}}(U)=d\dim_{\mathbb{Q}_\ell}U$. By Theorem B.56, $\dim_{\mathbb{Q}_\ell}H^1_f(G_M,U)=d\dim_{\mathbb{Q}_\ell}U+h^0(U)=h^1(U)$, and $H^1_f(G_M,U)\subseteq H^1(G_M,U)$ is an equality.

Y is crystalline. By the previous step the class of c lies in $H^1_f(G_M,U)$: there is $b\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}U$ with $1\otimes c(g)=gb-b$ for all $g\in G_M$ (G_M acting diagonally). Then $z=1\otimes y_0-b\in B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}Y$ satisfies

$$gz=1\otimes(y_0+c(g))-(b+1\otimes c(g))=z\qquad(g\in G_M),$$

and so do the elements $(m\otimes\lambda)z$ for $m\in M_0$, $\lambda\in E$ (the action of E on Y commutes with G_M). Invariants are left exact, so $0\to D_{\mathrm{cris}}(U)\to D_{\mathrm{cris}}(Y)\to D_{\mathrm{cris}}(E)=M_0\otimes_{\mathbb{Q}_\ell}E$ is exact, and the last map sends $(m\otimes\lambda)z$ to $m\otimes\lambda$; so it is onto, and $\dim_{M_0}D_{\mathrm{cris}}(Y)=\dim_{\mathbb{Q}_\ell}U+[E:\mathbb{Q}_\ell]=\dim_{\mathbb{Q}_\ell}Y$. Hence Y is crystalline, and so is $X=Y\otimes_E E(\kappa_n)$. □

Lemma 47.15. *Let $\mathcal{O} \subset \overline{\mathbb{Q}}_\ell$ be a coefficient ring with maximal ideal $\mathfrak{m}_\mathcal{O}$, and let C be a complete local Noetherian ring with finite residue field and maximal ideal $\mathfrak{m}_C$, together with a ring homomorphism $\mathcal{O} \to C$ mapping $\mathfrak{m}_\mathcal{O}$ into $\mathfrak{m}_C$. Assume that C is reduced and that ℓ is not a zero divisor in C. Then for every $f \in C$ with $f \neq 0$ there are the valuation ring A of a finite extension of the fraction field of $\mathcal{O}$ inside $\overline{\mathbb{Q}}_\ell$ and an $\mathcal{O}$-algebra homomorphism $y\colon C \to A$ with $y(\mathfrak{m}_C) \subseteq \mathfrak{m}_A$ and $y(f) \neq 0$.*

Proof. Reduction to a domain. C is reduced and Noetherian, so the intersection of its finitely many minimal primes is 0 and their union is the set of zero divisors. Choose a minimal prime Q with $f \notin Q$; then $\ell \notin Q$. C/Q satisfies the hypotheses, is a domain, and $f \neq 0$, $\ell \neq 0$ in it; a homomorphism $C/Q \to A$ as required gives one for C. So assume C is a domain. Then $\ell \neq 0$ lies in $\mathfrak{m}_C$, so $\dim C \geq 1$, and by Lemma 47.7 (for the non-zero element ℓf) there is a prime q with $\ell f \notin q$ and $\dim C/q = 1$; C/q again satisfies the hypotheses with $f \neq 0$, so we may assume $\dim C = 1$.

The one-dimensional case. Since $\ell \neq 0$ in the one-dimensional local domain C, $C/\ell C$ has dimension 0: it is an Artinian local ring with finite residue field, so its maximal ideal is nilpotent, $\mathfrak{m}_C^N \subseteq \ell C$ for some N, and $C/\ell C$, of finite length with each $\mathfrak{m}_C^i/\mathfrak{m}_C^{i+1}$ finite-dimensional over the finite residue field, is finite. Hence $C/\mathfrak{m}_\mathcal{O} C$ is finite and the $\mathfrak{m}_C$-adic and $\mathfrak{m}_\mathcal{O}$-adic topologies of C coincide; as C is complete and separated, C is a finitely generated $\mathcal{O}$-module (Nakayama's lemma for complete modules). The map $\mathcal{O} \to C$ is injective (its kernel is a prime of $\mathcal{O}$ not containing ℓ), so C is a domain finite over $\mathcal{O}$, and $k = C[\ell^{-1}]$ is a domain finite over the field $\mathrm{Frac}(\mathcal{O})$, hence a field. Choose an embedding $k \to \overline{\mathbb{Q}}_\ell$ over $\mathrm{Frac}(\mathcal{O}) \subset \overline{\mathbb{Q}}_\ell$, let y be its restriction to C (injective, so $y(f) \neq 0$) and A the valuation ring of the image of k; $y(C) \subseteq A$ because C is integral over $\mathcal{O}$. For $x \in \mathfrak{m}_C$, $x^N \in \ell C$, so $y(x)^N \in \ell A$ and $|y(x)|_\ell < 1$: $y(\mathfrak{m}_C) \subseteq \mathfrak{m}_A$. □

Theorem 47.16. *Let (ℓ, e, N, χ, o, m) be a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$ for a coefficient ring $\mathcal{O}$, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. There is a marking $g_\star$ such that for every dyadic Eisenstein deformation ring (R, r) for $g_\star$:*

(Da1) *R^0 is a finitely generated $\mathcal{O}$-module;*

(Da2) *every point φ of (R, r) of type I is Lie-irreducible automorphic for ι, and ρ_φ is admissible of stable type for (ι, e, N).*

Proof. Choice of the marking. By Theorem 48.1, case (b), there is a marking $g_\star$ with (Tp1) and (Tp2). Let (R, r) be a dyadic Eisenstein deformation ring for $g_\star$.

(Da1). By (Tp1) the hypothesis of Proposition 47.2, case (b), holds, so R^0 is a finitely generated $\mathcal{O}$-module.

Points are triangular lifts. Let φ be a point. Since R is local with residue field $\mathbb{F}_\mathcal{O}$, $R = \mathcal{O} + \mathfrak{m}_R$, so $|\varphi(y)|_\ell \leq 1$ for all $y \in R$. Choose $x_1, \ldots, x_n$ generating $\mathfrak{m}_R$ and a surjection $\pi\colon \mathcal{O}[[X_1, \ldots, X_n]] \to R$ with $X_i \mapsto x_i$; put $a_i = \varphi(x_i)$, let $E \subset \overline{\mathbb{Q}}_\ell$ be the finite extension of the fraction field of $\mathcal{O}$ generated by the a_i, and A its valuation ring. For $f \in \mathcal{O}[[X]]$ and $k \geq 1$ write $f = P_k + \sum_{|\alpha|=k} X^\alpha g_\alpha$ with P_k a polynomial; then $|\varphi(\pi f) - P_k(a)|_\ell \leq \max_i |a_i|_\ell^k \to 0$, so $\varphi(\pi f) = \lim_k P_k(a) \in A$ (A is closed). Thus $\varphi(R) \subseteq A$, A is an integral test ring, and $\varphi\colon R \to A$ maps $\mathfrak{m}_R$ into $\mathfrak{m}_A$. Put $r'' = \varphi \circ r\colon G_\mathbb{Q} \to \mathcal{G}_3(A)$. By Lemma 47.4, r'' is a triangular lift to A for $g_\star$, with $\rho_{r''} = \rho_\varphi$.

(Da2). Let φ be of type I. By Lemma 47.8, (Li2), applied to the triangular lift r'' (with $\rho_{r''} = \rho_\varphi$ irreducible), ρ_φ is irreducible on every open subgroup of G_K. By (Tp2) for r'', $\rho_\varphi \otimes \varepsilon^{-1}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions. ρ_φ takes

values in $\mathrm{GL}_3(E)$ with E finite over $\mathbb{Q}_\ell$, so by Lemma 42.7 (with $F = K$) the identity component $\mathbf{Z}^\circ$ of the Zariski closure of $\rho_\varphi(G_{K(\mu_{\ell^\infty})})$ acts irreducibly on $\overline{\mathbb{Q}}_\ell^3$; the stabiliser of a subspace is Zariski closed, so a subspace stable under $\rho_\varphi(G_{K(\mu_{\ell^\infty})})$ is stable under $\mathbf{Z}^\circ$, and $\rho_\varphi|_{G_{K(\mu_{\ell^\infty})}}$ is irreducible. Hence φ is Lie-irreducible automorphic for ι. Finally (Sb1) is type I, (Sb2) was just shown, and (Sb3), (Sb4) are Proposition 47.11, (Cv1), in case (b), applied to the triangular lift r'', whose $\rho_{r''}$ is ρ_φ; so ρ_φ is admissible of stable type for (ι, e, N). □

48 Triangular lifts over auxiliary fields

This section proves Theorem 48.1, the automorphy of Lie-irreducible triangular lifts and the finiteness in characteristic ℓ, for both kinds of Eisenstein data; Section 47 uses it. The proof passes to an auxiliary field. Theorem 48.3 gives a marking and an abelian CM field $L \supseteq K$ over which the triangular lifts have residual characteristic polynomials in characteristic ℓ (Ax1), are automorphic of conjugate self-dual type with the witness conditions when irreducible (Ax2), stay generic above ℓ (Ax3), and have a modular endoscopic corner (Ax4). Automorphy then descends from L to K along the abelian CM extension (Proposition 48.18, Proposition 48.19), and the corner of a lift of type II comes from a newform over $\mathbb{Q}$ (Proposition 48.14, Proposition 48.16).

An auxiliary field (Definition 48.2) is an abelian CM field, unramified over its totally real subfield at the finite places, on which the residual characters are non-degenerate (Ar1) and which satisfies two opposite requirements. Certain strict Selmer groups of the residual characters are non-zero (Ar2), while the Selmer ranks are bounded by a constant C_0 (Ar3) and the degree $[L^+ : \mathbb{Q}]$ exceeds $3C_0 + 7$ (Ar4); the constant C_0 and the degree enter the dimension estimates of Section 49 (Lemma 49.30, Proposition 49.29). Auxiliary fields exist (Proposition 48.4): along the layers of a cyclotomic ℓ-tower all conditions but the size hold at the level of the ℓ-rank of the class group of the layer (Proposition 48.5), and that rank is bounded along the tower by the theorem of Ferrero and Washington (Lemma 39.5, from Section 39), while the degree grows. The Euler-characteristic inequality of clause (iv) of (Ar5), for the Galois group of L^+ modulo tame inertia is Proposition 48.9. Given an auxiliary field, Theorem 48.3 follows from the $R = T$ theorem of Section 49 by restricting the triangular lifts to G_L (Lemma 48.10).

Theorem 48.1. *Let $\mathcal{O}$ be a coefficient ring, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and assume that (a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $e_\mathcal{O} = 1$, or (b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ valued in $\mathcal{O}^\times$ and $K = \mathbb{Q}(i)$. Form triangular lifts with K, $\mathcal{O}$ and $\Psi = \Psi_{\chi,e}$. Then there is a marking $g_\star$ such that, for triangular lifts for $g_\star$:*

(Tp1) *there is a subgroup U of finite index in $G_\mathbb{Q}$ such that for every test ring A of characteristic ℓ, every triangular lift r to A and every $g \in U \cap G_K$, the characteristic polynomials of $\underline{r}(g)$ and of $\underline{r_0}(g)$ (mapped to A) agree;*

(Tp2) *for every triangular lift r to an integral test ring such that $\rho_r|_V$ is irreducible for every open subgroup $V \subseteq G_K$, the representation $\rho_r \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions;*

(Tp3) *in case (a): for every triangular lift r of type II to an integral test ring with $\rho_r(g)_{22} = 1$ for all $g \in G_K$, every continuous $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ whose restriction to G_K is the corner of r and with $\operatorname{tr} W(c) = 0$ satisfies (Eo2) and the witness conditions over imaginary quadratic fields.*

Proof. By Theorem 48.3 there are a marking $g_\star$ and a CM field L, abelian over $\mathbb{Q}$ and containing K, with (Ax1)–(Ax4). Then (Tp1) is (Ax1) and (Tp3) is (Ax4). We prove (Tp2). Write ε for χ_{cyc} on G_K (and on its subgroups). Let A be an integral test ring, r a triangular lift to A with $\rho = \rho_r$ irreducible on every open subgroup of G_K, and put $r' = \rho \otimes \varepsilon^{-1}$. We check hypotheses 1–6 of Proposition 48.18 for r', with K, L and c; that proposition then gives the claim.

Continuity. The ring A is a discrete valuation ring finite over $\mathcal{O}$ inside $\overline{\mathbb{Q}}_\ell$, so it is the valuation ring of its fraction field and its $\mathfrak{m}_A$-adic topology is the ℓ-adic one; by (Tl1) ρ is continuous, and so is r'.

Hypothesis 1 (polarisation), with $P = J$. By (Tl1) and (Tl2), $r(c) = (1,-1)$; as $c^2 = 1$, for $s \in G_K$ with $r(s) = (\rho(s), 1)$ we get $r(csc) = (1,-1)(\rho(s),1)(1,-1) = (\theta(\rho(s)),1)$, so $\rho(csc) = J\,{}^t\rho(s)^{-1}J$ and ${}^t\rho(s)\,J\,\rho(csc) = J$. Since ε is the restriction of a character of $G_{\mathbb{Q}}$ and $\varepsilon(c)^2 = 1$, $\varepsilon(csc) = \varepsilon(s)$, hence ${}^t r'(s)\,J\,r'(csc) = \varepsilon(s)^{-2}J$.

Hypothesis 2. The extension L/K is finite, so G_L is open in G_K and $\rho|_{G_L}$ is irreducible; so is its twist $r'|_{G_L}$.

Hypothesis 3 (inertia away from ℓ). The character $\Psi = \Psi_{\chi,e}$ satisfies $\Psi(c) = 1$ (by (Ue5) in case (a), by (Dy3) in case (b)), so Lemma 47.9 applies to r. Let $v \nmid \ell$ be a finite place of K and $\bar{v} \mid v$; the inertia group $I_{\bar{v}}$ of G_K at $\bar{v}$ is the intersection with G_K of the inertia group of $G_{\mathbb{Q}}$ at $\bar{v}$. By Lemma 47.9, (Lo1), there are $P \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ and integers a_1, a_2, a_3 with $\rho(g) = P\,\mathrm{diag}(\Psi(g)^{a_1}, \Psi(g)^{a_2}, \Psi(g)^{a_3})P^{-1}$ for $g \in I_{\bar{v}}$. Put $\kappa_i = (\Psi^{a_i}\varepsilon^{-1})|_{D_{\bar{v}}}$, continuous characters of $D_{\bar{v}}$. The field generated by the ℓ-power roots of unity is unramified at the prime below v, so $\varepsilon(g) = 1$ for $g \in I_{\bar{v}}$, and $\det(X - r'(g)) = \det(X - \rho(g)) = \prod_i (X - \Psi(g)^{a_i}) = \prod_i (X - \kappa_i(g))$.

Hypothesis 4 (triangular above ℓ). Let $v \mid \ell$ be a place of K and $\bar{v} \mid v$. By Lemma 47.9, (Lo2), v lies below some $\bar{w} \in \{\bar{\ell}, c\bar{\ell}\}$, and there are $h \in \mathrm{GL}_3(A)$ and characters $\kappa_1, \kappa_2, \kappa_3$ of the decomposition group $D_{\bar{w}}$ of G_K at $\bar{w}$ such that $h^{-1}\rho(g)h$ is upper triangular with diagonal $(\kappa_1(g), \kappa_2(g), \kappa_3(g))$ for $g \in D_{\bar{w}}$. The group G_K acts transitively on the places of $\overline{\mathbb{Q}}$ above v, so $\bar{v} = \gamma\bar{w}$ with $\gamma \in G_K$, and $D_{\bar{v}} = \gamma D_{\bar{w}}\gamma^{-1}$. For $g \in D_{\bar{w}}$, $(\rho(\gamma)h)^{-1}\rho(\gamma g\gamma^{-1})(\rho(\gamma)h) = h^{-1}\rho(g)h$. Hence ρ is triangular on $D_{\bar{v}}$ with diagonal $(\kappa_a(\gamma^{-1}\cdot\gamma))_a$, and $r' = \rho \otimes \varepsilon^{-1}$ is triangular on $D_{\bar{v}}$ with diagonal $(\kappa_a(\gamma^{-1}\cdot\gamma)\,\varepsilon^{-1})_a$.

Hypothesis 5. Twisting by a character multiplies all diagonal characters of a triangular form by the same character, which preserves the inequalities $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}$; so r' and ρ are generic at the same places, and likewise $r'|_{G_L}$ and $\rho|_{G_L}$. If r' is generic at the place v of K below a place $w \mid \ell$ of L, then ρ is, (Ax3) makes $\rho|_{G_L}$ generic at w, and so is $r'|_{G_L}$.

Hypothesis 6. By hypothesis 2, $\rho|_{G_L}$ is irreducible, so by (Ax2) $\rho|_{G_L} \otimes \chi_{\mathrm{cyc}}^{-1} = r'|_{G_L}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.

By Proposition 48.18, $r' = \rho_r \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions. □

Definition 48.2. Let $K, \eta_K, \mathcal{O}, \mathbb{F}_{\mathcal{O}}, c$ and $\Psi\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ with $\Psi(c) = 1$ be as in Definition 43.16, with ℓ odd; let $\bar{\Psi}\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^\times$ be the reduction of Ψ, $\bar{\omega}\colon G_{\mathbb{Q}} \to \mathbb{F}_\ell^\times \subseteq \mathbb{F}_{\mathcal{O}}^\times$ the reduction of χ_{cyc}, $g_\star$ a marking and $M \geq 1$ an integer with $\ell \mid M$. For a CM field $L \subset \overline{\mathbb{Q}}$ with maximal totally real subfield L^+, the groups $G_L \subseteq G_{L^+}$ are subgroups of $G_{\mathbb{Q}}$, and $c \in G_{L^+}$.

The group Γ_L. Let N_L be the closed normal subgroup of G_{L^+} generated by the elements $s \in I_{\bar{v}} \cap G_{L^+}$, for all places $\bar{v} \nmid \ell$, with $\eta_K(s) = 1$ and $\bar{\Psi}(s) = 1$. Put $\Gamma_L = G_{L^+}/N_L$, let $\pi_L\colon G_{L^+} \to \Gamma_L$ be the projection and $\Gamma_L^0 = \pi_L(G_L)$. The characters η_K, $\bar{\Psi}$, $\bar{\omega}$ and χ_{cyc} of G_{L^+} factor through Γ_L; they are denoted by the same letters. For each place v of L^+ above ℓ fix a place $\bar{v} = \gamma_v\bar{\ell}$ of $\overline{\mathbb{Q}}$ above v with $\gamma_v \in G_K$, and put $D_v = D_{\bar{v}} \cap G_{L^+} \supseteq I_v = I_{\bar{v}} \cap G_{L^+}$ and $d_v = [L_v^+ : \mathbb{Q}_\ell]$. For each real place u of L^+ fix a complex conjugation $c_u \in G_{L^+}$ at u.

Selmer groups. Let F be a number field, N a closed normal subgroup of G_F, $\pi\colon G_F \to$

G_F/N the projection and Δ a closed subgroup of G_F/N; let W be a finite-dimensional $\mathbb{F}_{\mathcal{O}}$-vector space with a continuous linear action of Δ, and let $(H_t)_{t\in T}$ be a finite family of closed subgroups of G_F with $\pi(H_t)\subseteq\Delta$, with subspaces $b_t\subseteq W$ stable under $\pi(H_t)$. Put $H^0(\Delta;W,b)=\{X\in W^{\Delta}: X\in b_t\ \forall t\}$; $H^1(\Delta;W,b)$ is the quotient of the space of pairs $(x,(X_t)_t)$, with $x\colon\Delta\to W$ a continuous 1-cocycle and $X_t\in W$ such that $x(\pi(h))-(h-1)X_t\in b_t$ for all $h\in H_t$, by the pairs $(g\mapsto(g-1)X,\,(X_t)_t)$ with $X\in W$ and $X_t-X\in b_t$; and $H^2(\Delta;W,b)$ is the quotient of the space of pairs $(y,(y_t)_t)$, with $y\colon\Delta\times\Delta\to W$ a continuous 2-cocycle and $y_t\colon H_t\to W$ continuous such that $y(\pi(h),\pi(h'))-\big(h\,y_t(h')-y_t(hh')+y_t(h)\big)\in b_t$ for $h,h'\in H_t$, by the pairs $(d\beta,(y_t)_t)$ with $\beta\colon\Delta\to W$ continuous and $y_t(h)-\big(\beta(\pi(h))-(h-1)Y_t\big)\in b_t$ for some $Y_t\in W$. Write h^i for dimensions. For $\Delta=\Gamma_L$ or $\Delta=\Gamma_L^0$ we take $F=L^+$, $N=N_L$ and $\pi=\pi_L$; for $\Delta=\Gamma_L$ the family is $(D_v)_{v|\ell}$; for $\Delta=\Gamma_L^0$ it is $(D_v)_{v|\ell}$ together with $(cD_vc)_{v|\ell}$. The **strict** group $H^1_{\mathrm{str}}(\Delta,W)$ is $H^1(\Delta;W,b)$ with all $b_t=0$; the group $H^1(\Gamma_L,W)$ (all $b_t=W$) is continuous cohomology. For a character ϕ of Δ, $\mathbb{F}_{\mathcal{O}}(\phi)$ is $\mathbb{F}_{\mathcal{O}}$ with Δ acting by ϕ.

Auxiliary fields. A CM field $L\subset\overline{\mathbb{Q}}$ is an **auxiliary field of level** $C_0\in\mathbb{N}$ for $(K,\mathcal{O},\Psi,c,g_\star,M)$ if:

(Af1) L is abelian over $\mathbb{Q}$, $K\subseteq L$, $G_L=G_{L^+}\cap G_K$, and $g_\star\in G_L$;

(Af2) every finite place of L^+ is unramified in L, and every place of L^+ above a prime dividing M splits in L;

(Af3) for every place $\bar v\nmid\ell$ and every $s\in I_{\bar v}\cap G_{L^+}$ with $\bar\Psi(s)=1$ one has $\Psi(s)=1$;

(Af4) for every place $v\mid\ell$ of L^+: $\bar\omega|_{D_v}\neq1$, $\bar\Psi^2|_{D_v}\neq1$, and $\bar\Psi(s)=1$ for every $s\in I_v$ with $\chi_{\mathrm{cyc}}(s)=1$;

(Ar1) on G_L: $\bar\omega\neq1$, $\bar\omega\bar\Psi^{\pm1}\neq1$, and $\bar\omega\neq\bar\Psi^j$ for every $j\in\mathbb{Z}$; on G_{L^+}: $\bar\omega\bar\Psi^{\pm2}\eta_K\neq1$;

(Ar2) $H^1_{\mathrm{str}}(\Gamma_L,\mathbb{F}_{\mathcal{O}}(\bar\Psi^{-1}\eta_K))\neq0$ and $H^1_{\mathrm{str}}(\Gamma_L,\mathbb{F}_{\mathcal{O}}(\bar\Psi^{-2}\eta_K))\neq0$;

(Ar3) $h^1_{\mathrm{str}}(\Gamma_L,\mathbb{F}_{\mathcal{O}}(\bar\Psi^{-2}\eta_K))\le C_0$, $h^1_{\mathrm{str}}(\Gamma_L^0,\mathbb{F}_{\mathcal{O}}(\bar\Psi^{-1}))\le C_0$ and $h^1(\Gamma_L,\mathbb{F}_{\mathcal{O}})\le1+C_0$;

(Ar4) $[L^+:\mathbb{Q}]>3C_0+7$ and $d_v>5$ for every place $v\mid\ell$ of L^+;

(Ar5) (i) every open subgroup of Γ_L has only finitely many continuous homomorphisms to $\mathbb{Z}/\ell\mathbb{Z}$; (ii) there is $h\ge1$ such that every continuous homomorphism from Γ_L^0 to a finite abelian ℓ-group that is trivial on $\pi_L(I_v)$ and $\pi_L(cI_vc)$ for all $v\mid\ell$ takes values killed by h; (iii) for every $v\mid\ell$ there are $u_1,\dots,u_{d_v}\in I_v$ with $\bar\Psi(u_a)=1$, all but at most one with $\chi_{\mathrm{cyc}}(u_a)=1$, such that every continuous homomorphism from D_v to a finite abelian ℓ-group that is trivial on $u_1,\dots,u_{d_v}$ is trivial on I_v; (iv) for every W as above with $\Delta=\Gamma_L$ and open kernel, all D_v-stable subspaces $b_v\subseteq W$, and $\mathrm{Hom}_{\Gamma_L}(W,\mathbb{F}_{\mathcal{O}}(\bar\omega))=0$: $H^2(\Gamma_L;W,b)$ is finite-dimensional and

$$h^2(\Gamma_L;W,b)+h^0(\Gamma_L;W,b)+\sum_{v|\ell}d_v\dim b_v\le h^1(\Gamma_L;W,b)+\sum_{u|\infty}\dim W^{c_u=1};\qquad(48.1)$$

(Ag1) there are an integer $N'\ge1$ with $\ell\nmid N'$, a prime $w\nmid N'$, an integer $j\ge0$ and characters $\chi',\theta\colon G_{\mathbb{Q}}\to\overline{\mathbb{Q}}_\ell^{\times}$ of finite order such that: $\theta\neq1$, $\theta^\ell=1$, θ is trivial on $G_{\mathbb{Q}(\zeta_w)}$ and on G_L; χ' and η_K are trivial on $G_{\mathbb{Q}(\zeta_{N'})}$ and on every $s\in G_{\mathbb{Q}}$ acting on the N'-th roots of unity by $\zeta\mapsto\zeta^w$; $\chi'\neq\eta_K$, $\ell\nmid\operatorname{ord}\chi'$, $\chi'(c)=(-1)^j$; $\chi_{\mathrm{cyc}}^j\chi'\equiv\Psi$ modulo the maximal ideal of the integers of $\overline{\mathbb{Q}}_\ell$; and $(\chi_{\mathrm{cyc}}^j\chi')(s)^2\not\equiv1$ for some $s\in G_L$;

(Ag2) $\ell\nmid d_K$.

Polarised ordinary lifts over L. Let L satisfy (Af1)–(Af2) and let $n \in \{2,3\}$. Put $(w_{3,1}, w_{3,2}, w_{3,3}) = (1,0,-1)$ and $(w_{2,1}, w_{2,2}) = (1,-1)$, and let J_n be the $n \times n$ matrix with entries 1 on the antidiagonal and 0 elsewhere. For a test ring A, a **polarised ordinary lift of rank n over L** to A is a homomorphism $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(A)$ with homomorphisms $\psi_{v,a}\colon D_v \to A^\times$ ($v \mid \ell$, $1 \le a \le n$) such that

(Po1) for every $k \ge 1$ the maps $g \mapsto \rho(g) \bmod \mathfrak{m}_A^k$ and $\psi_{v,a} \bmod \mathfrak{m}_A^k$ are locally constant;

(Po2) $\rho(\pi_L(cg^{-1}c)) = J_n\, {}^t\rho(\pi_L(g))\, J_n$ for all $g \in G_L$;

(Po3) the off-diagonal entries of $\rho(\pi_L(g_\star)) - \rho(\pi_L(cg_\star^{-1}c))$ vanish;

(Po4) for every $v \mid \ell$ and all $g_1, \dots, g_n \in D_v$: $\prod_{a=1}^n (\rho(\pi_L(g_a)) - \psi_{v,a}(g_a)) = 0$, the product taken with $a = 1$ on the left;

(Po5) $\rho(\pi_L(g)) \equiv \mathrm{diag}(\bar\Psi(g)^{w_{n,1}}, \dots, \bar\Psi(g)^{w_{n,n}})$ and $\psi_{v,a}(g) \equiv \bar\Psi(g)^{w_{n,a}}$ modulo $\mathfrak{m}_A$, for $g \in G_L$, resp. $g \in D_v$.

Write $\rho_L\colon G_L \to \mathrm{GL}_n(A)$, $g \mapsto \rho(\pi_L(g))$. The field L has **residual characteristic polynomials in rank** 3 if for every test ring A of characteristic ℓ and every polarised ordinary lift of rank 3 over L to A with $\psi_{v,a}(g) = 1$ whenever $g \in I_v$ and $\bar\Psi(g) = 1$, the characteristic polynomial of $\rho_L(g)$ is $\prod_{a=1}^3 (X - \bar\Psi(g)^{w_{3,a}})$ for all $g \in G_L$. For a continuous character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$, L has **automorphic irreducible lifts in rank n with twist κ** (for ι) if for every integral test ring A and every polarised ordinary lift of rank n over L to A with $\psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for $g \in I_v$ such that ρ_L is irreducible over $\overline{\mathbb{Q}}_\ell$, the representation $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions. A continuous character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ is **algebraic** (for ι) if it corresponds through ι and the global Artin map to an algebraic Hecke character of L.

Theorem 48.3. *Let $\mathcal{O}$ be a coefficient ring, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and assume one of:*

(a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$ and $e_{\mathcal{O}} = 1$;

(b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$, and $K = \mathbb{Q}(i)$.

Put $\Psi = \Psi_{\chi,e}$ and form triangular lifts with K, $\mathcal{O}$ and Ψ. Then there are a marking $g_\star$ and a CM field $L \subset \overline{\mathbb{Q}}$, abelian over $\mathbb{Q}$ and containing K, such that, for triangular lifts for $g_\star$:

(Ax1) *there is a subgroup U of finite index in $G_{\mathbb{Q}}$ such that for every test ring A of characteristic ℓ, every triangular lift r to A and every $g \in U \cap G_K$, the characteristic polynomial of $\underline{r}(g)$ equals that of $\underline{r_0}(g)$ (mapped to A);*

(Ax2) *for every triangular lift r to an integral test ring such that $\rho_r|_{G_L}$ is irreducible, the representation $\rho_r|_{G_L} \otimes \chi_{\mathrm{cyc}}^{-1}$ of G_L is automorphic of conjugate self-dual type for ι and satisfies the witness conditions;*

(Ax3) *for every triangular lift r to an integral test ring such that $\rho_r|_V$ is irreducible for every open subgroup $V \subseteq G_K$, every place $v \mid \ell$ of K at which ρ_r is generic and every place $w \mid v$ of L, $\rho_r|_{G_L}$ is generic at w;*

(Ax4) *in case (a): for every triangular lift r of type II to an integral test ring with $\rho_r(g)_{22} = 1$ for all $g \in G_K$, every continuous $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ whose restriction to G_K is the corner of r and with $\operatorname{tr} W(c) = 0$ satisfies (Eo2) and the witness conditions over imaginary quadratic fields.*

Proof. Put $M = \ell N|d_K|$ in case (a) and $M = \ell N$ in case (b). By Proposition 48.4 (applied to the complex conjugation c of Definition 43.16) there are a marking $g_\star$, an integer C_0 and an auxiliary field L of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. By (Af1), L is a CM field, abelian over $\mathbb{Q}$, with $K \subseteq L$ and $G_L \subseteq G_K$. By Theorem 49.3, L has (Pp1)–(Pp3); let κ be an algebraic character as in (Pp3). We prove (Ax1)–(Ax4) for triangular lifts for $g_\star$.

(Ax1). Take $U = G_L$, of index $[L : \mathbb{Q}]$ in $G_\mathbb{Q}$; then $U \cap G_K = G_L$. Let A be a test ring of characteristic ℓ, r a triangular lift to A and $(\rho, (\psi_{v,a}))$ the polarised ordinary lift of rank 3 over L given by Lemma 48.10, with $\rho_L = \underline{r}|_{G_L}$ and $\psi_{v,a} = \Psi^{w_{3,a}}$ on I_v. As A has characteristic ℓ, the map $\mathcal{O} \to A$ kills $\mathfrak{m}_\mathcal{O}$ and factors through $\mathbb{F}_\mathcal{O}$, so the image of $\Psi(g)^k$ in A is that of $\bar{\Psi}(g)^k$ for every $k \in \mathbb{Z}$. In particular $\psi_{v,a}(g) = 1$ whenever $g \in I_v$ and $\bar{\Psi}(g) = 1$, and (Pp1) applies: for $g \in G_L$ the characteristic polynomial of $\underline{r}(g) = \rho_L(g)$ is $\prod_{a=1}^3 (X - \bar{\Psi}(g)^{w_{3,a}})$, which is the image in $A[X]$ of the characteristic polynomial $\prod_{a=1}^3 (X - \Psi(g)^{w_{3,a}})$ of $\underline{r_0}(g)$.

(Ax2). Let A be an integral test ring and r a triangular lift to A with $\rho_r|_{G_L}$ irreducible. The lift $(\rho, (\psi_{v,a}))$ of Lemma 48.10 has $\psi_{v,a}(g) = \Psi(g)^{w_{3,a}}$ for $g \in I_v$ and $\rho_L = \underline{r}|_{G_L} = \rho_r|_{G_L}$, which is irreducible over $\overline{\mathbb{Q}}_\ell$. By (Pp2), $\rho_r|_{G_L} \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.

(Ax3). This is Proposition 48.11, applied to $g_\star$ and L.

(Ax4). In case (a), κ is algebraic and L has automorphic irreducible lifts in rank 2 with twist κ, so Proposition 48.14 gives (Ax4). □

Proposition 48.4. *Let $\mathcal{O}$ be a coefficient ring and $c \in G_\mathbb{Q}$ a complex conjugation, and assume one of:*

(a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$; put $M = \ell N|d_K|$;

(b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$, and $K = \mathbb{Q}(i)$; put $M = \ell N$.

Put $\Psi = \Psi_{\chi,e}$. Then there are a marking $g_\star$, an integer $C_0 \geq 0$ and a CM field $L \subset \overline{\mathbb{Q}}$ which is an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$.

Proof. By Proposition 48.5 there are a marking $g_\star$, a finite abelian extension E of $\mathbb{Q}$ containing a primitive ℓ-th root of unity, and CM fields L_n ($n \geq 1$) with (Ly1) and (Ly2). The prime ℓ is odd, by (Ue1) in case (a) and by (Dy1) in case (b). By Lemma 39.5, applied to E, there is an integer $C_0 \geq 0$ with $\#(\mathrm{Cl}(E')/\mathrm{Cl}(E')^\ell) \leq \ell^{C_0}$ for every field E' generated over E by a primitive ℓ^k-th root of unity, $k \geq 0$; with $k = n + 1$ this gives $r_n \leq C_0$ for every $n \geq 1$. As $\ell \geq 3$, we may fix $n \geq 1$ with $\ell^n > 3C_0 + 7$, and put $L = L_n$.

By (Ly2), L satisfies (Af1)–(Af4), (Ar1), (Ar2), (Ar5), (Ag1), (Ag2), none of which involves the level, and (Ar3) with C_0 replaced by r_n; since $r_n \leq C_0$, the three inequalities of (Ar3) hold with C_0. By (Ly1), $[L^+ : \mathbb{Q}] \geq \ell^n > 3C_0 + 7$ and $d_v \geq \ell^n > 7 > 5$ for every place $v \mid \ell$ of L^+, which is (Ar4). Hence L is an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. □

Proposition 48.5. *Let $\mathcal{O}$ be a coefficient ring and $c \in G_\mathbb{Q}$ a complex conjugation, and assume one of:*

(a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$; put $M = \ell N|d_K|$;

(b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$, and $K = \mathbb{Q}(i)$; put $M = \ell N$.

Put $\Psi = \Psi_{\chi,e}$. Then there are a marking $g_\star$, a finite abelian extension $E \subset \overline{\mathbb{Q}}$ of $\mathbb{Q}$ containing a primitive ℓ-th root of unity, and for every integer $n \geq 1$ a CM field $L_n \subset \overline{\mathbb{Q}}$ such that, with E_n the field generated over E by a primitive ℓ^{n+1}-th root of unity and $r_n \geq 0$ the integer with $\#(\mathrm{Cl}(E_n)/\mathrm{Cl}(E_n)^\ell) = \ell^{r_n}$:

(Ly1) *$[L_n^+ : \mathbb{Q}] \geq \ell^n$, and $d_v \geq \ell^n$ for every place $v \mid \ell$ of L_n^+;*

(Ly2) *L_n satisfies (Af1)–(Af4), (Ar1), (Ar2), (Ar3) with $C_0 = r_n$, (Ar5), (Ag1) and (Ag2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$.*

Proof. Write $\chi = \chi_\flat \chi_\sharp$ with $\chi_\flat$ of order prime to ℓ and $\chi_\sharp$ of ℓ-power order (both powers of χ; in case (b) these are the χ', χ'' of Definition 38.31, in case (a) $\chi_\sharp = \mathbf{1}$ by (Ue3)). Since $\chi_\sharp$ takes values in $1 + \mathfrak{m}_\mathcal{O}$, $\bar\Psi = \bar\chi_\flat \bar\omega^e$.

Step 0: facts about the data.

(Ef1) ℓ is odd ((Ue1), (Dy1)); K is imaginary quadratic with $\ell \nmid d_K$ ((Ue6); $d_K = -4$ in case (b)), which is (Ag2); $2\ell \mid M$ and $|d_K| \mid M$ (case (a): N even by (Ue2), $M = \ell N |d_K|$; case (b): $2^{c_2(\chi)} \mid N$ with $c_2(\chi) \geq 4$ by (Dy6), so $4 \mid N \mid M$). Hence η_K, $\bar\Psi$, $\bar\omega$ are trivial on $G_{\mathbb{Q}(\zeta_M)}$ (χ is a character modulo N, $\bar\omega$ comes from $\mathbb{Q}(\zeta_\ell)$, η_K has conductor $|d_K|$); in particular they are unramified at every prime not dividing M.

(Ef2) $\Psi(c) = \chi(-1)(-1)^e = 1$ by (Ue5), (Dy3); $\bar\omega(c) = -1$.

(Ef3) There is an integer $0 \leq j < \ell - 1$ with $\bar\Psi(s) = \bar\omega(s)^j$ for every $s \in I_{\bar v}$ and every place $\bar v \mid \ell$. Indeed on $I_{\bar\ell}$, χ is χ_ℓ composed with $I_{\bar\ell} \to (\mathbb{Z}/\ell^a\mathbb{Z})^\times$; the prime-to-$\ell$ part of χ_ℓ is trivial on the ℓ-group $(1+\ell\mathbb{Z})/(1+\ell^a\mathbb{Z})$, hence factors through the cyclic group $(\mathbb{Z}/\ell\mathbb{Z})^\times$, on which $\bar\omega$ is an isomorphism onto $\mathbb{F}_\ell^\times$, the unique subgroup of order $\ell - 1$ of $\mathbb{F}_\mathcal{O}^\times$; its ℓ-power part reduces to 1. So $\bar\chi = \bar\omega^k$ on $I_{\bar\ell}$ for some k, $\bar\Psi = \bar\omega^{k+e}$ there, and conjugation (the characters are abelian) gives the other places above ℓ.

(Ef4) $\ker\bar\omega \cap \ker\bar\Psi \not\subseteq \ker\eta_K$. Case (a): $\ker\bar\omega \cap \ker\bar\Psi = \ker\bar\omega \cap \ker\chi$ (χ has order prime to ℓ); on $\ker\bar\omega = G_{\mathbb{Q}(\zeta_\ell)}$ the ℓ-component χ_ℓ, of order prime to ℓ, is trivial (it factors through $(\mathbb{Z}/\ell\mathbb{Z})^\times$), so $\ker\bar\omega \cap \ker\bar\Psi = \ker\bar\omega \cap \ker\chi^{(\ell)} = G_{L_{\ell,\chi}}$, and (Ue8) says $G_{L_{\ell,\chi}} \not\subseteq G_K$. Case (b): otherwise η_K factors through $(\bar\omega, \bar\Psi)\colon G_\mathbb{Q} \to \mathbb{F}_\ell^\times \times \mathbb{F}_\mathcal{O}^\times$; a homomorphism from a subgroup of this group to $\{\pm 1\} \subseteq \mathbb{F}_\mathcal{O}^\times$ extends to the whole group (values in $\mathbb{Q}/\mathbb{Z}$, then in μ_{q-1}, $q = \#\mathbb{F}_\mathcal{O}$), and every homomorphism $\mathbb{F}_\ell^\times \times \mathbb{F}_\mathcal{O}^\times \to \mathbb{F}_\mathcal{O}^\times$ is $(x,y) \mapsto x^\alpha y^\beta$; so $\eta_K = \bar\omega^\alpha \bar\Psi^\beta$. On $I_{\bar v}$, $\bar v \mid 2$, $\bar\omega$ and χ_{cyc} are trivial and $\bar\Psi = \bar\chi_2$; χ_2 has 2-power order and reduction is injective on its values, so the character ε_4 of $(\mathbb{Z}/2^a\mathbb{Z})^\times$ ($2^a \| N$) defining $\mathbb{Q}(i)$ equals χ_2^β. As χ_2 has conductor $2^{c_2(\chi)}$, $c_2(\chi) \geq 4$, $\chi_2(5)$ has order $2^{c_2(\chi)-2} \geq 4$ (5 generates the cyclic group $(1+4\mathbb{Z})/(1+2^a\mathbb{Z})$), while $\varepsilon_4(5) = 1$; so β is even and $-1 = \varepsilon_4(-1) = \chi_2(-1)^\beta = 1$, a contradiction.

(Ef5) There is $s_0 \in D_{\bar\ell} \cap G_K$ with $\bar\Psi(s_0)^2 \neq 1$. Case (a): $I_{\bar\ell} \subseteq G_K$ by (Ue6); on $I_{\bar\ell}$, $\bar\Psi^2 = \bar\chi_\ell^2 \bar\omega^{2e} = \bar\omega^{2e}$ by (Ue4), and $\bar\omega$ maps $I_{\bar\ell}$ onto $\mathbb{F}_\ell^\times$, so $\bar\omega^{2e} \neq 1$ on $I_{\bar\ell}$ by (Ue9). Case (b): Lemma 47.10.

(Ef6) Let $H_b = \ker\chi_\sharp$, an open normal subgroup of ℓ-power index with abelian quotient. For a place $\bar v \nmid \ell$ and $s \in I_{\bar v} \cap H_b$ with $\bar\Psi(s) = 1$: $\chi_{\mathrm{cyc}}(s) = 1$, so $\Psi(s) = \chi_\flat(s)$, a root of unity of order prime to ℓ congruent to 1, hence $\Psi(s) = 1$.

Step 1: the fields. By Dirichlet's theorem choose a prime $q \equiv -1 \pmod{8M}$ and a prime $w \equiv 1 \pmod{M}$; then $q, w \nmid M$, $q \neq w$ (as $M \geq 6$), and $w \equiv 1 \pmod{\ell}$. Let $K' = \mathbb{Q}(\sqrt{-q})$, of discriminant $-q$, with character η'. Every prime $p \mid M$ splits in K' ($-q \equiv 1$ modulo every odd $p \mid M$, and $-q \equiv 1 \pmod 8$). The character $\eta_K\eta'$ is quadratic, non-trivial (η' is ramified at q, η_K is not, by (Ef1)) and even ($\eta_K(c)\eta'(c) = 1$); let F_0 be its fixed field, a real quadratic field, ramified at q, and $H_0 = G_{F_0}$. For every place $\bar{v}$ above a prime $p \mid M$, $\eta'|_{D_{\bar{v}}} = 1$, so

$$D_{\bar{v}} \cap H_0 = D_{\bar{v}} \cap \ker \eta_K. \tag{48.2}$$

Let $\mathbb{Q}_w^{(\ell)} \subseteq \mathbb{Q}(\zeta_w)$ be the subfield of degree ℓ ($\ell \mid w-1$), F_b the fixed field of H_b, and, for $n \geq 1$, $\mathbb{Q}_n \subseteq \mathbb{Q}(\zeta_{\ell^{n+1}})$ the subfield of degree ℓ^n, totally ramified at ℓ. Put

$$L_n^+ = F_0\,\mathbb{Q}_w^{(\ell)} F_b\,\mathbb{Q}_n, \qquad L_n = L_n^+ K, \qquad P_n = G_{\mathbb{Q}_w^{(\ell)}} \cap H_b \cap G_{\mathbb{Q}_n},$$

so $G_{L_n^+} = H_0 \cap P_n$ and $G_{\mathbb{Q}}/P_n$ is an abelian ℓ-group. All four fields are abelian over $\mathbb{Q}$ and fixed by c (F_0 is real; the other three have Galois groups of odd order), hence by every complex conjugation: L_n^+ is totally real, $K \not\subseteq L_n^+$, and L_n is a CM field with maximal totally real subfield L_n^+ and $G_{L_n} = G_{L_n^+} \cap G_K$. Let E be the fixed field of $V = H_0 \cap G_{\mathbb{Q}_w^{(\ell)}} \cap H_b \cap \ker \eta_K \cap \ker \bar{\Psi} \cap \ker \bar{\omega}$: it is abelian over $\mathbb{Q}$ and contains μ_ℓ. Since $\mathbb{Q}(\zeta_{\ell^{n+1}}) = \mathbb{Q}(\zeta_\ell)\mathbb{Q}_n$ and $V \subseteq \ker \bar{\omega} = G_{\mathbb{Q}(\zeta_\ell)}$,

$$G_{L_n} \cap \ker \bar{\Psi} \cap \ker \bar{\omega} = V \cap G_{\mathbb{Q}_n} = V \cap G_{\mathbb{Q}(\zeta_{\ell^{n+1}})} = G_{E_n}. \tag{48.3}$$

Step 2: the marking and an ℓ-adic projection. For $s \in G_{\mathbb{Q}}$ let $s^\natural$ be the image of $z \in \widehat{\mathbb{Z}}$, with ℓ-component 0 and all other components 1, under $\widehat{\mathbb{Z}} \to \overline{\langle s \rangle}$; then $s^\natural$ lies in every closed subgroup containing s, has trivial image in every finite ℓ-group quotient of $G_{\mathbb{Q}}$, and $\phi(s^\natural) = \phi(s)$ for every character ϕ of order prime to ℓ. Let s_0 be as in (Ef5); $s_0 \in D_{\bar{\ell}} \cap \ker \eta_K \subseteq H_0$ by (48.2) ($\ell \mid M$). Put $g_\star = s_0^\natural$: then $g_\star \in D_{\bar{\ell}} \cap H_0 \cap G_K \cap P_n$ for all n, so $g_\star \in G_{L_n}$ for all n, and $\bar{\Psi}(g_\star)^2 = \bar{\Psi}(s_0)^2 \neq 1$, i.e. $\Psi(g_\star)^2 - 1 \in \mathcal{O}^\times$: $g_\star$ is a marking. Likewise choose $t \in I_{\bar{\ell}}$ with $\bar{\omega}(t) \neq 1$ ($\bar{\omega}$ maps $I_{\bar{\ell}}$ onto $\mathbb{F}_\ell^\times$, $\ell \geq 3$); $t \in \ker \eta_K$ by (Ef1), so $t \in H_0$ by (48.2) and $t^\natural \in I_{\bar{\ell}} \cap G_{L_n^+}$ with $\bar{\omega}(t^\natural) \neq 1$.

Fix $n \geq 1$ and write $L = L_n$. We verify (Ly1) and (Ly2).

(Ly1). $\mathbb{Q}_n \subseteq L^+$ gives $[L^+ : \mathbb{Q}] \geq \ell^n$; at $v \mid \ell$ the completion of L^+ contains that of $\mathbb{Q}_n$, of degree ℓ^n over $\mathbb{Q}_\ell$ ($\mathbb{Q}_n$ is totally ramified at ℓ), so $d_v \geq \ell^n$.

(Af1) holds by Steps 1 and 2. *(Af2).* As $K' \subseteq KF_0 \subseteq L$, $L = L^+K'$ and $G_L = G_{L^+} \cap \ker \eta'$. If $\bar{v}$ lies above $p \nmid M$, then $p \nmid d_K$ by (Ef1), so $I_{\bar{v}} \subseteq G_K$ and $I_{\bar{v}} \cap G_{L^+} \subseteq G_L$. If $p \mid M$, $D_{\bar{v}} \subseteq \ker \eta'$, so $D_{\bar{v}} \cap G_{L^+} \subseteq G_L$. *(Af3)*: $G_{L^+} \subseteq H_b$ and (Ef6). *(Af4).* Let $v \mid \ell$, $\bar{v} = \gamma_v \bar{\ell}$; $D_v = \gamma_v (D_{\bar{\ell}} \cap G_{L^+}) \gamma_v^{-1}$ as G_{L^+} is normal. It contains $\gamma_v t^\natural \gamma_v^{-1}$, with $\bar{\omega} \neq 1$, and $\gamma_v g_\star \gamma_v^{-1}$, with $\bar{\Psi}^2 \neq 1$. If $s \in I_v$ and $\chi_{\mathrm{cyc}}(s) = 1$, then $\bar{\Psi}(s) = \bar{\omega}(s)^j = 1$ by (Ef3).

(Ar1). Let $\phi\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^\times$ be a character trivial on G_L, and $x \in H_0 \cap \ker \eta_K$. For b large $x^{\ell^b} \in P_n$, so $x^{\ell^b} \in G_L$ and $\phi(x)^{\ell^b} = 1$; as ϕ has order prime to ℓ, $\phi(x) = 1$. So ϕ is trivial on G_{KF_0} and $\phi \in \{1, \eta_K, \eta_{F_0}, \eta'\}$ (here $\eta_{F_0} = \eta_K\eta'$). If moreover ϕ is unramified at q, then $\phi \in \{1, \eta_K\}$. The same argument for ϕ trivial on $G_{L^+} = H_0 \cap P_n$ gives $\phi \in \{1, \eta_{F_0}\}$, and $\phi = 1$ if ϕ is unramified at q. All characters below are unramified at q by (Ef1). On G_L: if $\phi = \bar{\omega}$, $\bar{\omega}\bar{\Psi}^{\pm 1}$ or $\bar{\omega}\bar{\Psi}^{-i}$ ($i \in \mathbb{Z}$) were trivial on G_L, then $\phi(c) = -1$ by (Ef2) excludes $\phi = 1$, and $\phi = \eta_K$ would make η_K trivial on $\ker \bar{\omega} \cap \ker \bar{\Psi}$, contradicting (Ef4). On G_{L^+}: $\phi = \bar{\omega}\bar{\Psi}^{\pm 2}\eta_K$ trivial on G_{L^+} would give $\phi = 1$, i.e. $\eta_K = \bar{\omega}^{-1}\bar{\Psi}^{\mp 2}$, contradicting (Ef4).

(Ar2). Let $a \in \{1, 2\}$ and $\kappa = \bar{\Psi}^{-a}\eta_K$, a character of $G_{\mathbb{Q}}$ with values in $\mathbb{F}_{\mathcal{O}}^\times$. The hypotheses of Lemma 48.6 (with $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, c, w) hold: $\kappa(c) = -1$ by (Ef2); $\kappa \neq \bar{\omega}$ by (Ef4); $\kappa(g_\star) = \bar{\Psi}(g_\star)^{-a} \neq 1$ with $g_\star \in D_{\bar{\ell}}$, and by conjugation $\kappa|_{D_{\bar{v}}} \neq 1$ for every $\bar{v} \mid \ell$; $w \equiv 1 \pmod{\ell}$,

and $D_{\bar v} \subseteq G_{\mathbb{Q}(\zeta_M)} \subseteq \ker\kappa$ for $\bar v \mid w$ (inertia at $w \nmid M$ fixes μ_M and Frobenius acts on it by $\zeta \mapsto \zeta^w = \zeta$), by (Ef1). Let y be the cocycle given there. *It descends to* Γ_L. The generators s of N_L have $\kappa(s) = 1$ and $y(s) = 0$: by (Yc2) if $s \in I_{\bar v}$ with $\bar v \nmid \ell w$, and by (Yc3) if $\bar v \mid w$, since $G_{L^+} \subseteq G_{\mathbb{Q}_w^{(\ell)}}$. The set $Z = \{g \in G_{L^+} : \kappa(g) = 1,\ y(g) = 0\}$ is a closed subgroup ($y(gg') = y(g) + y(g')$, $y(g^{-1}) = -y(g)$ there; y and κ are continuous), normal in G_{L^+} since $y(\gamma g\gamma^{-1}) = (1-\kappa(g))y(\gamma) + \kappa(\gamma)y(g)$ by the cocycle identity. So $N_L \subseteq Z$, κ is a character of Γ_L, and $y(gn) = y(g)$ for $n \in N_L$: $x(\pi_L(g)) = y(g)$ defines a continuous 1-cocycle x of Γ_L with values in $W = \mathbb{F}_{\mathcal{O}}(\kappa)$. *It is strict.* For $v \mid \ell$, (Yc1) at $\bar v$ gives X_v with $x(\pi_L(h)) = (h-1)X_v$ for $h \in D_v \subseteq D_{\bar v}$; so $(x, (X_v)_v)$ defines a class in $H^1_{\mathrm{str}}(\Gamma_L, W)$. *It is non-zero.* Otherwise $(x, (X_v)) = (g \mapsto (g-1)X, (X)_v)$ for some X, and $y(g) = \kappa(g)X - X$ on G_{L^+}, a closed normal subgroup of $G_{\mathbb{Q}}$ containing $g_\star$ with $\kappa(g_\star) \neq 1$; this contradicts (Yc4). Hence (Ar2).

(Ar3) with $C_0 = r_n$. L is a CM field with (Af1), (Af2), (Af4), and by (48.3) the field E' of Lemma 48.7 is E_n, so $r = r_n$ there.

(Ar5). Items (i)–(iii) by Lemma 48.8; item (iv) by Proposition 48.9.

(Ag1). Write $M = \ell^k N'$ with $\ell \nmid N'$; then $w \nmid N'$ and $w \equiv 1 \pmod{N'}$. Let $\tau\colon \mathbb{F}_{\mathcal{O}}^\times \to \overline{\mathbb{Q}}_\ell^\times$ be the Teichmüller lift, $\chi_0' = \tau \circ (\bar\Psi\bar\omega^{-j})$ with j from (Ef3), and θ a non-trivial character of $\mathrm{Gal}(\mathbb{Q}_w^{(\ell)}/\mathbb{Q}) \cong \mathbb{Z}/\ell\mathbb{Z}$ with values in $\mu_\ell(\overline{\mathbb{Q}}_\ell)$, viewed on $G_{\mathbb{Q}}$. We check (Ag1) for $(N', w, j, \chi_0', \theta)$. $\theta \neq 1$, $\theta^\ell = 1$, and θ is trivial on $G_{\mathbb{Q}(\zeta_w)}$ and on $G_L \subseteq G_{\mathbb{Q}_w^{(\ell)}}$. The character $\bar\Psi\bar\omega^{-j}$ is trivial on $G_{\mathbb{Q}(\zeta_M)}$ (Ef1) and on $I_{\bar\ell}$ (Ef3); as a character of $(\mathbb{Z}/\ell^k\mathbb{Z})^\times \times (\mathbb{Z}/N'\mathbb{Z})^\times$ trivial on the first factor (the image of $I_{\bar\ell}$), it is trivial on $G_{\mathbb{Q}(\zeta_{N'})}$, hence so is χ_0'; η_K is trivial on $G_{\mathbb{Q}(\zeta_{N'})}$ because $|d_K|$ divides M and is prime to ℓ (Ef1). An s acting on $\mu_{N'}$ by $\zeta \mapsto \zeta^w$ acts trivially, so lies in $G_{\mathbb{Q}(\zeta_{N'})}$. $\chi_0' \neq \eta_K$, since otherwise η_K would be trivial on $\ker\bar\Psi \cap \ker\bar\omega$ (Ef4). χ_0' takes values in μ_{q-1}, so $\ell \nmid \operatorname{ord}\chi_0'$. $\chi_0'(c) = \tau((-1)^j) = (-1)^j$ by (Ef2). The reduction of $\chi_{\mathrm{cyc}}^j\chi_0'$ is $\bar\omega^j\bar\Psi\bar\omega^{-j} = \bar\Psi$, so $\chi_{\mathrm{cyc}}^j\chi_0' \equiv \Psi$ modulo the maximal ideal of the integers of $\overline{\mathbb{Q}}_\ell$, and $(\chi_{\mathrm{cyc}}^j\chi_0')(g_\star)^2 \not\equiv 1$ with $g_\star \in G_L$. *(Ag2)* is (Ef1).

So L_n satisfies (Af1)–(Af4), (Ar1), (Ar2), (Ar3) with $C_0 = r_n$, (Ar5), (Ag1), (Ag2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, with $g_\star$ and E independent of n. □

Lemma 48.6. *Let ℓ be an odd prime, $\mathbb{F}$ a finite field of characteristic ℓ, $\bar\omega\colon G_{\mathbb{Q}} \to \mathbb{F}_\ell^\times \subseteq \mathbb{F}^\times$ the reduction of the cyclotomic character, $c \in G_{\mathbb{Q}}$ a complex conjugation and $\kappa\colon G_{\mathbb{Q}} \to \mathbb{F}^\times$ a continuous character with $\kappa(c) = -1$ and $\kappa \neq \bar\omega$. Assume that $\kappa|_{D_{\bar v}} \neq 1$ for every place $\bar v$ of $\overline{\mathbb{Q}}$ above ℓ. Let w be a prime with $w \equiv 1 \pmod\ell$ such that κ is trivial on $D_{\bar v}$ for every place $\bar v$ above w, and let $\mathbb{Q}_w^{(\ell)} \subseteq \mathbb{Q}(\zeta_w)$ be the subfield of degree ℓ over $\mathbb{Q}$. Then there is a continuous map $y\colon G_{\mathbb{Q}} \to \mathbb{F}$ with $y(st) = y(s) + \kappa(s)y(t)$ for all $s, t \in G_{\mathbb{Q}}$ such that:*

(Yc1) *for every place $\bar v$ above ℓ there is $b \in \mathbb{F}$ with $y(s) = \kappa(s)b - b$ for all $s \in D_{\bar v}$;*

(Yc2) *$y(s) = 0$ for every place $\bar v$ above a prime $p \notin \{\ell, w\}$ and every $s \in I_{\bar v}$ with $\kappa(s) = 1$;*

(Yc3) *$y(s) = 0$ for every place $\bar v$ above w and every $s \in I_{\bar v} \cap G_{\mathbb{Q}_w^{(\ell)}}$;*

(Yc4) *for every closed normal subgroup $U \subseteq G_{\mathbb{Q}}$ on which κ is not trivial there is no $b \in \mathbb{F}$ with $y(s) = \kappa(s)b - b$ for all $s \in U$.*

Proof. Two identities for cocycles. Let $y\colon G_{\mathbb{Q}} \to \mathbb{F}$ satisfy $y(st) = y(s) + \kappa(s)y(t)$. Then $y(1) = 2y(1)$, so $y(1) = 0$, and $0 = y(\gamma\gamma^{-1})$ gives $y(\gamma^{-1}) = -\kappa(\gamma)^{-1}y(\gamma)$. Hence, since $\kappa(\gamma s\gamma^{-1}) = \kappa(s)$,

$$y(\gamma s\gamma^{-1}) = y(\gamma) + \kappa(\gamma)y(s) + \kappa(\gamma s)y(\gamma^{-1}) = (1-\kappa(s))\,y(\gamma) + \kappa(\gamma)\,y(s) \qquad (\gamma, s \in G_{\mathbb{Q}}). \tag{48.4}$$

In particular, if $y(s) = \kappa(s)b - b$ for all s in a subgroup D, then $y(s') = \kappa(s')b' - b'$ for all $s' \in \gamma D\gamma^{-1}$, with $b' = \kappa(\gamma)b - y(\gamma)$; and if $\kappa(s) = 1$ and $y(s) = 0$, then $y(\gamma s\gamma^{-1}) = 0$.

The Selmer problem. The kernel of κ is open, so κ is ramified at finitely many primes; it is unramified at w, being trivial on $D_{\bar v}$ for $\bar v \mid w$. Let S consist of ∞, ℓ, w and the primes at which κ is ramified, and let $M = \mathbb{F}(\kappa)$, $\mathbb{F}$ with $G_{\mathbb{Q}}$ acting by κ; the action factors through G_S. Here $w \neq \ell$, since $w \equiv 1 \pmod{\ell}$. For each prime $p \in S$ fix a place $\bar p$ above p and put $D_p = D_{\bar p} \supseteq I_p = I_{\bar p}$. Define local conditions: $L_\ell = B^1(D_\ell, M)$; $L_w = Z^1(D_w, M)$; and for the other primes $p \in S$, $L_p = \{z \in Z^1(D_p, M) : z|_{N'_p} = 0\}$ with $N'_p = I_p \cap \ker\kappa$. Each L_p contains $B^1(D_p, M)$: for L_p with $p \neq \ell, w$ because N'_p acts trivially on M. Their dimensions:

- $\dim L_\ell = 1$: $x \mapsto (g \mapsto (\kappa(g) - 1)x)$ maps M onto $B^1(D_\ell, M)$ and is injective because $\kappa|_{D_\ell} \neq 1$.
- $\dim L_p = 1$ for $p \neq \ell, w$, by item 1 of Lemma 43.35 with $N' = N'_p$: it is normal in D_p (I_p is normal in D_p and $\ker\kappa$ is normal), it acts trivially, and $[I_p : N'_p] = \#\kappa(I_p)$ divides $\#\mathbb{F}^\times = q - 1$, which is prime to ℓ.
- $\dim L_w = 2$: κ is trivial on D_w, so $h^0(D_w, M) = 1$; $M^\vee = \mathbb{F}(\bar\omega\kappa^{-1})$, and $\bar\omega$ is trivial on D_w (inertia at $w \neq \ell$ fixes μ_ℓ, and Frobenius acts on μ_ℓ by $\zeta \mapsto \zeta^w = \zeta$), so $\#H^0(D_w, M^\vee) = q$ and, by local duality (Theorem B.29, item 2), $\#H^2(D_w, M) = q$; by the local Euler characteristic formula (item 4, $w \neq \ell$) $\#H^1(D_w, M) = q^2$. Since D_w acts trivially, $B^1(D_w, M) = 0$ and $\dim Z^1(D_w, M) = \dim H^1(D_w, M) = 2$.

We have $H^0(G_S, M^\vee) = 0$, because $\bar\omega\kappa^{-1} \neq 1$ on $G_{\mathbb{Q}}$ and $G_{\mathbb{Q}} \to G_S$ is onto. As $\kappa(c) = -1 \neq 1$ (ℓ odd), $H^0(G_S, M) = 0$ and $M^{c=1} = 0$. By item 2 of Lemma 43.35,

$$\dim H^1_{\mathcal{L}}(M) - \dim H^2_{\mathcal{L}}(M) = 0 - 0 + (1 - 1) + (2 - 1) + \sum_{p \in S,\ p \neq \ell, w} (1 - 1) = 1,$$

so $H^1_{\mathcal{L}}(M) \neq 0$: there is a Selmer cocycle z that is not a coboundary of G_S. Let $y = z \circ \pi_S$ with $\pi_S \colon G_{\mathbb{Q}} \to G_S$ the projection; y is continuous and satisfies the cocycle identity, the action of $G_{\mathbb{Q}}$ on M being through π_S.

(Yc4). First $U = G_{\mathbb{Q}}$: if $y(s) = \kappa(s)b - b$ for all s, then z is the coboundary of b, as π_S is onto; this is excluded. Let U be closed, normal, with $u_0 \in U$, $\kappa(u_0) \neq 1$, and suppose $y(u) = \kappa(u)b - b$ for $u \in U$. Then $y' = y - (\kappa(\cdot)b - b)$ is a cocycle vanishing on U. For $g \in G_{\mathbb{Q}}$ and $u \in U$, $y'(gu) = y'(g) + \kappa(g)y'(u) = y'(g)$, and $gu = (gug^{-1})g$ with $gug^{-1} \in U$ gives $y'(gu) = y'(gug^{-1}) + \kappa(u)y'(g) = \kappa(u)y'(g)$. With $u = u_0$, $(\kappa(u_0) - 1)y'(g) = 0$, so $y' = 0$ and y is a coboundary on $G_{\mathbb{Q}}$, which was excluded.

(Yc1). The condition $\mathrm{res}_\ell z \in L_\ell = B^1(D_\ell, M)$ gives b with $y(s) = \kappa(s)b - b$ on $D_{\bar\ell}$. Every place above ℓ is $\gamma\bar\ell$ with $\gamma \in G_{\mathbb{Q}}$, and $D_{\gamma\bar\ell} = \gamma D_{\bar\ell}\gamma^{-1}$; apply the consequence of (48.4).

(Yc2). Let $\bar v$ lie above $p \notin \{\ell, w\}$ and $s \in I_{\bar v}$ with $\kappa(s) = 1$. If $p \notin S$, then $\pi_S(s) = 1$ because the maximal extension unramified outside S is unramified at p, so $y(s) = z(1) = 0$. If $p \in S$, write $\bar v = \gamma\bar p$, so $s = \gamma t\gamma^{-1}$ with $t \in I_p$ and $\kappa(t) = 1$, i.e. $t \in N'_p$; as $\mathrm{res}_p z \in L_p$, $y(t) = 0$, and (48.4) gives $y(s) = 0$.

(Yc3). Let $\bar v$ lie above w, $I = I_{\bar v}$ and $P \subseteq I$ its wild inertia subgroup. Since κ is trivial on $D_{\bar v}$, $f = y|_I$ is a continuous homomorphism $I \to (\mathbb{F}, +)$. The group P is pro-w and $\mathbb{F}$ is an ℓ-group with $w \neq \ell$, so $f(P) = 0$, and f factors through the tame inertia group I/P, which is procyclic, isomorphic to $\prod_{q \neq w} \mathbb{Z}_q$ ([190], II.9); its image is a cyclic subgroup of $\mathbb{F}$, of order 1 or ℓ. On the other side, $\mathbb{Q}(\zeta_w)/\mathbb{Q}$ is totally ramified at w, so I maps onto $\mathrm{Gal}(\mathbb{Q}_w^{(\ell)}/\mathbb{Q}) \cong \mathbb{Z}/\ell\mathbb{Z}$ and $J = I \cap G_{\mathbb{Q}_w^{(\ell)}}$ is an open normal subgroup of index ℓ containing P (P has no non-trivial image

in a group of order ℓ). If $f \neq 0$, then $\ker f$ is also an open subgroup of index ℓ containing P. A procyclic group has at most one open subgroup of each index, so $\ker f/P = J/P$, i.e. $\ker f = J$. In both cases $f(J) = 0$, which is (Yc3). $\square$

Lemma 48.7. *Let $(K, \mathcal{O}, \Psi, c, g_\star, M)$ be as in Definition 48.2 and let $L \subset \overline{\mathbb{Q}}$ be a CM field satisfying (Af1), (Af2) and (Af4). Let $E' \subset \overline{\mathbb{Q}}$ be the fixed field of $G_L \cap \ker\bar\Psi \cap \ker\bar\omega$ and $r \geq 0$ the integer with $\#\big(\mathrm{Cl}(E')/\mathrm{Cl}(E')^\ell\big) = \ell^r$. Then*

$$h^1_{\mathrm{str}}(\Gamma_L, \mathbb{F}_\mathcal{O}(\bar\Psi^{-2}\eta_K)) \leq r, \qquad h^1_{\mathrm{str}}(\Gamma_L^0, \mathbb{F}_\mathcal{O}(\bar\Psi^{-1})) \leq r, \qquad h^1(\Gamma_L, \mathbb{F}_\mathcal{O}) \leq 1 + r;$$

that is, L satisfies (Ar3) with $C_0 = r$.

Proof. Step 1: the field E' and the subgroup $\Gamma' = \pi_L(G_{E'})$. By (Af1), L is abelian over $\mathbb{Q}$ and $\bar\Psi$, $\bar\omega$ are characters of $G_\mathbb{Q}$, so E' is abelian over $\mathbb{Q}$; it contains μ_ℓ and is totally imaginary (ℓ odd), hence a CM field, and $G_{E'}$ is normal in G_{L^+}. The generators s of N_L lie in inertia groups at places not above ℓ, where $\bar\omega$ is unramified, and satisfy $\eta_K(s) = \bar\Psi(s) = 1$; by (Af1), $G_{L^+} \cap \ker\eta_K = G_L$, so $N_L \subseteq G_{E'}$. Thus $\Gamma' = G_{E'}/N_L$ is an open normal subgroup of Γ_L, contained in Γ_L^0, and $\Gamma_L/\Gamma' \cong G_{L^+}/G_{E'}$ embeds into $\{\pm1\} \times \mathbb{F}_\mathcal{O}^\times \times \mathbb{F}_\ell^\times$ by $(\eta_K, \bar\Psi, \bar\omega)$: its order is prime to ℓ. Put $\Delta = \mathrm{Gal}(E'/L^+) = \Gamma_L/\Gamma'$. Conversely every element of $I_{\bar v} \cap G_{E'}$, $\bar v \nmid \ell$, is a generator of N_L, since $G_{E'} \subseteq \ker\eta_K \cap \ker\bar\Psi$. Hence: a continuous homomorphism $f\colon G_{E'} \to \mathbb{F}_\mathcal{O}$ factors through Γ' if and only if it vanishes on $I_{\bar v} \cap G_{E'}$ for every place $\bar v \nmid \ell$, i.e. if the abelian extension cut out by $\ker f$ is unramified at all finite places not above ℓ (it is unramified at the archimedean places since E' is totally imaginary).

Step 2: restriction is injective. Let $\Delta_0 \in \{\Gamma_L, \Gamma_L^0\}$ and $W = \mathbb{F}_\mathcal{O}(\phi)$ for a character ϕ of Δ_0 trivial on Γ'. The restriction $H^1(\Delta_0, W) \to \mathrm{Hom}_{\mathrm{cts}}(\Gamma', W)$ is injective: its kernel is $H^1(\Delta_0/\Gamma', W)$ (inflation–restriction), and Δ_0/Γ' is finite of order prime to ℓ while W is killed by ℓ. If moreover $W^{\pi_L(H_t)} = 0$ for every member H_t of the family defining the strict group, then $(x, (X_t)) \mapsto x$ is injective from $H^1_{\mathrm{str}}(\Delta_0, W)$ to $H^1(\Delta_0, W)$: if $x = (g \mapsto (g-1)X)$, subtracting the trivial pair $(g \mapsto (g-1)X, (X)_t)$ leaves $(0, (X_t - X))$, and the strict condition gives $(h-1)(X_t - X) = 0$ for $h \in H_t$, so $X_t = X$ and the class is 0. The image of a class consists of homomorphisms $f\colon G_{E'} \to \mathbb{F}_\mathcal{O}$ (composing with $G_{E'} \to \Gamma'$), with $f(\gamma s \gamma^{-1}) = \phi(\gamma) f(s)$ for γ in the preimage of Δ_0, by the cocycle identity.

Step 3: the two strict groups. (a) $\Delta_0 = \Gamma_L$, $\phi = \bar\Psi^{-2}\eta_K$, family $(D_v)_{v|\ell}$. By (Af2) ($\ell \mid M$) each D_v lies in $G_L \subseteq \ker\eta_K$, and by (Af4) $\bar\Psi^2|_{D_v} \neq 1$, so $W^{D_v} = 0$. (b) $\Delta_0 = \Gamma_L^0$, $\phi = \bar\Psi^{-1}$, family (D_v), (cD_vc); by (Af4) $\bar\Psi|_{D_v} \neq 1$ and $\bar\Psi(cgc) = \bar\Psi(g)$, so $W^{D_v} = W^{cD_vc} = 0$. In both cases Step 2 applies. For a strict class with image f: on $D_v \cap G_{E'}$ the character ϕ is trivial, so the coboundary $h \mapsto (h-1)X_v$ vanishes there and $f(D_{\bar v} \cap G_{E'}) = 0$ for the fixed place $\bar v$ above v, and in case (b) also $f(cD_{\bar v}c \cap G_{E'}) = 0$. Every place of $\overline{\mathbb{Q}}$ above ℓ is $\gamma\bar v$ with $\gamma \in G_{L^+}$ in case (a); in case (b) the place v splits in L by (Af2), into the places below $\bar v$ and $c\bar v$, so every place above ℓ is $\gamma\bar v$ or $\gamma c\bar v$ with $\gamma \in G_L$. By the equivariance in Step 2, f vanishes on $D_{\bar u} \cap G_{E'}$ for every place $\bar u \mid \ell$. With Step 1, $\ker f$ cuts out an abelian extension of E', of exponent ℓ, unramified everywhere and in which all places above ℓ split completely; so f factors through $\mathrm{Cl}(E')/\mathrm{Cl}(E')^\ell$ (Hilbert class field), a group of order ℓ^r. The space of homomorphisms from it to $\mathbb{F}_\mathcal{O}$ has $\mathbb{F}_\mathcal{O}$-dimension r, so both strict groups have dimension $\leq r$.

Step 4: the group $H^1(\Gamma_L, \mathbb{F}_\mathcal{O})$. Here $H^1(\Gamma_L, \mathbb{F}_\mathcal{O}) = \mathrm{Hom}_{\mathrm{cts}}(\Gamma_L, \mathbb{F}_\ell) \otimes_{\mathbb{F}_\ell} \mathbb{F}_\mathcal{O}$, so it suffices to bound $\dim_{\mathbb{F}_\ell} \mathrm{Hom}_{\mathrm{cts}}(\Gamma_L, \mathbb{F}_\ell)$ by $1 + r$. By Steps 1, 2 it injects into the space of homomorphisms $f\colon G_{E'} \to \mathbb{F}_\ell$ unramified outside ℓ with $f(\gamma s \gamma^{-1}) = f(s)$ for $\gamma \in G_{L^+}$. Fix a primitive ℓ-th root of unity ζ. Kummer theory identifies $\mathrm{Hom}_{\mathrm{cts}}(G_{E'}, \mu_\ell)$ with $E'^\times/E'^{\times\ell}$, Δ-equivariantly, and $f \mapsto \zeta^f$ carries the invariant f into the $\bar\omega$-part (for $\gamma \in G_{L^+}$, $\gamma(\zeta^{f(\gamma^{-1}s\gamma)}) = \zeta^{\bar\omega(\gamma)f(s)}$). The extension $E'(a^{1/\ell})$ is unramified at a place $u \nmid \ell$ if and only if $u(a) \equiv 0 \pmod\ell$. So

$\dim \mathrm{Hom}(\Gamma_L, \mathbb{F}_\ell) \le \dim B^{(\bar\omega)}$, where $B \subseteq E'^\times/E'^{\times\ell}$ is the subgroup of classes with $u(a) \in \ell\mathbb{Z}$ for every finite place $u \nmid \ell$. Let $\mathcal{O}_S = \mathcal{O}_{E'}[1/\ell]$. Sending a to the class of the ideal $\mathfrak{a}$ of $\mathcal{O}_S$ with $a\mathcal{O}_S = \mathfrak{a}^\ell$ gives an exact sequence of $\mathbb{F}_\ell[\Delta]$-modules

$$0 \to \mathcal{O}_S^\times/\mathcal{O}_S^{\times\ell} \to B \to \mathrm{Cl}(\mathcal{O}_S)[\ell]$$

(an element in the kernel has $\mathfrak{a} = b\mathcal{O}_S$, so $a = b^\ell u$ with $u \in \mathcal{O}_S^\times$; and an S-unit that is an ℓ-th power in E' is the ℓ-th power of an S-unit). The group $\mathrm{Cl}(\mathcal{O}_S)$ is a quotient of $\mathrm{Cl}(E')$, so $\dim \mathrm{Cl}(\mathcal{O}_S)[\ell] = \dim \mathrm{Cl}(\mathcal{O}_S)/\ell \le r$. It remains to show $\dim(\mathcal{O}_S^\times/\ell)^{(\bar\omega)} \le 1$.

Step 5: the $\bar\omega$-part of the S-units. Let $\mu = \mu(E')$ and $Y = (\mathcal{O}_S^\times/\mu) \otimes \mathbb{Z}_\ell$, a free $\mathbb{Z}_\ell$-module of finite rank (Dirichlet) with an action of Δ. Since $\mathcal{O}_S^\times/\mu$ is free, $0 \to \mu/\mu^\ell \to \mathcal{O}_S^\times/\ell \to Y/\ell Y \to 0$ is exact, and μ/μ^ℓ is one-dimensional, with Δ acting by $\bar\omega$. Let $\tilde\omega\colon \Delta \to \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ be the Teichmüller lift of $\bar\omega$ and $e = \#\Delta^{-1}\sum_\delta \tilde\omega(\delta)^{-1}\delta \in \mathbb{Z}_\ell[\Delta]$; its reduction is $e_{\bar\omega}$, so $(Y/\ell Y)^{(\bar\omega)} = (eY + \ell Y)/\ell Y$, and it suffices to show $eY = 0$, i.e. $e(Y \otimes \mathbb{Q}_\ell) = 0$ (Y is torsion-free). Let $y \in e(Y \otimes \mathbb{Q}_\ell)$, so $\delta y = \tilde\omega(\delta)y$. The valuation map $Y \otimes \mathbb{Q}_\ell \to \bigoplus_{u|\ell} \mathbb{Q}_\ell$ (places u of E' above ℓ) is Δ-equivariant for the permutation action, and its kernel is $(\mathcal{O}_{E'}^\times/\mu) \otimes \mathbb{Q}_\ell$, on which the complex conjugation $c|_{E'} \in \Delta$ acts trivially by the unit index bound. The image of y lies in the $\tilde\omega$-part of $\bigoplus_{u|\ell} \mathbb{Q}_\ell = \bigoplus_{v|\ell} \mathbb{Q}_\ell[\Delta/\Delta_v]$ (v the places of L^+ above ℓ, Δ_v the decomposition group of a place above v), which is 0: a vector of $\mathbb{Q}_\ell[\Delta/\Delta_v]$ on which Δ acts by $\tilde\omega$ is fixed by Δ_v only if $\tilde\omega|_{\Delta_v} = 1$, while $\bar\omega|_{D_v} \ne 1$ by (Af4), Δ_v being the image of D_v. So y is a unit class with $c\,y = y$; but $c\,y = \tilde\omega(c)y = -y$, hence $y = 0$. Therefore $\dim(\mathcal{O}_S^\times/\ell)^{(\bar\omega)} \le 1$, $\dim B^{(\bar\omega)} \le 1 + r$ by exactness of $(\cdot)^{(\bar\omega)}$, and $h^1(\Gamma_L, \mathbb{F}_\mathcal{O}) \le 1 + r$. □

Lemma 48.8. *Let $(K, \mathcal{O}, \Psi, c, g_\star, M)$ be as in Definition 48.2 and let $L \subset \overline{\mathbb{Q}}$ be a CM field satisfying (Af1), (Af2) and (Af4). Then L satisfies items (i), (ii) and (iii) of (Ar5); in (ii) one can take $h = \#\mathrm{Cl}(L)$.*

Proof. A remark used twice. Let $G' \subseteq G_{L^+}$ be a closed subgroup containing N_L, A a finite abelian ℓ-group and $f\colon G' \to A$ a continuous homomorphism trivial on N_L. For a place $\bar u$ of $\overline{\mathbb{Q}}$ not above ℓ, the subgroup $I_{\bar u} \cap G' \cap \ker \eta_K \cap \ker \bar\Psi$ consists of generators of N_L and has index in $I_{\bar u} \cap G'$ dividing $\#(\{\pm 1\} \times \mathbb{F}_\mathcal{O}^\times)$, which is prime to ℓ; so $f(I_{\bar u} \cap G')$ is an ℓ-group which is a quotient of a group of order prime to ℓ, hence trivial. Thus the extension cut out by $\ker f$ is unramified at all finite places not above ℓ.

(i). An open subgroup of Γ_L is $\pi_L(G_{F'})$ for a finite extension F' of L^+ with $N_L \subseteq G_{F'}$. A continuous homomorphism $f\colon \pi_L(G_{F'}) \to \mathbb{Z}/\ell\mathbb{Z}$ gives $f \circ \pi_L$ on $G_{F'}$, trivial on N_L, so by the remark its kernel cuts out an extension of F' of degree 1 or ℓ unramified outside the places above ℓ and ∞. By the theorem of Hermite and Minkowski there are only finitely many such extensions; each determines $\ker f$, and a homomorphism to $\mathbb{Z}/\ell\mathbb{Z}$ is determined by its kernel up to one of $\ell - 1$ automorphisms. So there are finitely many f.

(ii). Let $f\colon \Gamma_L^0 \to A$ be a continuous homomorphism to a finite abelian ℓ-group, trivial on $\pi_L(I_v)$ and $\pi_L(cI_vc)$ for all $v \mid \ell$, and put $f' = f \circ \pi_L$ on G_L (which contains N_L, the generators having $\eta_K = 1$). By the remark, f' is trivial on $I_{\bar u} \cap G_L$ for $\bar u \nmid \ell$. Let $v \mid \ell$ with fixed place $\bar v$. By (Af2) ($\ell \mid M$), v splits in L, so $D_{\bar v} \cap G_{L^+} \subseteq G_L$ and $I_v = I_{\bar v} \cap G_L$, $cI_vc = I_{c\bar v} \cap G_L$; the places of L above v are those below $\bar v$ and $c\bar v$, so every place $\bar u \mid \ell$ of $\overline{\mathbb{Q}}$ is $\gamma\bar v$ or $\gamma c\bar v$ for some v and some $\gamma \in G_L$, and $f'(I_{\bar u} \cap G_L) = f'(\gamma(I_{\bar v} \cap G_L)\gamma^{-1})$ or $f'(\gamma(I_{c\bar v} \cap G_L)\gamma^{-1})$, which is trivial as A is abelian. The field L is totally imaginary. So $\ker f'$ cuts out an unramified abelian extension of L, f' factors through $\mathrm{Gal}(H_L/L) \cong \mathrm{Cl}(L)$, and its values are killed by $h = \#\mathrm{Cl}(L)$.

(iii). Let $v \mid \ell$ be a place of L^+ and $F_v = L_v^+$, so $D_v \cong G_{F_v}$ and $d_v = [F_v : \mathbb{Q}_\ell]$. Let A_v be the maximal abelian pro-ℓ quotient of D_v and $T_v \subseteq A_v$ the image of I_v. By local class field theory

$T_v \cong \mathcal{O}_{F_v}^\times \otimes \mathbb{Z}_\ell \cong \mu_{\ell^\infty}(F_v) \times \mathbb{Z}_\ell^{d_v}$, and $\mu_\ell \not\subseteq F_v$ because $\bar\omega|_{D_v} \neq 1$ by (Af4); so T_v is free of rank d_v. Let $\langle\cdot\rangle\colon \mathbb{Z}_\ell^\times \to 1+\ell\mathbb{Z}_\ell$ be the projection with kernel $\mu_{\ell-1}$; $\chi^\flat = \langle\chi_{\mathrm{cyc}}\rangle$ is a character of D_v with values in the pro-ℓ group $1+\ell\mathbb{Z}_\ell \cong \mathbb{Z}_\ell$, so it factors through A_v, and on T_v it corresponds to $u \mapsto \langle \mathrm{N}_{F_v/\mathbb{Q}_\ell}(u)\rangle^{-1}$. Its image on T_v is a non-zero closed subgroup of $1+\ell\mathbb{Z}_\ell$ (it contains $\langle \mathrm{N}(1+\ell)\rangle^{-1} = (1+\ell)^{-d_v} \neq 1$), hence free of rank one, so $T_v = T_v' \oplus \mathbb{Z}_\ell t$ with $T_v' = T_v \cap \ker\chi^\flat$ free of rank $d_v - 1$. Choose a $\mathbb{Z}_\ell$-basis $t_1, \dots, t_{d_v-1}$ of T_v', put $t_{d_v} = t$, and choose $u_a' \in I_v$ mapping to t_a. Let $m = (\ell-1)\cdot \#\bar\Psi(D_v)$, prime to ℓ, and $u_a = (u_a')^m$. Then $\bar\Psi(u_a) = 1$; for $a < d_v$, $\chi_{\mathrm{cyc}}(u_a') \in \mu_{\ell-1}$ since $\chi^\flat(u_a') = 1$, so $\chi_{\mathrm{cyc}}(u_a) = 1$; and the images mt_a of the u_a form a $\mathbb{Z}_\ell$-basis of T_v ($m \in \mathbb{Z}_\ell^\times$). Let $f\colon D_v \to A$ be a continuous homomorphism to a finite abelian ℓ-group trivial on $u_1, \dots, u_{d_v}$. It factors through A_v, and its restriction to T_v is continuous and vanishes on the subgroup generated by the mt_a, which is dense in T_v; so $f(I_v) = 0$. □

Proposition 48.9. *Let $\mathcal{O}$ be a coefficient ring with residue field $\mathbb{F}_\mathcal{O}$ of odd characteristic ℓ and $\bar\omega$ the reduction of χ_{cyc}. Let $F \subset \overline{\mathbb{Q}}$ be a totally real number field, $K' \subseteq G_F$ an open normal subgroup of index prime to ℓ, N the closed normal subgroup of G_F generated by the groups $I_{\bar u} \cap K'$, $\bar u$ running over the places of $\overline{\mathbb{Q}}$ not above ℓ, $\Gamma = G_F/N$ with projection π, and for each place v of F above ℓ let $\bar v$ be a place of $\overline{\mathbb{Q}}$ above v, $D_v = D_{\bar v} \cap G_F$ and $d_v = [F_v : \mathbb{Q}_\ell]$; for each real place u of F let $c_u \in G_F$ be a complex conjugation at u. Take for $H^i(\Gamma; W, b)$ the family $(D_v)_{v|\ell}$. Then for every finite-dimensional $\mathbb{F}_\mathcal{O}$-vector space W with a continuous linear action of Γ with open kernel, all D_v-stable subspaces $b_v \subseteq W$ ($v \mid \ell$) with $\mathrm{Hom}_\Gamma(W, \mathbb{F}_\mathcal{O}(\bar\omega)) = 0$, the space $H^2(\Gamma; W, b)$ is finite-dimensional and*

$$h^2(\Gamma; W, b) + h^0(\Gamma; W, b) + \sum_{v|\ell} d_v \dim b_v \leq h^1(\Gamma; W, b) + \sum_{u|\infty} \dim W^{c_u=1}.$$

In particular, for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ as in Definition 48.2, every CM field $L \subset \overline{\mathbb{Q}}$ satisfies item (iv) of (Ar5): for every finite-dimensional $\mathbb{F}_\mathcal{O}$-vector space W with a continuous linear action of Γ_L with open kernel, all D_v-stable subspaces $b_v \subseteq W$ ($v \mid \ell$) and $\mathrm{Hom}_{\Gamma_L}(W, \mathbb{F}_\mathcal{O}(\bar\omega)) = 0$, the space $H^2(\Gamma_L; W, b)$ is finite-dimensional and

$$h^2(\Gamma_L; W, b) + h^0(\Gamma_L; W, b) + \sum_{v|\ell} d_v \dim b_v \leq h^1(\Gamma_L; W, b) + \sum_{u|\infty} \dim W^{c_u=1}.$$

Proof. Steps 1–4 prove the general inequality; Step 5 deduces (Ar5)(iv). The character χ_{cyc}, hence $\bar\omega$, is trivial on N (it is unramified at every place not above ℓ), so it factors through Γ. Let S_b be the set of finite places u of F not above ℓ such that $I_{\bar u} \not\subseteq K'$ for a place $\bar u$ above u (equivalently for all of them, K' being normal); it is finite, since the fixed field of K' is a finite extension of F, unramified outside finitely many places. Let S be the union of S_b, the places above ℓ and the archimedean places, and $G = G_{F,S}$. For every place $\bar u$ not above ℓ put $J_{\bar u} = I_{\bar u} \cap K'$; these generate N as a closed normal subgroup. If $\bar u$ lies above a place outside S, then $I_{\bar u} \subseteq K'$, so N contains the kernel of $G_F \to G$; hence $\Gamma = G/\bar N$, where $\bar N$, the image of N, is the closed normal subgroup of G generated by the images of the $J_{\bar u}$, $\bar u$ above S_b. Fix for each $u \in S_b$ a place $\bar u$ above it, with $D_u = D_{\bar u} \cap G_F \supseteq I_u = I_{\bar u} \cap G_F$, and $J_u = I_u \cap K'$. Let W, (b_v) be as in the statement and $W^\vee = \mathrm{Hom}_{\mathbb{F}_\ell}(W, \mu_\ell)$; via the trace form of $\mathbb{F}/\mathbb{F}_\ell$, $(W^\vee)^G \cong \mathrm{Hom}_\Gamma(W, \mathbb{F}(\bar\omega)) = 0$.

Step 1: the long exact sequence. By definition, $H^i(\Gamma; W, b)$ ($i = 0, 1, 2$) is the cohomology in degree i of the complex whose degree-i term consists of the pairs $(x, (x_v)_v)$, $x \in C^i(\Gamma, W)$, $x_v \in C^{i-1}(D_v, W/b_v)$, with differential $(x, (x_v)) \mapsto (dx, (\mathrm{res}_v x - dx_v))$ (the representatives X_t, y_t of Definition 48.2 with values in W matter only modulo b_t, and continuous maps to the finite

set W/b_v lift to W). This is the shifted mapping cone of $C^\bullet(\Gamma,W)\to\bigoplus_{v|\ell}C^\bullet(D_v,W/b_v)$, so with $A_v^i=H^i(D_v,W/b_v)$, $a_v^i=\dim A_v^i$, $h_c^i=h^i(\Gamma;W,b)$ there is an exact sequence

$$0\to H_c^0\to H^0(\Gamma,W)\to\bigoplus\nolimits_v A_v^0\to H_c^1\to H^1(\Gamma,W)\to\bigoplus\nolimits_v A_v^1\to H_c^2\to H^2(\Gamma,W)\xrightarrow{\rho}\bigoplus\nolimits_v A_v^2.$$

Let $K_2=\ker\rho$. All terms are finite: $H^1(\Gamma,W)\subseteq H^1(G,W)$ and $H^2(\Gamma,W)$ by Step 3 below and Theorem B.37, item 1; the A_v^i by Theorem B.29, item 1. In particular H_c^2 is finite-dimensional, and the alternating sum of dimensions gives, with the local Euler characteristic $a_v^0-a_v^1+a_v^2=-d_v\dim(W/b_v)$ (Theorem B.29, item 4),

$$h_c^0-h_c^1+h_c^2=h^0(\Gamma,W)-h^1(\Gamma,W)+\dim K_2+\sum_{v|\ell}a_v^2+\sum_{v|\ell}d_v(\dim W-\dim b_v).\tag{48.5}$$

Step 2: the local terms at S_b. Let $u\in S_b$. I_u/J_u is finite of order prime to ℓ (it embeds into G_F/K'), and $D_u/I_u\cong\widehat{\mathbb{Z}}$. Hence $H^2(D_u/J_u,W)=H^2(D_u/I_u,W^{I_u})=0$ and $\dim H^1(D_u/J_u,W)=\dim W^{D_u}$. J_u acts trivially on W ($J_u\subseteq N$), so inflation–restriction and the local Euler characteristic ($u\nmid\ell$) give

$$\dim\operatorname{Hom}_{D_u}(J_u,W)=h^1(D_u,W)-h^0(D_u,W)=h^2(D_u,W).\tag{48.6}$$

Next, $H^2(\pi(D_u),W)=0$. Indeed $\pi(I_u)$ is a quotient of I_u/J_u, finite of order prime to ℓ and normal in $\pi(D_u)$, and $Q=\pi(D_u)/\pi(I_u)$ is procyclic. Let F_∞ be the cyclotomic $\mathbb{Z}_\ell$-extension of F; it is unramified outside ℓ, so $N\subseteq G_{F_\infty}$ and Γ maps onto $\operatorname{Gal}(F_\infty/F)$, an open subgroup of $\operatorname{Gal}(\mathbb{Q}_\infty/\mathbb{Q})\cong1+\ell\mathbb{Z}_\ell$ (through $\langle\chi_{\mathrm{cyc}}\rangle$). A Frobenius at u maps to $\langle\mathrm{N}u\rangle$, which has infinite order since the integer $\mathrm{N}u\geq2$ is not a root of unity. So Q maps onto an infinite closed subgroup of $\mathbb{Z}_\ell$, its ℓ-Sylow subgroup is $\cong\mathbb{Z}_\ell$, and $H^2(\pi(D_u),W)=H^2(Q,W^{\pi(I_u)})=0$.

Step 3: from Γ to G. Inflation–restriction for $\bar N\subseteq G$ gives $h^0(\Gamma,W)=h^0(G,W)$ and an exact sequence $0\to H^1(\Gamma,W)\to H^1(G,W)\to\operatorname{Hom}_\Gamma(\bar N,W)\to H^2(\Gamma,W)\to H^2(G,W)$. A Γ-equivariant continuous homomorphism $f\colon\bar N\to W$ vanishing on the images of the J_u, $u\in S_b$, vanishes on their conjugates by equivariance (the J at the other places above u are G_F-conjugates of J_u), hence on $\bar N$; and $f|_{J_u}\in\operatorname{Hom}_{D_u}(J_u,W)$. By (48.6), $\dim\operatorname{Hom}_\Gamma(\bar N,W)\leq\sum_{u\in S_b}h^2(D_u,W)$; in particular $H^2(\Gamma,W)$ is finite. Let t be the dimension of the image of $H^1(G,W)$ in $\operatorname{Hom}_\Gamma(\bar N,W)$ and K_2' the image of K_2 in $H^2(G,W)$. Then $h^1(G,W)-h^1(\Gamma,W)=t$ and $\dim K_2\leq\dim K_2'+\dim\operatorname{Hom}_\Gamma(\bar N,W)-t$, so by (48.5) and Tate's formula (Theorem B.37, item 2; F is totally real, so the right side there is $\prod_u\#W^{c_u=1}/\#W$ and $\sum_{v|\ell}d_v=[F:\mathbb{Q}]$),

$$h_c^0-h_c^1+h_c^2\leq\sum_{u|\infty}\dim W^{c_u=1}-h^2(G,W)+\dim K_2'+\dim\operatorname{Hom}_\Gamma(\bar N,W)+\sum_{v|\ell}a_v^2-\sum_{v|\ell}d_v\dim b_v.\tag{48.7}$$

Step 4: Poitou–Tate. Since $(W^\vee)^G=0$, the restriction $R\colon H^2(G,W)\to\bigoplus_{v\in S\text{ finite}}H^2(F_v,W)$ is onto (Theorem B.37, item 3), so $h^2(G,W)=\dim\ker R+\sum_{v|\ell}h^2(D_v,W)+\sum_{u\in S_b}h^2(D_u,W)$. Let $z\in K_2$ with image $z'\in K_2'$. For $u\in S_b$, the restriction of z' to D_u factors through $H^2(\pi(D_u),W)=0$. For $v\mid\ell$, the image of $\mathrm{res}_v z'$ in A_v^2 is the v-component of $\rho(z)=0$; and $H^2(D_v,W)\to A_v^2$ is onto (its cokernel lies in $H^3(D_v,b_v)=0$), so $\mathrm{res}_v z'$ lies in a kernel of dimension $h^2(D_v,W)-a_v^2$. Hence $\dim K_2'\leq\dim\ker R+\sum_{v|\ell}(h^2(D_v,W)-a_v^2)$, and with Step 3,

$$\dim K_2'+\dim\operatorname{Hom}_\Gamma(\bar N,W)+\sum_{v|\ell}a_v^2\leq h^2(G,W).$$

Inserted into (48.7): $h_c^0-h_c^1+h_c^2\leq\sum_{u|\infty}\dim W^{c_u=1}-\sum_{v|\ell}d_v\dim b_v$, which is the general inequality.

Step 5: (Ar5)(iv). Let L be a CM field and take $F = L^+$ (totally real) and $K' = G_F \cap \ker \eta_K \cap \ker \bar{\Psi}$. It is open and normal in G_F, and G_F/K' embeds into $\{\pm 1\} \times \mathbb{F}_{\mathcal{O}}^\times$, of order prime to the odd prime ℓ. An element $s \in I_{\bar{u}} \cap G_{L^+}$, $\bar{u} \nmid \ell$, lies in K' exactly when $\eta_K(s) = 1$ and $\bar{\Psi}(s) = 1$, so the generators of N are those of N_L in Definition 48.2: $N = N_L$, $\Gamma = \Gamma_L$ and $\pi = \pi_L$. The places $\bar{v}$, the groups D_v, the degrees d_v, the conjugations c_u and the family $(D_v)_{v|\ell}$ are those of Definition 48.2. The general inequality is then (48.1), which is item (iv) of (Ar5). $\square$

Lemma 48.10. *Let K, $\mathcal{O}$, c, Ψ with $\Psi(c) = 1$, a marking $g_\star$ and an integer M with $\ell \mid M$ be as in Definition 48.2, and let L be a CM field satisfying (Af1)–(Af3) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. Let A be a test ring and r a triangular lift to A for $g_\star$. Then there is a polarised ordinary lift $(\rho, (\psi_{v,a}))$ of rank 3 over L to A such that $\rho_L(g) = \underline{r}(g)$ for all $g \in G_L$ and $\psi_{v,a}(g) = \Psi(g)^{w_{3,a}}$ (mapped to A) for all places $v \mid \ell$ of L^+, all a and all $g \in I_v$.*

Proof. Throughout, $G_L \subseteq G_K$ by (Af1), so $r(g) = (\underline{r}(g), 1)$ for $g \in G_L$ by (Tl1) and $\underline{r}$ is multiplicative on G_K.

r factors through Γ_L. By (Tl1), for each $k \geq 1$ the map $g \mapsto r(g) \bmod \mathfrak{m}_A^k$ is locally constant, so its kernel is open; the kernel of $r|_{G_{L^+}}$ is the intersection of these kernels with G_{L^+}, a closed normal subgroup of G_{L^+}. Let $s \in I_{\bar{v}} \cap G_{L^+}$ with $\bar{v} \nmid \ell$, $\eta_K(s) = 1$ and $\bar{\Psi}(s) = 1$. By (Af3), $\Psi(s) = 1$, so $r(s) = 1$ by (Tl3). Hence $N_L \subseteq \ker r$, and $\rho(\pi_L(g)) = \underline{r}(g)$ ($g \in G_L$) is a well-defined homomorphism $\rho\colon \Gamma_L^0 \to \mathrm{GL}_3(A)$ with $\rho_L = \underline{r}|_{G_L}$. (Po1) for ρ follows from (Tl1).

(Po2). By (Tl1) and (Tl2), $r(c) = (1, -1)$. For $g \in G_L$ we have $cg^{-1}c \in G_L$ (as $c \in G_{L^+}$ normalises G_L), and

$$r(cg^{-1}c) = (1,-1)(\underline{r}(g)^{-1}, 1)(1,-1) = (\theta(\underline{r}(g)^{-1}), 1) = (J\,{}^t\underline{r}(g)\,J, 1).$$

(Po3). Put $X = \underline{r}(g_\star)$; $g_\star \in G_L$ by (Af1), and by (Po2) $\underline{r}(cg_\star^{-1}c) = J\,{}^tXJ$, whose (i,j) entry is $X_{4-j,4-i}$. So the (i,j) entry of $D = X - J\,{}^tXJ$ is $X_{ij} - X_{4-j,4-i}$: hence $D_{13} = D_{31} = 0$, $D_{23} = -D_{12}$ and $D_{32} = -D_{21}$. By (Tl2), $D_{12} = D_{21} = 0$, so every off-diagonal entry of D vanishes.

(Po4) and the inertial characters. Let $v \mid \ell$ be a place of L^+ and $\bar{v} = \gamma_v \bar{\ell}$ with $\gamma_v \in G_K$ the place fixed in Definition 48.2. Since $\ell \mid M$, v splits in L by (Af2), so $D_v \subseteq G_L \subseteq G_K$, and $\gamma_v^{-1} D_v \gamma_v \subseteq D_\ell \cap G_K$, $\gamma_v^{-1} I_v \gamma_v \subseteq I_\ell$. Let h be as in (Tl4) and $P = \underline{r}(\gamma_v)h$. For $g \in D_v$,

$$P^{-1}\underline{r}(g)P = h^{-1}\underline{r}(\gamma_v^{-1}g\gamma_v)h$$

is upper triangular; let $\psi_{v,a}(g)$ be its a-th diagonal entry. As $g \mapsto P^{-1}\underline{r}(g)P$ is a homomorphism into the upper triangular group, each $\psi_{v,a}\colon D_v \to A^\times$ is a homomorphism, and it satisfies the continuity of (Po1) because $\underline{r}$ does. For $g_1, g_2, g_3 \in D_v$ put $U_a = P^{-1}(\underline{r}(g_a) - \psi_{v,a}(g_a))P$: an upper triangular matrix with (a,a) entry 0. With V_k the span of the first k standard basis vectors, $U_a V_k \subseteq V_k$ for all k and $U_a V_a \subseteq V_{a-1}$; hence $U_1U_2U_3A^3 = U_1U_2U_3V_3 \subseteq U_1U_2V_2 \subseteq U_1V_1 = 0$, and $\prod_{a=1}^3(\underline{r}(g_a) - \psi_{v,a}(g_a)) = P\,U_1U_2U_3\,P^{-1} = 0$, which is (Po4). If $g \in I_v$, then $\gamma_v^{-1}g\gamma_v \in I_\ell \cap G_K$ and (Tl4) gives $\psi_{v,a}(g) = \psi_a(\gamma_v^{-1}g\gamma_v) = \Psi(g)^{2-a} = \Psi(g)^{w_{3,a}}$, since Ψ is a character of $G_{\mathbb{Q}}$ with values in a commutative group.

(Po5). By (Tl1), $\underline{r}(g) \equiv \mathrm{T}(\Psi(g)) = \mathrm{diag}(\Psi(g)^{w_{3,1}}, \Psi(g)^{w_{3,2}}, \Psi(g)^{w_{3,3}})$ modulo $\mathfrak{m}_A$ for $g \in G_K$, in particular for $g \in G_L$. Since $h \equiv 1$, $P \equiv \mathrm{T}(\Psi(\gamma_v))$, which is diagonal and commutes with $\mathrm{T}(\Psi(g))$; so for $g \in D_v$, $P^{-1}\underline{r}(g)P \equiv \mathrm{T}(\Psi(g))$ and $\psi_{v,a}(g) \equiv \bar{\Psi}(g)^{w_{3,a}}$ modulo $\mathfrak{m}_A$.

Thus $(\rho, (\psi_{v,a}))$ is a polarised ordinary lift of rank 3 over L to A with the two stated properties. $\square$

Proposition 48.11. *Let $\mathcal{O}$ be a coefficient ring, $c \in G_{\mathbb{Q}}$ a complex conjugation, and assume (a) or (b), with K, M and $\Psi = \Psi_{\chi,e}$:*

(a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$, and $M = \ell N|d_K|$;

(b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$, $K = \mathbb{Q}(i)$ and $M = \ell N$.

Let $g_\star$ be a marking and L an auxiliary field of some level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. Let r be a triangular lift for $g_\star$ to an integral test ring such that $\rho_r|_V$ is irreducible for every open subgroup $V \subseteq G_K$. Then for every place $v \mid \ell$ of K at which ρ_r is generic and every place $w \mid v$ of L, the representation $\rho_r|_{G_L}$ is generic at w.

Proof. Let A and r be as in the statement, $\rho = \rho_r$ and $r' = \rho \otimes \chi_{\mathrm{cyc}}^{-1} \colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$. By (Af1), L is a CM field, abelian over $\mathbb{Q}$, with $K \subseteq L$; so L/K is finite and Galois and G_L is open in G_K. We check the hypotheses of Lemma 48.12 for $K \subseteq L$, $n = 3$, r' and a place $v \mid \ell$ of K at which ρ is generic.

Automorphy over L. By hypothesis (with $V = G_L$), $\rho|_{G_L}$ is irreducible, and so is $r'|_{G_L}$. By Lemma 48.10 there is a polarised ordinary lift $(\tilde\rho, (\psi_{u,a}))$ of rank 3 over L to A with $\tilde\rho_L = \underline{r}|_{G_L} = \rho|_{G_L}$ and $\psi_{u,a}(g) = \Psi(g)^{w_{3,a}}$ for $g \in I_u$, at every place $u \mid \ell$ of L^+. Since $\tilde\rho_L$ is irreducible over $\overline{\mathbb{Q}}_\ell$, (Pp2) shows that $\tilde\rho_L \otimes \chi_{\mathrm{cyc}}^{-1}|_{G_L} = r'|_{G_L}$ is automorphic of conjugate self-dual type for ι.

Triangular forms at v. Let $\bar v \mid v$ be a place of $\overline{\mathbb{Q}}$. By (Lo2), v lies below some $\bar u \in \{\bar\ell, c\bar\ell\}$, and there are $h \in \mathrm{GL}_3(A)$ and characters $\kappa_1, \kappa_2, \kappa_3$ of the decomposition group $D_{\bar u}$ of G_K at $\bar u$ such that $h^{-1}\rho(g)h$ is upper triangular with diagonal $(\kappa_a(g))$ for $g \in D_{\bar u}$, and $\kappa_a(g) = \Psi(g)^{2-a}$ for $g \in I_{\bar u}$. G_K acts transitively on the places of $\overline{\mathbb{Q}}$ above v, so $\bar v = \gamma\bar u$ with $\gamma \in G_K$, $D_{\bar v} = \gamma D_{\bar u}\gamma^{-1}$ and $I_{\bar v} = \gamma I_{\bar u}\gamma^{-1}$. For $g \in D_{\bar u}$, $(\rho(\gamma)h)^{-1}\rho(\gamma g\gamma^{-1})(\rho(\gamma)h) = h^{-1}\rho(g)h$; so ρ is triangular on $D_{\bar v}$ with diagonal (κ_a^γ), $\kappa_a^\gamma(s) = \kappa_a(\gamma^{-1}s\gamma)$, and $\kappa_a^\gamma(s) = \Psi(s)^{2-a}$ for $s \in I_{\bar v}$, as Ψ is a character of $G_{\mathbb{Q}}$ with commutative values.

Hypothesis 1 of Lemma 48.12. As ρ is generic at v, it is triangular on $D_{\bar v}$ with some diagonal (κ_i') such that $\kappa_i' \neq \kappa_j'\chi_{\mathrm{cyc}}$ for all i, j. A triangular form gives a $D_{\bar v}$-stable flag whose graded pieces are the diagonal characters, so by the Jordan–Hölder theorem (κ_i') and (κ_a^γ) are the same multiset, and $\kappa_a^\gamma \neq \kappa_b^\gamma\chi_{\mathrm{cyc}}$ for all a, b. The representation r' is triangular on $D_{\bar v}$ (same conjugating matrix) with diagonal $\mu_a = \kappa_a^\gamma\chi_{\mathrm{cyc}}^{-1}$, and $\mu_a \neq \mu_b\chi_{\mathrm{cyc}}$ for all a, b.

Hypothesis 2. Put $h_a = e(2-a) - 1$. For $s \in I_{\bar v}$, $\mu_a(s)\chi_{\mathrm{cyc}}(s)^{-h_a} = \Psi(s)^{2-a}\chi_{\mathrm{cyc}}(s)^{-e(2-a)} = \chi(s)^{2-a}$. As χ has finite order, $\ker\chi \cap I_{\bar v}$ is open in $I_{\bar v}$, and $\mu_a\chi_{\mathrm{cyc}}^{-h_a}$ is trivial on it.

Conclusion. By Lemma 48.12, $r'|_{G_L}$ is generic at every place $w \mid v$ of L: for every $\bar w \mid w$ it is triangular on the decomposition group of G_L at $\bar w$ with a diagonal (μ_i') such that $\mu_i' \neq \mu_j'\chi_{\mathrm{cyc}}$ for all i, j. Then $\rho|_{G_L} = r'|_{G_L} \otimes \chi_{\mathrm{cyc}}$ is triangular there with diagonal $(\mu_i'\chi_{\mathrm{cyc}})$, which satisfies the same inequalities. So $\rho_r|_{G_L}$ is generic at w. □

Lemma 48.12. *Let $K \subseteq L \subset \overline{\mathbb{Q}}$ be CM fields with L/K finite and Galois, $n \geq 2$, ℓ a prime, $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $r \colon G_K \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a continuous representation such that $r|_{G_L}$ is irreducible and automorphic of conjugate self-dual type for ι. Let $v \mid \ell$ be a place of K such that for every place $\bar v \mid v$ of $\overline{\mathbb{Q}}$, r is triangular on $D_{\bar v}$ with a diagonal $(\kappa_1, \dots, \kappa_n)$ satisfying*

1. $\kappa_a \neq \kappa_b\chi_{\mathrm{cyc}}|_{D_{\bar v}}$ for all a, b;

2. for each a there is an integer h_a such that $\kappa_a\chi_{\mathrm{cyc}}^{-h_a}$ is trivial on an open subgroup of $I_{\bar v}$.

Then $r|_{G_L}$ is generic at every place $w \mid v$ of L.

Proof. Fix a place $w \mid v$ of L and a place $\bar{w} \mid w$ of $\overline{\mathbb{Q}}$; it lies above v. Write $D = D_{\bar{w}} \supseteq I = I_{\bar{w}}$ for the decomposition and inertia groups of G_K at $\bar{w}$, $D' = D \cap G_L$ for the decomposition group of G_L at $\bar{w}$ (open and normal in D, as L/K is finite Galois), $W \subseteq D$ for the Weil group and $W' = W \cap D'$ for that of D', $q = q_v$, and f for the residue degree of w over v, so $q_w = q^f$. For $g \in W$ put $\|g\| = q^{n(g)}$. Let (κ_a) and (h_a) be as in the hypothesis for $\bar{v} = \bar{w}$, and $\nu_a = \kappa_a \chi_{\mathrm{cyc}}^{-h_a}$, a continuous character of D trivial on an open subgroup of I. As D is compact, each $\nu_a(D)$ is a compact subgroup of $\overline{\mathbb{Q}}_\ell^\times$, so the values of ν_a are ℓ-adic units.

Step 1: r is de Rham on D, and the characters of its Weil–Deligne representation. By hypothesis $r|_{G_L} \leftrightarrow_\iota \pi$ for a regular algebraic conjugate self-dual cuspidal π of $\mathrm{GL}_n(\mathbb{A}_L)$. By Theorem B.62, $r_{\ell,\iota}(\pi)$ is semisimple and, by (Bg1), unramified with the same characteristic polynomials of Frobenius as $r|_{G_L}$ at almost all places; $r|_{G_L}$ is irreducible, so $r|_{G_L} \cong r_{\ell,\iota}(\pi)$ by the Chebotarev density theorem and the Brauer–Nesbitt theorem. By (Bg2), $r|_{D'}$ is de Rham. A representation whose restriction to an open subgroup is de Rham is de Rham, and de Rham representations are potentially semistable ([95], [23]); so $r|_D$ is potentially semistable. Let $(V, \rho, N) = \mathrm{WD}(r|_D)$. We use the following properties of Fontaine's construction ([95]; [255], Section 1):

(F1) subrepresentations and quotients of potentially semistable representations are potentially semistable, and WD is exact and compatible with tensor products on them;

(F2) $\mathrm{WD}(r|_{D'}) = (V, \rho|_{W'}, N)$ (compatibility with restriction to open subgroups);

(F3) $\chi_{\mathrm{cyc}}|_D$ is crystalline and $\mathrm{WD}(\chi_{\mathrm{cyc}}|_D) = \|\cdot\|^\delta$ for a sign $\delta \in \{\pm 1\}$ fixed by the normalisation of the construction (φ acts on $D_{\mathrm{cris}}(\chi_{\mathrm{cyc}})$ by ℓ^{-1});

(F4) a continuous character ν of D trivial on an open subgroup of I is potentially semistable, with $\mathrm{WD}(\nu) = (\nu^\epsilon|_W, 0)$ for a sign $\epsilon \in \{\pm 1\}$ fixed by the normalisation.

Let $g \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ conjugate $r|_D$ into upper triangular form with diagonal (κ_a), and V_a the span of the first a columns of g^{-1}: a D-stable flag with $V_a/V_{a-1} \cong \kappa_a$. By (F1), (F3), (F4), $\kappa_a = \chi_{\mathrm{cyc}}^{h_a}\nu_a$ is potentially semistable with

$$\omega_a := \mathrm{WD}(\kappa_a) = \|\cdot\|^{\delta h_a}\, \nu_a^\epsilon|_W,$$

and V has a $\rho(W)$-stable flag whose graded pieces are $\omega_1, \dots, \omega_n$. In particular, for every $\Psi \in W$ the eigenvalues of $\rho(\Psi)$, with multiplicity, are $\omega_1(\Psi), \dots, \omega_n(\Psi)$, and the Jordan–Hölder constituents of (V, ρ) are the ω_a.

Step 2: $N = 0$. $r|_D$ is potentially semistable and triangular on D with diagonal (κ_a), and $\kappa_a\kappa_b^{-1}\chi_{\mathrm{cyc}}^{-(h_a-h_b)} = \nu_a\nu_b^{-1}$ is trivial on an open subgroup of I. By hypothesis 1 and (Tj1) of Lemma 48.13 (for the number field K, the place v and $\bar{v} = \bar{w}$), $N = 0$.

Step 3: purity over L forces genericity at w. By (F2) and Step 2, $\mathrm{WD}(r|_{D'}) = (V, \rho|_{W'}, 0)$. As $r|_{D'}$ is conjugate to $r_{\ell,\iota}(\pi)|_{D'}$, Theorem B.73 (with $F = L$, the place w, $\bar{v} = \bar{w}$; $n \geq 2$) shows that this Weil–Deligne representation, with zero monodromy, is pure in the sense of (Tj2) of Lemma 48.13 (for the number field L, the place w and an element $\Phi' \in W'$ acting on the residue field as $x \mapsto x^{q_w^{-1}}$): (Pu1), (Pu2) are exactly its conditions. $r|_{D'}$ is potentially semistable, triangular on D' with diagonal $(\kappa_a|_{D'})$, and $\kappa_a\kappa_b^{-1}\chi_{\mathrm{cyc}}^{-(h_a-h_b)}$ is trivial on an open subgroup of $I \cap D'$. So (Tj2) of Lemma 48.13 for $r|_{D'}$ with $m = 1$ gives $\kappa_a|_{D'} \neq \kappa_b\chi_{\mathrm{cyc}}|_{D'}$ for all a, b.

Conclusion. With the same g, $g\,r(s)g^{-1}$ is upper triangular with diagonal $(\kappa_a(s))$ for $s \in D'$, so $r|_{G_L}$ is triangular on D', the decomposition group of G_L at $\bar{w}$, with the diagonal $(\kappa_a|_{D'})$, which satisfies the inequalities of genericity. As $\bar{w} \mid w$ was arbitrary, $r|_{G_L}$ is generic at w. □

Lemma 48.13. *Let F be a number field, $v \mid \ell$ a place of F, $\bar v \mid v$ a place of $\overline{\mathbb{Q}}$, $D = D_{\bar v} \cap G_F \supseteq I = I_{\bar v} \cap G_F$ and $W \subseteq D$ the Weil group, $q = q_v$, and $\Phi \in W$ with $n(\Phi) = -1$. Let $n \geq 1$ and $r\colon D \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ be a continuous potentially semistable representation which is triangular on D with a diagonal $(\kappa_1, \dots, \kappa_n)$ such that for all a, b there is an integer h_{ab} with $\kappa_a \kappa_b^{-1} \chi_{\mathrm{cyc}}^{-h_{ab}}$ trivial on an open subgroup of I. Let $(V, \rho, N) = \mathrm{WD}(r)$.*

(Tj1) *If $\kappa_a \neq \kappa_b \chi_{\mathrm{cyc}}|_D$ for all a, b, then $N = 0$.*

(Tj2) *If $N = 0$ and (V, ρ, N) is* pure*, i.e. there are a real number k and $\rho(W)$-stable subspaces $\mathrm{Fil}_j V$ ($j \in k + \mathbb{Z}$), increasing, 0 for j small and V for j large, with $N(\mathrm{Fil}_j V) \subseteq \mathrm{Fil}_{j-2} V$, such that every eigenvalue α of $\rho(\Phi)$ on $\mathrm{gr}_j = \mathrm{Fil}_j V / \mathrm{Fil}_{j-1} V$ satisfies $|\sigma(\alpha)| = q^{j/2}$ for every field embedding $\sigma\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ and $N^i\colon \mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$ is an isomorphism for every integer $i \geq 1$, then every eigenvalue α of $\rho(\Phi)$ satisfies $|\iota(\alpha)| = q^{k/2}$, and $\kappa_a^m \neq (\kappa_b \chi_{\mathrm{cyc}})^m$ on D for all a, b and every integer $m \geq 1$.*

Proof. We use the following properties of Fontaine's construction ([95]; [255], Section 1):

(F1) subrepresentations and quotients of potentially semistable representations are potentially semistable, and WD is exact and compatible with tensor products and duals on them;

(F2) for an open subgroup $D' \subseteq D$ with Weil group $W' = W \cap D'$, $\mathrm{WD}(r|_{D'}) = (V, \rho|_{W'}, N)$;

(F3) $\chi_{\mathrm{cyc}}|_D$ is crystalline and $\mathrm{WD}(\chi_{\mathrm{cyc}}|_D) = \|\cdot\|^\delta$ for a sign $\delta \in \{\pm 1\}$ fixed by the normalisation of the construction;

(F4) a continuous character ν of D trivial on an open subgroup of I is potentially semistable with $\mathrm{WD}(\nu) = (\nu^\epsilon|_W, 0)$ for a sign $\epsilon \in \{\pm 1\}$ fixed by the normalisation.

Step 1: the graded pieces of V. Let $g \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ conjugate r into upper triangular form with diagonal (κ_a); the span V_a of the first a columns of g^{-1} is D-stable with $V_a / V_{a-1} \cong \kappa_a$. By (F1) each κ_a is potentially semistable; put $\omega_a = \mathrm{WD}(\kappa_a)$, a character of W (a one-dimensional Weil–Deligne representation has zero monodromy). By exactness, (V, ρ) has a $\rho(W)$-stable flag with graded pieces $\omega_1, \dots, \omega_n$; so for every $h \in W$ the eigenvalues of $\rho(h)$ with multiplicity are $\omega_1(h), \dots, \omega_n(h)$, and the Jordan–Hölder constituents of (V, ρ) are the ω_a. With $\nu_{ab} = \kappa_a \kappa_b^{-1} \chi_{\mathrm{cyc}}^{-h_{ab}}$, (F1), (F3), (F4) give

$$\omega_a \omega_b^{-1} = \|\cdot\|^{\delta h_{ab}} \nu_{ab}^\epsilon|_W.$$

As D is compact, $\nu_{ab}(D)$ is a compact subgroup of $\overline{\mathbb{Q}}_\ell^\times$, so the values of ν_{ab} are ℓ-adic units.

Step 2: (Tj1). By (38.5), $\rho(h) N \rho(h)^{-1} = \|h\| N$, i.e. N is a W-equivariant map $(V, \rho) \to (V, \|\cdot\|^{-1}\rho)$. Suppose $N \neq 0$. A simple subquotient of its image is a Jordan–Hölder constituent of both, so $\omega_a = \|\cdot\|^{-1} \omega_b$ for some a, b, i.e. $\|\cdot\|^{\delta h_{ab} + 1} = \nu_{ab}^{-\epsilon}$ on W. At Φ the left side is $q^{-(\delta h_{ab}+1)}$ and the right side an ℓ-adic unit; q is a positive power of ℓ, so $\delta h_{ab} + 1 = 0$, i.e. $h_{ab} = -\delta$, and then $\nu_{ab} = 1$ on W, which is dense in D, hence on D. So $\kappa_a = \kappa_b \chi_{\mathrm{cyc}}^{-\delta}$: for $\delta = -1$ this is $\kappa_a = \kappa_b \chi_{\mathrm{cyc}}$, for $\delta = 1$ it is $\kappa_b = \kappa_a \chi_{\mathrm{cyc}}$; both are excluded by hypothesis. Hence $N = 0$.

Step 3: (Tj2), the absolute values. As $N = 0$, the isomorphism $N^i\colon \mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$ is the zero map, so $\mathrm{gr}_{k+i} = \mathrm{gr}_{k-i} = 0$ for every integer $i \geq 1$. All indices lie in $k + \mathbb{Z}$, so $\mathrm{Fil}_{k-1} V = 0$ and $\mathrm{Fil}_k V = V$, i.e. $V = \mathrm{gr}_k$, and every eigenvalue α of $\rho(\Phi)$ satisfies $|\iota(\alpha)| = q^{k/2}$.

Step 4: (Tj2), potential genericity. Let $m \geq 1$ and suppose $\kappa_a^m = (\kappa_b \chi_{\mathrm{cyc}})^m$ on D. By (F1), (F3), $\omega_a^m = \mathrm{WD}(\kappa_a^m) = \mathrm{WD}(\kappa_b^m \chi_{\mathrm{cyc}}^m) = \omega_b^m \|\cdot\|^{\delta m}$, so $|\iota\omega_a(\Phi)|^m = |\iota\omega_b(\Phi)|^m q^{-\delta m}$. Both $\omega_a(\Phi)$ and $\omega_b(\Phi)$ are eigenvalues of $\rho(\Phi)$ (Step 1), of absolute value $q^{k/2}$ (Step 3), so $q^{-\delta m} = 1$, which is impossible as $q > 1$ and $m \geq 1$. Hence $\kappa_a^m \neq (\kappa_b \chi_{\mathrm{cyc}})^m$ for all a, b and $m \geq 1$. □

Proposition 48.14. *Let $\mathcal{O}$ be a coefficient ring, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $c \in G_{\mathbb{Q}}$ a complex conjugation, (K, ℓ, e, N, χ) a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$, $M = \ell N |d_K|$ and $\Psi = \Psi_{\chi,e}$. Let $g_\star$ be a marking, L an auxiliary field of some level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, and $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ an algebraic character such that L has automorphic irreducible lifts in rank 2 with twist κ for ι. Then for every triangular lift r for $g_\star$ of type II to an integral test ring with $\rho_r(g)_{22} = 1$ for all $g \in G_K$, every continuous $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ whose restriction to G_K is the corner of r and with $\operatorname{tr} W(c) = 0$ satisfies (Eo2) and the witness conditions over imaginary quadratic fields.*

Proof. Let A, r and W be as in the statement, $\rho = \rho_r$ and $\rho^\flat$ the corner of r, so $W|_{G_K} = \rho^\flat$. By (Ue1), ℓ is odd; by (Ue5), $\Psi(c) = \chi(-1)(-1)^e = 1$; $\ell \mid M$; and L satisfies (Af1)–(Af3), so Lemma 48.15 applies to r. By (Af1), L is a CM field, abelian over $\mathbb{Q}$, containing the imaginary quadratic field K. We check the hypotheses of Proposition 48.16 (numbered N1–N3 below) and of Proposition 48.17 (numbered I1–I5).

I1: $\det W = \eta_K$, of finite order. By (Tl1), (Tl2), $r(c) = (1, -1)$, so for $g \in G_K$, $\rho(cgc) = \theta(\rho(g)) = J\,{}^t\rho(g)^{-1}J$. As $\rho(g)$ is block diagonal for $\{e_1, e_3\} \sqcup \{e_2\}$ (type II), so is $\rho(g)^{-1}$, with corner $\rho^\flat(g)^{-1}$; the (i,j) entry of $J\,{}^tZJ$ is $Z_{4-j,4-i}$, so $\rho^\flat(cgc) = J_2\,{}^t\rho^\flat(g)^{-1}J_2$ and $\det\rho^\flat(cgc) = \det\rho^\flat(g)^{-1}$. Since $c^2 = 1$, $W(cgc) = W(c)W(g)W(c)^{-1}$ has determinant $\det W(g)$. Hence $\det\rho^\flat(g)^2 = 1$. By (Tl1), $\det\rho^\flat(g) \equiv \Psi(g)\Psi(g)^{-1} = 1$ modulo $\mathfrak{m}_A$, and $-1 \not\equiv 1$ as ℓ is odd; so $\det W = 1$ on G_K. Also $W(c)^2 = 1$ and $\operatorname{tr} W(c) = 0$, so $W(c)$ has eigenvalues $1, -1$ and $\det W(c) = -1$. Thus $\det W$ is the character of $\mathrm{Gal}(K/\mathbb{Q})$ that is -1 at c: $\det W = \eta_K$, of finite order.

N1 and I2 are (Ko1).

N2 and I3. By (Ko3) there is a polarised ordinary lift of rank 2 over L to A with $\rho'_L = \rho^\flat|_{G_L} = W|_{G_L}$ and $\psi'_{v,a} = \Psi^{w_{2,a}}$ on I_v; ρ'_L is irreducible over $\overline{\mathbb{Q}}_\ell$ by (Ko1). As L has automorphic irreducible lifts in rank 2 with twist κ for ι, $W|_{G_L} \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions; κ is algebraic by hypothesis.

N3 and I4. Let $D' = D_\ell \cap G_K$, open in D_ℓ and containing $D_\ell \cap G_L$ as $K \subseteq L$. By (Ko2) there are $Q \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ and continuous characters κ_1, κ_3 of D' such that $Q^{-1}W(s)Q$ is upper triangular with diagonal $\kappa_1(s), \kappa_3(s)$ for $s \in D'$, with $\kappa_1 = \Psi$ and $\kappa_3 = \Psi^{-1}$ on $D' \cap I_\ell = I_\ell \cap G_K$. On the open subgroup $I_\ell \cap G_K \cap \ker\chi$ of $D' \cap I_\ell$ (χ has finite order), $\Psi^{\pm 1} = \chi_{\mathrm{cyc}}^{\pm e}$. Take $P = Q^{-1}$ and the characters κ_1, $\kappa_2 = \kappa_3$.

I5. Let $p \neq \ell$ be a prime and $\bar{p} \mid p$. The extension of $\mathbb{Q}$ generated by the ℓ-power roots of unity is unramified at p, so $\chi_{\mathrm{cyc}} = 1$ and $\Psi = \chi$ on $I_{\bar{p}}$. If $p \nmid d_K$, then p is unramified in K and $I_{\bar{p}} \subseteq G_K$. The group $Z = \Psi(I_{\bar{p}})$ is finite, hence cyclic of some order n, equal to the group of n-th roots of unity, with a generator z_0. If $g, g' \in I_{\bar{p}}$ and $\Psi(g) = \Psi(g')$, then $g^{-1}g' \in I_{\bar{p}}$ has $\eta_K(g^{-1}g') = 1$ and $\Psi(g^{-1}g') = 1$, so $r(g^{-1}g') = 1$ by (Tl3) and $W(g) = W(g')$. Hence $W(g) = B(\Psi(g))$ for a homomorphism $B\colon Z \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$; $B(z_0)^n = 1$, so $B(z_0)$ is diagonalisable with eigenvalues $z_0^{b_1}, z_0^{b_2}$ for integers b_1, b_2, and $\det(X - W(g)) = (X - \Psi(g)^{b_1})(X - \Psi(g)^{b_2})$ for $g \in I_{\bar{p}}$: take $\kappa'_i = \Psi^{b_i}|_{D_{\bar{p}}}$. If $p \mid d_K$, then $p \nmid \ell N$ by (Ue6), (Ue7), so χ, hence Ψ, is unramified at p; for $g \in I_{\bar{p}} \cap G_K$, $r(g) = 1$ by (Tl3), so $W(g) = 1$. The subgroup $I_{\bar{p}} \cap G_K$ has index at most 2 in $I_{\bar{p}}$; for $g \in I_{\bar{p}} \smallsetminus G_K$, $W(g)^2 = W(g^2) = 1$, so $W(g)$ is diagonalisable with eigenvalues in $\{\pm 1\}$ and determinant $\eta_K(g) = -1$, i.e. with eigenvalues $1, -1$. So $\det(X - W(g)) = (X - 1)(X - \eta_K(g))$ for all $g \in I_{\bar{p}}$: take $\kappa'_1 = 1$, $\kappa'_2 = \eta_K|_{D_{\bar{p}}}$.

By Proposition 48.16, W satisfies (Eo2), and by Proposition 48.17 it satisfies the witness conditions over imaginary quadratic fields. □

Lemma 48.15. *Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, ℓ an odd prime, $\mathcal{O}$ a coefficient ring, χ a Dirichlet character with values in $\mathcal{O}^\times$, $e \geq 1$, $\Psi = \Psi_{\chi,e}$ with $\Psi(c) = 1$, $g_\star$ a marking,*

$M \geq 1$ with $\ell \mid M$, and L a CM field satisfying (Af1)–(Af3) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. Let A be an integral test ring, r a triangular lift for $g_\star$ to A of type II with $\rho_r(g)_{22} = 1$ for all $g \in G_K$, and $\rho^\flat \colon G_K \to \mathrm{GL}_2(A)$ its corner. Then:

(Ko1) *$\rho^\flat|_{G_L}$ is irreducible over $\overline{\mathbb{Q}}_\ell$;*

(Ko2) *$\rho^\flat$ is triangular on $D_\ell \cap G_K$ with a diagonal (κ_1, κ_3) of continuous characters $D_\ell \cap G_K \to A^\times$ such that $\kappa_1 \equiv \Psi$ and $\kappa_3 \equiv \Psi^{-1}$ modulo $\mathfrak{m}_A$, and $\kappa_1 = \Psi$, $\kappa_3 = \Psi^{-1}$ on $I_\ell \cap G_K$;*

(Ko3) *there is a polarised ordinary lift $(\rho', (\psi'_{v,a}))$ of rank 2 over L to A with $\rho'_L = \rho^\flat|_{G_L}$ and $\psi'_{v,a}(g) = \Psi(g)^{w_{2,a}}$ for every place $v \mid \ell$ of L^+, $a = 1, 2$ and $g \in I_v$.*

Proof. Write $\rho = \rho_r$ and $E \subset \overline{\mathbb{Q}}_\ell$ for the fraction field of A. For $g \in G_K$, $\rho(g)$ is block diagonal for the decomposition $E^3 = M' \oplus Ee_2$, $M' = Ee_1 \oplus Ee_3$, with $\rho(g)e_2 = e_2$; hence the corner $\rho^\flat$ (the action on M') is a homomorphism. By (Tl1), $\rho^\flat(g) \equiv \mathrm{diag}(\Psi(g), \Psi(g)^{-1})$ modulo $\mathfrak{m}_A$ for $g \in G_K$. By (Af1), L is abelian over $\mathbb{Q}$ with $K \subseteq L$, so G_L is an open normal subgroup of G_K with abelian quotient, and $g_\star \in G_L$. Write $\bar\Psi$ for the reduction of Ψ.

(Ko1). Suppose $\rho^\flat|_{G_L}$ is reducible over $\overline{\mathbb{Q}}_\ell$. As $\rho^\flat$ is irreducible and G_L is normal in G_K, Clifford's theorem makes $\rho^\flat|_{G_L} \otimes \overline{\mathbb{Q}}_\ell$ semisimple, a sum of two characters χ_1, χ_2 of G_L, and G_K permutes its isotypic components. Three cases. (i) $\chi_1 = \chi_2$: then $\rho^\flat(g_\star)$ is a scalar matrix $\lambda \cdot 1$ with $\lambda \in A$; modulo $\mathfrak{m}_A$ it is $\mathrm{diag}(\bar\Psi(g_\star), \bar\Psi(g_\star)^{-1})$, so $\bar\Psi(g_\star)^2 = 1$, contradicting $\Psi(g_\star)^2 - 1 \in \mathcal{O}^\times$. (ii) $\chi_1 \neq \chi_2$ and G_K fixes both isotypic lines: then they are G_K-stable and $\rho^\flat$ is reducible, a contradiction. (iii) $\chi_1 \neq \chi_2$ and some element of G_K swaps the two lines: the stabiliser H of the χ_1-line has index 2 in G_K and contains G_L; for $g \in G_K \smallsetminus H$, $\rho^\flat(g)$ swaps the two lines, so $\mathrm{tr}\,\rho^\flat(g) = 0$, and reducing modulo $\mathfrak{m}_A$ gives $\bar\Psi(g) + \bar\Psi(g)^{-1} = 0$, i.e. $\bar\Psi(g)^2 = -1$. Fix $g \in G_K \smallsetminus H$; as $g_\star \in G_L \subseteq H$, also $gg_\star \in G_K \smallsetminus H$, so $\bar\Psi(g)^2\bar\Psi(g_\star)^2 = -1 = \bar\Psi(g)^2$ and $\bar\Psi(g_\star)^2 = 1$, the same contradiction. Hence $\rho^\flat|_{G_L}$ is irreducible.

(Ko2). Put $D^\circ = D_\ell \cap G_K$, $I^\circ = I_\ell \cap G_K$. By (Tl4) there is $h \in \mathrm{GL}_3(A)$, $h \equiv 1$, with $h^{-1}\rho(g)h$ upper triangular for $g \in D^\circ$; its diagonal entries $\kappa_1, \kappa_2, \kappa_3$ are homomorphisms $D^\circ \to A^\times$, continuous by (Tl1), with $\kappa_a = \Psi^{2-a}$ on I° (Tl4) and $\kappa_a \equiv \Psi^{2-a}$ modulo $\mathfrak{m}_A$ (as $h \equiv 1$ and (Tl1)). So E^3 has the D°-stable flag $F_1 = E\,he_1 \subset F_2 = E\,he_1 + E\,he_2$ with graded characters $\kappa_1, \kappa_2, \kappa_3$, and by the Jordan–Hölder theorem the multiset $\{\kappa_1, \kappa_2, \kappa_3\}$ is that of the constituents of M' together with the trivial character (of Ee_2). Now $\Psi = \chi\chi_{\mathrm{cyc}}^e$ with χ of finite order and $e \geq 1$, and χ_{cyc} has infinite image on every open subgroup of I_ℓ; as I° is open in I_ℓ, $\Psi^{\pm 1}$ is non-trivial on I°, so $\kappa_1 \neq 1 \neq \kappa_3$. Hence $\kappa_2 = 1$ and the constituents of M' are κ_1, κ_3. Let $p' \colon E^3 \to M'$ be the projection along Ee_2, which is D°-equivariant. If $p'(F_1) = 0$ then $F_1 = Ee_2$ and $\kappa_1 = 1$; so $p'(F_1)$ is a D°-stable line of M' with character κ_1, and the quotient $M'/p'(F_1)$ has character κ_3. In a basis of M' whose first vector spans $p'(F_1)$, $\rho^\flat$ is upper triangular on D° with diagonal (κ_1, κ_3).

(Ko3). Let $(\tilde\rho, (\psi_{v,a}))$ be the polarised ordinary lift of rank 3 over L given by Lemma 48.10, with $\tilde\rho(\pi_L(g)) = \rho(g)$ for $g \in G_L$. Define $\rho'(x)$, for $x \in \Gamma_L^0$, as the corner of $\tilde\rho(x)$: a homomorphism, since $\tilde\rho(\Gamma_L^0) = \rho(G_L)$ consists of block diagonal matrices, with $\rho'_L = \rho^\flat|_{G_L}$. (Po1) and (Po5) for ρ' follow from those for $\tilde\rho$ (the corner of $\mathrm{diag}(\bar\Psi, 1, \bar\Psi^{-1})$ is $\mathrm{diag}(\bar\Psi^{w_{2,1}}, \bar\Psi^{w_{2,2}})$). (Po2): the (i,j) entry of $J_3\,{}^tX\,J_3$ is $X_{4-j,4-i}$, so for $i, j \in \{1,3\}$ the corner of $J_3\,{}^tX\,J_3$ has entries $X_{33}, X_{13}, X_{31}, X_{11}$ at the places $(1,1), (1,3), (3,1), (3,3)$, which is $J_2\,{}^tY\,J_2$ for the corner Y of X; apply this to (Po2) for $\tilde\rho$. (Po3): the off-diagonal entries of the corner of $\tilde\rho(\pi_L(g_\star)) - \tilde\rho(\pi_L(cg_\star^{-1}c))$ are its entries $(1,3)$ and $(3,1)$, which vanish by (Po3) for $\tilde\rho$. (Po4): let $v \mid \ell$ be a place of L^+ and $\bar v = \gamma_v\bar\ell$, $\gamma_v \in G_K$, the place fixed in Definition 48.2. Since $\ell \mid M$, v splits in L (Af2), so $D_v \subseteq G_L$, and $\gamma_v^{-1}D_v\gamma_v \subseteq D^\circ$, $\gamma_v^{-1}I_v\gamma_v \subseteq I^\circ$. Put $\psi'_{v,1}(g) = \kappa_1(\gamma_v^{-1}g\gamma_v)$ and

$\psi'_{v,2}(g) = \kappa_3(\gamma_v^{-1} g \gamma_v)$ for $g \in D_v$; with $Q \in \mathrm{GL}_2(E)$ conjugating $\rho^\flat$ to upper triangular form on D° as in (Ko2), $(\rho^\flat(\gamma_v)Q)^{-1}\rho^\flat(g)(\rho^\flat(\gamma_v)Q) = Q^{-1}\rho^\flat(\gamma_v^{-1}g\gamma_v)Q$ is upper triangular with diagonal $(\psi'_{v,1}(g), \psi'_{v,2}(g))$. For $g_1, g_2 \in D_v$ the conjugates of $\rho^\flat(g_1) - \psi'_{v,1}(g_1)$ and $\rho^\flat(g_2) - \psi'_{v,2}(g_2)$ are upper triangular with zero $(1,1)$, respectively $(2,2)$, entry, and the product of such matrices (in this order) is 0; so $(\rho'(\pi_L(g_1)) - \psi'_{v,1}(g_1))(\rho'(\pi_L(g_2)) - \psi'_{v,2}(g_2)) = 0$. The $\psi'_{v,a}$ are homomorphisms $D_v \to A^\times$ with the continuity of (Po1) (by (Ko2) and (Tl1)), $\psi'_{v,a} \equiv \bar\Psi^{w_{2,a}}$ modulo $\mathfrak{m}_A$, and for $g \in I_v$, $\psi'_{v,1}(g) = \Psi(\gamma_v^{-1}g\gamma_v) = \Psi(g)$ and $\psi'_{v,2}(g) = \Psi(g)^{-1}$, Ψ being a character of $G_\mathbb{Q}$ with commutative values. So $(\rho', (\psi'_{v,a}))$ is as claimed. □

Proposition 48.16. *Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $e \geq 1$, $L \subset \overline{\mathbb{Q}}$ a CM field abelian over $\mathbb{Q}$, and $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ a continuous representation such that:*

1. *$W|_{G_L}$ is irreducible;*
2. *there is an algebraic character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ such that $W|_{G_L} \otimes \kappa$ is automorphic of conjugate self-dual type for ι;*
3. *there are an open subgroup $D' \subseteq D_\ell$ containing $D_\ell \cap G_L$, continuous characters $\kappa_1, \kappa_2\colon D' \to \overline{\mathbb{Q}}_\ell^\times$ and $P \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that $P\,W(s)P^{-1}$ is upper triangular with diagonal entries $\kappa_1(s), \kappa_2(s)$ for all $s \in D'$, and $\kappa_1\chi_{\mathrm{cyc}}^{-e}$ and $\kappa_2\chi_{\mathrm{cyc}}^{e}$ are trivial on an open subgroup of $D' \cap I_\ell$.*

Then W satisfies (Eo2).

Proof. Write q_w for the size of the residue field at a finite place w, and for a finite place w of a number field F and a place $\bar w \mid w$, $\sigma_{\bar w}$ for an arithmetic Frobenius at $\bar w$ in G_F.

Step 1: an untwisted automorphic representation over L. By hypothesis 2, $W|_{G_L} \otimes \kappa \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal automorphic representation Π of $\mathrm{GL}_2(\mathbb{A}_L)$, and κ corresponds to an algebraic Hecke character ψ of L: ψ is a continuous character of $\mathbb{A}_L^\times/L^\times$ whose component at each complex place w is $z \mapsto z^{a_w}\bar z^{b_w}$ with $a_w, b_w \in \mathbb{Z}$, and for all but finitely many finite places w, κ is unramified at w, ψ_w is unramified and $\iota\kappa(\sigma_{\bar w}) = \psi_w(\varpi_w)$ (with the opposite normalisation of the correspondence, replace ψ by ψ^{-1}, again an algebraic Hecke character). Let $\Pi' = \Pi \otimes (\psi \circ \det)$, a cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_L)$. At all but finitely many finite w, Π_w is a subquotient of the normalised induction of unramified μ_1, μ_2, so Π'_w is the unramified subquotient of that of $\mu_1\psi_w, \mu_2\psi_w$ and has Satake parameters $\alpha\psi_w(\varpi_w)$, α running over those of Π_w; and

$$\iota \det(X - W(\sigma_{\bar w}^{-1})) = \iota \det(X - \kappa(\sigma_{\bar w})(W \otimes \kappa)(\sigma_{\bar w}^{-1})) = \prod_\alpha (X - q_w^{1/2}\alpha\,\psi_w(\varpi_w)).$$

Hence $W|_{G_L} \leftrightarrow_\iota \Pi'$. At a complex place w the Langlands parameter of Π'_w is that of Π_w times ψ_w, so its restriction to $\mathbb{C}^\times$ has the exponents of that of Π_w shifted by the integers a_w, b_w: Clozel's integrality and regularity conditions are preserved, and Π' is regular algebraic.

Step 2: a tower of cyclic steps. Let L^+ be the maximal totally real subfield of L, so $[L : L^+] = 2$. The group $\mathrm{Gal}(L^+/\mathbb{Q})$ is finite abelian, so it has a chain of subgroups with successive quotients cyclic of prime order; by Galois theory there are fields $\mathbb{Q} = F_0 \subset F_1 \subset \cdots \subset F_m = L^+$ with each F_i/F_{i-1} cyclic of prime degree (Galois, all subgroups being normal). Put $F_{m+1} = L$; F_{m+1}/F_m is cyclic of degree 2. The fields $F_0, \ldots, F_m$ are totally real. As $G_L \subseteq G_{F_i}$, $W|_{G_{F_i}}$ is irreducible for every i, by hypothesis 1.

Step 3: descent. We show by descending induction on $i \in \{0, \ldots, m+1\}$ that there is a regular algebraic cuspidal automorphic representation π_i of $\mathrm{GL}_2(\mathbb{A}_{F_i})$ with $W|_{G_{F_i}} \leftrightarrow_\iota \pi_i$. For

$i = m+1$ take $\pi_{m+1} = \Pi'$ (Step 1). Let $1 \le i \le m+1$ and π_i be given; write $E = F_i$, $F = F_{i-1}$, let σ generate $\mathrm{Gal}(E/F)$ and $\tilde\sigma \in G_F$ restrict to σ.

(a) $\pi_i^\sigma \cong \pi_i$. The component of π_i^σ at a finite place w of E is the component of π_i at the place $\sigma(w)$, transported by the isomorphism $\sigma\colon E_w \to E_{\sigma(w)}$, which carries uniformisers to uniformisers; so at almost all w it is unramified with the Satake parameters of $\pi_{i,\sigma(w)}$, and $q_w = q_{\sigma(w)}$. If $\sigma_{\bar w}$ is an arithmetic Frobenius at $\bar w \mid w$, then $\tilde\sigma\sigma_{\bar w}\tilde\sigma^{-1}$ is one at $\tilde\sigma\bar w$, which lies above $\sigma(w)$, and $W(\tilde\sigma\sigma_{\bar w}^{-1}\tilde\sigma^{-1})$ is conjugate to $W(\sigma_{\bar w}^{-1})$. Since $W|_{G_E} \leftrightarrow_\iota \pi_i$, at almost all w the Satake parameters of $\pi_{i,w}$ and $\pi_{i,\sigma(w)}$ are both determined by the same characteristic polynomial, hence equal. An unramified irreducible representation is determined by its Satake parameters, so π_i^σ and π_i have isomorphic components at almost all places; both are cuspidal, so $\pi_i^\sigma \cong \pi_i$ by Theorem B.60, (Js1).

(b) By Theorem B.74 there is a cuspidal automorphic representation π of $\mathrm{GL}_2(\mathbb{A}_F)$ with (Bc1) and (Bc2) for $\Pi = \pi_i$.

(c) π is regular algebraic. Let v be a real place of F (F is totally real) and $w \mid v$. If $i \le m$, E is totally real, v splits completely in E and $\pi_v \cong \pi_{i,w}$ by (Bc1). If $i = m+1$, w is complex, and by (Bc2) the parameter of $\pi_{i,w}$ is the restriction to $W_{\mathbb{C}} = \mathbb{C}^\times$ of that of π_v; the twist $|\det|^{-1/2}$ at v restricts to $z \mapsto |z\bar z|^{-1/2}$, which is the twist $|\det|^{-1/2}$ at w. In both cases the restriction to $\mathbb{C}^\times$ of the parameter of $\pi_v \otimes |\det|^{-1/2}$ is that of $\pi_{i,w} \otimes |\det|^{-1/2}$, which satisfies Clozel's conditions.

(d) By Theorem B.75 there is a continuous $r\colon G_F \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $r \leftrightarrow_\iota \pi$; its semisimplification r' has the same characteristic polynomials, so $r' \leftrightarrow_\iota \pi$.

(e) $r'|_{G_E} \cong W|_{G_E}$. Let T be the set of finite places w of E such that $v = w|_F$ splits completely in E, π_v and $\pi_{i,w}$ are unramified, r' and W are unramified at w and the relations $r' \leftrightarrow_\iota \pi$, $W|_{G_E} \leftrightarrow_\iota \pi_i$ hold at v, w; all but finitely many places of E of degree one over F lie in T. For $w \in T$, $E_w = F_v$, so $\sigma_{\bar w} \in G_E$ is also an arithmetic Frobenius at $\bar w$ in G_F, $q_w = q_v$, and $\pi_{i,w} \cong \pi_v$ by (Bc1); hence $r'(\sigma_{\bar w}^{-1})$ and $W(\sigma_{\bar w}^{-1})$ have the same characteristic polynomial. The places of E of degree one over F have Dirichlet density 1, so by the Chebotarev density theorem these Frobenius elements are dense in G_E; characteristic polynomials are continuous, so $r'|_{G_E}$ and $W|_{G_E}$ have the same characteristic polynomials. $r'|_{G_E}$ is semisimple (restriction of a semisimple representation to a normal subgroup of finite index, Clifford's theorem) and $W|_{G_E}$ is irreducible (Step 2), so they are isomorphic (Brauer–Nesbitt).

(f) The twist. Fix $A \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $W(g) = A\,r'(g)A^{-1}$ for $g \in G_E$. For $h \in G_F$ and $g \in G_E$, using $hgh^{-1} \in G_E$,

$$A\,r'(h)A^{-1}\,W(g) = A\,r'(hgh^{-1})r'(h)A^{-1} = W(hgh^{-1})\,A\,r'(h)A^{-1},$$

so $W(h)^{-1}A\,r'(h)A^{-1}$ commutes with $W(G_E)$ and is a scalar $\lambda(h)$ by Schur's lemma. Then $A\,r'(h)A^{-1} = \lambda(h)W(h)$, so $\lambda\colon G_F \to \overline{\mathbb{Q}}_\ell^\times$ is a continuous homomorphism, trivial on G_E. Let $\chi_\lambda = \iota\circ\lambda\circ\mathrm{Art}_F$, a character of $\mathbb{A}_F^\times/F^\times$ of finite order; at every finite v unramified in E, $\iota\lambda(\sigma_{\bar v}) = \chi_\lambda(\varpi_v)$. As $W(\sigma_{\bar v}^{-1}) = \lambda(\sigma_{\bar v})\,A\,r'(\sigma_{\bar v}^{-1})A^{-1}$, at almost all v the polynomial $\iota\det(X - W(\sigma_{\bar v}^{-1}))$ is $\prod_\alpha(X - q_v^{1/2}\alpha\chi_\lambda(\varpi_v))$ over the Satake parameters α of π_v. Put $\pi_{i-1} = \pi \otimes (\chi_\lambda \circ \det)$: it is cuspidal, unramified at almost all v with Satake parameters $\alpha\chi_\lambda(\varpi_v)$, so $W|_{G_F} \leftrightarrow_\iota \pi_{i-1}$; and it is regular algebraic, since at a real place χ_λ is 1 or the sign character, both trivial on $\mathbb{C}^\times$ after restriction of parameters. This completes the induction.

Step 4: the newform. By Step 3 with $i = 0$, $W \leftrightarrow_\iota \pi_0$ for a regular algebraic cuspidal π_0 of $\mathrm{GL}_2(\mathbb{A}_{\mathbb{Q}})$. By Theorem B.76 there are a normalised newform $f = \sum a_n q^n$ of weight $k \ge 2$, level N and character ε, and $j \in \mathbb{Z}$, such that for all but finitely many primes p: W is trivial on $I_{\bar p}$ and $\iota\det(X - W(\sigma_{\bar p}^{-1})) = X^2 - p^j a_p X + \varepsilon(p)p^{2j+k-1}$. Let $\rho = \rho_{f,\iota}$ be the representation of (Dg1) in Theorem B.59 and ρ^{ss} its semisimplification. For $p \nmid \ell N$, $\chi_{\mathrm{cyc}}(\sigma_{\bar p}) = p$,

so $(\rho^{\mathrm{ss}} \otimes \chi_{\mathrm{cyc}}^{-j})(\sigma_{\bar p}^{-1}) = p^j \rho^{\mathrm{ss}}(\sigma_{\bar p}^{-1})$ has characteristic polynomial $X^2 - p^j a_p X + p^{2j}\varepsilon(p)p^{k-1}$. By the Chebotarev density theorem, continuity and the Brauer–Nesbitt theorem (W is irreducible by hypothesis 1, hence semisimple),

$$W \cong \rho^{\mathrm{ss}} \otimes \chi_{\mathrm{cyc}}^{-j}.$$

Step 5: the weight. By Theorem B.77, applied to ρ^{ss}, $\rho^{\mathrm{ss}}|_{D_\ell}$ is Hodge–Tate with weights 0 and $1-k$; so $W|_{D_\ell}$ is Hodge–Tate with weights $-j$ and $1-k-j$. We use the standard facts ([95]): restriction to an open subgroup of D_ℓ (the Galois group of a finite extension of $\mathbb{Q}_\ell$) keeps a representation Hodge–Tate with the same weights; subrepresentations and quotients of Hodge–Tate representations are Hodge–Tate and the weights of the middle term of a short exact sequence are those of the two ends; and a character trivial on the inertia group is Hodge–Tate of weight 0 (Tate, Sen). By hypothesis 3 the line spanned by the first column of P^{-1} is stable under $W(D')$ with character κ_1, and D' acts on the quotient by κ_2. There is an open normal subgroup D'' of D' such that $\kappa_1\chi_{\mathrm{cyc}}^{-e}$ and $\kappa_2\chi_{\mathrm{cyc}}^{e}$ are trivial on $D'' \cap I_\ell$ (an open subgroup of $D' \cap I_\ell$ contains $D'' \cap I_\ell$ for some such D''); on D'' they are unramified, so $\kappa_1|_{D''}$ has weight e and $\kappa_2|_{D''}$ has weight $-e$. Hence $\{-j, 1-k-j\} = \{e, -e\}$. As $k \geq 2$, $1-k-j < -j$, so $-j = e$ and $1-k-j = -e$: $j = -e$ and $k = 2e+1$.

Step 6: (Eo2). By Steps 4 and 5, $W \otimes \chi_{\mathrm{cyc}}^{-e} \cong \rho^{\mathrm{ss}}$ is semisimple, and for every prime $p \nmid \ell N$ and $\bar p \mid p$ it is trivial on $I_{\bar p}$ with $\iota\det(X - (W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1})) = X^2 - a_p X + \varepsilon(p)p^{2e}$ for every arithmetic Frobenius σ at $\bar p$, by (Dg1) for ρ (the semisimplification has the same characteristic polynomials and is trivial on $I_{\bar p}$ when ρ is). As f is a normalised newform of weight $2e+1$, W satisfies (Eo2). □

Proposition 48.17. *Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $e \geq 1$, $L \subset \overline{\mathbb{Q}}$ a CM field abelian over $\mathbb{Q}$, and $W\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ a continuous representation such that:*

1. *$\det W$ has finite order;*
2. *$W|_{G_L}$ is irreducible;*
3. *there is an algebraic character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ such that $W|_{G_L} \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions;*
4. *there are an open subgroup $D' \subseteq D_\ell$ containing $D_\ell \cap G_L$, continuous characters $\kappa_1, \kappa_2\colon D' \to \overline{\mathbb{Q}}_\ell^\times$ and $P \in \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that $P\,W(s)P^{-1}$ is upper triangular with diagonal entries $\kappa_1(s), \kappa_2(s)$ for all $s \in D'$, and $\kappa_1\chi_{\mathrm{cyc}}^{-e}$ and $\kappa_2\chi_{\mathrm{cyc}}^{e}$ are trivial on an open subgroup of $D' \cap I_\ell$;*
5. *for every prime $p \neq \ell$ and every place $\bar p \mid p$ of $\overline{\mathbb{Q}}$ there are continuous characters κ_1', κ_2' of $D_{\bar p}$ with $\det(X - W(g)) = (X - \kappa_1'(g))(X - \kappa_2'(g))$ for all $g \in I_{\bar p}$.*

Then W satisfies the witness conditions over imaginary quadratic fields.

Proof. Fix an imaginary quadratic field K' such that $V = W|_{G_{K'}}$ is irreducible. We show (Wc1) and (Wc2) for V; the number τ of (Wc2) will be $-1/2$ for every π'. For a place $\bar u$ of $\overline{\mathbb{Q}}$ and a number field F, $D_{\bar u}$ and $I_{\bar u}$ denote the decomposition and inertia groups in $G_{\mathbb{Q}}$, and $D_{\bar u} \cap G_F$, $I_{\bar u} \cap G_F$ those in G_F.

Step 1: the flag at every place above ℓ. Let $\bar u \mid \ell$; as $G_{\mathbb{Q}}$ acts transitively on the places above ℓ, $\bar u = \gamma\bar\ell$ with $\gamma \in G_{\mathbb{Q}}$, $D_{\bar u} = \gamma D_\ell \gamma^{-1}$, $I_{\bar u} = \gamma I_\ell \gamma^{-1}$. Put $D'_{\bar u} = \gamma D' \gamma^{-1}$, open in $D_{\bar u}$; it contains $D_{\bar u} \cap G_L = \gamma(D_\ell \cap G_L)\gamma^{-1}$, G_L being normal in $G_{\mathbb{Q}}$. For $s \in$

$D'_{\bar u}$, $(PW(\gamma)^{-1})W(s)(PW(\gamma)^{-1})^{-1} = PW(\gamma^{-1}s\gamma)P^{-1}$ is upper triangular with diagonal $\kappa_1^\gamma(s), \kappa_2^\gamma(s)$, $\kappa_a^\gamma(s) = \kappa_a(\gamma^{-1}s\gamma)$, and since χ_{cyc} is a character of $G_{\mathbb{Q}}$ with commutative values, $\kappa_1^\gamma = \chi_{\mathrm{cyc}}^e$ and $\kappa_2^\gamma = \chi_{\mathrm{cyc}}^{-e}$ on an open subgroup $H_{\bar u}$ of $I_{\bar u}$.

Step 2: potential genericity. Let $F \in \{K', L\}$, θ a continuous character of G_F ($\theta = \mathbf{1}$ if $F = K'$, $\theta = \kappa$ if $F = L$), $\bar u \mid \ell$, and suppose $W|_{G_F} \otimes \theta$ is triangular on $D_{\bar u} \cap G_F$ with a diagonal (μ_1, μ_2). We claim $\mu_a^m \neq (\mu_b\chi_{\mathrm{cyc}})^m$ for all a, b and $m \geq 1$. Let $H = H_{\bar u} \cap G_F$, open in $I_{\bar u}$. On H the representation $W \otimes \theta$ has two stable flags, with graded characters (μ_1, μ_2) and $(\kappa_1^\gamma\theta, \kappa_2^\gamma\theta) = (\chi_{\mathrm{cyc}}^e\theta, \chi_{\mathrm{cyc}}^{-e}\theta)$; by the Jordan–Hölder theorem the multisets agree on H, so $\mu_a/(\mu_b\chi_{\mathrm{cyc}})$ is χ_{cyc}^{-1} (if $a = b$) or $\chi_{\mathrm{cyc}}^{\pm 2e-1}$ (if $a \neq b$) on H. Now $\chi_{\mathrm{cyc}}(H)$ is open in $\mathbb{Z}_\ell^\times$, hence contains a nontrivial element of the torsion-free group $1 + \ell^2\mathbb{Z}_\ell$, and $\pm 2e - 1 \neq 0$; so $(\mu_a/(\mu_b\chi_{\mathrm{cyc}}))^m$ is nontrivial on H. Consequences: (i) if V is generic at a place $v \mid \ell$ of K', it is triangular on $D_{\bar v} \cap G_{K'}$ for every $\bar v \mid v$, hence potentially generic at v: this is (Wc1) for V. (ii) $W|_{G_L} \otimes \kappa$ is triangular on $D_{\bar w} \cap G_L \subseteq D'_{\bar w}$ (Step 1) for every $\bar w \mid \ell$, hence potentially generic at every place of L above ℓ.

Step 3: the Galois representations of π' and Π. Let π' be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_{K'})$ with $V \leftrightarrow_\iota \pi'$ (V is semisimple). Put $\chi_0(x) = |x|_{\mathbb{A}} \cdot \iota \det W(\mathrm{Art}_{\mathbb{Q}}(x))^{-1}$, a continuous character of $\mathbb{A}_{\mathbb{Q}}^\times/\mathbb{Q}^\times$. We show $\pi'^c \cong \pi'^\vee \otimes (\chi_0 \circ \mathrm{N}_{K'/\mathbb{Q}} \circ \det)$, i.e. π' is polarizable (χ_0 has one infinite place). At almost every finite place u of K', with α, β the Satake parameters of π'_u and σ an arithmetic Frobenius at some $\bar u \mid u$: (1) $\iota \det W(\sigma^{-1}) = q_u\alpha\beta$, from $V \leftrightarrow_\iota \pi'$; (2) $\mathrm{Art}_{\mathbb{Q}}(\mathrm{N}_{K'/\mathbb{Q}}\varpi_u)$ is the image in $G_{\mathbb{Q}}^{ab}$ of $\mathrm{Art}_{K'}(\varpi_u)$, the class of σ, and $|\mathrm{N}_{K'/\mathbb{Q}}\varpi_u|_{\mathbb{A}} = q_u^{-1}$, so $\chi_0(\mathrm{N}\varpi_u) = q_u^{-1}\iota \det W(\sigma^{-1}) = \alpha\beta$; (3) the component of π'^c at u is π'_{cu} transported by c, and $W(c\sigma^{-1}c)$ is conjugate to $W(\sigma^{-1})$ in GL_2, so its Satake parameters are again α, β; (4) those of $\pi'^\vee \otimes (\chi_0 \circ \mathrm{N} \circ \det)$ are $\alpha^{-1}\alpha\beta = \beta$ and $\beta^{-1}\alpha\beta = \alpha$. Both representations are cuspidal, so they are isomorphic by Theorem B.60, (Js1). Hence Theorem B.62 applies to π'; $r_{\ell,\iota}(\pi')$ is semisimple and has the characteristic polynomials of V at almost all Frobenius elements, so $r_{\ell,\iota}(\pi') \cong V$ (Chebotarev, Brauer–Nesbitt). Likewise, by hypothesis 3, $W|_{G_L} \otimes \kappa \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal Π of $\mathrm{GL}_2(\mathbb{A}_L)$, which is polarizable with the trivial character, and $r_{\ell,\iota}(\Pi) \cong W|_{G_L} \otimes \kappa$ (irreducible by hypothesis 2).

Step 4: local set-up. Fix a finite place v of K' with $v \nmid \ell$, or with $v \mid \ell$ and V potentially generic at v; fix $\bar v \mid v$, let p be the prime below v and w the place of L below $\bar v$. Let $D = D_{\bar v}$, $D_{K'} = D \cap G_{K'}$, $D_L = D \cap G_L$, and $D_0 = D_{K'} \cap D_L$, intersected with $D'_{\bar v}$ if $p = \ell$; all are open in D, and W_0, $W_{K'}$, W_L denote their Weil groups. If $p = \ell$, $V|_{D_{K'}} \cong r_{\ell,\iota}(\pi')|_{D_{K'}}$ and $(W \otimes \kappa)|_{D_L}$ are de Rham by (Bg2), hence so are $W|_D$ (a representation de Rham on an open subgroup is de Rham, [95]) and all subquotients of these; de Rham representations are potentially semistable. We use, for $p = \ell$, the properties of Fontaine's construction ([95]; [255], Section 1): it is exact and compatible with tensor products on potentially semistable representations and with restriction to open subgroups; for $p \neq \ell$ the same properties of (Wd1) are immediate from the definition.

Step 5: the cuspidal support of π'_v. Let $(U, \rho, N) = \mathrm{WD}(V|_{D_{K'}})$ and $I = I_{\bar v} \cap G_{K'}$. The semisimplification of $\rho|_I$ is a sum of restrictions of two characters of $W_{K'}$. If $p \neq \ell$: take κ'_1, κ'_2 of hypothesis 5 for $\bar p = \bar v$. For $\sigma \in I$, $n(\sigma) = 0$, so $\rho(\sigma)$ commutes with N by (38.5) and $V(\sigma) = \rho(\sigma)\exp(t_\ell(\sigma)N)$ by (Wd1) is $\rho(\sigma)$ times a commuting unipotent matrix; hence $\det(X - \rho(\sigma)) = (X - \kappa'_1(\sigma))(X - \kappa'_2(\sigma))$. ρ is trivial on an open normal subgroup J of I, where this polynomial is $(X-1)^2$, so κ'_1, κ'_2 are trivial on J; then $\rho|_I$ and $(\kappa'_1 \oplus \kappa'_2)|_I$ are representations of the finite group I/J over a field of characteristic 0 with equal characteristic polynomials, hence equal traces, hence isomorphic. If $p = \ell$: V is triangular on $D_{K'}$ with some diagonal (μ_1, μ_2) (potential genericity at v); the μ_a are potentially semistable and by exactness $\rho^{\mathrm{ss}} \cong \mathrm{WD}(\mu_1) \oplus \mathrm{WD}(\mu_2)$, a sum of characters of $W_{K'}$. In both cases (Bg3) for π' (with $U = \{1\}$) shows that π'_v is an irreducible subquotient of the normalised induction of $\xi_1 \otimes \xi_2$ for characters

ξ_1, ξ_2 of $K_v'^{\times}$; the supercuspidal support of an irreducible representation is unique up to order (Bernstein–Zelevinsky), so every cuspidal support of π_v' is (ξ_1, ξ_2) up to order. By (Bg5) for π', $\rho^{\mathrm{ss}} \cong \lambda_1' \oplus \lambda_2'$ with $\iota\lambda_a'(\mathrm{Art}_{K_v'}(x)^{-1}) = \xi_a(x)|x|_v^{-1/2}$ for $x \in K_v'^{\times}$.

Step 6: the same over L. By Step 2 (ii), $w \nmid \ell$ or $W|_{G_L} \otimes \kappa$ is potentially generic at w, so (Wc2) for $W|_{G_L} \otimes \kappa$ (hypothesis 3), applied to Π, gives a real number τ_Π (independent of w) and a cuspidal support (ξ_1', ξ_2') of Π_w consisting of characters with $q_w^{\tau_\Pi - 1/2} < |\xi_a'(\varpi_w)| < q_w^{\tau_\Pi + 1/2}$. Then Π_w is an irreducible subquotient of the normalised induction of $\xi_1' \otimes \xi_2'$, and (Bg5) for Π gives that the semisimplification of the Weil group part of $\mathrm{WD}((W \otimes \kappa)|_{D_L})$ is $\lambda_1'' \oplus \lambda_2''$ with $\iota\lambda_a''(\mathrm{Art}_{L_w}(y)^{-1}) = \xi_a'(y)|y|_w^{-1/2}$.

Step 7: the ratios agree on W_0. We claim that after renumbering $\lambda_1'/\lambda_2' = \lambda_1''/\lambda_2''$ on W_0. If $p \neq \ell$: by compatibility with restriction, the semisimplified Weil group part of $\mathrm{WD}(W|_{D_0})$ is $\beta_1 \oplus \beta_2$ with $\beta_a = \lambda_a'|_{W_0}$; by compatibility with tensor products, that of $\mathrm{WD}((W \otimes \kappa)|_{D_0})$ is $\beta_1\nu \oplus \beta_2\nu$, where ν is the Weil group part of $\mathrm{WD}(\kappa|_{D_0})$; it is also $\lambda_1''|_{W_0} \oplus \lambda_2''|_{W_0}$, and a semisimple representation that is a sum of characters determines them as a multiset. If $p = \ell$: on $D_0 \subseteq D_{\bar v}'$, W is triangular with diagonal $(\kappa_1^\gamma, \kappa_2^\gamma)$ and $W \otimes \kappa$ with diagonal $(\kappa_1^\gamma\kappa, \kappa_2^\gamma\kappa)$ (Step 1), all potentially semistable characters; by exactness and compatibility with restriction, $\{\lambda_a'|_{W_0}\} = \{\mathrm{WD}(\kappa_a^\gamma|_{D_0})\}$ and $\{\lambda_a''|_{W_0}\} = \{\mathrm{WD}(\kappa_a^\gamma\kappa|_{D_0})\}$, and by compatibility with tensor products $\mathrm{WD}(\kappa_1^\gamma\kappa)/\mathrm{WD}(\kappa_2^\gamma\kappa) = \mathrm{WD}(\kappa_1^\gamma/\kappa_2^\gamma) = \mathrm{WD}(\kappa_1^\gamma)/\mathrm{WD}(\kappa_2^\gamma)$ on W_0.

Step 8: the window. Fix $\Phi_0 \in W_0$ with $n(\Phi_0) = -d < 0$ (relative to $\mathbb{Q}_p$); W_0 contains such elements, D_0 being open in D. Let f_v, f_w be the residue degrees of K_v', L_w over $\mathbb{Q}_p$; then $f_v \mid d$, $f_w \mid d$, $\Phi_0 = \mathrm{Art}_{K_v'}(x)^{-1}$ with $x = \varpi_v^{d/f_v}u$, $u \in \mathcal{O}_{K_v'}^\times$, and $\Phi_0 = \mathrm{Art}_{L_w}(y)^{-1}$ with $y = \varpi_w^{d/f_w}u'$, $u' \in \mathcal{O}_{L_w}^\times$; and $q_v^{d/f_v} = q_w^{d/f_w} = p^d$. Characters of $\mathcal{O}^\times$ have values of absolute value 1 (compact image), so by Steps 5 and 6

$$\Big|\frac{\iota\lambda_1'(\Phi_0)}{\iota\lambda_2'(\Phi_0)}\Big| = \Big|\frac{\xi_1(\varpi_v)}{\xi_2(\varpi_v)}\Big|^{d/f_v}, \qquad \Big|\frac{\iota\lambda_1''(\Phi_0)}{\iota\lambda_2''(\Phi_0)}\Big| = \Big|\frac{\xi_1'(\varpi_w)}{\xi_2'(\varpi_w)}\Big|^{d/f_w} \in (q_w^{-d/f_w}, q_w^{d/f_w}) = (p^{-d}, p^d),$$

the last by the window of Step 6. By Step 7 the two ratios are equal (possibly after inverting one, which preserves the interval), so $|\xi_1(\varpi_v)/\xi_2(\varpi_v)|^{d/f_v} \in (p^{-d}, p^d)$, i.e. $q_v^{-1} < |\xi_1(\varpi_v)/\xi_2(\varpi_v)| < q_v$. On the other hand $\lambda_1'\lambda_2'$ is the determinant of ρ^{ss}, which is the Weil group part of $\mathrm{WD}(\det V|_{D_{K'}})$ (for $p \neq \ell$ by (Wd1), $\det\exp(t_\ell(\sigma)N) = 1$; for $p = \ell$ from the triangular form, $\mathrm{WD}(\mu_1)\mathrm{WD}(\mu_2) = \mathrm{WD}(\mu_1\mu_2)$); $\det W$ has finite order (hypothesis 1), so this character has finite order and $|\iota\lambda_1'\lambda_2'(\mathrm{Art}_{K_v'}(\varpi_v)^{-1})| = 1$, i.e. $|\xi_1(\varpi_v)\xi_2(\varpi_v)| = q_v^{-1}$. Hence $|\xi_a(\varpi_v)|^2 = |\xi_1(\varpi_v)\xi_2(\varpi_v)| \cdot |\xi_a(\varpi_v)/\xi_b(\varpi_v)| \in (q_v^{-2}, 1)$ for $\{a,b\} = \{1,2\}$, that is

$$q_v^{-1} < |\xi_a(\varpi_v)| < 1 = q_v^{\tau+1/2} \quad (\tau = -1/2), \qquad a = 1, 2.$$

Conclusion. For every π' as in (Wc2), at every finite place v of K' with $v \nmid \ell$, or $v \mid \ell$ and V potentially generic at v, π_v' has a cuspidal support consisting of characters, and every character in a cuspidal support of π_v' lies in the window with $\tau_{\pi'} = -1/2$ (Steps 5 and 8). With Step 2 (i), V satisfies the witness conditions. As K' was arbitrary with V irreducible, W satisfies the witness conditions over imaginary quadratic fields. □

Proposition 48.18. *Let $K \subset L \subset \overline{\mathbb{Q}}$ with K imaginary quadratic and L a CM field abelian over $\mathbb{Q}$, let $c \in G_{\mathbb{Q}}$ be a complex conjugation, ℓ a prime and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Let $r\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ be continuous and assume:*

1. *there is $P \in \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ with ${}^t r(s)\, P\, r(csc) = \chi_{\mathrm{cyc}}(s)^{-2}P$ for all $s \in G_K$;*
2. *$r|_{G_L}$ is irreducible;*

3. *for every finite place $v \nmid \ell$ of K and every place $\bar{v} \mid v$ of $\overline{\mathbb{Q}}$ there are continuous characters $\kappa_1, \kappa_2, \kappa_3$ of $D_{\bar{v}}$ with $\det(X - r(g)) = \prod_{i=1}^{3}(X - \kappa_i(g))$ for all $g \in I_{\bar{v}}$;*

4. *for every place $v \mid \ell$ of K and every place $\bar{v} \mid v$, r is triangular on $D_{\bar{v}}$ with some diagonal;*

5. *for every place $w \mid \ell$ of L such that r is generic at the place of K below w, $r|_{G_L}$ is generic at w;*

6. *$r|_{G_L}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.*

Then r is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.

Proof. Step 1: the form is symmetric. Since $r|_{G_L}$ is irreducible, so is r. Transposing hypothesis 1 gives ${}^t r(csc)\,{}^t P\, r(s) = \varepsilon(s)^{-2}\,{}^t P$; replacing s by csc (note $c^2 = 1$ and $\varepsilon(csc) = \varepsilon(s)$, ε being a character of $G_{\mathbb{Q}}$) gives ${}^t r(s)\,{}^t P\, r(csc) = \varepsilon(s)^{-2}\,{}^t P$. So $P\, r(csc) P^{-1} = \varepsilon(s)^{-2}\,{}^t r(s)^{-1} = {}^t P\, r(csc)\,{}^t P^{-1}$ for all $s \in G_K$, and ${}^t P^{-1} P$ commutes with $r(G_K)$ (csc runs through G_K). By Schur's lemma ${}^t P^{-1} P = \lambda$ is a scalar, $P = \lambda\,{}^t P = \lambda^2 P$, so $\lambda = \pm 1$; $\lambda = -1$ would make P an invertible antisymmetric 3×3 matrix, impossible as $\det P = \det(-{}^t P) = -\det P$. Hence $\langle x, y\rangle = {}^t x P y$ is a non-degenerate symmetric bilinear form with $\langle r(\sigma)x, r(c\sigma c)y\rangle = \varepsilon(\sigma)^{-2}\langle x, y\rangle = \varepsilon(\sigma)^{1-3}\langle x, y\rangle$ for $\sigma \in G_K$.

Step 2: automorphy. By hypothesis 6, $r|_{G_L} \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal Π of $\mathrm{GL}_3(\mathbb{A}_L)$. By Theorem B.58, $r_{\ell,\iota}(\Pi)$ is semisimple and, at almost every finite place w of L, unramified with the same characteristic polynomials of Frobenius as $r|_{G_L}$; by the Chebotarev density theorem and continuity the characteristic polynomials of $r|_{G_L}$ and $r_{\ell,\iota}(\Pi)$ agree on all of G_L, and both being semisimple ($r|_{G_L}$ is irreducible) they are isomorphic (Brauer–Nesbitt). L/K is Galois with abelian group ($L/\mathbb{Q}$ is abelian), hence soluble; L is CM and K is not totally real; 3 is odd. With Step 1 and hypothesis 2, Theorem B.78 (with $F = K$, $F^+ = \mathbb{Q}$, $M = L$) gives $r \cong r_{\ell,\iota}(\pi)$ for a regular algebraic conjugate self-dual cuspidal π of $\mathrm{GL}_3(\mathbb{A}_K)$. By Theorem B.58, $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$, hence $r \leftrightarrow_\iota \pi$: r is automorphic of conjugate self-dual type for ι.

Step 3: (Wc1). Let $v \mid \ell$ be a place of K at which r is generic, and $\bar{v} \mid v$; let w be the place of L below $\bar{v}$. By hypothesis 5, $r|_{G_L}$ is generic at w, so by (Wc1) for $r|_{G_L}$ (hypothesis 6) it is potentially generic at w: it is triangular on $D_{\bar{v}} \cap G_L$ with a diagonal (κ'_i) such that $\kappa_i'^a \neq (\kappa'_j\varepsilon)^a$ for all i, j and $a \geq 1$. As r is generic at v, it is triangular on $D_{\bar{v}}$ with a diagonal (κ_i); restricted to $D_{\bar{v}} \cap G_L$ this is a diagonal of $r|_{G_L}$, so $\{\kappa_i|_{D_{\bar{v}}\cap G_L}\} = \{\kappa'_i\}$ as multisets (both are the one-dimensional composition factors). If $\kappa_i^a = (\kappa_j\varepsilon)^a$ on $D_{\bar{v}}$ for some i, j and $a \geq 1$, restriction would contradict the property of (κ'_i). So r is potentially generic at v.

Step 4: (Wc2). By hypothesis 2, $r|_{G_L}$ is irreducible; by Step 2, $r \leftrightarrow_\iota \pi$ with π regular algebraic conjugate self-dual cuspidal; by Step 2 again (from hypothesis 6), $r|_{G_L} \leftrightarrow_\iota \Pi$ with Π regular algebraic conjugate self-dual cuspidal. These, hypotheses 3, 4 and (Wc2) for $r|_{G_L}$ (hypothesis 6) are the hypotheses of Proposition 48.19, which gives (Wc2) for r. □

Proposition 48.19. *Let $K \subset L \subset \overline{\mathbb{Q}}$ with K imaginary quadratic and L a CM field abelian over $\mathbb{Q}$, ℓ a prime and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Let $r\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ be continuous and assume:*

1. *$r|_{G_L}$ is irreducible, $r \leftrightarrow_\iota \pi$ for a regular algebraic conjugate self-dual cuspidal automorphic representation π of $\mathrm{GL}_3(\mathbb{A}_K)$, and $r|_{G_L} \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal automorphic representation Π of $\mathrm{GL}_3(\mathbb{A}_L)$;*

2. *for every finite place $v \nmid \ell$ of K and every place $\bar{v} \mid v$ there are continuous characters $\kappa_1, \kappa_2, \kappa_3$ of $D_{\bar{v}}$ with $\det(X - r(g)) = \prod_i(X - \kappa_i(g))$ for all $g \in I_{\bar{v}}$;*

3. for every place $v \mid \ell$ of K and every place $\bar{v} \mid v$, r is triangular on $D_{\bar{v}}$ with some diagonal;

4. $r|_{G_L}$ satisfies (Wc2).

Then r satisfies (Wc2).

Proof. Step 1: r and $r|_{G_L}$ are the representations attached to π and Π. Since $r|_{G_L}$ is irreducible, so is r. As $\pi^c \cong \pi^\vee = \pi^\vee \otimes (\mathbf{1} \circ \mathrm{N}_{K/\mathbb{Q}} \circ \det)$, π is polarizable with the trivial character, and likewise Π; so Theorem B.62 gives continuous semisimple $r_{\ell,\iota}(\pi)$ and $r_{\ell,\iota}(\Pi)$ with (Bg1)–(Bg5). By (Bg1) and $r \leftrightarrow_\iota \pi$, at all but finitely many finite places u of K both r and $r_{\ell,\iota}(\pi)$ are unramified and their Frobenius elements have the same characteristic polynomial; by the Chebotarev density theorem these Frobenius elements are dense in G_K, and characteristic polynomials are continuous, so r and $r_{\ell,\iota}(\pi)$ have the same characteristic polynomials on G_K. Both are semisimple, so $r \cong r_{\ell,\iota}(\pi)$ (Brauer–Nesbitt). In the same way $r|_{G_L} \cong r_{\ell,\iota}(\Pi)$. Hence (Bg2)–(Bg5) hold for π with $r|_{D_{\bar{v}}}$ in place of $r_{\bar{v}}$, and for Π with $r|_{D_{\bar{v}} \cap G_L}$.

Step 2: every π' in (Wc2) is isomorphic to π. Let π' be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_3(\mathbb{A}_K)$ with $r \leftrightarrow_\iota \pi'$ (r is semisimple). At all but finitely many finite places u, π_u and π'_u are unramified and ι carries the characteristic polynomial of $r(\mathrm{Frob}_u^{-1})$ both to $\prod_\alpha (X - q_u \alpha)$ over the Satake parameters of π_u and to the same product for π'_u; so the two multisets of Satake parameters agree. An unramified irreducible representation of $\mathrm{GL}_3(K_u)$ is the unique unramified irreducible subquotient of the normalised induction of the unramified characters given by its Satake parameters, and permuting the characters does not change the Jordan–Hölder factors; hence $\pi_u \cong \pi'_u$ for all but finitely many u, and $\pi' \cong \pi$ by Theorem B.60, (Js1). So $\pi'_v \cong \pi_v$ for every v, and it suffices to find one real number τ such that at every finite place v of K with $v \nmid \ell$, or with $v \mid \ell$ and r potentially generic at v, π_v has a cuspidal support consisting of characters and every character ξ in a cuspidal support of π_v satisfies $q_v^{\tau-1/2} < |\xi(\varpi_v)| < q_v^{\tau+1/2}$.

Step 3: the number τ. $r|_{G_L}$ is semisimple and $r|_{G_L} \leftrightarrow_\iota \Pi$ with Π regular algebraic cuspidal, so by hypothesis 4 there is τ_Π such that at every finite place w of L with $w \nmid \ell$, or with $w \mid \ell$ and $r|_{G_L}$ potentially generic at w, every character ξ' in a cuspidal support of Π_w satisfies $q_w^{\tau_\Pi - 1/2} < |\xi'(\varpi_w)| < q_w^{\tau_\Pi + 1/2}$. Put $\tau = \tau_\Pi$. Fix now a finite place v of K with $v \nmid \ell$, or $v \mid \ell$ and r potentially generic at v; fix $\bar{v} \mid v$, let w be the place of L below $\bar{v}$ and f the residue degree of L_w/K_v, so $q_w = q_v^f$. Let $D = D_{\bar{v}}$ and $H = D \cap G_L$, the decomposition group of G_L at $\bar{v}$; H is the kernel of $D \to \mathrm{Gal}(L/K)$, normal of finite index in D. Let $W_D \subseteq D$ and $W_H = W_D \cap H$ be the Weil groups, $I \subseteq W_D$ the inertia group, $(V, \rho, N) = \mathrm{WD}(r|_D)$ and $(V, \rho_H, N_H) = \mathrm{WD}(r|_H)$.

Step 4: π_v has a cuspidal support of characters, and its Frobenius characters. We show that the semisimplification of $\rho|_I$ is a sum of restrictions of three characters of W_D. If $v \nmid \ell$, take $\kappa_1, \kappa_2, \kappa_3$ as in hypothesis 2. For $\sigma \in I$, $n(\sigma) = 0$, so $\rho(\sigma)$ commutes with N by (38.5), and by (Wd1) $r(\sigma) = \rho(\sigma)\exp(t_\ell(\sigma)N)$ is $\rho(\sigma)$ times a commuting unipotent matrix; hence $\det(X - \rho(\sigma)) = \prod_i (X - \kappa_i(\sigma))$. ρ is trivial on an open subgroup of I, hence on an open normal subgroup J of I, and there the characteristic polynomial is $(X-1)^3$, so the κ_i are trivial on J. So $\rho|_I$ and $\bigoplus_i \kappa_i|_I$ are representations of the finite group I/J over the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic 0 with the same characteristic polynomials, hence the same traces; so they are isomorphic. If $v \mid \ell$, r is triangular on D with a diagonal $(\kappa_1, \kappa_2, \kappa_3)$ (hypothesis 3). By (Bg2) for π and Step 1, $r|_D$ is de Rham, hence so are its subquotients, in particular the κ_i; de Rham representations are potentially semistable, and Fontaine's functor D_{pst} is exact on potentially semistable representations, so ρ has the semisimplification $\lambda_1 \oplus \lambda_2 \oplus \lambda_3$, where λ_i is the character of W_D of the one-dimensional Weil–Deligne representation $\mathrm{WD}(\kappa_i)$. In both cases (Bg3) for π, with $U = \{1\}$, shows that π_v is an irreducible subquotient of the normalised

induction of $\xi_1 \otimes \xi_2 \otimes \xi_3$ for characters ξ_i of $K_v^\times$. The supercuspidal support of an irreducible representation is unique up to order (Bernstein–Zelevinsky), so every cuspidal support of π_v is (ξ_1, ξ_2, ξ_3) up to order and consists of characters. By (Bg5) for π, the semisimplification of ρ is $\lambda_1 \oplus \lambda_2 \oplus \lambda_3$ with $\iota\lambda_i(\mathrm{Art}_{K_v}(x)^{-1}) = \xi_i(x)|x|_v^{-1}$ for $x \in K_v^\times$ (this fixes the λ_i also when $v \mid \ell$).

Step 5: restriction to H. The semisimplification of ρ_H is $\bigoplus_i \lambda_i|_{W_H}$. If $v \nmid \ell$: for any ℓ-adic representation s of W_D with $\mathrm{WD}(s) = (V, \rho_s, N_s)$, the subspaces $V_k = \ker N_s^k$ are stable under ρ_s (by (38.5)) and under s (by (Wd1), $s(g) = \rho_s(g)\exp(t_\ell(\sigma)N_s)$ for $g = \Phi^m\sigma$), and on V_k/V_{k-1}, killed by N_s, the two actions agree; so ρ_s and s have the same semisimplification. Applied to $r|_{W_D}$ and to $r|_{W_H}$ (over L_w), the semisimplification of ρ_H is that of $r|_{W_H}$, i.e. the restriction to W_H of the semisimplification of $r|_{W_D}$, which is that of ρ; as the $\lambda_i|_{W_H}$ are characters, this is $\bigoplus_i \lambda_i|_{W_H}$. If $v \mid \ell$: $r|_H$ is triangular with diagonal $(\kappa_i|_H)$, and Fontaine's construction commutes with restriction to the open subgroup H (D_{pst} is formed over all finite extensions), so $\mathrm{WD}(\kappa_i|_H)$ has the character $\lambda_i|_{W_H}$, and exactness gives the claim.

Step 6: the cuspidal support of Π_w. By Step 5, (Bg3) for Π (with $U = \{1\}$ and $\Psi_i = \lambda_i|_{W_H}$) shows that Π_w is an irreducible subquotient of the normalised induction of $\xi_1' \otimes \xi_2' \otimes \xi_3'$ for characters ξ_k' of $L_w^\times$, and (Bg5) for Π gives that the semisimplification of ρ_H is $\bigoplus_k \lambda_k'$ with $\iota\lambda_k'(\mathrm{Art}_{L_w}(y)^{-1}) = \xi_k'(y)|y|_w^{-1}$ for $y \in L_w^\times$. By Step 5 and the Jordan–Hölder theorem, $\{\lambda_k'\} = \{\lambda_i|_{W_H}\}$ as multisets. By local class field theory, the map $W_H^{\mathrm{ab}} \to W_D^{\mathrm{ab}}$ induced by the inclusion corresponds under Art_{L_w}, Art_{K_v} to the norm $\mathrm{N} = \mathrm{N}_{L_w/K_v}$; with $|\mathrm{N}y|_v = |y|_w$,

$$\iota\lambda_i|_{W_H}(\mathrm{Art}_{L_w}(y)^{-1}) = \iota\lambda_i(\mathrm{Art}_{K_v}(\mathrm{N}y)^{-1}) = \xi_i(\mathrm{N}y)\,|y|_w^{-1}.$$

So for each i there is k with $\xi_k' = \xi_i \circ \mathrm{N}$.

Step 7: potential genericity over L. Let $v \mid \ell$ and r potentially generic at v; we show $r|_{G_L}$ is potentially generic at w. Let $\bar{v}'$ be a place above w, hence above v, $D' = D_{\bar{v}'}$, $H' = D' \cap G_L$ (normal of finite index m in D'). r is triangular on D' with a diagonal (κ_i) with $\kappa_i^a \neq (\kappa_j\varepsilon)^a$ for all i, j and $a \geq 1$; then $r|_{G_L}$ is triangular on H' with diagonal $(\kappa_i|_{H'})$. If $(\kappa_i|_{H'})^a = (\kappa_j\varepsilon|_{H'})^a$ for some $a \geq 1$, the character $(\kappa_i/\kappa_j\varepsilon)^a$ of D' is trivial on H', so its m-th power is trivial and $\kappa_i^{am} = (\kappa_j\varepsilon)^{am}$, a contradiction.

Step 8: the window. If $v \nmid \ell$ then $w \nmid \ell$; if $v \mid \ell$, $r|_{G_L}$ is potentially generic at w by Step 7. As (ξ_1', ξ_2', ξ_3') is a cuspidal support of Π_w, Step 3 and Step 6 give, for every i, $q_w^{\tau-1/2} < |\xi_i(\mathrm{N}\varpi_w)| < q_w^{\tau+1/2}$. Now $\mathrm{N}\varpi_w = u\varpi_v^f$ with $u \in \mathcal{O}_{K_v}^\times$, and $|\xi_i(u)| = 1$ since $\xi_i(\mathcal{O}_{K_v}^\times)$ is a compact subgroup of $\mathbb{C}^\times$; so $|\xi_i(\mathrm{N}\varpi_w)| = |\xi_i(\varpi_v)|^f$, and with $q_w = q_v^f$, taking f-th roots, $q_v^{\tau-1/2} < |\xi_i(\varpi_v)| < q_v^{\tau+1/2}$. With Step 4 (the characters in any cuspidal support of π_v are ξ_1, ξ_2, ξ_3) and Step 2, r satisfies (Wc2) with $\tau_{\pi'} = \tau_\Pi$ for every π'. □

49 Residually Eisenstein $R = T$ over an auxiliary field

This section proves Theorem 49.3, an $R = T$ theorem for residually Eisenstein polarised ordinary lifts over an auxiliary field L, which Theorem 48.3 uses. It has three conclusions: in characteristic ℓ the polarised ordinary lifts of rank three have the residual characteristic polynomials (Pp1); irreducible lifts of rank three are automorphic after the twist by χ_{cyc}^{-1} (Pp2); and irreducible lifts of rank two are automorphic after an algebraic twist (Pp3). Rank two enters twice: through (Pp3) the corner of a lift of type II is modular (Proposition 48.14), and absorption in rank two bounds the endoscopic primes in rank three (Proposition 49.33). The argument is in the line of Skinner and Wiles [236] and of Thorne [256], and has three inputs: seeds, automorphic lifts through the residual representation (Subsection 49.1); the Hecke realisation Theorem 50.3 of Section 50, an ideal of the deformation ring that is finite over the weights, propagates through

nice primes and, in rank three, along thick links, has a seed component when a seed exists, and cuts out automorphic lifts; and the propagation theorem 49.12.

The propagation theorem is the core. An ideal with these properties absorbs every prime of irreducible type, so every irreducible lift is automorphic. In rank three the theorem takes absorption in rank two as a hypothesis, and it also gives an off-triangular bound, from which (Pp1) follows (Lemma 49.37). The proof compares dimensions: the presentations of the local charts of the entry algebra, variables against relations, bound the dimension of their components from below (Proposition 49.20), while the loci where propagation could fail, the non-nice loci, have smaller dimension (Proposition 49.29); since the core locus is connected (Lemma 49.15), modularity passes from the seed component to all components along chains (Lemma 49.34). Subsection 49.2 sets up the entry algebra and states the theorem, Subsection 49.3 constructs the local charts at the maximal core primes, and Subsection 49.4 treats the endoscopic core primes and the local propagation.

49.1 Seeds over an auxiliary field

This subsection defines the polarised ordinary deformation rings over an auxiliary field, with their entry and weight-zero algebras, prime types, local charts and modular ideals (Definition 49.2), defines admissible twists and seeds (Definition 49.1), states Theorem 49.3, and constructs the seeds. A seed is an irreducible polarised representation of G_L, residually congruent to the Eisenstein representation, ordinary at ℓ, and automorphic after a twist (conditions (Sp1)–(Sp6)); the propagation argument starts from it. Seeds of rank three and of rank two exist (Proposition 49.4, Proposition 49.10). They come from newforms congruent to Eisenstein series with an exact nebentypus, obtained through an auxiliary character of order ℓ (Proposition 49.5; Lemma 49.6, Lemma 49.7). Such congruences are the starting point of Ribet's construction [208], and here they are used in that constructive direction. The Galois representation of such a newform has the residual shape of the Eisenstein representation and stays irreducible over abelian fields (Lemma 49.8), and its adjoint and its algebraic twists are automorphic of conjugate self-dual type over the abelian CM field (Lemma 49.9). Proposition 49.5 and Lemma 49.8 are used again for the seeds of the symplectic case.

Definition 49.1. Let L be a CM field with $K \subseteq L$ and $G_L \subseteq G_{\mathbb{Q}}$, let $n \in \{2,3\}$, and let $c \in G_{\mathbb{Q}}$ be a complex conjugation. Characters of $G_{\mathbb{Q}}$ are restricted to G_L without change of notation; for $s \in G_L$ put $s^c = csc \in G_L$. Congruence of elements of $\overline{\mathbb{Z}}_\ell$ means congruence modulo the maximal ideal of $\overline{\mathbb{Z}}_\ell$.

Admissible twists. A continuous character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ is an **admissible twist of rank** n (for ι, c and M) if it is algebraic for ι and

(Ka1) $\kappa(s)\kappa(s^c) = \chi_{\mathrm{cyc}}(s)^{1-n}$ for all $s \in G_L$;

(Ka2) κ is trivial on $I_{\bar v} \cap G_L$ for every place $\bar v$ of $\overline{\mathbb{Q}}$ above a prime not dividing M;

(Ka3) there is an integer $m' \geq 1$ with $\ell \nmid m'$ such that $\kappa^{m'}$ is trivial on $I_{\bar v} \cap G_L$ for every place $\bar v \nmid \ell$.

Seeds. Let $j \geq 0$ and let $\chi'\colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell^\times$ be a character of finite order. For $1 \leq a \leq n$ put $\varphi_a = (\chi_{\mathrm{cyc}}^j \chi')^{w_{n,a}}$ and $\tau_a = {\chi'}^{w_{n,a}}$, characters of G_L. Let $m \geq 1$ and let $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ be a continuous character. A **seed of rank** n **and weight** m **for** (j,χ') **with twist** κ is a continuous representation $r\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that

(Sp1) r is irreducible;

(Sp2) there is $P \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with ${}^tP = P$ and ${}^t r(s)\, P\, r(s^c) = P$ for all $s \in G_L$;

(Sp3) for every $s \in G_L$, the characteristic polynomial of $r(s)$ has coefficients in $\overline{\mathbb{Z}}_\ell$ congruent to those of $\prod_{a=1}^{n}(X - \varphi_a(s))$;

(Sp4) for every place $\bar v \nmid \ell$, the restriction of r to $I_{\bar v} \cap G_L$ is conjugate to $s \mapsto \mathrm{diag}(\tau_1(s), \dots, \tau_n(s))$;

(Sp5) for every place $\bar v \mid \ell$, r is triangular on $D_{\bar v} \cap G_L$ with a diagonal $(\kappa_1, \dots, \kappa_n)$ such that $\kappa_a(s) = \chi_{\mathrm{cyc}}(s)^{m\, w_{n,a}}$ for $s \in I_{\bar v} \cap G_L$ and $\kappa_a(s) \equiv \varphi_a(s)$ for $s \in D_{\bar v} \cap G_L$;

(Sp6) $r \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.

Definition 49.2. Let L be a CM field satisfying (Af1) and (Af2) of Definition 48.2 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, let $n \in \{2, 3\}$ and put $d_L = [L^+ : \mathbb{Q}] = \sum_{v \mid \ell} d_v$.

Lifts to complete local rings. For $R \in \mathrm{CNL}_{\mathcal{O}}$, conditions (Po1)–(Po5) make sense with the test ring A replaced by R; a homomorphism $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(R)$ with homomorphisms $\psi_{v,a}\colon D_v \to R^\times$ satisfying them is a **polarised ordinary lift of rank n over L to R.** A **universal polarised ordinary lift** of rank n over L is a lift $(\rho^{\mathrm{u}}, (\psi^{\mathrm{u}}_{v,a}))$ to some $R_n^{\mathrm{po}} \in \mathrm{CNL}_{\mathcal{O}}$ such that for every $R' \in \mathrm{CNL}_{\mathcal{O}}$ and every polarised ordinary lift $(\rho', (\psi'_{v,a}))$ of rank n over L to R' there is exactly one morphism $f\colon R_n^{\mathrm{po}} \to R'$ of $\mathrm{CNL}_{\mathcal{O}}$ with $f \circ \rho^{\mathrm{u}} = \rho'$ and $f \circ \psi^{\mathrm{u}}_{v,a} = \psi'_{v,a}$ for all v, a.

Weights, the entry algebra and the weight-zero algebra. Fix a universal lift as above and write $\mathfrak{m} = \mathfrak{m}_{R_n^{\mathrm{po}}}$. The **weight** of the matrix position (a, b) is $w_{n,a} - w_{n,b}$. A **weight-zero monomial** is a product $\prod_{k=1}^{s} \rho^{\mathrm{u}}(\gamma_k)_{a_k b_k}$ with $s \geq 0$, $\gamma_k \in \Gamma_L^0$ and $\sum_k (w_{n,a_k} - w_{n,b_k}) = 0$. The **weight-zero algebra** $W_n^{\mathrm{po}} \subseteq R_n^{\mathrm{po}}$ is the set of y such that for every $k \geq 1$ some element of the $\mathcal{O}$-subalgebra generated by the weight-zero monomials and the values $\psi^{\mathrm{u}}_{v,a}(g)$ ($v \mid \ell$, $1 \leq a \leq n$, $g \in D_v$) is congruent to y modulo $\mathfrak{m}^k$; it is an $\mathcal{O}$-subalgebra, and $\mathfrak{m}_W = \mathfrak{m} \cap W_n^{\mathrm{po}}$. The **entry algebra** E_n^{po} is the W_n^{po}-subalgebra of R_n^{po} generated by all entries $\rho^{\mathrm{u}}(\gamma)_{ab}$; thus $W_n^{\mathrm{po}} \subseteq E_n^{\mathrm{po}} \subseteq R_n^{\mathrm{po}}$. The **inertial weight ideal** $\mathfrak{a}_n \subseteq W_n^{\mathrm{po}}$ is generated by $\mathfrak{m}_{\mathcal{O}}$ and the elements $\psi^{\mathrm{u}}_{v,a}(g) - 1$ with $v \mid \ell$, $1 \leq a \leq n$, $g \in I_v$ and $\bar\Psi(g) = 1$. An ideal $I \subseteq W_n^{\mathrm{po}}$ is **finite over the weights** if $\mathfrak{m}_W \subseteq \sqrt{I + \mathfrak{a}_n}$.

Prime types. Let C be a commutative ring and $\iota\colon E_n^{\mathrm{po}} \to C$ a ring homomorphism ($\iota = \mathrm{id}$ allowed). Let I_C^-, I_C^+, $I_C^{\mathrm{odd}} \subseteq C$ be the ideals generated by the elements $\iota(\rho^{\mathrm{u}}(\gamma)_{ab})$, $\gamma \in \Gamma_L^0$, with $a > b$, with $a < b$, and with $w_{n,a} - w_{n,b}$ odd, respectively. A prime $\mathfrak{p}$ of C is **off-triangular** if $I_C^- \not\subseteq \mathfrak{p}$ and $I_C^+ \not\subseteq \mathfrak{p}$; **of irreducible type** if it is off-triangular and, when $n = 3$, $I_C^{\mathrm{odd}} \not\subseteq \mathfrak{p}$; **of endoscopic type** if $n = 3$, it is off-triangular and $I_C^{\mathrm{odd}} \subseteq \mathfrak{p}$.

Local charts. Let $\mathfrak{x}$ be a prime of E_n^{po}. A **local chart at $\mathfrak{x}$** is a triple $(\mathcal{O}', R_{\mathfrak{x}}, \iota)$ of a coefficient ring $\mathcal{O}' \supseteq \mathcal{O}$, finite over $\mathcal{O}$ with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}' = \mathfrak{m}_{\mathcal{O}'}$, a ring $R_{\mathfrak{x}} \in \mathrm{CNL}_{\mathcal{O}'}$ and an $\mathcal{O}$-algebra homomorphism $\iota\colon E_n^{\mathrm{po}} \to R_{\mathfrak{x}}$ with $\iota^{-1}(\mathfrak{m}_{R_{\mathfrak{x}}}) = \mathfrak{x}$, such that for every $C \in \mathrm{CNL}_{\mathcal{O}'}$ and every $\mathcal{O}$-algebra homomorphism $f\colon E_n^{\mathrm{po}} \to C$ whose composite with $C \to \mathbb{F}_{\mathcal{O}'}$ equals that of ι, there is exactly one $\mathcal{O}'$-algebra homomorphism $h\colon R_{\mathfrak{x}} \to C$ with $h \circ \iota = f$. Its **chart lift** is $\rho_{\mathfrak{x}} = \iota \circ \rho^{\mathrm{u}}$, $\psi_{\mathfrak{x},v,a} = \iota \circ \psi^{\mathrm{u}}_{v,a}$; prime types in $R_{\mathfrak{x}}$ refer to $C = R_{\mathfrak{x}}$ with this ι.

Nice and thick primes. A prime $\mathfrak{p}$ of $R_{\mathfrak{x}}$ is **nice** if $\dim R_{\mathfrak{x}}/\mathfrak{p} = 1$, $\ell \in \mathfrak{p}$, $\mathfrak{p}$ is off-triangular, and for every $v \mid \ell$ and $a \neq b$ there is $g \in I_v$ with $\chi_{\mathrm{cyc}}(g) = 1$ and $\psi_{\mathfrak{x},v,a}(g) - \psi_{\mathfrak{x},v,b}(g) \notin \mathfrak{p}$. Let $n = 3$. A prime $\mathfrak{e}$ of $R_{\mathfrak{x}}$ is **thick** if it is of endoscopic type and there is a homomorphism of monoids $r\colon \Gamma_L^0 \to \mathrm{M}_3(R_{\mathfrak{x}}/\mathfrak{e})$, with entries continuous for the topology defined by the image of $\mathfrak{m}_{R_{\mathfrak{x}}}$, such that, with bars denoting reduction modulo $\mathfrak{e}$:

(Tk1) $r(\gamma)_{ab} = \overline{\rho_{\mathfrak{x}}(\gamma)_{ab}}$ for all γ whenever $w_{3,a} - w_{3,b}$ is even, and $r(\gamma)_{21} = r(\gamma)_{23} = 0$ for all γ;

(Tk2) for every $v \mid \ell$ and $g_1, g_2, g_3 \in D_v$,

$$\prod_{a=1}^{3} \left(r(\pi_L(g_a)) - \overline{\psi_{\mathfrak{x},v,a}(g_a)}\right) = 0,$$
$$\prod_{a=1}^{3} \left(r(\pi_L(c g_a^{-1} c)) - \overline{\psi_{\mathfrak{x},v,4-a}(g_a)}\right) = 0,$$

the products taken with $a = 1$ on the left;

(Tk3) for every field F' and injective homomorphism $j\colon R_{\mathfrak{x}}/\mathfrak{e} \to F'$ there is no $y \in F'^3$ with $y_2 = 1$ and $j(r(\gamma))\, y = j(r(\gamma)_{22})\, y$ for all $\gamma \in \Gamma_L^0$.

Two nice primes $\mathfrak{p}, \mathfrak{q}$ of $R_{\mathfrak{x}}$ of endoscopic type are **thickly linked** if some thick prime $\mathfrak{e}$ satisfies $\mathfrak{e} \subseteq \mathfrak{p} \cap \mathfrak{q}$; they are **thickly connected** if there are nice primes $\mathfrak{p} = \mathfrak{p}_0, \dots, \mathfrak{p}_k = \mathfrak{q}$ of endoscopic type, $k \geq 0$, with $\mathfrak{p}_{i-1}, \mathfrak{p}_i$ thickly linked for $1 \leq i \leq k$.

Modular ideals. Let $\mathcal{M} \subseteq W_n^{\mathrm{po}}$ be an ideal. A prime $\mathfrak{p}$ of E_n^{po} is **$\mathcal{M}$-modular** if $\mathcal{M} \subseteq \mathfrak{p} \cap W_n^{\mathrm{po}}$; a prime $\mathfrak{P}$ of $R_{\mathfrak{x}}$, for a local chart $(\mathcal{O}', R_{\mathfrak{x}}, \iota)$, is $\mathcal{M}$-modular if $\iota^{-1}(\mathfrak{P})$ is. The ideal $\mathcal{M}$

- **propagates through nice primes** if for every prime $\mathfrak{x}$ of E_n^{po}, every local chart at $\mathfrak{x}$, every $\mathcal{M}$-modular nice prime $\mathfrak{p}$ of $R_{\mathfrak{x}}$ of irreducible type and every prime $\mathfrak{P} \subseteq \mathfrak{p}$ of $R_{\mathfrak{x}}$, $\mathfrak{P}$ is $\mathcal{M}$-modular;
- ($n = 3$) **propagates along thick links** if for every prime $\mathfrak{x}$ of E_3^{po}, every local chart at $\mathfrak{x}$ and every pair of thickly connected nice primes $\mathfrak{p}, \mathfrak{q}$ of $R_{\mathfrak{x}}$ of endoscopic type such that some prime $\mathfrak{P} \subseteq \mathfrak{p}$ of irreducible type is $\mathcal{M}$-modular, every prime $\mathfrak{P}' \subseteq \mathfrak{q}$ of irreducible type is $\mathcal{M}$-modular;
- **has a seed component** if there are a prime ξ of E_n^{po} of irreducible type and a prime $\mathfrak{z}$ of W_n^{po} with $\mathcal{M} \subseteq \mathfrak{z} \subseteq \xi \cap W_n^{\mathrm{po}}$ and $\dim W_n^{\mathrm{po}}/\mathfrak{z} = 1 + n\, d_L$;
- **absorbs the primes of irreducible type** if every prime of E_n^{po} of irreducible type is $\mathcal{M}$-modular.

For $n = 3$, an **off-triangular bound** is an ideal $I \subseteq W_3^{\mathrm{po}}$, finite over the weights, with $I \subseteq \mathfrak{p} \cap W_3^{\mathrm{po}}$ for every off-triangular prime $\mathfrak{p}$ of E_3^{po}.

Theorem 49.3. *Let $\mathcal{O}$ be a coefficient ring, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $c \in G_{\mathbb{Q}}$ a complex conjugation, and assume (a) or (b), with K, M and $\Psi = \Psi_{\chi,e}$:*

(a) (K, ℓ, e, N, χ) is a unitary Eisenstein datum with χ taking values in $\mathcal{O}^\times$, and $M = \ell N |d_K|$;

(b) (ℓ, e, N, χ, o, m) is a dyadic Eisenstein datum with χ taking values in $\mathcal{O}^\times$, $K = \mathbb{Q}(i)$ and $M = \ell N$.

Let $g_\star$ be a marking and L an auxiliary field of some level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$. Then:

(Pp1) *L has residual characteristic polynomials in rank 3;*

(Pp2) *L has automorphic irreducible lifts in rank 3 with twist $\chi_{\mathrm{cyc}}^{-1}|_{G_L}$ for ι;*

(Pp3) *there is an algebraic character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ such that L has automorphic irreducible lifts in rank 2 with twist κ for ι.*

Proof. Fix data $(N', w, j, \chi', \theta)$ as in (Ag1) for L.

Step 0: standing facts. ℓ is odd by (Ue1), resp. (Dy1); K is imaginary quadratic; and $2\ell \mid M$, since N is even by (Ue2), resp. (Dy2), and $\ell N \mid M$. The character $\Psi = \chi\chi_{\mathrm{cyc}}^{e}$ is unramified at every prime not dividing ℓN. Let $\bar{v}$ be a place above a prime $p \nmid M$ and $s \in I_{\bar{v}} \cap G_L$; then $\Psi(s) = 1 = \chi_{\mathrm{cyc}}(s)$, so $\chi'(s) \equiv \Psi(s)\chi_{\mathrm{cyc}}(s)^{-j} = 1$ by (Ag1); as $\chi'(s)$ is a root of unity of order prime to ℓ (by (Ag1), $\ell \nmid \operatorname{ord}\chi'$) and reduction is injective on such roots of unity, $\chi'(s) = 1$. Finally $\kappa_3 := \chi_{\mathrm{cyc}}^{-1}|_{G_L}$ is an admissible twist of rank 3: it is algebraic (it corresponds to an integral power of the norm character), $\kappa_3(s)\kappa_3(csc) = \chi_{\mathrm{cyc}}(s)^{-2}$ because $\chi_{\mathrm{cyc}}(csc) = \chi_{\mathrm{cyc}}(s)$, which is (Ka1) for $n = 3$, and (Ka2), (Ka3) hold with $m' = 1$ because χ_{cyc} is unramified away from ℓ and $\ell \mid M$.

Step 1: seeds. The hypotheses of Proposition 49.4 and Proposition 49.10 hold by Step 0, (Af1), (Af2), (Ag1) and (Ag2); every prime dividing d_K divides M, as $M = \ell N|d_K|$ in case (a), and in case (b) $d_K = -4$ and N is even. They give $m_3 \geq 2$ and a seed of rank 3 and weight m_3 for (j, χ') with twist κ_3, and an admissible twist κ_2 of rank 2, $m_2 \geq 2$ and a seed of rank 2 and weight m_2 for (j, χ') with twist κ_2. The character κ_2 is algebraic.

Step 2: coefficients. A continuous character of the compact group G_L with values in $\overline{\mathbb{Q}}_\ell^\times$ takes values in the units of the integers of a finite extension of $\mathbb{Q}_\ell$ (Baire category: $\overline{\mathbb{Q}}_\ell^\times$ is the countable union of the closed subgroups $E^\times$, $E/\mathbb{Q}_\ell$ finite, so one of them has open, hence finite-index, preimage). Let $\mathcal{O}' \supseteq \mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$ containing $\mathcal{O}$, the values of κ_2 and $\tau(L)$ for every embedding $\tau\colon L \to \overline{\mathbb{Q}}_\ell$; the values of κ_3 lie in $\mathbb{Z}_\ell^\times$.

Step 3: one run gives absorption and an off-triangular bound. Let $p_2, p_3 \geq 1$ be integers. Apply Theorem 50.3 with $(n, \kappa_n, \mathcal{O}')$ and $p_0 = p_n$, for $n = 2, 3$: we obtain primes $p_n' \nmid p_n$, places v_n of L^+ above p_n', and by (Hk1) L is an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$ with universal polarised ordinary lifts of ranks 2 and 3, and by (Hk2) ideals $\mathcal{M}_n \subseteq W_n^{\mathrm{po}}$ finite over the weights that propagate through nice primes, $\mathcal{M}_3$ also along thick links. By Step 1 and (Hk3) both have a seed component. By Theorem 49.12, item 1, $\mathcal{M}_2$ absorbs the primes of irreducible type; by item 2 so does $\mathcal{M}_3$, and W_3^{po} contains an off-triangular bound.

Step 4: (Pp1). By Step 3 (with $p_2 = p_3 = 1$) and Lemma 49.37, L has residual characteristic polynomials in rank 3 for the coefficient ring $\mathcal{O}'$. Let A be a test ring of characteristic ℓ over $\mathcal{O}$ and $(\rho, (\psi_{v,a}))$ a lift as in the definition for $\mathcal{O}$. By Cohen's structure theorem $A \cong k[[T]]$ with $k = A/\mathfrak{m}_A$, and the image of $\mathcal{O}$, which is $\mathbb{F}_\mathcal{O}$ since $\mathfrak{m}_\mathcal{O}$ maps to 0, lies in k (a finite subfield of $k[[T]]$ lies in k, by Hensel's lemma for $X^q - X$). Choose a finite field k' with embeddings $k \to k'$ and $\mathbb{F}_{\mathcal{O}'} \to k'$ agreeing on $\mathbb{F}_\mathcal{O}$, and put $A' = k'[[T]] \supseteq A$, an $\mathcal{O}'$-algebra through $\mathcal{O}' \to \mathbb{F}_{\mathcal{O}'} \to k'$, which restricts on $\mathcal{O}$ to the given structure. Then A' is a test ring of characteristic ℓ over $\mathcal{O}'$, and $(\rho, (\psi_{v,a}))$ composed with $A \subseteq A'$ is a polarised ordinary lift for $\mathcal{O}'$ with the same condition on the $\psi_{v,a}$, conditions (Po1)–(Po5) being identities and congruences with residues in $\mathbb{F}_\mathcal{O} \subseteq \mathbb{F}_{\mathcal{O}'}$. Its characteristic polynomials are residual, and $A \to A'$ is injective, so those of ρ_L are residual.

Step 5: (Pp2) and (Pp3). Let $n \in \{2, 3\}$, A an integral test ring over $\mathcal{O}$ and $(\rho, (\psi_{v,a}))$ a polarised ordinary lift of rank n over L to A with $\psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for $g \in I_v$ and ρ_L irreducible over $\overline{\mathbb{Q}}_\ell$. Let $\mathcal{O}_2 \subset \overline{\mathbb{Q}}_\ell$ be the ring of integers of the compositum of the fraction fields of A and $\mathcal{O}'$; it is an integral test ring over $\mathcal{O}'$ containing A, with $\mathfrak{m}_A \subseteq \mathfrak{m}_{\mathcal{O}_2}$, so the lift composed with $A \subseteq \mathcal{O}_2$ is a polarised ordinary lift for $\mathcal{O}'$ (local constancy modulo $\mathfrak{m}_{\mathcal{O}_2}^k$ follows from that modulo $\mathfrak{m}_A^k$). Apply Step 3 with $p_2 = p_3 = 1$, and let $\mathcal{M} = \mathcal{M}_n$ be the ideal it provides. By Lemma 49.36 there is a local $\mathcal{O}'$-algebra homomorphism $f\colon R_n^{\mathrm{po}} \to \mathcal{O}_2$ with $f \circ \rho^{\mathrm{u}} = \rho$ and $f \circ \psi_{v,a}^{\mathrm{u}} = \psi_{v,a}$; let $\mathfrak{p}$ be its kernel on E_n^{po}, a prime. $\mathfrak{p}$ *is of irreducible type:* if $I_E^- \subseteq \mathfrak{p}$, all entries $\rho(\gamma)_{ab}$ with $a > b$ vanish and the line $\overline{\mathbb{Q}}_\ell e_1$ is stable under $\rho(\Gamma_L^0) = \rho_L(G_L)$; if $I_E^+ \subseteq \mathfrak{p}$, the line $\overline{\mathbb{Q}}_\ell e_n$ is stable; if $n = 3$ and $I_E^{\mathrm{odd}} \subseteq \mathfrak{p}$, the entries in positions $(1,2), (2,1), (2,3), (3,2)$ vanish and $\overline{\mathbb{Q}}_\ell e_2$ is stable; each contradicts the irreducibility of ρ_L. By Step 3, $\mathcal{M} \subseteq \mathfrak{p} \cap W_n^{\mathrm{po}}$, that is,

$f(\mathcal{M}) = 0$. By (Hk4), $\rho_L \otimes \kappa_n$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions. For $n = 3$ this is (Pp2) with twist $\chi_{\mathrm{cyc}}^{-1}|_{G_L}$; for $n = 2$ it is (Pp3) with the algebraic character $\kappa = \kappa_2$. $\square$

Proposition 49.4. *Let K be an imaginary quadratic field, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and let L be a CM field satisfying (Af1), (Af2) and (Ag1) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, where $2\ell \mid M$. Fix data $(N', w, j, \chi', \theta)$ as in (Ag1). Then there are an integer $m \geq 2$ and a seed of rank 3 and weight m for (j, χ') with twist $\chi_{\mathrm{cyc}}^{-1}|_{G_L}$.*

Proof. Step 1: the Eisenstein data. By (Ag1), χ' and η_K are Dirichlet characters modulo N' with $\chi'(w) = \eta_K(w) = 1$; let ψ be the primitive character inducing $\chi'\eta_K$, of conductor $N_0 \mid N'$. It is nontrivial ($\chi' \neq \eta_K$), of order prime to ℓ ($\ell \nmid \operatorname{ord}\chi'$, ℓ odd), $\psi(w) = 1$, $\ell \nmid N_0$, $w \nmid N_0$. The character θ is a Dirichlet character modulo w of order ℓ ($\theta \neq 1$, $\theta^\ell = 1$, trivial on $G_{\mathbb{Q}(\zeta_w)}$), so $\ell \mid w - 1$; ℓ is odd as $2\ell \mid M$. Choose $k \geq 3$ with $k \equiv j + 1 \pmod{\ell - 1}$ and put $\varepsilon = \psi\theta$, primitive modulo $N = N_0 w$. Then $\varepsilon(-1) = \chi'(c)\eta_K(c)\theta(c) = (-1)^j \cdot (-1) \cdot 1 = (-1)^k$, as θ has odd order and $\ell - 1$ is even. By Proposition 49.5 there is a normalised newform g of weight k, level N ($\ell \nmid N$) and character ε with $\iota^{-1}(a_p) \equiv 1 + \iota^{-1}(\varepsilon(p))p^{k-1}$ for all primes p. Let $\rho = \rho^{\mathrm{ar}}$ be its Galois representation and $\beta = \varepsilon\chi_{\mathrm{cyc}}^{k-1} = \det\rho$; put $m = k - 1 \geq 2$.

Step 2: residual comparison. Since $\bar\theta = 1$ and $\bar\chi_{\mathrm{cyc}}^{k-1} = \bar\chi_{\mathrm{cyc}}^{j}$ (its order divides $\ell - 1$), $\bar\beta = \eta_K\,\overline{\chi_{\mathrm{cyc}}^{j}\chi'}$. On G_L, η_K and θ are trivial ((Af1), (Ag1)), so $\beta = \chi'\chi_{\mathrm{cyc}}^{k-1}$ and $\beta \equiv \varphi_1$ there. By the last clause of (Ag1) there is $s \in G_L$ with $\beta(s)^2 \equiv (\chi_{\mathrm{cyc}}^{j}\chi')(s)^2 \not\equiv 1$.

Step 3: the representation. Let $R = \mathrm{ad}^0\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}(\mathfrak{sl}_2(\overline{\mathbb{Q}}_\ell))$, written as a matrix representation in the basis (E_{12}, H, E_{21}), $H = \mathrm{diag}(1, -1)$, and $r = R|_{G_L}$. (Sp1): r is irreducible by (Ne5) with $U = G_L$. (Sp2): let B be the Gram matrix of the trace form $(X, Y) \mapsto \mathrm{tr}(XY)$ in this basis; it is symmetric, invertible, and ${}^tR(g)BR(g) = B$ for $g \in G_{\mathbb{Q}}$. Put $P = BR(c)$. As $R(c)^2 = 1$, ${}^tP = {}^tR(c)B = BR(c)^{-1} = P$, and for $s \in G_L$, ${}^tr(s)\,P\,r(csc) = {}^tR(s)BR(c)R(c)R(s)R(c) = {}^tR(s)BR(s)R(c) = P$. (Sp3): if $\rho(s)$ has characteristic polynomial $X^2 - tX + d$, then $r(s)$ has $(X - 1)(X^2 - (t^2d^{-1} - 2)X + 1)$, integral as $d = \beta(s)$ is a unit; by (Ne1), $t \equiv 1 + \beta(s)$, so it is congruent to $(X - 1)(X - \beta(s))(X - \beta(s)^{-1})$, i.e. to $\prod_a (X - \varphi_a(s))$ for $s \in G_L$. (Sp4): for $\bar v \nmid \ell$, (Ne2) gives $\rho|_{I_{\bar v}} \cong \mathrm{diag}(1, \varepsilon)$, hence $R|_{I_{\bar v}} \cong \mathrm{diag}(\varepsilon^{-1}, 1, \varepsilon)$, and on $I_{\bar v} \cap G_L$, $\varepsilon = \chi'$; after reordering the basis this is $\mathrm{diag}(\tau_1, \tau_2, \tau_3)$. (Sp5): for $\bar v \mid \ell$, by (Ne3) ρ is triangular on $D_{\bar v}$ with diagonal (δ_1, δ_2); conjugation by upper triangular matrices preserves the flag $\langle E_{12}\rangle \subset \langle E_{12}, H\rangle$ and acts on the graded pieces by δ_1/δ_2, 1, δ_2/δ_1. So r is triangular on $D_{\bar v} \cap G_L$ with diagonal $(\kappa_1, \kappa_2, \kappa_3) = (\delta_1\delta_2^{-1}, 1, \delta_2\delta_1^{-1})$; on $I_{\bar v} \cap G_L$ these are $\chi_{\mathrm{cyc}}^{m}, 1, \chi_{\mathrm{cyc}}^{-m}$, i.e. $\chi_{\mathrm{cyc}}^{m\,w_{3,a}}$; and on $D_{\bar v} \cap G_L$, $\delta_1\delta_2^{-1} = \beta\delta_2^{-2} \equiv \beta \equiv \varphi_1$, $1 = \varphi_2$, $\delta_2\delta_1^{-1} \equiv \varphi_1^{-1} = \varphi_3$. (Sp6): by Step 2 and (Na1) of Lemma 49.9, $r \otimes \chi_{\mathrm{cyc}}^{-1}|_{G_L}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions (L is CM and abelian over $\mathbb{Q}$ by (Af1)).

Hence r is a seed of rank 3 and weight m for (j, χ') with twist $\chi_{\mathrm{cyc}}^{-1}|_{G_L}$. $\square$

Proposition 49.5. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $k \geq 3$, w a prime with $\ell \mid w - 1$, and $N_0 \geq 1$ an integer with $\ell \nmid N_0$ and $w \nmid N_0$. Let ψ be a primitive Dirichlet character modulo N_0 with $\psi(w) = 1$, θ a Dirichlet character modulo w of order ℓ, and $\varepsilon = \psi\theta$, a primitive character modulo $N = N_0 w$; assume $\varepsilon(-1) = (-1)^k$, and that $(\ell - 1) \nmid k$ or ψ is nontrivial of order prime to ℓ. Then there is a normalised newform $f = \sum_{n\geq 1} a_n q^n$ of weight k, level N and character ε such that for every prime p,*

$$\iota^{-1}(a_p) \equiv 1 + \iota^{-1}(\varepsilon(p))\,p^{k-1}$$

modulo the maximal ideal of the integers of $\overline{\mathbb{Q}}_\ell$ (with $\varepsilon(p) = 0$ for $p \mid N$).

Proof. Let $\mathcal{O}$ be a coefficient ring containing $\iota^{-1}(e^{2\pi i/N})$ and ι^{-1} of the values of ψ and θ; put $B = \iota(\mathcal{O})$, λ its maximal ideal, $\mathbb{F} = B/\lambda$, $\overline{\mathbb{F}}$ an algebraic closure. Then $N \geq w \geq 2\ell + 1 \geq 7$ and $\ell \nmid N$. Every value $\theta(n)$, $w \nmid n$, is an ℓ-th root of unity, so $\theta(n) \equiv 1 \pmod{\lambda}$; and $w \equiv 1 \pmod{\ell}$ gives $w^{k-1} \equiv 1$.

Two Eisenstein series congruent away from the constant term. By (Es1), $E = E_k(1, \varepsilon)$ and $E' = E_k(\theta, \psi)$ lie in $M_k(\Gamma_0(N), \varepsilon)$, with $a_0(E') = 0$ and $a_0(E) = L(1-k, \varepsilon)/2 \in \mathrm{Frac}(B)$. For $n \geq 1$ write $n = w^e n'$ with $w \nmid n'$. As $\varepsilon(d) = 0$ when $w \mid d$, and $\theta(n/d) = 0$ unless $w^e \mid d$,

$$a_n(E) = \sum_{d \mid n'} \varepsilon(d) d^{k-1}, \qquad a_n(E') = \psi(w)^e w^{e(k-1)} \sum_{d \mid n'} \theta(n'/d)\psi(d) d^{k-1}.$$

Both lie in B, and since $\psi(w) = 1$, $w^{e(k-1)} \equiv 1$ and $\theta(n'/d) \equiv 1 \equiv \theta(d)$, we get $a_n(E) \equiv a_n(E') \pmod{\lambda}$ for all $n \geq 1$.

The constant term of E lies in λ. Suppose not, and put $a = a_0(E)$; then $a^{-1} \in B$, and $D = a^{-1}(E - E') \in M_k(\Gamma_0(N), \varepsilon)$ has expansion at ∞ in $B[[q]]$, equal to 1 modulo λ. As $\Gamma(N) \subseteq \Gamma_1(N)$, (Kt2) gives $D \in M_k(N; B)$, and its image $\overline{D} \in M_k(N; \overline{\mathbb{F}})$ has q-expansion 1 at ∞, as has $1 \in M_0(N; \overline{\mathbb{F}})$. By (Kt4), $(\ell - 1) \mid k$ and $\overline{D} = A^{k/(\ell-1)}$. Let d be prime to N and $\delta \in \Gamma_0(N)$ with lower right entry $\equiv d \pmod{N}$ (lift $\mathrm{diag}(d^{-1}, d)$ from $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$). Then $D|_k\delta = \varepsilon(d)D$, so by (Kt2) and the compatibility of the action with base change (Kt1), $\delta \bmod N$ maps $\overline{D}$ to $\overline{\varepsilon}(d)\overline{D}$; it fixes A by (Kt4), and $A^{k/(\ell-1)} \neq 0$. Hence $\overline{\varepsilon}(d) = 1$ for all d. But $\overline{\varepsilon} = \overline{\psi}\,\overline{\theta} = \overline{\psi}$, which is nontrivial when $\psi \neq 1$ has order prime to ℓ (reduction is injective on roots of unity of order prime to ℓ); and if $(\ell - 1) \nmid k$ we already have a contradiction. So $a_0(E) \in \lambda$.

A cusp form with character exactly ε congruent to E. Let H be the form of Lemma 49.7 for $(N, k, \varepsilon, \mathcal{O})$ and $G = E - a_0(E)H \in M_k(\Gamma_0(N), \varepsilon)$. Its expansion at ∞ lies in $B[[q]]$, $a_0(G) = 0$, and $a_n(G) \equiv a_n(E) \pmod{\lambda}$ for $n \geq 1$. For $\gamma = \left(\begin{smallmatrix} a' & b' \\ c' & d' \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$: if $N \nmid c'$, $G|_k\gamma \to 0$ at $i\infty$ by (Es2) and Lemma 49.7; if $N \mid c'$, $\gamma \in \Gamma_0(N)$ and $G|_k\gamma = \varepsilon(d')G \to \varepsilon(d')a_0(G) = 0$. So G vanishes at every cusp: $G \in S_k(\Gamma_0(N), \varepsilon)$.

Hecke eigenvalues modulo λ. Let S be the set of $g \in S_k(\Gamma_0(N), \varepsilon)$ with all $a_n(g) \in B$. Since $S_k(\Gamma_0(N), \varepsilon)$ has a basis with coefficients in the field of values of ε ([229], Theorem 3.52), S spans it, and S embeds into B^{n_1} by the first n_1 coefficients for n_1 large; so S is free of finite rank over B. The Hecke operators T_n $(n \geq 1)$ act on $M_k(\Gamma_0(N), \varepsilon)$ by $a_m(T_n g) = \sum_{d \mid (m,n)} \varepsilon(d) d^{k-1} a_{mn/d^2}(g)$ $(m \geq 0)$, preserving cusp forms ([80, Proposition 5.3.1]); hence they preserve S, and $a_1(T_n g) = a_n(g)$. The series E is an eigenform of all T_n with eigenvalue $\sigma(n) = a_n(E)$ ([80, §§5.2–5.3]). For $m \geq 1$, $a_m(T_n G) \equiv a_m(T_n E) = \sigma(n) a_m(E) \equiv \sigma(n) a_m(G)$, and $a_0(T_n G) = 0 = a_0(G)$; so $T_n G - \sigma(n) G$ has all coefficients in λ, i.e. lies in λS (dividing by a uniformiser keeps the coefficients in B). Thus the image $\overline{G} \neq 0$ of G in $S/\lambda S$ ($a_1(G) \equiv 1$) is a common eigenvector of the commuting endomorphisms T_n with eigenvalues $\sigma(n) \bmod \lambda$. By the lemma of Deligne and Serre ([78, Lemme 6.11]) there are a discrete valuation ring $B' \supseteq B$ finite over B, of the form $\iota(\mathcal{O}')$ with maximal ideal λ', and a nonzero $f \in S \otimes_B B' \subseteq S_k(\Gamma_0(N), \varepsilon)$ with $T_n f = \lambda_n f$ and $\lambda_n \equiv \sigma(n) \pmod{\lambda'}$ for all n.

f is a newform. From $a_n(f) = a_1(T_n f) = \lambda_n a_1(f)$ we get $a_1(f) \neq 0$; normalise $a_1(f) = 1$. As ε is primitive modulo N, every newform of level $M \mid N$ with character ε has $N = \mathrm{cond}(\varepsilon) \mid M$, so by the theory of newforms ([13], [161]) $S_k(\Gamma_0(N), \varepsilon)$ is spanned by the newforms of level N and character ε, and a normalised common eigenform of all T_n in it is one of them (strong multiplicity one for the eigenvalues of T_p, $p \nmid N$). So f is a normalised newform of weight k, level N and character ε, and $a_p = \lambda_p \equiv \sigma(p) = 1 + \varepsilon(p)p^{k-1}$ for every prime p. □

Lemma 49.6. *For $M \geq 1$ and a Dirichlet character ε modulo M, $M_k(\Gamma_0(M), \varepsilon)$ is the space of holomorphic modular forms f of weight k for $\Gamma_1(M)$ with $f|_k\gamma = \varepsilon(d)f$ for $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(M)$,*

and $S_k(\Gamma_0(M),\varepsilon)$ its subspace of cusp forms. Let $k\ge 3$ and let ψ_1,ψ_2 be primitive Dirichlet characters modulo $u,v\ge 1$ (the trivial character being primitive modulo 1) with $\psi_1(-1)\psi_2(-1)=(-1)^k$. Put $\delta(\psi_1)=1$ if $u=1$ and $\delta(\psi_1)=0$ otherwise, and

$$E_k(\psi_1,\psi_2)(\tau)=\frac{\delta(\psi_1)}{2}L(1-k,\psi_2)+\sum_{n\ge1}\Big(\sum_{d\mid n}\psi_1(n/d)\,\psi_2(d)\,d^{k-1}\Big)q^n,\qquad q=e^{2\pi i\tau}.$$

(Es1) *$E_k(\psi_1,\psi_2)\in M_k(\Gamma_0(uv),\psi_1\psi_2)$, and $L(1-k,\psi_2)$ lies in the field generated over $\mathbb{Q}$ by the values of ψ_2.*

(Es2) *If $u=1$ and $v=N>1$, then for every $\gamma=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in\mathrm{SL}_2(\mathbb{Z})$ with $N\nmid c$, $(E_k(1,\psi_2)|_k\gamma)(\tau)\to 0$ as $\operatorname{Im}\tau\to\infty$.*

Proof. (Es1) is the classical theory of Eisenstein series with characters (F. Diamond and J. Shurman, *A First Course in Modular Forms*, Springer 2005, §4.5, where the series $2E_k(\psi_1,\psi_2)$ is denoted $E_k^{\psi_1,\psi_2}$ and shown to lie in $M_k(\Gamma_0(uv),\psi_1\psi_2)$ for $k\ge3$); $L(1-k,\psi_2)=-B_{k,\psi_2}/k$ with the generalised Bernoulli number $B_{k,\psi_2}=v^{k-1}\sum_{a=1}^{v}\psi_2(a)B_k(a/v)$ ([266], Theorem 4.2 and Proposition 4.1), a polynomial expression in the values of ψ_2 with rational coefficients.

(Es2). Write $\varepsilon=\psi_2$; it is primitive modulo N and $\varepsilon(-1)=(-1)^k$. Symbols introduced here are local to this proof. For τ in the upper half plane put

$$G(\tau)=\sum_{(x,y)\in\mathbb{Z}^2\setminus\{0\}}\overline{\varepsilon}(y)\,(xN\tau+y)^{-k}.$$

For $\tau=s+it$ with $t\ge1$ and $|s|\le1/2$ one has $|x\tau'+y|^2=(xs'+y)^2+x^2t'^2\ge c_0(x^2+y^2)$ for $\tau'=N\tau$ and a constant $c_0>0$ depending only on N (compare the two cases $|y|\le 2N|x|$ and $|y|>2N|x|$), so the series converges absolutely and uniformly on $\{t\ge1\}$ by periodicity, as $k\ge3$.

G is a nonzero multiple of $E_k(1,\varepsilon)$. The terms with $x=0$ give $\sum_{y\ne0}\overline{\varepsilon}(y)y^{-k}=2L(k,\overline{\varepsilon})$, since $\overline{\varepsilon}(-y)(-y)^{-k}=\overline{\varepsilon}(y)y^{-k}$. The terms with (x,y) and $(-x,-y)$ are equal for the same reason. For $x\ge1$, splitting $y=r+mN$ with r modulo N and using Lipschitz's formula $\sum_{m\in\mathbb{Z}}(z+m)^{-k}=\frac{(-2\pi i)^k}{(k-1)!}\sum_{n\ge1}n^{k-1}e^{2\pi inz}$,

$$\begin{aligned}\sum_{y}\overline{\varepsilon}(y)(xN\tau+y)^{-k}&=N^{-k}\frac{(-2\pi i)^k}{(k-1)!}\sum_{n\ge1}n^{k-1}e^{2\pi inx\tau}\sum_{r\bmod N}\overline{\varepsilon}(r)e^{2\pi inr/N}\\&=N^{-k}\frac{(-2\pi i)^k}{(k-1)!}\,g(\overline{\varepsilon})\sum_{n\ge1}\varepsilon(n)n^{k-1}q^{nx},\end{aligned}$$

where $g(\overline{\varepsilon})=\sum_r\overline{\varepsilon}(r)e^{2\pi ir/N}\ne0$ is the Gauss sum and $\sum_r\overline{\varepsilon}(r)e^{2\pi inr/N}=\varepsilon(n)g(\overline{\varepsilon})$ for all n because ε is primitive. Summing over $x\ge1$, $G=2L(k,\overline{\varepsilon})+C\sum_{n\ge1}\big(\sum_{d\mid n}\varepsilon(d)d^{k-1}\big)q^n$ with $C=2N^{-k}\frac{(-2\pi i)^k}{(k-1)!}g(\overline{\varepsilon})\ne0$. Next, $G\in M_k(\Gamma_0(N),\varepsilon)$ up to holomorphy at the cusps, which follows from the uniform bound: for $\gamma'=\left(\begin{smallmatrix}a'&b'\\c'&d'\end{smallmatrix}\right)\in\Gamma_0(N)$, $(G|_k\gamma')(\tau)=\sum\overline{\varepsilon}(y)\big((xNa'+yc')\tau+(xNb'+yd')\big)^{-k}$, and $(xN,y)\mapsto(xNa'+yc',\,xNb'+yd')$ is a bijection of $N\mathbb{Z}\times\mathbb{Z}\setminus\{0\}$ onto itself (as $N\mid c'$) with $xNb'+yd'\equiv yd'\pmod N$, so $\overline{\varepsilon}(y)=\varepsilon(d')\overline{\varepsilon}(xNb'+yd')$ and $G|_k\gamma'=\varepsilon(d')G$. Hence $G-C\,E_k(1,\varepsilon)$ lies in $M_k(\Gamma_0(N),\varepsilon)$ by (Es1) and is a constant c; applying $|_k\left(\begin{smallmatrix}1&0\\N&1\end{smallmatrix}\right)$ gives $c(N\tau+1)^{-k}=c$ for all τ, so $c=0$ and $G=C\,E_k(1,\varepsilon)$.

Constant terms. Let $\gamma=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in\mathrm{SL}_2(\mathbb{Z})$ with $N\nmid c$. Then $(G|_k\gamma)(\tau)=\sum\overline{\varepsilon}(y)\big((xNa+yc)\tau+(xNb+yd)\big)^{-k}$, and $(xN,y)\mapsto(xNa+yc,\,xNb+yd)$ is injective. Along $\tau=s+it$, $t\to\infty$,

each term with $xNa+yc\neq 0$ tends to 0, and the series is dominated uniformly for $t\geq 1$ by the convergent series above (the substitution is a bijection of $\mathbb{Z}^2\setminus\{0\}$ onto a subset of it); so the limit is the sum over the terms with $xNa+yc=0$ and $\overline{\varepsilon}(y)\neq 0$. Such a term has $\gcd(y,N)=1$ and $N\mid yc$, hence $N\mid c$, which is excluded. So $G|_k\gamma\to 0$, and $E_k(1,\varepsilon)|_k\gamma=C^{-1}G|_k\gamma\to 0$. □

Lemma 49.7. *Let ℓ be an odd prime, $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism, $N\geq 3$ an integer with $\ell\nmid N$, $k\geq 3$, and ε a Dirichlet character modulo N with $\varepsilon(-1)=(-1)^k$. Let $\mathcal{O}$ be a coefficient ring containing $\iota^{-1}(e^{2\pi i/N})$ and ι^{-1} of the values of ε, and $B=\iota(\mathcal{O})\subset\mathbb{C}$. Then there is $H\in M_k(\Gamma_0(N),\varepsilon)$ whose q-expansion at ∞ has coefficients in B and constant term 1, such that $(H|_k\gamma)(\tau)\to 0$ as $\operatorname{Im}\tau\to\infty$ for every $\gamma=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in\mathrm{SL}_2(\mathbb{Z})$ with $N\nmid c$.*

Proof. Since $\ell\nmid N$, B contains $1/N$ and $e^{2\pi i/N}$, so B is an R_N-subalgebra of $\mathbb{C}$; enlarging $\mathcal{O}$ by a finite unramified extension we may assume that the cusps of $X_N\otimes B$ are n_C disjoint sections over B. Let $\mathbb{F}$ be the residue field of B and $\overline{\mathbb{F}}$ an algebraic closure. Evaluation at the cusps (using the canonical differential of the Tate curve) gives B-linear maps $v_B\colon M_k(N;B)\to B^{n_C}$ and $v_{\overline{\mathbb{F}}}\colon M_k(N;\overline{\mathbb{F}})\to\overline{\mathbb{F}}^{\,n_C}$, compatible with reduction.

$v_{\overline{\mathbb{F}}}$ is surjective. On the smooth proper connected curve $X=X_N\otimes\overline{\mathbb{F}}$ (Kt1), $\omega^{\otimes k}(-C)\cong\Omega^1_X\otimes\omega^{\otimes(k-2)}$ by Kodaira–Spencer, so by Serre duality $H^1(X,\omega^{\otimes k}(-C))$ is dual to $H^0(X,\omega^{\otimes(2-k)})$. The discriminant is a nonzero section of $\omega^{\otimes 12}$ over X that vanishes at the cusps (its q-expansions are $q\prod_{n\geq 1}(1-q^n)^{24}$), so $\deg\omega>0$, $\deg\omega^{\otimes(2-k)}<0$ for $k\geq 3$, and $H^0(X,\omega^{\otimes(2-k)})=0$. The cohomology sequence of $0\to\omega^{\otimes k}(-C)\to\omega^{\otimes k}\to\omega^{\otimes k}|_C\to 0$ shows that $M_k(N;\overline{\mathbb{F}})\to H^0(C,\omega^{\otimes k}|_C)=\overline{\mathbb{F}}^{\,n_C}$, which is $v_{\overline{\mathbb{F}}}$, is surjective.

v_B is surjective. By (Kt3) ($k\geq 2$), $M_k(N;B)\otimes_B\overline{\mathbb{F}}\cong M_k(N;\overline{\mathbb{F}})$ compatibly with evaluation, so $v_B\otimes\overline{\mathbb{F}}$ is surjective, hence so is $v_B\otimes\mathbb{F}$ (a linear map defined over $\mathbb{F}$ that becomes surjective over $\overline{\mathbb{F}}$), and v_B is surjective by Nakayama's lemma, B^{n_C} being finite over the local ring B. Choose $s\in M_k(N;B)$ with value 1 at the standard cusp ∞ and value 0 at every other cusp.

Constant terms of s. By (Kt2), s is a modular form of weight k for $\Gamma(N)$ all of whose q-expansions lie in $B[[q^{1/N}]]$; for $\gamma\in\mathrm{SL}_2(\mathbb{Z})$ let $c(\gamma)=\lim_{t\to\infty}(s|_k\gamma)(it)$, the constant term of the expansion of $s|_k\gamma$. The cusp of $\Gamma(N)$ represented by $\gamma\infty$ is ∞ exactly when $\gamma\in\Gamma(N)\{\pm1\}U$, $U=\{\left(\begin{smallmatrix}1&n\\0&1\end{smallmatrix}\right)\}$; the expansion of s at any cusp is that of $s|_k\gamma'$ for some γ' representing it, and $s|_k(-\gamma')=(-1)^k s|_k\gamma'$, $s|_k(g\gamma' u)=(s|_k\gamma')|_k u$ for $g\in\Gamma(N)$, $u\in U$. Hence $c(\gamma)=0$ if $\gamma\notin\Gamma(N)\{\pm1\}U$, $c(gu)=1$ and $c(-gu)=(-1)^k$ for $g\in\Gamma(N)$, $u\in U$.

The averaged form. Let Σ be a set of representatives of $\Gamma_0(N)/\Gamma(N)$ ($\Gamma(N)$ is normal in $\mathrm{SL}_2(\mathbb{Z})$), and for $g\in\Gamma_0(N)$ let d_g be its lower right entry. Put

$$H=\frac{1}{2N}\sum_{g\in\Sigma}\overline{\varepsilon}(d_g)\,s|_k g.$$

Each term depends only on $g\Gamma(N)$, since s is $\Gamma(N)$-invariant and $d_{gh}\equiv d_g\pmod N$ for $h\in\Gamma(N)$. For $\delta\in\Gamma_0(N)$, $d_{g\delta}\equiv d_g d_\delta\pmod N$ and $g\mapsto g\delta$ permutes the cosets, so $H|_k\delta=\varepsilon(d_\delta)H$; thus $H\in M_k(\Gamma_0(N),\varepsilon)$. Its expansion at ∞ is a combination with coefficients in B ($2N$ is a unit in B, ℓ being odd and prime to N) of expansions of s at cusps, so it lies in $B[[q^{1/N}]]$, and in $B[[q]]$ because H is invariant under $U\subset\Gamma_1(N)$. For $\gamma\in\mathrm{SL}_2(\mathbb{Z})$ the limit of $(H|_k\gamma)(it)$ is $\frac{1}{2N}\sum_{g\in\Sigma}\overline{\varepsilon}(d_g)c(g\gamma)$. If $N\nmid c$, no $g\gamma$ lies in $\Gamma(N)\{\pm1\}U\subseteq\Gamma_0(N)$ (else $\gamma\in\Gamma_0(N)$), so the limit is 0. For $\gamma=1$, the cosets with $c(g)\neq 0$ are those of $\pm\left(\begin{smallmatrix}1&n\\0&1\end{smallmatrix}\right)$, n mod N, which are $2N$ distinct cosets as $N\geq 3$; each contributes $\overline{\varepsilon}(\pm1)(\pm1)^k=1$, because $\varepsilon(-1)=(-1)^k$. So the constant term of H is 1. □

Lemma 49.8. *Let ℓ be an odd prime, $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism, and $g=\sum a_n q^n$ a normalised newform of weight $k\geq 3$, level N with $\ell\nmid N$ and primitive character ε modulo N, such that*

$\iota^{-1}(a_p) \equiv 1 + \iota^{-1}(\varepsilon(p))p^{k-1}$ *for every prime* p. *Let* $\rho = \rho^{\mathrm{ar}} \colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ *be its Galois representation and* $\beta = \varepsilon\chi_{\mathrm{cyc}}^{k-1} = \det\rho$.

(Ne1) *For every* $s \in G_{\mathbb{Q}}$ *the characteristic polynomial of* $\rho(s)$ *has coefficients in* $\overline{\mathbb{Z}}_\ell$ *and is congruent to* $(X-1)(X-\beta(s))$.
