Proof. (Ne1). The compact group $\rho(G_{\mathbb{Q}})$ lies in $\mathrm{GL}_2(E)$ for a finite extension $E/\mathbb{Q}_\ell$ (Baire, as $\overline{\mathbb{Q}}_\ell^\times$ is a countable union of the closed $E^\times$) and stabilises an $\mathcal{O}_E$-lattice, so characteristic polynomials have coefficients in $\mathcal{O}_E$. For an arithmetic Frobenius σ at $p \nmid \ell N$, $\mathrm{tr}\,\rho(\sigma) = \iota^{-1}(a_p) \equiv 1 + \beta(\sigma)$ and $\det\rho(\sigma) = \beta(\sigma)$. The set of s with $\mathrm{tr}\,\rho(s) - 1 - \beta(s) \in \mathfrak{m}_{\mathcal{O}_E}$ is closed ($\mathfrak{m}_{\mathcal{O}_E}$ is closed and the maps are continuous) and contains all such σ, which are dense by the Chebotarev density theorem; so it is $G_{\mathbb{Q}}$, and the characteristic polynomial is $X^2 - (1+\beta(s))X + \beta(s)$ modulo $\mathfrak{m}$.

(Ne2). If $p \nmid N$, ρ is trivial on $I_{\bar{p}}$ by (Dg1) and ε is unramified at p; the semisimplification of the unramified $\rho|_{D_{\bar{p}}}$ is a sum of unramified characters whose values at σ are the eigenvalues of $\rho(\sigma)$, the roots of $X^2 - \iota^{-1}(a_p)X + \iota^{-1}(\varepsilon(p))p^{k-1}$ (for an arithmetic σ; for a general σ inducing $x \mapsto x^p$ the same, ρ being trivial on inertia), of absolute value $p^{(k-1)/2}$ under ι by (Dg2). If $p \mid N$, then $v_p(N) = v_p(\mathrm{cond}\,\varepsilon)$ as ε is primitive modulo N, and (Gn3) gives $\rho|_{D_{\bar{p}}} \cong \mathrm{diag}(\nu_1, \nu_2)$ with ν_1 unramified and the absolute values; on $I_{\bar{p}}$, $\nu_2 = \nu_1\nu_2 = \det\rho = \varepsilon\chi_{\mathrm{cyc}}^{k-1} = \varepsilon$, as χ_{cyc} is unramified at p.

(Ne3). As $\ell \nmid N$, $\iota^{-1}(a_\ell) \equiv 1 + \iota^{-1}(\varepsilon(\ell))\ell^{k-1} \equiv 1$ is a unit, and (Gn2) applies. The roots α, α' of $X^2 - \iota^{-1}(a_\ell)X + \iota^{-1}(\varepsilon(\ell))\ell^{k-1}$ are integral with $\alpha\alpha' \in \ell\overline{\mathbb{Z}}_\ell$ and α a unit, so $\alpha' \in \mathfrak{m}$ and $\alpha = \iota^{-1}(a_\ell) - \alpha' \equiv 1$. The unramified δ_2 is determined by $\delta_2(\sigma) = \alpha$ on the topological generator of $D_{\bar{\ell}}/I_{\bar{\ell}}$, and $\{s : \delta_2(s) \equiv 1\}$ is a closed subgroup containing $I_{\bar{\ell}}$ and σ; so $\delta_2 \equiv 1$ on $D_{\bar{\ell}}$. The determinant gives $\delta_1\delta_2 = \beta$; on $I_{\bar{\ell}}$, $\beta = \chi_{\mathrm{cyc}}^{k-1}$ as ε is unramified at ℓ.

A Clifford alternative. Let $M \subset \overline{\mathbb{Q}}$ be finite Galois over $\mathbb{Q}$ with $\rho|_{G_M}$ reducible. By (Gn1) and Clifford's theorem (G_M is normal), $\rho|_{G_M}$ is a sum of two characters ξ_1, ξ_2. If $\xi_1 = \xi_2$, $\rho(G_M)$ is scalar; then for s in the open subgroup $G_M \cap I_{\bar{\ell}}$ of $I_{\bar{\ell}}$, (Ne3) gives $\delta_1(s) = \delta_2(s)$, i.e. $\chi_{\mathrm{cyc}}(s)^{k-1} = 1$; but $\chi_{\mathrm{cyc}}(G_M \cap I_{\bar{\ell}})$ is open in $\mathbb{Z}_\ell^\times$, so it contains elements of infinite order: contradiction. Hence $\xi_1 \neq \xi_2$, $G_{\mathbb{Q}}$ permutes the two eigenlines, the stabiliser H of the ξ_1-line has index 2 and contains G_M, and $\rho \cong \mathrm{Ind}_H^{G_{\mathbb{Q}}}\xi$ for the character ξ of H on that line (Frobenius reciprocity, ρ irreducible of dimension 2). With ω the character of order 2 with kernel H, $\rho \otimes \omega \cong \rho$. Comparing (Ne1) for ρ and $\rho \otimes \omega$: for $s \notin H$ the residual roots $\{1, \bar{\beta}(s)\}$ and $\{-1, -\bar{\beta}(s)\}$ coincide, and $1 \neq -1$, so $\bar{\beta}(s) = -1$; for $s \in H$ and any $t \notin H$, $\bar{\beta}(s) = \bar{\beta}(ts)\bar{\beta}(t)^{-1} = 1$. So $\beta \equiv 1$ on $H \supseteq G_M$ and $\beta \equiv \omega$ on $G_{\mathbb{Q}}$; in particular $\beta^2 \equiv 1$ on $G_{\mathbb{Q}}$.

(Ne4). Apply the alternative with $M = L$: reducibility would give $\beta \equiv 1$ on G_L.

(Ne5). If $\rho\otimes\omega\cong\rho$ for $\omega\neq 1$ of order 2 with kernel H, the last two sentences of the alternative apply without change and give $\beta^2\equiv 1$: excluded. An open U contains G_M for some finite Galois $M/\mathbb{Q}$; a U-stable line would be G_M-stable, and the alternative would give $\rho\otimes\omega\cong\rho$; so $\rho|_U$ is irreducible. For $\mathrm{ad}^0\rho$: the trace form $(X,Y)\mapsto\mathrm{tr}(XY)$ on $\mathfrak{sl}_2(\overline{\mathbb{Q}}_\ell)$ is nondegenerate and invariant, so if W is a proper nonzero U-stable subspace, one of W, $W^\perp$ is a U-stable line $\overline{\mathbb{Q}}_\ell X$: $\rho(u)X\rho(u)^{-1}=c(u)X$. If X is nilpotent, $\ker X$ is a U-stable line for ρ, excluded. Otherwise X has eigenvalues $\pm a$, $a\neq 0$, and $\rho(u)$ permutes its two eigenlines; the subgroup of U fixing one of them is open (index at most 2) and leaves a line stable, excluded. So $\mathrm{ad}^0\rho|_U$ is irreducible. □

Lemma 49.9. *Let ℓ, ι, g (weight $k\geq 3$, level N, $\ell\nmid N$, primitive character ε), ρ and $\beta=\det\rho$ be as in Lemma 49.8, let $L\subset\overline{\mathbb{Q}}$ be a CM field abelian over $\mathbb{Q}$, and $c\in G_{\mathbb{Q}}$ a complex conjugation.*

(Na1) *If $\beta(s)^2\not\equiv 1$ for some $s\in G_{\mathbb{Q}}$, then $r_3=(\mathrm{ad}^0\rho)|_{G_L}\otimes\chi_{\mathrm{cyc}}^{-1}$ is irreducible, automorphic of conjugate self-dual type for ι, and satisfies the witness conditions.*

(Na2) *If $\beta(s)\not\equiv 1$ for some $s\in G_L$, and $\nu\colon G_L\to\overline{\mathbb{Q}}_\ell^\times$ is a continuous character, algebraic for ι, with $\nu(s)\nu(csc)\beta(s)=\chi_{\mathrm{cyc}}(s)^{-1}$ for all $s\in G_L$, then $r_2=\rho|_{G_L}\otimes\nu$ is irreducible, automorphic of conjugate self-dual type for ι, and satisfies the witness conditions.*

Proof. Throughout, two continuous semisimple representations of G_E (E a number field) whose characteristic polynomials agree at the Frobenius elements of almost all places are isomorphic (Chebotarev density and Brauer–Nesbitt); we call this *(CB)*. For a representation r of G_L attached to a cuspidal π, $r^c\colon s\mapsto r(csc)$ is attached to π^c and $r^\vee\otimes\chi_{\mathrm{cyc}}^{1-n}$ to $\pi^\vee$, by comparing the definitions in Section 13.

Step 1: the automorphic representation of g. Let π be the cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_{\mathbb{Q}})$ generated by g, in the unitary normalisation ([103]): for $p\nmid N$ it is unramified with Satake parameters $\{\alpha_p,\beta_p\}$ such that $p^{(k-1)/2}\alpha_p$, $p^{(k-1)/2}\beta_p$ are the roots of $X^2-a_pX+\varepsilon(p)p^{k-1}$, so $\iota^{-1}(p^{(k-1)/2}\alpha_p)$, $\iota^{-1}(p^{(k-1)/2}\beta_p)$ are the eigenvalues of $\rho(\sigma_p)$ for an arithmetic Frobenius σ_p at $p\nmid\ell N$; its central character ω_π has finite order ($\omega_\pi\leftrightarrow\varepsilon$); and the Langlands parameter of π_∞ restricted to $\mathbb{C}^\times$ is $z\mapsto\mathrm{diag}\big((z/\bar z)^{(k-1)/2},(z/\bar z)^{-(k-1)/2}\big)$. Fix a chain $\mathbb{Q}=E_0\subset E_1\subset\cdots\subset E_t=L$ with E_{i+1}/E_i cyclic of prime degree (a composition series of the abelian group $\mathrm{Gal}(L/\mathbb{Q})$).

Step 2: (Na1), automorphy. Assume $\beta^2\not\equiv 1$. If $\pi\cong\pi\otimes(\omega\circ\det)$ for a quadratic $\omega\neq 1$, then ρ and $\rho\otimes\omega$ have the same Frobenius characteristic polynomials at almost all primes, so $\rho\cong\rho\otimes\omega$ by (CB) and (Gn1) of Theorem B.80, contradicting (Ne5). By (Gj3), $\Pi_0=\mathrm{Ad}(\pi)$ is cuspidal. Inductively let $\Pi_{i+1}=\mathrm{BC}_{E_{i+1}/E_i}(\Pi_i)$ and $r^{(i)}=\mathrm{ad}^0\rho|_{G_{E_i}}$. By (Gj1), (Ac1), at almost all places w of E_i (above $p\nmid\ell N$, unramified in L, residue degree f) $\Pi_{i,w}$ is unramified with Satake parameters $\{(\alpha_p/\beta_p)^f,1,(\beta_p/\alpha_p)^f\}$, the eigenvalues of $r^{(i)}$ at a Frobenius element of w (this multiset is stable under inversion, so arithmetic or geometric Frobenius does not matter). Suppose Π_i is cuspidal and $\Pi_i\cong\Pi_i\otimes(\omega\circ\det)$ with $\omega\neq 1$ trivial on norms from E_{i+1}; let ω_G be the corresponding nontrivial character of $\mathrm{Gal}(E_{i+1}/E_i)$. Then $r^{(i)}\cong r^{(i)}\otimes\omega_G$ by (CB), $r^{(i)}$ being irreducible by (Ne5); an intertwiner A with $Ar^{(i)}(s)A^{-1}=\omega_G(s)r^{(i)}(s)$ is not scalar and commutes with $r^{(i)}(G_{E_{i+1}})$, so $r^{(i)}|_{G_{E_{i+1}}}$ is reducible by Schur's lemma, contradicting (Ne5). By (Ac3), Π_{i+1} is cuspidal. So $\Pi=\Pi_t$ is a cuspidal automorphic representation of $\mathrm{GL}_3(\mathbb{A}_L)$, and at almost all w the eigenvalues of $r_3(\mathrm{Frob}_w^{-1})$ are $\mathrm{N}w$ times its Satake parameters (as $\chi_{\mathrm{cyc}}^{-1}(\mathrm{Frob}_w^{-1})=\mathrm{N}w$): $r_3\leftrightarrow_\iota\Pi$. By (Gj2), (Ac2), at each complex place the parameter of Π restricted to $\mathbb{C}^\times$ is $\mathrm{diag}\big((z/\bar z)^{k-1},1,(z/\bar z)^{1-k}\big)$: integral, pairwise distinct exponents, so Π is regular algebraic. The Satake parameters of $\Pi^\vee$ at w are the inverses of those of Π_w, those of Π^c are those of Π_{cw}, and $r_3(c\,\mathrm{Frob}_w\,c)$ is conjugate to $\mathrm{ad}^0\rho(\mathrm{Frob}_w)\chi_{\mathrm{cyc}}^{-1}(\mathrm{Frob}_w)$ in $G_{\mathbb{Q}}$; so Π^c and

$\Pi^\vee$ agree at almost all places, and $\Pi^c \cong \Pi^\vee$ by (Js1). Hence r_3 is automorphic of conjugate self-dual type; it is irreducible by (Ne5).

Step 3: (Na2), automorphy. Assume $\beta \not\equiv 1$ on G_L; $\rho|_{G_L}$, hence $\rho|_{G_{E_i}}$ for all i, is irreducible by (Ne4). Let $\pi_0 = \pi$ and $\pi_{i+1} = \mathrm{BC}_{E_{i+1}/E_i}(\pi_i)$; the argument of Step 2 with $\rho|_{G_{E_i}}$ in place of $r^{(i)}$ shows that every π_i is cuspidal, with Satake parameters $\{\alpha_p^f, \beta_p^f\}$ at almost all w. As ν is algebraic and the inverse of an algebraic Hecke character is one, there is a Hecke character $\nu_{\mathbb{A}}$ of L with $\nu_{\mathbb{A}}(\varpi_w) = \iota\nu(\mathrm{Frob}_w^{-1})$ at almost all w, of type $z \mapsto z^a\bar{z}^b$ ($a, b \in \mathbb{Z}$) at each complex place. Put $\nu' = \nu_{\mathbb{A}} \,|\cdot|_{\mathbb{A}}^{k/2} (\omega_\pi \circ \mathrm{N}_{L/\mathbb{Q}})^{-1}$ and $\Pi' = \pi_t \otimes (\nu' \circ \det)$, cuspidal. At almost all w (residue degree f over p), the eigenvalues of $r_2(\mathrm{Frob}_w^{-1})$ are ι^{-1} of $\mathrm{N}w^{-(k-1)/2}\{\alpha_p^{-f}, \beta_p^{-f}\}\nu_{\mathbb{A}}(\varpi_w) = \mathrm{N}w^{1/2}\{\alpha_p^f, \beta_p^f\}\nu'(\varpi_w)$, using $\alpha_p\beta_p = \omega_\pi(p)$; so $r_2 \leftrightarrow_\iota \Pi'$. At a complex place the parameter of Π' on $\mathbb{C}^\times$ is $\mathrm{diag}(z^{a+k-1/2}\bar{z}^{b+1/2},\, z^{a+1/2}\bar{z}^{b+k-1/2})$, which after the twist by $|\det|^{-1/2}$ has distinct integral exponents: Π' is regular algebraic. Since $\rho^\vee \cong \rho \otimes \beta^{-1}$ and $\nu\nu^c\beta = \chi_{\mathrm{cyc}}^{-1}$, $r_2^\vee \otimes \chi_{\mathrm{cyc}}^{-1} \cong \rho|_{G_L} \otimes \beta^{-1}\nu^{-1}\chi_{\mathrm{cyc}}^{-1} = \rho|_{G_L} \otimes \nu^c \cong r_2^c$ (as $\rho(csc) = \rho(c)\rho(s)\rho(c)^{-1}$). Hence $\Pi'^\vee$ and Π'^c have the same Satake parameters at almost all places and $\Pi'^c \cong \Pi'^\vee$ by (Js1). So r_2 is irreducible and automorphic of conjugate self-dual type.

Step 4: local shape. Let r be r_3 (with $n = 3$) or r_2 (with $n = 2$). (i) At a place $\bar{v}$ above ℓ: by (Ne3), ρ is triangular on $D_{\bar{v}}$ with diagonal (δ_1, δ_2), $\delta_1\delta_2^{-1} = \chi_{\mathrm{cyc}}^{k-1}$ on $I_{\bar{v}}$. Conjugation by an upper triangular matrix preserves the flag $\langle E_{12}\rangle \subset \langle E_{12}, H\rangle \subset \mathfrak{sl}_2$ ($H = \mathrm{diag}(1,-1)$) and acts on the graded pieces by δ_1/δ_2, 1, δ_2/δ_1; so r is triangular on $D_{\bar{v}} \cap G_L$ with diagonal (κ_a), where on $I_{\bar{v}} \cap G_L$ the ratios κ_a/κ_b ($a \neq b$) are χ_{cyc}^h with $h \in \{\pm(k-1), \pm 2(k-1)\}$. If $\kappa_a^e = (\kappa_b\chi_{\mathrm{cyc}})^e$ for some $e \geq 1$, then $\chi_{\mathrm{cyc}}^{e(h-1)} = 1$ (resp. $\chi_{\mathrm{cyc}}^e = 1$ if $a = b$) on the open subgroup $I_{\bar{v}} \cap G_L$ of $I_{\bar{v}}$, impossible as $h \neq 1$ ($k \geq 3$) and χ_{cyc} has infinite order there. So r is generic and potentially generic at every place above ℓ, and (Wc1) holds. (ii) At $\bar{w}$ above $p \neq \ell$: by (Ne2), r restricted to $I_{\bar{w}} \cap G_L$ is a sum of characters of finite order (χ_{cyc} is unramified at p, and ν, being attached to an algebraic Hecke character, has finite order on inertia away from ℓ); and the semisimplification of $r|_{D_{\bar{w}} \cap G_L}$ is a sum of characters λ_a whose values at any element acting on the residue field as a power $x \mapsto x^{p^j}$ have absolute values (under ι) independent of a: for r_3 they are $\nu_1\nu_2^{-1}\chi_{\mathrm{cyc}}^{-1}, \chi_{\mathrm{cyc}}^{-1}, \nu_2\nu_1^{-1}\chi_{\mathrm{cyc}}^{-1}$, for r_2 they are $\nu_1\nu, \nu_2\nu$, and $|\iota\nu_1(\sigma)| = |\iota\nu_2(\sigma)|$.

Step 5: (Wc2). Let π' be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_L)$ with $r \leftrightarrow_\iota \pi'$. Then π'_w and Π_w (resp. Π'_w) are unramified with the same Satake parameters at almost all w, so π' is isomorphic to Π (resp. Π') by (Js1), hence conjugate self-dual, in particular polarizable; by (Bg1) and (CB), $r_{\ell,\iota}(\pi') \cong r$. Let w be a finite place of L, $\bar{w} \mid w$, $D = D_{\bar{w}} \cap G_L$, $q = q_w$, and $\mathrm{WD}(r|_D) = (V, \rho', N)$. If $w \nmid \ell$, r has finite image on inertia by Step 4 (ii), so $N = 0$ and $\rho'|_I = r|_I$ is a sum of characters, and the characters of the semisimplification of ρ' have values of equal absolute value at $\mathrm{Art}_{L_w}(\varpi_w)^{-1}$. If $w \mid \ell$: by (Lc2) applied to $\rho_{g,\iota}$, $\mathrm{a}(\rho_{g,\iota}|_{D_{\bar{\ell}}}) = v_\ell(N) = 0$, so $\mathrm{WD}(\rho|_{D_{\bar{\ell}}})$ is unramified with zero monodromy; χ_{cyc} and (for r_2) the character $\nu|_D = \det(r_2|_D)\det(\rho|_D)^{-1}$ are potentially semistable and one-dimensional, so with zero monodromy; as the Weil–Deligne functor of [95] commutes with restriction to D, tensor products and duals, $N = 0$ and $\rho'|_I$ is a sum of characters. Then (Pu2) of Theorem B.73 for π' gives $\mathrm{gr}_j = 0$ for j different from its weight, and (Pu1) shows that all eigenvalues of $\rho'(\Phi)$, $n(\Phi) = -1$, have the same absolute value. In both cases (Bg3) (with U the open subgroup of $\mathcal{O}_{L_w}^\times$ on which the inertial characters are trivial) shows that π'_w is a subquotient of the normalised induction of characters $\xi_1, \ldots, \xi_n$ of $L_w^\times$, and (Bg5) gives $\iota\lambda_a(\mathrm{Art}_{L_w}(x)^{-1}) = \xi_a(x)|x|_w^{(1-n)/2}$ for the characters λ_a of the semisimplification of ρ'; hence $|\xi_1(\varpi_w)| = \cdots = |\xi_n(\varpi_w)|$. The central character $\omega_{\pi'}$ is a Hecke character of L; $|\omega_{\pi'}|$ is trivial on the compact group $\mathbb{A}_L^1/L^\times$, so $|\omega_{\pi'}| = |\cdot|_{\mathbb{A}}^{\sigma_0}$ for a real σ_0; and the central character of π'_w is $\xi_1 \cdots \xi_n$. Therefore $|\xi_a(\varpi_w)| = q_w^{-\sigma_0/n}$ for every a and every finite w, and (Wc2) holds with $\tau_{\pi'} = -\sigma_0/n$. □

Proposition 49.10. *Let ℓ be odd, K an imaginary quadratic field, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and let L be a CM field satisfying (Af1), (Af2), (Ag1) and (Ag2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, where $2\ell \mid M$ and every prime dividing d_K divides M. Fix data $(N', w, j, \chi', \theta)$ as in (Ag1). Then there are an admissible twist κ of rank 2 for ι, c and M, an integer $m \geq 2$, and a seed of rank 2 and weight m for (j, χ') with twist κ.*

Proof. Step 1: the newform. By (Ag1), $\chi'^2\eta_K$ is a Dirichlet character modulo N' with value 1 at w; let ψ be the primitive character inducing it (possibly trivial), of conductor $N_0 \mid N'$, so $\psi(w) = 1$, $\ell \nmid N_0$, $w \nmid N_0$. As in the rank-3 case, θ is a character modulo w of order ℓ and $\ell \mid w - 1$. Choose $m \geq 2$ with $m \equiv j \pmod{\ell - 1}$, put $k = 2m + 1$ and $\varepsilon = \psi\theta$, primitive modulo $N = N_0 w$; $\varepsilon(-1) = \chi'(c)^2\eta_K(c)\theta(c) = -1 = (-1)^k$, and $(\ell - 1) \nmid k$ as k is odd. By Proposition 49.5 there is a normalised newform g of weight k, level N ($\ell \nmid N$) and character ε with $\iota^{-1}(a_p) \equiv 1 + \iota^{-1}(\varepsilon(p))p^{k-1}$ for all p. Let $\rho = \rho^{\mathrm{ar}}$ and $\beta = \varepsilon\chi_{\mathrm{cyc}}^{2m} = \det\rho$. Since $\bar\theta = 1$ and $\bar\chi_{\mathrm{cyc}}^{2m} = \bar\chi_{\mathrm{cyc}}^{2j}$, $\bar\beta = \eta_K\bar\varphi^2$; on G_L, where η_K and θ are trivial, $\beta \equiv \varphi^2$, and by the last clause of (Ag1) there is $s \in G_L$ with $\beta(s) \not\equiv 1$.

Step 2: the representation. Let $\mu = \chi_{\mathrm{cyc}}^{-m}\chi'^{-1}$, a character of $G_{\mathbb{Q}}$, and $r = \rho|_{G_L} \otimes \mu$. Then $\mu^2\beta = \chi'^{-2}\varepsilon = \eta_K\theta$, which is trivial on G_L. (Sp1): $\rho|_{G_L}$ is irreducible by (Ne4) ($L/\mathbb{Q}$ is abelian by (Af1)), hence so is r. (Sp2): let $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, so ${}^tAJA = \det(A)J$, and $P = J\rho(c)$. As $\rho(c)^2 = 1$ and $\det\rho(c) = \beta(c) = -1$, ${}^t\rho(c)J = -J\rho(c)^{-1} = -J\rho(c)$, so ${}^tP = -{}^t\rho(c)J = P$. For $s \in G_L$, $\mu(csc) = \mu(s)$ and ${}^t r(s)\, P\, r(csc) = \mu(s)^2\, {}^t\rho(s)J\rho(c)\rho(c)\rho(s)\rho(c) = (\mu^2\beta)(s)\, J\rho(c) = P$. (Sp3): the characteristic polynomial of $r(s)$ is $X^2 - \mu(s)tX + \mu(s)^2 d$ when that of $\rho(s)$ is $X^2 - tX + d$; by (Ne1) it is integral and congruent to $(X - \mu(s))(X - \mu(s)\beta(s))$. On G_L, $\bar\mu = \bar\chi_{\mathrm{cyc}}^{-j}\bar\chi'^{-1} = \bar\varphi^{-1}$ and $\bar\mu\bar\beta = \bar\varphi$, so this is $\prod_a(X - \varphi_a(s))$ modulo $\mathfrak{m}$. (Sp4): for $\bar v \nmid \ell$, by (Ne2) $r|_{I_{\bar v}\cap G_L} \cong \mu \cdot \mathrm{diag}(1, \varepsilon) = \mathrm{diag}(\chi'^{-1}, \chi'^{-1}\chi'^2\eta_K\theta) = \mathrm{diag}(\chi'^{-1}, \chi')$ there (χ_{cyc} is unramified at $p \neq \ell$), which is $\mathrm{diag}(\tau_1, \tau_2)$ after reordering. (Sp5): for $\bar v \mid \ell$, by (Ne3) r is triangular on $D_{\bar v} \cap G_L$ with diagonal $(\delta_1\mu, \delta_2\mu)$; on inertia $\delta_1 = \chi_{\mathrm{cyc}}^{2m}$, $\delta_2 = 1$ and $\mu = \chi_{\mathrm{cyc}}^{-m}$ (χ' is unramified at ℓ as $\ell \nmid N'$), giving $\chi_{\mathrm{cyc}}^{m}, \chi_{\mathrm{cyc}}^{-m}$; on $D_{\bar v} \cap G_L$, $\delta_1\mu = \beta\delta_2^{-1}\mu \equiv \beta\mu \equiv \varphi = \varphi_1$ and $\delta_2\mu \equiv \mu \equiv \varphi^{-1} = \varphi_2$.

Step 3: the twist. By (Ag2) and Lemma 49.11 there is an algebraic $\kappa_K\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$ with (Ik1)–(Ik3); let $\kappa = \kappa_K|_{G_L}$ ($G_L \subseteq G_K$ by (Af1)). It is algebraic (it corresponds to the composite of the Hecke character of κ_K with the norm $\mathbb{A}_L^\times \to \mathbb{A}_K^\times$). (Ka1) is (Ik1) for $s \in G_L$, as $\chi_{\mathrm{cyc}}^{1-2} = \chi_{\mathrm{cyc}}^{-1}$. (Ka2): a prime $p \nmid M$ does not divide ℓd_K (as $\ell \mid M$ and every prime dividing d_K divides M), so (Ik2) applies. (Ka3): for $p \nmid \ell d_K$, κ is trivial on inertia; for $p \mid d_K$ there is one prime of K above p, so the places $\bar v \mid p$ are G_K-conjugate and by (Ik3) κ_K has the same finite order m_p, prime to ℓ, on all $I_{\bar v} \cap G_K$; $m' = \mathrm{lcm}_{p \mid d_K} m_p$ works. So κ is an admissible twist of rank 2.

Step 4: (Sp6). $r \otimes \kappa = \rho|_{G_L} \otimes \nu$ with $\nu = \mu|_{G_L}\kappa$, which is algebraic (χ_{cyc}^{-m} corresponds to a power of the norm, χ'^{-1} has finite order, and κ is algebraic). For $s \in G_L$, $\nu(s)\nu(csc)\beta(s) = (\mu^2\beta)(s)\,\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{-1}$. By Step 1 and (Na2) of Lemma 49.9, $r \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.

Hence r is a seed of rank 2 and weight m for (j, χ') with the admissible twist κ. □

Lemma 49.11. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $K \subset \overline{\mathbb{Q}}$ an imaginary quadratic field with discriminant d_K, and $c \in G_{\mathbb{Q}}$ a complex conjugation. There is a continuous character $\kappa_K\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$, algebraic for ι, such that*

(Ik1) *$\kappa_K(s)\kappa_K(csc) = \chi_{\mathrm{cyc}}(s)^{-1}$ for all $s \in G_K$;*

(Ik2) *κ_K is trivial on $I_{\bar v} \cap G_K$ for every place $\bar v$ of $\overline{\mathbb{Q}}$ above a prime $p \nmid \ell d_K$;*

(Ik3) *for every place $\bar v$ above a prime $p \mid d_K$ with $p \neq \ell$, the restriction of κ_K to $I_{\bar v} \cap G_K$ has finite order prime to ℓ.*

Proof. Symbols introduced here are local to this proof. Let $\eta_K = \prod_v \eta_{K,v}$ be the quadratic idele class character of $\mathbb{Q}$ attached to K (so $\eta_{K,\infty}(-1) = -1$), fix the embedding $K \subset \mathbb{C}$ given by ι and the place above ∞, and let $\hat{\mathcal{O}}_K^\times = \prod_{\mathfrak{p}} \mathcal{O}_{K_\mathfrak{p}}^\times$; for $p \mid d_K$ write $\mathcal{O}_p^\times$ for the unit group of the completion of K at the unique prime above p.

Local characters. For each $p \mid d_K$ we choose a character $\lambda_p \colon \mathcal{O}_p^\times \to \mathbb{C}^\times$ of finite order, prime to ℓ if $p \neq \ell$, trivial on an open subgroup, with $\lambda_p|_{\mathbb{Z}_p^\times} = \eta_{K,p}|_{\mathbb{Z}_p^\times}$ and $\prod_{p \mid d_K} \lambda_p(u) = u$ for every $u \in \mathcal{O}_K^\times$ (embedded diagonally). If p is odd, let λ_p be the quadratic character of $\mathcal{O}_p^\times$ through the residue field $\mathbb{F}_p$; on $\mathbb{Z}_p^\times$ it is the Legendre symbol, which is $\eta_{K,p}|_{\mathbb{Z}_p^\times}$ (p ramified in K). If $p = 2$ and $K \neq \mathbb{Q}(i)$, let λ_2 be an extension of $\eta_{K,2}|_{\mathbb{Z}_2^\times}$ (trivial on $1 + 8\mathbb{Z}_2$) to the finite 2-group $\mathcal{O}_2^\times/(1 + 8\mathcal{O}_2)$, of 2-power order. If $K \neq \mathbb{Q}(i), \mathbb{Q}(\sqrt{-3})$, then $\mathcal{O}_K^\times = \{\pm 1\}$ and $\prod_p \lambda_p(-1) = \prod_{p<\infty} \eta_{K,p}(-1) = \eta_{K,\infty}(-1)^{-1} = -1$ by the product formula. If $K = \mathbb{Q}(i)$ ($d_K = -4$), define λ_2 on the subgroup $\mu_4\mathbb{Z}_2^\times$ by $\lambda_2(\zeta x) = \zeta\, \eta_{K,2}(x)$, consistent because $\mu_4 \cap \mathbb{Z}_2^\times = \{\pm 1\}$ and $\eta_{K,2}(-1) = -1$, trivial on $(1 + 8\mathcal{O}_2) \cap \mu_4\mathbb{Z}_2^\times$, and extend it to the 2-group $\mathcal{O}_2^\times/(1 + 8\mathcal{O}_2)$ with 2-power order. If $K = \mathbb{Q}(\sqrt{-3})$ ($d_K = -3$), define $\lambda_3(\zeta x) = \zeta\, \eta_{K,3}(x)$ on $\mu_6\mathbb{Z}_3^\times$ (consistent as $\mu_6 \cap \mathbb{Z}_3^\times = \{\pm 1\}$ and $\eta_{K,3}(-1) = -1$; trivial on $(1 + 9\mathcal{O}_3) \cap \mu_6\mathbb{Z}_3^\times$, since $\zeta_3 \notin \mathbb{Z}_3 + 9\mathcal{O}_3$) and extend it to $\mathcal{O}_3^\times/(1 + 9\mathcal{O}_3)$, of order $2 \cdot 3^b$, which is prime to ℓ if $\ell \neq 3$.

A Hecke character. Let $\lambda_f = \prod_{p \mid d_K} \lambda_p$ on $\hat{\mathcal{O}}_K^\times$ (trivial at the other primes) and $\Lambda(z, u) = z^{-1}\lambda_f(u)$ on $\mathbb{C}^\times \times \hat{\mathcal{O}}_K^\times$. It is trivial on $K^\times \cap (\mathbb{C}^\times \times \hat{\mathcal{O}}_K^\times) = \mathcal{O}_K^\times$, as $\Lambda(u, u) = u^{-1}\lambda_f(u) = 1$; so it defines a character of the open subgroup of finite index $K^\times(\mathbb{C}^\times \times \hat{\mathcal{O}}_K^\times)/K^\times$ of $\mathbb{A}_K^\times/K^\times$, which extends to a Hecke character Ψ of K ($\mathbb{C}^\times$ is divisible). It has infinity type $z \mapsto z^{-1}$, so it is algebraic. Its restriction to $\mathbb{A}_\mathbb{Q}^\times = \mathbb{Q}^\times\mathbb{R}^\times\hat{\mathbb{Z}}^\times$ equals $\eta_K|\cdot|_\mathbb{A}^{-1}$: both are trivial on $\mathbb{Q}^\times$, equal $x \mapsto x^{-1} = \operatorname{sign}(x)|x|^{-1}$ on $\mathbb{R}^\times$, and equal $\prod_p \eta_{K,p}$ on $\hat{\mathbb{Z}}^\times$. Hence for $x \in \mathbb{A}_K^\times$, $\Psi(x)\Psi(\bar{x}) = \Psi(\mathrm{N}_{K/\mathbb{Q}}x) = \eta_K(\mathrm{N}x)|\mathrm{N}x|_\mathbb{A}^{-1} = |x|_{\mathbb{A}_K}^{-1}$.

The Galois character. By the correspondence between algebraic Hecke characters and ℓ-adic characters (through ι and the global Artin map; [220, Ch. II]), there is a continuous $\kappa \colon G_K \to \overline{\mathbb{Q}}_\ell^\times$ and a sign $e \in \{\pm 1\}$, fixed by the normalisation of the Artin map, such that $\kappa(\mathrm{Frob}_v) = \iota^{-1}\Psi(\varpi_v)^e$ for every finite place $v \nmid \ell d_K$ of K (Frob_v an arithmetic Frobenius, ϖ_v a uniformiser at v), and whose restriction to the inertia group at a place $v \nmid \ell$ corresponds to $\Psi_v^e|_{\mathcal{O}_{K_v}^\times}$ under the local Artin map. So κ is unramified at $v \nmid \ell d_K$ and, at $v \mid d_K$ with $v \nmid \ell$, has order on inertia equal to that of λ_p, which is prime to ℓ ($p \neq \ell$). Since $c\,\mathrm{Frob}_v\,c$ is a Frobenius at $\bar{v}$, $\kappa(\mathrm{Frob}_v)\kappa(c\,\mathrm{Frob}_v\,c) = \iota^{-1}\big(\Psi(\varpi_v)\Psi(\bar{\varpi}_v)\big)^e = \mathrm{N}v^e = \chi_{\mathrm{cyc}}(\mathrm{Frob}_v)^e$; by the Chebotarev density theorem the continuous characters $s \mapsto \kappa(s)\kappa(csc)$ and χ_{cyc}^e of G_K coincide. Put $\kappa_K = \kappa^{-e}$: it is algebraic (the inverse of an algebraic Hecke character is algebraic), satisfies (Ik1), and (Ik2), (Ik3) hold as for κ. □

49.2 Propagation of modularity: the entry algebra and its core primes

This subsection states and proves the propagation theorem 49.12, from the local results of Subsections 49.3 and 49.4. The geometry takes place in the entry algebra, the algebra generated over the weight-zero algebra by the matrix entries of the universal polarised ordinary lift (Definition 49.2); it is graded by the torus, its weight-zero algebra is complete Noetherian local and its graded pieces are finite over it (Lemma 49.14). Every representation whose products of weight zero lie in a complete local ring factors through it (Lemma 49.16). Its core primes are described in Proposition 49.13, the core locus is connected and contains the seed points in its charts (Lemma 49.15), and the local charts are completions of localisations, whose primes have dimensions controlled by their traces on the weight-zero algebra (Lemma 49.17, Lemma 49.18). With these, propagation from a seed component along the connected core locus reduces to

propagation inside one chart, which the next two subsections provide.

Theorem 49.12. *Let ℓ be odd and let L be an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ such that universal polarised ordinary lifts of ranks 2 and 3 over L exist.*

1. *If an ideal $\mathcal{M}_2 \subseteq W_2^{\mathrm{po}}$ is finite over the weights, propagates through nice primes and has a seed component, then $\mathcal{M}_2$ absorbs the primes of irreducible type.*
2. *If an ideal $\mathcal{M}_2 \subseteq W_2^{\mathrm{po}}$ is finite over the weights and absorbs the primes of irreducible type, and an ideal $\mathcal{M}_3 \subseteq W_3^{\mathrm{po}}$ is finite over the weights, propagates through nice primes and along thick links and has a seed component, then $\mathcal{M}_3$ absorbs the primes of irreducible type and there is an off-triangular bound $I \subseteq W_3^{\mathrm{po}}$.*

Proof. The argument is commutative algebra on rings attached to L; it uses no statement about automorphy, over L or over K. We treat both items together. Let $n \in \{2, 3\}$, $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$, and $\mathcal{M} = \mathcal{M}_n$ as in the item; so $\mathcal{M}$ is finite over the weights, propagates through nice primes, has a seed component, and for $n = 3$ propagates along thick links. For $n = 3$ the hypotheses of item 2 on $\mathcal{M}_2$ and Proposition 49.33 give an ideal $I_3 \subseteq W$, finite over the weights, with $I_3 \subseteq \xi \cap W$ for every prime ξ of E of endoscopic type. Two facts are used throughout: modularity passes to larger primes, and being of irreducible type passes to smaller primes (it is defined by non-containments).

Step 1: the chart ideal. Let x be a core prime that is a maximal ideal and $(\mathcal{O}', R, \iota)$ a local chart at x. We define $J \subseteq R$ and show: (Jp0) $\dim R/P \geq n\,d_L + 2$ for every minimal prime P of J, and (Jp1)–(Jp3) of Lemma 49.34.

- If $n = 2$, or $n = 3$ and $I_E^{\mathrm{odd}} \not\subseteq x$, put $J = 0$. By (Qc4) of Proposition 49.19 there is a surjection $\phi\colon S = \mathcal{O}'[[X_1, \dots, X_N]] \to R$ with kernel $(f_1, \dots, f_h)$, $N \geq h + n\,d_L + 1$. The ring S is a complete Noetherian local domain of dimension $N + 1$ ([166, Theorem 15.4]), and $f_i \in \mathfrak{m}_S$ because $\ker\phi \subseteq \phi^{-1}(\mathfrak{m}_R) = \mathfrak{m}_S$. Since $\dim S \geq (n\,d_L{+}1){+}1{+}h$, Lemma 49.28 with $D = n\,d_L + 1$ applies to $\ker\phi$; through the bijection $P \mapsto \phi^{-1}(P)$ between primes of R and primes of S containing $\ker\phi$, under which $R/P \cong S/\phi^{-1}(P)$ and $R/(P+Q) \cong S/(\phi^{-1}(P) + \phi^{-1}(Q))$, its two items are (Jp0) and (Jp2) for the minimal primes of R. Every minimal prime P of R is of irreducible type: $I_R^- = R \not\subseteq P$ by (Qc3); if $I_R^+ \subseteq P$ then $\dim R/P \leq \dim R/I_R^+ < n\,d_L$ by (Nn1) of Proposition 49.29, against (Jp0); and if $n = 3$ and $I_R^{\mathrm{odd}} \subseteq P$, then (Qc3) gives $I_E^{\mathrm{odd}} \subseteq \iota^{-1}(P) \subseteq \iota^{-1}(\mathfrak{m}_R) = x$, against the case assumption. This is (Jp3); (Jp1) is trivial for $J = 0$.
- If $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$, let J be the ideal of Proposition 49.26. A prime of irreducible type does not contain I_R^{odd}, so (Ej1) gives (Jp1); (Ej2) gives (Jp0) and (Jp2); (Ej3) is (Jp3).

Step 2: local propagation. With x, $(\mathcal{O}', R, \iota)$ and J as in Step 1: if some $\mathcal{M}$-modular prime P_0 of R of irreducible type has $\dim R/P_0 \geq n\,d_L + 1$, then every minimal prime of R of irreducible type is $\mathcal{M}$-modular. This is Lemma 49.34, whose hypotheses on $\mathcal{M}$, I_3 and J hold by the above.

Step 3: charts and minimal primes. With x, $(\mathcal{O}', R, \iota)$ as in Step 1, R is flat over E by (Qc2), so going down holds for ι ([166, Theorem 9.5]), and $\iota^{-1}(\mathfrak{m}_R) = x$. (a) If P is a minimal prime of R, then $\iota^{-1}(P)$ is a minimal prime of E: for a prime $\eta \subseteq \iota^{-1}(P)$, going down gives $P' \subseteq P$ with $\iota^{-1}(P') = \eta$, and $P' = P$ by minimality. (b) Every minimal prime $\eta \subseteq x$ of E is $\iota^{-1}(P)$ for a minimal prime P of R: going down from $\mathfrak{m}_R$ gives P' with $\iota^{-1}(P') = \eta$; for a minimal prime $P \subseteq P'$, $\iota^{-1}(P) \subseteq \eta$ is prime, hence equal to η. (c) By (Qc3) a prime P of R is of irreducible type if and only if $\iota^{-1}(P)$ is, and by definition P is $\mathcal{M}$-modular if and only if $\iota^{-1}(P)$ is.

Step 4: three consequences. By (Eg1) of Proposition 49.13, E is Noetherian and has finitely many minimal primes. Let $\mathcal{T}$ be the set of minimal primes of E of irreducible type, $\mathcal{G} \subseteq \mathcal{T}$ those that are $\mathcal{M}$-modular, and $\mathcal{B} = \mathcal{T} \setminus \mathcal{G}$. Below, x is a core prime that is a maximal ideal, and $(\mathcal{O}', R, \iota)$ a local chart at x, which exists by (Qc1).

(i) *Gluing at x: if $\eta, \eta' \in \mathcal{T}$ lie in x and $\eta \in \mathcal{G}$, then $\eta' \in \mathcal{G}$.* By Step 3(b), (c), $\eta = \iota^{-1}(P)$ and $\eta' = \iota^{-1}(P')$ with P, P' minimal primes of R of irreducible type and P $\mathcal{M}$-modular. By (Jp1) $J \subseteq P$, and P is minimal over J, so $\dim R/P \geq n\,d_L + 2$ by (Jp0). Step 2 with $P_0 = P$ makes P' $\mathcal{M}$-modular, so $\eta' \in \mathcal{G}$ by Step 3(c).

(ii) *If $n = 2$, or $n = 3$ and $I_E^{\mathrm{odd}} \not\subseteq x$, then x contains a member of $\mathcal{T}$.* Take a minimal prime P of $R \neq 0$; by Step 1 it is of irreducible type; $\iota^{-1}(P) \subseteq x$ lies in $\mathcal{T}$ by Step 3(a), (c).

(iii) $\mathcal{G} \neq \emptyset$. Let ξ, $\mathfrak{z}$ be a seed component: ξ a prime of E of irreducible type, $\mathfrak{z}$ a prime of W with $\mathcal{M} \subseteq \mathfrak{z} \subseteq \xi \cap W$ and $\dim W/\mathfrak{z} = 1 + n\,d_L$. By (Eg5) there are a core prime x, maximal in E, and for a chart at x a prime P of R of irreducible type with $\iota^{-1}(P) \cap W = \mathfrak{z}$ and $\dim R/P = n\,d_L + 2$. Then P is $\mathcal{M}$-modular, and Step 2 makes every minimal prime of R of irreducible type $\mathcal{M}$-modular. A minimal prime $P_1 \subseteq P$ of R is of irreducible type, hence $\mathcal{M}$-modular, and $\iota^{-1}(P_1) \in \mathcal{G}$ by Step 3(a), (c).

Step 5: $\mathcal{B} = \emptyset$. Suppose not. Let $G = \bigcup_{\eta \in \mathcal{G}} V(\eta)$ and $B = \bigcup_{\eta \in \mathcal{B}} V(\eta)$, closed subsets of $\operatorname{Spec} E$ (finite unions), and let $\mathcal{C}$ be the set of core primes. (1) $\mathcal{C} \cap G \neq \emptyset$ and $\mathcal{C} \cap B \neq \emptyset$: a member η of $\mathcal{G}$ (Step 4(iii)), resp. of $\mathcal{B}$, satisfies $I_E^- \not\subseteq \eta$, so by (Eg2) it lies in a core prime, which belongs to $V(\eta)$. (2) $\mathcal{C} \subseteq G \cup B$: let $\mathcal{C}'$ be the set of maximal core primes x with $n = 2$ or $I_E^{\mathrm{odd}} \not\subseteq x$; by Step 4(ii) and since every member of $\mathcal{T}$ is in $\mathcal{G} \cup \mathcal{B}$, $\mathcal{C}' \subseteq G \cup B$, and $G \cup B$ is closed, so it suffices that $\mathcal{C}$ lies in the closure of $\mathcal{C}'$. Let y be a core prime with $n = 2$ or $I_E^{\mathrm{odd}} \not\subseteq y$, and $U \ni y$ open; by (Eg3) applied to $\operatorname{Spec} E$ and the open set U (for $n = 3$: $U \setminus V(I_E^{\mathrm{odd}})$, which contains y) there is a maximal core prime in it, a member of $\mathcal{C}' \cap U$; so y is in the closure of $\mathcal{C}'$. For $n = 2$ these y are all of $\mathcal{C}$; for $n = 3$, by (Eg4) every core prime is in the closure of the set of such y, hence in the closure of $\mathcal{C}'$. (3) By (Eg4) $\mathcal{C}$ is connected (it is non-empty by (1)); since $\mathcal{C} \cap G$ and $\mathcal{C} \cap B$ are non-empty, relatively closed and cover $\mathcal{C}$ by (2), they meet: some core prime lies in $G \cap B$. (4) By (Eg3) applied to the closed set $G \cap B$ and $U = \operatorname{Spec} E$, some core prime z that is a maximal ideal lies in $G \cap B$, i.e. $z \supseteq \eta$ with $\eta \in \mathcal{G}$ and $z \supseteq \eta'$ with $\eta' \in \mathcal{B}$. Step 4(i) gives $\eta' \in \mathcal{G}$, a contradiction.

Step 6: absorption. Let $\mathfrak{p}$ be a prime of E of irreducible type and $\eta \subseteq \mathfrak{p}$ a minimal prime. Then η is of irreducible type, so $\eta \in \mathcal{T} = \mathcal{G}$ by Step 5, and $\mathfrak{p}$ is $\mathcal{M}$-modular. For $n = 2$ this is item 1, and for $n = 3$ the first assertion of item 2.

Step 7: the off-triangular bound ($n = 3$). Put $I = \mathcal{M}_3 \cap I_3$. It is finite over the weights: if $\mathfrak{q}$ is a prime of W containing $I + \mathfrak{a}_3$, then $\mathcal{M}_3 I_3 \subseteq I \subseteq \mathfrak{q}$, so $\mathfrak{q} \supseteq \mathcal{M}_3 + \mathfrak{a}_3$ or $\mathfrak{q} \supseteq I_3 + \mathfrak{a}_3$, and in both cases $\mathfrak{q} \supseteq \mathfrak{m}_W$ because both ideals are finite over the weights; hence $\mathfrak{m}_W$ lies in the intersection of the primes containing $I + \mathfrak{a}_3$, which is $\sqrt{I + \mathfrak{a}_3}$. If $\mathfrak{p}$ is an off-triangular prime of E, it is of irreducible type, and then $\mathcal{M}_3 \subseteq \mathfrak{p} \cap W$ by Step 6, or of endoscopic type, and then $I_3 \subseteq \mathfrak{p} \cap W$; in both cases $I \subseteq \mathfrak{p} \cap W$. So I is an off-triangular bound. □

Proposition 49.13. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Call a prime x of E a* core prime *if $\mathfrak{m}_W \subseteq x$ and $I_E^- \not\subseteq x$. Then:*

(Eg1) *E is Noetherian;*

(Eg2) *every minimal prime η of E with $I_E^- \not\subseteq \eta$ is contained in a core prime that is a maximal ideal of E;*

(Eg3) *if $Z \subseteq \operatorname{Spec} E$ is closed, $U \subseteq \operatorname{Spec} E$ is open and $Z \cap U$ contains a core prime, then $Z \cap U$ contains a core prime that is a maximal ideal of E;*

(Eg4) *the set of core primes, with the topology induced from $\operatorname{Spec} E$, is connected or empty; and if $n = 3$, every core prime lies in the closure of the set of core primes x with $I_E^{\mathrm{odd}} \not\subseteq x$;*

(Eg5) *if $\mathfrak{z}$ is a prime of W and ξ a prime of E of irreducible type with $\mathfrak{z} \subseteq \xi \cap W$, there is a core prime x that is a maximal ideal of E such that for every local chart $(\mathcal{O}', R_x, \iota)$ at x there is a prime P of R_x of irreducible type with $\iota^{-1}(P) \cap W = \mathfrak{z}$ and $\dim R_x/P = \dim W/\mathfrak{z} + 1$.*

Proof. The proof uses only commutative algebra; in particular, no automorphy is used. Write $\rho = \rho^{\mathrm{u}}$. Every entry $\rho(\gamma)_{ab}$ lies in $\mathrm{gr}_{w_{n,a}-w_{n,b}}$, the weights of entries lie in $\{-2,\dots,2\}$, lower entries ($a > b$) have negative weight, and $\mathrm{gr}_i\mathrm{gr}_j \subseteq \mathrm{gr}_{i+j}$ by definition.

(Eg1). E is generated over W by the entries, hence by the modules gr_j, $|j| \le 2$, each finitely generated by (Gw3); so E is a W-algebra of finite type, and W is Noetherian by (Gw1). By Hilbert's basis theorem E is Noetherian.

(Eg3). The core primes are the points of $V(\mathfrak{m}_W E) \setminus V(I_E^-)$, and $V(\mathfrak{m}_W E)$ is homeomorphic to $\operatorname{Spec} \bar{E}$, $\bar{E} = E/\mathfrak{m}_W E$, a finitely generated algebra over the field $W/\mathfrak{m}_W$ by (Eg1), hence a Jacobson ring (Hilbert's Nullstellensatz; Atiyah–Macdonald, Chapter 5, Exercises 24–26). Let Z, U be as in (Eg3) and $p \in Z \cap U$ a core prime. The set $T = Z \cap V(\mathfrak{m}_W E) \cap U \cap (\operatorname{Spec} E \setminus V(I_E^-))$ contains p and is the intersection of a closed set $Y \ni p$ of $\operatorname{Spec} \bar{E}$ with an open set $\operatorname{Spec} \bar{E} \setminus V(\mathfrak{c})$, $\mathfrak{c} \not\subseteq p$. As $\bar{E}$ is Jacobson, p is the intersection of the maximal ideals containing it; if all of them contained $\mathfrak{c}$, so would p. So some maximal ideal $\mathfrak{n} \supseteq p$ of $\bar{E}$ lies outside $V(\mathfrak{c})$, and in Y since Y is closed; its preimage in E is a maximal ideal of E and a core prime in $Z \cap U$.

(Eg2). Let η be a minimal prime of E with $I_E^- \not\subseteq \eta$. By (Gw2) E is $\mathbb{Z}$-graded by the gr_j. For a prime $\mathfrak{p}$ of a $\mathbb{Z}$-graded ring, the ideal $\mathfrak{p}^*$ generated by the homogeneous elements of $\mathfrak{p}$ is prime (Bruns–Herzog [55], Lemma 1.5.6); as $\eta^* \subseteq \eta$ and η is minimal, $\eta = \eta^*$ is homogeneous. Suppose $I_E^- \subseteq \sqrt{\eta + \mathfrak{m}_W E}$. Since E is Noetherian, $(I_E^-)^M \subseteq \eta + \mathfrak{m}_W E$ for some $M \ge 1$. Let e be a lower entry, of weight $-q$ with $q \in \{1,2\}$, and $j = -2Mq$. A product of entries of weight $j \le -2M$ has at least M lower factors, because every factor has weight ≥ -2 and only lower factors have negative weight; so $\mathrm{gr}_j \subseteq (I_E^-)^M \subseteq \eta + \mathfrak{m}_W E$. Taking components of degree j, with η homogeneous and $(\mathfrak{m}_W E) \cap \mathrm{gr}_j = \mathfrak{m}_W \mathrm{gr}_j$ (as $\mathfrak{m}_W \subseteq \mathrm{gr}_0$ and the sum (Gw2) is direct), we get $\mathrm{gr}_j = (\eta \cap \mathrm{gr}_j) + \mathfrak{m}_W \mathrm{gr}_j$. By Nakayama's lemma for the finitely generated W-module $\mathrm{gr}_j/(\eta \cap \mathrm{gr}_j)$ ((Gw3); W is local), $\mathrm{gr}_j \subseteq \eta$; so $e^{2M} \in \mathrm{gr}_j \subseteq \eta$ and $e \in \eta$. Then every lower entry lies in η, i.e. $I_E^- \subseteq \eta$, a contradiction. Hence some prime $p \supseteq \eta + \mathfrak{m}_W E$ does not contain I_E^-: a core prime in $V(\eta)$. By (Eg3) with $Z = V(\eta)$ and $U = \operatorname{Spec} E$ there is a core prime containing η that is a maximal ideal of E.

(Eg4), (Eg5) are (Ck1), (Ck2) of Lemma 49.15. □

Lemma 49.14. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. For $j \in \mathbb{Z}$ let $\mathrm{gr}_j \subseteq E$ be the W-submodule generated by the products $\prod_{k=1}^{s} \rho^{\mathrm{u}}(\gamma_k)_{a_k b_k}$ with $s \ge 0$, $\gamma_k \in \Gamma_L^0$ and $\sum_k (w_{n,a_k} - w_{n,b_k}) = j$. Then:*

(Gw1) *W, with the maximal ideal $\mathfrak{m}_W$, is an object of $\mathrm{CNL}_{\mathcal{O}}$;*

(Gw2) *$E = \bigoplus_{j \in \mathbb{Z}} \mathrm{gr}_j$ as W-modules (the sum is direct), and $\mathrm{gr}_0 = W$;*

(Gw3) *each gr_j is a finitely generated W-module.*

Proof. The argument is commutative algebra; no automorphy is used, over L or over K. Write $R = R_n^{\mathrm{po}}$ with maximal ideal $\mathfrak{m}$, $\rho = \rho^{\mathrm{u}}$, $\psi_{v,a} = \psi_{v,a}^{\mathrm{u}}$, $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $[\,\cdot\,]\colon \mathbb{F}^\times \to \mathcal{O}^\times$ the Teichmüller lift (multiplicative), and W_0 for the $\mathcal{O}$-subalgebra of R generated by the weight-zero monomials and the values $\psi_{v,a}(g)$; so W is the set of $y \in R$ with $y \in W_0 + \mathfrak{m}^k$ for every k.

Step 1: the torus coaction. We have $R[[T]] \in \mathrm{CNL}_{\mathcal{O}}$. Let $D = \mathrm{diag}((1+T)^{w_{n,1}}, \dots, (1+T)^{w_{n,n}}) \in \mathrm{GL}_n(R[[T]])$. Then $(D\rho D^{-1}, (\psi_{v,a}))$ is a polarised ordinary lift of rank n over L to $R[[T]]$: (Po1) holds as D is constant; (Po2) because $J_n D^{-1} J_n = D$ (as $w_{n,n+1-a} = -w_{n,a}$), so ${J_n}^t (D\rho D^{-1}) J_n = D\, {J_n}^t \rho J_n\, D^{-1}$; (Po3) because conjugation by D multiplies the (a,b) entry by $(1+T)^{w_{n,a}-w_{n,b}}$; (Po4) because the $\psi_{v,a}$ are scalars; (Po5) because $D \equiv 1$. By the universal property there is a unique morphism $\tau\colon R \to R[[T]]$ of $\mathrm{CNL}_{\mathcal{O}}$ with $\tau(\rho(\gamma)_{ab}) = (1+T)^{w_{n,a}-w_{n,b}}\rho(\gamma)_{ab}$ and $\tau(\psi_{v,a}(g)) = \psi_{v,a}(g)$. In the language of Lemma 43.8, a product of entries of total weight j has torus weight j, and every element of W_0 has torus weight 0. Every $y \in W$ has torus weight 0: for $k \geq 1$ pick $w_k \in W_0$ with $y - w_k \in \mathfrak{m}^k$; then $\tau(y) - y = \tau(y - w_k) - (y - w_k) \in \mathfrak{m}_{R[[T]]}^k$ (τ is local), so $\tau(y) = y$ by Krull's intersection theorem.

Step 2: a weighted presentation. Let S be the set of triples (γ, a, b) ($\gamma \in \Gamma_L^0$, $1 \leq a, b \leq n$) and (v, a, g) ($v \mid \ell$, $1 \leq a \leq n$, $g \in D_v$), with $x_{\gamma,a,b} = \rho(\gamma)_{ab} - \delta_{ab}[\bar{\Psi}(\gamma)^{w_{n,a}}]$ of weight $w_{n,a} - w_{n,b} \in \{-2, \dots, 2\}$ and $x_{v,a,g} = \psi_{v,a}(g) - [\bar{\Psi}(g)^{w_{n,a}}]$ of weight 0. By (Po5) all x_s lie in $\mathfrak{m}$. Condition (Tc1) of Lemma 43.8: two morphisms $R \to B$ of $\mathrm{CNL}_{\mathcal{O}}$ that agree on all x_s agree on all entries and all $\psi_{v,a}(g)$ (they fix $\mathcal{O}$), hence give the same lift, hence are equal by the uniqueness in the universal property. Condition (Tc2) is Step 1 (constants have torus weight 0). So Lemma 43.8 gives a finite $\sigma \subseteq S$ and a surjection $\pi\colon P = \mathcal{O}[[X_s : s \in \sigma]] \to R$, $X_s \mapsto x_s$, such that every $y \in R$ of torus weight j lies in $\pi(P_j)$, where $P_j = \mathcal{O}[[X_\sigma]]_j$ ((Tp3)).

Step 3: the weight pieces of P. The set P_0 is a subring and $P_i P_j \subseteq P_{i+j}$. Let $E_j = \{m \in \mathbb{N}^\sigma : \mathrm{wt}(m) = j\}$. By Dickson's lemma the set of minimal elements (for the componentwise order) of $E_0 \setminus \{0\}$ is finite, say $m_1, \dots, m_k$, and it generates the monoid E_0: a non-zero $m \in E_0$ lies above some m_i, and $m - m_i \in E_0$ has smaller total degree. Choose for every $m \in E_0$ one $\kappa(m) \in \mathbb{N}^k$ with $m = \sum_i \kappa(m)_i m_i$; κ is injective. The continuous $\mathcal{O}$-algebra homomorphism $\phi\colon \mathcal{O}[[Y_1, \dots, Y_k]] \to P$, $Y_i \mapsto X^{m_i}$, maps onto P_0: its image lies in P_0, and $f = \sum_{m \in E_0} c_m X^m \in P_0$ is the image of $\sum_m c_m Y^{\kappa(m)}$. Hence $P_0 \cong \mathcal{O}[[Y]]/\ker\phi$ is a complete Noetherian local ring, $\mathcal{O} \to P_0$ is local and induces $\mathbb{F} \cong P_0/\mathfrak{m}_{P_0}$. Likewise the minimal elements $m_1', \dots, m_r'$ of E_j are finitely many, every $m \in E_j$ lies above one of them with difference in E_0, and grouping the terms of $f \in P_j$ accordingly gives $f = \sum_i X^{m_i'} f_i$ with $f_i \in P_0$: P_j is a finitely generated P_0-module.

Step 4: $W = \pi(P_0)$, and (Gw1). Let $f \in P_0$ and f_N the sum of its terms of total degree $< N$, a polynomial in P_0. Each monomial of f_N is a product of x_s of total weight 0; expanding the x_s (only those of weight 0 carry a constant), $\pi(f_N)$ is an $\mathcal{O}$-linear combination of products of entries and values $\psi_{v,a}(g)$ in which the weights of the entries add up to 0, so $\pi(f_N) \in W_0$; and $\pi(f) - \pi(f_N) \in \pi(\mathfrak{m}_P^N) \subseteq \mathfrak{m}^N$. Hence $\pi(f) \in W$. Conversely every $y \in W$ has torus weight 0 (Step 1), so $y \in \pi(P_0)$ (Step 2). Thus $W = \pi(P_0) \cong P_0/(P_0 \cap \ker\pi)$ is a complete Noetherian local ring with maximal ideal $\pi(\mathfrak{m}_{P_0})$; this ideal lies in $\mathfrak{m} \cap W = \mathfrak{m}_W$, and an element of W outside it is a unit of W, hence not in $\mathfrak{m}$; so $\mathfrak{m}_W$ is the maximal ideal of W, $\mathcal{O} \to W$ is local and $W/\mathfrak{m}_W \cong \mathbb{F}$. This is (Gw1).

Step 5: (Gw3). A product of entries of total weight j has torus weight j (Step 1), so lies in $\pi(P_j)$ (Step 2). As $\pi(P_0)\pi(P_j) \subseteq \pi(P_j)$, $\pi(P_j)$ is a W-module, finitely generated by Step 3, and it contains gr_j. Since W is Noetherian, gr_j is finitely generated.

Step 6: (Gw2). The weight-zero monomials lie in W and $1 \in \mathrm{gr}_0$ (the empty product), so $\mathrm{gr}_0 = W$. The ring E is the W-span of the products of entries, each of which lies in some gr_j; so $E = \sum_j \mathrm{gr}_j$. Every element of gr_j has torus weight j (τ is a ring homomorphism fixing W, Step 1). Let $y_j \in \mathrm{gr}_j$, $j \in J$ finite, with $\sum_j y_j = 0$; let $j_0 = \min J$, $K = \max J - j_0$ and $z_k = y_{j_0+k}$

($z_k = 0$ if $j_0 + k \notin J$). Applying τ and multiplying by $(1+T)^{-j_0}$,

$$\sum_{k=0}^{K} (1+T)^k z_k = 0 \quad \text{in } R[[T]], \qquad \text{so} \qquad \sum_{k=i}^{K} \binom{k}{i} z_k = 0 \quad (0 \le i \le K)$$

by comparing coefficients of T^i. For $i = K$ this gives $z_K = 0$, and by descending induction on i all $z_i = 0$. So the sum is direct. □

Lemma 49.15. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$, and call a prime x of E a core prime if $\mathfrak{m}_W \subseteq x$ and $I_E^- \not\subseteq x$. Then:*

(Ck1) *the set of core primes, with the topology induced from $\operatorname{Spec} E$, is connected or empty; and if $n = 3$, every core prime lies in the closure of the set of core primes x with $I_E^{\mathrm{odd}} \not\subseteq x$;*

(Ck2) *if $\mathfrak{z}$ is a prime of W and ξ a prime of E of irreducible type with $\mathfrak{z} \subseteq \xi \cap W$, there is a core prime x that is a maximal ideal of E such that for every local chart $(\mathcal{O}', R_x, \iota)$ at x there is a prime P of R_x of irreducible type with $\iota^{-1}(P) \cap W = \mathfrak{z}$ and $\dim R_x/P = \dim W/\mathfrak{z} + 1$.*

Proof. The argument is Galois cohomology of characters of Γ_L and commutative algebra; no automorphy is used, over L or over K. (Ar2) is used in both of its halves in rank 3: the class for $\bar\Psi^{-2}\eta_K$ gives the base point of Step 4, the class for $\bar\Psi^{-1}\eta_K$ the density of Step 5; in rank 2 only the first is used. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $\rho = \rho^{\mathrm{u}}$, $\mathfrak{m}$ for the maximal ideal of R_n^{po}, $\bar c = \pi_L(c)$, $\gamma^* = \bar c \gamma^{-1} \bar c$ for $\gamma \in \Gamma_L^0$, $\gamma_\star = \pi_L(g_\star) \in \Gamma_L^0$ (Af1), and U for the $n \times n$ matrix with entry 1 at $(n,1)$ and 0 elsewhere. As $\ell \mid M$, (Af2) gives $\pi_L(D_v) \subseteq \Gamma_L^0$; $\bar\Psi(c) = 1$ gives $\bar\Psi(\gamma^*) = \bar\Psi(\gamma)^{-1}$; and $\bar\Psi(\gamma_\star)^2 \neq 1$. The ring E is a W-algebra of finite type (generated by the gr_j, $|j| \le 2$, (Gw3)) and Noetherian ((Gw1)).

Step 0: core primes contain the upper entries. Let x be a core prime and $e_- = \rho(\gamma)_{ab} \notin x$ with $a > b$, of weight $-q < 0$. For an upper entry e_+ of weight $p > 0$, $e_+^q e_-^p$ is a weight-zero monomial with off-diagonal factors, so it lies in W and in $\mathfrak{m}$ (Po5): in $\mathfrak{m}_W \subseteq x$. Hence $e_+ \in x$, and $I_E^+ \subseteq x$. So the core primes are the primes containing $\mathfrak{m}_W E + I_E^+$ and not containing I_E^-.

Step 1: points from lower data. For a commutative $\mathbb{F}$-algebra $B \neq 0$, a *lower datum* over B is a map $\varrho\colon \Gamma_L^0 \to \mathrm{M}_n(B)$ such that: (L1) ϱ is multiplicative and each $\varrho(\gamma)$ is lower triangular with diagonal $\mathrm{diag}(\bar\Psi(\gamma)^{w_{n,1}}, \dots, \bar\Psi(\gamma)^{w_{n,n}})$; (L2) $\varrho(\gamma^*)_{ab} = \varrho(\gamma)_{n+1-b,n+1-a}$; (L3) $\varrho(\gamma_\star)_{ab} = \varrho(\gamma_\star^*)_{ab}$ for $a \neq b$; (L4) $\prod_{a=1}^n (\varrho(\pi_L(g_a)) - \bar\Psi(g_a)^{w_{n,a}}) = 0$ for $v \mid \ell$, $g_1, \dots, g_n \in D_v$ (product with $a = 1$ on the left); (L5) each entry function takes its values in a finite-dimensional $\mathbb{F}$-subspace of B and is locally constant. *Claim: there is exactly one ring homomorphism $\xi_\varrho\colon E \to B$ with $\xi_\varrho(\mathfrak{m}_W) = 0$ and $\xi_\varrho(\rho(\gamma)_{ab}) = \varrho(\gamma)_{ab}$ for all γ, a, b.* Existence: apply Lemma 49.16 with this B, $C = \mathbb{F} \subseteq B$ (an object of $\mathrm{CNL}_{\mathcal{O}}$ with $\mathfrak{m}_C = 0$), ϱ (invertible by (L1)) and $\psi_{v,a} = \bar\Psi^{w_{n,a}}|_{D_v}$: (Po2)–(Po4) are (L2)–(L4) ((Po2) by $(J_n {}^t X J_n)_{ab} = X_{n+1-b,n+1-a}$); (Cq1) and (Cq5) hold by (L1) and the choice of ψ; (Cq2) holds because a product of entries of total weight 0 with an off-diagonal factor has an upper factor, which is 0; (Cq3), (Cq4) are (L5). The resulting ξ kills $\mathfrak{m}_W$ since $\beta(\mathfrak{m}_W) \subseteq \mathfrak{m}_C = 0$. Uniqueness: on W every such homomorphism is $W \to W/\mathfrak{m}_W = \mathbb{F} \subseteq B$ (an $\mathcal{O}$-algebra map from $\mathbb{F}$ is unique), and E is generated over W by the entries. As upper entries go to 0, $\ker \xi_\varrho \supseteq \mathfrak{m}_W E + I_E^+$.

The tautological datum. Let x be a core prime and $\kappa = \kappa(x)$. The image ϱ_x of ρ in $\mathrm{M}_n(\kappa)$ is a lower datum over κ: (L1) by Step 0 and (Po5) ($\rho(\gamma)_{aa} \in W$ has residue $\bar\Psi(\gamma)^{w_{n,a}}$ and $\mathfrak{m}_W \subseteq x$); (L2)–(L4) by (Po2)–(Po4), the image of $\psi_{v,a}^{\mathrm{u}}(g) \in W$ being $\bar\Psi(g)^{w_{n,a}}$; (L5): an entry of weight j lies in gr_j, whose image in κ is the image of the finite-dimensional $\mathbb{F}$-space $\mathrm{gr}_j/\mathfrak{m}_W \mathrm{gr}_j$ ((Gw3));

by Chevalley's lemma Theorem B.154 ((Gw1); the $\mathfrak{m}^k \cap \mathrm{gr}_j$ decrease to 0) some $\mathfrak{m}^k \cap \mathrm{gr}_j$ lies in $\mathfrak{m}_W \mathrm{gr}_j$, and $\gamma \mapsto \rho(\gamma) \bmod \mathfrak{m}^k$ is locally constant (Po1). By uniqueness, ξ_{ϱ_x} is the map $E \to E/x \subseteq \kappa$; its kernel is x.

Step 2: operations on lower data. Let ϱ be a lower datum over B.

(a) *Scaling.* If $B = B_0[X]$ is a polynomial ring and ϱ comes from B_0, then $\varrho^{(X)}(\gamma)_{ab} = X^{w_{n,b}-w_{n,a}}\varrho(\gamma)_{ab}$ ($a \geq b$; the exponent is ≥ 0, and > 0 for $a > b$) is a lower datum over B: in $B[X^{-1}]$ it is $\Delta\varrho\Delta^{-1}$ with $\Delta = \mathrm{diag}(X^{-w_{n,a}})$, and $J_n\Delta^{-1}J_n = \Delta$; so (L1)–(L4) follow from those of ϱ, and (L5) is clear. At $X = 1$ it is ϱ; at $X = 0$ it is the diagonal datum $\varrho_{\mathrm{d}}(\gamma) = \mathrm{diag}(\bar{\Psi}(\gamma)^{w_{n,a}})$.

(b) *Corners.* Let $\beta\colon \Gamma_L^0 \to B$ be locally constant with values in a finite-dimensional $\mathbb{F}$-space. For a lower triangular matrix Y, $UY = Y_{11}U$, $YU = Y_{nn}U$ and $UYU = Y_{1n}U = 0$. Hence: $\varrho + \beta U$ is multiplicative if and only if $\beta(\gamma\gamma') = \beta(\gamma)\bar{\Psi}(\gamma') + \bar{\Psi}(\gamma)^{-1}\beta(\gamma')$; (L2) holds for $\varrho + \beta U$ if and only if $\beta(\gamma^*) = \beta(\gamma)$; (L3) is then automatic at $(n, 1)$; and in the expansion of the product (L4) for $\varrho + \beta U$ every term with two factors βU vanishes, while the terms with one such factor, at position i, equal $\beta(g_i)\prod_{a<i}(A_a)_{nn}\prod_{a>i}(A_a)_{11}\,U$, $A_a = \varrho(\pi_L(g_a)) - \bar{\Psi}(g_a)^{w_{n,a}}$: they depend only on the diagonals. Consequently: *if $\varrho_{\mathrm{d}} + \beta U$ and ϱ are lower data, so is $\varrho + \beta U$.* Moreover $\varrho_{\mathrm{d}} + \beta U$ is a lower datum if β satisfies the two identities above and $\beta(\pi_L(g)) = \lambda_v(\bar{\Psi}(g) - \bar{\Psi}(g)^{-1})$ on D_v for some $\lambda_v \in B$: then on $\pi_L(D_v)$, $\varrho_{\mathrm{d}} + \beta U = (1 + \lambda_v U)\varrho_{\mathrm{d}}(1 - \lambda_v U)$, and (L4) follows from the diagonal case by conjugation.

Step 3: two classes from (Ar2). Let χ be $\bar{\Psi}^{-2}\eta_K$ or $\bar{\Psi}^{-1}\eta_K$, a character of Γ_L with $\chi(\bar{c}) = -1$ and $\chi|_{\Gamma_L^0} = \bar{\Psi}^{-2}$, resp. $\bar{\Psi}^{-1}$; it is non-trivial on each $\pi_L(D_v)$ (Af4). By (Ar2) there is a strict continuous cocycle $y\colon \Gamma_L \to \mathbb{F}$ for χ whose class is non-zero; replacing y by $y + (g \mapsto (\chi(g)-1)\frac{y(\bar{c})}{2})$ we may assume $y(\bar{c}) = 0$ (ℓ odd), and $y \neq 0$. Then $y(\bar{c}\gamma\bar{c}) = -y(\gamma)$ and $y(\gamma^{-1}) = -\chi(\gamma)^{-1}y(\gamma)$, so $y(\gamma^*) = \chi(\gamma)^{-1}y(\gamma)$ for $\gamma \in \Gamma_L^0$; strictness gives X_v with $y(\pi_L(g)) = (\chi(g) - 1)X_v$ on D_v; and $y|_{\Gamma_L^0} \neq 0$ (otherwise $y(\gamma\bar{c}) = y(\gamma) + \chi(\gamma)y(\bar{c}) = 0$ too).

(a) For $\chi = \bar{\Psi}^{-2}\eta_K$ put $\beta_0 = \bar{\Psi} \cdot y|_{\Gamma_L^0}$. Then $\beta_0 \neq 0$, $\beta_0(\gamma\gamma') = \beta_0(\gamma)\bar{\Psi}(\gamma') + \bar{\Psi}(\gamma)^{-1}\beta_0(\gamma')$, $\beta_0(\gamma^*) = \beta_0(\gamma)$, and $\beta_0 = -X_v(\bar{\Psi} - \bar{\Psi}^{-1})$ on $\pi_L(D_v)$. By Step 2(b), for every $\mathbb{F}$-algebra B and $s \in B$, $\varrho_{\mathrm{d}} + s\beta_0 U$ is a lower datum over B.

(b) ($n = 3$.) For $\chi = \bar{\Psi}^{-1}\eta_K$ put $u = \bar{\Psi} \cdot y|_{\Gamma_L^0}$. Then $u \neq 0$, $u(\gamma\gamma') = u(\gamma)\bar{\Psi}(\gamma') + u(\gamma')$, $u(\gamma^*) = \bar{\Psi}(\gamma)^{-1}u(\gamma)$, and $u = \alpha_v(\bar{\Psi} - 1)$ on $\pi_L(D_v)$ with $\alpha_v = -X_v$.

Step 4: (Ck1), connectedness. Let $\mathcal{C}$ be the set of core primes, and $x_0 = \ker \xi_{\varrho_{\mathrm{d}}+\beta_0 U}$ over $B = \mathbb{F}$, a maximal ideal (the image is $\mathbb{F}$); x_0 contains $\mathfrak{m}_W$ and not the lower entry $\rho(\gamma)_{n1}$ with $\beta_0(\gamma) \neq 0$: $x_0 \in \mathcal{C}$. Let $x \in \mathcal{C}$, $\kappa = \kappa(x)$, and over $B = \kappa[X]$ let $\varrho_{\mathrm{line}} = \varrho_x^{(X)} + (1 - X)\beta_0 U$, a lower datum by Steps 2(a), 2(b), 3(a). Its kernel $\eta = \ker \xi_{\varrho_{\mathrm{line}}}$ is prime ($\kappa[X]$ is a domain). Composing with $X \mapsto 1$ gives a homomorphism with the properties of Step 1 for ϱ_x, hence equal to ξ_{ϱ_x}, so $\eta \subseteq x$; composing with $X \mapsto 0$ gives $\xi_{\varrho_{\mathrm{d}}+\beta_0 U}$ followed by $\mathbb{F} \subseteq \kappa$, so $\eta \subseteq x_0$. Also $\eta \supseteq \mathfrak{m}_W$ and $\eta \not\supseteq I_E^-$ (as $\eta \subseteq x$), so $\eta \in \mathcal{C}$. In $\mathrm{Spec}\, E$ the closure of $\{\eta\}$ is $V(\eta)$, which contains x and x_0; so x and x_0 lie in the closure of $\{\eta\}$ in $\mathcal{C}$, a connected set. Hence every point of $\mathcal{C}$ is in the connected component of x_0, and $\mathcal{C}$ is connected.

Step 5: (Ck1), density for $n = 3$. With u from Step 3(b), let $\varrho_u(\gamma)$ have rows $(\bar{\Psi}(\gamma), 0, 0)$, $(u(\gamma), 1, 0)$, $(\frac{1}{2}\bar{\Psi}(\gamma)^{-1}u(\gamma)^2,\ \bar{\Psi}(\gamma)^{-1}u(\gamma),\ \bar{\Psi}(\gamma)^{-1})$. It satisfies (L1), (L2), (L4), (L5), and on $\pi_L(D_v)$ it equals $n_v\varrho_{\mathrm{d}}n_v^{-1}$ with $n_v = 1 + \alpha_v(e_{21} + e_{32}) + \frac{1}{2}\alpha_v^2 e_{31}$ (e_{ab} the matrix units), which gives (L4).

Let $N = 1 + a(e_{21} - e_{32}) - \frac{a^2}{2}e_{31} = \exp(a(e_{21} - e_{32}))$ with $a = -u(\gamma_\star)/(\bar\Psi(\gamma_\star) + 1)$ ($\bar\Psi(\gamma_\star) \neq -1$). Since $(e_{21} - e_{32})J_3 + J_3{}^t(e_{21} - e_{32}) = 0$, $NJ_3{}^tN = J_3$, so $\varrho^\sharp = N\varrho_u N^{-1}$ satisfies (L1), (L2), (L4), (L5); its $(2,1)$ entry is $b^\sharp = u + a(\bar\Psi - 1)$, and (L3) reduces by (L2) to $b^\sharp(\gamma_\star) = b^\sharp(\gamma_\star^*)$, i.e. $u(\gamma_\star)(1-\bar\Psi(\gamma_\star)^{-1}) = -a(\bar\Psi(\gamma_\star) - \bar\Psi(\gamma_\star)^{-1})$, which holds by the choice of a. So $\varrho^\sharp$ is a lower datum over $\mathbb{F}$, and $b^\sharp \neq 0$: otherwise $u = a(1 - \bar\Psi)$, and $u(\gamma^*) = \bar\Psi(\gamma)^{-1}u(\gamma)$ gives $2a(1 - \bar\Psi(\gamma)^{-1}) = 0$ for all γ, so $a = 0$ and $u = 0$. Now let $x \in \mathcal{C}$ with $I_E^{\mathrm{odd}} \subseteq x$, $\kappa = \kappa(x)$. The odd lower entries vanish in ϱ_x, so $\varrho_x = \varrho_{\mathrm{d}} + e_x U$ with e_x its $(3,1)$ entry. Over $B = \kappa[X]$, $\varrho' = (\varrho^\sharp)^{(X)} + e_x U$ is a lower datum (Steps 2(a), 2(b)); its kernel η' is prime, $\eta' \subseteq x$ (at $X = 0$ it is ϱ_x), so $\eta' \in \mathcal{C}$, and $\eta' \not\supseteq I_E^{\mathrm{odd}}$ because $\xi_{\varrho'}(\rho(\gamma)_{21}) = Xb^\sharp(\gamma) \neq 0$ for some γ. As $x \in V(\eta')$, x lies in the closure of $\{\eta'\} \subseteq \{y \in \mathcal{C} : I_E^{\mathrm{odd}} \not\subseteq y\}$.

Step 6: (Ck2). Let $\mathfrak{z}$, ξ be as in (Ck2). (i) *A homogeneous prime over* $\mathfrak{z}$. By (Gw2), the degree-zero component of $\sum_i c_i y_i$ ($c_i \in \mathfrak{z}$, $y_i \in E$) is $\sum_i c_i(y_i)_0 \in \mathfrak{z}$; so $\mathfrak{z}E \cap W = \mathfrak{z}$ and $\mathfrak{z}E$ misses $W \setminus \mathfrak{z}$. An ideal maximal among those containing $\mathfrak{z}E$ and missing $W \setminus \mathfrak{z}$ is a prime Q with $Q \cap W = \mathfrak{z}$, and the ideal η generated by the homogeneous elements of Q is a prime (Bruns–Herzog [55], Lemma 1.5.6) with $\eta \cap W = \mathfrak{z}$ (it contains $\mathfrak{z}$ and lies in Q). (ii) η *is of irreducible type.* Let e_+ (weight $p > 0$), e_- (weight $-q < 0$) be an upper and a lower entry not in ξ. Then $e_+^q e_-^p \in W \setminus \xi \subseteq W \setminus \mathfrak{z}$, so $e_+^q e_-^p \notin \eta$ and $e_\pm \notin \eta$. If $n = 3$ and $o \notin \xi$ is an entry of odd weight j, then $o^p e_+^{-j}$ ($j < 0$) or $o^q e_-^j$ ($j > 0$) lies in $W \setminus \xi$, so $o \notin \eta$. (iii) $\mathrm{trdeg}_{\kappa(\mathfrak{z})}\,\kappa(\eta) = 1$. Every entry e of weight j satisfies $e \in W$, $e^q e_-^j \in W$ or $e^p e_+^{-j} \in W$ according as $j = 0$, $j > 0$, $j < 0$, and $e_+^q e_-^p \in W$; so the images of all entries in $\kappa(\eta)$, which generate it over $\kappa(\mathfrak{z})$, are algebraic over $\kappa(\mathfrak{z})(\bar e_-)$: the degree is ≤ 1. The domain E/η is graded with degree-zero part $W/\mathfrak{z}$; in a relation $\sum_i c_i \bar e_-^i = 0$, $c_i \in W/\mathfrak{z}$, the terms have distinct degrees $-iq$, so each vanishes and all $c_i = 0$: $\bar e_-$ is transcendental. (iv) *A maximal core prime above* η. Suppose $I_E^- \subseteq \sqrt{\eta + \mathfrak{m}_W E}$; then $(I_E^-)^M \subseteq \eta + \mathfrak{m}_W E$ for some M. For $j \leq -2M$, a product of entries of weight j has at least M lower factors (all weights are ≥ -2, only lower entries are negative), so $\mathrm{gr}_j \subseteq (\eta \cap \mathrm{gr}_j) + \mathfrak{m}_W \mathrm{gr}_j$ (degree-j components; η and $\mathfrak{m}_W E$ are homogeneous), and $\mathrm{gr}_j \subseteq \eta$ by Nakayama's lemma ((Gw3), W local). Then $e_-^{2M} \in \mathrm{gr}_{-2Mq} \subseteq \eta$, against (ii). So a prime $p \supseteq \eta + \mathfrak{m}_W E$ with $I_E^- \not\subseteq p$ exists. The ring $E/\mathfrak{m}_W E$ is of finite type over the field $\mathbb{F}$, hence Jacobson (Atiyah–Macdonald, Chapter 5, Exercises 24–26), so p is the intersection of the maximal ideals containing it, and one of them, x, does not contain I_E^-: a core prime that is a maximal ideal, with $\eta \subseteq x$, $x \cap W = \mathfrak{m}_W$, and E/x finite over $\mathbb{F}$ (Zariski's lemma). (v) *The prime of the chart.* Let $(\mathcal{O}', R, \iota)$ be a local chart at x, and E', $\mathfrak{x}'$ as in (Cx1), so $R = \widehat{A}$ with $A = E'_{\mathfrak{x}'}$. Let $h = \mathrm{ht}(x/\eta)$ and $\eta = \eta_0 \subsetneq \cdots \subsetneq \eta_h = x$ a chain of primes. The ring E' is free, hence flat, over E, so going down holds [166, Theorem 9.5]: there are primes $\mathfrak{x}' = \eta'_h \supsetneq \cdots \supsetneq \eta'_0$ of E' lying over the η_i; so $\mathrm{ht}(\mathfrak{x}'/\eta'_0) \geq h$. Put $\mathfrak{p} = \eta'_0 A$. Then $\dim R/\mathfrak{p}R = \dim A/\mathfrak{p} \geq h$ ($R/\mathfrak{p}R$ is the completion of $A/\mathfrak{p}$), and there is a minimal prime P of $\mathfrak{p}R$ with $\dim R/P = \dim R/\mathfrak{p}R$. As $R/\mathfrak{p}R$ is flat over $A/\mathfrak{p}$, going down shows $P \cap A = \mathfrak{p}$ (a strictly smaller contraction would give a prime strictly between $\mathfrak{p}R$ and P), so $\iota^{-1}(P) = \eta'_0 \cap E = \eta$ and $\iota^{-1}(P) \cap W = \mathfrak{z}$. The prime P is of irreducible type because I_R^-, I_R^+, I_R^{odd} are generated by the images under ι of the generators of I_E^-, I_E^+, I_E^{odd}, none of which is contained in η by (ii). Finally, $W/\mathfrak{z}$ is a quotient of the complete local ring W, hence universally catenary, and E/η is a domain of finite type over it; items 2 and 3 of Theorem B.155 for the prime x/η, which contracts to $\mathfrak{m}_W/\mathfrak{z}$, with $\mathrm{trdeg}_{\mathbb{F}}\, E/x = 0$ and (iii), give $h = \dim W/\mathfrak{z} + 1$. So $\dim R/P \geq \dim W/\mathfrak{z} + 1$, and $\dim R/P \leq \dim W/\mathfrak{z} + 1$ by Lemma 49.18 and (iii). □

Lemma 49.16. *Let L be a CM field satisfying (Af1) and (Af2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Let B be a commutative $\mathcal{O}$-algebra and $C \subseteq B$ an $\mathcal{O}$-subalgebra which, with a maximal ideal $\mathfrak{m}_C$, is an object of* $\mathrm{CNL}_{\mathcal{O}}$. *Let $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(B)$ and $\psi_{v,a}\colon D_v \to B^\times$ ($v \mid \ell$, $1 \leq a \leq n$)*

be homomorphisms satisfying (Po2)–(Po4) with the test ring replaced by B, and suppose:

(Cq1) *$\rho(\gamma)_{aa} \in C$ and $\rho(\gamma)_{aa} \equiv \bar{\Psi}(\gamma)^{w_{n,a}} \pmod{\mathfrak{m}_C}$ for all $\gamma \in \Gamma_L^0$ and $1 \le a \le n$;*

(Cq2) *every product $\prod_{k=1}^{s} \rho(\gamma_k)_{a_k b_k}$ with $\sum_k (w_{n,a_k} - w_{n,b_k}) = 0$ and $a_k \neq b_k$ for some k lies in $\mathfrak{m}_C$;*

(Cq3) *for $1 \le a, b \le n$ the C-submodule $M_{ab} \subseteq B$ generated by the $\rho(\gamma)_{ab}$, $\gamma \in \Gamma_L^0$, is finitely generated;*

(Cq4) *for $1 \le a, b \le n$ and $k \ge 1$ the map $\Gamma_L^0 \to M_{ab}/\mathfrak{m}_C^k M_{ab}$, $\gamma \mapsto \rho(\gamma)_{ab} + \mathfrak{m}_C^k M_{ab}$, is locally constant;*

(Cq5) *$\psi_{v,a}(g) \in C$ and $\psi_{v,a}(g) \equiv \bar{\Psi}(g)^{w_{n,a}} \pmod{\mathfrak{m}_C}$ for $g \in D_v$, and $g \mapsto \psi_{v,a}(g) \bmod \mathfrak{m}_C^k$ is locally constant on D_v for every $k \ge 1$.*

Then there are $\mathcal{O}$-algebra homomorphisms $\xi\colon E \to B$ and $\beta\colon W \to C$ with $\beta(\mathfrak{m}_W) \subseteq \mathfrak{m}_C$, $\xi(\rho^{\mathrm{u}}(\gamma)_{ab}) = \rho(\gamma)_{ab}$, $\xi(\psi^{\mathrm{u}}_{v,a}(g)) = \psi_{v,a}(g)$ and $\xi(y) = \beta(y)$ for all $\gamma \in \Gamma_L^0$, a, b, v, $g \in D_v$ and $y \in W$.

Proof. The idea is to undo the torus: conjugating ρ by $\mathrm{diag}(T^{w_{n,1}}, \dots, T^{w_{n,n}})$ over a Laurent polynomial ring gives a representation which is residually diagonal at a suitable maximal ideal, so the universal property of R_n^{po} applies at every finite level; evaluating at $T = 1$ returns ρ.

Step 1: the Laurent model. Let $B[T, T^{-1}]$ be the Laurent polynomial ring, $\tau = \mathrm{diag}(T^{w_{n,1}}, \dots, T^{w_{n,n}})$ and $\rho_T(\gamma) = \tau\rho(\gamma)\tau^{-1}$, so $\rho_T(\gamma)_{ab} = T^{w_{n,a}-w_{n,b}}\rho(\gamma)_{ab}$. For $j \in \mathbb{Z}$ let $P_j \subseteq B$ be the C-submodule generated by the products of entries of ρ of weight j (the empty product included in P_0). Let $B^\natural \subseteq B[T, T^{-1}]$ be the C-subalgebra generated by the entries of all $\rho_T(\gamma)$. A product of such entries is T^j times a product of entries of ρ of weight j, so

$$B^\natural = \bigoplus_{j \in \mathbb{Z}} T^j P_j, \qquad P_i P_j \subseteq P_{i+j}.$$

(a) $P_0 = C$: a product of weight 0 either has an off-diagonal factor, and lies in $\mathfrak{m}_C$ by (Cq2), or consists of diagonal entries, and lies in C by (Cq1); and $1 \in P_0$. (b) For $j \neq 0$, $P_j P_{-j} \subseteq \mathfrak{m}_C$: a product of weight $j \neq 0$ has an off-diagonal factor (diagonal entries have weight 0), so the product of a generator of P_j and one of P_{-j} has weight 0 and an off-diagonal factor, and lies in $\mathfrak{m}_C$ by (Cq2). (c) Put $\mathfrak{n} = \mathfrak{m}_C \oplus \bigoplus_{j \neq 0} T^j P_j$. By (a), (b) the degree-0 component of $(\sum_i T^i x_i)(\sum_j T^j y_j)$ with $y_0 \in \mathfrak{m}_C$ is $x_0 y_0 + \sum_{j \neq 0} x_{-j} y_j \in \mathfrak{m}_C$, so $\mathfrak{n}$ is an ideal; $B^\natural = C \oplus \bigoplus_{j \neq 0} T^j P_j$, so $B^\natural/\mathfrak{n} \cong C/\mathfrak{m}_C = \mathbb{F}_{\mathcal{O}}$, $\mathfrak{n}$ is maximal, and $\mathfrak{n} \cap C = \mathfrak{m}_C$. (d) $B^\natural$ is Noetherian: it is generated as a C-algebra by the elements $T^{w_{n,a}-w_{n,b}} m$, m in a finite generating set of M_{ab} (Cq3), and C is Noetherian (Hilbert's basis theorem). (e) $\bigcap_k \mathfrak{n}^k = 0$. The ideal $\mathfrak{n}$ is generated by elements homogeneous in T, hence so is $\mathfrak{n}^k$, and the homogeneous components of an element of $\mathfrak{n}^k$ lie in $\mathfrak{n}^k$. Let $y \in \bigcap_k \mathfrak{n}^k$ and $T^j y_j$ a component of y; it lies in $\bigcap_k \mathfrak{n}^k$, so by Krull's intersection theorem in the Noetherian ring $B^\natural$ (Atiyah–Macdonald, Theorem 10.17) there is $r \in \mathfrak{n}$ with $(1 - r)T^j y_j = 0$. The degree-j component of this is $(1 - r_0)y_j = 0$, with $r_0 \in \mathfrak{m}_C$ the degree-0 component of r; $1 - r_0$ is a unit of C, hence of B, so $y_j = 0$. Thus $y = 0$.

Step 2: lifts at finite levels. For $N \ge 0$ let $B_N = B^\natural/\mathfrak{n}^{N+1}$. It is a Noetherian local ring with nilpotent maximal ideal $\mathfrak{n}/\mathfrak{n}^{N+1}$ and residue field $\mathbb{F}_{\mathcal{O}}$, hence complete, and $\mathcal{O} \to C \to B_N$ is local; so $B_N \in \mathrm{CNL}_{\mathcal{O}}$. Let ρ_N, $\psi_{N,v,a}$ be the reductions of ρ_T and of $\psi_{v,a}$ (whose values lie in $C \subseteq B^\natural$ by (Cq5)) modulo $\mathfrak{n}^{N+1}$. They form a polarised ordinary lift of rank n over L to B_N:

- (Po2): $w_{n,n+1-a} = -w_{n,a}$ gives $J_n \tau J_n = \tau^{-1}$, so $\rho_T(\pi_L(cg^{-1}c)) = \tau J_n {}^t\rho(\pi_L(g)) J_n \tau^{-1} = J_n \tau^{-1} {}^t\rho(\pi_L(g))\, \tau J_n = J_n {}^t\rho_T(\pi_L(g))\, J_n$;

- (Po3), (Po4): the off-diagonal entries of $\rho_T(\pi_L(g_\star)) - \rho_T(\pi_L(cg_\star^{-1}c))$ are those of ρ times powers of T, and $\prod_a(\rho_T(\pi_L(g_a)) - \psi_{v,a}(g_a)) = \tau(\prod_a(\rho(\pi_L(g_a)) - \psi_{v,a}(g_a)))\tau^{-1} = 0$;
- (Po5): an off-diagonal entry $T^{w_{n,a}-w_{n,b}}\rho(\gamma)_{ab}$ has degree $w_{n,a} - w_{n,b} \neq 0$ (the weights are distinct), so lies in $\mathfrak{n}$; the diagonal entries and the $\psi_{v,a}(g)$ lie in C with the residues required, by (Cq1), (Cq5);
- (Po1): by (Cq4), for γ' near γ the difference $\rho(\gamma)_{ab} - \rho(\gamma')_{ab}$ lies in $\mathfrak{m}_C^k M_{ab}$, so $\rho_T(\gamma)_{ab} - \rho_T(\gamma')_{ab} \in \mathfrak{m}_C^k T^{w_{n,a}-w_{n,b}} M_{ab} \subseteq \mathfrak{n}^k$, because $T^{w_{n,a}-w_{n,b}} M_{ab} \subseteq B^\natural$ and $\mathfrak{m}_C \subseteq \mathfrak{n}$; likewise for $\psi_{v,a}$ by (Cq5).

By the universal property of R_n^{po} there is exactly one morphism $f_N\colon R_n^{\mathrm{po}} \to B_N$ of $\mathrm{CNL}_{\mathcal{O}}$ with $f_N \circ \rho^{\mathrm{u}} = \rho_N$ and $f_N \circ \psi_{v,a}^{\mathrm{u}} = \psi_{N,v,a}$. Composing f_{N+1} with $B_{N+1} \to B_N$ gives a morphism with the same property, so by uniqueness it is f_N. Since f_N is local, $f_N(\mathfrak{m}^{N+1}) = 0$, where $\mathfrak{m}$ is the maximal ideal of R_n^{po}.

Step 3: the weight-zero algebra goes to C. Let $W_0 \subseteq R_n^{\mathrm{po}}$ be the $\mathcal{O}$-subalgebra generated by the weight-zero products of entries of ρ^{u} and the $\psi_{v,a}^{\mathrm{u}}(g)$. Then $f_N(W_0)$ lies in the image of C in B_N: a weight-zero product goes to the class of T^0 times the corresponding product of entries of ρ, an element of $P_0 = C$ by Step 1 (a), and $\psi_{v,a}^{\mathrm{u}}(g)$ goes to the class of $\psi_{v,a}(g) \in C$. Put $\mathfrak{c}_N = \mathfrak{n}^{N+1} \cap C$, a decreasing sequence of ideals of C with $\bigcap_N \mathfrak{c}_N = 0$ by Step 1 (e). Let $y \in W$. For each N choose $y_N \in W_0$ with $y - y_N \in \mathfrak{m}^{N+1}$ (definition of W) and $c_N \in C$ with $f_N(y_N) = c_N + \mathfrak{n}^{N+1}$. Then $f_N(y) = f_N(y_N) = c_N + \mathfrak{n}^{N+1}$, and by the compatibility of Step 2, $c_M - c_N \in \mathfrak{c}_N$ for $M \geq N$. By Chevalley's lemma (Theorem B.154, applied to the module C over the complete Noetherian local ring C), for every k there is t with $\mathfrak{c}_t \subseteq \mathfrak{m}_C^k$; so (c_N) is a Cauchy sequence for the $\mathfrak{m}_C$-adic topology and converges to some $c \in C$. For fixed N and every k, $c - c_N = (c - c_M) + (c_M - c_N) \in \mathfrak{m}_C^k + \mathfrak{c}_N$ for M large, and $\bigcap_k(\mathfrak{m}_C^k + \mathfrak{c}_N) = \mathfrak{c}_N$ by Krull's intersection theorem in the Noetherian local ring $C/\mathfrak{c}_N$; so $f_N(y) = c + \mathfrak{n}^{N+1}$ for all N. Such a c is unique, since two of them differ by an element of $\bigcap_N \mathfrak{c}_N = 0$. Put $\beta(y) = c$. Uniqueness and the fact that the f_N are $\mathcal{O}$-algebra homomorphisms make β an $\mathcal{O}$-algebra homomorphism; if $y \in \mathfrak{m}_W$, then $f_0(y) = 0$, so $\beta(y) \in \mathfrak{n} \cap C = \mathfrak{m}_C$.

Step 4: the entry algebra goes to $B^\natural$. Let E' be the set of $y \in R_n^{\mathrm{po}}$ for which there is $z \in B^\natural$ with $f_N(y) = z + \mathfrak{n}^{N+1}$ for all N; such a z is unique by Step 1 (e). The set E' is an $\mathcal{O}$-subalgebra, it contains W (with $z = \beta(y)$, Step 3) and every entry $\rho^{\mathrm{u}}(\gamma)_{ab}$ (with $z = \rho_T(\gamma)_{ab}$), hence contains E, which is generated over W by these entries. The map $\xi_T\colon E \to B^\natural$, $y \mapsto z$, is an $\mathcal{O}$-algebra homomorphism with $\xi_T(\rho^{\mathrm{u}}(\gamma)_{ab}) = T^{w_{n,a}-w_{n,b}}\rho(\gamma)_{ab}$, $\xi_T(\psi_{v,a}^{\mathrm{u}}(g)) = \psi_{v,a}(g)$ and $\xi_T(y) = \beta(y)$ for $y \in W$.

Step 5: evaluation at $T = 1$. Let $\mathrm{ev}\colon B[T, T^{-1}] \to B$ be the B-algebra homomorphism with $T \mapsto 1$; it is the identity on C. Then $\xi = \mathrm{ev} \circ \xi_T$ and β have the stated properties. □

Lemma 49.17. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Let $\mathfrak{x}$ be a prime of E.*

(Cx1) *Let $(\mathcal{O}', R, \iota)$ be a local chart at $\mathfrak{x}$. Put $E' = \mathcal{O}' \otimes_{\mathcal{O}} E$, let $\theta\colon E' \to \mathbb{F}_{\mathcal{O}'}$ be the $\mathcal{O}'$-algebra homomorphism $a \otimes e \mapsto \bar{a} \cdot (\iota(e) \bmod \mathfrak{m}_R)$, $\mathfrak{x}' = \ker\theta$, and $\iota'\colon E' \to R$ the $\mathcal{O}'$-algebra homomorphism $a \otimes e \mapsto a\,\iota(e)$. Then E' is Noetherian, $\mathfrak{x}'$ is a maximal ideal of E' with $\{e \in E : 1 \otimes e \in \mathfrak{x}'\} = \mathfrak{x}$, and ι' induces an isomorphism from the $\mathfrak{x}'$-adic completion of the local ring $E'_{\mathfrak{x}'}$ onto R.*

(Cx2) *For every local chart $(\mathcal{O}', R, \iota)$ at $\mathfrak{x}$, R is a flat E-module through ι.*

(Cx3) *If $\mathfrak{x}$ is a maximal ideal of E with $\mathfrak{m}_W \subseteq \mathfrak{x}$, there is a local chart at $\mathfrak{x}$.*

Proof. The argument is commutative algebra; no automorphy is used, over L or over K.

Step 1: E is Noetherian and of finite type over W. Every entry $\rho^{\mathrm{u}}(\gamma)_{ab}$ lies in $\mathrm{gr}_{w_{n,a}-w_{n,b}}$ with $|w_{n,a}-w_{n,b}| \le 2$, so E is generated as a W-algebra by the modules gr_j, $|j| \le 2$, each finitely generated by (Gw3); W is Noetherian by (Gw1). Hence E is a W-algebra of finite type and Noetherian (Hilbert's basis theorem). For a coefficient ring $\mathcal{O}' \supseteq \mathcal{O}$ finite over $\mathcal{O}$, $\mathcal{O}'$ is a finitely generated torsion-free, hence free, module over the discrete valuation ring $\mathcal{O}$; so $E' = \mathcal{O}' \otimes_{\mathcal{O}} E$ is a free E-module of finite rank through $e \mapsto 1 \otimes e$, finite over E, and Noetherian.

Step 2: a universal property of completions. Let $\mathcal{O}'$ be a coefficient ring containing $\mathcal{O}$, finite over $\mathcal{O}$ with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}' = \mathfrak{m}_{\mathcal{O}'}$, let $\theta\colon E' \to \mathbb{F}_{\mathcal{O}'}$ be a surjective $\mathcal{O}'$-algebra homomorphism, $\mathfrak{x}' = \ker\theta$ (a maximal ideal), $A = E'_{\mathfrak{x}'}$, $\widehat{A}$ its $\mathfrak{x}'$-adic completion and $j\colon E \to \widehat{A}$ the composite $E \to E' \to A \to \widehat{A}$. Then $\widehat{A}$ is a complete Noetherian local ring with maximal ideal $\mathfrak{x}'\widehat{A}$ and residue field $E'/\mathfrak{x}' \cong \mathbb{F}_{\mathcal{O}'}$ through θ; as θ restricts to the residue map on $\mathcal{O}'$, $\widehat{A} \in \mathrm{CNL}_{\mathcal{O}'}$, and $j^{-1}(\mathfrak{m}_{\widehat{A}}) = \{e : \theta(1\otimes e) = 0\}$. We claim: for every $C \in \mathrm{CNL}_{\mathcal{O}'}$ and every $\mathcal{O}$-algebra homomorphism $f\colon E \to C$ with $(f(e) \bmod \mathfrak{m}_C) = \theta(1\otimes e)$ for all e, there is exactly one $\mathcal{O}'$-algebra homomorphism $h\colon \widehat{A} \to C$ with $h \circ j = f$. Existence: $f'(a\otimes e) = af(e)$ defines an $\mathcal{O}'$-algebra homomorphism $E' \to C$ whose reduction modulo $\mathfrak{m}_C$ is θ (both are $\mathcal{O}'$-linear and agree on $1\otimes E$); so $f'^{-1}(\mathfrak{m}_C) = \mathfrak{x}'$, f' maps $E' \setminus \mathfrak{x}'$ to units and extends to a local homomorphism $A \to C$; it maps $\mathfrak{x}'^k A$ into $\mathfrak{m}_C^k$, so it extends by continuity to $\widehat{A} \to C$, C being complete and separated. Uniqueness: let h be such a homomorphism. The kernel of $\widehat{A} \to C \to \mathbb{F}_{\mathcal{O}'}$ is a maximal ideal of the local ring $\widehat{A}$, so h is local and $h(\mathfrak{m}_{\widehat{A}}^k) \subseteq \mathfrak{m}_C^k$; thus h is continuous. On the image of E' it equals f' ($\mathcal{O}'$-linearity), hence on A (units), hence on $\widehat{A}$ by density.

Step 3: (Cx1). Let $(\mathcal{O}', R, \iota)$ be a local chart at $\mathfrak{x}$ and θ, $\mathfrak{x}'$, ι' as in (Cx1). The map θ is surjective since $\theta(a\otimes 1) = \bar{a}$, so $\mathfrak{x}'$ is maximal, and $1\otimes e \in \mathfrak{x}'$ if and only if $\iota(e) \in \mathfrak{m}_R$, i.e. $e \in \mathfrak{x}$. Apply Step 2 to this θ. The condition on f in Step 2 is exactly the condition in the definition of a local chart at $\mathfrak{x}$ for $(\mathcal{O}', R, \iota)$, because $\iota(e) \bmod \mathfrak{m}_R = \theta(1\otimes e)$. Taking $f = j$ in the property of R gives $h_1\colon R \to \widehat{A}$ with $h_1 \circ \iota = j$; taking $f = \iota$ in the property of $\widehat{A}$ gives $h_2\colon \widehat{A} \to R$ with $h_2 \circ j = \iota$. Then $h_2h_1 \circ \iota = \iota = \mathrm{id}_R \circ \iota$, so $h_2h_1 = \mathrm{id}_R$ by the uniqueness in the definition of a chart (with $C = R$, $f = \iota$), and $h_1h_2 = \mathrm{id}_{\widehat{A}}$ by the uniqueness of Step 2. Finally h_2 restricted to the image of E' is ι', as both are $\mathcal{O}'$-linear and agree on $1\otimes E$. So ι' maps $E' \setminus \mathfrak{x}'$ into $R^\times$ and induces the isomorphism h_2.

Step 4: (Cx2). By (Cx1), ι factors as $E \to E' \to E'_{\mathfrak{x}'} \to \widehat{E'_{\mathfrak{x}'}} \cong R$: a free extension (Step 1), a localisation, and the completion of a Noetherian local ring; free modules and localisations are flat, and the completion of a Noetherian local ring is flat over it [166, Theorem 8.8]; so R is flat over E.

Step 5: (Cx3). Let $\mathfrak{x}$ be maximal with $\mathfrak{m}_W \subseteq \mathfrak{x}$. The field $E/\mathfrak{x}$ is finitely generated as an algebra over $W/\mathfrak{m}_W = \mathbb{F}_{\mathcal{O}}$ (Step 1), hence a finite extension of degree f of $\mathbb{F}_{\mathcal{O}}$ (Zariski's lemma). Let $\mathcal{O}' \subset \overline{\mathbb{Q}}_\ell$ be the unramified extension of $\mathcal{O}$ of degree f, a coefficient ring finite over $\mathcal{O}$ with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}' = \mathfrak{m}_{\mathcal{O}'}$ and residue field of degree f over $\mathbb{F}_{\mathcal{O}}$, and fix an $\mathbb{F}_{\mathcal{O}}$-isomorphism $\lambda\colon E/\mathfrak{x} \to \mathbb{F}_{\mathcal{O}'}$. Then $\theta(a\otimes e) = \bar{a}\,\lambda(e \bmod \mathfrak{x})$ is a surjective $\mathcal{O}'$-algebra homomorphism $E' \to \mathbb{F}_{\mathcal{O}'}$, and with $\widehat{A}$, j as in Step 2, $j^{-1}(\mathfrak{m}_{\widehat{A}}) = \mathfrak{x}$ and the composite of j with $\widehat{A} \to \mathbb{F}_{\mathcal{O}'}$ is $e \mapsto \lambda(e \bmod \mathfrak{x})$. By Step 2, $(\mathcal{O}', \widehat{A}, j)$ is a local chart at $\mathfrak{x}$. □

Lemma 49.18. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Let $\mathfrak{x}$ be a prime of E and $(\mathcal{O}', R, \iota)$ a local chart at $\mathfrak{x}$. For every prime P of R, with $\eta = \iota^{-1}(P)$*

and $\mathfrak{q} = \eta \cap W$,

$$\dim R/P \;\leq\; \dim W/\mathfrak{q} + \operatorname{trdeg}_{\kappa(\mathfrak{q})} \kappa(\eta).$$

Proof. The argument is commutative algebra; no automorphy is used, over L or over K. Let P, $\eta = \iota^{-1}(P)$ and $\mathfrak{q} = \eta \cap W$ be as in the statement.

Step 1: passage to a localisation of a finite extension of E. Let $E' = \mathcal{O}' \otimes_{\mathcal{O}} E$, $\mathfrak{x}'$ and ι' be as in (Cx1); so E' is Noetherian, $\mathfrak{x}'$ is maximal, $A = E'_{\mathfrak{x}'}$ is a Noetherian local ring, and ι' induces an isomorphism $\widehat{A} \cong R$ of the $\mathfrak{x}'$-adic completion of A onto R, through which we identify the two. Put $\mathfrak{p}_A = P \cap A$ and $\mathfrak{p}' = \iota'^{-1}(P)$, primes of A and E' with $\mathfrak{p}' \subseteq \iota'^{-1}(\mathfrak{m}_R) = \mathfrak{x}'$ and $\mathfrak{p}_A = \mathfrak{p}'A$; and $\{e \in E : 1 \otimes e \in \mathfrak{p}'\} = \iota^{-1}(P) = \eta$, because $\iota(e) = \iota'(1 \otimes e)$. Since $P \supseteq \mathfrak{p}_A R$, and $R/\mathfrak{p}_A R \cong \widehat{A} \otimes_A A/\mathfrak{p}_A$ is the completion of the Noetherian local ring $A/\mathfrak{p}_A$, which has the same dimension (Atiyah–Macdonald, Proposition 10.13 and Corollary 11.19),

$$\dim R/P \leq \dim R/\mathfrak{p}_A R = \dim A/\mathfrak{p}_A = \operatorname{ht}(\mathfrak{x}'/\mathfrak{p}'),$$

the height of $\mathfrak{x}'/\mathfrak{p}'$ in $E'/\mathfrak{p}'$ (the last equality because $A/\mathfrak{p}_A$ is the localisation of $E'/\mathfrak{p}'$ at $\mathfrak{x}'/\mathfrak{p}'$).

Step 2: incomparability. The ring E' is a free E-module of finite rank through $e \mapsto 1 \otimes e$ ($\mathcal{O}'$ is finitely generated and torsion-free over the discrete valuation ring $\mathcal{O}$), so $E/\eta \to E'/\mathfrak{p}'$ is injective (Step 1) and integral. A strictly increasing chain of primes of $E'/\mathfrak{p}'$ ending at $\mathfrak{x}'/\mathfrak{p}'$ contracts to a strictly increasing chain of primes of E/η (incomparability, Atiyah–Macdonald, Corollary 5.9) ending at $\mathfrak{x}/\eta$, since $\{e : 1 \otimes e \in \mathfrak{x}'\} = \mathfrak{x}$ by (Cx1). Hence $\operatorname{ht}(\mathfrak{x}'/\mathfrak{p}') \leq \operatorname{ht}(\mathfrak{x}/\eta)$.

Step 3: the dimension inequality. The ring E is generated as a W-algebra by the finitely generated W-modules gr_j, $|j| \leq 2$ ((Gw3); every entry has weight in $\{-2, \dots, 2\}$), so E/η is a domain finitely generated as an algebra over its subring $W/\mathfrak{q}$, which is a Noetherian domain by (Gw1). The fraction fields of $W/\mathfrak{q}$ and E/η are $\kappa(\mathfrak{q})$ and $\kappa(\eta)$. Item 1 of Theorem B.155 for the prime $\mathfrak{x}/\eta$ of E/η, whose contraction to $W/\mathfrak{q}$ is $(\mathfrak{x} \cap W)/\mathfrak{q}$, gives

$$\operatorname{ht}(\mathfrak{x}/\eta) \leq \operatorname{ht}\big((\mathfrak{x} \cap W)/\mathfrak{q}\big) + \operatorname{trdeg}_{\kappa(\mathfrak{q})} \kappa(\eta) \leq \dim W/\mathfrak{q} + \operatorname{trdeg}_{\kappa(\mathfrak{q})} \kappa(\eta).$$

With Steps 1 and 2 this is the assertion. □

49.3 Local charts of the entry algebra at maximal core primes

This subsection constructs the local charts of the entry algebra at the maximal core primes and presents them (Proposition 49.19, Proposition 49.20); Theorem 49.12 uses them to bound the dimension of components from below. A chart represents the polarised ordinary lifts of its residual lift to rings of finite length (Lemma 49.24), so its tangent space is an ordinary Selmer group enlarged by the torus and its obstructions lie in a Borel cohomology group (Definition 49.22, Lemma 49.23). Mazur's relation count, in a graded form (Lemma 49.21), then gives a presentation with at most as many relations in each degree as the obstruction bound, and at the endoscopic core primes a presentation graded by parity. Ordinary flags over local rings are triangular with the prescribed diagonal (Lemma 49.25); this lemma is used again in Appendix E.

Proposition 49.19. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $E = E_n^{\mathrm{po}}$. Let x be a core prime of E that is a maximal ideal of E. Then:*

(Qc1) *there is a local chart at x;*

and for every local chart $(\mathcal{O}', R, \iota)$ at x:

(Qc2) *R is flat as an E-module through ι;*

(Qc3) *for every prime P of R: $I_R^- \subseteq P$ if and only if $I_E^- \subseteq \iota^{-1}(P)$, and likewise for I^+ and for I^{odd}; moreover $I_R^- = R$ and $I_R^+ \subseteq \mathfrak{m}_R$;*

(Qc4) *if $n = 2$, or $n = 3$ and $I_E^{\mathrm{odd}} \not\subseteq x$, there are integers $N, h \geq 0$ with $N \geq h + n\,d_L + 1$ and a surjective $\mathcal{O}'$-algebra homomorphism $\mathcal{O}'[[X_1, \ldots, X_N]] \to R$ whose kernel is generated by h elements;*

(Qc5) *for every $k \geq 1$ the maps $\gamma \mapsto \rho_x(\gamma) \bmod \mathfrak{m}_R^k$ on Γ_L^0 and $g \mapsto \psi_{x,v,a}(g) \bmod \mathfrak{m}_R^k$ on D_v ($v \mid \ell$, $1 \leq a \leq n$) are locally constant.*

Proof. The argument is commutative algebra; no automorphy is used, over L or over K. Write $W = W_n^{\mathrm{po}}$, $\rho = \rho^{\mathrm{u}}$ and $\mathfrak{m}$ for the maximal ideal of R_n^{po}. Since x is a core prime, $\mathfrak{m}_W \subseteq x = \iota^{-1}(\mathfrak{m}_R)$, so $\iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$.

(Qc1), (Qc2). x is a maximal ideal containing $\mathfrak{m}_W$, so a local chart exists by (Cx3); every local chart is flat over E by (Cx2).

(Qc3). The ideals I_R^-, I_R^+, I_R^{odd} are generated by the images under ι of the generators of I_E^-, I_E^+, I_E^{odd} (entries of the relevant positions). For a prime P of R, $I_R^- \subseteq P$ holds if and only if every such image lies in P, i.e. every generator lies in $\iota^{-1}(P)$, i.e. $I_E^- \subseteq \iota^{-1}(P)$; likewise for I^+ and I^{odd}. As x is a core prime, some lower entry e_- is not in $x = \iota^{-1}(\mathfrak{m}_R)$, so $\iota(e_-)$ is a unit and $I_R^- = R$. If e_- has weight $-q < 0$ and e_+ is an upper entry, of weight $p > 0$, then $e_+^q e_-^p$ is a weight-zero monomial with off-diagonal factors, hence an element of W with residue 0 (Po5), i.e. of $\mathfrak{m}_W \subseteq x$; as $e_- \notin x$, $e_+ \in x$. So every generator of I_R^+ lies in $\iota(x) \subseteq \mathfrak{m}_R$, and $I_R^+ \subseteq \mathfrak{m}_R$.

(Qc4) is (Qp1) of Proposition 49.20.

(Qc5). Let $1 \leq a, b \leq n$, $j = w_{n,a} - w_{n,b}$ and $k \geq 1$. The entries $\rho(\gamma)_{ab}$ lie in gr_j, a finitely generated module over the complete Noetherian local ring W ((Gw1), (Gw3)). The submodules $\mathfrak{m}^t \cap \mathrm{gr}_j$ decrease with intersection 0 (Krull's intersection theorem in R_n^{po}), so by Chevalley's lemma Theorem B.154 there is t with $\mathfrak{m}^t \cap \mathrm{gr}_j \subseteq \mathfrak{m}_W^k \mathrm{gr}_j$. By (Po1), $\gamma \mapsto \rho(\gamma) \bmod \mathfrak{m}^t$ is locally constant on Γ_L^0; hence so is $\gamma \mapsto \rho(\gamma)_{ab} \bmod \mathfrak{m}_W^k \mathrm{gr}_j$, and, as $\iota(\mathfrak{m}_W^k \mathrm{gr}_j) \subseteq \mathfrak{m}_R^k$, so is $\gamma \mapsto \rho_x(\gamma)_{ab} \bmod \mathfrak{m}_R^k$. The same argument with $\mathrm{gr}_0 = W \ni \psi_{v,a}^{\mathrm{u}}(g)$ and the local constancy of $\psi_{v,a}^{\mathrm{u}} \bmod \mathfrak{m}^t$ on D_v (Po1) gives the assertion for $\psi_{x,v,a}$. □

Proposition 49.20. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $E = E_n^{\mathrm{po}}$. Let x be a core prime of E that is a maximal ideal of E, and $(\mathcal{O}', R, \iota)$ a local chart at x.*

(Qp1) *If $n = 2$, or $n = 3$ and $I_E^{\mathrm{odd}} \not\subseteq x$, there are integers $N, h \geq 0$ with $N \geq h + n\,d_L + 1$ and a surjective $\mathcal{O}'$-algebra homomorphism $\mathcal{O}'[[X_1, \ldots, X_N]] \to R$ whose kernel is generated by h elements.*

(Qp2) *If $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$, there are integers $a, b, g \geq 0$ with $a \geq b + 3d_L + 1$ and a surjective $\mathcal{O}'$-algebra homomorphism $p\colon S = \mathcal{O}'[[Y_1, \ldots, Y_a, X_1, \ldots, X_g]] \to R$ with the following properties, where a power series is called* even *(resp.* odd*) if each of its monomials has even (resp. odd) total degree in $X_1, \ldots, X_g$:*

- **(Ep1)** *$\ker p$ is generated by even $F_1, \ldots, F_b \in S$ and odd $G_1, \ldots, G_g \in S$;*
- **(Ep2)** *for every $f \in \ker p$, the coefficients in f of the monomials Y_i and X_j lie in $\mathfrak{m}_{\mathcal{O}'}$;*

(Ep3) *for all* $\gamma \in \Gamma_L^0$ *and* $1 \le a', b' \le 3$, $\rho_x(\gamma)_{a'b'} = p(f)$ *for some* f *that is even if* $w_{3,a'} - w_{3,b'}$ *is even and odd otherwise; and for* $v \mid \ell$, $1 \le a' \le 3$, $g' \in D_v$, $\psi_{x,v,a'}(g') = p(f)$ *for some even* f*;*

(Ep4) I_R^{odd} *is the ideal generated by* $p(X_1), \dots, p(X_g)$.

Proof. The proof uses only Galois cohomology and commutative algebra; in particular, no automorphy over L or over K is used. Let ϖ be a uniformiser of $\mathcal{O}'$ and $\mathbb{F}'$ the residue field. For $y \in R$ let $[y] \in \mathcal{O}'$ be an element with the same residue.

Step 1: presentations by a basis of the cotangent space. (i) Let $y_1, \dots, y_m \in \mathfrak{m}_R$ have classes forming a basis of t_R^*, and $\Pi\colon \mathcal{O}'[[Z_1, \dots, Z_m]] \to R$ the continuous $\mathcal{O}'$-algebra homomorphism with $\Pi(Z_i) = y_i$. Then $\mathfrak{m}_R = \varpi R + \sum_i y_i R + \mathfrak{m}_R^2$, so Π is surjective by Nakayama's lemma and the complete Nakayama lemma [166, Thm. 8.4]; and its kernel is minimal in the sense of Lemma 49.21: if $f = c_0 + \sum_i c_i Z_i + q \in \ker\Pi$ with $q \in (Z)^2$, then $c_0 \in \mathfrak{m}_{\mathcal{O}'}$ (reduce modulo $\mathfrak{m}_R$) and $\sum_i c_i y_i \in \varpi R + \mathfrak{m}_R^2$, so all $c_i \in \mathfrak{m}_{\mathcal{O}'}$. (ii) The classes of the elements $\rho_x(\gamma)_{a'b'} - [\rho_x(\gamma)_{a'b'}]$ and $\psi_{x,v,a'}(g') - [\psi_{x,v,a'}(g')]$ span t_R^*: a linear form λ on t_R^* vanishing on them defines the homomorphism $R \to \mathbb{F}'[\varepsilon]$, $y \mapsto \bar{y} + \varepsilon\lambda(y - [y])$, which gives the same family in (Kr3) as $\lambda = 0$; by the injectivity in (Kr3), $\lambda = 0$.

Step 2: (Qp1). Let $N = \dim_{\mathbb{F}'} t_R^*$ and $\Pi\colon \mathcal{O}'[[X_1, \dots, X_N]] \to R$ as in Step 1 (i). Apply Lemma 49.21 with the trivial group $\mathsf{A} = \{0\}$ (every ring is graded, every homomorphism graded) and $d(0) = h_x^2$: (Ov) is (Kq2) in case (a). So $\ker\Pi$ is generated by $h \le h_x^2$ elements. By (Kq1) and (Kq3),

$$N \;\ge\; h_x^1 - h_x^0 + 1 \;\ge\; h_x^2 + n\,d_L + 1 \;\ge\; h + n\,d_L + 1.$$

This proves (Qp1) (for every maximal core prime; the hypothesis on I_E^{odd} in (Qp1) is not used).

Step 3: the parity presentation. Let $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$, θ the involution of (Kr4), $R^{\pm} = \{y \in R : \theta(y) = \pm y\}$, so $R = R^+ \oplus R^-$ (ℓ odd). By (Kr4) an odd entry $\rho_x(\gamma)_{a'b'}$ ($w_{3,a'} - w_{3,b'}$ odd) lies in R^-, and in $\mathfrak{m}_R$ since the odd entries of $\bar{\rho}_x$ vanish; even entries and the values $\psi_{x,v,a'}(g')$ lie in R^+, as do the constants $[\cdot]$. So the spanning set of Step 1 (ii) consists of elements of t_+^* (the even ones) and of t_-^* (the odd entries), and the odd entries span t_-^*, the even ones t_+^*. Let $a = \dim t_+^*$, $g = \dim t_-^*$; choose odd entries $x_1, \dots, x_g$ whose classes form a basis of t_-^*, and elements $y_1, \dots, y_a$ of the form $\rho_x(\gamma)_{a'b'} - [\rho_x(\gamma)_{a'b'}]$ ($w_{3,a'} - w_{3,b'}$ even) or $\psi_{x,v,a'}(g') - [\psi_{x,v,a'}(g')]$, whose classes form a basis of t_+^*. Let $S = \mathcal{O}'[[Y_1, \dots, Y_a, X_1, \dots, X_g]]$ and $p\colon S \to R$ with $p(Y_i) = y_i$, $p(X_j) = x_j$: surjective with minimal kernel by Step 1 (i), which is (Ep2). Weight Y_i by 0 and X_j by 1 in $\mathsf{A} = \mathbb{Z}/2\mathbb{Z}$; then S_0 and S_1 are the even and the odd power series of the statement. Let θ_S be the continuous $\mathcal{O}'$-algebra involution of S with $\theta_S(Y_i) = Y_i$, $\theta_S(X_j) = -X_j$; then $p \circ \theta_S = \theta \circ p$ (both are continuous and agree on the variables; θ is a local automorphism of R), and $f_{(0)} = \frac{1}{2}(f + \theta_S f)$, $f_{(1)} = \frac{1}{2}(f - \theta_S f)$. Hence $\ker p$ is homogeneous, and $p(S_0) = R^+$, $p(S_1) = R^-$.

Step 4: (Qp2). Apply Lemma 49.21 to p with $\mathsf{A} = \mathbb{Z}/2\mathbb{Z}$, $d(0) = h_{x,+}^2$, $d(1) = h_{x,-}^2$. To check (Ov), let $p'\colon C \to \bar{C}$, $I \subseteq C_e$ ($e \in \mathbb{Z}/2\mathbb{Z}$) and $\bar{\xi}$ be as there, and let θ_C, $\theta_{\bar{C}}$ act by $+1$ on the degree-0 part and by -1 on the degree-1 part: $\mathcal{O}'$-algebra involutions (the gradings are multiplicative and $\mathcal{O}'$ lies in degree 0), with $p' \circ \theta_C = \theta_{\bar{C}} \circ p'$ (p' graded), $\bar{\xi} \circ \theta = \theta_{\bar{C}} \circ \bar{\xi}$ ($\bar{\xi}$ maps $R^+ = p(S_0)$ and $R^- = p(S_1)$ into the degree 0 and 1 parts), and $\theta_C = \epsilon$ on I with $\epsilon = (-1)^e$. So (Kq2) in case (b) gives I' and ξ. Hence $\ker p$ is generated by even $F_1, \dots, F_b$ and odd $G_1, \dots, G_{g'}$ with $b \le h_{x,+}^2$ and $g' \le h_{x,-}^2$. By (Kq1) and (Kq3),

$$a \ge h_{x,+}^1 - h_{x,+}^0 + 1 \ge h_{x,+}^2 + 3d_L + 1 \ge b + 3d_L + 1, \qquad g \ge h_{x,-}^1 - h_{x,-}^0 \ge h_{x,-}^2 \ge g'.$$

Putting $G_j = 0$ (an odd power series: it has no monomials) for $g' < j \le g$ gives (Ep1) with exactly g odd generators. (Ep3): by (Kr4), $\rho_x(\gamma)_{a'b'} \in R^{(-1)^{w_{3,a'} - w_{3,b'}}}$, which is $p(S_0)$

or $p(S_1)$ accordingly, and $\psi_{x,v,a'}(g') \in R^+ = p(S_0)$. (Ep4): I_R^{odd} is generated by the odd entries; each $p(X_j) = x_j$ is one, and each odd entry lies in $R^- = p(S_1)$, while every odd power series is $\sum_j X_j f_j$ with $f_j \in S$ (every monomial of odd degree in the X_j contains some X_j); so $I_R^{\mathrm{odd}} = (p(X_1), \dots, p(X_g))$. □

Lemma 49.21. *Let $\mathcal{O}'$ be a coefficient ring with maximal ideal $\mathfrak{m}_{\mathcal{O}'}$ and residue field $\mathbb{F}'$, A an abelian group, σ a finite set with a map* $\mathrm{wt}\colon \sigma \to \mathsf{A}$*, and $P = \mathcal{O}'[[X_s : s \in \sigma]]$ with maximal ideal $\mathfrak{n}$. The* weight *of a monomial $\prod_s X_s^{m_s}$ is $\sum_s m_s \mathrm{wt}(s)$; for $f \in P$ and $a \in \mathsf{A}$, $f_{(a)}$ is the power series formed by the terms of f whose monomials have weight a, and $P_a = \{f \in P : f = f_{(a)}\}$; an ideal $\mathfrak{H}$ of P is* homogeneous *if $f_{(a)} \in \mathfrak{H}$ for all $f \in \mathfrak{H}$ and $a \in \mathsf{A}$. An* A-graded ring *is a ring C with additive subgroups C_a ($a \in \mathsf{A}$), all but finitely many zero, such that $C = \bigoplus_a C_a$ and $C_a C_b \subseteq C_{a+b}$; for an $\mathcal{O}'$-algebra C we require in addition that the image of $\mathcal{O}'$ lies in C_0. A homomorphism $q\colon C \to C'$ of A-graded rings is* graded *if $q(C_a) \subseteq C'_a$ for all a.*

Let $R \in \mathrm{CNL}_{\mathcal{O}'}$ and let $\Pi\colon P \to R$ be a surjective $\mathcal{O}'$-algebra homomorphism with $\Pi(X_s) \in \mathfrak{m}_R$ for all s, whose kernel $\mathfrak{J}$ is homogeneous and minimal*: for every $f \in \mathfrak{J}$ and $s \in \sigma$ the coefficient of X_s in f lies in $\mathfrak{m}_{\mathcal{O}'}$. A homomorphism $\xi\colon R \to C$ to an A-graded ring is* graded *if $\xi(\Pi(P_a)) \subseteq C_a$ for all a. Let $d\colon \mathsf{A} \to \mathbb{N}$ and suppose:*

(Ov) *for every $a \in \mathsf{A}$, every surjective graded $\mathcal{O}'$-algebra homomorphism $p\colon C \to \bar{C}$ between A-graded rings $C, \bar{C} \in \mathrm{CNL}_{\mathcal{O}'}$ of finite length whose kernel I satisfies $\mathfrak{m}_C I = 0$, $I \subseteq C_a$ and $\dim_{\mathbb{F}'} I > d(a)$, and every surjective graded $\mathcal{O}'$-algebra homomorphism $\bar{\xi}\colon R \to \bar{C}$, there are an ideal $I' \subseteq I$ of C with $\dim_{\mathbb{F}'} I/I' = 1$ and an $\mathcal{O}'$-algebra homomorphism $\xi\colon R \to C/I'$ whose composite with the projection $C/I' \to \bar{C}$ is $\bar{\xi}$.*

Then $\mathfrak{J}$ is generated by a family $(f_{a,i})_{a \in \mathsf{A},\, 1 \le i \le \mathrm{nf}(a)}$ with $f_{a,i} \in \mathfrak{J} \cap P_a$, where $\mathrm{nf}(a) \le d(a)$ for every a and $\mathrm{nf}(a) = 0$ for all but finitely many a.

Proof. Let ϖ be a uniformiser of $\mathcal{O}'$. The condition $\mathfrak{m}_C I = 0$ makes I a vector space over $C/\mathfrak{m}_C = \mathbb{F}'$.

Step 1: three facts on weights. (i) For $g \in P_b$ and $h \in P$ one has $(gh)_{(a)} = g\, h_{(a-b)}$ for all a. Hence an ideal generated by elements of single weights is homogeneous (for $\sum_k g_k h_k$ with $g_k \in P_{b_k}$ the weight-a component is $\sum_k g_k h_{k,(a-b_k)}$), and sums of homogeneous ideals are homogeneous. In particular $\mathfrak{n}^N$ is homogeneous (generated by the monomials $\varpi^e X^m$, $e + |m| = N$, each of a single weight), and so is $\mathfrak{n}\mathfrak{J}$: its elements are $\varpi F_0 + \sum_s X_s F_s$ with $F_0, F_s \in \mathfrak{J}$, with weight-$a$ component $\varpi F_{0,(a)} + \sum_s X_s F_{s,(a-\mathrm{wt}(s))} \in \mathfrak{n}\mathfrak{J}$, as $\mathfrak{J}$ is homogeneous. (ii) For $N \ge 1$ let $U_N \subseteq \mathsf{A}$ be the finite set of weights of the monomials X^m with $|m| < N$. For every $f \in P$, all monomials of $f - \sum_{a \in U_N} f_{(a)}$ have degree at least N, so $f - \sum_{a \in U_N} f_{(a)} \in \mathfrak{n}^N$; and $f_{(a)} \in \mathfrak{n}^N$ for $a \notin U_N$.

(iii) If $\mathfrak{H}$ is a homogeneous ideal, $B \subseteq \mathsf{A}$ is finite, $h_b \in P_b$ for $b \in B$ and $\sum_b h_b \in \mathfrak{H}$, then $h_b = (\sum_{b'} h_{b'})_{(b)} \in \mathfrak{H}$ for each b.

Step 2: the graded space of minimal relations. By the Artin–Rees lemma [166] there is $N_0 \ge 1$ with $\mathfrak{J} \cap \mathfrak{n}^{N_0} \subseteq \mathfrak{n}\mathfrak{J}$. Let $V = \mathfrak{J}/\mathfrak{n}\mathfrak{J}$, a finite-dimensional $\mathbb{F}'$-vector space ($\mathfrak{J}$ is finitely generated), and V_b the image of $\mathfrak{J} \cap P_b$. For $f \in \mathfrak{J}$ all $f_{(b)}$ lie in $\mathfrak{J}$, and by Step 1 (ii) $f - \sum_{b \in U_{N_0}} f_{(b)} \in \mathfrak{J} \cap \mathfrak{n}^{N_0} \subseteq \mathfrak{n}\mathfrak{J}$ and $V_b = 0$ for $b \notin U_{N_0}$. So the V_b span V, the image $\bar{f}$ of f is $\sum_{b \in U_{N_0}} \overline{f_{(b)}}$, and the sum $\sum_b V_b$ is direct by Step 1 (iii) applied to $\mathfrak{n}\mathfrak{J}$. Choose $f_{b,1}, \dots, f_{b,\mathrm{nf}(b)} \in \mathfrak{J} \cap P_b$ lifting a basis of V_b, $\mathrm{nf}(b) = \dim V_b$. Then $\mathfrak{J} = (f_{b,i})_{b,i} + \mathfrak{n}\mathfrak{J}$, so $\mathfrak{J} = (f_{b,i})_{b,i}$ by Nakayama's lemma, and $\mathrm{nf}(b) = 0$ for $b \notin U_{N_0}$. It remains to show $\dim V_a \le d(a)$ for every a. Suppose, to the contrary, that $\dim V_a > d(a)$ for some a.

Step 3: a graded small extension concentrated in weight a. Let $\mathfrak{W} \subseteq \mathfrak{J}$ be the preimage of $\bigoplus_{b \ne a} V_b$; it is an ideal of P containing $\mathfrak{n}\mathfrak{J}$. It is homogeneous: for $f \in \mathfrak{W}$ the V_a-component of

$\bar f$ is $\overline{f_{(a)}}$ (Step 2), so $f_{(a)} \in \mathfrak{n}\mathfrak{J} \subseteq \mathfrak{W}$, and $f_{(b)} \in \mathfrak{W}$ for $b \neq a$ since $\overline{f_{(b)}} \in V_b$. For every $f \in \mathfrak{J}$, $f - f_{(a)} \in \mathfrak{W}$; hence $\mathfrak{J} = \mathfrak{W} + (\mathfrak{J} \cap P_a)$. Also $\mathfrak{J} \cap (\mathfrak{W} + \mathfrak{n}^{N_0}) = \mathfrak{W} + (\mathfrak{J} \cap \mathfrak{n}^{N_0}) = \mathfrak{W}$, as $\mathfrak{W} \subseteq \mathfrak{J}$ and $\mathfrak{J} \cap \mathfrak{n}^{N_0} \subseteq \mathfrak{n}\mathfrak{J} \subseteq \mathfrak{W}$.

Put $C = P/(\mathfrak{W} + \mathfrak{n}^{N_0})$ and $\bar C = P/(\mathfrak{J} + \mathfrak{n}^{N_0})$: local rings of finite length with residue field $\mathbb{F}'$, objects of $\mathrm{CNL}_{\mathcal{O}'}$. Let C_b, $\bar C_b$ be the images of P_b. The two ideals are homogeneous (Step 1 (i)), so by Step 1 (ii) and (iii) $C = \bigoplus_{b \in U_{N_0}} C_b$ and $\bar C = \bigoplus_{b \in U_{N_0}} \bar C_b$; with $P_b P_{b'} \subseteq P_{b+b'}$ and $\mathcal{O}' \subseteq P_0$ these are A-graded $\mathcal{O}'$-algebras, and the projection $p\colon C \to \bar C$ is a surjective graded homomorphism. Its kernel I is the image of $\mathfrak{J}$, which is the image of $\mathfrak{J} \cap P_a$; so $I \subseteq C_a$. As $\mathfrak{n}\mathfrak{J} \subseteq \mathfrak{W}$, $\mathfrak{m}_C I = 0$. Finally $I \cong \mathfrak{J}/(\mathfrak{J} \cap (\mathfrak{W} + \mathfrak{n}^{N_0})) = \mathfrak{J}/\mathfrak{W} \cong V_a$, so $\dim_{\mathbb{F}'} I > d(a)$. Let $\bar\xi\colon R \to \bar C$ be the homomorphism induced by Π (as $R \cong P/\mathfrak{J}$); it is surjective and graded.

Step 4: the lift contradicts minimality. By (Ov) there are an ideal $I' \subseteq I$ with $\dim I/I' = 1$ and $\xi\colon R \to C' = C/I'$ with $(C' \to \bar C) \circ \xi = \bar\xi$. Let $\alpha\colon P \to C'$ be the projection and $\beta = \xi \circ \Pi$. Both composites with $C' \to \bar C$ are the projection $P \to \bar C$, so $\delta = \alpha - \beta$ takes values in I/I', which is killed by $\mathfrak{m}_{C'}$. Hence δ is $\mathcal{O}'$-linear and, writing $\bar f \in \mathbb{F}'$ for the residue of $f \in P$,

$$\delta(fh) = \alpha(f)\delta(h) + \beta(h)\delta(f) = \bar f\,\delta(h) + \bar h\,\delta(f) \qquad (f, h \in P).$$

Thus $\delta(1) = 0$, δ vanishes on $\mathcal{O}'$, on ϖP ($\delta(\varpi h) = \varpi\delta(h) = 0$) and on every $X_s X_t h$ (both residues $\bar X_s$, $\overline{X_t h}$ vanish). Let $f \in \mathfrak{J}$ and write $f = c + \sum_s c_s X_s + \sum_{s \le t} X_s X_t q_{st}$ with $c, c_s \in \mathcal{O}'$, $q_{st} \in P$. Reducing $\Pi(f) = 0$ modulo $\mathfrak{m}_R$ gives $c \in \mathfrak{m}_{\mathcal{O}'}$ (as $\Pi(X_s) \in \mathfrak{m}_R$), and $c_s \in \mathfrak{m}_{\mathcal{O}'}$ by minimality; so $\delta(f) = 0$. Also $\beta(f) = \xi(\Pi(f)) = 0$. Hence $\alpha(\mathfrak{J}) = 0$. But $\alpha(\mathfrak{J})$ is the image of I in C', namely $I/I' \neq 0$. This contradiction shows $\dim V_a \le d(a)$ for every a, and the family $(f_{a,i})$ of Step 2 has the asserted properties. □

Definition 49.22. Let L be a CM field satisfying (Af1) and (Af2) of Definition 48.2 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, and let $n \in \{2, 3\}$. Suppose that a universal polarised ordinary lift of rank n over L exists. Let x be a core prime of $E = E_n^{\mathrm{po}}$ that is a maximal ideal, let $(\mathcal{O}', R, \iota)$ be a local chart at x with residue field $\mathbb{F}'$, and let $\bar\rho_x\colon \Gamma_L^0 \to \mathrm{GL}_n(\mathbb{F}')$ and $\bar\psi_{x,v,a}\colon D_v \to \mathbb{F}'^{\times}$ be the reductions modulo $\mathfrak{m}_R$ of the chart lift. For $X \in \mathrm{M}_n(\mathbb{F}')$ write ${}^a X = J_n\,{}^t X\,J_n$ (the transpose in the antidiagonal). Put $\bar c = \pi_L(c)$; every element of Γ_L is uniquely γ or $\gamma\bar c$ with $\gamma \in \Gamma_L^0$.

The adjoint module. The module ad_x is the $\mathbb{F}'$-vector space $\mathrm{M}_n(\mathbb{F}')$ with the maps $X \mapsto g \cdot X$, $g \in \Gamma_L$, given for $\gamma \in \Gamma_L^0$ by

$$\gamma \cdot X = \bar\rho_x(\gamma)\,X\,\bar\rho_x(\gamma)^{-1}, \qquad (\gamma\bar c) \cdot X = -\bar\rho_x(\gamma)\,{}^a X\,\bar\rho_x(\gamma)^{-1}.$$

Borel subspaces. For a place $v \mid \ell$ of L^+, let $\mathfrak{b}_{x,v} \subseteq \mathrm{ad}_x$ be the set of X such that $P^{-1}XP$ is upper triangular for every $P \in \mathrm{GL}_n(\mathbb{F}')$ for which $P^{-1}\bar\rho_x(\pi_L(g))P$ is upper triangular with diagonal entries $\bar\psi_{x,v,1}(g), \dots, \bar\psi_{x,v,n}(g)$ for all $g \in D_v$. Write $\mathfrak{b}_x = (\mathfrak{b}_{x,v})_{v|\ell}$.

Parity parts. If $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$, put $t = \mathrm{diag}(-1, 1, -1)$,

$$\mathrm{ad}_x^{\pm} = \{X \in \mathrm{ad}_x :\ tXt^{-1} = \pm X\}, \qquad \mathfrak{b}_{x,v}^{\pm} = \mathfrak{b}_{x,v} \cap \mathrm{ad}_x^{\pm},$$

and $\mathfrak{b}_x^{\pm} = (\mathfrak{b}_{x,v}^{\pm})_{v|\ell}$; thus ad_x^{+} (resp. ad_x^{-}) consists of the matrices supported on the positions (a, b) with $w_{3,a} - w_{3,b}$ even (resp. odd).

Lemma 49.23. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $E = E_n^{\mathrm{po}}$. Let x be a core prime of E that is a maximal ideal, $(\mathcal{O}', R, \iota)$ a local chart at x, $\mathbb{F}'$ its residue field, and $t_R^* = \mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_{\mathcal{O}'}R)$. Call x* endoscopic *if $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$; then $t_\pm^* \subseteq t_R^*$ denote the ±1-eigenspaces of the involution induced by θ.*

(Kq0) *The maps of Definition 49.22 form a continuous $\mathbb{F}'$-linear action of Γ_L on ad_x with open kernel; each $\mathfrak{b}_{x,v}$ is stable under D_v (acting through π_L) and of dimension $n(n+1)/2$; if x is endoscopic, $\mathrm{ad}_x^{\pm}$ are Γ_L-stable and $\mathfrak{b}_{x,v}^{\pm}$ are D_v-stable. Hence the groups $H^i(\Gamma_L;\mathrm{ad}_x,\mathfrak{b}_x)$ and, if x is endoscopic, $H^i(\Gamma_L;\mathrm{ad}_x^{\pm},\mathfrak{b}_x^{\pm})$ ($i=0,1,2$; the $\mathbb{F}'$-spaces read as $\mathbb{F}_{\mathcal{O}}$-spaces) are defined; they are $\mathbb{F}'$-vector spaces, and h_x^i, $h_{x,\pm}^i$ denote their dimensions over $\mathbb{F}'$.*

(Kq1) $\dim_{\mathbb{F}'} t_R^* \geq h_x^1 - h_x^0 + 1$; *if x is endoscopic,* $\dim t_+^* \geq h_{x,+}^1 - h_{x,+}^0 + 1$ *and* $\dim t_-^* \geq h_{x,-}^1 - h_{x,-}^0$.

(Kq2) *Let $p\colon C \to \bar{C}$ be a surjective $\mathcal{O}'$-algebra homomorphism between rings $C, \bar{C} \in \mathrm{CNL}_{\mathcal{O}'}$ of finite length whose kernel I satisfies $\mathfrak{m}_C I = 0$, and $\bar{\xi}\colon R \to \bar{C}$ an $\mathcal{O}'$-algebra homomorphism. Suppose either (a) $d = h_x^2$, or (b) x is endoscopic, C and $\bar{C}$ carry $\mathcal{O}'$-algebra involutions θ_C, $\theta_{\bar{C}}$ with $p \circ \theta_C = \theta_{\bar{C}} \circ p$ and $\bar{\xi} \circ \theta = \theta_{\bar{C}} \circ \bar{\xi}$, $\theta_C(y) = \epsilon y$ for all $y \in I$ for some $\epsilon \in \{1,-1\}$, and $d = h_{x,+}^2$ if $\epsilon = 1$, $d = h_{x,-}^2$ if $\epsilon = -1$. If $\dim_{\mathbb{F}'} I > d$, there are an ideal $I' \subsetneq I$ of C with $\dim_{\mathbb{F}'} I/I' = 1$ and an $\mathcal{O}'$-algebra homomorphism $\xi\colon R \to C/I'$ whose composite with the projection $C/I' \to \bar{C}$ is $\bar{\xi}$.*

(Kq3) *These h^2 are finite, $h_x^1 - h_x^0 - h_x^2 \geq n\,d_L$, and, if x is endoscopic, $h_{x,+}^1 - h_{x,+}^0 - h_{x,+}^2 \geq 3d_L$ and $h_{x,-}^1 - h_{x,-}^0 - h_{x,-}^2 \geq 0$.*

Proof. The argument is Galois cohomology and commutative algebra; no automorphy is used, over L or over K. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $J = J_n$, $\bar{\rho} = \bar{\rho}_x$, $\bar{\psi}_{v,a} = \bar{\psi}_{x,v,a}$, $\bar{c} = \pi_L(c)$, ${}^aX = J\,{}^tX J$ for matrices over any ring; then ${}^a(XY) = {}^aY\,{}^aX$, ${}^a({}^aX) = X$. Let $\mathfrak{o} = \{Y \in \mathrm{M}_n(\mathbb{F}') : {}^aY = -Y\}$ and $\mathfrak{o}_{\mathrm{off}}$ its subspace of matrices with zero diagonal; as ^{a} maps the entry (a,b) to $(n+1-b, n+1-a)$, it preserves diagonal and off-diagonal positions, so $\mathfrak{o} = \mathfrak{o}_{\mathrm{diag}} \oplus \mathfrak{o}_{\mathrm{off}}$ with $\mathfrak{o}_{\mathrm{diag}} = \{\mathrm{diag}(y) : y_{n+1-a} = -y_a\}$ of dimension 1; $\dim \mathfrak{o} = n(n-1)/2$, so $\dim \mathfrak{o}_{\mathrm{off}} = n(n-1)/2 - 1$ (0 for $n=2$; for $n=3$, $\mathfrak{o}_{\mathrm{off}}$ is spanned by $e_{12} - e_{23}$ and $e_{21} - e_{32}$, both at odd positions). If x is endoscopic, t is as in Definition 49.22; otherwise put $t = 1$, $\theta = \mathrm{id}_R$ and $\mathrm{ad}_x^+ = \mathrm{ad}_x$, $\mathfrak{b}_{x,v}^+ = \mathfrak{b}_{x,v}$, so that case (a) of (Kq2) is the case $\epsilon = 1$ with trivial involutions. In all cases $t^{-1} = t$, $Jt = tJ$, hence ${}^a(tXt^{-1}) = t\,{}^aXt^{-1}$, and $\theta(\rho_x(\gamma)) = t\rho_x(\gamma)t^{-1}$ (entrywise) by (Kr4). Since L/L^+ is unramified at all finite places (Af2), $N_L \subseteq G_L$, so $\bar{c} \notin \Gamma_L^0$, $\bar{c}^2 = 1$ and $\Gamma_L = \Gamma_L^0 \rtimes \{1, \bar{c}\}$; and since every place $v \mid \ell$ splits in L ($\ell \mid M$, (Af2)), $\pi_L(D_v) \subseteq \Gamma_L^0$.

Step 1: polarised lifts are homomorphisms to a semidirect product; the action. For a commutative ring A let $\mathcal{G}(A) = \mathrm{GL}_n(A) \rtimes \{1, j\}$ with $jXj^{-1} = ({}^aX)^{-1}$ (an automorphism of order 2). For a homomorphism $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(A)$ let $r_\rho\colon \Gamma_L \to \mathcal{G}(A)$ be $r_\rho(\gamma) = \rho(\gamma)$, $r_\rho(\gamma\bar{c}) = \rho(\gamma)j$. As Γ_L is the semidirect product, r_ρ is a homomorphism if and only if $\rho(\bar{c}\gamma\bar{c}) = j\rho(\gamma)j^{-1} = ({}^a\rho(\gamma))^{-1}$ for all γ, i.e. (replacing γ by γ^{-1}) if and only if ρ satisfies (Po2). By (Kr2), $\bar{r} = r_{\bar{\rho}}$ is a homomorphism. For $X \in \mathrm{M}_n(\mathbb{F}')$, in $\mathcal{G}(\mathbb{F}'[\varepsilon])$ ($\varepsilon^2 = 0$) one has $\bar{r}(g)(1+\varepsilon X)\bar{r}(g)^{-1} = 1 + \varepsilon(g \cdot X)$ with $g \cdot X$ as in Definition 49.22 (for $g = \gamma\bar{c}$: $j(1+\varepsilon X)j^{-1} = ({}^a(1+\varepsilon X))^{-1} = 1 - \varepsilon\,{}^aX$). Conjugation being an action, $g \cdot X$ is an $\mathbb{F}'$-linear action; it is continuous with open kernel because $\bar{\rho}$ is locally constant (Kr2). More generally, if A is a local ring with residue field $\mathbb{F}'$, $I \subseteq A$ an ideal with $\mathfrak{m}_A I = 0$ (an $\mathbb{F}'$-vector space, $\mathrm{M}_n(I) = \mathrm{ad}_x \otimes_{\mathbb{F}'} I$), and $s \in \mathcal{G}(A)$ reduces to $\bar{r}(g)$, then

$$s(1+Y)s^{-1} = 1 + g \cdot Y, \qquad (1+Y)(1+Y') = 1 + Y + Y' \qquad (Y, Y' \in \mathrm{M}_n(I)), \tag{49.1}$$

g acting on the first factor of $\mathrm{ad}_x \otimes I$, because products of two elements of I vanish and conjugation by s on $\mathrm{M}_n(I)$ only depends on s modulo $\mathfrak{m}_A$.

Step 2: the module facts of (Kq0). (i) *Triangularisers.* Fix $v \mid \ell$. By (Af4) there is $h_v \in D_v$ with $\bar{\Psi}(h_v)^2 \neq 1$; as the exponents $w_{n,a}$ are $1, 0, -1$ or $1, -1$, the values $\bar{\Psi}(h_v)^{w_{n,a}} = \bar{\psi}_{v,a}(h_v)$ (Kr1) are pairwise distinct, and by (Kr1) $\bar{\rho}(\pi_L(h_v))$ is lower triangular with these diagonal

entries. By (Kr2), (Po4) holds for $(\bar\rho\circ\pi_L|_{D_v},\bar\psi_v)$. So (Fg2) (with $C=\mathbb{F}'$) gives P triangularising it; $U=P^{-1}\bar\rho(\pi_L(h_v))P$ is upper triangular with distinct diagonal entries, so $U=NDN^{-1}$ with D diagonal and N upper unitriangular, and $P_v=PN$ still triangularises (conjugation by N preserves upper triangularity and diagonals) and has eigenvectors of $\bar\rho(\pi_L(h_v))$ with distinct eigenvalues as columns. By (Fg3) every triangulariser is P_vB with B upper triangular, so $\mathfrak{b}_{x,v}=P_v\mathfrak{b}_nP_v^{-1}$, $\mathfrak{b}_n$ the upper triangular matrices: of dimension $n(n+1)/2$, and D_v-stable since $\bar\rho(\pi_L(g))P_vYP_v^{-1}\bar\rho(\pi_L(g))^{-1}=P_vU_gYU_g^{-1}P_v^{-1}$ with U_g upper triangular. (ii) *No invariants modulo* $\mathfrak{b}$. If $X\in\mathrm{ad}_x$ and $(g-1)X\in\mathfrak{b}_{x,v}$ for all $g\in D_v$, then $X\in\mathfrak{b}_{x,v}$. Indeed, with $X'=P_v^{-1}XP_v$ and $D=\mathrm{diag}(\bar\psi_{v,a}(h_v))$, $DX'D^{-1}-X'\in\mathfrak{b}_n$, and its (a,b)-entry for $a>b$ is $(\bar\psi_{v,a}(h_v)\bar\psi_{v,b}(h_v)^{-1}-1)X'_{ab}$, which forces $X'_{ab}=0$. (iii) $\mathrm{Hom}_{\Gamma_L}(\mathrm{ad}_x,\mathbb{F}(\bar\omega))=0$ ($\mathbb{F}$-linear maps). For $m\in\mathbb{Z}$ let F_m be the span of the matrix units e_{ab} with $a-b\geq m$. For lower triangular $Z\in\mathrm{GL}_n(\mathbb{F}')$, $Ze_{ab}Z^{-1}\in Z_{aa}(Z^{-1})_{bb}e_{ab}+F_{a-b+1}$; by (Kr1) the F_m are Γ_L^0-stable and γ acts on F_m/F_{m+1} by the scalars $\bar\Psi(\gamma)^{w_{n,a}-w_{n,b}}\in\mathbb{F}^\times$ on the lines $\mathbb{F}'e_{ab}$, $a-b=m$. If $f\neq0$ were a Γ_L-map to $\mathbb{F}(\bar\omega)$, take m maximal with $f(F_m)\neq0$ and $a-b=m$, $\lambda\in\mathbb{F}'$ with $f(\lambda e_{ab})\neq0$: then $\bar\omega(\gamma)f(\lambda e_{ab})=f(\gamma\cdot\lambda e_{ab})=\bar\Psi(\gamma)^{w_{n,a}-w_{n,b}}f(\lambda e_{ab})$, so $\bar\omega=\bar\Psi^{w_{n,a}-w_{n,b}}$ on G_L, contrary to (Ar1). (iv) *Parity.* If x is endoscopic, t commutes with $\bar\rho(\gamma)$ (Kr4) and ${}^a(tXt^{-1})=t\,{}^aXt^{-1}$, so $X\mapsto tXt^{-1}$ commutes with the action and $\mathrm{ad}_x^\pm$ are Γ_L-stable. The matrix t preserves the eigenlines of $\bar\rho(\pi_L(h_v))$, the columns of P_v, so $tP_v=P_vt'_v$ with $t'_v=\mathrm{diag}(s_1,s_2,s_3)$, $s_a=\pm1$; hence $t\mathfrak{b}_{x,v}t^{-1}=\mathfrak{b}_{x,v}$, $\mathfrak{b}_{x,v}=\mathfrak{b}^+_{x,v}\oplus\mathfrak{b}^-_{x,v}$, these are D_v-stable, and (ii) holds for them. As $\mathrm{tr}\,t'_v=\mathrm{tr}\,t=-1$, exactly one s_a is $+1$; $P_v^{-1}\mathfrak{b}^\pm_{x,v}P_v$ consists of the upper triangular matrices supported where $s_as_b=\pm1$, so $\dim\mathfrak{b}^+_{x,v}=3+1=4$, $\dim\mathfrak{b}^-_{x,v}=2$, while $\dim\mathrm{ad}_x^+=5$, $\dim\mathrm{ad}_x^-=4$. A Γ_L-map $\mathrm{ad}_x^\pm\to\mathbb{F}(\bar\omega)$ composed with the equivariant projection $X\mapsto\frac12(X\pm tXt^{-1})$ is a map from ad_x, so it vanishes by (iii). (v) *Complex conjugations.* Let $g=\gamma\bar c\in\Gamma_L$ with $g^2=1$, $B=\bar\rho(\gamma)$. Then $\bar r(g)^2=B({}^aB)^{-1}=1$, so ${}^aB=B$ and $S=BJ$ is symmetric (${}^tS=J\,{}^tB=({}^aB)J=S$). With $B^{-1}=JS^{-1}$, $g\cdot X=-BJ\,{}^tXJB^{-1}=-S\,{}^tXS^{-1}$, so $g\cdot X=X$ if and only if XS is antisymmetric: $\dim\mathrm{ad}_x^{g=1}=n(n-1)/2$. If x is endoscopic, $tB=Bt$ and $tJ=Jt$ give $tSt^{-1}=S$, so $X\in\mathrm{ad}_x^\pm$ iff $t(XS)t^{-1}=\pm XS$; the antisymmetric 3×3 matrices supported at $(1,3)$ are even and those at $(1,2),(2,3)$ odd, so $\dim(\mathrm{ad}_x^+)^{g=1}=1$, $\dim(\mathrm{ad}_x^-)^{g=1}=2$. This applies to $g=\bar c$ and to $g=\pi_L(c_u)$ for every real place u of L^+ ($c_u\notin G_L$ as L is CM, and $c_u^2=1$). This proves (Kq0); the groups H^i are $\mathbb{F}'$-spaces since all cochain spaces in their definition are, and their $\mathbb{F}$-dimensions are $[\mathbb{F}':\mathbb{F}]$ times their $\mathbb{F}'$-dimensions.

Step 3: Selmer cocycles. Let $(W,\mathfrak{b}_W)$ be $(\mathrm{ad}_x,\mathfrak{b}_x)$ or $(\mathrm{ad}_x^\pm,\mathfrak{b}_x^\pm)$, and Z_W the space of continuous cocycles $z\in Z^1(\Gamma_L,W)$ such that for every $v\mid\ell$ there is $X_v\in W$ with $z(\pi_L(h))-(h-1)X_v\in\mathfrak{b}_{W,v}$ for all $h\in D_v$. Then

$$\dim Z_W=h^1(\Gamma_L;W,\mathfrak{b}_W)+\dim W-h^0(\Gamma_L;W,\mathfrak{b}_W)\qquad\text{(dimensions over }\mathbb{F}').$$

Indeed, H^1 is the quotient of the space $\mathcal{Z}$ of pairs $(z,(X_v))$ as above by $\mathcal{B}=\{((g-1)X,(X_v)):X\in W,\ X_v-X\in\mathfrak{b}_{W,v}\}$. The fibres of $\mathcal{Z}\to Z_W$ are cosets of $\prod_v\{\Delta:(h-1)\Delta\in\mathfrak{b}_{W,v}\ \forall h\in D_v\}=\prod_v\mathfrak{b}_{W,v}$ (Step 2 (ii), (iv)), so $\dim\mathcal{Z}=\dim Z_W+\sum_v\dim\mathfrak{b}_{W,v}$; and $(X,(\beta_v))\mapsto((g-1)X,(X+\beta_v))$ maps $W\times\prod_v\mathfrak{b}_{W,v}$ onto $\mathcal{B}$ with kernel $\{(X,(-X)):X\in W^{\Gamma_L}\cap\bigcap_v\mathfrak{b}_{W,v}\}\cong H^0(\Gamma_L;W,\mathfrak{b}_W)$. Moreover the map $z\mapsto z(\bar c)$ sends Z_W onto $W^{\bar c=-1}$: $z(\bar c^2)=0$ gives $\bar c\cdot z(\bar c)=-z(\bar c)$, and the coboundary of $-\frac12Y$ (which lies in Z_W with $X_v=-\frac12Y$) takes the value Y at $\bar c$ for $Y\in W^{\bar c=-1}$. So, by Step 2 (v) with $g=\bar c$,

$$\dim\{z\in Z_W:z(\bar c)=0\}=h^1-h^0+\dim W^{\bar c=1}=h^1-h^0+\begin{cases}n(n-1)/2 & (W=\mathrm{ad}_x),\\ 1 & (W=\mathrm{ad}_x^+),\\ 2 & (W=\mathrm{ad}_x^-).\end{cases}\tag{49.2}$$

Step 4: the tangent space, (Kq1). The $\mathcal{O}'$-algebra homomorphisms $R\to\mathbb{F}'[\varepsilon]$ form an $\mathbb{F}'$-

vector space T dual to t_R^* ($h \mapsto$ the form $y \mapsto \varepsilon$-coefficient of $h(y)$ on $\mathfrak{m}_R$; classical), and θ acts on both compatibly, so $\dim t_\pm^* = \dim T^\pm$, where $T^\pm$ are the ±1-eigenspaces of the involution $h \mapsto h \circ \theta$ of T. By (Kr3), $h \in T$ corresponds to a family (ρ, ψ) over $\mathbb{F}'[\varepsilon]$ lifting $(\bar\rho, \bar\psi)$ with (Po1)–(Po4); write $\rho(\gamma) = (1+\varepsilon z_h(\gamma))\bar\rho(\gamma)$ and $z_h(\gamma\bar c) = z_h(\gamma)$, so that $r_\rho(g) = (1+\varepsilon z_h(g))\bar r(g)$ for all $g \in \Gamma_L$. The map $h \mapsto z_h$ is $\mathbb{F}'$-linear (the entries of ρ are those of $h \circ \rho_x$, linear in the form of h), and $z_{h\circ\theta} = t z_h t^{-1}$. By Step 1 and (49.1), r_ρ is a homomorphism iff z_h is a cocycle; (Po1) says z_h is continuous; and $z_h(\bar c) = 0$. *Marking.* Let $\bar A = \bar\rho(\pi_L(g_\star))$ and $A = \rho(\pi_L(g_\star))$. By (Po2), $\rho(\pi_L(c g_\star^{-1} c)) = {}^a A$, so (Po3) says that $A - {}^aA$ has zero off-diagonal entries; this holds for $\bar A$ (Kr2). With $z = z_h(\pi_L(g_\star))$, $A - {}^aA = \bar A - {}^a\bar A + \varepsilon(z\bar A - {}^a(z\bar A))$, and $z\bar A - {}^a(z\bar A) \in \mathfrak{o}$; so (Po3) is $\mu(z) = 0$ for the linear map $\mu\colon \mathrm{ad}_x \to \mathfrak{o}_{\mathrm{off}}$, $\mu(X) =$ off-diagonal part of $X\bar A - {}^a(X\bar A)$. If x is endoscopic, $\bar A$ commutes with t and $\mu(tXt^{-1}) = t\mu(X)t^{-1}$, so $\mu(\mathrm{ad}_x^+) \subseteq \mathfrak{o}_{\mathrm{off}} \cap \mathrm{ad}_x^+ = 0$. *Ordinarity.* Fix v. Over $C = \mathbb{F}'[\varepsilon]$, $(\rho \circ \pi_L|_{D_v}, \psi_v)$ satisfies the hypotheses on h_v in (Fg2) (residually distinct, residual characteristic polynomial by (Kr1)); so (Po4) at v holds iff some $Q \in \mathrm{GL}_n(\mathbb{F}'[\varepsilon])$ triangularises it ((Fg1), (Fg2)). Then $\bar Q = P_v B$ with B upper triangular (Fg3), and QB^{-1} triangularises too, so we may take $Q = (1 - \varepsilon X_v)P_v$. Then

$$Q^{-1}\rho(\pi_L(h))Q = \big(1 + \varepsilon P_v^{-1}(z_h(\pi_L(h)) - (h-1)X_v)P_v\big)U_h, \qquad U_h = P_v^{-1}\bar\rho(\pi_L(h))P_v,$$

which is upper triangular iff $z_h(\pi_L(h)) - (h-1)X_v \in \mathfrak{b}_{x,v}$, and then its diagonal determines ψ_v. Two choices of X_v differ by an element of $\mathfrak{b}_{x,v}$ (Step 2 (ii)), which changes $P_v^{-1}(\cdot)P_v$ by $U_h Y U_h^{-1} - Y$ with Y upper triangular, of zero diagonal; so ψ is determined by z_h. *Conclusion.* Conversely, for a continuous cocycle z with $z(\bar c) = 0$, $\mu(z(\pi_L(g_\star))) = 0$ and X_v as above, $\rho = (1+\varepsilon z)\bar\rho$ with ψ_v the diagonal of $Q^{-1}\rho Q$ (homomorphisms, as diagonals of a triangular representation) satisfies (Po1)–(Po4) by the same computations and (Fg1). So $h \mapsto z_h$ is an $\mathbb{F}'$-linear isomorphism of T onto $\{z \in Z_{\mathrm{ad}_x} : z(\bar c) = 0,\ \mu(z(\pi_L(g_\star))) = 0\}$, and of $T^\pm$ onto the same space formed with $Z_{\mathrm{ad}_x^\pm}$ (a cocycle with values in $\mathrm{ad}_x^\pm$ admits $X_v \in \mathrm{ad}_x^\pm$: project X_v by $X \mapsto \frac12(X \pm tXt^{-1})$, which preserves $\mathfrak{b}_{x,v}$ and commutes with D_v). By (49.2) and $\dim \mathfrak{o}_{\mathrm{off}} = n(n-1)/2 - 1$: $\dim T \ge h_x^1 - h_x^0 + 1$; $\dim T^+ \ge h_{x,+}^1 - h_{x,+}^0 + 1$ (no marking condition in ad_x^+); $\dim T^- \ge h_{x,-}^1 - h_{x,-}^0 + 2 - 2$. This is (Kq1).

Step 5: the obstruction, (Kq2). In case (a) put $\theta_C = \mathrm{id}$, $\theta_{\bar C} = \mathrm{id}$, $\epsilon = 1$. Let $(\bar\rho', \bar\psi') = (\bar\xi \circ \rho_x, \bar\xi \circ \psi_x)$, a family over $\bar C$ as in (Kr3), with $\theta_{\bar C}(\bar\rho'(\gamma)) = t\bar\rho'(\gamma)t^{-1}$ and $\theta_{\bar C}(\bar\psi') = \bar\psi'$, and $\bar r' = r_{\bar\rho'}$. On $\mathcal{G}(C)$ let τ be the involution $X \mapsto t^{-1}\theta_C(X)t$ (entrywise), $j \mapsto j$ (it respects $jXj^{-1} = ({}^aX)^{-1}$ by $Jt = tJ$); likewise on $\mathcal{G}(\bar C)$. On $\mathrm{M}_n(I) = \mathrm{ad}_x \otimes I$, $\tau(Y) = \epsilon\, t^{-1}Yt$, so the τ-fixed elements are $\mathrm{ad}_x^\epsilon \otimes I$. Since ℓ is odd, a lift s of a τ-fixed element can be replaced by the lift $\frac12(s + \tau(s))$, which is τ-fixed (*averaging*). The rings C, $\bar C$ are finite. (i) *Global cochain.* Let $U \subseteq \Gamma_L^0$ be an open normal subgroup on which $\bar\rho'$ is trivial; choose lifts in $\mathrm{GL}_n(C)$ of $\bar\rho'$ on the cosets of U, equal to 1 on U, average them, and extend by $\sigma(\gamma\bar c) = \sigma(\gamma)j$: a locally constant τ-fixed map $\sigma\colon \Gamma_L \to \mathcal{G}(C)$ lifting $\bar r'$ with $\sigma(1) = 1$, $\sigma(\bar c) = j$. Define k by $\sigma(g)\sigma(g')\sigma(gg')^{-1} = 1 + k(g,g')$; then k is continuous with values in $\mathrm{ad}_x^\epsilon \otimes I$, and expanding $\sigma(g)\sigma(g')\sigma(g'')$ in two ways with (49.1) gives $k(g,g') + k(gg',g'') = g \cdot k(g',g'') + k(g,g'g'')$: k is a 2-cocycle. (ii) *Local cochains.* Fix v and P_v, t_v' as in Step 2 ($t_v' = 1$ in case (a)), and for a matrix Q over C or $\bar C$ put $Q^\tau = t^{-1}\theta(Q)t_v'$, an involution. By (Fg2) over $\bar C$ some $\bar Q$ triangularises $(\bar\rho' \circ \pi_L|_{D_v}, \bar\psi_v')$; its residue is P_vB with B upper triangular (Fg3), and multiplying $\bar Q$ on the right by the inverse of an upper triangular lift of B we get $\bar Q \equiv P_v$. Then $\bar Q^\tau$ triangularises as well (because $t^{-1}\theta(\bar\rho')t = \bar\rho'$, $\theta(\bar\psi') = \bar\psi'$ and t_v' is diagonal) and $\bar Q^\tau \equiv t^{-1}P_v t_v' = P_v$; by (Fg3) $\bar Q^\tau = \bar Q B'$ with B' upper triangular, $B' \equiv 1$, so $\frac12(\bar Q + \bar Q^\tau) = \bar Q \cdot \frac12(1 + B')$ triangularises and is fixed by $Q \mapsto Q^\tau$. Replace $\bar Q$ by it, and let $Q_v \in \mathrm{GL}_n(C)$ be a lift with $Q_v^\tau = Q_v$ (average any lift with its image under $Q \mapsto Q^\tau$). Put $\bar u(h) = \bar Q^{-1}\bar\rho'(\pi_L(h))\bar Q$; this is an upper triangular homomorphism with $t_v'\theta(\bar u(h))t_v' = \bar u(h)$; choose a locally constant upper triangular lift u on D_v, $u(1) = 1$, fixed under $X \mapsto t_v'\theta_C(X)t_v'$ (averaging preserves upper triangularity). Define $k_v(h) \in \mathrm{M}_n(I)$ by $\sigma(\pi_L(h)) = (1 + k_v(h))Q_v u(h) Q_v^{-1}$; it

is continuous and τ-fixed (as $\tau(Q_v u(h) Q_v^{-1}) = Q_v u(h) Q_v^{-1}$), so k_v has values in $\mathrm{ad}_x^\epsilon \otimes I$. Writing $u(h)u(h') = (1+\beta(h,h'))u(hh')$ with β upper triangular with entries in I, (49.1) gives

$$k(\pi_L(h), \pi_L(h')) = k_v(h) + h \cdot k_v(h') - k_v(hh') + P_v \beta(h,h') P_v^{-1},$$

and $P_v \beta P_v^{-1} \in \mathfrak{b}_{x,v} \otimes I$; being also τ-fixed, it lies in $\mathfrak{b}_{x,v}^\epsilon \otimes I$. (iii) *The class.* For $\phi \in I^\vee = \mathrm{Hom}_{\mathbb{F}'}(I, \mathbb{F}')$ the pair $(\phi \circ k, (\phi \circ k_v)_v)$ is a pair as in the definition of $H^2(\Gamma_L; \mathrm{ad}_x^\epsilon, \mathfrak{b}_x^\epsilon)$ (by (i), (ii)); let $o(\phi)$ be its class, $\mathbb{F}'$-linear in ϕ. If $\dim I > d$, then $\dim I^\vee > \dim H^2$, so $o(\phi) = 0$ for some $\phi \neq 0$. Put $I' = \ker \phi$, an ideal ($\mathfrak{m}_C I = 0$) with $\dim I/I' = 1$, $C' = C/I'$, and identify I/I' with $\mathbb{F}'$ by ϕ. (iv) *A lift.* The equality $o(\phi) = 0$ means: there are a continuous $\beta\colon \Gamma_L \to \mathrm{ad}_x^\epsilon$ with $\phi k = d\beta$ and $Y_v \in \mathrm{ad}_x^\epsilon$ with $\phi k_v(h) - \beta(\pi_L(h)) + (h-1)Y_v \in \mathfrak{b}_{x,v}^\epsilon$ for $h \in D_v$. From $k(1,1) = k(\bar c, \bar c) = 0$ we get $\beta(1) = 0$ and $\bar c \cdot \beta(\bar c) = -\beta(\bar c)$; replacing β by $\beta + dX_0$ and Y_v by $Y_v + X_0$ with $X_0 = \frac{1}{2}\beta(\bar c)$ we may assume $\beta(\bar c) = 0$. Over C' put $\sigma'(g) = (1-\beta(g))\sigma(g)$. By (49.1), $\sigma'(g)\sigma'(g') = (1 - \beta(g) - g\cdot\beta(g') + \phi k(g,g'))\sigma(gg') = \sigma'(gg')$, so σ' is a homomorphism, locally constant, with $\sigma'(\bar c) = j$ and $\sigma'(\Gamma_L^0) \subseteq \mathrm{GL}_n(C')$; by Step 1, $\rho' = \sigma'|_{\Gamma_L^0}$ satisfies (Po1), (Po2) and lifts $\bar\rho'$. For $v \mid \ell$ and $h \in D_v$, with $b_h = \phi k_v(h) - \beta(\pi_L(h)) + (h-1)Y_v \in \mathfrak{b}_{x,v} \otimes \mathbb{F}'$ and $Q_v' = (1+Y_v)Q_v$,

$$\sigma'(\pi_L(h)) Q_v' = (1 - (h-1)Y_v + b_h)(1 + h\cdot Y_v) Q_v u(h) = (1 + Y_v + b_h) Q_v u(h),$$
$$Q_v'^{-1} \rho'(\pi_L(h)) Q_v' = (1 + P_v^{-1} b_h P_v) u(h),$$

upper triangular. Let $\psi'_{v,a}(h)$ be its diagonal entries: locally constant homomorphisms $D_v \to C'^\times$ lifting $\bar\psi'_{v,a}$; by (Fg1), (Po4) holds for (ρ', ψ'). (v) *The marking.* Let $\bar A = \bar\rho(\pi_L(g_\star))$, $A' = \rho'(\pi_L(g_\star))$, and κ the off-diagonal part of $A' - {}^a A'$; it lies in $\mathfrak{o}_{\mathrm{off}} \otimes \mathbb{F}' \subseteq \mathrm{M}_n(I/I')$, since $\bar\rho'$ is marked and ${}^a(A' - {}^a A') = -(A' - {}^a A')$. By (Kr1) and the marking of $\bar\rho$, $\bar A - {}^a \bar A = \mathrm{diag}(\delta_a)$ with $\delta_a = \bar\Psi(g_\star)^{w_{n,a}} - \bar\Psi(g_\star)^{-w_{n,a}}$ (as $w_{n,n+1-a} = -w_{n,a}$). For $n = 3$, $\delta = (\delta_1, 0, -\delta_1)$ with $\delta_1 \neq 0$ ($\bar\Psi(g_\star)^2 \neq 1$, $g_\star$ a marking) and $2\delta_1 \neq 0$ (ℓ odd), so the map $Y \mapsto [Y, \mathrm{diag}(\delta)]$, $Y_{ab} \mapsto (\delta_b - \delta_a) Y_{ab}$, is a bijection of $\mathfrak{o}_{\mathrm{off}}$ (it preserves $\mathfrak{o}$, since ${}^a\mathrm{diag}(\delta) = -\mathrm{diag}(\delta)$); for $n = 2$, $\mathfrak{o}_{\mathrm{off}} = 0$. Choose $Y \in \mathfrak{o}_{\mathrm{off}} \otimes \mathbb{F}'$ with $[Y, \mathrm{diag}(\delta)] = -\kappa$ and put $w = 1 + Y$. Then ${}^a w = 1 - Y = w^{-1}$, so $\rho'' = w\rho' w^{-1}$ still satisfies (Po2) (${}^a(wXw^{-1}) = w\,{}^aX w^{-1}$), (Po1), (Po4) with the same ψ' (triangularised by wQ_v'), lifts $\bar\rho'$, and $\rho''(\pi_L(g_\star)) - {}^a\rho''(\pi_L(g_\star)) = w(A' - {}^aA')w^{-1} = (A' - {}^aA') + [Y, \mathrm{diag}(\delta)]$ has off-diagonal part $\kappa - \kappa = 0$: (Po3). (vi) By (Kr3) there is $\xi\colon R \to C'$ with $\xi \circ \rho_x = \rho''$, $\xi \circ \psi_x = \psi'$; its composite with $C' \to \bar C$ corresponds to $(\bar\rho', \bar\psi')$, hence equals $\bar\xi$ by the injectivity in (Kr3). This proves (Kq2).

Step 6: the counts, (Kq3). Apply (Ar5)(iv) to $W = \mathrm{ad}_x$ (resp. $\mathrm{ad}_x^\pm$) read as $\mathbb{F}$-spaces, with $b_v = \mathfrak{b}_{x,v}$ (resp. $\mathfrak{b}_{x,v}^\pm$): the hypotheses hold by Step 1 and Step 2 (i), (iii), (iv). Dividing the inequality (48.1) by $[\mathbb{F}' : \mathbb{F}]$, using $\sum_{v|\ell} d_v = d_L$, the fact that the totally real field L^+ has exactly d_L real places, and Step 2 (i), (iv), (v):

$$h_x^2 + h_x^0 + d_L \tfrac{n(n+1)}{2} \le h_x^1 + d_L \tfrac{n(n-1)}{2}, \quad h_{x,+}^2 + h_{x,+}^0 + 4d_L \le h_{x,+}^1 + d_L, \quad h_{x,-}^2 + h_{x,-}^0 + 2d_L \le h_{x,-}^1 + 2d_L,$$

with all H^2 finite-dimensional. This is (Kq3). □

Lemma 49.24. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Let x be a core prime of E that is a maximal ideal of E, $(\mathcal{O}', R, \iota)$ a local chart at x with chart lift $(\rho_x, (\psi_{x,v,a}))$, $\mathbb{F}'$ the residue field of $\mathcal{O}'$ (and of R), and $\bar\rho_x\colon \Gamma_L^0 \to \mathrm{GL}_n(\mathbb{F}')$, $\bar\psi_{x,v,a}\colon D_v \to \mathbb{F}'^\times$ the reductions of ρ_x, $\psi_{x,v,a}$ modulo $\mathfrak{m}_R$. Then:*

(Kr1) *for every $\gamma \in \Gamma_L^0$ the matrix $\bar\rho_x(\gamma)$ is lower triangular with diagonal entries $\bar\Psi(\gamma)^{w_{n,1}}$, $\dots$, $\bar\Psi(\gamma)^{w_{n,n}}$, and $\bar\psi_{x,v,a}(g) = \bar\Psi(g)^{w_{n,a}}$ for $v \mid \ell$, $1 \le a \le n$, $g \in D_v$;*

(Kr2) *$(\rho_x, (\psi_{x,v,a}))$ consists of homomorphisms $\Gamma_L^0 \to \mathrm{GL}_n(R)$, $D_v \to R^\times$ satisfying (Po2)–(Po4) with the test ring replaced by R, and for every $k \geq 1$ the maps $\gamma \mapsto \rho_x(\gamma) \bmod \mathfrak{m}_R^k$ and $g \mapsto \psi_{x,v,a}(g) \bmod \mathfrak{m}_R^k$ are locally constant;*

(Kr3) *for every $A \in \mathrm{CNL}_{\mathcal{O}'}$ of finite length, $h \mapsto (h \circ \rho_x, (h \circ \psi_{x,v,a})_{v,a})$ is a bijection from the set of $\mathcal{O}'$-algebra homomorphisms $R \to A$ onto the set of families $(\rho, (\psi_{v,a}))$ of homomorphisms $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(A)$ and $\psi_{v,a}\colon D_v \to A^\times$ $(v \mid \ell,\ 1 \leq a \leq n)$ satisfying (Po1)–(Po4) with the test ring replaced by A, whose reductions modulo $\mathfrak{m}_A$ are $\bar{\rho}_x$ and $\bar{\psi}_{x,v,a}$;*

(Kr4) *if $n = 3$ and $I_E^{\mathrm{odd}} \subseteq x$, then $\bar{\rho}_x(\gamma)$ commutes with $t = \mathrm{diag}(-1, 1, -1)$ for every γ, and there is an $\mathcal{O}'$-algebra automorphism θ of R with $\theta \circ \theta = \mathrm{id}_R$, $\theta(\rho_x(\gamma)_{ab}) = (-1)^{w_{3,a} - w_{3,b}} \rho_x(\gamma)_{ab}$ and $\theta(\psi_{x,v,a}(g)) = \psi_{x,v,a}(g)$ for all $\gamma \in \Gamma_L^0$, $1 \leq a, b \leq 3$, $v \mid \ell$ and $g \in D_v$.*

Proof. The argument is commutative algebra; no automorphy is used, over L or over K. Write $\rho = \rho^{\mathrm{u}}$, $\psi = \psi^{\mathrm{u}}$ inside this proof only where no confusion arises with the lifts of (Kr3), which are written (ρ', ψ'); let $\mathfrak{m}$ be the maximal ideal of R_n^{po}, $\mathbb{F} = \mathbb{F}_{\mathcal{O}} \subseteq \mathbb{F}'$, and $W_0 \subseteq W$ the $\mathcal{O}$-subalgebra generated by the weight-zero monomials and the values $\psi_{v,a}(g)$, so that by definition of W every $y \in W$ has, for every t, some $y_t \in W_0$ with $y - y_t \in \mathfrak{m}^t$. Since x is a core prime, $\mathfrak{m}_W \subseteq x = \iota^{-1}(\mathfrak{m}_R)$. For $e \in E$ let $\bar{e} \in \mathbb{F}'$ be the residue of $\iota(e)$.

Step 0: two facts on W. (a) For every $y \in W$ and $k \geq 1$ there is $y' \in W_0$ with $y - y' \in \mathfrak{m}_W^k$. Indeed $W \in \mathrm{CNL}_{\mathcal{O}}$ (Gw1), the ideals $\mathfrak{m}^t \cap W$ decrease with intersection 0 (Krull's intersection theorem in R_n^{po}), so by Chevalley's lemma Theorem B.154 there is t with $\mathfrak{m}^t \cap W \subseteq \mathfrak{m}_W^k$; take $y' = y_t$. (b) An element $y \in W$ whose residue in $R_n^{\mathrm{po}}/\mathfrak{m} = \mathbb{F}$ is 0 lies in $\mathfrak{m} \cap W = \mathfrak{m}_W \subseteq x$, so $\bar{y} = 0$.

(Kr1). The diagonal entry $\rho(\gamma)_{aa}$ is a weight-zero monomial, so lies in W, and by (Po5) its residue is $\bar{\Psi}(\gamma)^{w_{n,a}}$; by (b) applied to $\rho(\gamma)_{aa} - \tau$ with $\tau \in \mathcal{O}$ of that residue, $\bar{\rho}_x(\gamma)_{aa} = \bar{\Psi}(\gamma)^{w_{n,a}}$. The same argument with $\psi_{v,a}(g) \in W$ gives the second assertion. As x is a core prime, $I_E^- \not\subseteq x$, so some lower entry $e_- = \rho(\gamma')_{ba}$ $(b > a)$, of weight $-q < 0$, is not in x. For an upper entry e_+, of weight $p > 0$, the product $e_+^q e_-^p$ is a weight-zero monomial with off-diagonal factors, whose residue is 0 by (Po5); by (b) it lies in x, and as x is prime and $e_- \notin x$, $e_+ \in x$. So $\bar{\rho}_x(\gamma)$ is lower triangular.

(Kr2). The determinant of $\rho(\gamma)$ is a sum of weight-zero monomials, so lies in W; it is a unit of R_n^{po}, hence not in $\mathfrak{m}_W$, hence a unit of the local ring W. So $\rho(\gamma) \in \mathrm{GL}_n(E)$, likewise $\psi_{v,a}(g) \in W^\times$, and $\rho_x = \iota \circ \rho$, $\psi_{x,v,a} = \iota \circ \psi_{v,a}$ are homomorphisms into $\mathrm{GL}_n(R)$ and $R^\times$. (Po2)–(Po4) are polynomial identities among entries of ρ and values of ψ, all in E; they hold in R_n^{po}, hence in E, hence after applying ι. Continuity: let $j = w_{n,a} - w_{n,b}$ and $k \geq 1$. The entries $\rho(\gamma)_{ab}$ lie in gr_j, a finitely generated W-module (Gw3); the submodules $\mathfrak{m}^t \cap \mathrm{gr}_j$ decrease with intersection 0, so by Theorem B.154 there is t with $\mathfrak{m}^t \cap \mathrm{gr}_j \subseteq \mathfrak{m}_W^k \mathrm{gr}_j$. By (Po1) for ρ, $\gamma \mapsto \rho(\gamma) \bmod \mathfrak{m}^t$ is locally constant, hence so is $\gamma \mapsto \rho(\gamma)_{ab} \bmod \mathfrak{m}_W^k \mathrm{gr}_j$, and since $\iota(\mathfrak{m}_W^k \mathrm{gr}_j) \subseteq \mathfrak{m}_R^k$ so is $\gamma \mapsto \rho_x(\gamma)_{ab} \bmod \mathfrak{m}_R^k$. The same with $\mathrm{gr}_0 = W$ gives the assertion for $\psi_{x,v,a}$.

(Kr3), the map is well defined. An $\mathcal{O}'$-algebra homomorphism $h\colon R \to A$ is local and induces the identity of $\mathbb{F}'$ (the composite $R \to A \to \mathbb{F}'$ is surjective, as $\mathcal{O}' \to \mathbb{F}'$ is, so its kernel is the maximal ideal $\mathfrak{m}_R$, and the induced map $\mathbb{F}' \to \mathbb{F}'$ is $\mathcal{O}'$-linear). So $(h \circ \rho_x, h \circ \psi_x)$ reduces to $(\bar{\rho}_x, \bar{\psi}_x)$, satisfies (Po2)–(Po4) by (Kr2), and (Po1) by (Kr2), as $h(\mathfrak{m}_R^k) \subseteq \mathfrak{m}_A^k$.

(Kr3), injectivity. Let $h, h'\colon R \to A$ give the same family, and $f = h \circ \iota$, $f' = h' \circ \iota\colon E \to A$. They agree on all entries $\rho(\gamma)_{ab}$ and values $\psi_{v,a}(g)$, hence on W_0. Choose k with $\mathfrak{m}_A^k = 0$. Since

$\iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$ and h, h' are local, $f(\mathfrak{m}_W^k) = f'(\mathfrak{m}_W^k) = 0$; by Step 0 (a), $f = f'$ on W. As E is generated over W by the entries, $f = f'$. By the definition of a local chart (with $C = A$; the composite of f with $A \to \mathbb{F}'$ is that of ι, as h induces the identity of $\mathbb{F}'$), $h = h'$.

(Kr3), surjectivity. Let $(\rho', (\psi'_{v,a}))$ be a family as in (Kr3). Let $C_A \subseteq A$ be the set of elements whose residue lies in $\mathbb{F}$. It is an $\mathcal{O}$-subalgebra; it is local with maximal ideal $\mathfrak{m}_A$ (an element of $C_A \setminus \mathfrak{m}_A$ is a unit of A whose inverse has residue in $\mathbb{F}^\times$) and residue field $\mathbb{F}$; and A is finite (of finite length over $\mathcal{O}'$, whose residue field is finite), so C_A is a finite local ring, hence complete and Noetherian. So $C_A \in \mathrm{CNL}_{\mathcal{O}}$. We check the hypotheses of Lemma 49.16 with $B = A$ and $C = C_A$. (Po2)–(Po4) hold for (ρ', ψ'). (Cq1) and (Cq5): by (Kr1), $\rho'(\gamma)_{aa}$ and $\psi'_{v,a}(g)$ have residues $\bar{\Psi}(\gamma)^{w_{n,a}}$, $\bar{\Psi}(g)^{w_{n,a}} \in \mathbb{F}$, so they lie in C_A with the required congruences; local constancy holds by (Po1) (with $\mathfrak{m}_A^k = 0$). (Cq2): let $y = \prod_k \rho(\gamma_k)_{a_k b_k}$ be a weight-zero monomial with some $a_k \neq b_k$; its residue in $\mathbb{F}$ is 0 by (Po5), so $\bar{y} = 0$ by Step 0 (b); the residue of $\prod_k \rho'(\gamma_k)_{a_k b_k}$ is $\prod_k \bar{\rho}_x(\gamma_k)_{a_k b_k} = \bar{y} = 0$, so this product lies in $\mathfrak{m}_A = \mathfrak{m}_{C_A}$. (Cq3): A is finite. (Cq4): ρ' is locally constant by (Po1). Hence there are $\mathcal{O}$-algebra homomorphisms $\xi\colon E \to A$ and $\beta\colon W \to C_A$ with $\beta(\mathfrak{m}_W) \subseteq \mathfrak{m}_A$, $\xi(\rho(\gamma)_{ab}) = \rho'(\gamma)_{ab}$, $\xi(\psi_{v,a}(g)) = \psi'_{v,a}(g)$ and $\xi|_W = \beta$. The two ring homomorphisms $E \to \mathbb{F}'$, $e \mapsto \xi(e) \bmod \mathfrak{m}_A$ and $e \mapsto \bar{e}$, agree on the entries (both give $\bar{\rho}_x$) and on $W = \mathcal{O} + \mathfrak{m}_W$ (both are $\mathcal{O}$-linear and kill $\mathfrak{m}_W$), hence on E. By the definition of a local chart there is an $\mathcal{O}'$-algebra homomorphism $h\colon R \to A$ with $h \circ \iota = \xi$; then $h \circ \rho_x = \xi \circ \rho = \rho'$ and $h \circ \psi_{x,v,a} = \psi'_{v,a}$.

(Kr4). The odd entries of ρ generate $I_E^{\mathrm{odd}} \subseteq x$, so $\bar{\rho}_x(\gamma)_{ab} = 0$ when $w_{3,a} - w_{3,b}$ is odd; as $(tXt^{-1})_{ab} = (-1)^{w_{3,a}-w_{3,b}} X_{ab}$, $\bar{\rho}_x(\gamma)$ commutes with t. Write ${}^a X = J_3\, {}^t X J_3$. Since $t^{-1} = t$ and $J_3 t = t J_3$ (conjugation by J_3 reverses the order of the diagonal entries of t), ${}^a(tXt^{-1}) = t\, {}^a X\, t^{-1}$. Hence $(t\rho t^{-1}, \psi)$ is again a polarised ordinary lift to R_3^{po}: (Po1) and (Po4) are preserved by conjugation, (Po2) by the identity just shown, (Po3) because conjugation by the diagonal matrix t preserves the vanishing of off-diagonal entries, and (Po5) because t commutes with diagonal matrices. By the universal property there is a morphism θ_{u} of R_3^{po} in $\mathrm{CNL}_{\mathcal{O}}$ with $\theta_{\mathrm{u}}(\rho(\gamma)_{ab}) = (-1)^{w_{3,a}-w_{3,b}} \rho(\gamma)_{ab}$ and $\theta_{\mathrm{u}}(\psi_{v,a}(g)) = \psi_{v,a}(g)$, and $\theta_{\mathrm{u}} \circ \theta_{\mathrm{u}} = \mathrm{id}$ by uniqueness. The morphism θ_{u} fixes W_0 pointwise (the sign of a weight-zero monomial is $+1$) and maps $\mathfrak{m}^t$ into itself; so for $y \in W$, $\theta_{\mathrm{u}}(y) - y = (\theta_{\mathrm{u}}(y - y_t)) - (y - y_t) \in \mathfrak{m}^t$ for all t, and $\theta_{\mathrm{u}}(y) = y$. Hence θ_{u} restricts to an $\mathcal{O}$-algebra involution θ_E of E fixing W. The homomorphism $\iota \circ \theta_E\colon E \to R$ has the same composite with $R \to \mathbb{F}'$ as ι: both are $\mathcal{O}$-linear and kill $\mathfrak{m}_W$ on W, and on an entry they give $(-1)^{w_{3,a}-w_{3,b}} \bar{\rho}_x(\gamma)_{ab} = \bar{\rho}_x(\gamma)_{ab}$ because the odd entries of $\bar{\rho}_x$ vanish. By the definition of a local chart (with $C = R$) there is an $\mathcal{O}'$-algebra homomorphism $\theta\colon R \to R$ with $\theta \circ \iota = \iota \circ \theta_E$. Then $\theta \circ \theta \circ \iota = \iota \circ \theta_E^2 = \iota$, so $\theta \circ \theta = \mathrm{id}_R$ by the uniqueness in the definition (with $f = \iota$); θ is an automorphism, and $\theta(\rho_x(\gamma)_{ab}) = \iota(\theta_E(\rho(\gamma)_{ab}))$, $\theta(\psi_{x,v,a}(g)) = \psi_{x,v,a}(g)$ are as stated. □

Lemma 49.25. *All symbols are local to this statement. Let C be a commutative local ring with maximal ideal $\mathfrak{m}_C$ and residue field k_C, $n \geq 1$, D a set, and $\rho\colon D \to \mathrm{M}_n(C)$, $\psi_1, \dots, \psi_n\colon D \to C$ maps. Say that $P \in \mathrm{GL}_n(C)$* triangularises *(ρ, ψ) if $P^{-1}\rho(g)P$ is upper triangular with diagonal entries $\psi_1(g), \dots, \psi_n(g)$ (in this order) for every $g \in D$.*

(Fg1) *If some P triangularises (ρ, ψ), then for all $g_1, \dots, g_n \in D$*

$$\prod_{a=1}^{n} (\rho(g_a) - \psi_a(g_a)) = 0,$$

the product taken with $a = 1$ on the left.

(Fg2) *Conversely, suppose that these products vanish for all $g_1, \dots, g_n \in D$, and that there is $h \in D$ such that $\psi_a(h) - \psi_b(h) \in C^\times$ for all $a \neq b$ and the characteristic polynomial of*

the reduction of $\rho(h)$ modulo $\mathfrak{m}_C$ is $\prod_{a=1}^{n}(X-\bar{\psi}_a(h))$, bars denoting reduction modulo $\mathfrak{m}_C$. Then some $P \in \mathrm{GL}_n(C)$ triangularises (ρ,ψ).

(Fg3) *Under the hypotheses of (Fg2), if P and Q both triangularise (ρ,ψ), then $P^{-1}Q$ is upper triangular.*

Proof. (Fg1). Put $U_a = P^{-1}\rho(g_a)P$, upper triangular with diagonal $(\psi_b(g_a))_b$, and $S_k = Ce_1 + \cdots + Ce_k$ ($S_0 = 0$). Then $U_a - \psi_a(g_a)$ is upper triangular with (a,a)-entry 0, so it maps S_a into S_{a-1}. Hence $\prod_{a=1}^{n}(U_a - \psi_a(g_a))$, applied to $C^n = S_n$, lands successively in $S_{n-1},\dots,S_0 = 0$; conjugating by P gives the claim.

(Fg2), idempotents. Write $M = \rho(h)$ and $\lambda_a = \psi_a(h)$. Taking $g_1 = \cdots = g_n = h$ gives $\prod_c(M-\lambda_c) = 0$ (the factors commute). Put

$$E_a = \prod_{b\neq a} \frac{M-\lambda_b}{\lambda_a-\lambda_b} \qquad (1 \le a \le n).$$

The polynomial $\sum_a \prod_{b\neq a}(X-\lambda_b)/(\lambda_a-\lambda_b) - 1 \in C[X]$ has degree $< n$ and vanishes at $\lambda_1,\dots,\lambda_n$, whose Vandermonde determinant $\prod_{a<b}(\lambda_b-\lambda_a)$ is a unit; so it is 0, and $\sum_a E_a = 1$. For $a \neq b$, E_aE_b is a multiple of $\prod_c(M-\lambda_c) = 0$, and so is $(M-\lambda_a)E_a$. Hence the E_a are orthogonal idempotents with sum 1, $C^n = \bigoplus_a V_a$ with $V_a = E_aC^n$, and M acts on V_a as multiplication by λ_a.

(Fg2), each V_a is free of rank one. V_a is a direct summand of C^n, hence finitely generated projective, hence free over the local ring C, of rank $\dim_{k_C} V_a/\mathfrak{m}_CV_a$. Reducing, $k_C^n = \bigoplus_a \bar{E}_a k_C^n$ with $\bar{E}_a k_C^n \subseteq \ker(\bar{M}-\bar{\lambda}_a)$. The $\bar{\lambda}_a$ are pairwise distinct roots of the characteristic polynomial $\prod_b(X-\bar{\lambda}_b)$ of $\bar{M}$, each of multiplicity one, so $\dim\ker(\bar{M}-\bar{\lambda}_a) \le 1$. As the dimensions add up to n, each V_a is free of rank 1; let v_a generate it, and let P have columns $v_1,\dots,v_n$. Then $P \in \mathrm{GL}_n(C)$, since the v_a form a basis of C^n.

(Fg2), the flag. Put $F_k = V_1 \oplus \cdots \oplus V_k$. Let $g \in D$ and $1 \le k \le n$. Taking $g_k = g$ and $g_a = h$ for $a \neq k$ in the product equation gives $L_k\,(\rho(g)-\psi_k(g))\,R_k = 0$ with $L_k = \prod_{a<k}(M-\lambda_a)$ and $R_k = \prod_{a>k}(M-\lambda_a)$. On V_b, R_k acts by $\prod_{a>k}(\lambda_b-\lambda_a)$, a unit for $b \le k$, so $R_k(F_k) = F_k$; and L_k acts by $\prod_{a<k}(\lambda_b-\lambda_a)$, which is 0 for $b < k$ and a unit for $b \ge k$, so $\ker L_k = F_{k-1}$. Therefore $(\rho(g)-\psi_k(g))F_k \subseteq F_{k-1}$, i.e. $\rho(g)v_k \in \psi_k(g)v_k + F_{k-1}$, which says that $P^{-1}\rho(g)P$ is upper triangular with (k,k)-entry $\psi_k(g)$.

(Fg3). With P as constructed, it suffices to show $P^{-1}Q$ upper triangular for every Q that triangularises (ρ,ψ) (then for two such P_1, Q, $P_1^{-1}Q = (P^{-1}P_1)^{-1}(P^{-1}Q)$ is upper triangular). Let $q_1,\dots,q_n$ be the columns of Q; then $(M-\lambda_k)q_k \in Cq_1 + \cdots + Cq_{k-1}$. We show $q_k \in F_k$ by induction on k. Assume $q_1,\dots,q_{k-1} \in F_{k-1}$. Writing $q_k = \sum_b u_b$ with $u_b \in V_b$, the V_b-component of $(M-\lambda_k)q_k$ is $(\lambda_b-\lambda_k)u_b$, which vanishes for $b \ge k$ because $(M-\lambda_k)q_k \in F_{k-1}$; for $b > k$, $\lambda_b-\lambda_k$ is a unit, so $u_b = 0$ and $q_k \in F_k$. Since $F_k = Cv_1 + \cdots + Cv_k$, the k-th column of $P^{-1}Q$ has zero entries below the k-th row. □

49.4 Endoscopic core primes and local propagation

This subsection proves the local statements of the propagation theorem. At an endoscopic core prime the rank-three chart carries an ideal whose components are chained through thick or irreducible components (Proposition 49.26), by an analysis of the minimal primes of determinantal sections of a power series ring (Lemma 49.27); chains of components of quotients by few elements are described in Lemma 49.28. The non-nice loci of a chart have dimension less than $n\,d_L$ (Proposition 49.29); one input is that the lower-triangular fibre of the entry algebra has

dimension at most $2C_0$ (Lemma 49.30), where C_0 bounds the Selmer ranks of the auxiliary field. Absorption in rank two bounds the endoscopic primes in rank three (Proposition 49.33), and local propagation moves a modular ideal through nice primes and along thick links inside a chart (Lemma 49.34). The subsection ends with the two consequences used in Theorem 49.3: lifts to test rings are classified by the universal lift (Lemma 49.36), and an off-triangular bound gives the residual characteristic polynomials in characteristic ℓ (Lemma 49.37).

Proposition 49.26. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, and suppose a universal polarised ordinary lift of rank 3 over L exists; write $E = E_3^{\mathrm{po}}$. Let x be a core prime of E that is a maximal ideal of E with $I_E^{\mathrm{odd}} \subseteq x$, and $(\mathcal{O}', R, \iota)$ a local chart at x. Then there is an ideal $J \subseteq R$ such that:*

(Ej1) *$J \subseteq P$ for every prime P of R with $I_R^{\mathrm{odd}} \not\subseteq P$;*

(Ej2) $\dim R/P \geq 3d_L + 2$ *for every minimal prime P of J, and any two minimal primes P, Q of J are joined by minimal primes $P = P_0, \dots, P_k = Q$ of J with* $\dim R/(P_{i-1} + P_i) \geq 3d_L + 1$ *for $1 \leq i \leq k$;*

(Ej3) *every minimal prime of J is of irreducible type or thick.*

Proof. The proof is commutative algebra on the chart; in particular, no automorphy over L or over K is used. Write $d = d_L$, $W = W_3^{\mathrm{po}}$, $\rho_x = \iota \circ \rho^{\mathrm{u}}$, $\psi_{x,v,a} = \iota \circ \psi_{v,a}^{\mathrm{u}}$, $\bar{c} = \pi_L(c)$, $\gamma^* = \bar{c}\gamma^{-1}\bar{c}$, $\gamma_\star = \pi_L(g_\star)$. The chart lift satisfies (Po2)–(Po4) in R (they hold for ρ^{u}, with entries in E, and ι is a ring homomorphism); so $\rho_x(\gamma^*)_{ab} = \rho_x(\gamma)_{4-b,4-a}$ and $\rho_x(\gamma_\star)_{ab} = \rho_x(\gamma_\star^*)_{ab}$ for $a \neq b$. A position (a, b) is *odd* if $w_{3,a} - w_{3,b}$ is odd, i.e. $(a, b) \in \{(1,2), (2,1), (2,3), (3,2)\}$, and *even* otherwise.

Step 0: the presentation. By (Qp2) there are a, b, g with $a \geq b + 3d + 1$ and $p\colon S = \mathcal{O}'[[Y_1, \dots, Y_a, X_1, \dots, X_g]] \to R$ with (Ep1)–(Ep4). An odd series lies in the ideal $(X_1, \dots, X_g)$ (each monomial has positive degree in the X_j). For each odd G_i let M_{ij} be the sum of the terms of G_i divisible by X_j and by no $X_{j'}$ with $j' < j$, divided by X_j; then $G_i = \sum_j M_{ij} X_j$, and the constant term of M_{ij} is the coefficient of X_j in G_i, which lies in $\mathfrak{m}_{\mathcal{O}'}$ by (Ep2). So $M = (M_{ij})$ has entries in $\mathfrak{m}_S$, and $G = MX$. Each F_i lies in $\mathfrak{m}_S$ (it is in $\ker p$, hence not a unit).

Step 1: the ideal J, and (Ej1). If $g = 0$, then $I_R^{\mathrm{odd}} = 0$ by (Ep4), every prime contains it, and $J = R$ satisfies (Ej1)–(Ej3) vacuously. Let $g \geq 1$ and $J = p(\det M)R$. From $\mathrm{adj}(M)MX = \det(M)X$ and $MX = G \in \ker p$ we get $p(\det M)\, p(X_j) = 0$ for all j. If P is a prime with $I_R^{\mathrm{odd}} \not\subseteq P$, then $p(X_j) \notin P$ for some j (Ep4), so $p(\det M) \in P$ and $J \subseteq P$.

Step 2: (Ej2). By (Ep1) and Step 0, p induces $R/J \cong S/I$ with $I = (F_1, \dots, F_b, MX, \det M)$; primes of R containing J correspond to primes of S containing I by $P \mapsto p^{-1}(P)$, with $R/P \cong S/p^{-1}(P)$, minimal primes to minimal primes, and $p^{-1}(P+Q) = p^{-1}(P) + p^{-1}(Q)$. Lemma 49.27 with $D = a - b \geq 3d + 1$ gives: every minimal prime P of J has $\dim R/P \geq a - b + 1 \geq 3d + 2$, and any two are joined by minimal primes with $\dim R/(P_{i-1} + P_i) \geq a - b \geq 3d + 1$.

Step 3: minimal primes are off-triangular. Let P be a minimal prime of J. By (Qc3), $I_R^- = R \not\subseteq P$. If $I_R^+ \subseteq P$, then $\dim R/P \leq \dim R/I_R^+ < 3d$ by (Nn1), against Step 2. So P is off-triangular; it is of irreducible type if $I_R^{\mathrm{odd}} \not\subseteq P$. It remains to show: if $I_R^{\mathrm{odd}} \subseteq P$, then P is thick. Fix such P; it is of endoscopic type, and $p(\det M) \in P$.

Step 4: a derivation along a kernel vector of M. Let $Q = R/P$, a domain, $\pi\colon R \to Q$ and $\varphi = \pi \circ p$. By (Ep4), $\varphi(X_j) = 0$, so φ kills every odd series. Since $\det \varphi(M) = \varphi(\det M) = 0$ in the domain Q, there is $0 \neq \nu \in Q^g$ with $\varphi(M)\nu = 0$ (solve over the fraction field and clear denominators). Let $D_0(f) = \sum_c \varphi(\partial f / \partial X_c)\nu_c$ for $f \in S$; it is additive with $D_0(ff') =$

$\varphi(f)D_0(f') + \varphi(f')D_0(f)$, and $D_0(X_j) = \nu_j$. If f is even, each $\partial f/\partial X_c$ is odd and $D_0(f) = 0$; in particular $D_0(F_i) = 0$, and $D_0(G_i) = \sum_j(\varphi(M_{ij})\nu_j + \varphi(X_j)D_0(M_{ij})) = (\varphi(M)\nu)_i = 0$. For $f = \sum_k s_k r_k$ with generators r_k of $\ker p$, $D_0(f) = \sum_k(\varphi(s_k)D_0(r_k) + \varphi(r_k)D_0(s_k)) = 0$. So $D_0 = D \circ p$ for an additive $D\colon R \to Q$ with $D(yy') = \pi(y)D(y') + \pi(y')D(y)$, $D(p(f)) = 0$ for even f, and $D(p(X_j)) = \nu_j$. By (Ep3): $\pi(\rho_x(\gamma)_{ab}) = 0$ at odd positions, $D(\rho_x(\gamma)_{ab}) = 0$ at even positions, and $D(\psi_{x,v,a}(g)) = 0$. Moreover $D(\mathfrak{m}_R^{k+1}) \subseteq \pi(\mathfrak{m}_R)^k Q$ for $k \geq 0$ (induction with the product rule).

Step 5: the modified representation. Call $Y \in \mathrm{M}_3(R)$ *balanced* if $\pi(Y_{ab}) = 0$ at odd positions and $D(Y_{ab}) = 0$ at even positions, and put

$$\theta(Y) = \begin{pmatrix} \pi(Y_{11}) & D(Y_{12}) & \pi(Y_{13}) \\ 0 & \pi(Y_{22}) & 0 \\ \pi(Y_{31}) & D(Y_{32}) & \pi(Y_{33}) \end{pmatrix}.$$

Products of balanced matrices are balanced and $\theta(YY') = \theta(Y)\theta(Y')$; $\theta(1) = 1$; and $\theta(Y - s\cdot 1) = \theta(Y) - \pi(s)\cdot 1$ if $D(s) = 0$.

Let $r(\gamma) = \theta(\rho_x(\gamma))$, a monoid homomorphism $\Gamma_L^0 \to \mathrm{M}_3(Q)$ by Step 4. Its entries are $\pi(\rho_x(\gamma)_{ab})$ or $D(\rho_x(\gamma)_{ab})$, locally constant modulo every power of $\pi(\mathfrak{m}_R)Q$ by (Qc5) and Step 4. (Tk1) holds by construction. (Tk2): the factors $\rho_x(\pi_L(g_a)) - \psi_{x,v,a}(g_a)$ of (Po4) are balanced, so applying θ to (Po4) gives the first product; for the second, (Po2) gives $\rho_x(\pi_L(cg_a^{-1}c)) - \psi_{x,v,4-a}(g_a) = J_3\,{}^t B_a J_3$ with $B_a = \rho_x(\pi_L(g_a)) - \psi_{x,v,4-a}(g_a)$, so the product over $a = 1,2,3$ is $J_3\,{}^t(B_3B_2B_1)J_3 = 0$ by (Po4) for (g_3, g_2, g_1), and θ gives the second product. (Tk3): let $j\colon Q \to F'$ be an injective homomorphism to a field and $y \in F'^3$ with $y_2 = 1$ and $j(r(\gamma))y = j(r(\gamma)_{22})y$ for all γ. The first row at $\gamma_\star$ and at $\gamma_\star^*$ reads $j(\pi(\rho_{11}))y_1 + j(D(\rho_{12})) + j(\pi(\rho_{13}))y_3 = j(\pi(\rho_{22}))y_1$, with $\rho = \rho_x(\gamma_\star)$, resp. the same with ρ_{11} replaced by ρ_{33} (polarisation: $\rho_x(\gamma_\star^*)_{11} = \rho_x(\gamma_\star)_{33}$, $\rho_x(\gamma_\star^*)_{22} = \rho_x(\gamma_\star)_{22}$; marking for the off-diagonal entries). Subtracting, $j(\pi(\rho_x(\gamma_\star)_{11} - \rho_x(\gamma_\star)_{33}))\,y_1 = 0$. The element $\rho_x(\gamma_\star)_{11} - \rho_x(\gamma_\star)_{33}$ is a unit of R: the diagonal entries of ρ^{u} lie in W with residues $\bar\Psi^{\pm 1}(\gamma_\star)$ (Po5), $\iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$ as $\mathfrak{m}_W \subseteq x$, and $\bar\Psi(\gamma_\star)^2 \neq 1$. So $y_1 = 0$, and likewise (third row) $y_3 = 0$. Then the first and third rows give $D(\rho_x(\gamma)_{12}) = D(\rho_x(\gamma)_{32}) = 0$ for all γ, and by polarisation $D(\rho_x(\gamma)_{21}) = D(\rho_x(\gamma^*)_{32}) = 0$, $D(\rho_x(\gamma)_{23}) = D(\rho_x(\gamma^*)_{12}) = 0$. As π kills the odd entries, the product rule makes D vanish on the ideal they generate, which is $I_R^{\mathrm{odd}} \ni p(X_j)$; so $\nu_j = D(p(X_j)) = 0$ for all j, a contradiction. Hence P is thick, which proves (Ej3). □

Lemma 49.27. *Let $\mathcal{O}'$ be a coefficient ring, $a, b, g, D \geq 0$ integers with $g \geq 1$ and $a = b + D$, $S = \mathcal{O}'[[Y_1, \ldots, Y_a, X_1, \ldots, X_g]]$ with maximal ideal $\mathfrak{m}_S$, $F_1, \ldots, F_b \in \mathfrak{m}_S$, and $M \in \mathrm{M}_g(S)$ with all entries in $\mathfrak{m}_S$. Let $I \subseteq S$ be the ideal generated by $F_1, \ldots, F_b$, the entries $\sum_j M_{ij}X_j$ $(1 \leq i \leq g)$ of MX, and $\det M$. Then:*

1. *$\dim S/P \geq D + 1$ for every minimal prime P of I;*
2. *any two minimal primes P, Q of I are joined by minimal primes $P = P_0, \ldots, P_k = Q$ of I, $k \geq 0$, with $\dim S/(P_{i-1} + P_i) \geq D$ for $1 \leq i \leq k$.*

Proof. For a matrix Z of indeterminates and a column z of indeterminates, Zz denotes the column with entries $\sum_j Z_{ij}z_j$; e_1 is the first standard basis column and $E_0 = \mathrm{diag}(0, 1, \ldots, 1)$, both of size g.

Step 1: the generic determinantal locus, polynomial version. Let A be a domain, $B = A[Z_{ij}, z_j : 1 \leq i, j \leq g]$, graded by total degree, and $\mathfrak{a} = (Zz, \det Z) \subseteq B$. Let $C = A[N_{ij}, U_{ij}, t]$ (a domain) and $\phi\colon B \to C$ the A-algebra homomorphism with $\phi(Z) = NE_0\,\mathrm{adj}(U)$ and $\phi(z) =$

tUe_1. We claim $\sqrt{\mathfrak{a}} = \ker\phi$. First, $\phi(Zz) = t\,NE_0\operatorname{adj}(U)Ue_1 = t\det(U)\,NE_0e_1 = 0$ and $\phi(\det Z) = \det N \det E_0 \det\operatorname{adj}(U) = 0$, so $\mathfrak{a} \subseteq \ker\phi$, a prime ideal; hence $\sqrt{\mathfrak{a}} \subseteq \ker\phi$. Conversely, let $\mathfrak{q} \supseteq \mathfrak{a}$ be prime, K the fraction field of $B/\mathfrak{q}$, $\psi\colon B \to K$ the quotient map, $\bar{M} = \psi(Z)$, $\bar{m} = \psi(z)$; then $\bar{M}\bar{m} = 0$ and $\det\bar{M} = 0$. Choose $0 \neq u \in K^g$ with $\bar{M}u = 0$ and $s \in K$ with $\bar{m} = su$ (if $\bar{m} \neq 0$ take $u = \bar{m}$, $s = 1$; otherwise any non-zero kernel vector and $s = 0$), and $\bar{U} \in \mathrm{GL}_g(K)$ with first column u. Then $\bar{M}\bar{U}$ has first column 0, so $\bar{M}\bar{U}E_0 = \bar{M}\bar{U}$, and $\bar{N} = \det(\bar{U})^{-1}\bar{M}\bar{U}$ satisfies $\bar{N}E_0\operatorname{adj}(\bar{U}) = \det(\bar{U})^{-1}\bar{M}\bar{U}\operatorname{adj}(\bar{U}) = \bar{M}$, while $s\bar{U}e_1 = \bar{m}$. The A-algebra homomorphism $\chi\colon C \to K$ with $N \mapsto \bar{N}$, $U \mapsto \bar{U}$, $t \mapsto s$ satisfies $\chi\circ\phi = \psi$ (both agree on Z and z), so $\ker\phi \subseteq \mathfrak{q}$. Hence $\ker\phi$ lies in every prime containing $\mathfrak{a}$, i.e. in $\sqrt{\mathfrak{a}}$. So $P_0 = \sqrt{\mathfrak{a}} = \ker\phi$ is a prime ideal; it is homogeneous, as the radical of an ideal generated by homogeneous elements; and $z_1 \notin P_0$, since $\phi(z_1) = tU_{11} \neq 0$.

Step 2: power series version. Let A be moreover Noetherian, $T = A[[Z_{ij}, z_j]]$, and $\mathfrak{P} = P_0T$. We claim: $\mathfrak{P}$ is prime, $\sqrt{\mathfrak{a}T} = \mathfrak{P}$, and $\operatorname{ht}\mathfrak{P} \leq g$. Write f_d for the homogeneous component of degree d of $f \in T$. As P_0 is generated by finitely many homogeneous $h_1, \ldots, h_r$, $\mathfrak{P}$ is the set of f with all $f_d \in P_0$ (if $f_d = \sum_i c_{i,d}h_i$ with $c_{i,d}$ homogeneous of degree $d - \deg h_i$, then $f = \sum_i(\sum_d c_{i,d})h_i$; the converse is clear). If $f, f' \notin \mathfrak{P}$, let d_0, d_0' be the least degrees with $f_{d_0} \notin P_0$, $f'_{d_0'} \notin P_0$; then $(ff')_{d_0+d_0'} \equiv f_{d_0}f'_{d_0'} \not\equiv 0 \pmod{P_0}$, so $ff' \notin \mathfrak{P}$: $\mathfrak{P}$ is prime. Some power P_0^k lies in $\mathfrak{a}$ (B is Noetherian), so $\mathfrak{P}^k \subseteq \mathfrak{a}T \subseteq \mathfrak{P}$ and $\sqrt{\mathfrak{a}T} = \mathfrak{P}$. Let $\mathfrak{Q} \subseteq \mathfrak{P}$ be a minimal prime of the ideal generated by the g entries of Zz. From $\operatorname{adj}(Z)Zz = \det(Z)z$ we get $\det(Z)z_1 \in \mathfrak{Q}$, and $z_1 \notin \mathfrak{P}$ (its only component z_1 is not in P_0), so $\det Z \in \mathfrak{Q}$; then $\mathfrak{a}T \subseteq \mathfrak{Q}$, $\mathfrak{P} \subseteq \mathfrak{Q}$, and $\mathfrak{Q} = \mathfrak{P}$ is minimal over g elements: $\operatorname{ht}\mathfrak{P} \leq g$ by Krull's height theorem.

Step 3: the chain property. Apply Step 2 with $A = S$, so $T = S[[Z, z]] = \mathcal{O}'[[Y, X, Z, z]]$ is a regular, hence Cohen–Macaulay, local ring of dimension $1 + a + g + g^2 + g$, and $\dim T/\mathfrak{P} = \dim T - \operatorname{ht}\mathfrak{P} \geq 1 + a + g^2 + g$ (Matsumura, Commutative Ring Theory, Theorem 17.4). The ring $T_1 = T/\mathfrak{a}T$ is a complete Noetherian local ring whose nilradical $\mathfrak{P}/\mathfrak{a}T$ is prime, and $\dim T_1 = \dim T/\mathfrak{P} \geq D+1+h$ with $h = b+g^2+g$, since $a = b+D$. The h elements F_i, $Z_{ij} - M_{ij}$, $z_j - X_j$ lie in the maximal ideal of T. By Lemma 49.28 (with this D and h), the ideal J_1 of T_1 they generate satisfies items 1 and 2 (in T_1). Let $\mathrm{ev}\colon T \to S$ be the continuous S-algebra homomorphism with $Z \mapsto M$, $z \mapsto X$. The substitution $Z \mapsto Z + M$, $z \mapsto z + X$ is an automorphism of $S[[Z, z]]$, so ev is surjective with kernel generated by the entries of $Z - M$ and $z - X$; and $\mathrm{ev}(Zz) = MX$, $\mathrm{ev}(\det Z) = \det M$. Hence $P \mapsto \mathrm{ev}^{-1}(P)$ is an inclusion-preserving bijection between the primes of S containing I and the primes of T containing $\mathfrak{a}T + (F_i, Z_{ij} - M_{ij}, z_j - X_j)$, with $S/P \cong T/\mathrm{ev}^{-1}(P)$ and $\mathrm{ev}^{-1}(P + Q) = \mathrm{ev}^{-1}(P) + \mathrm{ev}^{-1}(Q)$; the latter primes correspond in the same way to the primes of T_1 containing J_1. Minimal primes correspond to minimal primes, and items 1 and 2 for J_1 give items 1 and 2 for I. □

Lemma 49.28. *Let $(R, \mathfrak{m})$ be a complete Noetherian local ring whose nilradical is a prime ideal, let $D \geq 0$ and $h \geq 0$ be integers with $\dim R \geq D + 1 + h$, let $f_1, \ldots, f_h \in \mathfrak{m}$ and $J = (f_1, \ldots, f_h)$. Then:*

1. *$\dim R/P \geq D + 1$ for every minimal prime P of J;*
2. *for any two minimal primes P, Q of J there are minimal primes $P = P_0, P_1, \ldots, P_k = Q$ of J, $k \geq 0$, with $\dim R/(P_{i-1} + P_i) \geq D$ for $1 \leq i \leq k$.*

Proof. Put $T = V(J) \subseteq \operatorname{Spec} R$; it is non-empty because $J \subseteq \mathfrak{m}$, and it is homeomorphic to $\operatorname{Spec} R/J$. Its irreducible components are $T_i = V(P_i)$, $1 \leq i \leq m$, where $P_1, \ldots, P_m$ are the finitely many minimal primes of J, and $\dim T_i = \dim R/P_i$, $\dim(T_i \cap T_j) = \dim R/(P_i + P_j)$. All dimensions are finite since R is Noetherian local.

The connectedness dimension of T is at least D. Since the nilradical N of R is prime, $\operatorname{Spec} R = V(N)$ is irreducible. If $Z \subsetneq \operatorname{Spec} R$ is closed, $\operatorname{Spec} R \setminus Z$ is a non-empty open subset of an irreducible space, hence irreducible and connected; so the only closed Z with disconnected complement is $Z = \operatorname{Spec} R$ itself, and $c(R) = \dim R$. Also $\operatorname{sdim} R = \dim R$. By Theorem B.156 (applicable: R is complete Noetherian local and $f_i \in \mathfrak{m}$),

$$c(T) = c(R/J) \;\geq\; \min\{\dim R, \dim R - 1\} - h = \dim R - 1 - h \;\geq\; D.$$

A separation principle. Let $\{1, \dots, m\} = A \sqcup B$ with A, B non-empty, $U = \bigcup_{i \in A} T_i$, $V = \bigcup_{j \in B} T_j$ and $Z = U \cap V = \bigcup_{i \in A, j \in B} (T_i \cap T_j)$, a closed set. Then $T \setminus Z$ is disconnected: it is the union of $U \setminus Z$ and $V \setminus Z$, which are disjoint (a common point lies in $U \cap V = Z$) and open in $T \setminus Z$ (each is the complement of the closed set V, resp. U); and they are non-empty, because for $i \in A$ the component T_i is not contained in V (otherwise the irreducible set T_i would lie in some T_j with $j \neq i$, contradicting the maximality of the distinct components), so $T_i \setminus Z \supseteq T_i \setminus V \neq \emptyset$, and likewise for B. Hence $\dim Z \geq c(T) \geq D$.

Proof of 1. If $m = 1$, then $\dim R/P_1 = \dim R/J \geq \dim R - h \geq D + 1$ by Krull's inequality $\dim R/(f_1, \dots, f_h) \geq \dim R - h$ for a Noetherian local ring (Atiyah–Macdonald, Corollary 11.18). If $m \geq 2$, fix i and apply the separation principle to $A = \{i\}$, $B = \{1, \dots, m\} \setminus \{i\}$: the closed set $Z = T_i \cap \bigcup_{j \neq i} T_j$ has $\dim Z \geq D$, and $Z \neq T_i$ (shown above). A chain $Z_0 \subsetneq \cdots \subsetneq Z_e$ of irreducible closed subsets of Z with $e = \dim Z$ extends by $T_i \supsetneq Z_e$, so $\dim R/P_i = \dim T_i \geq \dim Z + 1 \geq D + 1$.

Proof of 2. Call i, j adjacent if $\dim(T_i \cap T_j) \geq D$, and let A be the set of indices joined to a given index i_0 by a chain of adjacent indices. If $B = \{1, \dots, m\} \setminus A$ were non-empty, every pair $i \in A$, $j \in B$ would have $\dim(T_i \cap T_j) < D$, so the finite union $Z = \bigcup_{i \in A, j \in B} (T_i \cap T_j)$ would have $\dim Z < D$, contradicting the separation principle. Hence every index is joined to i_0 by such a chain, and in terms of primes this is statement 2. □

Proposition 49.29. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists. Let x be a core prime of E_n^{po} that is a maximal ideal and $(\mathcal{O}', R, \iota)$ a local chart at x. Then:*

(Nn1) $\dim R/I_R^+ < n\, d_L$;

(Nn2) *for every ideal $I \subseteq W_n^{\mathrm{po}}$ finite over the weights, every place $v \mid \ell$ of L^+ and all $a \neq b$ in $\{1, \dots, n\}$,*

$$\dim R/\big(\iota(I)R + \mathfrak{m}_{\mathcal{O}} R + (\psi_{x,v,a}(g) - \psi_{x,v,b}(g) :\; g \in I_v,\; \chi_{\mathrm{cyc}}(g) = 1)\big) < n\, d_L.$$

Proof. The argument is commutative algebra and Galois cohomology of characters over L; no automorphy is used. Write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$, $\mathfrak{m}$ for the maximal ideal of R_n^{po}, $\rho = \rho^{\mathrm{u}}$, $\psi_{v,a} = \psi_{v,a}^{\mathrm{u}}$, $\rho_x = \iota \circ \rho$, $d = d_L$, ϖ a uniformiser of $\mathcal{O}$, and $[\,\cdot\,]\colon \mathbb{F}_{\mathcal{O}}^\times \to \mathcal{O}^\times$ the Teichmüller lift. The weights satisfy $w_{n,1} > \cdots > w_{n,n}$. For a prime P of R put $\eta_P = \iota^{-1}(P)$ and $\mathfrak{q}_P = \eta_P \cap W$.

Step 0: four tools. (T1) *Residues in the chart.* x is a core prime, so $\mathfrak{m}_W \subseteq x = \iota^{-1}(\mathfrak{m}_R)$. For $\gamma \in \Gamma_L^0$, $\rho(\gamma)_{aa} - [\bar{\Psi}(\gamma)^{w_{n,a}}]$ lies in W with residue 0 (Po5), hence in $\mathfrak{m}_W$; so $\rho_x(\gamma)_{aa} \equiv [\bar{\Psi}(\gamma)^{w_{n,a}}]$ and likewise $\psi_{x,v,a}(g) \equiv [\bar{\Psi}(g)^{w_{n,a}}]$ modulo $\mathfrak{m}_R$; and $\iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$. (T2) *Cutting by few elements.* Let $(S, \mathfrak{m}_S)$ be a Noetherian local ring, $I, J \subseteq S$ ideals and $t_1, \dots, t_m \in \mathfrak{m}_S$ such that every prime containing $I + (t_1, \dots, t_m)$ contains J. Then $\dim S/I \leq m + \dim S/(I + J)$. Indeed $\dim S/(I + (t)) \geq \dim S/I - m$ (Krull; Atiyah–Macdonald, Corollary 11.18, in S/I), and $\dim S/(I + (t))$ is $\dim S/\mathfrak{p}$ for a minimal prime $\mathfrak{p}$ of $I + (t)$, which contains $I + J$. (T3) *Characters*

with values in $1+\mathfrak{m}_Q$. Let Q be a complete Noetherian local domain of characteristic ℓ with finite residue field, H a profinite group and $\phi\colon H \to 1+\mathfrak{m}_Q$ a homomorphism such that $\phi \bmod \mathfrak{m}_Q^N$ is locally constant for every N. For each N, $(1+\mathfrak{m}_Q)/(1+\mathfrak{m}_Q^N)$ is a finite abelian ℓ-group ($Q/\mathfrak{m}_Q^N$ is finite, and $(1+y)^{\ell^N} = 1+y^{\ell^N}$), so $\phi_N = \phi \bmod \mathfrak{m}_Q^N$ is a continuous homomorphism to it. If $\phi^{h'} \equiv 1$ modulo every $\mathfrak{m}_Q^N$ for some $h' \geq 1$, then $\phi = 1$: by Krull's intersection theorem $\phi^{h'} = 1$; write $h' = \ell^e h''$, $\ell \nmid h''$, and $\phi(\gamma)^{h''} = 1+z$; then $1+z^{\ell^e} = 1$, so $z = 0$ in the domain Q; and with $\phi(\gamma) = 1+y$, $0 = y(h'' + y\sum_{i\geq 2}\binom{h''}{i}y^{i-2})$ with a unit second factor, so $y = 0$. (T4) *Fibres of off-triangular primes.* If η is a prime of E with $I_E^- \not\subseteq \eta$ and $I_E^+ \not\subseteq \eta$, then $\operatorname{trdeg}_{\kappa(\eta\cap W)}\kappa(\eta) \leq 1$. Indeed there are entries $e_+ = \rho(\gamma)_{ab}$ with $a<b$, of weight $p>0$, and $e_- = \rho(\gamma')_{a'b'}$ with $a'>b'$, of weight $-q<0$, outside η. Every entry e of weight j satisfies: $e \in W$ if $j=0$; $e^q e_-^j \in W$ if $j>0$; $e^p e_+^{-j} \in W$ if $j<0$; and $e_+^q e_-^p \in W$ (weight-zero products lie in W). So in $\kappa(\eta)$ the image of every entry is algebraic over $\kappa(\eta\cap W)(\bar{e}_-)$, and $\kappa(\eta)$ is generated over $\kappa(\eta\cap W)$ by these images, since E is generated over W by the entries. Moreover, E is of finite type over W: it is generated by the modules gr_j for the finitely many weights j of entries, each finitely generated by (Gw3).

Step 1: upper-triangular reductions are residual on W. Let t be the family of the following $m = 2 + C_0 + (n-1)d$ elements of $\mathfrak{m}_R$ (by (T1)): ϖ; $\rho_x(s_k)_{11} - 1$ for $1 \leq k \leq 1+C_0+d$; and, if $n=3$, $\rho_x(s'_b)_{22} - 1$ for $1 \leq b \leq d$. Let P be a prime of R containing I_R^+ and all members of t. We show $\iota(\mathfrak{m}_W) \subseteq P$. Let $Q = R/P$, a complete Noetherian local domain of characteristic ℓ ($\ell \in \varpi\mathcal{O}$) with finite residue field $\mathbb{F}_{\mathcal{O}'}$, and $\bar\rho$ the reduction of ρ_x. Its upper entries vanish, so $\chi_a(\gamma) = \bar\rho(\gamma)_{aa}$ is a homomorphism $\Gamma_L^0 \to Q^\times$, and by (T1) $\phi_a(\gamma) = \chi_a(\gamma)[\bar\Psi(\gamma)]^{-w_{n,a}}$ is a homomorphism to $1+\mathfrak{m}_Q$, locally constant modulo every $\mathfrak{m}_Q^N$ by (Qc5).

- $a=1$: $\phi_1(s_k) = 1$ for all k, since $\bar\Psi(s_k) = 1$; by (Ab1) applied to each $\phi_{1,N}$ of (T3), $\phi_1^h \equiv 1$ modulo every $\mathfrak{m}_Q^N$, so $\phi_1 = 1$ by (T3).
- $n=3$, $a=2$: by (Po2) the $(2,2)$ entries of $\rho_x(\pi_L(cg^{-1}c))$ and $\rho_x(\pi_L(g))$ agree ($g \in G_L$), so $\phi_2 = \chi_2$ satisfies the invariance of (Ab2), and $\phi_2(s'_b) = 1$; by (Ab2) and (T3), $\phi_2 = 1$.
- $a = n$: by (Po2), $\chi_n(\pi_L(cg^{-1}c)) = \chi_1(\pi_L(g)) = [\bar\Psi(g)] = [\bar\Psi(cg^{-1}c)]^{-1}$ for $g \in G_L$, and $g \mapsto cg^{-1}c$ is a bijection of G_L; so $\phi_n = 1$.

Thus $\chi_a = [\bar\Psi^{w_{n,a}}]$ for all a. Next, for $v \mid \ell$ and $1 \leq a \leq n$, the (a,a) entry of the lower triangular product in (Po4) gives $\prod_{b=1}^n(\chi_a(\pi_L(g_b)) - \bar\psi_{x,v,b}(g_b)) = 0$ in the domain Q for all $g_1,\dots,g_n \in D_v$. The sets $\{g \in D_v : \chi_a(\pi_L(g)) = \bar\psi_{x,v,b}(g)\}$ are subgroups; if none were all of D_v, choosing g_b outside the b-th one would make the product non-zero. So $\chi_a \circ \pi_L = \bar\psi_{x,v,b}$ on D_v for some b, and reducing modulo $\mathfrak{m}_Q$ (T1) gives $\bar\Psi^{w_{n,a}-w_{n,b}} = 1$ on D_v. As $w_{n,a} - w_{n,b} \in \{0, \pm 1, \pm 2\}$ and $\bar\Psi|_{D_v}$, $\bar\Psi^2|_{D_v}$ are non-trivial (Af4), $b = a$: $\bar\psi_{x,v,a} = [\bar\Psi^{w_{n,a}}]$ on D_v. Finally, an entry (a,b) of the lower triangular $\bar\rho$ that is non-zero has $a \geq b$ and weight $w_{n,a} - w_{n,b} \leq 0$, with equality only for $a = b$; so the image of a weight-zero product of entries of ρ is either 0 or a product of diagonal entries, i.e. of Teichmüller lifts. Hence, with $P_W = \iota^{-1}(P) \cap W$, an ideal of W containing $\mathfrak{m}_{\mathcal{O}}W$, every weight-zero product and every $\psi_{v,a}(g)$ is congruent modulo P_W to an element of $\mathcal{O}$, and Lemma 49.32 gives $\mathfrak{m}_W \subseteq P_W$, i.e. $\iota(\mathfrak{m}_W) \subseteq P$.

Step 2: the lower-triangular fibre of the chart. $\dim R/(I_R^+ + \iota(\mathfrak{m}_W)R) \leq 2C_0$. Let P be a prime containing $I_R^+ + \iota(\mathfrak{m}_W)R$. Then $\eta_P \supseteq I_E^+$ (the images of the generators of I_E^+ generate I_R^+) and $\mathfrak{q}_P \supseteq \mathfrak{m}_W$, so $\mathfrak{q}_P = \mathfrak{m}_W$. The domain E/η_P is of finite type over the field $W/\mathfrak{m}_W$ (Step 0), so its transcendence degree equals its dimension (Noether normalisation), and $\dim E/\eta_P \leq \dim E/(\mathfrak{m}_W E + I_E^+) \leq 2C_0$ by Lemma 49.30. By Lemma 49.18, $\dim R/P \leq \dim W/\mathfrak{m}_W + 2C_0 = 2C_0$.

Step 3: (Nn1). By Step 1, (T2) applies in R with $I = I_R^+$, $J = \iota(\mathfrak{m}_W)R$ and the m elements t; with Step 2,

$$\dim R/I_R^+ \le 2 + C_0 + (n-1)d + 2C_0 = (n-1)d + 3C_0 + 2 < n\,d,$$

because $d > 3C_0 + 7$ by (Ar4).

Step 4: (Nn2). Let $I \subseteq W$ be finite over the weights, $v \mid \ell$, $a \neq b$, and $\mathfrak{b}$ the ideal of (Nn2). It suffices to show $\dim R/P < n\,d$ for every prime $P \supseteq \mathfrak{b}$. If $I_R^+ \subseteq P$, this is Step 3. Otherwise P is off-triangular ($I_R^- = R$ by (Qc3)), so by (Qc3) $I_E^\pm \not\subseteq \eta_P$, and by (T4) and Lemma 49.18, $\dim R/P \le \dim W/\mathfrak{q}_P + 1$. The prime $\mathfrak{q}_P$ contains I, ϖ, and $\psi_{v,a}(g) - \psi_{v,b}(g)$ for $g \in I_v$ with $\chi_{\mathrm{cyc}}(g) = 1$. For $w \mid \ell$ let $u_{w,1}, \dots, u_{w,d_w} \in I_w$ be as in (Ar5)(iii), and K_v the set of k with $\chi_{\mathrm{cyc}}(u_{v,k}) = 1$, so $|K_v| \ge d_v - 1$. Let t' consist of ϖ and the elements $\psi_{w,e}(u_{w,k}) - 1$ ($w \mid \ell$, $1 \le e \le n$, $1 \le k \le d_w$) except those with $(w,e) = (v,b)$ and $k \in K_v$; they lie in $\mathfrak{m}_W$ ((Po5), $\bar\Psi(u_{w,k}) = 1$), and $|t'| \le 1 + n\,d - (d_v - 1)$. Let $\mathfrak{q}' \supseteq \mathfrak{q}_P + (t')$ be a prime of W. It contains $\psi_{v,b}(u_{v,k}) - 1 = (\psi_{v,a}(u_{v,k}) - 1) - (\psi_{v,a}(u_{v,k}) - \psi_{v,b}(u_{v,k}))$ for $k \in K_v$, hence all $\psi_{w,e}(u_{w,k}) - 1$. It contains $\mathfrak{a}_n$: $Q' = W/\mathfrak{q}'$ is a complete Noetherian local domain of characteristic ℓ with finite residue field (Gw1); for w, e, the homomorphism $\phi(g) = \bar\psi_{w,e}(g)[\bar\Psi(g)]^{-w_{n,e}}$ from D_w to $1 + \mathfrak{m}_{Q'}$ is locally constant modulo every $\mathfrak{m}_{Q'}^N$ ((Po1), and $\mathfrak{m}^k \cap W \subseteq \mathfrak{m}_W^N$ for large k by Chevalley's lemma Theorem B.154 and (Gw1)), and is trivial on the $u_{w,k}$; by (Ar5)(iii) each $\phi \bmod \mathfrak{m}_{Q'}^N$ is trivial on I_w, so ϕ is trivial on I_w by Krull's intersection theorem, and $\psi_{w,e}(g) - 1 \in \mathfrak{q}'$ for $g \in I_w$ with $\bar\Psi(g) = 1$. Hence $\mathfrak{q}' \supseteq I + \mathfrak{a}_n$, and $\mathfrak{q}' \supseteq \mathfrak{m}_W$ because I is finite over the weights. By (T2) in W,

$$\dim W/\mathfrak{q}_P \le |t'| + \dim W/\mathfrak{m}_W \le n\,d + 2 - d_v, \qquad \dim R/P \le n\,d + 3 - d_v < n\,d,$$

because $d_v > 5$ by (Ar4). □

Lemma 49.30. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $E = E_n^{\mathrm{po}}$. Then* $\dim E/(\mathfrak{m}_W E + I_E^+) \le 2C_0$.

Proof. The argument is Galois cohomology of characters of Γ_L and commutative algebra; no automorphy is used, over L or over K. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $W = W_n^{\mathrm{po}}$, $\rho = \rho^{\mathrm{u}}$, $\mathfrak{m}$ for the maximal ideal of R_n^{po}, $\bar c = \pi_L(c)$ and $\gamma^* = \bar c \gamma^{-1} \bar c$ for $\gamma \in \Gamma_L^0$ (an anti-automorphism of Γ_L^0). As $g_\star \in G_L$ (Af1), $\gamma_\star = \pi_L(g_\star) \in \Gamma_L^0$, and $\bar\Psi(\gamma_\star)^2 \neq 1$. Every place of L^+ above ℓ splits in L ((Af2), $\ell \mid M$), so $D_v \subseteq G_L$ and $\pi_L(D_v) \subseteq \Gamma_L^0$. Since $\bar\Psi(c) = 1$, $\bar\Psi(\gamma^*) = \bar\Psi(\gamma)^{-1}$ and $\bar\Psi(\bar c \gamma \bar c) = \bar\Psi(\gamma)$.

Step 0: the fibre algebra and its grading. Let $\bar A = E/(\mathfrak{m}_W E + I_E^+)$. By (Gw2), $E = \bigoplus_j \mathrm{gr}_j$ with $\mathrm{gr}_0 = W$, and $\mathfrak{m}_W E = \bigoplus_j \mathfrak{m}_W \mathrm{gr}_j$ and I_E^+ (generated by the upper entries, which are homogeneous) are homogeneous ideals; so $\bar A = \bigoplus_j \bar A_j$ with $\bar A_j$ the image of gr_j. A product of entries of positive weight has an upper factor, so $\bar A_j = 0$ for $j > 0$; $\bar A_0$ is the image of W, i.e. $\mathbb{F} = W/\mathfrak{m}_W$ (or 0); each $\bar A_j$ is a finite-dimensional $\mathbb{F}$-space by (Gw3). For $\gamma \in \Gamma_L^0$ let $\bar\rho(\gamma)$ be the image of $\rho(\gamma)$ in $\mathrm{M}_n(\bar A)$: it is lower triangular, multiplicative in γ, and its diagonal is $\mathrm{diag}(\bar\Psi(\gamma)^{w_{n,1}}, \dots, \bar\Psi(\gamma)^{w_{n,n}})$, because $\rho(\gamma)_{aa} \in W$ has residue $\bar\Psi(\gamma)^{w_{n,a}}$ (Po5); likewise the image of $\psi_{v,a}^{\mathrm{u}}(g)$ is $\bar\Psi(g)^{w_{n,a}}$. Moreover:

- *(continuity)* for each a, b the map $\gamma \mapsto \bar\rho(\gamma)_{ab}$ is locally constant: the submodules $\mathfrak{m}^k \cap \mathrm{gr}_j$ of the finitely generated W-module gr_j decrease with intersection 0 (Krull), so by Chevalley's lemma Theorem B.154 and (Gw1) some $\mathfrak{m}^k \cap \mathrm{gr}_j$ lies in $\mathfrak{m}_W \mathrm{gr}_j$, which maps to 0 in $\bar A$, and $\gamma \mapsto \rho(\gamma) \bmod \mathfrak{m}^k$ is locally constant (Po1);
- *(polarisation)* $\bar\rho(\gamma^*)_{ab} = \bar\rho(\gamma)_{n+1-b,n+1-a}$, by (Po2) and $(J_n {}^t X J_n)_{ab} = X_{n+1-b,n+1-a}$;

- *(marking)* $\bar\rho(\gamma_\star)_{ab} = \bar\rho(\gamma_\star^*)_{ab}$ for $a \neq b$, by (Po3);
- *(ordinarity)* for $v \mid \ell$ and $g_1, \dots, g_n \in D_v$, $\prod_{a=1}^n \big(\bar\rho(\pi_L(g_a)) - \bar\Psi(g_a)^{w_{n,a}}\big) = 0$, by (Po4).

Fix, for each $v \mid \ell$, elements $s_v, s_v' \in D_v$ with $\bar\Psi(s_v)^2 \neq 1$ and $\bar\Psi(s_v') \neq 1$ (Af4).

Step 1: two cocycle spaces. For an $\mathbb{F}$-vector space V (with trivial action) consider maps $\Gamma_L^0 \to V$.

(a) Let Z_2 be the space of locally constant $u\colon \Gamma_L^0 \to \mathbb{F}$ with $u(\gamma\gamma') = u(\gamma)\bar\Psi(\gamma') + \bar\Psi(\gamma)^{-1}u(\gamma')$, $u(\gamma^*) = u(\gamma)$, and for each $v \mid \ell$ some $\lambda_v \in \mathbb{F}$ with $u(\pi_L(g)) = \lambda_v(\bar\Psi(g) - \bar\Psi(g)^{-1})$ for $g \in D_v$. Then $\dim Z_2 \leq C_0$. Indeed, put $\chi = \bar\Psi^{-2}\eta_K$, a character of Γ_L with $\chi = \bar\Psi^{-2}$ on Γ_L^0 ($K \subseteq L$) and $\chi(\bar c) = -1$. For $u \in Z_2$ let $x = \bar\Psi^{-1}u$; then $x(\gamma\gamma') = x(\gamma) + \chi(\gamma)x(\gamma')$, $x(\gamma^*) = \bar\Psi(\gamma)^2 x(\gamma)$, hence (with $x(\gamma^{-1}) = -\chi(\gamma)^{-1}x(\gamma)$) $x(\bar c\gamma\bar c) = -x(\gamma)$. Define y on $\Gamma_L = \Gamma_L^0 \sqcup \Gamma_L^0\bar c$ by $y(\gamma) = y(\gamma\bar c) = x(\gamma)$. The cocycle identity $y(gh) = y(g) + \chi(g)y(h)$ holds in the four cases $g \in \Gamma_L^0$ or $\Gamma_L^0\bar c$, $h \in \Gamma_L^0$ or $\Gamma_L^0\bar c$:

The map y is continuous, $y(\bar c) = 0$, and on $\pi_L(D_v)$, $y(\pi_L(g)) = \lambda_v(1 - \bar\Psi(g)^{-2}) = (\chi(g) - 1)(-\lambda_v)$: a coboundary, so y is a strict cocycle (for the family $(D_v)_{v\mid\ell}$, with $X_v = -\lambda_v$). The map $u \mapsto y$ is injective and linear. A coboundary $y = (g \mapsto (\chi(g) - 1)X)$ has $y(\bar c) = -2X$, so the strict cocycles with $y(\bar c) = 0$ meet the coboundaries in 0 (ℓ odd), and they inject into $H^1_{\mathrm{str}}(\Gamma_L, \mathbb{F}(\bar\Psi^{-2}\eta_K))$ (the X_v are determined by y because $\chi|_{D_v} \neq 1$). By (Ar3), $\dim Z_2 \leq C_0$.

(b) ($n = 3$.) Let Z_1 be the space of locally constant $b\colon \Gamma_L^0 \to \mathbb{F}$ with $b(\gamma\gamma') = b(\gamma)\bar\Psi(\gamma') + b(\gamma')$, $b(\gamma_\star) = b(\gamma_\star^*)$, and for each $v \mid \ell$ some $\lambda_v, \mu_v \in \mathbb{F}$ with $b(\pi_L(g)) = \lambda_v(\bar\Psi(g) - 1)$ and $b(\pi_L(g)^*) = \mu_v(1 - \bar\Psi(g)^{-1})$ for $g \in D_v$. Then $\dim Z_1 \leq C_0$. Indeed, $x = \bar\Psi^{-1}b$ satisfies $x(\gamma\gamma') = x(\gamma) + \bar\Psi(\gamma)^{-1}x(\gamma')$, a continuous cocycle for $\mathbb{F}(\bar\Psi^{-1})$. On $\pi_L(D_v)$, $x = (\bar\Psi^{-1} - 1)(-\lambda_v)$; on $\pi_L(cD_vc)$, writing $\bar c\pi_L(g)\bar c = \pi_L(g^{-1})^*$, $x(\bar c\pi_L(g)\bar c) = \bar\Psi(g)^{-1}\mu_v(1 - \bar\Psi(g)) = (\bar\Psi(g)^{-1} - 1)\mu_v$, and $\bar\Psi(\bar c\pi_L(g)\bar c) = \bar\Psi(g)$: a coboundary as well. So x is strict for the family $(D_v)_v, (cD_vc)_v$ of Γ_L^0. The linear form $\mu(b) = b(\gamma_\star) - b(\gamma_\star^*)$ vanishes on Z_1, while on the coboundary $x = (\bar\Psi^{-1} - 1)X$, i.e. $b = (1 - \bar\Psi)X$, it takes the value $(\bar\Psi(\gamma_\star)^{-1} - \bar\Psi(\gamma_\star))X \neq 0$ for $X \neq 0$. Hence Z_1 meets the coboundaries in 0 and injects into $H^1_{\mathrm{str}}(\Gamma_L^0, \mathbb{F}(\bar\Psi^{-1}))$ ($\bar\Psi^{-1}$ is non-trivial on $\pi_L(D_v)$ and on $\pi_L(cD_vc)$, so the X_t are determined); by (Ar3), $\dim Z_1 \leq C_0$.

Step 2: from spans of values to cocycles. Let V be an $\mathbb{F}$-space and $\beta\colon \Gamma_L^0 \to V$ a map whose values span V, such that $\lambda \circ \beta \in Z$ for every linear form λ on V, where Z is a finite-dimensional space of functions. Then $\lambda \mapsto \lambda \circ \beta$ is injective on V^* (a form vanishing on all values vanishes on V), so $\dim V^* \leq \dim Z$ and $\dim V \leq \dim Z$.

Step 3: ordinarity on D_v. Write the entries of $\bar\rho$ below the diagonal as $b = \bar\rho_{21}$, and, if $n = 3$, $f = \bar\rho_{32}$, $e = \bar\rho_{31}$; if $n = 2$ put $e = \bar\rho_{21}$. Let $g, g' \in D_v$ and write $\bar\Psi$ for $\bar\Psi(g)$ etc.

- $n = 2$: the $(2,1)$ entry of the product in (Po4) for (g, g') is $e(g)(\bar\Psi(g') - \bar\Psi(g')^{-1}) + (\bar\Psi(g)^{-1} - \bar\Psi(g))e(g')$; with $g' = s_v$, $e = \lambda_v(\bar\Psi - \bar\Psi^{-1})$ on $\pi_L(D_v)$, $\lambda_v \in \bar A_{-2}$.
- $n = 3$, for (g_1, g_2, g_3): the $(2,1)$ entry is $(\bar\Psi(g_3) - \bar\Psi(g_3)^{-1})\big[b(g_1)(\bar\Psi(g_2) - 1) + (1 - \bar\Psi(g_1))b(g_2)\big]$, and the $(3,2)$ entry is $(\bar\Psi(g_1)^{-1} - \bar\Psi(g_1))\big[f(g_2)(1 - \bar\Psi(g_3)^{-1}) + (\bar\Psi(g_2)^{-1} - 1)f(g_3)\big]$. Taking $g_3 = s_v$, $g_2 = s_v'$, resp. $g_1 = s_v$, $g_3 = s_v'$: $b = \lambda_v(\bar\Psi - 1)$ and $f = \mu_v(1 - \bar\Psi^{-1})$ on $\pi_L(D_v)$, with $\lambda_v, \mu_v \in \bar A_{-1}$. If b and f vanish identically (in a quotient of $\bar A$), the $(3,1)$ entry is $e(g_1)(\bar\Psi(g_2) - 1)(\bar\Psi(g_3) - \bar\Psi(g_3)^{-1}) + (\bar\Psi(g_1)^{-1} - \bar\Psi(g_1))e(g_2)(\bar\Psi(g_3) - \bar\Psi(g_3)^{-1}) + (\bar\Psi(g_1)^{-1} - \bar\Psi(g_1))(\bar\Psi(g_2)^{-1} - 1)e(g_3)$, and $g_1 = g_3 = s_v$ gives $e = \lambda_v'(\bar\Psi - \bar\Psi^{-1})$ on $\pi_L(D_v)$.

Step 4: rank 2. Here $\bar{A}_{-1} = 0$ and $\bar{A}$ is generated as an $\mathbb{F}$-algebra by $V = \bar{A}_{-2}$, the span of the values $e(\gamma)$ (a product of entries of weight $-2k$ without upper factor is a product of k lower entries and diagonal entries). By multiplicativity, (polarisation) and Step 3, e satisfies the three conditions of Z_2 with values in V; for every linear form λ on V, $\lambda \circ e$ is locally constant (continuity, V finite-dimensional) and lies in Z_2. By Step 2 and Step 1(a), $\dim V \le C_0$, and $\bar{A}$, a quotient of a polynomial ring over $\mathbb{F}$ in $\dim V$ variables, has dimension $\le C_0 \le 2C_0$.

Step 5: rank 3. By (polarisation), $f(\gamma) = b(\gamma^*)$ and $b(\gamma) = f(\gamma^*)$, so $V_1 = \bar{A}_{-1}$ is the span of the values of b (a product of weight -1 without upper factor is one lower entry of weight -1 times diagonal entries). By multiplicativity, (marking), Step 3 and $b(\pi_L(g)^*) = f(\pi_L(g))$, every $\lambda \circ b$ lies in Z_1; so $p = \dim V_1 \le C_0$ by Steps 1(b), 2. Let $\bar{A}' = \bar{A}/V_1\bar{A}$, graded with $\bar{A}'_j = \bar{A}_j/(V_1\bar{A})_j$, and $V_2' \subseteq \bar{A}'_{-2}$ the span of the images of the values of e. In $\bar{A}'$, $b = f = 0$, so the $(3,1)$ entry of $\bar{\rho}(\gamma\gamma') = \bar{\rho}(\gamma)\bar{\rho}(\gamma')$ gives $e(\gamma\gamma') = e(\gamma)\bar{\Psi}(\gamma') + \bar{\Psi}(\gamma)^{-1}e(\gamma')$; (polarisation) gives $e(\gamma^*) = e(\gamma)$; Step 3 gives the condition on $\pi_L(D_v)$. Hence every $\lambda \circ e$, λ a linear form on V_2', lies in Z_2, and $q = \dim V_2' \le C_0$. Choose $\gamma_1, \dots, \gamma_q$ such that the images of $e(\gamma_i)$ span V_2', and a basis $y_1, \dots, y_p$ of V_1. Let $S \subseteq \bar{A}$ be the $\mathbb{F}$-subalgebra generated by the y_i and the $e(\gamma_i)$. By induction on k, $\bar{A}_{-k} \subseteq S$: for $k \le 1$ this is clear; for $k \ge 2$, $\bar{A}_{-k}$ is spanned by products of lower entries (times diagonal entries) of total weight $-k$; such a product with a factor of weight -1 lies in $V_1\bar{A}_{-k+1} \subseteq S$; otherwise it is a product of $k/2$ values of e, and $\bar{A}_{-2} = V_2 + V_1V_1 \subseteq \operatorname{span}(e(\gamma_i)) + (V_1\bar{A})_{-2} + V_1V_1 \subseteq S$ (as $(V_1\bar{A})_{-2} = V_1\bar{A}_{-1} = V_1V_1$), where V_2 is the span of the values of e in $\bar{A}$. So $\bar{A} = S$ is generated by $p + q \le 2C_0$ elements, and $\dim \bar{A} \le 2C_0$. □

Lemma 49.31. *Let ℓ be odd and L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, and $d_L = [L^+ : \mathbb{Q}]$. There are elements $s_1, \dots, s_{1+C_0+d_L} \in \Gamma_L^0$ with $\bar{\Psi}(s_a) = 1$, elements $s'_1, \dots, s'_{d_L} \in \Gamma_L^0$, each of the form $\pi_L(g)$ with $g \in I_v$ for some $v \mid \ell$ and $\bar{\Psi}(g) = 1$, and an integer $h \ge 1$ such that for every finite abelian ℓ-group A and every continuous homomorphism $\chi\colon \Gamma_L^0 \to A$:*

(Ab1) *if $\chi(s_a) = 1$ for all a, then $\chi^h = 1$;*

(Ab2) *if $\chi(\pi_L(cg^{-1}c)) = \chi(\pi_L(g))$ for all $g \in G_L$ and $\chi(s'_b) = 1$ for all b, then $\chi^h = 1$.*

Proof. Write $\bar{c} = \pi_L(c) \in \Gamma_L$; since $c^2 = 1$ and $G_{L^+} = G_L \sqcup cG_L$, $\bar{c}^2 = 1$, $\Gamma_L = \Gamma_L^0 \cup \bar{c}\Gamma_L^0$, and $\mathrm{cj}(\gamma) = \bar{c}\gamma\bar{c}$ is an automorphism of Γ_L^0 with $\mathrm{cj}^2 = \mathrm{id}$ and $\pi_L(cg^{-1}c) = \mathrm{cj}(\pi_L(g))^{-1}$ for $g \in G_L$.

Step 1: (Ab2). For each $v \mid \ell$ let $u_{v,1}, \dots, u_{v,d_v} \in I_v$ be as in (Ar5)(iii) (so $\bar{\Psi}(u_{v,k}) = 1$), let $s'_1, \dots, s'_{d_L}$ be the elements $\pi_L(u_{v,k})$, and let h be as in (Ar5)(ii). Let χ be as in (Ab2). For each v, $\chi \circ \pi_L$ restricted to D_v is a continuous homomorphism to A trivial on the $u_{v,k}$, hence trivial on I_v by (Ar5)(iii). For $g \in I_v$, $\chi(\pi_L(cgc)) = \chi(\pi_L(c(g^{-1})^{-1}c)) = \chi(\pi_L(g^{-1})) = 1$. So χ is trivial on $\pi_L(I_v)$ and $\pi_L(cI_vc)$ for all v, and $\chi^h = 1$ by (Ar5)(ii).

Step 2: elements of Γ_L detecting abelian ℓ-quotients. Let V be the $\mathbb{F}_\ell$-vector space of continuous homomorphisms $\Gamma_L \to \mathbb{F}_\ell$. An $\mathbb{F}_\ell$-basis of V stays linearly independent over $\mathbb{F}_\mathcal{O}$ inside the space of continuous homomorphisms $\Gamma_L \to \mathbb{F}_\mathcal{O}$, which is $H^1(\Gamma_L, \mathbb{F}_\mathcal{O})$; so $\dim V \le 1 + C_0$ by (Ar3). The evaluations $f \mapsto f(t)$, $t \in \Gamma_L$, have no common non-zero zero in V, so they span the dual of V, and there are $t_1, \dots, t_{1+C_0} \in \Gamma_L$ (repeat $t = 1$ if needed) such that $f \in V$ and $f(t_a) = 0$ for all a imply $f = 0$. Let $\varphi\colon \Gamma_L \to A$ be a continuous homomorphism to a finite abelian ℓ-group with $\varphi(t_a) = 1$ for all a. If $\varphi \ne 1$, its image A' is a non-trivial finite abelian ℓ-group, so $A'/A'^\ell \ne 0$ has a non-zero linear form, which gives a homomorphism $\theta\colon A' \to \mathbb{F}_\ell$ with $\theta \circ \varphi \ne 0$; then $\theta \circ \varphi \in V$ vanishes at all t_a, a contradiction. So $\varphi = 1$.

Step 3: (Ab1). For $\gamma \in \Gamma_L$ put $q(\gamma) = \gamma$ if $\gamma \in \Gamma_L^0$ and $q(\gamma) = \bar{c}\gamma \in \Gamma_L^0$ otherwise. Let e be the order of $\mathbb{F}_\mathcal{O}^\times$, prime to ℓ. Put $s_a = \big(q(t_a)\,\mathrm{cj}(q(t_a))\big)^e$ for $1 \le a \le 1 + C_0$ and $s_{1+C_0+b} = s'_b$

for $1 \le b \le d_L$. Then $\bar\Psi(s_a) = 1$, since $\bar\Psi$ takes values in $\mathbb{F}_{\mathcal{O}}^\times$, and $\bar\Psi(s'_b) = 1$. Let χ be trivial on all s_a. Then $\nu = \chi \cdot (\chi \circ \mathrm{cj})$ is a continuous homomorphism $\Gamma_L^0 \to A$ with $\nu \circ \mathrm{cj} = \nu$. If $\bar c \in \Gamma_L^0$, then $\Gamma_L = \Gamma_L^0$, and we put $\varphi = \nu$; otherwise put $\varphi(\gamma) = \nu(\gamma)$ and $\varphi(\bar c\gamma) = \nu(\gamma)$ for $\gamma \in \Gamma_L^0$. This φ is a homomorphism: for $\gamma, \gamma' \in \Gamma_L^0$, $(\bar c\gamma)(\bar c\gamma') = \mathrm{cj}(\gamma)\gamma'$ and $\gamma(\bar c\gamma') = \bar c\,\mathrm{cj}(\gamma)\gamma'$, and $\nu(\mathrm{cj}(\gamma)) = \nu(\gamma)$; it is continuous, its kernel containing the open subgroup $\ker\nu$ of Γ_L. As $t_a = \bar c^{\epsilon} q(t_a)$ with $\epsilon \in \{0,1\}$, $\varphi(t_a) = \nu(q(t_a))$, and $\nu(q(t_a))^e = \chi(s_a) = 1$; an element of the ℓ-group A of order dividing e is trivial, so $\varphi(t_a) = 1$ for all a, and $\varphi = 1$ by Step 2. Hence $\chi(\mathrm{cj}(\gamma)) = \chi(\gamma)^{-1}$ for $\gamma \in \Gamma_L^0$, and for $g \in G_L$, $\chi(\pi_L(cg^{-1}c)) = \chi(\mathrm{cj}(\pi_L(g)))^{-1} = \chi(\pi_L(g))$. Since moreover $\chi(s'_b) = 1$, Step 1 gives $\chi^h = 1$. □

Lemma 49.32. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$. Let $P \subseteq W$ be an ideal with $\mathfrak{m}_{\mathcal{O}} W \subseteq P$ such that every product $\prod_k \rho^{\mathrm{u}}(\gamma_k)_{a_k b_k}$ with $\sum_k (w_{n,a_k} - w_{n,b_k}) = 0$ and every $\psi^{\mathrm{u}}_{v,a}(g)$ $(v \mid \ell,\ 1 \le a \le n,\ g \in D_v)$ is congruent modulo P to the image of an element of $\mathcal{O}$. Then $\mathfrak{m}_W \subseteq P$.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of R_n^{po}. If $P = W$ there is nothing to prove; otherwise $P \subseteq \mathfrak{m}_W$, because W is local with maximal ideal $\mathfrak{m}_W$ by (Gw1) of Lemma 49.14. Let $W_0 \subseteq W$ be the $\mathcal{O}$-subalgebra generated by the weight-zero products and the $\psi^{\mathrm{u}}_{v,a}(g)$. The set of $x \in W$ congruent modulo P to the image of an element of $\mathcal{O}$ is an $\mathcal{O}$-subalgebra (congruences add and multiply) containing these generators, so it contains W_0.

The submodules $\mathfrak{m}^N \cap W$ of the W-module W decrease and have intersection 0 (Krull's intersection theorem in the Noetherian local ring R_n^{po}). By (Gw1), W is a complete Noetherian local ring, so by Chevalley's lemma (Theorem B.154) for every $k \ge 1$ there is N with $\mathfrak{m}^N \cap W \subseteq \mathfrak{m}_W^k$.

Let $y \in \mathfrak{m}_W$ and $k \ge 1$, and take N as above. By the definition of W there is $y_N \in W_0$ with $y - y_N \in \mathfrak{m}^N$, hence $y - y_N \in \mathfrak{m}^N \cap W \subseteq \mathfrak{m}_W^k$; and there is $c \in \mathcal{O}$ with $y_N - c \in P \subseteq \mathfrak{m}_W$. Then $c = y - (y - y_N) - (y_N - c) \in \mathfrak{m}_W$, so $c \in \mathfrak{m}_{\mathcal{O}}$, since $\mathcal{O} \to W$ is local ((Gw1)); hence $c \in P$. So $y = (y - y_N) + (y_N - c) + c \in \mathfrak{m}_W^k + P$. As k is arbitrary, $y \in \bigcap_k (P + \mathfrak{m}_W^k) = P$, by Krull's intersection theorem in the Noetherian local ring W/P. □

Proposition 49.33. *Let ℓ be odd and L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ such that universal polarised ordinary lifts of ranks 2 and 3 over L exist. If an ideal $\mathcal{M}_2 \subseteq W_2^{\mathrm{po}}$ is finite over the weights and absorbs the primes of irreducible type, then there is an ideal $I_3 \subseteq W_3^{\mathrm{po}}$, finite over the weights, with $I_3 \subseteq \xi \cap W_3^{\mathrm{po}}$ for every prime ξ of E_3^{po} of endoscopic type.*

Proof. The proof is commutative algebra on rings attached to L; in particular, no automorphy over L or over K is used. Write $W_n = W_n^{\mathrm{po}}$, $E_n = E_n^{\mathrm{po}}$, $R_n = R_n^{\mathrm{po}}$ with maximal ideal $\mathfrak{m}^{(n)}$, $\rho_n = \rho^{\mathrm{u}}$, $\psi_{n,v,a} = \psi^{\mathrm{u}}_{v,a}$ for the universal lifts of rank $n \in \{2,3\}$, and write $\rho_3(g)$ for $\rho_3(\pi_L(g))$. In rank 3 the positions (a,b) with $w_{3,a} - w_{3,b}$ odd are those with exactly one index equal to 2. Let $I^{\mathrm{odd}} = I^{\mathrm{odd}}_{E_3}$. If $I^{\mathrm{odd}} = E_3$, no prime of E_3 is of endoscopic type and $I_3 = W_3$ will do. Assume from now on $I^{\mathrm{odd}} \ne E_3$, and put $B = E_3/I^{\mathrm{odd}}$, $C = W_3/(I^{\mathrm{odd}} \cap W_3) \subseteq B$, $p\colon W_3 \to C$ the projection, and $\bar y$ the image in B of $y \in E_3$. By (Gw1) of Lemma 49.14, C is a non-zero quotient of an object of $\mathrm{CNL}_{\mathcal{O}}$, hence one itself; an element of W_3 with non-zero residue is a unit of W_3, so its image in B is a unit.

Step 1: topologies. For a finitely generated W_3-submodule $N \subseteq E_3$ and $k \ge 1$ there is t with $(\mathfrak{m}^{(3)})^t \cap N \subseteq \mathfrak{m}_{W_3}^k N$: the submodules $(\mathfrak{m}^{(3)})^t \cap N$ decrease with intersection 0 (Krull's intersection theorem in R_3), and Chevalley's lemma (Theorem B.154) applies over W_3 by (Gw1). With (Po1) this gives: for $1 \le a, b \le 3$ and N_{ab} the W_3-span of the entries $\rho_3(\gamma)_{ab}$, $\gamma \in \Gamma_L^0$ (finitely generated,

being a submodule of $\mathrm{gr}_{w_{3,a}-w_{3,b}}$, which is finite over the Noetherian ring W_3 by (Gw3)), the map $\gamma \mapsto \rho_3(\gamma)_{ab} \bmod \mathfrak{m}_{W_3}^k N_{ab}$ is locally constant; likewise $g \mapsto \psi_{3,v,a}(g) \bmod \mathfrak{m}_{W_3}^k$ (take $N = W_3$).

Step 2: the residual corner. For $\gamma, \gamma' \in \Gamma_L^0$ the odd entries of ρ_3 vanish in B, so the matrices $\bar\rho_3(\gamma)$ are block diagonal for the blocks $\{1,3\}$ and $\{2\}$; hence $\sigma(\gamma) = (\bar\rho_3(\gamma)_{ab})_{a,b\in\{1,3\}}$ and $\gamma \mapsto \bar\rho_3(\gamma)_{22}$ are multiplicative, $\sigma\colon \Gamma_L^0 \to \mathrm{GL}_2(B)$ is a homomorphism, and in W_3

$$\rho_3(\gamma\gamma')_{22} - \rho_3(\gamma)_{22}\rho_3(\gamma')_{22} = \rho_3(\gamma)_{21}\rho_3(\gamma')_{12} + \rho_3(\gamma)_{23}\rho_3(\gamma')_{32} \in I^{\mathrm{odd}} \cap W_3, \tag{49.3}$$

both products being of weight 0. Fix $v \mid \ell$. By (Af4) there is $g_1 \in D_v$ with $\bar\Psi(g_1)^2 \neq 1$. The elements $u_1 = \rho_3(g_1)_{22} - \psi_{3,v,1}(g_1)$, $u_3 = \rho_3(g_1)_{22} - \psi_{3,v,3}(g_1)$ and $\delta = (\rho_3(g_1)_{11} - \psi_{3,v,2}(g_1))(\rho_3(g_1)_{33} - \psi_{3,v,2}(g_1)) - \rho_3(g_1)_{13}\rho_3(g_1)_{31}$ lie in W_3 and by (Po5) have residues $1-\bar\Psi(g_1)$, $1-\bar\Psi(g_1)^{-1}$, $(\bar\Psi(g_1)-1)(\bar\Psi(g_1)^{-1}-1)$, all non-zero; so $\bar u_1, \bar u_3, \bar\delta$ are units of B. For $x, g, y \in D_v$ the product in (Po4) is a product of block diagonal matrices in B. Its $(2,2)$ entry for (g_1, g, g_1) is $\bar u_1(\bar\rho_3(g)_{22} - \bar\psi_{3,v,2}(g))\bar u_3 = 0$, so

$$\rho_3(g)_{22} - \psi_{3,v,2}(g) \in I^{\mathrm{odd}} \cap W_3 \qquad (g \in D_v). \tag{49.4}$$

Its $\{1,3\}$ block for (x, g_1, y) is $P_x\,\Theta\,Q_y = 0$, with $P_x = \sigma(x) - \bar\psi_{3,v,1}(x)$, $\Theta = \sigma(g_1) - \bar\psi_{3,v,2}(g_1)$, $Q_y = \sigma(y) - \bar\psi_{3,v,3}(y)$. Taking $y = g_1$ in $P_x\Theta\sigma(y) = \bar\psi_{3,v,3}(y)P_x\Theta$ gives $P_x\Theta^2 = (\bar\psi_{3,v,3}(g_1) - \bar\psi_{3,v,2}(g_1))P_x\Theta$, and with the Cayley–Hamilton identity $\Theta(\operatorname{tr}\Theta - \Theta) = \det\Theta$,

$$\det(\Theta)\,P_x = P_x\Theta(\operatorname{tr}\Theta - \Theta) = \big(\operatorname{tr}\Theta - \bar\psi_{3,v,3}(g_1) + \bar\psi_{3,v,2}(g_1)\big)P_x\Theta.$$

Multiplying on the right by Q_y gives $\det(\Theta)P_xQ_y = 0$, and $\det\Theta = \bar\delta$ is a unit, so $P_xQ_y = 0$ for all $x, y \in D_v$.

Step 3: the corner factors through E_2. Put $\psi'_{v,1} = \bar\psi_{3,v,1}$, $\psi'_{v,2} = \bar\psi_{3,v,3}$; recall $(w_{2,1}, w_{2,2}) = (w_{3,1}, w_{3,3}) = (1,-1)$. Then σ, $(\psi'_{v,a})$ satisfy the hypotheses of Lemma 49.16 for $n = 2$, B and C. (Po2): $(J_3{}^tXJ_3)_{ab} = X_{4-b,4-a}$ and $(J_2{}^tYJ_2)_{ab} = Y_{3-b,3-a}$ correspond under $1 \mapsto 1$, $2 \mapsto 3$. (Po3): the corner off-diagonal entries are the entries $(1,3)$, $(3,1)$. (Po4): Step 2. (Cq1), (Cq5): $\rho_3(\gamma)_{11}$, $\rho_3(\gamma)_{33}$, $\psi_{3,v,1}(g)$, $\psi_{3,v,3}(g)$ lie in W_3 with the residues of (Po5); local constancy by Step 1. (Cq2): a product of corner entries of weight 0 with an off-diagonal factor is the image of a weight-zero product of entries of ρ_3 with a factor in $\mathfrak{m}^{(3)}$ (Po5), an element of $\mathfrak{m}^{(3)} \cap W_3 = \mathfrak{m}_{W_3}$, whose image lies in $\mathfrak{m}_C$. (Cq3), (Cq4): the C-span of the $\sigma(\gamma)_{ab}$ is the image of $N_{a'b'}$ $(a', b' \in \{1,3\})$, finitely generated, and Step 1 gives the local constancy. By Lemma 49.16 there are $\mathcal{O}$-algebra homomorphisms $\xi\colon E_2 \to B$ and $\beta\colon W_2 \to C$, β local, with $\xi(\rho_2(\gamma)_{ab}) = \sigma(\gamma)_{ab}$, $\xi(\psi_{2,v,a}(g)) = \psi'_{v,a}(g)$ and $\xi = \beta$ on W_2. Put

$$I_3 = p^{-1}(\beta(\mathcal{M}_2)C) \subseteq W_3.$$

Step 4: I_3 lies in every endoscopic prime. Let $\mathfrak{p}$ be a prime of E_3 of endoscopic type; then $I^{\mathrm{odd}} \subseteq \mathfrak{p}$ and $\bar{\mathfrak{p}} = \mathfrak{p}/I^{\mathrm{odd}}$ is a prime of B. Let $\mathfrak{p}_2 = \xi^{-1}(\bar{\mathfrak{p}})$, a prime of E_2. Since $I^-_{E_3} \not\subseteq \mathfrak{p}$ and the lower entries $(2,1)$, $(3,2)$ are odd, some $\rho_3(\gamma)_{31} \notin \mathfrak{p}$; as $\xi(\rho_2(\gamma)_{21}) = \bar\rho_3(\gamma)_{31}$, $I^-_{E_2} \not\subseteq \mathfrak{p}_2$; likewise $I^+_{E_2} \not\subseteq \mathfrak{p}_2$ with the entry $(1,3)$. So $\mathfrak{p}_2$ is of irreducible type (rank 2), and by absorption $\mathcal{M}_2 \subseteq \mathfrak{p}_2 \cap W_2$, i.e. $\beta(\mathcal{M}_2) \subseteq \bar{\mathfrak{p}} \cap C = p(\mathfrak{p} \cap W_3)$. Hence $I_3 \subseteq \mathfrak{p} \cap W_3 + \ker p = \mathfrak{p} \cap W_3$, as $\ker p = I^{\mathrm{odd}} \cap W_3 \subseteq \mathfrak{p}$.

Step 5: I_3 is finite over the weights. Let $\mathfrak{q}$ be a prime of W_3 containing $I_3 + \mathfrak{a}_3$; we show $\mathfrak{m}_{W_3} \subseteq \mathfrak{q}$, which gives $\mathfrak{m}_{W_3} \subseteq \sqrt{I_3 + \mathfrak{a}_3}$. Here $\ker p \subseteq I_3 \subseteq \mathfrak{q}$ and $\mathfrak{m}_{\mathcal{O}}W_3 \subseteq \mathfrak{a}_3 \subseteq \mathfrak{q}$.

(i) $\beta(\mathfrak{m}_{W_2}) \subseteq p(\mathfrak{q})$. $\mathfrak{q}_2 = \beta^{-1}(p(\mathfrak{q}))$ is a prime of W_2. It contains $\mathcal{M}_2$, since $\beta(\mathcal{M}_2) \subseteq p(I_3) \subseteq p(\mathfrak{q})$, and $\mathfrak{a}_2$: β is an $\mathcal{O}$-algebra homomorphism and $\beta(\psi_{2,v,a}(g) - 1) = p(\psi_{3,v,a'}(g) - 1) \in p(\mathfrak{a}_3)$

for $g \in I_v$ with $\bar\Psi(g) = 1$, $a' = 1, 3$ for $a = 1, 2$ (because $C \to B$ is injective). As $\mathcal{M}_2$ is finite over the weights, $\mathfrak{m}_{W_2} \subseteq \sqrt{\mathcal{M}_2 + \mathfrak{a}_2} \subseteq \mathfrak{q}_2$.

(ii) $\rho_3(\gamma)_{22} - 1 \in \mathfrak{q}$ *for all* $\gamma \in \Gamma_L^0$. $W_3/\mathfrak{q}$ is a complete Noetherian local domain containing $\mathcal{O}/\mathfrak{m}_\mathcal{O}$, so of characteristic ℓ. By (49.3) and $\ker p \subseteq \mathfrak{q}$, $\chi(\gamma) = \rho_3(\gamma)_{22} + \mathfrak{q}$ is a homomorphism $\Gamma_L^0 \to (W_3/\mathfrak{q})^\times$ with values in $1+\mathfrak{m}$, $\mathfrak{m}$ the maximal ideal of $W_3/\mathfrak{q}$ ((Po5)). It is trivial on $\pi_L(I_v)$: for $g \in I_v$ with $\bar\Psi(g) = 1$, (49.4) gives $\chi(\pi_L(g)) = \psi_{3,v,2}(g) + \mathfrak{q} = 1$, since $\psi_{3,v,2}(g) - 1 \in \mathfrak{a}_3$; for general $g \in I_v$, $\bar\Psi(g)$ has order m prime to ℓ, so $\chi(\pi_L(g))^m = 1$, while $\chi(\pi_L(g))^{\ell^N} \equiv 1$ modulo $\mathfrak{m}^N$ for every N (characteristic ℓ); hence $\chi(\pi_L(g)) \equiv 1$ modulo every $\mathfrak{m}^N$, and $\chi(\pi_L(g)) = 1$ by Krull's intersection theorem. It is trivial on $\pi_L(cI_vc)$: by (Po2), $\rho_3(cg^{-1}c)_{22} = \rho_3(g)_{22}$ for $g \in G_L$, so $\chi(\pi_L(cgc)) = \chi(\pi_L(g))^{-1} = 1$ for $g \in I_v$. For $N \geq 1$ the ring $W_3/(\mathfrak{q} + \mathfrak{m}_{W_3}^N)$ is finite ($\mathbb{F}_\mathcal{O}$ is finite), the image of χ in it lies in the abelian ℓ-group $(1+\mathfrak{m})/(1+\mathfrak{m}^N)$, and the induced map is locally constant by Step 1, i.e. continuous. By (Ar5)(ii) there is $h \geq 1$, independent of N, with $\chi(\gamma)^h \equiv 1$ modulo $\mathfrak{m}^N$ for all N, hence $\chi(\gamma)^h = 1$. Write $h = \ell^e h'$ with $\ell \nmid h'$ and $\chi(\gamma)^{h'} = 1+z$. Then $(1+z)^{\ell^e} = 1+z^{\ell^e} = 1$, so $z = 0$ in the domain $W_3/\mathfrak{q}$; and with $\chi(\gamma) = 1+x$, $0 = (1+x)^{h'} - 1 = x\big(h' + x\sum_{i\geq 2}\binom{h'}{i}x^{i-2}\big)$ with the second factor a unit, so $x = 0$.

(iii) *Generators are constant modulo* $\mathfrak{q}$. Let $x = \prod_k \rho_3(\gamma_k)_{a_kb_k}$ be of weight 0. If some factor is odd, $x \in I^{\mathrm{odd}} \cap W_3 \subseteq \mathfrak{q}$. Otherwise each factor is a corner entry or a $(2,2)$ entry, and $x = x_cx_m$ with x_m the product of the $(2,2)$ factors, $x_m \equiv 1$ modulo $\mathfrak{q}$ by (ii), and x_c the product of the corner factors, of weight 0. Let $y \in W_2$ be the corresponding product of entries of ρ_2 (of weight 0), and $c \in \mathcal{O}$ with $y - c \in \mathfrak{m}_{W_2}$ ((Gw1) for $n = 2$). Then $p(x_c - c) = \beta(y - c) \in p(\mathfrak{q})$ by (i), so $x_c - c \in \mathfrak{q}$ and $x \equiv c$. Likewise $p(\psi_{3,v,a'}(g)) = \beta(\psi_{2,v,a}(g))$ is congruent to a constant modulo $p(\mathfrak{q})$ for $a' = 1, 3$, and $\psi_{3,v,2}(g) \equiv \rho_3(g)_{22} \equiv 1$ by (49.4) and (ii). By Lemma 49.32 (rank 3, $P = \mathfrak{q}$), $\mathfrak{m}_{W_3} \subseteq \mathfrak{q}$.

Steps 4 and 5 show that I_3 has the required properties. □

Lemma 49.34. *Let ℓ be odd, L an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and suppose a universal polarised ordinary lift of rank n over L exists; write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$. Let $\mathcal{M} \subseteq W$ be an ideal finite over the weights that propagates through nice primes and, if $n = 3$, along thick links; if $n = 3$ let moreover $I_3 \subseteq W$ be an ideal finite over the weights with $I_3 \subseteq \xi \cap W$ for every prime ξ of E of endoscopic type. Let x be a core prime of E that is a maximal ideal, $(\mathcal{O}', R, \iota)$ a local chart at x, and $J \subseteq R$ an ideal such that*

(Jp1) *$J \subseteq P$ for every prime P of R of irreducible type;*

(Jp2) *any two minimal primes P, Q of J are joined by minimal primes $P = P_0, \dots, P_k = Q$ of J with $\dim R/(P_{i-1} + P_i) \geq n\,d_L + 1$ for $1 \leq i \leq k$;*

(Jp3) *every minimal prime of J is of irreducible type or, if $n = 3$, thick.*

If some $\mathcal{M}$-modular prime P_0 of R of irreducible type satisfies $\dim R/P_0 \geq n\,d_L + 1$, then every minimal prime of R of irreducible type is $\mathcal{M}$-modular.

Proof. Throughout, prime types and modularity of primes of R are those of Definition 49.2 for $C = R$ with ι. Two facts are used without comment: modularity passes to larger primes ($P \subseteq P'$ gives $\iota^{-1}(P) \cap W \subseteq \iota^{-1}(P') \cap W$), and the conditions $I_R^- \not\subseteq P$, $I_R^+ \not\subseteq P$, $I_R^{\mathrm{odd}} \not\subseteq P$ pass to smaller primes, so a prime contained in a prime of irreducible type is of irreducible type. A nice prime is off-triangular, hence of irreducible type or (if $n = 3$) of endoscopic type, and no prime is both. A thick prime is of endoscopic type. The ring R is a complete Noetherian local ring, and $n\,d_L \geq 1$.

Step 1: nice primes above large primes. Let $I \subseteq W$ be finite over the weights and Q a prime of R with $I \subseteq \iota^{-1}(Q) \cap W$ and $\dim R/Q \geq n\,d_L + 1$. Then there is a nice prime $\mathfrak{p} \supseteq Q$. Indeed, let ϖ be a uniformiser of $\mathcal{O}$; its image in R lies in $\mathfrak{m}_R$ (the structure maps $\mathcal{O} \to \mathcal{O}' \to R$ are local). Consider the ideals $\mathfrak{a}_0 = I_R^+$ and, for $v \mid \ell$ and $a \neq b$, $\mathfrak{a}_{v,a,b} = \iota(I)R + \mathfrak{m}_{\mathcal{O}}R + (\psi_{x,v,a}(g) - \psi_{x,v,b}(g) : g \in I_v, \chi_{\mathrm{cyc}}(g) = 1)$; there are finitely many, and each has $\dim R/\mathfrak{a} < n\,d_L$ by (Nn1), (Nn2) of Proposition 49.29. By Lemma 49.35 (with $N = n\,d_L$) there is a prime $\mathfrak{p} \supseteq Q$ with $\dim R/\mathfrak{p} = 1$, $\varpi \in \mathfrak{p}$, and no $\mathfrak{a}_0$, $\mathfrak{a}_{v,a,b}$ contained in $\mathfrak{p}$. Then $\ell \in \varpi\mathcal{O}$ lies in $\mathfrak{p}$; $I_R^- = R \not\subseteq \mathfrak{p}$ by (Qc3) of Proposition 49.19 and $I_R^+ \not\subseteq \mathfrak{p}$, so $\mathfrak{p}$ is off-triangular; and since $\iota(I) \subseteq Q \subseteq \mathfrak{p}$ and $\mathfrak{m}_{\mathcal{O}}R = \varpi R \subseteq \mathfrak{p}$, the condition $\mathfrak{a}_{v,a,b} \not\subseteq \mathfrak{p}$ gives $g \in I_v$ with $\chi_{\mathrm{cyc}}(g) = 1$ and $\psi_{x,v,a}(g) - \psi_{x,v,b}(g) \notin \mathfrak{p}$. So $\mathfrak{p}$ is nice.

Step 2: saturation. Call a nice prime $\mathfrak{p}$ *saturated* if every prime $P' \subseteq \mathfrak{p}$ of irreducible type is $\mathcal{M}$-modular. If some $\mathcal{M}$-modular prime $P \subseteq \mathfrak{p}$ of irreducible type exists, $\mathfrak{p}$ is saturated: if $\mathfrak{p}$ is of irreducible type, it is $\mathcal{M}$-modular (it contains P), and propagation through nice primes makes every prime $P' \subseteq \mathfrak{p}$ $\mathcal{M}$-modular; if $\mathfrak{p}$ is of endoscopic type ($n = 3$), propagation along thick links applied to the pair $\mathfrak{p}, \mathfrak{p}$ (thickly connected with $k = 0$) does it.

Step 3: endoscopic nice primes above thick components ($n = 3$). Let $\mathfrak{e}$ be a minimal prime of J that is thick and $M' \supseteq \mathfrak{e}$ a prime with $\dim R/M' \geq 3d_L + 1$. Then there is a nice prime $\mathfrak{p}' \supseteq M'$ of endoscopic type. Indeed $\mathfrak{e}$ is of endoscopic type, so by (Qc3) the prime $\iota^{-1}(\mathfrak{e})$ of E is of endoscopic type, whence $I_3 \subseteq \iota^{-1}(\mathfrak{e}) \cap W \subseteq \iota^{-1}(M') \cap W$; Step 1 with $I = I_3$ gives a nice $\mathfrak{p}' \supseteq M'$, and $I_R^{\mathrm{odd}} \subseteq \mathfrak{e} \subseteq \mathfrak{p}'$ makes it endoscopic.

Step 4: good components. Call a minimal prime Q of J *good* if either (a) Q is of irreducible type and $\mathcal{M}$-modular, or (b) $n = 3$, Q is thick, and there are nice primes $\mathfrak{p}_0, \mathfrak{p}_1$ of endoscopic type with $Q \subseteq \mathfrak{p}_1$, $\mathfrak{p}_1$ thickly connected to $\mathfrak{p}_0$, and some $\mathcal{M}$-modular prime of irreducible type contained in $\mathfrak{p}_0$. *If Q is good and $M' \supseteq Q$ is a prime with $\dim R/M' \geq n\,d_L + 1$, there is a saturated nice prime containing M'.* In case (a), $\mathcal{M} \subseteq \iota^{-1}(Q) \cap W \subseteq \iota^{-1}(M') \cap W$, Step 1 with $I = \mathcal{M}$ gives a nice $\mathfrak{p} \supseteq M' \supseteq Q$, saturated by Step 2. In case (b), Step 3 gives a nice endoscopic $\mathfrak{p}' \supseteq M'$; the thick prime Q lies in $\mathfrak{p}_1 \cap \mathfrak{p}'$, so $\mathfrak{p}_1, \mathfrak{p}'$ are thickly linked and $\mathfrak{p}'$ is thickly connected to $\mathfrak{p}_0$; propagation along thick links makes every prime of irreducible type in $\mathfrak{p}'$ $\mathcal{M}$-modular, i.e. $\mathfrak{p}'$ is saturated.

Step 5: goodness passes along chains. Let Q, Q' be minimal primes of J with $\dim R/(Q + Q') \geq n\,d_L + 1$ and Q good. Choose a prime $M' \supseteq Q + Q'$ with $\dim R/M' = \dim R/(Q + Q')$. By Step 4 a saturated nice prime $\mathfrak{p} \supseteq M'$ exists. If Q' is of irreducible type, $Q' \subseteq \mathfrak{p}$ is $\mathcal{M}$-modular, so Q' is good by (a). Otherwise, by (Jp3), $n = 3$ and Q' is thick; Step 3 (with $\mathfrak{e} = Q'$) gives a nice endoscopic $\mathfrak{p}' \supseteq M'$. If Q is good by (a), then $Q \subseteq \mathfrak{p}'$ is an $\mathcal{M}$-modular prime of irreducible type, and (b) holds for Q' with $\mathfrak{p}_0 = \mathfrak{p}_1 = \mathfrak{p}'$. If Q is good by (b) with $\mathfrak{p}_0, \mathfrak{p}_1$, then the thick prime Q lies in $\mathfrak{p}_1 \cap \mathfrak{p}'$, so $\mathfrak{p}'$ is thickly connected to $\mathfrak{p}_0$ and (b) holds for Q' with $\mathfrak{p}_0$ and $\mathfrak{p}'$.

Step 6: a first good component. By (Jp1), $J \subseteq P_0$; let $Q_0 \subseteq P_0$ be a minimal prime of J. It is of irreducible type, being contained in P_0. Step 1 with $I = \mathcal{M}$ and $Q = P_0$ gives a nice $\mathfrak{p} \supseteq P_0$, saturated by Step 2 since $P_0 \subseteq \mathfrak{p}$; so $Q_0 \subseteq \mathfrak{p}$ is $\mathcal{M}$-modular and good by (a).

Step 7: conclusion. By (Jp2) every minimal prime of J is joined to Q_0 by a chain as in Step 5, so all minimal primes of J are good. Let P be a minimal prime of R of irreducible type. By (Jp1) $J \subseteq P$, and P is minimal over J because it is minimal over 0; so P is good. It is not thick (it is not of endoscopic type), so (a) holds: P is $\mathcal{M}$-modular. □

Lemma 49.35. *Let $(R, \mathfrak{m})$ be a Noetherian local ring, $\varpi \in \mathfrak{m}$, $N \geq 1$ an integer, $\mathfrak{a}_1, \ldots, \mathfrak{a}_s$ ideals of R with $\dim R/\mathfrak{a}_i < N$ for all i, and I an ideal of R with $\dim R/I \geq N + 1$. Then there is a prime $\mathfrak{p} \supseteq I$ of R with $\dim R/\mathfrak{p} = 1$, $\varpi \in \mathfrak{p}$ and $\mathfrak{a}_i \not\subseteq \mathfrak{p}$ for $1 \leq i \leq s$.*

Proof. We use two standard facts for a Noetherian local ring $(S, \mathfrak{m}_S)$ and $x \in \mathfrak{m}_S$: Krull's

inequality $\dim S/xS \geq \dim S - 1$ ([12, Cor. 11.18 and its proof]), and, if S is a domain and $x \neq 0$, $\dim S/xS \leq \dim S - 1$ (every prime containing x is non-zero, so a chain of primes above xS extends by (0)). Also $\dim R/\mathfrak{b} = \max\{\dim R/\mathfrak{p} : \mathfrak{p} \supseteq \mathfrak{b} \text{ prime}\}$, attained at a minimal prime of $\mathfrak{b}$. All dimensions are finite.

For a prime $\mathfrak{q} \supseteq I + \varpi R$ put $\delta(\mathfrak{q}) = \dim R/\mathfrak{q}$ and $\beta(\mathfrak{q}) = \max_i \dim R/(\mathfrak{a}_i + \mathfrak{q}) \in \{-\infty, 0, 1, \dots\}$.

Start. By Krull's inequality in R/I, $\dim R/(I+\varpi R) \geq N$; let $\mathfrak{q}_0$ be a minimal prime of $I+\varpi R$ with $\delta(\mathfrak{q}_0) = \dim R/(I+\varpi R) \geq N$. Since $R/(\mathfrak{a}_i + \mathfrak{q}_0)$ is a quotient of $R/\mathfrak{a}_i$, $\beta(\mathfrak{q}_0) < N \leq \delta(\mathfrak{q}_0)$.

Descent step: if $\mathfrak{q} \supseteq I + \varpi R$ is prime with $\delta(\mathfrak{q}) \geq 2$ and $\beta(\mathfrak{q}) < \delta(\mathfrak{q})$, there is a prime $\mathfrak{q}' \supseteq \mathfrak{q}$ with $\delta(\mathfrak{q}') = \delta(\mathfrak{q}) - 1$ and $\beta(\mathfrak{q}') < \delta(\mathfrak{q}')$. Let $Q_1, \dots, Q_r$ be the minimal primes of the ideals $\mathfrak{a}_i + \mathfrak{q}$ ($1 \leq i \leq s$) that are different from $\mathfrak{m}$; there are finitely many. As $\delta(\mathfrak{q}) \geq 2$, $\mathfrak{q} \neq \mathfrak{m}$. By prime avoidance $\mathfrak{m} \not\subseteq \mathfrak{q} \cup Q_1 \cup \dots \cup Q_r$, since $\mathfrak{m}$ is contained in none of these primes; choose $x \in \mathfrak{m}$ outside all of them. In the local domain $R/\mathfrak{q}$ the image of x is non-zero, so by the two facts $\dim R/(\mathfrak{q} + xR) = \delta(\mathfrak{q}) - 1$; let $\mathfrak{q}'$ be a minimal prime of $\mathfrak{q} + xR$ with $\delta(\mathfrak{q}') = \delta(\mathfrak{q}) - 1$. Let $\mathfrak{p}$ be a prime containing $\mathfrak{a}_i + \mathfrak{q}'$. Then $\mathfrak{p}$ contains a minimal prime Q of $\mathfrak{a}_i + \mathfrak{q}$. If $Q = \mathfrak{m}$, then $\mathfrak{p} = \mathfrak{m}$ and $\dim R/\mathfrak{p} = 0$. Otherwise $Q = Q_k$ for some k, and $\mathfrak{p} \supseteq Q_k + xR$ with $x \notin Q_k$, so, applying the two facts in the domain R/Q_k,

$$\dim R/\mathfrak{p} \leq \dim R/(Q_k + xR) = \dim R/Q_k - 1 \leq \dim R/(\mathfrak{a}_i + \mathfrak{q}) - 1 \leq \beta(\mathfrak{q}) - 1.$$

Hence $\beta(\mathfrak{q}') \leq \max\{0, \beta(\mathfrak{q}) - 1\}$. Both 0 and $\beta(\mathfrak{q}) - 1$ are $< \delta(\mathfrak{q}) - 1 = \delta(\mathfrak{q}')$, the first because $\delta(\mathfrak{q}) \geq 2$; so $\beta(\mathfrak{q}') < \delta(\mathfrak{q}')$, and $\mathfrak{q}' \supseteq \mathfrak{q} \supseteq I + \varpi R$.

End. Applying the descent step $\delta(\mathfrak{q}_0) - 1$ times (none if $\delta(\mathfrak{q}_0) = 1$) gives a prime $\mathfrak{p} \supseteq I + \varpi R$ with $\dim R/\mathfrak{p} = 1$ and $\beta(\mathfrak{p}) < 1$. If $\mathfrak{a}_i \subseteq \mathfrak{p}$ for some i, then $\dim R/(\mathfrak{a}_i + \mathfrak{p}) = \dim R/\mathfrak{p} = 1 \leq \beta(\mathfrak{p})$, a contradiction. So $\mathfrak{p}$ has all the required properties. □

Lemma 49.36. *Let L satisfy (Af1) and (Af2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, let $n \in \{2, 3\}$, and let $(\rho^{\mathrm{u}}, (\psi^{\mathrm{u}}_{v,a}))$ be a universal polarised ordinary lift of rank n over L to R^{po}_n. For every test ring A and every polarised ordinary lift $(\rho, (\psi_{v,a}))$ of rank n over L to A there is exactly one local $\mathcal{O}$-algebra homomorphism $f\colon R^{\mathrm{po}}_n \to A$ with $f \circ \rho^{\mathrm{u}} = \rho$ and $f \circ \psi^{\mathrm{u}}_{v,a} = \psi_{v,a}$ for all $v \mid \ell$ and $1 \leq a \leq n$.*

Proof. Let $k_A = A/\mathfrak{m}_A$ (a finite field) and let $\mathbb{F}_{\mathcal{O}} \to k_A$ be the injection induced by the local homomorphism $\mathcal{O} \to A$. Put $A_0 = \{x \in A : \ x \bmod \mathfrak{m}_A \in \mathbb{F}_{\mathcal{O}}\}$.

A_0 lies in $\mathrm{CNL}_{\mathcal{O}}$. The set A_0 is a subring containing $\mathfrak{m}_A$ and the image of $\mathcal{O}$; it is local with maximal ideal $\mathfrak{m}_A$ (an element of $A_0 \setminus \mathfrak{m}_A$ is a unit of A whose inverse again has residue in $\mathbb{F}_{\mathcal{O}}$), and $A_0/\mathfrak{m}_A \cong \mathbb{F}_{\mathcal{O}}$, so $\mathcal{O} \to A_0$ is local and induces an isomorphism of residue fields. Let ϖ_A be a uniformiser of A; it lies in $\mathfrak{m}_A \subseteq A_0$, and for $k \geq 1$ the k-th power of the ideal $\mathfrak{m}_A$ of A_0 is $\varpi_A^k A = \mathfrak{m}_A^k$ (every element $\varpi_A^k y$ equals $\varpi_A^{k-1} \cdot \varpi_A y$ with all factors in $\mathfrak{m}_A$). Hence the $\mathfrak{m}_{A_0}$-adic topology of A_0 is induced by that of A, and A_0 is complete, being closed in A (it is a union of cosets of the open subgroup $\mathfrak{m}_A$). Choose $e_1, \dots, e_t \in A$ whose residues form an $\mathbb{F}_{\mathcal{O}}$-basis of k_A; then $A = \sum_i A_0 e_i + \varpi_A A$, and successive approximation in the complete ring A_0 gives $A = \sum_i A_0 e_i$. Thus A is a Noetherian ring finite over its subring A_0, and A_0 is Noetherian by the Eakin–Nagata theorem.

The lift factors through A_0. By (Po5), for $\gamma \in \Gamma^0_L$ the diagonal entries of $\rho(\gamma)$ are congruent to elements of $\mathbb{F}_{\mathcal{O}}$ and the other entries lie in $\mathfrak{m}_A$, and $\psi_{v,a}(g)$ is congruent to an element of $\mathbb{F}^\times_{\mathcal{O}}$; hence ρ takes values in $\mathrm{GL}_n(A_0)$ (the inverse of $\rho(\gamma)$ is $\rho(\gamma^{-1})$) and $\psi_{v,a}$ in $A_0^\times$. Conditions (Po1)–(Po5) for A_0 are the same identities and congruences as for A, because $\mathfrak{m}_{A_0}^k = \mathfrak{m}_A^k$. So $(\rho, (\psi_{v,a}))$ is a polarised ordinary lift to $A_0 \in \mathrm{CNL}_{\mathcal{O}}$, and the universal property gives a morphism

$f_0\colon R_n^{\mathrm{po}} \to A_0$ with $f_0 \circ \rho^{\mathrm{u}} = \rho$ and $f_0 \circ \psi^{\mathrm{u}}_{v,a} = \psi_{v,a}$. Then $f = f_0$ followed by the inclusion $A_0 \subseteq A$ is a local $\mathcal{O}$-algebra homomorphism with the required property.

Uniqueness. Let $f'\colon R_n^{\mathrm{po}} \to A$ be a local $\mathcal{O}$-algebra homomorphism with the same property. Since R_n^{po} has residue field $\mathbb{F}_{\mathcal{O}}$, every element is $o+y$ with o in the image of $\mathcal{O}$ and $y \in \mathfrak{m}_{R_n^{\mathrm{po}}}$, and $f'(y) \in \mathfrak{m}_A$; hence f' takes values in A_0 and is a morphism of $\mathrm{CNL}_{\mathcal{O}}$ into A_0. By the uniqueness in the universal property, $f' = f_0$ as maps into A_0, so $f' = f$. □

Lemma 49.37. *Let L be an auxiliary field of some level for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ such that a universal polarised ordinary lift of rank 3 over L exists and W_3^{po} contains an off-triangular bound. Then L has residual characteristic polynomials in rank 3.*

Proof. Let I be an off-triangular bound, A a test ring of characteristic ℓ and $(\rho, (\psi_{v,a}))$ a polarised ordinary lift of rank 3 over L to A with $\psi_{v,a}(g) = 1$ whenever $g \in I_v$ and $\bar\Psi(g) = 1$. By Lemma 49.36 there is a local $\mathcal{O}$-algebra homomorphism $f\colon R_3^{\mathrm{po}} \to A$ with $f \circ \rho^{\mathrm{u}} = \rho$ and $f \circ \psi^{\mathrm{u}}_{v,a} = \psi_{v,a}$. Since A is a domain of characteristic ℓ and ℓ is a unit times a power of a uniformiser ϖ of $\mathcal{O}$, $f(\varpi) = 0$; so $\mathcal{O} \to A$ factors through $\mathbb{F}_{\mathcal{O}}$, and we regard $\mathbb{F}_{\mathcal{O}} \subseteq A$. Let $\mathfrak{p}$ be the kernel of f on E_3^{po}, a prime ideal. For $g \in G_L$ we have $\rho_L(g) = f(\rho^{\mathrm{u}}(\pi_L(g)))$, so it suffices to show that for every $\gamma \in \Gamma_L^0$ the characteristic polynomial of $X := \rho(\gamma)$ is $\prod_{a=1}^3 (T - \bar\Psi(\gamma)^{w_{3,a}})$.

Case 1: $\mathfrak{p}$ is off-triangular. Then $I \subseteq \mathfrak{p} \cap W_3^{\mathrm{po}} =: \mathfrak{q}$, a prime of W_3^{po}. Also $\mathfrak{a}_3 \subseteq \mathfrak{q}$: $f(\mathfrak{m}_{\mathcal{O}}) = 0$, and $f(\psi^{\mathrm{u}}_{v,a}(g) - 1) = \psi_{v,a}(g) - 1 = 0$ for $g \in I_v$ with $\bar\Psi(g) = 1$. Since I is finite over the weights, $\mathfrak{m}_W \subseteq \sqrt{I + \mathfrak{a}_3} \subseteq \mathfrak{q}$. Every $y \in W_3^{\mathrm{po}}$ is $o + z$ with o in the image of $\mathcal{O}$ and $z \in \mathfrak{m}_W$, because R_3^{po} has residue field $\mathbb{F}_{\mathcal{O}}$; hence $f(y)$ is the residue $\bar y \in \mathbb{F}_{\mathcal{O}}$ of y. Apply this to weight-zero monomials of the universal lift at γ. The diagonal entries have weight 0 and residue $\bar\Psi(\gamma)^{w_{3,a}}$ by (Po5), so $X_{aa} = \bar\Psi(\gamma)^{w_{3,a}}$. For $a \neq b$ the product $\rho^{\mathrm{u}}(\gamma)_{ab}\rho^{\mathrm{u}}(\gamma)_{ba}$ has weight 0 and lies in $\mathfrak{m}$ by (Po5), and so do $\rho^{\mathrm{u}}(\gamma)_{12}\rho^{\mathrm{u}}(\gamma)_{23}\rho^{\mathrm{u}}(\gamma)_{31}$ and $\rho^{\mathrm{u}}(\gamma)_{13}\rho^{\mathrm{u}}(\gamma)_{32}\rho^{\mathrm{u}}(\gamma)_{21}$ (weights $(w_{3,1} - w_{3,2}) + (w_{3,2} - w_{3,3}) + (w_{3,3} - w_{3,1}) = 0$); hence $X_{ab}X_{ba} = 0$ and $X_{12}X_{23}X_{31} = X_{13}X_{32}X_{21} = 0$. Expanding the determinant,

$$\det(T - X) = \prod_{a=1}^{3}(T - X_{aa}) - \sum_{\{a,b,e\}=\{1,2,3\},\, a<b} X_{ab}X_{ba}(T - X_{ee}) - X_{12}X_{23}X_{31} - X_{13}X_{32}X_{21} = \prod_{a=1}^{3}(T - \bar\Psi(\gamma)^{w_{3,a}}).$$

Case 2: $\mathfrak{p}$ is not off-triangular. Say $I_E^- \subseteq \mathfrak{p}$ (the case $I_E^+ \subseteq \mathfrak{p}$ is the same with lower triangular matrices). Then $\rho(\gamma)$ is upper triangular for all $\gamma \in \Gamma_L^0$, so $\det(T - \rho(\gamma)) = \prod_a (T - \delta_a(\gamma))$ with $\delta_a(\gamma) = \rho(\gamma)_{aa}$, and each $\delta_a\colon \Gamma_L^0 \to A^\times$ is a homomorphism. Put $\chi_a = \delta_a \cdot \bar\Psi^{-w_{3,a}}$; by (Po5) it takes values in $1 + \mathfrak{m}_A$, and by (Po1) and the openness of $\ker\bar\Psi$ its reduction $\chi_{a,k}$ modulo $1 + \mathfrak{m}_A^k$ has open kernel, for every $k \geq 1$. The group $(1 + \mathfrak{m}_A)/(1 + \mathfrak{m}_A^k)$ is a finite abelian ℓ-group (its order is a power of $|A/\mathfrak{m}_A|$). We show $\chi_a = 1$.

(i) Let $v \mid \ell$. Since $\ell \mid M$, v splits in L by (Af2), so $D_v \subseteq G_L$. Let $u \in I_v$ with $\bar\Psi(u) = 1$. By (Po4) with $g_1 = g_2 = g_3 = u$ and $\psi_{v,a}(u) = 1$, $(\rho(\pi_L(u)) - 1)^3 = 0$; the diagonal entries of this upper triangular matrix are $(\delta_b(\pi_L(u)) - 1)^3$, so $\delta_b(\pi_L(u)) = 1$ and $\chi_b(\pi_L(u)) = 1$ for all b, A being a domain. Take $u_1, \dots, u_{d_v}$ as in (Ar5)(iii); then $\chi_{a,k} \circ \pi_L|_{D_v}$ is a continuous homomorphism to a finite abelian ℓ-group trivial on the u_b, hence trivial on I_v.

(ii) For $g \in I_v$, (Po2) gives $\rho(\pi_L(cg^{-1}c)) = J_3\, {}^t\rho(\pi_L(g))\, J_3$, whose (a,a) entry is $\delta_{4-a}(\pi_L(g))$; and $\bar\Psi(cg^{-1}c) = \bar\Psi(g)^{-1}$ with $w_{3,4-a} = -w_{3,a}$. Hence $\chi_a(\pi_L(cg^{-1}c)) = \chi_{4-a}(\pi_L(g))$, and by (i) $\chi_{a,k}$ is trivial on $\pi_L(cI_vc)$.

(iii) By (Ar5)(ii) there is $h \geq 1$, independent of a and k, with $\chi_{a,k}^h = 1$ for all k; so $\chi_a(\gamma)^h - 1 \in \bigcap_k \mathfrak{m}_A^k = 0$. Write $h = \ell^s h'$ with $\ell \nmid h'$ and $\chi_a(\gamma) = 1 + x$, $x \in \mathfrak{m}_A$. In characteristic ℓ, $y := (1+x)^{\ell^s} = 1 + x^{\ell^s}$, and $0 = y^{h'} - 1 = (y-1)(y^{h'-1} + \cdots + 1)$ with the second factor $\equiv h' \not\equiv 0$ modulo $\mathfrak{m}_A$, a unit; so $x^{\ell^s} = 0$ and $x = 0$.

Thus $\delta_a = \bar{\Psi}^{w_{3,a}}$ on Γ_L^0 and $\det(T - \rho(\gamma)) = \prod_a (T - \bar{\Psi}(\gamma)^{w_{3,a}})$. □

50 The Hecke realisation

This section proves the Hecke realisation Theorem 50.3, the Hecke side of the $R = T$ theorem 49.3. Over an auxiliary field L it gives an ideal $\mathcal{M}$ of the weight-zero algebra W_n^{po} that is finite over the weights, propagates through nice primes and, for $n = 3$, along thick links (Hk2), has a seed component as soon as a seed exists (Hk3), and cuts out automorphic lifts: an irreducible polarised ordinary lift on which $\mathcal{M}$ vanishes is automorphic of conjugate self-dual type after the twist κ (Hk4). The ideal comes from ordinary automorphic forms on a definite unitary group over L^+, through Hida theory in the form of Geraghty [105]. The Galois side is the universal polarised ordinary determinant, a determinant in the sense of Chenevier [66] (Definition 50.2), and the Hecke algebra is a quotient of its ring; the ideal is then transported to the ring of marked lifts.

Subsection 50.1 states the theorem and its form for determinants, Theorem 50.6, at an auxiliary place v_0. Subsection 50.2 proves the latter from Proposition 50.11, Hida theory and patching for the definite unitary group, whose technical part, the Hecke ideals of zero-monodromy type and the patching at curve points over Taylor–Wiles levels, is in Appendix E. Subsection 50.3 passes from determinants to marked lifts.

50.1 The Hecke realisation and the ordinary Hecke ideal

This subsection defines rank-n Hecke data (Definition 50.1) and polarised ordinary determinants over an auxiliary field (Definition 50.2), and proves Theorem 50.3 from Theorem 50.6. The latter is the same statement for the universal determinant ring B_n^{po}: at a place v_0 above a prime that splits in L and at which $\bar{\Psi}$ is trivial and $\bar{\omega}$ is not, there is an ideal $\mathcal{J}$ of B_n^{po} that is finite over the weights, whose minimal primes all have dimension $1 + n\,d_L$ (Hd1), with the propagation properties (Hd2), containing the seed points (Hd3) and cutting out automorphic lifts (Hd4). The passage from Theorem 50.6 to Theorem 50.3 enlarges the coefficient ring (Lemma 50.4), constructs universal polarised ordinary lifts (Proposition 50.5), and transports $\mathcal{J}$ along the comparison morphism to the weight-zero algebra (Proposition 50.26, Subsection 50.3). The Hecke data are defined in rank n so that the same construction serves the auxiliary fields, in ranks two and three, and the links of the symplectic case, in rank four.

Definition 50.1. Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring and $\bar{\omega}$ the reduction of χ_{cyc} modulo $\mathfrak{m}_{\mathcal{O}}$. For a CM field $L \subset \overline{\mathbb{Q}}$ with maximal totally real subfield L^+, the groups $G_L \subseteq G_{L^+}$ are subgroups of $G_{\mathbb{Q}}$, and S_ℓ denotes the set of places of L^+ above ℓ.

Rank-n Hecke data. A **rank-n Hecke datum** over $\mathcal{O}$ is a tuple

$$\mathscr{H} = \big(n,\, L,\, c,\, (\bar{v})_{v \in S_\ell},\, \mathrm{St},\, v_0,\, \bar{v}_0,\, (\bar{\chi}_a)_{1 \leq a \leq n},\, (\xi_{v,a})_{v \in S_\ell,\, 1 \leq a \leq n}\big)$$

of an integer $n \geq 2$; a CM field $L \subset \overline{\mathbb{Q}}$; a complex conjugation $c \in G_{L^+}$ (the automorphism induced by complex conjugation for some embedding $\overline{\mathbb{Q}} \to \mathbb{C}$); for every $v \in S_\ell$ a place $\bar{v}$ of $\overline{\mathbb{Q}}$ above v; a finite set St of places of L^+ not above ℓ; a place $v_0 \notin \mathrm{St}$ of L^+ not above ℓ, with a place $\bar{v}_0$ of $\overline{\mathbb{Q}}$ above it; continuous characters $\bar{\chi}_1, \ldots, \bar{\chi}_n \colon G_L \to \mathbb{F}_{\mathcal{O}}^\times$, the **residual characters**; and,

for $v \in S_\ell$ and $1 \le a \le n$, homomorphisms $\xi_{v,a}\colon \mu_v \to \mathcal{O}^\times$, the **wild values**, where $\mu_v \subseteq D_v$ (defined below) depend only on $\bar{v}$; such that:

(Rd1) $\tau(\mathcal{O}_L) \subseteq \mathcal{O}$ for every embedding $\tau\colon L \to \overline{\mathbb{Q}}_\ell$, and L contains no primitive ℓ-th root of unity;

(Rd2) L/L^+ is unramified at every finite place, and every place in $S_\ell \cup \mathrm{St} \cup \{v_0\}$ splits in L;

(Rd3) v_0 lies above a prime $p \neq 2, \ell$ that is unramified in L;

(Rd4) the $\bar{\chi}_a$ are pairwise distinct, and each $\bar{\chi}_a$ is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a finite place of L^+ not in $S_\ell \cup \mathrm{St}$;

(Rd5) (polarisation) $\bar{\chi}_{n+1-a}(csc) = \bar{\chi}_a(s)^{-1}$ for all $s \in G_L$ and $1 \le a \le n$;

(Rd6) $\bar{\chi}_1, \dots, \bar{\chi}_n$ coincide on $D_{\bar{v}_0} \cap G_L$, and $\bar{\omega}$ is non-trivial on $D_{\bar{v}_0} \cap G_L$;

(Rd10) $\xi_{v,a}(g) = 1$ for every $v \in S_\ell$, $1 \le a \le n$ and every $g \in \mu_v$ that lies in the closure $\overline{[D_v, D_v]}$ of the commutator subgroup of D_v.

When the wild values play no role they are omitted from the notation, and $\mathscr{H}$ is written $(n, L, c, (\bar{v})_{v\in S_\ell}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1\le a\le n})$.

The Galois group of a datum. Let $N_{\mathscr{H}}$ be the closed normal subgroup of G_{L^+} generated by the elements $s \in I_{\bar{w}} \cap G_L$, for all places $\bar{w} \nmid \ell$ of $\overline{\mathbb{Q}}$, with $\bar{\chi}_a(s) = 1$ for $1 \le a \le n$. Put $\Gamma_{\mathscr{H}} = G_{L^+}/N_{\mathscr{H}}$, let $\pi_{\mathscr{H}}\colon G_{L^+} \to \Gamma_{\mathscr{H}}$ be the projection and $\Gamma^0_{\mathscr{H}} = \pi_{\mathscr{H}}(G_L)$. The characters $\bar{\chi}_a$ factor through $\Gamma^0_{\mathscr{H}}$ and χ_{cyc} through $\Gamma_{\mathscr{H}}$; they are denoted by the same letters. For $v \in S_\ell$ put $D_v = D_{\bar{v}} \cap G_{L^+} \supseteq I_v = I_{\bar{v}} \cap G_{L^+}$ (both contained in G_L by (Rd2)) and $d_v = [L_v^+ : \mathbb{Q}_\ell]$, and let $\mu_v \subseteq D_v$ be the preimage of the subgroup of elements of ℓ-power order of the abelianisation $D_v/\overline{[D_v, D_v]}$ (so μ_v is the set of $g \in D_v$ with $g^{\ell^k} \in \overline{[D_v, D_v]}$ for some $k \ge 0$).

Twists. A **twist** for $\mathscr{H}$ is a continuous character $\kappa\colon G_L \to \mathcal{O}^\times$ that corresponds through ι and the global Artin map to an algebraic Hecke character of L, such that

(Rd7) $\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{1-n}$ for all $s \in G_L$; κ is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w}$ above a finite place of L^+ not in $S_\ell \cup \mathrm{St}$; and there is an integer $m' \ge 1$ with $\ell \nmid m'$ such that $\kappa^{m'}$ is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w} \nmid \ell$.

Inertial weights. An **inertial weight** for $\mathscr{H}$ is a family $(\psi^\circ_{v,a})_{v\in S_\ell,\, 1\le a\le n}$ of continuous characters $\psi^\circ_{v,a}\colon I_v \to \mathcal{O}^\times$ such that

(Rd8) for every $v \in S_\ell$ there are de Rham characters $\phi_{v,1}, \dots, \phi_{v,n}\colon D_v \to \overline{\mathbb{Q}}_\ell^\times$ with $\phi_{v,a}|_{I_v} = \psi^\circ_{v,a}$ whose τ-Hodge–Tate weights are strictly decreasing in a for every field embedding $\tau\colon L_v^+ \to \overline{\mathbb{Q}}_\ell$; and $\psi^\circ_{v,a}(g) \equiv \bar{\chi}_a(g)$ modulo $\mathfrak{m}_{\mathcal{O}}$ for all $g \in I_v$.

Definition 50.2. Let $\mathcal{O}$ be a coefficient ring.

Residual settings. A **residual setting** of rank n over $\mathcal{O}$ is a tuple $(n, L, c, \Gamma, \Gamma^0, \pi, (D_v \supseteq I_v)_{v\in S_\ell}, (\bar{\chi}_a)_{1\le a\le n})$, where S_ℓ is the set of places of L^+ above ℓ, of one of the following two kinds:

(Rs1) for a rank-n Hecke datum $\mathscr{H} = (n, L, c, (\bar{v})_{v\in S_\ell}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1\le a\le n})$ over $\mathcal{O}$: its n, L, c, $\Gamma = \Gamma_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $\pi = \pi_{\mathscr{H}}$, $D_v \supseteq I_v$ and $\bar{\chi}_a$; the objects defined below from it are said to be **over** $\mathscr{H}$;

(Rs2) for a CM field L satisfying (Af1) and (Af2) for $(K,\mathcal{O},\Psi,c,g_\star,M)$ and $n\in\{2,3\}$: n, L, c, $\Gamma=\Gamma_L$, $\Gamma^0=\Gamma_L^0$, $\pi=\pi_L$, the groups $D_v\supseteq I_v$ ($v\mid\ell$) of Definition 48.2 and $\bar\chi_a=\bar\Psi^{w_{n,a}}$; the objects defined below from it are said to be **over** L.

In both cases $D_v\subseteq G_L$, and the $\bar\chi_a$ are characters of Γ^0. In this definition a residual setting $(n,L,c,\Gamma,\Gamma^0,\pi,(D_v\supseteq I_v),(\bar\chi_a))$ of rank n over $\mathcal{O}$ is fixed.

Determinants. For a commutative ring A and a group Γ_1, an **A-valued determinant of dimension n on Γ_1** is a multiplicative A-polynomial law $D\colon A[\Gamma_1]\to A$, homogeneous of degree n, in the sense of [66]. For $x\in A[\Gamma_1]$ its **characteristic polynomial** is $\chi_D(x)(X)=D(X-x)\in A[X]$, monic of degree n, and its **trace** $\mathrm{tr}_D(x)$ is minus the coefficient of X^{n-1}; tr_D is A-linear. For a homomorphism $\rho\colon\Gamma_1\to\mathrm{GL}_n(A)$, $\det\circ\rho$ is a determinant of dimension n with $\chi_{\det\circ\rho}(\gamma)$ the characteristic polynomial of $\rho(\gamma)$. For a ring homomorphism $f\colon A\to A'$, $f\circ D$ denotes the base change of D to A'. For $A\in\mathrm{CNL}_\mathcal{O}$ and Γ_1 profinite, continuity of D is meant in the sense of [66].

Polarised ordinary determinants. Let $\bar D_n=\det\circ\mathrm{diag}(\bar\chi_1,\dots,\bar\chi_n)$, an $\mathbb{F}_\mathcal{O}$-valued determinant of dimension n on Γ^0. For $A\in\mathrm{CNL}_\mathcal{O}$, a **polarised ordinary determinant of rank n** (over $\mathscr{H}$, resp. over L) to A is a tuple $(D,(\psi_{v,a}))$ of a continuous A-valued determinant D of dimension n on Γ^0 whose reduction modulo $\mathfrak{m}_A$ is $\bar D_n$, and continuous homomorphisms $\psi_{v,a}\colon D_v\to A^\times$ ($v\in S_\ell$, $1\le a\le n$) with $\psi_{v,a}\equiv\bar\chi_a$ modulo $\mathfrak{m}_A$, such that

(Od1) $\chi_D(\pi(cg^{-1}c))=\chi_D(\pi(g))$ for all $g\in G_L$;

(Od2) $\mathrm{tr}_D(\gamma\cdot\prod_{a=1}^n(\pi(g_a)-\psi_{v,a}(g_a)))=0$ for all $\gamma\in\Gamma^0$, $v\in S_\ell$ and $g_1,\dots,g_n\in D_v$, the product taken in $A[\Gamma^0]$ with $a=1$ on the left;

(Od3) (only over $\mathscr{H}$, case (Rs1)) $\psi_{v,a}(g)$ is the image of $\xi_{v,a}(g)$ under $\mathcal{O}\to A$, for all $v\in S_\ell$, $1\le a\le n$ and $g\in\mu_v$, where $\xi_{v,a}$ are the wild values of $\mathscr{H}$ and $\mu_v\subseteq D_v$ is as in Definition 50.1.

Over L (case (Rs2)) a polarised ordinary determinant is a tuple satisfying (Od1) and (Od2); over $\mathscr{H}$ (case (Rs1)) it satisfies (Od1), (Od2) and (Od3). A **universal polarised ordinary determinant** of rank n (over $\mathscr{H}$, resp. over L) is such a tuple $(D^\mathrm{u},(\psi^\mathrm{d}_{v,a}))$ to some $B_n^\mathrm{po}\in\mathrm{CNL}_\mathcal{O}$ such that for every $A\in\mathrm{CNL}_\mathcal{O}$ and every polarised ordinary determinant $(D,(\psi_{v,a}))$ of rank n to A (over the same setting) there is exactly one morphism $x\colon B_n^\mathrm{po}\to A$ of $\mathrm{CNL}_\mathcal{O}$ with $x\circ D^\mathrm{u}=D$ and $x\circ\psi^\mathrm{d}_{v,a}=\psi_{v,a}$; x is said to **classify** $(D,(\psi_{v,a}))$. An ideal $\mathcal{J}\subseteq B_n^\mathrm{po}$ is **finite over the weights** if $\mathfrak{m}_{B_n^\mathrm{po}}\subseteq\sqrt{\mathcal{J}+\mathfrak{b}_n}$, where $\mathfrak{b}_n$ is the ideal generated by $\mathfrak{m}_\mathcal{O}$ and the elements $\psi^\mathrm{d}_{v,a}(g)-1$ with $v\in S_\ell$, $1\le a\le n$, $g\in I_v$ and $\bar\chi_b(g)=1$ for $1\le b\le n$.

The comparison morphism. In case (Rs2), suppose that a universal polarised ordinary determinant $(B_n^\mathrm{po},D^\mathrm{u},(\psi^\mathrm{d}_{v,a}))$ and a universal polarised ordinary lift $(R_n^\mathrm{po},\rho^\mathrm{u},(\psi^\mathrm{u}_{v,a}))$ of rank n over L are given. If $(\det\circ\rho^\mathrm{u},(\psi^\mathrm{u}_{v,a}))$ is a polarised ordinary determinant, the morphism $\vartheta_n\colon B_n^\mathrm{po}\to R_n^\mathrm{po}$ classifying it is the **comparison morphism**. For an ideal $\mathcal{J}\subseteq B_n^\mathrm{po}$, $\mathcal{M}_\mathcal{J}\subseteq W_n^\mathrm{po}$ denotes the ideal of W_n^po generated by $\vartheta_n(\mathcal{J})$, whenever $\vartheta_n(B_n^\mathrm{po})\subseteq W_n^\mathrm{po}$.

Theorem 50.3. *Let $\mathcal{O}$, ι, c, K, M, Ψ be as in (a) or (b) of Theorem 49.3, let $g_\star$ be a marking and L an auxiliary field of level C_0 for $(K,\mathcal{O},\Psi,c,g_\star,M)$, with data (N',w,j,χ',θ) as in (Ag1). Let $n\in\{2,3\}$, let κ be an admissible twist of rank n for ι, c and M, and let $\mathcal{O}'\supseteq\mathcal{O}$ be a coefficient ring with $\kappa(G_L)\subseteq\mathcal{O}'^\times$ and $\tau(\mathcal{O}_L)\subseteq\mathcal{O}'$ for every embedding $\tau\colon L\to\overline{\mathbb{Q}}_\ell$. Then for every integer $p_0\ge1$ there are a prime $p\nmid p_0$ and a place v_0 of L^+ above p such that:*

(Hk1) *L is an auxiliary field of level C_0 for $(K,\mathcal{O}',\Psi,c,g_\star,M)$, and for these data there is a universal polarised ordinary lift of rank n over L;*

(Hk2) *there is an ideal $\mathcal{M} \subseteq W_n^{\mathrm{po}}$ that is finite over the weights and propagates through nice primes, and, if $n = 3$, propagates along thick links;*

(Hk3) *if for some $m \geq 2$ there is a seed of rank n and weight m for (j, χ') with twist κ, then $\mathcal{M}$ has a seed component;*

(Hk4) *for every integral test ring A over $\mathcal{O}'$ and every polarised ordinary lift $(\rho, (\psi_{v,a}))$ of rank n over L to A (for $\mathcal{O}'$) such that $\psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for all $v \mid \ell$, a and $g \in I_v$, ρ_L is irreducible over $\overline{\mathbb{Q}}_\ell$, and $f(\mathcal{M}) = 0$ for the morphism $f\colon R_n^{\mathrm{po}} \to A$ with $f \circ \rho^{\mathrm{u}} = \rho$ and $f \circ \psi_{v,a}^{\mathrm{u}} = \psi_{v,a}$, the representation $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.*

Proof. Recall that ℓ is odd, that $\ell N \mid M$, and that $\Psi = \Psi_{\chi,e} = \chi \chi_{\mathrm{cyc}}^e$ is unramified at every prime not dividing ℓN, since χ_{cyc} is unramified away from ℓ and χ, a Dirichlet character modulo N (in the unitary as in the dyadic Eisenstein datum), viewed as a character of $G_{\mathbb{Q}}$, is unramified away from N; $\bar{\Psi}$ and $\bar{\omega}$ are characters of $G_{\mathbb{Q}}$ with finite image.

Step 1: (Hk1). By Lemma 50.4, $g_\star$ is a marking for $(K, \mathcal{O}', \Psi, c)$ and L is an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$; the data $(N', w, j, \chi', \theta)$ of (Ag1) do not depend on the coefficients. By Proposition 50.5, applied with $\mathcal{O}'$, a universal polarised ordinary lift $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ of rank n over L exists. This is (Hk1). From now on all rings and lifts are for $\mathcal{O}'$.

Step 2: an element separating $\bar{\omega}$ from $\bar{\Psi}$. There is $g' \in G_L$ with $\bar{\Psi}(g') = 1$ and $\bar{\omega}(g') \neq 1$. Otherwise $\bar{\omega}|_{G_L}$ is trivial on $G_L \cap \ker \bar{\Psi}$, hence $\bar{\omega}|_{G_L} = \phi \circ \bar{\Psi}|_{G_L}$ for a homomorphism $\phi\colon C \to \mathbb{F}_{\mathcal{O}}^\times$ on the finite subgroup $C = \bar{\Psi}(G_L)$ of the cyclic group $\mathbb{F}_{\mathcal{O}}^\times$. C is cyclic, and every homomorphism $C \to \mathbb{F}_{\mathcal{O}}^\times$ is $y \mapsto y^j$ for some $j \in \mathbb{Z}$ (the homomorphisms form a cyclic group of order $|C|$, and $y \mapsto y$ has order $|C|$). So $\bar{\omega} = \bar{\Psi}^j$ on G_L, against (Ar1).

Step 3: the auxiliary place. Let $F \subset \overline{\mathbb{Q}}$ be the fixed field of $G_L \cap \ker \bar{\Psi} \cap \ker \bar{\omega}$, a normal subgroup of finite index of $G_{\mathbb{Q}}$ ($L/\mathbb{Q}$ is abelian by (Af1)); so $F/\mathbb{Q}$ is finite Galois and $L \subseteq F$. By the Chebotarev density theorem there is a prime p, unramified in F and not dividing $2Mp_0\,|\mathrm{disc}(L)|$, whose Frobenius class in $\mathrm{Gal}(F/\mathbb{Q})$ is the class of $g'|_F$. Choose a place $\bar{v}_0$ of $\overline{\mathbb{Q}}$ above p and an arithmetic Frobenius σ at $\bar{v}_0$ with $\sigma|_F = g'|_F$ (replace $\bar{v}_0$ by a conjugate). Since p is unramified in L and $\sigma|_L = g'|_L = \mathrm{id}$, the image of $D_{\bar{v}_0}$ in $\mathrm{Gal}(L/\mathbb{Q})$, generated by the Frobenius $\sigma|_L$, is trivial; so $D_{\bar{v}_0} \subseteq G_L$. Let v_0 be the place of L^+ below $\bar{v}_0$; it lies above $p \nmid p_0$, it splits in L (its decomposition group in $\mathrm{Gal}(L/L^+)$ is trivial), and $D_{\bar{v}_0} \cap G_{L^+} = D_{\bar{v}_0}$. As $p \nmid M$, $p \neq \ell$ and $\bar{\Psi}$, $\bar{\omega}$ are unramified at p, so $\bar{\Psi}(D_{\bar{v}_0})$ and $\bar{\omega}(D_{\bar{v}_0})$ are generated by $\bar{\Psi}(\sigma)$, $\bar{\omega}(\sigma)$; both characters are trivial on G_F, so $\bar{\Psi}(\sigma) = \bar{\Psi}(g') = 1$ and $\bar{\omega}(\sigma) = \bar{\omega}(g') \neq 1$. Thus $\bar{\Psi}$ is trivial and $\bar{\omega}$ is non-trivial on $D_{\bar{v}_0} \cap G_{L^+}$, and $p \nmid 2M\,|\mathrm{disc}(L)|$.

Step 4: the Hecke ideal. By (Ht1) of Proposition 50.26 there is a universal polarised ordinary determinant $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ of rank n over L, the comparison morphism ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) = W_n^{\mathrm{po}}$. The hypotheses of Theorem 50.6 hold by Steps 1 and 3 and the hypotheses on κ and $\mathcal{O}'$. Its weight hypothesis holds because $\Psi = \chi\,\chi_{\mathrm{cyc}}^e$ with χ of finite order and $e \geq 1$ in both (a) and (b). Its hypothesis that Ψ is trivial on the inertia groups above primes not dividing M holds because Ψ is unramified at every prime not dividing ℓN (recalled at the start of this proof) and $\ell N \mid M$. Let $\mathcal{J} \subseteq B_n^{\mathrm{po}}$ be the ideal it provides, and put $\mathcal{M} = \mathcal{M}_{\mathcal{J}}$, the ideal of W_n^{po} generated by $\vartheta_n(\mathcal{J})$.

Step 5: (Hk2). $\mathcal{M}$ is finite over the weights. The morphism $\vartheta_n\colon B_n^{\mathrm{po}} \to W_n^{\mathrm{po}}$ is a surjective homomorphism of local rings, so $\vartheta_n(\mathfrak{m}_{B_n^{\mathrm{po}}}) = \mathfrak{m}_W$; it is $\mathcal{O}'$-linear with $\vartheta_n \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}^{\mathrm{u}}$, so it maps the generators of $\mathfrak{b}_n$ onto the generators of $\mathfrak{a}_n$, and $\vartheta_n(\mathfrak{b}_n) = \mathfrak{a}_n$ by surjectivity. Let $y \in \mathfrak{m}_W$ and choose $z \in \mathfrak{m}_{B_n^{\mathrm{po}}}$ with $\vartheta_n(z) = y$. By (Hd1), $z^k \in \mathcal{J} + \mathfrak{b}_n$ for some $k \geq 1$, so

$y^k \in \vartheta_n(\mathcal{J}) + \mathfrak{a}_n \subseteq \mathcal{M} + \mathfrak{a}_n$. Hence $\mathfrak{m}_W \subseteq \sqrt{\mathcal{M} + \mathfrak{a}_n}$. Propagation through nice primes, and for $n = 3$ along thick links, is (Hd2).

Step 6: (Hk3). $\mathcal{J}$ satisfies the dimension condition of (Hd1) and, by (Hd3), the vanishing at the points of seeds required in (Ht2) of Proposition 50.26. So if for some $m \geq 2$ there is a seed of rank n and weight m for (j, χ') with twist κ, (Ht2) shows that $\mathcal{M}$ has a seed component.

Step 7: (Hk4). Let A, $(\rho, (\psi_{v,a}))$ and $f\colon R_n^{\mathrm{po}} \to A$ be as in (Hk4), with $f(\mathcal{M}) = 0$. Put $y = f \circ \vartheta_n\colon B_n^{\mathrm{po}} \to A$, a homomorphism of $\mathcal{O}'$-algebras. Then $y \circ D^{\mathrm{u}} = f \circ (\det \circ \rho^{\mathrm{u}}) = \det \circ (f \circ \rho^{\mathrm{u}}) = \det \circ \rho$ (base change of the determinant of a representation is the determinant of the base-changed representation), $y \circ \psi_{v,a}^{\mathrm{d}} = f \circ \psi_{v,a}^{\mathrm{u}} = \psi_{v,a}$, and $y(\mathcal{J}) = f(\vartheta_n(\mathcal{J})) \subseteq f(\mathcal{M}) = 0$. The remaining hypotheses of (Hd4) are those of (Hk4), and (Hd4) gives the conclusion of (Hk4).

Steps 1–7 give (Hk1)–(Hk4) for the prime $p \nmid p_0$ and the place v_0 of Step 3. □

Lemma 50.4. *Let L be an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ and let $\mathcal{O}' \supseteq \mathcal{O}$ be a coefficient ring. Then $g_\star$ is a marking for $(K, \mathcal{O}', \Psi, c)$, and L is an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$, where Ψ is regarded as a character with values in $\mathcal{O}'^{\times}$.*

Proof. Write $k = \mathbb{F}_{\mathcal{O}}$, $k' = \mathbb{F}_{\mathcal{O}'}$ and $f = [k' : k]$. Since $\mathcal{O} = \mathcal{O}' \cap \operatorname{Frac}\mathcal{O}$, we have $\mathfrak{m}_{\mathcal{O}} = \mathfrak{m}_{\mathcal{O}'} \cap \mathcal{O}$, so $k \to k'$ is an injective homomorphism of finite fields and the reduction $\bar{\Psi}'$ of Ψ modulo $\mathfrak{m}_{\mathcal{O}'}$ is $\bar{\Psi}$ followed by $k \subseteq k'$. In particular $\ker \bar{\Psi}' = \ker \bar{\Psi}$, and every condition of Definition 48.2 that involves $\bar{\Psi}$ only through equalities $\bar{\Psi}(s) = 1$, $\bar{\Psi}^j = \bar{\omega}$, or non-triviality of characters built from $\bar{\Psi}$, $\bar{\omega}$, η_K, is the same for $\mathcal{O}$ and $\mathcal{O}'$. The datum $(K, \mathcal{O}', \Psi, c)$ satisfies the standing requirements (Ψ continuous with values in $\mathcal{O}'^{\times}$, $\Psi(c) = 1$, ℓ odd).

The marking. We have $\eta_K(g_\star) = 1$, and $\Psi(g_\star)^2 - 1 \in \mathcal{O}^{\times} \subseteq \mathcal{O}'^{\times}$, because a unit of $\mathcal{O}$ lies outside $\mathfrak{m}_{\mathcal{O}} = \mathfrak{m}_{\mathcal{O}'} \cap \mathcal{O}$.

The group Γ_L and the conditions without coefficients. The subgroup N_L is defined by $\eta_K(s) = 1$ and $\bar{\Psi}(s) = 1$, so it is the same subgroup for $\mathcal{O}'$; hence Γ_L, Γ_L^0, π_L and the groups D_v, I_v are unchanged. (Af1), (Af2), (Ar4), (Ag2) do not involve the coefficients; (Af3), (Af4), (Ar1) and (Ar5)(i)–(iii) involve Ψ and $\bar{\Psi}$ only through the kernel of $\bar{\Psi}$, equalities of characters with values in $k^{\times} \subseteq k'^{\times}$, and homomorphisms to finite abelian ℓ-groups, so they hold for $\mathcal{O}'$. (Ag1) involves Ψ only through a congruence modulo the maximal ideal of the integers of $\overline{\mathbb{Q}}_\ell$, which does not depend on the coefficient ring.

Base change of Selmer groups. Let Δ, (H_t) be as in the definition and let W be a finite-dimensional k-vector space with a continuous action of Δ and subspaces b_t. Put $W' = W \otimes_k k'$ and $b_t' = b_t \otimes_k k'$. Choosing a k-basis $e_1, \dots, e_f$ of k', a continuous map $\Delta^i \to W'$ is the same as an f-tuple of continuous maps $\Delta^i \to W$, and the conditions defining the cocycle spaces and the coboundary spaces of $H^i(\Delta; W', b')$ are k-linear and are imposed coordinatewise (the action of Δ and the subspaces b_t' are base changed from k). Hence each of these spaces is the base change to k' of the corresponding space for (W, b), and since $k \to k'$ is flat, $H^i(\Delta; W', b') \cong H^i(\Delta; W, b) \otimes_k k'$ for $i = 0, 1, 2$; in particular

$$\dim_{k'} H^i(\Delta; W', b') = \dim_k H^i(\Delta; W, b).$$

For a character ϕ of Δ with values in $k^{\times}$, $k'(\phi) = k(\phi) \otimes_k k'$. Applied to $\phi = \bar{\Psi}^{-1}\eta_K, \bar{\Psi}^{-2}\eta_K$ on Γ_L, to $\phi = \bar{\Psi}^{-1}$ on Γ_L^0 and to the trivial character, this gives (Ar2) and (Ar3) for $\mathcal{O}'$ from those for $\mathcal{O}$.

Condition (Ar5)(iv) for $\mathcal{O}'$. Let W' be a finite-dimensional k'-vector space with a continuous k'-linear action of Γ_L with open kernel, $b_v' \subseteq W'$ D_v-stable k'-subspaces, and suppose $\operatorname{Hom}_{\Gamma_L}(W', k'(\bar{\omega})) = 0$ (homomorphisms of $k'[\Gamma_L]$-modules). Let W_0, $b_{0,v}$ denote W', b_v' regarded as k-vector spaces; they satisfy the hypotheses of (Ar5)(iv) for $\mathcal{O}$ except possibly the

vanishing of $\mathrm{Hom}_{\Gamma_L}(W_0, k(\bar\omega))$. The trace $\mathrm{Tr}\colon k' \to k$ is non-zero (the extension of finite fields is separable), so $\lambda \mapsto \mathrm{Tr}\circ\lambda$ is a k-linear injection $\mathrm{Hom}_{k'}(W', k') \to \mathrm{Hom}_k(W_0, k)$; both sides have k-dimension $f \dim_{k'} W'$, so it is a bijection. It commutes with the actions of Γ_L twisted by $\bar\omega$, because $\bar\omega$ takes values in $\mathbb{F}_\ell^\times \subseteq k^\times$ and Tr is k-linear; hence it restricts to a bijection $\mathrm{Hom}_{\Gamma_L}(W', k'(\bar\omega)) \to \mathrm{Hom}_{\Gamma_L}(W_0, k(\bar\omega))$, and the latter vanishes. So (Ar5)(iv) for $\mathcal{O}$ applies to (W_0, b_0). The groups $H^i(\Gamma_L; W', b')$ and $H^i(\Gamma_L; W_0, b_0)$ are the same abelian groups (the defining conditions are the same sets of equations), so $\dim_k$ of the latter is f times $\dim_{k'}$ of the former; likewise $\dim_k b_{0,v} = f \dim_{k'} b'_v$ and $\dim_k W_0^{c_u=1} = f \dim_{k'} W'^{c_u=1}$. Thus $H^2(\Gamma_L; W', b')$ is finite-dimensional, and (48.1) for (W_0, b_0) is f times (48.1) for (W', b'), which therefore holds.

All conditions (Af1)–(Ag2) hold for $(K, \mathcal{O}', \Psi, c, g_\star, M)$ with the same C_0. □

Proposition 50.5. *Let L be an auxiliary field of level C_0 for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ and $n \in \{2, 3\}$. Then a universal polarised ordinary lift of rank n over L exists.*

Proof. Step 1: the finiteness condition. $\Gamma_L^0 = \pi_L(G_L)$ is open in Γ_L, since G_L is open in G_{L^+} and the quotient map π_L is open; so every open subgroup of Γ_L^0 is open in Γ_L, and by (Ar5)(i) Γ_L^0 satisfies Mazur's condition Φ_ℓ of Theorem B.71. For $v \mid \ell$, D_v is the absolute Galois group of the completion L_v^+ (the decomposition group at $\bar v$); an open subgroup is the absolute Galois group of a finite extension E/L_v^+, whose continuous homomorphisms to $\mathbb{F}_\ell$ correspond by local class field theory to homomorphisms $E^\times/E^{\times\ell} \to \mathbb{F}_\ell$, a finite set. So D_v satisfies Φ_ℓ.

Step 2: framed lifts and characters. The character $\bar\Psi$ factors through Γ_L and has finite image, so $\bar\rho = \mathrm{diag}(\bar\Psi^{w_{n,1}}, \dots, \bar\Psi^{w_{n,n}})\colon \Gamma_L^0 \to \mathrm{GL}_n(\mathbb{F}_\mathcal{O})$ and $\bar\psi_{v,a} = \bar\Psi^{w_{n,a}}|_{D_v}$ are continuous. By Theorem B.71, item 1, applied to $(\Gamma_L^0, \bar\rho)$ and to $(D_v, \bar\psi_{v,a})$ with $n = 1$, there are objects $R^\square$, $R_{v,a}$ of $\mathrm{CNL}_\mathcal{O}$ with universal lifts $\rho^\square$ of $\bar\rho$ and $\chi_{v,a}$ of $\bar\psi_{v,a}$. For $A \in \mathrm{CNL}_\mathcal{O}$, a homomorphism $\Gamma \to \mathrm{GL}_m(A)$ of a profinite group is continuous for the $\mathfrak{m}_A$-adic topology if and only if its reductions modulo $\mathfrak{m}_A^k$ are locally constant for all k (the topology of $A = \varprojlim A/\mathfrak{m}_A^k$ is the inverse limit of the discrete topologies); so these are the lifts satisfying (Po1) and the reduction part of (Po5).

Step 3: the product. Let S be the completed tensor product over $\mathcal{O}$ of $R^\square$ and the finitely many $R_{v,a}$ ($v \mid \ell$, $1 \le a \le n$). It is an object of $\mathrm{CNL}_\mathcal{O}$ (a quotient of a power series ring over $\mathcal{O}$ in finitely many variables), and morphisms $S \to A$ in $\mathrm{CNL}_\mathcal{O}$ correspond bijectively to tuples of morphisms from the factors. Hence S, with $\rho_S = \rho^\square \otimes 1$ and $\psi_{S,v,a} = \chi_{v,a}$, represents the functor of tuples $(\rho, (\psi_{v,a}))$ satisfying (Po1) and (Po5).

Step 4: the equations. Let $I \subseteq S$ be the ideal generated by the entries of $\rho_S(\pi_L(cg^{-1}c)) - J_n\,{}^t\rho_S(\pi_L(g))\,J_n$ for $g \in G_L$, the off-diagonal entries of $\rho_S(\pi_L(g_\star)) - \rho_S(\pi_L(cg_\star^{-1}c))$, and the entries of $\prod_{a=1}^n(\rho_S(\pi_L(g_a)) - \psi_{S,v,a}(g_a))$ for $v \mid \ell$ and $g_1, \dots, g_n \in D_v$ (these expressions make sense, as in (Po2)–(Po4)). Then $I \subseteq \mathfrak{m}_S$: modulo $\mathfrak{m}_S$ all these matrices are computed from the diagonal representation $\bar\rho$ and the $\bar\psi_{v,a}$; $\bar\Psi(cg^{-1}c) = \bar\Psi(g)^{-1}$ because $\bar\Psi(c) = 1$ and $\bar\Psi$ has abelian image, and $J_n\,{}^t\mathrm{diag}(x_1, \dots, x_n)J_n = \mathrm{diag}(x_n, \dots, x_1)$ with $w_{n,n+1-a} = -w_{n,a}$, so the first matrices vanish; the second are diagonal; and the a-th factor of the third product is diagonal with (a,a)-entry 0, so the product of diagonal matrices vanishes. Put $R_n^{\mathrm{po}} = S/I$, an object of $\mathrm{CNL}_\mathcal{O}$, and let ρ^{u}, $\psi_{v,a}^{\mathrm{u}}$ be the images of ρ_S, $\psi_{S,v,a}$. They satisfy (Po1)–(Po5). If $(\rho', (\psi'_{v,a}))$ is a polarised ordinary lift of rank n over L to $R' \in \mathrm{CNL}_\mathcal{O}$, Step 3 gives a unique morphism $f\colon S \to R'$ with $f\circ\rho_S = \rho'$, $f\circ\psi_{S,v,a} = \psi'_{v,a}$; conditions (Po2)–(Po4) for (ρ', ψ') say exactly that f kills the generators of I, so f factors uniquely through R_n^{po}. Thus $(\rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ is a universal polarised ordinary lift of rank n over L. □

Theorem 50.6. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$ with data $(N', w, j, \chi', \theta)$ as in (Ag1), $d_L = [L^+ : \mathbb{Q}]$, $n \in \{2, 3\}$, and κ an admissible twist of*

rank n for ι, c and M with $\kappa(G_L) \subseteq \mathcal{O}'^{\times}$ and $\tau(\mathcal{O}_L) \subseteq \mathcal{O}'$ for every embedding $\tau\colon L \to \overline{\mathbb{Q}}_\ell$. Let v_0 be a place of L^+ above a prime $p \nmid 2M\,|\mathrm{disc}(L)|$ which splits in L and has a place $\bar{v}_0$ of $\overline{\mathbb{Q}}$ above it with $\bar{\Psi}$ trivial and $\bar{\omega}$ non-trivial on $D_{\bar{v}_0} \cap G_{L^+}$. Let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be a universal polarised ordinary determinant and $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ a universal polarised ordinary lift of rank n over L (both for $\mathcal{O}'$), such that the comparison morphism ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) \subseteq W_n^{\mathrm{po}}$. Assume that $\Psi\chi_{\mathrm{cyc}}^{-e}$ is trivial on an open subgroup of the inertia group $I_{\bar{\ell}}$ for some integer $e \geq 1$, and that Ψ is trivial on $I_{\bar{p}}$ for every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above a prime not dividing M. Then there is an ideal $\mathcal{J} \subseteq B_n^{\mathrm{po}}$ such that:

(Hd1) *$\mathcal{J}$ is finite over the weights, and $\dim B_n^{\mathrm{po}}/\mathfrak{q} = 1 + n\,d_L$ for every minimal prime $\mathfrak{q}$ of B_n^{po} over $\mathcal{J}$;*

(Hd2) *$\mathcal{M}_{\mathcal{J}}$ propagates through nice primes, and, if $n = 3$, along thick links;*

(Hd3) *for every $m \geq 2$, every seed r of rank n and weight m for (j, χ') with twist κ, and every homomorphism of $\mathcal{O}'$-algebras $x\colon B_n^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ with $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ and $x \circ \psi_{v,a}^{\mathrm{d}} = \kappa_{v,a}$ for all $v \mid \ell$ and a, where $\tilde{r}$ is a representation of Γ_L^0 with $\tilde{r} \circ \pi_L = r$ and $(\kappa_{v,1}, \dots, \kappa_{v,n})$ is a diagonal of r on D_v as in (Sp5), one has $x(\mathcal{J}) = 0$;*

(Hd4) *for every integral test ring A over $\mathcal{O}'$ and every polarised ordinary lift $(\rho, (\psi_{v,a}))$ of rank n over L to A (for $\mathcal{O}'$) with $\psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for all $v \mid \ell$, a and $g \in I_v$, such that ρ_L is irreducible over $\overline{\mathbb{Q}}_\ell$ and some homomorphism of $\mathcal{O}'$-algebras $y\colon B_n^{\mathrm{po}} \to A$ with $y \circ D^{\mathrm{u}} = \det \circ \rho$ and $y \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}$ satisfies $y(\mathcal{J}) = 0$: the representation $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.*

Proof. Let $\mathcal{J} \subseteq B_n^{\mathrm{po}}$ be an ideal as in Proposition 50.11. Its clauses (Hi2), (Hi3), (Hi4) are (Hd2), (Hd3), (Hd4). It remains to prove (Hd1). Write $B = B_n^{\mathrm{po}}$, $N = nd_L$, $\Lambda = \mathcal{O}'[[X_1, \dots, X_N]]$ with maximal ideal $\mathfrak{m}_\Lambda$.

If $\mathcal{J} = B$, then $\mathfrak{m}_B \subseteq B = \sqrt{\mathcal{J} + \mathfrak{b}_n}$ and there is no prime over $\mathcal{J}$, so (Hd1) holds. Let $\mathcal{J} \neq B$ and $C = B/\mathcal{J} \neq 0$, a local ring with maximal ideal $\mathfrak{m}_C$ the image of $\mathfrak{m}_B$, and let $\lambda\colon \Lambda \to C$ be as in (Hi1).

Coheight of the minimal primes. By Lemma 50.25, item 1, λ is injective and every minimal prime of C has coheight $N + 1$. The minimal primes $\mathfrak{q}$ of B over $\mathcal{J}$ are the preimages of the minimal primes $\bar{\mathfrak{q}}$ of C, with $B/\mathfrak{q} \cong C/\bar{\mathfrak{q}}$; so $\dim B/\mathfrak{q} = 1 + nd_L$.

Finite over the weights. As λ is injective, $\lambda(\Lambda)/\lambda(\mathfrak{m}_\Lambda) \cong \Lambda/\mathfrak{m}_\Lambda = \mathbb{F}_{\mathcal{O}'}$. By Lemma 50.25, item 2, applied to the ideal $\lambda(\mathfrak{m}_\Lambda)$ of $\lambda(\Lambda)$, $C/\lambda(\mathfrak{m}_\Lambda)C$ has finite length and $\mathfrak{m}_C^k \subseteq \lambda(\mathfrak{m}_\Lambda)C$ for some $k \geq 1$. By (Hi1), $\lambda(\mathfrak{m}_\Lambda)C$ is contained in the ideal of C generated by the images of $\mathfrak{m}_{\mathcal{O}'}$ and of the $\psi_{v,a}^{\mathrm{d}}(g) - 1$ ($v \mid \ell$, $g \in I_v$, $\bar{\Psi}(g) = 1$), which is the image of $\mathfrak{b}_n$. Hence $\mathfrak{m}_B^k \subseteq \mathcal{J} + \mathfrak{b}_n$, i.e. $\mathfrak{m}_B \subseteq \sqrt{\mathcal{J} + \mathfrak{b}_n}$: $\mathcal{J}$ is finite over the weights. This is (Hd1). □

50.2 Hida theory and patching for the definite unitary group

This subsection proves Proposition 50.11: an ideal $\mathcal{J}$ of the determinant ring such that $B_n^{\mathrm{po}}/\mathcal{J}$ is finite and torsion-free over the Iwasawa algebra $\mathcal{O}'[[X_1, \dots, X_{nd_L}]]$ of the weights (Hi1), with the propagation, seed and automorphy properties (Hi2)–(Hi4); with Lemma 50.25 it gives Theorem 50.6. The ideal is a Hecke ideal of zero-monodromy type (Definition 50.10), cut out by an ordinary Hecke algebra of a definite unitary group with a type at an auxiliary place (Definition 50.8). Hida theory, in Geraghty's form, gives the finiteness over the weights. Appendix E supplies three further facts: a Hecke ideal of zero-monodromy type with classical level modules

at every Taylor–Wiles level exists (Proposition E.1); the irreducible points of the classical ideal (Definition 50.7) with a parallel inertial weight are automorphic (Proposition E.25); and $R = T$ holds at the patchable curve points (Definition 50.9), the one-dimensional points at which the patching method of Taylor and Wiles [254] applies (Proposition E.32). This subsection connects them: a Hecke ideal of zero-monodromy type lies in the classical ideal (Lemma 50.12), and $R = T$ at patchable curve points gives propagation on the charts of the entry algebra (Proposition 50.15), because a nice prime of a chart gives a patchable curve point (Lemma 50.16). The lemmas on separable elements and Zariski closures (Lemma 50.19, Lemma 50.20, Lemma 50.21) are used again in rank four in Section 53.

Definition 50.7. Let $(n, L, c, \Gamma, \Gamma^0, \pi, (D_v \supseteq I_v)_{v\in S_\ell}, (\bar\chi_a))$ be a residual setting of rank n over a coefficient ring $\mathcal{O}$ (over a rank-n Hecke datum, or over a CM field L), $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over it, and $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ a continuous character. A homomorphism of $\mathcal{O}$-algebras $x\colon B_n^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ is a **classical ordinary point** (for ι and κ) if there are a homomorphism $\tilde r\colon \Gamma^0 \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with $r = \tilde r \circ \pi$ continuous on G_L, and a regular algebraic conjugate self-dual cuspidal automorphic representation Π of $\mathrm{GL}_n(\mathbb{A}_L)$, such that

(Cy1) $x \circ D^{\mathrm{u}} = \det \circ \tilde r$, and $\tilde r$ is absolutely irreducible;

(Cy2) $r \otimes \kappa \leftrightarrow_\iota \Pi$;

(Cy3) for every $v \in S_\ell$, r is triangular on D_v with diagonal $(x \circ \psi_{v,1}^{\mathrm{d}}, \dots, x \circ \psi_{v,n}^{\mathrm{d}})$;

(Cy4) for every $v \in S_\ell$ and every field embedding $\tau\colon L_v^+ \to \overline{\mathbb{Q}}_\ell$, the τ-Hodge–Tate weights of the characters $x \circ \psi_{v,1}^{\mathrm{d}}, \dots, x \circ \psi_{v,n}^{\mathrm{d}}$ of D_v (de Rham, as subquotients of the de Rham representation $r|_{D_v}$) are strictly decreasing in a, with Hodge–Tate weights normalised as in Section 13.

The **classical ideal** $\mathcal{J}_\kappa^{\mathrm{cl}} \subseteq B_n^{\mathrm{po}}$ is the intersection of the kernels of all classical ordinary points ($\mathcal{J}_\kappa^{\mathrm{cl}} = B_n^{\mathrm{po}}$ if there is none).

Definition 50.8. Let $\mathcal{O}$ be a coefficient ring, and let $(n, L, c, (\bar v)_{v|\ell}, \mathrm{St}, v_0)$ be one of the following:

(Us1) the integer n, the CM field L, the complex conjugation c, the places $\bar v$, the set St and the place v_0 of a rank-n Hecke datum $\mathscr{H}$ over $\mathcal{O}$ (the objects below are then **over** $\mathscr{H}$);

(Us2) $n \in \{2, 3\}$, a CM field L satisfying (Af1) and (Af2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$ with $\tau(\mathcal{O}_L) \subseteq \mathcal{O}$ for every embedding $\tau\colon L \to \overline{\mathbb{Q}}_\ell$, the places $\bar v$ of Definition 48.2, the set St of places of L^+ not above ℓ lying above a prime dividing M, and a place v_0 of L^+ above a prime $p \nmid 2M|\mathrm{disc}(L)|$ that splits in L (the objects below are then **over** L).

In both cases p denotes the prime below v_0.

The group. Let $\mathbb{G}_L$ be the group scheme over $\mathcal{O}_{L^+}$ with $\mathbb{G}_L(R) = \{g \in \mathrm{GL}_n(\mathcal{O}_L \otimes_{\mathcal{O}_{L^+}} R) : {}^t g^c\, g = 1\}$, where c acts on $\mathcal{O}_L$; this is the unitary group of the Hermitian form $\sum_i x_i \bar x_i$. For a place v of L^+ split in L and a place $\tilde v \mid v$ of L, the projection identifies $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ with $\mathrm{GL}_n(\mathcal{O}_{L_{\tilde v}})$.

Places. Let S_ℓ be the set of places of L^+ above ℓ, and put $T_L = S_\ell \cup \mathrm{St} \cup \{v_0\}$. For $v \in S_\ell$, $\tilde v$ is the place of L below $\bar v$; for the other $v \in T_L$ a place $\tilde v \mid v$ of L is fixed.

Type data and level. A **type datum** is a family $(V_v)_{v\in\mathrm{St}}$ of open normal subgroups $V_v \subseteq \mathbb{G}_L(\mathcal{O}_{L_v^+})$ together with a finite free $\mathcal{O}$-module τ with an $\mathcal{O}$-linear action of

$$H = \prod_{v\in\mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v.$$

Its **level** is $V = \prod_v V_v \subseteq \mathbb{G}_L(\mathbb{A}_{L^+}^\infty)$ with $V_v = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ for $v \notin \mathrm{St} \cup \{v_0\}$, the given V_v for $v \in \mathrm{St}$, and V_{v_0} the kernel of reduction $\mathbb{G}_L(\mathcal{O}_{L_{v_0}^+}) \to \mathbb{G}_L(\mathcal{O}_{L_{v_0}^+}/p)$.

The ordinary Hecke algebra of type τ. We use [105], §2, with $F = L$, $\mathbb{G} = \mathbb{G}_L$, $T = T_L$ and $U = V$. The module $\mathcal{S}_V$ is the Pontryagin dual of the space $S^{\mathrm{ord}}(V(\ell^\infty), \mathcal{K}/\mathcal{O})$ of ordinary forms of trivial weight ($\mathcal{K} = \mathcal{O}[1/\ell]$); $\Lambda^+ = \mathcal{O}[[T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)]]$ and $\Lambda_b = \mathcal{O}[[T_n(\ell^b)]]$ ($b \geq 1$; $T_n(\ell^b)$ the kernel of reduction modulo ℓ^b on the diagonal torus) act on $\mathcal{S}_V$ through the diamond operators $\langle u \rangle$; and $\mathbb{T}^{\mathrm{ord}}(V)$ is the Λ^+-subalgebra of $\mathrm{End}_{\mathcal{O}}(\mathcal{S}_V)$ generated by the operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ at the places w of L above places $v \notin T_L$ split in L, and $U_{\tilde{v}}^{(j)}$, $v \in S_\ell$, $1 \leq j \leq n$. Right translation by $\prod_{v \in \mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})$, which normalises $V(\ell^{b,c})$, gives an action of H on $\mathcal{S}_V$ commuting with $\mathbb{T}^{\mathrm{ord}}(V)$. Put

$$N_\tau = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_V),$$

a $\mathbb{T}^{\mathrm{ord}}(V)$-module through the action on $\mathcal{S}_V$, and let the **ordinary Hecke algebra of type τ** be the image $\mathbb{T}_\tau$ of $\mathbb{T}^{\mathrm{ord}}(V)$ in $\mathrm{End}_{\mathcal{O}}(N_\tau)$, with its structure of Λ^+-algebra. For a maximal ideal $\mathfrak{m}$ of $\mathbb{T}_\tau$, $\mathbb{T}_{\tau,\mathfrak{m}}$ is the localisation.

Levels at auxiliary places. In case (Us1), let Q be a finite set of places of L^+ split in L and not in T_L, and for $v \in Q$ let K'_v be a compact open subgroup of $\mathbb{G}_L(L_v^+)$ (not necessarily contained in $\mathbb{G}_L(\mathcal{O}_{L_v^+})$, so that conjugates by elements of $\prod_{v \in Q} \mathbb{G}_L(L_v^+)$ are allowed); write $K' = (K'_v)_{v \in Q}$. The **level at** K' of a type datum $((V_v), \tau)$ is the group $V(K')$ obtained from its level V by replacing V_v by K'_v for $v \in Q$. The objects $\mathcal{S}_{V(K')}$, $\mathbb{T}^{\mathrm{ord}}(V(K'))$, $N_\tau(K') = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_{V(K')})$ and $\mathbb{T}_\tau(K')$ (the image of $\mathbb{T}^{\mathrm{ord}}(V(K'))$ in $\mathrm{End}_{\mathcal{O}}(N_\tau(K'))$) are defined as above with $T = T_L \cup Q$ and $U = V(K')$; in particular the operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ are taken only at the places w above places $v \notin T_L \cup Q$ split in L. For $Q = \varnothing$ these are $\mathcal{S}_V$, $\mathbb{T}^{\mathrm{ord}}(V)$, N_τ and $\mathbb{T}_\tau$.

Definition 50.9. Let $(n, L, c, \Gamma, \Gamma^0, \pi, (D_v \supseteq I_v)_{v \in S_\ell}, (\bar{\chi}_a))$ be a residual setting of rank n over a coefficient ring $\mathcal{O}$ and $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over it. If the setting is that of a rank-n Hecke datum $\mathscr{H}$ (Rs1), v_0 and $\bar{v}_0$ are those of $\mathscr{H}$; if it is that of a CM field L (Rs2), let v_0 be a finite place of L^+ not above ℓ, split in L, with a place $\bar{v}_0$ of $\overline{\mathbb{Q}}$ above it. Write $B = B_n^{\mathrm{po}}$, $\gamma^* = \pi(c)\gamma^{-1}\pi(c)$ for $\gamma \in \Gamma^0$, $\Gamma' = \{\gamma \in \Gamma^0 : \chi_{\mathrm{cyc}}(\gamma) = 1\}$ and $\Delta_0 = \pi(D_{\bar{v}_0} \cap G_{L^+})$.

Curve points. A **curve point** of B is a tuple $(k, \rho, P, (\psi_{v,a}), f)$ of a finite field k containing $\mathbb{F}_\mathcal{O}$, with $A_k = k[[T]]$, fraction field F_k and an algebraic closure $\bar{F}_k$; a homomorphism $\rho\colon \Gamma^0 \to \mathrm{GL}_n(A_k)$ whose entries are continuous for the T-adic topology; a symmetric $P \in \mathrm{GL}_n(A_k)$ with $\rho(\gamma^*) = P^{-1}\,{}^t\rho(\gamma)\,P$ for all γ; continuous homomorphisms $\psi_{v,a}\colon D_v \to A_k^\times$ ($v \in S_\ell$, $1 \leq a \leq n$) such that $\rho \circ \pi$ is triangular over F_k on D_v with diagonal $(\psi_{v,1}, \ldots, \psi_{v,n})$; and a homomorphism of $\mathcal{O}$-algebras $f\colon B \to A_k$ with $f \circ D^{\mathrm{u}} = \det \circ \rho$ and $f \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}$. It is **patchable** if:

(Pj1) for every $v \in S_\ell$: $\psi_{v,a} \neq \psi_{v,b}$ for $a \neq b$, and $\psi_{v,a} \neq \psi_{v,b} \cdot \chi_{\mathrm{cyc}}|_{D_v}$ for $a < b$;

(Pj2) every open subset of Γ^0 meeting Γ' contains some $\sigma \in \Gamma'$ such that the characteristic polynomial of $\rho(\sigma)$ is separable over F_k;

(Pj3) the only $X \in \mathrm{M}_n(F_k)$ with $\chi_{\mathrm{cyc}}(\gamma)\rho(\gamma)X = X\rho(\gamma)$ for all $\gamma \in \Delta_0$ is $X = 0$.

A patchable curve point is **of irreducible type** if $\rho \otimes \bar{F}_k$ restricted to Γ' is irreducible, and **of endoscopic type** if there are integers $a, b \geq 1$ with $a+b = n$, $Q \in \mathrm{GL}_n(F_k)$ and homomorphisms $r_1\colon \Gamma^0 \to \mathrm{GL}_a(F_k)$, $r_2\colon \Gamma^0 \to \mathrm{GL}_b(F_k)$ such that $Q\rho(\gamma)Q^{-1} = \mathrm{diag}(r_1(\gamma), r_2(\gamma))$ for all γ; for $i = 1, 2$ there is an invertible P_i over F_k with $r_i(\gamma^*) = P_i^{-1}\,{}^t r_i(\gamma) P_i$ for all γ; $r_1 \otimes \bar{F}_k$ and $r_2 \otimes \bar{F}_k$ restricted to Γ' are irreducible; and 0 is the only $Y \in \mathrm{M}_{b \times a}(\bar{F}_k)$ with $Y r_1(\sigma) = r_2(\sigma) Y$ for all $\sigma \in \Gamma'$.

Normalised curve points. For $1 \le a \le n$, a curve point $(k, \rho, P, (\psi_{v,a}), f)$ is **normalised of shape** $(a, n-a)$ if $P = 1_n$ and, when $a < n$, every $\rho(\gamma)$ is block diagonal with diagonal blocks of sizes a and $n-a$; then $\rho(\gamma^*) = {}^t\rho(\gamma)$ for all $\gamma \in \Gamma^0$.

Stable and thick primes. For a prime $\mathfrak{q}$ of B let $\bar\kappa(\mathfrak{q})$ be an algebraic closure of its residue field and $D_\mathfrak{q}$ the base change of D^{u} to $\bar\kappa(\mathfrak{q})$. The prime $\mathfrak{q}$ is **stable** if $D_\mathfrak{q} = \det \circ r$ for an irreducible homomorphism $r\colon \Gamma^0 \to \mathrm{GL}_n(\bar\kappa(\mathfrak{q}))$. Let $\mathcal{I} \subseteq B[\Gamma^0]$ be the intersection, over $k \ge 1$ and the open normal subgroups H' of Γ^0, of the two-sided ideals generated by: the Cayley–Hamilton ideal of D^{u} (generated by the coefficients, in $B[\Gamma^0]$, of $\chi_{D'}(y)(y)$ for $y = \sum_{i=1}^m t_i y_i$, $y_i \in B[\Gamma^0]$, D' the base change of D^{u} to $B[t_1, \dots, t_m]$); the elements $\prod_{a=1}^n (\pi(g_a) - \psi^{\mathrm{d}}_{v,a}(g_a))$ ($v \in S_\ell$, $g_a \in D_v$, $a = 1$ on the left) and their images under the B-linear anti-involution $\gamma \mapsto \gamma^*$; the elements $\mathfrak{m}_B^k \cdot 1$; and $h - 1$ for $h \in H'$. The prime $\mathfrak{q}$ is **thick** if it is not stable and $\bar\kappa(\mathfrak{q})[\Gamma^0]$ modulo the two-sided ideal generated by the image of $\mathcal{I}$ is not a semisimple ring.

R = T at patchable curve points. An ideal $J \subseteq B$ has **R = T at patchable curve points** (for v_0) if for every patchable curve point $(k, \rho, P, (\psi_{v,a}), f)$ of irreducible type with $J \subseteq \ker f$, every prime $\mathfrak{q} \subseteq \ker f$ of B contains J. The ideal J has **R = T along thick chains** (for v_0) if for every $h \ge 0$, all patchable curve points $x_0, \dots, x_h$ of endoscopic type with homomorphisms $f_0, \dots, f_h$, all thick primes $\mathfrak{e}_1, \dots, \mathfrak{e}_h$ with $\mathfrak{e}_i \subseteq \ker f_{i-1} \cap \ker f_i$, and every stable prime $\mathfrak{q}_1$ with $J \subseteq \mathfrak{q}_1 \subseteq \ker f_0$, every prime $\mathfrak{q} \subseteq \ker f_h$ of B that is stable or thick contains J.

Definition 50.10. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, κ a twist for $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$. For $v \in S_\ell$, $1 \le j \le n$ and $z \in 1 + \ell\mathcal{O}_{L_v^+}$ let $d_j(z) \in T_n(\ell^1)$ be the element with z in the v-component of place j and 1 elsewhere, and $[u] \in \Lambda_1$ the group element of $u \in T_n(\ell^1)$.

An ideal $J \subseteq B$ is a **Hecke ideal of zero-monodromy type** (for ι and κ) if $J = B$ and B has no classical ordinary point for ι and κ, or there are $T \in \mathrm{CNL}_\mathcal{O}$, a homomorphism of $\mathcal{O}$-algebras $\lambda_T\colon \Lambda_1 \to T$, a T-module M and a surjective homomorphism of $\mathcal{O}$-algebras $f\colon B \to T$ with $J = \ker f$, such that:

(Zm1) M is faithful over T and free of finite rank over Λ_1 through λ_T; hence T is finite and torsion-free over Λ_1;

(Zm2) $\lambda_T([d_j(z)]) = (\chi_{\mathrm{cyc}}^{j-1}\kappa)(g_z)\, f(\psi^{\mathrm{d}}_{v,j}(g_z))$ for $v \in S_\ell$, $1 \le j \le n$, $z \in 1 + \ell\mathcal{O}_{L_v^+}$, where $g_z \in I_v$ is the image of z under the local Artin map of $L_v^+ = L_{\tilde v}$ normalised to send uniformisers to geometric Frobenius elements;

(Zm3) for every homomorphism of $\mathcal{O}$-algebras $y\colon T \to \overline{\mathbb{Q}}_\ell$ such that $y(\lambda_T([u])) = (w_0\lambda)(u)^{-1}$ for all $u \in T_n(\ell^1)$, for a dominant weight λ with $\lambda_{\tau,j} > \lambda_{\tau,j+1}$ for all τ, j (a **regular point**), and such that the semisimple representation ρ_y of $\Gamma^0_\mathscr{H}$ with $\det \circ \rho_y = y \circ f \circ D^{\mathrm{u}}$ ((Ch3)) is absolutely irreducible, the representation $\rho_y \circ \pi_\mathscr{H} \otimes \kappa$ is automorphic of conjugate self-dual type for ι, and for every $v \in S_\ell$, $\rho_y \circ \pi_\mathscr{H}$ is triangular on D_v with diagonal $(y \circ f \circ \psi^{\mathrm{d}}_{v,a})_{1 \le a \le n}$;

(Zm4) $x(J) = 0$ for every classical ordinary point x of B for ι and κ.

Proposition 50.11. *Let $\mathcal{O}'$, L with data $(N', w, j, \chi', \theta)$, d_L, n, κ, v_0, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$, $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi^{\mathrm{u}}_{v,a}))$ and ϑ_n be as in the hypotheses of Theorem 50.6. Then there is an ideal $\mathcal{J} \subseteq B_n^{\mathrm{po}}$ such that:*

(Hi1) *there is a homomorphism of $\mathcal{O}'$-algebras $\lambda\colon \mathcal{O}'[[X_1, \dots, X_{nd_L}]] \to B_n^{\mathrm{po}}/\mathcal{J}$ such that $B_n^{\mathrm{po}}/\mathcal{J}$ is a finite and torsion-free module over $\mathcal{O}'[[X_1, \dots, X_{nd_L}]]$ via λ, and λ maps the maximal ideal of $\mathcal{O}'[[X_1, \dots, X_{nd_L}]]$ into the ideal of $B_n^{\mathrm{po}}/\mathcal{J}$ generated by the images of $\mathfrak{m}_{\mathcal{O}'}$ and of the elements $\psi^{\mathrm{d}}_{v,a}(g) - 1$ with $v \mid \ell$, $1 \le a \le n$, $g \in I_v$ and $\bar\Psi(g) = 1$;*

(Hi2) *$\mathcal{M}_{\mathcal{J}}$ propagates through nice primes, and, if $n = 3$, along thick links;*

(Hi3) *for every $m \geq 2$, every seed r of rank n and weight m for (j, χ') with twist κ, and every homomorphism of $\mathcal{O}'$-algebras $x\colon B_n^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ with $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ and $x \circ \psi_{v,a}^{\mathrm{d}} = \kappa_{v,a}$ for all $v \mid \ell$ and a, where $\tilde{r}$ is a representation of Γ_L^0 with $\tilde{r} \circ \pi_L = r$ and $(\kappa_{v,1}, \dots, \kappa_{v,n})$ is a diagonal of r on D_v as in (Sp5), one has $x(\mathcal{J}) = 0$;*

(Hi4) *for every integral test ring A over $\mathcal{O}'$ and every polarised ordinary lift $(\rho, (\psi_{v,a}))$ of rank n over L to A (for $\mathcal{O}'$) with $\psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for all $v \mid \ell$, a and $g \in I_v$, such that ρ_L is irreducible over $\overline{\mathbb{Q}}_\ell$ and some homomorphism of $\mathcal{O}'$-algebras $y\colon B_n^{\mathrm{po}} \to A$ with $y \circ D^{\mathrm{u}} = \det \circ \rho$ and $y \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}$ satisfies $y(\mathcal{J}) = 0$: the representation $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions.*

Proof. The datum. Let St be the set of places of L^+ not above ℓ lying above a prime dividing M, $(\bar{v})$ the places of Definition 48.2 and $\mathscr{H}_L = (n, L, c, (\bar{v}), \mathrm{St}, v_0, \bar{v}_0, (\bar{\Psi}^{w_{n,a}}|_{G_L})_a)$. The hypotheses of Lemma 50.23 are among those of Theorem 50.6; so $\mathscr{H}_L$ is a rank-n Hecke datum over $\mathcal{O}'$ (In1) with $\Gamma_{\mathscr{H}_L} = \Gamma_L$, $\pi_{\mathscr{H}_L} = \pi_L$, the same $D_v \supseteq I_v$ (In2), κ is a twist for it (In3), and $(\Psi^{w_{n,a}}|_{I_v})$ is an inertial weight for it (In4), by the weight hypothesis of Theorem 50.6. Hence the residual setting of $\mathscr{H}_L$ in Definition 50.2 is that of L: $(B, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ is a universal polarised ordinary determinant over $\mathscr{H}_L$, and classical ordinary points and the classical ideal, curve points and the two R = T properties for v_0, and type data and $\mathbb{T}_\tau$, are the same over $\mathscr{H}_L$ as over L (the type data of Definition 50.8 are formed from the same L, $\bar{v}$, St, v_0); and for $g \in G_L$, $\bar{\Psi}^{w_{n,b}}(g) = 1$ for all b if and only if $\bar{\Psi}(g) = 1$, as $w_{n,1} = 1$, so the condition $\bar{\chi}_b(g) = 1$ for all b reads $\bar{\Psi}(g) = 1$. Below, Proposition E.1, Proposition E.25, Proposition E.32 and Lemma 50.12 are applied to $\mathscr{H}_L$ and κ.

By Proposition E.1 (for $\mathscr{H}_L$, κ and ι; its hypothesis that the wild values of $\mathscr{H}_L$ are trivial holds by (Wv2) of Lemma 50.24, as the reduction $\bar{\omega}$ of χ_{cyc} is non-trivial on D_v for every $v \in S_\ell$ by (Af4), the groups D_v of $\mathscr{H}_L$ being those of L by (In2)) there is a Hecke ideal $\mathcal{J}$ of zero-monodromy type for ι and κ (Definition 50.10, clauses (Zm1)–(Zm4)) which, if $\mathcal{J} \neq B$, has classical levels. We prove (Hi1)–(Hi4) for it.

(Hi3). Let r, $\tilde{r}$, $(\kappa_{v,a})$ and x be as in (Hi3). By (Sp6), $r \otimes \kappa \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal Π; $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ with $\tilde{r} \circ \pi_L = r$ continuous; and by (Sp5), for every $v \mid \ell$, r is triangular on $D_{\bar{v}} \cap G_L$ with diagonal $(\kappa_{v,a})_a = (x \circ \psi_{v,a}^{\mathrm{d}})_a$, where $D_{\bar{v}} \cap G_L = D_v$ because v splits in L ((Af2), $\ell \mid M$). Moreover $\tilde{r}$ is absolutely irreducible, because r is by (Sp1) and $\pi_L(G_L) = \Gamma_L^0$; and by (Sp5) the diagonal characters $\kappa_{v,a}$ are $\chi_{\mathrm{cyc}}^{m\, w_{n,a}}$ on an open subgroup of inertia, so their Hodge–Tate weights $m\, w_{n,a}$ strictly decrease in a ($m \geq 2$, $w_{n,a}$ strictly decreasing). So x satisfies (Cy1)–(Cy4): it is a classical ordinary point. Hence $\mathcal{J} \neq B$ (in the alternative $\mathcal{J} = B$ there is no classical ordinary point), and $x(\mathcal{J}) = 0$ by (Zm4).

(Hi4). Let A, $(\rho, (\psi_{v,a}))$ and y be as in (Hi4). The hypotheses of Proposition E.25 hold for $\mathscr{H}_L$, κ, the inertial weight $(\Psi^{w_{n,a}}|_{I_v})$, A, ρ and y: $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(A)$ with ρ_L continuous by (Po1) and irreducible over $\overline{\mathbb{Q}}_\ell$; $y \circ D^{\mathrm{u}} = \det \circ \rho$; $y(\psi_{v,a}^{\mathrm{d}}(g)) = \psi_{v,a}(g) = \Psi(g)^{w_{n,a}}$ for $g \in I_v$; $y(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$, because A is a subring of $\overline{\mathbb{Q}}_\ell$, so $\mathfrak{q} = \ker y$ is a prime containing $\mathcal{J}$ whose determinant over $\bar{\kappa}(\mathfrak{q}) \subseteq \overline{\mathbb{Q}}_\ell$ is $\det \circ \rho$ with ρ irreducible over $\overline{\mathbb{Q}}_\ell$, i.e. $\mathfrak{q}$ is stable, and Lemma 50.12 gives $\mathcal{J}_\kappa^{\mathrm{cl}} \subseteq \mathfrak{q}$; and the ratio condition holds with $h_{ab} = e(w_{n,a} - w_{n,b})$, because $\Psi^{w_{n,a}-w_{n,b}} \chi_{\mathrm{cyc}}^{-e(w_{n,a}-w_{n,b})} = (\Psi \chi_{\mathrm{cyc}}^{-e})^{w_{n,a}-w_{n,b}}$ and $\Psi \chi_{\mathrm{cyc}}^{-e}$, a character of $G_{\mathbb{Q}}$ trivial on an open subgroup of $I_{\bar{\ell}}$ ($e \geq 1$, weight hypothesis of Theorem 50.6), is trivial on an open subgroup of the conjugate $I_{\bar{v}}$, hence of I_v. The conclusion of Proposition E.25 is that of (Hi4).

(Hi2). By Proposition E.32 (its hypothesis on $\mathcal{J}$ is the choice above), $\mathcal{J}$ has R = T at patchable curve points (for v_0 and the place $\bar{v}_0$ of the hypotheses), and, if $n = 3$, along thick

chains. The comparison morphism exists with image in W_n^{po} by hypothesis, so Proposition 50.15, (Tq1) and (Tq2), shows that $\mathcal{M}_{\mathcal{J}}$ propagates through nice primes, and, if $n = 3$, along thick links.

(Hi1), the degenerate case. If $\mathcal{J} = B$, then $B/\mathcal{J} = 0$, and the zero homomorphism $\lambda\colon \Lambda_N \to 0$ satisfies (Hi1). Otherwise let T, λ_T, M and f (with $\mathcal{J} = \ker f$) be as in Definition 50.10.

Step 1: the weight algebra. $T_n(\ell^1) = \prod_{v\in S_\ell}\bigl(1+\ell\mathcal{O}_{L_v^+}\bigr)^n$. For each v, $1+\ell\mathcal{O}_{L_v^+}$ is a finitely generated $\mathbb{Z}_\ell$-module of rank d_v whose torsion consists of the ℓ-power roots of unity in L_v^+; by (Af4), $\bar\omega|_{D_v} \neq 1$, so $\zeta_\ell \notin L_v^+$ and $1+\ell\mathcal{O}_{L_v^+} \cong \mathbb{Z}_\ell^{d_v}$. Hence $T_n(\ell^1) \cong \mathbb{Z}_\ell^N$, and for topological generators $u_1,\dots,u_N$ the map $X_i \mapsto u_i - 1$ is an isomorphism $\Lambda_N \to \Lambda_1$ of complete local $\mathcal{O}'$-algebras; in particular Λ_1 is a Noetherian local domain with maximal ideal generated by $\mathfrak{m}_{\mathcal{O}'}$ and the $u_i - 1$.

Step 2: (Hi1). f induces an isomorphism $\bar f\colon B/\mathcal{J} \to T$, and T is finite and torsion-free over Λ_1 through λ_T by (Zm1). Let $\lambda\colon \Lambda_N \to B/\mathcal{J}$ be the composite of $\Lambda_N \cong \Lambda_1$ (Step 1), λ_T and $\bar f^{-1}$; then $B/\mathcal{J}$ is a finite and torsion-free Λ_N-module via λ. The maximal ideal of Λ_N is generated by $\mathfrak{m}_{\mathcal{O}'}$ and the X_i, and $\bar f(\lambda(X_i)) = \lambda_T([u_i]) - 1$. Each u_i is a finite product of elements $d_j(z)$ with $z \in 1+\ell\mathcal{O}_{L_v^+}$, and $[uu'] - 1 = [u]([u'] - 1) + ([u] - 1)$. For such z, $g_z = \mathrm{Art}(z) \in I_v$ lies in a pro-ℓ group, so $\bar\Psi(g_z) = 1$ ($\bar\Psi$ has order prime to ℓ) and $(\chi_{\mathrm{cyc}}^{j-1}\kappa)(g_z) = 1+\mu$ with $\mu \in \mathfrak{m}_{\mathcal{O}'}$; by (Zm2), $\lambda_T([d_j(z)]) - 1 = (1+\mu)\bigl(f(\psi_{v,j}^{\mathrm{d}}(g_z)) - 1\bigr) + \mu$. So $\bar f(\lambda(X_i))$ lies in the ideal of T generated by $\mathfrak{m}_{\mathcal{O}'}$ and the $f(\psi_{v,a}^{\mathrm{d}}(g)) - 1$ ($v \mid \ell$, $g \in I_v$, $\bar\Psi(g) = 1$), and applying $\bar f^{-1}$ gives the last clause of (Hi1). □

Lemma 50.12. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, κ a twist for $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $(B, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $\mathcal{J}_\kappa^{\mathrm{cl}}$ its classical ideal for ι and κ, and J a Hecke ideal of zero-monodromy type for ι and κ. Then $J \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$, and every stable prime $\mathfrak{q}$ of B with $J \subseteq \mathfrak{q}$ contains $\mathcal{J}_\kappa^{\mathrm{cl}}$.*

Proof. Step 0: $J \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$. If $J = B$, B has no classical ordinary point, so $\mathcal{J}_\kappa^{\mathrm{cl}} = B$. Otherwise every classical ordinary point kills J by (Zm4), and $\mathcal{J}_\kappa^{\mathrm{cl}}$ is the intersection of their kernels. In particular, if $J = B$ there is no prime containing J; assume from now on $J = \ker f$.

Step 1: a minimal prime with irreducible determinant. Let $\mathfrak{q} \supseteq J$ be stable and $\bar{\mathfrak{q}} = f(\mathfrak{q})$, a prime of T with $f^{-1}(\bar{\mathfrak{q}}) = \mathfrak{q}$ (f is surjective with kernel in $\mathfrak{q}$), so $B/\mathfrak{q} \cong T/\bar{\mathfrak{q}}$. Let $P \subseteq \bar{\mathfrak{q}}$ be a minimal prime of T, Ω_P an algebraic closure of $\mathrm{Frac}(T/P)$, and ρ_P the semisimple representation of $\Gamma^0_{\mathscr{H}}$ over Ω_P with determinant the base change of $f \circ D^{\mathrm{u}}$ (Ch3). Suppose $\rho_P = \rho_1 \oplus \rho_2$ with $\dim\rho_i \geq 1$. The coefficients of the characteristic polynomials of the $\rho_i(\gamma)$ are elementary symmetric functions in some of the roots of the characteristic polynomial of $\rho_P(\gamma)$, a monic polynomial over T/P; so they lie in the integral closure R_P of T/P in Ω_P, and by (Ch1) $\det\circ\rho_i$ is the base change of an R_P-valued determinant D_i of dimension $\dim\rho_i$, with $D_1 D_2$ the base change of $f \circ D^{\mathrm{u}}$ to R_P. By lying over there is a prime Q' of R_P over $\bar{\mathfrak{q}}/P$; an embedding of R_P/Q' into $\bar\kappa(\mathfrak{q})$ over $T/\bar{\mathfrak{q}} = B/\mathfrak{q}$ (R_P/Q' is algebraic over $T/\bar{\mathfrak{q}}$) shows that $D_{\mathfrak{q}}$ is a product of two determinants of dimensions $\dim\rho_1, \dim\rho_2$, so by (Ch3) the semisimple representation with determinant $D_{\mathfrak{q}}$ is a direct sum of two representations of these dimensions, contradicting the stability of $\mathfrak{q}$. Hence ρ_P is absolutely irreducible. By Burnside's theorem choose $\gamma_1,\dots,\gamma_{n^2} \in \Gamma^0_{\mathscr{H}}$ with $(\rho_P(\gamma_i))$ a basis of $\mathrm{M}_n(\Omega_P)$, and let $g_P \in T$ be the determinant of the matrix of traces $\bigl(\mathrm{tr}_{f\circ D^{\mathrm{u}}}(\gamma_i\gamma_j)\bigr)_{i,j}$. Its image in Ω_P is the Gram determinant of the basis for the non-degenerate trace form, so $g_P \notin P$. For every homomorphism $y\colon T \to \overline{\mathbb{Q}}_\ell$ with $y(P) = 0 \neq y(g_P)$ the semisimple ρ_y with $\det\circ\rho_y = y \circ f \circ D^{\mathrm{u}}$ has $\det(\mathrm{tr}\,\rho_y(\gamma_i\gamma_j)) \neq 0$, so the $\rho_y(\gamma_i)$ span $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ and ρ_y is absolutely irreducible.

Step 2: regular points separate T/P. Let $t \in T \smallsetminus P$. By (Zm1), $\Lambda_1 \to T/P$ is injective (a

non-zero element of Λ_1 is a non-zero-divisor on T, while the minimal prime P of the Noetherian ring T consists of zero-divisors), and T/P is a domain finite over $\Lambda_1 \cong \mathcal{O}[[X_1,\dots,X_N]]$, a normal domain (Lemma 50.14 (2)); so the minimal polynomial of t mod P over $\mathrm{Frac}(\Lambda_1)$ has coefficients in Λ_1 and a non-zero constant term c_0. For a dominant λ with $\lambda_{\tau,j} > \lambda_{\tau,j+1}$, the homomorphism $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$, $[u] \mapsto (w_0\lambda)(u)^{-1}$, has kernel $\mathfrak{P}_{k(\lambda)}$ with $k(\lambda)_{\tau,j} = -\lambda_{\tau,n+1-j}$; the set of these $k(\lambda)$ is dense in $(\mathbb{Z}_\ell^n)^I$ (given k^* and e, choose integers $k \equiv k^* \bmod \ell^e$ and add $\ell^e A\,j$ to $k_{\tau,j}$ for large A, making $k_{\tau,j}$ strictly increasing in j). By Lemma 50.13, $c_0 \notin \mathfrak{P}_{k(\lambda)}$ for some such λ; by lying over, $\Lambda_1/\mathfrak{P}_{k(\lambda)} \to \overline{\mathbb{Q}}_\ell$ extends to $y\colon T/P \to \overline{\mathbb{Q}}_\ell$, a regular point of T with $y(P) = 0$; $y(t)$ is a root of a polynomial with constant term $y(c_0) \neq 0$, so $y(t) \neq 0$.

Step 3: these points are classical. Let y be a regular point (for λ) with $y(P) = 0 \neq y(g_P)$ and $x = y \circ f$. By Step 1, ρ_y is absolutely irreducible, so (Cy1) holds with $\tilde{r} = \rho_y$; by (Zm3), $\rho_y \circ \pi_{\mathscr{H}} \otimes \kappa$ is automorphic of conjugate self-dual type, which is (Cy2), and $\rho_y \circ \pi_{\mathscr{H}}$ is triangular on D_v with diagonal $(x \circ \psi^{\mathrm{d}}_{v,a})_a$, which is (Cy3). (Cy4): let $v \in S_\ell$ and $1 \le j \le n$. By (Zm2) and $y(\lambda_T([u])) = (w_0\lambda)(u)^{-1}$, for $z \in 1 + \ell\mathcal{O}_{L_v^+}$, $x(\psi^{\mathrm{d}}_{v,j}(g_z)) = (\chi_{\mathrm{cyc}}^{j-1}\kappa)(g_z)^{-1}(w_0\lambda)(d_j(z))^{-1}$. Here g_z is the image of z under the local Artin map normalised as in Proposition E.5 (uniformisers to geometric Frobenius elements), the normalisation with which (Zm2) is established in Proposition E.2; for it, $\chi_{\mathrm{cyc}}(g_z) = \prod_\tau \tau(z)$ for units z (Lubin–Tate theory), τ running over the embeddings $L_v^+ \to \overline{\mathbb{Q}}_\ell$. As κ corresponds to an algebraic Hecke character, there are integers m_τ with $\kappa(g_z) = \prod_\tau \tau(z)^{m_\tau}$ for z in an open subgroup of $\mathcal{O}^\times_{L_v^+}$ ([220], Chapter II), and $(w_0\lambda)(d_j(z)) = \prod_\tau \tau(z)^{\lambda_{\tau,n+1-j}}$. Hence $x(\psi^{\mathrm{d}}_{v,j}(g_z)) = \prod_\tau \tau(z)^{h_{\tau,j}}$ on an open subgroup, with $h_{\tau,j} = (1-j) - m_\tau - \lambda_{\tau,n+1-j}$. A continuous character of D_v which is de Rham and equals $g_z \mapsto \prod_\tau \tau(z)^{a_\tau}$ on an open subgroup of inertia has τ-Hodge–Tate weight a_τ (Hodge–Tate weights as in Section 13, χ_{cyc} of weight 1; a Hodge–Tate character is locally algebraic and its weights are read off from the algebraic part, [220], Chapter III). So $x \circ \psi^{\mathrm{d}}_{v,j}$ has τ-Hodge–Tate weight $h_{\tau,j}$, and $h_{\tau,j} - h_{\tau,j+1} = 1 + \lambda_{\tau,n-j} - \lambda_{\tau,n+1-j} \ge 2$ as λ is regular: strictly decreasing in j; it is de Rham as a subquotient of the de Rham representation $\rho_y \circ \pi_{\mathscr{H}}|_{D_v}$ (automorphic, (Bg2) of Theorem B.62). So x is a classical ordinary point and $x(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$.

Step 4: conclusion. Let $b \in \mathcal{J}_\kappa^{\mathrm{cl}}$ and suppose $f(b) \notin P$. Then $t = f(b)g_P \notin P$, and Step 2 gives a regular point y with $y(P) = 0$ and $y(f(b))y(g_P) \neq 0$; by Step 3, $y(f(b)) = (y \circ f)(b) = 0$, a contradiction. So $f(b) \in P \subseteq \bar{\mathfrak{q}}$ and $b \in f^{-1}(\bar{\mathfrak{q}}) = \mathfrak{q}$. □

Lemma 50.13. *Let ℓ be an odd prime, F^+ a totally real field, $n \ge 1$, I the set of field embeddings $F^+ \to \overline{\mathbb{Q}}_\ell$, and $\mathcal{O}'$ a coefficient ring containing $\tau(\mathcal{O}_{F^+})$ for every $\tau \in I$. Let $T_n(\ell^1)$ be the kernel of reduction $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) \to T_n(\mathcal{O}_{F^+}/\ell)$ on the diagonal torus and $\Lambda_1 = \mathcal{O}'[[T_n(\ell^1)]]$. For $k = (k_{\tau,j}) \in (\mathbb{Z}^n)^I$ let $\chi_k\colon T_n(\ell^1) \to \overline{\mathbb{Q}}_\ell^\times$ be the character $\mathrm{diag}(u_1,\dots,u_n) \mapsto \prod_{\tau\in I}\prod_{j=1}^n \tau(u_j)^{k_{\tau,j}}$ and $\mathfrak{P}_k$ the kernel of the induced homomorphism of $\mathcal{O}'$-algebras $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$. If $\mathcal{K} \subseteq (\mathbb{Z}^n)^I$ is a set whose closure in $(\mathbb{Z}_\ell^n)^I$ has non-empty interior, then $\bigcap_{k\in\mathcal{K}} \mathfrak{P}_k = 0$.*

Proof. Step 1: coordinates. By Lemma 50.14, $T_n(\ell^1) = \prod_{v|\ell}(1 + \ell\mathcal{O}_{F_v^+})^n \cong \mathbb{Z}_\ell^N$ with $N = n\,|I|$, and for $v \mid \ell$ the ℓ-adic logarithm $\log\colon 1 + \ell\mathcal{O}_{F_v^+} \to \ell\mathcal{O}_{F_v^+}$ is an isomorphism of $\mathbb{Z}_\ell$-modules with inverse exp. Fix a $\mathbb{Z}_\ell$-basis $u_1,\dots,u_N$. Then $X_i \mapsto u_i - 1$ is an isomorphism $\mathcal{O}'[[X_1,\dots,X_N]] \to \Lambda_1$ (Lemma 50.14), and the homomorphism with kernel $\mathfrak{P}_k$ sends X_i to $\chi_k(u_i) - 1$. Let $\mathcal{O}'' \supseteq \mathcal{O}'$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$ containing all $\tau(\mathcal{O}_{F_v^+})$. Let $f \in \bigcap_{k\in\mathcal{K}} \mathfrak{P}_k$, viewed as a power series $f(X) \in \mathcal{O}'[[X]]$; we show $f = 0$.

Step 2: interpolation in the weight. Write $u_i = \mathrm{diag}(u_{i,1},\dots,u_{i,n})$ and put $a_{i,(\tau,j)} = \log\tau(u_{i,j}) \in \ell\mathcal{O}''$. For $k \in (\mathbb{Z}_\ell^n)^I$ put $w_i(k) = \sum_{(\tau,j)} a_{i,(\tau,j)}k_{\tau,j} \in \ell\mathcal{O}''$ and $E_i(k) = \exp(w_i(k)) - 1 \in \ell\mathcal{O}''$; for integral k, $E_i(k) = \chi_k(u_i) - 1$, as $\tau(u_{i,j})^k = \exp(k\log\tau(u_{i,j}))$. Since $|E_i(k)| \le |\ell| < 1$ and the coefficients of f are bounded, $k \mapsto f(E(k))$ is a uniformly convergent series of con-

tinuous functions on $(\mathbb{Z}_\ell^n)^I$, hence continuous; it vanishes on $\mathcal{K}$, hence on the closure of $\mathcal{K}$, which contains a set $k_0 + \ell^e(\mathbb{Z}_\ell^n)^I$ with $k_0 \in (\mathbb{Z}^n)^I$, $e \geq 1$. Put $c_i = \chi_{k_0}(u_i) \in 1 + \ell\mathcal{O}''$ and $f_0(X) = f\big(c_1(1+X_1)-1, \dots, c_N(1+X_N)-1\big) \in \mathcal{O}''[[X]]$, well defined because $c_i - 1$ is topologically nilpotent; $X_i \mapsto c_i(1+X_i)-1$ is an automorphism of $\mathcal{O}''[[X]]$ (inverse $X_i \mapsto c_i^{-1}(1+X_i)-1$), so $f = 0$ if $f_0 = 0$. As $\chi_{k_0+k'} = \chi_{k_0}\chi_{k'}$ and exp is additive, $f_0(E(k')) = f(E(k_0 + k')) = 0$ for every $k' \in \ell^e(\mathbb{Z}_\ell^n)^I$.

Step 3: the matrix $(a_{i,b})$ is invertible. By Step 1, the $\log u_i$ form a $\mathbb{Z}_\ell$-basis of $\prod_v(\ell\mathcal{O}_{F_v^+})^n$, so their images under the isomorphism $\prod_v(F_v^+)^n \otimes_{\mathbb{Q}_\ell} \overline{\mathbb{Q}}_\ell \to \overline{\mathbb{Q}}_\ell^{I\times\{1,\dots,n\}}$, $y \otimes 1 \mapsto (\tau(y_j))_{(\tau,j)}$ (from $F_v^+ \otimes_{\mathbb{Q}_\ell} \overline{\mathbb{Q}}_\ell \cong \prod_{\tau \text{ above } v} \overline{\mathbb{Q}}_\ell$), form a basis; these images are the rows of $A = (a_{i,b})$, so A is an invertible $N \times N$ matrix.

Step 4: $f_0 = 0$. Let $g(w) = f_0(\exp(w_1) - 1, \dots, \exp(w_N) - 1)$, a formal power series with coefficients in $\mathrm{Frac}(\mathcal{O}'')$ (the series $\exp(w_i) - 1$ have no constant term); it converges on $|w_i| \leq |\ell|$ and there equals the evaluation of f_0. Put $h(k') = g(Ak')$, a formal power series in $k' = (k'_b)$; choose $e' \geq e$ with $|\ell^{e'}| \max_{i,b} |a_{i,b}| \leq |\ell|$, so that h converges on the closed polydisc $|k'_b| \leq |\ell|^{e'}$ and vanishes on S^N, $S = \ell^{e'}\mathbb{Z}_\ell$, by Step 2. A power series $h \in \overline{\mathbb{Q}}_\ell[[k'_1, \dots, k'_N]]$ converging on the closed polydisc of radius $\rho = |\ell|^{e'}$ and vanishing on S^N is 0, by induction on N: write $h = \sum_m h_m(k'_1, \dots, k'_{N-1})\, k_N'^m$; for $s \in S^{N-1}$ the one-variable series $\sum_m h_m(s)t^m$ converges on $|t| \leq \rho$ and vanishes on the infinite set S, so it is 0 by Strassmann's theorem (a non-zero power series converging on a closed disc has only finitely many zeros in it); thus every h_m, which converges on the polydisc of radius ρ in $N-1$ variables, vanishes on S^{N-1}, and $h_m = 0$ by induction ($N = 0$: a constant vanishing at a point). Hence $h = 0$, so $g(w) = h(A^{-1}w) = 0$ as a formal power series, and $f_0(X) = g(\log(1 + X_1), \dots, \log(1 + X_N)) = 0$. By Step 2, $f = 0$. □

Lemma 50.14. *Let ℓ be an odd prime.*

1. *For every finite extension K of $\mathbb{Q}_\ell$, the ℓ-adic logarithm* $\log\colon 1 + \ell\mathcal{O}_K \to \ell\mathcal{O}_K$ *is an isomorphism of $\mathbb{Z}_\ell$-modules with inverse* exp. *In particular $1 + \ell\mathcal{O}_K \cong \mathbb{Z}_\ell^{[K:\mathbb{Q}_\ell]}$ is torsion-free.*

2. *Let F^+ be a totally real field, $n \geq 1$, $N = n[F^+ : \mathbb{Q}]$, $T_n(\ell^1)$ the kernel of reduction $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) \to T_n(\mathcal{O}_{F^+}/\ell)$ on the diagonal torus, and $\mathcal{O}'$ a coefficient ring. Then $T_n(\ell^1) = \prod_{v|\ell}(1+\ell\mathcal{O}_{F_v^+})^n \cong \mathbb{Z}_\ell^N$, and for every $\mathbb{Z}_\ell$-basis $u_1, \dots, u_N$ of $T_n(\ell^1)$ the map $X_i \mapsto u_i - 1$ is an isomorphism of complete local $\mathcal{O}'$-algebras $\mathcal{O}'[[X_1, \dots, X_N]] \to \mathcal{O}'[[T_n(\ell^1)]]$; in particular $\mathcal{O}'[[T_n(\ell^1)]]$ is a Noetherian normal local domain.*

Proof. 1. For $x \in \ell\mathcal{O}_K$ and $k \geq 1$, $v(x^k/k) \geq k - \log_\ell k \geq 1$ and $v(x^k/k!) \geq k - \frac{k-1}{\ell-1} \geq 1$, since $v(k!) \leq \frac{k-1}{\ell-1}$. So $\log(1 + x) = \sum_{k\geq 1}(-1)^{k+1}x^k/k$ and $\exp(x) = \sum_{k\geq 0} x^k/k!$ converge on $\ell\mathcal{O}_K$, log maps $1 + \ell\mathcal{O}_K$ into $\ell\mathcal{O}_K$ and exp maps $\ell\mathcal{O}_K$ into $1 + \ell\mathcal{O}_K$. These sets lie in the regions $|x| < |\ell|^{1/(\ell-1)}$, resp. $|y - 1| < |\ell|^{1/(\ell-1)}$ (as $1 > \frac{1}{\ell-1}$ for $\ell \geq 3$), where log and exp are mutually inverse isometries and $\log(yy') = \log y + \log y'$. Hence log is an isomorphism of $\mathbb{Z}_\ell$-modules with inverse exp, and $1 + \ell\mathcal{O}_K \cong \ell\mathcal{O}_K \cong \mathcal{O}_K \cong \mathbb{Z}_\ell^{[K:\mathbb{Q}_\ell]}$. (Consistently, a primitive ℓ^k-th root of unity ζ has $v(\zeta - 1) = \frac{1}{\ell^{k-1}(\ell-1)} < 1$, so $\zeta \notin 1 + \ell\mathcal{O}_K$.)

2. $\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell = \prod_{v|\ell} \mathcal{O}_{F_v^+}$, and the kernel of reduction modulo ℓ on $(\mathcal{O}_{F_v^+}^\times)^n$ is $(1+\ell\mathcal{O}_{F_v^+})^n$. By 1, $T_n(\ell^1) \cong \prod_v \mathbb{Z}_\ell^{n[F_v^+:\mathbb{Q}_\ell]} = \mathbb{Z}_\ell^N$, as $\sum_{v|\ell}[F_v^+ : \mathbb{Q}_\ell] = [F^+ : \mathbb{Q}]$. For $\Gamma = \mathbb{Z}_\ell^N$ with basis $u_1, \dots, u_N$, the map $X_i \mapsto u_i - 1$ is an isomorphism $\mathcal{O}'[[X_1, \dots, X_N]] \to \mathcal{O}'[[\Gamma]] = \varprojlim_m \mathcal{O}'[\Gamma/\ell^m\Gamma]$ of complete local $\mathcal{O}'$-algebras (the classical description of the Iwasawa algebra of $\mathbb{Z}_\ell^N$, by induction on N from the case $N = 1$). A power series ring in finitely many variables over the complete discrete valuation ring $\mathcal{O}'$ is a Noetherian regular, hence normal, local domain. □

Proposition 50.15. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and v_0 a place of L^+ above a prime $p \nmid 2M\,|\mathrm{disc}(L)|$ which splits in L and has a place $\bar{v}_0$ above it with $\bar{\Psi}$ trivial and $\bar{\omega}$ non-trivial on $D_{\bar{v}_0} \cap G_{L^+}$. Let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be a universal polarised ordinary determinant and $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ a universal polarised ordinary lift of rank n over L (both for $\mathcal{O}'$) such that the comparison morphism ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) \subseteq W_n^{\mathrm{po}}$, and let $J \subseteq B_n^{\mathrm{po}}$ be an ideal.*

(Tq1) *If J has $R = T$ at patchable curve points (for v_0, with the place $\bar{v}_0$), then $\mathcal{M}_J$ propagates through nice primes.*

(Tq2) *If $n = 3$ and J has $R = T$ at patchable curve points and along thick chains, then $\mathcal{M}_J$ propagates along thick links.*

Proof. Fix a prime $\mathfrak{x}$ of E, a local chart $(\mathcal{O}'', R, \iota)$ at $\mathfrak{x}$ and put $\varphi = \iota \circ \vartheta_n \colon B \to R$. For a prime P of R, $\iota^{-1}(P) \cap W$ is an ideal of W, and $\mathcal{M}_J$ is the ideal of W generated by $\vartheta_n(J)$; hence

$$P \text{ is } \mathcal{M}_J\text{-modular} \iff \vartheta_n(J) \subseteq \iota^{-1}(P) \iff J \subseteq \varphi^{-1}(P). \tag{$*$}$$

(Tq1). Let $\mathfrak{p}$ be an $\mathcal{M}_J$-modular nice prime of R of irreducible type and $P \subseteq \mathfrak{p}$ a prime. By Lemma 50.16 there is a patchable curve point $(k, \rho, J_n, (\psi_{v,a}), f)$ of B (for v_0, with $\bar{v}_0$) of irreducible type with $\ker f = \varphi^{-1}(\mathfrak{p})$; by $(*)$, $J \subseteq \ker f$. The prime $\mathfrak{q} = \varphi^{-1}(P)$ of B satisfies $\mathfrak{q} \subseteq \varphi^{-1}(\mathfrak{p}) = \ker f$, so R = T at patchable curve points gives $J \subseteq \mathfrak{q}$, and P is $\mathcal{M}_J$-modular by $(*)$. So $\mathcal{M}_J$ propagates through nice primes.

(Tq2). Let $n = 3$, and let $\mathfrak{p}, \mathfrak{q}$ be thickly connected nice primes of R of endoscopic type, through nice primes $\mathfrak{p} = \mathfrak{p}_0, \dots, \mathfrak{p}_h = \mathfrak{q}$ of endoscopic type and thick primes $\mathfrak{e}_i \subseteq \mathfrak{p}_{i-1} \cap \mathfrak{p}_i$ $(1 \le i \le h)$, such that some $\mathcal{M}_J$-modular prime $P \subseteq \mathfrak{p}$ is of irreducible type; let $P' \subseteq \mathfrak{q}$ be a prime of irreducible type. By Lemma 50.16, each $\mathfrak{p}_i$ gives a patchable curve point x_i of endoscopic type with homomorphism f_i, $\ker f_i = \varphi^{-1}(\mathfrak{p}_i)$. By Lemma 50.22 (Xk2), $\varphi^{-1}(\mathfrak{e}_i)$ is a thick prime of B, contained in $\ker f_{i-1} \cap \ker f_i$. By (Xk1), $\mathfrak{q}_1 = \varphi^{-1}(P)$ is stable; $J \subseteq \mathfrak{q}_1$ by $(*)$, and $\mathfrak{q}_1 \subseteq \ker f_0$. By (Xk1) again, $\varphi^{-1}(P')$ is a stable prime contained in $\varphi^{-1}(\mathfrak{q}) = \ker f_h$. R = T along thick chains therefore gives $J \subseteq \varphi^{-1}(P')$, and P' is $\mathcal{M}_J$-modular by $(*)$. So $\mathcal{M}_J$ propagates along thick links. □

Lemma 50.16. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$, $n \in \{2,3\}$, and v_0 a place of L^+ above a prime $p \nmid 2M\,|\mathrm{disc}(L)|$ which splits in L and has a place $\bar{v}_0$ above it with $\bar{\Psi}$ trivial and $\bar{\omega}$ non-trivial on $D_{\bar{v}_0} \cap G_{L^+}$. Let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be a universal polarised ordinary determinant and $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ a universal polarised ordinary lift of rank n over L (both for $\mathcal{O}'$) such that ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) \subseteq W_n^{\mathrm{po}}$. Let $\mathfrak{x}$ be a prime of E_n^{po}, $(\mathcal{O}'', R, \iota)$ a local chart at $\mathfrak{x}$, $\varphi = \iota \circ \vartheta_n \colon B_n^{\mathrm{po}} \to R$, and $\mathfrak{p}$ a nice prime of R. Then there are a finite field $k \supseteq \mathbb{F}_{\mathcal{O}''}$ and an injective local homomorphism of $\mathcal{O}''$-algebras $j \colon R/\mathfrak{p} \to k[[T]]$ such that, with $h \colon R \to k[[T]]$ the composite of the projection and j, $\rho = h \circ \rho_{\mathfrak{x}}$, $\psi_{v,a} = h \circ \psi_{\mathfrak{x},v,a}$ and $f = h \circ \varphi$:*

(Np1) *$(k, \rho, J_n, (\psi_{v,a}), f)$ is a patchable curve point of B_n^{po} (for v_0, with the place $\bar{v}_0$), and $\ker f = \varphi^{-1}(\mathfrak{p})$;*

(Np2) *it is of irreducible type if $\mathfrak{p}$ is of irreducible type, and of endoscopic type if $n = 3$ and $\mathfrak{p}$ is of endoscopic type.*

Proof. Write $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$, $B = B_n^{\mathrm{po}}$, $\rho(\gamma)$ for $\rho(\pi_L(g))$ when $\gamma = \pi_L(g)$, $A = k[[T]]$, $F = \mathrm{Frac}(A)$ and $\bar{F}$ for an algebraic closure of F.

Step 0: residues on the chart. The ring $E/\mathfrak{x}$ embeds into the finite field $R/\mathfrak{m}_R$, so $W/(\mathfrak{x}\cap W)$ is a domain inside a finite field, hence a field, and $\mathfrak{x}\cap W = \mathfrak{m}_W$ (W is local by (Gw1)). Thus $\iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$, and every $w \in W$ has $\iota(w) \equiv \bar{w}$ modulo $\mathfrak{m}_R$, where $\bar{w} \in \mathbb{F}_{\mathcal{O}'}$ is its residue. Diagonal entries $\rho^{\mathrm{u}}(\gamma)_{aa}$, the values $\psi^{\mathrm{u}}_{v,a}(g)$, and the coefficients of the characteristic polynomial of $\rho^{\mathrm{u}}(\gamma)$ (sums of products $\pm\prod_a \rho^{\mathrm{u}}(\gamma)_{a\sigma(a)}$ over permutations of subsets, of weight 0) lie in W, with residues given by (Po5): $\bar{\Psi}(\gamma)^{w_{n,a}}$, $\bar{\Psi}(g)^{w_{n,a}}$, and the coefficients of $\prod_a(X - \bar{\Psi}(\gamma)^{w_{n,a}})$. Let $\gamma_\star = \pi_L(g_\star)$ and $\gamma'_\star = \pi_L(cg_\star^{-1}c)$ ($g_\star \in G_L$ by (Af1)). By (Po3) the matrix $\rho^{\mathrm{u}}(\gamma_\star) - \rho^{\mathrm{u}}(\gamma'_\star)$ is diagonal, and by (Po2) its (a,a) entry is $\rho^{\mathrm{u}}(\gamma_\star)_{aa} - \rho^{\mathrm{u}}(\gamma_\star)_{n+1-a,n+1-a}$; so it equals $\zeta\,\mathrm{diag}(w_{n,1},\dots,w_{n,n})$ with $\zeta = \rho^{\mathrm{u}}(\gamma_\star)_{11} - \rho^{\mathrm{u}}(\gamma_\star)_{nn} \in W$ of residue $\bar{\Psi}(g_\star) - \bar{\Psi}(g_\star)^{-1} \neq 0$ ($g_\star$ is a marking). So $\zeta \in W^\times$ and $\iota(\zeta) \in R^\times$. Finally, for $k' \geq 1$ and an entry of weight j, $\rho^{\mathrm{u}}(\gamma)_{ab} \in \mathrm{gr}_j$, a finitely generated W-module (Gw3); the submodules $\mathfrak{m}^t \cap \mathrm{gr}_j$ ($\mathfrak{m}$ the maximal ideal of R_n^{po}) decrease to 0 (Krull), so by Theorem B.154 some $\mathfrak{m}^t \cap \mathrm{gr}_j$ lies in $\mathfrak{m}_W^{k'}\mathrm{gr}_j$; with (Po1), $\gamma \mapsto \rho_{\mathfrak{x}}(\gamma)_{ab} \bmod \iota(\mathfrak{m}_W^{k'}\mathrm{gr}_j)R \subseteq \mathfrak{m}_R^{k'}$ is locally constant, and likewise $g \mapsto \psi_{\mathfrak{x},v,a}(g) \bmod \mathfrak{m}_R^{k'}$ ($\mathrm{gr}_0 = W$).

Step 1: the curve. The ring $R/\mathfrak{p}$ is a complete Noetherian local domain of dimension 1 and characteristic ℓ ($\ell \in \mathfrak{p}$) with residue field $\mathbb{F}_{\mathcal{O}''}$. By Nagata's theorem (complete local rings are Nagata rings) its integral closure $\tilde{A}$ in its fraction field is a finite $R/\mathfrak{p}$-module; a domain finite over a complete local domain is local, so $\tilde{A}$ is a one-dimensional normal Noetherian local domain, i.e. a discrete valuation ring, complete as a finite module over a complete ring, of characteristic ℓ with finite residue field $k \supseteq \mathbb{F}_{\mathcal{O}''}$. By Cohen's structure theorem $\tilde{A} \cong k[[T]]$; let j be the inclusion $R/\mathfrak{p} \subseteq \tilde{A}$ followed by this isomorphism. It is injective, an $\mathcal{O}''$-algebra map, and local (an integral extension contracts the maximal ideal to the maximal ideal). Hence $h(\mathfrak{m}_R^{k'}) \subseteq T^{k'}A$ and $\ker h = \mathfrak{p}$.

Step 2: the curve point. By Step 0 and locality of h, $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(A)$ has T-adically continuous entries and the $\psi_{v,a}\colon D_v \to A^\times$ are continuous homomorphisms. The matrix $P = J_n$ is symmetric and invertible with $J_n^{-1} = J_n$, and (Po2) gives $\rho(\gamma^*) = J_n\,{}^t\rho(\gamma)J_n$, $\gamma^* = \pi_L(c)\gamma^{-1}\pi_L(c)$. Since ϑ_n classifies $(\det\circ\rho^{\mathrm{u}}, (\psi^{\mathrm{u}}_{v,a}))$ and $\vartheta_n(B) \subseteq W \subseteq E$, the determinants $\vartheta_n \circ D^{\mathrm{u}}$ and $\det\circ\rho^{\mathrm{u}}$, both E-valued, have the same characteristic polynomials on Γ_L^0 and are equal by (Ch1); applying $h\circ\iota$ gives $f \circ D^{\mathrm{u}} = \det\circ\rho$, and likewise $f \circ \psi^{\mathrm{d}}_{v,a} = h\circ\iota\circ\psi^{\mathrm{u}}_{v,a} = \psi_{v,a}$. The map f is a homomorphism of $\mathcal{O}'$-algebras with $\ker f = \varphi^{-1}(\ker h) = \varphi^{-1}(\mathfrak{p})$.

Step 3: triangularity on D_v. Fix $v \mid \ell$; $D_v \subseteq G_L$ since v splits in L ((Af2), $\ell \mid M$). By (Po4), $\prod_{a=1}^n(\rho(g_a) - \psi_{v,a}(g_a)) = 0$ for $g_1,\dots,g_n \in D_v$. For $0 \leq i \leq n$ let $V_i \subseteq F^n$ be the span of the images of $\prod_{a=i+1}^n(\rho(g_a) - \psi_{v,a}(g_a))$ over all $g_{i+1},\dots,g_n \in D_v$ ($V_n = F^n$); so $V_0 = 0$. For $i < n$ and $g, g' \in D_v$,

$$\rho(g')(\rho(g) - \psi_{v,i+1}(g)) = (\rho(g'g) - \psi_{v,i+1}(g'g)) - \psi_{v,i+1}(g)(\rho(g') - \psi_{v,i+1}(g')),$$

so V_i is $\rho(D_v)$-stable; then $(\rho(g) - \psi_{v,i}(g))V_i \subseteq V_{i-1}$ gives $V_{i-1} \subseteq V_i$ and D_v acts on V_i/V_{i-1} by $\psi_{v,i}$. With $d_i = \dim V_i/V_{i-1}$, the characteristic polynomial of $\rho(g)$ is $\prod_i(X - \psi_{v,i}(g))^{d_i}$. Reducing modulo T (Step 0) and comparing coefficients of X^{n-1}: $\sum_i d_i\bar{\Psi}(g)^{w_{n,i}} = \sum_i \bar{\Psi}(g)^{w_{n,i}}$ in k for all $g \in D_v$. By (Af4), $\bar{\Psi}^2|_{D_v} \neq 1$, so the characters $\bar{\Psi}^{w_{n,i}}|_{D_v}$ are pairwise distinct (their exponents differ by 1 or 2), and Artin's theorem on independence of characters gives $d_i \equiv 1 \pmod{\ell}$; as $0 \leq d_i \leq 3$ and ℓ is odd, $d_i = 1$. A basis $f_i \in V_i \smallsetminus V_{i-1}$ makes $\rho|_{D_v}$ upper triangular over F with diagonal $(\psi_{v,1},\dots,\psi_{v,n})$. So $(k, \rho, J_n, (\psi_{v,a}), f)$ is a curve point.

Step 4: (Pj1) and a separating inertia element. The prime $\mathfrak{p}$ is nice: for $a \neq b$ there is $g \in I_v$ with $\chi_{\mathrm{cyc}}(g) = 1$ and $\psi_{\mathfrak{x},v,a}(g) - \psi_{\mathfrak{x},v,b}(g) \notin \mathfrak{p}$, so $\psi_{v,a}(g) \neq \psi_{v,b}(g) = \psi_{v,b}(g)\chi_{\mathrm{cyc}}(g)$; this is (Pj1). Let $I_v^1 = I_v \cap \ker\chi_{\mathrm{cyc}}$. By (Af4), $\bar{\Psi} = 1$ on I_v^1, so $\psi_{v,a}(I_v^1) \subseteq 1 + TA$, which is torsion-free (if $z \neq 0$ and $m = \ell^e m'$, $\ell \nmid m'$, then $(1+z)^m = (1+z^{\ell^e})^{m'} \equiv 1 + m'z^{\ell^e} \not\equiv 1$ modulo higher powers

of z^{ℓ^e}). For $a<b$ let $\chi_{ab}=\psi_{v,a}/\psi_{v,b}$ on I_v^1, non-trivial by niceness; choose g_{ab} in its domain with $g_{ab}\notin\ker\chi_{ab}$. The subgroup Ξ generated by the g_{ab} maps under $(\chi_{ab})_{a<b}$ onto a finitely generated torsion-free abelian group $\Xi'\cong\mathbb{Z}^s$; the kernel K_{ab} of the ab-coordinate on Ξ' has non-zero torsion-free quotient, so $K_{ab}\otimes\mathbb{Q}\neq\Xi'\otimes\mathbb{Q}$. A $\mathbb{Q}$-vector space is not a union of finitely many proper subspaces; so some $\xi\in\Xi'$ lies outside all $K_{ab}\otimes\mathbb{Q}$, and a preimage $u\in I_v^1$ satisfies $\chi_{ab}(u)\neq 1$ for all $a<b$. Put $\bar u=\pi_L(u)\in\Gamma'=\ker\chi_{\mathrm{cyc}}|_{\Gamma_L^0}$: $\rho(\bar u)$ has the n distinct eigenvalues $\psi_{v,a}(u)\in 1+TA$, which generate a torsion-free group.

Step 5: (Pj3). Inertia at $\bar v_0$ dies in Γ_L: $p\neq\ell$ ($\ell\mid M$); η_K is unramified at p because $p\nmid\mathrm{disc}(L)$ and $K\subseteq L$; and $\bar\Psi$ is trivial on $D_{\bar v_0}\cap G_{L^+}$; so $I_{\bar v_0}\cap G_{L^+}\subseteq N_L$. Hence $\Delta_0=\pi_L(D_{\bar v_0}\cap G_{L^+})$ is topologically generated by $\pi_L(\phi)$ for a Frobenius $\phi\in D_{\bar v_0}\cap G_{L^+}\subseteq G_L$ (v_0 splits in L). As $\bar\omega$ is unramified at p and non-trivial on $D_{\bar v_0}\cap G_{L^+}$, $\bar\omega(\phi)\neq 1$. By Step 0 the characteristic polynomial of $\rho(\phi)$ is congruent to $(X-1)^n$ modulo T ($\bar\Psi(\phi)=1$), so its roots $\mu_i\in\bar F$, integral over A, have residue 1 for the valuation extending the T-adic one, while the roots $\chi_{\mathrm{cyc}}(\phi)\mu_i$ of the characteristic polynomial of $\chi_{\mathrm{cyc}}(\phi)\rho(\phi)$ have residue $\bar\omega(\phi)\neq 1$. So the two matrices have no common eigenvalue, and by Sylvester's theorem $\chi_{\mathrm{cyc}}(\phi)\rho(\phi)X=X\rho(\phi)$ forces $X=0$; a fortiori (Pj3).

Step 6: (Pj2) and the type. Fix $v\mid\ell$, u and $\bar u$ as in Step 4, and $D=\pi_L(D_v)$. The characteristic ℓ of F is odd. By Step 0, $\rho(\gamma_\star)-\rho(\gamma'_\star)=h(\iota(\zeta))\,\mathrm{diag}(w_{n,a})$ with $h(\iota(\zeta))\neq 0$, and $\rho(\gamma^*)=J_n\,{}^t\rho(\gamma)J_n$. The prime $\mathfrak{p}$ is off-triangular, so some entry $\rho_{\mathfrak{r}}(\gamma_1)_{ab}$ with $a>b$ is not in $\mathfrak{p}$, and $\rho(\gamma_1)_{ab}\neq 0$; likewise above the diagonal.

Residual trace condition. Suppose $\gamma\in\Gamma_L^0$ and $\emptyset\neq S\subseteq\{1,\dots,n\}$ is $\{1,\dots,n\}$ or (when $n=3$) $\{1,3\}$, with $\sum_{a\in S}\rho(\gamma\pi_L(g))_{aa}=0$ for all $g\in D_v$. The left side is $h\iota$ of an element of W with residue $\sum_{a\in S}\bar\Psi(\gamma)^{w_{n,a}}\bar\Psi(g)^{w_{n,a}}$ (Step 0), so this vanishes in k for all $g\in D_v$; by Artin's theorem (the $\bar\Psi^{w_{n,a}}|_{D_v}$ are distinct) $\bar\Psi(\gamma)^{w_{n,a}}=0$, absurd. So no such γ exists.

Case of irreducible type ($n=2$, or $n=3$ and some entry of odd weight of $\rho_{\mathfrak{r}}$ is not in $\mathfrak{p}$). By Lemma 50.17 (a), $\rho\otimes\bar F$ is irreducible. Let $U\subseteq\Gamma_L^0$ be an open subgroup, U_0 its normal core (open, of index m) and $N=U_0\cap\Gamma'$, normal in Γ_L^0. Apply Lemma 50.18 with $\Delta=\Gamma_L^0$, N, D and $t=\bar u^m\in D\cap N$: hypothesis 1 is Step 3, hypothesis 2 holds because $\rho(t)$ has the eigenvalues $\psi_{v,a}(u)^m$, pairwise distinct as $1+TA$ is torsion-free, and hypothesis 3 is the residual trace condition with $S=\{1,\dots,n\}$. So $\rho\otimes\bar F$ is irreducible on N, hence on $U\cap\Gamma'$; with $U=\Gamma_L^0$ the curve point is of irreducible type, and (Sx1) of Lemma 50.19 holds for $\Delta=\Gamma_L^0$ (profinite, open in Γ_L), $\Delta'=\Gamma'$ (closed, normal) and $\bar u$. That lemma gives (Pj2).

Case of endoscopic type ($n=3$, all entries of odd weight of $\rho_{\mathfrak{r}}$ in $\mathfrak{p}$). Then all entries of odd weight of ρ vanish, and by Lemma 50.17 (b), r_1 (the $\{1,3\}$-corner) and $r_2=\rho_{22}$ are homomorphisms and $r_1\otimes\bar F$ is irreducible. Here $F^3=(Fe_1+Fe_3)\oplus Fe_2$ is a decomposition into $\rho(D)$-stable summands; $r_2|_{D_v}$ is one of the composition factors $\psi_{v,1},\psi_{v,2},\psi_{v,3}$ of $\rho|_{D_v}$ (Step 3), and its residue is 1 (Step 0) while those of $\psi_{v,1},\psi_{v,3}$ are $\bar\Psi^{\pm1}|_{D_v}\neq 1$; so $r_2|_{D_v}=\psi_{v,2}$, and $r_1|_{D_v}$ has the composition factors $\psi_{v,1},\psi_{v,3}$, hence a D_v-stable line; and $r_1(\bar u^m)$ has the distinct eigenvalues $\psi_{v,1}(u)^m,\psi_{v,3}(u)^m$. Lemma 50.18 for r_1 (dimension 2), with the residual trace condition for $S=\{1,3\}$, shows that $r_1\otimes\bar F$ is irreducible on $U\cap\Gamma'$ for every open U. With Q the permutation matrix taking (e_1,e_3,e_2) to (e_1,e_2,e_3), $Q\rho Q^{-1}=\mathrm{diag}(r_1,r_2)$; $r_1(\gamma^*)=J_2\,{}^tr_1(\gamma)J_2$ and $r_2(\gamma^*)=r_2(\gamma)$ (the corner and centre of $J_3\,{}^tXJ_3$); $r_1\otimes\bar F$ and the character r_2 are irreducible on Γ'; and a non-zero $Y\in\mathrm{M}_{1\times2}(\bar F)$ with $Yr_1(\sigma)=r_2(\sigma)Y$ on Γ' would have a Γ'-stable kernel of dimension 1. So the curve point is of endoscopic type; (Sx2) of Lemma 50.19 holds with $\bar u$ ($\rho(\bar u)$ has three distinct eigenvalues generating a torsion-free group), and that lemma gives (Pj2).

Steps 2–6 prove (Np1) and (Np2). □

Lemma 50.17. *Let F be a field of characteristic $\neq 2$ with an algebraic closure $\bar{F}$, $n \in \{2,3\}$, Δ a group and $\rho\colon \Delta \to \mathrm{GL}_n(F)$ a homomorphism such that*

1. *for every $\gamma \in \Delta$ there is $\gamma' \in \Delta$ with $\rho(\gamma') = J_n\, {}^t\rho(\gamma)\, J_n$;*
2. *there are $g, g' \in \Delta$ and $\zeta \in F^\times$ with $\rho(g) - \rho(g') = \zeta \operatorname{diag}(w_{n,1}, \dots, w_{n,n})$;*
3. *$\rho(\gamma_1)_{ab} \neq 0$ for some $\gamma_1 \in \Delta$ and some $a > b$, and $\rho(\gamma_2)_{ab} \neq 0$ for some $\gamma_2 \in \Delta$ and some $a < b$.*

Then:

(a) *if $n = 2$, or if $n = 3$ and $\rho(\gamma_3)_{ab} \neq 0$ for some $\gamma_3 \in \Delta$ and some (a,b) with $w_{3,a} - w_{3,b}$ odd, the representation $\rho \otimes \bar{F}$ is irreducible;*

(b) *if $n = 3$ and $\rho(\gamma)_{ab} = 0$ for all $\gamma \in \Delta$ and all (a,b) with $w_{3,a} - w_{3,b}$ odd, then $r_1(\gamma) = \begin{pmatrix} \rho(\gamma)_{11} & \rho(\gamma)_{13} \\ \rho(\gamma)_{31} & \rho(\gamma)_{33} \end{pmatrix}$ defines a homomorphism $r_1\colon \Delta \to \mathrm{GL}_2(F)$, $\gamma \mapsto \rho(\gamma)_{22}$ a homomorphism $\Delta \to F^\times$, and $r_1 \otimes \bar{F}$ is irreducible.*

Proof. Write $V = \bar{F}^n$ with standard basis $e_1, \dots, e_n$, $J = J_n$, and $\beta(x,y) = {}^t x\, J\, y$, a non-degenerate symmetric bilinear form on V with $\beta(e_i, e_j) = 1$ if $i + j = n + 1$ and 0 otherwise.

Orthogonals of invariant subspaces are invariant. Let $U \subseteq V$ be stable under $\rho(\Delta)$ and $\delta \in \Delta$. By hypothesis 1 applied to δ there is δ' with $\rho(\delta') = J\, {}^t\rho(\delta) J$; as $J^2 = 1$, $\rho(\delta) = J\, {}^t\rho(\delta') J$. For $x \in U$ and $y \in U^\perp$ (orthogonal for β),

$$\beta(x, \rho(\delta) y) = {}^t x\, J\, J\, {}^t\rho(\delta')\, J\, y = {}^t(\rho(\delta') x)\, J\, y = \beta(\rho(\delta') x, y) = 0.$$

So $U^\perp$ is stable under $\rho(\Delta)$, and $\dim U^\perp = n - \dim U$.

Stable subspaces of the marking difference. $Z = \rho(g) - \rho(g') = \zeta \operatorname{diag}(w_{n,a})$ has the eigenvalues $\zeta w_{n,a}$, pairwise distinct because the $w_{n,a}$ are distinct integers with differences in $\{1,2\}$ and the characteristic is not 2. Hence every Z-stable subspace of V is spanned by some of the e_i; in particular a $\rho(\Delta)$-stable line is $\bar{F} e_i$ for some i.

(a). Suppose $U \subseteq V$ is $\rho(\Delta)$-stable with $0 \neq U \neq V$. As $n \leq 3$, one of U, $U^\perp$ is a stable line $\bar{F} e_i$. If $2i = n + 1$ (so $n = 3$, $i = 2$), then $e_2^\perp = \bar{F} e_1 + \bar{F} e_3$ is stable too, so $\rho(\gamma)_{12} = \rho(\gamma)_{32} = 0$ (from $\rho(\gamma) e_2 \in \bar{F} e_2$) and $\rho(\gamma)_{21} = \rho(\gamma)_{23} = 0$ (from the stability of $\bar{F} e_1 + \bar{F} e_3$) for all γ: all entries of odd weight vanish, contrary to the hypothesis of (a). If $i = 1$: $\rho(\gamma) e_1 \in \bar{F} e_1$ gives $\rho(\gamma)_{a1} = 0$ for $a > 1$, and the stability of $e_1^\perp = \bar{F} e_1 + \dots + \bar{F} e_{n-1}$ gives $\rho(\gamma)_{nb} = 0$ for $b < n$; for $n = 2$ and $n = 3$ these are all the entries below the diagonal, contrary to hypothesis 3. If $i = n$: symmetrically $\rho(\gamma)_{an} = 0$ for $a < n$ and, from $e_n^\perp = \bar{F} e_2 + \dots + \bar{F} e_n$, $\rho(\gamma)_{1b} = 0$ for $b > 1$, which are all entries above the diagonal, again contrary to hypothesis 3. So $\rho \otimes \bar{F}$ is irreducible.

(b). The positions of odd weight for $n = 3$ are $(1,2), (2,1), (2,3), (3,2)$. If these entries vanish, every $\rho(\gamma)$ preserves $\bar{F} e_1 + \bar{F} e_3$ and $\bar{F} e_2$, so r_1 and $\gamma \mapsto \rho(\gamma)_{22}$ are homomorphisms. We check the hypotheses of (a) for r_1 with $n = 2$, identifying the positions $1, 3$ with $1, 2$. Since $(J_3\, {}^t X\, J_3)_{ab} = X_{4-b,4-a}$, restricting to $a, b \in \{1,3\}$ gives $r_1(\gamma') = J_2\, {}^t r_1(\gamma) J_2$ (hypothesis 1). The $\{1,3\}$-corner of $\zeta \operatorname{diag}(1,0,-1)$ is $\zeta \operatorname{diag}(w_{2,1}, w_{2,2})$ (hypothesis 2). The entries of ρ below the diagonal are at $(2,1), (3,1), (3,2)$, of which only $(3,1)$ has even weight, so $\rho(\gamma_1)_{31} \neq 0$; likewise $\rho(\gamma_2)_{13} \neq 0$ (hypothesis 3). By (a) for $n = 2$, $r_1 \otimes \bar{F}$ is irreducible. □

Lemma 50.18. *Let $\bar{F}$ be an algebraically closed field, n a prime number, Δ a group, $\rho\colon \Delta \to \mathrm{GL}_n(\bar{F})$ an irreducible representation, N a normal subgroup of Δ and $D \subseteq \Delta$ a subgroup. Assume:*

1. *there are $\rho(D)$-stable subspaces $0 = V_0 \subset V_1 \subset \cdots \subset V_n = \bar{F}^n$ with $\dim V_k = k$;*

2. *there is $t \in D \cap N$ such that $\rho(t)$ has n pairwise distinct eigenvalues;*

3. *there is no $\gamma \in \Delta$ with $\operatorname{tr} \rho(\gamma g) = 0$ for all $g \in D$.*

Then the restriction of ρ to N is irreducible.

Proof. Let $V = \bar{F}^n$. By Clifford's theorem (A. H. Clifford, Ann. of Math. 38 (1937)), V is a semisimple $\bar{F}[N]$-module, its isotypic components $W_1, \dots, W_s$ are permuted transitively by $\rho(\Delta)$, and they have a common dimension n/s; each W_i is the sum of e copies of an irreducible $\bar{F}[N]$-module σ_i, $\dim \sigma_i$ independent of i. As n is prime, $s \in \{1, n\}$.

Case $s = 1$. Then $V|_N \cong \sigma^e$ with $e \dim \sigma = n$. If $e = 1$, $V|_N$ is irreducible, as claimed. Otherwise $e = n$, $\dim \sigma = 1$, and $\rho(h)$ is a scalar for every $h \in N$; this is excluded by $t \in N$ (hypothesis 2, $n \geq 2$).

Case $s = n$. Then $W_i = L_i$ are lines, and $\rho(\Delta)$ permutes $\{L_1, \dots, L_n\}$ transitively. As $t \in N$, $\rho(t)$ preserves each L_i; since its n eigenvalues are distinct, $L_1, \dots, L_n$ are exactly its eigenlines, and every $\rho(t)$-stable subspace is the sum of the L_i it contains. As $t \in D$, each V_k is $\rho(t)$-stable, so $V_k = \bigoplus_{i \in S_k} L_i$ with $S_1 \subset S_2 \subset \cdots \subset S_n$, $|S_k| = k$; let i_k be the element of $S_k \smallsetminus S_{k-1}$. Let $g \in D$. We show by induction on k that $\rho(g) L_{i_k} = L_{i_k}$. The line $\rho(g) L_{i_k}$ is some L_j and lies in $\rho(g) V_k = V_k$, so $j \in S_k$; if $j \in S_{k-1}$, then $L_{i_k} \subseteq \rho(g)^{-1} V_{k-1} = V_{k-1}$, which is false; so $j = i_k$. Hence D lies in the kernel Δ_0 of the permutation action of Δ on $\{L_1, \dots, L_n\}$.

The image of Δ in the symmetric group of $\{L_1, \dots, L_n\}$ is transitive, so its order is divisible by n; by Cauchy's theorem it contains an element of order n, which is an n-cycle because n is prime. Let $\gamma \in \Delta$ map to it. For $g \in D \subseteq \Delta_0$, γg acts on the lines by the same n-cycle, so in a basis $f_i \in L_i$ the matrix of $\rho(\gamma g)$ is monomial with a permutation without fixed points, and its diagonal entries vanish: $\operatorname{tr} \rho(\gamma g) = 0$ for all $g \in D$. This contradicts hypothesis 3. So the case $s = n$ does not occur, and $\rho|_N$ is irreducible. □

Lemma 50.19. *Let k be a field, $A = k[[T]]$, $F = \operatorname{Frac}(A)$ with an algebraic closure $\bar{F}$, $n \in \{2, 3\}$, Δ a profinite group, $\Delta' \subseteq \Delta$ a closed normal subgroup and $\rho \colon \Delta \to \mathrm{GL}_n(A)$ a homomorphism whose entries are continuous for the T-adic topology. Assume that there is $u \in \Delta'$ such that $\rho(u)$ has n pairwise distinct eigenvalues in $\bar{F}$ generating a torsion-free subgroup of $\bar{F}^\times$, and that one of the following holds:*

(Sx1) *for every open subgroup U of Δ, the restriction of $\rho \otimes \bar{F}$ to $U \cap \Delta'$ is irreducible;*

(Sx2) *$n = 3$, $\rho(\gamma)_{ab} = 0$ for all $\gamma \in \Delta$ whenever $w_{3,a} - w_{3,b}$ is odd, and for every open subgroup U of Δ the restriction to $U \cap \Delta'$ of $r_1 \otimes \bar{F}$ is irreducible, where $r_1(\gamma) = \begin{pmatrix} \rho(\gamma)_{11} & \rho(\gamma)_{13} \\ \rho(\gamma)_{31} & \rho(\gamma)_{33} \end{pmatrix}$.*

Then every open subset of Δ meeting Δ' contains some $\sigma \in \Delta'$ such that the characteristic polynomial of $\rho(\sigma)$ is separable over F.

Proof. Let $\mathcal{U} \subseteq \Delta$ be open with $s \in \mathcal{U} \cap \Delta'$, and put $y = \rho(s)$.

Step 1: a subgroup. Open normal subgroups form a basis of neighbourhoods of 1 in Δ, so there is an open normal V with $sV \subseteq \mathcal{U}$. Put $G_1 = V \cap \Delta'$, a closed subgroup of Δ; then $sh \in \mathcal{U} \cap \Delta'$ for all $h \in G_1$. Let $G_2 \subseteq G_1$ be the subgroup N of Lemma 50.20 for $L = F$ and the restriction of ρ to G_1 (so G_2 is the preimage of the identity component of the Zariski closure H of $\rho(G_1)$ in $\mathrm{GL}_n(\bar{F})$). For $f \in F[x_{ij}]$ the map $g \mapsto f(\rho(g))$ is continuous for the T-adic topology (the entries of ρ are, and f is a polynomial), so its zero set is closed in G_1; by (Zi1) and (Zi4),

G_2 is an open normal subgroup of finite index of G_1. An open subgroup of $G_1 = V \cap \Delta'$ contains $U_2 \cap \Delta'$ for some open subgroup U_2 of Δ, so by (Sx1), resp. (Sx2), $\rho \otimes \bar{F}$, resp. $r_1 \otimes \bar{F}$, is irreducible on G_2. As U_2 has finite index in the profinite Δ, G_2 has finite index in Δ', and a subgroup of index m contains the $m!$-th power of every element (action on cosets); so $u^N \in G_2$ for some $N \geq 1$, as $u \in \Delta'$.

Step 2: eigenbasis. Choose $P \in \mathrm{GL}_n(\bar{F})$ with $P^{-1}\rho(u)P = \mathrm{diag}(\alpha_1, \ldots, \alpha_n)$; in case (Sx2), $\rho(u)$ preserves $\bar{F}e_1 + \bar{F}e_3$ and $\bar{F}e_2$, and we take the first and third columns of P in $\bar{F}e_1 + \bar{F}e_3$ and the second equal to e_2. Put $\beta_i = \alpha_i^N$ and $D = \mathrm{diag}(\beta_1, \ldots, \beta_n)$. For $i \neq j$, $\beta_i/\beta_j = (\alpha_i/\alpha_j)^N$ is a non-trivial element ($\alpha_i \neq \alpha_j$, and the group generated by the α's is torsion-free) of a torsion-free group, so it has infinite order; in particular the β_i are pairwise distinct. For $b \in G_2$ and $q \geq 0$, $\sigma = s\, b\, u^{Nq} \in \mathcal{U} \cap \Delta'$, and $P^{-1}\rho(\sigma)P = M(b)D^q$ with $M(b) = P^{-1}y\rho(b)P$.

Step 3: the leading term of the discriminant. Let $w_1, \ldots, w_n$ be the pairwise distinct integers given by Lemma 50.21 for $E = \bar{F}$ and $\beta_1, \ldots, \beta_n$, and order them as $\mu_1 = w_{\tau(1)} > \mu_2 = w_{\tau(2)} > \ldots$. Let X be an indeterminate and $M \in \mathrm{M}_n(\bar{F})$. The characteristic polynomial of $M\,\mathrm{diag}(X^{w_1}, \ldots, X^{w_n})$ is $\sum_{j=0}^{n}(-1)^j c_j Y^{n-j}$ with $c_j = \sum_{|S|=j} m_S(M)\, X^{w_S}$, where S runs over j-subsets of $\{1, \ldots, n\}$, m_S is the principal minor on S and $w_S = \sum_{i \in S} w_i$ (multiplying column i by X^{w_i} multiplies each principal minor containing i by X^{w_i}). Its discriminant is $\delta = c_1^2 - 4c_2$ for $n = 2$, and $\delta = c_1^2c_2^2 - 4c_2^3 - 4c_1^3c_3 + 18c_1c_2c_3 - 27c_3^2$ for $n = 3$. Expanding the products of the c_j subset by subset, every term is a product of principal minors times X^e, e the sum of the w_S chosen. A term of c_j has exponent at most μ_1 for $j = 1$, $\mu_1 + \mu_2$ for $j = 2$, $\mu_1 + \mu_2 + \mu_3$ for $j = 3$, with equality only for $S = \{\tau(1)\}$, $\{\tau(1), \tau(2)\}$, $\{\tau(1), \tau(2), \tau(3)\}$ respectively. Hence for $n = 2$ the terms of c_1^2 have exponent at most $2\mu_1$, with equality only for $S = S' = \{\tau(1)\}$, and those of c_2 exponent $\mu_1 + \mu_2 < 2\mu_1$. For $n = 3$ the terms of $c_1^2c_2^2$ have exponent at most $4\mu_1 + 2\mu_2$, with equality only when both factors c_1 contribute $\{\tau(1)\}$ and both factors c_2 contribute $\{\tau(1), \tau(2)\}$; the other products have exponents at most $3\mu_1 + 3\mu_2$, $4\mu_1 + \mu_2 + \mu_3$, $3\mu_1 + 2\mu_2 + \mu_3$, $2\mu_1 + 2\mu_2 + 2\mu_3$, all smaller than $4\mu_1 + 2\mu_2$ because $\mu_1 > \mu_2 > \mu_3$. So δ, a Laurent polynomial in X, has the top term $C(M)X^{2\mu_1}$, resp. $C(M)X^{4\mu_1+2\mu_2}$, with

$$C(M) = M^2_{\tau(1)\tau(1)} \ (n = 2), \qquad C(M) = M^2_{\tau(1)\tau(1)}\, m_{\{\tau(1),\tau(2)\}}(M)^2 \ (n = 3).$$

Hence: if $C(M(b)) \neq 0$, the characteristic polynomial of $M(b)\,\mathrm{diag}(X^{w_1}, \ldots, X^{w_n})$ is separable over $\bar{F}(X)$, and by Lemma 50.21 there is $q \geq 0$ such that the characteristic polynomial of $M(b)D^q = P^{-1}\rho(\sigma)P$, $\sigma = s\, b\, u^{Nq}$, is separable; it is the characteristic polynomial of $\rho(\sigma)$, which has coefficients in F, so it is separable over F.

Step 4: a good b. It remains to find $b \in G_2$ with $C(M(b)) \neq 0$. For indices i put $f_i = Pe_i$ and $\varphi_i = e_i^t P^{-1} y$, a non-zero row vector; then $M(b)_{ii} = \varphi_i\, \rho(b)\, f_i$.

(i) A diagonal entry. If $\varphi_i \rho(b) f_i = 0$ for all $b \in G_2$, the span of $\rho(G_2)f_i$ is a non-zero G_2-stable subspace contained in $\ker \varphi_i$, hence proper, contradicting irreducibility on G_2. In case (Sx2) with $i \in \{1, 3\}$, $f_i \in \bar{F}e_1 + \bar{F}e_3$ and φ_i vanishes on e_2 (as y and P are block diagonal), so the same argument applies to r_1 on G_2.

(ii) Case (Sx1), $n = 2$: $C = M^2_{\tau(1)\tau(1)}$, non-zero for some b by (i).

(iii) Case (Sx1), $n = 3$. Put $Q_1(x) = (P^{-1}yxP)_{\tau(1)\tau(1)}$ and $Q_2(x) = m_{\{\tau(1),\tau(2)\}}(P^{-1}yxP)$, polynomials in the entries of x with coefficients in $\bar{F}$. $Q_1 \circ \rho$ is not identically zero on G_2 by (i). As Λ^2 is multiplicative, $Q_2(x)$ is the coefficient of $e_{\tau(1)} \wedge e_{\tau(2)}$ in $\Lambda^2(P^{-1}y)\Lambda^2(x)\Lambda^2(P)(e_{\tau(1)} \wedge e_{\tau(2)})$, a matrix coefficient of Λ^2; and $\Lambda^2(\rho \otimes \bar{F})$ is irreducible on G_2, since $\Lambda^2 V \cong V^* \otimes \Lambda^3 V$ equivariantly for $\dim V = 3$ (through the perfect pairing $V \otimes \Lambda^2 V \to \Lambda^3 V$) and the dual of an irreducible representation is irreducible. So the argument of (i) applied to $\Lambda^2\rho$ shows that $Q_2 \circ \rho$ is not identically zero on G_2. By (Zi3) of Lemma 50.20 (group G_1, its subgroup G_2 as N, $U = G_1$, $\sigma = 1$, polynomials Q_1, Q_2) there is $b \in G_2$ with $C(M(b)) = Q_1(\rho(b))^2 Q_2(\rho(b))^2 \neq 0$.

(iv) Case (Sx2). Here $M(b)$ is block diagonal: a 2×2 block $A(b)$ on the indices $\{1,3\}$ and the entry $m(b) = (y\rho(b))_{22} \neq 0$. If $\tau(1) = 2$, $C = m^2(m\,A_{\tau(2)\tau(2)})^2$; if $\tau(1) \neq 2 = \tau(2)$, $C = A^2_{\tau(1)\tau(1)}(A_{\tau(1)\tau(1)}m)^2$; if $\{\tau(1),\tau(2)\} = \{1,3\}$, $C = A^2_{\tau(1)\tau(1)}(\det A)^2$ with $\det A \neq 0$. In each case $C(M(b)) \neq 0$ as soon as one prescribed diagonal entry $A_{jj}(b) = M(b)_{jj}$, $j \in \{1,3\}$, is non-zero, which holds for some $b \in G_2$ by (i).

By Step 3, $\sigma = s\,b\,u^{Nq}$ for suitable $q \geq 0$ is the required element. □

Lemma 50.20. *Let L be a field with an algebraic closure $\bar{L}$, $n \geq 1$, G a group and $\rho\colon G \to \mathrm{GL}_n(L)$ a homomorphism. Let $H \subseteq \mathrm{GL}_n(\bar{L})$ be the Zariski closure of $\rho(G)$, H° its identity component, and $N = \{g \in G : \rho(g) \in H^\circ\}$. Then:*

(Zi1) *N is a normal subgroup of finite index of G;*

(Zi2) *for every subgroup U of finite index of G, $\rho(U \cap N)$ is Zariski dense in H°;*

(Zi3) *for every subgroup U of finite index of G, every $\sigma \in G$ and all polynomials $f_1, \ldots, f_r \in \bar{L}[x_{ij} : 1 \leq i,j \leq n]$ such that for each k there is $h \in N$ with $f_k(\rho(\sigma h)) \neq 0$, there is $g \in U \cap N$ with $f_k(\rho(\sigma g)) \neq 0$ for $k = 1, \ldots, r$;*

(Zi4) *if G is a topological group and for every $f \in L[x_{ij} : 1 \leq i,j \leq n]$ the set $\{g \in G : f(\rho(g)) = 0\}$ is closed in G, then N is open and closed in G.*

Proof. We use the basic facts on closed subgroups of $\mathrm{GL}_n(\bar{L})$ and their identity components from [41, Ch. I, 1.2–1.3]. *(Zi1).* N is the preimage of the normal subgroup H° of H under the homomorphism $\rho\colon G \to H$, so it is normal, and $gN \mapsto \rho(g)H^\circ$ is an injective map $G/N \to H/H^\circ$, so $[G : N] \leq [H : H^\circ] < \infty$.

$\rho(N)$ is dense in H°. Let $h_1H^\circ, \ldots, h_sH^\circ$ be the cosets of H° in H, with $h_1 = 1$. Then $\rho(G) = \bigcup_k (\rho(G) \cap h_kH^\circ)$, and the closure of $\rho(G) \cap h_kH^\circ$ lies in the closed set h_kH°. So H is the union of these closures, and as the cosets are disjoint, H° lies in the closure of $\rho(G) \cap H^\circ = \rho(N)$.

(Zi2). $U \cap N$ has finite index in N (at most $[G : U]$); let $n_1, \ldots, n_m \in N$ represent its cosets in N. The closure C of $\rho(U \cap N)$ is a closed subgroup contained in H°. Then $\rho(N) \subseteq \bigcup_k \rho(n_k)C$, a finite union of closed sets, so $H^\circ \subseteq \bigcup_k \rho(n_k)C \subseteq H^\circ$ by the previous paragraph. As H° is irreducible, $H^\circ = \rho(n_k)C$ for some k, and since $\rho(n_k) \in H^\circ$, $C = \rho(n_k)^{-1}H^\circ = H^\circ$.

(Zi3). Put $\varphi_k(x) = f_k(\rho(\sigma)x)$, a polynomial in the entries of x. By hypothesis $\varphi_k(\rho(h)) \neq 0$ for some $h \in N$, and $\rho(h) \in H^\circ$; so the zero set of φ_k in H° is a proper closed subset. As H° is irreducible, the union of these finitely many proper closed subsets is proper, i.e. $\varphi = \varphi_1 \cdots \varphi_r$ does not vanish identically on H°. If φ vanished on $\rho(U \cap N)$, it would vanish on its closure, which is H° by (Zi2). So there is $g \in U \cap N$ with $\prod_k f_k(\rho(\sigma g)) = \varphi(\rho(g)) \neq 0$.

(Zi4). H° is closed in $\mathrm{GL}_n(\bar{L})$, so it is the set of invertible zeros of finitely many polynomials $f'_1, \ldots, f'_s \in \bar{L}[x_{ij}]$. Their coefficients lie in a finite extension L' of L; choose an L-basis $e_1, \ldots, e_d$ of L' and write $f'_k = \sum_m e_m f_{k,m}$ with $f_{k,m} \in L[x_{ij}]$. For $x \in \mathrm{M}_n(L)$ the values $f_{k,m}(x)$ lie in L, so $f'_k(x) = 0$ if and only if $f_{k,m}(x) = 0$ for all m. Hence $N = \bigcap_{k,m}\{g : f_{k,m}(\rho(g)) = 0\}$ is closed. Its complement is the union of the finitely many cosets $gN \neq N$ (by (Zi1)), each closed because left translation is a homeomorphism of G; so N is also open. □

Lemma 50.21. *Let E be a field, $n \geq 1$ and $\beta_1, \ldots, \beta_n \in E^\times$ such that β_i/β_j has infinite order in $E^\times$ for all $i \neq j$. Then there are pairwise distinct integers $w_1, \ldots, w_n$ with the following property. Let X be an indeterminate and $M \in \mathrm{M}_n(E)$. If the characteristic polynomial of $M\,\mathrm{diag}(X^{w_1}, \ldots, X^{w_n}) \in \mathrm{M}_n(E(X))$ is separable over $E(X)$, then there is an integer $q \geq 0$ such that the characteristic polynomial of $M\,\mathrm{diag}(\beta_1^q, \ldots, \beta_n^q)$ is separable over E.*

Proof. Step 1: the weights. For $m \in \mathbb{Z}^n$ write $\beta^m = \prod_i \beta_i^{m_i}$. Let $\Lambda = \{m \in \mathbb{Z}^n : (\beta^m)^k = 1 \text{ for some } k \geq 1\}$, a subgroup (if $(\beta^m)^k = 1 = (\beta^{m'})^{k'}$ then $(\beta^{m+m'})^{kk'} = 1$). The quotient $\mathbb{Z}^n/\Lambda$ is torsion-free (if $km \in \Lambda$ with $k \geq 1$, then $m \in \Lambda$) and finitely generated, hence free; fix an isomorphism with $\mathbb{Z}^r$ and let q_i be the image of the i-th unit vector. For $i \neq j$, $q_i \neq q_j$: otherwise $(\beta_i/\beta_j)^k = 1$ for some $k \geq 1$. Let R exceed the absolute values of all coordinates of all $q_i - q_j$ and $\lambda(y) = \sum_{l=1}^r R^{l-1} y_l$. For $y \neq 0$ with all $|y_l| < R$, let l_0 be the largest index with $y_{l_0} \neq 0$; then $|\sum_{l<l_0} R^{l-1} y_l| \leq (R-1)\sum_{l<l_0} R^{l-1} = R^{l_0-1} - 1 < |R^{l_0-1} y_{l_0}|$, so $\lambda(y) \neq 0$. Hence $w_i = \lambda(q_i)$ are pairwise distinct, and

$$\beta^m = 1 \implies m \in \Lambda \implies \textstyle\sum_i m_i w_i = \lambda(\sum_i m_i q_i) = 0. \qquad (*)$$

Step 2: the discriminant as a polynomial on the torus. Let $t_1, \dots, t_n$ be indeterminates and $\Delta \in E[t_1, \dots, t_n]$ the discriminant of the characteristic polynomial of $M \operatorname{diag}(t_1, \dots, t_n)$, whose coefficients lie in $E[t_1, \dots, t_n]$. Write $\Delta = \sum_{\mu \in S} c_\mu t^\mu$ with $S \subseteq \mathbb{Z}^n_{\geq 0}$ finite. Under $t_i \mapsto X^{w_i}$ (a ring homomorphism to $E(X)$) the characteristic polynomial becomes that of $M \operatorname{diag}(X^{w_1}, \dots, X^{w_n})$, so by hypothesis $\Delta(X^{w_1}, \dots, X^{w_n}) \neq 0$; under $t_i \mapsto \beta_i^q$ it becomes that of $M \operatorname{diag}(\beta_1^q, \dots, \beta_n^q)$.

Step 3: Vandermonde. Suppose $\Delta(\beta_1^q, \dots, \beta_n^q) = 0$ for all $q \geq 0$. Let $\theta_1, \dots, \theta_p$ be the distinct values of β^μ, $\mu \in S$, and $C_k = \sum_{\mu \in S,\ \beta^\mu = \theta_k} c_\mu$. Then $\sum_k C_k \theta_k^q = \Delta(\beta_1^q, \dots, \beta_n^q) = 0$ for $q = 0, \dots, p-1$, and the Vandermonde matrix (θ_k^q) is invertible, so all $C_k = 0$. If $\beta^\mu = \beta^{\mu'}$, then $\beta^{\mu-\mu'} = 1$ and $\sum_i \mu_i w_i = \sum_i \mu_i' w_i$ by $(*)$; so all μ with $\beta^\mu = \theta_k$ give the same power X^{e_k}, $e_k = \sum_i \mu_i w_i$, and $\Delta(X^{w_1}, \dots, X^{w_n}) = \sum_k C_k X^{e_k} = 0$, a contradiction. Hence $\Delta(\beta_1^q, \dots, \beta_n^q) \neq 0$ for some $q \geq 0$, which is the claim. □

Lemma 50.22. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant and $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ a universal polarised ordinary lift of rank n over L (both for $\mathcal{O}'$) such that ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) \subseteq W_n^{\mathrm{po}}$. Let $\mathfrak{x}$ be a prime of E_n^{po}, $(\mathcal{O}'', R, \iota)$ a local chart at $\mathfrak{x}$ and $\varphi = \iota \circ \vartheta_n$.*

(Xk1) *For every prime P of R of irreducible type, $\varphi^{-1}(P)$ is a stable prime of B_n^{po}.*

(Xk2) *If $n = 3$, then for every thick prime $\mathfrak{e}$ of R, $\varphi^{-1}(\mathfrak{e})$ is a thick prime of B_n^{po}.*

Proof. Write $B = B_n^{\mathrm{po}}$, $W = W_n^{\mathrm{po}}$, $E = E_n^{\mathrm{po}}$ and $\Gamma = \Gamma_L^0$. *Preliminaries.* The ring $E/\mathfrak{x}$ embeds into the finite field $R/\mathfrak{m}_R$, so $W/(\mathfrak{x} \cap W)$ is a domain inside a finite field, hence a field, and $\mathfrak{x} \cap W = \mathfrak{m}_W$; thus $\varphi(\mathfrak{m}_B) \subseteq \iota(\mathfrak{m}_W) \subseteq \mathfrak{m}_R$ (ϑ_n is local) and $\iota(w)$ is a unit for every unit w of W. By (Po3) and (Po2), $\rho^{\mathrm{u}}(\pi_L(g_\star)) - \rho^{\mathrm{u}}(\pi_L(c g_\star^{-1} c)) = \zeta \operatorname{diag}(w_{n,a})$ with $\zeta = \rho^{\mathrm{u}}(\pi_L(g_\star))_{11} - \rho^{\mathrm{u}}(\pi_L(g_\star))_{nn} \in W$ (diagonal entries have weight 0), whose residue $\bar\Psi(g_\star) - \bar\Psi(g_\star)^{-1}$ is non-zero ($g_\star$ is a marking, (Po5)); so $\iota(\zeta) \in R^\times$. Since ϑ_n classifies $(\det \circ \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ and takes values in $W \subseteq E$, (Ch1) gives $\varphi \circ D^{\mathrm{u}} = \det \circ \rho_{\mathfrak{x}}$, and $\varphi \circ \psi_{v,a}^{\mathrm{d}} = \psi_{\mathfrak{x},v,a}$. For a prime Q of R and $\mathfrak{q} = \varphi^{-1}(Q)$, φ induces $B/\mathfrak{q} \hookrightarrow R/Q$; fix an algebraic closure K_Q of $\operatorname{Frac}(R/Q)$ and an embedding $\bar\kappa(\mathfrak{q}) \hookrightarrow K_Q$ extending it. Then $D_{\mathfrak{q}}$ base-changed to K_Q equals $\det \circ (\rho_{\mathfrak{x}} \bmod Q) \otimes K_Q$.

(Xk1). Let P be of irreducible type and $\mathfrak{q} = \varphi^{-1}(P)$. The field $\operatorname{Frac}(R/P)$ has characteristic 0 or ℓ, odd. Lemma 50.17 (a) applies to $\rho_P = \rho_{\mathfrak{x}} \bmod P$: hypothesis 1 is (Po2), hypothesis 2 holds with $\zeta = \iota(\zeta) \bmod P \neq 0$, and hypothesis 3 and the condition on odd entries hold because P is of irreducible type. So $\rho_P \otimes K_P$ is irreducible. By (Ch3) there is a semisimple $r \colon \Gamma \to \mathrm{GL}_n(\bar\kappa(\mathfrak{q}))$ with $D_{\mathfrak{q}} = \det \circ r$. Over the algebraically closed field $\bar\kappa(\mathfrak{q})$, r is a sum of absolutely irreducible representations, so $r \otimes K_P$ is semisimple, with $\det \circ (r \otimes K_P) = \det \circ (\rho_P \otimes K_P)$; by the uniqueness in (Ch3) over K_P, $r \otimes K_P \cong \rho_P \otimes K_P$, which is irreducible; so r is irreducible and $\mathfrak{q}$ is stable.

(Xk2), not stable. Let $n = 3$, $\mathfrak{e}$ thick with $r\colon \Gamma \to \mathrm{M}_3(R/\mathfrak{e})$ as in (Tk1)–(Tk3), $\mathfrak{q} = \varphi^{-1}(\mathfrak{e})$, $\kappa_0 = \bar{\kappa}(\mathfrak{q}) \subseteq K' = K_{\mathfrak{e}}$. As $\mathfrak{e}$ is of endoscopic type, $\rho_{\mathfrak{e}} = \rho_{\mathfrak{x}} \bmod \mathfrak{e}$ has vanishing entries of odd weight and preserves $\langle e_1, e_3\rangle$ and $\langle e_2\rangle$: it is reducible over K'. If $D_{\mathfrak{q}} = \det \circ r_0$ with r_0 irreducible over κ_0, then $r_0 \otimes K'$ is irreducible (absolutely irreducible), and (Ch3) over K' identifies it with the semisimplification of $\rho_{\mathfrak{e}} \otimes K'$, which is reducible: contradiction. So $\mathfrak{q}$ is not stable.

(Xk2), r kills $\mathcal{I}$. Extend r to a ring homomorphism $B[\Gamma] \to \mathrm{M}_3(R/\mathfrak{e})$ through $B \to R/\mathfrak{e}$ (and to polynomial base changes). By (Tk1) and the vanishing of the odd entries of $\rho_{\mathfrak{e}}$, every $r(\gamma)$ preserves $\langle e_1, e_3\rangle$ and has the same $\{1,3\}$-corner and $(2,2)$-entry as $\rho_{\mathfrak{e}}(\gamma)$; block upper triangular matrices form an algebra on which taking the diagonal blocks is multiplicative, so for every $y \in (R/\mathfrak{e})[t_1, \dots, t_m][\Gamma]$ the characteristic polynomial of $r(y)$ equals that of the block-diagonal $\rho_{\mathfrak{e}}(y)$, i.e. $\chi_{D'}(y)$ for the base change D' of D^{u}. By the Cayley–Hamilton theorem $\chi_{D'}(y)(r(y)) = 0$, so r kills the Cayley–Hamilton ideal. By (Tk2), and $\varphi \circ \psi^{\mathrm{d}}_{v,a} = \psi_{\mathfrak{x},v,a}$, r kills $\prod_{a=1}^{3}(\pi_L(g_a) - \psi^{\mathrm{d}}_{v,a}(g_a))$ and its image under $*$, which is $\prod_{a=1}^{3}(\pi_L(ch_a^{-1}c) - \psi^{\mathrm{d}}_{v,4-a}(h_a))$ with $h_a = g_{4-a}$ ($*$ reverses products and $\pi_L(g)^* = \pi_L(cg^{-1}c)$). For $k' \geq 1$, $r(\mathfrak{m}_B^{k'}) \subseteq \mathfrak{m}^{k'}\mathrm{M}_3(R/\mathfrak{e})$ with $\mathfrak{m}$ the maximal ideal of $R/\mathfrak{e}$; and since the entries of r are continuous and $(R/\mathfrak{e})/\mathfrak{m}^{k'}$ is finite, there is an open normal subgroup $H'_{k'}$ with $r(h) \equiv 1$ modulo $\mathfrak{m}^{k'}$ for $h \in H'_{k'}$. Every $t \in \mathcal{I}$ lies in the two-sided ideal generated by the four kinds of elements for k' and $H'_{k'}$, so $r(t) \in \mathfrak{m}^{k'}\mathrm{M}_3(R/\mathfrak{e})$ for every k', and $r(t) = 0$ by Krull's intersection theorem.

(Xk2), non-semisimplicity. Let $\mathcal{A} = \kappa_0[\Gamma]/\langle\mathcal{I}_0\rangle$, $\mathcal{I}_0$ the image of $\mathcal{I}$, and suppose $\mathcal{A}$ semisimple. By (Ch3), $D_{\mathfrak{q}} = \det \circ \rho_0$ with ρ_0 semisimple over κ_0; let $\mathfrak{K}$ be the kernel of $\rho_0\colon \kappa_0[\Gamma] \to \mathrm{M}_3(\kappa_0)$. For $y_0 = \sum_i c_i\gamma_i \in \kappa_0[\Gamma]$, $\chi_{D_{\mathfrak{q}}}(y_0)(y_0)$ is the specialisation $t_i \mapsto c_i$ of the image of $\chi_{D'}(\sum_i t_i\gamma_i)(\sum_i t_i\gamma_i)$, a κ_0-combination of images of Cayley–Hamilton generators, which lie in $\mathcal{I}$; so it vanishes in $\mathcal{A}$. For $x \in \mathfrak{K}$ and $y \in \kappa_0[\Gamma]$, $\chi_{D_{\mathfrak{q}}}(xy) = \det(X - \rho_0(xy)) = X^3$, hence $(xy)^3 = 0$ in $\mathcal{A}$: the image of $\mathfrak{K}$ is a nil two-sided ideal, contained in the Jacobson radical of $\mathcal{A}$, which is 0. So $\mathcal{A}$ is a quotient of $\kappa_0[\Gamma]/\mathfrak{K} \cong \rho_0(\kappa_0[\Gamma]) \subseteq \mathrm{M}_3(\kappa_0)$, finite-dimensional and semisimple over the algebraically closed κ_0, hence a product of matrix algebras over κ_0 (Wedderburn), and $\mathcal{A} \otimes_{\kappa_0} K' = K'[\Gamma]/\langle\mathcal{I}_0\rangle$ is semisimple. By the previous paragraph and the compatibility of $\kappa_0 \hookrightarrow K'$ with $B/\mathfrak{q} \hookrightarrow R/\mathfrak{e}$, $\sigma = r \otimes K'$ makes K'^3 a module over $\mathcal{A} \otimes K'$, hence a semisimple $K'[\Gamma]$-module. Its submodule $\langle e_1, e_3\rangle$ (stable as $r_{21} = r_{23} = 0$) then has a stable complement $K'y$ with $y_2 = 1$; comparing second coordinates in $\sigma(\gamma)y = \lambda(\gamma)y$ gives $\lambda(\gamma) = \sigma(\gamma)_{22}$, i.e. $\sigma(\gamma)y = \sigma(\gamma)_{22}y$ for all γ, contradicting (Tk3) with $F' = K'$. So $\mathcal{A}$ is not semisimple, and $\mathfrak{q}$ is thick. □

Lemma 50.23. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$ and $n \in \{2,3\}$, such that $\tau(\mathcal{O}_L) \subseteq \mathcal{O}'$ for every embedding $\tau\colon L \to \overline{\mathbb{Q}}_\ell$ and Ψ is trivial on $I_{\bar{p}}$ for every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above a prime not dividing M. Let v_0 be a place of L^+ above a prime $p \nmid 2M\,|\mathrm{disc}(L)|$ which splits in L, and $\bar{v}_0$ a place of $\overline{\mathbb{Q}}$ above v_0 such that $\bar{\Psi}$ is trivial and $\bar{\omega}$ is non-trivial on $D_{\bar{v}_0} \cap G_{L^+}$. Let* St *be the set of places of L^+ not above ℓ that lie above a prime dividing M, and $\bar{\chi}_a = \bar{\Psi}^{w_{n,a}}|_{G_L}$ for $1 \leq a \leq n$. Then:*

(In1) *for every family of homomorphisms $\xi_{v,a}\colon \mu_v \to \mathcal{O}'^{\times}$ ($v \in S_\ell$, $1 \leq a \leq n$) satisfying (Rd10) (for instance $\xi_{v,a} = 1$), $\mathscr{H}_L = (n, L, c, (\bar{v})_{v\in S_\ell}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1\leq a\leq n}, (\xi_{v,a}))$ is a rank-n Hecke datum over $\mathcal{O}'$, and (In2)–(In4) hold for it;*

(In2) *$N_{\mathscr{H}_L} = N_L$; hence $\Gamma_{\mathscr{H}_L} = \Gamma_L$, $\pi_{\mathscr{H}_L} = \pi_L$ and $\Gamma^0_{\mathscr{H}_L} = \Gamma^0_L$, and the groups $D_v \supseteq I_v$ and the integers d_v of $\mathscr{H}_L$ are those of Definition 48.2;*

(In3) *every admissible twist κ of rank n for ι, c and M with $\kappa(G_L) \subseteq \mathcal{O}'^{\times}$ is a twist for $\mathscr{H}_L$;*

(In4) *if $\Psi\chi_{\mathrm{cyc}}^{-e}$ is trivial on an open subgroup of $I_{\bar\ell}$ for some integer $e \geq 1$, then*

$$\left(\Psi^{w_{n,a}}|_{I_v}\right)_{v\in S_\ell,\, 1\leq a\leq n}$$

is an inertial weight for $\mathscr{H}_L$.

Proof. Two elementary facts are used throughout. (F1) If a place u of L^+ splits in L and $\bar u$ is a place of $\overline{\mathbb{Q}}$ above u, then $D_{\bar u} \cap G_{L^+} \subseteq G_L$: this group is the Galois group of the completion of $\overline{\mathbb{Q}}$ at $\bar u$ over L_u^+, and as u splits, the place of L below $\bar u$ has completion L_u^+, so the group fixes L. Hence $D_{\bar u} \cap G_L = D_{\bar u} \cap G_{L^+}$. (F2) For $k \in \{\pm 1, \pm 2\}$ and an element x of an abelian group with $x^2 \neq 1$, $x^k \neq 1$. The differences $w_{n,a} - w_{n,b}$ $(a \neq b)$ lie in $\{\pm 1, \pm 2\}$, so by (F2), for every $h \in G_L$ with $\bar\Psi(h)^2 \neq 1$ the values $\bar\chi_a(h) = \bar\Psi(h)^{w_{n,a}}$, $1 \leq a \leq n$, are pairwise distinct.

Step 1: the places. Every place of L^+ above a prime dividing M splits in L by (Af2); since $\ell \mid M$, this applies to every place in $S_\ell \cup \mathrm{St}$, and v_0 splits by hypothesis. The set St is finite (finitely many places lie above the finitely many primes dividing M) and consists of places not above ℓ. As $p \nmid 2M$ and $\ell \mid M$, $p \neq 2, \ell$; so v_0 is not above ℓ, and $v_0 \notin \mathrm{St}$ because $p \nmid M$. As $p \nmid \mathrm{disc}(L)$, p is unramified in L. Conversely, if u is a finite place of L^+ not in $S_\ell \cup \mathrm{St}$, the prime q below u satisfies $q \neq \ell$ and $q \nmid M$.

Step 2: (In1). The data have the required types: $n \geq 2$, L is CM, $c \in G_{L^+}$ is a complex conjugation, $\bar v$ lies above v for $v \in S_\ell$, St and v_0 are as required by Step 1, and the $\bar\chi_a$ are continuous characters $G_L \to \mathbb{F}_{\mathcal{O}'}^\times$ because Ψ is continuous with values in $\mathcal{O}'^\times$. The reduction of χ_{cyc} modulo $\mathfrak{m}_{\mathcal{O}'}$ is the character $\bar\omega$ of Definition 48.2, by which $G_{\mathbb{Q}}$ acts on the ℓ-th roots of unity.

(Rd1) $\tau(\mathcal{O}_L) \subseteq \mathcal{O}'$ is a hypothesis. By (Ar1), $\bar\omega \neq 1$ on G_L, so G_L moves a primitive ℓ-th root of unity and L contains none.

(Rd2) L/L^+ is unramified at every finite place by (Af2); the splitting is Step 1.

(Rd3) Step 1.

(Rd4) By (Af4), $\bar\Psi^2|_{D_v} \neq 1$ for $v \in S_\ell$, and $D_v \subseteq G_L$ by (F1); so some $h \in G_L$ has $\bar\Psi(h)^2 \neq 1$, and the $\bar\chi_a$ are pairwise distinct by the remark after (F2). If $\bar w$ lies above a finite place $u \notin S_\ell \cup \mathrm{St}$ of L^+, the prime below u does not divide M (Step 1), so Ψ, hence every $\bar\chi_a$, is trivial on $I_{\bar w} \cap G_L$ by hypothesis.

(Rd5) For $s \in G_L$, $\bar\Psi(csc) = \bar\Psi(c)^2\bar\Psi(s) = \bar\Psi(s)$, as $\bar\Psi$ has abelian values and $c^2 = 1$. Since $w_{n,n+1-a} = -w_{n,a}$, $\bar\chi_{n+1-a}(csc) = \bar\Psi(s)^{-w_{n,a}} = \bar\chi_a(s)^{-1}$.

(Rd10) holds for $(\xi_{v,a})$ by hypothesis; it involves no other component of $\mathscr{H}_L$, and the wild values enter none of (Rd1)–(Rd6), (In2)–(In4), so the choice of $(\xi_{v,a})$ does not affect the rest of the proof.

(Rd6) $\bar\Psi$ is trivial on $D_{\bar v_0} \cap G_L \subseteq D_{\bar v_0} \cap G_{L^+}$, so all $\bar\chi_a$ equal 1 there. By (F1) for $u = v_0$, $D_{\bar v_0} \cap G_L = D_{\bar v_0} \cap G_{L^+}$, on which $\bar\omega$ is non-trivial by hypothesis.

Step 3: (In2). Since $w_{n,1} = 1$, an element $s \in G_L$ satisfies $\bar\chi_a(s) = 1$ for all a if and only if $\bar\Psi(s) = 1$. For $s \in G_{L^+}$, $\eta_K(s) = 1$ means $s \in G_K$, and $G_{L^+} \cap G_K = G_L$ by (Af1). So the generators of $N_{\mathscr{H}_L}$ (the $s \in I_{\bar w} \cap G_L$, $\bar w \nmid \ell$, with all $\bar\chi_a(s) = 1$) are exactly the generators of N_L (the $s \in I_{\bar w} \cap G_{L^+}$, $\bar w \nmid \ell$, with $\eta_K(s) = \bar\Psi(s) = 1$). Both are the closed normal subgroup of G_{L^+} generated by this set, so $N_{\mathscr{H}_L} = N_L$, and $\Gamma_{\mathscr{H}_L} = \Gamma_L$, $\pi_{\mathscr{H}_L} = \pi_L$, $\Gamma^0_{\mathscr{H}_L} = \pi_L(G_L) = \Gamma^0_L$. The

groups $D_v = D_{\bar v} \cap G_{L^+} \supseteq I_v = I_{\bar v} \cap G_{L^+}$ and $d_v = [L_v^+ : \mathbb{Q}_\ell]$ are defined by the same formulas with the same places $\bar v$ in both definitions.

Step 4: (In3). Let κ be such a twist; it is a continuous character $G_L \to \mathcal{O}'^\times$, algebraic for ι in the sense of Definition 48.2, which is the condition of Definition 50.1. The first clause of (Rd7) is (Ka1), as $s^c = csc$. If $\bar w$ lies above a finite place $u \notin S_\ell \cup \mathrm{St}$ of L^+, the prime below $\bar w$ does not divide M (Step 1), so κ is trivial on $I_{\bar w} \cap G_L$ by (Ka2): this is the second clause. The third clause is (Ka3).

Step 5: (In4). Let $e \geq 1$ and $U_0 \subseteq I_{\bar\ell}$ open with $\Psi\chi_{\mathrm{cyc}}^{-e}$ trivial on U_0. Let $v \in S_\ell$. Since $\bar v = \gamma_v \bar\ell$, $I_{\bar v} = \gamma_v I_{\bar\ell} \gamma_v^{-1}$, and $\Psi\chi_{\mathrm{cyc}}^{-e}$, a character of $G_{\mathbb{Q}}$, is trivial on the open subgroup $\gamma_v U_0 \gamma_v^{-1}$ of $I_{\bar v}$; its intersection U with I_v is open in I_v (G_{L^+} is open in $G_{\mathbb{Q}}$). Through $\bar v$, D_v is the absolute Galois group of L_v^+ and I_v its inertia subgroup. Put $\phi_{v,a} = \Psi^{w_{n,a}}|_{D_v} \colon D_v \to \mathcal{O}'^\times \subseteq \overline{\mathbb{Q}}_\ell^\times$ and $\mu_a = (\Psi\chi_{\mathrm{cyc}}^{-e})^{w_{n,a}}|_{D_v}$, so $\phi_{v,a} = \chi_{\mathrm{cyc}}^{ew_{n,a}}\mu_a$ and μ_a is trivial on U. As U is open in I_v, there is an open subgroup $V \subseteq D_v$ with $V \cap I_v \subseteq U$; V is the absolute Galois group of a finite extension E of L_v^+, with inertia subgroup $V \cap I_v$, so $\mu_a|_V$ is unramified. An unramified character with values in the units of a finite extension of $\mathbb{Q}_\ell$ is crystalline, hence de Rham, of Hodge–Tate weight 0 at every embedding [52]. A representation W of D_v is de Rham if its restriction to an open subgroup V is, with the same Hodge–Tate weights: $(B_{\mathrm{dR}} \otimes W)^V$ is an E-vector space with a semilinear action of the finite group D_v/V if V is normal (one may shrink V to a normal open subgroup), and Galois descent gives the dimension of its invariants over L_v^+, compatibly with the filtration. So μ_a is de Rham with all τ-Hodge–Tate weights 0. The character χ_{cyc}^k is de Rham with τ-Hodge–Tate weight k for every $\tau \colon L_v^+ \to \overline{\mathbb{Q}}_\ell$ (normalisation fixed in Section 13), and a tensor product of de Rham characters is de Rham with the weights added. Hence $\phi_{v,a}$ is de Rham with τ-Hodge–Tate weight $e\,w_{n,a}$ for every τ, which is strictly decreasing in a because $e \geq 1$ and $w_{n,1} > \cdots > w_{n,n}$. Finally $\phi_{v,a}|_{I_v} = \Psi^{w_{n,a}}|_{I_v}$, and for $g \in I_v \subseteq G_L$ (by (F1)), $\Psi(g)^{w_{n,a}} \equiv \bar\Psi(g)^{w_{n,a}} = \bar\chi_a(g)$ modulo $\mathfrak{m}_{\mathcal{O}'}$. This is (Rd8). □

Lemma 50.24. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ and $v \in S_\ell$. Through $\bar v$, identify D_v with the absolute Galois group of L_v^+, and let* $\mathrm{Art} \colon (L_v^+)^\times \to D_v^{\mathrm{ab}} = D_v/\overline{[D_v, D_v]}$ *be the local Artin map. For an ℓ-power root of unity $\zeta \in L_v^+$ let $g_\zeta \in D_v$ be any element with image* $\mathrm{Art}(\zeta)$ *in D_v^{ab}.*

(Wv1) *$g_\zeta \in \mu_v$, and every $g \in \mu_v$ satisfies $g \in g_\zeta\overline{[D_v, D_v]}$ for some ℓ-power root of unity $\zeta \in L_v^+$; moreover $\chi_{\mathrm{cyc}}(g) = 1$ for every $g \in \mu_v$. Consequently, for $A \in \mathrm{CNL}_{\mathcal{O}}$ and a continuous homomorphism $\psi \colon D_v \to A^\times$, $\psi(g)$ equals the image of $\xi_{v,a}(g)$ in A for all $g \in \mu_v$ if and only if $\psi(g_\zeta)$ equals the image of $\xi_{v,a}(g_\zeta)$ for every ℓ-power root of unity $\zeta \in L_v^+$ (both sides being independent of the choice of g_ζ).*

(Wv2) *If the reduction $\bar\omega$ of χ_{cyc} is non-trivial on D_v, then $\mu_v = \overline{[D_v, D_v]}$, $\xi_{v,a} = 1$ for $1 \leq a \leq n$, and for every $A \in \mathrm{CNL}_{\mathcal{O}}$ every continuous homomorphism $\psi \colon D_v \to A^\times$ satisfies $\psi(g) = 1 = \xi_{v,a}(g)$ for $g \in \mu_v$.*

(Wv3) *Let R be a commutative $\mathcal{O}$-algebra, $P \subseteq R$ a prime ideal, $t \in R$ with $t^{\ell^k} = 1$ for some $k \geq 0$, and $y \colon R \to \overline{\mathbb{Q}}_\ell$ a homomorphism of $\mathcal{O}$-algebras with $y(P) = 0$ and $y(t) \in \mathcal{O}$. Then $t - y(t) \in P$; hence $y'(t) = y(t)$ for every homomorphism of $\mathcal{O}$-algebras $y' \colon R \to \overline{\mathbb{Q}}_\ell$ with $y'(P) = 0$.*

Proof. (Wv1). By local class field theory [190] (Chapter V, (1.3) and (1.4)), Art extends to an isomorphism of topological groups from the profinite completion $\widehat{F^\times}$ onto D_v^{ab}. Choosing a uniformiser, $F^\times = \varpi^{\mathbb{Z}} \times \mathcal{O}_F^\times$, so $\widehat{F^\times} \cong \widehat{\mathbb{Z}} \times \mathcal{O}_F^\times$ ($\mathcal{O}_F^\times$ is profinite), and $\mathcal{O}_F^\times = \mu_{q-1} \times U_F^1$ with

$U_F^1 \cong \mu_{\ell^\infty}(F) \times \mathbb{Z}_\ell^{[F:\mathbb{Q}_\ell]}$ [190] (Chapter II, (5.3) and (5.7)). In this product the elements of ℓ-power order are exactly those of $\mu_{\ell^\infty}(F)$: $\widehat{\mathbb{Z}}$ and $\mathbb{Z}_\ell^{[F:\mathbb{Q}_\ell]}$ are torsion-free, and μ_{q-1} has order prime to ℓ. Since μ_v is the preimage in D_v of the subgroup of elements of ℓ-power order of D_v^{ab} (Definition 50.1), μ_v is the preimage of $\mathrm{Art}(\mu_{\ell^\infty}(F))$: every g_ζ lies in μ_v, and each $g \in \mu_v$ has image $\mathrm{Art}(\zeta)$ for some $\zeta \in \mu_{\ell^\infty}(F)$, i.e. $g \in g_\zeta \overline{[D_v, D_v]}$. The character χ_{cyc} of D_v factors through D_v^{ab} and $\chi_{\mathrm{cyc}}(\mathrm{Art}(z)) = N_{F/\mathbb{Q}_\ell}(z)^{\pm 1}$ for $z \in \mathcal{O}_F^\times$ (the sign depends on the normalisation of Art and plays no role) [190] (Chapter V, (2.4) and the Lubin–Tate description of $\mathbb{Q}_\ell(\mu_{\ell^\infty})$). For $\zeta \in \mu_{\ell^\infty}(F)$, $N_{F/\mathbb{Q}_\ell}(\zeta)$ is an ℓ-power root of unity in $\mathbb{Q}_\ell$, hence 1 as ℓ is odd; so $\chi_{\mathrm{cyc}}(g) = 1$ for $g \in \mu_v$. For the last assertion: a continuous homomorphism $\psi\colon D_v \to A^\times$ into the commutative Hausdorff group $A^\times$ kills the commutators, hence their closure $\overline{[D_v, D_v]}$ (its kernel is closed); and $\xi_{v,a}$ is a homomorphism on $\mu_v \supseteq \overline{[D_v, D_v]}$ that is trivial on $\overline{[D_v, D_v]}$ by (Rd10). So both ψ and $\xi_{v,a}$ are constant on each coset $g\overline{[D_v, D_v]} \subseteq \mu_v$; by the first part every $g \in \mu_v$ lies in such a coset of some g_ζ, which gives the equivalence and the independence of the choice of g_ζ.

(Wv2). $\bar\omega$ is the character by which D_v acts on the ℓ-th roots of unity in $\overline{\mathbb{Q}}_\ell$, so $\bar\omega|_{D_v} \neq 1$ means that F contains no primitive ℓ-th root of unity. Then $\mu_{\ell^\infty}(F) = 1$ (a non-trivial finite group of ℓ-power roots of unity contains an element of order ℓ), so by (Wv1) μ_v is the preimage of the trivial subgroup, $\mu_v = \overline{[D_v, D_v]}$. By (Rd10), $\xi_{v,a}(g) = 1$ for every $g \in \mu_v$. A continuous $\psi\colon D_v \to A^\times$ is trivial on $\overline{[D_v, D_v]} = \mu_v$, as in the proof of (Wv1).

(Wv3). Put $R' = R/P$, a domain, and s the image of t. The homomorphism y factors through R' and restricts on $\mathcal{O}$ to the inclusion $\mathcal{O} \subseteq \overline{\mathbb{Q}}_\ell$, which is injective; so $\mathcal{O} \to R'$ is injective and $K = \mathrm{Frac}(\mathcal{O})$ is a subfield of $\mathrm{Frac}(R')$. As $s^{\ell^k} = 1$, s is algebraic over K; let $m \in K[X]$ be its minimal polynomial, monic and irreducible, dividing $X^{\ell^k} - 1$. Its roots (in an algebraic closure of K) are roots of $X^{\ell^k} - 1$, hence integral over $\mathcal{O}$, so its coefficients, being polynomials in the roots, are elements of K integral over $\mathcal{O}$; $\mathcal{O}$ is integrally closed, so $m \in \mathcal{O}[X]$. Then $m(s) \in R'$ is 0, and applying y gives $m(y(t)) = 0$. So m has the root $y(t) \in \mathcal{O} \subseteq K$; being irreducible over K, $m = X - y(t)$, whence $s = y(t)$, i.e. $t - y(t) \in P$. For y' as stated, $y'(t) - y(t) = y'(t - y(t)) \in y'(P) = 0$. □

Lemma 50.25. *Let $\mathcal{O}$ be a coefficient ring, $N \geq 0$, $\Lambda = \mathcal{O}[[X_1, \ldots, X_N]]$, and $C \neq 0$ a commutative ring with a ring homomorphism $\lambda\colon \Lambda \to C$ such that C is a finite and torsion-free Λ-module via λ ($\lambda(a)c = 0$ with $a \neq 0$ implies $c = 0$). Then:*

1. *λ is injective, and $\dim C/\mathfrak{q} = N + 1$ for every minimal prime $\mathfrak{q}$ of C;*
2. *if $\mathfrak{a} \subseteq \lambda(\Lambda)$ is an ideal of $\lambda(\Lambda)$ with $\lambda(\Lambda)/\mathfrak{a} \cong \mathbb{F}_\mathcal{O}$, then $C/\mathfrak{a}C$ has finite length; in particular every prime of C containing $\mathfrak{a}$ is maximal, and every element of the Jacobson radical of C has a power in $\mathfrak{a}C$ when C is local.*

Proof. Item 1. If $\lambda(a) = 0$ then $\lambda(a) \cdot 1 = 0$, so $a = 0$ or $1 = 0$ in C; hence λ is injective. C is Noetherian, being finite over the Noetherian ring Λ. Let $\mathfrak{q}$ be a minimal prime of C. Minimal primes of a Noetherian ring are associated primes, so $\mathfrak{q} = \mathrm{Ann}_C(c)$ for some $c \neq 0$. If $a \in \Lambda$ and $\lambda(a) \in \mathfrak{q}$, then $\lambda(a)c = 0$, so $a = 0$ by torsion-freeness. Hence $\Lambda \to C/\mathfrak{q}$ is injective, and it is finite, so integral. By the Cohen–Seidenberg theorems (lying over and going up for integral extensions, incomparability), $\dim C/\mathfrak{q} = \dim \Lambda$, and $\dim \Lambda = N + 1$ (Λ is a regular local ring of dimension $N + 1$).

Item 2. $C/\mathfrak{a}C$ is a finite module over $\lambda(\Lambda)/\mathfrak{a} \cong \mathbb{F}_\mathcal{O}$, i.e. a finite-dimensional $\mathbb{F}_\mathcal{O}$-vector space, hence of finite length, an Artinian ring. Its primes are maximal, so every prime of C containing $\mathfrak{a}$ is maximal; and its Jacobson radical is nilpotent. If C is local with maximal ideal $\mathfrak{m}_C$, the image of $\mathfrak{m}_C$ in $C/\mathfrak{a}C$ lies in its Jacobson radical, so $\mathfrak{m}_C^k \subseteq \mathfrak{a}C$ for some $k \geq 1$. □

50.3 From determinants to marked lifts

This subsection proves Proposition 50.26, which carries the ideal of the determinant ring to the deformation ring of marked lifts used in Theorem 50.3: the comparison morphism from B_n^{po} is onto the weight-zero algebra, and a seed point of the determinant ring gives a seed component. Surjectivity rests on Chenevier's theory of determinants [66] and on a density statement for complete Noetherian local rings (Lemma 50.27). The marking is what makes the passage possible: at the generic points of irreducible type the determinant comes from a marked lift (Proposition 50.28).

Proposition 50.26. *Let $\mathcal{O}'$ be a coefficient ring, L an auxiliary field of level C_0 for $(K, \mathcal{O}', \Psi, c, g_\star, M)$ with data $(N', w, j, \chi', \theta)$ as in (Ag1), $d_L = [L^+ : \mathbb{Q}]$, $n \in \{2, 3\}$, and let $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ be a universal polarised ordinary lift of rank n over L (for $\mathcal{O}'$).*

(Ht1) *A universal polarised ordinary determinant $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ of rank n over L (for $\mathcal{O}'$) exists; the comparison morphism ϑ_n exists, and $\vartheta_n(B_n^{\mathrm{po}}) = W_n^{\mathrm{po}}$.*

(Ht2) *Let κ be an admissible twist of rank n for ι, c and M, and $\mathcal{J} \subseteq B_n^{\mathrm{po}}$ an ideal such that $\dim B_n^{\mathrm{po}}/\mathfrak{q} = 1 + n\,d_L$ for every minimal prime $\mathfrak{q}$ of B_n^{po} over $\mathcal{J}$, and such that $x(\mathcal{J}) = 0$ for every seed r of some weight $m \geq 2$ for (j, χ') with twist κ and every homomorphism of $\mathcal{O}'$-algebras $x\colon B_n^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ with $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ and $x \circ \psi_{v,a}^{\mathrm{d}} = \kappa_{v,a}$ ($\tilde{r} \circ \pi_L = r$, $(\kappa_{v,a})_a$ a diagonal of r on D_v as in (Sp5)). If for some $m \geq 2$ there is a seed of rank n and weight m for (j, χ') with twist κ, then $\mathcal{M}_{\mathcal{J}}$ has a seed component.*

Proof. Recall $w_{n,\bar{a}} = -w_{n,a}$, $\{w_{n,a}\} = \{1, -1\}$ ($n = 2$) or $\{1, 0, -1\}$ ($n = 3$), the $w_{n,a}$ are distinct, and $(J_n\, {}^t X\, J_n)_{ab} = X_{\bar{b}\bar{a}}$ for every $n \times n$ matrix X. For a homomorphism $\rho\colon \Gamma \to \mathrm{GL}_n(A)$, $\chi_{\det \circ \rho}(x)$ is the characteristic polynomial of $\rho(x)$ for $x \in A[\Gamma]$ (ρ extended linearly), so $\mathrm{tr}_{\det \circ \rho}(x)$ is the trace of $\rho(x)$; for a ring homomorphism f, $\chi_{f \circ D}(f_* x) = f(\chi_D(x))$ and $\mathrm{tr}_{f \circ D}(f_* x) = f(\mathrm{tr}_D(x))$, where f_* is f on coefficients.

(Ht1), existence of B.

Step 1: finiteness conditions. $\Gamma_L^0 = \pi_L(G_L)$ is open in Γ_L (G_L is open in G_{L^+} and π_L is an open map), so its open subgroups are open in Γ_L and by (Ar5)(i) Γ_L^0 satisfies Φ_ℓ. For $v \mid \ell$, D_v is the absolute Galois group of L_v^+; an open subgroup is the absolute Galois group of a finite extension F/L_v^+, whose continuous homomorphisms to $\mathbb{F}_\ell$ correspond by local class field theory to homomorphisms $F^\times/F^{\times \ell} \to \mathbb{F}_\ell$, a finite set; so D_v satisfies Φ_ℓ. The determinant $\bar{D}_n = \det \circ \bar{\rho}$, $\bar{\rho} = \mathrm{diag}(\bar{\Psi}^{w_{n,1}}, \ldots, \bar{\Psi}^{w_{n,n}})$, is continuous ($\bar{\Psi}$ has finite image).

Step 2: the determinant ring. Let $k = \mathbb{F}_{\mathcal{O}}$; $W(k) \subseteq \mathcal{O}$ and $\mathcal{O}$ is finite free over $W(k)$. Let $(A(\bar{D}_n), D(\bar{D}_n))$ be given by (Ch2) of Theorem B.83 for $G = \Gamma_L^0$; it is Noetherian by Step 1. Put $A = A(\bar{D}_n) \otimes_{W(k)} \mathcal{O}$ and $D_A = D(\bar{D}_n) \otimes A$. A is finite over the complete Noetherian local ring $A(\bar{D}_n)$, hence complete and Noetherian, and $A/\mathfrak{m}_{A(\bar{D}_n)} A = \mathcal{O}/\ell\mathcal{O}$ is local with residue field k; so A is local and an object of $\mathrm{CNL}_{\mathcal{O}}$. Every object T of $\mathrm{CNL}_{\mathcal{O}}$ is a profinite local $W(k)$-algebra with residue field k, and local homomorphisms between such rings are continuous; hence morphisms $A \to T$ of $\mathrm{CNL}_{\mathcal{O}}$ correspond to continuous $W(k)$-algebra homomorphisms $A(\bar{D}_n) \to T$, and by (Ch2) (A, D_A) represents continuous T-valued determinants of dimension n on Γ_L^0 lifting $\bar{D}_n$.

Step 3: the characters and the product. For $v \mid \ell$ and $1 \leq a \leq n$, Theorem B.71, item 1, with $n = 1$ applied to D_v and $\bar{\Psi}^{w_{n,a}}|_{D_v}$ gives an object $R_{v,a}$ and a universal continuous character $\chi_{v,a}\colon D_v \to R_{v,a}^\times$ lifting $\bar{\Psi}^{w_{n,a}}$. The completed tensor product S over $\mathcal{O}$ of A and the finitely many $R_{v,a}$ is the coproduct in $\mathrm{CNL}_{\mathcal{O}}$; with D_S the base change of D_A and $\psi_{S,v,a}$ the image of $\chi_{v,a}$, S represents the tuples $(D, (\psi_{v,a}))$ of a continuous determinant lifting $\bar{D}_n$ and continuous characters lifting $\bar{\Psi}^{w_{n,a}}$.

Step 4: the conditions. Let $I \subseteq S$ be generated by the coefficients of $\chi_{D_S}(\pi_L(cg^{-1}c)) - \chi_{D_S}(\pi_L(g))$ ($g \in G_L$) and the elements $\mathrm{tr}_{D_S}(\gamma \prod_{a=1}^{n}(\pi_L(g_a) - \psi_{S,v,a}(g_a)))$ ($\gamma \in \Gamma_L^0$, $v \mid \ell$, $g_a \in D_v$; $D_v \subseteq G_L$ because v splits in L by (Af2), $\ell \mid M$). By the base-change rules recalled above, a morphism $f\colon S \to T$ kills I if and only if $(f \circ D_S, (f \circ \psi_{S,v,a}))$ satisfies (Od1) and (Od2). Moreover $I \subseteq \mathfrak{m}_S$: modulo $\mathfrak{m}_S$ the generators are computed from $\bar\rho$ and $\bar\Psi^{w_{n,a}}$; $\bar\Psi(cg^{-1}c) = \bar\Psi(g)^{-1}$ ($\bar\Psi(c) = 1$, abelian image) and $\{-w_{n,a}\} = \{w_{n,a}\}$, so $\bar\rho(\pi_L(cg^{-1}c))$ and $\bar\rho(\pi_L(g))$ have the same characteristic polynomial; and $\bar\rho(\prod_a(\pi_L(g_a) - \bar\Psi(g_a)^{w_{n,a}}))$ is a product of diagonal matrices whose a-th factor has (a,a)-entry 0, hence 0. Put $B = S/I$ with the images D^{u}, $\psi^{\mathrm{d}}_{v,a}$ of D_S, $\psi_{S,v,a}$. Then $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ is a universal polarised ordinary determinant of rank n over L.

(Ht1), the comparison morphism. $(\det \circ \rho^{\mathrm{u}}, (\psi^{\mathrm{u}}_{v,a}))$ is a polarised ordinary determinant to R: the maps $\gamma \mapsto \Lambda_i(\gamma)$ are polynomials in the entries of $\rho^{\mathrm{u}}(\gamma)$, continuous by (Po1); modulo $\mathfrak{m}_R$, $\det \circ \rho^{\mathrm{u}}$ is $\det \circ \bar\rho = \bar D_n$ and $\psi^{\mathrm{u}}_{v,a} \equiv \bar\Psi^{w_{n,a}}$ by (Po5); (Od1) holds because $\rho^{\mathrm{u}}(\pi_L(cg^{-1}c)) = J_n\, {}^t\rho^{\mathrm{u}}(\pi_L(g))\, J_n$ (Po2) has the characteristic polynomial of $\rho^{\mathrm{u}}(\pi_L(g))$; (Od2) holds because $\rho^{\mathrm{u}}(\gamma \prod_a(\pi_L(g_a) - \psi^{\mathrm{u}}_{v,a}(g_a))) = \rho^{\mathrm{u}}(\gamma) \cdot 0$ by (Po4). So ϑ exists.

(Ht1), $\vartheta(B) \subseteq W$. Let $X \subseteq B$ consist of the $\Lambda_i(\gamma)$ of D^{u} ($1 \le i \le n$, $\gamma \in \Gamma_L^0$) and the $\psi^{\mathrm{d}}_{v,a}(g)$. If two morphisms $f, f'\colon B \to T$ agree on X, then $f \circ D^{\mathrm{u}}$ and $f' \circ D^{\mathrm{u}}$ have the same characteristic polynomials at all γ, hence are equal by (Ch1), and $f \circ \psi^{\mathrm{d}}_{v,a} = f' \circ \psi^{\mathrm{d}}_{v,a}$; by uniqueness in the universal property $f = f'$. By Lemma 50.27, $B = \mathcal{O}[X] + \mathfrak{m}_B^k$ for every k. Now $\vartheta(\Lambda_i(\gamma))$ is the sum, with signs, of the principal $i \times i$ minors of $\rho^{\mathrm{u}}(\gamma)$, i.e. of products $\prod_{a \in S'} \rho^{\mathrm{u}}(\gamma)_{\sigma(a)a}$ with $S' \subseteq \{1, \dots, n\}$ and σ a permutation of S', whose weight is $\sum_{a \in S'}(w_{n,\sigma(a)} - w_{n,a}) = 0$; and $\vartheta(\psi^{\mathrm{d}}_{v,a}(g)) = \psi^{\mathrm{u}}_{v,a}(g)$. So $\vartheta(\mathcal{O}[X])$ lies in the $\mathcal{O}$-algebra W_0 generated by the weight-zero monomials and the values of the $\psi^{\mathrm{u}}_{v,a}$. For $y \in B$ and $k \ge 1$ write $y = y_0 + m$ with $y_0 \in \mathcal{O}[X]$, $m \in \mathfrak{m}_B^k$; then $\vartheta(y) - \vartheta(y_0) \in \mathfrak{m}_R^k$ with $\vartheta(y_0) \in W_0$. Hence $\vartheta(y) \in W$.

(Ht1), $W \subseteq \vartheta(B)$.

Step 5: the image. Put $A' = \vartheta(B) \cong B/\ker\vartheta$, a complete Noetherian local ring, hence Henselian, with maximal ideal $\vartheta(\mathfrak{m}_B) = A' \cap \mathfrak{m}_R$ (the image of $\mathfrak{m}_B$ is a maximal ideal of A' contained in $\mathfrak{m}_R$) and residue field k; so an element of A' outside $\mathfrak{m}_R$ is a unit of A'. A' is closed in R: $B = \varprojlim B/\mathfrak{m}_B^k$ is compact, ϑ is continuous ($\vartheta(\mathfrak{m}_B^k) \subseteq \mathfrak{m}_R^k$) and R is Hausdorff (Krull). Let $\mathcal{S} \subseteq \mathrm{M}_n(R)$ be the A'-submodule spanned by $\rho^{\mathrm{u}}(\Gamma_L^0)$; it contains 1 and is closed under products, and $\mathrm{tr}(Y) \in A'$ for $Y \in \mathcal{S}$, since $\mathrm{tr}\,\rho^{\mathrm{u}}(\gamma) = \vartheta(\Lambda_1(\gamma))$.

Step 6: the difference at the marking is diagonal. Let $Z = \rho^{\mathrm{u}}(\pi_L(g_\star)) - \rho^{\mathrm{u}}(\pi_L(cg_\star^{-1}c)) \in \mathcal{S}$ ($g_\star \in G_L$ by (Af1)). Its off-diagonal entries vanish by (Po3), and by (Po2) its (a,a)-entry is $x_a - x_{\bar a}$ with $x_a = \rho^{\mathrm{u}}(\pi_L(g_\star))_{aa}$. With $\zeta = x_1 - x_n$ this gives

$$Z = \zeta \cdot Y, \qquad Y = \mathrm{diag}(w_{n,1}, \dots, w_{n,n})$$

(for $n = 3$ the middle entry is $x_2 - x_2 = 0$). By (Po5), $\zeta \equiv \bar\Psi(g_\star) - \bar\Psi(g_\star)^{-1} \pmod{\mathfrak{m}_R}$, which is non-zero because $\bar\Psi(g_\star)^2 \ne 1$ ($g_\star$ is a marking); so $\zeta \in R^\times$.

Step 7: $\zeta \in A'$. $\mathrm{tr}(Z^2) = \zeta^2 \sum_a w_{n,a}^2 = 2\zeta^2 \in A'$, and $2 \in \mathcal{O}^\times$ (ℓ odd), so $\zeta^2 \in A'$. Choose $o \in \mathcal{O}$ with $\zeta \equiv o \pmod{\mathfrak{m}_R}$; then $o \in \mathcal{O}^\times$, $o^2 - \zeta^2 = (o-\zeta)(o+\zeta) \in A' \cap \mathfrak{m}_R$, and the derivative $2o$ of $X^2 - \zeta^2$ at o is a unit. Hensel's lemma in A' gives $d \in A'$ with $d^2 = \zeta^2$ and $d \equiv o$. Then $(d-\zeta)(d+\zeta) = 0$ in R and $d + \zeta \equiv 2o$ is a unit, so $\zeta = d \in A'$, a unit of A'. Hence $Y = \zeta^{-1}Z \in \mathcal{S}$.

Step 8: the matrix units on the diagonal. With e_{ab} the matrix units, $e_{aa} = \frac{1}{2}(Y^2 + Y)$ if $w_{n,a} = 1$, $e_{aa} = \frac{1}{2}(Y^2 - Y)$ if $w_{n,a} = -1$, and $e_{22} = 1 - Y^2$ if $n = 3$ (the weights are distinct); so $e_{aa} \in \mathcal{S}$ for all a.

Step 9: entry modules. For $1 \le a, b \le n$ let $\mathcal{E}_{ab} \subseteq R$ be the A'-submodule spanned by the entries $\rho^{\mathrm{u}}(\gamma)_{ab}$, $\gamma \in \Gamma_L^0$. Then $z \in \mathcal{E}_{ab}$ if and only if $z\, e_{ab} \in \mathcal{S}$: the set of such z is an A'-module containing each $\rho^{\mathrm{u}}(\gamma)_{ab}$, because $e_{aa}\rho^{\mathrm{u}}(\gamma)e_{bb} = \rho^{\mathrm{u}}(\gamma)_{ab}e_{ab}$; conversely the (a,b)-entry

of an element of $\mathcal{S}$ lies in $\mathcal{E}_{ab}$. Consequently: (i) $\mathcal{E}_{ab}\mathcal{E}_{bc} \subseteq \mathcal{E}_{ac}$, since $(z\,e_{ab})(z'e_{bc}) = zz'e_{ac}$; (ii) $\mathcal{E}_{aa} \subseteq A'$, since $z = \mathrm{tr}(z\,e_{aa})$; (iii) $\mathcal{E}_{ab} = \mathcal{E}_{\bar{b}\bar{a}}$, since by (Po2) $\rho^{\mathrm{u}}(\pi_L(cg^{-1}c))_{\bar{b}\bar{a}} = \rho^{\mathrm{u}}(\pi_L(g))_{ab}$, and $cg^{-1}c \in G_L$ for $g \in G_L$. Call $w_{n,a} - w_{n,b}$ the weight of (a,b); $(\bar{b},\bar{a})$ has the same weight.

Step 10: pairing positive and negative weights. Let $z \in \mathcal{E}_{ab}$ with $w_{n,a} > w_{n,b}$ and $z' \in \mathcal{E}_{cd}$ with $w_{n,c} < w_{n,d}$. Then $zz' \in \mathcal{E}_{ef}$ for some (e,f) of weight $(w_{n,a} - w_{n,b}) + (w_{n,c} - w_{n,d})$. Indeed, one of $b = c$, $d = a$, $\bar{a} = c$, $d = \bar{b}$ holds: for $n = 2$ the only pair is $(1,2),(2,1)$ with $b = c$; for $n = 3$, with $(a,b) \in \{(1,2),(1,3),(2,3)\}$ and $(c,d) \in \{(2,1),(3,1),(3,2)\}$, a check of the nine pairs gives $b = c$ for $(1,2),(2,1)$ and for $(1,3)$ or $(2,3)$ with $(3,1)$, $(3,2)$; $d = a$ for $(1,2),(3,1)$ and $(1,3),(2,1)$; $\bar{a} = c$ for $(1,2),(3,2)$ and $(2,3),(2,1)$. If $b = c$, $zz' \in \mathcal{E}_{ad}$ by (i); if $d = a$, $z'z \in \mathcal{E}_{cb}$; if $\bar{a} = c$, $z \in \mathcal{E}_{\bar{b}\bar{a}}$ by (iii) and $zz' \in \mathcal{E}_{\bar{b}d}$; if $d = \bar{b}$, $z'z \in \mathcal{E}_{c\bar{a}}$. In each case the weight is the sum, using $w_{n,\bar{a}} = -w_{n,a}$.

Step 11: weight-zero products lie in A'. Claim: if $z_k \in \mathcal{E}_{a_k b_k}$ $(1 \le k \le s)$ and $\sum_k (w_{n,a_k} - w_{n,b_k}) = 0$, then $\prod_k z_k \in A'$. Induction on s; $s = 0$ is clear. If all weights are 0, then $a_k = b_k$ and $z_k \in A'$ by (ii). Otherwise, the weights summing to 0, there are a factor of positive and one of negative weight; by Step 10 their product is an element of some $\mathcal{E}_{ef}$ whose weight is the sum, and replacing the two factors by it leaves the product and the total weight unchanged and lowers s. Every weight-zero monomial is such a product; and $\psi^{\mathrm{u}}_{v,a}(g) = \vartheta(\psi^{\mathrm{d}}_{v,a}(g)) \in A'$. So $W_0 \subseteq A'$; as A' is closed and every element of W is a limit of elements of W_0, $W \subseteq A'$. With the previous part, $\vartheta(B) = W$.

(Ht2).

Step 12: a point of B from the seed. Let r be a seed of rank n and weight $m \ge 2$ for (j,χ') with twist κ, $\tilde{r}$ with $\tilde{r} \circ \pi_L = r$, and $(\kappa_{v,a})_a$ a diagonal of r on D_v as in (Sp5) (for the fixed place $\bar{v}$ above v; $D_v = D_{\bar{v}} \cap G_L$). As G_L and D_v are compact and $\overline{\mathbb{Q}}_\ell$ is a countable union of closed subfields finite over $\mathbb{Q}_\ell$, Baire's theorem gives a finite extension E' of the fraction field of $\mathcal{O}$ containing the values of r and of the $\kappa_{v,a}$; the compact group $r(G_L)$ stabilises an $\mathcal{O}_{E'}$-lattice, so there is $h \in \mathrm{GL}_n(E')$ with $\tilde{r}' = h\tilde{r}h^{-1}$ valued in $\mathrm{GL}_n(\mathcal{O}_{E'})$, and the $\kappa_{v,a}$ take values in $\mathcal{O}_{E'}^\times$. Let $A_0 \subseteq \mathcal{O}_{E'}$ be the subring of elements with residue in $\mathbb{F}_{\mathcal{O}}$: it contains $\mathcal{O}$ and $\mathfrak{m}_{E'}$, is local with maximal ideal $\mathfrak{m}_{E'}$ and residue field $\mathbb{F}_{\mathcal{O}}$, and is a finitely generated $\mathcal{O}$-module (a submodule of $\mathcal{O}_{E'}$), hence an object of $\mathrm{CNL}_{\mathcal{O}}$ whose topology is the ℓ-adic one, induced from $\mathcal{O}_{E'}$. By (Sp3) and (Ag1) ($\chi^j_{\mathrm{cyc}}\chi' \equiv \Psi$), the characteristic polynomial of $\tilde{r}'(\gamma)$ has coefficients in $\mathcal{O}_{E'}$ congruent to those of $\prod_a (X - \bar{\Psi}(\gamma)^{w_{n,a}})$, which lie in $\mathbb{F}_{\mathcal{O}}$; so the $\Lambda_i(\gamma)$ of $\det \circ \tilde{r}'$ lie in A_0, and by (Ch1) $\det \circ \tilde{r}'$ is the base change of an A_0-valued determinant D_0. D_0 is continuous (Λ_i is a polynomial in the entries), and its reduction is $\bar{D}_n$ by (Ch1) (same characteristic polynomials). By (Sp5) and (Ag1), $\kappa_{v,a} \equiv \varphi_a \equiv \bar{\Psi}^{w_{n,a}}$, so $\kappa_{v,a}$ is a continuous character $D_v \to A_0^\times$ lifting $\bar{\Psi}^{w_{n,a}}$. (Od1): by (Sp2), $r(cs^{-1}c) = P^{-1}\,{}^t r(s)\,P$, which has the characteristic polynomial of $r(s)$. (Od2): in a basis in which $r|_{D_v}$ is upper triangular with diagonal $(\kappa_{v,1},\dots,\kappa_{v,n})$, the a-th factor of $\prod_{a=1}^n (r(g_a) - \kappa_{v,a}(g_a))$ is upper triangular with (a,a)-entry 0, so it maps $\langle e_1,\dots,e_a\rangle$ into $\langle e_1,\dots,e_{a-1}\rangle$ and the product ($a = 1$ on the left) is 0; hence $\mathrm{tr}(\tilde{r}'(\gamma)\prod_a(\cdots)) = 0$. (These identities hold in $A_0 \subseteq \mathcal{O}_{E'}$.) So $(D_0,(\kappa_{v,a}))$ is a polarised ordinary determinant to A_0; let $x_0 \colon B \to A_0$ classify it and $x \colon B \to \overline{\mathbb{Q}}_\ell$ be x_0 followed by the inclusion. Then x is a homomorphism of $\mathcal{O}$-algebras with $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}' = \det \circ \tilde{r}$ and $x \circ \psi^{\mathrm{d}}_{v,a} = \kappa_{v,a}$, so $x(\mathcal{J}) = 0$ by hypothesis.

Step 13: the component. $\ker x$ is a prime containing $\mathcal{J}$; let $\mathfrak{Z} \subseteq \ker x$ be a minimal prime over $\mathcal{J}$, so $\dim B/\mathfrak{Z} = 1 + n\,d_L$. By (Sp2), P is symmetric and invertible, and over the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic $\neq 2$ there is $Q \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with ${}^t Q J_n Q = P$ (both forms are congruent to the identity). Put $\rho' = Q\tilde{r}Q^{-1}$; then ${}^t\rho'(s) J_n \rho'(csc) = J_n$, and with $s = g^{-1}$, $\rho'(\pi_L(cg^{-1}c)) = J_n\,{}^t\rho'(\pi_L(g))\,J_n$. ρ' is irreducible by (Sp1) and $x \circ D^{\mathrm{u}} = \det \circ \rho'$. Proposition 50.28, applied to $\mathfrak{q} = \mathfrak{Z}$, $\Omega' = \overline{\mathbb{Q}}_\ell$, $\phi = x$ and ρ', gives $\ker\vartheta \subseteq \mathfrak{Z}$ and a prime ξ of

E_n^{po} of irreducible type with $\xi \cap W = \vartheta(\mathfrak{Z})$. As ϑ is onto W, $\mathfrak{z} = \vartheta(\mathfrak{Z})$ is an ideal of W with $W/\mathfrak{z} \cong B/(\mathfrak{Z} + \ker\vartheta) = B/\mathfrak{Z}$, a domain of dimension $1 + n\,d_L$; and $\mathcal{M}_{\mathcal{J}} = \vartheta(\mathcal{J})W = \vartheta(\mathcal{J}) \subseteq \mathfrak{z} = \xi \cap W$. So $\mathcal{M}_{\mathcal{J}}$ has a seed component. □

Lemma 50.27. *Let $\mathcal{O}$ be a coefficient ring, S an object of $\mathrm{CNL}_{\mathcal{O}}$ and $X \subseteq S$ a subset such that any two morphisms $f, f' \colon S \to T$ of $\mathrm{CNL}_{\mathcal{O}}$ with $f(x) = f'(x)$ for all $x \in X$ are equal. Then $S = \mathcal{O}[X] + \mathfrak{m}_S^k$ for every $k \geq 1$, where $\mathcal{O}[X]$ is the $\mathcal{O}$-subalgebra of S generated by X; that is, $\mathcal{O}[X]$ is dense in S.*

Proof. Fix $k \geq 1$, put $S_k = S/\mathfrak{m}_S^k$, $\mathfrak{m}_k = \mathfrak{m}_S/\mathfrak{m}_S^k$, and let $C_k \subseteq S_k$ be the image of $\mathcal{O}[X]$. We show $C_k = S_k$.

Step 1: the rings. S_k is a finite set: it has finite length with residue field $\mathbb{F}_{\mathcal{O}}$, which is finite. $\mathfrak{n} = C_k \cap \mathfrak{m}_k$ is a nilpotent ideal of C_k; since $\mathcal{O} \to \mathbb{F}_{\mathcal{O}}$ is onto and the image of $\mathcal{O}$ lies in C_k, $C_k/\mathfrak{n} = \mathbb{F}_{\mathcal{O}}$. An element of $C_k \setminus \mathfrak{n}$ is $o + y$ with o the image of a unit of $\mathcal{O}$ and $y \in \mathfrak{n}$ nilpotent, hence a unit of C_k. So C_k is local with maximal ideal $\mathfrak{n}$ and residue field $\mathbb{F}_{\mathcal{O}}$, and S_k is a finite C_k-module. Let $T = S_k \otimes_{C_k} S_k$, a finite ring and an $\mathcal{O}$-algebra through C_k. The ideal N generated by $\mathfrak{m}_k \otimes 1$ and $1 \otimes \mathfrak{m}_k$ is generated by finitely many nilpotent elements, hence nilpotent, and $T/N = \mathbb{F}_{\mathcal{O}} \otimes_{C_k} \mathbb{F}_{\mathcal{O}} = \mathbb{F}_{\mathcal{O}}$ because $C_k \to \mathbb{F}_{\mathcal{O}}$ is onto. Hence T is a local Artinian ring with residue field $\mathbb{F}_{\mathcal{O}}$, an object of $\mathrm{CNL}_{\mathcal{O}}$.

Step 2: the two morphisms agree. The maps $i_1, i_2 \colon S \to T$, $i_1(s) = \bar{s} \otimes 1$, $i_2(s) = 1 \otimes \bar{s}$, are local $\mathcal{O}$-algebra homomorphisms, i.e. morphisms of $\mathrm{CNL}_{\mathcal{O}}$, and $i_1(x) = i_2(x)$ for $x \in X$ because $\bar{x} \in C_k$. By hypothesis $i_1 = i_2$: $s \otimes 1 = 1 \otimes s$ in T for all $s \in S_k$.

Step 3: $C_k = S_k$. By Step 2 every element of T has the form $\sum_i s_i \otimes t_i = \sum_i s_i t_i \otimes 1$, so the multiplication map $\mu \colon T \to S_k$, which satisfies $\mu(a \otimes 1) = a$, is a bijection; it is C_k-linear. Let $d = \dim_{\mathbb{F}_{\mathcal{O}}} S_k/\mathfrak{n}S_k$; $d \geq 1$ since $\mathfrak{n}S_k \subseteq \mathfrak{m}_k \neq S_k$. Then

$$T \otimes_{C_k} \mathbb{F}_{\mathcal{O}} \cong (S_k/\mathfrak{n}S_k) \otimes_{\mathbb{F}_{\mathcal{O}}} (S_k/\mathfrak{n}S_k)$$

has dimension d^2, while μ identifies it with $S_k \otimes_{C_k} \mathbb{F}_{\mathcal{O}}$, of dimension d. So $d = 1$, i.e. $S_k = C_k \cdot 1 + \mathfrak{n}S_k$, and since $\mathfrak{n}$ is nilpotent, iterating gives $S_k = C_k + \mathfrak{n}^j S_k$ for all j, hence $S_k = C_k$ (Nakayama's lemma).

Thus every $s \in S$ is congruent modulo $\mathfrak{m}_S^k$ to an element of $\mathcal{O}[X]$. □

Proposition 50.28. *Let L be a CM field satisfying (Af1) and (Af2) for $(K, \mathcal{O}, \Psi, c, g_\star, M)$, $n \in \{2, 3\}$, and let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ and $(R_n^{\mathrm{po}}, \rho^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{u}}))$ be a universal polarised ordinary determinant and a universal polarised ordinary lift of rank n over L such that the comparison morphism ϑ_n exists and $\vartheta_n(B_n^{\mathrm{po}}) = W_n^{\mathrm{po}}$. Let $\mathfrak{q}$ be a prime of B_n^{po}, and suppose that there are an algebraically closed field Ω', a homomorphism of $\mathcal{O}$-algebras $\phi \colon B_n^{\mathrm{po}} \to \Omega'$ with $\mathfrak{q} \subseteq \ker\phi$, and a homomorphism $\rho' \colon \Gamma_L^0 \to \mathrm{GL}_n(\Omega')$, irreducible, with $\rho'(\pi_L(cg^{-1}c)) = J_n\,{}^t\rho'(\pi_L(g))\,J_n$ for all $g \in G_L$ and $\phi \circ D^{\mathrm{u}} = \det \circ \rho'$. Then:*

(Mk1) $\ker\vartheta_n \subseteq \mathfrak{q}$;

(Mk2) *there is a prime ξ of E_n^{po} of irreducible type with $\xi \cap W_n^{\mathrm{po}} = \vartheta_n(\mathfrak{q})$.*

Proof. Recall $w_{n,\bar{a}} = -w_{n,a}$, the $w_{n,a}$ are distinct elements of $\{1, 0, -1\}$, and $(J_n\,{}^tXJ_n)_{ab} = X_{\bar{b}\bar{a}}$. Since $c^2 = 1$, $(\gamma^*)^* = \gamma$ and $(\gamma\delta)^* = \delta^*\gamma^*$; for $\gamma = \pi_L(g)$, $g \in G_L$, $\gamma^* = \pi_L(cg^{-1}c)$. Put $\gamma_\star = \pi_L(g_\star)$ ($g_\star \in G_L$ by (Af1)). For a field F the trace form $(X, Y) \mapsto \mathrm{tr}(XY)$ on $\mathrm{M}_n(F)$ is non-degenerate ($\mathrm{tr}(e_{ab}e_{ba}) = 1$ for the matrix units). Every representation below is extended

linearly to the group ring; for a ring homomorphism f, $\mathrm{tr}_{f\circ D}(f_*x) = f(\mathrm{tr}_D(x))$ and $\chi_{f\circ D}(f_*x) = f(\chi_D(x))$.

Step 1: the generic determinant. $C = B/\mathfrak{q}$ is a quotient of an object of $\mathrm{CNL}_{\mathcal{O}}$ by a prime, so a domain and an object of $\mathrm{CNL}_{\mathcal{O}}$; let $\nu\colon B \to C$ be the projection, Ω an algebraic closure of the fraction field of C and $\iota\colon C \to \Omega$ the inclusion. Put $D_C = \nu\circ D^{\mathrm{u}}$, $\psi_{C,v,a} = \nu\circ\psi^{\mathrm{d}}_{v,a}$, $D_\Omega = \iota\circ D_C$. D_C is continuous, and reduces modulo $\mathfrak{m}_C$ to $\bar{D}_n = \det\circ\bar{\rho}$, $\bar{\rho} = \mathrm{diag}(\bar{\Psi}^{w_{n,1}},\dots,\bar{\Psi}^{w_{n,n}})$; so for $x \in C[\Gamma_L^0]$ the residue of $\mathrm{tr}_{D_C}(x)$ is $\mathrm{tr}\,\bar{\rho}(\bar{x})$, $\bar{x}$ the reduction of x. As $\mathfrak{q} \subseteq \ker\phi$, $\phi = \phi'\circ\nu$ for an $\mathcal{O}$-algebra homomorphism $\phi'\colon C \to \Omega'$, and $\phi'\circ D_C = \det\circ\rho'$. Both Ω and Ω' have characteristic $\neq 2$, since $2 \in \mathcal{O}^\times$. By (Ch3) of Theorem B.83 there is a semisimple $\rho_0\colon \Gamma_L^0 \to \mathrm{GL}_n(\Omega)$ with $\det\circ\rho_0 = D_\Omega$; then $\mathrm{tr}\,\rho_0(x) = \iota(\mathrm{tr}_{D_C}(x))$ for $x \in C[\Gamma_L^0]$.

Step 2: ρ_0 is irreducible; its Ω-span is $\mathrm{M}_n(\Omega)$. By Burnside's theorem the Ω'-span of $\rho'(\Gamma_L^0)$ is $\mathrm{M}_n(\Omega')$; choose $\gamma_1,\dots,\gamma_{n^2}$ with $\rho'(\gamma_i)$ a basis. By non-degeneracy of the trace form, $\det(\mathrm{tr}\,\rho'(\gamma_i\gamma_k))_{i,k} \neq 0$. This is $\phi'(G)$ with $G = \det(\mathrm{tr}_{D_C}(\gamma_i\gamma_k)) \in C$, so $G \neq 0$ and $\iota(G) = \det(\mathrm{tr}\,\rho_0(\gamma_i\gamma_k)) \neq 0$. If $\sum_i y_i\rho_0(\gamma_i) = 0$ with $y_i \in \Omega$, multiplying by $\rho_0(\gamma_k)$ and taking traces gives $\sum_i y_i\,\mathrm{tr}\,\rho_0(\gamma_i\gamma_k) = 0$ for all k, so $y = 0$. Hence the $\rho_0(\gamma_i)$ span $\mathrm{M}_n(\Omega)$, and ρ_0 is irreducible (a proper invariant subspace would be invariant under all of $\mathrm{M}_n(\Omega)$). Consequently a matrix X with $\mathrm{tr}(\rho_0(\gamma)X) = 0$ for all γ is 0, and a matrix commuting with all $\rho_0(\gamma)$, or with all ${}^t\rho_0(\gamma)$, is scalar.

Step 3: a symmetric invariant form. $\rho_1(\gamma) = {}^t\rho_0(\gamma^*)$ is a homomorphism: ${}^t\rho_0((\gamma\delta)^*) = {}^t(\rho_0(\delta^*)\rho_0(\gamma^*)) = \rho_1(\gamma)\rho_1(\delta)$. Its Ω-span is ${}^t\mathrm{M}_n(\Omega) = \mathrm{M}_n(\Omega)$, so it is irreducible. For $\gamma = \pi_L(g)$, (Od1) gives $\chi_{D^{\mathrm{u}}}(\gamma^*) = \chi_{D^{\mathrm{u}}}(\gamma)$, so $\rho_1(\gamma)$ and $\rho_0(\gamma)$ have the same characteristic polynomial; by (Ch1), $\det\circ\rho_1 = \det\circ\rho_0$, and by the uniqueness in (Ch3) there is $P \in \mathrm{GL}_n(\Omega)$ with ${}^t\rho_0(\gamma^*)P = P\rho_0(\gamma)$ for all γ. Replacing γ by γ^* gives $\rho_0(\gamma^*) = P^{-1}\,{}^t\rho_0(\gamma)P$, and transposing the first identity gives $\rho_0(\gamma^*) = {}^tP^{-1}\,{}^t\rho_0(\gamma)\,{}^tP$. So ${}^tPP^{-1}$ commutes with every ${}^t\rho_0(\gamma)$, hence ${}^tP = \lambda P$ with $\lambda \in \Omega$, and $P = \lambda^2 P$ gives $\lambda = \pm 1$. Suppose $\lambda = -1$. If $n = 3$, $\det P = \det{}^tP = -\det P$, impossible. If $n = 2$, $P = p\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ with $p \neq 0$, and $P^{-1}\,{}^tXP = \mathrm{tr}(X)\cdot 1 - X$ for every 2×2 matrix X ; so $\rho_0(\gamma^*) = \mathrm{tr}\,\rho_0(\gamma) - \rho_0(\gamma)$, and multiplying by $\rho_0(x)$ and taking traces, $\mathrm{tr}\,\rho_0(x\gamma) + \mathrm{tr}\,\rho_0(x\gamma^*) = \mathrm{tr}\,\rho_0(x)\,\mathrm{tr}\,\rho_0(\gamma)$ for $x,\gamma \in \Gamma_L^0$. This is ι of an identity between traces of D_C; as ι is injective it holds in C, and ϕ' carries it to $\mathrm{tr}(\rho'(x)Y_\gamma) = 0$ with $Y_\gamma = \rho'(\gamma) + \rho'(\gamma^*) - \mathrm{tr}\,\rho'(\gamma)\cdot 1$. By hypothesis $\rho'(\gamma^*) = J_2\,{}^t\rho'(\gamma)J_2$, and the Ω'-span of $\rho'(\Gamma_L^0)$ is $\mathrm{M}_2(\Omega')$, so $Y_\gamma = 0$; its $(1,2)$-entry is $2\rho'(\gamma)_{12}$. Thus $\rho'(\gamma)_{12} = 0$ for all γ and the second basis vector spans a ρ'-stable line, contradicting irreducibility. Hence ${}^tP = P$, and

$$\rho_0(\gamma^*) = P^{-1}\,{}^t\rho_0(\gamma)\,P \qquad (\gamma \in \Gamma_L^0). \tag{50.1}$$

Step 4: the square root at the marking. Let $x_\star = (\gamma_\star - \gamma_\star^*)^2 \in C[\Gamma_L^0]$ and $t = \frac{1}{2}\,\mathrm{tr}_{D_C}(x_\star) \in C$. Put $u = \bar{\Psi}(g_\star)$. Then $\bar{\Psi}(cg_\star^{-1}c) = u^{-1}$ and

$$\bar{\rho}(\gamma_\star) - \bar{\rho}(\gamma_\star^*) = \mathrm{diag}\big(u^{w_{n,a}} - u^{-w_{n,a}}\big)_a = \bar{\zeta}\,\mathrm{diag}(w_{n,1},\dots,w_{n,n})$$

with $\bar{\zeta} = u - u^{-1}$, since $w_{n,a} \in \{1,0,-1\}$; so the residue of t is $\frac{1}{2}\bar{\zeta}^2\sum_a w_{n,a}^2 = \bar{\zeta}^2$, and $\bar{\zeta} \neq 0$ because $u^2 \neq 1$ ($g_\star$ is a marking). C is complete local and $X^2 - t$ has the simple root $\bar{\zeta}$ modulo $\mathfrak{m}_C$ ($2\bar{\zeta} \neq 0$); by Hensel's lemma there is $\zeta \in C$ with $\zeta^2 = t$ and $\zeta \equiv \bar{\zeta}$, a unit of C.

Step 5: the normal form. Let $Z_0 = \rho_0(\gamma_\star) - \rho_0(\gamma_\star^*)$. By (50.1) and $(\gamma^*)^* = \gamma$, $P^{-1}\,{}^tZ_0P = \rho_0(\gamma_\star^*) - \rho_0(\gamma_\star) = -Z_0$. For the symmetric non-degenerate form $\langle y, y'\rangle = {}^tyPy'$ this says $\langle y, Z_0y'\rangle = -\langle Z_0y, y'\rangle$, and $\det(X + Z_0) = \det(X - {}^tZ_0) = \det(X - Z_0)$; so the characteristic polynomial of Z_0 is $X^2 + s$ ($n = 2$) or $X^3 + sX$ ($n = 3$), and comparing with $\mathrm{tr}(Z_0^2) = \iota(\mathrm{tr}_{D_C}(x_\star)) = 2\zeta^2$ gives $s = -\zeta^2$. Since $\zeta \neq 0$ and $2 \neq 0$ in Ω, Z_0 has the distinct eigenvalues

$\zeta, -\zeta$ (and 0 if $n = 3$); let e_+, e_- (and e_0) be eigenvectors. For eigenvectors y, y' with eigenvalues μ, μ', $\mu'\langle y, y'\rangle = -\mu\langle y, y'\rangle$, so $\langle y, y'\rangle = 0$ unless $\mu + \mu' = 0$: $\langle e_\pm, e_\pm\rangle = 0$, $\langle e_0, e_\pm\rangle = 0$, and by non-degeneracy $\alpha = \langle e_+, e_-\rangle \neq 0$ and $\beta = \langle e_0, e_0\rangle \neq 0$. Let $H \in \mathrm{GL}_n(\Omega)$ have the columns $e_+, \alpha^{-1}e_-$ ($n = 2$), resp. $e_+, \beta^{-1/2}e_0, \alpha^{-1}e_-$ ($n = 3$; a square root exists in Ω). Then ${}^tHPH = J_n$ and $H^{-1}Z_0H = \zeta\,\mathrm{diag}(w_{n,1}, \dots, w_{n,n})$. Put $\rho = H^{-1}\rho_0 H$ and $\psi_{v,a} = \iota \circ \psi_{C,v,a}$. By (50.1), $\rho(\gamma^*) = ({}^tHPH)^{-1}\,{}^t\rho(\gamma)\,({}^tHPH) = J_n\,{}^t\rho(\gamma)J_n$: this is (Po2). And

$$\rho(\gamma_\star) - \rho(\gamma_\star^*) = \zeta\,\mathrm{diag}(w_{n,1}, \dots, w_{n,n}), \tag{50.2}$$

which gives (Po3). ρ is irreducible with Ω-span $\mathrm{M}_n(\Omega)$, and $\mathrm{tr}\,\rho(x) = \iota(\mathrm{tr}_{D_C}(x))$. (Po4): for $v \mid \ell$ and $g_1, \dots, g_n \in D_v$ ($D_v \subseteq G_L$ by (Af2)) let $X = \prod_a(\rho(\pi_L(g_a)) - \psi_{v,a}(g_a))$; by (Od2), $\mathrm{tr}(\rho(\gamma)X) = \iota(\mathrm{tr}_{D_C}(\gamma\prod_a(\pi_L(g_a) - \psi_{C,v,a}(g_a)))) = 0$ for all γ, so $X = 0$ by Step 2.

Step 6: idempotents and residues. Let $y_\star = \zeta^{-1}(\gamma_\star - \gamma_\star^*) \in C[\Gamma_L^0]$ and $x_a = \frac{1}{2}(y_\star^2 + y_\star)$ if $w_{n,a} = 1$, $x_a = \frac{1}{2}(y_\star^2 - y_\star)$ if $w_{n,a} = -1$, $x_2 = 1 - y_\star^2$ if $n = 3$. By (50.2), $\rho(y_\star) = \mathrm{diag}(w_{n,a})$ and $\rho(x_a) = e_{aa}$; by Step 4, $\bar\rho(\bar y_\star) = \bar\zeta^{-1}(\bar\rho(\gamma_\star) - \bar\rho(\gamma_\star^*)) = \mathrm{diag}(w_{n,a})$ and $\bar\rho(\bar x_a) = e_{aa}$. Identify C with $\iota(C) \subseteq \Omega$. Then for $\gamma, \delta \in \Gamma_L^0$:

$$\rho(\gamma)_{aa} = \mathrm{tr}\,\rho(x_a\gamma) = \mathrm{tr}_{D_C}(x_a\gamma) \in C, \qquad \rho(\gamma)_{ab}\rho(\delta)_{ba} = \mathrm{tr}\,\rho(x_a\gamma x_b\delta) = \mathrm{tr}_{D_C}(x_a\gamma x_b\delta) \in C,$$

with residues $\mathrm{tr}(e_{aa}\bar\rho(\gamma)) = \bar\Psi(\gamma)^{w_{n,a}}$ and $\mathrm{tr}(e_{aa}\bar\rho(\gamma)e_{bb}\bar\rho(\delta)) = \bar\rho(\gamma)_{ab}\bar\rho(\delta)_{ba}$, which is 0 for $a \neq b$ ($\bar\rho$ is diagonal). So the diagonal entries of ρ lie in C with residues $\bar\Psi^{w_{n,a}}$, and $\rho(\gamma)_{ab}\rho(\delta)_{ba} \in \mathfrak{m}_C$ for $a \neq b$.

Step 7: entry modules. Let $\mathcal{S} \subseteq \mathrm{M}_n(\Omega)$ be the C-span of $\rho(\Gamma_L^0)$, a C-algebra containing the $e_{aa} = \rho(x_a)$, with $\mathrm{tr}(\mathcal{S}) \subseteq C$; let $M_{ab} \subseteq \Omega$ be the C-span of the $\rho(\gamma)_{ab}$. Then $z \in M_{ab}$ if and only if $z\,e_{ab} \in \mathcal{S}$ (the (a,b)-entries of elements of $\mathcal{S}$ lie in M_{ab}, and $e_{aa}\rho(\gamma)e_{bb} = \rho(\gamma)_{ab}e_{ab}$). Hence: (i) $M_{ab}M_{bc} \subseteq M_{ac}$; (ii) $M_{aa} \subseteq C$ (as $z = \mathrm{tr}(z\,e_{aa})$) and $1 \in M_{aa}$; (iii) $M_{ab} = M_{\bar b\bar a}$, because $\rho(\gamma^*)_{\bar b\bar a} = \rho(\gamma)_{ab}$ by (Po2) and $\gamma \mapsto \gamma^*$ is bijective; (iv) $M_{ab}M_{ba} \subseteq \mathfrak{m}_C$ for $a \neq b$, by bilinearity and Step 6. Call $w_{n,a} - w_{n,b}$ the weight of (a,b); it is 0 exactly when $a = b$.

Step 8: weight-zero products. (P) If $w_{n,a} > w_{n,b}$ and $w_{n,c} < w_{n,d}$, then one of $b = c$, $d = a$, $\bar a = c$, $d = \bar b$ holds . For $z \in M_{ab}$, $z' \in M_{cd}$ the product zz' then lies in M_{ad}, M_{cb}, $M_{\bar b d}$ resp. $M_{c\bar a}$ (by (i), and (iii) in the last two cases), a module of weight $(w_{n,a} - w_{n,b}) + (w_{n,c} - w_{n,d})$ (using $w_{n,\bar a} = -w_{n,a}$); if this weight is 0, the two factors are of the form M_{pq}, M_{qp} with $p \neq q$ (namely $(a,b),(b,a)$; $(c,a),(a,c)$; $(\bar b,\bar a),(\bar a,\bar b)$; $(\bar a,\bar b),(\bar b,\bar a)$), so $zz' \in \mathfrak{m}_C$ by (iv). Claim: for $z_k \in M_{a_kb_k}$, $1 \le k \le s$, with total weight 0, $\prod_k z_k \in C$, and $\prod_k z_k \in \mathfrak{m}_C$ if some $a_k \neq b_k$. Induction on s; $s = 0$ is clear. If all $a_k = b_k$, use (ii). Otherwise there are factors of positive and of negative weight; combine two of them by (P). If the combined weight is non-zero, the combined factor is off-diagonal and the induction hypothesis applies to $s - 1$ factors. If it is zero, the combined factor lies in $\mathfrak{m}_C$ and the remaining $s - 2$ factors have total weight 0, so their product lies in C by induction. This proves the claim.

Step 9: finiteness and continuity of the entry modules. Write $a \sim b$ if $M_{ab} \neq 0$. By (i) and since Ω is a field, $\sim$ is transitive; by (iii), $a \sim b$ implies $\bar b \sim \bar a$; $a \sim a$ by (ii). Some $a > b$ has $a \sim b$, since otherwise ρ is upper triangular and the first basis vector spans a stable line; likewise some $a < b$ has $a \sim b$ (the last basis vector). For $n = 2$ this gives $2 \sim 1$ and $1 \sim 2$. For $n = 3$: $2 \sim 1$ or $3 \sim 2$ gives the other by (iii) and then $3 \sim 1$ by transitivity, so in all cases $3 \sim 1$, and likewise $1 \sim 3$; then $a \sim b$ implies $b \sim a$. Now fix (a,b) with $M_{ab} \neq 0$ and choose $0 \neq y = \sum_l c_l\rho(\delta_l)_{ba} \in M_{ba}$ ($c_l \in C$; $y = 1$ if $a = b$). The map $\mu\colon M_{ab} \to C$, $z \mapsto zy$, is C-linear (values in $M_{aa} \subseteq C$) and injective; so M_{ab} is isomorphic to an ideal of the Noetherian ring C, hence finitely generated. Next, $\mu(\rho(\gamma)_{ab}) = \sum_l c_l\,\mathrm{tr}_{D_C}(x_a\gamma x_b\delta_l)$ is a C-linear combination of maps $\gamma \mapsto \mathrm{tr}_{D_C}(\eta\gamma\eta')$, $\eta, \eta' \in \Gamma_L^0$, which are continuous because D_C is continuous; so it is locally constant modulo every $\mathfrak{m}_C^N$. By the Artin–Rees lemma for the ideal $\mu(M_{ab})$ there is k_0

with $\mathfrak{m}_C^{N+k_0} \cap \mu(M_{ab}) \subseteq \mathfrak{m}_C^N \mu(M_{ab}) = \mu(\mathfrak{m}_C^N M_{ab})$; as μ is injective, $\gamma \mapsto \rho(\gamma)_{ab}$ is locally constant modulo $\mathfrak{m}_C^N M_{ab}$ for every N. If $M_{ab} = 0$ both statements are trivial.

Step 10: the point of the entry algebra. By Steps 5–9, $\rho\colon \Gamma_L^0 \to \mathrm{GL}_n(\Omega)$ and the $\psi_{v,a}\colon D_v \to \Omega^\times$ satisfy (Po2)–(Po4) and, with $C \subseteq \Omega$: (Cq1) by Step 6, (Cq2) by Step 8 (the entries $\rho(\gamma)_{ab}$ lie in M_{ab}), (Cq3) and (Cq4) by Step 9, and (Cq5) because $\psi_{C,v,a} = \nu \circ \psi_{v,a}^{\mathrm{d}}$ is continuous with values in $C^\times$ and reduces to $\bar{\Psi}^{w_{n,a}}$. By Lemma 49.16 there are $\mathcal{O}$-algebra homomorphisms $\xi_0\colon E \to \Omega$ and $\beta\colon W \to C$ with $\beta(\mathfrak{m}_W) \subseteq \mathfrak{m}_C$, $\xi_0(\rho^{\mathrm{u}}(\gamma)_{ab}) = \rho(\gamma)_{ab}$, $\xi_0(\psi_{v,a}^{\mathrm{u}}(g)) = \psi_{v,a}(g)$ and $\xi_0|_W = \iota \circ \beta$. Let $\xi = \ker \xi_0$, a prime of E as Ω is a field. Some lower entry $\rho(\gamma)_{ab}$ $(a > b)$ and some upper entry are non-zero (Step 9), so $I_E^- \not\subseteq \xi$ and $I_E^+ \not\subseteq \xi$; for $n = 3$, if $\rho(\gamma)_{ab} = 0$ for all γ whenever $w_{3,a} - w_{3,b}$ is odd, the second basis vector spans a stable line; so $I_E^{\mathrm{odd}} \not\subseteq \xi$. Thus ξ is of irreducible type.

Step 11: (Mk1) and (Mk2). Let $f = \beta \circ \vartheta\colon B \to C$ (recall $\vartheta(B) = W$); it is an $\mathcal{O}$-algebra homomorphism with $f(\mathfrak{m}_B) \subseteq \beta(\mathfrak{m}_W) \subseteq \mathfrak{m}_C$, a morphism of $\mathrm{CNL}_{\mathcal{O}}$. For $\gamma \in \Gamma_L^0$ and $1 \le i \le n$, $\vartheta(\Lambda_i(\gamma))$ is the i-th coefficient (up to sign) of the characteristic polynomial of $\rho^{\mathrm{u}}(\gamma)$, a polynomial in its entries, so $\iota(f(\Lambda_i(\gamma))) = \xi_0(\vartheta(\Lambda_i(\gamma)))$ is the same coefficient of $\rho(\gamma)$, i.e. of $\rho_0(\gamma)$, which is ι of the coefficient of $\chi_{D_C}(\gamma)$; by injectivity of ι, $f \circ D^{\mathrm{u}}$ and D_C have the same characteristic polynomials on Γ_L^0, hence are equal by (Ch1). Likewise $\iota(f(\psi_{v,a}^{\mathrm{d}}(g))) = \xi_0(\psi_{v,a}^{\mathrm{u}}(g)) = \iota(\psi_{C,v,a}(g))$. So f and ν both classify $(D_C, (\psi_{C,v,a}))$, and $f = \nu$ by uniqueness. Hence $\ker \vartheta \subseteq \ker f = \mathfrak{q}$, which is (Mk1). For $y = \vartheta(b) \in W$: $y \in \xi$ iff $\iota(\beta(y)) = 0$ iff $\nu(b) = 0$ iff $b \in \mathfrak{q}$; so $\xi \cap W = \vartheta(\mathfrak{q})$, which with Step 10 is (Mk2). □

51 Symplectic automorphy

This section proves Theorem 51.1, the automorphy theorem for the symplectic Eisenstein data attached to the characters of cases (II) and (III), which Proposition 44.3 uses: the datum is finite in weight zero (Sa1), has no endoscopic points (Sa2), and every irreducible point is automorphic (Sa3). The points of a symplectic datum are ordinary test representations, representations of $G_{\mathbb{Q}}$ over the valuation ring of a test field with an ordinary symplectic flag at ℓ (Definition 45.26, Lemma 45.37, Lemma 45.41), and the theorem follows from Theorem 51.4 on such representations. A test representation is essential if it is irreducible or a non-split block extension, and promodular if, after conjugation, its restriction to a fit and deep auxiliary tower is a point of a space of marked pairs at which a modular ideal vanishes (Definition 51.3). The core statement is Proposition 51.5: every essential test representation is promodular. Promodular test representations are not essential in characteristic ℓ, and in characteristic zero they are weakly pure, and automorphic when irreducible (Lemma 51.19).

The plan is that of Sections 48–50 in rank four. The auxiliary objects are totally real towers $\mathscr{T}$ and, over them, spaces of marked ordinary symplectic pairs with modular ideals (Definition 51.2, Definition 51.3). An essential test representation, restricted to a deep tower, is joined by a chain of residual pairs to the reduction of a seed pair (Section 52); every space carries a modular ideal, and modularity propagates along chains (Section 53); and seed pairs exist (Subsection 51.2). Subsection 51.1 proves the theorem from Proposition 51.5 and proves that proposition from these inputs; Subsection 51.3 proves the finiteness in weight zero and excludes endoscopic points through block extensions.

51.1 Automorphy at ordinary test representations and promodularity

This subsection proves Theorem 51.1 from Theorem 51.4, and Theorem 51.4 from Proposition 51.5 and Lemma 51.19. It defines the auxiliary towers, with their marked ordinary sym-

plectic pairs, residual pairs, chains and Selmer bounds (Definition 51.2), and the spaces of marked pairs over them, with modular ideals, seeds and promodular representations (Definition 51.3). The proof of Proposition 51.5 assembles the inputs of the next two sections. An essential test representation becomes, over a deep tower, a pair over a complete local ring whose reduction is chained to the reduction of a seed pair (Proposition 52.1, Proposition 52.14); every space carries a modular ideal (Theorem 53.1); and such an ideal, present on the component through one residual pair, is present on every component through a residual pair chained to it (Theorem 53.31). The propagation needs a Selmer bound C with $30(C+1)^2 \leq d$ for the degree d of the tower, and Proposition 51.6 supplies it: along the cyclotomic layers of a good tower the Selmer ranks stay bounded, by the theorem of Ferrero and Washington through Lemma 39.5, while the degree grows.

Theorem 51.1. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to some $(\psi, \mathfrak{h}, t, \chi)$, with odd prime ℓ. Then:*

(Sa1) *$\mathfrak{D}$ is finite in weight zero;*

(Sa2) *$\mathfrak{D}$ has no endoscopic points;*

(Sa3) *there is an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ such that every irreducible point of $\mathfrak{D}$ is automorphic for ι.*

Proof. Let $\mathfrak{D}$ be attached to $(\psi, \mathfrak{h}, t, \chi)$, with odd prime ℓ. Let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism as in (Ta2) of Theorem 51.4; (Ta1) of Theorem 51.4 also applies to $\mathfrak{D}$. A point r of $\mathfrak{D}$ is irreducible in the sense of Definition 44.2 exactly when it is irreducible in the sense of Definition 45.26 for the standard test field (both say that the $\overline{\mathbb{Q}}_\ell$-span of $r(G_{\mathbb{Q}})$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$).

(Sa1): $\mathfrak{D}$ is finite in weight zero. Suppose not. By Proposition 51.20 there are a test field (K, V, a) of characteristic ℓ, a point r of $\mathfrak{D}$ with values in V and a product $x = r(g_1)_{i_1 j_1} \cdots r(g_k)_{i_k j_k}$ with $\sum_s \mathrm{wt}_4(i_s, j_s) = (0,0)$ such that $x^{\ell^n} \neq x$ for every $n \geq 1$. By Lemma 45.37 there is u such that (r, u) is an ordinary test representation of $\mathfrak{D}$ with values in V. By (Zr1) of Proposition 45.36, r is irreducible, of diagonal type or of block type.

- If r is irreducible, it is essential, which contradicts (Ta1) for (r, u).
- If r is of diagonal type, (Zr2) of Proposition 45.36 gives $x^{\ell^n} = x$ for some $n \geq 1$, a contradiction.
- If r is of block type, (Zr3) of Proposition 45.36 gives an ordinary test representation (r_1, u_1) of $\mathfrak{D}$ with values in V such that every $r_1(g)$ is block diagonal and the matrices $(r_1(g)_{ab})_{a,b\in\{1,3\}}$ span $\mathrm{M}_2(K)$. By Proposition 51.23 there is an ordinary test representation (r_2, u_2) of $\mathfrak{D}$ with values in V such that r_2 is a non-split block extension, hence essential; this contradicts (Ta1) for (r_2, u_2).

Hence $\mathfrak{D}$ is finite in weight zero.

(Sa2): $\mathfrak{D}$ has no endoscopic points. Suppose r is a point of $\mathfrak{D}$ such that every $r(g)$ is block diagonal and the matrices $(r(g)_{ab})_{a,b\in\{1,3\}}$ span $\mathrm{M}_2(\overline{\mathbb{Q}}_\ell)$. By Lemma 45.41, r is a point of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ for the standard test field, and by Lemma 45.37 there is u such that (r, u) is an ordinary test representation of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$. By Proposition 51.23, applied with $K = \overline{\mathbb{Q}}_\ell$, there is an ordinary test representation (r', u') of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ such that r' is a non-split block extension and $r'(g)$, $r(g)$ have the same characteristic polynomial for every g. As r' is essential, (Ta2) shows that r' is weakly pure for ι. Weak purity depends only on the

characteristic polynomials of the $r(\sigma)$ (the eigenvalues of $r(\sigma)$ and $r'(\sigma)$ coincide), so r is weakly pure for ι, with the same open subgroup H and integer M as in the definition of weak purity in Definition 45.26. But (r,u) is an ordinary test representation with values in $\overline{\mathbb{Z}}_\ell$ and every $r(g)$ is block diagonal, so by Lemma 51.25 r is not weakly pure for ι. This contradiction shows that $\mathfrak{D}$ has no endoscopic points.

(Sa3): every irreducible point is automorphic for ι. Let r be an irreducible point of $\mathfrak{D}$. By Lemma 45.41 and Lemma 45.37 there is u such that (r,u) is an ordinary test representation of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$, and r is irreducible for the standard test field. By (Ta2), r satisfies (Sy2) for ι, that is, r is automorphic for ι. The same ι serves for every irreducible point. □

Definition 51.2. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with odd prime ℓ, coefficient ring $\mathcal{O}$ (maximal ideal $\mathfrak{m}_\mathcal{O}$, residue field $\mathbb{F}_\mathcal{O}$), characters $(\kappa_1,\kappa_2,\kappa_3,\kappa_4)=(\theta,\Psi,\alpha,\mathbf{1})$, and put $T'=T\setminus\{\ell\}$. Bars denote reduction modulo $\mathfrak{m}_\mathcal{O}$. Indices i,j run over $\{1,2,3,4\}$. Characters of $G_\mathbb{Q}$ are evaluated on $G_F\subseteq G_\mathbb{Q}$ by restriction.

Weights. Put $w_\alpha=(1,0)$, $w_\beta=(-1,1)$, $w_\Psi=(0,1)$, $w_\theta=(1,1)$ in $\mathbb{Z}^2$. The **odd roots** are $\pm w_\alpha,\pm w_\beta,\pm w_\theta$, and the **roots** are the odd roots and $\pm w_\Psi$. For $i\neq j$, $\mathrm{wt}_4(i,j)$ is a root. For a set $\Sigma_0\subseteq\mathbb{Z}^2$ and a ring R, a matrix $Y\in \mathrm{M}_4(R)$ is **supported in** Σ_0 if $Y_{ij}=0$ whenever $i\neq j$ and $\mathrm{wt}_4(i,j)\notin\Sigma_0$; a map r with values in $\mathrm{M}_4(R)$ is supported in Σ_0 if all its values are, and it **has an entry of weight** w if $r(g)_{ij}\neq 0$ for some g and some i,j with $\mathrm{wt}_4(i,j)=w$. Put $\Sigma_P=\{w_\beta,-w_\alpha,-w_\theta,-w_\Psi\}$, $\Sigma_M=\{-w_\alpha,-w_\beta,-w_\Psi,-w_\theta\}$, $\Sigma_V=\{w_\beta,-w_\alpha,-w_\theta\}$, $\Sigma_Q=\{-w_\alpha,-w_\Psi,-w_\theta\}$, $\Sigma_A=\{-w_\beta,-w_\Psi,-w_\theta\}$.

Labellings. A **labelling** is $\epsilon\in\{0,1\}$; let $\lambda_0=\mathrm{id}$ and let λ_1 be the permutation $1\mapsto 3$, $2\mapsto 4$, $3\mapsto 1$, $4\mapsto 2$, and put $\kappa_i^\epsilon=\kappa_{\lambda_\epsilon(i)}$. The labelling is **admissible** if $\epsilon=0$, or $\bar\Psi(g)=1$ for all $g\in D_\ell$.

Auxiliary towers. An **auxiliary tower** for $\mathfrak{D}$ is a tuple $\mathscr{T}=(\epsilon,E,F,g_\mathscr{T},\Sigma,(\bar v)_{v\in\Sigma})$ of an admissible labelling ϵ, an imaginary quadratic field $E\subset\overline{\mathbb{Q}}$, a totally real number field $F\subset\overline{\mathbb{Q}}$ abelian over $\mathbb{Q}$, an element $g_\mathscr{T}\in G_F$, a finite set Σ and places $\bar v$ of $\overline{\mathbb{Q}}$ above ℓ, such that every place of $\overline{\mathbb{Q}}$ above ℓ is G_F-conjugate to $\bar v$ for exactly one $v\in\Sigma$, and $\bar v$ and $\bar\ell$ induce the same place of E. Put $L=FE$ (a CM field), $d=[F:\mathbb{Q}]$, $G_L\subseteq G_F$, $G'=\{g\in G_L:\chi_{\mathrm{cyc}}(g)=1\}$, and let $D_v\supseteq I_v$ be the decomposition and inertia groups of $\bar v$ in G_F. For a finite set W of primes, the **frame** of $\mathscr{T}$ with extra primes W consists of the characters $\chi_i^\mathscr{T}=\kappa_i^\epsilon|_{G_F}$, the **root characters** $\mathrm{rt}_w=(\chi_1^\mathscr{T}/\chi_2^\mathscr{T})^{w_1}(\chi_1^\mathscr{T}/\chi_3^\mathscr{T})^{w_2}$ for $w=(w_1,w_2)\in\mathbb{Z}^2$, the set $N_W\subseteq G_F$ of all $g\in I_{\bar w}\cap G_F$ with $\bar r_0(g)=1$, $\bar w$ running over the places of $\overline{\mathbb{Q}}$ not above ℓ nor above a prime of W, and the sets $\mu_v=\{s\in D_v:\ s^{\ell^a}\in\overline{[D_v,D_v]}\text{ for some }a\geq 0\}$. Write $N=N_\emptyset$ and $U_v=\{s\in I_v:\chi_{\mathrm{cyc}}(s)=1,\ \bar r_0(s)=1\}$.

The tower is **good** if:

(Oq1) d is even, and $I_{\bar w}\cap G_F\subseteq G_L$ for every place $\bar w$ of $\overline{\mathbb{Q}}$;

(Oq2) every prime of S splits in E;

(Oq3) for every $w\in\mathbb{Z}^2$ some $g\in G_L$ has $\overline{\mathrm{rt}_w}(g)\neq\bar\omega_\ell(g)$; for every root w some $g\in G_L$ has $\overline{\mathrm{rt}_w}(g)\neq 1$; and for some root w and every $1\leq n\leq 4$ some $g\in G_L$ has $\overline{\mathrm{rt}_w}(g)^n\neq 1$;

(Oq4) every homomorphism $\eta\colon G_L\to\mathbb{F}_\mathcal{O}^\times$ with $\eta^2=1$, trivial on $G_L\cap\ker\omega_\ell$, and such that for every i there is j with $\eta\,\bar\kappa_i^\epsilon=\bar\kappa_j^\epsilon$ on G_L, is trivial;

(Oq5) $\chi(g)=1$ for every $g\in I_{\bar w}\cap G_F$ with $\bar r_0(g)=1$, $\bar w$ any place not above ℓ; and there is $m\geq 1$ prime to ℓ with $\chi(g)^m=1$ for all $g\in G_F$ with $\chi_{\mathrm{cyc}}(g)=1$;

(Oq6) $\bar r_0(g)=1$ for every $g\in I_{\bar w}\cap G_F$, $\bar w$ any place above ℓ;

(Oq7) the residues $\bar\kappa_i^\xi(g_{\mathscr{T}})$, $1 \le i \le 4$, are pairwise distinct;

(Oq8) for every place $\bar w$ above ℓ, either $\bar\omega_\ell(g) \ne 1$ for some $g \in I_{\bar w} \cap G_F$, or there is $g \in D_{\bar w} \cap G_F$ with $\bar\omega_\ell(g) = 1$, $\overline{\mathrm{rt}_{w_\Psi}}(g) = 1$ and $\overline{\mathrm{rt}_{w_\alpha}}(g) \ne 1$.

It is **of case (II)** if:

(Uq1) $\overline{\mathrm{rt}_{w_\Psi}}^2 = 1$ on G_F, $\overline{\mathrm{rt}_{w_\Psi}}$ is trivial on $I_{\bar w} \cap G_F$ for every place $\bar w$ and on $D_{\bar w} \cap G_F$ for every place $\bar w$ above ℓ;

(Uq2) there is a real quadratic field k_0 in which 2 and ℓ split such that $\overline{\mathrm{rt}_{w_\Psi}}(g) = 1$ if and only if $g \in G_{k_0}$, for $g \in G_F$;

(Uq3) ξ has order a power of 2 and is unramified at every odd prime;

(Uq4) for every place $\bar w$ above ℓ some $g \in D_{\bar w} \cap G_F$, and for every place $\bar w$ above 2 some $g \in I_{\bar w} \cap G_F$, has $\overline{\mathrm{rt}_{w_\alpha}}(g)^4 \ne 1$.

It is **of case (III)** if $\ell \ge 5$, $T' = \emptyset$, χ has finite order prime to ℓ, and there is an imaginary quadratic field E' with $\ell \nmid \mathrm{disc}(E')$, in which ℓ and every prime of S split, such that for $g \in G_F$: $\overline{\mathrm{rt}_{w_\alpha}}(g) = 1$ if $g \in G_{E'}$ and $\overline{\mathrm{rt}_{w_\alpha}}(g) = -1$ otherwise. It is **fit** if it is good and either $\mathfrak{D}$ is attached to a host character in case (II) and the tower is of case (II), or $\mathfrak{D}$ is attached to a host character in case (III), $\ell \ge 5$, $T' = \emptyset$ and χ has finite order prime to ℓ. It is **deep** if $\chi|_{G_F}$ has finite order prime to ℓ, and **tame** if for every place $\bar w$ above ℓ and $g \in I_{\bar w}$ (in $G_{\mathbb{Q}}$) some g^m with m prime to ℓ lies in G_F.

Order, layers, primes. For auxiliary towers $\mathscr{T}, \mathscr{T}'$ we write $\mathscr{T} \le \mathscr{T}'$ if they have the same labelling and the same E, $F \subseteq F'$, $g^{\ell^j} \in G_{F'}$ for some $j \ge 0$ and all $g \in G_F$, and $g_{\mathscr{T}'} = g_{\mathscr{T}}^{\ell^{j'}}$ for some $j' \ge 0$. A field F' is the **layer** of index $m \ge 0$ over F if $G_{F'} = \{g \in G_F : \chi_{\mathrm{cyc}}(g)^{\ell-1} \equiv 1 \pmod{\ell^{m+1}}\}$. For a prime w, w **dies in** F if every continuous homomorphism $G_{\mathbb{Q}} \to \mathbb{Z}/\ell\mathbb{Z}$ that is trivial on the inertia groups of all places not above w is trivial on G_F; and w **splits for** $\mathscr{T}$ if $D_{\bar w} \subseteq G_F \cap \ker \bar r_0 \cap \ker \omega_\ell$ for every place $\bar w$ above w.

Marked ordinary pairs. Let $\mathscr{T}$ be an auxiliary tower, W a finite set of primes, R a commutative ring and $a\colon \mathcal{O} \to R$ a ring homomorphism. A **marked ordinary pair** over $(\mathscr{T}, W)$ with values in R (for a) is $P = (r, (n_v)_{v\in\Sigma})$ with $r\colon G_F \to \mathrm{M}_4(R)$ a homomorphism of monoids and $n_v \in \mathrm{M}_4(R)$ such that, with $\psi^P_{v,i}(s) = (n_v^{-1} r(s) n_v)_{ii}$:

(Mq1) $r(g)$ has similitude $a(\theta(g))$ for all $g \in G_F$, and $r(g) = 1$ for $g \in N_W$;

(Mq2) $r(g_{\mathscr{T}})$ is diagonal;

(Mq3) each n_v has similitude 1, is lower triangular and has all diagonal entries 1;

(Mq4) $n_v^{-1} r(s) n_v$ is upper triangular for $s \in D_v$, and $\psi^P_{v,i}(s) = 1$ for $s \in \mu_v$ and all i.

If $\mathscr{T} \le \mathscr{T}'$ (with fields $F \subseteq F'$ and index sets Σ, Σ'), a pair $P' = (r', (n'_{v'}))$ over $\mathscr{T}'$ **lies over** a pair $P = (r, (n_v))$ over $\mathscr{T}$ with values in the same ring if $r' = r|_{G_{F'}}$ and for every $v' \in \Sigma'$ there are $v \in \Sigma$ and $g \in G_F$ with $g(\bar v) = \bar v'$ and $n'^{-1}_{v'} r(g) n_v$ upper triangular. For $f\colon R \to R'$ put $f(P) = (f \circ r, (f(n_v)))$ (entrywise); P is **continuous** for an ideal I of R if every $g \mapsto r(g)_{ij} \bmod I^k$ is locally constant. When R is local with residue field κ_R and a is local, the **reduction** of P is its image under $R \to \kappa_R$.

Residual pairs. Let $a\colon \mathcal{O} \to R$ with $a(\mathfrak{m}_{\mathcal{O}}) = 0$. A **residual pair** over $(\mathscr{T}, W)$ with values in R is a marked ordinary pair $c = (r, (n_v))$ for a with $g \mapsto r(g)$ locally constant, such that

(Wq1) $r(g)_{ii} = a(\chi_i^{\mathscr{T}}(g))$ for $g \in G_F$, and $\psi_{v,i}^c(s) = a(\chi_i^{\mathscr{T}}(s))$ for $s \in D_v$;

(Wq2) either r is supported in Σ_P and every n_v in Σ_Q, or r is supported in Σ_M.

It **lies in** V if r is supported in Σ_V and every n_v is supported in Σ_Q with $(n_v)_{31} \neq 0$; it **lies in** A if r is supported in Σ_A and $(n_v)_{21} \neq 0$ for all v. It is **good** if one of the following holds: it has entries of weights $-w_\Psi$ and one of $w_\beta, -w_\alpha$; it has entries of weights $-w_\alpha$ and $-w_\beta$; it lies in V and has an entry of weight $-w_\alpha$; it lies in V, has entries of weights w_β and $-w_\theta$, and for every v some $s \in D_v$ has $a(\mathrm{rt}_{w_\alpha}(s)) \neq 1$. It is **good in case (III)** if it is good, or it lies in A and has an entry of weight $-w_\Psi$, or it lies in A and has entries of weights $-w_\beta$ and $-w_\theta$. Two residual pairs c, c' with values in a field k are **linked** if there is a residual pair with values in $k[X]$ (for a followed by $k \subseteq k[X]$) whose images under $X \mapsto 0$ and $X \mapsto 1$ are c and c'. A **chain** from c to c' is a sequence $c = c_0, c_1, \dots, c_m = c'$ $(m \geq 0)$ of good residual pairs with c_{t-1}, c_t linked for $1 \leq t \leq m$; a **chain in case (III)** is the same with "good in case (III)".

Selmer bounds. Let k be a field and $a\colon \mathcal{O} \to k$ with $a(\mathfrak{m}_\mathcal{O}) = 0$. For $w \in \mathbb{Z}^2$ let $Z(w)$ be the k-space of locally constant $z\colon G_F \to k$ with $z(gh) = z(g) + a(\mathrm{rt}_w(g))z(h)$, $z(N) = 0$, and $z(g_{\mathscr{T}}) = 0$ if $w \neq 0$; $Z_v(w)$ the space of locally constant $z\colon D_v \to k$ with the same cocycle identity; and $Z^{\mathrm{str}}(w) \subseteq Z(w)$ the subspace of z for which there are $y_v \in k$ with $z(s) = y_v - a(\mathrm{rt}_w(s))y_v$ for all $v \in \Sigma$, $s \in D_v$. An integer $C \geq 0$ is a **Selmer bound** for $(\mathscr{T}, a)$ in degree d if $\#\Sigma \leq C$, $\dim Z^{\mathrm{str}}(w) \leq C$ for every root w, $\dim Z(w) \leq C$ for $w \in \{0, w_\Psi, -w_\Psi\}$, and $\dim Z(w) \leq d + C$ and $\dim \prod_v Z_v(w) \leq d + C$ for every odd root w.

Definition 51.3. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with prime ℓ, coefficient ring $\mathcal{O}$, characters κ_i and e, and put $(m_1, m_2, m_3, m_4) = (e+1, e, 1, 0)$. Let $\mathscr{T}$ be an auxiliary tower for $\mathfrak{D}$ and $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring with residue field $\mathbb{F}_{\mathcal{O}'}$. Pairs are over $(\mathscr{T}, \emptyset)$; for an $\mathcal{O}'$-algebra R they are taken for $\mathcal{O} \subseteq \mathcal{O}' \to R$.

Spaces. A **space** for $(\mathscr{T}, \mathcal{O}')$ is a tuple $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi_{v,i}^B))$ with:

(Zq1) $B \in \mathrm{CNL}_{\mathcal{O}'}$ with maximal ideal $\mathfrak{m}_B$; A a B-algebra of finite type with $B \to A$ injective; $P = (r_P, (n_v))$ a marked ordinary pair with values in A, continuous for $\mathfrak{m}_B A$, such that the entries of all $r_P(g)$ and all n_v generate A as a B-algebra;

(Zq2) maps $\mathrm{cp}\colon G_F \to B[X]$ and $\psi_{v,i}^B\colon D_v \to B$ such that $\mathrm{cp}(g)$ maps to the characteristic polynomial of $r_P(g)$ and $\psi_{v,i}^B(s)$ to $\psi_{v,i}^P(s)$, both are continuous for the $\mathfrak{m}_B$-adic topology (coefficientwise), and modulo $\mathfrak{m}_B$ they are $\prod_i (X - \bar{\chi}_i^{\mathscr{T}}(g))$ and $\bar{\chi}_i^{\mathscr{T}}(s)$;

(Zq3) two $\mathcal{O}'$-algebra homomorphisms $B \to R$, $R \in \mathrm{CNL}_{\mathcal{O}'}$, that agree on all coefficients of all $\mathrm{cp}(g)$ and on all $\psi_{v,i}^B(s)$ are equal;

(Zq4) for every $R \in \mathrm{CNL}_{\mathcal{O}'}$, every residual pair c with values in $\mathbb{F}_{\mathcal{O}'}$ and every marked ordinary pair Q with values in R, continuous for $\mathfrak{m}_R$, with reduction c, there is an $\mathcal{O}'$-algebra homomorphism $f\colon A \to R$ with $f(P) = Q$;

(Zq5) for every residual pair c with values in $\mathbb{F}_{\mathcal{O}'}[X]$ there is an $\mathcal{O}'$-algebra homomorphism $f\colon A \to \mathbb{F}_{\mathcal{O}'}[X]$ with $f(P) = c$ and $f(\mathfrak{m}_B) = 0$.

Let $\mathfrak{J} \subseteq B$ be an ideal and $\mathfrak{p}$ a prime of A. The ideal $\mathfrak{J}$ is **somewhere at** $\mathfrak{p}$ if some minimal prime $\mathfrak{q} \subseteq \mathfrak{p}$ of A contains $\mathfrak{J}A$, and **everywhere at** $\mathfrak{p}$ if every minimal prime $\mathfrak{q} \subseteq \mathfrak{p}$ of A contains $\mathfrak{J}A$. For a ring homomorphism $y\colon A \to C$, $\mathfrak{J}$ is **local at** y if every prime $\mathfrak{q}$ of B with $y(\mathfrak{q}) = 0$ contains $\mathfrak{J}$.

Weights and seeds. A pair P with values in $\overline{\mathbb{Q}}_\ell$ **has weights** $h \in \mathbb{Z}^4$ if there is an open subgroup $U \subseteq G_F$ with $\psi_{v,i}^P(s)^2 = \chi_{\mathrm{cyc}}(s)^{h_i}$ for all v, i and $s \in U \cap I_v$. It is a **seed** for ι if $r_P|_{G'}$

is irreducible (the $\overline{\mathbb{Q}}_\ell$-span of $r_P(G')$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$), and there are $h \in \mathbb{Z}^4$ with $h_i - h_{i+1} \in 2\mathbb{Z}_{\geq 2}$ $(i = 1, 2, 3)$ such that P has weights h, a continuous character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$, integers a and $k \geq 1$ with $a + h_1$ even and $(\kappa(s)^2\chi_{\mathrm{cyc}}(s)^{-a})^k = 1$ for every s in the inertia group in G_L of a place above ℓ, and a regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_4(\mathbb{A}_L)$ with $r_P|_{G_L} \otimes \kappa \leftrightarrow_\iota \pi$. For a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$, a **seed pair** with values in $\mathcal{O}_1$ is a marked ordinary pair Q with values in $\mathcal{O}_1$, continuous for $\mathfrak{m}_{\mathcal{O}_1}$, whose reduction satisfies (Wq1) and (Wq2) and whose image in $\overline{\mathbb{Q}}_\ell$ is a seed for ι.

Modular ideals. Let $\mathscr{X}$ be a space for $(\mathscr{T}, \mathcal{O}')$ and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. An ideal $\mathfrak{J} \subseteq B$ is **modular** for ι if:

(Jq1) $\mathfrak{m}_B^n \subseteq \mathfrak{J} + \mathfrak{m}_{\mathcal{O}'}B + (\psi_{v,i}^B(s) - 1 :\ v \in \Sigma,\ 1 \leq i \leq 4,\ s \in I_v)$ for some $n \geq 1$;

(Jq2) for every finite field k with an $\mathcal{O}'$-algebra structure and every $\mathcal{O}'$-algebra homomorphism $y\colon A \to k[[t]]$ with $y(\mathfrak{m}_B) \subseteq tk[[t]]$, $y(\mathfrak{J}) = 0$, such that for all v and $i \neq j$ some $s \in U_v$ has $y(\psi_{v,i}^P(s)) \neq y(\psi_{v,j}^P(s))$, and such that $y \circ r_P$ is irreducible over the fraction field of $k[[t]]$, $\mathfrak{J}$ is local at y;

(Jq3) $\mathfrak{J}$ is local at every $\mathcal{O}'$-algebra homomorphism $y\colon A \to \overline{\mathbb{Q}}_\ell$ such that $y(P)$ is a seed for ι;

(Jq4) for every $\mathcal{O}'$-algebra homomorphism $y\colon A \to \overline{\mathbb{Q}}_\ell$ with $y(\mathfrak{J}) = 0$ such that $y(P)$ has weights $(2m_1, 2m_2, 2m_3, 2m_4)$, every homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $r|_{G_F} = y \circ r_P$ is weakly pure for ι;

(Jq5) for every such y, every continuous homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $r|_{G_F} = y \circ r_P$, $r(g)$ of similitude $\theta(g)$ for all g, and $r|_{G_L}$ irreducible, satisfies (Sy2) for ι.

Promodular representations. Let (K, V, a) be a test field and ι as above. A homomorphism $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ is **promodular** for $\mathfrak{D}$ and ι if there are a fit and deep auxiliary tower $\mathscr{T}$, a coefficient ring $\mathcal{O}' \supseteq \mathcal{O}$, a space $\mathscr{X} = (B, A, P, \dots)$ for $(\mathscr{T}, \mathcal{O}')$, an ideal $\mathfrak{J} \subseteq B$ modular for ι, a ring homomorphism $y\colon A \to V$ and a homomorphism $r_1\colon G_{\mathbb{Q}} \to \mathrm{M}_4(V)$ of monoids such that: y restricts to a on $\mathcal{O}'$; $y(\mathfrak{m}_B) \subseteq \mathfrak{m}_V$; $y(\mathfrak{J}) = 0$; $r_1 = uru^{-1}$ for some $u \in \mathrm{GL}_4(K)$; $r_1(g)$ has similitude $a(\theta(g))$ for all g; $r_1|_{G_F} = y \circ r_P$; and $y(\psi_{v,i}^P(s)) = a(\kappa_i(s))$ for all v, i and $s \in I_v$.

Theorem 51.4. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to some $(\psi, \mathfrak{h}, t, \chi)$, with odd prime ℓ. Then:*

(Ta1) *for every test field (K, V, a) of characteristic ℓ and every ordinary test representation (r, u) of $\mathfrak{D}$ with values in V, the representation r is not essential;*

(Ta2) *there is an isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ such that for every ordinary test representation (r, u) of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ (for the standard test field): if r is essential, then r is weakly pure for ι; if r is irreducible, then r satisfies (Sy2) for ι.*

Proof. An isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ exists: both are algebraically closed fields of characteristic 0 of the cardinality of the continuum, hence have transcendence bases over $\mathbb{Q}$ of the same cardinality (Steinitz). Fix one.

(Ta1). Let (K, V, a) be a test field of characteristic ℓ and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V. If r were essential, it would be promodular for $\mathfrak{D}$ and ι by Proposition 51.5, hence not essential by item 1 of Lemma 51.19. So r is not essential.

(Ta2). Let (r, u) be an ordinary test representation of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ for the standard test field. If r is essential, it is promodular for $\mathfrak{D}$ and ι by Proposition 51.5, hence weakly pure for ι by item 2 of Lemma 51.19. If r is irreducible, it is essential, hence promodular, and item 2 of Lemma 51.19 gives (Sy2) for ι. □

Proposition 51.5. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to some $(\psi, \mathfrak{h}, t, \chi)$ and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. For every test field (K, V, a) and every ordinary test representation (r, u) of $\mathfrak{D}$ with values in V such that r is essential, r is promodular for $\mathfrak{D}$ and ι.*

Proof. Write k_V for the residue field of V. By Definition 44.1, $\mathfrak{D}$ is attached in case (II) or in case (III).

Step 0: two facts on towers. (a) The order $\leq$ is transitive: if $\mathscr{T} \leq \mathscr{T}' \leq \mathscr{T}''$, the labellings and the fields E agree, $F \subseteq F' \subseteq F''$, for $g \in G_F$ we have $g^{\ell^j} \in G_{F'}$ and then $(g^{\ell^j})^{\ell^{j_2}} \in G_{F''}$, and $g_{\mathscr{T}''} = g_{\mathscr{T}'}^{\ell^{j'_2}} = g_{\mathscr{T}}^{\ell^{j'+j'_2}}$. (b) If w dies in F_1 and $F \supseteq F_1$, then w dies in F, as $G_F \subseteq G_{F_1}$.

Step 1: a deep fit tower, a seed pair, and a pair chained to it. Case (II). By Proposition 52.1 there are a fit, tame auxiliary tower $\mathscr{T}_1$ of case (II), $u' \in \mathrm{GL}_4(K)$ and $r' = u'ru'^{-1}$ with $r'(g)$ of similitude $a(\theta(g))$, with the property stated there. By (Xq1) of Proposition 51.6 (for $\mathscr{T}_1$) there is a C which is a Selmer bound for $(\mathscr{T}, a_0)$ in degree $[F : \mathbb{Q}]$ for every $\mathscr{T} \geq \mathscr{T}_1$ with layer field and every $a_0\colon \mathcal{O} \to k$ killing $\mathfrak{m}_{\mathcal{O}}$; by (Xq2) with $n = 30(C+1)^2$ there is a deep $\mathscr{T} \geq \mathscr{T}_1$ whose field F is a layer over F_1 with $d = [F : \mathbb{Q}] \geq 30(C+1)^2$; by (Xq3), $\mathscr{T}$ is good, fit and of case (II). By Proposition 51.8 (for $\mathscr{T}$, ι) there are $\mathcal{O}_1 \supseteq \mathcal{O}$ and a seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ whose reduction lies in V and has an entry of weight $-w_\alpha$ or entries of weights $w_\beta, -w_\theta$. The property of $\mathscr{T}_1$ applied to $\mathscr{T}$ and Q gives $\mathcal{O}_2 \supseteq \mathcal{O}_1$ such that (Nq1), (Nq2) hold for every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}_2$.

Case (III). By Proposition 52.14 there are a fit, tame auxiliary tower $\mathscr{T}_0$ of case (III), u' and $r' = u'ru'^{-1}$ as above, with the property stated there. $\mathscr{T}_0$ is good. By Proposition 51.14 (for $\mathscr{T}_0$, ι, (K, V, a)) there are a prime w splitting for $\mathscr{T}_0$ and a residual pair s_0 over $(\mathscr{T}_0, \{w\})$ with values in k_V, supported in Σ_M, with the seed property stated there. The property of $\mathscr{T}_0$ applied to (w, s_0) gives a tame $\mathscr{T}_1 \geq \mathscr{T}_0$ in whose field F_1 the prime w dies; $\mathscr{T}_1$ is fit by (Xq3). By (Xq1), (Xq2) of Proposition 51.6 for $\mathscr{T}_1$ there are C as in case (II) and a deep $\mathscr{T} \geq \mathscr{T}_1$ with layer field F and $d = [F : \mathbb{Q}] \geq 30(C+1)^2$; $\mathscr{T}$ is good and fit by (Xq3), $\mathscr{T} \geq \mathscr{T}_0$ by Step 0(a), and w dies in F by Step 0(b). The seed property of (w, s_0) gives $\mathcal{O}_1 \supseteq \mathcal{O}$ and a seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ whose image in k_V lies over s_0, lies in A and has entries of weights $-w_\beta$, $-w_\theta$; the property of $\mathscr{T}_1$ then gives $\mathcal{O}_2 \supseteq \mathcal{O}_1$ such that (Nq3), (Nq4) hold for every $\mathcal{O}' \supseteq \mathcal{O}_2$.

In both cases we now have a fit and deep tower $\mathscr{T}$ (field F, $d = [F : \mathbb{Q}] \geq 30(C+1)^2$), C, Q, $\mathcal{O}_2$, and r'.

Step 2: coefficients, space and modular ideal. By Theorem 53.1 (for $\mathscr{T}$, ι) there is $\mathcal{O}_3 \supseteq \mathcal{O}$ as stated there. Let $\mathcal{O}'$ be the ring of integers of the compositum in $\overline{\mathbb{Q}}_\ell$ of the fraction fields of $\mathcal{O}_2$ and $\mathcal{O}_3$; it is a coefficient ring containing both. By Proposition 51.17 there is a space $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ for $(\mathscr{T}, \mathcal{O}')$, and by Theorem 53.1 an ideal $\mathfrak{J} \subseteq B$ modular for ι. By (Nq1), resp. (Nq3), there are $R \in \mathrm{CNL}_{\mathcal{O}'}$, an injective $f\colon R \to V$ restricting to a on $\mathcal{O}'$ with $f(\mathfrak{m}_R) \subseteq \mathfrak{m}_V$, and a continuous marked ordinary pair P_R with values in R with the stated properties; let s be its reduction, a residual pair with values in $\mathbb{F}_{\mathcal{O}'}$. Let t be the reduction of Q modulo $\mathfrak{m}_{\mathcal{O}'}$. By (Nq2), resp. (Nq4), there is a chain in case (III) from s to t (in case (II) a chain, which is a chain in case (III) since good residual pairs are good in case (III)).

Step 3: the seed point; $\mathfrak{J}$ is somewhere at the reduction of the seed. Through $\mathcal{O}_1 \subseteq \mathcal{O}'$, Q is a marked ordinary pair with values in $\mathcal{O}'$ (for $\mathcal{O} \subseteq \mathcal{O}'$), continuous for $\mathfrak{m}_{\mathcal{O}'}$ (as $\mathfrak{m}^k_{\mathcal{O}_1}\mathcal{O}' \subseteq \mathfrak{m}^k_{\mathcal{O}'}$), with reduction t; t is a residual pair: it satisfies (Wq1), (Wq2) by the definition of seed pairs, and $g \mapsto t(g)$ is locally constant by continuity. By (Zq4) with $R = \mathcal{O}'$ there is an $\mathcal{O}'$-algebra homomorphism $f_1\colon A \to \mathcal{O}'$ with $f_1(P) = Q$. Let $y_1\colon A \to \overline{\mathbb{Q}}_\ell$ be f_1 followed by the inclusion and $x_1\colon A \to \mathbb{F}_{\mathcal{O}'}$ be f_1 followed by reduction, so $y_1(P)$ is the image of Q in $\overline{\mathbb{Q}}_\ell$, a seed, and $x_1(P) = t$. By (Jq3), $\mathfrak{J}$ is local at y_1. The kernel $\ker y_1 = \ker f_1$ is prime ($\mathcal{O}'$ is a domain); choose a minimal prime $\mathfrak{q}_1 \subseteq \ker f_1$ of A (minimal primes below a given prime exist by Zorn's lemma).

Then $\mathfrak{q}_1 \cap B$ is a prime of B killed by y_1, so $\mathfrak{J} \subseteq \mathfrak{q}_1 \cap B$ and $\mathfrak{J}A \subseteq \mathfrak{q}_1$; and $\mathfrak{q}_1 \subseteq \ker f_1 \subseteq \ker x_1$. So $\mathfrak{J}$ is somewhere at $\ker x_1$.

Step 4: the point of r'; propagation. By (Zq4) for R, $c = s$ and P_R there is an $\mathcal{O}'$-algebra homomorphism $f_0 \colon A \to R$ with $f_0(P) = P_R$; let $x_0 \colon A \to \mathbb{F}_{\mathcal{O}'}$ be f_0 followed by $R \to R/\mathfrak{m}_R = \mathbb{F}_{\mathcal{O}'}$, so $x_0(P) = s$ is a residual pair. The integer C is a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d (Step 1, with $k = \mathbb{F}_{\mathcal{O}'}$) and $30(C+1)^2 \le d$. By Theorem 53.31 and Steps 2, 3, $\mathfrak{J}$ is everywhere at $\ker x_0$.

Step 5: promodularity. Put $y = f \circ f_0 \colon A \to V$ and $r_1 = r'$. (i) y restricts to a on $\mathcal{O}'$, since f_0 is an $\mathcal{O}'$-algebra homomorphism and $f|_{\mathcal{O}'} = a$. (ii) $x_0|_B$ is an $\mathcal{O}'$-algebra homomorphism onto the field $\mathbb{F}_{\mathcal{O}'}$, so its kernel is a maximal ideal of the local ring B, i.e. $\mathfrak{m}_B$; hence $f_0(\mathfrak{m}_B) \subseteq \mathfrak{m}_R$ and $y(\mathfrak{m}_B) \subseteq f(\mathfrak{m}_R) \subseteq \mathfrak{m}_V$. (iii) R is a domain (f is injective into V), so $\ker f_0$ is prime; choose a minimal prime $\mathfrak{q}_0 \subseteq \ker f_0$ of A; as $\ker f_0 \subseteq \ker x_0$ and $\mathfrak{J}$ is everywhere at $\ker x_0$, $\mathfrak{J}A \subseteq \mathfrak{q}_0 \subseteq \ker f_0 = \ker y$; so $y(\mathfrak{J}) = 0$. (iv) $r_1 = u' r u'^{-1}$ with $u' \in \mathrm{GL}_4(K)$, and $r_1(g)$ has similitude $a(\theta(g))$. (v) $y \circ r_P$ is the first component of $f(f_0(P)) = f(P_R)$, which is $r'|_{G_F} = r_1|_{G_F}$. (vi) For $v \in \Sigma$, $s' \in I_v$: since ring homomorphisms commute with inverses of matrices, $y(\psi^P_{v,i}(s')) = \psi^{f(P_R)}_{v,i}(s') = a(\kappa_i(s'))$. With $\mathscr{T}$ fit and deep, $\mathcal{O}'$, $\mathscr{X}$ and $\mathfrak{J}$ modular for ι, this is the definition: r is promodular for $\mathfrak{D}$ and ι. □

Proposition 51.6. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and $\mathscr{T}_1$ a good auxiliary tower for $\mathfrak{D}$ with field F_1.*

(Xq1) *There is an integer $C \ge 0$ such that for every auxiliary tower $\mathscr{T} \ge \mathscr{T}_1$ whose field F is a layer over F_1, every field k and every ring homomorphism $a \colon \mathcal{O} \to k$ with $a(\mathfrak{m}_\mathcal{O}) = 0$, C is a Selmer bound for $(\mathscr{T}, a)$ in degree $[F : \mathbb{Q}]$.*

(Xq2) *For every integer n there is a deep auxiliary tower $\mathscr{T} \ge \mathscr{T}_1$ whose field F is a layer over F_1 and satisfies $[F : \mathbb{Q}] \ge n$.*

(Xq3) *If $\mathscr{T} \le \mathscr{T}'$ are auxiliary towers for $\mathfrak{D}$ and $\mathscr{T}$ is good, of case (II), fit, or deep, then so is $\mathscr{T}'$.*

Proof. Write $\mathscr{T}_1 = (\epsilon, E, F_1, g_1, \Sigma_1, (\bar v))$ and $d_1 = [F_1 : \mathbb{Q}]$. Two facts are used throughout. (P1) For a finite field $\mathbb{F}$ of characteristic ℓ and $j \ge 0$, $x \mapsto x^{\ell^j}$ is injective on $\mathbb{F}^\times$ (its order is prime to ℓ). (P2) The residual characters $\bar\kappa_i$, $\bar\omega$ and $\overline{\mathrm{rt}_w}$ take values in $\mathbb{F}_\mathcal{O}^\times$, and $\overline{\mathrm{rt}_w}$ for a tower $\mathscr{T}' \ge \mathscr{T}$ is the restriction of $\overline{\mathrm{rt}_w}$ for $\mathscr{T}$ (same labelling). For $m \ge 0$ let $H_m = \{g \in G_\mathbb{Q} : \chi_{\mathrm{cyc}}(g)^{\ell-1} \equiv 1 \pmod{\ell^{m+1}}\}$. It is the preimage under $G_\mathbb{Q} \to (\mathbb{Z}/\ell^{m+1}\mathbb{Z})^\times$ (onto) of the subgroup of order $\ell - 1$ of this cyclic group of order $(\ell-1)\ell^m$, so H_m is open and normal of index ℓ^m with cyclic quotient; its fixed field $\mathbb{Q}_m \subseteq \mathbb{Q}(\mu_{\ell^{m+1}})$ is totally real ($\chi_{\mathrm{cyc}}(c) = -1$) and has exactly one place above ℓ (ℓ is totally ramified in $\mathbb{Q}(\mu_{\ell^{m+1}})$). The layer of index m over F_1 is $F_1\mathbb{Q}_m$, with $G_{F_1\mathbb{Q}_m} = G_{F_1} \cap H_m$.

Step 1: (Xq3). Let $\mathscr{T} = (\epsilon, E, F, g_\mathscr{T}, \dots) \le \mathscr{T}' = (\epsilon, E, F', g_\mathscr{T}^{\ell^{j'}}, \dots)$, with $g^{\ell^j} \in G_{F'}$ for all $g \in G_F$; let $L' = F'E$, $d' = [F' : \mathbb{Q}]$. For a closed subgroup $X \subseteq G_F$ and $g \in X$, $g^{\ell^j} \in X \cap G_{F'}$. Hence, by (P1), (P2): every clause of the form "some g in $X \cap G_F$ has $\lambda(g) \ne \lambda'(g)$", for residual characters λ, λ' and X one of G_E, $I_{\bar w}$, $D_{\bar w}$, passes from $\mathscr{T}$ to $\mathscr{T}'$ (replace g by g^{ℓ^j}; note $G_L \ni g \mapsto g^{\ell^j} \in G_{F'} \cap G_E = G_{L'}$), and every clause of the form "$\lambda = \lambda'$ on a subset of G_F" passes trivially to the smaller subset of $G_{F'}$. Suppose that $\mathscr{T}$ is good. (Oq1): $d' = d\,[F' : F]$ is even, and $I_{\bar w} \cap G_{F'} \subseteq G_L \cap G_{F'} = G_{L'}$. (Oq2) does not involve F. (Oq3) and (Oq8) are of the first form (with λ' the constant 1 or $\bar\omega$, and for the n-th power clause $\lambda = \overline{\mathrm{rt}_w}^{\,n}$); (Oq5), (Oq6) are of the second form. (Oq7): $\bar\kappa_i^\epsilon(g_\mathscr{T}^{\ell^{j'}}) = \bar\kappa_i^\epsilon(g_\mathscr{T})^{\ell^{j'}}$ are pairwise distinct by (P1). (Oq4): L' is abelian over $\mathbb{Q}$, so $G_{L'}$ is normal in G_L, and $G_L/G_{L'}$ is a finite ℓ-group (every element

has ℓ-power order). Consequently a character of G_L with values in $\mathbb{F}_{\mathcal{O}}^{\times}$ that is trivial on $G_{L'}$ is trivial, and $\bar\omega(G_L) = \bar\omega(G_{L'})$ (the quotient $\bar\omega(G_L)/\bar\omega(G_{L'})$ is an image of $G_L/G_{L'}$ of order prime to ℓ). Let $\eta\colon G_{L'} \to \mathbb{F}_{\mathcal{O}}^{\times}$ be as in (Oq4) for $\mathscr{T}'$. Being trivial on $G_{L'} \cap \ker\bar\omega$, $\eta = \lambda\circ\bar\omega$ for a character λ of $\bar\omega(G_{L'}) = \bar\omega(G_L)$ with $\lambda^2 = 1$; put $\eta_0 = \lambda\circ\bar\omega$ on G_L. Then $\eta_0^2 = 1$, η_0 is trivial on $G_L \cap \ker\bar\omega$, and for each i with its j the character $\eta_0\bar\kappa_i^{\epsilon}/\bar\kappa_j^{\epsilon}$ of G_L is trivial on $G_{L'}$, hence trivial. By (Oq4) for $\mathscr{T}$, $\eta_0 = 1$, so $\eta = 1$. Thus $\mathscr{T}'$ is good. If $\mathscr{T}$ is of case (II): (Uq1), (Uq2) (with the same k_0) are of the second form, (Uq3) does not involve F, and (Uq4) is of the first form. Fitness is goodness together with conditions on $\mathfrak{D}$ and, in case (II), the case of the tower; so it passes. If $\chi|_{G_F}$ has finite order prime to ℓ, so has $\chi|_{G_{F'}}$.

Step 2: (Xq2). By (Oq5) for $\mathscr{T}_1$ there is $m_0 \ge 1$ prime to ℓ with $\chi(g)^{m_0} = 1$ for $g \in G_{F_1}$, $\chi_{\mathrm{cyc}}(g) = 1$; put $e_0 = (\ell-1)m_0$, prime to ℓ. If $g \in G_{F_1}$ and $\chi_{\mathrm{cyc}}(g)^{\ell-1} = 1$, then $g^{\ell-1} \in G_{F_1} \cap \ker\chi_{\mathrm{cyc}}$, so $\chi(g)^{e_0} = 1$. The Dirichlet character χ has open kernel, so $U = \ker\chi^{e_0}$ is open. The closed sets $(G_{F_1} \cap H_m) \setminus U$ decrease with m and their intersection is empty (an element of all H_m has $\chi_{\mathrm{cyc}}^{\ell-1} = 1$); by compactness there is m_1 with $G_{F_1} \cap H_m \subseteq U$ for $m \ge m_1$. Next, $\chi_{\mathrm{cyc}}(G_{F_1})$ is open in $\mathbb{Z}_\ell^{\times}$, so its image under $x \mapsto x^{\ell-1}$ is an open subgroup of $1+\ell\mathbb{Z}_\ell \cong \mathbb{Z}_\ell$, i.e. $1+\ell^b\mathbb{Z}_\ell$ for some $b \ge 1$; hence $[G_{F_1} : G_{F_1}\cap H_m] = \ell^{m+1-b}$ for $m+1 \ge b$. Choose $m \ge \max(m_1, b)$ with $d_1\ell^{m+1-b} \ge n$ and put $F = F_1\mathbb{Q}_m$. It is a number field, abelian over $\mathbb{Q}$ ($G_{\mathbb{Q}}/(G_{F_1} \cap H_m)$ embeds into $G_{\mathbb{Q}}/G_{F_1} \times G_{\mathbb{Q}}/H_m$), totally real (every complex conjugation lies in G_{F_1} and in H_m), $[F:\mathbb{Q}] = d_1\ell^{m+1-b} \ge n$, and $g^{\ell^m} \in G_F$ for all $g \in G_{F_1}$ (as G_{F_1}/G_F embeds into $G_{\mathbb{Q}}/H_m$, of order ℓ^m). Let Σ be the set of places of F above ℓ. For $v \in \Sigma$ choose a place $\bar u_v$ of $\overline{\mathbb{Q}}$ above v inducing on E the same place as $\bar\ell$: take any place $\bar u$ above v; if it induces the other place of E above ℓ, replace it by $c\bar u$ for a complex conjugation $c \in G_F$, which lies above v and induces c of that place, as $c|_E \ne 1$. The places of $\overline{\mathbb{Q}}$ above v form one G_F-orbit, and each place above ℓ lies above exactly one $v \in \Sigma$. So $\mathscr{T} = (\epsilon, E, F, g_1^{\ell^m}, \Sigma, (\bar u_v))$ is an auxiliary tower, $\mathscr{T}_1 \le \mathscr{T}$ (with $j = j' = m$), F is the layer of index m over F_1, and χ^{e_0} is trivial on $G_F \subseteq U$, so $\mathscr{T}$ is deep.

Step 3: the fields along the layers. Let $K \subset \overline{\mathbb{Q}}$ be the fixed field of $G_{F_1} \cap \ker\bar r_0 \cap \ker\bar\omega$: a finite abelian extension of $\mathbb{Q}$ (an intersection of normal subgroups of finite index with abelian quotients, as F_1 is abelian and $\bar r_0$ is diagonal) containing μ_ℓ. By Lemma 39.5 there is $r \ge 0$ with $\#(\mathrm{Cl}(K')/\mathrm{Cl}(K')^\ell) \le \ell^r$ for every field K' generated over K by a primitive ℓ^n-th root of unity, $n \ge 0$. Put $C = r + 1 + 2d_1$. Let $\mathscr{T} \ge \mathscr{T}_1$ have field $F = F_1\mathbb{Q}_m$, $d = [F:\mathbb{Q}]$, and let K_F be the fixed field of $G' = G_F \cap \ker\bar r_0 \cap \ker\bar\omega = G_K \cap H_m$. On G_K the values of χ_{cyc} lie in $1+\ell\mathbb{Z}_\ell$, on which $x \mapsto x^{\ell-1}$ is an automorphism preserving each $1+\ell^{m+1}\mathbb{Z}_\ell$; so $G' = \{g \in G_K : \chi_{\mathrm{cyc}}(g) \equiv 1 \pmod{\ell^{m+1}}\}$ and $K_F = K(\mu_{\ell^{m+1}})$. Thus r bounds the ℓ-rank of $\mathrm{Cl}(K_F)$. The places of F above ℓ lie above the unique place of $\mathbb{Q}_m$ above ℓ, so their number $\#\Sigma$ (the G_F-orbits of places above ℓ) is at most $[F:\mathbb{Q}_m] \le d_1$. K_F is finite abelian over $\mathbb{Q}$, contains F and μ_ℓ, and $\Delta = G_F/G'$ embeds into $(\mathbb{F}_{\mathcal{O}}^{\times})^4 \times \mathbb{F}_\ell^{\times}$ by $(\bar\kappa_1, \dots, \bar\kappa_4, \bar\omega)$, so $[K_F : F]$ is prime to ℓ.

Step 4: reduction to the residue field. Let k, a be as in (Xq1) and $\iota\colon \mathbb{F}_{\mathcal{O}} \to k$ the field embedding induced by a, so $a(\mathrm{rt}_w(g)) = \iota(\overline{\mathrm{rt}_w}(g))$. Let $X(k)$ denote any of $Z(w)$, $Z^{\mathrm{str}}(w)$, $\prod_v Z_v(w)$ formed with a, and $X(\mathbb{F}_{\mathcal{O}})$ the same with $\bar a\colon \mathcal{O} \to \mathbb{F}_{\mathcal{O}}$. Choose a basis (b_t) of k over $\iota(\mathbb{F}_{\mathcal{O}})$. A locally constant map on a profinite group takes finitely many values, and the constants y_v of the strict condition are finitely many; expanding all of them in finitely many b_t, the defining conditions (the cocycle identity, whose coefficients $\iota(\overline{\mathrm{rt}_w}(g))$ lie in $\iota(\mathbb{F}_{\mathcal{O}})$, vanishing on N and at $g_{\mathscr{T}}$, the coboundary conditions) hold if and only if they hold for each coordinate. Hence $X(k) = X(\mathbb{F}_{\mathcal{O}}) \otimes_{\mathbb{F}_{\mathcal{O}}} k$ and $\dim_k X(k) = \dim_{\mathbb{F}_{\mathcal{O}}} X(\mathbb{F}_{\mathcal{O}})$. From now on $k = \mathbb{F}_{\mathcal{O}}$ and $\varphi_w = \overline{\mathrm{rt}_w}\colon G_F \to \mathbb{F}_{\mathcal{O}}^{\times}$, trivial on G'.

Step 5: the root characters. Since $\theta = \alpha\Psi$, $\kappa_1\kappa_4 = \kappa_2\kappa_3$ and also $\kappa_1^1\kappa_4^1 = \alpha\Psi = \kappa_2^1\kappa_3^1$; with $\chi_i = \chi_i^{\mathscr{T}}$, $\mathrm{rt}_{w_\alpha} = \chi_1/\chi_2$, $\mathrm{rt}_{w_\beta} = \chi_2/\chi_3$, $\mathrm{rt}_{w_\Psi} = \chi_1/\chi_3$, $\mathrm{rt}_{w_\theta} = \chi_1^2/(\chi_2\chi_3) = \chi_1/\chi_4$. So for every root w, $\varphi_w = \bar\chi_i/\bar\chi_j$ with $i \ne j$, and $\varphi_w(g_{\mathscr{T}}) \ne 1$ by (Oq7) ($\mathscr{T}$ is good by Step 1). Further

$\mathrm{rt}_{\pm w_\Psi} = (\kappa_1^\epsilon/\kappa_3^\epsilon)^{\pm 1}$ is $\Psi^{\pm 1}$ ($\epsilon = 0$) or $\Psi^{\mp 1}$ ($\epsilon = 1$) on G_F, and $\Psi(c) = 1$ by (Sg1) for every complex conjugation c (all are conjugate in $G_\mathbb{Q}$); so $\varphi_w(c) = 1$ for $w \in \{0, w_\Psi, -w_\Psi\}$.

Step 6: restriction to G'. Let $w = 0$ or a root and $z \in Z(w)$. As φ_w is trivial on G', $f = z|_{G'}$ is a continuous homomorphism. For $\gamma \in G_F$, $s \in G'$: $z(1) = 0$, $z(\gamma^{-1}) = -\varphi_w(\gamma)^{-1} z(\gamma)$, so $z(\gamma s \gamma^{-1}) = z(\gamma) + \varphi_w(\gamma) z(s) + \varphi_w(\gamma s) z(\gamma^{-1}) = \varphi_w(\gamma) f(s)$. For a place $\bar{u} \nmid \ell$, $I_{\bar{u}} \cap G' \subseteq N$ ($\bar{r}_0 = 1$ on G'), so $f(I_{\bar{u}} \cap G') = 0$. Thus $f \in H_{\varphi_w}$ in the notation of Lemma 51.7 (for $\mathbb{F} = \mathbb{F}_\mathcal{O}$, F, $K' = K_F$). The map $z \mapsto f$ is injective: if $f = 0$, then $z(gs) = z(g)$ for $s \in G'$, so z is inflated from a cocycle of the finite group Δ, of order prime to ℓ, hence $z(g) = \varphi_w(g) y - y$ for some y; for $w = 0$ this is 0, and for a root w, $z(g_\mathscr{T}) = 0$ and $\varphi_w(g_\mathscr{T}) \neq 1$ give $y = 0$. If $z \in Z^{\mathrm{str}}(w)$, then for $v \in \Sigma$ and $s \in D_v \cap G'$, $z(s) = y_v - \varphi_w(s) y_v = 0$; every place $\bar{u} \mid \ell$ is $\gamma \bar{v}$ with $\gamma \in G_F$, $v \in \Sigma$, and $D_{\bar{u}} \cap G' = \gamma (D_v \cap G') \gamma^{-1}$ (G' is normal in G_F), so $f(D_{\bar{u}} \cap G') = 0$ by the equivariance; thus $f \in H^{\mathrm{str}}_{\varphi_w}$. By Lemma 51.7 (with r, $n_\ell = \#\Sigma \leq d_1$ and d) and Step 5:

$$\dim Z^{\mathrm{str}}(w) \leq r \quad (w \text{ a root}), \qquad \dim Z(w) \leq 1 + r + d_1 \quad (w \in \{0, \pm w_\Psi\}),$$
$$\dim Z(w) \leq d + 1 + r + d_1 \quad (w \text{ a root}).$$

Step 7: the local spaces. Let w be a root and $v \in \Sigma$; D_v is the decomposition group in G_F of $\bar{v}$, isomorphic to G_{F_v} for the completion F_v of F at the place v, and $Z_v(w)$ is the space Z^1 of continuous cocycles with values in $M = \mathbb{F}_\mathcal{O}(\varphi_w)$. Write $h^i = \dim_{\mathbb{F}_\mathcal{O}} H^i(F_v, M)$, so that $\#H^i = q^{h^i}$, $q = \#\mathbb{F}_\mathcal{O}$. The coboundaries are the image of $y \mapsto (s \mapsto \varphi_w(s) y - y)$, with kernel H^0, so $\dim Z_v(w) = h^1 + 1 - h^0$. By Theorem B.29, item 4 ($v \mid \ell$), $h^1 = h^0 + h^2 + [F_v : \mathbb{Q}_\ell]$, and by item 2, $\#H^2(F_v, M) = \#H^0(F_v, M^\vee) \leq \#M^\vee = q$, so $h^2 \leq 1$. Hence $\dim Z_v(w) \leq 2 + [F_v : \mathbb{Q}_\ell]$, and as $\sum_{v \in \Sigma} [F_v : \mathbb{Q}_\ell] = d$, $\dim \prod_v Z_v(w) \leq d + 2\#\Sigma \leq d + 2d_1$.

Step 8: (Xq1). With $C = r + 1 + 2d_1$: $\#\Sigma \leq d_1 \leq C$; $\dim Z^{\mathrm{str}}(w) \leq r \leq C$ for every root; $\dim Z(w) \leq r + 1 + d_1 \leq C$ for $w \in \{0, \pm w_\Psi\}$; $\dim Z(w) \leq d + C$ and $\dim \prod_v Z_v(w) \leq d + C$ for every odd root (Steps 6, 7). By Step 4 the same holds over every k. So C is a Selmer bound for $(\mathscr{T}, a)$ in degree d, for every $\mathscr{T} \geq \mathscr{T}_1$ with layer field. □

Lemma 51.7. *Let ℓ be an odd prime, $\mathbb{F}$ a finite field of characteristic ℓ, $F \subset \overline{\mathbb{Q}}$ a totally real number field with $d = [F : \mathbb{Q}]$ and n_ℓ places above ℓ, and $K' \subset \overline{\mathbb{Q}}$ a finite abelian extension of $\mathbb{Q}$ containing F and a primitive ℓ-th root of unity, with $[K' : F]$ prime to ℓ. Let $r \geq 0$ be an integer with $\#(\mathrm{Cl}(K')/\mathrm{Cl}(K')^\ell) \leq \ell^r$, and $\varphi \colon G_F \to \mathbb{F}^\times$ a character trivial on $G_{K'}$. Let H_φ be the $\mathbb{F}$-vector space of continuous homomorphisms $f \colon G_{K'} \to \mathbb{F}$ such that $f(I_{\bar{u}} \cap G_{K'}) = 0$ for every place $\bar{u}$ of $\overline{\mathbb{Q}}$ not above ℓ and $f(\gamma s \gamma^{-1}) = \varphi(\gamma) f(s)$ for all $\gamma \in G_F$, $s \in G_{K'}$, and $H^{\mathrm{str}}_\varphi \subseteq H_\varphi$ the subspace of those f with $f(D_{\bar{u}} \cap G_{K'}) = 0$ for every place $\bar{u}$ above ℓ. Let $c \in G_F$ be a complex conjugation. Then*

$$\dim_\mathbb{F} H^{\mathrm{str}}_\varphi \leq r, \qquad \dim_\mathbb{F} H_\varphi \leq \begin{cases} 1 + r + n_\ell, & \varphi(c) = 1, \\ 1 + r + n_\ell + d, & \varphi(c) = -1. \end{cases}$$

Proof. Put $\Delta = \mathrm{Gal}(K'/F) = G_F/G_{K'}$, of order prime to ℓ. Since K' contains μ_ℓ and ℓ is odd, K' is totally imaginary; as $K'/\mathbb{Q}$ is abelian, all complex conjugations of $G_\mathbb{Q}$ have the same image $c' \neq 1$ in $\mathrm{Gal}(K'/\mathbb{Q})$, and $c' \in \Delta$ since F is totally real. As $\varphi(c)^2 = 1$ and ℓ is odd, $\varphi(c) \in \{1, -1\}$ and the two cases are exclusive. For an $\mathbb{F}[\Delta]$-module X and a character $\lambda \colon \Delta \to \mathbb{F}^\times$ put $X^{(\lambda)} = \{x \in X : \delta x = \lambda(\delta) x \ \forall \delta\}$; it is the image of the idempotent $e_\lambda = \#\Delta^{-1} \sum_\delta \lambda(\delta)^{-1} \delta \in \mathbb{F}[\Delta]$, so $X \mapsto X^{(\lambda)}$ is exact.

Step 1: the strict space. Let $f \in H^{\mathrm{str}}_\varphi$, $f \neq 0$. Its kernel is an open subgroup of $G_{K'}$ of index ℓ^a, normal with abelian quotient of exponent ℓ; it cuts out an abelian extension of K'

unramified at every finite place not above ℓ (by the inertia condition), in which every place above ℓ splits completely (by the decomposition condition), and unramified at the archimedean places (K' is totally imaginary). By class field theory f factors through $\mathrm{Gal}(H_{K'}/K') \cong \mathrm{Cl}(K')$, $H_{K'}$ the Hilbert class field, and then through $\mathrm{Cl}(K')/\mathrm{Cl}(K')^\ell$. So H_φ^{str} embeds $\mathbb{F}$-linearly into $\mathrm{Hom}(\mathrm{Cl}(K')/\mathrm{Cl}(K')^\ell, \mathbb{F})$, of $\mathbb{F}$-dimension $\le r$.

Step 2: H_φ as an eigenspace. Let H be the $\mathbb{F}_\ell$-space of continuous homomorphisms $h\colon G_{K'} \to \mathbb{F}_\ell$ with $h(I_{\bar u} \cap G_{K'}) = 0$ for all $\bar u \nmid \ell$. Writing a continuous homomorphism $f\colon G_{K'} \to \mathbb{F}$ in an $\mathbb{F}_\ell$-basis of $\mathbb{F}$ identifies such f (with the inertia condition) with $H \otimes_{\mathbb{F}_\ell} \mathbb{F}$. The group G_F acts on H by $(\gamma \cdot h)(s) = h(\gamma^{-1} s \gamma)$ (it preserves the inertia condition as $\gamma^{-1} I_{\bar u} \gamma = I_{\gamma^{-1}\bar u}$), and $G_{K'}$ acts trivially since h is a homomorphism to an abelian group; so Δ acts. The condition $f(\gamma s \gamma^{-1}) = \varphi(\gamma) f(s)$ says $\gamma^{-1} \cdot f = \varphi(\gamma) f$. Hence

$$H_\varphi = (H \otimes_{\mathbb{F}_\ell} \mathbb{F})^{(\varphi^{-1})}.$$

Step 3: Kummer theory. Fix a primitive $\zeta \in \mu_\ell \subset K'$ and let $\log_\zeta\colon \mu_\ell \to \mathbb{F}_\ell$ be the inverse of $x \mapsto \zeta^x$. For $a \in K'^\times$ and $\alpha \in \overline{\mathbb{Q}}$ with $\alpha^\ell = a$, $h_a(s) = \log_\zeta(s(\alpha)/\alpha)$ is a continuous homomorphism $G_{K'} \to \mathbb{F}_\ell$ independent of α, and $a \mapsto h_a$ is an isomorphism $K'^\times/K'^{\times\ell} \to \mathrm{Hom}_{\mathrm{cts}}(G_{K'}, \mathbb{F}_\ell)$. For a finite place $\mathfrak{q} \nmid \ell$ of K', $K'(\alpha)/K'$ is unramified at $\mathfrak{q}$ if and only if $\mathrm{ord}_\mathfrak{q}(a) \in \ell\mathbb{Z}$. So $a \mapsto h_a$ maps the subgroup B of classes with $\mathrm{ord}_\mathfrak{q}(a) \in \ell\mathbb{Z}$ for all finite $\mathfrak{q} \nmid \ell$ isomorphically onto H. For $\gamma \in G_F$, $\gamma(\alpha)$ is an ℓ-th root of $\gamma(a)$ and $\gamma(\zeta^x) = \zeta^{\bar\omega(\gamma)x}$, so

$$h_{\gamma a}(s) = \log_\zeta \gamma((\gamma^{-1} s \gamma)(\alpha)/\alpha) = \bar\omega(\gamma)\, h_a(\gamma^{-1} s \gamma) = \bar\omega(\gamma)\, (\gamma \cdot h_a)(s).$$

Writing B additively, $\delta \cdot h_a = \varphi(\delta)^{-1} h_a$ holds if and only if $h_{\delta a} = \bar\omega(\delta)\varphi(\delta)^{-1} h_a$, i.e. $\delta a = \bar\omega(\delta)\varphi(\delta)^{-1} a$; extending $\mathbb{F}$-linearly, $(H \otimes \mathbb{F})^{(\varphi^{-1})} \cong (B \otimes_{\mathbb{F}_\ell} \mathbb{F})^{(\psi)}$ with $\psi = \bar\omega\varphi^{-1}$ (as characters of Δ). Moreover $\psi(c') = -\varphi(c)^{-1} = -\varphi(c)$.

Step 4: S-units and the class group. Let S be the set of places of K' above ℓ and $\mathcal{O}_S = \mathcal{O}_{K'}[1/\ell]$. Sending $a \in B$ to the class of the ideal $\mathfrak{a}$ of $\mathcal{O}_S$ with $a\mathcal{O}_S = \mathfrak{a}^\ell$ gives an exact sequence of $\mathbb{F}_\ell[\Delta]$-modules $0 \to \mathcal{O}_S^\times/\mathcal{O}_S^{\times\ell} \to B \to \mathrm{Cl}(\mathcal{O}_S)[\ell]$ (if $\mathfrak{a} = b\mathcal{O}_S$ then $a = b^\ell u$ with $u \in \mathcal{O}_S^\times$; an S-unit that is an ℓ-th power in K' is the ℓ-th power of an S-unit). $\mathrm{Cl}(\mathcal{O}_S)$ is a quotient of $\mathrm{Cl}(K')$, and $\dim A[\ell] = \dim A/\ell A$ for a finite abelian group A, so $\dim_{\mathbb{F}_\ell} \mathrm{Cl}(\mathcal{O}_S)[\ell] \le r$. Tensoring with $\mathbb{F}$ and taking ψ-parts (both exact),

$$\dim_{\mathbb{F}} (B \otimes \mathbb{F})^{(\psi)} \le \dim_{\mathbb{F}} (\mathcal{O}_S^\times/\ell \otimes \mathbb{F})^{(\psi)} + r.$$

Let $\mu = \mu(K')$ and $Y = (\mathcal{O}_S^\times/\mu) \otimes \mathbb{Z}_\ell$, a free $\mathbb{Z}_\ell$-module of finite rank with Δ-action. As $\mathcal{O}_S^\times/\mu$ is free, $0 \to \mu/\mu^\ell \to \mathcal{O}_S^\times/\ell \to Y/\ell Y \to 0$ is exact, and $\dim \mu/\mu^\ell = 1$. Let $W = W(\mathbb{F})$ be the Witt vectors, $Q_W = W[1/\ell]$, $\tilde\psi\colon \Delta \to W^\times$ the Teichmüller lift of ψ, and $e = \#\Delta^{-1} \sum_\delta \tilde\psi(\delta)^{-1}\delta \in W[\Delta]$, an idempotent reducing to e_ψ. With $Y_W = Y \otimes_{\mathbb{Z}_\ell} W$ we have $Y/\ell Y \otimes_{\mathbb{F}_\ell} \mathbb{F} = Y_W/\ell Y_W$, and $Y_W = eY_W \oplus (1-e)Y_W$ with eY_W free over W, so $(Y_W/\ell Y_W)^{(\psi)} = e_\psi(Y_W/\ell Y_W) \cong eY_W/\ell eY_W$ has $\mathbb{F}$-dimension $\dim_{Q_W} eV$, where $V = \mathcal{O}_S^\times \otimes_{\mathbb{Z}} Q_W = Y \otimes_{\mathbb{Z}_\ell} Q_W$. So

$$\dim_{\mathbb{F}} H_\varphi \le 1 + r + \dim_{Q_W} eV. \tag{51.1}$$

Step 5: the multiplicity of $\tilde\psi$ in V. For a transitive Δ-set Δ/Δ_0, an element $x = \sum_g x_g\, g$ of $Q_W[\Delta/\Delta_0]$ with $\delta x = \tilde\psi(\delta) x$ for all δ satisfies $x_{\delta g} = \tilde\psi(\delta) x_g$; so it is determined by x_{Δ_0}, and it is 0 if $\tilde\psi|_{\Delta_0} \ne 1$ (take $\delta \in \Delta_0$, $g = \Delta_0$). Hence $\dim eQ_W[\Delta/\Delta_0] \le 1$, with 0 when $\tilde\psi|_{\Delta_0} \ne 1$. The valuations at S give an exact sequence of $Q_W[\Delta]$-modules $0 \to \mathcal{O}_{K'}^\times \otimes Q_W \to V \to Q_W[S]$, and S is the disjoint union over the n_ℓ places $v \mid \ell$ of F of transitive Δ-sets; so $\dim eV \le \dim e(\mathcal{O}_{K'}^\times \otimes Q_W) + n_\ell$. By Dirichlet's unit theorem the logarithmic embedding $\mathcal{O}_{K'}^\times \to \mathbb{R}^{S_\infty}$,

S_∞ the archimedean places of K', is Δ-equivariant for the permutation action, has kernel μ and its image spans the hyperplane of vectors with coordinate sum 0, a Δ-stable complement of the invariant line $\mathbb{R}(1,\dots,1)$. So the traces of $\delta \in \Delta$ on $(\mathcal{O}_{K'}^\times/\mu)\otimes\mathbb{Q}$ and on $\mathbb{Q}[S_\infty]$ differ by 1, and therefore $(\mathcal{O}_{K'}^\times \otimes Q_W)\oplus Q_W \cong Q_W[S_\infty]$ as $Q_W[\Delta]$-modules. The set S_∞ is the disjoint union over the d real places of F of transitive Δ-sets whose stabiliser is $\{1, c'\}$ (each archimedean place of K' is complex). Since $\tilde{\psi}(c') = 1$ exactly when $\psi(c') = 1$, that is when $\varphi(c) = -1$,

$$\dim e(\mathcal{O}_{K'}^\times \otimes Q_W) \le \dim eQ_W[S_\infty] \le \begin{cases} 0, & \varphi(c) = 1, \\ d, & \varphi(c) = -1. \end{cases}$$

With (51.1) this gives the bound for H_φ. □

51.2 Seeds in cases (II) and (III) and spaces of marked pairs

This subsection constructs the seed pairs from which modularity is propagated, and proves that spaces of marked ordinary symplectic pairs exist over good auxiliary towers (Proposition 51.17). In case (II) a seed pair exists over every good deep tower of case (II) (Proposition 51.8). It is the induction to $\mathbb{Q}$ of an ordinary Hilbert eigenform of mixed weight over a real quadratic field that is congruent to an Eisenstein series (Proposition 51.9); such forms come from Hida families of nearly ordinary Hilbert modular forms [128] and from Hilbert modular forms congruent to one (Lemma 51.11), and the induced representation embeds into GSp_4 with the required residual shape and flags (Lemma 51.12, Lemma 51.13). In case (III) the seed is the symplectic tensor product of a newform congruent to an Eisenstein series, as in Subsection 49.1, with a dihedral representation (Proposition 51.14, Lemma 51.15, Lemma 51.16); its residual pair is ramified at one auxiliary prime, which dies in the larger towers over which the seed pair is used. In both cases the seed is automorphic over an abelian CM field and irreducible over the cyclotomic tower.

Proposition 51.8. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (II), let $\mathscr{T}$ be a good and deep auxiliary tower for $\mathfrak{D}$ of case (II), and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Then there are a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and a seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι whose reduction $\bar{Q}$ lies in V and either has an entry of weight $-w_\alpha$, or has entries of weights w_β and $-w_\theta$.*

Proof. Let $\mathscr{T} = (\epsilon, E, F, g_{\mathscr{T}}, \Sigma, (\bar{v})_{v\in\Sigma})$, write $\kappa_i = \kappa_i^\epsilon$, bars for reduction, and $\mathfrak{m}_1$ for the maximal ideal of the coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ constructed below (enlarged finitely often). For both labellings $\{\kappa_1,\kappa_3\} = \{\theta,\alpha\}$, $\{\kappa_2,\kappa_4\} = \{\Psi, \mathbf{1}\}$, $\mathrm{rt}_{w_\alpha} = \kappa_1/\kappa_2 = \alpha$ and $\mathrm{rt}_{w_\Psi} = \kappa_1/\kappa_3 = \Psi^{\pm1}$; and $\bar{\alpha} = \bar{\xi}$, since $\overline{\chi_{\mathrm{cyc}}\omega_\ell^{-1}} = 1$.

Step 1: the real quadratic field. Let k_0 be the real quadratic field of (Uq2), in which 2 and ℓ split, and $\phi\colon G_\mathbb{Q} \to \{\pm1\} \subset \mathbb{Z}_\ell^\times$ its quadratic character. By (Uq1), $\bar{\Psi}$ has values ±1 on G_F, and by (Uq2) its kernel there is $G_{F'} = G_F \cap G_{k_0}$, $F' = Fk_0$; so $\bar{\Psi} = \bar{\phi}$ on G_F. (a) By (Oq7) the residues $\bar{\kappa}_i(g_{\mathscr{T}})$ are pairwise distinct; they are $x\varsigma, \varsigma, x, 1$ with $x = \bar{\xi}(g_{\mathscr{T}})$, $\varsigma = \bar{\Psi}(g_{\mathscr{T}}) \in \{\pm1\}$. So $\varsigma = -1$ (else $x\varsigma = x$), $g_{\mathscr{T}} \notin G_{k_0}$, $\phi(g_{\mathscr{T}}) = -1$, and $x^2 \ne 1$; $u = g_{\mathscr{T}}^2$ lies in $G_{F'}$. (b) For every place $\bar{w}$ above ℓ, $D_{\bar{w}} \cap G_F \subseteq G_{F'}$ by (Uq1), (Uq2); in particular $D_v \subseteq G_{F'}$ for $v \in \Sigma$. (c) For every place $\bar{w}$ above ℓ there is $h \in D_{\bar{w}} \cap G_{F'}$ with $\bar{\xi}(h)^2 \ne 1$: by (Uq4) some $h \in D_{\bar{w}} \cap G_F$ has $\bar{\alpha}(h)^4 \ne 1$, and $h \in G_{F'}$ by (b). (d) Some $g \in G'$ lies outside G_{k_0}: otherwise $\phi|_{G_L}$ factors through $\chi_{\mathrm{cyc}}(G_L)$, an open subgroup of $\mu_{\ell-1} \times (1+\ell\mathbb{Z}_\ell)$, and being of order ≤ 2 it is trivial on the pro-ℓ part, i.e. on $G_L \cap \ker\omega_\ell$; then $\eta = \bar{\Psi}|_{G_L} = \bar{\phi}|_{G_L}$ satisfies $\eta^2 = 1$, is trivial on $G_L \cap \ker\omega_\ell$, and permutes the $\bar{\kappa}_i$ on G_L ($\eta\bar{\theta} = \bar{\alpha}$, $\eta\bar{\alpha} = \bar{\theta}$, $\eta\bar{\Psi} = 1$, $\eta\cdot 1 = \bar{\Psi}$, as $\bar{\Psi}^2 = 1$); by (Oq4) $\eta = 1$, against (Oq3) for the root w_Ψ. In particular $k_0 \not\subseteq L$; and $L = FE$ is a CM field abelian over $\mathbb{Q}$.

Step 2: the Hilbert eigenform. Let $\mathfrak{l}_1, \mathfrak{l}_2$ be the places of k_0 above ℓ and $\xi_0 = \xi|_{G_{k_0}}$, of finite order. Its hypotheses in Proposition 51.9: a complex conjugation in G_{k_0} is conjugate in $G_{\mathbb{Q}}$ to c, and $\xi(c) = -1$ (Sg1); ξ is unramified at ℓ (Uq3); 2 splits in k_0, so a place of k_0 above 2 has norm 2 and contains the inertia groups $I_{\bar{w}}$ above it, and by (Uq4) some $g \in I_{\bar{w}} \cap G_F$ has $\bar{\xi}(g) \neq 1$, so ξ_0 is ramified there; the last two hypotheses are Step 1 (c). So there are $k, t \geq 2$ divisible by $\ell - 1$, and ρ with (Hm1)–(Hm5). A continuous homomorphism from a compact group to $\mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ takes values in GL_2 of a finite extension of $\mathbb{Q}_\ell$ (Baire category) and preserves a lattice; so, conjugating, ρ takes values in $\mathrm{GL}_2(\mathcal{O}_1)$ for a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$.

Step 3: a Ribet lattice diagonal at u, and the ordinary lines. The characteristic polynomial of $\rho(u)$ reduces to $(X-1)(X-x^2)$ (Hm2), with distinct roots by Step 1 (a); by Hensel its roots $a_1 \equiv x^2$, $a_2 \equiv 1$ lie in $\mathcal{O}_1$, the lattice is the sum of the two eigenlines, and in an adapted basis $\rho(u) = \mathrm{diag}(a_1, a_2)$; write $\rho(g) = \left(\begin{smallmatrix} a_g & b_g \\ c_g & d_g \end{smallmatrix}\right)$. The semisimplification of $\bar{\rho}$ is $\bar{\xi}_0 \oplus 1$ (Brauer–Nesbitt and (Hm2)), so $\bar{\rho}$ has a stable line, which is an eigenline of $\bar{\rho}(u)$; hence all $\bar{b}_g = 0$ or all $\bar{c}_g = 0$, in either case $b_g c_{g'} \in \mathfrak{m}_1$ for all g, g', the diagonal of $\bar{\rho}$ consists of characters, and comparing at u, $\bar{a} = \bar{\xi}_0$, $\bar{d} = 1$. Not all c_g vanish ((Hm1)); with $n = \min_g v(c_g)$, ϖ a uniformiser and $\rho_1 = \mathrm{diag}(1, \varpi^n)^{-1} \rho\, \mathrm{diag}(1, \varpi^n)$, one gets $\rho_1(g) \in \mathrm{GL}_2(\mathcal{O}_1)$ (if $n = 0$ use $b_g c_{g'} \in \mathfrak{m}_1$ with $c_{g'}$ a unit), $\rho_1(u) = \mathrm{diag}(a_1, a_2)$, and

$$\bar{\rho}_1(g) = \begin{pmatrix} \bar{\xi}(g) & 0 \\ \bar{y}(g) & 1 \end{pmatrix}, \qquad \bar{y}(gh) = \bar{y}(g)\bar{\xi}(h) + \bar{y}(h), \qquad \bar{y} \neq 0.$$

$\bar{y}|_{G_{F'}} \neq 0$: otherwise take $h \in G_{F'}$ with $\bar{\xi}(h) \neq 1$ (Step 1 (c)); for $g \in G_{k_0}$, $\bar{y}(gh) = \bar{y}(g)\bar{\xi}(h)$ and, as $ghg^{-1} \in G_{F'}$ (F' is Galois over $\mathbb{Q}$), $\bar{y}(gh) = \bar{y}(ghg^{-1}g) = \bar{y}(g)$; so $\bar{y} = 0$. *Lines.* Let $\bar{w}$ be a place above ℓ, $D = D_{\bar{w}} \cap G_{k_0}$, $\kappa_1^{\bar{w}}, \kappa_2^{\bar{w}}$ the characters of (Hm4), and $h \in D$ with $\bar{\xi}(h) \neq 1$ (Step 1 (c)). The D-stable line of (Hm4) is the $\kappa_1^{\bar{w}}(h)$-eigenline of $\rho_1(h)$, its other eigenvalue $\kappa_2^{\bar{w}}(h)$ being residually different. If $\bar{w}$ induces $\mathfrak{l}_1$: $\kappa_1^{\bar{w}}(h) \equiv \bar{\xi}(h) \not\equiv 1 \equiv d_h$, so the line is spanned by $(\kappa_1^{\bar{w}}(h) - d_h,\ c_h)$, whose first coordinate is a unit, i.e. by $(1, z_{\bar{w}})$ with $z_{\bar{w}} \in \mathcal{O}_1$ (enlarging $\mathcal{O}_1$ by $\kappa_1^{\bar{w}}(h)$), and $\rho_1(s) = \mathrm{low}(z_{\bar{w}}) \left(\begin{smallmatrix} \kappa_1^{\bar{w}}(s) & * \\ 0 & \kappa_2^{\bar{w}}(s) \end{smallmatrix}\right) \mathrm{low}(z_{\bar{w}})^{-1}$ for $s \in D$. If $\bar{w}$ induces $\mathfrak{l}_2$: $\kappa_1^{\bar{w}}(h) \equiv 1$, so the line is spanned by $(b_h,\ \kappa_1^{\bar{w}}(h) - a_h)$, whose second coordinate is a unit, i.e. by $(w_{\bar{w}}, 1)$ with $w_{\bar{w}} \in \mathfrak{m}_1$ ($b_h \in \mathfrak{m}_1$), and $\rho_1(s) = \mathrm{up}(w_{\bar{w}}) \left(\begin{smallmatrix} \kappa_2^{\bar{w}}(s) & 0 \\ * & \kappa_1^{\bar{w}}(s) \end{smallmatrix}\right) \mathrm{up}(w_{\bar{w}})^{-1}$ for $s \in D$.

Step 4: the induced representation. Choose $b_1, b_2 \in \mathcal{O}_1^\times$ (Hensel; ℓ odd) with $b_i^2 = a_i$, $\bar{b}_1 = -\bar{\kappa}_1(g_{\mathscr{T}})$, $\bar{b}_2 = -\bar{\kappa}_2(g_{\mathscr{T}})$; this is possible as $\bar{\kappa}_1(g_{\mathscr{T}}) \in \{-x, x\}$ and $\bar{\kappa}_2(g_{\mathscr{T}}) \in \{-1, 1\}$ by Step 1 (a). Put $\mu = \chi_{\mathrm{cyc}}^k \xi \phi$, a character of $G_{\mathbb{Q}}$ with $\mu|_{G_{k_0}} = \det \rho_1$ (Hm2). Then $\mu(g_{\mathscr{T}}) = -b_1 b_2$: $\mu(g_{\mathscr{T}})^2 = \mu(u) = \det \rho_1(u) = (b_1 b_2)^2$, and residually $\bar{\mu}(g_{\mathscr{T}}) = \bar{\omega}_\ell(g_{\mathscr{T}})^k x \cdot (-1) = -x$ while $-\bar{b}_1 \bar{b}_2 = -\bar{\kappa}_1 \bar{\kappa}_2(g_{\mathscr{T}}) = -x$ (for $\epsilon = 0$: $(-x)(-1)$; for $\epsilon = 1$: $x \cdot 1$), and $x \neq -x$. Let $R_0 \colon G_F \to \mathrm{GL}_4(\mathcal{O}_1)$ be the matrix, in the basis $(f_1, \ldots, f_4)$ given by the columns of P_b (Lemma 51.12), of the induced representation $\mathrm{Ind}_{G_{F'}}^{G_F}(\rho_1|_{G_{F'}})$ written in the basis $(e_1, e_2, g_{\mathscr{T}} e_1, g_{\mathscr{T}} e_2)$: for $h \in G_{F'}$

$$R_0(h) = \mathrm{ix}_b(\rho_1(h), \rho_1(g_{\mathscr{T}}^{-1} h g_{\mathscr{T}})), \qquad R_0(g_{\mathscr{T}}) = P_b^{-1} \begin{pmatrix} 0 & \rho_1(u) \\ 1_2 & 0 \end{pmatrix} P_b = \mathrm{diag}(-b_1, -b_2, b_1, b_2)$$

(Ie2), and $R_0(g_{\mathscr{T}} h) = R_0(g_{\mathscr{T}}) R_0(h)$. It is a continuous homomorphism ($G_{F'}$ is normal of index 2 in G_F, $g_{\mathscr{T}} \notin G_{F'}$, $g_{\mathscr{T}}^2 = u$), with values in $\mathrm{GL}_4(\mathcal{O}_1)$ by (Ie0); over $\overline{\mathbb{Q}}_\ell$, $R_0 \cong V|_{G_F}$ for $V = \mathrm{Ind}_{G_{k_0}}^{G_{\mathbb{Q}}} \rho$ (Mackey: $G_{\mathbb{Q}} = G_{k_0} G_F$, $G_{k_0} \cap G_F = G_{F'}$). $R_0(g)$ has similitude $\mu(g)$: for $h \in G_{F'}$, $\det \rho_1(h) = \mu(h) = \mu(g_{\mathscr{T}}^{-1} h g_{\mathscr{T}}) = \det \rho_1(g_{\mathscr{T}}^{-1} h g_{\mathscr{T}})$ and (Ie1) applies; for $g_{\mathscr{T}}$, (Ie2) and (Ie1) give similitude $-b_1 b_2 = \mu(g_{\mathscr{T}})$. Residually $\bar{\theta} = \bar{\xi}\bar{\Psi}$ and $\bar{\mu} = \bar{\xi}\bar{\phi}$ agree on G_F, so θ/μ has values in $1 + \mathfrak{m}_1$ there, on which squaring is a topological automorphism; let $\delta \colon G_F \to 1 + \mathfrak{m}_1$ be the

continuous character with $\delta^2 = \theta/\mu$, and

$$R = \delta\, R_0 \colon G_F \to \mathrm{GL}_4(\mathcal{O}_1).$$

For $v \in \Sigma$ define n_v: by Step 1 (b) and (a), $D_v \subseteq G_{F'}$ and the places $\bar v$, $g_{\mathscr{T}}^{-1}\bar v$ induce the two different places of k_0 above ℓ ($g_{\mathscr{T}}$ acts non-trivially on k_0). If $\bar v$ induces $\mathfrak{l}_1$, put $n_v = \mathrm{fi}_b^+(z_{\bar v}, w_{g_{\mathscr{T}}^{-1}\bar v})$; otherwise $n_v = \mathrm{fi}_b^-(z_{g_{\mathscr{T}}^{-1}\bar v}, w_{\bar v})$. Here d, e of Lemma 51.12 are units because $w \in \mathfrak{m}_1$.

Step 5: properties. (R1) $R(g)$ has similitude $\delta^2\mu = \theta$. (R2) $R(g_{\mathscr{T}}) = \delta(g_{\mathscr{T}})\mathrm{diag}(-b_1, -b_2, b_1, b_2)$ is diagonal, with residues $(\bar\kappa_1, \bar\kappa_2, -\bar\kappa_1, -\bar\kappa_2)(g_{\mathscr{T}}) = (\bar\kappa_1, \bar\kappa_2, \bar\kappa_3, \bar\kappa_4)(g_{\mathscr{T}})$, since $\bar\delta = 1$ and, for both labellings, $\bar\kappa_3(g_{\mathscr{T}}) = -\bar\kappa_1(g_{\mathscr{T}})$ and $\bar\kappa_4(g_{\mathscr{T}}) = -\bar\kappa_2(g_{\mathscr{T}})$ by Step 1 (a). (R3) For $h \in G_{F'}$, with $h' = g_{\mathscr{T}}^{-1} h g_{\mathscr{T}}$ and $\bar\xi(h') = \bar\xi(h)$, (Ie3) gives

$$\bar R(h) = \mathrm{diag}(\bar\xi, 1, \bar\xi, 1)(h) + u_h(E_{21} - E_{43}) + v_h(E_{41} - E_{23}),$$
$$u_h = -\tfrac{1}{2}(\bar\beta\bar y(h) + \bar y(h')), \qquad v_h = \tfrac{1}{2}(\bar y(h') - \bar\beta\bar y(h)),$$

$\bar\beta = \bar b_1 \bar b_2^{-1} \neq 0$. On $G_{F'}$, $(\bar\kappa_1, \dots, \bar\kappa_4) = (\bar\xi, 1, \bar\xi, 1)$ (as $\bar\Psi = 1$ there), and $\bar R(g_{\mathscr{T}} h) = \bar R(g_{\mathscr{T}})\bar R(h)$ with $\bar R(g_{\mathscr{T}})$ diagonal. So $\bar R$ has diagonal $(\bar\kappa_i)$ on G_F and is supported in $\{-w_\alpha, w_\beta, -w_\theta\} = \Sigma_V$. Choose $h \in G_{F'}$ with $\bar y(h) \neq 0$ (Step 3); then $-2(u_h + v_h) = 2\bar\beta\bar y(h) \neq 0$, so $u_h \neq 0$, and $\bar R$ has an entry of weight $-w_\alpha$ at $(2,1)$, or $v_h \neq 0$, and $\bar R$ has entries of weights $-w_\theta$ at $(4,1)$ and w_β at $(2,3)$. (R4) Let $v \in \Sigma$, $s \in D_v$, $s' = g_{\mathscr{T}}^{-1} s g_{\mathscr{T}}$. If $\bar v$ induces $\mathfrak{l}_1$, Step 3 gives $\rho_1(s) = A_z$ with $z = z_{\bar v}$, $(p, r) = (\kappa_1^{\bar v}(s), \kappa_2^{\bar v}(s))$, and $\rho_1(s') = B_w$ with $w = w_{g_{\mathscr{T}}^{-1}\bar v}$, $(p', r') = (\kappa_1^{g_{\mathscr{T}}^{-1}\bar v}(s'), \kappa_2^{g_{\mathscr{T}}^{-1}\bar v}(s'))$, in the notation of (Ie5); if $\bar v$ induces $\mathfrak{l}_2$, the same holds with the roles of s and s' exchanged. By (Ie5), $n_v^{-1} R(s) n_v$ is upper triangular with diagonal

$$\psi_v(s) = \delta(s)(\kappa_1^{(1)},\ \kappa_1^{(2)},\ \kappa_2^{(2)},\ \kappa_2^{(1)}),$$

where $\kappa_i^{(j)}$ is the character of (Hm4) at the one of $\bar v$, $g_{\mathscr{T}}^{-1}\bar v$ that induces $\mathfrak{l}_j$, evaluated at s resp. s'. Residually $\bar\psi_v = (\bar\xi, 1, \bar\xi, 1) = (\bar\kappa_1, \dots, \bar\kappa_4)$ on D_v (Hm4), as $\bar\Psi = 1$ on D_v. On I_v: $\psi_v = \delta\,(\chi_{\mathrm{cyc}}^{k+t}, \chi_{\mathrm{cyc}}^{k}, 1, \chi_{\mathrm{cyc}}^{-t})$ ($\chi_{\mathrm{cyc}}(s') = \chi_{\mathrm{cyc}}(s)$). By (Ie4), n_v is lower triangular with diagonal entries 1 and similitude 1, $(\bar n_v)_{32} = 2\bar b_2 \bar w\, \bar d^{-1}$ or $2\bar b_2 \bar w\, \bar e^{-1}$ vanishes ($w \in \mathfrak{m}_1$), so $\bar n_v$ is supported in Σ_Q, and $(\bar n_v)_{31} = \mp 1 \neq 0$. (R5) If $s \in D_v$ and $s^{\ell^a} \in \overline{[D_v, D_v]}$, then $s \in I_v$ ($D_v/I_v \cong \hat{\mathbb{Z}}$ is torsion-free), $\chi_{\mathrm{cyc}}(s)$ is an ℓ-power root of unity in $\mathbb{Z}_\ell^\times$, hence 1, so all χ_{cyc}-powers above are 1 at s; and $\delta(s)^2 = (\theta/\mu)(s) = (\chi_{\mathrm{cyc}}^{1+e-k}\omega_\ell^{-1}\chi\phi)(s) = \chi(s)$ (here $\omega_\ell(s)$ is a root of unity of order dividing $\ell - 1$ with residue $\bar\chi_{\mathrm{cyc}}(s) = 1$, and $\phi(s) = 1$ as ℓ is unramified in k_0), where $\chi(s)^{\ell^a} = 1$ and $\chi|_{G_F}$ has order prime to ℓ (the tower is deep), so $\delta(s)^2 = 1$ and $\delta(s) = 1$ ($\delta(s) \in 1 + \mathfrak{m}_1$). So $\psi_{v,i}(s) = 1$. (R6) Let $g \in I_{\bar w} \cap G_F$, $\bar w$ not above ℓ, with $\bar r_0(g) = 1$. Then $\bar\Psi(g) = 1$, so $g \in G_{F'}$; $\bar\xi(g) = \bar\alpha(g) = 1$, and ξ has order prime to ℓ, so $\xi(g) = 1 = \xi(g_{\mathscr{T}}^{-1} g g_{\mathscr{T}})$; by (Hm3) at $\bar w$ and at $g_{\mathscr{T}}^{-1}\bar w$, $\rho_1(g) = \rho_1(g_{\mathscr{T}}^{-1} g g_{\mathscr{T}}) = 1$, so $R_0(g) = 1$; and $(\theta/\mu)(g) = \chi(g)\omega_\ell(g)^{-1}\phi(g) = 1$ ($\chi(g) = 1$ by (Oq5), ω_ℓ unramified at $\bar w$, $g \in G_{k_0}$), so $\delta(g) = 1$ and $R(g) = 1$.

Step 6: the seed pair. $Q = (R, (n_v)_{v\in\Sigma})$ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for $\mathcal{O} \subseteq \mathcal{O}_1$: (Mq1) by (R1), (R6); (Mq2) by (R2); (Mq3) by (R4); (Mq4) by (R4), (R5). It is continuous for $\mathfrak{m}_1$. Its reduction satisfies (Wq1) by (R3), (R4), and (Wq2), since $\Sigma_V \subseteq \Sigma_P$ and every $\bar n_v$ is supported in Σ_Q; it lies in V and has an entry of weight $-w_\alpha$, or entries of weights w_β and $-w_\theta$, by (R3), (R4). Its image P' in $\overline{\mathbb{Q}}_\ell$ is a seed for ι. *Irreducibility on G':* Lemma 51.13 (Ia2) applies to ρ (isomorphic to ρ_1), L, $g_1 = g_{\mathscr{T}}$, a place $\bar w = \bar v$ ($v \in \Sigma$) and $U = I_{\bar v} \cap G_{k_0}$, with (a_1, a_2), (a_1', a_2') the pairs $(k+t, -t)$ and $(k, 0)$ in the appropriate order (Hm4), $|k + 2t| \neq |k|$, and $g \in G' \setminus G_{k_0}$ from Step 1 (d); so $V|_{G'}$ is irreducible, hence so is $R|_{G'} \cong \delta \otimes V|_{G'}$, and by Burnside the span of $R(G')$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$. *Weights:* on the open subgroup $U_0 = G_F \cap \ker\omega_\ell \cap \ker\chi$

and $s \in U_0 \cap I_v$, $\psi_{v,i}(s)^2 = \chi_{\mathrm{cyc}}(s)^{h_i}$ with

$$h = (1+e-k)(1,1,1,1) + 2\,(k+t,\ k,\ 0,\ -t),$$

by (R4) and $\delta^2 = \chi_{\mathrm{cyc}}^{1+e-k}\omega_\ell^{-1}\chi\phi$ (ϕ is unramified at ℓ); $h_1 - h_2 = h_3 - h_4 = 2t$ and $h_2 - h_3 = 2k$ lie in $2\mathbb{Z}_{\geq 2}$. *The character and automorphy:* take $\kappa = \delta^{-1}|_{G_L}$, $a = k-1-e$ (so $a+h_1 = 2(k+t)$ is even) and k' the order of the finite-order character $\omega_\ell\chi^{-1}\phi$ on G_F: then $\kappa^2\chi_{\mathrm{cyc}}^{-a} = \omega_\ell\chi^{-1}\phi$ on G_L, so $(\kappa(s)^2\chi_{\mathrm{cyc}}(s)^{-a})^{k'} = 1$; and $r_{P'}|_{G_L} \otimes \kappa = R_0|_{G_L} \cong V|_{G_L} \leftrightarrow_\iota \Pi$ for a regular algebraic cuspidal Π of $\mathrm{GL}_4(\mathbb{A}_L)$ by Lemma 51.13 (Ia1), whose hypotheses are (Hm1), (Hm5) ($p_i \neq q_i$ as $|p_i - q_i| \in \{k+2t, k\}$, and $k+2t \neq k$) and $k_0 \not\subseteq L$. So Q is a seed pair with values in $\mathcal{O}_1$ for ι, as asserted. □

Proposition 51.9. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $k_0 \subset \overline{\mathbb{Q}}$ a real quadratic field in which ℓ splits, with places $\mathfrak{l}_1 \neq \mathfrak{l}_2$ above ℓ; for $i = 1,2$ let $\tau_i\colon k_0 \to \overline{\mathbb{Q}}_\ell$ be the embedding inducing $\mathfrak{l}_i$ and ∞_i the real place $\iota \circ \tau_i$ of k_0. Let $\xi_0\colon G_{k_0} \to \overline{\mathbb{Q}}_\ell^\times$ be a continuous character of finite order such that: $\xi_0(c') = -1$ for every complex conjugation $c' \in G_{k_0}$; ξ_0 is unramified at $\mathfrak{l}_1$ and $\mathfrak{l}_2$; ξ_0 is ramified at some place of k_0 of absolute norm 2; $\bar{\xi}_0(g)^2 \neq 1$ for some $g \in G_{k_0}$; and for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ some $g \in D_{\bar{w}} \cap G_{k_0}$ has $\bar{\xi}_0(g) \neq 1$. Then there are integers $k, t \geq 2$ divisible by $\ell - 1$ and a continuous homomorphism $\rho\colon G_{k_0} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that:*

(Hm1) *$\rho|_U$ is irreducible for every open subgroup $U \subseteq G_{k_0}$;*

(Hm2) *$\det\rho = \chi_{\mathrm{cyc}}^k\xi_0$, and for every $g \in G_{k_0}$ the characteristic polynomial of $\rho(g)$ has coefficients in $\overline{\mathbb{Z}}_\ell$ and reduces to $(X-1)(X-\bar{\xi}_0(g))$;*

(Hm3) *for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ not above ℓ, the restriction of ρ to $I_{\bar{w}} \cap G_{k_0}$ is conjugate to $s \mapsto \mathrm{diag}(1, \xi_0(s))$;*

(Hm4) *for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ, with $D = D_{\bar{w}} \cap G_{k_0} \supseteq I = I_{\bar{w}} \cap G_{k_0}$, there are continuous characters $\kappa_1, \kappa_2\colon D \to \overline{\mathbb{Q}}_\ell^\times$ and a D-stable line on which D acts by κ_1, with D acting on the quotient by κ_2, such that: if $\bar{w}$ induces $\mathfrak{l}_1$ on k_0, then $\kappa_1 = \chi_{\mathrm{cyc}}^{k+t}$ and $\kappa_2 = \chi_{\mathrm{cyc}}^{-t}$ on I, and $\bar{\kappa}_1 = \bar{\xi}_0$, $\bar{\kappa}_2 = 1$ on D; if $\bar{w}$ induces $\mathfrak{l}_2$, then $\kappa_1 = \chi_{\mathrm{cyc}}^k$ and $\kappa_2 = 1$ on I, and $\bar{\kappa}_1 = 1$, $\bar{\kappa}_2 = \bar{\xi}_0$ on D;*

(Hm5) *$\rho \leftrightarrow_\iota \pi$ for a regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_2(\mathbb{A}_{k_0})$ such that, for $i = 1,2$, the Langlands parameter of π_{∞_i} restricted to $\mathbb{C}^\times \subset W_{\mathbb{R}}$ is $z \mapsto \mathrm{diag}(z^{p_i}\bar{z}^{q_i},\ z^{q_i}\bar{z}^{p_i})$ with $p_i, q_i \in \frac{1}{2}+\mathbb{Z}$, $p_1+q_1 = p_2+q_2$, $|p_1-q_1| = k+2t$ and $|p_2-q_2| = k$.*

Proof. Throughout, $\mathrm{Frob}_\mathfrak{q}$ is an arithmetic Frobenius, and ξ_0 is also viewed, by class field theory, as a character of the narrow ray class group modulo its conductor $\mathfrak{f}$, with $\xi_0(\mathfrak{q}) = \xi_0(\mathrm{Frob}_\mathfrak{q})$; $\mathfrak{f}$ is prime to ℓ (ξ_0 is unramified at $\mathfrak{l}_1, \mathfrak{l}_2$) and ξ_0 has sign $(1,1)$ (it is -1 on complex conjugations). As ξ_0 is unramified at $\mathfrak{l}_i$ and some $g \in D_{\bar{w}}$ ($\bar{w} \mid \mathfrak{l}_i$) has $\bar{\xi}_0(g) \neq 1$, $\bar{\xi}_0(\mathfrak{l}_i) \neq 1$ for $i = 1,2$. Let $I = \{\tau_1, \tau_2\}$; an element of $\mathbb{Z}[I]$ is written (a_1, a_2), and τ_i corresponds to the real place $\infty_i = \iota\circ\tau_i$.

Step 1: a parallel-weight cusp form with opposite stabilisations. By Proposition 51.10 (with $B = 2$) there are an integer $k \geq 2$ divisible by $\ell - 1$ and a non-zero eigenform $F_0 \in S_{k+1}(\mathfrak{f}\mathfrak{l}_1\mathfrak{l}_2, \xi_0)$ with eigenvalues $\lambda_0(\mathfrak{q})$, ℓ-integral, $\lambda_0(\mathfrak{q}) \equiv 1 + \xi_0(\mathfrak{q})$ for $\mathfrak{q} \nmid \mathfrak{f}\ell$, $\lambda_0(\mathfrak{l}_1) \equiv 1$, $\lambda_0(\mathfrak{l}_2) \equiv \xi_0(\mathfrak{l}_2)$. Fix an integer $t \geq 2$ divisible by $\ell - 1$.

Step 2: the point of F_0 on Hida's algebra. Let $N = \mathfrak{f}$ and let $\mathcal{O}$ be a coefficient ring containing $\tau_i(\mathcal{O}_{k_0})$, the values of ξ_0, the $\lambda_0(\mathfrak{q})$ and the e-th roots of unity, $e = \#G_{\mathrm{tor}}$. Viewed

as a function on $\mathrm{GL}_2(\mathbb{A}_{k_0})$ ([230], Section 2; [236], Section 3.1), F_0 is a cusp form of parallel weight $k+1$, i.e. of arithmetic weight $(n_0,v_0)=((k-1,k-1),(0,0))$, of level $V_1(\mathfrak{f})\cap U(\ell)$, invariant under the Iwahori subgroups at $\mathfrak{l}_1,\mathfrak{l}_2$ (its character ξ_0 is trivial on $\mathfrak{r}_\ell^\times$), with characters $(\psi,\psi')=(\xi_0,\mathbf{1})$; its eigenvalues for Hida's $T(\mathfrak{q})$ ($\mathfrak{q}\nmid\mathfrak{f}\ell$) and $T(\varpi_{\mathfrak{l}_i})$ (double coset of $\mathrm{diag}(1,\varpi_{\mathfrak{l}_i})$, with $v_0=0$ no normalisation) are Shimura's $\lambda_0(\mathfrak{q})$ and $\lambda_0(\mathfrak{l}_i)$ ([236], pp. 29–30), units at $\mathfrak{l}_i$, so F_0 is nearly ordinary. By (Hf2) it defines $\lambda_0\colon\mathbf{h}\to\mathcal{O}$ with $\lambda_0|_{\mathcal{O}[[G]]}=P_0:=P_{n_0,0,\xi_0,\mathbf{1}}$, $P_0(z,a)=\xi_0(z)\mathcal{N}(z)^{k-1}$. Its kernel is a prime of $\mathbf{h}$ containing a minimal prime $\mathfrak{a}$; by (Hf1), $\mathbb{I}=\mathbf{h}/\mathfrak{a}$ is a domain, finite and torsion-free over A, hence $A\to\mathbb{I}$ is injective and integral; $\mathbb{I}$ is local (a domain finite over the complete local ring A), and λ_0 factors through $\mathbb{I}$.

Step 3: a point of non-parallel weight on the same component. Put $n'=(k+2t-1,\,k-1)$, $v'=(0,t)$: an arithmetic weight with $n'+2v'=(k+2t-1)t$ and $k'=n'+2t=(k+2t+1,\,k+1)$. Let $P'=P_{n',v',\xi_0,\mathbf{1}}$, i.e. $P'(z,a)=P_0(z,a)\,\mathcal{N}(z)^{2t}a^{v'}$, and $\mathfrak{p}'=\ker(P'|_A)$; $P'|_A\colon A\to\mathcal{O}$ is surjective, so $A/\mathfrak{p}'=\mathcal{O}$. By lying over there is a prime $\mathfrak{P}\subset\mathbb{I}$ with $\mathfrak{P}\cap A=\mathfrak{p}'$; $\mathbb{I}/\mathfrak{P}$ is a domain finite over $\mathcal{O}$, hence contained in a coefficient ring $\mathcal{O}'$. Let $\lambda'\colon\mathbf{h}\to\mathbb{I}\to\mathbb{I}/\mathfrak{P}\subseteq\mathcal{O}'$. (a) $\lambda'|_A=P'|_A$: both are $\mathcal{O}$-algebra maps $A\to\mathcal{O}'$ with kernel $\mathfrak{p}'$, i.e. the identity of $A/\mathfrak{p}'=\mathcal{O}$. (b) $\lambda'=\lambda_0$ on G_{tor}: the image u in $\mathbb{I}$ of $g\in G_{\mathrm{tor}}$ satisfies $\prod_{\zeta^e=1}(u-\zeta)=u^e-1=0$ in the domain $\mathbb{I}$, with all $\zeta\in\mathcal{O}$, so $u=\zeta$ for some $\zeta\in\mathcal{O}$, and both λ' and λ_0 (which factor through $\mathbb{I}$ and are $\mathcal{O}$-linear) send g to ζ. (c) $P'=P_0$ on G_{tor}: for $g=(z,a)$ of finite order $\mathcal{N}(z)$ and $\tau_2(a)$ are roots of unity in $\mathbb{Z}_\ell^\times$, of order dividing $\ell-1$, and $(\ell-1)\mid t$. Since $G=W\times G_{\mathrm{tor}}$ and λ' is continuous (an $\mathcal{O}$-algebra map from a complete local noetherian $\mathcal{O}$-algebra with finite residue field to $\mathcal{O}'$ is local, and $\mathbf{h}$ is finite over A), $\lambda'|_{\mathcal{O}[[G]]}=P'$. (d) $\lambda'\equiv\lambda_0$: both factor through the local ring $\mathbb{I}$, so $\overline{\lambda'(h)}=\overline{\lambda_0(h)}$ for every $h\in\mathbf{h}$.

Step 4: the classical form f' and its Galois representation. By (Hf2) there is a non-zero nearly ordinary common eigenform f' of weight (k',w'), level $V_1(\mathfrak{f})\cap U(\ell)$ and characters $(\xi_0,\mathbf{1})$, with eigenvalues $\iota\lambda'$. By (Hf3) let $\sigma'=\sigma_{\lambda'}$ and $\sigma_0=\sigma_{\lambda_0}$, semisimple, unramified outside $\mathfrak{f}\ell$, with $\det(1-\sigma'(\mathrm{Frob}_{\mathfrak{q}})X)=1-\lambda'(T(\mathfrak{q}))X+\lambda'(\langle\mathfrak{q}\rangle)\mathrm{N}\mathfrak{q}X^2$. As $\langle\mathfrak{q}\rangle$ is the class of $\mathfrak{q}$ in $Z(N)$ and $\mathcal{N}(\langle\mathfrak{q}\rangle)=\mathrm{N}\mathfrak{q}=\chi(\mathrm{Frob}_{\mathfrak{q}})$, $\lambda'(\langle\mathfrak{q}\rangle)\mathrm{N}\mathfrak{q}=P'(\langle\mathfrak{q}\rangle)\mathrm{N}\mathfrak{q}=\xi_0(\mathfrak{q})\mathrm{N}\mathfrak{q}^{k+2t}$; by Chebotarev density, $\det\sigma'=\xi_0\chi^{k+2t}$. By Step 3 (d), $\mathrm{tr}\,\sigma'(\mathrm{Frob}_{\mathfrak{q}})=\lambda'(T(\mathfrak{q}))\equiv\lambda_0(\mathfrak{q})\equiv1+\xi_0(\mathfrak{q})$ for $\mathfrak{q}\nmid\mathfrak{f}\ell$. Put

$$\rho=\sigma'\otimes\chi^{-t}\colon G_{k_0}\to\mathrm{GL}_2(\overline{\mathbb{Q}}_\ell),\qquad\det\rho=\chi^k\xi_0.$$

Step 5: (Hm2). ρ takes values in $\mathrm{GL}_2(\mathcal{O}'')$, after conjugation, for a coefficient ring $\mathcal{O}''$. Indeed, G_{k_0} is the union of the closed subgroups $\rho^{-1}(\mathrm{GL}_2(E))$ over the countably many finite extensions E of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$ (E is complete, hence closed); by the Baire category theorem one of them has non-empty interior, so is open, hence of finite index in the compact group G_{k_0}, and adjoining the entries of ρ at finitely many coset representatives gives a finite extension E' with $\rho(G_{k_0})\subseteq\mathrm{GL}_2(E')$. The $\mathcal{O}_{E'}$-module L spanned by $\rho(G_{k_0})\mathcal{O}_{E'}^2$ is bounded (as $\rho(G_{k_0})$ is compact), hence finitely generated, spans E'^2 and is $\rho(G_{k_0})$-stable; in an $\mathcal{O}_{E'}$-basis of L, ρ takes values in $\mathrm{GL}_2(\mathcal{O}'')$ with $\mathcal{O}''=\mathcal{O}_{E'}$. So characteristic polynomials have coefficients in $\overline{\mathbb{Z}}_\ell$. As $\mathrm{N}\mathfrak{q}^t\equiv1$ ($(\ell-1)\mid t$), $\mathrm{tr}\,\rho(\mathrm{Frob}_{\mathfrak{q}})\equiv1+\xi_0(\mathrm{Frob}_{\mathfrak{q}})$ and $\det\rho(\mathrm{Frob}_{\mathfrak{q}})\equiv\xi_0(\mathrm{Frob}_{\mathfrak{q}})$ (as $\chi^k\equiv1$). The sets of g with $\mathrm{tr}\,\rho(g)-1-\xi_0(g)\in\mathfrak{m}_{\mathcal{O}''}$, resp. $\det\rho(g)-\xi_0(g)\in\mathfrak{m}_{\mathcal{O}''}$, are closed and contain the Frobenius elements, which are dense (Chebotarev); hence the characteristic polynomial of $\rho(g)$ reduces to $(X-1)(X-\bar\xi_0(g))$ for every g.

Step 6: (Hm4). Let $\bar w$ be a place above ℓ, $D=D_{\bar w}\cap G_{k_0}\supseteq I=I_{\bar w}\cap G_{k_0}$, a decomposition group at $\mathfrak{p}=\mathfrak{l}_i$ ($k_{0,\mathfrak{p}}=\mathbb{Q}_\ell$, $\mathfrak{r}_{\mathfrak{p}}=\mathbb{Z}_\ell$). By (Hf3), $\sigma'|_D\cong\left(\begin{smallmatrix}\epsilon'&*\\0&\delta'\end{smallmatrix}\right)$ and $\sigma_0|_D\cong\left(\begin{smallmatrix}\epsilon_0&*\\0&\delta_0\end{smallmatrix}\right)$, with $\delta'(\mathrm{rec}_{\mathfrak{p}}(x))=\lambda_{f'}(x^{-v'}T(x))$ and $\delta_0(\mathrm{rec}_{\mathfrak{p}}(x))=\lambda_{F_0}(T(x))$. (a) *Units.* For $u\in\mathbb{Z}_\ell^\times$, $T(u)$ is the double coset of $\mathrm{diag}(1,u)=u\cdot\mathrm{diag}(u^{-1},1)$, which normalises the level group; $\mathrm{diag}(u^{-1},1)$ acts trivially on f' and F_0 (character $\psi'=\mathbf{1}$, [129], Section 3, where $\langle1,a\rangle=T(a^{-1},1)$ is the double coset of $\mathrm{diag}(a^{-1},1)$), and the central element u acts by the central character, whose finite-order

part is ξ_0 (it agrees with ξ_0 at almost all primes by the formula for $\lambda'(\langle\mathfrak{q}\rangle)$, and finite-order Hecke characters agreeing at almost all primes are equal), trivial on $\mathfrak{r}_\mathfrak{p}^\times$. So $\lambda_{f'}(T(u)) = \lambda_{F_0}(T(u)) = 1$, and with $\mathcal{N}(\mathrm{rec}_\mathfrak{p}(u)) = u^{-1}$:

$$\delta'|_I = \chi^{v'_\mathfrak{p}}, \qquad \delta_0|_I = \mathbf{1}, \qquad v'_{\mathfrak{l}_1} = 0,\ v'_{\mathfrak{l}_2} = t.$$

(b) *Residues.* D^{ab} is topologically generated by $\mathrm{rec}_\mathfrak{p}(\mathbb{Z}_\ell^\times)$ and $\mathrm{rec}_\mathfrak{p}(\ell)$, which acts on unramified extensions as the arithmetic Frobenius in this normalisation. On $\mathrm{rec}_\mathfrak{p}(\ell)$, δ' and δ_0 take the values λ' and λ_0 of the element $T(\varpi_\mathfrak{p})$ of $\mathbf{h}$ (normalised by ϖ^{-v} in weight (k,w)), congruent by Step 3 (d); on units both are $\equiv 1$ ($\bar\chi^t = \bar\omega_\ell^t = 1$). Hence $\bar\delta' = \bar\delta_0$ is unramified with $\bar\delta_0(\mathrm{Frob}_\mathfrak{p}) = \bar\lambda_0(\mathfrak{p})$: $\bar\delta' = \mathbf{1}$ on D if $\mathfrak{p} = \mathfrak{l}_1$, and $\bar\delta' = \bar\xi_0|_D$ if $\mathfrak{p} = \mathfrak{l}_2$ (ξ_0 is unramified at $\mathfrak{l}_2$, $\bar\xi_0(\mathrm{Frob}) = \bar\xi_0(\mathfrak{l}_2)$). (c) Put $\kappa_1 = \epsilon'\chi^{-t}$, $\kappa_2 = \delta'\chi^{-t}$: $\rho|_D$ has a D-stable line with character κ_1 and quotient κ_2, $\kappa_1\kappa_2 = \det\rho = \chi^k\xi_0$, and $\xi_0|_I = \mathbf{1}$. If $\mathfrak{p} = \mathfrak{l}_1$: $\kappa_2|_I = \chi^{-t}$, $\kappa_1|_I = \chi^{k+t}$, $\bar\kappa_2 = \mathbf{1}$, $\bar\kappa_1 = \bar\xi_0$. If $\mathfrak{p} = \mathfrak{l}_2$: $\kappa_2|_I = \mathbf{1}$, $\kappa_1|_I = \chi^k$, $\bar\kappa_2 = \bar\xi_0$, $\bar\kappa_1 = \mathbf{1}$ (using $\bar\chi^k = \bar\chi^t = \mathbf{1}$). This is (Hm4).

Step 7: the automorphic representation and (Hm5). Let π' be a cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_{k_0})$ on which the projection of f' is non-zero; for $\mathfrak{q} \nmid \mathfrak{f}\ell$ the projection is fixed by $\mathrm{GL}_2(\mathcal{O}_\mathfrak{q})$, and $\pi'_\mathfrak{q}$ is the irreducible normalised induction of unramified μ_1, μ_2 with $\lambda'(T(\mathfrak{q})) = \mathrm{N}\mathfrak{q}^{1/2}(\mu_1 + \mu_2)(\varpi_\mathfrak{q})$ or $\mathrm{N}\mathfrak{q}^{1/2}(\mu_1^{-1} + \mu_2^{-1})(\varpi_\mathfrak{q})$, according as the double coset acts through $\mathrm{diag}(1,\varpi)$ or its inverse (the eigenvalue of the double coset on the spherical vector), the same alternative for all $\mathfrak{q}$. At the real place ∞_i, $\pi'_{\infty_i} \cong D_{k'_i} \otimes |\det|^s$, a holomorphic discrete series of weight $k'_1 = k + 2t + 1$, $k'_2 = k + 1$, twisted by one s (the central character is algebraic); so π' is regular algebraic. Let $r = r_{\ell,\iota}(\pi')$ (Theorem B.85), so that $r(\mathrm{Frob}_\mathfrak{q}^{-1})$ has eigenvalues $\iota^{-1}(\mathrm{N}\mathfrak{q}^{1/2}\mu_i(\varpi_\mathfrak{q}))$. Since $r_{\ell,\iota}(\Pi \otimes |\det|^a) = r_{\ell,\iota}(\Pi) \otimes \chi^a$ and $r_{\ell,\iota}(\Pi^\vee) \otimes \chi = r_{\ell,\iota}(\Pi)^\vee$ (comparison of Satake parameters at unramified places and Chebotarev), comparing traces at $\mathrm{Frob}_\mathfrak{q}$ gives, by Chebotarev and Brauer–Nesbitt (all representations semisimple), $\sigma' \cong r_{\ell,\iota}(\Pi_0)$ with $\Pi_0 = \pi'^\vee \otimes |\det|$ in the first case and $\Pi_0 = \pi' \otimes |\det|$ in the second; hence $\rho \cong r_{\ell,\iota}(\Pi)$, $\Pi = \Pi_0 \otimes |\det|^{-t}$, and $\rho \leftrightarrow_\iota \Pi$. Π is regular algebraic cuspidal, $\Pi_{\infty_i} \cong D_{k'_i} \otimes |\det|^{s'}$ with one s'; the Langlands parameter of $D_\kappa \otimes |\det|^{s'}$ on $\mathbb{C}^\times$ is $z \mapsto \mathrm{diag}(z^p\bar z^q, z^q\bar z^p)$ with $p = \frac{\kappa-1}{2} + s'$, $q = -\frac{\kappa-1}{2} + s'$, and $p, q \in \frac{1}{2} + \mathbb{Z}$ because Π is regular algebraic: in the sense of [68] the exponents of the Langlands parameter of each Π_{∞_i} on $\mathbb{C}^\times$ lie in $\frac{n-1}{2} + \mathbb{Z}$, here $n = 2$. So $p_1 + q_1 = p_2 + q_2 = 2s'$, $|p_1 - q_1| = k + 2t$, $|p_2 - q_2| = k$: (Hm5).

Step 8: (Hm3). ρ is unramified outside $\mathfrak{f}\ell$, and so is ξ_0; this gives (Hm3) at places not above $\mathfrak{f}\ell$. Let $\bar w$ lie above $\mathfrak{q} \mid \mathfrak{f}$. The component of $\pi'_\mathfrak{q}$ is fixed by the $\mathfrak{q}$-part of $V_1(\mathfrak{f})$, conjugate to $K_1(\mathfrak{q}^c) = \{\left(\begin{smallmatrix} a & b \\ c' & d \end{smallmatrix}\right) : c' \equiv 0,\ d \equiv 1 \bmod \mathfrak{q}^c\}$, $c = v_\mathfrak{q}(\mathfrak{f})$, so the conductor of $\pi'_\mathfrak{q}$ is at most c, while its central character restricted to $\mathcal{O}_\mathfrak{q}^\times$ is that of ξ_0, of conductor exactly c (Step 6 (a)). An irreducible infinite-dimensional representation of $\mathrm{GL}_2(k_{0,\mathfrak{q}})$ whose conductor equals that of its central character is an irreducible principal series $\mu_1 \boxplus \mu_2$ with μ_1 unramified (Casselman's theory of the conductor: twists of Steinberg and supercuspidal representations have conductor larger than that of their central character). Hence $\Pi_\mathfrak{q}$, a twist by an unramified character of $\pi'_\mathfrak{q}$ or of $\pi'^\vee_\mathfrak{q}$, is $\mu'_1 \boxplus \mu'_2$ with μ'_1 unramified; by Theorem B.85, $\rho|_{I_{\bar w} \cap G_{k_0}} \cong \mathbf{1} \oplus \nu$ for a finite-order ν, and $\nu = \det\rho = \xi_0$ on inertia. So $\rho|_{I_{\bar w} \cap G_{k_0}}$ is conjugate to $s \mapsto \mathrm{diag}(1, \xi_0(s))$.

Step 9: (Hm1). (a) ρ is irreducible: otherwise its semisimplification is $\theta_1 \oplus \theta_2$ with continuous characters θ_i of G_{k_0}; by Step 6, $\theta_1|_{I_1} \in \{\chi^{k+t}, \chi^{-t}\}$ on inertia I_1 at $\mathfrak{l}_1$ and $\theta_1|_{I_2} \in \{\chi^k, \mathbf{1}\}$ at $\mathfrak{l}_2$, say $\theta_1|_{I_j} = \chi^{a_j}$ with $a_1 \neq a_2$ (as $t \geq 2$, $k \geq 2$). By class field theory θ_1 corresponds to a character of the idèles trivial on $k_0^\times$; its components at the places not above ℓ have finite order on local units and at the real places, and at $\mathfrak{l}_j$ it is $u \mapsto \chi^{a_j}(\mathrm{rec}_{\mathfrak{l}_j}(u)) = u^{-a_j}$ on $\mathbb{Z}_\ell^\times$. Evaluating at a global unit ε of infinite order, replaced by a power that kills the finitely many finite-order components, gives $\tau_1(\varepsilon)^{-a_1}\tau_2(\varepsilon)^{-a_2} = 1$, and with $\tau_1(\varepsilon)\tau_2(\varepsilon) = \pm 1$, $\tau_1(\varepsilon)^{2(a_2-a_1)} = 1$, impossible as $\tau_1(\varepsilon)$ is not a root of unity. (b) Let $U \subseteq G_{k_0}$ be open with $\rho|_U$ reducible; replacing U by its

normal core we may assume U normal. By Clifford's theorem $\rho|_U$ is semisimple. If $\rho|_U \cong \theta \oplus \theta$, then $\rho(U)$ consists of scalars, so the image of ρ in PGL_2 is finite, and on an open subgroup of I_1 the ratio $\kappa_1/\kappa_2 = \chi^{k+2t}$ of the diagonal characters of Step 6 would have finite order, which is false. If $\rho|_U \cong \theta \oplus \theta'$ with $\theta \neq \theta'$, the stabiliser H of θ has index 2 and $\rho \cong \mathrm{Ind}_H^{G_{k_0}} \tilde\theta$ for a character $\tilde\theta$ of H; then $\bar\rho^{\mathrm{ss}} = (\mathrm{Ind}_H \bar{\tilde\theta})^{\mathrm{ss}}$ is $\mathbf{1} \oplus \bar\xi_0$ (Step 5 and Brauer–Nesbitt), so $\mathrm{Ind}_H \bar{\tilde\theta}$ is reducible, $\bar{\tilde\theta}$ is invariant under G_{k_0}/H and extends to ν on G_{k_0}, and $\{\mathbf{1}, \bar\xi_0\} = \{\nu, \nu\eta_H\}$ with η_H the quadratic character of H; hence $\bar\xi_0 = \eta_H^{\pm 1}$ and $\bar\xi_0^2 = \mathbf{1}$, contrary to the hypothesis. So $\rho|_U$ is irreducible for every open U.

Conclusion. $k, t \geq 2$ are divisible by $\ell - 1$ and ρ satisfies (Hm1)–(Hm5). The hypothesis that ξ_0 is ramified at a place of norm 2 was not used. □

Proposition 51.10. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, k_0 a real quadratic field in which $\ell = \mathfrak{l}_1\mathfrak{l}_2$ splits, and ξ_0 a finite-order character of the narrow ray class group modulo an integral ideal $\mathfrak{f}$ prime to ℓ, of sign $(1,1)$ (totally odd), such that $\xi_0(\mathfrak{l}_1) \not\equiv 1$ and $\xi_0(\mathfrak{l}_2) \not\equiv 1$. Then for every $B \geq 1$ there are an integer $k \geq B$ divisible by $\ell - 1$ and a non-zero $F \in S_{k+1}(\mathfrak{f}\mathfrak{l}_1\mathfrak{l}_2, \xi_0)$ which is an eigenvector of every $T(\mathfrak{q})$, with eigenvalue $\lambda_F(\mathfrak{q})$, such that $|\iota^{-1}\lambda_F(\mathfrak{q})|_\ell \leq 1$ for all $\mathfrak{q}$ and*

$$\lambda_F(\mathfrak{q}) \equiv 1 + \xi_0(\mathfrak{q}) \quad (\mathfrak{q} \nmid \mathfrak{f}\ell), \qquad \lambda_F(\mathfrak{l}_1) \equiv 1, \qquad \lambda_F(\mathfrak{l}_2) \equiv \xi_0(\mathfrak{l}_2), \qquad \lambda_F(\mathfrak{q}) \equiv 1 \quad (\mathfrak{q} \mid \mathfrak{f}).$$

Proof. Let $\mathcal{O} \subset \overline{\mathbb{Q}}_\ell$ be a coefficient ring containing ι^{-1} of the values of ξ_0, with uniformiser ϖ and maximal ideal $\mathfrak{m}_{\mathcal{O}}$; put $\mathfrak{n} = \mathfrak{f}\mathfrak{l}_1\mathfrak{l}_2$. We identify $\mathcal{O}$ with $\iota(\mathcal{O}) \subset \mathbb{C}$ where convenient.

Step 1: the weight and a form congruent to one. Let N_0 be as in Lemma 51.11 for k_0, ℓ (ℓ splits, so ℓ does not divide the discriminant), and let $k \geq \max(B, 2)$ be divisible by $(\ell-1)\ell^{N_0}$. Let $G \in M_k(\mathcal{O}_{k_0}, \mathbf{1})$ be the form of Lemma 51.11: $c_\lambda(0, G) = 1$ and $c(\mathfrak{m}, G) \in \mathfrak{m}_{\mathcal{O}}$ for all λ and all $\mathfrak{m} \neq 0$.

Step 2: the weight-one Eisenstein series with opposite stabilisations. Let η be the trivial character viewed modulo $\mathfrak{a} = \mathfrak{l}_2$ (so $\eta(\mathfrak{c}) = 1$ if $\mathfrak{l}_2 \nmid \mathfrak{c}$ and 0 otherwise; sign 0), and ψ_1 the character ξ_0 viewed modulo $\mathfrak{b} = \mathfrak{f}\mathfrak{l}_1$ (sign $(1,1)$). As $0 + (1,1) \equiv (1,1)$, (Hb4) gives $E = E_1(\eta, \psi_1) \in M_1(\mathfrak{n}, \xi_0)$ with $c_\lambda(0, E) = 0$ for all λ ($\mathfrak{a} \neq 1 \neq \mathfrak{b}$) and $c(\mathfrak{m}, E) = \sum_{\mathfrak{r}|\mathfrak{m}} \eta(\mathfrak{m}\mathfrak{r}^{-1})\psi_1(\mathfrak{r}) \in \mathcal{O}$. Being the Dirichlet convolution of two completely multiplicative functions, $c(\cdot, E)$ is multiplicative, with $c(\mathcal{O}_{k_0}, E) = 1$ and local factors $a_{\mathfrak{q}}(e) = c(\mathfrak{q}^e, E)$:

Hence, for all $\mathfrak{m} \neq 0$,

$$\begin{gathered} c(\mathfrak{m}\mathfrak{q}, E) + \xi_0(\mathfrak{q}) c(\mathfrak{m}\mathfrak{q}^{-1}, E) = (1 + \xi_0(\mathfrak{q})) c(\mathfrak{m}, E) \quad (\mathfrak{q} \nmid \mathfrak{f}\ell), \\ c(\mathfrak{m}\mathfrak{l}_1, E) = c(\mathfrak{m}, E), \quad c(\mathfrak{m}\mathfrak{l}_2, E) = \xi_0(\mathfrak{l}_2) c(\mathfrak{m}, E), \quad c(\mathfrak{m}\mathfrak{q}, E) = c(\mathfrak{m}, E) \quad (\mathfrak{q} \mid \mathfrak{f}). \end{gathered} \tag{Ep}$$

Step 3: the product $H = EG$. By (Hb3), $H \in M_{k+1}(\mathfrak{n}, \xi_0)$. We show that $c(\mathfrak{m}, H) \in \mathcal{O}$ and $c(\mathfrak{m}, H) \equiv c(\mathfrak{m}, E)$ for all $\mathfrak{m} \neq 0$. Write $\mathfrak{m} = (b)\mathfrak{t}_\lambda^{-1}$, $b \in \mathfrak{t}_\lambda$ totally positive. The coefficient of $e_F(bz)$ in $E_\lambda G_\lambda$ is $\sum a_\lambda^E(b_1) a_\lambda^G(b_2)$ over $b_1 + b_2 = b$ with $b_i \in \{0\} \cup \{x \in \mathfrak{t}_\lambda : x \gg 0\}$ (a finite sum). Dividing by $\mathrm{N}(\mathfrak{t}_\lambda)^{(k+1)/2} = \mathrm{N}(\mathfrak{t}_\lambda)^{1/2}\mathrm{N}(\mathfrak{t}_\lambda)^{k/2}$,

$$c(\mathfrak{m}, H) = c(\mathfrak{m}, E)\, c_\lambda(0, G) + c_\lambda(0, E)\, c(\mathfrak{m}, G) + \sum_{\substack{b_1 + b_2 = b \\ b_1, b_2 \gg 0}} c\big((b_1)\mathfrak{t}_\lambda^{-1}, E\big)\, c\big((b_2)\mathfrak{t}_\lambda^{-1}, G\big),$$

and $c_\lambda(0, G) = 1$, $c_\lambda(0, E) = 0$, while every term of the sum lies in $\mathfrak{m}_{\mathcal{O}}$.

Step 4: an integral lattice. Let $L = \{f \in M_{k+1}(\mathfrak{n}, \xi_0) : c(\mathfrak{m}, f) \in \mathcal{O} \text{ for all } \mathfrak{m} \neq 0\}$, an $\mathcal{O}$-module containing H. By (Hb1) there are $\mathfrak{m}_1, \dots, \mathfrak{m}_r$ such that $f \mapsto (c(\mathfrak{m}_i, f))_i$ is injective on

$M_{k+1}(\mathfrak{n},\xi_0)$; it embeds L into $\mathcal{O}^r$, so L is finitely generated and torsion-free, hence free over $\mathcal{O}$. If $f_1,\dots,f_s\in L$ are $\mathcal{O}$-linearly independent they are $\mathbb{C}$-linearly independent (the matrix of their coefficients has entries in the field $\iota(\operatorname{Frac}\mathcal{O})$, and its rank does not change over $\mathbb{C}$); so for every coefficient ring $\mathcal{O}'\supseteq\mathcal{O}$ the map $L\otimes_{\mathcal{O}}\mathcal{O}'\to M_{k+1}(\mathfrak{n},\xi_0)$, $f\otimes a\mapsto \iota(a)f$, is injective. By (Hb2) every $T(\mathfrak{q})$ preserves L (its coefficient $\xi_0(\mathfrak{q})\mathrm{N}\mathfrak{q}^k$ lies in $\mathcal{O}$), and these endomorphisms commute. An $f\in L$ with all $c(\mathfrak{m},f)\in\mathfrak{m}_{\mathcal{O}}$ lies in ϖL. Finally $H\notin\varpi L$, since $c(\mathcal{O}_{k_0},H)\equiv c(\mathcal{O}_{k_0},E)=1$.

Step 5: H is an eigenvector modulo ϖ. Define $t(\mathfrak{q})\in\mathcal{O}$ by $t(\mathfrak{q})=1+\xi_0(\mathfrak{q})$ for $\mathfrak{q}\nmid\mathfrak{f}\ell$, $t(\mathfrak{l}_1)=1$, $t(\mathfrak{l}_2)=\xi_0(\mathfrak{l}_2)$, $t(\mathfrak{q})=1$ for $\mathfrak{q}\mid\mathfrak{f}$. For $\mathfrak{q}\nmid\mathfrak{f}\ell$, $\mathrm{N}\mathfrak{q}$ is prime to ℓ and $(\ell-1)\mid k$, so $\mathrm{N}\mathfrak{q}^k\equiv 1$; by (Hb2), Step 3 and (Ep),

$$c(\mathfrak{m},H|T(\mathfrak{q}))=c(\mathfrak{m}\mathfrak{q},H)+\xi_0(\mathfrak{q})\mathrm{N}\mathfrak{q}^k c(\mathfrak{m}\mathfrak{q}^{-1},H)\equiv(1+\xi_0(\mathfrak{q}))c(\mathfrak{m},E)\equiv t(\mathfrak{q})\,c(\mathfrak{m},H).$$

For $\mathfrak{q}\mid\mathfrak{n}$, $c(\mathfrak{m},H|U(\mathfrak{q}))=c(\mathfrak{m}\mathfrak{q},H)\equiv c(\mathfrak{m}\mathfrak{q},E)=t(\mathfrak{q})c(\mathfrak{m},E)\equiv t(\mathfrak{q})c(\mathfrak{m},H)$ by (Ep). By Step 4, $H|T(\mathfrak{q})-t(\mathfrak{q})H\in\varpi L$ for every $\mathfrak{q}$: the image of H in $L/\varpi L$ is a non-zero common eigenvector of the commuting endomorphisms $T(\mathfrak{q})$, with eigenvalues $t(\mathfrak{q})$ mod ϖ.

Step 6: lifting. By the lemma of Deligne and Serre ([78], Lemme 6.11: for a free module of finite rank over a discrete valuation ring with a family of commuting endomorphisms, a non-zero common eigenvector modulo the maximal ideal lifts to a common eigenvector over a finite extension, with eigenvalues lifting the given ones) there are a coefficient ring $\mathcal{O}'\supseteq\mathcal{O}$ and a non-zero $F\in L\otimes_{\mathcal{O}}\mathcal{O}'$, viewed in $M_{k+1}(\mathfrak{n},\xi_0)$ by Step 4, with $F|T(\mathfrak{q})=\lambda_F(\mathfrak{q})F$, $\lambda_F(\mathfrak{q})\in\mathcal{O}'$ and $\lambda_F(\mathfrak{q})\equiv t(\mathfrak{q})$ for all $\mathfrak{q}$. These are the asserted congruences.

Step 7: F is a cusp form. Suppose not. By (Hb5) ($\kappa=k+1\geq 3$) there are finite-order characters η_1,η_2 of a narrow ray class group modulo some $\mathfrak{c}$, with $\eta_1\eta_2(\mathfrak{q})=\xi_0(\mathfrak{q})$ for $\mathfrak{q}\nmid\mathfrak{n}$, such that $\lambda_F(\mathfrak{q})=\eta_1(\mathfrak{q})+\eta_2(\mathfrak{q})\mathrm{N}\mathfrak{q}^k$ for $\mathfrak{q}\nmid\mathfrak{n}$ and $\lambda_F(\mathfrak{l}_i)\in\{0,\eta_1(\mathfrak{l}_i),\eta_2(\mathfrak{l}_i)\ell^k\}$ ($\mathrm{N}\mathfrak{l}_i=\ell$). Enlarge $\mathcal{O}'$ to contain the values of η_1,η_2 and write bars for reduction modulo its maximal ideal. (a) For $\mathfrak{q}\nmid\mathfrak{n}\mathfrak{c}$: $\bar\eta_1(\mathfrak{q})+\bar\eta_2(\mathfrak{q})=1+\bar\eta_1(\mathfrak{q})\bar\eta_2(\mathfrak{q})$, i.e. $(\bar\eta_1(\mathfrak{q})-1)(\bar\eta_2(\mathfrak{q})-1)=0$. Every class of the narrow ray class group modulo $\mathfrak{c}\mathfrak{n}$ contains a prime $\mathfrak{q}\nmid\mathfrak{n}\mathfrak{c}$ (Chebotarev density theorem for ray class fields), so this group is the union of the kernels of the homomorphisms $\bar\eta_1,\bar\eta_2$; a group is not the union of two proper subgroups, hence $\bar\eta_1=\mathbf{1}$ or $\bar\eta_2=\mathbf{1}$. (b) $\lambda_F(\mathfrak{l}_i)$ is a unit (congruent to 1 or to the root of unity $\xi_0(\mathfrak{l}_2)$), so it is neither 0 nor $\eta_2(\mathfrak{l}_i)\ell^k$; hence $\lambda_F(\mathfrak{l}_i)=\eta_1(\mathfrak{l}_i)\neq 0$, η_1 is unramified at $\mathfrak{l}_1,\mathfrak{l}_2$, and $\bar\eta_1(\mathfrak{l}_1)=1$, $\bar\eta_1(\mathfrak{l}_2)=\bar\xi_0(\mathfrak{l}_2)$. As ξ_0 is unramified at $\mathfrak{l}_1,\mathfrak{l}_2$, so is η_2 (it agrees with $\xi_0\eta_1^{-1}$ at all primes off $\mathfrak{n}\mathfrak{c}$), and we may take $\mathfrak{c}$ prime to ℓ. If $\bar\eta_1=\mathbf{1}$, then $\bar\xi_0(\mathfrak{l}_2)=1$, contrary to the hypothesis. If $\bar\eta_2=\mathbf{1}$, then $\bar\eta_1(\mathfrak{q})=\bar\xi_0(\mathfrak{q})$ for all $\mathfrak{q}\nmid\mathfrak{n}\mathfrak{c}$, hence $\bar\eta_1=\bar\xi_0$ on the narrow ray class group modulo $\mathfrak{c}\mathfrak{f}$ (Chebotarev again), and evaluating at the class of $\mathfrak{l}_1$ gives $1=\bar\eta_1(\mathfrak{l}_1)=\bar\xi_0(\mathfrak{l}_1)$, contrary to the hypothesis. So $F\in S_{k+1}(\mathfrak{n},\xi_0)$. □

Lemma 51.11. *Let k_0 be a real quadratic field, ℓ an odd prime not dividing the discriminant of k_0, and $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism. There is $N_0\geq 0$ such that for every integer $k\geq 2$ divisible by $(\ell-1)\ell^{N_0}$ there is $G\in M_k(\mathcal{O}_{k_0},\mathbf{1})$ with $c_\lambda(0,G)=1$ for every $\lambda\in\mathrm{Cl}^+(k_0)$ and $c(\mathfrak{m},G)\in\mathbb{Q}$, $|\iota^{-1}c(\mathfrak{m},G)|_\ell<1$ for every non-zero integral ideal $\mathfrak{m}$.*

Proof. Let D be the discriminant of k_0 and χ_D the even quadratic Dirichlet character of k_0, so that $\zeta_{k_0}(s)=\zeta(s)L(s,\chi_D)$ and $\chi_D(\ell)\neq 0$. Let $L_\ell(s,\chi_D)$ be the Kubota–Leopoldt ℓ-adic L-function: it is a continuous function of $s\in\mathbb{Z}_\ell$ ($\chi_D\neq\mathbf{1}$), and $L_\ell(1-k,\chi_D)=(1-\chi_D\omega^{-k}(\ell)\ell^{k-1})L(1-k,\chi_D\omega^{-k})$ for $k\geq 1$, ω the Teichmüller character ([266], Theorem 5.11); since χ_D is even and non-trivial, $L_\ell(1,\chi_D)\neq 0$ (Brumer; [266], Corollary 5.30). Put $c=v_\ell(L_\ell(1,\chi_D))$ and choose $N_0\geq\max(c,0)$ such that $|L_\ell(s,\chi_D)-L_\ell(1,\chi_D)|_\ell<|L_\ell(1,\chi_D)|_\ell$ whenever $|s-1|_\ell\leq\ell^{-N_0}$ (continuity at $s=1$).

Let $k\geq 2$ be divisible by $(\ell-1)\ell^{N_0}$; k is even. *The value $\zeta_{k_0}(1-k)$ has valuation at most $-1-N_0+c$.* By Theorem B.19, $\ell B_k\equiv -1\pmod\ell$ as $(\ell-1)\mid k$, so $v_\ell(\zeta(1-k))=$

$v_\ell(-B_k/k) = -1 - v_\ell(k) \le -1 - N_0$. As $\omega^{-k} = \mathbf{1}$, $L_\ell(1-k,\chi_D) = (1-\chi_D(\ell)\ell^{k-1})L(1-k,\chi_D)$ with $v_\ell(1-\chi_D(\ell)\ell^{k-1}) = 0$, and $|(1-k)-1|_\ell = |k|_\ell \le \ell^{-N_0}$ gives $v_\ell(L_\ell(1-k,\chi_D)) = c$; so $v_\ell(L(1-k,\chi_D)) = c$, in particular $L(1-k,\chi_D) \ne 0$, and $v_\ell(\zeta_{k_0}(1-k)) = -1 - v_\ell(k) + c \le -1 - N_0 + c$.

The form. Apply (Hb4) of Theorem B.86 with $\eta = \psi_1 = \mathbf{1}$, $\mathfrak{a} = \mathfrak{b} = \mathcal{O}_{k_0}$, signs $q = r = 0$ (allowed, k even) and $\kappa = k > 1$: $E_k(\mathbf{1},\mathbf{1}) \in M_k(\mathcal{O}_{k_0},\mathbf{1})$ has $c(\mathfrak{m},E_k(\mathbf{1},\mathbf{1})) = \sum_{\mathfrak{r}|\mathfrak{m}} \mathrm{N}\mathfrak{r}^{k-1} \in \mathbb{Z}$ and $c_\lambda(0,E_k(\mathbf{1},\mathbf{1})) = 2^{-2}\zeta_{k_0}(1-k)$ for every λ (no Euler factor is removed, the modulus being 1). Put $G = 4\,\zeta_{k_0}(1-k)^{-1}E_k(\mathbf{1},\mathbf{1})$. Then $c_\lambda(0,G) = 1$, $c(\mathfrak{m},G) = 4\zeta_{k_0}(1-k)^{-1}\sum_{\mathfrak{r}|\mathfrak{m}} \mathrm{N}\mathfrak{r}^{k-1} \in \mathbb{Q}$, and, ℓ being odd,

$$v_\ell\big(c(\mathfrak{m},G)\big) \;\ge\; 1 + N_0 - c \;\ge\; 1.$$

□

Lemma 51.12. *Let R be a commutative ring and $b_1, b_2 \in R$ with $2, b_1, b_2 \in R^\times$. Put*

$$P_b = \begin{pmatrix} -b_1 & 0 & b_1 & 0 \\ 0 & b_2 & 0 & b_2 \\ 1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{pmatrix}, \qquad G(c) = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & c \\ 0 & 0 & -c & 0 \end{pmatrix} \quad (c \in R),$$

for $A, B \in \mathrm{M}_2(R)$ let $\mathrm{diag}(A,B) \in \mathrm{M}_4(R)$ be the block diagonal matrix and $\mathrm{ix}_b(A,B) = P_b^{-1}\mathrm{diag}(A,B)P_b$, and put $\mathrm{low}(x) = \left(\begin{smallmatrix} 1 & 0 \\ x & 1 \end{smallmatrix}\right)$, $\mathrm{up}(x) = \left(\begin{smallmatrix} 1 & x \\ 0 & 1 \end{smallmatrix}\right)$. For $z, w \in R$ with $d = b_1zw - b_2$ and $e = b_1 - b_2zw$ in $R^\times$ put

$$\mathrm{fi}_b^+(z,w) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -b_1z/b_2 & 1 & 0 & 0 \\ -1 & 2b_2w/d & 1 & 0 \\ -b_1z/b_2 & (b_2+b_1zw)/d & b_1z/b_2 & 1 \end{pmatrix},$$

$$\mathrm{fi}_b^-(z,w) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -z & 1 & 0 & 0 \\ 1 & 2b_2w/e & 1 & 0 \\ z & (b_1+b_2zw)/e & z & 1 \end{pmatrix}.$$

Then:

(Ie0) $\det P_b = -4b_1b_2$, *so* $P_b \in \mathrm{GL}_4(R)$; $\mathrm{ix}_b(AA',BB') = \mathrm{ix}_b(A,B)\,\mathrm{ix}_b(A',B')$ *and* $\mathrm{ix}_b(1,1) = 1$.

(Ie1) ${}^tP_b\,G(-b_1b_2)\,P_b = -2b_1b_2J_4$. *Hence, if $X \in \mathrm{M}_4(R)$ and $\nu \in R$ satisfy ${}^tX\,G(-b_1b_2)\,X = \nu\,G(-b_1b_2)$, then $P_b^{-1}XP_b$ has similitude ν. For $A, B \in \mathrm{M}_2(R)$ and $c \in R$,*

$${}^t\mathrm{diag}(A,B)\,G(c)\,\mathrm{diag}(A,B) = \mathrm{diag}\big(\det(A)\varepsilon,\; c\det(B)\varepsilon\big)$$

with $\varepsilon = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$; in particular $\mathrm{ix}_b(A,B)$ has similitude ν if $\det A = \det B = \nu$.

(Ie2) *For $D = \mathrm{diag}(b_1^2, b_2^2)$ the block matrix $Y = \left(\begin{smallmatrix} 0 & D \\ 1_2 & 0 \end{smallmatrix}\right)$ satisfies*

$${}^tY\,G(-b_1b_2)\,Y = -b_1b_2\,G(-b_1b_2) \quad \textit{and} \quad P_b^{-1}YP_b = \mathrm{diag}(-b_1,-b_2,b_1,b_2).$$

(Ie3) *For $X, y, y' \in R$,*

$$\mathrm{ix}_b\Big(\begin{pmatrix} X & 0 \\ y & 1 \end{pmatrix}, \begin{pmatrix} X & 0 \\ y' & 1 \end{pmatrix}\Big) = \mathrm{diag}(X,1,X,1) + u\,(E_{21} - E_{43}) + v\,(E_{41} - E_{23}),$$

with $u = -\frac{1}{2}(b_1b_2^{-1}y + y')$ and $v = \frac{1}{2}(y' - b_1b_2^{-1}y)$; the positions $(2,1),(4,3)$ have weight $-w_\alpha$, $(4,1)$ weight $-w_\theta$ and $(2,3)$ weight w_β.

(Ie4) $\mathrm{fi}_b^{\pm}(z,w)$ *is lower triangular with all diagonal entries* 1 *and has similitude* 1*;* $\mathrm{fi}_b^{+}(z,w)_{31} = -1$, $\mathrm{fi}_b^{-}(z,w)_{31} = 1$, $\mathrm{fi}_b^{+}(z,w)_{32} = 2b_2wd^{-1}$, $\mathrm{fi}_b^{-}(z,w)_{32} = 2b_2we^{-1}$. *The positions* $(2,1),(4,3)$ *have weight* $-w_\alpha$, $(3,1),(4,2)$ *weight* $-w_\Psi$, $(4,1)$ *weight* $-w_\theta$ *and* $(3,2)$ *weight* $-w_\beta$.

(Ie5) *Let* $p,q,r,p',q',r' \in R$, $A_z = \mathrm{low}(z)\left(\begin{smallmatrix} p & q \\ 0 & r \end{smallmatrix}\right)\mathrm{low}(z)^{-1}$ *and* $B_w = \mathrm{up}(w)\left(\begin{smallmatrix} r' & 0 \\ q' & p' \end{smallmatrix}\right)\mathrm{up}(w)^{-1}$. *Then* $\mathrm{fi}_b^{+}(z,w)^{-1}\,\mathrm{ix}_b(A_z,B_w)\,\mathrm{fi}_b^{+}(z,w)$ *and* $\mathrm{fi}_b^{-}(z,w)^{-1}\,\mathrm{ix}_b(B_w,A_z)\,\mathrm{fi}_b^{-}(z,w)$ *are upper triangular with diagonal* (p,p',r',r).

Proof. Write e_1,e_2,e_3,e_4 for the standard basis of R^4, so that the columns of P_b are $f_1 = -b_1e_1+e_3$, $f_2 = b_2e_2-e_4$, $f_3 = b_1e_1+e_3$, $f_4 = b_2e_2+e_4$; $\mathrm{ix}_b(A,B)$ is the matrix of $\mathrm{diag}(A,B)$ in the basis $(f_1,\dots,f_4)$.

(Ie0): the multiplicativity holds because ix_b is conjugation by P_b of the block diagonal embedding, which is multiplicative. The value of $\det P_b$: after the permutation $(1,3,2,4)$ of rows and columns P_b becomes block diagonal with blocks $\left(\begin{smallmatrix} -b_1 & b_1 \\ 1 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} b_2 & b_2 \\ -1 & 1 \end{smallmatrix}\right)$, of determinants $-2b_1$ and $2b_2$.

(Ie1): the Gram identity is a polynomial identity; given it, ${}^t(P_b^{-1}XP_b)\,J_4\,(P_b^{-1}XP_b) = (-2b_1b_2)^{-1}\,{}^tP_b\,{}^tX\,G\,X\,P_b = \nu J_4$ for $G = G(-b_1b_2)$. The block formula is ${}^tA\varepsilon A = \det(A)\varepsilon$ in each block.

(Ie2): ${}^tYG(c)Y = \mathrm{diag}(c\varepsilon, {}^tD\varepsilon D) = \mathrm{diag}(c\varepsilon, \det(D)\varepsilon)$, and $\det D = b_1^2b_2^2 = c^2$ for $c = -b_1b_2$; and $YP_b = P_b\,\mathrm{diag}(-b_1,-b_2,b_1,b_2)$ is a polynomial identity.

(Ie3), (Ie4), (Ie5) and the polynomial identities above were verified by computer check C3, listed in Appendix B, as identities of polynomials with integer coefficients in independent indeterminates after multiplying by the denominators: (Ie3) as $2b_2\,\mathrm{diag}(A,B)P_b = P_bT'$ with $T' = 2b_2(\mathrm{diag}(X,1,X,1) + u(E_{21}-E_{43}) + v(E_{41}-E_{23}))$; the similitude in (Ie4) as ${}^tN\,J_4\,N = s^2J_4$ for $N = s\,\mathrm{fi}_b^{\pm}(z,w)$ with $s = b_2d$, resp. $s = e$. For (Ie5) the computation uses the flags: put $V^+ = (e_1+ze_2,\ we_3+e_4,\ e_3,\ e_2)$ and $V^- = (e_3+ze_4,\ we_1+e_2,\ e_1,\ e_4)$ (columns), both of determinant -1. It verifies that $\mathrm{adj}(V^{\pm})\,P_b\,N^{\pm}$ is upper triangular with diagonal entries $2b_1b_2d$, $-2b_2^2$, d^2, $-b_2^2d$ (case $+$), resp. $-2e$, $-2b_1b_2$, $-e^2$, $-e$ (case $-$), all units, so $P_b\,\mathrm{fi}_b^{\pm}(z,w) = V^{\pm}U^{\pm}$ with $U^{\pm}$ upper triangular and invertible; and that $\mathrm{adj}(V^+)\,\mathrm{diag}(A_z,B_w)\,V^+$ and $\mathrm{adj}(V^-)\,\mathrm{diag}(B_w,A_z)\,V^-$ are upper triangular with diagonal $-(p,p',r',r)$. Hence $(V^{\pm})^{-1}\mathrm{diag}(\cdot)V^{\pm}$ is upper triangular with diagonal (p,p',r',r), and so is its conjugate by the invertible upper triangular $U^{\pm}$, which is $\mathrm{fi}_b^{\pm}(z,w)^{-1}\mathrm{ix}_b(\cdot)\,\mathrm{fi}_b^{\pm}(z,w)$. The computation is checked by a second, independent implementation (exact rationals, Gauss–Jordan inverses of the matrices as stated, at random rational points). The weights: $\boldsymbol{\lambda} = (1,0,1,0)$, $\boldsymbol{\mu} = (1,1,0,0)$ give $\mathrm{wt}_4(2,1) = \mathrm{wt}_4(4,3) = (-1,0)$, $\mathrm{wt}_4(2,3) = (-1,1)$, $\mathrm{wt}_4(4,1) = (-1,-1)$, $\mathrm{wt}_4(3,1) = \mathrm{wt}_4(4,2) = (0,-1)$, $\mathrm{wt}_4(3,2) = (1,-1)$. □

(Ia1) *there is a regular algebraic cuspidal automorphic representation* Π *of* $\mathrm{GL}_4(\mathbb{A}_L)$ *with* $V|_{G_L} \leftrightarrow_\iota \Pi$*;*

(Ia2) *suppose that there are a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ, an open subgroup U of $I_{\bar{w}} \cap G_{k_0}$, an element $g_1 \in G_{\mathbb{Q}} \setminus G_{k_0}$ and integers a_1, a_2, a_1', a_2' with $|a_1 - a_2| \neq |a_1' - a_2'|$, such that $\rho|_U$ is conjugate to a map into upper triangular matrices with diagonal $(\chi_{\mathrm{cyc}}^{a_1}, \chi_{\mathrm{cyc}}^{a_2})$ and $s \mapsto \rho(g_1^{-1} s g_1)$ on U is conjugate to a map into upper triangular matrices with diagonal $(\chi_{\mathrm{cyc}}^{a_1'}, \chi_{\mathrm{cyc}}^{a_2'})$. If some element of G_L' lies outside G_{k_0}, then $V|_{G_L'}$ is irreducible, i.e. the $\overline{\mathbb{Q}}_\ell$-span of $V(G_L')$ is* $\mathrm{End}(V)$.

Proof. We use *(CB)*: two continuous semisimple representations of G_E (E a number field) whose characteristic polynomials agree at the Frobenius elements of almost all places are isomorphic (Chebotarev density and Brauer–Nesbitt). Put $M = Lk_0$. As $k_0 \not\subseteq L$, $G_L \not\subseteq G_{k_0}$, so $G_{\mathbb{Q}} = G_{k_0} G_L$, $G_{k_0} \cap G_L = G_M$ and $[G_L : G_M] = 2$; Mackey's formula gives

$$V|_{G_L} \cong \mathrm{Ind}_{G_M}^{G_L} X, \qquad X = \rho|_{G_M}.$$

M is abelian over $\mathbb{Q}$, hence over k_0; and every field E with $k_0 \subseteq E \subseteq M$ has $\rho|_{G_E}$ irreducible (G_E is open in G_{k_0}).

Step 1: base change to M. Choose $k_0 = E_0 \subset E_1 \subset \cdots \subset E_t = M$ with E_{j+1}/E_j cyclic of prime degree (a composition series of $\mathrm{Gal}(M/k_0)$), and put $\pi^{(0)} = \pi$, $\pi^{(j+1)} = \mathrm{BC}_{E_{j+1}/E_j}(\pi^{(j)})$. By induction on j: $\pi^{(j)}$ is cuspidal and $\rho|_{G_{E_j}} \leftrightarrow_\iota \pi^{(j)}$. Indeed, by (Ac1), at almost all places w of E_{j+1} above u of E_j, with residue degree f, the Satake parameters of $\pi_w^{(j+1)}$ are the f-th powers of those of $\pi_u^{(j)}$, while $\rho(\mathrm{Frob}_w^{-1}) = \rho(\mathrm{Frob}_u^{-1})^f$ and $\mathrm{N}w^{1/2} = (\mathrm{N}u^{1/2})^f$. If $\pi^{(j+1)}$ were not cuspidal, then by (Ac3) $\pi^{(j)} \cong \pi^{(j)} \otimes (\omega \circ \det)$ for a Hecke character $\omega \neq 1$ of E_j trivial on norms from E_{j+1}; with ω_G the corresponding non-trivial character of $\mathrm{Gal}(E_{j+1}/E_j)$, (CB) gives $\rho|_{G_{E_j}} \cong \rho|_{G_{E_j}} \otimes \omega_G$ (both irreducible), and an intertwiner A with $A\rho(s)A^{-1} = \omega_G(s)\rho(s)$ is not scalar (as $\omega_G \neq 1$ and $\rho(s) \neq 0$) and commutes with $\rho(G_{E_{j+1}})$, so $\rho|_{G_{E_{j+1}}}$ is reducible by Schur's lemma: a contradiction. Put $\pi_M = \pi^{(t)}$, so $X \leftrightarrow_\iota \pi_M$. By (Ac2), applied along the chain, at a complex place w of M above ∞_i the Langlands parameter of $\pi_{M,w}$ is the restriction of that of π_{∞_i} to $\mathbb{C}^\times$, i.e. $z \mapsto \mathrm{diag}(z^{p_i}\bar{z}^{q_i}, z^{q_i}\bar{z}^{p_i})$ (the other identification of W_{M_w} with $\mathbb{C}^\times$ exchanges z and $\bar{z}$, which gives the same parameter up to conjugation).

Step 2: (Ia1). Let σ be the non-trivial element of $\mathrm{Gal}(M/L)$; it is non-trivial on k_0 (otherwise it fixes $Lk_0 = M$), so it maps the places of M above ∞_1 to places above ∞_2. If $\pi_M \cong \pi_M^\sigma$, then at a complex place w above ∞_1 the components $\pi_{M,w}$ and $\pi_{M,\sigma w}$ are isomorphic, so $\{p_1, q_1\} = \{p_2, q_2\}$ by Step 1, against $|p_1 - q_1| \neq |p_2 - q_2|$. So $\Pi_0 = \mathrm{AI}_{M/L}(\pi_M)$ is cuspidal by (Ai3); put $\Pi = \Pi_0 \otimes |\det|_{\mathbb{A}_L}$, cuspidal. At almost all finite places v of L:

so $V|_{G_L} \leftrightarrow_\iota \Pi$. At a complex place v of L the two places of M above it are w and σw, above ∞_1 and ∞_2 in some order; by (Ai2) and Step 1 the parameter of $\Pi_{0,v}$ on $\mathbb{C}^\times$ is the sum of $z^{p_i}\bar{z}^{q_i}$, $z^{q_i}\bar{z}^{p_i}$ over $i = 1, 2$, and that of $\Pi_v \otimes |\det|^{-3/2} = \Pi_{0,v} \otimes |\det|^{-1/2}$ has the exponents $(p_i - \frac{1}{2}, q_i - \frac{1}{2})$, $(q_i - \frac{1}{2}, p_i - \frac{1}{2})$, which are integers. With $s = p_1 + q_1 = p_2 + q_2$ and $\delta_i = |p_i - q_i| > 0$, the four exponents of z are $\frac{1}{2}(s \pm \delta_1) - \frac{1}{2}$, $\frac{1}{2}(s \pm \delta_2) - \frac{1}{2}$, pairwise distinct since $\delta_1 \neq \delta_2$. So Π is regular algebraic in the sense of [68].

Step 3: (Ia2). Let $g' \in G_L' \setminus G_{k_0}$ and $H = G_L' \cap G_{k_0} = \{h \in G_M : \chi_{\mathrm{cyc}}(h) = 1\}$, a closed normal subgroup of $G_{\mathbb{Q}}$ with $G_{\mathbb{Q}}/H$ abelian ($M(\mu_{\ell^\infty})/\mathbb{Q}$ is abelian); $[G_L' : H] = 2$, $G_{\mathbb{Q}} = G_{k_0} G_L'$, and Mackey's formula gives $V|_{G_L'} \cong \mathrm{Ind}_H^{G_L'}(\rho|_H)$. For $m \in G_{k_0}$ put $\rho^{g'}(m) = \rho(g'^{-1} m g')$, a homomorphism on G_{k_0}. (i) $\rho|_H$ is irreducible. Otherwise let $\mathcal{S}$ be the set of H-stable lines, non-empty and permuted by G_{k_0}. If $\#\mathcal{S} = 1$ its line is G_{k_0}-stable, against the irreducibility of ρ. If $\#\mathcal{S} = 2$, the stabiliser of one line is a closed subgroup of index ≤ 2 of G_{k_0}, hence open, on which ρ is reducible: a contradiction. If $\#\mathcal{S} \geq 3$, every $\rho(h)$, $h \in H$, is scalar. Fix $g_2 \in G_{k_0}$ with $\rho(g_2)$

not scalar (ρ is irreducible). As G_{k_0}/H is abelian, $\rho(g)\rho(g_2)\rho(g)^{-1} = c(g)\rho(g_2)$ with $c(g) \in \overline{\mathbb{Q}}_\ell^\times$; c is a continuous homomorphism, and multiplication by $c(g)$ preserves the multiset of eigenvalues of $\rho(g_2)$, so $c(g)^2 = 1$. On the open subgroup $\ker c$ the matrices $\rho(g)$ commute with $\rho(g_2)$ and preserve one of its eigenspaces, a line: a contradiction. (ii) $\rho|_H \not\cong \rho^{g'}|_H$. Otherwise $\mathrm{Hom}_H(\rho, \rho^{g'})$ is a line (Schur's lemma, by (i)) spanned by an invertible A; for $m \in G_{k_0}$, $\rho^{g'}(m)A\rho(m)^{-1}$ again intertwines $\rho|_H$ and $\rho^{g'}|_H$ (H is normal), so it equals $\nu(m)A$ for a continuous character ν of G_{k_0}, and $\rho^{g'} \cong \rho \otimes \nu$. Writing $g' = g_1 y$ with $y \in G_{k_0}$, $\rho^{g'}(s) = \rho(y)^{-1}\rho(g_1^{-1}sg_1)\rho(y)$, so on U both $\rho^{g'}$ and $\rho \otimes \nu$ are triangularisable, with diagonal characters $\{\chi_{\mathrm{cyc}}^{a_1'}, \chi_{\mathrm{cyc}}^{a_2'}\}$ and $\{\chi_{\mathrm{cyc}}^{a_1}\nu, \chi_{\mathrm{cyc}}^{a_2}\nu\}$; isomorphic representations have the same Jordan–Hölder constituents, so these multisets agree. Either $\chi_{\mathrm{cyc}}^{a_1'} = \chi_{\mathrm{cyc}}^{a_1}\nu$ and $\chi_{\mathrm{cyc}}^{a_2'} = \chi_{\mathrm{cyc}}^{a_2}\nu$, whence $\chi_{\mathrm{cyc}}^{(a_1'-a_2')-(a_1-a_2)} = 1$ on U, or $\chi_{\mathrm{cyc}}^{a_1'} = \chi_{\mathrm{cyc}}^{a_2}\nu$ and $\chi_{\mathrm{cyc}}^{a_2'} = \chi_{\mathrm{cyc}}^{a_1}\nu$, whence $\chi_{\mathrm{cyc}}^{(a_1'-a_2')+(a_1-a_2)} = 1$ on U. Both exponents are non-zero, as $|a_1 - a_2| \neq |a_1' - a_2'|$; but $\chi_{\mathrm{cyc}}(U)$ is an open subgroup of $\mathbb{Z}_\ell^\times$ (U is open in $I_{\bar{w}}$ and $\chi_{\mathrm{cyc}}(I_{\bar{w}}) = \mathbb{Z}_\ell^\times$), which contains elements of infinite order: a contradiction. (iii) As a representation of H, $\mathrm{Ind}_H^{G_L'}(\rho|_H) = \rho|_H \oplus g'\rho|_H$ with $g'\rho|_H \cong \rho^{g'}|_H$; the two summands are irreducible and non-isomorphic, so the only H-stable subspaces are 0, the two summands and the whole space, and g' exchanges the summands. Hence $V|_{G_L'}$ is irreducible, and by Burnside's theorem the span of $V(G_L')$ is $\mathrm{End}(V)$. □

Proposition 51.14. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (III), let $\mathscr{T}_0$ be a good auxiliary tower for $\mathfrak{D}$ of case (III), $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and (K, V, a) a test field; write k_V for the residue field of V and $\bar{a}\colon \mathcal{O} \to k_V$ for a followed by reduction. Then there are a prime w that splits for $\mathscr{T}_0$ and a residual pair s over $(\mathscr{T}_0, \{w\})$ with values in k_V (for $\bar{a}$), supported in Σ_M, such that for every good auxiliary tower $\mathscr{T} \geq \mathscr{T}_0$ in whose field w dies there are a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and a seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι such that the image $\bar{Q}_V$ of Q under $\mathcal{O}_1 \xrightarrow{a} V \to k_V$ lies over s, lies in A, and has entries of weights $-w_\beta$ and $-w_\theta$.*

Proof. Let ϵ, E, F_0, $g_0 = g_{\mathscr{T}_0}$, Σ_0, $(\bar{v})$ be the data of $\mathscr{T}_0$ and E' the imaginary quadratic field of case (III); $\ell \geq 5$, $T = \{\ell\}$, χ has finite order prime to ℓ. Write $\kappa_i = \kappa_i^\epsilon$, bars for reduction, η for the quadratic character of $E'/\mathbb{Q}$, and for a tower $\mathscr{T}$ write $L_{\mathscr{T}}$, $G'_{\mathscr{T}}$ for its L, G'. Put $\bar{\Phi} = \bar{\kappa}_1/\bar{\kappa}_4\colon G_{\mathbb{Q}} \to \mathbb{F}_{\mathcal{O}}^\times$.

Step 1: relations among the characters. For both labellings $\kappa_1\kappa_4 = \kappa_2\kappa_3 = \theta$, $\kappa_1/\kappa_2 = \kappa_3/\kappa_4 = \alpha$ and $\kappa_1/\kappa_3 \in \{\Psi, \Psi^{-1}\}$; so $\mathrm{rt}_{w_\alpha} = \alpha$, $\mathrm{rt}_{w_\Psi} = \Psi^{\pm 1}$, $\mathrm{rt}_{w_\theta} = \kappa_1^2/(\kappa_2\kappa_3) = \kappa_1/\kappa_4$, and $\bar{\alpha} = \bar{\xi}$ (as $\overline{\chi_{\mathrm{cyc}}\omega_\ell^{-1}} = 1$). By case (III), $\bar{\alpha} = \eta$ on G_{F_0}, so $\bar{\alpha}^2 = 1$ there. Let $\mathscr{T} \geq \mathscr{T}_0$ be good, with field $F \supseteq F_0$ and $L = L_{\mathscr{T}}$, $M = LE'$. (a) $\bar{\Phi}^2 \neq 1$ on G_M: otherwise $\bar{\Psi}^4 = 1$ on G_L (as $\bar{\Phi} = \bar{\Psi}^{\pm 1}\bar{\alpha}$ on G_L, $\bar{\alpha}^2 = 1$ and $g^2 \in G_M$ for $g \in G_L$), so every $\overline{\mathrm{rt}_w}$, w a root, being $\bar{\Psi}^a\bar{\alpha}^b$, satisfies $\overline{\mathrm{rt}_w}^4 = 1$ on G_L, contradicting the last clause of (Oq3). (b) Some $g \in G'_{\mathscr{T}}$ lies outside $G_{E'}$: otherwise $\eta|_{G_L}$ factors through $\chi_{\mathrm{cyc}}(G_L)$, an open subgroup of $\mu_{\ell-1} \times (1 + \ell\mathbb{Z}_\ell)$, and being of order ≤ 2 it is trivial on the pro-ℓ part, i.e. on $G_L \cap \ker\omega_\ell$; since $\eta = \bar{\alpha}$ on G_L and $\bar{\alpha}\bar{\kappa}_1 = \bar{\kappa}_2$, $\bar{\alpha}\bar{\kappa}_2 = \bar{\kappa}_1$, $\bar{\alpha}\bar{\kappa}_3 = \bar{\kappa}_4$, $\bar{\alpha}\bar{\kappa}_4 = \bar{\kappa}_3$ there, (Oq4) gives $\bar{\alpha} = 1$ on G_L, contradicting (Oq3) for the root w_α. In particular $E' \not\subseteq L$. (c) $\bar{\Phi} \neq 1$ on G_L and $\bar{\Phi} \neq \bar{\omega}_\ell^{-1}$: (Oq3) for the roots w_θ and $-w_\theta$. (d) $\bar{\Phi}(g_0) \neq 1$ and $\bar{\alpha}(g_0) \neq 1$, so $g_0 \notin G_{E'}$: (Oq7). (e) $\bar{\Phi}(c) = -1$: $\bar{\Phi}(c)$ is $\bar{\theta}(c) = \bar{\xi}(c)\bar{\Psi}(c)$ or $\bar{\alpha}(c)/\bar{\Psi}(c)$, and $\xi(c) = -1$, $\Psi(c) = 1$ by (Sg1). (f) For every place $\bar{v}$ above ℓ some $h \in D_{\bar{v}}$ has $\bar{\Phi}(h) \neq 1$: $\bar{\Phi}$ is $\overline{\xi\Psi}$ or $\overline{\xi\Psi^{-1}}$, which is $\neq 1$ at σ_ℓ by (Sg2) ($\ell \in T$), and $D_{\bar{v}}$ is conjugate to D_ℓ. (g) $D_{\bar{v}} \subseteq G_{E'}$ for $\bar{v}$ above ℓ, as ℓ splits in E'.

Step 2: the newform. By Kronecker–Weber, $\bar{\Phi}$ is a Dirichlet character of order prime to ℓ, so its restriction to I_ℓ is $\bar{\omega}_\ell^{c_0}$ for some c_0. Let ψ_0 be the Teichmüller lift of $\bar{\Phi}\bar{\omega}_\ell^{-c_0}$: a Dirichlet character of order prime to ℓ, unramified at ℓ, primitive of some conductor N_0 with $\ell \nmid N_0$. The

construction of Step 4 below does not use Steps 2 and 3, and fixes an integer $m \geq 1$; we take it first, and then choose $k \geq 2m+3$ with $k-1 \equiv c_0 \pmod{\ell-1}$. Then $\psi_0(-1) = \bar{\Phi}(c)(-1)^{c_0} = (-1)^k$ by (e). The fixed field Ω_0 of $G_{F_0} \cap \ker \bar{r}_0 \cap \ker \omega_\ell \cap \ker \psi_0 \cap G_{E'}$ is abelian over $\mathbb{Q}$; choose (Dirichlet) a prime $w \notin S$, $w \nmid N_0 \operatorname{disc}(E')$, splitting completely in Ω_0. Then w splits for $\mathscr{T}_0$, $\ell \mid w-1$, $\psi_0(w) = 1$. Let θ_w be a Dirichlet character modulo w of order ℓ; then $\varepsilon = \psi_0\theta_w$ is primitive modulo $N_0 w$ with $\varepsilon(-1) = (-1)^k$. If $\psi_0 = 1$ then $\bar{\Phi} = \bar{\omega}_\ell^{k-1}$, and $(\ell-1) \mid k$ would give $\bar{\Phi} = \bar{\omega}_\ell^{-1}$, excluded by (c). So Proposition 49.5 gives a newform f of weight k, level $N_0 w$ and character ε with $\iota^{-1}(a_p) \equiv 1 + \iota^{-1}(\varepsilon(p))p^{k-1}$, and Lemma 49.8 applies to it: ρ, $\beta = \varepsilon\chi_{\mathrm{cyc}}^{k-1}$, $\bar{\beta} = \bar{\psi}_0\bar{\omega}_\ell^{k-1} = \bar{\Phi}$ ($\bar{\theta}_w = 1$).

Step 3: a Ribet lattice diagonal at g_0. ρ is irreducible ((Ne4) with $\mathbb{Q}$, $\bar{\beta} \neq 1$) and continuous, so it preserves a lattice over some coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$, which we enlarge finitely often below. The characteristic polynomial of $\rho(g_0)$ is $\equiv (X - \bar{\Phi}(g_0))(X-1)$ (Ne1) with distinct residual roots (d), so by Hensel its roots lie in $\mathcal{O}_1$, the lattice is the sum of the two eigenlines, and in an adapted basis $\rho(g) = \left(\begin{smallmatrix} a_g & b_g \\ c_g & d_g \end{smallmatrix}\right)$ with $\rho(g_0)$ diagonal, $\bar{a}_{g_0} = \bar{\Phi}(g_0)$. The reduction is reducible (its semisimplification is $\bar{\Phi} \oplus \mathbf{1}$), and a stable line is an eigenline of $\bar{\rho}(g_0)$; so all $\bar{b}_g = 0$ or all $\bar{c}_g = 0$, in either case $b_g c_{g'} \in \mathfrak{m}_{\mathcal{O}_1}$ for all g, g', the diagonal of $\bar{\rho}$ consists of characters, and $\bar{a} = \bar{\Phi}$, $\bar{d} = \mathbf{1}$ (compare at g_0). Not all c_g vanish (ρ irreducible); let $n = \min_g v(c_g)$, ϖ a uniformiser, and $\rho_1 = D^{-1}\rho D$, $D = \operatorname{diag}(1, \varpi^n)$. Then $\rho_1(g) = \left(\begin{smallmatrix} a_g & \varpi^n b_g \\ \varpi^{-n} c_g & d_g \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathcal{O}_1)$, $\varpi^n b_g \in \mathfrak{m}_{\mathcal{O}_1}$ (if $n = 0$ use $b_g c_{g'} \in \mathfrak{m}$ with $c_{g'}$ a unit), $\rho_1(g_0)$ is diagonal, and

$$\bar{\rho}_1(g) = \begin{pmatrix} \bar{\Phi}(g) & 0 \\ \bar{x}(g) & 1 \end{pmatrix}, \qquad \bar{x}(gh) = \bar{x}(g)\bar{\Phi}(h) + \bar{x}(h), \qquad \bar{x} \neq 0.$$

If F is a number field Galois over $\mathbb{Q}$ with $\bar{\Phi}|_{G_F} \neq 1$, then $\bar{x}|_{G_F} \neq 0$: otherwise, for $h \in G_F$ with $\bar{\Phi}(h) \neq 1$ and any g, $\bar{x}(gh) = \bar{x}(g)\bar{\Phi}(h)$ and $\bar{x}(gh) = \bar{x}(ghg^{-1})\bar{\Phi}(g) + \bar{x}(g) = \bar{x}(g)$, so $\bar{x}(g) = 0$ for all g. *Flags of ρ_1.* For $\bar{v}$ above ℓ, (Ne3) gives a $D_{\bar{v}}$-stable line with character $\delta_1 = \beta\delta_2^{-1}$ (δ_2 unramified, $\bar{\delta}_2 = 1$ on $D_{\bar{v}}$, $\delta_1 = \chi_{\mathrm{cyc}}^{k-1}$ on $I_{\bar{v}}$). With $h \in D_{\bar{v}}$ as in (f), this line is the $\delta_1(h)$-eigenline of $\rho_1(h)$, $\delta_1(h) \equiv \bar{\Phi}(h) \not\equiv 1 \equiv d_h$; it is spanned by $(\delta_1(h) - d_h,\ \varpi^{-n}c_h)$, whose first coordinate is a unit. So it is spanned by $(1, x_{\bar{v}})$ with $x_{\bar{v}} \in \mathcal{O}_1$ (after enlarging $\mathcal{O}_1$ by $\delta_1(h)$), and $\operatorname{low}(x_{\bar{v}})^{-1}\rho_1(s)\operatorname{low}(x_{\bar{v}}) = \left(\begin{smallmatrix} \delta_1(s) & * \\ 0 & \delta_2(s) \end{smallmatrix}\right)$ for $s \in D_{\bar{v}}$.

Step 4: the dihedral factor. Let $m_0 = \#\mathcal{O}_{E'}^\times$. The character $(z,u) \mapsto (z/\bar{z})^{m_0}$ of $\mathbb{C}^\times \times \hat{\mathcal{O}}_{E'}^\times$ is trivial on $\mathcal{O}_{E'}^\times$ ($(u/\bar{u})^{m_0} = u^{2m_0} = 1$), so it extends to a Hecke character Ψ_1 of E'; $\Psi_2 = \Psi_1/\Psi_1^c$ ($\Psi_1^c(x) = \Psi_1(\bar{x})$) is unramified at every finite place, $\Psi_2\Psi_2^c = 1$, with infinity type $z \mapsto (z/\bar{z})^{2m_0}$. By the correspondence between algebraic Hecke characters and ℓ-adic characters ([220, Ch. II]) there is a continuous $\kappa_2 \colon G_{E'} \to \mathcal{O}_1^\times$ (enlarging $\mathcal{O}_1$) with $\iota\kappa_2(\mathrm{Frob}_v^{-1}) = \Psi_2(\varpi_v)$ for $v \nmid \ell$, unramified outside ℓ, whose restriction to the inertia group of a place above ℓ ($E'_\mathfrak{l} = \mathbb{Q}_\ell$) is the algebraic character given by the infinity type: $\kappa_2|_{I_{\bar{v}}} = \chi_{\mathrm{cyc}}^{\pm 2m_0}$, the sign depending on the prime of E' below $\bar{v}$. By Chebotarev, $\kappa_2(h)\kappa_2(g_0 h g_0^{-1}) = 1$. Let N_1 be the order of the reduction of κ_2 (a character into a finite field), $\kappa = \kappa_2^{N_1}$, $m = 2m_0N_1$, $\Psi_\kappa = \Psi_2^{N_1}$ (type $(z/\bar{z})^{\pm m}$). Then $\bar{\kappa} = 1$, $\kappa(h)\kappa(g_0 h g_0^{-1}) = 1$, κ is unramified outside ℓ, and for every $\bar{v}$ above ℓ there is $s_{\bar{v}} \in \{1, -1\}$ with $\kappa|_{I_{\bar{v}}} = \chi_{\mathrm{cyc}}^{s_{\bar{v}}m}$. As in Step 1, $\kappa(g_0^2) = \kappa(g_0 g_0^2 g_0^{-1})^{-1} = \kappa(g_0^2)^{-1}$, so $\kappa(g_0^2) = \pm 1$, hence $= 1$ ($\bar{\kappa} = 1$, ℓ odd). For $h \in G_{E'}$ put $A(h) = \frac{1}{2}\left(\begin{smallmatrix} \kappa+\kappa^{-1} & \kappa-\kappa^{-1} \\ \kappa-\kappa^{-1} & \kappa+\kappa^{-1} \end{smallmatrix}\right)(h) = P_0 \operatorname{diag}(\kappa(h), \kappa(h)^{-1}) P_0^{-1}$, $P_0 = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, and $\tau(h) = A(h)$, $\tau(g_0 h) = HA(h)$. Since $HP_0 = P_0\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $HA(h)H^{-1} = A(g_0 h g_0^{-1})$, and with $A(g_0^2) = 1 = H^2$ this makes $\tau \colon G_\mathbb{Q} \to \mathrm{GL}_2(\mathcal{O}_1)$ a continuous homomorphism ($2 \in \mathcal{O}_1^\times$). It satisfies ${}^t\tau H \tau = H$ (for A: $(\frac{\kappa+\kappa^{-1}}{2})^2 - (\frac{\kappa-\kappa^{-1}}{2})^2 = 1$), $\tau(g_0) = H$, $\bar{\tau} = \operatorname{diag}(1, \eta)$, $\tau \cong \operatorname{Ind}_{G_{E'}}^{G_\mathbb{Q}} \kappa$ over $\overline{\mathbb{Q}}_\ell$ (Frobenius reciprocity, $(1,1)$ spans a κ-line, and $\operatorname{Ind}\kappa$ is irreducible as $\kappa^2 \neq 1$), and on $D_{\bar{v}} \subseteq G_{E'}$ ((g)) $\tau = \left(\begin{smallmatrix} a & b \\ b & a \end{smallmatrix}\right)$ with $a + bs_{\bar{v}} = \kappa^{s_{\bar{v}}}$, $a - bs_{\bar{v}} = \kappa^{-s_{\bar{v}}}$, equal to χ_{cyc}^m, χ_{cyc}^{-m} on $I_{\bar{v}}$.

Step 5: the twist and the representation R. Let $\gamma = \theta\theta_w\beta^{-1} = \theta\psi_0^{-1}\chi_{\mathrm{cyc}}^{1-k}$; $\bar\gamma = \bar\kappa_1\bar\kappa_4\bar\Phi^{-1} = \bar\kappa_4^2$. With λ the Teichmüller lift of $\bar\kappa_4$, $\gamma\lambda^{-2}$ takes values in $1+\mathfrak{m}_{\mathcal{O}_1}$, on which squaring is a topological automorphism (ℓ odd); put $\delta = \lambda(\gamma\lambda^{-2})^{1/2}$, so $\delta^2\beta = \theta\theta_w$, $\bar\delta = \bar\kappa_4$. Define

$$R(g) = \delta(g)\,\mathrm{tn}\big(\rho_1(g), \tau(g)\big) \in \mathrm{GL}_4(\mathcal{O}_1), \qquad n_{\bar v} = \mathrm{fl}(x_{\bar v}, s_{\bar v}) \quad (\bar v \mid \ell).$$

By (Te1) R is a continuous homomorphism, and by (Te0) $R \otimes \overline{\mathbb{Q}}_\ell \cong \delta \otimes \rho \otimes \mathrm{Ind}\,\kappa$. Its properties: (R1) $R(g)$ has similitude $\delta^2 \det\rho_1 = \theta\theta_w$ ((Te2)). (R2) $R(g_0)$ is diagonal ((Te3)), hence so is every power. (R3) $\bar R(g) = \bar\delta(g)\big(\mathrm{diag}(\bar\Phi, \bar\Phi\eta, \eta, 1) - \bar x\eta E_{32} + \bar x E_{41}\big)(g)$ by (Te3); on G_{F_0}, using $\eta = \bar\alpha$ and Step 1, its diagonal is $(\bar\kappa_1, \bar\kappa_2, \bar\kappa_3, \bar\kappa_4)$, its only other possibly non-zero entries are $(3,2)$ and $(4,1)$, of weights $-w_\beta, -w_\theta \in \Sigma_A \cap \Sigma_M$, and $\bar R(g)_{41} = \bar\delta(g)\bar x(g)$. (R4) For $\bar v$ above ℓ, $n_{\bar v}$ is lower unitriangular of similitude 1 with $(n_{\bar v})_{21} = s_{\bar v}$ ((Te4)), and for $s \in D_{\bar v}$, $n_{\bar v}^{-1}R(s)n_{\bar v}$ is upper triangular with diagonal $\psi_{\bar v} = \delta\cdot(\delta_1\kappa^{s_{\bar v}},\ \delta_1\kappa^{-s_{\bar v}},\ \delta_2\kappa^{s_{\bar v}},\ \delta_2\kappa^{-s_{\bar v}})$ ((Te5) with Steps 3, 4). Residually $\bar\psi_{\bar v} = \bar\delta(\bar\Phi, \bar\Phi, 1, 1)$, which is $(\bar\kappa_1, \dots, \bar\kappa_4)$ on $D_{\bar v}$ as $\eta = 1$ there. On $I_{\bar v}$: $\theta = \chi_{\mathrm{cyc}}^{e+1}\varphi$ with $\varphi = \omega_\ell^{-1}\chi$ of order dividing $\ell - 1$ (ξ, ψ_0, θ_w unramified at ℓ), so $\delta^2 = \chi_{\mathrm{cyc}}^{e+2-k}\varphi$ and $\psi_{\bar v,i}^2 = \chi_{\mathrm{cyc}}^{h_i}\varphi$ with

$$h = (e+2-k)(1,1,1,1) + 2\,(k-1+m,\ k-1-m,\ m,\ -m),$$

and $h_1 - h_2 = h_3 - h_4 = 4m$, $h_2 - h_3 = 2(k-1-2m)$ lie in $2\mathbb{Z}_{\ge 2}$ (as $k \ge 2m+3$). In particular the $\psi_{\bar v,i}$ are pairwise distinct on every open subgroup of $I_{\bar v}$. (R5) $\psi_{\bar v,i}(s) = 1$ if $s \in D_{\bar v}$ and $s^{\ell^b} \in \overline{[D_{\bar v}, D_{\bar v}]}$ for some b: the image of s in the torsion-free group $D_{\bar v}/I_{\bar v} \cong \hat{\mathbb{Z}}$ is 0, so $s \in I_{\bar v}$ and unramified characters (δ_2, and $\delta_1\chi_{\mathrm{cyc}}^{1-k}$) are 1 at s; $\chi_{\mathrm{cyc}}(s)$ is an ℓ-power root of unity in $\mathbb{Z}_\ell^\times$, hence 1, so $\kappa^{\pm1}(s) = \delta_1(s) = 1$; characters of finite order prime to ℓ (λ, χ, ω_ℓ) are 1 at s, so $\gamma(s) = 1$ and $\delta(s) = \lambda(s)(\gamma\lambda^{-2})(s)^{1/2} = 1$. (R6) Let $\bar p$ be a place above a prime $p \ne \ell$ and $g \in I_{\bar p} \cap G_{F_0}$ with $\bar r_0(g) = 1$, and assume $p \ne w$ or $\theta_w(g) = 1$. Then $R(g) = 1$: $\bar\alpha(g) = 1$, so $g \in G_{E'}$ and $\tau(g) = 1$ (κ unramified at p); $\varepsilon(g) = \psi_0(g)\theta_w(g) = 1$, because $\psi_0(g)$ is the Teichmüller lift of $\bar\Phi(g) = 1$ and θ_w is unramified at $p \ne w$, so $\rho_1(g) = 1$ by (Ne2); $\lambda(g) = 1$, and $\theta(g) = (\xi\chi)(g)$ is a root of unity of order prime to ℓ with $\bar\theta(g) = 1$, so $\theta(g) = 1$, $\gamma(g) = 1$ and $\delta(g) = 1$.

Step 6: the residual pair s. Let $\bar a_1 \colon \mathcal{O}_1 \to V \to k_V$ be a followed by reduction; it kills $\mathfrak{m}_{\mathcal{O}_1}$ ($a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$). Let s be the image under $\bar a_1$ of $(R|_{G_{F_0}}, (n_{\bar v})_{v\in\Sigma_0})$. It is a marked ordinary pair over $(\mathscr{T}_0, \{w\})$ for $\bar a$: (Mq1) by (R1) and $\bar a_1(\theta_w(g)) = 1$ ($\theta_w(g)$ is an ℓ-th root of unity), and by (R6) on $N_{\{w\}}$; (Mq2) by (R2); (Mq3) and the triangularity in (Mq4) by (R4); the condition on μ_v by (R5). Its r is locally constant (reduction of a continuous map to $\mathcal{O}_1$), (Wq1) holds by (R3), (R4), and r is supported in Σ_M by (R3), which also gives (Wq2). So s is a residual pair over $(\mathscr{T}_0, \{w\})$ with values in k_V, supported in Σ_M, and w splits for $\mathscr{T}_0$ (Step 2).

Step 7: the seed pairs. Let $\mathscr{T} \ge \mathscr{T}_0$ be good, with field F, places $(\bar v')_{v'\in\Sigma}$ and $g_{\mathscr{T}} = g_0^{\ell^j}$, such that w dies in F; then $\theta_w|_{G_F} = 1$ (θ_w composed with $\mu_\ell \cong \mathbb{Z}/\ell\mathbb{Z}$ is trivial on the inertia groups of all places not above w). Put $Q = (R|_{G_F}, (n_{\bar v'})_{v'\in\Sigma})$, with values in $\mathcal{O}_1$ for the inclusion $\mathcal{O} \subseteq \mathcal{O}_1$. It is a marked ordinary pair over $(\mathscr{T}, \emptyset)$: (Mq1) by (R1) with $\theta_w = 1$ on G_F and by (R6) (at $p = w$, $\theta_w(g) = 1$ on G_F); (Mq2) by (R2); (Mq3), (Mq4) by (R4), (R5). It is continuous for $\mathfrak{m}_{\mathcal{O}_1}$, and its reduction satisfies (Wq1), (Wq2) by (R3), (R4) as in Step 6. Its image P in $\overline{\mathbb{Q}}_\ell$ is a seed for ι: by Step 1 (a), (b), Lemma 51.16 applies to f, E', $g_1 = g_0$, κ, Ψ_κ ($a = \pm m$, $k - 1 > 2m$) and $L = L_{\mathscr{T}}$ (a CM field abelian over $\mathbb{Q}$); by (Ta2) $r_P|_{G'_{\mathscr{T}}}$ is irreducible (twisting by δ does not change the span); P has weights h with the open subgroup $U = G_F \cap \ker\omega_\ell \cap \ker\chi$, by (R4); with the character $\delta^{-1}|_{G_L}$, the integers $a' = k - 2 - e$ (so $a' + h_1 = 2(k-1+m)$ is even) and $\ell - 1$, $\big(\delta^{-2}(s)\chi_{\mathrm{cyc}}(s)^{-a'}\big)^{\ell-1} = \varphi(s)^{-(\ell-1)} = 1$ on inertia above ℓ; and $r_P|_{G_L} \otimes \delta^{-1} \cong (\rho \otimes \mathrm{Ind}\,\kappa)|_{G_L} \leftrightarrow_\iota \Pi$ with Π regular algebraic cuspidal, by (Ta1). So Q is a seed pair with values in $\mathcal{O}_1$.

Step 8: $\bar{Q}_V$ lies over s, lies in A, and has the two entries. Its representation is $\bar{a}_1 \circ R|_{G_F}$, the restriction of that of s. Let $v' \in \Sigma$; choose $v \in \Sigma_0$ and $g \in G_{F_0}$ with $g\bar{v} = \bar{v}'$ (every place above ℓ is G_{F_0}-conjugate to some $\bar{v}$). Put $B = n_{\bar{v}'}^{-1} R(g) n_{\bar{v}}$. For $h \in D_{\bar{v}'} = g D_{\bar{v}} g^{-1}$, $X_1(h) = n_{\bar{v}'}^{-1} R(h) n_{\bar{v}'}$ and $X_2(h) = n_{\bar{v}}^{-1} R(g^{-1}hg) n_{\bar{v}}$ are upper triangular, with $BX_2(h) = X_1(h)B$, and on $I' = I_{\bar{v}'} \cap U$ the squares of their diagonal characters are $\chi_{\mathrm{cyc}}^{h_i}$ in both cases (χ_{cyc} is invariant under conjugation), pairwise distinct as h_i are distinct and χ_{cyc} has infinite order on I'. Let $V_1 \subset \cdots \subset V_4$ be the standard flag. $B(V_1)$ is an $X_1(I')$-stable line on which I' acts by a character with square $\chi_{\mathrm{cyc}}^{h_1}$; if j is minimal with $B(V_1) \subseteq V_j$, its non-zero image in V_j/V_{j-1} is I'-equivariant, so $\chi_{\mathrm{cyc}}^{h_1} = \chi_{\mathrm{cyc}}^{h_j}$ on I' and $j = 1$; passing to V/V_1 and inducting, B is upper triangular. Hence $\bar{a}_1(B)$ is upper triangular: $\bar{Q}_V$ lies over s. It lies in A: its representation is supported in Σ_A by (R3), and $(n_{\bar{v}'})_{21} = s_{\bar{v}'} = \pm 1 \neq 0$ in k_V. Finally F is Galois over $\mathbb{Q}$ and $\bar{\Phi} \neq 1$ on G_F (Step 1 (c)), so $\bar{x}(g) \neq 0$ for some $g \in G_F$ (Step 3), and $\bar{a}_1$ is injective on $\mathbb{F}_{\mathcal{O}_1}$ and $\bar{\delta}(g), \eta(g)$ are units: by (R3) the entries $(4,1)$ and $(3,2)$ of $\bar{Q}_V(g)$ are non-zero, of weights $-w_\theta$ and $-w_\beta$. □

Lemma 51.15. *Let R be a commutative ring. For $g = (g_{ab}), t = (t_{ab}) \in \mathrm{M}_2(R)$ put*

$$\mathrm{tn}(g,t) = \begin{pmatrix} g_{11}t_{11} & g_{11}t_{12} & -g_{12}t_{12} & g_{12}t_{11} \\ g_{11}t_{21} & g_{11}t_{22} & -g_{12}t_{22} & g_{12}t_{21} \\ -g_{21}t_{21} & -g_{21}t_{22} & g_{22}t_{22} & -g_{22}t_{21} \\ g_{21}t_{11} & g_{21}t_{12} & -g_{22}t_{12} & g_{22}t_{11} \end{pmatrix} \in \mathrm{M}_4(R),$$

let $H = \mathrm{diag}(1,-1)$, $\mathrm{low}(x) = \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix}$, and for $x, s \in R$ put $\mathrm{fl}(x,s) = \mathrm{tn}(\mathrm{low}(x), 1)\,(1 + sE_{21} - sE_{43})$, where E_{ij} are the matrix units. Then:

(Te0) $\mathrm{tn}(g,t) = P\,(g \otimes t)\,P^{-1}$, *where $g \otimes t$ is the Kronecker product (block form $\left(\begin{smallmatrix} g_{11}t & g_{12}t \\ g_{21}t & g_{22}t \end{smallmatrix}\right)$), $P = \mathrm{diag}(1_2, W^{-1})$ in block form and $W = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$; in particular, over a field, $g \mapsto \mathrm{tn}(\rho(g), \tau(g))$ is isomorphic to $\rho \otimes \tau$;*

(Te1) $\mathrm{tn}(gg', tt') = \mathrm{tn}(g,t)\,\mathrm{tn}(g',t')$ *and* $\mathrm{tn}(1,1) = 1$; *in particular $g \mapsto \delta(g)\,\mathrm{tn}(\rho(g), \tau(g))$ is a homomorphism of monoids $\Gamma \to \mathrm{M}_4(R)$ for homomorphisms of monoids $\rho, \tau \colon \Gamma \to \mathrm{M}_2(R)$ and $\delta \colon \Gamma \to R$ from a group Γ;*

(Te2) *if ${}^t t\,H\,t = H$, then $\mathrm{tn}(g,t)$ has similitude $\det g$;*

(Te3) *for $\Phi, x, \eta \in R$, $\mathrm{tn}(\left(\begin{smallmatrix} \Phi & 0 \\ x & 1 \end{smallmatrix}\right), \mathrm{diag}(1,\eta)) = \mathrm{diag}(\Phi, \Phi\eta, \eta, 1) - x\eta\,E_{32} + x\,E_{41}$, and $\mathrm{wt}_4(3,2) = -w_\beta$, $\mathrm{wt}_4(4,1) = -w_\theta$; tn of two diagonal matrices is diagonal;*

(Te4) $\mathrm{fl}(x,s)$ *is lower triangular with all diagonal entries 1, has similitude 1, and $\mathrm{fl}(x,s)_{21} = s$;*

(Te5) *if $s \in \{1,-1\}$, $g = \mathrm{low}(x)\left(\begin{smallmatrix} p & q \\ 0 & r \end{smallmatrix}\right)\mathrm{low}(x)^{-1}$ and $t = \left(\begin{smallmatrix} a & b \\ b & a \end{smallmatrix}\right)$, then $\mathrm{fl}(x,s)^{-1}\,\mathrm{tn}(g,t)\,\mathrm{fl}(x,s)$ is upper triangular with diagonal $\big(p(a+bs),\ p(a-bs),\ r(a+bs),\ r(a-bs)\big)$.*

Proof. Let $W = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, $P = \mathrm{diag}(1_2, W^{-1})$ in block form, and let $g \otimes t$ be the Kronecker product, with block form $\left(\begin{smallmatrix} g_{11}t & g_{12}t \\ g_{21}t & g_{22}t \end{smallmatrix}\right)$. Then

$$\mathrm{tn}(g,t) = P\,(g \otimes t)\,P^{-1} = \begin{pmatrix} g_{11}t & g_{12}\,tW \\ g_{21}\,W^{-1}t & g_{22}\,W^{-1}tW \end{pmatrix}, \tag{51.2}$$

as one reads off entry by entry; this is (Te0).

(Te1): by (51.2) and $(g\otimes t)(g'\otimes t') = gg'\otimes tt'$, $1\otimes 1 = 1$. A product of a scalar homomorphism and a homomorphism of monoids into $\mathrm{M}_4(R)$ is one, since scalars are central.

(Te2): with $\varepsilon = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ one has ${}^t g\,\varepsilon\, g = (\det g)\varepsilon$, hence ${}^t(g\otimes t)(\varepsilon\otimes H)(g\otimes t) = ({}^t g\varepsilon g)\otimes({}^t tHt) = \det(g)\,\varepsilon\otimes H$ when ${}^t tHt = H$. Conjugating by P and using ${}^t P^{-1}(\varepsilon\otimes H)P^{-1} = J_4$ gives ${}^t\mathrm{tn}(g,t)\,J_4\,\mathrm{tn}(g,t) = \det(g)J_4$.

(Te3), (Te4), (Te5) are identities between explicit 4×4 matrices whose entries are polynomials with integer coefficients in $\Phi, x, \eta, s, p, q, r, a, b$ (for (Te5), with $s^2 = 1$, checked for $s = 1$ and $s = -1$ separately; $\mathrm{fl}(x,s)$ is unipotent, so its inverse is $\sum_{k=0}^{3}(1-\mathrm{fl}(x,s))^k$); they were verified as polynomial identities, hence hold in every commutative ring, by computer check C4, listed in Appendix B, which also verifies (51.2), the identity ${}^t P^{-1}(\varepsilon\otimes H)P^{-1} = J_4$ and the general formula ${}^t\mathrm{tn}(g,t)J_4\mathrm{tn}(g,t) = \det(g)\,{}^t P^{-1}(\varepsilon\otimes {}^t tHt)P^{-1}$, by two independent implementations. The weights: $\boldsymbol{\lambda} = (1,0,1,0)$, $\boldsymbol{\mu} = (1,1,0,0)$ give $\mathrm{wt}_4(3,2) = (1,-1) = -w_\beta$ and $\mathrm{wt}_4(4,1) = (-1,-1) = -w_\theta$. For diagonal g, t all entries of the table with an off-diagonal factor vanish, and the remaining non-zero entries are on the diagonal. □

Lemma 51.16. *Let ℓ, ι and a newform f of weight $k \geq 3$ be as in Lemma 49.8, with Galois representation ρ and $\beta = \det\rho$. Let $E' \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field, $g_1 \in G_{\mathbb{Q}} \setminus G_{E'}$, and $\kappa\colon G_{E'} \to \overline{\mathbb{Q}}_\ell^\times$ a continuous character such that $\kappa(h)\kappa(g_1 h g_1^{-1}) = 1$ for all $h \in G_{E'}$, and such that there are a Hecke character Ψ_κ of E' and an integer $a \neq 0$ with $\Psi_\kappa(z) = (z/\bar z)^a$ on $(E'\otimes\mathbb{R})^\times = \mathbb{C}^\times$ (for one of the two identifications) and $\iota\kappa(\mathrm{Frob}_v^{-1}) = \Psi_\kappa(\varpi_v)$ for all but finitely many finite places v of E'. Let $V = \rho\otimes\mathrm{Ind}_{G_{E'}}^{G_{\mathbb{Q}}}\kappa$, a representation of $G_{\mathbb{Q}}$ of dimension 4. Let $L \subset \overline{\mathbb{Q}}$ be a CM field abelian over $\mathbb{Q}$ with $E' \not\subseteq L$, put $M = LE'$, and assume $k-1 \neq 2|a|$ and $\beta(s)^2 \not\equiv 1$ for some $s \in G_M$. Then:*

(Ta1) *there is a regular algebraic cuspidal automorphic representation Π of $\mathrm{GL}_4(\mathbb{A}_L)$ with $V|_{G_L} \leftrightarrow_\iota \Pi$;*

(Ta2) *if some $g \in G_L$ with $\chi_{\mathrm{cyc}}(g) = 1$ lies outside $G_{E'}$, then the restriction of V to $G_L' = \{g \in G_L : \chi_{\mathrm{cyc}}(g) = 1\}$ is irreducible, i.e. the $\overline{\mathbb{Q}}_\ell$-span of $V(G_L')$ is $\mathrm{End}(V)$.*

Proof. We use the following fact *(CB)*: two continuous semisimple representations of G_E (E a number field) whose characteristic polynomials agree at the Frobenius elements of almost all places are isomorphic (Chebotarev density and Brauer–Nesbitt); for characters it says that two continuous characters agreeing at almost all Frobenius elements are equal. For $\hat g \in G_{\mathbb{Q}} \setminus G_{E'}$ write $\hat g = g_1 y$ with $y \in G_{E'}$; then $\kappa(\hat g h \hat g^{-1}) = \kappa(g_1(yhy^{-1})g_1^{-1}) = \kappa(yhy^{-1})^{-1} = \kappa(h)^{-1}$ for $h \in G_{E'}$:

$$\kappa(\hat g h \hat g^{-1}) = \kappa(h)^{-1} \qquad (h \in G_{E'},\ \hat g \in G_{\mathbb{Q}} \setminus G_{E'}). \tag{51.3}$$

The hypothesis on β gives $\beta(s) \not\equiv 1$ for some $s \in G_M$; as every field E with $\mathbb{Q} \subseteq E \subseteq M$ is Galois over $\mathbb{Q}$ (M is abelian over $\mathbb{Q}$), (Ne4) shows that $\rho|_{G_E}$ is irreducible for all such E; and (Ne5) shows that $\rho|_U$ is irreducible for every open subgroup $U \subseteq G_{\mathbb{Q}}$.

Step 1: κ has infinite order on every open subgroup of $G_{E'}$. Suppose that $n \geq 1$ and $\kappa^n = 1$ on an open subgroup $G_{E''}$, $E'' \supseteq E'$; we derive a contradiction. The Hecke character $\Psi_\kappa^n \circ \mathrm{N}_{E''/E'}$ of E'' is then 1 at almost all finite places (at an unramified w above v with residue degree f, $\Psi_\kappa(\mathrm{N}\varpi_w) = \Psi_\kappa(\varpi_v)^f = \iota\kappa(\mathrm{Frob}_w^{-1})$), hence trivial by (Js1) for $n = 1$; but at a complex place its archimedean component is $z \mapsto (z/\bar z)^{\pm na} \neq 1$.

Step 2: the induced representation over L. Since $E' \not\subseteq L$, $G_L \not\subseteq G_{E'}$, so $G_{\mathbb{Q}} = G_{E'}G_L$ and $G_{E'} \cap G_L = G_M$, $[G_L : G_M] = 2$. By Mackey's formula and $\rho\otimes\mathrm{Ind}\,\kappa \cong \mathrm{Ind}(\rho|_{G_{E'}}\otimes\kappa)$,

$$V|_{G_L} \cong \mathrm{Ind}_{G_M}^{G_L} X, \qquad X = (\rho\otimes\kappa)|_{G_M}.$$

Fix $\hat{g} \in G_L \setminus G_M$ and put $X^{\hat{g}}(h) = X(\hat{g}h\hat{g}^{-1})$; it is X conjugated by $\rho(\hat{g})$ on the factor ρ, so $\det X^{\hat{g}} = \beta\kappa^{-2}$ on G_M by (51.3), while $\det X = \beta\kappa^2$.

Step 3: the automorphic representation of f and its base change to M. Let π be the cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$ generated by f, in the unitary normalisation ([103]): for $p \nmid \ell N$ it is unramified with Satake parameters $\{\alpha_p, \beta_p\}$ such that $\iota^{-1}(p^{(k-1)/2}\alpha_p)$, $\iota^{-1}(p^{(k-1)/2}\beta_p)$ are the eigenvalues of $\rho(\sigma_p)$ for an arithmetic Frobenius σ_p ([76]); its central character ω_π has finite order and $\alpha_p\beta_p = \omega_\pi(p)$; and the Langlands parameter of π_∞ restricted to $\mathbb{C}^\times$ is $z \mapsto \mathrm{diag}((z/\bar{z})^{(k-1)/2}, (z/\bar{z})^{-(k-1)/2})$. Put $\pi_1 = \pi \otimes (\omega_\pi^{-1}|\cdot|^{k/2}) \circ \det$. Then $\rho \leftrightarrow_\iota \pi_1$:

and the parameter of $\pi_{1,\infty}$ on $\mathbb{C}^\times$ is $z \mapsto \mathrm{diag}(z^{k-1/2}\bar{z}^{1/2},\, z^{1/2}\bar{z}^{k-1/2})$ (twist by $|z\bar{z}|^{k/2}$; $\omega_\pi \circ \mathrm{N}$ is trivial on $\mathbb{C}^\times$). Choose a chain $\mathbb{Q} = E_0 \subset E_1 \subset \cdots \subset E_t = M$ with E_{i+1}/E_i cyclic of prime degree (a composition series of the abelian group $\mathrm{Gal}(M/\mathbb{Q})$), and put $\pi^{(0)} = \pi_1$, $\pi^{(i+1)} = \mathrm{BC}_{E_{i+1}/E_i}(\pi^{(i)})$. By induction on i: $\pi^{(i)}$ is cuspidal, $\rho|_{G_{E_i}} \leftrightarrow_\iota \pi^{(i)}$, and at each complex place of E_i the parameter of $\pi^{(i)}$ is $z \mapsto \mathrm{diag}(z^{k-1/2}\bar{z}^{1/2}, z^{1/2}\bar{z}^{k-1/2})$. Indeed, by (Ac1) at almost all places w of E_{i+1} above u of E_i with residue degree f the Satake parameters of $\pi_w^{(i+1)}$ are the f-th powers of those of $\pi_u^{(i)}$, and $\rho(\mathrm{Frob}_w^{-1}) = \rho(\mathrm{Frob}_u^{-1})^f$ with $\mathrm{N}w^{1/2} = (\mathrm{N}u^{1/2})^f$; (Ac2) gives the archimedean parameters (a restriction of the parameter of $\pi_{1,\infty}$ to $\mathbb{C}^\times$). If $\pi^{(i+1)}$ were not cuspidal, then by (Ac3) $\pi^{(i)} \cong \pi^{(i)} \otimes (\omega \circ \det)$ for a character $\omega \neq 1$ of E_i trivial on norms from E_{i+1}; with ω_G the corresponding non-trivial character of $\mathrm{Gal}(E_{i+1}/E_i)$, (CB) gives $\rho|_{G_{E_i}} \cong \rho|_{G_{E_i}} \otimes \omega_G$ (both irreducible), and an intertwiner A with $A\rho(s)A^{-1} = \omega_G(s)\rho(s)$ is not scalar (as $\omega_G \neq 1$ and $\rho(s) \neq 0$) and commutes with $\rho(G_{E_{i+1}})$, so $\rho|_{G_{E_{i+1}}}$ is reducible by Schur's lemma: a contradiction.

Step 4: the twist by κ. Put $\pi_X = \pi^{(t)} \otimes (\Psi_\kappa \circ \mathrm{N}_{M/E'} \circ \det)$, cuspidal. At almost all places w of M above v of E' with residue degree f, $\iota\kappa(\mathrm{Frob}_w^{-1}) = \Psi_\kappa(\varpi_v)^f = (\Psi_\kappa \circ \mathrm{N}_{M/E'})(\varpi_w)$, so $X \leftrightarrow_\iota \pi_X$. At a complex place w of M let $a_w = a$ or $-a$ according to the embedding of E' that w induces; the parameter of $\pi_{X,w}$ is $z \mapsto \mathrm{diag}(z^{k-1/2+a_w}\bar{z}^{1/2-a_w},\, z^{1/2+a_w}\bar{z}^{k-1/2-a_w})$.

Step 5: (Ta1). Let σ be the non-trivial element of $\mathrm{Gal}(M/L)$, restriction of $\hat{g}$. If $\pi_X \cong \pi_X^\sigma$, then, since $X^{\hat{g}} \leftrightarrow_\iota \pi_X^\sigma$ ($\hat{g}\,\mathrm{Frob}_w\hat{g}^{-1}$ is a Frobenius element at σw), $\det X$ and $\det X^{\hat{g}}$ agree at almost all Frobenius elements, hence are equal by (CB), and Step 2 gives $\kappa^4 = 1$ on G_M, contradicting Step 1. So $\Pi_0 = \mathrm{AI}_{M/L}(\pi_X)$ is cuspidal by (Ai3); put $\Pi = \Pi_0 \otimes |\det|_{\mathbb{A}_L}$, cuspidal. At almost all finite places v of L:

so $V|_{G_L} \leftrightarrow_\iota \Pi$. At a complex place v of L the two places w, w' of M above it differ by σ, which is non-trivial on E', so $\{a_w, a_{w'}\} = \{a, -a\}$; by (Ai2) and Step 4 the parameter of $\Pi_v \otimes |\det|^{-3/2}$ on $\mathbb{C}^\times$ is $z \mapsto \mathrm{diag}(z^{p_i}\bar{z}^{q_i})$ with

$$(p_i) = (k-1+a,\ a,\ k-1-a,\ -a), \qquad (q_i) = (-a,\ k-1-a,\ a,\ k-1+a),$$

integers, and the p_i are pairwise distinct because $a \neq 0$ and $k-1 \neq \pm 2a$. So Π is regular algebraic in the sense of [68].

Step 6: (Ta2). Let $H = \{h \in G_M : \chi_{\mathrm{cyc}}(h) = 1\}$, a closed normal subgroup of $G_\mathbb{Q}$ with $G_\mathbb{Q}/H$ abelian ($M(\mu_{\ell^\infty})/\mathbb{Q}$ is abelian). By hypothesis some $g' \in G'_L$ lies outside $G_{E'}$, hence outside G_M; so $G'_L \cap G_M = H$, $[G'_L : H] = 2$ and $G_L = G_M G'_L$, and Mackey's formula gives $V|_{G'_L} \cong \mathrm{Ind}_H^{G'_L}(X|_H)$. (i) $\rho|_H$ is irreducible. Otherwise let $\mathcal{S}$ be the set of H-stable lines in $\overline{\mathbb{Q}}_\ell^2$, non-empty and permuted by $G_\mathbb{Q}$. If $\#\mathcal{S} = 1$ its line is $G_\mathbb{Q}$-stable, contradicting the irreducibility of ρ. If $\#\mathcal{S} = 2$, the stabiliser of one line is a closed subgroup of index ≤ 2, hence open, on which ρ is reducible: contradiction. If $\#\mathcal{S} \geq 3$, every $\rho(h)$, $h \in H$, is scalar; since $G_\mathbb{Q}/H$ is abelian, $\rho(g)\rho(g_2)\rho(g)^{-1} = c(g)\rho(g_2)$ with $c(g) \in \overline{\mathbb{Q}}_\ell^\times$, for a fixed g_2 with $\rho(g_2)$ not scalar (it exists, ρ being irreducible) and all $g \in G_\mathbb{Q}$; c is a continuous homomorphism, and multiplication by $c(g)$ preserves the multiset of eigenvalues of $\rho(g_2)$, so $c(g)^2 = 1$. On the open subgroup

$U = \ker c$ the matrices $\rho(U)$ commute with $\rho(g_2)$ and preserve an eigenline of it: contradiction with (Ne5). (ii) $X|_H$ is irreducible by (i), and $X|_H \ncong X^{g'}|_H$: otherwise $\kappa^4 = 1$ on H by Step 2 (with g' in place of $\hat{g}$), so $\kappa^4 = \varphi \circ \chi_{\mathrm{cyc}}$ on G_M for a continuous character φ of the compact group $\chi_{\mathrm{cyc}}(G_M) \cong G_M/H$; conjugating by $\hat{g}$ and using (51.3) and $\chi_{\mathrm{cyc}}(\hat{g}h\hat{g}^{-1}) = \chi_{\mathrm{cyc}}(h)$ gives $\kappa^{-4} = \kappa^4$ on G_M, i.e. $\kappa^8 = 1$ on G_M, contradicting Step 1. (iii) As an H-representation $\mathrm{Ind}_H^{G'_L}(X|_H) = X|_H \oplus g'X|_H$ with $g'X|_H \cong X^{g'}|_H$; the two summands are irreducible and non-isomorphic, so the only H-stable subspaces are 0, the two summands and the whole space, and g' exchanges the summands. Hence $V|_{G'_L}$ is irreducible, and by Burnside's theorem the span of $V(G'_L)$ is $\mathrm{End}(V)$. □

Proposition 51.17. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and $\mathscr{T}$ a good auxiliary tower for $\mathfrak{D}$. For every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}$ there is a space for $(\mathscr{T}, \mathcal{O}')$.*

Proof. Let $\mathbb{F} = \mathbb{F}_{\mathcal{O}'}$, $\mathfrak{m}'$ the maximal ideal of $\mathcal{O}'$, $[x] \in \mathcal{O}'$ the Teichmüller lift of $x \in \mathbb{F}$, and $\bar{\chi}_i$ the residual characters of the frame, with values in $\mathbb{F}^\times$; $\theta(g)$ is read in $\mathcal{O}'$. As $\theta = \alpha\Psi$, $\chi_1\chi_4 = \chi_2\chi_3 = \theta|_{G_F}$ for both labellings, so $\bar{r} = \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_4)$ has similitude $\bar{\theta}$.

Step 1: the universal near-diagonal datum. For $A \in \mathrm{CNL}_{\mathcal{O}'}$, a *near-diagonal datum* over A is a pair (r, ψ) of a continuous homomorphism $r\colon G_F \to \mathrm{GL}_4(A)$ with $r \equiv \bar{r}$ modulo $\mathfrak{m}_A$, $r(g)$ of similitude $\theta(g)$, $r(N) = 1$ and $r(g_{\mathscr{T}})$ diagonal, and of continuous characters $\psi_{v,i}\colon D_v \to A^\times$ ($v \in \Sigma$, $1 \le i \le 4$) with $\psi_{v,i} \equiv \bar{\chi}_i$ modulo $\mathfrak{m}_A$ and $\psi_{v,i}(\mu_v) = 1$. Let $\Gamma = G_F/\overline{\langle N \rangle}$, the quotient by the closed normal subgroup generated by N; as $N \subseteq \ker \bar{r}$, $\bar{r}$ factors through Γ. Γ satisfies Φ_ℓ: for $\Gamma' \subseteq \Gamma$ open with preimage H, let $H_0 = H \cap \ker \bar{r}$, with fixed field L'; a continuous $f\colon H \to \mathbb{F}_\ell$ vanishing on N vanishes on $I_{\bar{w}} \cap H_0 \subseteq N$ for all $\bar{w} \nmid \ell$, so $f|_{H_0}$ factors through $G_{L',S'}$, S' the places above ℓ and ∞; the kernel of restriction lies in $\mathrm{Hom}(H/H_0, \mathbb{F}_\ell)$, finite, and the image is finite by Theorem B.71, item 2. By Theorem B.71, item 1, there are universal framed lifts $(R^\square, r^\square)$ of $\bar{r}$ on Γ and $(R_{v,i}, \psi_{v,i}^\square)$ of $\bar{\chi}_i|_{D_v}$ ($n = 1$). Their completed tensor product $S_0 \in \mathrm{CNL}_{\mathcal{O}'}$ represents pairs of such lifts. Let $I_0 \subseteq S_0$ be generated by the entries of ${}^t r^\square(g) J_4 r^\square(g) - \theta(g) J_4$, the off-diagonal entries of $r^\square(g_{\mathscr{T}})$ and the $\psi_{v,i}^\square(s) - 1$, $s \in \mu_v$. The residual datum $(\bar{r}, (\bar{\chi}_i|_{D_v}))$ satisfies these equations $(\bar{\chi}_i(s)^{\ell^a} = \bar{\chi}_i(s^{\ell^a}) = 1$ for $s \in \mu_v$, so $\bar{\chi}_i(s) = 1$, the order of $\mathbb{F}^\times$ being prime to ℓ), so $I_0 \subseteq \mathfrak{m}_{S_0}$ and $\mathbf{R} = S_0/I_0 \in \mathrm{CNL}_{\mathcal{O}'}$, with the images $(r_{\mathrm{u}}, \psi_{\mathrm{u}})$, has the property: (U) for every near-diagonal datum (r, ψ) over $A \in \mathrm{CNL}_{\mathcal{O}'}$ there is exactly one $\mathcal{O}'$-algebra homomorphism $F\colon \mathbf{R} \to A$ with $F \circ r_{\mathrm{u}} = r$, $F \circ \psi_{\mathrm{u}} = \psi$.

Step 2: the $\mathbb{Z}^2$-weighted presentation. For $t_1, t_2 \in 1 + \mathfrak{m}_A$ and $X = \mathrm{T}_4(t_1, t_2)$, (XrX^{-1}, ψ) is again a near-diagonal datum: conjugation by a matrix of similitude t_1t_2 preserves similitudes, diagonality of $r(g_{\mathscr{T}})$, $r(N) = 1$, continuity and the reduction. By (U) for $\mathbf{R}[[T]]$ and $\mathbf{R}[[T_1, T_2]]$ there are morphisms $\varrho_1\colon \mathbf{R} \to \mathbf{R}[[T]]$ (for $\mathrm{T}_4(1+T, 1)$) and $\varrho\colon \mathbf{R} \to \mathbf{R}[[T_1, T_2]]$ (for $\mathrm{T}_4(1 + T_1, 1 + T_2)$). Let S_1 be the set of indices $s = (g, i, j)$, $g \in G_F$, and $s = (v, i, t)$, $t \in D_v$, and put $x_{(g,i,j)} = r_{\mathrm{u}}(g)_{ij} - \delta_{ij}[\bar{\chi}_i(g)]$, $x_{(v,i,t)} = \psi_{\mathrm{u},v,i}(t) - [\bar{\chi}_i(t)]$, all in $\mathfrak{m}_{\mathbf{R}}$, with $\mathrm{wt}(g, i, j) = \mathrm{wt}_4(i, j)$, $\mathrm{wt}(v, i, t) = (0, 0)$; then $\varrho(x_s) = (1+T_1)^{w_1}(1+T_2)^{w_2}x_s$ for $\mathrm{wt}(s) = (w_1, w_2)$, and similarly for ϱ_1 with $w_1 \in \{-1, 0, 1\}$. Two morphisms from $\mathbf{R}$ agreeing on all x_s agree on $(r_{\mathrm{u}}, \psi_{\mathrm{u}})$, hence are equal by (U). So Lemma 43.8 (for ϱ_1) gives a finite $\sigma \subseteq S_1$ such that $\pi\colon P = \mathcal{O}'[[X_s : s \in \sigma]] \to \mathbf{R}$, $X_s \mapsto x_s$, is surjective, and Lemma 45.18 ($d = 2$, ϱ) gives: $\mathfrak{a} = \ker \pi$ is homogeneous, and every element of torus weight w lies in $\mathbf{R}_w = \pi(\mathcal{O}'[[X_\sigma]]_w)$. In particular $r_{\mathrm{u}}(g)_{ij} \in \mathbf{R}_{\mathrm{wt}_4(i,j)}$ and $\psi_{\mathrm{u},v,i}(t) \in \mathbf{R}_{(0,0)}$. Elements of $\mathfrak{a}$ have constant term in $\mathfrak{m}'$ (compose π with $\mathbf{R} \to \mathbb{F}$). Products of power series of weights w, w' have weight $w + w'$, so $\mathbf{R}_w\mathbf{R}_{w'} \subseteq \mathbf{R}_{w+w'}$.

Step 3: the rings B and A_0; continuity. Let $m_1, \dots, m_p$ generate the monoid of weight-0 exponents (Gordan). The continuous map $\mathcal{O}'[[Y_1, \dots, Y_p]] \to P$, $Y_k \mapsto X^{m_k}$, has image $P_0 = \mathcal{O}'[[X_\sigma]]_{(0,0)}$ (write each weight-0 exponent as $\sum c_k m_k$; distinct exponents give distinct c, and the resulting series converges). Hence $B = \mathbf{R}_{(0,0)} = \pi(P_0)$ is a quotient of $\mathcal{O}'[[Y]]$

containing $\mathcal{O}'$: $B \in \mathrm{CNL}_{\mathcal{O}'}$, with maximal ideal $\mathfrak{m}_B = \pi(\mathfrak{m}_{P_0})$, $\mathfrak{m}_{P_0}$ generated by $\mathfrak{m}'$ and the X^{m_k}. For $w \in \mathbb{Z}^2$ let $m'_1, \dots, m'_q$ be the minimal exponents of weight w (Dickson); grouping the terms of $h \in \mathcal{O}'[[X_\sigma]]_w$ by a chosen minimal $m'_k \le m$ gives $h = \sum_k X^{m'_k} h_k$ with $h_k \in P_0$, so $\mathbf{R}_w = \sum_k \pi(X^{m'_k})B$. Put $A_0 = B[x_s : s \in \sigma] \subseteq \mathbf{R}$; it contains every $\mathbf{R}_w$, all entries of r_u and all ψ_u, and is of finite type over B. *Continuity:* let D bound the degrees of the m_k and of the m'_k for $w \in \mathcal{W}_4 = \{\mathrm{wt}_4(i,j)\}$; for $y \in \mathbf{R}_w \cap \mathfrak{m}_{\mathbf{R}}^{D(k+2)}$ write $y = \pi(h')$ with $h' \in \mathfrak{m}_P^{D(k+2)}$; by homogeneity of $\mathfrak{a}$ also $y = \pi(h'_{(w)})$, and $h'_{(w)} \in \mathfrak{m}_P^{D(k+2)}$. In the grouping, a term bX^m ($b \in \mathfrak{m}'^e$, $e + |m| \ge D(k+2)$) contributes $bX^{m-m'_k}$, a product of e factors of $\mathfrak{m}'$ and at least $(|m| - D)/D$ of the X^{m_k}, hence in $\mathfrak{m}_{P_0}^{k+1}$, a closed ideal. So

$$\mathbf{R}_w \cap \mathfrak{m}_{\mathbf{R}}^{D(k+2)} \subseteq \mathfrak{m}_B^k A_0 \quad (w \in \mathcal{W}_4), \qquad \mathbf{R}_{(0,0)} \cap \mathfrak{m}_{\mathbf{R}}^{D(k+2)} \subseteq \mathfrak{m}_B^k \tag{51.4}$$

(for $w = (0,0)$ the only minimal exponent is 0). As r_u and ψ_u are $\mathfrak{m}_{\mathbf{R}}$-adically continuous, (51.4) makes $g \mapsto r_\mathrm{u}(g)_{ij}$ continuous for $\mathfrak{m}_B A_0$, and the characteristic polynomial coefficients of $r_\mathrm{u}(g)$ (sums of products $\prod_i r_\mathrm{u}(g)_{i\pi(i)}$ of weight 0, so in B) and the ψ_u continuous for $\mathfrak{m}_B$.

Step 4: B is generated by traces and ψ. Let $f, f' \colon B \to R'$ be $\mathcal{O}'$-algebra homomorphisms to $R' \in \mathrm{CNL}_{\mathcal{O}'}$ agreeing on all coefficients of the characteristic polynomials $\mathrm{cp}_\mathrm{u}(g)$ of $r_\mathrm{u}(g)$ and on all $\psi_{\mathrm{u},v,i}(t)$; they are continuous, so their equalizer E is a closed $\mathcal{O}'$-subalgebra. Write $r_\mathrm{u}(g_{\mathscr{F}}) = \mathrm{diag}(d_1, \dots, d_4)$, $d_i \in B$, $d_i \equiv \bar\chi_i(g_{\mathscr{F}})$; by (Oq7) $d_i - d_j \in B^\times$ for $i \ne j$. The polynomial $p = f(\mathrm{cp}_\mathrm{u}(g_{\mathscr{F}})) = f'(\mathrm{cp}_\mathrm{u}(g_{\mathscr{F}})) = \prod_j (X - f(d_j))$ vanishes at $f'(d_i)$, and $f'(d_i) - f(d_j)$ is a unit for $j \ne i$ (distinct residues); so $f'(d_i) = f(d_i)$. By Lemma 51.18 (with $R = \mathbf{R}$, $\Lambda = \mathcal{O}'$, $\nu = \theta$, $g_* = g_{\mathscr{F}}$, r_u through Γ), every product of entries of weight $(0,0)$ is a polynomial in traces with coefficients in $\mathcal{O}'[d_i, (d_i - d_j)^{-1}] \subseteq B$; hence it lies in E. Every $\pi(X^m)$ with m of weight 0 is a product of x_s; expanding $x_s = r_\mathrm{u}(g)_{ij} - \delta_{ij}[\bar\chi_i(g)]$ (constants only at weight-0 entries) writes it as an $\mathcal{O}'$-combination of weight-0 products of entries and of ψ_u's, all in E. As E is closed and $B = \pi(P_0)$, $E = B$, i.e. $f = f'$.

Step 5: flags; the space. Let $A = A_0[Y_{v,ij} : v \in \Sigma, 1 \le j < i \le 4]/I$, n_v the lower unitriangular matrix with entries $Y_{v,ij}$ below the diagonal, $n_v^* = -J_4\, {}^t n_v J_4$, and I generated by the entries of ${}^t n_v J_4 n_v - J_4$, the entries (i,j), $i > j$, of $n_v^* r_\mathrm{u}(s) n_v$ and $(n_v^* r_\mathrm{u}(s) n_v)_{ii} - \psi_{\mathrm{u},v,i}(s)$ for $s \in D_v$. The residue map of $\mathbf{R}$ on A_0 and $Y \mapsto 0$ kill I (the residual datum is diagonal), so $A \ne 0$ and the kernel $\mathfrak{b}$ of $B \to A$ lies in $\mathfrak{m}_B$. Put $\bar B = B/\mathfrak{b} \in \mathrm{CNL}_{\mathcal{O}'}$, r_P, n_v the images in A, $P = (r_P, (n_v))$, $\mathrm{cp}(g)$ and $\psi_{v,i}^B$ the images of $\mathrm{cp}_\mathrm{u}(g)$ and $\psi_{\mathrm{u},v,i}$ in $\bar B$. Once ${}^t n_v J_4 n_v = J_4$, $n_v^* = n_v^{-1}$. Then: P is a marked ordinary pair ((Mq1), (Mq2) from Step 1, (Mq3), (Mq4) from I and $\psi_\mathrm{u}(\mu_v) = 1$), with $\psi_{v,i}^P = \psi_{v,i}^B$; (Zq1): $\bar B \to A$ is injective, A is of finite type over $\bar B$ and generated by the entries of r_P (through the x_s) and of the n_v, and P is continuous for $\mathfrak{m}_{\bar B} A$ by Step 3; (Zq2) by Step 3 and the reduction $\bar r$; (Zq3) by Step 4, composing with $B \to \bar B$.

Step 6: scaling. Let $c = (r_c, (n_{c,v}))$ be a residual pair. By (Wq2), r_c is supported in Σ_P or in Σ_M; let $\tau(w) = -2w_1 - w_2$ in the first case and $\tau(w) = -w_1 - 2w_2$ in the second. A check on $\mathcal{W}_4$ gives $\tau \ge 1$ on Σ_P, resp. Σ_M, and $|\tau| \le 3$ on $\mathcal{W}_4$. So off-diagonal entries (i,j) of r_c with $\tau(\mathrm{wt}_4(i,j)) \le 0$ vanish. With (a,b) the coefficients of τ and a unit u, $X_u = \mathrm{T}_4(u^a, u^b)$ multiplies the entry (i,j) by $u^{\tau(\mathrm{wt}_4(i,j))}$.

(Zq5). Let c have values in $\mathbb{F}[X]$ and put $C = \mathbb{F}[[u, X]] \in \mathrm{CNL}_{\mathcal{O}'}$. Then $(X_u r_c X_u^{-1}, (\bar\chi_i|_{D_v}))$ is a near-diagonal datum over C: its off-diagonal entries lie in uC (as $\tau \ge 1$ where r_c is non-zero), its diagonal is $\bar\chi_i$ by (Wq1), similitudes and the other conditions are those of c, and $\psi_{v,i}^c = \bar\chi_i|_{D_v}$ is trivial on μ_v. Let $F_0 \colon \mathbf{R} \to C$ be given by (U). Then $F_0(x_s) = u^{\tau(\mathrm{wt}(s))}\xi_s$ with $\xi_s = r_c(g)_{ij} \in \mathbb{F}[X]$ for $s = (g,i,j)$, $i \ne j$, and $\xi_s = 0$ otherwise, and $\xi_s \ne 0$ only if $\tau(\mathrm{wt}(s)) \ge 1$. For $h = \sum b_m X^m \in \mathcal{O}'[[X_\sigma]]_w$, only exponents with $|m| \le \tau(w)$ contribute, so $F_0(\pi(h)) = u^{\tau(w)} p_h$ with $p_h \in \mathbb{F}[X]$ (and 0 if $\tau(w) < 0$). Hence $F_0(A_0) \subseteq \mathbb{F}[X][u]$, and

$f_0 = (u \mapsto 1) \circ F_0|_{A_0} \colon A_0 \to \mathbb{F}[X]$ is an $\mathcal{O}'$-algebra homomorphism with $f_0(r_{\mathrm{u}}(g)_{ij}) = r_c(g)_{ij}$, $f_0(\psi_{\mathrm{u}}) = \psi^c$, and $f_0(\mathfrak{m}_B) = 0$ (for $w = (0,0)$, p_h is the residue of the constant term). Sending $Y_{v,ij} \mapsto (n_{c,v})_{ij}$ kills I ((Mq3), (Mq4) for c), giving $f \colon A \to \mathbb{F}[X]$ with $f(P) = c$, $f(\mathfrak{m}_{\bar{B}}) = 0$.

(Zq4). Let $R' \in \mathrm{CNL}_{\mathcal{O}'}$, c with values in $\mathbb{F}$ and $Q = (r_Q, (n_{Q,v}))$ with values in R', continuous, with reduction c. First let $\mathfrak{m}_{R'}^{K+1} = 0$. Let $S \subseteq R'((u))$ be the $R'[[u]]$-submodule generated by 1 and $\mathfrak{m}_{R'}^k u^{-3k}$, $1 \le k \le K$; it is a subring, finite over $R'[[u]]$; $J = \mathfrak{m}_{R'} R'[[u]] + \sum_k \mathfrak{m}_{R'}^k u^{-3k} R'[[u]]$ is an ideal with $J^{K+1} = 0$ and $S/J \cong \mathbb{F}[[u]]$, so S is local with maximal ideal $J + uS$, and $(J+uS)^{K+2} \subseteq uS$ shows that S is complete: $S \in \mathrm{CNL}_{\mathcal{O}'}$. The entries $u^\tau r_Q(g)_{ij}$ of $X_u r_Q X_u^{-1}$ lie in S (if $\tau < 0$ then $i \ne j$, $r_c(g)_{ij} = 0$ and $r_Q(g)_{ij} \in \mathfrak{m}_{R'}$), and those with $i \ne j$ lie in $J + uS$; with $\psi^Q_{v,i}$ (continuous characters by (Mq4), $\equiv \bar{\chi}_i$ by (Wq1), trivial on μ_v) this is a near-diagonal datum over S (r_Q is locally constant as $\mathfrak{m}_{R'}$ is nilpotent). Let $F \colon \mathbf{R} \to S$ be given by (U); $F(x_s) = u^{\tau(\mathrm{wt}(s))} y_s$ with $y_s \in R'$, and $y_s \in \mathfrak{m}_{R'}$ when $\tau(\mathrm{wt}(s)) \le 0$. For $h \in \mathcal{O}'[[X_\sigma]]_w$ a monomial X^m contributes 0 unless at most K of its factors have $\tau \le 0$, and then $\sum_{\tau(\mathrm{wt}(s))\ge 1} m_s \le \tau(w) + 3K$; so $F(\pi(h)) = u^{\tau(w)} z$ with $z \in R'$ a finite sum. Thus $F(A_0) \subseteq R'[u, u^{-1}]$, and $f_0 = (u \mapsto 1) \circ F|_{A_0}$ satisfies $f_0(r_{\mathrm{u}}) = r_Q$, $f_0(\psi_{\mathrm{u}}) = \psi^Q$; with $Y_{v,ij} \mapsto (n_{Q,v})_{ij}$ it gives $f \colon A \to R'$ with $f(P) = Q$. Such f is unique: two of them agree on the generators of A over $\bar{B}$, and on $\bar{B}$ by (Zq3), as both send $\mathrm{cp}(g)$ to the characteristic polynomial of $r_Q(g)$ and ψ^B to ψ^Q. For general R' apply this to $R'/\mathfrak{m}_{R'}^{K+1}$ and Q modulo $\mathfrak{m}_{R'}^{K+1}$, $K \ge 0$; by uniqueness the maps are compatible, and their limit $f \colon A \to \varprojlim R'/\mathfrak{m}_{R'}^{K+1} = R'$ satisfies $f(P) = Q$.

So $(\bar{B}, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ is a space for $(\mathscr{T}, \mathcal{O}')$. □

Lemma 51.18. *Let R be a commutative ring, $\Lambda \subseteq R$ a subring, Γ a group and $r \colon \Gamma \to \mathrm{GL}_4(R)$ a homomorphism such that $r(g)$ has similitude $\nu(g) \in \Lambda^\times$ for every $g \in \Gamma$. Let $g_* \in \Gamma$ with $r(g_*) = \mathrm{diag}(d_1, d_2, d_3, d_4)$ and $d_i - d_j \in R^\times$ for $i \ne j$, and let Λ' be the subring of R generated by Λ, the d_i and the $(d_i - d_j)^{-1}$. Then every product $r(g_1)_{i_1 j_1} \cdots r(g_k)_{i_k j_k}$ with $k \ge 0$, $g_t \in \Gamma$ and $\sum_{t=1}^k \mathrm{wt}_4(i_t, j_t) = (0,0)$ lies in the Λ'-subalgebra of R generated by the traces $\mathrm{tr}\, r(g)$, $g \in \Gamma$.*

Proof. Let $\mathcal{A}$ be the Λ'-subalgebra generated by the traces, and E_i the diagonal matrix unit with entry 1 at (i,i).

Step 1: idempotents. By Lagrange interpolation, $E_i = \prod_{j \ne i} (d_i - d_j)^{-1} (r(g_*) - d_j) = \sum_{a=0}^3 \beta_{i,a}\, r(g_*)^a$ with $\beta_{i,a} \in \Lambda'$, and $r(g_*)^a = r(g_*^a)$, $r(g_*^0) = 1$.

Step 2: closed walks. For indices $i_1, \dots, i_k$ (put $i_{k+1} = i_1$) and $h_1, \dots, h_k \in \Gamma$,

$$\prod_{t=1}^k r(h_t)_{i_t i_{t+1}} = \mathrm{tr}\big(E_{i_1} r(h_1) E_{i_2} r(h_2) \cdots E_{i_k} r(h_k)\big) = \sum_{a_1, \dots, a_k} \beta_{i_1,a_1} \cdots \beta_{i_k,a_k}\, \mathrm{tr}\, r\big(g_*^{a_1} h_1 g_*^{a_2} h_2 \cdots g_*^{a_k} h_k\big) \in \mathcal{A}.$$

Step 3: the symplectic flip. From ${}^t r(g) J_4 r(g) = \nu(g) J_4$ and $J_4^{-1} = -J_4$ we obtain

$$r(g)^{-1} = \nu(g)^{-1} J_4^{-1}\, {}^t r(g)\, J_4.$$

As J_4 has exactly one non-zero entry, ± 1, in each row and column, at the positions $(a, 5-a)$, this gives $r(g^{-1})_{ab} = \pm \nu(g)^{-1} r(g)_{5-b,5-a}$, i.e.

$$r(g)_{ij} = \pm \nu(g)\, r(g^{-1})_{5-j,5-i} \qquad (1 \le i, j \le 4),$$

with a sign depending only on (i,j).

Step 4: reduction to balanced products. To a product $P = \prod_t r(g_t)_{i_t j_t}$ attach the vector $v(P) = \sum_t (e_{i_t} - e_{j_t}) \in \mathbb{Z}^4$, whose coordinate at x is the number of factors with $i_t = x$ minus the number with $j_t = x$. Then $\sum_t \mathrm{wt}_4(i_t, j_t) = (\boldsymbol{\lambda} \cdot v(P), \boldsymbol{\mu} \cdot v(P))$. If this is $(0,0)$, then $v_1 + v_3 = 0$, $v_1 + v_2 = 0$ and $v_1 + v_2 + v_3 + v_4 = 0$, so $v(P) = n(P)\,(e_1 - e_2 - e_3 + e_4)$ for an integer $n(P)$. We show $P \in \mathcal{A}$ by induction on $|n(P)|$. If $n(P) = 0$, the directed multigraph on $\{1,2,3,4\}$ with one edge $i_t \to j_t$ for each factor has equal in- and out-degree at every vertex, so its edges are partitioned into closed walks (remove a closed walk, which exists from any vertex of positive degree, and repeat); P is the product of the corresponding products of Step 2, hence in $\mathcal{A}$. If $n = n(P) > 0$, the vertices 2 and 3 have in-degree exceeding out-degree by n each; edges with both ends in $\{2,3\}$ do not change the total excess of $\{2,3\}$, so some factor $r(g)_{ij}$ has $i \in \{1,4\}$, $j \in \{2,3\}$. Replace it by $\pm\nu(g) r(g^{-1})_{5-j,5-i}$ (Step 3): $P = \pm\nu(g) P'$ with $\nu(g) \in \Lambda$, and $v(P') - v(P) = (e_{5-j} - e_{5-i}) - (e_i - e_j) = (e_2 + e_3) - (e_1 + e_4)$, so $n(P') = n - 1$ and P' still has weight sum $(0,0)$. If $n < 0$, the same argument with the vertices 1, 4 gives a factor with $i \in \{2,3\}$, $j \in \{1,4\}$, whose replacement raises n by 1. By induction $P \in \mathcal{A}$. □

51.3 Finiteness in weight zero and block extensions

This subsection proves the remaining clauses of Theorem 51.1. Promodular test representations are not essential in characteristic ℓ; in characteristic zero they are weakly pure, and automorphic when irreducible (Lemma 51.19). Finiteness in weight zero, (Sa1), follows from a curve test (Proposition 51.20): the universal symplectic Eisenstein lift has a weighted presentation with homogeneous kernel and entries (Proposition 51.21), and finiteness can be checked on one-dimensional quotients. The absence of endoscopic points, (Sa2), comes from block extensions. A block diagonal ordinary test representation deforms to a non-split block extension with the same characteristic polynomials (Proposition 51.23), using a non-zero integral cocycle with an ordinary condition at ℓ (Proposition 51.24); that extension is essential, hence weakly pure by Theorem 51.4, and weak purity depends only on the characteristic polynomials; but in characteristic zero a block diagonal test representation is not weakly pure (Lemma 51.25). At every place of T the Eisenstein point lies on exactly one component of the local deformation space (Proposition 51.22), which gives the universal lift used here.

Lemma 51.19. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with odd prime ℓ and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism.*

1. *If (K, V, a) is a test field of characteristic ℓ and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is promodular for $\mathfrak{D}$ and ι, then r is not essential.*
2. *If (r, u) is an ordinary test representation of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ (for the standard test field) such that r is promodular for $\mathfrak{D}$ and ι, then r is weakly pure for ι; if moreover r is irreducible, then r satisfies (Sy2) for ι.*

Proof. In both parts let $\mathscr{T} = (\epsilon, E, F, g_{\mathscr{T}}, \Sigma, (\bar{v}))$, $\mathcal{O}'$, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$, $\mathfrak{J}$, y, $u_1 \in \mathrm{GL}_4(K)$ and $r_1 = u_1 r u_1^{-1}$ be as in the definition of promodularity; $\mathscr{T}$ is fit, hence good, and $L = FE$. Write $P = (r_P, (n_v))$.

Step 0: the root characters. Since $\theta = \alpha\Psi$, $\kappa_i = \alpha^{\lambda_i}\Psi^{\mu_i}$; for $\epsilon = 1$, $(\kappa_i^1) = (\alpha, \mathbf{1}, \theta, \Psi) = (\alpha^{\lambda_i}\Psi^{1-\mu_i})$. In both cases $\chi_1^{\mathscr{T}}/\chi_2^{\mathscr{T}} = \alpha$ and $\chi_1^{\mathscr{T}}/\chi_3^{\mathscr{T}} = \Psi^{\pm 1}$, so $\chi_i^{\mathscr{T}}/\chi_j^{\mathscr{T}} = \mathrm{rt}_{\mathrm{wt}_4(i,j)}$ on G_F, and $\mathrm{wt}_4(i,j)$ is a root for $i \neq j$. By (Oq3), for $i \neq j$ there is $h \in G_L$ with $\bar{\chi}_i^{\mathscr{T}}(h) \neq \bar{\chi}_j^{\mathscr{T}}(h)$. As $(\chi_i^{\mathscr{T}})_i$ is a permutation of $(\kappa_i|_{G_F})_i$, the four characters $\bar{\kappa}_i|_{G_L}$ are pairwise distinct. (D)

Part 1. *Step 1: y kills $\mathfrak{m}_B$.* As K has characteristic ℓ, $a(\ell) = 0$; the kernel of $a|_{\mathcal{O}'}$ is a prime ideal of the discrete valuation ring $\mathcal{O}'$ containing $\ell \neq 0$, hence equals $\mathfrak{m}_{\mathcal{O}'}$, and

$a|_{\mathcal{O}'} = j \circ (\mathcal{O}' \to \mathbb{F}_{\mathcal{O}'})$ for an embedding of fields $j\colon \mathbb{F}_{\mathcal{O}'} \to V$. Hence $y(\mathfrak{m}_{\mathcal{O}'}B) = 0$. For $v \in \Sigma$ and $s \in I_v$, $y(\psi^B_{v,i}(s)) = y(\psi^P_{v,i}(s)) = a(\kappa_i(s)) = j(\bar\kappa_i(s)) = 1$ by (Zq2), promodularity and (Oq6). With $y(\mathfrak{J}) = 0$, (Jq1) gives $y(\mathfrak{m}_B)^n = 0$, and V is a domain, so $y(\mathfrak{m}_B) = 0$. Since $B = \mathcal{O}' + \mathfrak{m}_B$, $y|_B = j \circ (B \to B/\mathfrak{m}_B = \mathbb{F}_{\mathcal{O}'})$.

Step 2: characteristic polynomials on G_F. For $g \in G_F$, $r_1(g) = y(r_P(g))$, so by (Zq2) and Step 1 its characteristic polynomial is the image under y of $\mathrm{cp}(g)$, namely $\prod_i (X - j(\bar\chi_i^{\mathscr{T}}(g))) = \prod_i (X - a(\kappa_i(g)))$. Conjugation by u_1 does not change it, so $\det(X - r(g)) = \prod_i (X - a(\kappa_i(g)))$ for $g \in G_F$.

Step 3: $\operatorname{tr} r(g) = \sum_i a(\kappa_i(g))$ for every $g \in G_{\mathbb{Q}}$. Let $q = \#\mathbb{F}_{\mathcal{O}}$ and $d_i = a(\kappa_i(g))$; then $d_i = j(\bar\kappa_i(g))$ and $d_i^{q-1} = 1$. As $[G_{\mathbb{Q}} : G_F]$ is finite, $g^N \in G_F$ for some $N \geq 1$, and by Step 2 every eigenvalue $x \in K$ of $r(g)$ satisfies $x^N = d_i^N$ for some i, so $x^{N(q-1)} = 1$. Hence $\Delta = \operatorname{tr} r(g) - \sum_i d_i$ is a sum of roots of unity of K, so algebraic over $\mathbb{F}_\ell$, and lies in a finite subfield of K. By (Ot2) the diagonal entries of $r(g)$ are congruent to d_i modulo $\mathfrak{m}_V$, so $\Delta \in \mathfrak{m}_V$. A non-zero element of a finite field satisfies $\Delta^m = 1$ for some $m \geq 1$ and is then a unit of V; so $\Delta = 0$.

Step 4: a trace identity. As the κ_i take values in a commutative group, Step 3 gives

$$\operatorname{tr} r(xgh) = \operatorname{tr} r(xhg) \qquad \text{for all } x, g, h \in G_{\mathbb{Q}}. \tag{51.5}$$

Step 5: r is not irreducible. If the K-span of $r(G_{\mathbb{Q}})$ were $\mathrm{M}_4(K)$, then by linearity (51.5) gives $\operatorname{tr}(Y(r(g)r(h) - r(h)r(g))) = 0$ for all $Y \in \mathrm{M}_4(K)$, so $r(g)r(h) = r(h)r(g)$ by non-degeneracy of the trace form; then $\mathrm{M}_4(K)$, the span of $r(G_{\mathbb{Q}})$, would be commutative, which it is not.

Step 6: r is not a non-split block extension. Suppose it were. By condition (i), $r(g)$ maps the span of e_2, e_4 to itself; write $A_1(g)$, $A_2(g) \in \mathrm{M}_2(K)$ for the submatrices on the indices $\{1,3\}$ and $\{2,4\}$. Both A_1 and A_2 are multiplicative (block triangularity), $\operatorname{tr} r(g) = \operatorname{tr} A_1(g) + \operatorname{tr} A_2(g)$, and $\det(X - r(g)) = p_1(g)p_2(g)$ with $p_k(g) = \det(X - A_k(g))$. Let $g_0 = g_{\mathscr{T}} \in G_F$. By Step 2 and (Oq7) (and injectivity of j), $\det(X - r(g_0))$ has four distinct roots, so $p_1(g_0)$ and $p_2(g_0)$ are coprime, and by Cayley–Hamilton $M = p_1(g_0)(A_2(g_0))$ is invertible: from $\lambda p_1 + \mu p_2 = 1$ we get $\lambda(A_2(g_0))M = 1$. Write $p_1(g_0) = X^2 - tX + \delta$. Since $p_1(g_0)(A_1(g_0)) = 0$, multiplicativity gives, for every $z \in G_{\mathbb{Q}}$,

$$\operatorname{tr}(MA_2(z)) = \operatorname{tr} r(g_0^2 z) - t \operatorname{tr} r(g_0 z) + \delta \operatorname{tr} r(z),$$

and with (51.5) applied to $x = g_0^2 x'$, $g_0 x'$, x', $\operatorname{tr}(MA_2(x'gh)) = \operatorname{tr}(MA_2(x'hg))$ for all x', g, h. By condition (ii) the $A_2(x')$ span $\mathrm{M}_2(K)$, so $\operatorname{tr}\big((A_2(g)A_2(h) - A_2(h)A_2(g))MY\big) = 0$ for all $Y \in \mathrm{M}_2(K)$, whence $(A_2(g)A_2(h) - A_2(h)A_2(g))M = 0$ and, M being invertible, $A_2(g)A_2(h) = A_2(h)A_2(g)$. Then $\mathrm{M}_2(K)$ would be commutative. So r is not essential.

Part 2. Here $(K, V, a) = (\overline{\mathbb{Q}}_\ell, \overline{\mathbb{Z}}_\ell, \mathrm{id})$, so $y\colon A \to \overline{\mathbb{Z}}_\ell \subseteq \overline{\mathbb{Q}}_\ell$ is an $\mathcal{O}'$-algebra homomorphism with $y(\mathfrak{J}) = 0$, and $r_1 = u_1 r u_1^{-1}$ takes values in $\mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$.

Step 7: weights. Let $U = G_F \cap \ker\chi \cap \ker\omega_\ell$, an open subgroup ($\chi$, ω_ℓ have finite order). Let $s \in U \cap I_v$; s lies in an inertia group above ℓ, where ξ is unramified by (Sg1) ($\ell \in T$), so $\xi(s) = 1$; then $\Psi(s) = \chi_{\mathrm{cyc}}(s)^e$, $\alpha(s) = \chi_{\mathrm{cyc}}(s)$, $\theta(s) = \chi_{\mathrm{cyc}}(s)^{e+1}$, i.e. $\kappa_i(s) = \chi_{\mathrm{cyc}}(s)^{m_i}$ with $(m_i) = (e+1, e, 1, 0)$. By promodularity $\psi^{y(P)}_{v,i}(s) = y(\psi^P_{v,i}(s)) = \kappa_i(s)$, so $y(P)$ has weights $(2m_1, \ldots, 2m_4)$.

Step 8: weak purity. r_1 is a homomorphism to $\mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $r_1|_{G_F} = y \circ r_P$, so by (Jq4) it is weakly pure for ι. Weak purity depends only on characteristic polynomials, which r and r_1 share; so r is weakly pure.

Step 9: automorphy. Let r be irreducible. (a) *Continuity.* By (Ot1) the entries of r lie in $j(\Lambda)$ for a complete discrete valuation ring Λ with finite residue field and an injective local $j\colon \Lambda \to \overline{\mathbb{Z}}_\ell$, continuous for the $\mathfrak{m}_\Lambda$-adic topology. $j(\Lambda)$ has characteristic 0, so Λ contains $\mathbb{Z}_\ell$

and is finite over it (complete discrete valuation ring with finite residue field); $j(\Lambda)$ is the ring of integers of a finite extension of $\mathbb{Q}_\ell$, on which the $\mathfrak{m}_\Lambda$-adic and the ℓ-adic topologies agree. So r, hence r_1, is continuous. (b) $r_1(g)$ has similitude $\theta(g)$ by promodularity. (c) $r_1|_{G_L}$ *is irreducible.* r_1 is irreducible, $H = G_L$ is normal of finite index in $G_\mathbb{Q}$ with $G_\mathbb{Q}/H$ abelian ($L = FE$ is abelian over $\mathbb{Q}$). Suppose $r_1|_H$ reducible. By Clifford's theorem $r_1|_H$ is semisimple, so $\dim \mathrm{End}_H(r_1) \geq 2$. The finite abelian group $G_\mathbb{Q}/H$ acts on $\mathrm{End}_H(r_1)$ by $Y \mapsto r_1(g) Y r_1(g)^{-1}$; decompose into eigenspaces for its characters (characteristic 0, $\overline{\mathbb{Q}}_\ell$ algebraically closed). The trivial eigenspace is $\mathrm{End}_{G_\mathbb{Q}}(r_1) = \overline{\mathbb{Q}}_\ell$ (Schur), so some character $\varphi \neq \mathbf{1}$ of $G_\mathbb{Q}/H$ has a non-zero Y with $r_1(g)Y = \varphi(g) Y r_1(g)$ for all g; Y is a non-zero homomorphism between the irreducible representations r_1 and $r_1 \otimes \varphi$, hence invertible, and $Y^{-1} r_1(g) Y = \varphi(g) r_1(g)$. Taking traces, $\mathrm{tr}\, r_1(g) = 0$ whenever $\varphi(g) \neq 1$. Fix g_1 with $\varphi(g_1) \neq 1$; then $\mathrm{tr}\, r(g_1 h) = \mathrm{tr}\, r_1(g_1 h) = 0$ for all $h \in H$. By (Ot2), $\mathrm{tr}\, r(z) \equiv \sum_i \kappa_i(z) \pmod{\mathfrak{m}_\ell}$, so $\sum_i \bar{\kappa}_i(g_1)\bar{\kappa}_i(h) = 0$ in $\overline{\mathbb{F}}_\ell$ for all $h \in H$. By (D) and Artin's independence of characters, $\bar{\kappa}_i(g_1) = 0$ for all i, which is absurd. (d) By (Jq5), r_1 satisfies (Sy2) for ι. Condition (Sy2) depends only on the isomorphism class of the representation (irreducibility of restrictions, the relation $\leftrightarrow_\iota$ through characteristic polynomials, and the witness conditions, which are conditions on the representation up to isomorphism); so r satisfies (Sy2) for ι. □

Proposition 51.20. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with odd prime ℓ. Assume that for every test field (K, V, a) of characteristic ℓ, every point r of $\mathfrak{D}$ with values in V, every $k \geq 0$, all $g_1, \ldots, g_k \in G_\mathbb{Q}$ and all indices with $\sum_{s=1}^k \mathrm{wt}_4(i_s, j_s) = (0,0)$, the product $x = r(g_1)_{i_1 j_1} \cdots r(g_k)_{i_k j_k}$ satisfies $x^{\ell^n} = x$ for some integer $n \geq 1$. Then $\mathfrak{D}$ is finite in weight zero.*

Proof. Let $\sigma, \mathrm{wt}, \mathfrak{a}$, $R = \mathcal{O}[[X_\sigma]]/\mathfrak{a}$ and r_u be as in Proposition 51.21. Write $P = \mathcal{O}[[X_s : s \in \sigma]]$, $P_w = \mathcal{O}[[X_\sigma]]_w$, $\mathfrak{m}_P$ its maximal ideal and $\pi\colon P \to R$ the quotient map. As the elements of $\mathfrak{a}$ have constant term 0, $R \in \mathrm{CNL}_\mathcal{O}$ with $\mathfrak{m}_R = \pi(\mathfrak{m}_P)$. Let R^0 be the $\mathcal{O}$-subalgebra of R generated by the products $r_\mathrm{u}(g_1)_{i_1 j_1} \cdots r_\mathrm{u}(g_k)_{i_k j_k}$ with $\sum_s \mathrm{wt}_4(i_s, j_s) = (0,0)$.

Step 1: reduction to R. Let r_A be a symplectic Eisenstein lift to $A \in \mathrm{CNL}_\mathcal{O}$. By (Uw2), $r_A = f \circ r_\mathrm{u}$ entrywise for an $\mathcal{O}$-algebra homomorphism f, so the products of weight $(0,0)$ of r_A are the images of those of r_u, and the subalgebra they generate is $f(R^0)$. It therefore suffices to show that R^0 is a finitely generated $\mathcal{O}$-module.

Step 2: the weight-zero projection. If $h \in \mathfrak{a}$ then $h_{(0)} \in \mathfrak{a}$, so $\mathrm{E}(\pi(h')) = \pi(h'_{(0)})$ is a well-defined $\mathcal{O}$-linear map $\mathrm{E}\colon R \to R$ with image $C = \pi(P_0)$. For $p \in P_0$ and $h' \in P$, $(ph')_{(0)} = p\, h'_{(0)}$; hence $\mathrm{E}(cy) = c\,\mathrm{E}(y)$ for $c \in C$, $y \in R$, and $\mathrm{E}(c) = c$. Consequently $\mathfrak{p}R \cap C = \mathfrak{p}$ for every ideal $\mathfrak{p}$ of C: if $\sum_i a_i y_i \in C$ with $a_i \in \mathfrak{p}$, it equals $\mathrm{E}(\sum_i a_i y_i) = \sum_i a_i \mathrm{E}(y_i) \in \mathfrak{p}$. A power series in $\mathfrak{m}_P^N$ has its coefficient of X^n in $\mathfrak{m}_\mathcal{O}^{\max(0, N - |n|)}$, and $h'_{(0)}$ keeps some of these coefficients, so $\mathrm{E}(\mathfrak{m}_R^N) \subseteq \mathfrak{m}_R^N$: E is continuous.

Step 3: C is a complete local Noetherian $\mathcal{O}$-algebra. By Gordan's lemma the monoid $\{n \in \mathbb{N}^\sigma : \sum_s n_s \mathrm{wt}(s) = (0,0)\}$ is generated by finitely many non-zero $n^{(1)}, \ldots, n^{(k)}$. The continuous homomorphism $\mathcal{O}[[Y_1, \ldots, Y_k]] \to P$, $Y_i \mapsto X^{n^{(i)}} \in \mathfrak{m}_P$, has image P_0: the image lies in the closed subring P_0, and for $h' = \sum_n c_n X^n \in P_0$, choosing $\alpha(n) \in \mathbb{N}^k$ with $\sum_i \alpha(n)_i n^{(i)} = n$ (an injective choice), $\sum_n c_n Y^{\alpha(n)}$ maps to h'. So $C = \pi(P_0)$ is a quotient of $\mathcal{O}[[Y_1, \ldots, Y_k]]$: complete, local, Noetherian, with residue field $\mathbb{F}_\mathcal{O}$ and $\mathfrak{m}_C = C \cap \mathfrak{m}_R$.

Step 4: $R^0 \subseteq C \subseteq \overline{R^0}$ (closure in R). By (Uw1), a product $r_\mathrm{u}(g_1)_{i_1 j_1} \cdots r_\mathrm{u}(g_k)_{i_k j_k}$ of total weight w is $\pi(h')$ with $h' \in P_w$; so it lies in C if $w = (0,0)$, and E maps it to itself if $w = (0,0)$ and to 0 otherwise. Hence $R^0 \subseteq C$, and E maps the $\mathcal{O}$-subalgebra R_2 generated by all entries of r_u into R^0. We show that R_2 is dense in R; then $C = \mathrm{E}(R) \subseteq \overline{\mathrm{E}(R_2)} \subseteq \overline{R^0}$ by continuity. Fix $N \geq 1$, let $Q = R/\mathfrak{m}_R^N$, a finite local ring in $\mathrm{CNL}_\mathcal{O}$, and $Q_0 \subseteq Q$ the image of R_2. An element of

Q_0 outside $\mathfrak{m}_Q$ is a unit of finite order of Q, so its inverse is a power of it; thus Q_0 is local with residue field $\mathbb{F}_{\mathcal{O}}$, and $Q \otimes_{Q_0} Q$ is a finite local ring with residue field $\mathbb{F}_{\mathcal{O}}$ (modulo the nilpotent ideal generated by $\mathfrak{m}_Q \otimes 1$ and $1 \otimes \mathfrak{m}_Q$ it is $\mathbb{F}_{\mathcal{O}} \otimes_{\mathbb{F}_{\mathcal{O}}} \mathbb{F}_{\mathcal{O}}$), so it lies in $\mathrm{CNL}_{\mathcal{O}}$. The two $\mathcal{O}$-algebra homomorphisms $R \to Q \otimes_{Q_0} Q$, $x \mapsto \bar{x} \otimes 1$ and $x \mapsto 1 \otimes \bar{x}$, agree on the entries of r_{u}, so they carry r_{u} to the same symplectic Eisenstein lift, and they are equal by the uniqueness in (Uw2). Let $Q_1 = Q/Q_0$ and $p \colon Q \to Q_1$ the projection; the map $Q \otimes_{Q_0} Q \to Q \otimes_{Q_0} Q_1$, $x \otimes y \mapsto x \otimes p(y)$, sends $\bar{x} \otimes 1$ to 0 and $1 \otimes \bar{x}$ to $1 \otimes p(\bar{x})$, so $Q \otimes_{Q_0} Q_1 = 0$. Then $\mathbb{F}_{\mathcal{O}} \otimes_{Q_0} Q_1 = (Q/\mathfrak{m}_Q) \otimes_Q (Q \otimes_{Q_0} Q_1) = 0$, and $Q_1 = 0$ by Nakayama's lemma. So $R_2 + \mathfrak{m}_R^N = R$ for every N.

Step 5: $C/\mathfrak{m}_{\mathcal{O}}C$ is Artinian. Suppose not. Then some minimal prime $\mathfrak{p}_0$ of $\mathfrak{m}_{\mathcal{O}}C$ has $\dim C/\mathfrak{p}_0 \geq 1$; applying Lemma 47.7 to the complete local domain $C/\mathfrak{p}_0$ and the image of an element of $\mathfrak{m}_C \setminus \mathfrak{p}_0$ gives a prime $\mathfrak{p} \supseteq \mathfrak{p}_0$ of C with $\dim C/\mathfrak{p} = 1$; choose $t \in \mathfrak{m}_C \setminus \mathfrak{p}$. By Step 2, $\mathfrak{p}R$ does not meet $C \setminus \mathfrak{p}$; an ideal $\mathfrak{Q}$ of R maximal among those containing $\mathfrak{p}R$ and disjoint from $C \setminus \mathfrak{p}$ is prime with $\mathfrak{Q} \cap C = \mathfrak{p}$. The ring $R/\mathfrak{Q}$ is a complete local Noetherian domain of characteristic ℓ ($\ell \in \mathfrak{m}_{\mathcal{O}}C \subseteq \mathfrak{p}$) in which t is a non-zero non-unit, so $\dim R/\mathfrak{Q} \geq 1$, and Lemma 47.7 gives a prime $\mathfrak{Q}' \supseteq \mathfrak{Q}$ with $t \notin \mathfrak{Q}'$ and $\dim R/\mathfrak{Q}' = 1$. Let $\tilde{A}$ be the normalisation of $R/\mathfrak{Q}'$, a complete discrete valuation ring of characteristic ℓ, finite over $R/\mathfrak{Q}'$, with finite residue field, and $\psi \colon R \to R/\mathfrak{Q}' \to \tilde{A}$. Then $\psi(\mathfrak{m}_R) \subseteq \mathfrak{m}_{\tilde{A}}$, $\psi(\mathfrak{m}_R^N) \subseteq \mathfrak{m}_{\tilde{A}}^N$, $\psi(\mathfrak{m}_{\mathcal{O}}) = 0$, and $\psi(t)$ is a non-zero element of $\mathfrak{m}_{\tilde{A}}$. *A test field.* Let K be an algebraic closure of $\mathrm{Frac}(\tilde{A})$ and V a valuation ring of K dominating $\tilde{A}$ (Chevalley). Then $V \cap \mathrm{Frac}(\tilde{A})$ is a valuation ring containing $\tilde{A}$ and not the whole field (a uniformiser lies in $\mathfrak{m}_V$), so it is $\tilde{A}$, and the inclusion $j \colon \tilde{A} \to V$ is injective and local. The algebraic closure $\bar{F}$ of $\mathbb{F}_{\mathcal{O}} = \psi(\mathcal{O})$ in K lies in V (its elements are roots of unity or 0). The residue field of $\overline{\mathbb{Z}}_\ell$ is an algebraic closure of $\mathbb{F}_{\mathcal{O}}$; choose an $\mathbb{F}_{\mathcal{O}}$-isomorphism from it onto $\bar{F}$ and let $a \colon \overline{\mathbb{Z}}_\ell \to \bar{F} \subseteq V$ be the composite with reduction; then $a(\mathfrak{m}_\ell) = 0$ and a restricts to ψ on $\mathcal{O}$. The residue field k_V of V is algebraically closed and algebraic over the finite residue field of $\tilde{A}$, so $\bar{F} \to k_V$ is onto: every element of V is congruent modulo $\mathfrak{m}_V$ to an element of $a(\overline{\mathbb{Z}}_\ell)$. So (K, V, a) is a test field of characteristic ℓ. *A point.* Put $r = j \circ \psi \circ r_{\mathrm{u}}$. The homomorphism $j \circ \psi \colon R \to V$ restricts to a on $\mathcal{O}$ and maps $\mathfrak{m}_R$ into $\mathfrak{m}_V$, and $(r, 1)$ satisfies (Ot1) with $(\Lambda, j) = (\tilde{A}, j)$: K is algebraic over $\tilde{A}$, the entries of r lie in $j(\tilde{A})$, and $g \mapsto \psi(r_{\mathrm{u}}(g)_{ab})$ is continuous because r_{u} is and $\psi(\mathfrak{m}_R^N) \subseteq \mathfrak{m}_{\tilde{A}}^N$. So r is a point of $\mathfrak{D}$ with values in V. *The contradiction.* Let $F' = \{y \in \tilde{A} : y^{\ell^n} = y \text{ for some } n \geq 1\}$. It is a subring ($y \mapsto y^{\ell^m}$ is a ring endomorphism in characteristic ℓ, and a common m serves for two elements), it contains $\psi(\mathcal{O}) = \mathbb{F}_{\mathcal{O}}$, and it injects into the residue field of $\tilde{A}$: if $y, y' \in F'$ have the same residue, $d = y - y' \in \mathfrak{m}_{\tilde{A}}$ satisfies $d = d^{\ell^{mk}} \in \mathfrak{m}_{\tilde{A}}^{\ell^{mk}}$ for all k, so $d = 0$. So F' is finite, hence closed in $\tilde{A}$, and its non-zero elements are units. By the hypothesis, applied to (K, V, a) and r, ψ maps every product of weight $(0, 0)$ of r_{u} into F', hence $\psi(R^0) \subseteq F'$, and by continuity $\psi(\overline{R^0}) \subseteq F'$. By Step 4, $t \in C \subseteq \overline{R^0}$, so $\psi(t) \in F'$ is a non-zero non-unit: a contradiction.

Step 6: conclusion. $C/\mathfrak{m}_{\mathcal{O}}C$ is an Artinian local ring with finite residue field, hence finite, and its maximal ideal is nilpotent, so the $\mathfrak{m}_C$-adic and $\mathfrak{m}_{\mathcal{O}}$-adic topologies on C coincide; C is complete and separated, so by Nakayama's lemma for complete modules C is a finitely generated $\mathcal{O}$-module. As $\mathcal{O}$ is Noetherian and $R^0 \subseteq C$, R^0 is a finitely generated $\mathcal{O}$-module; by Step 1, $\mathfrak{D}$ is finite in weight zero. □

Proposition 51.21. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$. There are a finite set σ, a map* $\mathrm{wt} \colon \sigma \to \mathbb{Z}^2$*, a homogeneous ideal $\mathfrak{a}$ of $\mathcal{O}[[X_s : s \in \sigma]]$ all of whose elements have constant term* 0*, and, with $R = \mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a}$ and R_w the image of $\mathcal{O}[[X_\sigma]]_w$, a symplectic Eisenstein lift r_{u} to R such that:*

(Uw1) *$r_{\mathrm{u}}(g)_{ij} \in R_{\mathrm{wt}_4(i,j)}$ for all $g \in G_{\mathbb{Q}}$ and $1 \leq i, j \leq 4$;*

(Uw2) *for every $A \in \mathrm{CNL}_{\mathcal{O}}$ and every symplectic Eisenstein lift r_A to A there is exactly one $\mathcal{O}$-algebra homomorphism $f\colon R \to A$ with $f(r_{\mathrm{u}}(g)_{ij}) = r_A(g)_{ij}$ for all g, i, j.*

Proof. Throughout, A denotes an object of $\mathrm{CNL}_{\mathcal{O}}$. We use that $\mathcal{O}$-algebra homomorphisms between objects of $\mathrm{CNL}_{\mathcal{O}}$ are morphisms, and that for a symplectic Eisenstein lift r to A and an $\mathcal{O}$-algebra homomorphism $f\colon A \to A'$ in $\mathrm{CNL}_{\mathcal{O}}$, $f \circ r$ is a symplectic Eisenstein lift (apply f to (Se1)–(Se3); in (Se4) replace y by $f \circ y$).

Step 1: the group of the problem and Mazur's ring. Let $N_T \subseteq G_{\mathbb{Q}}$ be the closed normal subgroup generated by the sets $I'_{\bar{w}} = \{g \in I_{\bar{w}} : \bar{r}_0(g) = 1\}$, $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above a prime not in T, and $\Gamma = G_{\mathbb{Q}}/N_T$; $\bar{r}_0$ factors through Γ. The kernel of a lift is a closed normal subgroup, so a lift satisfies (Se2) if and only if it factors through Γ, and lifts satisfying (Se2) are the same as continuous homomorphisms $\Gamma \to \mathrm{GL}_4(A)$ reducing to $\bar{r}_0$. Γ satisfies Φ_ℓ: let $\Gamma' \subseteq \Gamma$ be open with preimage $H \supseteq N_T$, open in $G_{\mathbb{Q}}$, and put $H_0 = H \cap \ker \bar{r}_0$, open and normal in H, with fixed field L, a number field. For a continuous $f\colon H \to \mathbb{F}_\ell$ vanishing on N_T, the restriction $f|_{H_0}$ vanishes on the inertia groups $I_{\bar{w}} \cap H_0 \subseteq I'_{\bar{w}}$ of $G_L = H_0$ at places above primes not in T, so it factors through G_{L,T_L}, T_L the places of L above $T \cup \{\infty\}$. Restriction to H_0 has kernel inside $\mathrm{Hom}(H/H_0, \mathbb{F}_\ell)$, finite, and image inside $\mathrm{Hom}_{\mathrm{cont}}(G_{L,T_L}, \mathbb{F}_\ell)$, finite by Theorem B.71, item 2; so $\mathrm{Hom}_{\mathrm{cont}}(\Gamma', \mathbb{F}_\ell)$ is finite. By Theorem B.71, item 1, the lifts of $\bar{r}_0$ satisfying (Se2) are represented by some $R^{\square} \in \mathrm{CNL}_{\mathcal{O}}$ with a lift $r^{\square}$, and for each $v \in T$ the lifts of $\bar{r}_0|_{D_v}$ are represented by some $(R_v^{\square}, r_v^{\square})$. For a lift r write c_r for its classifying morphism. Let $\psi_v = c_{r^{\square}|_{D_v}} : R_v^{\square} \to R^{\square}$.

Step 2: (Se4) is a closed condition. Fix $v \in T$, let (B_v, ρ_v, x_v) be as in Proposition 51.22 and $\varphi_v = c_{\rho_v}\colon R_v^{\square} \to B_v$. (2a) φ_v is surjective. Its image C is a quotient of $R_v^{\square}$, a complete Noetherian local ring with $\mathfrak{m}_{\mathcal{O}} \subseteq \mathfrak{m}_C$ and residue field $\mathbb{F}_{\mathcal{O}}$, containing the entries of ρ_v. Every $b \in B_v$ is $o + m$ with $o \in \mathcal{O}$, $m \in \mathfrak{m}_{B_v}$, and o is unique modulo $\mathfrak{m}_{\mathcal{O}}$; so every $\mathbb{F}_{\mathcal{O}}$-linear form λ on $V = \mathfrak{m}_{B_v}/(\mathfrak{m}_{B_v}^2 + \mathfrak{m}_C B_v)$ gives a well-defined map $D(o + m) = \lambda(m)$ with $D(bb') = \bar{b}D(b') + \bar{b}'D(b)$ and $D(C) = 0$. The two $\mathcal{O}$-algebra homomorphisms $B_v \to \mathbb{F}_{\mathcal{O}}[\epsilon]$ ($\epsilon^2 = 0$), $b \mapsto \bar{b}$ and $b \mapsto \bar{b} + \epsilon D(b)$, agree on the entries of ρ_v, hence are equal by (Uc1); so $\lambda = 0$, $V = 0$ and $\mathfrak{m}_{B_v} = \mathfrak{m}_{B_v}^2 + \mathfrak{m}_C B_v$. By Nakayama's lemma $B_v/\mathfrak{m}_C B_v = \mathbb{F}_{\mathcal{O}}$, and as B_v is separated for the $\mathfrak{m}_C$-adic topology ($\mathfrak{m}_C B_v \subseteq \mathfrak{m}_{B_v}$), Nakayama's lemma for complete modules over C gives $B_v = C \cdot 1 = C$. (2b) Let $\mathfrak{P}_v = \ker \varphi_v$. For a lift ρ of $\bar{r}_0|_{D_v}$ to A the following are equivalent: (i) $\rho = y \circ \rho_B$ for some (B, ρ_B, x, y) as in (Se4); (ii) $\rho = f \circ \rho_v$ for an $\mathcal{O}$-algebra homomorphism $f\colon B_v \to A$; (iii) $c_\rho(\mathfrak{P}_v) = 0$. (i)⇒(ii) is (Uc2); (ii)⇒(i) with (B_v, ρ_v, x_v, f); (ii)⇒(iii) since $c_\rho = f \circ \varphi_v$ by uniqueness of classifying morphisms; (iii)⇒(ii) since $c_\rho = f \circ \varphi_v$ for the homomorphism f induced on $R_v^{\square}/\mathfrak{P}_v \cong B_v$, and then $f \circ \rho_v = f \circ \varphi_v \circ r_v^{\square} = \rho$.

Step 3: the universal ring. Let $\mathfrak{a}^{\square} \subseteq R^{\square}$ be the ideal generated by the entries of ${}^t r^{\square}(g) J_4 r^{\square}(g) - \theta(g) J_4$ ($g \in G_{\mathbb{Q}}$, $r^{\square}$ viewed on $G_{\mathbb{Q}}$), the entries $r^{\square}(\phi)_{ij}$ with $\lambda_i \neq \lambda_j$, the entries $(1,3)$ and $(3,1)$ of $r^{\square}(g_0) + \theta(g_0) r^{\square}(g_0^{-1})$, and $\psi_v(\mathfrak{P}_v)$ for $v \in T$. For a lift r to A satisfying (Se2), c_r applied entrywise to $r^{\square}$ is r, and $c_r \circ \psi_v = c_{r|_{D_v}}$; so by Step 2, r is a symplectic Eisenstein lift if and only if $c_r(\mathfrak{a}^{\square}) = 0$. The representation r_0 is a symplectic Eisenstein lift to $\mathcal{O}$: on $I_{\bar{w}}$ above a prime $p \notin T$ ($p \neq \ell$) the characters χ_{cyc}, ω_ℓ are trivial and χ, ξ have order prime to ℓ (the ℓ-power part of χ is unramified at $p \notin S_\ell(\chi)$, and ξ has order prime to ℓ), so $\kappa_i(g)$ is a root of unity of order prime to ℓ, equal to 1 when it is 1 modulo $\mathfrak{m}_{\mathcal{O}}$: this is (Se2). (Se1) and (Se3) hold as r_0 is diagonal with similitude θ. For (Se4) take $B = \mathcal{O}$, $\rho_B = r_0|_{D_v}$, $x = y = \mathrm{id}$: at ℓ, $\rho_B(s_0)$ has characteristic polynomial $\prod_j (X - \kappa_j(s_0))$, Π_i is diagonal with only the entry (i,i) possibly non-zero, so $\Pi_j \rho_B(g) \Pi_i = 0$ for $i < j$ and $\Pi_i(\rho_B(s) - \kappa_i(s))\Pi_i = 0$; at $v \in T \setminus \{\ell\}$ and $g \in I_v$ with $\chi(g) = 1$, $\chi_{\mathrm{cyc}}(g) = \omega_\ell(g) = \xi(g) = 1$ (ξ is unramified at v by (Sg1)), so $r_0(g) = 1$. Hence c_{r_0} kills $\mathfrak{a}^{\square}$, $R = R^{\square}/\mathfrak{a}^{\square}$ is non-zero and lies in $\mathrm{CNL}_{\mathcal{O}}$, and the image r_{u} of $r^{\square}$ in R, viewed on $G_{\mathbb{Q}}$, is a symplectic Eisenstein lift. If r_A is a symplectic Eisenstein lift to

A, then c_{r_A} kills $\mathfrak{a}^\square$ and induces $f\colon R \to A$ with $f \circ r_{\mathrm{u}} = r_A$; if f' is another, then $f \circ q$ and $f' \circ q$ ($q\colon R^\square \to R$) classify the same lift, so $f = f'$. This is the universality (Uw2) for (R, r_{u}); let $\beta\colon R \to \mathcal{O}$ be the homomorphism with $\beta \circ r_{\mathrm{u}} = r_0$.

Step 4: torus stability. Let r be a symplectic Eisenstein lift to A, $t_1, t_2 \in 1 + \mathfrak{m}_A$, $X = \mathrm{T}_4(t_1, t_2)$ and $r^t(g) = Xr(g)X^{-1}$. Then r^t is a lift ($X \equiv 1$), and a symplectic Eisenstein lift. X has similitude $t_1 t_2$, and if X has similitude $\nu \in A^\times$ and Y similitude θ', then ${}^tX^{-1}J_4X^{-1} = \nu^{-1}J_4$ and ${}^t(XYX^{-1})J_4(XYX^{-1}) = \nu\theta'\,{}^tX^{-1}J_4X^{-1} = \theta' J_4$: this gives (Se1). (Se2) is clear, and (Se3) holds because the entry (i,j) of XYX^{-1} is $t_1^{\lambda_i-\lambda_j}t_2^{\mu_i-\mu_j}Y_{ij}$ and $h(r^t) = Xh(r)X^{-1}$. For (Se4) at v, let (B, ρ_B, x, y) be as there for r, $B' = B[[u_1, u_2]]$ (a domain in $\mathrm{CNL}_{\mathcal{O}}$), $X' = \mathrm{T}_4(1+u_1, 1+u_2)$ and $\rho_{B'} = X'\rho_B X'^{-1}$, a lift of $\bar{r}_0|_{D_v}$. It satisfies the local condition at v: the similitude is preserved as above; for $v = \ell$, $\rho_{B'}(s_0)$ has the characteristic polynomial of $\rho_B(s_0)$, its Π_i are $X'\Pi_i X'^{-1}$, and the ordinary identities are conjugated by X'; for $v \neq \ell$, $\rho_B(g) = 1$ implies $\rho_{B'}(g) = 1$. With $x'\colon B' \to \mathcal{O}$ extending x by $u_i \mapsto 0$ and $y'\colon B' \to A$ extending y by $u_i \mapsto t_i - 1 \in \mathfrak{m}_A$, $x' \circ \rho_{B'} = x \circ \rho_B = r_0|_{D_v}$ and $y' \circ \rho_{B'} = X(y \circ \rho_B)X^{-1} = r^t|_{D_v}$. Applying this to the lift r_{u} composed with $R \to R[[T]]$ and $(t_1, t_2) = (1+T, 1)$, respectively $(1, 1+T)$, and (Uw2) for $R[[T]] \in \mathrm{CNL}_{\mathcal{O}}$, gives morphisms $\varrho_1, \varrho_2\colon R \to R[[T]]$ with

$$\varrho_1\big(r_{\mathrm{u}}(g)_{ij}\big) = (1+T)^{\lambda_i-\lambda_j} r_{\mathrm{u}}(g)_{ij}, \qquad \varrho_2\big(r_{\mathrm{u}}(g)_{ij}\big) = (1+T)^{\mu_i-\mu_j} r_{\mathrm{u}}(g)_{ij}. \tag{51.6}$$

Step 5: the presentation. Let $\Sigma_0 = G_{\mathbb{Q}} \times \{1, \dots, 4\}^2$ and, for $s = (g, i, j)$, $x_s = r_{\mathrm{u}}(g)_{ij} - r_0(g)_{ij} \in \mathfrak{m}_R$, $w_\lambda(s) = \lambda_i - \lambda_j$, $w_\mu(s) = \mu_i - \mu_j$. As $r_0(g)_{ij} = 0$ for $i \neq j$ and ϱ_1, ϱ_2 fix $\mathcal{O}$, (51.6) holds with x_s in place of $r_{\mathrm{u}}(g)_{ij}$. Apply Lemma 43.8 to R, $(x_s)_{s\in\Sigma_0}$, w_λ (values in $\{-1, 0, 1\}$) and ϱ_1: (Tc1) holds because morphisms f, f' agreeing on all x_s satisfy $f \circ r_{\mathrm{u}} = f' \circ r_{\mathrm{u}}$, so $f = f'$ by (Uw2); (Tc2) is (51.6). By (Tp1) there is a finite $\sigma \subseteq \Sigma_0$ such that the continuous $\mathcal{O}$-algebra homomorphism $\pi\colon P = \mathcal{O}[[X_s : s \in \sigma]] \to R$ with $\pi(X_s) = x_s$ is surjective. Then Lemma 43.10 applies to π twice: with $\rho = \varrho_1$ and the $\mathbb{Z}$-weights $w_\lambda|_\sigma$, and with $\rho = \varrho_2$ and $w_\mu|_\sigma$. Write $f^\lambda_{(a)}$, $f^\mu_{(b)}$ for the weight components for these $\mathbb{Z}$-weights and P^λ_a, P^μ_b for the corresponding sets. Put $\mathrm{wt}(s) = \mathrm{wt}_4(i,j) = (w_\lambda(s), w_\mu(s))$ and $\mathfrak{a} = \ker\pi$. A monomial has $\mathbb{Z}^2$-weight (a,b) if and only if it has λ-weight a and μ-weight b, so $f_{((a,b))} = (f^\lambda_{(a)})^\mu_{(b)}$. *$\mathfrak{a}$ is homogeneous*: for $f \in \mathfrak{a}$, $f^\lambda_{(a)} \in \mathfrak{a}$ by item 1 for ϱ_1, and then $(f^\lambda_{(a)})^\mu_{(b)} \in \mathfrak{a}$ by item 1 for ϱ_2. *Constant terms vanish*: $\beta \circ \pi$ is a continuous $\mathcal{O}$-algebra homomorphism $P \to \mathcal{O}$ with $\beta(x_s) = 0$, i.e. the constant term map, so $f(0) = \beta(\pi(f)) = 0$ for $f \in \mathfrak{a}$. *(Uw1)*: fix g, i, j, $y = r_{\mathrm{u}}(g)_{ij}$ and $(a,b) = \mathrm{wt}_4(i,j)$. By (51.6) and item 2 for both tori, $y = \pi(h) = \pi(h')$ with $h \in P^\lambda_a$, $h' \in P^\mu_b$. Then $h - h' \in \mathfrak{a}$, so by homogeneity $(h-h')^\lambda_{(a)} = h - h'_{((a,b))}$ and $(h-h')_{((a,b))} = h_{((a,b))} - h'_{((a,b))}$ lie in $\mathfrak{a}$ (note $(h')^\lambda_{(a)} = h'_{((a,b))}$ as $h' \in P^\mu_b$); subtracting, $h - h_{((a,b))} \in \mathfrak{a}$, and $y = \pi(h_{((a,b))})$ lies in the image of $\mathcal{O}[[X_\sigma]]_{(a,b)}$. Transporting r_{u} through the isomorphism $\mathcal{O}[[X_s : s \in \sigma]]/\mathfrak{a} \cong R$ induced by π gives the finite set σ, the map wt, the homogeneous ideal $\mathfrak{a}$ with constant terms 0 and the symplectic Eisenstein lift satisfying (Uw1) and (Uw2). □

Proposition 51.22. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ and set T, and let $v \in T$. There are a domain $B_v \in \mathrm{CNL}_{\mathcal{O}}$, a lift ρ_v of $\bar{r}_0|_{D_v}$ to B_v satisfying the local condition at v, and an $\mathcal{O}$-algebra homomorphism $x_v\colon B_v \to \mathcal{O}$ with $x_v \circ \rho_v = r_0|_{D_v}$, such that:*

(Uc1) *for every $A \in \mathrm{CNL}_{\mathcal{O}}$, any two $\mathcal{O}$-algebra homomorphisms $f, f'\colon B_v \to A$ with $f \circ \rho_v = f' \circ \rho_v$ are equal;*

(Uc2) *for every $A \in \mathrm{CNL}_{\mathcal{O}}$, every domain $B \in \mathrm{CNL}_{\mathcal{O}}$, every lift ρ_B of $\bar{r}_0|_{D_v}$ to B satisfying the local condition at v, and all $\mathcal{O}$-algebra homomorphisms $x\colon B \to \mathcal{O}$ and $y\colon B \to A$ with $x \circ \rho_B = r_0|_{D_v}$, there is an $\mathcal{O}$-algebra homomorphism $f\colon B_v \to A$ with $f \circ \rho_v = y \circ \rho_B$.*

Proof. Step 1: the universal ring of the local condition. $r_0|_{D_v}$ satisfies the local condition at v: $r_0(g)$ has similitude $\theta(g)$; for $v = \ell$, r_0 is diagonal, so its characteristic polynomial at s_0 is $\prod_j(X - \kappa_j(s_0))$, each Π_i is diagonal and supported on the entry (i,i), and the identities of the ordinary condition hold; for $v \neq \ell$, on I_v the characters χ_{cyc}, ω_ℓ and ξ (Sg1) are trivial, so $\kappa_1 = \kappa_2 = \chi$ and $\kappa_3 = \kappa_4 = 1$ there, and $r_0(g) = 1$ for $g \in I_v$ with $\chi(g) = 1$. Let $(R_v^\square, \rho_v^\square)$ be Mazur's universal lift of $\bar{r}_0|_{D_v}$ and $\mathfrak{I} \subseteq R_v^\square$ the ideal generated by the entries of ${}^t\rho_v^\square(g)J_4\rho_v^\square(g) - \theta(g)J_4$ ($g \in D_v$) and, for $v = \ell$, by the coefficients of the characteristic polynomial of $\rho_v^\square(s_0)$ minus those of $\prod_j(X - \kappa_j(s_0))$ and the entries of $\Pi_j\rho_v^\square(g)\Pi_i$ ($i < j$) and of $\Pi_i(\rho_v^\square(s) - \kappa_i(s))\Pi_i$ ($s \in I_\ell$), for $v \neq \ell$ by the entries of $\rho_v^\square(g) - 1$ ($g \in I_v$, $\chi(g) = 1$). Then $R_v = R_v^\square/\mathfrak{I} \in \mathrm{CNL}_\mathcal{O}$ with the image ρ_v of $\rho_v^\square$ is universal: for every $A \in \mathrm{CNL}_\mathcal{O}$ and every lift ρ of $\bar{r}_0|_{D_v}$ to A satisfying the local condition at v there is exactly one $\mathcal{O}$-algebra homomorphism $f\colon R_v \to A$ with $f \circ \rho_v = \rho$ (the morphism $R_v^\square \to A$ classifying ρ kills $\mathfrak{I}$, and $\mathcal{O}$-algebra homomorphisms are morphisms). Let $x_v\colon R_v \to \mathcal{O}$ classify $r_0|_{D_v}$ and $\mathfrak{q}_v = \ker x_v$.

Step 2: the component. By (Yc5) of Proposition 45.6 if $v = \ell$, and of Proposition 45.16 if $v \neq \ell$, applied to (R_v, ρ_v, x_v), R_v has exactly one minimal prime ideal $\mathfrak{P}$ contained in $\mathfrak{q}_v$. Put $B_v = R_v/\mathfrak{P}$, a domain in $\mathrm{CNL}_\mathcal{O}$, and let $\bar{\rho}_v$ be the image of ρ_v, a lift of $\bar{r}_0|_{D_v}$ to B_v satisfying the local condition at v (its identities are images of those of ρ_v). As $\mathfrak{P} \subseteq \mathfrak{q}_v$, x_v induces $\bar{x}_v\colon B_v \to \mathcal{O}$ with $\bar{x}_v \circ \bar{\rho}_v = r_0|_{D_v}$.

Step 3: (Uc1). If $f, f'\colon B_v \to A$ satisfy $f \circ \bar{\rho}_v = f' \circ \bar{\rho}_v$, their composites with $R_v \to B_v$ classify the same lift $f \circ \bar{\rho}_v$ (continuous, f being local), so they are equal by universality; $R_v \to B_v$ is onto, so $f = f'$.

Step 4: (Uc2). Let B, ρ_B, x, y be as in (Uc2), and $\gamma\colon R_v \to B$ the homomorphism with $\gamma \circ \rho_v = \rho_B$. Then $x \circ \gamma$ classifies $x \circ \rho_B = r_0|_{D_v}$, so $x \circ \gamma = x_v$, and $\ker\gamma \subseteq \mathfrak{q}_v$. As B is a domain, $\ker\gamma$ is prime; it contains a minimal prime of R_v, which is contained in $\mathfrak{q}_v$ and so equals $\mathfrak{P}$. Hence γ factors as $\bar{\gamma} \circ (R_v \to B_v)$, and $f = y \circ \bar{\gamma}$ satisfies $f \circ \bar{\rho}_v = y \circ \rho_B$.

So $(B_v, \bar{\rho}_v, \bar{x}_v)$ has the required properties. □

Proposition 51.23. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, (K, V, a) a test field and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that every $r(g)$ is block diagonal and the K-span of the matrices $(r(g)_{ab})_{a,b\in\{1,3\}}$, $g \in G_\mathbb{Q}$, is $\mathrm{M}_2(K)$. Then there is an ordinary test representation (r', u') of $\mathfrak{D}$ with values in V such that r' is a non-split block extension and $r'(g)$ and $r(g)$ have the same characteristic polynomial for every $g \in G_\mathbb{Q}$.*

Proof. Let (Λ, j) be as in (Ot1) for (r, u) and identify Λ with $j(\Lambda) \subseteq V$, with fraction field $E \subseteq K$. The entries of u and of all $r(g)$ lie in Λ, and $\det u \in \Lambda \cap V^\times = \Lambda^\times$ (j is local), so $u \in \mathrm{GL}_4(\Lambda)$. As $a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$, $\ell \in \mathfrak{m}_\Lambda$. Write $\nu(g) = a(\theta(g))$.

Step 1: the module $\mathsf{T} = \mathfrak{u}(\Lambda)$. (1a) Products: $\mathfrak{h}(R)\mathfrak{h}(R) = 0$, and $XYX' \in \mathfrak{h}(R)$ for X, X' block diagonal and $Y \in \mathfrak{h}(R)$. Since $\langle Yx, x'\rangle + \langle x, Yx'\rangle = 0$ characterises $\mathfrak{sp}_4$ and $\langle Xx, Xx'\rangle = \nu\langle x, x'\rangle$ for X of similitude ν, $XYX^{-1} \in \mathfrak{sp}_4$ for $Y \in \mathfrak{sp}_4$. Hence $\rho(g)Y = r(g)Yr(g)^{-1}$ defines an action of $G_\mathbb{Q}$ on T. The condition $Y \in \mathfrak{sp}_4$ means that J_4Y is symmetric; for $Y \in \mathfrak{h}(R)$, $J_4Y = Y_{41}E_{11} + Y_{43}E_{13} - Y_{21}E_{31} - Y_{23}E_{33}$, so $\mathfrak{u}(R) = \{Y \in \mathfrak{h}(R) : Y_{43} = -Y_{21}\}$, and T is free with basis $E_{41}, E_{23}, E_{21} - E_{43}$. For $Y \in \mathfrak{u}(R)$, $1 + Y$ has similitude 1: ${}^t(1+Y)J_4(1+Y) = J_4 + {}^tYJ_4Y$ and ${}^tYJ_4 = -J_4Y$, $Y^2 = 0$. By (Ot1), $g \mapsto \rho(g)Y$ modulo $\mathfrak{m}_\Lambda^n\mathsf{T}$ is locally constant. (1b) Complex conjugation. By (Sg1), $\Psi(c) = 1$ and $\xi(c) = -1$; $\chi_{\mathrm{cyc}}(c) = -1$ and $\omega_\ell(c) = -1$ ($\omega_\ell(c)^2 = 1$ and $\omega_\ell(c) \equiv \chi_{\mathrm{cyc}}(c)$ modulo ℓ, ℓ odd); so $\alpha(c) = -1$, $\theta(c) = -1$ and $r(c) \equiv \mathrm{diag}(-1, 1, -1, 1)$ modulo $\mathfrak{m}_V$ by (Ot2). The map $X\colon Y \mapsto r(c)Yr(c)^{-1}$ on the free Λ-module $\mathfrak{h}(\Lambda)$ satisfies $X^2 = 1$ and $X \equiv -1$ modulo $\mathfrak{m}_\Lambda$. As $2 \in \Lambda^\times$, $e = (X + 1)/2$ is an idempotent with image in $\mathfrak{m}_\Lambda\mathfrak{h}(\Lambda)$, so $e = e^n$ has image in $\mathfrak{m}_\Lambda^n\mathfrak{h}(\Lambda)$ for all n and $e = 0$. Hence $r(c)Yr(c)^{-1} = -Y$ for all $Y \in \mathfrak{h}(\Lambda)$, hence for all $Y \in \mathfrak{h}(K)$ by linearity; in particular $\rho(c) = -1$ on T. (1c) The element σ_ℓ. By

(Ot2) and since $r(\sigma_\ell)$ has entries in Λ, $\rho(\sigma_\ell)$ is, modulo $\mathfrak{m}_\Lambda$, diagonal on the basis of (1a) with entries $\bar\kappa_4/\bar\kappa_1$, $\bar\kappa_2/\bar\kappa_3$, $\bar\kappa_2/\bar\kappa_1 = \bar\kappa_4/\bar\kappa_3$ at σ_ℓ, all $\neq 1$ by (Ae1). So $\det(\rho(\sigma_\ell)-1) \in \Lambda^\times$ and $Y \mapsto \rho(\sigma_\ell)Y - Y$ is bijective on T; and $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$ by (Sg2). (1d) The submodule $\mathsf{P} = \{Y \in \mathsf{T} : u^{-1}Yu \text{ is strictly upper triangular}\}$ is saturated and $\rho(D_\ell)$-stable (by (Ot4), $u^{-1}r(h)u$ is upper triangular for $h \in D_\ell$). It is non-zero: let $F_n = \langle ue_1, \dots, ue_n\rangle_E$. The blocks of $r(\sigma_\ell)$ have characteristic polynomials $p_{\mathrm{A}}, p_{\mathrm{B}}$ over Λ whose roots reduce to $\bar\kappa_1(\sigma_\ell), \bar\kappa_3(\sigma_\ell)$ and to $\bar\kappa_2(\sigma_\ell), \bar\kappa_4(\sigma_\ell)$, distinct across the blocks by (Ae1); so they are coprime over E, and by the Cayley–Hamilton theorem $E_{\mathrm{A}} = q(r(\sigma_\ell))$ for a polynomial q over E. As $u^{-1}r(\sigma_\ell)u$ is upper triangular, $E_{\mathrm{A}}F_n \subseteq F_n$ and $F_n = (F_n \cap V_{\mathrm{A}}) \oplus (F_n \cap V_{\mathrm{B}})$; the line F_n/F_{n-1} comes from V_{A} or from V_{B}, and $r(\sigma_\ell)$ acts on it by $d_n(\sigma_\ell) \equiv \kappa_n(\sigma_\ell)$, a root of p_{A} or p_{B} respectively. By (Ae1) it comes from V_{A} for $n = 1, 3$ and from V_{B} for $n = 2, 4$. So $F_1 \subseteq V_{\mathrm{A}}$, $F_2 = F_1 \oplus L_2$ with $L_2 = F_2 \cap V_{\mathrm{B}}$ a line, and $F_3 = V_{\mathrm{A}} \oplus L_2$ (over E). Choose $x_0 \in V_{\mathrm{A}} \setminus F_1$ and $0 \neq b_0 \in L_2$, and let $Y_0 \in \mathrm{M}_4(E)$ kill V_{B} and F_1 and send x_0 to b_0. Then $Y_0 \in \mathfrak{h}(E)$, $Y_0 \neq 0$, and $Y_0F_1 = Y_0F_2 = 0$, $Y_0F_3 \subseteq L_2 \subseteq F_2$, $Y_0F_4 \subseteq F_2$: $u^{-1}Y_0u$ is strictly upper triangular. As u has similitude 1, $\langle ue_a, ue_b\rangle = (J_4)_{ab}$, so $F_2 \perp F_1$; the form $\beta(x,x') = \langle Y_0x, x'\rangle$ on V_{A} vanishes if $x \in F_1$ or $x' \in F_1$ ($Y_0x \in L_2 \subseteq F_2$), so it is a multiple of $(x,x') \mapsto \lambda(x)\lambda(x')$ for a linear form λ with kernel F_1, hence symmetric; with $\langle V_{\mathrm{B}}, V_{\mathrm{B}}\rangle = 0$ this gives $\langle Y_0x, x'\rangle + \langle x, Y_0x'\rangle = 0$ for all x, x', i.e. $Y_0 \in \mathfrak{u}(E)$. A non-zero multiple of Y_0 by an element of Λ lies in $\mathsf{P} \setminus \{0\}$. (1e) Let $N = \ker r \subseteq \ker \rho$. For a place of $\overline{\mathbb{Q}}$ above a prime $p \notin S$, the characters θ, Ψ, α are unramified at p (χ is a character modulo the integer of the datum, whose prime factors lie in S, ξ is unramified outside S by (Sg1), and $\chi_{\mathrm{cyc}}, \omega_\ell$ are unramified away from ℓ), so $\bar r_0$ is trivial on its inertia group, and r is trivial there by (Ot3), as $p \notin T$.

Step 2: a cocycle. By Step 1, Proposition 51.24 applies to ℓ, S, c, D_ℓ, $s = \sigma_\ell$, Λ, T, ρ, P and N ($\ell \in S$ by (Sg1), ℓ odd), giving $z_0 \neq 0$ and y_0. Let ϖ be a uniformiser of Λ, $z = \varpi z_0$ and $y = \varpi y_0$. Then $z \neq 0$, $z(g) \in \mathfrak{u}(\Lambda)$ has entries in $\mathfrak{m}_\Lambda$, $z(gh) = z(g) + r(g)z(h)r(g)^{-1}$, $z(c) = 0$, $z(g) = 0$ for $g \in \ker r$ in the inertia group of a place not above ℓ, $g \mapsto z(g)$ is continuous for the $\mathfrak{m}_\Lambda$-adic topology, and $w(h) = z(h) - (r(h)yr(h)^{-1} - y) \in \mathsf{P}$ for $h \in D_\ell$ (P is a submodule).

Step 3: the ordinary test representation (r', u'). Put $r'(g) = (1+z(g))r(g)$ and $u' = (1-y)u$. By the cocycle relation and $\mathfrak{h}\mathfrak{h} = 0$, $r'(g)r'(h) = (1 + z(g) + r(g)z(h)r(g)^{-1})r(gh) = r'(gh)$, so r' is a homomorphism to $\mathrm{GL}_4(V)$. (Ot1): the entries of $r'(g)$ and u' lie in Λ and are continuous in g. (Ot2): $r'(g) - a(r_0(g)) = (r(g) - a(r_0(g))) + z(g)r(g)$ has entries in $\mathfrak{m}_V$, and $1 + z(g)$ has similitude 1 (1a), so $r'(g)$ has similitude $\nu(g)$. (Ot3): both clauses concern g in an inertia group of a place not above ℓ with $r(g) = 1$; then $z(g) = 0$ and $r'(g) = 1$. (Ot4): $1 - y$ has similitude 1, so u' does. For $h \in D_\ell$, using $y^2 = yz(h) = 0$ and $(y + z(h))r(h)y = 0$ (1a),

$$(1+y)(1+z(h))r(h)(1-y) = \big(1 + w(h)\big)r(h), \qquad u'^{-1}r'(h)u' = \big(1 + u^{-1}w(h)u\big)\big(u^{-1}r(h)u\big),$$

with $(1-y)^{-1} = 1+y$. As $u^{-1}w(h)u$ is strictly upper triangular and $u^{-1}r(h)u$ upper triangular, $u'^{-1}r'(h)u'$ is upper triangular with the same diagonal entries as $u^{-1}r(h)u$, so (Ot4) holds for (r', u').

Step 4: r' is a non-split block extension with the characteristic polynomials of r. The rows of $z(g)$ indexed by A vanish and $z(g)r(g)$ has non-zero entries only in rows B and columns A; so $r'(g)$ agrees with $r(g)$ except in the entries (i,j), $i \in \mathrm{B}$, $j \in \mathrm{A}$. (i) Hence $r'(g)_{ij} = 0$ for $i \in \mathrm{A}$, $j \in \mathrm{B}$; and $r'(g)$ is block lower triangular with the diagonal blocks of $r(g)$, so $\det(x - r'(g)) = \det(x - r(g))$. (ii) Write $X_{\mathrm{A}}(g) = (r(g)_{ab})_{a,b\in\mathrm{A}}$, $X_{\mathrm{B}}(g) = (r(g)_{ab})_{a,b\in\mathrm{B}}$. The pairing of V_{A} with V_{B} has matrix $P_0 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, and the similitude relation for the block diagonal $r(g)$ gives ${}^tX_{\mathrm{A}}P_0X_{\mathrm{B}} = \nu P_0$, so $X_{\mathrm{B}} = \nu P_0^{-1}\,{}^tX_{\mathrm{A}}^{-1}P_0 = \nu \det(X_{\mathrm{A}})^{-1}X_{\mathrm{A}}$, since $P_0^{-1}\,{}^tMP_0$ is the adjugate of a 2×2 matrix M. So the K-span of the $X_{\mathrm{B}}(g)$, which are the $\{2,4\}$-blocks of

$r'(g)$, equals the K-span of the $X_{\mathrm{A}}(g)$, which is $\mathrm{M}_2(K)$ by hypothesis. (iii) Suppose $Y \in \mathfrak{h}(K)$ and $(1-Y)r'(g)(1+Y)$ is block diagonal for all g. Using $\mathfrak{h}\mathfrak{h} = 0$ and $r(g)Y \in \mathfrak{h}(K)$,

$$(1-Y)(1+z(g))r(g)(1+Y) = r(g) + \bigl(z(g) - Y + r(g)Yr(g)^{-1}\bigr)r(g),$$

whose entries outside the diagonal blocks are those of the second term; so $z(g) = Y - r(g)Yr(g)^{-1}$ for all g. At $g = c$, $0 = z(c) = Y + Y$ by (1b), so $Y = 0$ and $z = 0$, a contradiction. Hence r' is a non-split block extension, (r', u') is an ordinary test representation of $\mathfrak{D}$ with values in V, and $r'(g)$, $r(g)$ have the same characteristic polynomial for every g. □

Proposition 51.24. *Let ℓ be an odd prime, S a finite set of primes with $\ell \in S$, $c \in G_{\mathbb{Q}}$ a complex conjugation, $D_\ell \supseteq I_\ell$ the decomposition and inertia groups of a place of $\overline{\mathbb{Q}}$ above ℓ, and $s \in D_\ell$ with $\chi_{\mathrm{cyc}}(s) = 1$. Let Λ be a complete discrete valuation ring with finite residue field and $\ell \in \mathfrak{m}_\Lambda$, T a free Λ-module of finite rank, and $\rho\colon G_{\mathbb{Q}} \to \mathrm{Aut}_\Lambda(\mathsf{T})$ a homomorphism such that $g \mapsto \rho(g)x$ modulo $\mathfrak{m}_\Lambda^n\mathsf{T}$ is locally constant for all $n \geq 1$ and $x \in \mathsf{T}$. Let $\mathsf{P} \subseteq \mathsf{T}$ be a non-zero Λ-submodule, stable under $\rho(D_\ell)$ and saturated ($ax \in \mathsf{P}$ with $0 \neq a \in \Lambda$ implies $x \in \mathsf{P}$), and let $N \subseteq \ker\rho$ be a subgroup containing the inertia group of every place of $\overline{\mathbb{Q}}$ above a prime not in S. Assume that $x \mapsto \rho(s)x - x$ is bijective on T and that $\rho(c)x = -x$ for all $x \in \mathsf{T}$. Then there are a map $z\colon G_{\mathbb{Q}} \to \mathsf{T}$, not identically zero, and $y \in \mathsf{T}$ such that:*

1. *$g \mapsto z(g)$ modulo $\mathfrak{m}_\Lambda^n\mathsf{T}$ is locally constant for every $n \geq 1$, and $z(gh) = z(g) + \rho(g)z(h)$ for all $g, h \in G_{\mathbb{Q}}$;*
2. *$z(c) = 0$;*
3. *$z(g) = 0$ for every $g \in N$ that lies in the inertia group of a place of $\overline{\mathbb{Q}}$ not above ℓ;*
4. *$z(h) - (\rho(h)y - y) \in \mathsf{P}$ for every $h \in D_\ell$.*

Proof. Let ϖ be a uniformiser and E the fraction field of Λ, $q = \#\Lambda/\mathfrak{m}_\Lambda$, and $\varphi = \rho(s) - 1\colon \mathsf{T} \to \mathsf{T}$, bijective by hypothesis. Put $S_\infty = S \cup \{\infty\}$, $G_S = G_{\mathbb{Q},S_\infty}$, and let H_S be the kernel of $G_{\mathbb{Q}} \to G_S$; it contains the inertia group of every place of $\overline{\mathbb{Q}}$ above a prime not in S. For every prime $p \in S \setminus \{\ell\}$ fix a place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p with decomposition and inertia groups $D_p \supseteq I_p$; through the places, D_p and D_ℓ are decomposition groups in the sense of Theorem B.29 and Theorem B.37, and we write $H^i(D_p, \cdot)$. For $n \geq 1$ put $\mathsf{T}_n = \mathsf{T}/\varpi^n\mathsf{T}$, let P_n be the image of P in T_n, and let $G_{\mathbb{Q}}$ act on T_n through ρ.

Step 0: the modules. (0a) T/P is torsion-free by saturation, hence free; P is free of some rank $d \geq 1$; and $\mathsf{P} \cap \varpi^k\mathsf{T} = \varpi^k\mathsf{P}$ for $k \geq 0$ by saturation. Hence $\mathsf{P}_n \cong \mathsf{P}/\varpi^n\mathsf{P}$ has $q^{nd} \geq 2^n$ elements, $\mathsf{T}_n/\mathsf{P}_n \cong (\mathsf{T}/\mathsf{P})/\varpi^n(\mathsf{T}/\mathsf{P})$, and $\bigcap_n(\mathsf{P} + \varpi^n\mathsf{T}) = \mathsf{P}$, as $\bigcap_n \varpi^n(\mathsf{T}/\mathsf{P}) = 0$. (0b) $\varphi(\mathsf{P}) = \mathsf{P}$ and φ induces a bijection of T/P. Indeed $\varphi(\mathsf{P}) \subseteq \mathsf{P}$ since $s \in D_\ell$; $\varphi \otimes E$ is injective on the finite-dimensional space $\mathsf{P} \otimes E$, hence bijective; for $p \in \mathsf{P}$ the element $x = \varphi^{-1}(p) \in \mathsf{T}$ lies in $\mathsf{P} \otimes E$, so $ax \in \mathsf{P}$ for some $0 \neq a \in \Lambda$, and $x \in \mathsf{P}$ by saturation. So φ maps P onto P; the induced map on T/P is onto, and injective: if $\varphi(x) \in \mathsf{P}$ then $\varphi(x) = \varphi(p)$ with $p \in \mathsf{P}$, and $x = p$. Consequently φ induces bijections of T_n and of $\mathsf{T}_n/\mathsf{P}_n$ for every n. (0c) Fix $n \geq 1$ and put $M = \mathsf{T}_n$. As $\ell \in \mathfrak{m}_\Lambda = \varpi\Lambda$, M is a finite $\mathbb{Z}/\ell^n\mathbb{Z}$-module. The kernel of the action of $G_{\mathbb{Q}}$ on M is the intersection of the finitely many sets $\{g : \rho(g)x \equiv x \bmod \varpi^n\mathsf{T}\}$, x running through representatives of M, which are open by the local constancy hypothesis; so the action is continuous. This kernel is a closed normal subgroup containing $\ker\rho \supseteq N$, hence the inertia groups above primes not in S, hence H_S: M is a continuous G_S-module. Since φ is bijective on M and on M/P_n, we have $H^0(G_S, M) = H^0(D_\ell, M) = H^0(D_\ell, M/\mathsf{P}_n) = 0$. Every complex conjugation is $c' = \tau c \tau^{-1}$ with $\tau \in G_{\mathbb{Q}}$, so $\rho(c') = -1$, and $x = \rho(c')x$ gives $2x = 0$, $x = 0$

(ℓ odd): $M^{c'=1}=0$. Finally $H^0(G_S,M^\vee)=0$: s acts trivially on μ_{ℓ^n} as $\chi_{\mathrm{cyc}}(s)=1$, so an s-invariant $f\in M^\vee$ satisfies $f(\rho(s)^{-1}x)=f(x)$ for all x, i.e. f vanishes on the image of $\rho(s)^{-1}-1=-\rho(s)^{-1}\varphi$, which is M.

Step 1: normalised Selmer cocycles. For $n\geq 1$ let Σ_n be the set of maps $\zeta\colon G_{\mathbb{Q}}\to \mathsf{T}_n$ such that

- ζ is locally constant, $\zeta(gh)=\zeta(g)+\rho(g)\zeta(h)$ for all g,h, and $\zeta(H_S)=0$;
- $\zeta(c)=0$;
- $\zeta(g)=0$ for every prime $p\in S\setminus\{\ell\}$ and every $g\in I_p$ with $\rho(g)=1$;
- there is $y\in\mathsf{T}_n$ with $\zeta(h)-(\rho(h)y-y)\in\mathsf{P}_n$ for every $h\in D_\ell$.

All four conditions are Λ-linear, so Σ_n is a Λ-module, and reduction modulo ϖ^n maps Σ_{n+1} into Σ_n (P_{n+1} maps onto P_n). A cocycle vanishing on the normal subgroup H_S, which acts trivially, satisfies $\zeta(gh)=\zeta(g)$ for $h\in H_S$, so it is inflated from a continuous cocycle of G_S; hence Σ_n injects into $Z^1(G_S,\mathsf{T}_n)$, which is finite because $H^1(G_S,\mathsf{T}_n)$ is finite (Theorem B.37, item 1) and the coboundaries are an image of T_n. So Σ_n is finite.

Step 2: $\#\Sigma_n\geq\#\mathsf{P}_n\geq 2^n$. Fix n and $M=\mathsf{T}_n$. For primes $p\in S\setminus\{\ell\}$ let $L_p=H^1_{\mathrm{ur}}(D_p,M)$, the kernel of restriction to I_p, and let L_ℓ be the image of $H^1(D_\ell,\mathsf{P}_n)\to H^1(D_\ell,M)$. Let $\mathrm{Sel}\subseteq H^1(G_S,M)$ be the classes whose restriction to D_p lies in L_p for every prime $p\in S$. (2a) For $p\in S\setminus\{\ell\}$, $\#L_p=\#H^0(D_p,M)$: by inflation–restriction $L_p\cong H^1(D_p/I_p,M^{I_p})$; $D_p/I_p\cong\hat{\mathbb{Z}}$ is topologically generated by a Frobenius Fr, so $\#L_p=\#(M^{I_p}/(\mathrm{Fr}-1)M^{I_p})=\#\ker(\mathrm{Fr}-1\mid M^{I_p})=\#M^{D_p}$, the middle equality because M^{I_p} is finite. (2b) $\#L_\ell\geq\#\mathsf{P}_n$: the kernel of $H^1(D_\ell,\mathsf{P}_n)\to H^1(D_\ell,M)$ is the image of $H^0(D_\ell,M/\mathsf{P}_n)=0$ (Step 0c; P_n is D_ℓ-stable), and by Theorem B.29, item 4, for the finite $\mathbb{Z}/\ell^n\mathbb{Z}$-module P_n and $[\mathbb{Q}_\ell:\mathbb{Q}_\ell]=1$, $\#H^1(D_\ell,\mathsf{P}_n)=\#H^0(D_\ell,\mathsf{P}_n)\,\#H^2(D_\ell,\mathsf{P}_n)\,\#\mathsf{P}_n\geq\#\mathsf{P}_n$. (2c) The count. Sel is the kernel of $H^1(G_S,M)\to\bigoplus_p H^1(D_p,M)/L_p$ (primes $p\in S$), so

$$\#\mathrm{Sel}\ \geq\ \#H^1(G_S,M)\Big/\prod_p[H^1(D_p,M):L_p].$$

By Theorem B.37, item 2, for $F=\mathbb{Q}$ (one real place, $|\#M|_\infty=\#M$, $H^0(\mathbb{R},M)=M^{c'=1}=0$) and $H^0(G_S,M)=0$: $\#H^1(G_S,M)=\#H^2(G_S,M)\,\#M$. By Theorem B.29, item 4, and (2a), $[H^1(D_p,M):L_p]=\#H^2(D_p,M)$ for $p\neq\ell$; with $H^0(D_\ell,M)=0$ and (2b), $[H^1(D_\ell,M):L_\ell]=\#H^2(D_\ell,M)\,\#M/\#L_\ell\leq\#H^2(D_\ell,M)\,\#M/\#\mathsf{P}_n$. By Theorem B.37, item 3, and $H^0(G_S,M^\vee)=0$, the restriction $H^2(G_S,M)\to\bigoplus_p H^2(D_p,M)$ is onto, so $\#H^2(G_S,M)\geq\prod_p\#H^2(D_p,M)$. Together, $\#\mathrm{Sel}\geq\#\mathsf{P}_n$. (2d) Sel injects into Σ_n. For a class with cocycle $w\in Z^1(G_S,M)$, viewed on $G_{\mathbb{Q}}$, put $\zeta(g)=w(g)-(\rho(g)x-x)$ with $x=-\frac{1}{2}w(c)$, so that $\zeta(c)=w(c)+2x=0$. Two cocycles of one class with value 0 at c differ by $g\mapsto\rho(g)x'-x'$ with $-2x'=0$, i.e. $x'=0$; so the class determines ζ, and distinct classes give distinct ζ. The first two conditions of Step 1 hold. For $p\in S\setminus\{\ell\}$ the restriction to I_p is trivial: $\zeta(g)=\rho(g)x_p-x_p$ on I_p for some x_p, which is 0 if $\rho(g)=1$. At ℓ: $\zeta|_{D_\ell}=u+(h\mapsto\rho(h)y-y)$ with $u\in Z^1(D_\ell,\mathsf{P}_n)$, $y\in M$, so $\zeta(h)-(\rho(h)y-y)=u(h)\in\mathsf{P}_n$. Hence $\#\Sigma_n\geq\#\mathrm{Sel}\geq\#\mathsf{P}_n\geq 2^n$.

Step 3: division by ϖ. Let $m\geq 2$ and let $\zeta\in\Sigma_m$ reduce to 0 in Σ_1. Multiplication by ϖ induces an injective Λ-linear, $G_{\mathbb{Q}}$-equivariant map $\iota\colon\mathsf{T}_{m-1}\to\mathsf{T}_m$ with image $\varpi\mathsf{T}_m$, the kernel of $\mathsf{T}_m\to\mathsf{T}_1$; so $\zeta=\iota\circ\zeta'$ for a unique $\zeta'\colon G_{\mathbb{Q}}\to\mathsf{T}_{m-1}$, and ζ' satisfies the first three conditions of Step 1. For the fourth, let y be as there for ζ. Reducing modulo ϖ, $\varphi(\bar y)\in\mathsf{P}_1$, so $\bar y\in\mathsf{P}_1$ by Step 0b, and $y=p+\iota(y')$ with $p\in\mathsf{P}_m$, $y'\in\mathsf{T}_{m-1}$. Then for $h\in D_\ell$

$$\iota(\zeta'(h)-(\rho(h)y'-y'))=\zeta(h)-(\rho(h)y-y)+(\rho(h)p-p)\in\mathsf{P}_m.$$

If $\iota(x) \in \mathsf{P}_m$, lift x to $\tilde{x} \in \mathsf{T}$: $\varpi\tilde{x} = p' + \varpi^m t$ with $p' \in \mathsf{P}$, $t \in \mathsf{T}$, so $p' \in \mathsf{P} \cap \varpi\mathsf{T} = \varpi\mathsf{P}$, and $\tilde{x} - \varpi^{m-1}t \in \mathsf{P}$, i.e. $x \in \mathsf{P}_{m-1}$. So $\zeta' \in \Sigma_{m-1}$, and $\zeta \mapsto \zeta'$ is injective: the kernel of $\Sigma_m \to \Sigma_1$ has at most $\#\Sigma_{m-1}$ elements.

Step 4: a compatible non-zero family. For $m \geq k$ let $\Sigma_{m,k} \subseteq \Sigma_k$ be the image of Σ_m. It decreases with m, and Σ_k is finite, so $\Sigma_{m,k} = \Sigma_k^\infty$ for all $m \geq m(k)$. Reduction maps Σ_{k+1}^∞ onto Σ_k^∞: for $x \in \Sigma_k^\infty$ and $m \geq \max(m(k), m(k+1))$, x is the image of some $w \in \Sigma_m$, whose image in Σ_{k+1} lies in $\Sigma_{m,k+1} = \Sigma_{k+1}^\infty$ and maps to x. Suppose $\Sigma_1^\infty = 0$. Then $\Sigma_m \to \Sigma_1$ is zero for $m \geq m_1 = \max(m(1), 2)$, so $\#\Sigma_m \leq \#\Sigma_{m-1}$ for all $m \geq m_1$ by Step 3, and $\#\Sigma_m \leq \#\Sigma_{m_1-1}$ for all $m \geq m_1$, contradicting $\#\Sigma_m \geq 2^m$ (Step 2). So there is $\zeta_1 \neq 0$ in Σ_1^∞, and lifting successively, $\zeta_k \in \Sigma_k^\infty$ with ζ_{k+1} reducing to ζ_k for all $k \geq 1$.

Step 5: the integral cocycle. T is ϖ-adically complete and separated, so $z(g) = \lim_k \zeta_k(g)$ defines $z\colon G_\mathbb{Q} \to \mathsf{T}$ with $z(g) \equiv \zeta_k(g)$ modulo $\varpi^k\mathsf{T}$. It is not identically zero ($\zeta_1 \neq 0$); modulo ϖ^n it is ζ_n, locally constant; the cocycle relation and $z(c) = 0$ hold modulo every ϖ^k, hence hold. This is (1) and (2). (3) Let $g \in N$ lie in the inertia group of a place $\bar{w}$ above a prime $p \neq \ell$. If $p \notin S$, then $g \in H_S$ and $\zeta_k(g) = 0$ for all k. If $p \in S$, then $\bar{w} = \tau\bar{p}$ for some $\tau \in G_\mathbb{Q}$ and $g = \tau g'\tau^{-1}$ with $g' \in I_p$ and $\rho(g') = \rho(\tau)^{-1}\rho(g)\rho(\tau) = 1$, since $N \subseteq \ker\rho$; so $z(g') = 0$ by the third condition at every level, and

$$z(g) = z(\tau) + \rho(\tau)z(g') + \rho(\tau g')z(\tau^{-1}) = z(\tau) + \rho(\tau)z(\tau^{-1}) = z(\tau\tau^{-1}) = 0.$$

(4) By Step 0b choose $y \in \mathsf{T}$ with $\varphi(y) - z(s) \in \mathsf{P}$. For $k \geq 1$ let $y_k \in \mathsf{T}_k$ be as in the fourth condition for ζ_k. At $h = s$, $\varphi(y_k) \equiv \zeta_k(s) \equiv \varphi(y)$ modulo P_k, so $y_k \equiv y$ modulo P_k by Step 0b, and for $h \in D_\ell$, modulo $\varpi^k\mathsf{T}$,

$$z(h) - (\rho(h)y - y) \equiv \big(\zeta_k(h) - (\rho(h)y_k - y_k)\big) + (\rho(h) - 1)(y_k - y) \in \mathsf{P}_k,$$

as P_k is D_ℓ-stable. Hence $z(h) - (\rho(h)y - y) \in \bigcap_k(\mathsf{P} + \varpi^k\mathsf{T}) = \mathsf{P}$ by Step 0a. This is (4). □

Lemma 51.25. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in $\overline{\mathbb{Z}}_\ell$ (for the standard test field) such that every $r(g)$ is block diagonal. Then r is not weakly pure for any isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$.*

Proof. Write $r_1(g) = (r(g)_{ab})_{a,b\in\{1,3\}}$ and $r_2(g) = (r(g)_{ab})_{a,b\in\{2,4\}}$. Since every $r(g)$ is block diagonal, $V_1 = \langle e_1, e_3\rangle$ and $V_2 = \langle e_2, e_4\rangle$ are $r(G_\mathbb{Q})$-stable, r_1, r_2 are homomorphisms to $\mathrm{GL}_2(\overline{\mathbb{Z}}_\ell)$, and the eigenvalues of $r(g)$ are those of $r_1(g)$ together with those of $r_2(g)$. Put $\delta_1 = \det r_1$ and $\delta_2 = \det r_2$.

Step 1: $\delta_1\delta_2 = \theta^2$. The form $B(x, y) = {}^t x J_4 y$ vanishes on $V_1 \times V_1$ and on $V_2 \times V_2$ (the entries $(J_4)_{ab}$ with $a, b \in \{1, 3\}$ or $a, b \in \{2, 4\}$ are 0), and its matrix on $V_1 \times V_2$ in the bases (e_1, e_3), (e_2, e_4) is $P = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. By (Ot2), $B(r(g)x, r(g)y) = \theta(g)B(x, y)$, so ${}^t r_1(g)\, P\, r_2(g) = \theta(g)P$; taking determinants, $\delta_1(g)\delta_2(g) = \theta(g)^2$.

Step 2: $\delta_1 = \theta\alpha$ on I_ℓ. By (Ot4), $F_i = u\langle e_1, \ldots, e_i\rangle$ $(0 \leq i \leq 4)$ is a D_ℓ-stable flag and $s \in D_\ell$ acts on F_i/F_{i-1} by $d_i(s)$; so each d_i is a character of D_ℓ, and $d_i(s) - \kappa_i(s) \in \mathfrak{m}_\ell$, with equality $d_i = \kappa_i$ on I_ℓ. The subspaces $F_i \cap V_1$ are D_ℓ-stable, and $(F_i \cap V_1)/(F_{i-1} \cap V_1)$ embeds into F_i/F_{i-1}; as $\dim V_1 = 2$, exactly two indices $a < b$ give non-zero quotients, and in a basis of V_1 adapted to this flag $r_1(s)$ is upper triangular with diagonal $(d_a(s), d_b(s))$. Hence for $s \in D_\ell$

$$\det(X - r_1(s)) = \big(X - d_a(s)\big)\big(X - d_b(s)\big), \qquad \delta_1(s) = d_a(s)d_b(s).$$

Take $s = \sigma_\ell \in D_\ell$ ($\ell \in T$, (Sg2)). By (Ot2), $r_1(\sigma_\ell) \equiv \mathrm{diag}(\theta(\sigma_\ell), \alpha(\sigma_\ell))$ modulo $\mathfrak{m}_\ell$, so in $\overline{\mathbb{F}}_\ell[X]$

$$\big(X - \bar{d}_a(\sigma_\ell)\big)\big(X - \bar{d}_b(\sigma_\ell)\big) = \big(X - \bar{\theta}(\sigma_\ell)\big)\big(X - \bar{\alpha}(\sigma_\ell)\big),$$

with $\bar{d}_i(\sigma_\ell) = \bar{\kappa}_i(\sigma_\ell)$. Now $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$ by (Sg2), so $\omega_\ell(\sigma_\ell)$ is an $(\ell-1)$-th root of unity congruent to 1, hence equal to 1; thus $\alpha(\sigma_\ell) = \xi(\sigma_\ell)$ and $\theta(\sigma_\ell) = \xi(\sigma_\ell)\Psi(\sigma_\ell)$. By (Sg2) with $i = 0, 1, -1$, $\bar{\xi}(\sigma_\ell)$, $\overline{\xi\Psi}(\sigma_\ell)$ and $\overline{\xi\Psi^{-1}}(\sigma_\ell)$ differ from 1. Hence $\bar{\kappa}_2(\sigma_\ell) = \bar{\Psi}(\sigma_\ell)$ differs from $\bar{\theta}(\sigma_\ell)$ (ratio $\bar{\xi}(\sigma_\ell)$) and from $\bar{\alpha}(\sigma_\ell)$ (ratio $\overline{\xi\Psi^{-1}}(\sigma_\ell)$), and $\bar{\kappa}_4(\sigma_\ell) = 1$ differs from $\bar{\theta}(\sigma_\ell)$ and $\bar{\alpha}(\sigma_\ell)$. So $a, b \notin \{2, 4\}$, $(a, b) = (1, 3)$, and $\delta_1(s) = d_1(s)d_3(s) = \theta(s)\alpha(s)$ for $s \in I_\ell$.

Step 3: $\delta_1 = \chi_{\mathrm{cyc}}^{e+2}\varepsilon_1$ and $\delta_2 = \chi_{\mathrm{cyc}}^{e}\varepsilon_2$ with characters $\varepsilon_1, \varepsilon_2$ of finite order. We have $\theta\alpha = \alpha^2\Psi = \chi_{\mathrm{cyc}}^{e+2}\varepsilon_0$ with $\varepsilon_0 = \omega_\ell^{-2}\xi^2\chi$ of finite order. Put $\eta = \delta_1(\theta\alpha)^{-1} \colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell^{\times}$, a character, continuous by (Ot1) (the inclusion of the discrete valuation ring of (Ot1) into $\overline{\mathbb{Z}}_\ell$ is local, hence continuous). Since η is a character, $\eta(I_{\bar{w}})$ is the same group for all places $\bar{w}$ above a given prime. By Step 2, $\eta(I_\ell) = 1$. Let $p \notin S$; then $p \notin T$ and $p \neq \ell$, the characters $\chi, \xi, \omega_\ell, \chi_{\mathrm{cyc}}$ are unramified at p ((Sg1); χ has modulus N, whose prime factors are in S), so $I_{\bar{w}} \subseteq \ker \bar{r}_0$ for $\bar{w} \mid p$, $r(I_{\bar{w}}) = 1$ by (Ot3), and $\eta(I_{\bar{w}}) = 1$. Let $p \in S$, $p \neq \ell$. By (Ot3), r is trivial on $I_p \cap \ker\chi$ if $p \in T$ and on $I_{\bar{p}} \cap \ker \bar{r}_0$ if $p \notin T$, subgroups of finite index of I_p (χ and $\bar{r}_0$ have finite image), so $\delta_1(I_p)$ is finite; and $\theta\alpha = \chi_{\mathrm{cyc}}^{e+2}\varepsilon_0$ has finite image on I_p, χ_{cyc} being unramified at p. So $\eta(I_p)$ is finite. Let $n \geq 1$ be a common multiple of the orders of the groups $\eta(I_p)$, $p \in S$. Then η^n is trivial on every inertia group, so the fixed field of its kernel (a closed normal subgroup) is an abelian extension of $\mathbb{Q}$ unramified at every prime; by Minkowski's theorem it is $\mathbb{Q}$, so $\eta^n = \mathbf{1}$. Thus $\delta_1 = \chi_{\mathrm{cyc}}^{e+2}\varepsilon_1$ with $\varepsilon_1 = \varepsilon_0\eta$ of finite order, and by Step 1, since $\theta = \alpha\Psi = \chi_{\mathrm{cyc}}^{e+1}\omega_\ell^{-1}\xi\chi$,

$$\delta_2 = \theta^2\delta_1^{-1} = \chi_{\mathrm{cyc}}^{e}\varepsilon_2, \qquad \varepsilon_2 = \omega_\ell^{-2}\xi^2\chi^2\varepsilon_1^{-1},$$

of finite order.

Step 4: weak purity fails. Let ι be an isomorphism and suppose r weakly pure for ι, with H and M as in the definition. Let H' be the normal core of the open subgroup $H \cap \ker\varepsilon_1 \cap \ker\varepsilon_2$; it is open and normal, of some finite index m. Choose a prime $p \nmid \ell M$, a place $\bar{p}'$ above p and an arithmetic Frobenius element $\Phi \in D_{\bar{p}'}$ for p, and put $\sigma = \Phi^m$. Then $\sigma \in H' \subseteq H$ (the image of Φ in $G_{\mathbb{Q}}/H'$ has order dividing m), σ is an arithmetic Frobenius element for p^m at $\bar{p}'$, $\varepsilon_1(\sigma) = \varepsilon_2(\sigma) = 1$, and $\chi_{\mathrm{cyc}}(\sigma) = p^m$ (on roots of unity of order prime to p, reduction modulo $\bar{p}'$ is injective, so $\sigma(\zeta) = \zeta^{p^m}$). Let x_1, x_3 be the eigenvalues of $r_1(\sigma)$ and x_2, x_4 those of $r_2(\sigma)$, all non-zero; by Step 3, $x_1x_3 = p^{m(e+2)}$ and $x_2x_4 = p^{me}$. Applying (45.1) with $f = m$ to $(x, y) = (x_1, x_2)$ and (x_3, x_4) and multiplying,

$$p^{m(e+2)} = |\iota(x_1x_3)| < p^{2m}\,|\iota(x_2x_4)| = p^{2m}\,p^{me} = p^{m(e+2)},$$

since ι fixes $\mathbb{Q}$. This contradiction proves the lemma. □

52 Essential test representations: cases (II) and (III)

This section proves Proposition 52.1 and Proposition 52.14, the two reductions that Proposition 51.5 uses. An essential ordinary test representation is, after conjugation and restriction to a deep auxiliary tower, a marked pair over a complete local ring whose reduction is a residual pair chained to the reduction of any seed pair (in case (III), of any seed pair over a given residual pair). The method is Ribet's lattice argument [208] in GSp_4. A torus conjugation over a discrete valuation ring makes the entries integral with a tight set of non-zero reductions (Lemma 52.5), and gives a Ribet-type lattice whose reduction has a prescribed non-split entry (Proposition 52.4). Its reduction is then moved, by links (affine lines of residual pairs with a fixed core) and by Gysin steps (new entries ramified at auxiliary split primes), until it reaches the reduction of a seed pair. The towers along which this happens must be fit and tame, with

a prescribed labelling, and their existence is proved for each case (Proposition 52.9, Proposition 52.18). Subsections 52.1 and 52.2 treat case (II), the lattices and then the towers and steps, and Subsection 52.3 adapts the argument to case (III).

52.1 Case (II): lattices, chains and Ribet-type lattices

This subsection proves Proposition 52.1 from Proposition 52.2: in case (II) an essential ordinary test representation has a lattice over a complete discrete valuation ring inside V, and a chain with values in the residue field from its reduction to the reduction of any seed pair. The lattice is chosen in two steps. A normal form diagonalises the representation at a separating element and puts its flag at ℓ in lower unipotent shape (Proposition 52.3); then a torus conjugation produces a Ribet-type lattice, whose reduction is supported in a prescribed set of positions and has an entry of a prescribed weight (Proposition 52.4). Two lemmas carry the computation: the torus vertex lemma, which sorts the possible tight sets into six shapes (Lemma 52.5), and the vanishing of odd entries that are cocycles and local coboundaries at ℓ (Lemma 52.6). The identity for the similitude of lower unitriangular matrices (Lemma 52.7) is used again in Section 53.

Proposition 52.1. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (II), $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, (K, V, a) a test field and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is essential. Then there are a fit and tame auxiliary tower $\mathscr{T}_1$ for $\mathfrak{D}$ of case (II) and a homomorphism $r'\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ with $r' = u' r u'^{-1}$ for some $u' \in \mathrm{GL}_4(K)$ and $r'(g)$ of similitude $a(\theta(g))$ for all g, with the following property. For every deep auxiliary tower $\mathscr{T} \geq \mathscr{T}_1$ (field F, places $\bar{v}$, $v \in \Sigma$), every coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and every seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι whose reduction lies in V and either has an entry of weight $-w_\alpha$ or has entries of weights w_β and $-w_\theta$, there is a coefficient ring $\mathcal{O}_2 \supseteq \mathcal{O}_1$ such that for every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}_2$:*

(Nq1) *there are $R \in \mathrm{CNL}_{\mathcal{O}'}$, an injective ring homomorphism $f\colon R \to V$ that restricts to a on $\mathcal{O}'$ and maps $\mathfrak{m}_R$ into $\mathfrak{m}_V$, and a marked ordinary pair P_R over $(\mathscr{T}, \emptyset)$ with values in R, continuous for $\mathfrak{m}_R$, whose reduction is a residual pair, such that $f(P_R)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{f(P_R)}(s) = a(\kappa_i(s))$ for all $v \in \Sigma$, $1 \leq i \leq 4$ and $s \in I_v$;*

(Nq2) *there is a chain from the reduction of P_R to the reduction of Q modulo $\mathfrak{m}_{\mathcal{O}'}$ (both with values in $\mathbb{F}_{\mathcal{O}'}$).*

Proof. Take $\mathscr{T}_1$ and r' from Proposition 52.2. Let $\mathscr{T} \geq \mathscr{T}_1$ be deep, $\mathcal{O}_1 \supseteq \mathcal{O}$ and Q as in the statement, and let Λ, j, a_Λ, P_Λ and a chain $c_0, \dots, c_m$ with links $L_1, \dots, L_m$ (residual pairs with values in $k_V[X]$) be given by (Lc1), (Lc2).

Step 1: the residue field of V and the choice of $\mathcal{O}_2$. The map $\bar{a}$ kills $\mathfrak{m}_\ell$ ($a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$), so it induces a field embedding $\overline{\mathbb{F}}_\ell \to k_V$, which is onto because every element of V is congruent modulo $\mathfrak{m}_V$ to an element of $a(\overline{\mathbb{Z}}_\ell)$. Every c_t and every L_t is locally constant on the compact group G_F and has finitely many flags, so only finitely many elements of k_V occur as entries of the c_t and as coefficients of entries of the L_t; together with the image of the finite residue field $\mathbb{F}_\Lambda$ under $\Lambda \to V \to k_V$ they lie in $\bar{a}(\mathbb{F})$ for a finite subfield $\mathbb{F} \subset \overline{\mathbb{F}}_\ell$. Choose a coefficient ring $\mathcal{O}_2 \supseteq \mathcal{O}_1$ whose residue field contains $\mathbb{F}$ (an unramified extension), and let $\mathcal{O}' \supseteq \mathcal{O}_2$.

Step 2: (Nq1). Write $\mathcal{O}' = \sum_{i=1}^n \mathcal{O} b_i$ ($\mathcal{O}'$ is finite over $\mathcal{O}$) and let $R = j(\Lambda)[a(b_1), \dots, a(b_n)] \subseteq V$. Each $a(b_i)$ is integral over $a(\mathcal{O}) = j(a_\Lambda(\mathcal{O})) \subseteq j(\Lambda)$, so R is a finite $j(\Lambda)$-module containing $a(\mathcal{O}')$. Hence R is Noetherian and complete, and, being a domain finite over the complete local ring $j(\Lambda) \cong \Lambda$, it is local. Its maximal ideal lies in $\mathfrak{m}_V$: for $x \in \mathfrak{m}_R$ some power lies in

$j(\mathfrak{m}_\Lambda)R \subseteq \mathfrak{m}_V$ ($R/\mathfrak{m}_\Lambda R$ is Artinian local, j is local), and $\mathfrak{m}_V$ is prime. So $R \cap \mathfrak{m}_V = \mathfrak{m}_R$ and $R/\mathfrak{m}_R$ embeds into k_V, with image the field generated by the images of $\mathbb{F}_\Lambda$ and of $\mathbb{F}_{\mathcal{O}'}$, which is $\bar{a}(\mathbb{F}_{\mathcal{O}'})$ by Step 1. Thus R, with structure map $a|_{\mathcal{O}'}$ (local, as units of $\mathcal{O}'$ go to units), lies in $\mathrm{CNL}_{\mathcal{O}'}$, and the inclusion $f\colon R \to V$ is injective, restricts to a on $\mathcal{O}'$ and maps $\mathfrak{m}_R$ into $\mathfrak{m}_V$. Let $P_R = j(P_\Lambda)$, with entries in $j(\Lambda) \subseteq R$: it is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in R for $\mathcal{O} \subseteq \mathcal{O}' \to R$ (the conditions (Mq1)–(Mq4) are identities transported by j, and $j \circ a_\Lambda = a|_{\mathcal{O}}$); it is continuous for $\mathfrak{m}_R$ because $j(\mathfrak{m}_\Lambda)^k R \subseteq \mathfrak{m}_R^k$; its reduction is the image of the reduction of P_Λ under the field embedding $\mathbb{F}_\Lambda \to R/\mathfrak{m}_R$, hence a residual pair (local constancy, (Mq1)–(Mq4), (Wq1), (Wq2) are preserved by an injective ring homomorphism); and $f(P_R) = j(P_\Lambda)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{f(P_R)}(s) = a(\kappa_i(s))$ on I_v by (Lc1).

Step 3: (Nq2). Let $\bar{a}'\colon \mathbb{F}_{\mathcal{O}'} \to k_V$ be induced by $\bar{a}$; it is injective and, by Step 1, its image contains every entry of the c_t and every coefficient of the L_t. Let c_t' and L_t' be obtained by applying $(\bar{a}')^{-1}$ entrywise (coefficientwise for L_t). Every condition in the definitions of residual pairs, of good residual pairs, of links and of chains is a conjunction of polynomial identities and non-vanishing conditions among entries, flags and values $\bar{a}(\kappa_i(g))$, $\bar{a}(\mathrm{rt}_w(s))$, together with evaluation at $X = 0, 1$; the injective homomorphisms $\mathbb{F}_{\mathcal{O}'} \to k_V$ and $\mathbb{F}_{\mathcal{O}'}[X] \to k_V[X]$ commute with these evaluations and preserve and reflect identities and non-vanishing. So $c_0', \dots, c_m'$ is a chain with values in $\mathbb{F}_{\mathcal{O}'}$ (for the reduction $\mathcal{O} \to \mathbb{F}_{\mathcal{O}'}$), with links L_t'. Its ends are the reduction of P_R (identified with $\mathbb{F}_{\mathcal{O}'}$ through Step 2: both have image under $\bar{a}'$ equal to the image of P_Λ in k_V) and the reduction of Q modulo $\mathfrak{m}_{\mathcal{O}'}$ (both have image the image of Q in k_V), by injectivity of $\bar{a}'$. This is (Nq2). □

Proposition 52.2. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (II), $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, (K, V, a) a test field with residue field k_V and $\bar{a}\colon \overline{\mathbb{Z}}_\ell \to k_V$ the composite of a and reduction, and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is essential. Then there are a fit and tame auxiliary tower $\mathscr{T}_1$ for $\mathfrak{D}$ of case (II) and a homomorphism $r'\colon G_\mathbb{Q} \to \mathrm{GL}_4(V)$ with $r' = u' r u'^{-1}$ for some $u' \in \mathrm{GL}_4(K)$ and $r'(g)$ of similitude $a(\theta(g))$ for all g, with the following property. For every deep auxiliary tower $\mathscr{T} \geq \mathscr{T}_1$ (field F, places $\bar{v}$, $v \in \Sigma$), every coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and every seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι whose reduction lies in V and either has an entry of weight $-w_\alpha$ or has entries of weights w_β and $-w_\theta$, there are:*

(Lc1) *a complete discrete valuation ring Λ with finite residue field, an injective local homomorphism $j\colon \Lambda \to V$, a ring homomorphism $a_\Lambda\colon \mathcal{O} \to \Lambda$ with $j \circ a_\Lambda = a|_{\mathcal{O}}$, and a marked ordinary pair P_Λ over $(\mathscr{T}, \emptyset)$ with values in Λ (for a_Λ), continuous for $\mathfrak{m}_\Lambda$, whose reduction is a residual pair, such that $j(P_\Lambda)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{j(P_\Lambda)}(s) = a(\kappa_i(s))$ for all $v \in \Sigma$, $1 \leq i \leq 4$ and $s \in I_v$;*

(Lc2) *a chain, with values in k_V (for $\bar{a}|_{\mathcal{O}}$), from the image of P_Λ under $\Lambda \to V \to k_V$ to the image of Q under $\mathcal{O}_1 \xrightarrow{\bar{a}} k_V$.*

Proof. Step 1: labelling, first tower, lattice. Let ϵ be the admissible labelling given by Proposition 52.3 for (r, u), and $\mathscr{T}_0$ a fit and tame auxiliary tower of case (II) with labelling ϵ (Ux1), field F_0 and index set Σ_0. Put $g_\circ = g_{\mathscr{T}_0}$; by (Oq7) the $\chi_i(g_\circ)$ are pairwise distinct ($\bar{a}$ is injective on $\mathbb{F}_{\mathcal{O}}$). Proposition 52.3 gives h, $r^\natural = h^{-1} r h$ and n with (Nz1)–(Nz3), and, r being essential, (Nz4). These are the hypotheses of Proposition 52.4, which gives $\mathrm{T} = \mathrm{T}_4(t_1, t_2)$, $r' = \mathrm{T} r^\natural \mathrm{T}^{-1}$, n' with (Ql0)–(Ql3). Put $u' = \mathrm{T} h^{-1} \in \mathrm{GL}_4(K)$: $r' = u' r u'^{-1}$, and $r'(g)$ has similitude $a(\theta(g))$; its entries lie in V and its similitude is a unit, so $r'(g) \in \mathrm{GL}_4(V)$. Let $c = \bar{r}'$ and $\bar{n} = \overline{n'}$. By (Ql0), $\bar{n}^{-1} c(s) \bar{n}$ is upper triangular with diagonal $\chi_i(s)$ for $s \in D_\ell$, and $c(g)_{ii} = \chi_i(g)$; by (Ql1),

c is supported in Σ_P and $\bar{n}$ in Σ_Q. The clauses of (Nz2), (Nz3) on I_ℓ, on I_v for $v \in T \setminus \{\ell\}$ and on the inertia away from T pass to (r', n') (conjugation by the diagonal T keeps the diagonal of $n^{-1} r^\natural(s) n$ and the identity matrix). So (r', n') satisfies the hypotheses of (Ux3) for every fit tower with labelling ϵ whose marking is a power of $g_\circ$.

Step 2: the Gysin pair and the tower $\mathscr{T}_1$. (Ux3) for $\mathscr{T}_0$ gives flags $n_{0,v}$ ($v \in \Sigma_0$) and elements $g_{0,v} \in G_{\mathbb{Q}}$ with $g_{0,v}(\bar{\ell}) = \bar{v}$ and $n_{0,v}^{-1} r'(g_{0,v}) n'$ upper triangular, such that the reduction $p = (c|_{G_{F_0}}, (\bar{n}_{0,v}))$ is a residual pair over $(\mathscr{T}_0, \emptyset)$ with flags supported in Σ_Q. (Gz) of Proposition 52.11 applied to $\mathscr{T}_0$, $W = \emptyset$ and $p = p'$ gives a finite set W' of primes splitting for $\mathscr{T}_0$ and a residual pair s over $(\mathscr{T}_0, W')$ with (Gz1)–(Gz3): its first component and flags are supported in Σ_Q, it has the same $-w_\Psi$ part as p, and its first component has an entry of weight $-w_\alpha$. (Ux2) gives a tame auxiliary tower $\mathscr{T}_1 \geq \mathscr{T}_0$ in whose field every $w \in W'$ dies; by (Xq3) it is fit and of case (II). These $\mathscr{T}_1$ and r' are those of the statement.

Step 3: three facts. (F1) *Isolated entries survive restriction.* Let $\mathscr{T}$ be a tower with field F, $H \supseteq G_F$ a subgroup of $G_{\mathbb{Q}}$ in which G_F is normal, and $y\colon H \to \mathrm{M}_4(k_V)$ a homomorphism of monoids with $y(g)_{ii} = \chi_i(g)$ and, for some $i \neq j$, $y(gh)_{ij} = \chi_i(g) y(h)_{ij} + y(g)_{ij} \chi_j(h)$. If $y(g)_{ij} = 0$ for $g \in G_F$ and $\chi_i(g_{\mathscr{T}}) \neq \chi_j(g_{\mathscr{T}})$, then $y_{ij} = 0$ on H: for $g \in H$ and $h_0 = g_{\mathscr{T}}$, $y(gh_0)_{ij} = y(g)_{ij} \chi_j(h_0)$, and also $y(gh_0)_{ij} = y((gh_0 g^{-1}) g)_{ij} = \chi_i(h_0) y(g)_{ij}$ (as $gh_0 g^{-1} \in G_F$ and χ_i is a character); so $(\chi_j - \chi_i)(h_0)\, y(g)_{ij} = 0$. For a tower $\mathscr{T} \geq \mathscr{T}_0$ the marking is $g_\circ^{\ell^{j'}}$, and $\chi_i(g_\circ)^{\ell^{j'}}$ are pairwise distinct ($x \mapsto x^\ell$ is injective on k_V), so (F1) applies with every $i \neq j$. If $y(g)$ has similitude $\bar{a}(\theta(g)) \neq 0$, then $y(g^{-1}) = \bar{a}(\theta(g))^{-1} J_4^{-1}\, {}^t y(g) J_4$, whose entries $(3,1)$ and $(2,1)$ are $-\bar{a}(\theta(g))^{-1} y(g)_{42}$ and $\bar{a}(\theta(g))^{-1} y(g)_{43}$; so y has an entry of weight $-w_\Psi$ (resp. $-w_\alpha$) if and only if y_{31} (resp. y_{21}) is not identically zero, on H and on G_F alike.

(F2) *The flag coordinate* $(3,1)$. Let $X \in \mathrm{M}_4(k_V)$ be supported in Σ_P with diagonal $(\chi_i(g))_i$ for some g, and y, y' lower unitriangular. If $y^{-1} X y'$ is upper triangular, then comparing first columns, $X y' e_1 = \lambda y e_1$ with λ the first coordinate of $X y' e_1$, which is $\chi_1(g)$ since $X_{12} = X_{13} = X_{14} = 0$; the third coordinate, with $X_{32} = X_{34} = 0$, gives

$$y_{31}\, \chi_1(g) = X_{31} + \chi_3(g)\, y'_{31}. \tag{52.1}$$

(F3) *Products.* If $y^{-1} X y'$ and $y'^{-1} Z y'$ are upper triangular, so is $y^{-1} X Z y' = (y^{-1} X y')(y'^{-1} Z y')$.

Step 4: (Lc1). Let $\mathscr{T} \geq \mathscr{T}_1$ be deep, with field F and places $\bar{v}$, $v \in \Sigma$; it is fit with labelling ϵ by (Xq3), and $\mathscr{T} \geq \mathscr{T}_0$. (Ux3) gives flags n_v with entries in $j'(\Lambda')$ and $g_v \in G_{\mathbb{Q}}$ with $g_v(\bar{\ell}) = \bar{v}$ and $n_v^{-1} r'(g_v) n'$ upper triangular, such that $P = (r'|_{G_F}, (n_v))$ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in V, $\psi^P_{v,i}(s) = a(\kappa_i(s))$ on I_v, and its reduction $c_{\mathscr{T}} = (c|_{G_F}, (\bar{n}_v))$ is a residual pair with flags supported in Σ_Q. *Enlarging Λ'.* Let L_0 be the fraction field of $j'(\Lambda')$; every element of K is algebraic over L_0 ((Nz1); $\Lambda' \supseteq \Lambda$). $V \cap L_0$ is a valuation ring of L_0 containing the discrete valuation ring $j'(\Lambda')$ and not containing $j'(\pi')^{-1}$ for a uniformiser π', so it equals $j'(\Lambda')$; as K/L_0 is algebraic, the value group of V lies in the divisible hull of that of L_0, so V has rank one. If K has characteristic 0, Λ' contains $\mathbb{Z}_\ell$, a and j' agree on $\mathbb{Z}$, and for $x \in \mathbb{Z}_\ell$ and integers $m \equiv x$ modulo ℓ^e, $a(x) - j'(x) \in \ell^e V$ for all e; rank one gives $\bigcap_e \ell^e V = 0$, so $a = j'$ on $\mathbb{Z}_\ell$ and every element of $a(\mathcal{O})$ is integral over $j'(\mathbb{Z}_\ell)$. If K has characteristic ℓ, $a(\mathcal{O})$ is a finite field. In both cases $L_1 = L_0(a(\mathcal{O}))$ is a finite extension of L_0, and $\Lambda_1 = V \cap L_1$ is the valuation ring of the unique extension to L_1 of the valuation of the complete discrete valuation ring $j'(\Lambda')$: a complete discrete valuation ring with finite residue field, containing $j'(\Lambda')$ and the integral elements $a(\mathcal{O})$. Let $j_1\colon \Lambda_1 \to V$ be the inclusion (injective, local) and $a_\Lambda = a|_{\mathcal{O}}$ viewed in Λ_1. Then $P_\Lambda = j_1^{-1}(P)$ (entrywise) has values in Λ_1; the identities (Mq1)–(Mq4) for P with a are identities in $j_1(\Lambda_1)$, so P_Λ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in Λ_1 for a_Λ; it is $\mathfrak{m}_{\Lambda_1}$-adically continuous because the $\mathfrak{m}_{\Lambda'}$-adic and $\mathfrak{m}_{\Lambda_1}$-adic topologies agree on $j'(\Lambda')$ (Λ_1 is finite over it). Its reduction is mapped by the field embedding of the residue field of Λ_1 into k_V

to $c_{\mathscr{T}}$; residual pairs are defined by polynomial identities and non-vanishing conditions, which an injective field homomorphism reflects, so the reduction of P_Λ is a residual pair. $j_1(P_\Lambda) = P$ has first component $r'|_{G_F}$ and $\psi = a(\kappa_i(s))$ on I_v. This is (Lc1) with $(\Lambda, j) = (\Lambda_1, j_1)$.

Step 5: the pairs of the chain. Let $\mathcal{O}_1 \supseteq \mathcal{O}$ and Q be as in the statement and $\bar{Q} = (r_{\bar{Q}}, (n_{\bar{Q},v}))$ its image under $\mathcal{O}_1 \to k_V$: a residual pair over $(\mathscr{T}, \emptyset)$ lying in V (residual pairs and the conditions "lies in V" and "has an entry of weight w" are preserved by the injective field embedding of the residue field of $\mathcal{O}_1$ into k_V). Every $w \in W'$ dies in F (it dies in the field of $\mathscr{T}_1 \subseteq F$). (Ux4) gives a residual pair $c_3 = (r_s|_{G_F}, (n_{3,v}))$ over $(\mathscr{T}, \emptyset)$ lying over s: for every $v \in \Sigma$ there are $v_0 \in \Sigma_0$ and $g \in G_{F_0}$ with $g(\bar{v}_0) = \bar{v}$ and $n_{3,v}^{-1} r_s(g) n_{s,v_0}$ upper triangular. *Supports of c_3.* $r_s(g)$ and n_{s,v_0} are lower triangular and supported in Σ_Q (Gz1), and Σ_Q is closed under the sums of two weights that are roots ($-w_\alpha - w_\Psi = -w_\theta$; the other sums are not roots), so $L = r_s(g) n_{s,v_0}$ is lower triangular supported in Σ_Q; $n_{3,v}^{-1} L$ is upper and lower triangular, hence a diagonal matrix D, and $n_{3,v} = LD^{-1}$ is supported in Σ_Q. So c_3 has first component supported in $\Sigma_Q \subseteq \Sigma_P \cap \Sigma_M$ and flags in Σ_Q. By (Rl3), $c_3^\flat$ is a residual pair supported in $\{-w_\alpha\}$; by (Uq1) for the fit tower $\mathscr{T}$ of case (II), $\bar{a}(\mathrm{rt}_{w_\Psi}(s)) = 1$ for $s \in D_v$, so (Rl4) with $y_v = (n_{\bar{Q},v})_{31}$ gives a residual pair c_4 with $r_{c_4} = r_s^\flat|_{G_F}$, flags supported in Σ_Q, $(n_{c_4,v})_{21} = (n_{3,v})_{21}$ and $(n_{c_4,v})_{31} = (n_{\bar{Q},v})_{31}$.

Step 6: the links. (i) $c_{\mathscr{T}}$ and c_3: both first components are supported in Σ_P and all flags in Σ_Q. By (Gz2), $r_s(g)_{31} = c(g)_{31}$ and $r_s(g)_{42} = c(g)_{42}$ for $g \in G_{F_0} \supseteq G_F$, and $(n_{s,v_0})_{31} = (\bar{n}_{0,v_0})_{31}$. Fix v, and v_0, g as in Step 5, and put $g' = g g_{0,v_0} \in G_{\mathbb{Q}}$; then $g'(\bar{\ell}) = \bar{v} = g_v(\bar{\ell})$, so $g' = g_v d$ with $d \in D_\ell$, and by (F3) (with $Z = c(d)$) $\bar{n}_v^{-1} c(g') \bar{n}$ is upper triangular. Applying (52.1) three times (to $(\bar{n}_v, c(g'), \bar{n})$, $(n_{3,v}, r_s(g), n_{s,v_0})$, $(\bar{n}_{0,v_0}, c(g_{0,v_0}), \bar{n})$; all matrices X involved are supported in Σ_P) and $c(g')_{31} = c(g)_{31}\chi_1(g_{0,v_0}) + \chi_3(g) c(g_{0,v_0})_{31}$ (the first component is supported in Σ_P):

$$(\bar{n}_v)_{31}\chi_1(g') = c(g)_{31}\chi_1(g_{0,v_0}) + \chi_3(g)\,(\bar{n}_{0,v_0})_{31}\chi_1(g_{0,v_0}) = (n_{3,v})_{31}\,\chi_1(g)\chi_1(g_{0,v_0}).$$

So $(\bar{n}_v)_{31} = (n_{3,v})_{31}$, and (Rl1) links $c_{\mathscr{T}}$ and c_3. (ii) c_3 and c_4: first components supported in Σ_M, equal entries $(2,1)$, $(4,3)$ (kept by $\flat$), equal flag coordinates $(2,1)$: linked by (Rl2). (iii) c_4 and $\bar{Q}$: first components supported in $\{-w_\alpha\} \subseteq \Sigma_P$ and $\Sigma_V \subseteq \Sigma_P$, flags in Σ_Q, no entries of weight $-w_\Psi$ in either, equal flag coordinates $(3,1)$: linked by (Rl1).

Step 7: goodness. $c_{\mathscr{T}}$. By (Ql3) there are two cases. (a) c has an entry of weight $-w_\Psi$. The places $(3,1)$ and $(2,3)$ are isolated in c: $c(gh)_{31} = \chi_3(g)c(h)_{31} + c(g)_{31}\chi_1(h)$ because $c_{32} = c_{34} = 0$, and $c(gh)_{23} = \chi_2(g)c(h)_{23} + c(g)_{23}\chi_3(h)$ because $c_{13} = c_{24} = 0$. By (F1) with $H = G_{\mathbb{Q}}$, $c|_{G_F}$ has entries of weights $-w_\Psi$ and w_β ((Ql2); the place of w_β is $(2,3)$): $c_{\mathscr{T}}$ is good. (b) Otherwise c is supported in Σ_V, $\bar{n}_{31} \neq 0$, $\bar{\Psi} = 1$ on D_ℓ and the condition on c_{23} of (Ql3) holds. Then $c_{\mathscr{T}}$ lies in V: its first component is supported in Σ_V, its flags in Σ_Q, and (52.1) for $(\bar{n}_v, c(g_v), \bar{n})$ gives $(\bar{n}_v)_{31}\chi_1(g_v) = \chi_3(g_v)\bar{n}_{31} \neq 0$. If $c|_{G_F}$ had no entry of weight $-w_\alpha$, then, the place $(2,1)$ being isolated in c ($c_{31} = 0$, $c_{24} = 0$), (F1) would give $c_{21} = 0$ on $G_{\mathbb{Q}}$; the second coordinate of $c(s)\bar{n}e_1 = \chi_1(s)\bar{n}e_1$ ($s \in D_\ell$) would read $\chi_2(s)\bar{n}_{21} + c(s)_{23}\bar{n}_{31} = \chi_1(s)\bar{n}_{21}$, and $\chi_1 = \chi_3$ on D_ℓ (χ_1/χ_3 is $\bar{a} \circ \Psi^{\pm 1}$), so $c(s)_{23} = m(\chi_3(s) - \chi_2(s))$ with $m = \bar{n}_{21}/\bar{n}_{31}$, contrary to (Ql3). So $c_{\mathscr{T}}$ lies in V and has an entry of weight $-w_\alpha$: it is good. *c_3.* The place $(2,1)$ is isolated in the lower triangular r_s; by (Gz3), (F1) with $H = G_{F_0}$ (in which G_F is normal, F being abelian over $\mathbb{Q}$) and the similitude remark of (F1), c_3 has an entry of weight $-w_\alpha$. If it has one of weight $-w_\Psi$, it is good. Otherwise its first component is supported in $\Sigma_Q \backslash \{-w_\Psi\} \subseteq \Sigma_V$; in case (a) this cannot happen ($r_s(g)_{31} = c(g)_{31}$ on G_F, non-zero for some g); in case (b) $(n_{3,v})_{31} = (\bar{n}_v)_{31} \neq 0$, so c_3 lies in V with an entry of weight $-w_\alpha$: good. *c_4.* Its first component is supported in $\{-w_\alpha\} \subseteq \Sigma_V$ and has the entries $(2,1)$, $(4,3)$ of c_3, hence an entry of weight $-w_\alpha$; its flags are supported in Σ_Q with $(n_{c_4,v})_{31} = (n_{\bar{Q},v})_{31} \neq 0$ as $\bar{Q}$ lies in V: good. *$\bar{Q}$.* It lies in V; if it has an entry of weight $-w_\alpha$ it is good; otherwise it has entries of weights w_β and $-w_\theta$, and for every v, (Uq4) gives $s \in D_v$ with $\overline{\mathrm{rt}_{w_\alpha}}(s)^4 \neq 1$, so $\bar{a}(\mathrm{rt}_{w_\alpha}(s)) \neq 1$: good.

Step 8: (Lc2). $c_{\mathscr{T}}, c_3, c_4, \bar{Q}$ are good residual pairs over $(\mathscr{T}, \emptyset)$ with values in k_V (for $\bar{a}|_{\mathcal{O}}$), consecutive ones linked (Step 6): a chain from the image $c_{\mathscr{T}}$ of P_Λ in k_V to the image $\bar{Q}$ of Q. □

Proposition 52.3. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, (K, V, a) a test field with maximal ideal $\mathfrak{m}_V$ and residue field k_V, and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V. Then there is an admissible labelling ϵ with the following property. For every $g_\circ \in G_{\mathbb{Q}}$ such that the residues of $a(\kappa_i^\epsilon(g_\circ))$, $1 \le i \le 4$, in k_V are pairwise distinct, there are $h \in \mathrm{GL}_4(K)$, a homomorphism $r^\natural = h^{-1}rh \colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ and $n \in \mathrm{GL}_4(V)$ such that:*

(Nz1) *there are a complete discrete valuation ring Λ with finite residue field and an injective local homomorphism $j \colon \Lambda \to V$ such that every element of K is algebraic over $j(\Lambda)$, the entries of n and of every $r^\natural(g)$ lie in $j(\Lambda)$, and $g \mapsto j^{-1}(r^\natural(g)_{ik})$ is continuous for the $\mathfrak{m}_\Lambda$-adic topology, for all i, k;*

(Nz2) *for every $g \in G_{\mathbb{Q}}$, $r^\natural(g)$ has similitude $a(\theta(g))$ and the entries of*

$$r^\natural(g) - \mathrm{diag}(a(\kappa_1^\epsilon(g)), \dots, a(\kappa_4^\epsilon(g)))$$

lie in $\mathfrak{m}_V$; $r^\natural(g_\circ)$ is diagonal; $r^\natural(g) = 1$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$, $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above a prime not in T, and for every $g \in I_v$ with $\chi(g) = 1$, $v \in T \setminus \{\ell\}$;

(Nz3) *n is lower triangular with all diagonal entries 1 and has similitude 1; $n_{ik} \in \mathfrak{m}_V$ whenever $i > k$ and $\mathrm{wt}_4(i,k) \ne -w_\Psi$; for every $s \in D_\ell$ the matrix $n^{-1}r^\natural(s)n$ is upper triangular with diagonal entries $\psi_i(s)$ such that $\psi_i(s) - a(\kappa_i^\epsilon(s)) \in \mathfrak{m}_V$, and $\psi_i(s) = a(\kappa_i(s))$ if $s \in I_\ell$;*

(Nz4) *if r is essential, then $r^\natural$ has entries of weights w_Ψ and $-w_\Psi$ and an entry of at least one of the weights w_β, $-w_\alpha$, $-w_\theta$.*

Proof. Step 1: the residual flag and the choice of ϵ. By (Ot2), $\bar{r}(g) = \mathrm{diag}(c_1(g), \dots, c_4(g))$; by (Ot4), $\bar{u} \in \mathrm{GL}_4(k_V)$ has similitude 1 and $\bar{u}^{-1}\bar{r}(s)\bar{u}$ is upper triangular with diagonal $(c_1(s), \dots, c_4(s))$ for $s \in D_\ell$. So the flag $F_j = \mathrm{span}(\bar{u}e_1, \dots, \bar{u}e_j)$ is D_ℓ-stable, D_ℓ acts on F_j/F_{j-1} by c_j, and F_2 is isotropic and $F_3 = F_1^\perp$ ($\langle \bar{u}e_a, \bar{u}e_b\rangle = \langle e_a, e_b\rangle$, which vanishes for $a, b \le 3$ unless $\{a, b\} = \{2, 3\}$). The ratios $c_1/c_2 = c_3/c_4 = \bar{\alpha}$, $c_2/c_3 = \bar{\beta}$ and $c_1/c_4 = \bar{\theta}$ (on D_ℓ) are non-trivial at σ_ℓ: $\bar{\alpha} = \bar{\xi}$, $\bar{\beta}^{-1} = \bar{\xi}\bar{\Psi}^{-1}$, $\bar{\theta} = \bar{\xi}\bar{\Psi}$, and $\overline{\xi\Psi^i}(\sigma_\ell) \ne 1$ for all i by (Sg2) ($\ell \in T$). Only $c_1/c_3 = c_2/c_4 = \bar{\Psi}$ may be trivial on D_ℓ. Since $\bar{r}(s)$ is diagonal, every $x = \sum_i x_i e_i \in F_j$ satisfies $\sum_i (c_i(s) - c_j(s)) x_i e_i \in F_{j-1}$ for all $s \in D_\ell$ ($F_0 = 0$). Hence:

(A) if $\bar{\Psi} \ne 1$ on D_ℓ, the c_i are pairwise distinct, and inductively, if $F_{j-1} = \mathrm{span}(e_1, \dots, e_{j-1})$, then $x_i = 0$ for $x \in F_j$ and $i > j$, so $F_j = \mathrm{span}(e_1, \dots, e_j)$ and $\bar{u}$ is upper triangular; put $\epsilon = 0$ and $t = 0$;

(B) if $\bar{\Psi} = 1$ on D_ℓ, then $c_1 = c_3 \ne c_2 = c_4$, so $F_1 = k_V(x_1e_1 + x_3e_3)$; for $z = \sum_i z_i e_i \in F_2 \setminus F_1$, $(c_1 - c_2)(\sigma_\ell)(z_1e_1 + z_3e_3) \in F_1$ with $(c_1 - c_2)(\sigma_\ell) \ne 0$, so $F_2 = F_1 + k_V(y_2e_2 + y_4e_4)$ with $y_2e_2 + y_4e_4 = z - z_1e_1 - z_3e_3 \ne 0$, and $x_1y_4 - x_3y_2 = \langle x_1e_1 + x_3e_3, y_2e_2 + y_4e_4\rangle = 0$. (B1) If $x_1 \ne 0$, put $\epsilon = 0$ and $t = x_3/x_1$; then $y_2 \ne 0$ (else $y_4 = 0$ too) and $y_4 = ty_2$. (B2) If $x_1 = 0$, put $\epsilon = 1$ (admissible, as $\bar{\Psi} = 1$ on D_ℓ) and $t = 0$; then $x_3 \ne 0$, $y_2 = 0$, $F_1 = k_V e_3$, $F_2 = \mathrm{span}(e_3, e_4)$ and $F_3 = e_3^\perp = \mathrm{span}(e_1, e_3, e_4)$.

Let w be the identity matrix if $\epsilon = 0$, and for $\epsilon = 1$ the permutation matrix with $we_i = e_{\lambda_1(i)}$ ($e_1 \mapsto e_3$, $e_2 \mapsto e_4$, $e_3 \mapsto e_1$, $e_4 \mapsto e_2$); it has similitude ± 1, is block lower triangular, and $w^{-1}\mathrm{diag}(d_1, \dots, d_4)w = \mathrm{diag}(d_{\lambda_\epsilon(1)}, \dots, d_{\lambda_\epsilon(4)})$. Put $\bar{n}_0 = 1 + t(E_{31} + E_{42})$, lower unitriangular

of similitude 1 (its entries satisfy $y_{43} = -y_{21}$, $y_{42} = y_{31} - y_{21}y_{32}$). *Claim:* $w^{-1}\bar{u} = \bar{n}_0\bar{b}_0$ *with* $\bar{b}_0$ *upper triangular and invertible.* In (A) and (B2), $w^{-1}F_j = \mathrm{span}(e_1, \dots, e_j)$ for all j (in (B2): $w^{-1}e_3 = e_1$, $w^{-1}e_4 = e_2$, $w^{-1}e_1 = e_3$), so $w^{-1}\bar{u}$ is upper triangular. In (B1), the flag of the columns of $\bar{n}_0$ is $\langle e_1 + te_3\rangle = F_1$, then $F_1 + \langle e_2 + te_4\rangle = F_2$, then $F_1^{\perp} = F_3$ ($\bar{n}_0$ is symplectic); so $\bar{n}_0^{-1}\bar{u}$ stabilises the standard flag, i.e. is upper triangular.

Step 2: diagonalising at $g_\circ$. Let $g_\circ$ be as in the statement, so the residues $\overline{a(\kappa_i(g_\circ))}$ are pairwise distinct (κ^ϵ is a permutation of κ), and let $X = r(g_\circ)$, of similitude $\nu = a(\theta(g_\circ))$. Let Λ, j be as in (Ot1) and L_0 the fraction field of $j(\Lambda)$. $V \cap L_0$ is a valuation ring of L_0 containing the discrete valuation ring $j(\Lambda)$ and not the inverse of j of a uniformiser (j is local), so $V \cap L_0 = j(\Lambda)$. The characteristic polynomial of X has coefficients in $j(\Lambda)$ and splits in the algebraically closed K; its roots are integral over V, hence lie in V, and their residues are the $\overline{a(\kappa_i(g_\circ))}$; number them $\lambda_1, \dots, \lambda_4$ accordingly (pairwise distinct). Let $L' = L_0(\lambda_1, \dots, \lambda_4)$, finite over L_0, and $\Lambda' = V \cap L'$: the valuation ring of the unique extension to L' of the valuation of the complete discrete valuation ring $j(\Lambda)$, a complete discrete valuation ring with finite residue field; let $j' \colon \Lambda' \to V$ be the inclusion (injective, local). The matrix $X - \lambda_i$ reduces to $\mathrm{diag}(\overline{\lambda_k} - \overline{\lambda_i})_k$, so the i-th column of its adjugate lies in its kernel (as $\det(X - \lambda_i) = 0$) and has i-th coordinate $\equiv \prod_{k \neq i}(\overline{\lambda_k} - \overline{\lambda_i}) \neq 0$; dividing by that coordinate gives an eigenvector $p_i \in \Lambda'^4$, $p_i \equiv e_i$. Since $\langle Xp_i, Xp_k\rangle = \nu\langle p_i, p_k\rangle$, $\langle p_i, p_k\rangle = 0$ unless $\lambda_i\lambda_k = \nu$, which residually happens only for $\{i,k\} = \{1,4\}, \{2,3\}$ ($\kappa_1\kappa_4 = \kappa_2\kappa_3 = \theta$ and the residues are distinct); $\langle p_1, p_4\rangle \equiv 1$, $\langle p_2, p_3\rangle \equiv 1$ are units, and replacing p_4, p_3 by $p_4/\langle p_1, p_4\rangle$, $p_3/\langle p_2, p_3\rangle$ we get $P = (p_1, \dots, p_4) \in \mathrm{GL}_4(\Lambda')$ with ${}^tPJ_4P = J_4$ and $P \equiv 1$. Put $h = Pw \in \mathrm{GL}_4(\Lambda')$ (a similitude) and $r^\natural = h^{-1}rh$. If X is block lower triangular, so is P: for $i \in \{2,4\}$, write $p_i = (p', p'')$ in the coordinates $\{1,3\}$, $\{2,4\}$; the $\{1,3\}$-block A of X has eigenvalues with residues $\overline{\lambda_1}, \overline{\lambda_3} \neq \overline{\lambda_i}$, so $A - \lambda_i$ is invertible and $(A - \lambda_i)p' = 0$ gives $p' = 0$.

Step 3: (Nz1), (Nz2). The entries of $r^\natural(g)$ are Λ'-linear combinations of those of $r(g)$ with fixed coefficients, so they lie in $j'(\Lambda')$ and are $\mathfrak{m}_{\Lambda'}$-adically continuous in g (Λ' is finite over $j(\Lambda)$); every element of K is algebraic over $j'(\Lambda') \supseteq j(\Lambda)$. Conjugation by the similitude h preserves similitudes and the identity, so $r^\natural(g)$ has similitude $a(\theta(g))$ and the vanishing conditions of (Ot3) pass to $r^\natural$. Modulo $\mathfrak{m}_V$, $r^\natural(g) \equiv w^{-1}\mathrm{diag}(c_i(g))w = \mathrm{diag}(\overline{a(\kappa_i^\epsilon(g))})$; and $r^\natural(g_\circ) = w^{-1}\mathrm{diag}(\lambda_1, \dots, \lambda_4)w$ is diagonal.

Step 4: (Nz3). Let $m = h^{-1}u \in \mathrm{GL}_4(\Lambda')$ (the entries of u lie in $j(\Lambda)$ by (Ot1), h^{-1} has entries in Λ' as $\det h$ is a unit of V lying in L'); it is a similitude, and $\bar{m} = w^{-1}\bar{u} = \bar{n}_0\bar{b}_0$ (Step 1; $\bar{P} = 1$). For lower unitriangular n_1 and upper triangular b_1 the leading $k \times k$ block of n_1b_1 is the product of the leading blocks, so the leading principal minors of $\bar{m}$ are those of $\bar{b}_0$, all non-zero; hence those of m are units of Λ', and Gaussian elimination without pivoting gives $m = nb$ with n lower triangular with diagonal 1 and b upper triangular, both in $\mathrm{GL}_4(\Lambda')$; by uniqueness of this factorisation over k_V, $\bar{n} = \bar{n}_0$, so $n_{ik} \in \mathfrak{m}_V$ for $i > k$ except at $(3,1), (4,2)$, the places of weight $-w_\Psi$. *n has similitude* 1. Let $\tau(Y) = J_4^{-1}\,{}^tY^{-1}J_4$, an automorphism of $\mathrm{GL}_4(K)$; for a similitude Y of multiplier μ, ${}^tYJ_4Y = \mu J_4$ gives $\tau(Y) = \mu^{-1}Y$. Since $(J_4^{-1}ZJ_4)_{ab} = \pm Z_{5-a,5-b}$ with sign $+$ on the diagonal, τ maps lower unitriangular matrices to lower unitriangular ones and upper triangular to upper triangular. From $\tau(n)\tau(b) = \tau(m) = \mu^{-1}m = n(\mu^{-1}b)$ and uniqueness, $\tau(n) = n$, i.e. ${}^tnJ_4n = J_4$. *The flag.* For $s \in D_\ell$, $n^{-1}r^\natural(s)n = b\,(m^{-1}r^\natural(s)m)\,b^{-1} = b\,(u^{-1}r(s)u)\,b^{-1}$ is upper triangular with the diagonal entries $\psi_i(s) = d_i(s)$ of (Ot4): $\psi_i(s) = a(\kappa_i(s))$ for $s \in I_\ell$, and $\psi_i(s) \equiv a(\kappa_i(s)) \equiv a(\kappa_i^\epsilon(s))$ modulo $\mathfrak{m}_V$ for $s \in D_\ell$, the second congruence being trivial for $\epsilon = 0$ and, for $\epsilon = 1$, a consequence of $\bar{\Psi} = 1$ on D_ℓ: $(\kappa_i^1) = (\alpha, \mathbf{1}, \theta, \Psi)$ and $(\kappa_i) = (\theta, \Psi, \alpha, \mathbf{1})$ agree residually on D_ℓ as $\bar{\theta} = \bar{\Psi}\bar{\alpha}$.

Step 5: (Nz4). If r is irreducible, the K-span of $r^\natural(G_\mathbb{Q})$ is $h^{-1}\mathrm{M}_4(K)h = \mathrm{M}_4(K)$, so no entry vanishes identically (each entry is a non-zero linear functional on $\mathrm{M}_4(K)$); in particular

$r^\natural$ has entries of weights w_Ψ (place $(1,3)$), $-w_\Psi$ ($(3,1)$) and w_β ($(2,3)$). Let r be a non-split block extension: every $r(g)$ is block lower triangular, in particular X, so P, w, h, h^{-1} and every $r^\natural(g)$ are block lower triangular. For block lower triangular Y, Z the $\{2,4\}$-block of YZ is the product of the $\{2,4\}$-blocks; so the $\{2,4\}$-block of $r^\natural(g)$ is $h_{\mathrm{B}}^{-1} r(g)_{\mathrm{B}} h_{\mathrm{B}}$ with h_{B} the (invertible) $\{2,4\}$-block of h, and these span $\mathrm{M}_2(K)$: the entries $(2,4)$ (weight w_Ψ) and $(4,2)$ (weight $-w_\Psi$) of $r^\natural$ are active. The places (i,k) with $i \in \{2,4\}$, $k \in \{1,3\}$ have weights $-w_\alpha$ ($(2,1),(4,3)$), w_β ($(2,3)$), $-w_\theta$ ($(4,1)$). If none of them were active in $r^\natural$, every $r^\natural(g)$ would be block diagonal. Write $h = h_{\mathrm{D}} + h_{\mathrm{L}}$ with h_{D} block diagonal (invertible) and h_{L} supported at the places $i \in \{2,4\}$, $k \in \{1,3\}$, and $Y = h_{\mathrm{L}} h_{\mathrm{D}}^{-1}$, supported at the same places; then $Y^2 = 0$, $h = (1+Y)h_{\mathrm{D}}$ and $(1-Y)r(g)(1+Y) = h_{\mathrm{D}} r^\natural(g) h_{\mathrm{D}}^{-1}$ is block diagonal for every g, contrary to clause (iii) of non-split block extensions. So $r^\natural$ has an entry of one of the weights $w_\beta, -w_\alpha, -w_\theta$. □

Proposition 52.4. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, (K,V,a) a test field with maximal ideal $\mathfrak{m}_V$, residue field k_V and reduction $x \mapsto \bar{x}$, ϵ an admissible labelling, and $g_\circ \in G_{\mathbb{Q}}$ such that the $\overline{a(\kappa_i^\epsilon(g_\circ))}$, $1 \le i \le 4$, are pairwise distinct. Let $r^\natural \colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ be a homomorphism and $n \in \mathrm{GL}_4(V)$ such that:*

- *there are a complete discrete valuation ring Λ with finite residue field and an injective local homomorphism $j \colon \Lambda \to V$ such that the entries of n and of every $r^\natural(g)$ lie in $j(\Lambda)$ and $g \mapsto j^{-1}(r^\natural(g)_{ik})$ is $\mathfrak{m}_\Lambda$-adically continuous for all i,k;*
- *$r^\natural(g)$ has similitude $a(\theta(g))$ and $r^\natural(g) - \mathrm{diag}(a(\kappa_i^\epsilon(g)))_i$ has entries in $\mathfrak{m}_V$, for all g; $r^\natural(g_\circ)$ is diagonal; $r^\natural(g) = 1$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$, $\bar{w}$ above a prime not in T;*
- *n is lower triangular with diagonal entries 1 and similitude 1, $n_{ik} \in \mathfrak{m}_V$ for $i > k$ with $\mathrm{wt}_4(i,k) \neq -w_\Psi$, and for $s \in D_\ell$ the matrix $n^{-1} r^\natural(s) n$ is upper triangular with diagonal entries $\psi_i(s)$, $\psi_i(s) - a(\kappa_i^\epsilon(s)) \in \mathfrak{m}_V$;*
- *$r^\natural$ has an entry of weight $-w_\Psi$ and an entry of at least one of the weights $w_\beta, -w_\alpha, -w_\theta$.*

Then there are $t_1, t_2 \in K^\times$ such that, with $\mathrm{T} = \mathrm{T}_4(t_1,t_2)$, $r' = \mathrm{T} r^\natural \mathrm{T}^{-1}$ and $n' = \mathrm{T} n \mathrm{T}^{-1}$:

(Ql0) *there are a complete discrete valuation ring Λ' with finite residue field and an injective local homomorphism $j' \colon \Lambda' \to V$ such that the entries of n' and of every $r'(g)$ lie in $j'(\Lambda')$ and $g \mapsto j'^{-1}(r'(g)_{ik})$ is $\mathfrak{m}_{\Lambda'}$-adically continuous; $r'(g)$ has similitude $a(\theta(g))$ and diagonal entries $r^\natural(g)_{ii}$; $r'(g_\circ)$ is diagonal; $r'(g) = 1$ whenever $r^\natural(g) = 1$; n' is lower triangular with diagonal entries 1 and similitude 1; and $n'^{-1} r'(s) n'$ is upper triangular with diagonal entries $\psi_i(s)$ for $s \in D_\ell$.*

Let $c(g) = \overline{r'(g)}$ and $\bar{n} = \overline{n'}$ (entrywise). Then:

(Ql1) *c is supported in Σ_P and $\bar{n}$ is supported in Σ_Q;*

(Ql2) *c has an entry of weight w_β;*

(Ql3) *either c has an entry of weight $-w_\Psi$, or c is supported in Σ_V, $\bar{n}_{31} \neq 0$, $\bar{\Psi}(s) = 1$ for all $s \in D_\ell$, and there is no $m \in k_V$ with $c(s)_{23} = m(\overline{a(\kappa_3^\epsilon(s))} - \overline{a(\kappa_2^\epsilon(s))})$ for all $s \in D_\ell$.*

Proof. Step 1: the data of the vertex lemma. As j is injective and local, $j^{-1}(\mathfrak{m}_V) = \mathfrak{m}_\Lambda$. For a root w let E_w be the set of $j^{-1}(r^\natural(g)_{ik})$, $g \in G_{\mathbb{Q}}$, $i \neq k$ with $\mathrm{wt}_4(i,k) = w$; by the congruence, $E_w \subseteq \mathfrak{m}_\Lambda$. Put $n_{-w_\alpha} = j^{-1}(n_{21})$, $n_{-w_\beta} = j^{-1}(n_{32})$, $n_{-w_\Psi} = j^{-1}(n_{31})$, $n_{-w_\theta} = j^{-1}(n_{41})$; they lie in $\mathfrak{m}_\Lambda$ except possibly n_{-w_Ψ}. By the last hypothesis, E_{-w_Ψ} and some E_w with $w \in \Sigma_V =$

$\{w_\beta, -w_\alpha, -w_\theta\}$ contain non-zero elements. Lemma 52.5 gives $p \in K$ with $p^2 = j(\varpi)$ (ϖ a uniformiser of Λ) and integers A, B such that $t = (t_1, t_2) = (p^A, p^B)$ satisfies (Tv1) and (Tv2).

Step 2: the lower unipotent symplectic matrices. By Lemma 52.7, a lower triangular matrix y with diagonal entries 1 has similitude 1 if and only if $y_{43} = -y_{21}$ and $y_{42} = y_{31} - y_{21}y_{32}$.

Step 3: (Ql0). Let $\Lambda' = \Lambda[X]/(X^2 - \varpi)$, a complete discrete valuation ring with uniformiser the class π' of X and the same finite residue field ($X^2 - \varpi$ is Eisenstein), and $j'\colon \Lambda' \to K$ the extension of j with $j'(\pi') = p$; it is injective ($X^2 - \varpi$ is irreducible over the fraction field of Λ, and j is injective), and $j'(\Lambda') \subseteq V$ is local because $p \in V$ has positive valuation ($2v(p) = v(j(\varpi)) > 0$). For $y \in j(\Lambda)$ non-zero and an integer e, $p^e y$ lies in V if and only if it lies in $j'(\Lambda')$: both say that its valuation, a multiple of $v(p)$, is ≥ 0. The off-diagonal entries of $r'(g)$ are $t^{\mathrm{wt}_4(i,k)} r^\natural(g)_{ik}$, in V by (Tv1); its diagonal entries are those of $r^\natural(g)$. The entries $n'_{21}, n'_{32}, n'_{31}, n'_{41}$ are $t^w j(n_w)$, in V by (Tv1); n' is lower triangular with diagonal 1 and similitude 1 (T has similitude $t_1 t_2$, and conjugation by a similitude preserves similitudes), so by Step 2 $n'_{43} = -n'_{21}$ and $n'_{42} = n'_{31} - n'_{21}n'_{32}$ lie in V too. So all these entries lie in $j'(\Lambda')$. Continuity holds because $\mathfrak{m}_\Lambda \Lambda' = \mathfrak{m}_{\Lambda'}^2$ and multiplication by the fixed element p^e is continuous. The remaining clauses of (Ql0) are preserved by conjugation with the diagonal matrix T: similitudes, diagonal entries, diagonality of $r'(g_\circ)$, $r'(g) = 1$ where $r^\natural(g) = 1$, lower unitriangularity, and $n'^{-1} r'(s) n' = \mathrm{T}(n^{-1} r^\natural(s) n)\mathrm{T}^{-1}$ is upper triangular with the same diagonal.

Step 4: the residual pair and its tight set. $c\colon G_\mathbb{Q} \to \mathrm{M}_4(k_V)$ is a homomorphism of monoids, locally constant by (Ql0), with $c(g)_{ii} = \bar{a}(\kappa_i^\epsilon(g))$ where $\bar{a}$ is a followed by reduction ($\bar{a}(\mathfrak{m}_\mathcal{O}) = 0$ because $a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$), $c(g_\circ)$ diagonal, $c(g) = 1$ on the inertia elements of the hypothesis. Write $\delta_i(s) = \bar{a}(\kappa_i^\epsilon(s))$. Let $\mathcal{S}$ be the set of roots w such that c has an entry of weight w, or $w = \mathrm{wt}_4(i,k)$ with $(i,k) \in \{(2,1),(3,2),(3,1),(4,1)\}$ and $\bar{n}_{ik} \neq 0$. Since $r'(g)_{ik} = t^w j(x)$ with $x \in E_w$, and $n'_{ik} = t^w j(n_w)$ for these four places, an element of V having non-zero residue exactly when it is a unit, $\mathcal{S} = S_t$, and by (Tv2) $\mathcal{S}$ satisfies one of (Zc1)–(Zc6). From the upper triangularity of $\bar{n}^{-1} c(s) \bar{n}$ with $(1,1)$ entry $\bar{\psi}_1(s) = \delta_1(s)$: $c(s)\bar{n}e_1 = \delta_1(s)\bar{n}e_1$, that is

$$c(s)_{i1} + c(s)_{i2}\bar{n}_{21} + c(s)_{i3}\bar{n}_{31} + c(s)_{i4}\bar{n}_{41} = \bar{n}_{i1}\,\delta_1(s) \qquad (s \in D_\ell,\ 1 \leq i \leq 4). \tag{52.2}$$

Step 5: two exclusions. (a) If $-w_\alpha \notin \mathcal{S}$, then $-w_\theta \notin \mathcal{S}$. Indeed $c_{21} = c_{43} = 0$ identically and $\bar{n}_{21} = 0$. Apply Lemma 52.6 to c and $(i,k) = (4,1)$ (weight $-w_\theta$): (Ov1) holds as $c(g)_{42}c(h)_{21} = 0 = c(g)_{43}c(h)_{31}$; (Ov2) holds with $m = \bar{n}_{41}$ by (52.2) for $i = 4$. So $c_{41} = 0$ and $\bar{n}_{41} = 0$, i.e. $-w_\theta \notin \mathcal{S}$ (its only places are $(4,1)$ in c and in $\bar{n}$). (b) If $w_\beta \notin \mathcal{S}$ and $w_\Psi \notin \mathcal{S}$, then $-w_\alpha \notin \mathcal{S}$. Indeed $c_{23} = c_{13} = c_{24} = 0$. Apply Lemma 52.6 to $(i,k) = (2,1)$: (Ov1) holds as $c(g)_{23}c(h)_{31} = 0 = c(g)_{24}c(h)_{41}$; (Ov2) holds with $m = \bar{n}_{21}$ by (52.2) for $i = 2$. So $c_{21} = 0$ and $\bar{n}_{21} = 0$. Moreover $c(g)$ has similitude $\nu = \bar{a}(\theta(g)) \neq 0$, so $c(g^{-1}) = c(g)^{-1} = \nu^{-1} J_4^{-1}\, {}^t c(g)\, J_4$, whose $(2,1)$ entry is $\nu^{-1} c(g)_{43}$; hence $c_{43} = 0$ and $-w_\alpha \notin \mathcal{S}$.

Step 6: the case (Zc1). In (Zc2), $w_\beta, w_\Psi \notin \mathcal{S} \ni -w_\alpha$, contradicting (b); in (Zc4) likewise. In (Zc3), (Zc5), (Zc6), $-w_\alpha \notin \mathcal{S} \ni -w_\theta$, contradicting (a). So (Zc1): $w_\beta, -w_\Psi \in \mathcal{S} \subseteq \Sigma_P$.

Step 7: (Ql1), (Ql2). Every non-zero off-diagonal entry of c has its weight in $\mathcal{S} \subseteq \Sigma_P$. The lower entries of $\bar{n}$ have weights $-w_\alpha$ at $(2,1),(4,3)$, $-w_\Psi$ at $(3,1),(4,2)$, $-w_\theta$ at $(4,1)$ and $-w_\beta$ at $(3,2)$; as $-w_\beta \notin \Sigma_P$, $\bar{n}_{32} = 0$, so $\bar{n}$ is supported in Σ_Q. The weight w_β is in $\mathcal{S}$ and is not the weight of a lower entry, so c has an entry of weight w_β, necessarily at $(2,3)$.

Step 8: (Ql3). Suppose c has no entry of weight $-w_\Psi$. Then c is supported in $\Sigma_P \setminus \{-w_\Psi\} = \Sigma_V$, and $-w_\Psi \in \mathcal{S}$ comes from the flag: $\bar{n}_{31} \neq 0$. In (52.2) for $i = 3$, $c_{31} = 0$ (weight $-w_\Psi$), $c_{32} = 0$ (weight $-w_\beta \notin \Sigma_P$), $c_{34} = 0$ (weight $w_\alpha \notin \Sigma_P$), so $\delta_3(s)\bar{n}_{31} = \delta_1(s)\bar{n}_{31}$ and $\delta_1 = \delta_3$ on D_ℓ. Now $\kappa_1^\epsilon(\kappa_3^\epsilon)^{-1}$ is $\theta\alpha^{-1} = \Psi$ for $\epsilon = 0$ and $\alpha\theta^{-1} = \Psi^{-1}$ for $\epsilon = 1$, and $\bar{a}$ is injective on $\mathbb{F}_\mathcal{O}$; so $\bar{\Psi} = 1$ on D_ℓ. Finally, if $c(s)_{23} = m(\delta_3(s) - \delta_2(s))$ on D_ℓ for some m, apply Lemma 52.6 to $(i,k) = (2,3)$ (weight w_β): (Ov1) holds since $c_{13} = c_{24} = 0$ (weight $w_\Psi \notin \Sigma_P$), and (Ov2) is the

assumption; so $c_{23} = 0$, contradicting (Ql2). □

Lemma 52.5. *Let Λ be a discrete valuation ring with maximal ideal $\mathfrak{m}_\Lambda$ and uniformiser ϖ, K an algebraically closed field, $V \subseteq K$ a valuation ring of K with group of units $V^\times$, and $j\colon \Lambda \to V$ an injective local ring homomorphism. For $t = (t_1, t_2) \in (K^\times)^2$ and $w = (w_1, w_2) \in \mathbb{Z}^2$ put $t^w = t_1^{w_1} t_2^{w_2}$. Let there be given, for every root w, a subset $E_w \subseteq \mathfrak{m}_\Lambda$, and for every $w \in \Sigma_M$ an element $n_w \in \Lambda$, with $n_w \in \mathfrak{m}_\Lambda$ for $w \neq -w_\Psi$. Assume that E_{-w_Ψ} contains a non-zero element and that E_w contains a non-zero element for some $w \in \Sigma_V$. Then there are $p \in K$ with $p^2 = j(\varpi)$ and integers A, B such that $t = (p^A, p^B)$ satisfies:*

(Tv1) *$t^w j(x) \in V$ for every root w and every $x \in E_w$, and $t^w j(n_w) \in V$ for every $w \in \Sigma_M$;*

(Tv2) *the set S_t of roots w such that $t^w j(x) \in V^\times$ for some $x \in E_w$, or $w \in \Sigma_M$ and $t^w j(n_w) \in V^\times$, satisfies one of*

- **(Zc1)** $w_\beta, -w_\Psi \in S_t \subseteq \Sigma_P$;
- **(Zc2)** $-w_\alpha, -w_\Psi \in S_t \subseteq \Sigma_Q$;
- **(Zc3)** $-w_\theta, -w_\Psi \in S_t \subseteq \{-w_\theta, -w_\Psi\}$;
- **(Zc4)** $-w_\alpha, -w_\beta \in S_t \subseteq \Sigma_M$;
- **(Zc5)** $-w_\theta, -w_\beta \in S_t \subseteq \{-w_\theta, -w_\Psi, -w_\beta\}$;
- **(Zc6)** $-w_\theta, w_\alpha \in S_t \subseteq \{-w_\theta, -w_\Psi, -w_\beta, w_\alpha\}$.

Proof. Step 1: valuations. Let $v\colon K^\times \to \Gamma$ be the valuation of V (with Γ totally ordered, written additively), and v_Λ the normalised valuation of Λ. As K is algebraically closed, choose $p \in K$ with $p^2 = j(\varpi)$. Since j is injective and local, $j(\varpi) \neq 0$ lies in the maximal ideal of V, so $\gamma = v(p)$ satisfies $2\gamma = v(j(\varpi)) > 0$, hence $\gamma > 0$. A non-zero $x \in \Lambda$ is $x = u\varpi^k$ with $u \in \Lambda^\times$, $k = v_\Lambda(x)$, and $j(u) \in V^\times$; so for $t = (p^A, p^B)$ and a root w,

$$v(t^w j(x)) = (w \cdot \lambda + 2k)\gamma, \qquad \lambda = (A, B). \tag{52.3}$$

As $\gamma > 0$ in a totally ordered group, $t^w j(x) \in V$ if and only if $w \cdot \lambda + 2k \geq 0$, and $t^w j(x) \in V^\times$ if and only if $w \cdot \lambda + 2k = 0$.

Step 2: the linear program. Let $\mathcal{C}$ be the set of pairs (w, k), w a root and $k \geq 0$ an integer, such that $k = v_\Lambda(x)$ for some non-zero $x \in E_w$, or $w \in \Sigma_M$, $n_w \neq 0$ and $k = v_\Lambda(n_w)$. If $(w, 0) \in \mathcal{C}$ then $w = -w_\Psi$, since $E_w \subseteq \mathfrak{m}_\Lambda$ and $n_w \in \mathfrak{m}_\Lambda$ for $w \neq -w_\Psi$. Let $\mathcal{F}$ be the set of $\lambda \in \mathbb{Z}^2$ with $w \cdot \lambda + 2k \geq 0$ for all $(w, k) \in \mathcal{C}$; $(0, 0) \in \mathcal{F}$. By hypothesis there are $(-w_\Psi, k_0) \in \mathcal{C}$ and $(w', k_1) \in \mathcal{C}$ with $w' \in \Sigma_V$. For $\lambda = (A, B) \in \mathcal{F}$ the first gives $B \leq 2k_0$; so $B^* = \max\{B : (A, B) \in \mathcal{F}\}$ exists. The second gives, according as $w' = w_\beta, -w_\alpha, -w_\theta$, $A \leq B + 2k_1$, $A \leq 2k_1$, $A \leq -B + 2k_1$; so on $\{(A, B^*) \in \mathcal{F}\}$ the integer A is bounded above by $|B^*| + 2k_1$, and $A^* = \max\{A : (A, B^*) \in \mathcal{F}\}$ exists. Put $\lambda^* = (A^*, B^*)$, $t = (p^{A^*}, p^{B^*})$ and $\phi(w, k) = w \cdot \lambda^* + 2k$. As $\lambda^* \in \mathcal{F}$, Step 1 gives (Tv1), and S_t is the set $\mathcal{T}$ of roots w with $\phi(w, k) = 0$ for some $(w, k) \in \mathcal{C}$.

Step 3: four tight directions. If $\lambda^* + (a, b) \notin \mathcal{F}$, some $(w, k) \in \mathcal{C}$ has $0 \leq \phi(w, k) < -(w_1 a + w_2 b)$. Every root has $w_1, w_2 \in \{-1, 0, 1\}$.

- $(a, b) = (1, 0)$: excluded from $\mathcal{F}$ by maximality of A^*; then $0 \leq \phi < -w_1$ forces $w_1 = -1$ and $\phi = 0$, so $\mathcal{T}$ contains one of $-w_\alpha = (-1, 0)$, $w_\beta = (-1, 1)$, $-w_\theta = (-1, -1)$.
- $(a, b) = (0, 1)$: excluded by maximality of B^*; then $w_2 = -1$, $\phi = 0$: $\mathcal{T}$ contains one of $-w_\Psi = (0, -1)$, $-w_\beta = (1, -1)$, $-w_\theta$.

- Parity. A tight root with $w_1 = -1$ gives $A^* \equiv 0$ (for $(-1,0)$) or $A^* \equiv B^*$ (for $(-1,\pm1)$) modulo 2; a tight root with $w_2 = -1$ gives $B^* \equiv 0$ or $A^* \equiv B^*$. In all four combinations $A^* \equiv B^* \pmod 2$. Hence $\phi(w,k)$ is even for $w = \pm(1,-1), \pm(1,1)$.
- $(a,b) = (-1,1)$: excluded (second coordinate $B^* + 1$); then $0 \le \phi < w_1 - w_2$. Here $w_1 - w_2 = 2$ only for $w = (1,-1)$, where ϕ is even, so $\phi = 0$; otherwise $w_1 - w_2 = 1$, $w \in \{(1,0),(0,-1)\}$ and $\phi = 0$. So $\mathcal{T}$ contains one of w_α, $-w_\Psi$, $-w_\beta$.
- $(a,b) = (1,1)$: excluded; then $0 \le \phi < -(w_1 + w_2)$, which is 2 only for $(-1,-1)$ (then ϕ even, $\phi = 0$) and 1 for $(-1,0),(0,-1)$. So $\mathcal{T}$ contains one of $-w_\alpha$, $-w_\Psi$, $-w_\theta$.

Step 4: signs. Let $w \in \mathcal{T}$ with $\phi(w,k) = 0$. If $w \ne -w_\Psi$ then $k \ge 1$ (Step 2), so $w \cdot \lambda^* = -2k < 0$; if $w = -w_\Psi$ then $-B^* = -2k \le 0$. Writing $A = A^*$, $B = B^*$: $w_\alpha \in \mathcal{T} \Rightarrow A < 0$; $-w_\alpha \in \mathcal{T} \Rightarrow A > 0$; $w_\beta \in \mathcal{T} \Rightarrow B < A$; $-w_\beta \in \mathcal{T} \Rightarrow A < B$; $w_\theta \in \mathcal{T} \Rightarrow A + B < 0$; $-w_\theta \in \mathcal{T} \Rightarrow A + B > 0$; $w_\Psi \in \mathcal{T} \Rightarrow B < 0$; $-w_\Psi \in \mathcal{T} \Rightarrow B \ge 0$. Together with the four disjunctions of Step 3 these are exactly the hypotheses (h1)–(h8), (m1)–(m4) of computer check C5, listed in Appendix B, with the letter of a root true if and only if the root lies in $\mathcal{T}$.

Step 5: the six shapes. Computer check C5 establishes, for all integers A, B, that under these hypotheses the set of true letters satisfies one of six conditions, which in terms of roots are (Zc1)–(Zc6). The reduction to finitely many cases is proved there: each hypothesis is a sign condition on one of A, B, $A - B$, $A + B$, the four lines $A = 0$, $B = 0$, $A = \pm B$ cut $\mathbb{R}^2$ into seventeen cones on which these signs are constant, and each cone meets $[-2,2]^2$ in a lattice point; so the exhaustive check over $(A,B) \in [-2,2]^2$ and all 2^8 assignments covers every integer pair (the second method there decides each assignment by exact Fourier–Motzkin elimination). Hence $S_t = \mathcal{T}$ satisfies one of (Zc1)–(Zc6), which is (Tv2). □

Lemma 52.6. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$ (maximal ideal $\mathfrak{m}_\mathcal{O}$), ϵ an admissible labelling, k a field, $\bar{a}\colon \mathcal{O} \to k$ a ring homomorphism with $\bar{a}(\mathfrak{m}_\mathcal{O}) = 0$, and $g_\circ \in G_\mathbb{Q}$ such that the $\bar{a}(\kappa_i^\epsilon(g_\circ))$, $1 \le i \le 4$, are pairwise distinct. Let $c\colon G_\mathbb{Q} \to \mathrm{M}_4(k)$ be a locally constant homomorphism of monoids such that $c(g)_{ii} = \bar{a}(\kappa_i^\epsilon(g))$ for all g and i, $c(g_\circ)$ is diagonal, and $c(g) = 1$ for every $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$ and every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a prime not in T. Let $i \ne j$ be indices such that $\mathrm{wt}_4(i,j)$ is an odd root and*

(Ov1) *$c(g)_{ix}\, c(h)_{xj} = 0$ for all $g, h \in G_\mathbb{Q}$ and all $x \notin \{i,j\}$;*

(Ov2) *there is $m \in k$ with $c(s)_{ij} = m\big(\bar{a}(\kappa_j^\epsilon(s)) - \bar{a}(\kappa_i^\epsilon(s))\big)$ for all $s \in D_\ell$.*

Then $c(g)_{ij} = 0$ for all $g \in G_\mathbb{Q}$, and $m = 0$.

Proof. Step 1: the character and the cocycle. The odd roots are the roots with non-zero first coordinate, so $\lambda_i \ne \lambda_j$. The permutation λ_ϵ preserves $\boldsymbol{\lambda}$ (λ_1 exchanges $1,3$ and $2,4$), so $a = \lambda_\epsilon(i)$, $b = \lambda_\epsilon(j)$ satisfy $\lambda_a \ne \lambda_b$, and $\gamma = \kappa_a \kappa_b^{-1} = \kappa_i^\epsilon (\kappa_j^\epsilon)^{-1}$ is one of α ($(a,b) = (1,2),(3,4)$), θ ($(1,4)$), $\beta^{-1} = \alpha\Psi^{-1}$ ($(3,2)$) or the inverse of one of these ((a,b) reversed). Since $\bar{a}$ kills $\mathfrak{m}_\mathcal{O}$, it factors as $\mathcal{O} \to \mathbb{F}_\mathcal{O} \xrightarrow{\iota} k$ with ι a field embedding; so $\bar{a} \circ \gamma = \iota \circ \bar{\gamma}$, and k is an $\mathbb{F}_\mathcal{O}$-vector space through ι. Write $\delta_x(g) = \bar{a}(\kappa_x^\epsilon(g)) \in k^\times$. By (Ov1),

$$c(gh)_{ij} = \sum_x c(g)_{ix} c(h)_{xj} = \delta_i(g)\, c(h)_{ij} + c(g)_{ij}\, \delta_j(h),$$

so $z(g) = c(g)_{ij} \delta_j(g)^{-1}$ satisfies $z(gh) = z(g) + \iota(\bar{\gamma}(g)) z(h)$. It is locally constant (c is, and δ_j takes finitely many values on the cosets of an open subgroup, $\bar{\kappa}_x$ having open kernel).

Step 2: the local conditions. (i) If $g \in I_{\bar{w}}$, $\bar{w}$ above a prime not in T, and $\bar{\theta}(g) = \bar{\Psi}(g) = \bar{\alpha}(g) = 1$, then $\bar{r}_0(g) = 1$, so $c(g) = 1$ and $z(g) = 0$. (ii) At ℓ: by (Ov2), for $s \in D_\ell$, $z(s) = m(\delta_j(s) - \delta_i(s))\delta_j(s)^{-1} = \iota(\bar{\gamma}(s))(-m) - (-m)$. (iii) At $v \in T$, $v \neq \ell$: then $v \in S_\ell(\chi)$, so the v-component of the ℓ-power order part of χ is a non-trivial character of $(\mathbb{Z}/v^e\mathbb{Z})^\times$ of ℓ-power order ($e \geq 1$), whence $\ell \mid v - 1$; χ_{cyc} is unramified at v with Frobenius value v, so $\bar{\chi}_{\mathrm{cyc}}$ is trivial on D_v. By (Sg2), $\overline{\xi\Psi^n}(\sigma_v) \neq 1$ for every n, and $\bar{\alpha} = \bar{\xi}$, $\bar{\theta} = \bar{\xi}\bar{\Psi}$, $\bar{\beta}^{-1} = \bar{\xi}\bar{\Psi}^{-1}$ (as $\bar{\chi}_{\mathrm{cyc}} = \bar{\omega}_\ell$); hence $\bar{\gamma}(\sigma_v) \neq 1$. Let $M = \mathbb{F}_{\mathcal{O}}$ with $D_v \cong G_{\mathbb{Q}_v}$ acting through $\bar{\gamma}$. Then $H^0(\mathbb{Q}_v, M) = 0$ ($\bar{\gamma}(\sigma_v) - 1$ is invertible), the Cartier dual $M^\vee$ has σ_v acting by $\bar{\gamma}(\sigma_v)^{-1}\bar{\chi}_{\mathrm{cyc}}(\sigma_v) = \bar{\gamma}(\sigma_v)^{-1} \neq 1$, so $H^0(\mathbb{Q}_v, M^\vee) = 0$ and by local duality $H^2(\mathbb{Q}_v, M) = 0$; by the local Euler characteristic formula for $v \neq \ell$, $H^1(\mathbb{Q}_v, M) = 0$ (Theorem B.29, items 2 and 4, [249]). So every continuous cocycle of D_v with values in M is a coboundary.

Step 3: $z = 0$. Let $\pi\colon k \to \mathbb{F}_{\mathcal{O}}$ be $\mathbb{F}_{\mathcal{O}}$-linear. Then $\pi \circ z$ is locally constant and $\pi(z(gh)) = \pi(z(g)) + \bar{\gamma}(g)\pi(z(h))$. By Step 2, (i) it vanishes on the inertia elements named in the definition of residual Selmer cocycles, (ii) on D_ℓ it equals $\bar{\gamma}(s)y_\ell - y_\ell$ with $y_\ell = -\pi(m)$, and (iii) for $v \in T \setminus \{\ell\}$ its restriction to D_v is a continuous cocycle with values in M, hence a coboundary. So $\pi \circ z$ is a residual Selmer cocycle for γ, and by (Sg6) $\pi(z(g)) = \bar{\gamma}(g)y_\pi - y_\pi$ for some $y_\pi \in \mathbb{F}_{\mathcal{O}}$. As $c(g_\circ)$ is diagonal, $z(g_\circ) = 0$; and $\bar{\gamma}(g_\circ) \neq 1$ because $\delta_i(g_\circ) \neq \delta_j(g_\circ)$. Hence $(\bar{\gamma}(g_\circ) - 1)y_\pi = 0$, $y_\pi = 0$ and $\pi \circ z = 0$. Since the $\mathbb{F}_{\mathcal{O}}$-linear functionals separate the points of k, $z = 0$, that is $c(g)_{ij} = 0$ for all g.

Step 4: $m = 0$. By (Ae1) of Lemma 45.27, $\bar{\kappa}_a(\sigma_\ell) \neq \bar{\kappa}_b(\sigma_\ell)$, i.e. $\delta_i(\sigma_\ell) \neq \delta_j(\sigma_\ell)$ (ι is injective). With $s = \sigma_\ell \in D_\ell$ in (Ov2) and $c(\sigma_\ell)_{ij} = 0$, $m(\delta_j(\sigma_\ell) - \delta_i(\sigma_\ell)) = 0$, so $m = 0$. □

Lemma 52.7. *Let B be a commutative ring and $y \in \mathrm{M}_4(B)$ lower triangular with diagonal entries 1. Then y has similitude 1 if and only if*

$$y_{43} = -y_{21} \qquad \text{and} \qquad y_{42} = y_{31} - y_{21}y_{32}.$$

Proof. Write $y_{21} = a$, $y_{31} = b$, $y_{32} = c$, $y_{41} = d$, $y_{42} = e$, $y_{43} = f$. As $(J_4)_{14} = (J_4)_{23} = 1$, $(J_4)_{32} = (J_4)_{41} = -1$, the rows of $J_4 y$ are the fourth row of y, the third row, minus the second and minus the first:

$$(d, e, f, 1), \quad (b, c, 1, 0), \quad (-a, -1, 0, 0), \quad (-1, 0, 0, 0).$$

The rows of ${}^t y$ are $(1, a, b, d)$, $(0, 1, c, e)$, $(0, 0, 1, f)$, $(0, 0, 0, 1)$, so

$${}^t y\, J_4\, y = \begin{pmatrix} 0 & e + ac - b & f + a & 1 \\ b - ac - e & 0 & 1 & 0 \\ -a - f & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}.$$

This equals J_4 if and only if $e + ac - b = 0$ and $f + a = 0$, which are the two identities. □

52.2 Case (II): towers, Gysin steps and links between residual pairs

This subsection constructs the towers and the steps of the chains in case (II). A fit and tame auxiliary tower of case (II) with a prescribed admissible labelling exists (Proposition 52.9); its fields are cut out by two odd quadratic characters and an abelian condition (Lemma 52.10). Along such towers the lattice can be lifted from $\mathbb{Q}$ to the tower, auxiliary primes can be killed, and residual pairs can be restricted (Proposition 52.8). The steps of a chain are of two kinds.

A Gysin step produces a residual pair with a new entry, ramified with prescribed inertial values at an auxiliary split prime (Proposition 52.11), from a cocycle that is locally trivial at a finite set of places and ramified at one auxiliary place (Lemma 52.12). A link joins two residual pairs by an affine line with a fixed core, moving the Levi part or one flag coordinate (Lemma 52.13).

Proposition 52.8. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$.*

(Ux1) *If $\mathfrak{D}$ is attached to a host character in case (II), then for every admissible labelling ϵ there is a fit and tame auxiliary tower of case (II) for $\mathfrak{D}$ with labelling ϵ.*

(Ux2) *If $\mathscr{T}$ is a fit and tame auxiliary tower and W a finite set of primes each of which splits for $\mathscr{T}$, there is a tame auxiliary tower $\mathscr{T}' \geq \mathscr{T}$ such that every $w \in W$ dies in the field of $\mathscr{T}'$.*

(Ux3) *Let $\mathscr{T}$ be a fit auxiliary tower with labelling ϵ, field F and places $\bar{v}$ ($v \in \Sigma$), (K, V, a) a test field with residue field k_V, and let $r' \colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$, $n' \in \mathrm{GL}_4(V)$ satisfy the following conditions.*

- *There are a complete discrete valuation ring Λ' with finite residue field and an injective local homomorphism $j' \colon \Lambda' \to V$ such that the entries of n' and of every $r'(g)$ lie in $j'(\Lambda')$ and are $\mathfrak{m}_{\Lambda'}$-adically continuous in g.*
- *$r'(g)$ has similitude $a(\theta(g))$ and diagonal entries congruent to $a(\kappa_i^{\epsilon}(g))$ modulo $\mathfrak{m}_V$.*
- *$r'(g_{\mathscr{T}})$ is diagonal.*
- *$r'(g) = 1$ for $g \in I_{\bar{w}}$ with $\bar{r}_0(g) = 1$, $\bar{w}$ above a prime not in T, and for $g \in I_v$ with $\chi(g) = 1$, $v \in T \setminus \{\ell\}$.*
- *n' is lower triangular with diagonal 1 and similitude 1.*
- *For $s \in D_\ell$, $n'^{-1} r'(s) n'$ is upper triangular with diagonal entries $\psi_i(s) \equiv a(\kappa_i^{\epsilon}(s))$ modulo $\mathfrak{m}_V$, and $\psi_i(s) = a(\kappa_i(s))$ for $s \in I_\ell$.*
- *The reductions of r' and n' are supported in Σ_P and Σ_Q respectively.*

Then there are $n_v \in \mathrm{GL}_4(V)$ with entries in $j'(\Lambda')$, $v \in \Sigma$, such that $P = (r'|_{G_F}, (n_v)_v)$ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in V (for a), $\psi^P_{v,i}(s) = a(\kappa_i(s))$ for $s \in I_v$, the reduction of P is a residual pair over $(\mathscr{T}, \emptyset)$ with values in k_V whose flags are supported in Σ_Q, and for every $v \in \Sigma$ there is $g_v \in G_{\mathbb{Q}}$ with $g_v(\bar{\ell}) = \bar{v}$ such that $n_v^{-1} r'(g_v) n'$ is upper triangular.

(Ux4) *Let $\mathscr{T}_0 \leq \mathscr{T}$ be fit auxiliary towers, W a finite set of primes each of which splits for $\mathscr{T}_0$ and dies in the field of $\mathscr{T}$, k a field and $\bar{a} \colon \mathcal{O} \to k$ a ring homomorphism with $\bar{a}(\mathfrak{m}_{\mathcal{O}}) = 0$. For every residual pair s over $(\mathscr{T}_0, W)$ with values in k whose first component is supported in Σ_Q, there is a residual pair over $(\mathscr{T}, \emptyset)$ with values in k lying over s.*

Proof. (Ux1) is Proposition 52.9.

(Ux2). Let $w \in W$. As w splits for $\mathscr{T}$, $D_{\bar{w}} \subseteq \ker \omega_\ell$ for a place $\bar{w}$ above w, so $w \neq \ell$ (ω_ℓ is non-trivial on $I_{\bar{\ell}}$) and $w \equiv 1 \pmod{\ell}$ (the Frobenius at w acts on μ_ℓ by w); in particular w is odd. Let K_w be the subfield of degree ℓ of $\mathbb{Q}(\mu_w)$: cyclic of degree ℓ, totally real (ℓ is odd), totally ramified at w and unramified elsewhere. By the Kronecker–Weber theorem, the fixed field of the kernel of a non-trivial continuous homomorphism $G_{\mathbb{Q}} \to \mathbb{Z}/\ell\mathbb{Z}$ that is trivial on all inertia groups at places not above w is a cyclic field of degree ℓ unramified outside w, hence contained in some $\mathbb{Q}(\mu_{w^n})$; as $\ell \neq w$, the only subfield of degree ℓ of $\mathbb{Q}(\mu_{w^n})$ (Galois group $(\mathbb{Z}/w^n)^\times$,

cyclic) is K_w. So w dies in every field containing K_w. Let F' be the compositum of F and the K_w, $w \in W$: totally real, abelian over $\mathbb{Q}$, and $\mathrm{Gal}(F'/F)$ is an elementary abelian ℓ-group, so $g^\ell \in G_{F'}$ for $g \in G_F$; put $g_{\mathscr{T}'} = g^\ell_{\mathscr{T}}$, and keep ϵ and E. Every $G_{F'}$-orbit of places above ℓ contains a place inducing the same place of E as $\bar\ell$: it is $G_{F'}g\bar v$ for some $v \in \Sigma$ and $g \in G_F$; the place $g\bar v$ induces $g|_E$ of the place induced by $\bar v$, which is that of $\bar\ell$; if $g|_E \neq \mathrm{id}$, take $h \in G_{F'}$ with $h|_E \neq \mathrm{id}$ (it exists: F' is totally real and E imaginary), so $hg|_E = \mathrm{id}$ and $hg\bar v$ is in the orbit. Let Σ' be the set of these orbits and $\bar v'$ such representatives. Then $\mathscr{T}' = (\epsilon, E, F', g_{\mathscr{T}'}, \Sigma', (\bar v'))$ is an auxiliary tower with $\mathscr{T} \leq \mathscr{T}'$, every $w \in W$ dies in F', and $\mathscr{T}'$ is tame: for $\bar w$ above ℓ and $g \in I_{\bar w}$, tameness of $\mathscr{T}$ gives m prime to ℓ with $g^m \in G_F$; F'/F is unramified above ℓ (each K_w is), so $g^m \in I_{\bar w} \cap G_F$ acts trivially on F'.

(Ux3). Let ψ_i be the diagonal entries of $n'^{-1}r'(s)n'$, $s \in D_\ell$; they are continuous characters of D_ℓ with values in $V^\times$ ($n'^{-1}r'(\cdot)n'$ is an upper triangular representation with continuous entries). Fix $v \in \Sigma$ and $g_v \in G_{\mathbb{Q}}$ with $g_v(\bar\ell) = \bar v$ ($G_{\mathbb{Q}}$ acts transitively on the places above ℓ); then $g_v^{-1}D_v g_v \subseteq D_\ell$ and $g_v^{-1}I_v g_v \subseteq I_\ell$. Let $Y = r'(g_v)n'$, a similitude of multiplier $\mu = a(\theta(g_v))$ with entries in $j'(\Lambda')$, and $\bar Y = X\bar n$ its reduction, $X = \overline{r'(g_v)}$ supported in Σ_P with diagonal $(\delta_i) = (\overline{a(\kappa_i^\epsilon(g_v))})$ and $\bar n = \overline{n'}$ supported in Σ_Q. The first row of X is $\delta_1 e_1^t$ (weights $w_\alpha, w_\Psi, w_\theta \notin \Sigma_P$ at $(1,2),(1,3),(1,4)$), so $\bar Y_{11} = \delta_1$, $\bar Y_{12} = 0$; $\bar Y_{22} = X_{22} + X_{23}\bar n_{32} = \delta_2$ ($X_{24} = 0$, $\bar n_{32} = 0$); $\bar Y_{32} = X_{32} + X_{33}\bar n_{32} + X_{34}\bar n_{42} = 0$ (X_{32}, X_{34} have weights $-w_\beta$, $w_\alpha \notin \Sigma_P$). The leading principal minors of $\bar Y$ are δ_1, $\delta_1\delta_2$ (the leading 2×2 block is lower triangular), $\det \bar Y_{[3],[3]} = \det \bar Y\,(\bar Y^{-1})_{44} = \bar\mu^2\bar\mu^{-1}(\bar Y^\dagger)_{44} = \bar\mu\,\delta_1$ (a similitude of multiplier μ has determinant μ^2), and $\bar\mu^2$: all non-zero. So the leading principal minors of Y are units of $j'(\Lambda')$, and $Y = n_v b_v$ with n_v lower triangular with diagonal 1 and b_v upper triangular, both with entries in $j'(\Lambda')$. As in any such factorisation, b_v has first row that of Y and $(n_v)_{i2} = (Y_{i2} - (n_v)_{i1}(b_v)_{12})/(b_v)_{22}$, so modulo $\mathfrak{m}_V$: $\overline{(n_v)_{32}} = \bar Y_{32}/\bar Y_{22} = 0$, and $\bar n_v$ is supported in Σ_Q (the only lower place of weight outside Σ_Q is $(3,2)$). *n_v has similitude* 1*:* $\tau(Z) = J_4^{-1}\,{}^tZ^{-1}J_4$ is an automorphism of $\mathrm{GL}_4(K)$ preserving lower unitriangular and upper triangular matrices ($(J_4^{-1}ZJ_4)_{ab} = \pm Z_{5-a,5-b}$, with sign $+$ on the diagonal), and $\tau(Y) = \mu^{-1}Y$; uniqueness of the factorisation gives $\tau(n_v) = n_v$. *The pair.* Put $P = (r'|_{G_F}, (n_v)_{v\in\Sigma})$. (Mq1): similitudes by hypothesis; $N = N_\emptyset$ consists of $g \in I_{\bar w} \cap G_F$ with $\bar r_0(g) = 1$, $\bar w$ not above ℓ; if $\bar w$ lies above a prime not in T, $r'(g) = 1$ by hypothesis; if above $v \in T \setminus \{\ell\}$, then $\bar w = \sigma\bar v$ for some $\sigma \in G_{\mathbb{Q}}$, $\chi(g) = 1$ by (Oq5), and $\sigma^{-1}g\sigma \in I_v$ with $\chi(\sigma^{-1}g\sigma) = 1$, so $r'(g) = r'(\sigma)r'(\sigma^{-1}g\sigma)r'(\sigma)^{-1} = 1$. (Mq2), (Mq3): by hypothesis and the above. (Mq4): for $s \in D_v$, $s' = g_v^{-1}sg_v \in D_\ell$ and $n_v^{-1}r'(s)n_v = b_v\,(n'^{-1}r'(s')n')\,b_v^{-1}$ is upper triangular with diagonal $\psi^P_{v,i}(s) = \psi_i(s')$; in particular $\psi^P_{v,i}(s) = a(\kappa_i(s))$ for $s \in I_v$. Let $s \in \mu_v$, $s^{\ell^a} \in \overline{[D_v, D_v]}$, and $D' = g_v^{-1}D_v g_v$, $I' = g_v^{-1}I_v g_v$, $s' = g_v^{-1}sg_v$. Since $D'/I' \cong \hat{\mathbb{Z}}$ is torsion-free and abelian, $s' \in I'\,\overline{[D',D']}$: $s' = tc$ with $t \in I'$, $c \in \overline{[D',D']}$. The characters ψ_i, κ_i kill c, so $\psi_i(s') = \psi_i(t) = a(\kappa_i(t)) = a(\kappa_i(s')) = a(\kappa_i(s))$. Finally $\kappa_i(s) = 1$: $\chi_{\mathrm{cyc}}(s)$ is a root of unity of ℓ-power order in $\mathbb{Z}_\ell^\times$ (ℓ odd), hence 1, so $\omega_\ell(s) = 1$; $\xi(s)$ has order prime to ℓ and dividing ℓ^a; $\chi(s) = 1$ by (Oq5) ($\chi(s)^m = 1$ with m prime to ℓ, and $\chi(s)^{\ell^a} = 1$); so $\Psi(s) = \alpha(s) = \theta(s) = 1$. So $\psi^P_{v,i} = 1$ on μ_v, and P is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in V. *Its reduction* is locally constant (continuity of the entries), satisfies (Wq1) (the diagonal of $\overline{r'(g)}$ is $\overline{a(\kappa_i^\epsilon(g))}$ by hypothesis, and $\overline{\psi^P_{v,i}(s)} = \overline{\psi_i(s')} = \overline{a(\kappa_i^\epsilon(s'))} = \overline{a(\kappa_i^\epsilon(s))}$), and (Wq2): $\overline{r'}$ is supported in Σ_P and the $\bar n_v$ in Σ_Q. Finally $n_v^{-1}r'(g_v)n' = b_v$ is upper triangular, and the entries of n_v lie in $j'(\Lambda')$.

(Ux4). Write $s = (r_s, (n_{s,v_0})_{v_0\in\Sigma_0})$, $\chi_i = \bar a \circ \chi_i^{\mathscr{T}_0}$, Σ_0, F_0 for $\mathscr{T}_0$ and Σ, F for $\mathscr{T}$. Put $r = r_s|_{G_F}$. For $v \in \Sigma$ choose $v_0 \in \Sigma_0$ and $g \in G_{F_0}$ with $g(\bar v_0) = \bar v$; $L = r_s(g)n_{s,v_0}$ is lower triangular ($r_s(g)$ is supported in $\Sigma_Q \subseteq \Sigma_M$) with diagonal $\Delta = \mathrm{diag}(\chi_i(g))$, of similitude $\bar a(\theta(g))$, as is Δ ($\chi_1\chi_4 = \chi_2\chi_3 = \bar a \circ \theta$); put $n_v = L\Delta^{-1}$: lower unitriangular of similitude 1, and $n_v^{-1}r_s(g)n_{s,v_0} = \Delta$ is upper triangular. Let $c = (r, (n_v))$. (Mq2): $g_{\mathscr{T}}$ is a power of $g_{\mathscr{T}_0}$. (Mq3): shown. (Mq4) and (Wq1): for $s_1 \in D_v$, $s_0 = g^{-1}s_1 g \in D_{v_0}$ and $n_v^{-1}r(s_1)n_v =$

$\Delta\,(n_{s,v_0}^{-1} r_s(s_0) n_{s,v_0})\,\Delta^{-1}$ is upper triangular with diagonal $\chi_i(s_0) = \chi_i(s_1)$; if $s_1 \in \mu_v$ then $s_0 \in \mu_{v_0}$ ($g^{-1}\overline{[D_v, D_v]}g \subseteq \overline{[D_{v_0}, D_{v_0}]}$), where these values are 1 by (Mq4) for s. The diagonal of r is that of r_s. (Wq2): r is supported in $\Sigma_Q \subseteq \Sigma_M$. Local constancy is inherited. (Mq1): similitudes are inherited; let $g' \in N_\emptyset$ for $\mathscr{T}$, in $I_{\bar w} \cap G_F$ with $\bar r_0(g') = 1$, $\bar w$ above a prime $q \neq \ell$. If $q \notin W$, $g' \in N_W$ for $\mathscr{T}_0$ and $r(g') = 1$. If $q \in W$: as q splits for $\mathscr{T}_0$, $D_{\bar w} \subseteq G_{F_0} \cap \ker \bar r_0$, so on $I_{\bar w}$ the matrices $r_s(h)$ are lower unitriangular, of similitude 1, supported in Σ_Q, hence of the form $1 + A$ with $A = a(E_{21} - E_{43}) + b(E_{31} + E_{42}) + eE_{41}$ (for lower unitriangular y, the first row of ${}^t y J_4 y$ is $(0,\, y_{42} + y_{21}y_{32} - y_{31},\, y_{43} + y_{21},\, 1)$, so similitude 1 forces $y_{43} = -y_{21}$ and $y_{42} = y_{31} - y_{21}y_{32}$, with $y_{32} = 0$ here); since $A^2 = (ba - ab)E_{41} = 0$ (the only non-zero products of the matrix units involved are $E_{42}E_{21} = E_{43}E_{31} = E_{41}$), $(1+A)^n = 1 + nA$, and these matrices have order 1 or ℓ in characteristic ℓ. So $r_s(I_{\bar w})$ is a finite ℓ-group (finite by local constancy); $r_s|_{I_{\bar w}}$ kills the wild inertia group (pro-q) and factors through the tame quotient $\prod_{p \neq q} \mathbb{Z}_p$, so its image is cyclic of order 1 or ℓ, and its kernel contains the kernel of every surjection $I_{\bar w} \to \mathbb{Z}/\ell\mathbb{Z}$ (all such have the same kernel). Since q dies in F and $q \equiv 1 \pmod{\ell}$ (as in (Ux2)), F contains the field K_q of (Ux2), and $I_{\bar w} \to \mathrm{Gal}(K_q/\mathbb{Q}) \cong \mathbb{Z}/\ell\mathbb{Z}$ is surjective (K_q is totally ramified at q); so r_s is trivial on $I_{\bar w} \cap G_{K_q} \supseteq I_{\bar w} \cap G_F \ni g'$. Hence c is a residual pair over $(\mathscr{T}, \emptyset)$, and it lies over s by construction. □

Proposition 52.9. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to a host character in case (II). For every admissible labelling ϵ there is a fit and tame auxiliary tower of case (II) for $\mathfrak{D}$ with labelling ϵ.*

Proof. Let $\mathfrak{D}$ be attached to $(\psi, \mathfrak{h}, t, \chi)$ in case (II) and let ϵ be admissible. Then $N = N_{\mathfrak{h}}$, $p' = m = 1$, so $\chi_{\mathrm{pr}} = \mathbf{1}$ and $\xi = \chi_{\mathrm{dy}}$ is a primitive odd character modulo $2^{n'}$, and S is the set of primes dividing $2\ell N$. From $2^{n'} \geq 2^{c_2(\chi)+6} o_\psi \ell^3 N_\psi^2$ we get $n' \geq c_2(\chi) + 6$ and $n' \geq 11$.

Step 0: facts about the characters.

(a) $\Psi = \chi\chi_{\mathrm{cyc}}^e$, ξ and ω_ℓ are unramified outside S, $\Psi(c) = 1$, $\xi(c) = \omega_\ell(c) = -1$ ((Sg1) and $\chi_{\mathrm{cyc}}(c) = -1$), and $\bar\alpha = \bar\xi$ because $\bar\chi_{\mathrm{cyc}} = \bar\omega_\ell$. ξ has 2-power order and is unramified at every odd prime (its modulus is $2^{n'}$).

(b) *Decomposition of χ.* Write $\chi'' = \chi''_\circ \chi''_\ell$ with χ''_ℓ the ℓ-component of χ'' and $\chi''_\circ$ the product of its other components, and put $\kappa_\circ = \chi''_\circ$: a character of ℓ-power order ℓ^j, unramified at ℓ and outside S, with $\kappa_\circ(c) = 1$ ($\kappa_\circ(c)^2 = 1$ and ℓ^j is odd). The ℓ-component of χ' has order prime to ℓ, so it factors through $(\mathbb{Z}/\ell\mathbb{Z})^\times$ and equals ω_ℓ^b for some b; hence $\chi' = \chi^{(\ell)}\omega_\ell^b$ with $\chi^{(\ell)}$ of order prime to ℓ, unramified at ℓ and outside S, and of even order (case (II)). So

$$\chi = \chi^{(\ell)}\,\omega_\ell^b\,\kappa_\circ\,\chi''_\ell, \qquad \bar\Psi = \overline{\chi^{(\ell)}}\,\bar\omega_\ell^{\,b+e},$$

the second because $\kappa_\circ$, χ''_ℓ have ℓ-power order. If $\chi_{\mathrm{cyc}}(g) = 1$, then g fixes μ_{ℓ^∞}, so $\omega_\ell(g) = \chi''_\ell(g) = 1$ and $\chi(g) = \chi'(g)\kappa_\circ(g)$.

(c) *An element with $\bar\Psi = -1$.* $\chi^{(\ell)}$ has even order $2k'$, so some σ has $\chi^{(\ell)}(\sigma)^{k'} \neq 1$; as its square is 1, $\chi^{(\ell)}(\sigma^{k'}) = -1$. Choose $\tau \in I_{\bar\ell}$ with $\omega_\ell(\tau) = \omega_\ell(\sigma^{k'})$; $\chi^{(\ell)}(\tau) = 1$. Then $t_0 = (\sigma^{k'}\tau^{-1})^{\ell^j}$ has $\omega_\ell(t_0) = 1$, $\kappa_\circ(t_0) = 1$, $\chi^{(\ell)}(t_0) = (-1)^{\ell^j} = -1$, hence $\bar\Psi(t_0) = -1$ by (b).

(d) *An element at 2.* Let $c' = \max(c_2(\chi), 2)$ and $y_2 \in I_{\bar 2}$ map to $1 + 2^{c'} \in \mathbb{Z}_2^\times$. The 2-component of χ has conductor $2^{c_2(\chi)}$, so $\chi(y_2) = 1$; χ_{cyc}, ω_ℓ are unramified at 2, so $\Psi(y_2) = 1$ and $\omega_\ell(y_2) = 1$; the 2-component of $\kappa_\circ$ is a character of a 2-group of odd order, so $\kappa_\circ(y_2) = 1$. As χ_{dy} is primitive, its restriction to the cyclic group $(1 + 4\mathbb{Z})/(1 + 2^{n'}\mathbb{Z})$ is injective (a

non-trivial kernel would contain $1+2^{n'-1}$, and χ_{dy} would factor modulo $2^{n'-1}$); so $\xi(y_2)$ has order $2^{n'-c'} \geq 16$, and $\bar\xi(y_2)$, of the same order, has $\bar\xi(y_2)^n \neq 1$ for $1 \leq n \leq 4$ and for every odd n.

(e) *An element at ℓ.* Let $\sigma_\ell \in D_\ell$ be the arithmetic Frobenius element of (Sg2), with $\chi_{\mathrm{cyc}}(\sigma_\ell) = 1$. Write $N = \ell^k N'$ with $\ell \nmid N'$ and $\chi = \chi_\ell \chi_\circ$ (ℓ-component and a character modulo N'). Then $\omega_\ell(\sigma_\ell) = \chi_\ell(\sigma_\ell) = 1$, $\Psi(\sigma_\ell) = \chi_\circ(\ell)$, $\xi(\sigma_\ell) = \chi_{\mathrm{dy}}(\ell)$. The order o of $\chi_\circ(\ell)$ divides the order of ℓ in $(\mathbb{Z}/N'\mathbb{Z})^\times$, so $o < N$; write $o = 2^s u$ with u odd, and put $y_\ell = \sigma_\ell^{\ell^j o} \in D_\ell$. Then $\omega_\ell(y_\ell) = \Psi(y_\ell) = \kappa_\circ(y_\ell) = 1$. Let $v = v_2(\ell^2-1) \geq 3$. We claim $n' \geq s+v+3$. Let f be the order of ℓ modulo $\mathrm{lcm}(4, \mathrm{ord}\,\vartheta)$, so $\ell^f \equiv 1 \pmod 4$ and $n_0 = n_0(\ell,\chi) = v_2(\ell^f-1) \geq 2$. If f is even, $\ell^2-1 \mid \ell^f-1$, so $2n_0 \geq 2v \geq v+3$. If f is odd, $\ell \equiv \ell^f \equiv 1 \pmod 4$, $(\ell^f-1)/(\ell-1) = \sum_{i<f} \ell^i$ is odd, so $n_0 = v_2(\ell-1) = v-1$ and $2n_0 = 2v-2 \geq v+1$. In both cases $\log_2 \ell + 2n_0 > v+2$. From $2^{n'} \geq \ell N 4^{n_0} > \ell\, 2^s 4^{n_0}$ we get $n' > s + \log_2\ell + 2n_0 > s+v+2$, which is the claim. Now $\xi(y_\ell)^4 = \chi_{\mathrm{dy}}(\ell^2)^{2^{s+1}\ell^j u}$, and $\chi_{\mathrm{dy}}(\ell^2)$ has order $2^{n'-v}$ (injectivity as in (d)); since $\ell^j u$ is odd and $n'-v > s+1$, $\xi(y_\ell)^4 \neq 1$, hence $\bar\xi(y_\ell)^4 \neq 1$.

Step 1: the real quadratic field and the subgroup. By Dirichlet's theorem choose a prime $q_0 \notin S$ with $q_0 \equiv 1 \pmod 8$ and $q_0 \equiv 1 \pmod p$ for every odd $p \in S$. Let $k_0 = \mathbb{Q}(\sqrt{q_0})$, real quadratic, with character η_0: ramified exactly at q_0, $\eta_0(c) = 1$, and every prime of S, in particular 2 and ℓ, splits in k_0, so η_0 is trivial on $D_{\bar p}$ for every place $\bar p$ above a prime of S. Fix $i_0 \in I_{\bar q_0}$ with $\eta_0(i_0) = -1$. Put $S' = S \cup \{q_0\}$ and

$$H' = \{g \in G_{\mathbb{Q}} :\ \bar\Psi(g) = \eta_0(g),\ \kappa_\circ(g) = 1\},$$

the kernel of the continuous character $g \mapsto (\bar\Psi(g)\eta_0(g), \kappa_\circ(g))$: it is open, contains the commutator subgroup, contains c ($\bar\Psi(c) = 1 = \eta_0(c)$, $\kappa_\circ(c) = 1$), and contains $I_{\bar p}$ for $p \notin S'$ (all three characters are unramified there). Apply Lemma 52.10 to $\mathfrak{D}, \epsilon, S', H'$; it gives $q_1, q_2 \notin S'$, E, F, L, J. The characters $\Psi, \xi, \omega_\ell, \kappa_\circ, \chi^{(\ell)}, \eta_0$ are unramified at q_1, q_2, so (Zf3) preserves their values. Two consequences:

(f) if $g \in G_{\mathbb{Q}}$ has $\kappa_\circ(g) = 1$ and $\bar\Psi(g) \in \{\pm 1\}$, there is $g' \in G_L$ with $\Psi(g') = \Psi(g)$, $\xi(g') = \xi(g)$, $\omega_\ell(g') = \omega_\ell(g)$: choose $a \in \{0,1\}$ with $\eta_0(g\, i_0^a) = \bar\Psi(g)$; then $g\, i_0^a \in H'$ (Ψ, $\kappa_\circ$ are unramified at q_0) and (Zf3) applies;

(g) $H' \cap D_{\bar p} \subseteq G_L$ for every place $\bar p$ above a prime of S', by (Zf1) and $G_L = H' \cap J$; and on $G_F \subseteq H'$, $\bar\Psi = \eta_0$ and $\kappa_\circ = \mathbf{1}$.

Step 2: four elements of G_L.

- $y_c \in G_L$ with $\bar\xi(y_c) = -1$, $\bar\Psi(y_c) = 1$, $\bar\omega_\ell(y_c) = -1$: (f) applied to c, by (a), (b).
- y_2 of (d) lies in H' ($\bar\Psi(y_2) = 1 = \eta_0(y_2)$ since 2 splits in k_0; $\kappa_\circ(y_2) = 1$) and in $D_{\bar 2}$, so $y_2 \in G_L$ by (g); $\bar\Psi(y_2) = 1$, $\omega_\ell(y_2) = 1$.
- $y_\Psi \in G_L$ with $\bar\Psi(y_\Psi) = -1$, $\omega_\ell(y_\Psi) = 1$, $\bar\xi(y_\Psi)^2 \neq 1$: (f) applied to t_0 of (c) gives $y' \in G_L$ with $\bar\Psi(y') = -1$, $\omega_\ell(y') = 1$; put $y_\Psi = y'$ if $\bar\xi(y')^2 \neq 1$, and $y_\Psi = y'y_2$ otherwise ($\bar\xi(y'y_2)^2 = \bar\xi(y_2)^2 \neq 1$, $\bar\Psi(y'y_2) = -1$, $\omega_\ell(y'y_2) = 1$).
- y_ℓ of (e) lies in $H' \cap D_\ell$ ($\bar\Psi(y_\ell) = 1 = \eta_0(y_\ell)$, $\kappa_\circ(y_\ell) = 1$), so $y_\ell \in G_L$ by (g).

Let $\mathscr{T} = (\epsilon, E, F, y_\Psi, \Sigma, (\bar v))$ be the auxiliary tower of (Zf4) with $g_\star = y_\Psi$; (Oq1), (Oq2) hold. Put $\varsigma = (-1)^\epsilon$. From $(\kappa_i^0) = (\theta, \Psi, \alpha, \mathbf{1})$, $(\kappa_i^1) = (\alpha, \mathbf{1}, \theta, \Psi)$ and (a): $\chi_1^{\mathscr{T}}/\chi_2^{\mathscr{T}} = \alpha$, $\chi_1^{\mathscr{T}}/\chi_3^{\mathscr{T}} = \Psi^\varsigma$, so on G_F

$$\overline{\mathrm{rt}_w} = \bar\xi^{w_1}\,\bar\Psi^{\varsigma w_2} \qquad (w = (w_1, w_2)).$$

The odd roots have w_1 odd, the roots $\pm w_\Psi$ have $w_1 = 0$, $w_2 = \pm 1$.

Step 3: the clauses. For a place $\bar w$ above p write $\bar w = h(\bar p)$; for $y \in D_{\bar p} \cap G_F$, $hyh^{-1} \in D_{\bar w} \cap G_F$ (G_F is normal) has the same character values, and likewise for inertia.

(Oq3) Let $w \in \mathbb{Z}^2$. If w_1 is even, $\overline{\mathrm{rt}_w}(y_c) = (-1)^{w_1} = 1 \neq -1 = \bar\omega_\ell(y_c)$; if w_1 is odd, $\overline{\mathrm{rt}_w}(y_2) = \bar\xi(y_2)^{w_1} \neq 1 = \bar\omega_\ell(y_2)$ by (d). For an odd root $\overline{\mathrm{rt}_w}(y_2) \neq 1$, and for $\pm w_\Psi$, $\overline{\mathrm{rt}_w}(y_\Psi) = (-1)^{\pm\varsigma} = -1 \neq 1$. For w_α and $1 \le n \le 4$, $\overline{\mathrm{rt}_{w_\alpha}}(y_2)^n = \bar\xi(y_2)^n \neq 1$ by (d).

(Oq4) Let η be as there and i the index with $\kappa_i^\epsilon = \mathbf{1}$; then $\eta = \bar\kappa_j^\epsilon$ on G_L for some j, and $\eta(y_2) = \eta(y_\Psi) = 1$ since $\omega_\ell(y_2) = \omega_\ell(y_\Psi) = 1$. But $\bar\theta(y_2) = \bar\xi(y_2)\bar\Psi(y_2) = \bar\xi(y_2) \neq 1$, $\bar\Psi(y_\Psi) = -1$, $\bar\alpha(y_2) = \bar\xi(y_2) \neq 1$; so $\kappa_j^\epsilon = \mathbf{1}$ and $\eta = 1$.

(Oq5) Let $g \in I_{\bar w} \cap G_F$, $\bar w$ not above ℓ, with $\bar r_0(g) = 1$. Then $\chi_{\mathrm{cyc}}(g) = 1$ and $\kappa_\circ(g) = 1$, so $\chi(g) = \chi^{(\ell)}(g)$ by (b), and $\overline{\chi^{(\ell)}}(g) = \bar\Psi(g) = 1$, so $\chi^{(\ell)}(g) = 1$ (order prime to ℓ). For $g \in G_F$ with $\chi_{\mathrm{cyc}}(g) = 1$, $\chi(g) = \chi'(g)$ by (b), so $\chi(g)^{m_0} = 1$ with $m_0 = \operatorname{ord}\chi'$ prime to ℓ.

(Oq6) For $g \in I_{\bar w} \cap G_F$, $\bar w$ above ℓ: $\bar\Psi(g) = \eta_0(g) = 1$ (ℓ splits in k_0), $\bar\alpha(g) = \bar\xi(g) = 1$ (ξ is unramified at ℓ), $\bar\theta = \bar\alpha\bar\Psi$; so $\bar r_0(g) = 1$.

(Oq7) $(\bar\theta, \bar\Psi, \bar\alpha, \mathbf{1})(y_\Psi) = (-x, -1, x, 1)$ with $x = \bar\xi(y_\Psi)$, $x^2 \neq 1$, $x \neq 0$: these four are pairwise distinct ($-x = x$ would give $x = 0$; the other coincidences give $x = \pm 1$ or $-1 = 1$), and λ_ϵ permutes them.

(Oq8) For $\bar w = h(\bar\ell)$ the conjugate of y_ℓ lies in $D_{\bar w} \cap G_F$, with $\bar\omega_\ell = 1$, $\overline{\mathrm{rt}_{w_\Psi}} = \bar\Psi^\varsigma = 1$ and $\overline{\mathrm{rt}_{w_\alpha}} = \bar\xi \neq 1$ ((e)).

(Uq1), (Uq2) On G_F, $\overline{\mathrm{rt}_{w_\Psi}} = \bar\Psi^\varsigma = \eta_0$ by (g); so its square is 1, it is trivial on $D_{\bar w} \cap G_F$ for $\bar w$ above ℓ (ℓ splits in k_0), and on $I_{\bar w} \cap G_F$ for every $\bar w$: away from q_0 because η_0 is unramified there, above q_0 because $\bar\Psi$ is. For $g \in G_F$, $\overline{\mathrm{rt}_{w_\Psi}}(g) = 1$ if and only if $\eta_0(g) = 1$, i.e. $g \in G_{k_0}$; and $2, \ell$ split in the real quadratic field k_0.

(Uq3) By (a).

(Uq4) $\overline{\mathrm{rt}_{w_\alpha}} = \bar\xi$; the conjugates of $y_\ell \in D_\ell \cap G_F$ and of $y_2 \in I_{\bar 2} \cap G_F$ have $\bar\xi^4 \neq 1$ by (e), (d).

So $\mathscr{T}$ is good, of case (II), and fit ($\mathfrak{D}$ is attached in case (II)). *Tame*: for $g \in I_{\bar w}$, $\bar w$ above ℓ, let $m_1 = \#\mathbb{F}_{\mathcal{O}}^\times$, prime to ℓ. Then $\bar\Psi(g^{m_1}) = 1 = \eta_0(g^{m_1})$ and $\kappa_\circ(g^{m_1}) = 1$ ($\kappa_\circ$ is unramified at ℓ), so $g^{m_1} \in H' \cap D_{\bar w} \subseteq G_L \subseteq G_F$ by (g). Hence $\mathscr{T}$ is a fit and tame auxiliary tower of case (II) with labelling ϵ. □

Lemma 52.10. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with set of primes S, ϵ an admissible labelling, $S' \supseteq S$ a finite set of primes, and $H' \subseteq G_{\mathbb{Q}}$ an open subgroup that contains the commutator subgroup of $G_{\mathbb{Q}}$, contains c, and contains $I_{\bar p}$ for every place $\bar p$ of $\overline{\mathbb{Q}}$ above a prime $p \notin S'$. Then there are primes $q_1 \neq q_2$, neither in S', and characters $\eta_1, \eta_2 \colon G_{\mathbb{Q}} \to \{\pm 1\}$ such that, with E the fixed field of $\ker\eta_1$, F the fixed field of $H' \cap \ker(\eta_1\eta_2)$, $L = FE$ and $J = \ker\eta_1 \cap \ker\eta_2$:*

(Zf1) *for $k = 1, 2$, $\eta_k(c) = -1$, η_k is trivial on $I_{\bar w}$ for every place $\bar w$ not above q_k and non-trivial on $I_{\bar w}$ for every place $\bar w$ above q_k; J contains $D_{\bar p}$ for every place $\bar p$ above a prime of S', and g^2 for every $g \in G_{\mathbb Q}$;*

(Zf2) *E is an imaginary quadratic field in which every prime of S' splits; F is a totally real number field of even degree, abelian over $\mathbb Q$; $G_F = H' \cap \ker(\eta_1\eta_2)$, $G_L = H' \cap J$, and $I_{\bar w} \cap G_F \subseteq G_L$ for every place $\bar w$ of $\overline{\mathbb Q}$;*

(Zf3) *for every $g \in H'$ there is $g' \in G_L$ with $\gamma(g') = \gamma(g)$ for every homomorphism γ from $G_{\mathbb Q}$ to an abelian group that is trivial on the inertia groups of all places above q_1 and above q_2;*

(Zf4) *for every $g_\star \in G_F$ there are a finite set Σ and places $\bar v$ ($v \in \Sigma$) of $\overline{\mathbb Q}$ above ℓ such that $(\epsilon, E, F, g_\star, \Sigma, (\bar v)_{v\in\Sigma})$ is an auxiliary tower for $\mathfrak D$ satisfying (Oq1) and (Oq2).*

Proof. Step 1: the characters, (Zf1). The congruences $q \equiv 7 \pmod 8$ and $q \equiv -1 \pmod p$ for every odd $p \in S'$ define one class modulo $8\prod_p p$ prime to the modulus. By Dirichlet's theorem choose a prime $q_1 \notin S'$ in this class, and a prime $q_2 \notin S' \cup \{q_1\}$ in the same class. Let η_k be the character of $\mathbb Q(\sqrt{-q_k})$. As $q_k \equiv 3 \pmod 4$, η_k is ramified exactly at q_k (trivial on $I_{\bar w}$ for $\bar w$ not above q_k, non-trivial on $I_{\bar w}$ for $\bar w$ above q_k; for the latter use the conjugation invariance of the abelian character η_k) and $\eta_k(c) = -1$. For odd $p \in S'$, $-q_k \equiv 1 \pmod p$ is a non-zero square, and $-q_k \equiv 1 \pmod 8$; so every $p \in S'$ splits in $\mathbb Q(\sqrt{-q_k})$, that is η_k is trivial on $D_{\bar p}$ for every place $\bar p$ above p. Both characters take values in $\{\pm1\}$, so $\eta_k(g^2) = 1$. This is (Zf1).

Step 2: the fields, (Zf2). The subgroup $H'' = H' \cap \ker(\eta_1\eta_2)$ is open and contains the commutator subgroup, so F is a finite abelian extension of $\mathbb Q$ with $G_F = H''$. The character $\eta_1\eta_2$ is non-trivial (on $I_{\bar w}$, $\bar w$ above q_1, η_1 is non-trivial and η_2 is trivial by (Zf1)), so $[G_{\mathbb Q} : \ker(\eta_1\eta_2)] = 2$ divides $[G_{\mathbb Q} : H''] = [F : \mathbb Q]$. Since $c \in H'$ and $\eta_1\eta_2(c) = (-1)^2 = 1$, $c \in G_F$; every complex conjugation is hch^{-1} with $h \in G_{\mathbb Q}$ and G_F is normal, so all complex conjugations fix F and F is totally real. $\ker\eta_1$ has index 2 and does not contain c, so $E = \mathbb Q(\sqrt{-q_1})$ is imaginary quadratic, and the primes of S' split in it by Step 1. Next $G_L = G_F \cap G_E = H' \cap \ker(\eta_1\eta_2) \cap \ker\eta_1 = H' \cap J$. Finally let $g \in I_{\bar w} \cap G_F$. If $\bar w$ is not above q_1, then $\eta_1(g) = 1$ by (Zf1). If $\bar w$ is above q_1, then $\bar w$ is not above q_2, so $\eta_2(g) = 1$ and $\eta_1(g) = (\eta_1\eta_2)(g) = 1$. In both cases $g \in G_F \cap \ker\eta_1 = G_L$.

Step 3: moving into G_L, (Zf3). For $k = 1, 2$ fix a place $\bar q_k$ above q_k and $i_k \in I_{\bar q_k}$ with $\eta_k(i_k) = -1$ (Zf1). Then $\eta_{3-k}(i_k) = 1$ by (Zf1), and $i_k \in H'$ because $q_k \notin S'$. Let $g \in H'$ and choose $a_k \in \{0, 1\}$ with $(-1)^{a_k} = \eta_k(g)$; put $g' = g\, i_1^{a_1} i_2^{a_2}$. Then $g' \in H'$ and $\eta_k(g') = \eta_k(g)(-1)^{a_k} = 1$ for $k = 1, 2$, so $g' \in H' \cap J = G_L$ by (Zf2); and for γ as in (Zf3), $\gamma(g') = \gamma(g)\gamma(i_1)^{a_1}\gamma(i_2)^{a_2} = \gamma(g)$.

Step 4: the places above ℓ, (Zf4). The places of $\overline{\mathbb Q}$ above ℓ form one $G_{\mathbb Q}$-orbit, and its G_F-orbits are the fibres of the restriction to the finitely many places of F above ℓ; let Σ be the finite set of these G_F-orbits. Since $\ell \in S \subseteq S'$ splits in E, there are exactly two places of E above ℓ, and every element of $G_{\mathbb Q} \setminus G_E$, in particular $c \in G_F$, exchanges them. For $v \in \Sigma$ pick $\bar w \in v$; put $\bar v = \bar w$ if $\bar w$ and $\bar\ell$ induce the same place of E, and $\bar v = c(\bar w)$ otherwise. In the second case $\bar v \in v$ because $c \in G_F$, and the place of E below $c(\bar w)$ is the image under c of the place below $\bar w$, i.e. the place below $\bar\ell$. A place above ℓ lies in exactly one G_F-orbit, so it is G_F-conjugate to $\bar v$ for exactly one $v \in \Sigma$. With ϵ admissible, E imaginary quadratic, F totally real and abelian over $\mathbb Q$, and $g_\star \in G_F$, the tuple $(\epsilon, E, F, g_\star, \Sigma, (\bar v)_v)$ is an auxiliary tower for $\mathfrak D$. Its field $L = FE$ is the field of the lemma; (Oq1) is the even degree and the last assertion of (Zf2), and (Oq2) holds because $S \subseteq S'$ and every prime of S' splits in E. □

Proposition 52.11. *Let $\mathfrak D$ be a symplectic Eisenstein datum with coefficient ring $\mathcal O$, $\mathscr T$ a fit auxiliary tower for $\mathfrak D$ (field F, index set Σ), k a field, $\bar a\colon \mathcal O \to k$ a ring homomorphism with $\bar a(\mathfrak m_{\mathcal O}) = 0$, and W a finite set of primes each of which splits for $\mathscr T$. All residual pairs are with*

values in k; for a residual pair $c = (r_c, (n_{c,v}))$, its $-w_\Psi$ part *is the family of the entries $r_c(g)_{31}$, $r_c(g)_{42}$ ($g \in G_F$) and $(n_{c,v})_{31}$ ($v \in \Sigma$), and its $-w_\alpha$* part *the family of the entries $r_c(g)_{21}$, $r_c(g)_{43}$ and $(n_{c,v})_{21}$.*

(Gz) *Let p, p' be residual pairs over $(\mathscr{T}, W)$ whose first components are supported in Σ_P and whose flags are supported in Σ_Q. Then there are a finite set $W' \supseteq W$ of primes, each of which splits for $\mathscr{T}$, and residual pairs s, s' over $(\mathscr{T}, W')$ such that:*

- **(Gz1)** *the first components and all flags of s and s' are supported in Σ_Q;*
- **(Gz2)** *s has the same $-w_\Psi$ part as p, and s' the same $-w_\Psi$ part as p';*
- **(Gz3)** *the first component of s has an entry of weight $-w_\alpha$;*
- **(Gz4)** *s and s' have the same $-w_\alpha$ part.*

(Yz) *Let p be a residual pair over $(\mathscr{T}, W)$ whose first component is supported in Σ_M. Then there are a finite set $W' \supseteq W$ of primes, each of which splits for $\mathscr{T}$, and a residual pair s over $(\mathscr{T}, W')$ whose first component and flags are supported in Σ_Q, which has the same $-w_\alpha$ part as p, and whose first component has an entry of weight $-w_\Psi$.*

Proof. Step 0: notation. Let ϵ be the labelling of $\mathscr{T}$ and $\chi_i = \bar{a} \circ \chi_i^{\mathscr{T}}$, characters $G_F \to k^\times$ with values in the finite field $k_0 = \bar{a}(\mathcal{O})$; put $\chi_{ij} = \chi_i/\chi_j$ and $\Delta(g) = \mathrm{diag}(\chi_1(g), \dots, \chi_4(g))$. As $\chi_1\chi_4 = \chi_2\chi_3 = \bar{a} \circ \theta$ (for $\epsilon = 0$ the frame is $(\theta, \Psi, \alpha, \mathbf{1})$, for $\epsilon = 1$ it is $(\alpha, \mathbf{1}, \theta, \Psi)$, and $\Psi\alpha = \theta$), $\Delta(g)$ has similitude $\bar{a}(\theta(g))$, and $\chi_{43} = \chi_{21}$, $\chi_{42} = \chi_{31}$, $\chi_{41} = \chi_{21}\chi_{31}$. By (Oq7), $\chi_{21}(g_{\mathscr{T}})$, $\chi_{31}(g_{\mathscr{T}})$, $\chi_{41}(g_{\mathscr{T}})$ are $\neq 1$. For $a, b, e \in k$ put

$$\mathrm{Hs}(a, b, e) = 1 + a(E_{21} - E_{43}) + b(E_{31} + E_{42}) + eE_{41}.$$

It is lower triangular with diagonal 1, supported in Σ_Q (weights $-w_\alpha$ at $(2,1), (4,3)$, $-w_\Psi$ at $(3,1), (4,2)$, $-w_\theta$ at $(4,1)$), and of similitude 1: ${}^t\mathrm{Hs}(a, b, e)\, J_4\, \mathrm{Hs}(a, b, e) = J_4$.

A direct multiplication gives

$$\begin{aligned} \mathrm{Hs}(a, b, e)\mathrm{Hs}(a', b', e') &= \mathrm{Hs}(a + a',\ b + b',\ e + e' + ba' - ab'), \\ \Delta(g)\mathrm{Hs}(a, b, e)\Delta(g)^{-1} &= \mathrm{Hs}(\chi_{21}(g)a, \chi_{31}(g)b, \chi_{41}(g)e). \end{aligned} \tag{52.4}$$

In particular $\mathrm{Hs}(a, b, e)^{-1} = \mathrm{Hs}(-a, -b, -e)$.

Step 1: pairs from cocycle data. Let W' be a finite set of primes and let $x, y, d\colon G_F \to k$ be locally constant with

$$\begin{aligned} x(gh) &= x(g) + \chi_{21}(g)x(h), \qquad y(gh) = y(g) + \chi_{31}(g)y(h), \\ d(gh) &= d(g) + \chi_{41}(g)d(h) + \chi_{21}(g)y(g)x(h) - \chi_{31}(g)x(g)y(h), \end{aligned} \tag{52.5}$$

vanishing at $g_{\mathscr{T}}$ and on $N_{W'}$, and for every $v \in \Sigma$ let $a_v, b_v, e_v \in k$ satisfy, for all $s \in D_v$,

$$x(s) = (1 - \chi_{21}(s))a_v, \quad y(s) = (1 - \chi_{31}(s))b_v, \quad d(s) = (1 - \chi_{41}(s))e_v + (\chi_{31}(s) - \chi_{21}(s))a_v b_v. \tag{52.6}$$

Assume $\chi_i(s) = 1$ for all i, v and $s \in \mu_v$. Put $r(g) = \mathrm{Hs}(x(g), y(g), d(g))\Delta(g)$ and $n_v = \mathrm{Hs}(a_v, b_v, e_v)$. *Claim: $c = (r, (n_v))$ is a residual pair over $(\mathscr{T}, W')$ with first component and flags supported in Σ_Q, with $r(g)_{21} = \chi_1(g)x(g)$, $r(g)_{31} = \chi_1(g)y(g)$, $(n_v)_{21} = a_v$, $(n_v)_{31} = b_v$.* By (52.4), $r(g)r(h) = \mathrm{Hs}(x(g), y(g), d(g))\, \mathrm{Hs}(\chi_{21}(g)x(h), \chi_{31}(g)y(h), \chi_{41}(g)d(h))\, \Delta(gh)$, which is $r(gh)$ by (52.5); and $r(1) = 1$ (the cocycle identities at $g = h = 1$ give $x(1) = y(1) = d(1) = 0$). So r is a homomorphism of monoids, locally constant, with $r(g)$ of similitude $\bar{a}(\theta(g))$, $r(g) = 1$

on $N_{W'}$ (there x, y, d vanish and $\chi_i = 1$, as $\bar{r}_0(g) = 1$), $r(g_{\mathscr{T}}) = \Delta(g_{\mathscr{T}})$ diagonal: (Mq1), (Mq2). (Mq3) holds for n_v. For $s \in D_v$, by (52.4),

$$n_v \Delta(s) n_v^{-1} \Delta(s)^{-1} = \mathrm{Hs}\big((1-\chi_{21}(s))a_v,\ (1-\chi_{31}(s))b_v,\ (1-\chi_{41}(s))e_v + (\chi_{31}(s)-\chi_{21}(s))a_v b_v\big),$$

which is $\mathrm{Hs}(x(s), y(s), d(s))$ by (52.6); hence $n_v^{-1} r(s) n_v = \Delta(s)$: upper triangular with $\psi^c_{v,i}(s) = \chi_i(s)$, equal to 1 on μ_v: (Mq4) and (Wq1). The supports are in $\Sigma_Q \subseteq \Sigma_P$ (Wq2). The entries are read off.

Step 2: two linearisations. For locally constant x, y, d with the first two identities of (52.5), put $f_+ = d + xy$ and $f_- = d - xy$. Then for all g, h

$$f_+(gh) - f_+(g) - \chi_{41}(g) f_+(h) - 2\chi_{21}(g) y(g) x(h) = \Theta(g,h),$$
$$f_-(gh) - f_-(g) - \chi_{41}(g) f_-(h) + 2\chi_{31}(g) x(g) y(h) = \Theta(g,h),$$

where $\Theta(g,h) = d(gh) - d(g) - \chi_{41}(g) d(h) - \chi_{21}(g) y(g) x(h) + \chi_{31}(g) x(g) y(h)$.

So the third identity of (52.5) holds if and only if f_+, equivalently f_-, satisfies the corresponding linear identity. Likewise, for $s \in D_v$ and given a_v, b_v with the first two identities of (52.6), and any $m_2 \in k$:

- if $f_+(s) = (\chi_{41}(s) - 1) m_2 - 2\chi_{21}(s) y(s) a_v$ for all $s \in D_v$, then the third identity of (52.6) holds with $e_v = -m_2 - a_v b_v$;
- if $f_-(s) = (\chi_{41}(s) - 1) m_2 + 2\chi_{31}(s) x(s) b_v$ for all $s \in D_v$, then it holds with $e_v = -m_2 + a_v b_v$.

Step 3: the data of the given pairs. Let $c = (r_c, (n_{c,v}))$ be a residual pair over $(\mathscr{T}, W)$. (i) If r_c is supported in Σ_P, the place $(3,1)$ is isolated ($r_{c,32} = r_{c,34} = 0$, weights $-w_\beta, w_\alpha$), so $y_c(g) = r_c(g)_{31} / \chi_1(g)$ satisfies the second identity of (52.5); it vanishes at $g_{\mathscr{T}}$ and on N_W. For $s \in D_v$, $n_{c,v}^{-1} r_c(s) n_{c,v}$ is upper triangular with $(1,1)$ entry $\chi_1(s)$ (Wq1), so $r_c(s) n_{c,v} e_1 = \chi_1(s) n_{c,v} e_1$; the third coordinate (with $r_{c,12} = r_{c,13} = r_{c,14} = r_{c,32} = r_{c,34} = 0$ on Σ_P) gives $y_c(s) = (1 - \chi_{31}(s))(n_{c,v})_{31}$. (ii) If r_c is lower triangular (support Σ_M), the place $(2,1)$ is isolated, $x_c(g) = r_c(g)_{21} / \chi_1(g)$ satisfies the first identity of (52.5), vanishes at $g_{\mathscr{T}}$ and on N_W, and the second coordinate of the same eigenvector identity gives $x_c(s) = (1 - \chi_{21}(s))(n_{c,v})_{21}$. (iii) For every residual pair, $r_c(g^{-1}) = \bar{a}(\theta(g))^{-1} J_4^{-1}\, {}^t r_c(g) J_4$, whose $(3,1)$ and $(2,1)$ entries are $-\bar{a}(\theta(g))^{-1} r_c(g)_{42}$ and $\bar{a}(\theta(g))^{-1} r_c(g)_{43}$; so the entries $(4,2)$ (resp. $(4,3)$) of r_c are determined by its entries $(3,1)$ (resp. $(2,1)$), and the $-w_\Psi$ part (resp. $-w_\alpha$ part) of c is determined by $\chi_1 y_c$ and the $(n_{c,v})_{31}$ (resp. $\chi_1 x_c$ and the $(n_{c,v})_{21}$). (iv) By (Wq1) and (Mq4), $\chi_i(s) = \psi^c_{v,i}(s) = 1$ for $s \in \mu_v$.

Step 4: the auxiliary places. Let $\mathcal{E}$ be a finite k_0-vector space with a locally constant action $\rho_{\mathcal{E}}$ of G_F, which is trivial on every $g \in N_W$, and let S_0 be the set of places of F that are archimedean or lie above ℓ, above a prime of W, or above one of the finitely many primes at which $\bar{r}_0$ is ramified. Then $\rho_{\mathcal{E}}$ is unramified outside S_0: an inertia element at a place outside S_0 lies in N_W ($\bar{r}_0$ is unramified there). The subgroup $G_F \cap \ker \rho_{\mathcal{E}} \cap \ker \bar{r}_0 \cap \ker \omega_\ell$ is open in $G_{\mathbb{Q}}$; let L' be the Galois closure over $\mathbb{Q}$ of its fixed field. Infinitely many primes split completely in L' (Chebotarev); let Q be the set of places of F above those of them that are not ℓ, not in W and unramified for $\bar{r}_0$. Then Q is infinite, $Q \cap S_0 = \emptyset$, and for every place $\bar{w}$ above a place of Q, $D_{\bar{w}} \subseteq G_{L'}$, so $\rho_{\mathcal{E}}(D_{\bar{w}}) = 1$, $\omega_\ell(D_{\bar{w}}) = 1$; and every prime below a place of Q splits for $\mathscr{T}$. Let $m_0 \in \mathcal{E} \setminus \{0\}$. Lemma 52.12 gives $S_1 \subseteq Q$ and a cocycle c_0 with (Rk1)–(Rk3). Suppose $\rho_{\mathcal{E}}(g_{\mathscr{T}}) - 1$ is invertible on $\mathcal{E}$; choose m^* with $c_0(g_{\mathscr{T}}) = \rho_{\mathcal{E}}(g_{\mathscr{T}}) m^* - m^*$ and put $c_1(g) = c_0(g) - \rho_{\mathcal{E}}(g) m^* + m^*$. Let W' be W together with the primes below the places of S_1; they all split for $\mathscr{T}$. Then: c_1 is a locally constant cocycle with $c_1(g_{\mathscr{T}}) = 0$; (Rk2) holds for

c_1 (with $m - m^*$); $c_1(g) = c_0(g) \in \mathbb{F}_\ell m_0 \setminus \{0\}$ for the g of (Rk3); and c_1 vanishes on $N_{W'}$: let $g \in N_{W'}$ lie in $I_{\bar{w}}$, $\bar{w}$ above a place v of F. Then $g \in N_W$, so $\rho_{\mathcal{E}}(g) = 1$ and the coboundary term vanishes at g; $v \notin S_1$ (the prime below v is not in W'); if $v \notin S_0$, $c_0(g) = 0$ by (Rk1); if $v \in S_0$, $c_0(g) = \rho_{\mathcal{E}}(g)m - m = 0$ by (Rk2).

Step 5: (Gz). Let $p_1 = p$, $p_2 = p'$, $y_j = y_{p_j}$ and $b_{j,v} = (n_{p_j,v})_{31}$ (Step 3 (i)). Let $Y \subseteq k$ be the k_0-span of the finitely many values of y_1, y_2 (locally constant on the compact G_F), $\mathcal{E} = k_0 \oplus Y \oplus Y$ and

$$\rho_{\mathcal{E}}(g)(t, u_1, u_2) = \big(\chi_{21}(g)t,\ \chi_{41}(g)u_1 + 2\chi_{21}(g)y_1(g)t,\ \chi_{41}(g)u_2 + 2\chi_{21}(g)y_2(g)t\big).$$

This is an action: the identity $\rho_{\mathcal{E}}(gh) = \rho_{\mathcal{E}}(g)\rho_{\mathcal{E}}(h)$ in the coordinate u_j reads $\chi_{21}(gh)y_j(gh) = \chi_{41}(g)\chi_{21}(h)y_j(h) + \chi_{21}(g)y_j(g)\chi_{21}(h)$, which is the cocycle identity of y_j times $\chi_{21}(gh)$, as $\chi_{41} = \chi_{21}\chi_{31}$. It is trivial on N_W, and $\rho_{\mathcal{E}}(g_{\mathscr{T}}) = \mathrm{diag}(\chi_{21}, \chi_{41}, \chi_{41})(g_{\mathscr{T}})$ ($y_j(g_{\mathscr{T}}) = 0$), so $\rho_{\mathcal{E}}(g_{\mathscr{T}}) - 1$ is invertible. Step 4 with $m_0 = (1, 0, 0)$ gives W' and $c_1 = (x, f_1, f_2)$. The cocycle identity of c_1 says: x satisfies the first identity of (52.5), and $f_j(gh) = f_j(g) + \chi_{41}(g)f_j(h) + 2\chi_{21}(g)y_j(g)x(h)$. Put $d_j = f_j - xy_j$: by Step 2, (x, y_j, d_j) satisfies (52.5). They vanish at $g_{\mathscr{T}}$ and on $N_{W'}$ (y_j vanishes on $N_W \supseteq N_{W'}$). For $v \in \Sigma$ the places $\bar{v}$ lie above S_0, so (Rk2) gives $m_v = (m_{v,1}, m_{v,2,1}, m_{v,2,2})$ with $c_1(s) = \rho_{\mathcal{E}}(s)m_v - m_v$ on D_v: $x(s) = (1 - \chi_{21}(s))a_v$ with $a_v = -m_{v,1}$, and $f_j(s) = (\chi_{41}(s) - 1)m_{v,2,j} - 2\chi_{21}(s)y_j(s)a_v$. With $y_j(s) = (1 - \chi_{31}(s))b_{j,v}$ (Step 3 (i)), Step 2 gives (52.6) for (x, y_j, d_j) with $(a_v, b_{j,v}, e_{j,v})$, $e_{j,v} = -m_{v,2,j} - a_v b_{j,v}$. By Step 3 (iv) and Step 1, $s_j = \big(\mathrm{Hs}(x, y_j, d_j)\Delta, (\mathrm{Hs}(a_v, b_{j,v}, e_{j,v}))_v\big)$ is a residual pair over $(\mathscr{T}, W')$ with first component and flags supported in Σ_Q: (Gz1). Its entries $(3, 1)$ are $\chi_1 y_j = r_{p_j,31}$ and its flag coordinates $(3, 1)$ are $b_{j,v}$, so by Step 3 (iii) s_j and p_j have the same $-w_\Psi$ part: (Gz2) with $(s, s') = (s_1, s_2)$. Both have $(2, 1)$ entries $\chi_1 x$ and flag coordinates $(2, 1)$ equal to a_v, so the same $-w_\alpha$ part (Step 3 (iii)): (Gz4). For the g of (Rk3), $c_1(g) = (x(g), f_1(g), f_2(g)) \in \mathbb{F}_\ell(1, 0, 0) \setminus \{0\}$, so $x(g) \neq 0$ and s_1 has the entry $\chi_1(g)x(g) \neq 0$ of weight $-w_\alpha$: (Gz3).

Step 6: (Yz). Let $x = x_p$ and $a_v = (n_{p,v})_{21}$ (Step 3 (ii)), $X \subseteq k$ the k_0-span of the values of x, $\mathcal{E} = k_0 \oplus X$ and

$$\rho_{\mathcal{E}}(g)(t, u) = \big(\chi_{31}(g)t,\ \chi_{41}(g)u - 2\chi_{31}(g)x(g)t\big),$$

an action by the same computation (now with the cocycle identity of x), trivial on N_W, with $\rho_{\mathcal{E}}(g_{\mathscr{T}}) = \mathrm{diag}(\chi_{31}, \chi_{41})(g_{\mathscr{T}})$. Step 4 with $m_0 = (1, 0)$ gives W' and $c_1 = (y, f)$: y satisfies the second identity of (52.5) and $f(gh) = f(g) + \chi_{41}(g)f(h) - 2\chi_{31}(g)x(g)y(h)$. Put $d = f + xy$; by Step 2 (with $f_- = f$), (x, y, d) satisfies (52.5), and all three vanish at $g_{\mathscr{T}}$ and on $N_{W'}$. For $v \in \Sigma$, (Rk2) gives $(m_{v,1}, m_{v,2})$ with $y(s) = (1 - \chi_{31}(s))b_v$, $b_v = -m_{v,1}$, and $f(s) = (\chi_{41}(s) - 1)m_{v,2} + 2\chi_{31}(s)x(s)b_v$; with $x(s) = (1 - \chi_{21}(s))a_v$, Step 2 gives (52.6) with $e_v = -m_{v,2} + a_v b_v$. By Step 1, $s = \big(\mathrm{Hs}(x, y, d)\Delta, (\mathrm{Hs}(a_v, b_v, e_v))_v\big)$ is a residual pair over $(\mathscr{T}, W')$ with first component and flags supported in Σ_Q; its $(2, 1)$ entries are $\chi_1 x = r_{p,21}$ and its flag coordinates $(2, 1)$ are $a_v = (n_{p,v})_{21}$, so it has the same $-w_\alpha$ part as p (Step 3 (iii)); and for the g of (Rk3), $y(g) \neq 0$, so its first component has the entry $\chi_1(g)y(g) \neq 0$ of weight $-w_\Psi$. □

Lemma 52.12. *Let F be a number field, ℓ an odd prime, $\omega_\ell\colon G_F \to \mathbb{F}_\ell^\times$ the cyclotomic character modulo ℓ, and M a finite $\mathbb{F}_\ell$-vector space with a continuous action ρ of G_F. Let S_0 be a finite set of places of F containing the archimedean places, the places above ℓ and the finite places at which ρ is ramified, and let Q be an infinite set of finite places of F not in S_0 such that for every $v \in Q$ and every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above v, $\rho(D_{\bar{w}}) = 1$ and $\omega_\ell(D_{\bar{w}}) = 1$. Then for every $m_0 \in M \setminus \{0\}$ there are a finite set $S_1 \subseteq Q$ and a continuous cocycle $c\colon G_F \to M$ (that is, $c(gh) = c(g) + \rho(g)c(h)$) such that:*

(Rk1) *$c(g) = 0$ for every g in the inertia group $I_{\bar{w}} \subseteq G_F$ of a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a finite place of F not in $S_0 \cup S_1$;*

(Rk2) *for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a place in S_0 there is $m \in M$ with $c(s) = \rho(s)m - m$ for all $s \in D_{\bar{w}}$;*

(Rk3) *there is $g \in G_F$ with $\rho(g) = 1$ and $c(g) \in \mathbb{F}_\ell m_0 \setminus \{0\}$.*

Proof. Step 1: the auxiliary places. Let $v \in Q$, $D = D_{\bar{v}}$, $I = I_{\bar{v}}$, and let p be the residue characteristic of v; $p \neq \ell$ as $v \notin S_0$. As D acts trivially on M, coboundaries vanish on D and $H^1(F_v, M) = \mathrm{Hom}_{\mathrm{cont}}(D, M)$. As D acts trivially on M and on μ_ℓ ($\omega_\ell(D) = 1$), it acts trivially on $M^\vee$; by local duality and the local Euler characteristic formula for $v \nmid \ell$ (Theorem B.29, items 2 and 4), $\#H^2(F_v, M) = \#H^0(F_v, M^\vee) = \#M$ and $\#H^1(F_v, M) = \#H^0(F_v, M)\,\#H^2(F_v, M) = \#M^2$. The kernel of the restriction $\mathrm{Hom}(D, M) \to \mathrm{Hom}(I, M)$ consists of the homomorphisms factoring through $D/I \cong \hat{\mathbb{Z}}$, which are determined by their (arbitrary) value at a Frobenius element: it has $\#M$ elements, so the image has $\#M$ elements. A continuous homomorphism from I to the elementary abelian ℓ-group M kills the wild inertia group (a pro-p group) and factors through the tame quotient, which is isomorphic to $\prod_{q \neq p} \mathbb{Z}_q$; so it factors through the quotient $\mathbb{Z}_\ell$, and $\#\mathrm{Hom}(I, M) \leq \#\mathrm{Hom}(\mathbb{Z}_\ell, M) = \#M$. Hence the restriction maps onto $\mathrm{Hom}(I, M)$, and $\mathrm{Hom}(I, \mathbb{F}_\ell m_0)$, which has exactly ℓ elements (homomorphisms through $I \to \mathbb{Z}_\ell \to \mathbb{F}_\ell$), lies in its image. Put

$$L_v = \{\phi \in H^1(F_v, M) :\ \phi(I) \subseteq \mathbb{F}_\ell m_0\}, \qquad \#L_v = \#M \cdot \ell.$$

Step 2: the size of S_1. The module M is a G_{F,S_0}-module (ρ is unramified outside S_0), and $N = \#H^1(G_{F,S_0}, M)$ is finite (Theorem B.37, item 1). Choose $n \geq 0$ with $\ell^n > N \cdot (\#M)^{1+\#S_0+[F:\mathbb{Q}]}$ and a set $S_1 \subseteq Q$ of n places (Q is infinite); $S_1 \cap S_0 = \emptyset$. Put $S = S_0 \cup S_1$ and, for finite $v \in S_0$, $L_v = 0$. Let

$$\mathrm{Sel} = \ker\Big(H^1(G_{F,S}, M) \to \bigoplus_{v \in S,\ v \nmid \infty} H^1(F_v, M)/L_v\Big).$$

Step 3: a lower bound for #Sel. We have

$$\#\mathrm{Sel} \geq \#H^1(G_{F,S}, M) / \prod_v \#(H^1(F_v, M)/L_v),$$

the product over the finite $v \in S$. By the global Euler characteristic formula,

$$\#H^1(G_{F,S}, M) = \#H^0\,\#H^2(G_{F,S}, M) \prod_{v \mid \infty} |\#M|_v / \#H^0(F_v, M) \geq \#H^2(G_{F,S}, M),$$

since $\#H^0(F_v, M) \leq \#M \leq |\#M|_v$ at archimedean v. By the exact sequence of Theorem B.37, item 3, the image of $H^2(G_{F,S}, M)$ in $\bigoplus_v H^2(F_v, M)$ has index at most $\#H^0(G_{F,S}, M^\vee) \leq \#M$, so $\#H^2(G_{F,S}, M) \geq \prod_v \#H^2(F_v, M)/\#M$. Locally, for finite $v \in S_0$,

$$\#(H^1(F_v, M)/L_v) = \#H^0(F_v, M)\,\#H^2(F_v, M)\,(\#M)^{\delta_v [F_v:\mathbb{Q}_\ell]} \leq \#H^2(F_v, M)\,(\#M)^{1+\delta_v [F_v:\mathbb{Q}_\ell]},$$

with $\delta_v = 1$ if $v \mid \ell$ and 0 otherwise (Theorem B.29, item 4); for $v \in S_1$, $\#(H^1(F_v, M)/L_v) = \#M^2/(\ell \#M) = \#H^2(F_v, M)/\ell$ (Step 1). As $\sum_{v \mid \ell} [F_v : \mathbb{Q}_\ell] = [F : \mathbb{Q}]$, and all groups are finite,

$$\#\mathrm{Sel} \ \geq\ \frac{\ell^n}{(\#M)^{1+\#S_0+[F:\mathbb{Q}]}} \ >\ N.$$

Step 4: a class ramified at S_1. Let H be the kernel of $G_{F,S} \to G_{F,S_0}$; it is the closed normal subgroup generated by the images of the inertia groups $I_{\bar{w}}$, $\bar{w}$ above S_1, and acts trivially on M.

Suppose every class $\kappa \in \mathrm{Sel}$ restricts to 0 on $I_{\bar v}$ for every $v \in S_1$. For a cocycle c representing κ, $c|_H$ is a homomorphism, and $c(\sigma h \sigma^{-1}) = c(\sigma) + \sigma c(h) - \sigma h \sigma^{-1} c(\sigma) = \sigma c(h)$ for $h \in H$; as every inertia group above a place of S_1 is conjugate to some $I_{\bar v}$, $c|_H$ vanishes on all of them, hence on H by continuity. By inflation–restriction, κ lies in the image of the injective inflation map $H^1(G_{F,S_0}, M) \to H^1(G_{F,S}, M)$, so $\#\mathrm{Sel} \le N$, contrary to Step 3. Hence there are $\kappa \in \mathrm{Sel}$ and $v \in S_1$ with $\kappa|_{I_{\bar v}} \neq 0$.

Step 5: the cocycle. Let $c\colon G_F \to M$ be the inflation of a cocycle representing κ. (Rk1): c factors through $G_{F,S}$, whose quotient map kills the inertia groups above finite places outside S. (Rk3): coboundaries vanish on $I_{\bar v}$ ($D_{\bar v}$ acts trivially), so $c|_{I_{\bar v}}$ is the non-zero homomorphism $\kappa|_{I_{\bar v}}$, which takes values in $\mathbb{F}_\ell m_0$ as $\mathrm{res}_v \kappa \in L_v$; take $g \in I_{\bar v}$ with $c(g) \neq 0$; then $\rho(g) = 1$. (Rk2): for a finite $v \in S_0$, $\mathrm{res}_v \kappa = 0$, so $c(s) = \rho(s)m - m$ on $D_{\bar v}$ for some m. Every other place above v is $\sigma\bar v$ with $\sigma \in G_F$, with $D_{\sigma\bar v} = \sigma D_{\bar v} \sigma^{-1}$, and for $t = \sigma s \sigma^{-1}$, $c(t) = c(\sigma) + \sigma(\rho(s)m - m) - \rho(t)c(\sigma) = \rho(t)m' - m'$ with $m' = \sigma m - c(\sigma)$. At an archimedean place, $D_{\bar w}$ has order at most 2, prime to ℓ, so every cocycle on it is a coboundary. □

Lemma 52.13. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ (field F, index set Σ), W a finite set of primes, k a field and $\bar a\colon \mathcal{O} \to k$ a ring homomorphism with $\bar a(\mathfrak{m}_{\mathcal{O}}) = 0$. All residual pairs below are over $(\mathscr{T}, W)$ with values in k (for $\bar a$); for a residual pair c write $c = (r_c, (n_{c,v})_{v\in\Sigma})$.*

(Rl1) *Let c, c' be residual pairs such that $r_c, r_{c'}$ are supported in Σ_P and all $n_{c,v}, n_{c',v}$ in Σ_Q, with $r_c(g)_{31} = r_{c'}(g)_{31}$ and $r_c(g)_{42} = r_{c'}(g)_{42}$ for all $g \in G_F$ and $(n_{c,v})_{31} = (n_{c',v})_{31}$ for all v. Then c and c' are linked.*

(Rl2) *Let c, c' be residual pairs such that $r_c, r_{c'}$ are supported in Σ_M, with $r_c(g)_{21} = r_{c'}(g)_{21}$ and $r_c(g)_{43} = r_{c'}(g)_{43}$ for all g and $(n_{c,v})_{21} = (n_{c',v})_{21}$ for all v. Then c and c' are linked.*

(Rl3) *For $X \in \mathrm{M}_4(k)$ let $X^\flat$ keep the diagonal entries and the entries of weight $-w_\alpha$ (places $(2,1)$, $(4,3)$) of X and replace the others by 0. If c is a residual pair with r_c supported in Σ_M, then $c^\flat = (r_c^\flat, (n_{c,v}^\flat)_v)$ is a residual pair with $r_c^\flat$ and all $n_{c,v}^\flat$ supported in $\{-w_\alpha\}$.*

(Rl4) *Let c be a residual pair with r_c and all $n_{c,v}$ supported in $\{-w_\alpha\}$, and assume $\bar a(\mathrm{rt}_{w_\Psi}(s)) = 1$ for all $v \in \Sigma$ and $s \in D_v$. Then for every family $(y_v)_{v\in\Sigma}$ in k there is a residual pair c^y with $r_{c^y} = r_c$, all $n_{c^y,v}$ supported in Σ_Q, $(n_{c^y,v})_{21} = (n_{c,v})_{21}$ and $(n_{c^y,v})_{31} = y_v$.*

Proof. Step 0: the defining identities and their weights. For $X \in \mathrm{M}_4(R)$ put $X^\dagger = J_4^{-1}\, {}^t X\, J_4$; its (a,b) entry is $\pm X_{5-b,5-a}$, and $\mathrm{wt}_4(5-b,5-a) = \mathrm{wt}_4(a,b)$ (because $\lambda_{5-i} = 1-\lambda_i$, $\mu_{5-i} = 1-\mu_i$). X has similitude $\nu \neq 0$ if and only if $X^\dagger X = \nu$. Let $c = (r, (n_v))$ with values in a commutative ring R (k or $k[X]$) with locally constant r, and $\chi_i = \bar a \circ \chi_i^{\mathscr{T}}$. Then c is a residual pair supported as stated if and only if the following hold for all $g, h \in G_F$, $v \in \Sigma$, $s \in D_v$, $u \in \mu_v$:

(I1) $r(gh) = r(g)r(h)$, $r(1) = 1$;

(I2) $r(g)^\dagger = \nu(g)\, r(g^{-1})$ with $\nu(g) = \bar a(\theta(g))$ (given (I1), this is the similitude condition);

(I3) $r(g) = 1$ for $g \in N_W$; $r(g_{\mathscr{T}})_{ab} = 0$ for $a \neq b$; $r(g)_{ii} = \chi_i(g)$;

(I4) n_v lower triangular with diagonal 1 and $n_v^\dagger n_v = 1$ (similitude 1);

(I5) $(n_v^\dagger r(s) n_v)_{ab} = 0$ for $a > b$ and $(n_v^\dagger r(s) n_v)_{ii} = \chi_i(s)$ (then $\psi = \chi_i$ on D_v, in particular $= 1$ on μ_v by (Mq4) for χ_i, which holds as it holds for the given residual pairs);

(I6) the support conditions.

(For (I5): $n_v^{-1} = n_v^\dagger$ by (I4).) Each of (I1)–(I5) is an equation among entries in which every monomial is a product of at most three entries of matrices of the pair (and constants), and every monomial contributing to the (a,b) entry of a product has weights adding up to $\mathrm{wt}_4(a,b)$, which is a root or 0.

Step 1: (Rl1) and (Rl2). Call a weight *free* if it lies in $\mathcal{F}$ and *core* otherwise, where for (Rl1) $\mathcal{F} = \{w_\beta, -w_\alpha, -w_\theta\}$ (core weights 0, $-w_\Psi$) and for (Rl2) $\mathcal{F} = \{-w_\beta, -w_\Psi, -w_\theta\}$ (core weights 0, $-w_\alpha$). By the hypotheses, c and c' have the same entries at all places of core weight (the diagonal by (Wq1); for (Rl1) $(4,2)$ of the flags because $(n_v)_{42} = (n_v)_{31} - (n_v)_{21}(n_v)_{32}$ and $(n_v)_{32} = 0$ in Σ_Q; for (Rl2) $(4,3)$ of the flags because $(n_v)_{43} = -(n_v)_{21}$; both identities hold for lower unitriangular matrices of similitude 1 by Lemma 52.7, applied over k), and all their entries outside $\mathcal{F} \cup \{\text{core}\}$ vanish. A sum of two or three free weights, plus possibly a core weight, is never a root or 0: for (Rl1) every free weight has first coordinate -1 and every core weight first coordinate 0, so such sums have first coordinate ≤ -2; for (Rl2) every free weight has second coordinate -1 and every core weight second coordinate 0, so such sums have second coordinate ≤ -2; while roots and 0 have coordinates in $\{-1,0,1\}$. Hence in (I1)–(I5) no monomial has two free factors. Let $c_X = (1-X)c + Xc'$ (entrywise, values in $k[X]$). Its core entries are constants and its free entries are of degree ≤ 1 in X, so each side of each identity (I1)–(I5) for c_X is a polynomial of degree ≤ 1 in X; it vanishes at $X=0$ and $X=1$ (identities for c and c'), hence identically. r_{c_X} is locally constant, and the supports are those of c and c' ((Wq2): Σ_P with flags in Σ_Q, resp. Σ_M). So c_X is a residual pair with values in $k[X]$ whose images under $X \mapsto 0, 1$ are c, c': they are linked.

Step 2: (Rl3). If Y, Z are lower triangular, $(YZ)^\flat = Y^\flat Z^\flat$: a monomial $Y_{ax}Z_{xb}$ has weights in $\Sigma_M \cup \{0\}$ adding up to $\mathrm{wt}_4(a,b)$; no two elements of Σ_M add up to 0 or $-w_\alpha$ (the sums are $(-2,0),(0,-1),(-1,-1),(-2,-1),(2,-2),(1,-2),(0,-2),(0,-2),(-1,-2),(-2,-2)$), so for $\mathrm{wt}_4(a,b) \in \{0, -w_\alpha\}$ the monomials of $(YZ)_{ab}$ are those with $x \in \{a,b\}$, which are the monomials of $(Y^\flat Z^\flat)_{ab}$; and for other (a,b), $(Y^\flat Z^\flat)_{ab} = 0$ since its monomials have weights in $\{0, -w_\alpha, -2w_\alpha\}$ and $-2w_\alpha$ is not a root. Also $(Y^\dagger)^\flat = (Y^\flat)^\dagger$ ($\dagger$ preserves weights). Now r_c and $n_{c,v}$ are lower triangular (support Σ_M, (Mq3)), so are $n_{c,v}^\dagger$ and products. Apply $\flat$ to (I1), (I2), (I4): they hold for $c^\flat$. (I3): $1^\flat = 1$, diagonal matrices are fixed, diagonal entries are kept. (I5): $n_{c,v}^\dagger r_c(s) n_{c,v}$ is lower and upper triangular, hence equal to $\mathrm{diag}(\chi_i(s))$; applying $\flat$, $(n_{c,v}^\flat)^\dagger r_c^\flat(s) n_{c,v}^\flat = \mathrm{diag}(\chi_i(s))$. $r_c^\flat$ is locally constant and supported in $\{-w_\alpha\} \subseteq \Sigma_M$, which is (Wq2).

Step 3: (Rl4). Fix v, write $n = n_{c,v}$, $a_v = n_{21}$; as n is supported in $\{-w_\alpha\}$ and has similitude 1, $n = 1 + a_v(E_{21} - E_{43})$ (E_{ab} the matrix units): its entries $(3,1),(3,2),(4,1)$ vanish by the support condition, and $n_{43} = -a_v$, $n_{42} = n_{31} - n_{21}n_{32} = 0$ by Lemma 52.7. Put $m = 1 + y_v(E_{31} + E_{42})$ and $n^y = nm = 1 + a_vE_{21} + y_vE_{31} + y_vE_{42} - a_vE_{43} - a_vy_vE_{41}$. It is lower triangular with diagonal 1, its entries satisfy $n^y_{43} = -n^y_{21}$ and $n^y_{42} = n^y_{31} - n^y_{21}n^y_{32}$, so it has similitude 1 by Lemma 52.7; it is supported in Σ_Q, with $n^y_{21} = a_v$, $n^y_{31} = y_v$. For $s \in D_v$, as in Step 2, $n^{-1}r_c(s)n = \mathrm{diag}(\chi_i(s)) =: \Delta$, so $(n^y)^{-1}r_c(s)n^y = m^{-1}\Delta m$. Now $\Delta m - m\Delta = y_v((\chi_3 - \chi_1)(s)E_{31} + (\chi_4 - \chi_2)(s)E_{42})$, and $\chi_1/\chi_3 = \bar{a} \circ \mathrm{rt}_{w_\Psi}$, $\chi_2/\chi_4 = \chi_1/\chi_3$ (the frame characters satisfy $\chi_1^{\mathscr{T}}\chi_4^{\mathscr{T}} = \chi_2^{\mathscr{T}}\chi_3^{\mathscr{T}}$, both equal to $\theta|_{G_F}$, as $(\kappa_1\kappa_4, \kappa_2\kappa_3) = (\theta, \Psi\alpha)$ and λ_ϵ exchanges these two pairs or fixes them), so by hypothesis m commutes with Δ and $(n^y)^{-1}r_c(s)n^y = \Delta$. Hence $c^y = (r_c, (n_v^y))$ satisfies (Mq3), (Mq4) and (Wq1); (Mq1), (Mq2), local constancy and (Wq2) concern r_c only. □

52.3 Case (III)

This subsection proves Proposition 52.14, the counterpart of Proposition 52.1 for case (III), from Proposition 52.15. The difference is that the seed pairs of case (III) lie over a residual pair ramified at an auxiliary prime (Subsection 51.2), so the chain must end at a seed pair over a given residual pair and must consist of residual pairs that are good in case (III), the condition under which Theorem 53.31 propagates modularity. The lattice pair of an essential test representation along fit towers has an integral model with good reduction (Lemma 52.16); residual pairs pass along towers with their isolated entries and flags (Lemma 52.17); and fit and tame towers of case (III) with a prescribed labelling exist (Proposition 52.18).

Proposition 52.14. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (III), $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, (K, V, a) a test field with residue field k_V of V, and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is essential. Then there are a fit and tame auxiliary tower $\mathscr{T}_0$ for $\mathfrak{D}$ of case (III) and a homomorphism $r'\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ with $r' = u'ru'^{-1}$ for some $u' \in \mathrm{GL}_4(K)$ and $r'(g)$ of similitude $a(\theta(g))$ for all g, with the following property. For every prime w that splits for $\mathscr{T}_0$ and every residual pair s over $(\mathscr{T}_0, \{w\})$ with values in k_V (for a followed by reduction) supported in Σ_M, there is a tame auxiliary tower $\mathscr{T}_1 \geq \mathscr{T}_0$ in whose field w dies such that for every deep auxiliary tower $\mathscr{T} \geq \mathscr{T}_1$ (field F, places $\bar{v}$, $v \in \Sigma$), every coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and every seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι whose image under $\mathcal{O}_1 \xrightarrow{a} V \to k_V$ lies over s, lies in A and has entries of weights $-w_\beta$ and $-w_\theta$, there is a coefficient ring $\mathcal{O}_2 \supseteq \mathcal{O}_1$ such that for every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}_2$:*

(Nq3) *there are $R \in \mathrm{CNL}_{\mathcal{O}'}$, an injective ring homomorphism $f\colon R \to V$ that restricts to a on $\mathcal{O}'$ and maps $\mathfrak{m}_R$ into $\mathfrak{m}_V$, and a marked ordinary pair P_R over $(\mathscr{T}, \emptyset)$ with values in R, continuous for $\mathfrak{m}_R$, whose reduction is a residual pair, such that $f(P_R)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{f(P_R)}(s') = a(\kappa_i(s'))$ for all $v \in \Sigma$, $1 \leq i \leq 4$ and $s' \in I_v$;*

(Nq4) *there is a chain in case (III) from the reduction of P_R to the reduction of Q modulo $\mathfrak{m}_{\mathcal{O}'}$.*

Proof. Take $\mathscr{T}_0$ and r' from Proposition 52.15. Let w, s be as in the statement and $\mathscr{T}_1$ the tower given by Proposition 52.15 for (w, s). Let $\mathscr{T} \geq \mathscr{T}_1$ be deep, $\mathcal{O}_1 \supseteq \mathcal{O}$ and Q as in the statement, and let Λ, j, a_Λ, P_Λ and a chain in case (III) $c_0, \dots, c_m$ with links $L_1, \dots, L_m$ (residual pairs with values in $k_V[X]$) be given by (Jx1), (Jx2).

Step 1: the residue field of V and the choice of $\mathcal{O}_2$. The map $\bar{a}$ kills $\mathfrak{m}_\ell$ ($a(\mathfrak{m}_\ell) \subseteq \mathfrak{m}_V$), so it induces a field embedding $\overline{\mathbb{F}}_\ell \to k_V$, which is onto because every element of V is congruent modulo $\mathfrak{m}_V$ to an element of $a(\overline{\mathbb{Z}}_\ell)$. Every c_t and every L_t is locally constant on the compact group G_F and has finitely many flags, so only finitely many elements of k_V occur as entries of the c_t and as coefficients of entries of the L_t; together with the image of the finite residue field $\mathbb{F}_\Lambda$ under $\Lambda \to V \to k_V$ they lie in $\bar{a}(\mathbb{F})$ for a finite subfield $\mathbb{F} \subset \overline{\mathbb{F}}_\ell$. Choose a coefficient ring $\mathcal{O}_2 \supseteq \mathcal{O}_1$ whose residue field contains $\mathbb{F}$ (an unramified extension), and let $\mathcal{O}' \supseteq \mathcal{O}_2$.

Step 2: (Nq3). Write $\mathcal{O}' = \sum_{i=1}^n \mathcal{O} b_i$ ($\mathcal{O}'$ is finite over $\mathcal{O}$) and let $R = j(\Lambda)[a(b_1), \dots, a(b_n)] \subseteq V$. Each $a(b_i)$ is integral over $a(\mathcal{O}) = j(a_\Lambda(\mathcal{O})) \subseteq j(\Lambda)$, so R is a finite $j(\Lambda)$-module containing $a(\mathcal{O}')$. Hence R is Noetherian and complete, and, being a domain finite over the complete local ring $j(\Lambda) \cong \Lambda$, it is local. Its maximal ideal lies in $\mathfrak{m}_V$: for $x \in \mathfrak{m}_R$ some power lies in $j(\mathfrak{m}_\Lambda)R \subseteq \mathfrak{m}_V$ ($R/\mathfrak{m}_\Lambda R$ is Artinian local, j is local), and $\mathfrak{m}_V$ is prime. So $R \cap \mathfrak{m}_V = \mathfrak{m}_R$ and $R/\mathfrak{m}_R$ embeds into k_V, with image the field generated by the images of $\mathbb{F}_\Lambda$ and of $\mathbb{F}_{\mathcal{O}'}$, which is $\bar{a}(\mathbb{F}_{\mathcal{O}'})$ by Step 1. Thus R, with structure map $a|_{\mathcal{O}'}$ (local, as units of $\mathcal{O}'$ go to units), lies in $\mathrm{CNL}_{\mathcal{O}'}$, and the inclusion $f\colon R \to V$ is injective, restricts to a on $\mathcal{O}'$ and maps $\mathfrak{m}_R$ into $\mathfrak{m}_V$. Let

$P_R = j(P_\Lambda)$, with entries in $j(\Lambda) \subseteq R$: it is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in R for $\mathcal{O} \subseteq \mathcal{O}' \to R$ (the conditions (Mq1)–(Mq4) are identities transported by j, and $j \circ a_\Lambda = a|_{\mathcal{O}}$); it is continuous for $\mathfrak{m}_R$ because $j(\mathfrak{m}_\Lambda)^k R \subseteq \mathfrak{m}_R^k$; its reduction is the image of the reduction of P_Λ under the field embedding $\mathbb{F}_\Lambda \to R/\mathfrak{m}_R$, hence a residual pair (local constancy, (Mq1)–(Mq4), (Wq1), (Wq2) are preserved by an injective ring homomorphism); and $f(P_R) = j(P_\Lambda)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{f(P_R)}(s') = a(\kappa_i(s'))$ on I_v by (Jx1).

Step 3: (Nq4). Let $\bar{a}' \colon \mathbb{F}_{\mathcal{O}'} \to k_V$ be induced by $\bar{a}$; it is injective and, by Step 1, its image contains every entry of the c_t and every coefficient of the L_t. Let c_t' and L_t' be obtained by applying $(\bar{a}')^{-1}$ entrywise (coefficientwise for L_t). Every condition in the definitions of residual pairs, of residual pairs good in case (III) (good, lying in V or in A, entries of given weights, the non-vanishing of $\bar{a}(\mathrm{rt}_{w_\alpha}(s')) - 1$ at some $s' \in D_v$), of links and of chains in case (III) is a conjunction of polynomial identities and non-vanishing conditions among entries, flags and values $\bar{a}(\kappa_i(g))$, $\bar{a}(\mathrm{rt}_w(s'))$, together with evaluation at $X = 0, 1$; the injective homomorphisms $\mathbb{F}_{\mathcal{O}'} \to k_V$ and $\mathbb{F}_{\mathcal{O}'}[X] \to k_V[X]$ commute with these evaluations and preserve and reflect identities and non-vanishing. So $c_0', \dots, c_m'$ is a chain in case (III) with values in $\mathbb{F}_{\mathcal{O}'}$ (for the reduction $\mathcal{O} \to \mathbb{F}_{\mathcal{O}'}$), with links L_t'. Its ends are the reduction of P_R (both have image under $\bar{a}'$ equal to the image of P_Λ in k_V) and the reduction of Q modulo $\mathfrak{m}_{\mathcal{O}'}$ (both have image the image of Q in k_V), by injectivity of $\bar{a}'$. This is (Nq4). □

Proposition 52.15. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, attached to a host character in case (III), $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, (K, V, a) a test field with residue field k_V and $\bar{a}$ the composite of a and reduction, and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is essential. Then there are a fit and tame auxiliary tower $\mathscr{T}_0$ for $\mathfrak{D}$ of case (III) and a homomorphism $r' \colon G_\mathbb{Q} \to \mathrm{GL}_4(V)$ with $r' = u' r u'^{-1}$ for some $u' \in \mathrm{GL}_4(K)$ and $r'(g)$ of similitude $a(\theta(g))$ for all g, with the following property. For every prime w that splits for $\mathscr{T}_0$ and every residual pair s over $(\mathscr{T}_0, \{w\})$ with values in k_V (for $\bar{a}|_{\mathcal{O}}$) supported in Σ_M, there is a tame auxiliary tower $\mathscr{T}_1 \geq \mathscr{T}_0$ in whose field w dies such that for every deep auxiliary tower $\mathscr{T} \geq \mathscr{T}_1$ (field F, places $\bar{v}$, $v \in \Sigma$), every coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ and every seed pair Q over $(\mathscr{T}, \emptyset)$ with values in $\mathcal{O}_1$ for ι whose image under $\mathcal{O}_1 \xrightarrow{\bar{a}} k_V$ lies over s, lies in A and has entries of weights $-w_\beta$ and $-w_\theta$, there are:*

(Jx1) *a complete discrete valuation ring Λ with finite residue field, an injective local homomorphism $j \colon \Lambda \to V$, a ring homomorphism $a_\Lambda \colon \mathcal{O} \to \Lambda$ with $j \circ a_\Lambda = a|_{\mathcal{O}}$, and a marked ordinary pair P_Λ over $(\mathscr{T}, \emptyset)$ with values in Λ (for a_Λ), continuous for $\mathfrak{m}_\Lambda$, whose reduction is a residual pair, such that $j(P_\Lambda)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{j(P_\Lambda)}(s') = a(\kappa_i(s'))$ for all $v \in \Sigma$, $1 \leq i \leq 4$ and $s' \in I_v$;*

(Jx2) *a chain in case (III), with values in k_V (for $\bar{a}|_{\mathcal{O}}$), from the image of P_Λ under $\Lambda \to V \to k_V$ to the image of Q under $\mathcal{O}_1 \xrightarrow{\bar{a}} k_V$.*

Proof. Step 1: labelling, first tower, lattice pair. Let ϵ be the admissible labelling given by Lemma 52.16 for (r, u), and $\mathscr{T}_0$ a fit and tame auxiliary tower of case (III) with labelling ϵ (Proposition 52.18), with field F_0 and index set Σ_0. Lemma 52.16 for $\mathscr{T}_0$ gives u', $r' = u' r u'^{-1}$ with $r'(g)$ of similitude $a(\theta(g))$, and a residual pair p_0 over $(\mathscr{T}_0, \emptyset)$ whose first component is supported in Σ_P and whose flags are supported in Σ_Q, with (Kp1), (Kp2) for every fit tower $\mathscr{T} \geq \mathscr{T}_0$. These $\mathscr{T}_0$ and r' are those of the statement.

Step 2: the Gysin pairs and the tower $\mathscr{T}_1$. Let w and s be as in the statement. (Yz) for $\mathscr{T}_0$, $W = \{w\}$ and $p = s$ (its first component is supported in Σ_M) gives a finite set $W' \supseteq \{w\}$ of primes splitting for $\mathscr{T}_0$ and a residual pair p_2 over $(\mathscr{T}_0, W')$ whose first component and flags are

supported in Σ_Q, which has the same $-w_\alpha$ part as s, and whose first component has an entry of weight $-w_\Psi$. Since $N_{W'} \subseteq N_\emptyset$ and the other conditions on a residual pair do not involve the set of primes, p_0 is also a residual pair over $(\mathscr{T}_0, W')$. (Gz) for $\mathscr{T}_0$, W', $p = p_0$ and $p' = p_2$ (first components supported in Σ_P, as $\Sigma_Q \subseteq \Sigma_P$; flags in Σ_Q) gives a finite set $W'' \supseteq W'$ of primes splitting for $\mathscr{T}_0$ and residual pairs s_3, s_4 over $(\mathscr{T}_0, W'')$ with: first components and flags supported in Σ_Q (Gz1); s_3 has the same $-w_\Psi$ part as p_0 and s_4 the same $-w_\Psi$ part as p_2 (Gz2); the first component of s_3 has an entry of weight $-w_\alpha$ (Gz3); s_3, s_4 have the same $-w_\alpha$ part (Gz4). (Ux2) for the fit and tame $\mathscr{T}_0$ and W'' gives a tame auxiliary tower $\mathscr{T}_1 \geq \mathscr{T}_0$ in whose field F_1 every prime of W'' dies, in particular w. This is the tower $\mathscr{T}_1$ of the statement.

Step 3: the pairs over a deep tower. Let $\mathscr{T} \geq \mathscr{T}_1$ be deep, with field F and places $\bar{v}$ ($v \in \Sigma$), and let $\mathcal{O}_1 \supseteq \mathcal{O}$ and Q be as in the statement. The order is transitive (immediate from its definition), so $\mathscr{T}_0 \leq \mathscr{T}$, and $\mathscr{T}$ is fit by (Xq3). Every prime of W'' dies in F, because it dies in $F_1 \subseteq F$ ($G_F \subseteq G_{F_1}$). (Kp1) for $\mathscr{T}$ is (Jx1). By (Kp2), the image $c_{\mathscr{T}}$ of P_Λ in k_V is a good residual pair over $(\mathscr{T}, \emptyset)$ lying over p_0, with first component supported in Σ_P and flags in Σ_Q, which has an entry of weight $-w_\Psi$ or lies in V. (Ux4) for $\mathscr{T}_0 \leq \mathscr{T}$ applied to (W'', s_3), (W'', s_4) and (W', p_2) (first components supported in Σ_Q; $W' \subseteq W''$) gives residual pairs q_3, q_4, q_2 over $(\mathscr{T}, \emptyset)$ lying over s_3, s_4, p_2. Their first components are the restrictions to G_F of those of s_3, s_4, p_2, hence supported in Σ_Q, and by (Hv3) their flags are supported in Σ_Q. Finally let $\bar{Q}$ be the image of Q under $\mathcal{O}_1 \xrightarrow{\bar{a}} k_V$. The reduction of the seed pair Q is a marked ordinary pair (the conditions (Mq1)–(Mq4) are identities preserved by reduction), locally constant (Q is continuous for $\mathfrak{m}_{\mathcal{O}_1}$), and satisfies (Wq1), (Wq2) by definition of seed pairs; $\bar{a}$ kills $\mathfrak{m}_{\mathcal{O}_1}$ and the induced map on the residue field is an injective field homomorphism, which preserves these conditions. So $\bar{Q}$ is a residual pair over $(\mathscr{T}, \emptyset)$; by hypothesis it lies over s, lies in A (its first component is supported in Σ_A and $(n_{\bar{Q},v})_{21} \neq 0$ for all v) and has entries of weights $-w_\beta$ and $-w_\theta$.

Step 4: entries surviving restriction. $\mathscr{T}$ is good, G_F is normal in G_{F_0} (F is abelian over $\mathbb{Q}$), and the first components of s_3 and p_2 are homomorphisms on G_{F_0} supported in Σ_Q with diagonal entries $\bar{a}(\kappa_i^\epsilon(g))$ (Wq1) and similitudes $\bar{a}(\theta(g)) \neq 0$ (Mq1); so (Hv1) applies with $H = G_{F_0}$. By (Gz3) and the similitude clause of (Hv1), $r_{s_3}(g)_{21} \neq 0$ for some $g \in G_{F_0}$; the place $(2,1)$ is isolated ($\Sigma_Q \subseteq \Sigma_M$), so $r_{s_3}(g)_{21} \neq 0$ for some $g \in G_F$: q_3 has an entry of weight $-w_\alpha$. Likewise, p_2 has an entry of weight $-w_\Psi$, so $r_{p_2}(g)_{31} \neq 0$ for some $g \in G_{F_0}$; the place $(3,1)$ is isolated (support in Σ_Q), so $r_{p_2}(g)_{31} \neq 0$ for some $g \in G_F$: q_2 has an entry of weight $-w_\Psi$.

Step 5: the links.

(i) $c_{\mathscr{T}}$ and q_3. They lie over p_0 and s_3, whose first components are supported in Σ_P and which have the same $-w_\Psi$ part (Gz2); by (Hv2) $c_{\mathscr{T}}$ and q_3 have the same $-w_\Psi$ part. Both first components are supported in Σ_P and all flags in Σ_Q, so (Rl1) links them.

(ii) q_3 and q_4. They lie over s_3, s_4, whose first components are supported in Σ_M and which have the same $-w_\alpha$ part (Gz4); by (Hv2) so do q_3, q_4, whose first components are supported in Σ_M; (Rl2) links them.

(iii) q_4 and q_2. They lie over s_4, p_2, whose first components are supported in Σ_P and which have the same $-w_\Psi$ part (Gz2); by (Hv2) so do q_4, q_2; first components in Σ_P, flags in Σ_Q: (Rl1) links them.

(iv) q_2 and $\bar{Q}$. They lie over p_2 and s, whose first components are supported in Σ_M and which have the same $-w_\alpha$ part (Yz); by (Hv2) q_2 and $\bar{Q}$ have the same $-w_\alpha$ part. Their first components are supported in $\Sigma_Q \subseteq \Sigma_M$ and $\Sigma_A \subseteq \Sigma_M$; (Rl2) links them.

Step 6: goodness in case (III).

- $c_{\mathscr{T}}$ is good (Kp2).
- q_3 has an entry of weight $-w_\alpha$ (Step 4). If it has one of weight $-w_\Psi$, it is good (entries of weights $-w_\Psi$ and $-w_\alpha$). Otherwise its first component is supported in $\Sigma_Q \setminus \{-w_\Psi\} = \{-w_\alpha, -w_\theta\} \subseteq \Sigma_V$; moreover $c_{\mathscr{T}}$, having the same $-w_\Psi$ part as q_3 (Step 5 (i)), has no entry of weight $-w_\Psi$, so by (Kp2) it lies in V and $(n_{c_{\mathscr{T}},v})_{31} \neq 0$, whence $(n_{q_3,v})_{31} \neq 0$ for all v. With its flags in Σ_Q, q_3 lies in V and has an entry of weight $-w_\alpha$: it is good.
- q_4 has the same $-w_\alpha$ part as q_3, hence an entry of weight $-w_\alpha$, and the same $-w_\Psi$ part as q_2, hence an entry of weight $-w_\Psi$ (Step 4): it is good.
- q_2 has an entry of weight $-w_\Psi$ (Step 4). It has the same $-w_\alpha$ part as $\bar{Q}$, whose first component is supported in $\Sigma_A \not\ni -w_\alpha$; so the entries $(2,1)$, $(4,3)$ of the first component of q_2 vanish, its first component is supported in $\{-w_\Psi, -w_\theta\} \subseteq \Sigma_A$, and $(n_{q_2,v})_{21} = (n_{\bar{Q},v})_{21} \neq 0$ for all v. So q_2 lies in A and has an entry of weight $-w_\Psi$: it is good in case (III).
- $\bar{Q}$ lies in A and has entries of weights $-w_\beta$ and $-w_\theta$: it is good in case (III).

Step 7: (Jx2). $c_{\mathscr{T}}, q_3, q_4, q_2, \bar{Q}$ are residual pairs over $(\mathscr{T}, \emptyset)$ with values in k_V (for $\bar{a}|_{\mathcal{O}}$), good in case (III) (Step 6), consecutive ones linked (Step 5): a chain in case (III) from the image $c_{\mathscr{T}}$ of P_Λ in k_V to the image $\bar{Q}$ of Q. □

Lemma 52.16. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, (K, V, a) a test field with residue field k_V and $\bar{a}\colon \overline{\mathbb{Z}}_\ell \to k_V$ the composite of a and reduction, and (r, u) an ordinary test representation of $\mathfrak{D}$ with values in V such that r is essential. Then there is an admissible labelling ϵ with the following property. For every fit auxiliary tower $\mathscr{T}_0$ for $\mathfrak{D}$ with labelling ϵ (field F_0, index set Σ_0) there are $u' \in \mathrm{GL}_4(K)$, a homomorphism $r'\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(V)$ with $r' = u'ru'^{-1}$ and $r'(g)$ of similitude $a(\theta(g))$ for all g, and a residual pair p_0 over $(\mathscr{T}_0, \emptyset)$ with values in k_V (for $\bar{a}|_{\mathcal{O}}$) whose first component is supported in Σ_P and all of whose flags are supported in Σ_Q, such that for every fit auxiliary tower $\mathscr{T} \geq \mathscr{T}_0$ (field F, places $\bar{v}$, $v \in \Sigma$) there are:*

(Kp1) *a complete discrete valuation ring Λ with finite residue field, an injective local homomorphism $j\colon \Lambda \to V$, a ring homomorphism $a_\Lambda\colon \mathcal{O} \to \Lambda$ with $j \circ a_\Lambda = a|_{\mathcal{O}}$, and a marked ordinary pair P_Λ over $(\mathscr{T}, \emptyset)$ with values in Λ (for a_Λ), continuous for $\mathfrak{m}_\Lambda$, whose reduction is a residual pair, such that $j(P_\Lambda)$ has first component $r'|_{G_F}$ and $\psi_{v,i}^{j(P_\Lambda)}(s) = a(\kappa_i(s))$ for all $v \in \Sigma$, $1 \leq i \leq 4$ and $s \in I_v$;*

(Kp2) *the image $c_{\mathscr{T}}$ of P_Λ under $\Lambda \xrightarrow{j} V \to k_V$ is a residual pair over $(\mathscr{T}, \emptyset)$ with values in k_V (for $\bar{a}|_{\mathcal{O}}$) which lies over p_0, whose first component is supported in Σ_P and all of whose flags are supported in Σ_Q, and which either has entries of weights $-w_\Psi$ and w_β, or lies in V and has an entry of weight $-w_\alpha$; in particular $c_{\mathscr{T}}$ is good.*

Proof. Step 1: labelling and lattice. Let ϵ be the admissible labelling given by Proposition 52.3 for (r, u), and $\mathscr{T}_0$ a fit auxiliary tower with labelling ϵ. Put $g_\circ = g_{\mathscr{T}_0}$; by (Oq7) the $\bar{\kappa}_i^\epsilon(g_\circ)$ are pairwise distinct, hence so are the residues $\chi_i(g_\circ)$ of the $a(\kappa_i^\epsilon(g_\circ))$. Proposition 52.3 gives $h \in \mathrm{GL}_4(K)$, $r^\natural = h^{-1}rh$ and n with (Nz1)–(Nz3), and, r being essential, (Nz4): $r^\natural$ has an entry of weight $-w_\Psi$ and one of at least one of the weights $w_\beta, -w_\alpha, -w_\theta$. These are the hypotheses of Proposition 52.4 (its first bullet is (Nz1), its second (Nz2), its third (Nz3)), which gives $\mathrm{T} = \mathrm{T}_4(t_1, t_2)$, $r' = \mathrm{T}r^\natural\mathrm{T}^{-1}$ and $n' = \mathrm{T}n\mathrm{T}^{-1}$ with (Ql0)–(Ql3), for some Λ', j'. Put $u' = \mathrm{T}h^{-1}$;

then $r' = u' r u'^{-1}$, $r'(g)$ has similitude $a(\theta(g))$, a unit of V, and entries in V, so $r'(g) \in \mathrm{GL}_4(V)$. Let $c = \bar{r}'$ and $\bar{n} = \overline{n'}$. By (Ql0) and the congruences of (Nz2), (Nz3): $c(g)_{ii} = \chi_i(g)$, and for $s \in D_\ell$ the matrix $\bar{n}^{-1} c(s) \bar{n}$ is upper triangular with diagonal entries $\chi_i(s)$; by (Ql1), c is supported in Σ_P and $\bar{n}$ in Σ_Q.

Step 2: the hypotheses of (Ux3). Let $\mathscr{T}$ be a fit auxiliary tower with labelling ϵ whose marking $g_{\mathscr{T}}$ is a power of $g_\circ$. Then (r', n') satisfies the hypotheses of (Ux3) for $\mathscr{T}$, with (Λ', j') of (Ql0): entries in $j'(\Lambda')$ and continuity by (Ql0); $r'(g)$ has similitude $a(\theta(g))$ and diagonal entries $r^\natural(g)_{ii} \equiv a(\kappa_i^\epsilon(g))$ modulo $\mathfrak{m}_V$ by (Ql0) and (Nz2); $r'(g_{\mathscr{T}})$ is diagonal as a power of the diagonal $r'(g_\circ)$; $r'(g) = 1$ on the inertia elements named in (Nz2), since $r^\natural(g) = 1$ there and (Ql0); n' is lower triangular with diagonal 1 and similitude 1, and $n'^{-1} r'(s) n'$ is upper triangular with diagonal entries $\psi_i(s)$ for $s \in D_\ell$, where $\psi_i(s) \equiv a(\kappa_i^\epsilon(s))$ and $\psi_i(s) = a(\kappa_i(s))$ on I_ℓ by (Nz3); the reductions are supported in Σ_P and Σ_Q by (Ql1).

Step 3: the pair p_0. By Step 2 for $\mathscr{T}_0$, (Ux3) gives flags n_{0,v_0} ($v_0 \in \Sigma_0$) and $g_{0,v_0} \in G_{\mathbb{Q}}$ with $g_{0,v_0}(\bar{\ell}) = \bar{v}_0$ and $n_{0,v_0}^{-1} r'(g_{0,v_0}) n'$ upper triangular, such that the reduction $p_0 = (c|_{G_{F_0}}, (\bar{n}_{0,v_0}))$ is a residual pair over $(\mathscr{T}_0, \emptyset)$ with values in k_V whose flags are supported in Σ_Q; its first component is supported in Σ_P.

Step 4: (Kp1). Let $\mathscr{T} \geq \mathscr{T}_0$ be fit, with field F and places $\bar{v}$, $v \in \Sigma$. By definition of the order it has labelling ϵ and $g_{\mathscr{T}} = g_\circ^{\ell^{m_1}}$ for some $m_1 \geq 0$, so Step 2 applies: (Ux3) gives flags n_v with entries in $j'(\Lambda')$ and $g_v \in G_{\mathbb{Q}}$ with $g_v(\bar{\ell}) = \bar{v}$ and $n_v^{-1} r'(g_v) n'$ upper triangular, such that $P = (r'|_{G_F}, (n_v))$ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in V (for a), $\psi^P_{v,i}(s) = a(\kappa_i(s))$ for $s \in I_v$, and its reduction $c_{\mathscr{T}} = (c|_{G_F}, (\bar{n}_v))$ is a residual pair over $(\mathscr{T}, \emptyset)$ with values in k_V whose flags are supported in Σ_Q.

Enlarging Λ'. Let L_0 be the fraction field of $j'(\Lambda')$. The ring Λ' of Proposition 52.4 contains Λ of (Nz1) with $j'|_\Lambda = j$, so every element of K is algebraic over L_0 by (Nz1). $V \cap L_0$ is a valuation ring of L_0 containing the discrete valuation ring $j'(\Lambda')$ and not containing $j'(\pi')^{-1}$ for a uniformiser π' (j' is local), so it equals $j'(\Lambda')$; as K/L_0 is algebraic, the value group of V lies in the divisible hull of that of L_0, so V has rank one. If K has characteristic 0, Λ' has characteristic 0 and residue characteristic ℓ, so it contains $\mathbb{Z}_\ell$; a and j' agree on $\mathbb{Z}$, and for $x \in \mathbb{Z}_\ell$ and integers $m \equiv x$ modulo ℓ^e, $a(x) - j'(x) = a(x-m) - j'(x-m) \in \ell^e V$ for all e; rank one gives $\bigcap_e \ell^e V = 0$, so $a = j'$ on $\mathbb{Z}_\ell$ and every element of $a(\mathcal{O})$ is integral over $j'(\mathbb{Z}_\ell)$. If K has characteristic ℓ, $a(\mathcal{O})$ is a finite field. In both cases $L_1 = L_0(a(\mathcal{O}))$ is a finite extension of L_0, and $\Lambda_1 = V \cap L_1$ is the valuation ring of the unique extension to L_1 of the valuation of the complete discrete valuation ring $j'(\Lambda')$: a complete discrete valuation ring with finite residue field, containing $j'(\Lambda')$ and the integral elements $a(\mathcal{O})$. Let $j_1 \colon \Lambda_1 \to V$ be the inclusion (injective and local) and $a_\Lambda = a|_{\mathcal{O}}$ viewed in Λ_1. Then $P_\Lambda = j_1^{-1}(P)$ (entrywise) has values in Λ_1; (Mq1)–(Mq4) for P and a are identities in $j_1(\Lambda_1)$, so P_Λ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in Λ_1 for a_Λ. It is $\mathfrak{m}_{\Lambda_1}$-adically continuous, because the $\mathfrak{m}_{\Lambda'}$-adic and $\mathfrak{m}_{\Lambda_1}$-adic topologies agree on $j'(\Lambda')$ (Λ_1 is finite over it). Its reduction is mapped by the field embedding of the residue field of Λ_1 into k_V to $c_{\mathscr{T}}$; residual pairs are defined by polynomial identities and non-vanishing conditions, which an injective field homomorphism reflects, so the reduction of P_Λ is a residual pair. Finally $j_1(P_\Lambda) = P$ has first component $r'|_{G_F}$ and $\psi = a(\kappa_i(s))$ on I_v. This is (Kp1) with $(\Lambda, j) = (\Lambda_1, j_1)$, and the image of P_Λ in k_V is $c_{\mathscr{T}}$.

Step 5: $c_{\mathscr{T}}$ lies over p_0. Its first component is $c|_{G_F} = (c|_{G_{F_0}})|_{G_F}$. Let $v \in \Sigma$. By the definition of $\mathscr{T}_0$ there are $v_0 \in \Sigma_0$ and $g \in G_{F_0}$ with $g(\bar{v}_0) = \bar{v}$. Then $g g_{0,v_0}(\bar{\ell}) = \bar{v} = g_v(\bar{\ell})$, so $d = g_v^{-1} g g_{0,v_0}$ lies in the decomposition group D_ℓ of $\bar{\ell}$ in $G_{\mathbb{Q}}$, and

$$\bar{n}_v^{-1} c(g) \bar{n}_{0,v_0} = \left(\bar{n}_v^{-1} c(g_v) \bar{n}\right) \left(\bar{n}^{-1} c(d) \bar{n}\right) \left(\bar{n}_{0,v_0}^{-1} c(g_{0,v_0}) \bar{n}\right)^{-1}.$$

The first factor is upper triangular (Step 4), the second by Step 1, and the third is the inverse

of an invertible upper triangular matrix (Step 3). So $\bar{n}_v^{-1} c(g) \bar{n}_{0,v_0}$ is upper triangular, and $c_{\mathscr{T}}$ lies over p_0.

Step 6: supports and goodness. The first component $c|_{G_F}$ is supported in Σ_P, the flags in Σ_Q. $\mathscr{T}$ is good (fit), G_F is normal in $G_{\mathbb{Q}}$ ($F/\mathbb{Q}$ is abelian), and every $c(g)$ has the similitude $\bar{a}(\theta(g)) \neq 0$, so (Hv1) applies to $y = c$, $H = G_{\mathbb{Q}}$. By (Ql3) there are two cases.

(a) c has an entry of weight $-w_\Psi$. By (Hv1), $c(g)_{31} \neq 0$ for some $g \in G_{\mathbb{Q}}$; the place $(3,1)$ is isolated in c (c is supported in Σ_P), so by (Hv1) $c(g)_{31} \neq 0$ for some $g \in G_F$. By (Ql2), c_{23} is not identically zero (the only place of weight w_β is $(2,3)$), and $(2,3)$ is isolated, so $c(g)_{23} \neq 0$ for some $g \in G_F$. Thus $c_{\mathscr{T}}$ has entries of weights $-w_\Psi$ and w_β.

(b) Otherwise, by (Ql3), c is supported in Σ_V, $\bar{n}_{31} \neq 0$, $\bar{\Psi}(s) = 1$ for $s \in D_\ell$, and there is no $m \in k_V$ with $c(s)_{23} = m(\chi_3(s) - \chi_2(s))$ for all $s \in D_\ell$. *$c_{\mathscr{T}}$ lies in V.* Its first component is supported in Σ_V and its flags in Σ_Q. Let $v \in \Sigma$, and compare the first columns in the upper triangularity of $\bar{n}_v^{-1} c(g_v) \bar{n}$: $c(g_v)\bar{n}e_1 = \lambda \bar{n}_v e_1$ with λ the first coordinate of $c(g_v)\bar{n}e_1$, which is $\chi_1(g_v)$ because $c_{12} = c_{13} = c_{14} = 0$ (weights $w_\alpha, w_\Psi, w_\theta \notin \Sigma_P$); the third coordinates, with $c_{31} = c_{32} = c_{34} = 0$ (weights $-w_\Psi, -w_\beta, w_\alpha \notin \Sigma_V$), give $(\bar{n}_v)_{31}\chi_1(g_v) = \chi_3(g_v)\bar{n}_{31} \neq 0$. *$c_{\mathscr{T}}$ has an entry of weight $-w_\alpha$.* The place $(2,1)$ is isolated in c: in $c(gh)_{21} = \sum_x c(g)_{2x} c(h)_{x1}$ the terms $x = 3, 4$ vanish since $c_{31} = 0$ and $c_{24} = 0$. If $c_{\mathscr{T}}$ had no entry of weight $-w_\alpha$, then $c_{21} = 0$ on G_F by (Hv1) (similitude clause), hence on $G_{\mathbb{Q}}$ by (Hv1). The second coordinate of $c(s)\bar{n}e_1 = \chi_1(s)\bar{n}e_1$ ($s \in D_\ell$; Step 1) would read $\chi_2(s)\bar{n}_{21} + c(s)_{23}\bar{n}_{31} = \chi_1(s)\bar{n}_{21}$ (with $c(s)_{21} = 0$ and $c(s)_{24} = 0$). Since χ_1/χ_3 is $\bar{a} \circ \Psi$ or $\bar{a} \circ \Psi^{-1}$ (for $\epsilon = 0$, 1) and $\bar{\Psi} = 1$ on D_ℓ, $\chi_1 = \chi_3$ on D_ℓ, so $c(s)_{23} = m(\chi_3(s) - \chi_2(s))$ with $m = \bar{n}_{21}/\bar{n}_{31}$, contrary to (Ql3). So $c_{\mathscr{T}}$ lies in V and has an entry of weight $-w_\alpha$.

In case (a) $c_{\mathscr{T}}$ is good by the first clause of goodness, in case (b) by the third. □

Lemma 52.17. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, k a field, $\bar{a}\colon \mathcal{O} \to k$ a ring homomorphism with $\bar{a}(\mathfrak{m}_{\mathcal{O}}) = 0$, ϵ an admissible labelling, and $\delta_i = \bar{a} \circ \kappa_i^\epsilon$ ($1 \leq i \leq 4$). For a residual pair $c = (r_c, (n_{c,v})_v)$ with values in k over an auxiliary tower with field F, its $-w_\Psi$* part *is the family of the entries $r_c(g)_{31}$, $r_c(g)_{42}$ ($g \in G_F$) and $(n_{c,v})_{31}$ (all v), and its $-w_\alpha$* part *the family of the entries $r_c(g)_{21}$, $r_c(g)_{43}$ and $(n_{c,v})_{21}$.*

(Hv1) *Let $\mathscr{T}$ be a good auxiliary tower with labelling ϵ and field F, $H \subseteq G_{\mathbb{Q}}$ a subgroup containing G_F as a normal subgroup, and $y\colon H \to \mathrm{M}_4(k)$ a homomorphism of monoids with $y(g)_{ii} = \delta_i(g)$ for $g \in H$ and all i. Call a place (i,j), $i \neq j$,* isolated *in y if $y(gh)_{ij} = \delta_i(g)y(h)_{ij} + y(g)_{ij}\delta_j(h)$ for all $g, h \in H$. If (i,j) is isolated in y and $y(g)_{ij} = 0$ for all $g \in G_F$, then $y(g)_{ij} = 0$ for all $g \in H$. The places $(3,1)$ and $(2,3)$ are isolated if y is supported in Σ_P; the place $(2,1)$ is isolated if y is supported in Σ_M; the place $(3,1)$ is isolated if y is supported in Σ_Q. If every $y(g)$ has a similitude in $k^\times$, then for every subgroup $H' \subseteq H$, $y|_{H'}$ has an entry of weight $-w_\Psi$ (resp. $-w_\alpha$) if and only if $y(g)_{31} \neq 0$ (resp. $y(g)_{21} \neq 0$) for some $g \in H'$.*

(Hv2) *Let $\mathscr{T}_0 \leq \mathscr{T}$ be auxiliary towers with labelling ϵ, W_0, W finite sets of primes, p, p' residual pairs over $(\mathscr{T}_0, W_0)$ with values in k (for $\bar{a}$), and q, q' residual pairs over $(\mathscr{T}, W)$ with values in k such that q lies over p and q' lies over p'. If the first components of p and p' are supported in Σ_P and p, p' have the same $-w_\Psi$ part, then q, q' have the same $-w_\Psi$ part. If the first components of p and p' are supported in Σ_M and p, p' have the same $-w_\alpha$ part, then q, q' have the same $-w_\alpha$ part.*

(Hv3) *In the situation of (Hv2), if the first component and all flags of p are supported in Σ_Q, then all flags of q are supported in Σ_Q.*

Proof. (Hv1). Since $\bar{a}$ kills $\mathfrak{m}_{\mathcal{O}}$, it factors through a field embedding $\mathbb{F}_{\mathcal{O}} \to k$; by (Oq7) the residues $\bar{\kappa}_i^{\epsilon}(g_{\mathscr{T}})$ are pairwise distinct, hence so are the $\delta_i(g_{\mathscr{T}})$. Put $h_0 = g_{\mathscr{T}} \in G_F$ and let $g \in H$. By isolation and $y(h_0)_{ij} = 0$, $y(gh_0)_{ij} = y(g)_{ij}\delta_j(h_0)$. Also $gh_0 = (gh_0g^{-1})g$ with $gh_0g^{-1} \in G_F$ (normality), so by isolation $y(gh_0)_{ij} = \delta_i(gh_0g^{-1})y(g)_{ij} + y(gh_0g^{-1})_{ij}\delta_j(g) = \delta_i(h_0)y(g)_{ij}$, δ_i being a character. Hence $(\delta_j(h_0) - \delta_i(h_0))y(g)_{ij} = 0$ and $y(g)_{ij} = 0$.

Isolation: $y(gh)_{ij} = \sum_x y(g)_{ix}y(h)_{xj}$, and (i,j) is isolated as soon as $y(g)_{ix}y(h)_{xj} = 0$ for $x \notin \{i,j\}$. If y is supported in $\Sigma_P = \{w_\beta, -w_\alpha, -w_\theta, -w_\Psi\}$: for $(3,1)$, $y_{32} = 0$ (weight $-w_\beta$) and $y_{34} = 0$ (weight w_α); for $(2,3)$, $y_{13} = 0$ and $y_{24} = 0$ (weight w_Ψ). If y is lower triangular, for $(2,1)$ the terms $x = 3,4$ contain $y_{2x} = 0$. If y is supported in $\Sigma_Q = \{-w_\alpha, -w_\Psi, -w_\theta\}$, it is lower triangular with $y_{32} = 0$ (weight $-w_\beta$), so for $(3,1)$ the terms $x = 2,4$ vanish.

Similitudes: write $X^\dagger = J_4^{-1}\,{}^tXJ_4$; a matrix X has similitude ν if and only if $X^\dagger X = \nu$. With J_4 having entries $J_{14} = J_{23} = 1$, $J_{32} = J_{41} = -1$, one has $J_4^{-1} = -J_4$ and $(X^\dagger)_{ab} = s_at_bX_{5-b,5-a}$ with $(s_1,s_2,s_3,s_4) = (-1,-1,1,1)$, $(t_1,t_2,t_3,t_4) = (-1,-1,1,1)$; in particular $(X^\dagger)_{31} = -X_{42}$ and $(X^\dagger)_{21} = X_{43}$. If $y(g)$ has similitude $\nu(g) \in k^\times$ and $g^{-1} \in H'$ (a subgroup), then $y(g^{-1}) = y(g)^{-1} = \nu(g)^{-1}y(g)^\dagger$, whose entries $(3,1)$ and $(2,1)$ are $-\nu(g)^{-1}y(g)_{42}$ and $\nu(g)^{-1}y(g)_{43}$. The places of weight $-w_\Psi$ are $(3,1),(4,2)$ and those of weight $-w_\alpha$ are $(2,1),(4,3)$, so the last assertion follows.

Two identities. Let $X \in \mathrm{M}_4(k)$ with diagonal entries $x_1,\dots,x_4$, and let $y, y' \in \mathrm{M}_4(k)$ be lower triangular with diagonal entries 1 such that $y^{-1}Xy'$ is upper triangular. Then $Xy'e_1 = y(y^{-1}Xy')e_1 = \lambda\, ye_1$ with $\lambda = (y^{-1}Xy')_{11}$, and comparing first coordinates ($y_{11} = 1$), λ is the first coordinate of $Xy'e_1$.

- If X is supported in Σ_P, then $X_{12} = X_{13} = X_{14} = 0$ (weights $w_\alpha, w_\Psi, w_\theta$), so $\lambda = x_1$; the third coordinates, with $X_{32} = X_{34} = 0$, give
$$y_{31}\,x_1 = X_{31} + x_3\,y'_{31}. \tag{52.7}$$
- If X is lower triangular, then $\lambda = x_1$ and the second coordinates give
$$y_{21}\,x_1 = X_{21} + x_2\,y'_{21}. \tag{52.8}$$

(Hv2). Write $F_0 \subseteq F$ for the fields and Σ_0, Σ for the index sets, $p = (r_p, (n_{p,v_0}))$, and likewise for p', q, q'. By definition of lying over, $r_q = r_p|_{G_F}$ and $r_{q'} = r_{p'}|_{G_F}$, so the entries of the first components of q, q' in either part agree. Fix $v \in \Sigma$. There are $v_0, v_0' \in \Sigma_0$ and $g, g' \in G_{F_0}$ with $g(\bar{v}_0) = \bar{v} = g'(\bar{v}_0')$, $n_{q,v}^{-1}r_p(g)n_{p,v_0}$ and $n_{q',v}^{-1}r_{p'}(g')n_{p',v_0'}$ upper triangular. Then $\bar{v}_0' = g'^{-1}g(\bar{v}_0)$ is G_{F_0}-conjugate to $\bar{v}_0$, so $v_0' = v_0$ (uniqueness of the representative in the definition of an auxiliary tower), and $d = g'^{-1}g \in G_{F_0}$ fixes $\bar{v}_0$, i.e. $d \in D_{v_0}$. By (Mq4) for p', $n_{p',v_0}^{-1}r_{p'}(d)n_{p',v_0}$ is upper triangular, hence so is

$$n_{q',v}^{-1}r_{p'}(g)n_{p',v_0} = \big(n_{q',v}^{-1}r_{p'}(g')n_{p',v_0}\big)\big(n_{p',v_0}^{-1}r_{p'}(d)n_{p',v_0}\big).$$

All flags are lower triangular with diagonal entries 1 (Mq3), and $r_p(g)$, $r_{p'}(g)$ have the same diagonal entries $\delta_i(g)$ by (Wq1) for $\mathscr{T}_0$, with $\delta_1(g) \neq 0$. In the first case, (52.7) for $(X,y,y') = (r_p(g), n_{q,v}, n_{p,v_0})$ and $(r_{p'}(g), n_{q',v}, n_{p',v_0})$ gives

$$(n_{q,v})_{31}\delta_1(g) = r_p(g)_{31} + \delta_3(g)(n_{p,v_0})_{31} = r_{p'}(g)_{31} + \delta_3(g)(n_{p',v_0})_{31} = (n_{q',v})_{31}\delta_1(g),$$

the middle equality because p, p' have the same $-w_\Psi$ part. In the second case (52.8) gives the same with $(2,1)$ and δ_2. So $(n_{q,v})_{31} = (n_{q',v})_{31}$, resp. $(n_{q,v})_{21} = (n_{q',v})_{21}$, for all v.

(Hv3). Fix $v \in \Sigma$ and v_0, g as above for q and p. The matrices $r_p(g)$ and n_{p,v_0} are lower triangular and supported in Σ_Q. A product YZ of two such matrices is of the same kind: it

is lower triangular, and its $(3,2)$ entry is $Y_{32}Z_{22} + Y_{33}Z_{32} = 0$, the only lower place of weight outside Σ_Q being $(3,2)$. So $L = r_p(g)n_{p,v_0}$ is lower triangular, supported in Σ_Q, and invertible ($r_p(g)$ has a non-zero similitude, n_{p,v_0} similitude 1). The matrix $D = n_{q,v}^{-1}L$ is upper triangular by assumption and lower triangular as a product of lower triangular matrices, hence diagonal and invertible; so $n_{q,v} = LD^{-1}$ is supported in Σ_Q. □

Proposition 52.18. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum attached to a host character in case (III). For every admissible labelling ϵ there is a fit and tame auxiliary tower of case (III) for $\mathfrak{D}$ with labelling ϵ.*

Proof. Let $\mathfrak{D}$ be attached to $(\psi, \mathfrak{h}, t, \chi)$ in case (III) and let ϵ be admissible. Then $N = N_{\mathfrak{h}}$, $p' = p_1(\psi)$, $m = \operatorname{ord}\chi$ is odd, $\chi \neq \mathbf{1}$, $\xi = \chi_{\mathrm{dy}}\chi_{\mathrm{pr}}$ with χ_{dy} primitive modulo $2^{n'}$ and χ_{pr} modulo p', and S is the set of primes dividing $2\ell N p'$; $2^{n'} \geq 8\ell^2$ gives $n' \geq 8$.

Step 0: facts about the data.

(a) $\ell \geq 5$: ℓ is odd, $3 \in B_\psi$ and $\ell \notin B_\psi$.

(b) $\ell \nmid N$ and $p' \nmid N$, $p' \neq \ell$. Indeed $\ell \nmid N_\psi$ and $p' \neq \ell$ because the odd prime factors of N_ψ and p' (odd, being prime to $2N_\psi$) lie in B_ψ; $(\ell - 1) \mid 2e$ with $0 < e < t$ gives $\ell \leq 2e + 1 < 2t + 1 < \min(q, d)$, so $\ell \neq q, d$; and $p' \nmid 2N_\psi$, $p' < \min(q, d)$ by bigness. So χ is unramified at ℓ and at p', and ξ is unramified at ℓ.

(c) $\ell \nmid m$. The map $u \mapsto (u \bmod 2^{a+2}$ modulo $\pm 1,\ \psi(u),\ (u/q),\ (u/d))$ has kernel $H_{\mathfrak{h}}$, so $(\mathbb{Z}/N\mathbb{Z})^\times/H_{\mathfrak{h}}$ has exponent dividing $\operatorname{lcm}(2^a, o_\psi, 2)$; χ factors through it, and $\ell \nmid o_\psi$ ($\ell \notin B_\psi$). Hence $\chi'' = \mathbf{1}$, $S_\ell(\chi) = \emptyset$, $T = \{\ell\}$, $T' = \emptyset$.

(d) $\chi(c) = 1$ ($\chi(c)^2 = 1$, m odd), so $1 = \Psi(c) = (-1)^e$ by (Sg1): e is even. The 2-component of χ has odd order on a 2-group, so χ is unramified at 2; χ_{pr} is unramified at 2. $\bar{\alpha} = \bar{\xi}$, $\bar{\Psi} = \bar{\chi}\,\bar{\omega}_\ell^e$, and $\bar{\omega}_\ell^{2e} = \mathbf{1}$ as $(\ell - 1) \mid 2e$. ξ, χ, ω_ℓ are unramified outside S; $\xi(c) = -1$.

Step 1: the field E' and the subgroup. By Dirichlet's theorem choose a prime $q_0 \notin S$ with $q_0 \equiv 7 \pmod 8$ and $q_0 \equiv -1 \pmod p$ for every odd $p \in S$. Let $E' = \mathbb{Q}(\sqrt{-q_0})$, with character η': imaginary quadratic of discriminant $-q_0$, so $\ell \nmid \operatorname{disc}(E')$; ramified exactly at q_0; $\eta'(c) = -1$; every prime of S, in particular ℓ and 2, splits in E' ($-q_0 \equiv 1$ modulo 8 and modulo every odd $p \in S$). Fix $i' \in I_{\bar{q}_0}$ with $\eta'(i') = -1$. Put $S' = S \cup \{q_0\}$ and

$$H' = \{g \in G_{\mathbb{Q}} :\ \xi(g) = \eta'(g),\ \bar{\omega}_\ell(g)^e = 1\} :$$

open, containing the commutator subgroup, containing c ($\xi(c) = -1 = \eta'(c)$, $(-1)^e = 1$ by (d)), and $I_{\bar{p}}$ for $p \notin S'$. Apply Lemma 52.10 to $\mathfrak{D}, \epsilon, S', H'$: it gives q_1, q_2, E, F, L, J. The characters $\xi, \eta', \chi, \omega_\ell$ are unramified at $q_1, q_2 \notin S'$, so (Zf3) preserves their values. On $G_F \subseteq H'$: $\xi = \eta'$ and $\bar{\Psi} = \bar{\chi}$.

Step 2: elements.

- *At ℓ.* For every place $\bar{w}$ above ℓ and $g \in I_{\bar{w}}$: $\xi(g^2) = 1$ ((b)), $\eta'(g^2) = 1$, $\bar{\omega}_\ell(g^2)^e = \bar{\omega}_\ell(g)^{2e} = 1$ ((d)); so $g^2 \in H' \cap D_{\bar{w}} \subseteq H' \cap J = G_L$ by (Zf1), (Zf2). As $\bar{\omega}_\ell$ maps $I_{\bar{\ell}}$ onto $\mathbb{F}_\ell^\times$, of order $\ell - 1 \geq 4$, there is $g_I \in I_{\bar{\ell}}$ with $\bar{\omega}_\ell(g_I)^2 \neq 1$; put $y_I = g_I^2 \in G_L$. Then $\bar{\xi}(y_I) = 1$, $\bar{\Psi}(y_I) = \bar{\chi}(y_I) = 1$ ((b)), $\bar{\omega}_\ell(y_I) \neq 1$.

- *The marking.* Let $g_1 \in I_{\bar{2}}$ map to $1 + 2^{n'-1} \in \mathbb{Z}_2^\times$. As χ_{dy} is primitive, it is injective on the cyclic group $(1 + 4\mathbb{Z})/(1 + 2^{n'}\mathbb{Z})$ (a non-trivial kernel would contain $1 + 2^{n'-1}$, and χ_{dy} would factor modulo $2^{n'-1}$), so $\chi_{\mathrm{dy}}(1 + 2^{n'-1})$ has order 2, i.e. equals -1; with (d),

$\xi(g_1) = -1$, $\chi(g_1) = 1$, $\omega_\ell(g_1) = 1$, and $\eta'(g_1) = 1$ as 2 splits in E'. Choose $a_0 \in (\mathbb{Z}/N\mathbb{Z})^\times$ with $\chi(a_0) \neq 1$ ($\chi \neq \mathbf{1}$) and, by (b) and the Chinese remainder theorem, $u_0 \in G_\mathbb{Q}$ acting on μ_N through a_0 and trivially on $\mu_{\ell p'}$; put $g_2 = u_0^{2^{n'}}$. Then $\chi(g_2) = \chi(a_0)^{2^{n'}} \neq 1$ ($\chi(a_0) \neq 1$ has odd order), $\chi_{\mathrm{dy}}(g_2) = 1$ (its order divides $2^{n'-1}$), $\chi_{\mathrm{pr}}(g_2) = 1$, $\omega_\ell(g_2) = 1$. Let $y_0' = g_1\, i'\, g_2^2$: $\xi(y_0') = -1 = \eta'(y_0')$ and $\omega_\ell(y_0') = 1$, so $y_0' \in H'$, and (Zf3) gives $y_0 \in G_L$ with $\bar\xi(y_0) = -1$, $\omega_\ell(y_0) = 1$ and $\bar\chi(y_0) = \bar\chi(g_2)^2 =: x_0$. Since $\chi(g_2)^2$ is a root of unity of odd order dividing m, different from 1, and $\ell \nmid m$, x_0 has odd order > 1: $x_0 \neq \pm 1$. Also $\bar\Psi(y_0) = \bar\chi(y_0)\bar\omega_\ell(y_0)^e = x_0$.

Let $\mathscr{T} = (\epsilon, E, F, y_0, \Sigma, (\bar v))$ be the tower of (Zf4) with $g_\star = y_0$; (Oq1), (Oq2) hold. With $\varsigma = (-1)^\epsilon$: from $(\kappa_i^0) = (\theta, \Psi, \alpha, \mathbf{1})$ and $(\kappa_i^1) = (\alpha, \mathbf{1}, \theta, \Psi)$, $\chi_1^{\mathscr{T}}/\chi_2^{\mathscr{T}} = \alpha$ and $\chi_1^{\mathscr{T}}/\chi_3^{\mathscr{T}} = \Psi^\varsigma$, so $\overline{\mathrm{rt}_w} = \bar\xi^{w_1}\bar\Psi^{\varsigma w_2}$ on G_F ($\bar\alpha = \bar\xi$); so $\overline{\mathrm{rt}_w}(y_0) = (-1)^{w_1} z^{w_2}$ with $z = x_0^\varsigma$, again of odd order > 1, so $z \neq \pm 1$.

Step 3: the clauses. Conjugation by $h \in G_\mathbb{Q}$ moves elements of $D_{\bar p} \cap G_F$, $I_{\bar p} \cap G_F$ to any place above p without changing character values.

(Oq3) For every w, $\overline{\mathrm{rt}_w}(y_I) = 1 \neq \bar\omega_\ell(y_I)$. For the roots: $\pm w_\alpha$ give -1; $\pm w_\Psi$ give $z^{\pm 1} \neq 1$; $\pm w_\beta = \pm(-1, 1)$ and $\pm w_\theta = \pm(1, 1)$ give $-z^{\pm 1} \neq 1$. For w_θ and $1 \leq n \leq 4$: if $(-z)^n = 1$ then $z^{2n} = 1$; with $z^m = 1$, m odd, $z^{\gcd(n,m)} = 1$, and $\gcd(n, m) \in \{1, 3\}$; gcd $= 1$ gives $z = 1$, and gcd $= 3$ (so $n = 3$) gives $(-z)^3 = -1 \neq 1$; both are contradictions.

(Oq4) With η as there, $\eta = \bar\kappa_j^\epsilon$ on G_L for some j (take the index i with $\kappa_i^\epsilon = \mathbf{1}$), and $\eta(y_0) = 1$ as $\omega_\ell(y_0) = 1$. The residues $(\bar\theta, \bar\Psi, \bar\alpha, \mathbf{1})(y_0) = (-x_0, x_0, -1, 1)$ are pairwise distinct ($x_0 \neq 0, \pm 1$, $-1 \neq 1$), so $\bar\kappa_j^\epsilon(y_0) = 1$ forces $\kappa_j^\epsilon = \mathbf{1}$, and $\eta = 1$.

(Oq5) For $g \in I_{\bar w} \cap G_F$, $\bar w$ not above ℓ, with $\bar r_0(g) = 1$: $\bar\chi(g) = \bar\Psi(g) = 1$ on G_F, so $\chi(g) = 1$ ($\ell \nmid m$); and $\chi^m = \mathbf{1}$ with $\ell \nmid m$.

(Oq6) For $g \in I_{\bar w} \cap G_F$, $\bar w$ above ℓ: $\bar\alpha(g) = \bar\xi(g) = 1$ and $\bar\Psi(g) = \bar\chi(g) = 1$ by (b).

(Oq7) The residues at $g_{\mathscr{T}} = y_0$ are pairwise distinct (see (Oq4)), and λ_ϵ permutes them.

(Oq8) The first alternative: conjugates of y_I lie in $I_{\bar w} \cap G_F$ with $\bar\omega_\ell \neq 1$.

Case (III) $\ell \geq 5$ by (a); $T' = \emptyset$ and χ has finite order m prime to ℓ by (c); E' is imaginary quadratic, $\ell \nmid \mathrm{disc}(E')$, ℓ and every prime of S split in E'; and for $g \in G_F$, $\overline{\mathrm{rt}_{w_\alpha}}(g) = \bar\xi(g) = \eta'(g)$, which is 1 if $g \in G_{E'}$ and -1 otherwise.

So $\mathscr{T}$ is good and of case (III), and fit ($\mathfrak{D}$ is attached in case (III), $\ell \geq 5$, $T' = \emptyset$, χ of order prime to ℓ). *Tame*: for $g \in I_{\bar w}$, $\bar w$ above ℓ, $g^2 \in G_L \subseteq G_F$ by Step 2, and 2 is prime to ℓ. Hence $\mathscr{T}$ is a fit and tame auxiliary tower of case (III) with labelling ϵ. □

53 The rank-four Hecke chain

This section proves the two rank-four statements that Proposition 51.5 uses: every space of marked pairs over a fit and deep auxiliary tower carries a modular ideal (Theorem 53.1), and a modular ideal present on one component through a residual pair is present on all components through every residual pair chained to it in case (III), provided the tower has degree $d \geq 30(C+1)^2$ for a Selmer bound C (Theorem 53.31). They play the parts of the Hecke realisation and of the propagation theorem of Sections 49 and 50. The Hecke side is built over the CM field $L = FE$ of a link, which carries a rank-four Hecke datum (Lemma 53.2). There the rank-n Hecke

chain in rank four, Theorem 53.10, gives a Hecke ideal of zero-monodromy type with $R = T$ at patchable curve points, automorphy at classical irreducible points, purity and stability under twists; it rests on the results of Appendix E. A comparison map from the universal rank-four determinant ring of the link to the space (Lemma 53.7) carries this ideal to the space, and the conditions (Jq1)–(Jq5) of a modular ideal are checked one by one along it.

Subsection 53.1 sets up links, twists and comparison maps and transports the finiteness over the weights (Jq1). Subsection 53.2 transports $R = T$, locality at seed points, purity and classicality, (Jq2)–(Jq5), and descends automorphy from L to imaginary quadratic fields and to the symplectic condition (Sy2). Subsection 53.3 proves the propagation theorem from local charts in rank four, whose reducible and coincidence loci are small.

53.1 The Hecke side in rank four: links, twists and comparison maps

This subsection proves Theorem 53.1 from Theorem 53.10 and the transport lemmas 53.11–Lemma 53.23, and states Theorem 53.10. A link of a fit and deep tower is a rank-four Hecke datum over $L = FE$, with the residual characters of the tower twisted (Lemma 53.2). The twists exist: algebraic characters of a CM field with a prescribed product with their conjugate, unramified at the finite places not above ℓ (Lemma 53.5). Universal polarised ordinary determinants exist over the datum (Lemma 53.6), by Chenevier's theory of determinants [66], and the comparison map classifies the twisted determinant of the points of a space (Lemma 53.7). The subsection also defines the Taylor–Wiles data and the classical level modules of a rank-n Hecke datum (Definition 53.8, Definition 53.9), with which Appendix E works; Theorem 53.10 is assembled from the results of that appendix and from Lemma 50.12. Finiteness over the weights then passes to the space (Lemma 53.11).

Theorem 53.1. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$, and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Then there is a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$ such that for every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}_1$ and every space $\mathscr{X} = (B, A, P, \dots)$ for $(\mathscr{T}, \mathcal{O}')$, some ideal of B is modular for ι.*

Proof. Symbols introduced here are local to this proof.

Step 1: the coefficient ring. By Lemma 53.2, $L = FE$ is a CM field with $L^+ = F$, unramified over F at every finite place, every place of F above ℓ splits in L, L contains no primitive ℓ-th root of unity, and c is a complex conjugation in G_F; let $\mathcal{O}_1^\flat$, ν, γ, t be as given there. By Lemma 53.5 with $m = -3$ there is a continuous character κ of G_L, algebraic for ι, with (Tw1)–(Tw4), (Kw1) and values in a coefficient ring $\mathcal{O}_\kappa$. Let $\mathcal{O}_1$ be a coefficient ring containing $\mathcal{O}_1^\flat$ and $\mathcal{O}_\kappa$ (the integral closure of $\mathbb{Z}_\ell$ in the compositum of their fraction fields).

Step 2: the link. Let $\mathcal{O}' \supseteq \mathcal{O}_1$ and let $\mathscr{X} = (B, A, P, \dots)$ be a space for $(\mathscr{T}, \mathcal{O}')$. Then κ takes values in $\mathcal{O}'^\times$ and satisfies (Tw1) for $m = -3$, (Tw2), (Tw4), so Lemma 53.2 gives a rank-4 Hecke datum $\mathscr{H}$ over $\mathcal{O}'$ with CM field L and complex conjugation c, with (Lk6)–(Lk8). By the twist clause of Lemma 53.5 ($n = 4$, $m = 1 - n$, $\mathcal{O}'$ containing $\mathcal{O}_\kappa$), κ is a twist for $\mathscr{H}$; its wild values are trivial (Lk7).

Step 3: the universal rings. The pair $(\bar{D}_4, (\bar{\chi}_a|_{D_v}))$ is a polarised ordinary determinant of rank 4 over $\mathscr{H}$ to $\mathbb{F}_{\mathcal{O}'} \in \mathrm{CNL}_{\mathcal{O}'}$: (Od1) since $\{\bar{\chi}_a(cg^{-1}c)\}_a = \{\bar{\chi}_{5-a}(g)\}_a$ by (Rd5); (Od2) since $\mathrm{tr}_{\bar{D}_4}(\gamma' \prod_a (g_a - \bar{\chi}_a(g_a))) = \sum_b \bar{\chi}_b(\gamma') \prod_a (\bar{\chi}_b(g_a) - \bar{\chi}_a(g_a))$, whose b-th term has the factor $a = b$ equal to 0; (Od3) since each $\bar{\chi}_a$ has order prime to ℓ and so is trivial on μ_v, as the trivial wild values are. By Lemma 53.6 there is a universal polarised ordinary determinant $(B_4^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ of rank 4 over $\mathscr{H}$; let ϕ_0 be the morphism of Lemma 53.7 for $n = 0$ (its hypotheses: (Lk1)–(Lk4), (Lk6), (Lk7) and (Tw1), (Tw2), (Tw4)).

Step 4: the Hecke ideals. By (Hf1) of Theorem 53.10 for $(\mathscr{H}, \kappa, B_4^{\mathrm{po}}, \iota)$ there is a Hecke ideal J_0 of zero-monodromy type with (Hf2)–(Hf5), $J_0 \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$, and, if $J_0 \neq B_4^{\mathrm{po}}$, R = T at patchable curve points. By (Hf2), J_0 is finite over the weights: $B_4^{\mathrm{po}}/(J_0 + \mathfrak{b}_4)$ is a finite module over $\Lambda_{4d}/\mathfrak{m}_{\Lambda_{4d}} = \mathbb{F}_{\mathcal{O}'}$, as λ maps $\mathfrak{m}_{\Lambda_{4d}}$ into the image of $\mathfrak{b}_4$, hence an Artinian local ring, whose maximal ideal is nilpotent.

Step 5: the modular ideal. Let $\mathfrak{J} = \phi_0(J_0)B$. For (Jq1), by Lemma 53.11 for J_0, some $\mathfrak{m}_B^k$ lies in $\phi_0(J_0)B + \mathfrak{m}_{\mathcal{O}'}B + (\psi_{v,i}^B(s) - 1) = \mathfrak{J} + \mathfrak{m}_{\mathcal{O}'}B + (\psi_{v,i}^B(s) - 1)$. For (Jq2), let y be as in (Jq2) and $\mathfrak{q}$ a prime of B with $y(\mathfrak{q}) = 0$; as $y(\mathfrak{J}) = 0$, $y(\phi_0(J_0)) = 0$, so $J_0 \neq B_4^{\mathrm{po}}$ and J_0 has R = T at patchable curve points; by Lemma 53.12, $\phi_0(J_0) \subseteq \mathfrak{q}$, so $\mathfrak{J} \subseteq \mathfrak{q}$, i.e. $\mathfrak{J}$ is local at y. For (Jq3), take y with $y(P)$ a seed; then Lemma 53.17 for J_0 ($J_0 \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$, (Hf2), (Hf5); κ has (Kw1) by Step 1) gives $\phi_0(J_0) \subseteq \mathfrak{q}$ for every prime $\mathfrak{q}$ with $y(\mathfrak{q}) = 0$, so $\mathfrak{J} \subseteq \mathfrak{q}$. (Jq4) follows from Lemma 53.22 for J_0 ((Hf4); $\mathscr{T}$ is good as it is fit, and ν has (Lk5)), as $\mathfrak{J} \supseteq \phi_0(J_0)$. (Jq5) follows from Lemma 53.23 for J_0 ((Hf3)), as $\mathfrak{J} \supseteq \phi_0(J_0)$. Hence $\mathfrak{J}$ is modular for ι. □

Lemma 53.2. *Symbols introduced in this statement are local to it. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with prime ℓ, coefficient ring $\mathcal{O}$, character θ, set of primes S and complex conjugation c, and let $\mathscr{T}$ be a fit and deep auxiliary tower for $\mathfrak{D}$. Then $L = FE$ is a CM field with $L^+ = F$, L/F is unramified at every finite place, every place of F above ℓ splits in L, L contains no primitive ℓ-th root of unity, c is a complex conjugation in $G_F = G_{L^+}$, and there are a coefficient ring $\mathcal{O}_1 \supseteq \mathcal{O}$, continuous homomorphisms $\nu, \gamma\colon G_L \to \mathcal{O}_1^\times$ and a continuous homomorphism $t\colon G_L \to \mathbb{Z}_\ell$ such that*

(Lk1) *$\nu(s)\nu(csc)\theta(s)\chi_{\mathrm{cyc}}(s)^3 = 1$, $\gamma(s)\gamma(csc) = 1$ and $t(s) + t(csc) = 0$ for all $s \in G_L$;*

(Lk2) *$\gamma(s) \equiv 1$ modulo $\mathfrak{m}_{\mathcal{O}_1}$ for all s; $\ker t \subseteq \ker \gamma$; and t is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ not above ℓ;*

(Lk3) *ν is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a prime not in S, and for some integer $m \geq 1$ with $\ell \nmid m$, ν^m is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w}$ not above ℓ;*

(Lk4) *$\nu(g) = 1$ and $t(g) = 0$ for every $v \in \Sigma$ and $g \in \mu_v$;*

(Lk5) *for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ there are integers a, b with b odd and $k \geq 1$ such that $(\nu\chi_{\mathrm{cyc}}^{-a})^k$ and $(\gamma^2\chi_{\mathrm{cyc}}^{-b})^k$ are trivial on $I_{\bar{w}} \cap G_L$;*

and such that for every coefficient ring $\mathcal{O}' \supseteq \mathcal{O}_1$ and every continuous character $\kappa\colon G_L \to \mathcal{O}'^\times$ satisfying (Tw1) with $m = -3$, (Tw2) and (Tw4) for (L, c), there is a rank-4 Hecke datum over $\mathcal{O}'$,

$$\mathscr{H} = (4, L, c, (\bar{v})_{v\in\Sigma}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1\leq a\leq 4}, (\xi_{v,a})),$$

where the places of F above ℓ are indexed by Σ through $v \mapsto$ the place of F below $\bar{v}$, with:

(Lk6) *the residual characters: $\bar{\chi}_a$ is the reduction modulo $\mathfrak{m}_{\mathcal{O}'}$ of $\nu\kappa^{-1}\chi_a^{\mathscr{T}}|_{G_L}$ for $1 \leq a \leq 4$;*

(Lk7) *trivial wild values: $\xi_{v,a} = 1$ for all $v \in \Sigma$ and $1 \leq a \leq 4$;*

(Lk8) *every place of F not above ℓ that lies above a prime of S belongs to* St.

Proof. Symbols introduced here are local to this proof. Write $\chi_a^{\mathscr{T}}$ for $\chi_a^{\mathscr{T}}|_{G_L}$ where no confusion arises; recall $(\kappa_1, \kappa_2, \kappa_3, \kappa_4) = (\theta, \Psi, \alpha, \mathbf{1})$ and $\theta = \alpha\Psi = \chi_{\mathrm{cyc}}^{e+1}\omega_\ell^{-1}\xi\chi$.

Step 0: the fields. $E \not\subseteq F$ (F is totally real), so $L = FE$ is a CM field with $L^+ = F$, and c, which fixes the totally real field F and not E, lies in $G_F \setminus G_L$ and is a complex conjugation

for L. By (Oq1), L/F is unramified at every finite place. The primes of S, among them 2 and ℓ (Sg1), split in E (Oq2); hence every place of F above a prime $p \in S$ splits in L, as $L \otimes_F F_v = F_v \otimes_{\mathbb{Q}_p} (E \otimes \mathbb{Q}_p) \cong F_v \times F_v$. By (Oq3) with $w = 0$ ($\mathrm{rt}_0 = \mathbf{1}$), $\bar{\omega}_\ell$ is non-trivial on G_L, so L contains no primitive ℓ-th root of unity.

Step 1: three characters. (a) $\chi_{\mathrm{cyc}}\omega_\ell^{-1}$ takes values in $1 + \ell\mathbb{Z}_\ell$, which for odd ℓ is uniquely 2-divisible (log is an isomorphism onto $\ell\mathbb{Z}_\ell$); so $\gamma_{\mathbb{Q}} = \exp(\frac{1}{2}\log(\chi_{\mathrm{cyc}}\omega_\ell^{-1}))$ is a continuous character $G_{\mathbb{Q}} \to 1 + \ell\mathbb{Z}_\ell$ with $\gamma_{\mathbb{Q}}^2 = \chi_{\mathrm{cyc}}\omega_\ell^{-1}$, unramified outside ℓ. (b) Let $\varphi_0 = (\omega_\ell^{e+3}\xi\chi)^{-1}$, a Dirichlet character unramified outside S (Sg1); write $\varphi_0 = \varphi\varphi_\ell$ with φ of order prime to ℓ and φ_ℓ of ℓ-power order, both powers of φ_0. As ω_ℓ and ξ have order prime to ℓ and $\chi|_{G_F}$ has order prime to ℓ (deep), $\varphi_\ell|_{G_F} = 1$. Moreover $\omega_\ell(c) = -1$, $\xi(c) = -1$ and $\chi(c) = \Psi(c)\chi_{\mathrm{cyc}}(c)^{-e} = (-1)^e$ (Sg1), so $\varphi_0(c) = 1$ and $\varphi(c) = 1$. By Lemma 53.3 (2 and every prime of S split in E) there is $\kappa_0 \colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ of finite order m_0 prime to ℓ with (Ie1) for φ and (Ie2). (c) Let $\bar{w}$ be a place above ℓ; by Lemma 53.4 (ℓ splits in E) there are $\mathcal{O}_\beta$, $t_E \colon G_E \to \mathbb{Z}_\ell$ and $\beta \colon G_E \to \mathcal{O}_\beta^\times$ with (Ia1)–(Ia4).

Step 2: $\mathcal{O}_1$, ν, γ, t. Let $\mathcal{O}_1$ be the integral closure of $\mathbb{Z}_\ell$ in the finite extension of $\mathbb{Q}_\ell$ generated by $\mathcal{O}$, $\mathcal{O}_\beta$, the m_0-th roots of unity and $\tau(L)$ for the finitely many embeddings $\tau \colon L \to \overline{\mathbb{Q}}_\ell$; it is a coefficient ring containing $\mathcal{O}$. Put $\epsilon_e \in \{0, 1\}$ with $\epsilon_e \equiv e$ modulo 2 and

$$\nu = \kappa_0|_{G_L} \cdot \gamma_{\mathbb{Q}}|_{G_L}^{-(e+4)} \cdot \beta|_{G_L}^{\epsilon_e}, \qquad \gamma = \beta|_{G_L}, \qquad t = t_E|_{G_L},$$

continuous, with values in $\mathcal{O}_1^\times$ (κ_0 takes values in the m_0-th roots of unity, $\gamma_{\mathbb{Q}}$ in $\mathbb{Z}_\ell^\times$).

Step 3: (Lk1)–(Lk5). (Lk1): for $s \in G_L$, $csc \in G_L$ and $c \notin G_E$; by (Ie1), (Ia2) and as $\gamma_{\mathbb{Q}}$ is a character of $G_{\mathbb{Q}}$ with abelian values, $\nu(s)\nu(csc) = \varphi(s)\gamma_{\mathbb{Q}}(s)^{-2(e+4)} = \varphi_0(s)(\chi_{\mathrm{cyc}}\omega_\ell^{-1})(s)^{-(e+4)} = \chi_{\mathrm{cyc}}(s)^{-(e+4)}\omega_\ell(s)\xi(s)^{-1}\chi(s)^{-1}$ (using $\varphi_\ell(s) = 1$), which is $(\theta(s)\chi_{\mathrm{cyc}}(s)^3)^{-1}$; $\gamma(s)\gamma(csc) = 1$ and $t(s) + t(csc) = 0$ by (Ia2). (Lk2) is (Ia1) and (Ia3) restricted to G_L. (Lk3): at a place above a prime not in S (in particular not above ℓ), κ_0 is trivial on inertia by (Ie2), $\gamma_{\mathbb{Q}}$ is unramified, and β is trivial on inertia by (Ia3) and $\ker t_E \subseteq \ker\beta$; at any place not above ℓ the last two still hold, so ν^{m_0} is trivial on inertia there. (Lk4): let $v \in \Sigma$, $g \in \mu_v$, so $g^{\ell^k} \in \overline{[D_v, D_v]}$ for some k. A continuous homomorphism from D_v to an abelian Hausdorff group kills $\overline{[D_v, D_v]}$. Hence $\ell^k t(g) = 0$, so $t(g) = 0$, and $\beta(g) = 1$; $\kappa_0(g)^{\ell^k} = 1$ with $\kappa_0(g)$ of order prime to ℓ, so $\kappa_0(g) = 1$; $\gamma_{\mathbb{Q}}(g)^{\ell^k} = 1$ in the torsion-free group $1 + \ell\mathbb{Z}_\ell$, so $\gamma_{\mathbb{Q}}(g) = 1$. Thus $\nu(g) = 1$. (Lk5): let $\bar{u}$ be a place above ℓ. Since ℓ splits in E, $\bar{u}$ induces on E either the place of $\bar{w}$ or its conjugate; in the first case $I_{\bar{u}} \cap G_E$ is G_E-conjugate to $I_{\bar{w}} \cap G_E$ and $\beta^2\chi_{\mathrm{cyc}}^{-b}$ with $b = b_0$ (odd, from (Ia4)) is trivial on an open subgroup of it by (Ia4); in the second, $I_{\bar{u}} \cap G_E$ is G_E-conjugate to $c(I_{\bar{w}} \cap G_E)c$ and by (Ia2) the same holds with $b = -b_0$. An open subgroup of the compact group $I_{\bar{u}} \cap G_L$ has finite index, so $(\beta^2\chi_{\mathrm{cyc}}^{-b})^{k_1}$ is trivial on $I_{\bar{u}} \cap G_L$ for some $k_1 \geq 1$, with b odd. Further $\gamma_{\mathbb{Q}}^{-2(e+4)} = \chi_{\mathrm{cyc}}^{-(e+4)}\omega_\ell^{e+4}$, so $\nu^2 = \kappa_0^2\omega_\ell^{e+4}\chi_{\mathrm{cyc}}^{-(e+4)}\beta^{2\epsilon_e}$, and with $2a = -(e+4) + b\epsilon_e$ (even, as b is odd and $\epsilon_e \equiv e$) the character $\nu^2\chi_{\mathrm{cyc}}^{-2a} = \kappa_0^2\omega_\ell^{e+4}(\beta^2\chi_{\mathrm{cyc}}^{-b})^{\epsilon_e}$ has finite order on $I_{\bar{u}} \cap G_L$; so $(\nu\chi_{\mathrm{cyc}}^{-a})^k$ is trivial there for some $k \geq 1$, and the same k may be taken for both characters.

Step 4: the auxiliary element. The characters $\bar{\chi}_a^{\mathscr{J}}/\bar{\chi}_b^{\mathscr{J}}$ ($a \neq b$) are root characters: $\chi_a^{\mathscr{J}}\chi_{5-a}^{\mathscr{J}} = \theta$ for both labellings, so with $\mathrm{rt}_{w_\alpha} = \chi_1^{\mathscr{J}}/\chi_2^{\mathscr{J}}$, $\mathrm{rt}_{w_\Psi} = \chi_1^{\mathscr{J}}/\chi_3^{\mathscr{J}}$, $\mathrm{rt}_{w_\beta} = \chi_2^{\mathscr{J}}/\chi_3^{\mathscr{J}}$, $\mathrm{rt}_{w_\theta} = \chi_1^{\mathscr{J}}/\chi_4^{\mathscr{J}}$ one has $\chi_2^{\mathscr{J}}/\chi_4^{\mathscr{J}} = \mathrm{rt}_{w_\Psi}$ and $\chi_3^{\mathscr{J}}/\chi_4^{\mathscr{J}} = \mathrm{rt}_{w_\alpha}$. By (Oq3) they are non-trivial on G_L. Let $H \subseteq G_L$ be the common kernel of $\bar{\chi}_1^{\mathscr{J}}, \ldots, \bar{\chi}_4^{\mathscr{J}}$; one of these characters is trivial ($\kappa_4 = \mathbf{1}$), and the others are products of powers of $\bar{\chi}_1^{\mathscr{J}}/\bar{\chi}_2^{\mathscr{J}}$ and $\bar{\chi}_1^{\mathscr{J}}/\bar{\chi}_3^{\mathscr{J}}$ times that trivial one, so H is the common kernel of $\overline{\mathrm{rt}_{w_\alpha}}$ and $\overline{\mathrm{rt}_{w_\Psi}}$ on G_L. The characters of the finite abelian group G_L/H, which embeds into $\mathbb{F}_{\mathcal{O}}^\times \times \mathbb{F}_{\mathcal{O}}^\times$ through these two, are the products of their powers, i.e. the $\overline{\mathrm{rt}_w}$, $w \in \mathbb{Z}^2$ (a character of a subgroup of a product of two cyclic groups extends to the product, whose characters are products of powers of the two coordinates). By (Oq3), $\bar{\omega}_\ell|_{G_L}$ is none of them, so $\bar{\omega}_\ell$ is non-trivial

on H: there is $g_1 \in G_L$ with $\bar\chi_a^{\mathscr{J}}(g_1) = 1$ for all a and $\bar\omega_\ell(g_1) \neq 1$.

Step 5: the data. Let $\mathcal{O}' \supseteq \mathcal{O}_1$ and κ be as in the statement, and $\lambda = \nu\kappa^{-1}$, so $\lambda(s)\lambda(csc) = \theta(s)^{-1}$ for $s \in G_L$ by (Lk1) and (Tw1). Let $\bar\chi_a$ be the reduction of $\lambda\chi_a^{\mathscr{J}}$, $\xi_{v,a} = 1$, and St the set of places of F above the primes of $S \setminus \{\ell\}$. Let $M \subset \overline{\mathbb{Q}}$ be the fixed field of $G_L \cap \ker\bar\theta \cap \ker\bar\Psi \cap \ker\bar\alpha \cap \ker\bar\omega_\ell$, a finite Galois extension of $\mathbb{Q}$ ($L/\mathbb{Q}$ is Galois, F being abelian). By the Chebotarev density theorem for M/F there are infinitely many places v_0 of F, unramified in M, with a place $\bar v_0$ above them whose Frobenius in $\mathrm{Gal}(M/F)$ is the image of g_1; choose v_0 above a prime $p \notin S$ unramified in L. Then $D_{\bar v_0} \cap G_F$ maps into the subgroup generated by the image of g_1, which lies in $\mathrm{Gal}(M/L)$; so $D_{\bar v_0} \cap G_F \subseteq G_L$ (v_0 splits in L), the $\bar\chi_a^{\mathscr{J}}$ are trivial on $D_{\bar v_0} \cap G_L$ and $\bar\omega_\ell$ is not. Now the conditions of Definition 50.1 for $\mathscr{H}$, with S_ℓ indexed by Σ: (Rd1) by the choice of $\mathcal{O}_1 \subseteq \mathcal{O}'$ and Step 0; (Rd2) by Step 0 and the choice of v_0; (Rd3) as $p \notin S \ni 2, \ell$ and p is unramified in L; (Rd4): the $\bar\chi_a$ are pairwise distinct, their ratios being the non-trivial characters $\overline{\mathrm{rt}_w}$ of Step 4; at a place $\bar u$ above a place of F not in $S_\ell \cup \mathrm{St}$, i.e. above a prime not in S, ν is trivial on inertia by (Lk3), κ by (Tw2), and θ, Ψ, α are unramified (Sg1: χ has conductor dividing N, whose primes lie in S, ξ is unramified outside S, χ_{cyc} and ω_ℓ outside ℓ); (Rd5): $\bar\chi_{5-a}(csc)\bar\chi_a(s)$ is the reduction of $\lambda(csc)\lambda(s)\chi_{5-a}^{\mathscr{J}}(s)\chi_a^{\mathscr{J}}(s) = \theta(s)^{-1}\theta(s) = 1$; (Rd6): on $D_{\bar v_0} \cap G_L$ all $\bar\chi_a$ equal $\bar\lambda$, and $\bar\omega_\ell$, the reduction of χ_{cyc}, is non-trivial there; (Rd10) holds as $\xi_{v,a} = 1$. (Lk6), (Lk7) hold by construction, and (Lk8) by the choice of St. □

Lemma 53.3. *Let ℓ be an odd prime, $E \subset \overline{\mathbb{Q}}$ an imaginary quadratic field in which 2 splits, S a finite set of primes containing 2, each of which splits in E, and $\varphi\colon G_{\mathbb{Q}} \to \overline{\mathbb{Q}}_\ell^\times$ a character of finite order prime to ℓ, unramified at every prime not in S, with $\varphi(c) = 1$ for a complex conjugation c. Then there is a continuous character $\kappa_0\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ of finite order prime to ℓ such that*

(Ie1) *$\kappa_0(s)\kappa_0(\sigma s\sigma^{-1}) = \varphi(s)$ for all $s \in G_E$ and $\sigma \in G_{\mathbb{Q}} \setminus G_E$;*

(Ie2) *κ_0 is trivial on $I_{\bar w} \cap G_E$ for every place $\bar w$ of $\overline{\mathbb{Q}}$ above a prime not in S.*

Proof. Symbols introduced here are local to this proof. Write $x \mapsto \bar x$ for the non-trivial automorphism of E and of $\mathbb{A}_E^\times$, $\mathcal{V}\colon G_{\mathbb{Q}}^{\mathrm{ab}} \to G_E^{\mathrm{ab}}$ for the transfer, and view φ also as the character $\varphi \circ \mathrm{Art}_{\mathbb{Q}}$ of $\mathbb{A}_{\mathbb{Q}}^\times/\mathbb{Q}^\times$, of order m prime to ℓ. We use from global class field theory: Art_E is surjective with kernel the image of the closure Y of $E^\times E_\infty^\times$; on the image of $\mathbb{A}_{\mathbb{Q}}^\times$ it is $\mathcal{V} \circ \mathrm{Art}_{\mathbb{Q}}$; it maps $\mathcal{O}_{E_w}^\times$ onto the image of the inertia groups above w; and for $s \in G_E$, $\sigma \in G_{\mathbb{Q}} \setminus G_E$, $\mathcal{V}(s) = s \cdot \sigma s\sigma^{-1}$ modulo commutators. As φ has finite order, φ_∞ is trivial on $\mathbb{R}_{>0}$, and $\varphi_\infty(-1) = \varphi(c) = 1$; so $\varphi_\infty = 1$. As 2 splits in E, the discriminant of E is $\equiv 1$ modulo 8, so $E \neq \mathbb{Q}(i), \mathbb{Q}(\sqrt{-3})$ and $\mathcal{O}_E^\times = \{\pm 1\}$.

Let $U_0 = \prod_w \mathcal{O}_{E_w}^\times$, w over the finite places of E not above S (components 1 at the other places).

Claim. If $a, a' \in \mathbb{A}_{\mathbb{Q}}^\times$ and $u, u' \in U_0$ satisfy $\mathrm{Art}_E(au) = \mathrm{Art}_E(a'u')$, then $\varphi(a) = \varphi(a')$. Indeed, $y = au(a'u')^{-1} \in Y$: there are $\alpha_i \in E^\times$, $z_i \in E_\infty^\times$ with $\alpha_i z_i \to y$. Put $x = a/a' \in \mathbb{A}_{\mathbb{Q}}^\times$ and $\beta_i = \bar\alpha_i/\alpha_i$. The finite parts of β_i converge to the finite part of $\bar y/y = (\bar u/u)(u'/\bar u')$ (as $\bar x = x$), a unit idele whose components at the places above S are 1. For large i, β_i is therefore a unit at every finite place, and $|\beta_i|_\infty = 1$; so $\beta_i \in \mathcal{O}_E^\times = \{\pm 1\}$; at a place w_2 above $2 \in S$, $\beta_i \to 1$ in E_{w_2} excludes -1. So $\alpha_i \in \mathbb{Q}^\times$ for large i, and the finite part y_f of y is the limit of the α_i in $\mathbb{A}_{\mathbb{Q},f}^\times$ (closed in $\mathbb{A}_{E,f}^\times$). Now $x = y\,u'/u$, so u'/u has components in $\mathbb{Q}_p^\times \cap \mathcal{O}_{E_w}^\times = \mathbb{Z}_p^\times$ at the primes $p \notin S$ and 1 at the primes of S, where φ is unramified, resp. not involved; and for large i, $\varphi(x) = \varphi(x\alpha_i^{-1}) = \varphi_f(y_f\alpha_i^{-1})\,\varphi_f(u'/u)\,\varphi_\infty(x_\infty\alpha_i^{-1}) = 1$, the first factor because $y_f\alpha_i^{-1} \to 1$ and φ_f has open kernel, the second as just said, the third as $\varphi_\infty = 1$.

Construction. $K = \mathcal{V}(G_{\mathbb{Q}}^{\mathrm{ab}})\,\mathrm{Art}_E(U_0)$ is a compact subgroup of G_E^{ab}, and by the Claim $\mu_0(\mathcal{V}(\mathrm{Art}_{\mathbb{Q}}(a))\,\mathrm{Art}_E(u)) = \varphi(a)$ is a well-defined homomorphism on K. It is continuous: $G_{\mathbb{Q}}^{\mathrm{ab}} \times \mathrm{Art}_E(U_0) \to K$ is a continuous surjection of compact Hausdorff groups, hence a quotient map, and μ_0 composed with it is $(g,k) \mapsto \varphi(g)$. Its kernel is open in K, so contains $K \cap N$ for an open subgroup N of the profinite group G_E^{ab}; μ_0 factors through the subgroup $K/(K\cap N)$ of the finite group G_E^{ab}/N and extends to a character μ of it with values in the divisible group of roots of unity of $\overline{\mathbb{Q}}_\ell^\times$. Let $\mathrm{ord}(\mu) = m'\ell^j$ with $\ell \nmid m'$, choose $u_0 \in \mathbb{Z}$ with $u_0 \equiv 0$ modulo ℓ^j and $u_0 \equiv 1$ modulo mm', and put $\kappa_0 = \mu^{u_0}$ (as a character of G_E), of finite order dividing m', prime to ℓ.

Verification. For $s \in G_E$ and $\sigma \in G_{\mathbb{Q}} \setminus G_E$, $\kappa_0(s)\kappa_0(\sigma s\sigma^{-1}) = \mu(\mathcal{V}(s))^{u_0} = \varphi(s)^{u_0} = \varphi(s)$, which is (Ie1). For a place $\bar w$ above a prime not in S, the image of $I_{\bar w}\cap G_E$ in G_E^{ab} is $\mathrm{Art}_E(\mathcal{O}_{E_w}^\times) \subseteq \mathrm{Art}_E(U_0)$, on which μ is $\mu_0 = 1$; this is (Ie2). □

Lemma 53.4. *Let ℓ be an odd prime, $E \subset \overline{\mathbb{Q}}$ an imaginary quadratic field in which ℓ splits, and $\bar w$ a place of $\overline{\mathbb{Q}}$ above ℓ. There are a coefficient ring $\mathcal{O}_\beta$ and continuous homomorphisms $t\colon G_E \to \mathbb{Z}_\ell$ and $\beta\colon G_E \to \mathcal{O}_\beta^\times$ such that*

(Ia1) *$\beta(s) \equiv 1$ modulo $\mathfrak{m}_{\mathcal{O}_\beta}$ for all s, and $\ker t \subseteq \ker\beta$;*

(Ia2) *$t(s) + t(\sigma s\sigma^{-1}) = 0$ and $\beta(s)\beta(\sigma s\sigma^{-1}) = 1$ for all $s \in G_E$ and $\sigma \in G_{\mathbb{Q}} \setminus G_E$;*

(Ia3) *t is trivial on $I_{\bar u} \cap G_E$ for every place $\bar u$ of $\overline{\mathbb{Q}}$ not above ℓ;*

(Ia4) *for some odd integer b_0, $\beta(s)^2 = \chi_{\mathrm{cyc}}(s)^{b_0}$ for all s in an open subgroup of $I_{\bar w} \cap G_E$.*

Proof. Symbols introduced here are local to this proof. Let $\ell = \mathfrak{l}\bar{\mathfrak{l}}$ in E, with $\mathfrak{l}$ the place of $\bar w$, so $E_{\mathfrak{l}} = E_{\bar{\mathfrak{l}}} = \mathbb{Q}_\ell$; $x \mapsto \bar x$ is the non-trivial automorphism of E, of $\mathbb{A}_E^\times$ and of C_E, and $\mathrm{Art}_E(\bar x) = \sigma\mathrm{Art}_E(x)\sigma^{-1}$ for $\sigma \in G_{\mathbb{Q}} \setminus G_E$. For $z \in \mathbb{Z}_\ell^\times$ let $\langle z\rangle = z\,\omega(z)^{-1} \in 1 + \ell\mathbb{Z}_\ell$ (ω the Teichmüller lift), and $\log\colon 1+\ell\mathbb{Z}_\ell \to \ell\mathbb{Z}_\ell$, exp its inverse ($\ell$ odd). Let $U^\ell = \prod_{w\nmid\ell}\mathcal{O}_{E_w}^\times$, $U_\ell = \mathcal{O}_{E_{\mathfrak{l}}}^\times \times \mathcal{O}_{E_{\bar{\mathfrak{l}}}}^\times = \mathbb{Z}_\ell^\times \times \mathbb{Z}_\ell^\times$, and Γ the quotient of $\mathbb{A}_E^\times$ by the closure of $E^\times U^\ell E_\infty^\times$; by class field theory Art_E identifies Γ with the Galois group of the maximal abelian extension of E unramified outside ℓ, a profinite group, and the image H of U_ℓ is a compact open subgroup with Γ/H the class group of E, of order h.

Step 1: the kernel of $U_\ell \to H$. If $u \in U_\ell$ lies in the closure of $E^\times U^\ell E_\infty^\times$, there are $\alpha_i \in E^\times$, $v_i \in U^\ell$, z_i with $\alpha_i v_i z_i \to u$; at the finite places $w \nmid \ell$ the components of $\alpha_i v_i$ tend to 1, and at $\mathfrak{l}, \bar{\mathfrak{l}}$ those of α_i tend to units; so for large i, α_i is a unit at every finite place, hence $\alpha_i \in \mathcal{O}_E^\times$, a finite group, and u has components (ζ,ζ) with $\zeta \in \mathcal{O}_E^\times$, a root of unity.

Step 2: t. $t_0(u_1,u_2) = \log\langle u_1\rangle - \log\langle u_2\rangle$ is a continuous homomorphism $U_\ell \to \ell\mathbb{Z}_\ell$, trivial on (ζ,ζ) for roots of unity ζ, so by Step 1 it factors through a continuous homomorphism $t_0\colon H \to \ell\mathbb{Z}_\ell$ (H carries the quotient topology of the compact U_ℓ). Write $h = \ell^v h'$ with $\ell \nmid h'$ and put $t(g) = t_0(g^h)/h'$ for $g \in \Gamma$ ($g^h \in H$), a continuous homomorphism $\Gamma \to \ell\mathbb{Z}_\ell$ (Γ is abelian, and $g \mapsto g^h$ is continuous into the open subgroup H). Since $\overline{(u_1,u_2)} = (u_2,u_1)$, $t_0(\bar g) = -t_0(g)$, hence $t(\bar g) = -t(g)$. Composing with $G_E \to G_E^{\mathrm{ab}} \to \Gamma$ (inverse of Art_E) gives $t\colon G_E \to \mathbb{Z}_\ell$ with (Ia2) for t, and (Ia3), as inertia at places $w \nmid \ell$ maps into the image of $\mathcal{O}_{E_w}^\times \subseteq U^\ell$, which is trivial in Γ.

Step 3: β. Put $\beta = \exp(-t/2)$, a continuous homomorphism $G_E \to 1+\ell\mathbb{Z}_\ell \subseteq \mathbb{Z}_\ell^\times$; take $\mathcal{O}_\beta = \mathbb{Z}_\ell$. Then $\beta \equiv 1$ modulo ℓ, $\ker t \subseteq \ker\beta$, and $\beta(s)\beta(\sigma s\sigma^{-1}) = \exp(-(t(s)+t(\sigma s\sigma^{-1}))/2) = 1$: (Ia1), (Ia2). For (Ia4): the image of $I_{\bar w}\cap G_E$ in Γ is the image of $\mathcal{O}_{E_{\mathfrak{l}}}^\times = \mathbb{Z}_\ell^\times$ (embedded as $(u_1,1)$), and on the open subgroup where $u_1 \in 1+\ell\mathbb{Z}_\ell$, $t = t_0(u_1^h,1)/h' = \ell^v \log u_1$, so $\beta^2 = \exp(-\ell^v \log u_1) = u_1^{-\ell^v}$. By local class field theory with the arithmetic normalisation

(Lubin–Tate), $\chi_{\mathrm{cyc}}(\mathrm{Art}_{\mathbb{Q}_\ell}(u_1)) = u_1^{-1}$ for $u_1 \in \mathbb{Z}_\ell^\times$, and Art_E restricted to $E_\mathfrak{l}^\times$ is the local Artin map of $E_\mathfrak{l} = \mathbb{Q}_\ell$ followed by $G_{E_\mathfrak{l}}^{\mathrm{ab}} \to G_E^{\mathrm{ab}}$, with $G_{E_\mathfrak{l}}$ identified with $D_{\bar w} \cap G_E$. Hence $\beta^2 = \chi_{\mathrm{cyc}}^{b_0}$ with $b_0 = \ell^v$, odd, on an open subgroup of $I_{\bar w} \cap G_E$. □

Lemma 53.5. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $L \subset \overline{\mathbb{Q}}$ a CM field with maximal totally real subfield L^+ such that L/L^+ is unramified at every finite place, every place of L^+ above ℓ splits in L, and L contains no primitive ℓ-th root of unity, $c \in G_{L^+}$ a complex conjugation, and m an integer. Then there is a continuous character $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$, algebraic for ι, such that*

(Tw1) *$\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^m$ for all $s \in G_L$;*

(Tw2) *κ is trivial on $I_{\bar w} \cap G_L$ for every place $\bar w$ of $\overline{\mathbb{Q}}$ above a finite place of L not above ℓ;*

(Tw3) *$\kappa(G_L) \subseteq \mathcal{O}_\kappa^\times$ for some coefficient ring $\mathcal{O}_\kappa$;*

(Tw4) *for every place $\bar w$ of $\overline{\mathbb{Q}}$ above ℓ, κ is trivial on every $g \in D_{\bar w} \cap G_L$ whose image in the abelianisation $(D_{\bar w} \cap G_L)/\overline{[D_{\bar w} \cap G_L, D_{\bar w} \cap G_L]}$ has ℓ-power order;*

(Kw1) *for every place $\bar w$ of $\overline{\mathbb{Q}}$ above ℓ there are integers h and $k \geq 1$ such that $(\kappa\chi_{\mathrm{cyc}}^{-h})^k$ is trivial on $I_{\bar w} \cap G_L$.*

In particular, let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ whose CM field is L and whose complex conjugation is c, and take $m = 1 - n$. Then for every coefficient ring $\mathcal{O}'$ containing $\mathcal{O}$ and $\mathcal{O}_\kappa$, $\mathscr{H}$ is a rank-n Hecke datum over $\mathcal{O}'$, κ is a twist for it, with $m' = 1$ in (Rd7), and κ is trivial on μ_v for every $v \in S_\ell$.

Proof. Symbols introduced here are local to this proof. For a finite place w of L fix a place $\bar w$ of $\overline{\mathbb{Q}}$ above it and identify G_{L_w} with $D_{\bar w} \cap G_L$; for a continuous character ψ of G_L put $\psi_w = \psi \circ \mathrm{Art}_{L_w}\colon L_w^\times \to \overline{\mathbb{Q}}_\ell^\times$, which does not depend on the choice of $\bar w$ (decomposition groups above w are conjugate in G_L and ψ factors through G_L^{ab}). As $\mathrm{Art}_{L_w}(\mathcal{O}_{L_w}^\times)$ is the image of $I_{\bar w} \cap G_L$ in $G_{L_w}^{ab}$, ψ is trivial on $I_{\bar w} \cap G_L$ if and only if ψ_w is trivial on $\mathcal{O}_{L_w}^\times$. Moreover Art_{L_w} identifies $G_{L_w}^{ab}$ with the profinite completion of $L_w^\times$, whose torsion subgroup is the group $\mu(L_w) \subseteq \mathcal{O}_{L_w}^\times$ of roots of unity; so the elements of G_{L_w} whose image in $G_{L_w}^{ab}$ has ℓ-power order are those whose image is $\mathrm{Art}_{L_w}(\zeta)$ with $\zeta \in \mu_{\ell^\infty}(L_w)$, the roots of unity of ℓ-power order, and ψ is trivial on them if and only if ψ_w is trivial on $\mu_{\ell^\infty}(L_w)$. We use from global class field theory: Art_L is surjective, with kernel the connected component of C_L; on the image of $L_w^\times$ in C_L it is Art_{L_w} followed by $G_{L_w}^{ab} \to G_L^{ab}$; and on the image of $C_{L^+} \to C_L$ (induced by $\mathbb{A}_{L^+} \subseteq \mathbb{A}_L$) it is $\mathcal{V} \circ \mathrm{Art}_{L^+}$, where $\mathcal{V}\colon G_{L^+}^{ab} \to G_L^{ab}$ is the transfer. Since $[G_{L^+} : G_L] = 2$ with coset representatives $1, c$, $\mathcal{V}(s) = s \cdot csc$ modulo commutators for $s \in G_L$. Finally, a continuous character ψ of a profinite group G into $\overline{\mathbb{Q}}_\ell^\times$ takes values in $\mathcal{O}_E^\times$ for a finite extension $E/\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$: G is the countable union of the closed subgroups $\psi^{-1}(E^\times)$, so by Baire's theorem one of them has non-empty interior, hence is open of finite index; adjoining the finitely many values on coset representatives gives a finite E with $\psi(G) \subseteq E^\times$, and $\psi(G)$ is compact, so it lies in $\mathcal{O}_E^\times$.

Step 1: a character with the right conjugate product. Let S be the set of places of L above ℓ. Then $S^c = S$, and every $v \in S$ is unramified over L^+ and, by hypothesis, $v^c \neq v$. Choose one place v_1 in each pair $\{v, v^c\} \subseteq S$ and a place $\bar v_1$ above it, and put $\overline{v_1^c} = c\bar v_1$. Let $\chi = \chi_{\mathrm{cyc}}^m|_{G_{L^+}}$; as χ_{cyc} takes the value -1 on every complex conjugation, χ takes the value $(-1)^m$ on all of them. Put $\psi_{v_1} = \chi_{\mathrm{cyc}}^m|_{G_{L_{v_1}}}$ and $\psi_{v_1^c} = \mathbf{1}$, both de Rham. In the notation of Lemma B.26, for $g \in G_{L_{v_1}}$, $\psi_{v_1}(g)\psi_{v_1^c}(cgc) = \chi_{\mathrm{cyc}}(g)^m = \chi(g)$, and for $g \in G_{L_{v_1^c}}$, $\psi_{v_1^c}(g)\psi_{v_1}(cgc) = \chi_{\mathrm{cyc}}(cgc)^m = \chi(g)$, since χ_{cyc} is a character of $G_\mathbb{Q}$; so the hypothesis of Lemma B.26 holds on all of G_{L_v}, in

particular on inertia. By Lemma B.26 (for $F = L$) there is a continuous $\theta\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ with $\theta(s)\theta(csc) = \chi_{\mathrm{cyc}}(s)^m$ for $s \in G_L$ and $\theta|_{I_{\bar v}} = \psi_v|_{I_{\bar v}}$ for $v \in S$. For $v \in S$, $\theta|_{G_{L_v}}\psi_v^{-1}$ is unramified, hence crystalline, so $\theta|_{G_{L_v}}$ is de Rham. Hence θ is algebraic for ι: every continuous character of G_L that is de Rham at all places above ℓ corresponds through ι and the global Artin map to an algebraic Hecke character ([220, Ch. III]; [69, Lemma 4.1.3]), and θ_w is then trivial on $\mathcal{O}_{L_w}^\times$ for all but finitely many w. Moreover, for $v \in S$, θ_v is trivial on $\mu_{\ell^\infty}(L_v)$: on $\mathcal{O}_{L_v}^\times$ it equals $\psi_v \circ \mathrm{Art}_{L_v}$, which is 1 or $x \mapsto \mathrm{N}_{L_v/\mathbb{Q}_\ell}(x)^{\pm m}$ (the sign fixed by the normalisation of the Artin map), and for $\zeta \in \mu_{\ell^\infty}(L_v)$, $\mathrm{N}_{L_v/\mathbb{Q}_\ell}(\zeta)$ is a root of unity of ℓ-power order in $\mathbb{Q}_\ell$, hence 1 as ℓ is odd.

Step 2: the local defects. Let T be the finite set of finite places $w \nmid \ell$ of L with $\theta_w|_{\mathcal{O}_{L_w}^\times} \neq 1$, and for $w \in T$ let $\lambda_w = \theta_w^{-1}|_{\mathcal{O}_{L_w}^\times}$. Each λ_w has finite order: if $w \mid p$, then $\mathcal{O}_{L_w}^\times$ is the product of a finite group and the pro-p group $1 + \mathfrak{p}_w$, whose image is a pro-p subgroup of some $\mathcal{O}_E^\times$ (by the fact recalled above), which is the product of a finite group and a pro-ℓ group; since $p \neq \ell$ that image is finite.

Step 3: the defects are trivial on the units of L^+. Let $\eta = \theta \circ \mathcal{V}$, a continuous character of G_{L^+}. For $s \in G_L$, $\eta(s) = \theta(s)\theta(csc) = \chi_{\mathrm{cyc}}(s)^m$, so $\eta\chi_{\mathrm{cyc}}^{-m}$ is trivial on G_L and equals ε^e with $e \in \{0, 1\}$, where $\varepsilon\colon G_{L^+} \to \{\pm 1\}$ has kernel G_L. Now χ_{cyc} is unramified at every finite place not above ℓ, and ε at every finite place since L/L^+ is unramified there; so for every finite place $u \nmid \ell$ of L^+, $\eta \circ \mathrm{Art}_{L_u^+}$ is trivial on $\mathcal{O}_{L_u^+}^\times$. By the compatibility of Art_L with the transfer, for $b \in \mathcal{O}_{L_u^+}^\times$ embedded in $\prod_{w|u} L_w^\times$,

$$\prod_{w|u} \theta_w(b) = \eta(\mathrm{Art}_{L_u^+}(b)) = 1, \qquad \text{so} \qquad \prod_{w|u,\ w\in T} \lambda_w(b) = 1. \qquad (*)$$

Step 4: a correcting character. Let $U = \prod_{w\nmid\ell} \mathcal{O}_{L_w}^\times \times \prod_{w|\ell} \mu_{\ell^\infty}(L_w)$ (w over the finite places of L), a compact subgroup of $\mathbb{A}_L^\times$ contained in the unit ideles, and $\lambda\colon U \to \overline{\mathbb{Q}}_\ell^\times$, $\lambda((u_w)_w) = \prod_{w\in T} \lambda_w(u_w)$, a continuous character of finite order, trivial on the factors at the places above ℓ. Let $G = G_L^{ab}$, $A = \mathcal{V}(G_{L^+}^{ab})$ and $\bar U = \mathrm{Art}_L(U)$ (image of U in C_L followed by Art_L), compact subgroups of G.

Claim: if $u \in U$ and $\mathrm{Art}_L(u) \in A$, then $\lambda(u) = 1$. As Art_{L^+} is surjective, A is the image under Art_L of $\mathbb{A}_{L^+}^\times$; so $u = a\,y$ with $a \in \mathbb{A}_{L^+}^\times$ and y in the closure of $L^\times L_\infty^\times$ in $\mathbb{A}_L^\times$ (the preimage of the connected component of C_L): there are $\alpha_i \in L^\times$, $z_i \in L_\infty^\times$ with $\alpha_i z_i \to y$. Let $x \mapsto \bar x$ be the automorphism of $\mathbb{A}_L^\times$ induced by the non-trivial automorphism of L/L^+; it fixes $\mathbb{A}_{L^+}^\times$ and preserves $L^\times$, $L_\infty^\times$ and U. Put $\beta_i = \bar\alpha_i/\alpha_i \in L^\times$. The finite parts of β_i converge to the finite part of $\bar y/y = \bar u/u$, a unit idele. Hence for large i, β_i is a unit at every finite place (the unit ideles form an open subgroup of the finite ideles), and for every embedding $\tau\colon L \to \mathbb{C}$, $|\tau(\beta_i)| = |\overline{\tau(\alpha_i)}/\tau(\alpha_i)| = 1$, as L is CM. By Kronecker's theorem β_i is a root of unity in L. Fix a place u_0 of L^+ above ℓ; it splits as $w_0 w_0^c$, and we identify $L_{w_0} = L_{u_0}^+ = L_{w_0^c}$. The components of u at w_0, w_0^c are $\zeta_0, \zeta_0' \in \mu_{\ell^\infty}(L_{u_0}^+)$, so $y_{w_0} = a_{u_0}^{-1}\zeta_0$, $y_{w_0^c} = a_{u_0}^{-1}\zeta_0'$, and $(\beta_i)_{w_0} \to (\bar y/y)_{w_0} = \zeta_0'/\zeta_0$. The roots of unity of L form a finite group embedded in $L_{w_0}^\times$, so for large i, $\beta_i = \zeta$ for a fixed root of unity $\zeta \in L$ whose image in L_{w_0} is ζ_0'/ζ_0, of ℓ-power order; as L contains no primitive ℓ-th root of unity, $\zeta = 1$, i.e. $\alpha_i \in L^{+\times}$ for large i. Hence for each finite place u' of L^+ the components of y at the places $w \mid u'$ are the images of one element of $L_{u'}^{+\times}$ (the limit of the α_i in the closed subgroup $L_{u'}^{+\times}$ of $\prod_{w|u'} L_w^\times$), and the same holds for $u = ay$; for $u' \nmid \ell$, as the components of u are units, they are the images of one $b_{u'} \in \mathcal{O}_{L_{u'}^+}^\times$. By $(*)$, $\lambda(u) = \prod_{u'\nmid\ell} \prod_{w|u',\, w\in T} \lambda_w(b_{u'}) = 1$.

By the claim, $\mu_0(x\,\mathrm{Art}_L(u)) = \lambda(u)$ ($x \in A$, $u \in U$) is a well-defined homomorphism on the compact subgroup $K = A\bar U$ of G; it is continuous, since $A \times U \to K$, $(x, u) \mapsto x\,\mathrm{Art}_L(u)$, is

a continuous surjection of compact Hausdorff groups, hence a quotient map, and μ_0 composed with it is $(x,u)\mapsto\lambda(u)$. It has finite order, so its kernel is open in K and contains $K\cap N$ for an open subgroup N of the profinite group G; μ_0 factors through the subgroup $K/(K\cap N)$ of the finite abelian group G/N and extends to a character of G/N with values in the divisible group of roots of unity of $\overline{\mathbb{Q}}_\ell^\times$. This gives a continuous character $\mu\colon G_L\to\overline{\mathbb{Q}}_\ell^\times$ of finite order with $\mu\circ\mathcal{V}=1$, $\mu_w|_{\mathcal{O}_{L_w}^\times}=\lambda_w$ for $w\in T$, $\mu_w|_{\mathcal{O}_{L_w}^\times}=1$ for finite $w\nmid\ell$, $w\notin T$, and $\mu_w|_{\mu_{\ell^\infty}(L_w)}=1$ for $w\mid\ell$. For $s\in G_L$, $\mu(s)\mu(csc)=\mu(\mathcal{V}(s))=1$.

Step 5: the twist. Put $\kappa=\theta\mu$. Then $\kappa(s)\kappa(csc)=\chi_{\mathrm{cyc}}(s)^m$ for $s\in G_L$, which is (Tw1). For a finite place $w\nmid\ell$, $\kappa_w|_{\mathcal{O}_{L_w}^\times}=\lambda_w^{-1}\lambda_w=1$ if $w\in T$ and $=1\cdot1$ otherwise, which is (Tw2). For $w\mid\ell$, $\kappa_w=\theta_w\mu_w$ is trivial on $\mu_{\ell^\infty}(L_w)$ by Steps 1 and 4, which is (Tw4) by the remark at the start. For (Kw1), let $\bar w$ be a place of $\overline{\mathbb{Q}}$ above ℓ, lying above $v\in S$; then $\bar w=g\bar v$ for some $g\in G_L$ (the places of $\overline{\mathbb{Q}}$ above v are G_L-conjugate), so $I_{\bar w}\cap G_L=g(I_{\bar v}\cap G_L)g^{-1}$. Put $h=m$ if v is one of the chosen places v_1 and $h=0$ if $v=v_1^c$. By Step 1, $\theta\chi_{\mathrm{cyc}}^{-h}$ is trivial on $I_{\bar v}\cap G_L$; as θ and χ_{cyc} are characters of G_L, it is trivial on the conjugate $I_{\bar w}\cap G_L$. With k the order of μ, $(\kappa\chi_{\mathrm{cyc}}^{-h})^k=(\theta\chi_{\mathrm{cyc}}^{-h})^k\mu^k$ is trivial on $I_{\bar w}\cap G_L$, which is (Kw1). μ has finite order, so it is algebraic (it corresponds to a Hecke character of finite order), and κ, a product of algebraic characters, is algebraic for ι. (Tw3) is the fact recalled at the start, applied to κ.

The twist for a datum. Let $\mathscr{H}$, $\mathcal{O}$, $\mathcal{O}'$ be as in the statement; $\mathcal{O}\subseteq\mathcal{O}'$ is a local homomorphism and $\mathbb{F}_{\mathcal{O}}\subseteq\mathbb{F}_{\mathcal{O}'}$. The hypotheses on L hold by (Rd1) and (Rd2). Each condition of Definition 50.1 over $\mathcal{O}'$ follows from the one over $\mathcal{O}$: (Rd1) since $\mathcal{O}\subseteq\mathcal{O}'$; the residual characters take values in $\mathbb{F}_{\mathcal{O}}^\times\subseteq\mathbb{F}_{\mathcal{O}'}^\times$ and (Rd4), (Rd5) do not involve the coefficient ring; in (Rd6) the reduction of χ_{cyc} modulo $\mathfrak{m}_{\mathcal{O}'}$ is that modulo $\mathfrak{m}_{\mathcal{O}}$ followed by the injection $\mathbb{F}_{\mathcal{O}}\to\mathbb{F}_{\mathcal{O}'}$, so it is non-trivial on $D_{\bar v_0}\cap G_L$; the wild values take values in $\mathcal{O}^\times\subseteq\mathcal{O}'^\times$ and (Rd10) is unchanged. Finally κ takes values in $\mathcal{O}_\kappa^\times\subseteq\mathcal{O}'^\times$, is algebraic, satisfies $\kappa(s)\kappa(csc)=\chi_{\mathrm{cyc}}(s)^{1-n}$ by (Tw1), and is trivial on $I_{\bar w}\cap G_L$ for every $\bar w$ above a finite place of L^+ not in S_ℓ by (Tw2), a fortiori for those not in $S_\ell\cup\mathrm{St}$; the last clause of (Rd7) holds with $m'=1$. So κ is a twist for $\mathscr{H}$ over $\mathcal{O}'$. For $v\in S_\ell$, $D_v=D_{\bar v}\cap G_{L^+}=D_{\bar v}\cap G_L$ (as v splits in L), and μ_v is the set of its elements whose image in the abelianisation of D_v has ℓ-power order; by (Tw4), κ is trivial on μ_v. □

Lemma 53.6. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ such that some polarised ordinary determinant of rank n over $\mathscr{H}$ to some $A\in\mathrm{CNL}_{\mathcal{O}}$ exists. Then a universal polarised ordinary determinant of rank n over $\mathscr{H}$ exists.*

Proof. Symbols introduced here are local to this proof. Let $k=\mathbb{F}_{\mathcal{O}}$, $W(k)\subseteq\mathcal{O}$ its Witt vectors, and $\pi=\pi_{\mathscr{H}}$.

Step 1: $\Gamma^0_{\mathscr{H}}$ satisfies Φ_ℓ. Let $U\subseteq\Gamma^0_{\mathscr{H}}$ be open; shrinking it we may assume that $\tilde U=\pi^{-1}(U)\cap G_L$ lies in the kernel of all $\bar\chi_a$. For a place $\bar w\nmid\ell$, $I_{\bar w}\cap\tilde U$ consists of elements s with $\bar\chi_a(s)=1$ for all a, hence lies in $N_{\mathscr{H}}$. So every continuous homomorphism $U\to\mathbb{Z}/\ell$ gives a $\mathbb{Z}/\ell$-extension of the fixed field of $\tilde U$ unramified outside ℓ and the infinite places; there are finitely many (Hermite–Minkowski).

Step 2: the pieces. By (Ch2) there is a universal continuous determinant $D(\bar D_n)$ on $\Gamma^0_{\mathscr{H}}$ lifting $\bar D_n$, with values in a profinite local $W(k)$-algebra A_0, Noetherian by Step 1; put $A_1=A_0\hat\otimes_{W(k)}\mathcal{O}$, a complete Noetherian local $\mathcal{O}$-algebra with residue field k, universal for continuous determinants lifting $\bar D_n$ to objects of $\mathrm{CNL}_{\mathcal{O}}$. For $v\in S_\ell$ let $D_v(\ell)$ be the maximal pro-ℓ quotient of D_v^{ab}; by local class field theory it is the product of a finite group and $\mathbb{Z}_\ell^{[L_v^+:\mathbb{Q}_\ell]+1}$, so $\Lambda_v=\mathcal{O}[[D_v(\ell)]]$ is complete Noetherian local with residue field k. For $A\in\mathrm{CNL}_{\mathcal{O}}$, the continuous characters $\psi\colon D_v\to A^\times$ with $\psi\equiv\bar\chi_a$ are exactly $\psi=[\bar\chi_a]\psi'$, $[\bar\chi_a]$ the Teichmüller lift (values in $\mathcal{O}^\times$, as $\bar\chi_a$ has order prime to ℓ), and ψ' a continuous character into the pro-ℓ group $1+\mathfrak{m}_A$, i.e. factoring

through $D_v(\ell)$; these correspond to the morphisms $\Lambda_v \to A$. Let $A_2 = A_1 \hat{\otimes}_{\mathcal{O}} \hat{\bigotimes}_{v,a} \Lambda_v$ (completed tensor product over $\mathcal{O}$, one factor for each $v \in S_\ell$ and $1 \le a \le n$), complete Noetherian local with residue field k; it carries a continuous determinant D_2 and characters $\psi_{2,v,a}$, universal for tuples $(D, (\psi_{v,a}))$ of a continuous determinant lifting $\bar{D}_n$ and continuous characters lifting $\bar{\chi}_a$, to objects of $\mathrm{CNL}_{\mathcal{O}}$.

Step 3: the conditions. Let $\mathcal{I} \subseteq A_2$ be the ideal generated by the coefficients of $\chi_{D_2}(\pi(cg^{-1}c)) - \chi_{D_2}(\pi(g))$ $(g \in G_L)$, the elements $\mathrm{tr}_{D_2}(\gamma \prod_a (\pi(g_a) - \psi_{2,v,a}(g_a)))$ $(\gamma \in \Gamma^0_{\mathscr{H}}$, $v \in S_\ell$, $g_a \in D_v)$, and $\psi_{2,v,a}(g) - \xi_{v,a}(g)$ $(g \in \mu_v)$. A morphism $A_2 \to A$ kills $\mathcal{I}$ if and only if the corresponding tuple satisfies (Od1)–(Od3). By hypothesis some tuple satisfying them exists, so $\mathcal{I} \neq A_2$, and $B = A_2/\mathcal{I}$ (complete, as ideals of complete Noetherian local rings are closed) lies in $\mathrm{CNL}_{\mathcal{O}}$. The images of D_2 and the $\psi_{2,v,a}$ form a polarised ordinary determinant of rank n over $\mathscr{H}$ to B, and by the two universal properties every polarised ordinary determinant to some $A \in \mathrm{CNL}_{\mathcal{O}}$ is classified by exactly one morphism $B \to A$. □

Lemma 53.7. *Symbols introduced in this statement are local to it. Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\nu, \gamma \colon G_L \to \mathcal{O}'^{\times}$ and $t \colon G_L \to \mathbb{Z}_\ell$ continuous homomorphisms with (Lk1)–(Lk4), $\kappa \colon G_L \to \mathcal{O}'^{\times}$ a continuous character with (Tw1) for $m = -3$, (Tw2) and (Tw4), and $\mathscr{H} = (4, L, c, (\bar{v})_{v\in\Sigma}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a), (\xi_{v,a}))$ a rank-4 Hecke datum over $\mathcal{O}'$ with (Lk6) and (Lk7). Let $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,a}))$ be a space for $(\mathscr{T}, \mathcal{O}')$, $(B_4^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$, $n \ge 0$ an integer, and $\lambda_n = \nu\kappa^{-1}\gamma^n \colon G_L \to \mathcal{O}'^{\times}$. Then there is exactly one morphism $\phi_n \colon B_4^{\mathrm{po}} \to B$ of $\mathrm{CNL}_{\mathcal{O}'}$ such that*

(Cm1) *$\phi_n(\chi_{D^{\mathrm{u}}}(\pi_{\mathscr{H}}(g)))(X) = \lambda_n(g)^4 \,\mathrm{cp}(g)(\lambda_n(g)^{-1}X)$ for every $g \in G_L$ (ϕ_n applied coefficientwise);*

(Cm2) *$\phi_n(\psi^{\mathrm{d}}_{v,a}(g)) = \lambda_n(g)\,\psi^B_{v,a}(g)$ for every $v \in \Sigma$, $1 \le a \le 4$ and $g \in D_v$.*

In particular, under the injection $B \to A$, the determinant $\phi_n \circ D^{\mathrm{u}} \circ \pi_{\mathscr{H}}|_{G_L}$ becomes $\det \circ \rho_n$ for $\rho_n = \lambda_n\, r_P|_{G_L} \colon G_L \to \mathrm{GL}_4(A)$.

Proof. Write $f \colon B \to A$ for the structure map, injective by (Zq1), $r = r_P$, $\pi = \pi_{\mathscr{H}}$, and Λ_i for the coefficients of characteristic polynomials as in Theorem B.83. Since r is a homomorphism of monoids from a group, $r(g)r(g^{-1}) = r(1) = 1$, so $r(g) \in \mathrm{GL}_4(A)$, and $\rho_n = \lambda_n r|_{G_L}$ is a homomorphism $G_L \to \mathrm{GL}_4(A)$. The characteristic polynomial of $\rho_n(g)$ is $\lambda_n(g)^4\,\mathrm{charpoly}(r(g))(\lambda_n(g)^{-1}X)$, which is the image under f of $\mathrm{cp}_n(g) := \lambda_n(g)^4\mathrm{cp}(g)(\lambda_n(g)^{-1}X) \in B[X]$, by (Zq2); in particular all $\Lambda_i(\rho_n(g))$ lie in $f(B)$.

Step 1: a determinant over B on G_L. By (Ch1), $\det \circ \rho_n$ is the base change of a determinant with values in the subring of A generated by the $\Lambda_i(\rho_n(g))$, which lies in $f(B)$; transporting along $f^{-1} \colon f(B) \to B$ gives a B-valued determinant D_1 of dimension 4 on G_L with $f \circ D_1 = \det \circ \rho_n$ and $\chi_{D_1}(g) = \mathrm{cp}_n(g)$. As f is injective, every identity between the Λ_j of finite products of elements of G_L that holds for ρ_n holds for D_1. The maps $g \mapsto \Lambda_i(\chi_{D_1}(g))$ are continuous for the $\mathfrak{m}_B$-adic topology, since λ_n is continuous with values in $\mathcal{O}'$ and the coefficients of cp are continuous by (Zq2).

Step 2: ρ_n kills the generators of $N_{\mathscr{H}}$. Let $s \in I_{\bar{w}} \cap G_L$ with $\bar{w} \nmid \ell$ and $\bar{\chi}_a(s) = 1$ for all a. Among $\chi_1^{\mathscr{T}}, \dots, \chi_4^{\mathscr{T}}$ one is trivial (the character $\kappa_4 = \mathbf{1}$ of the datum sits at index 4 for the labelling 0 and at index 2 for the labelling 1); for that index a_0, (Lk6) gives $\bar{\nu}(s)\bar{\kappa}(s)^{-1} = 1$, and $\kappa(s) = 1$ by (Tw2), so $\bar{\nu}(s) = 1$ and then $\bar{\chi}_a^{\mathscr{T}}(s) = 1$ for all a, i.e. $\bar{r}_0(s) = 1$. Hence $s \in N$ and $r(s) = 1$ by (Mq1). By (Lk3), $\nu(s)^m = 1$ with $\ell \nmid m$; writing $\nu(s) = 1 + y$ with $y \in \mathfrak{m}_{\mathcal{O}'}$, $0 = (1+y)^m - 1 = y(m + yz)$ with $z \in \mathcal{O}'$ and $m + yz$ a unit, so $y = 0$ and $\nu(s) = 1$. By

(Lk2), $t(s)=0$, so $\gamma(s)=1$ as $\ker t \subseteq \ker\gamma$. Thus $\rho_n(s)=1$. The set of such s is stable under conjugation by G_{L^+}: conjugation by $g\in G_L$ moves $I_{\bar w}$ to $I_{g\bar w}$ and does not change $\bar\chi_a(s)$; and $\bar\chi_a(csc)=\bar\chi_{5-a}(s)^{-1}=1$ by (Rd5). So the abstract subgroup N_0 generated by these s is normal in G_{L^+}, $\rho_n(N_0)=1$, and $N_{\mathscr{H}}$ is the closure of N_0.

Step 3: descent to $\Gamma^0_{\mathscr{H}}$. Let $h\in N_{\mathscr{H}}$. For finitely many $g_1,\dots,g_k\in G_L$ and a word w in letters $x,y_1,\dots,y_k$, the map $h'\mapsto\Lambda_j(w(h',g_1,\dots,g_k))$ (computed with D_1) is continuous on G_L (Step 1, and continuity of multiplication), and for $h'\in N_0$ it equals $\Lambda_j(w(1,g_1,\dots,g_k))$ (Step 2 and Step 1); as N_0 is dense in $N_{\mathscr{H}}$ and B is Hausdorff, this equality holds for $h'=h$. Now let T be a commutative B-algebra and $r'=\sum_k c_kg_k\in T[G_L]$. By (Ch1), $\Lambda_i((h-1)r')=\Lambda_i(\sum_k c_k\,hg_k-\sum_k c_k\,g_k)$ (for the base change of D_1 to T) is a universal integer polynomial in the c_k and the Λ_j of finite products of the elements $hg_1,\dots,hg_k,g_1,\dots,g_k$; by what was just shown these Λ_j do not change when h is replaced by 1, so $\Lambda_i((h-1)r')=\Lambda_i(0)=0$ for $i\geq 1$, and $D_{1,T}(1+(h-1)r')=1$. Hence $h-1\in\ker(D_1)$ (Theorem B.88). The two-sided ideal K of $B[G_L]$ generated by the $h-1$, $h\in N_{\mathscr{H}}$, lies in $\ker(D_1)$, and $B[G_L]/K=B[\Gamma^0_{\mathscr{H}}]$ ($N_{\mathscr{H}}$ is normal in G_L). By (Ck1) there is a determinant D of dimension 4 on $\Gamma^0_{\mathscr{H}}$ with $D_1=D\circ\pi$; so $\chi_D(\pi(g))=\mathrm{cp}_n(g)$, and D is continuous because $\Gamma^0_{\mathscr{H}}$ carries the quotient topology of the compact group G_L and the $\Lambda_i\circ\chi_{D_1}$ are continuous.

Step 4: the ordinary characters. For $v\in\Sigma$ the matrices $n_v^{-1}r(s)n_v$, $s\in D_v$, are upper triangular (Mq4) and invertible, so $\psi^P_{v,a}$ is a homomorphism $D_v\to A^\times$; as f is injective and $f\circ\psi^B_{v,a}=\psi^P_{v,a}$ (Zq2), $\psi^B_{v,a}$ is a homomorphism $D_v\to B^\times$, continuous by (Zq2). Put $\psi_{v,a}=\lambda_n|_{D_v}\,\psi^B_{v,a}$ ($D_v\subseteq G_L$ as v splits in L), a continuous homomorphism $D_v\to B^\times$.

Step 5: $(D,(\psi_{v,a}))$ is a polarised ordinary determinant of rank 4 over $\mathscr{H}$ to B. $B\in\mathrm{CNL}_{\mathcal{O}'}$ by (Zq1). Reduction: $\gamma\equiv 1$ by (Lk2), so $\bar\lambda_n=\bar\nu\bar\kappa^{-1}$; by (Zq2) and (Lk6),

$$\chi_D(\pi(g))\equiv\prod_a(X-\bar\lambda_n(g)\bar\chi_a^{\mathscr{T}}(g))=\prod_a(X-\bar\chi_a(g))$$

and $\psi_{v,a}\equiv\bar\lambda_n\bar\chi_a^{\mathscr{T}}=\bar\chi_a$ modulo $\mathfrak{m}_B$; by the uniqueness in (Ch1) over the field $B/\mathfrak{m}_B$ (π is surjective), D reduces to $\bar D_4$. (Od1): for $g\in G_L$, $r(g)$ has similitude $\theta(g)$ (Mq1), so $r(g)^{-1}$ is conjugate to $\theta(g)^{-1}\,{}^tr(g)$ and has the characteristic polynomial of $\theta(g)^{-1}r(g)$; and $r(cg^{-1}c)=r(c)r(g)^{-1}r(c)^{-1}$ ($c\in G_F$). Hence $\rho_n(cg^{-1}c)$ has the characteristic polynomial of $\lambda_n(cgc)^{-1}\theta(g)^{-1}r(g)$. By (Lk1) and (Tw1),

$$\begin{aligned}\lambda_n(g)\lambda_n(cgc)&=\nu(g)\nu(cgc)\kappa(g)^{-1}\kappa(cgc)^{-1}(\gamma(g)\gamma(cgc))^n\\&=\theta(g)^{-1}\chi_{\mathrm{cyc}}(g)^{-3}\chi_{\mathrm{cyc}}(g)^3=\theta(g)^{-1},\end{aligned}$$

so $\lambda_n(cgc)^{-1}\theta(g)^{-1}=\lambda_n(g)$, and $\rho_n(cg^{-1}c)$, $\rho_n(g)$ have the same characteristic polynomial; by injectivity of f, $\chi_D(\pi(cg^{-1}c))=\chi_D(\pi(g))$. (Od2): let $x\in G_L$, $v\in\Sigma$, $g_1,\dots,g_4\in D_v$. As tr is Λ_1, linear and compatible with base change,

$$f(\mathrm{tr}_D(\pi(x)\prod_a(\pi(g_a)-\psi_{v,a}(g_a))))=\mathrm{tr}(\rho_n(x)\prod_a M'_a)$$

with $M'_a=\rho_n(g_a)-f(\psi_{v,a}(g_a))$. The matrices $M_a=n_v^{-1}M'_an_v=\lambda_n(g_a)(n_v^{-1}r(g_a)n_v-\psi^P_{v,a}(g_a))$ are upper triangular with $(M_a)_{aa}=0$. For such matrices the first k columns of $M_1\cdots M_k$ vanish (induction on k: column $j\leq k$ of $(M_1\cdots M_{k-1})M_k$ is $\sum_{i\leq j}(M_k)_{ij}$ times column i of $M_1\cdots M_{k-1}$, which vanishes for $i\leq k-1$, and the term $i=j=k$ has $(M_k)_{kk}=0$), so $M_1\cdots M_4=0$, hence $\prod_a M'_a=0$ and the trace is 0; by injectivity of f, (Od2) holds (for $\gamma\in\Gamma^0_{\mathscr{H}}$ take x with $\pi(x)=\gamma$). (Od3): let $g\in\mu_v$. Then $\nu(g)=1$ and $t(g)=0$ by (Lk4), so $\gamma(g)=1$ by (Lk2); $\kappa(g)=1$ by (Tw4) (μ_v consists of the elements of $D_v=D_{\bar v}\cap G_L$ whose image in the abelianisation has ℓ-power order); and $f(\psi^B_{v,a}(g))=\psi^P_{v,a}(g)=1$ by (Mq4). So $\psi_{v,a}(g)=1=\xi_{v,a}(g)$ by (Lk7).

Step 6: the morphism. By the universal property there is exactly one morphism $\phi_n\colon B_4^{\mathrm{po}} \to B$ of $\mathrm{CNL}_{\mathcal{O}'}$ with $\phi_n \circ D^{\mathrm{u}} = D$ and $\phi_n \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}$; it satisfies (Cm1) by Step 3 and (Cm2) by Step 4. Conversely, if ϕ satisfies (Cm1) and (Cm2), then $\phi \circ D^{\mathrm{u}}$ and D have the same characteristic polynomials at every element of $\Gamma^0_{\mathscr{H}} = \pi(G_L)$, so they are equal by (Ch1), and $\phi \circ \psi_{v,a}^{\mathrm{d}} = \psi_{v,a}$; so $\phi = \phi_n$ by uniqueness in the universal property. The last sentence is $f \circ D_1 = \det \circ \rho_n$. $\square$

Definition 53.8. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ and $S = S_\ell \cup \mathrm{St} \cup \{v_0\}$. A profinite group G **satisfies** Φ_ℓ if every open subgroup of G has only finitely many continuous homomorphisms to $\mathbb{Z}/\ell$. For a closed subgroup H of a profinite group G let $\mathrm{PL}(H)$ be the intersection of the open normal subgroups U of G such that for every $h \in H$ some h^{ℓ^e} lies in U.

Levels. For a finite set Q of places of L^+ outside S, not above ℓ and split in L, let N^Q be the closed normal subgroup of G_{L^+} generated by the $s \in I_{\bar{w}} \cap G_L$ with $\bar{\chi}_a(s) = 1$ $(1 \le a \le n)$, for all places $\bar{w}$ of $\overline{\mathbb{Q}}$ above neither ℓ nor a place of Q. Put $\Gamma^Q = G_{L^+}/N^Q$, $\pi^Q\colon G_{L^+} \to \Gamma^Q$, $\Gamma^{0,Q} = \pi^Q(G_L)$; as $N^Q \subseteq N_{\mathscr{H}}$ there is a unique continuous surjection $h^Q\colon \Gamma^Q \to \Gamma_{\mathscr{H}}$ with $h^Q \circ \pi^Q = \pi_{\mathscr{H}}$. ($\Gamma^{\varnothing} = \Gamma_{\mathscr{H}}$.)

Taylor–Wiles data. A **Taylor–Wiles datum** of size $q \ge 0$ for $\mathscr{H}$ consists of an open normal subgroup $H \subseteq \Gamma_{\mathscr{H}}$, elements $\sigma_1, \dots, \sigma_q \in \Gamma'$, an integer $b \ge 1$ and, for every $N \ge 1$, places $v_{N,1}, \dots, v_{N,q}$ of L^+ with $Q_N = \{v_{N,1}, \dots, v_{N,q}\}$, places $\bar{w}_{N,j}$ of $\overline{\mathbb{Q}}$ above $v_{N,j}$ with $w_{N,j}$ the place of L below, and elements $\phi_{N,j}, \tau_{N,j} \in D_{\bar{w}_{N,j}} \cap G_L$, such that, writing $\Gamma_N = \Gamma^{Q_N}$, $h_N = h^{Q_N}$, $H_N = h_N^{-1}(H)$, $\Phi_{N,j} = \pi^{Q_N}(\phi_{N,j})$, $\mathrm{T}_{N,j} = \pi^{Q_N}(\tau_{N,j})$ and $q_{N,j} = \mathrm{N}w_{N,j}$:

(Tg1) $H = \{\gamma \in \Gamma^0_{\mathscr{H}} :\ \bar{\chi}_a(\gamma) = 1 \text{ for } 1 \le a \le n,\ \chi_{\mathrm{cyc}}(\gamma) \equiv 1 \bmod \ell\}$;

(Tg2) for every N the places $v_{N,j}$ are pairwise distinct, not in S, not above ℓ and split in L; $q_{N,j} \equiv 1 \bmod \ell^N$; $\phi_{N,j}^{-1}$ is a Frobenius element at $\bar{w}_{N,j}$ (for the norm $q_{N,j}$); $\tau_{N,j} \in I_{\bar{w}_{N,j}}$ and $I_{\bar{w}_{N,j}}$ is the closed subgroup generated by $\tau_{N,j}$ and the kernel of the maximal pro-ℓ quotient of $I_{\bar{w}_{N,j}} \cap G_L$;

(Tg3) (approximation) $h_N(\Phi_{N,j})\sigma_j^{-1} \in H$ for all N, j, and for every open normal subgroup $V \supseteq \mathrm{PL}(H)$ of $\Gamma_{\mathscr{H}}$ and every j there is N_0 with $h_N(\Phi_{N,j})\sigma_j^{-1} \in V$ for $N \ge N_0$;

(Tg4) (tame relation) $h_N(\mathrm{T}_{N,j}) = 1$, $\mathrm{T}_{N,j}^{-q_{N,j}}\Phi_{N,j}^{-1}\mathrm{T}_{N,j}\Phi_{N,j} \in \mathrm{PL}(H_N)$, and $\ker h_N$ is contained in the closure of the subgroup generated by $\mathrm{PL}(H_N)$ and the conjugates of $\mathrm{T}_{N,1}, \dots, \mathrm{T}_{N,q}$;

(Tg5) (uniform finiteness) H and every H_N have only finitely many continuous homomorphisms to $\mathbb{Z}/\ell$, at most b for every H_N;

(Tg6) $D_v \cap G_L$ $(v \in S_\ell)$ and $D_{\bar{u}} \cap G_L$ $(u \in \mathrm{St}$, $\bar{u}$ above $u)$ satisfy Φ_ℓ.

For a curve point $x = (k, \rho, P, (\psi_{v,a}), f)$ of a universal polarised ordinary determinant over $\mathscr{H}$, **eigenvalue data** of x along the datum are $\alpha_{j,i} \in A_k$ $(1 \le j \le q,\ 1 \le i \le n)$ with $\alpha_{j,1}, \dots, \alpha_{j,n}$ pairwise distinct and $\det(X - \rho(\sigma_j)) = \prod_{i=1}^n (X - \alpha_{j,i})$.

Definition 53.9. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with residue field $\mathbb{F}$, $(B, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$ $(B = B_n^{\mathrm{po}})$, and $J \subseteq B$ an ideal. Put $D = n\,[L^+ : \mathbb{Q}]$ and $\Lambda_D = \mathcal{O}[[X_1, \dots, X_D]]$.

Weight variables. A family of **weight variables** is a family $\mathbf{w} = (v_k, a_k, \gamma_k, c_k)_{1 \le k \le D}$ with $v_k \in S_\ell$, $1 \le a_k \le n$, $\gamma_k \in I_{v_k}$ and $c_k \in \mathcal{O}$ such that $c_k \bar{\chi}_{a_k}(\gamma_k) = 1$ in $\mathbb{F}$. For $A \in \mathrm{CNL}_{\mathcal{O}}$ and continuous characters $\psi_{v,a}\colon D_v \to A^\times$ with $\psi_{v,a} \equiv \bar{\chi}_a$ modulo $\mathfrak{m}_A$, the **weight map** is

the homomorphism of $\mathcal{O}$-algebras $\lambda\colon \Lambda_D \to A$ with $\lambda(X_k) = c_k\psi_{v_k,a_k}(\gamma_k) - 1$ (well defined, as $c_k\psi_{v_k,a_k}(\gamma_k) - 1 \in \mathfrak{m}_A$).

Taylor–Wiles bases. A **Taylor–Wiles base** for J is a pair $(\mathbf{w}, M)$ of weight variables and a B-module M such that, for the weight map $\lambda_B\colon \Lambda_D \to B$ of $(\psi^{\mathrm{d}}_{v,a})$,

(Hl1) M is free of finite rank as a Λ_D-module through λ_B, and for every prime ideal $\mathfrak{p}$ of B: $\mathrm{Ann}_B(M) \subseteq \mathfrak{p}$ if and only if $J \subseteq \mathfrak{p}$.

Level groups at Q. Let $Q = \{v_1, \dots, v_q\}$ be a finite set of places of L^+, not in $S_\ell \cup \mathrm{St} \cup \{v_0\}$, not above ℓ and split in L, with places $\bar{w}_j$ of $\overline{\mathbb{Q}}$ above v_j, w_j the place of L below $\bar{w}_j$ and k_j its residue field. Put $G_Q = \prod_j \mathrm{GL}_n(L_{w_j})$, $K_Q = \prod_j \mathrm{GL}_n(\mathcal{O}_{L_{w_j}})$, $\mathrm{Iw}_Q \subseteq K_Q$ the product of the Iwahori subgroups (matrices upper triangular modulo w_j), and $\mathrm{Iw}_{1,Q} \subseteq \mathrm{Iw}_Q$ the subgroup of the elements whose diagonal entries modulo w_j have order prime to ℓ in $k_j^\times$. It is normal in Iw_Q, and $\Delta_Q = \mathrm{Iw}_Q/\mathrm{Iw}_{1,Q} \cong \prod_j (k_j^\times(\ell))^n$ ($k_j^\times(\ell)$ the ℓ-Sylow subgroup) through the diagonal entries modulo w_j.

Level modules. Let $(\mathbf{w}, M)$ be a Taylor–Wiles base for J. A **level module** at Q for $(\mathbf{w}, M)$ is a tuple $(R, D_R, (\psi_{R,v,a}), \beta, P, \rho)$ of $R \in \mathrm{CNL}_{\mathcal{O}}$; a continuous R-valued determinant D_R of dimension n on $\Gamma^{0,Q}$ reducing to $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$ and continuous characters $\psi_{R,v,a}\colon D_v \to R^\times$ with $\psi_{R,v,a} \equiv \bar{\chi}_a$, satisfying (Od1), (Od2), (Od3) of Definition 50.2 with π^Q, $\Gamma^{0,Q}$ in place of π, Γ^0; a homomorphism of $\mathcal{O}$-algebras $\beta\colon R \to B$ with $\beta \circ D_R = D^{\mathrm{u}} \circ h^Q$ (base change of D_R along β equals the pull-back of D^{u} along h^Q) and $\beta \circ \psi_{R,v,a} = \psi^{\mathrm{d}}_{v,a}$; an R-module P, regarded as a Λ_D-module through the weight map λ_R of $(\psi_{R,v,a})$; and an R-linear action ρ of G_Q on P; such that

(Hl2) $P^{\mathrm{Iw}_{1,Q}}$ is a finitely generated Λ_D-module, and a projective $\Lambda_D[\Delta_Q]$-module for the induced action of Δ_Q;

(Hl3) there is an additive bijection $e\colon P^{K_Q} \to M$ with $e(tm) = \beta(t)e(m)$ for $t \in R$, $m \in P^{K_Q}$.

Classical level modules. Let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism. A **level point** of the level module for ι is a tuple $(\theta, r, Y, \pi, \mathrm{sp}, (\sigma_j)_j)$ of a ring homomorphism $\theta\colon R \to \overline{\mathbb{Q}}_\ell$; a continuous homomorphism $r\colon \Gamma^{0,Q} \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with $\theta \circ D_R = \det \circ r$; a complex vector space Y with a representation π of G_Q; an additive map $\mathrm{sp}\colon P \to Y$ with $\mathrm{sp}(tm) = \iota(\theta(t))\,\mathrm{sp}(m)$ and $\mathrm{sp}(\rho(g)m) = \pi(g)\mathrm{sp}(m)$; and irreducible smooth representations σ_j of $\mathrm{GL}_n(L_{w_j})$ such that, for every j: Y is spanned by the images of the $\mathrm{GL}_n(L_{w_j})$-equivariant linear maps $\sigma_j \to Y$ ($\mathrm{GL}_n(L_{w_j})$ acting on Y through the j-th factor of G_Q); and, if the Weil–Deligne representation $\mathrm{rec}(\sigma_j \otimes |\det|^{(1-n)/2})$ has monodromy $N = 0$ and is trivial on the commutator subgroup of the Weil group, then it is isomorphic to the Frobenius-semisimplification $\mathrm{WD}(r \circ \pi^Q|_{D_{\bar{w}_j}})^{F\text{-}ss}$ transported by ι.

(Hl4) The level module is **classical** if for some ι the level points separate P: every $m \in P$ with $\mathrm{sp}(m) = 0$ for all level points for ι is 0.

The ideal J has **classical levels** if there is a Taylor–Wiles base $(\mathbf{w}, M)$ for J such that for every finite set Q as above (with places $\bar{w}_j$) there is a classical level module at Q for $(\mathbf{w}, M)$.

Theorem 53.10. *Let $\mathscr{H}$ be a rank-n Hecke datum with $n = 4$ over a coefficient ring $\mathcal{O}'$ whose wild values are trivial ($\xi_{v,a} = 1$ for all $v \in S_\ell$ and $1 \le a \le 4$), κ a twist for $\mathscr{H}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $d = [L^+ : \mathbb{Q}]$ and $\Lambda_{4d} = \mathcal{O}'[[X_1, \dots, X_{4d}]]$. Then:*

(Hf1) *B has a Hecke ideal J of zero-monodromy type for ι and κ which satisfies (Hf2)–(Hf5) and, if $J \neq B$, has classical levels and has $R = T$ at patchable curve points (for v_0, with the place $\bar{v}_0$); every such J satisfies $J \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$;*

(Hf2) *(finiteness, a property of an ideal $J \subseteq B$) there is a homomorphism of $\mathcal{O}'$-algebras $\lambda\colon \Lambda_{4d} \to B/J$ such that B/J is a finite and torsion-free Λ_{4d}-module via λ, and λ maps the maximal ideal of Λ_{4d} into the ideal generated by the images of $\mathfrak{m}_{\mathcal{O}'}$ and of the elements $\psi_{v,a}^{\mathrm{d}}(g) - 1$ with $v \in S_\ell$, $1 \le a \le 4$, $g \in I_v$ and $\bar{\chi}_b(g) = 1$ for $1 \le b \le 4$;*

(Hf3) *(classicality, a property of an ideal $J \subseteq B$) for every inertial weight $(\psi_{v,a}^\circ)$ for $\mathscr{H}$ such that for all $v \in S_\ell$ and $1 \le a, b \le 4$ some integer h_{ab} makes $\psi_{v,a}^\circ(\psi_{v,b}^\circ)^{-1}\chi_{\mathrm{cyc}}^{-h_{ab}}$ trivial on an open subgroup of I_v, every integral test ring A over $\mathcal{O}'$, every homomorphism $\rho\colon \Gamma^0_{\mathscr{H}} \to \mathrm{GL}_4(A)$ with $\rho_L = \rho \circ \pi_{\mathscr{H}}|_{G_L}$ continuous and irreducible over $\overline{\mathbb{Q}}_\ell$, and every homomorphism of $\mathcal{O}'$-algebras $y\colon B \to A$ with $y \circ D^{\mathrm{u}} = \det \circ \rho$, $y(\psi_{v,a}^{\mathrm{d}}(g)) = \psi_{v,a}^\circ(g)$ for all $v \in S_\ell$, a and $g \in I_v$, and $y(J) = 0$: the representation $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι;*

(Hf4) *(purity at arithmetic points, a property of an ideal $J \subseteq B$) for every homomorphism of $\mathcal{O}'$-algebras $y\colon B \to \overline{\mathbb{Q}}_\ell$ with $y(J) = 0$ for which there are integers $h_{v,a,\tau}$ ($v \in S_\ell$, $1 \le a \le 4$, τ a continuous field embedding $L_v^+ \to \overline{\mathbb{Q}}_\ell$), strictly increasing in a for every v and τ, such that $y(\psi_{v,a}^{\mathrm{d}}(\sigma)) = \prod_\tau \tau(u_\sigma)^{h_{v,a,\tau}}$ for all σ in an open subgroup of I_v, where $u_\sigma \in \mathcal{O}^\times_{L_v^+}$ is the unit with $\mathrm{Art}_{L_v^+}(u_\sigma)$ equal to the image of σ in D_v^{ab}: there are a continuous semisimple representation $\rho\colon G_L \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $\det \circ \rho = y \circ D^{\mathrm{u}} \circ \pi_{\mathscr{H}}|_{G_L}$, finitely many continuous representations $\rho_i'\colon G_L \to \mathrm{GL}_{d_i}(\overline{\mathbb{Q}}_\ell)$ and integers $d_i, m_i \ge 1$ ($1 \le i \le k$) such that*

$$\det\bigl(X - \rho(g)\bigr) = \prod_{i=1}^{k}\prod_{j=0}^{m_i-1} \det\bigl(X - \chi_{\mathrm{cyc}}(g)^{-j}\rho_i'(g)\bigr) \qquad (g \in G_L),$$

and, if $m_i = 1$ for all i, then for all but finitely many finite places w of L the representation ρ is unramified at w and any two eigenvalues α, α' of $\rho(\mathrm{Frob}_w)$ satisfy $|\iota(\alpha)| < \mathrm{N}w\,|\iota(\alpha')|$;

(Hf5) *(stability under twists, a property of an ideal $J \subseteq B$) for every continuous homomorphism $\beta\colon \Gamma^0_{\mathscr{H}} \to B^\times$ with $\beta(g) \equiv 1$ modulo $\mathfrak{m}_B$, $\beta(\pi_{\mathscr{H}}(csc)) = \beta(\pi_{\mathscr{H}}(s))^{-1}$ for $s \in G_L$, β trivial on $\pi_{\mathscr{H}}(I_{\bar{w}} \cap G_L)$ for every place $\bar{w}$ above a place in $\mathrm{St} \cup \{v_0\}$, and β trivial on μ_v for $v \in S_\ell$: the morphism $\tau_\beta\colon B \to B$ of $\mathrm{CNL}_{\mathcal{O}'}$ classifying the polarised ordinary determinant $(D^{\mathrm{u}}_\beta, (\beta|_{D_v}\psi_{v,a}^{\mathrm{d}}))$, where D^{u}_β is D^{u} composed with the B-algebra automorphism of $B[\Gamma^0_{\mathscr{H}}]$ with $\gamma \mapsto \beta(\gamma)\gamma$, satisfies $\tau_\beta(J) \subseteq J$.*

Proof. Step 0: the ideal. By Proposition E.1 (for $n = 4$; its hypothesis is that the wild values are trivial) B has a Hecke ideal J of zero-monodromy type for ι and κ which, if $J \neq B$, has classical levels, and, if B has a classical ordinary point, $J = \ker\theta$ with $\theta\colon B \to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}_0$ the surjection of (Gd2) for a type datum $((V_v), \tau)$ over $\mathscr{H}$ with V_v the kernel of reduction modulo ϖ_v^c (c as in Proposition E.5) satisfying (Zt), a maximal ideal $\mathfrak{m}$ with residue field $\mathbb{F}_{\mathcal{O}'}$ satisfying (Mx), χ_0 with $\chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))$, $\mathfrak{a}_0 = \mathfrak{a}_{\chi_0}$ and $\mathcal{C} = \mathcal{C}_{\chi_0}$; in particular θ satisfies the three identities of (Gd2).

If B has no classical ordinary point, then $J = B$ is a Hecke ideal of zero-monodromy type (Definition 50.10) and (Hf2)–(Hf5) hold for it: $B/J = 0$ is a finite torsion-free module over Λ_{4d} via the zero map, which maps the maximal ideal into 0; no homomorphism y of $\mathcal{O}'$-algebras kills B ($y(1) = 1$), so (Hf3), (Hf4) are empty; and $\tau_\beta(B) \subseteq B$. From now on B has a classical ordinary point and J is as above; $J \neq B$, as a classical ordinary point kills J (Zm4).

Step 1: (Hf1). J is of zero-monodromy type with classical levels, so by Proposition E.32 it has $\mathrm{R} = \mathrm{T}$ at patchable curve points (for v_0, with $\bar{v}_0$). Every Hecke ideal of zero-monodromy type for ι and κ is contained in $\mathcal{J}_\kappa^{\mathrm{cl}}$ by Lemma 50.12.

Step 2: (Hf2). Let (T, λ_T, M, f) be data for J as in Definition 50.10; f induces an isomorphism $B/J \cong T$. For $v \in S_\ell$ the group $1+\ell\mathcal{O}_{L_v^+}$ is torsion-free: if $\zeta \neq 1$ in it had order ℓ^k, $k \geq 1$, then $\zeta' = \zeta^{\ell^{k-1}}$ would be a primitive ℓ-th root of unity in it, with $v(\zeta'-1) = v(\ell)/(\ell-1) < v(\ell)$ (ℓ odd, v the normalised valuation), contradicting $\zeta' \equiv 1$ modulo ℓ. It is a finitely generated pro-ℓ abelian group, open in $\mathcal{O}_{L_v^+}^\times$, hence a free $\mathbb{Z}_\ell$-module of rank $d_v = [L_v^+ : \mathbb{Q}_\ell]$. So $T_4(\ell^1) = \prod_{v\in S_\ell}\prod_{j=1}^4 d_j(1+\ell\mathcal{O}_{L_v^+})$ is free over $\mathbb{Z}_\ell$ of rank $4\sum_v d_v = 4d$; for a basis $u_1, \dots, u_{4d}$, $X_i \mapsto [u_i]-1$ is an isomorphism of $\mathcal{O}'$-algebras $\Lambda_{4d} \to \Lambda_1$. (This is the only place where the modulus defining $T_4(\ell^1)$ is used.) Let λ be the composite $\Lambda_{4d} \to \Lambda_1 \xrightarrow{\lambda_T} T \cong B/J$. By (Zm1), B/J is finite and torsion-free over Λ_{4d} via λ. The maximal ideal of Λ_{4d} is generated by $\mathfrak{m}_{\mathcal{O}'}$ and the X_i; each u_i is a finite product of elements $d_j(z)$, $z \in 1+\ell\mathcal{O}_{L_v^+}$, and $[uu']-1 = [u]([u']-1)+([u]-1)$, so it suffices that $\lambda_T([d_j(z)])-1$ corresponds to an element of the ideal $\mathfrak{b}$ of B/J generated by the images of $\mathfrak{m}_{\mathcal{O}'}$ and of the $\psi_{v,a}^{\mathrm{d}}(g)-1$ ($g \in I_v$, $\bar{\chi}_b(g) = 1$ for all b). Now $g_z \in I_v$ lies in the image of the pro-ℓ group $1+\ell\mathcal{O}_{L_v^+}$ under the local Artin map, so $\bar{\chi}_b(g_z) = 1$ (the $\bar{\chi}_b$ have order prime to ℓ), and $\mu = (\chi_{\mathrm{cyc}}^{j-1}\kappa)(g_z) - 1 \in \mathfrak{m}_{\mathcal{O}'}$ (a continuous homomorphism from a pro-ℓ group to $\mathcal{O}'^\times$ lands in $1+\mathfrak{m}_{\mathcal{O}'}$). By (Zm2), $\lambda_T([d_j(z)])-1 = (1+\mu)(f(\psi_{v,j}^{\mathrm{d}}(g_z))-1)+\mu$, which corresponds to an element of $\mathfrak{b}$.

Step 3: (Hf3). Let $(\psi_{v,a}^\circ)$, A, ρ and y be as in (Hf3), with $y(J) = 0$. The integral test ring A is a subring of $\overline{\mathbb{Q}}_\ell$, so $\mathfrak{q} = \ker y$ is a prime of B whose residue field $\kappa(\mathfrak{q}) = \mathrm{Frac}(y(B)) \subseteq \overline{\mathbb{Q}}_\ell$ contains $\mathcal{O}'[1/\ell] \supseteq \mathbb{Q}_\ell$; hence $\overline{\mathbb{Q}}_\ell$ is an algebraic closure of $\kappa(\mathfrak{q})$, and the base change of D^{u} to it is $y \circ D^{\mathrm{u}} = \det\circ\rho$. As $\rho_L = \rho\circ\pi_{\mathscr{H}}|_{G_L}$ is irreducible over $\overline{\mathbb{Q}}_\ell$ and $\pi_{\mathscr{H}}(G_L) = \Gamma^0_{\mathscr{H}}$, ρ is irreducible over $\overline{\mathbb{Q}}_\ell$, so $\mathfrak{q}$ is stable (the condition does not depend on the choice of algebraic closure). By Lemma 50.12, $\mathcal{J}_\kappa^{\mathrm{cl}} \subseteq \mathfrak{q}$, i.e. $y(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$. The remaining hypotheses of Proposition E.25 ($n = 4$) are those of (Hf3), so $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι.

Step 4: (Hf4). The hypotheses of Lemma E.29 ($n = 4$, $\mathfrak{a} = \mathfrak{a}_0$, θ of Step 0) hold, and its conclusion for $J = \ker\theta$ is (Hf4).

Step 5: (Hf5). The hypotheses of Lemma E.27 ($n = 4$; trivial wild values; the type datum, $\mathfrak{m}$, χ_0, $\mathfrak{a}_0$ and θ of Step 0) hold, and its conclusion is (Hf5) for J. □

Lemma 53.11. *In the setting of Lemma 53.7, let $\phi_0\colon B_4^{\mathrm{po}} \to B$ be the morphism given there for $n = 0$, and let $J_0 \subseteq B_4^{\mathrm{po}}$ be an ideal finite over the weights. Then there is $k \geq 1$ with*

$$\mathfrak{m}_B^k \subseteq \phi_0(J_0)B + \mathfrak{m}_{\mathcal{O}'}B + (\psi_{v,a}^B(s) - 1 :\ v \in \Sigma,\ 1 \leq a \leq 4,\ s \in I_v).$$

Proof. Let I be the ideal on the right. B is Noetherian (Zq1), so $\mathfrak{m}_B$ is finitely generated and it suffices to show $\mathfrak{m}_B \subseteq \sqrt{I}$, i.e. $\mathfrak{m}_B \subseteq \mathfrak{q}$ for every prime $\mathfrak{q} \supseteq I$. Fix such $\mathfrak{q}$, let $R = B/\mathfrak{q}$, a complete Noetherian local domain, $\pi\colon B \to R$ the projection, and $k_0 = \pi(\mathcal{O}')$. As $\mathfrak{m}_{\mathcal{O}'} \subseteq \mathfrak{q}$ and $\mathfrak{q} \cap \mathcal{O}'$ is a proper prime ideal, $k_0 \cong \mathcal{O}'/\mathfrak{m}_{\mathcal{O}'} = \mathbb{F}_{\mathcal{O}'}$, which is also the residue field of R; so $R \in \mathrm{CNL}_{\mathcal{O}'}$.

Step 1: $\pi\circ\phi_0$ takes values in k_0. The ideal $\mathfrak{b}_4$ is generated by $\mathfrak{m}_{\mathcal{O}'}$ and the $\psi_{v,a}^{\mathrm{d}}(g)-1$ with $g \in I_v$ and $\bar{\chi}_b(g) = 1$ for all b. For such g, (Cm2) gives $\pi\phi_0(\psi_{v,a}^{\mathrm{d}}(g)) = \lambda_0(g)\pi(\psi_{v,a}^B(g)) = \lambda_0(g)$, as $\psi_{v,a}^B(g) - 1 \in I$. One of the $\chi_b^{\mathscr{J}}$ is trivial, so by (Lk6) $\bar{\lambda}_0(g) = \bar{\chi}_b(g) = 1$ for that b, i.e. $\lambda_0(g) - 1 \in \mathfrak{m}_{\mathcal{O}'}$; hence $\pi\phi_0(\mathfrak{b}_4) = 0$. Since J_0 is finite over the weights, every $x \in \mathfrak{m}_{B_4^{\mathrm{po}}}$ has a

power in $J_0+\mathfrak{b}_4$, which $\pi\phi_0$ kills ($\phi_0(J_0)\subseteq I$); as R is a domain, $\pi\phi_0(\mathfrak{m}_{B_4^{\mathrm{po}}})=0$. Every $x\in B_4^{\mathrm{po}}$ is $a+y$ with $a\in\mathcal{O}'$ and $y\in\mathfrak{m}_{B_4^{\mathrm{po}}}$ (the residue field is $\mathbb{F}_{\mathcal{O}'}$), so $\pi\phi_0(x)=\pi(a)\in k_0$.

Step 2: the generators of B map into k_0. For $v\in\Sigma$ and $s\in D_v$ ($\subseteq G_L$), (Cm2) and Step 1 give $\pi(\psi^B_{v,a}(s))=\lambda_0(s)^{-1}\pi\phi_0(\psi^{\mathrm{d}}_{v,a}(s))\in k_0$. For $g\in G_L$, (Cm1) gives that $\lambda_0(g)^j$ times the coefficient of X^{4-j} in $\mathrm{cp}(g)$ is the image under ϕ_0 of a coefficient of $\chi_{D^{\mathrm{u}}}(\pi_{\mathscr{H}}(g))$, so all coefficients of $\pi(\mathrm{cp}(g))$ lie in k_0. Let $g\in G_F$; then $g^2\in G_L$ ($[G_F:G_L]=2$). For any $M\in\mathrm{M}_4(A)$, $\det(X^2-M^2)=\det(X-M)\det(X+M)$, so the characteristic polynomials P_1 of $r_P(g)$ and P_2 of $r_P(g^2)$ satisfy $P_2(X^2)=P_1(X)P_1(-X)$; by (Zq2) and the injectivity of $B\to A$ (Zq1), $\mathrm{cp}(g^2)(X^2)=\mathrm{cp}(g)(X)\,\mathrm{cp}(g)(-X)$ in $B[X]$. In an algebraic closure of the fraction field of R, every root of $\pi(\mathrm{cp}(g))$ is a root of $\pi(\mathrm{cp}(g^2))(X^2)$, whose coefficients lie in the finite field k_0; so the roots, and hence the coefficients of the monic polynomial $\pi(\mathrm{cp}(g))$, are algebraic over k_0. An element $y\in R$ algebraic over k_0 lies in k_0: choose $a\in k_0$ with $y-a\in\mathfrak{m}_R$; if $y\neq a$, then $y-a$ is a non-zero element of the domain R algebraic over the field k_0, hence a unit of $k_0[y]\subseteq R$, contradicting $y-a\in\mathfrak{m}_R$.

Step 3: conclusion. Let $\sigma\colon B\to R$ be the composite of $B\to B/\mathfrak{m}_B=\mathbb{F}_{\mathcal{O}'}$ with the isomorphism $\mathbb{F}_{\mathcal{O}'}\to k_0\subseteq R$; it is a homomorphism of $\mathcal{O}'$-algebras. If $y\in B$ and $\pi(y)=\pi(a)$ with $a\in\mathcal{O}'$, then $y-a\in\mathfrak{q}\subseteq\mathfrak{m}_B$, so $\sigma(y)=\sigma(a)=\pi(a)=\pi(y)$. By Step 2 this applies to all coefficients of all $\mathrm{cp}(g)$ and all $\psi^B_{v,a}(s)$, so $\pi=\sigma$ by (Zq3), and $\pi(\mathfrak{m}_B)=\sigma(\mathfrak{m}_B)=0$, i.e. $\mathfrak{m}_B\subseteq\mathfrak{q}$. □

53.2 Transport of $R=T$, locality and classicality along the comparison maps

This subsection checks the conditions (Jq2)–(Jq5) of a modular ideal on a space, by transport from the Hecke side along the comparison maps. $R=T$ at patchable curve points passes to the space (Lemma 53.12); the inputs are separable elements for curve points of irreducible type, which exist in every coset of a finite-index subgroup for a non-virtually-abelian absolutely irreducible group in GL_4 (Lemma 53.13, Lemma 53.14), and the shape of the residual characters of a link, which have no quadratic symmetry (Lemma 53.16). Locality at seed points (Lemma 53.17) comes from the regular classical ordinary points given by the seeds after a parity twist (Lemma 53.18) and from the locality of a finite Hecke ideal at such points (Lemma 53.20), where tangent vectors with constant inertial weights vanish (Lemma 53.21). Purity passes directly along the comparison map (Lemma 53.22). Classicality (Lemma 53.23) comes from automorphy over L (Lemma 53.24) with the witness conditions (Lemma 53.25), descended to imaginary quadratic fields (Lemma 53.26) to give condition (Sy2). The lemma 53.25 is used again in Appendix E.

Lemma 53.12. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, $\mathscr{T}$ a fit and deep auxiliary tower for it, $\mathcal{O}_1,\nu,\gamma,t$ as given by Lemma 53.2, $\mathcal{O}'\supseteq\mathcal{O}_1$ a coefficient ring, κ and $\mathscr{H}$ (with places $v_0,\bar{v}_0$) the datum given there, $\mathscr{X}=(B,A,P,\dots)$ a space for $(\mathscr{T},\mathcal{O}')$, $(B_4^{\mathrm{po}},D^{\mathrm{u}},(\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$, ϕ_0 as in Lemma 53.7, and $J_0\subseteq B_4^{\mathrm{po}}$ an ideal with $R=T$ at patchable curve points (for v_0, with $\bar{v}_0$). Then for every finite field k with an $\mathcal{O}'$-algebra structure and every $\mathcal{O}'$-algebra homomorphism $y\colon A\to k[[T]]$ with $y(\mathfrak{m}_B)\subseteq Tk[[T]]$ and $y(\phi_0(J_0))=0$, such that for all $v\in\Sigma$ and $i\neq j$ some $s\in U_v$ has $y(\psi^P_{v,i}(s))\neq y(\psi^P_{v,j}(s))$ and $y\circ r_P$ is irreducible over the fraction field of $k[[T]]$, every prime $\mathfrak{q}$ of B with $y(\mathfrak{q})=0$ contains $\phi_0(J_0)$.*

Proof. Symbols introduced here are local to this proof. Let k, y be as in the statement, $r=r_P$, $\pi=\pi_{\mathscr{H}}$, $\Gamma^0=\Gamma^0_{\mathscr{H}}$, F_k the fraction field of $k[[T]]$, and $\lambda=\lambda_0=\nu\kappa^{-1}$. The map $B\to A$ is injective (Zq1); we regard B as a subring of A.

Step 0: scalars. $B \in \mathrm{CNL}_{\mathcal{O}'}$, so $\mathfrak{m}_{\mathcal{O}'} \subseteq \mathfrak{m}_B$ and $y(\mathfrak{m}_{\mathcal{O}'}) \subseteq k \cap Tk[[T]] = 0$ (y is $\mathcal{O}'$-linear and $k[[T]]$ is an $\mathcal{O}'$-algebra through k). Hence $\mathcal{O}' \to k$ factors through $\mathbb{F}_{\mathcal{O}'}$, $k \supseteq \mathbb{F}_{\mathcal{O}'} \supseteq \mathbb{F}_{\mathcal{O}}$, and an element $u \in \mathcal{O}'$ maps to its residue $\bar{u}$. In particular λ maps to $\bar{\lambda} = \bar{\nu}\bar{\kappa}^{-1}$, a locally constant character $G_L \to k^\times$, and χ_{cyc} maps to $\bar{\omega}$. Put $R(g) = y(r(g)) \in \mathrm{M}_4(k[[T]])$ for $g \in G_F$; $r(g)$ is invertible ($r(g)r(g^{-1}) = r(1) = 1$), so $R(g) \in \mathrm{GL}_4(k[[T]])$. By (Zq1) the entries of r are locally constant modulo $(\mathfrak{m}_B A)^j$ for every j, and $y((\mathfrak{m}_B A)^j) \subseteq T^j k[[T]]$; so the entries of R are continuous for the T-adic topology. By (Zq2), $y(\mathrm{cp}(g))$ is the characteristic polynomial of $R(g)$ and is congruent to $\prod_a (X - \bar{\chi}_a^{\mathscr{T}}(g))$ modulo T, and $y(\psi_{v,a}^P(s)) = y(\psi_{v,a}^B(s)) \equiv \bar{\chi}_a^{\mathscr{T}}(s)$ modulo T.

Step 1: the representation. For $g \in G_L$ put $\rho_L(g) = \bar{\lambda}(g)R(g)$, a continuous homomorphism $G_L \to \mathrm{GL}_4(k[[T]])$. Let $s \in I_{\bar{w}} \cap G_L$, $\bar{w} \nmid \ell$, with $\bar{\chi}_a(s) = 1$ for all a. One of $\chi_1^{\mathscr{T}}, \dots, \chi_4^{\mathscr{T}}$ is trivial (the character $\mathbf{1}$ of the datum), so (Lk6) gives $\bar{\lambda}(s) = 1$ and then $\bar{\chi}_a^{\mathscr{T}}(s) = 1$ for all a, i.e. $\bar{r}_0(s) = 1$; so $s \in N$ and $r(s) = 1$ (Mq1), whence $\rho_L(s) = 1$. Such elements are permuted by conjugation by G_L (which moves $I_{\bar{w}}$ to $I_{g\bar{w}}$ and fixes the values $\bar{\chi}_a(s)$) and by c ($\bar{\chi}_a(csc) = \bar{\chi}_{5-a}(s)^{-1} = 1$ by (Rd5)). So the kernel of ρ_L, a closed normal subgroup, contains $N_{\mathscr{H}}$, and $\rho_L = \rho \circ \pi|_{G_L}$ for a homomorphism $\rho\colon \Gamma^0 \to \mathrm{GL}_4(k[[T]])$ whose entries are continuous for the T-adic topology (Γ^0 carries the quotient topology).

Step 2: the homomorphism f. Put $f = y \circ \phi_0\colon B_4^{\mathrm{po}} \to k[[T]]$, a homomorphism of $\mathcal{O}'$-algebras. For $g \in G_L$, (Cm1) and Step 0 give $f(\chi_{D^{\mathrm{u}}}(\pi(g)))(X) = \bar{\lambda}(g)^4\, y(\mathrm{cp}(g))(\bar{\lambda}(g)^{-1}X)$, the characteristic polynomial of $\rho(\pi(g))$. So the $k[[T]]$-valued determinants $f \circ D^{\mathrm{u}}$ and $\det \circ \rho$ on $\Gamma^0 = \pi(G_L)$ have the same characteristic polynomials and are equal by (Ch1). For $v \in \Sigma$ and $g \in D_v$ ($\subseteq G_L$, as v splits in L) put $\psi_{v,a}(g) = \bar{\lambda}(g)\, y(\psi_{v,a}^P(g))$; then $f(\psi_{v,a}^{\mathrm{d}}(g)) = \psi_{v,a}(g)$ by (Cm2).

Step 3: triangularity. By (Mq3), (Mq4), n_v is invertible and $n_v^{-1}r(s)n_v$ is upper triangular with diagonal $(\psi_{v,a}^P(s))_a$ for $s \in D_v$. Applying y and multiplying by $\bar{\lambda}(s)$: $y(n_v)^{-1}\rho(\pi(s))y(n_v)$ is upper triangular with diagonal $(\psi_{v,a}(s))_a$. Hence each $\psi_{v,a}$ is a homomorphism $D_v \to k[[T]]^\times$ (diagonal entries of products of upper triangular matrices multiply), continuous by (Zq2), Step 0 and local constancy of $\bar{\lambda}$, and $\rho \circ \pi$ is triangular over F_k on D_v with diagonal $(\psi_{v,1}, \dots, \psi_{v,4})$.

Step 4: the symmetric matrix. Since $c \in G_F$ and $c^2 = 1$, we have $r(c)^2 = 1$. By (Mq1), ${}^t r(g) J_4 r(g) = \theta(g) J_4$, so $r(g)^{-1} = \theta(g)^{-1} J_4^{-1}\, {}^t r(g) J_4$. By (Lk1) and (Tw1),

$$\lambda(g)\lambda(cgc) = \theta(g)^{-1}\chi_{\mathrm{cyc}}(g)^{-3}\chi_{\mathrm{cyc}}(g)^3 = \theta(g)^{-1} \qquad (g \in G_L).$$

Put $M = y(J_4 r(c)) \in \mathrm{GL}_4(k[[T]])$. For $\gamma = \pi(g)$, $g \in G_L$, $\gamma^* = \pi(cg^{-1}c)$ and

$$\rho(\gamma^*) = \bar{\lambda}(cgc)^{-1}\bar{\theta}(g)^{-1}\, y(r(c)J_4^{-1}\, {}^t r(g) J_4 r(c)) = \bar{\lambda}(g)\, M^{-1}\, {}^t R(g)\, M = M^{-1}\, {}^t\rho(\gamma)\, M.$$

Moreover $\theta(c) = \alpha(c)\Psi(c) = \chi_{\mathrm{cyc}}(c)\omega_\ell(c)^{-1}\xi(c) = (-1)(-1)(-1) = -1$ by (Sg1), so ${}^t r(c) J_4 = -J_4 r(c)^{-1} = -J_4 r(c)$, and ${}^t(J_4 r(c)) = {}^t r(c)\, {}^t J_4 = -{}^t r(c) J_4 = J_4 r(c)$: M is symmetric. Thus $x = (k, \rho, M, (\psi_{v,a}), f)$ is a curve point of B_4^{po} (Steps 1–4), with $J_0 \subseteq \ker f$ since $y(\phi_0(J_0)) = 0$.

Step 5: (Pc1) and (Pj1). By Step 0 and (Lk6), the characteristic polynomial of $\rho(\pi(g))$ is congruent modulo T to $\prod_a (X - \bar{\lambda}(g)\bar{\chi}_a^{\mathscr{T}}(g)) = \prod_a (X - \bar{\chi}_a(g))$, and $\psi_{v,a} \equiv \bar{\lambda}\bar{\chi}_a^{\mathscr{T}} = \bar{\chi}_a$ modulo T: (Pc1). Let $v \in \Sigma$, $a \neq b$, and $s \in U_v$ with $y(\psi_{v,a}^P(s)) \neq y(\psi_{v,b}^P(s))$ (hypothesis). Then $s \in I_v \subseteq D_v$, $\chi_{\mathrm{cyc}}(s) = 1$, $\bar{r}_0(s) = 1$, so $\bar{\chi}_a(s) = \bar{\lambda}(s) = \bar{\chi}_b(s)$, and $\psi_{v,a}(s) \neq \psi_{v,b}(s) = \psi_{v,b}(s)\chi_{\mathrm{cyc}}(s)$. This is (Pc2), and it gives both clauses of (Pj1).

Step 6: (Pc3). (a) The F_k-span of $R(G_F)$ is $\mathrm{M}_4(F_k)$. By (Mq2), $R(g_{\mathscr{T}})$ is diagonal; by Step 0 its diagonal entries reduce modulo T to the $\bar{\chi}_a^{\mathscr{T}}(g_{\mathscr{T}}) = \bar{\kappa}_a^{\epsilon}(g_{\mathscr{T}})$ in some order, pairwise distinct by (Oq7). So $R(g_{\mathscr{T}})$ has four distinct eigenvalues with eigenlines $F_k e_1, \dots, F_k e_4$, and every F_k-linear endomorphism Z of $V = F_k^4$ commuting with $R(G_F)$ is diagonal. By hypothesis V is an irreducible $F_k[G_F]$-module, so by Schur's lemma $Z - Z_{11}$, which commutes with $R(G_F)$

and kills e_1, is 0: the commutant is F_k. By the Jacobson density theorem the span of $R(G_F)$ is $\mathrm{End}_{F_k}(V)$. (b) Hence $\bar V = \bar F_k^4$ is an irreducible $\bar F_k[G_F]$-module. Fix $g_1 \in G_F \setminus G_L$ ($L \neq F$). The characters $\bar\chi_a^{\mathscr{T}}|_{G_L} = \bar\lambda^{-1}\bar\chi_a$ are pairwise distinct (Rd4); if $\sum_a \bar\chi_a^{\mathscr{T}}(g_1)\bar\chi_a^{\mathscr{T}}(h) = 0$ for all $h \in G_L$, Dedekind's independence of characters would give $\bar\chi_a^{\mathscr{T}}(g_1) = 0$. So some $g = g_1 h \notin G_L$ has $\operatorname{tr} R(g) \equiv \sum_a \bar\chi_a^{\mathscr{T}}(g) \neq 0$ modulo T. Suppose $\bar V$ is reducible for G_L, and let W be a non-zero G_L-stable subspace of minimal dimension and $W' = R(g)W$, G_L-stable (G_L is normal). $W + W'$ is G_F-stable ($G_F = G_L \cup gG_L$, $g^2 \in G_L$), so equals $\bar V$; $W \cap W'$ is G_L-stable in W, so it is 0 or W, and $W' = W$ would make W G_F-stable, so $W = \bar V$. Hence $\bar V = W \oplus W'$, and $R(g)$ maps W to W' and W' to $R(g^2)W = W$, so $\operatorname{tr} R(g) = 0$: contradiction. So $\bar V$ is irreducible for G_L, hence for $\rho_L = \bar\lambda R|_{G_L}$, and $\rho \otimes \bar F_k$ is irreducible on $\Gamma^0 = \pi(G_L)$.

Step 7: (Pc4), (Pc5). The tower is fit, hence good, so (Xr1) and (Xr2) of Lemma 53.16 hold; they are (Pc4) and (Pc5).

Step 8: (Pj3). v_0 splits in L (Rd2), so $D_{\bar v_0} \cap G_F \subseteq G_L$; by (Rd6) the $\bar\chi_a$ agree on it, with common value $\bar\chi_1$, and some g in it has $e_0 = \bar\omega(g) \neq 1$. Put $\delta = \pi(g) \in \Delta_0$ and $A_0 = \rho(\delta) \in \mathrm{GL}_4(k[[T]])$. Let $Z \in \mathrm{M}_4(F_k)$ with $\chi_{\mathrm{cyc}}(\gamma)\rho(\gamma)Z = Z\rho(\gamma)$ on Δ_0; multiplying by a non-zero element of $k[[T]]$ we may assume $Z \in \mathrm{M}_4(k[[T]])$, and $e_0 A_0 Z = Z A_0$. The $k[[T]]$-linear map $\Phi(Y) = e_0 A_0 Y - Y A_0$ on $\mathrm{M}_4(k[[T]])$ reduces modulo T to $\bar\Phi(Y) = (e_0 - 1)\bar\chi_1(g)Y + e_0 N Y - Y N$, where $N = \bar A_0 - \bar\chi_1(g)$ is nilpotent by (Pc1) and Cayley–Hamilton. Left and right multiplication by N commute and are nilpotent, so $Y \mapsto e_0 N Y - Y N$ is nilpotent, and $\bar\Phi$ is a non-zero scalar plus a nilpotent map, hence invertible. So $\det\Phi \in k[[T]]^\times$, Φ is injective and $Z = 0$.

Step 9: conclusion. By Steps 5–7 and Lemma 53.13, x satisfies (Pj2) and is of irreducible type; with Steps 5 and 8 it is a patchable curve point of irreducible type with $J_0 \subseteq \ker f$. Let $\mathfrak{q}$ be a prime of B with $y(\mathfrak{q}) = 0$ and $\mathfrak{q}' = \phi_0^{-1}(\mathfrak{q})$, a prime of B_4^{po}; $f(\mathfrak{q}') \subseteq y(\mathfrak{q}) = 0$, so $\mathfrak{q}' \subseteq \ker f$. As J_0 has R = T at patchable curve points, $J_0 \subseteq \mathfrak{q}'$, i.e. $\phi_0(J_0) \subseteq \mathfrak{q}$. □

Lemma 53.13. *Let $\mathscr{H}$ be a rank-4 Hecke datum over a coefficient ring $\mathcal{O}$, $(B_4^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$ and $(k, \rho, P, (\psi_{v,a}), f)$ a curve point of B_4^{po} such that:*

(Pc1) *for every $\gamma \in \Gamma^0$ the characteristic polynomial of $\rho(\gamma)$ is congruent to $\prod_{a=1}^4 (X - \bar\chi_a(\gamma))$ modulo T, and $\psi_{v,a}(g) \equiv \bar\chi_a(g)$ modulo T for all $v \in S_\ell$, a and $g \in D_v$;*

(Pc2) *for every $v \in S_\ell$ and $a \neq b$ there is $g \in D_v$ with $\chi_{\mathrm{cyc}}(g) = 1$, $\bar\chi_a(g) = \bar\chi_b(g)$ and $\psi_{v,a}(g) \neq \psi_{v,b}(g)$;*

(Pc3) *$\rho \otimes \bar F_k$ is an irreducible representation of Γ^0;*

(Pc4) *every homomorphism $\eta\colon \Gamma^0 \to \{\pm 1\}$ that is trivial on $\Gamma^0 \cap \ker\bar\omega$ and such that for every a there is b with $\eta\bar\chi_a = \bar\chi_b$ is trivial;*

(Pc5) *there are a, b such that $(\bar\chi_a\bar\chi_b^{-1})^m \neq 1$ for $1 \leq m \leq 4$.*

Then the curve point satisfies (Pj2) and $\rho \otimes \bar F_k$ restricted to Γ' is irreducible.

Proof. Symbols introduced here are local to this proof. Write $\Gamma = \Gamma^0$, $A_k = k[[T]]$, F_k, $\bar F_k$ as in the statement, $\bar\rho = \rho \otimes \bar F_k$, and $\Gamma' = \Gamma \cap \ker\chi_{\mathrm{cyc}}$, a closed normal subgroup with Γ/Γ' abelian. The group $1 + TA_k$ is torsion-free: if $(1+x)^N = 1$ with $0 \neq x \in TA_k$, write $N = \ell^j N'$ with $\ell \nmid N'$ and $z = x^{\ell^j} \neq 0$; then $(1+z)^{N'} = 1 + N'z +$ (terms of higher T-order) $\neq 1$.

Step A: a regular element of Γ'. Fix $v \in S_\ell$ and let H be the subgroup of $g \in D_v$ with $\chi_{\mathrm{cyc}}(g) = 1$ and $\bar\chi_c(g) = 1$ for all c; let e be the exponent of the finite group $\{(\bar\chi_c(g))_c : g \in D_v, \chi_{\mathrm{cyc}}(g) = 1\}$. For $a \neq b$ let $\theta_{ab} = \psi_{v,a}\psi_{v,b}^{-1}|_H$, a homomorphism $H \to 1 + TA_k$ by (Pc1).

For the element s_{ab} of (Pc2), $\psi_{v,a}(s_{ab})\psi_{v,b}(s_{ab})^{-1} \in 1 + TA_k$ (by (Pc1) and $\bar\chi_a(s_{ab}) = \bar\chi_b(s_{ab})$) is $\neq 1$, so $h_{ab} = s_{ab}^e \in H$ has $\theta_{ab}(h_{ab}) \neq 1$ (torsion-freeness). Enumerate the twelve pairs as $p = 1, \dots, 12$ and, for $c \in \mathbb{Z}^{12}$, put $h(c) = \prod_p h_p^{c_p} \in H$. For each q, $c \mapsto \theta_q(h(c))$ is a homomorphism $\mathbb{Z}^{12} \to 1 + TA_k$, non-zero at the q-th unit vector, into a torsion-free group; so its kernel has rank ≤ 11 and lies in a hyperplane $\{\lambda \cdot c = 0\}$, $0 \neq \lambda \in \mathbb{Z}^{12}$, which meets $[-M, M]^{12}$ in at most $(2M+1)^{11}$ points. For $2M + 1 > 12$ some $c \in [-M, M]^{12}$ lies in none of the twelve kernels. Put $u = h(c)$: then $u \in D_v$, its image lies in Γ', and $\theta_{ab}(u)$ has infinite order for $a \neq b$. As ρ is triangular over F_k on D_v with diagonal $(\psi_{v,a})$, the eigenvalues of $\rho(u^m)$ are $\psi_{v,a}(u)^m$, pairwise distinct for every $m \geq 1$: the characteristic polynomial of every $\rho(u^m)$, $m \geq 1$, is separable, and $\rho(u)$ satisfies (Xs3) over $\bar F_k$.

Step B: irreducible type. Suppose $\bar\rho|_{\Gamma'}$ is reducible, and let $W \subseteq \bar V = \bar F_k^4$ be a non-zero Γ'-stable subspace of minimal dimension. The subspaces $\bar\rho(\gamma)W$, $\gamma \in \Gamma$, are Γ'-stable and irreducible (Γ' is normal), and their sum is Γ-stable, so equals $\bar V$ by (Pc3); hence $\bar V|_{\Gamma'}$ is semisimple. Its isotypic components have multiplicity one: on a component $W_i^{e_i}$ the element $\bar\rho(u)$, $u \in \Gamma'$ from Step A, would have each eigenvalue on W_i with multiplicity $\geq e_i$, while its characteristic polynomial is separable. So $\bar V = W_1 \oplus \cdots \oplus W_t$ with pairwise non-isomorphic irreducible Γ'-modules W_i, these are all the Γ'-stable irreducible subspaces, Γ permutes them transitively, $t \geq 2$, and $t \mid 4$ as they have equal dimension. The stabiliser S of W_1 contains Γ', so it is normal with Γ/S abelian of order $t \in \{2, 4\}$; let $\eta\colon \Gamma \to \{\pm 1\}$ be a non-trivial character trivial on S. The linear map Φ acting on $\bar\rho(\gamma)W_1$ by $\eta(\gamma)$ is well defined, and $\Phi\bar\rho(\delta)\Phi^{-1} = \eta(\delta)\bar\rho(\delta)$ for $\delta \in \Gamma$ (both sides send $\bar\rho(\gamma)W_1$ to $\bar\rho(\delta\gamma)W_1$, with the factor $\eta(\delta\gamma)\eta(\gamma)^{-1}$). So $\rho(\delta)$ and $\eta(\delta)\rho(\delta)$ have the same characteristic polynomial; reducing modulo T with (Pc1), $\prod_a(X - \bar\chi_a(\delta)) = \prod_a(X - \eta(\delta)\bar\chi_a(\delta))$ for all δ. The semisimple representations $\bigoplus_a \bar\chi_a$ and $\bigoplus_a \eta\bar\chi_a$ of Γ over $\bar k$ have the same characteristic polynomials, hence the same constituents (Brauer–Nesbitt): for every a there is b with $\eta\bar\chi_a = \bar\chi_b$. Moreover η is trivial on $\Gamma \cap \ker\bar\omega$: η factors through $\Gamma/\Gamma' \cong C = \chi_{\mathrm{cyc}}(\Gamma) \subseteq \mathbb{Z}_\ell^\times = \mu_{\ell-1} \times (1+\ell\mathbb{Z}_\ell)$, and $C = (C \cap \mu_{\ell-1}) \times (C \cap (1+\ell\mathbb{Z}_\ell))$ (orders prime to each other); squaring is bijective on the pro-ℓ group $C \cap (1+\ell\mathbb{Z}_\ell)$ (ℓ odd), so the quadratic character η is trivial on it, and $\Gamma \cap \ker\bar\omega$ maps into it. By (Pc4), $\eta = 1$: contradiction. So $\bar\rho|_{\Gamma'}$ is irreducible: the curve point is of irreducible type, and by Burnside's theorem the $\bar F_k$-span of $\rho(\Gamma')$ is $\mathrm{M}_4(\bar F_k)$ (Xs2).

Step C: (Xs4) for Γ'. Let $N \subseteq \Gamma'$ be a normal subgroup of finite index m with $\rho(N)$ commutative. For $\gamma \in \Gamma$, $\gamma u \gamma^{-1} \in \Gamma'$, so $\gamma u^m \gamma^{-1} = (\gamma u \gamma^{-1})^m \in N$; hence the normal core $N_0 = \bigcap_\gamma \gamma N \gamma^{-1}$ of N in Γ contains u^m, and $\rho(N_0)$ is commutative. $\rho(u^m)$ has four distinct eigenvalues (Step A) with eigenlines $\ell_1, \dots, \ell_4 \subseteq \bar V$; every $\rho(n)$, $n \in N_0$, commutes with $\rho(u^m)$, so preserves each ℓ_i; two lines with the same character of N_0 would carry the same eigenvalue of u^m, so the ℓ_i are the joint eigenspaces of $\rho(N_0)$, with distinct characters ϕ_i. As N_0 is normal in Γ, $\bar\rho(\gamma)$ permutes them: $\bar\rho(\gamma)\ell_i = \ell_{\pi(\gamma)i}$ for a homomorphism $\pi\colon \Gamma \to S_4$, transitive by (Pc3). Let $h \in \ker\pi$. Then $\bar\rho(h)$ is diagonal in a basis of the ℓ_i with eigenvalues $\beta_i(h)$, integral over A_k (roots of a monic polynomial over A_k); fix a maximal ideal over (T) of the integral closure of A_k in $\bar F_k$ and write $\tilde\beta_i(h)$ for the residue, so that $\tilde\beta_i$ is a character of $\ker\pi$ with values in $\bar k^\times$, and $\prod_i(X - \tilde\beta_i(h)) = \prod_a(X - \bar\chi_a(h))$ by (Pc1). By Brauer–Nesbitt for the semisimple representations $\bigoplus_i \tilde\beta_i$ and $\bigoplus_a \bar\chi_a|_{\ker\pi}$, $\{\tilde\beta_i\} = \{\bar\chi_a|_{\ker\pi}\}$ as multisets. For $\gamma \in \Gamma$ with $\pi(\gamma)1 = i$, $\beta_i(h) = \beta_1(\gamma^{-1}h\gamma)$, so $\tilde\beta_i = \tilde\beta_1 \circ \mathrm{conj}_{\gamma^{-1}}$; $\tilde\beta_1 = \bar\chi_{a_0}|_{\ker\pi}$ for some a_0, and $\bar\chi_{a_0}$ is a character of Γ, so $\tilde\beta_i = \bar\chi_{a_0}|_{\ker\pi}$ for all i. Hence all $\bar\chi_a$ coincide on $\ker\pi$, and each $\bar\chi_a\bar\chi_b^{-1}$ is a character of $\pi(\Gamma) \subseteq S_4$. The abelianisation of every subgroup of S_4 has exponent $1, 2, 3$ or 4, so $(\bar\chi_a\bar\chi_b^{-1})^n = 1$ for some $1 \leq n \leq 4$, for all a, b, contradicting (Pc5). So every normal subgroup of finite index of Γ', in particular every open one, has non-commuting images.

Step D: (Xs1) for Γ'. Let $f \in \bar F_k[x_{ij}]$. Its coefficients lie in a finite-dimensional F_k-subspace

with basis $c_1, \dots, c_s$; write $f = \sum_j c_j f_j$ with $f_j \in F_k[x_{ij}]$ and choose $0 \neq d \in A_k$ with $df_j \in A_k[x_{ij}]$. As $\rho(g)$ has entries in F_k, $f(\rho(g)) = 0$ if and only if $(df_j)(\rho(g)) = 0$ for all j; each $g \mapsto (df_j)(\rho(g)) \in A_k$ is continuous for the T-adic topology (the entries of ρ are), and A_k is Hausdorff, so the zero set is closed.

Step E: (Pj2). Let $U_0 \subseteq \Gamma$ be open with some $\sigma \in U_0 \cap \Gamma'$. As Γ is profinite there is an open normal subgroup H' with $\sigma H' \subseteq U_0$; $V_0 = H' \cap \Gamma'$ has finite index in Γ'. By Steps A–D and Lemma 53.14 for $G = \Gamma'$, $K = \bar{F}_k$ (characteristic $\ell \neq 2$) and $\bar{\rho}|_{\Gamma'}$, some $g \in V_0$ makes the characteristic polynomial of $\rho(\sigma g)$ separable over $\bar{F}_k$, hence over F_k (the discriminant is non-zero), and $\sigma g \in U_0 \cap \Gamma'$. □

Lemma 53.14. *Let K be an algebraically closed field of characteristic different from 2, G a topological group and $\rho\colon G \to \mathrm{GL}_4(K)$ a homomorphism such that:*

(Xs1) *for every polynomial $f \in K[x_{ij} : 1 \leq i, j \leq 4]$ the set $\{g \in G : f(\rho(g)) = 0\}$ is closed in G;*

(Xs2) *the K-span of $\rho(G)$ is $\mathrm{M}_4(K)$;*

(Xs3) *there is $u \in G$ such that $\rho(u)$ has eigenvalues $a_1, \dots, a_4$ with a_i/a_j of infinite order in $K^\times$ for all $i \neq j$;*

(Xs4) *every open normal subgroup of finite index $N \subseteq G$ contains g, h with $\rho(g)\rho(h) \neq \rho(h)\rho(g)$.*

Then for every subgroup $U \subseteq G$ of finite index and every $\sigma \in G$ there is $g \in U$ such that the characteristic polynomial of $\rho(\sigma g)$ is separable.

Proof. Fix U and σ.

Step 0: an eigenbasis of u. The a_i are pairwise distinct ($a_i/a_j \neq 1$ has infinite order), so $\rho(u) = P\,\mathrm{diag}(a_1, \dots, a_4)P^{-1}$ for some $P \in \mathrm{GL}_4(K)$. Replacing ρ by $g \mapsto P^{-1}\rho(g)P$ preserves (Xs1) (a polynomial in the entries of $P^{-1}yP$ is a polynomial in the entries of y), (Xs2), (Xs3), (Xs4) and the characteristic polynomials. So we assume $\rho(u) = \mathrm{diag}(a_1, \dots, a_4)$.

Step 1: the subgroup N and a diagonal element. Let N be the subgroup of Lemma 50.20 for $L = K$: normal of finite index by (Zi1), open by (Zi4) and (Xs1). By (Xs4), $\rho(N)$ is not commutative. $U \cap N$ has finite index, so among $u^0, u^1, \dots, u^{[G:U\cap N]}$ two lie in the same left coset and $t = u^k \in U \cap N$ for some $k \geq 1$. Then $\rho(t) = \mathrm{diag}(\beta_1, \dots, \beta_4)$ with $\beta_i = a_i^k$, and $\beta_i/\beta_j = (a_i/a_j)^k$ has infinite order for $i \neq j$; in particular the β_i are pairwise distinct. Let $w_1, \dots, w_4$ be the pairwise distinct integers given by Lemma 50.21 for $E = K$ and $\beta_1, \dots, \beta_4$, and τ the permutation with $w_{\tau(1)} > \cdots > w_{\tau(4)}$.

Step 2: the relations R_g. For $g \in G$ and indices i, j write $R_g(i,j)$ if $\rho(gh)_{ij} \neq 0$ for some $h \in N$. R_g depends only on the coset gN. Properties:

(a) If $R_g(i,j)$ and $R_{g'}(j,l)$, then $R_{gg'}(i,l)$. Take $h, h' \in N$ with $\rho(gh)_{ij} \neq 0$, $\rho(g'h')_{jl} \neq 0$. For $q \geq 0$, $ght^q g'h' = gg' \cdot (g'^{-1}ht^q g'h') \in gg'N$ (N normal), and $\rho(ght^q g'h')_{il} = \sum_s \rho(gh)_{is}\rho(g'h')_{sl}\,\beta_s^q$. If all these vanished, the Vandermonde matrix of the distinct β_s would force $\rho(gh)_{is}\rho(g'h')_{sl} = 0$ for every s, false for $s = j$.

(b) If $R_g(i,j)$, then $R_{g^{-1}}(j,i)$. By (Xs2) some h has $\rho(h)_{ji} \neq 0$ (otherwise the span of $\rho(G)$ lies in $\{y : y_{ji} = 0\}$), so $R_h(j,i)$; by (a), $R_{gh}(i,i)$, and inductively $R_{h(gh)^m}(j,i)$ for all $m \geq 0$. With $d = [G : N]$, $(gh)^d \in N$ (G/N is a group of order d), so $h(gh)^{d-1} = g^{-1}(gh)^d \in g^{-1}N$ and $R_{g^{-1}}(j,i)$.

(c) R_1 is an equivalence relation: reflexive as $\rho(1) = 1$, symmetric by (b), transitive by (a).

(d) For every g and i there is j with $R_g(i,j)$: row i of the invertible $\rho(g)$ is non-zero.

(e) Every class of R_1 has at least two elements. First, $R_1(j,l)$ for some $j \neq l$: otherwise every $\rho(h)$, $h \in N$, is diagonal, and $\rho(N)$ is commutative. Suppose the class of i is $\{i\}$. By (Xs2) choose g with $\rho(g)_{ji} \neq 0$; then $R_g(j,i)$, and $R_g(l,i)$ by (a) from $R_1(l,j)$. If $R_g(a,i)$ and $\rho(g)_{as} \neq 0$, then $R_{g^{-1}}(i,a)$ by (b) and $R_g(a,s)$, so $R_1(i,s)$ by (a), and $s = i$. Applied to $a = j$ and $a = l$: rows $j \neq l$ of $\rho(g)$ vanish outside column i, so they are proportional, contradicting $\det \rho(g) \neq 0$.

Step 3: the dichotomy. Either (A) $R_\sigma(i,i)$ for all i, or (B) there is a partition $\{1,2,3,4\} = I \sqcup J$, $|I| = |J| = 2$, such that $R_\sigma(a,b)$ fails for a,b both in I or both in J and holds for $a \in I, b \in J$ and for $a \in J, b \in I$. Suppose (A) fails at i_0. By (d) take j_0 with $R_\sigma(i_0,j_0)$. Then $R_1(i_0,j_0)$ fails (else $R_\sigma(i_0,i_0)$ by (a) with $R_1(j_0,i_0)$). So the classes $I \ni i_0$ and $J \ni j_0$ of R_1 are distinct; by (e) each has at least two elements, so $|I| = |J| = 2$ and $I \sqcup J = \{1,2,3,4\}$. By (a), R_1-equivalent indices may be exchanged in R_σ on either side. Hence: $R_\sigma(a,b)$ holds for $a \in I$, $b \in J$; $R_\sigma(a,a')$ fails for $a,a' \in I$ (it would give $R_\sigma(i_0,i_0)$); $R_\sigma(b,b')$ fails for $b,b' \in J$ (it would give $R_\sigma(b,j_0)$, then with $R_{\sigma^{-1}}(j_0,i_0)$ from (b) and (a), $R_1(b,i_0)$, but $b \notin I$); and for $b \in J$, (d) gives c with $R_\sigma(b,c)$, necessarily $c \in I$, so $R_\sigma(b,a)$ for every $a \in I$.

Step 4: an element of U with a separable twist. Case (A). Consider the polynomials $f_1 = x_{\tau(1)\tau(1)}$ and $f_2 = \operatorname{adj}(x)_{\tau(4)\tau(4)}$ in the entries x. $f_1(\rho(\sigma h)) \neq 0$ for some $h \in N$ by $R_\sigma(\tau(1),\tau(1))$. By (b), $R_{\sigma^{-1}}(\tau(4),\tau(4))$: $\rho(\sigma^{-1}h')_{\tau(4)\tau(4)} \neq 0$ for some $h' \in N$. Put $h = \sigma^{-1}h'^{-1}\sigma \in N$; then $(\sigma h)^{-1} = \sigma^{-1}h'$ and $\operatorname{adj}(\rho(\sigma h)) = \det \rho(\sigma h)\, \rho(\sigma^{-1}h')$, so $f_2(\rho(\sigma h)) \neq 0$. By (Zi3) there is $g \in U \cap N$ with $f_1(\rho(\sigma g))f_2(\rho(\sigma g)) \neq 0$, and by (Zd1) the characteristic polynomial of $\rho(\sigma g)\operatorname{diag}(X^{w_1},\dots,X^{w_4})$ is separable over $K(X)$. Case (B). Let $i \in I$, $j \in J$ be the indices of larger weight. By (Zi3) applied to x_{ij} and x_{ji} (each non-zero somewhere on $\rho(\sigma N)$ by $R_\sigma(i,j)$, $R_\sigma(j,i)$) there is $g \in U \cap N$ with $\rho(\sigma g)_{ij}\rho(\sigma g)_{ji} \neq 0$. As $g \in N$ and $R_\sigma(a,b)$ fails for a,b in the same block, $\rho(\sigma g)_{ab} = 0$ there; and $\det \rho(\sigma g) \neq 0$. By (Zd2) the characteristic polynomial of $\rho(\sigma g)\operatorname{diag}(X^{w_1},\dots,X^{w_4})$ is separable over $K(X)$.

Step 5: specialisation. By Lemma 50.21 with $M = \rho(\sigma g)$, there is $q \geq 0$ such that the characteristic polynomial of $\rho(\sigma g)\operatorname{diag}(\beta_1^q,\dots,\beta_4^q) = \rho(\sigma g t^q)$ is separable. As $g \in U$ and $t \in U$, $gt^q \in U$ is the required element. □

Lemma 53.15. *Let K be a field of characteristic different from 2, X an indeterminate, $x \in \mathrm{M}_4(K)$, $w_1,\dots,w_4$ pairwise distinct integers and $D = \operatorname{diag}(X^{w_1},\dots,X^{w_4})$. The characteristic polynomial of xD is separable over $K(X)$ in each of the following cases:*

(Zd1) *$x_{\tau(1)\tau(1)} \neq 0$, and the principal minor of x on the rows and columns $\{\tau(1),\tau(2),\tau(3)\}$, that is $\operatorname{adj}(x)_{\tau(4)\tau(4)}$, is non-zero, where τ is the permutation of $\{1,2,3,4\}$ such that $w_{\tau(1)} > w_{\tau(2)} > w_{\tau(3)} > w_{\tau(4)}$;*

(Zd2) *there is a partition $\{1,2,3,4\} = I \sqcup J$ with $|I| = |J| = 2$ such that $x_{ab} = 0$ whenever $a,b \in I$ or $a,b \in J$, $\det x \neq 0$, and $x_{ij}x_{ji} \neq 0$, where $i \in I$ and $j \in J$ are the indices of the larger weight in I and in J.*

Proof. We compute in the ring $K[X,X^{-1}] \subseteq K(X)$; for a non-zero f there, $\deg f$ is the largest exponent with non-zero coefficient, so $\deg(fg) = \deg f + \deg g$ and $\deg(f+g) \leq \max(\deg f, \deg g)$, with equality if the degrees differ. Conjugating by a permutation matrix changes neither the characteristic polynomial nor the hypotheses (it permutes indices, weights and principal minors together), so we may relabel indices freely. For $S \subseteq \{1,2,3,4\}$ let m_S be

the principal minor of x on S and $w_S = \sum_{a\in S} w_a$. Multiplying column a by X^{w_a} multiplies every principal minor containing a by X^{w_a}, so

$$\det(Y - xD) = Y^4 - c_1Y^3 + c_2Y^2 - c_3Y + c_4, \qquad c_k = \sum_{|S|=k} m_S\, X^{w_S}.$$

(Zd1). Relabel so that $w_1 > w_2 > w_3 > w_4$; put $g_1 = w_1 - w_2$, $g_2 = w_2 - w_3$, $g_3 = w_3 - w_4$, all positive. The unique 1-subset of largest weight is $\{1\}$, the unique 3-subset of largest weight is $\{1,2,3\}$, the largest 2-subset weight is $w_1 + w_2$ (only for $\{1,2\}$) and the next is $w_1 + w_3$. Hence: $\deg c_1 = w_1$ with leading coefficient $x_{11} \neq 0$; $\deg c_3 = w_1 + w_2 + w_3$ with leading coefficient $m_{\{1,2,3\}} \neq 0$; $c_4 = \det(x)X^{w_1+w_2+w_3+w_4}$ has degree at most $w_1 + w_2 + w_3 + w_4$ (or is 0); and c_2 has degree at most $w_1 + w_2$, exactly $w_1 + w_2$ with leading coefficient $m_{\{1,2\}}$ if $m_{\{1,2\}} \neq 0$, and at most $w_1 + w_3$ if $m_{\{1,2\}} = 0$. With $b = -c_1$, $c = c_2$, $d = -c_3$, $e = c_4$, the discriminant of $Y^4 + bY^3 + cY^2 + dY + e$ is

$$\begin{aligned}\delta = {} & 256e^3 - 192bde^2 - 128c^2e^2 + 144cd^2e - 27d^4 + 144b^2ce^2 - 6b^2d^2e - 80bc^2de \\ & + 18bcd^3 + 16c^4e - 4c^3d^2 - 27b^4e^2 + 18b^3cde - 4b^3d^3 - 4b^2c^3e + b^2c^2d^2.\end{aligned}$$

Case $m_{\{1,2\}} \neq 0$. The monomial $b^2c^2d^2$ has degree exactly $\Theta = 6w_1 + 4w_2 + 2w_3$ and leading coefficient $x_{11}^2 m_{\{1,2\}}^2 m_{\{1,2,3\}}^2 \neq 0$. Every other monomial has degree at most $\Theta - (n_1g_1 + n_2g_2 + n_3g_3)$ with non-negative integers n_i, not all 0:

So $\deg\delta = \Theta$ and $\delta \neq 0$.

Case $m_{\{1,2\}} = 0$. Now $\deg c \leq w_1 + w_3$. The monomial $-4b^3d^3$ has degree exactly $\Theta' = 6w_1+3w_2+3w_3$ and leading coefficient $-4(-x_{11})^3(-m_{\{1,2,3\}})^3 = -4x_{11}^3 m_{\{1,2,3\}}^3$, non-zero because the characteristic is not 2. Every other monomial has degree at most $\Theta' - (n_1g_1 + n_2g_2 + n_3g_3)$ with $n_i \geq 0$ not all 0:

So $\deg\delta = \Theta'$ and $\delta \neq 0$. In both cases the characteristic polynomial of xD is separable.

Why no 2×2 *minor is needed.* The top 2×2 minor $m_{\{1,2\}}$ only decides which monomial of δ dominates. When it vanishes, c_2 loses its top degree and the monomial $-4b^3d^3$, which does not contain c, takes over; its coefficient -4 is a unit exactly because the characteristic is not 2. In terms of roots: the roots of the characteristic polynomial have X-degrees w_1, w_4 and, for the middle pair, approximately the two square roots of $-d/b = -c_3/c_1$ (degree $w_2 + w_3$), which are distinct because $2 \neq 0$.

(Zd2). Relabel so that $I = \{1,2\}$, $J = \{3,4\}$, $w_1 > w_2$, $w_3 > w_4$; so $i = 1$, $j = 3$. In block form $xD = \begin{pmatrix} 0 & B \\ C & 0 \end{pmatrix}$ with $B = x_{IJ}\,\mathrm{diag}(X^{w_3}, X^{w_4})$ and $C = x_{JI}\,\mathrm{diag}(X^{w_1}, X^{w_2})$, where x_{IJ}, x_{JI} are the 2×2 blocks of x. Over $K(X)(Y)$, by the Schur complement of the invertible block $Y \cdot 1_2$,

$$\det\begin{pmatrix} Y & -B \\ -C & Y \end{pmatrix} = Y^2 \det(Y - CY^{-1}B) = \det(Y^2 - CB),$$

so the characteristic polynomial is $\chi(Y) = \psi(Y^2)$ with $\psi(Z) = Z^2 - \mathrm{tr}(CB)Z + \det(CB)$. Here $\det(CB) = \det(x_{IJ})\det(x_{JI})X^{w_1+w_2+w_3+w_4}$ and $\det x = \det(x_{IJ})\det(x_{JI})$, so $\det(CB) \neq 0$. Further

$$\mathrm{tr}(CB) = \sum_{a\in I,\ b\in J} x_{ab}x_{ba}X^{w_a+w_b},$$

whose exponent $w_1 + w_3$ is strictly larger than the other three, with coefficient $x_{13}x_{31} \neq 0$; so $\deg \mathrm{tr}(CB)^2 = 2(w_1 + w_3) > w_1 + w_2 + w_3 + w_4 \geq \deg(4\det(CB))$, and the discriminant $\mathrm{tr}(CB)^2 - 4\det(CB)$ of ψ is non-zero. So ψ has two distinct roots $z_1 \neq z_2$ in an algebraic

closure, both non-zero as $z_1 z_2 = \det(CB) \neq 0$. The roots of χ are $\pm\sqrt{z_1}$, $\pm\sqrt{z_2}$: $\sqrt{z_k} \neq -\sqrt{z_k}$ since $z_k \neq 0$ and $2 \neq 0$, and $\pm\sqrt{z_1} \neq \pm\sqrt{z_2}$ since their squares differ. So χ has four distinct roots and is separable. □

Lemma 53.16. *In the setting of Lemma 53.7, assume that $\mathscr{T}$ is good. Then:*

(Xr1) *every map $\eta\colon \Gamma^0_{\mathscr{H}} \to \{\pm 1\}$ which is a homomorphism, trivial on $\Gamma^0_{\mathscr{H}} \cap \ker\bar{\omega}$, and such that for every a there is b with $\eta\bar{\chi}_a = \bar{\chi}_b$, is trivial;*

(Xr2) *there are a, b with $(\bar{\chi}_a\bar{\chi}_b^{-1})^m \neq 1$ for $1 \leq m \leq 4$.*

Proof. Put $\lambda = \nu\kappa^{-1}$, so that $\bar{\chi}_a \circ \pi_{\mathscr{H}} = \bar{\lambda}\,\bar{\chi}_a^{\mathscr{T}}$ on G_L by (Lk6); in particular $\bar{\chi}_a\bar{\chi}_b^{-1} \circ \pi_{\mathscr{H}} = \bar{\chi}_a^{\mathscr{T}}/\bar{\chi}_b^{\mathscr{T}}$ on G_L.

(Xr1): Let η be as stated and $\eta' = \eta \circ \pi_{\mathscr{H}}|_{G_L}$, a homomorphism $G_L \to \{\pm 1\} \subseteq \mathbb{F}_{\mathcal{O}}^\times$ with $\eta'^2 = 1$, trivial on $G_L \cap \ker\omega_\ell$ (as $\bar{\omega}_\ell = \bar{\omega}$ and $\pi_{\mathscr{H}}(G_L \cap \ker\bar{\omega}) \subseteq \Gamma^0_{\mathscr{H}} \cap \ker\bar{\omega}$). Dividing $\eta\bar{\chi}_a = \bar{\chi}_b$ by $\bar{\lambda}$ gives $\eta'\bar{\kappa}_a^\epsilon = \bar{\kappa}_b^\epsilon$ on G_L. By (Oq4), $\eta' = 1$, so $\eta = 1$ ($\pi_{\mathscr{H}}(G_L) = \Gamma^0_{\mathscr{H}}$).

(Xr2): By (Oq3) there is a root w such that for every $1 \leq m \leq 4$ some $g \in G_L$ has $\overline{\mathrm{rt}_w}(g)^m \neq 1$. So $\mathrm{rt}_w = \chi_a^{\mathscr{T}}/\chi_b^{\mathscr{T}}$ for some $a \neq b$, and $(\bar{\chi}_a\bar{\chi}_b^{-1})^m(\pi_{\mathscr{H}}(g)) = \overline{\mathrm{rt}_w}(g)^m \neq 1$. □

Lemma 53.17. *Let $\mathfrak{D}$, $\mathscr{T}$ (fit and deep), $\mathcal{O}_1, \nu, \gamma, t$, $\mathcal{O}' \supseteq \mathcal{O}_1$, κ, $\mathscr{H}$, $\mathscr{X} = (B, A, P, \dots)$, $(B_4^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ and ϕ_0 be as in Lemma 53.12, where κ moreover has (Kw1) (for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ there are integers e and $k' \geq 1$ such that $(\kappa\chi_{\mathrm{cyc}}^{-e})^{k'}$ is trivial on $I_{\bar{w}} \cap G_L$), $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $J_0 \subseteq B_4^{\mathrm{po}}$ an ideal with $J_0 \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$ (for ι and κ) and the properties (Hf2) and (Hf5). Then for every $\mathcal{O}'$-algebra homomorphism $y\colon A \to \overline{\mathbb{Q}}_\ell$ such that $y(P)$ is a seed for ι, every prime $\mathfrak{q}$ of B with $y(\mathfrak{q}) = 0$ contains $\phi_0(J_0)$.*

Proof. Symbols introduced here are local to this proof. Write $\pi = \pi_{\mathscr{H}}$ and $B^{\mathrm{po}} = B_4^{\mathrm{po}}$. Let $y\colon A \to \overline{\mathbb{Q}}_\ell$ be an $\mathcal{O}'$-algebra homomorphism such that $y(P)$ is a seed for ι, with weights h, and let $\mathfrak{q}$ be a prime of B with $y(\mathfrak{q}) = 0$.

Step 1: a point of B^{po}. Choose $n \in \{0, 1\}$ with $n \equiv h_1$ modulo 2 and put $x = y \circ \phi_n$. By Lemma 53.18 (its hypothesis (Kw1) on κ is one of ours), x is a classical ordinary point for ι and κ, its representation $\tilde{r}$ is absolutely irreducible on $\Gamma^0_{\mathscr{H}} \cap \ker\bar{\omega}$, and integers $m_{v,a}$ with gaps ≥ 2 and $k \geq 1$ as in Lemma 53.20 exist. The character κ satisfies $\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{-3}$ for $s \in G_L$ ((Tw1) with $m = -3$, as required of κ in Lemma 53.2). As J_0 has (Hf2) and $J_0 \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$, Lemma 53.20 shows that every prime $\mathfrak{q}' \subseteq \ker x$ of B^{po} contains J_0.

Step 2: the prime $\mathfrak{q}$. $\mathfrak{q}' = \phi_n^{-1}(\mathfrak{q})$ is a prime of B^{po} with $x(\mathfrak{q}') = y(\phi_n(\mathfrak{q}')) \subseteq y(\mathfrak{q}) = 0$, so $\mathfrak{q}' \subseteq \ker x$ and $J_0 \subseteq \mathfrak{q}'$, i.e. $\phi_n(J_0) \subseteq \mathfrak{q}$. If $n = 0$ we are done.

Step 3: from ϕ_1 to ϕ_0. Let $n = 1$. The character $\gamma\colon G_L \to \mathcal{O}'^\times$ is trivial on $I_{\bar{w}} \cap G_L$ for every place $\bar{w} \nmid \ell$ ((Lk2): t vanishes there and $\ker t \subseteq \ker\gamma$), and $\gamma(csc) = \gamma(s)^{-1}$ (Lk1); so it is trivial on the generators of $N_{\mathscr{H}}$ and their conjugates under G_L and c, hence (being continuous) on $N_{\mathscr{H}}$, and $\gamma = \gamma_0 \circ \pi|_{G_L}$ for a continuous homomorphism $\gamma_0\colon \Gamma^0_{\mathscr{H}} \to \mathcal{O}'^\times \subseteq (B^{\mathrm{po}})^\times$. Put $\beta = \gamma_0^{-1}$. It satisfies the hypotheses of (Hf5): $\beta \equiv 1$ modulo $\mathfrak{m}_{B^{\mathrm{po}}}$ (Lk2); $\beta(\pi(csc)) = \beta(\pi(s))^{-1}$ (Lk1); β is trivial on $\pi(I_{\bar{w}} \cap G_L)$ for all $\bar{w} \nmid \ell$, in particular above $\mathrm{St} \cup \{v_0\}$; and β is trivial on μ_v ((Lk4) gives $t(\mu_v) = 0$, then (Lk2)). So $\tau_\beta(J_0) \subseteq J_0$. Now $\phi_1 \circ \tau_\beta$ satisfies (Cm1) and (Cm2) for $n = 0$: for $g \in G_L$, τ_β maps $\chi_{D^{\mathrm{u}}}(\pi(g))(X)$ to $\chi_{D^{\mathrm{u}}_\beta}(\pi(g))(X) = D^{\mathrm{u}}(X - \beta(\pi(g))\pi(g)) = \beta(\pi(g))^4\chi_{D^{\mathrm{u}}}(\pi(g))(\beta(\pi(g))^{-1}X)$, and applying ϕ_1 with (Cm1) gives $(\beta\lambda_1)(g)^4\,\mathrm{cp}(g)((\beta\lambda_1)(g)^{-1}X)$ with $\beta(\pi(g))\lambda_1(g) = \gamma(g)^{-1}\nu(g)\kappa(g)^{-1}\gamma(g) = \lambda_0(g)$; and $\phi_1(\tau_\beta(\psi^{\mathrm{d}}_{v,a}(g))) = \phi_1(\beta(\pi(g))\psi^{\mathrm{d}}_{v,a}(g)) = \lambda_0(g)\psi^B_{v,a}(g)$ by (Cm2). By the uniqueness in Lemma 53.7, $\phi_0 = \phi_1 \circ \tau_\beta$. Hence $\phi_0(J_0) = \phi_1(\tau_\beta(J_0)) \subseteq \phi_1(J_0) \subseteq \mathfrak{q}$ by Step 2. □

Lemma 53.18. *Let $\mathfrak{D}$, $\mathscr{T}$ (fit and deep), $\mathcal{O}_1, \nu, \gamma, t$, $\mathcal{O}' \supseteq \mathcal{O}_1$, κ, $\mathscr{H}$, $\mathscr{X} = (B, A, P, \dots)$ and $(B_4^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be as in Lemma 53.12, and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and suppose that κ has (Kw1): for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above ℓ there are integers e and $k' \geq 1$ such that $(\kappa\chi_{\mathrm{cyc}}^{-e})^{k'}$ is trivial on $I_{\bar{w}} \cap G_L$. Let $y\colon A \to \overline{\mathbb{Q}}_\ell$ be an $\mathcal{O}'$-algebra homomorphism such that $y(P)$ is a seed for ι with weights $h \in \mathbb{Z}^4$ (as in the definition of a seed), let $n \geq 0$ be an integer with $n \equiv h_1$ modulo 2, ϕ_n as in Lemma 53.7, and $x = y \circ \phi_n\colon B_4^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$. Then x is a classical ordinary point for ι and κ; the representation $\tilde{r}$ of its definition restricted to $\Gamma^0_{\mathscr{H}} \cap \ker\bar{\omega}$ is absolutely irreducible; and there are integers $m_{v,a}$ with $m_{v,a} \geq m_{v,b} + 2$ for $a < b$ and $k \geq 1$ with $\bigl(x(\psi_{v,a}^{\mathrm{d}}(g))\chi_{\mathrm{cyc}}(g)^{-m_{v,a}}\bigr)^k = 1$ for all $v \in \Sigma$, a and $g \in I_v$.*

Proof. Symbols introduced here are local to this proof. Write $\pi = \pi_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $B^{\mathrm{po}} = B_4^{\mathrm{po}}$, $r_y = y \circ r_P\colon G_F \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ (invertible values: similitude $\theta(g)$, (Mq1)). As $y(P)$ is a seed with weights h: the span of $r_y(G')$ is $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$; $h_i - h_{i+1} \in 2\mathbb{Z}$ and $h_i - h_{i+1} \geq 4$; there are an open normal subgroup $U \subseteq G_F$ with $y(\psi_{v,a}^P(s))^2 = \chi_{\mathrm{cyc}}(s)^{h_a}$ for $s \in U \cap I_v$, a continuous character $\kappa_s\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$, integers a_s with $a_s + h_1$ even and $k_s \geq 1$ with $(\kappa_s^2\chi_{\mathrm{cyc}}^{-a_s})^{k_s} = 1$ on the inertia groups in G_L of all places above ℓ, and a regular algebraic cuspidal π_s of $\mathrm{GL}_4(\mathbb{A}_L)$ with $r_y|_{G_L} \otimes \kappa_s \leftrightarrow_\iota \pi_s$. Hence $n \equiv h_1 \equiv h_a \equiv a_s$ modulo 2 for all a.

Step 1: continuity of r_y on G_L. Put $\rho_L = \lambda_n\, r_y|_{G_L}$. By (In1) x is continuous, and D^{u} is continuous, so $t(g) = x(\mathrm{tr}_{D^{\mathrm{u}}}(\pi(g)))$ is continuous on G_L. By (Cm1) and (Zq2), $x(\chi_{D^{\mathrm{u}}}(\pi(g)))(X) = \det(X - \rho_L(g))$, so $t(g) = \mathrm{tr}\,\rho_L(g)$. As $G' \subseteq G_L$ and λ_n takes non-zero scalar values, the span of $\rho_L(G')$ is that of $r_y(G')$, namely $\mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$; choose $g_1, \dots, g_{16} \in G'$ with $\rho_L(g_i)$ a basis. The Gram matrix $\Gamma = (t(g_ig_j))_{i,j}$ of the non-degenerate trace form is invertible, and for $g \in G_L$, $\rho_L(g) = \sum_j c_j(g)\rho_L(g_j)$ with $(c_j(g))_j = \Gamma^{-1}(t(gg_i))_i$, continuous in g. So ρ_L, and $r_y|_{G_L} = \lambda_n^{-1}\rho_L$, are continuous.

Step 2: (Cy1) and irreducibility. By Step 1, (In2) applies: there are E, $u \in \mathrm{GL}_4(E)$ and a continuous $\tilde{r}\colon \Gamma^0 \to \mathrm{GL}_4(\mathcal{O}_E) \subseteq \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $r := \tilde{r} \circ \pi|_{G_L} = u\rho_L u^{-1}$, continuous, and $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$. χ_{cyc} is trivial on inertia groups at places not above ℓ, so $N_{\mathscr{H}} \subseteq \ker\bar{\omega}$ and $\pi^{-1}(\Gamma^0 \cap \ker\bar{\omega}) \cap G_L = G_L \cap \ker\bar{\omega} \supseteq G'$. Hence the span of $\tilde{r}(\Gamma^0 \cap \ker\bar{\omega})$ contains $u\,\mathrm{span}(\rho_L(G'))\,u^{-1} = \mathrm{M}_4(\overline{\mathbb{Q}}_\ell)$: $\tilde{r}$ restricted to $\Gamma^0 \cap \ker\bar{\omega}$ is absolutely irreducible, and so is $\tilde{r}$. This is (Cy1) and the second assertion.

Step 3: (Cy3). Let $v \in \Sigma$ and $s \in D_v \subseteq G_L$. By (Mq4), $n_v^{-1}r_P(s)n_v$ is upper triangular with diagonal $(\psi_{v,a}^P(s))_a$; $y(n_v)$ is invertible (Mq3). With $w_v = u\,y(n_v)$, $w_v^{-1}r(s)w_v = \lambda_n(s)\,y(n_v)^{-1}r_y(s)y(n_v)$ is upper triangular with diagonal $(\lambda_n(s)y(\psi_{v,a}^P(s)))_a = (x(\psi_{v,a}^{\mathrm{d}}(s)))_a$ by (Cm2). This is (Cy3).

Step 4: weights at ℓ, (Cy4) and the integers $m_{v,a}$. Let $v \in \Sigma$; by (Lk5) at $\bar{v}$ there are integers a_v, b_v odd and $k_v \geq 1$ with $(\nu\chi_{\mathrm{cyc}}^{-a_v})^{k_v} = (\gamma^2\chi_{\mathrm{cyc}}^{-b_v})^{k_v} = 1$ on I_v. By (Kw1) at $\bar{v}$ there are integers e_v and $k_v' \geq 1$ with $(\kappa\chi_{\mathrm{cyc}}^{-e_v})^{k_v'} = 1$ on $I_{\bar{v}} \cap G_L = I_v$ (v splits in L). Put $K = k_vk_v'$ and

$$m_{v,a} = a_v - e_v + \tfrac{1}{2}(nb_v + h_a) \in \mathbb{Z} \qquad (nb_v + h_a \equiv n + h_1 \equiv 0 \bmod 2).$$

On $U \cap I_v$, by (Cm2),

$$x(\psi_{v,a}^{\mathrm{d}})^{2K} = \nu^{2K}\gamma^{2nK}\kappa^{-2K}y(\psi_{v,a}^P)^{2K} = \chi_{\mathrm{cyc}}^{2Ka_v + nKb_v - 2Ke_v + Kh_a} = \chi_{\mathrm{cyc}}^{2Km_{v,a}}.$$

With $j_v = [I_v : U \cap I_v]$ and $U \cap I_v$ normal in I_v, $g^{j_v} \in U \cap I_v$ for $g \in I_v$, so

$$\bigl(x(\psi_{v,a}^{\mathrm{d}}(g))\chi_{\mathrm{cyc}}(g)^{-m_{v,a}}\bigr)^{2Kj_v} = 1;$$

take k the product of the $2Kj_v$ over $v \in \Sigma$. For $a < b$, $m_{v,a} - m_{v,b} = (h_a - h_b)/2 \geq 2(b-a) \geq 2$. Finally $x \circ \psi_{v,a}^{\mathrm{d}} \cdot \chi_{\mathrm{cyc}}^{-m_{v,a}}$ is a character of D_v trivial on an open subgroup of I_v, hence potentially

unramified and de Rham with all Hodge–Tate weights 0; so $x \circ \psi_{v,a}^{\mathrm{d}}$ is de Rham with τ-Hodge–Tate weight $m_{v,a}$ for every τ, strictly decreasing in a. This is (Cy4) and the third assertion.

Step 5: (Cy2). Put $R = r \otimes \kappa = u\,\nu\gamma^n\, r_y|_{G_L}\, u^{-1} \cong \mu \otimes (r_y|_{G_L} \otimes \kappa_s)$ with $\mu = \nu\gamma^n\kappa_s^{-1}$, a continuous character of G_L. For every place $\bar{w}$ above ℓ, with a_w, b_w odd, k_w from (Lk5) at $\bar{w}$, on $I_{\bar{w}} \cap G_L$: $\mu^{2k_wk_s} = \chi_{\mathrm{cyc}}^{k_wk_s(2a_w+nb_w-a_s)}$ and $N_w = (2a_w + nb_w - a_s)/2 \in \mathbb{Z}$ (as $n \equiv a_s$, b_w odd); so $\mu\chi_{\mathrm{cyc}}^{-N_w}$ has finite order on $I_{\bar{w}} \cap G_L$ and μ is de Rham at $\bar{w}$ (as in Step 4). A continuous character of G_L de Rham at all places above ℓ is algebraic for ι (J.-P. Serre, Abelian ℓ-adic representations and elliptic curves, Ch. III; Clozel–Harris–Taylor 2008, Lemma 4.1.3): it corresponds through ι and the global Artin map to an algebraic Hecke character ψ' of L; taking $\psi = \psi'$ or ψ'^{-1} according to the normalisation of the Artin map (the inverse of an algebraic Hecke character is algebraic), $\iota\mu(\mathrm{Frob}_w^{-1}) = \psi_w(\varpi_w)$ at all finite w where both are unramified, i.e. $\mu \leftrightarrow_\iota \psi$. Let $\Pi = \pi_s \otimes (\psi \circ \det)$: cuspidal, and regular algebraic (the infinity type of ψ is integral, so the infinitesimal character of Π_∞ is that of $\pi_{s,\infty}$ shifted by an integer at each embedding). At almost all w the Satake parameters of Π_w are $\psi_w(\varpi_w)\alpha$, α those of $\pi_{s,w}$, and ι carries the eigenvalues of $R(\mathrm{Frob}_w^{-1})$ to $\psi_w(\varpi_w)\mathrm{N}w^{3/2}\alpha$; so $R \leftrightarrow_\iota \Pi$. Conjugate self-duality. (Od1) for $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ says that $r(cg^{-1}c)$ and $r(g)$ have the same characteristic polynomial for $g \in G_L$; the eigenvalues of ${}^t r(cgc)^{-1}$ are those of $r(cg^{-1}c)$, so the absolutely irreducible representations r and $(r^c)^\vee$ have equal determinants (Theorem B.83, (Ch1)) and are isomorphic ((Ch3)): $r^c \cong r^\vee$. With (Tw1) for $m = -3$, $R^c = r^c\kappa^c \cong r^\vee\kappa^{-1} \cdot \kappa\kappa^c = R^\vee\chi_{\mathrm{cyc}}^{-3}$. Now Π^c (with $\Pi_w^c \cong \Pi_{cw}$) has R^c attached, and $\Pi^\vee$ (Satake parameters α^{-1}) has $R^\vee\chi_{\mathrm{cyc}}^{-3}$ attached: So the cuspidal representations Π^c and $\Pi^\vee$ have isomorphic unramified components at almost all places (the characteristic polynomial determines the Satake parameters), and $\Pi^c \cong \Pi^\vee$ by Theorem B.60, (Js1). So Π is regular algebraic, conjugate self-dual and cuspidal with $r \otimes \kappa \leftrightarrow_\iota \Pi$: (Cy2). With Steps 2–4, x is a classical ordinary point for ι and κ. □

Lemma 53.19. *In the setting of Lemma 53.7, let $n \geq 0$ be an integer, $y\colon A \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}'$-algebra homomorphism and $x = y \circ \phi_n\colon B_4^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$. Then:*

(In1) *x is continuous for the $\mathfrak{m}$-adic topology of B_4^{po}, $\mathfrak{m}$ its maximal ideal, and the ℓ-adic topology of $\overline{\mathbb{Q}}_\ell$;*

(In2) *if moreover $g \mapsto y(r_P(g))$ is continuous on G_L, there are a finite extension E of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$ containing $\mathcal{O}'$, with ring of integers $\mathcal{O}_E \supseteq x(B_4^{\mathrm{po}})$, a matrix $u \in \mathrm{GL}_4(E)$ and a continuous homomorphism $\rho\colon \Gamma^0_{\mathscr{H}} \to \mathrm{GL}_4(\mathcal{O}_E)$ such that $\rho(\pi_{\mathscr{H}}(g)) = u\,\lambda_n(g)\,y(r_P(g))\,u^{-1}$ for all $g \in G_L$ and $x \circ D^{\mathrm{u}} = \det \circ \rho$.*

Proof. Symbols introduced here are local to this proof. Write $B^{\mathrm{po}} = B_4^{\mathrm{po}}$, $\pi = \pi_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$.

Step 1: integrality and continuity. For $b \in \mathfrak{m}$ there is a homomorphism $\mathcal{O}'[[T]] \to B^{\mathrm{po}}$, $T \mapsto b$ (completeness); let $z = x(b)$, algebraic over $\mathbb{Q}_\ell$, and $f \in \mathcal{O}'[T]$ primitive with $f(z) = 0$. If $|z| \geq 1$, write $f = Pf_1$ in $\mathcal{O}'[T]$ with P monic having as roots the roots of f of absolute value < 1 (its coefficients are integral and lie in the fraction field of $\mathcal{O}'$, the set of these roots being stable under its Galois group) and f_1 primitive with all roots of absolute value ≥ 1, so that its constant term has the largest absolute value among its coefficients and is a unit; then $f_1(z) = 0$, while f_1 is a unit of $\mathcal{O}'[[T]]$, so its image $f_1(b)$ is a unit of B^{po} and $f_1(z) = x(f_1(b)) \neq 0$: contradiction. So $|x(b)| < 1$ for $b \in \mathfrak{m}$, and $|x(b)| \leq 1$ for all b ($b \in \mathcal{O}' + \mathfrak{m}$). Let $b_1, \dots, b_q$ generate $\mathfrak{m}$, E_0 the finite extension of $\mathbb{Q}_\ell$ generated by the fraction field of $\mathcal{O}'$ and the $x(b_i)$, and $\delta < 1$ the absolute value of its uniformisers. Every element of $\mathfrak{m}^k$ is a combination of monomials of degree k in the b_i with coefficients in B^{po}, so its image has absolute value $\leq \delta^k$: this is (In1); it uses no hypothesis on y. As $\mathcal{O}'[b_1, \dots, b_q]$ is dense in B^{po} (every element is a convergent power series in

the b_i, by Cohen's structure theorem), $x(B^{\mathrm{po}})$ lies in the closure of $\mathcal{O}'[x(b_1),\dots,x(b_q)]$, hence in the ring of integers of E_0, and in that of every finite extension of E_0.

Step 2: a lattice. From now on assume that $g \mapsto y(r_P(g))$ is continuous on G_L (the hypothesis of (In2)). Put $\rho_L(g) = \lambda_n(g)\, y(r_P(g))$ for $g \in G_L$, a continuous homomorphism $G_L \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ (λ_n is continuous). G_L is the countable union of the closed subgroups $\rho_L^{-1}(\mathrm{GL}_4(E'))$, E' over the finite extensions of E_0 in $\overline{\mathbb{Q}}_\ell$ ($\mathrm{GL}_4(E')$ is closed, E' being complete); by Baire's theorem one of them has non-empty interior, hence is open of finite index, and adjoining the entries of ρ_L at finitely many coset representatives gives a finite extension $E \supseteq E_0$ with $\rho_L(G_L) \subseteq \mathrm{GL}_4(E)$. The compact subgroup $\rho_L(G_L)$ stabilises an $\mathcal{O}_E$-lattice of E^4, so there is $u \in \mathrm{GL}_4(E)$ with $u\rho_L(G_L)u^{-1} \subseteq \mathrm{GL}_4(\mathcal{O}_E)$. By Step 1, $E \supseteq \mathcal{O}'$ and $x(B^{\mathrm{po}}) \subseteq \mathcal{O}_E$.

Step 3: factorisation through Γ^0. Let $s \in I_{\bar w} \cap G_L$, $\bar w$ a place of $\overline{\mathbb{Q}}$ not above ℓ, with $\bar\chi_a(s) = 1$ for all a. One of the $\chi_a^{\mathscr{T}}$ is trivial, so (Lk6) and $\kappa(s) = 1$ (Tw2) give $\bar\nu(s) = 1$; then (Lk6) gives $\bar\chi_a^{\mathscr{T}}(s) = \bar\chi_a(s) = 1$ for all a, hence $\bar r_0(s) = 1$, and $r_P(s) = 1$ by (Mq1). $\nu(s)^m = 1$ with $\ell \nmid m$ (Lk3) and $\bar\nu(s) = 1$ give $\nu(s) = 1$ (a root of unity of order prime to ℓ that is $\equiv 1$ modulo the maximal ideal is 1); $t(s) = 0$ and $\ker t \subseteq \ker\gamma$ (Lk2) give $\gamma(s) = 1$. So $\lambda_n(s) = 1$ and $\rho_L(s) = 1$. The conjugates of such s by G_L are of the same kind (inertia at the conjugate place, same values of the $\bar\chi_a$), and so are those by c: $csc \in I_{c\bar w} \cap G_L$ and $\bar\chi_a(csc) = \bar\chi_{5-a}(s)^{-1} = 1$ (Rd5). The subgroup they generate is normal in $G_{L^+} = G_L \cup cG_L$, so its closure is $N_{\mathscr{H}}$; as $\ker\rho_L$ is closed, $N_{\mathscr{H}} \subseteq \ker\rho_L$. Since $\pi|_{G_L}\colon G_L \to \Gamma^0 = G_L/N_{\mathscr{H}}$ is a quotient map, $u\rho_L u^{-1} = \rho \circ \pi|_{G_L}$ for a continuous homomorphism $\rho\colon \Gamma^0 \to \mathrm{GL}_4(\mathcal{O}_E)$.

Step 4: the determinant. For $g \in G_L$, $\mathrm{cp}(g) \in B[X]$ maps to the characteristic polynomial of $r_P(g)$ (Zq2), so by (Cm1)

$$x\big(\chi_{D^{\mathrm{u}}}(\pi(g))\big)(X) = \lambda_n(g)^4\, y(\mathrm{cp}(g))(\lambda_n(g)^{-1}X) = \det\big(X - \lambda_n(g)y(r_P(g))\big) = \det\big(X - \rho(\pi(g))\big).$$

As $\pi(G_L) = \Gamma^0$, the $\overline{\mathbb{Q}}_\ell$-valued determinants $x \circ D^{\mathrm{u}}$ and $\det\circ\rho$ of dimension 4 on Γ^0 have the same characteristic polynomials at all elements of Γ^0, so they are equal by Theorem B.83, (Ch1). This is (In2). □

Lemma 53.20. *Let $\mathscr{H}$ be a rank-4 Hecke datum over a coefficient ring $\mathcal{O}'$, with CM field L and complex conjugation c. Let $\kappa\colon G_L \to \mathcal{O}'^{\times}$ be a continuous character with $\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{-3}$ for all $s \in G_L$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$, and $J \subseteq B$ an ideal with (Hf2) and $J \subseteq \mathcal{J}_\kappa^{\mathrm{cl}}$. Let $x\colon B \to \overline{\mathbb{Q}}_\ell$ be a classical ordinary point for ι and κ, with $\tilde r$ as in its definition, such that $\tilde r$ restricted to $\Gamma^0_{\mathscr{H}} \cap \ker\bar\omega$ is absolutely irreducible and there are integers $m_{v,a}$ with $m_{v,a} \geq m_{v,b} + 2$ for $a < b$ and $k \geq 1$ with $\big(x(\psi^{\mathrm{d}}_{v,a}(g))\chi_{\mathrm{cyc}}(g)^{-m_{v,a}}\big)^k = 1$ for all $v \in S_\ell$, a and $g \in I_v$. Then every prime ideal $\mathfrak{q} \subseteq \ker x$ of B contains J.*

Proof. Symbols introduced here are local to this proof. Write $\pi = \pi_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $r = \tilde r \circ \pi|_{G_L}$, $d = [L^+ : \mathbb{Q}] = \sum_{v\in S_\ell} d_v$, $\Lambda = \Lambda_{4d}$, and $\mathfrak{p} = \ker x$, a prime of B with $J \subseteq \mathcal{J}_\kappa^{\mathrm{cl}} \subseteq \mathfrak{p}$.

Step 1: irreducibility over $L(\mu_{\ell^\infty})$. The kernel of $\bar\omega$ on G_L is $G' = G_{L(\mu_\ell)}$ (χ_{cyc} has values in $\mathbb{Z}_\ell^\times$ and $\mathbb{Z}_\ell \cap \mathfrak{m}_{\mathcal{O}'} = \ell\mathbb{Z}_\ell$), and $\pi(G') = \Gamma^0 \cap \ker\bar\omega$, so $r|_{G'}$ is absolutely irreducible on $V = \overline{\mathbb{Q}}_\ell^4$. Let $H = G_{L(\mu_{\ell^\infty})}$, closed and normal in G'; $G'/H \cong \mathrm{Gal}(L(\mu_{\ell^\infty})/L(\mu_\ell))$ is isomorphic through χ_{cyc} to a closed subgroup of $1 + \ell\mathbb{Z}_\ell \cong \mathbb{Z}_\ell$ (ℓ odd), so it is pro-ℓ and procyclic, with a topological generator σ. The sum of the H-irreducible subspaces of V is non-zero and G'-stable (H is normal), hence equal to V: $V|_H$ is semisimple. G' permutes its isotypic components $U_1,\dots,U_t$ transitively (the sum over an orbit is G'-stable), all of the same dimension, so $t \mid 4$; the stabiliser of U_1 is closed (r is continuous), of index t and contains H, so t is the index of an open subgroup of the pro-ℓ group G'/H, a power of the odd prime ℓ. Hence $t = 1$: $V \cong W \otimes \overline{\mathbb{Q}}_\ell^m$ as H-modules,

W irreducible, H acting on the first factor. The span of $r(H)$ is $\mathcal{A} = \mathrm{End}(W) \otimes 1$ (Burnside), with commutant $\mathcal{C} = 1 \otimes \mathrm{M}_m(\overline{\mathbb{Q}}_\ell)$, whose commutant is $\mathcal{A}$. Conjugation by $r(g)$, $g \in G'$, preserves $r(H)$, hence $\mathcal{A}$ and $\mathcal{C}$, and on $\mathcal{C}$ it is inner (Skolem–Noether): $r(g)(1 \otimes X)r(g)^{-1} = 1 \otimes m_g X m_g^{-1}$ with $m_g \in \mathrm{GL}_m(\overline{\mathbb{Q}}_\ell)$ unique up to a scalar; then $r(g)(1 \otimes m_g)^{-1}$ commutes with $\mathcal{C}$, so $r(g) = w_g \otimes m_g$ with $w_g \in \mathrm{GL}(W)$. $g \mapsto \mathrm{Ad}(m_g)$ is a homomorphism, trivial on H. Let $\lambda \subseteq \overline{\mathbb{Q}}_\ell^m$ be an eigenline of m_{g_σ} for a lift g_σ of σ; then $m_g\lambda = \lambda$ for every g in the subgroup generated by g_σ and H, which is dense in G'. The set of $g \in G'$ with $r(g)(W \otimes \lambda) = W \otimes \lambda$ is closed and contains this subgroup, so $W \otimes \lambda$ is G'-stable; by irreducibility $m = 1$. So $r|_H$ is irreducible.

Step 2: the tangent space at x has dimension at most $4d$. Let $R_0 = B/\mathfrak{p} \cong x(B)$; by Lemma 53.21 (last assertion) it is a domain, finite over $\mathcal{O}'$, so $K_0 = R_0[1/\ell]$ is its fraction field, a finite (separable, characteristic 0) extension of $K' = \mathcal{O}'[1/\ell]$, and K_0 is the residue field $\kappa(\mathfrak{p})$ of $B_\mathfrak{p}$, embedded in $\overline{\mathbb{Q}}_\ell$ by x. Let $T = \mathrm{Hom}_B(\mathfrak{p}/\mathfrak{p}^2, \overline{\mathbb{Q}}_\ell) = \mathrm{Hom}_{K_0}(\mathfrak{p}B_\mathfrak{p}/\mathfrak{p}^2B_\mathfrak{p}, \overline{\mathbb{Q}}_\ell)$, so that $\dim_{\overline{\mathbb{Q}}_\ell} T = \dim_{K_0} \mathfrak{p}B_\mathfrak{p}/\mathfrak{p}^2B_\mathfrak{p}$. (a) Every $\phi \in T$ is the restriction to $\mathfrak{p}$ of a unique $\mathcal{O}'$-linear $\delta\colon B \to \overline{\mathbb{Q}}_\ell$ with $x + \epsilon\delta$ a ring homomorphism. Existence: let $C = B/\mathfrak{p}^2$ and let C_ϕ be the push-out of the square-zero extension $0 \to \mathfrak{p}/\mathfrak{p}^2 \to C \to R_0 \to 0$ along ϕ, a square-zero extension of R_0 by the R_0-module $\overline{\mathbb{Q}}_\ell$. After inverting ℓ it is a square-zero extension of K_0, finite separable over K', hence formally étale, so it has a K'-algebra section s; then $e \mapsto (\bar{e}, e - s(\bar{e}))$ identifies $C_\phi[1/\ell]$ with $K_0 \oplus \overline{\mathbb{Q}}_\ell\epsilon$, and composing $B \to C \to C_\phi \to C_\phi[1/\ell]$ with x on K_0 gives $x' = x + \epsilon\delta\colon B \to \overline{\mathbb{Q}}_\ell[\epsilon]$ with $\delta|_\mathfrak{p} = \phi$. Uniqueness: the difference of two such δ vanishes on $\mathfrak{p}$, so it is an $\mathcal{O}'$-derivation $R_0 \to \overline{\mathbb{Q}}_\ell$; it extends to a K'-derivation of K_0, which is 0 as K_0/K' is finite separable. (b) For $\phi \in T$ with $x' = x + \epsilon\delta$ as in (a), $v \in S_\ell$ and $1 \le a \le 4$, $x'(\psi^{\mathrm{d}}_{v,a}(g)) = x(\psi^{\mathrm{d}}_{v,a}(g))(1 + \epsilon h_{v,a}(g))$ defines a homomorphism $h_{v,a}\colon D_v \to \overline{\mathbb{Q}}_\ell$, continuous by Lemma 53.21 (last assertion) and continuity of $\psi^{\mathrm{d}}_{v,a}$. It factors through D_v^{ab}, in which the image of I_v is the image of $\mathcal{O}^\times_{L_v^+}$ under the local Artin map; continuous homomorphisms $\mathcal{O}^\times_{L_v^+} \to \overline{\mathbb{Q}}_\ell$ form a space of dimension d_v ($\mathcal{O}^\times_{L_v^+}$ is a finite group times $\mathbb{Z}_\ell^{d_v}$). So $\phi \mapsto (h_{v,a}|_{I_v})_{v,a}$ is a linear map Φ from T to a space of dimension $\sum_v 4d_v = 4d$. (c) Φ is injective: if $\Phi(\phi) = 0$ then $x'(\psi^{\mathrm{d}}_{v,a}(g)) = x(\psi^{\mathrm{d}}_{v,a}(g))$ for $g \in I_v$, and Lemma 53.21 applies with $n = 4$ ($\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{1-4}$; $r|_{G_{L(\mu_{\ell^\infty})}}$ irreducible by Step 1; the integers $m_{v,a}$ and k of the hypothesis): $x' = x$, so $\delta = 0$ and $\phi = 0$. Hence $\dim_{K_0} \mathfrak{p}B_\mathfrak{p}/\mathfrak{p}^2B_\mathfrak{p} \le 4d$, and $\dim B_\mathfrak{p} \le 4d$ (the dimension of a Noetherian local ring is at most its embedding dimension).

Step 3: $\dim(B/J)_\mathfrak{p} \ge 4d$. Let $A = B/J \ne 0$ (as $J \subseteq \mathfrak{p}$) and $\lambda\colon \Lambda \to A$ as in (Hf2): A is a finite torsion-free Λ-module, so λ is injective. Let $\mathfrak{p}_A = \mathfrak{p}/J$, $\mathfrak{p}_0 = \lambda^{-1}(\mathfrak{p}_A)$, and $\mathfrak{q}_A \subseteq \mathfrak{p}_A$ a minimal prime of A. Its elements are zero-divisors of A (A Noetherian), so $\lambda^{-1}(\mathfrak{q}_A) = 0$ by torsion-freeness, and $\Lambda \subseteq A/\mathfrak{q}_A$ is a finite extension of domains with Λ regular, hence normal. By going-down ([166, Theorem 9.4(ii)]) every chain of primes descending from $\mathfrak{p}_0$ lifts to one descending from $\mathfrak{p}_A/\mathfrak{q}_A$, so $\dim A_{\mathfrak{p}_A} \ge \mathrm{ht}\,\mathfrak{p}_0$. $\Lambda/\mathfrak{p}_0$ embeds in $A/\mathfrak{p}_A \cong R_0$, finite over $\mathcal{O}'$ and containing $\mathcal{O}'$, so $\dim \Lambda/\mathfrak{p}_0 = 1$; Λ is a regular local ring of dimension $4d + 1$, hence catenary with $\mathrm{ht}\,\mathfrak{p}_0 + \dim \Lambda/\mathfrak{p}_0 = 4d + 1$ ([166, Theorem 17.4]). So $\dim(B/J)_\mathfrak{p} = \dim A_{\mathfrak{p}_A} \ge 4d$.

Step 4: conclusion. $(B/J)_\mathfrak{p} = B_\mathfrak{p}/JB_\mathfrak{p}$, so $4d \le \dim B_\mathfrak{p}/JB_\mathfrak{p} \le \dim B_\mathfrak{p} \le 4d$ by Steps 2 and 3. Thus $B_\mathfrak{p}$ has dimension equal to its embedding dimension: it is regular, hence a domain ([166, Theorem 14.3]). If $JB_\mathfrak{p} \ne 0$, it contains a non-zero element f, a non-zero-divisor, and $\dim B_\mathfrak{p}/JB_\mathfrak{p} \le \dim B_\mathfrak{p}/fB_\mathfrak{p} = \dim B_\mathfrak{p} - 1$ ([166, Theorem 13.6]), a contradiction. So $JB_\mathfrak{p} = 0$: for $j \in J$ there is $s \in B \smallsetminus \mathfrak{p}$ with $sj = 0$. If $\mathfrak{q} \subseteq \mathfrak{p}$ is prime, then $s \notin \mathfrak{q}$ and $sj = 0 \in \mathfrak{q}$, so $j \in \mathfrak{q}$. Hence $J \subseteq \mathfrak{q}$. □

Lemma 53.21. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, with CM field L and complex conjugation c, let $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ be a universal polarised ordinary determinant of*

rank n over $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $\kappa\colon G_L \to \overline{\mathbb{Q}}_\ell^\times$ a continuous character with $\kappa(s)\kappa(csc) = \chi_{\mathrm{cyc}}(s)^{1-n}$ for all $s \in G_L$. Let $x\colon B \to \overline{\mathbb{Q}}_\ell$ be a classical ordinary point for ι and κ, with $\tilde{r}$ as in its definition, and put $r = \tilde{r} \circ \pi_{\mathscr{H}}|_{G_L}$. Assume that the restriction of r to $G_{L(\mu_{\ell^\infty})}$ is irreducible on $\overline{\mathbb{Q}}_\ell^n$, and that there are integers $m_{v,a}$ ($v \in S_\ell$, $1 \le a \le n$) with $m_{v,a} \ge m_{v,b}+2$ for $a < b$ and $k \ge 1$ with $\left(x(\psi^{\mathrm{d}}_{v,a}(g))\chi_{\mathrm{cyc}}(g)^{-m_{v,a}}\right)^k = 1$ for all $v \in S_\ell$, $1 \le a \le n$ and $g \in I_v$. Then every homomorphism of $\mathcal{O}'$-algebras $x'\colon B \to \overline{\mathbb{Q}}_\ell[\epsilon]$ with $x'(b) \equiv x(b)$ modulo ϵ for all $b \in B$ and

$$x'(\psi^{\mathrm{d}}_{v,a}(g)) = x(\psi^{\mathrm{d}}_{v,a}(g)) \qquad (v \in S_\ell,\ 1 \le a \le n,\ g \in I_v)$$

is equal to x. Moreover (without the assumptions on r, $m_{v,a}$ and k) $B/\ker x$ is a finite $\mathcal{O}'$-module, and every homomorphism of $\mathcal{O}'$-algebras $x'\colon B \to \overline{\mathbb{Q}}_\ell[\epsilon]$ with $x' \equiv x$ modulo ϵ is continuous for the $\mathfrak{m}_B$-adic topology of B and the ℓ-adic topology of $\overline{\mathbb{Q}}_\ell[\epsilon] \cong \overline{\mathbb{Q}}_\ell^2$.

Proof. Symbols introduced here are local to this proof. Write $\pi = \pi_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $A_\epsilon = \overline{\mathbb{Q}}_\ell[\epsilon]$, $\psi_{v,a} = x \circ \psi^{\mathrm{d}}_{v,a}$, $\psi'_{v,a} = x' \circ \psi^{\mathrm{d}}_{v,a}$, $D' = x' \circ D^{\mathrm{u}}$, and $x' = x + \epsilon\delta$, so that $\delta\colon B \to \overline{\mathbb{Q}}_\ell$ is $\mathcal{O}'$-linear with $\delta(bb') = x(b)\delta(b') + x(b')\delta(b)$.

Step 0: an element with distinct weights. For $v \in S_\ell$ write $\psi_{v,a}|_{I_v} = \chi_{\mathrm{cyc}}^{m_{v,a}}\eta_{v,a}$ with $\eta_{v,a}^k = 1$. The subgroup $I'_v = \bigcap_a \ker \eta_{v,a}$ is open in I_v (each $\eta_{v,a}$ is continuous of finite order), and $\chi_{\mathrm{cyc}}(I_v)$ is open in $\mathbb{Z}_\ell^\times$, so $\chi_{\mathrm{cyc}}(I'_v)$ is an open subgroup of $\mathbb{Z}_\ell^\times$, which is infinite while $\mathbb{Z}_\ell^\times$ has only finitely many roots of unity; choose $g_v \in I'_v$ with $\chi_{\mathrm{cyc}}(g_v)$ not a root of unity. Then $c_{v,a} = \psi_{v,a}(g_v) = \chi_{\mathrm{cyc}}(g_v)^{m_{v,a}}$ are pairwise distinct, and for $a < b$ the character $\psi_{v,a}\psi_{v,b}^{-1}\chi_{\mathrm{cyc}}^{-1}$ takes at g_v the value $\chi_{\mathrm{cyc}}(g_v)^{m_{v,a}-m_{v,b}-1} \ne 1$ (as $m_{v,a} - m_{v,b} - 1 \ge 1$); so $\psi_{v,a} \ne \psi_{v,b}\chi_{\mathrm{cyc}}$ on D_v.

Step 1: x' is continuous. Let $\mathfrak{p} = \ker x$. The domain $B/\mathfrak{p} \cong x(B) \subseteq \overline{\mathbb{Q}}_\ell$ is a complete Noetherian local $\mathcal{O}'$-algebra; by Cohen's structure theorem it is finite over a subring $\mathcal{O}'[[Y_1, \dots, Y_e]]$, and $e = 0$, since otherwise $x(Y_1)$, algebraic over the fraction field of $\mathcal{O}'$, would satisfy $Q(Y_1) = 0$ in $B/\mathfrak{p}$ for a non-zero $Q \in \mathcal{O}'[Y]$, impossible in $\mathcal{O}'[[Y_1, \dots, Y_e]]$. So $B/\mathfrak{p}$ is a finite $\mathcal{O}'$-module, hence so is $C = B/\mathfrak{p}^2$ ($\mathfrak{p}/\mathfrak{p}^2$ is finitely generated over $B/\mathfrak{p}$). As x' vanishes on $\mathfrak{p}^2$ it factors through C; $C/\ell C$ is a finite local ring, so $\mathfrak{m}_B^N$ maps into ℓC for some N, and an $\mathcal{O}'$-linear map from the finite $\mathcal{O}'$-module C to $A_\epsilon \cong \overline{\mathbb{Q}}_\ell^2$ is ℓ-adically continuous. So x' is continuous for the $\mathfrak{m}_B$-adic topology. This step uses only that x' lifts x, and proves the last assertion of the statement.

Step 2: a representation lifting $\tilde{r}$. D' is an A_ϵ-valued determinant of dimension n on Γ^0 (base change of D^{u}), and its reduction modulo ϵ is $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ (Cy1), with $\tilde{r}$ absolutely irreducible, so $\tilde{r}\colon \overline{\mathbb{Q}}_\ell[\Gamma^0] \to \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ is surjective (Burnside). Let $R = A_\epsilon[\Gamma^0]/\ker(D')$ with the determinant $\tilde{D}$ induced by D' (Theorem B.88, (Ck1)). The characteristic polynomials of $\tilde{D}$ are those of D', so $\mathrm{CH}(\tilde{D})$ is the image of $\mathrm{CH}(D') \subseteq \ker(D')$ ((Ck2)), and $\tilde{D}$ is Cayley–Hamilton. A_ϵ is Artinian local, hence henselian, with residue field $\overline{\mathbb{Q}}_\ell$, and the residual determinant is that of the surjection $R \otimes \overline{\mathbb{Q}}_\ell \to \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ induced by $\tilde{r}$ (its kernel contains the image of $\ker(D')$, by (Ck1) applied to $\det \circ \tilde{r}$). By Theorem B.89 there is an isomorphism of A_ϵ-algebras $\rho\colon R \to \mathrm{M}_n(A_\epsilon)$ with $\tilde{D} = \det \circ \rho$. Let $r''\colon \Gamma^0 \to \mathrm{GL}_n(A_\epsilon)$ be $\gamma \mapsto \rho(\gamma)$. Its reduction modulo ϵ is a surjective, hence irreducible, representation with determinant $\det \circ \tilde{r}$, so it is conjugate to $\tilde{r}$ (Theorem B.83, (Ch3)); conjugating ρ by a lift of the conjugating matrix we may assume $r'' \equiv \tilde{r}$ modulo ϵ. Continuity: choose $\gamma_1, \dots, \gamma_{n^2} \in \Gamma^0$ with $\tilde{r}(\gamma_i)$ a basis of $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$; by Nakayama the $r''(\gamma_i)$ form an A_ϵ-basis of $\mathrm{M}_n(A_\epsilon)$, and the Gram matrix $G = (\mathrm{tr}(r''(\gamma_i)r''(\gamma_j)))_{i,j}$ is invertible (its reduction is the Gram matrix of the non-degenerate trace form). Writing $r''(\gamma) = \sum_j a_j(\gamma) r''(\gamma_j)$, the vector $(a_j(\gamma))_j$ is G^{-1} applied to $(\mathrm{tr}(r''(\gamma\gamma_i)))_i = (x'(\mathrm{tr}_{D^{\mathrm{u}}}(\gamma\gamma_i)))_i$, which is continuous in γ by continuity of D^{u} and Step 1. So r'' is continuous.

Step 3: the tangent cocycle. Write $r''(\pi(g)) = (1 + \epsilon z(g))r(g)$ for $g \in G_L$. From $r''(\pi(gh)) = r''(\pi(g))r''(\pi(h))$, $z(gh) = z(g) + r(g)z(h)r(g)^{-1}$: $z\colon G_L \to \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ is a continuous 1-cocycle for $\mathrm{Ad}\, r$, which is also $\mathrm{Ad}\, r'$ for $r' = r \otimes \kappa$.

Claim (traces determine the class). Let $\sigma\colon G \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ be an absolutely irreducible representation of a group G and $u\colon G \to \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ a 1-cocycle for $\mathrm{Ad}\,\sigma$ with $\mathrm{tr}(u(g)\sigma(g)) = 0$ for all g. Then there is $Y \in \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ with $u(g) = Y - \sigma(g)Y\sigma(g)^{-1}$. Indeed $w(g) = u(g)\sigma(g)$ satisfies $w(gh) = w(g)\sigma(h) + \sigma(g)w(h)$; extend w and σ linearly to $\overline{\mathbb{Q}}_\ell[G]$, so that $w(ab) = w(a)\sigma(b) + \sigma(a)w(b)$ and $\mathrm{tr}\, w = 0$. If $\sigma(a) = 0$ then $0 = \mathrm{tr}\, w(ab) = \mathrm{tr}(w(a)\sigma(b))$ for all b, and $\sigma(\overline{\mathbb{Q}}_\ell[G]) = \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ (Burnside) with the trace form non-degenerate gives $w(a) = 0$. So $w = \Delta\circ\sigma$ for a linear $\Delta\colon \mathrm{M}_n \to \mathrm{M}_n$ with $\Delta(XX') = \Delta(X)X' + X\Delta(X')$; every derivation of $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ is inner, $\Delta(X) = YX - XY$, and $u(g) = w(g)\sigma(g)^{-1} = Y - \sigma(g)Y\sigma(g)^{-1}$.

Step 4: the polarisation of the lift. By (Od1) for D' (the base change of an identity of characteristic polynomials), the continuous representations $\rho_1(g) = r''(\pi(cgc))$ and $\rho_2(g) = {}^t r''(\pi(g))^{-1}$ of G_L have equal characteristic polynomials: that of $\rho_1(g)$ is $\chi_{D'}(\pi(c\,g\,c)) = \chi_{D'}(\pi(g^{-1}))$, that of $\rho_2(g)$. Modulo ϵ both are absolutely irreducible with the same determinant (Theorem B.83, (Ch1)), hence conjugate ((Ch3)): there is $Q \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with $r(cgc) = Q\,{}^t r(g)^{-1}Q^{-1}$. Write $\rho_1 = (1+\epsilon u_1)\bar\rho_1$ and $Q\rho_2 Q^{-1} = (1+\epsilon u_2)\bar\rho_1$ with $\bar\rho_1(g) = r(cgc)$; equality of traces gives $\mathrm{tr}((u_1-u_2)(g)\bar\rho_1(g)) = 0$, so by the Claim $u_1 - u_2 = Y - \bar\rho_1 Y \bar\rho_1^{-1}$, and with $Q'' = (1+\epsilon Y)Q$,

$$r''(\pi(cgc)) = Q''\,{}^t r''(\pi(g))^{-1}\,Q''^{-1} \qquad (g \in G_L).$$

Put $r''' = (r''\circ\pi)\otimes\kappa$, a lift of r'. As $\kappa(cgc)\kappa(g) = \chi_{\mathrm{cyc}}(g)^{1-n}$, we have

$$r'''(cgc) = \chi_{\mathrm{cyc}}(g)^{1-n} Q''\,{}^t r'''(g)^{-1} Q''^{-1},$$

and modulo ϵ, $r'(cgc) = \chi_{\mathrm{cyc}}(g)^{1-n} Q\,{}^t r'(g)^{-1} Q^{-1}$. Let V be $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ with the action of $G_{L^+} = G_L \sqcup cG_L$ of Theorem B.72 for r' and $\mathbf{P} = Q$: $g\cdot X = r'(g)Xr'(g)^{-1}$ ($g \in G_L$), $c\cdot X = -Q\,{}^t X Q^{-1}$ (an action, as shown there; $Q\,{}^t Q^{-1} = \lambda$ is a scalar with $\lambda^2 = 1$). Comparing ϵ-parts of the relation for r''', with $r''' = (1+\epsilon z)r'$:

$$z(cgc) = Y - r'(cgc)Yr'(cgc)^{-1} - Q\,{}^t z(g) Q^{-1},$$

hence, with $W = c\cdot Y$,

$$c\cdot z(cgc) = z(g) + W - g\cdot W \qquad (g \in G_L).$$

So the class of z in $H^1(G_L, V)$ is fixed by c. As V is a $\mathbb{Q}$-vector space and $[G_{L^+} : G_L] = 2$, restriction $H^1(G_{L^+}, V) \to H^1(G_L, V)^c$ is an isomorphism (inflation–restriction; the cohomology of a group of order 2 with coefficients in a $\mathbb{Q}$-vector space vanishes in positive degree). Hence there is a continuous cocycle $Z\colon G_{L^+} \to V$ whose restriction to G_L is cohomologous to z; subtracting a coboundary we take $Z|_{G_L} = z$.

Step 5: local conditions away from ℓ. Let $\bar w$ be a place of $\overline{\mathbb{Q}}$ above a finite place $w \nmid \ell$ of L^+, $I = I_{\bar w} \cap G_{L^+}$ and $I_0 = \{s \in I \cap G_L : \bar\chi_a(s) = 1,\ 1 \le a \le n\}$, a normal subgroup of finite index of I (the $\bar\chi_a$ have finite image). $I_0 \subseteq N_{\mathscr{H}}$, so $r''\circ\pi$ and r are trivial on I_0, $z|_{I_0} = 0$, and I_0 acts trivially on V (the action of $g \in G_L$ is $\mathrm{Ad}\, r(g)$); so $Z|_I$ is inflated from a cocycle of the finite group I/I_0 with values in a $\overline{\mathbb{Q}}_\ell$-vector space, hence a coboundary (average over I/I_0). So $Z|_D$ lies in H^1_f for every decomposition group D at w. At archimedean places $H^1_f = 0$ and H^1 of a group of order at most 2 with coefficients in V vanishes.

Step 6: local conditions at ℓ. Let $v \in S_\ell$; $D_v = D_{\bar v} \cap G_{L^+} \subseteq G_L$ (Rd2) is a decomposition group at v, identified with $\mathrm{Gal}(\overline{\mathbb{Q}}_\ell/L_v^+)$, with inertia I_v. By (Od2) for D' and Step 2, $\mathrm{tr}\big(\rho(\gamma)\prod_{a=1}^n (r''(g_a) - \psi'_{v,a}(g_a))\big) = 0$ for all $\gamma \in \Gamma^0$, $g_a \in D_v$; the $\rho(\gamma)$ span $\mathrm{M}_n(A_\epsilon)$ and the trace form is non-degenerate, so $\prod_{a=1}^n (r''(g_a) - \psi'_{v,a}(g_a)) = 0$ (product with $a = 1$ on the left; $r''(g)$ stands for $r''(\pi(g))$). With all $g_a = g_v$ of Step 0 and $\psi'_{v,a}(g_v) = \psi_{v,a}(g_v) = c_{v,a}$ (hypothesis on

x'), $\prod_a (r''(g_v) - c_{v,a}) = 0$ with distinct $c_{v,a} \in \overline{\mathbb{Q}}_\ell$. Hence $E_a = \prod_{b \neq a} (r''(g_v) - c_{v,b})/(c_{v,a} - c_{v,b})$ are orthogonal idempotents with $\sum_a E_a = 1$ and $r''(g_v)E_a = c_{v,a}E_a$ (Lagrange interpolation). Each $E_a A_\epsilon^n$ is a direct summand, hence free, of rank 1: modulo ϵ it is the $c_{v,a}$-eigenline of $r(g_v)$, whose characteristic polynomial is $\prod_a (X - c_{v,a})$ by (Cy3). Choose generators e_a and let $M \in \mathrm{GL}_n(A_\epsilon)$ have columns $e_1, \dots, e_n$. For $1 \leq j \leq i \leq n$ and $g \in D_v$, apply the identity with $g_a = g_v$ for $a \neq i$ and $g_i = g$ to e_j: the factors with $a > i$ multiply e_j by the unit $\prod_{a>i}(c_{v,j} - c_{v,a})$, and the factors with $a < i$ act invertibly on $\bigoplus_{b \geq i} E_b A_\epsilon^n$ and kill $E_b A_\epsilon^n$ for $b < i$. So the components of $(r''(g) - \psi'_{v,i}(g))e_j$ in $E_b A_\epsilon^n$, $b \geq i$, vanish. For $j < i$ this says that $r''(g)e_j \in \bigoplus_{b \leq j} E_b A_\epsilon^n$; for $j = i$ that the e_i-coefficient of $r''(g)e_i$ is $\psi'_{v,i}(g)$. Thus $T''(g) = M^{-1} r''(g) M$ is upper triangular with diagonal $(\psi'_{v,1}(g), \dots, \psi'_{v,n}(g))$ for $g \in D_v$. Write $M = M_0(1 + \epsilon M_1)$ and $T'' = T + \epsilon T_1$; then $T(g) = M_0^{-1} r(g) M_0$ is upper triangular with diagonal $(\psi_{v,a}(g))_a$ and

$$z_T(g) := T_1(g)T(g)^{-1} = M_0^{-1} z(g) M_0 + \big(T(g) M_1 T(g)^{-1} - M_1\big) \qquad (g \in D_v),$$

a cocycle of $\mathrm{Ad}\, T$ cohomologous to $M_0^{-1} z M_0$, with upper triangular values; its diagonal entries $T_1(g)_{aa}/\psi_{v,a}(g)$ are the ϵ-parts of $\psi'_{v,a}(g)/\psi_{v,a}(g)$, which vanish on I_v by the hypothesis on x'. By Lemma 42.8, items 1 and 3, $T|_{D_v}$ and z_T take values in $\mathrm{M}_n(E)$ for a finite extension E of $\mathbb{Q}_\ell$. The hypotheses of Lemma 44.14 hold for $M = L_v^+$, $\rho = T|_{D_v}$, the integers $m_{v,1} > \cdots > m_{v,n}$ and $u = z_T$ (Step 0 and the hypothesis on $\psi_{v,a}\chi_{\mathrm{cyc}}^{-m_{v,a}}$). So the class of z_T, and hence, transporting by $X \mapsto M_0 X M_0^{-1}$, that of $z|_{D_v} = Z|_{D_v}$, lies in H^1_f; the twist by κ does not change Ad. Every other decomposition group at v is hD_vh^{-1} with $h \in G_{L^+}$, and $Z(hyh^{-1}) = h \cdot Z(y) + (1 - hyh^{-1}) \cdot Z(h)$ for $y \in D_v$, so its class is the transport of that at D_v by the isomorphism $h\cdot$, and lies in H^1_f. By Steps 5 and 6, Z is a Bloch–Kato cocycle for V over L^+.

Step 7: vanishing. By Lemma 42.8, item 1, choose a finite extension E of $\mathbb{Q}_\ell$ containing the entries of $r'(G_L)$ and of Q. The restriction of $r' = r \otimes \kappa$ to $G_{L(\mu_{\ell^\infty})}$ is irreducible (twisting by a character keeps invariant subspaces), $r' \leftrightarrow_\iota \Pi$ for the regular algebraic conjugate self-dual cuspidal Π of (Cy2), $n \geq 2$, and Q satisfies the relation of Theorem B.72 for $F = L$, $F^+ = L^+$; $V = \mathrm{ad}_E\, r' \otimes_E \overline{\mathbb{Q}}_\ell$. By Theorem B.72, $H^1_f(L^+, V) = 0$, so $Z(g) = g \cdot X - X$ for some $X \in V$, and for $g \in G_L$, $z(g) = r(g) X r(g)^{-1} - X$. Then $r''(\pi(g)) = (1 + \epsilon z(g)) r(g) = (1 - \epsilon X) r(g) (1 + \epsilon X)$ for $g \in G_L$, and as $\pi(G_L) = \Gamma^0$, $r'' = (1 - \epsilon X)\tilde{r}(1 + \epsilon X)$ on Γ^0.

Step 8: conclusion. First, $D' = \det \circ r'' = \det \circ \tilde{r} = x \circ D^{\mathrm{u}}$ (equal characteristic polynomials, (Ch1)). Second, for $v \in S_\ell$ the idempotents E_a of Step 6 are polynomials in $r''(g_v)$, so $E_a = (1 - \epsilon X) E_a^0 (1 + \epsilon X)$ with E_a^0 the same polynomials in $r(g_v)$, and by Step 6 (the case $j = i$, which also holds for x in place of x') $E_a r''(g) E_a = \psi'_{v,a}(g) E_a$ and $E_a^0 r(g) E_a^0 = \psi_{v,a}(g) E_a^0$ for $g \in D_v$; conjugating the second by $1 - \epsilon X$ gives $E_a r''(g) E_a = \psi_{v,a}(g) E_a$, and $E_a \neq 0$, so $\psi'_{v,a} = \psi_{v,a}$ on D_v. Let $A \subseteq A_\epsilon$ be the $\mathcal{O}'$-subalgebra generated by $x(B) \cup x'(B)$. It is a finite $\mathcal{O}'$-module (Step 1), with no idempotents other than $0, 1$ (as A_ϵ is local), hence a complete local Noetherian $\mathcal{O}'$-algebra; its residue field is generated by the images of $x(B)$ and $x'(B)$, both $\mathbb{F}_{\mathcal{O}'}$ (an $\mathcal{O}'$-algebra map $B \to$ a field has kernel the maximal ideal $\mathfrak{m}_B$), so $A \in \mathrm{CNL}_{\mathcal{O}'}$, and $x, x' \colon B \to A$ are morphisms of $\mathrm{CNL}_{\mathcal{O}'}$. They classify the same polarised ordinary determinant $(x \circ D^{\mathrm{u}}, (\psi_{v,a})) = (D', (\psi'_{v,a}))$ (continuous by Step 1), so $x = x'$ by the universal property. □

Lemma 53.22. *In the setting of Lemma 53.7, assume moreover that $\mathscr{T}$ is good and that ν satisfies (Lk5). Let ϕ_0 be the morphism given there for $n = 0$ and $J_0 \subseteq B_4^{\mathrm{po}}$ an ideal with the purity property (Hf4). Then every ideal $\mathfrak{J} \subseteq B$ containing $\phi_0(J_0)$ satisfies (Jq4): for every $\mathcal{O}'$-algebra homomorphism $y \colon A \to \overline{\mathbb{Q}}_\ell$ with $y(\mathfrak{J}) = 0$ such that $y(P)$ has weights $(2e+2, 2e, 2, 0)$, every homomorphism $r \colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $r|_{G_F} = y \circ r_P$ is weakly pure for ι.*

Proof. Symbols introduced here are local to this proof. Let y and r be as in the statement, $(m_1, m_2, m_3, m_4) = (e + 1, e, 1, 0)$, and $x = y \circ \phi_0 \colon B_4^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ (with $B \subseteq A$ by (Zq1)); then

$x(J_0) \subseteq y(\mathfrak{J}) = 0$. By (Cm1), (Cm2) and (Zq2), for $g \in G_L$ the characteristic polynomial $\chi_{x\circ D^{\mathrm{u}}}(\pi_{\mathscr{H}}(g))$ is that of $\lambda_0(g)\, y(r_P(g)) = \lambda_0(g) r(g)$, and $x(\psi^{\mathrm{d}}_{v,a}(\sigma)) = \lambda_0(\sigma)\, y(\psi^P_{v,a}(\sigma))$ for $\sigma \in D_v$.

Step 1: x is arithmetic in the sense of (Hf4). Fix $v \in \Sigma$ and identify D_v with G_{F_v} ($F_v = L_v^+$). By the weights, $y(\psi^P_{v,a})^2 = \chi_{\mathrm{cyc}}^{2m_a}$ on $U \cap I_v$ for an open U; so $y(\psi^P_{v,a})\chi_{\mathrm{cyc}}^{-m_a}$ is a continuous character of $U \cap I_v$ with values in $\{\pm 1\}$, trivial on an open subgroup. By (Lk5), $\nu\chi_{\mathrm{cyc}}^{-a_v}$ has finite order on I_v for some integer a_v, hence is trivial on an open subgroup. As κ corresponds to an algebraic Hecke character, there are integers $n_{v,\tau}$ with $\kappa(\mathrm{Art}_{F_v}(u)) = \prod_\tau \tau(u)^{n_{v,\tau}}$ for u in an open subgroup of $\mathcal{O}_{F_v}^\times$, τ running over the field embeddings $F_v \to \overline{\mathbb{Q}}_\ell$. Finally $\chi_{\mathrm{cyc}}(\mathrm{Art}_{F_v}(u)) = \mathrm{N}_{F_v/\mathbb{Q}_\ell}(u)^{-1} = \prod_\tau \tau(u)^{-1}$ for $u \in \mathcal{O}_{F_v}^\times$ (Lubin–Tate theory, for the arithmetic normalisation). Hence on an open subgroup of I_v, with σ the image of $\mathrm{Art}_{F_v}(u_\sigma)$,

$$x(\psi^{\mathrm{d}}_{v,a}(\sigma)) = \nu(\sigma)\kappa(\sigma)^{-1}\chi_{\mathrm{cyc}}(\sigma)^{m_a} = \prod_\tau \tau(u_\sigma)^{h_{v,a,\tau}}, \qquad h_{v,a,\tau} = -a_v - n_{v,\tau} - m_a,$$

and $h_{v,a,\tau}$ is strictly increasing in a because $m_1 > m_2 > m_3 > m_4$.

Step 2: the decomposition of (Hf4) is trivial. By (Hf4) for J_0 there are a continuous semisimple $\rho\colon G_L \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ with $\det\circ\rho = x \circ D^{\mathrm{u}} \circ \pi_{\mathscr{H}}|_{G_L}$ and ρ'_i, d_i, m'_i ($1 \le i \le k$) with $\chi_{\rho(g)} = \prod_i \prod_{j<m'_i} \chi_{\chi_{\mathrm{cyc}}(g)^{-j}\rho'_i(g)}$. Suppose $m'_i \ge 2$ for some i. All these representations are continuous on the compact group G_L, so their characteristic polynomials have integral coefficients and can be reduced; let σ_{ij} be the semisimplified reduction of $\chi_{\mathrm{cyc}}^{-j}\rho'_i$ over $\overline{\mathbb{F}}_\ell$. The reduction of $\chi_{\rho(g)} = \chi_{x\circ D^{\mathrm{u}}}(\pi_{\mathscr{H}}(g))$ is $\prod_a (X - \bar\chi_a(g))$ ($x\circ D^{\mathrm{u}}$ lifts $\bar D_4$), so by the Brauer–Nesbitt theorem $\bigoplus_{i,j}\sigma_{ij} \cong \bigoplus_a \bar\chi_a$. Choose a with $\bar\chi_a \subseteq \sigma_{i0}$; then $\bar\omega^{-1}\bar\chi_a \subseteq \sigma_{i1} = \bar\omega^{-1}\sigma_{i0}$ ($\bar\omega$ the reduction of χ_{cyc}), so $\bar\omega^{-1}\bar\chi_a = \bar\chi_b$ for some b on G_L. By (Lk6), $\bar\chi_a/\bar\chi_b = \bar\chi_a^{\mathscr{T}}/\bar\chi_b^{\mathscr{T}}$, which is $\overline{\mathrm{rt}_w}$ for some $w \in \mathbb{Z}^2$ (for $a = b$, $w = 0$; otherwise, as $\chi_a^{\mathscr{T}}\chi_{5-a}^{\mathscr{T}} = \theta$ for both labellings, the ratios are $\chi_1^{\mathscr{T}}/\chi_2^{\mathscr{T}} = \mathrm{rt}_{w_\alpha} = \chi_3^{\mathscr{T}}/\chi_4^{\mathscr{T}}$, $\chi_1^{\mathscr{T}}/\chi_3^{\mathscr{T}} = \mathrm{rt}_{w_\Psi} = \chi_2^{\mathscr{T}}/\chi_4^{\mathscr{T}}$, $\chi_2^{\mathscr{T}}/\chi_3^{\mathscr{T}} = \mathrm{rt}_{w_\beta}$, $\chi_1^{\mathscr{T}}/\chi_4^{\mathscr{T}} = \mathrm{rt}_{w_\theta}$ and their inverses); so $\overline{\mathrm{rt}_w} = \bar\omega$ on G_L, contradicting (Oq3). Hence all $m'_i = 1$, and by (Hf4) there is a finite set Z of finite places of L such that for $w \notin Z$, ρ is unramified at w and any two eigenvalues α, α' of $\rho(\mathrm{Frob}_w)$ satisfy $|\iota(\alpha)| < \mathrm{N}w\,|\iota(\alpha')|$.

Step 3: weak purity. Take $H = G_L$, open in $G_{\mathbb{Q}}$, and M the product of ℓ and the primes below the places in Z. Let $p \nmid M$, $\vec{p}'$ a place above p, $f \ge 1$, and $\sigma \in G_L$ an arithmetic Frobenius element for p^f at $\vec{p}'$; let w be the place of L below $\vec{p}'$, with residue degree f_w over $\mathbb{F}_p$. The image of $D_{\vec{p}'} \cap G_L$ in the Galois group of the residue field extension is the closure of the group generated by $x \mapsto x^{\mathrm{N}w}$, and contains $x \mapsto x^{p^f}$; so $f_w \mid f$, $p^f = \mathrm{N}w^k$ with $k = f/f_w \ge 1$, and $\sigma \in \mathrm{Frob}_w^k(I_{\vec{p}'} \cap G_L)$. As ρ is unramified at w, the eigenvalues of $\rho(\sigma)$ are the α^k, α an eigenvalue of $\rho(\mathrm{Frob}_w)$ (with multiplicity), and those of $r(\sigma)$ are $\lambda_0(\sigma)^{-1}\alpha^k$, since $\rho(\sigma)$ and $\lambda_0(\sigma)r(\sigma)$ have the same characteristic polynomial. For two of them, $z = \lambda_0(\sigma)^{-1}\alpha^k$ and $z' = \lambda_0(\sigma)^{-1}\alpha'^k$, Step 2 gives $|\iota(z)|/|\iota(z')| = (|\iota(\alpha)|/|\iota(\alpha')|)^k < \mathrm{N}w^k = p^f$, which is (45.1). □

Lemma 53.23. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum, $\mathscr{T}$ a fit and deep auxiliary tower for it, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\mathcal{O}_1, \nu, \gamma, t$ as given by Lemma 53.2, $\mathcal{O}' \supseteq \mathcal{O}_1$ a coefficient ring, $\kappa\colon G_L \to \mathcal{O}'^\times$ a character with (Tw1) for $m = -3$, (Tw2), (Tw4) that is a twist for the datum $\mathscr{H}$ given there, $\mathscr{X} = (B, A, P, \dots)$ a space for $(\mathscr{T}, \mathcal{O}')$, a universal polarised ordinary determinant of rank 4 over $\mathscr{H}$ with ring B_4^{po}, the morphism $\phi_0\colon B_4^{\mathrm{po}} \to B$ of Lemma 53.7, and an ideal $J_0 \subseteq B_4^{\mathrm{po}}$ with the property (Hf3) (for ι and κ). Then every ideal $\mathfrak{J} \subseteq B$ containing $\phi_0(J_0)$ satisfies (Jq5) for ι.*

Proof. Symbols introduced here are local to this proof. Let $\mathfrak{J} \supseteq \phi_0(J_0)$, and let $y\colon A \to \overline{\mathbb{Q}}_\ell$ be an $\mathcal{O}'$-algebra homomorphism with $y(\mathfrak{J}) = 0$ such that $y(P)$ has weights $(2m_1, \dots, 2m_4) =$

$(2e+2, 2e, 2, 0)$, and $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ continuous with $r|_{G_F} = y \circ r_P$, $r(g)$ of similitude $\theta(g)$ for all g, and $r|_{G_L}$ irreducible. Put $r' = \nu\, r|_{G_L}$, continuous and irreducible.

Step 1: automorphy. $y(\phi_0(J_0)) \subseteq y(\mathfrak{J}) = 0$. The tower is fit, hence good, ν satisfies (Lk5), κ is a twist for $\mathscr{H}$, and J_0 has (Hf3); so Lemma 53.24 applies: r' is automorphic of conjugate self-dual type for ι.

Step 2: (Qw1) for r'. Let $w \nmid \ell$ be a finite place of L, $\bar{w} \mid w$, $D = D_{\bar{w}} \cap G_L \supseteq I = I_{\bar{w}} \cap G_L$, and $\bar{\chi} = (\bar{\chi}_1, \dots, \bar{\chi}_4)\colon G_L \to (\mathbb{F}^\times_{\mathcal{O}'})^4$. If $s \in I$ and $\bar{\chi}(s) = 1$: one of $\chi_1^{\mathscr{T}}, \dots, \chi_4^{\mathscr{T}}$ is trivial (the character $\mathbf{1}$ of the datum), so (Lk6) gives $\bar{\nu}\bar{\kappa}^{-1}(s) = 1$ and then $\bar{\chi}_a^{\mathscr{T}}(s) = 1$ for all a; so $\bar{r}_0(s) = 1$, $s \in N$, $r_P(s) = 1$ (Mq1) and $r(s) = 1$. Hence $r|_I = \varphi \circ \bar{\chi}|_I$ for a homomorphism φ from the finite abelian group $\bar{\chi}(I)$ to $\mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$, which is diagonalisable: $r|_I$ is conjugate to $\mathrm{diag}(\varphi_i \circ \bar{\chi})$ for characters φ_i of $\bar{\chi}(I)$. Extend each φ_i to a character φ_i' of the finite abelian group $\bar{\chi}(D) \supseteq \bar{\chi}(I)$. By (Lk3), ν^m is trivial on I for some $m \geq 1$, so $\nu(I)$ is finite. Thus $r'(I)$ is finite and $r'|_I$ is conjugate to $s \mapsto \mathrm{diag}(\Psi_i(s))$ with the characters $\Psi_i = (\varphi_i' \circ \bar{\chi})\, \nu$ of D.

Step 3: (Qw2) for r'. Let $\bar{w}$ be a place of $\overline{\mathbb{Q}}$ above ℓ. It is $g\bar{v}$ for some $v \in \Sigma$ and $g \in G_F$, and $D_v \subseteq G_L$ (v splits in L), so $D_{\bar{w}} \cap G_L = g D_v g^{-1}$ and $I_{\bar{w}} \cap G_L = g I_v g^{-1}$ (G_L is normal in G_F). By (Mq3), (Mq4), $y(n_v)^{-1} r(s) y(n_v)$ is upper triangular with diagonal $(y(\psi^P_{v,a}(s)))_a$ for $s \in D_v$. For $t = gsg^{-1}$, $r'(t) = \nu(t)\, r(g) r(s) r(g)^{-1}$; so r' is triangular on gD_vg^{-1}, conjugated by $r(g)y(n_v)$, with diagonal $(\kappa_a)_a$, $\kappa_a(t) = \nu(t)\, y(\psi^P_{v,a}(g^{-1}tg))$. By the weights there is an open subgroup U of G_F with $y(\psi^P_{v,a}(s))^2 = \chi_{\mathrm{cyc}}(s)^{2m_a}$ for $s \in U \cap I_v$; hence $\epsilon_{ab} = y(\psi^P_{v,a}) y(\psi^P_{v,b})^{-1} \chi_{\mathrm{cyc}}^{-(m_a - m_b)}$ is a continuous character of $U \cap I_v$ with values in $\{\pm 1\}$, so trivial on an open subgroup U_{ab}. As $\chi_{\mathrm{cyc}}(g^{-1}tg) = \chi_{\mathrm{cyc}}(t)$, the character $\kappa_a \kappa_b^{-1} \chi_{\mathrm{cyc}}^{-(m_a - m_b)}$ is $t \mapsto \epsilon_{ab}(g^{-1}tg)$, trivial on the open subgroup $gU_{ab}g^{-1}$ of $I_{\bar{w}} \cap G_L$. This is (Qw2) with $h_{ab} = m_a - m_b$.

Step 4: witness conditions and descent. L is a CM field, r' is irreducible, continuous, automorphic of conjugate self-dual type (Step 1) and satisfies (Qw1), (Qw2) (Steps 2, 3); by Lemma 53.25, $\nu\, r|_{G_L}$ satisfies the witness conditions. By Lemma 53.26 (its hypotheses are those on y and r above), r satisfies (Sy2) for ι. So $\mathfrak{J}$ satisfies (Jq5). □

Lemma 53.24. *In the setting of Lemma 53.7, assume moreover that $\mathscr{T}$ is good, that ν satisfies (Lk5) and that κ is a twist for $\mathscr{H}$; let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism and $J_0 \subseteq B_4^{\mathrm{po}}$ an ideal with the property (Hf3) for ι and κ. Let $y\colon A \to \overline{\mathbb{Q}}_\ell$ be an $\mathcal{O}'$-algebra homomorphism with $y(\phi_0(J_0)) = 0$ such that $y(P)$ has weights $(2e+2, 2e, 2, 0)$, and $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ a continuous homomorphism with $r|_{G_F} = y \circ r_P$ and $r|_{G_L}$ irreducible. Then $r|_{G_L} \otimes \nu$ is automorphic of conjugate self-dual type for ι.*

Proof. Symbols introduced here are local to this proof. Put $x = y \circ \phi_0\colon B_4^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ and $(m_1, \dots, m_4) = (e+1, e, 1, 0)$; $x(J_0) = 0$.

Steps 1–2: integrality and the representation. The map $g \mapsto y(r_P(g)) = r(g)$ is continuous on G_L. By Lemma 53.19 with $n = 0$ there are a finite extension E of $\mathbb{Q}_\ell$ containing $\mathcal{O}'$, whose ring of integers A contains $x(B_4^{\mathrm{po}})$, $u \in \mathrm{GL}_4(E)$ and a continuous homomorphism $\rho\colon \Gamma^0_{\mathscr{H}} \to \mathrm{GL}_4(A)$ with $\rho(\pi_{\mathscr{H}}(g)) = u\, \lambda_0(g)\, r(g)\, u^{-1}$ for $g \in G_L$ and $x \circ D^{\mathrm{u}} = \det \circ \rho$. A is an integral test ring over $\mathcal{O}'$, and x is a homomorphism $B_4^{\mathrm{po}} \to A$. Let $\rho_L = \rho \circ \pi_{\mathscr{H}}|_{G_L}$, continuous and isomorphic to $\lambda_0\, r|_{G_L}$, hence irreducible over $\overline{\mathbb{Q}}_\ell$.

Step 3: the inertial weight. Put $\psi^\circ_{v,a} = x \circ \psi^{\mathrm{d}}_{v,a}|_{I_v} = \lambda_0\, y(\psi^P_{v,a})|_{I_v}$ (Cm2), with values in $A^\times$. Its extension $\phi_{v,a} = \lambda_0\, y(\psi^P_{v,a})$ to D_v is a character (the diagonal of the triangular $n_v^{-1} r(s) n_v$, (Mq4)), congruent to $\bar{\chi}_a$ by (Lk6). On an open subgroup of I_v: $y(\psi^P_{v,a}) = \chi_{\mathrm{cyc}}^{m_a}$ (the weights give $y(\psi^P_{v,a})^2 = \chi_{\mathrm{cyc}}^{2m_a}$, and a continuous character with values in $\{\pm 1\}$ has open kernel), $\nu = \chi_{\mathrm{cyc}}^{a_v}$ for an integer a_v (Lk5), $\kappa(\mathrm{Art}(w)) = \prod_\tau \tau(w)^{n_{v,\tau}}$ for integers $n_{v,\tau}$ (κ is algebraic), and $\chi_{\mathrm{cyc}}(\mathrm{Art}(w)) = \prod_\tau \tau(w)^{-1}$ (Lubin–Tate, arithmetic normalisation), w in the

units of L_v^+ and τ over the field embeddings $L_v^+ \to \overline{\mathbb{Q}}_\ell$; so $\phi_{v,a}(\mathrm{Art}(w)) = \prod_\tau \tau(w)^{h_{v,a,\tau}}$ with $h_{v,a,\tau} = -a_v - n_{v,\tau} - m_a$; so $\phi_{v,a}$ is locally algebraic, hence de Rham, with τ-Hodge–Tate weight $-h_{v,a,\tau} = a_v + n_{v,\tau} + m_a$ (the character $u \mapsto \tau(u)^{-1}$ on inertia being that of weight 1), strictly decreasing in a. Thus $(\psi_{v,a}^\circ)$ is an inertial weight for $\mathscr{H}$ (Rd8), and $\psi_{v,a}^\circ(\psi_{v,b}^\circ)^{-1}\chi_{\mathrm{cyc}}^{-(m_a-m_b)}$ is trivial on an open subgroup of I_v.

Step 4: conclusion. All hypotheses of (Hf3) hold for J_0, $(\psi_{v,a}^\circ)$, A, ρ and $x\colon B_4^{\mathrm{po}} \to A$ ($x(J_0) = 0$, $x(\psi_{v,a}^{\mathrm{d}}(g)) = \psi_{v,a}^\circ(g)$). Hence $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι, and so is the isomorphic representation $\lambda_0 \kappa\, r|_{G_L} = \nu\, r|_{G_L}$. □

Lemma 53.25. *Let F be a CM field, $n \geq 2$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and $r\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ an irreducible continuous representation which is automorphic of conjugate self-dual type for ι. Assume:*

(Qw1) *for every finite place $v \nmid \ell$ of F and every place $\bar v \mid v$, $r(I_{\bar v})$ is finite and $r|_{I_{\bar v}}$ is conjugate to $s \mapsto \mathrm{diag}(\Psi_1(s), \dots, \Psi_n(s))$ for some characters $\Psi_1, \dots, \Psi_n$ of $D_{\bar v}$;*

(Qw2) *for every place $v \mid \ell$ of F and every place $\bar v \mid v$, r is triangular on $D_{\bar v}$ with some diagonal $(\kappa_1, \dots, \kappa_n)$ such that for all a, b there is an integer h_{ab} with $\kappa_a \kappa_b^{-1} \chi_{\mathrm{cyc}}^{-h_{ab}}$ trivial on an open subgroup of $I_{\bar v}$.*

Then r satisfies the witness conditions, with $\tau_\pi = 0$ in (Wc2).

Proof. Step 0: the automorphic representation. Let Π be regular algebraic conjugate self-dual cuspidal with $r \leftrightarrow_\iota \Pi$. By Theorem B.62 ($\Pi$ is polarizable with the trivial character), $r_{\ell,\iota}(\Pi)$ is semisimple and, by (Bg1), has the Frobenius characteristic polynomials of r at almost all places; as r is irreducible, $r \cong r_{\ell,\iota}(\Pi)$ (Chebotarev, Brauer–Nesbitt). The absolute value of the central character ω_Π is a continuous homomorphism $\mathbb{A}_F^\times / F^\times \to \mathbb{R}_{>0}$, trivial on the compact group of idele classes of norm one, hence $|\omega_\Pi| = |\cdot|_{\mathbb{A}}^s$ for a real s; from $\Pi^\vee \cong \Pi^c$, $\omega_\Pi^{-1} = \omega_\Pi \circ c$, and as the idelic norm is c-invariant, $s = -s = 0$. So $|\omega_{\Pi_v}(\varpi_v)| = 1$ for every finite place v.

Step 1: a criterion for the window. Let v be a finite place and $\bar v \mid v$, $(V, \rho, N) = \mathrm{WD}(r|_{D_{\bar v}})$ (for $v \mid \ell$, $r|_{D_{\bar v}}$ is de Rham by (Bg2), hence potentially semistable). Suppose $N = 0$ and that $\rho|_{I_{\bar v}}$ has a semisimplification $\bigoplus_i \Psi_i'|_{I_{\bar v}}$ with characters Ψ_i' of $W_{\bar v}$ of finite order on $I_{\bar v}$. Then Π_v has a cuspidal support of characters $\xi_1, \dots, \xi_n$ of $F_v^\times$ with $|\xi_i(\varpi_v)| = 1$ for all i. Indeed, the $\Psi_i' \circ \mathrm{Art}_{F_v}$ are trivial on an open subgroup U of $\mathcal{O}_{F_v}^\times$, so (Bg3) gives characters ξ_i, trivial on U, with Π_v a subquotient of the normalised induction of $\xi_1 \otimes \cdots \otimes \xi_n$. By Theorem B.73 ($v \mid \ell$) or Theorem B.90 ($v \nmid \ell$), $(V, \rho, 0)$ is pure; by (Pu2), resp. (Pv2), the zero map is an isomorphism $\mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$ for $i \geq 1$, so these spaces vanish, $V = \mathrm{gr}_k$, and every eigenvalue α of $\rho(\Phi)$, $n(\Phi) = -1$, has $|\iota(\alpha)| = q_v^{k/2}$. By (Bg5) the semisimplification of ρ is $\bigoplus_i \lambda_i$ with $\iota\lambda_i(\mathrm{Art}_{F_v}(\varpi_v)^{-1}) = \xi_i(\varpi_v) q_v^{(n-1)/2}$, and $\lambda_i(\mathrm{Art}_{F_v}(\varpi_v)^{-1})$ is an eigenvalue of $\rho(\Phi)$ for a geometric Frobenius Φ (characters factor through $W_{\bar v}^{\mathrm{ab}}$). So $|\xi_i(\varpi_v)| = q_v^{(k-n+1)/2}$ for all i. The centre of $\mathrm{GL}_n(F_v)$ acts on the normalised induction, hence on Π_v, through $\prod_i \xi_i$, so $\prod_i |\xi_i(\varpi_v)| = |\omega_{\Pi_v}(\varpi_v)| = 1$ (Step 0), and $|\xi_i(\varpi_v)| = 1$.

Step 2: places $v \nmid \ell$. By (Qw1), r is trivial on an open subgroup J of $I_{\bar v}$; in (Wd1), $\exp(t_\ell(\sigma)N) = 1$ with $t_\ell(\sigma) \neq 0$ for some $\sigma \in J$, so $N = 0$, and $\rho|_{I_{\bar v}} = r|_{I_{\bar v}}$ is the sum of the characters $\Psi_i|_{I_{\bar v}}$ of finite order. Step 1 applies.

Step 3: places $v \mid \ell$, the monodromy. Let $v \mid \ell$, $\bar v \mid v$, and let (κ_a) be a diagonal of r on $D = D_{\bar v}$ with $\kappa_a \neq \kappa_b \chi_{\mathrm{cyc}}|_D$ for all a, b (i.e. r generic at v with this diagonal at $\bar v$). The κ_a are the Jordan–Hölder constituents of $r|_D$, so (Qw2), which concerns the multiset of diagonal characters, holds for them. $r|_D$ is potentially semistable ((Bg2)), so (Tj1) of Lemma 48.13 (for F, v, $\bar v$ and this diagonal) gives $N = 0$. By Step 0, $r|_D$ is conjugate to $r_{\ell,\iota}(\Pi)|_D$, so by Theorem B.73

$(V,\rho,0)$ is pure, with the conditions (Pu1), (Pu2), which are those of (Tj2) of Lemma 48.13; hence every eigenvalue of $\rho(\Phi)$ has absolute value $q_v^{k/2}$ under ι, and $\kappa_a^m \neq (\kappa_b\chi_{\mathrm{cyc}})^m$ on D for all a,b and $m \geq 1$.

Step 4: (Wc1). With v, $\bar{v}$, (κ_a) as in Step 3, Step 3 gives $\kappa_a^m \neq (\kappa_b\chi_{\mathrm{cyc}})^m$ on D for all a,b and $m \geq 1$. As $\bar{v} \mid v$ was arbitrary, r is potentially generic at every place at which it is generic: (Wc1).

Step 5: places $v \mid \ell$ where r is potentially generic. Then r is generic at v (take $m=1$), so $N=0$ by Step 3; ρ is trivial on an open subgroup of $I_{\bar{v}}$, so $\rho|_{I_{\bar{v}}}$ factors through a finite group, is semisimple, and its constituents are the restrictions to $I_{\bar{v}}$ of the characters $\mathrm{WD}(\kappa_a)$ of $W_{\bar{v}}$ (WD is exact on potentially semistable representations, [95], applied along the triangular flag), characters of $W_{\bar{v}}$ of finite order on inertia. Step 1 applies.

Step 6: (Wc2). Let π be regular algebraic cuspidal with $r \leftrightarrow_\iota \pi$. At almost all places both π_w and Π_w are unramified with Satake parameters determined by the Frobenius characteristic polynomial of r, so $\pi_w \cong \Pi_w$, and $\pi \cong \Pi$ by (Js1). By Steps 1, 2 and 5, at every finite $v \nmid \ell$, and every $v \mid \ell$ at which r is potentially generic, π_v has a cuspidal support of characters, and every character ξ in it satisfies $|\xi(\varpi_v)| = 1 \in (q_v^{-1/2}, q_v^{1/2})$; cuspidal supports are unique up to order, so this holds for every cuspidal support. This is (Wc2) with $\tau_\pi = 0$. □

Lemma 53.26. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with characters θ and integer e, $\mathscr{T}$ a fit and deep auxiliary tower for it with fields $F \subseteq L$, $\mathcal{O}_1$ and ν as given by Lemma 53.2, $\mathcal{O}' \supseteq \mathcal{O}_1$ a coefficient ring, $\mathscr{X} = (B, A, P, \dots)$ a space for $(\mathscr{T}, \mathcal{O}')$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $y\colon A \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}'$-algebra homomorphism such that $y(P)$ has weights $(2e+2, 2e, 2, 0)$. Let $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ be a continuous homomorphism with $r|_{G_F} = y \circ r_P$, $r(g)$ of similitude $\theta(g)$ for all $g \in G_{\mathbb{Q}}$ and $r|_{G_L}$ irreducible, such that $\nu\, r|_{G_L}$ is automorphic of conjugate self-dual type for ι and satisfies the witness conditions. Then r satisfies (Sy2) for ι.*

Proof. Symbols introduced here are local to this proof. For a CM field $M \subset \overline{\mathbb{Q}}$ the complex conjugation c lies in G_{M^+} (it fixes every totally real field) and not in G_M; for a character υ of G_M put $\upsilon^c(s) = \upsilon(csc)$.

Step 0: characters. By (Sg1), $\xi(c) = -1$ and $\Psi(c) = 1$; $\chi_{\mathrm{cyc}}(c) = -1$; and $\omega_\ell(c) = -1$, since $\omega_\ell(c)^2 = 1$ and $\bar{\omega}_\ell(c) = \bar{\chi}_{\mathrm{cyc}}(c) = -1 \neq 1$ (ℓ odd). Hence $\alpha(c) = -1$ and

$$\theta(c) = \alpha(c)\Psi(c) = -1.$$

Further $\theta = \chi_{\mathrm{cyc}}^{e+1}\theta_{\mathrm{f}}$ with $\theta_{\mathrm{f}} = \omega_\ell^{-1}\xi\chi$ of finite order. Put $\Phi = \theta^{-1}\chi_{\mathrm{cyc}}^{-3} = \chi_{\mathrm{cyc}}^{-(e+4)}\theta_{\mathrm{f}}^{-1}$. For every imaginary quadratic field K fix, by Lemma 53.30 (with $k = -(e+4)$ and the character θ_{f}^{-1} of finite order), a continuous character $\lambda_K\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$, algebraic for ι, with $\lambda_K\lambda_K^c = \Phi$ on G_K and $\lambda_K(I_{\bar{v}} \cap G_K)$ finite for every place $\bar{v}$ above a prime $p \neq \ell$. We use two facts on Hecke characters. (H1) If υ is a character of G_M algebraic for ι, there is an algebraic Hecke character Υ of M with Υ_w unramified and $\Upsilon_w(\varpi_w) = \iota\upsilon(\mathrm{Frob}_w^{-1})$ for all but finitely many finite places w of M: the Hecke character to which υ corresponds, or its inverse, according to the normalisation of the correspondence (inverses of algebraic Hecke characters are algebraic). (H2) A Hecke character Ξ of a number field M that is unramified with $\Xi_w(\varpi_w) = 1$ at every finite place w outside a finite set T is trivial: it is trivial on $M_w^\times$ for these w; given $x \in \mathbb{A}_M^\times$, weak approximation gives $\delta \in M^\times$ close to x at the places in T and the infinite places, and then x is close to $\delta\, x_1$, where x_1 has the components of $\delta^{-1}x$ outside these places and 1 at them; so $\Xi(x) = 1$ by continuity.

Step 1: polarisation, and the condition (Vj3). Let M be a CM field, $K \subseteq M$ an imaginary quadratic field, $\rho = r|_{G_M} \otimes \lambda_K|_{G_M}$, $\mu = \chi_{\mathrm{cyc}}^{-3}|_{G_{M^+}}$, and $\langle x, x' \rangle = {}^t x\, J_4\, r(c)\, x'$ on $\overline{\mathbb{Q}}_\ell^4$, a non-degenerate bilinear form. (a) (ρ,μ) satisfies (Vj1) with c and $\langle\ ,\ \rangle$. For $\sigma \in G_M$, $r(c)r(c\sigma c) =$

$r(\sigma)r(c)$ as $c^2=1$, and $r(\sigma)$ has similitude $\theta(\sigma)$, so

$$\langle\rho(\sigma)x,\rho(c\sigma c)x'\rangle=\lambda_K(\sigma)\lambda_K(c\sigma c)\,{}^t x\,{}^t r(\sigma)J_4 r(\sigma)\,r(c)\,x'=\Phi(\sigma)\theta(\sigma)\langle x,x'\rangle=\mu(\sigma)\langle x,x'\rangle.$$

From ${}^t r(c)J_4r(c)=\theta(c)J_4$ and $r(c)^{-1}=r(c)$ we get ${}^t r(c)J_4=\theta(c)J_4r(c)$, and with ${}^tJ_4=-J_4$, $\langle x',x\rangle={}^t x\,{}^t r(c)\,{}^t J_4\,x'=-\theta(c)\langle x,x'\rangle=\langle x,x'\rangle$ by Step 0. As $-\mu(c)=-\chi_{\mathrm{cyc}}(c)^{-3}=1$, this is $\langle x,x'\rangle=-\mu(c)\langle x',x\rangle$. So the sign that (Vj1) demands for the multiplier χ_{cyc}^{-3} is the sign $-\theta(c)$ of the form given by the similitude; this is where $\theta(c)=-1$ enters. (b) (Vj3) holds for (ρ,μ) over M if and only if ρ is automorphic of conjugate self-dual type for ι. In (Vj3), $\mu\chi_{\mathrm{cyc}}^3=\mathbf{1}$, so the character χ_1 of $\mathbb{A}_{M^+}^\times/(M^+)^\times$ there satisfies $\mathbf{1}\leftrightarrow_\iota\chi_1$: for almost all finite places w of M^+, $\chi_{1,w}$ is unramified with $\chi_{1,w}(\varpi_w)=1$, so $\chi_1=\mathbf{1}$ by (H2). Conversely $\chi_1=\mathbf{1}$ has $\chi_{1,v}(-1)=1=(-1)^4$ at every real place v and $\mathbf{1}\leftrightarrow_\iota\mathbf{1}$, and with it the condition on π in (Vj3) reads $\pi^c\cong\pi^\vee$. So (Vj3) says exactly that $\rho\leftrightarrow_\iota\pi$ for a regular algebraic conjugate self-dual cuspidal automorphic representation π of $\mathrm{GL}_4(\mathbb{A}_M)$. (The twist by λ_K makes the sign condition of (Vj3) hold for every e. With $\rho=r|_{G_M}$ and $\mu=\theta|_{G_{M^+}}$, (Vj1) holds with the same form, but the character of (Vj3) is then forced to be the algebraic Hecke character χ_1 with $\theta\chi_{\mathrm{cyc}}^3\leftrightarrow_\iota\chi_1$, whose ℓ-adic character has Hodge–Tate weight $-(e+4)$ and the value $\theta(c)\chi_{\mathrm{cyc}}(c)^3=1$ on complex conjugations; by the relation between these and $\chi_{1,v}(-1)$ at a real place v ([17], Appendix A.2), $\chi_{1,v}(-1)=(-1)^e$, and the condition $\chi_{1,v}(-1)=(-1)^4$ fails for odd e.)

Step 2: twists with trivial conjugate product. Let M be a CM field, ρ_1 a continuous representation of G_M automorphic of conjugate self-dual type for ι, and υ a character of G_M algebraic for ι with $\upsilon\upsilon^c=\mathbf{1}$. Then $\rho_1\otimes\upsilon$ is automorphic of conjugate self-dual type for ι. Let $\rho_1\leftrightarrow_\iota\Pi$ with Π regular algebraic, conjugate self-dual and cuspidal, and Υ as in (H1). At almost all finite places w the Satake parameters of $(\Pi\otimes(\Upsilon\circ\det))_w$ are the $\zeta\,\Upsilon_w(\varpi_w)$, ζ running over those of Π_w, and ι carries the eigenvalues of $(\rho_1\otimes\upsilon)(\mathrm{Frob}_w^{-1})$ to the $\mathrm{N}w^{3/2}\zeta\cdot\Upsilon_w(\varpi_w)$; so $\rho_1\otimes\upsilon\leftrightarrow_\iota\Pi\otimes(\Upsilon\circ\det)$, which is cuspidal and regular algebraic (twisting by an algebraic Hecke character shifts the infinitesimal character at each complex place by an integral scalar). Let $\Upsilon^c=\Upsilon\circ c$. For almost all w, $c(\varpi_w)$ is a uniformiser at cw and $c\,\mathrm{Frob}_w\,c$ is an arithmetic Frobenius at cw, so $(\Upsilon\Upsilon^c)_w(\varpi_w)=\iota(\upsilon\upsilon^c)(\mathrm{Frob}_w^{-1})=1$; by (H2), $\Upsilon^c=\Upsilon^{-1}$. Hence $(\Pi\otimes(\Upsilon\circ\det))^c\cong\Pi^\vee\otimes(\Upsilon^{-1}\circ\det)=(\Pi\otimes(\Upsilon\circ\det))^\vee$.

Step 3: from L to every imaginary quadratic field. For a CM field M and an imaginary quadratic field $K\subseteq M$ let $\mathrm{A}(M,K)$ be the assertion that $r|_{G_M}\otimes\lambda_K|_{G_M}$ is automorphic of conjugate self-dual type for ι. (R1) If $K_1,K_2\subseteq M$, then $\mathrm{A}(M,K_1)\Leftrightarrow\mathrm{A}(M,K_2)$: $\upsilon=\lambda_{K_2}\lambda_{K_1}^{-1}$ on G_M is algebraic for ι with $\upsilon\upsilon^c=\Phi\Phi^{-1}=\mathbf{1}$; apply Step 2 to υ and to υ^{-1}. (R2) If $K\subseteq F'\subseteq M$ with F', M CM fields, M/F' soluble Galois and $r|_{G_M}$ irreducible, then $\mathrm{A}(F',K)\Leftrightarrow\mathrm{A}(M,K)$: apply Theorem B.78 to F' (not totally real, as it contains K), M, $n=4$, $\rho=r|_{G_{F'}}\otimes\lambda_K|_{G_{F'}}$ and $\mu=\chi_{\mathrm{cyc}}^{-3}|_{G_{F'+}}$. (Vj1) holds by Step 1(a); (Vj2) holds since a subspace stable under $\rho(G_M)$ is stable under $r(G_M)$; (Vj3) is $\mathrm{A}(F',K)$ by Step 1(b) for F'; and (Vj4), which is (Vj3) for $(r|_{G_M}\otimes\lambda_K|_{G_M},\chi_{\mathrm{cyc}}^{-3}|_{G_{M^+}})$ over M, is $\mathrm{A}(M,K)$ by Step 1(b) for M. The start. By Lemma 53.2, L is a CM field with $L^+=F$; $E\subseteq L$, and L is abelian over $\mathbb{Q}$ as F is, so L/E is abelian. The character ν is algebraic for ι: at every place $\bar w$ above ℓ, by (Lk5), $\nu\chi_{\mathrm{cyc}}^{-a}$ (with the integer a given there) has finite order on $I_{\bar w}\cap G_L$, so it is potentially unramified, hence de Rham, and ν is de Rham at $\bar w$; a continuous character of G_L that is de Rham at all places above ℓ is algebraic for ι ([220, Ch. III]; [69, Lemma 4.1.3]). So $\upsilon_0=\lambda_E|_{G_L}\nu^{-1}$ is algebraic for ι, and $\upsilon_0\upsilon_0^c=\Phi\,(\nu\nu^c)^{-1}=\theta^{-1}\chi_{\mathrm{cyc}}^{-3}\cdot\theta\chi_{\mathrm{cyc}}^3=\mathbf{1}$ on G_L by (Lk1). By hypothesis $\nu\,r|_{G_L}$ is automorphic of conjugate self-dual type, so by Step 2 so is $(\nu\,r|_{G_L})\otimes\upsilon_0=r|_{G_L}\otimes\lambda_E|_{G_L}$: $\mathrm{A}(L,E)$ holds. By (R2) for $E\subseteq L$ ($r|_{G_L}$ irreducible), $\mathrm{A}(E,E)$ holds. Now let K' be an imaginary quadratic field with $r|_{G_{K'}}$ irreducible. If $K'=E$, $\mathrm{A}(K',K')$ holds. Otherwise $r|_{G_E}$ is irreducible (as $r|_{G_L}$ is), and Lemma 53.29 (for E and K') gives an imaginary quadratic field $K''\notin\{E,K'\}$ with $r|_{G_{EK''}}$

and $r|_{G_{K'K''}}$ irreducible. For distinct imaginary quadratic fields K_1, K_2 the compositum K_1K_2 is a CM field (a totally imaginary quadratic extension of its real quadratic subfield), Galois of degree 2 over K_1 and over K_2. Hence, by (R2), (R1), (R2), (R2), (R1), (R2) in turn,

$$\mathrm{A}(E,E) \Rightarrow \mathrm{A}(EK'',E) \Rightarrow \mathrm{A}(EK'',K'') \Rightarrow \mathrm{A}(K'',K'') \\ \Rightarrow \mathrm{A}(K''K',K'') \Rightarrow \mathrm{A}(K''K',K') \Rightarrow \mathrm{A}(K',K').$$

In both cases $\rho' = r|_{G_{K'}} \otimes \lambda_{K'}$ is automorphic of conjugate self-dual type: $\rho' \leftrightarrow_\iota \Pi'$ with Π' regular algebraic, conjugate self-dual and cuspidal.

Step 4: automorphy over K'. Let Υ be as in (H1) for $\upsilon = \lambda_{K'}$. At almost all finite places w of K', $r(\mathrm{Frob}_w^{-1}) = \rho'(\mathrm{Frob}_w^{-1})\lambda_{K'}(\mathrm{Frob}_w^{-1})^{-1}$, so ι carries its eigenvalues to the $\mathrm{N}w^{3/2}\zeta\,\Upsilon_w(\varpi_w)^{-1}$, ζ over the Satake parameters of Π'_w; these $\zeta\,\Upsilon_w(\varpi_w)^{-1}$ are the Satake parameters of $(\Pi' \otimes (\Upsilon^{-1} \circ \det))_w$. Hence $r|_{G_{K'}} \leftrightarrow_\iota \Pi' \otimes (\Upsilon^{-1} \circ \det)$, a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_4(\mathbb{A}_{K'})$. This is the first part of (Sy2).

Step 5: the witness conditions over K'. We apply Lemma 53.25 to the CM field K', $n = 4$ and ρ', which is continuous, irreducible (as $r|_{G_{K'}}$ is) and automorphic of conjugate self-dual type (Step 3). (Qw1): let $v \nmid \ell$ be a finite place of K' above the prime p and $\bar{v} \mid v$. By Lemma 53.27, r maps the inertia group of $\bar{v}$ in $G_{\mathbb{Q}}$ to a finite group and, on it, is conjugate to $s \mapsto \mathrm{diag}(\psi_1(s), \dots, \psi_4(s))$ with characters ψ_i of the decomposition group of $\bar{v}$ in $G_{\mathbb{Q}}$; by Step 0, $\lambda_{K'}$ takes finitely many values on $I_{\bar{v}} = I_{\bar{v}}^{\mathbb{Q}} \cap G_{K'}$. So $\rho'(I_{\bar{v}})$ is finite and $\rho'|_{I_{\bar{v}}}$ is conjugate to $s \mapsto \mathrm{diag}\big(\psi_i(s)\lambda_{K'}(s)\big)_i$, with characters $\psi_i\lambda_{K'}$ of $D_{\bar{v}}$. (Qw2): let $v \mid \ell$ and $\bar{v} \mid v$. By Lemma 53.28, r is triangular on the decomposition group of $\bar{v}$ in $G_{\mathbb{Q}}$ with a diagonal $(\kappa_1, \dots, \kappa_4)$ such that $\kappa_i\chi_{\mathrm{cyc}}^{-m_i}$, $(m_1, \dots, m_4) = (e+1, e, 1, 0)$, is trivial on an open subgroup V_i of its inertia group. With the same conjugating matrix, ρ' is triangular on $D_{\bar{v}}$ with diagonal $(\kappa_i\lambda_{K'})_i$, and $(\kappa_i\lambda_{K'})(\kappa_j\lambda_{K'})^{-1}\chi_{\mathrm{cyc}}^{-(m_i-m_j)} = (\kappa_i\chi_{\mathrm{cyc}}^{-m_i})(\kappa_j\chi_{\mathrm{cyc}}^{-m_j})^{-1}$ is trivial on the open subgroup $V_i \cap V_j \cap G_{K'}$ of $I_{\bar{v}}$. By Lemma 53.25, ρ' satisfies (Wc1) and (Wc2), with $\tau = 0$. Untwisting. For a place $v \mid \ell$ of K' and $\bar{v} \mid v$, the triangular forms of $r|_{G_{K'}}$ and of $\rho' = r|_{G_{K'}} \otimes \lambda_{K'}$ on $D_{\bar{v}}$ correspond (same conjugating matrix), the diagonals differing by the factor $\lambda_{K'}$; the conditions $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}$ and $\kappa_i^h \neq (\kappa_j\chi_{\mathrm{cyc}})^h$ involve only the ratios κ_i/κ_j. So $r|_{G_{K'}}$ is generic, resp. potentially generic, at v if and only if ρ' is, and (Wc1) for ρ' gives (Wc1) for $r|_{G_{K'}}$. For (Wc2) we first show $|\Upsilon| = \|\cdot\|^t$ for a real t, $\|\cdot\|$ the idelic norm of K': $|\Upsilon|$ is a continuous homomorphism $\mathbb{A}_{K'}^\times / K'^\times \to \mathbb{R}_{>0}$, trivial on the compact group $\prod_w \mathcal{O}_{K'_w}^\times$; on $K'^\times_\infty = \mathbb{C}^\times$, which is connected, the algebraic character Υ is $z \mapsto z^{n_1}\bar{z}^{n_2}$ with integers n_1, n_2, so $|\Upsilon(z)| = |z|^{n_1+n_2} = \|z\|^{(n_1+n_2)/2}$; with $t = (n_1+n_2)/2$, $|\Upsilon|\,\|\cdot\|^{-t}$ is trivial on $K'^\times$, $\mathbb{C}^\times$ and $\prod_w \mathcal{O}_{K'_w}^\times$, so it factors through the finite class group and takes values in the torsion of $\mathbb{R}_{>0}$, which is trivial. Hence $|\Upsilon_v(\varpi_v)| = q_v^{-t}$ for every finite place v. Now let π be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_4(\mathbb{A}_{K'})$ with $r|_{G_{K'}} \leftrightarrow_\iota \pi$ ($r|_{G_{K'}}$ is semisimple, being irreducible). As in Step 2, $\rho' \leftrightarrow_\iota \pi \otimes (\Upsilon \circ \det)$, regular algebraic and cuspidal. Let v be a finite place with $v \nmid \ell$, or $v \mid \ell$ and $r|_{G_{K'}}$ potentially generic at v (equivalently, ρ' potentially generic at v). If π_v is a subquotient of the normalised induction of $\xi_1 \otimes \cdots \otimes \xi_4$, then $\pi_v \otimes (\Upsilon_v \circ \det)$ is a subquotient of that of $\xi_1\Upsilon_v \otimes \cdots \otimes \xi_4\Upsilon_v$, and conversely; so the cuspidal supports of π_v are those of $(\pi \otimes (\Upsilon \circ \det))_v$ multiplied by Υ_v^{-1}. By (Wc2) for ρ', π_v has a cuspidal support consisting of characters, and every character ξ in a cuspidal support of π_v has $q_v^{-1/2} < |\xi(\varpi_v)\Upsilon_v(\varpi_v)| < q_v^{1/2}$, that is $q_v^{t-1/2} < |\xi(\varpi_v)| < q_v^{t+1/2}$. This is (Wc2) for $r|_{G_{K'}}$ with $\tau_\pi = t$. As K' was an arbitrary imaginary quadratic field with $r|_{G_{K'}}$ irreducible, Steps 4 and 5 give (Sy2) for r and ι. □

Lemma 53.27. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with prime ℓ, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ with field F, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \dots)$ a space for $(\mathscr{T}, \mathcal{O}')$, $y\colon A \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}'$-algebra homomorphism and $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ a homomorphism with $r|_{G_F} = y \circ r_P$. Then*

for every prime $p \neq \ell$ and every place $\bar{p} \mid p$ of $\overline{\mathbb{Q}}$: $r(I_{\bar{p}})$ is a finite abelian group commuting with $r(D_{\bar{p}})$, and there are continuous characters $\Psi_1, \dots, \Psi_4 \colon D_{\bar{p}} \to \overline{\mathbb{Q}}_\ell^\times$ such that $r|_{I_{\bar{p}}}$ is conjugate to $s \mapsto \operatorname{diag}(\Psi_1(s), \dots, \Psi_4(s))$.

Proof. Symbols introduced here are local to this proof. Let $H = G_F \cap \ker \bar{r}_0$. It is an open normal subgroup of $G_{\mathbb{Q}}$ (G_F is open and normal as $F/\mathbb{Q}$ is Galois, and $\bar{r}_0$ is a locally constant homomorphism on $G_{\mathbb{Q}}$), and $G_{\mathbb{Q}}/H$ embeds into $\operatorname{Gal}(F/\mathbb{Q}) \times \bar{r}_0(G_{\mathbb{Q}})$, which is abelian ($F/\mathbb{Q}$ abelian, $\bar{r}_0$ diagonal); so the closure of the commutator subgroup of $G_{\mathbb{Q}}$ lies in H.

Let $p \neq \ell$, $\bar{p} \mid p$, $D = D_{\bar{p}} \supseteq I = I_{\bar{p}}$. If $s \in I \cap H$, then $s \in I_{\bar{p}} \cap G_F$ with $\bar{r}_0(s) = 1$ and $\bar{p} \nmid \ell$, so $s \in N$, $r_P(s) = 1$ by (Mq1), and $r(s) = y(r_P(s)) = 1$. Hence $r|_I$ factors through $I/(I \cap H)$, which embeds into the finite abelian group $G_{\mathbb{Q}}/H$: $r(I)$ is finite abelian. For $d \in D$ and $s \in I$, $dsd^{-1}s^{-1}$ lies in I (I is normal in D) and in the commutator subgroup, hence in $I \cap H$, so $r(d)r(s)r(d)^{-1} = r(s)$: $r(I)$ commutes with $r(D)$.

As $r(I)$ is a finite abelian group of matrices over the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic 0, $V = \overline{\mathbb{Q}}_\ell^4$ is the direct sum of the joint eigenspaces V_χ, χ running over the characters of I (through r) that occur, and $r|_I$ acts on V_χ by χ. Each χ is trivial on the open subgroup $I \cap H$, hence continuous, and satisfies $\chi(dsd^{-1}) = \chi(s)$ for $d \in D$ (as $r(dsd^{-1}) = r(s)$). The quotient D/I is isomorphic to $\widehat{\mathbb{Z}}$, a free profinite group, so the projection $D \to D/I$ has a continuous section on a topological generator: there is $\phi \in D$ such that $t \mapsto \phi^t$, $t \in \widehat{\mathbb{Z}}$, is a continuous homomorphism whose composite with $D \to D/I$ is an isomorphism; then $(s, t) \mapsto s\phi^t$ is a homeomorphism $I \times \widehat{\mathbb{Z}} \to D$. Put $\Psi_\chi(s\phi^t) = \chi(s)$. It is a homomorphism, since $s\phi^t s'\phi^{t'} = s(\phi^t s' \phi^{-t})\phi^{t+t'}$ and $\chi(\phi^t s' \phi^{-t}) = \chi(s')$, and continuous, as χ is. Listing each χ with multiplicity $\dim V_\chi$ gives characters $\Psi_1, \dots, \Psi_4$ of D, and in a basis adapted to $V = \bigoplus_\chi V_\chi$, $r(s) = \operatorname{diag}(\Psi_1(s), \dots, \Psi_4(s))$ for $s \in I$. □

Lemma 53.28. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with prime ℓ and integer e, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ with field F, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \dots)$ a space for $(\mathscr{T}, \mathcal{O}')$, and $y \colon A \to \overline{\mathbb{Q}}_\ell$ an $\mathcal{O}'$-algebra homomorphism such that $y(P)$ has weights $(2e + 2, 2e, 2, 0)$. Let $r \colon G_{\mathbb{Q}} \to \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ be a continuous homomorphism with $r|_{G_F} = y \circ r_P$, and put $(m_1, m_2, m_3, m_4) = (e + 1, e, 1, 0)$. Then for every place $\bar{u}$ of $\overline{\mathbb{Q}}$ above ℓ the representation r is triangular on $D_{\bar{u}}$ with a diagonal $(\kappa_1, \dots, \kappa_4)$ of continuous characters of $D_{\bar{u}}$ such that, for $a = 1, \dots, 4$, the character $\kappa_a \chi_{\mathrm{cyc}}^{-m_a}$ is trivial on an open subgroup of $I_{\bar{u}}$.*

Proof. Symbols introduced here are local to this proof.

Step 1: reduction to the marked places. By the definition of an auxiliary tower, $\bar{u} = g\bar{v}$ for some $v \in \Sigma$ and $g \in G_F$; then $D_{\bar{u}} = gD_{\bar{v}}g^{-1}$ and $I_{\bar{u}} = gI_{\bar{v}}g^{-1}$. Suppose $b \in \mathrm{GL}_4(\overline{\mathbb{Q}}_\ell)$ is such that $b\,r(s)\,b^{-1}$ is upper triangular with diagonal entries $\kappa_a(s)$ for $s \in D_{\bar{v}}$, with continuous characters κ_a of $D_{\bar{v}}$ and open subgroups $V_a \subseteq I_{\bar{v}}$ on which $\kappa_a \chi_{\mathrm{cyc}}^{-m_a}$ is trivial. For $s \in D_{\bar{u}}$, $(b\,r(g)^{-1})\,r(s)\,(b\,r(g)^{-1})^{-1} = b\,r(g^{-1}sg)\,b^{-1}$ is upper triangular with diagonal entries $\kappa_a(g^{-1}sg)$; the characters $s \mapsto \kappa_a(g^{-1}sg)$ of $D_{\bar{u}}$ are continuous, and since $\chi_{\mathrm{cyc}}(g^{-1}sg) = \chi_{\mathrm{cyc}}(s)$, the character $s \mapsto \kappa_a(g^{-1}sg)\chi_{\mathrm{cyc}}(s)^{-m_a}$ is trivial on the open subgroup gV_ag^{-1} of $I_{\bar{u}}$. So it suffices to treat $\bar{u} = \bar{v}$ with $v \in \Sigma$. Write $D = D_{\bar{v}} \supseteq I = I_{\bar{v}}$ (in $G_{\mathbb{Q}}$), so that $D_v = D \cap G_F$ and $I_v = I \cap G_F$.

Step 2: the flag on D_v. Let $P = (r_P, (n_w)_{w \in \Sigma})$. By (Mq3), n_v is lower triangular with diagonal entries 1, so $y(n_v)$ is invertible; put $b = y(n_v)^{-1}$. For $s \in D_v$, $X(s) = b\,r(s)\,b^{-1} = y(n_v^{-1} r_P(s) n_v)$ is upper triangular by (Mq4), with diagonal entries $\psi_a(s) = \psi_{v,a}^{y(P)}(s)$. As $y(P)$ has weights $(2m_1, \dots, 2m_4)$, there is an open subgroup $U \subseteq G_F$ with $\psi_a(s)^2 = \chi_{\mathrm{cyc}}(s)^{2m_a}$ for all a and all $s \in U \cap I_v$.

Step 3: a test element of infinite cyclotomic order. U is open in $G_{\mathbb{Q}}$ (as G_F is), hence of finite index, so $N = \bigcap_{g \in G_{\mathbb{Q}}} gUg^{-1}$ is a finite intersection (the conjugate gUg^{-1} depends only on the coset gU) and is an open normal subgroup of $G_{\mathbb{Q}}$ contained in U. The cyclotomic character maps I onto $\mathbb{Z}_\ell^\times$ ($\mathbb{Q}_\ell(\mu_{\ell^\infty})/\mathbb{Q}_\ell$ is totally ramified with group $\mathbb{Z}_\ell^\times$), and $N \cap I$ has finite index in I, so $\chi_{\mathrm{cyc}}(N \cap I)$ is a closed subgroup of finite index of $\mathbb{Z}_\ell^\times$, hence open, hence contains $1 + \ell^j \mathbb{Z}_\ell$ for some $j \geq 1$, whose non-trivial elements have infinite order ($1 + \ell\mathbb{Z}_\ell$ is torsion-free, ℓ being odd). Choose $s_0 \in N \cap I$ with $z = \chi_{\mathrm{cyc}}(s_0)$ of infinite order.

Step 4: the flag is stable under D. Let $g \in D$ and $s_1 = g s_0 g^{-1}$. As N is normal in $G_{\mathbb{Q}}$ and I is normal in D, $s_1 \in N \cap I \subseteq U \cap I_v \subseteq D_v$, and $\chi_{\mathrm{cyc}}(s_1) = z$. For $t = 0, 1$ the matrix $M_t = X(s_t)^2$ is upper triangular with diagonal entries $\psi_a(s_t)^2 = d_a$, where $d_a = z^{2m_a}$; the d_a are pairwise distinct, since $m_1 > m_2 > m_3 > m_4$ (as $e \geq 2$) and z has infinite order. Put $B = b\, r(g)\, b^{-1}$; from $g\, s_0^2 = s_1^2\, g$ we get $BM_0 = M_1 B$. We show $B_{ij} = 0$ for $i > j$, by induction on $j - i \in \{-3, -2, -1\}$. Let $i > j$ and assume $B_{i'j'} = 0$ whenever $i' > j'$ and $j' - i' < j - i$. In $(BM_0)_{ij} = \sum_{k \leq j} B_{ik} (M_0)_{kj}$ the terms with $k < j$ vanish ($i > k$ and $k - i < j - i$), so $(BM_0)_{ij} = B_{ij} d_j$; in $(M_1 B)_{ij} = \sum_{k \geq i} (M_1)_{ik} B_{kj}$ the terms with $k > i$ vanish ($k > j$ and $j - k < j - i$), so $(M_1 B)_{ij} = d_i B_{ij}$. Hence $B_{ij}(d_j - d_i) = 0$ and $B_{ij} = 0$. So $b\, r(g)\, b^{-1}$ is upper triangular for every $g \in D$. The diagonal entries $\kappa_a(g) = (b\, r(g)\, b^{-1})_{aa}$ are multiplicative in g (the diagonal of a product of upper triangular matrices is the product of the diagonals) and continuous, as r is: r is triangular on D with diagonal $(\kappa_1, \ldots, \kappa_4)$.

Step 5: the weights. κ_a restricts to ψ_a on D_v. The group $V = U \cap I_v = U \cap I$ is an open subgroup of I, and on V, $(\kappa_a \chi_{\mathrm{cyc}}^{-m_a})^2 = \psi_a^2 \chi_{\mathrm{cyc}}^{-2m_a} = 1$ by Step 2. So $\kappa_a \chi_{\mathrm{cyc}}^{-m_a}$ maps V to $\{\pm 1\}$; its kernel in V is closed of index at most 2, hence open in V and in I, and $\kappa_a \chi_{\mathrm{cyc}}^{-m_a}$ is trivial on it. With Step 1 this proves the lemma. □

Lemma 53.29. *Let ℓ be a prime, $n \geq 1$, $r\colon G_{\mathbb{Q}} \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a homomorphism, and $K, K' \subset \overline{\mathbb{Q}}$ imaginary quadratic fields such that $r|_{G_K}$ and $r|_{G_{K'}}$ are irreducible. Then there is an imaginary quadratic field $K'' \subset \overline{\mathbb{Q}}$ with $K'' \neq K$, $K'' \neq K'$, such that $r|_{G_{KK''}}$ and $r|_{G_{K'K''}}$ are irreducible.*

Proof. Symbols introduced here are local to this proof.

Step 1: restriction to a subgroup of index 2. Let G be a group, $\rho\colon G \to \mathrm{GL}(V)$ an irreducible representation on a finite-dimensional $\overline{\mathbb{Q}}_\ell$-vector space, $H \subseteq G$ a subgroup of index 2 and $\eta\colon G \to \{\pm 1\}$ the character with kernel H. We show: if $\rho|_H$ is reducible, then $\rho \otimes \eta \cong \rho$. Let $W \subseteq V$ be a non-zero proper H-invariant subspace and $g \in G \setminus H$. As H is normal, $\rho(g)W$ is H-invariant, and $\rho(g)\rho(g)W = W$ since $g^2 \in H$; as $G = H \cup gH$, the subspaces $W + \rho(g)W$ and $W \cap \rho(g)W$ are G-invariant. By irreducibility, $W + \rho(g)W = V$, and $W \cap \rho(g)W \neq V$ (it lies in $W \neq V$), so $W \cap \rho(g)W = 0$ and $V = W \oplus \rho(g)W$. Let $A \in \mathrm{GL}(V)$ be 1 on W and -1 on $\rho(g)W$. Every $s \in H$ preserves W, and $\rho(s)\rho(g)W = \rho(g)\rho(g^{-1}sg)W = \rho(g)W$ as $g^{-1}sg \in H$; so $A\rho(s) = \rho(s)A$. Every $s \in G \setminus H$ satisfies $s \in gH$ and $sg \in H$, so $\rho(s)W = \rho(g)W$ and $\rho(s)\rho(g)W = \rho(sg)W = W$; so $A\rho(s) = -\rho(s)A$. Hence $A\rho(s)A^{-1} = \eta(s)\rho(s)$ for all $s \in G$, i.e. A is an isomorphism $\rho \to \rho \otimes \eta$.

Step 2: few characters fix ρ. With G, ρ, V as in Step 1 and $\dim V = n$, the set $X(\rho)$ of homomorphisms $\chi\colon G \to \overline{\mathbb{Q}}_\ell^\times$ with $\rho \otimes \chi \cong \rho$ has at most n^2 elements. Indeed, let G act on $\mathrm{End}(V)$ by $s \cdot B = \rho(s) B \rho(s)^{-1}$. For $\chi \in X(\rho)$ an isomorphism $A_\chi\colon \rho \to \rho \otimes \chi$ is a non-zero $A_\chi \in \mathrm{End}(V)$ with $A_\chi \rho(s) = \chi(s)\rho(s)A_\chi$, i.e. $s \cdot A_\chi = \chi(s)^{-1} A_\chi$. Common eigenvectors of G for pairwise distinct characters are linearly independent, so $|X(\rho)| \leq \dim \mathrm{End}(V) = n^2$.

Step 3: distinct fields give distinct characters. For an imaginary quadratic field $F \neq K$, KF is biquadratic over $\mathbb{Q}$, $G_{KF} = G_K \cap G_F$ has index 2 in G_K; let $\eta_F\colon G_K \to \{\pm 1\}$ be the character with kernel G_{KF}. If $F_1 \neq F_2$ are imaginary quadratic fields different from K with $\eta_{F_1} = \eta_{F_2}$, then $G_{KF_1} = G_{KF_2}$, so $KF_1 = KF_2 =: M$ by Galois theory. Writing $K = \mathbb{Q}(\sqrt{-a})$,

$F_1 = \mathbb{Q}(\sqrt{-b})$ with $a, b > 0$, the three quadratic subfields of M are K, F_1 and the real field $\mathbb{Q}(\sqrt{ab})$; so the only imaginary quadratic subfield of M other than K is F_1, and $F_2 = F_1$, a contradiction. Hence $F \mapsto \eta_F$ is injective on imaginary quadratic fields $F \neq K$, and likewise $F \mapsto \eta'_F$ (the character of $G_{K'}$ with kernel $G_{K'F}$) on those $F \neq K'$.

Step 4: choice of K''. Let B be the set of imaginary quadratic fields $F \notin \{K, K'\}$ with $\eta_F \in X(r|_{G_K})$ or $\eta'_F \in X(r|_{G_{K'}})$. By Steps 2 and 3, $|B| \leq 2n^2$. There are infinitely many imaginary quadratic fields (for instance $\mathbb{Q}(\sqrt{-p})$, p prime), so there is an imaginary quadratic $K'' \notin B \cup \{K, K'\}$. As $\eta_{K''} \notin X(r|_{G_K})$, Step 1 (for $G = G_K$, $H = G_{KK''}$, $\rho = r|_{G_K}$, irreducible by hypothesis) shows that $r|_{G_{KK''}}$ is irreducible; in the same way $r|_{G_{K'K''}}$ is irreducible. □

Lemma 53.30. *Let ℓ be an odd prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $K \subset \overline{\mathbb{Q}}$ an imaginary quadratic field, $c \in G_\mathbb{Q}$ a complex conjugation, k an integer and $\varphi\colon G_\mathbb{Q} \to \overline{\mathbb{Q}}_\ell^\times$ a continuous character of finite order. Then there is a continuous character $\psi\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$, algebraic for ι, such that $\psi(s)\psi(csc) = \chi_{\mathrm{cyc}}(s)^k\varphi(s)$ for all $s \in G_K$, and such that $\psi(I_{\bar{v}} \cap G_K)$ is finite for every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above a prime $p \neq \ell$.*

Proof. Symbols introduced here are local to this proof. Let $\eta_K\colon G_\mathbb{Q} \to \{\pm 1\}$ be the character with kernel G_K; as K is imaginary, $c \notin G_K$ and $\eta_K(c) = -1$.

Step 1: the kernel of the transfer. Let $\mathcal{V}\colon G_\mathbb{Q}^{ab} \to G_K^{ab}$ be the transfer. With the coset representatives $1, c$ of G_K in $G_\mathbb{Q}$ one has $\mathcal{V}(s) = s \cdot csc$ modulo commutators for $s \in G_K$, and $\mathcal{V}(c) = c^2 = 1$. We use from global class field theory ([11], [190]): $\mathrm{Art}_\mathbb{Q}$ and Art_K are surjective, their kernels are the connected components of $C_\mathbb{Q}$ and C_K, and the connected component of C_K is the closure of the image of $K_\infty^\times = \mathbb{C}^\times$; Art_K composed with the map $C_\mathbb{Q} \to C_K$ induced by $\mathbb{A}_\mathbb{Q}^\times \subseteq \mathbb{A}_K^\times$ is $\mathcal{V} \circ \mathrm{Art}_\mathbb{Q}$; and on the image of $\mathbb{R}^\times$ in $C_\mathbb{Q}$, $\mathrm{Art}_\mathbb{Q}$ is the local Artin map $\mathbb{R}^\times \to \mathrm{Gal}(\mathbb{C}/\mathbb{R})$, which sends -1 to complex conjugation, followed by the inclusion of a decomposition group at infinity.

We claim that $\ker \mathcal{V} = \{1, \bar{c}\}$, where $\bar{c}$ is the image of c (all complex conjugations are conjugate in $G_\mathbb{Q}$, so they have the same image $\bar{c}$ in $G_\mathbb{Q}^{ab}$). We saw $\bar{c} \in \ker \mathcal{V}$. Let $g \in \ker \mathcal{V}$ and write $g = \mathrm{Art}_\mathbb{Q}(a)$ with $a \in \mathbb{A}_\mathbb{Q}^\times$. Then $\mathrm{Art}_K(a) = 1$, so there are $\alpha_i \in K^\times$ and $z_i \in \mathbb{C}^\times$ with $\alpha_i z_i \to a$ in $\mathbb{A}_K^\times$; on finite components, $\alpha_i \to a_f$ in the finite ideles $\mathbb{A}_{K,f}^\times$. Let $x \mapsto \bar{x}$ be the automorphism of $\mathbb{A}_K^\times$ induced by the non-trivial automorphism of K; it fixes $\mathbb{A}_\mathbb{Q}^\times$ and preserves $K^\times$. Then $\beta_i = \bar{\alpha}_i/\alpha_i \in K^\times$ converges to $\bar{a}_f/a_f = 1$ in $\mathbb{A}_{K,f}^\times$. The unit ideles form an open subgroup of $\mathbb{A}_{K,f}^\times$, so for large i, β_i is a unit at every finite place, i.e. $\beta_i \in \mathcal{O}_K^\times$, a finite group as K is imaginary quadratic; a sequence in a finite subset of a Hausdorff group converging to 1 is eventually 1, so $\alpha_i \in \mathbb{Q}^\times$ for large i. Now $\mathbb{Q}^\times$ is discrete in $\mathbb{A}_{\mathbb{Q},f}^\times$ ($\mathbb{Q}^\times \cap \widehat{\mathbb{Z}}^\times = \{\pm 1\}$ and $\widehat{\mathbb{Z}}^\times$ is open), and $\mathbb{A}_{\mathbb{Q},f}^\times$ is a closed subgroup of $\mathbb{A}_{K,f}^\times$ with the induced topology; so the convergent sequence α_i is eventually constant, equal to some $q \in \mathbb{Q}^\times$, and $a_f = q$. Then $b = q^{-1}a \in \mathbb{A}_\mathbb{Q}^\times$ has trivial finite components, so $b \in \mathbb{R}^\times$, and $g = \mathrm{Art}_\mathbb{Q}(b) \in \{1, \bar{c}\}$.

Step 2: the part of finite order. Since $\varphi(c)^2 = \varphi(c^2) = 1$, put $\varphi_1 = \varphi$ if $\varphi(c) = 1$ and $\varphi_1 = \varphi\eta_K$ if $\varphi(c) = -1$; then $\varphi_1(c) = 1$ and $\varphi_1 = \varphi$ on G_K. As a character of $G_\mathbb{Q}^{ab}$, φ_1 is trivial on $\ker \mathcal{V}$ by Step 1. The image $H = \mathcal{V}(G_\mathbb{Q}^{ab})$ is a closed subgroup of G_K^{ab}, and $\mathcal{V}$ induces a continuous bijection $G_\mathbb{Q}^{ab}/\ker \mathcal{V} \to H$ of compact Hausdorff groups, hence a homeomorphism; so $\lambda_0(\mathcal{V}(g)) = \varphi_1(g)$ defines a continuous character λ_0 of H of finite order. Its kernel is open in H, so it contains $H \cap N$ for an open subgroup N of the profinite group G_K^{ab}; λ_0 factors through the subgroup $H/(H \cap N)$ of the finite abelian group G_K^{ab}/N and extends to a character of G_K^{ab}/N with values in the divisible group of roots of unity of $\overline{\mathbb{Q}}_\ell^\times$. This gives a continuous character

$\lambda\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$ of finite order with $\lambda \circ \mathcal{V} = \varphi_1$, so that for $s \in G_K$

$$\lambda(s)\lambda(csc) = \lambda(\mathcal{V}(s)) = \varphi_1(s) = \varphi(s).$$

Step 3: the character. By Lemma 49.11 (ℓ odd) there is a continuous character $\kappa_K\colon G_K \to \overline{\mathbb{Q}}_\ell^\times$, algebraic for ι, with (Ik1)–(Ik3). Put $\psi = \kappa_K^{-k}\lambda$. For $s \in G_K$, by (Ik1) and Step 2,

$$\psi(s)\psi(csc) = \big(\kappa_K(s)\kappa_K(csc)\big)^{-k}\lambda(s)\lambda(csc) = \chi_{\mathrm{cyc}}(s)^k\varphi(s).$$

λ has finite order, so $\iota \circ \lambda \circ \mathrm{Art}_K$ is a Hecke character of finite order, which is algebraic; products and inverses of characters algebraic for ι are algebraic for ι (the corresponding algebraic Hecke characters multiply); so ψ is algebraic for ι. Finally let $\bar{v}$ lie above a prime $p \neq \ell$: κ_K is trivial on $I_{\bar{v}} \cap G_K$ if $p \nmid d_K$ by (Ik2), and of finite order there if $p \mid d_K$ by (Ik3); λ has finite order; so $\psi(I_{\bar{v}} \cap G_K)$ is finite. □

53.3 Propagation in rank four: local charts

This subsection proves the propagation theorem in rank four, Theorem 53.31, as Subsections 49.2–49.4 prove it in ranks two and three, and with two of their lemmas, on chains of components and on one-dimensional primes (Lemma 49.28, Lemma 49.35). Its main input is Proposition 53.32: the completed local rings of a space at residual pairs good in case (III) are flat completions with a presentation that obeys the Euler-characteristic count (Proposition 53.34, Lemma 53.35, Lemma 53.36), and their reducible and coincidence loci have small dimension (Proposition 53.39, Lemma 53.33). The bound for the reducible loci is the core. It goes through reducible tangent spaces graded by a symplectic cocharacter (Definition 53.38, Definition 53.40): they do not grow under degeneration along the grading (Lemma 53.43), and at the diagonal limit pairs at most one odd root contributes to the degree (Lemma 53.44), which gives the tangent bound Lemma 53.42 and with it Lemma 53.41. Off the reducibility ideals a lift of a residual pair is irreducible (Lemma 53.45), and the fibre dimension over the Hecke side is controlled at irreducible primes (Lemma 53.47).

Theorem 53.31. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with $d = [F : \mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \dots)$ a space for $(\mathscr{T}, \mathcal{O}')$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\mathfrak{J} \subseteq B$ an ideal modular for ι, and $C \geq 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d with $30(C+1)^2 \leq d$. Let $x_0, x_1\colon A \to \mathbb{F}_{\mathcal{O}'}$ be $\mathcal{O}'$-algebra homomorphisms such that $x_0(P)$ is a residual pair and there is a chain in case (III) from $x_0(P)$ to $x_1(P)$. If $\mathfrak{J}$ is somewhere at $\ker x_1$, then $\mathfrak{J}$ is everywhere at $\ker x_0$.*

Proof. The argument is commutative algebra on the rings of the space and its charts, in the pattern of the unitary Theorem 49.12; it uses no automorphy of the points of $\mathfrak{D}$, nor over L; the only Galois-theoretic and modularity input is Proposition 53.32. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}'}$, ϖ' for a uniformiser of $\mathcal{O}'$, $\sigma = \#\Sigma$ and $N = 2d + 1 - 2\sigma$. As C is a Selmer bound, $1 \leq \sigma \leq C$, and $d \geq 30(C+1)^2$ gives

$$d + 20C + 1 < N, \qquad 2d + 1 - d/\sigma + 2 + 4\sigma < N. \tag{53.1}$$

Part A: one residual point. Let $x\colon A \to \mathbb{F}$ be an $\mathcal{O}'$-algebra homomorphism such that $x(P)$ is a residual pair good in case (III), and suppose $\mathfrak{J}$ is somewhere at $\ker x$. We show that $\mathfrak{J}$ is everywhere at $\ker x$. Let R, f be as in Proposition 53.32 and $\phi = f|_B$.

(A1) *Minimal primes.* By (Vx1) (f is flat with $f^{-1}(\mathfrak{m}_R) = \ker x$) and going down, (a) for a minimal prime $\mathcal{P}$ of R, $f^{-1}(\mathcal{P})$ is a minimal prime of A contained in $f^{-1}(\mathfrak{m}_R) = \ker x$; (b) every

minimal prime $\eta \subseteq \ker x$ of A is $f^{-1}(\mathcal{P})$ for a minimal prime $\mathcal{P}$ of R (going down from $\mathfrak{m}_R$ gives $\mathcal{P}'$ with $f^{-1}(\mathcal{P}') = \eta$; a minimal $\mathcal{P} \subseteq \mathcal{P}'$ has $f^{-1}(\mathcal{P}) \subseteq \eta$ prime, hence equal). For a prime $\mathcal{P}$ of R and $\eta = f^{-1}(\mathcal{P})$: $\mathfrak{J}A \subseteq \eta$ if and only if $\phi(\mathfrak{J}) \subseteq \mathcal{P}$. So it suffices to show: if $\phi(\mathfrak{J}) \subseteq \mathcal{P}_0$ for one minimal prime $\mathcal{P}_0$ of R, then for all.

(A2) *Chains of minimal primes.* By (Vx2), $R \cong S/I$ with $S = \mathcal{O}'[[X_1, \dots, X_a]]$, a complete Noetherian local domain of dimension $a+1$, and I generated by b elements, which lie in $\mathfrak{m}_S$ (the preimage of $\mathfrak{m}_R$). Since $b + 2 + 2d \le a + 2\sigma$, $\dim S \ge (N+1) + 1 + b$, and Lemma 49.28 with $D = N+1$, $h = b$ applies; through the correspondence between primes of R and primes of S containing I, any two minimal primes $\mathcal{P}, \mathcal{Q}$ of R are joined by minimal primes $\mathcal{P} = \mathcal{P}_0, \dots, \mathcal{P}_k = \mathcal{Q}$ with $\dim R/(\mathcal{P}_{t-1} + \mathcal{P}_t) \ge N+1$. It therefore suffices to show, for minimal primes $\mathcal{P}, \mathcal{Q}$ of R with $\dim R/(\mathcal{P} + \mathcal{Q}) \ge N+1$: if $\phi(\mathfrak{J}) \subseteq \mathcal{P}$, then $\phi(\mathfrak{J}) \subseteq \mathcal{Q}$.

(A3) *A nice prime.* Let $\mathfrak{a}_1, \dots, \mathfrak{a}_s$ be the ideals of (Vx3). For $v \in \Sigma$ and $i \ne j$ let $\mathfrak{c}_{v,i,j}$ be the ideal generated by the $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s))$, $s \in U_v$, and $\mathfrak{b}_{v,i,j} = \phi(\mathfrak{J})R + \varpi' R + \mathfrak{c}_{v,i,j}$. Let $\mathcal{L}$ be the finite set of minimal primes $\mathfrak{q}$ of the ideals $\mathfrak{b}_{v,i,j}$ (R is Noetherian) that contain no $\mathfrak{a}_k$. For $\mathfrak{q} \in \mathcal{L}$: $\phi^{-1}(\mathfrak{q})$ contains $\mathfrak{J}$, $\mathfrak{m}_{\mathcal{O}'}B$ and the $\psi^B_{v,i}(s) - \psi^B_{v,j}(s)$, $s \in U_v$ (by (Zq2) $\phi(\psi^B_{v,i}(s)) = f(\psi^P_{v,i}(s))$), so (Vx0) gives $\dim B/\phi^{-1}(\mathfrak{q}) \le 2d + 1 - d/\sigma$, and (Vx3)(a) gives $\dim R/\mathfrak{q} \le 2d + 1 - d/\sigma + 2 + 4\sigma < N$ by (53.1). Also $\dim R/\mathfrak{a}_k \le d + 20C + 1 < N$. Now Lemma 49.35, applied to ϖ', N, the ideals $\mathfrak{a}_k$ and the members of $\mathcal{L}$, and $I = \mathcal{P} + \mathcal{Q}$, gives a prime $\mathfrak{p} \supseteq \mathcal{P} + \mathcal{Q}$ with $\dim R/\mathfrak{p} = 1$, $\varpi' \in \mathfrak{p}$, containing no $\mathfrak{a}_k$ and no member of $\mathcal{L}$. Then $\mathfrak{p}$ contains no $\mathfrak{b}_{v,i,j}$: otherwise it would contain a minimal prime $\mathfrak{q}$ of $\mathfrak{b}_{v,i,j}$, which contains some $\mathfrak{a}_k$ (then so does $\mathfrak{p}$) or lies in $\mathcal{L}$. As $\mathfrak{p} \supseteq \mathcal{P} \supseteq \phi(\mathfrak{J})$ and $\varpi' \in \mathfrak{p}$, it follows that $\mathfrak{c}_{v,i,j} \not\subseteq \mathfrak{p}$ for all v, $i \ne j$; by (Vx3)(b) the matrices $f(r_P(g))$ modulo $\mathfrak{p}$ span M_4 over the fraction field of $R/\mathfrak{p}$.

(A4) *The curve point.* The ring $R/\mathfrak{p}$ is a complete Noetherian local domain of dimension 1 with residue field $\mathbb{F}$ and of characteristic ℓ ($\ell \in \varpi'\mathcal{O}'$). Its normalisation is finite over it, hence a complete local normal domain of dimension 1, i.e. a complete discrete valuation ring of characteristic ℓ with finite residue field $k \supseteq \mathbb{F}$, so isomorphic to $k[[t]]$; this gives an injective local homomorphism $j\colon R/\mathfrak{p} \to k[[t]]$, and k is an $\mathcal{O}'$-algebra through $\mathcal{O}' \to \mathbb{F} \subseteq k$. Let $y\colon A \to k[[t]]$ be f followed by $R \to R/\mathfrak{p} \xrightarrow{j} k[[t]]$, an $\mathcal{O}'$-algebra homomorphism. Then: $y(\mathfrak{m}_B) \subseteq tk[[t]]$ (x kills $\mathfrak{m}_B$, as $x|_B$ is an $\mathcal{O}'$-algebra map from the local ring B to $\mathbb{F}$, so $f(\mathfrak{m}_B) \subseteq \mathfrak{m}_R$ by (Vx1), and j is local); $y(\mathfrak{J}) = 0$ ($\phi(\mathfrak{J}) \subseteq \mathfrak{p}$); for all v and $i \ne j$ some $s \in U_v$ has $y(\psi^P_{v,i}(s)) \ne y(\psi^P_{v,j}(s))$ ($\mathfrak{c}_{v,i,j} \not\subseteq \mathfrak{p}$ and j is injective); and $y \circ r_P$ is irreducible over the fraction field of $k[[t]]$, which contains that of $R/\mathfrak{p}$ (A3). By (Jq2), $\mathfrak{J}$ is local at y. The prime $\phi^{-1}(\mathcal{Q})$ of B satisfies $y(\phi^{-1}(\mathcal{Q})) \subseteq j(\mathcal{Q}/\mathfrak{p}) = 0$ since $\mathcal{Q} \subseteq \mathfrak{p}$; hence $\mathfrak{J} \subseteq \phi^{-1}(\mathcal{Q})$, i.e. $\phi(\mathfrak{J}) \subseteq \mathcal{Q}$. With (A1), (A2) this proves Part A.

Part B: along the chain. Let $c_0 = x_0(P), c_1, \dots, c_m = x_1(P)$ be a chain in case (III), with c_{t-1}, c_t linked by a residual pair L_t with values in $\mathbb{F}[X]$ ($1 \le t \le m$). By (Zq5) there are $\mathcal{O}'$-algebra homomorphisms $f_t\colon A \to \mathbb{F}[X]$ with $f_t(P) = L_t$ and $f_t(\mathfrak{m}_B) = 0$. Two $\mathcal{O}'$-algebra homomorphisms $A \to \mathbb{F}$ that kill $\mathfrak{m}_B$ and agree on the entries of P are equal: they agree on B (both are the reduction $B \to B/\mathfrak{m}_B = \mathbb{F}$) and the entries of P generate A over B (Zq1). Every $\mathcal{O}'$-algebra homomorphism $A \to \mathbb{F}$ kills $\mathfrak{m}_B$ (as in (A4)). Put $x^{(t)} = \mathrm{ev}_0 \circ f_{t+1}$ for $t < m$ and $x^{(m)} = x_1$; then $x^{(t)}(P) = c_t$, $x^{(0)} = x_0$ and $\mathrm{ev}_1 \circ f_t = x^{(t)}$ for $1 \le t \le m$. Each c_t is a residual pair good in case (III). We show by descending induction on t that $\mathfrak{J}$ is everywhere at $\ker x^{(t)}$. For $t = m$: by hypothesis $\mathfrak{J}$ is somewhere at $\ker x_1$, and Part A applies. For $t < m$, the ideal $\ker f_{t+1}$ is a prime of A ($\mathbb{F}[X]$ is a domain) contained in $\ker x^{(t)}$ and in $\ker x^{(t+1)}$; a minimal prime $\eta \subseteq \ker f_{t+1}$ of A exists and lies in $\ker x^{(t+1)}$, so it contains $\mathfrak{J}A$ by the induction hypothesis; as $\eta \subseteq \ker x^{(t)}$, $\mathfrak{J}$ is somewhere at $\ker x^{(t)}$, and Part A gives everywhere. For $t = 0$ this is the assertion. □

Proposition 53.32. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit*

and deep auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F : \mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\mathfrak{J} \subseteq B$ an ideal modular for ι, and $C \geq 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d with $30(C+1)^2 \leq d$. Then:

(Vx0) *$d/\#\Sigma$ is an integer, and for every $v \in \Sigma$, all $i \neq j$ and every prime $\mathfrak{q}$ of B containing $\mathfrak{J}$, $\mathfrak{m}_{\mathcal{O}'}B$ and $\psi^B_{v,i}(s) - \psi^B_{v,j}(s)$ for all $s \in U_v$,*

$$\dim B/\mathfrak{q} + d/\#\Sigma \leq 2d + 1.$$

Moreover, for every $\mathcal{O}'$-algebra homomorphism $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ such that $x(P)$ is a residual pair good in case (III), there are $R \in \mathrm{CNL}_{\mathcal{O}'}$ and an $\mathcal{O}'$-algebra homomorphism $f\colon A \to R$ such that:

(Vx1) *R is a flat A-module through f, and $f^{-1}(\mathfrak{m}_R) = \ker x$;*

(Vx2) *there are integers $a, b \geq 0$ with $b + 2 + 2d \leq a + 2\#\Sigma$ and a surjective $\mathcal{O}'$-algebra homomorphism $\mathcal{O}'[[X_1, \dots, X_a]] \to R$ whose kernel is generated by b elements;*

(Vx3) *there are finitely many ideals $\mathfrak{a}_1, \dots, \mathfrak{a}_s$ of R with $\dim R/\mathfrak{a}_k \leq d + 20C + 1$ for all k such that every prime $\mathfrak{p}$ of R containing none of the $\mathfrak{a}_k$ satisfies:*

- *(a) if $\mathfrak{p}$ contains $f(\mathfrak{J})R$, $\mathfrak{m}_{\mathcal{O}'}R$ and, for some $v \in \Sigma$ and $i \neq j$, all $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s))$ with $s \in U_v$, then $\dim R/\mathfrak{p} \leq \dim B/\phi^{-1}(\mathfrak{p}) + 2 + 4\#\Sigma$, where $\phi\colon B \to A \xrightarrow{f} R$;*
- *(b) either the matrices $f(r_P(g))$ modulo $\mathfrak{p}$, $g \in G_F$, span M_4 over the fraction field of $R/\mathfrak{p}$, or there are $v \in \Sigma$ and $i \neq j$ with $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s)) \in \mathfrak{p}$ for all $s \in U_v$.*

Proof. (Vx0). A fit tower is good, and an ideal modular for ι satisfies (Jq1): $\mathfrak{m}_B^n \subseteq \mathfrak{J} + \mathfrak{m}_{\mathcal{O}'}B + (\psi^B_{v,i}(s) - 1 : \ v \in \Sigma,\ 1 \leq i \leq 4,\ s \in I_v)$ for some $n \geq 1$. These are the hypotheses of Lemma 53.33, which gives that $d/\#\Sigma$ is an integer and the inequality of (Vx0).

(Vx1)–(Vx3). Under the hypotheses of the statement, Proposition 53.34 gives, for every x as in the statement, R and f with (Yw1)–(Yw3), which are (Vx1)–(Vx3). □

Lemma 53.33. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a good auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F : \mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, and $\mathfrak{J} \subseteq B$ an ideal such that $\mathfrak{m}_B^n \subseteq \mathfrak{J} + \mathfrak{m}_{\mathcal{O}'}B + (\psi^B_{v,i}(s) - 1 : \ v \in \Sigma,\ 1 \leq i \leq 4,\ s \in I_v)$ for some $n \geq 1$. Then $d/\#\Sigma$ is an integer, and for every $v \in \Sigma$, all $i \neq j$ and every prime $\mathfrak{q}$ of B containing $\mathfrak{J}$, $\mathfrak{m}_{\mathcal{O}'}B$ and $\psi^B_{v,i}(s) - \psi^B_{v,j}(s)$ for all $s \in U_v$,*

$$\dim B/\mathfrak{q} + d/\#\Sigma \leq 2d + 1.$$

Proof. Step 0: the local degree. The places of F above ℓ correspond bijectively to the G_F-orbits of places of $\overline{\mathbb{Q}}$ above ℓ, hence to Σ. As $F/\mathbb{Q}$ is Galois, all of them have the same local degree $\delta = [F_u : \mathbb{Q}_\ell]$, and $\#\Sigma \cdot \delta = d$.

Step 1: the local characters. For $u \in \Sigma$ and $1 \leq m \leq 4$, the map $s \mapsto \psi^B_{u,m}(s)$ on D_u is a continuous homomorphism to $B^\times$ for the $\mathfrak{m}_B$-adic topology, trivial on μ_u, with $\psi^B_{u,m}(t) - 1 \in \mathfrak{m}_B$ for $t \in I_u$, and $\psi^B_{u,m}(s)\psi^B_{u,5-m}(s) = \theta(s)$ (image in B). Indeed $B \to A$ is injective (Zq1) and maps $\psi^B_{u,m}(s)$ to $\psi^P_{u,m}(s)$ (Zq2), the diagonal entries of the upper triangular $n_u^{-1}r_P(s)n_u$ (Mq4), which is a homomorphism in s, has similitude $\theta(s)$ (as n_u has similitude 1), and for an upper

triangular Y with ${}^tYJ_4Y = \mu J_4$ the entries $(1,4)$ and $(2,3)$ give $Y_{11}Y_{44} = Y_{22}Y_{33} = \mu$; triviality on μ_u is (Mq4); continuity and the congruence modulo $\mathfrak{m}_B$ to $\bar\chi_m^{\mathscr{T}}(t)$ are (Zq2), and $\bar\chi_m^{\mathscr{T}}(t) = 1$ for $t \in I_u$ by (Oq6).

Step 2: pinning elements. Call R *admissible* if it is a complete Noetherian local ring with finite residue field of characteristic ℓ; then $1+\mathfrak{m}_R$ is a pro-ℓ group. (P1) For every $u \in \Sigma$ there are $s_{u,1}, \dots, s_{u,\delta} \in I_u$ such that every continuous homomorphism $\kappa\colon D_u \to R^\times$, R admissible, with $\kappa(I_u) \subseteq 1+\mathfrak{m}_R$, $\kappa(\mu_u) = 1$ and $\kappa(s_{u,k}) = 1$ for all k, is trivial on I_u. Indeed, κ factors through D_u^{ab}, and by local class field theory the image of I_u in D_u^{ab} is topologically isomorphic to $\mathcal{O}_{F_u}^\times = \mu_{q-1} \times (1+\mathfrak{m}_{F_u})$, with $1+\mathfrak{m}_{F_u} \cong \Theta \times \mathbb{Z}_\ell^\delta$, Θ a finite ℓ-group (q the residue cardinality; structure of the units of a local field). κ kills μ_{q-1} (order prime to ℓ, target pro-ℓ); every $t \in I_u$ whose image lies in Θ has $t^{\ell^a} \in \overline{[D_u, D_u]}$ for some a, so $t \in \mu_u$ and $\kappa(t) = 1$; choose $s_{u,k} \in I_u$ whose images form a $\mathbb{Z}_\ell$-basis of the factor $\mathbb{Z}_\ell^\delta$; by continuity κ kills this factor. (P2) For $v \in \Sigma$ there is $s_0 \in I_v$ such that any two continuous homomorphisms $\kappa, \kappa'\colon D_v \to R^\times$, R admissible, with values in $1+\mathfrak{m}_R$ on I_v, equal on U_v and at s_0, are equal on I_v. Indeed, $\bar r_0(I_v) = 1$ by (Oq6), so $U_v = I_v \cap \ker\chi_{\mathrm{cyc}}$, and $\lambda = \kappa/\kappa'$ factors through $I_v/U_v \cong \chi_{\mathrm{cyc}}(I_v)$, a closed subgroup of $\mathbb{Z}_\ell^\times = \mu_{\ell-1} \times (1+\ell\mathbb{Z}_\ell)$, hence of the form $H_1 \times H_2$ with $H_1 \subseteq \mu_{\ell-1}$ and H_2 closed in $1+\ell\mathbb{Z}_\ell \cong \mathbb{Z}_\ell$, so procyclic; λ kills H_1; take s_0 with $\chi_{\mathrm{cyc}}(s_0) = (1, h_2)$, h_2 a topological generator of H_2; then $\lambda(s_0) = 1$ forces $\lambda = 1$.

Step 3: parameters. Fix v, $i \neq j$, $\mathfrak{q}$ as in the statement. Choose an index a: $a = j$ if $j \neq 5-i$, and otherwise any $a \notin \{i, 5-i\}$; in both cases $\{a, 5-a, i, 5-i\} = \{1,2,3,4\}$. Consider the family x of elements of B:

$$\psi^B_{u,a}(s_{u,k}) - 1 \ (u \in \Sigma,\ k \le \delta), \qquad \psi^B_{u,i}(s_{u,k}) - 1 \ (u \in \Sigma \setminus \{v\},\ k \le \delta), \qquad \psi^B_{v,i}(s_0) - \psi^B_{v,j}(s_0),$$

with $\#\Sigma\delta + (\#\Sigma - 1)\delta + 1 = 2d - \delta + 1$ members, all in $\mathfrak{m}_B$ (Step 1). *Claim: the only prime $\mathfrak{p}$ of B containing $\mathfrak{q}$ and all members of x is $\mathfrak{m}_B$.* Let $\mathfrak{p}$ be such, $R = B/\mathfrak{p}$ (admissible: $B \in \mathrm{CNL}_{\mathcal{O}'}$), and $\kappa_{u,m}$ the composite of $\psi^B_{u,m}$ with $B \to R$: continuous, values in $1+\mathfrak{m}_R$ on I_u, trivial on μ_u, with $\kappa_{u,m}\kappa_{u,5-m} = 1$ on I_u (the image of $\theta(t)$ in R is its residue, as $\mathfrak{m}_{\mathcal{O}'}B \subseteq \mathfrak{p}$, and $\bar\theta(t) = 1$ by (Oq6)). By (P1), $\kappa_{u,a} = 1$ on I_u for all u, and $\kappa_{u,i} = 1$ on I_u for $u \neq v$. By (P2), $\kappa_{v,i} = \kappa_{v,j}$ on I_v ($\mathfrak{p} \supseteq \mathfrak{q}$ contains $\psi^B_{v,i} - \psi^B_{v,j}$ on U_v, and the last member of x). If $a = j$, then $\kappa_{v,i} = \kappa_{v,a} = 1$ on I_v; otherwise $j = 5-i$ and $\kappa_{v,i}^2 = \kappa_{v,i}\kappa_{v,5-i} = 1$ on I_v, and an element $y \in 1+\mathfrak{m}_R$ with $y^2 = 1$ is 1 ($y+1 \equiv 2$ is a unit, ℓ odd). So $\kappa_{u,i} = 1$ and $\kappa_{u,a} = 1$ on I_u for all u, hence also $\kappa_{u,5-i} = \kappa_{u,5-a} = 1$, i.e. all $\psi^B_{u,m}(t) - 1$ ($t \in I_u$) lie in $\mathfrak{p}$. With $\mathfrak{J} \subseteq \mathfrak{q} \subseteq \mathfrak{p}$ and $\mathfrak{m}_{\mathcal{O}'}B \subseteq \mathfrak{p}$, the hypothesis gives $\mathfrak{m}_B^n \subseteq \mathfrak{p}$, so $\mathfrak{p} = \mathfrak{m}_B$.

Step 4: the bound. By the claim, the images of the members of x generate an ideal of the Noetherian local ring $B/\mathfrak{q}$ whose radical is the maximal ideal. By Krull's dimension theorem (the dimension of a Noetherian local ring is at most the number of generators of any ideal primary to its maximal ideal), $\dim B/\mathfrak{q} \le 2d - \delta + 1$, i.e. $\dim B/\mathfrak{q} + d/\#\Sigma \le 2d + 1$. □

Proposition 53.34. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F:\mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\mathfrak{J} \subseteq B$ an ideal modular for ι, and $C \ge 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d with $30(C+1)^2 \le d$. Then for every $\mathcal{O}'$-algebra homomorphism $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ such that $x(P)$ is a residual pair good in case (III), there are $R \in \mathrm{CNL}_{\mathcal{O}'}$ and an $\mathcal{O}'$-algebra homomorphism $f\colon A \to R$ such that:*

(Yw1) *R is a flat A-module through f, and $f^{-1}(\mathfrak{m}_R) = \ker x$;*

(Yw2) *there are integers $a, b \ge 0$ with $b + 2 + 2d \le a + 2\#\Sigma$ and a surjective $\mathcal{O}'$-algebra homomorphism $\mathcal{O}'[[X_1, \dots, X_a]] \to R$ whose kernel is generated by b elements;*

(Yw3) *there are finitely many ideals $\mathfrak{a}_1, \dots, \mathfrak{a}_s$ of R with $\dim R/\mathfrak{a}_k \le d + 20C + 1$ for all k such that every prime $\mathfrak{p}$ of R containing none of the $\mathfrak{a}_k$ satisfies:*

- *(a) if $\mathfrak{p}$ contains $f(\mathfrak{J})R$, $\mathfrak{m}_{\mathcal{O}'}R$ and, for some $v \in \Sigma$ and $i \ne j$, all $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s))$ with $s \in U_v$, then $\dim R/\mathfrak{p} \le \dim B/\phi^{-1}(\mathfrak{p}) + 2 + 4\#\Sigma$, where $\phi\colon B \to A \xrightarrow{f} R$;*
- *(b) either the matrices $f(r_P(g))$ modulo $\mathfrak{p}$, $g \in G_F$, span M_4 over the fraction field of $R/\mathfrak{p}$, or there are $v \in \Sigma$ and $i \ne j$ with $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s)) \in \mathfrak{p}$ for all $s \in U_v$.*

Proof. Fix x as in the statement and put $\mathfrak{m} = \ker x$. We take for R the completion $\widehat{A} = \varprojlim_n A/\mathfrak{m}^n$ of A at $\mathfrak{m}$ and for $f\colon A \to R$ the canonical homomorphism; (Yw2) and (Yw3) for this pair are Lemma 53.35 and Proposition 53.39, whose hypotheses are those of the statement (Lemma 53.35 without ι and $\mathfrak{J}$). It remains to show that $R \in \mathrm{CNL}_{\mathcal{O}'}$ and (Yw1).

Step 1: A is Noetherian and $\mathfrak{m}$ is maximal with residue field $\mathbb{F}_{\mathcal{O}'}$. By (Zq1), $B \in \mathrm{CNL}_{\mathcal{O}'}$ is Noetherian and A is a B-algebra of finite type, hence a quotient of a polynomial ring in finitely many variables over B; by Hilbert's basis theorem A is Noetherian. The homomorphism x is $\mathcal{O}'$-linear, so its image contains the image of $\mathcal{O}' \to \mathbb{F}_{\mathcal{O}'}$, which is all of $\mathbb{F}_{\mathcal{O}'}$; thus x is surjective, $\mathfrak{m}$ is a maximal ideal and x induces an isomorphism $A/\mathfrak{m} \cong \mathbb{F}_{\mathcal{O}'}$ of $\mathcal{O}'$-algebras. Moreover $x(\mathfrak{m}_{\mathcal{O}'}A) = 0$ since $\mathfrak{m}_{\mathcal{O}'}$ maps to 0 in $\mathbb{F}_{\mathcal{O}'}$; so $\mathfrak{m}_{\mathcal{O}'}A \subseteq \mathfrak{m}$.

Step 2: $R \in \mathrm{CNL}_{\mathcal{O}'}$. Since $\mathfrak{m}$ is maximal, $A/\mathfrak{m}^n = A_{\mathfrak{m}}/\mathfrak{m}^n A_{\mathfrak{m}}$ for every n (every element of $A \setminus \mathfrak{m}$ is a unit modulo $\mathfrak{m}^n$), so R is also the $\mathfrak{m}A_{\mathfrak{m}}$-adic completion of the Noetherian local ring $A_{\mathfrak{m}}$. The completion of a Noetherian local ring at its maximal ideal is a complete Noetherian local ring with maximal ideal $\mathfrak{m}_R = \mathfrak{m}R$ and the same residue field (Matsumura, Commutative Ring Theory, Theorems 8.7, 8.8 and 8.11); thus $R/\mathfrak{m}_R = A/\mathfrak{m} \cong \mathbb{F}_{\mathcal{O}'}$, and the structure map $\mathcal{O}' \to R$ induces this isomorphism on residue fields. It is local, because $\mathfrak{m}_{\mathcal{O}'}$ maps into $\mathfrak{m}R = \mathfrak{m}_R$ by Step 1. Hence $R \in \mathrm{CNL}_{\mathcal{O}'}$.

Step 3: (Yw1). The homomorphism f is the composite $A \to A_{\mathfrak{m}} \to R$. Localisation $A \to A_{\mathfrak{m}}$ is flat, and the completion of the Noetherian ring $A_{\mathfrak{m}}$ at an ideal is flat over it (Matsumura, Theorem 8.8); a composite of flat homomorphisms is flat, so R is a flat A-module through f. Finally, the composite $A \xrightarrow{f} R \to R/\mathfrak{m}_R$ is the projection $A \to A/\mathfrak{m}$ followed by the isomorphism $A/\mathfrak{m} \cong R/\mathfrak{m}_R$ of Step 2, whose kernel is $\mathfrak{m}$; hence $f^{-1}(\mathfrak{m}_R) = \mathfrak{m} = \ker x$.

Steps 2 and 3 with Lemma 53.35 and Proposition 53.39 give R and f with (Yw1)–(Yw3). □

Lemma 53.35. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F : \mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, and $C \ge 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d with $30(C+1)^2 \le d$. Let $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ be an $\mathcal{O}'$-algebra homomorphism such that $x(P)$ is a residual pair good in case (III), and let R be the completion of A at the maximal ideal $\ker x$. Then there are integers $a, b \ge 0$ with $b + 2 + 2d \le a + 2\#\Sigma$ and a surjective $\mathcal{O}'$-algebra homomorphism $\mathcal{O}'[[X_1, \dots, X_a]] \to R$ whose kernel is generated by b elements.*

Proof. Let $\mathbb{F}'$ be the residue field of $\mathcal{O}'$ and ϖ a uniformiser. A residual pair good in case (III) is in particular a residual pair, and the tower is fit and deep; so Lemma 53.36 applies to x and gives $h^i = h^i(\Gamma; W, b)$ and an integer $0 \le m \le 2\#\Sigma$ with (Yd1)–(Yd3). (The Selmer bound C and goodness of $x(P)$ beyond being a residual pair are not used.)

Step 1: a presentation by a basis of the cotangent space. Let $a = \dim_{\mathbb{F}'} t_R^*$ (finite, R being Noetherian), $y_1, \dots, y_a \in \mathfrak{m}_R$ with classes forming a basis of t_R^*, $S = \mathcal{O}'[[X_1, \dots, X_a]]$ with maximal ideal $\mathfrak{n}$, and $\Pi\colon S \to R$ the continuous $\mathcal{O}'$-algebra homomorphism with $\Pi(X_i) = y_i$. Then $\mathfrak{m}_R = \varpi R + \sum_i y_i R + \mathfrak{m}_R^2$, so $\mathfrak{m}_R = \varpi R + \sum_i y_i R = \mathfrak{n}R$ by Nakayama's lemma; R is

$\mathfrak{n}$-adically separated, S is $\mathfrak{n}$-adically complete and $R/\mathfrak{n}R = \mathbb{F}'$ is generated by 1, so $R = \Pi(S)$ by the complete Nakayama lemma [166, Thm. 8.4]. The kernel is minimal in the sense of Lemma 49.21: if $f = c_0 + \sum_i c_i X_i + q \in \ker\Pi$ with $q \in (X_1, \dots, X_a)^2$, then $c_0 \in \mathfrak{m}_{\mathcal{O}'}$ (reduce modulo $\mathfrak{m}_R$), hence $\sum_i c_i y_i \in \varpi R + \mathfrak{m}_R^2$, and as the classes of the y_i are independent in t_R^*, all $c_i \in \mathfrak{m}_{\mathcal{O}'}$.

Step 2: the relations. Apply Lemma 49.21 to Π with the trivial group $\mathsf{A} = \{0\}$ (every ring is graded with $C = C_0$, every ideal homogeneous, every homomorphism graded) and $d(0) = h^2 + 2\#\Sigma - m \geq 0$. Condition (Ov) then asks: for every surjective $\mathcal{O}'$-algebra homomorphism $p\colon C \to \bar{C}$ of rings of finite length in $\mathrm{CNL}_{\mathcal{O}'}$ with kernel I, $\mathfrak{m}_C I = 0$, $\dim_{\mathbb{F}'} I > d(0)$, and every surjective $\bar{\xi}\colon R \to \bar{C}$, an ideal $I' \subseteq I$ of codimension 1 and a lift $\xi\colon R \to C/I'$ of $\bar{\xi}$; this is (Yd2). So $\ker\Pi$ is generated by $b \leq h^2 + 2\#\Sigma - m$ elements.

Step 3: the count. By (Yd1), $a \geq h^1 - h^0 + 2 - m$, and by (Yd3), $h^2 + 2d \leq h^1 - h^0$. Hence

$$b + 2 + 2d \leq h^2 + 2d + 2\#\Sigma - m + 2 \leq h^1 - h^0 + 2 - m + 2\#\Sigma \leq a + 2\#\Sigma.$$

So Π is a surjection $\mathcal{O}'[[X_1, \dots, X_a]] \to R$ whose kernel is generated by b elements, with $b + 2 + 2d \leq a + 2\#\Sigma$. □

Lemma 53.36. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F : \mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring with residue field $\mathbb{F}'$, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi_{v,i}^B))$ a space for $(\mathscr{T}, \mathcal{O}')$, and $x\colon A \to \mathbb{F}'$ an $\mathcal{O}'$-algebra homomorphism such that $c = x(P) = (r_c, (n_{c,v})_{v\in\Sigma})$ is a residual pair. Let R be the completion of A at the maximal ideal $\ker x$ and $t_R^* = \mathfrak{m}_R/(\mathfrak{m}_R^2 + \mathfrak{m}_{\mathcal{O}'}R)$. Let $\widetilde{N}$ be the closed normal subgroup of G_F generated by N, $\Gamma = G_F/\widetilde{N}$ with projection π, $W = \mathfrak{sp}_4(\mathbb{F}')$ with G_F acting by $g \cdot X = r_c(g) X r_c(g)^{-1}$, $\mathfrak{b} \subseteq W$ the subspace of upper triangular matrices, and $b_v = n_{c,v}\mathfrak{b}\, n_{c,v}^{-1}$ for $v \in \Sigma$. Then the action of G_F on W factors through a continuous $\mathbb{F}'$-linear action of Γ with open kernel and each b_v is stable under D_v, so that the groups $H^i(\Gamma; W, b)$ for the family $(D_v)_{v\in\Sigma}$ are defined; they are $\mathbb{F}'$-vector spaces, and h^i denotes their dimension over $\mathbb{F}'$. Moreover there is an integer m with $0 \leq m \leq 2\#\Sigma$ such that:*

(Yd1) $\dim_{\mathbb{F}'} t_R^* \geq h^1 - h^0 + 2 - m$;

(Yd2) *for every surjective $\mathcal{O}'$-algebra homomorphism $p\colon C \to \bar{C}$ between rings $C, \bar{C} \in \mathrm{CNL}_{\mathcal{O}'}$ of finite length whose kernel I satisfies $\mathfrak{m}_C I = 0$ and $\dim_{\mathbb{F}'} I > h^2 + 2\#\Sigma - m$, and every $\mathcal{O}'$-algebra homomorphism $\bar{\xi}\colon R \to \bar{C}$, there are an ideal $I' \subseteq I$ of C with $\dim_{\mathbb{F}'} I/I' = 1$ and an $\mathcal{O}'$-algebra homomorphism $\xi\colon R \to C/I'$ whose composite with the projection $C/I' \to \bar{C}$ is $\bar{\xi}$;*

(Yd3) *h^2 is finite and $h^1 - h^0 - h^2 \geq 2d$.*

Proof. Write $\mathbb{F} = \mathbb{F}_{\mathcal{O}}$, $J = J_4$, and a for the structure map $\mathcal{O} \to C$ of an $\mathcal{O}'$-algebra C. For $C \in \mathrm{CNL}_{\mathcal{O}'}$ and an ideal I with $\mathfrak{m}_C I = 0$, I is an $\mathbb{F}'$-vector space, $\mathrm{M}_4(I) = \mathrm{M}_4(\mathbb{F}') \otimes_{\mathbb{F}'} I$, and for $Y \in \mathrm{M}_4(I)$ and invertible $s \in \mathrm{M}_4(C)$ with residue s_0 one has $s(1+Y)s^{-1} = 1 + s_0 Y s_0^{-1}$ and $(1+Y)(1+Y') = 1 + Y + Y'$. Rings of finite length in $\mathrm{CNL}_{\mathcal{O}'}$ are finite (the residue field $\mathbb{F}'$ is finite), and a continuous map to them from a profinite group is locally constant. Let $\mathfrak{t}$, $\mathfrak{n}^-$ be the subspaces of diagonal and of strictly lower triangular matrices in W, and for a root w let W_w be the subspace of W of matrices supported on the entries (i,j) with $\mathrm{wt}_4(i,j) = w$.

Step 0: matrix facts. (a) If $X \in \mathrm{M}_4(C)$ has similitude $\nu \in C^\times$, then $\det(X)^2 = \nu^4$, so X is invertible; if moreover X is upper triangular (or diagonal), then $X_{11}X_{44} = X_{22}X_{33} = \nu$ (the entries $(1,4)$ and $(2,3)$ of ${}^tXJX$). (b) The equation ${}^tXJ + JX = 0$ links the entry (i,j)

only to the entry $(5-j, 5-i)$, which lies in the same one of the three regions (diagonal, strictly upper, strictly lower) and has the same weight ($\lambda_{5-k} = 1-\lambda_k$, $\mu_{5-k} = 1-\mu_k$). Hence $W = \mathfrak{t} \oplus \bigoplus_w W_w$ (w over the roots), $W = \mathfrak{b} \oplus \mathfrak{n}^-$, and $\mathfrak{t} = \{\mathrm{diag}(y_1, y_2, -y_2, -y_1)\}$ has dimension 2. As $J^2 = -1$, $X \in W$ implies ${}^tX \in W$, so transposition exchanges the strictly upper and strictly lower parts of W, and $\dim W = 10$ gives $\dim \mathfrak{b} = 6$, $\dim \mathfrak{n}^- = 4$. Conjugation by a matrix of similitude $\nu \in \mathbb{F}'^\times$ preserves W. (c) *Cayley transform.* Let C be a ring in which 2 is a unit. For strictly lower (resp. upper) triangular $Y \in \mathfrak{sp}_4(C)$, $X = (1+Y)(1-Y)^{-1}$ is lower (resp. upper) unitriangular of similitude 1, and every such X arises from exactly one Y, namely $Y = (X-1)(X+1)^{-1}$. Hence, for a surjection $C \to \bar{C}$ of rings in which 2 is a unit: every lower unitriangular matrix of similitude 1 over $\bar{C}$ lifts to one over C (lift Y entrywise); and every upper triangular (resp. diagonal) matrix $\bar{X}$ of similitude $\bar{\nu}$ over $\bar{C}$ lifts, for any lift $\nu \in C^\times$ of $\bar{\nu}$, to an upper triangular (resp. diagonal) matrix of similitude ν: write $\bar{X} = \bar{D}\bar{U}$ with $\bar{D}$ its diagonal (similitude $\bar{\nu}$ by (a)) and $\bar{U}$ upper unitriangular of similitude 1, lift $\bar{D} = \mathrm{diag}(\bar{d}_1, \bar{d}_2, \bar{\nu}/\bar{d}_2, \bar{\nu}/\bar{d}_1)$ by $\mathrm{diag}(d_1, d_2, \nu/d_2, \nu/d_1)$ and $\bar{U}$ by the Cayley transform. (d) Let $C \to \bar{C}$ be surjective in $\mathrm{CNL}_{\mathcal{O}'}$ with kernel I, $\mathfrak{m}_C I = 0$, $\nu \in C^\times$ with residue $\nu_0 \in \mathbb{F}'$. Every $\bar{X} \in \mathrm{M}_4(\bar{C})$ of similitude $\bar{\nu}$ lifts to some X of similitude ν: take any lift X_0; $E = {}^tX_0 J X_0 - \nu J \in \mathrm{M}_4(I)$ is antisymmetric; choose $Z \in \mathrm{M}_4(I)$ with $JZ = -\frac{1}{2}\nu_0^{-1}E$; then ${}^tZJ + JZ = JZ - {}^t(JZ) = -\nu_0^{-1}E$ and $X = X_0(1+Z)$ has ${}^tXJX = \nu J + E + \nu_0({}^tZJ + JZ) = \nu J$.

Step 1: the action, θ and the μ-conditions. (i) N is stable under conjugation in G_F ($\bar{r}_0$ has abelian image) and $r_c(N) = 1$ by (Mq1); as r_c is a locally constant homomorphism into $\mathrm{GL}_4(\mathbb{F}')$, its kernel is an open normal subgroup containing N, hence $\widetilde{N}$. So the action on W (which preserves W by Step 0 (b), $r_c(g)$ having similitude $\theta(g)$) factors through Γ, is $\mathbb{F}'$-linear and has open kernel. The same argument shows: for every marked ordinary pair (or pair satisfying (Mq1)) $(r, (n_v))$ with values in a finite ring, locally constant, $r(\widetilde{N}) = 1$. (ii) $\theta(\widetilde{N}) = 1$ in $\mathcal{O}$, and $\bar{\omega}_\ell(\widetilde{N}) = 1$. For $g \in N$ (in $I_{\bar{w}}$, $\bar{w} \nmid \ell$, with $\bar{r}_0(g) = 1$): $\chi_{\mathrm{cyc}}(g) = \omega_\ell(g) = 1$ (unramified away from ℓ); $\chi(g) = 1$ by (Oq5) (a fit tower is good); $\bar{\theta}(g) = 1$ gives $\bar{\xi}(g) = 1$, and as ξ has order prime to ℓ, $\xi(g) = 1$. So $\theta(g) = \chi_{\mathrm{cyc}}(g)^{e+1}\omega_\ell(g)^{-1}\xi(g)\chi(g) = 1$; θ being a character, $\theta(\widetilde{N}) = 1$. (iii) Each b_v is D_v-stable: for $s \in D_v$, $\bar{u}(s) = n_{c,v}^{-1} r_c(s) n_{c,v}$ is invertible and upper triangular (Mq4) with a similitude, so $s \cdot b_v = n_{c,v}\bar{u}(s)\mathfrak{b}\,\bar{u}(s)^{-1}n_{c,v}^{-1} = b_v$. All cochain spaces defining $H^i(\Gamma; W, b)$ are $\mathbb{F}'$-spaces, hence so are the H^i. (iv) Fix $v \in \Sigma$. By local class field theory $D_v^{\mathrm{ab}} = D_v/\overline{[D_v, D_v]}$ is the profinite completion of $F_v^\times$, whose torsion subgroup is the finite cyclic group of roots of unity in F_v; so the elements of ℓ-power order in D_v^{ab} form a finite cyclic group, generated by the image of some $s_v \in D_v$, and μ_v is its preimage. For $s \in \mu_v$ and a continuous character γ of D_v, $\gamma(s)^{\ell^k} = 1$ for some k. Applied to χ_{cyc}: $\chi_{\mathrm{cyc}}(s)$ is a torsion element of $\mathbb{Z}_\ell^\times$ of ℓ-power order, hence 1 (ℓ odd); to ω_ℓ, ξ and χ, whose orders on D_v are prime to ℓ (for χ because the tower is deep): they are 1. Hence $\theta(s) = 1$ for $s \in \mu_v$. (v) Let C be a finite $\mathcal{O}'$-algebra and $Q = (r, (n_v))$ a locally constant tuple satisfying (Mq1)–(Mq3) and the upper triangularity in (Mq4). Then each $\psi_{v,i}^Q$ is a locally constant homomorphism $D_v \to C^\times$ (diagonal of an upper triangular representation), hence trivial on $\overline{[D_v, D_v]}$, and $\psi_{v,1}^Q\psi_{v,4}^Q = \psi_{v,2}^Q\psi_{v,3}^Q = a \circ \theta$ on D_v by Step 0 (a) (n_v has similitude 1). So, by (iv): *Q satisfies (Mq4) if and only if $\psi_{v,1}^Q(s_v) = \psi_{v,2}^Q(s_v) = 1$ for all $v \in \Sigma$* (then $\psi_{v,3}^Q(s_v) = \psi_{v,4}^Q(s_v) = \theta(s_v) = 1$, and every $s \in \mu_v$ has image a power of that of s_v in D_v^{ab}).

Step 2: two module facts. (i) $\mathrm{Hom}_\Gamma(W, \mathbb{F}(\bar{\omega}_\ell)) = 0$ ($\mathbb{F}$-linear maps). By (Wq1), (Wq2), $r_c(g) = \Delta(g)(1+U(g))$ with $\Delta(g) = \mathrm{diag}(\bar{\chi}_i^{\mathscr{J}}(g))$ and $U(g)$ supported in $\Sigma_0 \in \{\Sigma_P, \Sigma_M\}$. Let $f\colon \mathbb{Z}^2 \to \mathbb{Z}$ be $f(w) = 2w_1 + 3w_2$ if $\Sigma_0 = \Sigma_M$ and $f(w) = 2w_1 + w_2$ if $\Sigma_0 = \Sigma_P$; then $f < 0$ on Σ_0 For $m \in \mathbb{Z}$ let $M_{<m}$ be the span of the matrix units E_{ij} with $f(\mathrm{wt}_4(i,j)) < m$ ($\mathrm{wt}_4(i,i) = 0$), and $W_{<m} = W \cap M_{<m}$, $W_{\le m} = W_{<m+1}$. Since $\mathrm{wt}_4(i,k) = \mathrm{wt}_4(i,j) + \mathrm{wt}_4(j,k)$, $U(g)$ is nilpotent and $(1+U(g))X(1+U(g))^{-1} \in X + M_{<f(w)}$ for X supported in weight w; and $\Delta(g)X\Delta(g)^{-1} = \overline{\mathrm{rt}_w}(g)X$, because $\chi_1^{\mathscr{J}}\chi_4^{\mathscr{J}} = \chi_2^{\mathscr{J}}\chi_3^{\mathscr{J}}$ ($\theta = \alpha\Psi$) gives $\chi_i^{\mathscr{J}}/\chi_j^{\mathscr{J}} = \mathrm{rt}_{\mathrm{wt}_4(i,j)}$. So

the $W_{\le m}$ are G_F-stable and g acts on $W_{\le m}/W_{<m}$ by $\overline{\mathrm{rt}_w}(g)$ on the image of W_w ($f(w)=m$) and trivially on that of $\mathfrak{t}$ ($m=0$). If $\phi\neq 0$ were a Γ-map $W\to\mathbb{F}(\bar\omega_\ell)$, take m minimal with $\phi(W_{\le m})\neq 0$ and $X\in W_w$ ($f(w)=m$, or $w=0$ and $X\in\mathfrak{t}$) with $\phi(X)\neq 0$: then $\bar\omega_\ell(g)\phi(X)=\phi(g\cdot X)=\overline{\mathrm{rt}_w}(g)\phi(X)$ for all $g\in G_F$, contradicting the first clause of (Oq3). (ii) For a real place u of F and a complex conjugation $c_u\in G_F$ at u: c_u is conjugate in $G_{\mathbb{Q}}$ to c, so $\theta(c_u)=\theta(c)=\chi_{\mathrm{cyc}}(c)\omega_\ell(c)^{-1}\xi(c)\Psi(c)=(-1)(-1)(-1)(1)=-1$ by (Sg1). Thus $\gamma=r_c(c_u)$ has $\gamma^2=1$ and similitude -1, and Lemma 53.37 (over $\mathbb{F}'$, of characteristic $\ell\neq 2$) gives $\dim_{\mathbb{F}'}W^{c_u=1}=4$.

Step 3: (Yd3). Apply Proposition 48.9 with the totally real field F and $K'=G_F\cap\ker\bar r_0$, open normal of index dividing $\#(\mathbb{F}^\times)^4$, prime to ℓ. The closed normal subgroup generated by the $I_{\bar u}\cap K'$, $\bar u\nmid\ell$, is $\widetilde{N}$, since their union is N. The places of F above ℓ correspond to Σ ($v\mapsto$ the place below $\bar v$; every place of $\overline{\mathbb{Q}}$ above ℓ is G_F-conjugate to exactly one $\bar v$), with $D_v=D_{\bar v}\cap G_F$. Take W as an $\mathbb{F}$-space with the action of Step 1 (i) and the D_v-stable b_v (Step 1 (iii)); the hypothesis on Hom is Step 2 (i). So $H^2(\Gamma;W,b)$ is finite-dimensional and, all spaces being $\mathbb{F}'$-spaces whose $\mathbb{F}$-dimensions are $[\mathbb{F}':\mathbb{F}]$ times their $\mathbb{F}'$-dimensions, dividing by $[\mathbb{F}':\mathbb{F}]$ and using $\dim b_v=6$ (Step 0 (b)), $\sum_v[F_v:\mathbb{Q}_\ell]=d$, the d real places of F and Step 2 (ii):

$$h^2+h^0+6d\le h^1+4d.$$

This is (Yd3) (finiteness of h^1 is shown in Step 5).

Step 4: Artinian points of R. Let $\mathfrak{m}=\ker x$, $f_R\colon A\to R$ the canonical map and $P_R=f_R(P)$. Since $A/\mathfrak{m}^k=R/\mathfrak{m}^kR$, $f_R^{-1}(\mathfrak{m}_R)=\mathfrak{m}$ and $R=f_R(A)+\mathfrak{m}_R^k$ for all k. For $C\in\mathrm{CNL}_{\mathcal{O}'}$ of finite length let $\mathcal{D}(C)$ be the set of marked ordinary pairs over $(\mathscr{T},\emptyset)$ with values in C, continuous for $\mathfrak{m}_C$, with reduction c, and $\mathcal{D}'(C)\supseteq\mathcal{D}(C)$ the same with only the upper triangularity in (Mq4). *Claim: $\xi\mapsto\xi(P_R)$ is a bijection from the $\mathcal{O}'$-algebra homomorphisms $R\to C$ onto $\mathcal{D}(C)$.* Every $\mathcal{O}'$-algebra homomorphism from R or B to C or to $\mathbb{F}'$ is local (its composite to $\mathbb{F}'$ is surjective, so its kernel is the maximal ideal). Given ξ, $\xi(P_R)$ is a marked ordinary pair (all conditions are identities between entries, preserved by ring homomorphisms), its reduction is the image of P under $A\to R\to R/\mathfrak{m}_R=A/\mathfrak{m}$, i.e. $x(P)=c$, and it is continuous because $\xi f_R(\mathfrak{m}_BA)\subseteq\mathfrak{m}_C$ and P is continuous for $\mathfrak{m}_BA$ (Zq1). Injectivity: if $\xi_1(P_R)=\xi_2(P_R)$, the homomorphisms $y_j=\xi_jf_R$ agree on the entries of all $r_P(g)$ and n_v, hence on the images in A of the coefficients of $\mathrm{cp}(g)$ and of the $\psi^B_{v,i}(s)$ (Zq2); by (Zq3) $y_1|_B=y_2|_B$, and by the generation in (Zq1) $y_1=y_2$; as $\mathfrak{m}_C^k=0$ for some k and $R=f_R(A)+\mathfrak{m}_R^k$, $\xi_1=\xi_2$. Surjectivity: for $Q\in\mathcal{D}(C)$, (Zq4) gives $y\colon A\to C$ with $y(P)=Q$; the composite $A\to C\to\mathbb{F}'$ sends P to $c=x(P)$, so equals x by the injectivity argument (with $C=\mathbb{F}'$); hence $y(\mathfrak{m})\subseteq\mathfrak{m}_C$, $y(\mathfrak{m}^k)=0$, and y factors through $A/\mathfrak{m}^k=R/\mathfrak{m}^kR$, giving ξ with $\xi(P_R)=Q$. The bijection is compatible with homomorphisms $C\to C'$.

Step 5: tangent spaces, (Yd1). Let $\mathbb{F}'[\varepsilon]$ be the dual numbers. The $\mathcal{O}'$-algebra homomorphisms $R\to\mathbb{F}'[\varepsilon]$ form an $\mathbb{F}'$-vector space T dual to t_R^* (classical; $\xi\mapsto$ the ε-coefficient of ξ on $\mathfrak{m}_R$), finite-dimensional as R is Noetherian. An element of $\mathcal{D}'(\mathbb{F}'[\varepsilon])$ is uniquely $r(g)=(1+\varepsilon z(g))r_c(g)$, $n_v=n_{c,v}(1+\varepsilon y_v)$ with $z(g),y_v\in\mathrm{M}_4(\mathbb{F}')$, and, writing $Y_v=n_{c,v}y_vn_{c,v}^{-1}$ and $\bar u(s)=n_{c,v}^{-1}r_c(s)n_{c,v}$: similitude $a(\theta(g))=\bar\theta(g)$ holds iff $z(g)\in W$; r is a homomorphism iff z is a 1-cocycle; $r(N)=1$ iff $z(\widetilde{N})=0$ (Step 1 (i)), i.e. iff z factors through Γ; continuity iff z is locally constant; (Mq2) iff $z(g_{\mathscr{T}})\in\mathfrak{t}$; (Mq3) iff $y_v\in\mathfrak{n}^-$; and

$$n_v^{-1}r(s)n_v=(1+\varepsilon\,n_{c,v}^{-1}(z(s)+(s-1)Y_v)n_{c,v})\bar u(s),$$

upper triangular iff $z(s)+(s-1)Y_v\in b_v$ ($s\in D_v$). So $\mathcal{D}'(\mathbb{F}'[\varepsilon])$ is in $\mathbb{F}'$-linear bijection with

$$T'=\{(z,(y_v)):\ z\in Z^1(\Gamma,W)\text{ continuous},\ z(\pi(g_{\mathscr{T}}))\in\mathfrak{t},\ y_v\in\mathfrak{n}^-,\\ z(\pi(s))+(s-1)n_{c,v}y_vn_{c,v}^{-1}\in b_v\ \forall v,\ s\in D_v\},$$

and T with the subspace corresponding to $\mathcal{D}(\mathbb{F}'[\varepsilon])$ (Step 4; linearity: the entries of $\xi(P_R)$ are ξ applied to entries of P_R). *The μ-map.* For $t=(z,(y_v))\in T'$ let $\delta_{v,i}(t)$ be the (i,i) entry of $n_{c,v}^{-1}(z(\pi(s_v))+(s_v-1)Y_v)n_{c,v}$. The corresponding pair has $\psi_{v,i}(s_v)=(1+\varepsilon\delta_{v,i}(t))\psi^c_{v,i}(s_v)=1+\varepsilon\delta_{v,i}(t)$ (diagonal of a product of upper triangular matrices; $\psi^c_{v,i}(s_v)=1$ by (Mq4) for c). Let $\mu_T\colon T'\to\mathbb{F}'^{\Sigma\times\{1,2\}}$, $t\mapsto(\delta_{v,i}(t))_{v,i\le 2}$, and $m=\operatorname{rank}\mu_T\le 2\#\Sigma$. By Step 1 (v), $T\cong\ker\mu_T$. Hence $\dim T'=\dim t_R^*+m<\infty$. *Counting T'.* Let $T_0'\supseteq T'$ be defined without the condition at $g_{\mathscr{T}}$, $\mathcal{Z}$ the space of pairs $(z,(X_v))$ with z a continuous cocycle and $z(\pi(s))-(s-1)X_v\in b_v$, and $\mathcal{B}\subseteq\mathcal{Z}$ the pairs $((g-1)X,(X_v))$ with $X_v-X\in b_v$, so $H^1(\Gamma;W,b)=\mathcal{Z}/\mathcal{B}$. The map $T_0'\times\prod_v b_v\to\mathcal{Z}$, $((z,(y_v)),(\beta_v))\mapsto(z,(\beta_v-n_{c,v}y_vn_{c,v}^{-1}))$, is well defined ($b_v$ is D_v-stable) and bijective, because $W=b_v\oplus n_{c,v}\mathfrak{n}^-n_{c,v}^{-1}$ (Step 0 (b), conjugated by $n_{c,v}$). The map $W\times\prod_v b_v\to\mathcal{B}$, $(X,(\beta_v))\mapsto((g-1)X,(X+\beta_v))$, is surjective with kernel $\{(X,(-X)):X\in W^\Gamma\cap\bigcap_v b_v\}\cong H^0(\Gamma;W,b)$. As T_0' is finite-dimensional (T' has codimension at most $\dim W/\mathfrak{t}=8$ in it), so are $\mathcal{Z}$ and H^1, and

$$\dim T_0'=\dim\mathcal{Z}-6\#\Sigma=h^1+(10+6\#\Sigma-h^0)-6\#\Sigma=h^1-h^0+10,\qquad \dim T'\ge h^1-h^0+2.$$

So $\dim_{\mathbb{F}'}t_R^*=\dim T'-m\ge h^1-h^0+2-m$: (Yd1).

Step 6: obstructions, (Yd2). Let $p\colon C\to\bar C$, I, $\bar\xi$ be as in (Yd2), and $\bar Q=\bar\xi(P_R)=(\bar r',(\bar n_v'))\in\mathcal{D}(\bar C)$ (Step 4); its reduction is c. For an ideal $I_0\subseteq I$, $C/I_0\to\bar C$ has kernel I/I_0, killed by $\mathfrak{m}_C$. (i) *Global cochain.* $\bar r'$ is locally constant with $\bar r'(\widetilde{N})=1$ (Step 1 (i)) and $a\circ\theta\colon G_F\to C^\times$ is locally constant with $\theta(\widetilde{N})=1$ (Step 1 (ii)); both factor through Γ. Choose an open normal $U\subseteq\Gamma$ on which both are trivial, representatives of Γ/U (with 1 for U), lifts $\sigma(\gamma)\in\mathrm{M}_4(C)$ of $\bar r'(\gamma)$ of similitude $a(\theta(\gamma))$ (Step 0 (d); $\sigma(1)=1$), and put $\sigma(\gamma u)=\sigma(\gamma)$ for $u\in U$. Define $k(g,g')\in\mathrm{M}_4(I)$ by $\sigma(g)\sigma(g')=(1+k(g,g'))\sigma(gg')$ (both sides lift $\bar r'(gg')$; $\sigma(gg')$ is invertible by Step 0 (a)). As $1+k$ has similitude 1, $k(g,g')\in W\otimes I$; k is locally constant, and expanding $\sigma(g)\sigma(g')\sigma(g'')$ in two ways gives $k(g,g')+k(gg',g'')=g\cdot k(g',g'')+k(g,g'g'')$: a continuous 2-cocycle. (ii) *Local cochains.* Fix v. By Step 0 (c) let $n_v\in\mathrm{M}_4(C)$ be a lower unitriangular lift of $\bar n_v'$ of similitude 1; its residue is $n_{c,v}$. The map $\bar u'(s)=\bar n_v'^{-1}\bar r'(\pi(s))\bar n_v'$ is upper triangular of similitude $a(\theta(s))$; as in (i), using Step 0 (c), choose a locally constant upper triangular lift $u\colon D_v\to\mathrm{M}_4(C)$ of similitude $a\circ\theta$ with $u(1)=1$. Define $k_v(s)\in W\otimes I$ by $\sigma(\pi(s))=(1+k_v(s))n_vu(s)n_v^{-1}$ and the upper triangular $\beta_v(s,s')\in\mathfrak{b}\otimes I$ by $u(s)u(s')=(1+\beta_v(s,s'))u(ss')$. Then

$$\sigma(\pi(s))\sigma(\pi(s'))=\big(1+k_v(s)+s\cdot k_v(s')+n_{c,v}\beta_v(s,s')n_{c,v}^{-1}-k_v(ss')\big)\sigma(\pi(ss')),$$

so $k(\pi(s),\pi(s'))-\big(s\cdot k_v(s')-k_v(ss')+k_v(s)\big)\in b_v\otimes I$. (iii) *The class.* For $\lambda\in I^\vee=\mathrm{Hom}_{\mathbb{F}'}(I,\mathbb{F}')$, $(\lambda\circ k,(\lambda\circ k_v)_v)$ is a pair as in the definition of $H^2(\Gamma;W,b)$; let $o(\lambda)$ be its class, $\mathbb{F}'$-linear in λ. Then $V=\ker o$ has $\dim V\ge\dim I-h^2$. Let $I_1=\bigcap_{\lambda\in V}\ker\lambda$, an ideal with $\dim I/I_1=\dim V$; choose a basis $\lambda_1,\dots,\lambda_q$ of V and $i_1,\dots,i_q\in I$ with $\lambda_a(i_b)=\delta_{ab}$, so that $w\equiv\sum_b(\mathrm{id}\otimes\lambda_b)(w)\otimes i_b$ modulo $W\otimes I_1$ for $w\in W\otimes I$. As $o(\lambda_b)=0$ there are continuous $\beta_b\colon\Gamma\to W$ and $Y_{b,v}\in W$ with $\lambda_b\circ k=d\beta_b$, $(d\beta)(g,g')=g\cdot\beta(g')-\beta(gg')+\beta(g)$, and $\lambda_b(k_v(s))-\beta_b(\pi(s))+(s-1)Y_{b,v}\in b_v$. Put $\beta=\sum_b\beta_b\otimes i_b$, $Y_v=\sum_b Y_{b,v}\otimes i_b$. Then, modulo I_1: $k=d\beta$ and $b_s:=k_v(s)-\beta(\pi(s))+(s-1)Y_v\in b_v\otimes(I/I_1)$. (iv) *A lift without the μ-condition over $C_1=C/I_1$.* Over C_1 put $\sigma'(g)=(1-\beta(g))\sigma(g)$. Then $\sigma'(g)\sigma'(g')=(1-\beta(g)-g\cdot\beta(g')+k(g,g'))\sigma(gg')=\sigma'(gg')$, so $r'(g)=\sigma'(\pi(g))$ is a locally constant homomorphism of similitude $a\circ\theta$ with $r'(N)=1$, lifting $\bar r'$. For $s\in D_v$, $\sigma'(\pi(s))(1+Y_v)n_v=(1-\beta(\pi(s))+k_v(s)+s\cdot Y_v)n_vu(s)=(1+b_s)(1+Y_v)n_vu(s)$, so with $\tilde n_v=(1+Y_v)n_v$, $\tilde n_v^{-1}r'(s)\tilde n_v=(1+n_{c,v}^{-1}b_sn_{c,v})u(s)$ is upper triangular. *Normalising the flag:* write $n_{c,v}^{-1}Y_vn_{c,v}=Y^{\mathfrak{b}}+Y^-$ in $(\mathfrak{b}\oplus\mathfrak{n}^-)\otimes(I/I_1)$ and $n_v'=\tilde n_v(1-Y^{\mathfrak{b}})=n_v(1+Y^-)$: lower unitriangular of similitude 1, and $n_v'^{-1}r'(s)n_v'=(1+Y^{\mathfrak{b}})\tilde n_v^{-1}r'(s)\tilde n_v(1-Y^{\mathfrak{b}})$ is upper triangular. *The element $g_{\mathscr{T}}$:* $\bar r'(g_{\mathscr{T}})$ is diagonal; let D_1 be a diagonal lift over C_1 of similitude $a(\theta(g_{\mathscr{T}}))$ (Step 0 (c)), so $r'(g_{\mathscr{T}})=(1+\kappa)D_1$ with $\kappa=\kappa_{\mathfrak{t}}+\kappa_{\mathrm{off}}\in(\mathfrak{t}\oplus\bigoplus_w W_w)\otimes(I/I_1)$. The residue

$r_c(g_{\mathscr{T}}) = \mathrm{diag}(\bar{\chi}_i^{\mathscr{T}}(g_{\mathscr{T}}))$ ((Mq2), (Wq1)) acts on W_w, $w = \mathrm{wt}_4(i,j)$, by $\bar{\chi}_i^{\mathscr{T}}(g_{\mathscr{T}})/\bar{\chi}_j^{\mathscr{T}}(g_{\mathscr{T}}) \neq 1$ (Oq7); so there is $Y_{\mathscr{T}} \in \bigoplus_w W_w \otimes (I/I_1)$ with $Y_{\mathscr{T}} - g_{\mathscr{T}} \cdot Y_{\mathscr{T}} = -\kappa_{\mathrm{off}}$, and $r'' = (1+Y_{\mathscr{T}})r'(1-Y_{\mathscr{T}})$ has $r''(g_{\mathscr{T}}) = (1+\kappa_{\mathfrak{t}})D_1$ diagonal, similitude $a \circ \theta$, $r''(N) = 1$. Normalise $(1+Y_{\mathscr{T}})n'_v$ as above to a lower unitriangular n''_v of similitude 1 with $n''^{-1}_v r''(s) n''_v$ upper triangular. Thus $Q_1 = (r'', (n''_v)) \in \mathcal{D}'(C_1)$ lifts $\bar{Q}$. (v) *The μ-conditions.* For $t = (z, (y_v)) \in T'$ and $j \in I/I_1$ put $Q_1 \cdot (t,j) = \big((1+z(\pi(g))j)r''(g), (n''_v(1+y_v j))\big)$. The computations of Step 5, with ε replaced by j (using $\mathfrak{m}_{C_1}(I/I_1) = 0$), show $Q_1 \cdot (t,j) \in \mathcal{D}'(C_1)$, lifting $\bar{Q}$, with $\psi_{v,i}(s_v) = \psi_{v,i}^{Q_1}(s_v) + \delta_{v,i}(t)j$ (as $\psi_{v,i}^{Q_1}(s_v) \equiv 1$ modulo $\mathfrak{m}_{C_1}$). Let $e_{v,i} = \psi_{v,i}^{Q_1}(s_v) - 1$ $(i = 1,2)$, which lies in I/I_1 because $\bar{Q}$ satisfies (Mq4). The $\mathbb{F}'$-linear map $(I/I_1)^\vee \to \mathbb{F}'^{\Sigma\times\{1,2\}}/\mu_T(T')$, $\lambda \mapsto$ the class of $(\lambda(e_{v,i}))$, has source of dimension $\dim V \geq \dim I - h^2 > 2\#\Sigma - m$, the dimension of the target; take $\lambda \neq 0$ in its kernel, $t \in T'$ with $\mu_T(t) = (\lambda(e_{v,i}))$, and $j_0 \in I/I_1$ with $\lambda(j_0) = 1$. Then $Q_2 = Q_1 \cdot (t, -j_0)$ has $\psi_{v,i}^{Q_2}(s_v) - 1 = e_{v,i} - \delta_{v,i}(t)j_0 \in \ker\lambda$ for $i = 1,2$. Let $I' \subseteq I$ be the preimage of $\ker\lambda$: an ideal with $\dim I/I' = 1$. The image Q_3 of Q_2 over C/I' has $\psi_{v,1}(s_v) = \psi_{v,2}(s_v) = 1$ for all v, so $Q_3 \in \mathcal{D}(C/I')$ by Step 1 (v), lifting $\bar{Q}$. (vi) By Step 4 there is $\xi\colon R \to C/I'$ with $\xi(P_R) = Q_3$; its composite with $C/I' \to \bar{C}$ sends P_R to $\bar{Q} = \bar{\xi}(P_R)$, hence is $\bar{\xi}$ by the injectivity in Step 4. This proves (Yd2). □

Lemma 53.37. *Let k be a field of characteristic different from 2, $\mathfrak{sp}_4(k) = \{X \in \mathrm{M}_4(k) : {}^tXJ_4 + J_4X = 0\}$, and $\gamma \in \mathrm{GL}_4(k)$ with $\gamma^2 = 1$ and similitude -1, i.e. ${}^t\gamma J_4\gamma = -J_4$. Then $X \mapsto \gamma X\gamma^{-1}$ preserves $\mathfrak{sp}_4(k)$, and its eigenspaces for the eigenvalues -1 and $+1$ have dimensions 6 and 4. For $\gamma = \mathrm{diag}(-1,1,-1,1)$ the (-1)-eigenspace is the sum of the root spaces $\mathfrak{sp}_4(k) \cap \big(\bigoplus_{\mathrm{wt}_4(i,j)=w} kE_{ij}\big)$ of the six odd roots w, and the $(+1)$-eigenspace is the sum of the diagonal part and the root spaces of $\pm w_\Psi$.*

Proof. Preservation. From ${}^t\gamma J_4\gamma = -J_4$: ${}^t\gamma J_4 = -J_4\gamma^{-1}$ and $J_4\gamma = -{}^t\gamma^{-1}J_4$. For $X \in \mathfrak{sp}_4(k)$ and $Y = \gamma X\gamma^{-1}$,

$$ {}^tY J_4 + J_4 Y = {}^t\gamma^{-1}\,{}^tX\,({}^t\gamma J_4) + (J_4\gamma)X\gamma^{-1} = -{}^t\gamma^{-1}\big({}^tXJ_4 + J_4X\big)\gamma^{-1} = 0. $$

The eigenspaces of γ on V are Lagrangian. As $\gamma^2 = 1$ and $2 \in k^\times$, $V = V_+ \oplus V_-$ with $V_\pm = \ker(\gamma \mp 1)$ (projectors $(1 \pm \gamma)/2$). For $v, w \in V_\varepsilon$, $\langle \gamma v, \gamma w\rangle = {}^tv\,{}^t\gamma J_4\gamma\, w = -\langle v, w\rangle$ and $\langle \gamma v, \gamma w\rangle = \varepsilon^2\langle v, w\rangle = \langle v, w\rangle$; so $2\langle v, w\rangle = 0$ and V_ε is isotropic. Isotropic subspaces of a non-degenerate alternating space of dimension 4 have dimension at most 2, and $\dim V_+ + \dim V_- = 4$; so $\dim V_\pm = 2$.

Dimensions. Since ${}^tJ_4 = -J_4$, $X \in \mathfrak{sp}_4(k)$ if and only if J_4X is symmetric (${}^t(J_4X) = -{}^tXJ_4$), so $X \mapsto J_4X$ is an isomorphism of $\mathfrak{sp}_4(k)$ onto the space Sym of symmetric 4×4 matrices, i.e. of symmetric bilinear forms $b_X(v,w) = {}^tvJ_4Xw$ on V. Using $\gamma^{-1} = \gamma$ and $J_4\gamma = -{}^t\gamma J_4$ (the second identity above with ${}^t\gamma^{-1} = {}^t\gamma$),

$$ J_4(\gamma X\gamma^{-1}) = -{}^t\gamma\,(J_4X)\,\gamma, \qquad \text{i.e.} \qquad b_{\gamma X\gamma^{-1}}(v,w) = -b_X(\gamma v, \gamma w). $$

A symmetric bilinear form b on $V_+ \oplus V_-$ is the sum of its restrictions b_{++} to $V_+ \times V_+$, b_{--} to $V_- \times V_-$ and its mixed part b_{+-} (determined by $V_+ \times V_-$), and these three spaces have dimensions 3, 3 and 4. The map $b \mapsto b(\gamma\cdot, \gamma\cdot)$ is $+1$ on b_{++} and b_{--} and -1 on b_{+-}. With the sign, conjugation by γ is -1 on a space of dimension 6 and $+1$ on a space of dimension 4, which together span $\mathfrak{sp}_4(k)$.

The diagonal case. For $\gamma = \mathrm{diag}(\gamma_1,\dots,\gamma_4) = \mathrm{diag}(-1,1,-1,1)$ (similitude -1: ${}^t\gamma J_4\gamma$ multiplies $(J_4)_{ij}$, $i+j=5$, by $\gamma_i\gamma_j = -1$), conjugation multiplies E_{ij} by $\gamma_i\gamma_j$. Write $\gamma_i = (-1)^{\lambda_i}$ with $\lambda = (1,0,1,0)$, the exponents of t_1 in $\mathrm{T}_4(t_1,t_2) = \mathrm{diag}(t_1t_2, t_2, t_1, 1)$; then $\gamma_i\gamma_j = (-1)^{\lambda_i - \lambda_j} = (-1)^{w_1}$ for $w = \mathrm{wt}_4(i,j)$. $\mathfrak{sp}_4(k)$ is the sum of its diagonal part (eigenvalue $+1$)

and of the root spaces, each of which is spanned by matrix units of one weight and hence is an eigenspace for $(-1)^{w_1}$. The roots with w_1 odd are $\pm w_\alpha = \pm(1,0)$, $\pm w_\beta = \pm(-1,1)$, $\pm w_\theta = \pm(1,1)$; those with w_1 even are $\pm w_\Psi = \pm(0,1)$. This is the last assertion (and the dimensions 6, 4 agree with the general count).

Computer check. Computer check C6, listed in Appendix B, checks the diagonal case exactly over $\mathbb{Z}[1/2]$ (the integral root-vector basis and the eigenvalue of each basis vector) and, by an independent null-space computation, the dimensions 6 and 4 for 200 random involutions of similitude -1 over $\mathbb{Q}$ and modulo $3, 5, 7$; it is a check of the proof above, not a part of it. □

Definition 53.38. The **reducibility types** are the nine sets of roots

$$\Sigma_1^{\mathrm{red}} = \{w_\beta, -w_\beta, -w_\alpha, -w_\theta, -w_\Psi\}, \quad \Sigma_2^{\mathrm{red}} = \{w_\beta, -w_\beta, w_\alpha, w_\theta, w_\Psi\},$$
$$\Sigma_3^{\mathrm{red}} = \{w_\theta, -w_\theta, w_\Psi, w_\beta, -w_\alpha\}, \quad \Sigma_4^{\mathrm{red}} = \{w_\theta, -w_\theta, -w_\Psi, -w_\beta, w_\alpha\},$$
$$\Sigma_5^{\mathrm{red}} = \{w_\alpha, -w_\alpha, -w_\theta, -w_\Psi, -w_\beta\}, \quad \Sigma_6^{\mathrm{red}} = \{w_\alpha, -w_\alpha, w_\theta, w_\Psi, w_\beta\},$$
$$\Sigma_7^{\mathrm{red}} = \{w_\Psi, -w_\Psi, w_\beta, -w_\alpha, -w_\theta\}, \quad \Sigma_8^{\mathrm{red}} = \{w_\Psi, -w_\Psi, -w_\beta, w_\alpha, w_\theta\},$$
$$\Sigma_9^{\mathrm{red}} = \Sigma_Y = \{w_\beta, -w_\beta, w_\theta, -w_\theta\}.$$

For a commutative ring R, a set Γ, a map $r\colon \Gamma \to \mathrm{M}_4(R)$ and a set of roots Σ_0, the **reducibility ideal** $\mathrm{Red}_{\Sigma_0}(r) \subseteq R$ is the ideal generated by the entries $r(g)_{ij}$ with $g \in \Gamma$, $i \neq j$ and $\mathrm{wt}_4(i,j) \notin \Sigma_0$. For a ring homomorphism $\varphi\colon R \to K$ to a field, $\varphi \circ r$ is supported in Σ_0 if and only if $\ker\varphi \supseteq \mathrm{Red}_{\Sigma_0}(r)$.

Proposition 53.39. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with field F, index set Σ and $d = [F:\mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\mathfrak{J} \subseteq B$ an ideal modular for ι, and $C \geq 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d with $30(C+1)^2 \leq d$. Let $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ be an $\mathcal{O}'$-algebra homomorphism such that $x(P)$ is a residual pair good in case (III), R the completion of A at the maximal ideal $\ker x$, $f\colon A \to R$ the canonical homomorphism and $\phi\colon B \to A \xrightarrow{f} R$. Then there are finitely many ideals $\mathfrak{a}_1, \ldots, \mathfrak{a}_s$ of R with $\dim R/\mathfrak{a}_k \leq d + 20C + 1$ for all k such that every prime $\mathfrak{p}$ of R containing none of the $\mathfrak{a}_k$ satisfies:*

(a) if $\mathfrak{p}$ contains $f(\mathfrak{J})R$, $\mathfrak{m}_{\mathcal{O}'}R$ and, for some $v \in \Sigma$ and $i \neq j$, all $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s))$ with $s \in U_v$, then $\dim R/\mathfrak{p} \leq \dim B/\phi^{-1}(\mathfrak{p}) + 2 + 4\#\Sigma$;

(b) either the matrices $f(r_P(g))$ modulo $\mathfrak{p}$, $g \in G_F$, span M_4 over the fraction field of $R/\mathfrak{p}$, or there are $v \in \Sigma$ and $i \neq j$ with $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s)) \in \mathfrak{p}$ for all $s \in U_v$.

Proof. Put $\mathfrak{m} = \ker x$, $c = x(P)$ and $Q = f(P) = (f \circ r_P, (f(n_v)))$, where $P = (r_P, (n_v))$.

Step 0: the chart. By (Zq1), A is a finitely generated algebra over the Noetherian ring B, hence Noetherian; x is $\mathcal{O}'$-linear, so it is onto $\mathbb{F}_{\mathcal{O}'}$ and $\mathfrak{m}$ is a maximal ideal with $A/\mathfrak{m} = \mathbb{F}_{\mathcal{O}'}$. The completion R of the Noetherian ring A at the maximal ideal $\mathfrak{m}$ is a complete Noetherian local ring with maximal ideal $\mathfrak{m}_R = \mathfrak{m}R$ and residue field $A/\mathfrak{m}$, and $A \xrightarrow{f} R \to R/\mathfrak{m}_R$ is x (Matsumura, Commutative Ring Theory, Theorems 8.7, 8.8 and 8.11); since $\mathfrak{m}_{\mathcal{O}'}A \subseteq \mathfrak{m}$, $R \in \mathrm{CNL}_{\mathcal{O}'}$. A ring homomorphism carries marked ordinary pairs to marked ordinary pairs (the conditions (Mq1)–(Mq4) are equations among the entries, and f is an $\mathcal{O}'$-algebra map), so Q is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in R for $\mathcal{O} \subseteq \mathcal{O}' \to R$, with $\psi^Q_{v,i} = f \circ \psi^P_{v,i}$. Since $x(\mathfrak{m}_B) = 0$ ($x|_B$ is an $\mathcal{O}'$-algebra map from the local ring B to $\mathbb{F}_{\mathcal{O}'}$), $f(\mathfrak{m}_B A) \subseteq \mathfrak{m}_R$; as P is continuous for $\mathfrak{m}_B A$, every $g \mapsto f(r_P(g)_{ij}) \bmod \mathfrak{m}_R^k$ is locally constant, so Q is continuous for $\mathfrak{m}_R$, and its reduction

is $x(P) = c$. Finally $\Sigma \neq \emptyset$: places of $\overline{\mathbb{Q}}$ above ℓ exist, and each is G_F-conjugate to $\bar{v}$ for some $v \in \Sigma$.

Step 1: the ideals. As c is good in case (III), either (G) c is good, or (A) c is not good, lies in A, and has an entry of weight $-w_\Psi$ or entries of weights $-w_\beta$ and $-w_\theta$. Put $\mathcal{K} = \{1, \dots, 9\}$ in case (G) and $\mathcal{K} = \{1, \dots, 8\}$ in case (A), and let the ideals of the statement be $\mathfrak{a}_k = \mathrm{Red}_{\Sigma_k^{\mathrm{red}}}(f \circ r_P)$, $k \in \mathcal{K}$. By Step 0, Lemma 53.41 applies to c, R and Q ((Rx1) in case (G), (Rx2) in case (A)) and gives $\dim R/\mathfrak{a}_k \leq d + 20C + 1$ for $k \in \mathcal{K}$.

Now let $\mathfrak{p}$ be a prime of R containing no $\mathfrak{a}_k$, $k \in \mathcal{K}$, let K be the fraction field of $R/\mathfrak{p}$, $\pi\colon R \to R/\mathfrak{p} \subseteq K$, and $\bar{r} = \pi \circ f \circ r_P$; $\ker \pi = \mathfrak{p}$.

Step 2: the case $\mathfrak{p} \not\supseteq \mathrm{Red}_{\Sigma_Y}(f \circ r_P)$. We show that the K-span of $\bar{r}(G_F)$ is $\mathrm{M}_4(K)$. In this case $\mathfrak{p}$ contains none of the nine ideals $\mathrm{Red}_{\Sigma_k^{\mathrm{red}}}(f \circ r_P)$ (in case (G) by the choice of $\mathfrak{p}$; in case (A) the ninth by assumption, the others by the choice of $\mathfrak{p}$). A fit tower is good. Lemma 53.45, applied to c, R, Q (Step 0) and $\varphi = \pi$, gives the claim. In case (G) this applies to every $\mathfrak{p}$ as above, because $9 \in \mathcal{K}$.

Step 3: the case $\mathfrak{p} \supseteq \mathrm{Red}_{\Sigma_Y}(f \circ r_P)$. Then we are in case (A). We show that $\bar{r}$ is supported in Σ_Y, has entries of weights $w_\beta, -w_\beta, w_\theta, -w_\theta$, and that for some $v \in \Sigma$ and $(i,j) \in \{(1,2),(2,4)\}$, $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s)) \in \mathfrak{p}$ for all $s \in D_v$. The support statement is the last sentence of Definition 53.38. For the entries, the four pairs $(k,w) = (1,w_\theta), (2,-w_\theta), (3,-w_\beta), (4,w_\beta)$ satisfy $\Sigma_Y \setminus \Sigma_k^{\mathrm{red}} = \{w\}$.

Fix such (k,w); $k \leq 4$ lies in $\mathcal{K}$, so $\mathfrak{a}_k \not\subseteq \mathfrak{p}$, and some generator of $\mathfrak{a}_k$ is not in $\mathfrak{p}$: there are $g \in G_F$ and $i \neq j$ with $\mathrm{wt}_4(i,j) \notin \Sigma_k^{\mathrm{red}}$ and $\bar{r}(g)_{ij} \neq 0$. As $\bar{r}$ is supported in Σ_Y, $\mathrm{wt}_4(i,j) \in \Sigma_Y \setminus \Sigma_k^{\mathrm{red}} = \{w\}$; so $\bar{r}$ has an entry of weight w. For the coincidence, pick $v \in \Sigma$ (Step 0). Since c lies in A, the image of $f((n_v)_{21})$ in $R/\mathfrak{m}_R$ is $x((n_v)_{21})$, the $(2,1)$ entry of the marking of c at v, which is non-zero, so $f((n_v)_{21})$ is a unit of the local ring R and $\pi(f((n_v)_{21})) \neq 0$. The pair $\pi(Q)$ is a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in K (Step 0, applied to π), its representation $\bar{r}$ is supported in Σ_Y and its marking at v has non-zero $(2,1)$ entry. By Lemma 53.46, $\pi(f(\psi^P_{v,i}(s))) = \pi(f(\psi^P_{v,j}(s)))$ for all $s \in D_v$, for $(i,j) = (1,2)$ or $(i,j) = (2,4)$, i.e. the differences lie in $\ker \pi = \mathfrak{p}$.

Step 4: (b). If $\mathfrak{p} \not\supseteq \mathrm{Red}_{\Sigma_Y}(f \circ r_P)$, Step 2 gives the first alternative of (b) (the matrices $f(r_P(g))$ modulo $\mathfrak{p}$ span M_4 over K). Otherwise Step 3 gives $v \in \Sigma$ and $i \neq j$ with $f(\psi^P_{v,i}(s)) - f(\psi^P_{v,j}(s)) \in \mathfrak{p}$ for all $s \in D_v$, in particular for all $s \in U_v \subseteq D_v$: the second alternative.

Step 5: (a). We show $\dim R/\mathfrak{p} \leq \dim B/\phi^{-1}(\mathfrak{p}) + 2 + 4\#\Sigma$ for every $\mathfrak{p}$ as above, which contains (a). Lemma 53.47 applies to the fit tower $\mathscr{T}$, the space $\mathscr{X}$, c, R, f (Step 0) and $\mathfrak{q} = \mathfrak{p}$, with $\phi = f|_B$ as in the statement: its first alternative holds by Step 2 if $\mathfrak{p} \not\supseteq \mathrm{Red}_{\Sigma_Y}(f \circ r_P)$, its second by Step 3 otherwise.

Steps 1, 4 and 5 give the ideals $\mathfrak{a}_k$, $k \in \mathcal{K}$, with the required properties. □

Definition 53.40. Let $\mathscr{T}$ be an auxiliary tower for a symplectic Eisenstein datum and k a field. Indices i, j run over $\{1,2,3,4\}$, and E_{ij} denotes the matrix unit. A **marked pair** with values in k is $c = (r, (n_v)_{v \in \Sigma})$ with $r\colon G_F \to \mathrm{GL}_4(k)$ a group homomorphism and $n_v \in \mathrm{M}_4(k)$ of similitude 1.

Reducible tangent spaces. For a marked pair $c = (r, (n_v))$ and a set S of roots, the **reducible tangent space** $\mathrm{T}_S(c)$ is the set of pairs $\xi = (x, (y_v)_{v \in \Sigma})$ of a map $x\colon G_F \to \mathfrak{sp}_4(k)$ and elements $y_v \in \mathfrak{sp}_4(k)$ such that:

(Ut1) x is locally constant, $x(gh) = x(g) + r(g)\,x(h)\,r(g)^{-1}$ for all $g, h \in G_F$, $x(g) = 0$ for $g \in N$, and $x(g_{\mathscr{F}})$ is diagonal;

(Ut2) $x(g)\,r(g)$ is supported in S for every $g \in G_F$;

(Ut3) for every $v \in \Sigma$, the entries (i,j) with $i \le j$ of $n_v^{-1} y_v n_v$ vanish;

(Ut4) for every $v \in \Sigma$ and $s \in D_v$, the matrix $n_v^{-1}(x(s) + r(s)\, y_v\, r(s)^{-1} - y_v)n_v$ is upper triangular.

All conditions are k-linear in ξ, so $\mathrm{T}_S(c)$ is a k-vector space under pointwise operations. It is the space of first-order deformations of c that keep the similitude, the conditions at N and $g_{\mathscr{T}}$, the support in S and the ordinary flags at the places of Σ.

Gradings. A **symplectic grading** is $m = (m_1, m_2, m_3, m_4) \in \mathbb{Z}^4$ with $m_1 + m_4 = m_2 + m_3$. A matrix $Y \in \mathrm{M}_4(k)$ is **m-filtered** if $Y_{ij} = 0$ whenever $m_i < m_j$, and its **m-leading part** $\mathrm{gr}_m Y$ is the matrix with entries Y_{ij} where $m_i = m_j$ and 0 elsewhere.

Lemma 53.41. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit and deep auxiliary tower for $\mathfrak{D}$ with field F, $d = [F:\mathbb{Q}]$, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $C \ge 0$ a Selmer bound for $(\mathscr{T}, \mathcal{O} \to \mathbb{F}_{\mathcal{O}'})$ in degree d, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ an $\mathcal{O}'$-algebra homomorphism such that $c = x(P)$ is a residual pair, R the completion of A at the maximal ideal $\ker x$, $f\colon A \to R$ the canonical homomorphism and $Q = (r_Q, (n_v)) = f(P)$.*

(Rx1) *If c is good, then $\dim R/\mathrm{Red}^{\mathrm{red}}_{\Sigma_k}(r_Q) \le d + 20C + 1$ for $1 \le k \le 9$.*

(Rx2) *If c lies in A and has an entry of weight $-w_\Psi$ or entries of weights $-w_\beta$ and $-w_\theta$, then $\dim R/\mathrm{Red}^{\mathrm{red}}_{\Sigma_k}(r_Q) \le d + 20C + 1$ for $1 \le k \le 8$.*

Proof. Put $k = \mathbb{F}_{\mathcal{O}'}$, $\mathfrak{m} = \ker x$, $c = x(P) = (r_c, (n_v^c))$, $P = (r_P, (n_v))$, $Q = (r_Q, (n_v^Q)) = f(P)$, and let ϖ be a uniformiser of the discrete valuation ring $\mathcal{O}'$. For $u \in R$ write $\bar u$ for its residue in k. Fix $S = \Sigma_t^{\mathrm{red}}$ ($1 \le t \le 9$ for (Rx1), $1 \le t \le 8$ for (Rx2)), $I = \mathrm{Red}_S(r_Q)$, $\bar R = R/I$ and $\pi\colon R \to \bar R$.

Step 0: the completion. By (Zq1), A is of finite type over the Noetherian ring B, hence Noetherian; x is $\mathcal{O}'$-linear, so onto k, and $\mathfrak{m}$ is maximal. Hence R is a complete Noetherian local ring with maximal ideal $\mathfrak{m}_R = \mathfrak{m}R$, residue field k, $u \mapsto \bar u$ restricted along f is x, and f induces $A/\mathfrak{m}^2 \cong R/\mathfrak{m}_R^2$ (see [166, Thms. 8.7 and 8.11]). Q is a marked ordinary pair with values in R (the conditions (Mq1)–(Mq4) are equations in the entries), and its reduction is c. As $x(\mathfrak{m}_B) = 0$ ($x|_B$ is an $\mathcal{O}'$-algebra map from the local ring B to k), $f(\mathfrak{m}_B A) \subseteq \mathfrak{m}_R$; since P is continuous for $\mathfrak{m}_B A$, every $g \mapsto r_Q(g)_{ij} \bmod \mathfrak{m}_R^2$ is locally constant.

Step 1: the unit case. If r_c is not supported in S, some $r_c(g)_{ij} \ne 0$ with $i \ne j$, $\mathrm{wt}_4(i,j) \notin S$; then $r_Q(g)_{ij} \in I$ is a unit of R, $\bar R = 0$ and $\dim \bar R = -\infty$. Assume from now on that r_c is supported in S. Then every generator of I has residue 0, so $I \subseteq \mathfrak{m}_R$ and $\bar R$ is a Noetherian local ring with maximal ideal $\bar{\mathfrak{m}} = \mathfrak{m}_R/I$ and residue field k. Put $t^* = \bar{\mathfrak{m}}/(\bar{\mathfrak{m}}^2 + \varpi \bar R)$, a finite-dimensional k-space.

Step 2: tangent vectors. For $\lambda \in \mathrm{Hom}_k(t^*, k)$ define $D_\lambda\colon \bar R \to k$ by $D_\lambda(u) = \lambda(u - \tilde u \bmod \bar{\mathfrak{m}}^2 + \varpi \bar R)$, where $\tilde u$ is the image in $\bar R$ of any $o \in \mathcal{O}'$ with the same residue as u; two such o differ by an element of $\varpi\mathcal{O}'$, so D_λ is well defined. It is k-linear in λ, vanishes on the image of $\mathcal{O}'$, and $D_\lambda(uu') = \bar u\, D_\lambda(u') + \bar u'\, D_\lambda(u)$.

Hence $\phi_\lambda\colon R \to k[\epsilon]$ ($\epsilon^2 = 0$), $u \mapsto \bar u + \epsilon D_\lambda(\pi(u))$, is an $\mathcal{O}'$-algebra homomorphism with $\phi_\lambda(I) = 0$ and $\phi_\lambda(\mathfrak{m}_R) \subseteq \epsilon k$, so $\phi_\lambda(\mathfrak{m}_R^2) = 0$. Write $D = D_\lambda \circ \pi$, applied to matrices entrywise, and put

$$x_\lambda(g) = D(r_Q(g))\, r_c(g)^{-1}, \qquad y_{\lambda,v} = D(n_v^Q)\, (n_v^c)^{-1},$$

so that $\phi_\lambda(r_Q(g)) = (1 + \epsilon x_\lambda(g)) r_c(g)$ and $\phi_\lambda(n_v^Q) = (1 + \epsilon y_{\lambda,v}) n_v^c$. The map $\Lambda\colon \lambda \mapsto \xi_\lambda = (x_\lambda, (y_{\lambda,v}))$ is k-linear.

Step 3: $\xi_\lambda \in \mathrm{T}_S(c)$. Write $x = x_\lambda$, $y_v = y_{\lambda,v}$, $r = r_c$, $n = n_v^c$. $\mathfrak{sp}_4$: by (Mq1) $r_Q(g)$ has similitude $\theta(g)$, and $\phi_\lambda(\theta(g)) = a(\theta(g)) \in k$; so ${}^t r(1+\epsilon\,{}^t x)J_4(1+\epsilon x)r = {}^t r J_4 r$, i.e. ${}^t r({}^t x J_4 + J_4 x)r = 0$, and $x(g) \in \mathfrak{sp}_4(k)$; likewise $y_v \in \mathfrak{sp}_4(k)$ from (Mq3). (Ut1): x is locally constant by Step 0 (as ϕ_λ kills $\mathfrak{m}_R^2$); applying ϕ_λ to $r_Q(gh) = r_Q(g)r_Q(h)$ gives $(1+\epsilon x(gh))r(gh) = (1+\epsilon(x(g)+r(g)x(h)r(g)^{-1}))r(gh)$; $r_Q(g) = 1$ on N gives $x(N) = 0$; $r_Q(g_{\mathscr{T}})$ and $r(g_{\mathscr{T}})$ are diagonal (Mq2), so $x(g_{\mathscr{T}})$ is diagonal. (Ut2): $(x(g)r(g))_{ij} = D(r_Q(g)_{ij})$, and for $i \neq j$, $\mathrm{wt}_4(i,j) \notin S$, $r_Q(g)_{ij} \in I = \ker\pi$. (Ut3): n_v^Q, n are lower unitriangular (Mq3), so $D(n_v^Q)$ is strictly lower triangular, and so is $n^{-1}y_v n = n^{-1}D(n_v^Q)$. (Ut4): for $s \in D_v$, ϕ_λ applied to (Mq4) says that

$$\big((1+\epsilon y_v)n\big)^{-1}(1+\epsilon x(s))r(s)(1+\epsilon y_v)n = n^{-1}r(s)n + \epsilon\, n^{-1}\big(x(s)+r(s)y_v r(s)^{-1} - y_v\big)n \cdot n^{-1}r(s)n$$

is upper triangular; $n^{-1}r(s)n$ is upper triangular and invertible (Mq4 for c), so $n^{-1}(x(s) + r(s)y_v r(s)^{-1} - y_v)n$ is upper triangular.

Step 4: Λ is injective. Let $\xi_\lambda = 0$. Then $\psi_\lambda = \phi_\lambda \circ f$ and $\psi_0 = \phi_0 \circ f$ are $\mathcal{O}'$-algebra homomorphisms $A \to k[\epsilon]$ that agree on all entries of all $r_P(g)$ and n_v. Their restrictions to B agree on the coefficients of every $\mathrm{cp}(g)$ (these map to the coefficients of the characteristic polynomial of $r_P(g)$, (Zq2)) and on every $\psi_{v,i}^B(s)$ (these map to $(n_v^{-1}r_P(s)n_v)_{ii}$, and $n_v^{-1} = J_4^{-1}\,{}^t n_v J_4$ as n_v has similitude 1); as $k[\epsilon] \in \mathrm{CNL}_{\mathcal{O}'}$, (Zq3) gives $\psi_\lambda|_B = \psi_0|_B$. By (Zq1) the entries generate A over B, so $\psi_\lambda = \psi_0$. Both ϕ_λ, ϕ_0 kill $\mathfrak{m}_R^2$ and $R = f(A) + \mathfrak{m}_R^2$ (Step 0), so $\phi_\lambda = \phi_0$, i.e. $D_\lambda \circ \pi = 0$; as $\pi(\mathfrak{m}_R) = \bar{\mathfrak{m}}$ and $D_\lambda(\mu) = \lambda(\mu \bmod \bar{\mathfrak{m}}^2 + \varpi\bar{R})$ for $\mu \in \bar{\mathfrak{m}}$, $\lambda = 0$. Hence $\dim_k t^* \le \dim_k \mathrm{T}_S(c)$.

Step 5: dimension. The surjection $\bar{\mathfrak{m}}/\bar{\mathfrak{m}}^2 \to t^*$ has kernel $(\varpi\bar{R} + \bar{\mathfrak{m}}^2)/\bar{\mathfrak{m}}^2$, the image of the $\bar{R}$-module $\varpi\bar{R}$ generated by $\varpi \in \bar{\mathfrak{m}}$; as $\bar{R}$ acts on $\bar{\mathfrak{m}}/\bar{\mathfrak{m}}^2$ through k, this kernel is at most one-dimensional. By Theorem B.157 applied to $\bar{R}$,

$$\dim \bar{R} \le \dim_k \bar{\mathfrak{m}}/\bar{\mathfrak{m}}^2 \le \dim_k t^* + 1 \le \dim_k \mathrm{T}_S(c) + 1.$$

Step 6: the bound. Apply Lemma 53.42 with $k = \mathbb{F}_{\mathcal{O}'}$, $a\colon \mathcal{O} \subseteq \mathcal{O}' \to k$ (so $a(\mathfrak{m}_{\mathcal{O}}) = 0$), the Selmer bound C for $(\mathscr{T}, a)$ in degree d, the residual pair c over $(\mathscr{T}, \emptyset)$ and the type S, in which r_c is supported (Step 1). For (Rx1), c is good and (Nb1) gives $\dim \mathrm{T}_S(c) \le d + 20C$. For (Rx2), c lies in A, has an entry of weight $-w_\Psi$ or entries of weights $-w_\beta, -w_\theta$, and $S \neq \Sigma_Y = \Sigma_9^{\mathrm{red}}$ as $t \le 8$; (Nb2) gives the same bound. With Step 5, $\dim R/\mathrm{Red}_S(r_Q) \le d + 20C + 1$. □

Lemma 53.42. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ with field F, $d = [F:\mathbb{Q}]$, k a field, $a\colon \mathcal{O} \to k$ a ring homomorphism with $a(\mathfrak{m}_{\mathcal{O}}) = 0$, $C \ge 0$ a Selmer bound for $(\mathscr{T}, a)$ in degree d, $c = (r, (n_v))$ a residual pair over $(\mathscr{T}, \emptyset)$ with values in k, and S a reducibility type such that r is supported in S.*

(Nb1) *If c is good, then $\dim_k \mathrm{T}_S(c) \le d + 20C$.*

(Nb2) *If c lies in A, has an entry of weight $-w_\Psi$ or entries of weights $-w_\beta$ and $-w_\theta$, and $S \neq \Sigma_Y$, then $\dim_k \mathrm{T}_S(c) \le d + 20C$.*

Proof. Write $\chi_i = \chi_i^{\mathscr{T}}$ and $r_0(g) = \mathrm{diag}(a(\chi_1(g)), \dots, a(\chi_4(g)))$. By (Mq1) $r(g)$ has similitude $a(\theta(g)) \in k^\times$, so $r\colon G_F \to \mathrm{GL}_4(k)$; by (Mq3) each n_v has similitude 1 and is lower unitriangular. So c is a marked pair. By (Wq1), the diagonal of $r(g)$ is that of $r_0(g)$, and $U_v(s) = n_v^{-1}r(s)n_v$ is upper triangular (Mq4) with $U_v(s)_{11} = a(\chi_1(s))$ for $s \in D_v$. As r is supported in S, every root w such that c has an entry of weight w lies in S. Below we exhibit in each case a symplectic grading m and a marked pair $c_0 = (r_0, (n_v^0))$ such that $r(g)$, n_v are m-filtered, $\mathrm{gr}_m r(g) =$

$r_0(g)$, $\mathrm{gr}_m n_v = n_v^0$; then Lemma 53.43 gives $\dim \mathrm{T}_S(c) \le \dim \mathrm{T}_S(c_0)$, and Lemma 53.44 gives $\dim \mathrm{T}_S(c_0) \le d + 19C \le d + 20C$. In all cases an off-diagonal entry (i,j) of $r(g)$ or n_v that may be non-zero has $m_i > m_j$, except where said otherwise; then the matrix is m-filtered and its m-leading part is its diagonal part plus the entries with $m_i = m_j$.

Case 1: c has entries of weights $-w_\Psi$ and one of $w_\beta, -w_\alpha$, or of weights $-w_\alpha$ and $-w_\beta$. Then S satisfies the hypothesis of (Nl1) of Lemma 53.44. Take $n_v^0 = 1$. By (Wq2), either (P) r is supported in $\Sigma_P = \{w_\beta, -w_\alpha, -w_\theta, -w_\Psi\}$ and every n_v in $\Sigma_Q = \{-w_\alpha, -w_\Psi, -w_\theta\}$: take $m = (0,2,1,3)$; or (M) r is supported in $\Sigma_M = \{-w_\alpha, -w_\beta, -w_\Psi, -w_\theta\}$: take $m = (0,1,2,3)$.

So $\mathrm{gr}_m r(g) = r_0(g)$ and $\mathrm{gr}_m n_v = 1$, and (Nl1) applies.

Case 2: c lies in V and has an entry of weight $-w_\alpha$, or entries of weights w_β and $-w_\theta$. Then S satisfies the first hypothesis of (Nl2). Take $m = (0,1,0,1)$ ($m_1 + m_4 = m_2 + m_3 = 1$), $b_v = (n_v)_{31} \ne 0$ and $n_v^0 = 1 + b_v(E_{31} + E_{42})$. r is supported in $\Sigma_V = \{w_\beta, -w_\alpha, -w_\theta\}$, at positions $(2,3),(2,1),(4,3),(4,1)$, all with $m_i - m_j = 1$; the off-diagonal positions with $m_i = m_j$ are those of $\pm w_\Psi$, not in Σ_V, so $\mathrm{gr}_m r(g) = r_0(g)$. n_v is lower unitriangular and supported in Σ_Q, so $(n_v)_{32} = 0$ and its entries at $(2,1),(4,3),(4,1)$ have $m_i - m_j = 1$, those at $(3,1),(4,2)$ have $m_i = m_j$; and $(n_v)_{42} = (n_v)_{31} - (n_v)_{32}(n_v)_{21} = (n_v)_{31}$ by Lemma 52.7, n_v being lower unitriangular of similitude 1. Hence $\mathrm{gr}_m n_v = n_v^0$. For the character hypothesis of (Nl2), let $s \in D_v$ and compare the $(3,1)$ entries of $r(s)n_v = n_v U_v(s)$: row 3 of $r(s)$ has only the diagonal entry (the weights $-w_\Psi, -w_\beta, w_\alpha$ at $(3,1),(3,2),(3,4)$ are not in Σ_V), so the left side is $a(\chi_3(s))(n_v)_{31}$; as $U_v(s)$ is upper triangular and n_v lower unitriangular, the right side is $(n_v)_{31}U_v(s)_{11} = (n_v)_{31}a(\chi_1(s))$. As $(n_v)_{31} \ne 0$, $a(\chi_1(s)) = a(\chi_3(s))$. (Nl2) applies.

(Nb1). A good residual pair is in Case 1 (first two clauses of goodness) or Case 2 (last two clauses; the condition on rt_{w_α} in the fourth clause is not used).

(Nb2). Here r is supported in $\Sigma_A = \{-w_\beta, -w_\Psi, -w_\theta\}$ and $(n_v)_{21} \ne 0$; $S \ne \Sigma_Y$ contains $-w_\Psi$ or both $-w_\beta, -w_\theta$, the hypothesis of (Nl3). Take $m = (0,0,1,1)$ ($m_1 + m_4 = m_2 + m_3 = 1$), $b_v = (n_v)_{21}$ and $n_v^0 = 1 + b_v(E_{21} - E_{43})$. The positions of Σ_A are $(3,2),(3,1),(4,2),(4,1)$, all with $m_i - m_j = 1$; the off-diagonal positions with $m_i = m_j$ carry $\pm w_\alpha \notin \Sigma_A$; so $\mathrm{gr}_m r(g) = r_0(g)$. For the lower unitriangular n_v, the entries at $(2,1),(4,3)$ have $m_i = m_j$, the others below the diagonal $m_i - m_j = 1$, and $(n_v)_{43} = -(n_v)_{21}$ (Lemma 52.7); so $\mathrm{gr}_m n_v = n_v^0$. For the character hypothesis, compare the $(2,1)$ entries of $r(s)n_v = n_v U_v(s)$, $s \in D_v$: row 2 of $r(s)$ has only the diagonal entry (weights $-w_\alpha, w_\beta, w_\Psi$ at $(2,1),(2,3),(2,4)$ are not in Σ_A), so the left side is $a(\chi_2(s))(n_v)_{21}$, and the right side is $(n_v)_{21}U_v(s)_{11} = (n_v)_{21}a(\chi_1(s))$. As $(n_v)_{21} \ne 0$, $a(\chi_1(s)) = a(\chi_2(s))$, and (Nl3) applies. □

Lemma 53.43. *Let $\mathscr{T}$ be an auxiliary tower for a symplectic Eisenstein datum, with index set Σ, k a field, S a set of roots and m a symplectic grading. Let $c = (r, (n_v))$ and $c_0 = (r_0, (n_v^0))$ be marked pairs with values in k such that, for all $g \in G_F$ and $v \in \Sigma$, the matrices $r(g)$ and n_v are m-filtered, $r_0(g) = \mathrm{gr}_m r(g)$ and $n_v^0 = \mathrm{gr}_m n_v$. Then $\dim_k \mathrm{T}_S(c) \le \dim_k \mathrm{T}_S(c_0)$.*

Proof. If $\mathrm{T}_S(c_0)$ is infinite-dimensional there is nothing to prove; assume it is finite-dimensional. Let $s_0 = m_1 + m_4 = m_2 + m_3$, so $m_i + m_{5-i} = s_0$ for all i.

Step 1: degrees of matrices. For $p \in \mathbb{Z}$ call $Y \in \mathrm{M}_4(k)$ *of degree at least p* if $Y_{ij} = 0$ whenever $m_i - m_j < p$, and let $Y^{[p]}$ be the matrix with entries Y_{ij} where $m_i - m_j = p$ and 0 elsewhere; so m-filtered means of degree at least 0, and $\mathrm{gr}_m Y = Y^{[0]}$. Three facts:

(a) If A has degree at least p and B degree at least q, then AB has degree at least $p+q$ and $(AB)^{[p+q]} = A^{[p]}B^{[q]}$. Indeed $(AB)_{ij} = \sum_l A_{il}B_{lj}$, a term can be non-zero only if $m_i - m_l \ge p$ and $m_l - m_j \ge q$, which forces $m_i - m_j \ge p+q$; if $m_i - m_j = p+q$, the non-zero terms have $m_i - m_l = p$ and $m_l - m_j = q$, which is the (i,j) entry of $A^{[p]}B^{[q]}$.

(b) Put $Y^\dagger = J_4^{-1}\,{}^tY\,J_4$. Its (i,j) entry is $\pm Y_{5-j,5-i}$, and $m_{5-j} - m_{5-i} = (s_0 - m_j) - (s_0 - m_i) = m_i - m_j$. Hence $Y \mapsto Y^\dagger$ preserves "degree at least p" and $(Y^\dagger)^{[p]} = (Y^{[p]})^\dagger$. A matrix X lies in $\mathfrak{sp}_4(k)$ if and only if $X^\dagger = -X$, and n has similitude 1 if and only if $n^{-1} = n^\dagger$. Consequently $X \in \mathfrak{sp}_4(k)$ implies $X^{[p]} \in \mathfrak{sp}_4(k)$; and $n_v^{-1} = n_v^\dagger$ is m-filtered with $(n_v^{-1})^{[0]} = (n_v^0)^\dagger = (n_v^0)^{-1}$, as n_v^0 has similitude 1.

(c) The entries of $Y^{[p]}$ are entries of Y or 0; so if a given entry of Y vanishes, the same entry of $Y^{[p]}$ vanishes, and if Y is diagonal (upper triangular) so is $Y^{[p]}$.

Also $r(g)^{-1} = r(g^{-1})$ is m-filtered with $\mathrm{gr}_m\, r(g^{-1}) = r_0(g^{-1}) = r_0(g)^{-1}$.

Step 2: the filtration. Let $P = \{m_i - m_j\}$, a finite set of integers with smallest element $p_- \le 0$ and largest $p_+ \ge 0$. For $p \in \mathbb{Z}$ let $F_p \subseteq \mathrm{T}_S(c)$ be the subspace of $\xi = (x, (y_v))$ such that every $x(g)$ and every y_v has degree at least p. Then $F_{p_-} = \mathrm{T}_S(c)$, $F_{p_+ + 1} = 0$ and $F_{p+1} \subseteq F_p$. For $\xi \in F_p$ put $\lambda_p(\xi) = (g \mapsto x(g)^{[p]}, (y_v^{[p]})_v)$; λ_p is k-linear with kernel F_{p+1}.

Step 3: $\lambda_p(F_p) \subseteq \mathrm{T}_S(c_0)$. Let $\xi = (x, (y_v)) \in F_p$, and write $x^{[p]}(g) = x(g)^{[p]}$. By Step 1(b), $x^{[p]}(g), y_v^{[p]} \in \mathfrak{sp}_4(k)$. (Ut1): $x^{[p]}$ is locally constant (its entries are entries of x or 0); by Step 1(a) applied to $r(g)\,x(h)\,r(g^{-1})$ (degrees $0, p, 0$), the degree-p part of $x(gh) = x(g) + r(g)x(h)r(g)^{-1}$ is $x^{[p]}(gh) = x^{[p]}(g) + r_0(g)\,x^{[p]}(h)\,r_0(g)^{-1}$; $x^{[p]}(g) = 0$ for $g \in N$; and $x^{[p]}(g_{\mathscr{T}})$ is diagonal by Step 1(c). (Ut2): $x(g)r(g)$ has degree at least p with $(x(g)r(g))^{[p]} = x^{[p]}(g)\,r_0(g)$ by Step 1(a); its entries (i,j) with $i \ne j$ and $\mathrm{wt}_4(i,j) \notin S$ vanish, hence those of $x^{[p]}(g)r_0(g)$ vanish (Step 1(c)). (Ut3): by Step 1(a),(b), $n_v^{-1} y_v n_v$ has degree at least p with degree-p part $(n_v^0)^{-1} y_v^{[p]} n_v^0$, whose entries (i,j), $i \le j$, vanish by Step 1(c). (Ut4): for $s \in D_v$, $Z = x(s) + r(s) y_v r(s)^{-1} - y_v$ has degree at least p with $Z^{[p]} = x^{[p]}(s) + r_0(s)\,y_v^{[p]}\,r_0(s)^{-1} - y_v^{[p]}$; so $n_v^{-1} Z n_v$ has degree at least p with degree-p part $(n_v^0)^{-1} Z^{[p]} n_v^0$, which is upper triangular by Step 1(c). Hence $\lambda_p(\xi) \in \mathrm{T}_S(c_0)$.

Step 4: counting. Let $H_p \subseteq \mathrm{T}_S(c_0)$ be the subspace of elements $(x', (y'_v))$ with $x'(g)^{[p]} = x'(g)$ and $y_v'^{[p]} = y'_v$ for all g, v (homogeneous of degree p). By Step 3, $\lambda_p(F_p) \subseteq H_p$. The sum $\sum_{p \in P} H_p$ is direct, since an element of H_p has non-zero entries only at positions (i,j) with $m_i - m_j = p$. Therefore

$$\dim \mathrm{T}_S(c) = \sum_{p=p_-}^{p_+} \dim F_p/F_{p+1} = \sum_p \dim \lambda_p(F_p) \le \sum_{p \in P} \dim H_p \le \dim \mathrm{T}_S(c_0),$$

where $\dim F_p/F_{p+1} = \dim \lambda_p(F_p)$ because $\ker \lambda_p = F_{p+1}$, and $\lambda_p(F_p)$ is zero for $p \notin P$ (then every $Y^{[p]}$ is 0, so $F_p = F_{p+1}$). □

Lemma 53.44. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ with field F and index set Σ, $d = [F : \mathbb{Q}]$, k a field, $a\colon \mathcal{O} \to k$ a ring homomorphism with $a(\mathfrak{m}_\mathcal{O}) = 0$, and $C \ge 0$ a Selmer bound for $(\mathscr{T}, a)$ in degree d. Put $r_0(g) = \mathrm{diag}(a(\chi_1^{\mathscr{T}}(g)), \dots, a(\chi_4^{\mathscr{T}}(g)))$ for $g \in G_F$, let $(b_v)_{v \in \Sigma}$ be non-zero elements of k, and let S be a reducibility type.*

(Nl1) *If S contains $-w_\Psi$ and one of $w_\beta, -w_\alpha$, or contains $-w_\alpha$ and $-w_\beta$, then*

$$\dim_k \mathrm{T}_S(r_0, (1)_v) \le d + 19C.$$

(Nl2) *If S contains $-w_\alpha$, or contains w_β and $-w_\theta$, and $a(\chi_1^{\mathscr{T}}(s)) = a(\chi_3^{\mathscr{T}}(s))$ for all $v \in \Sigma$ and $s \in D_v$, then*

$$\dim_k \mathrm{T}_S(r_0, (1 + b_v(E_{31} + E_{42}))_v) \le d + 19C.$$

(Nl3) *If $S \neq \Sigma_Y$, S contains $-w_\Psi$ or contains $-w_\beta$ and $-w_\theta$, and $a(\chi_1^{\mathscr{T}}(s)) = a(\chi_2^{\mathscr{T}}(s))$ for all $v \in \Sigma$ and $s \in D_v$, then*

$$\dim_k \mathrm{T}_S(r_0, (1 + b_v(E_{21} - E_{43}))_v) \leq d + 19C.$$

In each item the second entry is a family of matrices of similitude 1*, so the pair is a marked pair.*

Proof. Write $\chi_i = \chi_i^{\mathscr{T}}$ and $\rho_w = a \circ \mathrm{rt}_w$. As $a(\ell) = 0$ and ℓ is odd, 2 is invertible in k. Let $c = (r_0, (n_v))$ be the pair of one of the items, with $n_v = 1$, $1 + b_v(E_{31} + E_{42})$ or $1 + b_v(E_{21} - E_{43})$. Let $P = \{(i,j) : i + j \leq 5\}$ (ten positions). The weights at P are: 0 at $(1,1), (2,2)$; $w_\Psi, -w_\Psi$ at $(1,3), (3,1)$; and the six odd roots $w_\alpha, w_\theta, w_\beta, -w_\alpha, -w_\beta, -w_\theta$ at $(1,2), (1,4), (2,3), (2,1), (3,2), (4,1)$, the *odd positions*.

Step 0: the markings and the entries. n_v has similitude 1 by Lemma 52.7: it is lower unitriangular, and $n_{43} = -n_{21}$, $n_{42} = n_{31} - n_{21}n_{32}$ hold for both markings ($1 + b(E_{31} + E_{42})$: $n_{21} = n_{43} = n_{32} = 0$, $n_{42} = n_{31} = b$; $1 + b(E_{21} - E_{43})$: $n_{43} = -n_{21} = -b$, $n_{42} = n_{31} = n_{32} = 0$). The characters satisfy $\chi_i\chi_{5-i} = \theta|_{G_F}$ (the labelling permutes $(\theta, \Psi, \alpha, \mathbf{1})$, whose products $\kappa_1\kappa_4 = \kappa_2\kappa_3 = \theta$ are the similitude of r_0), hence $\chi_i/\chi_j = \mathrm{rt}_{\mathrm{wt}_4(i,j)}$:

Let $\xi = (x, (y_v)) \in \mathrm{T}_S(c)$ and write $x_{ij}(g) = x(g)_{ij}$. As $(r_0(g)Yr_0(g)^{-1})_{ij} = \rho_{\mathrm{wt}_4(i,j)}(g)Y_{ij}$, (Ut1) gives: x_{ij} is locally constant, $x_{ij}(gh) = x_{ij}(g) + \rho_{\mathrm{wt}_4(i,j)}(g)x_{ij}(h)$, $x_{ij}(N) = 0$, and $x_{ij}(g_{\mathscr{T}}) = 0$ for $i \neq j$ (note $\mathrm{wt}_4(i,j) = 0$ only for $i = j$). So $x_{ij} \in Z(\mathrm{wt}_4(i,j))$. If $i \neq j$ and $\mathrm{wt}_4(i,j) \notin S$, then $x_{ij} = 0$: by (Ut2) $0 = (x(g)r_0(g))_{ij} = x_{ij}(g)\, a(\chi_j(g))$ and $a(\chi_j(g)) \in k^\times$.

Step 1: local coboundaries. For $v \in \Sigma$ and a character $\rho\colon D_v \to k^\times$ let $B_v(\rho)$ be the k-space of functions $s \mapsto (1 - \rho(s))t$ on D_v, $t \in k$. Call an odd-position entry x_{ij} *locally trivial* if $x_{ij}|_{D_v} \in B_v(\rho_{\mathrm{wt}_4(i,j)}|_{D_v})$ for every v; then $x_{ij} \in Z^{\mathrm{str}}(\mathrm{wt}_4(i,j))$ by Step 0. For $s \in D_v$ put $Z^v(s) = x(s) + r_0(s)y_v r_0(s)^{-1} - y_v$; then

$$Z^v(s)_{ij} = x_{ij}(s) - \big(1 - \rho_{\mathrm{wt}_4(i,j)}(s)\big)(y_v)_{ij}, \qquad \text{so } Z^v_{ij} \equiv x_{ij}|_{D_v} \bmod B_v(\rho_{\mathrm{wt}_4(i,j)}|_{D_v}),$$

$Z^v(s) \in \mathfrak{sp}_4(k)$, and $n_v^{-1}Z^v(s)n_v$ is upper triangular by (Ut4).

Step 2: the count under a one-odd hypothesis. Suppose there is an odd position (i_0, j_0) such that *every $\xi \in \mathrm{T}_S(c)$ with $x_{i_0j_0} = x_{11} = x_{22} = 0$ has its six odd-position entries locally trivial.* Let $\Phi_1\colon \mathrm{T}_S(c) \to Z(\mathrm{wt}_4(i_0,j_0)) \times Z(0) \times Z(0)$, $\xi \mapsto (x_{i_0j_0}, x_{11}, x_{22})$ (Step 0); as $\mathrm{wt}_4(i_0,j_0)$ is an odd root, its image has dimension at most $(d + C) + C + C$. On $K = \ker \Phi_1$ consider

$$\Phi_2\colon K \to \prod_{(i,j)\in P} M_{ij} \times \prod_{v\in\Sigma} k^{\{(i,j):\, i>j\}}, \qquad \xi \mapsto \Big((x_{ij})_{(i,j)\in P},\ \big((n_v^{-1}y_v n_v)_{ij}\big)_{v,\, i>j}\Big),$$

with $M_{ij} = Z^{\mathrm{str}}(\mathrm{wt}_4(i,j))$ at odd positions and $M_{ij} = Z(\mathrm{wt}_4(i,j))$ at the four positions of weight $0, \pm w_\Psi$; it is well defined by Step 0 and the hypothesis. The target has dimension at most $10C + 6\,\#\Sigma \leq 16C$ (Selmer bound: $\dim Z^{\mathrm{str}}(w) \leq C$ for roots, $\dim Z(w) \leq C$ for $w \in \{0, \pm w_\Psi\}$, $\#\Sigma \leq C$). Φ_2 is injective: an element X of $\mathfrak{sp}_4(k)$ is determined by its entries at P,

so $\Phi_2(\xi) = 0$ forces $x = 0$; and $n_v^{-1}y_v n_v$ has vanishing entries on and above the diagonal by (Ut3), and below it by $\Phi_2(\xi) = 0$, so $y_v = 0$. Hence $\dim \mathrm{T}_S(c) \leq (d + 3C) + 16C = d + 19C$. It remains to verify the one-odd hypothesis in each item; the table of the nine types is in Definition 53.38.

Step 3: (Nl1). Here $n_v = 1$, so $Z^v(s)$ is upper triangular and $Z^v_{ij} = 0$ for $i > j$: the entries at the lower odd positions $(2,1), (3,2), (4,1)$ are locally trivial for every ξ (Step 1). The types

satisfying the hypothesis of (Nl1) are $\Sigma_1^{\mathrm{red}}, \Sigma_5^{\mathrm{red}}, \Sigma_7^{\mathrm{red}}$, and each contains exactly one of the roots $w_\alpha, w_\theta, w_\beta$ of the upper odd positions:

Take (i_0, j_0) the position of that root; the other two upper odd entries vanish by Step 0. So all six odd entries of every ξ with $x_{i_0 j_0} = 0$ are locally trivial.

Step 4: (Nl2). Here $n = n_v = 1 + bX$ with $X = E_{31} + E_{42}$, $b = b_v \neq 0$, $X^2 = 0$, $n^{-1} = 1 - bX$. Let $Z \in \mathfrak{sp}_4(k)$ with $U = n^{-1} Z n$ upper triangular ($U \in \mathfrak{sp}_4(k)$ as n has similitude 1). Then

$$Z_{21} = -b\, Z_{23}, \qquad Z_{41} = -b^2 Z_{23}, \qquad Z_{32} = 2b\, Z_{12} + b^2 Z_{14}.$$

On D_v, $a(\chi_1) = a(\chi_3)$ gives $\rho_{-w_\alpha} = \rho_{w_\beta} = \rho_{-w_\theta} =: \rho^-$ and $\rho_{w_\alpha} = \rho_{w_\theta} = \rho_{-w_\beta} =: \rho^+$

so by Step 1, modulo $B_v(\rho^-)$: $x_{21} \equiv -b\, x_{23}$, $x_{41} \equiv -b^2 x_{23}$; modulo $B_v(\rho^+)$: $x_{32} \equiv 2b\, x_{12} + b^2 x_{14}$ (restrictions to D_v). As $b, 2 \in k^\times$: if one of x_{21}, x_{23}, x_{41} is locally trivial, all three are; if two of x_{12}, x_{14}, x_{32} are, all three are. The types satisfying the hypothesis of (Nl2) are $\Sigma_1^{\mathrm{red}}, \Sigma_3^{\mathrm{red}}, \Sigma_5^{\mathrm{red}}, \Sigma_6^{\mathrm{red}}, \Sigma_7^{\mathrm{red}}, \Sigma_Y$, and the choice

$$(i_0, j_0) = (2,3), (2,3), (1,2), (1,2), (2,3), (1,4)$$

respectively makes one entry of the first triple and two of the second equal to $x_{i_0 j_0}$ or of weight outside S (hence 0 by Step 0):

So every ξ with $x_{i_0 j_0} = 0$ has its six odd entries locally trivial.

Step 5: (Nl3). Here $n = 1 + bX$ with $X = E_{21} - E_{43}$, $b = b_v \neq 0$, $X^2 = 0$. For $Z \in \mathfrak{sp}_4(k)$ with $n^{-1} Z n$ upper triangular,

$$Z_{21} = b^2 Z_{12} + b\,(Z_{11} - Z_{22}), \qquad Z_{32} = 0, \qquad Z_{41} = 0.$$

On D_v, $a(\chi_1) = a(\chi_2)$ gives $\rho_{\pm w_\alpha} = 1$, and $\rho_0 = 1$; as $B_v(1) = 0$, Step 1 gives $Z_{ij}^v = x_{ij}|_{D_v}$ for $(i,j) \in \{(1,1), (2,2), (1,2), (2,1)\}$. Hence for ξ with $x_{11} = x_{22} = 0$: $x_{21}(s) = b^2 x_{12}(s)$ for $s \in D_v$; and for every ξ the entries x_{32}, x_{41} are locally trivial ($Z_{32}^v = Z_{41}^v = 0$). The types satisfying the hypothesis of (Nl3) are $\Sigma_1^{\mathrm{red}}, \Sigma_4^{\mathrm{red}}, \Sigma_5^{\mathrm{red}}, \Sigma_7^{\mathrm{red}}, \Sigma_8^{\mathrm{red}}$; take

$$(i_0, j_0) = (2,3), (1,4), (1,2), (2,3), (1,4)$$

respectively.

Then for ξ with $x_{i_0 j_0} = x_{11} = x_{22} = 0$: $x_{14} = x_{23} = 0$ (one is $x_{i_0 j_0}$, the other has weight outside S); one of x_{12}, x_{21} is 0 (it is $x_{i_0 j_0}$ or has weight outside S), so both vanish on every D_v ($b \neq 0$) and are locally trivial; and x_{32}, x_{41} are locally trivial. This is the one-odd hypothesis, and Step 2 concludes. □

Lemma 53.45. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a good auxiliary tower for $\mathfrak{D}$ with field F, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, c a residual pair over $(\mathscr{T}, \emptyset)$ with values in $\mathbb{F}_{\mathcal{O}'}$, $R \in \mathrm{CNL}_{\mathcal{O}'}$, and $Q = (r_Q, (n_v))$ a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in R (for $\mathcal{O} \subseteq \mathcal{O}' \to R$), continuous for $\mathfrak{m}_R$, with reduction c. Let $\varphi\colon R \to K$ be a ring homomorphism to a field such that $\ker\varphi$ contains none of the ideals $\mathrm{Red}_{\Sigma_k^{\mathrm{red}}}(r_Q)$, $1 \leq k \leq 9$. Then the K-span of the matrices $\varphi(r_Q(g))$, $g \in G_F$, is $\mathrm{M}_4(K)$.*

Proof. Write $r = \varphi \circ r_Q\colon G_F \to \mathrm{M}_4(K)$ and let $\mathcal{A}$ be the K-span of $r(G_F)$. We show: if $\mathcal{A} \neq \mathrm{M}_4(K)$, then r is supported in some Σ_k^{red}, i.e. $\ker\varphi \supseteq \mathrm{Red}_{\Sigma_k^{\mathrm{red}}}(r_Q)$ (last sentence of Definition 53.38); this is the contrapositive of the statement.

Step 1: $\mathcal{A}$ is a subalgebra containing the diagonal matrices. r_Q is a homomorphism of monoids, so $r(1) = 1$ and $r(g)r(h) = r(gh)$; hence $\mathcal{A}$ is a K-subalgebra of $\mathrm{M}_4(K)$. By (Mq2),

$X = r(g_{\mathscr{T}})$ is diagonal, with entries $x_i = \varphi(r_Q(g_{\mathscr{T}})_{ii})$. As Q has reduction c and c satisfies (Wq1), $r_Q(g_{\mathscr{T}})_{ii} \equiv \chi_i^{\mathscr{T}}(g_{\mathscr{T}})$ modulo $\mathfrak{m}_R$; by (Oq7) the residues $\bar{\kappa}_i^{\epsilon}(g_{\mathscr{T}})$ are pairwise distinct, so for $i \neq j$ the difference $r_Q(g_{\mathscr{T}})_{ii} - r_Q(g_{\mathscr{T}})_{jj}$ is a unit of the local ring R and $x_i \neq x_j$. Then $E_{ii} = \prod_{j \neq i}(X - x_j)/(x_i - x_j) \in \mathcal{A}$ for every i.

Step 2: the pattern. Let P be the set of pairs (i,j) with $E_{ij} \in \mathcal{A}$. For $Y \in \mathcal{A}$ we have $E_{ii} Y E_{jj} = Y_{ij} E_{ij} \in \mathcal{A}$ and $Y = \sum_{i,j} Y_{ij} E_{ij}$. Hence: $(i,j) \notin P$ if and only if $r(g)_{ij} = 0$ for all $g \in G_F$; $\mathcal{A}$ is spanned by the E_{ij}, $(i,j) \in P$; $(i,i) \in P$; and P is transitive, as $E_{ij}E_{jk} = E_{ik}$. Moreover, with $1' = 4$, $2' = 3$, $3' = 2$, $4' = 1$: if $(i,j) \in P$ then $(j', i') \in P$. Indeed, for $g \in G_F$ the matrix $Y = r(g)$ has similitude $\nu = \varphi(\theta(g))$, a unit, by (Mq1), so ${}^t Y J_4 Y = \nu J_4$ gives $J_4^{-1}\,{}^t Y J_4 = \nu Y^{-1} = \nu\, r(g^{-1}) \in \mathcal{A}$ (as $r(g)r(g^{-1}) = 1$); by linearity $J_4^{-1}\,{}^t Y J_4 \in \mathcal{A}$ for all $Y \in \mathcal{A}$, and $J_4^{-1}\,{}^t E_{ij} J_4 = \pm E_{j'i'}$.

The map $(i,j) \mapsto (j', i')$ preserves weights and exchanges the two entries of each weight $\pm w_\alpha$, $\pm w_\Psi$ and fixes the entries of weight $\pm w_\beta, \pm w_\theta$.

So $(i,j) \in P$ depends only on $\mathrm{wt}_4(i,j)$ for $i \neq j$.

Step 3: a proper pattern lies in a type. Suppose $\mathcal{A} \neq \mathrm{M}_4(K)$; by Step 2 some $(i_0, j_0) \notin P$. Let $U = \{k : (k, j_0) \in P\}$; then $j_0 \in U$ and $i_0 \notin U$. If $a \notin U$ and $b \in U$, then $(a,b) \notin P$: otherwise $(a,b), (b,j_0) \in P$ give $(a,j_0) \in P$ by transitivity. Let W_U be the set of roots w such that every pair (a,b), $a \neq b$, with $\mathrm{wt}_4(a,b) = w$ has $a \in U$ or $b \notin U$. If $i \neq j$ and $\mathrm{wt}_4(i,j) \notin W_U$, some pair (a,b) of the same weight has $a \notin U$, $b \in U$, so $(a,b) \notin P$, hence $(i,j) \notin P$ by the last sentence of Step 2, and $r(g)_{ij} = 0$ for all g. Thus r is supported in W_U. Finally, U is a non-empty proper subset of $\{1,2,3,4\}$, and for each of the fourteen such sets W_U is one of the reducibility types.

Hence r is supported in some Σ_k^{red}, which proves the contrapositive. □

Lemma 53.46. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ an auxiliary tower for $\mathfrak{D}$ with index set Σ, K a field, $a\colon \mathcal{O} \to K$ a ring homomorphism and $P = (r, (n_v))$ a marked ordinary pair over $(\mathscr{T}, \emptyset)$ with values in K (for a) such that r is supported in Σ_Y. If $v \in \Sigma$ and $(n_v)_{21} \neq 0$, then $\psi_{v,1}^P(s) = \psi_{v,2}^P(s)$ for all $s \in D_v$, or $\psi_{v,2}^P(s) = \psi_{v,4}^P(s)$ for all $s \in D_v$.*

Proof. Write $n = n_v$, $V = K^4$ with standard basis $e_1, \dots, e_4$, and $\omega(x,y) = {}^t x J_4 y$; so $\omega(e_i, e_j) = (J_4)_{ij}$ is non-zero only for $\{i,j\} = \{1,4\}$ or $\{2,3\}$. For $s \in D_v$ put $T(s) = n^{-1} r(s) n$, upper triangular with diagonal $\psi_i(s) = \psi_{v,i}^P(s)$ by (Mq4).

Step 1: the flag. Put $F_k = n\langle e_1, \dots, e_k\rangle$. Since $r(s)ne_k = nT(s)e_k = \sum_{j \leq k} T(s)_{jk}\, ne_j$, each F_k is $r(s)$-stable and $r(s)$ acts on F_k/F_{k-1} by $\psi_k(s)$. By (Mq3), n has similitude 1, so $\omega(nx, ny) = \omega(x,y)$; as $\langle e_1\rangle^\perp = \langle e_1, e_2, e_3\rangle$, we get $F_3 = F_1^\perp$.

Step 2: $\psi_1\psi_4 = \psi_2\psi_3$. By (Mq1), $r(s)$ has similitude $\nu = a(\theta(s))$, hence so has $T(s)$. For an upper triangular T with ${}^t T J_4 T = \nu J_4$, the $(1,4)$ entry gives $T_{11}T_{44} = \nu$ and the $(2,3)$ entry gives $T_{22}T_{33} = \nu$.

So $\psi_1(s)\psi_4(s) = \psi_2(s)\psi_3(s)$, and all $\psi_i(s)$ are non-zero ($r(s)r(s^{-1}) = 1$).

Step 3: an eigenplane. The vector $u = ne_1 = (1, x_2, x_3, x_4)$ (first column of n, unit diagonal by (Mq3)) has $x_2 = (n_v)_{21} \neq 0$, and $r(s)u = \psi_1(s)u$ (Step 1, $k = 1$). The off-diagonal entries of weight in $\Sigma_Y = \{\pm w_\beta, \pm w_\theta\}$ are $(2,3), (3,2)$ (weights $\pm w_\beta$) and $(1,4), (4,1)$ (weights $\pm w_\theta$), so every $r(s)$ preserves $V_{14} = \langle e_1, e_4\rangle$ and $V_{23} = \langle e_2, e_3\rangle$. Writing $u = u' + u''$ with $u' = (1,0,0,x_4) \in V_{14}$ and $u'' = (0, x_2, x_3, 0) \in V_{23}$, both non-zero, $r(s)u' = \psi_1(s)u'$ and $r(s)u'' = \psi_1(s)u''$. So $W = \langle u', u''\rangle$ is a plane on which every $r(s)$, $s \in D_v$, acts by the scalar $\psi_1(s)$; W is isotropic for ω ($V_{14} \perp V_{23}$, and each of u', u'' is isotropic as ω is alternating), and $u \in W$, so $W \subseteq u^\perp = F_3$.

Step 4: conclusion. If $W \subseteq F_2$, take $w \in W \setminus F_1$ (possible, $\dim W = 2$): its class in F_2/F_1 is non-zero and $r(s)w = \psi_1(s)w$, so $\psi_2(s) = \psi_1(s)$ for all $s \in D_v$. Otherwise take $w \in W \setminus F_2 \subseteq F_3$: in the same way $\psi_3(s) = \psi_1(s)$ for all $s \in D_v$, and Step 2 gives $\psi_4(s) = \psi_2(s)\psi_3(s)/\psi_1(s) = \psi_2(s)$. The alternative does not depend on s, since W and the F_k do not. □

Lemma 53.47. *Let $\mathfrak{D}$ be a symplectic Eisenstein datum with coefficient ring $\mathcal{O}$, $\mathscr{T}$ a fit auxiliary tower for $\mathfrak{D}$ with field F and index set Σ, $\mathcal{O}' \supseteq \mathcal{O}$ a coefficient ring, $\mathscr{X} = (B, A, P, \mathrm{cp}, (\psi^B_{v,i}))$ a space for $(\mathscr{T}, \mathcal{O}')$, $x\colon A \to \mathbb{F}_{\mathcal{O}'}$ an $\mathcal{O}'$-algebra homomorphism such that $c = x(P)$ is a residual pair over $(\mathscr{T}, \emptyset)$, R the completion of A at the maximal ideal $\ker x$ and $f\colon A \to R$ the canonical homomorphism; put $\phi = f|_B\colon B \to R$. Let $\mathfrak{q}$ be a prime of R, K the fraction field of $R/\mathfrak{q}$ and $\bar{r}\colon G_F \to \mathrm{M}_4(K)$ the composite of $f \circ r_P$ with $R \to R/\mathfrak{q} \subseteq K$. If the K-span of $\bar{r}(G_F)$ is $\mathrm{M}_4(K)$, or $\bar{r}$ is supported in Σ_Y and has entries of weights w_β, $-w_\beta$, w_θ and $-w_\theta$, then*

$$\dim R/\mathfrak{q} \leq \dim B/\phi^{-1}(\mathfrak{q}) + 2 + 4\#\Sigma.$$

Proof. Symbols introduced here are local to this proof. Let $\mathfrak{m} = \ker x$, $\mathfrak{p} = f^{-1}(\mathfrak{q})$ (a prime of A contained in $\mathfrak{m}$) and $\mathfrak{p}_B = \mathfrak{p} \cap B = \phi^{-1}(\mathfrak{q})$ ($B \subseteq A$ by (Zq1)). As $x|_B$ is a surjective homomorphism of the local ring B onto a field, $\mathfrak{m} \cap B = \mathfrak{m}_B$. A is a finitely generated algebra over the Noetherian ring B (Zq1), hence Noetherian.

Step 1: reduction to A. R is the $\mathfrak{m}$-adic completion of the Noetherian local ring $A_{\mathfrak{m}}$, and $R/\mathfrak{p}R$ is the completion of $(A/\mathfrak{p})_{\mathfrak{m}}$; a Noetherian local ring and its completion have the same dimension. Since $\mathfrak{q} \supseteq \mathfrak{p}R$, $\dim R/\mathfrak{q} \leq \dim R/\mathfrak{p}R = \dim(A/\mathfrak{p})_{\mathfrak{m}} = \mathrm{ht}(\mathfrak{m}/\mathfrak{p})$.

Step 2: the dimension inequality. $A/\mathfrak{p}$ is a domain, finitely generated over its subring $B/\mathfrak{p}_B$, a Noetherian domain; $\mathfrak{m}/\mathfrak{p}$ lies over $\mathfrak{m}_B/\mathfrak{p}_B$ and both residue fields are $\mathbb{F}_{\mathcal{O}'}$. By the dimension inequality ([166, Thm. 15.5]), $\mathrm{ht}(\mathfrak{m}/\mathfrak{p}) \leq \mathrm{ht}(\mathfrak{m}_B/\mathfrak{p}_B) + \mathrm{trdeg}_{K_B} K_A$, where $K_B \subseteq K_A$ are the fraction fields of $B/\mathfrak{p}_B \subseteq A/\mathfrak{p}$; and $\mathrm{ht}(\mathfrak{m}_B/\mathfrak{p}_B) = \dim B/\mathfrak{p}_B$ as B is local. So it suffices to show $\mathrm{trdeg}_{K_B} K_A \leq 2 + 4\#\Sigma$.

Step 3: generators. f induces an injection $A/\mathfrak{p} \to R/\mathfrak{q} \subseteq K$; we regard $K_B \subseteq K_A \subseteq K$. The matrices $\bar{r}(g)$ have similitude $\nu(g)$, the image of $\theta(g) \in \mathcal{O}$ (Mq1), so $\nu(g) \in K_B$; $\bar{r}(g_{\mathscr{T}})$ is diagonal (Mq2); its diagonal entries are pairwise distinct, because their reductions modulo $\mathfrak{m}_R \supseteq \mathfrak{q}$ are the residues $\bar{\kappa}^c_i(g_{\mathscr{T}})$ of the residual pair c (Wq1), pairwise distinct by (Oq7). By the hypothesis and Lemma 53.48 there are $s, t \in K$ such that every subfield of K containing s, t, the $\nu(g)$, the traces and the diagonal of $\bar{r}(g_{\mathscr{T}})$ contains all entries of all $\bar{r}(g)$. For $v \in \Sigma$ the matrix n_v is lower triangular with diagonal entries 1 and similitude 1 (Mq3); writing its entries below the diagonal as $a = (n_v)_{21}$, $b = (n_v)_{31}$, $c' = (n_v)_{41}$, $d = (n_v)_{32}$, $e = (n_v)_{42}$, $h = (n_v)_{43}$, the entries $(2,1)$ and $(3,1)$ of ${}^t n_v J_4 n_v = J_4$ give $b - ad - e = 0$ and $-a - h = 0$, so $e = b - ad$ and $h = -a$. Let $T \subseteq K$ consist of s, t and the images of a, b, c', d for all $v \in \Sigma$, so $\#T \leq 2 + 4\#\Sigma$, and let $E \subseteq K$ be the algebraic closure in K of $K_B(T)$, a subfield.

Step 4: $K_A \subseteq E$. The traces of $\bar{r}(g)$ are images of coefficients of $\mathrm{cp}(g) \in B[X]$ (Zq2), so lie in K_B; the diagonal entries of $\bar{r}(g_{\mathscr{T}})$ are roots of the image of the monic $\mathrm{cp}(g_{\mathscr{T}})$, hence algebraic over K_B and in E. So E satisfies the hypotheses of Lemma 53.48, and all entries of all $\bar{r}(g)$ lie in E; so do the images of all entries of all n_v by Step 3. These entries generate A as a B-algebra (Zq1), so $A/\mathfrak{p} \subseteq E$ and $K_A \subseteq E$. Hence $\mathrm{trdeg}_{K_B} K_A \leq \mathrm{trdeg}_{K_B} E = \mathrm{trdeg}_{K_B} K_B(T) \leq \#T \leq 2 + 4\#\Sigma$, and with Steps 1 and 2, $\dim R/\mathfrak{q} \leq \dim B/\phi^{-1}(\mathfrak{q}) + 2 + 4\#\Sigma$. □

Lemma 53.48. *Let K be a field, Γ a group, $r\colon \Gamma \to \mathrm{M}_4(K)$ a homomorphism of monoids and $\nu\colon \Gamma \to K$ a map such that $r(g)$ has similitude $\nu(g)$ for every g, and $g_0 \in \Gamma$ such that $r(g_0)$ is diagonal with pairwise distinct diagonal entries. Assume that the K-span of $r(\Gamma)$ is $\mathrm{M}_4(K)$,*

or that r is supported in Σ_Y and has entries of weights w_β, $-w_\beta$, w_θ and $-w_\theta$. Then there are $s,t \in K$ such that every subfield $E \subseteq K$ containing s, t, all $\nu(g)$, all traces $\operatorname{tr} r(g)$ and the diagonal entries of $r(g_0)$ contains all entries of all $r(g)$, $g \in \Gamma$.

Proof. Symbols introduced here are local to this proof. Write E_{ij} for the matrix units, $D = r(g_0) = \operatorname{diag}(d_1, \dots, d_4)$, and for a subfield E as in the statement let $\mathcal{A}_E$ be the E-linear span of $r(\Gamma)$; as r is a homomorphism of monoids, $\mathcal{A}_E$ is an E-algebra containing $r(1) = 1$ and D, and $\operatorname{tr}(\mathcal{A}_E) \subseteq E$. Since $r(g)r(g^{-1}) = 1$, every $r(g)$ is invertible.

Step 1 (any such E). $E_{ii} = \prod_{j \neq i}(D - d_j)/(d_i - d_j) \in \mathcal{A}_E$, so $r(g)_{ij}E_{ij} = E_{ii}r(g)E_{jj} \in \mathcal{A}_E$ for all g, i, j. Taking traces: $r(g)_{ii} \in E$; $r(g)_{ij}r(h)_{ji} \in E$; and $r(g)_{ij}r(h)_{jk}r(h')_{ki} \in E$ for distinct i, j, k (trace of $r(g)_{ij}E_{ij} \cdot r(h)_{jk}E_{jk} \cdot r(h')_{ki}E_{ki}$). Consequently: (a) if $x \in E$ is a non-zero (i,j)-entry of some $r(g)$, then every (j,i)-entry $r(h)_{ji}$ lies in E; (b) if $x \in E$, $x' \in E$ are non-zero (i,j)- and (j,k)-entries of some $r(g)$, $r(g')$ (i, j, k distinct), then every (k,i)-entry lies in E.

Step 2: first alternative. The K-span of $r(\Gamma)$ is $\mathrm{M}_4(K)$, so $E_{ii}\mathrm{M}_4(K)E_{jj} \neq 0$ shows that for all $i \neq j$ some $r(g)_{ij} \neq 0$. Choose g_{12}, g_{13} with $s = r(g_{12})_{12} \neq 0$, $t = r(g_{13})_{13} \neq 0$. Let J_4 have $(J_4)_{i,\sigma(i)} = \varepsilon_i$ with $\sigma = (1\,4)(2\,3)$, $(\varepsilon_1, \dots, \varepsilon_4) = (1, 1, -1, -1)$, so $J_4^{-1} = -J_4$; from ${}^t r(g) J_4 r(g) = \nu(g) J_4$, $r(g)^{-1} = -\nu(g)^{-1} J_4 \, {}^t r(g) J_4$, i.e. $r(g^{-1})_{ij} = -\nu(g)^{-1}\varepsilon_i\varepsilon_{\sigma(j)} r(g)_{\sigma(j)\sigma(i)}$. Hence $r(g_{13}^{-1})_{24} = -\nu(g_{13})^{-1}t$ and $r(g_{12}^{-1})_{34} = \nu(g_{12})^{-1}s$, non-zero. Now let E be as in the statement. Then $s, t, -\nu(g_{13})^{-1}t, \nu(g_{12})^{-1}s \in E$ are non-zero entries at $(1,2), (1,3), (2,4), (3,4)$, so by (a) all entries at $(2,1), (3,1), (4,2), (4,3)$ lie in E; choosing non-zero such entries (they exist), (a) gives all entries at $(1,2), (1,3), (2,4), (3,4)$. By (b) with $(1,2), (2,4)$: all entries at $(4,1)$; then (a): all entries at $(1,4)$. By (b) with $(3,1), (1,2)$: all entries at $(2,3)$; with $(2,1), (1,3)$: all entries at $(3,2)$. With the diagonal (Step 1), all entries of all $r(g)$ lie in E.

Step 3: second alternative. The weights are $\mathrm{wt}_4(1,4) = w_\theta$, $\mathrm{wt}_4(2,3) = w_\beta$ and their negatives at $(4,1)$, $(3,2)$ (with $\boldsymbol{\lambda} = (1,0,1,0)$, $\boldsymbol{\mu} = (1,1,0,0)$), so r is supported on the diagonal and the positions $(1,4), (4,1), (2,3), (3,2)$, and each of these carries a non-zero entry of some $r(g)$. Choose $s \neq 0$ a $(1,4)$-entry and $t \neq 0$ a $(2,3)$-entry. For E as in the statement, (a) gives all $(4,1)$- and $(3,2)$-entries in E; choosing non-zero ones, (a) gives all $(1,4)$- and $(2,3)$-entries; with the diagonal and the vanishing of the other entries, all entries lie in E. □

A The construction beneath (TCS)

This appendix explains the construction that is expected to produce a theta chain system (TCS), Hypothesis 21.1. It is not part of the proof, and the paragraphs headed "Sketch." are heuristic arguments, not proofs. A theta chain system is stated in Section 21 through its records, the base translate packets of Definition 19.1; this appendix describes the chains of theta lifts that are expected to produce these records. In Alpöge's account the chain is a sequence of iterated theta lifts $\mathrm{U}(X_0) \to \mathrm{U}(X_1) \to \cdots \to \mathrm{U}(X_m)$ between unitary groups, which wins multiplicity m [4], and the see-saw, the Bessel periods and the work of Rallis belong to it. The construction follows the formal development [3], which we have not verified.

We recall what (TCS) asserts; Section 21 reads its statement clause by clause. At every large scale x of a set of scales containing λ-windows, and over prescribed good-host data at that scale (Definition 11.4), (TCS) asks for a base translate packet: one loss datum and one slope record for every translate $u \in A_x$, with constants common to all scales. Clause (Rr1) asks the loss data to satisfy (Lm2) and (Lm5)–(Lm7) of Definition 5.5. Clause (Rr2) makes the numerical data explicit: rank sizes, integer weights in prescribed boxes, the selected good-orbit choices, and orbit corrections with common constants. Clause (Rr3) holds under the eventual bound for Tate–Shafarevich groups. It asks for lower completions, kernel hypotheses and a word bound; for covolume, chain, deep-cover, component and model data; for explicit arrays of divided weights; for unitary Shimura data that satisfy (Aj1) and (Aj3) of Theorem 29.14; and for reference comparison data that meet every hypothesis of Theorem 20.2.

The clauses are consumed by one result, Proposition 21.2. It uses all of (Rr1) and (Rr3), and all of (Rr2) except the exact formula for L_c, of which it needs only an upper bound. It obtains the bounds (Ms1) and (Ms3) for model slopes from Theorem 29.14, and the realisation estimate (Ri1) from Theorem 20.2. Both theorems are proved in the body of the paper. Beneath (TCS) they appear only through their hypotheses, which the construction must meet. The same holds in two further places. The covolume inequality is Theorem 19.26, and the construction supplies the data to which it applies. The local losses are bounded by the Ribet budget Theorem 22.1, and the construction must meet its hypotheses at the members it builds.

The sections follow the construction. Section A.1 shows how three statements combine into (TCS): a class of families with a selection, a table of heights and depths at every scale, and the reading of the packets from the selected members. Section A.2 chooses the tables, so that the orbit shares in (Rr1) are small. Sections A.3 and A.4 build the arithmetic and automorphic material of the chain: theta kernels on a CM elliptic curve, integral at the primes inert in the imaginary quadratic field, and theta lifts along the rows of a grid of hermitian spaces, with separation of Bessel functionals, Rallis towers, the see-saw and an identity for multiplicities. Section A.5 builds the members of the packets from this material in two passes. Sections A.6 and A.7 prove the approximate orthogonality of Poincaré series at the members, which gives the slope records. Section A.8 supplies the covolume data, and Section A.9 attaches the Galois-theoretic records to the members. Where no statement printed here covers a step of the construction, a short sketch says what the step must achieve and why it is plausible.

A.1 What a theta chain system asks for, and how the construction supplies it

The proof of (TCS) from the construction is a composition of three statements, and this section states two of them. Proposition A.1 fixes one class $\mathfrak{A}$ of families together with a selection σ, before λ, the host requirement and ε, and returns, for every small ε, a family of the class over the prescribed host requirement. Proposition A.19, stated in Section A.2, chooses one pair of integer

tables of heights and depths at every scale, before any context or member, and shows that the members built on these tables have the numerical content of (Rr1) and (Rr2). Proposition A.2 reads the packets and their completions from the members that the selection picks: its first item gives (Rr1) and (Rr2), its second the lower completions and kernel data, its third the covolume, chain, deep-cover and model data with (Aj1) and (Aj3), and its fourth the reference data for Theorem 20.2. The choices are made in a fixed order: the class and the selection; then ε; then thresholds; then the profile and the exponents; then the tables; then contexts and members; and last the constants and the tails. The threshold on ε that (TCS) allows may depend on λ and on the host requirement, and the bound $\varepsilon_0(\lambda, G)$ of Proposition A.1 depends on exactly these. The second subsection collects the bookkeeping that lets finitely many separately proved properties hold on the same selected objects.

A.1.1 The three inputs and their composition

The class of Proposition A.1 is defined by a witnessed equivalence, so a selection over it exists automatically. The substance of the statement is that actual design families belong to the class. One row parameter must serve the whole family, and at every real size there must be bundles, linked for that parameter, at the members of the family. The statement also fixes the number of words of every context, $|\mathcal{W}_{x,u}| = \lceil 3\Gamma_{x,u}^2 x^{C_H} \rceil$, which (TCS) uses in its word bound. Proposition A.2 then reads the packets of (TCS) from the selected members. Its second item rests on the packet-level row records of Theorem A.71, and its local defect data on the Galois-theoretic records of Theorem A.105. Its third item asks for the covolume, deep-cover and model data that Section A.8 constructs at realised points, and its fourth for reference data that meet every hypothesis of Theorem 20.2. The sketch after Proposition A.2 explains how these attachments are expected to go.

Proposition A.1. *Let $p = p_A$ be the final parameter of the row-parameter construction. There are one class $\mathfrak{A}$ of parametrised families carrying member objects, a selection σ over it and an E_{all}-selection structure, all defined before λ, the host requirements and ε. Membership in $\mathfrak{A}$ is defined by an equivalence, described in the sketch below, with one linked row parameter per family and built E_{all}-bundles of every real size at the member objects of the family. Here $R_{\mathrm{all}}, E_{\mathrm{all}}$ are a joint slot and bundle predicate for the twenty-six joint row conclusions, and the norm predicate is the predicate $\mathcal{H}_{\mathrm{norm}}$ of the row-parameter construction. The class has the seven duties and the conclusions below.*

Fix $\lambda > 1$ and a predicate $G(s, \phi, \mathfrak{h}, T, t)$ on a scale $s = (x, \varepsilon, J)$, a frame ϕ, a host $\mathfrak{h}$ on that frame, its top set T and its rank t. Assume the following host-existence condition: for every $0 < \varepsilon < 1/52$ there are constants C_{T_2}, $C_8 \geq 1$, $C_5, c_6, C_b > 0$, a common J, a set W containing λ-windows and a real X_H such that every $x \in W$ with $x \geq X_H$ admits a complete choice of the data of the concrete good-host requirement of Definition 11.4 with these constants and with $G((x, \varepsilon, J), \phi_x, \mathfrak{h}_x, T_x, t_x)$. The predicate G depends only on these host data; it prescribes no later constant profile, exponent pair, table, context or member.

There is $\varepsilon_0 = \varepsilon_0(\lambda, G) > 0$ such that for every $0 < \varepsilon \leq \varepsilon_0$ with $\varepsilon < 1/52$ and every structural threshold triple $\mathfrak{K}$ there is a family $\mathcal{F} \in \mathfrak{A}$ of parameter ε which is large for $\mathfrak{K}$ at its own design parameter

$$C_H(\mathcal{F}) = C_F(\mathcal{F}) \geq 1.$$

Its scales contain λ-windows, its twists are good, and every retained member satisfies G at its own scale, frame, host, tops and rank. The good-host data with their common constants, the admissible profile, the constants c_D, c_h in their nested eventual ranges and the canonical tables of heights and depths are chosen in the construction, subject to the host requirement G; they

are not prescribed in advance. The profile, the exponent pair and the tables are common to all translates and are fixed before the contexts and members of the family. For the chosen collection there is a cutoff $X \geq X_H$ with

$$I(x) = A_x \quad (x \in W,\ x > X), \qquad I(x) = \varnothing \quad \text{otherwise.}$$

Every retained member uses one context word scale $\Gamma_{x,u}$ in all its word tests, and

$$|\mathcal{W}_{x,u}| = \left\lceil 3\Gamma_{x,u}^{2} x^{C_H(\mathcal{F})} \right\rceil .$$

In particular the word-count bounds (Rk13) of the row linkage hold with coefficient 3.

For this family and the selection fixed above, the following hold.

1. *For every retained scale x and every $u \in A_x$ there are a context $K_{x,u}$, a base point $\beta_{x,u}$ and a bundle $b_{x,u}$ linked to it for p. Their frames, hosts, tops, spacing sets, ranks and auxiliary primes are those chosen in the good-host collection of the family, with translate u. The profile and the top tables are the common ones chosen for this family.*

2. *The base point satisfies $\mathrm{Good}_{\mathrm{E}}(\mathfrak{S}(p)) \wedge R_{\mathrm{all}}$. Its layered datum is admissible, and its size datum and canonical instance form a part whose member has all conclusions (a)–(e) of Proposition A.18. This part is the one used by its linked bundle.*

3. *The family belongs to $\mathfrak{A}$ and $\sigma(\mathcal{F}, x, u) = b_{x,u}$. It carries the seven duties and the profile and member ties of (Rk6) and (Rk7) of the row linkage. The twenty-six joint row conclusions hold for this selection and this class, with their closed-family and eventual quantifiers. In particular the class norm condition is on its standard restriction.*

The class and the selection are chosen before the later local indices and before the conditional Sha assertions are tested. The lower realisation data needed by a row conclusion are those of its selected bundle.

The joint slot and bundle predicate are chosen, before the class and the selection are fixed, so that they also carry the row assertion of the supply of Galois and depth-zero conditions. Consequently every member of the returned family satisfies the Galois preconditions (Gv1)–(Gv19) and the depth-zero tie (Ze1)–(Ze3), including every subclause of (Ze2), on its pair

$$(D_{x,i}, \mathrm{nch}(O_{x,i})), \qquad \mathfrak{o}_{x,i} = (O_{x,i}, \ell_{x,i}).$$

The member data, objects, coefficient rings, local indices and comparison maps are those of this construction; no family, object, part or selection is replaced to obtain these conditions.

The loss datum $\mathfrak{M}_{x,i}$ of each returned member is the canonical numerical reading of its datum $D_{x,i}$, its size datum $\mathcal{S}_{x,i}$ and its supplied canonical instance $I_{x,i}$, with the common orbit-constant tuple $\mathfrak{k}_{\mathrm{orb}}$ and the constant C_e chosen before the tables. Explicitly:

- *its group is the frame group A, its arithmetic datum is that of the host, its tops are the tops T, and its ranks satisfy $(k, m, t_R, e_2, o) = (k, m, t, e, o)$;*
- *its top heights and depths are the zero extensions of the top tables $a^{\mathrm{top}}, b^{\mathrm{top}}$; its weights are*

$$w_j(z) = \mathrm{fill}(I_{x,i}, b^{\mathrm{top}}, j, z) = \tilde{b}_{\tau_z, j}, \qquad \varsigma_j = \frac{k + (2j-1)(t+1)}{2}$$

for the shifts in the integer-weight description;

- *its orbit origins, representative map and full good sets are those of the ordered good-host selection, fixed before the tables; fix one common* $C_N > 0$ *with* $N_{\mathrm{orb}} \le C_N \log x$ *on the common tail, and write*

$$\rho_B = \frac{8nx^{-\varepsilon/8}x^{\varepsilon}L_c}{k} + \frac{C_{\mathrm{band}}C_N(\log x)L_c}{k}.$$

  Its candidate predicate uses this wider band ρ_B*, the threshold* $p_0 = k^2x^{26}$ *and the original order cutoffs. Its orbit constants are the prescribed capped expression in the low regime and, in the high regime, the canonical infimum, with the same endpoint arrays, middle floor* $\lfloor 4S_c \rfloor$*, integer depth ceiling, degree and separation;*

- *its size entries are* S_c, η_S*,* $N = k + m(t+1)$ *and*

$$L_a(\mathfrak{M}_{x,i}) = L_c = C_\Lambda N_{\mathrm{orb}}^2 \log a, \qquad C_{\mathrm{La}} = C_\Lambda.$$

  The no-gain normalization is $C_r = 1$*. The common constants, the wider-band prescription and the full good sets are fixed before the tables, contexts and parts;*

- *its place field is the original large coefficient field* L*, its support is* $\mathrm{supp}(\mathcal{S}_{x,i})$*, and its place weight is* $[L_w : \mathbb{Q}_p]\log p/[L : \mathbb{Q}]$*. Its gain is the member-truncated gain* $\mathrm{gain}_j^{\flat}(w)$*, which vanishes at the dropped primes of the member; its correction and companion terms, served sets and tops, and partial weights are those of the same canonical instance and part. Its correction exponents are* $\epsilon_p = \max(0, \lceil C_e f k^2 \log_p a \rceil)$*, with all eight orbit constants read at their selected prescribed values.*

These assignments define the loss record before the canonical-table conclusions are applied. They do not identify an independently given compatible loss record with this one.

Proof. Sketch. The proof separates a formal part from a constructive one. The class $\mathfrak{A}$ is defined by an equivalence: a family belongs to it exactly when there is one row parameter at which the family has its seven duties and, at every retained member (x, i) and every real size c, a bundle built over the member's own datum and member object $(D_{x,i}, \mathfrak{o}_{x,i})$ that satisfies the joint row predicate fixed beforehand. The selection σ chooses, for each family of the class, one such parameter and one such bundle at the family's size; class and selection are thus defined before λ, the host requirement and ε, and the joint row conclusions apply to them because the duties of a selection are exactly what membership provides. The selection is therefore automatic, and the substance of the statement is that actual families belong to the class.

For this, λ and G are fixed, and $\varepsilon_0(\lambda, G)$ is the minimum of the finitely many positive bounds of the inputs used; by Lemma A.4 their structural restrictions combine into one, by pointwise maxima of thresholds (Definition A.3). In this order one then chooses a good-host collection satisfying G, a profile large for the combined restriction, $c_D \ge 415$, $c_h \ge 402$, and the canonical tables of Proposition A.19, all before any context or member; the members are those of Theorem A.52 for the concrete system of Theorem A.51, and one set of words with an injective code is fixed at each scale before the translates, which gives $|\mathcal{W}_{x,u}| = \lceil 3\Gamma_{x,u}^2 x^{C_H} \rceil$. The numerical fields are elementary: every size parameter of a member is at most x^H with H depending only on c_D, c_h, while the budgets involve $b = e^{x^{\varepsilon}}$, so each inequality reduces to $Cx^A e^{-x^a} \to 0$ or $(\log x)^A/x^a \to 0$ on one common tail; and $N_{\mathrm{orb}} = O_\varepsilon(\log x)$ gives $L_c \le x^{\varepsilon+\varepsilon/100}$. Among the seven duties, the wall duty is the small-share inequality of the chosen tables (Lemma A.17) read at the actual members, the twisting duty holds after the auxiliary prime used for twisting is replaced by the least prime $q_* \equiv 1 \pmod{\ell_0 N_{\mathfrak{h}}}$, and the others are readings retained by

the member construction. Finally, a supply of linked bundles at every real size over the same member datum and object, at one family-wide row parameter, gives membership through the reverse implication of the defining equivalence, and items 1–3 are read at the selected bundles, with Proposition A.18 giving item 2. The argument is bookkeeping; its depth lies entirely in the inputs it cites, namely the member construction, the canonical tables and the supply of linked bundles at every real size.

The good-host collection over which the family is built is chosen in the course of the construction, subject only to the host requirement G. Whether the construction can instead be carried out over a collection of good-host data fixed in advance, as (TCS) prescribes, is open. □

Proposition A.2. *Choose the structural threshold triple used in Proposition A.1 so that it dominates the threshold $\mathfrak{K}_{\mathrm{dg}}$ of the diagonal expansions at the selected packets, before ε, the good-host data, the class and the family are chosen; then the returned design family is large for $\mathfrak{K}_{\mathrm{dg}}$. Fix one complete collection of good-host data. Take the class and the selection of Proposition A.1, the design family over this prescribed collection returned by Proposition A.1 with its member objects, and its tables and constants of Proposition A.19. The construction of Proposition A.1 chooses its own collection of good-host data; whether its class, selection and member objects can be attached to a prescribed complete collection, as is done here, is an open question, and the proposition concerns these data whenever such an attachment exists. Then, after enlarging a common cutoff, the following hold.*

1. *At each retained scale, the loss and slope records of its members, indexed by $u \in A_x$, form a base translate packet P_x with the selected host, frame, tops, spacing set, rank, auxiliary primes and final top profile. These packets satisfy (Rr1) and (Rr2) of Hypothesis 21.1.*

2. *Under the eventual Sha assumption of (Rr3) of that proposition, the same packets admit the twenty-four common constants and compatible lower completion data (Pl1), with all numbered conditions and exclusions stated in (Rr3). Their kernel data satisfy (Kc1)–(Kc4), finite total measure and both scalar inequalities specified there. Their word count has the bound stated there.*

3. *These completions admit the base covolume, chain, deep-cover, component and model-slope realisations required in (Rr3), including its field and metric identifications, common constants, precision data and joint inequalities, and the unitary Shimura data with every hypothesis of (Aj1) and (Aj3) as quantified there.*

4. *The reference data, denominators and local arrays satisfy all hypotheses of Theorem 20.2 on one common tail, with the same records and constants as in (Rr3), including its support, signed-index, Gram, denominator, weighted-defect, frame and main-term identities. The member also satisfies (Ri2), (Ri3) and (Ri4) as demanded there. No field, lattice, metric, map, local value, orbit mass or final selected profile is replaced by a substitute.*

The constants do not depend on the scale or on any local index. Every finite-Sha, word-size and nonzero-map antecedent, and the order of every inner integer choice, are as in (Pl2) and (Rr3).

Proof. Sketch. The statement attaches (TCS), Hypothesis 21.1, to the construction: its packets should be the loss and slope records of the members selected by Proposition A.1, built on the tables of Proposition A.19. Item 1 is read from these two statements: the selected members carry the prescribed frame, host, tops, spacing set, rank and auxiliary primes, and items 1–4 of Proposition A.19 give (Rr1) and (Rr2). For item 2 the structural threshold is first enlarged so

that the returned family is also large for the threshold of the diagonal expansion; at the family's own design exponent $c = C_H = C_F$, Theorem A.71 then gives the row records and the kernel hypotheses, and the word count of Proposition A.1, with coefficient 3 and the context's own word scale, gives the word bound. The member inputs of that theorem are the ties of each selected member with its context (Proposition A.114), its Poincaré frame, its counting operator and its Gauss ranks; and since every twist of a selected base point is good, specialising the twist condition to the exponent 1 gives the good twist data of Definition A.104.

It remains to show four attachments. First, the family must be built over the collection of good-host data prescribed in (TCS), whereas Proposition A.1 chooses its collection in the course of the construction, subject only to the host requirement. Whether that construction can be carried out over a prescribed collection is open. It is expected to be possible because the construction uses the good-host data only as data fixed at the start, and its bound $\varepsilon_0(\lambda, G)$ depends only on λ and the requirement, as the threshold of (TCS) may. Second, every selected member must satisfy the Galois preconditions (Galois representations compatible with the base changes of its automorphic representations, residual irreducibility, depth zero at the auxiliary primes g_1, g_2) and the depth-zero tie; once they hold, Theorem A.105 gives the local defect data and the hypotheses of Theorem 22.1. Heuristically, the members are cohomological automorphic representations of unitary groups over a CM field, for which base change and Galois representations with local–global compatibility are available [153, 231, 67, 56], and the depth-zero types at g_1, g_2 are chosen so that their inertia polynomials pass a test designed to exclude small invariant subspaces of the residual representation. Third, the unitary Shimura data of signature $(k + j - 1, m - j)$, the component sets and the arrays required by (Aj1) and (Aj3) of Theorem 29.14 must be constructed over the realised points of the covolume construction (Proposition A.92), with which (TCS) asks them to be compatible; that theorem only consumes these data. Fourth, the reference lattices, pairings, signed indices and denominators must be constructed so that every hypothesis of Theorem 20.2 holds on the same objects; the period service supplies part of these data, and the rest is a finite list of support, frame and scalar identities that the construction is expected to satisfy by design. Once the four attachments are supplied, the maximum of finitely many cutoffs gives the lower completion of (TCS) on a common tail. □

A.1.2 Restrictions, thresholds and linked rows

Many readers impose lower thresholds on the same family, and each of them is proved separately. Two simple facts let all of them hold at once. A threshold is a restriction of the class of families, and finitely many restrictions intersect in a restriction whose bounds are the pointwise maxima of the given ones (Lemma A.4); so one structural profile meets every closed law. One slot and one bundle predicate are fixed before any class, and a finite conjunction of properties that hold for linked rows on one selection holds on the same selection (Lemma A.5); so the separately proved row services hold on the same selected bundles.

Definition A.3. A **structural profile** carried by a parametrised host family $\mathcal{F}$ consists of a real number $C_H(\mathcal{F})$, its **chosen design parameter**, and four ordered lists of real numbers: $\mathbf{c}_{\mathrm{pre}}(\mathcal{F})$ of length 1, $\mathbf{c}_{\mathrm{out}}(\mathcal{F})$ of length 16, a list of length 9, and $\mathbf{c}_{\mathrm{last}}(\mathcal{F})$ of length 32. For each real u, write $\mathbf{c}_{\mathrm{mid}}(\mathcal{F}; u)$ for the length-10 list obtained by putting u before that length-9 list. In particular $\mathbf{c}_{\mathrm{mid}}(\mathcal{F}; C_H(\mathcal{F}))$ uses the chosen design parameter. The profile and chosen design parameter are part of the data of the family. For a family linked to a row parameter κ in the sense of (Rk6) of the row linkage, its length-9 list is

$$(C_\Gamma, C_{\mathrm{sz}}, C_{\mathrm{sz}}, C_{\mathrm{sz}}, C_{\mathrm{sz}}, C_{\mathrm{sz}}, C_{\mathrm{err}}, C_\Lambda, C_F),$$

namely entries 2 to 10 of $\mathbf{C}(\kappa)^{\mathrm{mid}}(u)$ for every real u. The generic notion of structural profile does not require a linked row parameter.

A **structural threshold** is a triple

$$\mathfrak{K}_{\mathrm{str}} = (k_{\mathrm{pre}}, k_{\mathrm{mid}}, k_{\mathrm{last}}) \in \mathbb{R} \times (\mathbb{R}^{<\infty} \to \mathbb{R}) \times (\mathbb{R}^{<\infty} \to \mathbb{R}).$$

A family with a structural profile is **large for** $\mathfrak{K}_{\mathrm{str}}$ if

$$\begin{aligned} k_{\mathrm{pre}} &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{pre}}(\mathcal{F}),\\ k_{\mathrm{mid}}\big(\mathbf{c}_{\mathrm{out}}(\mathcal{F})\big) &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{mid}}(\mathcal{F}; C_H(\mathcal{F})),\\ k_{\mathrm{last}}\big(\mathbf{c}_{\mathrm{out}}(\mathcal{F}) \parallel \mathbf{c}_{\mathrm{mid}}(\mathcal{F}; C_H(\mathcal{F}))\big) &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{last}}(\mathcal{F}). \end{aligned}$$

A **restriction** $\mathfrak{r}_{\mathrm{str}}$ consists of a real number $\varepsilon_{\mathfrak{r}} > 0$ and a function

$$\mathfrak{K}_{\mathfrak{r}} \colon (0, 1/52) \longrightarrow \mathbb{R} \times (\mathbb{R}^{<\infty} \to \mathbb{R})^2.$$

Here the subscript $\mathfrak{r}$ denotes this fixed restriction. For a class $\mathcal{B}$ of parametrised host families with slope records and structural profiles, its **restriction by** $\mathfrak{r}_{\mathrm{str}}$ is the class $\mathcal{B}[\mathfrak{r}]$ of the same enriched families $\mathcal{F} \in \mathcal{B}$ whose parameter and profile satisfy

$$0 < \varepsilon < \min(\varepsilon_{\mathfrak{r}}, 1/52), \qquad \mathcal{F} \text{ is large for } \mathfrak{K}_{\mathfrak{r}}(\varepsilon).$$

In particular the profile and $C_H(\mathcal{F})$ in this test are the data already carried by $\mathcal{F}$.

The **intersection restriction** of $\mathfrak{r}_{\mathrm{str}}$ and $\mathfrak{r}'_{\mathrm{str}}$ is denoted $\mathfrak{r}_{\mathrm{str}} \vee \mathfrak{r}'_{\mathrm{str}}$. Its upper parameter bound is $\min(\varepsilon_{\mathfrak{r}}, \varepsilon_{\mathfrak{r}'})$. For each $\varepsilon \in (0, 1/52)$, write

$$\mathfrak{K}_{\mathfrak{r}}(\varepsilon) = (k_{\mathrm{pre}}, k_{\mathrm{mid}}, k_{\mathrm{last}}), \qquad \mathfrak{K}_{\mathfrak{r}'}(\varepsilon) = (k'_{\mathrm{pre}}, k'_{\mathrm{mid}}, k'_{\mathrm{last}}).$$

The threshold triple of the intersection restriction has scalar entry $\max(k_{\mathrm{pre}}, k'_{\mathrm{pre}})$ and, for every finite real list c, function values

$$\max\big(k_{\mathrm{mid}}(c), k'_{\mathrm{mid}}(c)\big), \qquad \max\big(k_{\mathrm{last}}(c), k'_{\mathrm{last}}(c)\big).$$

Lemma A.4. *For every class $\mathcal{B}$ of parametrised host families with slope records and structural profiles, and every two restrictions,*

$$\mathcal{B}[\mathfrak{r}_{\mathrm{str}} \vee \mathfrak{r}'_{\mathrm{str}}] = \mathcal{B}[\mathfrak{r}] \cap \mathcal{B}[\mathfrak{r}'].$$

Consequently every nonempty finite intersection of restrictions of $\mathcal{B}$ is a single restriction of $\mathcal{B}$. Its upper parameter bound is the minimum of the given upper bounds, and each of its three threshold entries is the pointwise maximum of the corresponding entries. The same enriched family, including its structural profile and chosen design parameter, occurs in each class in this identity.

Proof. Fix an enriched family $\mathcal{F}$ with parameter ε. The bound $0 < \varepsilon < \min(\varepsilon_{\mathfrak{r}}, \varepsilon_{\mathfrak{r}'}, 1/52)$ is equivalent to the parameter bounds required by both restrictions. For any two real lower bounds a_1, a_2 and any real c, the inequality $\max(a_1, a_2) \le c$ is equivalent to $a_1 \le c$ and $a_2 \le c$.

Apply this equivalence first to every entry of $\mathbf{c}_{\mathrm{pre}}(\mathcal{F})$. Apply it next to every entry of $\mathbf{c}_{\mathrm{mid}}(\mathcal{F}; C_H(\mathcal{F}))$, evaluating both middle threshold functions at the same list $\mathbf{c}_{\mathrm{out}}(\mathcal{F})$. Finally

apply it to every entry of $\mathbf{c}_{\mathrm{last}}(\mathcal{F})$, evaluating both last threshold functions at the same concatenated list

$$\mathbf{c}_{\mathrm{out}}(\mathcal{F}) \parallel \mathbf{c}_{\mathrm{mid}}(\mathcal{F}; C_H(\mathcal{F})).$$

These three equivalences say exactly that $\mathcal{F}$ is large for the intersection threshold if and only if it is large for both original thresholds. Together with membership in $\mathcal{B}$ and the parameter bounds, they prove the displayed class identity.

For a nonempty finite collection, successively apply the two-restriction identity. A finite minimum of positive upper bounds is positive; the minimum and each pointwise maximum are associative. This gives the stated single restriction and the formula for all its entries. □

Lemma A.5. *Fix a parameter p, a finite set I_{row}, and for every $s \in I_{\mathrm{row}}$ a property $H_s(\mathfrak{A}, \sigma)$ of classes and selections. Suppose that for every s the property $\mathrm{Row}(\cdot, \cdot, H_s)$ holds linked at p.*

Put $G = \mathrm{Good}_{\mathrm{E}}(\mathfrak{S}(p))$. There are a large-base slot R over $\mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p))$ and a bundle predicate E such that

$$\mathrm{RowE}(G \wedge R, \mathrm{Lk}_p, E)$$

and, for every class $\mathfrak{A}$ and every E-selection σ for the slot $G \wedge R$,

$$\bigwedge_{s \in I_{\mathrm{row}}} H_s(\mathfrak{A}, \sigma).$$

More precisely, for any slots R_s and bundle predicates E_s for which the individual linked row properties hold, these conclusions hold with the pointwise conjunctions

$$R = \bigwedge_{s \in I_{\mathrm{row}}} R_s, \qquad E(\kappa, b) = \bigwedge_{s \in I_{\mathrm{row}}} E_s(\kappa, b).$$

The empty conjunctions are the predicates that are always true.

Proof. Outline. The eventual quantifiers and the largeness of triples are closed under finite conjunction (take the minimum of the upper bounds on ε and successive maxima of the thresholds, and unions of the demands), so the pointwise conjunctions R and E give a large-base slot and the row assertion for $G \wedge R$; and an E-selection for $G \wedge R$ is, with the same row parameter and bundles, an E_s-selection for $G \wedge R_s$ for every s, so each H_s holds on the same selection. □

Sketch: the row services at one parameter. The selected bundles must carry, at one row parameter, a finite list of row services: arithmetic services at the auxiliary primes, a period and valuation service at the selected points, stage-zero and counting services, a definite-side service, and the services of the chain of lifts described at the end of Section A.4. Each service is a property of linked bundles that holds eventually in the scale and persists when the parameter is enlarged. Finitely many such properties can therefore be met at one parameter, by enlarging the parameter to the largest of their thresholds (Lemma A.4) and conjoining them on one selection (Lemma A.5). What each service needs is its own supply on the actual bundles, and all of these supplies are read from the same CM data: the abelian variety and the CM type of the host, the theta functions on the CM elliptic curve, and the auxiliary primes g_1, g_2. Heuristically this is why one parameter can serve all of them: the services ask for finitely many explicit facts about one CM configuration, and each such fact holds once the scale is large.

A.2 Small orbit shares: canonical tables of heights and depths

This section chooses, at every scale and before any member is built, a pair of integer tables of heights and depths, and shows that members built on these tables satisfy the numerical clauses of (Rr1) and (Rr2) (Proposition A.19). The difficult clause is (Lm5) of Definition 5.5: it asks that the canonical orbit constants have a small *mean* over a box of heights and depths. A pointwise bound would fail, but a mean only needs a majorant with small mean. Theorem A.9 gives one: a universal majorant whose mean over the box is at most CNN_1/Y (clause (Om1)), and which has the separated rank property (clause (Om2)). The majorant is universal over unramified quadratic settings, and the separated rank property does not depend on the setting (Lemma A.10). This is what allows the tables to be chosen before the members: one pair of tables serves every translate. A finite averaging step then selects the tables (Lemma A.16, Lemma A.17). The numerical clauses of a member over a context are Proposition A.18, and from these numerical data alone the body of the paper derives the linking property (Theorem 18.4, with Lemma 18.5).

A.2.1 A universal majorant for the orbit constants

An unramified quadratic setting carries weight arrays on an orbit and the integral orbit lattices of polynomial representations (Definition A.6). The canonical orbit constant of a weight array, and the separated rank property, are defined in Definition A.7, and the explicit flat depth and level of the majorant in Definition A.8. Theorem A.9 is the main result of the section. Its proof passes from a majorant in one fixed setting to all unramified quadratic settings at once, using that the separated rank property does not depend on the setting (Lemma A.10).

Definition A.6. Let p be a prime and $n \geq 2$, $k \geq 1$ integers. Positions are the residues $s \in \{0, \dots, n-1\}$; a position is **even** or **odd** according to s.

Settings. An **unramified quadratic setting at** (p, n) is a tuple $\mathfrak{t} = (\mathcal{W}, \mathcal{O}, F_{\mathfrak{t}}, K_{\mathfrak{t}}, j, \iota, \sigma, \varpi)$ of discrete valuation rings $\mathcal{W}, \mathcal{O}$ with fraction fields $F_{\mathfrak{t}}, K_{\mathfrak{t}}$, a ring homomorphism $j\colon \mathcal{W} \to \mathcal{O}$, a field homomorphism $\iota\colon F_{\mathfrak{t}} \to K_{\mathfrak{t}}$, a field automorphism σ of $F_{\mathfrak{t}}$ and an element $\varpi \in \mathcal{O}$, such that:

(Qs1) $p \geq 5$ and n is even;

(Qs2) p is a uniformiser of $\mathcal{W}$, $\mathcal{W}$ is complete for the p-adic topology and $|\mathcal{W}/p\mathcal{W}| = p^n$;

(Qs3) $\sigma^n = \mathrm{id}$, and for every $x \in \mathcal{W}$ there is $y \in \mathcal{W}$ with $\sigma(x) = x^p + py$;

(Qs4) $\iota(x) = j(x)$ for $x \in \mathcal{W}$, $\mathcal{O}$ is a finitely generated $\mathcal{W}$-module through j, and $\mathcal{O}$ is complete;

(Qs5) ϖ is a uniformiser of $\mathcal{O}$, $\varpi^2 = p$ and $|\mathcal{O}/\varpi\mathcal{O}| = p^{2n}$;

(Qs6) every integer is a square in $\mathcal{O}$.

Weight arrays. A **weight array** of rank k is a family $\mu = (\mu_s)_{0 \leq s < n}$ of vectors $\mu_s = (\mu_{s,1}, \dots, \mu_{s,k}) \in \mathbb{Z}^k$; it is **dominant** if every μ_s is nonincreasing. Its **twisted entries** are $\mu^\natural_s = \mu_s$ for even s and $\mu^\natural_{s,a} = -\mu_{s,k+1-a}$ $(1 \leq a \leq k)$ for odd s; put $\nu_s(\mu) = (\mu^\natural_{s,a} - \mu^\natural_{s,k})_{1 \leq a \leq k}$ and

$$\mathrm{tp}(\mu) = \sum_{s=0}^{n-1} \mu^\natural_{s,1}.$$

If μ is dominant, every $\mu^\natural_s$ is nonincreasing and every $\nu_s(\mu)$ is a nonincreasing vector of nonnegative integers.

Lattices of one induced module. Let K be the fraction field of a discrete valuation ring $\mathcal{O}$, and $X = (X_{ab})_{1\le a,b\le k}$ a matrix of indeterminates. An $\mathcal{O}$-lattice in K^k is the $\mathcal{O}$-span of the columns of some $g \in \mathrm{GL}_k(K)$, a **basis matrix** of it. For such a lattice Λ and a nonincreasing $\eta \in \mathbb{Z}^k$ put

$$H^0_\Lambda(\eta) = \bigcap_g \det(g)^{-\eta_k} \cdot \{P \in K[X] :\ P(gX) \in \nabla_{\mathcal{O}}(\eta - \eta_k)\},$$

the intersection over all basis matrices g of Λ, where $\nabla_{\mathcal{O}}(\eta-\eta_k) \subseteq \mathcal{O}[X] \subseteq K[X]$ and $P(gX)$ is P evaluated at the matrix product gX.

Orbit spaces and orbit lattices. Fix a setting $\mathfrak{t}$ at (p,n) and a dominant weight array μ of rank k; write $K = K_{\mathfrak{t}}$. Take matrices of indeterminates $X^{(s)}$, $0 \le s < n$, each $k \times k$. For $\mathcal{O}$-submodules $M_s \subseteq K[X]$ let $\bigotimes_s M_s$ be the $\mathcal{O}$-span of the products $\prod_s P_s(X^{(s)})$ with $P_s \in M_s$. The **orbit space** $V_{\mathfrak{t}}(\mu)$ is the K-span of the products $\prod_s P_s(X^{(s)})$ with $P_s \in \nabla_K(\nu_s(\mu))$, and $V_{\mathfrak{t}}(\mu)^* = \mathrm{Hom}_K(V_{\mathfrak{t}}(\mu), K)$. For an $\mathcal{O}$-submodule $M \subseteq V_{\mathfrak{t}}(\mu)$ put $M^\vee = \{\phi \in V_{\mathfrak{t}}(\mu)^* : \phi(M) \subseteq \mathcal{O}\}$.

A **$\mathcal{W}$-lattice** is the $\mathcal{W}$-span $L \subseteq F_{\mathfrak{t}}^k$ of the columns of a matrix in $\mathrm{GL}_k(F_{\mathfrak{t}})$. Its **twist** at the position s is the $\mathcal{O}$-lattice $L^{(s)} \subseteq K^k$ spanned by the vectors $\iota(\sigma^s(v))$, $v \in L$ ($\iota \circ \sigma^s$ applied to each coordinate). The **orbit lattice** of L is

$$H_{\mathfrak{t}}(\mu, L) = V_{\mathfrak{t}}(\mu) \cap \bigotimes_s H^0_{L^{(s)}}(\mu^\natural_s).$$

Edges. An **edge** (L', L) is a pair of $\mathcal{W}$-lattices with $pL \subseteq L' \subseteq L$ and $|L/L'| = p^n$; L' is its source and L its target. Its **midpoint** at the position s is the $\mathcal{O}$-lattice $L'^{(s)} + \varpi L^{(s)}$, and its **edge lattices** are

$$R_{\mathfrak{t}}(\mu; L', L) = \varpi^{-\mathrm{tp}(\mu)}\Big(V_{\mathfrak{t}}(\mu) \cap \bigotimes_s H^0_{L'^{(s)}+\varpi L^{(s)}}(\mu^\natural_s)\Big),$$
$$R^\vee_{\mathfrak{t}}(\mu; L', L) = \varpi^{-\mathrm{tp}(\mu)}\Big(V_{\mathfrak{t}}(\mu) \cap \bigotimes_s H^0_{L'^{(s)}+\varpi L^{(s)}}(\mu^\natural_s)\Big)^\vee.$$

Source and target lattices. For an integer $t_{\mathrm{d}} \ge 0$ (the depth) and a $\mathcal{W}$-lattice L put

$$N^{\mathrm{src}}_{\mathfrak{t}}(\mu, t_{\mathrm{d}}, L) = \varpi^{-t_{\mathrm{d}}} H_{\mathfrak{t}}(\mu, L) \ \cap \bigcap_{(L,L_1)\ \text{edge}} R_{\mathfrak{t}}(\mu; L, L_1),$$
$$N^{\mathrm{tgt}}_{\mathfrak{t}}(\mu, t_{\mathrm{d}}, L) = \varpi^{-t_{\mathrm{d}}} H_{\mathfrak{t}}(\mu, L)^\vee \ \cap \bigcap_{(L_1,L)\ \text{edge}} R^\vee_{\mathfrak{t}}(\mu; L_1, L),$$

the intersections over all edges with source L, respectively with target L. The **edge pairing** is

$$\langle F, G\rangle_\mu = G(p^{\mathrm{tp}(\mu)} F) \qquad (F \in V_{\mathfrak{t}}(\mu),\ G \in V_{\mathfrak{t}}(\mu)^*).$$

Definition A.7. Let $\mathfrak{t}$ be an unramified quadratic setting at (p,n), μ a dominant weight array of rank k, $t_{\mathrm{d}}, D, c_{\mathrm{sep}} \ge 0$ integers and κ a real number.

Separated rank. The array μ has the **separated rank property for** $(t_{\mathrm{d}}, D, \kappa, c_{\mathrm{sep}})$ **in** $\mathfrak{t}$ if $4(D+1) \le c_{\mathrm{sep}}$ and for every $\mathcal{W}$-lattice L there are an integer $M \ge 0$, edges (L'_i, L) with target L and vectors $F_i \in V_{\mathfrak{t}}(\mu)$ $(1 \le i \le M)$ such that:

(Sv1) $F_i \in N^{\mathrm{src}}_{\mathfrak{t}}(\mu, t_{\mathrm{d}}, L'_i)$ for every i;

(Sv2) $F_i \in \varpi^{c_{\mathrm{sep}}} R_{\mathfrak{t}}(\mu; L'_i, L_1)$ for every i and every edge (L'_i, L_1) with source L'_i and $L_1 \ne L$;

(Sv3) there are an integer $n_{\mathrm{rk}} \geq (1-\kappa)\dim_{K_{\mathrm{t}}} V_{\mathrm{t}}(\mu)$, an $\mathcal{O}$-linear map $u\colon \mathcal{O}^{n_{\mathrm{rk}}} \to N_{\mathrm{t}}^{\mathrm{tgt}}(\mu, t_{\mathrm{d}}, L)$ and a matrix $B \in \mathrm{M}_{n_{\mathrm{rk}}\times M}(\mathcal{O})$ with

$$\sum_{i=1}^{M} B_{ji}\,\langle F_i, u(y)\rangle_{\mu} = p^{D} y_j \qquad (y \in \mathcal{O}^{n_{\mathrm{rk}}},\ 1 \leq j \leq n_{\mathrm{rk}}).$$

(In (Sv2) the edges (L_i', L_1) are those with the same source as the i-th edge and different from it.)

Base weight arrays. Let $T \subseteq \{0, \dots, n-1\}$, $\alpha, \beta\colon T \to \mathbb{Z}$ and $c_{\mathrm{md}} \geq 0$ an integer. A weight array μ of rank $k \geq 2$ is a **base array for** $(T, \alpha, \beta, c_{\mathrm{md}})$ if

(Bw1) for $s \in T$: $\mu_{s,1} = \alpha(s)$, $\mu_{s,k} = -\beta(s)$ and $|\mu_{s,a}| \leq c_{\mathrm{md}}$ for $1 < a < k$;

(Bw2) for $s \notin T$: $|\mu_{s,a}| \leq c_{\mathrm{md}}$ for $1 \leq a \leq k$.

The elements of T are the **tops**, $\alpha(s)$ the **heights** and $\beta(s)$ the **depths**.

Canonical orbit constant. For $p, n, k \geq 2$, T, α, β, c_{md} as above and integers $t_{\mathrm{d}}, D, c_{\mathrm{sep}} \geq 0$, let $\mathcal{K}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}, D, c_{\mathrm{sep}})$ be the set of real $\kappa \geq 0$ such that every dominant base array μ of rank k for $(T, \alpha, \beta, c_{\mathrm{md}})$ has the separated rank property for $(t_{\mathrm{d}}, D, \kappa, c_{\mathrm{sep}})$ in every unramified quadratic setting at (p, n). When this set is nonempty, the **canonical orbit constant** is

$$\kappa^{\mathrm{can}}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}, D, c_{\mathrm{sep}}) = \inf \mathcal{K}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}, D, c_{\mathrm{sep}}) \ \geq 0.$$

The parameters $c_{\mathrm{md}}, t_{\mathrm{d}}, D, c_{\mathrm{sep}}$ may themselves be functions of (T, α, β); the constant is then formed with their values at (T, α, β).

Definition A.8. Let p be a prime, $n \geq 2$ and $k \geq 2$ integers, $T \subseteq \{0, \dots, n-1\}$ with $N = |T|$, $G_{\mathrm{gap}}, N_1, c_{\mathrm{md}}, c_{\mathrm{sep}} \geq 0$ integers, Y, a, b' real numbers with $a \geq 1$, and $C_0, C_A, C_t > 0$ real constants. Put

$$a_0 = \lceil a \rceil, \quad \Lambda = C_0 N_1^2 \log a_0, \quad Q = p^{G_{\mathrm{gap}}}, \quad c = c_{\mathrm{sep}} + 2Nc_{\mathrm{md}} + 2nc_{\mathrm{md}}, \quad \ell = \log_p(8a_0 + k - 1) + 1,$$

and let N_{e} be the number of even elements of T. If $N_{\mathrm{e}} \geq 1$, for an odd $y \in T$ let $d^-(y)$ be the least integer $d \geq 1$ such that $(y-d) \bmod n$ is an even element of T, and $y^- = (y - d^-(y)) \bmod n$.

Explicit flat depth. For $A, B\colon T \to \mathbb{Z}_{\geq 0}$ let

$$x(A,B) = \sum_{\substack{y \in T \\ y \text{ odd}}} \min\Big(B(y), \frac{A(y^-)}{p^{d^-(y)}}\Big) + C_t N\Big(\frac{a_0}{p^2} + \frac{b'}{p} + \frac{\Lambda a_0}{pk} + \frac{\Lambda b'}{k} + kQ + Qc\Big) + \frac{N\Lambda b'}{k},$$

the first sum being 0 when $N_{\mathrm{e}} = 0$, and

$$t^{\exp}(A,B) = \max\big(\lceil x(A,B) \rceil, 0\big) \in \mathbb{Z}_{\geq 0}.$$

Explicit level.

$$D_1^{\exp} = N_{\mathrm{e}}\big(C_A Y^2 N_1^2 k^2 \ell + 4Nk \log_p a_0\big) + 8Nk \log_p a_0 + 4N\lceil (k+1)\ell \rceil.$$

When the constants must be shown we write $t^{\exp}_{C_0,C_t}$ and $D^{\exp}_{1,C_A}$.

Theorem A.9. *There is a real $T_0 > 0$ such that for every real $C_0 \geq T_0$ there are reals $T_2 > 0$ and $C > 0$ with the following property for every real $C_H \geq T_2$.*

*Let p be a prime, $n, k \geq 1$ integers, $T \subseteq \{0, \dots, n-1\}$, $G_{\mathrm{gap}}, N_1, c_{\mathrm{md}}, D, c_{\mathrm{sep}} \geq 0$ integers and $Y, Y_{\mathrm{b}}, a, b', b_{\mathrm{lo}}, b_{\mathrm{up}}$ real numbers. Put $N = |T|$, the **orbit scale** $L_c = C_0 N_1^2 \log a$, and*

$$\delta_{\mathrm{w}} = \frac{C_H N_1 L_c}{k} + \frac{2(b_{\mathrm{up}} - b_{\mathrm{lo}})}{b'}.$$

Assume:

1. *$1 \leq Y$, $k^2 Y^2 \leq p$, $1 \leq N_1$ and $2N_1 + 3 \leq k$;*
2. *T has at least two even elements, and for every even $s \in T$, with s' the next even element of T after s in the cyclic order of $\mathbb{Z}/n$ and $g = (s' - s) \bmod n \in \{1, \dots, n-1\}$, one has $g \leq G_{\mathrm{gap}}$, and at most N_1 odd $y \in T$ satisfy $0 < (y - s) \bmod n < g$;*
3. *$8 \log(NY) \leq L_c$;*
4. *$0 < b'$, $b_{\mathrm{lo}} \leq b' \leq b_{\mathrm{up}}$ and $Y_{\mathrm{b}} N L_c b'/k \leq b_{\mathrm{up}} - b_{\mathrm{lo}} \leq b'/2$;*
5. *$C_H \leq Y_{\mathrm{b}}$, $2Y_{\mathrm{b}} N L_c < k$, $kY^2 Y_{\mathrm{b}} N L_c \log a \leq a/b'$ and $C_H N L_c^2 \leq k$;*
6. *$\delta_{\mathrm{w}} < 1/6$, $p < a/b'$, and no odd integer $d \geq 1$ satisfies $(a/b')(1 - 2\delta_{\mathrm{w}}) \leq p^d \leq (a/b')(1 + 2\delta_{\mathrm{w}})$;*
7. *$c_{\mathrm{md}} \leq L_c b'/k$, $C_H N Y^2 (N_1^5 + k^3) \log_p a \leq D$, $8(D+1) \leq c_{\mathrm{sep}}$ and $C_H k^3 N p^{4G_{\mathrm{gap}}} (c_{\mathrm{sep}} + N c_{\mathrm{md}} + n c_{\mathrm{md}}) Y \leq b'$.*

Let $I_a = \mathbb{Z} \cap [\lceil a \rceil, \lfloor a + a/(kY) \rfloor]$ and $I_b = \mathbb{Z} \cap [\lceil b_{\mathrm{lo}} \rceil, \lfloor b_{\mathrm{up}} \rfloor]$. For an odd $y \in T$ let $d^-(y)$ be the least integer $d \geq 1$ such that $(y - d) \bmod n$ is an even element of T (it exists by item 2), and $y^- = (y - d^-(y)) \bmod n$. For $\alpha, \beta \colon T \to \mathbb{Z}$ put $c' = c_{\mathrm{sep}} + CNk \log_p a + 4N c_{\mathrm{md}} + 2n c_{\mathrm{md}}$ and

$$\begin{aligned} t_I(\alpha, \beta) = {} & \sum_{\substack{y \in T \\ y \text{ odd}}} \min\Big(\beta(y), \frac{\alpha(y^-)}{p^{d^-(y)}}\Big) + CNN_1\Big(\frac{a}{p^2} + \frac{b'}{p} + \frac{L_c a}{pk} + \frac{L_c b'}{k}\Big) \\ & + CN\big(p^{G_{\mathrm{gap}}} c' + k p^{G_{\mathrm{gap}}} + k \log_p a + c_{\mathrm{md}}\big) + 2n c_{\mathrm{md}}. \end{aligned}$$

Then there is a function $\kappa \colon \mathbb{Z}^T \times \mathbb{Z}^T \to [0, \infty)$ such that:

(Om1) Mean. *If I_a and I_b are nonempty,*

$$\frac{1}{|I_a|^N |I_b|^N} \sum_{\alpha \in I_a^T} \sum_{\beta \in I_b^T} \kappa(\alpha, \beta) \leq \frac{CNN_1}{Y}.$$

(Om2) Separated rank. *For every unramified quadratic setting $\mathfrak{t}$ at (p, n), all $\alpha \in I_a^T$, $\beta \in I_b^T$, every dominant base array μ of rank k for $(T, \alpha, \beta, c_{\mathrm{md}})$ and every integer $t_{\mathrm{d}} \geq t_I(\alpha, \beta)$, the array μ has the separated rank property for $(t_{\mathrm{d}}, D, \kappa(\alpha, \beta), c_{\mathrm{sep}})$ in $\mathfrak{t}$.*

Proof. Let T_0 be the constant of the orbit majorant in one fixed unramified quadratic setting, whose constants do not depend on the setting, and for $C_0 \geq T_0$ let T_2, C be the constants it provides; we show that the same T_0, T_2, C have the asserted property. Fix $C_H \geq T_2$ and data satisfying items 1–7, and put $N = |T|$.

No setting at (p,n). If there is no unramified quadratic setting at (p,n), let $\kappa = 0$. Then (Om2) holds vacuously, and (Om1) holds because the mean of κ is 0 while $CNN_1/Y \geq 0$ ($C > 0$, $N_1 \geq 1$ and $Y \geq 1$ by item 1).

Some setting $\mathfrak{t}_0$ at (p,n). Otherwise fix one, and let $\kappa = \kappa_{\mathfrak{t}_0} \colon \mathbb{Z}^T \times \mathbb{Z}^T \to [0,\infty)$ be the function given by that majorant for these data and $\mathfrak{t}_0$; its hypotheses are exactly items 1–7 for (C_0, C_H), and its function t_I is the one of this statement (same data and same C). Its item 1 is (Om1). For (Om2), let $\mathfrak{t}$ be any unramified quadratic setting at (p,n), $\alpha \in I_a^T$, $\beta \in I_b^T$, μ a dominant base array of rank k for $(T, \alpha, \beta, c_{\mathrm{md}})$ and $t_{\mathrm{d}} \geq t_I(\alpha,\beta)$ an integer. By item 2 of that majorant, μ has the separated rank property for $(t_{\mathrm{d}}, D, \kappa(\alpha,\beta), c_{\mathrm{sep}})$ in $\mathfrak{t}_0$; by Lemma A.10, applied to the settings $\mathfrak{t}_0$ and $\mathfrak{t}$ at the same (p,n), it has it in $\mathfrak{t}$. □

Lemma A.10. *Let $\mathfrak{t}_1, \mathfrak{t}_2$ be unramified quadratic settings at the same (p,n), μ a dominant weight array of rank k, $t_{\mathrm{d}}, D, c_{\mathrm{sep}} \geq 0$ integers and κ real. If μ has the separated rank property for $(t_{\mathrm{d}}, D, \kappa, c_{\mathrm{sep}})$ in $\mathfrak{t}_1$, then it has it in $\mathfrak{t}_2$.*

Proof. Outline. Two unramified quadratic settings at the same (p,n) are isomorphic, compatibly with j, ι, σ and ϖ: the rings $\mathcal{W}$ are identified by the uniqueness of complete discrete valuation rings with uniformiser p and a given perfect residue field [221], the automorphisms σ by their common reduction, and the fields $K_{\mathfrak{t}}$ as the extension by ϖ, with $\varpi^2 = p$, of the unramified quadratic extension of $F_{\mathfrak{t}}$; this isomorphism transports lattices, edges, orbit and edge lattices, source and target lattices and the edge pairing, and with them the data of (Sv1)–(Sv3). □

A.2.2 Gram windows and the raw step

The majorant in one fixed setting is a local computation, and its local input is one correction step at the identity vertex: a symmetric family of relaxed blocks must be realised, up to a controlled error, by a polynomial with bounded denominator that becomes integral after every substitution off a fixed plane. The keys of this step and a residue-line detector are given in Lemma A.13, and the step itself is Proposition A.14, for which we give a sketch. Every other step of the orbit mean has a complete proof. Two further results enter the tables: the Gram-window theorem for one segment, which is derived from the majorant and bounds the mean of the segment deficiency over a window of heights (Theorem A.11), and symbol spaces of almost full rank (Proposition A.12).

Theorem A.11. *There is a real $T_0 > 0$ such that for every real $C_0 \geq T_0$ there is a real $T_1 \geq 0$ such that for all reals $C_E, C_m \geq T_1$ there are reals $T_2, C_A > 0$ with the following property for every real $C_H \geq T_2$. Let $p, n, k, T, G_{\mathrm{gap}}, N_1, c_{\mathrm{md}}, D, c_{\mathrm{sep}}, Y, Y_{\mathrm{b}}, a, b', b_{\mathrm{lo}}, b_{\mathrm{up}}$ satisfy items 1–7 of Theorem A.9 for (C_0, C_H), $N = |T|$, let a_0, Λ, Q, c be as in Definition A.8, $J = \lfloor \Lambda b'/k \rfloor$, $W_a^+ = \mathbb{Z} \cap [a_0, \lfloor a + a/(kY) \rfloor + J + c_{\mathrm{md}}]$, $W_b^+ = \mathbb{Z} \cap [\lceil b_{\mathrm{lo}} \rceil, \lfloor b_{\mathrm{up}} \rfloor + J + c_{\mathrm{md}}]$,*

$$E = C_E\Big(\frac{a_0}{p^2} + \frac{b'}{p} + \frac{\Lambda N_1 a_0}{pk} + \frac{\Lambda b'}{k} + k^2 N_1 Q^2 c\Big), \qquad m = C_m k N_1 Q c + 12c,$$

$$\ell = \log_p(8a_0 + k - 1) + 1, \qquad D_{\mathrm{seg}} = C_A Y^2 N_1^2 k^2 \ell + 4Nk \log_p a_0.$$

Let $\mathfrak{t}$ be an unramified quadratic setting at (p,n) and $s \in T$ even; let s^+ be the next even element of T after s in the cyclic order of $\mathbb{Z}/n$, and $\sigma(s)$ the set consisting of s^+ and the odd $y \in T$ with $0 < (y-s) \bmod n < (s^+ - s) \bmod n$. For $A \in (W_a^+)^T$, $B \in (W_b^+)^T$ the number $\kappa_s^{\mathrm{seg}}(A, B; D_{\mathrm{seg}})$, formed in $\mathfrak{t}$ with the parameters (a_0, b', Λ, E, m), depends on A only through $A|_{\sigma(s)}$. Then for

every $B \in (W_b^+)^T$

$$\frac{1}{|W_a^+|^{|\sigma(s)|}} \sum_{A|_{\sigma(s)} \in (W_a^+)^{\sigma(s)}} \kappa_s^{\mathrm{seg}}(A, B; D_{\mathrm{seg}}) \le \frac{C_A \, |\sigma(s)| \, N_1}{Y}.$$

Proof. Outline. For fixed heights the segment Fock lattice is the direct sum of the block lattices, so the segment deficiency is at most the sum of the block badnesses divided by the rank; the block badness is then averaged over the heights one digit class at a time, using averaging bounds for the levels of a block and a comparison of masses when one far height is raised, and since the rank is comparable to the mass this gives the mean bound $C_A|\sigma(s)|N_1/Y$. □

Proposition A.12. *There is a real $C_0 > 0$ such that for every real $C_{\mathrm{La}} \ge C_0$ there are reals $C_{\mathrm{rk}}, C_{\mathrm{deg}}, C_{\mathrm{g}} > 0$ with the following property for every real $C \ge C_{\mathrm{g}}$. Let $(\mathfrak{t}, k, r, T, L_1, L_2, c_{\mathrm{md}}, c_0, D, c_{\mathrm{sep}}, \delta, h_{\mathrm{o}}, x, a, Y, \alpha, \beta, \mu)$ be a Type II configuration for C, with $\mathfrak{t}$ at (p, n), let (J, f) be a frame system of rank r for T with parameters $(L_2, N_{\mathrm{tl}}(r, \delta, h_{\mathrm{o}}, x), G_{\mathrm{tl}}(r, \delta, h_{\mathrm{o}}, x))$, and take its symbol data for C_{La}. Let $E' \in \mathbb{Z}^n_{\ge 0}$ with $E'_s \le \min(E_0, d_s(\mu))$ for $s \in T$, and let $N \subseteq \mathcal{O}[x]$ be the $\mathcal{O}$-span of $\mathrm{Gen}(X^{\mathrm{sym}}, d_{E'})$. Then:*

1. *there is an $\mathcal{O}$-submodule $S \subseteq \mathcal{O}[x]$ which is a direct summand of the $\mathcal{O}$-module $\mathcal{O}[x]$ and free of finite rank with an $\mathcal{O}$-basis consisting of elements of $\mathrm{Gen}(X^{\mathrm{sym}}, d_{E'})$, such that*

$$\mathrm{rank}_{\mathcal{O}} S \;\ge\; p^{-nrK}\Big(1 - \frac{C_{\mathrm{rk}}|T|r^2k}{Y}\Big) \prod_{s \in T} \binom{d_s(\mu) + k - 1}{k - 1};$$

2. *every monomial x^e occurring in an element of N has*

$$\mathrm{nd}(e) \;\le\; C_{\mathrm{deg}}|T|\Big(\frac{\ell\, a}{pk} + a\, p^{-L_1} + kQ\Big).$$

Proof. Outline. One selects inside N a direct summand S with a basis of generators whose rank is the dimension of the reduction of N modulo ϖ; the discriminant of the frame system is nonzero modulo ϖ, and multiplication by it maps the reduction of the span of the coarse generators into the reduction of N, so the rank bound follows from the count of coarse generators, while the bound on normal degrees follows from the degree caps of the symbol spaces and the label condition. □

Lemma A.13. *Use an unramified quadratic setting and the bihomogeneous substitution $\mathrm{sub}_g^{\mathrm{bh},(1)}$ ($g \in \mathrm{GL}_k(\mathcal{W})$), with $k \ge 2$, $n \ge 2$. For each position u write $V_{u,a} = x_{u,a}$ and $C_{u,a} = y_{u,a}$ if u is even, and $V_{u,a} = y_{u,a}$ and $C_{u,a} = x_{u,a}$ if u is odd. Let s be even, y odd, $1 \le d < n$ and $y \equiv s + d \pmod n$, and put $q = p^d$. Define*

$$K_{s,y} = \sum_{a=1}^{k} V_{s,a}^q C_{y,a}, \qquad W_{s,y,c} = V_{y,c}V_{s,1}^q - V_{y,1}V_{s,c}^q \quad (2 \le c \le k).$$

Then $\mathrm{sub}_g^{\mathrm{bh},(1)}(K_{s,y})$ and $\mathrm{sub}_g^{\mathrm{bh},(1)}(W_{s,y,c})$ are ϖ-integral for every $g \in \mathrm{GL}_k(\mathcal{W})$. At $g = 1$ they equal, respectively,

$$\varpi\left(V_{s,1}^q C_{y,1} + \varpi^{q-1}\sum_{a=2}^{k} V_{s,a}^q C_{y,a}\right), \qquad \varpi\left(V_{y,c}V_{s,1}^q - \varpi^{q-1}V_{y,1}V_{s,c}^q\right).$$

Let $T \subseteq \{0,\dots,n-1\}$ be the top set, and let S be its set of even elements, with $|S| \geq 2$, let s^+ be the cyclic successor in S, and let $G_s = (s^+ - s) \bmod n \in \{1,\dots,n-1\}$. For $2 \leq c \leq k$ put

$$L_c = \prod_{s\in S} V_{s,1}^{p^{G_s}-1} - \prod_{s\in S} V_{s,c}^{p^{G_s}-1}, \qquad D_{s_0} = V_{s_0,1} \prod_{c=2}^{k} L_c \quad (s_0 \in S).$$

If $\Pi_1(g) \neq \Pi_1(1)$, then $\mathrm{sub}_g^{\mathrm{bh},(1)}(D_{s_0})$ is ϖ-integral. At the identity,

$$\mathrm{sub}_1^{\mathrm{bh},(1)}(L_c) = \prod_{s\in S} V_{s,1}^{p^{G_s}-1} - \varpi^{\sum_{s\in S}(p^{G_s}-1)} \prod_{s\in S} V_{s,c}^{p^{G_s}-1}.$$

All polynomials are formed over the same coefficient ring and in the same variables.

Proof. Outline. Modulo ϖ the substitution sends $V_{u,b}$ to $V_{u,1}$ times an entry of the first row of the reduced inverse matrix at u, and since σ reduces to the p-power Frobenius these entries at y are the q-th powers of those at s, which makes the reduced keys vanish; for the detector, the same Frobenius relations along the even tops show that the substituted detector vanishes modulo ϖ when $\Pi_1(g) \neq \Pi_1(1)$, and the formulas at the identity come from direct substitution. □

Proposition A.14. *There is a real $T_0 > 0$ such that for every real $C_0 \geq T_0$ there is a real $T_1 \geq 0$ such that for every real $C_E \geq T_1$ there are reals $T_2, C_t^* > 0$ with the following property for all reals $C_t \geq C_t^*$ and $C_H \geq T_2$. Let the data $p, n, k, T, \dots, b_{\mathrm{up}}$ satisfy items 1–7 of Theorem A.9 for (C_0, C_H); let $N, a_0, \Lambda, Q, c, J_0, W_a^+, W_b^+, E$ be the quantities formed from these data and C_E in the realisation of symmetric block families at the identity vertex, form $x(A,B)$ with (C_0, C_t), and put*

$$\delta = \frac{C_H N_1 \Lambda}{k} + \frac{2(b_{\mathrm{up}} - b_{\mathrm{lo}})}{b'}, \qquad \kappa_1 = 13 k N_1 Q,$$
$$\mu_j = 12c + j\kappa_1, \quad E_j = (c-j)\kappa_1 \quad (0 \leq j \leq c).$$

Let $\mathfrak{t}$ be an unramified quadratic setting at (p,n), $A \in (W_a^+)^T$, $B \in (W_b^+)^T$, $t_{\mathrm{bh}} = \lfloor x(A,B) - NJ_0 \rfloor$, and form kept blocks, relaxed blocks, clean polynomials and the modules $\mathcal{M}$ with $(a_0, b', \Lambda, E, \delta, c)$ and A, B. Then (the clause is named (Rs2) for reference):

(Rs2) *for every integer $1 \leq j \leq c$, every relaxed tuple β at slack E_j and every family $v = (v_s)_s$ with $v_s \in \Sigma_{\beta_s}^{(\mu_j)}$ there are a polynomial R clean at order $\mathrm{ord}(\beta)$ and elements*

$$\tau_\epsilon \in \mathcal{M}(\mu_{j-\epsilon}, E_{j-\epsilon}, \mathrm{ord}(\beta) + \epsilon) \qquad (1 \leq \epsilon < j)$$

such that

$$\mathrm{sub}_1^{\mathrm{bh},(1)}(R) - \mathrm{sym}_\beta(v) - \sum_{\epsilon=1}^{j-1} \varpi^\epsilon \tau_\epsilon \quad \text{is } \varpi^j\text{-integral.}$$

Proof. Sketch. Clause (Rs2) is one step of a ϖ-adic approximation. The aim is to realise a symmetric family $\mathrm{sym}_\beta(v)$ of integral segment vectors, at the identity vertex, as $\mathrm{sub}_1^{\mathrm{bh},(1)}(F)$ of a bihomogeneous polynomial F that has denominator at most $\varpi^{\mathrm{ord}(\beta)}$ and becomes ϖ^c-integral after every substitution off the plane $\Pi_1(1)$; this is the local input of Theorem A.11 and of the orbit mean (Om1) of Theorem A.9. Given (Rs2), a strong induction on j produces such an F modulo ϖ^c, since each correction τ_ϵ is treated by the step at level $j - \epsilon$; this induction is elementary. The inputs of the step are proved in Lemma A.13: the keys $K_{s,y}$ and $W_{s,y,c}$

are divisible by ϖ after every substitution, with leading terms $\varpi V_{s,1}^{q} C_{y,1}$ and $\varpi V_{y,c} V_{s,1}^{q}$ at the identity up to terms carrying a further factor ϖ^{q-1}, and the detector D_{s_0} is divisible by ϖ off the plane while its value at the identity has a monomial leading term.

The argument should run as follows. (i) Choose an integral basis of standard columns for the polynomial space cut out by the capacity conditions of every prefix of letters, the same basis for all prefixes, whose admissible columns span the integral intersection. (ii) Realise each column generator as a product of boundedly many keys, each divided by ϖ, so that the denominator grows by one per key, in agreement with the order $\mathrm{ord}(\beta)$, and the initial form at the identity is the prescribed column; then multiply by a fixed power of the detector times a fixed standard monomial, which makes the product clean off the plane. (iii) Expand the product: the leading term is $\mathrm{sym}_{\beta}(v)$, and a term in which ϵ factors are replaced by their corrections is ϖ^{ϵ} times a polynomial that must be shown to lie in $\mathcal{M}(\mu_{j-\epsilon}, E_{j-\epsilon}, \mathrm{ord}(\beta)+\epsilon)$. Heuristically, (iii) is what the parameters are calibrated for: passing from level j to $j-\epsilon$ lowers the margin $\mu_j = 12c + j\kappa_1$ and raises the slack $E_j = (c-j)\kappa_1$ by $\epsilon\kappa_1$, with $\kappa_1 = 13kN_1Q$, which is room for the bounded change in degrees and capacities caused by perturbing ϵ factors of bounded degree, so the perturbed terms should again be relaxed tuples in the larger module. Step (i) is an integral form of a standard-monomial basis for spaces of polynomials in vectors and covectors cut out by stability under the operators $\mathsf{E}_{cd}^{(J)}$; over the unramified ring $\mathcal{O}$ such bases are expected to exist, the delicate point being that one basis must serve all prefixes at once. □

A.2.3 One table at every scale

The mean of the canonical orbit constant over the full box follows from the majorant (Corollary A.15). Since the requirement is a mean over a finite box, a finite averaging argument selects one profile, jointly for all the candidate means (Lemma A.16), and hence one canonical profile with uniformly small orbit shares (Lemma A.17). Proposition A.18 records the numerical clauses that a member built over a context satisfies, and Proposition A.19 assembles them into the table at every scale and its identities at the constructed members.

Corollary A.15. *Let T_0 be as in Theorem A.9, $C_0 \geq T_0$, let T_2, C be as there for C_0, and $C_H \geq T_2$. Let $p, n, k, T, G_{\mathrm{gap}}, N_1, c_{\mathrm{md}}, D, c_{\mathrm{sep}}, Y, Y_{\mathrm{b}}, a, b', b_{\mathrm{lo}}, b_{\mathrm{up}}$ satisfy items 1–7 of Theorem A.9, with $N = |T|$, and let $t_{\mathrm{d}} \colon \mathbb{Z}^T \times \mathbb{Z}^T \to \mathbb{Z}_{\geq 0}$ satisfy $t_{\mathrm{d}}(\alpha,\beta) \geq t_I(\alpha,\beta)$ for all $\alpha \in I_a^T$, $\beta \in I_b^T$. Then for all $\alpha \in I_a^T$, $\beta \in I_b^T$ the set $\mathcal{K}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}(\alpha,\beta), D, c_{\mathrm{sep}})$ is nonempty, so the canonical orbit constant*

$$\kappa^{\mathrm{can}}(\alpha,\beta) = \kappa^{\mathrm{can}}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}(\alpha,\beta), D, c_{\mathrm{sep}}) \geq 0$$

is defined, and, if I_a and I_b are nonempty,

$$\frac{1}{|I_a|^N |I_b|^N} \sum_{\alpha \in I_a^T} \sum_{\beta \in I_b^T} \kappa^{\mathrm{can}}(\alpha,\beta) \leq \frac{CNN_1}{Y}.$$

Proof. Let $\kappa \colon \mathbb{Z}^T \times \mathbb{Z}^T \to [0,\infty)$ be the function given by Theorem A.9 for these data and constants.

The majorant lies in the canonical set. Fix $\alpha \in I_a^T$ and $\beta \in I_b^T$. Then $\kappa(\alpha,\beta) \geq 0$. Let $\mathfrak{t}$ be an unramified quadratic setting at (p,n) and μ a dominant base array of rank k for $(T, \alpha, \beta, c_{\mathrm{md}})$. The integer $t_{\mathrm{d}}(\alpha,\beta)$ is at least $t_I(\alpha,\beta)$ by hypothesis, so (Om2) of Theorem A.9, applied with this $\mathfrak{t}$, α, β, μ and depth $t_{\mathrm{d}}(\alpha,\beta)$, shows that μ has the separated rank property for $(t_{\mathrm{d}}(\alpha,\beta), D, \kappa(\alpha,\beta), c_{\mathrm{sep}})$ in $\mathfrak{t}$. As $\mathfrak{t}$ and μ were arbitrary,

$$\kappa(\alpha,\beta) \in \mathcal{K}_{p,n,k}(T, \alpha, \beta; c_{\mathrm{md}}, t_{\mathrm{d}}(\alpha,\beta), D, c_{\mathrm{sep}}).$$

This set is therefore nonempty; it consists of nonnegative reals, so its infimum $\kappa^{\mathrm{can}}(\alpha,\beta)$ exists and

$$0 \le \kappa^{\mathrm{can}}(\alpha,\beta) \le \kappa(\alpha,\beta).$$

Averaging. Suppose I_a, I_b nonempty; they are finite, so $I_a^T \times I_b^T$ is a nonempty finite set and $|I_a|^N |I_b|^N > 0$. Summing the pointwise inequality over $I_a^T \times I_b^T$ and dividing by $|I_a|^N |I_b|^N$ gives that the mean of κ^{can} is at most the mean of κ, which is at most CNN_1/Y by (Om1) of Theorem A.9. □

Lemma A.16. *Fix $0 < \epsilon < 1/52$, put*

$$\theta = \epsilon/100, \qquad \gamma = \frac{1}{2} - \frac{11399}{1200}\epsilon,$$

and let $x \ge \max\{1, 48^{1/\gamma}\}$. Put

$$\delta = x^{-\epsilon/8}, \qquad b = \exp(x^{\epsilon}), \qquad a = xb.$$

Let b' be any real number. Let T be a finite set, let $n, k, L_a > 0$ be real numbers and let $m \ge 1$ be an integer, with

$$|T| \le 2n\delta, \qquad n \le x^{2+8\epsilon+\theta}, \qquad m \le x^{\theta}\sqrt{x\delta}.$$

Define the finite sets

$$\mathcal{A} = \left\{ \alpha \in \mathbb{Z}^T : \lceil a \rceil \le \alpha_t \le \left\lfloor a + \frac{a}{kx^{13}} \right\rfloor \text{ for every } t \in T \right\},$$
$$\mathcal{B} = \left\{ \beta \in \mathbb{Z}^T : \lceil b' \rceil \le \beta_t \le \left\lfloor b' + \frac{2n\delta x^{\epsilon} L_a b'}{k} \right\rfloor \text{ for every } t \in T \right\}.$$

Assume $\mathcal{A}, \mathcal{B}$ are nonempty. Let $\mathcal{C}$ be a finite set of primes $p < \exp(x^{\epsilon/3})$. For every $p \in \mathcal{C}$, let $s_p : \mathcal{A} \times \mathcal{B} \to \mathbb{R}_{\ge 0}$ satisfy

$$\frac{1}{|\mathcal{A}||\mathcal{B}|} \sum_{\alpha \in \mathcal{A}} \sum_{\beta \in \mathcal{B}} s_p(\alpha,\beta) \le m|T|x^{-12}.$$

Then there exists one pair $(\alpha^*, \beta^*) \in \mathcal{A} \times \mathcal{B}$ such that

$$\sum_{p \in \mathcal{C}} \frac{\log p}{p} \left(21_{s_p(\alpha^*,\beta^*) > x^{-\epsilon}} + 4 s_p(\alpha^*, \beta^*) \right) \le x^{-9}.$$

In particular, if the same fixed arithmetic orbit data give, for every pair $(\alpha,\beta) \in \mathcal{A} \times \mathcal{B}$, orbit masses $\Sigma_p(\alpha,\beta)$ as in Definition 5.2, with candidate set exactly $\mathcal{C}$, and

$$s_p(\alpha,\beta) = \Sigma_p(\alpha,\beta) \quad (p \in \mathcal{C}),$$

then the selected profile satisfies the small-share inequality (Lm5) of Definition 5.5, with its depths in the displayed short window.

Proof. First, $\gamma > 0$, since $11399/(1200 \cdot 52) < 1/2$. We derive a harmonic bound using only the candidate cutoff. Put $t = x^{\epsilon/3}$ and $M = \lceil \exp(t) \rceil - 1$. Here $t \ge 1$, so $M \ge 1$. Every $p \in \mathcal{C}$ is an integer at most M, and $M < \exp(t)$. Thus, using the elementary integral estimate for the harmonic sum,

$$\sum_{p \in \mathcal{C}} \frac{\log p}{p} \le t \sum_{q=1}^{M} \frac{1}{q} \le t(1 + \log M) \le t(1+t) \le t(2+t).$$

The harmonic estimate holds also for $M = 1$; for $M \geq 2$, it follows from $\sum_{q=2}^{M} q^{-1} \leq \int_1^M u^{-1}\,du$.

Write $Q = |\mathcal{A}||\mathcal{B}| > 0$, and define on the finite product

$$Z(\alpha,\beta) = \sum_{p\in\mathcal{C}} \frac{\log p}{p}\left(\mathbf{1}_{s_p(\alpha,\beta)>x^{-\epsilon}} + s_p(\alpha,\beta)\right).$$

For any $s \geq 0$, one has $\mathbf{1}_{s>x^{-\epsilon}} \leq x^{\epsilon}s$. Exchanging finite sums and using the assumed mean bound at each candidate therefore gives

$$\frac{1}{Q}\sum_{\alpha\in\mathcal{A}}\sum_{\beta\in\mathcal{B}} Z(\alpha,\beta) \leq (x^{\epsilon}+1)m|T|x^{-12}\sum_{p\in\mathcal{C}}\frac{\log p}{p}.$$

The size hypotheses imply

$$m|T| \leq 2x^{5/2+(125/16)\epsilon+2\theta}.$$

Indeed, the two factors of δ, with powers 1 and $1/2$, subtract $3\epsilon/16$ from the 8ϵ contribution in the upper bound for n. For $x \geq 1$, we also have

$$x^{\epsilon}+1 \leq 2x^{\epsilon}, \qquad x^{\epsilon/3}(2+x^{\epsilon/3}) \leq 3x^{2\epsilon/3}.$$

Consequently

$$\begin{aligned}\frac{1}{Q}\sum_{\alpha,\beta} Z(\alpha,\beta) &\leq 12x^{-19/2+(125/16+1/50+5/3)\epsilon}\\ &= 12x^{-19/2+(11399/1200)\epsilon} = 12x^{-9-\gamma} \leq x^{-9}/4.\end{aligned}$$

The last step uses $x^{\gamma} \geq 48$. A nonempty finite set contains an element with value at most its average, so there is one pair (α^*,β^*) with $Z(\alpha^*,\beta^*) \leq x^{-9}/4$. Since $2I+4s \leq 4(I+s)$ for $I, s \geq 0$, its asserted weighted sum is at most $4Z(\alpha^*,\beta^*) \leq x^{-9}$.

This argument also covers $T = \varnothing$: the two product boxes are singletons, and the nonnegative means are then zero. Empty candidate sets cause no difficulty. For the conditional application, substitute the stated equality with the orbit masses into the same finite sum. Box membership gives the short window for the selected integer depths. No arithmetic datum, orbit representative, or profile value is changed after selection. □

Lemma A.17. *Let $T_0 > 0$ be as in Theorem A.9. Fix*

$$0 < \varepsilon < 1/52, \qquad C_0 \geq T_0,$$

and let $T_2, C_M > 0$ be the constants of that theorem for C_0. Fix constants

$$C_H \geq T_2, \quad C_D \geq C_H, \quad C_{\mathrm{band}} \geq 2C_H, \quad C_{\mathrm{t1}} \geq 2C_M, \quad C_{\mathrm{t2}} \geq C_M, \quad C_{\mathrm{orb}} \geq 0.$$

There is $X > 1$, depending only on these fixed constants and ε, with the following property.

Let $x \geq X$, let an arithmetic datum on H, its tops $T \subseteq H$, ordering and orbit representatives be fixed, and put

$$n = |H|, \qquad \theta = \varepsilon/100, \qquad \delta = x^{-\varepsilon/8}.$$

Let $k, m \geq 1$ be integers such that

$$n \leq x^{2+8\varepsilon+\theta}, \quad |T| \leq 2n\delta, \quad x^{9/2+10\varepsilon-\theta} \leq k \leq x^{9/2+10\varepsilon+\theta}, \quad m \leq x^{\theta}\sqrt{x\delta}.$$

Put

$$r = \lceil (32+64\varepsilon)/\varepsilon \rceil + 1, \quad G = G_{\mathrm{orb}}, \quad N_1 = N_{\mathrm{orb}}, \quad N_* = 2n\delta,$$

$$a = x\exp(x^{\varepsilon}), \quad X' = \exp(x^{\varepsilon/3}), \quad b' = a/X', \quad L_c = C_0 N_1^2 \log a.$$

Let $\Delta > 0$ *satisfy* $\log \Delta \le x^{\varepsilon/4}/2$, *put* $c_G = 16k\Delta$, *and suppose*

$$4N_* x^{\varepsilon} L_c/k + C_{\mathrm{band}} N_1 L_c/k \le \rho \le x^{-2}.$$

Form the candidate set $\mathcal{C}$ *with* $p_0 = k^2 x^{26}$. *For each inert prime fix* $G_p \subseteq R_p$, *before any height or depth table. For every high candidate* $p \ge p_0$ *and* $v \in G_p$, *require that* $P_p(v) \subseteq \{0, \dots, n_p - 1\}$, $n_p = \mathrm{ord}(h_p)$, *satisfies (Go2),(Go3) for these same parameters.*

Define the nonempty integer intervals and product boxes

$$I_a = \mathbb{Z} \cap [\lceil a \rceil, \lfloor a + a/(kx^{13}) \rfloor], \quad I_b = \mathbb{Z} \cap [\lceil b' \rceil, \lfloor b' + N_* x^{\varepsilon} L_c b'/k \rfloor], \qquad \mathcal{A} = I_a^T, \quad \mathcal{B} = I_b^T.$$

For every candidate p *and* $v \in G_p$, *put* $n_p = \mathrm{ord}(h_p)$, $P = P_p(v)$, *and* $N_p(v) = |P|$. *For a high candidate define*

$$D_p = \left\lceil C_D (40 n_p \delta) x^{26} (N_1^5 + k^3) \log_p a \right\rceil, \quad c_{\mathrm{sep},p} = 8(D_p + 1),$$

$$c_{\mathrm{cor},p} = c_{\mathrm{sep},p} + C_{\mathrm{t2}}(40 n_p \delta) k \log_p a + 4(40 n_p \delta) c_G + 2 n_p c_G.$$

For $(\alpha, \beta) \in \mathcal{A} \times \mathcal{B}$, *define*

$$\alpha_{p,v}(i) = \alpha(v + i h_p), \qquad \beta_{p,v}(i) = \beta(v + i h_p) \qquad (i \in P).$$

For odd $i \in P$, *let* $d^-_{p,v}(i)$ *be the least* $d \in \{1, \dots, n_p\}$ *for which* $(i - d) \bmod n_p$ *is an even element of* P, *and put* $d^-_{p,v}(i) = 0$ *if there is none. Set*

$$S_{p,v}(\alpha, \beta) = \sum_{\substack{i \in P,\ i \text{ odd} \\ d^-_{p,v}(i) > 0}} \min\left(\beta_{p,v}(i), \frac{\alpha_{p,v}((i - d^-_{p,v}(i)) \bmod n_p)}{p^{d^-_{p,v}(i)}} \right),$$

$$\begin{aligned} t_{p,v}(\alpha, \beta) = {} & S_{p,v}(\alpha, \beta) + C_{\mathrm{t1}} N_p(v) N_1 \left(\frac{a}{p^2} + \frac{L_c a}{pk} \right) \\ & + C_{\mathrm{t2}} N_p(v) \left(p^G c_{\mathrm{cor},p} + k p^G + k \log_p a + c_G \right) + 2 n_p c_G. \end{aligned}$$

Define

$$\kappa_p(v; \alpha, \beta) = \begin{cases} \min\{1, C_{\mathrm{orb}} N_p(v) r^2 k / x^{26}\}, & p \in \mathcal{C},\ p < p_0, \\ \kappa^{\mathrm{can}}_{p, n_p, k}(P_p(v), \alpha_{p,v}, \beta_{p,v}; \lfloor c_G \rfloor, \lceil t_{p,v}(\alpha, \beta) \rceil, D_p, c_{\mathrm{sep},p}), & p \in \mathcal{C},\ p \ge p_0, \\ 0, & p \notin \mathcal{C}. \end{cases}$$

All these constants are defined and lie in $[0, 1]$. *There is one pair* $(\alpha^*, \beta^*) \in \mathcal{A} \times \mathcal{B}$ *for which*

$$\Sigma_p(\alpha, \beta) = m \sum_{v \in G_p} \kappa_p(v; \alpha, \beta)$$

satisfies

$$\sum_{p \in \mathcal{C}} \frac{\log p}{p} \left(21_{\Sigma_p(\alpha^*, \beta^*) > x^{-\varepsilon}} + 4\Sigma_p(\alpha^*, \beta^*) \right) \le x^{-9}.$$

Thus the selected orbit constants have the small-share inequality (Lm5).

At this same pair, for every high candidate, every $v \in G_p$, *every unramified quadratic setting at* (p, n_p), *and every dominant base array with exactly these local endpoints and middle bound* $\lfloor c_G \rfloor$, *the separated rank property holds with depth* $\lceil t_{p,v}(\alpha^*, \beta^*) \rceil$, *degree* D_p, *constant* $\kappa_p(v; \alpha^*, \beta^*)$ *and separation* $c_{\mathrm{sep},p}$. *All representatives, local origins and numerical choices in this conclusion are the ones fixed above.*

Proof. Outline. On a common tail the height and depth boxes are nonempty and, at every high candidate and good representative, the data satisfy items 1–7 of Theorem A.9 with a depth function at least t_I, so Corollary A.15 bounds the local mean of the canonical constant; this local mean equals the mean over the global tables, the low candidates are bounded pointwise, and Lemma A.16 then selects one pair (α^*, β^*) with the small-share inequality, at which the separated rank property holds as at every pair. □

Proposition A.18. *Let $0 < \varepsilon < \frac{1}{52}$, $\mathbf{C}$ an admissible constant family, $c_D \geq 0$, $c_h \geq 402$, and put $\theta = \varepsilon/100$. There is x_0 such that for every context K with these parameters, scale (x, ε, J) and $x \geq x_0$, with $\varepsilon_z = \varepsilon/J$:*

(a) $0 \leq a(t) \leq H_x(1 + \frac{1}{kx^{13}})$ for every top t, and $\tilde{b}_{\tau,j} \geq W_x$ for every $\tau \in \Phi$ and $1 \leq j \leq m$;

(b) $x^{2+8\varepsilon-\theta} \leq |A| \leq x^{2+8\varepsilon+\theta}$, $m \leq x^{\theta}(x\delta_1)^{1/2}$, $x^{9/2+10\varepsilon-\theta} \leq k \leq x^{9/2+10\varepsilon+\theta}$, $t \leq x^{401+\theta}$, $o \leq x^{\theta}$, and $2^e \leq |A| \leq o\,2^e$;

(c) $\log \Delta_D \leq x^{\varepsilon/4}/2$, $mh_0 > 0$, $\log(mh_0) \leq x^{\varepsilon/4}$, and $\log d \geq x^{\varepsilon_z/5-\varepsilon_z/100}$;

(d) if $X'(\mathfrak{s}) \leq T(\omega)$ for every word ω, then for every assembled datum D over K and every layered datum on D admissible at K, the size datum L attached to it has $S_c = 4k\Delta_D$, $\eta_S = mh_0$, $C_t = 401$, and its support contains every place w with $p(w) \leq X''(\mathfrak{s}, |A|) = x|A|X'(\mathfrak{s})$;

(e) the budget $L_a = \log(a(\mathfrak{s})\,\mathrm{rd}_E)$ of the host field E satisfies $x^{\varepsilon} \leq L_a \leq x^{\varepsilon+\theta}$.

Proof. Take x_0 at least the threshold of the construction of the size datum L, $x_0 \geq 2^{1/\theta}$, $x_0 \geq C_8^{1/\theta}$, $x_0 \geq x_1$ with $x_1 = x_1(\varepsilon)$ the threshold beyond which the sizes of a scale bound the rank entry t, and so large that for $x \geq x_0$: $\log(2x^{c_D}) \leq x^{\varepsilon/4}/2$; $\log(8x^{c_h+1}) \leq x^{\varepsilon/4}$; and $(\log x)^2 \geq 2C_8^2$.

(a) By (Cx3e), $0 < H_x \leq a(t) \leq H_x + H_x/(kx^{13})$. By (Cx3f), $\tilde{b}_{\tau,j} = b^1(\tau) + (j-1)h_0 + \frac{h_0}{2} \geq b^1(\tau)$. At the top place of t, $b^1(\tau) = b(t) + \lfloor B_x/x \rfloor \geq b(t) \geq B_x \geq W_x$ ((Cx3e), $x|A| \geq 1$). At thick places $b^1(\tau) \geq \lceil e^L \rceil \geq e^L \geq B_x \geq W_x$, since $B_x = e^L\, x\, e^{-x^{\varepsilon/3}} \leq e^L$ for $x \geq x_0$ (enlarging x_0 so that $x^{\varepsilon/3} \geq \log x$). At thin places $b^1(\tau) = \lceil W_x \rceil \geq W_x$.

(b) By (Cx3a): $x^{2+8\varepsilon} \leq |A| \leq 2x^{2+8\varepsilon} \leq x^{2+8\varepsilon+\theta}$, $m \leq 2(x\delta_1)^{1/2} \leq x^{\theta}(x\delta_1)^{1/2}$ and $x^{9/2+10\varepsilon} \leq k \leq 2x^{9/2+10\varepsilon} \leq x^{9/2+10\varepsilon+\theta}$, as $x^{\theta} \geq 2$; $t \leq x^{401}$ by the bound of the rank entry in terms of the sizes of a scale, since the rank datum of K has the sizes of (x, ε, J) by (Cx3a) and $x \geq x_1$; $o \leq C_8 \leq x^{\theta}$ by (Cx3b). For the frame (e, A, h, a_0) (Definition 3.11), $h\colon A \to H_e = (\mathbb{Z}/2^{e+2}\mathbb{Z})^{\times}/\{\pm 1\}$ is surjective and $|H_e| = 2^e$, so $2^e \leq |A|$; h is injective on $A_0 = \langle a_0 \rangle$, so $|A_0| \leq 2^e$ and $|A| = o|A_0| \leq o2^e$.

(c) $\Delta_D = \lceil x^{c_D} \rceil \leq 2x^{c_D}$ and $0 < mh_0 \leq 2\sqrt{x} \cdot 2(x^{c_h} + 1) \leq 8x^{c_h+1}$; use the choice of x_0. By (Cx3b) there is Y with $x^{1/J} \leq Y \leq x$ satisfying (Hg6), so $\log d > \frac{1}{2}Y^{\varepsilon/5}(\log Y)^2 \geq \frac{1}{2}x^{\varepsilon_z/5}(\log x)^2 J^{-2}$. Since $J \leq C_8$ (Cx3b) and $(\log x)^2 \geq 2C_8^2$, this is $\geq x^{\varepsilon_z/5} \geq x^{\varepsilon_z/5-\varepsilon_z/100}$.

(d) S_c, η_S, C_t are validity values of L, which keeps those of the size datum over the context, and the support clause is the condition (Rf1) of the refilling of a size datum by a canonical instance, which L satisfies. Finally $X''(\mathfrak{s}, |A|) = a(\mathfrak{s})/w''(\mathfrak{s}, |A|) = x|A|X'(\mathfrak{s})$ by the definition of the derived quantities of a scale.

(e) By Lemma 19.16, $1 \leq \mathrm{rd}_E \leq N_{\mathfrak{h}}$, and by (Hg6) (through (Cx3b)) $\log N_{\mathfrak{h}} \leq 2Y^{\varepsilon/5}(\log Y)^2 \leq 2x^{\varepsilon/5}(\log x)^2$. As $\log a(\mathfrak{s}) = \log x + x^{\varepsilon}$,

$$x^{\varepsilon} \leq L_a \leq x^{\varepsilon} + \log x + 2x^{\varepsilon/5}(\log x)^2 \leq x^{\varepsilon+\theta},$$

the last inequality for $x \ge x_0$ after enlarging x_0 (the left side is $x^{\varepsilon}(1+o(1))$ and $x^{\theta} \to \infty$). $\square$

Proposition A.19. ***Canonical projection convention.*** *The conditional phrase* constructed using these exact tables and their standard canonical instances *below has the following precise meaning. Fix the ordered host group, its arithmetic datum, frame, tops and full good-representative sets before the tables. Use one common tuple* $\mathfrak{k}_{\mathrm{orb}}$*, one* $C_e \ge 0$*,* $C_r = 1$*, and the common short-depth constant* $C_\Lambda = C_{\mathrm{La}}$*. Choose* $C_N > 0$ *with* $N_{\mathrm{orb}} \le C_N \log x$ *on the common tail, and prescribe*

$$\delta = x^{-\varepsilon/8}, \quad N_* = 2n\delta, \quad L_c = C_{\mathrm{La}} N_{\mathrm{orb}}^2 \log a, \qquad \rho_B = \frac{4N_* x^{\varepsilon} L_c}{k} + \frac{C_{\mathrm{band}} C_N (\log x) L_c}{k}.$$

The same wider band ρ_B *is fixed before the tables, contexts and canonical refill; it is used in all candidate and no-gain readings.*

At a returned member, its loss datum means the following explicit projection, not an arbitrary independently chosen record. Its group, arithmetic datum, frame, tops and (k, m, t_R, e_2, o) *are the retained host data* $(A, \mathfrak{A}, T; k, m, t, e, o)$*. Its heights and depths are the selected tables, zero extended off* T *where an expression requires this; its weights are the actual fillings* $\mathrm{fill}_j(z) = \tilde{b}_{\tau(z),j}$ *and its shifts are* $[k + (2j-1)(t+1)]/2$*. Its representative map, orbit origins and full good sets are those of this same ordered host. Its candidates, low capped constants, high canonical infima, piecewise correction degrees and real thresholds are the computed prescriptions of Definition 5.2 and Definition 18.3 and of the refilling of a size datum by a canonical instance, on this instance and tuple, with* $p_0 = k^2 x^{26}$*,* $\rho = \rho_B$*,* $c_G = 4S_c$*, and integer depth* $\lceil t_p(v) \rceil$ *in the high canonical infimum. Its size entries are*

$$N = k + m(t+1), \quad S_c = 4k\Delta_D, \quad \eta = mh_0, \quad L_a = L_c.$$

Its place field is the original large coefficient field L*, its place set is the support of the returned size datum, and*

$$\ell(w) = \frac{[L_w : \mathbb{Q}_{p(w)}]}{[L : \mathbb{Q}]} \log p(w).$$

Its place gain is the truncated member gain; its corrections, companion terms, served sets, served tops and partial weights are read from the same canonical instance and supplied part. Its error exponent is the canonical $\max(0, \lceil C_e f k^2 \log_p a \rceil)$*. These are field assignments and computed-reading conventions, made in the construction before any properties of this proposition are invoked; none assumes the small-share inequality or (Lm2), (Lm5), (Lm6), (Lm7). No field of an arbitrary loss record or of the stored canonical instance is replaced by this convention. For every fixed collection of complete good-host data there are a common tail, one tuple* $\mathfrak{k}_{\mathrm{orb}}$ *of eight nonnegative real constants, one* $C_e \ge 0$*, common* $\varepsilon_z > 0, C_t$*, and at each retained scale one pair of integer height and depth tables, chosen before its contexts or members are constructed. The tables satisfy the prescribed windows and the averaged canonical small-share choice. Whenever the common-profile class and members of Proposition A.1 are constructed using these exact tables and their standard canonical instances, the following properties hold at every retained member.*

1. *Its loss datum has the selected rank datum and rank sizes, with* t_R *the fixed selected rank. Its heights, depths, weights and shifts satisfy the integer weights and boxes for the same* $c_D > 397, c_h \ge 402$ *used in constructing the member. The field in these integer-weight conditions is its host field, and its thick subset is the selected one.*

2. *Its top set, Frobenius translations, orbit representatives and good representatives are the chosen finite good-orbit selection. Its base representative function is the standard orbit representative function of the canonical instance used in its size datum.*

3. *Its correction degrees, orbit thresholds and correction errors satisfy (Nc2)–(Nc4) for the same* $(\mathfrak{k}_{\mathrm{orb}}, C_e)$*. In particular*

$$\epsilon_p = \left\lceil C_e f k^2 \log_p a \right\rceil^+, \qquad L_c = C_{\mathrm{La}} N_{\mathrm{orb}}^2 \log a, \qquad C_{\mathrm{La}} \geq 1.$$

All remaining components of the tuple are used at their actual prescribed values, including the two prime regimes.

4. *Its loss datum has (Lm2), (Lm5), (Lm6) and (Lm7) for* (ε_z, C_t)*; its frame exponent* e_2 *is the selected frame exponent. Its residual density is at most* x^{-2}*. Its served sets, gain, corrections, companion terms, served tops and partial weights are the ones read from the same canonical instance and part.*

The constants and the enlarged cutoff do not depend on the scale or the member. No final top profile, depth, orbit choice, local value or part is altered to obtain these identities.

Proof. Sketch. The loss condition (Lm5) of Definition 5.5 asks for a small *mean* of canonical orbit constants over a height–depth box, not for a pointwise bound. The universal majorant of Theorem A.9 has mean at most CNN_1/Y over the box in every unramified quadratic setting, so a finite averaging argument (Lemma A.16, Lemma A.17) selects at each scale one pair of integer height and depth tables, before any context or member, for which the weighted candidate sum is at most x^{-9}; since the majorant does not depend on the setting, one pair serves every translate. The proof then establishes the numerical part. From Definition 18.3, $N_{\mathrm{orb}} = O_\varepsilon(1+\log x)$, hence $x^\varepsilon \leq L_c \leq x^{\varepsilon+\varepsilon/100}$ and the band width ρ_B is at most x^{-2}; the middle bound is $c_G = 16k\Delta_S$ on both sides; the inert primes of the loss datum are exactly the signal and inert classes of the host; and with the normalisation $C_r = 1$ the no-gain predicate is the disjunction (Dr1)–(Dr3) of Definition 5.2. The member operation changes only divisor lattices, word heights and word lattices, so it keeps the tables, the canonical instance and all orbit readings; under the numerical reading of the member, Proposition A.18 gives (Lm2) and (Lm7) with $C_t = 401$ and $\varepsilon_z = \varepsilon/C_8$, and the identity $\sum_{w|p}[L_w : \mathbb{Q}_p] = [L : \mathbb{Q}]$ gives the place weights of (Lm6). Finally, if the member's good sets, candidates and arrays are those of the selector, the canonical constants agree, the actual masses equal the selector's, and (Lm5) holds for every context built on the one selected pair.

It remains to show that the actual construction realises exactly these readings: its finite group and ordering give the least orbit representatives, its top arrays are the selected tables, its good sets and candidate predicate are those of the selector, and its loss projection (the shifts $\frac{1}{2}(k + (2j-1)(t+1))$, the band, the truncated gain and the place weights) agrees with the loss data of the class, with $C_r = 1$ built into the common profile; and that the dominant arrays, local settings and coefficient rings of the canonical instance are those of the high-prime conclusion of Lemma A.17. Heuristically these are identities between two descriptions of the same finite data: the selector's prescription is modelled on the canonical instance, both are computed from the same host, scale and top numbers, and the member construction receives the tables as input and never reselects them. The one point needing care is that the selector allows any fixed good subset satisfying its finite conditions, so the member's good sets must be shown to be that subset itself rather than another subset with the same properties. The mean bound of Theorem A.9 on which the selection rests depends in turn on the raw step Proposition A.14. □

A.3 Theta kernels on the CM base: integrality at inert primes

In Alpöge's account the vanishing of Stepanov's auxiliary function at the rational points becomes divisibility at inert primes: on a CM curve, for p inert in K, a derivative of order a of the theta

function divided by Ω^a is divisible by p to the power $a/p+a/p^3+\cdots-O(\log a)$ [4]. This section proves the integrality statement that underlies such divisibility. Let $K=\mathbb{Q}(\sqrt{-d})$, and let $\ell\geq 5$ be a prime inert in K. All integrality at ℓ reduces to one statement about one CM elliptic curve: the formal exponential of a good Weierstrass model is integral in the logarithmic coordinates of Lubin and Tate (Proposition A.25). Theta tensors, their torsion translates and the kernel families of a CM base inherit this property, so the theta kernels of a CM base are integral at the primes inert in K (Proposition A.28). That this integrality is the arithmetic source of the gains at inert primes, which offset the local losses in (Rr1), is our reading. The gains of Definition 5.3 are defined abstractly, and the construction carries the reading through the served kernel entries and their column valuations. In this section "inert" means inert in K; it is not the classes of inert primes of the loss data.

A.3.1 Formal groups of CM elliptic curves at inert primes

The CM base is built over the CM elliptic lattice $\Lambda=\delta\,\sigma_K(\mathfrak{c})$; CM bases carry kernel families $e_{B,\chi}$ indexed by characters of the ideals of the CM field E (Definition A.20), and Definition A.21 says what it means for a theta series to be integral in formal-group coordinates at an inert prime. At a prime $\ell\geq 5$ inert in K the curve has supersingular reduction, so its formal group has height two over $\mathbb{Z}_\ell$ and, with its action of $\mathcal{O}_K$, height one as a formal $\mathcal{O}_{K_\ell}$-module. Two classical facts then apply: height-one formal modules over the completed maximal unramified extension are of Lubin–Tate type (Theorem A.22), and commutative formal group laws over a $\mathbb{Q}$-algebra have logarithms (Theorem A.23). With good Weierstrass models over that ring (Proposition A.24) they give Proposition A.25.

Definition A.20. Let $\mathfrak{c}$ be a non-zero ideal of $\mathcal{O}_K$ of norm prime to $2d$ and $\delta\in\mathbb{C}$ with $\delta^{12}=g_2(\sigma_K\mathfrak{c})^3-27g_3(\sigma_K\mathfrak{c})^2$, and put $\Lambda=\delta\,\sigma_K(\mathfrak{c})$; the notation of Definition A.21 is used for this Λ. Put $\alpha(x)=(-1)^{\mathrm{round}(\frac{\sqrt{d}}{2}H(x,x))}$ and, for subgroups $\Theta_1,\Theta_2\subset V_{N,N'}$ with $\Theta_1\cap\Theta_2$ of finite index in Θ_2 and G entire on $V_{N,N'}$,

$$I_{\Theta_1,\Theta_2}G=[\Theta_2:\Theta_1\cap\Theta_2]^{-1/2}\sum_q\alpha(q)\,U_qG,$$

q running over representatives of $\Theta_2/(\Theta_1\cap\Theta_2)$.

(Kb1) CM bases. A **CM base** B over Λ consists of the following data and of an entire function θ_0 on $\mathbb{C}^\Phi$, its **standard theta function**.

- A point $u\in\Lambda$ with $\omega_K u/2\notin\Lambda$ and $(1-\omega_K)u/2\notin\Lambda$. Put $r=[E:K]=|\Phi|$, $A=A(\Lambda)$, and on $\mathbb{C}^\Phi$

$$H_0(z,z')=A^{-1}\sum_{\tau\in\Phi}z_\tau\overline{z'_\tau},\qquad \alpha_0(x)=e^{\pi i(\sqrt{d}/2)H_0(x,x)},$$

$$M_0=\text{the subgroup generated by }\{(w\,\tau(a))_{\tau\in\Phi}:\ w\in\Lambda,\ a\in\mathfrak{a}_0\}.$$

With the one-variable operator $(U_t^{(1)}G)(z)=G(z+t)\exp(-\pi z\bar{t}/A-\pi|t|^2/(2A))$, put

$$F_B(z)=\frac{(U_{u/2}^{(1)}\sigma^*)(z)}{(U_{u/2}^{(1)}\sigma^*)(0)}\qquad(z\in\mathbb{C}).$$

- A K-linear isomorphism $\Gamma_0\colon E^4 \to K^{4r}$, the coordinates of K^{4r} indexed by $\{1,\dots,4\}\times\Phi$, that is an isometry from $\sum_{\nu=1}^{4}\operatorname{Tr}_{E/K}(x_\nu\bar{y}_\nu)$ to the standard form $\sum_j x_j\bar{y}_j$, and the $\mathbb{C}$-linear automorphism g_C of $\mathbb{C}^{\{1,\dots,4\}\times\Phi}$ with

$$g_C\big((\tau(x_\nu))_{\nu,\tau}\big) = \big(\sigma_K((\Gamma_0 x)_j)\big)_j \qquad (x\in E^4).$$

- For every rational prime q that splits in K: a K-linear isometry $\Gamma_q\colon E^4\to K^{4r}$ for the same two forms with $\mathbb{Z}_{(q)}\Gamma_q(\mathfrak{a}_0^4) = \mathbb{Z}_{(q)}\mathcal{O}_K^{4r}$; a prime $\mathfrak{p}_q$ of $\mathcal{O}_K$ above q; $\pi_q\in\mathcal{O}_K$ with $\mathfrak{p}_q^h = \pi_q\mathcal{O}_K$, h the class number of K; and $\rho_q\in\mathbb{C}$ with $\rho_q^{2h} = \sigma_K(\pi_q)/\sigma_K(\bar{\pi}_q)$. Put $y_q = v_{\mathfrak{p}_q}\big(\det_K(\Gamma_q\Gamma_0^{-1})\big)$, $v_{\mathfrak{p}_q}$ the normalised valuation; it is required that $y_q\neq 0$ for only finitely many q, and

$$\kappa = \prod_{q \text{ split},\ y_q\neq 0} \rho_q^{-y_q}.$$

- On $\mathbb{C}^{4r} = \mathbb{C}^{\{1,\dots,4\}\times\Phi}$ put $H_{\mathrm{st}}(z,w) = A^{-1}\sum_j z_j\bar{w}_j$, $\alpha_{\mathrm{st}}(x) = e^{\pi i(\sqrt{d}/2)H_{\mathrm{st}}(x,x)}$, U_t^{st} the translate of Definition A.21 for H_{st}, $F_B^{\otimes 4r}(z) = \prod_j F_B(z_j)$ and $M' = g_C(M_0^4)$, and for G entire on $\mathbb{C}^{4r}$

$$\mathsf{I}_{\Lambda^{4r},M'}G = [M' : \Lambda^{4r}\cap M']^{-1/2}\sum_m \alpha_{\mathrm{st}}(m)\,U_m^{\mathrm{st}}G,$$

  m running over representatives in M' of $M'/(\Lambda^{4r}\cap M')$.

- θ_0 satisfies, for all $x\in M_0$ and $z\in\mathbb{C}^\Phi$,

$$\alpha_0(x)\,\theta_0(z+x)\,e^{-\pi H_0(z,x)-\pi H_0(x,x)/2} = \theta_0(z),$$

  and for all $z_1,\dots,z_4\in\mathbb{C}^\Phi$

$$\prod_{\nu=1}^{4}\theta_0(z_\nu) = \kappa\,\big(\mathsf{I}_{\Lambda^{4r},M'}F_B^{\otimes 4r}\big)\big(g_C(z_1,\dots,z_4)\big).$$

(Kb2) Characters of ideals. A **character of the ideals of** E is a complex function χ on the $\mathcal{O}_E$-submodules of E with $\chi(\mathfrak{a}_1\mathfrak{a}_2) = \chi(\mathfrak{a}_1)\chi(\mathfrak{a}_2)$ whenever $\mathfrak{a}_1\bar{\mathfrak{a}}_1 = \mathfrak{a}_2\bar{\mathfrak{a}}_2 = \mathcal{O}_E$, and $\chi(z\mathcal{O}_E) = \prod_{\tau\in\Phi}\tau(z)^{-1}$ for $z\in E$ with $z\bar{z}=1$.

(Kb3) The kernel family. For a CM base B over Λ with standard theta function θ_0 and a character χ of the ideals of E, put $\theta_0^{\otimes}(z) = \prod_{a,b}\theta_0\big((z_{\tau ab})_{\tau\in\Phi}\big)$ on $V_{N,N'}$; for $L\subset E^N$ let $\det L$ be the $\mathcal{O}_E$-span of the $\det A$ with $A\mathcal{O}_E^N\subseteq L$. The **kernel family** of (B,χ) assigns to every admitted pair (L,L') the function

$$e_{B,\chi}(L,L') = \chi(\det L)^{N'/2}\,\chi(\det L')^{-N/2} \cdot I_{\Theta(L,\mathcal{O}_E^{N'}),\,\Theta(L,L')}\,I_{\Theta(\mathcal{O}_E^N,\mathcal{O}_E^{N'}),\,\Theta(L,\mathcal{O}_E^{N'})}\,\theta_0^{\otimes}$$

on $V_{N,N'}$; when B is fixed it is written e_χ.

Definition A.21. All other notation is local. **Host and CM lattice.** Let $\mathfrak{h} = (q,d,Q_S,\alpha)$ be a host for a frame with $\alpha(-1) = ((-1,-1),0)$, let $E = E_{\mathfrak{h}}$ be its field, read ϵ_2 on $\mathrm{Gal}(E/\mathbb{Q})$ through the isomorphism induced by α, write $x\mapsto\bar{x}$ for the automorphism of E corresponding to $((-1,-1),0)$ (complex conjugation) and E^+ for its fixed field. By (Hr1), d is a prime with

$d \equiv 7 \pmod{16}$. Assume that E is unramified over E^+ at every finite place: for every maximal ideal P of $\mathcal{O}_E$ some $\theta \in \mathcal{O}_E$ has $\theta - \bar{\theta} \notin P$. Fix $s_d \in E$ and a field embedding $\varphi_0 \colon E \hookrightarrow \mathbb{C}$ with

$$s_d^2 = -d, \qquad \sigma(s_d) = \epsilon_2(\sigma)\, s_d \quad (\sigma \in \mathrm{Gal}(E/\mathbb{Q})), \qquad \varphi_0(s_d) = i\sqrt{d};$$

write $\sqrt{-d} = s_d$, $K = \mathbb{Q}(\sqrt{-d}) \subseteq E$ and $\sigma_K = \varphi_0|_K$, through which K is viewed inside $\mathbb{C}$ (so $\sigma_K(\sqrt{-d}) = i\sqrt{d}$), and put $\omega_K = (1+\sqrt{-d})/2$. Let $\mathfrak{b}$ be an integral ideal of $\mathcal{O}_E$ with

$$\mathcal{D}_{E/K} = \mathfrak{b}\,\bar{\mathfrak{b}}, \qquad \mathfrak{b} + \bar{\mathfrak{b}} = \mathcal{O}_E, \qquad \sigma(\mathfrak{b}) = \mathfrak{b} \ \text{ for every } \sigma \in \mathrm{Gal}(E/\mathbb{Q}) \text{ with } \epsilon_2(\sigma) = 1,$$

where $\mathcal{D}_{E/K}$ is the relative different, and put

$$\Phi = \{\tau \colon E \hookrightarrow \mathbb{C} : \ \tau|_K = \sigma_K\}, \qquad \mathfrak{a}_0 = \mathfrak{b}^{-1}.$$

Thus Φ is the full CM type of E over σ_K, and $\mathfrak{a}_0$ is a fractional ideal of E, in general not contained in $\mathcal{O}_E$. Let $\Lambda \subset \mathbb{C}$ be a lattice with $\omega_K\Lambda \subseteq \Lambda$ and $g_2(\Lambda)^3 - 27g_3(\Lambda)^2 = 1$; $A(\Lambda) > 0$ is its covolume.

Lattices and theta lattices. For $N \geq 1$ put $h_N(x,y) = \sum_i \bar{x}_i y_i$ on E^N. A pair (L, L') of $\mathcal{O}_E$-submodules $L \subset E^N$, $L' \subset E^{N'}$ is **admitted** if N, N' are even and each is **self-dual**: finitely generated, spanning, and equal to $\{y : \ h(x,y) \in \mathcal{O}_E \text{ for all } x \text{ in it}\}$. Put

$$Y(L,L') = \mathcal{O}_E\text{-span of } \{aA : \ a \in \mathfrak{a}_0, \ A \in \mathrm{M}_{N'\times N}(E), \ AL \subseteq L'\},$$
$$h_Y(x,y) = \mathrm{Tr}_{E/K} \textstyle\sum_{a,b} x_{ab}\overline{y_{ab}} \in K.$$

Let $V = V_{N,N'} = \mathbb{C}^{\Phi\times N'\times N}$ with coordinates $z_{\tau ab}$, $\iota(A) = (\tau(A_{ab}))_{\tau ab}$, and let $\Theta(L,L') \subset V$ be the subgroup generated by $w\,\iota(A)$, $w \in \Lambda$, $A \in Y(L,L')$ (the **theta lattice**). Put $H(z,w) = A(\Lambda)^{-1}\sum_{\tau ab} z_{\tau ab}\overline{w_{\tau ab}}$ and, for $t \in V$ and $G \colon V \to \mathbb{C}$, $(U_tG)(z) = G(z+t)\exp\bigl(-\pi H(z,t) - \frac{\pi}{2}H(t,t)\bigr)$.

Prime-to-p notions. Let $p \geq 5$ be a prime with $\left(\frac{-d}{p}\right) = -1$. Two $\mathcal{O}_E$-modules M, M_1 (in the same E^N) are **p-locally equal** if $sM \subseteq M_1$ and $sM_1 \subseteq M$ for some integer s prime to p. A point $t \in V$ is **prime-to-p torsion** for $\Theta(L,L')$ if $nt \in \Theta(L,L')$ for some integer $n \geq 1$ prime to p. A family $b_1, \ldots, b_r \in \mathrm{M}_{N'\times N}(E)$ is an **orthonormal p-basis** of $Y = Y(L,L')$ if it is K-linearly independent, $sb_i \in Y$ for some s prime to p, every $y \in Y$ has $sy \in \sum_i \mathcal{O}_K b_i$ for some s prime to p, and $h_Y(b_i, b_j) = \delta_{ij}$.

p-adic series. Let $\lambda \colon \overline{\mathbb{Q}} \to \mathbb{C}_p$ be a field embedding, extended to $\mathbb{C}$ by $\lambda(x) = 0$ for $x \notin \overline{\mathbb{Q}}$. For G entire on V let $\widehat{G}_\lambda \in \mathbb{C}_p[[z_{\tau ab}]]$ be the series whose coefficients are the images under λ of the Taylor coefficients of G at 0. A **good model** is a change of variables C over $\mathbb{C}_p$, with scaling $u \in \mathbb{C}_p^\times$, carrying $y^2 = x^3 - \frac{1}{4}\lambda(g_2(\Lambda))x - \frac{1}{4}\lambda(g_3(\Lambda))$ to a general Weierstrass equation W with coefficients of absolute value ≤ 1 and discriminant 1; $\log_W \in \mathbb{C}_p[[X]]$ is the formal logarithm of W in the parameter $X = -x/y$, with $\log_W(X) = X + O(X^2)$. Let σ^* be the unique odd entire function with $(\sigma^*)'(0) = 1$ and $\sigma^*(z+\omega)\exp\bigl(-\pi z\bar{\omega}/A(\Lambda) - \pi|\omega|^2/(2A(\Lambda))\bigr) = \pm\sigma^*(z)$ for $\omega \in \Lambda$, sign $+$ exactly when $\omega/2 \in \Lambda$; $\widehat{\sigma^*}_\lambda$ its series.

Integrality in formal-group coordinates. A family e assigning to every admitted (L,L') an entire function $e(L,L')$ on $V_{N,N'}$ is **integral in formal-group coordinates at** (p,λ) if for every admitted (L,L'), every series

$$F = \sum_{k=1}^{m} r_k \left(U_{t_k}\, e(L_k, L_k')\right)^\wedge_\lambda$$

with $|r_k| \le 1$, t_k prime-to-p torsion for $\Theta(L, L')$, and (L_k, L_k') admitted and p-locally equal to (L, L') componentwise, every good model C (scaling u, $\varepsilon = u^{-1}$) and every orthonormal p-basis $b_1, \dots, b_r$ of $Y(L, L')$, all coefficients of the series

$$F\Big(\Big(\sum_{i=1}^{r} \varepsilon\, \lambda\big(\tau(b_{i,ab})\big) \log_W(X_i)\Big)_{\tau ab}\Big) \cdot \prod_{i=1}^{r} \frac{\varepsilon X_i}{\widehat{\sigma^*}_\lambda\big(\varepsilon \log_W(X_i)\big)}$$

in $\mathbb{C}_p[[X_1, \dots, X_r]]$ have absolute value at most 1. The family is **integral at inert primes** if this holds for every prime $p \ge 5$ with $\left(\frac{-d}{p}\right) = -1$ and every λ.

Theorem A.22. *All notation is local. Let K_0 be a finite extension of $\mathbb{Q}_p$ with valuation ring $\mathcal{O}$, uniformiser π and residue field of cardinality q. Let $\breve{\mathcal{O}}$ be the valuation ring of the completion of the maximal unramified extension of K_0 in $\mathbb{C}_p$. A* formal $\mathcal{O}$-module *over a commutative $\mathcal{O}$-algebra R is a one-dimensional commutative formal group law $G(X, Y) \in R[[X, Y]]$ with a ring homomorphism $a \mapsto [a]_G$ from $\mathcal{O}$ to the endomorphisms of G over R such that $[a]_G(X) \equiv aX \pmod{X^2}$; over $R = \breve{\mathcal{O}}$ it has* height one *if the coefficient of X^q in $[\pi]_G(X)$ is a unit of $\breve{\mathcal{O}}$.*

(a) Put $\log_\pi(X) = \sum_{k \ge 0} \pi^{-k} X^{q^k} \in K_0[[X]]$. The power series

$$F_\pi(X, Y) = \log_\pi^{-1}\big(\log_\pi(X) + \log_\pi(Y)\big), \qquad [a]_\pi(X) = \log_\pi^{-1}\big(a \log_\pi(X)\big) \quad (a \in \mathcal{O})$$

have coefficients in $\mathcal{O}$, and they form a formal $\mathcal{O}$-module over $\mathcal{O}$ of height one, with $[\pi]_\pi(X) \equiv X^q \pmod{\pi}$.

(b) Every formal $\mathcal{O}$-module G of height one over $\breve{\mathcal{O}}$ is isomorphic over $\breve{\mathcal{O}}$ to F_π: there is $\theta(X) \in \breve{\mathcal{O}}[[X]]$ with $\theta(X) \equiv \varepsilon X \pmod{X^2}$, $\varepsilon \in \breve{\mathcal{O}}^\times$, such that $\theta(F_\pi(X, Y)) = G(\theta(X), \theta(Y))$ and $\theta \circ [a]_\pi = [a]_G \circ \theta$ for all $a \in \mathcal{O}$.

Proof. Outline. Part (a) follows from Hazewinkel's functional-equation lemma applied to $\log_\pi$ [124], and part (b) from the Lubin–Tate uniqueness of the formal module attached to a Lubin–Tate series, together with the classification of formal $\mathcal{O}$-modules by height [124]. □

Theorem A.23. *Let R be a commutative $\mathbb{Q}$-algebra and let $F(X, Y)$ be a commutative formal group law of dimension $d \ge 0$ over R. There is a unique vector of formal power series $\ell_F(X) \in R[[X_1, \dots, X_d]]^d$ with zero constant term and linear term X such that*

$$\ell_F(F(X, Y)) = \ell_F(X) + \ell_F(Y).$$

The formal map ℓ_F has a compositional inverse. If G is a commutative formal group law of dimension e over R and $u : F \to G$ is a homomorphism of formal group laws, then

$$\ell_G(u(X)) = du(0)\, \ell_F(X),$$

where $du(0) \in M_{e,d}(R)$ is the linear term of u.

Proof. Outline. The logarithm is the characteristic-zero logarithm of a commutative formal group law [124], compositionally invertible because its linear term is the identity, and the homomorphism identity and uniqueness follow because an additive formal map over a rational algebra equals its linear term, by Euler's identity applied to its homogeneous components. □

Proposition A.24. *All notation is local. Let $d \geq 1$ be a squarefree integer with $d \equiv 3 \pmod 4$, put $K = \mathbb{Q}(\sqrt{-d}) \subset \mathbb{C}$ and $\omega_K = (1 + i\sqrt{d})/2$, so that $\mathcal{O}_K = \mathbb{Z}[\omega_K]$. Let $L \subset \mathbb{C}$ be a lattice with $\omega_K L \subseteq L$, with Weierstrass invariants $g_2(L)$, $g_3(L)$. Let $\ell \geq 5$ be a prime with $\ell \nmid d$ and let $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ be an isomorphism of fields. Let $\breve{\mathbb{Q}}_\ell \subseteq \mathbb{C}_\ell$ be the closure of the subfield generated by the roots of unity of order prime to ℓ, and $\breve{\mathbb{Z}}_\ell$ its valuation ring. If moreover d is a prime with $d > 3$, then there is $\lambda \in \mathbb{C}_\ell^\times$ such that*

$$a = \lambda^4\, \iota(g_2(L)) \in \breve{\mathbb{Z}}_\ell, \qquad b = \lambda^6\, \iota(g_3(L)) \in \breve{\mathbb{Z}}_\ell, \qquad a^3 - 27b^2 \in \breve{\mathbb{Z}}_\ell^\times.$$

Proof. Outline. An elliptic curve with complex multiplication by $\mathcal{O}_K$ and good reduction away from d exists over $\mathbb{Q}(j(\mathcal{O}_K))$; Galois conjugation over a subfield of the Hilbert class field, which is unramified above ℓ, moves its invariant to $j(L)$, and a short Weierstrass model with unit discriminant at the place of ι is then carried to the invariants of L by a scaling (λ^4, λ^6). □

Proposition A.25. *All notation is local; d, K, ω_K, L, ℓ, ι, $\breve{\mathbb{Q}}_\ell$ and $\breve{\mathbb{Z}}_\ell$ are as in Proposition A.24. For a, b in a field of characteristic zero put $c_2 = a/20$, $c_3 = b/28$ and, for $k \geq 4$,*

$$c_k = \frac{3}{(2k+1)(k-3)} \sum_{m=2}^{k-2} c_m\, c_{k-m},$$

(the coefficients of $\wp(z) = z^{-2} + \sum_{k\geq 2} c_k z^{2k-2}$ for $y^2 = 4x^3 - ax - b$), and

$$u_{a,b}(Z) = Z\left(1 + \sum_{k\geq 2} c_k Z^{2k}\right)\left(1 - \sum_{k\geq 2} (k-1) c_k Z^{2k}\right)^{-1},$$

the formal expansion of $-2\wp(z)/\wp'(z)$. Put $\log_{\mathrm{LT}}(X) = \sum_{j\geq 0} \ell^{-j} X^{\ell^{2j}}$. Assume that $-d$ is not a square modulo ℓ. Let $\lambda \in \mathbb{C}_\ell^\times$ and

$$a = \lambda^4 \iota(g_2(L)), \qquad b = \lambda^6 \iota(g_3(L)), \qquad a, b \in \breve{\mathbb{Z}}_\ell, \qquad a^3 - 27b^2 \in \breve{\mathbb{Z}}_\ell^\times.$$

Then there is $\varepsilon \in \breve{\mathbb{Z}}_\ell^\times$ such that every coefficient of the power series $u_{a,b}(\varepsilon \log_{\mathrm{LT}}(X)) \in \mathbb{C}_\ell[[X]]$ lies in $\breve{\mathbb{Z}}_\ell$.

Proof. Write $F = \breve{\mathbb{Q}}_\ell$, $R = \breve{\mathbb{Z}}_\ell$, $q = \ell^2$, and let E be the curve $y^2 = 4x^3 - ax - b$ over F; the substitution $y = 2Y$ gives $Y^2 = x^3 - \frac{a}{4}x - \frac{b}{4}$, a Weierstrass equation with coefficients in R (2 is a unit, as $\ell \geq 5$) and discriminant $-16(4(-\frac{a}{4})^3 + 27(\frac{b}{4})^2) = a^3 - 27b^2 \in R^\times$, so E has good reduction and this equation is its Néron model over R ([233], Chapter IV, §6: a Weierstrass model that is smooth over R is a Néron model).

The formal group and its exponential. Let $G \in R[[t_1, t_2]]$ be the formal group law of this equation in the parameter $t = -x/Y = -2x/y$ ([234], Chapter IV, §1), with invariant differential dx/y and formal logarithm $\log_G \in F[[t]]$ normalised by $\log_G(t) \equiv t \pmod{t^2}$ ([234], Chapter IV, §4, §5). Over the field F of characteristic zero, the formal Laurent series $x(z) = z^{-2} + \sum_{k\geq 2} c_k z^{2k-2}$ (with the c_k of the statement) and $y(z) = x'(z)$ satisfy $y^2 = 4x^3 - ax - b$ (the recursion of the c_k is the coefficient comparison in $\wp'' = 6\wp^2 - \frac{a}{2}$), and $dx/y = dz$. Hence $t(z) = -2x(z)/y(z) = u_{a,b}(z)$ is a formal parametrisation with $\log_G(u_{a,b}(z)) = z$; that is, $u_{a,b}$ is the compositional inverse of $\log_G$.

The formal module. Over $\mathbb{C}_\ell$, E is isomorphic (by $(x, y) \mapsto (\lambda^{-2}x, \lambda^{-3}y)$) to the image under ι of the curve $y^2 = 4x^3 - g_2(L)x - g_3(L)$, whose endomorphism ring is $\mathcal{O}_K$ acting through

$z \mapsto \alpha z$ on $\mathbb{C}/L$. So $\mathcal{O}_K$ acts on $E_{\mathbb{C}_\ell}$, and $[\alpha]^*(dx/y) = \varphi(\alpha)\,dx/y$ for the embedding $\varphi = \iota|_K \colon K \to \mathbb{C}_\ell$. Since ℓ is unramified in K, $\varphi(K) \subseteq F$. Every endomorphism is defined over a finite Galois extension F' of F; for $\tau \in \mathrm{Gal}(F'/F)$, $\tau([\alpha])$ multiplies dx/y by $\tau(\varphi(\alpha)) = \varphi(\alpha)$, and an endomorphism is determined by its action on the invariant differential in characteristic zero; so $\tau([\alpha]) = [\alpha]$ and $[\alpha]$ is defined over F. By the Néron property it extends to the Néron model, hence gives $[\alpha]_G \in \mathrm{End}_R(G)$ with $[\alpha]_G(t) \equiv \varphi(\alpha)t \pmod{t^2}$. As $\mathrm{End}_R(G)$ contains $\mathbb{Z}_\ell$ (by continuity) and $\mathcal{O} := \mathcal{O}_K \otimes \mathbb{Z}_\ell = \mathbb{Z}_\ell[\omega_K]$ is the unramified quadratic extension $\mathbb{Z}_{\ell^2}$ ($-d$ is not a square modulo ℓ), G is a formal $\mathcal{O}$-module over R (with R an $\mathcal{O}$-algebra through φ), uniformiser $\pi = \ell$, residue cardinality $q = \ell^2$.

Height one. The reduction $\tilde{E}$ over $\overline{\mathbb{F}}_\ell$ is supersingular: its invariant is the reduction of $\iota(j(L))$, and by Deuring's criterion (S. Lang, Elliptic functions, 2nd ed., Chapter 13, §4, Theorem 12) the reduction of an elliptic curve with complex multiplication by $\mathcal{O}_K$ at a prime above ℓ is supersingular when ℓ is inert in K. Hence the formal group of $\tilde{E}$ has height 2, i.e. $[\ell]_G(t) \bmod \ell$ is a series in t^{ℓ^2} whose coefficient of t^{ℓ^2} is nonzero ([234], Chapter IV, §7, and Chapter V, Theorem 3.1); so the coefficient of t^q in $[\pi]_G$ is a unit of R, and G has height one as a formal $\mathcal{O}$-module.

Conclusion. By Theorem A.22(b) there is an isomorphism $\theta \colon F_\pi \to G$ of formal $\mathcal{O}$-modules over R with $\theta(X) \in R[[X]]$ and $\theta(X) \equiv \varepsilon X \pmod{X^2}$, $\varepsilon \in R^\times$, where F_π has logarithm $\log_\pi(X) = \sum_{j\ge 0} \ell^{-j} X^{\ell^{2j}} = \log_{\mathrm{LT}}(X)$ (Theorem A.22(a)). By Theorem A.23 over F, $\log_G(\theta(X)) = \varepsilon \log_{\mathrm{LT}}(X)$; applying the compositional inverse $u_{a,b}$ of $\log_G$ gives $\theta(X) = u_{a,b}(\varepsilon \log_{\mathrm{LT}}(X))$. So every coefficient of $u_{a,b}(\varepsilon \log_{\mathrm{LT}}(X))$ lies in $R = \breve{\mathbb{Z}}_\ell$. □

A.3.2 Theta kernels and the Hecke reading

The one-dimensional statement passes to the standard theta tensors (Lemma A.26). The theta kernels of a CM base are covariant under the unitary group (Proposition A.27), which transports integrality between admitted pairs, and together these give Proposition A.28. For the kernel family of a tied entry the integrality takes the form of a host condition at the inert-class and signal primes ≥ 5 (Lemma A.29); this condition is stronger than integrality of the coefficients. Finally, integrality survives the normalised Hecke reading: the Hecke reading preserves the integral model ball (Lemma A.30), on the integral models of unitary Shimura data of Section A.8 (Proposition A.103).

Lemma A.26. *Let $p \ge 5$ be inert in K and let $\lambda : \overline{\mathbb{Q}} \to \mathbb{C}_p$ be a field embedding. For even nonnegative integers N, N', put $m = N'N$ and, in the ordered matrix coordinates,*

$$Y_{\mathrm{st}} = M_{N'\times N}(A_0), \quad h_Y(x,y) = \mathrm{Tr}_{E/K} \sum_{a,b} x_{ab}\overline{y_{ab}},$$

$$T_{N,N'}(z) = \prod_{a=1}^{N'} \prod_{b=1}^{N} T_B((z_{\tau ab})_\tau), \qquad \Theta_{\mathrm{st}} = M_0^m, \qquad H_{\mathrm{st}} = \bigoplus_{a,b} H_0.$$

Let s satisfy $ns \in \Theta_{\mathrm{st}}$ for some positive integer n prime to p. Let $b_1, \dots, b_d$ be an orthonormal p-basis of Y_{st}; it is a K-basis of $M_{N'\times N}(E)$, spans SY_{st} over $S = O_K \otimes \mathbb{Z}_{(p)}$, and satisfies $h_Y(b_i, b_j) = \delta_{ij}$. Thus $d = rm$.

For every good model W, with scaling u, $\varepsilon_W = u^{-1}$ and normalized logarithm $\log_W$, all coefficients of

$$(U_s^{H_{\mathrm{st}}} T_{N,N'})^\wedge_\lambda \left(\left(\sum_{i=1}^{d} \varepsilon_W \lambda(\tau((b_i)_{ab})) \log_W(X_i) \right)_{\tau ab} \right) \prod_{i=1}^{d} \frac{\varepsilon_W X_i}{\widehat{S_{L\lambda}}(\varepsilon_W \log_W(X_i))}$$

belong to $\mathcal{O}_{\mathbb{C}_p}$. The quotients are read by cancelling their common simple zero. For $m = 0$ the expression is the constant 1*. All theta functions, torsion points, coefficient directions and model corrections are those of the data fixed above.*

Proof. Outline. One extends λ to a field isomorphism $\mathbb{C} \to \mathbb{C}_p$, fixes a good elliptic scaling and a Lubin–Tate unit by Proposition A.24 and Proposition A.25, proves integrality of one copy of T_B in Lubin–Tate logarithmic coordinates of a local frame from its finite-intertwiner identity, takes the product over the $m = N'N$ matrix positions, passes to the given orthonormal p-basis through a quadratic-unitary transition matrix and the Lubin–Tate substitution of Theorem A.22(a), and finally compares with an arbitrary good model using the algebraicity of the Taylor coefficients. □

Proposition A.27. *In the notation of Proposition A.28, let (M, M') be an admitted pair, $M \subset E^N$, $M' \subset E^{N'}$, and let $\gamma \in \mathrm{GL}_N(E)$, $\gamma' \in \mathrm{GL}_{N'}(E)$ satisfy $\bar{\gamma}^{\mathsf{T}}\gamma = 1$, $\bar{\gamma}'^{\mathsf{T}}\gamma' = 1$. Then for every $z \in V_{N,N'}$, writing $z_\tau \in \mathrm{M}_{N'\times N}(\mathbb{C})$ for its τ-component and $\tau(\gamma)$ for the entrywise image,*

$$e_\chi(\gamma M, \gamma' M')(z) = e_\chi(M, M')\Big(\big(\overline{\tau(\gamma')}\big)^{\mathsf{T}}\, z_\tau\, \tau(\gamma)\big)_{\tau\in\Phi}\Big).$$

Proof. Outline. One first proves the composition law $I_{23}I_{12} = I_{13}$ for the finite intertwiners on the one-dimensional theta lines of the period lattices, the phase being 1 by positivity of a local quadratic sum split by an isotropic projection (from the unramified Cartan decomposition); then computes the scalar for changing the standard pair by one unitary factor through the Cayley theta identity, whose sign is fixed by an element of norm -1 modulo a suitable integer; and finally transports an arbitrary pair and cancels the determinant factors by the principal-ideal rule of (Kb2) in Definition A.20. □

Proposition A.28. *Let $\mathfrak{c}$ be a non-zero ideal of $\mathcal{O}_K$ of norm prime to $2d$, $\delta \in \mathbb{C}$ with $\delta^{12} = g_2(\sigma_K\mathfrak{c})^3 - 27g_3(\sigma_K\mathfrak{c})^2$ and $\Lambda = \delta\,\sigma_K(\mathfrak{c})$; let B be a CM base over Λ and χ a character of the ideals of E. Then the kernel family $e_\chi = e_{B,\chi}$ is integral in formal-group coordinates at inert primes in the sense of Definition A.21.*

Proof. Fix a prime $p \geq 5$ with $(\frac{-d}{p}) = -1$ and λ. For an admitted pair (L, L'), a good model (scaling u, $\varepsilon = u^{-1}$) and an orthonormal p-basis $b = (b_1, \dots, b_r)$ of $Y(L, L')$, and $F \in \mathbb{C}_p[[z_{\tau ab}]]$, put

$$T_b(F) = F(Z_b)\cdot P_r, \qquad Z_b = \Big(\sum_i \varepsilon\,\lambda\big(\tau(b_{i,ab})\big)\log_W(X_i)\Big)_{\tau ab},$$
$$P_r = \prod_{i=1}^{r} \frac{\varepsilon X_i}{\widehat{\sigma^*_\lambda}(\varepsilon\log_W(X_i))}.$$

The substituted series have no constant term, so $F \mapsto F(Z_b)$ is a well-defined $\mathbb{C}_p$-linear map (each coefficient is a finite sum). Call F *good for* (L, L') if $T_b(F)$ has all coefficients of absolute value ≤ 1 for every good model and every orthonormal p-basis b of $Y(L, L')$. We must show: every F as in Definition A.21 for the family $e = e_\chi$ is good for (L, L').

Step 1 (integral combinations). By linearity $T_b(\sum_k r_k F_k) = \sum_k r_k T_b(F_k)$; by the ultrametric inequality, if each F_k is good for (L, L') and $|r_k| \leq 1$, then $\sum_k r_k F_k$ is good for (L, L').

Step 2 (p-local equality). Let $L, L_1 \subset E^N$ and $L', L'_1 \subset E^{N'}$ be p-locally equal via integers s, s' prime to p. If $AL \subseteq L'$ then $(ss'A)L_1 \subseteq s'A(L) \subseteq s'L' \subseteq L'_1$; with the symmetric statement,

$ss'\,Y(L,L') \subseteq Y(L_1,L_1')$ and $ss'\,Y(L_1,L_1') \subseteq Y(L,L')$, hence also $ss'\Theta(L,L') \subseteq \Theta(L_1,L_1')$ and conversely. Consequently the two modules Y have the same orthonormal p-bases (linear independence and orthonormality are intrinsic; the two span conditions transfer after multiplying by ss', prime to p), so a series is good for (L,L') if and only if it is good for (L_1,L_1'); and a point is prime-to-p torsion for $\Theta(L,L')$ if and only if it is for $\Theta(L_1,L_1')$.

Step 3 (unitary pull-back). Let $\gamma \in \mathrm{GL}_N(E)$ and $\gamma' \in \mathrm{GL}_{N'}(E)$ satisfy $\bar\gamma^{\mathsf T}\gamma = 1$ and $\bar\gamma'^{\mathsf T}\gamma' = 1$, and put $\pi(z)_\tau = \tau(\bar\gamma'^{\mathsf T})\, z_\tau\, \tau(\gamma)$ on V. Since E is a CM field, $\tau(\bar x) = \overline{\tau(x)}$, so $\tau(\gamma),\tau(\gamma')$ are unitary complex matrices and $H(\pi z,\pi w) = H(z,w)$ ($\sum_{ab} z_{ab}\overline{w_{ab}} = \mathrm{tr}(z\bar w^{\mathsf T})$). (i) $A\gamma M \subseteq \gamma' M'$ if and only if $\bar\gamma'^{\mathsf T} A\gamma M \subseteq M'$, so $x \mapsto \bar\gamma'^{\mathsf T} x\gamma$ maps $Y(\gamma M,\gamma' M')$ onto $Y(M,M')$ ($\mathfrak a_0$-multiples correspond) and π maps $\Theta(\gamma M,\gamma' M')$ onto $\Theta(M,M')$; in particular πt is prime-to-p torsion for $\Theta(M,M')$ when t is for $\Theta(\gamma M,\gamma' M')$. The same map preserves h_Y (by $\gamma\bar\gamma^{\mathsf T} = 1$, $\gamma'\bar\gamma'^{\mathsf T} = 1$ and cyclicity of the trace), K-linear independence and $\mathcal O_K$-spans, so $b_i' = \bar\gamma'^{\mathsf T} b_i \gamma$ is an orthonormal p-basis of $Y(M,M')$ whenever b is one of $Y(\gamma M,\gamma' M')$. (ii) For G entire, $U_t(G\circ\pi) = (U_{\pi t}G)\circ\pi$, by H-invariance. (iii) If G has algebraic Taylor coefficients, those of $G\circ\pi$ are integral polynomials in them and in the algebraic entries of $\tau(\gamma),\tau(\gamma')$, and since λ is a ring homomorphism on $\overline{\mathbb Q}$, $\widehat{(G\circ\pi)}_\lambda(Z_b) = \widehat G_\lambda(Z_{b'})$. Hence: *if $\widehat G_\lambda$ is good for (M,M') and G has algebraic Taylor coefficients, then $\widehat{(G\circ\pi)}_\lambda$ is good for $(\gamma M,\gamma' M')$.*

Step 4 (pairs p-locally equal to the standard pair). Let (M,M') be admitted and p-locally equal to $(\mathcal O_E^N,\mathcal O_E^{N'})$, and t' prime-to-p torsion for $\Theta(M,M')$. A translated kernel at a p-locally standard pair is a p-integral combination of standard translates: $U_{t'}e_\chi(M,M') = \sum_k c_k U_{s_k}\theta_0^{\otimes}$ with c_k algebraic, $|\lambda(c_k)| \le 1$, s_k prime-to-p torsion for the standard theta lattice. Each $U_{s_k}\theta_0^{\otimes}$ has algebraic Taylor coefficients, as every torsion translate of $\theta_0^{\otimes}$ does, so $\big(U_{t'}e_\chi(M,M')\big)^\wedge_\lambda = \sum_k \lambda(c_k)(U_{s_k}\theta_0^{\otimes})^\wedge_\lambda$. Since N,N' are even, the integrality of torsion translates of $\theta_0^{\otimes}$ in formal-group coordinates makes each summand good for the standard pair, Step 2 good for (M,M'), and Step 1 the sum good for (M,M').

Step 5 (assembly). Let (L,L') be admitted and $F = \sum_k r_k (U_{t_k}e_\chi(L_k,L_k'))^\wedge_\lambda$ as in Definition A.21. By Step 1 it suffices that each summand is good for (L,L'); by Step 2 it suffices that it is good for (L_k,L_k'), and t_k is prime-to-p torsion for $\Theta(L_k,L_k')$. So let (L,L') be admitted and t prime-to-p torsion for $\Theta(L,L')$. Every admitted pair is a unitary translate of a p-locally standard one at an inert prime: $L = \gamma M$, $L' = \gamma' M'$ with γ,γ' as in Step 3 and (M,M') admitted and p-locally standard. By Proposition A.27, $e_\chi(L,L') = e_\chi(M,M')\circ\pi$, so by Step 3(ii) $U_t e_\chi(L,L') = \big(U_{\pi t}e_\chi(M,M')\big)\circ\pi$, where πt is prime-to-p torsion for $\Theta(M,M')$ (Step 3(i)). The function $G = U_{\pi t}e_\chi(M,M')$ has algebraic Taylor coefficients (as do all torsion translates of the kernels) and $\widehat G_\lambda$ is good for (M,M') (Step 4); by Step 3(iii), $\big(U_t e_\chi(L,L')\big)^\wedge_\lambda$ is good for (L,L'). □

Lemma A.29. *Let t be a tied kernel entry of an object of an assembled datum D, $p \ge 5$ a prime of class zero or of signal class, and $\lambda\colon \overline{\mathbb Q} \to \mathbb C_p$ a field embedding. Then e_t satisfies the stable host condition at (p,λ).*

Proof. Outline. The class of p forces $\left(\frac{-d}{p}\right) = -1$, so Proposition A.28 makes e_t integral in formal-group coordinates at (p,λ); a good model with its formal logarithm, a Lubin–Tate law and a Frobenius lift give unitarily stable curve data at p; and applying the integrality to every integral combination of e_t and an orthonormal p-basis, then translating it into host-log integrality, gives the stable host condition. □

Lemma A.30. *Let F be the coefficient number field of a unitary moduli system in the setting of the integral-frame lemma for Hecke neighbours, with its fixed complex embedding. Let λ be a finite place of F, and let $\mathcal S_F$ be a space of algebraic sections with natural framed evaluations.*

Its theta-generator degree is the same even integer $n \geq 2$ as in the Hecke reading dictionary. A model frame at a point x consists of a semiabelian $\mathcal{O}_E$-model over a complete characteristic-zero discrete valuation ring O with finite residue field, coefficient embedding $F \hookrightarrow \mathrm{Frac}(O)$ inducing λ, a primitive theta generator nonzero at a special-fibre point, and separate integral bases of the generic eigenspace intersections in its Lie module. Evaluation in such a frame is in $\mathrm{Frac}(O)$.

Write $\mathcal{B}_\lambda \subseteq \mathcal{S}_F$ for the sections whose evaluation belongs to O in every such model frame, allowing every finite extension of the complete coefficient field. Fix a split prime $\mathfrak{P} \neq \bar{\mathfrak{P}}$ over an odd rational prime p different from the residue characteristic of λ, put $Q = N\mathfrak{P}$, and fix a type k and the prescribed Hecke representatives.

Assume the moduli datum and good level are those of the PEL Hecke quotient construction, and $p \nmid N$. The prescribed finite kernels at every model frame satisfy the explicit ideal bounds, isotropy and cardinality conditions of that construction. Take their quotient points, maps, primitive cubical comparisons and transported half levels from that construction, retaining the prescribed transversals. Their marked frames and complex readings satisfy the Hecke reading dictionary. Use on the quotient the canonical forward-trace theta generator constructed from the source model generator. Its quotient tangent frames are the prescribed $p^{-1}df$ of the source frames. An F-linear geometric operator $H : \mathcal{S}_F \to \mathcal{S}_F$ is defined by the finite trace in those frames:

$$\mathrm{ev}_x(Hs) = Q^{-kn} \sum_C \mathrm{ev}_{z_C}(s).$$

Then $H\mathcal{B}_\lambda \subseteq \mathcal{B}_\lambda$. On the same complex row readings its operator is

$$\Phi_{Hs}(h) = \mu_0(\mathfrak{P})^{-k} Q^{-kn/2} \sum_{a \in R_c} \Phi_s(ha).$$

In particular this normalised row operator preserves the image of $\mathcal{B}_\lambda$ under the prescribed reading map.

Proof. Outline. For $s \in \mathcal{B}_\lambda$ and a model frame, the PEL Hecke quotient construction and the forward theta trace identify each quotient frame in the trace with a model frame of the kind defining $\mathcal{B}_\lambda$ over a finite extension, so every $\mathrm{ev}_{z_C}(s)$ is integral there; since Q^{-kn} is a p-power unit, $\mathrm{ev}_x(Hs)$ is integral and lies in $\mathrm{Frac}(O)$, hence in O, and the Hecke reading dictionary with geometric scalar $Q^{-kn/2}$ gives the stated complex operator. □

Sketch: from integral kernels to served entries and gains. The loss data of (Rr1) need, at each inert prime, a lower bound for the valuation of certain kernel columns, the gain of Definition 5.3. The construction is expected to obtain it as follows. The kernel entries of a selected bundle are written in standard normalising series, after a hyperbolic substitution, and the host condition of Lemma A.29 turns integrality in Lubin–Tate coordinates into integral expansions along the Frobenius orbits of the inert primes. The minors of these expansions then have valuations bounded below by orbit sums, and these lower bounds are the gains that the linking inequality uses. The entries with these properties, together with structural, archimedean and jet conditions, are called served kernel entries, and a served selection is a selection whose kernel entries are served. Heuristically the mechanism is Alpöge's divisibility: the gain $\gamma_p = p/(p^2-1) = \sum_{e \text{ odd}} p^{-e}$ underlying Definition 5.3 has the shape of his exponent $a/p + a/p^3 + \cdots$. The delicate step is the comparison of the expansion of the host logarithm with the orbit expansion through one common normalising series: it must show that normalising the series costs no valuation at the inert primes.

A.4 The chain of theta lifts: Bessel periods, Rallis towers, the see-saw and multiplicity

This section constructs the chain of lifts. Along a row of a grid of hermitian spaces over a CM extension E/F, definite and indefinite unitary groups are linked by theta lifts: consecutive discrete series models along the row stand in the theta-pair relation (Definition A.31, Proposition A.32), and the row theta lifts of multiplicity maps converge and factor through a multiplicity map at the end of the row (Proposition A.33). Three properties of the chain are proved, and Alpöge names their ingredients: the see-saw, Bessel periods and Rallis [4]. First, the theta–Bessel functionals of a row separate the trivial eigenspace (Proposition A.38). Second, a linear relation among top tails gives the same relation among bottom periods, by see-saw transport (Proposition A.42). Third, rational period pairings equal spectral inner products up to unit phases (Proposition A.47). In all three, nonvanishing is propagated rather than computed: separation reduces to the nonvanishing of one archimedean Bessel form (Proposition A.35), the ascent carries a nonzero restriction period up to the top (Proposition A.37), and the see-saw carries relations down. The phases of the multiplicity identity have valuation 0 at every finite place, so the comparison loses nothing at any prime. All surjectivity of theta maps passes through one theorem, Theorem A.40, whose inductive step is Rallis' step, under an assumption of the shape of the Rallis inner product formula (Proposition A.41).

A.4.1 Theta pairs along a row

Definition A.31 fixes theta pairs of signed parameters and the theta-pair relation, in both directions and on both branches. Along a row of a grid, regular signed parameters give discrete series models whose neighbours satisfy this relation, with the attached characters (Proposition A.32). The row theta lift composes the lifts along the row, and Proposition A.33 shows that it converges and lands in a multiplicity map at the end of the row. This row of lifts is the chain of Alpöge's account, in our reading; its length is the number of lifts.

Definition A.31. (Xp1) Admissible quadruples. Let $t \geq 1$ be an integer and $b_t = (\frac{t-1}{2} - i)_{0 \leq i < t}$ (the centred block of length t). A quadruple $(\alpha, \beta, \gamma, \delta)$ of finite lists of rational numbers with $L = |\alpha| + |\beta| + |\gamma| + |\delta| \geq 1$ is **admissible for** t if, with $N = L + t$, $p = |\alpha| + |\beta|$ and $q = |\gamma| + |\delta|$:

(a) each of $\alpha, \beta, \gamma, \delta$ is strictly decreasing, and the L entries of $\alpha\beta\gamma\delta$ are pairwise distinct;

(b) the entries of α and γ are positive and those of β and δ are negative;

(c) every entry e of $\alpha\beta\gamma\delta$ lies in $\frac{t+1}{2} + \mathbb{Z}$ and satisfies $|e| \geq \frac{t+1}{2}$;

(d) $|x - y| > N^3$ and $|x - y| \geq 120\, L \min(p, q)^{3/2}$ for every entry x of $\alpha\beta$ and every entry y of $\gamma\delta$.

An admissible quadruple is **of type** $+$ if moreover $|x - y| > N^3$ for every entry x of $\alpha b_t \delta$ and every entry y of $\gamma\beta$; it is **of type** $-$ if moreover $|x - y| > N^3$ for every entry x of $\alpha\delta$ and every entry y of $\gamma b_t \beta$.

(Xp2) Negated signed sets; sign flip. For finite lists ℓ, ℓ' of rational numbers and $c \in \mathbb{Q}$ put

$$[\ell \,|\, \ell']_c = \{(-x - c, +) : x \text{ an entry of } \ell\} \cup \{(-x - c, -) : x \text{ an entry of } \ell'\}.$$

The **sign flip** of a signed parameter S is $S^{\mathrm{fl}} = \{(x, -\epsilon) : (x, \epsilon) \in S\}$.

(Xp3) Theta pairs. Let $t \geq 1$ be an integer, S, S' signed parameters and $c, c' \in \mathbb{Q}$. The pair (S, S') is a **theta pair of step t with exponents** (c, c') if there is a quadruple $(\alpha, \beta, \gamma, \delta)$ (a **witness**) with

$$S = [\alpha\beta \,|\, \gamma\delta]_c$$

and one of:

(+) $(\alpha, \beta, \gamma, \delta)$ is admissible for t of type $+$, and $S' = [\alpha b_t \delta \,|\, \gamma\beta]_{c'}$;

(−) $(\alpha, \beta, \gamma, \delta)$ is admissible for t of type $-$, and $S' = [\alpha\delta \,|\, \gamma b_t \beta]_{c'}$.

(Xp4) The theta-pair relation. Let S, S' be signed parameters and $a_S, a_T \in \mathbb{Q}$. The pair (S, S') satisfies the **theta-pair relation with exponents** (a_S, a_T) if there is an integer $t \geq 1$ such that one of:

(f) (forward) (S, S') is a theta pair of step t with exponents (a_T, a_S), and $|x + a_T| \geq \frac{t+3}{2}$ for every $(x, \epsilon) \in S$;

(b) (backward) (S', S) is a theta pair of step t with exponents (a_S, a_T).

Proposition A.32. *For every real ε and every $C_F \geq 6510$ there is x_0 such that the following holds. Let D be an assembled datum over a context with scale $\mathfrak{s} = (x, \varepsilon, J)$, $x \geq x_0$, with a size datum at $\mathfrak{s}$ satisfying the size-row conditions; let R be real data of D with the level choice (Wr6) at the base tuple, $\mathcal{J}$ a grid for R with grid constants $(1, C_F, b(\mathfrak{s}))$, and $\mathcal{W}$ a Weil datum of $\mathcal{J}$ lying over R, with family θ. Put $M_0 = M_{Y_0}$. Then there are discrete series models M_i of $V_{\mathrm{grid}(i,0)}$ for θ, $1 \leq i \leq m$, such that*

(a) $\sigma_{M_i}(\tau) = \sigma_{\mathrm{grid}(i,0)}(\tau)$ for $0 \leq i \leq m$ and $\tau \in \Phi$;

(b) for $0 \leq i < m$ and $\tau \in \Phi$ there are $a_S, a_T \in \mathbb{Q}$, infinity exponents at τ of the attached characters $\chi_S(p)$ and $\chi_T(p)$ of the pair $p = \mathrm{chi}(i, 0)$, such that the pair $(\Pi_\tau(M_{i+1})^{\mathrm{fl}}, \Pi_\tau(M_i))$ satisfies the theta-pair relation with exponents (a_S, a_T).

Proof. All auxiliary parameters below are local. Put $s = r + 6$, $n_i = r + is$, $q = m/2$ and $N_* = N_{\mathrm{gr}}$. The rank conditions give r odd, s odd, $r \geq 2m + 2$ and $q \leq n_i/4$. From (Jk3) and (R3), $k \geq f \geq m^4$ and $m \geq 44$, so in particular $r > 1800$. Only these numerical consequences and (Jk1) will be needed; the argument is uniform in the scale, so one may take $x_0 = 1$.

Fix τ and abbreviate the gap $g(D, 1)$ by g, the centres $\mathrm{cen}_D(1, \tau, j)$ by c_j, and the entries $v_{\tau,a}, b_{\tau,l}$ by v_a, b_l. Set $\epsilon_l = +$ for odd l and $\epsilon_l = -$ for even l. Define the following local signed sets:

$$P_i = \{(v_a, +) : 1 \leq a \leq k - 1\} \cup \{(-b_l, \epsilon_l) : 1 \leq l \leq m\} \cup \bigcup_{j=m-i+1}^{m} \{(z, +) : z \in \mathrm{bl}(c_j, s)\},$$

where the last union is empty for $i = 0$, let

$$d_i = \begin{cases} -\frac{1}{2} & i \text{ odd}, \\ 0 & i \text{ even}, \end{cases}$$

and put

$$S_i = \{(-z - d_i, \epsilon) : (z, \epsilon) \in P_i\}. \tag{1}$$

The first two parts of P_0 are exactly $\mathrm{SP}_0(\tau)$; thus $S_0 = \Pi_\tau(M_0)$ by (Xl2b)(c).

We check both regularity and the inequalities used below. By (Pa1) all cloud entries v_a are distinct and lie strictly above every $-b_l$. By (Jk1),

$$b_{l+1} - b_l \geq t + 2N_*^3 + 1 \geq s + 2N_*^3 > 2N_*^3, \tag{2}$$

because $t \geq k+m+4 = r+5 = s-1$. The centres are integers and $c_j - c_{j+1} = g$. Their defining floor gives $c_m \geq v_1 + \frac{3}{2}g - \frac{1}{2}$. Each block has length s and radius $(s-1)/2$, and

$$g \geq 2N_*^3 + 2s + 3. \tag{3}$$

Consequently the blocks are disjoint from each other and lie strictly above the cloud. All entries of P_i are therefore distinct integers. Its cardinality is n_i, and its negative signs are precisely those of the $m/2$ even-indexed lower entries.

Entries of opposite sign in P_i differ by more than $2N_*^3$. For two lower entries this is (2). A negative lower entry is $-b_l$ with even $l \geq 2$, whereas every cloud entry is greater than $-b_1$, giving a difference greater than $b_l - b_1 \geq b_2 - b_1$. The positive added blocks lie still higher. These cases exhaust the opposite-sign pairs.

Since s and r are odd, n_i is odd for even i and even for odd i. Thus (1) lies in the Harish-Chandra lattice $(n_i - 1)/2 + \mathbb{Z}$. Enumerate its entries in strictly decreasing order and give each entry its indicated sign. The resulting parameter is regular, has q negative signs and $n_i - q$ positive signs, exactly the signature of $V_{\mathrm{grid}(i,0)}$ in (Jg5),(Jg6). These two signature numbers are positive. By Harish-Chandra's existence theorem for the discrete series of $\mathrm{U}(p,q)$ with a given parameter, it has a discrete series representation.

For each $i \geq 1$ and each τ, use the frame $B_{\mathrm{grid}(i,0)}(\tau)$ from (Jw2)(a). Its sign multiplicities are the signature just computed. Reorder its columns so that their signs match the signed decreasing enumeration of S_i; call the resulting frame B_i'. Then

$$(B_i')^* J_\tau(V_{\mathrm{grid}(i,0)}) B_i' = J_{\epsilon_i}, \qquad \sigma_{\mathrm{grid}(i,0)} B_i' = B_i' J_{\epsilon_i}.$$

Transport the discrete series just obtained by $P_i^{\mathrm{mod}} = (B_i')^{-1}$ to the original hermitian space. Its model involution is

$$(P_i^{\mathrm{mod}})^{-1} J_{\epsilon_i} P_i^{\mathrm{mod}} = \sigma_{\mathrm{grid}(i,0)}.$$

Make these finitely many choices at all archimedean places and use the given family θ to form the models M_i. The equality in (a) at $i = 0$ is (Jw5), and at $i \geq 1$ is the displayed identity.

We now construct the theta-pair witness for every adjacent pair. Fix $i < m$, put $c = c_{m-i}$, $L = n_i$ and $N = L + s$. Then $N \leq N_*$. Every entry z of P_i satisfies

$$c - z \geq g - \tfrac{s-1}{2}. \tag{4}$$

For $i = 0$ this follows from $z \leq v_1$ and the bound on c_m; for $i > 0$, the largest possible entry is $c_{m-i+1} + (s-1)/2$ and the next centre is g higher. Let β be the decreasing list of $z - c$ for positive-sign entries of P_i, and δ the decreasing list of $z - c$ for negative-sign entries; put $\alpha = \gamma = \varnothing$. All these entries are negative integers. Equations (3),(4) give $|z - c| \geq (s+1)/2$, so they lie in $(s+1)/2 + \mathbb{Z}$ and meet the sign and absolute-value conditions of (Xp1).

Opposite-sign differences are greater than $2N_*^3 > N^3$. They also satisfy the second inequality of (Xp1)(d): since $q \leq L/4$ and $N > 1800$,

$$120L \min(L-q, q)^{3/2} = 120Lq^{3/2} \leq 15L^{5/2} \leq 15N^{5/2} < 2N^3 \leq 2N_*^3. \tag{5}$$

For the type $-$ condition, the only additional comparisons are between δ and the centred block b_s. By (4) their distances are at least $g - (s-1) > N_*^3 \geq N^3$. Hence $(\varnothing, \beta, \varnothing, \delta)$ is admissible for s of type $-$.

The attached-character exponents have the required exact values. By (Wr6)(a), $\eta = \eta^C$. The law (Fe4), continuity and density of the diagonal $E^\times$ in the archimedean units give infinity exponent $1/2$ for η at every τ, with the prescribed family θ. By (Jg4), χ_{m-i} has exponent c. The dimensions n_{i+1} and n_i have opposite parity, so the attached characters of $p = \mathrm{chi}(i,0)$ have exponents

$$a_S = c + d_i, \qquad a_T = c + d_{i+1}. \tag{6}$$

Indeed the odd-dimensional space contributes exactly the factor η^{-1}. These are half-integers, as required for infinity exponents.

Finally (1) and the definitions of the two lists give

$$S_i = [\,\beta \,|\, \delta\,]_{a_S}, \qquad S_{i+1}^{\mathrm{fl}} = [\,\delta \,|\, b_s\beta\,]_{a_T}. \tag{7}$$

For the old entries this follows by cancelling the centre c in (6); all old signs are reversed in the second expression. For the newly added block it follows from $\mathrm{bl}(c,s) = c + b_s$ and the invariance of b_s under negation. Thus (7) is branch $-$ of the theta-pair definition for $(S_i, S_{i+1}^{\mathrm{fl}})$ with exponents (a_S, a_T). The backward alternative of (Xp4) says exactly that $(S_{i+1}^{\mathrm{fl}}, S_i)$ satisfies the theta-pair relation with these exponents. This proves (b) for every i, τ, using the same models that establish (a). □

Proposition A.33. *Let D be an assembled master datum, R real data of D, $\mathcal{J}$ a grid for R, $\mathcal{W}$ a Weil datum of $\mathcal{J}$ with family θ, and $\mathcal{M}$ a row-normalised volume datum of $\mathcal{J}$. Let $M_0, \dots, M_m$ be discrete series models of $V_{\mathrm{grid}(0,0)}, \dots, V_{\mathrm{grid}(m,0)}$ for θ such that $\sigma_{M_i}(\tau) = \sigma_{\mathrm{grid}(i,0)}(\tau)$ for $0 \le i \le m$ and $\tau \in \Phi$, and such that for $0 \le i < m$ and $\tau \in \Phi$ there are infinity exponents a_S, a_T at τ of $\chi_S(\mathrm{chi}(i,0))$ and $\chi_T(\mathrm{chi}(i,0))$ for which $\big(\Pi_\tau(M_{i+1})^{\mathrm{fl}}, \Pi_\tau(M_i)\big)$ satisfies the theta-pair relation with exponents (a_S, a_T).*

Then there are, for every $0 \le n \le m$ and every $w \in M_0^\infty$, maps $\rho \mapsto \mathbf{v}_w^n(\rho)$ from the real vectors of $\mathcal{J}$ to M_n^∞ such that for every $T \in \mathrm{Mult}(M_0, \varnothing, 1)$, every coset datum Φ and every $0 \le n \le m$ there is $F_n \in \mathrm{Mult}(M_n, \varnothing, 1)$ with the following property: for every real vector ρ and every $w \in M_0^\infty$ the iterated lift defining the row part $\Theta_{\rho,\Phi}^{(n)}(T(w))$ converges and

$$\Theta_{\rho,\Phi}^{(n)}\big(T(w)\big) = F_n\big(\mathbf{v}_w^n(\rho)\big).$$

In particular ($n = m$) the row theta lift $\Theta_{\rho,\Phi}(T(w)) = \Theta_{\rho,\Phi}^{(m)}(T(w))$ converges and equals $F_m(\mathbf{v}_w^m(\rho))$.

Proof. Outline. The proof is an induction on n, starting from $\mathbf{v}_w^0(\rho) = w$ and $F_0 = T$: at the step from n to $n+1$ the pair $\mathrm{chi}(n,0)$, the models M_n and M_{n+1} (whose signed parameters satisfy the theta-pair relation by hypothesis), the frames of the Weil datum and its coset vectors, which are vacua, satisfy the hypotheses of the one-step lifting proposition for theta pairs, and that proposition supplies $\mathbf{v}_w^{n+1}(\rho)$ and F_{n+1} together with the integrability that gives the convergence and the value of the lift along $\mathrm{right}(n,0)$. □

A.4.2 Bessel periods and separation

Definition A.34 defines theta lifts along paths of the grid, the top Bessel pairing and the theta–Bessel functionals. Proposition A.35 factors these functionals through one archimedean Bessel form, which reduces separation to the nonvanishing of that form, and allows the quantifiers to be exchanged. The nonvanishing is supplied from below: restriction periods of row forms against K-finite core forms do not all vanish (Proposition A.36), and a nonzero restriction

period gives a nonzero top Bessel pairing (Proposition A.37). Together these give separation (Proposition A.38).

Definition A.34. Let $\mathcal{J}$ be a grid for R, $\mathcal{W}$ a Weil datum of $\mathcal{J}$ and $\mathcal{M}$ a volume datum of $\mathcal{J}$. Functions on G_{V_X} are called functions at the node X.

(Jf1) Theta lift along an arrow. Let $a\colon X \to Y$ be an arrow with pair p, f a Schwartz function of a and F a function at X. The **theta lift** $\mathcal{L}_a(f)F$ is the function at Y given by the downward and upward theta lifts (Zw13) of a see-saw tower for the Weil action ω_p on (S_p, T_p), formed with the measure ν_X and the set $\mathcal{F}_X$:

$$\mathcal{L}_a(f)F = \begin{cases} \Lambda^{\downarrow}_{\omega_p}(F; f) & a = \mathrm{right}(i,j) \text{ or } \mathrm{down}(t,i,j) \ (X \text{ the node of } T_p), \\ \Lambda^{\uparrow}_{\omega_p}(F; f) & a = \mathrm{coreDown}(i) \text{ or } \mathrm{col}(t,j) \ (X \text{ the node of } S_p), \\ \overline{\Lambda^{\downarrow}_{\omega_p}(\overline{F}; f)} & a = \mathrm{coreUp}(i), \end{cases}$$

and the lift **converges** at (f, F) if the lift of (Zw13) on the right converges (at $(\overline{F}, f)$ for $\mathrm{coreUp}(i)$).

(Jf2) Paths and iterated lifts. A **path** from X to Y is a finite sequence of arrows $a_1\colon X = X_0 \to X_1, \dots, a_n\colon X_{n-1} \to X_n = Y$; a **pure datum** on it is a family $(f_1, \dots, f_n)$ of Schwartz functions of $a_1, \dots, a_n$. The **iterated lift** of F along a path with pure datum is $\mathcal{L}_{a_n}(f_n) \cdots \mathcal{L}_{a_1}(f_1)F$; it **converges** if each lift $\mathcal{L}_{a_l}(f_l)$ converges at its argument $\mathcal{L}_{a_{l-1}}(f_{l-1}) \cdots \mathcal{L}_{a_1}(f_1)F$. A **total datum** is a finitely supported complex function c on the pure data of the path; its lift is $\sum_d c(d) \cdot$(iterated lift with d) and converges if each lift with d in the support converges. The **row path** is $\mathrm{right}(0,0), \dots, \mathrm{right}(m-1,0)$ from $\mathrm{grid}(0,0)$ to $\mathrm{grid}(m,0)$; the **down path** at (t,i) of length n is $\mathrm{down}(t,i,n-1), \dots, \mathrm{down}(t,i,0)$ from $\mathrm{grid}(i,n)$ to $\mathrm{grid}(i,0)$.

(Jf3) Row theta lift. For a real vector ρ, a coset datum Φ and a function u at $\mathrm{grid}(0,0)$ (that is, on $\mathrm{U}(Y_0)(\mathbb{A}_F)$), the **row theta lift** $\Theta_{\rho,\Phi}(u)$ is the iterated lift of u along the row path with the pure datum $(d_0(\rho,\Phi), \dots, d_{m-1}(\rho,\Phi))$, a function at $\mathrm{grid}(m,0)$; the row theta lift **converges** if this iterated lift converges.

(Jf4) Top Bessel pairing. The **top embedding** $s\colon G_{V_+} \to G_{V_{\mathrm{grid}(m,0)}}$ sends h to the element acting as $\iota_{\mathrm{top}} h \iota_{\mathrm{top}}^{-1}$ on $\iota_{\mathrm{top}}(V_+) \otimes \mathbb{A}$ and as the identity on its orthogonal complement (the element related to h, (Bd4)). For a function φ at $\mathrm{top}(0)$ and a function F at $\mathrm{grid}(m,0)$ the **top Bessel pairing** is the Bessel period

$$\mathcal{B}(\varphi, F) = \mathcal{P}_{d_{\mathrm{top}}}(\varphi, F) = \int_{\mathcal{F}_{\mathrm{top}(0)}} \int_{\mathcal{F}_N} \varphi(h)\, F(n\, s(h))\, \overline{\psi_{d_{\mathrm{top}}}(n)}\, d\nu_N(n)\, d\nu_{\mathrm{top}(0)}(h)$$

of (Bd3) with $(\mu, \mathcal{F}) = (\nu_{\mathrm{top}(0)}, \mathcal{F}_{\mathrm{top}(0)})$, the pair $(\nu_N, \mathcal{F}_N)$, the map s and the character ψ of $\mathcal{W}$; it **converges** at (φ, F) if $n \mapsto \varphi(h) F(n\, s(h)) \overline{\psi_{d_{\mathrm{top}}}(n)}$ is ν_N-integrable on $\mathcal{F}_N$ for every h, and the resulting inner integral is $\nu_{\mathrm{top}(0)}$-integrable on $\mathcal{F}_{\mathrm{top}(0)}$. (This is weaker than the convergence of (Bd3).)

(Jf5) Theta-Bessel functionals. For a real vector ρ, $\xi \in W_+^*$, a column form Ψ, a coset datum Φ and a function u at $\mathrm{grid}(0,0)$, the **theta-Bessel functional** is

$$\ell_{\rho,\xi,\Psi,\Phi}(u) = \mathcal{B}(\varphi_{\xi,\Psi}, \Theta_{\rho,\Phi}(u)),$$

and it **converges** at u if the row theta lift $\Theta_{\rho,\Phi}(u)$ converges and $\mathcal{B}$ converges at $(\varphi_{\xi,\Psi}, \Theta_{\rho,\Phi}(u))$.

(Jf6) Row forms and separating vectors. Let $\mathcal{H}^\infty = \bigotimes_{\tau\in\Phi} \mathcal{H}_\tau^\infty$ (algebraic tensor product) for the model M_{Y_0}, and $E_{\mathrm{triv}} = \mathrm{M}_R^{\mathrm{good}}(P_1)$, the space of realised forms of R at the trivial level. For $w \in \mathcal{H}^\infty$ and a multiplicity map T (multilinear on $\prod_\tau \mathcal{H}_\tau^\infty$) the **row form** $T(w)$ is the function at $\mathrm{grid}(0,0)$ given by the linear extension of T to $\mathcal{H}^\infty$. A pair (ρ,ξ) of a real vector and $\xi \in W_+^*$ **separates** w (for $\mathcal{J},\mathcal{W},\mathcal{M}$) if for every $T \in E_{\mathrm{triv}}$ with $T \neq 0$ there are a column form Ψ and a coset datum Φ such that $\ell_{\rho,\xi,\Psi,\Phi}$ converges at $T(w)$ and $\ell_{\rho,\xi,\Psi,\Phi}(T(w)) \neq 0$. It **separates** w **in span** if for every such T there are a column form Ψ and a finitely supported function c on the coset data such that $\ell_{\rho,\xi,\Psi,\Phi}$ converges at $T(w)$ for every Φ in the support of c and $\sum_\Phi c(\Phi)\,\ell_{\rho,\xi,\Psi,\Phi}(T(w)) \neq 0$.

Proposition A.35. *Let $\mathcal{J}$ be a grid for real data R, $\mathcal{W}$ a Weil datum of $\mathcal{J}$ with family θ, $\mathcal{M}$ a row-normalised volume datum of $\mathcal{J}$, and $w \in \mathcal{H}^\infty$. Assume:*

(Sw1) there are a discrete series model M_B of $V_{\mathrm{grid}(m,0)}$ for θ, with smooth vectors $\mathcal{H}_\tau^\infty(M_B)$, and a map $\rho \mapsto \mathbf{v}(\rho)$ from the real vectors of $\mathcal{J}$ to $\bigotimes_\tau \mathcal{H}_\tau^\infty(M_B)$ such that for every $T \in E_{\mathrm{triv}}$ and every coset datum Φ there is $F' \in \mathrm{Mult}(M_B,\varnothing,1)$ with $\Theta_{\rho,\Phi}(T(w)) = F'(\mathbf{v}(\rho))$ for every real vector ρ (F' extended linearly to the tensor product);

(Sw2) $\ell_{\rho,\xi,\Psi,\Phi}$ converges at $T(w)$ for all $T \in E_{\mathrm{triv}}$, real vectors ρ, $\xi \in W_+^*$, column forms Ψ and coset data Φ;

(Sw3) for every $T \in E_{\mathrm{triv}}$ with $T \neq 0$ there are ρ,ξ,Ψ,Φ with $\ell_{\rho,\xi,\Psi,\Phi}(T(w)) \neq 0$.

Then there are a real vector ρ_0 and $\xi_0 \in W_+^*$ such that (ρ_0,ξ_0) separates w for $(\mathcal{J},\mathcal{W},\mathcal{M})$. More precisely, under (Sw1) alone there is a function a of pairs (ρ,ξ) such that for all $T \in E_{\mathrm{triv}}$, column forms Ψ and coset data Φ there is $l \in \mathbb{C}$ with

$$\ell_{\rho,\xi,\Psi,\Phi}(T(w)) = a(\rho,\xi)\,l \qquad \text{for all real vectors } \rho \text{ and all } \xi \in W_+^*.$$

Proof. Sketch. The proposition is an exchange of quantifiers. Condition (Sw3) gives, for each nonzero $T \in E_{\mathrm{triv}}$, some pair (ρ,ξ) at which a theta–Bessel functional of $T(w)$ is nonzero; the conclusion asks for one pair (ρ_0,ξ_0) that works for every T at once. This follows from the factorisation $\ell_{\rho,\xi,\Psi,\Phi}(T(w)) = a(\rho,\xi)\,l$, in which a depends only on (ρ,ξ) and l only on (T,Ψ,Φ): one nonzero value for a fixed T_0 gives $a(\rho_0,\xi_0) \neq 0$, every nonzero T has $l \neq 0$ for suitable (Ψ,Φ), and the product is then nonzero.

The factorisation is the core of the proof. By (Sw1) the theta lift of $T(w)$ is a multiplicity map F' evaluated at a vector $\mathbf{v}(\rho)$ of one discrete series model, so the functional is the top Bessel pairing $\beta(\xi,v)$ of the scalar form $\varphi_{\xi,\Psi}$ with $F'(v)$. As a function of its components (ξ_τ,v_τ) at one real place τ, the others fixed, β is continuous, invariant under the definite unitary group $\mathrm{U}(V_+)(F_\tau)$ embedded as the stabiliser H_z, and transforms by the nondegenerate character ψ_d under the unipotent group N_d. These properties come from unimodularity, the compactness of $\Gamma_{V_+}\backslash G_{V_+}$ (V_+ being totally definite) and of $(N_d \cap \Gamma_B)\backslash N_d$, and the Banach–Steinhaus theorem; so β is a local archimedean Bessel form for an irreducible finite-dimensional representation of H_z and an irreducible unitary discrete series of $\mathrm{U}(B)(F_\tau)$ (Definition A.81). By the uniqueness of archimedean Bessel models [139] such forms span a space of dimension at most one at each place, so $\beta = l\,\Lambda$, where Λ is the bilinear form equal to $\prod_\tau b_\tau(\xi_\tau,v_\tau)$ on pure tensors for fixed local forms b_τ, and $a(\rho,\xi) = \Lambda(\xi,\mathbf{v}(\rho))$. Thus the dependence on the pair is purely archimedean, and separation reduces to the nonvanishing of one archimedean form; this is how Proposition A.38 uses the proposition. □

Proposition A.36. *For every real ε and every $C_F \geq 6510$ there is x_0 such that the following holds. Let D be an assembled master datum with size data of scale $x \geq x_0$ and parameter ε satisfying the size-row conditions; let R be real data of D with a level choice at the base tuple; let $\mathcal{J}$ be a grid for R with grid constants $(1, C_F, b)$, b the constant of the size data; let $\mathcal{W}$ be a Weil datum of $\mathcal{J}$ with infinite-type family θ and $\mathcal{M}$ a row-normalised volume datum of $\mathcal{J}$. Let M_0 be a discrete series model on Y_0 with the parameters of M_{Y_0}, and M_P a discrete series model on $V_{\mathrm{core}(0)}$ with the discrete-series parameter of $\mathrm{core}(0)$. Then for every nonzero row form T of level $g_1 g_2$ for (θ, M_0) and every nonzero $w \in \bigotimes_\tau \mathcal{H}_\tau^\infty(M_0)$ there are a core form $y \in \mathrm{CF}_\theta(\mathrm{core}(0), M_P)$ and $v \in \mathrm{KF}(M_P)$ with*

$$\mathrm{per}_0\big(y(v), T(w)\big) \neq 0.$$

Proof. Outline. A pack of controlled loss for the extension of Y_0 into $V_{\mathrm{core}(0)}$ and the depth estimate of the grid give a scale s; for a suitable vector w_0 the function $u = T(w_0)$ is bounded, nonzero and Lipschitz (by the loss clauses of the pack), so a short-vector estimate for cusp forms shows that u is large at an s-long point x, the identity term then dominates the pairing of u with a Poincaré series at x, this Poincaré series is the value of a core form, and a transfer lemma for K-finite vectors passes from w_0 to every nonzero w. □

Proposition A.37. *Let D be an assembled master datum whose type primes $p_{\mathrm{de}}, p'_{\mathrm{de}}$ are both prime to $Q_S q$ (the integers Q_S and q of the host of D), let R be real data of D with the level choice (Wr6) at the base tuple, $\mathcal{J}$ a grid for R (any grid constants), $\mathcal{W}$ a Weil datum of $\mathcal{J}$ and $\mathcal{M}$ a row-normalised volume datum of $\mathcal{J}$. Let v be a core volume, $\Psi = (\Psi_i)_{0 \leq i \leq m}$ a column chain for v, and u a row-rapid function at $\mathrm{grid}(0,0)$ with*

$$\mathrm{per}_0(\Psi_0, u) \neq 0.$$

Then there are a real vector ρ and a coset datum Φ of $\mathcal{J}$ with

$$\mathcal{B}\big(\Psi_m, \Theta_{\rho,\Phi}(u)\big) \neq 0.$$

Proof. By the existence theorem for good rung decomposition systems fitting the ends, whose hypotheses are those of the statement, there are a rung decomposition system $\mathfrak{r}$ of $\mathcal{J}$ that fits the ends for $(v, \mathcal{W}, \mathcal{M})$ and line lattices Γ^L such that $\mathfrak{r}$ is good for $(v, \mathcal{W}, \Gamma^L)$. Form the conditions NZB_k and $\mathrm{NZJ}_k(\Gamma^L)$ of (Ay7) for $(\mathcal{W}, \mathcal{M}, v, \mathfrak{r}, \Psi, u)$; the hypotheses of the rung proposition for good rung decomposition systems (with its three parts (a), (b), (c) used below) hold for these data.

NZB_k **holds for** $0 \leq k \leq r-1$**.** We argue by induction on k. For $k = 0$: since $\mathrm{per}_0(\Psi_0, u) \neq 0$, part (a) of the rung proposition gives $\mathrm{NZJ}_0(\Gamma^L)$, and part (b) with $k = 0$ (allowed, as $r \geq 1$) gives NZB_0. Let $0 \leq k \leq r-2$ and assume NZB_k. Part (c) gives $\mathrm{NZJ}_{k+1}(\Gamma^L)$, and part (b) with $k+1 \leq r-1$ gives NZB_{k+1}.

The top rung gives the top Bessel pairing. Take $k = r-1$, so $2k+2 = m$. By NZB_{r-1} there are a real vector ρ and a coset datum Φ with

$$\mathcal{P}^B_{r-1}\big(\overline{\Psi_m}, \overline{\Theta^{(m)}_{\rho,\Phi}(u)}\big) \neq 0.$$

The function Ψ_m at $\mathrm{core}(m) = \mathrm{top}(0)$ has rapid decay because Ψ is a column chain (Jc4), and $\Theta^{(m)}_{\rho,\Phi}(u)$ at $\mathrm{grid}(m,0)$ has rapid decay because u is row-rapid (Jc5). Since $\mathfrak{r}$ fits the ends, the

second clause of (Ay6) applied to $\varphi = \Psi_m$ and $F = \Theta^{(m)}_{\rho,\Phi}(u)$ gives $\mathcal{B}(\Psi_m, \Theta^{(m)}_{\rho,\Phi}(u)) \neq 0$. Finally the row part $\Theta^{(m)}_{\rho,\Phi}(u)$ is the iterated lift of u along $\mathrm{right}(0,0), \dots, \mathrm{right}(m-1,0)$ with the data $d_0(\rho,\Phi), \dots, d_{m-1}(\rho,\Phi)$ (Jc5), that is, along the row path with the row datum, which is the row theta lift $\Theta_{\rho,\Phi}(u)$ of (Jf3). Hence $\mathcal{B}(\Psi_m, \Theta_{\rho,\Phi}(u)) \neq 0$. □

Proposition A.38. *For every real ε and every $C_F \geq 6510$ there is x_0 such that the following holds. Let D be an assembled datum over a context with scale $\mathfrak{s} = (x, \varepsilon, J)$ with $x \geq x_0$, and suppose that D has a size datum at $\mathfrak{s}$ satisfying the size-row conditions. Let R be real data of D with the level choice (Wr6) at the base tuple, $\mathcal{J}$ a grid for R with grid constants $(1, C_F, b(\mathfrak{s}))$, $\mathcal{W}$ a Weil datum of $\mathcal{J}$ lying over R, and $\mathcal{M}$ a row-normalised volume datum of $\mathcal{J}$. Then for every nonzero $w \in \mathcal{H}^\infty$ there are a real vector ρ of $\mathcal{J}$ and $\xi \in W_+^*$ (W_+ for the family of $\mathcal{W}$) such that (ρ, ξ) separates w for $(\mathcal{J}, \mathcal{W}, \mathcal{M})$.*

Proof. **Choice of x_0.** Given ε and $C_F \geq 6510$, let x_1, x_2, x_3 be the thresholds for (ε, C_F) of Proposition A.36, of the row-service lemma for the row chain (whose clauses (Sv1)–(Sv5) are used below) and of the lemma that writes K-finite core forms as combinations of reachable functions, and $x_0 = \max(x_1, x_2, x_3)$. Fix data $D, R, \mathcal{J}, \mathcal{W}, \mathcal{M}$ as in the statement with $x \geq x_0$, let $\theta = \vartheta_\infty$ be the family of $\mathcal{W}$ ((Jw5)), and fix $w \in \mathcal{H}^\infty$, $w \neq 0$.

Step 1: the type primes are prime to $Q_S q$. By (Cx1), $p_\delta, p_{\delta'} \equiv 1 \pmod{N_\mathfrak{h}}$ with $N_\mathfrak{h} = Q_S q d$. A prime ℓ dividing both p_δ and $Q_S q$ would be p_δ itself and divide $N_\mathfrak{h}$, contradicting $p_\delta \equiv 1 \pmod{N_\mathfrak{h}}$. Likewise for $p_{\delta'}$. So the hypothesis on the type primes in Proposition A.37 holds.

Step 2: weak separation at w. Let $T \in E_{\mathrm{triv}}$, $T \neq 0$, and put $u = T(w)$. By (Sv2) of the row-service lemma, $w' \mapsto T(w')$ is a nonzero row form of level $g_1 g_2$ for (θ, M_{Y_0}). By (Sv1) there is a discrete series model M_P of $V_{\mathrm{core}(0)}$ with the core-zero parameter $\Pi_D^{\mathrm{core}}(1,\tau)$ at every τ and with the involutions and frames of $\mathcal{W}$ at core(0). Applying Proposition A.36 with $M_0 = M_{Y_0}$ and this M_P (its discrete-series parameter of core(0) is $\Pi_D^{\mathrm{core}}(1,\tau)$, the grid constants being $(1, C_F, b(\mathfrak{s}))$) gives $y \in \mathrm{CF}_\theta(\mathrm{core}(0), M_P)$ and $u' \in \mathrm{KF}(M_P)$ with

$$\mathrm{per}_0(y(u'), u) \neq 0.$$

A core volume v exists: every $\mathrm{U}(V_{\mathrm{core}(i)})(\mathbb{A}_F)$ is a second countable locally compact group in which the rational points form a discrete subgroup, so it carries a Haar measure and a measurable fundamental domain. By the lemma on K-finite core forms, $y(u') = \sum_{j=1}^{J} c_j F_j$ with $c_j \in \mathbb{C}$ and F_j reachable for v. Each F_j is the first member of a column chain, so it has rapid decay and is bounded (ht ≥ 1); by (Sv3), u is row-rapid, so u, its row part of length 0, has rapid decay and is bounded; and $\nu_{\mathrm{grid}(0,0)}(\mathcal{F}_{\mathrm{grid}(0,0)}) < \infty$, the Haar pair of the row-normalised datum being one of the unitary group $\mathrm{U}(Y_0)$, whose quotient by the rational points has finite volume (its centre is anisotropic). Hence every $h \mapsto F_j(s_0(h))u(h)$ is integrable on $\mathcal{F}_{\mathrm{grid}(0,0)}$, $\mathrm{per}_0(\cdot, u)$ is linear on these functions, and

$$0 \neq \mathrm{per}_0(y(u'), u) = \sum_j c_j \, \mathrm{per}_0(F_j, u),$$

so $\mathrm{per}_0(F_j, u) \neq 0$ for some j. By (Jc4) there are a column chain $\Psi = (\Psi_i)_{0 \leq i \leq m}$ for v with $\Psi_0 = F_j$, a column form Ψ^{c} and $\xi \in W_+^*$ with $\Psi_m = \varphi_{\xi,\Psi^{\mathrm{c}}}$. By Step 1 and Proposition A.37 (any grid constants), applied to v, Ψ and the row-rapid u, there are a real vector ρ and a coset datum Φ with

$$\ell_{\rho,\xi,\Psi^{\mathrm{c}},\Phi}(T(w)) = \mathcal{B}(\varphi_{\xi,\Psi^{\mathrm{c}}}, \Theta_{\rho,\Phi}(u)) \neq 0.$$

This is (Sw3) of Proposition A.35 for w.

Step 3: the remaining hypotheses of the exchange. (Sw2): every $T \in E_{\mathrm{triv}}$ gives a row form of level $g_1 g_2$ (Sv2), so (Sv4) gives the convergence of all $\ell_{\rho,\xi,\Psi,\Phi}$ at $T(w)$. (Sw1): a row form of level $g_1 g_2$ comes from a multiplicity map of M_{Y_0} of level $K_{\mathrm{grid}(0,0)}(g_1 g_2 \mathcal{O}_E)$ with trivial character, which satisfies the conditions of (Hh4) for the empty level set; so every $T \in E_{\mathrm{triv}}$ lies in $\mathrm{Mult}(M_{Y_0}, \varnothing, 1)$ through $T(w')$, and (Sv5) with $\mathbf{v} = \mathbf{v}_w$ gives (Sw1).

Step 4: conclusion. By Proposition A.35 (with $\mathcal{M}$ row-normalised) there is (ρ_0, ξ_0) separating w for $(\mathcal{J}, \mathcal{W}, \mathcal{M})$. □

A.4.3 Rallis towers and the see-saw

Surjectivity of the downward theta maps is organised in Rallis towers (Definition A.39): Hecke parameters at the stages, downward theta maps between them, Petersson structures with eigen-elements, an archimedean step relation, and a condition on the L-values along the chain. Every composite of downward theta maps of a well-formed tower with these two conditions is surjective (Theorem A.40). The inductive step is Rallis' step (Proposition A.41): the adjoint of a downward theta map sends an eigen-element with nonvanishing L-value to an eigen-element with the stepped parameter. The step assumes an identity $\mathrm{RIP}(D)$ of the shape of the Rallis inner product formula [203, 152], and this assumption is carried by Theorem A.40. In the other direction, see-saw transport carries linear relations from the top of the chain to its bottom (Proposition A.42).

Definition A.39. Let D be a master datum with CM extension E/F and CM type Φ.

(Xo1) Hecke parameters. Let S be a finite set of finite places of F and S_E the set of places of E above S. A **parameter family outside** S is a map B assigning to every finite place $w \notin S_E$ of E a finite multiset $B(w)$ of nonzero complex numbers; B is **bounded by** (n, κ) if $|B(w)| \le n$ and $|b| \le \mathrm{N}(w)^{\kappa}$ for every w and every $b \in B(w)$. Let V be a hermitian space with a self-dual lattice Λ and, for a finite place v of F, $K_v \subseteq \mathrm{U}(V)(F_v)$ the stabiliser of $\Lambda \otimes \mathcal{O}_{F_v}$. A function $\phi\colon G_V \to \mathbb{C}$ has **Hecke parameter** B **outside** S (for Λ) if for every finite place $v \notin S$ the function $\overline{\phi}$ is right K_v-invariant and is an eigenfunction of the spherical Hecke algebra $\mathcal{H}(\mathrm{U}(V)(F_v), K_v)$ acting by right convolution, whose eigencharacter has, at every place w of E above v, the Satake parameter $B(w)$ (normalised induction, read after base change to $\mathrm{GL}_{\dim V}(E_w)$). For a Hecke character χ of E unramified at w, $\chi(w)$ is its value at a uniformiser of E_w. For Hecke characters χ_S, χ_T unramified outside S_E and an integer $t \ge 1$ the **stepped parameter** is the parameter family

$$\mathrm{st}_{\chi_S,\chi_T,t}(B)(w) = \{\chi_S(w)\chi_T(w)^{-1} b :\ b \in B(w)\} + \{\chi_S(w)\,\mathrm{N}(w)^{\frac{t-1}{2}-i} :\ 0 \le i < t\} \quad \text{(A.1)}$$

(sum of multisets), and the **partial** L**-function** is $L^S(z, B \times \chi) = \prod_{w \notin S_E} \prod_{b \in B(w)} (1 - b\,\chi(w)\,\mathrm{N}(w)^{-z})^{-1}$ wherever the product converges absolutely.

(Xo2) Rallis tower data. A **Rallis tower datum T** over D consists of integers $n \ge 1$ (the **base rank**), $t \ge 1$ (the **step**), $m \ge 0$ (the **length**), a finite set S of finite places of F, an archimedean family θ, an additive character ψ of $\mathbb{A}_F$, Hecke characters $\chi_S(k), \chi_T(k)$ of E for $0 \le k < m$ (the **step characters**), and:

- for $0 \le j \le m$ a **stage** $s_j = (V_j, M_j, \Lambda_j, J_j, \kappa_j, \mu_j, \mathcal{F}_j)$: a hermitian space V_j of dimension $n + jt$, a discrete series model M_j of V_j, a self-dual lattice Λ_j of V_j, a subgroup $J_j \subseteq G_{V_j,f}$ (the **level**) with a map $\kappa_j\colon J_j \to \mathbb{C}^{\times}$ (the **level character**), and a Haar pair $(\mu_j, \mathcal{F}_j)$ of V_j; its **space of forms** is $\mathcal{C}_j = \mathrm{Mult}(M_j, J_j, \kappa_j)$;

- for $0 \le k < m$ a **step** $p_k = (\omega_k, f_k, \mathrm{It}_k, \mathrm{io}_k)$: a Weil action ω_k on (V_k, V_{k+1}), a function $f_k\colon \mathbb{W}^\circ(V_k, V_{k+1}) \to \mathbb{C}$, a linear map $\mathrm{It}_k\colon \mathcal{P}(V_k, V_{k+1}) \to \mathrm{Hom}_{\mathbb{C}}(M_{k+1}^\infty, M_k^\infty)$ (the **lifting operator**) and a linear map $\mathrm{io}_k\colon \mathcal{C}_{k+1} \to \mathcal{C}_k$ (the **downward theta map**).

For $P \in \mathcal{P}(V_k, V_{k+1})$ write $F_{k,P} = F_P(f_k)$ for the Fock vector of (Wo7) formed at every τ with the pair setup of the models: $B_S = f_{k,\tau}^{-1}$, $\sigma_S = f_{k,\tau}^{-1} J_{\varepsilon_{k,\tau}} f_{k,\tau}$ from M_k and B_T, σ_T likewise from M_{k+1}. The **composites** are $\Theta_0 = \mathrm{id}_{\mathcal{C}_0}$ and $\Theta_{k+1} = \Theta_k \circ \mathrm{io}_k\colon \mathcal{C}_{k+1} \to \mathcal{C}_0$.

(Xo3) Well-formed Rallis tower data. **T** is **well formed** if:

(a) ψ is standard of sign -1; $\chi_S(k)$ and $\chi_T(k)$ are unramified at every finite place of E outside S_E;

(b) (stages) for every j: the Witt index of V_j is less than t; there is an open subgroup $U \subseteq G_{V_j}$ with $U \cap G_{V_j,f} \subseteq J_j$ and $\kappa_j = 1$ on $U \cap G_{V_j,f}$; every element of J_j stabilises $\Lambda_j \otimes \mathcal{O}_{F_v}$ at every finite place v; every $g \in G_{V_j,f}$ with g_v in the stabiliser of $\Lambda_j \otimes \mathcal{O}_{F_v}$ for $v \notin S$ and $g_v = 1$ for $v \in S$ lies in J_j and has $\kappa_j(g) = 1$; κ_j is multiplicative and $|\kappa_j| = 1$;

(c) (Weil data) for every k, ω_k is an oriented Weil datum for $(\psi, V_k, V_{k+1}, \chi_S(k), \chi_T(k))$;

(d) (vacua) f_k is a nonzero oriented theta function with $a_{\tau,z} f_k = 0$ for every τ and z (annihilation operators formed with σ_S, σ_T as above), and f_k is a lattice vacuum for $\Lambda^\circ_{\{v\}}(\Lambda_k, \Lambda_{k+1})$ at every finite place $v \notin S$;

(e) (level law) $\omega_k(g,h) F_{k,P} = \kappa_k(g)\,\kappa_{k+1}(h)^{-1} F_{k,P}$ for all P, $g \in J_k$, $h \in J_{k+1}$;

(f) (coefficient support) for every covolume-one pair (ν, X) of $\mathbb{W}^\circ(V_k, V_{k+1})$, every P and every $g \in G_{V_k}$ such that g_v stabilises $\Lambda_k \otimes \mathcal{O}_{F_v}$ for all finite $v \notin S$ and $g \notin G_{V_k,\infty} J_k$, the **Weil coefficient** $\int_X (\omega_k(g,1)F_{k,P})(x)\,\overline{F_{k,P}(x)}\,d\nu(x)$ vanishes;

(g) (lifting operator) $\mathrm{It}_k \neq 0$, and for every τ: if g lies in the τ-component of $G_{V_k,\infty}$ and $F_{k,P'} = \omega_k(g,1)F_{k,P}$, then $\mathrm{It}_k(P') = \sigma_{k,\tau}(g) \circ \mathrm{It}_k(P)$ ($\sigma_{k,\tau}(g)$ acting on the τ-factor of M_k^∞ through θ_τ and $f_{k,\tau}$); if h lies in the τ-component of $G_{V_{k+1},\infty}$ and $F_{k,P'} = \omega_k(1,h)F_{k,P}$, then $\mathrm{It}_k(P') \circ \sigma_{k+1,\tau}(h) = \mathrm{It}_k(P)$; the same two rules hold infinitesimally (for X in the Lie algebras, with $F_{k,P'}$ the derivative of $r \mapsto \omega_k(\exp rX, 1)F_{k,P}$ at 0 and $\mathrm{It}_k(P') = X \circ \mathrm{It}_k(P)$, respectively of $r \mapsto \omega_k(1, \exp rX)F_{k,P}$ and $\mathrm{It}_k(P') + \mathrm{It}_k(P) \circ X = 0$); and for every P and every vector w of the algebraic tensor product of the $H_{k,\tau}$ there is $c \ge 0$ with $|\langle \mathrm{It}_k(P)(\otimes v), w\rangle| \le c \prod_\tau \|v_\tau\|$ for every vector v of M_{k+1};

(h) (downward theta map) for all $G \in \mathcal{C}_{k+1}$, P, $v \in M_{k+1}^\infty$ and $g \in G_{V_k}$, the function $h \mapsto (\omega_k(g,h)F_{k,P})(0)\,G(v)(h)$ is μ_{k+1}-integrable on $\mathcal{F}_{k+1}$, and

$$\Lambda^{\downarrow}_{\omega_k}\big(G(v); F_{k,P}\big)(g) = \mathrm{io}_k(G)\big(\mathrm{It}_k(P)v\big)(g) \tag{A.2}$$

with the Haar pair $(\mu_{k+1}, \mathcal{F}_{k+1})$ in (Zw13).

(Xo4) Petersson structures, eigen-elements, chain parameters. The **tensor inner product** on M_j^∞ is the hermitian inner product, linear in the first variable, with $\langle \otimes v, \otimes v'\rangle = \prod_\tau \langle v'_\tau, v_\tau\rangle_{H_{j,\tau}}$, the inner products of the $H_{j,\tau}$ being conjugate-linear in the first argument as in (Hh4). A **Petersson structure** on $\mathcal{C}_j$ is a positive definite hermitian form $\langle\cdot,\cdot\rangle_j$ on $\mathcal{C}_j$, linear in the first variable, such that for all $x, y \in \mathcal{C}_j$ and $v, v' \in M_j^\infty$ the function $x(v)\overline{y(v')}$ is μ_j-integrable on $\mathcal{F}_j$ and

$$\int_{\mathcal{F}_j} x(v)\,\overline{y(v')}\,d\mu_j = \langle x, y\rangle_j\,\langle v, v'\rangle. \tag{A.3}$$

An **eigen-element with parameter** B is a nonzero $u \in \mathcal{C}_j$ such that every nonzero value $u(v)$ ($v \in M_j^\infty$) has Hecke parameter B outside S for Λ_j. The **chain parameters** of a parameter family B outside S are $B_0 = B$ and $B_{k+1} = \mathrm{st}_{\chi_S(k),\chi_T(k),t}(B_k)$, the stepped parameter of (Xo1).

(Xo5) The archimedean step relation. The **signed parameter** of a discrete series model M at τ is $\Pi_\tau(M) = \{(\lambda_{\tau,i}, \varepsilon_{\tau,i})\}_i \subseteq \mathbb{R} \times \{+,-\}$ ($+$ for the entries 1 of J_ε). The step k of $\mathbf{T}$ satisfies the **archimedean step relation** if for every $\tau \in \Phi$, with a_S, a_T the infinity exponents of $\chi_S(k), \chi_T(k)$ at τ:

(a) the pair $(\Pi_\tau(M_k), \Pi_\tau(M_{k+1}))$ is a theta pair of step t with exponents (a_T, a_S) that has a witness satisfying branch $(+)$ of (Xp3) of Definition A.31; explicitly, there is a quadruple $(\alpha, \beta, \gamma, \delta)$ admissible for t of type $+$ ((Xp1) there) with

$$\Pi_\tau(M_k) = \{(-x - a_T, +) : x \in \alpha\beta\} \cup \{(-x - a_T, -) : x \in \gamma\delta\},$$
$$\Pi_\tau(M_{k+1}) = \{(-x - a_S, +) : x \in \alpha b_t \delta\} \cup \{(-x - a_S, -) : x \in \gamma\beta\},$$

$b_t = \left(\frac{t-1}{2} - i\right)_{0 \le i < t}$;

(b) (far from the exponent) $|x + a_T| \ge \frac{t+3}{2}$ for every $(x, \epsilon) \in \Pi_\tau(M_k)$, that is, $|e| \ge \frac{t+3}{2}$ for every entry e of $\alpha\beta\gamma\delta$.

$\mathbf{T}$ satisfies the archimedean step relation if every step does.

(Xo6) Right domains, continued values; the chain L-value condition. A **right domain** is an open set $U \subseteq \mathbb{C}$ that contains a half-plane $\{\mathrm{Re}\, z > \sigma\}$ and satisfies $z + r \in U$ for all $z \in U$ and all real $r \ge 0$. Let h be a complex function defined on a half-plane $\{\mathrm{Re}\, z > \sigma_0\}$. A complex number l is a **continued value** of h at $z_* \in \mathbb{C}$ if there are a right domain $U \ni z_*$ and a function $\tilde{h}$ meromorphic on U and holomorphic at z_*, with $\tilde{h}(z_*) = l$ and $\tilde{h} = h$ on some half-plane $\{\mathrm{Re}\, z > \sigma_1\}$. $\mathbf{T}$ satisfies the **chain L-value condition** if for every parameter family B outside S bounded by $(n, \frac{n-1}{2})$ and every $k < m$, the function $z \mapsto L^S(z + \frac{1}{2}, B_k \times \chi_T(k)^{-1})$ (chain parameters of B; partial L-function of (Xo1) for the character $\chi_T(k)^{-1}$, on a right half-plane where its product converges absolutely) has a nonzero continued value at $z = \frac{t}{2}$.

Theorem A.40. *Let D be an assembled datum with* RIP(D) *and let* $\mathbf{T}$ *be a well-formed Rallis tower datum over D, of length m, that satisfies the archimedean step relation and the chain L-value condition. Then for every $0 \le k \le m$ the composite $\Theta_k \colon \mathcal{C}_k \to \mathcal{C}_0$ is surjective.*

Proof. Outline. After Petersson structures are fixed on the finite-dimensional spaces $\mathcal{C}_j$, an induction on k using Rallis' step Proposition A.41 and the chain L-value condition attaches to every eigen-element $u \in \mathcal{C}_0$ with parameter B an eigen-element $x \in \mathcal{C}_k$ with parameter B_k such that $\langle y, x\rangle_k = \langle \Theta_k(y), u\rangle_0$ for all $y \in \mathcal{C}_k$; an element of $\mathcal{C}_0$ orthogonal to $\Theta_k(\mathcal{C}_k)$ is then split into eigen-elements with distinct parameters, these parameters stay distinct along the chain, and the linear independence of eigen-elements with distinct parameters forces the element to vanish. □

Proposition A.41. *Let D be an assembled datum with* RIP(D), $\mathbf{T}$ *a well-formed Rallis tower datum over D with step t and finite set S, and k smaller than its length, such that the step k satisfies the archimedean step relation. Let $\langle\cdot,\cdot\rangle_k$ and $\langle\cdot,\cdot\rangle_{k+1}$ be Petersson structures on $\mathcal{C}_k$ and $\mathcal{C}_{k+1}$, and let $u \in \mathcal{C}_k$ be an eigen-element with parameter B such that $z \mapsto L^S(z + \frac{1}{2}, B \times \chi_T(k)^{-1})$*

has a nonzero continued value at $z = \frac{t}{2}$ (right domains and continued values as in (Xo6)). Then there is an eigen-element $x \in \mathcal{C}_{k+1}$ with parameter $\mathrm{st}_{\chi_S(k),\chi_T(k),t}(B)$ such that

$$\langle y, x\rangle_{k+1} = \langle \mathrm{io}_k(y), u\rangle_k \qquad \text{for every } y \in \mathcal{C}_{k+1}.$$

Proof. Sketch. This is Rallis' step: an eigen-element u at stage k whose partial L-function $L^S(z+\frac{1}{2}, B \times \chi_T(k)^{-1})$ has a nonzero continued value at $z = \frac{t}{2}$ is seen by the downward theta map, through an eigen-element x at stage $k+1$ that represents the functional $y \mapsto \langle \mathrm{io}_k(y), u\rangle_k$ and has the stepped parameter $\mathrm{st}_{\chi_S(k),\chi_T(k),t}(B)$. The space $\mathcal{C}_{k+1}$ is finite-dimensional (automorphic forms of fixed archimedean type and level), so this functional has a Riesz representative x; it remains to show that x is nonzero and an eigen-element with the stepped parameter. The argument should run as in Rallis' method [204]. (i) Form the upward theta lift $\theta(u)$, the integral of u against the theta kernel of a Fock vector $F_{k,P}$. (ii) By the Rallis inner product property $\mathrm{RIP}(D)$, an assumption of the statement, applied to the complex conjugate of u, whose parameter is $\overline{B}$, the Petersson norm of $\theta(u)$ is the continued L-value of the statement times a semilocal doubling zeta integral [199] over the places of S and the archimedean places; the identity assumed as $\mathrm{RIP}(D)$ has the shape of the Rallis inner product formula [152, 132, 101]. (iii) Show that $\theta(u)$ lies in the span of the values of $\mathcal{C}_{k+1}$ at K-finite vectors and is adjoint to io_k through the lifting operator, so that x is a nonzero multiple of $\theta(u)$ once $\theta(u) \neq 0$. (iv) Show by the unramified theta correspondence that $\theta(u)$ has Hecke parameter $\mathrm{st}_{\chi_S(k),\chi_T(k),t}(B)$ outside S.

Heuristically, the L-value in (ii) is nonzero by assumption, and the semilocal integral should be nonzero: at the places of S the level law and the coefficient support (Xo3)(e),(f) of Definition A.39 reduce it to a volume, and at a real place the archimedean step relation (Xo5) places the two discrete series in the archimedean theta correspondence [162], where the doubling integral of the Fock vector against a highest-weight matrix coefficient is expected to be a positive real. Step (iii) needs only that the lift has the discrete series type and the level prescribed by the tower, and step (iv) is the explicit shape of the unramified correspondence: the parameter B twisted by $\chi_S(k)\chi_T(k)^{-1}$, together with the segment $\chi_S(k)(w)\mathrm{N}(w)^{(t-1)/2-i}$, $0 \le i < t$, contributed by the t extra dimensions. Through this step the downward theta maps of a Rallis tower are onto (Theorem A.40). □

Proposition A.42. *Let c be a see-saw tower over D, $m = 2n+2$, and $(t_s)_{s\in\mathcal{T}}$ a family of tuples of c satisfying the see-saw laws; data of t_s carry the superscript s. Let I be a finite set, $s\colon I \to \mathcal{T}$, $\alpha\colon I \to \mathbb{C}$, and for $i \in I$ let $\lambda_i \in \mathrm{Ram}_0^{s(i)}$ and $F_i \in \mathcal{C}_T^{s(i)}$. If*

$$\sum_{i\in I} \alpha_i \, c_{n+1}^{\mathrm{top},s(i)} \ \mathrm{tl}^{s(i)}\big(\mathrm{up}_{n+1}^{s(i)}\lambda_i,\ F_i\big) = 0,$$

then for all $y \in \mathrm{Fr}_0$ and $x \in M_0^\infty$

$$\sum_{i\in I} \alpha_i \, c^{\mathrm{bot},s(i)} \ \mathrm{per}_0^{s(i)}\big(\lambda_i,\ \mathrm{dn}_{m-1}^{s(i)}(\mathrm{io}_T^{s(i)}F_i),\ y,\ x\big) = 0.$$

Proof. **Climbing stays ramified.** For every tuple t of the family, $\lambda \in \mathrm{Ram}_0$ and $k \le n+1$: $\mathrm{up}_k\lambda \in \mathrm{Ram}_{2k}$. Induction on k: if $\mathrm{up}_k\lambda \in \mathrm{Ram}_{2k}$ with $2k+2 \le m$, then S_{2k} preserves Ram_{2k} ($2k \le m$), K_{2k} maps it into Ram_{2k+1} and K_{2k+1} maps that into Ram_{2k+2} ($2k+1 < m$), by (Zw28).

Descent along the double steps. We prove by induction on $k \in \{0, \dots, n\}$ the claim (D_k): for every finite set I', $s' \colon I' \to \mathcal{T}$, $\beta \colon I' \to \mathbb{C}$, $\lambda'_i \in \mathrm{Ram}_0^{s'(i)}$ and $G_i \in \mathcal{C}_{2k}^{s'(i)}$, if

$$\sum_i \beta_i W_{i,k} \, \mathrm{per}_{2k}^{s'(i)}(\mathrm{up}_k \lambda'_i, G_i, y, x) = 0$$

for all $y \in \mathrm{Fr}_{2k}$, $x \in M_{2k}^{\infty}$, then

$$\sum_i \beta_i \Big(\prod_{j<2k} c_{i,j}^I \Big) \mathrm{per}_0^{s'(i)}(\lambda'_i, \mathrm{dn}_{2k} G_i, y, x) = 0$$

for all $y \in \mathrm{Fr}_0$, $x \in M_0^{\infty}$ (constants, W and maps of $t_{s'(i)}$). (D_0) is the hypothesis itself ($W_{i,0} = 1$, $\mathrm{up}_0 = \mathrm{dn}_0 = \mathrm{id}$). Let $k+1 \le n$ and assume (D_k); take data as in (D_{k+1}). Since $W_{i,k+1} = W_{i,k} c_{i,2k}^V c_{i,2k}^K c_{i,2k+1}^K$ and $\mathrm{up}_{k+1} \lambda'_i = K_{2k+1} K_{2k} S_{2k} (\mathrm{up}_k \lambda'_i)$, the hypothesis of ($\mathrm{D}_{k+1}$) is the hypothesis of the double-step lemma (linear relations among periods pass down a double step of the see-saw tower) at $j = 2k$ (a link step, as $2k \le m-4$) for the coefficients $\beta_i W_{i,k}$, the ramified columns $\mathrm{up}_k \lambda'_i \in \mathrm{Ram}_{2k}$ and the $G_i \in \mathcal{C}_{2k+2}$. That lemma gives, for all $y \in \mathrm{Fr}_{2k}$ and x,

$$\sum_i \beta_i W_{i,k} \, c_{i,2k}^I c_{i,2k+1}^I \, \mathrm{per}_{2k}\big(\mathrm{up}_k \lambda'_i, \mathrm{io}_{2k}\mathrm{io}_{2k+1} G_i, y, x\big) = 0,$$

which is the hypothesis of (D_k) for the coefficients $\beta_i c_{i,2k}^I c_{i,2k+1}^I$ and $\mathrm{io}_{2k}\mathrm{io}_{2k+1} G_i \in \mathcal{C}_{2k}$. Its conclusion is that of (D_{k+1}), since $\big(\prod_{j<2k} c_{i,j}^I\big) c_{i,2k}^I c_{i,2k+1}^I = \prod_{j<2k+2} c_{i,j}^I$ and $\mathrm{dn}_{2k}\mathrm{io}_{2k}\mathrm{io}_{2k+1} = \mathrm{dn}_{2k+2}$.

The last two steps. Put $\mu_i = \mathrm{up}_n \lambda_i \in \mathrm{Ram}_{2n} = \mathrm{Ram}_{m-2}$. As $c_{n+1}^{\mathrm{top}} = W_{i,n} c_{i,2n}^V c_{i,2n}^K c_{i,2n+1}^K c^P$ and $\mathrm{up}_{n+1} \lambda_i = K_{2n+1} K_{2n} S_{2n} \mu_i$, the hypothesis is that of the last-steps lemma (linear relations among tails pass down the last two steps of the see-saw tower) for the coefficients $\alpha_i W_{i,n}$, the μ_i and the F_i. It gives, for all $y \in \mathrm{Fr}_{2n}$ and x,

$$\sum_i \alpha_i W_{i,n} \, c_{i,2n}^I c_{i,2n+1}^I \, \mathrm{per}_{2n}\big(\mathrm{up}_n \lambda_i, \mathrm{io}_{2n}\mathrm{io}_T F_i, y, x\big) = 0.$$

(D_n) for the coefficients $\alpha_i c_{i,2n}^I c_{i,2n+1}^I$ and $\mathrm{io}_{2n}\mathrm{io}_T F_i \in \mathcal{C}_{2n}$ gives

$$\sum_i \alpha_i \Big(\prod_{j<2n+2} c_{i,j}^I \Big) \mathrm{per}_0(\lambda_i, \mathrm{dn}_{2n}\mathrm{io}_{2n}\mathrm{io}_T F_i, y, x) = 0.$$

Since $2n+2 = m$, the product is c^{bot} and $\mathrm{dn}_{2n}\mathrm{io}_{2n} = \mathrm{dn}_{2n+1} = \mathrm{dn}_{m-1}$; this is the claim. □

A.4.4 The multiplicity identity

Definition A.43 defines multiplicity data and the unit-phase multiplicity identity, which compares rational period pairings with spectral inner products. Surjectivity for the tower of a true column chain comes from the doubling method (Proposition A.45). The multiplicity core (Proposition A.46) combines the bottom and level hypotheses, the family conditions and nonvanishing member projections into the identity, through the identity at a realisation (Proposition A.44). Eventually every linked bundle then has the identity (Proposition A.47). Because the phases are units at every finite place, the identity transfers period lattices to spectral lattices with no loss at any prime.

Definition A.43. Let L be a number field with a fixed embedding $\sigma \colon L \to \mathbb{C}$; for $\varphi \in L^n$ write $\sigma(\varphi) \in \mathbb{C}^n$ for the vector of the $\sigma(\varphi_i)$. For a finite place w of L let $v_w \colon L^{\times} \to \mathbb{Z}$ be its normalised valuation. Inner products of complex inner product spaces are conjugate-linear in the first argument.

(Mu1) Members and tuples. A **multiplicity datum** $\mathfrak{m}$ over (L,σ) consists of: a finite set $\Omega_{\mathfrak{m}}$ of **members** and a finite set $\mathcal{T}_{\mathfrak{m}}$ of **tuples** with a **base tuple** $t_0 \in \mathcal{T}_{\mathfrak{m}}$; a map $w \mapsto t_{\mathfrak{m}}(w)$ from the finite places of L to $\mathcal{T}_{\mathfrak{m}}$ (the **tuple map**);

(Mu2) Columns. for every member ω an integer $a(\omega) \geq 0$ and a function $n_\omega \colon \mathbb{C}^{a(\omega)} \to \mathbb{R}_{\geq 0}$ (the **column norm** at σ);

(Mu3) Periods. for every tuple t an integer $d(t) \geq 0$, and for every member ω and tuple t a map $\mathrm{Pt}_{\omega,t} \colon L^{a(\omega)} \times L^{d(t)} \to L$ (the **period pairing**);

(Mu4) Row space and row theta maps. a finite-dimensional complex inner product space $\mathcal{E}_{\mathfrak{m}}$ with a subspace $\mathcal{E}^{\circ}_{\mathfrak{m}}$, and for every tuple t a σ-semilinear map $\vartheta_t \colon L^{d(t)} \to \mathcal{E}_{\mathfrak{m}}$ (the **row theta map**: theta lift of the rational row forms read through their rational structure);

(Mu5) Spectral side. a finite-dimensional complex inner product space $H_{\mathfrak{m}}$, a conjugate-linear map $s_{\mathfrak{m}} \colon \mathcal{E}_{\mathfrak{m}} \to H_{\mathfrak{m}}$ and, for every member ω, a $\mathbb{C}$-linear map $P_\omega \colon \mathbb{C}^{a(\omega)} \to H_{\mathfrak{m}}$ (the **member projection**).

A **multiplicity system** for $\mathfrak{m}$ is a tuple (V, a, U, ζ) of a $\mathbb{C}$-linear map $V \colon \mathcal{E}_{\mathfrak{m}} \to \mathcal{E}_{\mathfrak{m}}$, a function $a \colon \Omega_{\mathfrak{m}} \to \mathbb{C}$, matrices $U_\omega \in M_{a(\omega)}(\mathbb{C})$ $(\omega \in \Omega_{\mathfrak{m}})$ and a function $\zeta \colon \Omega_{\mathfrak{m}} \times \mathcal{T}_{\mathfrak{m}} \to \mathbb{C}$ such that:

(Mv1) Isometry on the distinguished subspace. $V(e) \in \mathcal{E}^{\circ}_{\mathfrak{m}}$ and $\|V(e)\| = \|e\|$ for every $e \in \mathcal{E}^{\circ}_{\mathfrak{m}}$;

(Mv2) Column unitarity. $n_\omega(U_\omega x) = n_\omega(x)$ for every ω and $x \in \mathbb{C}^{a(\omega)}$;

(Mv3) Nonzero constants. $a(\omega) \neq 0$ for every ω;

(Mv4) The identity. for every ω, t, $\varphi \in L^{a(\omega)}$ and $F \in L^{d(t)}$:

$$\zeta(\omega,t)\,\sigma\big(\mathrm{Pt}_{\omega,t}(\varphi,F)\big) = a(\omega)\,\big\langle s_{\mathfrak{m}}\big(V(\vartheta_t(F))\big),\, P_\omega\big(U_\omega\,\sigma(\varphi)\big)\big\rangle_{H_{\mathfrak{m}}}. \tag{A.4}$$

It is **unit-phase** if moreover

(Mv5) Unit phases. $\zeta(\omega,t) \neq 0$ for all ω, t; $\zeta(\omega,t_0) = 1$ for all ω; and for every member ω, every finite place w of L and every $k \in L$ with $\sigma(k) = \zeta(\omega, t_{\mathfrak{m}}(w))$, $v_w(k) = 0$;

and **root-of-unity** if instead every $\zeta(\omega,t)$ is a root of unity and $\zeta(\omega,t_0) = 1$ for all ω. The datum $\mathfrak{m}$ satisfies the **unit-phase multiplicity identity** if it admits a unit-phase multiplicity system, and the **root-of-unity multiplicity identity** if it admits a root-of-unity multiplicity system.

Proposition A.44. *Let D be an assembled datum and W a real package over a member object of D such that* $\mathrm{Bot}(W)$ *holds, $\vartheta_t(F) \in \mathcal{E}^{\circ}_{\mathfrak{m}(W)}$ for every tuple t and $F \in L^{d(t)}$,* $\mathrm{Joint}(W)$ *holds and* $\mathrm{PuNZ}(D)$ *holds. Then $\mathfrak{m}(W)$ satisfies the unit-phase multiplicity identity.*

Proof. Sketch. The identity (Mv4) of Definition A.43 compares two pairings attached to the same real package W: the rational period pairing $\mathrm{Pt}_{\omega,t}(\varphi,F)$ of a column vector with a row form, and the spectral inner product of the theta lift $\vartheta_t(F)$, moved by an isometry V of the sharp subspace, with the member projection of the column vector. The argument should run as follows. Choose a central element from the joint condition on W, the corresponding common shift V_z, a conjugate model vector and coordinate isomorphisms on the columns; the package conditions express the column periods through the bottom periods, with coefficients that are

units at every finite place. It remains to show a global period comparison: on every row e of the sharp-level subspace, the bottom-period functional must be a fixed nonzero multiple of $e \mapsto \langle s_W(V_z e), P_\omega(A_\omega \varphi)\rangle$, uniformly in the tuple and the row coefficient, where A_ω is the column transport used for the bottom relations; the transport must carry the frame norm to the member-space norm up to one positive factor, V_z must preserve the sharp subspace and its norm, and the nonvanishing of the member projections, PuNZ(D), must supply an anchor at which the functional is nonzero. Given these, the rest is elementary: if the comparison reads $c_\omega(t)\,\sigma(\mathrm{Pt})\,b_\omega = p_\omega \langle s_W(V_z \vartheta_t(F)), P_\omega(U_\omega \sigma(\varphi))\rangle$ with $p_\omega b_\omega c_\omega(t_0) \neq 0$, then $\zeta(\omega, t) = c_\omega(t)/c_\omega(t_0)$ and $a(\omega) = p_\omega/(b_\omega c_\omega(t_0))$ satisfy (Mv4), $\zeta(\omega, t_0) = 1$, and the valuation clause of (Mv5) is the unit-coefficient property of the bottom relations. Heuristically the comparison should hold because both sides are computed from one theta integral along the chain of lifts: unfolding the spectral inner product against the member projection should produce the bottom period, with a constant made of local factors that does not depend on the tuple, and the realisation is built so that its columns are read through the same rational structure as the periods. The identity is the last step of the multiplicity core Proposition A.46, which gives the multiplicity row Proposition A.47. □

Proposition A.45. *For every column datum w with laws and every later state Z of w,* Onto($D(w, Z)$) *holds.*

Proof. Let $D = D(w, Z)$. By the Rallis inner product property of every assembled datum, obtained by the doubling method, RIP(D) holds ((Mq5) of the package conditions). Since the Rallis inner product property gives onto theta maps, Onto(D) holds. (The argument uses no property of D beyond being an assembled datum: Onto holds for every assembled datum.) □

Proposition A.46. *Let D be an assembled datum and W a real package over a member object of D such that* Bot(W) *and* Lev(W) *hold, the indefinite realisation of W admits a realisation recursion,* FamAll(W) *holds and* PuNZ(D) *holds. Then $\mathfrak{m}(W)$ satisfies the unit-phase multiplicity identity.*

Proof. Step 1: W is served. Every real package is served, so Served(W) holds; this uses only the character frame (Mq9) of W, not the bottom hypotheses nor the realisation recursion.

Step 2: the joint condition. From FamAll(W) and Step 1, the proposition that the family-all and served conditions give the joint condition yields Joint(W) ((Mq10) of the package conditions): a central element z of the finite adelic part of GA(Y_0) and, for every word u, bottom data pinned at z, a map of the member space isometric up to a positive scale and unit coefficients satisfying the bottom relation.

Step 3: the row theta maps land in the sharp level subspace. From Bot(W) and Lev(W), the level proposition for row theta maps gives $\vartheta_t(F) \in \mathcal{E}^\circ_{\mathfrak{m}(W)}$ for every tuple t and every $F \in L^{d(t)}$.

Step 4: the identity. The hypotheses of Proposition A.44 are Bot(W) (assumed), the conclusion of Step 3, Joint(W) (Step 2) and PuNZ(D) (assumed). Hence $\mathfrak{m}(W)$ satisfies the unit-phase multiplicity identity.

Remark. The hypothesis that the indefinite realisation of W admits a realisation recursion is not used. □

Proposition A.47. *Let p be a parameter of a norm-choice extension. Then eventually in the row parameters κ and the context K the following holds: for every base point β at K that is good for p, every $c \in \mathbb{R}$ and every bundle b over $(D(\beta), \mathfrak{o}(\beta), c)$ that is linked to β for p, the multiplicity datum $\mathfrak{m}(b)$ satisfies the unit-phase multiplicity identity. In the terms of (Rk8): the*

predicate "$\mathfrak{m}(b)$ satisfies the unit-phase multiplicity identity" holds eventually at linked bundles for p.

Proof. Step 1: the row filter is closed under finite conjunction. Let $P_1(\kappa, K)$ and $P_2(\kappa, K)$ hold eventually in the row parameters and the context, with data $\varepsilon_0^{(i)}$, threshold families $\mathbf{K}_0^{(i)}$, constants $c_1^{(i)}$, $c_2^{(i)}$ and, for positive κ, $x_0^{(i)}$ $(i = 1, 2)$, as in (Rk1) of the row carrier. Put $\varepsilon_0 = \min(\varepsilon_0^{(1)}, \varepsilon_0^{(2)})$. For $0 < \varepsilon \le \varepsilon_0$ with $\varepsilon < \frac{1}{52}$ and reals $C_8 \ge 1$, C_5, c_6, C_b, let $\mathbf{K}_0$ be the threshold family whose preliminary entry and whose two functions are the maxima of those of $\mathbf{K}_0^{(1)}$ and $\mathbf{K}_0^{(2)}$; largeness ((Lc4) of the definition of contexts) consists of lower bounds on entries, so a constant family large with respect to $\mathbf{K}_0$ is large with respect to both. For such $\mathbf{C}$ take $c_1 = \max(c_1^{(1)}, c_1^{(2)})$, for $c_D \ge c_1$ take $c_2 = \max(c_2^{(1)}, c_2^{(2)})$, and for $c_h \ge c_2$ and positive κ take $x_0 = \max(x_0^{(1)}, x_0^{(2)})$. Then every context $K \models \kappa$ of scale $x \ge x_0$ has $P_1(\kappa, K)$ and $P_2(\kappa, K)$.

Step 2: the eventual properties. By the true-package proposition, eventually at linked bundles for p every linked bundle satisfies the point conditions and has a true real package. In particular the hypothesis of the nonvanishing theorem for member projections, which rests on the convergent Siegel–Weil formula, holds, so eventually at linked bundles for p the datum of the base point satisfies PuNZ. By Step 1, eventually in κ and K both hold at once: for every base point β at K that is good for p, every c and every bundle b over $(D(\beta), \mathfrak{o}(\beta), c)$ linked to β for p, (i) b satisfies the point conditions, (ii) $W = W(b)$ is true and (iii) PuNZ$(D(\beta))$ holds. We show that for every such b the datum $\mathfrak{m}(b)$ satisfies the unit-phase multiplicity identity; this proves the statement in the same filter.

Step 3: one linked bundle. Fix κ, K, β, c, b as in Step 2 and write $D = D(\beta)$, $W = W(b)$. By (ii) there are a column datum w with laws and a later state Z of w with $D = D(w, Z)$, and AllFam(W) holds. By Proposition A.45, Onto(D) holds. By (P10) of (i), $r_S \ge 1$. Hence the proposition on the family conditions of a true real package applies to (w, Z, W) and gives FamAll(W). The family conditions AllFam(W) contain the package hypotheses, among them Bot(W) and Lev(W), and a realisation recursion of the indefinite realisation of W ((Mq3) of the package conditions). Together with PuNZ(D) from (iii), all hypotheses of Proposition A.46 hold, and so $\mathfrak{m}(W)$ satisfies the unit-phase multiplicity identity. Finally $\mathfrak{m}(W(b)) = \mathfrak{m}(b)$, since both are read off the same indefinite realisation Q_b ((Mq1) of the package conditions, (Rk9) of the row carrier). □

Sketch: what the chain supplies to the rows. The three properties of the chain enter the construction as row services at one parameter, as described in the sketch at the end of Section A.1. Separation gives the functional row and the multiplicity identity gives the multiplicity row; the rows of the Hecke kernel datum κ record an eigenvalue law on the same lifts, and a comparison tie fixes the real normalisations of the selected bundle. What must be added to the three properties is their attachment to the selected bundles. The analytic grid on which separation is proved must be chosen above one threshold for all members at once, the constant-function fit must hold on the same grid, and the realisation at which the multiplicity identity is proved must be the one carried by the member. Heuristically each of these is a matter of choosing the auxiliary data of the chain (grids, test functions, base tuples) once the scale is large, since each property holds for every admissible choice and the choices form a nonempty set above a threshold.

A.5 The members: Hida settings and the two passes

A packet has one member for every translate $u \in A_x$, and the loss datum and slope record of the member are read from automorphic objects built at its context. This section builds them. The members come from an abstract producer, a two-pass system with seven named hypotheses (H0)–(H6) (Definition A.48, Theorem A.49). A first pass climbs the levels of a state to a core with the slot Built; a second pass enlarges the field of coefficients while keeping every reference datum. For the concrete system (Definition A.50) five of the hypotheses are proved, namely (H0), (H1), (H2), (H5) and (H6) (Theorem A.51); the export property (H3) and the second pass (H4) are the hypotheses of the member step Theorem A.52, and they are sketched in the last subsection. The automorphic data at a member are called a Hida setting: unitary automorphic data with an archimedean test function and transports between levels, not a p-adic Hida family. The spectral input is classical. Discrete series of $\mathrm{U}(p,q)$ above an explicit gap have integrable lowest-K-type coefficients, Harish-Chandra's formal degree and Schur orthogonality hold, and together they make evaluation at the lowest K-type an exact bijection onto conjugate rows. The count identity comes from the Tamagawa number 2 of unitary groups: volumes are masses (Proposition A.59).

A.5.1 Two-pass systems and the member step

A two-pass system (Definition A.48) consists of contexts, pre-bases, frames and bases with enlargements, stage tuples, cores with slots, assembled data, layered data and demands. Theorem A.49 is pure assembly: from a baseline (H0), largeness of forced data (H1), a first pass (H2), export (H3), a second pass (H4), properties of cores (H5) and layers from cores (H6) it produces, eventually in the context, an assembled datum with layered data and a core with the final slot. The concrete system is Definition A.50, and Theorem A.51 proves for it all hypotheses except (H3) and (H4). The member step Theorem A.52 then gives, over every complete good-host witness and *given* (H3) and (H4), a good context and a member that satisfies the numerical clauses of Proposition A.18 and the member clauses of Proposition A.53.

Definition A.48. An **avoidance map** is a map A from the set of rational primes to the set of finite subsets of $\mathbb{Z}_{\geq 1}$. For avoidance maps A, A' write $A' \leq A$ if $A'(\ell) \subseteq A(\ell)$ for every prime ℓ, and $A \cup A'$ for the map $\ell \mapsto A(\ell) \cup A'(\ell)$; the **empty** avoidance map has all values $\varnothing$.

A **two-pass system** consists of the following data.

(Tp1) Contexts. A set $\mathcal{K}$ of **contexts** and a filter $\mathfrak{E}$ on $\mathcal{K}$. A property of contexts holds **eventually** if the set of contexts having it belongs to $\mathfrak{E}$.

(Tp2) Pre-bases, frames, bases. For every $K \in \mathcal{K}$ a set $\mathcal{P}(K)$ of **pre-bases over** K. For every pre-base P a set $\mathcal{F}(P)$ of **frames**, a set $\mathfrak{X}(P)$, and a set $\mathcal{B}(P)$ of **bases over** P. Every base B carries three subfields $F_{\mathrm{ex}}(B)$, $F_{\mathrm{fix}}(B)$, $F_{\mathrm{L}}(B)$ of $\mathbb{C}$ (the exact, fixed and large coefficient fields). A base B **contains** a pair (S_1, S_2) of finite subsets of $\mathbb{C}$ if $S_1 \subseteq F_{\mathrm{fix}}(B)$ and $S_2 \subseteq F_{\mathrm{L}}(B)$. For $B, B' \in \mathcal{B}(P)$, B' is an **enlargement** of B if $F_{\mathrm{ex}}(B') = F_{\mathrm{ex}}(B)$, $F_{\mathrm{fix}}(B') = F_{\mathrm{fix}}(B)$ and $F_{\mathrm{L}}(B) \subseteq F_{\mathrm{L}}(B')$.

(Tp3) Twisting data. For every base $B \in \mathcal{B}(P)$ a set $\mathcal{T}(B)$ of **twisting data**. Every $T \in \mathcal{T}(B)$ has a finite set $\mathrm{pl}(T)$ of primes, for every $f \in \mathcal{F}(P)$ a **character set** $\Xi(f,T) \subseteq \mathfrak{X}(P)$, and a relation "$T$ **avoids** A" with avoidance maps A, such that T avoids every $A' \leq A$ whenever it avoids A. For every finite set S of primes there is an **untwisted datum** $\upsilon(B,S) \in \mathcal{T}(B)$ with $\mathrm{pl}(\upsilon(B,S)) = S$, avoiding every avoidance map, and with

$\Xi(f, \upsilon(B,S)) = \Xi_0(f)$ for every $f \in \mathcal{F}(P)$, where $\Xi_0(f) \subseteq \mathfrak{X}(P)$ is a set attached to f alone. A twisting datum T is **untwisted** if $T = \upsilon(B, \mathrm{pl}(T))$.

(Tp4) Forced twisting data. For every $K \in \mathcal{K}$, a property "T is **forced at** K" of pairs (B,T) with $B \in \mathcal{B}(P)$, $P \in \mathcal{P}(K)$, $T \in \mathcal{T}(B)$.

(Tp5) Stages, cores, assembled data. A set $\mathcal{D}$ of **assembled data**, and for each $D \in \mathcal{D}$ a set $\mathcal{O}(D)$ of **objects of** D. For every base B a set $\mathcal{X}(B)$ of **stage tuples** with a map $X \mapsto D(X) \in \mathcal{D}$. For $K \in \mathcal{K}$, $B \in \mathcal{B}(P)$ with $P \in \mathcal{P}(K)$, $X \in \mathcal{X}(B)$, $f \in \mathcal{F}(P)$ and $T \in \mathcal{T}(B)$, a set $\mathcal{C}(K,X,f,T)$ of **cores**, each core c with an object $O(c) \in \mathcal{O}(D(X))$. A **slot** is a property of tuples (K,X,f,T,c) with $c \in \mathcal{C}(K,X,f,T)$.

(Tp6) Layered data. For each $D \in \mathcal{D}$ a set $\mathcal{L}(D)$ of **layered data on** D, each $Y \in \mathcal{L}(D)$ with an object $O(Y) \in \mathcal{O}(D)$.

Demands and large data. Let $K \in \mathcal{K}$. A **demand at** K is a quadruple $\rho = (S_1, P_1, A, S_2)$ of maps assigning: to every $P \in \mathcal{P}(K)$, $f \in \mathcal{F}(P)$ and subfield F of $\mathbb{C}$, a finite set $S_1(P,f,F)$ of algebraic numbers in $\mathbb{C}$; to every such (P,f,F) and subfield F_0 of $\mathbb{C}$, a finite set $P_1(P,f,F,F_0)$ of primes and an avoidance map $A(P,f,F,F_0)$; and to every such (P,f,F,F_0) and subset $\Xi \subseteq \mathfrak{X}(P)$, a finite set $S_2(P,f,F,F_0,\Xi)$ of algebraic numbers in $\mathbb{C}$. A triple (B,f,T) with $B \in \mathcal{B}(P)$, $P \in \mathcal{P}(K)$, $f \in \mathcal{F}(P)$, $T \in \mathcal{T}(B)$ **meets** ρ if, with $F = F_{\mathrm{ex}}(B)$ and $F_0 = F_{\mathrm{fix}}(B)$,

$$B \text{ contains } \big(S_1(P,f,F),\, S_2(P,f,F,F_0,\Xi(f,T))\big),$$
$$P_1(P,f,F,F_0) \subseteq \mathrm{pl}(T), \qquad T \text{ avoids } A(P,f,F,F_0).$$

A property of such triples holds **for large data at** K if there is a demand at K such that every triple meeting it has the property.

Theorem A.49. *Fix a two-pass system. Let* BP *be a property of pairs* (B,f) *with* $B \in \mathcal{B}(P)$, $f \in \mathcal{F}(P)$*; let* Q, Q' *be slots; let* Ex *and* τ *be properties of pairs* (D,O) *with* $D \in \mathcal{D}$, $O \in \mathcal{O}(D)$*; let* V *and* M *be properties of assembled data; and let* Π *be a property of triples* (K,D,Y) *with* $K \in \mathcal{K}$, $D \in \mathcal{D}$, $Y \in \mathcal{L}(D)$*. Assume:*

(H0) Baseline. *Eventually in* K*, there are* $P \in \mathcal{P}(K)$ *and* $f_0 \in \mathcal{F}(P)$ *such that for every map* S_1 *from subfields of* $\mathbb{C}$ *to finite sets of algebraic numbers and every map* S_2 *from pairs of subfields of* $\mathbb{C}$ *to finite sets of algebraic numbers there is* $B \in \mathcal{B}(P)$ *with* $\mathrm{BP}(B,f_0)$ *which contains* $\big(S_1(F_{\mathrm{ex}}(B)),\, S_2(F_{\mathrm{ex}}(B), F_{\mathrm{fix}}(B))\big)$*.*

(H1) Forced data are large. *For every* $K \in \mathcal{K}$*, "*T *is forced at* K*" holds for large data* (B,f,T) *at* K*.*

(H2) First pass. *Eventually in* K*, the following holds for large data* (B,f,T) *at* K*: if* $\mathrm{BP}(B,f)$*,* T *is forced at* K *and* T *is untwisted, then there are* $X \in \mathcal{X}(B)$ *and* $c \in \mathcal{C}(K,X,f,T)$ *with* $Q(K,X,f,T,c)$*.*

(H3) Export. *Eventually in* K*, the following holds for large data* (B,f,T) *at* K*: if* $\mathrm{BP}(B,f)$ *and* T *is untwisted, then* $\mathrm{Ex}(D(X),O(c))$ *for every* $X \in \mathcal{X}(B)$ *and every* $c \in \mathcal{C}(K,X,f,T)$ *with* $Q(K,X,f,T,c)$*.*

(H4) Second pass. *Eventually in* K*, the following holds for large data* (B,f,T) *at* K*: if* $\mathrm{BP}(B,f)$ *and* T *is untwisted, then for every* $X \in \mathcal{X}(B)$ *and* $c \in \mathcal{C}(K,X,f,T)$ *with* $Q(K,X,f,T,c)$ *and* $\mathrm{Ex}(D(X),O(c))$*, every avoidance map* A *and every map* S_2 *from*

subsets of $\mathfrak{X}(P)$ to finite sets of algebraic numbers, there are an enlargement $B' \in \mathcal{B}(P)$ of B and $T' \in \mathcal{T}(B')$ with

$$\mathrm{pl}(T') = \mathrm{pl}(T), \qquad T' \text{ avoids } A, \qquad S_2(\Xi(f, T')) \subseteq F_{\mathrm{L}}(B'),$$

and $X' \in \mathcal{X}(B')$, $c' \in \mathcal{C}(K, X', f, T')$ with $Q(K, X', f, T', c')$, $\tau(D(X'), O(c'))$ and $Q'(K, X', f, T', c')$.

(H5) Cores. *For every core $c \in \mathcal{C}(K, X, f, T)$ the assembled datum $D(X)$ has V and M.*

(H6) Layers from cores. *Eventually in K: for every $B \in \mathcal{B}(P)$ with $P \in \mathcal{P}(K)$, $X \in \mathcal{X}(B)$, $f \in \mathcal{F}(P)$, $T \in \mathcal{T}(B)$ and $c \in \mathcal{C}(K, X, f, T)$ such that $D(X)$ has V, there is $Y \in \mathcal{L}(D(X))$ with $O(Y) = O(c)$ and $\Pi(K, D(X), Y)$.*

Then eventually in K there are $D \in \mathcal{D}$ and $Y \in \mathcal{L}(D)$ such that $\Pi(K, D, Y)$, $\tau(D, O(Y))$ and $M(D)$ hold, and there are $P \in \mathcal{P}(K)$, $B \in \mathcal{B}(P)$, $X \in \mathcal{X}(B)$, $f \in \mathcal{F}(P)$, $T \in \mathcal{T}(B)$ and a core $c \in \mathcal{C}(K, X, f, T)$ with $Q'(K, X, f, T, c)$, $D = D(X)$ and $O(Y) = O(c)$.

Proof. Step 1: large data form a filter. Let $K \in \mathcal{K}$ and let $p_1, \dots, p_r$ be properties of triples that hold for large data at K, with demands $\rho_i = (S_1^i, P_1^i, A^i, S_2^i)$. Put $\rho = (S_1, P_1, A, S_2)$ with

$$S_1 = \bigcup_i S_1^i, \quad P_1 = \bigcup_i P_1^i, \quad A = \bigcup_i A^i, \quad S_2 = \bigcup_i S_2^i,$$

the unions taken argument by argument. Finite unions of finite sets of algebraic numbers, of finite sets of primes and of avoidance maps are again of the same kind, so ρ is a demand at K. If (B, f, T) meets ρ, it meets every ρ_i: containment of a pair passes to pairs of subsets; $P_1^i \subseteq P_1 \subseteq \mathrm{pl}(T)$; and $A^i \leq A$, so T avoids A^i by (Tp3). Hence the conjunction $p_1 \wedge \cdots \wedge p_r$ holds for large data at K.

Step 2: one context. Let $\mathcal{K}_0, \mathcal{K}_2, \mathcal{K}_3, \mathcal{K}_4, \mathcal{K}_6 \in \mathfrak{E}$ be the sets of contexts at which the statements in (H0), (H2), (H3), (H4), (H6) hold. Their intersection $\mathcal{K}^*$ belongs to $\mathfrak{E}$. Fix $K \in \mathcal{K}^*$. By (H1), (H2)–(H4) at K and Step 1 there is one demand $\rho = (S_1, P_1, A, S_2)$ at K such that every triple (B, f, T) meeting ρ is forced at K and has the three properties stated in (H2), (H3), (H4).

Step 3: a base and the untwisted datum. Let $P \in \mathcal{P}(K)$ and $f_0 \in \mathcal{F}(P)$ be given by (H0) at K. Apply (H0) to the maps

$$S_1'(F) = S_1(P, f_0, F), \qquad S_2'(F, F_0) = S_2(P, f_0, F, F_0, \Xi_0(f_0)),$$

whose values are finite sets of algebraic numbers. This gives $B \in \mathcal{B}(P)$ with $\mathrm{BP}(B, f_0)$ containing $(S_1(P, f_0, F), S_2(P, f_0, F, F_0, \Xi_0(f_0)))$, where $F = F_{\mathrm{ex}}(B)$, $F_0 = F_{\mathrm{fix}}(B)$. Put $T = \upsilon(B, P_1(P, f_0, F, F_0))$. By (Tp3), $\Xi(f_0, T) = \Xi_0(f_0)$, $\mathrm{pl}(T) = P_1(P, f_0, F, F_0)$ and T avoids $A(P, f_0, F, F_0)$. So (B, f_0, T) meets ρ. Moreover $T = \upsilon(B, \mathrm{pl}(T))$ is untwisted, and T is forced at K by the choice of ρ.

Step 4: the two passes. By (H2) applied to (B, f_0, T) there are $X \in \mathcal{X}(B)$ and $c \in \mathcal{C}(K, X, f_0, T)$ with $Q(K, X, f_0, T, c)$. By (H3), $\mathrm{Ex}(D(X), O(c))$. Apply (H4) with the empty avoidance map and the map $S_2 \equiv \varnothing$. It gives an enlargement $B' \in \mathcal{B}(P)$ of B, $T' \in \mathcal{T}(B')$, $X' \in \mathcal{X}(B')$ and $c' \in \mathcal{C}(K, X', f_0, T')$ with $\tau(D(X'), O(c'))$ and $Q'(K, X', f_0, T', c')$.

Step 5: the layered datum. By (H5), $D(X')$ has V and M. Since $K \in \mathcal{K}_6$, (H6) applied to (B', X', f_0, T', c') gives $Y \in \mathcal{L}(D(X'))$ with $O(Y) = O(c')$ and $\Pi(K, D(X'), Y)$. Put $D = D(X')$. Then $\Pi(K, D, Y)$ and $M(D)$ hold, and $\tau(D, O(Y))$ holds because $O(Y) = O(c')$. The core c' over (K, X', f_0, T'), with P, B', X', f_0, T', satisfies Q', $D = D(X')$ and $O(Y) = O(c')$.

So the conclusion holds at every context of $\mathcal{K}^* \in \mathfrak{E}$. Since a filter is closed under supersets, it holds eventually. $\square$

Definition A.50. The **concrete two-pass system** has:

(Tp1) $\mathcal{K}$ the set of contexts and $\mathfrak{E}$ the context filter;

(Tp2) $\mathcal{P}(K)$ the pre-bases over K; $\mathcal{F}(P)$ the frames over P; $\mathfrak{X}(P)$ the Hecke characters of the host field; $\mathcal{B}(P)$ the bases over P, with $F_{\mathrm{ex}}(B), F_{\mathrm{fix}}(B), F_{\mathrm{L}}(B)$ the exact, fixed and large coefficient fields;

(Tp3) $\mathcal{T}(B)$ the twisting data over B, with $\mathrm{pl}(T)$, $\Xi(f,T)$, avoidance, and $\upsilon(B,S)$ the untwisted datum with prime set S; $\Xi_0(f) = \{1, \delta_f, \delta'_f\}$;

(Tp4) "forced at K" as defined for the concrete twisting data;

(Tp5) $\mathcal{D}$ the assembled master data, $\mathcal{O}(D)$ the objects of D ((Xh1)); $\mathcal{X}(B)$ the stage tuples over B with $X \mapsto D(X)$; $\mathcal{C}(K,X,f,T)$ the cores over (K,X,f,T) ((Xh2)) with their objects $O(c)$;

(Tp6) $\mathcal{L}(D)$ the layered data on D with $Y \mapsto O(Y)$ ((Ly) of the definition of layered data).

That these data satisfy the axioms of a two-pass system is Theorem A.51.

Theorem A.51. *1. The concrete two-pass system is a two-pass system.*

2. *Fix $c_0 \in \mathbb{R}$ and put $Q = \mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0)))$ (a core c over (K,X,f,T) has Q if $X = (B; C(w), Z)$ for a column datum w over (B,f,T) and a state Z of w at which c is Built with canonical entries for $\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0))$), let V be the volume–mass identity and Π admissibility. Then (H0), (H1), (H2) and (H6) hold for the concrete two-pass system with* BP, Q, V, Π.

3. *Consequently, for every slot Q' and all properties Ex, τ of pairs (D,O) and M of assembled data such that (H3), (H4) and (H5) hold with $\mathrm{BP}, Q, Q', \mathrm{Ex}, \tau, V, M$, the conclusion of the two-pass producer theorem (which gives the conclusion of Theorem A.49 at all contexts with sufficiently large parameters) holds for the concrete two-pass system with $\mathrm{BP}, Q, Q', \mathrm{Ex}, \tau, V, M, \Pi$.*

4. *(H5) holds with V and with M the stability of the spaces $\mathcal{M}_t$ of (Xh2) in the definition of cores; so for this M the conclusion of item 3 holds for every Q', Ex, τ satisfying (H3) and (H4).*

5. *(Adjoined base property.) Let A be a property of (K,B,f,T) that holds eventually at all contexts for large data, and let $Q_A = \mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p_A))$ with $p_A = (\mathcal{N}_{\mathrm{or}}(c_0)_A, \varnothing, \Gamma_\top)$ the parameter with A adjoined, as in the lemma on adjoining an eventual base condition ($\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0))$ being the slot system of $(\mathcal{N}_{\mathrm{or}}(c_0), \varnothing, \Gamma_\top)$). Then (H0), (H1), (H2), (H5), (H6) hold with $\mathrm{BP}, Q_A, V, M, \Pi$, and for every Q', Ex, τ such that (H3) and (H4) hold with $\mathrm{BP}, Q_A, Q', \mathrm{Ex}, \tau$, the conclusion of the two-pass producer theorem holds with $\mathrm{BP}, Q_A, Q', \mathrm{Ex}, \tau, V, M, \Pi$.*

Proof. 1. (Tp1): $\mathfrak{E}$ is a filter on the set of contexts, by the filter lemma for contexts. (Tp2), (Tp4)–(Tp6) only name sets and maps, which Definition A.50 supplies. (Tp3): if T avoids A and $A' \le A$, then $N(v) \notin A(\ell_w) \supseteq A'(\ell_w)$ for all w and $v \in Q_w$, so T avoids A'. For a finite set S of primes, $\upsilon(B,S)$ ($\mathrm{pl} = S$, $Q_w = \varnothing$, $k_w = 0$, $\psi_w = 1$) is a twisting datum: (Tx1) holds for the trivial character with $k_w = 0$ (order $1 = \ell_w^0$, unramified everywhere, so ramified exactly at $Q_w = \varnothing$, trivial on $\mathbb{A}_{E^+}^\times$ and on every $E_v^\times$), (Tx2) is vacuous, and (Tx3) holds. It avoids every

avoidance map because all Q_w are empty. Its character set is $\{1, \delta_f, \delta'_f\} \cup \{\delta_f, \delta'_f\} = \Xi_0(f)$, since $\xi_{f,v}(w) \in \{\delta_f, \delta'_f\}$. The notion "untwisted" is the one of (Tp3) by definition.

2. (H0) is the baseline proposition for good contexts. (H1) is the lemma that forced twisting data are large. (H2): by Proposition A.54, eventually in K, for large data (B, f, T) at K with $\mathrm{BP}(B, f)$, T forced and untwisted, there are a column datum w over (B, f, T), a state Z of w and a core c over $(K, (B; C(w), Z), f, T)$ Built with canonical entries for $\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0))$ at (w, Z); with $X = (B; C(w), Z) \in \mathcal{X}(B)$ this is $c \in \mathcal{C}(K, X, f, T)$ with $Q(K, X, f, T, c)$. (H6) is the proposition on layered data from cores (it holds at every context, hence eventually).

3. By 1 and 2, all of (H0)–(H6) hold for the concrete two-pass system, whose contexts and filter are the contexts and the context filter, as the two-pass producer theorem requires; that theorem applies.

4. (H5) with these V, M is the core lemma for the concrete two-pass system; then item 3 applies.

5. (H0), (H1), (H5) and (H6) do not involve the slot Q, so they hold as in items 2 and 4. (H2) for Q (item 2) and the eventual largeness of A give (H2) for Q_A by the lemma on adjoining an eventual base condition (first-pass transfer: enlarge the demand by that of A and insert the proof of A into the Built record). With (H3), (H4) for Q_A as assumed, all of (H0)–(H6) hold for the concrete two-pass system with Q_A, and the two-pass producer theorem applies as in item 3. □

Theorem A.52. *Fix $c_0 \in \mathbb{R}$, and let Q be either $\mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0)))$ or Q_A for a property A of (K, B, f, T) that holds eventually at all contexts for large data. Let Q', Ex, τ be properties such that (H3) and (H4) hold for the concrete two-pass system with $\mathrm{BP}, Q, Q', \mathrm{Ex}, \tau, V, M$. There is $\varepsilon_0 > 0$ such that for all $0 < \varepsilon \le \varepsilon_0$ with $\varepsilon < \frac{1}{52}$ and all $C_8 \ge 1$, $C_5, c_6, C_b > 0$ there is a threshold family $\mathbf{K}_0$ such that for every admissible $\mathbf{C}$ with this C_8, large with respect to $\mathbf{K}_0$, there is $c_1 \ge 0$ such that for every $c_D \ge c_1$ there is $c_2 \ge 402$ such that for every $c_h \ge c_2$ there is x_0 with the following property.*

Let $x \ge x_0$, $J \ge 1$, and let a complete witness of $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$ with $\kappa = (C_{T_2}, C_8, C_5, c_6, C_b)$ (C_{T_2} that of $\mathbf{C}$) be given, with its element $u_0 \in A$ (no clause of Definition 11.4 restricts u_0 beyond $u_0 \in A$, so u_0 may be any element of A). Then for all top tables $a, b\colon A \to \mathbb{Z}$ satisfying the windows (Cx3e), every finite set Ω of words with $|\Omega| = \lceil 3\Gamma^2 x^{C_F} \rceil$, $\Gamma = \exp(C_\Gamma m^5 f L)$, every base word $\omega_0 \in \Omega$ and every injective word code $c\colon \Omega \to \{0,1\}^{k-2}$ there are Harish-Chandra parameters and a level choice Lv such that, with the pre-character datum $\mathfrak{P}$ formed from the witness and these Ω, ω_0 by the existence theorem for good pre-character data,

$$K = (x, \varepsilon, J, \mathbf{C}, c_D, c_h, \mathfrak{P}, q_0, a, b, c, \mathrm{Lv})$$

is a context good for (C_5, c_6, C_b) with $X'(\mathfrak{s}) \le T(\omega)$ for every word ω; there are an assembled datum D and layered data $Y \in \mathcal{L}(D)$ with $\Pi(K, D, Y)$, $\tau(D, O(Y))$ and $M(D)$, together with $P, B, X, f, \mathsf{T}, c'$ with $Q'(K, X, f, \mathsf{T}, c')$, $D = D(X)$ and $O(Y) = O(c')$; and there is a record part $(L, I, (N^{\mathrm{gl}}_\omega)_\omega)$ of Y (a size datum L of D, a canonical instance I over L, and $\mathcal{O}_L$-submodules N^{gl}_ω of the divisor spaces of the words ω), whose member satisfies (a)–(e) of Proposition A.18 and (Mc1)–(Mc5) of Proposition A.53; in particular the member is formed from the witness, u_0 and these a, b, c, it satisfies (La4) and M, and, if τ is "all twists good" ((Xh5) in the definition of cores), it satisfies τ with the object $O(Y)$. The member carries the same supplied canonical gate instance I, lattice instance $\mathrm{Gy}(O(Y))$, gathering ties and instance constants $5, 4, 12, 3$, with the parameter-fill, lattice-tie, gathering-filling and forced local-value equations of the record part. Its underlying object remains $O(Y) = O(c')$.

Proof. By item 4 (for $Q = \mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c_0)))$) or item 5 (for $Q = Q_A$) of Theorem A.51, the

conclusion of the two-pass producer theorem holds for the concrete two-pass system with $\mathrm{BP}, Q, Q', \mathrm{Ex}, \tau, V, M, \Pi$. Let ε_0 be its constant, decreased if necessary below $\frac{1}{52}$. Given $\varepsilon, C_8, C_5, c_6, C_b$ take its threshold family $\mathbf{K}_0$; given $\mathbf{C}$ take its c_1 and replace it by $\max(c_1, 0)$; given c_D take its c_2 and replace it by $\max(c_2, 402)$; given c_h let x_0 be the maximum of: its x_0; the thresholds of the existence theorem for good pre-character data (for $\varepsilon, \mathbf{C}, c_D, c_h, C_5, c_6, C_b$), of the existence theorem for level choices (for ε), of the record-part construction and of Proposition A.18 (for $\varepsilon, \mathbf{C}, c_D, c_h$), and of Proposition A.53 (for $\varepsilon, \mathbf{C}, c_D, c_h, C_5, c_6, C_b$). All of these are chosen before x, the witness and the member.

Let $x \geq x_0$, $J \geq 1$, a witness and $a, b, \Omega, \omega_0, c$ as in the statement be given. By the existence theorem for good pre-character data, which holds for all such $a, b, \Omega, \omega_0, c$, there are Harish-Chandra parameters such that $(x, \varepsilon, J, \mathbf{C}, c_D, c_h, \mathfrak{P}, q_0, a, b, c)$ satisfies (Cx1)–(Cx3) with $\Gamma = \exp(C_\Gamma m^5 f L)$ and the goodness clauses for (C_5, c_6, C_b). By the conclusion of the two-pass producer theorem, $d_\omega(\mathfrak{P})$ is a positive integer and $mL \leq \log \theta_\omega$ for every word, with $d^* = d(\mathfrak{P})$, $D^* = D(\mathfrak{P})$. So the existence theorem for level choices gives a level choice $\mathrm{Lv} = (T, \pi_T, d(\mathfrak{P}), D(\mathfrak{P}), \exp(C_\Gamma m^5 f L))$ for $\mathfrak{P}$. Again by the conclusion of the two-pass producer theorem, K is a context, hence a context good for (C_5, c_6, C_b) (the goodness clauses hold), and there are $D, Y, P, B, X, f, \mathsf{T}, c'$ with the listed properties. For every word ω, $m \geq 1$ and (Lv3) give $\log X'(\mathfrak{s}) = x^{\varepsilon/3} \leq x^\varepsilon = L \leq mL \leq \log \theta_\omega \leq \log T(\omega)$, so $X'(\mathfrak{s}) \leq T(\omega)$. Since $\Pi(K, D, Y)$, $x \geq x_0$ and $X'(\mathfrak{s}) \leq T(\omega)$ for all ω, the record-part construction gives a record part $(L, I, (N^{\mathrm{gl}}_\omega)_\omega)$ of Y, and Proposition A.18 gives (a)–(e) for it (the size datum of its member is L with its lattices and lengths set; (a)–(e) concern only K and the scale, top numbers, validity values and support of L, which the member keeps). Finally Proposition A.53 applies to the witness, $a, b, \Omega, \omega_0, c$, the parameters, Lv, K, D, Y and the record part, and gives (Mc1)–(Mc5); with $\Pi(K, D, Y)$ (which contains (La4)), $M(D)$ (M is the stability of the spaces $\mathcal{M}_t$, item 4 of Theorem A.51) and, when τ is "all twists good", $\tau(D, O(Y))$, (Mc5) gives the last assertions.

The conclusion of the record-part construction on the supplied instance is obtained before the member is formed. Use its I, $\mathrm{Gy}(O(Y))$, gathering ties and constants as the readings of the supplied part. The member operation retains these components, the scale, top table, lift weights, fillings and local F-values. Its four displayed equations therefore remain valid, unchanged, on the member. The underlying object and its theta and kernel data are unchanged, so the already established Q', τ and object identities are unaffected. □

Proposition A.53. *Let $0 < \varepsilon < \frac{1}{52}$, $\mathbf{C}$ an admissible constant family, $c_D \geq 0$, $c_h \geq 402$ and $C_5, c_6, C_b > 0$. There is x_0 such that the following holds for every $x \geq x_0$ and $J \geq 1$. Let a complete witness of $\mathfrak{G}(x, \varepsilon, J, \kappa, \mathfrak{h}, T, t)$, $\kappa = (C_{T_2}, C_8, C_5, c_6, C_b)$, be given, with rank datum $\mathfrak{R}$, host data, primes g_1, g_2, p_1, p_2, q_0, spacing set S and $u_0 \in A$; let $a, b, \Omega, \omega_0, c$ and Harish-Chandra parameters be as in the existence theorem for good pre-character data, with pre-character datum $\mathfrak{P}$; let* Lv *be a level choice for $\mathfrak{P}$ such that $K = (x, \varepsilon, J, \mathbf{C}, c_D, c_h, \mathfrak{P}, q_0, a, b, c, \mathrm{Lv})$ is a context and $X'(\mathfrak{s}) \leq T(\omega)$ for every word ω. Let D be an assembled datum over K, Y a layered datum on D with $\Pi(K, D, Y)$, $(L, X, (N^{\mathrm{gl}}_\omega)_\omega)$ a record part of Y as given by the record-part construction, and $(D^\natural, L^\natural, X, Y)$ its member. Then:*

(Mc1) Provenance. *$D^\natural$ is built over $\mathfrak{P}$ (so with the rank datum $\mathfrak{R}$, the host data, the auxiliary primes g_1, g_2, the distinguished primes p_1, p_2 and the words Ω of the witness and of that existence theorem, the word ω carrying the code $c(\omega)$) with the level primes of* Lv*, which contain $\{g_1, g_2, p_1, p_2, q_0\}$; K satisfies (Cx3) with the tops T, the spacing set S and the element u_0 of the witness; and the top numbers of $L^\natural$ at a top $t' \in T$ are $a(t'), b(t')$.*

(Mc2) Host arithmetic. *For $i = 1, 2$ there is $\pi_i \in \mathcal{O}_E \cap K$ with $\pi_i \bar{\pi}_i = g_i$, and $g_i \equiv 1 \pmod{N_\mathfrak{h}}$; p_1, p_2 split completely in E; every level prime of $D^\natural$ (that is, of* Lv*) splits in*

K.

(Mc3) Tame and Minkowski conditions. *(La2)(e) and the Minkowski choice of D_Γ in (La2)(f) hold for $D^\natural$.*

(Mc4) The auxiliary level prime. *q_0 is a level prime of $D^\natural$, $q_0 \equiv 1 \pmod{\ell_0 N_\mathfrak{h}}$ with ℓ_0 as in (Hg5), and*

$$\log q_0 \le L(\mathfrak{s}), \qquad q_0 < X'(\mathfrak{s}),$$
$$q_0 \le W_{\mathrm{tg}}(L^\natural) := \frac{m\, b(\mathfrak{s})\, x^{\varepsilon}}{k\,(m+t)\,\log\bigl(3(b(\mathfrak{s}) + S_c + \eta_S + t + 1)\bigr)},$$

with S_c, η_S those of $L^\natural$ and k, m, t those of $\mathfrak{R}$; moreover $q_0 \notin \{p_1, p_2, g_1, g_2\}$ and $q_0 \neq T(\omega)$ for every word ω.

(Mc5) Tuples, stability, twists. *(La4) holds for $D^\natural$; if the spaces $\mathcal{M}_t$ of D are stable, so are those of $D^\natural$; and if D with the twist packs and the theta record of $O(Y)$ has all twists good, so has $D^\natural$ with the same object.*

Proof. Outline. The member changes only the divisor lattices and word heights of D and the lengths and lattices N_ω of L, so (Mc1), (Mc3) and (Mc5) follow because the conditions involved read only retained data; (Mc2) follows from (Hg5) and the norm equation of the Gauss primes, which makes them split in K; and (Mc4) follows from the size bounds of (Hg5), (Hg6) and the bounds of Proposition A.18 for k, t, S_c, η_S, combined with elementary growth inequalities in x. □

A.5.2 The first pass

The first pass, (H2) for the concrete system, is Proposition A.54: over every forced untwisted datum, the stage steps lead to a core with the slot Built. Its proof is a short assembly of the stage steps, which the following sketch describes.

Sketch: the stage steps of the first pass. A state records, level by level, the data chosen so far: a row of theta series at the first levels, then a saturated state with its coefficient order and normalised theta generators, then a measured Hida setting with transports at the third level, and the fourth level on top of it. At the fourth level a core is assembled and receives the slot Built; theta data with record functions, whose multiplicities are Petersson-isometric, and ambient and divisor data complete it. Each step asks for finitely many new objects (levels, characters, discrete series models, theta lifts at a given level, integral structures) chosen compatibly with the earlier ones. Heuristically each step should hold because the objects it asks for exist individually by classical results: discrete series models of given level and signature, theta lifts of them at controlled level, and integral structures on finite-dimensional spaces of automorphic forms. The work is to make the choices compatible and uniform in the context, and the compatibility conditions are finitely many closed conditions, each met above a threshold. The climb from a saturated state at the third level to a record of level three, and the assembly of the Built core at level four, carry most of this bookkeeping.

Proposition A.54. *Let $c \in \mathbb{R}$ and $\mathfrak{S} = \mathfrak{S}(\mathcal{N}_{\mathrm{or}}(c))$. Eventually in K, for large data (B, f, T) at K: if $\mathrm{BP}(B, f)$, T is forced at K and T is untwisted, then there are a column datum w over (B, f, T), a state Z of w and a core over $(K, (B; C(w), Z), f, T)$ that is Built with canonical entries for $\mathfrak{S}$ at (w, Z).*

Proof. Step 1: stage steps compose. Let p, q, r be properties of tuples (K, B, f, T, w). (a) If p implies q for every tuple, then $p \Rightarrow q$ is a stage step (it holds at every context, with every demand). (b) If $p \Rightarrow q$ and $p \Rightarrow q'$ are stage steps, so is $p \Rightarrow q \wedge q'$; (c) if $p \Rightarrow q$ and $q \Rightarrow r$ are stage steps, so is $p \Rightarrow r$. For (b) and (c): the sets of contexts at which the two statements hold belong to the filter of "eventually", hence so does their intersection; at such a context K the two large-data statements hold for all triples meeting demands $\rho_1 = (S_1^1, P_1^1, A^1, S_2^1)$ and $\rho_2 = (S_1^2, P_1^2, A^2, S_2^2)$. The argumentwise union $\rho = (S_1^1 \cup S_1^2, P_1^1 \cup P_1^2, A^1 \cup A^2, S_2^1 \cup S_2^2)$ is a demand (finite unions of finite sets of algebraic numbers, of finite sets of primes and of avoidance maps), and a triple meeting ρ meets ρ_1 and ρ_2: containment passes to subsets, $P_1^i \subseteq P_1^1 \cup P_1^2 \subseteq \mathrm{pl}(T)$, and $A^i \leq A^1 \cup A^2$, so T avoids A^i by (Tp3). For such a triple with $\mathrm{BP}(B, f)$ and T forced, a column datum with p has q and q' (case (b)), resp. has q and therefore r (case (c)).

Step 2: the chain of stage steps. The start property implies "pinned" (by definition), so by (a) start $\Rightarrow$ pinned is a stage step. By the stage proposition from the start to level three, start $\Rightarrow \mathrm{Has}_3(\mathfrak{S})$; with (b), start $\Rightarrow$ pinned $\wedge\, \mathrm{Has}_3(\mathfrak{S})$. By the same proposition, $\mathfrak{S}$ satisfies the level-three move condition, so the stage proposition from level three to level four (through the archimedean spectral setting) gives pinned $\wedge\, \mathrm{Has}_3(\mathfrak{S}) \Rightarrow \mathrm{Has}_4(\mathfrak{S})$; by (c) and (b), start $\Rightarrow$ pinned $\wedge\, \mathrm{Has}_4(\mathfrak{S})$. By the divisor, ambient and start proposition and the existence of theta data over every level-four record, $\mathrm{AmbEx}(\mathfrak{S})$, $\mathrm{DivEx}(\mathfrak{S})$ and $\mathrm{ThEx}(\mathfrak{S})$ hold, so the proposition constructing the core from level four gives pinned $\wedge\, \mathrm{Has}_4(\mathfrak{S}) \Rightarrow \mathrm{Has}_C(\text{Built with canonical entries for } \mathfrak{S})$. By (c),

$$\text{start} \implies \mathrm{Has}_C(\text{Built with canonical entries for } \mathfrak{S})$$

is a stage step.

Step 3: a column datum with the start property. The statement of Step 2 and the existence of column data with the start property (from the divisor, ambient and start proposition) both hold eventually and for large data; as in Step 1, both hold at every context of one set of the filter, for every triple meeting one demand. For such a triple (B, f, T) with $\mathrm{BP}(B, f)$, T forced and untwisted, the divisor, ambient and start proposition gives a column datum w over (B, f, T) with the start property, and Step 2 gives $\mathrm{Has}_C(\dots)$ at w: a state Z of w and a core over $(K, (B; C(w), Z), f, T)$ that is Built with canonical entries for $\mathfrak{S}$ at (w, Z). □

A.5.3 Discrete series, formal degrees and masses

The spectral input at the members is classical, and the results here are proved. Under the gap hypothesis every Hida setting has the decay property and an integrable archimedean test function (Proposition A.55). Harish-Chandra's existence theorem and formal degree formula for discrete series [119], in the normalisation of the compact dual, are Theorem A.58, and Schur orthogonality holds for multiplicity maps of realised data (Proposition A.57). Together they make evaluation at the vector matching the lowest K-type an exact map of row multiplicity maps onto the conjugate rows (Proposition A.56). Finally, for every based hermitian space of constant signature, volumes are masses (Proposition A.59); this gives (H5) and the count identity.

Proposition A.55. *Let D be an assembled master datum with the gap hypothesis and X a Hida setting for D. Then X has the decay property and its archimedean test function ϕ_X is integrable for μ_∞.*

Proof. Outline. The decay property follows from the decay proposition for Hida settings, and integrability of ϕ_X from the integrability of discrete-series test functions, whose hypotheses

(Harish-Chandra parameters, lowest K-types and the opposite-sign gap of (Sp8)) are checked at every archimedean place. □

Proposition A.56. *Let D be an assembled master datum with the gap hypothesis, $(R, \Phi_2, e_{\mathcal{E}})$ a row package of D whose level characters are those of the tuple μ_0 and such that R has models, X a Hida setting for D whose instance is the standard instance of D and which pins E, and $t \in \mathbf{G}(\mathbb{A})$ a finite point at which R is visible in X. Then there is a unit vector $v_0 \in \prod_\tau \mathcal{H}_\tau^\infty$ such that*

1. *for every $T \in \mathrm{M}_R^{\mathrm{row}}$ and every $f \in L_X^2$ with $f(y) = T(v_0)(\iota_X^{-1}(y)\, t)$ for μ_X-almost every $y \in \mathcal{F}_X$, one has $f \in \overline{\mathrm{H}}_X^{\mathrm{row}}$;*
2. *for every $f \in \overline{\mathrm{H}}_X^{\mathrm{row}}$ there is $T \in \mathrm{M}_R^{\mathrm{row}}$ with $f(y) = T(v_0)(\iota_X^{-1}(y)\, t)$ for μ_X-almost every $y \in \mathcal{F}_X$.*

Proof. Outline. Harish-Chandra's conjugate-parameter and uniqueness theorems give antiunitary intertwiners that define v_0; Schur orthogonality makes the operator of ϕ_X times the level idempotent a projector with the matrix-coefficient identity, which attaches to each row vector an intertwiner from the discrete series, cuspidal because the constant terms of discrete-series matrix coefficients vanish; assertion 2 then follows from the bijection between such intertwiners and multiplicity maps, and assertion 1 from the Schur orthogonality of Proposition A.57 and the same projector. □

Proposition A.57. *Let D be an assembled master datum and $(R, \Phi_2, e_{\mathcal{E}})$ a row package of D such that R has models. Then for every $T \in \mathrm{M}_R^{\mathrm{row}}$:*

1. *for all $v, v' \in \prod_\tau \mathcal{H}_\tau^\infty$ the function $g \mapsto \overline{T(v)(g)}\, T(v')(g)$ is ν_R-integrable on $\mathcal{F}_R$;*
2. *there is $a \in \mathbb{C}$ such that $\int_{\mathcal{F}_R} \overline{T(v)}\, T(v')\, d\nu_R = a \prod_\tau \langle v_\tau, v'_\tau \rangle$ for all $v, v' \in \prod_\tau \mathcal{H}_\tau^\infty$.*

Proof. Outline. One realises the discrete series of the row package as a discrete series model of Y_0, checks condition by condition that every $T \in \mathrm{M}_R^{\mathrm{row}}$ is a multiplicity map of this model with the row level character, and applies Schur orthogonality for multiplicity maps to the Haar pair $(\nu_R, \mathcal{F}_R)$. □

Theorem A.58. *Let $N \geq 1$, $\varepsilon \in \{\pm\}^N$ and $\lambda \in \mathbb{R}^N$ strictly decreasing with $\lambda_a - \frac{N-1}{2} \in \mathbb{Z}$ for all a.*

1. *There is a discrete series of G_ε with parameter λ.*
2. *Let* cd *be a compact-dual Haar family and* sc *a scale for* cd*. Then for every discrete series σ of G_ε with parameter λ, $\mathrm{d}_{\mathrm{HC}}(\lambda)$ is a formal degree of σ for $\mathrm{sc}(N, \varepsilon)\, \mu_\varepsilon$.*

Proof. Outline. Both parts are Harish-Chandra's existence theorem and formal degree formula for discrete series in the compact-dual normalisation, once the scaled measure $\mathrm{sc}(N, \varepsilon)\, \mu_\varepsilon$ is identified with the compact-dual Haar measure by transporting the invariant holomorphic top form along conjugation by the permutation matrix that orders the signs. □

Proposition A.59. *Let E/F be a CM extension of number fields unramified at every finite place,* cd *a compact-dual Haar family and* vol *a function on based hermitian spaces over E such that* $(\mathrm{cd}, \mathrm{vol})$ *has the volume tie. Then $\mathrm{vol}(W) = \mathrm{mass}_E(n)$ for every based hermitian space W over E of rank n with $\mathrm{sig}_\tau(W) = (P, Q)$ for every τ (the same pair (P, Q) for all τ).*

Proof. Let W be a based hermitian space of rank n with $\mathrm{sig}_\tau(W) = (P, Q)$ for every $\tau \in \Phi$, and $W_0 = E^n$ with the standard basis, Gram matrix 1_n and base lattice $\mathcal{O}_E^n$, a definite based hermitian space of rank n. We show $\mathrm{vol}(W) = \mathrm{vol}(W_0)$; since $\mathrm{cd}_{N,0}$ is a probability measure for every N (Sp1), the definite case of the volume–mass identity gives $\mathrm{vol}(W_0) = \mathrm{mass}_E(n)$. Fix Ω_0 as in the local volume formulas for the Gram-twisted top form and let $d = |\Phi| = [F : \mathbb{Q}]$.

The archimedean constants. Let $\tau \in \Phi$. All invariant complex top forms on $\mathfrak{gl}_n(\mathbb{C})$, the common complexified Lie algebra of $\mathrm{U}(P', Q')$ ($P' + Q' = n$), are complex multiples of $\Omega^\tau_{\mathbb{C}}$, and multiplying the form by $z \in \mathbb{C}^\times$ divides all densities against it by $|z|$. Hence (Sp1) says: for every $P' + Q' = n$ there is $c \in (0, \infty)$ with $\mathrm{cd}_{P',Q'} = c\,\nu^\tau_{P',Q'}$ and $\mathrm{cd}_{n,0} = c\,\nu^\tau_{n,0}$. The second equation determines $c = c_\tau$ independently of (P', Q'):

$$\mathrm{cd}_{P',Q'} = c_\tau\,\nu^\tau_{P',Q'} \qquad (P' + Q' = n,\ \tau \in \Phi). \tag{A.5}$$

The Tamagawa measure is a fixed multiple of the volume measure. Let $W' \in \{W, W_0\}$, of signature (P', Q') at every τ, with Gram matrix Γ' and $\delta = \det \Gamma' \in F^\times$. By the volume tie (Vm2) there are a volume measure $\mu_{W'}$ for W' relative to cd and a measurable fundamental domain $\mathcal{F}_{W'}$ of $\mathrm{U}(W')(F)$, and $\mathrm{vol}(W') = \mu_{W'}(\mathcal{F}_{W'})$. Choose A_τ with $A_\tau^* J_{P',Q'} A_\tau = \tau(\Gamma')$ (Sylvester), Borel sets $B_\tau \subseteq \mathrm{U}(P', Q')$, and put $B_\infty = \{h_\infty :\ A_\tau \tau(h_\tau) A_\tau^{-1} \in B_\tau\ (\tau \in \Phi)\}$. The stabiliser $K_{\mathrm{f}}(W') = \prod_{v<\infty} K_v(W')$ of $\widehat{L_0(W')}$ is open in $\mathrm{U}(W')(\mathbb{A}_{F,\mathrm{f}})$. By the construction of the Tamagawa measure (absolute convergence of its local factors and the product formula defining it) with $\omega = \omega_{W'}$, then the local volume formulas for the Gram-twisted top form and (A.5),

$$\begin{aligned}
\tau_{\mathrm{U}(W')}\big(K_{\mathrm{f}}(W') \times B_\infty\big) &= |d_F|^{-n^2/2} L(1,\chi)^{-1} \prod_{v<\infty} \lambda_v |\omega_{W'}|_v(K_v(W')) \\
&\quad \cdot \prod_{\tau\in\Phi} |\omega_{W'}|_\tau\big(\{h_\tau : A_\tau \tau(h_\tau) A_\tau^{-1} \in B_\tau\}\big) \\
&= |d_F|^{-n^2/2} L(1,\chi)^{-1} \prod_{v<\infty} \lambda_v |\omega_{W_0}|_v(K_v(W_0)) \\
&\quad \cdot \prod_{v<\infty} |\delta|_v^n \prod_{\tau\in\Phi} |\tau(\delta)|^n \cdot \prod_{\tau\in\Phi} c_\tau^{-1} \mathrm{cd}_{P',Q'}(B_\tau).
\end{aligned}$$

The splitting of the infinite product is legitimate because $|\delta|_v = 1$ for almost all v, and the product formula for $\delta \in F^\times$ gives $\prod_{v<\infty} |\delta|_v \prod_\tau |\tau(\delta)| = 1$ (the real places of F are the restrictions of $\tau \in \Phi$, each once). With

$$\Lambda = |d_F|^{-n^2/2} L(1,\chi)^{-1} \prod_{v<\infty} \lambda_v |\omega_{W_0}|_v(K_v(W_0)) \prod_{\tau\in\Phi} c_\tau^{-1} \in (0, \infty)$$

(positive by the absolute convergence of the local factors), which depends on E/F, n, Ω_0 and cd but not on W', and by (Vm1),

$$\tau_{\mathrm{U}(W')}\big(K_{\mathrm{f}}(W') \times B_\infty\big) = \Lambda \prod_\tau \mathrm{cd}_{P',Q'}(B_\tau) = \Lambda\,\mu_{W'}\big(K_{\mathrm{f}}(W') \times B_\infty\big).$$

Taking for each B_τ a compact neighbourhood of 1, the set $K_{\mathrm{f}}(W') \times B_\infty$ has positive finite Haar measure, so by uniqueness of Haar measure $\tau_{\mathrm{U}(W')} = \Lambda\,\mu_{W'}$.

Conclusion. The Tamagawa number of a unitary group is 2 [269], [195], [150]: $\tau_{\mathrm{U}(W')}(\mathcal{F}_{W'}) = 2$. Therefore $\mathrm{vol}(W') = \mu_{W'}(\mathcal{F}_{W'}) = 2/\Lambda$ for both $W' = W$ and $W' = W_0$. Hence $\mathrm{vol}(W) = \mathrm{vol}(W_0) = \mathrm{mass}_E(n)$. □

A.5.4 Export and the second pass

The export property (H3) asks for one universal twist function N_0 with the conditions (Ex1) and (Ex2) attached to the actual theta datum (Proposition A.60). The second pass (H4) asks for a simultaneous twist and point lift, a reference-preserving extension of the realised data, and one new core that meets uniform demands (Proposition A.61). Its main input is the reference-preserving coefficient enlargement Proposition A.62. The reason the reference estimates survive the enlargement is that the second pass keeps the geometric core, the reference models, the vacuum, the theta maps and the small rational coordinate space literally, so that the signed indices scale exactly, $I'(v') = e(v'/v)\, I(v)$ (item 5 of Proposition A.62). All three statements are given with sketches.

Proposition A.60. *For an assembled datum D and an object O, let* $\mathrm{Ex}(D, O)$ *mean the following two assertions, for the integral Hecke-form datum E_O of the theta datum* $\mathrm{xd}(O)$.

(Ex1) *There is one function N_0 assigning a nonnegative integer to each twist situation i of D, such that at every nonzero index situation i: if its Bloch–Kato set condition holds, then for every $\epsilon' > 0$, every choice of finite sets $\mathcal{S}(j, b)$ indexing bases of the full-rank Hecke-form subspaces of E_O ($1 \le j \le m$, $b \in \{0, 1\}$), and every finite set A of places of the host field, there are a finite set Q of split places, an integer $k' \ge 0$ and a character ψ of the corresponding ray-class quotient, with values in the k'-th coefficient extension at i, such that every power ψ^a with $\gcd(a, \ell_i) = 1$ is a good twist for these same $N_0, \epsilon', \mathcal{S}, A, Q, k'$.*

(Ex2) *There is one family of finite sets $\mathcal{S}(i, j, b)$ such that for every place w with $\mu_{\mathrm{at}}(w) \neq \mu_0$, the Bloch–Kato set condition holds at the situation $i(w)$ read from* $\mathrm{nch}(O)$, *and the twist input $(E_O, N_0, \mathcal{S})$ is admissible at $i(w)$ in the sense of (Xh5): all its prescribed Hecke-form subspaces have full rank and the corresponding sets $\mathcal{S}(i(w), j, b)$ index bases of them.*

Fix a parameter p whose norm choices carry the full extension law. Put

$$Q = \mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p)).$$

Then (H3) of Theorem A.49 holds for this Q and Ex*: eventually in the context K, for large data (B, f, T) at K, if* $\mathrm{BP}(B, f)$ *and T is untwisted, then* $\mathrm{Ex}(D(X), O(c))$ *for every stage tuple X over B and every core c with $Q(K, X, f, T, c)$. The same N_0 and the same admissible basis sets are used in (Ex1) and (Ex2).*

Proof. Sketch. The proposition is the export condition (H3) of Theorem A.49 for the concrete two-pass system of Theorem A.51: every core produced by the first pass (Proposition A.54) must carry one twist input, built from its own theta datum, that the second pass can use. Clause (Ex2) is a finiteness and admissibility assertion: at each twisted place the Hecke-form subspaces cut out of the integral Hecke-form datum E_O must have full rank, and finite sets indexing bases of them must be fixed once and for all, together with the Bloch–Kato set condition at the situations $i(w)$. Heuristically this should follow from the integrality of the theta datum: the normalised Hecke operators preserve the integral sections (Lemma A.30), so the Hecke-form subspaces should be lattices of full rank in their rational spans, and finitely many basis indices can then be chosen.

Clause (Ex1) is the substantial one. For one threshold function N_0, fixed in advance, and for every finite set A of places, one needs a finite set Q of split places and one ray-class character ψ of ℓ-power order, ramified only at Q, such that the Bloch–Kato Selmer group [34] of each twisted representation $\psi_s^{-1}\chi_s^{-1}\rho_s$ of a good signature s, with unrestricted conditions at Q, has

normalised length at most $\nu_\ell + \varepsilon_T(s)$, where ν_ℓ is the cyclotomic valuation of the host field and $\sum_s \varepsilon_T(s) \le \ell^{-2}$ (Definition A.104). The argument should run as in the classical constructions of auxiliary twists: by the Chebotarev density theorem [65] there are infinitely many split places outside A with prescribed Frobenius behaviour, and a character ramified at a suitable finite set of them should cut the Selmer group of the twist down to the part forced by the ℓ-power roots of unity, which ν_ℓ measures. That a single ψ serves all its powers ψ^a with $\ell \nmid a$ is heuristically automatic once the coefficients of ρ_s, χ_s and of the local conditions lie in a field linearly disjoint from the values of ψ: the automorphism $\zeta \mapsto \zeta^a$ of the coefficient extension then fixes all the data except ψ, sends ψ to ψ^a, and preserves Selmer lengths.

The local Hecke inputs of this construction (the exact complex reading of the geometric Hecke transform, the preservation of integral sections and the bound for the denominators of theta values) are proved, but they do not by themselves give (Ex1) or (Ex2). It remains to construct the twist with one threshold function valid for all twist situations, to attach it to the actual theta datum and numerical choice of each first-pass core, and to verify the remaining clauses of goodness: admissibility of the character, the Hecke-lattice index and inclusion conditions, and the theta-value and tame-valuation conditions. The Selmer bound obtained in this way is the input from which Proposition A.108 produces the Selmer allowances of the members in Theorem A.105. □

Proposition A.61. *Fix a parameter p whose norm choices carry the full extension law. Fix an arbitrary large-base slot R over $\mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p))$ in the sense of (Rk7) of the definition of parameters and their slot systems; R is fixed before all choices of the second pass. Put*

$$Q = \mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p)), \qquad Q' = \mathrm{Good}_{\mathrm{E}}(\mathfrak{S}(p)) \wedge R.$$

For a pair (D, O) put $\tau(D, O)$ equal to the assertion that $(D, \mathrm{nch}(O), \mathrm{xd}(O))$ has all twists good, including the conjugation conditions in (Xh5). Then (H4) of Theorem A.49 holds for these Q, Q', Ex, τ.

Explicitly, eventually in the context K, for large data (B, f, T) at K with $\mathrm{BP}(B, f)$ and T untwisted, the following assertion holds. Given a stage tuple X over B and a core c with

$$Q(K, X, f, T, c), \qquad \mathrm{Ex}(D(X), O(c)),$$

for every avoidance map A and every map S_2 from subsets of $\mathfrak{X}(P)$ to finite sets of algebraic numbers there are an enlargement B' of B, a twisting datum T' over B', a stage tuple X' over B' and a core c' such that

$$\mathrm{pl}(T') = \mathrm{pl}(T), \qquad T' \text{ avoids } A, \qquad S_2(\Xi(f, T')) \subseteq F_{\mathrm{L}}(B'),$$

$$Q(K, X', f, T', c'), \qquad Q'(K, X', f, T', c'), \qquad \tau(D(X'), O(c')).$$

The pre-base and frame are those of B; the enlargement retains the exact and fixed embedded fields and enlarges the ambient coefficient field. The construction of c' keeps the reference models, the vacuum and both theta maps of c, through Proposition A.62. All data in the conclusion belong to the one new core c'. No positivity of the dimensions of the definite form spaces is imposed.

Proof. Sketch. The proposition is the second-pass condition (H4) of Theorem A.49. From a first-pass core c that is Built with canonical entries and satisfies the export property of Proposition A.60, one must produce, after an enlargement of the coefficient field, one new core c' that is again Built, is Good, has the prescribed large-base slot R, and has all twists good. The argument should run in four steps.

First, at each twisted place choose, through (Ex1), one character ψ all of whose powers prime to ℓ are good twists, with its auxiliary split places outside the requested avoidance set, and adjoin its values and the finitely many requested algebraic numbers to the ambient coefficient field, keeping the pre-base, the frame and the exact and fixed fields; this gives the enlargement B' and a twisting datum T' with $\mathrm{pl}(T') = \mathrm{pl}(T)$. Second, transport the realised row data to the enlarged field by Proposition A.62. That transport keeps the geometric core, the reference models, the vacuum and both theta maps, and multiplies the signed reference indices by the ramification indices, so the places of nonzero index correspond, also when the definite form spaces are zero. Third, lift the pinned point and its state over the enlarged field and rebuild, in order, the level-three record (by promoting the kept numerical choice with its original pre-state, level and saturation data), the level-four record, the ambient, divisor and theta data, and from these three inputs the core with canonical entries. Fourth, replace the numerical choice inside this one Built record by one with the good-twist property: by the definition of the slots this gives Good while keeping the original canonical kernel entries, and the conjugation conditions with the same admissible twist input give all twists good. Since R is fixed before all choices, its finite field, prime and avoidance demands can be added to the requests by finite unions, and the new core then has R as well.

The reductions in the third and fourth steps and the finite-demand argument are proved, but they rest on Proposition A.62 and on stage constructions of the first pass whose proofs are not complete, and they need the finiteness statement for the kept numerical choice in a form with arbitrary spectral and geometric arguments. It remains to construct the simultaneous twisting datum and the lift of the point and state over the enlarged field, all attached to the one chosen character, and to assemble one context tail and one large-data demand from the finitely many construction demands. Heuristically the construction is a base change: the enlargement changes only the coefficient field and the twist characters, the geometric objects are defined over the exact field, which does not change, and the twists are chosen at split places outside a finite set, of which there are always enough. □

Proposition A.62. *Eventually at all contexts K, for large data (B', f', T') over K, the following holds for every pinned column datum w' over (B', f', T').*

Let (B, f, T) be over the same context, with the same pre-base and frame, and let w be pinned over (B, f, T) with the same pre-extension as w'. Assume

$$F_{\mathrm{ex}}(B') = F_{\mathrm{ex}}(B), \qquad F_{\mathrm{fix}}(B) \subseteq F_{\mathrm{fix}}(B'), \qquad L = F_{\mathrm{L}}(B) \subseteq L' = F_{\mathrm{L}}(B').$$

Let Z be a state of w, with its exact field datum and group compatibilities, and let W_t be a set of places of L. Suppose realised row data $\mathcal{R}$ over $(D(w, Z), I, T, W_t)$ are given with:

1. *their real data R analytically characterised, their geometric half analytically characterised, their geometric core canonical with the prescribed coefficient ring and frame, their standard definite bridges, and positive-dimensional moduli host spaces;*

2. *the standard row-realisation premises: the right and left Hecke lattices are good with rational inert adjoints; the Hecke, group-unitarity and group-equivariance laws; the block law; both lift tests; the conditional lift-onto law; uniformisation; the full member-lattice law; the level law for the W-spaces; the theta theorem law; the parts law; the auxiliary choice laws; and admissibility at 1 with type separation.*

No positivity of the dimensions of the automorphic form spaces is assumed.

For every state Z' of w' with its exact field datum, the group compatibility with f' and I', and the volume tie, there are realised row data $\mathcal{R}'$ over

$$(D(w', Z'), I', T', W'_t), \qquad W'_t = \{v' \in \mathrm{Pl}(L') : \mathrm{reschar}(v') \in \mathrm{pl}(T')\},$$

whose real data and geometric half are analytically characterised, whose real data R' satisfy the group law (chiW) of (Xl2b)(j) in the definition of realised row data, and whose definite bridges are standard, with the following simultaneous compatibilities.

1. *The exact field F_c, moduli host, level objects, coefficient datum, schemes, all uniformisations, host spaces, dictionaries, functions μ, compact levels, component constants, characters χ_W, base points and lattice maps of the geometric core are the same as for $\mathcal{R}$. Only its embedding into L' is extended. The pinned exact coefficient ring is unchanged up to its unique embedded-field identification.*

2. *The additive character, archimedean embedding family, self-dual host lattices, level matrices, auxiliary group places, placewise group embedding, complex coefficient spaces of the V_i and their representations, fixed column vacua, column Fock bilinear maps and column coefficient matrices are the same as for $\mathcal{R}$. For every embedding $\sigma' : L' \hookrightarrow \mathbb{C}$, the discrete-series model, its action, inner product, signs, frame, extremal-vector indexing and host Hilbert module are the old ones at $\sigma'|_L$. The Haar measures and fundamental domains of the W_i-models are retained; the reference definite-side measures are retained as specified next.*

3. *At the reference tuple μ_0 the column Weil representation, its chosen Schwartz vector, the definite Hilbert model, its Haar measure and fundamental domain, and both theta maps are those of $\mathcal{R}$. The complex readings of the definite form maps agree on every pair of base-tuple coefficient functions with identical embedded polynomial values.*

4. *The integers $n_W(i)$ and the geometric weights and degrees $\kappa_i = (a_{P,i}, a_{M,i}, n_i)$ are unchanged. In the coordinate spaces $L^{n_W(i)} \subseteq (L')^{n_W(i)}$, the small F_c-rational coordinate space is*

   $$\mathrm{FW}_i'^{F_c} = \mathrm{FW}_i^{F_c},$$

   as the image of $\mathrm{FW}_i^{F_c}$ itself, not its L'-span. For x in this space,

   $$j'_{i,\sigma'}(x) = j_{i,\sigma'|_L}(x).$$

   The points defining its local norms and those norms are the same, and the coordinate characters and group actions are extended coefficientwise. For every geometric cusp section s,

   $$e'_i(s) = e_i(s) \quad \text{in } (L')^{n_W(i)}.$$

   Consequently its distinguished complex reading and every coefficient coordinate agree with those of $\mathcal{R}$. The geometric extremal vector at σ' is the old one at $\sigma'|_L$.

5. *Let $v' \mid v$ be finite places, with ramification index $e(v'/v)$. At each row step the definite lift lattice, its hermitian form and its hermitian dual, and the reference theta-image and member lattices used in the signed indices are their $\mathcal{O}_{L'}$-coefficient extensions under the same reading maps. Thus each of the two signed relative indices I_i, J_i satisfies*

   $$I'_i(v') = e(v'/v) I_i(v), \qquad J'_i(v') = e(v'/v) J_i(v).$$

In particular the nonzero-index place set at zero error corresponds exactly:

$$v \in W_1(\mathcal{R}; 0) \quad \Longleftrightarrow \quad v' \in W_1(\mathcal{R}'; 0).$$

Here W_1 is the set obtained from the nonzero reference row indices and their conjugates. The same equivalence holds simultaneously at every place above v.

All the data in these conclusions belong to the one realised row $\mathcal{R}'$.

Proof. Sketch. The proposition says that realised row data survive an enlargement $L \subseteq L'$ of the coefficient field with the same exact field, with every reference object kept unchanged. The argument runs by transport along the inclusion $\iota\colon L \to L'$. Every complex embedding σ' of L' restricts to the embedding $\sigma'\iota$ of L, so all analytic objects at σ' (discrete-series models, frames, inner products and theta maps) can be taken to be the old ones at $\sigma'\iota$. The geometric core, with its exact field, moduli host, uniformisations and level structures, is carried over unchanged, only its embedding being extended; this transport, the preservation of the core and tie laws on the enlarged geometric half, and the retention of the level pins are proved.

The lattice part is pure coefficient extension. At a place $v' \mid v$ the lattices are the $\mathcal{O}_{L'}$-extensions of the old ones under the same reading maps, hermitian duality commutes with this flat extension, and for lattices $M \subseteq N$ the length of $\mathcal{O}_{L'_{v'}} \otimes (N/M)$ is $e(v'/v)$ times the length of N/M. This gives $I'_i(v') = e(v'/v)I_i(v)$ and $J'_i(v') = e(v'/v)J_i(v)$, so the places of nonzero index correspond, in rank zero as well (item 5). The integral reference comparison, the phase and short-theta comparisons, the convergence and cuspidal growth of the global theta integrals, their factorisation through finite relations and the smooth extension at the same level are also proved.

It remains to prove existence. The inner and last theta lifts, the projected chain map and the multiplicity-space theta map must be shown to exist for the enlarged data. The conjugate-linear model identification, the polynomial frame identification, the integer determinant shift and the compact splitting characters must be attached to the retained data. The characterised real data and geometric half must then be assembled simultaneously in one realised row, with one context tail for all the large-data demands. Heuristically nothing new should be needed: the characterisations of the real data and of the geometric half are analytic conditions read through complex embeddings, which all factor through L, so the old objects should satisfy them as they stand, and the only fresh choices, the splitting and auxiliary characters, are finite in number and constrained at finitely many places. This is the mechanism by which the reference estimates survive the second pass: the reference data are kept unchanged, and the signed indices scale by the ramification indices. □

A.6 Approximate orthogonality I: Gram blocks of Poincaré series

The slope inequality of the body of the paper needs the mean slope of the target lattice, not its maximal slope, and this comes from near-orthogonal frames (Theorem 14.2, Theorem 14.8). Alpöge describes the input as a bound for the norm of a suitably projected Poincaré series, an "approximate orthogonality of the columns of the integral structure" [4]. This section and the next supply it at the members. Each member carries a Poincaré frame realisation for every word, and the off-diagonal Gram blocks of these frames unfold exactly into term operators over double cosets (Lemma A.64, Lemma A.65). Near-orthogonality thus becomes an exact lattice-point problem with no error term. The row records (Ro1)–(Ro4) of Theorem 15.3, proved in the body, turn bounds for these operators into the row estimates (Rw1), and each kind of row

has its own control. Loop rows are bounded by Siegel products of local densities (Proposition A.66); non-generic rows by a point sum over B-points (Proposition A.67, with the point sum Proposition A.87 of Section A.7); and the main row needs a *lower* bound, obtained from density domination (Proposition A.68), whose archimedean factor is the engine place theorem A.78 and whose finite-place factor is a local theta majorant (Proposition A.69). Theorem A.71 collects the resulting records and kernel hypotheses at the packets, which is what the second item of Proposition A.2 reads.

A.6.1 Unfolding the Gram blocks

Definition A.63 attaches to a member Hida and Poincaré setting its Poincaré frame realisations. The inner product of two Poincaré series unfolds over double cosets (Lemma A.64), and in orthonormal coefficient bases the Gram blocks of a frame realisation are exactly the term operators of the double cosets (Lemma A.65). Both proofs are standard unfolding, and we give their ideas.

Definition A.63. Let $\mathfrak{X}$ be a member Hida and Poincaré setting and let frame data $(\mathcal{H}, D^*, (D_\omega, \kappa_\omega, A_\omega)_\omega)$ of a frame realisation be given, indexed by the same words ω. For a column system $(h_c)_{c\in R_\omega}$ of ω and $T \in \mathrm{Cu}_\omega$ let $T_c^\sharp \in V_\omega$ $(c \in R_\omega)$ be the vector with $\langle T_c^\sharp, v\rangle = T(v)(1, h_c)$ for all $v \in V_\omega$; the **coefficient product** of this column system is

$$\langle T, T'\rangle_{\mathrm{Cu}_\omega} = \sum_{c\in R_\omega} \langle T_c'^\sharp, T_c^\sharp\rangle_{V_\omega} \qquad (T, T' \in \mathrm{Cu}_\omega).$$

The frame data form a **Poincaré frame realisation** of $\mathfrak{X}$ if:

(Fj1) Trivial rational stabilisers. For every word ω and every $h \in H_\omega(\mathbb{A}_{F,f})$,

$$H_\omega(F) \cap hK_\omega h^{-1} = \{1\}.$$

(Fj2) Poincaré frames. For every word ω one has $\kappa_\omega = c_\omega^{-1}$, and there are a column system of ω and an orthonormal basis $(T_{\omega,i})_{1\le i\le D_\omega}$ of Cu_ω for its coefficient product such that

$$\langle A_\omega e_i, A_{\omega'} e_j\rangle_{\mathcal{H}} = \langle P_\omega T_{\omega,i}, P_{\omega'} T_{\omega',j}\rangle_{\mathcal{L}} \qquad (1 \le i \le D_\omega,\ 1 \le j \le D_{\omega'})$$

for all words ω, ω'.

Lemma A.64. *Let G be a locally compact second countable group with a left Haar measure μ, let $\Gamma \le G$ be a countable subgroup and $S, S' \le \Gamma$ subgroups. Let $R \subseteq \Gamma$ contain exactly one element of every double coset $S\gamma S'$ $(\gamma \in \Gamma)$, and for $r \in R$ put $S_r = S \cap rS'r^{-1}$. Let $D, D' \subseteq \Gamma$ satisfy $\Gamma = \bigsqcup_{\delta\in D} S\delta = \bigsqcup_{\delta\in D'} S'\delta$. Let $F_\Gamma, F_S \subseteq G$ and $F_r \subseteq G$ $(r \in R)$ be Borel sets such that every orbit Γx, Sx, $S_r x$ $(x \in G)$ meets F_Γ, F_S, F_r respectively in exactly one point. Let $f, g\colon G \to \mathbb{C}$ be Borel functions with $f(sx) = f(x)$ for $s \in S$ and $g(s'x) = g(x)$ for $s' \in S'$ $(x \in G)$, such that*

$$\sum_{r\in R} \int_{F_r} |f(x)|\,|g(r^{-1}x)|\,d\mu(x) < \infty \tag{A.6}$$

and $\sum_{\delta\in D'} |g(\delta x)| < \infty$ for every $x \in G$. Put $P_g(x) = \sum_{\delta\in D'} g(\delta x)$.

(i) P_g is Borel, does not depend on the choice of D', and $P_g(\gamma x) = P_g(x)$ for $\gamma \in \Gamma$, $x \in G$.

(ii) For every $r \in R$ the function $x \mapsto \overline{f(x)}\, g(r^{-1}x)$ is integrable on F_r, the function $\overline{f}P_g$ is integrable on F_S, and

$$\int_{F_S} \overline{f(x)}\, P_g(x)\, d\mu(x) = \sum_{r\in R} \int_{F_r} \overline{f(x)}\, g(r^{-1}x)\, d\mu(x),$$

the series converging absolutely.

(iii) If moreover $\sum_{\delta\in D} |f(\delta x)| < \infty$ for every $x \in G$ and $P_f(x) = \sum_{\delta\in D} f(\delta x)$, then $\overline{P_f}P_g$ is integrable on F_Γ and $\int_{F_\Gamma} \overline{P_f(x)}\, P_g(x)\, d\mu(x) = \int_{F_S} \overline{f(x)}\, P_g(x)\, d\mu(x)$.

(iv) Let $f_1, \dots, f_m$ and $g_1, \dots, g_n$ be Borel functions such that every pair $(f, g) = (f_i, g_j)$ satisfies all hypotheses above, including those of (iii). Then the matrix $M = \big(\int_{F_\Gamma} \overline{P_{f_i}}\, P_{g_j}\, d\mu\big)_{i,j}$ and the matrices $Y_r = \big(\int_{F_r} \overline{f_i(x)}\, g_j(r^{-1}x)\, d\mu(x)\big)_{i,j}$ $(r \in R)$ satisfy

$$\sum_{r\in R} \|Y_r\|_{\mathrm{HS}} < \infty \qquad \text{and} \qquad M = \sum_{r\in R} Y_r.$$

Proof. Sketch. This is the classical unfolding of an inner product of two Poincaré series, written with fundamental sets in place of quotient measures, so that no regularity of the quotients is needed. The core of the proof is an enumeration of $S'\backslash\Gamma$ through double cosets: if $\Sigma_r \subseteq S$ contains one element of each coset σS_r, then $(r, \sigma) \mapsto S' r^{-1}\sigma^{-1}$ is a bijection from the pairs with $r \in R$, $\sigma \in \Sigma_r$ onto $S'\backslash\Gamma$, so that

$$P_g(x) = \sum_{r\in R} \sum_{\sigma\in\Sigma_r} g(r^{-1}\sigma^{-1}x).$$

Integrating against $\overline{f}$ over F_S and substituting $x = \sigma y$, using the S-invariance of f and the left invariance of μ, turns the inner sum into an integral over $\bigsqcup_{\sigma\in\Sigma_r} \sigma^{-1}F_S$, which is again a fundamental set for S_r. A second elementary fact replaces this set by F_r: the integral of an invariant function does not depend on the fundamental set, because left multiplication is free and two fundamental sets are countable disjoint unions of translates of pieces of one another. For nonnegative functions the computation is justified by Tonelli's theorem; the summability assumption on $\sum_r \int_{F_r} |f(x)|\, |g(r^{-1}x)|\, d\mu(x)$ then gives absolute convergence and, by dominated convergence, the same computation for $\overline{f}$ and g. Part (iii) folds P_f in the same way, and (iv) is the entrywise version with $\sum_r \|Y_r\|_{\mathrm{HS}} < \infty$. The result is an exact identity with no error term: the matrix of inner products of Poincaré series is the absolutely convergent sum, over the double cosets $S\gamma S'$, of the terms Y_r. This is how near-orthogonality becomes a lattice-point problem in the row estimates of Theorem 15.3. □

Lemma A.65. *Let $\mathfrak{X}$ be a member Hida and Poincaré setting and let frame data of a frame realisation form a Poincaré frame realisation of $\mathfrak{X}$. Let ω, ω' be words, fix column systems $(h_c)_{c\in R_\omega}$ of ω and $(h_{c'})_{c'\in R_{\omega'}}$ of ω' (the same one if $\omega = \omega'$), put $J_\omega T = (T_c^\sharp)_{c\in R_\omega} \in \bigoplus_{c\in R_\omega} V_\omega$ for $T \in \mathrm{Cu}_\omega$, likewise $J_{\omega'}$, and $\mathcal{H}_1 = \mathrm{Hom}(\bigoplus_{c'\in R_{\omega'}} V_{\omega'}, \bigoplus_{c\in R_\omega} V_\omega)$.*

(i) J_ω is a conjugate-linear bijection of Cu_ω onto $\bigoplus_{c\in R_\omega} V_\omega$ with $\langle J_\omega T, J_\omega T'\rangle = \langle T', T\rangle_{\mathrm{Cu}_\omega}$; the coefficient product of ω does not depend on the column system; and $D_\omega = \dim_{\mathbb{C}} \mathrm{Cu}_\omega = |R_\omega| \dim_{\mathbb{C}} V_\omega$.

(ii) Define $\Theta\colon \mathcal{H}_1 \to \mathrm{Hom}(\mathbb{C}^{D_{\omega'}}, \mathbb{C}^{D_\omega})$ by $\langle e_i, \Theta(Z) e_j\rangle = \langle Z\, J_{\omega'} T_{\omega',j},\, J_\omega T_{\omega,i}\rangle$. Then Θ is a conjugate-linear bijection with $\|\Theta(Z)\| = \|Z\|$ for all Z, and $\Theta(1) = 1$ if $\omega = \omega'$. If $Y \in \mathcal{H}_1$ satisfies $\mathcal{K}_{\omega,\omega'}(T, T') = \langle Y J_{\omega'} T', J_\omega T\rangle$ for all $T \in \mathrm{Cu}_\omega$, $T' \in \mathrm{Cu}_{\omega'}$, then

$$\mathrm{Gr}_{\omega\omega'} = \Theta(Y).$$

(iii) For every countable family (y_t) in $\mathcal{H}_1$ with $\sum_t \|y_t\| < \infty$ one has $\sum_t \|\Theta(y_t)\| = \sum_t \|y_t\|$, $\Theta(\sum_t y_t) = \sum_t \Theta(y_t)$ and $\|\sum_t \Theta(y_t)\| = \|\sum_t y_t\|$. If a vector $K \in \mathcal{H}_1$ has a pair expansion at scale ϑ with price C_{pr}, main constant C_{mn}, loop share β_{lp} and non-generic share β_{ng}, with vectors (y_t, z_t), then $\Theta(K)$ has a pair expansion with the same scale, price, constants, shares, terms, rows, labels, row normalisation, label matrix, corank and scalar pairs, with vectors $(\Theta(y_t), z_t)$.

Proof. Sketch. The lemma is a dictionary between two descriptions of the same finite-dimensional data, and once one formula is in place its proof is linear algebra. By the column decomposition (Yt1), every finite adele can be written as $f = a h_c k$ with $a \in H_\omega(F)$, h_c a column representative and $k \in K_\omega$, and the writing is unique because $H_\omega(F) \cap h_c K_\omega h_c^{-1}$ is trivial by (Fj1). The transformation laws of a cusp form $T \in \mathrm{Cu}_\omega$ then give

$$T(v)(s, a h_c k) = \chi_\omega(k)\, \langle T_c^\sharp, \pi_\omega(a_\infty^{-1} s) v \rangle.$$

This formula is the core of the proof. It shows that T is determined by its column vectors $T_c^\sharp$, and conversely, by the uniqueness of the decomposition, that any family $(q_c)_c$ defines a cusp form through it; so J_ω is a conjugate-linear bijection carrying the coefficient product to the inner product of $\bigoplus_c V_\omega$, and the independence of the column system follows from the unitarity of π_ω and $|\chi_\omega| = 1$. Writing an operator Y in the orthonormal bases $J_\omega T_{\omega,i}$ and $J_{\omega'} T_{\omega',j}$ gives Θ, which is a Hilbert–Schmidt isometry by Parseval, and the definition of the Gram matrices through the kernel $\mathcal{K}_{\omega,\omega'}$ gives $\mathrm{Gr}_{\omega\omega'} = \Theta(Y)$. Being additive, real-linear and isometric, Θ carries absolutely summable series term by term, which is (iii): a pair expansion of the kernel operator is a pair expansion of the Gram matrix with the same scale, constants and shares. In this way the expansions obtained from the unfolding Lemma A.64 become statements about the Gram matrices of the Poincaré frame realisations (Definition A.63), to which the row estimates of Theorem 15.3 apply without loss. □

A.6.2 Loop rows and non-generic rows

The terms of the loop rows are bounded by a product of local densities of an integral genus, and Proposition A.66 gives an explicit bound for this Siegel product when the discriminant module is $\mathcal{O}_E/(T)$. The non-generic rows are controlled through family systems, a generic mass bound and a pinned point sum (Proposition A.67); the statement is proved relative to the conditions (Na1)–(Na4), which the members must satisfy.

Proposition A.66. *All symbols introduced here are local to this statement and to the results that cite it. Let E be a CM field with (Um), F its maximal totally real subfield, $f = [F : \mathbb{Q}]$, d_F the discriminant of F, (V, h) a definite hermitian space over E of dimension k, $T \geq 1$ an integer, L an integral lattice in V with $L^\vee / L \simeq \mathcal{O}_E / T\mathcal{O}_E$ as $\mathcal{O}_E$-modules ($T = 1$ is the case $L^\vee = L$), and $a \geq 1$ an integer with $k \geq a^2 + 2$. For a nondegenerate hermitian $a \times a$ matrix Z over E let*

$$\mathrm{dens}(Z) = g_\infty(\Phi_\infty, Z) \prod_{w < \infty} g_w(\mathbf{1}_{(L \otimes \mathcal{O}_{F_w})^a}, Z),$$

with Φ_∞ smooth, compactly supported and equal to 1 on a neighbourhood of $\{X : \mathrm{gram}(X) = Z\}$. For a finite place w of F let q_w be the order of its residue field and v_w its valuation. Then $\mathrm{dens}(Z) = 0$ unless Z is positive definite at every real place τ of F, and in that case

$$\mathrm{dens}(Z) \leq \rho_T\, m_0(Z),$$

where

$$m_0(Z) := \bigl(1+3\cdot 2^{a^2-k}\bigr)^f\,|d_F|^{-(ka-a^2/2)}\prod_{\tau}\frac{(2\pi)^{ka-a(a-1)/2}}{\prod_{j=0}^{a-1}\Gamma(k-j)}\,\tau(\det Z)^{k-a},$$

$$\rho_T := \prod_{w\mid T} q_w^{-a\,v_w(T)}\,\frac{1-q_w^{a^2-k}}{1-q_w^{a^2+1-k}} \;\le\; T^{-fa}\prod_{w\mid T}\bigl(1-q_w^{-1}\bigr)^{-1} \;\le\; 1$$

(the products over the finite places w of F dividing T; $\rho_1=1$). In particular $\mathrm{dens}(Z)\le m_0(Z)$*, and clause (Ok3) of the one-loop amplitude bound for the loop rows holds with $m=m_0$ (and $m_0(Z):=0$ for Z not totally positive definite) whenever its lattice L is integral with $L^\vee/L\simeq \mathcal{O}_E/T\mathcal{O}_E$ for some integer $T\ge 1$ and $k\ge a^2+2$; the majorant m_0 does not depend on T.*

Proof. Sketch. By Siegel's formula [232], in the unitary form of Theorem B.158, the product $\mathrm{dens}(Z)$ is, for $2a<k$, the mass-weighted average, over the genus of L, of the number of representations of Z; it does not depend on the additive character, so one may use the standard one. The bound is obtained by estimating the product place by place. At the real places the density is computed exactly: the Gram map is proper on a definite space, and the archimedean density is $(2\pi)^{ka-a(a-1)/2}\prod_{j<a}\Gamma(k-j)^{-1}\tau(\det Z)^{k-a}$ when Z_τ is positive definite and 0 otherwise. At a finite place w the localised lattice is free over a principal ideal domain, its local dual is the completion of $L^\vee$, and $L_w^\vee/L_w\simeq \mathcal{O}_{E_w}/T\mathcal{O}_{E_w}$. A uniform local estimate, valid for $k\ge a^2+1$ (and $k\ge a^2+2$ at the places dividing T), bounds the density by $q_w^{-v_w(\delta_w)(ka-a^2/2)}(1-q_w^{a^2-k})^{-1}$, with an extra factor $q_w^{-av_w(T)}$ and a slightly weaker Euler factor at $w\mid T$. The core of the proof is this local estimate together with the fact that the product of the local bounds is explicit: the local differents contribute $|d_F|^{-(ka-a^2/2)}$, and the Euler factors give $\zeta_F(k-a^2)\le\zeta(k-a^2)^f\le(1+3\cdot 2^{a^2-k})^f$. The places dividing T are collected in $\rho_T\le 1$, so the majorant m_0 does not depend on T. This is the bound that controls the loop rows: it is the majorant of the one-loop amplitudes from which the loop records of the row estimates Theorem 15.3 are obtained. □

Proposition A.67. *All symbols introduced here are local to this statement and to the results that cite it. Let $r\ge 0$, $k\ge 4r+7$, $A\ge 0$ and $e_N\ge 0$ be integers with*

$$40(r+1)^2+2(2r+2)+5+e_N+6\le A(r+1)^2,$$

put $m=2r+2$, let C_h be real and C_B, $C_{g,0}$ the numbers of Theorem A.86 for $(A_w,C_h)=(A,C_h)$, and let $K,C_j\ge 0$ be real. Let a pair expansion at scale $\vartheta\ge 0$ be given, E a CM field of degree $2f$ with CM type Φ, $T,T',g\ge 1$ integers, P the set of points of length $r+1$ over E, and let sets Cl*, N and maps* $\mathrm{cl}\colon\mathcal{M}_{\mathrm{n}}\to\mathrm{Cl}$, $\mathrm{pt}\colon\mathcal{M}_{\mathrm{n}}\to P$, $\mathrm{nm}\colon\mathcal{M}_{\mathrm{n}}\to N$ *be such that every occupied point is a B-point for (T,T') and (Ng1), (Ng2), (Ng3) hold for*

$$w=\mathrm{wp},\qquad P_{\mathrm{n}}(\gamma)=(TT')^{6f}\max\Bigl(1,\prod_{v\in\Phi}\bigl|\iota_v G_{T,T'}(\gamma)\bigr|\Bigr)^6,\qquad S_w=64^{f(r+1)}.$$

Suppose:

(Na1) Family systems *for every $\gamma\in P_{\mathrm{oc}}$ a family system of type* ngen *at γ for $(\mathcal{M}_{\mathrm{n}},z,\mathrm{cl},\mathrm{pt},\mathrm{nm})$ with parameters r,k is given;*

(Na2) Generic mass *for every $\gamma\in P_{\mathrm{oc}}$, with the places, heights, volume and generic local masses of the system of (Na1), $\prod_{p\in\Pi}H_p\le H(\gamma)$ and $V\prod_{p\in\Pi}n_p^\circ\le K\,H(\gamma)^{e_N}\,n(\gamma)$, $H(\gamma)$ formed with T,T',g;*

(Na3) Point sums *there are $C_g \ge C_{g,0}$, primes g_1, g_2, a real $b \ge 2$ and point-sum data at the places $v \in \Phi$ such that C_g, $(r, k, E, \Phi, g_1, g_2, 2\pi/(\mathrm{rd}_E g_1 g_2), T, T', b)$ and these data satisfy all hypotheses of Theorem A.86, and for every $\gamma \in P_{\mathrm{oc}}$: $J_\gamma \le C_j \prod_{v\in\Phi} \mathrm{os}_v(\tilde\gamma_v)$ $(0\cdot\infty = 0)$, J_γ that of the system of (Na1);*

(Na4) Collapse *with*

$$T_{\mathrm{pt}} = K\,(TT')^{6f}\,C_j\,\exp(C_B m^5 f \log b)\prod_{v\in\Phi}\mathrm{bm}_v,$$

numbers $d, d', D^* > 0$ with $dd'/D^* = \vartheta$ and all further numbers of the collapse lemma for the non-generic row normalisation (by the main-row mass algebra) are given that satisfy the hypotheses of its item (ii) for c_{rw} of the pair expansion, these r, A, f, C_B, S_w, T_{pt} and b, and for constants $C_{\mathrm{St}}, C_T, C'_g \ge 0$ in place of its $C_{\mathrm{St}}, C_T, C_g$.

Then there are functions $J, n_{\mathrm{g}}\colon P \to [0,\infty)$ and $a_2\colon \mathrm{Cl}\times P\times N \to [0,\infty)$ such that $(\mathrm{Cl}, P, N, \mathrm{cl}, \mathrm{pt}, \mathrm{nm}, w, P_{\mathrm{n}}, J, n_{\mathrm{g}}, a_2, S_w, T_{\mathrm{pt}})$ are non-generic row data with parameters r, k having (Ng1)–(Ng4) and (Ng6),

$$c_{\mathrm{rw}}\,S_w\,T_{\mathrm{pt}} \le \exp(C_{\mathrm{ng}}\,m^5 f\log b)\,\vartheta, \qquad C_{\mathrm{ng}} = C_B + C_{\mathrm{St}} + 12C_T + (A/4+1)C'_g + 5,$$

and, for every $\gamma \in P_{\mathrm{oc}}$, data as in Lemma 16.4 with these r, k and $C_0 = 1$ satisfying its items 1 and 2 and (Nv1), (Nv2).

Proof. Outline. The functions J, n_{g} and a_2 are read off the family systems of (Na1) at the occupied points and set to 0 elsewhere; the properties of family systems then give (Ng4) and the data of Lemma 16.4, (Ng6) follows from Proposition A.87 once its hypotheses are checked from (Na2), (Na3) and a weight comparison at B-points, and the bound on $c_{\mathrm{rw}}S_wT_{\mathrm{pt}}$ is item (ii) of the collapse lemma under (Na4). □

A.6.3 The main row and the packet records

The main row needs a lower bound. At the selected members it comes from density domination (Proposition A.68), which combines an archimedean factor, the engine place of Section A.7, with a finite-place factor. The finite-place factor rests on local block kernels: they are positive semidefinite and vanish between points of different modulus (Lemma A.70), and they admit local theta majorants of every block size (Proposition A.69). Theorem A.71 then records the row estimates and the kernel hypotheses at the selected packets; its kernel data use Corollary 14.18 of the body.

Proposition A.68. *In the setting of Theorem A.71, let X be the threshold of the selected family in Proposition A.114, let $x \in W$ with $x > X$, $u \in A_x$, and let $\mathfrak{X}$ be the member Hida and Poincaré setting of u given by Proposition A.114. Fix the arithmetic main-row normalisation on the original completions of the member. Let ω, ω' be words, $(h_c)_c$ a column system of ω, ρ a row labelling of the main-row data of $(\mathfrak{X}, \omega, \omega')$, and let n_{c} be the constant of Siegel's formula for the row representatives of these data ($\mathcal{R} = Q_\omega$); form* al, *σ, ϕ, a^{mem}_ϱ, $\tilde a_\varrho$ and $k^{\mathrm{top}}_{\mathrm{mem}}$ with this n_{c}. Then:*

1. *Γ_w is finite for every top point w, the product defining* al *converges absolutely to a positive number, every eligible term at a top point has a normal representative, and every term t that has a normal representative satisfies $d(t) \le e_{\mathrm{dn}}\,\mathrm{al}$, where $e_{\mathrm{dn}} = \exp\bigl(9f\,2^{2r+2-k}\bigr)$ and $f = [F:\mathbb{Q}]$; call a real $s \ge 0$* admissible *if $d(t) \le s\,\mathrm{al}$ for every eligible term t that has a normal representative (so $s = e_{\mathrm{dn}}$ is admissible);*

2. *for every admissible s, every finite set P of top points and every finite set R of values of ρ, the matrix*
$$\Big[s\,\frac{\mathrm{K}^{\mathrm{top}}(y,y')}{\phi(y)\,\phi(y')} - \sum_{\varrho\in R} a_{\varrho}^{\mathrm{mem}}(y)\,\overline{a_{\varrho}^{\mathrm{mem}}(y')} \Big]_{y,y'\in P}$$
is positive semidefinite;

3. *for every admissible s, every finite set P of points over E of level $r+1$ and every finite set R of values of ρ, the matrix $\big[s\,k_{\mathrm{mem}}^{\mathrm{top}}(v,v') - \sum_{\varrho\in R}\tilde{a}_{\varrho}(v)\overline{\tilde{a}_{\varrho}(v')}\big]_{v,v'\in P}$ is positive semidefinite, and $\tilde{a}_{\varrho}(v)\neq 0$ only if v has level $r+1$.*

Proof. Outline. After the arithmetic facts of the member are collected (the extension E/F is unramified at the finite places, the signature, an element of trace one, the flag and its row representatives, the main-row normalisation, normal representatives of eligible terms and the finiteness of the sets Γ_w), item 1 follows from a local computation of the level factors, whose product converges to al and bounds the densities, item 2 is a positivity statement for main rows whose hypotheses (a partner identity, a fibre identity from Siegel's formula for the row representatives, and equal norms on the supports) are verified for the normalised density $d(t)/\mathrm{al}$, and item 3 is item 2 transported by the sign twist σ. □

Proposition A.69. *Fix the local setting and θ, and put $R = R_\theta$.*

(i) For all integers $s\geq 1$, $m\geq 0$ and every finite set Q of pairs (h,t), h a point of size m and $t\in E^\times$, the kernel $((h,t),(h',t'))\mapsto \mathrm{N}_s(h,h';t,t')$ is positive semidefinite on Q.

(ii) If $s\geq 1$, h,h' are points of one size, $t,t'\in E^\times$ and $\mathrm{N}_s(h,h';t,t')\neq 0$, then $t^{-1}-t'^{-1}\in R$.

(iii) For every integer $s\geq 1$ and every finite set Q of points of one size there is a local theta majorant of block size s on Q.

(iv) For every integer $m\geq 0$ there is a family $(\Theta(x))_{x\in E}$ of complex functions on pairs of points of size m such that $\Theta(x+y)=\Theta(x)$ for $x\in E$, $y\in R$, $\Theta(t)(h,h')=\mathrm{N}_1(h,h';t,t)$ for every $t\in E^\times$ and all points h,h' of size m, and the restriction of Θ to $Q\times Q$ is a local theta majorant of block size 1 on Q for every finite set Q of points of size m.

Proof. Outline. Parts (i) and (ii) are properties of the block kernels (Lemma A.70 and a support lemma for the kernels); for block size 1 the kernel N_1 evaluated at a unit section of E/R is a local theta majorant, which gives (iv) and (iii) for $s=1$, and larger block sizes follow by induction on s, through majorants over the compact cells Ω_j of units and a limit along a subsequence (Bolzano–Weierstrass), the defining conditions being closed and involving finitely many entries. □

Lemma A.70. *Fix the local setting and θ.*

(a) For all integers $s\geq 1$, $m\geq 0$ and every finite set Q of pairs (h,t), h a point of size m and $t\in E^\times$, the kernel $((h,t),(h',t'))\mapsto \mathrm{N}_s(h,h';t,t')$ is positive semidefinite on Q; and N_0 is positive semidefinite on every finite set of points of one size.

(b) If $s\geq 0$, h,h' are points of one size, $t,t'\in E^\times$ and $\mathrm{N}_s(h,h';t,t')\neq 0$ (for $s=0$: $\mathrm{N}_0(h,h')\neq 0$), then $|\det\bar{h}|\,|t|^s = |\det\bar{h}'|\,|t'|^s$. In particular $\mathrm{N}_s(h,h';t,t)\neq 0$ implies $|\det\bar{h}| = |\det\bar{h}'|$.

Proof. Points of size 0 are only $\varnothing$, with $\mathrm{N}_0(\varnothing,\varnothing)=1$; so let the points have size $n\geq 1$.

The local kernel is a Gram kernel. Let P be a finite set of points of size n. The orbit integrals of a point vanish outside finitely many marked classes, so the set C_P of classes $c\in \mathrm{Cl}_{n-1}$ with $\mathrm{B}(w,c)\neq 0$ for some $w\in P$ is finite, and for $w,w'\in P$ the series (Fk4) reduces to

$$\mathrm{K}(w,w')=\sum_{c\in C_P}\frac{\mathrm{B}(w,c)\,\overline{\mathrm{B}(w',c)}}{n_{\mathrm{Aut}}(c)},$$

with $n_{\mathrm{Aut}}(c)$ a positive integer. Hence K is hermitian on P and $\sum_{w,w'\in P}v_w\overline{v_{w'}}\,\mathrm{K}(w,w')=\sum_{c\in C_P}|\sum_w v_w\mathrm{B}(w,c)|^2/n_{\mathrm{Aut}}(c)\geq 0$ for every $v\in\mathbb{C}^P$. This is the second assertion of (a).

(a). The map $(h,t)\mapsto h\cdot(s,t)$ is injective (h is the point with the last block removed and t the entry of that block). On Q, $\mathrm{N}_s(h,h';t,t')=d(h,t)\,\mathrm{K}(h\cdot(s,t),h'\cdot(s,t'))\,d(h',t')$ with $d(h,t)=|t|^{s(s-1)/2}>0$, so the matrix of N_s on Q is $D\,\mathcal{K}\,D$ with D positive diagonal and $\mathcal{K}$ the matrix of K on the image of Q, positive semidefinite by the previous paragraph.

(b). Put $w=h\cdot(s,t)$, $w'=h'\cdot(s,t')$ ($w=h$, $w'=h'$ if $s=0$). If $\mathrm{K}(w,w')\neq 0$, some c has $\mathrm{B}(w,c)\neq 0\neq\mathrm{B}(w',c)$, so by the same finiteness lemma for orbit integrals $|N_{E/F}(\det\bar w)|_F=|N_{E/F}(\det Y_c)|_F=|N_{E/F}(\det\bar w')|_F$. Since $\bar w$ is block diagonal with blocks $\bar h$ and tJ_s, $\det\bar w=\pm\det\bar h\,t^s$, and $|\cdot|$ is multiplicative. □

Theorem A.71. *Fix one complete collection of good-host witnesses, take the selected class, selection, member objects and tables named above, and let P_x ($x\in W$, $x\geq X$) be the packets they form. The construction of Proposition A.1 chooses its own collection of good-host witnesses; whether its selected class, selection and member objects can be attached to a prescribed complete collection, as is done here, is an open question, and the theorem concerns these data whenever such an attachment exists. Assume the eventual Sha hypothesis of (Rr3) of Hypothesis 21.1. Equip every packet member $u\in A_x$ with the lower completion data in which the frame realisation, word scale, Gram blocks $\mathrm{Gr}_{\omega\omega'}$, frame data D_ω, D^* and the row parameters are those determined by the member's selected tied local data: k_{d} the dimension of the definite part of its hermitian space, r_{f} the length of the isotropic flag of its Bessel data, f_∞ the number of archimedean places of its totally real field, $g_1^{\mathrm{aux}},g_2^{\mathrm{aux}}$ its two selected auxiliary primes, and T_{amp} its amplitude threshold at the constant C_{A} below. Let $\mathcal{F}$ be the family these packets form (item 3 of Proposition A.1), taken at its design choice ((Rk13) of the row carrier). The word-size constant of these completions is $C_0=3$, and the word scale Γ_{w} of a member is the word scale of its context.*

Then there are real constants

$$C_{\mathrm{A}}\geq 1,\quad 0<c_{\mathrm{lp}}\leq\tfrac{1}{3},\quad C_{\mathrm{ng}}\geq 0,\quad C_{\mathrm{lb}}\geq 1,\quad A_{\mathrm{lb}}\geq 1,$$

and an integer $C_0^{\mathrm{ng}}\geq 0$, none of which depends on the scale, the member, the words or the local indices, such that for every real $c>0$ there is a real $Y_{\mathrm{X}}(c)$ with the following in the pointwise interpretation (Pl2) at every $x\in W$ with $x\geq Y_{\mathrm{X}}(c)$ and every member $u\in A_x$.

(X1) If the member has word sizes for C_0, then for all words $\omega\neq\omega'$ there are data with (Ro1)–(Ro4) of Theorem 15.3 for the constants $C_0,C_{\mathrm{A}},c_{\mathrm{lp}},C_{\mathrm{ng}},C_{\mathrm{lb}},A_{\mathrm{lb}},C_0^{\mathrm{ng}}$, with $K_0=32C_{\mathrm{lb}}^{32}$ and the member's row parameters.

(X2) The member satisfies the inequalities of (Rw2) with exponent c for $(C_{\mathrm{A}},c_{\mathrm{lp}},C_{\mathrm{ng}})$.

(X3) If the member has word sizes for C_0, then it satisfies the kernel hypotheses of Corollary 14.18 for C_0 and the exponent c: a measure space (X,μ) with $\mu(X)<\infty$, measurable $\mathrm{ls},\mathrm{kd},\mathrm{na},\mathrm{fa}$, a real $\tau_*>0$ and $c_{\mathrm{id}},\epsilon_{\mathrm{N}},\epsilon_{\mathrm{F}},\kappa\geq 0$ with (Kc1)–(Kc4), $\kappa\,\mu(X)<1$ and $1+\epsilon_{\mathrm{N}}+\epsilon_{\mathrm{F}}\leq(1-\kappa\,\mu(X))(1+x^{-c}/12)$.

In particular, for the common exponent $c > 0$ chosen in (Pl3), whatever its size (at the design choice, $c = C_H(\mathcal{F})$ by (Rk13) of the row carrier), the packets satisfy on the tail $x \geq Y_{\mathrm{X}}(c)$ (Ro1)–(Ro4), (Rw2) and the kernel hypotheses of (Pc5) demanded in (Rr3), with one common C_0, one common c and one common $(C_{\mathrm{A}}, c_{\mathrm{lp}}, C_{\mathrm{ng}})$.

Proof. Outline. The constants are fixed first, independently of the exponent, from propositions on the row data, the loop records and the row sizes of the members, and for each $c > 0$ the threshold $Y_{\mathrm{X}}(c)$ is the largest of the thresholds of these propositions and of those on the amplitude and the kernel data; then (X1) combines the row data giving (Ro1), (Ro3), (Ro4) of Theorem 15.3 with a loop-row bound giving (Ro2), (X2) collects the size and amplitude inequalities of (Rw2), and (X3) follows from the kernel data through a comparison corollary for the kernel hypotheses of Corollary 14.18. □

A.7 Approximate orthogonality II: the engine place and Bessel amplitudes

This section supplies the archimedean inputs of Section A.6. The engine place gives the local kernel clauses behind the lower bound for the main row (Ro4); the bounds for Bessel amplitudes feed the loop rows (Ro2) and the point sums of the non-generic rows (Ro3). The place theorem A.78 is an assembly of four steps: positivity on a cut (Proposition A.73), interpolation on a long cut (Lemma A.74), decay of matrix coefficients at a large gap (Theorem A.75), and an energy identity (Proposition A.76, Proposition A.77). It needs only $h > \max(261n^4,\, n^5 + 5(C_b + 3)^2 n^3)$, and $h \geq \frac{1}{2}n^{19}$ suffices when $C_b \leq 11$. At a member the cut is non-empty because the word code of the context is injective, so that distinct words differ by Δ_D in one coordinate (Proposition A.79). The engine place should not be confused with the pointwise Bessel bound at large gap, Theorem A.84, which drives the amplitude bounds of the second subsection.

A.7.1 The engine place

Definition A.72 sets up the engine energies at a place: normalised kernels, jet energies, the Bessel energy, extensions of words and pointwise bounds. The J-pairing inequality gives positivity on the cut (Proposition A.73). Grids with small Lagrange totals interpolate on a long cut (Lemma A.74), and smooth matrix coefficients of discrete series decay polynomially at a large gap (Theorem A.75). Engine places have an energy model (Proposition A.76), from which the limit clause follows (Proposition A.77). The place theorem A.78 assembles these four steps, and Proposition A.79 checks its hypotheses at the engine place of a member at a complex place, for the actual words of one context.

Definition A.72. Let a local kernel datum of rank r be given, with $T = T(z)$, $T' = T(z')$, and a **type** $0 \leq l \leq k-1$ with sign $s = (-1)^{k-l-1}$ in (Pk6). Only (Pk5), (Pk7) and s enter below; the data $F, P, \chi, \mathsf{g}, \mathsf{d}$ of (Pk6) do not. Cut words are those for the cut I_l. Put $\sqrt{x} = 0$ for $x < 0$.

Weight of a local point. For a local point $h = ((s_1, t_1), \dots, (s_a, t_a))$ with block starts $\beta_j = 1 + s_1 + \cdots + s_{j-1}$ put $\mathrm{n_e}(h) = \prod_j \phi_j$ with $\phi_j = (|t_j|^2 - TT')^{k-1}$ if $\beta_j + s_j - 1 = r + 1$ and $s_j = 1$, and $\phi_j = |t_j|^{2s_j(\mathrm{dm}_{\beta_j + s_j - 1} + s_j - 3)}$ otherwise.

Normalised kernels and jet energies. For $\mathrm{nn}\colon \mathbb{R} \to (0, \infty)$ and a word w put $\mathrm{nc}(w) = \prod_{(\pm, y) \in w} \mathrm{nn}(y)$ (over the positions of w; the point of a letter $(-, y+1)$ is $y+1$). For a coefficient Φ of rank r, $0 \leq i \leq r+1$, a word w and local points a, b:

$$\mathrm{NP}_{\mathrm{nn}}(\Phi)_{i,w}(a,b) = \frac{\sqrt{\mathrm{n_e}(a)}\sqrt{\mathrm{n_e}(b)}}{\mathrm{nc}(w)}\, K_{i,w}(\Phi)(a,b), \qquad \mathrm{Ew}_{\mathrm{nn}}(\Phi)_{i,w}(h) = \mathrm{Re}\,\mathrm{NP}_{\mathrm{nn}}(\Phi)_{i,w}(h,h)$$

(the **jet energy** of Φ at h; $K_{i,w}(\Phi)(a,b)=0$ unless a,b have level i). We write $\mathrm{Ew}(\Phi)_{i,w}$ for $\mathrm{nn}\equiv 1$.

Bessel energy. For $c\in\mathbb{C}^{r+1}$ let $\mathrm{bigPt}(c)=((1,c_0),\dots,(1,c_r))$ (a local point of level $r+1$ when all $c_j\neq 0$), and

$$\mathrm{jN2}(\Phi)=\int_{\mathbb{C}^{r+1}}\max\bigl(\mathrm{Ew}(\Phi)_{r+1,\varnothing}(\mathrm{bigPt}(c)),0\bigr)\,dc\in[0,\infty],$$

the lower integral with respect to Lebesgue measure.

Extensions. For a finite $Y\subset\mathbb{R}$ and integers $N,m'\geq 0$, a word w' is a (Y,N,m')**-extension** of a word w if w' is a cut word, $|w'|\leq N$, and $w'=L\,w$ (concatenation) for a word L with $|L|\leq m'$ whose letters are $(+,y)$ or $(-,y+1)$ with $y\in Y$.

Pointwise bound at the place. For $\kappa\geq 0$, Φ satisfies the **pointwise bound with constant** κ if for every local point γ of level $r+1$ with $G(\gamma)=|\det M_{r+1}(\gamma)|^2-TT'|\det M_r(\gamma)|^2>0$: $\max(\mathrm{Ew}(\Phi)_{r+1,\varnothing}(\gamma),0)\leq\kappa\,\mathrm{jN2}(\Phi)$ in $[0,\infty]$.

Block growth bound. For $\omega_1,\omega_2\in\mathbb{C}$ with $\mathrm{Im}(\bar\omega_1\omega_2)\neq 0$ put $L=\mathbb{Z}\omega_1+\mathbb{Z}\omega_2$ and $L^\vee=\{\sigma\in\mathbb{C}:\exp(2i\,\mathrm{Im}(\sigma\omega))=1\text{ for all }\omega\in L\}$. Let $\mathrm{nn}\colon\mathbb{R}\to(0,\infty)$, $Y\subset\mathbb{R}$ finite and $K,N\geq 0$ integers. A coefficient Φ of rank r satisfies the **block growth bound for** (nn,Y,K,N) if, with $\mathrm{NP}=\mathrm{NP}_{\mathrm{nn}}(\Phi)$ and $\mathrm{Ew}=\mathrm{Ew}_{\mathrm{nn}}(\Phi)$: for all integers $b\geq 1$, $s\geq 2$ with $b+s-1\leq r+1$, every local point h of level $b-1$ and every Y-admissible word w with $|w|+K\leq N$ such that for every (Y,N,K)-extension w' of w the function $t\mapsto\mathrm{Ew}_{b+s-2,w'}(h\cdot(s-1,t))$ is bounded above on $\mathbb{C}^\times$, and for all $\omega_1,\omega_2,z_0\in\mathbb{C}$ with $\mathrm{Im}(\bar\omega_1\omega_2)\neq 0$, there is a function $\kappa\colon\mathbb{C}\to\mathbb{C}$ with

$$\frac{|\,\mathrm{Im}(\bar\omega_1\omega_2)|}{\pi}\sum_{\omega\in L}\max\bigl(\mathrm{Ew}_{b+s-1,w}(h\cdot(s,z_0+\omega)),0\bigr)\leq\sum_{\sigma\in L^\vee}|\kappa(\sigma)|,$$

$$|\kappa(\sigma)|\leq\limsup_{t\to 0,\ t\neq 0}\bigl|\mathrm{NP}_{b+s-2,w}(h\cdot(s-1,t),h\cdot(s-1,(t^{-1}+\sigma)^{-1}))\bigr|\quad(\sigma\in L^\vee)$$

in $[0,\infty]$ ($h\cdot(m,c)$ as in Definition 15.7; as $h\cdot(s,0)$ is not a local point, $\mathrm{Ew}_{b+s-1,w}(h\cdot(s,0))$ is read as 0).

Compact coefficients. A coefficient Φ of rank r is **compact** if it is smooth, there is R with $\|g\|\leq R$ whenever $\Phi(g)\neq 0$ ($\|g\|$ the Frobenius norm of the matrix of g), and there is $\varepsilon>0$ with $G_f(g)\geq\varepsilon$ whenever $\Phi(g)\neq 0$ (G_f of Definition A.81).

Engine places. Let $k\geq 2$ and let a Bessel datum of rank r (Definition A.81) be given with π,π' irreducible of Harish-Chandra parameters $u=(u_0,\dots,u_{k-1})$, $u'=(u'_0,\dots,u'_{k-1})$ (strictly decreasing); let $0\leq l\leq k-1$ and $C_b\geq 0$. Write $\mathfrak{g}_r=\{X:X^*H_r+H_rX=0\}$, $(R_XH)(g)=\frac{d}{d\tau}|_{\tau=0}H(g\exp\tau X)$, $(L_XH)(g)=\frac{d}{d\tau}|_{\tau=0}H(\exp(-\tau X)g)$, and $R_{\mathbf{Z}}=R_{Z_1}\cdots R_{Z_q}$ for a finite sequence $\mathbf{Z}=(Z_1,\dots,Z_q)$ in $\mathfrak{g}_r$. An **engine place of type** l **with constant** C_b on the given datum is a local kernel datum such that:

(EP0) (normalised measures) for every $0\leq\rho\leq r$ the Haar measure dn on N_ρ of its Bessel datum of rank ρ is the **normalised** one: for $\rho=0$ the unit point mass on the trivial group N_0, and for $\rho<r$ the measure on $\mathrm{N}_{\rho+1}$ is the image of the product of Lebesgue measure on $\mathbb{C}^{n_\rho}\times\mathbb{R}$ ($\mathbb{C}=\mathbb{R}^2$) and the normalised measure on N_ρ under $(X,\lambda,\nu)\mapsto\mathrm{Rn}(X,(),\lambda)\,\mathrm{diag}(1,\nu,1)$, where $\mathrm{Rn}(X,u,\lambda)$ is the slice matrix of the local kernels with $j=1$ (blocks of sizes $(1,n_\rho,1)$, u empty);

(EP1) its Bessel datum of rank r has the same z,z',π,π',μ as the given one (its Haar measures may differ, subject to (EP0)), and its sign is $s=(-1)^{k-l-1}$;

(EP2) its top datum is frame-compatible for the parameters $(u_0,\dots,u_{k-1})$, $(u'_0,\dots,u'_{k-1})$, read as $(u_1,\dots,u_k)$, $(u'_1,\dots,u'_k)$ there, with $l_0=l+1$; so its cut is the cut I_l;

(EP3) (the top lift is a differential operator of controlled order and growth) for every cut word w and every $e \in \{0,1\}^w$ there are integers $o, \kappa \geq 0$ with $o \leq C_b|w|n$ and $\kappa \leq C_b(r+1)o$; finitely many smooth maps $E_1, \dots, E_{n_f}$ from $\{g \in \mathrm{G}_r : G_f(g) > 0\}$ to the linear endomorphisms of $\mathrm{Hom}(\mathcal{E}', \mathcal{E})$ such that for every $\varepsilon > 0$ and integer $i \geq 0$ there is C with $\|(L_{X_1} \cdots L_{X_a} R_{X_{a+1}} \cdots R_{X_i} E_j)(g)\| \leq C\|g\|^{3(r+1)i}$ for all j, all $0 \leq a \leq i$, all $X_1, \dots, X_i \in \mathfrak{g}_r$ with entries of modulus at most 1 and all g with $G_f(g) \geq \varepsilon$; and finitely many terms t, each given by a finite sequence $\mathbf{X}_t$ in $\mathfrak{g}_r$, a polynomial P_t of total degree at most κ in the matrix entries of g and their conjugates, integers $a_t, b_t, c_t \geq 0$ and finitely many pairs $(j_{t,1}, \mathbf{Z}_{t,1}), \dots, (j_{t,q}, \mathbf{Z}_{t,q})$ ($1 \leq j_{t,i} \leq n_f$, $\mathbf{Z}_{t,i}$ finite sequences in $\mathfrak{g}_r$) with $|\mathbf{X}_t| + \sum_i |\mathbf{Z}_{t,i}| \leq o$, such that for every smooth coefficient H of rank r and every g with $G_f(g) > 0$

$$(\Theta_{w,e}H)(g) = \sum_t P_t(g)\, D_{r+1}(g)^{-a_t}\, \overline{D_{r+1}(g)}^{\,-b_t}\, G_f(g)^{-c_t} \cdot \big((R_{\mathbf{Z}_{t,1}} E_{j_{t,1}})(g) \circ \cdots \circ (R_{\mathbf{Z}_{t,q}} E_{j_{t,q}})(g)\big)\big((R_{\mathbf{X}_t} H)(g)\big);$$

and, on $\{G_f > 0\}$, $\Theta_{w,e}$ commutes with the translations $H \mapsto \pi(h)\, H(h^{-1}\nu^{-1} \cdot \nu' h')\, \pi'(h')^{-1}$ ($h \in \mathrm{H}_z$, $h' \in \mathrm{H}_{z'}$, $\nu, \nu' \in \mathrm{N}_r$) of smooth coefficients.

The engine energies of the place are those above, formed with its kernels $K_{i,w}$ and its type l.

Proposition A.73. *Let an engine place of type l (with any constant) on a Bessel datum of rank r be given ($k \geq 2$). Let $0 \leq j \leq r$, w a cut word and $ys = (y_1, \dots, y_m) \in \mathbb{R}^m$ with entries pairwise differing by more than 2 such that w^+_{ys} and w^-_{ys} are cut words. Then $q_w(y_a) > 0$ for $1 \leq a \leq m$, and for all families x, x' of nice coefficients of rank $r - j$ indexed by $\{0,1\}^{w^+_{ys}}$ and $\{0,1\}^{w^-_{ys}}$*

$$\big|\mathrm{J}_{j,w}(ys; x, x')\big|^2 \prod_{a=1}^{m} q_w(y_a) \leq \Lambda_{j,w^+_{ys}}(x,x)\, \Lambda_{j,w^-_{ys}}(x',x').$$

Proof. Sketch. The inequality is the Cauchy–Schwarz inequality for a positive semidefinite form, and the work lies in exhibiting that form. The first step is positivity on the cut: because w^+_{ys} is a cut word for the type data of the engine place, the stage function satisfies $q_w(y_a) > 0$ for every a, so $\kappa_L = \prod_a q_w(y_a) > 0$. Next, the three pairings are moved to a radial model. With $v = w^+_{ys}$, $v' = w^-_{ys}$ and R the radial map, the level forms become $\Lambda_{j,v}(x,x) = C_j\, \mathrm{fm}_0(\mathrm{RR}^{(0)}_v \mathrm{R}x, \mathrm{R}x)$ and likewise for v', with one constant $C_j > 0$, and the J-pairing becomes $C_j\, \mathrm{fm}_0(J_L \mathrm{RR}^{(0)}_w \mathrm{R}x, \mathrm{R}x')$. A twisted radial descent supplies a class of radial functions, containing the images of nice coefficients, on which $B(Z, Z') = \mathrm{fm}_0(\mathrm{RR}^{(0)}_v Z, Z')$ is sesquilinear and positive semidefinite. The core of the proof is a pair of identities in the algebra of operators acting on radial functions,

$$\mathrm{Ps}^\dagger_L\, \mathrm{RR}_v = J_L\, \mathrm{RR}_w, \qquad \mathrm{RR}_{v'} = \kappa_L\, \mathrm{Ps}^\dagger_L\, \mathrm{RR}_v\, \mathrm{Ps}_L,$$

obtained by fusing the stages of the word one letter at a time; the separation of the letters by more than 2 ensures that no stage function vanishes at the points where a fusion is performed. With these identities the J-pairing is $C_j B(X, \mathrm{Ps}_L X')$ and the level form of v' is $C_j \kappa_L B(\mathrm{Ps}_L X', \mathrm{Ps}_L X')$, where $X = \mathrm{R}x$ and $X' = \mathrm{R}x'$, so the Cauchy–Schwarz inequality for B gives the claim. In the engine place theorem A.78 this is the step of positivity on the cut. □

Lemma A.74. *Let $y_- < y_+$ be reals with $y_+ - y_- \geq 1$, let $D \geq 0$ and $N \geq K \geq 1$ be integers, $\delta \geq 3$ real, let P be a nonzero real polynomial of degree at most D and $q\colon \mathbb{R} \to \mathbb{R}$ a*

function that is continuous and positive on $[y_-, y_+ - 1]$. *Take the cut* $I = [y_-, y_+]$, *the finite set* $\mathcal{L} = \{y_- + t\delta : \ t \in \mathbb{Z},\ 0 \le t \le (y_+ - 1 - y_-)/\delta\}$, *and let* $\mathcal{W}$ *be the set of cut words* w *with* $|w| \le N$, $\mathrm{wt}^{\mathrm{loc}}(w) > 0$ *and every letter of the form* $(+, y)$ *or* $(-, y+1)$ *with* $y \in \mathcal{L}$; $\mathcal{W}$ *is finite and contains* $\varnothing$. *Grids are formed with* $\mathcal{W}$ *as the set of admitted words. For a word* w *put* $q_w(y) = q(y) \prod_{(+,y')\in w} \frac{y-y'+1}{y-y'} \prod_{(-,y')\in w} \frac{y'-y}{y'-y-1}$ *(products over the positions of* w*).*

(i) Let $d \ge 0$ *be an integer and* $w \in \mathcal{W}$ *with* $|w| + K \le N$ *and*

$$y_+ - y_- \ge 1 + \delta\big(K(d+1) + 3|w| + 2D\big).$$

Then w *has a grid of degree* d, *with all nodes in* $\mathcal{L} \subseteq [y_-, y_+ - 1]$ *and Lagrange total* $\mathrm{Lt} \le \big((2/\delta)^d/d!\big)^K$.

(ii) Put $\beta^2 = 2^N \max_{y_- \le y \le y_+ - 1} |P(y)P(y+1)|/q(y)$. *For every word* w, *every grid of any degree for* w *and every node* y *of it,* $q_w(y) > 0$ *and* $|P(y)P(y+1)| \le \beta^2 q_w(y)$.

In particular, if $y_+ - y_- \ge 1 + \delta(K(2r+1) + 3N + 2D)$, *the datum with these* I, $\mathcal{W}$, q_w *satisfies (Kx1) with* $G_{\mathrm{W}}(j) = ((2/\delta)^{2j}/(2j)!)^K$, $G_{\mathrm{L}}(b,s) = ((2/\delta)^{2(b-1)+s}/(2(b-1)+s)!)^K$, $G_{\mathrm{T}}(s) = ((2/\delta)^{r+1-s}/(r+1-s)!)^K$, *and (Kx6) with* $\beta_j = \beta'_{b,s} = \beta$.

Proof. Outline. For (i), the nodes are chosen among the points of $\mathcal{L}$ that lie at distance more than 3 from every letter value of w and avoid the zeros of $P(y)P(y+1)$, of which there are at least $K(d+1)$, and the Lagrange total factorises over the K blocks and is bounded by the spacing δ of the nodes; for (ii), every factor of $q_w(y)$ coming from a letter of w exceeds $\frac{1}{2}$ because the node is more than 2 away from each letter value, so $q_w(y) \ge 2^{-N} q(y)$; the particular case follows by applying (i) to the degrees occurring in (Kx1). □

Theorem A.75. *Let* $k \ge 1$, $r \ge 0$ *be integers,* $n = 2r + k + 1$, *let* H *be the matrix of signature* $(k+r, r+1)$ *of (Dp4) in the definition of square-integrable representations with Harish-Chandra parameter relative to a sign vector, with* $\mathrm{U}(H)$ *and its Lie algebra* $\mathfrak{u}(H)$ *as there, and* $\|g\| = (\sum_{i,j} |g_{ij}|^2)^{1/2}$. *Let* $\varepsilon \in \{+,-\}^n$ *be a sign vector with* p *entries* $+$ *and* q *entries* $-$, $q_0 = \min(p,q)$, *and*

$$\theta(\varepsilon) = \max\big(npq + 1,\ 16\, n\, q_0 + 8\sqrt{2q_0}\big).$$

Let $\lambda \in \mathbb{R}^n$ *be strictly decreasing with* $\lambda_a - \frac{n-1}{2} \in \mathbb{Z}$, *let* $h > 0$ *with* $|\lambda_a - \lambda_b| \ge h$ *whenever* $\varepsilon_a \ne \varepsilon_b$, *and let* σ *be a unitary representation of* $\mathrm{U}(H)$ *on a Hilbert space* $\mathcal{H}$ *which, after conjugation by a unitary Cayley transform carrying* H *to* $\mathrm{diag}(\varepsilon)$, *is square-integrable with Harish-Chandra parameter* λ *relative to* ε *((Dp5); in particular* σ *is irreducible and square-integrable). Words* w *in* $\mathfrak{u}(H)$ *and* $d\sigma(w)u$ *for smooth* u *are as in (Dp6). Then for every integer* $m \ge 0$ *with* $\theta(\varepsilon) + m < h$ *there are* $C \ge 0$ *and a finite set* $\mathcal{W}$ *of words in* $\mathfrak{u}(H)$ *such that for all smooth vectors* $u, v \in \mathcal{H}$ *and all* $g \in \mathrm{U}(H)$

$$\|g\|^m\, |\langle v, \sigma(g)u\rangle| \le C\Big(\sum_{w\in\mathcal{W}} \|d\sigma(w)u\|\Big)\Big(\sum_{w\in\mathcal{W}} \|d\sigma(w)v\|\Big).$$

Proof. Outline. After a unitary Cayley transform, the proof combines a one-sided decay bound $|\langle w_0, \sigma(y)u\rangle| \le C_1 \|y\|^{-A} S(u)$ for a fixed nonzero K-finite vector w_0 with the Schur orthogonality relations, which express $\langle v, \sigma(g)u\rangle$ as an integral over the group of a product of two such coefficients, and then bounds $\|g\|^m$ times this integral by the Cauchy–Schwarz inequality and the integrability of a negative power of $\|y\|$ over the group. □

Proposition A.76. *Let $C_b \geq 0$, let $r \geq 0$, $k \geq 2$, $N_{\mathrm{tot}} \geq 1$ be integers, $n = 2r + k + 1$, and let $A_{\mathrm{E}}, m_{\mathrm{E}}, A_{\mathrm{T}}, m_{\mathrm{T}}$ be the numbers given for $(C_b, r, k, N_{\mathrm{tot}})$ by the adjointness and transfer propositions for the engine energy system. Let an engine place of type l with constant C_b on a Bessel datum of rank r be given, with admitted words $\mathcal{W}$, an integer N_{top} and the data F, P, χ of (Pk6), and let $[\alpha, \beta] = I_l$. Suppose:*

(Em1) *$u_i - u_0 \in \mathbb{Z}$ and $u_i' - u_0 \in \mathbb{Z}$ for $0 \leq i \leq k-1$;*

(Em2) *χ takes values in $[0,1]$, $\chi = 0$ on $(-\infty, \frac{1}{2}]$ and $\chi = 1$ on $[1, \infty)$;*

(Em3) *there are reals $\lambda_0 \geq \lambda_1 \geq \cdots \geq \lambda_{n-1}$ with $\lambda_l < \min(u_l, u_l') + 2$ and, if $l \geq 1$, $\lambda_{l-1} > \max(u_l, u_l') - 2$, such that $P(Y) = \prod_{t=0}^{n-1}(Y + \lambda_t)$ and $\mathrm{qd}(Y + \frac{n-1}{2})F = P(Y)F$ for every $Y \in [\alpha, \beta]$;*

(Em4) *there is $A_0 > 2(k+r)(r+1)$ such that F lies in $\mathcal{D}_r(\max(A_0, A_{\mathrm{E}}, A_{\mathrm{T}}), \max(4, m_{\mathrm{E}}, m_{\mathrm{T}}))$ and, for every $\varepsilon > 0$, $\chi(G_f/\varepsilon)F$ lies in $\mathcal{D}_r(A_0, nN_{\mathrm{top}} + 5)$ (each with some constant);*

(Em5) *every $w \in \mathcal{W}$ with $|w| \leq N_{\mathrm{top}}$ is a cut word;*

(Em6) *$N_{\mathrm{top}} \leq N_{\mathrm{tot}}$, and there is a real $L \geq 16\, e\, N_{\mathrm{tot}}(r+1)^2(1 + \sqrt{C_7})$, $C_7 = e^{28}(1 + C_{\mathrm{res}})^2$, with $6N_{\mathrm{tot}}L \leq \beta - \alpha$ and $nL \leq \beta - \alpha$.*

Then the energy system of the engine place for $(F, (\lambda_0, \ldots, \lambda_{n-1}), N_{\mathrm{tot}}, L)$, formed with this χ, together with $C_{\mathrm{m}} = \Gamma_0^{-1}$ and $\sigma_{\mathrm{m}} = 1$, is an energy model of the level-zero kernels of the datum. Consequently the datum satisfies (Pk14) with

$$J = \Gamma_0^{-1} \int_\Omega \|(\mathrm{R}F)(c,g)\|_{\mathrm{HS}}^2 \, d\mu(c,g) < \infty.$$

Proof. Outline. The proof checks that the energy system of the engine place satisfies (Ey1)–(Ey5) and the hypotheses of the energy limit theorem for energy systems: (Em3) makes $s\,P$ positive on the cut, the box words are cut words whose weights are positive definite, the energy identities are proved for nice approximations of F and passed to the limit, and the level-zero kernels are real by a self-adjointness argument for the Capelli operators; the resulting identity $g^{\mathrm{loc}}_{\varepsilon,0,w}(\varnothing,\varnothing) = \Gamma_0^{-1} E(\varepsilon, w)$ gives an energy model, and (Pk14) follows from Proposition A.77. □

Proposition A.77. *Let a local kernel datum with admitted words $\mathcal{W}$ and integer N_{top} be given. An **energy model** of its level-zero kernels consists of an energy system $\mathcal{S}$ satisfying (Ey1)–(Ey5) and the remaining hypotheses of the energy limit theorem for energy systems, with $N_{\mathrm{tot}} \geq N_{\mathrm{top}}$, and reals $C_{\mathrm{m}}, \sigma_{\mathrm{m}} > 0$, such that every $w \in \mathcal{W}$ with $|w| \leq N_{\mathrm{top}}$, read as a signed word (the letter $(\pm, y)$ as the pair $(\pm, y)$), is admitted for $\mathcal{S}$, has $\mathrm{size}(w) = \mathrm{wt}^{\mathrm{loc}}(w)$, and satisfies*

$$g^{\mathrm{loc}}_{\varepsilon,0,w}(\varnothing,\varnothing) = C_{\mathrm{m}}\, E(\sigma_{\mathrm{m}}\varepsilon, w) \qquad (\varepsilon > 0).$$

If the datum has an energy model, it satisfies (Pk14) with $J = C_{\mathrm{m}}\,\mathrm{jn}$.

Proof. By the energy limit theorem for energy systems, $\mathrm{jn} < \infty$; it is ≥ 0 as the integral of the nonnegative function $\mathrm{dens}(\varnothing)$, so $J = C_{\mathrm{m}}\mathrm{jn}$ is a real ≥ 0. Let $w \in \mathcal{W}$ with $|w| \leq N_{\mathrm{top}} \leq N_{\mathrm{tot}}$. By the same theorem, $E(\varepsilon', w) \to \mathrm{size}(w)\,\mathrm{jn}$ as $\varepsilon' \to 0^+$. As $\varepsilon \to 0^+$, $\varepsilon' = \sigma_{\mathrm{m}}\varepsilon \to 0^+$, so $g^{\mathrm{loc}}_{\varepsilon,0,w}(\varnothing,\varnothing) = C_{\mathrm{m}} E(\sigma_{\mathrm{m}}\varepsilon, w) \to C_{\mathrm{m}}\,\mathrm{size}(w)\,\mathrm{jn} = \mathrm{wt}^{\mathrm{loc}}(w)\,J$. □

Theorem A.78. *Let $r \geq 1$, $k \geq 2$ be integers, $n = 2r + k + 1$, $N_{\mathrm{top}} = 20(r+1)$, $n_{\mathrm{d}} = 5$, $C_b \geq 0$, and let an engine place of type l with constant C_b on a Bessel datum of rank r be given, with the data F, P, χ of (Pk6) and the Harish-Chandra parameters $u = (u_0, \dots, u_{k-1})$, $u' = (u'_0, \dots, u'_{k-1})$ of π, π'; write $I_l = [y_-, y_+]$. Suppose:*

(Pl1) Integrality. *$u_i - u_0 \in \mathbb{Z}$ and $u'_i - u_0 \in \mathbb{Z}$ for $0 \leq i \leq k-1$.*

(Pl2) Cut-off. *χ takes values in $[0,1]$, $\chi = 0$ on $(-\infty, \frac{1}{2}]$ and $\chi = 1$ on $[1, \infty)$.*

(Pl3) Test coefficient and gap. *$F(g) = \sum_{i=1}^{N} P_i\, \sigma(g)\, Q_i$, where σ is an irreducible square-integrable unitary representation of G_r on a Hilbert space $\mathcal{H}$ with Harish-Chandra parameter λ relative to a sign vector $\mathbf{j} \in \{+,-\}^n$ with $k+r$ entries $+$ and $r+1$ entries $-$, and $Q_i \colon \mathcal{E}' \to \mathcal{H}$, $P_i \colon \mathcal{H} \to \mathcal{E}$ are bounded linear maps with $Q_i(\mathcal{E}')$ and $P_i^*(\mathcal{E})$ consisting of smooth vectors; and there is a real h with $|\lambda_a - \lambda_b| \geq h$ whenever $\mathbf{j}_a \neq \mathbf{j}_b$ and*

$$h > \max\bigl(261\, n^4,\ n^5 + 5(C_b+3)^2 n^3\bigr).$$

(Pl4) Casimir polynomial. *There are reals $\mu_0 \geq \mu_1 \geq \cdots \geq \mu_{n-1}$ with $\mu_l < \min(u_l, u'_l) + 2$ and, if $l \geq 1$, $\mu_{l-1} > \max(u_l, u'_l) - 2$, such that $P(Y) = \prod_{t=0}^{n-1}(Y + \mu_t)$ for every $Y \in \mathbb{R}$, and $\mathrm{qd}(Y + \frac{n-1}{2})F = P(Y)F$ for every $Y \in [y_-, y_+]$.*

(Pl5) Long cut. *There is a real $L \geq 16\, e\, N_{\mathrm{top}}(r+1)^2(1+\sqrt{C_7})$ with $6N_{\mathrm{top}}L \leq y_+ - y_-$ and $nL \leq y_+ - y_-$.*

Take as admitted words the finite set $\mathcal{W}$ of Lemma A.74 for $(y_-, y_+, D, N, K, \delta) = (y_-, y_+, n, N_{\mathrm{top}}, 5, 3)$ and the polynomial P, as cut I_l, as functions q_w those of the wave and lift grids on the cut, the constants $G_{\mathrm{W}}, G_{\mathrm{L}}, G_{\mathrm{T}}$ and $\beta_j = \beta'_{b,s} = \beta$ of Lemma A.74 (for this q) and the constant C_{T} of the top-grid weight bound for $N = N_{\mathrm{top}}$, $K = 5$. Then the datum, with $N_{\mathrm{top}} \geq n_{\mathrm{d}}$, has the lower block clauses and satisfies (Pk14); its coefficients Φ_m of (Kx10) are, for each $\varepsilon > 0$, $\Phi_m(g) = s((4 - \|g\|_{\mathrm{F}}^2/(m+1)^2)/3)\chi(G_f(g)/\varepsilon)F(g)$ for any fixed smooth $s \colon \mathbb{R} \to [0,1]$ with $s = 0$ on $(-\infty, 0]$ and $s = 1$ on $[1, \infty)$, and it has an energy model of its level-zero kernels. In particular, if $C_b \leq 11$, the gap hypothesis of (Pl3) holds whenever $h \geq \frac{1}{2}n^{19}$.

Proof. We verify the hypotheses of part (ii) of the archimedean product theorem for local kernel data: (Kx1)–(Kx6), (Kx9), (Kx13); for every $\varepsilon > 0$ nice coefficients Φ_m with (Tn1), (Tn3), (Tn5) (with (Tn6)) and with (Kx11), (Kx12); an energy model of the level-zero kernels. Throughout, $n \geq 5$ (as $r \geq 1$, $k \geq 2$).

The cut and the cut words. By (EP2) the top datum is frame-compatible for (u, u'), read as $(u_1, \dots, u_k)$, $(u'_1, \dots, u'_k)$, with $l_0 = l + 1$; so the cut I_{l+1} of (Ft0), used below for the slice, descent and top clauses, is I_l, and the cut words there are those of the wave and lift grids on the cut. With $m_* = \min(u_l, u'_l)$, $M_* = \max(u_l, u'_l)$ we have $I_l = [2 - M_*, -m_* - 2]$, so $y_+ - y_- = M_* - m_* - 4$.

Sizes of the cut. By (Pl5), $y_+ - y_- \geq nL \geq 16e \cdot 20(r+1)^3 n > 800\, n(r+1)^3$. Hence (S1) $y_+ - y_- \geq 1 + 3(5(2r+1) + 3N_{\mathrm{top}} + 2n) = 196 + 210r + 6n$; (S2) $y_+ - y_- \geq 9(2r+1) + 6N_{\mathrm{top}} + 1 = 138r + 130$; (S3) $M_* - m_* = y_+ - y_- + 4 \geq 5$; each because $800n(r+1)^3 \geq 800n(r+1) > 196 + 210r + 6n$ and $> 138r + 130$.

Positivity of q. Let $y \in [y_-, y_+ - 1]$. The one-letter words $((+, y))$ and $((-, y+1))$ are cut words (one letter, value in I_l), so Proposition A.73 applies with $j = 0$, $w = \varnothing$ (a cut word), $ys = (y)$ (its entries pairwise differ by more than 2 vacuously; $w^+_{ys} = ((+, y))$, $w^-_{ys} = ((-, y+1))$ are cut words) and gives $q(y) = q_{\varnothing}(y) > 0$. Also q is a polynomial, hence continuous.

(Kx1) and (Kx6). By (Pl4), P is a nonzero real polynomial of degree n. Apply Lemma A.74 with $y_- < y_+$ ($y_+ - y_- \geq 1$ by (S3)), $D = n$, $N = N_{\mathrm{top}} \geq K = 5$, $\delta = 3$, this P and this q (continuous and positive on $[y_-, y_+ - 1]$ by the previous paragraph). Its admitted words are $\mathcal{W}$ and its q_w are those of the wave and lift grids on the cut. By (S1) the hypothesis of its final sentence holds, so the datum satisfies (Kx1) with $G_{\mathrm{W}}, G_{\mathrm{L}}, G_{\mathrm{T}}$ and (Kx6) with $\beta_j = \beta'_{b,s} = \beta$. In particular every admitted word is a cut word of length at most N_{top} with $\mathrm{wt}^{\mathrm{loc}} > 0$, $\varnothing \in \mathcal{W}$, and $\mathcal{W}$ is finite.

(Kx2), (Kx3), (Kx13). By the lemma on the slice, wave-isometry and descent clauses of engine places, whose hypotheses are an engine place of type l with constant C_b on a Bessel datum of rank r, $k \geq 2$, and the cut I_{l+1} of (Ft0), which is I_l.

(Kx4). By the Fourier identity for engine places (engine place, $k \geq 2$, cut I_l): (Kx4) holds for every nice Φ, every $0 \leq j \leq r$, every cut word w with $\mathrm{wt}^{\mathrm{loc}}(w) > 0$ and all local points of level j; for $\mathrm{wt}^{\mathrm{loc}}(w) = 0$ (Kx4) asserts nothing.

(Kx5). Let Φ, $0 \leq j \leq r$, a cut word w, $ys \in \mathbb{R}^m$ with $w^{\pm}_{ys}$ cut words and families x, x' of nice coefficients be given. The entries of ys are letter values of distinct positions of the cut word w^+_{ys}, so they pairwise differ by more than 2. Hence Proposition A.73 (engine place of type l, $k \geq 2$, the q_w of the wave and lift grids, which are the q_w of the datum) gives $q_w(y) > 0$ for y in ys and the inequality of (Kx5).

(Kx9). (a) (Kx15) is part (c) of the top-clause lemma for engine places, and (Kx16) is the completeness of the type projections for frame-compatible top data (the top datum is frame-compatible); (b) is part (b) of the top-clause lemma; (d) is its part (a), for every cut word w, with $q_t \leq C_b|w|n$ and $\kappa_e = C_b(C_b+3)(r+1)|w|n$. The hypotheses of the top-clause lemma are an engine place of type l with constant C_b on a Bessel datum of rank $r \geq 1$, $k \geq 2$, and the cut I_{l+1} of (Ft0). (c) is the top-grid weight bound for frame-compatible top data: the top datum is frame-compatible for (u, u') with $l_0 = l+1$, so its u_{l_0}, u'_{l_0} are u_l, u'_l and $M - m = M_* - m_* \geq 5$ by (S3); P is continuous; $N = N_{\mathrm{top}} \geq K = 5$; and every admitted word has length at most N_{top}. So (Kx9)(c) holds with C_{T}.

Decay of the test coefficient. The decay lemma for cut-off discrete-series coefficients applies to the Bessel datum of rank r ($k \geq 1$), σ, λ, $\mathbf{j}$, the gap $h > 0$, the maps P_i, Q_i of (Pl3), and any smooth χ_1 with χ_1 and all its derivatives bounded: then $\chi_1(G_f/\varepsilon)F \in \mathcal{D}_r(A, M)$ whenever $\theta(\mathbf{j}) + \max(\lceil A \rceil, 0) + 2(r+1)M < h$. Both χ (smooth by (Pk6), with values in $[0,1]$ and constant outside $[\frac{1}{2}, 1]$ by (Pl2), so every derivative is continuous with support in $[\frac{1}{2}, 1]$) and $\chi_1 \equiv 1$ qualify. We also use that $\mathcal{D}_r(A, M) \subseteq \mathcal{D}_r(A, M')$ for integers $0 \leq M' \leq M$ (fewer derivatives are bounded), with the same constant.

The truncations. Fix $\varepsilon > 0$ and s as in the statement, and let $\Phi_m = s((4 - \|g\|^2_{\mathrm{F}}/(m+1)^2)/3)F_\varepsilon$; these are the coefficients of the lemma on cut-off truncations and of the lemma on truncations at the top level, and they are nice by the former, whose standing hypothesis holds as χ vanishes on $(-\infty, \frac{1}{2})$ by (Pl2). Every word of $\mathcal{W}^+$ is a cut word of length at most $N_{\mathrm{top}}+3$: the words of $\mathcal{W}$, and the words $w^{\pm}_{\mathbf{n}}$ of decay grids of $w \in \mathcal{W}$, which are cut words of length $|w|+3$ by definition. For a cut word w' the operator $\mathrm{RR}_{w'}$ is defined, since the factors $\mathrm{R}_a(x)$, $\widetilde{\mathrm{R}}_a(x)$ are evaluated at differences of letter values of distinct positions, which exceed 2 in absolute value, so $x \neq 1$.

(Tn1). By the existence of decay grids on a long cut: the cut I_l contains $[y_-, y_+]$, every admitted word is a cut word of length at most N_{top}, and $y_+ - y_- \geq 9(2r+1) + 6N_{\mathrm{top}} + 1$ by (S2).

(Tn5) with (Tn6). Let $w \in \mathcal{W}$, $0 \leq j \leq r$, h_0 a local point of level j and $ys \in \mathbb{R}^{m'}$, $m' \in \{0, 3\}$, with $w' = w^+_{ys}$ a cut word; $|w'| \leq N_{\mathrm{top}} + 3$. Apply the lemma on cut-off truncations to w' and j with $A_{\mathrm{B}} = 2(k+r)(r+1)+1$. Its hypothesis (1) holds since $A_{\mathrm{B}} > 2(k+\rho)(\rho+1)$

for $\rho = r - j \le r$. For (2), its numbers A_1, m_1, A_2, A_0, M_0 are those of part (b) of the gap budget of the truncation clauses with $x = |w'|$ (same A_{B}, same n_ρ), and by that part (b) (with $r \ge 1$, $k \ge 2$ and the sign vector $\mathbf{j}$ of (Pl3)) $\theta(\mathbf{j}) + \lceil A_0 + 1 \rceil + 2(r+1)M_0 < 261n^4 \le h_* < h$; so $F_\varepsilon \in \mathcal{D}_r(A_0+1, M_0)$ by the decay paragraph. Conclusion (a) of the lemma on cut-off truncations is (Tn5) with (Tn6) for w', j, h_0.

(Tn3) at levels $i \le r$. For $w' \in \mathcal{W}^+$ and $j = i$, the same check (with $x = |w'| \le N_{\mathrm{top}}+3$) gives the hypotheses of the lemma on cut-off truncations, whose conclusion (b) is $K_{i,w'}(\Phi_m)(p,q) \to K_{i,w'}(F_\varepsilon)(p,q)$ for local points of level i; for other points both sides vanish.

(Tn3) at the level $r+1$. For $w \in \mathcal{W}^+$ hypothesis (i) of the lemma on truncations at the top level is (Kx9)(d), proved above for every cut word, with $o_w = \max q_t \le \lfloor C_b|w|n \rfloor$ (o_w is an integer) and $\kappa_w = C_b(C_b+3)(r+1)|w|n$. By part (a) of the gap budget of the truncation clauses, with $x = |w| \le N_{\mathrm{top}} + 3$, $\theta(\mathbf{j}) + \lceil A_{\mathrm{orb}} + \kappa_w \rceil + 2(r+1)\lfloor C_b|w|n \rfloor < n^5 + 5(C_b+3)^2 n^3 \le h_* < h$, so $F_\varepsilon \in \mathcal{D}_r(A_{\mathrm{orb}} + \kappa_w, \lfloor C_b|w|n \rfloor) \subseteq \mathcal{D}_r(A_{\mathrm{orb}} + \kappa_w, o_w)$: hypothesis (ii). By the final sentence of the lemma on truncations at the top level, (Tn3) holds at the level $r+1$ for ε and (Φ_m), with the same Φ_m.

(Kx11) and (Kx12) for these Φ_m. The Φ_m are nice and the admitted words are cut words of positive weight, so parts (b) and (c) of the continuity and germ-rate lemma for engine places (engine place of type l with constant C_b, $k \ge 2$) give (Kx11) and (Kx12).

Energy model. Apply Proposition A.76 with $N_{\mathrm{tot}} = N_{\mathrm{top}} = 20(r+1)$ and the numbers $A_{\mathrm{E}}, m_{\mathrm{E}}, A_{\mathrm{T}}, m_{\mathrm{T}}$ of the adjointness and transfer propositions for the engine energy system, for $(C_b, r, k, N_{\mathrm{tot}})$ (they do not depend on C_b): (Em1) is (Pl1); (Em2) is (Pl2); (Em3) is (Pl4) with $\lambda_t = \mu_t$ and $[\alpha, \beta] = [y_-, y_+]$; (Em5) holds as every admitted word is a cut word; (Em6) is (Pl5) with $N_{\mathrm{top}} \le N_{\mathrm{tot}}$. For (Em4) take $A_0 = 2(k+r)(r+1)+1 > 2(k+r)(r+1)$. By the decay budget of the energy model (for $r \ge 0$, $k \ge 2$, $N_{\mathrm{tot}} = 20(r+1)$, this A_0 and the sign vector $\mathbf{j}$ with $k+r$ entries $+$ and $r+1$ entries $-$), $\theta(\mathbf{j}) + \lceil \max(A_0, A_{\mathrm{E}}, A_{\mathrm{T}}) \rceil + 2(r+1)\max(4, m_{\mathrm{E}}, m_{\mathrm{T}}) < 261n^4 < h$, so the decay paragraph with $\chi_1 \equiv 1$ gives $F \in \mathcal{D}_r(\max(A_0, A_{\mathrm{E}}, A_{\mathrm{T}}), \max(4, m_{\mathrm{E}}, m_{\mathrm{T}}))$; and $\theta(\mathbf{j}) + A_0 + 2(r+1)(nN_{\mathrm{top}} + 5) < 261n^4 < h$ by the same lemma, so the decay paragraph with χ gives $F_\varepsilon \in \mathcal{D}_r(A_0, nN_{\mathrm{top}} + 5)$ for every $\varepsilon > 0$. Hence the place has an energy model of its level-zero kernels.

Conclusion. All hypotheses of part (ii) of the archimedean product theorem hold for the datum with admitted words $\mathcal{W}$ and $N_{\mathrm{top}} \ge n_{\mathrm{d}}$, the cut I_l, the q_w and the constants named in the statement; so it has the lower block clauses and satisfies (Pk14), the coefficients of (Kx10) being the Φ_m. If $C_b \le 11$, then $h_* < \frac{1}{2}n^{19}$ by part (c) of the gap budget of the truncation clauses, so $h \ge \frac{1}{2}n^{19}$ gives $h > h_*$. □

Proposition A.79. *In the setting of Theorem A.71 there is a real Y_{ins} with the following property. Let $x \in W$ with $x \ge Y_{\mathrm{ins}}$, let $a \in A_x$ be a member with word sizes for the fixed word-size constant C_0, and let $\mathfrak{X}$ be its member Hida and Poincaré setting determined by the selected tied local data, with assembled datum D. Fix a local choice (φ, ν, m) of $\mathfrak{X}$, distinct member words $\omega \ne \omega'$, a place $\tau \in \Phi$, and a Bessel place formed by the selected tied local data at this choice for (ω, ω') at τ at scale 1, with its given section μ. Put $u = u_{\omega,\tau}$, $u' = u_{\omega',\tau}$, $r = r_S = m_D/2 - 1$ and $n = k + m_D - 1 = 2r + k + 1$, where m_D denotes the rank-datum integer of D.*

Let $a_\tau, b_\tau \in \mathcal{H}^\infty_{X,\tau}$, $\xi_\tau \in \mathcal{E}$, $\xi'_\tau \in \mathcal{E}'$ and $c^{\mathrm{coef}}_\tau \in \mathbb{C}$ be given. Define the prescribed coefficient by

$$F_{\mathrm{given}}(g)\eta = c^{\mathrm{coef}}_\tau \, \langle a_\tau, \sigma^\varphi_\tau(g) b_\tau \rangle \, \xi_\tau \langle \xi'_\tau, \eta \rangle \qquad (\eta \in \mathcal{E}').$$

Then there are an integer $1 \le l \le k-2$ with $c(\omega)_l \ne c(\omega')_l$ (and hence $u_l \ne u'_l$, using zero-based coordinates for u, u'), and an engine place of type l with constant $C_b = 11$ on the Bessel datum of the given place, whose data have $F = F_{\mathrm{given}}$ and whose P, χ satisfy (Pl1)–(Pl5) with the same

representation $\sigma = \sigma^{\varphi}_{\tau}$, $\lambda = \lambda_{\tau}$, $\mathbf{j} = \varepsilon_S$ and $h = n^{19}/2$. In particular $F = \sum_i P_i \sigma Q_i$ with $Q_i(\mathcal{E}')$ and $P_i^*(\mathcal{E})$ consisting of smooth vectors; χ is a cut-off of (Pl2); $P(Y) = \prod_{s=0}^{n-1}(Y + \lambda_{\tau,s})$ for all real Y and $\mathrm{qd}(Y + (n-1)/2)F = P(Y)F$ on the cut; and I_l is long as in (Pl5).

Proof. Outline. By the context tie Proposition A.114 the word code of the context is injective, so two distinct words differ in some bit l with $1 \le l \le k-2$, whence $|u_l - u'_l| = \Delta_D$ and the cut I_l has length $\Delta_D - 4$, which gives (Pl5) on a tail in x; the engine place of type l with $C_b = 11$ is obtained from the existence result for engine places, (Pl1) comes from the half-integrality of u, u', (Pl3) from the square-integrability of σ^{φ}_{τ} with parameter λ_{τ} and the gap of the member parameter, and the order conditions of (Pl4) from its interlacing, the prescribed coefficient is written as one term $P_1 \sigma Q$, the eigen-equation of (Pl4) follows from the centrality of the coefficients of the quantum determinant, and an explicit smooth cut-off gives (Pl2). □

A.7.2 Bessel amplitudes and point sums

At a complex place the Bessel places, Bessel sections, amplitudes and Bessel masses are defined in Definition A.80, and the hermitian space, Bessel subgroups, Bessel transform, big-cell pairing and orbital integrals in Definition A.81. The minor-weighted local amplitude bound of a term is Proposition A.82. Its bound (Aq1) does not depend on the following lemma; its clause for degenerate pairs rests in addition on an absolute bound with size decay, Lemma A.83, which we sketch. The main analytic input is the pointwise Bessel bound at large gap (Theorem A.84), and the constants are uniform on a parameter ball, independently of the place (Proposition A.85). A second bound of the same kind controls the weighted point sum of orbital squares over B-points (Theorem A.86), and this gives the point sum (Ng6) of the non-generic row (Proposition A.87).

Definition A.80. Fix integers $r \ge 0$, $k \ge 1$ and put $n = 2r + k + 1$.

Bessel places. A **Bessel place** of rank r consists of a Bessel datum of rank r (vectors $z, z' \in W$ with $T(z), T(z') > 0$, representations π of H_z on $\mathcal{E}$ and π' of $\mathrm{H}_{z'}$ on $\mathcal{E}'$, the section μ of (Pk4)), a real number $c_\psi > 0$ (the **character constant**) with the characters

$$\psi_z(g) = \exp\bigl(i\,\mathrm{Re}(c_\psi\,\ell_z(g))\bigr), \qquad \psi_{z'}(g) = \exp\bigl(i\,\mathrm{Re}(c_\psi\,\ell_{z'}(g))\bigr)$$

of N_r, a Haar measure dg on G_r, the Haar probability measures dh, dh' on H_z, $\mathrm{H}_{z'}$, a Haar measure dn on N_r, a Haar measure $dg_{\deg}$ on G_r (for formal degrees), and measures ν_S, ν'_S on G_r with

$$\int \phi\, dg = \iiint \phi(hnx)\, dh\, dn\, d\nu_S(x) = \iiint \phi(h'nx)\, dh'\, dn\, d\nu'_S(x) \qquad (\phi \ge 0 \text{ measurable}).$$

Bessel sections. Let a Bessel place be given and $\lambda \in \mathbb{R}^n$ a Harish-Chandra parameter. A **Bessel section at** λ is a tuple $A = (\mathcal{H}, \sigma, B, B', v_0, c_N, \deg)$ where

(Bs1) σ is an irreducible square-integrable unitary representation of G_r on a Hilbert space $\mathcal{H}$ with Harish-Chandra parameter λ relative to ε (after conjugation by a Cayley transform from the standard form of the unitary group to G_r); $\mathcal{H}^{\infty}$ is its space of smooth vectors;

(Bs2) $B\colon \mathcal{H}^{\infty} \to \mathcal{E}$ and $B'\colon \mathcal{H}^{\infty} \to \mathcal{E}'$ are **Bessel maps**: linear, with

$$B(\sigma(hn)v) = \psi_z(n)\,\pi(h)B(v)$$

for $h \in \mathrm{H}_z$, $n \in \mathrm{N}_r$, $v \in \mathcal{H}^{\infty}$ (and likewise for B' with z', π'), and continuous in the sense that $\|B(v)\| \le C \sum_w \|d\sigma(w)v\|$ for some C and finitely many words w in the Lie algebra of G_r;

(Bs3) $v_0 \in \mathcal{H}^\infty$ is nonzero and lies in the lowest K-type of σ;

(Bs4) $c_N > 0$ and, with $\Phi_A(g) = B(\sigma(g)v_0)$ and $\Phi'_A(g) = B'(\sigma(g)v_0)$,

$$\int \|\Phi_A\|^2 \, d\nu_S = c_N \dim \mathcal{E}, \qquad \int \|\Phi'_A\|^2 \, d\nu'_S = c_N \dim \mathcal{E}';$$

(Bs5) $\deg > 0$ is the formal degree of σ with respect to $dg_{\deg}$: $\int \langle w, \sigma(g)v\rangle \overline{\langle w', \sigma(g)v'\rangle} \, dg_{\deg} = \langle v', v\rangle\langle w, w'\rangle / \deg$ for all $v, w, v', w' \in \mathcal{H}$.

Amplitudes and Bessel masses. For a Bessel section A, a measure ν on G_r and $\gamma \in \mathrm{G}_r$ the **amplitude** is

$$J_A(\nu, \gamma) = c_N^{-1} \int \Phi_A(\gamma x) \otimes \Phi'_A(x)^* \, d\nu(x) \in \mathrm{Hom}(\mathcal{E}', \mathcal{E}),$$

its **Bessel mass** is

$$M(A) = \int_{(\mathbb{C}^\times)^r \times \Omega} w(c, \zeta) \, \|J_A(dg, g_{c,\zeta})\|_{\mathrm{HS}}^2 \, dc \, d\zeta \in [0, \infty],$$

and its **unit amplitude** is $j_A(\nu, \gamma) = M(A)^{-1/2} J_A(\nu, \gamma)$ if $0 < M(A) < \infty$, and $j_A(\nu, \gamma) = 0$ otherwise.

Relative points and root measures. Let p be a point over $\mathbb{C}$ of length $r+1$, and let $S_r = \mathrm{diag}((-1)^{r-b})_{0 \le b \le r}$ be the **sign matrix** of the flag. An element $\gamma \in \mathrm{G}_r$ is a **relative point** of p if $G_f(\gamma) \neq 0$ and $\widehat{Z}(\gamma)\, S_r = L \, \mathrm{pm}(p) \, U$ with L lower and U upper unitriangular. A measure μ_R on G_r is a **root measure** of p at γ if $\gamma = n_1 g_0 n_2$ with $n_1, n_2 \in \mathrm{N}_r$, $\widehat{Z}(g_0)\, S_r = \mathrm{pm}(p)$, and μ_R is the image under $x \mapsto n_2^{-1} x n_2$ of a measure μ_0 concentrated on the group $R'_{g_0} = \{s \in \mathrm{N}_r : \ g_0 s g_0^{-1} \in \mathrm{N}_r\}$ whose image under the **right root coordinates** $s \mapsto$ (the e_i-coordinate of $sf'_j)_{(i,j)}$, (i,j) running over the pairs $i < j$ of indices in one block of p, is $(c_\psi/2\pi)^{\#}$ times Lebesgue measure ($\#$ the number of such pairs). Then μ_R is concentrated on $\{s \in \mathrm{N}_r : \ \gamma s \gamma^{-1} \in \mathrm{N}_r\} = \gamma^{-1} R_\gamma \gamma$. For $\theta > 0$, a measure ν on G_r is a **root quotient of scale** θ at γ if for some point p and some root measure μ_R of p at γ

$$\int \phi \, dg = \theta \iint \phi(sx) \, d\mu_R(s) \, d\nu(x) \qquad (\phi \ge 0 \text{ measurable}).$$

Definition A.81. The space and the group. Let $k \ge 1$ and $\rho \ge 0$ be integers and $n = 2\rho + k + 1$. On $V_\rho = \mathbb{C}^n$, with standard basis $e_0, \dots, e_{n-1}$, let H_ρ be the matrix with $(H_\rho)_{a,n-1-a} = (H_\rho)_{n-1-a,a} = 1$ for $a < \rho$, $(H_\rho)_{aa} = 1$ for $\rho \le a < \rho + k$, $(H_\rho)_{\rho+k,\rho+k} = -1$ and all other entries 0, and put $h(v, w) = w^* H_\rho v$ (linear in v). Write $e_a^* = e_{n-1-a}$ $(a < \rho)$, $X_a = \mathrm{span}(e_0, \dots, e_{a-1})$ and $W = \mathrm{span}(e_\rho, \dots, e_{\rho+k})$, of signature $(k, 1)$; so $h(e_a, e_b^*) = \delta_{ab}$, the e_a are isotropic and V_ρ has signature $(k + \rho, \rho + 1)$. Let $\mathrm{G}_\rho = \{g \in \mathrm{GL}_n(\mathbb{C}) : g^* H_\rho g = H_\rho\}$, $\mathrm{N}_\rho = \{g \in \mathrm{G}_\rho : ge_a \in e_a + X_a \ (a < \rho), \ gw \in w + X_\rho \ (w \in W)\}$ (the unipotent radical of the parabolic subgroup stabilising the flag $X_1 \subset \cdots \subset X_\rho$), and for $z \in W$ put $T(z) = -h(z, z)$,

$$\ell_z(g) = \sum_{a=0}^{\rho-2} g_{a,a+1} + (gz)_{\rho-1}, \qquad \psi_z(g) = \exp(\ell_z(g) - \overline{\ell_z(g)}) \qquad (\ell_z = 0 \text{ if } \rho = 0),$$

and $\mathrm{H}_z = \{g \in \mathrm{G}_\rho : ge_a = e_a, \ ge_a^* = e_a^* \ (a < \rho), \ gz = z\}$. The space $V_{\rho'}$ for $\rho' \le \rho$ is identified with $\mathrm{span}(e_{\rho-\rho'}, \dots, e_{n-1-\rho+\rho'}) \subseteq V_\rho$ and $\mathrm{G}_{\rho'}$ with the subgroup of G_ρ fixing e_a, e_a^* for $a < \rho - \rho'$; W is the same space at every ρ'.

Bessel data. A **Bessel datum** of rank ρ consists of

(Pk1) vectors $z, z' \in W$ with $T(z) > 0$ and $T(z') > 0$ (then $z^{\perp} \cap W$ is positive definite and $\mathrm{H}_z \cong \mathrm{U}(k)$ is compact);

(Pk2) finite-dimensional Hilbert spaces $\mathcal{E}, \mathcal{E}'$ and continuous unitary representations π of H_z on $\mathcal{E}$ and π' of $\mathrm{H}_{z'}$ on $\mathcal{E}'$;

(Pk3) Haar measures dg on G_ρ and dn on N_ρ and the Haar probability measures dh, dh' on H_z, $\mathrm{H}_{z'}$;

(Pk4) a smooth map μ from $\Omega = \{\zeta \in \mathbb{C} : |\zeta|^2 > T(z)T(z')\}$ to the unitary group $\mathrm{U}(W, h)$ with $h(\mu(\zeta)z', z) = \zeta$.

A **coefficient** is a function $F \colon \mathrm{G}_\rho \to \mathrm{Hom}(\mathcal{E}', \mathcal{E})$.

Bessel transform. For a coefficient F and $g \in \mathrm{G}_\rho$,

$$(\mathcal{J}F)(g) = \int_{\mathrm{H}_z} \int_{\mathrm{N}_\rho} \int_{\mathrm{H}_{z'}} \int_{\mathrm{N}_\rho} \psi_z(n)\, \overline{\psi_{z'}(n')}\, \pi(h)\, F(h^{-1}n^{-1}gn'h')\, \pi'(h')^{-1}\, dn'\, dh'\, dn\, dh. \tag{A.7}$$

The big cell and the pairing. For $c \in (\mathbb{C}^\times)^\rho$ and $\zeta \in \Omega$ let $g_{c,\zeta} \in \mathrm{G}_\rho$ be given by $g_{c,\zeta} e_a = c_a e_a^*$, $g_{c,\zeta} e_a^* = \bar{c}_a^{-1} e_a$ $(a < \rho)$ and $g_{c,\zeta}|_W = \mu(\zeta)$, and put $w(c,\zeta) = \prod_{a<\rho} |c_a|^{2(n-2a-2)}\, (|\zeta|^2 - T(z)T(z'))^{k-1}$. The **big-cell pairing** of coefficients F, F' is

$$\beta(F, F') = \int_{(\mathbb{C}^\times)^\rho \times \Omega} w(c,\zeta)\, \big\langle (\mathcal{J}F')(g_{c,\zeta}), (\mathcal{J}F)(g_{c,\zeta}) \big\rangle_{\mathrm{HS}}\, dc\, d\zeta \tag{A.8}$$

(Lebesgue measure on $\mathbb{C}^{\rho+1} = \mathbb{R}^{2\rho+2}$); it is linear in F and conjugate-linear in F'.

Invariants of a double coset. Put $f_a = f'_a = e_a$ $(a < \rho)$, $f_\rho = z$, $f'_\rho = z'$, and for $g \in \mathrm{G}_\rho$ let $\widehat{Z}(g)$ be the $(\rho+1) \times (\rho+1)$ matrix $\widehat{Z}(g)_{ab} = h(g f'_b, f_a)$, $D_l(g)$ $(0 \le l \le \rho+1)$ its leading principal $l \times l$ minor $(D_0 = 1)$ and

$$G_f(g) = |D_{\rho+1}(g)|^2 - T(z)T(z')\, |D_\rho(g)|^2. \tag{A.9}$$

Orbital integrals. Let $\gamma \in \mathrm{G}_\rho$, $R_\gamma = \{m \in \mathrm{N}_\rho : \gamma^{-1} m \gamma \in \mathrm{N}_\rho\}$ and dm a Haar measure on R_γ. A **cut** at γ is a measurable $\vartheta \ge 0$ on $\mathrm{H}_z \times \mathrm{N}_\rho \times \mathrm{H}_{z'} \times \mathrm{N}_\rho$ with $\int_{R_\gamma} \vartheta(h, mn, h', \gamma^{-1} m \gamma n')\, dm = 1$ for all (h, n, h', n'). The **orbital integral** of F at (γ, dm, ϑ) is

$$\mathcal{O}_\gamma(F) = \int \vartheta(h,n,h',n')\, \psi_z(n)\, \overline{\psi_{z'}(n')}\, \pi(h)\, F(h^{-1}n^{-1}\gamma n' h')\, \pi'(h')^{-1}\, dn'\, dh'\, dn\, dh. \tag{A.10}$$

Base frames and representatives. For $v \in V_\rho$ let v_W be its component in W and $\mathrm{pr}_z(v) = v_W - \frac{h(v_W, z)}{h(z,z)} z$. A **base frame** is a pair (ν', m_0) with $\nu' \in W$, $h(\nu', z') = 0$, $h(\nu', \nu') = 1$, and $m_0 \in \mathrm{G}_\rho$ fixing all e_a, e_a^* $(a < \rho)$ with $m_0 z' = \sqrt{T(z')/T(z)}\, z$. For γ with $\det \widehat{Z}(\gamma) \neq 0$ put $\mathrm{cof}_R(\gamma) = \sum_b \mathrm{adj}(\widehat{Z}(\gamma))_{b\rho}\, \gamma f'_b$ and $\mathrm{cof}_L(\gamma) = \sum_a \overline{\mathrm{adj}(\widehat{Z}(\gamma))_{\rho a}}\, f_a$. An element $\gamma \in \mathrm{G}_\rho$ is **framed** by (ν', m_0) if $\mathrm{pr}_z(\mathrm{cof}_R(\gamma)) = a \det \widehat{Z}(\gamma)\, m_0 \nu'$ and $\mathrm{pr}_{z'}(\gamma^{-1}\mathrm{cof}_L(\gamma)) = a' \overline{\det \widehat{Z}(\gamma)}\, \nu'$ for some reals $a, a' > 0$, and $\mathrm{pr}_z(u) = m_0\, \mathrm{pr}_{z'}(\gamma^{-1} u)$ for every u with $h(u, f_a) = h(u, \gamma f'_a) = 0$ for all $a \le \rho$.

Proposition A.82. *Let $C_h, C_n, C_1 \ge 0$. Let C_a, C_b, C_k and the lower bound $\max(C_{g,0}, C_{g,1})$ for C_g be as in the assembly of the clauses (Am2), (Am3) on the parameter ball for (C_h, C_n, C_1) and $C_M = 0$, and let C_g be a real at least this bound and at least the constant $C_{g,0}$ of part (b) of the construction of the Bessel place of a member for $(C_h, C_u) = (C_h, C_n)$. Let $C_K \ge 0$. Let C_{gf} be the constant of the change of scale of a point-sum datum by a torus translate. Then the following*

holds for every assembled master datum D with rank datum $(\dots;k,m,t)$, $n=k+m-1$, $r=r_S$, with $C_n\le m^2$, $C_g\le m^7$ and $8C_{gf}\le n^{23/2}$, and every $\tau\in\Phi$ at which D satisfies (Zn1)–(Zn4).

Let u,u' be Harish-Chandra parameters of D at τ satisfying (P2) for C_g, let $b\ge\max(2,u_0,u_0',b_{\tau,m})$, let $T,T',c_\psi,v,\theta>0$ satisfy (Mp1) with $C_T=C_c=C_h$, and let local data of D at τ for (u,u',T,T',v,θ) be given, with character constant c_ψ and representation π on $\mathcal{E}$. Let reals g,L,C_l,C_g',C_S be such that $(v,g,b,L,C_l,C_g',C_S,C_K,\theta)$ satisfy the conditions of the constant clause (Am4) for Bessel amplitude data at large gap, and $TT'\theta^2\le 2^{r+1}b^{C_Sm^2}$. Put $R=C_nkm^3$, let $\mathcal{P}\subseteq\lambda_\tau+\mathbb{Z}^n$ with $\lambda_\tau\in\mathcal{P}$ and, for $\lambda\in\mathcal{P}$, Bessel sections A_λ at λ; put $A_0=A_{\lambda_\tau}$. Let p be a point over $\mathbb{C}$ of length $r+1$, γ a relative point of p, $G=G_f(\gamma)$ (then $G>0$), and ν a root quotient at γ of a scale θ' with $b^{-C_1m^2}\le\theta'\le b^{C_1m^2}$. Assume the decomposition condition (As3) of that assembly for these data, $\mu_0=\lambda_\tau$ and R; the conditions (As1), (As2) and (As4) are not assumed. (As3) need not be assumed if the conditions (Dz1) and (Dz2) for decomposition data on a parameter ball hold for these data, $\mu_0=\lambda_\tau$ and R. Put

$$X=\max(G,G^{-1})\prod_{l\in\mathrm{be}(p)}\max\bigl(|D_l(p)|,|D_l(p)|^{-1}\bigr)^{2(m+4)},$$

$$\Lambda=b^{(C_b+11C_a)m^4+C_Km^2}\max(1,G^{-1})^{10m^2}\,X,$$

$B=b^{C_km^2}(e\,n^3)^{(r+1)/2}$ and $t=t(T',\mathrm{vU}(n)\,\alpha\,\deg(A_0),u')$. Then $|D_l(\gamma)|=|D_l(p)|$ for $0\le l\le r+1$, and for every integer $0\le l\le r+1$ and every integer $q\ge0$ with $q\,l\le C_nkm^3$,

$$n_0(T)\,G^k\,\|J_{A_0}(\nu,\gamma)\|_{\mathrm{HS}}^2\,|D_l(\gamma)|^{2q}\le\Lambda\,t^{-k}\,\dim\mathcal{E}\;B^{2q}.$$

Moreover, if $n\le b^c$ for a real $c\ge0$, then $B\le b^{(C_k+1+2c)m^2}$; and if the place satisfies the compact-dual normalisation (Cd) of the formal degree, then $t=t(T',\deg(A_0),u')$. In particular, at a complex place τ of archimedean amplitude records with $n_\tau=n_0(T)G^k$, $h_\tau=\|J_{A_0}(\nu,\gamma)\|_{\mathrm{HS}}^2$, $d_\tau=\dim\mathcal{E}$, $\lambda_\tau=\Lambda$, $t_\tau=t$, $D_{\tau,l}=|D_l(\gamma)|$, $Q\le C_nkm^3$ and $b^{(C_k+1+2c)m^2}\le H$ (in place of the constant B of the records), the inequality of (Aq1) holds at τ.

Degenerate-pair clause. *Let $A>0$. There is a real $C_d\ge1$ such that the following holds for the same data whenever, in addition,*

(Dg1) *$T'/T\le A$;*

(Dg2) *$k^{3r}g^m\le T'\,t$, with t as above;*

(Dg3) *$g\ge1$, $v\ge1$, $k\ge C_d$ and $n\le b^c$.*

Put $\kappa=1$ if $D_r(\gamma)=0$, and otherwise $c_\gamma=|D_{r+1}(\gamma)|/(|D_r(\gamma)|\sqrt{TT'})$ (then $c_\gamma>1$, as $G>0$) and $\kappa=(1+c_\gamma)/\sqrt{c_\gamma^2-1}$. With $\mathrm{be}(p)$ and $D_l(p)$ as above put

$$\Lambda_d=b^{C_dm^4}\max(G,G^{-1})^{C_dm^2}\prod_{l\in\mathrm{be}(p)}\max\bigl(|D_l(p)|,|D_l(p)|^{-1}\bigr)^{C_dm}$$

$$\cdot\Bigl(b^{C_dm}\max_{l\in\mathrm{be}(p)}\max\bigl(1,|D_l(p)|^{-1}\bigr)\Bigr)^{2C_dr^3},$$

$$\mathrm{sz}_d=\prod_{l=1}^{r+1}\max\bigl(1,|D_l(\gamma)|/b^{C_dm^2}\bigr).$$

Then for every integer q with $0\le q\le C_nkm^2$,

$$n_0(T)\,G^k\,\|J_{A_0}(\nu,\gamma)\|_{\mathrm{HS}}^2\,\kappa^{2k}\,T^{-k}\le\Lambda_d\Bigl(\frac{C_d}{k}\Bigr)^k\dim\mathcal{E}\;\mathrm{sz}_d^{-2q/(r+1)}.$$

In particular, at a complex place τ of degenerate-pair records with the identifications above, $T_1 = T$, $\kappa_\tau = \kappa$, $\mu_\tau = \Lambda_d$, $Q_d \le C_n k m^2$ and $H \ge b^{C_d m^2}$, the inequality of (Aq5) holds at τ for this C_d. All constants above depend only on (C_h, C_n, C_1, C_K) and c (and C_d also on A), not on D, τ, the local data or the sections.

Proof. Outline. Leading principal minors are unchanged by unitriangular factors, so $|D_l(\gamma)| = |D_l(p)|$ and $G > 0$; the bound (Aq1) then follows from a minor-weighted one-level amplitude bound, whose clauses are supplied by the Bessel place of a member (mass comparability and the constant clause), a weight bound at the point p and the assembly of (Am2), (Am3) on the parameter ball, while the degenerate-pair clause combines this bound, with size decay, with the absolute bound Lemma A.83 through a numerical lemma for degenerate pairs. □

Lemma A.83. *Let $C_h, C_n, C_1, C_K \ge 0$, $c \ge 0$ and $A > 0$. There are reals $C_{ab} \ge 2$ and $C_{hb} \ge 0$, depending only on (C_h, C_n, C_1, C_K), c and A, such that the following holds. Let D, τ, k, m, n, $r = r_S$, $u, u', b, T, T', c_\psi, v, \theta$, the local data with representations π on $\mathcal{E}$ and π' on $\mathcal{E}'$, g, L, C_l, C'_g, C_S, $\mathcal{P}$, the sections A_λ, $A_0 = A_{\lambda_\tau}$, the point p, the relative point γ of p and the root quotient ν satisfy all hypotheses of Proposition A.82 for (C_h, C_n, C_1, C_K) (with (As3), or (Dz1) and (Dz2)), together with $T'/T \le A$, $v \ge 1$ and $n \le b^c$. If $D_r(\gamma) \ne 0$, then for every integer q with $0 \le q \le C_n k m^2$,*

$$\big\| J_{A_0}(\nu, \gamma) \big\|_{\mathrm{op}} \le P_{ab} \Big(\frac{C_{ab}}{k\, v} \Big)^{r(k-2-r)} |D_r(\gamma)|^{-(k-2-r)}\, \mathrm{sz}_{ab}^{-q/(r+1)},$$

where $\| \cdot \|_{\mathrm{op}}$ is the operator norm for the Hilbert norms of $\mathcal{E}'$ and $\mathcal{E}$,

$$P_{ab} = \Big(b^{C_{ab} m} \max_{l \in \mathrm{be}(p)} \max(1, |D_l(p)|^{-1}) \Big)^{C_{ab} r^3}, \qquad \mathrm{sz}_{ab} = \prod_{l=1}^{r+1} \max(1, |D_l(\gamma)| / b^{C_{hb} m^2}).$$

Proof. Sketch. The lemma is used only in the degenerate-pair clause of Proposition A.82; the main bound (Aq1) of that proposition does not depend on it. Its role is to control the amplitude when the pair is nearly degenerate, that is when $G = G_f(\gamma)$ is small and the factor $\max(G, G^{-1})$ makes the non-degenerate bound useless. The bound sought involves only the minor $D_r(\gamma)$ and not G; combined with $G = TT' |D_r(\gamma)|^2 (c_\gamma^2 - 1)$ and with the non-degenerate bound with size decay, it gives the degenerate-pair inequality, and this combination is carried out in the proof of Proposition A.82.

The argument should run in two steps. First, an absolute bound at every parameter λ of the ball $\mathcal{P}$: since $J_A(\nu, \gamma) = c_N^{-1} \int \Phi_A(\gamma x) \otimes \Phi'_A(x)^*\, d\nu(x)$ (Definition A.80), its operator norm is at most $c_N^{-1} \int \|\Phi_A(\gamma x)\|\, \|\Phi'_A(x)\|\, d\nu(x)$, and it remains to bound this integral by moments of majorants of the two Bessel functions, using the leading minors $D_l(p)$, $l \in \mathrm{be}(p)$, of the point and the normal form of the root measure. Second, size decay: a bound that is uniform over the parameters of the ball should convert into decay in the minors $D_l(\gamma)$, since a unit shift of the parameter changes the amplitude by an operator given by a Pieri rule whose size is governed by these minors; a mechanism of this kind already produces the factor $|D_l(\gamma)|^{2q}$ in the first part of Proposition A.82. Heuristically, the shape of the bound is that of lowest-K-type coefficients of discrete series whose parameter has size about k: the dependence on γ through the power $|D_r(\gamma)|^{-(k-2-r)}$ reflects their homogeneity in the leading minor, the factor $(C_{ab}/(kv))^{r(k-2-r)}$ is of the factorial size produced by Gamma-function normalisations such as the formal degree and the constant c_N, and the dependence on b and on the minors of p is polynomial, as in P_{ab}. It remains to prove the moment bounds and the passage to size decay with constants depending only on (C_h, C_n, C_1, C_K), c and A. □

Theorem A.84. *For a point p over $\mathbb{C}$ of length $r+1$ put $G_{T,T'}(p) = |D_{r+1}(p)|^2 - TT'|D_r(p)|^2 \in \mathbb{R}$. For $\mu, \mu' \in \mathbb{R}^n$ put $\|\mu - \mu'\|_1 = \sum_s |\mu_s - \mu'_s|$, and say that μ has gaps $\geq g$ if $|\mu_s - \mu_{s'}| \geq g$ for all $s \neq s'$.*

For every $C_h \geq 0$ there are constants $C_b \geq 0$ and $C_{g,0}$ such that for all $C_g \geq C_{g,0}$ the following holds. Let $r \geq 0$, $k \geq 2$ be integers, $b \geq 2$, and let a point-sum datum of rank r with scale $\kappa = 1$ be given whose representation σ has Harish-Chandra parameter λ and whose coefficient is F. Assume that there is $\lambda_0 \in \mathbb{R}^n$ such that

(Bp1) *λ_0 is strictly decreasing with $\lambda_{0,s} - \frac{n-1}{2} \in \mathbb{Z}$ for all s, and the standard conditions (Xb1)–(Xb5) for (C_h, C_g, b) hold with λ_0 in place of λ;*

(Bp2) *λ_0 has gaps $\geq 200\,\|\lambda - \lambda_0\|_1$.*

Then for every point p over $\mathbb{C}$ of length $r+1$ with $G_{T,T'}(p) \neq 0$,

$$\max\bigl(\mathrm{pw}_{T,T'}(p), 0\bigr)\,\mathrm{os}(p) \leq b^{C_b m^4}\,\max\bigl(1, G_{T,T'}(p)^{-1}\bigr)^{10m^2}\,\mathrm{bm}$$

in $[0,\infty]$ (with $0 \cdot \infty = 0$; for $G_{T,T'}(p) < 0$ the maximum is 1). In particular, if $C_u \geq 0$, $C'_g \geq 200\,C_u$, λ_0 has gaps $\geq C'_g\,k\,m^3$ and $\|\lambda - \lambda_0\|_1 \leq C_u\,k\,m^3$, then (Bp2) holds, and the bound holds with $\max(1, G_{T,T'}(p)^{-1})^{Cm^2}$ for every $C \geq 10$.

Proof. Outline. The bound is deduced from a general eigen-decay bound for point sums, whose hypotheses are checked from the standard conditions (Xb1)–(Xb5): they make b large compared with n and the gaps of λ_0 large compared with m^3, the coefficient has eigen-decay because the parameter λ has a gap far above the decay threshold $\theta(\varepsilon)$ of discrete-series coefficients, and it satisfies the big-cell regularity bound by the regularity of discrete-series coefficients at a large gap; for $G_{T,T'}(p) < 0$ the orbital square vanishes. □

Proposition A.85. *Let $C_h, C_a \geq 0$, let C_b, $C_{g,0}$ be the constants of Theorem A.84 for C_h, let $C_g \geq C_{g,0}$, $B \geq 0$, $R \geq 0$. Let $r \geq 0$, $k \geq 2$ be integers, $n = 2r + k + 1$, $m = 2r + 2$, $b \geq 2$, and let a Bessel place of rank r be given, with $T = T(z)$, $T' = T(z')$. Let $\mu_0 \in \mathbb{R}^n$, let p be a point over $\mathbb{C}$ of length $r+1$ with $\mathrm{pw}_{T,T'}(p) > 0$, γ a relative point of p and ν a root quotient at γ. Let $\mathcal{P} \subseteq \mu_0 + \mathbb{Z}^n$ be a set with $\mu_0 \in \mathcal{P}$ and, for every $\lambda \in \mathcal{P}$, let A_λ be a Bessel section at λ. Put $\delta(\lambda) = \|\lambda - \mu_0\|_1$ and $j(\lambda) = j_{A_\lambda}(\nu, \gamma)$, an element of the space $\mathrm{Hom}(\mathcal{E}', \mathcal{E})$ with the Hilbert–Schmidt norm, and for $\lambda \in \mathcal{P}$ and $0 \leq l \leq r+1$ let $\mathcal{G}_l(\lambda)$ be the set of l-element subsets $I \subseteq \{0, \ldots, n-1\}$ with $\lambda + \varepsilon_I \in \mathcal{P}$. Assume:*

(F1) *for every $\lambda \in \mathcal{P}$ with $\delta(\lambda) \leq R$, the section A_λ satisfies (Ab1) and (Ab2) for (C_h, C_g, C_a, b), p, γ and ν;*

(F2) *for every integer $0 \leq l \leq r+1$ and every $\lambda \in \mathcal{P}$ with $\delta(\lambda) + l \leq R$, the sections $A_0 = A_\lambda$ and $A_I = A_{\lambda + \varepsilon_I}$ ($I \in \mathcal{G}_l(\lambda)$) satisfy (Me1)–(Me3) for this l, $\mathcal{G} = \mathcal{G}_l(\lambda)$ and B.*

Then the data $(\mathcal{P}, \delta, \mu_0, j)$ satisfy (Am2) with

$$w = \mathrm{pw}_{T,T'}(p), \qquad \beta_1 = b^{(C_b + 11C_a)m^4}\,\max\bigl(1, G_f(\gamma)^{-1}\bigr)^{10m^2},$$

and (Am3) with $D_l = D_l(p)$ ($0 \leq l \leq r+1$), the radius R and the constant B. The numbers β_1 (for fixed $G_f(\gamma)$) and B do not depend on λ, on the place, or on the sections.

Proof. **(Am2).** Let $\lambda \in \mathcal{P}$ with $\delta(\lambda) \le R$. By (F1), the pointwise bound for unit amplitudes at a Bessel place applies to the Bessel section A_λ at λ, the point p, the relative point γ and the root quotient ν, and gives $\mathrm{pw}_{T,T'}(p)^+ \|j_{A_\lambda}(\nu,\gamma)\|_{\mathrm{HS}}^2 \le \beta_1$. Since $\mathrm{pw}_{T,T'}(p) > 0$, $\mathrm{pw}_{T,T'}(p)^+ = w$, so $w\|j(\lambda)\|^2 \le \beta_1$. This is (Am2); $w > 0$ as required there.

(Am3). Let $0 \le l \le r+1$ and $\lambda \in \mathcal{P}$ with $\delta(\lambda) + l \le R$. By (F2), the minor expansion of unit amplitudes at a Bessel place applies with $A_0 = A_\lambda$, $\mathcal{G} = \mathcal{G}_l(\lambda)$, $A_I = A_{\lambda+\varepsilon_I}$, and gives numbers a_I ($I \in \mathcal{G}_l(\lambda)$) and the sign $\epsilon_{r,l} \in \{1,-1\}$ with $\sum_I |\epsilon_{r,l} a_I| \le B$ and

$$D_l(p)\, j(\lambda) = D_l(p)\, j_{A_\lambda}(\nu,\gamma) = \sum_{I \in \mathcal{G}_l(\lambda)} \epsilon_{r,l} a_I\, j_{A_{\lambda+\varepsilon_I}}(\nu,\gamma) = \sum_{I \in \mathcal{G}_l(\lambda)} \epsilon_{r,l} a_I\, j(\lambda+\varepsilon_I).$$

The coefficients of (Am3) are the numbers $\epsilon_{r,l} a_I$. The family $(\lambda+\varepsilon_I)_{I \in \mathcal{G}_l(\lambda)}$ is finite (at most $\binom{n}{l}$ members), lies in $\mathcal{P}$ by the definition of $\mathcal{G}_l(\lambda)$, and $\delta(\lambda+\varepsilon_I) \le \delta(\lambda) + \|\varepsilon_I\|_1 = \delta(\lambda) + l$ by the triangle inequality, as ε_I has exactly l entries equal to 1 and the others 0. (If $\mathcal{G}_l(\lambda)$ is empty, the identity reads $D_l(p) j(\lambda) = 0$, an expansion with no terms.) This is (Am3).

Uniformity. β_1 is built from C_b, C_a, m, b and $G_f(\gamma)$ only, and C_b depends only on C_h by Theorem A.84; B is the given constant. Neither depends on λ, on the place or on the sections. □

Theorem A.86. *All symbols introduced here are local to this statement and to the results that cite it. For all real $A_w \ge 0$ and C_h there are real numbers C_B and $C_{g,0}$ with the following property. Let $C_g \ge C_{g,0}$, let $r \ge 0$ and $k \ge 2r+5$ be integers with k even, $m = 2r+2$, $n = 2r+k+1$, let E be a CM field of degree $2f$ with CM type Φ, let $g_1 \ne g_2$ be primes and $\kappa = 2\pi/(\mathrm{rd}_E\, g_1 g_2)$, and let $T, T' \ge 1$ be integers and $b \ge 2$ real. Suppose that at every $v \in \Phi$ a point-sum datum of rank r with scale κ is given, with $T(z_v) = T$, $T(z_v') = T'$, satisfying the standard conditions (Xb1)–(Xb5) for (C_h, C_g, b), whose Harish-Chandra parameter has the form $\lambda^{(v)} = (v_0, \dots, v_{k-2}, -b_0, \dots, -b_{m-1})$ with integers v_i, b_j, and with $|\lambda_s^{(v)} - \lambda_{s'}^{(v)}| \ge C_g m^4$ for $s \ne s'$. Then*

$$\sum_\gamma \mathrm{wp}(\gamma)\, |\mathrm{pw}_{T,T'}(\gamma)|\, \mathrm{nw}_{T,T'}(\gamma)^{A_w(r+1)^2} \prod_{v \in \Phi} \mathrm{os}_v(\tilde\gamma_v) \;\le\; \exp(C_B\, m^5 f \log b) \prod_{v \in \Phi} \mathrm{bm}_v,$$

the sum over all B-points γ for (T,T') (a sum of terms in $[0,\infty]$, with $0 \cdot \infty = 0$).

Proof. Outline. For each B-point the leading minors of its turned local images are those of the point rescaled by powers of rd_E, so that at each place the weights are bounded by a power of one leading minor; a one-place Bessel bound then estimates each local factor by bm_v up to a negative power of $\iota_v G_{T,T'}(\gamma)$, these powers are absorbed by $|N_{E/\mathbb{Q}}(G_{T,T'}(\gamma))| \ge 1$, and the sum over the B-points is controlled by a weighted count of B-points. □

Proposition A.87. *All symbols introduced here are local to this statement and to the results that cite it. Let $A \ge 0$ be an integer and C_h real, and let C_B, $C_{g,0}$ be the numbers of Theorem A.86 for $(A_w, C_h) = (A, C_h)$. Let non-generic row data be given for a pair expansion or, more generally, data as in Definition 15.2 with a countable set S of terms in place of $\mathcal{M}_{\mathrm{n}}$ (as in (i) of Theorem 15.5), and let $C_g \ge C_{g,0}$, $(r, k, E, \Phi, g_1, g_2, \kappa, T, T', b)$ and point-sum data at the places $v \in \Phi$ satisfy all hypotheses of Theorem A.86, with r and k those of these data. Let $C_w, C_j \ge 0$ and suppose:*

(Xb6) Point tie *there is an injective map $\gamma \mapsto \hat\gamma$ from P_{oc} to the set of B-points for (T,T');*

(Xb7) Weight tie $w(\gamma) P_{\mathrm{n}}(\gamma) n_{\mathrm{g}}(\gamma) \le C_w\, \mathrm{wp}(\hat\gamma)\, |\mathrm{pw}_{T,T'}(\hat\gamma)|\, \mathrm{nw}_{T,T'}(\hat\gamma)^{A(r+1)^2}$ *for $\gamma \in P_{\mathrm{oc}}$;*

(Xb8) Jacobian tie $J(\gamma) \le C_j \prod_{v\in\Phi} \mathrm{os}_v(\tilde{\hat{\gamma}}_v)$ *for* $\gamma \in P_{\mathrm{oc}}$ *(with* $0\cdot\infty = 0$*);*

(Xb9) Normalisation $C_w C_j \exp(C_B m^5 f \log b) \prod_{v\in\Phi} \mathrm{bm}_v \le T_{\mathrm{pt}}$.

Then these data have the point sum (Ng6).

Proof. Let $F \subseteq P_{\mathrm{oc}}$ be finite. For $\gamma \in F$ the four factors $w(\gamma)$, $P_{\mathrm{n}}(\gamma)$, $n_{\mathrm{g}}(\gamma)$, $J(\gamma)$ are nonnegative, so by (Xb7) and (Xb8)

$$w(\gamma)P_{\mathrm{n}}(\gamma)n_{\mathrm{g}}(\gamma)J(\gamma) \le C_w C_j\, a(\hat{\gamma}),$$
$$a(\beta) = \mathrm{wp}(\beta)\,|\mathrm{pw}_{T,T'}(\beta)|\,\mathrm{nw}_{T,T'}(\beta)^{A(r+1)^2} \prod_{v\in\Phi} \mathrm{os}_v(\tilde{\beta}_v) \in [0,\infty]$$

(if $C_j = 0$ then $J(\gamma) = 0$ by (Xb8), and the bound holds with the convention $0\cdot\infty = 0$). By (Xb6) the B-points $\hat{\gamma}$, $\gamma \in F$, are distinct, and the terms $a(\beta)$ are nonnegative, so $\sum_{\gamma\in F} a(\hat{\gamma})$ is at most the sum of $a(\beta)$ over all B-points β for (T,T'). By Theorem A.86 (with $A_w = A$) that sum is at most $\exp(C_B m^5 f \log b)\prod_v \mathrm{bm}_v$. With (Xb9),

$$\sum_{\gamma\in F} w(\gamma)P_{\mathrm{n}}(\gamma)n_{\mathrm{g}}(\gamma)J(\gamma) \le C_w C_j \exp(C_B m^5 f \log b) \prod_{v\in\Phi} \mathrm{bm}_v \le T_{\mathrm{pt}}.$$

(In particular the left side is finite.) As F was arbitrary, this is (Ng6). □

A.8 Covolumes: deep covers, short generators and heights

Alpöge lists the computation of covolumes among the inputs of the proof [4]; in our reading this item covers the covolume bound of the body, Theorem 19.26, with the model slopes of Theorem 29.14 that feed it. This section proves no new covolume inequality. The construction supplies the data on which the inequality of the body applies: chain data, deep-cover data (Definition 19.8), component and height data (Definition 19.10) and model-slope data, at realised points of the constructed families (Proposition A.92). Proposition A.90 applies the covolume bound to the constructed families, and Lemma A.91 turns it into the covolume row. The data rest on two mechanisms. Deep lattices are eigenlattices of small groups of level automorphisms, and therefore have short generators. Heights of components are bounded below by the logarithm of the size of short generators and above by Bergman volumes, and an effective arithmetic Hilbert–Samuel inequality joins the two bounds.

A.8.1 The covolume row

Definition A.88 defines the covolume class of constructed families, and Definition A.89 the Petersson lattices of a uniformised moduli datum with their component invariants: rank, degree, covering degree and height. Proposition A.90 applies Theorem 19.26, together with Theorem 19.24, Theorem 19.20 and Theorem 19.18 of the body, to these families; the data it needs are Proposition A.92, and Lemma A.91 links the resulting bound to a row parameter.

Definition A.88. (Yv1) Largeness at a design parameter. Let $\mathcal{F}$ be a parametrised host family with a structural profile, $\mathfrak{K} = (k_{\mathrm{pre}}, k_{\mathrm{mid}}, k_{\mathrm{last}})$ a structural threshold and u a real number. Then $\mathcal{F}$ is **large for** $(\mathfrak{K}, u)$ if

$$\begin{aligned} k_{\mathrm{pre}} &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{pre}}(\mathcal{F}),\\ k_{\mathrm{mid}}\big(\mathbf{c}_{\mathrm{out}}(\mathcal{F})\big) &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{mid}}(\mathcal{F};u),\\ k_{\mathrm{last}}\big(\mathbf{c}_{\mathrm{out}}(\mathcal{F}) \parallel \mathbf{c}_{\mathrm{mid}}(\mathcal{F};u)\big) &\le c \quad \text{for every entry } c \text{ of } \mathbf{c}_{\mathrm{last}}(\mathcal{F}). \end{aligned}$$

Thus $\mathcal{F}$ is large for $\mathfrak{K}$ in the sense of Definition A.3 exactly when it is large for $(\mathfrak{K}, C_H(\mathcal{F}))$. The real u is called a **design parameter**; it need not be the chosen one.

(Yv2) The covolume clause. Let b be a bundle. The base level of $\mathrm{Cx}_3(b)$ carries a positive integer $D(b)$, the dimension of the realisation, and for every lift j a frame $X_j(b)$ (in the convention of Definition 19.5) and a lattice $M_j(b)$ of the size required by that frame. The indefinite scale of the face $\mathrm{fc}(z_s)$ carries real numbers $\ell^{\mathrm{m}}_j(b)$ for every lift j, the **covolume main terms**, and a real number $\ell^{\mathrm{u}}(b)$, the **covolume unit**; for reals C, C_H the numerical tuple $\mathrm{num}(b; C, C_H)$ has the **covolume entries** $\ell_{3,j} = \ell^{\mathrm{m}}_j(b) + C\,\ell^{\mathrm{u}}(b)$, which do not involve C_H (the design parameter enters $\mathrm{num}(b; C, C_H)$ only through its height entry). The **clause L_3 of $\mathrm{Cx}_3(b)$ at base level** holds at $\mathrm{num}(b; C, C_H)$ if

$$\frac{\mathrm{lcv}\big(M_j(b), X_j(b)\big)}{D(b)} \le \ell^{\mathrm{m}}_j(b) + C\,\ell^{\mathrm{u}}(b) \qquad \text{for every lift } j.$$

In particular whether it holds does not depend on C_H.

(Yv3) The covolume class. $\mathcal{B}_{\mathrm{cv}}$ is the class of the parametrised host families $\mathcal{F}$ of the construction of the lattice side, with their member data $D_{x,i}$, member objects $\mathfrak{o}_{x,i}$ and size constant $C_{\mathrm{sz}}(\mathcal{F})$, with slope records, structural profiles and covolume records, that satisfy the seven duties and the conditions of the standard restriction, in which, at every member (x, i):

(i) $\mathrm{Pt}_{x,i}$ is the set of points of the construction at $(D_{x,i}, \mathfrak{o}_{x,i}, C_{\mathrm{sz}}(\mathcal{F}))$ that satisfy its **point conditions** and its **arithmetic ties** (the size condition on the coefficient field, and the Green series tie of the member datum $D_{x,i}$); for every bundle b over $(D_{x,i}, \mathfrak{o}_{x,i}, C_{\mathrm{sz}}(\mathcal{F}))$ and every $t \in \mathrm{Cmp}_2(b)$ the point package $\mathrm{pt}(b, t)$ is a point of the construction at this member;

For a point $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, write $R = R_{\mathfrak{z}}$ for its carried real data, $T = T_{\mathfrak{z}}$ for its geometric core and $\mathcal{H} = \mathcal{H}_{\mathfrak{z}}$ for its geometric half, in the sense of the conditions (Xl2a)–(Xl2c) on the levels of a state. The following are clauses of these point conditions on the same carried data.

The **size condition on the coefficient field** in the arithmetic ties above means the following. Put $D = D_{x,i}$ and let $F_c \subseteq \mathbb{C}$ be the coefficient field of the carried geometric core T. Write $\mathcal{O}_D$ for the coefficient ring of the member datum and $\varphi_D : \mathcal{O}_D \hookrightarrow \mathbb{C}$ for its fixed complex embedding. The carried coefficient-ring identification is an isomorphism

$$e_D : \mathcal{O}_{F_c} \xrightarrow{\sim} \mathcal{O}_D, \qquad \varphi_D(e_D(u)) = u \quad (u \in \mathcal{O}_{F_c}),$$

with u read through the given inclusion $F_c \subseteq \mathbb{C}$. Consequently F_c is the rationality field:

$$F_c = \mathbb{Q}(\varphi_D(\mathcal{O}_D)).$$

With f, r and $\ell = x^{\varepsilon}$ the ranks and logarithmic scale of the member size datum, put

$$P_0 = 19 f r^2 \ell + 198 f^2 \ell, \qquad d_c = [F_c : \mathbb{Q}].$$

The two field-size conditions are

$$\log d_c \le P_0, \qquad \frac{\log |\operatorname{disc}(F_c)|}{d_c} \le P_0.$$

They concern the field F_c itself, not the larger realisation coefficient field L. These conditions are imposed on the points and assert no existence of points or fields.

The real data R have the level choice of (Wr6) of the Weil laws of the real data, with the lattices, level elements, frame primes and characters already carried by the point. The real data R satisfy their characterisation laws: the base-tuple level and character laws, group reductions, record, family, model, chain and theta-lift laws specified in the hypotheses of the analytic characterisation of geometric halves; the core characters χ_W are those of R, and the core's two imaginary-quadratic primes are those of the character frame of R. This clause does not impose the separate rank inequality in that proposition. The primitive rows satisfy (U4) and the full uniformity law (U10) of stage-3 states, for their carried coordinate maps, action and character. In particular, for every $a < m$ and $\sigma : L \to \mathbb{C}$, $j_{a,\sigma}$ sends finite L-linearly independent families to complex-linearly independent families, its image spans $H_{W_a,\sigma}$, and its intertwining with the level action is, through the carried Hecke model,

$$j_{a,\sigma}(\rho_{\mathrm{FW}}(g)x) = \sigma(\chi_a^{\mathrm{FW}}(g))\, g \cdot j_{a,\sigma}(x).$$

The geometric half $\mathcal{H}$ also satisfies the condition (GeoAct) of (Xl2e) on the levels of a state, with its F_c-linear action on the cusp space, its top character and its notion of integral forms through integral framed points. These are conditions on the points, not conclusions about projectors or slopes.

The primitive-row clauses of these point conditions also require, for every lift $1 \le j \le m$, $d_{\mathfrak{z},j} = D_{\mathfrak{z}} > 0$ and that the coordinate pullback $M_{\mathfrak{z},j}$ of (Rk11) of the row carrier be a finitely generated $\mathcal{O}_L$-module with L-span $L^{d_{\mathfrak{z},j}}$. These clauses are part of the point conditions defining $\mathrm{Pt}_{x,i}$; they assert neither the existence of such a point nor that every point of the construction satisfies them. Finally $\mathcal{H}$ satisfies the condition (JEvBar) of (Xl2e) on the levels of a state: put $\sigma_c = \sigma|_{F_c}$ and let $\bar\sigma_c$ be its complex conjugate. For every $a < m$ and σ with σ_c not good, $\bar\sigma_c$ is good and $V_{a+1,\bar\sigma_c} = W_a$; there are a vector family $v' = (v'_\rho)_\rho$ of $M_{W_a,\sigma}$ with $\|v'_\rho\| = 1$ at every archimedean place ρ of the maximal real host field, and a σ_c-semilinear map $J : \mathrm{Cusp}_{a+1}(\kappa_a) \to H_{W_a,\sigma}$, such that

$$\mathrm{ev}_{a,\sigma,v'}(J(f)) = \overline{\phi_{a+1,\bar\sigma_c,\kappa_a}(f)} \qquad (f \in \mathrm{Cusp}_{a+1}(\kappa_a)).$$

Here the maps, models, weights and evaluations are those of R, T and $\mathcal{H}$. These clauses assert no existence of a point and do not replace its real data or its geometric half.

(ii) the covolume record of a point $\mathfrak{z}$ consists of its realisation lattices $M_{\mathfrak{z},j}$ at base level for all lifts $1 \le j \le m$ with their archimedean frames, the common dimension $D_{\mathfrak{z}}$ of the realisation (not the rank of $M_{\mathfrak{z},j}$), and its realisation places and weights; and if $\mathfrak{z} = \mathrm{pt}(b,t)$, then for all reals C, C_H the clause L_3 of $\mathrm{Cx}_3(b)$ at base level holds at $\mathrm{num}(b; C, C_H)$ if and only if $\mathrm{lcv}(M_{\mathfrak{z},j}, X_{\mathfrak{z},j})/D_{\mathfrak{z}} \le \mathrm{mt}_j(\mathfrak{z}) + C\,\mathrm{ue}(x,i)$ for every $j \in \{1,\dots,m\}$.

Definition A.89. A **uniformised moduli datum** $\mathfrak{m} = (\mathfrak{u}, (U_\sigma, V_\sigma, \mathrm{dict}_\sigma)_\sigma)$ consists of a unitary Shimura datum $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $r = p+q$, and, for every embedding $\sigma\colon F \to \mathbb{C}$, a uniformisation U_σ of $\mathrm{Sh} \otimes_\sigma \mathbb{C}$ whose components k carry frame data (Xl2d), a hermitian space V_σ over E of rank r, and a **dictionary** $\mathrm{dict}_\sigma(g) = (k(g), \mathrm{fr}(g))$ assigning to $g \in \mathrm{U}(V_\sigma)(\mathbb{A})$ a component of U_σ and a frame $\mathrm{fr}(g) \in \mathcal{D}_{k(g)}$. The geometric core at a stage j ($\mathcal{X}_j$ over F_c with $U_{j,\sigma}$, $V_{j,\sigma}$, $\mathrm{dict}_{j,\sigma}$ of (Xl2a)) and a deep cover $\mathcal{Y} = (F', \delta, (U_\sigma, \mathrm{dict}_\sigma)_\sigma, K_f)$ at V (Sh_2 over F',

$V_\sigma = V$; written $\mathfrak{m}_{\mathcal{Y}}$) are uniformised moduli data. For $\sigma\colon F \to \mathbb{C}$ put $\sigma^{\mathrm{g}} = \sigma$ if σ is good and $\sigma^{\mathrm{g}} = \bar\sigma$ otherwise. Fix $\mathfrak{m}$ and a real number $\xi > 0$, the **Lie parameter**.

(Vy1) Cusp forms of integral weight. An **integral weight** is a pair $G = (a, n)$ of a function $a\colon \mathrm{Ix} \to \mathbb{Z}$ and an even integer n; put $|a| = \sum_{(\tau,i)\in \mathrm{Ix}} a(\tau, i)$. Algebraic forms of weight G, the F-space $\mathrm{Alg}_F(G)$, valuations and integral forms are defined by (Zj2)–(Zj4) read with these integer exponents. For a component k of U_σ the **frame weight** $\lambda_k(G)$ is given by $\lambda_k(G)(\tau, i) = a(\tau, i - p_0) + n/2$ for $i > p_0$ and $\lambda_k(G)(\tau, i) = -a(\bar\tau, p_0 + 1 - i) - n/2$ for $i \le p_0$ (embeddings read through σ, as for $\lambda_k(a, n)$ in (Xl2d)). The **cusp space** $\mathrm{Cusp}_{\mathfrak{m}}(G) \subseteq \mathrm{Alg}_F(G)$ is the F-subspace of the f whose readings $(f_\sigma(k, \cdot))_k$ satisfy the cusp condition (Hh7) for the frame weights $(\lambda_k(G))_k$ at every good σ; for the geometric core at stage j and a weight (a, n) of (Zj2) it is $\mathrm{Cusp}_j(a, n)$ of (Xl2a). Its integral forms are $\Lambda_{\mathfrak{m}}(G) = \mathrm{Cusp}_{\mathfrak{m}}(G)^{\mathrm{int}}$.

(Vy2) Petersson norms. For $\sigma\colon F \to \mathbb{C}$ let $(\nu_\sigma, \Omega_\sigma)$ be a Haar pair of $\mathrm{U}(V_{\sigma^{\mathrm{g}}})$ with $0 < \nu_\sigma(\Omega_\sigma) < \infty$, and let $\nu^1_\sigma = \nu_\sigma(\Omega_\sigma)^{-1}\nu_\sigma|_{\Omega_\sigma}$. The **Petersson norm** at σ of $f \in \mathrm{Alg}_F(G)$ is

$$\|f\|_{G,\sigma} = (2\pi\xi)^{-|a|/2}\Big(\int_{\Omega_\sigma} \big\|f_{\sigma^{\mathrm{g}}}(k(g), \cdot)\big\|_{\lambda_{k(g)}(G)}\big(\mathrm{fr}(g)\big)^2\, d\nu^1_\sigma(g)\Big)^{1/2},$$

with the dictionary $\mathrm{dict}_{\sigma^{\mathrm{g}}}(g) = (k(g), \mathrm{fr}(g))$, and $\|f\|_{G,\sigma} = 0$ if the integral is infinite.

(Vy3) Petersson lattices. For an F-subspace $C \subseteq \mathrm{Cusp}_{\mathfrak{m}}(G)$ and a family $N = (N_\sigma)_\sigma$ of functions $C \to [0, \infty)$, the pair (C^{int}, N), $C^{\mathrm{int}} = C \cap \Lambda_{\mathfrak{m}}(G)$, is **good** if C is finite-dimensional, C with the norms N_v (one for the fixed embedding v of each infinite place of F) is a hermitian space over F with $N_{\bar\sigma}(f) = N_\sigma(f)$, and C^{int} is a finitely generated $\mathcal{O}_F$-module spanning C; it is then a hermitian lattice. The **Petersson lattice** of weight G is $(\Lambda_{\mathfrak{m}}(G), (\|\cdot\|_{G,\sigma})_\sigma)$; $\mathfrak{m}$ is **good at** G if it is good; $\mathrm{rk}_{\mathfrak{m}}(G) = \mathrm{rk}\,\Lambda_{\mathfrak{m}}(G)$, and $\widehat{\mu}_{\mathfrak{m}}(G) = \widehat{\mu}(\Lambda_{\mathfrak{m}}(G))$ when $\mathfrak{m}$ is good at G and $\Lambda_{\mathfrak{m}}(G) \neq 0$.

(Vy4) Components; rank and degree on a component. $\mathrm{Comp}(\mathfrak{m})$ is the set of irreducible components of $\mathrm{Sh} \otimes_{K_{\mathsf{L}}} F$. A framed S-point (x, u, s) **lies on** $Z \in \mathrm{Comp}(\mathfrak{m})$ if every point of $\mathrm{Spec}\, S$ is mapped into Z by x, and **off** Z if none is. A form f is **supported on** Z if $f(y) = 0$ for every framed point y off Z; $\mathrm{Cusp}_{\mathfrak{m},Z}(G)$ is the space of cusp forms supported on Z and $\Lambda_{\mathfrak{m},Z}(G)$ its set of integral forms. A frame (k, x) lies on Z if $y_{k,x}$ does. The **Petersson norm on** Z, $\|f\|_{G,\sigma,Z}$, is defined as in (Vy2) with ν^1_σ replaced by $\nu_\sigma(\Omega_{\sigma,Z})^{-1}\nu_\sigma|_{\Omega_{\sigma,Z}}$, $\Omega_{\sigma,Z} = \{g \in \Omega_\sigma : \mathrm{dict}_{\sigma^{\mathrm{g}}}(g) \text{ lies on } Z\}$ (and $\|f\|_{G,\sigma,Z} = 0$ if $\nu_\sigma(\Omega_{\sigma,Z}) = 0$). $\mathfrak{m}$ is **good at** G **on** Z if $(\Lambda_{\mathfrak{m},Z}(G), (\|\cdot\|_{G,\sigma,Z})_\sigma)$ is good (Vy3). The **rank** and the **degree** on Z are $\mathrm{rc}_Z(G) = \mathrm{rk}\,\Lambda_{\mathfrak{m},Z}(G)$ and $\mathrm{gc}_Z(G) = \mathrm{rk}\,\Lambda_{\mathfrak{m},Z}(G) \cdot \widehat{\mu}(\Lambda_{\mathfrak{m},Z}(G))$ ($\mathrm{gc}_Z(G) = 0$ if the rank is 0 or $\mathfrak{m}$ is not good at G on Z).

(Vy5) Covering degree and height of a component. The **flag dimension** is $D_{\mathrm{fl}} = |\Phi_{\mathsf{H}}|\, r(r-1)/2$. For $Z \in \mathrm{Comp}(\mathfrak{m})$ let $\kappa(Z)$ be its function field and Ω_Z the field of fractions of $\kappa(Z)[X_{\tau,i,j} : \tau\colon E \to \mathbb{C},\ 1 \le i < j \le m_\tau]$. A **generic framed point** of Z is a framed Ω_Z-point $y_Z = (x_Z, u, s)$ with x_Z the generic point of Z for which there is a framed $\kappa(Z)$-point (x^0, u^0, s^0) with x^0 the generic point of Z and $u_{\tau,i} = u^0_{\tau,i} + \sum_{j>i} X_{\tau,i,j}u^0_{\tau,j}$ for all $(\tau, i) \in \mathrm{Ix}$; one generic framed point y_Z is fixed for every Z. For a basis $b = (b_1, \dots, b_N)$ of $C = \mathrm{Cusp}_{\mathfrak{m},Z}(G)$ the **image ideal** $I_Z(G; b) \subseteq F[x_1, \dots, x_N]$ is the ideal generated by the homogeneous P with $P(b_1(y_Z), \dots, b_N(y_Z)) = 0$. The **covering degree** $\mathrm{dg}_Z(G)$ is the integer δ such that $I_Z(G; b)$ has a Chow form over F in dimension D_{fl} and degree δ for some basis b, and 0 if there is none. For a polynomial f in blocks $u_i = (u_{i,1}, \dots, u_{i,N})$ and an $N \times n'$ matrix M let $f \circ M$ be obtained by substituting $\sum_l M_{jl}u'_{i,l}$ for $u_{i,j}$; $|g|_v$ is the maximum

of the normalised absolute values at the finite place v of the coefficients of g; and for g in $D_{\mathrm{fl}}+1$ blocks of N complex variables $m(g)=\int\log|g(z_0,\dots,z_{D_{\mathrm{fl}}})|\,d\mu(z_0)\cdots d\mu(z_{D_{\mathrm{fl}}})$, μ the invariant probability measure on the unit sphere of $\mathbb{C}^N$. The **height** $\mathrm{ht}_Z(G)$ of Z is a real number h (one fixed choice if several exist, and 0 if none exists) for which there are: a basis b of C; an $N\times n'$ matrix w over F whose columns span F^N and for which the elements $\sum_j w_{jl}b_j$ $(1\le l\le n')$ generate $\Lambda_{\mathfrak{m},Z}(G)$ over $\mathcal{O}_F$; matrices $A_\sigma\in\mathrm{GL}_N(\mathbb{C})$ with $|A_\sigma^{-1}(\sigma(c_j))_j|=\|\sum_j c_jb_j\|_{G,\sigma,Z}$ for all $c\in F^N$ and $|A_{\bar\sigma}^{-1}\bar z|=|A_\sigma^{-1}z|$ for $z\in\mathbb{C}^N$; and a Chow form f over F of $I_Z(G;b)$ in dimension $D=D_{\mathrm{fl}}$ and degree δ, such that

$$(D+1)\,\delta\,h=\frac{1}{[F:\mathbb{Q}]}\Big(\sum_{v\text{ finite}}\log|f\circ w|_v+\sum_{\sigma\colon F\to\mathbb{C}}\Big(m(f^\sigma\circ A_\sigma)+\frac{(D+1)\,\delta}{2}\sum_{l=1}^{N-1}\frac{1}{l}\Big)\Big),$$

f^σ obtained by applying σ to the coefficients.

(Vy6) Lattice of a deep cover over core forms. Let $\mathcal{Y}$ be a deep cover at V of the unitary Shimura datum of a moduli scheme $\mathcal{X}$ over $F_c\subseteq F'$. A form $g\in\mathrm{Alg}_{F'}(G)$ on Sh_2 is a **pull-back** of a form f on $\mathcal{X}$ if $g(y_2)=f(y)$ for every algebraically closed field $k\supseteq F'$ and all framed k-points y_2 of Sh_2 and y of $\mathcal{X}$ such that y_2 lies over y. For a set B of forms on $\mathcal{X}$, the **lattice of $\mathcal{Y}$ over** B at G is

$$\Lambda_{\mathcal{Y}}(G;B)=\Lambda_{\mathfrak{m}_{\mathcal{Y}}}(G)\cap\mathrm{span}_{F'}\{g:\ g\text{ is a pull-back of some }f\in B\},$$

with the Petersson norms of $\mathfrak{m}_{\mathcal{Y}}$.

Proposition A.90. *There is $\varepsilon_1>0$ and, for every $\varepsilon\in(0,\varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F}\in\mathcal{B}_{\mathrm{cv}}$ with parameter ε and every real number C_H for which $\mathcal{F}$ is large for $(\mathfrak{K}(\varepsilon),C_H)$ there are real numbers $C_0\ge0$ and x_0 such that for every real $x\ge x_0$ with $x>x_1$, every $i\in I(x)$, every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$, every real $C\ge C_0$ and every $j\in\{1,\dots,m\}$*

$$\frac{\mathrm{lcv}(M_{\mathfrak{z},j},X_{\mathfrak{z},j})}{D_{\mathfrak{z}}}\le\mathrm{mt}_j(\mathfrak{z})+C\,\mathrm{ue}(x,i).$$

In particular (take $C_H=C_H(\mathcal{F})$), for a restriction $\mathfrak{r}_{\mathrm{str}}$ with $\varepsilon_{\mathfrak{r}}=\varepsilon_1$ and $\mathfrak{K}_{\mathfrak{r}}(\varepsilon)=\mathfrak{K}(\varepsilon)$ for $\varepsilon<\min(\varepsilon_1,1/52)$, every family in $\mathcal{B}_{\mathrm{cv}}[\mathfrak{r}]$ has the covolume bound.

Proof. Let ε_1 and $\mathfrak{K}(\varepsilon)$, $0<\varepsilon<\varepsilon_1$, be those of Proposition A.92. Fix $\varepsilon\in(0,\varepsilon_1)$, a family $\mathcal{F}\in\mathcal{B}_{\mathrm{cv}}$ of parameter ε and a real C_H for which $\mathcal{F}$ is large for $(\mathfrak{K}(\varepsilon),C_H)$. By Proposition A.92 (with $u=C_H$), $\mathcal{F}$ carries chain data, deep-cover data, component data and model-slope data with (Su1)–(Su5); let $C_6,C_{\mathrm{top}},C_{\mathrm{F}},C',C_4\ge0$ be the constants named there. The design parameter C_H is used only in this step.

Step 1: (Ms1)–(Ms4). $\mathcal{F}$ carries chain, deep-cover, component and model-slope data, and by (Su5) the data (Aj1)–(Aj3) are given and hold at every real $x>x_1$, every $i\in I(x)$, every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$ and every lift $j<m$; these are the hypotheses of Theorem 29.14. That theorem gives a re-choice of the model slopes $\mathrm{ns}(Z)$, all other entries of the model-slope data kept, after which $\mathcal{F}$ has (Ms1), and (Ms3) for its constant C_{ms}, at all large points with $j<m$. The re-choice changes neither the chain, deep-cover and component data nor the entries $E,M,B,L,\mathrm{wn},\mathrm{wsp}$; (Ms4) reads only T^{d}, B, rd_E, L, wn, wsp and $\mathrm{ue}(x,i)$, so by (Su4) it still holds with C_4. (Ms2) holds at every point with $j<m$: by (Aj1) the datum level is $N=M$ and at most $4|\Phi|n^2$ primes divide $2\,\mathrm{disc}(E)\,M$, where $\Phi=\Phi_{\mathsf{H}}$ and $n=p+q$; by the definition of the threshold in Definition 21.3 and $g>0$, $4|\Phi|n^2\le4|\Phi|n^2(1+\|u\|_\infty/g)=b_0(u,g)$, and $b_0(u,g)<\lfloor B\rfloor+1$ by (Aj2); as the

number of these primes and $\lfloor B \rfloor$ are integers, the number is at most $\lfloor B \rfloor$. Neither E, M, B nor (Aj1), (Aj2) is changed by the re-choice of the model slopes. Put $C_{\mathrm{M}} = \max(C_{\mathrm{ms}}, C_4) \geq 0$. Both (Ms3) and (Ms4) remain true when their constant is increased to C_{M}:

Taking as threshold the maximum of e and of the thresholds of (Ms1), (Ms3) and of (Su4), $\mathcal{F}$ has (Ms1)–(Ms4) for the constant C_{M}.

Step 2: (Ht1)–(Ht5). At every point with $j < m$ put $e_* = C_{\mathrm{M}}(\mathrm{lz} \cdot \mathrm{wn} + \mathrm{wsp}) + 2\, c^{\mathrm{HT}}_{E,M}(B)\, \mathrm{wn}$. Then $e_* \geq 0$: $C_{\mathrm{M}} \geq 0$, $\mathrm{lz} \cdot \mathrm{wn} + \mathrm{wsp} \geq 0$ (Step 1), $\mathrm{wn} \geq 0$, and $c^{\mathrm{HT}}_{E,M}(B) \geq 0$ as a finite sum of terms $\big(\frac{1}{p-1} + \frac{40\, v_p(\mathrm{disc}(E))}{[E:\mathbb{Q}]} + \delta_{p,2}\big) \log p \geq 0$. So the component data may be taken with $e^{\mathrm{ms}} = e_*$; the entry e^{ms} occurs in none of (Lc1)–(Lc6), (Dp0)–(Dp5), (Ht1), (Ht2), (Ht4), (Ht5), (Ms1)–(Ms4), which therefore still hold. By Theorem 19.18, applied with (Ms1)–(Ms4) for C_{M} and with (Ht1), (Ht2), (Ht4), (Ht5) for C' from (Su3), $\mathcal{F}$ has (Ht1)–(Ht5) for the constant $C_{\mathrm{ht}} = \max\big(C', C_{\mathrm{M}}(C_{\mathrm{M}} + 120)\big) \geq 0$.

Step 3: (Dp6). $\mathcal{F}$ carries chain, deep-cover and component data with (Ht1)–(Ht5) for $C_{\mathrm{ht}} \geq 0$, so by Theorem 19.20 it has (Dp6) with the constant $C_{\mathrm{U}} = 8C_{\mathrm{ht}} + 4$.

Step 4: (Lc7). By (Su2) and Step 3, $\mathcal{F}$ carries chain and deep-cover data with (Dp0)–(Dp6), (Dp0) for C_{top}, (Dp5) for C_{F} and (Dp6) for C_{U}. By Theorem 19.24 it has (Lc7) with the constant $C_7 = \max\big(C_{\mathrm{top}}, 2(C_{\mathrm{F}} + C_{\mathrm{U}}) + 9\big)$.

Step 5: the bound. By (Su1) and Step 4, $\mathcal{F}$ carries chain data with (Lc1)–(Lc7), (Lc6) for C_6 and (Lc7) for C_7. By Theorem 19.26 it has the covolume bound with $C_0 = C_6 + C_7 + 1 \geq 0$: there is x_0 such that the displayed inequality holds for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, every $C \geq C_0$ and every lift j. This is the assertion for $\mathcal{F}$ and C_H.

The restricted class. Let $\mathfrak{r}_{\mathrm{str}}$ be as stated and $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}[\mathfrak{r}]$. By Definition A.3, its parameter satisfies $0 < \varepsilon < \min(\varepsilon_1, 1/52)$ and $\mathcal{F}$ is large for $\mathfrak{K}_{\mathfrak{r}}(\varepsilon) = \mathfrak{K}(\varepsilon)$, that is, by (Yv1) of Definition A.88, large for $(\mathfrak{K}(\varepsilon), C_H(\mathcal{F}))$. The assertion with $C_H = C_H(\mathcal{F})$ gives $C_0 \geq 0$ and x_0 as in the definition of the covolume bound in Definition 19.5. □

Lemma A.91. *Let $p = (\mathcal{N}, S, \Gamma)$ be a parameter such that every norm choice of $\mathcal{N}$ extends with its law. Assume the ray-class-field statement and the four published real-group inputs (discrete-series cover, Harish–Chandra modules, rapid decay of cusp forms, Casselman–Wallach globalisation), and that the services (S1) h_{PA} (primitivity), (S3) h_{DivG} (divisor rows), (S8)* good *(goodness) and (S9)* geo *(geometric weak ties) hold linked at p. Then the covolume row* $\mathrm{EvWC}(\top, L_3)$ *holds linked at p. Explicitly: there are a large-base slot R over* $\mathrm{Built}_{\mathrm{E}}(\mathfrak{S}(p))$ *and a bundle predicate E with* $\mathrm{RowE}(\mathrm{Good}_{\mathrm{E}}(\mathfrak{S}(p)) \wedge R, \mathrm{Lk}_p, E)$ *such that for every class $\mathfrak{A}$ and every E-selection σ over $\mathfrak{A}$ there is $\varepsilon_1 > 0$ such that for every $0 < \varepsilon \leq \varepsilon_1$ there is a threshold triple $\mathfrak{K}$ with the following property: for every $\mathcal{F} \in \mathfrak{A}^{\mathrm{st}}$ of parameter ε and every real C_H for which $\mathcal{F}$ is large for $(\mathfrak{K}, C_H)$, there is $C_0 \geq 0$ such that for every $C \geq C_0$ there is x_0 such that the clause L_3 of* $\mathrm{Cx}_3(\sigma(\mathcal{F}, x, i))$ *at base level holds at* $\mathrm{num}(\sigma(\mathcal{F}, x, i); C, C_H)$ *for all members (x, i) of $\mathcal{F}$ with $x \geq x_0$.*

Proof. Outline. The point properties of the selection, together with the inclusion of the families in $\mathcal{B}_{\mathrm{cv}}$, show that the selected points are realised points at all large members; the covolume bound Proposition A.90, applied with a common refinement of the two structural thresholds involved, then gives the covolume inequality at these points, which by (ii) of (Yv3) of Definition A.88 is the clause L_3 at base level. □

Proposition A.92. *There is $\varepsilon_1 > 0$ and, for every $\varepsilon \in (0, \varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that every family $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ of parameter $\varepsilon \in (0, \varepsilon_1)$ that is large for $(\mathfrak{K}(\varepsilon), u)$ for some real u carries chain data, deep-cover data, component data and model-slope data with the following properties.*

(Su1) *(Lc1)–(Lc6) hold, (Lc6) for some constant* $C_6 \geq 0$.

(Su2) *(Dp0)–(Dp5) hold, (Dp0) for some constant* $C_{\mathrm{top}} \geq 0$ *and (Dp5) for some constant* $C_{\mathrm{F}} \geq 0$.

(Su3) *There is a real* $C' \geq 0$ *such that the inequalities (Ht1), (Ht2), (Ht4), (Ht5) hold with the constant* C' *for all large points with* $j < m$.

(Su4) *There is a real* $C_4 \geq 0$ *such that (Ms4) holds with the constant* C_4 *for all large points with* $j < m$.

(Su5) *For every real* $x > x_1$, *every* $i \in I(x)$, *every* $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ *and every lift* $j < m$, *the data (Aj1), (Aj2), (Aj3) are given and hold for these component data and model-slope data.*

Proof. Outline. One takes the intersection of the structural thresholds of four supply results for the covolume data (for the main terms, the bad parts, the lattice slopes and the deep covers, the last being Proposition A.93); the realised covolume objects of a point then give chain data, which satisfy (Lc1)–(Lc6) at large points, and the deep-cover, component and model-slope data supplied by Proposition A.93 give (Su2)–(Su5). □

A.8.2 Deep covers and short generators

The main terms, the top lift and the deep-cover, component and model-slope data over the realised core lattices are Proposition A.93. On a covering cover, the deep lattice is the eigenlattice of a character of a small group of level automorphisms that keep integral forms and Petersson norms (Proposition A.94). A section whose translates have a non-vanishing group determinant gives descent maps into the eigenlattice (Lemma A.95), and with these the deep lattice is spanned by vectors of norm at most $\exp(P\varkappa)$ (Proposition A.96).

Proposition A.93. *There is* $\varepsilon_1 > 0$ *and, for every* $\varepsilon \in (0, \varepsilon_1)$, *a structural threshold* $\mathfrak{K}(\varepsilon)$, *such that every family* $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ *of parameter* ε *that is large for* $(\mathfrak{K}(\varepsilon), u)$ *for some real* u *has the following properties.*

(Hq1) Size of the main terms *There is a real* A *such that for all large points* $|\mathrm{mt}_j(\mathfrak{z})| \leq x^A\, b(x)$.

(Hq2) Top lift *There is a real* $C_{\mathrm{top}} \geq 0$ *such that for all large points at which* $L^{\mathrm{c}}_{\mathfrak{z},m}$ *is a non-zero hermitian lattice,* $2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},m}) \geq -\mathrm{mt}_m(\mathfrak{z}) - C_{\mathrm{top}}\,\mathrm{ue}(x,i)$.

(Hq3) Deep covers *For every real* $x > x_1$, *every* $i \in I(x)$, *every* $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ *and every lift* $j < m$ *the data fields of deep-cover data are given, such that (Dp1), (Dp2), (Dp3) hold for all large points with* $j < m$, *(Dp5) holds for all large points with* $j < m$ *with some constant* $C_{\mathrm{F}} \geq 0$, *and* $2\,\widehat{\mu}(B_{\mathfrak{z},j}) - 2\,b(x) \leq 2\,\widehat{\mu}(L^{\mathrm{c}}_{\mathfrak{z},j})$ *with* $B_{\mathfrak{z},j} \neq 0$ *for all large points with* $j < m$ *at which* $L^{\mathrm{c}}_{\mathfrak{z},j}$ *is a non-zero hermitian lattice.*

(Hq4) Components and model slopes *With these deep-cover data the family carries component data and model-slope data such that: there is a real* $C' \geq 0$ *for which (Ht1), (Ht2), (Ht4), (Ht5) hold with the constant* C' *for all large points with* $j < m$; *there is a real* $C_4 \geq 0$ *for which (Ms4) holds with the constant* C_4 *for all large points with* $j < m$; *and for every real* $x > x_1$, *every* $i \in I(x)$, *every* $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ *and every lift* $j < m$ *the data (Aj1), (Aj2), (Aj3) are given and hold for these component data and model-slope data.*

Proof. Outline. One intersects the structural thresholds of five supply results for the data of a point (sizes and divided weights, covering covers, rank comparisons, heights, which is Proposition A.102, and an arithmetic Hilbert–Samuel bound); at a large pair the deep-cover data are taken from the cusp spaces and Petersson lattices of a covering cover $\mathcal{Y}$ at the shifted weights, with deep lattice $B_{\mathcal{Y}}$ and the descent maps of the cover, the component data from the irreducible components at the twisted weight, and (Hq1)–(Hq4) are then read off from these five results. □

Proposition A.94. *There is $\varepsilon_1 > 0$ and, for every $\varepsilon \in (0, \varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon), u)$ for some real u there are real numbers $C \geq 0$ and x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$ with rank datum (k, m, t) and derived ranks f, r, every lift $j < m$ and every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with $\mathfrak{m} = \mathfrak{m}_{\mathcal{Y}}$ with field F', $z = f\, r\, x^{\varepsilon}$, the core weight κ and the weight constant $c_0 = c_0(j)$ of $\mathfrak{z}$ at j, $W = w(c_0 h, 0)$ and $B_{\mathcal{Y}} = \Lambda_{\mathcal{Y}}(\kappa; \mathrm{Typ}^{\mathrm{c}}_{\mathfrak{z},j})$, there are a finite group H, for every integral weight G a map ρ_G from H to the F'-linear endomorphisms of $\mathrm{Alg}_{F'}(G)$, and a homomorphism $\chi\colon H \to F'^{\times}$ such that:*

1. *for all integral weights G, G', all $\gamma, \gamma' \in H$, $y \in \mathrm{Alg}_{F'}(G)$ and $y' \in \mathrm{Alg}_{F'}(G')$: $\rho_G(\gamma\gamma') = \rho_G(\gamma') \circ \rho_G(\gamma)$, $\rho_G(1)$ is the identity, and $\rho_{G+G'}(\gamma)(yy') = \rho_G(\gamma)(y)\, \rho_{G'}(\gamma)(y')$, yy' being the product of algebraic forms;*
2. *for every integral weight G and every $\gamma \in H$: $\rho_G(\gamma)$ maps $\mathrm{Cusp}_{\mathfrak{m}}(G)$ into itself and $\Lambda_{\mathfrak{m}}(G)$ into itself, and $\|\rho_G(\gamma)y\|_{G,\sigma} = \|y\|_{G,\sigma}$ for every $y \in \mathrm{Cusp}_{\mathfrak{m}}(G)$ and every embedding $\sigma\colon F' \to \mathbb{C}$;*
3. *every value of χ is a root of unity, and $\log|H| \leq 45\, z^2$;*
4. *$B_{\mathcal{Y}} = \{y \in \Lambda_{\mathfrak{m}}(\kappa) :\ \rho_\kappa(\gamma)y = \chi(\gamma)y$ for every $\gamma \in H\}$;*
5. *there is $\vartheta \in \Lambda_{\mathfrak{m}}(W)$ such that the group determinant $D_\vartheta = \det\big(\rho_W(\gamma_1\gamma_2)\vartheta\big)_{\gamma_1,\gamma_2 \in H}$, an algebraic form of weight $|H|\, W$, satisfies $D_\vartheta\, y \neq 0$ for every non-zero finite sum y of algebraic forms of integral weights, and such that $\|y{\cdot}\rho_W(\gamma)\vartheta\|_{G+W,\sigma} \leq \exp(C\, z^9)\, \|y\|_{G,\sigma}$ for every $\gamma \in H$, every integral weight G, every $y \in \mathrm{Cusp}_{\mathfrak{m}}(G)$ with $y{\cdot}\rho_W(\gamma)\vartheta \in \mathrm{Cusp}_{\mathfrak{m}}(G{+}W)$ and every embedding $\sigma\colon F' \to \mathbb{C}$.*

Proof. Sketch. The covering cover $\mathcal{Y}$ is a moduli scheme of deeper level: its level is $g_1 g_2$ times a cofactor prime to $g_1 g_2$, and a type frame identifies the level structure modulo the type primes with $(\mathbb{Z}/g_v)^r$. The argument should take for H the finite group of level automorphisms that reduce to the unipotent level group modulo $g_1 g_2$, acting on algebraic forms by pull-back along the change of level structure. Pull-back of forms is multiplicative, which gives (1); it preserves the cusp condition and integrality, and it preserves Petersson norms because these are defined by invariant Haar measures, which gives (2). For χ one takes the generic character of H built from non-trivial additive characters modulo g_1 and g_2, so that its values are roots of unity; the order of H is at most $(g_1 g_2)^{O(r^2)}$, and the size conditions on the auxiliary primes should give $\log|H| \leq 45 z^2$, which is (3). Item (4) is Galois descent along the level cover: a form on the cover descends to a form of type χ on the core exactly when H acts on it through χ, so the integral pull-backs of the core type forms are the integral χ-eigenforms. Item (5) asks for one integral form ϑ of weight W whose translates have a non-degenerate group determinant. Heuristically such forms exist because H acts faithfully on the function field of the cover: by the normal basis theorem some form has translates whose group matrix is invertible (the group determinant factors over the irreducible representations of H, after Dedekind and Frobenius), so $D_\vartheta \neq 0$ is

the avoidance of a single hypersurface of degree $|H|$ in the space of forms of weight W, and a Siegel-lemma argument [37] in the lattice of integral cusp forms, whose covolume is controlled by the flat degree of the cover, should produce such a ϑ of controlled size. The bound $\exp(Cz^9)$ for multiplication by its translates should then follow from a comparison between the supremum of ϑ and its Petersson norm. Items (1)–(4) are what Proposition A.96 uses, and (1), (2) and (5) are the conditions under which Lemma A.95 constructs descent maps into the eigenlattice of (4). □

Lemma A.95. *Let $\mathfrak{m}$ be a uniformised moduli datum with field F' and a Lie parameter, let G_- and W be integral weights, $G = G_- + W$ and $G_+ = G + W$, and suppose that $\mathfrak{m}$ is good at G and at G_+. Let H be a finite group, for every integral weight G' let $\rho_{G'}$ be a map from H to the F'-linear endomorphisms of $\mathrm{Alg}_{F'}(G')$, and let $\chi\colon H \to F'^{\times}$ be a homomorphism whose values are roots of unity, such that:*

1. *$\rho_{G'}(1)$ is the identity, $\rho_{G'}(\gamma\gamma') = \rho_{G'}(\gamma')\circ\rho_{G'}(\gamma)$ and $\rho_{G'+G''}(\gamma)(yy') = \rho_{G'}(\gamma)(y)\,\rho_{G''}(\gamma)(y')$ for all integral weights G', G'', all $\gamma, \gamma' \in H$, $y \in \mathrm{Alg}_{F'}(G')$, $y' \in \mathrm{Alg}_{F'}(G'')$;*
2. *for $G' \in \{W, G\}$ and $\gamma \in H$, $\rho_{G'}(\gamma)$ maps $\mathrm{Cusp}_{\mathfrak{m}}(G')$ into itself and $\Lambda_{\mathfrak{m}}(G')$ into itself, and $\|\rho_G(\gamma)y\|_{G,\sigma} = \|y\|_{G,\sigma}$ for $y \in \mathrm{Cusp}_{\mathfrak{m}}(G)$ and every embedding $\sigma\colon F' \to \mathbb{C}$.*

Let $\vartheta \in \Lambda_{\mathfrak{m}}(W)$ be such that $D_\vartheta = \det(\rho_W(\gamma_1\gamma_2)\vartheta)_{\gamma_1,\gamma_2\in H}$ satisfies $D_\vartheta\, y \neq 0$ for every non-zero finite sum y of algebraic forms of integral weights; let $B \geq 0$ be such that $\|y \cdot \rho_W(\gamma)\vartheta\|_{G,\sigma} \leq B\,\|y\|_{G_-,\sigma}$ for every $\gamma \in H$, every $y \in \mathrm{Cusp}_{\mathfrak{m}}(G_-)$ with $y\cdot\rho_W(\gamma)\vartheta \in \mathrm{Cusp}_{\mathfrak{m}}(G)$ and every σ; and let b be a real number with $|H|^3B^2 \leq e^{2b}$. Put $\Lambda^\chi = \{y \in \Lambda_{\mathfrak{m}}(G) :\ \rho_G(\gamma)y = \chi(\gamma)y \text{ for every } \gamma \in H\}$. Then, with $n = |H|$, there are F'-linear maps $\phi_1, \dots, \phi_n\colon \mathrm{Cusp}_{\mathfrak{m}}(G_-) \to \mathrm{Cusp}_{\mathfrak{m}}(G)$ such that $\phi_k(\Lambda_{\mathfrak{m}}(G_-)) \subseteq \Lambda^\chi$ for every k; $y = 0$ whenever $\phi_k(y) = 0$ for all k; $\sum_{k=1}^n \|\phi_k(y)\|^2_{G,\sigma} \leq e^{2b}\|y\|^2_{G_-,\sigma}$ for every $y \in \mathrm{Cusp}_{\mathfrak{m}}(G_-)$ and every σ; and $n \operatorname{rk}\Lambda^\chi \leq \mathrm{rk}_{\mathfrak{m}}(G_+)$.

Proof. **Products and the graded algebra.** We use the commutative algebra of finite sums of algebraic forms, with the weight grading and the pointwise product. The given maps on its homogeneous pieces extend linearly to an anti-action on this algebra by algebra automorphisms: the inverse of $\rho(\gamma)$ is $\rho(\gamma^{-1})$, and the product law is hypothesis (1). Products of two cusp forms are cusp forms at the sum weight. To read this also for forms not supported on a single component, decompose each form by the finitely many open and closed irreducible components of the smooth moduli scheme. Restriction followed by zero extension is a natural algebraic form and preserves the cusp condition on each uniformisation component. Products on different components vanish, and the products on each single component are cusp forms, since products of cusp forms on a component are cusp forms. Summing gives the assertion. Products of integral forms are integral: their valuations at every integral framed point add. These facts apply at weights $G_- + W = G$ and $G + W = G_+$.

Write $\vartheta_h = \rho_W(h)\vartheta$. Hypothesis (2) gives $\vartheta_h \in \Lambda_{\mathfrak{m}}(W)$ for every h. For $y \in \mathrm{Cusp}_{\mathfrak{m}}(G_-)$ define

$$\phi_h(y) = \sum_{\gamma\in H} \chi(\gamma)^{-1}\rho_G(\gamma)(y\vartheta_h).$$

Products and cusp stability show that these are F'-linear maps to $\mathrm{Cusp}_{\mathfrak{m}}(G)$. Enumerate H once to obtain the requested $\phi_1, \dots, \phi_n$.

The character and integral lattice. For $\delta \in H$, the anti-action law and the substitution

$\eta = \gamma\delta$ give

$$\begin{aligned}\rho_G(\delta)\phi_h(y) &= \sum_{\gamma\in H} \chi(\gamma)^{-1}\rho_G(\gamma\delta)(y\vartheta_h)\\ &= \chi(\delta)\sum_{\eta\in H}\chi(\eta)^{-1}\rho_G(\eta)(y\vartheta_h) = \chi(\delta)\phi_h(y).\end{aligned}$$

A root of unity and its inverse are algebraic integers, so every $\chi(\gamma)^{-1}$ belongs to $\mathcal{O}_{F'}$. If y is integral, each product $y\vartheta_h$ is integral, and its image under $\rho_G(\gamma)$ is integral by hypothesis (2). The sum is consequently integral and has the displayed character. This proves $\phi_h(\Lambda_{\mathfrak{m}}(G_-)) \subseteq \Lambda^{\chi}$.

Joint injectivity by an adjugate. The product and anti-action laws give, as an identity in the algebra of forms,

$$\phi_h(y) = \sum_{\gamma\in H} (\rho_W(h\gamma)\vartheta)\chi(\gamma)^{-1}\rho_{G_-}(\gamma)y.$$

Let M be the matrix with rows h, columns γ, and entries $M_{h,\gamma} = \rho_W(h\gamma)\vartheta$. Thus the vector of the $\phi_h(y)$ is Mv, where $v_\gamma = \chi(\gamma)^{-1}\rho_{G_-}(\gamma)y$. The determinant of this matrix is exactly D_ϑ, using the same enumeration for rows and columns. If every $\phi_h(y) = 0$, multiplication by the adjugate yields $D_\vartheta v_\gamma = 0$ for every γ. Each v_γ is an algebraic form, so the stated non-zero-divisor hypothesis gives $v_\gamma = 0$. At $\gamma = 1$ this is $y = 0$. No cusp stability at weight G_- for the action is needed in this step.

The simultaneous norm bound. Fix y and an embedding σ. Every $y\vartheta_h$ is a cusp form of weight G, so the conditional multiplication bound in the hypothesis applies to it. Since G is good, its Petersson norm is a Hermitian norm and satisfies the triangle inequality. The isometry in hypothesis (2) and $|\sigma(\chi(\gamma))| = 1$ therefore give

$$\|\phi_h(y)\|_{G,\sigma} \le \sum_{\gamma\in H}\|\rho_G(\gamma)(y\vartheta_h)\|_{G,\sigma} = n\|y\vartheta_h\|_{G,\sigma} \le nB\|y\|_{G_-,\sigma}.$$

All quantities are nonnegative. Squaring and summing over the n choices of h proves

$$\sum_h \|\phi_h(y)\|^2_{G,\sigma} \le n^3B^2\|y\|^2_{G_-,\sigma} \le e^{2b}\|y\|^2_{G_-,\sigma}.$$

This uses only the given values of the source norm and its multiplication bound, not goodness at G_-.

The rank count. Define an $\mathcal{O}_{F'}$-linear map

$$\Psi : (\Lambda^{\chi})^H \longrightarrow \Lambda_{\mathfrak{m}}(G_+), \qquad \Psi((f_h)_h) = \sum_{h\in H} f_h\vartheta_h.$$

Products of cusp forms and integral forms justify this codomain. Suppose its value is zero. Apply the algebraic action $\rho_{G_+}(\gamma)$ to the equality. The eigenvector equations for the f_h, the product law, and the anti-action law give

$$0 = \chi(\gamma)\sum_{h\in H} f_h\,\rho_W(h\gamma)\vartheta \qquad (\gamma\in H).$$

The scalar $\chi(\gamma)$ is invertible. Hence $M^{\mathsf{T}}(f_h)_h = 0$ for the same matrix M as above. The adjugate again yields $D_\vartheta f_h = 0$, and the non-zero-divisor hypothesis forces every $f_h = 0$. Thus Ψ is injective.

Goodness at G makes $\Lambda_{\mathfrak{m}}(G)$ a finitely generated torsion-free $\mathcal{O}_{F'}$-module; its submodule Λ^{χ} is finitely generated and torsion-free as well, since $\mathcal{O}_{F'}$ is Noetherian. Goodness at G_+ gives the same property for the target. Tensor the injection Ψ with the fraction field F'; localisation is exact. Taking dimensions gives

$$n \operatorname{rk} \Lambda^{\chi} \le \operatorname{rk} \Lambda_{\mathfrak{m}}(G_+) = \operatorname{rk}_{\mathfrak{m}}(G_+).$$

This proves every assertion, including zero source or eigenlattice ranks. □

Proposition A.96. *There is $\varepsilon_1 > 0$ and, for every $\varepsilon \in (0, \varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon), u)$ for some real u there is a real number x_0 such that for every real $x \ge x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, every lift $j < m$ and every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with $\mathfrak{m} = \mathfrak{m}_{\mathcal{Y}}$ with field F', the weight data of $\mathfrak{z}$ at j and $B_{\mathcal{Y}} = \Lambda_{\mathcal{Y}}(\kappa; \mathrm{Typ}^{\mathrm{c}}_{\mathfrak{z},j})$: there is a set $s \subseteq B_{\mathcal{Y}}$ with $\|y\|_{\kappa,\sigma} \le e^{P_{\mathfrak{z}}\varkappa}$ for every $y \in s$ and every embedding $\sigma\colon F' \to \mathbb{C}$, and $B_{\mathcal{Y}} \subseteq \operatorname{span}_{F'} s$.*

Proof. Outline. By Proposition A.94, $B_{\mathcal{Y}}$ is the χ-eigenlattice of a finite group H acting isometrically on the integral cusp forms of weight κ, with $\log|H| \le 45z^2$; a bound for minimal generators gives integral generators of the cusp space of norm at most $\exp(Cz^2\varkappa)$, an eigenlattice lemma turns them into generators of $B_{\mathcal{Y}}$ of norm at most $|H|\exp(Cz^2\varkappa)$, and the size condition $z^{12} \le P_{\mathfrak{z}}$ bounds the exponent by $P_{\mathfrak{z}}\varkappa$. □

A.8.3 Heights and Bergman volumes

A short spanning family of a lattice over a number field gives short integral generators (Lemma A.98), and the height of a component is bounded below by minus the logarithm of a bound for its short generators (Lemma A.97). From above, the Bergman volume of a component is bounded by its covering degree times its height plus a shift (Proposition A.99); Hirzebruch–Mumford proportionality makes the unit volumes of the components equal (Proposition A.100); and an effective arithmetic Hilbert–Samuel inequality on each component, with explicit parameters, joins the two sides (Lemma A.101). The heights of the components then follow from their volume slopes, the tower datum and the budget (Proposition A.102). The last statement provides integral models of unitary Shimura data with level, arc, transition and Siegel conditions, and a dominating model over the ring of integers (Proposition A.103); these are the models on which the Hecke reading of Section A.3 acts.

Lemma A.97. *Let $\mathfrak{m}$ be a uniformised moduli datum with coefficient field F and Lie parameter $\xi > 0$, $Z \in \mathrm{Comp}(\mathfrak{m})$ and G an integral weight such that $\mathfrak{m}$ is good at G on Z and $\mathrm{dg}_Z(G) > 0$. Let $\Lambda \ge 1$ and let $w_1, \dots, w_n \in \mathrm{Cusp}_{\mathfrak{m},Z}(G)$ satisfy $\Lambda_{\mathfrak{m},Z}(G) = \mathbb{Z}w_1 + \cdots + \mathbb{Z}w_n$ and $\|w_l\|_{G,\sigma,Z} \le \Lambda$ for $1 \le l \le n$ and every embedding $\sigma\colon F \to \mathbb{C}$. Then*

$$\mathrm{ht}_Z(G) + \log \Lambda \ge 0.$$

Proof. If no height exists, the convention gives $\mathrm{ht}_Z(G) = 0$, and the assertion follows from $\Lambda \ge 1$. Otherwise fix data b, w', A_σ, f as in (Vy5) for which $h = \mathrm{ht}_Z(G)$ satisfies the defining identity there. Write $N = \dim_F \mathrm{Cusp}_{\mathfrak{m},Z}(G)$, $D = D_{\mathrm{fl}}$, $\delta = \mathrm{dg}_Z(G) > 0$, and $B = D + 1$. The nonzero Chow form f has degree δ in each of its B blocks. In particular $N \ge 1$.

The given short generators may be used in the finite part. Let $W \in \mathrm{M}_{N,n}(F)$ have as its lth column the coordinates of w_l in b. Since the w_l generate the integral lattice over $\mathbb{Z}$,

they also generate it over $\mathcal{O}_F$: their $\mathcal{O}_F$-span lies in that lattice and contains its $\mathbb{Z}$-span. The columns of both W and w' therefore generate the same $\mathcal{O}_F$-module. Consequently $W = w'U$ and $w' = WV$ for rectangular matrices U, V over $\mathcal{O}_F$. Substitution of an integral linear combination of variables cannot increase a finite Gauss norm: expand each monomial, noting that every resulting coefficient is an integral linear combination of the original coefficients. Applying this to both identities gives

$$|f \circ W|_v = |f \circ w'|_v \qquad (v \text{ finite}).$$

Moreover the columns of W span F^N, since the lattice spans the cusp space by goodness. The norm identity for A_σ gives

$$|A_\sigma^{-1}\sigma(W_l)| = \|w_l\|_{G,\sigma,Z} \le \Lambda. \tag{1}$$

Here W_l denotes column l. Thus it suffices to prove the following polynomial estimate, with the same matrices A_σ and W:

$$\frac{1}{[F:\mathbb{Q}]}\left(\sum_{v \text{ finite}} \log|f \circ W|_v + \sum_\sigma \left(m(f^\sigma \circ A_\sigma) + \frac{B\delta}{2}H_{N-1}\right)\right) \ge -B\delta \log\Lambda, \quad H_{N-1} = \sum_{j=1}^{N-1}\frac{1}{j}. \tag{2}$$

A directional leading coefficient gives the sharp sphere-mean inequality. We give the analytic calculation used in (2). Let p be a nonzero complex polynomial, homogeneous separately in B blocks of N variables, and choose a nonzero vector $v \in \mathbb{C}^N$ and a block a. Expand

$$p(z_1, \dots, z_a + tv, \dots, z_B) = \sum_{j=0}^{l} t^j q_j(z), \qquad q_l \ne 0.$$

Put $q = q_l$ and $r = |v| > 0$. The polynomial q is invariant under translation of block a by a multiple of v: replacing z_a by $z_a + sv$ replaces t by $t + s$ and leaves the leading coefficient unchanged. It is multihomogeneous, and its total degree is that of p minus l.

Put $u = v/r$. For a sphere point z_a, rotate its component along u by $e^{i\theta}$ and leave its orthogonal component fixed. This unitary map preserves the invariant sphere probability measure. For fixed z the resulting value of p is a polynomial in $e^{i\theta}$ whose leading coefficient is $q(z)(\langle u, z_a\rangle/r)^l$, except on a set of sphere measure zero. Jensen's one-variable formula, in its elementary form saying that the circle mean of the logarithm of the absolute value of a polynomial is at least the logarithm of the absolute value of its leading coefficient, therefore gives, after averaging over all blocks,

$$m(p) \ge m(q) - l\log r - \frac{l}{2}H_{N-1}. \tag{3}$$

For completeness, the last constant is exact. The mean of $\log|\langle u, z_a\rangle|$ on the unit sphere of $\mathbb{C}^N$ is $-H_{N-1}/2$. For $N = 1$ the absolute value is 1. For $N > 1$ its squared absolute value has density $(N-1)(1-t)^{N-2}\,dt$ on $(0,1)$; integration of $\frac{1}{2}\log t$ against this density gives the stated value. The logarithms of nonzero polynomials are integrable on these products of spheres, so these averages and the interchange with the circle average are legitimate. One can see the integrability by passing, using homogeneity, to projective coordinate charts: there the logarithm differs from that of a nonzero holomorphic polynomial by a smooth function. Local integrability of the latter logarithm and a finite chart cover give the assertion. Thus no value assigned on a zero locus affects (3).

Induction combines the sphere estimate with the finite Gauss norms. For a nonzero polynomial p over F, multihomogeneous of degrees $a_1, \dots, a_B$, put $e = a_1 + \cdots + a_B$ and

$$J(p) = \frac{1}{[F:\mathbb{Q}]}\left(\sum_{v \text{ finite}} \log|p \circ W|_v + \sum_\sigma m(p^\sigma \circ A_\sigma)\right).$$

The full rank of W makes the linear substitution injective on polynomial rings, so $p \circ W \neq 0$. We prove by induction on e that

$$J(p) \geq -e\left(\log \Lambda + \frac{1}{2} H_{N-1}\right). \tag{4}$$

If $e = 0$, p is a nonzero constant; the product formula gives $J(p) = 0$.

Suppose $e > 0$. Some block and some column W_l give a nonconstant polynomial in t after the translation of that block by tW_l. Indeed, if every such translation left p unchanged, the fact that the columns span F^N would make p independent of that block; applying this to every block would make it constant. Choose such a block and column, and let q be the leading coefficient in t, of degree $l_0 \geq 1$. Then $q \neq 0$ is multihomogeneous of total degree $e - l_0$.

At a finite place,

$$|q \circ W|_v \leq |p \circ W|_v. \tag{5}$$

In fact, after substituting W in every block, the translation by tW_l is the replacement of the lth variable of the chosen block by that variable plus t. This substitution has integer coefficients, and extraction of a coefficient cannot increase its Gauss norm. This proves (5), including the possible binomial coefficients.

At each embedding apply (3) to $p^\sigma \circ A_\sigma$ and the vector $v_\sigma = A_\sigma^{-1}\sigma(W_l)$. This vector is nonzero because $W_l \neq 0$ and A_σ is invertible; by (1) its norm is at most Λ. The leading coefficient is precisely $q^\sigma \circ A_\sigma$. Therefore

$$m(p^\sigma \circ A_\sigma) \geq m(q^\sigma \circ A_\sigma) - l_0\left(\log \Lambda + \frac{1}{2} H_{N-1}\right). \tag{6}$$

Sum (5) and (6), divide by $[F : \mathbb{Q}]$, and use that the number of embeddings of F is $[F : \mathbb{Q}]$. The inductive hypothesis for q yields

$$J(p) \geq J(q) - l_0\left(\log \Lambda + \frac{1}{2} H_{N-1}\right) \geq -e\left(\log \Lambda + \frac{1}{2} H_{N-1}\right),$$

which proves (4).

The harmonic correction in the height cancels exactly. Apply (4) to the Chow form f, whose total degree is $e = B\delta$. Adding $B\delta H_{N-1}/2$ gives (2). By the first step the finite terms are the terms defining the height h, with the same Petersson norm matrices A_σ. Hence

$$B\delta h \geq -B\delta \log \Lambda.$$

Since $B = D + 1 > 0$ and $\delta > 0$, division proves $h + \log \Lambda \geq 0$. The calculation uses the Hilbert norms only through (1); it introduces neither a pointwise bound for cusp forms nor a factor depending on the number of generators. □

Lemma A.98. *Let K be a number field of degree $d = [K : \mathbb{Q}]$ and root discriminant $\mathrm{rd}_K = |d_K|^{1/d}$, let V be a finite-dimensional K-vector space and $L \subseteq V$ a finitely generated $\mathcal{O}_K$-submodule, and put $m = \dim_K(KL)$. For every embedding $\sigma\colon K \to \mathbb{C}$ let $N_\sigma\colon V \to \mathbb{R}$ satisfy, for all $a \in K$ and $x, y \in V$,*

$$N_\sigma(x) \geq 0, \qquad N_\sigma(ax) = |\sigma(a)|\, N_\sigma(x), \qquad N_\sigma(x + y) \leq N_\sigma(x) + N_\sigma(y).$$

Let $A \in \mathbb{R}$ and $s \subseteq L$ with $\mathrm{span}_K\, s = V$ and $N_\sigma(y) \leq A$ for every $y \in s$ and every σ. Then there are an integer $0 \leq n \leq 2dm$, elements $w_1, \ldots, w_n \in V$ and a real number Λ with

$$L = \mathbb{Z}w_1 + \cdots + \mathbb{Z}w_n, \qquad N_\sigma(w_l) \leq \Lambda\ (1 \leq l \leq n,\ \text{all } \sigma), \qquad 1 \leq \Lambda \leq \max(1,\ d^4\, m\, \mathrm{rd}_K\, A).$$

Proof. The inclusion $s \subseteq L$ and the spanning hypothesis imply $KL = V$, so $\dim_K V = m$. Homogeneity with the scalar 0 gives $N_\sigma(0) = 0$. If $m = 0$, then $V = L = 0$; take $n = 0$ and $\Lambda = 1$. This proves the assertion for every real A in that case. Henceforth $m \geq 1$. Then s is nonempty, and its bound together with nonnegativity gives $A \geq 0$.

Choose $y_1, \dots, y_m \in s$ forming a K-basis of V. Since a number field has a $\mathbb{Q}$-basis of algebraic integers whose conjugates are bounded in terms of the root discriminant (not necessarily an integral basis of $\mathcal{O}_K$), there are d elements $a_1, \dots, a_d \in \mathcal{O}_K$, linearly independent over $\mathbb{Q}$, with

$$|\sigma(a_i)| \leq \sqrt{d}\,\mathrm{rd}_K \qquad (1 \leq i \leq d, \text{ every } \sigma).$$

They form a $\mathbb{Q}$-basis of K. Consequently the $h = dm$ vectors $a_i y_j$ form a $\mathbb{Q}$-basis of V. Enumerate them as $e_1, \dots, e_h$. They belong to L, and homogeneity gives the simultaneous bounds

$$N_\sigma(e_l) \leq B, \qquad B = \sqrt{d}\,\mathrm{rd}_K A \geq 0.$$

We construct an integral basis of L with controlled coordinates in this particular rational basis. Since $\mathcal{O}_K$ is finitely generated as an abelian group and L is finitely generated over $\mathcal{O}_K$, L is finitely generated as an abelian group. Every element of a fixed finite generating family has rational coordinates in (e_l). Clearing their denominators gives an integer $H \geq 1$ such that

$$\sum_{l=1}^{h} \mathbb{Z} e_l \;\subseteq L\; \subseteq \sum_{l=1}^{h} H^{-1}\mathbb{Z} e_l.$$

For $0 \leq i \leq h$, put

$$V_i = \mathrm{span}_{\mathbb{Q}}(e_1, \dots, e_i), \qquad L_i = L \cap V_i.$$

Thus $L_0 = 0$ and $L_h = L$. For $i \geq 1$, let $\pi_i : V_i \to \mathbb{Q}$ be the coefficient of e_i. The group $\pi_i(L_i)$ is a subgroup of $H^{-1}\mathbb{Z}$ containing $\mathbb{Z}$, because $e_i \in L_i$. It therefore equals $q_i\mathbb{Z}$ for a positive rational number $q_i \leq 1$. Choose a lift $v_i \in L_i$ with $\pi_i(v_i) = q_i$. Subtract integer multiples of $e_1, \dots, e_{i-1}$ to obtain a vector $w_i \in L_i$ of the form

$$w_i = q_i e_i + \sum_{j<i} c_{ij} e_j, \qquad |c_{ij}| \leq \tfrac{1}{2}.$$

Indeed each rational coordinate can be reduced to $[-1/2, 1/2]$ by subtraction of an integer; these subtractions preserve membership in L_i and its i-th coordinate.

For any $x \in L_i$, its i-th coordinate is an integer multiple kq_i. Hence $x - kw_i \in L_{i-1}$. Conversely L_{i-1} and w_i are contained in L_i, and no nonzero integer multiple of w_i belongs to V_{i-1} because $q_i > 0$. Thus

$$L_i = L_{i-1} \oplus \mathbb{Z} w_i.$$

Induction shows that $w_1, \dots, w_h$ are a $\mathbb{Z}$-basis of L.

For a rational scalar c, every field embedding has $|\sigma(c)| = |c|$. Applying the triangle inequality and homogeneity to the displayed expression for w_i therefore gives, for every σ,

$$N_\sigma(w_i) \leq q_i N_\sigma(e_i) + \sum_{j<i} |c_{ij}| N_\sigma(e_j) \leq \left(1 + \frac{i-1}{2}\right) B \leq hB = d^{3/2} m\,\mathrm{rd}_K A.$$

Since $d \geq 1$ and $A \geq 0$, this is at most $d^4 m\,\mathrm{rd}_K A$. Take

$$n = h = dm, \qquad \Lambda = \max(1, d^4 m\,\mathrm{rd}_K A).$$

Then $0 \leq n \leq 2dm$, the vectors generate L over $\mathbb{Z}$, and every required seminorm is at most Λ. The argument also applies when $A = 0$: all the displayed seminorm bounds are then zero, while $\Lambda = 1$. This completes the proof. □

Proposition A.99. *There is $\varepsilon_1 > 0$ and, for every $\varepsilon \in (0, \varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon), u)$ for some real u there is a real number x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, every lift $j < m$ and every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with coefficient field F' and $\mathfrak{m} = \mathfrak{m}_{\mathcal{Y}}$ taken with the Lie parameter ξ_{h}, the following holds. Let $Z \in \mathrm{Comp}(\mathfrak{m})$, let λ be a weight array of the unitary Shimura datum of $\mathfrak{m}$, $G = w(\lambda, 0)$, let $w_1, \dots, w_n \in \Lambda_{\mathfrak{m},Z}(G)$ and let Λ_2, t be real numbers. Suppose that $\mathfrak{m}$ is good at G on Z, is birational on Z at G and has no base locus at G on Z; that $\mathrm{dg}_Z(G) > 0$; that $\Lambda_{\mathfrak{m},Z}(G)$ is the set of $\mathbb{Z}$-linear combinations of $w_1, \dots, w_n$; that $\|w_l\|_{G,\sigma,Z} \leq \Lambda_2$ for $1 \leq l \leq n$ and every embedding $\sigma\colon F' \to \mathbb{C}$; that $\Lambda_2 \geq 1$; and that $\log \Lambda_2 \leq t$. Then*

$$\mathrm{bv}_Z(G; t) \leq \max\bigl(0,\ \mathrm{dg}_Z(G)\,(\mathrm{ht}_Z(G) + t)\bigr).$$

Proof. Sketch. The inequality bounds an arithmetic volume by an arithmetic self-intersection, and the argument should run as follows. The generators $w_1, \dots, w_n$ define a map from the flag space over Z to projective space; since $\mathfrak{m}$ is birational on Z at G and has no base locus there, this map is defined everywhere and is birational onto its image X_Z, a variety of dimension $D = D_{\mathrm{fl}}$ and degree $\mathrm{dg}_Z(G) > 0$. In particular the image ideal has a Chow form, and its Mahler measure for the Petersson metrics gives a height in the sense of (Vy5) of Definition A.89, so that $\mathrm{ht}_Z(G)$ is a genuine height and not the conventional value 0; this has to be verified as part of the proof. Equip $\mathcal{O}(1)$ on the closure of X_Z over $\mathcal{O}_{F'}$ with the metric induced by the Bergman kernel of the Petersson norm and shift it by t. By the reproducing property $|w_l(y)|^2 \leq \|w_l\|^2_{G,\sigma,Z}\,\mathrm{Berg}(y)$, every generator has pointwise norm at most $\Lambda_2 \leq e^t$, so after the shift the bundle is generated by sections of norm at most 1 at every place and is therefore nef. Its arithmetic self-intersection is computed from the Chow form by the comparison of Bost, Gillet and Soulé [48], and with the normalisation of (Vy5) it is at most $[F' : \mathbb{Q}](D+1)\,\mathrm{dg}_Z(G)\,(\mathrm{ht}_Z(G) + t)$. The small lattice forms of weight $8kG$, being integral and bounded by e^{8kt} times the $8k$-th power of the Bergman kernel, inject into the small sections of the $8k$-th power of the shifted bundle on a normal model dominating X_Z. For a nef hermitian line bundle the arithmetic volume equals the self-intersection (arithmetic Hilbert–Samuel [111], [1], [276], and its extension to nef bundles [182], [272]), and dividing by the normalisation of bv_Z gives the bound. Under the same conditions Lemma A.97 gives $\mathrm{ht}_Z(G) + t \geq \mathrm{ht}_Z(G) + \log \Lambda_2 \geq 0$, so under these conditions the maximum is attained by its second term. □

Proposition A.100. *There is $\varepsilon_1 > 0$ and, for every $\varepsilon \in (0, \varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F} \in \mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon), u)$ for some real u there is a real number x_0 such that for every real $x \geq x_0$ with $x > x_1$, every $i \in I(x)$, every $\mathfrak{z} \in \mathrm{Pt}_{x,i}$, every lift $j < m$ and every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with $\mathfrak{m} = \mathfrak{m}_{\mathcal{Y}}$ taken with the Lie parameter ξ_{h} and unitary Shimura datum with CM type Φ:*

1. *for every $Z \in \mathrm{Comp}(\mathfrak{m})$ and every weight array λ such that $i \mapsto \lambda(\tau, i)$ is strictly decreasing for every $\tau \in \Phi$, $\mathrm{vol}_Z(w(\lambda, 0)) = \mathrm{td}_Z(\lambda)$;*
2. *$v_0(Z) > 0$ for every $Z \in \mathrm{Comp}(\mathfrak{m})$, and $v_0(Z) = v_0(Z')$ for all $Z, Z' \in \mathrm{Comp}(\mathfrak{m})$.*

Proof. Sketch. This is Hirzebruch–Mumford proportionality [188], read on the flag space over a component. The flag space over Z has dimension $D_{\mathrm{fl}} = |\Phi|\,r(r-1)/2$, which is the dimension of the full flag variety of each factor of the compact dual, and a weight $w(\lambda, 0)$ defines an automorphic line bundle on it whose direct image to Z is the automorphic vector bundle of

highest weight λ. On a smooth projective toroidal compactification [7], [87], [154], cusp forms of weight $k\,w(\lambda,0)$ supported on Z are the sections of the k-th power of the canonical extension twisted down by the divisor at infinity, and this twist changes their number only by $O(k^{D_{\mathfrak{fl}}-1})$. For strictly decreasing λ the canonical extension should be nef and big, as it is on the compact dual where the line bundle is ample, so that by asymptotic Riemann–Roch $\mathrm{vol}_Z(w(\lambda,0))$ is its top self-intersection. Mumford's theorem expresses this Chern number as the volume of Z times the corresponding Chern number on the compact dual, which is the degree $\mathrm{vdm}(\lambda)$ of the line bundle on the flag variety; the factor is independent of λ, and evaluating at the standard array u_{std} identifies it with $v_0(Z)$, which gives (1). The factor is positive because the volume of an arithmetic quotient is positive, which is the first half of (2). The equality of the unit volumes of different components should follow because the components are permuted by Galois conjugation and by Hecke translations, both of which preserve top Chern numbers of automorphic bundles. □

Lemma A.101. *There is $\varepsilon_1>0$ and, for every $\varepsilon\in(0,\varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F}\in\mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon),u)$ for some real u there is a real number x_0 such that for every real $x\ge x_0$ with $x>x_1$, every $i\in I(x)$, every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$ with rank datum of derived rank r, every lift $j<m$ and every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with $\mathfrak{m}=\mathfrak{m}_{\mathcal{Y}}$ taken with the Lie parameter ξ_{h} and the weight data of $\mathfrak{z}$ at j (Φ the CM type of the core datum; write $D=D_{\mathfrak{fl}}$, $P=P_{\mathfrak{z}}$): for every divided weight u_1 there is a function $w\colon\Phi\to\mathbb{Z}$ with $|w(\tau)|\le 3r$ for all τ such that, with the weight array $\lambda_T(\tau,i)=u_M(\tau,i)-w(\tau)$:*

1. *$\mathfrak{m}$ is good at $w(\lambda_T,0)$ on every $Z\in\mathrm{Comp}(\mathfrak{m})$;*
2. *for every $Z\in\mathrm{Comp}(\mathfrak{m})$ with $\delta=\mathrm{dg}_Z(w(u_1,0))\ge 1$ and $d=\mathrm{rc}_Z(w(\lambda_T,0))>0$: Z has a height at $w(u_1,0)$ (so that $h=\mathrm{ht}_Z(w(u_1,0))$ is one), $\delta\le e^P$, the number $z_H=1-N^{\mathrm{b}}\delta/d$ satisfies $0\le z_H\le 1$, and there are real numbers $n,\Lambda,\beta\ge 1$ and J with $\log n\le P$, $\log\beta\le P$, $\log\Lambda\le P(\varkappa/T+1)$, $J\le 4\big(DP(\varkappa/T+1)+TP\big)+2P(\varkappa/T)D$ and, with $g=\mathrm{gc}_Z(w(\lambda_T,0))$,*

$$(1-z_H)\Big(Th-3(D+1)|h|-J-26D^2\log(\varrho T)-(T+D+1)\log\beta-(T+D^2)(G+2)\Big)\\ -z_H\big(T\log(2\varrho\sqrt{\beta})+2P\varkappa\big)\le\frac{g}{d},$$

where $\varrho=\Lambda\big(nD\delta(2+|h|+\log\Lambda)\big)^{26}$ and $G=\frac{1}{2}(D+1)(\log n+1)+1$.

Proof. Sketch. The statement is an effective arithmetic Hilbert–Samuel inequality on each component: up to explicit errors, the normalised arithmetic degree g/d of the Petersson lattice at the high weight $w(\lambda_T,0)$ is at least T times the height h of Z at the divided weight u_1. The weight λ_T is chosen so that, up to a parallel shift w with $|w|\le 3r$, it is the weight $\kappa_{\mathfrak{fl}}+u_2+(D+T)u_1$ of a fixed form of weight $\kappa_{\mathfrak{fl}}+u_2+Du_1$ multiplied by monomials of degree T in forms of weight u_1; this weight identity at the point $\mathfrak{z}$ is where the shift w comes from. The argument should run as follows. On a smooth projective toroidal compactification of the flag space over Z on which the relevant Hodge bundle is generated [7], [154], the forms of weight u_1 (and u_2) are birational, so the image ideal has a Chow form of dimension D and degree δ, which gives the existence of the height h. The products of degree T should span a sublattice of rank $N^{\mathrm{b}}\delta$, the proportion $1-z_H$ of the rank d, and an effective arithmetic Hilbert–Samuel theorem bounds its slope below by Th minus the displayed error terms; the inputs are Kawamata–Viehweg vanishing [143], [263], L^2 extension [194], [79], GAGA [219], and the theory of Chow forms and heights [48], [197]. The complementary part of the lattice, of proportion z_H, is controlled only through short generators:

the lattices at the intermediate weights are spanned by vectors of Petersson norm at most $e^{P\varkappa}$, the frame norms are bounded by Λ and the Bergman kernel by β, which accounts for the term $z_H\big(T\log(2\varrho\sqrt{\beta})+2P\varkappa\big)$. Since arithmetic degrees are additive in an exact sequence of hermitian lattices, g/d is the average of the two slopes with weights $1-z_H$ and z_H, and combining the two bounds gives (2), once the image degree is identified with dg_Z, the Chow height with ht_Z, and $\log \mathrm{dg}_Z(w(u_1,0))\le P$ is shown. Item (1) is the regularity of the Petersson lattice at $w(\lambda_T,0)$ on each component, the same goodness that the covering domain provides at the other weights of the construction. The inequality is used component by component in the effective Hilbert–Samuel bound for the covering cover, which compares the heights of the components with the arithmetic degrees of the Petersson lattices. □

Proposition A.102. *There is $\varepsilon_1>0$ and, for every $\varepsilon\in(0,\varepsilon_1)$, a structural threshold $\mathfrak{K}(\varepsilon)$, such that for every family $\mathcal{F}\in\mathcal{B}_{\mathrm{cv}}$ of parameter ε that is large for $(\mathfrak{K}(\varepsilon),u)$ for some real u there are real numbers $C\ge 0$ and x_0 such that for every real $x>x_1$, every $i\in I(x)$, every $\mathfrak{z}\in\mathrm{Pt}_{x,i}$ and every lift $j<m$, with the weight data of $\mathfrak{z}$ at j:*

1. *if $x\ge x_0$: for every covering cover $\mathcal{Y}$ of $\mathfrak{z}$ at j, with $\mathfrak{m}_{\mathcal{Y}}$ taken with the Lie parameter ξ_{h} of the core data, and every divided weight u_1 there are model-slope entries E, $M\ge 1$, $B\ge 128$, L, $\mathrm{wn}\ge 0$, $\mathrm{wsp}\ge 0$ and real numbers $\mathrm{vs}(Z)$, $Z\in\mathrm{Comp}(\mathfrak{m}_{\mathcal{Y}})$, such that (Aj1)–(Aj3) hold at $(\mathfrak{z},j)$ for $\mathcal{Z}=\mathrm{Comp}(\mathfrak{m}_{\mathcal{Y}})$, $D^{\mathrm{fl}}=D_{\mathrm{fl}}$, these volume slopes and these entries, and, with $h_Z=\mathrm{ht}_Z(w(u_1,0))$ and $\rho=\rho(u_1)$ there are reals $c^{\mathrm{s}},c^{\mathrm{c}}\ge 0$ such that for every $Z\in\mathrm{Comp}(\mathfrak{m}_{\mathcal{Y}})$*

$$h_Z+c^{\mathrm{s}}\ge 0,\qquad (1-\rho)\max\big(0,\mathrm{vs}(Z)+c^{\mathrm{s}}\big)\le h_Z+c^{\mathrm{s}}+c^{\mathrm{c}},$$

and $T\,c^{\mathrm{c}}\le C\,\mathrm{ue}(x,i)$, $c^{\mathrm{s}}\big(6D_{\mathrm{fl}}+10+2\rho T\big)\le C\,\mathrm{ue}(x,i)$ and $T\big(\mathrm{lz}\cdot\mathrm{wn}+\mathrm{wsp}\big)\le C\,\mathrm{ue}(x,i)$;

2. *(at every point) there are a finite non-empty set $\mathcal{Z}$, an integer $D^{\mathrm{fl}}\ge 0$, real numbers $\mathrm{vs}(Z)$ ($Z\in\mathcal{Z}$) and model-slope entries E, $M\ge 1$, $B\ge 128$, L, $\mathrm{wn}\ge 0$, $\mathrm{wsp}\ge 0$ for which (Aj1)–(Aj3) hold at $(\mathfrak{z},j)$.*

Proof. Outline. By the proportionality Proposition A.100 and a comparison of image degrees, the covering degree at the divided weight is positive and at most $\mathrm{td}_Z(u_1')/(1-\rho)$; short generators of the Petersson lattices give c^{s} with $h_Z+c^{\mathrm{s}}\ge 0$ by Lemma A.97, and a multiplicity constant together with a height cost gives c^{c}; the height inequality then follows by bounding the counting volume by a Bergman volume and this by Proposition A.99, the volume slopes being the suprema of the slope sets so obtained. □

Proposition A.103. *Let $\mathfrak{u}=(E,\mathsf{H},\mathsf{U},p,q,\mathsf{L},\mathrm{Sh},F)$ be a unitary Shimura datum with $p+q\ge 1$, level $\mathsf{L}=(N,\mathfrak{n},A)$ good at every prime and $A=1$, and let a system of moduli schemes $(\mathrm{Sh}_{\mathsf{L}'})$ extending $\mathfrak{u}$ be given. Then there are:*

1. *for every prime ℓ and every ℓ-adic place v, a family $(\mathcal{Y}^{v}_{\mathsf{L}',F'})$, indexed by the levels L' for H good at ℓ and the coefficient fields F' for L', of integral models of $\mathrm{Sh}_{\mathsf{L}'}$ over $\mathcal{O}_{F',v}$, every member of which satisfies (Gl1) and (Gl4), and which satisfies (Gl6) and (Gl7);*

2. *an integral model $\mathcal{Y}$ of Sh over $\mathcal{O}_F$ satisfying (Gl8), and satisfying (Gl9) with respect to the families of part 1.*

Proof. Sketch. The statement asks for integral models of the unitary Shimura varieties at every prime, including the primes of bad reduction, in the semiabelian form of Definition 31.2; it is the arithmetic setting in which the normalised Hecke reading Lemma A.30 takes place. At a prime ℓ and an ℓ-adic place v, the argument should run as follows. Choose an auxiliary odd prime $n \neq \ell$ and a power $m = n^{j'} \geq 3$, and use the moduli of principally polarised abelian schemes with symplectic level-m structure, which is smooth over $\mathbb{Z}_{(\ell)}[e^{2\pi i/m}]$, as a Siegel family. For each level good at ℓ, map the moduli scheme with auxiliary level m to it, take the normalisation of the closure of the image in a toroidal compactification of the Siegel family, and descend along the auxiliary level; this gives normal flat models whose transition maps between levels are finite, which is (Gl6), and whose comparison with the Siegel family is built in, which is (Gl7). The level-structure conditions (Gl1) are functoriality of this construction together with the extension of prime-to-ℓ torsion over the abelian locus. The arcs (Gl4) come from Mumford's construction of degenerating abelian varieties from degeneration data [187], [87], and their existence and uniqueness over complete discrete valuation rings rest on Grothendieck's semistable reduction theorem [227]. At primes of good reduction these are the arithmetic toroidal compactifications of [154]; at the remaining finitely many primes the normalisation construction is the one of [156] (compare [155]). Finally the model over $\mathcal{O}_F$ is obtained by gluing a smooth model over $\mathcal{O}_F[1/N]$ with normalisations at the finitely many remaining primes, chosen to dominate the local models; then its generic fibre descends, which is (Gl8), and the domination is (Gl9). □

A.9 Attachment at the members: Galois representations and the Ribet budget

The local losses of the lattices are bounded in the body by the Ribet budget for one coefficient extension, Theorem 22.1, together with its whole local theory. Alpöge's "congruences between lifts and forms" [4] are, in our reading, this budget. Beneath (TCS) no new local theory is needed: what is needed is to attach the hypotheses of the budget to the actual members. Theorem A.105 does this relative to four inputs, good cuts (Proposition A.106), the member Ribet supply (Proposition A.107), the Selmer budget of the chosen twists (Proposition A.108) and bounds at the generator primes (Proposition A.109), and it requires good twist data (Definition A.104). The budget is asked of one global coefficient extension, so the members never need roots of unity in their coefficients. The p-adic lifting theory needed at the members is proved (Theorem A.111). What the attachment needs beyond it is arithmetic of the actual members: Galois representations at the points of the members (Proposition A.110), position data at large primes, the corner design of the hub, and the Selmer clause of twist goodness. The last subsection treats the ties of a selected member with its context.

A.9.1 The Ribet budget at the members

Definition A.104 defines good twist data of a parametrised host family. Theorem A.105 shows that the actual members carry the records, the budget data and the Galois Ribet items of Theorem 22.1, given its four inputs. The four inputs, and the existence of hub data for member data with the Galois preconditions (Proposition A.110), are stated with sketches. The Galois representations attached to cohomological automorphic representations of unitary groups [231, 67] are the expected source of the hub data.

Definition A.104. A parametrised host family $\mathcal{F}$ has **good twist data** if there is a real x_0 such that for every $x \geq x_0$ with $x > x_1(\mathcal{F})$ and every member (x, i), with $D = D_{x,i}$, $\nu = \mathrm{nch}(O_{x,i})$ and $\vartheta = \mathrm{xd}(O_{x,i})$:

1. ν satisfies the conjugation conditions: for every place w with $\mu_{\mathrm{at}}(w) \neq \mu_0$ the normalised twist packs of ν at $\bar{w}$ and w coincide, and $\epsilon(\bar{w}) \neq \epsilon(w)$ when $\bar{w} \neq w$;

2. there is a twist input $\mathcal{I}$ for D whose integral Hecke-form datum is that of ϑ such that for every place w with $\mu_{\mathrm{at}}(w) \neq \mu_0$, $\mathcal{I}$ is admissible at $i(w)$ and the twist $(\epsilon(w), Q(w), k'(w), \psi'_w)$ is good for $\mathcal{I}$ at $i(w)$.

Theorem A.105. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1 and good twist data, such that at every member (x,i), $x > x_1$, the member datum $D_{x,i}$ with its numerical choice has the Galois preconditions and the depth-zero tie. Then $\mathcal{F}$ has local defect data formed from its actual members as in Proposition A.106, with (Ld3) and (Ld4), together with local bound records, Ribet records, budget data, inert budget data, Galois Ribet items at every point (j,w,r,π) of every member (x,i), $x > x_1$, real numbers $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$ and a real x_0, such that for every $x \geq x_0$ with $x > x_1$ and every member (x,i) with finite Sha lengths there are an integer $N_{x,i} \geq 1$ with $4 \mid N_{x,i}$ and integers $S^{\mathrm{rm}}_{x,i}, \eta^{\mathrm{rm}}_{x,i} \geq 0$ for which, with $\mathcal{F}'$ the coefficient extension of $\mathcal{F}$ along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ at the local components of these members (and along $\mathcal{O}_r \subseteq \mathcal{O}_r$ elsewhere), the Galois Ribet items of $\mathcal{F}'$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10) at every point of (x,i), the Ribet records have (Rf3), and the local defect data and local bound records have (Lq2), (Lq4), (Lq5), (Lq6) and (Lq8).*

Proof. Local defect data. By Proposition A.106, $\mathcal{F}$ has local defect data formed from its actual members with (Ld3) and (Ld4), for any choice of the error allowances $\mathrm{ex}_{x,i}$; these are fixed in the last step and (Ld3), (Ld4) do not involve them. Every twisted place $w \in W_{x,i}$ is the place $w(a)$ of a twisted local index, so $\mu_{\mathrm{at}}(w) \neq \mu_0$.

Items, records and budget data. By Proposition A.107, applied to these local defect data (its hypotheses are those of the theorem), there are local bound records with $\mathrm{sl}(r,\pi) \leq \lambda^{\mathrm{BK}}_{x,i}(w)$ for $r \in R_{x,i}(j,w)$ and $\pi \in Z_r$, Ribet records with (Rf3), budget data, inert budget data, Galois Ribet items and constants $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$, x_0 and integers $N_{x,i}$, $S^{\mathrm{rm}}_{x,i}$, $\eta^{\mathrm{rm}}_{x,i}$ such that the Galois Ribet items of the coefficient extension $\mathcal{F}'$ along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10). The local bound records of $\mathcal{F}'$ are those of $\mathcal{F}$ (Definition 17.4), and of their entries these conditions read only sl, lt and $\mathrm{la}_{x,i}$; the Selmer allowances $\mathrm{sa}_{x,i}$ and the auxiliary allowances $\mathrm{ga}_{x,i}$ may therefore be replaced below without affecting them or (Rf3).

Selmer allowances: (Lq2) and (Lq6). By Proposition A.108 (good twist data) there are $\nu_{x,i}(\ell) \geq 0$ and C_1 with items 1 and 2 there for all large members. Put $\mathrm{sa}_{x,i}(\ell) = \nu_{x,i}(\ell)$. For a large member with finite Sha lengths, $w \in W_{x,i}$ with $\ell = \ell_{x,i}(w) \notin G_{x,i}$, $r \in R_{x,i}(j,w)$ and $\pi \in Z_r$: since $\mu_{\mathrm{at}}(w) \neq \mu_0$, item 1 applies at w and gives

$$\mathrm{sl}(r,\pi) \leq \lambda^{\mathrm{BK}}_{x,i}(w) \leq \nu_{x,i}(\ell) + \ell^{-2} = \mathrm{sa}_{x,i}(\ell) + \ell^{-2},$$

which is (Lq2). As $\nu_{x,i} \geq 0$, item 2 gives $\sum_{\ell \in P_{x,i} \setminus G_{x,i}} \log \ell \cdot \mathrm{sa}_{x,i}(\ell) \leq \sum_{\ell} \log \ell \cdot \nu_{x,i}(\ell) \leq C_1\, f\, m\, b\, x^{2\varepsilon}$, which is (Lq6).

Auxiliary allowances: (Lq4) and (Lq8). By Proposition A.109, applied to the same local defect data, there are $\mathrm{ga}_{x,i}$ with (Lq4) and (Lq8); take these as the auxiliary allowances.

Error allowances: (Lq5). Define $\mathrm{ex}_{x,i}$ by (13.7) from $\mathrm{sa}_{x,i}$, $\mathrm{la}_{x,i}$ and $\mathrm{ga}_{x,i}$ (and $\mathrm{ex}_{x,i}(\ell) = 0$ for $\ell \notin P_{x,i}$); it takes values in $[0,\infty)$ since $\mathrm{sa}, \mathrm{ga} \geq 0$ and $\mathrm{la}_{x,i} = a_{x,i} \geq 0$ on $P_{x,i} \setminus G_{x,i}$ by (Ub9). Then (Lq5) holds by definition. Finally take for x_0 the largest of the thresholds above. □

Proposition A.106. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1, such that at every member (x,i), $x > x_1$, the member datum $D_{x,i}$ with its numerical choice has the Galois preconditions and the depth-zero tie. Then $\mathcal{F}$ has local defect*

data, with arbitrary error allowances, formed from its actual members: at (x,i) the twisted places are the places $w(a)$ of the twisted local indices a of $D_{x,i}$ (those with $\mu(a) \neq \mu_0$: the local type differs from the base type), with residue characteristic ℓ_a and weight the log weight times the ramification index; the local components at (j,w) are the Hecke lattices $(\mathcal{O}_a, \mathcal{Z}_a, \mathbb{T}_a, M_a)$ of the twisted indices a with $(j(a), w(a)) = (j,w)$; the good set of a is Z_a^{gd}; the kept set $\widehat{Z}_a$ contains Z_a^{gd} and no element of $Z_a \setminus Z_a^{\mathrm{gd}}$; $N_{\mathrm{lev}}(x,i)$ is the order $n_{x,i}^{\mathrm{rw}}$ of the finite group of rows of $D_{x,i}$; and these local defect data have (Ld3) and (Ld4). Moreover, at every member (x,i), $x > x_1$, kept sets $\widehat{Z}_a \subseteq \mathcal{Z}_a$ are given at every local index a of $D_{x,i}$ with $Z_a^{\mathrm{gd}} \neq \emptyset$ (for the twisted ones those above; for the others sets with the same two properties: containing Z_a^{gd} and no element of $Z_a \setminus Z_a^{\mathrm{gd}}$), such that

(Kn) ***Kept points are tame, monodromy-free and squarefree at the auxiliary primes*** *for every such a, every automorphic representation Π at a with $\mathrm{pt}_a(\Pi) \in \widehat{Z}_a$, every $k \in \{1,2\}$ and every place $w \mid g_k$ of the host field E, with n the dimension of the local parameter of Π_w and q_w the cardinality of the residue field of w: (i) for every $\sigma \in I_w$ in the wild set at w, the inertia polynomial of Π_w at σ is $(X-1)^n$; (ii) Π_w has zero monodromy; (iii) for every $\gamma \in I_w$ such that γ and the wild set at w topologically generate I_w, every root z of the inertia polynomial of Π_w at γ of multiplicity at least $\mathrm{thr}(w,n)$ satisfies $z^{q_w-1} = 1$; here $\mathrm{thr}(w,n) = 2$ if w lies above a prime p that splits completely in E and $n = 1$ or $16n^2 < p$, and $\mathrm{thr}(w,n) = 1$ otherwise.*

Proof. Sketch. The local defect data are read off the member: the twisted places, the Hecke lattices of the twisted local indices, the good sets Z_a^{gd} and the order $n_{x,i}^{\mathrm{rw}} = \prod_{k=1}^{2} |\mathrm{GL}_r(\mathbb{F}_{g_k})|^f$ of the finite group G_0 of rows, so that only the kept sets and the properties (Ld3), (Ld4) and (Kn) need an argument. The cut should come from the good idempotent e_0 of the depth-zero tie, a central idempotent of $\mathbb{C}[G_0]$ formed from the series elements of the good tuples of labels. For a finite group of order n and a central idempotent e of its complex group algebra, ne has coefficients in $\mathbb{Z}[\zeta_n]$ and therefore lifts to a central element of $\mathcal{O}[G_0]$ as soon as $\mathcal{O}$ contains a primitive n-th root of unity, without inverting n; the depth-zero tie supplies such a root in every $\mathcal{O}_a$, and a central action on M_a commuting with $\mathbb{T}_a$. By the series localisation (Ze3), e_0 acts on the type spaces of each eigensystem by 1 or by 0, so the image α of $n_{x,i}^{\mathrm{rw}} e_0$ acts by $n_{x,i}^{\mathrm{rw}}$ on the eigenvectors of the good eigensystems and by 0 off the kept set, the set of eigensystems on which e_0 does not vanish; this is (Ld4) with $N_{\mathrm{lev}}(x,i) = n_{x,i}^{\mathrm{rw}}$. The condition (Kn) is the depth-zero tie read at the kept points: a kept point has a good label, which is squarefree and avoids the paired character, and for such labels the tie gives zero monodromy, trivial action of wild inertia, and an inertia polynomial at the auxiliary places whose repeated roots come only from the paired character and so lie in the multiplicative group of the residue field, which is (iii) when the threshold is 2. For (Ld3), localisation uniqueness leaves at most one twisted index at each pair (j,w), and theta injectivity in the Galois preconditions makes $\sum_{x \in Z_a^{\mathrm{gd}}} m_a(x)$ the rank of the good part, which is at most the dimension of the image of the theta map of the twisted part; by the rank condition this equals the corresponding dimension for the base part. It remains to show that this dimension is the zero-space rank $\mathrm{rk}_j(x,i)$ recorded in the numerical data of the family; heuristically this holds because the numerical data of a member are computed from the same base part, but the identification is not among the conditions of the statement. (Ld3) and (Ld4) are among the properties read by Lemma A.113 and Theorem A.105. □

Proposition A.107. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1 and good twist data, such that every member datum $D_{x,i}$, $x > x_1$, with its numerical choice has the Galois preconditions and the depth-zero tie, and let local defect data*

of $\mathcal{F}$ be formed from its actual members as in Proposition A.106. Then there are local bound records with $\mathrm{sl}(r,\pi) \le \lambda^{\mathrm{BK}}_{x,i}(w)$ for $r \in R_{x,i}(j,w)$ and $\pi \in Z_r$, Ribet records, budget data with $\{2,3\} \cap (P_{x,i} \setminus G_{x,i}) \subseteq \mathcal{P}^{\mathrm{sm}}_{x,i}$, inert budget data, Galois Ribet items at every point (j,w,r,π) of every member (x,i), $x > x_1$, real numbers $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \ge 1$ and a real x_0 such that the hypotheses of Theorem 22.1 hold: for every $x \ge x_0$ with $x > x_1$ and every member (x,i) with finite Sha lengths there are an integer $N_{x,i} \ge 1$ with $4 \mid N_{x,i}$ and integers $S^{\mathrm{rm}}_{x,i}, \eta^{\mathrm{rm}}_{x,i} \ge 0$ for which, with $\mathcal{F}'$ the coefficient extension of $\mathcal{F}$ along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ at the local components of these members (and along $\mathcal{O}_r \subseteq \mathcal{O}_r$ elsewhere), the Galois Ribet items of $\mathcal{F}'$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10) at every point of (x,i); and the Ribet records have (Rf3).

Proof. Sketch. The statement asks that the conditions (Ub1)–(Ub10) of the Ribet budget theorem 22.1 hold at the actual members, after one coefficient extension $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ per member. The argument starts from the hub data of the members (whose existence is Proposition A.110): a supply statement for the records attached to hub data, itself resting on further member inputs (the corner design, a Selmer comparison and quantitative inputs), gives local bound records, Ribet records with (Rf3), budget data, inert budget data and Galois Ribet items with (Ub1), (Ub3°), (Ub8) and (Ub9). Given these, Lemma 22.17 shows that the same conditions, together with the local conditions (Ll1) and (Ll2), survive the coefficient extension; this step is complete. It remains to show (Ub2), (Ub4)–(Ub7′) and (Ub10) for the items of the extended family. Except for (Ub6), these are local conditions on the Galois representations at the member points: their Hodge jumps at the places above ℓ lie in windows of length at most the size H of the budget data, the representations are crystalline or de Rham with prescribed jumps, and at primes of split and of small type there are column data with the column properties. Heuristically these should hold because the jumps are read from the regular infinitesimal characters and the weights and character exponents fixed in the construction, which are polynomially bounded in x, and because local–global compatibility at $\ell = p$ [18], [58] turns the local components of the members at places above ℓ into the corresponding p-adic Hodge-theoretic conditions. Condition (Ub10), at the kept points that are not good, should follow from the non-vanishing criterion Proposition 22.7, whose first two conditions hold at such points, once the cut is formed with the kept sets of Proposition A.106. Condition (Ub6) concerns the large primes and has a different character: it needs, at each member, congruence and position data for the large primes (low jumps, base sizes, and avoidance of an exceptional set of primes), from which the vanishing of the local losses at large primes Proposition 28.1 applies; no construction of these data at the members is known yet, and this is the main missing input. The primes 2 and 3 need no separate treatment, since they are placed among the small primes $\mathcal{P}^{\mathrm{sm}}_{x,i}$ and are covered by (Ub7). □

Proposition A.108. *For a member (x,i) and a place w of the coefficient field with $\mu_{\mathrm{at}}(w) \ne \mu_0$, put $\psi_w = \mathrm{side}_{\epsilon(w)}(\psi'_w) \circ \mathrm{Art}_{i(w),Q(w)}$ and $\psi_{w,s} = \mathrm{side}_{\mathrm{side}(s)}(\psi_w)$, with the side convention of (Xh5) in the definition of cores over a stage tuple, and let $\lambda^{\mathrm{BK}}_{x,i}(w) \in [0,\infty]$ be the largest, over the signature triples s at $i(w)$ that are good for the Bloch–Kato reduction, of the normalised length of the Bloch–Kato Selmer group with the coefficient module, local conditions and action $\psi^{-1}_{w,s}\chi_s^{-1}\rho_s$ of that reduction (and $\lambda^{\mathrm{BK}}_{x,i}(w) = 0$ if there is no good signature triple at $i(w)$); and let $\ell(w)$ be the residue characteristic of w. Let $\mathcal{F}$ be a parametrised host family with slope records and defect data and with good twist data. Then there are reals $\nu_{x,i}(\ell) \ge 0$, for the members (x,i) and primes ℓ, and a real C such that for all large members:*

1. *$\lambda^{\mathrm{BK}}_{x,i}(w) \le \nu_{x,i}(\ell(w)) + \ell(w)^{-2}$ for every w with $\mu_{\mathrm{at}}(w) \ne \mu_0$;*
2. *$\sum_\ell \log \ell \cdot \nu_{x,i}(\ell) \le C\, f\, m\, b\, x^{2\varepsilon}$.*

Proof. Sketch. The argument should take for $\nu_{x,i}(\ell)$ the cyclotomic valuation $\mathrm{cyv}_\ell(E_{x,i}; tr)$ of the host field of the member for the exponent $M = tr$, where t is odd and $r = k + m - 1$ is odd: the largest k with $\chi_\ell(\sigma)^M \equiv 1 \pmod{\ell^k}$ for all $\sigma \in G_{E_{x,i}}$, so that $\ell^{\nu_{x,i}(\ell)}$ is the order of the invariants of $G_{E_{x,i}}$ on $\mathbb{Q}_\ell/\mathbb{Z}_\ell(M)$. This is the natural size of the part of a Bloch–Kato Selmer group of a twist that the choice of twist cannot remove. Item 2 is then elementary: for a host satisfying the normalisation (Hn3) of Definition 7.5 with $4M + 1 < \min(q, d)$, the cyclotomic valuation vanishes at every prime not dividing Q_S and is at most $v_\ell(Q_S) + v_\ell(M)$ otherwise, so $\sum_\ell \log \ell \cdot \nu_{x,i}(\ell) \le \log Q_S + \log M \le 2 \log n + \log t + \log r$ by the bound on Q_S in Definition 7.2, and the size condition (Lm7) of Definition 5.5 bounds this by $C \log x$, which is at most $C\, f\, m\, b\, x^{2\varepsilon}$. What this needs, and what remains to be shown, is that the host of each member datum is a host of the kind just described, with (Hn3), (Fr4) and $4tr + 1 < \min(q, d)$ as for the host of a context, and with ranks equal to those of the loss data of the member; heuristically this holds because the members are produced over contexts whose hosts have these properties (Theorem A.52). Item 1 is the Selmer clause of the goodness of the chosen twist: for each signature triple s good for the Bloch–Kato reduction there is $\varepsilon_T(s) \ge 0$, with $\sum_s \varepsilon_T(s) \le \ell^{-2}$, such that the normalised Selmer length of the twist of the representation of s by $\psi_w^{\pm 1}$ is at most $\nu_{x,i}(\ell) + \varepsilon_T(s)$. Taking the largest over the good s gives item 1, since each $\varepsilon_T(s)$ is at most ℓ^{-2}. The twist is the one already chosen with the good twist data (Definition A.104), specialised to the exponent 1, so nothing new is chosen; what remains is to verify that the goodness of a twist, unfolded, contains exactly this clause with ν_ℓ the cyclotomic valuation above. □

Proposition A.109. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1, such that every member datum $D_{x,i}$, $x > x_1$, with its numerical choice has the Galois preconditions and the depth-zero tie, and let local defect data of $\mathcal{F}$ be formed from its actual members as in Proposition A.106. Then there are functions $\mathrm{ga}_{x,i}$ from the set of primes to $[0, \infty)$ such that (Lq4) and (Lq8) hold.*

Proof. Sketch. The statement bounds the cut defects at the two auxiliary primes $\ell \in G_{x,i} = \{g_1, g_2\}$, where the depth-zero structure of the members is concentrated. The argument should run as follows, with absolute constants $C_T = 40$ and $C = 8C_T$. At every twisted index a over $\ell \in G_{x,i}$ one proves a paired-character bound: the local quantity $\eta_{\mathrm{loc}}(a)$ is at most $\sum_\pi m(\pi)$, over the good eigensystems π, times a sum of a polynomial in n_V, η, t, f, r, the Selmer length s_π, the lengths $\mathrm{len}_\ell(E, e)$ for $0 < e < t$, $v_\ell(h_E)$, and valuations of the discriminant and of roots of unity at the tame places. Its ingredients are: lifting exponents at the places above ℓ from the tame potentially crystalline lifting theorem A.111, in its form for Ribet fibre products at places of degree one (at the places above ℓ, $E_w = \mathbb{Q}_\ell$), applied to the twisted good points; local losses from Theorem 25.3, with the local Bloch–Kato count Theorem B.43 and local Tate duality Theorem B.29; Galois Ribet data at the index with (Gd1)–(Gd5), to be obtained from a good Galois family by a choice of idempotent and Burnside's theorem; the Ribet-type bound Theorem 22.11 with the class-number bound; and the central cut operator, which contributes $v_\ell(n^{\mathrm{rw}}_{x,i})$. That contribution is at most $2fr^2$: $v_g(|\mathrm{GL}_r(\mathbb{F}_g)|) = r(r-1)/2$, and for the other auxiliary prime g', $v_g(g'^i - 1) \le i \log g' / \log g \le 2i$ because $\log g' \le 2 \log g$, so that $v_g(n^{\mathrm{rw}}_{x,i}) \le f\big(r(r-1)/2 + r(r+1)\big) \le 2fr^2$. Three inputs remain to be established at the members: the index lemma by which the cut operator contributes exactly the term $v_\ell(n^{\mathrm{rw}}_{x,i})$ (the arithmetic of the bound $2fr^2$ is elementary, as just shown), the Galois Ribet data at the index, and, above all, the local input of the lifting step, namely that the twisted good points become crystalline over one tame Galois extension, with inertia acting through at most $n_V + 1$ characters of finite order prime to ℓ and with Hodge jumps in a prescribed window. Heuristically the last is what depth zero means: the depth-zero tie gives zero monodromy and tame inertia at the places above g_k,

and by local–global compatibility at $\ell = p$ [18], [58] the corresponding Galois representations are potentially crystalline with tame inertial type. Specialised at the hub data of the member, once its parameters are shown to be polynomially bounded in x and the multiplicity bound (Ld3) is available, the paired-character bound gives (Lq4) with $\mathrm{ga}_{x,i}(\ell) = C x^{C} \eta_{\mathrm{sz}}(x,i)$, and (Lq8) is the sum of $\log \ell \cdot \mathrm{ga}_{x,i}(\ell)$ over the two auxiliary primes, which is small against $f\, m\, b\, x^{2\varepsilon}$ because $b = e^{x^{\varepsilon}}$ grows faster than any polynomial in x. □

Proposition A.110. *Let D be a member datum and ν a numerical choice of D such that (D,ν) has the Galois preconditions. Then D has hub data.*

Proof. Sketch. Hub data consist of integral Galois representations at all eigensystems of every local index, and of their complements at the theta eigensystems, and their construction should follow the standard route from automorphic to Galois representations. For every local index a and every $x \in \mathcal{Z}_a$ choose an automorphic representation Π with $\mathrm{pt}_a(\Pi) = x$. Its base change to GL_{n_V} over E is an isobaric sum of conjugate self-dual cuspidal representations with regular infinitesimal character, so it has an attached Galois representation ρ_Π [231], [67], compatible with Π at every finite place; this is the compatibility that the admissibility of the member datum asks for. By local–global compatibility and the convention that all statements at a use one coefficient ring $\mathcal{O}_a$ with fixed embeddings, the characteristic polynomial of ρ_Π at a Frobenius element at every place split out of a is the Hecke polynomial $H_{a,x,w}$. By compactness of G_E there is a G_E-stable $\mathcal{O}_a$-lattice, which gives $\mathbf{r}_{a,x}\colon G_E \to \mathrm{GL}_{n_V}(\mathcal{O}_a)$; after semisimplification over K_a the Frobenius polynomials are unchanged, by the Brauer–Nesbitt theorem and the Chebotarev density theorem B.18, and the large-coefficient condition ensures that the irreducible constituents are defined over K_a. This is (Zh1). At a theta eigensystem $\pi \in Z_a$ the base-change list contains the entry $(1, \mu_a \otimes \eta^{-1}, t)$, a character repeated with the shifts $|\cdot|^{(t-1)/2-b}$; on the Galois side these give the characters $\chi_{a,c} = \chi_{a,1}\varepsilon_a^{1-c}$, and the provisions of the Galois preconditions assert accordingly that $\mathbf{r}_{a,\pi} \otimes K_a$ splits as a representation of dimension r plus $\chi_{a,1}, \dots, \chi_{a,t}$, and a G_E-stable lattice in the first summand gives the complement $\boldsymbol{\rho}_{a,\pi}$, which is (Zh2). What remains is to make precise, at each eigensystem of the member, which Galois representation is attached to it, compatibly with the chosen coefficient embeddings; once this is fixed, each step above is standard. □

A.9.2 Lifting and cut congruences

The quantitative tame potentially crystalline lifting theorem (Theorem A.111) is the p-adic input of the bounds at the generator primes. The cut congruence modules at the actual members are bounded for every Hecke lattice (Proposition A.112); the commuting-endomorphism hypotheses in the statement are not used in the proof. The local defect data formed from the actual members then have the properties (Ld1)–(Ld9) that the budget needs (Lemma A.113).

Theorem A.111. *Let $C \geq 40$ be an integer, p a prime, $L/\mathbb{Q}_p$ a finite extension with ring of integers O, and $K'/\mathbb{Q}_p$ a finite Galois extension with maximal unramified subfield K'_0. Put $I' = G_{K'_0}$ and choose $\mathrm{Fr} \in G_{\mathbb{Q}_p}$ inducing arithmetic Frobenius on K'_0. Let Σ be a finite set of continuous characters $I' \to L^\times$, trivial on $G_{K'}$, of finite order prime to p, containing 1, and stable under conjugation by Fr^{-1}. Define*

$$r = \max_{\chi,\chi' \in \Sigma} \min\{ s \geq 1 : (\chi/\chi')(\mathrm{Fr}^{-s} g \mathrm{Fr}^{s}) = (\chi/\chi')(g) \text{ for every } g \in I' \}.$$

Let $f : T_1 \to T_2$ be a surjective continuous O-linear $G_{\mathbb{Q}_p}$-equivariant map of finite free O-lattices.

Write $V_i = T_i[1/p]$. Suppose both V_i are crystalline over the same K', and

$$D_{\mathrm{cris},K'}(V_i) = \sum_{\chi\in\Sigma} D_{\mathrm{cris},K'}(V_i)^{I'=\chi} \qquad (i=1,2).$$

Let $N,\eta,H\in\mathbb{N}$ satisfy $N\geq 2$, $1\leq\eta<H$, and $|\Sigma|\leq N$. Suppose a finite set $U\subset\mathbb{Z}$ contains 0, satisfies

$$U\subset[-\eta,H], \qquad |U|\leq N+1,$$

and contains every labelled filtration jump of both representations. Here a filtration jump is an integer j with nonzero gr^j of the corresponding de Rham filtration, with no Hodge–Tate index shift. If

$$C(HN^2+N^3)<p,$$

then

$$p^{C[Nr+\eta(N+r)]}H^1_f(\mathbb{Q}_p,T_2)\subseteq \mathrm{im}\big(H^1_f(\mathbb{Q}_p,T_1)\to H^1_f(\mathbb{Q}_p,T_2)\big).$$

For clarity, $H^1_f(\mathbb{Q}_p,T)$ denotes the subgroup of continuous integral cohomology whose image in $H^1(G_{\mathbb{Q}_p},B_{\mathrm{cris}}\otimes_{\mathbb{Q}_p}T[1/p])$ is zero. Thus coboundaries in the integral cohomology are those of vectors in T, not arbitrary vectors in $T[1/p]$.

Proof. Outline. After a finite coefficient extension, the two representations and the kernel of f are crystalline over a common tamely ramified extension $K=F(\pi_0)$ with $\pi_0^e=-p$, $e=p^{(p-1)!}-1$, with distinguished inertia supported on at most N characters; a class of $H^1_f(\mathbb{Q}_p,T_2)$ is realised in the crystalline realisation of the exact sequence $0\to\ker f\to T_1\to T_2\to 0$, lifted to T_1 by an obstruction-lifting lemma at an explicit power of p, and turned back into an integral cocycle, which gives the inclusion with an exponent at most $7[Nr+\eta(N+r)]\leq C[Nr+\eta(N+r)]$; a descent of coefficients returns to O. □

Proposition A.112. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1, such that at every member (x,i), $x>x_1$, the member datum $D_{x,i}$ with its numerical choice has the Galois preconditions and the depth-zero tie. Then local defect data of $\mathcal{F}$ formed from its actual members as in Proposition A.106 have the property (Ld6).*

Proof. Let local defect data of $\mathcal{F}$ be formed from its actual members as in Proposition A.106. Let (x,i) be a member with $x>x_1$, $1\leq j\leq m$, $w\in W_{x,i}$ with $\ell=\ell_{x,i}(w)\notin G_{x,i}$, and $r\in R_{x,i}(j,w)$. By the definition of local defect data, $(\mathcal{O}_r,\mathcal{Z}_r,\mathbb{T}_r,M_r)$ is a Hecke lattice over ℓ and $Z_r\subseteq\widehat{Z}_r\subseteq\mathcal{Z}_r$. Since cut congruence modules are bounded by the congruence ideals,

$$\mathrm{df}^{\mathrm{cut}}(r)=\mathrm{df}^{\widehat{Z}_r}_{Z_r}(M_r)\leq\sum_{\pi\in Z_r}m_r(\pi)\,\mathrm{cg}^{\widehat{Z}_r}_{Z_r}(\pi)=\sum_{\pi\in Z_r}m_r(\pi)\,\mathrm{cg}(r,\pi).$$

Since $N_{\mathrm{lev}}(x,i)\geq 1$ is an integer, $v_\ell(N_{\mathrm{lev}}(x,i))\geq 0$, so each summand is at most $m_r(\pi)(\mathrm{cg}(r,\pi)+v_\ell(N_{\mathrm{lev}}(x,i)))$ (in $[0,\infty]$, with the usual conventions for these defects). This is the inequality of (Ld6) at (x,i,j,w,r); as it holds at every member with $x>x_1$, (Ld6) holds with $x_0=x_1+1$. □

Lemma A.113. *Let $\mathcal{F}$ be a parametrised host family with slope records and defect data, with threshold x_1 and good twist data, such that at every member (x,i), $x>x_1$, the member datum $D_{x,i}$ with its numerical choice has the Galois preconditions and the depth-zero tie. Then $\mathcal{F}$ has local defect data formed from its actual members as in Proposition A.106 with the properties (Ld3), (Ld4), (Ld7), (Ld8) and (Ld9).*

Proof. **Step 1: the records.** By Theorem A.105, applied to $\mathcal{F}$ (its hypotheses are exactly those of the lemma), $\mathcal{F}$ has local defect data formed from its actual members with (Ld3) and (Ld4), together with local bound records, Ribet records, budget data, inert budget data, Galois Ribet items at every point (j, w, r, π) of every member (x, i) with $x > x_1$, real numbers $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$ and a real x_0, such that for every $x \geq x_0$ with $x > x_1$ and every member with finite Sha lengths there are integers $N_{x,i}$, $S^{\mathrm{rm}}_{x,i}$, $\eta^{\mathrm{rm}}_{x,i}$ for which the Galois Ribet items of the coefficient extension along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10), the Ribet records have (Rf3), and the local defect data and local bound records have (Lq2), (Lq4), (Lq5), (Lq6) and (Lq8). We fix these objects for the rest of the proof.

Step 2: the Ribet bound by prime type. The objects of Step 1 are the data required by Theorem 22.1: a family with local defect data, local bound records, Ribet records, budget data and inert budget data; Galois Ribet items at every point of every member beyond x_1; constants $c_{\mathrm{sp}}, c_{\mathrm{in}}, c_{\mathrm{sm}}, C_{\mathrm{bud}} \geq 1$; and a real x_0 beyond which, at every member with finite Sha lengths, the items of the coefficient extension along $\mathcal{O}_r \subseteq \mathcal{O}_r(N_{x,i})$ satisfy (Ub1), (Ub2), (Ub3°), (Ub4)–(Ub10). Its item 2 gives that the Ribet records have (Rf1), (Rf2), (Rf4) and (Rf5); its item 3 gives (Lq3) and (Lq7) (the latter with the constant $19C_3^3$ named there).

Step 3: lattice index bounds. With (Rf3) from Step 1, the Ribet records have (Rf1)–(Rf5), so Theorem 13.13 gives (Lq1).

Step 4: congruence ideals and auxiliary primes. The local bound records now have (Lq1) (Step 3), (Lq2) (Step 1), (Lq3) (Step 2), (Lq4) and (Lq5) (Step 1); so Theorem 13.16 gives (Ld7) and (Ld8).

Step 5: the error budget. The local bound records have (Lq5), (Lq6), (Lq8) (Step 1) and (Lq7) (Step 2); so Theorem 13.17 gives (Ld9).

The local defect data of Step 1 are formed from the actual members and have (Ld3), (Ld4) (Step 1), (Ld7), (Ld8) (Step 4) and (Ld9) (Step 5). □

A.9.3 The ties of a selected member

A selected member must be tied to the context from which it was built: its concrete context, Hida setting, words, Harish-Chandra parameters and thresholds must be the original ones (Proposition A.114). This tie is used at several places above, for instance in the engine place of a member (Proposition A.79).

Proposition A.114. *Fix any such selected family with its prescribed complete good-host witness collection, its threshold X, one admissible common constant profile $\mathbf{C}$, and one choice of*

$$0 < \varepsilon < 1/52, \qquad c_D > 397, \qquad c_h \geq \max\{402, c_2\}$$

and prescribed J, all fixed before the scale, member and word indices. Here c_2 is one threshold furnished, for $(\varepsilon, \mathbf{C}, c_D)$, by the size conditions for the threshold configurations of contexts, chosen once for these common data before c_h and before (x, u). These are the common profile and exponent choices of the selected family, not choices depending on (x, u).

For every $x \in W$ with $x > X$ and every $u \in A_x$ there are a context $K_{x,u}$, a concrete base $B_{x,u}$ whose pre-base is over $K_{x,u}$, and a stage tuple $\mathcal{X}_{x,u}$ over $B_{x,u}$, with the following identifications of objects.

1. *The context has scale (x, ε, J) and exactly $\mathbf{C}, c_D, c_h$. Its host, frame, tops, spacing set, rank and auxiliary primes are the prescribed ones at x with the member's translate u; the prescribed top tables and common profile are retained. Put $D_{x,u} = D(\mathcal{X}_{x,u})$ and let $\mathbf{F}_{x,u}$ be*

*its stage-*0 *column family. The setting determined by the member's selected tied local data is a member Hida and Poincaré setting for* $(D_{x,u}, \mathbf{F}_{x,u})$*, with its data and normalizations.*

2. *The member words, word code, Gauss primes and Harish–Chandra arrays, and those of* $D_{x,u}$*, are those of the pre-character datum of this* $K_{x,u}$*, with (Cx2) of the definition of contexts. In particular the word tuple used in (Hj5) is this tuple, not the separate row tuple. The shared row entries* v_τ, b_τ *are the context's entries.*

3. *Under the identification of the member's archimedean place set with* Φ*,*

$$k_{\mathrm{d}} = k, \qquad r_{\mathrm{f}} = m/2 - 1, \qquad f_\infty = |\Phi|, \qquad g_1^{\mathrm{aux}} = g_1, \quad g_2^{\mathrm{aux}} = g_2.$$

For every ordered pair of distinct member words, the amplitude threshold configuration of the member is the threshold configuration of this context at $(\omega, \omega'; l(\omega, \omega'))$*. Thus*

$$\Delta = \lceil x^{c_D} \rceil, \quad \varrho = \tfrac{1}{2}|d_E|^{1/[E:\mathbb{Q}]}, \quad \kappa = \pi/\varrho, \quad g = g_1 g_2, \quad \nu_\tau^{\mathrm{last}} = 0,$$

the first weights are $u_{\omega,\tau,1}$*, the nodes are* $b_{\tau,j}$*, the top flag and top weight are the top data of the context, the word vectors are* $(c(\omega)_1, \dots, c(\omega)_{k-2}, 0)$ *and likewise for* ω'*, and the norms are the same* $T(\omega), T(\omega')$*. The cut index satisfies* $1 \le l \le k-2$ *and* $c(\omega)_l \ne c(\omega')_l$*.*

These identifications hold without a condition on word sizes; the constant $C_0 = 3$ *and the word-size conditions enter only the results that use them. The hyperbolic flag rank* r_{f} *is distinct from the total row rank* $k + m - 1$*. No decay, term estimate, amplitude bound or other class duty is part of this conclusion.*

Proof. Sketch. The statement identifies objects rather than estimating them: the member of the selected family at (x, u) is to be the member produced over one concrete context, with every datum of that context carried over unchanged. For a member produced by Theorem A.52 (under the export and second-pass properties that theorem assumes) the identifications should hold by construction. That theorem forms the context $K = (x, \varepsilon, J, \mathbf{C}, c_D, c_h, \mathfrak{P}, q_0, a, b, c, \mathrm{Lv})$ from the prescribed good-host witness at x, with the translate u as its base element, the top tables a, b, the word set, the base word and an injective word code c, and it chooses the Harish-Chandra parameters and the level; the assembled datum, its stage tuple and the member are then built over this K. So the host, frame, tops, spacing set, rank and auxiliary primes of item 1 are those of the witness, and the words, code, Gauss primes and Harish-Chandra arrays of item 2 are those of the pre-character datum of K. Item 3 is the definition of the threshold configuration of a context at a pair of words, evaluated at K: the values $\Delta = \lceil x^{c_D} \rceil$, $\varrho = \frac{1}{2}|d_E|^{1/[E:\mathbb{Q}]}$, $\kappa = \pi/\varrho$, $g = g_1 g_2$ and the rank $(k, \frac{m}{2} - 1)$ over Φ are those of that definition, and because the word code is injective two distinct words differ at some coordinate $l \le k - 2$, which gives the cut index. The order of choices is compatible: the threshold c_2 attached to threshold configurations depends only on $(\varepsilon, \mathbf{C}, c_D)$, and Theorem A.52 likewise fixes its own lower bound for c_h after c_D, so that c_h can be taken above both before the scale and the member are chosen. The selection retains these objects, since it follows from the construction of Proposition A.1 that the selected members are the produced members themselves, with the setting determined by their selected tied local data; there is no analytic content here, every datum named being an input or an output of the producer. The good-host collection over which the family is built is, however, chosen in the course of that construction. Whether the identifications can instead be obtained over a collection of good-host data fixed in advance, as (TCS) prescribes, is open. The identification is what Proposition A.79 uses to make the cut of the engine place non-empty, and it is also read by the loop-row and amplitude bounds at the members. □

Sketch: the remaining ties of a selected member. Besides its context, a selected member must be tied to its Poincaré frame, to its counting operator and to its Gauss ranks, and the members of a parametrised host family must carry the member fields that the family's definition names. Each tie asserts that an object constructed in one part of the construction is literally the object used in another: the member built by the two passes of Section A.5 is the one whose frame enters the Gram blocks of Section A.6, and whose counting operator and level ranks enter the main row. Heuristically these ties hold by construction, because the selection of Section A.1 retains the member data, objects and comparison maps of the construction and replaces none of them (Proposition A.1); what remains is to read each field of the later statements off the retained data, with the constants of the context fixed before the thresholds that depend on them.

B Quoted results

This appendix states the results that the paper quotes from the literature, 174 in all, grouped by field in Subsections B.1–B.10. In place of a proof, each statement is followed by its sources and, for most statements, the translation from the notation of the sources to ours. A quoted result is used as it is stated in its source; where the statement printed here is a special case of the result in the source or a standard reformulation of it, the note after the statement says so. The opening of each subsection says what is quoted there and in which Parts and sections it is used. Subsection B.11 lists the computations cited in proofs.

B.1 Analytic number theory

The first five statements are the classical facts on Dirichlet L-functions: the analytic continuation of $L(s,\chi)$ with the Laurent expansion of ζ at 1 (Theorem B.1), the non-vanishing of $L(1,\chi)$ for non-principal χ (Theorem B.2), Chebyshev's bound $\prod_{p\le n} p < 4^n$ (Lemma B.3), and the functional equations of ζ and of $L(s,\chi)$ for primitive χ (Theorem B.4, Theorem B.12). All five are used in Part I, three of them again in Part II, and Chebyshev's bound also in Part III. Part VII uses the functional equations, the non-vanishing and Chebyshev's bound, together with the values of Dirichlet L-functions at non-positive integers as generalised Bernoulli numbers (Theorem B.11), for the minus part (Section 37). The other six statements concern primes in arithmetic progressions and a possible exceptional real zero: the Landau–Page theorem, an effective bound for a real zero, Montgomery's zero-density estimate, Linnik's theorem on the least prime, and the theorems of Thorner and Zaman that carry the exceptional zero as a secondary main term, in the prime number theorem for progressions and in the Chebotarev density theorem. They are used in Part II, for almost all quadratic twists (Section 10) and for good hosts (Section 11).

Theorem B.1. *Let $N \ge 1$ and let χ be a Dirichlet character modulo N. The function defined for $\operatorname{Re} s > 1$ by $\sum_{n\ge1} \chi(n) n^{-s}$ extends to a meromorphic function $L(s,\chi)$ on $\mathbb{C}$. If $\chi \ne \chi_{0,N}$, this function is entire. If $\chi = \chi_{0,N}$, its only pole is a simple pole at $s = 1$, with residue $\varphi(N)/N$. In particular $\zeta(s)$ is holomorphic on $\mathbb{C}\setminus\{1\}$, and $\zeta(s) - \frac{1}{s-1}$ extends to an entire function whose value at $s = 1$ is γ:*

$$\zeta(s) = \frac{1}{s-1} + \gamma + O(|s-1|) \qquad (s \to 1).$$

Proof. [180] (the analytic continuation of $\zeta(s)$ with its Laurent expansion at $s = 1$, and of $L(s,\chi)$), [75], [260]. Notation as in the references: $L(s,\chi)$ for a character χ modulo N, with

Euler factors 1 at the primes dividing N; for $\chi = \chi_{0,N}$ one has $L(s,\chi_{0,N}) = \zeta(s)\prod_{p\mid N}(1-p^{-s})$, whence the residue $\prod_{p\mid N}(1-p^{-1}) = \varphi(N)/N$. $\square$

Theorem B.2. *Let $N \geq 1$ and let χ be a Dirichlet character modulo N with $\chi \neq \chi_{0,N}$. Then $L(1,\chi) \neq 0$.*

Proof. Dirichlet's theorem, [180] (the non-vanishing of $L(1,\chi)$ in the proof of Dirichlet's theorem on primes in arithmetic progressions), [75]. Notation as in the references; $L(1,\chi)$ is the value at $s = 1$ of the entire function of Theorem B.1, equal to the conditionally convergent series $\sum_{n\geq 1}\chi(n)/n$. $\square$

Lemma B.3. *For every integer $n \geq 1$, $\prod_{p\leq n} p < 4^n$, the product running over the primes $p \leq n$. Consequently, for every real $x \geq 0$,*

$$\sum_{p\leq x} \log p \leq x \log 4.$$

Proof. See [118, Chapter XXII] (the bound $\vartheta(n) < 2n\log 2$, by the argument of Erdős with the middle binomial coefficient); see also [180] (Chebyshev estimates, Chapter 2). The second form follows from the first: for $x \geq 1$ the sum equals $\log\prod_{p\leq\lfloor x\rfloor} p < \lfloor x\rfloor \log 4 \leq x\log 4$, and for $0 \leq x < 2$ it is 0. $\square$

Theorem B.4. *The function $\xi(s) = \pi^{-s/2}\,\Gamma(s/2)\,\zeta(s)$ is holomorphic on $\mathbb{C}\setminus\{0,1\}$ and satisfies*

$$\xi(1-s) = \xi(s) \qquad (s \in \mathbb{C}\setminus\{0,1\}).$$

Moreover $\zeta(0) = -\tfrac{1}{2}$.

Proof. Riemann's functional equation, [180] (Chapter 10), [75] (Chapter 8), [260] (Chapter II). Notation as in the references; ξ here is the completed zeta function without the factor $\tfrac{1}{2}s(s-1)$ of Riemann's normalisation, so that it has simple poles at $s = 0$ and $s = 1$. The value $\zeta(0) = -\tfrac{1}{2}$ follows from the functional equation and the residue 1 of ζ at $s = 1$. $\square$

Theorem B.5. *There is an absolute constant $c_{\mathrm{P}} > 0$ such that for every $q \geq 3$, every real primitive Dirichlet character χ modulo q and every real β with $0 < \beta < 1$ and $L(\beta,\chi) = 0$,*

$$1 - \beta \geq \frac{c_{\mathrm{P}}}{q^{1/2}\log^2 q}.$$

Proof. [75] (Chapter 14: the bound $\beta < 1 - c\,q^{-1/2}\log^{-2} q$, from the lower bound $L(1,\chi) \gg q^{-1/2}$ given by the class number formula and the bound $L'(\sigma,\chi) \ll \log^2 q$ for $1 - 1/\log q \leq \sigma \leq 1$); an explicit form with $c_{\mathrm{P}} = 40$ for $q \geq 3$ is in M. A. Bennett, G. Martin, K. O'Bryant and A. Rechnitzer, *Explicit bounds for primes in arithmetic progressions*, Illinois J. Math. 62 (2018), Proposition 1.11. The notation is that of the references. $\square$

Theorem B.6. *There is an absolute constant $c_{\mathrm{LP}} > 0$ such that for every real $Z \geq 3$ there is at most one real primitive Dirichlet character $\chi \neq \mathbf{1}$ of modulus at most Z for which $L(s,\chi)$ has a real zero β with*

$$1 - \frac{c_{\mathrm{LP}}}{\log Z} < \beta < 1.$$

Proof. This is the theorem of Landau and Page; see [75] (Chapter 14), [180] (Chapter 11), [134] (Chapter 5), and E. Landau (1918) and A. Page, *On the number of primes in an arithmetic progression*, Proc. London Math. Soc. (2) 39 (1935). It follows from Landau's inequality: for distinct real primitive characters $\chi_1 \neq \chi_2$ (both $\neq \mathbf{1}$) of moduli q_1, q_2 with real zeros β_1, β_2, one has $\min(\beta_1, \beta_2) < 1 - c/\log(q_1 q_2)$; take $c_{\mathrm{LP}} = c/2$. The notation is that of the references, and the constant is effective. $\square$

Theorem B.7. *For an integer $M \geq 2$, an integer b and real X let $\vartheta(X; M, b) = \sum \log p$, the sum over the primes $p \leq X$ with $p \equiv b \pmod M$.*

1. *For every integer $M \geq 2$ the product $\prod_{\chi \bmod M} L(s, \chi)$ has no zero in the region $\operatorname{Re} s \geq 1 - 1/(13 \log(M(|\operatorname{Im} s| + 3)))$, except possibly one real zero $\beta_1 < 1$. If it exists, it is called the* exceptional zero modulo M*; there is then exactly one real non-principal character χ_1 modulo M with $L(\beta_1, \chi_1) = 0$.*

2. *There are absolute, effectively computable constants $c_4 > 0$ and A_4 such that for every integer $M \geq 2$, every integer b with $\gcd(b, M) = 1$ and every real $X \geq M^{12}$,*

$$\Big|\vartheta(X; M, b) - \frac{X - \chi_1(b) X^{\beta_1}/\beta_1}{\varphi(M)}\Big| \leq A_4\Big(e^{-c_4 \log X/\log M} + e^{-c_4 (\log X)^{3/5} (\log\log X)^{-1/5}}\Big) \frac{X - \chi_1(b) X^{\beta_1}/\beta_1}{\varphi(M)},$$

where the term $\chi_1(b) X^{\beta_1}/\beta_1$ is omitted (in both places) when there is no exceptional zero modulo M.

Proof. [259]: item 1 is the statement on the exceptional zero in Section 1.1 (from McCurley's zero-free region for $\prod_{\chi \bmod q} L(s, \chi)$), item 2 is Corollary 1.4 with Remark 1.5 (numbering of arXiv:2108.10878v2). Notation: $q \mapsto M$, $a \mapsto b$, $x \mapsto X$; the left side of Corollary 1.4 is $\vartheta(X; M, b)$; its main term $\lambda x/\varphi(q)$ with $\lambda = \lambda(x, q, a, x) = 1 - \chi_1(a) x^{\beta_1 - 1}/\beta_1$ (Remark 1.5; $\lambda = 1$ if β_1 does not exist) is $(X - \chi_1(b) X^{\beta_1}/\beta_1)/\varphi(M)$; the implied constant of its O-term is A_4. That $\beta_1 < 1$ is the classical non-vanishing of $L(s, \chi)$ on $\operatorname{Re} s \geq 1$. $\square$

Theorem B.8. *For a Dirichlet character χ and reals α, T let $N(\alpha, T, \chi)$ be the number of zeros ρ of $L(s, \chi)$, counted with multiplicity, with $\alpha \leq \operatorname{Re} \rho \leq 1$ and $|\operatorname{Im} \rho| \leq T$. There is an absolute constant C_{M} such that for all $\frac{1}{2} \leq \alpha < 1$, $Q \geq 1$ and $T \geq 2$,*

$$\sum_{q \leq Q} \sideset{}{^*}\sum_{\chi \bmod q} N(\alpha, T, \chi) \leq C_{\mathrm{M}} \, (Q^2 T)^{3(1-\alpha)/(2-\alpha)} \, (\log(QT))^9,$$

where $\sum^*$ runs over the primitive characters modulo q.

Proof. [179, Theorem 12.2]; the large sieve density estimates go back to [35]. The notation is that of the reference: $\sum^*$ runs over primitive characters, and $N(\alpha, T, \chi)$ is the number of zeros in the rectangle $\alpha \leq \sigma \leq 1$, $|t| \leq T$. $\square$

Theorem B.9. *There is an absolute real number $A \geq 1$ such that, for every integer $M > 2$ and every integer a with $\gcd(a, M) = 1$, there is a prime p satisfying*

$$p \equiv a \pmod M, \qquad p \leq M^A.$$

Proof. This is Linnik's theorem on the least prime in an arithmetic progression [163]. Here M denotes the modulus, a a reduced residue class, and A an absolute exponent. $\square$

Theorem B.10. *Let L/F be a Galois extension of number fields with group G, let $C \subseteq G$ be a conjugacy class, and for $x \geq 2$ let $\pi_C(x) = \pi_C(x, L/F)$ be the number of prime ideals $\mathfrak{p}$ of F with $\mathrm{N}_{F/\mathbb{Q}}\mathfrak{p} \leq x$ that are unramified in L and whose Artin symbol is C. Let $H \subseteq G$ be an abelian subgroup with $C \cap H \neq \varnothing$, choose $g_C \in C \cap H$, let $K = L^H$, and identify each character χ of $H = \mathrm{Gal}(L/K)$ with a primitive Hecke character of K of conductor $\mathfrak{f}_\chi$ (class field theory). Put*

$$\mathcal{Q} = \max_{\chi \in \widehat{H}} \mathrm{N}_{K/\mathbb{Q}}\mathfrak{f}_\chi, \qquad Q = D_K\, \mathcal{Q}\, n_K^{\,n_K}, \qquad \mathrm{Li}(x) = \int_2^x \frac{dt}{\log t}.$$

1. *At most one real character $\chi_1 \in \widehat{H}$ has a Hecke L-function $L(s, \chi_1, L/K)$ with a real zero β_1 such that $1 - \frac{1}{8 \log Q} < \beta_1 < 1$; if it exists, β_1 is called the Landau–Siegel zero. Put $\theta_1 = \chi_1(g_C)$ if β_1 exists and $\theta_1 = 0$ otherwise.*

2. *There are absolute, effectively computable constants $c_2, c_3, A_5 > 0$ such that, if $x \geq Q^{c_2}$,*

$$\pi_C(x) = \frac{|C|}{|G|}\big(\mathrm{Li}(x) - \theta_1 \,\mathrm{Li}(x^{\beta_1})\big)\big(1 + E\big),$$

$$|E| \leq A_5\Big(\exp\Big[-\frac{c_3 \log x}{\log Q}\Big] + \exp\Big[-\frac{(c_3 \log x)^{1/2}}{n_K^{1/2}}\Big]\Big),$$

   the term $\theta_1 \,\mathrm{Li}(x^{\beta_1})$ being omitted if β_1 does not exist.

3. *(Stark's bound.) There is an absolute constant $c_S > 0$ such that, if $\chi \in \widehat{H}$ is real and $L(\beta, \chi, L/K) = 0$ for a real $\beta = 1 - \lambda/\log Q$ with $\lambda > 0$, then $\lambda \geq c_S Q^{-2}$.*

Proof. [258]: item 1 is the statement attributed to Stark in Section 1.2 (before Theorem 1.4), together with Theorem 3.1 (the exceptional zero is real, simple and attached to a real Hecke character); item 2 is Theorem 1.4 (with Theorem 1.1 for the constants c_2, c_3; A_5 is the implied constant of its O-term); item 3 is Theorem 3.3 (Stark's bound, from Stark, Invent. Math. 23 (1974), Theorem 1'). The numbering is that of arXiv:1803.02823v3. The notation is that of the source, with the implied constants named. $\square$

Theorem B.11. *Let $f \geq 1$ and let χ be a primitive Dirichlet character modulo f (for $f = 1$, $\chi = \chi_{0,1}$ and $L(s, \chi) = \zeta(s)$). For every integer $k \geq 1$,*

$$L(1 - k, \chi) = -\frac{B_{k,\chi}}{k}, \qquad B_{k,\chi} = f^{\,k-1} \sum_{a=1}^{f} \chi(a)\, B_k\Big(\frac{a}{f}\Big),$$

where $L(1-k, \chi)$ is the value of the meromorphic continuation, which is holomorphic at $1 - k$.

Proof. [266], Chapter 4, Theorem 4.2, with Proposition 4.1 for the expression of $B_{k,\chi}$ through Bernoulli polynomials. Washington's n is our k; for $f = 1$ his $B_{k,1}$ is $B_k(1)$, so that $\zeta(0) = -B_1(1) = -\frac{1}{2}$. $\square$

Theorem B.12. *Let $q \geq 3$ and let χ be a primitive Dirichlet character modulo q. Let $a \in \{0, 1\}$ with $\chi(-1) = (-1)^a$, let $\tau(\chi) = \sum_{m=1}^{q} \chi(m) e^{2\pi i m/q}$ be its Gauss sum, and put*

$$\xi(s, \chi) = \Big(\frac{q}{\pi}\Big)^{(s+a)/2} \Gamma\Big(\frac{s + a}{2}\Big) L(s, \chi).$$

Then $\xi(s,\chi)$ is entire, $|\tau(\chi)| = q^{1/2}$, and with $W(\chi) = \tau(\chi)/(i^a q^{1/2})$, so that $|W(\chi)| = 1$,

$$\xi(s,\chi) = W(\chi)\,\xi(1-s,\overline{\chi}) \qquad (s \in \mathbb{C}).$$

Proof. [75] (Chapter 9, the functional equation in the form $\xi(1-s,\overline{\chi}) = \frac{i^a q^{1/2}}{\tau(\chi)}\xi(s,\chi)$, and Chapter 2 for $|\tau(\chi)| = q^{1/2}$), [180] (Chapter 10). Notation as in the references, except that the root number is written $W(\chi) = \tau(\chi)/(i^a q^{1/2})$, the inverse of Davenport's factor $i^a q^{1/2}/\tau(\chi)$ (the two have modulus 1). □

B.2 Algebraic number theory and class field theory

From class field theory and the arithmetic of number fields the paper quotes ray class fields (Theorem B.13), used for good hosts in Part II; the unit theorem and the conductor–discriminant formula (Theorem B.14, Theorem B.15), used for the joint packet supply in Part IV (Section 19); decomposition in cyclotomic fields and global reciprocity (Theorem B.16, Theorem B.17), used in the Ribet budget theorem (Section 22); and the Chebotarev density theorem (Theorem B.18), used in Parts V and VII and in Appendix E. The arithmetic of cyclotomic fields, namely the theorem of von Staudt and Clausen, Gauss sums with Stickelberger's factorisation, the Davenport–Hasse relation, Stickelberger's theorem and reciprocity for the Brauer group of $\mathbb{Q}$, enters the minus part of the Sha bound (Section 37); the theorem of von Staudt and Clausen is used again in Section 51 and Stickelberger's theorem in Section 44. Steinitz's classification of finitely generated modules over a Dedekind domain and Borel's ranks of the K-groups of a ring of integers (Theorem B.24, Theorem B.25) are used for the second cohomology of Tate twists (Section 40). The characters of CM fields of Barnet-Lamb, Gee, Geraghty and Taylor (Lemma B.26) are used in Parts VIII and IX, and the Hasse norm theorem and Landherr's classification of hermitian forms (Theorem B.27, Theorem B.28) in Appendix D (Section D.4).

Theorem B.13. *Let K be a number field and $\mathfrak{m}$ a non-zero ideal of $\mathcal{O}_K$. Let $I_K(\mathfrak{m})$ be the group of fractional ideals of K coprime to $\mathfrak{m}$, and $P_K(\mathfrak{m})$ its subgroup of principal ideals (α) with $\alpha \equiv 1 \pmod{}^{\times}\mathfrak{m}$. Put $\mathrm{Cl}_K(\mathfrak{m}) = I_K(\mathfrak{m})/P_K(\mathfrak{m})$, let h_K be the class number of K and $\mathcal{O}_{K,\mathfrak{m}}^{\times}$ the group of units $u \in \mathcal{O}_K^{\times}$ with $u \equiv 1 \pmod{\mathfrak{m}}$.*

1. *$\mathrm{Cl}_K(\mathfrak{m})$ is finite, of order*
$$|\mathrm{Cl}_K(\mathfrak{m})| = \frac{h_K\,|(\mathcal{O}_K/\mathfrak{m})^{\times}|}{[\mathcal{O}_K^{\times} : \mathcal{O}_{K,\mathfrak{m}}^{\times}]}.$$
2. *There is a finite abelian extension L/K, the ray class field of K modulo $\mathfrak{m}$, unramified at every prime ideal of K not dividing $\mathfrak{m}$, such that the Artin map $\mathfrak{p} \mapsto \left(\frac{L/K}{\mathfrak{p}}\right)$ on the prime ideals $\mathfrak{p} \nmid \mathfrak{m}$, extended multiplicatively to $I_K(\mathfrak{m})$, is surjective onto $\mathrm{Gal}(L/K)$ with kernel $P_K(\mathfrak{m})$. In particular a prime ideal $\mathfrak{p} \nmid \mathfrak{m}$ has trivial Artin symbol in L/K if and only if $\mathfrak{p} \in P_K(\mathfrak{m})$.*
3. *Through this isomorphism every character of $\mathrm{Gal}(L/K)$ is a character of $\mathrm{Cl}_K(\mathfrak{m})$, and the primitive Hecke character inducing it has conductor dividing $\mathfrak{m}$; in particular its norm is at most $\mathrm{N}\mathfrak{m}$.*

Proof. This is classical class field theory (Takagi's existence theorem and Artin's reciprocity law in ideal-theoretic form); see [190], Ch. VI. Item 1 is the exact sequence for the ray class group

modulo $\mathfrak{m}$ (with a modulus without infinite places); item 2 is the existence of the ray class field and the reciprocity isomorphism $\mathrm{Cl}_K(\mathfrak{m}) \cong \mathrm{Gal}(L/K)$ given by the Artin symbol; item 3 is the definition of the conductor of a character of $\mathrm{Cl}_K(\mathfrak{m})$, the smallest modulus through which it factors, which divides $\mathfrak{m}$. Neukirch writes $J^{\mathfrak{m}}$, $P^{\mathfrak{m}}$ and $\mathrm{Cl}_K^{\mathfrak{m}}$ for $I_K(\mathfrak{m})$, $P_K(\mathfrak{m})$ and $\mathrm{Cl}_K(\mathfrak{m})$. $\square$

Theorem B.14. *Let K be a number field with r_1 real embeddings and r_2 conjugate pairs of complex embeddings. Its roots of unity form a finite cyclic group $\mu(K)$, and*

$$\mathcal{O}_K^{\times} \simeq \mu(K) \times \mathbb{Z}^{r_1+r_2-1}$$

as abelian groups.

Proof. This is Dirichlet's unit theorem, including the torsion subgroup identification; see [190, Chapter I]. $\square$

Theorem B.15. *Let L/K be a finite abelian extension of number fields with Galois group G. For each $\chi \in \widehat{G} = \mathrm{Hom}(G, \mathbb{C}^{\times})$, let $\mathfrak{f}_0(\chi)$ be the finite part of the conductor of the finite-order Hecke character obtained by composing χ with the Artin map for L/K. Then the relative discriminant ideal is*

$$\mathfrak{d}_{L/K} = \prod_{\chi \in \widehat{G}} \mathfrak{f}_0(\chi).$$

For $K = \mathbb{Q}$, this says that the absolute discriminant of L is the product of the positive integer conductors of the corresponding primitive Dirichlet characters.

Proof. This is the conductor–discriminant formula, [173, Chapter V, Theorem 3.27]. The ideal denoted $\mathrm{disc}(L/K)$ there is $\mathfrak{d}_{L/K}$ here, and its factor $f_0(\chi \circ \phi_{L/K})$ is the finite conductor ideal $\mathfrak{f}_0(\chi)$. Over $\mathbb{Q}$, the norm of that ideal is the conductor of the corresponding primitive Dirichlet character, so taking ideal norms gives the last assertion. $\square$

Theorem B.16. *Let $n \geq 1$, $L = \mathbb{Q}(\zeta_n)$, and identify $\mathrm{Gal}(L/\mathbb{Q})$ with $(\mathbb{Z}/n\mathbb{Z})^{\times}$ by $\sigma_u(\zeta_n) = \zeta_n^u$. For a rational prime p, write $n = p^a n'$, $p \nmid n'$. At any prime of L above p, the inertia and decomposition groups are respectively*

$$I_p = \{u : u \equiv 1 \pmod{n'}\}, \qquad D_p = \{u : u \equiv p^b \pmod{n'} \text{ for some } b \geq 0\}.$$

In particular the ramification index is $\varphi(p^a)$; $L/\mathbb{Q}$ is unramified outside n.

For every intermediate field $\mathbb{Q} \subseteq E \subseteq L$, restriction sends these groups onto the inertia and decomposition groups at the restricted prime of E. Thus those groups are the images of I_p, D_p in $\mathrm{Gal}(E/\mathbb{Q})$. All notation is local.

Proof. These are the classical cyclotomic decomposition formulas. The p-power cyclotomic factor is totally ramified at p; the prime-to-p factor is unramified, with arithmetic Frobenius acting by $\zeta_{n'} \mapsto \zeta_{n'}^p$. The Chinese remainder identification gives the displayed groups. Restriction of decomposition and inertia groups in a finite Galois tower gives the final assertion. See [175, §6, Proposition 6.2 and Theorem 6.4]. $\square$

Theorem B.17. *Let L/F be a finite abelian extension of number fields. There is a continuous surjective homomorphism*

$$\mathrm{rec}_{F,L} : C_F \longrightarrow \mathrm{Gal}(L/F), \qquad \ker \mathrm{rec}_{F,L} = N_{L/F} C_L.$$

Its pullback to $\mathbb{A}_F^\times$ kills $F^\times$. For every place v of F and $w \mid v$, its restriction to $F_v^\times$ is the local reciprocity map into $D_w = \mathrm{Gal}(L_w/F_v)$, followed by inclusion in $\mathrm{Gal}(L/F)$; its local kernel is $N_{L_w/F_v} L_w^\times$. At finite v, local units map onto inertia. At an unramified finite place, units map to 1 and a uniformiser maps to arithmetic Frobenius. At a real place becoming complex, positive elements map to 1 and negative elements to complex conjugation; at a split real or complex place the local map is trivial.

Proof. This is global Artin reciprocity and its local compatibility: [173, Chapter V, Proposition 5.2 and Theorem 5.3; Chapter I, Theorem 1.1 and 1.6]. The real normalization follows from $N_{\mathbb{C}/\mathbb{R}}\mathbb{C}^\times = \mathbb{R}_{>0}$. □

Theorem B.18. *Let L/F be a finite Galois extension of number fields and $C \subseteq \mathrm{Gal}(L/F)$ a subset stable under conjugation. Then the set of finite places v of F unramified in L whose Frobenius class in $\mathrm{Gal}(L/F)$ is contained in C has Dirichlet density $\#C/[L:F]$.*

Proof. [65]; in the form stated (Dirichlet density): [190], Chapter VII, Theorem 13.4. For a conjugation-stable C apply the theorem to each conjugacy class contained in C and add the densities. □

Theorem B.19. *Let the Bernoulli numbers $B_j \in \mathbb{Q}$ be defined by $t/(e^t-1) = \sum_{j\ge 0} B_j t^j/j!$. Then $B_0 = 1$, $B_1 = -\tfrac{1}{2}$, $B_j = 0$ for every odd $j \ge 3$, and for every even $j \ge 2$*

$$B_j + \sum_{\substack{p \text{ prime} \\ (p-1)\mid j}} \frac{1}{p} \in \mathbb{Z}.$$

Proof. [266], Chapter 5, Theorem 5.10 (von Staudt–Clausen); the values B_0, B_1 and the vanishing for odd $j \ge 3$ follow from the generating function, since $t/(e^t-1) + t/2$ is even ([266], Chapter 4). Notation as in the reference. □

Theorem B.20. *Let $m \ge 2$ be an integer, $K = \mathbb{Q}(\mu_m) \subset \overline{\mathbb{Q}}$, and for $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ let $\sigma_t \in \mathrm{Gal}(K/\mathbb{Q})$ be the automorphism with $\sigma_t(\zeta) = \zeta^{\tilde t}$ for $\zeta \in \mu_m$, where $\tilde t \in \{1,\dots,m-1\}$ is the representative of t. Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_K$ not dividing m, p its residue characteristic, $k = \mathcal{O}_K/\mathfrak{p}$ and $q = |k|$, so that $m \mid q-1$. Let $\chi_\mathfrak{p} \colon k^\times \to \mu_m$ be the m-th power residue character: $\chi_\mathfrak{p}(x \bmod \mathfrak{p})$ is the element of μ_m congruent to $x^{(q-1)/m}$ modulo $\mathfrak{p}$, for $x \in \mathcal{O}_K \setminus \mathfrak{p}$. Fix a primitive p-th root of unity $\zeta_p \in \overline{\mathbb{Q}}$ and put, for $j \in \mathbb{Z}$,*

$$\mathrm{g}_\mathfrak{p}(j) = \sum_{c \in k^\times} \chi_\mathfrak{p}(c)^{-j}\, \zeta_p^{\mathrm{Tr}_{k/\mathbb{F}_p}(c)} \in \mathbb{Q}(\mu_{mp}).$$

Then:

1. *if $m \nmid j$, then $\mathrm{g}_\mathfrak{p}(j)\,\mathrm{g}_\mathfrak{p}(-j) = \chi_\mathfrak{p}(-1)^j\, q$;*
2. *$\mathrm{g}_\mathfrak{p}(1)^m \in K$, and as ideals of $\mathcal{O}_K$*

$$\mathrm{g}_\mathfrak{p}(1)^m\, \mathcal{O}_K = \prod_{t \in (\mathbb{Z}/m\mathbb{Z})^\times} \sigma_t^{-1}(\mathfrak{p})^{\tilde t}.$$

Proof. [266], Chapter 6 (Gauss sums and Stickelberger's theorem; item 1 is the classical evaluation $g(\alpha)g(\alpha^{-1}) = \alpha(-1)q$ for a nontrivial multiplicative character α of a finite field of q elements, here $\alpha = \chi_{\mathfrak{p}}^{-j}$; item 2 is Stickelberger's factorisation $(g^m) = \mathfrak{p}^{m\theta}$ with $\theta = \sum_t \{\tilde{t}/m\}\sigma_t^{-1}$, so that $m\theta = \sum_t \tilde{t}\,\sigma_t^{-1}$). Notation: the Gauss sum attached to $\mathfrak{p}$ in the references is $\mathrm{g}_{\mathfrak{p}}(1)$ here, the sum over $k^\times$ being the sum over k with the convention that the character vanishes at 0; texts differ in naming the power residue character or its inverse, and the normalisation stated here is the one in which the character $\chi_{\mathfrak{p}}^{-1}$ produces the ideal $\mathfrak{p}^{\theta}$. $\square$

Theorem B.21. *Let k be a finite field of characteristic p, k'/k a finite extension of degree s, $\zeta_p \in \overline{\mathbb{Q}}$ a primitive p-th root of unity, and for a finite field $\kappa \supseteq \mathbb{F}_p$ and a character $\alpha\colon \kappa^\times \to \overline{\mathbb{Q}}^\times$ put $\mathrm{g}_\kappa(\alpha) = \sum_{c\in\kappa^\times} \alpha(c)\,\zeta_p^{\mathrm{Tr}_{\kappa/\mathbb{F}_p}(c)}$. If α is a nontrivial character of $k^\times$, then*

$$-\mathrm{g}_{k'}(\alpha\circ \mathrm{N}_{k'/k}) = \bigl(-\mathrm{g}_k(\alpha)\bigr)^s.$$

Proof. The Davenport–Hasse relation (H. Davenport and H. Hasse, *Die Nullstellen der Kongruenzzetafunktionen in gewissen zyklischen Fällen*, J. Reine Angew. Math. 172 (1935)); see also [266], Chapter 6, and the chapter on Gauss and Jacobi sums of Ireland and Rosen, *A Classical Introduction to Modern Number Theory*. Notation as in the references, with the additive character $c \mapsto \zeta_p^{\mathrm{Tr}_{\kappa/\mathbb{F}_p}(c)}$ of κ; the trace of k' is the trace of k composed with $\mathrm{Tr}_{k'/k}$. $\square$

Theorem B.22. *Let ℓ be an odd prime and $R \geq 1$. For a place v of $\mathbb{Q}$ write $\mathrm{res}_v\colon H^2(G_{\mathbb{Q}}, \mu_{\ell^R}) \to H^2(G_{\mathbb{Q}_v}, \mu_{\ell^R})$ for the restriction to a decomposition group at v. Then:*

1. *$H^2(G_{\mathbb{R}}, \mu_{\ell^R}) = 0$, and for every prime p the map $\mathrm{inv}_p\colon H^2(G_{\mathbb{Q}_p}, \mu_{\ell^R}) \to \mathbb{Q}/\mathbb{Z}$, the composite of the map to the Brauer group $\mathrm{Br}(\mathbb{Q}_p)$ induced by $\mu_{\ell^R} \subset \overline{\mathbb{Q}}_p^\times$ with the Hasse invariant, is injective;*
2. *for every $\xi \in H^2(G_{\mathbb{Q}}, \mu_{\ell^R})$, $\mathrm{res}_p(\xi) = 0$ for all but finitely many primes p, and*

$$\sum_p \mathrm{inv}_p(\mathrm{res}_p\,\xi) = 0.$$

In particular, if $\mathrm{res}_v(\xi) = 0$ for every place $v \neq v_0$, then $\mathrm{res}_{v_0}(\xi) = 0$.

Proof. Kummer theory and Hilbert's Theorem 90 identify $H^2(G_K, \mu_{\ell^R})$ with $\mathrm{Br}(K)[\ell^R]$ for $K = \mathbb{Q}, \mathbb{Q}_p, \mathbb{R}$, compatibly with restriction [222]; the Hasse invariant $\mathrm{Br}(\mathbb{Q}_p) \to \mathbb{Q}/\mathbb{Z}$ is an isomorphism, $\mathrm{Br}(\mathbb{R})$ has order 2, and the sequence $0 \to \mathrm{Br}(\mathbb{Q}) \to \bigoplus_v \mathrm{Br}(\mathbb{Q}_v) \to \mathbb{Q}/\mathbb{Z} \to 0$ is exact (Albert, Brauer, Hasse, Noether) [190], [172]. Item 1: $H^2(G_{\mathbb{R}}, \mu_{\ell^R})$ is killed by 2 and by ℓ^R. Item 2 is the exactness in the middle restricted to ℓ^R-torsion. The last sentence follows from item 2 and the injectivity in item 1. Notation as in the references. $\square$

Theorem B.23. *Let $Q \geq 3$ be an integer with $Q \not\equiv 2 \pmod 4$, $K = \mathbb{Q}(\zeta_Q)$, $G = \mathrm{Gal}(K/\mathbb{Q})$, and for b prime to Q let $\sigma_b \in G$ be the automorphism with $\sigma_b(\zeta_Q) = \zeta_Q^b$. Put*

$$\theta_Q = \sum_{\substack{1\leq b\leq Q\\ \gcd(b,Q)=1}} \Bigl\{\frac{b}{Q}\Bigr\}\sigma_b^{-1} \in \mathbb{Q}[G],$$

where $\{y\}$ is the fractional part of y. Then for every integer a prime to Q the element $(a-\sigma_a)\theta_Q$ lies in $\mathbb{Z}[G]$ and annihilates the ideal class group of K.

Proof. [266], Chapter 6, Lemma 6.9 (integrality of $(a-\sigma_a)\theta_Q$) and Theorem 6.10 (Stickelberger's theorem: if $\beta \in \mathbb{Z}[G]$ and $\beta\theta_Q \in \mathbb{Z}[G]$, then $\beta\theta_Q$ annihilates the ideal class group of $\mathbb{Q}(\zeta_Q)$), applied with $\beta = a - \sigma_a$. Notation as in the reference (m there is Q, c there is a). □

Theorem B.24. *Let $\mathcal{O}$ be a Dedekind domain, $n \geq 1$, and $\mathfrak{a}_1, \dots, \mathfrak{a}_n$, $\mathfrak{b}_1, \dots, \mathfrak{b}_n$ nonzero fractional ideals of $\mathcal{O}$. Then $\mathfrak{a}_1 \oplus \cdots \oplus \mathfrak{a}_n \cong \mathfrak{b}_1 \oplus \cdots \oplus \mathfrak{b}_n$ as $\mathcal{O}$-modules if and only if $\mathfrak{a}_1 \cdots \mathfrak{a}_n$ and $\mathfrak{b}_1 \cdots \mathfrak{b}_n$ have the same class in the ideal class group of $\mathcal{O}$.*

Proof. [245] and [246]. Standard modern accounts: [176, §1] ($\mathfrak{a} \oplus \mathfrak{b} \cong \mathcal{O} \oplus \mathfrak{a}\mathfrak{b}$, and the class of the product is an invariant through the top exterior power); [71, §4]. Notation as in these sources. □

Theorem B.25. *Let L be a number field and $m \geq 2$. The group $K_m(\mathcal{O}_L)$ is finitely generated, and $\dim_{\mathbb{Q}} K_m(\mathcal{O}_L) \otimes \mathbb{Q}$ is 0 if m is even, $r_1(L) + r_2(L)$ if $m \equiv 1 \pmod 4$, and $r_2(L)$ if $m \equiv 3 \pmod 4$.*

Proof. [39] (the stable real cohomology of the arithmetic groups $\mathrm{SL}_n(\mathcal{O}_L)$), translated into ranks of K-groups through the rational Hurewicz isomorphism onto the primitives of $H_\bullet(\mathrm{GL}(\mathcal{O}_L);\mathbb{Q})$; finite generation: D. Quillen, *Finite generation of the groups K_i of rings of algebraic integers*, Lecture Notes in Math. 341 (1973), 179–198. See also C. Weibel, *The K-book*, Ch. VI (Borel's theorem on the ranks). Borel's r_1, r_2 agree with ours. □

Lemma B.26. *Let ℓ be a prime, $F \subset \overline{\mathbb{Q}}$ an imaginary CM field with maximal totally real subfield F^+, $c \in G_{F^+}$ a complex conjugation, and S a finite set of finite places of F containing every place above ℓ, with $S^c = S$ and every $v \in S$ unramified over F^+. For $v \in S$ fix a place $\bar{v}$ of $\overline{\mathbb{Q}}$ above v, choosing $\overline{v^c} = c\bar{v}$ when $v^c \neq v$, and put $G_{F_v} = D_{\bar{v}} \subseteq G_F$, $I_{F_v} = I_{\bar{v}}$. For characters ψ_v of G_{F_v} ($v \in S$) define the character $\psi_{v^c}^c$ of G_{F_v} by $\psi_{v^c}^c(g) = \psi_{v^c}(cgc)$ if $v^c \neq v$, and by $\psi_{v^c}^c(g) = \psi_v(sgs^{-1})$ if $v^c = v$, where $s \in G_{F^+} \setminus G_F$ is any element with $s\bar{v} = \bar{v}$. Let $\chi\colon G_{F^+} \to \overline{\mathbb{Q}}_\ell^\times$ be a continuous character taking the same value on all complex conjugations in G_{F^+}, and for $v \in S$ let $\psi_v\colon G_{F_v} \to \overline{\mathbb{Q}}_\ell^\times$ be a continuous character, de Rham if $v \mid \ell$, such that*

$$(\psi_v\, \psi_{v^c}^c)|_{I_{F_v}} = \chi|_{I_{F_v}} \qquad (v \in S).$$

Then there is a continuous character $\theta\colon G_F \to \overline{\mathbb{Q}}_\ell^\times$ with $\theta(g)\,\theta(cgc) = \chi(g)$ for all $g \in G_F$, and $\theta|_{I_{F_v}} = \psi_v|_{I_{F_v}}$ for all $v \in S$.

Proof. [17], Lemma A.2.5, part (1) (Appendix A.2, "Building fields and characters"). *Notation.* Their $\theta\theta^c = \chi|_{G_F}$ is $\theta(g)\theta(cgc) = \chi(g)$; their condition "$\chi(c_v)$ is independent of $v \mid \infty$" is the condition on complex conjugations. Their ψ_{vc}^c, a character of G_{F_v}, is ψ_{vc} transported by c; with $G_{F_{v^c}} = D_{c\bar{v}} = cD_{\bar{v}}c$ this is $g \mapsto \psi_{v^c}(cgc)$, and when $v^c = v$ the group $D_{c\bar{v}}$ is $hD_{\bar{v}}h^{-1}$ for $h \in G_F$ with $h\bar{v} = c\bar{v}$, so the transport is $g \mapsto \psi_v(h^{-1}cgch)$, which is the formula of the statement with $s = h^{-1}c$ (fixing $\bar{v}$, not in G_F); another choice of s differs by an element of $D_{\bar{v}} \cap G_F$, whose conjugation does not change a character of the abelianisation. The statement is part (1) as printed, nothing added. □

Theorem B.27. *Let F be a number field and $\delta, x \in F^\times$. Suppose that for every real embedding $\sigma\colon F \to \mathbb{R}$ there are $a, b \in \mathbb{R}$ with $\sigma(x) = a^2 - \sigma(\delta)b^2$, and that for every finite place v of F there are $a, b \in F_v$ with $x = a^2 - \delta b^2$ in F_v. Then there are $a, b \in F$ with $x = a^2 - \delta b^2$.*

Proof. This is Hasse's norm theorem [123] for the extension $F(\sqrt{\delta})/F$, which is cyclic of degree at most 2; see [190], Chapter VI, Section 4. *Notation.* If δ is not a square in F, then $a^2 - \delta b^2$ is

the norm of $a+b\sqrt{\delta}$ from $E = F(\sqrt{\delta})$, and the local hypothesis at a place v says that x is a norm from $E \otimes_F F_v$; at a complex place this holds for every x, so complex places are omitted. If $\delta = d^2$ is a square in F, the conclusion holds without hypotheses: $x = a^2 - \delta b^2$ with $a = (x+1)/2$, $b = (x-1)/(2d)$. □

Theorem B.28. *Let E be a CM field and $G, G' \in \mathrm{M}_r(E)$ nondegenerate hermitian matrices ($\bar{G}^\top = G$, $\bar{G}'^\top = G'$). Suppose that for every embedding $\tau\colon E \to \mathbb{C}$ the hermitian matrices $\tau(G)$ and $\tau(G')$ have the same signature, and that $\det G' = z\bar{z} \det G$ for some $z \in E$. Then there is $\gamma \in \mathrm{GL}_r(E)$ with*

$$\bar{x}^\top \bar{\gamma}^\top G \gamma\, y = \bar{x}^\top G'\, y \qquad \text{for all } x, y \in E^r,$$

that is, the hermitian forms of G and G' are isometric.

Proof. Landherr's theorem [158] (Abh. Math. Sem. Univ. Hamburg 11 (1936), 245–248); see [214], Chapter 10: for a quadratic extension E/F of number fields, two nondegenerate hermitian forms over E are isometric if and only if they have the same dimension, the same discriminant in $F^\times/\mathrm{N}_{E/F}(E^\times)$, and the same signature at every real place of F that does not split in E. Only the sufficiency is quoted. *Notation.* Here F is the maximal totally real subfield of E, so every real place of F is complex in E and every embedding τ of E restricts to a real place of F; the signature at that place is the signature of $\tau(G)$, which does not depend on the choice of τ above it, since the other choice gives the complex conjugate of $\tau(G)$, whose signature is the same. The determinant of a hermitian matrix lies in $F^\times$, and the condition $\det G' = z\bar{z} \det G$ says that the discriminants agree modulo $\mathrm{N}_{E/F}(E^\times)$ (with $z \neq 0$, as both determinants are nonzero). The isometry is the displayed identity, that is $\bar{\gamma}^\top G \gamma = G'$. □

B.3 Galois cohomology and Iwasawa theory

This subsection quotes the duality theorems and Euler characteristic formulas of Tate and Poitou, finiteness theorems for continuous cohomology, and three further finiteness theorems. Local Tate duality with the local Euler characteristic formula (Theorem B.29) is used in Parts V, VII, VIII and IX and in Appendix E; Tate's global Euler characteristic formula with the end of the Poitou–Tate sequence (Theorem B.37) is used in Parts VIII and IX and in Appendix E; and local duality and the Euler characteristic for ℓ-adic representations (Theorem B.36) are used in Part VIII and in Section 47. Tate's theorems on continuous cohomology of ℓ-adic lattices, its finite generation and its description as an inverse limit (Theorem B.30, Theorem B.31, Lemma B.33), are used in Parts V and VII, and Poitou–Tate duality for finite modules (Theorem B.34) in Part VII and Appendix E. Part VII also uses Kato's finiteness of Selmer groups of modular forms away from the centre (Theorem B.32, Section 38) and the vanishing of the Iwasawa μ-invariant of abelian fields by Ferrero and Washington (Theorem B.35, Section 39). The finite presentation theorem of Shafarevich and Koch and the nine-term Poitou–Tate sequence (Theorem B.38, Theorem B.39) are used for the Selmer bounds at Taylor–Wiles levels (Section E.4).

Theorem B.29. *Let F be a number field, v a finite place of F, ℓ a prime, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of G_{F_v}. Then:*

1. *$H^i(F_v, M)$ is finite for every $i \geq 0$, and $H^i(F_v, M) = 0$ for $i \geq 3$;*
2. *$H^2(F_v, \mu_{\ell^r}) \cong \mathbb{Z}/\ell^r\mathbb{Z}$, and for $i = 0, 1, 2$ the cup product*

$$H^i(F_v, M) \times H^{2-i}(F_v, M^\vee) \longrightarrow H^2(F_v, \mu_{\ell^r})$$

is a perfect pairing of finite groups;

3. *if $v \nmid \ell$ and I_v acts trivially on M, then $H^1_{\mathrm{ur}}(F_v, M)$ and $H^1_{\mathrm{ur}}(F_v, M^\vee)$ are the exact annihilators of each other under the pairing in item 2 with $i = 1$;*

4. *(local Euler characteristic formula) $\#H^1(F_v, M) = \#H^0(F_v, M)\,\#H^2(F_v, M)\,(\#M)^{[F_v:\mathbb{Q}_\ell]}$ if $v \mid \ell$, and $\#H^1(F_v, M) = \#H^0(F_v, M)\,\#H^2(F_v, M)$ if $v \nmid \ell$.*

Proof. This is Tate's local duality theorem and Tate's local Euler characteristic formula, [249]; in the form stated: [172], Chapter I, Corollary 2.3 (item 1 and the perfect pairing of item 2, with $H^2(F_v, \mu_{\ell^r}) = \mathrm{Br}(F_v)[\ell^r] \cong \mathbb{Z}/\ell^r\mathbb{Z}$ by the invariant map), Theorem 2.6 (item 3) and Theorem 2.8 (item 4); see also [222], Chapter II, Section 5. Notation: Milne's K is F_v, his M^D is $M^\vee$, and his H^1_{nr} is H^1_{ur}. □

Theorem B.30. *Let G be a profinite group and ℓ a prime such that $H^i(G, M)$ is finite for every $i \geq 0$ and every finite discrete G-module M of ℓ-power order. Let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$ and T a finitely generated $\mathcal{O}$-module with a continuous $\mathcal{O}$-linear action of G (ℓ-adic topology on T). Then for every $i \geq 0$ the continuous cochain cohomology group $H^i(G, T)$ is a finitely generated $\mathcal{O}$-module.*

Proof. J. Tate, *Relations between K_2 and Galois cohomology*, Invent. Math. 36 (1976), 257–274, Section 2: for a finitely generated $\mathbb{Z}_\ell$-module T with continuous action and finite $H^i(G, T/\ell T)$, the groups $H^i(G, T)$ are finitely generated $\mathbb{Z}_\ell$-modules; see also [191], Chapter II, Section 7. This gives the statement. Indeed, T is finitely generated over $\mathbb{Z}_\ell$ because $\mathcal{O}$ is; a finitely generated $\mathbb{Z}_\ell$-module on which $\mathcal{O}$ acts is a finitely generated $\mathcal{O}$-module; and Tate's hypothesis is the case $M = T/\ell T$ of ours. For $G = G_{F_v}$ with F_v a finite extension of $\mathbb{Q}_p$ (any p) the hypothesis holds by Theorem B.29(1). □

Theorem B.31. *Let G be a profinite group, ℓ a prime, T a finitely generated $\mathbb{Z}_\ell$-module with a continuous $\mathbb{Z}_\ell$-linear action of G (ℓ-adic topology on T), and $T_n = T/\ell^n T$ for $n \geq 1$, a finite discrete G-module. Let $i \geq 1$ and suppose that $H^{i-1}(G, T_n)$ is finite for every $n \geq 1$. Then the map*

$$H^i(G, T) \longrightarrow \varprojlim_n H^i(G, T_n)$$

induced by the projections $T \to T_n$, from continuous cochain cohomology to the inverse limit along the maps induced by $T_{n+1} \to T_n$, is an isomorphism.

Proof. J. Tate, *Relations between K_2 and Galois cohomology*, Invent. Math. 36 (1976), 257–274, Section 2 (Proposition 2.2 and the exact sequence $0 \to \varprojlim_n{}^1 H^{i-1}(G, T_n) \to H^i(G, T) \to \varprojlim_n H^i(G, T_n) \to 0$ preceding it); the $\varprojlim^1$ of an inverse system of finite groups vanishes. See also [137], Section 2, and [191], Chapter II, Section 7. Notation: Tate's M and $M/\ell^n M$ are T and T_n. □

Theorem B.32. *Let $f = \sum_{n \geq 1} a_n q^n$ be a normalised newform of weight $k \geq 2$, level N and Nebentypus ε_f ($f|_k\gamma = \varepsilon_f(d) f$ for $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(N)$, so that the Euler factor of $L(f, s)$ at $\ell \nmid N$ is $(1 - a_\ell \ell^{-s} + \varepsilon_f(\ell)\ell^{k-1-2s})^{-1}$), let $F_f = \mathbb{Q}(a_n : n \geq 1) \subset \mathbb{C}$, let λ be a finite place of F_f above the prime p, with completion F_λ and ring of integers $\mathcal{O}_\lambda$, and let $V_{F_\lambda}(f)$ be the two-dimensional F_λ-linear representation of $G_\mathbb{Q}$ attached to f in [141], 6.3. For $r \in \mathbb{Z}$ write $V_{F_\lambda}(f)(r) = V_{F_\lambda}(f) \otimes \chi_{\mathrm{cyc}}^r$.*

1. *For every prime $\ell \nmid Np$, $V_{F_\lambda}(f)$ is unramified at ℓ and $\det(1 - \mathrm{Frob}_\ell^{-1} u \mid V_{F_\lambda}(f)) = 1 - a_\ell u + \varepsilon_f(\ell)\ell^{k-1}u^2$, where Frob_ℓ is an arithmetic Frobenius at ℓ.*

2. *Let $K \subset \overline{\mathbb{Q}}$ be a finite abelian extension of $\mathbb{Q}$ and r an integer with $1 \le r \le k-1$ and $r \ne k/2$. Then $\mathrm{Sel}(K,T)$ is finite for every $G_{\mathbb{Q}}$-stable $\mathcal{O}_\lambda$-lattice T of $V_{F_\lambda}(f)(r)$.*

Proof. Part 2 is [141], Theorem 14.2(1), for any prime p and any finite place λ; Kato's Selmer group $\mathrm{Sel}(K,T) \subseteq H^1(K, T \otimes \mathbb{Q}/\mathbb{Z})$ ([141], 14.1) imposes at each place one local condition of the form of Definition 22.2, so the group $\mathrm{Sel}(K,T)$ of Definition 22.2 (conditions at every decomposition group) is a subgroup of Kato's and is finite. Part 1 is [141], (14.10.3), recalled there as known (Carayol, Saito): $\det(1 - \mathrm{Fr}_\ell^{-1} u \,;\, H^0(\mathbb{Q}_\ell^{\mathrm{ur}}, V_{F_\lambda}(f))) = 1 - a_\ell u + \varepsilon(\ell)\ell^{k-1}u^2$ for ℓ not below λ, with Fr_ℓ the arithmetic Frobenius; for $\ell \nmid N$ the right side has degree 2, so the inertia invariants are all of $V_{F_\lambda}(f)$. Notation: Kato's κ is χ_{cyc}, his ε is ε_f, his p is the residue characteristic of λ. □

Lemma B.33. *Let G be a profinite group and $(A_n)_{n\ge 1}$ an inverse system of finite discrete G-modules, with continuous actions and surjective G-equivariant transition maps $A_{n+1} \to A_n$; let $A = \varprojlim_n A_n$ with the inverse-limit topology. For every $i \ge 1$ there is an exact sequence*

$$0 \to \varprojlim_n{}^1 H^{i-1}(G, A_n) \to H^i(G, A) \to \varprojlim_n H^i(G, A_n) \to 0,$$

in which $H^i(G,A)$ is continuous cochain cohomology and the second map is induced by the projections $A \to A_n$. In particular, if $H^{i-1}(G, A_n)$ is finite for every n, the natural map $H^i(G,A) \to \varprojlim_n H^i(G, A_n)$ is an isomorphism.

Proof. [191], Chapter II, Section 7, Theorem 2.7.5 and Corollary 2.7.6; the same statement for continuous cochains is in [252, Section 2]. The last sentence holds because an inverse system of finite groups satisfies the Mittag-Leffler condition, so its $\varprojlim^1$ vanishes. Notation as in the references; $H^i(G,A)$ is $H^i_{\mathrm{cts}}(G,A)$ there. □

Theorem B.34. *Let F be a number field with no real place, ℓ a prime, S a finite set of places of F containing the places above ℓ and the archimedean places, $r \ge 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of $G_{F,S}$; put $M^\vee = \mathrm{Hom}(M, \mu_{\ell^r})$. Then:*

1. *$H^i(G_{F,S}, M)$ is finite for every $i \ge 0$;*
2. *$\mathrm{Sha}^1_S(F,M)$ and $\mathrm{Sha}^2_S(F, M^\vee)$ are finite and there is a perfect pairing*

$$\mathrm{Sha}^1_S(F,M) \times \mathrm{Sha}^2_S(F, M^\vee) \to \mathbb{Q}/\mathbb{Z};$$

   in particular $\#\mathrm{Sha}^1_S(F,M) = \#\mathrm{Sha}^2_S(F,M^\vee)$;
3. *$H^i(G_{F,S}, M) = 0$ for every $i \ge 3$.*

Proof. [172], Ch. I, Theorem 4.10: parts (a), (b) and (c) there; in (c) the groups $H^i(G_{F,S}, M)$ for $i \ge 3$ are identified with the sum of the $H^i(F_v, M)$ over the real places v, which is empty here. See also [191], Chapter VIII, Section 6 (Poitou–Tate duality) and Section 3 (cohomological dimension of $G_{F,S}$). Milne's K, M^D and $\mathrm{Sha}^i(G_S, M)$ are our F, $M^\vee$ and $\mathrm{Sha}^i_S(F,M)$; the hypothesis that $\#M$ is a unit outside S holds because S contains the places above ℓ. The statement is specialised to fields without real places, which is the case needed here; the prime $\ell = 2$ is then covered without modified cohomology at the real places. □

Theorem B.35. *Let p be a prime, K a finite abelian extension of $\mathbb{Q}$, K_∞/K the cyclotomic $\mathbb{Z}_p$-extension, K_n its subfield with $[K_n : K] = p^n$, and A_n the p-Sylow subgroup of the ideal class group of K_n. Let $\mu, \lambda \geq 0$ and ν be the Iwasawa invariants of K_∞/K, so that $\#A_n = p^{\mu p^n + \lambda n + \nu}$ for all sufficiently large n. Then $\mu = 0$.*

Proof. [90], for every prime p; another proof is due to Sinnott [235]; see also [266], Chapter 7. The invariants are those of Iwasawa's theorem ([266], Chapter 13). The prime p is that of the cited works. □

Theorem B.36. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and U a finite-dimensional $\mathbb{Q}_\ell$-vector space with a continuous linear action of G_M; write $h^i(U) = \dim_{\mathbb{Q}_\ell} H^i(G_M, U)$ (continuous cochains) and $U^*(1) = \mathrm{Hom}_{\mathbb{Q}_\ell}(U, \mathbb{Q}_\ell) \otimes \chi_{\mathrm{cyc}}$. Then the groups $H^i(G_M, U)$ are finite-dimensional, they vanish for $i \geq 3$, and*

$$h^0(U) - h^1(U) + h^2(U) = -[M : \mathbb{Q}_\ell] \dim_{\mathbb{Q}_\ell} U, \qquad h^2(U) = h^0\big(U^*(1)\big).$$

Proof. J. Tate, *Duality theorems in Galois cohomology over number fields* [249] (local Euler characteristic formula and local duality for finite modules), passed to ℓ-adic coefficients through a G_M-stable $\mathbb{Z}_\ell$-lattice $T \subset U$ and the finiteness of $H^i(G_M, T/\ell^n T)$ (continuous cohomology of T is the inverse limit, and $H^i(G_M, U) = H^i(G_M, T) \otimes \mathbb{Q}$). This is the form used by Bloch and Kato [34], p. 356 (proof of (3.8)), who cite J.-P. Serre, *Cohomologie galoisienne*, II.5.7, for the Euler characteristic, and local duality for the second formula. □

Theorem B.37. *Let F be a number field and ℓ a prime; assume that ℓ is odd or that F has no real place. Let S be a finite set of places of F containing the places above ℓ and the archimedean places, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of $G_{F,S}$. For $v \in S$, $H^i(F_v, M)$ is formed through a decomposition group at v and its map to $G_{F,S}$. Then:*

1. *$H^i(G_{F,S}, M)$ is finite for every $i \geq 0$;*
2. *(Tate's global Euler characteristic formula)*

$$\frac{\#H^0(G_{F,S}, M) \cdot \#H^2(G_{F,S}, M)}{\#H^1(G_{F,S}, M)} = \prod_{v|\infty} \frac{\#H^0(F_v, M)}{|\#M|_v};$$

3. *the sequence*

$$H^2(G_{F,S}, M) \longrightarrow \bigoplus_{v \in S,\ v \nmid \infty} H^2(F_v, M) \longrightarrow H^0(G_{F,S}, M^\vee)^* \longrightarrow 0,$$

whose first map is the sum of the restrictions and * the Pontryagin dual, is exact.

Proof. [172], Ch. I, Theorem 4.10 (finiteness, and the Poitou–Tate nine-term exact sequence, whose last three terms are those of item 3) and Theorem 5.1 (the Euler characteristic); see also [191, Ch. VIII]. Notation: Milne's K, G_S, M^D are F, $G_{F,S}$, $M^\vee$; his hypothesis that $\#M$ is a unit outside S holds since S contains the places above ℓ. In the nine-term sequence the archimedean places contribute $\hat{H}^2(F_v, M)$, which vanishes under the hypothesis: for ℓ odd because $\mathrm{Gal}(\mathbb{C}/F_v)$ has order at most 2 and $\#M$ is odd, and when F has no real place because that group is trivial at every archimedean place; this is why they are omitted in item 3. Items 1

and 2 hold in Milne's theorems for every prime ℓ; when F has no real place every archimedean factor of item 2 is $\#M/|\#M|_v = (\#M)^{-1}$, also for $\ell = 2$ (compare the example in the footnote to Theorem 5.1 of loc. cit.). Theorem 5.1 of [172], Ch. I, assumes only that S is a finite nonempty set of places containing the archimedean ones and that the order of M is invertible in the ring of S-integers; it carries no hypothesis on ℓ, its archimedean factors use the ordinary invariants $H^0(F_v, M)$, and its footnote treats $M = \mathbb{Z}/2\mathbb{Z}$, where a complex place contributes $2/4$. The Poitou–Tate sequence behind item 3 is stated for every prime, with Tate cohomology at the archimedean places, in [174]. □

Theorem B.38. *Let K be a number field, ℓ an odd prime and S a finite set of places of K containing all places above ℓ. Let $K_S(\ell)$ be the maximal pro-ℓ extension of K (in a fixed algebraic closure) unramified at all finite places outside S, and $G_S(\ell) = \mathrm{Gal}(K_S(\ell)/K)$. Then $H^1(G_S(\ell), \mathbb{Z}/\ell)$ and $H^2(G_S(\ell), \mathbb{Z}/\ell)$ are finite; that is, the pro-ℓ group $G_S(\ell)$ is finitely generated and has finitely many defining relations.*

Proof. See [147] (Shafarevich–Koch theorem on the generator and relation ranks of $G_S(p)$); [191, Chapter X, §7]. For odd ℓ the archimedean places do not ramify in pro-ℓ extensions, so including them in S or not gives the same group. □

Theorem B.39. *Let F be a number field and ℓ a prime; assume that ℓ is odd or that F has no real place. Let S be a finite set of places of F containing the places above ℓ and the archimedean places, $S_f \subseteq S$ its finite places, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of $G_{F,S}$. For $v \in S_f$, $H^i(F_v, M)$ is formed through a decomposition group at v and its map to $G_{F,S}$. Write $H^i(M) = H^i(G_{F,S}, M)$, $P^i(M) = \prod_{v \in S_f} H^i(F_v, M)$, * for the Pontryagin dual, and $\lambda^i_M \colon H^i(M) \to P^i(M)$ for the product of the restriction maps. Then:*

1. *$H^i(M)$ and $H^i(F_v, M)$ ($v \in S_f$) are finite for every $i \geq 0$;*
2. *$\mathrm{Sha}^1_S(F, M)$ and $\mathrm{Sha}^2_S(F, M^\vee)$ are finite, and the cup product followed by the sum of the local invariants induces a perfect pairing $\mathrm{Sha}^1_S(F, M) \times \mathrm{Sha}^2_S(F, M^\vee) \to \mathbb{Q}/\mathbb{Z}$;*
3. *the sequence*

$$\begin{aligned} 0 \to H^0(M) \xrightarrow{\lambda^0_M} P^0(M) \xrightarrow{\beta^0} H^2(M^\vee)^* \\ \to H^1(M) \xrightarrow{\lambda^1_M} P^1(M) \xrightarrow{\beta^1} H^1(M^\vee)^* \\ \to H^2(M) \xrightarrow{\lambda^2_M} P^2(M) \xrightarrow{\beta^2} H^0(M^\vee)^* \to 0 \end{aligned}$$

is exact, where $\beta^i((x_v)_v)(y) = \sum_{v \in S_f} \mathrm{inv}_v(x_v \cup \mathrm{res}_v(y))$ for $y \in H^{2-i}(M^\vee)$, the cup product being taken with values in $H^2(F_v, \mu_{\ell^r})$.

Proof. This is the Poitou–Tate theorem, [172], Chapter I, Theorem 4.10: (a) gives item 1 (with Corollary 2.3 for the local groups), (b) item 2, and (c) the nine-term exact sequence of item 3; see also [191], Chapter VIII, Theorems 8.6.7 and 8.6.10. Milne's K, G_S, M^D are F, $G_{F,S}$, $M^\vee$ here. His hypothesis that $\#M$ is a unit outside S holds since S contains the places above ℓ. In Milne's sequence the archimedean places contribute the Tate cohomology groups $\hat{H}^i(F_v, M)$, $i = 0, 1, 2$, and the Tate–Shafarevich groups are formed over all of S. Under the hypothesis these archimedean groups vanish (for ℓ odd, $\mathrm{Gal}(\mathbb{C}/F_v)$ has order at most 2 and $\#M$ is odd, so the Tate cohomology is killed by 2 and by ℓ^r; when F has no real place the group is trivial at every archimedean place), which is why the products run over S_f only. The maps β^i are those of Milne's sequence: the duals of $\lambda^{2-i}_{M^\vee}$ composed with local Tate duality. □

B.4 p-adic Hodge theory

Part V is the main user of p-adic Hodge theory. Its Wach modules, relay classes and losses at the places above ℓ (Sections 23–25) rest on Fontaine's ring A_{inf} with the map θ and B_{dR}^{+} (Theorem B.40), on the theorem of Bhatt and Scholze that crystalline lattices come from prismatic F-crystals (Theorem B.41), and on the invariants of $\mathbb{C}_p$ over the cyclotomic tower of Tate and Ax–Sen–Tate (Theorem B.42); all three are used in Appendix C as well. The finite parts of Bloch and Kato, with their dimensions, their orthogonality under local duality and the unramified case (Theorem B.43, Theorem B.44, Theorem B.46, Theorem B.49, Theorem B.50, Theorem B.56), and Fontaine's stability of crystalline representations (Theorem B.45) are used in Part V and in Parts VIII and IX. Fontaine's (φ,Γ)-modules (Theorem B.51, Theorem B.52) are used for the lossless local conditions at large primes (Section 28), and the formula of Cherbonnier and Colmez for the dual exponential and Tate's computation of the first cohomology of the twists of $\mathbb{C}_p$ (Theorem B.48, Theorem B.47) in Section 25. Outside Parts V, VIII and IX, the bounds of Fargues for the Hodge–Tate map (Theorem B.53, Theorem B.54) are used for linked stages in Part VI (Section 35), Fontaine's weak admissibility (Theorem B.55) in Section 38, and Kisin's crystalline lifting rings (Theorem B.57) in Section 47.

Theorem B.40. *Let p be a prime, $[\cdot]\colon \mathcal{O}_{\mathbb{C}_p^{\flat}} \to A_{\mathrm{inf}}$ the Teichmüller map, $x \mapsto x^{\sharp}$ the map $\mathcal{O}_{\mathbb{C}_p^{\flat}} \to \mathcal{O}_{\mathbb{C}_p}$, $\varepsilon \in \mathcal{O}_{\mathbb{C}_p^{\flat}}$ the element defined by ζ (so $(\varepsilon^{1/p^k})^{\sharp} = \zeta_{p^k}$), $p^{\flat} \in \mathcal{O}_{\mathbb{C}_p^{\flat}}$ an element with $(p^{\flat})^{\sharp} = p$, $q = [\varepsilon^{1/p}]$ and $\xi_0 = \sum_{k=0}^{p-1} q^k$. The group $G_{\mathbb{Q}_p}$ acts on $\mathcal{O}_{\mathbb{C}_p^{\flat}}$ and, by functoriality of Witt vectors, on A_{inf}, with $\sigma[x] = [\sigma x]$.*

(Ai1) *A_{inf} is an integral domain; θ is a surjective $G_{\mathbb{Q}_p}$-equivariant ring homomorphism with $\theta([x]) = x^{\sharp}$; $\ker\theta = \xi_0 A_{\mathrm{inf}}$; and $(p,\xi_0) = (p,[p^{\flat}])$ as ideals of A_{inf}.*

(Ai2) *A_{inf} is separated and complete for the topology defined by the ideals $(p,[p^{\flat}])^n$, $n \geq 1$; the Teichmüller map is continuous for this topology and the valuation topology of $\mathcal{O}_{\mathbb{C}_p^{\flat}}$; and the action of $G_{\mathbb{Q}_p}$ on A_{inf} is continuous for it.*

(Ai3) *For every $b \geq 1$ the natural map $A_{\mathrm{inf}}[1/p]/\xi_0^b A_{\mathrm{inf}}[1/p] \to B_{\mathrm{dR}}^{+}/\xi_0^b B_{\mathrm{dR}}^{+}$ is an isomorphism; B_{dR}^{+} is a complete discrete valuation ring, and the kernel of the extension $\theta\colon B_{\mathrm{dR}}^{+} \to \mathbb{C}_p$ is $\xi_0 B_{\mathrm{dR}}^{+} = t B_{\mathrm{dR}}^{+}$; $\overline{\mathbb{Q}}_p \subset B_{\mathrm{dR}}^{+}$ compatibly with θ, and $\sigma(t) = \chi_{\mathrm{cyc}}(\sigma)t$.*

(Ai4) *(de Rham comparison) If F is a finite extension of $\mathbb{Q}_p$ and V a de Rham representation of G_F, $D = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_F}$ with $\mathrm{Fil}^j D = D \cap (t^j B_{\mathrm{dR}}^{+} \otimes_{\mathbb{Q}_p} V)$, then the natural map $B_{\mathrm{dR}} \otimes_F D \to B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V$ is a G_F-equivariant isomorphism (G_F acting trivially on D) which maps $\sum_{j\in\mathbb{Z}} t^{k-j} B_{\mathrm{dR}}^{+} \otimes_F \mathrm{Fil}^j D$ onto $t^k B_{\mathrm{dR}}^{+} \otimes_{\mathbb{Q}_p} V$ for every $k \in \mathbb{Z}$.*

Proof. Fontaine [94], Sections 1–3 (the ring $R = \mathcal{O}_{\mathbb{C}_p^{\flat}}$, $W(R)$, θ and its kernel generated by an element of the form ξ_0, the weak topology, B_{dR}^{+} and t) and [96] (admissibility, the filtered comparison for de Rham representations); see also [52] (the chapters on A_{inf}, B_{dR} and de Rham representations). Fontaine's R and ε are ours; the ideal equality $(p,\xi_0) = (p,[p^{\flat}])$ holds because modulo p, $\xi_0 \equiv [(\varepsilon-1)/(\varepsilon^{1/p}-1)]$ and this element of R has the valuation of $p^{\flat}$. □

Theorem B.41. *Let p be a prime and K a finite extension of $\mathbb{Q}_p$ with ring of integers $\mathcal{O}_K$. An* object over $\mathcal{O}_K$ *is a bounded prism (A,I) in the sense of Bhatt–Scholze together with a ring homomorphism $\mathcal{O}_K \to A/I$; a morphism $f\colon (A,I) \to (B,J)$ is a homomorphism of δ-rings with $f(I) \subseteq J$ inducing an $\mathcal{O}_K$-algebra map $A/I \to B/J$. Let T be a finite free $\mathbb{Z}_p$-module of rank d with a continuous $\mathbb{Z}_p$-linear action of G_K such that $T[1/p]$ is crystalline. Then there is a datum $\mathcal{E}$ consisting of:*

(Bs1) *for every object (A, I) over $\mathcal{O}_K$, a finite projective A-module $\mathcal{E}(A)$ of rank d and an A-linear isomorphism $\varphi_{\mathcal{E},A}\colon (A \otimes_{\varphi_A,A} \mathcal{E}(A))[1/I] \to \mathcal{E}(A)[1/I]$;*

(Bs2) *for every morphism $f\colon (A, I) \to (B, J)$ over $\mathcal{O}_K$, an f-semilinear map $\mathcal{E}(f)\colon \mathcal{E}(A) \to \mathcal{E}(B)$ whose B-linear extension $B \otimes_{f,A} \mathcal{E}(A) \to \mathcal{E}(B)$ is an isomorphism, with $\mathcal{E}(\mathrm{id}) = \mathrm{id}$, $\mathcal{E}(g \circ f) = \mathcal{E}(g) \circ \mathcal{E}(f)$, and compatible with the isomorphisms $\varphi_{\mathcal{E},A}$, $\varphi_{\mathcal{E},B}$;*

such that the following holds for the evaluation at Fontaine's ring. Put $\mu_\varepsilon = [\varepsilon] - 1$, $\tilde{\xi} = \sum_{k=0}^{p-1}[\varepsilon]^k = \varphi(\mu_\varepsilon)/\mu_\varepsilon$ and $\tilde{\theta} = \theta \circ \varphi^{-1}\colon A_{\mathrm{inf}} \to \mathcal{O}_{\mathbb{C}_p}$. Then $(A_{\mathrm{inf}}, \tilde{\xi}A_{\mathrm{inf}})$ with $\mathcal{O}_K \subseteq \mathcal{O}_{\mathbb{C}_p} \cong A_{\mathrm{inf}}/\tilde{\xi}A_{\mathrm{inf}}$ (via $\tilde{\theta}$) is an object over $\mathcal{O}_K$, every $\sigma \in G_K$ acts on it by a morphism over $\mathcal{O}_K$, and with $M = \mathcal{E}(A_{\mathrm{inf}})$, $\varphi_M = \varphi_{\mathcal{E},A_{\mathrm{inf}}}$ and the semilinear action $\sigma \mapsto \mathcal{E}(\sigma)$ of G_K on M:

(Bs3) *there is an isomorphism of $W(\mathbb{C}_p^\flat)$-modules $M \otimes_{A_{\mathrm{inf}}} W(\mathbb{C}_p^\flat) \cong T \otimes_{\mathbb{Z}_p} W(\mathbb{C}_p^\flat)$, equivariant for G_K (acting diagonally on the right) and carrying $\varphi_M \otimes \varphi$ to $1 \otimes \varphi$, which restricts to an isomorphism $M[1/\mu_\varepsilon] \cong T \otimes_{\mathbb{Z}_p} A_{\mathrm{inf}}[1/\mu_\varepsilon]$.*

(Bs4) *Let $B'^{+} = \varprojlim_b A_{\mathrm{inf}}[1/p]/\tilde{\xi}^b A_{\mathrm{inf}}[1/p]$ be the completion of $A_{\mathrm{inf}}[1/p]$ at $\ker\tilde{\theta}$ and $B'_{\mathrm{dR}} = B'^{+}[1/\tilde{\xi}]$, with G_K acting through its action on A_{inf}. The image of μ_ε in B'^{+} is a unit, so (Bs3) induces an isomorphism $M \otimes_{A_{\mathrm{inf}}} B'_{\mathrm{dR}} \cong T \otimes_{\mathbb{Z}_p} B'_{\mathrm{dR}}$ carrying $M \otimes_{A_{\mathrm{inf}}} B'^{+}$ onto $T \otimes_{\mathbb{Z}_p} B'^{+}$. Under it, the B'^{+}-submodule generated by the images of the elements $\varphi_M(1 \otimes m) \in M[1/\tilde{\xi}]$, $m \in M$, equals the B'^{+}-submodule of $T \otimes_{\mathbb{Z}_p} B'_{\mathrm{dR}}$ generated by $(T \otimes_{\mathbb{Z}_p} B'_{\mathrm{dR}})^{G_K}$.*

(Bs5) *The datum is functorial in T: if T' is another such module with datum $\mathcal{E}'$, every G_K-equivariant $\mathbb{Z}_p$-linear map $f\colon T \to T'$ induces A-linear maps $\mathcal{E}(f)_A\colon \mathcal{E}(A) \to \mathcal{E}'(A)$, for all objects (A, I) over $\mathcal{O}_K$, such that $\mathcal{E}'(g) \circ \mathcal{E}(f)_A = \mathcal{E}(f)_B \circ \mathcal{E}(g)$ for every morphism $g\colon (A, I) \to (B, J)$ over $\mathcal{O}_K$, $\varphi_{\mathcal{E}',A} \circ (1 \otimes \mathcal{E}(f)_A) = \mathcal{E}(f)_A \circ \varphi_{\mathcal{E},A}$ after inverting I, $\mathcal{E}(\mathrm{id}_T)_A = \mathrm{id}$, $\mathcal{E}(f' \circ f)_A = \mathcal{E}(f')_A \circ \mathcal{E}(f)_A$, and the isomorphisms (Bs3) for T and T' carry $\mathcal{E}(f)_{A_{\mathrm{inf}}} \otimes 1$ to $f \otimes 1$.*

(Bs6) *Full faithfulness: the maps of (Bs5) exist for arbitrary data. Let T_0, T_1 be finite free $\mathbb{Z}_p$-modules with continuous G_K-actions, crystalline after inverting p, and let $\mathcal{E}_0$, $\mathcal{E}_1$ be data as in (Bs1), (Bs2), each with an isomorphism $c_\nu\colon \mathcal{E}_\nu(A_{\mathrm{inf}}) \otimes_{A_{\mathrm{inf}}} W(\mathbb{C}_p^\flat) \cong T_\nu \otimes_{\mathbb{Z}_p} W(\mathbb{C}_p^\flat)$ with the properties of (Bs3). Then every G_K-equivariant $\mathbb{Z}_p$-linear $f\colon T_0 \to T_1$ induces A-linear maps $\mathcal{E}(f)_A\colon \mathcal{E}_0(A) \to \mathcal{E}_1(A)$, for all objects (A, I) over $\mathcal{O}_K$, compatible with the maps $\mathcal{E}_\nu(g)$ of (Bs2) and with the Frobenius isomorphisms, such that $c_1 \circ (\mathcal{E}(f)_{A_{\mathrm{inf}}} \otimes 1) = (f \otimes 1) \circ c_0$.*

Proof. Bhatt and Scholze [31]: the datum $\mathcal{E}$ is a prismatic F-crystal in vector bundles on the absolute prismatic site of $\mathrm{Spf}(\mathcal{O}_K)$ (their Definition 1.1 and 4.1: (Bs1) and (Bs2) are the definition of a vector bundle with Frobenius on the ringed site); its existence with étale realisation T is the essential surjectivity in their Theorem 5.6 (Theorem 1.2 of the introduction), stated for T finite free over $\mathbb{Z}_p$ with $T[1/p]$ crystalline. The prism $(A_{\mathrm{inf}}, \ker\tilde{\theta})$ with $\ker\tilde{\theta} = ([p]_q)$, $q = [\varepsilon]$, $\mu = q - 1$, is the perfect prism of $\mathcal{O}_{\mathbb{C}_p}$ (their §5, standing notation before Theorem 5.2), and M is the Breuil–Kisin–Fargues module of the restriction of $\mathcal{E}$ to $\mathrm{Spf}(\mathcal{O}_{\mathbb{C}_p})$, with its G_K-equivariant structure from the descent along $\mathrm{Spf}(\mathcal{O}_{\mathbb{C}_p}) \to \mathrm{Spf}(\mathcal{O}_K)$. (Bs3) is the construction following their Theorem 5.2: $T = (M \otimes W(\mathbb{C}_p^\flat))^{\varphi=1}$, Artin–Schreier theory gives $M \otimes W(\mathbb{C}_p^\flat) \cong T \otimes W(\mathbb{C}_p^\flat)$ extending the identity of T on φ-invariants, and it restricts to $M[1/\mu] \cong T \otimes A_{\mathrm{inf}}[1/\mu]$ by [30], Lemma 4.26; the G_K-equivariance is used in the proof of their Proposition 5.3. (Bs4) is the commutativity of the diagram of their Construction 5.5, which they deduce from Theorem 5.2 and their Remark 5.4: for an F-crystal on $\mathrm{Spf}(\mathcal{O}_K)$ with crystalline étale realisation T, the lattice

$F = \varphi^*M \otimes_{A_{\mathrm{inf}}} B^+_{\mathrm{dR}}$ attached to its restriction to $\mathrm{Spf}(\mathcal{O}_{\mathbb{C}_p})$ in the construction following Theorem 5.2 (the image of φ^*M under the Frobenius, inside $M \otimes B_{\mathrm{dR}} \cong T \otimes B_{\mathrm{dR}}$, the isomorphism coming from $M[1/\mu] \cong T \otimes A_{\mathrm{inf}}[1/\mu]$ because μ is invertible at the Hodge–Tate point) is $D_{\mathrm{dR}}(V) \otimes_K B^+_{\mathrm{dR}}$, the image of $B^+_{\mathrm{dR}} \otimes_K (V \otimes B_{\mathrm{dR}})^{G_K}$ under the natural map; their B^+_{dR} (Notation 5.1: the completion of $A_{\mathrm{inf}}[1/p]$ at $\tilde{\theta}$, uniformiser $[p]_q$) is our B'^+. (Bs5) is the full faithfulness in their Theorem 5.6 (Theorem 1.2: the étale realisation is an equivalence of categories between prismatic F-crystals in vector bundles on $\mathcal{O}_K$ and lattices in crystalline representations of G_K): a map of realisations is the realisation of a unique map of F-crystals, i.e. a compatible family of A-linear maps commuting with Frobenius and base change, and the identification (Bs3) is natural in the crystal. (Bs6) is the same full faithfulness applied to $\mathcal{E}_0$, $\mathcal{E}_1$: since c_ν has the properties of (Bs3), it identifies the étale realisation $(\mathcal{E}_\nu(A_{\mathrm{inf}}) \otimes W(\mathbb{C}_p^\flat))^{\varphi=1}$ of $\mathcal{E}_\nu$ G_K-equivariantly with T_ν; so f is a map of étale realisations, hence the realisation of a unique map of F-crystals $\mathcal{E}_0 \to \mathcal{E}_1$, whose components are the maps $\mathcal{E}(f)_A$, and $c_1 \circ (\mathcal{E}(f)_{A_{\mathrm{inf}}} \otimes 1) = (f \otimes 1) \circ c_0$ holds on φ-invariants, hence everywhere by $W(\mathbb{C}_p^\flat)$-linearity. *Notation.* Their $q, \mu, \tilde{\xi}, \tilde{\theta}$ are our $[\varepsilon]$, μ_ε, $\tilde{\xi}$, $\tilde{\theta}$, with ε the element of Theorem B.40, $\varepsilon^\sharp = 1$. □

Theorem B.42. *Let p be a prime, $F \subset \overline{\mathbb{Q}}_p$ a finite extension of $\mathbb{Q}_p$, $F_\infty = F(\mu_{p^\infty})$, $\widehat{F}_\infty$ the closure of F_∞ in $\mathbb{C}_p$, $\mathfrak{m}_{F_\infty}$ the maximal ideal of the valuation ring of F_∞, and $H_F = \mathrm{Gal}(\overline{\mathbb{Q}}_p/F_\infty) \subseteq G_F$, acting on $\mathbb{C}_p$ by continuity.*

1. *(Ax–Sen–Tate) For every closed subgroup H of $G_{\mathbb{Q}_p}$, $\{c \in \mathbb{C}_p : hc = c \text{ for all } h \in H\}$ is the closure in $\mathbb{C}_p$ of the fixed field of H in $\overline{\mathbb{Q}}_p$. In particular the H_F-invariants of $\mathbb{C}_p$ form $\widehat{F}_\infty$, and the G_F-invariants form F.*
2. *(Tate) If $j \neq 0$ is an integer and $c \in \mathbb{C}_p$ satisfies $\chi_{\mathrm{cyc}}(g)^j\, gc = c$ for all $g \in G_F$, then $c = 0$.*
3. *(Tate) For every finite extension $L \subset \overline{\mathbb{Q}}_p$ of F_∞ with valuation ring $\mathcal{O}_L$, $\mathrm{Tr}_{L/F_\infty}(\mathcal{O}_L) \supseteq \mathfrak{m}_{F_\infty}$.*

Proof. Tate [251], Section 3: item 3 is the statement that the cyclotomic tower is deeply ramified (the different of a finite extension of the layers tends to the unit ideal), proved for a totally ramified $\mathbb{Z}_p$-extension; F_∞ is such an extension of $F(\mu_{p^n})$ for n large, and a finite extension of F_∞ is a finite extension of that $\mathbb{Z}_p$-extension. Item 2 is $H^0(G_F, \mathbb{C}_p(j)) = 0$ for $j \neq 0$, in the notation $\mathbb{C}_p(j) = \mathbb{C}_p \otimes \mathbb{Z}_p(j)$, where an invariant $c \otimes \epsilon^{\otimes j}$ is exactly a solution of $\chi_{\mathrm{cyc}}(g)^j gc = c$. Item 1 for closed subgroups of $G_{\mathbb{Q}_p}$ in general is due to Ax [15], Sen and Tate; see also [52], Section 2 and the chapter on Sen theory, for all three items. □

Theorem B.43. *Let p be a prime, K a finite extension of $\mathbb{Q}_p$ and V a finite-dimensional continuous $\mathbb{Q}_p$-linear representation of G_K which is de Rham. Put $D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}$ and $\mathrm{Fil}^0 D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V) \cap (\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)$. Then*

$$\dim_{\mathbb{Q}_p} H^1_f(G_K, V) = \dim_{\mathbb{Q}_p} H^0(G_K, V) + \dim_{\mathbb{Q}_p} (D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 D_{\mathrm{dR}}(V)).$$

Proof. [34], Corollary 3.8.4. *Notation.* Their K, V, $H^1_f(K, V)$ (the kernel of $H^1(K, V) \to H^1(K, B_{\mathrm{crys}} \otimes V)$) are ours; their $D_{\mathrm{dR}}(V)/D^0_{\mathrm{dR}}(V)$ is $D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 D_{\mathrm{dR}}(V)$. □

Theorem B.44. *Let ℓ be a prime and F_v a finite extension of $\mathbb{Q}_\ell$, with absolute Galois group G_{F_v} and inertia subgroup I_{F_v}. Then $H^1_f(G_{F_v}, \mathbb{Q}_\ell) \subseteq H^1(G_{F_v}, \mathbb{Q}_\ell) = \mathrm{Hom}_{\mathrm{cont}}(G_{F_v}, \mathbb{Q}_\ell)$ consists exactly of the homomorphisms that vanish on I_{F_v}.*

Proof. [34], Example 3.9 (case $r = 0$: "$H^1_f(K, \mathbb{Q}_p) \subset \mathrm{Hom}(\mathrm{Gal}(\overline{K}/K), \mathbb{Q}_p)$ are the unramified homomorphisms"). *Notation.* Their K, p are F_v, ℓ; their H^1_f is the kernel of $H^1(K, V) \to H^1(K, B_{\mathrm{crys}} \otimes V)$, which is the local condition of Definition 22.2 at a place above ℓ. □

Theorem B.45. *Let p be a prime and K a finite extension of $\mathbb{Q}_p$. If V and V' are crystalline finite-dimensional continuous $\mathbb{Q}_p$-linear representations of G_K, then every G_K-stable subspace of V, every quotient of V by a G_K-stable subspace, $V \oplus V'$, $V \otimes_{\mathbb{Q}_p} V'$ and the dual V^* are crystalline.*

Proof. [94]; [52], Theorem 5.2.1 (the category of B-admissible representations of an (F, G)-regular ring B is stable under subobjects, quotients, direct sums, tensor products and duals) with $B = B_{\mathrm{cris}}$, which is $(\mathbb{Q}_p, G_K)$-regular ([52], §9.1). *Notation.* Here B_{cris}-admissible means crystalline in the sense fixed in Section 13. □

Theorem B.46. *Let p be a prime and F a finite extension of $\mathbb{Q}_p$ with maximal unramified subfield F_0.*

1. *For every integer $i \geq 1$, $H^0(G_F, t^i B^+_{\mathrm{dR}}) = H^1(G_F, t^i B^+_{\mathrm{dR}}) = 0$.*
2. *Let V be a de Rham representation of G_F on a finite-dimensional $\mathbb{Q}_p$-vector space, $V^*(1) = \mathrm{Hom}_{\mathbb{Q}_p}(V, \mathbb{Q}_p(1))$, $H^1_f(F, V) = \ker\big(H^1(G_F, V) \to H^1(G_F, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_p} V)\big)$ and $H^1_g(F, V) = \ker\big(H^1(G_F, V) \to H^1(G_F, B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)\big)$. Then $H^1_f(F, V) \subseteq H^1_g(F, V)$ and*

$$\dim_{\mathbb{Q}_p} H^1_g(F, V) = \dim_{\mathbb{Q}_p} H^1_f(F, V) + \dim_{\mathbb{Q}_p} D_{\mathrm{cris}}\big(V^*(1)\big)^{\varphi=1}.$$

Proof. Item 2: Bloch and Kato [34], Corollary 3.8.4 (with their definitions of H^1_f and H^1_g in Section 3; the inclusion $H^1_f \subseteq H^1_g$ comes from $B_{\mathrm{cris}} \subset B_{\mathrm{dR}}$). Item 1 is the consequence of Tate's theorem $H^0(G_F, \mathbb{C}_p(j)) = H^1(G_F, \mathbb{C}_p(j)) = 0$ for $j \neq 0$ [251], applied to the graded pieces $t^j B^+_{\mathrm{dR}}/t^{j+1} B^+_{\mathrm{dR}} \cong \mathbb{C}_p(j)$, $j \geq i$, and passage to the limit; it is used in this form in [34], Section 3, and stated in [52]. *Notation.* Their K is our F. □

Theorem B.47. *Let p be a prime, F a finite extension of $\mathbb{Q}_p$, $j \in \mathbb{Z}$, and $c\colon G_F \to \mathbb{C}_p$ a continuous map with $c(\sigma\tau) = c(\sigma) + \chi_{\mathrm{cyc}}(\sigma)^j \sigma\big(c(\tau)\big)$ for $\sigma, \tau \in G_F$.*

1. *If $j \neq 0$, there is $y \in \mathbb{C}_p$ with $c(\sigma) = \chi_{\mathrm{cyc}}(\sigma)^j \sigma(y) - y$ for all $\sigma \in G_F$.*
2. *If $j = 0$, there are $\alpha \in F$ and $y \in \mathbb{C}_p$ with $c(\sigma) = \alpha \log \chi_{\mathrm{cyc}}(\sigma) + \sigma(y) - y$ for all $\sigma \in G_F$.*

Proof. Tate, *p-divisible groups*, Driebergen 1966 (published 1967) [251], Section 3.3, Theorem 2: $H^1_{\mathrm{cont}}(G_F, \mathbb{C}_p(j)) = 0$ for $j \neq 0$, and $H^1_{\mathrm{cont}}(G_F, \mathbb{C}_p)$ is a one-dimensional F-vector space spanned by the class of the homomorphism $\log \chi_{\mathrm{cyc}}$. Notation: $\mathbb{C}_p(j)$ is $\mathbb{C}_p$ with the action $\sigma \mapsto \chi_{\mathrm{cyc}}(\sigma)^j \sigma$; a continuous 1-cocycle is a map c as in the statement, and it is zero in H^1 exactly when it has the form $\sigma \mapsto \chi_{\mathrm{cyc}}(\sigma)^j \sigma(y) - y$. □

Theorem B.48. *Let p be a prime, K_0 a finite unramified extension of $\mathbb{Q}_p$, $e \geq 0$ an integer, $T = \mathbb{Z}_p(-e)$ with basis e_{-e}, on which G_{K_0} acts by χ^{-e}_{cyc}, and $V = T \otimes_{\mathbb{Z}_p} \mathbb{Q}_p$; V is crystalline. Let $f \in \mathcal{O}_{K_0}[[X]]$ with $\psi(f(\pi)) = f(\pi)$, so that $y = f(\pi) \otimes e_{-e} \in \mathbf{D}(T)^{\psi=1}$, and let $n \geq 1$. Then:*

1. *(Fontaine; Cherbonnier–Colmez II.1; [25], Theorem II.8.) The classes $h^1_{K_m,V}(y)$, $m \geq 1$, form an element of $H^1_{\mathrm{Iw}}(K_0, T) = \varprojlim_{\mathrm{cor}} H^1(K_m, T)$; in particular $h^1_{K_n,V}(y)$ is the image of a class in $H^1(K_n, T)$.*

2. *(Cherbonnier–Colmez IV.2.1; [25], Theorem II.6.)*
$$\exp^*_{K_n,V^*(1)}\big(h^1_{K_n,V}(y)\big) = p^{-n}\,\partial_V\big(\varphi^{-n}(y)\big).$$

3. *(Kato's formula; [25], Proposition II.5, applied over K_n as in the proof of Theorem II.6.) The map $D_{\mathrm{dR}}(V|_{G_{K_n}}) \to H^1(K_n, B_{\mathrm{dR}}\otimes_{\mathbb{Q}_p} V)$, $x \mapsto [\sigma \mapsto \log\chi_{\mathrm{cyc}}(\sigma)\,x]$, is an isomorphism, and $\exp^*_{K_n,V^*(1)}$ is the composite of $H^1(K_n,V) \to H^1(K_n, B_{\mathrm{dR}}\otimes_{\mathbb{Q}_p} V)$ with its inverse.*

Proof. Quoted from L. Berger, *Bloch and Kato's exponential map: three explicit formulas*, Doc. Math. Extra Vol. Kato (2003), 99–129 [25]: item 1 is Theorem II.8 (due to Fontaine, proved by Cherbonnier and Colmez, J. Amer. Math. Soc. 12 (1999), II.1) together with the sentence preceding it (for $y \in \mathbf{D}(T)^{\psi=1}$ the $h^1_{K_m,V}(y)$ are compatible under corestriction and define an element of $H^1_{\mathrm{Iw}}(K,T)$); item 2 is Theorem II.6, which the text attributes to Cherbonnier and Colmez, loc. cit., IV.2.1, for $y \in \mathbf{D}^\dagger_{\mathrm{rig}}(V)^{\psi=1} \supset \mathbf{D}(V)^{\psi=1}$ (inclusion as in Proposition I.5 there), every crystalline V of G_F, $F = W(k)[1/p]$, and every $n \geq 1$; item 3 is Proposition II.5, which the proof of Theorem II.6 applies over F_n. The map h^1 is that of Proposition I.5 (with the normalisation $\log^0_p(\chi(\gamma))$; for Γ_n with torsion, i.e. $p = 2$ and $n = 1$, by corestriction, §I.3 there). Notation: Berger's F, F_n, $\varepsilon^{(n)}$, χ are K_0, K_n, ζ_{p^n}, χ_{cyc}; the statement is the case $V = \mathbb{Q}_p(-e)$, $y \in \mathbf{D}(T)^{\psi=1}$ of the printed results. The criterion for $\psi(f(\pi)) = f(\pi)$ is the one printed in the proof of Lemma II.1 there. □

Theorem B.49. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and V a de Rham representation of G_M on a finite-dimensional $\mathbb{Q}_\ell$-vector space; put $V^*(1) = \mathrm{Hom}_{\mathbb{Q}_\ell}(V,\mathbb{Q}_\ell)\otimes\chi_{\mathrm{cyc}}$. Let*
$$\langle\ ,\ \rangle\colon H^1(G_M,V)\times H^1\big(G_M,V^*(1)\big) \longrightarrow H^2\big(G_M,\mathbb{Q}_\ell(1)\big)$$
be the cup product followed by the evaluation map $V\otimes_{\mathbb{Q}_\ell} V^*(1) \to \mathbb{Q}_\ell(1)$. Then $H^1_f(G_M,V)$ and $H^1_f(G_M,V^*(1))$ are exact annihilators of each other: a class $c \in H^1(G_M,V)$ lies in $H^1_f(G_M,V)$ if and only if $\langle c,y\rangle = 0$ for every $y \in H^1_f(G_M,V^*(1))$, and symmetrically.

Proof. [34], Proposition 3.8 (case $l = p$, under the hypothesis made there that V is de Rham). *Notation.* Their K, p, V, V^* are M, ℓ, V, $\mathrm{Hom}_{\mathbb{Q}_\ell}(V,\mathbb{Q}_\ell)$; their $H^1_f(K,V)$ is the kernel of $H^1(K,V) \to H^1(K, B_{\mathrm{crys}}\otimes V)$, ours; the pairing is the cup product into $H^2(K,\mathbb{Q}_p(1)) \cong \mathbb{Q}_p$. □

Theorem B.50. *Let p be a prime, F a finite extension of $\mathbb{Q}_p$, L a finite extension of $\mathbb{Q}_p$ with ring of integers $\mathcal{O}_L$, and $\mathcal{D}_L = L/\mathcal{O}_L$. For an $\mathcal{O}_L$-module X write $X(1) = X\otimes_{\mathbb{Z}_p}\mathbb{Z}_p(1)$. Let T be a free $\mathcal{O}_L$-module of finite rank with a continuous $\mathcal{O}_L$-linear action of G_F, $V = T\otimes_{\mathcal{O}_L} L$, and*
$$T^* = \mathrm{Hom}_{\mathcal{O}_L}(T,\mathcal{O}_L(1)), \qquad V^* = \mathrm{Hom}_L(V,L(1)) = T^*\otimes_{\mathcal{O}_L} L,$$
$$W^* = V^*/T^* = \mathrm{Hom}_{\mathcal{O}_L}(T,\mathcal{D}_L(1)),$$
with G_F acting by $(gf)(x) = g\,f(g^{-1}x)$, W^* discrete. Let $H^1_f(F,T)$ be the inverse image of $H^1_f(F,V)$ under the natural map $H^1(F,T) \to H^1(F,V)$, and let $H^1_f(F,W^*)$ be the image of $H^1_f(F,V^*)$ under the natural map $H^1(F,V^*) \to H^1(F,W^*)$. Then:

1. *the local invariant gives isomorphisms*
$$H^2(F,\mathcal{O}_L(1)) \cong \mathcal{O}_L, \qquad H^2(F,L(1)) \cong L, \qquad H^2(F,\mathcal{D}_L(1)) \cong \mathcal{D}_L,$$
compatible with the maps induced by $\mathcal{O}_L \subset L \to \mathcal{D}_L$; and the cup products composed with the evaluation maps give $\mathcal{O}_L$-bilinear perfect pairings
$$H^1(F,V)\times H^1(F,V^*) \to L, \qquad H^1(F,T)\times H^1(F,W^*) \to \mathcal{D}_L;$$

2. *if V is de Rham, $H^1_f(F,T)$ and $H^1_f(F,W^*)$ are exact orthogonal complements of each other under the second pairing.*

Proof. Item 1 is local Tate duality with $\mathcal{O}_L$-coefficients, [209], Chapter I, Theorem 4.1 (with $\Phi = L$, $\mathcal{O} = \mathcal{O}_L$, $\mathbf{D} = \mathcal{D}_L$, $i = 1$), which refers to [172], Corollary I.2.3, and [222], II.5.2. Item 2 is [209], Chapter I, Proposition 4.3(i), case (c) (residue characteristic p, with the chosen subspaces $H^1_f(F,V)$, $H^1_f(F,V^*)$, which are orthogonal complements of each other for V de Rham by [34], Proposition 3.8, as recorded with coefficients in L in [209], Chapter I, Remark 7.1; the $\mathbb{Q}_p$-form is Theorem B.49), with $H^1_f(F,T)$ and $H^1_f(F,W^*)$ defined as inverse image and image as in Definition I.3.4 there. *Notation.* Rubin's K, T, V, T^*, V^*, W^*, $\mathbf{D}$, $\langle\ ,\ \rangle_K$ are our F, T, V, T^*, V^*, W^*, $\mathcal{D}_L$ and the pairings of item 1; "orthogonal complements" there means exact annihilators of each other. □

Theorem B.51. *Let p be an odd prime, K a finite unramified extension of $\mathbb{Q}_p$ with residue field k_K, $\mathcal{O}_K = W(k_K)$, and $w\colon \mathcal{O}_K \to W(\mathbb{C}_p^\flat)$ the map of Witt vectors induced by the embedding of k_K into $\mathcal{O}_{\mathbb{C}_p^\flat}$ lifting $k_K \subset \mathcal{O}_{\mathbb{C}_p}/\mathfrak{m}$; $W(\mathbb{C}_p^\flat)$ carries its Witt vector Frobenius φ and the action of G_K. Put $\pi = [\varepsilon] - 1$. Then:*

(Fi1) The rings *Let $w(\mathcal{O}_K)[[\pi]] \subseteq A_{\mathrm{inf}}$ be the ring of the series $\sum_{m\geq 0} w(a_m)\pi^m$, $a_m \in \mathcal{O}_K$ (convergent for the topology of (Ai2), as $\pi \in (p,[p^\flat])$). The p-adic closure $\mathcal{O}_{\mathcal{E}_K}$ in $W(\mathbb{C}_p^\flat)$ of $w(\mathcal{O}_K)[[\pi]][1/\pi]$ is a complete discrete valuation ring with uniformiser p and residue field $\mathbf{E}_K$ (reduction modulo p being the reduction $W(\mathbb{C}_p^\flat) \to \mathbb{C}_p^\flat$, under which $\pi \mapsto \bar{\pi}$); it is stable under φ and G_K, and H_K acts trivially on it. The p-adic closure $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}}$ in $W(\mathbb{C}_p^\flat)$ of the maximal unramified extension of $\mathcal{O}_{\mathcal{E}_K}$ in $W(\mathbb{C}_p^\flat)$ is stable under φ and G_K, $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}}/p\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} = \mathbf{E}^{\mathrm{sep}} \subset \mathbb{C}_p^\flat$, and $(\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}})^{H_K} = \mathcal{O}_{\mathcal{E}_K}$.*

(Fi2) Representations *For a $\mathbb{Z}_p$-module T of finite type with a continuous $\mathbb{Z}_p$-linear action of G_K put $\mathbf{D}(T) = (\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathbb{Z}_p} T)^{H_K}$, with $\varphi\otimes 1$ and the induced action of Γ_K. The functor $T \mapsto \mathbf{D}(T)$ is exact; if T is free of rank d, then $\mathbf{D}(T)$ is a free $\mathcal{O}_{\mathcal{E}_K}$-module of rank d and the natural map $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathcal{O}_{\mathcal{E}_K}} \mathbf{D}(T) \to \mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathbb{Z}_p} T$ is a G_K-equivariant isomorphism commuting with φ; if $pT = 0$, $\mathbf{D}(T) = (\mathbf{E}^{\mathrm{sep}} \otimes_{\mathbb{F}_p} T)^{H_K}$ is the module of Theorem B.52.*

(Fi3) Étale φ-modules *If M is a free $\mathcal{O}_{\mathcal{E}_K}$-module of finite rank d with a φ-semilinear map $\varphi_M\colon M \to M$ whose linearisation $\mathcal{O}_{\mathcal{E}_K} \otimes_{\varphi,\mathcal{O}_{\mathcal{E}_K}} M \to M$ is an isomorphism, then $T(M) = (\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathcal{O}_{\mathcal{E}_K}} M)^{\varphi=1}$ is a free $\mathbb{Z}_p$-module of rank d and the natural map $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathbb{Z}_p} T(M) \to \mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}} \otimes_{\mathcal{O}_{\mathcal{E}_K}} M$ is an isomorphism commuting with φ.*

Proof. This is Fontaine's theory of (φ,Γ)-modules [93], Part A: (Fi3) is the equivalence between $\mathbb{Z}_p$-representations of the absolute Galois group of a field of characteristic p and étale φ-modules over a Cohen ring of it (§A.1), applied to $\mathbf{E}_K$, whose Cohen ring is $\mathcal{O}_{\mathcal{E}_K}$ with the unramified closure $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}}$ (§A.1, A.3.1); (Fi2) is the equivalence between $\mathbb{Z}_p$-representations of finite type of G_K and étale (φ,Γ_K)-modules over $\mathcal{O}_{\mathcal{E}_K}$, an exact functor (§A.3.4), the case $pT = 0$ being the reduction $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}}/p = \mathbf{E}^{\mathrm{sep}}$; (Fi1) is the explicit description of these rings inside $W(\mathrm{Fr}\,R) = W(\mathbb{C}_p^\flat)$ for K unramified, where $\mathcal{O}_{\mathcal{E}_K}$ is the p-adic completion of $\mathcal{O}_K[[\pi]][1/\pi]$ (§A.3.1; also [26], §I). *Notation.* Fontaine's R, $\mathcal{O}_{\mathcal{E}}$, $\mathcal{O}_{\widehat{\mathcal{E}^{\mathrm{ur}}}}$, $D(V)$, $\pi = [\varepsilon] - 1$ are $\mathcal{O}_{\mathbb{C}_p^\flat}$, $\mathcal{O}_{\mathcal{E}_K}$, $\mathcal{O}_{\widehat{\mathcal{E}}^{\mathrm{ur}}}$, $\mathbf{D}(T)$, π. □

Theorem B.52. *Let p be an odd prime, K a finite extension of $\mathbb{Q}_p$, $K_\infty = K(\mu_{p^\infty})$, $H_K = \mathrm{Gal}(\overline{K}/K_\infty)$ and $\Gamma_K = \mathrm{Gal}(K_\infty/K)$. Let $\mathbf{E}_K$ be the field of norms of K_∞/K, a complete discretely valued field of characteristic p with the Frobenius $\varphi(x) = x^p$ and a continuous action*

of Γ_K commuting with φ, and $\mathbf{E}^{\mathrm{sep}}$ a separable closure of $\mathbf{E}_K$, with its continuous action of G_K commuting with φ, under which $H_K \cong \mathrm{Gal}(\mathbf{E}^{\mathrm{sep}}/\mathbf{E}_K)$ and $(\mathbf{E}^{\mathrm{sep}})^{H_K} = \mathbf{E}_K$. If K is unramified over $\mathbb{Q}_p$ with residue field k_K, then $\mathbf{E}_K = k_K((\bar\pi))$ with $\varphi(\bar\pi) = \bar\pi^p$ and $g(\bar\pi) = (1+\bar\pi)^{\chi_{\mathrm{cyc}}(g)} - 1$ for $g \in \Gamma_K$, where $\bar\pi = \varepsilon - 1$ for a compatible system $\varepsilon = (\zeta_{p^m})_m$ of primitive p^m-th roots of unity.

*An **étale (φ,Γ_K)-module** over $\mathbf{E}_K$ is a finite-dimensional $\mathbf{E}_K$-vector space D with a φ-semilinear map $\varphi_D\colon D \to D$ whose image spans D over $\mathbf{E}_K$, and a continuous semilinear action of Γ_K commuting with φ_D; morphisms are the $\mathbf{E}_K$-linear maps commuting with φ_D and with Γ_K. For a finite-dimensional $\mathbb{F}_p$-vector space V with a continuous linear action of G_K (discrete topology) put*

$$\mathbf{D}(V) = \left(\mathbf{E}^{\mathrm{sep}} \otimes_{\mathbb{F}_p} V\right)^{H_K},$$

with $\varphi_{\mathbf{D}(V)} = \varphi \otimes 1$ and the action of $\Gamma_K = G_K/H_K$ induced by the diagonal action of G_K. Then:

(Fe1) *$\mathbf{D}(V)$ is an étale (φ,Γ_K)-module with $\dim_{\mathbf{E}_K} \mathbf{D}(V) = \dim_{\mathbb{F}_p} V$, and the natural map $\mathbf{E}^{\mathrm{sep}} \otimes_{\mathbf{E}_K} \mathbf{D}(V) \to \mathbf{E}^{\mathrm{sep}} \otimes_{\mathbb{F}_p} V$ is a G_K-equivariant isomorphism commuting with φ;*

(Fe2) *$V \mapsto \mathbf{D}(V)$ is an exact equivalence of categories from the category of such representations (morphisms: G_K-equivariant $\mathbb{F}_p$-linear maps) to the category of étale (φ,Γ_K)-modules over $\mathbf{E}_K$, with quasi-inverse $D \mapsto \left(\mathbf{E}^{\mathrm{sep}} \otimes_{\mathbf{E}_K} D\right)^{\varphi=1}$.*

Proof. This is Fontaine's theorem [93], Part A, §A.3.4 (Théorème A.3.4.3), in the case of representations killed by p (Fontaine's construction in characteristic 0 through Γ_K is made for $p \neq 2$): Fontaine proves the equivalence between $\mathbb{Z}_p$-representations of finite type of G_K and étale (φ,Γ_K)-modules over $\mathcal{O}_{\mathcal{E}_K}$, and $\mathcal{O}_{\mathcal{E}_K}/p = \mathbf{E}_K$, $\mathcal{O}_{\widehat{\mathcal{E}^{\mathrm{ur}}}}/p = \mathbf{E}^{\mathrm{sep}}$; the case killed by p is the underlying statement for étale φ-modules over $\mathbf{E}_K$ (Fontaine, §A.1), to which the action of Γ_K is added by functoriality. The field of norms is that of Fontaine and Wintenberger [97]; its description for K unramified is Fontaine, §A.3.1. *Notation.* Fontaine's E_K, E^{sep}, $D(V)$, $\Phi\Gamma^{\mathrm{et}}(E_K)$ are $\mathbf{E}_K$, $\mathbf{E}^{\mathrm{sep}}$, $\mathbf{D}(V)$ and the étale (φ,Γ_K)-modules above. □

Theorem B.53. *Let p be a prime and K an extension of $\mathbb{Q}_p$, complete for a valuation $v\colon K \to \mathbb{R}\cup\{+\infty\}$ with $v(p) = 1$ (no hypothesis on the residue field; v need not be discrete); let $\overline{K}$ be an algebraic closure of K, v the extended valuation and $\mathcal{O}_{\overline{K}}$ its valuation ring. Let Γ be a commutative finite flat group scheme over $\mathcal{O}_K$ of order a power of p, with Cartier dual Γ^D and ω_{Γ^D} the $\mathcal{O}_K$-module of invariant differentials of Γ^D. For $x \in \Gamma(\mathcal{O}_{\overline{K}}) = \mathrm{Hom}(\Gamma^D_{\mathcal{O}_{\overline{K}}}, \mathbb{G}_m)$ let $\alpha_\Gamma(x) = x^*\frac{dT}{T} \in \omega_{\Gamma^D} \otimes_{\mathcal{O}_K} \mathcal{O}_{\overline{K}}$ (the Hodge–Tate map). Then the cokernel of*

$$\alpha_\Gamma \otimes 1\colon\ \Gamma(\mathcal{O}_{\overline{K}}) \otimes_{\mathbb{Z}} \mathcal{O}_{\overline{K}} \longrightarrow \omega_{\Gamma^D} \otimes_{\mathcal{O}_K} \mathcal{O}_{\overline{K}}$$

is killed by every element of $\mathcal{O}_{\overline{K}}$ of valuation $\geq \frac{1}{p-1}$: for every $a \in \mathcal{O}_{\overline{K}}$ with $v(a) \geq \frac{1}{p-1}$, $a\,(\omega_{\Gamma^D} \otimes \mathcal{O}_{\overline{K}})$ is contained in the $\mathcal{O}_{\overline{K}}$-span of $\alpha_\Gamma(\Gamma(\mathcal{O}_{\overline{K}}))$.

Proof. Fargues, La filtration canonique des points de torsion des groupes p-divisibles [89], Section 5.4, Théorème 3 (p. 935), deduced there from Théorème 2 and attributed to Théorème 6 of Fargues, La filtration de Harder–Narasimhan des schémas en groupes finis et plats, J. reine angew. Math. 645 (2010); standing notation of the paper (p. 911 and p. 911–912): K complete for a real valuation with $v(p) = 1$, no hypothesis on the residue field, finite flat group schemes commutative of order a power of p, $\alpha_G\colon G(\mathcal{O}_{\overline{K}}) \to \omega_{G^D} \otimes \mathcal{O}_{\overline{K}}$. Notation: Fargues writes G for Γ. □

Theorem B.54. *Let p be a prime and K an extension of $\mathbb{Q}_p$, complete for a valuation $v\colon K \to \mathbb{R}\cup\{+\infty\}$ with $v(p)=1$ (no hypothesis on the residue field); let C be the completion of an algebraic closure of K, $\mathcal{O}_C$ its ring of integers, and v the extended valuation. Let H be a p-divisible group over $\mathcal{O}_K$ with Cartier dual H^D, Tate module $T_p(H)$, and Hodge–Tate map $\alpha_H\colon T_p(H)\to \omega_{H^D}\otimes\mathcal{O}_C$, $x\mapsto (x^D)^*\frac{dT}{T}$. Then the cohomology of the complex of $\mathcal{O}_C$-modules*

$$0 \longrightarrow \mathrm{Lie}(H)\otimes\mathcal{O}_C(1) \xrightarrow{{}^t(\alpha_{H^D}\otimes 1)(1)} T_p(H)\otimes_{\mathbb{Z}_p}\mathcal{O}_C \xrightarrow{\alpha_H\otimes 1} \omega_{H^D}\otimes\mathcal{O}_C \longrightarrow 0$$

is killed by every element of $\mathcal{O}_C$ of valuation $\geq \frac{1}{p-1}$. In particular the left map is injective, the composite is zero, and every $\kappa\in\mathcal{O}_C$ with $v(\kappa)\geq\frac{1}{p-1}$ satisfies $\kappa\,(\omega_{H^D}\otimes\mathcal{O}_C)\subseteq \mathrm{im}(\alpha_H\otimes 1)$.

Proof. Fargues, La filtration canonique des points de torsion des groupes p-divisibles [89], Théorème 2 (Section 5.3.2), which is Théorème II.1.1 of [88]; the finite flat version (cokernel of $\alpha_G\otimes 1$ for a finite flat group scheme G over $\mathcal{O}_K$ killed by elements of valuation $\geq\frac{1}{p-1}$) is Théorème 3 of [89]. Notation: Fargues writes $\omega_H^\vee$ for $\mathrm{Lie}(H)$, $\mathcal{O}_{\widehat{\overline{K}}}$ for $\mathcal{O}_C$. □

Theorem B.55. *Let L be a finite unramified extension of $\mathbb{Q}_p$ with Frobenius automorphism σ, and V a crystalline representation of G_L on a finite-dimensional $\mathbb{Q}_p$-vector space. Then $D=D_{\mathrm{cris}}(V)=(B_{\mathrm{cris}}\otimes_{\mathbb{Q}_p}V)^{G_L}$ is an L-vector space of dimension $\dim_{\mathbb{Q}_p}V$ with a bijective σ-semilinear endomorphism φ (from $\varphi\otimes 1$), the inclusion $B_{\mathrm{cris}}\subset B_{\mathrm{dR}}$ induces an isomorphism $D\cong D_{\mathrm{dR}}(V)=(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_p}V)^{G_L}$, through which D carries the exhaustive separated decreasing filtration $\mathrm{Fil}^iD=(\mathrm{Fil}^iB_{\mathrm{dR}}\otimes V)^{G_L}$, and D is **weakly admissible**: for every φ-stable L-subspace $D'\subseteq D$, with the induced filtration $\mathrm{Fil}^iD'=D'\cap\mathrm{Fil}^iD$,*

$$t_H(D')\leq t_N(D'),\qquad \text{with equality for } D'=D,$$

where $t_H(D')=\sum_{i\in\mathbb{Z}} i\dim_L(\mathrm{Fil}^iD'/\mathrm{Fil}^{i+1}D')$ and $t_N(D')=v_p(\det A)$ for the matrix A of $\varphi|_{D'}$ in any L-basis of D' ($v_p(p)=1$; this does not depend on the basis).

Proof. [96], Proposition 5.4.2 (admissible filtered φ-modules are weakly admissible; here with $N=0$), with the definition of t_H, t_N in Section 4 there and the equivalence of crystalline representations with admissible filtered φ-modules (Section 5); see also [70] (the converse, not used) and [52], Theorem 9.3.4 and Section 8.2. For L unramified, $L_0=L$ and $D_{\mathrm{cris}}(V)\otimes_{L_0}L=D_{\mathrm{cris}}(V)$. Independence of the basis: a change of basis by P replaces A by $P^{-1}A\sigma(P)$, and $v_p(\det\sigma(P))=v_p(\det P)$. □

Theorem B.56. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and V a de Rham representation of G_M on a finite-dimensional $\mathbb{Q}_\ell$-vector space. Let $D_{\mathrm{dR}}(V)=(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)^{G_M}$ with the filtration $\mathrm{Fil}^iD_{\mathrm{dR}}(V)=(\mathrm{Fil}^iB_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)^{G_M}$, and let $H^1_f(G_M,V)$ be the kernel of $H^1(G_M,V)\to H^1(G_M,B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)$. Then*

$$\dim_{\mathbb{Q}_\ell}H^1_f(G_M,V)=\dim_{\mathbb{Q}_\ell}(D_{\mathrm{dR}}(V)/\mathrm{Fil}^0D_{\mathrm{dR}}(V))+\dim_{\mathbb{Q}_\ell}H^0(G_M,V).$$

Proof. [34], Corollary 3.8.4 ("In particular,

$$\dim_{\mathbf{Q}_p}H^1_f(K,V)=\dim_{\mathbf{Q}_p}(DR(V)/DR(V)^0)+\dim_{\mathbf{Q}_p}H^0(K,V)",$$

for V a de Rham representation of $\mathrm{Gal}(\overline{K}/K)$, K finite over $\mathbf{Q}_p$). *Notation.* Their K, p, $DR(V)$, $DR(V)^0$ are M, ℓ, $D_{\mathrm{dR}}(V)$, $\mathrm{Fil}^0D_{\mathrm{dR}}(V)$; their $H^1_f(K,V)$ is the kernel of $H^1(K,V)\to H^1(K,B_{\mathrm{crys}}\otimes V)$, which is the local condition of Definition 22.2 at a place above ℓ (a class lies in the kernel exactly when a representing cocycle c satisfies $c(g)\otimes 1=gy-y$ for some $y\in V\otimes B_{\mathrm{cris}}$). □

Theorem B.57. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and $\mathcal{O}' \subset \overline{\mathbb{Q}}_\ell$ a coefficient ring with residue field $\mathbb{F}'$ whose fraction field contains the image of every field embedding $M \to \overline{\mathbb{Q}}_\ell$. Let $n \geq 1$, $\bar\rho\colon G_M \to \mathrm{GL}_n(\mathbb{F}')$ continuous, and $(R^\square, \rho^\square)$ the universal lifting ring of $\bar\rho$: $R^\square$ is a complete local Noetherian $\mathcal{O}'$-algebra with residue field $\mathbb{F}'$, $\rho^\square\colon G_M \to \mathrm{GL}_n(R^\square)$ is a continuous lift of $\bar\rho$, and for every complete local Noetherian $\mathcal{O}'$-algebra B with residue field $\mathbb{F}'$ every continuous lift of $\bar\rho$ to $\mathrm{GL}_n(B)$ is $f \circ \rho^\square$ for exactly one local $\mathcal{O}'$-algebra homomorphism $f\colon R^\square \to B$. For every field embedding $\tau\colon M \to \overline{\mathbb{Q}}_\ell$ let H_τ be a multiset of n integers. Then there is an ideal $\mathfrak{a} \subseteq R^\square$ such that $R^\square/\mathfrak{a}$ is reduced and has no ℓ-torsion, and such that for every valuation ring A of a finite extension of the fraction field of $\mathcal{O}'$ inside $\overline{\mathbb{Q}}_\ell$ and every $\mathcal{O}'$-algebra homomorphism $x\colon R^\square \to A$ with $x(\mathfrak{m}_{R^\square}) \subseteq \mathfrak{m}_A$: $x(\mathfrak{a}) = 0$ if and only if the representation $x \circ \rho^\square$ of G_M is crystalline and has τ-Hodge–Tate weights H_τ for every τ.*

Proof. See [17], Section 1.4 (the rings $R^\square_{\mathcal{O},\bar\rho,\{H_\tau\},\mathrm{cris}}$), whose existence is deduced there from [144], Corollary 2.6.2 and Theorem 2.5.5(2).

The published statement. With $\mathcal{O}$ the ring of integers of a finite extension L of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$ containing the image of each embedding $K \to \overline{\mathbb{Q}}_\ell$, $K/\mathbb{Q}_\ell$ finite, $\bar\rho\colon G_K \to \mathrm{GL}_n(\mathbb{F})$ and n-element multisets $\{H_\tau\}$ of integers: the universal lifting ring $R^\square_{\mathcal{O},\bar\rho}$ has a quotient $R^\square_{\mathcal{O},\bar\rho,\{H_\tau\},\mathrm{cris}}$, uniquely characterised by being reduced without ℓ-torsion and by the property that a $\overline{\mathbb{Q}}_\ell$-point of $R^\square_{\mathcal{O},\bar\rho}$ factors through it if and only if it corresponds to a representation $G_K \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ which is de Rham with $\mathrm{HT}_\tau = H_\tau$ for all τ and crystalline.

Comparison of notation. Their K, L, $\mathcal{O}$, $\mathbb{F}$ are our M, the fraction field of $\mathcal{O}'$, $\mathcal{O}'$, $\mathbb{F}'$; $\mathfrak{a}$ is the kernel of $R^\square \to R^\square_{\mathcal{O}',\bar\rho,\{H'_\tau\},\mathrm{cris}}$. In [17] the cyclotomic character has Hodge–Tate weight -1, so their multisets are $H'_\tau = \{-h : h \in H_\tau\}$. A homomorphism x as in the statement is a $\overline{\mathbb{Q}}_\ell$-point (it is local and lands in the valuation ring of a finite extension), and crystalline representations are de Rham. □

B.5 Automorphic forms and Galois representations

The automorphic input is used in Parts VII–IX and Appendix E. Its core is the Galois representations attached to automorphic representations, with local–global compatibility: Deligne's representations of newforms (Theorem B.59), the conjugate self-dual and polarizable cases of Shin, Chenevier–Harris, Barnet-Lamb–Gee–Geraghty–Taylor and Caraiani, with purity (Theorem B.58, Theorem B.62, Theorem B.73, Theorem B.90), Thorne's ordinary criterion (Theorem B.94) and the corresponding statements for GL_2 over $\mathbb{Q}$ and over totally real fields, together with the strong multiplicity one of Jacquet and Shalika (Theorem B.60); they are used in the counts of the plus part (Section 38), which also quotes the classical theory of newforms, Clozel's theorems on rationality and cohomological representations, Borel's injectivity of cuspidal cohomology and the valence formula, and in most sections of Part IX and in Appendix E. Part VIII uses the vanishing of adjoint Bloch–Kato Selmer groups of Newton and Thorne and of Thorne (Theorem B.68, Theorem B.69, Theorem B.70, Theorem B.72) in the one-character bounds (Sections 42 and 44), and Mazur's representability of framed deformations (Theorem B.71) for its deformation rings, which Part IX and Appendix E use as well. Part IX moves automorphy between fields by base change, descent and automorphic induction (Arthur and Clozel, Langlands, Barnet-Lamb–Gee–Geraghty–Taylor, Gelbart and Jacquet), and it quotes Katz's modular forms over rings and Hida's nearly ordinary families of Hilbert modular forms. Chenevier's theory of determinants (Theorem B.83 and the related statements of Chenevier and of Bellaïche–Chenevier) is used in Sections 50 and 53 and in Appendix E, which quotes in addition Geraghty's control theorems for ordinary forms on definite unitary groups (Theorem B.91,

Theorem B.98), the local Langlands correspondence for GL_n, Labesse's base change for unitary groups and the description of the discrete spectrum of GL_n by Moeglin and Waldspurger.

Theorem B.58. *Let E be a CM field, $n \geq 1$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_E)$ that is regular algebraic and conjugate self-dual. Then there is a continuous semisimple representation $r_{\ell,\iota}(\pi)\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that for every finite place $v \nmid \ell$ of E at which π_v is unramified, every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above v and every arithmetic Frobenius σ at $\bar{v}$: $r_{\ell,\iota}(\pi)$ is trivial on the inertia subgroup $I_{\bar{v}}$, and*

$$\iota\Big(\det\big(X - r_{\ell,\iota}(\pi)(\sigma^{-1})\big)\Big) = \prod_{\alpha}(X - q_v^{(n-1)/2}\alpha),$$

α running over the Satake parameters of π_v with multiplicity. In particular $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$.

Proof. [67], Theorem 3.2.3 (all n), and [231], Theorem 1.2 (n odd, or a mild condition at infinity for n even), building on [121] and [69]. For cuspidal π, regular algebraic in the sense of [68] is the same as cohomological, the hypothesis of these theorems ([68], Lemma 3.14). *Notation.* The theorems give, at every finite place $v \nmid \ell$, the compatibility $\iota\,\mathrm{WD}(r_{\ell,\iota}(\pi)|_{G_{E_v}})^{\text{F-ss}} \prec \mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})$ (equality of semisimplifications, the monodromy of the left side dominated by that of the right), with rec normalised as in [121] (uniformisers to geometric Frobenius elements). For unramified π_v, contained in the normalised induction of the unramified character with values $\alpha_1, \ldots, \alpha_n$ at ϖ_v, the right side is unramified with zero monodromy and geometric Frobenius acting with eigenvalues $q_v^{(n-1)/2}\alpha_i$. So the Weil–Deligne representation of $r_{\ell,\iota}(\pi)$ at v has zero monodromy and an inertia action, through a finite quotient, whose semisimplification is trivial; it is therefore trivial, $r_{\ell,\iota}(\pi)$ is trivial on $I_{\bar{v}}$ for every $\bar{v} \mid v$, and σ^{-1} (a geometric Frobenius) has the stated characteristic polynomial. □

Theorem B.59. *Let $g = \sum_{n\geq 1} a_n q^n$ be a normalised newform of weight $k \geq 2$, level L and character ε.*

(Dg1) *For every prime ℓ and every isomorphism $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ there is a continuous representation $\rho_{g,\iota}\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that for every prime $p \nmid \ell L$ and every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p, $\rho_{g,\iota}$ is trivial on $I_{\bar{p}}$ and $\iota(\det(X - \rho_{g,\iota}(\sigma^{-1}))) = X^2 - a_pX + \varepsilon(p)p^{k-1}$ for every arithmetic Frobenius σ at $\bar{p}$.*

(Dg2) *For every prime $p \nmid L$, both roots of $X^2 - a_pX + \varepsilon(p)p^{k-1}$ have absolute value $p^{(k-1)/2}$.*

Proof. (Dg1): [76], Théorème 6.1 (for $k = 2$ the representation on the Tate module of the Jacobian, Eichler–Shimura and Igusa). Deligne's representation is cut out of étale cohomology, where the trace of geometric Frobenius is a_p; in the other common normalisation (arithmetic Frobenius with characteristic polynomial $X^2 - a_pX + \varepsilon(p)p^{k-1}$) the contragredient has the property stated, since the eigenvalues of $\rho^\vee(\sigma^{-1})$ are those of $\rho(\sigma)^{-1}$ inverted, i.e. those of $\rho(\sigma)$. (Dg2): [77], Théorème 8.2, with the reduction in [76] of the Ramanujan–Petersson conjecture to the Weil conjectures. □

Theorem B.60. *Let F be a number field and $n \geq 1$.*

(Js1) *If π, π' are cuspidal automorphic representations of $\mathrm{GL}_n(\mathbb{A}_F)$ with $\pi_v \cong \pi'_v$ for all but finitely many places v of F, then $\pi \cong \pi'$.*

(Js2) *If π is a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ whose central character is unitary, and v is a finite place at which π_v is unramified, then every Satake parameter α of π_v satisfies $q_v^{-1/2} < |\alpha| < q_v^{1/2}$.*

Proof. [136]: (Js1) is the strong multiplicity one theorem (part II, Theorem 4.4; see also [198]); (Js2) is part I, Corollary 2.5, for the unitary cuspidal representation π (a cuspidal automorphic representation with unitary central character is unitary). *Notation.* Their Hecke matrix of π_v has as eigenvalues the Satake parameters, the values at ϖ_v of the unramified characters whose normalised induction contains π_v. □

Theorem B.61. *Let $k \geq 2$ and $L \geq 1$ be integers, and let $S_k(\Gamma_1(L))$ be the space of cusp forms of weight k for $\Gamma_1(L)$.*

(Nw1) *Distinct normalised newforms of weight k whose levels divide L (of any characters) are linearly independent elements of $S_k(\Gamma_1(L))$.*

(Nw2) *The Fourier coefficients a_n of a normalised newform are algebraic integers.*

(Nw3) *If $g = \sum_{n\geq 1} a_n q^n$ is a normalised newform of weight k, level L' and character ε, and $\sigma \in \mathrm{Aut}(\mathbb{C})$, then $g^\sigma = \sum_{n\geq 1} \sigma(a_n) q^n$ is a normalised newform of weight k, level L' and character $\sigma \circ \varepsilon$.*

Proof. (Nw1): the newform theory of [13] and, for $\Gamma_0(L)$ with character (hence for $\Gamma_1(L)$, the direct sum of these spaces over the characters modulo L), [161]: $S_k(\Gamma_1(L))$ is the direct sum, over the normalised newforms g of level $L' \mid L$, of the spans of the forms $g(dz)$, $d \mid L/L'$; in particular the newforms themselves are linearly independent. (Nw2) and (Nw3): [229], Theorem 3.52 and the discussion following it ($S_k(\Gamma_1(L))$ has a basis of forms with rational integral Fourier coefficients, stable under the Hecke operators; $\mathrm{Aut}(\mathbb{C})$ acts on q-expansions compatibly with the Hecke operators and the diamond operators, preserving the space of newforms of each level). □

Theorem B.62. *Let F be a CM field with maximal totally real subfield F^+ and complex conjugation c, $n \geq 1$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ which is **polarizable**: there is a continuous character $\chi\colon \mathbb{A}_{F^+}^\times/(F^+)^\times \to \mathbb{C}^\times$, with $\chi_v(-1)$ independent of the infinite place v of F^+, such that $\pi^c \cong \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det)$. Then there is a continuous semisimple representation $r_{\ell,\iota}(\pi)\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that, for every finite place v of F and every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above v, writing $r_{\bar{v}}$ for the restriction of $r_{\ell,\iota}(\pi)$ to $D_{\bar{v}}$ (identified with G_{F_v}), $W_{\bar{v}} \subseteq D_{\bar{v}}$ for its Weil group and $\mathcal{O}_v = \mathcal{O}_{F_v}$:*

(Bg1) *if $v \nmid \ell$ and π_v is unramified, then $r_{\ell,\iota}(\pi)$ is trivial on $I_{\bar{v}}$ and $\iota(\det(X - r_{\ell,\iota}(\pi)(\sigma^{-1}))) = \prod_\alpha (X - q_v^{(n-1)/2}\alpha)$ for every arithmetic Frobenius σ at $\bar{v}$, α running over the Satake parameters of π_v with multiplicity; in particular $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$;*

(Bg2) *if $v \mid \ell$, then $r_{\bar{v}}$ is de Rham, and for every field embedding $\tau\colon F_v \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}_\ell$ the τ-Hodge–Tate weights of $r_{\bar{v}}$ are the n numbers $z - \frac{n-1}{2}$, z running over the infinitesimal character of π at the complex embedding $\iota \circ \tau|_F$ of F;*

(Bg3) *if $U \subseteq \mathcal{O}_v^\times$ is a subgroup and there are characters $\Psi_1, \ldots, \Psi_n$ of $W_{\bar{v}}$, each trivial on the image of $\mathrm{Art}_{F_v}(U)$ in $W_{\bar{v}}^{\mathrm{ab}}$, such that the semisimplification of the restriction to $I_{\bar{v}}$ of the representation ρ of $\mathrm{WD}(r_{\bar{v}})$ is isomorphic to $\bigoplus_i \Psi_i|_{I_{\bar{v}}}$ (for $v \mid \ell$, $\mathrm{WD}(r_{\bar{v}})$ is defined by*

(Bg2), since de Rham representations are potentially semistable), then π_v is isomorphic to an irreducible subquotient of the normalised parabolic induction from the upper triangular Borel subgroup of $\mathrm{GL}_n(F_v)$ of $\xi_1 \otimes \cdots \otimes \xi_n$, for some characters $\xi_1, \dots, \xi_n$ of $F_v^\times$ trivial on U;

(Bg4) *if $v \mid \ell$ and π_v is unramified, then $r_{\bar v}$ is crystalline, $\mathrm{WD}(r_{\bar v}) = (V, \rho, N)$ has $N = 0$ and ρ trivial on $I_{\bar v}$, and $\iota(\det(X - \rho(\Phi))) = \prod_\alpha (X - q_v^{(n-1)/2}\alpha)$ for every $\Phi \in W_{\bar v}$ with $n(\Phi) = -1$ (a geometric Frobenius), α as in (Bg1);*

(Bg5) *if π_v is isomorphic to an irreducible subquotient of the normalised parabolic induction from the upper triangular Borel subgroup of $\mathrm{GL}_n(F_v)$ of $\xi_1 \otimes \cdots \otimes \xi_n$, for characters $\xi_1, \dots, \xi_n$ of $F_v^\times$, then the semisimplification of the representation ρ of $\mathrm{WD}(r_{\bar v})$ is isomorphic to $\lambda_1 \oplus \cdots \oplus \lambda_n$, where λ_i is the character of $W_{\bar v}$ with $\iota(\lambda_i(\mathrm{Art}_{F_v}(x)^{-1})) = \xi_i(x)\,|x|_v^{(1-n)/2}$ for $x \in F_v^\times$ (characters of $W_{\bar v}$ factor through $W_{\bar v}^{\mathrm{ab}}$, identified with $F_v^\times$ by Art_{F_v});*

(Bg7) *if $v \nmid \ell$, then the Frobenius-semisimplification of $\mathrm{WD}(r_{\bar v})$, transported to $\mathbb{C}$ by ι, is isomorphic to $\mathrm{rec}_{F_v}(\pi_v \otimes |\det|_v^{(1-n)/2})$, where rec_{F_v} is the local Langlands correspondence of Harris–Taylor (uniformisers corresponding to geometric Frobenius elements); in particular the monodromy operators of $\mathrm{WD}(r_{\bar v})$ and of $\mathrm{rec}_{F_v}(\pi_v)$ are conjugate.*

Proof. [17], Theorem 2.1.1 (in the published version, which incorporates [56] and [58]), together with [18], Theorem 1.1, and [58], Theorem 1.1, for places above ℓ at which π_v has no Iwahori fixed vector.

The published statements. For a regular algebraic cuspidal polarized automorphic representation (π, χ) of $\mathrm{GL}_n(\mathbb{A}_F)$ of weight a (that is, π_∞ has the infinitesimal character of the dual of the algebraic representation Ξ_a with highest weights $a_{\tau'}$, $\tau' \colon F \to \mathbb{C}$), Theorem 2.1.1 of [17] gives a continuous semisimple $r_{\ell,\iota}(\pi)$ with: (2) for $v \nmid \ell$, $\iota\mathrm{WD}(r_{\ell,\iota}(\pi)|_{G_{F_v}})^{F\text{-}ss} \cong \mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})$; (3) $r_{\ell,\iota}(\pi)$ is de Rham and $\mathrm{HT}_\tau = \{a_{\iota\tau,1} + n - 1, a_{\iota\tau,2} + n - 2, \dots, a_{\iota\tau,n}\}$, in the convention in which the cyclotomic character has Hodge–Tate weight -1; (4) for $v \mid \ell$ with π_v having an Iwahori fixed vector, the isomorphism of (2) holds, $r_{\ell,\iota}(\pi)$ is semistable at v and crystalline if π_v is unramified. Here rec is the local Langlands correspondence of [121], normalised through the Artin map sending uniformisers to geometric Frobenius elements. For an arbitrary $v \mid \ell$, [18] gives $\mathrm{WD}(r_{\ell,\iota}(\pi)|_{G_{F_v}})^{\mathrm{ss}} \cong \iota^{-1}\mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})^{\mathrm{ss}}$ (its Theorem 1.1, for (π, χ) regular algebraic, essentially conjugate self-dual and cuspidal over an imaginary CM field, which is our polarizability; there the Frobenius semisimplification of the left side is $\prec$ the right side, which contains the isomorphism of semisimplifications), and the isomorphism up to Frobenius semisimplification when π has Shin-regular weight (automatic for n odd); [58], Theorem 1.1, gives the latter for all π with $\pi^\vee \cong \pi \circ c$. Only the semisimplified form is used in (Bg1)–(Bg5); (Bg7) is (2) itself, for $v \nmid \ell$ (with $\mathrm{WD}(\cdot)^{F\text{-}ss}$ the Frobenius-semisimplification, which keeps the monodromy operator; twisting by the unramified character $|\det|_v^{(1-n)/2}$ does not change it, by (Ln2) of Theorem B.92). In [17], a polarized automorphic representation is a pair (π, χ) as in our hypothesis; the further normalisation $\chi_v(-1) = (-1)^n$ for F imaginary is achieved by replacing χ by $\chi\delta_{F/F^+}$, which does not change $\chi \circ \mathrm{N}_{F/F^+}$. Regular algebraic means there that π_∞ has the infinitesimal character of an irreducible algebraic representation, which is the notion fixed in Section 13.

Notation. (Bg2): the infinitesimal character of $\Xi_a^\vee$ at $\iota\tau$ is $\{-(a_{\iota\tau,i} + \frac{n+1}{2} - i)\}_i = \{\frac{n-1}{2} - h : h \in \mathrm{HT}_\tau\}$ (Definition 38.10: V_μ has infinitesimal character $\{\mu_i + \frac{n+1}{2} - i\}$, its dual the negatives); changing the sign convention of Hodge–Tate weights gives $\{z - \frac{n-1}{2}\}$. (Bg1): if

π_v is unramified and contained in the normalised induction of unramified characters μ_i with $\mu_i(\varpi_v) = \alpha_i$, then $\mathrm{rec}(\pi_v \otimes |\det|^{(1-n)/2}) = \bigoplus_i \mu_i |\cdot|^{(1-n)/2} \circ \mathrm{Art}^{-1}$ is unramified with $N = 0$ and a geometric Frobenius acting with eigenvalues $q_v^{(n-1)/2}\alpha_i$; by (2), $\mathrm{WD}(r)$ has $N = 0$ and trivial inertia action, so r is trivial on $I_{\bar v}$ by (Wd1), and σ^{-1} is a geometric Frobenius. (Bg4): the same computation with (4). (Bg3): the correspondence rec maps characters ξ of $F_v^\times$ to $\xi\circ\mathrm{Art}^{-1}$, supercuspidal representations of $\mathrm{GL}_m(F_v)$ to irreducible m-dimensional representations of W_{F_v}, and is compatible with supercuspidal supports: if π_v is an irreducible subquotient of the normalised induction of supercuspidals $\sigma_1 \otimes \cdots \otimes \sigma_k$, then $\mathrm{rec}(\pi_v)^{\mathrm{ss}} \cong \bigoplus_j \mathrm{rec}(\sigma_j)$ ([121], through the classification of [275]; [125]). Under the hypothesis of (Bg3), every irreducible constituent $\rho_j = \mathrm{rec}(\sigma_j)$ of the semisimplification (twisted by the unramified $|\cdot|^{(1-n)/2}$) has a restriction to $I_{\bar v}$ containing some $\Psi_i|_{I_{\bar v}}$; then $\mathrm{Hom}_{I_{\bar v}}(\Psi_i, \rho_j) \neq 0$ is stable under $W_{\bar v}$, so $\rho_j \otimes \Psi_i^{-1}$ has nonzero inertia invariants stable under $W_{\bar v}$, is unramified by irreducibility, hence one-dimensional (an irreducible representation of $W_{\bar v}/I_{\bar v} \cong \mathbb{Z}$). So each σ_j is a character ξ_j of $F_v^\times$, π_v is a subquotient of the normalised induction of $\xi_1 \otimes \cdots \otimes \xi_n$, and $\{\xi_j \circ \mathrm{Art}^{-1}|_I\} = \{\Psi_i|_I\}$ as multisets; as Art maps $\mathcal{O}_v^\times$ onto the image of inertia in $W_{\bar v}^{\mathrm{ab}}$ (in either normalisation, the two differing by $x \mapsto x^{-1}$), each ξ_j is trivial on U. (Bg5): by (2) for $v \nmid \ell$, and by [18], Theorem 1.1, for $v \mid \ell$, $\mathrm{WD}(r_{\bar v})^{\mathrm{ss}} \cong \iota^{-1}\mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})^{\mathrm{ss}}$ (a Weil–Deligne representation and its Frobenius semisimplification have the same semisimplification). The supercuspidal support of $\pi_v \otimes |\det|_v^{(1-n)/2}$ is $(\xi_i|\cdot|_v^{(1-n)/2})_i$, so by the compatibility of rec with supercuspidal supports the right side is $\bigoplus_i \iota^{-1}\mathrm{rec}(\xi_i|\cdot|_v^{(1-n)/2})$, and $\mathrm{rec}(\xi)$ is the character λ with $\lambda(\mathrm{Art}_{F_v}(x)^{-1}) = \xi(x)$: the normalisation of [121] sends uniformisers to geometric Frobenius elements, that of Art_{F_v} to arithmetic ones. □

Theorem B.63. *Let K be an imaginary quadratic field, $n \geq 1$, π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_K)$ and $\sigma \in \mathrm{Aut}(\mathbb{C})$. Then there is a regular algebraic cuspidal automorphic representation π' of $\mathrm{GL}_n(\mathbb{A}_K)$ with $\pi'_f \cong {}^\sigma\pi_f = \pi_f \otimes_{\mathbb{C},\sigma} \mathbb{C}$, whose infinitesimal character at $\sigma \circ \phi$ equals that of π at ϕ for both embeddings $\phi\colon K \to \mathbb{C}$.*

Proof. [68], Théorème 3.13: for a regular algebraic cuspidal π of GL_n over a number field, cohomological for the coefficient system V (Lemme 3.14), and $\sigma \in \mathrm{Aut}(\mathbb{C})$, there is a cuspidal representation π', cohomological for ${}^\sigma V$, with $\pi'_f \cong {}^\sigma\pi_f$ (and π_f is defined over a number field). *Notation.* Here ${}^\sigma V$ is the algebraic representation whose factor at the embedding $\sigma \circ \phi$ is the factor of V at ϕ; by the cohomological criterion the infinitesimal character of π' at $\sigma \circ \phi$ is that of the dual of this factor, i.e. that of π at ϕ, and π' is regular algebraic. □

Theorem B.64. *Let K be an imaginary quadratic field, $n \geq 1$, $\mu, \mu' \in \mathbb{Z}^n$ dominant and $U \subseteq \mathrm{GL}_n(\mathbb{A}_{K,f})$ an open compact subgroup. If S is a finite set of pairwise non-isomorphic cuspidal automorphic representations π of $\mathrm{GL}_n(\mathbb{A}_K)$, each cohomological for $V_{\mu,\mu'}$ and with $\pi_f^U \neq 0$, then $|S| \leq h^*(U, V_{\mu,\mu'})$.*

Proof. [40], Corollary 5.5: for an arithmetic group the map from cuspidal cohomology to the full cohomology is injective. *Notation.* The locally symmetric space $\mathrm{GL}_n(K)\backslash(G_\infty/K_\infty \times \mathrm{GL}_n(\mathbb{A}_{K,f})/U)$ is the disjoint union of the $\Gamma_j(U)\backslash G_\infty/K_\infty$, whose cohomology with coefficients in the local system of $V_{\mu,\mu'}$ is $H^*(\Gamma_j(U), V_{\mu,\mu'})$ (complex coefficients, G_∞/K_∞ contractible, stabilisers finite); its cuspidal cohomology is $\bigoplus_\pi m(\pi)\, H^*(\mathfrak{g}, K_\infty; \pi_\infty \otimes V_{\mu,\mu'}) \otimes \pi_f^U$ over the isomorphism classes of cuspidal π ([68], §3; $m(\pi) = 1$ for GL_n, [228]), and each $\pi \in S$ contributes at least 1 to its dimension. □

Theorem B.65. *Let K be an imaginary quadratic field with embeddings $\tau, \bar\tau$, $n \geq 1$, and $\mu, \mu' \in \mathbb{Z}^n$ dominant. Let π be a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_K)$ whose infinitesimal*

character at τ is that of the dual of V_μ and at $\bar\tau$ that of the dual of $V_{\mu'}$. Then π is cohomological for $V_{\mu,\mu'}$.

Proof. [68], Lemme 3.14 (with §3.5): a cuspidal automorphic representation of GL_n over a number field whose infinitesimal character is that of the dual of an irreducible algebraic representation V has archimedean component the essentially tempered generic representation with that infinitesimal character (it is generic by Shalika's theorem and its parameter is bounded by [136]), and that representation has nonzero $(\mathfrak{g}, K_\infty)$-cohomology with coefficients in V. *Notation.* Here $\mathrm{Res}_{K/\mathbb{Q}}\mathrm{GL}_n(\mathbb{C}) = \mathrm{GL}_n(\mathbb{C}) \times \mathrm{GL}_n(\mathbb{C})$ through $(\tau, \bar\tau)$, whose irreducible algebraic representations are the $V_{\mu,\mu'}$; the matching of the central characters on $\mathbb{R}_{>0} \subset K_\infty$ follows from the equality of infinitesimal characters, $\mathbb{R}_{>0}$ being connected. □

Theorem B.66. *Let $g = \sum_{n\geq 1} a_n q^n$ be a normalised newform of weight $k \geq 2$, level L and character ε, let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ a continuous semisimple representation such that, for all but finitely many primes p and every place $\bar p \mid p$ of $\overline{\mathbb{Q}}$, ρ is trivial on $I_{\bar p}$ and $\iota(\det(X - \rho(\sigma^{-1}))) = X^2 - a_p X + \varepsilon(p)p^{k-1}$ for every arithmetic Frobenius σ at $\bar p$. For a prime v write ρ_v for the restriction of ρ to the decomposition group of a place of $\overline{\mathbb{Q}}$ above v, identified with $G_{\mathbb{Q}_v}$.*

(Lc1) *For every prime $v \neq \ell$, $\mathrm{a}(\rho_v) = v_v(L)$.*

(Lc2) *ρ_ℓ is potentially semistable and $\mathrm{a}(\rho_\ell) = v_\ell(L)$.*

Proof. Proof of (Lc1). By [59], Théorème (A), for the base field $\mathbb{Q}$: for $v \neq \ell$ the Frobenius-semisimplified Weil–Deligne representation of the ℓ-adic representation attached to g at v corresponds, under the local Langlands correspondence for $\mathrm{GL}_2(\mathbb{Q}_v)$, to the local component π_v of the automorphic representation of g; the local correspondence preserves conductors, and the conductor exponent of π_v is $v_v(L)$ by Casselman's theory of the newvector ([61] treats the unramified case; the newform level is treated in Casselman, *On some results of Atkin and Lehner*, Math. Ann. 201 (1973)).

Proof of (Lc2). By the main theorem of [213], the restriction to $G_{\mathbb{Q}_\ell}$ of the ℓ-adic representation attached to g is potentially semistable (Tsuji) and the Weil–Deligne representation attached to it by Fontaine [95] corresponds to π_ℓ under the local Langlands correspondence; the conductors are compared as for (Lc1). Frobenius semisimplification does not change $\mathrm{a}(\cdot)$, which depends only on the restriction to inertia and on N.

The representation ρ. The representation attached to g in these papers is Deligne's ([76], in the normalisation of (Dg1) of Theorem B.59); it is irreducible (Ribet, *Galois representations attached to eigenforms with Nebentypus*, 1977), hence semisimple, and by the Chebotarev density theorem and the Brauer–Nesbitt theorem every continuous semisimple ρ with the stated Frobenius characteristic polynomials is isomorphic to it; isomorphic representations have isomorphic restrictions and Weil–Deligne representations. □

Theorem B.67. *Let $\Gamma \leq \mathrm{SL}_2(\mathbb{Z})$ be a subgroup of finite index m containing -1 and $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$, let $k \geq 0$ be an even integer and $F = \sum_{n\geq 0} b_n q^n$ $(q = e^{2\pi i z})$ a nonzero modular form of weight k for Γ. Then $b_n \neq 0$ for some integer n with $0 \leq n \leq km/12$.*

Proof. By the valence formula ([229], Proposition 2.16), for nonzero F the sum over the points P of the compactified curve $\Gamma\backslash\mathfrak{H}^*$ of the orders $\nu_P(F)$, measured in local parameters and divided by the order of the stabiliser at elliptic points, equals $km/12$, where $m = [\mathrm{SL}_2(\mathbb{Z}) : \Gamma] = [\mathrm{PSL}_2(\mathbb{Z}) :$

$\Gamma/\{\pm1\}]$ as $-1 \in \Gamma$. All terms are nonnegative for holomorphic F; at the cusp ∞, whose width is 1 because the stabiliser of ∞ in $\Gamma/\{\pm1\}$ contains, hence is generated by, the image of $\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}$, the local parameter is q and $\nu_\infty(F) = \min\{n : b_n \neq 0\}$. Hence $\min\{n : b_n \neq 0\} \leq km/12$. □

Theorem B.68. *Let $f = \sum_{n\geq1} a_n q^n$ be a normalised newform of weight $k \geq 2$ and character ε, and let η' be a quadratic Dirichlet character such that $\eta'(p)a_p = a_p$ for all but finitely many primes p; let $K' \subset \overline{\mathbb{Q}}$ be the quadratic field with $G_{K'} = \ker\eta'$. Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and $V\colon G_\mathbb{Q} \to \mathrm{GL}_2(E)$ a continuous representation, semisimple over $\overline{\mathbb{Q}}_\ell$, such that for all but finitely many primes p, V is unramified at p and $\iota(\det(X - V(\sigma^{-1}))) = X^2 - a_pX + \varepsilon(p)p^{k-1}$ for every arithmetic Frobenius σ at p. If $K' \not\subseteq \mathbb{Q}(\mu_{\ell^\infty})$, then $H^1_f(\mathbb{Q}, \mathrm{ad}_E V) = 0$, where $\mathrm{ad}_E V$ is $\mathrm{M}_2(E)$ with g acting by $X \mapsto V(g)XV(g)^{-1}$.*

Proof. This is [192], Theorem 5.4, case (2) ("π has CM by an extension K/F, and $K \not\subset F(\zeta_{p^\infty})$"), for the totally real field $F = \mathbb{Q}$, any prime ℓ and any ι.

Their π is the cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$ generated by f, twisted by $|\det|^{(2-k)/2}$ so that it is regular algebraic with $r_{\pi,\iota}$ having the stated characteristic polynomials of geometric Frobenius elements; "π has CM by $K'/\mathbb{Q}$" means $\pi \cong \pi \otimes \eta'$, which holds exactly when $\eta'(p)a_p = a_p$ for almost all p (strong multiplicity one for GL_2, [136]); their K is K'. As in Theorem B.69, $V \otimes_E \overline{\mathbb{Q}}_\ell \cong r_{\pi,\iota}$ by Chebotarev and Brauer–Nesbitt ([220], I.2.2), and $H^1_f(\mathbb{Q}, \mathrm{ad}_E V)$ injects into $H^1_f(\mathbb{Q}, \mathrm{ad}\, V \otimes_E \overline{\mathbb{Q}}_\ell)$ (an E-linear projection $\overline{\mathbb{Q}}_\ell \to E$ retracts the inclusion equivariantly). The local conditions of [192] are those of Definition 22.2. □

Theorem B.69. *Let $f = \sum_{n\geq1} a_n q^n$ be a normalised newform of weight $k \geq 2$ and character ε without complex multiplication, that is, there is no quadratic Dirichlet character η' with $\eta'(p)a_p = a_p$ for all but finitely many primes p. Let ℓ be a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and $V\colon G_\mathbb{Q} \to \mathrm{GL}_2(E)$ a continuous representation, semisimple over $\overline{\mathbb{Q}}_\ell$, such that for all but finitely many primes p, V is unramified at p and $\iota(\det(X - V(\sigma^{-1}))) = X^2 - a_pX + \varepsilon(p)p^{k-1}$ for every arithmetic Frobenius σ at p. Then $H^1_f(\mathbb{Q}, \mathrm{ad}_E V) = 0$, where $\mathrm{ad}_E V$ is $\mathrm{M}_2(E)$ with g acting by $X \mapsto V(g)XV(g)^{-1}$.*

Proof. This is [192], Theorem B(1), for the totally real field $F = \mathbb{Q}$, any prime ℓ and any ι ("no additional conditions are required").

Their π is the cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$ generated by f, twisted by $|\det|^{(2-k)/2}$ so that it is regular algebraic with $r_{\pi,\iota}$ having the stated characteristic polynomials of geometric Frobenius elements; π is non-CM in their sense ($\pi \not\cong \pi \otimes \eta'$ for every quadratic character η') exactly when f is without complex multiplication as defined here, by strong multiplicity one for GL_2 ([136]); $V \otimes_E \overline{\mathbb{Q}}_\ell \cong r_{\pi,\iota}$ by Chebotarev and Brauer–Nesbitt ([220], I.2.2), both being semisimple with the same characteristic polynomials of Frobenius elements at almost all primes; and $H^1_f(\mathbb{Q}, \mathrm{ad}_E V)$ injects into $H^1_f(\mathbb{Q}, \mathrm{ad}\, V \otimes_E \overline{\mathbb{Q}}_\ell)$ (an E-linear projection $\overline{\mathbb{Q}}_\ell \to E$ retracts the inclusion equivariantly). □

Theorem B.70. *Let $F \subset \overline{\mathbb{Q}}$ be a CM field with maximal totally real subfield F^+, $c \in G_{F^+}$ a complex conjugation, $n \geq 1$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$. Let $E \subset \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ and $r\colon G_F \to \mathrm{GL}_n(E)$ a continuous representation, absolutely irreducible, with $r \leftrightarrow_\iota \pi$, and let $\mathbf{P} \in \mathrm{GL}_n(E)$ satisfy*

$$r(cgc) = \chi_{\mathrm{cyc}}(g)^{1-n}\, \mathbf{P}\, {}^t r(g)^{-1}\, \mathbf{P}^{-1} \qquad (g \in G_F).$$

Then the formulas $g\cdot X = r(g)Xr(g)^{-1}$ ($g\in G_F$) and $c\cdot X = -\mathbf{P}\,{}^tX\,\mathbf{P}^{-1}$ define a continuous E-linear action of G_{F^+} on $\mathrm{M}_n(E)$; write $\mathrm{ad}_E\, r$ for this representation. Assume that every element of $r(G_F)$ has all its eigenvalues in E, and let $\mathbf{Z}\subseteq \mathrm{GL}_{n,E}$ be the Zariski closure of $r(G_{F(\mu_{\ell^\infty})})$, with identity component $\mathbf{Z}^\circ$. If $\mathbf{Z}^\circ$ acts absolutely irreducibly on E^n and $\mathbf{Z}^\circ(\overline{\mathbb{Q}}_\ell)$ contains an element with n distinct eigenvalues, then

$$H^1_f(F^+, \mathrm{ad}_E\, r) = 0.$$

For an imaginary quadratic field $F = K$ one has $F^+ = \mathbb{Q}$, and the conclusion reads $H^1_f(\mathbb{Q}, \mathrm{ad}_E\, r) = 0$.

Proof. This is [192], Theorem A (for the CM field F; any prime ℓ; no hypothesis on the residual representation), combined with Lemma 2.28(2) of the same paper (if the identity component of the Zariski closure of H contains regular semisimple elements and acts absolutely irreducibly on E^n, then H is enormous, under the standing assumption of that lemma that the characteristic polynomials of the elements of H split over E), applied to $H = r(G_{F(\mu_{\ell^\infty})})$ after conjugating r into GL_n of the ring of integers of E (the image is compact).

Notation. "Of unitary type" in [192] means $\pi^c\cong\pi^\vee$; their $r_{\pi,\iota}$ satisfies $r^c_{\pi,\iota}\cong r^\vee_{\pi,\iota}\otimes\chi_{\mathrm{cyc}}^{1-n}$ on G_F (multiplier $\epsilon^{1-n}\delta^n_{F/F^+}$), and G_{F^+} acts on $\mathrm{ad}\, r_{\pi,\iota} = \mathrm{End}(V)$ through conjugation on G_F and by $X\mapsto -X^*$ for complex conjugation, X^* the adjoint for the pairing $\langle x,y\rangle = {}^t x\,\mathbf{P}^{-1}y$, so that $X^* = \mathbf{P}\,{}^tX\,\mathbf{P}^{-1}$.

The action. Applying the displayed relation twice shows that $\mathbf{P}\,{}^t\mathbf{P}^{-1}$ commutes with $r(G_F)$, hence is a scalar λ by absolute irreducibility, with $\lambda^2=1$; so $c\cdot(c\cdot X)=X$, and $c\cdot(g\cdot(c\cdot X)) = r(cgc)Xr(cgc)^{-1}$; as $G_{F^+} = G_F\sqcup cG_F$ this defines an action.

Comparison with $r_{\pi,\iota}$. An absolutely irreducible r with $r\leftrightarrow_\iota\pi$ is isomorphic over $\overline{\mathbb{Q}}_\ell$ to $r_{\pi,\iota}$ (Chebotarev and Brauer–Nesbitt, [220], I.2.2), and two E-forms of an absolutely irreducible representation that are isomorphic over $\overline{\mathbb{Q}}_\ell$ are isomorphic over E (the space of intertwiners is defined over E); the matrix $\mathbf{P}$ is unique up to a scalar (Schur), so $\mathrm{ad}_E\, r$ depends only on r up to isomorphism, and its Bloch–Kato Selmer group, whether formed with coefficients E or $\overline{\mathbb{Q}}_\ell$, injects into the one formed with $\overline{\mathbb{Q}}_\ell$ (an E-linear projection $\overline{\mathbb{Q}}_\ell\to E$ retracts the inclusion equivariantly). The condition on $\mathbf{Z}^\circ(\overline{\mathbb{Q}}_\ell)$ is the condition "contains regular semisimple elements" of Lemma 2.28: the regular semisimple locus is open, and $\mathbf{Z}^\circ(E)$ is Zariski dense in the connected group $\mathbf{Z}^\circ$ over the field E of characteristic 0. The group H^1_f of [192] is the Bloch–Kato group (unramified classes at $v\nmid\ell$, kernel of $H^1\to H^1(\cdot\otimes B_{\mathrm{cris}})$ at $v\mid\ell$), as in Definition 22.2. □

Theorem B.71. *Let ℓ be a prime and $\mathcal{O}$ a coefficient ring with residue field of characteristic ℓ. A profinite group Γ satisfies* Mazur's condition Φ_ℓ *if $\mathrm{Hom}_{\mathrm{cont}}(\Gamma',\mathbb{F}_\ell)$ is finite for every open subgroup $\Gamma'\subseteq\Gamma$.*

1. *If Γ satisfies Φ_ℓ and $\bar\rho\colon\Gamma\to\mathrm{GL}_n(\mathbb{F}_\mathcal{O})$ is continuous, the functor on $\mathrm{CNL}_\mathcal{O}$ sending A to the set of continuous homomorphisms $\rho\colon\Gamma\to\mathrm{GL}_n(A)$ reducing to $\bar\rho$ is represented by an object $R^\square$ of $\mathrm{CNL}_\mathcal{O}$ and a universal lift $\rho^\square\colon\Gamma\to\mathrm{GL}_n(R^\square)$.*
2. *For a number field F and a finite set S of places of F, $G_{F,S}$ satisfies Φ_ℓ.*

Proof. [167, §1.1–1.2]: item 2 is Mazur's observation that $\mathrm{Hom}(\Gamma',\mathbb{F}_\ell)$ for an open $\Gamma'\subseteq G_{F,S}$ classifies abelian extensions of exponent ℓ of a number field unramified outside S, finite in number by class field theory (Hermite–Minkowski); item 1 is the framed form of his existence theorem (Schlessinger's criteria hold for the functor of lifts without any irreducibility hypothesis, and Φ_ℓ makes its tangent space $Z^1(\Gamma,\mathrm{ad}\,\bar\rho)$ finite-dimensional, so the pro-representing ring is

Noetherian). Notation: $R^{\square}$, $\rho^{\square}$ as there; $\mathrm{CNL}_{\mathcal{O}}$ is Mazur's category of complete Noetherian local $\mathcal{O}$-algebras with residue field $\mathbb{F}_{\mathcal{O}}$. □

Theorem B.72. *Let $F \subset \overline{\mathbb{Q}}$ be a CM field with maximal totally real subfield F^+, $c \in G_{F^+}$ a complex conjugation, $n \geq 2$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$. Let $E \subset \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathbb{Q}_\ell$ and $r\colon G_F \to \mathrm{GL}_n(E)$ a continuous representation with $r \leftrightarrow_\iota \pi$, and let $\mathbf{P} \in \mathrm{GL}_n(E)$ satisfy*

$$r(cgc) = \chi_{\mathrm{cyc}}(g)^{1-n}\,\mathbf{P}\,{}^t r(g)^{-1}\,\mathbf{P}^{-1} \qquad (g \in G_F).$$

Assume that the restriction of r to $G_{F(\mu_{\ell^\infty})}$ is irreducible on $\overline{\mathbb{Q}}_\ell^n$. Then the formulas $g \cdot X = r(g)Xr(g)^{-1}$ $(g \in G_F)$ and $c \cdot X = -\mathbf{P}\,{}^t X\,\mathbf{P}^{-1}$ define a continuous E-linear action of G_{F^+} on $\mathrm{M}_n(E)$, and, writing $\mathrm{ad}_E\, r$ for this representation,

$$H^1_f(F^+, \mathrm{ad}_E\, r) = 0 \quad \textit{and} \quad H^1_f(F^+, \mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell) = 0.$$

For an imaginary quadratic field $F = K$ one has $F^+ = \mathbb{Q}$, and the conclusion reads $H^1_f(\mathbb{Q}, \mathrm{ad}_E\, r) = 0 = H^1_f(\mathbb{Q}, \mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell)$.

Proof. This is [257], Theorem 6.1 (stated as Theorem A in the introduction), with $p = \ell$: if F is a CM number field, $n \geq 2$, (π, χ) is a regular algebraic, cuspidal, polarized automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, $\iota\colon \overline{\mathbb{Q}}_p \to \mathbb{C}$ is an isomorphism and $r_{\pi,\iota}|_{G_{F(\zeta_{p^\infty})}}$ is irreducible, then $H^1_f(F^+, \mathrm{ad}\, r_{\pi,\iota}) = 0$; no hypothesis on the residual representation, on the prime, or on F/F^+ (the reductions to F/F^+ everywhere unramified and $[F^+ : \mathbb{Q}]$ even are made inside its proof).

Notation. A regular algebraic conjugate self-dual cuspidal π ($\pi^c \cong \pi^\vee$) gives the polarized pair $(\pi, \delta^n_{F/F^+})$ in the sense of [17], Section 2.1, to which [257] refers (the sign condition at the real places holds as $\delta_{F/F^+,v}(-1) = -1$ for every real place v of F^+, F being totally imaginary); then $r^c_{\pi,\iota} \cong r^\vee_{\pi,\iota} \otimes \chi_{\mathrm{cyc}}^{1-n}$ on G_F, and G_{F^+} acts on $\mathrm{ad}\, r_{\pi,\iota} = \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ by conjugation through $r_{\pi,\iota}$ on G_F and by $X \mapsto -\mathbf{P}\,{}^t X\,\mathbf{P}^{-1}$ for c, the same extension as in [192] (which [257] takes over unchanged, Section 6.3). The group H^1_f there is the Bloch–Kato group (unramified classes at $v \nmid \ell$, the kernel of $H^1 \to H^1(\cdot \otimes B_{\mathrm{cris}})$ at $v \mid \ell$), as in Definition 22.2.

Comparison of r with $r_{\pi,\iota}$. The restriction of r to $G_{F(\mu_{\ell^\infty})}$ is irreducible over $\overline{\mathbb{Q}}_\ell$, so r is absolutely irreducible. An absolutely irreducible r with $r \leftrightarrow_\iota \pi$ is isomorphic over $\overline{\mathbb{Q}}_\ell$ to $r_{\pi,\iota}$ (equal characteristic polynomials of Frobenius elements at almost all places, Chebotarev and Brauer–Nesbitt, [220], I.2.2); so $r_{\pi,\iota}|_{G_{F(\zeta_{\ell^\infty})}}$ is irreducible and the theorem applies to π. We check that the formulas define an action. Applying the displayed relation twice shows that $\mathbf{P}\,{}^t\mathbf{P}^{-1}$ commutes with $r(G_F)$, hence is a scalar λ with $\lambda^2 = 1$ (Schur), so $c \cdot (c \cdot X) = X$; and $c \cdot (g \cdot (c \cdot X)) = r(cgc)Xr(cgc)^{-1}$; as $c \notin G_F$ (F is totally imaginary) and $[G_{F^+} : G_F] = 2$, $G_{F^+} = G_F \sqcup cG_F$ and this defines an action, continuous because r is. If $u \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ conjugates r to $r_{\pi,\iota}$, then $u\mathbf{P}\,{}^t u$ satisfies the displayed relation for $r_{\pi,\iota}$, and by Schur it is a scalar multiple of the matrix used for $r_{\pi,\iota}$; the action $c \cdot X = -\mathbf{P}\,{}^t X\mathbf{P}^{-1}$ does not change when $\mathbf{P}$ is scaled, so $X \mapsto uXu^{-1}$ is a G_{F^+}-isomorphism $\mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell \cong \mathrm{ad}\, r_{\pi,\iota}$, and $H^1_f(F^+, \mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell) = 0$. Finally an E-linear projection $\overline{\mathbb{Q}}_\ell \to E$ retracting the inclusion is G_{F^+}-equivariant on M_n (the action is E-linear), and the Bloch–Kato conditions are functorial, so $H^1_f(F^+, \mathrm{ad}_E\, r)$ injects into $H^1_f(F^+, \mathrm{ad}_E\, r \otimes_E \overline{\mathbb{Q}}_\ell) = 0$. □

Theorem B.73. *Let F be a CM field, $n \geq 2$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$. Let $v \mid \ell$ be a place of F, $\bar{v} \mid v$ a place of $\overline{\mathbb{Q}}$, and $(V, \rho, N) = \mathrm{WD}(r_{\ell,\iota}(\pi)|_{D_{\bar{v}}})$ (defined, since the restriction is de Rham by (Bg2), hence potentially semistable). Let $\Phi \in W_{\bar{v}}$ with $n(\Phi) = -1$. Then (V, ρ, N)*

is pure*: there are a real number k and subspaces $\mathrm{Fil}_j V$ ($j \in k + \mathbb{Z}$) stable under $\rho(W_{\bar v})$, with $\mathrm{Fil}_{j-1}V \subseteq \mathrm{Fil}_j V$, $\mathrm{Fil}_j V = 0$ for j small, $\mathrm{Fil}_j V = V$ for j large and $N(\mathrm{Fil}_j V) \subseteq \mathrm{Fil}_{j-2}V$, such that, writing $\mathrm{gr}_j = \mathrm{Fil}_j V/\mathrm{Fil}_{j-1}V$:*

(Pu1) *for every j, every eigenvalue α of the endomorphism of gr_j induced by $\rho(\Phi)$ is algebraic over $\mathbb{Q}$ and satisfies $|\sigma(\alpha)| = q_v^{j/2}$ for every field embedding $\sigma\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$;*

(Pu2) *for every integer $i \geq 1$, N^i induces an isomorphism $\mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$.*

Proof. This follows from [58], Theorem 1.1 and the paragraph following it, with [56], Theorem 1.2, and [255], Section 1 and Lemma 1.4.

The published statements. Let Π be a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, $n \geq 2$, with $\Pi^\vee \cong \Pi \circ c$ and Π_∞ cohomological for an irreducible algebraic representation, and $R_\ell(\Pi)$ its Galois representation (Shin, Chenevier–Harris). [58], Theorem 1.1: for every place $y \mid \ell$ of F, $\mathrm{WD}(R_\ell(\Pi)|_{G_{F_y}})^{F\text{-ss}} \cong \iota^{-1}\mathcal{L}_{n,F_y}(\Pi_y)$, the local Langlands correspondence in the geometric normalisation (for n odd this is due to [18], as Π then has Shin-regular weight). [56], Theorem 1.2: Π is tempered at every finite place. As stated in [58], p. 1, temperedness of Π_y makes $\iota^{-1}\mathcal{L}_{n,F_y}(\Pi_y)$ pure of some weight in the sense of [255] (Lemma 1.4(3) there), so the Frobenius semisimplification of $\mathrm{WD}(R_\ell(\Pi)|_{G_{F_y}})$ is pure, and so is $\mathrm{WD}(R_\ell(\Pi)|_{G_{F_y}})$ itself ([255], Lemma 1.4(1)).

Definitions of [255], Section 1. A Weil–Deligne representation (V, r, N) of W_{F_v} satisfies $r(\sigma)Nr(\sigma)^{-1} = |\mathrm{Art}^{-1}(\sigma)|N$ with the Artin map sending uniformisers to geometric Frobenius elements; for a geometric Frobenius Φ this is $\rho(\Phi)N\rho(\Phi)^{-1} = q_v^{-1}N$, which is (38.5) with $n(\Phi) = -1$. A Weil q-number of weight j is an $\alpha \in \overline{\mathbb{Q}}_\ell$ with $\sigma(\alpha)\overline{\sigma(\alpha)} = q^j$ for every embedding σ (so α is algebraic); (V, r, N) is strictly pure of weight j if every eigenvalue of $r(\Phi)$ is a Weil q_v-number of weight j (for some, equivalently every, lift Φ of Frobenius), mixed if it has an increasing filtration by Weil–Deligne subrepresentations with strictly pure graded pieces, the j-th of weight j (then $N(\mathrm{Fil}_j) \subseteq \mathrm{Fil}_{j-2}$), and pure of weight k if it is mixed with all weights in $k + \mathbb{Z}$ and $N^i\colon \mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$ is an isomorphism for every integer $i \geq 1$. This is (Pu1)–(Pu2). The functor WD of [255] at $\ell = p$ is Fontaine's, as in (Wd2).

Comparison of notation. Regular algebraic cuspidal representations are those with cohomological archimedean component ([68], Section 3), and conjugate self-dual means $\pi^\vee \cong \pi^c$, so π satisfies the hypotheses on Π. $R_\ell(\Pi)$ and $r_{\ell,\iota}(\pi)$ are semisimple and attached to π at almost all places ((Bg1) of Theorem B.62), hence isomorphic by the Chebotarev density theorem and the Brauer–Nesbitt theorem; isomorphic representations have isomorphic Weil–Deligne representations, and $D_{\bar v}$ is identified with G_{F_v}. □

Theorem B.74. *Let E/F be a cyclic extension of number fields of prime degree, σ a generator of $\mathrm{Gal}(E/F)$, $n \geq 1$, and Π a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_E)$ such that $\Pi^\sigma \cong \Pi$, where Π^σ is the representation $g \mapsto \Pi(\sigma(g))$. Then there is a cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_F)$ such that for every place v of F and every place w of E above v:*

(Bc1) *if v splits completely in E, then $\Pi_w \cong \pi_v$, where E_w and F_v are identified;*

(Bc2) *if v is archimedean, the Langlands parameter of Π_w is the restriction to the Weil group of E_w of the Langlands parameter of π_v.*

Proof. See [9], Chapter 3, Theorems 4.2 and 5.1, and for $n = 2$ [159]. The statements there are as follows. For E/F cyclic of prime degree, every cuspidal π of $\mathrm{GL}_n(\mathbb{A}_F)$ has a base change

$\Pi = \pi_E$, an automorphic representation of $\mathrm{GL}_n(\mathbb{A}_E)$ whose local component at every place $w \mid v$ is the local base change of π_v; a cuspidal Π with $\Pi^\sigma \cong \Pi$ is the base change of exactly $[E:F]$ representations π, all cuspidal and twists of one another by the characters of $\mathbb{A}_F^\times / F^\times \mathrm{N}_{E/F}\mathbb{A}_E^\times$. In the notation used here: at a place v split in E, $E \otimes_F F_v = \prod_{w\mid v} E_w$ with $E_w = F_v$, and the local base change of π_v is π_v at each w, which is (Bc1); at an archimedean place the local base change is defined by restriction of Langlands parameters to the Weil group of E_w ([9], Chapter 1), which is (Bc2). Only the existence of one cuspidal π with (Bc1), (Bc2) is stated; the twist ambiguity is not used. □

Theorem B.75. *Let F be a totally real field, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_F)$. Then there is a continuous representation $r\colon G_F \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $r \leftrightarrow_\iota \pi$.*

Proof. See [59], [253], [33] (Galois representations attached to Hilbert modular eigenforms of weights $k_v \geq 2$ of equal parity: Carayol when $[F:\mathbb{Q}]$ is odd or π is discrete series at some finite place, Taylor and Blasius–Rogawski in the remaining cases), and in the present normalisation [17], Theorem 2.1.1 (2), which allows F totally real: for a regular algebraic cuspidal polarized (π,χ), $\iota\mathrm{WD}(r_{l,\iota}(\pi)|_{G_{F_v}})^{F\text{-ss}} \cong \mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})$ for $v \nmid \ell$. For GL_2, $\pi^\vee \cong \pi \otimes (\omega_\pi^{-1} \circ \det)$ with ω_π the central character, so (π,ω_π) is polarized in the sense of op. cit., Section 2.1, once $\omega_{\pi,v}(-1)$ is independent of the real place v; this holds because π_v is a twist $D_{k_v} \otimes |\det|^{t_v}$ of a discrete series, $\omega_{\pi,v}(-1) = (-1)^{k_v}$, regular algebraicity gives $t_v - k_v/2 \in \mathbb{Z}$, and $2t_v$ is independent of v because ω_π is trivial on a subgroup of finite index of the totally positive units (Dirichlet's unit theorem). At an unramified $v \nmid \ell$, π_v is the irreducible unramified subquotient of the normalised induction of unramified μ_1, μ_2, $\mathrm{rec}(\pi_v \otimes |\det|^{-1/2}) = \mu_1|\cdot|^{-1/2} \oplus \mu_2|\cdot|^{-1/2}$ (composed with the inverse Artin map, uniformisers going to geometric Frobenius elements in the normalisation of op. cit.) with $N = 0$, so r is unramified at v and a geometric Frobenius σ^{-1} has the eigenvalues $\iota^{-1}(q_v^{1/2}\mu_i(\varpi_v))$; this is $r \leftrightarrow_\iota \pi$. □

Theorem B.76. *Let π be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$. Then there are a normalised newform $f = \sum_{n\geq 1} a_n q^n$ of some weight $k \geq 2$, level N and character ε, and an integer j, such that for every prime $p \nmid N$ the component π_p is unramified and*

$$\prod_{\alpha} (X - p^{1/2}\alpha) = X^2 - p^j a_p X + \varepsilon(p)\, p^{2j+k-1},$$

α running over the Satake parameters of π_p with multiplicity.

Proof. By [103], Section 5, together with [135] and Casselman's theory of the newvector (W. Casselman, *On some results of Atkin and Lehner*, Math. Ann. 201 (1973)), a normalised newform f of weight $k \geq 2$, level N and character ε generates a cuspidal automorphic representation $\pi(f)$ of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$ with $\pi(f)_\infty \cong D_k$, the discrete series of weight k with central character trivial on $\mathbb{R}_{>0}$, unramified at every $p \nmid N$ and with $L(s,\pi(f)) = L(s + \frac{k-1}{2}, f)$; conversely every cuspidal automorphic representation π_0 with $\pi_{0,\infty} \cong D_k$ is $\pi(f)$ for exactly one normalised newform f of weight k.

Notation. (i) Write $\pi = \pi_0 \otimes |\det|^t$ with $t \in \mathbb{R}$ such that the central character of π_0 is unitary. The representation π_0 is cuspidal and unitary, hence $\pi_{0,\infty}$ is unitary and generic. Regular algebraicity in the sense of [68] says that the Langlands parameter of $\pi_\infty \otimes |\det|^{-1/2}$ restricted to $\mathbb{C}^\times$ is $z^{p_1}\bar z^{q_1} \oplus z^{p_2}\bar z^{q_2}$ with integers p_i, q_i and $p_1 \neq p_2$. An irreducible principal series of $\mathrm{GL}_2(\mathbb{R})$ has $p_i = q_i$, so regularity forces $p_1 - p_2$ to be a nonzero integer, i.e. the ratio of the two inducing characters is $|\cdot|^s$ times a sign with $\mathrm{Re}\, s$ a nonzero integer, which is not unitary for an irreducible principal series (the complementary series has $|\mathrm{Re}\, s| < 1$). Hence

$\pi_{0,\infty} \cong D_k$ for some $k \geq 2$, and then the exponents are $p = k/2 + t - 1$, $q = t - k/2$ (and their exchange), so $t - k/2 \in \mathbb{Z}$. (ii) For $p \nmid N$, $L_p(s, \pi(f)) = (1 - a_p p^{-(k-1)/2} p^{-s} + \varepsilon(p) p^{-2s})^{-1}$, so the Satake parameters α_0, β_0 of $\pi(f)_p$ satisfy $\alpha_0 + \beta_0 = a_p p^{-(k-1)/2}$ and $\alpha_0 \beta_0 = \varepsilon(p)$; those of $\pi_p = \pi(f)_p \otimes |\det|^t$ are $p^{-t}\alpha_0, p^{-t}\beta_0$. With $j = 1 - t - k/2 \in \mathbb{Z}$, the numbers $p^{1/2}\alpha$ have sum $a_p p^{1-t-k/2} = p^j a_p$ and product $\varepsilon(p) p^{1-2t} = \varepsilon(p) p^{2j+k-1}$. (If a reference lifts the complex conjugate form instead, the statement holds with that newform.) □

Theorem B.77. *Let $f = \sum_{n \geq 1} a_n q^n$ be a normalised newform of weight $k \geq 2$, level N and character ε, ℓ a prime, $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $\rho \colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ a continuous semisimple representation such that for all but finitely many primes p and every place $\bar{p} \mid p$, ρ is trivial on $I_{\bar{p}}$ and $\iota(\det(X - \rho(\sigma^{-1}))) = X^2 - a_p X + \varepsilon(p) p^{k-1}$ for every arithmetic Frobenius σ at $\bar{p}$. Then $\rho|_{D_\ell}$ is Hodge–Tate with Hodge–Tate weights 0 and $1 - k$.*

Proof. By [86], the ℓ-adic representation attached to an eigenform of weight $k \geq 2$ (realised in the étale cohomology of a modular curve with coefficients in the $(k-2)$-nd symmetric power of the first relative cohomology of the universal elliptic curve, where geometric Frobenius elements have trace a_p) carries a Hodge–Tate structure of weights 0 and $k-1$ up to the sign convention (in the normalisation of [86]: Hodge–Tate weights 0 and $k+1$ for an eigenform of weight $k+2 \geq 2$). *Notation.* This representation is Deligne's $\rho_{f,\iota}$ of (Dg1) in Theorem B.59. By the hypothesis on ρ and (Dg1) of Theorem B.59, ρ and $\rho_{f,\iota}$ have the same characteristic polynomial at every arithmetic Frobenius element at all but finitely many primes; these elements are dense in $G_{\mathbb{Q}}$ (Chebotarev density theorem), so by continuity the characteristic polynomials agree on all of $G_{\mathbb{Q}}$, and by the Brauer–Nesbitt theorem ρ, being semisimple, is isomorphic to the semisimplification of $\rho_{f,\iota}$, which is Hodge–Tate with the same weights as $\rho_{f,\iota}$ (on Hodge–Tate representations $\mathbb{C}_\ell \otimes (\cdot)$ is exact and the weights of a representation are those of its composition factors). The sign is fixed by the determinant: $\iota \det \rho(\sigma^{-1}) = \varepsilon(p) p^{k-1} = \varepsilon(p) \chi_{\mathrm{cyc}}(\sigma^{-1})^{1-k}$, so $\det \rho = \varepsilon' \chi_{\mathrm{cyc}}^{1-k}$ with ε' of finite order (Chebotarev), of Hodge–Tate weight $1 - k$ with χ_{cyc} of weight 1. The two weights 0 and $\pm(k-1)$ must add up to it. □

Theorem B.78. *Let $F \subset \overline{\mathbb{Q}}$ be a CM field that is not totally real, with maximal totally real subfield F^+, let $\delta_F \colon G_{F^+} \to \{\pm 1\}$ be the character with kernel G_F, and let $M \supseteq F$ be a CM field such that M/F is a soluble Galois extension; M^+ is the maximal totally real subfield of M. Let $n \geq 1$, ℓ a prime, $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $r \colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, $\mu \colon G_{F^+} \to \overline{\mathbb{Q}}_\ell^\times$ continuous homomorphisms such that*

(Vj1) *there are a complex conjugation $c \in G_{F^+}$ and a non-degenerate bilinear form $\langle\ ,\ \rangle$ on $\overline{\mathbb{Q}}_\ell^n$ with $\langle x, y\rangle = -\mu(c)\langle y, x\rangle$ and $\langle r(\sigma)x, r(c\sigma c)y\rangle = \mu(\sigma)\langle x, y\rangle$ for all $\sigma \in G_F$ and $x, y \in \overline{\mathbb{Q}}_\ell^n$;*

(Vj2) *$r|_{G_M}$ is irreducible.*

Then the following are equivalent:

(Vj3) *there are a regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_F)$ and a continuous character $\chi \colon \mathbb{A}_{F^+}^\times / (F^+)^\times \to \mathbb{C}^\times$ with $\chi_v(-1) = (-1)^n$ at every real place v of F^+ and $\pi^c \cong \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det)$, such that $r \leftrightarrow_\iota \pi$ and $\mu \chi_{\mathrm{cyc}}^{n-1} \leftrightarrow_\iota \chi$;*

(Vj4) *the same holds for M, M^+, $r|_{G_M}$ and $\mu|_{G_{M^+}}$ in place of F, F^+, r and μ.*

In particular, if n is odd and

1. *there are a complex conjugation $c \in G_{F^+}$ and a non-degenerate symmetric bilinear form $\langle\ ,\ \rangle$ on $\overline{\mathbb{Q}}_\ell^n$ with $\langle r(\sigma)x, r(c\sigma c)y\rangle = \chi_{\mathrm{cyc}}(\sigma)^{1-n}\langle x, y\rangle$ for all $\sigma \in G_F$ and $x, y \in \overline{\mathbb{Q}}_\ell^n$;*

2. $r|_{G_M}$ *is irreducible;*

3. $r|_{G_M} \cong r_{\ell,\iota}(\Pi)$ *for a regular algebraic conjugate self-dual cuspidal automorphic representation* Π *of* $\mathrm{GL}_n(\mathbb{A}_M)$*,*

then $r \cong r_{\ell,\iota}(\pi)$ *for a regular algebraic conjugate self-dual cuspidal automorphic representation* π *of* $\mathrm{GL}_n(\mathbb{A}_F)$*.*

Proof. This is [17], Lemma 2.2.2 (proved there in the same way as Lemma 4.2.2 of [69]): for M/F soluble Galois with M CM and (r,μ) a polarised ℓ-adic representation of G_F with $r|_{G_M}$ irreducible, (r,μ) is automorphic if and only if $(r|_{G_M}, \mu|_{G_{M^+}})$ is.

The notation of op. cit. (Section 2.1 there). A polarised ℓ-adic representation of G_F is a pair (r,μ) of continuous homomorphisms with a non-degenerate pairing such that $\langle x,y\rangle = \varepsilon\langle y,x\rangle$ and $\langle r(\sigma)x, r(c\sigma c)y\rangle = \mu(\sigma)\langle x,y\rangle$, and, F being imaginary, $\varepsilon = -\mu(c)$: this is (Vj1). A polarised automorphic representation is a pair (π,χ) with χ a continuous character of $\mathbb{A}_{F^+}^\times/(F^+)^\times$, $\chi_v(-1)$ independent of $v \mid \infty$, $\pi^c \cong \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det)$ and, F being imaginary, $\chi_v(-1) = (-1)^n$ for all $v \mid \infty$. (r,μ) is automorphic if $(r,\mu) \cong (r_{\ell,\iota}(\pi), r_{\ell,\iota}(\chi)\chi_{\mathrm{cyc}}^{1-n})$ for a regular algebraic cuspidal polarised (π,χ), with $r_{\ell,\iota}(\pi)$ as in op. cit., Theorem 2.1.1 (the representation of Theorem B.62), and $r_{\ell,\iota}(\chi)$ the ℓ-adic character of the algebraic character χ.

From $\cong$ *to* $\leftrightarrow_\iota$. If $r \cong r_{\ell,\iota}(\pi)$, then $r \leftrightarrow_\iota \pi$ by local-global compatibility at the unramified places (Theorem B.62). Conversely, if $r \leftrightarrow_\iota \pi$ with r irreducible (as $r|_{G_M}$ is, by (Vj2)), then r and $r_{\ell,\iota}(\pi)$ have the same characteristic polynomials on a dense set of Frobenius elements (Chebotarev), hence on all of G_F; so $r_{\ell,\iota}(\pi)^{\mathrm{ss}} \cong r$ (Brauer–Nesbitt), and a representation whose semisimplification is irreducible is irreducible, so $r_{\ell,\iota}(\pi) \cong r$. For characters, $\leftrightarrow_\iota$ and equality agree by the Chebotarev density theorem and continuity. So (Vj3) and (Vj4) are the automorphy of (r,μ) and of $(r|_{G_M}, \mu|_{G_{M^+}})$.

The special case. Take $\mu = \chi_{\mathrm{cyc}}^{1-n}\delta_F$. Then $\mu(c) = (-1)^{1-n}\cdot(-1) = -1$ for n odd, so the form of (Vj1) is symmetric: hypothesis 1 is (Vj1), and hypothesis 2 is (Vj2). In (Vj3) (and (Vj4)) $\mu\chi_{\mathrm{cyc}}^{n-1} = \delta_F$ forces χ to be the quadratic character of F/F^+, which satisfies $\chi_v(-1) = -1 = (-1)^n$ and $\chi \circ \mathrm{N}_{F/F^+} = 1$; so (Vj3) says that $r \leftrightarrow_\iota \pi$ with π regular algebraic, cuspidal and conjugate self-dual, and likewise over M, as $\mu|_{G_{M^+}} = \chi_{\mathrm{cyc}}^{1-n}\delta_M$. Hypothesis 3 gives (Vj4) (the representation $r_{\ell,\iota}(\Pi)$ of Theorem B.58 is attached to Π at almost all places), and (Vj3) gives $r \cong r_{\ell,\iota}(\pi)$ with $r_{\ell,\iota}(\pi)$ as in Theorem B.58, by the argument of the previous paragraph. □

Theorem B.79. *Let* $N \geq 3$*,* $\zeta_N = e^{2\pi i/N} \in \mathbb{C}$*,* $R_N = \mathbb{Z}[1/N, \zeta_N]$*, let* X_N *be the compactified moduli scheme over* R_N *of elliptic curves with a full level* N *structure of Weil-pairing determinant* ζ_N*,* $C \subset X_N$ *its divisor of cusps and* ω *the Hodge bundle. For an* R_N*-algebra* B *and* $k \in \mathbb{Z}$ *put* $M_k(N;B) = H^0(X_N \otimes_{R_N} B, \omega^{\otimes k})$*. Then:*

(Kt1) X_N *is a smooth proper curve over* R_N *with geometrically connected fibres,* C *is finite étale over* R_N*, and* $\omega^{\otimes 2} \cong \Omega^1_{X_N/R_N}(C)$ *(Kodaira–Spencer). Evaluation on the Tate curve with its canonical differential and its level* N *structures gives, at each cusp, an injective* q*-expansion map* $M_k(N;B) \to B[[q^{1/N}]]$*; the* ***value*** *of* f *at the cusp is the constant coefficient. The group* $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ *acts on* X_N *over* R_N *through the level structures, compatibly with* ω*; this action permutes the cusps and acts on each* $M_k(N;B)$*.*

(Kt2) *Through the complex uniformisation,* $M_k(N;\mathbb{C})$ *is the space of holomorphic modular forms of weight* k *for* $\Gamma(N)$*; the element* $\gamma \bmod N$ *of* $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$*,* $\gamma \in \mathrm{SL}_2(\mathbb{Z})$*, acts by* $f \mapsto f|_k\gamma$*; the* q*-expansions of* f *at the cusps are the Fourier expansions in* $e^{2\pi i\tau/N}$ *of the functions* $f|_k\gamma$*,* $\gamma \in \mathrm{SL}_2(\mathbb{Z})$*, the expansion at the standard cusp* ∞ *being that of* f *itself. If*

$B \subset \mathbb{C}$ is a subring containing R_N and $f \in M_k(N;\mathbb{C})$ has its expansion at ∞ in $B[[q^{1/N}]]$, then f lies in $M_k(N;B)$, and all q-expansions of f lie in $B[[q^{1/N}]]$ (q-expansion principle).

(Kt3) *If $k \geq 2$, then for every homomorphism of R_N-algebras $B \to B'$ the natural map $M_k(N;B) \otimes_B B' \to M_k(N;B')$ is an isomorphism.*

(Kt4) *Let F be an algebraically closed field of characteristic $p \nmid N$ with an R_N-algebra structure, and let $\mathcal{R} = \bigoplus_{k\in\mathbb{Z}} H^0(Y, \omega^{\otimes k})$, $Y = (X_N \setminus C) \otimes F$. The Hasse invariant $A \in M_{p-1}(N;F)$ is fixed by $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$ and all its q-expansions equal 1; a homogeneous element of $\mathcal{R}$ is determined by its weight and any one of its q-expansions; and the kernel of the q-expansion map of $\mathcal{R}$ at any cusp is the ideal $(A-1)\mathcal{R}$. Consequently, if $f \in M_k(N;F)$ and $g \in M_{k'}(N;F)$, $k \geq k'$, have the same nonzero q-expansion at one cusp, then $k \equiv k' \pmod{p-1}$ and $f = A^{(k-k')/(p-1)}g$.*

Proof. For (Kt1)–(Kt3), see N. Katz, *p-adic properties of modular schemes and modular forms*, Modular functions of one variable III, Lecture Notes in Math. 350 (1973), Chapter 1 (the moduli problem of level $N \geq 3$ and its compactification, §1.2; q-expansions and the q-expansion principle, §1.6; Theorem 1.7.1: for $n \geq 3$ and $k \geq 2$, $H^0(X,\omega^k) \otimes K \to H^0(X, \omega^k \otimes K)$ is an isomorphism for every $\mathbb{Z}[1/n]$-module K, which gives (Kt3) after base change to R_N), and Appendix A1 (Kodaira–Spencer); the complex uniformisation and the identification of q-expansions with Fourier expansions of $f|_k\gamma$ are in loc. cit., A1.2 and §1.6, and [76]. For (Kt4), see N. Katz, *A result on modular forms in characteristic p*, Modular functions of one variable V, Lecture Notes in Math. 601 (1977), 53–61, §I (for any p and any $N \geq 3$ prime to p, over an algebraically closed field: the definition of A through $\eta^p = A(E,\omega,\alpha)\eta$ in $H^1(E,\mathcal{O}_E)$, which does not involve the level structure, whence the invariance; all q-expansions of A are 1; a homogeneous element is determined by its weight and any one q-expansion; the kernels of the q-expansion maps are $(A-1)\mathcal{R}$). *The consequence in (Kt4).* If $k \not\equiv k' \pmod{p-1}$, then $f - g$ lies in the kernel $(A-1)\mathcal{R}$; since $A - 1 \equiv 0$ in $\mathcal{R}/(A-1)\mathcal{R}$, this quotient is graded by $\mathbb{Z}/(p-1)\mathbb{Z}$ and the q-expansion map factors injectively through it. The forms f and g have nonzero images (their q-expansion is nonzero) in different graded pieces, while $f - g$ has image 0, a contradiction. So $k \equiv k'$, and f and $A^{(k-k')/(p-1)}g$ are homogeneous of weight k with the same q-expansion at that cusp, hence equal. □

Theorem B.80. *Let $g = \sum_{n\geq 1} a_n q^n$ be a normalised newform of weight $k \geq 2$, level L_g and character ε, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and $\rho^{\mathrm{ar}} = \rho_{g,\iota}^\vee$, so that $\iota \det(X - \rho^{\mathrm{ar}}(\sigma)) = X^2 - a_p X + \varepsilon(p)p^{k-1}$ for every prime $p \nmid \ell L_g$ and arithmetic Frobenius σ at a place above p, and $\det \rho^{\mathrm{ar}} = \varepsilon\chi_{\mathrm{cyc}}^{k-1}$. Then:*

(Gn1) *The representation ρ^{ar} is irreducible.*

(Gn2) *If $\ell \nmid L_g$ and $\iota^{-1}(a_\ell)$ is an ℓ-adic unit, let α be the root of $X^2 - \iota^{-1}(a_\ell)X + \iota^{-1}(\varepsilon(\ell))\ell^{k-1}$ that is an ℓ-adic unit. Then for every place $\bar{\ell}$ of $\overline{\mathbb{Q}}$ above ℓ, ρ^{ar} is triangular on $D_{\bar{\ell}}$ with a diagonal (δ_1,δ_2) such that δ_2 is trivial on $I_{\bar{\ell}}$ and $\delta_2(\sigma) = \alpha$ for every arithmetic Frobenius σ at $\bar{\ell}$.*

(Gn3) *If $p \neq \ell$ is a prime with $p \mid L_g$ and $v_p(L_g) = v_p(\operatorname{cond}\varepsilon)$, then for every place $\bar{p}$ above p the restriction of ρ^{ar} to $D_{\bar{p}}$ is conjugate to $s \mapsto \operatorname{diag}(\nu_1(s),\nu_2(s))$ for characters ν_1,ν_2 of $D_{\bar{p}}$ with ν_1 trivial on $I_{\bar{p}}$, and $|\iota\nu_1(\sigma)| = |\iota\nu_2(\sigma)| = p^{(k-1)/2}$ for every $\sigma \in D_{\bar{p}}$ acting on the residue field as $x \mapsto x^p$.*

Proof. For (Gn1), see K. Ribet, *Galois representations attached to eigenforms with Nebentypus*, Modular functions of one variable V, Lecture Notes in Math. 601 (1977), Theorem 2.3 (irreducibility of $\rho_{g,\iota}$, hence of its contragredient). For (Gn2), see [270], Theorem 2.1.4 (the case $F = \mathbb{Q}$, with ρ^{ar} the representation of op. cit., whose arithmetic Frobenius traces are the a_p). For g ordinary at the place of ι, the restriction to a decomposition group at ℓ is an extension of an unramified character, sending an arithmetic Frobenius to the unit root α, by a character. This is triangular on $D_{\bar{\ell}}$ in the sense of Definition 38.4 with δ_2 the unramified quotient. For another place $\gamma\bar{\ell}$, conjugate by $\rho^{\mathrm{ar}}(\gamma)$. For (Gn3), see H. Carayol, [59], Théorème (A): for $p \neq \ell$ the Frobenius-semisimplified Weil–Deligne representation of $\rho^{\mathrm{ar}}|_{D_{\bar{p}}}$ corresponds under the local Langlands correspondence (suitably normalised) to the local component π_p of the automorphic representation of g. By Casselman's theory of the conductor (*On some results of Atkin and Lehner*, Math. Ann. 201 (1973)), π_p has conductor exponent $v_p(L_g)$ and central character of conductor exponent $v_p(\operatorname{cond}\varepsilon)$; when these are equal and positive, π_p is a principal series $\pi(\mu_1, \mu_2)$ with μ_1 unramified and μ_2 ramified, so the Weil–Deligne representation is a sum of two characters with trivial monodromy, one of them unramified, and $\rho^{\mathrm{ar}}|_{D_{\bar{p}}}$, which then has finite image on inertia, is conjugate to the corresponding diagonal representation. In the unitary normalisation π_p is unitary. An irreducible unitary principal series of $\mathrm{GL}_2(\mathbb{Q}_p)$ with $\mu_1\mu_2^{-1}$ ramified is not a complementary series (those have $\mu_1\mu_2^{-1} = |\cdot|^{\pm 2s}$, [135]), so $|\mu_1(p)| = |\mu_2(p)|$, whence $|\iota\nu_1(\sigma)| = |\iota\nu_2(\sigma)|$; as $|\iota(\nu_1\nu_2)(\sigma)| = |\iota(\varepsilon\chi_{\mathrm{cyc}}^{k-1})(\sigma)| = p^{k-1}$, both equal $p^{(k-1)/2}$. □

Theorem B.81. *Let E/F be a cyclic extension of number fields of prime degree, $n \geq 1$, and Π a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$. There is an isobaric automorphic representation $\mathrm{BC}_{E/F}(\Pi)$ of $\mathrm{GL}_n(\mathbb{A}_E)$ such that:*

(Ac1) *for every finite place v of F unramified in E at which Π_v is unramified with Satake parameters $\{\alpha_1, \dots, \alpha_n\}$, and every place $w \mid v$ of E with residue degree f, $\mathrm{BC}_{E/F}(\Pi)_w$ is unramified with Satake parameters $\{\alpha_1^f, \dots, \alpha_n^f\}$;*

(Ac2) *for every archimedean place $w \mid v$, the Langlands parameter of $\mathrm{BC}_{E/F}(\Pi)_w$ is the restriction of that of Π_v to the Weil group of E_w;*

(Ac3) *$\mathrm{BC}_{E/F}(\Pi)$ is cuspidal if and only if $\Pi \not\cong \Pi \otimes (\omega \circ \det)$ for every Hecke character $\omega \neq 1$ of F trivial on $\mathrm{N}_{E/F}(\mathbb{A}_E^\times)$.*

Proof. See [9, Chapter 3, Theorems 4.2 and 5.1] (global base change for E/F cyclic of prime degree, for representations induced from cuspidal ones, with local components the local base changes at all places; the base change of a cuspidal Π is cuspidal unless $\Pi \cong \Pi \otimes \omega$ for a nontrivial character ω of $F^\times \mathrm{N}_{E/F}(\mathbb{A}_E^\times)\backslash\mathbb{A}_F^\times$, in which case it is induced from cuspidal representations of smaller groups). Local base change of unramified representations [9, Chapter 1, §4–§6] and at archimedean places (restriction of Langlands parameters) gives (Ac1) and (Ac2). □

Theorem B.82. *Let π be a cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_\mathbb{Q})$. There is an isobaric automorphic representation $\mathrm{Ad}(\pi)$ of $\mathrm{GL}_3(\mathbb{A}_\mathbb{Q})$ such that:*

(Gj1) *for every prime p at which π_p is unramified with Satake parameters $\{\alpha, \beta\}$, $\mathrm{Ad}(\pi)_p$ is unramified with Satake parameters $\{\alpha/\beta, 1, \beta/\alpha\}$;*

(Gj2) *the Langlands parameter of $\mathrm{Ad}(\pi)_\infty$ is the composite of that of π_∞ with the adjoint representation $\mathrm{GL}_2(\mathbb{C}) \to \mathrm{GL}(\mathfrak{sl}_2(\mathbb{C})) \cong \mathrm{GL}_3(\mathbb{C})$;*

(Gj3) *$\mathrm{Ad}(\pi)$ is cuspidal if and only if there is no Hecke character $\omega \neq 1$ of $\mathbb{Q}$ with $\omega^2 = 1$ and $\pi \otimes (\omega \circ \det) \cong \pi$.*

Proof. See [104, Theorem 9.3] (existence of the lift with local components the local lifts at every place, and the cuspidality criterion: $\mathrm{Ad}(\pi)$ is cuspidal if and only if π is not monomial, i.e. $\pi \ncong \pi \otimes \omega$ for every quadratic character $\omega \neq 1$), with the local lifts of [104, §3] (for an unramified principal series the induced representation from $(\mu_1\mu_2^{-1}, 1, \mu_2\mu_1^{-1})$, which gives (Gj1); at the archimedean place the lift is defined through Langlands' parametrisation, which gives (Gj2)). □

Theorem B.83. *Let $n \geq 1$. For a commutative ring A, a group G, an A-valued determinant D of dimension n on G and $x \in A[G]$ write $\chi_D(x)(X) = D(X - x) = \sum_{i=0}^{n}(-1)^i\Lambda_i(x)X^{n-i}$.*

(Ch1) *(Amitsur's formula.) For $m \geq 1$, $1 \leq i \leq n$ and $g_1, \ldots, g_m \in G$, $\Lambda_i(t_1g_1 + \cdots + t_mg_m) \in A[t_1, \ldots, t_m]$ is a polynomial with integer coefficients, depending only on n, m and i, in the elements $\Lambda_j(w)$ ($1 \leq j \leq n$), w running over the finite products of the g_k. Consequently D is the base change of a determinant with values in the subring of A generated by the $\Lambda_i(g)$, $g \in G$; and two A-valued determinants of dimension n on G with $\chi_D(g) = \chi_{D'}(g)$ for all $g \in G$ are equal.*

(Ch2) *(The universal continuous determinant.) Let k be a finite field of characteristic ℓ, $W(k)$ its ring of Witt vectors, G a profinite group and $\bar{D}$ a continuous k-valued determinant of dimension n on G. There are a profinite local $W(k)$-algebra $A(\bar{D})$ with residue field k and a continuous $A(\bar{D})$-valued determinant $D(\bar{D})$ of dimension n on G lifting $\bar{D}$, such that for every profinite local $W(k)$-algebra A with residue field k and every continuous A-valued determinant D of dimension n on G lifting $\bar{D}$ there is exactly one continuous $W(k)$-algebra homomorphism $f\colon A(\bar{D}) \to A$ with $f \circ D(\bar{D}) = D$. If G satisfies Φ_ℓ, then $A(\bar{D})$ is Noetherian.*

(Ch3) *(Determinants over algebraically closed fields.) If k is an algebraically closed field and D a k-valued determinant of dimension n on G, there is a semisimple representation $\rho\colon G \to \mathrm{GL}_n(k)$ with $D = \det \circ \rho$, unique up to isomorphism.*

(Ch4) *(Gluing.) Let G be a compact topological group, A a compact topological ring, $(A_i)_{i\in I}$ a family of topological rings, $\iota\colon A \to \prod_{i\in I} A_i$ a continuous injective ring homomorphism, and D_i a continuous A_i-valued determinant of dimension n on G for each i. If for every g in a dense subset $X \subseteq G$ the family $(\chi_{D_i}(g))_i$ of characteristic polynomials lies in $\iota(A)[t]$, then there is a continuous A-valued determinant D of dimension n on G such that D_i is the base change of D along the i-th component of ι for every i.*

Proof. All references are to [66]. (Ch1) is Amitsur's formula (1.4), (1.5) of §1.10 (Lemma 1.12 (ii)) with Corollary 1.14 and its proof; that a homogeneous polynomial law is determined by its values $D(t_1g_1 + \cdots + t_mg_m)$ on the generic elements is recalled in §1.1 and §1.5 (the functions $D[\alpha]$), and $D(t_1g_1 + \cdots + t_mg_m) = \Lambda_n(t_1g_1 + \cdots + t_mg_m)$. (Ch2) is Proposition 3.3 with Lemma 3.2 (the functor on profinite local $W(k)$-algebras with residue field k) and Proposition 3.7 (Noetherian under Mazur's condition, called (F) there); continuity of an A-valued determinant for profinite A means continuity of the maps $\Lambda_i\colon G \to A$ (§2.30). (Ch3) is Theorem 2.12 (with $R = k[G]$). (Ch4) is Example 2.32 (glueing determinants), whose proof uses Corollary 1.14 and the closedness of $\iota(A)$ (A compact); continuity of D there means continuity of the Λ_i (§2.30). In Chenevier's notation, d is n, p is ℓ and σ_i is Λ_i. □

Theorem B.84. *Let F be a totally real field, p an odd prime, $\iota\colon \overline{\mathbb{Q}}_p \to \mathbb{C}$ an isomorphism, I the set of embeddings $\sigma\colon F \to \overline{\mathbb{Q}}_p$ (identified through ι with the real places), $t = \sum_{\sigma\in I}\sigma \in \mathbb{Z}[I]$, $\mathfrak{r}_p = \mathcal{O}_F \otimes \mathbb{Z}_p$, N an integral ideal prime to p, and $\mathcal{O} \subset \overline{\mathbb{Q}}_p$ a coefficient ring containing $\sigma(\mathcal{O}_F)$*

for all σ. Put $Z(N) = \varprojlim_\alpha \mathrm{Cl}_F(Np^\alpha)$ (ray class groups), $G = Z(N) \times \mathfrak{r}_p^\times$, $G = W \times G_{\mathrm{tor}}$ a decomposition with W free of finite rank over $\mathbb{Z}_p$ and G_{tor} finite, $A = \mathcal{O}[[W]]$, and $\mathcal{N}\colon Z(N) \to \mathbb{Z}_p^\times$ the p-adic cyclotomic character (via class field theory). An arithmetic weight *is $(n, v) \in \mathbb{Z}[I]^2$ with $n \geq 0$, $v \geq 0$ and $n + 2v = [n + 2v]\,t$, $[n + 2v] \in \mathbb{Z}$; it has $k = n + 2t$. For such (n, v), $\alpha \geq 1$ and finite-order characters ψ of $\mathrm{Cl}_F(Np^\alpha)$ and ψ' of $(\mathcal{O}_F/p^\alpha)^\times$, let $P_{n,v,\psi,\psi'}\colon \mathcal{O}[[G]] \to \overline{\mathbb{Q}}_p$ be the $\mathcal{O}$-algebra homomorphism induced by $(z, a) \mapsto \psi(z)\psi'(a)\mathcal{N}(z)^{[n+2v]}a^v$, $a^v = \prod_\sigma \sigma(a)^{v_\sigma}$, and let $S_{k,w}(Np^\alpha, \psi', \psi; \mathbb{C})$ be Hida's space of holomorphic cusp forms on $\mathrm{GL}_2(\mathbb{A}_F)$ of weight (k, w), level $V_1(N) \cap U(p^\alpha)$ and characters (ψ, ψ'), with the Hecke operators $T(\mathfrak{q})$, $\mathfrak{q} \nmid Np$, $T(x)$ ($0 \neq x \in \mathfrak{r}_\mathfrak{p}$, $\mathfrak{p} \mid p$; double coset of $\mathrm{diag}(1, x)$), and $\langle\mathfrak{q}\rangle$, and its nearly ordinary part (where $x^{-v}T(x)$ acts invertibly for x a uniformiser). Then there is a compact $\mathcal{O}[[G]]$-algebra $\mathbf{h} = \mathbf{h}^{\mathrm{n.ord}}(N; \mathcal{O})$, topologically generated over $\mathcal{O}[[G]]$ by elements $T(\mathfrak{q})$, $T(x)$, with:*

(Hf1) $\mathbf{h}$ *is a finitely generated torsion-free A-module; every irreducible component of* $\operatorname{Spec}\mathbf{h}$ *is* $\operatorname{Spec}\mathbb{I}$ *for an integral domain $\mathbb{I}$ finite and torsion-free over A.*

(Hf2) *If $\lambda\colon \mathbf{h} \to \overline{\mathbb{Q}}_p$ is an $\mathcal{O}$-algebra homomorphism whose restriction to $\mathcal{O}[[G]]$ is $P_{n,v,\psi,\psi'}$ for an arithmetic weight (n, v), then there is a non-zero common eigenform $f \in S_{k,w}(Np^\alpha, \psi', \psi; \mathbb{C})$ in the nearly ordinary part on which every $T(\mathfrak{q})$, $T(x)$, $\langle\mathfrak{q}\rangle$ acts by $\iota\lambda(\cdot)$, the operators $T(x)$ normalised by x^{-v}. Conversely, every nearly ordinary common eigenform in some $S_{k,w}(Np^\alpha, \psi', \psi; \mathbb{C})$ defines such a λ.*

(Hf3) *For λ as in (Hf2) there is a unique semisimple continuous $\sigma_\lambda\colon G_F \to \mathrm{GL}_2(\overline{\mathbb{Q}}_p)$, unramified outside Np, with $\det(1 - \sigma_\lambda(\mathrm{Frob}_\mathfrak{q})X) = 1 - \lambda(T(\mathfrak{q}))X + \lambda(\langle\mathfrak{q}\rangle)\mathrm{N}\mathfrak{q}X^2$ for $\mathfrak{q} \nmid Np$. For every $\mathfrak{p} \mid p$ and every decomposition group $D_\mathfrak{p}$ there are characters ϵ, δ of $D_\mathfrak{p}$ with $\sigma_\lambda|_{D_\mathfrak{p}} \cong \left(\begin{smallmatrix}\epsilon & * \\ 0 & \delta\end{smallmatrix}\right)$ and $\delta(\mathrm{rec}_\mathfrak{p}(x)) = \lambda_f(x^{-v}T(x))$ for $0 \neq x \in \mathfrak{r}_\mathfrak{p}$, where $\lambda_f(h)$ is the eigenvalue of the classical operator h on f and $\mathrm{rec}_\mathfrak{p}$ is local reciprocity normalised by $\mathcal{N}(\mathrm{rec}_\mathfrak{p}(u)) = \mathrm{N}_{F_\mathfrak{p}/\mathbb{Q}_p}(u)^{-1}$ for $u \in \mathfrak{r}_\mathfrak{p}^\times$.*

Proof. (Hf1): [127], Theorem 2.4, as restated in [128], p. 118 ("$\mathbf{h}^{\mathrm{n.ord}}(S; \mathcal{O})$ is of finite type and torsion free as A-module") and Remark (i) on p. 119 (irreducible components $\mathrm{Spec}(\mathbb{I})$, $\mathbb{I}$ finite and torsion-free over A), and in [129], p. 336. (Hf2): [129], Corollary 3.3 ($\bar{S}^{\mathrm{n.ord}}(N)[P_{n,v,\psi,\psi'}] = S_{k,w}^{\mathrm{n.ord}}(Np^\alpha, \psi', \psi; \mathcal{O})$, the character $G \ni (z, a) \mapsto \psi(z)\psi'(a)\mathcal{N}(z)^{[n+2v]}a^v$), its proof on p. 336 (control isomorphism $\mathbf{h}_P^{\mathrm{n.ord}}/P\mathbf{h}_P^{\mathrm{n.ord}} \cong \mathbf{h}_{k,w}^{\mathrm{n.ord}}(Np^\alpha, \psi', \psi; K)$ from [127], Theorem 2.4; Hida notes that the argument there, written for ψ' trivial, applies to general characters), the duality Theorem 3.1, and p. 337 ("each specialization $\mathbf{f}_P$ is a common eigenform and is classical"); the independence of the weight (3.2) = [127], Theorem 2.3, for all (n, v) with $n \geq 0$, $v \geq 0$, $n + 2v \in \mathbb{Z}t$; weights $k = n + 2t$, $w = t - v$ in the normalisation of [129] ($w = v + k - t$ with the automorphy factor $\det^{-w}(cz + d)^k$ in [128], p. 117). (Hf3): [128], Theorem I (i)–(iv) (for any continuous λ into an integral domain in $\mathcal{C}$ of characteristic $\neq 2$, in particular a coefficient ring) and Proposition 2.3 (for λ on $\mathbf{h}_{k,w}^{\mathrm{n.ord}}(S(p^\alpha); \mathcal{O})$, $n \geq 0$, $v \geq 0$, $n + 2v \in \mathbb{Z}t$: δ corresponds to $\xi_\mathfrak{p}$ with $\lambda(x^{-v}T(x)) = \xi_\mathfrak{p}(x)$); the normalisation of local reciprocity is that of [130], Theorem 3.1(4) ($\mathcal{N}([u, F_\mathfrak{p}]) = N_{F_\mathfrak{p}/\mathbb{Q}_p}(u)^{-1}$, $\mathcal{N}(\mathrm{Frob}_l) = l$). For parallel weight the local shape is Wiles' theorem as stated in [236], (3.2), whose $T(\mathfrak{q})$, $S(\mathfrak{q})$ are Shimura's operators for $\mathfrak{q} \nmid \mathfrak{n}$ (op. cit., p. 30) and whose $T_0(\mathfrak{p}_i) = (\lambda^{(\mathfrak{p}_i)})^{-v}T(\mathfrak{p}_i)$ is the normalised operator above. As for notation, Hida's $\mathfrak{r}$, $\mathfrak{r}_p$, $\mathbf{G}$, $\mathbf{W}$, $\mathbf{A}$, $\mathcal{N}$ are $\mathcal{O}_F$, $\mathfrak{r}_p$, G, W, A, $\mathcal{N}$; his π, $\phi_\mathfrak{q}$ are σ_λ, $\mathrm{Frob}_\mathfrak{q}$. □

Theorem B.85. *Let F be a totally real field, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_F)$. Then there is a continuous semisimple $r_{\ell,\iota}(\pi)\colon G_F \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ with $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$ such that for every finite place $v \nmid \ell$: if π_v is isomorphic to the irreducible normalised induction of characters μ_1, μ_2 of $F_v^\times$, then*

$r_{\ell,\iota}(\pi)|_{I_v} \cong \nu_1 \oplus \nu_2$ *for characters* ν_i *of* I_v *of finite order with* $\iota \circ \nu_i \circ \mathrm{Art}_{F_v} = \mu_i^{-1}$ *on* $\mathcal{O}_{F_v}^\times$*, where* Art_{F_v} *is the Artin map normalised to send uniformisers to geometric Frobenius elements.*

Proof. By [17], Theorem 2.1.1 (2), which allows F totally real, for a regular algebraic cuspidal polarized (π, χ) there is a continuous semisimple $r_{\ell,\iota}(\pi)$ with $\iota\mathrm{WD}(r_{\ell,\iota}(\pi)|_{G_{F_v}})^{F\text{-ss}} \cong \mathrm{rec}(\pi_v \otimes |\det|_v^{(1-n)/2})$ for $v \nmid \ell$ (Carayol, Taylor, Blasius–Rogawski for $n = 2$: [59], [253]). For GL_2 every regular algebraic cuspidal π is polarized by $\chi = \omega_\pi$, the central character: $\pi^\vee \cong \pi \otimes (\omega_\pi^{-1} \circ \det)$, and $\omega_{\pi,v}(-1)$ is independent of the real place v. Indeed $\pi_v \cong D_{k_v} \otimes |\det|^{t_v}$ is a twist of a discrete series, $\omega_{\pi,v}(-1) = (-1)^{k_v}$, regular algebraicity gives $t_v - k_v/2 \in \mathbb{Z}$, and $2t_v$ is independent of v because ω_π is trivial on a subgroup of finite index of the totally positive units (Dirichlet's unit theorem); so the parity of k_v is independent of v. If π_v is the irreducible normalised induction of μ_1, μ_2, then $\mathrm{rec}(\pi_v \otimes |\det|^{-1/2}) = (\mu_1|\cdot|^{-1/2} \oplus \mu_2|\cdot|^{-1/2}) \circ \mathrm{Art}_{F_v}^{-1}$ with monodromy $N = 0$; the Weil–Deligne representation of a representation with $N = 0$ has the same restriction to inertia as the representation (Grothendieck's monodromy theorem), Frobenius-semisimplification does not change the restriction to inertia, and $|\cdot|$ is trivial on units. In the normalisation of op. cit. (uniformisers to geometric Frobenius) this gives the stated ν_i. The relation $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$ is the unramified case. □

Theorem B.86. *Let* F *be a totally real field of degree* n *with narrow class group* $\mathrm{Cl}^+(F)$*, let* $\mathfrak{n}$ *be a non-zero integral ideal,* $\kappa \geq 1$ *an integer and* ψ *a character of finite order of the narrow ray class group modulo* $\mathfrak{n}$ *(extended by* $\psi(\mathfrak{a}) = 0$ *for* $\mathfrak{a}$ *not prime to* $\mathfrak{n}$*). Let* $M_\kappa(\mathfrak{n}, \psi) \supseteq S_\kappa(\mathfrak{n}, \psi)$ *be Shimura's spaces of Hilbert modular forms and cusp forms of parallel weight* κ*, level* $\mathfrak{n}$ *and character* ψ*: tuples* $f = (f_\lambda)_{\lambda \in \mathrm{Cl}^+(F)}$ *of holomorphic functions on* $\mathfrak{H}^n$*, attached to fixed representatives* $\mathfrak{t}_\lambda$ *prime to a given finite set of primes, with Fourier expansions* $f_\lambda(z) = a_\lambda(0) + \sum_{b \in \mathfrak{t}_\lambda,\, b \gg 0} a_\lambda(b) e_F(bz)$*,* normalised coefficients $c(\mathfrak{m}, f) = a_\lambda(b)\mathrm{N}(\mathfrak{t}_\lambda)^{-\kappa/2}$ *for* $\mathfrak{m} = (b)\mathfrak{t}_\lambda^{-1}$ *(*$\mathfrak{m}$ *a non-zero integral ideal) and* constant terms $c_\lambda(0, f) = a_\lambda(0)\mathrm{N}(\mathfrak{t}_\lambda)^{-\kappa/2}$*. Then:*

(Hb1) $M_\kappa(\mathfrak{n}, \psi)$ *is finite-dimensional over* $\mathbb{C}$*, and an* $f \in M_\kappa(\mathfrak{n}, \psi)$ *with* $c(\mathfrak{m}, f) = 0$ *for all non-zero integral* $\mathfrak{m}$ *is* 0*.*

(Hb2) *For every prime* $\mathfrak{q}$ *there is an endomorphism* $T(\mathfrak{q})$ *of* $M_\kappa(\mathfrak{n}, \psi)$ *preserving* $S_\kappa(\mathfrak{n}, \psi)$*; these endomorphisms commute, and for all non-zero integral* $\mathfrak{m}$

$$c(\mathfrak{m}, f|T(\mathfrak{q})) = c(\mathfrak{m}\mathfrak{q}, f) + \psi(\mathfrak{q})\mathrm{N}\mathfrak{q}^{\kappa-1} c(\mathfrak{m}\mathfrak{q}^{-1}, f),$$

with $c(\mathfrak{m}\mathfrak{q}^{-1}, f) = 0$ *if* $\mathfrak{q} \nmid \mathfrak{m}$*. For* $\mathfrak{q} \mid \mathfrak{n}$ *one writes* $U(\mathfrak{q}) = T(\mathfrak{q})$*.*

(Hb3) *If* $f \in M_\kappa(\mathfrak{n}, \psi)$ *and* $g \in M_{\kappa'}(\mathfrak{n}', \psi')$ *(same representatives* $\mathfrak{t}_\lambda$*), then* $fg = (f_\lambda g_\lambda)_\lambda \in M_{\kappa+\kappa'}(\mathfrak{n} \cap \mathfrak{n}', \psi\psi')$*.*

(Hb4) *Let* η, ψ_1 *be (possibly imprimitive) finite-order characters of the narrow ray class groups modulo integral ideals* $\mathfrak{a}, \mathfrak{b}$*, with signs* $q, r \in (\mathbb{Z}/2\mathbb{Z})^n$*,* $q + r \equiv (\kappa, \ldots, \kappa)$*. There is* $E_\kappa(\eta, \psi_1) \in M_\kappa(\mathfrak{a}\mathfrak{b}, \eta\psi_1)$ *with*

$$c(\mathfrak{m}, E_\kappa(\eta, \psi_1)) = \sum_{\mathfrak{r} \mid \mathfrak{m}} \eta(\mathfrak{m}\mathfrak{r}^{-1})\psi_1(\mathfrak{r})\mathrm{N}\mathfrak{r}^{\kappa-1}$$

for all non-zero integral $\mathfrak{m}$*; if* $\kappa > 1$*, then* $c_\lambda(0, E_\kappa(\eta, \psi_1)) = 2^{-n}\eta^{-1}(\mathfrak{t}_\lambda)L(\psi_1\eta^{-1}, 1-\kappa)$ *if* $\mathfrak{a} = 1$ *and* 0 *otherwise; if* $\kappa = 1$ *and* $\mathfrak{a} \neq 1 \neq \mathfrak{b}$*, then* $c_\lambda(0, E_1(\eta, \psi_1)) = 0$ *for all* λ*. Here* $L(\chi, s)$ *is the L-function of* χ *with the Euler factors at the primes dividing the modulus removed.*

(Hb5) *Let $\kappa \geq 2$ and let $f \in M_\kappa(\mathfrak{n}, \psi)$, $f \notin S_\kappa(\mathfrak{n}, \psi)$, be an eigenvector of every $T(\mathfrak{q})$ with eigenvalue $\lambda_f(\mathfrak{q})$. Then there are finite-order characters η_1, η_2 of narrow ray class groups, with $\eta_1\eta_2(\mathfrak{q}) = \psi(\mathfrak{q})$ for $\mathfrak{q} \nmid \mathfrak{n}$, such that $\lambda_f(\mathfrak{q}) = \eta_1(\mathfrak{q}) + \eta_2(\mathfrak{q})\mathrm{N}\mathfrak{q}^{\kappa-1}$ for $\mathfrak{q} \nmid \mathfrak{n}$, and $\lambda_f(\mathfrak{q}) \in \{0,\ \eta_1(\mathfrak{q}),\ \eta_2(\mathfrak{q})\mathrm{N}\mathfrak{q}^{\kappa-1}\}$ for $\mathfrak{q} \mid \mathfrak{n}$, where $\eta_i(\mathfrak{q}) = 0$ if η_i is ramified at $\mathfrak{q}$.*

Proof. See [230], Section 2 (the spaces $M_\kappa(\mathfrak{n}, \psi)$, $S_\kappa(\mathfrak{n}, \psi)$, the normalised coefficients $C(\mathfrak{m}, f)$, the Hecke operators and their action on $C(\mathfrak{m}, f)$, formula (2.23)) and Proposition 3.4 (existence of the Eisenstein series); [73], Section 2.1 (definitions, (47)–(49): normalised coefficients $c(\mathfrak{m}, f) = C(\mathfrak{m}, f)$ and constant terms $c_\lambda(0, f)$) and Proposition 2.1 (formulas (50)–(52): Fourier coefficients and constant terms of $E_k(\eta, \psi)$, imprimitive characters allowed, constant term 0 in weight one when both moduli are $\neq 1$). For (Hb1), finite dimensionality and the q-expansion principle are in [230], Section 2; for parallel weight $\kappa \geq 1$ a form all of whose non-constant coefficients vanish has constant components f_λ, and a constant satisfying (47) of [73] with a factor $(cz + d)^{-\kappa}$, $c \neq 0$, vanishes. For (Hb3), the automorphy factor $\det(\gamma)^{\kappa/2}(cz + d)^{-\kappa}$ is multiplicative in κ, and the character condition on Γ_λ and the condition $S(\mathfrak{m})f = \psi(\mathfrak{m})f$ are multiplicative (adelically: products of functions on $\mathrm{GL}_2(\mathbb{A}_F)$). For (Hb5), the space $M_\kappa(\mathfrak{n}, \psi)$ is the direct sum of $S_\kappa(\mathfrak{n}, \psi)$ and the Hecke-stable space spanned by the translates $E_\kappa(\eta_1, \eta_2)|B(\mathfrak{c})$ with $\eta_1\eta_2 = \psi$, $\mathrm{cond}(\eta_1)\mathrm{cond}(\eta_2)\mathfrak{c} \mid \mathfrak{n}$, on whose summand for (η_1, η_2) the operators $T(\mathfrak{q})$, $\mathfrak{q} \nmid \mathfrak{n}$, act by $\eta_1(\mathfrak{q}) + \eta_2(\mathfrak{q})\mathrm{N}\mathfrak{q}^{\kappa-1}$ and $U(\mathfrak{q})$, $\mathfrak{q} \mid \mathfrak{n}$, has eigenvalues among 0, $\eta_1(\mathfrak{q})$, $\eta_2(\mathfrak{q})\mathrm{N}\mathfrak{q}^{\kappa-1}$ ([230], Sections 2–3; the same classification is the input of [236], Section 3.4). *Notation.* Shimura's $C(\mathfrak{m}, f)$ is $c(\mathfrak{m}, f)$; Dasgupta–Darmon–Pollack's $E_k(\eta, \psi)$ is $E_\kappa(\eta, \psi_1)$ here. □

Theorem B.87. *Let M/L be a cyclic extension of number fields of prime degree p, σ a generator of $\mathrm{Gal}(M/L)$, $n \geq 1$, and π a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_M)$; write π^σ for $g \mapsto \pi(\sigma(g))$. There is an isobaric automorphic representation $\mathrm{AI}_{M/L}(\pi)$ of $\mathrm{GL}_{np}(\mathbb{A}_L)$ such that:*

(Ai1) *for every finite place v of L unramified in M such that π_w is unramified for every place $w \mid v$ of M, $\mathrm{AI}_{M/L}(\pi)_v$ is unramified, and its multiset of Satake parameters is the union of those of the π_w, $w \mid v$, if v splits completely in M, and is $\{\gamma :\ \gamma^p = \alpha\}$, α running over the Satake parameters of π_w (each γ once for each α), if v is inert in M with $w \mid v$;*

(Ai2) *for every complex place v of L, the Langlands parameter of $\mathrm{AI}_{M/L}(\pi)_v$ is the direct sum of the Langlands parameters of the π_w, $w \mid v$;*

(Ai3) *$\mathrm{AI}_{M/L}(\pi)$ is cuspidal if and only if $\pi \not\cong \pi^\sigma$.*

Proof. See [9, Chapter 3, §6] (automorphic induction from $\mathrm{GL}_n(\mathbb{A}_M)$ to $\mathrm{GL}_{np}(\mathbb{A}_L)$ for M/L cyclic of prime degree, derived there from base change; secondary sources number the theorem 6.2). The statement there is as follows. There is an automorphic representation $\Pi = I_M^L(\pi)$, induced from cuspidal, whose local component at every place v is the local automorphic induction of $(\pi_w)_{w|v}$, i.e. whose local Langlands parameter is the induction of the parameter of π_w from the Weil group of M_w to that of L_v when v does not split, and the sum over $w \mid v$ when v splits; and Π is cuspidal exactly when π is not isomorphic to its Galois conjugates (for prime p, $\pi \cong \pi^{\sigma^i}$ for some $0 < i < p$ if and only if $\pi \cong \pi^\sigma$). In the notation used here: at an unramified inert v the induction of the unramified character of W_{M_w} with $\mathrm{Frob}_w \mapsto \alpha$ (and $\mathrm{Frob}_w = \mathrm{Frob}_v^p$) has Frob_v-eigenvalues the p-th roots of α, which is (Ai1) for inert v; complex places of L split completely in M, which is (Ai2). □

Theorem B.88. *Let A be a commutative ring, R an A-algebra and $D\colon R \to A$ a determinant of dimension d. Let*

$$\ker(D) = \{r \in R :\ D_T(1+rr') = 1 \text{ for every commutative } A\text{-algebra } T \text{ and every } r' \in R \otimes_A T\},$$

and let $\mathrm{CH}(D)$ be the two-sided ideal of R generated by the coefficients of $\chi_{D'}(t_1 r_1 + \cdots + t_m r_m)(t_1 r_1 + \cdots + t_m r_m) \in R[t_1, \ldots, t_m]$, for $m \geq 1$, $r_1, \ldots, r_m \in R$ and D' the base change of D to $A[t_1, \ldots, t_m]$.

(Ck1) *$\ker(D)$ is also the set of $r \in R$ with $D_T(1 + r'r) = 1$ for all T and $r' \in R \otimes_A T$; it is a two-sided ideal of R, and it is the largest two-sided ideal K of R such that $D = \tilde{D} \circ \pi$ for the projection $\pi\colon R \to R/K$ and a determinant $\tilde{D}$ of dimension d on the A-algebra R/K.*

(Ck2) *$\mathrm{CH}(D) \subseteq \ker(D)$.*

Proof. This is [66, Lemma 1.19 (i), (ii) and Lemma 1.21], stated there for polynomial laws $P \in \mathcal{M}_A^d(R, S)$ that are multiplicative and homogeneous of degree d; (Ck1) is the case $S = A$, and the factorisation $\tilde{D}$ is again homogeneous of degree d and multiplicative (loc. cit., remark after Lemma 1.18). □

Theorem B.89. *Let A be a henselian local commutative ring with residue field k, R an A-algebra and $D\colon R \to A$ a determinant of dimension d which is Cayley–Hamilton, that is $\mathrm{CH}(D) = 0$. Assume that the residual determinant $D \otimes_A k\colon R \otimes_A k \to k$ is the determinant of a surjective homomorphism of k-algebras $R \otimes_A k \to \mathrm{M}_d(k)$. Then there is an isomorphism of A-algebras $\rho\colon R \to \mathrm{M}_d(A)$ with $D = \det \circ \rho$.*

Proof. By [66], Theorem 2.22(i), if D is Cayley–Hamilton and A is henselian, and the residual determinant is split and absolutely irreducible, then there is an A-algebra isomorphism $\rho\colon R \to \mathrm{M}_d(A)$ with $D = \det \circ \rho$. By the remark after Definition 2.19 there, a determinant $R \otimes_A k \to k$ is split and absolutely irreducible if and only if it is the determinant of a surjective k-representation $R \otimes_A k \to \mathrm{M}_d(k)$, which is the hypothesis stated here. □

Theorem B.90. *Let F be a CM field, $n \geq 2$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$. Let $v \nmid \ell$ be a finite place of F, $\bar{v} \mid v$ a place of $\overline{\mathbb{Q}}$, $(V, \rho, N) = \mathrm{WD}(r_{\ell,\iota}(\pi)|_{D_{\bar{v}}})$ and $\Phi \in W_{\bar{v}}$ with $n(\Phi) = -1$. Then (V, ρ, N) is pure: there are a real number k and $\rho(W_{\bar{v}})$-stable subspaces $\mathrm{Fil}_j V$ ($j \in k + \mathbb{Z}$), increasing in j, zero for j small and equal to V for j large, with $N(\mathrm{Fil}_j V) \subseteq \mathrm{Fil}_{j-2} V$, such that, with $\mathrm{gr}_j = \mathrm{Fil}_j V / \mathrm{Fil}_{j-1} V$:*

(Pv1) *every eigenvalue α of the endomorphism of gr_j induced by $\rho(\Phi)$ is algebraic over $\mathbb{Q}$ with $|\sigma(\alpha)| = q_v^{j/2}$ for every field embedding $\sigma\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$;*

(Pv2) *for every integer $i \geq 1$, N^i induces an isomorphism $\mathrm{gr}_{k+i} \to \mathrm{gr}_{k-i}$.*

Proof. This follows from [56], Theorem 1.1 and Theorem 1.2, with [255], Section 1 and Lemma 1.4.

The published statements. [56], Theorem 1.1: let $n \geq 2$, L a CM field, Π cuspidal automorphic of $\mathrm{GL}_n(\mathbb{A}_L)$ with $\Pi^\vee \cong \Pi \circ c$ and Π_∞ cohomological for an irreducible algebraic representation, $R_\ell(\Pi)$ its Galois representation (Shin, Chenevier–Harris); for $p \neq \ell$ and a place $y \mid p$ of L, $\mathrm{WD}(R_\ell(\Pi)|_{G_{L_y}})^{F\text{-ss}} \cong \iota^{-1}\mathcal{L}_{n,L_y}(\Pi_y)$, the local Langlands correspondence in the geometric normalisation. Theorem 1.2 (same hypotheses): Π is tempered at every finite place.

As stated on p. 2 of loc. cit., temperedness makes $\iota^{-1}\mathcal{L}_{n,L_y}(\Pi_y)$ pure ([255], Lemma 1.4(3)), so $\mathrm{WD}(R_\ell(\Pi)|_{G_{L_y}})^{F\text{-ss}}$ is pure, and then so is $\mathrm{WD}(R_\ell(\Pi)|_{G_{L_y}})$ ([255], Lemma 1.4(1)). The definitions of pure, mixed and strictly pure Weil–Deligne representations of [255], Section 1, give (Pv1), (Pv2), as in the published form recorded in Theorem B.73 for the places above ℓ; the functor WD for $p \neq \ell$ there is Grothendieck's, which is (Wd1).

Comparison of notation. Regular algebraic cuspidal means cohomological at infinity ([68], Section 3) and conjugate self-dual means $\pi^\vee \cong \pi^c$, so π satisfies the hypotheses on Π. $R_\ell(\Pi)$ and $r_{\ell,\iota}(\pi)$ are semisimple with the same Frobenius characteristic polynomials at almost all places ((Bg1) of Theorem B.62), hence isomorphic (Chebotarev, Brauer–Nesbitt), and $D_{\bar v}$ is identified with G_{F_v}. □

Theorem B.91. *Let ℓ be a prime, $n \geq 2$, F an imaginary CM field with maximal totally real subfield F^+ such that every place of F^+ above ℓ splits in F, and $\mathcal{O}$ the ring of integers of a finite extension of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$ containing the image of every embedding $F \to \overline{\mathbb{Q}}_\ell$. Let $\mathbb{G}$ be a unitary group over $\mathcal{O}_{F^+}$ attached to an involution of the second kind on $\mathrm{M}_n(F)$ and an order of $\mathrm{M}_n(F)$ stable under it and maximal at the places split over F^+, such that $\mathbb{G}(F^+ \otimes_{\mathbb{Q}} \mathbb{R})$ is compact and $\mathbb{G}$ is quasi-split at every finite place of F^+. Let T be a finite set of finite places of F^+, all split in F, containing the set S_ℓ of places above ℓ, and $U = \prod_v U_v \subseteq \mathbb{G}(\mathbb{A}_{F^+}^\infty)$ a compact open subgroup with $U_v = \mathbb{G}(\mathcal{O}_{F_v^+})$ for $v \in S_\ell$ and for every $v \notin T$ split in F. For $1 \leq b \leq c$ let $U(\ell^{b,c}) \subseteq U$ be the subgroup whose components at $v \in S_\ell$ are the groups $\mathrm{Iw}(\tilde v^{b,c})$; let $S^{\mathrm{ord}}(U(\ell^\infty), \mathcal{K}/\mathcal{O}) = \varinjlim_c S^{\mathrm{ord}}(U(\ell^{c,c}), \mathcal{K}/\mathcal{O})$ be the space of ordinary forms of trivial weight with coefficients in $\mathcal{K}/\mathcal{O}$, $\mathcal{K} = \mathcal{O}[1/\ell]$, and $\mathcal{S}$ its Pontryagin dual; let $\mathfrak{l} = \prod_{v \in S_\ell} v$ (an ideal of $\mathcal{O}_{F^+}$) and, for $b \geq 1$, let $T_n(\mathfrak{l}^b)$ and $T_n(\ell^b)$ be the kernels of the reductions $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) \to T_n(\mathcal{O}_{F^+}/\mathfrak{l}^b)$ and $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) \to T_n(\mathcal{O}_{F^+}/\ell^b)$ (T_n the diagonal torus; $T_n(\ell^b) \subseteq T_n(\mathfrak{l}^b)$, with equality if ℓ is unramified in F^+); let $\Lambda^+ = \mathcal{O}[[T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell)]]$, $\Lambda_b^{\mathfrak{l}} = \mathcal{O}[[T_n(\mathfrak{l}^b)]]$ and $\Lambda_b = \mathcal{O}[[T_n(\ell^b)]]$, so that $\Lambda_b \subseteq \Lambda_b^{\mathfrak{l}} \subseteq \Lambda^+$, acting on $\mathcal{S}$ through the diamond operators $\langle u \rangle$; and let $\mathbb{T}^{\mathrm{ord}}(U)$ be the Λ^+-subalgebra of $\mathrm{End}_{\mathcal{O}}(\mathcal{S})$ generated by the Hecke operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ at the places w of F above places $v \notin T$ split in F, and the operators $U_{\tilde v}^{(j)}$, $v \in S_\ell$, $1 \leq j \leq n$. If $b_0 \geq 1$ and $U(\ell^{b_0,b_0})$ is sufficiently small, then:*

(Gy1) *$\mathcal{S}$ is a free $\Lambda_{b_0}^{\mathfrak{l}}$-module of finite rank;*

(Gy2) *$\mathbb{T}^{\mathrm{ord}}(U)$ is commutative and finite as a $\Lambda_{b_0}^{\mathfrak{l}}$-module, and, if $\mathcal{S} \neq 0$, $\Lambda_{b_0}^{\mathfrak{l}} \to \mathbb{T}^{\mathrm{ord}}(U)$ is injective;*

(Gy3) *(classicality; objects of §2.2 and §2.6 of [105]) let λ be a dominant weight for $\mathbb{G}$, w_0 the longest element of the Weyl group, ν the weight with components $(n-1, n-2, \dots, 0)$ at every embedding, give $\mathbb{T}^{\mathrm{ord}}(U)$ the $\Lambda_1^{\mathfrak{l}}$-structure $u \mapsto (w_0\nu)^{-1}(u)\langle u \rangle$ ($u \in T_n(\mathfrak{l})$), and its restriction to Λ_1. For a character $\alpha\colon T_n(\mathfrak{l}) \to \overline{\mathbb{Q}}_\ell^\times$ of finite order let $\mathfrak{P}_{\lambda,\alpha}^{\mathfrak{l}}$ be the kernel of the homomorphism $\Lambda_1^{\mathfrak{l}} \to \overline{\mathbb{Q}}_\ell$ induced by the character $\alpha\,(w_0\nu)^{-1}(w_0\lambda)^{-1}$; for a character $\alpha\colon T_n(\ell^1) \to \overline{\mathbb{Q}}_\ell^\times$ of finite order let $\mathfrak{P}_{\lambda,\alpha}$ be the kernel of the homomorphism $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$ induced by the restriction of $\alpha\,(w_0\nu)^{-1}(w_0\lambda)^{-1}$ to $T_n(\ell^1)$. For $r \geq 1$, α a character of finite order of $T_n(\mathfrak{l})$ or of $T_n(\ell^1)$, and a field $A \supseteq \mathcal{O}$ containing the values of α, let $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, A)$ be the subspace of the ordinary forms of weight λ and level $U(\ell^{r,r})$ with coefficients in A on which the operator $\langle u \rangle$ of weight λ acts by $\alpha(u)$ for every u in the domain of α, and $\mathbb{T}_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, A)$ the A-algebra of endomorphisms of it generated by the operators of weight λ. Now let $\alpha\colon T_n(\mathfrak{l}) \to \overline{\mathbb{Q}}_\ell^\times$ be a character of finite order, $r \geq 1$ with $T_n(\mathfrak{l}^r) \subseteq \ker\alpha$, $\mathfrak{P} = \mathfrak{P}_{\lambda,\alpha}^{\mathfrak{l}}$ and $\mathcal{K}'$ the fraction field of $\Lambda_1^{\mathfrak{l}}/\mathfrak{P}$. Then the action on $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K}')$ induces a surjection of finite $\mathcal{K}'$-algebras $\mathbb{T}^{\mathrm{ord}}(U) \otimes_{\Lambda_1^{\mathfrak{l}}} (\Lambda_1^{\mathfrak{l}})_{\mathfrak{P}}/\mathfrak{P} \to$*

$\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}),\alpha,\mathcal{K}')$, *and its kernel is nilpotent. If* α *is trivial and* $\gamma\colon T_n(\mathcal{O}_{F^+}/\mathfrak{l})\to\mathcal{O}^\times$ *is a character, write* $\mathbb{T}^{\mathrm{ord}}(U)_\gamma$ *for the maximal quotient of* $\mathbb{T}^{\mathrm{ord}}(U)$ *on which* $\langle u\rangle=\gamma(u)$ *for* $u\in T_n(\mathcal{O}_{F^+}/\mathfrak{l})$ *(Teichmüller representatives,* $\Lambda^+=\Lambda_1^{\mathfrak{l}}[T_n(\mathcal{O}_{F^+}/\mathfrak{l})]$*); then the action on the ordinary forms of weight* λ *and Iwahori level* $U(\ell^{0,1})$ *on which* $T_n(\mathcal{O}_{F^+}/\mathfrak{l})$ *acts through* $\gamma\,\omega^{w_0\lambda}$ *(*$\omega^{w_0\lambda}$ *the Teichmüller lift of the reduction of* $w_0\lambda$*) induces a surjection* $\mathbb{T}^{\mathrm{ord}}(U)_\gamma\otimes_{\Lambda_1^{\mathfrak{l}}}(\Lambda_1^{\mathfrak{l}})_{\mathfrak{P}}/\mathfrak{P}\to\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{0,1}),\gamma\omega^{w_0\lambda},\mathcal{K}')$ *with nilpotent kernel (*$\mathfrak{P}=\mathfrak{P}^{\mathfrak{l}}_{\lambda,1}$*).*

Proof. This is [105], Proposition 2.5.3 (freeness of the dual of the space of ordinary forms of level $U(\ell^\infty)$ over Λ_{b_0}) and Corollary 2.5.4 (the ordinary Hecke algebras are finite faithful Λ_{b_0}-algebras, equal to the Λ^+-subalgebras of $\mathrm{End}(S^{\mathrm{ord}}(U(\ell^\infty), \mathcal{K}/\mathcal{O}))$ generated by the operators listed), in the numbering of the 2010 version of that paper; commutativity is Lemma 2.3.3 there. (Gy3) is Lemma 2.6.4 there (first surjection; the renormalised Λ-structure is Definition 2.6.2, $\wp_{\lambda,\alpha}$ is Definition 2.6.3(2), and the Hecke algebra $\widetilde{\mathbb{T}}^{T,\mathrm{ord}}_{\lambda,\{\chi_v\}}(U(\ell^{r,r}), \alpha, K')$ there, with $R = \emptyset$, is our $\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, \mathcal{K}')$); the passage between $\widetilde{\mathbb{T}}$ and $\mathbb{T}$ (the latter generated by fewer operators) is immediate there (*the analogous results for* $\mathbb{T}$ *follow immediately*). The action on the dual $\mathcal{S}$ is through the duality of Remark 2.4.6 there, under which $\mathrm{End}_\mathcal{O}$ of a module and of its dual are identified. As for notation, Geraghty's K, $\mathcal{O}$, F, F^+, G, l, $\lambda = 0$, $R = \emptyset$ are our $\mathcal{K}$, $\mathcal{O}$, F, F^+, $\mathbb{G}$, ℓ; his ideal $\mathfrak{l}$ (the product of the places in S_l, §2.3), $T_n(\mathfrak{l}^b)$, $\Lambda = \mathcal{O}[[T_n(\mathfrak{l})]]$ and $\Lambda_b = \mathcal{O}[[T_n(\mathfrak{l}^b)]]$ (Definition 2.5.1) are our $\mathfrak{l}$, $T_n(\mathfrak{l}^b)$, $\Lambda^{\mathfrak{l}}_1$, $\Lambda^{\mathfrak{l}}_b$, and his $\wp_{\lambda,\alpha}$ (Definition 2.6.3(2), α a character of finite order of $T_n(\mathfrak{l})$, r with $T_n(\mathfrak{l}^r) \subseteq \ker\alpha$) is our $\mathfrak{P}^{\mathfrak{l}}_{\lambda,\alpha}$; his $S^{\mathrm{ord}}_{\lambda,\{\chi_v\}}(U(l^{r,r}), \alpha, A)$ is the maximal subspace on which $\langle u\rangle = \alpha(u)$ for all $u \in T_n(\mathfrak{l})$ (paragraph before Definition 2.6.3); the subgroups $\mathrm{Iw}(\tilde{v}^{b,c})$ are unipotent modulo $\varpi^b_{\tilde{v}}$ (§2.1), so our $U(\ell^{b,c})$ is his $U(l^{b,c})$. The groups $T_n(\ell^b)$, the algebras Λ_b and the ideals $\mathfrak{P}_{\lambda,\alpha} \subseteq \Lambda_1$ (reduction modulo the rational ℓ^b) are notation of ours, not Geraghty's; they enter no claim of this quotation; his $\mathbb{T}^{T,\mathrm{ord}}_0(U(l^\infty), \mathcal{O})$ is our $\mathbb{T}^{\mathrm{ord}}(U)$. The last sentence of (Gy3) is the remark following the proof of Lemma 2.6.4 there ("Taking α to be the trivial character in the lemma ..."), for the algebras with fixed character γ of Definition 2.6.3 and the paragraph before it. (Gy4) is Proposition 2.2.7 there (a consequence of Corollaire 5.3 and Théorème 5.4 of J.-P. Labesse, *Changement de base CM et séries discrètes*; Théorème 5.4 there is stated for E/F unramified at all finite places and U quasi-split at the finite inert places, with Labesse's standing hypothesis $[F : \mathbb{Q}] \geq 2$, which we add), combined with Lemma 2.2.5 there (the isomorphism of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ with $\mathrm{Hom}_{\mathbb{G}(F^+_\infty)}(\xi^\vee_{\lambda,\iota}, \mathcal{A})$, $\mathcal{A}$ semisimple) to turn the automorphic π with $\pi_\infty \cong \xi^\vee_{\lambda,\iota}$ into a constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$. (Gy5) is Proposition 2.7.2 there, parts 1, 2, 3 and 5 with $R = \emptyset$ (proof: Labesse, Corollaire 5.3, and Chenevier–Harris, Theorem 3.2.5); the characteristic polynomial in (i) is the unramified case of part 1 written in Hecke eigenvalues, as in property 2 of Proposition 2.7.3 there (whose proof derives it from Proposition 2.7.2 by the argument of Proposition 3.4.2 of Clozel–Harris–Taylor); the potential semistability in (iv) is part 4. (Gy6) is Corollary 2.7.8 part 1 there, with Definition 2.7.1(a) for regularity and Lemma 2.7.5 for the line. Normalisations: Section 2.7 there (local Langlands as in §3.1 of Clozel–Harris–Taylor, geometric Frobenius, ε of Hodge–Tate weight -1, as the proof of Corollary 2.7.8 shows: $\chi_{\tilde{v},j} = \varepsilon^{-(j-1)}\psi_{\tilde{v},j}$ has Hodge–Tate number $\lambda_{\tau,n-j+1} + (j-1)$). (Gy7)(a) is Lemma 5.1.1 there (with the notation of the start of §5.1: δ_{B_n}, $\mathrm{Iw}(v^{b,c})$, $T_n(v^b)$, $\alpha^{(j)}_{\varpi_v}$; the map is the composite of the inclusion into $\sigma^{N_n(\mathcal{O})}$ and the projection, hence $T_n(\mathcal{O})$-equivariant); (Gy7)(b) is the definition before Definition 5.1.2, Definition 5.1.2 and Lemma 5.1.3(2) there; (Gy7)(c) is the description of ϕ_λ before Definition 2.6.2 there ($\phi_\lambda(T_w) = T_w$, $\phi_\lambda(U^{(j)}_{0,\varpi}) = U^{(j)}_{\lambda,\varpi}$, $\phi_\lambda(\langle u\rangle) = (w_0\lambda)(u^{-1})\langle u\rangle$), through which Lemma 2.6.4 is stated, with $U^{(j)}_{\lambda,\varpi} = (w_0\lambda)(\alpha^{(j)}_\varpi)^{-1} U^{(j)}_\varpi$

as in the proof of Lemma 2.7.5 there. The places $v \in T \smallsetminus S_\ell$ carry an arbitrary level U_v (loc. cit. §2.3: "we do not specify U_v for $v \in T - (S_l \cup R)$"). □

Theorem B.92. *Let K be a finite extension of $\mathbb{Q}_p$, W_K its Weil group, $|\cdot|$ the normalised absolute value of K, and $\mathrm{Art}_K\colon K^\times \to W_K^{\mathrm{ab}}$ the local Artin map, normalised so that uniformisers go to geometric Frobenius elements. There is a family of bijections rec_K, one for each $n \geq 1$, from the set of isomorphism classes of irreducible smooth representations of $\mathrm{GL}_n(K)$ over $\mathbb{C}$ to the set of isomorphism classes of n-dimensional Frobenius-semisimple Weil–Deligne representations of W_K over $\mathbb{C}$, such that:*

(Ln1) $\mathrm{rec}_K(\chi) = \chi \circ \mathrm{Art}_K^{-1}$ *for every smooth character χ of $K^\times = \mathrm{GL}_1(K)$;*

(Ln2) $\mathrm{rec}_K(\pi \otimes (\chi \circ \det)) = \mathrm{rec}_K(\pi) \otimes \mathrm{rec}_K(\chi)$ *for every π and every smooth character χ of $K^\times$;*

(Ln3) $\det \mathrm{rec}_K(\pi) = \mathrm{rec}_K(\omega_\pi)$, *where ω_π is the central character of π, and* $\mathrm{rec}_K(\pi^\vee) = \mathrm{rec}_K(\pi)^\vee$;

(Ln4) $L(s, \pi_1 \times \pi_2) = L(s, \mathrm{rec}_K(\pi_1) \otimes \mathrm{rec}_K(\pi_2))$ *and* $\varepsilon(s, \pi_1 \times \pi_2, \psi) = \varepsilon(s, \mathrm{rec}_K(\pi_1) \otimes \mathrm{rec}_K(\pi_2), \psi)$ *for all π_1, π_2 and every non-trivial additive character ψ of K;*

(Ln5) *π is supercuspidal if and only if* $\mathrm{rec}_K(\pi)$ *is irreducible (in particular has monodromy 0);*

(Ln6) *(compatibility with the Langlands classification) if π is the Langlands quotient of a multisegment $(\Delta_1, \ldots, \Delta_r)$, i.e. the unique irreducible quotient of the normalised parabolic induction of $Q(\Delta_1) \otimes \cdots \otimes Q(\Delta_r)$ with the segments ordered so that Δ_i does not precede Δ_j for $i < j$, where $Q(\Delta)$ is the essentially square-integrable representation attached to the segment Δ, then* $\mathrm{rec}_K(\pi) \cong \bigoplus_{i=1}^r \mathrm{rec}_K(Q(\Delta_i))$.

The family is uniquely determined by (Ln1), (Ln2), (Ln3), (Ln4) on supercuspidal representations together with (Ln6).

Proof. Existence: [121], Theorem A (properties (Ln1)–(Ln5) for supercuspidal representations, and the extension to all irreducible smooth representations through the Bernstein–Zelevinsky and Zelevinsky classification, Introduction and Section VII); independently [125]; uniqueness by Henniart's characterisation through L- and ε-factors of pairs. The extension to all representations by (Ln6) and the resulting properties (Ln1)–(Ln4) for all π are explained in Harris–Taylor, loc. cit., and in T. Wedhorn, *The local Langlands correspondence for* $\mathrm{GL}(n)$ *over p-adic fields*, ICTP Lecture Notes 2008, Sections 3 and 4. Normalisation: Harris and Taylor normalise Art_K so that uniformisers correspond to geometric Frobenius elements, as here; their rec is the map of this statement. □

Theorem B.93. *Let F be a finite extension of $\mathbb{Q}_p$, $n \geq 1$, and* rec *the local Langlands correspondence of Harris–Taylor for $\mathrm{GL}_n(F)$ over $\mathbb{C}$. For $\sigma \in \mathrm{Aut}(\mathbb{C})$ and a representation π of $\mathrm{GL}_n(F)$ on a complex vector space X, let π^σ be the representation on $X \otimes_{\mathbb{C},\sigma} \mathbb{C}$, and for a Weil–Deligne representation (r, N) on Y let $\sigma(r, N)$ be $(r \otimes 1, N \otimes 1)$ on $Y \otimes_{\mathbb{C},\sigma} \mathbb{C}$. Then for every irreducible smooth representation π of $\mathrm{GL}_n(F)$ over $\mathbb{C}$ and every $\sigma \in \mathrm{Aut}(\mathbb{C})$,*

$$\mathrm{rec}\big(\pi^\sigma \otimes |\det|^{(1-n)/2}\big) \cong \sigma\Big(\mathrm{rec}\big(\pi \otimes |\det|^{(1-n)/2}\big)\Big).$$

Proof. See Caraiani, Emerton, Gee, Geraghty, Paškūnas and Shin, *Patching and the p-adic local Langlands correspondence*, Cambridge J. Math. 4 (2016), §1.5 (the map $r_p(\pi) = \mathrm{rec}_p(\pi \otimes |\det|^{(1-n)/2})$ is independent of the choice of the isomorphism $\overline{\mathbb{Q}}_p \cong \mathbb{C}$ and commutes with automorphisms of $\mathbb{C}$), who cite C. Breuil and P. Schneider, *First steps towards p-adic Langlands functoriality*, J. Reine Angew. Math. 610 (2007), §4. The property goes back to Henniart's characterisation of rec. □

Theorem B.94. *Let F be an imaginary CM field, $n \geq 1$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\lambda = (\lambda_\tau)_\tau$ with $\lambda_\tau = (\lambda_{\tau,1} \geq \cdots \geq \lambda_{\tau,n}) \in \mathbb{Z}^n$ for every embedding $\tau\colon F \to \overline{\mathbb{Q}}_\ell$, and Π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ of weight $\iota\lambda$ (Π_∞ has the infinitesimal character of the dual of the irreducible algebraic representation of $\prod_\tau \mathrm{GL}_n$ of highest weight $(\lambda_{\iota^{-1}\sigma})_\sigma$).*

(To1) *There is a continuous semisimple $r_\iota(\Pi)\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, unique up to isomorphism, with $r_\iota(\Pi)^c \cong r_\iota(\Pi)^\vee \varepsilon^{1-n}$, de Rham at the places above ℓ with $\mathrm{HT}_\tau(r_\iota(\Pi)) = \{\lambda_{\tau,n}, \lambda_{\tau,n-1}+1, \ldots, \lambda_{\tau,1}+n-1\}$, and such that for* every *finite place w of F*

$$\mathrm{WD}\big(r_\iota(\Pi)|_{G_{F_w}}\big)^{\text{F-ss}} \cong \mathrm{rec}^T(\iota^{-1}\Pi_w).$$

(To2) *Let $w \mid \ell$, ϖ_w a uniformiser of F_w, e_w the absolute ramification index of F_w, and v_ℓ the valuation with $v_\ell(\ell) = 1$. Then Π is ι-ordinary at w (in the sense of [105], Definition 5.1.2, recalled in (Gy7) of Theorem B.91) if and only if there are smooth characters $\chi_{w,1}, \ldots, \chi_{w,n}\colon F_w^\times \to \overline{\mathbb{Q}}_\ell^\times$ such that $\iota^{-1}\Pi_w$ is a subquotient of the normalised induction $\text{n-Ind}_{B_n}^{\mathrm{GL}_n(F_w)}(\chi_{w,1} \otimes \cdots \otimes \chi_{w,n})$ and, for $1 \leq i \leq n$,*

$$v_\ell(\chi_{w,i}(\varpi_w)) = \frac{1}{e_w} \sum_{\tau\colon F_w \to \overline{\mathbb{Q}}_\ell} \Big(\lambda_{\tau,n+1-i} - \frac{n-1}{2} + i - 1\Big);$$

the tuple $(\chi_{w,1}, \ldots, \chi_{w,n})$ is then uniquely determined by $\iota^{-1}\Pi_w$.

(To3) *If Π is ι-ordinary at $w \mid \ell$, with $(\chi_{w,i})$ as in (To2), then $r_\iota(\Pi)|_{G_{F_w}}$ is conjugate to an upper triangular representation with diagonal characters $\psi_1, \ldots, \psi_n$ (in this order) such that $\psi_i(\mathrm{Art}_{F_w}(z)) = \chi_{w,i}(z) \prod_\tau \tau(z)^{-(\lambda_{\tau,n-i+1}+i-1)}$ for all $z \in \mathcal{O}_{F_w}^\times$.*

Proof. See [256], Theorem 2.2 (for (To1), with $\chi = \delta_{F/F^+}^n$, i.e. RACSDC; existence by [67], Theorem 3.2.3, local-global compatibility with monodromy by [56] for $w \nmid \ell$ and [58] for $w \mid \ell$; uniqueness by Chebotarev), Lemma 2.3 (for (To2), with the remark following it on the uniqueness of the tuple; Thorne proves it from Lemma 5.1.1 of [105]) and Theorem 2.4 (for (To3), formula (2.1) there). The normalisations are those of §1 of [256]: local Artin maps send uniformisers to geometric Frobenius elements, $\mathrm{HT}_\tau(\varepsilon) = \{-1\}$, $\mathrm{rec}_{F_w}^T(\pi) = \mathrm{rec}_{F_w}(\pi \otimes |\cdot|^{(1-n)/2})$. *Notation.* Thorne's v, π, $r_\iota(\pi)$ are our w, Π, $r_\iota(\Pi)$; his weight $\iota\lambda$ with $(\iota\lambda)_\tau = \lambda_{\iota^{-1}\tau}$ is ours. □

Theorem B.95. *Let F be a number field and $\mathbb{A}_F$ its adeles.*

(Mw1) *Let $m, k \geq 1$ and let τ be a unitary cuspidal automorphic representation of $\mathrm{GL}_m(\mathbb{A}_F)$. The normalised parabolic induction to $\mathrm{GL}_{km}(\mathbb{A}_F)$, from the standard parabolic subgroup of type $(m, \ldots, m)$, of $\tau|\det|^{(k-1)/2} \otimes \tau|\det|^{(k-3)/2} \otimes \cdots \otimes \tau|\det|^{(1-k)/2}$ has a unique irreducible quotient $\mathrm{Sp}(\tau, k)$, and $\mathrm{Sp}(\tau, k)$ occurs in the discrete spectrum of $\mathrm{GL}_{km}(\mathbb{A}_F)$. Conversely, every irreducible automorphic representation of $\mathrm{GL}_N(\mathbb{A}_F)$ in the discrete spectrum is isomorphic to $\mathrm{Sp}(\tau, k)$ for a unique pair (τ, k) with $km = N$.*

(Mw2) *Let $r \geq 1$, and for $1 \leq i \leq r$ let τ_i be a unitary cuspidal automorphic representation of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$ and $k_i \geq 1$; let $\Pi = \mathrm{Sp}(\tau_1, k_1) \boxplus \cdots \boxplus \mathrm{Sp}(\tau_r, k_r)$ be the isobaric sum, an automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, $n = \sum_i k_i m_i$. Then for every finite place w of F, with $K = F_w$ and $|\cdot|$ the normalised absolute value of K,*

$$\mathrm{rec}_K(\Pi_w) \cong \bigoplus_{i=1}^{r} \bigoplus_{a=0}^{k_i-1} \mathrm{rec}_K(\tau_{i,w}) \otimes \mathrm{rec}_K\big(|\cdot|^{(k_i-1)/2-a}\big) \tag{B.1}$$

as Weil–Deligne representations (monodromy operators included).

Proof. (Mw1) is the main theorem of [178] (the residual spectrum of GL_N, with the cuspidal spectrum the case $k = 1$; uniqueness of (τ, k) from the cuspidal support, Jacquet–Shalika). For (Mw2), by [178] the representation $\mathrm{Sp}(\tau, k)$ is the restricted tensor product of its local components, and at a finite place w the component $\mathrm{Sp}(\tau, k)_w$ is the unique irreducible quotient of the corresponding local induced representation of $\tau_w|\det|^{(k-1)/2} \otimes \cdots \otimes \tau_w|\det|^{(1-k)/2}$, with τ_w irreducible, generic (Shalika) and unitary. By the Bernstein–Zelevinsky classification and the Jacquet–Shalika bound, write τ_w as the irreducible induced representation of essentially square-integrable $Q(\Delta_j)|\det|^{e_j}$ with $|e_j| < \frac{1}{2}$. Then this quotient is the Langlands quotient of the multisegment formed by the shifted segments $\Delta_j|\cdot|^{e_j+(k-1)/2-a}$, so (Ln6) of Theorem B.92 and (Ln2) give $\mathrm{rec}_K(\mathrm{Sp}(\tau,k)_w) \cong \bigoplus_a \mathrm{rec}_K(\tau_w) \otimes \mathrm{rec}_K(|\cdot|^{(k-1)/2-a})$ (the L-parameter ϕ_ψ attached to the Arthur parameter $\tau \boxtimes \mathrm{Sym}^{k-1}$). The local component of an isobaric sum is the local isobaric sum (Langlands; Jacquet–Shalika, *On Euler products and the classification of automorphic forms II*, 1981), the irreducible subquotient of the induced representation of the components whose Langlands parameter is the direct sum of theirs (Langlands classification and its compatibility with rec_K, [121]). *Notation.* Our $\mathrm{Sp}(\tau, k)$ is the residual representation attached to (τ, k) in [178]; our rec_K is that of Theorem B.92. □

Theorem B.96. *Let F be a totally real field with $[F : \mathbb{Q}] \geq 2$, let E/F be a totally imaginary quadratic extension, and let U be an inner form of the quasi-split unitary group in $n \geq 1$ variables for E/F. Let σ occur in the discrete automorphic spectrum of U, with σ_∞ discrete series. Assume property $(*)$: for a pseudo-coefficient f_∞ of σ_∞, the integer traces $\mathrm{tr}\,\sigma'_\infty(f_\infty)$, for discrete automorphic σ' with $\sigma'_f \cong \sigma_f$, have the same sign as $\mathrm{tr}\,\sigma_\infty(f_\infty)$.*

Then there are positive integers $n_1, \ldots, n_s$ with $\sum_i n_i = n$ and discrete automorphic representations π_i of $\mathrm{GL}_{n_i}(\mathbb{A}_E)$ with $\pi_i^c \cong \pi_i^\vee$ such that $\pi = \boxplus_i \pi_i$ is a weak base change of σ. Here $\pi_v = \bigotimes_{w|v} \pi_w$ is viewed on $(\mathrm{Res}_{E/F}\mathrm{GL}_n)(F_v)$. At every split finite place v the correspondence $\sigma_v \mapsto \pi_v$ is local base change. At every finite v where E/F and U are unramified and σ_v is spherical, π_v is its unramified local base change. At infinity π_∞ is cohomological, with the coefficient system of the archimedean base-change construction, and its infinitesimal character is the base change of that of σ_∞. If, in addition, every π_i is cuspidal, then π_∞ itself is the archimedean base change of σ_∞.

Property $(*)$ is automatic when $U(F \otimes_{\mathbb{Q}} \mathbb{R})$ is compact.

Proof. This is [153], Corollaire 5.3, with the standing hypotheses at the beginning of Section 5 and the compactness remark immediately preceding the corollary. The notation θ_{n_i}-invariant there means $\pi_i^c \cong \pi_i^\vee$. Weak base change is defined in Section 4.10; the cohomological coefficient system is the one in Lemma 4.4 of Section 4.6. As in loc. cit., the last archimedean conclusion is stated only under the additional hypothesis that every discrete summand is cuspidal. The statement makes no splitting assumption at a chosen coefficient prime, no quasi-splitness hypothesis at the finite places and no hypothesis that E/F is unramified at the finite places. □

Theorem B.97. *Let F be a number field. Here a cuspidal automorphic representation of $\mathrm{GL}_m(\mathbb{A}_F)$ is an irreducible representation of the form $\tau \otimes |\det|^t$ with $t \in \mathbb{R}$ and τ an irreducible subrepresentation of the space of cusp forms on $\mathrm{GL}_m(F)\backslash\mathrm{GL}_m(\mathbb{A}_F)$ with unitary central character. Let $(\sigma_i)_{i\in I}$ and $(\sigma'_j)_{j\in J}$ be finite families of cuspidal automorphic representations of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$ and $\mathrm{GL}_{m'_j}(\mathbb{A}_F)$ respectively ($m_i, m'_j \geq 1$). Suppose that for all but finitely many finite places w of F all $\sigma_{i,w}$ and $\sigma'_{j,w}$ are unramified and*

$$\bigsqcup_{i\in I} \alpha_w(\sigma_i) = \bigsqcup_{j\in J} \alpha_w(\sigma'_j)$$

as multisets. Then there is a bijection $s\colon I \to J$ with $m'_{s(i)} = m_i$ and $\sigma'_{s(i)} \cong \sigma_i$ for every $i \in I$.

Proof. This is the classification of isobaric automorphic representations of Jacquet and Shalika, [136], part II, Theorem 4.4: two isobaric sums $\boxplus_i \sigma_i$ and $\boxplus_j \sigma'_j$ of cuspidal automorphic representations (real twists $|\det|^t$ allowed) whose local components are isomorphic at almost all places have the same constituents up to order. *Notation.* At a finite place w where all constituents are unramified, the local component of $\boxplus_i \sigma_i$ is the unramified representation of $\mathrm{GL}_{\sum m_i}(F_w)$ whose Satake parameters are $\bigsqcup_i \alpha_w(\sigma_i)$, and an unramified representation is determined by its Satake parameters; so the hypothesis says that the two isobaric sums have isomorphic local components at almost all places. For a single cuspidal representation on each side this is strong multiplicity one, (Js1) of Theorem B.60. □

Theorem B.98. *Let ℓ, n, F, F^+, $\mathcal{O}$ (with uniformiser ϖ), $\mathbb{G}$ and T be as in Theorem B.91, and $\mathcal{K} = \mathcal{O}[1/\ell]$. For a compact open subgroup $U' \subseteq \mathbb{G}(\mathbb{A}_{F^+}^\infty)$ and an $\mathcal{O}$-module A let $S(U', A)$ be the $\mathcal{O}$-module of functions $\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+}^\infty)/U' \to A$ (automorphic forms of trivial weight). U' is* sufficiently small *if for some place v of F^+ its projection to $\mathbb{G}(F_v^+)$ contains no element of finite order other than* 1.

(Gk1) *Let A be an $\mathcal{O}$-algebra, $U'' \subseteq \mathbb{G}(\mathbb{A}_{F^+}^\infty)$ a sufficiently small compact open subgroup whose components at the places $v \in S_\ell$ lie in $\mathbb{G}(\mathcal{O}_{F_v^+})$, and $U' \subseteq U''$ an open normal subgroup. Then $S(U', A)$, with the finite group U''/U' acting by right translation, $(gf)(x) = f(xg)$, is a finite free $A[U''/U']$-module.*

(Gk2) *Let U be as in Theorem B.91 and A one of $\mathcal{O}$, $\mathcal{K}/\mathcal{O}$, $\mathcal{O}/\varpi^\gamma$, $\varpi^{-\gamma}\mathcal{O}/\mathcal{O}$ ($\gamma \geq 1$). For all $1 \leq b \leq c$ the inclusion $S^{\mathrm{ord}}(U(\ell^{b,b}), A) \to S^{\mathrm{ord}}(U(\ell^{b,c}), A)$ is an isomorphism.*

(Gk3) *(module-level classicality) Let U, b_0, $\mathcal{S}$, $\mathfrak{l}$, $T_n(\mathfrak{l}^b)$, $\Lambda_1^{\mathfrak{l}}$ and the $\Lambda_1^{\mathfrak{l}}$-structure given by $u \mapsto (w_0\nu)^{-1}(u)\langle u\rangle$ ($u \in T_n(\mathfrak{l})$) be as in Theorem B.91, λ a dominant weight, $\alpha\colon T_n(\mathfrak{l}) \to \overline{\mathbb{Q}}_\ell^\times$ a character of finite order, $r \geq 1$ with $T_n(\mathfrak{l}^r) \subseteq \ker\alpha$, and $\mathfrak{P}_{\lambda,\alpha}^{\mathfrak{l}} \subseteq \Lambda_1^{\mathfrak{l}}$ as in (Gy3); suppose that $\mathcal{O}$ contains the values of α, so that $\Lambda_1^{\mathfrak{l}}/\mathfrak{P}_{\lambda,\alpha}^{\mathfrak{l}} = \mathcal{O}$ and $\mathcal{K}' = \mathcal{K}$. Let $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K})$ be the space of ordinary forms of weight λ and level $U(\ell^{r,r})$ on which $\langle u\rangle$ acts by $\alpha(u)$ for all $u \in T_n(\mathfrak{l})$, as in (Gy3). Then there is an isomorphism of $\mathcal{K}$-vector spaces*

$$\mathcal{S}_{\mathfrak{P}}/\mathfrak{P}\mathcal{S}_{\mathfrak{P}} \cong \mathrm{Hom}_{\mathcal{K}}(S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K}), \mathcal{K}) \qquad (\mathfrak{P} = \mathfrak{P}_{\lambda,\alpha}^{\mathfrak{l}},\ \mathcal{S}_{\mathfrak{P}} = \mathcal{S} \otimes_{\Lambda_1^{\mathfrak{l}}} (\Lambda_1^{\mathfrak{l}})_{\mathfrak{P}})$$

which carries the action of $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u\rangle$ on the left to the transposes of the operators assigned to them by (Gy7)(c) on the right, and which is equivariant for right translation by every $g \in \mathbb{G}(\mathbb{A}_{F^+}^\infty)$ with $g_v = 1$ for $v \in S_\ell$ and $gU(\ell^{r,r})g^{-1} = U(\ell^{r,r})$ (acting on both sides, the left side dually to right translation of ordinary forms of level $U(\ell^\infty)$ when g normalises all $U(\ell^{c,c})$).

(Gk4) *(forms of weight λ) Let U be as in Theorem B.91 and λ a dominant weight for $\mathbb{G}$. Let M_λ be the finite free $\mathcal{O}$-module of [105], Definition 2.2.3, with its action ξ_λ of $\prod_{v\in S_\ell}\mathbb{G}(\mathcal{O}_{F_v^+})$, and $\epsilon_\lambda\colon M_\lambda\to\mathcal{O}$ the natural $\mathcal{O}$-linear projection onto the lowest weight space, equivariant for $\prod_{v\in S_\ell}\mathrm{Iw}(\tilde{v}^{0,1})$ acting on $\mathcal{O}$ through the character $w_0\lambda$. For an $\mathcal{O}$-module A and a compact open subgroup $U'\subseteq\mathbb{G}(\mathbb{A}_{F^+}^\infty)$ whose components at the places of S_ℓ lie in $\mathbb{G}(\mathcal{O}_{F_v^+})$, let $S_\lambda(U',A)$ be the $\mathcal{O}$-module of functions $f\colon\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+}^\infty)\to M_\lambda\otimes_{\mathcal{O}}A$ with $\xi_\lambda(u_{S_\ell})f(xu)=f(x)$ for all $u\in U'$ and x (u_{S_ℓ} the components at S_ℓ; for $\lambda=0$ this is $S(U',A)$), with the operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$ and $\langle u\rangle$ ($u\in T_n(\mathcal{O}_{F^+}\otimes\mathbb{Z}_\ell)$) of weight λ of (Gy7)(c) on the levels $U(\ell^{b,c})$; for A one of $\mathcal{O}$, $\mathcal{K}/\mathcal{O}$, $\mathcal{O}/\varpi^\gamma$, $\varpi^{-\gamma}\mathcal{O}/\mathcal{O}$ ($\gamma\geq 1$) the* ordinary part $S_\lambda^{\mathrm{ord}}(U(\ell^{b,c}),A)=e\,S_\lambda(U(\ell^{b,c}),A)$ *is the image of the ordinary idempotent $e=\lim_r U(\ell)^{r!}$, $U(\ell)=\prod_{v\in S_\ell}\prod_{j=1}^n U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$, of the (finite) Hecke algebra of that level, and is the largest $\mathcal{O}$-submodule on which every $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$ acts invertibly; $S_\lambda^{\mathrm{ord}}(U(\ell^{b,c}),\mathcal{K})=S_\lambda^{\mathrm{ord}}(U(\ell^{b,c}),\mathcal{O})\otimes_{\mathcal{O}}\mathcal{K}$; and $S_\lambda^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})=\varinjlim_c S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}),\mathcal{K}/\mathcal{O})$. Then:*

- *(a) if U' is sufficiently small, then $S_\lambda(U',A)=S_\lambda(U',\mathcal{O})\otimes_{\mathcal{O}}A$;*
- *(b) for $b\geq 1$ the inclusions identify $S_\lambda^{\mathrm{ord}}(U(\ell^{b,b}),\mathcal{K}/\mathcal{O})$ with the submodule of $S_\lambda^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})$ fixed by the operators $\langle u\rangle$, $u\in T_n(\mathfrak{l}^b)$, compatibly with the operators, where $\mathfrak{l}=\prod_{v\in S_\ell}v$ (an ideal of $\mathcal{O}_{F^+}$) and $T_n(\mathfrak{l}^b)$ is the kernel of reduction $T_n(\mathcal{O}_{F^+}\otimes\mathbb{Z}_\ell)\to T_n(\mathcal{O}_{F^+}/\mathfrak{l}^b)$;*
- *(c) the maps $f\mapsto\epsilon_\lambda\circ f$ induce an isomorphism $\lambda_*\colon S_\lambda^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})\to S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})$ which commutes with the $T_w^{(j)}$, carries $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$ to the operator $U_{\tilde{v}}^{(j)}$ of trivial weight, and satisfies $\lambda_*(\langle u\rangle f)=(w_0\lambda)(u)\,\langle u\rangle\lambda_*(f)$ for $u\in T_n(\mathcal{O}_{F^+}\otimes\mathbb{Z}_\ell)$;*
- *(d) the space $S_\lambda(\overline{\mathbb{Q}}_\ell)=\bigcup_{U'}S_\lambda(U',\overline{\mathbb{Q}}_\ell)$ (U' over the compact open subgroups as above), with $\mathbb{G}(\mathbb{A}_{F^+}^\infty)$ acting by $(g\cdot f)(x)=\xi_\lambda(g_{S_\ell})f(xg)$ (ξ_λ extended to $\prod_{v\in S_\ell}\mathbb{G}(F_v^+)$ on $M_\lambda\otimes\overline{\mathbb{Q}}_\ell$), is a semisimple admissible representation, and $S_\lambda(U',\overline{\mathbb{Q}}_\ell)$ is its subspace of U'-invariants.*

Proof. All references are to [105]. (Gk1) is Lemma 2.2.6 there (proved as Lemma 3.3.1 of [69]), for the trivial weight $\lambda=0$ and no places carrying a character ($R=\varnothing$), where $S_0(U',A)$ is the space of functions of the statement and the hypothesis "$u_\ell\in\mathbb{G}(\mathcal{O}_{F^+,\ell})$ for every $u\in U''$" is our condition on the components at S_ℓ; (Gk2) is Lemma 2.5.2 there, for the same data. (Gk3) is the first display of the proof of Lemma 2.6.4 there (with γ trivial and $\mathcal{K}'=\mathcal{K}$, as arranged there by enlarging $\mathcal{K}$), combined with the isomorphism $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}),\alpha,\mathcal{K}/\mathcal{O})^\vee\otimes_{\mathcal{O}}\mathcal{K}\cong\mathrm{Hom}_{\mathcal{K}}(S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}),\alpha,\mathcal{K}),\mathcal{K})$ displayed after it; its compatibility with the Hecke operators is the one used there to obtain the surjection of (Gy3). As for the equivariance, every map in that chain (restriction to the forms of level $U(\ell^{r,r})$ on which $T_n(\mathfrak{l})$ acts through α, the twist ϕ_λ of weight λ at the places of S_ℓ before Definition 2.6.2 there, Pontryagin duality, and $-\otimes\mathcal{K}$) is natural and changes only the components at S_ℓ or the coefficients, so it commutes with right translation by an element g as stated, which acts on forms of every level $U(\ell^{b,c})$ it normalises by $f\mapsto f(\cdot\,g)$. (Gk4): the objects are those of Definition 2.2.4 there ($R=\varnothing$), §2.4 (for the four coefficient modules listed: the idempotent $e=\lim U(\ell)^{r!}$ before Definition 2.4.2, Definition 2.4.2 and the sentence after it, "the largest $\mathcal{O}$-submodule on which each of the operators $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$ acts invertibly"; the space with coefficients in $\mathcal{K}$ is used in the proof of Lemma 2.6.4 there as $S^{\mathrm{ord}}(\mathcal{O})\otimes\mathcal{K}$, which we take as its definition) and §2.6 (the morphism $\lambda\colon M_\lambda\to\mathcal{O}(w_0\lambda)$, "evaluation at the identity or projection to the lowest weight space"); (a) is the paragraph after Lemma 2.2.5 there ("if U is sufficiently small then $S_{\lambda,\{\chi_v\}}(U,A)=S_{\lambda,\{\chi_v\}}(U,\mathcal{O})\otimes A$"); (b) is the first display of the proof of Proposition 2.5.3 there, which rests on Lemma 2.5.2 there for

weight λ (the operators on the limit being those of the finite levels, the double cosets having common representatives in $\mathbb{G}(F_\ell^+)$ for all levels, proof of Lemma 2.5.2); (c) is Proposition 2.6.1 there (the isomorphism λ_*, defined in its proof by $f \mapsto \lambda \circ f$ on $S_\lambda(U(\ell^{c,c}), \varpi^{-r}\mathcal{O}/\mathcal{O})$, $c \geq r$, and the direct limit over c); (d) is Definition 2.2.4 there (the action $(g \cdot f)(h) = g_{S_l} f(hg)$ on $S_\lambda(A)$ for a $\mathcal{K}$-module A, and $S_\lambda(U, A)$ its U-invariants) with Lemma 2.2.5 there and the sentence after it (the space of automorphic forms is semisimple admissible, so $S_\lambda(\overline{\mathbb{Q}}_\ell)$ is). Here U, $U(\ell^{b,c})$, S^{ord} are those of Theorem B.91. □

Theorem B.99. *Let k be a finite field of characteristic ℓ, $W(k)$ its ring of Witt vectors, G a profinite group, $\bar{k}$ an algebraic closure of k, and $\bar{\rho}\colon G \to \mathrm{GL}_d(\bar{k})$ a continuous semisimple representation such that $\det(1 + t\bar{\rho}(g)) \in k[t]$ for all $g \in G$. Let $H_0 \subseteq \ker\bar{\rho}$ be the smallest closed normal subgroup of G contained in $\ker\bar{\rho}$ such that $\ker\bar{\rho}/H_0$ is a pro-ℓ group. Let A be a commutative profinite local $W(k)$-algebra with residue field k and D a continuous A-valued determinant of dimension d on G whose reduction modulo $\mathfrak{m}_A$ is $\det\circ\bar{\rho}$. Then D factors through $A[G] \to A[G/H_0]$: there is a determinant D' on G/H_0 with D equal to D' composed with this map.*

Proof. See [66, §3.1 and Lemma 3.8] (there p is the characteristic of k). The proof there reduces to finite A and a finite quotient of G; the radical of the finite ring $A[G]/\ker D$ is the kernel of the map to $\bar{\rho}(k[G])$, so $\ker\bar{\rho}$ maps into the ℓ-group $1 + \mathrm{Rad}$. □

Theorem B.100. *Let A be a henselian local ring in which 2 is invertible, S an A-algebra which is integral over A, τ an A-linear map $S \to S$ with $\tau^2 = \mathrm{id}_S$ which is either a ring homomorphism or a ring anti-homomorphism, and $I \subseteq \mathrm{rad}(S)$ a two-sided ideal with $\tau(I) = I$. Let $\epsilon_1, \ldots, \epsilon_k$ be orthogonal idempotents of S/I such that the set $\{\epsilon_1, \ldots, \epsilon_k\}$ is stable under the map induced by τ on S/I. Then there are orthogonal idempotents $e_1, \ldots, e_k$ of S with e_i lifting ϵ_i for each i and such that the set $\{e_1, \ldots, e_k\}$ is stable under τ.*

Proof. This is [21], Lemma 1.8.2. (In the statement of loc. cit. the stable set is written as a subset of R; it is a subset of S/I, on which τ acts since $\tau(I) = I$.) □

Theorem B.101. *Let A be a commutative ring, R an A-algebra, S a commutative A-algebra and $D\colon R \to S$ an S-valued determinant of dimension d (a multiplicative A-polynomial law $R \to S$, homogeneous of degree d). For a commutative A-algebra C and $r \in R \otimes_A C$ define $\Lambda_i(r) \in S \otimes_A C$ by $D(t - r) = \sum_{i=0}^{d}(-1)^i\Lambda_i(r)t^{d-i}$ in $(S \otimes_A C)[t]$, and $\Lambda_i = 0$ for $i > d$.*

(Am1) *$D(1 + rr') = D(1 + r'r)$ for all $r, r' \in R$ (and likewise after any base change $A \to C$).*

(Am2) *(Amitsur's formula.) For $m \geq 1$, $i \geq 0$ and $r_1, \ldots, r_m \in R$, $\Lambda_i(t_1r_1 + \cdots + t_mr_m) \in S[t_1, \ldots, t_m]$ equals $P_{m,i}((\Lambda_j(w))_{j,w})$, where w runs over the finite products of the r_k and $P_{m,i}$ is a polynomial with integer coefficients in the variables (t_k) and $(\Lambda_j(w))$ which depends only on m and i (not on A, R, S, D or d).*

Proof. This is [66], Lemma 1.12 (i) and (ii), with Amitsur's formula in the explicit form (1.5) there: $\Lambda_i(t_1r_1 + \cdots + t_mr_m) = \sum_{\ell(w)=i}\epsilon(w)\Lambda(w)$, the sum over the words w of length i in the letters t_kr_k, with $\epsilon(w) \in \{\pm 1\}$ and $\Lambda(w) = \prod_k \Lambda_{l_k}(w_k)$ for the Lyndon factorisation $w = w_1^{l_1} \cdots w_q^{l_q}$, which depend only on the word. □

Theorem B.102. *Let A be a commutative ring, R an A-algebra and $D\colon R \to A$ a determinant of dimension d.*

(Cd1) *Assume that* $\operatorname{Spec}(A)$ *is connected and let* $e \in R$ *be an idempotent. The polynomial map* $D_e\colon eRe \to A$, $x \mapsto D(x+1-e)$, *is a determinant on the* A*-algebra* eRe *(with unit* e*) of some dimension* $r(e) \le d$*; one has* $r(e) + r(1-e) = d$*, and the restriction of* D *to the* A*-subalgebra* $eRe \oplus (1-e)R(1-e)$ *is the product determinant* $x \mapsto D_e(ex)\, D_{1-e}((1-e)x)$*. If* D *is Cayley–Hamilton, so is* D_e*.*

(Cd2) *If* D *is Cayley–Hamilton of dimension* 1*, then the structure map* $A \to R$ *is an isomorphism and* D *is the identity.*

Proof. (Cd1) is [66], Lemma 2.4 (1)–(3); (Cd2) is [66], Lemma 2.6. □

B.6 Shimura varieties, abelian varieties and moduli

All these results are used in Part VI and Appendix D.Lan's fine PEL moduli spaces with liftable full level, their Kodaira–Spencer isomorphism, their comparison with the complex uniformisation and their projective toroidal compactifications (Theorem B.105, Theorem B.106, Theorem B.114, Theorem B.108), and the degeneration data of Faltings–Chai and Lan with Mumford's construction (Theorem B.109, Theorem B.111, Theorem B.112), are used for the integral models with uniformised degenerations (Section 32) and for good origins (Section 33). The extension of semiabelian homomorphisms, the theorem of the cube, Moret-Bailly's cubical structures and his theorem on the group $K(L)$, Grothendieck's theorems on semistable reduction, Grothendieck–Messing theory, Serre's tensor construction, Zarhin's trick, quotients by finite subgroup schemes and the potentially good reduction of elliptic curves with complex multiplication are used in Sections 31–34 and 35. Appendix D uses, besides several of these, Lefschetz's very ampleness theorem, Rapoport's freeness theorem, the Hodge and conjugate filtrations of de Rham cohomology in characteristic p, the universal vector extension of Mazur and Messing, and the openness and closedness of the polarisation locus (Sections D.2 and D.5).

Theorem B.103. *Let* $A \to S$ *be an abelian scheme over a* $\mathbb{Q}$*-scheme. There is a normalized Poincaré line bundle* $\mathcal{P}_A$ *on* $A \times_S A^\vee$*, rigidified on both zero sections. For a homomorphism* $Q : A \to A^\vee$*, put*

$$\mathcal{P}_Q = (\mathrm{id}_A \times Q)^* \mathcal{P}_A.$$

Normalized biextensions on $A \times_S A$ *are classified by these homomorphisms; equality of the homomorphisms gives a unique normalized biextension isomorphism. In particular, for a rigidified line bundle* $\mathcal{M}$*,*

$$\Lambda(\mathcal{M}) = m^*\mathcal{M} \otimes \mathrm{pr}_1^*\,\mathcal{M}^{-1} \otimes \mathrm{pr}_2^*\,\mathcal{M}^{-1} \simeq \mathcal{P}_{\phi_{\mathcal{M}}}.$$

The line bundle $\mathcal{M}$ *has a unique compatible cubical structure. It is relatively ample if and only if* $\phi_{\mathcal{M}}$ *is a polarisation. These statements and normalized identifications commute with arbitrary base change. The bundle* $\mathcal{P}_Q$ *is bilinear in its two arguments, and interchanging the arguments replaces* Q *by its dual* $Q^\vee$*, using* $A = A^{\vee\vee}$*.*

In addition, the following integral clause holds. Let R *be a complete discrete valuation ring and* A/R *an abelian scheme with identity* e*. Every line bundle* $\mathcal{L}$ *rigidified by* $e^*\mathcal{L} \simeq R$ *has a unique compatible normalized cubical structure: a trivialization*

$$\bigotimes_{I \subseteq \{1,2,3\}} m_I^*\mathcal{L}^{(-1)^{3-|I|}} \simeq \mathcal{O}_{A^3}, \qquad m_\varnothing = e,$$

with the usual symmetry and cocycle identities, equal to the identity on a coordinate-zero face under the rigidifications. Formation of this structure commutes with base change, in particular to the fraction field and valued extensions.

Proof. These are the normalized Poincaré universal property, the theorem of the cube for abelian schemes, and the polarisation criterion for a line bundle. They are quoted at their standard relative statements: [186], the theorem of the cube and duality theory; [181], Chapter I, 2.6; and [154], Construction 1.3.2.7, Lemma 1.3.2.10, Proposition 1.3.2.15 and Proposition 3.2.3.1.

For the integral clause apply the theorem of the cube in its rigidified cubical form over an abelian scheme over a complete discrete valuation ring, [181], Chapter I, §2. The rigidification fixes the coordinate-zero normalization; the symmetry and cocycle conditions characterize its unique compatible cubical trivialization. This uniqueness also identifies every base change with the corresponding normalized cubical structure. No Poincaré classification over a non-$\mathbb{Q}$ base beyond this cubical clause is asserted here. □

Theorem B.104. *Let S be a noetherian normal scheme, let $U \subseteq S$ be a dense open subscheme, and let G, H be semiabelian schemes over S. Every homomorphism of U-group schemes*

$$f_U : H_U \longrightarrow G_U$$

extends uniquely to a homomorphism of S-group schemes $f : H \to G$.

Proof. This is the semiabelian homomorphism extension theorem, [87, Chapter I, Proposition 2.7]; see also [154, Proposition 3.3.1.5]. The base is noetherian and normal, the subscheme is open and dense, and both group schemes are semiabelian, exactly as required by that theorem. □

Theorem B.105. *Let E be a CM field and $M \neq 0$ a finite projective $\mathcal{O}_E$-module with a perfect alternating $\mathbb{Z}$-pairing ψ. Suppose*

$$\psi(ax, y) = \psi(x, \bar{a}y), \quad J \in \mathrm{End}_{E\otimes\mathbb{R}}(M_{\mathbb{R}}), \quad J^2 = -1,$$
$$\psi(Jx, Jy) = \psi(x, y), \quad \psi(Jx, x) > 0 \ (x \neq 0).$$

Set

$$g = \tfrac{1}{2}\operatorname{rank}_{\mathbb{Z}} M, \quad P_a(T) = \det_{\mathbb{C}}(T - a \mid (M_{\mathbb{R}}, J)), \quad F_{\mathrm{ref}} = \mathbb{Q}(\textit{coefficients of } P_a : \ a \in \mathcal{O}_E).$$

Fix $N \geq 3$. The following functor on F_{ref}-schemes is represented by a smooth separated quasi-projective scheme with its universal tuple.

Over S, its objects are tuples $(A, \phi_{\mathrm{pol}}, \iota, \alpha_N, \nu_N)$, where A/S is an abelian scheme of dimension g, ϕ_{pol} is a principal polarisation, ι is a unital $\mathcal{O}_E$-action, and

$$\phi_{\mathrm{pol}}\iota(a) = \iota(\bar{a})^{\vee}\phi_{\mathrm{pol}}, \qquad \det(T - \iota(a) \mid \mathrm{Lie}(A/S)) = P_a(T) \quad (a \in \mathcal{O}_E).$$

The level consists of $\mathcal{O}_E$-linear $\alpha_N : (M/NM)_S \xrightarrow{\sim} A[N]$ and $\nu_N : (\mathbb{Z}/N)_S \xrightarrow{\sim} \mu_{N,S}$ satisfying

$$e_N^{\phi_{\mathrm{pol}}}(\alpha_N(x), \alpha_N(y)) = \nu_N(\psi(x, y) \bmod N).$$

It is required to lift to compatible analogous pairs (α_m, ν_m) over a tower of finite étale surjections $S_m \to S$, indexed by $N \mid m$, with $S_N = S$. For $N \mid l \mid m$ the transition $S_m \to S_l$ is finite étale surjective and the pair at m reduces to the pair at l: multiplication by m/l on $A[m]$, reduction on M/mM, and the (m/l)th power on μ_m. Isomorphisms preserve every component of the tuple; the functor assigns isomorphism classes.

Proof. This is the full-level PEL representability theorem of [154], Definition 1.4.1.2, Theorem 1.4.1.11, Corollary 1.4.1.12 and Corollary 7.2.3.10, with the liftability condition of Definition

1.3.6.2 and with no allowed positive residue characteristics. The lattice is self-dual, so the polarisation is principal.

Here is the sign convention in this formulation. In the Tate-twisted convention use the pairing

$$\langle x, y\rangle_{\mathrm{tw}} = -2\pi i\,\psi(x, y), \qquad h(a + bi) = a + bJ.$$

Then the real form associated to $\langle x, h(i)y\rangle_{\mathrm{tw}}$ is $-\psi(x, Jy)$, whose value at (x, x) is $\psi(Jx, x) > 0$. The $+i$ subspace of $h(i)$ has determinant $P_a(T)$ as stated. Inverting every cyclotomic trivialisation converts the twisted pairing convention into the displayed pairing condition and preserves all tower transition equations. Thus the determinant and positivity conventions agree. The level is taken over the entire reflex field; no single cyclotomic component is selected. □

Theorem B.106. *Let $E, M, \psi, J, N, F_{\mathrm{ref}}$ be as in Theorem B.105, and let X/F_{ref} be its fine full-level moduli scheme, with universal tuple $(A, \phi_{\mathrm{pol}}, \iota, \alpha_N, \nu_N)$. Put*

$$\omega_A = \mathrm{Lie}(A/X)^\vee, \qquad \omega_{A^\vee} = \mathrm{Lie}(A^\vee/X)^\vee.$$

Let $\mathcal{R}$ be the coherent subsheaf of $\omega_A \otimes_{\mathcal{O}_X} \omega_{A^\vee}$ generated locally by

$$\phi_{\mathrm{pol}}^*(y) \otimes z - \phi_{\mathrm{pol}}^*(z) \otimes y \quad (y, z \in \omega_{A^\vee})$$

and

$$\iota(a)^*(x) \otimes y - x \otimes (\iota(a)^\vee)^*(y) \quad (a \in \mathcal{O}_E,\ x \in \omega_A,\ y \in \omega_{A^\vee}).$$

The Kodaira–Spencer morphism induces an isomorphism

$$(\omega_A \otimes_{\mathcal{O}_X} \omega_{A^\vee})/\mathcal{R} \xrightarrow{\sim} \Omega^1_{X/F_{\mathrm{ref}}}.$$

Proof. This is the universal PEL Kodaira–Spencer theorem, [154], Definition 2.3.5.1 and Proposition 2.3.5.2, applied to the identity morphism of the smooth moduli scheme. The identity is flat and étale, so the indicated morphism is an isomorphism. An integral basis of $\mathcal{O}_E$ suffices for the endomorphism relations, giving the stated coherent subsheaf.

The negative Tate-twisted pairing and inversion of the cyclotomic trivialisations in Theorem B.105 identify its functor with this full-level moduli problem, leaving the universal abelian scheme, polarisation and action unchanged. Thus the coherent-sheaf relations agree exactly with those displayed here. □

Theorem B.107. *Let S be a normal locally noetherian scheme, $G \to S$ a semiabelian scheme, and let U be either an open subscheme of S that is schematically dense in S or, when S is irreducible, its generic point. Write $G_U = G \times_S U$.*

1. *Every rigidified line bundle on G carries exactly one cubical structure compatible with its rigidification, and every isomorphism of rigidified line bundles on G respects these cubical structures (the forgetful functor from cubical line bundles on G to rigidified line bundles on G is an equivalence of categories).*

2. *Restriction from cubical line bundles on G to cubical line bundles on G_U is fully faithful: every isomorphism of cubical line bundles on G_U between the restrictions of two cubical line bundles on G is the restriction of exactly one isomorphism of cubical line bundles on G.*

3. *If $\mathcal{L}_U$ is a cubical line bundle on G_U whose underlying line bundle is symmetric, $\mathcal{L}_U \cong [-1]^*\mathcal{L}_U$, then $\mathcal{L}_U$ is isomorphic, as a cubical line bundle, to the restriction of a cubical line bundle on G.*

Proof. Moret-Bailly, *Pinceaux de variétés abéliennes* [181]: (1) is Ch. I, 2.6; (2) is Ch. II, 3.2.1–3.2.3; (3) is Ch. II, 3.3. We read them in the form of [154]: (1) is Proposition 3.2.3.1 under its condition 2 (S normal; the fibres of G over the maximal points of S are extensions of abelian varieties by tori), (2) is Proposition 3.3.2.2(1), (3) is Theorem 3.3.2.3 under its condition 2. Notation: Lan's cubical $\mathbb{G}_m$-torsors are the cubical line bundles of Section 29.1; the trivialisation of $\Theta(\mathcal{L})$ at the origin of G^3 is a rigidification of $\mathcal{L}$, which is the rigidification meant in (1). Lan states these results for a normal base scheme; we use them only for locally noetherian ones. □

Theorem B.108. *Let E, (M, ψ, J) and $N \geq 3$ be as in Theorem B.105, with reflex field $F_{\mathrm{ref}} \subset \mathbb{C}$, and let $\mathcal{M}_N$ be the full-level scheme of Theorem B.105 over F_{ref}, with universal tuple $(A, \phi_{\mathrm{pol}}, \iota, \alpha_N, \nu_N)$. Let Σ be a compatible collection of admissible rational polyhedral cone decomposition data for $\mathcal{M}_N$ which is projective and smooth in the sense of [156] (Def. 2.1, 2.2, 2.7: each cone decomposition satisfies Cond. 6.2.5.25 of Lan's book [154], and Σ satisfies Cond. 6.3.3.2 there), induced by a compatible collection* pol *of polarisation functions, and let $d \geq 1$ be divisible by the integers d_0 of [156] (Prop. 4.19, 5.1). Let p be a prime with $N/p^{v_p(N)} \geq 3$. Then there are a normal scheme $\mathcal{X}_p$, projective and flat over $\mathcal{O}_{F_{\mathrm{ref}},(p)}$, an open subscheme $\mathcal{X}_p^\circ \subseteq \mathcal{X}_p$ dense in every fibre over $\mathcal{O}_{F_{\mathrm{ref}},(p)}$ with $\mathcal{X}_p^\circ \otimes F_{\mathrm{ref}} = \mathcal{M}_N$, a proper surjection $\mathcal{X}_p \to \mathcal{X}_p^{\min}$ onto a normal scheme projective and flat over $\mathcal{O}_{F_{\mathrm{ref}},(p)}$, and a semiabelian scheme $G_p \to \mathcal{X}_p$ with a polarisation of its restriction to $\mathcal{M}_N$ and a ring homomorphism $\iota_p \colon \mathcal{O}_E \to \mathrm{End}(G_p)$, such that:*

1. *over $\mathcal{M}_N$, (G_p, ι_p) with the polarisation is $(A, \iota, \phi_{\mathrm{pol}})$;*

2. *$\mathcal{X}_p$ is the disjoint union of locally closed strata, each flat over $\mathcal{O}_{F_{\mathrm{ref}},(p)}$, normal, and with dense characteristic-0 fibre; $\mathcal{X}_p^\circ$ is one stratum; the formal completion of $\mathcal{X}_p$ along a stratum is canonically isomorphic to Lan's formal scheme $\mathfrak{X}_{\Phi,\delta,\sigma}$ of a representative (Φ, δ, σ) of the stratum, and the pull-back of G_p to it is the Mumford family over $\mathfrak{X}_{\Phi,\delta,\sigma}$ (Lan's book, Def. 6.2.5.28);*

3. *the Hodge bundle $\omega_p = \det e^*\Omega^1_{G_p/\mathcal{X}_p}$ is the pull-back of an ample invertible sheaf on $\mathcal{X}_p^{\min}$;*

4. *there is an effective Cartier divisor D_p on $\mathcal{X}_p$ with $(D_p)_{\mathrm{red}} = \mathcal{X}_p \setminus \mathcal{X}_p^\circ$ such that $\mathcal{O}(-D_p)$ is relatively ample over $\mathcal{X}_p^{\min}$; its ideal is the pull-back of the ideal of the schematic closure in $\mathcal{X}_p^{\min}$ of the closed subscheme of $\mathcal{X}_p^{\min} \otimes F_{\mathrm{ref}}$ defined by Lan's characteristic-0 ideal $\mathcal{J}_{d\,\mathrm{pol}}$, which is defined from Σ,* pol *and d on the characteristic-0 minimal compactification;*

5. *(extension property) let S be an irreducible noetherian normal $\mathcal{O}_{F_{\mathrm{ref}},(p)}$-scheme with generic point η, $x \colon \eta \to \mathcal{M}_N$ a morphism, and suppose that there is a degenerating family of type $\mathcal{M}_N$ over S in the sense of Lan's book, Def. 5.3.2.1 (a semiabelian scheme with $\mathcal{O}_E$-action, a homomorphism to its dual and a level structure over η) whose restriction to η defines the morphism x. Then x extends (necessarily uniquely) to a morphism $S \to \mathcal{X}_p$ over $\mathcal{O}_{F_{\mathrm{ref}},(p)}$ if Lan's condition holds at every geometric point $\bar{s}$ of S: for every complete discrete valuation ring V with algebraically closed residue field and every dominant morphism $\mathrm{Spec}\, V \to S$ centred at $\bar{s}$, after a finite extension of $\mathrm{Frac}\, V$ the valuation of the degeneration datum of the pulled-back family lies in one cone of Σ;*

6. *(characteristic 0) $\mathcal{X}_p \otimes F_{\mathrm{ref}} \to \mathcal{X}_p^{\min} \otimes F_{\mathrm{ref}}$ is Lan's characteristic-0 toroidal compactification $\mathcal{M}_\Sigma^{\mathrm{tor}}$ of $\mathcal{M}_N$ for Σ with its map to the minimal compactification (Lan's book, Thm. 6.4.1.1*

and 7.2.4.1, with $\square = \emptyset$), the identification restricting to the identity of $\mathcal{M}_N$; in particular $D_p \otimes F_{\mathrm{ref}}$ is the divisor on $\mathcal{M}_\Sigma^{\mathrm{tor}}$ of the pull-back of $\mathcal{J}_{d\,\mathrm{pol}}$, the same for every p.

Proof. Quoted from K.-W. Lan, Integral models of toroidal compactifications with projective cone decompositions [156], Theorem 6.1 and its proof, Construction 3.12, Corollaries 4.23, 6.6, 6.7 and Proposition 5.15; the setting is that of Lan, Compactifications of PEL-type Shimura varieties in ramified characteristics [155], Sect. 2, with a single lattice ($J = \{j_0\}$, $(g_{j_0}, L_{j_0}) = (1, M)$) and $\mathcal{O} = \mathcal{O}_E$.

Location of each clause. Main clause: Theorem 6.1 (normal scheme projective and flat over $\vec{\mathsf{S}}_0 = \operatorname{Spec} \mathcal{O}_{F_0,(p)}$, F_0 the reflex field, containing $\vec{\mathsf{M}}_{\mathcal{H}}$ as an open fibrewise dense subscheme, with a tautological degenerating family). Item 1: 6.1(1). Item 2: 6.1(3) (strata flat over $\vec{\mathsf{S}}_0$ and normal; $\vec{\mathsf{M}}_{\mathcal{H}}$ the open stratum), the proof of Proposition 5.15 (the characteristic-0 fibre of each stratum is dense in it), 6.1(4) (completions and Mumford families). Item 3: 6.1(2): $\omega_J^{\mathrm{tor}} \cong \omega_{j_0}^{\otimes a_{j_0}}$ with $\omega_{j_0} = \det \mathrm{Lie}_{G_{j_0}}^\vee$ is the pull-back of the ample $\omega_J^{\min}$, and ω_{j_0} descends to an invertible sheaf $\omega_{j_0}^{\min}$ with $(\omega_{j_0}^{\min})^{\otimes a_{j_0}} \cong \omega_J^{\min}$; a positive power of $\omega_{j_0}^{\min}$ being ample, $\omega_{j_0}^{\min}$ is ample (EGA II 4.5.6), and $\omega_p = \omega_{j_0}$ is its pull-back. Item 4: Corollary 6.7 and its proof (the pull-back of $\vec{\mathcal{J}}_{\mathcal{H},d\,\mathrm{pol}}$, defined in Construction 3.12 as the ideal of the schematic closure of the subscheme defined by $\mathcal{J}_{\mathcal{H},d\,\mathrm{pol}}$, is $\mathcal{O}(-\mathsf{D})$). Item 5: 6.1(6), which asserts the extension under the condition ("if"; no converse is stated there). Item 6: Construction 3.12 (by Theorem 3.10, i.e. Lan's book Thm. 7.3.3.4, for Σ projective and smooth the characteristic-0 toroidal compactification is the normalised blow-up $\mathsf{M}^{\mathrm{tor}}_{\mathcal{H},d_0\mathrm{pol}}$, the generic fibre of the p-integral one), Corollary 4.23 with Corollary 6.6 (Σ smooth satisfying Cond. 6.3.3.2, $\Sigma' = \Sigma$: the canonical morphism (4.24) from Lan's characteristic-0 $\mathsf{M}^{\mathrm{tor}}_{\mathcal{H},\Sigma}$ to $\mathsf{M}^{\mathrm{tor}}_{\mathcal{H},d\,\mathrm{pol}}$ is an isomorphism); normalised blow-ups commute with the flat base change $\mathcal{O}_{F_0,(p)} \to F_0$, and the restriction of $\vec{\mathcal{J}}$ to the generic fibre is $\mathcal{J}$, so the generic fibre of $\vec{\mathsf{M}}^{\mathrm{tor}}_{\mathcal{H},d\,\mathrm{pol}}$ is $\mathsf{M}^{\mathrm{tor}}_{\mathcal{H},d\,\mathrm{pol}}$; the characteristic-0 objects do not involve p.

Notation. Lan's PEL datum $(\mathcal{O}, \star, L, \langle\,,\rangle, h_0)$ is $(\mathcal{O}_E,\ a \mapsto \bar{a},\ M,\ 2\pi i\,\psi,\ J)$; the level $\mathcal{H}$ is the principal congruence subgroup $\mathcal{U}(N) \subseteq G(\widehat{\mathbb{Z}})$; Lan's reflex field F_0 is F_{ref}; Lan's $\vec{\mathsf{M}}^{\mathrm{tor}}_{\mathcal{H}}$, $\vec{\mathsf{M}}_{\mathcal{H}}$, $\vec{\mathsf{M}}^{\min}_{\mathcal{H}}$, D, (G, λ, i) are $\mathcal{X}_p$, $\mathcal{X}_p^\circ$, $\mathcal{X}_p^{\min}$, D_p, $(G_p, \text{polarisation}, \iota_p)$. Lan's standing hypothesis (Theorem 6.1, Construction 3.12) is that the image $\mathcal{H}^p$ of $\mathcal{H}$ in $G(\widehat{\mathbb{Z}}^p)$ is neat; here $\mathcal{H}^p$ is the principal congruence subgroup of level $N/p^{v_p(N)} \geq 3$, which is neat (Lan's book, Def. 1.4.1.8, Serre's lemma). Over F_{ref}, Lan's $\mathsf{M}_{\mathcal{H}}$ is the moduli problem of Lan's book, Def. 1.4.1.4 (with $\square = \emptyset$), whose level-$\mathcal{U}(N)$ structures are the symplectic-liftable principal level-N structures (α_N, ν_N); this is the functor of Theorem B.105, so $\mathsf{M}_{\mathcal{H}} = \mathcal{M}_N$. Lan's Cond. 1.4.3.10 on L is assumed in his Sect. 2; with $\mathcal{O} = \mathcal{O}_E$ maximal it holds. □

Theorem B.109. *Let R be a noetherian normal domain, complete with respect to an ideal I with $\operatorname{rad}(I) = I$; put $S = \operatorname{Spec} R$, $S_0 = \operatorname{Spec} R/I$, η the generic point, and write ^{for} for formal completion along S_0.*

1. *(Raynaud extension.) Let G be a semiabelian scheme over S such that $G \times_S S_0$ is an extension of an abelian scheme A_0 by an isotrivial torus T_0. Then there are, uniquely up to unique isomorphism, an abelian scheme A and a torus T over S and an extension $0 \to T \to \widetilde{G} \to A \to 0$ whose formal completion is the extension $0 \to T^{\mathrm{for}} \to G^{\mathrm{for}} \to A^{\mathrm{for}} \to 0$ of G^{for} (the Raynaud extension of G). The natural functor*

$$\mathrm{CUB}_S(\widetilde{G}, \mathbb{G}_{m,S}) \longrightarrow \mathrm{CUB}_{S^{\mathrm{for}}}(G^{\mathrm{for}}, \mathbb{G}_{m,S^{\mathrm{for}}}), \qquad \mathcal{N} \mapsto \mathcal{N}^{\mathrm{for}},$$

from cubical $\mathbb{G}_m$-torsors on the scheme $\widetilde{G}$ over S to cubical $\mathbb{G}_m$-torsors on the formal scheme G^{for}, induced by the isomorphism $\widetilde{G}^{\mathrm{for}} \cong G^{\mathrm{for}}$, is fully faithful, and its essential

image contains all cubical $\mathbb{G}_m$-torsors on G^{for} coming from a cubical $\mathbb{G}_m$-torsor on A^{for}. In particular, if all tori over S_0 are isotrivial, this functor is an equivalence of categories.

2. *(Association of degeneration data and Mumford's construction.) Let $\mathrm{DEG}_{\mathrm{ample}}$ be the category of pairs $(G, \mathcal{L})$ of a semiabelian scheme G over S as in (1) with abelian generic fibre G_η and an ample cubical invertible sheaf $\mathcal{L}$ on G, rigidified along the unit section, such that $\mathcal{L}^{\mathrm{for}}$ is in the essential image of the functor of (1) (a rigidified invertible sheaf on G has a unique cubical structure). Let $\mathrm{DD}_{\mathrm{ample}}$ be the category of ample degeneration data $(A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi)$: an extension $\widetilde{G}$ of an abelian scheme A by a torus with character group X, given by $c\colon X \to A^\vee$; an étale sheaf Y of free abelian groups of the same rank with $c^\vee\colon Y \to A$; an injective $\phi\colon Y \to X$ with finite cokernel; a cubical ample invertible sheaf $\widetilde{\mathcal{L}}$ on $\widetilde{G}$ inducing a polarisation λ_A of A with $\lambda_A c^\vee = c\phi$; a trivialisation τ of the biextension $(c^\vee \times c)^*\mathcal{P}_A^{-1}$ over η, symmetric with respect to ϕ in the sense that $(\mathrm{id}_Y \times \phi)^*\tau$ is symmetric (equivalently a period homomorphism $\iota\colon Y_\eta \to \widetilde{G}_\eta$ over $c^\vee$); and a cubical trivialisation ψ of $\iota^*\widetilde{\mathcal{L}}_\eta^{-1}$ compatible with $\tau \circ (\mathrm{id}_Y \times \phi)$ (this compatibility forces the symmetry of τ); with the positivity conditions, read after a finite étale surjective base change over which X and Y are constant (none if they are constant over S), through the cubical isomorphism $\widetilde{\mathcal{L}} \cong \pi^*\mathcal{M}$, with a cubical invertible sheaf $\mathcal{M}$ on A, determined by a cubical trivialisation s of $i^*\widetilde{\mathcal{L}}$ (where $i\colon T \to \widetilde{G}$ is the torus and $\pi\colon \widetilde{G} \to A$ the projection), so that $\tau(y, \phi(y))$ is a trivialisation of $(c^\vee(y) \times c\phi(y))^*\mathcal{P}_A^{-1}$ and $\psi(y)$ one of $\mathcal{M}(c^\vee(y))^{-1}$ over η: the* condition on τ, *that $\tau(y, \phi(y))$ extends over S for every y and is 0 modulo I for $y \neq 0$; and the* condition on ψ, *that $\psi(y)$ extends over S for every y and that, for every $n \geq 1$, $\psi(y)$ is 0 modulo I^n for all but finitely many y. The condition on τ does not involve s; the condition on ψ does, and an object of $\mathrm{DD}_{\mathrm{ample}}$ is required to satisfy it for one choice of s. For a given s, the condition on ψ implies the condition on τ; if moreover $\mathcal{M}$ is symmetric and, for every y, $\psi(-y)$ corresponds to $\psi(y)$ under an isomorphism $[-1]^*\mathcal{M} \cong \mathcal{M}$ (we say that ψ is* even *through s), then the condition on τ implies the condition on ψ for this s. Then the Fourier expansions of the sections of the $\mathcal{L}^{\otimes k}$ attach to every $(G, \mathcal{L}) \in \mathrm{DEG}_{\mathrm{ample}}$, functorially in isomorphisms, a tuple $F_{\mathrm{ample}}(G, \mathcal{L}) = (A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi)$ as above, with $\widetilde{G}$ the Raynaud extension of G and $\widetilde{\mathcal{L}}^{\mathrm{for}} \cong \mathcal{L}^{\mathrm{for}}$, whose τ satisfies the condition on τ; if ψ is even through some s, then $F_{\mathrm{ample}}(G, \mathcal{L})$ is an object of $\mathrm{DD}_{\mathrm{ample}}$. Mumford's construction is a functor $M_{\mathrm{ample}}\colon \mathrm{DD}_{\mathrm{ample}} \to \mathrm{DEG}_{\mathrm{ample}}$ with $F_{\mathrm{ample}}(M_{\mathrm{ample}}(\mathfrak{d})) \cong \mathfrak{d}$ for every object $\mathfrak{d}$ of $\mathrm{DD}_{\mathrm{ample}}$, and $M_{\mathrm{ample}}(F_{\mathrm{ample}}(G, \mathcal{L})) \cong (G, \mathcal{L})$ whenever $F_{\mathrm{ample}}(G, \mathcal{L})$ is an object of $\mathrm{DD}_{\mathrm{ample}}$; thus F_{ample} and M_{ample} are quasi-inverse equivalences between $\mathrm{DD}_{\mathrm{ample}}$ and the full subcategory of $\mathrm{DEG}_{\mathrm{ample}}$ of the $(G, \mathcal{L})$ with $F_{\mathrm{ample}}(G, \mathcal{L})$ in $\mathrm{DD}_{\mathrm{ample}}$, which contains every $(G, \mathcal{L})$ whose ψ is even through some s. (Ampleness for symmetric sheaves.) Let G be a semiabelian scheme over S with G_η an abelian variety, and $\mathcal{L}$ a cubical invertible sheaf on G with $\mathcal{L}_\eta$ nondegenerate (its homomorphism $\lambda_{\mathcal{L}_\eta}\colon G_\eta \to G_\eta^\vee$ is an isogeny). If $\mathcal{L}_\eta$ is symmetric, then $\mathcal{L}$ is ample if and only if $\mathcal{L}_\eta$ is ample, and if and only if $\lambda_{\mathcal{L}_\eta}$ is a polarisation.*

3. *($\mathcal{O}$-structures.) Let $\mathcal{O}$ be an order in a finite-dimensional semisimple $\mathbb{Q}$-algebra with positive involution $\star$. The equivalence of (2), in its polarised form $\mathrm{DEG}_{\mathrm{pol}} \simeq \mathrm{DD}_{\mathrm{pol}}$, induces an equivalence $\mathrm{DD}_{\mathrm{PE},\mathcal{O}} \simeq \mathrm{DEG}_{\mathrm{PE},\mathcal{O}}$ between triples (G, λ, i) with (G, λ) a polarised degeneration and $i\colon \mathcal{O} \to \mathrm{End}_S(G)$ restricting to an $\mathcal{O}$-structure of (G_η, λ_η), and polarised degeneration data with an $\mathcal{O}$-action i_A on A and $\mathcal{O}$-module structures on X and Y compatible with c, $c^\vee$, ϕ, λ_A and τ.*

4. *(Fourier expansions.) Let $(G, \mathcal{L}) \in \mathrm{DEG}_{\mathrm{ample}}$ with $F_{\mathrm{ample}}(G, \mathcal{L}) = (A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi)$, $\pi\colon \widetilde{G} \to A$, and suppose X, Y constant and $\widetilde{\mathcal{L}} \cong \pi^*\mathcal{M}$ as cubical sheaves for a cubical*

invertible sheaf $\mathcal{M}$ on A. For $\chi \in X$ put $\mathcal{O}_\chi = (\mathrm{Id}, c(\chi))^*\mathcal{P}_A$ and $\mathcal{M}_\chi = \mathcal{M} \otimes \mathcal{O}_\chi$. Then $\Gamma(G^{\mathrm{for}}, \mathcal{L}^{\mathrm{for}})$ is the I-adic completion of $\bigoplus_{\chi \in X} \Gamma(A, \mathcal{M}_\chi)$ (the decomposition into weights of the torus), which defines K-linear maps $\sigma_\chi \colon \Gamma(G_\eta, \mathcal{L}_\eta) \to \Gamma(A_\eta, \mathcal{M}_{\chi,\eta})$, and: (a) $\sigma_\chi \neq 0$ for every $\chi \in X$; (b) for all $y \in Y$, $\chi \in X$, $\psi(y)\tau(y,\chi) \circ T^*_{c^\vee(y)} \circ \sigma_\chi = \sigma_{\chi+\phi(y)}$, where $\psi(y)\tau(y,\chi)$ is read, by $\mathcal{M}_\chi(c^\vee(y))^{-1} \cong \mathcal{M}(c^\vee(y))^{-1} \otimes \mathcal{O}_\chi(c^\vee(y))^{-1}$, as an isomorphism $T^*_{c^\vee(y)}\mathcal{M}_{\chi,\eta} \to \mathcal{M}_{\chi+\phi(y),\eta}$; the sections $\psi(y)$, $\tau(y,\chi)$ are the unique ones satisfying (b) and the normalisation $\tau(y,0) = 1$ (the inverse of $\tau(y,0)$ is the isomorphism $c^\vee(y)^*\mathcal{O}_A \cong \mathcal{O}_S$), which implies $\psi(0) = 1$ (the rigidification) and $\tau(0,\chi) = 1$; replacing $\mathcal{M}$ by $\mathcal{M} \otimes \mathcal{O}_{\chi_0}$ shifts the indices of the σ_χ by χ_0 and changes neither τ nor ψ as a trivialisation of $\iota^*\widetilde{\mathcal{L}}_\eta^{-1}$; (c) for $n \geq 1$, $F_{\mathrm{ample}}(G, \mathcal{L}^{\otimes n}) = (A, X, Y, n\phi, c, c^\vee, \widetilde{\mathcal{L}}^{\otimes n}, \tau, \psi^n)$; (d) $\deg \lambda_\eta = [X : \phi(Y)]^2 \deg \lambda_A$ for the polarisations λ_η of G_η and λ_A of A induced by $\mathcal{L}$, $\widetilde{\mathcal{L}}$.

5. *(Torsion of Mumford quotients at points.) Let $(A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi) \in \mathrm{DD}_{\mathrm{ample}}$ with X, Y constant and $\widetilde{\mathcal{L}} = \pi^*\mathcal{M}$ for an ample invertible sheaf $\mathcal{M}$ on A, where $\pi \colon \widetilde{G} \to A$, such that ψ, read through $\widetilde{\mathcal{L}} = \pi^*\mathcal{M}$, satisfies the condition on ψ of (2) (the tuple $(A, \mathcal{M}, X, Y, \phi, c, c^\vee, \tau, \psi)$ is then an object of $\mathrm{DD}^{\mathrm{split}}_{\mathrm{ample}}$). Let $(\widetilde{P}, \widetilde{\mathcal{L}})$ be a relatively complete model of it (in the sense of [154], Def. 4.5.1.2), and G the Mumford quotient of $\widetilde{G}$ by Y attached to it ([154], Constr. 4.5.2.17, Def. 4.5.2.18). For $y \in Y$, $\chi \in X$ let $I_{y,\chi} \subseteq K$ be the invertible R-submodule defined by $\tau(y,\chi)$. For $s \in S$ put $Y_s = \{z \in Y : I_{z,\phi(z)} \cdot \mathcal{O}_{S,s} = \mathcal{O}_{S,s}\}$. Then $Y_s = \{z \in Y : \iota(z) \in \widetilde{G}(\mathrm{Spec}\, \mathcal{O}_{S,s})\}$, and for every integer $n \geq 1$ there is a natural exact sequence of group schemes over $\kappa(s)$*

$$0 \to \widetilde{G}[n]_s \to G[n]_s \to \tfrac{1}{n}Y_s/Y_s \to 0.$$

Proof. [87], Ch. II, Thm. 6.2, and Ch. III; [154], Ch. 3–5. The statement is the text printed in Lan's book (numbering and pages of the book): (1) is the setting of Sect. 3.3.3 (p. 165; there R is only a noetherian integral domain), Prop. 3.3.3.6 and Def. 3.3.3.8 (p. 166; the ample cubical sheaf on G assumed in Prop. 3.3.3.6 exists because S is normal, Remark 3.3.3.9) and Prop. 3.3.3.11 (p. 167); (2) is the setting of Sect. 4.1 (p. 175), Def. 4.2.1.1 (p. 176), Lemma 4.2.1.7 and Defs. 4.2.1.10–4.2.1.13 (pp. 177–180), Thm. 4.2.1.14 (p. 180), Thm. 4.4.16 (p. 215) and Cor. 4.5.4.9 (p. 246), and its last two sentences are Lemma 4.2.1.6 (p. 177) under the assumptions of Lemma 4.2.1.4 (p. 176); (3) is Defs. 5.1.1.2–5.1.1.3 and Thm. 5.1.1.4 (pp. 286–287); (4) is Sect. 4.3.1 ((4.3.1.2)–(4.3.1.7), Remark 4.3.1.1, Lemma 4.3.1.8, pp. 191–193), Cor. 4.3.4.2 (p. 209) and Lemma 3.4.4.3 (p. 174); (5) is Def. 4.5.1.1 (p. 216), Def. 4.5.1.2 (pp. 216–217), Constr. 4.5.2.17 and Def. 4.5.2.18 (pp. 232–233), Prop. 4.5.3.11 and Cor. 4.5.3.12 (pp. 241–242; cf. Faltings–Chai III, Prop. 5.10, Cor. 5.11, and Mumford 1972, Cor. 4.11), with $I_{y,\chi}$ as in Def. 4.2.4.6 (pp. 189–190); in (2), the symmetry of τ is Def. 4.2.1.13, item 6, and the remark that the compatibility of ψ forces it is on pp. 178–179, where the positivity conditions are stated after the base change named (Defs. 4.2.1.10–4.2.1.11, Lemma 4.2.1.12); the isomorphism $\widetilde{\mathcal{L}} \cong \pi^*\mathcal{M}$ through which ψ is read is the one determined by a cubical trivialisation s (p. 178 and Sect. 4.2.3, pp. 184–185, where the cubical trivialisations form a torsor under X and two choices of $\mathcal{M}$ differ by some $\mathcal{O}_\chi$, Lemma 4.2.3.1), and Def. 4.2.1.13 (p. 180) requires both positivity conditions. From Lemma 4.2.1.12 (p. 179; proof in Sect. 4.2.4, pp. 189–190) (2) uses two implications: from the condition on ψ to the condition on τ, for every s; and from the condition on τ to the condition on ψ when ψ is even through s. In the even case $\psi(y)\psi(-y) = \tau(y, \phi(y))$ (by (4.2.3.4), p. 188, at $(y, -y)$, with $\psi(0) = 1$) and $I_y = I_{-y}$ (Defs. 4.2.4.5–4.2.4.6, pp. 189–190) give $I_y^2 = I_{y,\phi(y)}$, so $v(\psi(y)) = \frac{1}{2}v(\tau(y, \phi(y)))$ for every valuation v of K, a quadratic form in y, which is the form in which the printed proof argues; in particular $I_y \subseteq R$ by Lemma 4.2.4.2

(p. 189). That $F_{\mathrm{ample}}(G,\mathcal{L})$ satisfies the condition on τ is Prop. 4.3.1.9, item 5 (p. 194), proved on pp. 195–196 from the Fourier expansion and (4.2.4.7) for any choice of $\mathcal{M}$; with the even case this gives the condition on ψ, hence membership in $\mathrm{DD}_{\mathrm{ample}}$, when ψ is even through some s. That the condition on ψ involves s: replacing s by its product with a character $\chi_0 \in X$ shifts the weights by χ_0 (p. 185; Remark 4.3.1.1, p. 192) and multiplies $\psi(y)$, read through the new $\mathcal{M}$, by $\tau(y,\chi_0)^{\pm 1}$, while τ does not change (Lemma 4.3.1.14, p. 196); on the Tate curve over $k[[t]]$ with $q=t^2$, $\psi(y)=t^{y^2}$ becomes t^{y^2-2yj}, not integral at $y=j\neq 0$. In (5), $\mathrm{DD}^{\mathrm{split}}_{\mathrm{ample}}$ is Def. 4.5.1.1 (p. 216), whose objects carry the positivity condition on ψ read through the given $\mathcal{M}$. Notation map: Lan's $G^\natural$ is $\widetilde{G}$, his $\mathcal{L}^\natural$ is $\widetilde{\mathcal{L}}$, his CUB the categories of cubical torsors; ι (period map), τ, ψ, X, Y, ϕ as above; in the principally polarised case ϕ is an isomorphism and Y is identified with X, $c^\vee$ with c via λ_A. □

Theorem B.110. *Let S be a locally noetherian normal scheme and $0\to\mathbb{T}\xrightarrow{i}\widetilde{G}\xrightarrow{\pi}A\to 0$ an exact sequence of smooth commutative group schemes with connected fibres over S, with $\mathbb{T}$ a split torus and A an abelian scheme.*

1. *Every cubical $\mathbb{G}_m$-torsor on $\widetilde{G}$ is isomorphic, as a cubical torsor, to $\pi^*\mathcal{M}$ for a cubical $\mathbb{G}_m$-torsor $\mathcal{M}$ on A.*
2. *The category $\mathrm{CUB}_S(A,\mathbb{G}_{m,S})$ is equivalent to the category of pairs $(\mathcal{L},s)$, where $\mathcal{L}$ is an object of $\mathrm{CUB}_S(\widetilde{G},\mathbb{G}_{m,S})$ and s is a trivialisation of $i^*\mathcal{L}$ in $\mathrm{CUB}_S(\mathbb{T},\mathbb{G}_{m,S})$ (equivalently, in the category $\mathrm{EXT}_S(\mathbb{T},\mathbb{G}_{m,S})$ of commutative group extensions of $\mathbb{T}$ by $\mathbb{G}_{m,S}$).*

Proof. K.-W. Lan, Arithmetic compactifications of PEL-type Shimura varieties, LMS Monographs 36 (2013) [154], Sect. 3.2.5 (pp. 160–161), after Moret-Bailly, Pinceaux de variétés abéliennes [181], Ch. I, 7.2.1–7.2.4. Item 1 is Cor. 3.2.5.7 (p. 161: for S locally noetherian and normal and a finite étale surjection $S'\to S$ splitting the torus, $\mathrm{EXT}_{S'}(\mathbb{G}_{m,S'},\mathbb{G}_{m,S'})=0$, and hence every cubical $\mathbb{G}_m$-torsor over $\widetilde{G}_{S'}$ comes from $A_{S'}$), applied with the identity of S as the splitting cover. Item 2 is Prop. 3.2.5.4 (p. 160), stated by Lan for any torus over any base scheme and an exact sequence of smooth commutative group schemes with connected geometric fibres, here specialised; the parenthesis is Prop. 3.2.5.3 (p. 160: $\mathrm{CUB}_S(\mathbb{T},\mathbb{G}_{m,S})$ is equivalent to $\mathrm{EXT}_S(\mathbb{T},\mathbb{G}_{m,S})$). The same numbers hold in Lan's Harvard thesis (2008). Notation map: Lan's T, G, H are $\mathbb{T}$, $\widetilde{G}$, A. □

Theorem B.111. *Let R, I, S, η be as in Theorem B.109, and let $(G,\mathcal{L}_1)$, $(G,\mathcal{L}_2)$ be objects of $\mathrm{DEG}_{\mathrm{ample}}$ with the same semiabelian scheme G, with $F_{\mathrm{ample}}(G,\mathcal{L}_k)=(A,X,Y,\phi_k,c,c^\vee,\widetilde{\mathcal{L}}_k,\tau_k,\psi_k)$ ($k=1,2$; the entries $A,X,Y,c,c^\vee$ depend only on G), and let $\lambda_k\colon G_\eta\to G_\eta^\vee$ be the polarisation induced by $\mathcal{L}_{k,\eta}$.*

1. *If $N_1\lambda_1=N_2\lambda_2$ for some positive integers N_1,N_2, then $\tau_1=\tau_2$.*
2. *Let $(G,\mathcal{L})$ be a third object of $\mathrm{DEG}_{\mathrm{ample}}$ with $\mathcal{L}\cong\mathcal{L}_1\otimes\mathcal{L}_2$ and*

$$F_{\mathrm{ample}}(G,\mathcal{L})=(A,X,Y,\phi,c,c^\vee,\widetilde{\mathcal{L}},\tau,\psi).$$

Then $\widetilde{\mathcal{L}}\cong\widetilde{\mathcal{L}}_1\otimes\widetilde{\mathcal{L}}_2$. If $\tau_1=\tau_2$, then $\phi=\phi_1+\phi_2$, $\tau=\tau_1=\tau_2$ and $\psi=\psi_1\psi_2$ (read through this isomorphism).

Proof. See [154] (the printed book, London Math. Soc. Monographs 36, Princeton 2013), Sect. 4.3.4: item (1) is Proposition 4.3.4.5 (p. 211), item (2) is Lemma 4.3.4.1 (p. 209; after Faltings–Chai, Degeneration of abelian varieties, Ch. II, Lemma 6.1); the isomorphism $\widetilde{\mathcal{L}} \cong \widetilde{\mathcal{L}}_1 \otimes \widetilde{\mathcal{L}}_2$ is the first paragraph of the printed proof of Lemma 4.3.4.1 ($\widetilde{\mathcal{L}}_k \cong \pi^*\mathcal{M}_k$ gives $\widetilde{\mathcal{L}} \cong \pi^*(\mathcal{M}_1 \otimes \mathcal{M}_2)$), and it is the identification through which the printed equality $\psi = \psi_1\psi_2$ is read. (In Lan's Harvard thesis, 2008, the same results are Lemma 4.3.4.1 and Proposition 4.3.4.6.) Notation: Lan's objects of $\mathrm{DEG}_{\mathrm{ample}}(R, I)$ (book, Definition 4.2.1.1) with their data as in his Corollary 4.3.1.16 and Theorem 4.2.1.14 are the objects of $\mathrm{DEG}_{\mathrm{ample}}$ of Theorem B.109(2) with F_{ample}; Lan's $\mathcal{L}^\natural$ is our $\widetilde{\mathcal{L}}$; his $\lambda_k \colon G \to G^\vee$ is the unique extension of the polarisation of G_η (his Convention 4.2.1.5 and Proposition 3.3.1.5), so $N_1\lambda_1 = N_2\lambda_2$ on G is equivalent to the same equality on G_η. □

Theorem B.112. *Let R, I, S, η, K be as in Theorem B.109. For an object $\mathfrak{d} = (A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi)$ of $\mathrm{DD}_{\mathrm{ample}}$ let $i \colon T \to \widetilde{G}$ and $\pi \colon \widetilde{G} \to A$ be the torus and the projection of the extension defined by c, and for an integer $n \geq 1$ put*

$$\mathfrak{d}^{(n)} = (A,\ X,\ Y,\ (2n+1)\phi,\ c,\ c^\vee,\ \widetilde{\mathcal{L}}^{\otimes n+1} \otimes [-1]^*\widetilde{\mathcal{L}}^{\otimes n},\ \tau,\ \psi^{n+1}[-1]^*\psi^n).$$

A split object *is a tuple $\mathfrak{e} = (A, \mathcal{M}, X, Y, \phi, c, c^\vee, \tau, \psi)$ with X and Y constant, $\mathcal{M}$ an ample invertible sheaf on A, and $\bar{\mathfrak{e}} = (A, X, Y, \phi, c, c^\vee, \pi^*\mathcal{M}, \tau, \psi)$ an object of $\mathrm{DD}_{\mathrm{ample}}$ (the* image *of $\mathfrak{e}$), such that ψ, read through the identity of $\pi^*\mathcal{M}$, satisfies the condition on ψ of Theorem B.109(2); for $y \in Y$ let $I_y \subseteq K$ be the invertible R-submodule defined by $\psi(y)$, a trivialisation over η of $\mathcal{M}(c^\vee(y))^{-1}$, and for $n \geq 1$ put*

$$\mathfrak{e}^{(n)} = (A,\ \mathcal{M}^{\otimes n+1} \otimes [-1]^*\mathcal{M}^{\otimes n},\ X,\ Y,\ (2n+1)\phi,\ c,\ c^\vee,\ \tau,\ \psi^{n+1}[-1]^*\psi^n).$$

A star *is a finite subset $\mathrm{St} \subseteq X$ generating X with $0 \in \mathrm{St}$ and $-\mathrm{St} = \mathrm{St}$; a split object satisfies* Condition 4.5.1.6 for St *if $I_y \cdot I_{y,\alpha} \subseteq R$ for all $y \in Y$ and all $\alpha \in \mathrm{St}$.*

1. *(Descent of $\widetilde{\mathcal{L}}$ to A.) Let $\mathfrak{d} \in \mathrm{DD}_{\mathrm{ample}}$ with X constant. Every cubical trivialisation s of $i^*\widetilde{\mathcal{L}}$ determines a cubical invertible sheaf $\mathcal{M}$ on A and a cubical isomorphism $\widetilde{\mathcal{L}} \cong \pi^*\mathcal{M}$, both depending uniquely on the choice of s, and $\mathcal{M}$ is ample because $\widetilde{\mathcal{L}}$ is.*

2. *(Twisting.) (a) For every $\mathfrak{d} \in \mathrm{DD}_{\mathrm{ample}}$ there is an integer $n_0 > 0$ such that $\mathfrak{d}^{(n)}$ is an object of $\mathrm{DD}^*_{\mathrm{ample}}$ (item (3)), in particular of $\mathrm{DD}_{\mathrm{ample}}$, for every $n \geq n_0$. (b) For every split object $\mathfrak{e}$ and every star St there is an integer $n_1 > 0$ such that $\mathfrak{e}^{(n)}$ satisfies Condition 4.5.1.6 for St for every $n \geq n_1$. (c) If a split object satisfies Condition 4.5.1.6 for a star St, then the pair $(\widetilde{P}_{(\phi,\psi),\mathrm{St}}, \widetilde{\mathcal{L}})$ of [154], Constr. 4.5.1.5, is a relatively complete model of it.*

3. *(Mumford's construction on split objects.) Fix a star St_0, and let $\mathrm{DD}^{\mathrm{split},*}_{\mathrm{ample}}$ be the category of split objects satisfying Condition 4.5.1.6 for St_0. The Mumford quotient attached to the relatively complete model of (2)(c) defines a functor $M^{\mathrm{split},*}_{\mathrm{ample}} \colon \mathrm{DD}^{\mathrm{split},*}_{\mathrm{ample}} \to \mathrm{DEG}_{\mathrm{ample}}$, $\mathfrak{e} \mapsto (G, \mathcal{L})$, with G that Mumford quotient. Let $\mathrm{DD}^*_{\mathrm{ample}}$ be the full subcategory of $\mathrm{DD}_{\mathrm{ample}}$ of the objects $\mathfrak{d}$ for which there are a finite étale surjection $S' = \operatorname{Spec} R' \to S$ (with $I' = \mathrm{rad}(I \cdot R')$) over which X and Y are constant and an ample invertible sheaf $\mathcal{M}'$ on $A \otimes_R R'$ with $\widetilde{\mathcal{L}} \otimes_R R' \cong \pi^*\mathcal{M}'$, such that $(A, \mathcal{M}', X, Y, \phi, c, c^\vee, \tau, \psi) \otimes_R R'$ is an object of $\mathrm{DD}^{\mathrm{split},*}_{\mathrm{ample}}(R', I')$. Then $M^{\mathrm{split},*}_{\mathrm{ample}}$ extends to a functor $M^*_{\mathrm{ample}} \colon \mathrm{DD}^*_{\mathrm{ample}} \to \mathrm{DEG}_{\mathrm{ample}}$ compatible with finite étale surjective base changes: for every $\mathfrak{e}$ in $\mathrm{DD}^{\mathrm{split},*}_{\mathrm{ample}}$ the image $\bar{\mathfrak{e}}$ lies in $\mathrm{DD}^*_{\mathrm{ample}}$ and $M^*_{\mathrm{ample}}(\bar{\mathfrak{e}}) \cong M^{\mathrm{split},*}_{\mathrm{ample}}(\mathfrak{e})$. The functor M_{ample} extends M^*_{ample}: $M_{\mathrm{ample}}(\mathfrak{d}) \cong M^*_{\mathrm{ample}}(\mathfrak{d})$ for every $\mathfrak{d}$ in $\mathrm{DD}^*_{\mathrm{ample}}$.*

4. *(Compatibility with the forgetful functors.) There is a functor M from the category of the tuples $(A, X, Y, c, c^\vee, \tau)$ underlying objects of $\mathrm{DD}_{\mathrm{ample}}$, with their isomorphisms, to the category of semiabelian schemes over S, with isomorphisms of group schemes, such that M_{ample} and M are compatible under the forgetful functors $(A, X, Y, \phi, c, c^\vee, \widetilde{\mathcal{L}}, \tau, \psi) \mapsto (A, X, Y, c, c^\vee, \tau)$ and $(G, \mathcal{L}) \mapsto G$. In particular, if two objects of $\mathrm{DD}_{\mathrm{ample}}$ have the same $(A, X, Y, c, c^\vee, \tau)$, the semiabelian schemes of their images under M_{ample} are isomorphic as group schemes over S.*

5. *(Independence of the Mumford quotient.) For $j = 1, 2$ let $\mathfrak{e}_j = (A, \mathcal{M}_j, X, Y, \phi_j, c, c^\vee, \tau, \psi_j)$ be split objects with the same $(A, X, Y, c, c^\vee, \tau)$, each with a relatively complete model, and G_j the attached Mumford quotients, with the identifications $G_j^{\mathrm{for}} \cong \widetilde{G}^{\mathrm{for}}$ of [154], Constr. 4.5.2.17. Then G_1 and G_2 are group schemes over S, and there is a unique homomorphism $G_1 \to G_2$ of group schemes over S whose formal completion is the identity of $\widetilde{G}^{\mathrm{for}}$; it is an isomorphism.*

Proof. [154] (numbering and pages of the book), following Mumford 1972 and [87], Ch. III. Split objects are the objects of $\mathrm{DD}^{\mathrm{split}}_{\mathrm{ample}}(R, I)$ of Def. 4.5.1.1 (p. 216: tuples as in Def. 4.2.1.13 with the positivity conditions for ψ and τ, ψ being viewed as a trivialisation of $(c^\vee)^*\mathcal{M}^{-1}$), with the natural functor to $\mathrm{DD}_{\mathrm{ample}}(R, I)$ given there; I_y and $I_{y,\chi}$ are as in Defs. 4.2.4.5–4.2.4.6; stars and Condition 4.5.1.6 as in Constr. 4.5.1.5 and Cond. 4.5.1.6 (pp. 217–219). (1) is the paragraph of p. 178 preceding the proof of Lemma 4.2.1.8 ("By [112, XI, 1.11], $\mathcal{M}$ is ample because $\mathcal{L}^\natural$ is", Raynaud, Faisceaux amples sur les schémas en groupes, LNM 119), with Prop. 3.2.5.4 (p. 160) and Cor. 3.2.5.7 (p. 161): over the normal noetherian S with X constant, $i^*\widetilde{\mathcal{L}}$ is trivial and its cubical trivialisations correspond to the pairs $(\mathcal{M}, \widetilde{\mathcal{L}} \cong \pi^*\mathcal{M})$. (2)(a) is Lemma 4.5.4.5 (p. 244) with the second tuple taken trivial, which that lemma allows ("an object in $\mathrm{DD}_{\mathrm{IS}}(R, I)$ such that all of ϕ_2, $\mathcal{L}_2^\natural$, and ψ_2 are trivial"); (2)(b) is Cor. 4.5.1.8 (pp. 221–222), first tuple, with $\mathcal{M}'$ trivial; (2)(c) is Prop. 4.5.1.15 (p. 224). (3) is Def. 4.5.4.1 (p. 242), (4.5.4.2), Def. 4.5.4.3 and Prop. 4.5.4.4 (p. 243), and Cor. 4.5.4.9 (p. 246: M_{IS} extends M^*_{ample} and restricts to M_{ample}); that the image of an object of $\mathrm{DD}^{\mathrm{split},*}_{\mathrm{ample}}$ lies in $\mathrm{DD}^*_{\mathrm{ample}}$ is Def. 4.5.4.3 with $S' = S$ (the identity is a finite étale surjection and $\mathrm{rad}(I) = I$), which is what "extends" in Prop. 4.5.4.4 presupposes. (4) is Thm. 4.4.16 (p. 215: M_{ample}, M_{pol}, M_{IS}, M "are compatible with each other under the natural forgetful functors"; $M\colon \mathrm{DD}(R, I) \to \mathrm{DEG}(R, I)$, $(A, X, Y, c, c^\vee, \tau) \mapsto G$, morphisms of both categories being isomorphisms over S respecting all structures), with Cor. 4.5.4.9; the last sentence applies M to the identity of the common tuple. (5) is Thm. 4.5.3.6 (p. 237: a unique homomorphism with given formal completion) applied to $\mathrm{Id}_{\widetilde{G}}$ and Id_Y, Cor. 4.5.3.7 (p. 238: G depends up to isomorphism only on $(A, X, Y, c, c^\vee, \tau)$, independently of ϕ, ψ, $\mathcal{M}$ and the relatively complete model, by a canonical isomorphism inducing the identity of the formal completions) and Cor. 4.5.3.8 (p. 239: G is a group scheme); cf. Mumford 1972, Thm. 4.6, Cors. 4.7–4.8, and Faltings–Chai III, Thm. 5.5, Cors. 5.6–5.7. Notation map: Lan's $G^\natural$, $\mathcal{L}^\natural$, $\bigstar$ are $\widetilde{G}$, $\widetilde{\mathcal{L}}$, St; his $P^\natural_{(\phi,\psi),\bigstar}$ is $\widetilde{P}_{(\phi,\psi),\mathrm{St}}$. □

Theorem B.113. *Let R be a strictly henselian discrete valuation ring with fraction field K and residue field k, K^s a separable closure of K, $I = \mathrm{Gal}(K^s/K)$, ℓ a prime invertible in k, A an abelian variety over K, and $\mathcal{G}$ a semiabelian scheme over R with an isomorphism $\mathcal{G}_K \cong A$, whose special fibre $\mathcal{G}_k$ is an extension of an abelian variety of dimension a by a torus of dimension t. Then $(\sigma - 1)^2 = 0$ on the Tate module $T_\ell(A)$ for every $\sigma \in I$, and the module of invariants $T_\ell(A)^I$ is a free $\mathbb{Z}_\ell$-module of rank $2a + t$.*

Proof. A. Grothendieck, *Modèles de Néron et monodromie*, Exposé IX of [227]: the identity component of the Néron model of A is $\mathcal{G}$ (a semiabelian model is the identity component of the

Néron model; see also [45], Section 7.4), $T_\ell(A)^I$ is identified with T_ℓ of the identity component of the special fibre of the Néron model, of rank $2a+t$ (Exposé IX, Section 2), and semiabelian reduction is equivalent to the action of I on $T_\ell(A)$ being unipotent of level at most two, $(\sigma-1)^2=0$ (Exposé IX, Proposition 3.5). □

Theorem B.114. *Let (E,M,ψ,J) and $N\geq 3$ be as in Theorem B.105, let $\mathcal{M}_{N,\mathbb{C}}=\mathcal{M}_N\otimes_{F_{\mathrm{ref}}}\mathbb{C}$, formed with the inclusion $F_{\mathrm{ref}}\subseteq\mathbb{C}$, and $\mathcal{M}_{N,\mathbb{C}}^{\mathrm{an}}$ its complex analytic space. Let G be the group scheme over $\mathbb{Z}$ with*

$$G(R)=\{(\gamma,c)\in \mathrm{GL}_{\mathcal{O}_E\otimes R}(M\otimes R)\times R^\times:\ \psi(\gamma x,\gamma y)=c\,\psi(x,y)\},\qquad \nu(\gamma,c)=c,$$

written γ, and $\mathcal{H}_N=\ker\big(G(\widehat{\mathbb{Z}})\to G(\mathbb{Z}/N\mathbb{Z})\big)$. Let $X=\{\gamma J\gamma^{-1}:\gamma\in G(\mathbb{R})\}$, identified with $G(\mathbb{R})/\mathrm{Stab}_{G(\mathbb{R})}(J)$ and given the complex structure for which $J'\mapsto\ker(J'+i)\subseteq M_{\mathbb{C}}$ maps each connected component of X biholomorphically onto an open subset of $G(\mathbb{C})/P_0(\mathbb{C})$, P_0 the stabiliser of $\ker(J+i)$; let X_0 be the connected component containing J, $G(\mathbb{Q})_0$ its stabiliser in $G(\mathbb{Q})$, and $\Gamma^{(1)}=\mathcal{H}_N\cap G(\mathbb{Q})_0$, acting on X_0 by conjugation. For $J'\in X_0$ let $A_{J'}=(M_{\mathbb{R}},J')/M$ with the $\mathcal{O}_E$-action ι induced by that of M, let $\phi_{J'}$ be the polarisation with Riemann form ψ on $H_1(A_{J'},\mathbb{Z})=M$, and

$$x(J')=(A_{J'},\phi_{J'},\iota,\alpha_N,\nu_N),\qquad \alpha_N(x)=N^{-1}x \bmod M,\quad \nu_N(c)=\exp(-2\pi i\,c/N).$$

Then:

(Lan1) *For $J'\in X_0$, $\phi_{J'}$ is a principal polarisation, $e_n^{\phi_{J'}}(n^{-1}x,n^{-1}y)=\exp(-2\pi i\,\psi(x,y)/n)$ for all $n\geq 1$ and $x,y\in M$, and $x(J')$ is an object of $\mathcal{M}_N(\mathbb{C})$.*

(Lan2) *$\Gamma^{(1)}$ acts on X_0 without fixed points; $(x(J'))_{J'\in X_0}$ is a holomorphic family; and $J'\mapsto x(J')$ induces an isomorphism of complex analytic spaces from $\Gamma^{(1)}\backslash X_0$ onto an open and closed complex analytic subspace of $\mathcal{M}_{N,\mathbb{C}}^{\mathrm{an}}$, along which the universal tuple pulls back to the family $(x(J'))_{J'\in X_0}$.*

Proof. K.-W. Lan, *Comparison between analytic and algebraic constructions of toroidal compactifications of PEL-type Shimura varieties*, J. reine angew. Math. 664 (2012), 163–228, Sections 2.2–2.5, cited from the author's compilation of the paper (errata corrected; page numbers are those of the compilation). (Lan1): Section 2.2, p. 10 (the Weil pairing e^{λ_h} on $G_h[n]=\frac{1}{n}L/L$ is realised as $(x,y)\mapsto\mathbf{e}(n\langle x,y\rangle)$; Remark 2.2.1: the sign is a convention) and Section 2.3, p. 11 (the canonical $\hat{\alpha}_h\colon L\otimes\widehat{\mathbb{Z}}\to \mathrm{T}\,G_h$ matches $\langle\,,\rangle$ with e^{λ_h}, its $\mathcal{H}$-orbit is an integral level structure, and $(G_h,\lambda_h,i_h,\alpha_{h,\mathcal{H}})$ is an object of $\mathsf{M}_{\mathcal{H}}(\mathbb{C})$); λ_h is induced by $\mathrm{sgn}(h)$ times the identity (Section 2.2, p. 9; p. 14). (Lan2): end of Section 2.4, p. 14 (the tuples form a holomorphic family over $X\times G(\mathbb{A}^\infty)/\mathcal{H}$); (2.5.2), Assumption 2.5.4 and the text after it, p. 15 ($\mathrm{Sh}_{\mathcal{H}}=G(\mathbb{Q})\backslash X\times G(\mathbb{A}^\infty)/\mathcal{H}=\coprod_{i\in I}\Gamma^{(g_i)}\backslash X_0$, I finite, $\Gamma^{(g_i)}=g_i\mathcal{H}g_i^{-1}\cap G(\mathbb{Q})_0$ acting without fixed points, for any g_i with $G(\mathbb{A}^\infty)=\coprod_i G(\mathbb{Q})_0 g_i\mathcal{H}$; the family descends to $\mathrm{Sh}_{\mathcal{H}}$); Lemma 2.5.6, the paragraph after it and Definition 2.5.7, p. 16 ($\mathrm{Sh}_{\mathcal{H}}$ is isomorphic, as a complex analytic space and compatibly with the families, to $\mathsf{M}_{\mathcal{H},\mathrm{an},L\otimes\mathbb{Q}}$, the analytification of the open and closed subscheme of $\mathsf{M}_{\mathcal{H},\mathbb{C}}$ of the components over which $(H_1(G_s,\mathbb{Q}),\langle\,,\rangle_{\lambda_s},h_0)\cong(L\otimes\mathbb{Q},\langle\,,\rangle,h_0)$). (Lan2) is this isomorphism on the piece of (2.5.2) for the representative $g_1=1$; the pieces are open and closed in $\mathrm{Sh}_{\mathcal{H}}$ since $G(\mathbb{A}^\infty)/\mathcal{H}$ is discrete, and on it the family is $(G_h,\lambda_h,i_h,\alpha_{h,\mathcal{H}})$, $h\in X_0$. Complex structure of X: Section 2.3, pp. 10–11 ($X=G(\mathbb{R})/\mathcal{U}_\infty$; its connected components embed as open complex submanifolds of $G(\mathbb{C})/P_{h_0}(\mathbb{C})$ through $h\mapsto\mathsf{P}_h=\{\sqrt{-1}x-h(\sqrt{-1})x\}$, Lemma 2.1.2), and $\mathsf{P}_h=\ker(h(\sqrt{-1})+\sqrt{-1})$. *Notation.* Lan's PEL-type $\mathcal{O}$-lattice $(L,\langle\,,\rangle,h_0)$ (Section 1.1, p. 4) is $(M,-2\pi\sqrt{-1}\,\psi,J)$ with $\mathcal{O}=\mathcal{O}_E$ and $h_0(\sqrt{-1})=J$: his condition (2)(a) is $\psi(Jx,Jy)=\psi(x,y)$

with $\psi(ax,y)=\psi(x,\bar a y)$, and (2)(b), $-\sqrt{-1}\langle x,h_0(\sqrt{-1})x\rangle = 2\pi\,\psi(Jx,x)>0$, is the positivity of Theorem B.105; then $\langle\,,\rangle$ is $\mathbb{Z}(1)$-valued and $\mathbf{e}(n\langle n^{-1}x,n^{-1}y\rangle)=\exp(-2\pi\sqrt{-1}\,\psi(x,y)/n)$. The set $\square$ of primes is empty (Condition 1.2.5 and the sentence after it, p. 6), $F_0=F_{\mathrm{ref}}$ with its inclusion into $\mathbb{C}$, $\mathcal{H}=\mathcal{H}_N$, neat as $N\geq 3$ (Remark 1.1.4). Lan's moduli problem $\mathsf{M}_{\mathcal{H}}$ (Definition 1.2.2, Theorem 1.2.4) is $\mathcal{M}_N$ of Theorem B.105: the integral level-$\mathcal{H}_N$ structures of type $(L\otimes\widehat{\mathbb{Z}},\langle\,,\rangle)$ are the liftable pairs (α_N,ν_N) ([154], Definition 1.3.6.2 and Lemma 1.3.6.6), they force the polarisation to be principal since $\langle\,,\rangle$ is perfect on L, and in characteristic 0 the determinantal condition given by $(L\otimes\mathbb{R},\langle\,,\rangle,h_0)$ is $\det(T-\iota(a)\mid\mathrm{Lie})=P_a(T)$ (p. 10: $\mathrm{Lie}\,G_h\cong V_0$). On X_0 one has $\mathrm{sgn}(h)=1$: the sign of the definite form $-\sqrt{-1}\langle x,h(\sqrt{-1})x\rangle$ is locally constant on X (definiteness is an open condition, and $X\to\mathrm{End}(L\otimes\mathbb{R})$ is continuous) and is $+1$ at h_0; so λ_h has Riemann form ψ, and $(G_h,\lambda_h,i_h,\alpha_{h,\mathcal{H}})$ is $x(J')$ for $J'=h(\sqrt{-1})$, the canonical $\hat\alpha_h$ reducing to α_N and the pairing to ν_N. Not used here: the members of the family at $g\neq 1$ (modification by $\mathbb{Q}^\times$-isogenies, p. 11) and the components of $\mathsf{M}_{\mathcal{H},\mathbb{C}}$ outside the rational class of the datum, which pp. 1–2 of the paper attribute to the failure of the Hasse principle. $\square$

Theorem B.115. *Let R be a strictly henselian discrete valuation ring with fraction field K, residue field k and $I=\mathrm{Gal}(K^s/K)$, ℓ a prime invertible in k, A an abelian variety over K with a principal polarisation λ, and $\mathcal{G}$ a semiabelian scheme over R with $\mathcal{G}_K\cong A$; let $\mathcal{T}\subseteq\mathcal{G}_k$ be the maximal subtorus of the special fibre. The specialisation maps identify $T_\ell(\mathcal{G}_k)$ with $T_\ell(A)^I$ (via $\mathcal{G}[\ell^n](R)\cong\mathcal{G}_k[\ell^n](k)$ and $\mathcal{G}[\ell^n](R)\subseteq A[\ell^n](K^s)$), hence $T_\ell(\mathcal{T})$ with a submodule $T_\ell(A)_{\mathrm{t}}$ of $T_\ell(A)^I$. Then, for the Weil pairing $e^\lambda\colon T_\ell(A)\times T_\ell(A)\to\mathbb{Z}_\ell(1)$ of λ,*

$$T_\ell(A)_{\mathrm{t}}=\{u\in T_\ell(A):\ e^\lambda(u,u')=1 \text{ for all } u'\in T_\ell(A)^I\}.$$

Proof. A. Grothendieck, *Modèles de Néron et monodromie*, Exposé IX of [227], the orthogonality theorem ("théorème d'orthogonalité"): for semistable reduction, the toric part of $T_\ell(A)$ and the invariants $T_\ell(A')^I$ of the dual are exact orthogonals of each other under the Weil pairing $T_\ell(A)\times T_\ell(A')\to\mathbb{Z}_\ell(1)$; the identification of $T_\ell(A)^I$ with the Tate module of the special fibre of the Néron model, whose identity component is $\mathcal{G}$ ([45], 7.4), is in the same exposé, Section 2. With $A'=A$ via the principal polarisation λ one obtains the statement. $\square$

Theorem B.116. *Let $S\hookrightarrow\tilde S$ be a closed immersion of affine schemes defined by an ideal $\mathcal{I}$ with $\mathcal{I}^2=0$.*

1. *Let A be an abelian scheme over S and $\tilde A$ an abelian scheme over $\tilde S$ with $\tilde A\times_{\tilde S}S=A$. For every abelian scheme $\tilde A'$ over $\tilde S$ with $\tilde A'\times_{\tilde S}S=A$ there is a canonical isomorphism $c_{\tilde A'}\colon H^1_{\mathrm{dR}}(\tilde A'/\tilde S)\to H^1_{\mathrm{dR}}(\tilde A/\tilde S)$ reducing to the identity of $H^1_{\mathrm{dR}}(A/S)$, and $\tilde A'\mapsto c_{\tilde A'}(\omega_{\tilde A'})$ is a bijection from the set of isomorphism classes of such liftings $\tilde A'$ of A (isomorphisms reducing to the identity of A) onto the set of $\mathcal{O}_{\tilde S}$-submodules $M\subseteq H^1_{\mathrm{dR}}(\tilde A/\tilde S)$ with $H^1_{\mathrm{dR}}(\tilde A/\tilde S)/M$ projective and $M\otimes_{\mathcal{O}_{\tilde S}}\mathcal{O}_S=\omega_A$ in $H^1_{\mathrm{dR}}(A/S)$.*
2. *Let $\tilde A,\tilde B$ be abelian schemes over $\tilde S$, $A=\tilde A\times_{\tilde S}S$, $B=\tilde B\times_{\tilde S}S$, and $f\colon A\to B$ a homomorphism. There is a canonical morphism $f^*\colon H^1_{\mathrm{dR}}(\tilde B/\tilde S)\to H^1_{\mathrm{dR}}(\tilde A/\tilde S)$ reducing to $H^1_{\mathrm{dR}}(f)$, and f lifts to a homomorphism $\tilde A\to\tilde B$ if and only if $f^*(\omega_{\tilde B})\subseteq\omega_{\tilde A}$. At most one homomorphism $\tilde A\to\tilde B$ lifts f.*

Proof. K.-W. Lan, *Arithmetic compactifications of PEL-type Shimura varieties*, London Math. Soc. Monographs 36, Princeton 2013, Section 2.1.6: the canonical morphisms are Proposition 2.1.6.4 (with Proposition 2.1.6.2), the Hodge sequence is (2.1.6.6), and parts 1 and 2 (the

existence criterion) are Propositions 2.1.6.8 and 2.1.6.9, p. 114 ("an analogue of a weaker form of the main theorem in Grothendieck–Messing theory"; cf. [171], [168]). *Notation.* Lan states part 1 in the first de Rham homology $H_1^{\mathrm{dR}}(\tilde{A}/\tilde{S})$, the dual of $H^1_{\mathrm{dR}}(\tilde{A}/\tilde{S})$, with the submodule $\mathrm{Lie}^{\vee}_{\tilde{A}'^{\vee}/\tilde{S}}$ (the kernel of $H_1^{\mathrm{dR}} \to \mathrm{Lie}_{\tilde{A}'/\tilde{S}}$, (2.1.6.7)); passing to annihilators under the perfect pairing $H_1^{\mathrm{dR}} \times H^1_{\mathrm{dR}} \to \mathcal{O}_{\tilde{S}}$ turns it into $\omega_{\tilde{A}'}$ and his condition on M into the one above (an annihilator of a submodule with projective quotient has projective quotient, and annihilators commute with $\otimes\mathcal{O}_S$ for such submodules). Lan's set $\mathrm{Lift}(A; S \hookrightarrow \tilde{S})$ (Definition 2.1.2.1) consists of the isomorphism classes of smooth liftings with an identification of the reduction; a smooth lifting of A has a section lifting the zero section ($\tilde{S}$ affine, smoothness), and with it is an abelian scheme, and two abelian liftings that are isomorphic as liftings are isomorphic as abelian schemes after composing with a translation by a section reducing to zero (rigidity; Mumford–Fogarty–Kirwan, loc. cit. below, Ch. 6, §1); so the bijection is one of liftings that are abelian schemes, as stated. Lan's Proposition 2.1.6.9 lifts f to a morphism of schemes $\tilde{f}$; then $\tilde{f} - \tilde{f}(0)$ (subtraction of the section $\tilde{f}(0)$, which reduces to the zero section) is a morphism of abelian schemes preserving the zero sections, hence a homomorphism, and it still lifts f; conversely a homomorphism lifting f is a morphism lifting f. Uniqueness: if two homomorphisms $\tilde{f}_1, \tilde{f}_2$ lift f, the homomorphism $\tilde{f}_1 - \tilde{f}_2$ is zero on A, which has the same underlying space as $\tilde{A}$, so by the rigidity lemma (D. Mumford, J. Fogarty, F. Kirwan, *Geometric invariant theory*, Prop. 6.1 and Cor. 6.4) it factors through the zero section on every connected component of $\tilde{S}$, i.e. $\tilde{f}_1 = \tilde{f}_2$. □

Theorem B.117. *Let $k \subset \mathbb{C}$ be an imaginary quadratic field with ring of integers $\mathcal{O}_k$.*

1. *(Algebraicity.) If Z is an elliptic curve over $\mathbb{C}$ with $\mathrm{End}(Z) \cong \mathcal{O}_k$, then $j(Z)$ is an algebraic number; hence there are a number field $M \subset \mathbb{C}$ and an elliptic curve Z_M over M with $Z_M \otimes_M \mathbb{C} \cong Z$, and M may be chosen so that every endomorphism of $Z_M \otimes_M \mathbb{C}$ is defined over M.*

2. *(Potentially good reduction.) If M is a number field and Z_M an elliptic curve over M whose endomorphism ring over $\overline{M}$ is an order in an imaginary quadratic field, then Z_M has potentially good reduction at every finite place of M: there is a finite extension M'/M such that $Z_M \otimes_M M'$ has good reduction at every finite place of M', that is, extends to an abelian scheme over $\mathcal{O}_{M'}$.*

Proof. Item 1: the algebraicity of $j(Z)$ (indeed $k(j(Z))$ is the Hilbert class field of k) is the first main theorem of complex multiplication for elliptic curves (Deuring; Shimura–Taniyama), [233], Chapter II, §4, Theorem II.4.3; an elliptic curve over $\mathbb{C}$ with algebraic j-invariant is defined over $\mathbb{Q}(j)$, and its endomorphisms, finitely many generators of a $\mathbb{Z}$-module of rank 2, are defined over a finite extension (each is defined over $\overline{\mathbb{Q}}$ because homomorphisms between abelian varieties over an algebraically closed field do not change under extension to a larger algebraically closed field). Item 2: J.-P. Serre and J. Tate [224], §4, Theorem 6 (an abelian variety with complex multiplication, over a field with a discrete valuation with finite residue field, has potentially good reduction at every place), and [233], Chapter II, §6, for elliptic curves; the global extension M' is obtained since Z_M has good reduction outside finitely many places and good reduction persists under finite extensions; an elliptic curve over M' with good reduction at every finite place is the generic fibre of its Néron model, an abelian scheme over $\mathcal{O}_{M'}$ ([45], §1.4). The notation agrees with that of the sources. □

Theorem B.118. *Let R be a commutative ring which is free of finite rank as a $\mathbb{Z}$-module, S a scheme, A an abelian scheme over S with a ring homomorphism $\iota\colon R \to \mathrm{End}_S(A)$, and M a finitely generated projective R-module.*

(i) The functor $T \mapsto M \otimes_R A(T)$ on S-schemes is represented by an abelian scheme $M \otimes_R A$ over S. For R-linear maps $f\colon M \to N$ of finitely generated projective R-modules and R-linear homomorphisms $\phi\colon A \to B$ of abelian schemes with R-action there is a homomorphism $f \otimes \phi\colon M \otimes_R A \to N \otimes_R B$, given on T-points by $m \otimes a \mapsto f(m) \otimes \phi(a)$; in particular a commutative ring P acting R-linearly on M acts on $M \otimes_R A$ through M.

(ii) There is a canonical isomorphism of $\mathcal{O}_S$-modules $\mathrm{Lie}_S(M \otimes_R A) \cong M \otimes_R \mathrm{Lie}_S(A)$, functorial in M and A.

Since $M \otimes_R A$ is defined by the functor of (i), its base change along any morphism $S' \to S$ is $M \otimes_R A_{S'}$, compatibly with (i) and (ii).

Proof. B. Conrad, Gross–Zagier revisited, in: Heegner points and Rankin L-series, MSRI Publ. 49, Cambridge University Press (2004), 67–163, §7 (representability of $T \mapsto M \otimes_R A(T)$ by an abelian scheme, after Serre); Z. Amir-Khosravi, [5], §1, the definition of the Serre tensor construction (with the action of a commuting ring P through M and the maps $f \otimes \phi$) and the lemma of the subsection on the Lie algebra and the Tate module (the canonical isomorphism $\mathrm{Lie}_S(M \otimes_R A) \cong M \otimes_R \mathrm{Lie}_S(A)$, proved from $\mathrm{Lie}_S(A)(U) = \ker(A(U[\epsilon]) \to A(U))$ and the flatness of M). Amir-Khosravi allows non-commutative R and right modules; here R is commutative. Notation: identical. □

Theorem B.119. *Let R be a complete noetherian normal local domain, $S = \operatorname{Spec} R$ with generic point η and closed fibre S_0, and G a semiabelian scheme over S with abelian generic fibre, with Raynaud extension $0 \to \mathbb{T} \to \widetilde{G} \xrightarrow{\pi} A \to 0$. For a closed subgroup scheme $H \subseteq G$, flat and quasi-finite over S, let H^f be its largest subscheme finite over S (an open and closed subgroup), $H^\mu \subseteq H^f$ the unique finite flat subgroup of multiplicative type extending $H \cap \mathbb{T}_0$ ($\mathbb{T}_0$ the maximal torus of the closed fibre G_0), and $H^{ab} = H^f/H^\mu$.*

1. *For every $m \geq 1$ there are canonical isomorphisms of group schemes over S*

$$G[m]^\mu \cong \mathbb{T}[m], \qquad G[m]^f \cong \widetilde{G}[m], \qquad G[m]^{ab} \cong A[m],$$

   characterised by inducing on formal completions the isomorphisms given by $G^{\mathrm{for}} \cong \widetilde{G}^{\mathrm{for}}$.

2. *Let $\mathcal{L}$ be a cubical $\mathbb{G}_m$-torsor on G_η with $K(\mathcal{L})$ finite which admits a cubical extension over G (this holds if S is regular). Then $K(\mathcal{L})$ extends to a unique closed subgroup K_S of G flat and quasi-finite over S (its schematic closure); there is a unique alternating pairing $e_S^{\mathcal{L}}\colon K_S \times_S K_S \to \mathbb{G}_{m,S}$ extending $e^{\mathcal{L}}$; and (orthogonality) K_S^f is the annihilator of K_S^μ under $e_S^{\mathcal{L}}$, and the induced pairing on K_S^{ab} is a perfect duality.*

3. *If moreover the cubical torsor on $\widetilde{G}$ whose formal completion is that of the cubical extension of $\mathcal{L}$ is $\pi^*\mathcal{M}$ for a cubical $\mathbb{G}_m$-torsor $\mathcal{M}$ on A, then K_S^{ab} corresponds under the isomorphisms of (1) to $K(\mathcal{M}) \subseteq A$, and the pairing induced on it by $e_S^{\mathcal{L}}$ is $e^{\mathcal{M}}$.*

Proof. Moret-Bailly, Pinceaux de variétés abéliennes [181], Ch. IV, Théorème 2.4, in the form of K.-W. Lan, Arithmetic compactifications of PEL-type Shimura varieties (Harvard thesis, 2008), Theorem 3.4.2.6 (items 1, 2, 4, 5) with the definitions of Section 3.4.1 ((3.4.1.1)–(3.4.1.5)) and the isomorphisms (3.4.2.1)–(3.4.2.3) (after Grothendieck, SGA 7 I, Exp. IX, 7.3); the orthogonality is Grothendieck's theorem of orthogonality (SGA 7 I, Exp. IX, 2.4) in Moret-Bailly's form, which has no hypothesis on the residue characteristic. Notation: Lan writes $K_S^\natural$ for the abelian part transported to A, T for $\mathbb{T}$. □

Theorem B.120. *Let S be a scheme and A an abelian scheme over S whose dual abelian scheme $A^\vee$ exists, and let $\lambda\colon A \to A^\vee$ be a polarisation, that is, a homomorphism whose base change to every geometric point $\bar{s}$ of S is the homomorphism $\phi_{\mathcal{L}}$ of an ample line bundle $\mathcal{L}$ on $A_{\bar{s}}$. Then the abelian scheme $(A \times_S A^\vee)^4$ admits a principal polarisation, that is, a polarisation which is an isomorphism onto its dual.*

Proof. This is Zarhin's trick: [273] for abelian varieties over a field, and [181] for abelian schemes over a base, where the same construction (a principal polarisation of $(A \times_S A^\vee)^4$ built from λ and the endomorphism of A^4 given by a quaternion matrix with integer entries a, b, c, d, $a^2 + b^2 + c^2 + d^2 \equiv -1$ modulo an integer killing $\ker\lambda$) works over S. Notation: $A^\vee$, $\phi_{\mathcal{L}}$ as in Section 29.1. □

Theorem B.121. *Let k be an algebraically closed field, X an abelian variety over k and $K \subseteq X$ a finite subgroup scheme. Then there are an abelian variety Y over k and a homomorphism $p\colon X \to Y$ which is finite, flat and surjective, such that*

$$K \times_k X \longrightarrow X \times_Y X, \qquad (h, x) \longmapsto (x + h, x),$$

is an isomorphism.

Proof. [186], §12, Theorem 1 (quotient of a variety by a free action of a finite group scheme) and its application to a finite subgroup scheme of an abelian variety in the same section (X/K is an abelian variety); for reduced K, §7, Theorem 4. □

Theorem B.122. *Let k be a field, X an abelian variety over k and $\mathcal{M}$ an ample line bundle on X. Then for every integer $n \geq 3$ the line bundle $\mathcal{M}^{\otimes n}$ is very ample over k: it is generated by $H^0(X, \mathcal{M}^{\otimes n})$, and for a k-basis $s_0, \ldots, s_N$ of $H^0(X, \mathcal{M}^{\otimes n})$ the morphism $X \to \mathbb{P}^N_k$ defined by $s_0, \ldots, s_N$ is a closed immersion. In particular this holds for a complex abelian variety.*

Proof. **Algebraically closed k.** This is Lefschetz's theorem, [186], Section 17 (Theorem of Lefschetz), where the base field is an arbitrary algebraically closed field; for $k = \mathbb{C}$ see also [32], Theorem 4.5.1. Notation: X, $\mathcal{M}$ are X, L there.

Arbitrary k. Let K be an algebraic closure of k, and write X_K, $\mathcal{M}_K$ for the base changes. Then X_K is an abelian variety over K. The line bundle $\mathcal{M}_K$ is ample: some power $\mathcal{M}^{\otimes m}$ has sections defining a closed immersion $X \to \mathbb{P}^M_k$, and its base change $X_K \to \mathbb{P}^M_K$ is a closed immersion defined by the pulled-back sections of $\mathcal{M}_K^{\otimes m}$. By the algebraically closed case, $\mathcal{M}_K^{\otimes n}$ is very ample over K.

Put $V = H^0(X, \mathcal{M}^{\otimes n})$. The morphism $\operatorname{Spec} K \to \operatorname{Spec} k$ is flat and X is quasi-compact and separated, so flat base change [239] gives $V \otimes_k K \cong H^0(X_K, \mathcal{M}_K^{\otimes n})$; hence a k-basis $s_0, \ldots, s_N$ of V is a K-basis of $H^0(X_K, \mathcal{M}_K^{\otimes n})$.

Global generation. Let $\mathcal{C}$ be the cokernel of the evaluation map $V \otimes_k \mathcal{O}_X \to \mathcal{M}^{\otimes n}$, a coherent sheaf. Pull-back is right exact, so the pull-back of $\mathcal{C}$ to X_K is the cokernel of the evaluation map over K, which is zero because $\mathcal{M}_K^{\otimes n}$ is generated by its global sections. The projection $X_K \to X$ is flat and surjective, so each local ring map $\mathcal{O}_{X,x} \to \mathcal{O}_{X_K,x'}$ (x' over x) is faithfully flat, and $\mathcal{C}_x \otimes \mathcal{O}_{X_K,x'} = 0$ forces $\mathcal{C}_x = 0$. Hence $\mathcal{C} = 0$.

Closed immersion. Let $\varphi\colon X \to \mathbb{P}^N_k$ be the morphism defined by $s_0, \ldots, s_N$. Its base change along $\mathbb{P}^N_K \to \mathbb{P}^N_k$ is the morphism $X_K \to \mathbb{P}^N_K$ defined by the same sections, which is a closed immersion because they form a basis of the complete linear system of the very ample $\mathcal{M}_K^{\otimes n}$. The morphism $\mathbb{P}^N_K \to \mathbb{P}^N_k$ is the base change of $\operatorname{Spec} K \to \operatorname{Spec} k$, which is flat, surjective and quasi-compact; so $\{\mathbb{P}^N_K \to \mathbb{P}^N_k\}$ is an fpqc covering. Being a closed immersion is fpqc local on the base [240], so φ is a closed immersion. □

Theorem B.123. *Let K be a number field with ring of integers $\mathcal{O}_K$, let k be a perfect field of characteristic $p > 0$ with ring of Witt vectors $W(k)$, and let X be an abelian variety of dimension g over k with a ring homomorphism $m\colon \mathcal{O}_K \to \mathrm{End}_k(X)$, $m(1) = \mathrm{id}$. Then $H^1_{\mathrm{cris}}(X/W(k))$ is a free $\mathcal{O}_K \otimes_{\mathbb{Z}} W(k)$-module, and $H^1_{\mathrm{dR}}(X/k) = H^1_{\mathrm{cris}}(X/W(k))/p$ is a free $\mathcal{O}_K \otimes_{\mathbb{Z}} k$-module; both have rank $2g/[K:\mathbb{Q}]$. No hypothesis is made on the ramification of p in K.*

Proof. [205, Lemme 1.3] (stated there for an arbitrary number field F with ring of integers $\mathfrak{o}$, an abelian variety over a perfect field of characteristic $p > 0$ with an action of $\mathfrak{o}$: $H^1_{\mathrm{cris}}(X)$ is a free $\mathfrak{o} \otimes W(k)$-module), and the paragraph following its proof (the reduction modulo p of $H^1_{\mathrm{cris}}(X)$ is H^1_{DR}, hence a free $\mathfrak{o} \otimes k$-module). *Notation.* Rapoport's F and $\mathfrak{o}$ are our K and $\mathcal{O}_K$. The rank is forced by $\mathrm{rk}_{W(k)} H^1_{\mathrm{cris}} = 2g$ and $\mathrm{rk}_{\mathbb{Z}} \mathcal{O}_K = [K:\mathbb{Q}]$. Rapoport's proof uses only that $\mathcal{O}_K \otimes W(k)$ is a Dedekind ring (a finite product of discrete valuation rings, ramified or not) over which H^1_{cris} is torsion free, and that the trace of $m(a)$ is rational; it makes no use of an unramifiedness hypothesis. (The condition that fails at ramified p is Rapoport's condition (*) of Définition 1.1 on $\mathrm{Lie}(X)$, which is not part of this statement.) □

Theorem B.124. *Let p be a prime, S a scheme with $p\mathcal{O}_S = 0$, $F_S\colon S \to S$ its absolute Frobenius, and $f\colon A \to S$ an abelian scheme of relative dimension g. Put $\omega_{A/S} = f_*\Omega^1_{A/S}$.*

(i) The $\mathcal{O}_S$-modules $\omega_{A/S}$, $R^1 f_* \mathcal{O}_A$ and $H^1_{\mathrm{dR}}(A/S) = R^1 f_* \Omega^\bullet_{A/S}$ are locally free of ranks g, g, $2g$, and their formation commutes with every base change $S' \to S$.

(ii) (Hodge filtration.) There is an exact sequence $0 \to \omega_{A/S} \to H^1_{\mathrm{dR}}(A/S) \to R^1 f_* \mathcal{O}_A \to 0$.

(iii) (Conjugate filtration.) The conjugate spectral sequence $E_2^{a,b} = F_S^* R^a f_* \Omega^b_{A/S} \Rightarrow H^{a+b}_{\mathrm{dR}}(A/S)$ gives an exact sequence

$$0 \to F_S^* R^1 f_* \mathcal{O}_A \to H^1_{\mathrm{dR}}(A/S) \to F_S^* \omega_{A/S} \to 0.$$

(iv) Both sequences are functorial: a homomorphism $u\colon A \to B$ of abelian schemes over S induces, by pull-back, a morphism from the sequence (ii) (resp. (iii)) of B to that of A, acting on H^1_{dR} by u^* and on the outer terms of (iii) by F_S^* of the maps u^* on $R^1 f_* \mathcal{O}$ and on ω.

(v) (Duality.) Let $A^\vee$ be the dual abelian scheme and $\mathrm{Lie}(A^\vee/S)$ its Lie algebra along the zero section. There is a canonical isomorphism $\lambda_A\colon \mathrm{Lie}(A^\vee/S) \to R^1 f_* \mathcal{O}_A$, compatible with base change, and natural: for a homomorphism $u\colon A \to B$ of abelian schemes over S with transpose $u^\vee\colon B^\vee \to A^\vee$, $\lambda_A \circ \mathrm{Lie}(u^\vee) = u^* \circ \lambda_B$.

Proof. (i) and (ii): [28, Proposition 2.5.2 (i), (iii)] (local freeness and base change of $R^q f_* \Omega^p$ and of H^i_{dR}, degeneration of the Hodge–de Rham spectral sequence at E_1) and Lemme 2.5.3 (the exact sequence (2.5.3.1) $0 \to \omega_A \to H^1_{\mathrm{DR}}(A/S) \to R^1 f_* \mathcal{O}_A \to 0$ of locally free modules commuting with base change; there $\omega_A = e^* \Omega^1_{A/S}$, which equals $f_* \Omega^1_{A/S}$ as $\Omega^1_{A/S} \cong f^* \omega_A$, p. 100); over a perfect field: [193, Corollary 5.11]. (v): [28, 5.1.1] (the isomorphism λ_A from the tangent sheaf of $A^\vee$ along the zero section to $R^1 f_* \mathcal{O}_A$, defined through line bundles on $A[\varepsilon]$; see also p. 100), Lemme 5.1.4 and Théorème 5.1.6 (in whose proof $\Psi^0_A = \lambda_A$); naturality is the functoriality (5.1.3.3) of the Poincaré bundle, $(\mathrm{Id}_{B^\vee} \times u)^* \mathcal{L}_B \cong (u^\vee \times \mathrm{Id}_A)^* \mathcal{L}_A$. (iii): the conjugate spectral sequence and the identification of its E_2 terms $F^*_{\mathrm{abs}}(R^a \pi_* \Omega^b_{X/S})$, under the hypothesis that the $R^a \pi_* \Omega^b$ commute with base change, are [142, Theorem 7.4] (via Cartier's isomorphism, Theorem 7.2); the hypothesis (7.4.0) is (i). In degree one the sequence of low

degree terms is $0 \to E_2^{1,0} \to H^1_{\mathrm{dR}} \to E_2^{0,1} \xrightarrow{d_2} E_2^{2,0}$, and $H^1_{\mathrm{dR}} \to E_2^{0,1} = F_S^*\omega_{A/S}$ is surjective because on the fibre at every point s (all terms commute with base change by (i)) the ranks are $g + g = 2g$. (iv): functoriality of the de Rham complex, of the Hodge filtration and of the Cartier isomorphism. *Notation.* Katz's π, X, F_{abs} are f, A, F_S. □

Theorem B.125. *Let S be a scheme and $f\colon A \to S$ an abelian scheme with unit section e and dual abelian scheme $A^\vee$. Put $\omega_A = e^*\Omega^1_{A/S}$, let $W(M)$ denote the vector group $T \mapsto \Gamma(T, M \otimes_{\mathcal{O}_S} \mathcal{O}_T)$ of a quasi-coherent $\mathcal{O}_S$-module M, let $A_1 \subset A$ be the first infinitesimal neighbourhood of e, and $\Delta^1(A) \subset A \times_S A$ that of the diagonal, with projections p_1, p_2, and $\tau\colon A_1 \to \Delta^1(A)$ the morphism with $p_1\tau = e \circ \pi$, $p_2\tau =$ the inclusion ($\pi\colon A_1 \to S$ the structure map). For an S-scheme T, a* rigidified extension *of A_T by $\mathbb{G}_m$ is an extension $0 \to \mathbb{G}_{m,T} \to E \to A_T \to 0$ of fppf sheaves of commutative groups together with a morphism of T-pointed T-schemes $r\colon (A_T)_1 \to E$ lifting the inclusion $(A_T)_1 \subset A_T$; their isomorphism classes form a group under Baer sum, and* $\mathrm{Extrig}(A, \mathbb{G}_m)$ *is the Zariski sheaf associated with $T \mapsto$ this group. Then:*

(a) For every quasi-coherent $\mathcal{O}_S$-module M, every homomorphism of sheaves of groups $A \to W(M)$ is zero; and $f_*\mathcal{O}_A = \mathcal{O}_S$ universally.

(b) For an extension $0 \to \mathbb{G}_m \to E \to A \to 0$, E is representable and $E \to A$ is smooth. $\mathrm{Extrig}(A, \mathbb{G}_m)$ *is represented by a smooth commutative S-group scheme, and there is an exact sequence*

$$0 \to W(\omega_A) \to \mathrm{Extrig}(A, \mathbb{G}_m) \to \underline{\mathrm{Ext}}^1(A, \mathbb{G}_m) \to 0,$$

whose second map forgets the rigidification and whose first map sends η to the trivial extension $\mathbb{G}_m \times A$ with the rigidification given by the pointed morphism $A_1 \to \mathbb{G}_m$ corresponding to η under $\mathrm{Hom}_{S\text{-pointed}}(A_1, \mathbb{G}_m) \cong \omega_A$. Moreover $\underline{\mathrm{Ext}}^1(A, \mathbb{G}_m) \cong A^\vee = \underline{\mathrm{Pic}}^0(A)$, an extension corresponding to the class of the line bundle of its underlying $\mathbb{G}_m$-torsor.

(c) Let $0 \to \omega_A \to E(A^\vee) \to A^\vee \to 0$ be the universal extension of $A^\vee$ by a vector group. The canonical morphism $E(A^\vee) \to \mathrm{Extrig}(A, \mathbb{G}_m)$ is an isomorphism, functorial in A; both $E(A^\vee)$ and $\mathrm{Extrig}(A, \mathbb{G}_m)$ are compatible with arbitrary base change.

(d) The $\mathcal{O}_S$-modules $H^1_{\mathrm{dR}}(A/S) = R^1 f_*\Omega^\bullet_{A/S}$ and $R^q f_*\Omega^p_{A/S}$ are locally free, their formation commutes with base change, and the Hodge–de Rham spectral sequence degenerates at E_1.

(e) Let S be affine. Every rigidified extension (E, r) of A by $\mathbb{G}_m$ carries a unique integrable connection ∇ on the $\mathbb{G}_m$-torsor E over A, compatible with the group structure, whose pull-back $\tau^*(\nabla)$ carries the unit section of π^*e^*E to r; this defines an isomorphism from the group $\mathrm{Ext}^\natural(A, \mathbb{G}_m)$ of isomorphism classes of extensions with such connections onto $\mathrm{Extrig}(A, \mathbb{G}_m)(S)$. On the trivial extension, a connection given by a unit $1 + w$ of $\mathcal{O}_{\Delta^1(A)}$, $w \in \Gamma(A, \Omega^1_{A/S})$, corresponds to the rigidification given by the unit $1 + \tau^*w$, and $\tau^*\colon \Gamma(A, \Omega^1_{A/S}) \to \Gamma(S, \omega_A)$ is an isomorphism.

(f) Let $P^\natural$ be the Zariski sheaf associated with $S' \mapsto \{$isomorphism classes of line bundles with integrable connection on $A_{S'}\}$, and $E^\natural = P^\natural \times_{\underline{\mathrm{Pic}}(A)} A^\vee$. Then $P^\natural(S) \cong \mathbb{H}^1(A, \Omega^{\bullet\times}_{A/S})$, $\Omega^{\bullet\times}_{A/S} = [\mathcal{O}_A^\times \xrightarrow{d\log} \Omega^1_{A/S} \xrightarrow{d} \Omega^2_{A/S} \to \cdots]$, by sending $(\mathcal{L}, \nabla)$ to the Čech class of its transition functions and connection forms; the split exact sequence of complexes $0 \to \Omega^\bullet_{A/S} \to \Omega^{\bullet\times}_{A_{S[\varepsilon]}/S[\varepsilon]} \to \Omega^{\bullet\times}_{A/S} \to 0$ induces a canonical isomorphism $H^1_{\mathrm{dR}}(A/S) \cong \mathrm{Lie}(P^\natural)$, and hence $H^1_{\mathrm{dR}}(A/S) \cong \mathrm{Lie}(E^\natural)$, since $\mathrm{Lie}(A^\vee) \to \mathrm{Lie}(\underline{\mathrm{Pic}}(A))$ is an isomorphism; $E^\natural$ is a smooth group scheme. Forgetting the connection gives an exact sequence $0 \to \omega_A \to$

$P^\natural \to \underline{\mathrm{Pic}}(A) \to \underline{\mathbb{H}}^2(\Omega^{\geq 1}_{A/S})$ *compatible with* $0 \to \mathbb{H}^1(\Omega^{\geq 1}_{A/S}) \to \mathbb{H}^1(\Omega^{\bullet\times}_{A/S}) \to H^1(A, \mathcal{O}_A^\times)$*, the kernel consisting of the trivial bundle with the connections given by* $\Gamma(A, \Omega^1_{A/S}) = \Gamma(S, \omega_A)$*.*

(g) Forgetting the horizontal isomorphism $s^*\mathcal{L} \cong p_1^*\mathcal{L} \otimes p_2^*\mathcal{L}$ *is an isomorphism* $\mathrm{Ext}^\natural(A, \mathbb{G}_m) \to E^\natural$*. Together with (e) and (f) this gives an isomorphism between* $H^1_{\mathrm{dR}}(A/S)$ *and the Lie algebra of* $\mathrm{Extrig}(A, \mathbb{G}_m)$*.*

Proof. B. Mazur, W. Messing, *Universal extensions and one dimensional crystalline cohomology*, Lecture Notes in Math. 370, Springer 1974 [168], Chapter I: (a) Corollary (1.5), p. 7, and (1.9)(b), p. 9; (b) (2.6) and (2.6.1), p. 21 (the dual abelian scheme A^* exists and is isomorphic to $\underline{\mathrm{Ext}}^1(A, \mathbb{G}_m)$, citing Oort and Serre there), the first map as in the proof of Proposition (2.2.1), pp. 15–16, and (1.2), p. 3; the description of $\underline{\mathrm{Ext}}^1$ by torsors and line bundles, (4.1.6), p. 48, and p. 51; (c) Proposition (2.6.7), p. 24, with the base-change remark in its proof; (d) (4.1.1), p. 44; (e) Section 3, standing hypothesis "over an affine base S", p. 26; construction (3.2.1), pp. 34–36; Proposition (3.2.3)(a), p. 36, proof pp. 36–42, the trivial extension in item 3), p. 40; (f) (4.1.2), (4.1.3), p. 46, Proposition (4.1.4), pp. 46–47, Lemma (4.1.5), p. 47, Definition (4.1.6) and Proposition (4.1.7), p. 48; (g) (4.2) and Proposition (4.2.1), pp. 48–49; the conclusion is announced at the head of Section 4, p. 44 ("We shall establish an isomorphism between $H^1_{\mathrm{DR}}(A)$ and the lie algebra of $\mathrm{Extrig}(A, \mathbb{G}_m)$"). *Notation.* Mazur–Messing write A^* for $A^\vee$, $\underline{\omega}_A$ for ω_A, $\mathrm{Inf}^1(A)$ for A_1, $\tau_1(\Omega^\cdot_A)$ for $\Omega^{\geq 1}_{A/S}$, Ω^*_A for $\Omega^{\bullet\times}_{A/S}$, $\mathrm{Ext}^\natural$ (with a natural sign) for $\mathrm{Ext}^\natural$, $\underline{P}^\natural$ for $P^\natural$. □

Theorem B.126. *Let S be a locally noetherian scheme, A an abelian scheme over S and $\lambda\colon A \to A^\vee$ a homomorphism of S-group schemes which is symmetric ($\lambda^\vee = \lambda$ under the canonical identification $A \cong A^{\vee\vee}$). Then the set of points $s \in S$ such that, for a geometric point $\bar{s}$ over s, $\lambda_{\bar{s}} = \phi_{\mathcal{M}}$ for an ample line bundle $\mathcal{M}$ on $A_{\bar{s}}$, is open and closed in S. In particular, if S is connected and this holds at one point, then λ is a polarisation of A over S (it holds at every point).*

Proof. See D. Mumford, J. Fogarty, F. Kirwan, Geometric Invariant Theory, 3rd ed., Springer 1994, Ch. 6, §2, Proposition 6.10 (this statement has not been checked against the text of loc. cit.). Notation: $A^\vee$ is Mumford's $\hat{A}$, $\phi_{\mathcal{M}}$ is Mumford's $\phi_{\mathcal{M}}$ ($= \Lambda(\mathcal{M})$ read as a homomorphism to the dual). The last sentence is the case of a connected base: a non-empty open and closed subset of a connected space is the whole space; "polarisation over S" is the fibrewise condition (as in [154], printed book, Definition 1.3.2.16 with Proposition 1.3.2.15(1), p. 65; in Lan's 2008 thesis these are Definitions 1.3.2.19–1.3.2.20 with Proposition 1.3.2.18(1)). □

B.7 Arakelov geometry and heights

Bost's slope inequality for hermitian lattices (Lemma B.127) is used for the slope inequality of Part III (Section 14), and the comparison of Arakelov degree with Minkowski covolume (Theorem B.128) for the reference budget of Part IV (Section 20). The model slopes and good root towers of Part VI rest on the heights of projective schemes of Burgos Gil, Philippon and Sombra (Proposition B.129, Proposition B.132) and on Zhang's arithmetic Hilbert–Samuel theorem and semipositivity (Theorem B.130, Theorem B.131), in Sections 29–31; the facts of good towers (Section 34) use Moret-Bailly models with torsion sections and the Faltings height of elliptic curves with complex multiplication (Theorem B.133, Theorem B.134). The remaining statements are used in Appendix D: Banaszczyk's transference theorem for base settings (Section D.1); Zhang's absolute Siegel lemma, Moret-Bailly's key formula and Autissier's matrix lemma for the cusp mean (Section D.2); and Mourougane's arithmetic Segre classes and the arithmetic Chow rings of Burgos Gil, Kramer and Kühn for flat determinants (Section D.4).

Lemma B.127. *Let K be a number field, let $\overline{E}$ and $\overline{F}$ be hermitian lattices over $\mathcal{O}_K$ of positive rank, and let $\varphi\colon E_K \to F_K$ be a non-zero K-linear map with $\varphi(E) \subseteq F$. Put*

$$h(\varphi) = \frac{1}{[K:\mathbb{Q}]} \sum_{\sigma\colon K \to \mathbb{C}} \log \|\varphi_\sigma\|,$$

where $\|\varphi_\sigma\|$ is the operator norm of $\varphi_\sigma\colon E \otimes_\sigma \mathbb{C} \to F \otimes_\sigma \mathbb{C}$ for the hermitian norms of $\overline{E}$ and $\overline{F}$ at σ. Then

$$\widehat{\mu}_{\min}(\overline{E}) \leq \widehat{\mu}_{\max}(\overline{F}) + h(\varphi),$$

and if φ is injective, $\widehat{\mu}_{\max}(\overline{E}) \leq \widehat{\mu}_{\max}(\overline{F}) + h(\varphi)$.

Proof. Bost's slope inequality [46], in the form of [47], §4.1.4, Proposition 4.5, (4.11): for hermitian vector bundles $\overline{E'}$, $\overline{F}$ over $\operatorname{Spec}\mathcal{O}_K$ with $\operatorname{rk} E' > 0$ and an injective K-linear map $\psi\colon E'_K \to F_K$,

$$\widehat{\mu}(\overline{E'}) \leq \widehat{\mu}_{\max}(\overline{F}) + h(\overline{E'}, \overline{F}, \psi),$$

where $h(\overline{E'}, \overline{F}, \psi) = [K:\mathbb{Q}]^{-1}\bigl(\sum_{\mathfrak{p}} \log \|\psi\|_{\mathfrak{p}} + \sum_\sigma \log \|\psi_\sigma\|\bigr)$ (Bost's (4.10)); Proposition 4.6 there is the version for filtered bundles. Notation: $\widehat{\mu}$, $\widehat{\mu}_{\max}$, $\widehat{\mu}_{\min}$ are those of Section 14 (Bost's normalised slopes, §4.1.1). The two forms stated follow at once. If $\psi(E') \subseteq F$, then $\|\psi\|_{\mathfrak{p}} \leq 1$ for every $\mathfrak{p}$, so $h(\overline{E'}, \overline{F}, \psi) \leq h(\psi)$, the archimedean height of the statement.

- Injective φ: let $E' \subseteq E$ be a non-zero submodule with the induced norms and $\widehat{\mu}(\overline{E'}) = \widehat{\mu}_{\max}(\overline{E})$. The restriction $\psi = \varphi|_{E'_K}$ is injective, $\psi(E') \subseteq F$, and $\|\psi_\sigma\| \leq \|\varphi_\sigma\|$; so $\widehat{\mu}_{\max}(\overline{E}) \leq \widehat{\mu}_{\max}(\overline{F}) + h(\varphi)$.
- Non-zero φ: let $E' = E/(E \cap \ker\varphi)$, a torsion-free quotient of positive rank with the quotient norms, and $\psi\colon E'_K \to F_K$ the injective map induced by φ. Then $\psi(E') = \varphi(E) \subseteq F$ and $\|\psi_\sigma\| = \|\varphi_\sigma\|$ (the quotient norm by the kernel preserves operator norms), so $\widehat{\mu}_{\min}(\overline{E}) \leq \widehat{\mu}(\overline{E'}) \leq \widehat{\mu}_{\max}(\overline{F}) + h(\varphi)$.

See also H. Chen, *Explicit uniform estimation of rational points I. Estimation of heights*, Ann. Inst. Fourier 59 (2009), Section 2. □

Theorem B.128. *Let K be a totally complex number field, let $N = [K:\mathbb{Q}] = 2s$, and choose one embedding $v\colon K \hookrightarrow \mathbb{C}$ from each complex-conjugate pair. Let $\overline{M}$ be a hermitian $\mathcal{O}_K$-lattice of rank $r \geq 1$, with norms at the conjugate embeddings obtained by complex conjugation. In*

$$\bigoplus_{v|\infty} M \otimes_{\mathcal{O}_K, v} \mathbb{C}$$

use the real Euclidean inner product $\operatorname{Re}\sum_{v|\infty}\langle\,\cdot,\cdot\,\rangle_v$. Let $\operatorname{covol}(\overline{M})$ be the covolume of the diagonal image of M for this metric. Then

$$\operatorname{covol}(\overline{M}) = 2^{-rs}\,|\operatorname{disc}(K)|^{r/2} \exp\bigl(-\widehat{\deg}(\overline{M})\bigr).$$

Proof. This is the classical degree–Minkowski-covolume formula for hermitian lattices; see [183]. Here the Arakelov degree is unnormalised, each complex pair contributes one complex summand to the Euclidean space, and that summand has its unweighted real Euclidean metric. □

Proposition B.129. *Let $\mathcal{S}$ be a projective scheme of finite type over* $\operatorname{Spec}\mathbb{Z}$. *A hermitian line bundle on $\mathcal{S}$ is* ***semipositive*** *if its metric is the uniform limit of a sequence of smooth semipositive metrics, and* ***DSP*** *if it is isometric to $\overline{\mathcal{A}} \otimes \overline{\mathcal{A}}'^{\otimes -1}$ for semipositive hermitian line bundles $\overline{\mathcal{A}}$, $\overline{\mathcal{A}}'$ on $\mathcal{S}$. If $\mathcal{S}$ has relative dimension $m-1$ over* $\operatorname{Spec}\mathbb{Z}$ *and $\overline{\mathcal{M}}_1, \dots, \overline{\mathcal{M}}_m$ are DSP hermitian line bundles on $\mathcal{S}$, then $h_{\overline{\mathcal{M}}_1,\dots,\overline{\mathcal{M}}_m}(\mathcal{S}) \in \mathbb{R}$ denotes the height of $\mathcal{S}$ with respect to them in the sense of Burgos Gil, Philippon and Sombra.*

Let $\pi\colon \mathcal{W} \to \mathcal{V}$ be a morphism between two projective schemes of finite type over $\operatorname{Spec}\mathbb{Z}$ *of relative dimensions $d+b-1$ and $b-1$, respectively, with $b, d \geq 0$. Let $\overline{\mathcal{L}}_i$, $i = 1, \dots, d$, and $\overline{\mathcal{H}}_j$, $j = 1, \dots, b$, be DSP hermitian line bundles on $\mathcal{W}$ and $\mathcal{V}$, respectively. Then*

$$h_{\pi^*\overline{\mathcal{H}}_1,\dots,\pi^*\overline{\mathcal{H}}_b,\overline{\mathcal{L}}_1,\dots,\overline{\mathcal{L}}_d}(\mathcal{W}) = \deg_{\mathcal{L}_1,\dots,\mathcal{L}_d}(\mathcal{W}_\eta)\, h_{\overline{\mathcal{H}}_1,\dots,\overline{\mathcal{H}}_b}(\mathcal{V}),$$

where $\mathcal{W}_\eta$ denotes the fibre of $\mathcal{W}$ over the generic point η of $\mathcal{V}$ and $\deg_{\mathcal{L}_1,\dots,\mathcal{L}_d}(\mathcal{W}_\eta)$ its degree with respect to the restrictions of $\mathcal{L}_1, \dots, \mathcal{L}_d$. In particular, if π is not dominant, then $h_{\pi^*\overline{\mathcal{H}}_1,\dots,\pi^*\overline{\mathcal{H}}_b,\overline{\mathcal{L}}_1,\dots,\overline{\mathcal{L}}_d}(\mathcal{W}) = 0$.

Proof. [109, Proposition 2.3] (numbered as in arXiv:1408.3222). *Notation.* Here π, $\mathcal{W}$, $\mathcal{V}$, b, d, $\overline{\mathcal{L}}_i$, $\overline{\mathcal{H}}_j$, $\mathcal{W}_\eta$, deg and h are those of loc. cit.; its "finitely generated projective schemes over $\operatorname{Spec}(\mathbb{Z})$" are rendered as projective schemes of finite type over $\operatorname{Spec}\mathbb{Z}$. Hermitian line bundles and semipositive metrics are as in §1 of loc. cit. (with reference to Definition 1.4.1 of Burgos Gil, Philippon and Sombra, Arithmetic geometry of toric varieties. Metrics, measures and heights, Astérisque 360 (2014), and to Maillot's Definition 4.5.5); DSP (difference of semipositive) is as in §2 of loc. cit., with reference to the same Definition 1.4.1; the heights are the global heights of that Astérisque volume, which for semipositive metrics on arithmetic varieties are the arithmetic intersection numbers in the sense of Gillet and Soulé (Introduction of loc. cit.). The proof in loc. cit. reduces by linearity and continuity to ample line bundles with smooth semipositive metrics and proceeds by induction on d through the arithmetic Bézout formula; the case $d = 0$ is Moriwaki, Arithmetic height functions over finitely generated fields, Invent. Math. 140 (2000), Proposition 1.3(2), for dominant π, and Theorem 1.5.11(2) of the Astérisque volume in general. □

Theorem B.130. *Let $\mathcal{X}$ be an integral scheme of dimension $D+1$, projective and flat over* $\operatorname{Spec}\mathbb{Z}$ *(its generic fibre may be singular). A Hermitian line bundle $\overline{\mathcal{M}}$ on $\mathcal{X}$ has a* smooth *metric if its pull-back along every holomorphic map from a polydisc to $\mathcal{X}(\mathbb{C})$ is smooth (for instance the restriction of a smooth metric on an ambient complex manifold), and is* relatively semipositive *if (i) $\deg(\mathcal{M}|_C) \geq 0$ for every closed integral curve C contained in a fibre of $\mathcal{X} \to \operatorname{Spec}\mathbb{Z}$, and (ii) for every holomorphic map f from a polydisc to $\mathcal{X}(\mathbb{C})$ the curvature form $\frac{\partial\bar\partial}{\pi i}\log\|l\|$ of $f^*\overline{\mathcal{M}}$ (l a local invertible section) is semipositive. For a lattice Γ in a finite-dimensional real normed space V put $\chi(\Gamma) = -\log \operatorname{vol}(V/\Gamma)$, for the Haar measure giving the unit ball volume* 1.

Let $\overline{\mathcal{L}}$, $\overline{\mathcal{N}}$ be Hermitian line bundles on $\mathcal{X}$ with smooth metrics such that $\mathcal{L}_\mathbb{Q}$ is ample and $\overline{\mathcal{L}}$ is relatively semipositive. Then, as $N \to \infty$,

$$\chi_{\sup}(\Gamma(\mathcal{X}, \mathcal{L}^{\otimes N} \otimes \mathcal{N})) = \frac{N^{D+1}}{(D+1)!}\,\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1}) + o(N^{D+1}),$$

where $\chi_{\sup}$ is χ of the lattice $\Gamma(\mathcal{X}, \mathcal{L}^{\otimes N} \otimes \mathcal{N})$ in $\Gamma(\mathcal{X}_\mathbb{R}, \mathcal{L}^{\otimes N} \otimes \mathcal{N})$ with the sup norm over $\mathcal{X}(\mathbb{C})$, and $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1})$ is computed on a generic resolution of singularities of $\mathcal{X}$ (it does not depend on the resolution).

Proof. [276], Theorem (1.4), with the definitions (1.1)–(1.3) there. Notation: Zhang's arithmetic variety of dimension d is our $\mathcal{X}$ with $d = D+1$; his $c_1(L)^d$ is $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1})$; his $\chi_{\sup}$ is χ for

the sup norm as above. Zhang states that the case of a regular generic fibre and a relatively ample $\overline{\mathcal{L}}$ with positive curvature is due to Gillet and Soulé (his Lemma (1.5)) and reduces the general case to it by generic resolution and Minkowski's theorem. □

Theorem B.131. *(A) Let X be a projective variety over $\mathbb{C}$ and L an ample line bundle on X with a continuous metric $\|\cdot\|$. The metric is called **semiample** if for every $\varepsilon > 0$ there is $n \geq 1$ such that for every $x \in X(\mathbb{C})$ there is a non-zero section l of $L^{\otimes n}$ with $\|l\|_{\sup} \leq e^{n\varepsilon}\|l\|(x)$. If there are an embedding i of X into a compact complex manifold Y and a Hermitian line bundle $\overline{M}$ on Y with M ample and semipositive curvature form such that $i^*\overline{M}$ is isometric to $(L, \|\cdot\|)$, then the metric is semiample.*

*(B) Let $\mathcal{X}$ be an arithmetic variety of absolute dimension $D+1$ and $\overline{\mathcal{L}}$ a Hermitian line bundle on $\mathcal{X}$ with smooth metric such that $\mathcal{L}_{\mathbb{Q}}$ is ample, $\overline{\mathcal{L}}$ is relatively semipositive, and the metric of $\overline{\mathcal{L}}$ on $\mathcal{L}_{\mathbb{C}}$ is semiample (i.e. $\overline{\mathcal{L}}$ is **relatively semiample**). If $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}}) \cdot [D_x]) \geq 0$ for the Zariski closure D_x of every $x \in \mathcal{X}(\overline{\mathbb{Q}})$, then $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1}) \geq 0$.*

Proof. [276]: (A) is the archimedean case of Theorem (3.5), with the definition (3.1) of a semiample metrized line bundle (the equivalent form with sections is the one stated in (3.1)); (B) is Lemma (5.4), under the assumptions of Theorem (5.2) ($L_{\mathbb{Q}}$ ample, $\overline{L}$ relatively semiample with smooth metric), with the definition of relatively semiample in (5.1). Notation: Zhang's arithmetic variety of dimension d is $\mathcal{X}$ with $d = D+1$; his height $h_L(x) = \deg(\overline{L}|_{D_x})/\deg(D_x)$; his $c_1(\overline{L})^d$ is $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}})^{D+1})$. For an arithmetic variety over $\mathbb{Z}$ the archimedean metric is a conjugation-invariant metric over $\mathbb{C}$ (Zhang's $K_0 = \mathbb{R}$, $K = \mathbb{C}$). □

Proposition B.132. *Let K be $\mathbb{R}$, $\mathbb{C}$ or a field complete with respect to the absolute value of a non-trivial discrete valuation, with valuation ring K°, uniformiser ϖ and residue field k; let X be a projective variety over K and X^{an} its analytification (for $K = \mathbb{R}$, the complex space $X^{\mathrm{an}}_{\mathbb{C}}$).*

1. ***(Local heights.)** To each d-dimensional cycle Y of X and each family $(\overline{L}_i, s_i)$, $i = 0, \ldots, d$, of DSP metrized line bundles with rational sections meeting Y properly, the local height $h_{\overline{L}_0,\ldots,\overline{L}_d}(Y; s_0, \ldots, s_d) \in \mathbb{R}$ is determined inductively by $h(\varnothing) = 0$ and*

$$h_{\overline{L}_0,\ldots,\overline{L}_d}(Y; s_0, \ldots, s_d) = h_{\overline{L}_0,\ldots,\overline{L}_{d-1}}(Y \cdot \operatorname{div} s_d; s_0, \ldots, s_{d-1}) - \int_{X^{\mathrm{an}}} \log \|s_d\|_d \, c_1(\overline{L}_0) \wedge \cdots \wedge c_1(\overline{L}_{d-1}) \wedge \delta_Y.$$

   For smooth metrics in the Archimedean case, $c_1(\overline{L}) = \partial\bar{\partial} \log \|s\|^2$ for a non-vanishing local section s, and $\delta_Y(\omega) = (2\pi i)^{-d} \int_{Y^{\mathrm{an}}} \omega$.

2. ***(Algebraic metrics.)** If K is non-Archimedean, Y is prime, and the metrics of the $\overline{L}_i$ are algebraic, induced by proper models $(\mathcal{X}, \mathcal{L}_i, e_i)$ over K° with a common $\mathcal{X}$, then the recursion in (1) reads*

$$h_{\overline{L}_0,\ldots,\overline{L}_d}(Y; s_0, \ldots, s_d) = h_{\overline{L}_0,\ldots,\overline{L}_{d-1}}(Y \cdot \operatorname{div} s_d; s_0, \ldots, s_{d-1}) - \frac{\log|\varpi|}{e_0 \cdots e_d} \sum_{V \in \widetilde{\mathcal{Y}}_o^{(0)}} \operatorname{ord}_V(s_d^{\otimes e_d}) \deg_{\mathcal{L}_0,\ldots,\mathcal{L}_{d-1}}(V),$$

   where $\widetilde{\mathcal{Y}}$ is the normalisation of the closure $\mathcal{Y}$ of Y in $\mathcal{X}$ and $\widetilde{\mathcal{Y}}_o^{(0)}$ the set of irreducible components of its special fibre.

3. ***(Global heights.)*** *Let X be a projective variety over $\mathbb{Q}$, with the places v of $\mathbb{Q}$ and the absolute values $|\cdot|_\infty$ and $|\cdot|_p$, $|p|_p = p^{-1}$, all with weight 1. Let $\overline{L}_0, \dots, \overline{L}_d$ be line bundles on X with DSP metrics at every place whose metrics at all but finitely many primes are induced by one proper model over the ring of S-integers. For a d-dimensional cycle Y of X and rational sections $s_0, \dots, s_d$ meeting Y properly, $\sum_v h_{\overline{L}_{0,v},\dots,\overline{L}_{d,v}}(Y; s_0, \dots, s_d)$ is a real number that does not depend on the sections; it is the global height $h_{\overline{L}_0,\dots,\overline{L}_d}(Y)$.*

Proof. [108] (Burgos Gil, Philippon, Sombra, Arithmetic geometry of toric varieties. Metrics, measures and heights, Astérisque 360 (2014)), Chapter 1. Item (1) is the definition of local heights, Definition 1.4.11 (number as cited in [109], §2), with the normalisations of §1.1 (definition of the first Chern form and of the signed measure $c_1(\overline{L}_0) \wedge \cdots \wedge c_1(\overline{L}_{d-1}) \wedge \delta_Y$ for smooth metrics; the remark reducing varieties over $\mathbb{R}$ to $X_\mathbb{C}$). Item (2) is the Remark following Definition 1.4.11, obtained there from the description of algebraic metrics and of the measure $c_1(\overline{L}_0)\wedge\cdots\wedge c_1(\overline{L}_{d-1})\wedge\delta_Y$ attached to algebraic metrics (§1.3, Definition of that measure through the normalisation $\widetilde{\mathcal{Y}}$). Item (3) is the definition of the global height over an adelic field (§1.5), with $\mathbb{Q}$ as an adelic field with weights 1; the independence of the sections holds by the product formula and the theorem on the properties of local heights, item (3) (change of the section by a rational function changes the local height by $\log|f(Z)|_v$), and every cycle is integrable for such quasi-algebraic metrics (§1.5, proposition on quasi-algebraic metrics). *Notation.* Here ϖ, $\widetilde{\mathcal{Y}}_o^{(0)}$, $\deg_{\mathcal{L}_0,\dots,\mathcal{L}_{d-1}}$ and ord_V are those of loc. cit. □

Theorem B.133. *Let K_0 be a number field, A an abelian variety of dimension $g \geq 1$ over K_0, L_A a symmetric ample line bundle on A defining a principal polarisation, $r_0 \in L_A(0)$ non-zero, and $r \geq 2$ an **even** integer.*

1. *(Existence.) There are a finite extension K/K_0 with $A[r^2] \subseteq A(K)$ and a Moret-Bailly model of $(A_K, L_A \otimes K, r_0 \otimes 1, A[r^2](K))$ over $\mathcal{O}_K$.*

2. *(Base change.) If $(\mathcal{G}, i, \mathcal{M}, (\|\cdot\|_\sigma), \varphi, u, (\varepsilon_P)_{P\in F})$ is a Moret-Bailly model of $(A_K, L_A \otimes K, r_0 \otimes 1, F)$ over $\mathcal{O}_K$ and K'/K is finite, the base changes of all the data form a Moret-Bailly model of $(A_{K'}, L_A\otimes K', r_0\otimes 1, F)$ over $\mathcal{O}_{K'}$, whose Moret-Bailly lattice is $\Lambda\otimes_{\mathcal{O}_K}\mathcal{O}_{K'}$, Λ the Moret-Bailly lattice of the given model.*

3. *(Independence.) Two Moret-Bailly models of $(A_K, L_A \otimes K, r_0 \otimes 1, F)$ over $\mathcal{O}_K$ have the same Moret-Bailly lattice in $H^0(A_K, L_A \otimes K)$.*

4. *(Translates.) Let $(\mathcal{G}, i, \mathcal{M}, (\|\cdot\|_\sigma), \varphi, u, (\varepsilon_x)_{x\in A[r^2](K)})$ be a Moret-Bailly model of $(A_K, L_A\otimes K, r_0 \otimes 1, A[r^2](K))$ over $\mathcal{O}_K$. There are isomorphisms of line bundles on $\mathcal{G}$*

$$j\colon [r]^*\mathcal{M} \to \mathcal{M}^{\otimes r^2}, \qquad i_x\colon t_{\varepsilon_x}^*\mathcal{M}^{\otimes r^2} \to \mathcal{M}^{\otimes r^2} \quad (x \in A[r^2](K)),$$

t_{ε_x} the translation by the section ε_x, which are isometric for the cubist metrics (and their tensor powers) at every $\sigma\colon K \to \mathbb{C}$, and such that, with $\psi_x(s) = i_x\big(t_{\varepsilon_x}^* j([r]^* s)\big)$, for every set $\Sigma \subseteq A[r^2](K)$ of representatives of $A[r^2]/A[r]$ the map

$$H^0(\mathcal{G}_K, \mathcal{M}_K)^\Sigma \to H^0(\mathcal{G}_K, \mathcal{M}_K^{\otimes r^2}), \qquad (s_x)_{x\in\Sigma} \mapsto \sum_{x\in\Sigma} \psi_x(s_x),$$

is an isomorphism of K-vector spaces.

Proof. F. Pazuki, Theta height and Faltings height, Bull. Soc. Math. France 140 (2012), 19–49 (arXiv:0907.1458): item 1 is Theorem 3.4 (i) for $F = A_{r^2}(\overline{\mathbb{Q}})$ together with Definition 3.1 (the sections ε_P, $P \in F$, force $F \subseteq A(K)$) and Remark 3.3; item 2 is Theorem 3.4 (iv), the lattice statement being the isometric isomorphism $j^*\pi_*\overline{\mathcal{L}} \to \tilde{\pi}_*\tilde{\overline{\mathcal{L}}}$ there; item 3 is Theorem 3.4 (iii) (the canonical isomorphisms $(\pi_*\mathcal{L})_{\overline{\mathbb{Q}}} \simeq H^0(A,L) \simeq (\pi'_*\mathcal{L}')_{\overline{\mathbb{Q}}}$ extend to an isometric isomorphism $\pi_*\overline{\mathcal{L}} \simeq \pi'_*\overline{\mathcal{L}'}$); item 4 is Proposition 5.1 (i) (the isomorphism $j\colon [r]^*\mathcal{L} \simeq \mathcal{L}^{\otimes r^2}$ compatible with the rigidification, §2.3.1, and a good choice of the $i_x\colon t_x^*\mathcal{L}^{\otimes r^2} \simeq \mathcal{L}^{\otimes r^2}$ extend to isometric isomorphisms of Hermitian line bundles over $\mathcal{G}$) together with Proposition 2.5 (the map $\Phi = \sum_{x\in\Sigma}\psi_x$ is an isomorphism; proof by the irreducibility of the representation of the theta group of $L^{\otimes r^2}$, Mumford, On the equations defining abelian varieties I, Invent. Math. 1 (1966)). Pazuki attributes Theorem 3.4 to J.-B. Bost, Intrinsic heights of stable varieties and abelian varieties, Duke Math. J. 82 (1996), §4.3.2, and L. Moret-Bailly [181]. Notation: Pazuki's MB-model $(\pi\colon \mathcal{A} \to \operatorname{Spec}\mathcal{O}_K, i, \overline{\mathcal{L}}, \varphi, (\varepsilon_P))$ is our $(\mathcal{G}, i, \mathcal{M}$ with the cubist metrics$, \varphi, (\varepsilon_P))$; his φ is compatible with the rigidification ("since $\mathcal{L}_K$ is cubist, it is automatically rigidified", §5.1), which is our generator u of (Mb3); his $\pi_*\mathcal{L}$ with the identification of its generic fibre with $H^0(A,L)$ is our Moret-Bailly lattice; his level r is even throughout (§2.3.1, Definition 3.2, §5.1). □

Theorem B.134. *Let K be an imaginary quadratic field of discriminant D_K, χ_K the quadratic Dirichlet character of K (the Kronecker symbol $(D_K/\cdot)$, primitive modulo $|D_K|$) and $L(s,\chi_K)$ its Dirichlet L-function. Let $k \subseteq \overline{\mathbb{Q}}$ be a number field and A an elliptic curve over k whose ring of $\overline{\mathbb{Q}}$-endomorphisms is isomorphic to $\mathcal{O}_K$ and whose Néron model $\mathcal{A} \to \operatorname{Spec}\mathcal{O}_k$ is an abelian scheme. For a non-zero rational section s of $\pi_*\Omega^1_{\mathcal{A}/\mathcal{O}_k}$ put*

$$h^{\mathrm{Falt}}(A) = \frac{1}{[k:\mathbb{Q}]}\sum_{\mathfrak{p}} \operatorname{ord}_{\mathfrak{p}}(s)\log \mathrm{N}(\mathfrak{p}) - \frac{1}{2[k:\mathbb{Q}]}\sum_{\sigma\colon k\to\mathbb{C}} \log\Big|\int_{A^\sigma(\mathbb{C})} s^\sigma \wedge \overline{s^\sigma}\Big|$$

(independent of s). Then

$$h^{\mathrm{Falt}}(A) = -\frac{1}{2}\,\frac{L'(0,\chi_K)}{L(0,\chi_K)} - \frac{1}{4}\log|D_K| - \frac{1}{2}\log(2\pi).$$

Proof. This is [8], Theorem A (p. 2; proved as Theorem 9.5.5), in the case $d = 1$: $E = K$, $F = \mathbb{Q}$, $D_F = 1$, χ the quadratic character of $K/\mathbb{Q}$ with its L-function without archimedean factors, and the left side the average of $h^{\mathrm{Falt}}_{(K,\Phi)}$ over the two CM types of K. The normalisation of the Faltings height is their Definition 9.1.4 (with h^{Falt}_f and h^{Falt}_∞ as displayed above), and by their Theorem 9.1.5 (Colmez, Théorème 0.3 of *Périodes des variétés abéliennes à multiplication complexe*, Ann. of Math. 1993) $h^{\mathrm{Falt}}_{(K,\Phi)} = h^{\mathrm{Falt}}(A)$ for every A with complex multiplication by $\mathcal{O}_K$ of type Φ. *Notation.* Here A with its $\mathcal{O}_K$-action has one of the two CM types Φ, and A with the action precomposed with complex conjugation of K has the other, so both values $h^{\mathrm{Falt}}_{(K,\Phi)}$ equal $h^{\mathrm{Falt}}(A)$ and so does their average. For $d = 1$ the statement is the Chowla–Selberg formula in Colmez's form (their §1.1). □

Theorem B.135. *Let $n \geq 1$, let $\mathbb{R}^n$ carry its Euclidean inner product $u\cdot v$ and norm $\|\cdot\|$, let $\Gamma \subset \mathbb{R}^n$ be a lattice (the subgroup generated by n linearly independent vectors) and $\Gamma^* = \{u \in \mathbb{R}^n : u\cdot v \in \mathbb{Z}$ for all $v \in \Gamma\}$ its dual lattice. For $1 \leq i \leq n$ let $\lambda_i(\Gamma) = \min\{s > 0 : \dim \operatorname{span}_{\mathbb{R}}(\Gamma \cap \{\|v\| \leq s\}) \geq i\}$ be the i-th successive minimum. Then*

$$\lambda_i(\Gamma)\,\lambda_{n-i+1}(\Gamma^*) \leq n \qquad (1 \leq i \leq n).$$

Proof. [16]: the quantity $\xi_n = \sup_\Gamma \max_{1\le i\le n} \lambda_i(\Gamma)\lambda_{n-i+1}(\Gamma^*)$ satisfies $\xi_n \le n$ for every n. Notation: the paper writes L, L^* for Γ, Γ^*; the definitions of the dual lattice and of the successive minima are those of the paper. □

Theorem B.136. *Let K be a number field and $\overline{M} = (M, (\|\cdot\|_\sigma)_\sigma)$ a Hermitian lattice over $\mathcal{O}_K$ of rank $n \ge 1$. For a finite extension K'/K let $\overline{M}_{K'}$ be the Hermitian lattice $M \otimes_{\mathcal{O}_K} \mathcal{O}_{K'}$ over $\mathcal{O}_{K'}$ with the norms $\|\cdot\|_{\sigma'} = \|\cdot\|_{\sigma'|_K}$ (extended to $M \otimes_{\mathcal{O}_K,\sigma'|_K} \mathbb{C}$), and for $0 \ne v \in M \otimes_{\mathcal{O}_K} K'$ let $\overline{M}_{K'}(v) = \big(K'v \cap (M \otimes_{\mathcal{O}_K} \mathcal{O}_{K'})\big)$ with the induced norms (a Hermitian lattice of rank one). Put $H_n = \sum_{k=1}^{n} \frac{1}{k}$. Then for every $\varepsilon > 0$ there are a finite extension K'/K and $0 \ne v \in M \otimes_{\mathcal{O}_K} K'$ with*

$$\widehat{\mu}\big(\overline{M}_{K'}(v)\big) \;\ge\; \widehat{\mu}(\overline{M}) - \tfrac{1}{2}\,(H_n - 1) - \varepsilon.$$

Proof. This is the first-minimum case of Zhang's theorem on the successive minima of heights over $\overline{\mathbb{Q}}$ [276] (see also Roy–Thunder, An absolute Siegel's lemma, J. reine angew. Math. 476 (1996)), with the exact constant of Gaudron and Rémond (É. Gaudron, G. Rémond, Corps de Siegel, J. reine angew. Math. 726 (2017), 187–247, §5.2), in the form stated in É. Gaudron, Minima and slopes of rigid adelic spaces, Chapter II of Arakelov Geometry and Diophantine Applications, Lecture Notes in Math. 2276 (2021), §4.2: for a rigid adelic space E over an algebraic extension K of $\mathbb{Q}$, $c_I(n,K) = \sup_{\dim E=n} \lambda_1(E) H(E)^{-1/n} = \sup_{\dim E=n} \lambda_1(E) \exp \mu(E)$, where $\lambda_1(E) = \inf\{H_E(x) : x \in E \smallsetminus \{0\}\}$, $H_E(x) = \exp \int_{V(K)} \log \|x\|_{E,v}\, d\sigma(v)$ and $\mu(E) = -\frac{1}{n} \log H(E)$; and $c_I(n,\overline{\mathbb{Q}}) = \exp(\frac{H_n-1}{2})$ (op. cit. p. 61, case (2), attributed to [Gaudron–Rémond, §5.2]). Hence $\lambda_1(E) \le \exp(\frac{H_n-1}{2} - \mu(E))$ for every E of dimension n over $\overline{\mathbb{Q}}$. *Notation.* The Hermitian lattice $\overline{M}$, extended to $\overline{\mathbb{Q}}$, is the rigid adelic space E with the lattice norms at the finite places and $\|\cdot\|_\sigma$ at the infinite ones (Gaudron's measure σ gives each embedding weight $1/[K' : \mathbb{Q}]$, slopes and heights being invariant under scalar extension, op. cit. p. 43); $\mu(E) = \widehat{\mu}(\overline{M})$; for v as in the statement, $\log H_E(v) = -\widehat{\mu}(\overline{M}_{K'}(v))$ (product formula applied to a generator of the rank-one lattice, normalised by $[K' : \mathbb{Q}]$); $\lambda_1(E)$ is the infimum of $H_E(v)$ over all $v \ne 0$, each defined over a finite extension, whence the ε. □

Theorem B.137. *Let K_0 be a number field, A an abelian variety of dimension $g \ge 1$ over K_0 and L a symmetric ample line bundle on A defining a principal polarisation. Then there are a finite extension K/K_0 and the following data:*

- *a smooth separated commutative group scheme $\pi\colon \mathcal{G} \to \operatorname{Spec} \mathcal{O}_K$ of finite type, every connected component of every fibre of which is an extension of an abelian variety by a torus, with an isomorphism $\mathcal{G}_K \cong A_K$;*
- *a line bundle $\mathcal{M}$ on $\mathcal{G}$ with a cubical structure, and an isomorphism $\varphi\colon \mathcal{M}|_{\mathcal{G}_K} \cong L_K$;*
- *for every $\sigma\colon K \to \mathbb{C}$ the **cubist metric** $\|\cdot\|_\sigma$ on $\mathcal{M}_\sigma$: the Hermitian metric for which the trivialisation of $\Theta(\mathcal{M})_\sigma$ given by the cubical structure has norm 1; for it $\varepsilon^*\mathcal{M}$ (ε the unit section) with the induced metrics is isometric to $\mathcal{O}_K$ with the trivial metrics, and the curvature form of $\|\cdot\|_\sigma$ is invariant under translations of $A_\sigma(\mathbb{C})$;*
- *a closed subscheme of $\mathcal{G}$, finite and flat over $\mathcal{O}_K$, whose generic fibre corresponds to $A_K[2]$ under $\mathcal{G}_K \cong A_K$;*

such that for every finite extension K'/K, with $\mathcal{G}' = \mathcal{G} \times_{\mathcal{O}_K} \mathcal{O}_{K'}$ and $\mathcal{M}'$ the pull-back of $\mathcal{M}$: the $\mathcal{O}_{K'}$-module $E' = H^0(\mathcal{G}', \mathcal{M}')$ is projective of rank one, $E' \otimes_{\mathcal{O}_{K'}} K' = H^0(A_{K'}, \mathcal{M}|_{A_{K'}})$, and

the Hermitian lattice $\overline{E'}$ *with the norms*

$$\|s\|^2_{L^2,\sigma'} = \int_{A_{\sigma'}(\mathbb{C})} \|s(x)\|^2_{\sigma'}\, d\mu_{\sigma'}(x) \qquad (\sigma'\colon K' \to \mathbb{C},\ \mu_{\sigma'} \text{ the Haar probability measure})$$

satisfies

$$\frac{\widehat{\deg}\,\overline{E'}}{[K':\mathbb{Q}]} = -\frac{1}{2}\,h_F(A) - \frac{g}{4}\log(2\pi).$$

Here $h_F(A)$ *is the stable Faltings height in Deligne's normalisation: for a finite extension* K''/K_0 *and a semiabelian scheme* $\mathcal{S}$ *over* $\mathcal{O}_{K''}$ *with generic fibre* $A_{K''}$, $h_F(A) = \widehat{\deg}\,\overline{\omega}_{\mathcal{S}}/[K'':\mathbb{Q}]$, *where* $\omega_{\mathcal{S}} = \varepsilon^*\Omega^g_{\mathcal{S}/\mathcal{O}_{K''}}$ *carries the norms* $\|\alpha\|^2_{\sigma''} = \frac{i^{g^2}}{(2\pi)^g}\int_{A_{\sigma''}(\mathbb{C})} \alpha\wedge\overline{\alpha}$; *it does not depend on* K'' *and* $\mathcal{S}$.

Proof. F. Pazuki, Theta height and Faltings height, Bull. Soc. Math. France 140 (2012), 19–49 (arXiv:0907.1458), Definition 3.1 (an MB-model of $(A, L, \varnothing)$: in particular a subscheme of $\mathcal{A}$, finite and flat over $\mathcal{O}_K$, whose generic fibre is the Mumford group $K(L^2)$, which is $A[2]$ for a principal polarisation), Theorem 3.4 (i) existence of an MB-model $(\pi\colon \mathcal{A} \to \operatorname{Spec}\mathcal{O}_K, i, \overline{\mathcal{L}}, \varphi)$, (iv) its base change to $\mathcal{O}_{K'}$ is again an MB-model, (v) Arakelov slope: $\pi_*\overline{\mathcal{L}}$ is semistable and $\widehat{\deg}\,\pi_*\overline{\mathcal{L}}/([K:\mathbb{Q}]\rho(L)) = -\frac{1}{2}h_F(A) + \frac{1}{4}\log(\rho(L)/(2\pi)^g)$, here with $\rho(L) = c_1(L)^g/g! = 1$ (principal polarisation); §3.1 for semistable group schemes, cubist Hermitian line bundles (the section of $\mathcal{D}_3(\overline{\mathcal{L}})$ of norm one; $\varepsilon^*\overline{\mathcal{L}} \simeq \overline{\mathcal{O}}$; translation invariant c_1), local freeness of $\pi_*\mathcal{L}$ (of rank $\rho(L)$) and the L^2 metric for the normalised Haar measure; Definition 2.1 and §2.2 for h_F in Deligne's normalisation. Pazuki attributes (i)–(v) to J.-B. Bost, Intrinsic heights of stable varieties and abelian varieties, Duke Math. J. 82 (1996), 21–70, §4.3.2, resting on L. Moret-Bailly, Pinceaux de variétés abéliennes [181] and Sur l'équation fonctionnelle de la fonction thêta de Riemann, Compositio Math. 75 (1990). In the case of good reduction it is [46, Théorème 4.2 ii)]. Notation: Pazuki's $\pi_*\mathcal{L}$, $\overline{\mathcal{L}}$, i are E' (over K'), $(\mathcal{M}, \|\cdot\|_\sigma)$ and the isomorphism $\mathcal{G}_K \cong A_K$; the identification of the generic fibre of $\pi_*\mathcal{L}$ with $H^0(A, L)$ is his Theorem 3.4 (iii) together with flat base change. □

Theorem B.138. *Let* K *be a number field and* A *an abelian variety of dimension* $g \geq 1$ *over* K *with a principal polarisation. For* $\sigma\colon K \to \mathbb{C}$ *write* $A_\sigma(\mathbb{C}) = \operatorname{Lie}(A_\sigma)/\Pi_\sigma$, *let* H_σ *be the positive definite Hermitian form on* $\operatorname{Lie}(A_\sigma)$ *whose imaginary part on* Π_σ *is the Riemann form of the polarisation, and* $\rho_\sigma = \min_{0\neq l\in\Pi_\sigma} H_\sigma(l,l)^{1/2}$. *Then for every* $\varepsilon \in]0,1[$

$$h_F(A) - \frac{g}{2}\log\pi + \frac{g}{2}\log\Big(\frac{2\pi^2}{\varepsilon}\Big) \;\geq\; \frac{(1-\varepsilon)\pi}{6[K:\mathbb{Q}]}\sum_{\sigma\colon K\to\mathbb{C}} \frac{1}{\rho_\sigma^2}.$$

Proof. P. Autissier [14, Corollaire 1.4] (a consequence of his Théorème 1.1, the lower bound $h_{\mathrm{Fa}}(A) \geq \frac{1}{[K:\mathbb{Q}]}\sum_\sigma\big(\frac{\pi}{6\rho_\sigma^2} + g\ln(\kappa\rho_\sigma\sqrt{g})\big)$ with ρ_σ truncated at $\sqrt{\pi/(3g)}$, which rests on Bost's lower bound for h_{Fa}, proved in the appendix of [102]). Notation: Autissier's diamètre d'injectivité $\rho(A_\sigma; L_\sigma) = \min_{\gamma\neq 0}\sqrt{H_L(\gamma;\gamma)}$ with H_L the Riemann form on T_{A_σ} is our ρ_σ; his height h_{Fa} is the stable Faltings height with the norm $\|\varphi\|^2 = \frac{i^{g^2}}{2^g}\int\varphi\wedge\overline{\varphi}$ on ω; Deligne's normalisation uses $\frac{i^{g^2}}{(2\pi)^g}$, so $\|\cdot\|_{\mathrm{Del}} = \pi^{-g/2}\|\cdot\|_{\mathrm{Aut}}$ and $h_{\mathrm{Fa}} = h_F - \frac{g}{2}\log\pi$, which gives the displayed form. □

Theorem B.139. *Let* $\mathcal{Y}$ *be a regular arithmetic variety over* $\mathbb{Z}$, $\overline{W} = (W, h)$ *a Hermitian vector bundle of rank* 2 *on* $\mathcal{Y}$ *(smooth metric invariant under complex conjugation),* $\pi\colon \mathbb{P}(W) \to \mathcal{Y}$ *the bundle of lines in* W, $\mathcal{S} \subseteq \pi^*W$ *the tautological line with the metric induced by* h, *and*

$\hat\zeta = \widehat{c}_1(\overline{\mathcal{S}}^\vee) \in \widehat{\mathrm{CH}}^1(\mathbb{P}(W))_\mathbb{Q}$. *Let* $c_1 = c_1(W,h)$, $c_2 = c_2(W,h)$ *be the Chern forms on* $\mathcal{Y}(\mathbb{C})$ *and define forms* s'_m *of type* (m,m) *and* R_m *of type* $(m-1,m-1)$ *by*

$$\sum_{m\ge 0} s'_m\, t^m = \left(1 + c_1 t + c_2 t^2\right)^{-1}, \qquad R_0 = 0, \qquad R_m = -\sum_{p+q=m-1} \frac{s'_p\, s'_q}{q+1} \quad (m \ge 1), \tag{B.2}$$

and classes $\hat s_m \in \widehat{\mathrm{CH}}^m(\mathcal{Y})_\mathbb{Q}$ *by* $\sum_m \hat s_m t^m = \left(1 + \widehat{c}_1(\overline{W})t + \widehat{c}_2(\overline{W})t^2\right)^{-1}$. *Then for every* $m \ge 0$

$$\pi_*(\hat\zeta^{\,1+m}) = \hat s_m - a(R_m) \qquad \text{in } \widehat{\mathrm{CH}}^m(\mathcal{Y})_\mathbb{Q}. \tag{B.3}$$

Proof. This is [184], Theorem 4 (§8.1),

$$\widehat{c}_t(\overline{E}^\star)\cdot \widehat{s}_t(\overline{E}) = 1 \quad \text{with} \quad \widehat{s}_m = \widehat{s}'_m + a(R_m)$$
$$\text{and} \quad \widehat{s}'_m = \widehat{\pi}_*(\widehat{c}_1(\mathcal{O}_{\overline{E}}(1))^{r-1+m}),$$

in rank $r = 2$, together with Theorem 3 and Proposition 6 there, for the base $\operatorname{Spec}\mathbb{Z}$ ($K = \mathbb{Q}$). *Notation.* Mourougane's $\mathbb{P}(E)$ is the variety of hyperplanes of E; we take $E = W^\vee$ with the dual metric, so that $\mathbb{P}(E)$ is the bundle of lines in W, $\mathcal{O}_{\overline{E}}(1)$ (quotient of π^*E with the quotient metric) is $\overline{\mathcal{S}}^\vee$, and $\overline{E}^\star = \overline{W}$. His total Segre form satisfies $\left(\sum t^m c_m(E^\star,h)\right)\left(\sum t^m s'_m(E,h)\right) = 1$ pointwise (Proposition 6), which is the first identity of (B.2). His $R_t = \sum_{m\ge0} t^m R_{m+1} = s'_t S_t$ with $S_{m+1} = -\sum_{a+b+c=m} \mathcal{H}^{r-1+c}_{r-1-a-b} c_a(E^\star,h) s^b_c(E,h)$ (Theorem 3); for $r = 2$ only $a = b = 0$ contributes ($\mathcal{H}^{\cdot}_0 = 0$ and $\mathcal{H}^{\cdot}_a$ is an empty sum for $a < 0$), $\mathcal{H}^{1+m}_1 = \mathcal{H}_1 \binom{1}{1}\binom{1+m}{1}^{-1} = \frac{1}{m+1}$ and $s^0_m = s'_m$, so $S_{m+1} = -\frac{1}{m+1} s'_m$ and $R_{m+1} = -\sum_{p+q=m} \frac{s'_p s'_q}{q+1}$, which is (B.2) and the second display of the rank-2 example on p. 21 of the paper. Degree 0: $\widehat{s}'_0 = \pi_*(\hat\zeta) = 1$.

Framework. The push-forward π_* of the statement and the rules $a(\eta)\cdot x = a(\eta \wedge \omega(x))$ and $\widehat{\deg}\, a(\eta) = \frac12 \int \eta$ used with it are (GA2), (GA3) and (GA5) of Lemma D.89, which applies to π ($\mathcal{Y}$ and $\mathbb{P}(W)$ are regular, flat and projective over $\mathbb{Z}$, π is smooth of relative dimension 1) and to the structure morphisms, and which is proved from [106]; its push-forward is the push-forward of Gillet and Soulé ([110]) that [184], §8, takes as known. The arithmetic Chern classes $\widehat{c}_1(\overline{W})$, $\widehat{c}_2(\overline{W})$ of the statement, and $\hat\zeta = \widehat{c}_1(\overline{\mathcal{S}}^\vee)$ (rank 1), are the arithmetic Chern classes of Gillet and Soulé, which [184], §8, takes as known; they are the classes of Lemma D.90, obtained from [107]. □

Proposition B.140. *Let* $\mathbb{Z}$ *carry its embedding into* $\mathbb{C}$ *and complex conjugation. Call a regular scheme* X*, flat and quasi-projective over* $\operatorname{Spec}\mathbb{Z}$*, of relative dimension* d*, an arithmetic variety over* $\mathbb{Z}$*; put* $X_\infty = X(\mathbb{C})$ *and let* F_∞ *be complex conjugation on* X_∞*. For such* X *there are groups* $\widehat{\mathrm{CH}}^p(X, \mathcal{D}_{\log})$ *of classes* $[y, \mathfrak{g}_y]$ *of pairs of a* p*-codimensional cycle* y *and a Green form* $\mathfrak{g}_y = (\omega_y, \widetilde{g}_y)$ *for the class of* y*, with maps*

$$\zeta[y,\mathfrak{g}_y] = [y] \in \mathrm{CH}^p(X), \qquad \omega[y,\mathfrak{g}_y] = \omega_y, \qquad \mathrm{a}(\widetilde{x}) = [0, \mathrm{a}(\widetilde{x})] \quad (\widetilde{x} \in \widetilde{\mathcal{D}}^{2p-1}_{\log}(X,p)),$$

where $\widetilde{\mathcal{D}}^{2p-1}_{\log}(X,p) = \{x \in E^{p-1,p-1}_{\log,\mathbb{R}}(X_\infty)(p-1) : F^*_\infty x = \bar x\}/(\operatorname{Im}\partial + \operatorname{Im}\bar\partial)$*,* $E_{\log}$ *denoting forms with logarithmic singularities at infinity and* $(p-1)$ *the twist by* $(2\pi i)^{p-1}$*, and where on Green objects* $\mathrm{a}(\widetilde{x}) = (-\mathrm{d}_\mathcal{D}x, -\widetilde{x})$ *with* $\mathrm{d}_\mathcal{D}x = -2\partial\bar\partial x$ *in this degree. Then:*

(BK1) $\widehat{\mathrm{CH}}^*(X, \mathcal{D}_{\log})_\mathbb{Q}$ *is a commutative and associative* $\mathbb{Q}$*-algebra with unit, compatible with* ω *and* ζ*. If* y *and* z *are cycles whose generic fibres intersect properly,* $[y,\mathfrak{g}_y]\cdot[z,\mathfrak{g}_z]$ *is the class of* $((y_\mathbb{Q}\cdot z_\mathbb{Q}, \mathfrak{g}_y * \mathfrak{g}_z), [y\cdot z]_{\mathrm{fin}})$*; and if* $\mathfrak{g}_y = \mathrm{a}(\widetilde{x})$*, then* $\mathfrak{g}_y * \mathfrak{g}_z = \mathrm{a}(\widetilde{x \wedge \omega_z})$.

(BK2) *For a morphism $f\colon X \to Y$ of arithmetic varieties over $\mathbb{Z}$ there is a pull-back*

$$f^*\colon \widehat{\mathrm{CH}}^p(Y, \mathcal{D}_{\log}) \to \widehat{\mathrm{CH}}^p(X, \mathcal{D}_{\log}),$$

compatible with the pull-back of forms via ω and of cycles via ζ, with $f^* \circ \mathrm{a} = \mathrm{a} \circ f^*$ (on the right, the pull-back of forms), with $(g \circ f)^* = f^* \circ g^*$, and inducing an algebra morphism on $\widehat{\mathrm{CH}}^*(\cdot, \mathcal{D}_{\log})_{\mathbb{Q}}$.

(BK3) *Let $f\colon X \to Y$ be a proper morphism of arithmetic varieties over $\mathbb{Z}$ of relative dimension e such that $f_{\mathbb{R}}$ is a smooth proper morphism of proper varieties. Then there is a push-forward $f_*\colon \widehat{\mathrm{CH}}^p(X, \mathcal{D}_{\log}) \to \widehat{\mathrm{CH}}^{p-e}(Y, \mathcal{D}_{\log})$, compatible with the push-forward of forms via ω and of cycles via ζ, with $(g \circ f)_* = g_* \circ f_*$ for another such g, and*

$$f_*(f^*(\alpha) \cdot \beta) = \alpha \cdot f_*(\beta) \in \widehat{\mathrm{CH}}^{p+q-e}(Y, \mathcal{D}_{\log})_{\mathbb{Q}} \qquad (\alpha \in \widehat{\mathrm{CH}}^p(Y, \mathcal{D}_{\log}),\ \beta \in \widehat{\mathrm{CH}}^q(X, \mathcal{D}_{\log})).$$

This f_* is the push-forward of the abstract theory for the covariant f-pseudo-morphism $f_*\mathcal{D}_{\log,X} \xleftarrow{u} \mathcal{F} \xrightarrow{v} \mathcal{D}_{\log,Y}(-e)[-2e]$, where $\mathcal{F}(U,p) = \varinjlim_{\overline{Y},D} \mathcal{D}(E_{X\times_Y \overline{Y}}(\log X \times_Y D), p)$ (limit over the compactifications $\overline{Y}$ of U dominating Y with normal crossing boundary $D = \overline{Y} \setminus U$), u is the natural morphism, an isomorphism on global sections, and $v(\omega) = f_!\omega = (2\pi i)^{-e} \int_f \omega$; and $f_* \circ \mathrm{a} = \mathrm{a} \circ f_{\#}$, $\omega \circ f_* = f_{\#} \circ \omega$, with $f_{\#} = v \circ u^{-1}$ on global sections.

(BK4) *The assignment $[y, (\omega_y, \widetilde{g}_y)] \mapsto [y, 2(2\pi i)^{d-p+1}[g_y]_X]$, where $[g]_X(\eta) = (2\pi i)^{-d} \int_{X_\infty} \eta \wedge g$, induces a well-defined map $\Psi\colon \widehat{\mathrm{CH}}^p(X, \mathcal{D}_{\log}) \to \widehat{\mathrm{CH}}^p(X)$ to the arithmetic Chow group of Gillet and Soulé, compatible with products and pull-backs; if $X_{\mathbb{R}}$ is projective, Ψ is an isomorphism, compatible with push-forwards. The current $g = 2(2\pi i)^{d-p+1}[g_y]_X$ is a Green current for y in the sense of Gillet and Soulé: $F_\infty^* g = (-1)^{p-1} g$ and $g(dd^c\eta) = \int_{X_\infty} \eta \wedge \omega - \int_{\widetilde{Y}} \imath^*\eta$ for all test forms η, with $\omega = (2\pi i)^{-p}\omega_y$ ($\imath\colon \widetilde{Y} \to X_\infty$ a resolution of the support of y, extended linearly).*

(BK5) *For $S = \operatorname{Spec}\mathbb{Z}$, the arithmetic degree $\widehat{\deg}\colon \widehat{\mathrm{CH}}^1(S, \mathcal{D}_{\log}) \to \mathbb{R}$, induced by*

$$\Big(\sum_j n_j \mathfrak{p}_j, (0, \widetilde{g})\Big) \mapsto \sum_j n_j \log|\mathbb{Z}/\mathfrak{p}_j| + g,$$

is an isomorphism, compatible under Ψ with the arithmetic degree of Gillet and Soulé.

Proof. This is [106] (J. I. Burgos Gil, J. Kramer, U. Kühn, Cohomological arithmetic Chow rings), specialised to the arithmetic ring $\mathbb{Z}$ (an arithmetic ring there: subrings of a number field with that field as fraction field), with the Gillet complex $\mathcal{D}_{\log}$ (contravariant $\mathcal{D}_{\log}$-arithmetic Chow groups). Locations, by the labels of the printed text: the definitions of arithmetic ring, arithmetic variety, $\widehat{\mathrm{CH}}^p$ (def:gacg) and of ζ, a, ω in the chapter on abstract arithmetic Chow groups; a on truncated relative cohomology in the section on truncated relative cohomology groups; $\mathrm{d}_{\mathcal{D}}$ and the product of the Deligne algebra in degrees $2p$, $2p-1$ in the review of Deligne algebras; $\widetilde{\mathcal{D}}^{2p-1}_{\log}(X,p)$ at the beginning of the section on contravariant $\mathcal{D}_{\log}$-arithmetic Chow rings. (BK1): the theorem on the multiplicative structure of $\widehat{\mathrm{CH}}^*(X, \mathcal{D}_{\log})_{\mathbb{Q}}$ there, formula (eq:6) with Theorem thm:2, and Proposition prop:explicit (i). (BK2): the theorem on inverse images in that section, and Theorem thm:6 (iii) of the abstract theory ($\omega \circ f^* = f^{\#} \circ \omega$, $\zeta \circ f^* = f^* \circ \zeta$, $f^* \circ \mathrm{a} = \mathrm{a} \circ f^{\#}$), with $f^{\#}$ the pull-back of forms for the complexes $\mathcal{D}_{\log}$. (BK3): the theorem on direct images of contravariant arithmetic Chow rings (stated there as

a consequence of Theorem thm:properpushlog and Theorem thm:18), the construction of $\mathcal{F}$, u, v preceding Theorem thm:properpushlog, Definitions def:21 and def:22 (pseudo-morphisms and the induced direct image), and Theorem thm:18 (iii) of the abstract theory. (BK4): the Lemma and its proof preceding Theorem thm:24, Theorem thm:24, and equation eq:26 for $[\cdot]_X$. (BK5): the paragraph on the arithmetic degree map (eq:ar-deg), with the remark that the map a of loc. cit. is minus that of Gillet and Soulé and that the factor 2 is explained by Theorem thm:24. *Notation.* Their arithmetic Chow groups are written $\widehat{\mathrm{CH}}$ here, their map from forms to arithmetic Chow groups is written a here, their X_F for $F = \mathbb{Q}$ is $X_{\mathbb{Q}}$; their general arithmetic ring A is specialised to $\mathbb{Z}$. □

Proposition B.141. *Let X be a regular scheme, flat and projective over* $\operatorname{Spec}\mathbb{Z}$ *(an arithmetic variety over $\mathbb{Z}$ in the sense of Proposition B.140), of relative dimension d, and take the empty normal crossing divisor on $X_{\mathbb{R}}$. A hermitian vector bundle $\overline{E} = (E, h)$ on X is a vector bundle E with a smooth hermitian metric h on E_∞ over $X_\infty = X(\mathbb{C})$, invariant under complex conjugation. For a local frame ξ of E_∞ let $K(\xi) = \bar\partial(\partial h(\xi)\cdot h(\xi)^{-1})$ be the curvature matrix and, for a symmetric polynomial ϕ, let $\phi(E,h) = \phi(-K(\xi))$ be the Chern form (independent of ξ, closed, with component of degree k in $E^{k,k}\cap E^{2k}_{\mathbb{R}}(k)$, where (k) is the twist by $(2\pi i)^k$). Then:*

(BC1) *The natural inclusion $\mathcal{D}_{\log}\subseteq\mathcal{D}_{\mathrm{l,ll}}$ induces an isomorphism*

$$\iota\colon \widehat{\mathrm{CH}}^*(X,\mathcal{D}_{\log})\to\widehat{\mathrm{CH}}^*(X,\mathcal{D}_{\mathrm{l,ll}}),$$

compatible with inverse images, intersection products and arithmetic degrees; and

$$\widehat{\mathrm{CH}}^*(X,\mathcal{D}_{\mathrm{l,ll}}) = \widehat{\mathrm{CH}}^*(X,\mathcal{D}_{\mathrm{ls}}).$$

(BC2) *The assignment $[y,(\omega_y,\widetilde{g}_y)]\mapsto[y,2(2\pi i)^{d-p+1}[g_y]_X]$ induces an isomorphism*

$$\Psi\colon \widehat{\mathrm{CH}}^p(X,\mathcal{D}_{\mathrm{ls}})\to\widehat{\mathrm{CH}}^p(X)$$

onto the arithmetic Chow group of Gillet and Soulé, compatible with products and pull-backs.

(BC3) *For every $k\geq 0$ and every hermitian vector bundle $\overline{E}$ of rank n on X there is a class $\widehat{c}_k(\overline{E})\in\widehat{\mathrm{CH}}^k(X,\mathcal{D}_{\mathrm{ls}})$ (the class $\widehat{\phi}(\overline{E})$ for ϕ the k-th elementary symmetric polynomial e_k in n variables) such that:*

1. *$f^*\widehat{c}_k(\overline{E}) = \widehat{c}_k(f^*\overline{E})$ for every morphism $f\colon X'\to X$ of regular schemes flat and projective over $\mathbb{Z}$;*
2. *if $\overline{E} = \overline{L}_1\oplus\cdots\oplus\overline{L}_n$ is an orthogonal direct sum of hermitian line bundles, then $\widehat{c}_k(\overline{E}) = e_k(\widehat{c}_1(\overline{L}_1),\dots,\widehat{c}_1(\overline{L}_n))$;*
3. *for hermitian line bundles $\overline{L}$, $\overline{M}$: $\widehat{c}_1(\overline{L}\otimes\overline{M}) = \widehat{c}_1(\overline{L})+\widehat{c}_1(\overline{M})$;*
4. *$\omega(\widehat{c}_k(\overline{E})) = e_k(-K(\xi))$, the Chern form of degree k;*
5. *$\Psi(\widehat{c}_k(\overline{E}))$ is the k-th arithmetic Chern class of $\overline{E}$ defined by Gillet and Soulé.*

(BC4) *The forgetful map $\zeta\colon\widehat{\mathrm{CH}}^*(X,\mathcal{D}_{\mathrm{ls}})\to\mathrm{CH}^*(X)$ is compatible with inverse images and with Chern classes: $\zeta(\widehat{c}_k(\overline{E})) = c_k(E)$.*

(BC5) *The sequence $H^{2p-1}_{\mathcal{D}}(X_{\mathbb{R}},\mathbb{R}(p))\xrightarrow{\mathrm{a}}\widehat{\mathrm{CH}}^p(X,\mathcal{D}_{\mathrm{l,ll}})\xrightarrow{(\zeta,-\omega)}\mathrm{CH}^p(X)\oplus\mathrm{Z}\mathcal{D}^{2p}_{\mathrm{l,ll}}(X,p)$ is exact, where $H^{2p-1}_{\mathcal{D}}(X_{\mathbb{R}},\mathbb{R}(p)) = H^{2p-1}(\mathcal{D}_{\mathrm{l,ll}}(X,p))$ is the subgroup of $\widetilde{\mathcal{D}}^{2p-1}_{\mathrm{l,ll}}(X,p)$ of classes of $\mathrm{d}_{\mathcal{D}}$-closed elements and* a *is its restriction.*

Proof. This is [107] (J. I. Burgos Gil, J. Kramer, U. Kühn, Arithmetic characteristic classes of automorphic vector bundles), specialised to the arithmetic ring $\mathbb{Z}$, to the empty normal crossing divisor and to smooth metrics; the paper's arithmetic varieties are regular (its section on non-regular varieties says so by contrast). Locations, by the labels of the printed text. (BC1): the paragraph defining the log-log arithmetic Chow groups (the natural inclusion $\mathcal{D}_{\log} \to \mathcal{D}_{\mathrm{l,ll}}$), Theorem thm:7 (the induced morphism, compatible with inverse images, intersection products and arithmetic degrees; an isomorphism when the divisor is empty and X is projective), Remark rem:3 and the Remark after Theorem thm:11 (X projective: $\mathcal{D}_{\mathrm{ls}} = \mathcal{D}_{\mathrm{l,ll}}$ and the groups agree). (BC2): Theorem thm:8. (BC3): Theorem thm:11 with $\phi = e_k$, $B = \mathbb{Z}$ and empty divisor (a log-singular metric along the empty divisor is a smooth metric): items Functoriality, Normalization, Twist by a line bundle (with $n = 1$, $\phi = T$: $\phi(T_1+T) = T_1+T$), Compatibility with characteristic forms, Compatibility with the definition of Gillet and Soulé; the Chern forms and their basic properties in the subsection on Chern forms for hermitian metrics (Theorem thm:20). (BC5): Theorem thm:16 (second exact sequence), with the identification of H^{2p-1} of the complex $\mathcal{D}_{\mathrm{l,ll}}$ with Deligne–Beilinson cohomology as in the paragraph on Green objects with values in $\mathcal{D}_{\mathrm{l,ll}}$; the same exact sequence in the normalisation of Gillet and Soulé is [110], Theorem 3.3.5 (ii), p. 128, with $H^{p-1,p-1}(X_{\mathbb{R}})$ identified on p. 130 with $\mathrm{Ker}(dd^c)$ on $\widetilde{A}^{p-1,p-1}(X_{\mathbb{R}})$ (read in print). (BC4): the list in the section "Some remarks on the properties" (items on the inverse image of $\widehat{c}_r$ and on the forgetful morphism ζ, "compatible with inverse images and Chern classes"). Remark on the grounding: for the empty divisor the classes are defined in the printed proof as Ψ^{-1} of the classes of Gillet and Soulé (H. Gillet, C. Soulé, Characteristic classes for algebraic vector bundles with hermitian metric I, II, Ann. of Math. 131 (1990)), and "all the properties stated in the theorem can be checked as in" that paper; (BC4) is stated in the summary list without a separate proof. *Notation.* Their arithmetic Chow groups are written $\widehat{\mathrm{CH}}$ here, their arithmetic Chern classes $\widehat{c}_r$, and their log-log and log-singular complexes $\mathcal{D}_{\mathrm{l,ll}}$ and $\mathcal{D}_{\mathrm{ls}}$. □

B.8 Algebraic and complex geometry

Part VI and Appendix D use resolution of singularities, in Kollár's form of Hironaka's theorem (Theorem B.142), and the asymptotic Hodge theory of a polarised variation of Hodge structure along a normal crossings divisor: Schmid's nilpotent orbit theorem, the Hodge norm estimates of Kashiwara and of Cattani, Kaplan and Schmid, and Griffiths's seminegativity of the last Hodge quotient (Theorem B.145, Theorem B.146, Theorem B.147, Theorem B.144). These are used for good origins, the facts of good towers and base settings (Sections 33, 34 and D.1). The other statements of algebraic geometry (finite free quotients, nef and big line bundles, GAGA, localized Chern characters, flattening by blow-up, quotients by finite locally free group schemes and norms of ample line bundles) are used in Part VI, four of them for linked stages (Section 35). Part IX quotes four facts of commutative algebra on Noetherian local rings: Chevalley's lemma, the dimension formula, Grothendieck's connectedness theorem and the bound of the Krull dimension by the embedding dimension (Theorem B.154, Theorem B.155, Theorem B.156, Theorem B.157), used in Sections 49, 50 and 53.

Theorem B.142. *Let k be a field of characteristic zero. A divisor $E = \sum_i E^i$ on a smooth variety X over k is a* ***simple normal crossing divisor*** *if every E^i is smooth and for every point $x \in X$ there are local coordinates $z_1, \dots, z_n$ in the maximal ideal $\mathfrak{m}_x$ of $\mathcal{O}_{x,X}$ such that for every i either $x \notin E^i$, or $E^i = (z_{c(i)} = 0)$ in a neighbourhood of x, with $c(i) \neq c(i')$ for $i \neq i'$.*

(A) (Strong resolution.) Let X be a quasi-projective variety over k. There is a birational and projective morphism $\Pi\colon R(X) \to X$ such that $R(X)$ is smooth, Π is an isomorphism over the smooth locus X^{ns}, and $\Pi^{-1}(\mathrm{Sing}\, X)$ is a divisor with simple normal crossings.

(B) (Principalisation.) Let X be a smooth scheme of finite type over k and $I \subseteq \mathcal{O}_X$ an ideal sheaf that is not zero on any irreducible component of X. There is a finite sequence of blow-ups $\Pi\colon X_r \to X_{r-1} \to \cdots \to X_0 = X$ with smooth centres (so that X_r is smooth and Π is projective) such that $\Pi^* I \subseteq \mathcal{O}_{X_r}$ is the ideal sheaf of a simple normal crossing divisor and Π is an isomorphism over $X \setminus \operatorname{cosupp} I$.

Proof. [131] (Main Theorems I and II, the original theorem); in the strong form stated here [148], Chapter 3: (A) is Theorem 3.27 (Resolution of singularities, II), (B) is Theorem 3.35 (Principalization, IV), items (1)–(3) with $E = \varnothing$, and the definition of simple normal crossing divisors is Definition 3.24; the remark that a composite of blow-ups with smooth centres has smooth source and is birational and projective follows Theorem 3.26 there. Notation as in loc. cit.; $\operatorname{cosupp} I$ is the closed subset where $I \neq \mathcal{O}_X$. □

Theorem B.143. *Let a finite group Γ act freely on a quasi-projective scheme X of finite type over a field K. Then the fppf quotient $Y = X/\Gamma$ is a quasi-projective K-scheme, and $X \to Y$ is a finite étale surjective Γ-torsor.*

Proof. The scheme-quotient and torsor assertions are the finite constant-group case of [241], Lemma 66.14.2. The constant group scheme is finite étale, so its torsor is finite étale. Write $\pi : X \to Y$ for this torsor. Finite type over K descends along this finite étale surjective cover, so Y is of finite type over K.

For completeness, quasi-projectivity follows by the ample-norm argument. Choose a very ample line bundle $\mathcal{B}$ on X and form

$$\mathcal{N} = \bigotimes_{\gamma \in \Gamma} \gamma^* \mathcal{B}.$$

Permuting the factors gives a canonical linearisation. Descent for invertible sheaves along the torsor gives a line bundle $\mathcal{C}$ on Y whose pullback is $\mathcal{N}$.

We verify the affine-section criterion for its ampleness. For any closed point $y \in Y$ and open neighbourhood U of y, there are an integer $n > 0$ and a section s of $\mathcal{B}^{\otimes n}$ nonzero on the finite fibre over y, vanishing on $X \setminus \pi^{-1}(U)$, and with affine nonvanishing locus. Indeed embed X in projective space by $\mathcal{B}$, take its projective closure, and choose a homogeneous polynomial vanishing on the boundary and on the closure of $X \setminus \pi^{-1}(U)$, but nonzero on that finite fibre. Such a polynomial of sufficiently large degree exists by interpolation on a finite closed subscheme disjoint from that closed set. Its projective nonvanishing locus intersected with the closure is affine and lies inside X.

The norm $\bigotimes_\gamma \gamma^* s$ is invariant, so descends to a section of $\mathcal{C}^{\otimes n}$. Its nonvanishing preimage is the intersection of the translates of the affine nonvanishing locus of s. This is affine because X is separated; it is invariant and lies in $\pi^{-1}(U)$. Its quotient is affine, with coordinate ring the invariants, by the affine quotient construction. Thus sections of positive powers of $\mathcal{C}$ give affine neighbourhoods of all closed points, refining every open neighbourhood. Since Y is of finite type over a field, closed points detect nonempty closed subsets, and this proves the affine-section criterion for ampleness. Hence Y has an ample line bundle and is quasi-projective over K. □

Theorem B.144. *Let S be a complex manifold and $(\mathcal{H}_\mathbb{Z}, \mathcal{F}^\bullet, Q)$ a polarised variation of Hodge structure of weight w on S, $\mathcal{H} = \mathcal{H}_\mathbb{Z} \otimes \mathcal{O}_S$. Let a be the largest integer with $\mathcal{F}^a = \mathcal{H}$ and give the holomorphic vector bundle $\mathcal{E} = \mathcal{H}/\mathcal{F}^{a+1}$ the Hodge metric, i.e. the metric of the Hodge form $Q(C\cdot, \bar{\cdot})$ transported by the isomorphism $\mathcal{H}^{a,w-a} \to \mathcal{E}$ from the Hodge summand $\mathcal{H}^{a,w-a}$ (the orthogonal complement of $\mathcal{F}^{a+1}$). Then $\mathcal{E}$ is Griffiths seminegative: for every holomorphic section s of $\mathcal{E}$ on an open subset of S, the function $\log \|s\|^2$ is plurisubharmonic where $s \neq 0$.*

Proof. [114, §7], curvature of the Hodge bundles; in print: [216, Lemma (7.18), p. 271] (curvature of F^p/F^{p+1} with the metric $i^{2p-w}Q(\cdot,\bar{\cdot})$ transported from $\mathcal{H}^{p,w-p}$), and Lemma (7.19), p. 272; see also [196]. The curvature of the Hodge bundle $\mathcal{H}^{p,w-p}$ is $-\sigma_p^*\wedge\sigma_p-\sigma_{p+1}\wedge\sigma_{p+1}^*$ up to the sign conventions, where σ_p is the second fundamental form (the Higgs field) $\mathcal{H}^{p,w-p}\to\mathcal{H}^{p-1,w-p+1}\otimes\Omega^1$; for the last quotient ($p=a$: $\mathcal{H}^{a-1,w-a+1}=0$, so $\sigma_a=0$) only the term $-\sigma_{a+1}\wedge\sigma_{a+1}^*$ survives, so $(\Theta(X,\bar X)v,v)=-\|\sigma_{a+1}^*(\bar X)v\|^2\le 0$ for every $(1,0)$-vector X and $v\in\mathcal{E}$ (Schmid, loc. cit., the last display of the proof of (7.18)). For a holomorphic section $s\neq 0$ with Chern connection D, Schmid's identity (7.13), $\partial\bar\partial\|s\|^2=(Ds,Ds)-(\Theta s,s)$, gives

$$\partial\bar\partial\log\|s\|^2(X,\bar X)=\frac{\|s\|^2\|D_Xs\|^2-|(D_Xs,s)|^2}{\|s\|^4}-\frac{(\Theta(X,\bar X)s,s)}{\|s\|^2}\ge 0$$

by the Cauchy–Schwarz inequality, so $\log\|s\|^2$ is plurisubharmonic. Notation: $\mathcal{F}^\bullet$ is the Hodge filtration, C the Weil operator. □

Theorem B.145. *Let $1\le a\le d$, $\Delta=\{z\in\mathbb{C}:|z|<1\}$, $\Delta_\rho=\{|z|<\rho\}$, $V=\Delta^d$, $V^*=\{t\in V:t_1\cdots t_a\neq 0\}$ and $D=V\smallsetminus V^*$. Let $(\mathbb{H},\mathcal{F}^\bullet,Q)$ be a polarised variation of Hodge structure of weight w on V^*: $\mathbb{H}$ a local system of free $\mathbb{Z}$-modules of finite rank, Q a flat non-degenerate $(-1)^w$-symmetric bilinear form on $\mathbb{H}$, and $\mathcal{F}^\bullet$ a decreasing filtration of $\mathcal{H}=\mathbb{H}\otimes_{\mathbb{Z}}\mathcal{O}_{V^*}$ by holomorphic subbundles satisfying Griffiths transversality and inducing at every point a Hodge structure of weight w polarised by Q. Let H be the space of flat sections of $\mathbb{H}\otimes\mathbb{C}$ over the universal cover of V^*, T_j ($1\le j\le a$) the monodromy of the loop $\theta\mapsto(\frac12,\dots,\frac12e^{i\theta},\dots,\frac12,0,\dots,0)$ ($e^{i\theta}$ in the j-th place, $\frac12$ in the other first a places) acting on H, and assume every T_j unipotent; the T_j commute, and we put $N_j=\log T_j$. For $s\in H$ let $\tilde s=\exp(-\sum_{j=1}^a\frac{\log t_j}{2\pi i}N_j)s$, a single-valued holomorphic section of $\mathcal{H}\otimes\mathbb{C}$ over V^*; Deligne's canonical extension $\widehat{\mathcal{H}}$ of $\mathcal{H}\otimes\mathbb{C}$ is the holomorphic vector bundle on V with frame $\tilde s_1,\dots,\tilde s_r$ for a basis $s_1,\dots,s_r$ of H, and its fibre at every $x\in D$ is identified with H by $\tilde s(x)\mapsto s$. Then there is $\rho\in(0,1]$ such that:*

1. *each $\mathcal{F}^p|_{V^*\cap\Delta_\rho^d}$ extends to a holomorphic subbundle $\widehat{\mathcal{F}}^p$ of $\widehat{\mathcal{H}}|_{\Delta_\rho^d}$;*
2. *with $F_0^p\subseteq H$ the fibre of $\widehat{\mathcal{F}}^p$ at 0, $N=N_1+\cdots+N_a$ and W the monodromy weight filtration of N on H centred at w, the pair $(W,F_0^\bullet)$ is a mixed Hodge structure on H (rational structure $H_{\mathbb{Q}}$ the flat sections of $\mathbb{H}\otimes\mathbb{Q}$), with $NF_0^p\subseteq F_0^{p-1}$ and $NW_k\subseteq W_{k-2}$, polarised by N: for every $k\ge 0$ the pure Hodge structure of weight $w+k$ induced on the primitive part $P_{w+k}=\ker(N^{k+1}\colon\mathrm{Gr}^W_{w+k}\to\mathrm{Gr}^W_{w-k-2})$ is polarised by the form $Q(\cdot,N^k\cdot)$.*

For $a=1$ this is the case of one punctured coordinate with parameters $t_2,\dots,t_d$.

Proof. Clause 1 is the nilpotent orbit theorem of W. Schmid, *Variation of Hodge structure: the singularities of the period mapping*, Invent. Math. 22 (1973), 211–319, Theorem 4.12 (several variables; unpunctured parameters as in E. Cattani, A. Kaplan and W. Schmid, *Degeneration of Hodge structures*, Ann. of Math. (2) 123 (1986), 457–535, Section 1): the untwisted period map $\exp(-\sum_j\frac{\log t_j}{2\pi i}N_j)\mathcal{F}^\bullet$ extends holomorphically over V, which is the statement that the $\mathcal{F}^p$ extend to subbundles of $\widehat{\mathcal{H}}$. In this form it is used, for $V=\Delta^l$ and the divisor $\{z_1\cdots z_l=0\}$ with unipotent monodromies, in M. Kashiwara, *The asymptotic behavior of a variation of polarized Hodge structure*, Publ. RIMS 21 (1985), 853–875, (4.1.5)–(4.1.6). For clause 2, restrict to the disc $\phi(s)=(s,\dots,s,0,\dots,0)$ (s in the first a places): the pulled-back variation on Δ^* has monodromy $T_1\cdots T_a=\exp N$, and $\phi^*\tilde s=\exp(-\frac{\log s}{2\pi i}N)s$ is its canonical-extension frame, so its limit Hodge filtration is $F_0^\bullet$; clause 2 is then Schmid's theorem that the limit mixed Hodge structure in one variable is polarised by N (loc. cit., Theorem 6.16 with Lemma 6.4, printed there

for the cohomology of a family of polarised projective manifolds over Δ^*; for an abstract polarised variation on Δ^* the same statement is printed in [212], "Overview of the results", subsection "The limiting mixed Hodge structure", theorems "Limiting $\mathfrak{sl}_2$-Hodge structure" (items 1–3: each primitive subspace $\ker N^{k+1}$ of the k-th weight space is polarised by the hermitian pairing $Q(\cdot, N^k\cdot)$) and "Limiting mixed Hodge structure", for polarised complex variations with the hermitian form attached to Q; see also Cattani–Kaplan–Schmid, loc. cit., Section 2). Notation: Q is Schmid's polarisation S, W his $W(N)$ shifted to be centred at w, F_0 his limit filtration F_∞. □

Theorem B.146. *Let $1 \le a \le d$, $V = \Delta^d$, $V^* = \{t \in V : t_1 \cdots t_a \neq 0\}$, and let $(\mathbb{H}, \mathcal{F}^\bullet, Q)$ be a polarised variation of Hodge structure on V^* whose monodromies $T_1, \dots, T_a$ around the divisors $\{t_j = 0\}$ are unipotent; $N_j = \log T_j$. For $t \in V^*$ let $|u|_t^2 = Q(C_t u, \bar u)$ be the Hodge norm on $\mathbb{H}_t \otimes \mathbb{C}$ (C_t the Weil operator) and $y_j(t) = -\log|t_j|$. For a numbering $(j_1, \dots, j_a)$ of $\{1, \dots, a\}$ and $1 \le \nu \le a$ let $W(\nu)$ be the monodromy weight filtration (centred at 0: $NW_k \subseteq W_{k-2}$ and $N^k\colon \mathrm{Gr}_k \cong \mathrm{Gr}_{-k}$) of $N = \sum_{\mu \ge \nu} N_{j_\mu}$. Then there is $M > 0$ such that for every subanalytic set $U \subseteq V^*$ relatively compact in V, every $\varepsilon > 0$, every flat section u of $\mathbb{H} \otimes \mathbb{C}$ over U and all integers $p_1, \dots, p_a$ with $u \in \bigcap_\nu W_{p_\nu}(\nu)$ there is $C > 0$ with*

$$|u|_t^2 \;\le\; C\, y_{j_1}^{p_1} \Big(\frac{y_{j_2}}{y_{j_1}}\Big)^{p_2} \cdots \Big(\frac{y_{j_a}}{y_{j_{a-1}}}\Big)^{p_a}$$

for all $t \in U$ with $y_{j_\nu}(t) > M$ ($1 \le \nu \le a$) and $y_{j_\nu}(t)/y_{j_{\nu-1}}(t) > \varepsilon$ ($2 \le \nu \le a$).

Proof. M. Kashiwara [140, Theorem 3.4.1 (p. 870)], applied with $X = V$, $Y = \{t_1 \cdots t_a = 0\}$ (a normal crossing hypersurface), $x_0 = 0$, $\alpha = \{1, \dots, a\}$, $f_j = t_j$, and his $\alpha_\nu = \{j_\mu : \mu \ge \nu\}$; there the estimate is stated with $\sim$ (bounded above and below by positive multiples), of which only the upper bound is stated here. The same estimates are due independently to E. Cattani, A. Kaplan and W. Schmid [64, Section 5] (see [140, p. 855]). Notation: Kashiwara's $|u|_x$, $y_\nu = -\log|f_{j_\nu}|$, $W_p(\alpha_\nu)$ are $|u|_t$, y_{j_ν}, $W_p(\nu)$. □

Theorem B.147. *In the setting of Theorem B.146, fix a numbering $(j_1, \dots, j_a)$ of $\{1, \dots, a\}$. The filtrations $\widehat{W}(\nu) = W(\nu) \otimes \mathcal{O}$ of $\widehat{\mathcal{H}}$ ($1 \le \nu \le a$; flat filtrations, sections of $\widehat{\mathcal{H}}$ being combinations of the frame $\tilde s$) form a distributive family. Let $\widehat{\mathcal{H}} = \bigoplus_{p \in \mathbb{Z}^a} U_p$ be a splitting into C^∞ subbundles near 0 with $\widehat{W}_k(\nu) = \bigoplus_{p:\, p_\nu \le k} U_p$ for all ν, k, and $\|\cdot\|$ a C^∞ hermitian norm on $\widehat{\mathcal{H}}$ near 0. Then for every $\varepsilon > 0$ there are $C \ge 1$ and a neighbourhood V' of 0 such that for every $t \in V' \cap V^*$ with $y_{j_\nu}(t)/y_{j_{\nu-1}}(t) > \varepsilon$ ($2 \le \nu \le a$) and every $u = \sum_p u_p \in \widehat{\mathcal{H}}_t$, $u_p \in U_{p,t}$,*

$$C^{-1} \sum_p m_p(t) \|u_p\|^2 \;\le\; |u|_t^2 \;\le\; C \sum_p m_p(t) \|u_p\|^2, \qquad m_p = y_{j_1}^{p_1} \Big(\frac{y_{j_2}}{y_{j_1}}\Big)^{p_2} \cdots \Big(\frac{y_{j_a}}{y_{j_{a-1}}}\Big)^{p_a}.$$

Proof. M. Kashiwara [140, Theorem 3.4.2 (p. 870)], with $X = V$, $Y = \{t_1 \cdots t_a = 0\}$, $x_0 = 0$, $\alpha = \{1, \dots, a\}$, $\alpha_\nu = \{j_\mu : \mu \ge \nu\}$; for unipotent monodromy his $E^+(\mathcal{O} \otimes H_\mathbb{C})$ (characterised in 3.3.1 by residues with eigenvalues λ, $0 \le \operatorname{Re}\lambda < 1$) is Deligne's canonical extension $\widehat{\mathcal{H}}$, and $E^+(\mathcal{O} \otimes W(\alpha_\nu))$ is $\widehat{W}(\nu)$. Kashiwara's $\sim$ is, by his Definition 1.9.3 with (1.9.5), the two-sided comparison displayed, with one constant for all u and all points. Same estimates: [64, Section 5]. □

Theorem B.148. *Let X be an irreducible complex projective variety of dimension n and L a nef line bundle on X. Then:*

1. $h^0(X, L^{\otimes m}) = \dfrac{(L^n)}{n!}\, m^n + O(m^{n-1})$ *as* $m \to \infty$;

2. L *is big if and only if* $(L^n) > 0$;

3. *if* L *is big and* P *is an effective Cartier divisor on* X*, then* $H^0(X, L^{\otimes m} \otimes \mathcal{O}_X(-P)) \neq 0$ *for all sufficiently large* m.

Proof. (1) [160, I, Corollary 1.4.41]; (2) [160, I, Theorem 2.2.16]; (3) [160, I, Proposition 2.2.6] (Kodaira's lemma). Notation: $L^{\otimes m} = \mathcal{O}_X(mD)$ for a Cartier divisor D of L; $(L^n) = (D^n)$. □

Theorem B.149. *Let* X *be a reduced projective scheme over* $\mathbb{C}$ *(a closed reduced subscheme of some* $\mathbb{P}^N_{\mathbb{C}}$*, not necessarily irreducible),* X^{an} *the associated complex analytic space, and* $\mathcal{F}$ *a coherent* $\mathcal{O}_X$*-module with analytification* $\mathcal{F}^{\mathrm{an}} = \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_{X^{\mathrm{an}}}$*. Then for every* $i \geq 0$ *the natural map*

$$H^i(X, \mathcal{F}) \longrightarrow H^i(X^{\mathrm{an}}, \mathcal{F}^{\mathrm{an}})$$

is bijective. In particular, for an invertible sheaf $\mathcal{M}$ *on* X*, every holomorphic section of* $\mathcal{M}^{\mathrm{an}}$ *over* X^{an} *is the analytification of exactly one section of* $\mathcal{M}$ *over* X.

Proof. This is Serre's comparison theorem [219], Théorème 1 (Section 12), stated there for coherent algebraic sheaves on projective algebraic varieties over $\mathbb{C}$ in the sense of Serre's *Faisceaux algébriques cohérents* (closed subvarieties of a projective space, with the Zariski topology); a reduced projective scheme over $\mathbb{C}$ with a coherent sheaf is such a variety with such a sheaf, and the map of the statement is Serre's map ε. The last sentence is the case $i = 0$, $\mathcal{F} = \mathcal{M}$. □

Theorem B.150. *Let* S *be a noetherian universally catenary scheme with a dimension function* δ*, let* Y *be a quasi-compact scheme locally of finite type over* S*,* $i\colon Z \to Y$ *a closed immersion, and* E *an object of* $D(\mathcal{O}_Y)$ *represented by a bounded complex of finite locally free* $\mathcal{O}_Y$*-modules with* $E|_{Y \smallsetminus Z} \cong 0$*. Bivariant classes* $A^p(Z \to Y)$ *are as in the Stacks Project, Definition 42.33.1: for every* $Y' \to Y$ *locally of finite type, maps* $c \cap -\colon \mathrm{CH}_k(Y') \to \mathrm{CH}_{k-p}(Y' \times_Y Z)$ *compatible with proper push-forward, flat pull-back and the Gysin maps of zero schemes of sections of invertible modules. Then there are classes* $P_p(Z \to Y, E) \in A^p(Z \to Y)$*,* $p \geq 0$*, depending only on the isomorphism class of* E*; put* $\mathrm{ch}(Z \to Y, E) = \sum_{p \geq 0} P_p(Z \to Y, E)/p!$ *and* $\mathrm{ch}_p = P_p/p!$*. They satisfy:*

(L1) Push-forward $i_* \circ \mathrm{ch}_p(Z \to Y, E) = \mathrm{ch}_p(E)$*, the ordinary Chern character of* E*; in particular, for* $Z = Y$ *the localized Chern character is the ordinary one.*

(L2) Restriction *for* $f\colon Y' \to Y$ *locally of finite type,* $\mathrm{ch}_p(f^{-1}Z \to Y', Lf^*E)$ *is the restriction of* $\mathrm{ch}_p(Z \to Y, E)$ *to* Y'*, i.e.* $\mathrm{ch}_p(f^{-1}Z \to Y', Lf^*E) \cap \alpha = \mathrm{ch}_p(Z \to Y, E) \cap \alpha$ *for* $\alpha \in \mathrm{CH}_*(Y')$.

(L3) Change of support *if* $Z \subseteq Z' \subseteq Y$ *are closed subschemes, then* $\mathrm{ch}_p(Z' \to Y, E) = (Z \to Z')_* \circ \mathrm{ch}_p(Z \to Y, E)$.

(L4) Additivity *for a distinguished triangle* $E_1 \to E_2 \to E_3 \to E_1[1]$ *of such objects with* $E_1|_{Y \smallsetminus Z} \cong 0 \cong E_3|_{Y \smallsetminus Z}$*:* $\mathrm{ch}(Z \to Y, E_2) = \mathrm{ch}(Z \to Y, E_1) + \mathrm{ch}(Z \to Y, E_3)$.

(L5) Multiplicativity *for closed subschemes* Z_1, Z_2 *and such objects* F_1, F_2 *with* $F_j|_{Y \smallsetminus Z_j} \cong 0$*:* $\mathrm{ch}(Z_1 \cap Z_2 \to Y, F_1 \otimes^{\mathbf{L}} F_2) = \mathrm{ch}(Z_1 \to Y, F_1)\, \mathrm{ch}(Z_2 \to Y, F_2)$ *(product of bivariant classes).*

Proof. [244, Chapter 42 (Chow Homology)]: Definition 42.33.1 (bivariant classes), Lemma 42.50.2 with equation (42.50.2.1) (construction; (L1)), Definition 42.50.3 (the localized Chern character), Lemma 42.50.4 ((L2)), Lemma 42.50.8 ((L3)), Lemma 42.52.5 ((L4)), Lemma 42.52.6 ((L5)). Hypothesis (3) of Situation 42.50.1 holds here because E is a bounded complex of finite locally free modules, and Y is quasi-compact. □

Theorem B.151. *Let S be a quasi-compact and quasi-separated scheme, $U \subseteq S$ a quasi-compact open subscheme, $f\colon X \to S$ a morphism of finite presentation and $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module of finite type such that $\mathcal{F}|_{f^{-1}(U)}$ is of finite presentation and flat over U. Then there is a U-admissible blow-up $b\colon S' \to S$ (the blow-up of S in a closed subscheme of finite presentation disjoint from U) such that the strict transform of $\mathcal{F}$, i.e. the quotient of the pull-back of $\mathcal{F}$ to $X \times_S S'$ by its subsheaf of sections supported in the preimage of $S \setminus U$, is of finite presentation and flat over S'.*

Proof. [243, Theorem 38.30.7, Tag 0815], a result of Raynaud and Gruson [206, première partie, Théorème 5.2.2]. Notation: identical; the case used later is $X = S$, where flat and of finite presentation means locally free of finite rank. □

Theorem B.152. *Let S be a scheme, G a finite locally free S-group scheme and X an S-scheme with an action $\alpha\colon G \times_S X \to X$ of G which is free, i.e. the morphism $G \times_S X \to X \times_S X$, $(g, x) \mapsto (\alpha(g, x), x)$, is a monomorphism, and such that for every point x of X the image of $G \times_S \operatorname{Spec} \kappa(x) \to X$, $g \mapsto \alpha(g, x)$, is contained in an affine open subscheme of X. Then there is a morphism of S-schemes $p\colon X \to Y$ with $p \circ \alpha = p \circ \mathrm{pr}_2$ which is finite, locally free and surjective, and such that*

$$G \times_S X \longrightarrow X \times_Y X, \qquad (g, x) \longmapsto (\alpha(g, x), x),$$

is an isomorphism.

Proof. [226], Exp. V, Th. 4.1 (existence of the quotient of a finite locally free groupoid whose orbits lie in affine open subschemes; for a free action, part (iv): p finite locally free and $G \times_S X \cong X \times_Y X$). The same statement is Theorem (4.16)(i)–(ii) of Ch. IV of the book draft *Abelian varieties* of B. Edixhoven, G. van der Geer and B. Moonen. □

Theorem B.153. *Let Y be a scheme, $f\colon X \to Y$ a quasi-compact morphism and $g\colon X' \to X$ a finite surjective morphism such that $g_*\mathcal{O}_{X'}$ is a locally free $\mathcal{O}_X$-module. Then for every invertible $\mathcal{O}_{X'}$-module $\mathcal{L}'$ ample relative to $f \circ g$, its norm $\mathrm{N}_{X'/X}(\mathcal{L}')$ ([81], §6.5) is ample relative to f.*

Proof. [81], Proposition (6.6.1) (case $g_*\mathcal{O}_{X'}$ locally free). □

Theorem B.154. *Let $(A, \mathfrak{m})$ be a complete Noetherian local ring, M a finitely generated A-module and $M_1 \supseteq M_2 \supseteq \cdots$ a decreasing sequence of A-submodules of M with $\bigcap_{t \geq 1} M_t = 0$. Then for every $k \geq 1$ there is $t \geq 1$ with $M_t \subseteq \mathfrak{m}^k M$.*

Proof. This is Chevalley's lemma; see [274, Ch. VIII, §5, Theorem 13] (for ideals of a complete semi-local ring), and, in the stated form for finitely generated modules over a complete local ring, e.g. [170, Lemma 9.7]. The notation agrees with that of these references. □

Theorem B.155. *Let A be a Noetherian domain, $B \supseteq A$ a domain that is finitely generated as an A-algebra, P a prime of B and $\mathfrak{p} = P \cap A$.*

1. $\operatorname{ht} P + \operatorname{trdeg}_{\kappa(\mathfrak{p})} \kappa(P) \leq \operatorname{ht} \mathfrak{p} + \operatorname{trdeg}_A B$.

2. *If A is universally catenary, equality holds in 1.*

3. *Every complete Noetherian local ring, and every quotient of one, is universally catenary.*

Proof. Item 1 is the dimension inequality and item 2 the dimension formula of Ratliff, [166, Theorems 15.5 and 15.6]. Item 3: a complete Noetherian local ring is a quotient of a regular local ring by Cohen's structure theorem [166, Theorem 29.4], a regular local ring is Cohen–Macaulay, a Cohen–Macaulay ring is universally catenary [166, Theorem 17.9], and a quotient of a universally catenary ring is universally catenary (finitely generated algebras over the quotient are finitely generated over the ring). Notation is that of the reference. □

Theorem B.156. *For a Noetherian topological space T of finite dimension, the* connectedness dimension *is*

$$c(T) = \min\{\dim Z : \ Z \subseteq T \text{ closed}, \ T \setminus Z \text{ disconnected}\},$$

where the empty space counts as disconnected and has dimension -1; for $T \neq \emptyset$ the subdimension $\operatorname{sdim} T$ *is the minimum of the dimensions of the irreducible components of T. For a ring C write $c(C) = c(\operatorname{Spec} C)$ and $\operatorname{sdim} C = \operatorname{sdim} \operatorname{Spec} C$. Let $(R, \mathfrak{m})$ be a complete Noetherian local ring and let $a_1, \dots, a_h \in \mathfrak{m}$. Then*

$$c(R/(a_1, \dots, a_h)) \ \geq \ \min\{c(R), \ \operatorname{sdim} R - 1\} - h.$$

Proof. See Grothendieck [225], Exposé XIII, Théorème 2.1; Brodmann–Sharp [53], Theorem 19.2.9, where the right side is $\min\{c(R), \operatorname{sdim} R - 1\} - \operatorname{ara}(\mathfrak{a})$ with $\operatorname{ara}(\mathfrak{a})$ the arithmetic rank of $\mathfrak{a} = (a_1, \dots, a_h)$ (the least number of elements generating an ideal with the radical of $\mathfrak{a}$); here $\operatorname{ara}(\mathfrak{a}) \leq h$. The notation is that of these references, with the convention of Brodmann–Sharp, Chapter 19, that the empty space is disconnected of dimension -1. □

Theorem B.157. *Let $(A, \mathfrak{m})$ be a Noetherian local ring with residue field $\kappa = A/\mathfrak{m}$. Then $\dim_\kappa \mathfrak{m}/\mathfrak{m}^2$ is finite and the Krull dimension of A satisfies $\dim A \leq \dim_\kappa \mathfrak{m}/\mathfrak{m}^2$.*

Proof. This is the dimension theorem for Noetherian local rings: $\dim A$ equals the least number of generators of an $\mathfrak{m}$-primary ideal, and $\mathfrak{m}$ is generated by $\dim_\kappa \mathfrak{m}/\mathfrak{m}^2$ elements by Nakayama's lemma. See M. F. Atiyah and I. G. Macdonald, Introduction to Commutative Algebra (1969), Corollary 11.15, and [166], Theorem 13.4 and the remarks following it. The notation there is the same. □

B.9 Representation theory and groups

Siegel's formula for unitary groups in Weil's convergent range (Theorem B.158) is used for the row estimates of Part III (Section 15). Strong approximation, Minkowski's lemma on torsion-free congruence subgroups and the reduction theory of Borel and Harish-Chandra (Theorem B.159, Theorem B.160, Theorem B.165) are used for good root towers in Part VI and Appendix D. Part VII uses the principal series of GL_n over a p-adic field and the theorem of Borel and Serre for the plus part (Section 38), and van der Kallen's homological stability and the theorem of Quillen and Milnor–Moore for the second cohomology of Tate twists (Section 40). Appendix E uses the principal series again, the zero-monodromy types of Schneider and Zink, the Bernstein presentation of the Iwahori–Hecke algebra and the braid relations in the pro-p Iwahori Hecke ring (Sections E.1 and E.5).

Theorem B.158. *Let E/F be a CM extension, let V be a nondegenerate hermitian space over E of dimension n with form $\langle\,,\rangle$, let $G=\mathrm{U}(V)$, and let $a\geq 1$ be an integer with $2a<n$. For an F-algebra R write $V_R=V\otimes_F R$ and let* $\mathrm{gram}\colon V_R^a\to \mathrm{Herm}_a(R)$, $\mathrm{gram}(x)=(\langle x_i,x_j\rangle)_{i,j}$, *be the Gram map,* Herm_a *denoting hermitian $a\times a$ matrices over $E\otimes_F R$. For a place w of F let dx_w be the Haar measure on $V_{F_w}^a$ that is self-dual for the pairing $(x,y)\mapsto \psi_w(\mathrm{tr}_{E_w/F_w}\sum_i\langle x_i,y_i\rangle)$, and db_w the Haar measure on* $\mathrm{Herm}_a(F_w)$ *that is self-dual for $(b,b')\mapsto\psi_w(\mathrm{tr}\,bb')$. Let $\Phi=\Phi_\infty\otimes\bigotimes_{w<\infty}\Phi_w$, where Φ_∞ is a smooth compactly supported function on $V_{F_\infty}^a$, $F_\infty=F\otimes_{\mathbb{Q}}\mathbb{R}$, each Φ_w is a Schwartz–Bruhat function on $V_{F_w}^a$, and Φ_w is the characteristic function of $(L\otimes\mathcal{O}_{F_w})^a$ for all but finitely many w, for an $\mathcal{O}_E$-lattice $L\subset V$ (an* admissible test function*). Let $T\in\mathrm{Herm}_a(F)$ be nondegenerate. Then:*

1. *for every Haar measure μ on $G(\mathbb{A}_F)$, the quotient $[G]$ has finite volume $\mu([G])$;*
2. *for every place w (with ∞ standing for the product of the archimedean places), the image under* gram *of the measure $\Phi_w\,dx_w$, restricted to the open set of x with* $\det\mathrm{gram}(x)$ *invertible, has a continuous density $b\mapsto g_w(\Phi_w,b)$ with respect to db_w on the open set of nondegenerate matrices, and the product $\prod_{w<\infty}g_w(\Phi_w,T)$ converges;*
3. *the function $\vartheta_T(g)=\sum_{X\in V^a,\ \mathrm{gram}(X)=T}\Phi(g^{-1}X)$ on $[G]$ is integrable, and*

$$\frac{1}{\mu([G])}\int_{[G]}\vartheta_T(g)\,d\mu(g)=g_\infty(\Phi_\infty,T)\prod_{w<\infty}g_w(\Phi_w,T).$$

Proof. [268], Chapter VI, section 52, Theorem 5 and formula (41), together with Chapter III, section 37, Proposition 6 and formula (29), and Chapter IV, section 42. In Weil's notation take $k=F$, the algebra with involution $\mathrm{End}_E(V)$ with its adjoint involution, and $X=V^a$. This is type (I_2) with $\epsilon=1/2$, so his condition (B) is $n>2a$. His invariant map is $x\mapsto x^*hx$, namely the displayed Gram map. The auxiliary local hypothesis of Theorem 5 holds at a finite place: condition (B) gives a nonempty full-rank zero-Gram fibre there by section 38, and Witt extension makes the full local unitary group transitive on each full-rank Gram fibre. If r is the Witt index of V, then $r\leq n/2$ and hence $n-r>a$; Proposition 8 in section 51 gives absolute convergence. Formula (41), with its normalized Haar specialization, gives the asserted mean as the product of the local relative-gauge integrals. Proposition 6 identifies these with continuous pushforward densities; section 42 gives absolute convergence of the product. Nondegenerate T forces every tuple in its fibre to have full rank, so its full-rank sum is ϑ_T.

The following calculation identifies the measures, with no unspecified local scalar. Choose rational F-bases on $X=V^a$ and $Y=\mathrm{Herm}_a$. Let dx_w^0,db_w^0 be the coordinate measures obtained from the ψ_w-self-dual measure on F_w. For the two nondegenerate F-bilinear pairings displayed in the statement let B_X,B_Y be their matrices in these bases. Fourier inversion and linear change of variables give

$$dx_w=|\det B_X|_w^{1/2}dx_w^0,\qquad db_w=|\det B_Y|_w^{1/2}db_w^0.$$

Let g_w^0 be the pushforward density for the same Gram map with the coordinate measures dx_w^0,db_w^0. Consequently the relative density for the measures in the statement is

$$g_w(\Phi_w,T)=\left|\frac{\det B_X}{\det B_Y}\right|_w^{1/2}g_w^0(\Phi_w,T).$$

Both determinants lie in $F^\times$. The product formula makes the product of the displayed positive factors equal to one, including the archimedean factors; only finitely many finite factors

differ from one. Thus the product of Weil's relative-gauge densities equals the product in the statement, also at dyadic and split places. This is a measure comparison, with no Weil-index factor.

Weil uses the Haar measure for which the right quotient has volume one. Inversion transfers it to the left quotient because $\mathrm{U}(V)$ is unimodular, replacing the action uX by $g^{-1}X$ and preserving total volume. For any Haar μ, its normalization is $\mu/\mu([G])$, so the mean is unchanged. Quotient finiteness (item 1) is the classical finite-volume theorem for unitary groups (Borel–Harish-Chandra). Smooth compactly supported archimedean test functions belong to the Schwartz space used there, as do the given finite factors. For hermitian b, b', $\mathrm{tr}(bb') \in F_w$, so the matrix pairing also equals $\frac{1}{2}\operatorname{Tr}_{E_w/F_w}\mathrm{tr}(bb')$, if written in that alternative convention. □

Theorem B.159. *Let K be a number field, $\mathbb{A}_K$ its ring of adeles, and H a connected, simply connected, absolutely almost simple linear algebraic group over K. Let S be a finite set of places of K, and let $\mathbb{A}_K^S$ be the ring of adeles of K with the components at the places of S omitted, so that $H(K)$ embeds diagonally in $H(\mathbb{A}_K^S)$. If the group $H_S = \prod_{v\in S} H(K_v)$ is not compact, then $H(K)$ is dense in $H(\mathbb{A}_K^S)$.*

Proof. M. Kneser, Strong approximation, in: Algebraic Groups and Discontinuous Subgroups, Proc. Sympos. Pure Math. 9 (1966) [146]; V. P. Platonov, Izv. Akad. Nauk SSSR 33 (1969); stated in this form (for global fields, with the converse) as Theorem 2.3 of A. S. Rapinchuk, Strong approximation for algebraic groups, in: Arithmetic, geometry, cryptography and coding theory 2009, Contemp. Math. 521 (2010), 15–32; see also [200], §7.4. Notation: Rapinchuk's G, $\mathbb{A}_S$, G_S are our H, $\mathbb{A}_K^S$, H_S; only the sufficiency half is quoted. □

Theorem B.160. *Let $n \geq 1$ and $m \geq 3$ be integers. Then the kernel of the reduction map $\mathrm{GL}_n(\mathbb{Z}) \to \mathrm{GL}_n(\mathbb{Z}/m\mathbb{Z})$ is torsion-free. Equivalently: if $A \in \mathrm{GL}_n(\mathbb{Z})$ has finite order and $A - 1_n \in m\,\mathrm{M}_n(\mathbb{Z})$, then $A = 1_n$.*

Proof. This is Minkowski's lemma (H. Minkowski, Zur Theorie der positiven quadratischen Formen, J. Reine Angew. Math. 101 (1887)), in the form printed in [223], Lecture I, Lemma 1: "If $m \geq 3$, the kernel of $\mathrm{GL}_n(\mathbb{Z}) \to \mathrm{GL}_n(\mathbb{Z}/m\mathbb{Z})$ is torsion free." The second sentence restates it: an element of finite order of the kernel is trivial. The hypothesis $m \geq 3$ cannot be dropped: -1_n has order 2 and lies in the kernel for $m = 2$. □

Theorem B.161. *Let F_v be a non-archimedean local field with ring of integers $\mathcal{O}_v$, $n \geq 1$, $G = \mathrm{GL}_n(F_v)$, $B = TN$ the upper triangular Borel subgroup with diagonal torus T and unipotent radical N, $\bar{N}$ the lower triangular unipotent subgroup and δ_B the modulus character of B. For characters $\xi_1, \dots, \xi_n$ of $F_v^\times$ let $I(\xi_1, \dots, \xi_n)$ be the normalised induction: the smooth functions $f\colon G \to \mathbb{C}$ with $f(tug) = \delta_B^{1/2}(t)\prod_i \xi_i(t_i) f(g)$ for $t = \mathrm{diag}(t_1, \dots, t_n) \in T$, $u \in N$, G acting by right translation. For a smooth representation V of G, V_N is its Jacquet module (the coinvariants of N), a smooth representation of T.*

(Ps1) *Every irreducible subquotient of $I(\xi_1, \dots, \xi_n)$ is isomorphic to a subrepresentation of $I(\xi_{s(1)}, \dots, \xi_{s(n)})$ for some permutation s of $\{1, \dots, n\}$.*

(Ps2) *If $\xi_i\xi_j^{-1} \neq |\cdot|_v$ for all $i \neq j$, then $I(\xi_1, \dots, \xi_n)$ is irreducible.*

(Ps3) *(Jacquet's lemma) If $K \subseteq G$ is a compact open subgroup with $K = (K \cap \bar{N})(K \cap T)(K \cap N)$, then for every admissible representation V of G the projection $V \to V_N$ maps V^K onto $(V_N)^{K\cap T}$.*

Proof. (Ps1): [27], Theorem 2.9 (an irreducible subquotient of a representation induced from a cuspidal representation of a Levi subgroup embeds into the induction of a Weyl conjugate; here the Levi subgroup is T, whose characters are cuspidal, and the Weyl group S_n acts by permuting the ξ_i). (Ps2): [275], Theorem 4.2 (a product of segments that are pairwise not linked is irreducible; the one-element segments $\{\xi_i\}$, $\{\xi_j\}$ are linked exactly when $\xi_j = \xi_i|\cdot|_v^{\pm 1}$), equivalently [27], Theorem 4.2 for GL_n. (Ps3): [62], Theorem 3.3.3. *Notation.* The normalised induction of [27] is $I(\xi_1,\dots,\xi_n)$ (functions transforming on the left, $\delta_B^{1/2}$ included). □

Theorem B.162. *Let F be a number field with ring of integers $\mathcal{O}_F$, $n \geq 1$, and Γ a torsion-free subgroup of $\mathrm{GL}_n(F)$ commensurable with $\mathrm{GL}_n(\mathcal{O}_F)$. Then there are integers $d, r_0, \dots, r_d \geq 0$ and an exact sequence of $\mathbb{C}[\Gamma]$-modules*

$$0 \to \mathbb{C}[\Gamma]^{r_d} \to \cdots \to \mathbb{C}[\Gamma]^{r_1} \to \mathbb{C}[\Gamma]^{r_0} \to \mathbb{C} \to 0,$$

where $\mathbb{C}$ carries the trivial action.

Proof. [43], §11: Γ is an arithmetic subgroup of $\mathrm{Res}_{F/\mathbb{Q}}\mathrm{GL}_n$; it acts freely and properly on the contractible Borel–Serre bordification $\overline{X}$ of its symmetric space with compact quotient, a compact manifold with corners, so $\Gamma\backslash\overline{X}$ is a finite $K(\Gamma,1)$ complex and Γ is of type (FL) (loc. cit., 11.4). The cellular chain complex of the universal cover of a finite $K(\Gamma,1)$ CW complex, tensored with $\mathbb{C}$, is the stated resolution (r_q the number of q-cells). □

Theorem B.163. *Let R be a commutative ring of Bass stable rank at most $s \geq 1$. For all integers $i \geq 0$ and $n \geq 2i + s + 2$, the map $H_i(\mathrm{GL}_n(R),\mathbb{Z}) \to H_i(\mathrm{GL}_{n+1}(R),\mathbb{Z})$ induced by $\mathrm{stab}_{n,n+1}$ is an isomorphism.*

Proof. [262, Theorem 4.11]: surjectivity and injectivity of $H_i(\mathrm{GL}_n(R)) \to H_i(\mathrm{GL}_{n+1}(R))$ for n beyond $\max(2i, i+s-1)$, respectively $\max(2i+1, i+s)$ (restated by M. Schlichting [215] as bijectivity of $H_i(\mathrm{GL}_{n-1}) \to H_i(\mathrm{GL}_n)$ for $n-1 \geq \max(2i, s+i)$). The range $n \geq 2i+s+2$ stated here lies inside each of these forms, whether the published inequalities are strict or not. Notation: van der Kallen's $\mathrm{sr}(R)$ is the stable rank; for a commutative noetherian ring of Krull dimension d, $\mathrm{sr}(R) \leq d+1$ (Bass's stable range theorem [19]), so a Dedekind domain has stable rank at most 2. □

Theorem B.164. *Let R be a commutative ring, $\mathrm{GL}(R) = \varinjlim_n \mathrm{GL}_n(R)$ along the stabilisations, $\mathcal{H} = H_\bullet(\mathrm{GL}(R);\mathbb{Q})$ and $\iota_n \colon H_\bullet(\mathrm{GL}_n(R);\mathbb{Q}) \to \mathcal{H}$ the natural maps. Then:*

1. *there is a unique product μ on $\mathcal{H}$ with $\mu(\iota_n x \otimes \iota_m y) = \iota_{n+m}(\oplus_*(x \times y))$, where $\oplus \colon \mathrm{GL}_n(R) \times \mathrm{GL}_m(R) \to \mathrm{GL}_{n+m}(R)$ is the block sum and $\times$ the homology cross product; with it and the coproduct Δ induced by the diagonal maps, $\mathcal{H}$ is a connected graded commutative and cocommutative Hopf algebra over $\mathbb{Q}$;*
2. *$\mathcal{H}$ is the free graded-commutative algebra on its graded subspace $\mathcal{P}$ of primitive elements, and $\mathcal{P}_m \cong K_m(R) \otimes \mathbb{Q}$ for $m \geq 1$ (through the rational Hurewicz map of $B\mathrm{GL}(R)^+$).*

Proof. D. Quillen's plus construction [202], which gives

$$H_\bullet(\mathrm{GL}(R)) = H_\bullet(B\mathrm{GL}(R)^+) \quad \text{and} \quad K_m(R) = \pi_m(B\mathrm{GL}(R)^+),$$

with the H-space structure of $B\mathrm{GL}(R)^+$ induced by block sum ([164]); [177] (a connected commutative cocommutative Hopf algebra over $\mathbb{Q}$ is the free graded-commutative algebra on

its primitives, and for a connected H-space the rational Hurewicz map is an isomorphism onto the primitives). See also [267, Ch. IV]. Well-definedness of μ on the colimit: the two ways of stabilising a block sum differ by conjugation by a permutation matrix, and inner automorphisms act trivially on group homology. □

Theorem B.165. *The notation introduced here is local to this result and to the results that apply it. Let H be a linear algebraic group over $\mathbb{Q}$. A subgroup $\Gamma \subseteq H(\mathbb{Q})$ is* arithmetic *if for some faithful $\mathbb{Q}$-representation $H \hookrightarrow \mathrm{GL}(V_{\mathbb{Q}})$ and some lattice $L \subset V_{\mathbb{Q}}$ (a finitely generated subgroup spanning $V_{\mathbb{Q}}$ over $\mathbb{Q}$) it is commensurable with $\{\gamma \in H(\mathbb{Q}) : \gamma L = L\}$.*

1. *For every faithful $\mathbb{Q}$-representation $H \hookrightarrow \mathrm{GL}(V_{\mathbb{Q}})$ and every lattice $L \subset V_{\mathbb{Q}}$, the stabiliser $\{\gamma \in H(\mathbb{Q}) : \gamma L = L\}$ is arithmetic; every arithmetic subgroup is a discrete subgroup of $H(\mathbb{R})$.*
2. *If H is connected and has no nontrivial character defined over $\mathbb{Q}$, then for every arithmetic subgroup Γ the group $H(\mathbb{R})$ is unimodular and every Borel fundamental domain of Γ in $H(\mathbb{R})$ (for the action by left multiplication) has finite Haar measure.*
3. *If H is connected and reductive and $P \subseteq H$ is a parabolic subgroup defined over $\mathbb{Q}$, then for every arithmetic subgroup Γ the double coset space $\Gamma\backslash H(\mathbb{Q})/P(\mathbb{Q})$ is finite.*

Proof. **Quotation.** Parts (1) and (2): [42] (independence of arithmeticity of the representation and the lattice; discreteness; the finite-volume criterion: $\Gamma\backslash H(\mathbb{R})$ has finite invariant volume if and only if the identity component of H has no nontrivial $\mathbb{Q}$-character). Part (3), the finiteness of the number of cusps: [38]; also A. Borel, Introduction aux groupes arithmétiques (Hermann, 1969), and V. Platonov and A. Rapinchuk, Algebraic groups and number theory (Academic Press, 1994), Chapter 4. Unimodularity in (2): a locally compact group containing a lattice is unimodular.

Notation map. We use it for $H = \mathrm{Res}_{K/\mathbb{Q}} H'$, H' a linear algebraic group over a number field K: then $H(\mathbb{Q}) = H'(K)$, $H(\mathbb{R}) = H'(K \otimes_{\mathbb{Q}} \mathbb{R})$, a parabolic K-subgroup P' of H' gives the parabolic $\mathbb{Q}$-subgroup $\mathrm{Res}_{K/\mathbb{Q}} P'$, and the $\mathbb{Q}$-characters of H correspond to the K-characters of H'; a K-vector space V with an $\mathcal{O}_K$-lattice L is a $\mathbb{Q}$-vector space with the lattice L. □

Theorem B.166. *Let F be a finite extension of $\mathbb{Q}_p$, $n \geq 1$, $G = \mathrm{GL}_n(F)$, $K = \mathrm{GL}_n(\mathcal{O}_F)$, $I_F \subseteq W_F$ the inertia and Weil groups, and* rec *the local Langlands correspondence of Harris–Taylor between irreducible smooth representations of G over $\mathbb{C}$ and n-dimensional Frobenius-semisimple Weil–Deligne representations (r, N) of W_F over $\mathbb{C}$. Let $\tau \colon I_F \to \mathrm{GL}_n(\mathbb{C})$ be an* ***inertial type****: a representation with open kernel which extends to W_F. Then there is a finite-dimensional smooth irreducible representation $\sigma(\tau)$ of K over $\mathbb{C}$ such that for every irreducible smooth representation π of G over $\mathbb{C}$: the restriction $\pi|_K$ contains a copy of $\sigma(\tau)$ if and only if $\mathrm{rec}(\pi)|_{I_F} \cong \tau$ and $N = 0$ on $\mathrm{rec}(\pi)$; in this case $\pi|_K$ contains exactly one copy of $\sigma(\tau)$.*

Proof. See [57, Theorem 3.7] (stated there over $\overline{\mathbb{Q}}_p$ through a fixed isomorphism $\overline{\mathbb{Q}}_p \cong \mathbb{C}$; the underlying results are over $\mathbb{C}$). It summarises [217, Proposition 6.2 and §6] ($\sigma(\tau) = \sigma_{\mathcal{P}_{\max}}(\lambda)$ for the maximal partition-valued function), and [74, Theorem 4.1]. The two conditions on $\mathrm{rec}(\pi)$ are unchanged when rec is replaced by $\pi \mapsto \mathrm{rec}(\pi \otimes |\det|^s)$ for any s, since this twists $\mathrm{rec}(\pi)$ by an unramified character, which is trivial on I_F and does not change N. So the statement does not depend on the normalisation of rec. □

Theorem B.167. *Let K be a finite extension of $\mathbb{Q}_p$ with ring of integers $\mathcal{O}_K$, uniformiser ϖ and residue field of order q; let $G = \mathrm{GL}_n(K)$, $\mathrm{Iw} \subseteq \mathrm{GL}_n(\mathcal{O}_K)$ the subgroup of matrices that are*

*upper triangular modulo ϖ, and $\mathcal{H} = C_c(\mathrm{Iw}\backslash G/\mathrm{Iw})$ the algebra of compactly supported bi-*Iw*-invariant functions $G \to \mathbb{C}$ under convolution for the Haar measure giving* Iw *measure* 1. *For $g \in G$ put $T_g = 1_{\mathrm{Iw}g\mathrm{Iw}}$; for $w \in S_n$ let $T_w = T_g$ with g the permutation matrix of w; for $\lambda \in \mathbb{Z}^n$ put $\varpi^\lambda = \mathrm{diag}(\varpi^{\lambda_1}, \dots, \varpi^{\lambda_n})$, call λ dominant if $\lambda_1 \geq \cdots \geq \lambda_n$, and put $\langle \rho, \lambda \rangle = \sum_{i=1}^n \frac{n+1-2i}{2}\lambda_i$. For $1 \leq a < n$ let $s_a = (a\ a{+}1) \in S_n$, and let $\ell(w)$ be the number of inversions of w. Then:*

(IH1) *(Iwahori–Matsumoto) $T_{s_a}^2 = (q-1)T_{s_a} + q \cdot 1$, and $T_{s_a w} = T_{s_a}T_w$ whenever $\ell(s_a w) = \ell(w) + 1$; the elements T_g, g running over representatives of* Iw$\backslash G/$Iw*, form a basis of $\mathcal{H}$.*

(IH2) *(Bernstein) There is a unique homomorphism of groups $\lambda \mapsto \Theta_\lambda$ from $\mathbb{Z}^n$ to $\mathcal{H}^\times$ with $\Theta_\lambda = q^{-\langle \rho, \lambda \rangle} T_{\varpi^\lambda}$ for dominant λ; its linear extension $\Theta\colon \mathbb{C}[\mathbb{Z}^n] \to \mathcal{H}$ is an injective homomorphism of algebras, and $(\lambda, w) \mapsto \Theta_\lambda T_w$ is a bijection from $\mathbb{Z}^n \times S_n$ onto a basis of $\mathcal{H}$.*

(IH3) *(Bernstein relation) For $1 \leq a < n$, $\alpha^\vee = e_a - e_{a+1}$ and every $\mu \in \mathbb{Z}^n$,*

$$T_{s_a}\Theta_\mu = \Theta_{s_a(\mu)}T_{s_a} + (1-q)\,\frac{\Theta_{s_a(\mu)} - \Theta_\mu}{1 - \Theta_{-\alpha^\vee}},$$

the fraction being the element $\Theta(z)$ for the Laurent polynomial $z = (x^{s_a(\mu)} - x^\mu)/(1 - x^{-\alpha^\vee})$.

(IH4) *(Bernstein's centre) $\Theta(\mathbb{C}[\mathbb{Z}^n]^{S_n})$ is the centre of $\mathcal{H}$.*

Proof. See [116], Sections 1 and 2, for a split group G with split maximal torus A and Borel subgroup $B = AN$, the Iwahori subgroup I being the inverse image of $B(k)$ in $G(\mathcal{O})$; the results are originally due to Iwahori–Matsumoto (Publ. Math. IHÉS 25, 1965) for (IH1) and to Bernstein, as presented in G. Lusztig, *Affine Hecke algebras and their graded version*, J. Amer. Math. Soc. 2 (1989), Section 3, for (IH2)–(IH4). *Notation.* Here $G = \mathrm{GL}_n$, A the diagonal torus, N the upper triangular unipotent matrices, so that $I = \mathrm{Iw}$, $X_*(A) = \mathbb{Z}^n$ with $\pi^\mu = \varpi^\mu$; a coweight μ is dominant for B exactly when $\mu_1 \geq \cdots \geq \mu_n$ (it is the condition $\pi^\mu(I \cap N)\pi^{-\mu} \subseteq I \cap N$ of the cited text, Section 1); ρ is half the sum of the roots $e_i - e_j$, $i < j$, so $\langle \rho, \mu \rangle$ is as stated; the simple coroots are $e_a - e_{a+1}$ with simple reflections s_a. In the cited text Θ_λ is defined through the universal unramified principal series and shown (Remark after Lemma *bases*) to equal $q^{\langle \rho, -\lambda_1 + \lambda_2 \rangle} T_{\pi^{\lambda_1}} T_{\pi^{\lambda_2}}^{-1}$ for $\lambda = \lambda_1 - \lambda_2$ with λ_1, λ_2 dominant, which is the homomorphism of (IH2). Lemma *bases* gives $\mathbb{C}[X_*] \otimes \mathcal{H}_0 \cong \mathcal{H}$, $\pi^\mu \otimes h \mapsto \Theta_\mu h$, with $\mathcal{H}_0$ spanned by the T_w, $w \in S_n$, which is the basis statement of (IH2). Finally, (IH3) is the displayed Bernstein relation there, and (IH4) is the theorem of Section 2 that R^W is the centre of $\mathcal{H}$. $\square$

Theorem B.168. *Let K be a finite extension of $\mathbb{Q}_p$ with ring of integers $\mathcal{O}_K$, uniformiser ϖ and residue field of order q. Let $G = \mathrm{GL}_n(K)$,* Iw $\subseteq \mathrm{GL}_n(\mathcal{O}_K)$ *the matrices upper triangular modulo ϖ, and* $\mathrm{Iw}_p \subseteq$ Iw *those that are moreover unipotent modulo ϖ. Let $\mathcal{N} \subseteq G$ be the group of monomial matrices and, for $g \in \mathcal{N}$, $\ell(g)$ the integer with $|\mathrm{Iw}g\mathrm{Iw}/\mathrm{Iw}| = q^{\ell(g)}$. Let $\mathcal{H}^{(1)}$ be the ring of compactly supported bi-Iw_p-invariant functions $G \to \mathbb{Z}$ under convolution for the Haar measure giving* Iw_p *measure* 1, *and put $T_g = 1_{\mathrm{Iw}_p g \mathrm{Iw}_p}$. Then $G = \bigsqcup_g \mathrm{Iw}_p g \mathrm{Iw}_p$ with g running over $\mathcal{N}$ modulo the diagonal matrices $\equiv 1$ modulo ϖ, $|\mathrm{Iw}_p g \mathrm{Iw}_p/\mathrm{Iw}_p| = q^{\ell(g)}$, and for $g, g' \in \mathcal{N}$ with $\ell(gg') = \ell(g) + \ell(g')$*

$$T_g T_{g'} = T_{gg'}.$$

Proof. See [264], Theorem 1, the Iwahori–Matsumoto presentation of the pro-p Iwahori Hecke ring of a split reductive group (braid relations), specialised to GL_n; for the Iwahori subgroup itself these are the relations of N. Iwahori and H. Matsumoto (Publ. Math. IHÉS 25, 1965). *Notation.* The pro-p Iwahori subgroup is Iw_p, the group $W(1)$ of loc. cit. is $\mathcal{N}$ modulo the diagonal matrices $\equiv 1 \bmod \varpi$, and its length is the length of the image in the extended affine Weyl group, which equals $\log_q |\mathrm{Iw} g \mathrm{Iw}/\mathrm{Iw}|$. $\square$

B.10 Combinatorics and other

Amitsur's formula for the determinant of a sum of matrices (Theorem B.169) is used in the Ribet budget theorem (Section 22). Artin's basis of the polynomial ring over the symmetric polynomials, the hook-content formula and the classical expansions of Schur polynomials (Theorem B.170, Theorem B.171, Theorem B.172) are used for the model slopes of Part VI (Section 29), and the degree of the complete flag variety (Theorem B.173) for the properties of good root towers (Section 30). Borsuk's nerve theorem (Theorem B.174) is used for the second cohomology of Tate twists in Part VII (Section 40).

Theorem B.169. *Let C be a commutative ring, $N, k \geq 1$ integers, $A_1, \dots, A_k \in \mathrm{M}_N(C)$, and $t_1, \dots, t_k$ commuting indeterminates. For a word $w = i_1 i_2 \cdots i_p$ in the alphabet $\{1, \dots, k\}$ put $A_w = A_{i_1} A_{i_2} \cdots A_{i_p}$ and $t_w = t_{i_1} t_{i_2} \cdots t_{i_p}$. Then, in the ring of formal power series $C[[t_1, \dots, t_k]]$,*

$$\det\Big(1 - \sum_{i=1}^{k} t_i A_i\Big) = \prod_{w} \det(1 - t_w A_w),$$

the product running over all Lyndon words w in the alphabet $\{1, \dots, k\}$ (the non-empty words that are strictly smaller, for the lexicographic order, than each of their proper suffixes); it converges in the $(t_1, \dots, t_k)$-adic topology, since t_w has degree equal to the length of w and there are finitely many words of each length.

Proof. [6]; short proof from Lyndon's factorisation of the free monoid by C. Reutenauer and M.-P. Schützenberger [207]; the form used here is [92, (1.12)], applied to the matrices $t_i A_i$ with entries in $C[[t_1, \dots, t_k]]$. The identity is one of formal power series with coefficients that are integral polynomials in the entries of the A_i, so it holds over every commutative ring. $\square$

Theorem B.170. *Let $n \geq 1$, let $\Lambda_n \subseteq \mathbb{R}[y_1, \dots, y_n]$ be the subring of symmetric polynomials and $P_k = \sum_{i=1}^{n} y_i^k$.*

(a) $\mathbb{R}[y_1, \dots, y_n]$ is a free Λ_n-module with basis the monomials $y_1^{e_1} \cdots y_n^{e_n}$ with $0 \leq e_i \leq i - 1$ for every i.

(b) $\Lambda_n = \mathbb{R}[P_1, \dots, P_n]$.

Proof. (a) is E. Artin's basis theorem ([10]; it holds over any commutative ring of coefficients). (b) is the fundamental theorem on symmetric polynomials ($\Lambda_n = \mathbb{R}[e_1, \dots, e_n]$ for the elementary symmetric polynomials) combined with Newton's identities $k e_k = \sum_{i=1}^{k} (-1)^{i-1} e_{k-i} P_i$, which express $e_1, \dots, e_n$ as polynomials in $P_1, \dots, P_n$ over $\mathbb{Q}$. Notation: y_i are the variables of one block of the Chern-root ring in the application, P_k its power sums. $\square$

Theorem B.171. *Let $n \geq 1$ and $w = (w_1, \dots, w_n)$ indeterminates. For $e = (e_1, \dots, e_n) \in \mathbb{N}^n$ let $a_e(w) = \det(w_i^{e_j})_{1 \leq i,j \leq n}$, and let $\delta_n = (n-1, n-2, \dots, 1, 0)$, so that $a_{\delta_n}(w) = \prod_{1 \leq i < i' \leq n} (w_i - w_{i'})$. Let $\lambda = (\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n \geq 0)$ be a partition with at most n parts, $|\lambda| = \sum_i \lambda_i$.*

(a) $a_{\lambda+\delta_n}$ *is divisible by* a_{δ_n} *in* $\mathbb{Z}[w]$*, and the quotient, the* Schur polynomial

$$s_\lambda(w) = a_{\lambda+\delta_n}(w)/a_{\delta_n}(w),$$

equals $\sum_T w^T$*, the sum over the semistandard Young tableaux* T *of shape* λ *with entries in* $\{1,\dots,n\}$*, where* $w^T = \prod_i w_i^{\#\{\text{entries of } T \text{ equal to } i\}}$*. In particular* s_λ *is homogeneous of degree* $|\lambda|$ *and all its coefficients are non-negative integers.*

(b) (Hook-content formula.) $s_\lambda(1,\dots,1) = \prod_{x\in\lambda} \dfrac{n+c(x)}{h(x)}$*, where for the cell* $x=(i,j)$ *of the diagram of* λ *(row* i*, column* j*) the content is* $c(x) = j-i$ *and the hook length is* $h(x) = \lambda_i - j + \lambda'_j - i + 1$*,* λ' *the conjugate partition.*

Proof. Classical; see [165], Chapter I: (a) is the definition of s_λ as a quotient of alternants, Ch. I, (3.1), together with the combinatorial description, Ch. I, (5.12) (Jacobi's bialternant formula and Littlewood's tableau formula); (b) is Ch. I, §3, Example 4, at $q=1$ (Stanley's hook-content formula). Notation: w plays the role of the negatives of the entries of one block of a weight in the application; s_λ is used only inside the calculus of the Chern-root ring. □

Theorem B.172. *Let* $m, M \geq 1$*, and let* $u=(u_1,\dots,u_m)$*,* $w=(w_1,\dots,w_M)$ *be indeterminates. For a partition* λ *with more than* m *parts put* $s_\lambda(u)=0$*;* λ' *is the conjugate partition. For partitions* $\mu\subseteq\lambda$ *let* $s_{\lambda/\mu}(w) = \sum_T w^T$*, the sum over the semistandard tableaux* T *of skew shape* λ/μ *with entries in* $\{1,\dots,M\}$*; in particular all coefficients of* $s_{\lambda/\mu}$ *are non-negative integers, and* $s_{\lambda/\lambda}=1$*.*

(a) (Basis.) For every $r\geq 0$ *the* $s_\lambda(u)$ *with* $|\lambda|=r$ *and at most* m *parts form a basis of the real vector space of symmetric polynomials in* u*, homogeneous of degree* r*.*

(b) (Power sums.) For $r\geq 1$*,* $\sum_{i=1}^m u_i^r = \sum_{j=0}^{r-1}(-1)^j\, s_{(r-j,1^j)}(u)$*, where* $(r-j,1^j)$ *is the hook with first row* $r-j$ *and* j *further rows of length one.*

(c) (Dual Cauchy identity.) $\prod_{i=1}^m\prod_{j=1}^M(1+u_iw_j) = \sum_\lambda s_\lambda(u)\, s_{\lambda'}(w)$*, the sum over all partitions* λ *(only finitely many terms are non-zero).*

(d) (Branching.) For every partition λ*,* $s_\lambda(u_1,\dots,u_m,w_1,\dots,w_M) = \sum_{\mu\subseteq\lambda} s_\mu(u)\, s_{\lambda/\mu}(w)$*.*

(e) (Littlewood–Richardson positivity.) For partitions λ,μ*,* $s_\lambda(u)s_\mu(u) = \sum_\nu c^\nu_{\lambda\mu}\, s_\nu(u)$ *with non-negative integers* $c^\nu_{\lambda\mu}$ *(the sum over* ν *with* $|\nu| = |\lambda|+|\mu|$*).*

Proof. Classical; see [165], Chapter I: (a) is (3.2)–(3.3) (the Schur polynomials in m variables with at most m parts form a basis of the symmetric polynomials); (b) is §3, Example 11 (the expansion of p_r in hook Schur functions, a case of the Murnaghan–Nakayama rule), specialised to m variables, where the s_λ with more than m parts vanish; (c) is (4.3'); (d) is (5.9) with the tableau formula (5.12) for skew Schur functions; (e) is the Littlewood–Richardson rule (9.2), or (5.3) with the positivity of skew Schur functions. Notation: u will be the shifted entries of one side of one block of a weight, w a vector of ones. □

Theorem B.173. *Let* $n\geq 2$*,* $G=\mathrm{SL}_n(\mathbb{C})$*,* $B\subseteq G$ *the Borel subgroup of upper triangular matrices and* $N = n(n-1)/2 = \dim G/B$*. Let* $\lambda=(\lambda_1,\dots,\lambda_n)\in\mathbb{Z}^n$ *with* $\lambda_1>\lambda_2>\cdots>\lambda_n$ *(a regular dominant weight, taken modulo* $\mathbb{Z}(1,\dots,1)$*), let* V_λ *be the irreducible representation*

of G with highest weight λ, $v_\lambda \in V_\lambda$ a highest weight vector, $e_\lambda \colon G/B \to \mathbb{P}(V_\lambda)$, $gB \mapsto [g\,v_\lambda]$, and $\mathcal{L}_\lambda = e_\lambda^* \mathcal{O}(1)$. Then e_λ is a closed embedding and

$$\int_{G/B} c_1(\mathcal{L}_\lambda)^N = N! \prod_{1 \le i < j \le n} \frac{\lambda_i - \lambda_j}{j - i}.$$

Proof. [201]: the Proposition of the section on degrees of Schubert varieties ($\deg_\lambda(X_w) = \ell(w)!\,\mathfrak{D}_w(\lambda)$ for dominant λ, with $\deg_\lambda(X_w) = \langle [X_w] \cdot c_1(\mathcal{L}_\lambda)^{\ell(w)} \rangle$ and e_λ an embedding for regular λ), applied to the longest element $w_\circ$ ($X_{w_\circ} = G/B$, $\ell(w_\circ) = N$), and the Corollary $\mathfrak{D}_{w_\circ}(y) = \prod_{\alpha>0}(y, \alpha^\vee)/(\rho, \alpha^\vee)$ of the section on the asymptotic expression for degrees (there attributed to Stembridge; it is Weyl's dimension formula plus the asymptotics of $\dim V_{k\lambda}$; the formula goes back to Borel and Hirzebruch). Notation: for SL_n the positive roots are $\alpha = \epsilon_i - \epsilon_j$ $(i < j)$, $(\lambda, \alpha^\vee) = \lambda_i - \lambda_j$ and $(\rho, \alpha^\vee) = j - i$. □

Theorem B.174. *Let $C_1, \dots, C_q$ ($q \ge 1$) be nonempty compact convex subsets of a finite-dimensional real vector space. Let $\mathcal{K}$ be the nerve of the family: the abstract simplicial complex with vertex set $\{1, \dots, q\}$ whose simplices are the nonempty subsets $J \subseteq \{1, \dots, q\}$ with $\bigcap_{j \in J} C_j \neq \emptyset$. Then the geometric realisation of $\mathcal{K}$ is homotopy equivalent to $C_1 \cup \cdots \cup C_q$.*

Proof. [44] (the nerve theorem: a compact metric space that is the union of finitely many closed sets all of whose nonempty intersections are absolute retracts has the homotopy type of the nerve). The convex case stated here is the special case in which every nonempty intersection is a nonempty compact convex set of a Euclidean space, hence an absolute retract. The C_j are the closed sets of the cover, and $\mathcal{K}$ is Borsuk's nerve. □

B.11 Computer checks cited in proofs

The proofs of nine results cite nine computer checks, C1–C9, listed below in the order in which they are first cited, each with what it computes and the results whose proofs cite it. In the proofs of Lemma 51.12, Lemma 51.15 and Lemma 52.5 the computation is a step of the proof: the first two establish identities between explicit matrices with polynomial entries, and the third is a finite case check, whose reduction to finitely many cases is proved in the text. The other six computations accompany steps that are proved in the text and check them by a second route; for Theorem D.87, the closed form of the sphere moments is Lemma D.94. The code and its documentation are available from the authors.

- C1, cited in Theorem 34.20: the inequality $8\pi e^\gamma < 49$ in exact rational arithmetic from $\gamma < 0.5773$ and $\pi < 3.1416$; and, for $E = \mathbb{Q}(\sqrt{-d})$ with $d \in \{7, 23, 71, 103, 199\}$ and $p, q \le 12$, a numerical comparison of the flat height with $\frac{p-q}{2}$ times the Chowla–Selberg average of Lemma 34.21, and of the bound (Fd3).
- C2, cited in Lemma 34.21 and Theorem 34.20: the normalisations in the period of an elliptic curve with complex multiplication by $\mathbb{Q}(\sqrt{-d})$, numerically for seven discriminants, against the eta-quotient form of the Chowla–Selberg formula and against a published Faltings height.
- C3, cited in Lemma 51.12: clauses (Ie3)–(Ie5), that is, the explicit form of the induced embedding on pairs of lower triangular matrices, the similitude of the flag matrices and the triangular shape after conjugation by them, as identities of polynomials with integer coefficients after clearing denominators; with a second implementation in exact rational arithmetic at random rational points.

- C4, cited in Lemma 51.15: clauses (Te3)–(Te5), together with the Kronecker-product form of the tensor embedding and its similitude formula, as polynomial identities, by two independent implementations.
- C5, cited in Lemma 52.5: under the sign hypotheses (h1)–(h8), (m1)–(m4) on two integers A, B, one of the six conditions that become (Zc1)–(Zc6) holds; exhaustively over $(A, B) \in [-2, 2]^2$ and all 2^8 assignments, with a second method by exact Fourier–Motzkin elimination.
- C6, cited in Lemma 53.37: for an involution of similitude -1 acting on $\mathfrak{sp}_4$, the diagonal case exactly over $\mathbb{Z}[1/2]$, and the dimensions 6 and 4 of the eigenspaces for 200 random involutions over $\mathbb{Q}$ and modulo 3, 5 and 7.
- C7, cited in Theorem D.87 and Lemma D.94: the sphere-moment integrals of the fibre square in closed form, by generating functions.
- C8, cited in Lemma D.88: the symbolic steps of the push-forward of the powers of the relative tangent class along a $\mathbb{P}^1$-bundle, and its coefficients for $N \leq 60$.
- C9, cited in Lemma D.94: the moments S_k for $1 \leq k \leq 12$ in exact rational arithmetic, by two methods that share no step (the double integral against Q_k, and the Funk–Hecke expansion in Legendre polynomials on $S^2 \times S^2$), with a direct quadrature for $k \leq 3$.

C Weight words along Frobenius orbits

This appendix proves the three colength bounds on which the row bound Proposition 26.2 of Section 26 rests, one for each configuration of weight word treated at the primes of inert type: Proposition C.1 for alternating words with a thin site (Section C.1), Proposition C.52 for alternating words that are thick at every site (Section C.2), and Proposition C.77 for long Frobenius orbits whose thick sites form isolated clusters (Section C.3). No other result of the paper uses the appendix. Its proofs are long and their interest is combinatorial: they decide, site by site along the Frobenius orbit, at what cost a crystalline class can be lifted along a surjection of lattices.

The pattern is that of the lifting exponent of Section 24, carried out along longer arcs of sites. The sites are divided by *cuts*, a class is split into relay classes at the cuts (Proposition 24.4), and each relay class is lifted along the arc that ends at its cut, with the level data of the arc recording the weight word (Subsection 23.1). For alternating words with a thin site this gives first a killing exponent with few exceptional classes: $\ell^e H^1_f(D, T_2)$ lies in $\Phi_* H^1_f(D, T_1)$ plus the span of at most $4nm$ classes, with e of size h/ℓ^2 plus lower-order terms (Proposition C.2). On long orbits with isolated thick clusters it gives a lifting exponent of size $h/(\ell-1)^{j+1} + (G+1)(j+1) + \log_\ell h$, with no exceptional classes (Proposition C.79). In both cases the colength follows by the generator count Lemma 27.3 and Lemma 27.14. For words that are thick everywhere the lifting is done at the down sites, with an exponent of order H'/ℓ^2, on a submodule reached in at most six steps of bounded generation and three steps of bounded length (Proposition C.57). The appendix uses the Wach modules, levels, relay classes and lifting lemmas of Sections 23 and 24, the two counting lemmas of Section 27, and the Γ-weight separation lift of Section 28.

C.1 Alternating weight words: splitting along arcs

This section proves Proposition C.1, the colength bound for an alternating weight word with a thin site, which is item 1 of the row bound Proposition 26.2 in Section 26. The colength follows

from a killing exponent with at most $4nm$ exceptional classes (Proposition C.2) by the counting lemmas 27.3 and Lemma 27.14. The cuts are the sites c for which $c+1$ is thin; a crystalline class is split into relay classes at the cuts, and the relay class at each cut is lifted along the arc that ends there (Proposition C.4). The lifting of one graded section is proved separately for arcs of length one, two and three (Proposition C.25). Subsection C.1.1 sets up the arcs, Subsection C.1.2 treats one cut, and Subsections C.1.3 and C.1.4 lift graded sections along arcs of each length.

C.1.1 Colength bounds and the arc setup

The subsection states Proposition C.1 and Proposition C.2 and reduces the exponent to the arc part Proposition C.4; when b is below $160\,\mathrm{Sg}$, the first-order lifting exponent is at most $160\,\mathrm{Sg}$ (Lemma C.3). The arc setup Proposition C.5 writes every crystalline class as the class of an extension by the trivial lattice whose unit lifts to the Wach module at every cut up to ℓ^{r_0}, with $r_0 \le 3\,\mathrm{Sg}$. It rests on Wach lifting along onto maps of lattices (Proposition C.6): a site vector lifts up to an explicit power of ℓ, computed from the killing indices of the cokernel along the Frobenius cycle (Lemma C.7). Proposition C.6 is used again in Sections C.2 and C.3.

Proposition C.1. *Let $\ell \ge 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, L as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Let $M_a, h_a \ge 0$ be integers such that every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$, and $e = e(M_\bullet, h_\bullet)$. Suppose that some site is thin, that $\epsilon_{a+1} \ne \epsilon_a$ for every a, that no three consecutive sites $a, a+1, a+2$ are all thick, and that $20w \le b$, $20\eta \le b$, $20S \le b$. Then the colength of Φ is at most*

$$68\,c_{\mathrm{ur}}\Big((n+1)\,d_2\Big(\frac{h}{\ell^2} + \frac{w+\eta}{\ell} + S + 1 + \log_\ell(2h) + \eta\,\beta_{320}\Big) + n\,m\,e\Big).$$

Proof. Put $D = G_F$, $H = H^1_f(D, T_2)$ and $H' = \Phi_* H^1_f(D, T_1) \subseteq H$; the colength of Φ is $\mathrm{nl}(H/H')$.

The three inputs. (i) V_2 is crystalline, hence de Rham, so by Lemma 27.3 H is generated by at most $g = (n+1)d_2$ elements. (ii) The hypotheses of the statement are those of Proposition C.2, which gives an integer e_0 with $0 \le e_0 \le 55\,c_{\mathrm{ur}}\,\mathrm{Sg} + 13S + \eta\beta_{320}$, $\mathrm{Sg} = h/\ell^2 + (w+S+\eta)/\ell + \log_\ell(2h) + 1$, and a finite $Z \subseteq H$ with $|Z| \le 4nm$ and $\ell^{e_0} H \subseteq H' + \sum_{z\in Z} \mathcal{O}_L z$. (iii) ℓ is odd, F is unramified, L contains $\sigma(F(\mu_\ell))$ for every embedding σ, V_1, V_2 are crystalline, $\Phi(T_1) = T_2$, and every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$; so Proposition 24.1, applied with $a^-_{\tau_a} = M_a$ and $a^+_{\tau_a} = h_a$, gives $\ell^e H \subseteq H'$ with $e = e(M_\bullet, h_\bullet)$; in particular $\ell^e z \in H'$ for every $z \in Z$.

The colength. By Lemma 27.14 with these g, e_0, Z and $e' = e$,

$$\mathrm{nl}(H/H') \le (n+1)\,d_2\,e_0 + 4nm\,e.$$

Put $X = h/\ell^2 + (w+\eta)/\ell + S + 1 + \log_\ell(2h) + \eta\beta_{320}$. Every term of X is non-negative ($h \ge 1$, so $\log_\ell(2h) > 0$), and $(w+S+\eta)/\ell \le (w+\eta)/\ell + S$, so $\mathrm{Sg} \le X - \eta\beta_{320}$, hence, as $c_{\mathrm{ur}} \ge 1$, $e_0 \le 55c_{\mathrm{ur}}(X - \eta\beta_{320}) + \eta\beta_{320} + 13S \le 55c_{\mathrm{ur}}X + 13X \le 68\,c_{\mathrm{ur}}X$. Hence

$$\mathrm{nl}(H/H') \le 68\,c_{\mathrm{ur}}\,(n+1)\,d_2\,X + 4\,n\,m\,e \le 68\,c_{\mathrm{ur}}\big((n+1)\,d_2\,X + n\,m\,e\big),$$

which is the assertion. □

Proposition C.2. *Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D = G_F$, L with ring of integers $\mathcal{O}_L$ as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Suppose that some site is thin, that $\epsilon_{a+1} \neq \epsilon_a$ for every a, that no three consecutive sites $a, a+1, a+2$ are all thick, and that $20w \leq b$, $20\eta \leq b$, $20S \leq b$. Put*

$$\mathrm{Sg} = \frac{h}{\ell^2} + \frac{w + S + \eta}{\ell} + \log_\ell(2h) + 1.$$

Then there are an integer e with $0 \leq e \leq 55\, c_{\mathrm{ur}}\,\mathrm{Sg} + 13S + \eta\,\beta_{320}$ and a finite subset $Z \subseteq H^1_f(D, T_2)$ with $|Z| \leq 4nm$ such that

$$\ell^e\, H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1) + \sum_{z\in Z} \mathcal{O}_L z.$$

Proof. Put $H = H^1_f(D, T_2)$ and $H_1 = \Phi_* H^1_f(D, T_1)$. Since all terms of Sg are non-negative ($h \geq 1$), $\mathrm{Sg} \geq 1 + \log_\ell(2h) \geq 1$.

Case 1: some site is thick and $b < 160\,\mathrm{Sg}$. By Lemma C.3 there is an integer e' with $0 \leq e' \leq 19\, c_{\mathrm{ur}}\,\mathrm{Sg} \leq 55\, c_{\mathrm{ur}}\,\mathrm{Sg}$ and $\ell^{e'} H \subseteq H_1$; take $e = e'$ and $Z = \emptyset$.

Case 2: no site is thick, or $160\,\mathrm{Sg} \leq b$. The hypotheses of Proposition C.4 hold; let C, len_c, J_c, κ_c be as there, and r_0, σ, E, X_c, Z_c the data it provides. We first record three facts about the cuts.

(a) *The arcs partition the orbit:* $\sum_{c\in C} \mathrm{len}_c = n$. Some site a is thin, so $a - 1 \in C \neq \emptyset$; for $c \in C$ the integer $d = n$ satisfies $c - d = c \in C$, so $1 \leq \mathrm{len}_c \leq n$. Put $A_c = \{c - t :\ 0 \leq t < \mathrm{len}_c\}$, a set of len_c residues. Every $a \in \mathbb{Z}/n$ lies in some A_c: let $t \geq 0$ be least with $a + t \in C$ ($t \leq n - 1$); then $c = a + t \in C$, and for $1 \leq d \leq t$ the residue $c - d = a + (t - d)$ is not in C by minimality, so $t < \mathrm{len}_c$ and $a = c - t \in A_c$. The sets are disjoint: if $c - t = c' - t'$ with $t < \mathrm{len}_c$, $t' < \mathrm{len}_{c'}$ and $t < t'$, then $c = c' - (t' - t)$ with $1 \leq t' - t < \mathrm{len}_{c'}$, so $c \notin C$, a contradiction; hence $t = t'$ and $c = c'$.

(b) $\mathrm{len}_c \leq 3$. For $1 \leq d < \mathrm{len}_c$, $c - d \notin C$, so the site $c - d + 1$ is not thin, hence thick by (Ow3). Thus the $\mathrm{len}_c - 1$ consecutive sites $c - \mathrm{len}_c + 2, \ldots, c$ are thick; as no three consecutive sites are thick, $\mathrm{len}_c \leq 3$.

(c) $\kappa_c \leq 13S + 3\,\mathrm{Sg}$. Each W_a consists of S consecutive integers i with $1 \leq |i| \leq s_a + S \leq h$ (because $s_a > \eta \geq 0$; and $s_a + S \leq b + \eta + S$ at a thick site, $s_a + S \leq w + S$ at a thin one, both $\leq h$). For $k \geq 1$ at most $S/\ell^k + 1$ of them are divisible by ℓ^k, and none if $\ell^k > h$; so $\sum_{i\in W_a} v_\ell(i) = \sum_{k\geq 1} \#\{i \in W_a :\ \ell^k \mid i\} \leq S/(\ell - 1) + \log_\ell h$. The set J_c is a union of $\mathrm{len}_c \leq 3$ such windows, so $|J_c| \leq \mathrm{len}_c S$, $0 \notin J_c$, and

$$\kappa_c \leq \mathrm{len}_c + \mathrm{len}_c(\mathrm{len}_c + 1)S + \frac{3S}{\ell - 1} + 3\log_\ell h \leq 3 + 12S + \frac{3S}{10} + 3\log_\ell(2h) \leq 13S + 3\,\mathrm{Sg}.$$

The exponent and the exceptional classes. Let $\kappa = \max_{c\in C} \kappa_c$, $e = r_0 + 3\sigma + \kappa + E$ and $Z = \bigcup_{c\in C} Z_c \subseteq H$. For $x \in H$ write $\ell^{r_0+2\sigma} x = \sum_c x_c$ with $x_c \in X_c$; then $\ell^{\sigma+\kappa+E} x_c = \ell^{\kappa-\kappa_c}\, \ell^{\sigma+\kappa_c+E} x_c \in H_1 + \sum_{z\in Z_c} \mathcal{O}_L z$, hence $\ell^e x \in H_1 + \sum_{z\in Z} \mathcal{O}_L z$. By (b) and (a), $|Z| \leq \sum_c m\,\mathrm{len}_c(\mathrm{len}_c + 1) \leq 4m \sum_c \mathrm{len}_c = 4nm$. By the bounds of Proposition C.4 and (c),

$$0 \leq e \leq 3\,\mathrm{Sg} + 9\,\mathrm{Sg} + 13S + 3\,\mathrm{Sg} + 40\,\mathrm{Sg} + \eta\beta_{320} = 55\,\mathrm{Sg} + 13S + \eta\beta_{320}.$$

As $c_{\mathrm{ur}} \geq 1$, in both cases $0 \leq e \leq 55\, c_{\mathrm{ur}}\,\mathrm{Sg} + 13S + \eta\beta_{320}$, $|Z| \leq 4nm$, $Z \subseteq H$, and $\ell^e H \subseteq H_1 + \sum_{z\in Z} \mathcal{O}_L z$. □

Lemma C.3. *Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D = G_F$, L as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ with $20w \leq b$, $20\eta \leq b$, $20S \leq b$, and some site thick. Put*

$$\mathrm{Sg} = \frac{h}{\ell^2} + \frac{w + S + \eta}{\ell} + \log_\ell(2h) + 1,$$

and suppose $b < 160\,\mathrm{Sg}$. Let $(M'_a, h'_a) = (\eta, s_a + S)$ if $\epsilon_a = 1$ and $(M'_a, h'_a) = (s_a + S, \eta)$ if $\epsilon_a = -1$. Then $e' = e(M'_\bullet, h'_\bullet)$ is defined, $0 \leq e' \leq 19\, c_{\mathrm{ur}}\,\mathrm{Sg}$, and

$$\ell^{e'} H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1).$$

Proof. The windows and the lifting. Since some site is thick, $h = b + \eta + S$. Every size satisfies $s_a \leq b+\eta$: at a thick site by (Ow3), at a thin site because $s_a \leq w \leq b/20$. By (Ow1) every Hodge jump of V_1 at τ_a lies in $[s_a, s_a+S]\cup[-\eta, \eta] \subseteq [-M'_a, h'_a]$ if $\epsilon_a = 1$, and in $[-s_a-S, -s_a]\cup[-\eta, \eta] \subseteq [-M'_a, h'_a]$ if $\epsilon_a = -1$. So e' is defined, and Proposition 24.1 (with $p = \ell$ odd, $K = F$ unramified, L containing $\sigma(F(\mu_\ell))$ for every σ, V_1, V_2 crystalline, $\Phi(T_1) = T_2$, $a^-_{\tau_a} = M'_a$, $a^+_{\tau_a} = h'_a$) gives $\ell^{e'} H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1)$, with $e' = e_{\mathrm{A}} = \lfloor c_{\mathrm{ur}}(2 + \mathrm{wt}/\ell + \log_\ell(\mathrm{wt} + 1))\rfloor \geq 0$.

The size of e'. With $a^-_{\tau_a} = M'_a$, $a^+_{\tau_a} = h'_a$ we have $\mathrm{wt} = \max_a(s_a + S + \eta) \leq h + \eta$, as $s_a + S \leq b + \eta + S = h$. Since $\eta \leq b/20 \leq h/20$, $\mathrm{wt} \leq \frac{21}{20}h$; and $\mathrm{wt} + 1 \leq h + \eta + 1 \leq 2h$ because $h \geq b + \eta \geq 1 + \eta$. Since all terms of Sg are non-negative ($h \geq 1$), $\mathrm{Sg} \geq 1 + \log_\ell(2h) \geq 1$. Now $h = b + \eta + S \leq \frac{11}{10}b < \frac{11}{10} \cdot 160\,\mathrm{Sg} = 176\,\mathrm{Sg}$, and $\ell \geq 11$, so

$$\frac{\mathrm{wt}}{\ell} \leq \frac{21}{20} \cdot \frac{176}{11}\,\mathrm{Sg} = \frac{84}{5}\,\mathrm{Sg}, \qquad 2 + \log_\ell(\mathrm{wt} + 1) \leq 1 + \big(1 + \log_\ell(2h)\big) \leq 2\,\mathrm{Sg}.$$

Hence $e' \leq c_{\mathrm{ur}}\big(2 + \mathrm{wt}/\ell + \log_\ell(\mathrm{wt} + 1)\big) \leq c_{\mathrm{ur}}\big(\frac{84}{5} + 2\big)\mathrm{Sg} < 19\, c_{\mathrm{ur}}\,\mathrm{Sg}$. □

Proposition C.4. *Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D = G_F$, L with ring of integers $\mathcal{O}_L$ as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Suppose that some site is thin, that $\epsilon_{a+1} \neq \epsilon_a$ for every a, that no three consecutive sites are all thick, that $20w \leq b$, $20\eta \leq b$, $20S \leq b$, and that either no site is thick or $160\,\mathrm{Sg} \leq b$, where $\mathrm{Sg} = h/\ell^2 + (w + S + \eta)/\ell + \log_\ell(2h) + 1$. Let $C = \{c \in \mathbb{Z}/n :\ c + 1$ is thin$\}$ (the* cuts*); for $c \in C$ let len_c be the least integer $d \geq 1$ with $c - d \in C$, let*

$$J_c = \bigcup_{0\leq t<\mathrm{len}_c} W_{c-t}, \qquad W_a = \begin{cases} \{i \in \mathbb{Z} :\ -s_a - S \leq i < -s_a\} & \text{if } \epsilon_a = 1, \\ \{i \in \mathbb{Z} :\ s_a \leq i < s_a + S\} & \text{if } \epsilon_a = -1, \end{cases}$$

and $\kappa_c = \mathrm{len}_c + \sum_{i\in J_c}\big(\mathrm{len}_c + 1 + v_\ell(i)\big)$. Then there are integers $r_0, \sigma, E \geq 0$ with

$$r_0 \leq 3\,\mathrm{Sg}, \qquad \sigma \leq 3\,\mathrm{Sg}, \qquad E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320},$$

and, for every $c \in C$, an $\mathcal{O}_L$-submodule $X_c \subseteq H^1_f(D, T_2)$ and a finite subset $Z_c \subseteq H^1_f(D, T_2)$ with $|Z_c| \leq m\,\mathrm{len}_c(\mathrm{len}_c + 1)$, such that

$$\ell^{r_0+2\sigma} H^1_f(D, T_2) \subseteq \sum_{c\in C} X_c \qquad \text{and} \qquad \ell^{\sigma+\kappa_c+E} X_c \subseteq \Phi_* H^1_f(D, T_1) + \sum_{z\in Z_c} \mathcal{O}_L z \quad (c \in C).$$

Proof. **Parameters.** Let $(M_a, h_a)_a$ be the window of Proposition C.5: $(\eta, s_a + S)$ if $\epsilon_a = 1$, $(s_a + S, \eta)$ if $\epsilon_a = -1$; it contains the Hodge jumps of V_1, V_2 and of every extension V_Y produced there. Let h_B, M, m_X, c', H_c, Π_c be as in Proposition C.25 and σ_B as in Proposition C.10. Some site is thin and its size exceeds $\eta \geq 0$, so $w \geq 1$ and $h_B \geq 1$. Put $G = g = w + S$ and $m' = R = m_X$, and $j = 1$. For $c \in C$ the site $c+1$ is thin, so $M_{c+1} \leq \max(\eta, s_{c+1} + S) \leq w + S = G$ (sizes exceed η); every $M_a \leq h_B$ (at a thick site $s_a + S \leq b + \eta + S$), and $m_X = (\ell - 1)M > 2h_B \geq \max(g, 1 + \max_a M_a)$. So G, g, m', R satisfy the hypotheses of Proposition 24.4 (for T_2 and any Y of Proposition C.5) and of Proposition C.10; I_c and $\rho_{c,1}$ are formed for $\mathbf{N}_2 = \mathbf{N}(T_2)$ with these parameters, and $\sigma' = \sigma_\ell(w + S, m_X, 1) = \lfloor (w + S + M)\ell/(\ell - 1)^2 \rfloor + 1 \leq \sigma_B$ (Lemma 24.6).

$\sigma_B \leq 3\,\mathrm{Sg}$**.** With $q = \ell/(\ell - 1)^2$ ($\ell \geq 11$): $q \leq \min(0.11, 1.21/\ell)$ and $q/(\ell - 1) \leq 1.331/\ell^2$ (equalities at $\ell = 11$, ratios decreasing). As $M \leq 2h_B/(\ell - 1) + 1$,

$$\sigma_B \leq (2(w + S) + M)q + 2 \leq \frac{2.42\,(w + S)}{\ell} + \frac{2.662\,h_B}{\ell^2} + 2.11 \leq 3\,\mathrm{Sg},$$

since $h_B \leq h$ ($h_B = h$ if some site is thick, $h_B = w + S < h$ otherwise) and $\log_\ell(2h) \geq 0$. Also $\mathrm{Sg} \geq 1$.
