Step 1 (relay classes are Γ-invariant). Let $w_0 \in I_c$ and $u \in \mathbb{Z}_\ell^\times$. Then $\gamma_u w_0 \in I_c$ (Lemma C.16 (d)) and $\rho_{c,1}(\gamma_u w_0) = \rho_{c,1}(w_0)$. Indeed, $\gamma_u W_{w_0} \in X\mathbf{N}_E$ and $(\gamma_v - 1)\gamma_u W_{w_0} = \gamma_u(\gamma_v - 1)w_0 = (\gamma_v - 1)\gamma_u w_0$ for all v, so $W_{\gamma_u w_0} = \gamma_u W_{w_0}$ by the uniqueness in (Hf1). If τ is a relay correction of w_0 with V, then $\gamma_u V - W_{\gamma_u w_0} = \gamma_u(V - W_{w_0}) \in X^R\mathbf{N}_E$ and $\gamma_u\tau - \ell^{\sigma'}\varphi(\gamma_u V) = \gamma_u(\tau - \ell^{\sigma'}\varphi(V)) \in X^{m'}\lambda_1^g P_1(\mathbf{N}_{2,c})[1/\ell]$, because γ_u commutes with φ, preserves $P_1(\mathbf{N}_{2,c})$ and multiplies X and $\lambda_1 = Q_0$ by units (Lemma C.16 (b)); so $\gamma_u\tau$ is a relay correction of $\gamma_u w_0$, and $\rho_{c,1}(\gamma_u w_0) = \mathrm{cl}(\gamma_u y)$ with $y = \ell^{\sigma'}\varphi(w_0) - \tau$, a Herr vector of precision m' (Ry2). Now $\gamma_u y$ is a Herr vector of precision m', $(\gamma_u - 1)y = (\varphi - 1)(z_u(y))$ with $z_u(y) \in X^{m'}\mathbf{N}_2$ and $(\gamma_v - 1)z_u(y) \in X^{m'}\mathbf{N}_2$ for all v; by (Hc4) and (Hc3) of Lemma 23.28, $\mathrm{cl}(\gamma_u y) = \mathrm{cl}(y) + \mathrm{cl}((\varphi - 1)z_u(y)) = \mathrm{cl}(y) = \rho_{c,1}(w_0)$.

Step 2 (splitting). Let $x \in H^1_f(D, T_2)$, and let $r_0 \leq 3\,\mathrm{Sg}$, $0 \to T_2 \xrightarrow{\iota'} Y \xrightarrow{\pi} \mathcal{O}_L \to 0$ with $[Y] = x$ and $x_c \in \mathbf{N}(Y)_c$ ($c \in C$) be as in Proposition C.5; r_0 does not depend on x. The cuts satisfy the hypotheses of Proposition 24.4: $C \neq \emptyset$, and len_c is the least $d \geq 1$ with $c - d \in C$; also $j = 1 \leq \mathrm{len}_c$. So there are $\tau'_c \in P_1(\mathbf{N}_{2,c})$ and $w_c \in I_c$ with

$$\mathbf{N}(\iota')(w_c) = \varphi^{e-1}(X_{c'}) - \ell^{\sigma'}x_c, \qquad X_{c'} = \ell^{\sigma'}\varphi(x_{c'}) - \mathbf{N}(\iota')(\tau'_{c'}), \qquad \ell^{r_0 + 2\sigma'}x = \sum_{c \in C} \rho_{c,1}(w_c),$$

where $e = \mathrm{len}_c$. Put $\bar{w}_c = (\ell - 1)^{-1}\sum_{u \in \mu_{\ell-1}} \gamma_u w_c \in I_c$; it is Δ-invariant (that is, fixed by γ_u for $u \in \mu_{\ell-1}$), and $\rho_{c,1}(\bar{w}_c) = \rho_{c,1}(w_c)$ by Step 1 and (Ry4). Hence $\ell^{r_0 + 2\sigma'}x = \sum_c \rho_{c,1}(\bar{w}_c)$.

Step 3 (the vectors $\bar{w}_c$ satisfy the hypotheses of Proposition C.10). Fix $c \in C$, $e = \mathrm{len}_c$. Since $\mathbf{N}(\iota')$ is $\mathbf{A}_{F,L}$-linear and commutes with φ, $X_{c'} \in P_1(\mathbf{N}(Y)_{c'})$, so $\varphi^{e-1}(X_{c'}) \in P_e(\mathbf{N}(Y)_{c'})$ (as $\varphi^{e-1}(a\varphi(y)) = \varphi^{e-1}(a)\varphi^e(y)$), and $\ell^{\sigma'}x_c \in \mathbf{N}(Y)_c$. Both modules are γ_u-stable and $\mathbf{N}(\iota')$ commutes with γ_u, so $\mathbf{N}(\iota')(\bar{w}_c) = p - y$ with $p \in P_e(\mathbf{N}(Y)_{c'})$, $y \in \mathbf{N}(Y)_c$. (i) *Arc membership.* Every Hodge jump of V_Y at τ_a lies in $[-M_a, h_a] \subseteq [-(s_a + S), s_a + S] \subseteq [-H_c(a), H_c(a)]$ ($s_a + S \leq w + S$ at thin sites, $\leq h_B$ everywhere, as in Lemma C.16 (1)); so $(H_c(a), H_c(a))_a$ is a window of V_Y, and Lemma C.50 (Ae2) (with c', e, $H = H_c$) gives $\Pi_c\bar{w}_c \in P_e(\mathbf{N}_{2,c'})$. (ii) *Pole bounds.* Let $\mathbf{n}$ be a frame at c' of $\mathbf{N}_2$ fixed by the γ_u, $u \in \mu_{\ell-1}$, and let $\mathbf{n}_Y$ be any frame at c' of $\mathbf{N}(Y)$ (it is free by (Wm1)). Lemma C.51 (with c', e, $a = c$, $H = H_c$, $m = m_X \geq 2H_c(c - s)$) gives $t \geq 0$ and an arc coordinate vector of $\ell^t\bar{w}_c$ for $\mathbf{n}$, e, H_c, m_X that is pole-bounded by B^c, provided that $\varphi^e(\varepsilon_{c'+3}D_{\mathrm{cris}}(V_2)) \cap \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}+S+1}D_{\mathrm{cris}}(V_2)) = 0$ for every $s < e$ with $\epsilon_{c-s} = 1$. This holds: by the remark in Definition 23.3, $\varphi^{-(s+4)}$ maps $\varphi^e(\varepsilon_{c'+3}D_{\mathrm{cris}}(V_2))$ into the τ_{c-s}-component $\varepsilon_{c-s-1}D_{\mathrm{cris}}(V_2)$, whose filtration is that of $D_{\mathrm{dR},\tau_{c-s}}(V_2)$ (F unramified, V_2

crystalline); as $\epsilon_{c-s}=1$, every jump there is $\le h_{c-s}=s_{c-s}+S$, so $\varepsilon_{c-s-1}\mathrm{Fil}^{s_{c-s}+S+1}D_{\mathrm{cris}}(V_2)=0$, and the intersection is 0 because φ is bijective on $D_{\mathrm{cris}}(V_2)$ and Fil^u is an $F\otimes L$-submodule. With $\bar w_c\in I_c$ and Δ-invariant, all hypotheses of Proposition C.10 on $w=\bar w_c$ hold.

Step 4 (conclusion). Let $E\ge 0$ and Z_c ($c\in C$) be as in Proposition C.10, and put $E^+=\max(E,\sigma_B)$; then $E^+\le\max(40\,\mathrm{Sg}+\eta\beta_{320},3\,\mathrm{Sg})=40\,\mathrm{Sg}+\eta\beta_{320}$ and $|Z_c|\le m\,\mathrm{len}_c(\mathrm{len}_c+1)$. Let X_c be the $\mathcal{O}_L$-span of the classes $\rho_{c,1}(w_0)$, w_0 running over the vectors satisfying the hypotheses of Proposition C.10 at c. For such w_0, $\Pi_c w_0\in P_e(\mathbf{N}_{2,c'})$ and $\Pi_c P_e(\mathbf{N}_{2,c'})\subseteq\mathbf{N}_{2,c}$ (Lemma 23.15 (2), window (H_c,H_c)), so $\Pi_c^2 w_0\in\mathbf{N}_2$ and $\rho_{c,1}(w_0)\in H^1_f(D,T_2)$ by (Ry7); thus $X_c\subseteq H^1_f(D,T_2)$, and Proposition C.10 gives $\ell^{\sigma_B+\kappa_c+E^+}X_c\subseteq\Phi_*H^1_f(D,T_1)+\sum_{z\in Z_c}\mathcal{O}_L z$. By Steps 2 and 3, $\ell^{r_0+2\sigma'}x\in\sum_c X_c$ for every $x\in H^1_f(D,T_2)$, hence $\ell^{r_0+2\sigma_B}H^1_f(D,T_2)\subseteq\sum_c X_c$ as $\sigma'\le\sigma_B$. The assertion follows with r_0, the exponent $\sigma_B\le 3\,\mathrm{Sg}$ in place of σ, and E^+ in place of E. □

Proposition C.5. *Let ℓ, F, n, $D=G_F$, L, (τ_a), $\Phi\colon V_1\to V_2$ ($T_1\to T_2$) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.25. For $a\in\mathbb{Z}/n$ put $(M_a,h_a)=(\eta,\ s_a+S)$ if $\epsilon_a=1$ and $(M_a,h_a)=(s_a+S,\ \eta)$ if $\epsilon_a=-1$, and $\varepsilon_a=(\iota\otimes\mathrm{id})(e_a)\in A_{\mathrm{inf}}\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L$. Then every Hodge jump of V_1 and of V_2 at τ_a lies in $[-M_a,h_a]$, and there is an integer r_0 with $0\le r_0\le 3\,\mathrm{Sg}$ such that for every $x\in H^1_f(D,T_2)$ there are a pair (V_Y,Y) and an exact sequence $0\to T_2\xrightarrow{\iota'}Y\xrightarrow{\pi}\mathcal{O}_L\to 0$ of G_F-equivariant $\mathcal{O}_L$-linear maps with $[Y]=x$, such that every Hodge jump of V_Y at τ_a lies in $[-M_a,h_a]$ ($a\in\mathbb{Z}/n$), and for every $c\in C$ there is $x_c\in\mathbf{N}(Y)_c$ with*

$$(1\otimes\pi)\big(\iota_Y(x_c)\big)=\ell^{r_0}\varepsilon_c.$$

Proof. **Windows.** Every Hodge jump of V_1 and of V_2 at τ_a lies in $[-M_a,h_a]$ by Lemma C.9 (1).

The extension. Let $x\in H^1_f(D,T_2)$ ($=H^1_f(F,T_2)$ of Proposition 23.27: both are the inverse image of $H^1_f(D,V_2)$). Lemma 23.26 gives a pair (V_Y,Y) and $0\to T_2\to Y\to\mathcal{O}_L\to 0$ with $[Y]=x$ whose jumps at τ_a lie in $[-M_a,h_a]$.

Lifting the unit. Let r_c ($c\in\mathbb{Z}/n$) be the integers of Proposition C.6 formed with the window $(M_a,h_a)_a$; they depend only on ℓ and the weight word. Let $\mathbf{1}\in\mathbf{N}(\mathcal{O}_L)$ be as in Proposition C.8, and $c\in C$. Apply Proposition C.6 ($\ell\ge 5$) to the surjection $\pi\colon Y\to\mathcal{O}_L$, the window (M_a,h_a) of V_Y and $y=e_c\mathbf{1}\in\mathbf{N}(\mathcal{O}_L)_c$: there is $x'_c\in\mathbf{N}(Y)_c$ with $\mathbf{N}(\pi)(x'_c)=\ell^{r_c}e_c\mathbf{1}$. By (Ex3) and (Ex2) (writing $e_c=\sum_i f_i\otimes\lambda_i$ with $f_i\in\mathcal{O}_F$, $\lambda_i\in\mathcal{O}_L$),

$$(1\otimes\pi)\big(\iota_Y(x'_c)\big)=\iota_{\mathcal{O}_L}\big(\mathbf{N}(\pi)(x'_c)\big)=\ell^{r_c}\,(\iota\otimes\mathrm{id})(e_c)\,\iota_{\mathcal{O}_L}(\mathbf{1})=\ell^{r_c}\varepsilon_c.$$

Let $r_0=\max_{c\in C}r_c$ and $x_c=\ell^{r_0-r_c}x'_c$. By Lemma C.9 (2), $r_c\le 3\,\mathrm{Sg}$ for every $c\in C$, so $0\le r_0\le 3\,\mathrm{Sg}$. □

Proposition C.6. *Let $\ell\ge 5$ be a prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F\subseteq K\subseteq F(\mu_\ell)$ as in Proposition 23.7, $d=|\Delta_K|$, and $f\colon T\to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K. Let $M_a,h_a\ge 0$ be integers such that every Hodge jump of V at every embedding of K over τ_a lies in $[-M_a,h_a]$ ($a\in\mathbb{Z}/n$), and put $H(a)=M_a+h_a$, $H_{\max}=\max_a H(a)$, $c_H=\lceil 1+\log_\ell(H_{\max}+1)\rceil$ and, for $c\in\mathbb{Z}/n$,*

$$s_c=\sum_{a\ge 0}\frac{H(c+a+1)+c_H+3}{d^a}\in(0,\infty],\qquad r_c=\Big\lfloor\min(\lfloor s_c\rfloor,H_{\max})\frac{\ell}{d(\ell-1)}\Big\rfloor+c_H$$

($s_c=\infty$ when $d=1$, and then the minimum is $H_{\max}$). Then for every $c\in\mathbb{Z}/n$ and every $y\in\mathbf{N}(T'')_c$ there is $x\in\mathbf{N}(T)_c$ with $\mathbf{N}(f)(x)=\ell^{r_c}y$. For $K=F$ (pairs, G_F, the embedding τ_a itself, $d=\ell-1$) the constants are $s_c=\sum_{a\ge0}(H(c+a+1)+c_H+3)/(\ell-1)^a$ and $r_c=\lfloor\min(\lfloor s_c\rfloor,H_{\max})\ell/(\ell-1)^2\rfloor+c_H$.

Proof. The data ℓ, F, L, (τ_a), K, f, $(M_a, h_a)_a$ satisfy the hypotheses of Lemma C.7, and d, $H(a)$, $H_{\max}$, c_H, s_c, r_c are defined there by the same formulas as here. Let $c \in \mathbb{Z}/n$. By (Ki2) of Lemma C.7, ℓ^{r_c} is killing at c, that is, $\ell^{r_c}\mathbf{N}(T'')_c \subseteq \mathbf{N}(f)(\mathbf{N}(T)_c)$. Hence for $y \in \mathbf{N}(T'')_c$ there is $x \in \mathbf{N}(T)_c$ with $\mathbf{N}(f)(x) = \ell^{r_c}y$. □

Lemma C.7. *Let $\ell \geq 5$ be a prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a field K with $F \subseteq K \subseteq F(\mu_\ell)$ as in Proposition 23.7, $d = |\Delta_K|$ and $e = (\ell-1)/d$, and $f\colon T \to T''$ a G_K-equivariant $\mathcal{O}_L$-linear surjection of the lattices of pairs (V,T), (V'',T'') over K. Let $M_a, h_a \geq 0$ be integers such that every Hodge jump of V at every embedding of K over τ_a lies in $[-M_a, h_a]$ ($a \in \mathbb{Z}/n$), and put $H(a) = M_a + h_a$, $H_{\max} = \max_a H(a)$, $c_H = \lceil 1 + \log_\ell(H_{\max}+1)\rceil$ and, for $c \in \mathbb{Z}/n$,*

$$s_c = \sum_{a\geq 0} \frac{H(c+a+1)+c_H+3}{d^a} \in (0,\infty], \qquad r_c = \Big\lfloor \min(\lfloor s_c\rfloor, H_{\max})\frac{\ell}{d(\ell-1)}\Big\rfloor + c_H$$

($s_c = \infty$ when $d = 1$, and then the minimum is $H_{\max}$). Write $\mathbf{N}''_c = \mathbf{N}(T'')_c$ and $\mathbf{N}'_c = \mathbf{N}(f)(\mathbf{N}(T)_c)$, and call $t \in e_c\mathbf{A}_{F,L}$ killing at c *if $t\,\mathbf{N}''_c \subseteq \mathbf{N}'_c$. The **killing index** at c is*

$$\sigma_c = \min\{s \geq 0 :\ X^s \text{ is killing at } c\}.$$

Then σ_c is well defined, and for every $c \in \mathbb{Z}/n$:

(Ki1) *$\sigma_c \leq \min(\lfloor s_c\rfloor, H_{\max})$, and for every integer $m \geq 1$*

$$\sigma_c \leq \sum_{a=0}^{m-1} \frac{H(c+a+1)+c_H+3}{d^a} + \frac{\sigma_{c+m}}{d^m} \leq \sum_{a=0}^{m-1} \frac{H(c+a+1)+c_H+3}{d^a} + \frac{H_{\max}}{d^m}.$$

(Ki2) *For all integers $0 \leq j \leq \sigma_c$ and $D \geq \mathrm{dsc}_{\ell,d}(j,\sigma_c)$, $\ell^D X^j$ is killing at c. In particular ℓ^{r_c} is killing at c.*

(Ki3) *Let $\pi \in e_c\mathbf{A}_{F,L}$ with $\pi = X^d v$ for a unit v of $e_c\mathbf{A}_{F,L}$, $E \in \mathbb{Z}_\ell[Y]$ monic of degree e with all other coefficients in $\ell\mathbb{Z}_\ell$ (for instance E_Δ of Definition 23.23 with $\Delta = \Delta_K$, by Lemma 23.24(Rr3)), and $A_c = \lceil \sigma_c/d\rceil$. Then $A_c \leq H_{\max}/d+1$, and π^{A_c} and $E(\pi)^{\lceil A_c/e\rceil + r_c}$ are killing at c.*

(Ki4) *Let $t \in e_c\mathbf{A}_{F,L}$ be killing at c and let $y \in \mathbf{N}''_c$, and suppose $\gamma_u(t) = t$ and $\gamma_u(y) = y$ for all $u \in \Delta_K$. Then there is $x \in \mathbf{N}(T)_c$ with $\gamma_u(x) = x$ for all $u \in \Delta_K$ and $\mathbf{N}(f)(x) = ty$.*

For $K = F$ (G_F, pairs, the embedding τ_a itself, $d = \ell-1$, $e = 1$, $\Delta_F = \mu_{\ell-1}$, $\mathrm{dsc}_{\ell,\ell-1} = \mathrm{dsc}_\ell$) and $E(Y) = Y + \ell$ this is the statement with $s_c = \sum_a (H(c+a+1)+c_H+3)/(\ell-1)^a$, $r_c = \lfloor \min(\lfloor s_c\rfloor, H_{\max})\ell/(\ell-1)^2\rfloor + c_H$, $\pi = X^{\ell-1}v$, $A_c = \lceil \sigma_c/(\ell-1)\rceil$, $A_c \leq H_{\max}/(\ell-1)+1$ and $(\pi+\ell)^{A_c+r_c}$.

Proof. **Setting.** Put $\mathbf{N} = \mathbf{N}(T'')$ and $\mathbf{N}' = \mathbf{N}(f)(\mathbf{N}(T))$, so $\mathbf{N}'_a = e_a\mathbf{N}' = \mathbf{N}(f)(\mathbf{N}(T)_a)$ and $\mathbf{N}_a = \mathbf{N}''_a$. By (Ex1), $\mathbf{N}(T)$ is a Wach module over K with window $(M_a,h_a)_a$; by Lemma 23.25 (V is crystalline, hence de Rham) every Hodge jump of V'' at an embedding of K over τ_a is one of V at that embedding, so by (Ex1) $\mathbf{N}$ is a Wach module over K with the same window. By (Ex3), $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ (extended to $\mathbf{N}(T)[1/Q]$) and with every γ_u, $u \in \Gamma_K$. Hence $(\gamma_u - 1)\mathbf{N}' = \mathbf{N}(f)((\gamma_u-1)\mathbf{N}(T)) \subseteq X\mathbf{N}'$ for all $u \in \Gamma_K$ by (Wm3) for $\mathbf{N}(T)$, and applying $\mathbf{N}(f)$ to (Wm2) for $\mathbf{N}(T)$ gives $Q^{h_a}\mathbf{N}'_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}'_{a-1})$ for all a; so Lemma 23.20 (over K) applies to $\mathbf{N}$, $\mathbf{N}'$. By Proposition 23.18 (over K), $X^{H_{\max}}$ is killing at every a, so σ_a is well defined and $\sigma_a \leq H_{\max}$. Put $k_H = c_H + 3$.

Step 1: $\sigma_{a-1} \le H(a) + k_H + \sigma_a/d$ for every a. Let $s = \max(\sigma_a, 1)$ and $b = c_H + 1$. Then $X^s \mathbf{N}_a \subseteq \mathbf{N}'_a$, and $s \le H_{\max} + 1$ gives $2 + \log_\ell s \le 2 + \log_\ell(H_{\max} + 1) \le 1 + c_H = b$. Item 4 of Lemma 23.20 gives $\sigma_{a-1} \le M_a + h_a + \lceil s/d \rceil + c_H + 1$. Finally $\lceil s/d \rceil \le \sigma_a/d + 1$: for $\sigma_a = 0$ both sides are 1, and for $\sigma_a \ge 1$, $\lceil \sigma_a/d \rceil \le \sigma_a/d + (d-1)/d$. Hence $\sigma_{a-1} \le H(a) + c_H + 2 + \sigma_a/d$.

Step 2: (Ki1). By induction on $m \ge 1$, Step 1 at the indices $c+1, \dots, c+m$ gives the first inequality of (Ki1): for $m = 1$ it is Step 1 at $a = c+1$, and the step from m to $m+1$ inserts $\sigma_{c+m} \le H(c+m+1) + k_H + \sigma_{c+m+1}/d$. The second inequality follows from $\sigma_{c+m} \le H_{\max}$. If $d \ge 2$, letting $m \to \infty$ gives $\sigma_c \le s_c$ (the series converges, its terms being at most $(H_{\max} + k_H) d^{-a}$), and since σ_c is an integer, $\sigma_c \le \lfloor s_c \rfloor$; if $d = 1$, $s_c = \infty$. In both cases $\sigma_c \le H_{\max}$.

Step 3: (Ki2), descent to powers of ℓ. Apply Lemma 23.21 with $\Gamma = \Gamma_K$, a closed subgroup of $\mathbb{Z}_\ell^\times$ containing $1 + \ell\mathbb{Z}_\ell$ of index $|\Delta_K| = d$ (Lemma 23.24(Rr7)), $D = N = \mathbf{N}_c$ (free by (Wm1), so X is injective) and $N' = \mathbf{N}'_c$: by (Wm3) $(\gamma_u - 1)\mathbf{N}_c \subseteq X\mathbf{N}_c$, and $(\gamma_u - 1)\mathbf{N}'_c = e_c(\gamma_u - 1)\mathbf{N}' \subseteq X\mathbf{N}'_c$ ($\gamma_u(e_c) = e_c$), for $u \in \Gamma_K$; X^{σ_c} kills $\mathbf{N}_c/\mathbf{N}'_c$. Item 1 gives the first claim of (Ki2). For $j = 0$, item 2 gives $\mathrm{dsc}_{\ell,d}(0, \sigma_c) \le \lfloor \sigma_c \ell/(d(\ell-1)) \rfloor$, and by (Ki1)

$$\mathrm{dsc}_{\ell,d}(0, \sigma_c) \le \Big\lfloor \min(\lfloor s_c \rfloor, H_{\max}) \frac{\ell}{d(\ell-1)} \Big\rfloor \le r_c,$$

so ℓ^{r_c} is killing at c.

Step 4: (Ki3). First, $A_c \le \sigma_c/d + 1 \le H_{\max}/d + 1$ by (Ki1). Since $\mathbf{N}'_c$ and $\mathbf{N}_c$ are $e_c\mathbf{A}_{F,L}$-modules, every multiple wt ($w \in e_c\mathbf{A}_{F,L}$) of a killing element t is killing, and so is every X^k with $k \ge \sigma_c$. Now $\pi^{A_c} = v^{A_c} X^{dA_c}$ with $dA_c \ge \sigma_c$, so π^{A_c} is killing. Write $E(Y) = Y^e + \ell g(Y)$ with $g \in \mathbb{Z}_\ell[Y]$, put $B = \lceil A_c/e \rceil$ and $N = B + r_c$, and expand

$$E(\pi)^N = \sum_{i=0}^{N} \binom{N}{i} \pi^{ei}\, \ell^{N-i} g(\pi)^{N-i}.$$

For $i \ge B$, $ei \ge A_c$ and the term is a multiple of π^{A_c}; for $i < B$, $N - i > r_c$ and the term is a multiple of ℓ^{r_c}, killing by (Ki2). The killing elements form an additive group, so $E(\pi)^N$ is killing. (For $e = 1$, $E(Y) = Y + \ell$: $B = A_c$ and this is $(\pi + \ell)^{A_c + r_c}$.)

Step 5: (Ki4), Δ_K-averaging. The group Δ_K is finite, of order d dividing $\ell - 1$, so $d \in \mathcal{O}_L^\times$. Choose $x_0 \in \mathbf{N}(T)_c$ with $\mathbf{N}(f)(x_0) = ty$ and put

$$x = \frac{1}{d} \sum_{u \in \Delta_K} \gamma_u(x_0).$$

Each γ_u ($u \in \Gamma_K \supseteq \Delta_K$) is semilinear and preserves $\mathbf{N}(T)$ (definition of a Wach module over K), and $\gamma_u(e_c) = e_c$, so $x \in \mathbf{N}(T)_c$; as Δ_K is a group and $\gamma_u \gamma_{u'} = \gamma_{uu'}$, $\gamma_{u'}(x) = x$ for $u' \in \Delta_K$. Since $\mathbf{N}(f)$ commutes with γ_u (Ex3) and $\gamma_u(ty) = \gamma_u(t)\gamma_u(y) = ty$,

$$\mathbf{N}(f)(x) = \frac{1}{d} \sum_{u \in \Delta_K} \gamma_u(ty) = ty.$$

□

Proposition C.8. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, and let $(L, \mathcal{O}_L)$ be the trivial pair (G_F acting trivially). Then there is $\mathbf{1} \in \mathbf{N}(\mathcal{O}_L)$ with $\iota_{\mathcal{O}_L}(\mathbf{1}) = 1 \otimes 1$ in $A_{\mathrm{inf}}[1/\mu_\varepsilon] \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$.*

Proof. By (Ex5) of Proposition 23.7 (with $K = F$, $s = 1$, ℓ odd) there are a datum $\mathcal{E}_1$ given by Theorem B.41 (for F and $p = \ell$) for the trivial lattice $T_1 = \mathcal{O}_L$ (a free $\mathbb{Z}_\ell$-module of rank

$[L:\mathbb{Q}_\ell]$ with trivial action) and an isomorphism c_1 with the properties of (Bs3) for it such that $\mathbf{N}(\mathcal{O}_L)=\mathcal{E}_1(\mathbf{A}_F)$ and $\iota_{\mathcal{O}_L}=c_1\circ\mathcal{E}_1(\iota)$, where $\iota\colon \mathbf{A}_F\to A_{\mathrm{inf}}$ is the morphism over $\mathcal{O}_F$ of Lemma 23.8.

Let $\mathcal{E}_0(A)=A\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L$ for every object (A,I) over $\mathcal{O}_F$, with $\varphi_{\mathcal{E}_0,A}(a\otimes(b\otimes\lambda))=a\varphi_A(b)\otimes\lambda$ and $\mathcal{E}_0(g)=g\otimes 1$. This is a datum as in (Bs1), (Bs2): $\mathcal{E}_0(A)$ is free of rank $[L:\mathbb{Q}_\ell]$, $\varphi_{\mathcal{E}_0,A}$ is an isomorphism already before inverting I, the linearisation of $g\otimes 1$ is the isomorphism $B\otimes_{g,A}(A\otimes\mathcal{O}_L)\cong B\otimes\mathcal{O}_L$, and all compatibilities are clear. The identity c_0 of $W(\mathbb{C}_\ell^\flat)\otimes_{\mathbb{Z}_\ell}\mathcal{O}_L$ has the properties of (Bs3) for $T_0=\mathcal{O}_L$: it is G_F-equivariant (G_F acts trivially on $\mathcal{O}_L$), carries $\varphi_{\mathcal{E}_0,A_{\mathrm{inf}}}\otimes\varphi=\varphi\otimes 1$ to $1\otimes\varphi$ on $\mathcal{O}_L\otimes W(\mathbb{C}_\ell^\flat)$ (the same map), and restricts to the identity of $A_{\mathrm{inf}}[1/\mu_\varepsilon]\otimes\mathcal{O}_L$.

By (Bs6) of Theorem B.41, applied to $\mathrm{id}\colon T_0=\mathcal{O}_L\to T_1=\mathcal{O}_L$, there are maps $\mathcal{E}(\mathrm{id})_A\colon \mathcal{E}_0(A)\to\mathcal{E}_1(A)$ with $\mathcal{E}_1(g)\circ\mathcal{E}(\mathrm{id})_A=\mathcal{E}(\mathrm{id})_B\circ\mathcal{E}_0(g)$ for morphisms $g\colon A\to B$ over $\mathcal{O}_F$, and $c_1\circ(\mathcal{E}(\mathrm{id})_{A_{\mathrm{inf}}}\otimes 1)=c_0$. Put $\mathbf{1}=\mathcal{E}(\mathrm{id})_{\mathbf{A}_F}(1\otimes 1)\in\mathcal{E}_1(\mathbf{A}_F)=\mathbf{N}(\mathcal{O}_L)$. Then, with $g=\iota$,

$$\iota_{\mathcal{O}_L}(\mathbf{1})=c_1\big(\mathcal{E}_1(\iota)\,\mathcal{E}(\mathrm{id})_{\mathbf{A}_F}(1\otimes 1)\big)=c_1\big(\mathcal{E}(\mathrm{id})_{A_{\mathrm{inf}}}(\iota(1)\otimes 1)\big)=c_0(1\otimes 1)=1\otimes 1.$$

□

Lemma C.9. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1\to V_2$ ($T_1\to T_2$) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.25. For $a\in\mathbb{Z}/n$ put $(M_a,h_a)=(\eta,\ s_a+S)$ if $\epsilon_a=1$ and $(M_a,h_a)=(s_a+S,\ \eta)$ if $\epsilon_a=-1$. Then:*

1. *every Hodge jump of V_1 and of V_2 at τ_a lies in $[-M_a,h_a]$ ($a\in\mathbb{Z}/n$);*
2. *the integers r_c of Proposition C.6 formed with the window $(M_a,h_a)_a$ satisfy $r_c\le 3\,\mathrm{Sg}$ for every $c\in C$.*

Proof. **1.** By (Ow1), a jump of V_1 at τ_a lies in $[s_a,s_a+S]\cup[-\eta,\eta]\subseteq[-\eta,s_a+S]$ if $\epsilon_a=1$ and in $[-s_a-S,-s_a]\cup[-\eta,\eta]\subseteq[-s_a-S,\eta]$ if $\epsilon_a=-1$, i.e. in $[-M_a,h_a]$; the jumps of V_2 are among those of V_1 (Lemma 24.2 (1)).

2. Here $H(a)=M_a+h_a=s_a+S+\eta$, $H_{\max}=\max_a H(a)$, $c_H=\lceil 1+\log_\ell(H_{\max}+1)\rceil$, $s_c=\sum_{a\ge 0}(H(c+a+1)+c_H+3)/(\ell-1)^a$ and $r_c=\lfloor\min(\lfloor s_c\rfloor,H_{\max})\,\ell/(\ell-1)^2\rfloor+c_H$. Let $c\in C$; then $c+1$ is thin, so $H(c+1)\le w+S+\eta$ by (Ow3). Every $H(a)\le h+\eta$: at a thick site $s_a\le b+\eta$ and $h=b+\eta+S$; at a thin site $s_a\le w$, and $w+S\le h$ (if some site is thick, $w\le b$ because $20w\le b$; otherwise $h=w+S+\eta+1$). Also $h\ge\eta+1$ ($b\ge 1$), so $H_{\max}+1\le h+\eta+1\le 2h$ and $c_H\le 2+\log_\ell(2h)$. Hence, with the geometric series ($\ell\ge 11$),

$$s_c\le(w+S+\eta)+(c_H+3)+\frac{h+\eta+c_H+3}{\ell-2}.$$

Put $q=\ell/(\ell-1)^2$; for $\ell\ge 11$, $q\le\min(0.11,\ 1.21/\ell)$ and $q/(\ell-2)\le 1.5/\ell^2$ (both hold at $\ell=11$ and the left sides times ℓ, resp. ℓ^2, decrease in ℓ). Therefore

$$r_c\le q\,s_c+c_H\le\frac{1.21(w+S+\eta)}{\ell}+\frac{1.5(h+\eta)}{\ell^2}+(c_H+3)\Big(0.11+\frac{1.5}{121}\Big)+c_H.$$

Here $1.5(h+\eta)/\ell^2\le 1.5h/\ell^2+0.14\,\eta/\ell$, and $(c_H+3)\cdot 0.1224+c_H\le 1.1224\,c_H+0.368\le 2.62+1.1224\log_\ell(2h)$. Comparing term by term with $3\,\mathrm{Sg}=3h/\ell^2+3(w+S+\eta)/\ell+3\log_\ell(2h)+3$ (and $\log_\ell(2h)\ge 0$) gives $r_c\le 3\,\mathrm{Sg}$. □

C.1.2 Relay classes at a cut and the universal part

The result of this subsection is Proposition C.10: the relay classes at one cut lift along the onto map up to the killer valuation, modulo few exceptional classes; it is used in Proposition C.4. Its main input is the universal part at a cut (Proposition C.11), assembled from four packages: a Δ-invariant frame at the start of the arc adapted to the high and low jumps (Proposition C.12); killer-polynomial denominators for the coordinates of arc relay vectors off the low coordinates (Proposition C.13); an exceptional family of at most $m\,\mathrm{len}(\mathrm{len}+1)$ vectors on the low coordinates (Proposition C.21); and the realisation of coordinate vectors that are Hodge-integral modulo γ by arc relay vectors (Proposition C.22). The remaining lemmas are a calculus of arc coordinates and levels, and a membership criterion along an arc (Proposition C.24).

Proposition C.10. *Let ℓ, F, n, $D = G_F$, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25, and put $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$. Let $M_a, h_a \geq 0$ ($a \in \mathbb{Z}/n$) be integers such that every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$ (by Lemma 24.2 (1) and (Ex1), $(M_a, h_a)_a$ is then a window of both $\mathbf{N}_1$ and $\mathbf{N}_2$), and let G, g, m', R be integers with $G \geq M_{c+1}$ for every $c \in C$, $g \geq G$, $m' \geq 1 + \max_a M_a$ and $R \geq \max(m', g)$; put $\sigma_B = \lceil (2(w+S) + m_X/(\ell-1))\,\ell/(\ell-1)^2 \rceil + 1$, and form I_c, $\rho_{c,1}$ for $\mathbf{N}_2$ (and I_c^1, $\rho_{c,1}^1$ for $\mathbf{N}_1$) with $j = 1$ and these G, g, m', R. For $c \in C$ let $B^c = (B_s^c)_{s<\mathrm{len}_c}$ be $B_s^c = s_{c-s} + S$ if $\epsilon_{c-s} = 1$ and $B_s^c = \infty$ if $\epsilon_{c-s} = -1$.*

Then there are an integer E with $0 \leq E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320}$ and, for every $c \in C$, a finite subset $Z_c \subseteq H^1_f(D, T_2)$ with $|Z_c| \leq m\,\mathrm{len}_c(\mathrm{len}_c+1)$, such that the following holds. Let $c \in C$ and $w \in I_c$ with $\gamma_u(w) = w$ for $u \in \mu_{\ell-1}$, such that $\Pi_c\, w \in P_{\mathrm{len}_c}(\mathbf{N}_{2,c'})$ and, for every frame $\mathbf{n}$ at c' of $\mathbf{N}_2$ consisting of vectors fixed by γ_u ($u \in \mu_{\ell-1}$), some $\ell^t w$ ($t \geq 0$) has an arc coordinate vector for $\mathbf{n}$, len_c, H_c and m_X that is pole-bounded by B^c. Then

$$\ell^{\,\sigma_B + \kappa_c + \max(E, \sigma_B)} \rho_{c,1}(w) \in \Phi_* H^1_f(D, T_1) + \sum_{z \in Z_c} \mathcal{O}_L z.$$

Proof. **Conventions.** Whenever a cut $c \in C$ occurs, $e = \mathrm{len}_c$ and $c' = c - e$; so $c' + e = c$, and $c' \in C$, i.e. the site $c'+1$ is thin. Put $R_c = e_c \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ (a domain), $\Pi = \Pi_c = \prod_{s<e} Q_s^{H_c(c-s)}$ and $U = P_e(\mathbf{N}_{2,c'})$. Unless said otherwise, a *coordinate vector* is an arc coordinate vector for $\mathbf{N}_2$, a frame at c' named in the text, e, H_c and m_X. We write $\rho = \rho_{c,1}$ and $\rho^1 = \rho^1_{c,1}$. Here $H^1(F,T) = H^1(D,T)$ for $D = G_F$, and $H^1_f(F,T)$ of Proposition 23.27 and $H^1_f(D,T)$ are both the inverse image of $H^1_f(D,V)$.

Steps 1 and 2 (window and calculus of coordinate vectors). By Lemma C.16 (1), every Hodge jump of V_2 at τ_a lies in $[-H_c(a), H_c(a)]$ and

$$\Pi\, U \subseteq \mathbf{N}_{2,c}, \qquad \Pi\, \mathbf{N}_{2,c} \subseteq U. \tag{1}$$

Below, (a) linearity, (b) Γ-equivariance, (c) vanishing and (d) the relay-class facts refer to the parts of Lemma C.16, for the frame named in the text.

Step 3 (the data at the cut; E and Z_c). Let $E = E_{\mathrm{arc}}$ of Proposition C.25 (it does not depend on c), so $0 \leq E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320}$, and $E^+ = \max(E, \sigma_B)$. Let $c \in C$. Proposition C.11 gives a Δ-invariant frame $\mathbf{n}$ at c' with crystalline frame (d_k), a set $\mathcal{R}$ with $|\mathcal{R}| \leq me$, and $J_1, \ldots, J_{g_0}$, $g_0 \leq me(e+1)$, as in (U1)–(U5). By (U5), applied to J_i, there is $y_i \in I_c$ with $\Pi y_i \in U$ such that $\ell^{\sigma_B} J_i$ is a coordinate vector of y_i. Put $Z_c = \{\rho(y_1), \ldots, \rho(y_{g_0})\}$, so $|Z_c| \leq m\,\mathrm{len}_c(\mathrm{len}_c + 1)$. By (1), $\Pi^2 y_i \in \mathbf{N}_2$, and Π^2 is a finite product of the Q_s, so $\rho(y_i) \in H^1_f$ by (Ry7). Z_c depends only on c.

Step 4 (the killer polynomial). Let $w_0 \in I_c$ be the vector w of the statement and $x = \rho(w_0)$. Its hypotheses are those of (U3) for the Δ-invariant frame $\mathbf{n}$, which gives a Δ-invariant coordinate vector f of $\ell^{\sigma_B} w_0$ with the properties listed there. Let $P = P_{J_c,e}$ (formed with u_0), $v = P(\gamma_{u_0})(\ell^{\sigma_B} w_0) \in I_c$ and $g_P = P(\gamma_{u_0})f$; by (b), g_P is a coordinate vector of v and $\Pi v \in U$; g_P is Δ-invariant because the γ_u commute. The sets W_a consist of integers of absolute value at least $s_a > \eta \geq 0$, so $0 \notin J_c$, and Lemma 23.22 (2) (with $p = \ell$ odd, $m = v_\ell(u_0 - 1) = 1$) gives $v_\ell(P(1)) = e + \sum_{i \in J_c}(e + 1 + v_\ell(i)) = \kappa_c$; write $P(1) = \vartheta \ell^{\kappa_c}$ with $\vartheta \in \mathbb{Z}_\ell^\times$. By (d),

$$\rho(v) = P(1)\, \ell^{\sigma_B} x = \vartheta\, \ell^{\sigma_B + \kappa_c} x. \qquad (2)$$

Step 5 (splitting off the low coordinates). Let g_P'' have entries $g_{P,k}$ for $k \notin \mathcal{R}$ and 0 for $k \in \mathcal{R}$, and $g_P^{\mathcal{R}} = g_P - g_P''$. Both are Δ-invariant, have $\Pi(g_P'')_k, \Pi(g_P^{\mathcal{R}})_k \in R_c$ (as $\Pi g_{P,k} \in R_c$ by (b)), and are Hodge-integral modulo γ by (U3). By (U5) there are $u'', u^{\mathcal{R}} \in I_c$ with $\Pi u'', \Pi u^{\mathcal{R}} \in U$ such that $\ell^{\sigma_B} g_P''$, $\ell^{\sigma_B} g_P^{\mathcal{R}}$ are coordinate vectors of u'', $u^{\mathcal{R}}$. By (a), 0 is a coordinate vector of $\ell^{\sigma_B} v - u'' - u^{\mathcal{R}} \in I_c$, whose product with Π lies in U; by (d) and (2),

$$\rho(u'') + \rho(u^{\mathcal{R}}) = \ell^{\sigma_B} \rho(v) = \vartheta\, \ell^{2\sigma_B + \kappa_c} x. \qquad (3)$$

Step 6 (the low coordinates give Z_c). $g_P^{\mathcal{R}}$ satisfies the hypotheses of (U4), which gives $o \in \mathcal{O}_L^{g_0}$ and $h \in \mathcal{H}_{\mathbf{n}}$ with $g_P^{\mathcal{R}} - \sum_i o_i J_i = X^{\ell-1} h$. As h is Hodge-integral, Proposition C.23 gives $x_h \in \mathbf{N}_{2,c}$ such that $\ell^{\sigma_B} h$ is a coordinate vector of x_h; $\Pi x_h \in U$ by (1). By (a), 0 is a coordinate vector of $u^{\mathcal{R}} - \sum_i o_i y_i - X^{\ell-1} x_h$, which lies in I_c (as $X^{\ell-1} x_h \in X\mathbf{N}_{2,c}$) and whose product with Π lies in U. By (d) and (Ry5),

$$\rho(u^{\mathcal{R}}) = \sum_i o_i\, \rho(y_i) \in \sum_{z \in Z_c} \mathcal{O}_L z. \qquad (4)$$

Step 7 (lifting the high coordinates). Let $k \notin \mathcal{R}$. By (U3), $g_{P,k}$ is admissible at c in the sense of Proposition C.25 (Δ-invariant, $\nu_c g_{P,k} \in R_c$, and the congruence conditions at the $s < e$ with $\epsilon_{c-s} = -1$), and by (U1) the index k satisfies the filtration condition there. So Proposition C.25 gives $w_1^{(k)} \in I_c^1$, a finite product λ_k' of the Q_s and $z_k \in X\mathbf{N}_{2,c}$ with $\lambda_k' w_1^{(k)} \in \mathbf{N}_1$, $\Pi\, \mathbf{N}(\Phi)(w_1^{(k)}) \in U$, and $\ell^E g_{P,k} \mathbf{e}_k$ a coordinate vector of $\mathbf{N}(\Phi)(w_1^{(k)}) - z_k$. Put $u_1 = \ell^{E^+ - E} \sum_{k \notin \mathcal{R}} w_1^{(k)} \in I_c^1$, $\lambda' = \prod_{k \notin \mathcal{R}} \lambda_k'$ and $z = \ell^{E^+ - E} \sum_{k \notin \mathcal{R}} z_k \in X\mathbf{N}_{2,c}$. Then $\lambda' u_1 \in \mathbf{N}_1$, and by (a) and the linearity of $\mathbf{N}(\Phi)$, $\ell^{E^+} g_P''$ is a coordinate vector of $\mathbf{N}(\Phi)(u_1) - z$; it is also one of $\ell^{E^+ - \sigma_B} u''$. Hence 0 is a coordinate vector of $D_0 = \ell^{E^+ - \sigma_B} u'' - \mathbf{N}(\Phi)(u_1) + z$, and $\Pi D_0 \in U$ (for z by (1)). By (c), $D_0 \in X\mathbf{N}_{2,c}$, so $\ell^{E^+ - \sigma_B} u'' - \mathbf{N}(\Phi)(u_1) \in X\mathbf{N}_{2,c}$. Now Lemma 24.9 (window $(M_a, h_a)_a$ for both lattices; $j = 1$ and G, g, m', R as in the statement) gives

$$\ell^{E^+ - \sigma_B} \rho(u'') = \Phi_* \rho^1(u_1) \in \Phi_* H_f^1(D, T_1). \qquad (5)$$

Step 8. Multiplying (3) by $\ell^{E^+ - \sigma_B}$ and using (4), (5):

$$\vartheta\, \ell^{\sigma_B + \kappa_c + E^+} x = \ell^{E^+ - \sigma_B} \rho(u'') + \ell^{E^+ - \sigma_B} \rho(u^{\mathcal{R}}) \in \Phi_* H_f^1(D, T_1) + \sum_{z \in Z_c} \mathcal{O}_L z,$$

and dividing by the unit ϑ gives the assertion, with $E^+ = \max(E, \sigma_B)$. □

Proposition C.11. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N} = \mathbf{N}(T_2)$, $r = \dim_L V_2$, and fix*

Proof. Let $c \in C$ and $e = \mathrm{len}_c$. By Proposition C.12 there is a low frame $(\mathbf{n}, R)$ at c: a Δ-invariant frame $\mathbf{n}$ at c' of $\mathbf{N}$, with crystalline frame (d_k), and $R \subseteq \{1,\dots,r\}$ with $|R| \leq m\,e$, satisfying (U1) and (U2). For this low frame, Proposition C.13 is (U3) and Proposition C.21 is (U4); and Proposition C.22, applied to the Δ-invariant frame $\mathbf{n}$, is (U5). □

Proposition C.12. *Let* ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ *(*$T_1 \to T_2$*) and the weight word* $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ *satisfy the hypotheses of Proposition C.25; put* $\mathbf{N} = \mathbf{N}(T_2)$ *and* $r = \dim_L V_2$. *Let* $c \in C$ *and* $e = \mathrm{len}_c$. *A* low frame at c *is a pair* $(\mathbf{n}, R)$ *of a* Δ*-invariant frame* $\mathbf{n}$ *at* c' *of* $\mathbf{N}$*, with crystalline frame* (d_k)*, and a set* $R \subseteq \{1,\dots,r\}$ *with* $|R| \leq m\,e$*, such that*

(U1) *for* $k \notin R$ *and* $s < e$ *with* $\epsilon_{c-s} = 1$*:* $\varphi^e(d_k) \in \varphi^{s+4}\big(\mathrm{Fil}^{\,s_{c-s}} D_{\mathrm{cris}}(V_2)\big)$*;*

(U2) *for* $s < e$ *with* $\epsilon_{c-s} = -1$*:* $\varphi^{s+4}\big(\varepsilon_{c-s-1}\mathrm{Fil}^{-\eta} D_{\mathrm{cris}}(V_2)\big) \subseteq \sum_{k\in R} L\,\varphi^e(d_k)$.

Then a low frame at c exists.

Proof. Write $D = D_{\mathrm{cris}}(V_2)$, $R_0 = e_{c'}\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $\Delta = \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$, and ε_b for the idempotents of D (Lemma 23.10).

Step 1: a Δ-invariant frame exists. $\mathbf{N}$ is a Wach module ((Ex1) of Proposition 23.7), so by Lemma 24.15 $\mathbf{N}_{c'}$ has a Δ-invariant frame $\mathbf{n}^0$; let (d_k^0) be its crystalline frame.

Step 2: changing the frame by a constant matrix. Let $g = (g_{kj}) \in \mathrm{GL}_r(\mathcal{O}_L)$ and $n_k = \sum_j g_{kj} n_j^0$ (with g_{kj} acting as $e_{c'}(1 \otimes g_{kj})$). Then $\mathbf{n}$ is a frame at c', Δ-invariant because γ_δ fixes the coefficients. The horizontal section through n_k is $\sum_j g_{kj} H_j^0$ (it lies in $n_k + X\mathbf{N}_E$ and is γ_u-fixed; uniqueness in (Hf2) of Lemma 23.9), and Ev is linear over the constants $\mathcal{O}_L$ ((Ev2), (Ev3) of Lemma 23.11: $\mathrm{Ev}(fW) = e(f)\mathrm{Ev}(W)$ and $e(e_{c'}(1 \otimes \lambda))$ acts on $d_j^0 \in \varepsilon_{c'+3}D$ as λ). Hence $d_k = \sum_j g_{kj} d_j^0$ and $\varphi^e(d_k) = \sum_j g_{kj}\varphi^e(d_j^0)$, as φ is L-linear.

Step 3: the subspaces. By Lemma 23.10 (2), (d_k^0) is an L-basis of $\varepsilon_{c'+3}D$. The Frobenius of D is bijective, L-linear, and maps $\varepsilon_b D$ onto $\varepsilon_{b+1}D$; so $\beta_k^0 = \varphi^e(d_k^0)$ is an L-basis of $D' = \varepsilon_{c+3}D$, and $D_0 = \bigoplus_k \mathcal{O}_L\beta_k^0$ is a lattice in D'. For $s < e$ put $a = c - s$ and

$$W_s = \varphi^{s+4}\big(\varepsilon_{a-1}\mathrm{Fil}^{\,s_a}D\big)\ (\epsilon_a = 1), \qquad G_s = \varphi^{s+4}\big(\varepsilon_{a-1}\mathrm{Fil}^{-\eta}D\big)\ (\epsilon_a = -1),$$

L-subspaces of D' ($\mathrm{Fil}^u D$ is an $F \otimes L$-submodule, so $\varepsilon_{a-1}\mathrm{Fil}^u D \subseteq \mathrm{Fil}^u D \cap \varepsilon_{a-1}D$). By the remark in Definition 23.3, $\varepsilon_{a-1}D$ is the τ_a-component of $D = D_{\mathrm{dR}}(V_2)$, so $\dim_L \varepsilon_{a-1}\mathrm{Fil}^u D = \dim_L \mathrm{Fil}^u D_{\mathrm{dR},\tau_a}(V_2)$. Every Hodge jump of V_2 at τ_a is one of V_1 (Lemma 24.2 (1)). If $\epsilon_a = 1$ these lie in $[s_a, s_a+S] \cup [-\eta, \eta]$ by (Ow1) of Definition 23.1, and $s_a > \eta$; so the jumps below s_a are the low ones, of total multiplicity at most m by (Ow2), and $\mathrm{codim}_{D'} W_s \le m$. If $\epsilon_a = -1$ they lie in $[-s_a - S, -s_a] \cup [-\eta, \eta]$ with $-s_a < -\eta$; so the jumps $\ge -\eta$ are the low ones and $\dim G_s \le m$. Put $W = \bigcap_{\epsilon_{c-s}=1} W_s$ and $G = \sum_{\epsilon_{c-s}=-1} G_s$ (over $s < e$); then $\mathrm{codim}\, W + \dim G \le m\,e$.

Step 4: an adapted lattice basis. $W_0 = W \cap D_0$ is saturated in D_0, so D_0/W_0 is a finitely generated torsion-free, hence free, $\mathcal{O}_L$-module and $D_0 = W_0 \oplus C_0$ with $\mathrm{rank}\, C_0 = \mathrm{codim}\, W$. Put $Z = G + LC_0$. Then $Z \cap D_0 = C_0 \oplus (Z \cap W_0)$ (if $z = w + c$ with $c \in C_0 \subseteq Z$, then $w \in Z$), and $Z \cap W_0$ is saturated in W_0, so $W_0 = (Z \cap W_0) \oplus W_1$. Hence $D_0 = (Z \cap D_0) \oplus W_1$, and $\mathrm{rank}(Z \cap D_0) = \dim Z \le \dim G + \mathrm{codim}\, W \le m\,e$. Choose an $\mathcal{O}_L$-basis (β_k) of D_0 whose first $|R|$ members, indexed by a set R, form a basis of $Z \cap D_0$ and whose others form a basis of W_1; write $\beta_k = \sum_j g_{kj}\beta_j^0$ with $g \in \mathrm{GL}_r(\mathcal{O}_L)$.

Step 5: the low frame. Let $\mathbf{n}$ be the frame of Step 2 for this g. It is a Δ-invariant frame at c' with $\varphi^e(d_k) = \beta_k$, and $|R| \le m\,e$. (U1): for $k \notin R$, $\beta_k \in W_1 \subseteq W \subseteq W_s \subseteq \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}}D)$ for every $s < e$ with $\epsilon_{c-s} = 1$. (U2): for $s < e$ with $\epsilon_{c-s} = -1$, $G_s \subseteq G \subseteq Z = L(Z \cap D_0) = \sum_{k \in R} L\beta_k$, since $Z \cap D_0$ is a lattice in Z. So $(\mathbf{n}, R)$ is a low frame at c. □

Proposition C.13. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word satisfy the hypotheses of Proposition C.25; put $\mathbf{N} = \mathbf{N}(T_2)$, $r = \dim_L V_2$. Let $c \in C$, $e = \mathrm{len}_c$, and $(\mathbf{n}, R)$ a low frame at c. Then for every Δ-invariant $w \in e_c\mathbf{N}[1/\lambda_\infty]$ with $(\gamma_u - 1)(w) \in X\mathbf{N}$ for all $u \in \mathbb{Z}_\ell^\times$, $\Pi_c w \in P_e(\mathbf{N}_{c'})$, and some $\ell^t w$ having an arc coordinate vector for $\mathbf{n}$, e, H_c, m_X that is pole-bounded by B^c, there is a Δ-invariant arc coordinate vector f of $\ell^{\sigma_B} w$ for $\mathbf{n}$, e, H_c, m_X such that for every $k \notin R$: $\mu_c f_k \in e_c\mathbf{A}_{F,L}$; $\mu_c(\gamma_{u_0} - 1)f_k \in X^{\ell-1}\delta_c\, e_c\mathbf{A}_{F,L}$; $\nu_c(\gamma_{u_0} - 1)P_c(\gamma_{u_0})f_k \in X^{\ell-1}\nu_c^+\, e_c\mathbf{A}_{F,L}$; $\nu_c P_c(\gamma_{u_0})f_k \in e_c\mathbf{A}_{F,L}$; and for every $s < e$ with $\epsilon_{c-s} = -1$ there are $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $\nu_c(\ell^\kappa P_c(\gamma_{u_0})f_k - e_c(1 \otimes x)) \in Q_s^{s_{c-s}+S} e_c\mathbf{A}_{F,L}$; and the vector whose k-th entry is $P_c(\gamma_{u_0})f_k$ for $k \notin R$ and 0 for $k \in R$, and the vector whose k-th entry is 0 for $k \notin R$ and $P_c(\gamma_{u_0})f_k$ for $k \in R$, are both Hodge-integral modulo γ.*

Proof. Throughout, w_0 denotes the vector w of the statement; for $s < e$ write $a_s = c - s$, and define $\alpha, \alpha' \in \mathbb{Z}^e$ by $\alpha_s = -(s_{a_s} + S)$, $\alpha'_s = -(s_{a_s} + S)$ if $\epsilon_{a_s} = 1$, and $\alpha_s = 0$, $\alpha'_s = s_{a_s}$ if

$\epsilon_{a_s} = -1$; thus $I_\alpha = \mu_c^{-1}\mathcal{R}$ and $I_{\alpha'} = \mu_c^{-1}\delta_c\mathcal{R}$. Since Π divides a power of λ_e, every $h \in \mathcal{K}_c$ with $\Pi h \in \mathcal{R}$ lies in $\mathcal{R}[1/\lambda_e]$. We use the coordinate calculus of Lemma C.16 ((1) window, (a) linearity, (b) equivariance) and Lemma C.17; its hypothesis $m_X \geq 2H_c(x)$ holds because $m_X = (\ell-1)(\lfloor 2h_B/(\ell-1)\rfloor+1) > 2h_B$ and $h_B \geq H_c(x)$ for all x ($w+S \leq b+\eta+S$ as $20w \leq b$).

Step 0: windows and low coordinates. Fix $s < e$ and $a = a_s$. By (Ow1) and Lemma 24.2 (1), every Hodge jump of V_2 at τ_a lies in $[s_a, s_a+S]\cup[-\eta,\eta]$ if $\epsilon_a = 1$ and in $[-s_a-S,-s_a]\cup[-\eta,\eta]$ if $\epsilon_a = -1$; recall $s_a > \eta$. By the remark in Definition 23.3, for $\mathbf{v} \in \mathcal{O}_L^r$ and $u \in \mathbb{Z}$ the condition $\delta_e(\mathbf{v}) \in \varphi^{s+4}(\mathrm{Fil}^u D_2)$ says that $\varphi^{-(s+4)}\delta_e(\mathbf{v})$, an element of $\varepsilon_{a-1}D_2$, lies in $\varepsilon_{a-1}\mathrm{Fil}^u D_2$, whose jumps are the Hodge jumps of V_2 at τ_a. Hence:

(W1) $\varepsilon_{a-1}\mathrm{Fil}^u D_2 = 0$ for $u > s_a + S$;

(W2) $\varepsilon_{a-1}\mathrm{Fil}^u D_2 = \varepsilon_{a-1}D_2$ for $u \leq -(s_a+S)$; so $\delta_e(\mathbf{v}) \in \varphi^{s+4}(\mathrm{Fil}^u D_2)$ for all $\mathbf{v}$ and all $u \leq -(s_a+S)$, in particular for $u = -H_c(a)$ (Lemma C.16 (1));

(W3) if $\epsilon_a = -1$ and $u > -s_a$, then $\varepsilon_{a-1}\mathrm{Fil}^u D_2 \subseteq \varepsilon_{a-1}\mathrm{Fil}^{-\eta} D_2$ (there is no jump in $[-s_a+1, -\eta-1]$).

By Lemma 23.10 (2) the d_k form an L-basis of $\varepsilon_{c'+3}D_2$, so the $\varphi^e(d_k)$ are L-linearly independent. Let $(g_i, \mathbf{v}_i, \alpha_i)$ be a section decomposition, $k \notin R$, and i with $v_{i,k} \neq 0$. We claim:

(V) if $\delta_e(\mathbf{v}_i) \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha_i(s)} D_2)$, then $\alpha_i(s) \geq -(s_a+S)$ when $\epsilon_a = 1$, and $\alpha_i(s) \geq s_a$ when $\epsilon_a = -1$.

If $\epsilon_a = 1$ and $\alpha_i(s) < -(s_a+S)$, (W1) gives $\delta_e(\mathbf{v}_i) = 0$, so $\mathbf{v}_i = 0$ by independence, a contradiction. If $\epsilon_a = -1$ and $\alpha_i(s) < s_a$, then $-\alpha_i(s) > -s_a$ and (W3) and (U2) give $\delta_e(\mathbf{v}_i) \in \varphi^{s+4}(\varepsilon_{a-1}\mathrm{Fil}^{-\eta} D_2) \subseteq \sum_{k' \in R} L\varphi^e(d_{k'})$, so $v_{i,k} = 0$ by independence, a contradiction.

We also use: (Δ-*invariant multiples of* X) if $h \in X\mathcal{R}$ is Δ-invariant then $h \in \pi_0\mathcal{R}$ and h/π_0 is Δ-invariant. Indeed, if $h \neq 0$ has lowest term $a_j X^j$ ($j \geq 1$), then $\gamma_\omega(h)$ has lowest term $a_j\omega^j X^j$ ($\gamma_\omega(X) = \omega X + O(X^2)$), so $\omega^j = 1$ for all $\omega \in \mu_{\ell-1}$, $(\ell-1) \mid j$ and $h \in X^{\ell-1}\mathcal{R} = \pi_0\mathcal{R}$; as π_0 is Δ-invariant and $\mathcal{R}$ a domain, h/π_0 is Δ-invariant.

Step 1: a Δ-invariant coordinate vector. By Lemma C.14 (frame $\mathbf{n}$ at c', e, H_c, m_X; $\sigma_B \geq (2H_c(c'+1)+m_X/(\ell-1))\ell/(\ell-1)^2$ as $H_c(c'+1) = w+S$; $\Pi w_0 \in U$) there is a coordinate vector f^1 of $\ell^{\sigma_B}w_0$ with $\Pi f_k^1 \in \mathcal{R}$. Put $f = (\ell-1)^{-1}\sum_{\omega\in\mu_{\ell-1}}\gamma_\omega(f^1)$. By (b) each $\gamma_\omega(f^1)$ is a coordinate vector of $\gamma_\omega(\ell^{\sigma_B}w_0) = \ell^{\sigma_B}w_0$, so by (a) f is a coordinate vector of $\ell^{\sigma_B}w_0$; f is Δ-invariant, and $\Pi f_k \in \mathcal{R}$ since $\gamma_\omega(\Pi) \in \Pi\mathcal{R}^\times$.

Step 2: restriction of poles, $\mu_c f_k \in \mathcal{R}$ for $k \notin R$. Let f^0 be a coordinate vector of $\ell^t w_0$ that is pole-bounded by B^c, with decomposition $(g_i, \mathbf{v}_i, \alpha_i)$ as in (Gs2). By Lemma C.17 (1), $\ell^t f$ and $\ell^{\sigma_B}f^0$ are coordinate vectors of $\ell^{\sigma_B+t}w_0$, so by Lemma C.17 (2) $\ell^t f_k - \ell^{\sigma_B}f_k^0 \in X\Pi\mathcal{R} \subseteq \mathcal{R}$. Fix $k \notin R$ and i with $v_{i,k} \neq 0$, and $s < e$. If $\epsilon_{a_s} = 1$: either $\alpha_i(s) \geq 0$, or the Fil-condition of (Gs2) holds and (V) gives $\alpha_i(s) \geq -(s_{a_s}+S)$. If $\epsilon_{a_s} = -1$: if $\alpha_i(s) < 0$, the Fil-condition holds and (V) gives $\alpha_i(s) \geq s_{a_s} > 0$, impossible; so $\alpha_i(s) \geq 0$. Hence $\alpha_i \geq \alpha$, $g_i \in I_\alpha$ and $f_k^0 = \sum_i g_i v_{i,k} \in I_\alpha$. As $\alpha \leq 0$, $\mathcal{R} \subseteq I_\alpha$, so $\ell^t f_k \in I_\alpha$; since $f_k \in \mathcal{R}[1/\lambda_e]$, item 2 of Lemma C.18 (with $c = \ell^t$) gives $f_k \in I_\alpha$, i.e. $\mu_c f_k \in \mathcal{R}$.

Step 3: $(\gamma-1)f = \pi_0 G$ with $G \in \mathcal{H}_{\mathbf{n}}$. Since γ fixes e_c, $z = (\gamma-1)w_0 \in X\mathbf{N}\cap e_c\mathbf{N} = X\mathbf{N}_c$, and z is Δ-invariant ($\gamma_\omega\gamma = \gamma\gamma_\omega$). In a Δ-invariant $\mathcal{R}$-basis of $\mathbf{N}_c$ (Lemma 24.15) the coordinates of z are Δ-invariant elements of $X\mathcal{R}$, hence in $\pi_0\mathcal{R}$ with Δ-invariant quotients (Step 0); so $z = \pi_0 y_0$ with $y_0 \in \mathbf{N}_c$ Δ-invariant. By Lemma C.16 (1), $\Pi y_0 \in U$, and Lemma 23.13 (2) (frame $\mathbf{n}$ at c', e, H_c, m_X) gives $t_1, \kappa_1 \geq 0$ and a coordinate vector g^1 of $\ell^{t_1}y_0$ with $\ell^{\kappa_1}g^1$ Hodge-graded. Put $g = (\ell-1)^{-1}\sum_\omega \gamma_\omega(g^1)$: as in Step 1 it is a Δ-invariant coordinate vector of $\ell^{t_1}y_0$, and $\ell^{\kappa_1}g$

is Hodge-graded, because $(\gamma_\omega(g_i), \mathbf{v}_i, \alpha_i)$ is a section decomposition of $\gamma_\omega(\ell^{\kappa_1} g^1)$ with the same $\mathbf{v}_i$ ($\gamma_\omega(I_\eta) = I_\eta$ by Lemma 23.8 (2)), and sums and $\mathbb{Z}_\ell$-multiples of Hodge-graded vectors are Hodge-graded (concatenate decompositions).

By (a), (b), $(\gamma-1)f$ is a coordinate vector of $\ell^{\sigma_B}(\gamma-1)w_0 = \ell^{\sigma_B}\pi_0 y_0$; by Lemma C.17 (1), $\pi_0 g$ is a coordinate vector of $\ell^{t_1}\pi_0 y_0$. So $\ell^{t_1}(\gamma-1)f$ and $\ell^{\sigma_B}\pi_0 g$ are coordinate vectors of $\ell^{\sigma_B+t_1}\pi_0 y_0$, and $d = \ell^{t_1}(\gamma-1)f - \ell^{\sigma_B}\pi_0 g$ has entries $d_k \in X\Pi\mathcal{R}$ (Lemma C.17 (2)). The d_k are Δ-invariant, so $d_k = \pi_0 d_k'$ with $d_k' \in \mathcal{R}$ (Step 0); then $X^{\ell-1}(v d_k') = d_k \in \Pi\mathcal{R} = I_{(H_c(c-s))_s}$, and item 2 of Lemma C.18 (with $c = X^{\ell-1}$) gives $v d_k' \in \Pi\mathcal{R}$, so $d_k' \in \Pi\mathcal{R}$. Put

$$G = \ell^{-t_1}\big(\ell^{\sigma_B} g + d'\big) \in \mathcal{K}_c^r, \qquad \text{so that} \qquad (\gamma-1)f = \pi_0 G.$$

We have $G \in \mathcal{H}_{\mathbf{n}}$: first, $y = \Pi G_k$ satisfies $\ell^{t_1} y = \ell^{\sigma_B}\Pi g_k + \Pi d_k' \in \mathcal{R}$ and $\pi_0 y = \Pi(\gamma-1)f_k = \gamma(\Pi f_k)\cdot\Pi/\gamma(\Pi) - \Pi f_k \in \mathcal{R}$; writing $r_1 = \ell^{t_1} y \in \mathcal{R}$, the series $X^{\ell-1} v\, r_1 = \ell^{t_1}\pi_0 y$ has all coefficients in $\ell^{t_1}\mathcal{O}_L$, hence so has r_1 (v a unit, $X^{\ell-1}$ shifts coefficients), and $y \in \mathcal{R}$. Second, $\ell^{\kappa_1+t_1} G = \ell^{\sigma_B}(\ell^{\kappa_1} g) + \ell^{\kappa_1} d'$ is Hodge-graded: $\ell^{\kappa_1} g$ is, and d' has the section decomposition $(d_k', \mathbf{e}_k, (H_c(a_s))_s)_k$ ($d_k' \in \Pi\mathcal{R} = Q^{(H_c(a_s))_s}\mathcal{R}$), which satisfies (Gs1) by (W2).

Step 4: restriction of the γ-difference, $\mu_c(\gamma-1)f_k \in X^{\ell-1}\delta_c\mathcal{R}$ for $k \notin R$. Let $(g_i, \mathbf{v}_i, \alpha_i)$ be a decomposition as in (Gs1) of $\ell^\kappa G$, $\kappa = \kappa_1 + t_1$, and $k \notin R$. For every i with $v_{i,k} \neq 0$ and every $s < e$, (V) gives $\alpha_i(s) \geq \alpha_s'$; so $\ell^\kappa G_k = \sum_i g_i v_{i,k} \in I_{\alpha'}$, and, as $G_k \in \mathcal{R}[1/\lambda_e]$ ($\Pi G_k \in \mathcal{R}$), item 2 of Lemma C.18 gives $G_k \in I_{\alpha'}$. Hence $\mu_c(\gamma-1)f_k = \pi_0\mu_c G_k \in \pi_0\delta_c\mathcal{R} = X^{\ell-1}\delta_c\mathcal{R}$.

Step 5: the operator $P_c(\gamma)$. Let $k \notin R$. Apply Lemma C.20 to f_k, with $e = \mathrm{len}_c$, S, $\epsilon_s = \epsilon_{a_s}$, $b_s = s_{a_s} \geq 1$ (sizes exceed $\eta \geq 0$), $J = J_c$ (the union of the windows W_{a_s}, as required there), u_0, and $P = P_{J_c,e} = P_c$; then its μ, δ, ν^+, ν are $\mu_c, \delta_c, \nu_c^+, \nu_c$. Its hypotheses are Steps 2 and 4, and f_k is Δ-invariant (Step 1). Its items 1, 2, 3 give $\nu_c P_c(\gamma) f_k \in \mathcal{R}$, $\nu_c(\gamma-1)P_c(\gamma)f_k \in X^{\ell-1}\nu_c^+\mathcal{R}$, and, for $s < e$ with $\epsilon_{a_s} = -1$, $\kappa \geq 0$ and $x \in \mathcal{O}_L$ with $\nu_c(\ell^\kappa P_c(\gamma)f_k - e_c(1\otimes x)) \in Q_s^{s_{a_s}+S}\mathcal{R}$.

Step 6: the two split vectors. Let f^{out} have entries $P_c(\gamma)f_k$ for $k \notin R$ and 0 for $k \in R$, and $f^{\mathrm{in}} = P_c(\gamma)f - f^{\mathrm{out}}$. By Step 5, $(\gamma-1)f^{\mathrm{out}} = X^{\ell-1}h$ with $h_k \in \nu_c^{-1}\nu_c^+\mathcal{R}$ for $k \notin R$ and $h_k = 0$ for $k \in R$. Then $h \in \mathcal{H}_{\mathbf{n}}$: $\Pi h_k \in \mathcal{R}$ because ν_c has exponent $s_{a_s} \leq H_c(a_s)$ at Q_s; and $(h_k, \mathbf{e}_k, \beta')_{k\notin R}$, with $\beta_s' = -s_{a_s}$ if $\epsilon_{a_s} = 1$ and $\beta_s' = s_{a_s}+S$ if $\epsilon_{a_s} = -1$, is a section decomposition satisfying (Gs1): at $\epsilon_{a_s} = 1$, $\delta_e(\mathbf{e}_k) = \varphi^e(d_k) \in \varphi^{s+4}(\mathrm{Fil}^{s_{a_s}} D_2)$ by (U1) ($k \notin R$); at $\epsilon_{a_s} = -1$, by (W2). So f^{out} is Hodge-integral modulo γ. Next, $\mathcal{H}_{\mathbf{n}}$ is stable under every γ_u (if $\Pi h_k \in \mathcal{R}$ then $\Pi\gamma_u(h_k) = \gamma_u(\Pi h_k)\,\Pi/\gamma_u(\Pi) \in \mathcal{R}$; section decompositions are transported as in Step 3), and $\gamma_u(\pi_0) \in \pi_0\mathcal{R}^\times$ ($\gamma_u(X) \in X\mathcal{R}^\times$, Lemma 23.8 (2)); so $\pi_0\mathcal{H}_{\mathbf{n}}$ is stable under every polynomial in γ, and

$$(\gamma-1)P_c(\gamma)f = P_c(\gamma)((\gamma-1)f) = P_c(\gamma)(\pi_0 G) \in \pi_0\mathcal{H}_{\mathbf{n}} = X^{\ell-1}\mathcal{H}_{\mathbf{n}}$$

by Step 3. Hence $(\gamma-1)f^{\mathrm{in}} = (\gamma-1)P_c(\gamma)f - (\gamma-1)f^{\mathrm{out}} \in X^{\ell-1}\mathcal{H}_{\mathbf{n}}$, and f^{in} is Hodge-integral modulo γ.

Steps 1–6 give a Δ-invariant coordinate vector f of $\ell^{\sigma_B} w_0$ with all asserted properties. □

Lemma C.14. *Let ℓ be an odd prime, F, L, (τ_a) and a pair (V,T) as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$ of rank r. Let $c' \in \mathbb{Z}/n$, $e \geq 1$, $c = c'+e$, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$, $\Pi = \Lambda_{c,e}(H)$, let $m \geq 1$ with $m \geq 2H(c-s)$ for $0 \leq s < e$, and let σ be an integer with $\sigma \geq \big(2H(c'+1)+m/(\ell-1)\big)\ell/(\ell-1)^2$. Let $\mathbf{n}$ be a frame at c' of $\mathbf{N}$. Then for every $y \in e_c\mathbf{N}[1/\lambda_\infty]$ with $\Pi y \in P_e(\mathbf{N}_{c'})$ there is an arc coordinate vector f of $\ell^\sigma y$ for $\mathbf{n}$, e, H, m with $\Pi f_k \in e_c\mathbf{A}_{F,L}$ for all k; one can take the admissible exponent $\kappa = s_\ell(2m-2)$ and $\kappa' = 0$.*

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$, $U = P_e(\mathbf{N}_{c'})$, $s = s_\ell$, $E = 2H(c'+1)$, and $\Lambda' = e_{c'}(\mathcal{O}_F \otimes \mathcal{O}_L)$.

Step 1: superadditivity. $s(a)+s(b)\le s(a+b)$ for $a,b\ge 0$: with $J(k)=\lfloor k/(\ell-1)\rfloor$ we have $J(a)+J(b)\le J(a+b)$, and $v_\ell(J_1!)+v_\ell(J_2!)\le v_\ell((J_1+J_2)!)$ (the binomial coefficient is an integer), while $J\mapsto J+v_\ell(J!)$ is nondecreasing.

Step 2: the inverse of the horizontal matrix. Let $h=(h_{kj})$ be the matrix with $H_k=\sum_j h_{kj}n_j$ (horizontal sections through the frame), $h=\sum_{i\ge 0}h_iX^i$ with $h_i\in M_r(e_{c'}E)$, $h_0=I$ ((Hf2) of Lemma 23.9) and $\ell^{s(i)}h_i\in M_r(\Lambda')$ ((Hf3), applied to an $\mathbf{A}_{F,L}$-basis of $\mathbf{N}$ extending $\mathbf{n}$ by frames at the other sites; $H_k\in e_{c'}\mathbf{N}_E$ by the uniqueness in (Hf2), as $e_{c'}$ commutes with every γ_u). Put $g=h^{-1}=\sum_{k\ge 0}(I-h)^k$ (convergent, $I-h\in XM_r(e_{c'}E[[X]])$), $g=\sum_i g_iX^i$. Each g_i is a sum of products $\pm h_{i_1}\cdots h_{i_k}$ with $i_1+\cdots+i_k=i$, $i_j\ge 1$, so $\ell^{s(i)}g_i\in M_r(\Lambda')$ by Step 1. Put $U_m=\sum_{i<m}h_iX^i$, $G_m=\sum_{i<m}g_iX^i$; then $G_mU_m=I+\sum_{m\le i\le 2m-2}w_iX^i$ with $w_i=\sum_{i_1+i_2=i,\ i_1,i_2<m}g_{i_1}h_{i_2}$, so $\ell^{s(i)}w_i\in M_r(\Lambda')$. Let $\kappa=s(2m-2)$; it is admissible and $\kappa\ge s(i)$ for $i\le 2m-2$; and $T_\kappa(H_k)=\sum_j\ell^\kappa(U_m)_{kj}n_j$.

Step 3: scalars. By Lemma C.15, for $0\le i<m$ there are $\alpha_i,\beta_i\in\mathbb{Z}_\ell[[X]]$ with $\ell^\sigma\varphi^e(X)^i=\ell^{s(i)}\alpha_i+D\beta_i$, $D=(X\lambda_{e-1})^mQ_{e-1}^E$, and $D\in X\Pi^2\mathbb{Z}_\ell[[X]]$ (for $s=e-1$, $c-s=c'+1$ and the exponent of Q_{e-1} in Π^2 is E; for $s<e-1$, Q_s^m divides λ_{e-1}^m and $m\ge 2H(c-s)$). Also $\varphi^e(X)^i=(X\lambda_e)^i\in X\Pi^2\mathbb{Z}_\ell[[X]]$ for $i\ge m$.

Step 4: the coordinate vector. Write $\Pi y=\sum_j b_j\varphi^e(n_j)$ with $b_j\in R_c$ (U is generated by the $\varphi^e(n_j)$), and $a_j=b_j/\Pi\in\mathcal{K}_c$. Define

$$f_k=\sum_j a_j\sum_{i<m}\varphi^e\big(\ell^{s(i)}(g_i)_{jk}\big)\alpha_i,$$

so $\Pi f_k=\sum_j b_j(\cdots)\in R_c$. By Step 3, $f=a(\ell^\sigma\varphi^e(G_m)-D\,B)$ with $B_{jk}=\sum_{i<m}\varphi^e((g_i)_{jk})\beta_i$ (row vector $a=(a_j)$, φ^e applied entrywise). Hence

$$f\cdot\ell^\kappa\varphi^e(U_m)=\ell^{\sigma+\kappa}a+a\,\mathcal{E},\qquad \mathcal{E}=\ell^{\sigma+\kappa}\sum_{m\le i\le 2m-2}\varphi^e(w_i)\varphi^e(X)^i-D\,\ell^\kappa B\,\varphi^e(U_m).$$

Every entry of $\mathcal{E}$ lies in $X\Pi^2R_c$: in the first sum $\ell^\kappa\varphi^e(w_i)$ is integral ($\kappa\ge s(i)$) and $\varphi^e(X)^i\in X\Pi^2$ ($i\ge m$); in the second, $\ell^\kappa B\varphi^e(U_m)$ is a sum of terms $\ell^\kappa\varphi^e(g_{i_1}h_{i_2})\beta_{i_1}\varphi^e(X)^{i_2}$ with $i_1,i_2<m$, integral because $s(i_1)+s(i_2)\le s(2m-2)=\kappa$ (Step 1), and $D\in X\Pi^2$. As $\varphi_{\mathbf{N}}$ is φ-semilinear, $\varphi^e(T_\kappa(H_k))=\sum_{j'}\ell^\kappa\varphi^e(U_m)_{kj'}\varphi^e(n_{j'})$, so

$$\sum_k\Pi f_k\,\varphi^e(T_\kappa(H_k))=\sum_{j'}\Big(\ell^{\sigma+\kappa}b_{j'}+\sum_j b_j\mathcal{E}_{jj'}\Big)\varphi^e(n_{j'})=\ell^\kappa\Pi(\ell^\sigma y)+\sum_{j,j'}b_j\mathcal{E}_{jj'}\varphi^e(n_{j'}),$$

and the last sum lies in $X\Pi^2U$. So $\ell^\kappa\Pi(\ell^\sigma y)-\sum_k\Pi f_k\varphi^e(T_\kappa(H_k))\in X\Pi^2U$: f is an arc coordinate vector of $\ell^\sigma y$ with $(\kappa,0)$, and $\Pi f_k\in R_c$. □

Lemma C.15. *Let ℓ be an odd prime, $m\ge 1$ and $E\ge 0$ integers, and σ an integer with*

$$\sigma\ \ge\ \Big(E+\frac{m}{\ell-1}\Big)\frac{\ell}{(\ell-1)^2}.$$

Then for every integer i with $0\le i<m$,

$$\ell^\sigma(XQ)^i\ \in\ \ell^{s_\ell(i)}\,\mathbb{Z}_\ell[[X]]+X^mQ^E\,\mathbb{Z}_\ell[[X]],$$

and consequently, for every integer $e\ge 1$,

$$\ell^\sigma\varphi^e(X)^i\ \in\ \ell^{s_\ell(i)}\,\mathbb{Z}_\ell[[X]]+(X\lambda_{e-1})^mQ_{e-1}^E\,\mathbb{Z}_\ell[[X]].$$

Proof. Write $R = \mathbb{Z}_\ell[[X]]$, $s = s_\ell(i)$ and $K = E + m/(\ell-1)$, so that $\sigma \geq K\ell/(\ell-1)^2$. Since $\varphi(X) = (1+X)^\ell - 1$,

$$Q = \sum_{k=1}^{\ell} \binom{\ell}{k} X^{k-1} = X^{\ell-1} + \ell\alpha, \qquad \alpha \in \mathbb{Z}_\ell[X],$$

because ℓ divides $\binom{\ell}{k}$ for $1 \leq k \leq \ell-1$.

Case $s \leq \sigma$. Then $\ell^\sigma (XQ)^i = \ell^s \cdot \ell^{\sigma-s}(XQ)^i \in \ell^s R$.

Case $s > \sigma$. Put $d = s - \sigma \geq 1$. From $K\ell/(\ell-1)^2 \leq \sigma < s \leq i\ell/(\ell-1)^2$ we get $i > K \geq E$, so $z = i - E \geq 1$ and $(XQ)^i = Q^E X^i Q^z$. By the binomial theorem

$$X^i Q^z = \sum_{t=0}^{z} \binom{z}{t} \ell^t \alpha^t X^{\,i+(\ell-1)(z-t)}.$$

A term with $t \geq d$ lies in $\ell^d R$, so ℓ^σ times it lies in $\ell^s R$. A term with $t \leq d-1$ has X-adic order at least $i+(\ell-1)(z-d+1)$, and this is at least m: indeed, with $s \leq i\ell/(\ell-1)^2$, $\sigma \geq K\ell/(\ell-1)^2$ and $m = (\ell-1)(K-E)$,

$$\begin{aligned}(i + (\ell-1)(z-d+1)) - m \;&\geq\; i + (\ell-1)(i-E+1) - \frac{(i-K)\ell}{\ell-1} - (\ell-1)(K-E) \\ &= (i-K)\frac{\ell(\ell-2)}{\ell-1} + K + \ell - 1 > 0,\end{aligned}$$

as $i > K$ and $\ell \geq 3$. So such a term lies in $X^m R$. Hence $\ell^\sigma X^i Q^z \in \ell^s R + X^m R$, and multiplying by Q^E gives $\ell^\sigma (XQ)^i \in \ell^s R + X^m Q^E R$.

Consequence. φ is a ring endomorphism of R fixing ℓ, with $\varphi^{e-1}(XQ) = \varphi^e(X)$, $\varphi^{e-1}(Q) = Q_{e-1}$ and $\varphi^{e-1}(X) = X\lambda_{e-1}$ (induction: $\varphi^{k+1}(X) = \varphi^k(XQ) = \varphi^k(X)Q_k$). Applying φ^{e-1} to the first assertion gives the second. □

Lemma C.16. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N}_2 = \mathbf{N}(T_2)$. Let $c \in C$, $e = \mathrm{len}_c$, $R_c = e_c \mathbf{A}_{F,L}$, $\Pi = \Pi_c$, $U = P_e(\mathbf{N}_{2,c'})$, and let $\mathbf{n}$ be a frame at c' of $\mathbf{N}_2$; in (a)–(d) a* coordinate vector *is an arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, e, H_c and m_X.*

(1) Window *For every a, every Hodge jump of V_1 and of V_2 at τ_a has absolute value at most $s_a + S \leq H_c(a)$. Hence $(H_c(a), H_c(a))_a$ is a window of $\mathbf{N}_2$ as in (Ex1), and $\Pi U \subseteq \mathbf{N}_{2,c}$, $\Pi \mathbf{N}_{2,c} \subseteq U$.*

(a) Linearity *If f, f' are coordinate vectors of $y, y' \in e_c\mathbf{N}_2[1/\lambda_\infty]$ and $o, o' \in R_c$, then $of + o'f'$ is a coordinate vector of $oy + o'y'$.*

(b) Equivariance *Let $u \in \mathbb{Z}_\ell^\times$. Then $\gamma_u(Q_s) \in Q_s\,\mathbb{Z}_\ell[[X]]^\times$ ($s \geq 0$), $\gamma_u(X) \in X\,\mathbb{Z}_\ell[[X]]^\times$ and $\gamma_u(U) = U$; if f is a coordinate vector of y, then $\gamma_u(f) = (\gamma_u f_k)_k$ is a coordinate vector of $\gamma_u(y)$. Hence for $P \in \mathbb{Z}_\ell[Y]$, $P(\gamma_u)f$ is a coordinate vector of $P(\gamma_u)y$, and $\Pi P(\gamma_u)y \in U$ if $\Pi y \in U$.*

(c) Vanishing *If $y \in e_c\mathbf{N}_2[1/\lambda_\infty]$, $\Pi y \in U$ and 0 is a coordinate vector of y, then $y \in X\mathbf{N}_{2,c}$.*

(d) Relay classes *Let I_c and $\rho = \rho_{c,1}$ be formed for $\mathbf{N}_2$ with a window and parameters G, g, m', R as in Lemma 24.5 ($j = 1$), and $u_0 \in \mathbb{Z}_\ell^\times$. Then I_c is a γ_u-stable $\mathcal{O}_L$-module containing $X\mathbf{N}_{2,c}$; if $y \in I_c$, $\Pi y \in U$ and 0 is a coordinate vector of y, then $\rho(y) = 0$; and $\rho(P(\gamma_{u_0})y) = P(1)\rho(y)$ for $y \in I_c$ and $P \in \mathbb{Z}_\ell[Y]$.*

(e) The source lattice *The last two assertions of (1) and items (a), (b), (c) hold with* $\mathbf{N}_1 = \mathbf{N}(T_1)$ *in place of* $\mathbf{N}_2$ *(frames of* $\mathbf{N}_1$*,* $U = P_e(\mathbf{N}_{1,c'})$*, coordinate vectors for* $\mathbf{N}_1$*).*

Proof. **(1).** A jump of V_2 at τ_a is a jump of V_1 (Lemma 24.2 (1)); by (Ow1) its absolute value is at most $\max(s_a+S,\eta) = s_a+S$ (sizes exceed η). By (Ow3), $s_a \le w$ at a thin site and $s_a \le b+\eta$ at a thick one; so $s_a+S \le w+S = H_c(c'+1)$ at the thin site $c'+1$, and $s_a+S \le h_B$ everywhere ($h_B = b+\eta+S$ if some site is thick; otherwise all sites are thin and $h_B = w+S$). By (Ex1) of Proposition 23.7, $\mathbf{N}_2$ is a Wach module with window $(H_c(a), H_c(a))_a$, and Lemma 23.15 (2) gives the two inclusions.

(a). If κ is admissible, so is every $\kappa_1 \ge \kappa$, and $T_{\kappa_1}(H_k) = \ell^{\kappa_1-\kappa}T_\kappa(H_k)$; multiplying the defining relation by $\ell^{\kappa_1-\kappa}\ell^{\kappa_1'-\kappa'}$ shows that it holds for all $\kappa_1 \ge \kappa$, $\kappa_1' \ge \kappa'$. So f, f' satisfy it with a common pair, and the relation for $of + o'f'$ follows as $X\Pi^2 U$ is an R_c-module; also $\Pi(of_k + o'f_k') \in R_c$.

(b). $\gamma_u(X) = X\varepsilon_u$ with $\varepsilon_u = ((1+X)^u - 1)/X$ of constant term u, and $\varphi^{s+1}(X) = X\lambda_{s+1}$; as γ_u commutes with φ, $\gamma_u(\lambda_{s+1}) = \lambda_{s+1}\varphi^{s+1}(\varepsilon_u)/\varepsilon_u$, so $\gamma_u(Q_s) = Q_s\varphi^{s+1}(\varepsilon_u)/\varphi^s(\varepsilon_u)$, a unit multiple ($\varphi$ preserves constant terms). Hence $\gamma_u(\Pi) = \Pi\upsilon$ with υ a unit, and $\gamma_u(U) = U$ (γ_u commutes with φ, preserves $\mathbf{N}_{2,c'}$ and R_c). Let f be a coordinate vector of y with (κ,κ'). Applying γ_u to the defining relation and dividing by υ,

$$\ell^{\kappa'}\Big(\ell^{\kappa}\Pi\gamma_u(y) - \sum_k \Pi\gamma_u(f_k)\varphi^e\big(\gamma_u T_\kappa(H_k)\big)\Big) \in X\Pi^2 U.$$

By definition

$$T_\kappa(H_k) - \ell^\kappa H_k = -\sum_j \sum_{i\ge m_X} \ell^\kappa h_{kj,i} X^i n_j \in X^{m_X}\mathbf{N}_E,$$

and $\gamma_u(H_k) = H_k$ (Lemma 23.9 (Hf2)); so $\gamma_u T_\kappa(H_k) - T_\kappa(H_k) = (\gamma_u - 1)(T_\kappa(H_k) - \ell^\kappa H_k) \in X^{m_X}\mathbf{N}_E \cap \mathbf{N}_{2,c'} = X^{m_X}\mathbf{N}_{2,c'}$ (coefficients in the basis $\mathbf{n}$, which is also a basis of $e_{c'}\mathbf{N}_E$ over $e_{c'}E[[X]]$ by (Hf2), as $n_k \in H_k + X\mathbf{N}_E$). Further $\varphi^e(X^{m_X}\mathbf{N}_{2,c'}) \subseteq (X\lambda_e)^{m_X}U \subseteq X\Pi^2 U$, because $m_X = (\ell-1)M > 2h_B \ge 2H_c(c-s)$ for $s < e$ and $m_X \ge 1$, and $\Pi\gamma_u(f_k) = \upsilon^{-1}\gamma_u(\Pi f_k) \in R_c$. So $\gamma_u(f)$ satisfies the defining relation for $\gamma_u(y)$ with the same (κ,κ'). The rest follows with (a).

(c). The defining relation reads $\ell^{\kappa+\kappa'}\Pi y \in X\Pi^2 U$; by saturation (Lemma 23.15 (3), $f = X\Pi^2$, $f' = 1$), $\Pi y = X\Pi^2 p$ with $p \in U$; as $e_c\mathbf{N}_2[1/\lambda_\infty]$ is torsion free over the domain R_c, $y = X\Pi p \in X\,\Pi U \subseteq X\mathbf{N}_{2,c}$ by (1).

(d). I_c is an $\mathcal{O}_L$-module (Ry4) and contains $X\mathbf{N}_{2,c}$, on which ρ vanishes (Ry5); it is γ_u-stable, as $(\gamma_{u'} - 1)\gamma_u y = \gamma_u(\gamma_{u'} - 1)y \in X\mathbf{N}_2$. The second assertion follows from (c). For the third, Lemma 23.22 (3) (module $e_c\mathbf{N}_2[1/\lambda_\infty]$, endomorphism γ_{u_0}, stable submodule $X\mathbf{N}_{2,c}$, $f = 1$; $(\gamma_{u_0} - 1)y \in X\mathbf{N}_2 \cap e_c\mathbf{N}_2[1/\lambda_\infty] = X\mathbf{N}_{2,c}$) gives $P(\gamma_{u_0})y - P(1)y \in X\mathbf{N}_{2,c}$, and (Ry4), (Ry5) give $\rho(P(\gamma_{u_0})y) = P(1)\rho(y)$.

(e). By (1), every Hodge jump of V_1 at τ_a has absolute value at most $H_c(a)$, so (Ex1) and Lemma 23.15 (2) give the two inclusions for $\mathbf{N}_1$; the proofs of (a), (b), (c) use of $\mathbf{N}_2$ only these inclusions, (Hf2) of Lemma 23.9, Lemma 23.15 (3) and $m_X > 2h_B$, all of which hold for $\mathbf{N}_1$, and go through unchanged. □

Lemma C.17. *Let* ℓ*,* F*,* L*,* (τ_a) *and a pair* (V,T) *be as in Proposition 23.7,* $\mathbf{N} = \mathbf{N}(T)$ *of rank* r*,* $c \in \mathbb{Z}/n$*,* $e \ge 0$*,* $a = c+e$*,* $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$*,* $\Pi = \Lambda_{a,e}(H)$*,* $m \ge 1$ *with* $m \ge 2H(a-s)$ *for* $s < e$*, and* $\mathbf{n}$ *a frame of* $\mathbf{N}$ *at* c*;* coordinate vector *means arc coordinate vector for* $\mathbf{n}$*,* e*,* H*,* m*.*

1. *If* f *is a coordinate vector of* $y \in \mathbf{N}[1/\lambda_\infty]$ *and* $o \in e_a\mathbf{A}_{F,L}$*, then* of *is a coordinate vector of* oy*; if* f' *is a coordinate vector of* y'*, then* $f+f'$ *is a coordinate vector of* $y+y'$*.*

2. *If f and f' are coordinate vectors of the same element, then $f_k - f'_k \in X\Pi\, e_a\mathbf{A}_{F,L}$ for every $k \le r$.*

Proof. Write $R = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ and $U = P_e(\mathbf{N}_c)$, an $\mathbf{A}_{F,L}$-module.

Item 1. Multiplying (23.1) for f by o gives (23.1) for of and oy with the same κ, κ', and $\Pi o f_k \in R$. For the sum, let (κ_1, κ'_1), (κ_2, κ'_2) be the exponents of f, f', and $\kappa = \max(\kappa_1, \kappa_2)$, $\kappa' = \max(\kappa'_1, \kappa'_2)$. An integer $\ge$ an admissible one is admissible, and $T_\kappa(H_k) = \ell^{\kappa-\kappa_i} T_{\kappa_i}(H_k)$ by the definition of the truncation; multiplying the relation for f by $\ell^{\kappa'-\kappa'_1}\ell^{\kappa-\kappa_1}$ (an element of $\mathcal{O}_L$) gives (23.1) for f with (κ, κ'), likewise for f', and adding gives it for $f + f'$ and $y + y'$.

Item 2. By item 1 (with $o = -1$), $f - f'$ is a coordinate vector of 0. By (Ac4) of Lemma 23.14 there are $t \ge 0$ and $g_k \in R$ with $\ell^t(f_k - f'_k) = X\Pi g_k$. As $\Pi f_k, \Pi f'_k \in R$, $X\Pi^2 g_k = \ell^t \Pi(f_k - f'_k) \in \ell^t R$. Now $G = X\Pi^2$ is a monic polynomial in X, so its reduction modulo a uniformiser ϖ of $\mathcal{O}_L$ is a nonzero element of the domain $(\mathcal{O}_L/\varpi)[[X]]$; hence $Gh \in \varpi R$ implies $h \in \varpi R$, and by induction $Gh \in \varpi^j R$ implies $h \in \varpi^j R$ (R is a domain). So $g_k \in \ell^t R$ and $f_k - f'_k = X\Pi(g_k/\ell^t) \in X\Pi R$. □

Lemma C.18. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$, $R = \mathcal{O}_L[[X]]$ with γ_u ($u \in \mathbb{Z}_\ell^\times$) acting $\mathcal{O}_L$-linearly by $X \mapsto (1+X)^u - 1$, $\mathcal{K}$ the fraction field of R, and $e \ge 1$. For $\alpha \in \mathbb{Z}^e$ put $I_\alpha = \prod_{s<e} Q_s^{\alpha_s} R \subseteq \mathcal{K}$, and for $t < e$ put $R^{(t)} = R[1/\prod_{s<e,\, s\ne t} Q_s] \subseteq \mathcal{K}$.*

1. (Membership level by level.) *For $h \in \mathcal{K}$ and $\alpha \in \mathbb{Z}^e$: $h \in I_\alpha$ if and only if $h \in Q_t^{\alpha_t} R^{(t)}$ for every $t < e$. In particular $I_\alpha \cap I_\beta = I_{\max(\alpha,\beta)}$ (componentwise maximum) for $\alpha, \beta \in \mathbb{Z}^e$.*

2. (Saturation.) *Let $c \in R$ be such that $c(x_0) \ne 0$ for every root x_0 of every Q_s, $s < e$ (for instance $c \in \mathcal{O}_L \setminus \{0\}$, or $c = X^j$ with $j \ge 0$). If $h \in R[1/\lambda_e]$ and $ch \in I_\alpha$, then $h \in I_\alpha$.*

3. (Invariant residues are constants.) *Let $t < e$, $u_0 \in \mathbb{Z}_\ell^\times$ with $v_\ell(u_0 - 1) = 1$, and $h \in R^{(t)}$ with $\gamma_\delta(h) = h$ for every $\delta \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ and $(\gamma_{u_0} - 1)(h) \in Q_t^N R^{(t)}$ for an integer $N \ge 1$. Then there are an integer $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $\ell^\kappa h - x \in Q_t^N R^{(t)}$.*

Proof. Evaluation. For a root $x_0 = \zeta - 1$ of Q_t we have $|x_0| < 1$, so $g \mapsto g(x_0)$ is a ring homomorphism $\mathrm{ev}_{x_0} \colon R \to \mathcal{O}_L[\zeta] \subset \overline{\mathbb{Q}}_\ell$. For $s \ne t$ the roots of Q_s have a different order, so $Q_s(x_0) \ne 0$; hence ev_{x_0} extends to a ring homomorphism $R^{(t)} \to \overline{\mathbb{Q}}_\ell$. Moreover $\mathrm{ev}_{x_0}(c) = c \ne 0$ for $c \in \mathcal{O}_L \setminus \{0\}$, and $\mathrm{ev}_{x_0}(X^j) = x_0^j \ne 0$ since $\zeta \ne 1$.

Step 1: a divisibility fact. Let $t < e$, $a \ge 0$, $g \in R$, and let $z \in R$ with $z(x_0) \ne 0$ for every root x_0 of Q_t (for instance a product of an element c as in item 2 and of powers of the Q_s, $s \ne t$, $s < e$). If $Q_t^a \mid zg$ in R, then $Q_t^a \mid g$. Indeed, for $a \ge 1$ write $zg = Q_t^a w$; evaluating at a root x_0 of Q_t gives $z(x_0)g(x_0) = 0$ with $z(x_0) \ne 0$, so g vanishes at all roots of Q_t and $g = Q_t g'$ with $g' \in R$; as R is a domain, $zg' = Q_t^{a-1} w$, and induction on a gives $Q_t^{a-1} \mid g'$. Consequently, if $a_t \ge 0$ and $Q_t^{a_t} \mid g$ for every $t < e$, then $\prod_{t<e} Q_t^{a_t} \mid g$: by induction on the number of levels already collected, if $g = \prod_{t\in T} Q_t^{a_t} y$ with $y \in R$ and $t' \notin T$, then $Q_{t'}^{a_{t'}} \mid (\prod_{t\in T} Q_t^{a_t}) y$, so $Q_{t'}^{a_{t'}} \mid y$ by the first part.

Item 1. If $h = \prod_s Q_s^{\alpha_s} y$ with $y \in R$, then for each t the factor $\prod_{s\ne t} Q_s^{\alpha_s} y$ lies in $R^{(t)}$, so $h \in Q_t^{\alpha_t} R^{(t)}$. Conversely, suppose $h = Q_t^{\alpha_t} y_t$ with $y_t \in R^{(t)}$ for every $t < e$. Choose $N \ge 0$ with $N \ge -\alpha_t$ and $(\lambda^{(t)})^N y_t \in R$ for every t, and put $g = \lambda_e^N h$. Since $\lambda_e = Q_t \lambda^{(t)}$,

$$g = Q_t^{N+\alpha_t} (\lambda^{(t)})^N y_t \in Q_t^{N+\alpha_t} R \qquad (t < e),$$

with $N+\alpha_t \geq 0$. In particular $g \in R$, and by Step 1, $g \in \prod_t Q_t^{N+\alpha_t} R$; hence $h = \lambda_e^{-N} g \in I_\alpha$. For the last claim: $I_{\max(\alpha,\beta)} \subseteq I_\alpha \cap I_\beta$ because $Q_s^{\max(\alpha_s,\beta_s)-\alpha_s} \in R$; and if $h \in I_\alpha \cap I_\beta$, then for each t, $h \in Q_t^{\alpha_t} R^{(t)}$ and $h \in Q_t^{\beta_t} R^{(t)}$, so $h \in Q_t^{\max(\alpha_t,\beta_t)} R^{(t)}$, and $h \in I_{\max(\alpha,\beta)}$ by the first part.

Item 2. Write $h = \lambda_e^{-N} g$ with $g \in R$ and $N \geq 0$ so large that $N + \alpha_t \geq 0$ for all t. Then $cg = \lambda_e^N ch \in I_{\alpha+(N,\dots,N)}$, so $Q_t^{N+\alpha_t} \mid cg$ in R for each t (the other factors $Q_s^{N+\alpha_s}$ lie in R). By Step 1 (with $z = c$, which does not vanish at the roots of Q_t by hypothesis), $Q_t^{N+\alpha_t} \mid g$ for every t, hence $g \in \prod_t Q_t^{N+\alpha_t} R$ and $h \in I_\alpha$.

Item 3. *Transport of γ_u.* For $g \in R$, $\gamma_u(g) = g\big((1+X)^u - 1\big)$, and evaluating the series $(1+X)^u = \sum_k \binom{u}{k} X^k$ at $x_0 = \zeta - 1$ gives ζ^u (for $u \in \mathbb{Z}_{\geq 0}$ this is the binomial theorem; both sides are continuous in $u \in \mathbb{Z}_\ell$, the right side because ζ^u depends only on $u \bmod \ell^{t+1}$). Hence $\mathrm{ev}_{\zeta-1} \circ \gamma_u = \mathrm{ev}_{\zeta^u - 1}$ on R, and, both sides being ring homomorphisms and $\gamma_u(Q_s) \in Q_s R^\times$ (Lemma 23.8(2)), also on $R^{(t)}$; here ζ^u is again of exact order ℓ^{t+1}.

One value at all roots. By hypothesis $(\gamma_{u_0} - 1)(h) \in Q_t^N R^{(t)} \subseteq Q_t R^{(t)}$ and $(\gamma_\delta - 1)(h) = 0$ lie in $Q_t R^{(t)}$, which every ev_{x_0} kills. So $h(\zeta^u - 1) = h(\zeta - 1)$ for every ζ of exact order ℓ^{t+1} and every u in the subgroup $U \subseteq \mathbb{Z}_\ell^\times$ generated by u_0 and $\mu_{\ell-1}$. The image of U in $(\mathbb{Z}/\ell^{t+1})^\times$ is everything: reduction modulo ℓ maps $\mu_{\ell-1}$ bijectively onto $\mathbb{F}_\ell^\times$, so its image has order $\ell - 1$; by Lemma 23.22(1) (with $m = 1$), $v_\ell(u_0^k - 1) = 1 + v_\ell(k)$ for $k \neq 0$, so u_0 has order ℓ^t modulo ℓ^{t+1}; the two orders are coprime, so the image of U has order $(\ell-1)\ell^t = |(\mathbb{Z}/\ell^{t+1})^\times|$. Since every ζ' of exact order ℓ^{t+1} is ζ^u for some u prime to ℓ, h takes one value y_0 at all roots of Q_t.

The value lies in L. Write $h = g/(\lambda^{(t)})^N$ with $g \in R$. Let $\tau \in \mathrm{Gal}(\overline{\mathbb{Q}}_\ell / L)$. It is continuous on the complete field $L(\zeta)$ and fixes the coefficients of g (in $\mathcal{O}_L$) and of $\lambda^{(t)}$ (in $\mathbb{Z}_\ell$), so $\tau(h(\zeta - 1)) = h(\tau(\zeta) - 1) = y_0$, as $\tau(\zeta)$ has exact order ℓ^{t+1}. Hence $y_0 \in L$, and there is $\kappa \geq 0$ with $x = \ell^\kappa y_0 \in \mathcal{O}_L$.

Conclusion. $h' = \ell^\kappa h - x \in R^{(t)}$ vanishes at every root of Q_t. Choose M with $g' = (\lambda^{(t)})^M h' \in R$; g' vanishes at every root of Q_t, so $g' \in Q_t R$ by Lemma 23.8(3), and $h' = (\lambda^{(t)})^{-M} g' \in Q_t R^{(t)}$.

Higher order. Put $u' = u_0^{\ell^e}$; by Lemma 23.22(1), $v_\ell(u' - 1) = 1 + e$, so $u' \equiv 1 \bmod \ell^e$, and $\gamma_{u_0}^{\ell^e} = \gamma_{u'}$. Each γ_u maps $Q_t^a R^{(t)}$ onto itself ($\gamma_u(Q_s) \in Q_s R^\times$, Lemma 23.8(2)). We show $h' \in Q_t^k R^{(t)}$ for $k = 1, \dots, N$ by induction; let $1 \leq k < N$ and $h' \in Q_t^k R^{(t)}$. Then $(\gamma_{u_0} - 1)(h') = \ell^\kappa (\gamma_{u_0} - 1)(h) \in Q_t^{k+1} R^{(t)}$ (x is fixed by γ_{u_0}), so $(\gamma_{u'} - 1)(h') = \big(\sum_{j<\ell^e} \gamma_{u_0}^j\big)(\gamma_{u_0} - 1)(h') \in Q_t^{k+1} R^{(t)}$. Choose $M' \geq 0$ with $h' \in I_\eta$, $\eta_t = k$, $\eta_s = -M'$ ($s \neq t$) (item 1); by item 2 of Lemma C.19, $(\gamma_{u'} - u'^k)(h') \in I_{\eta + \mathbf{1}_t} \subseteq Q_t^{k+1} R^{(t)}$, where $\mathbf{1}_t$ is the t-th unit vector. Subtracting, $c\,h' \in Q_t^{k+1} R^{(t)}$ with $c = u'^k - 1 \in \mathbb{Z}_\ell$, $c \neq 0$ ($v_\ell(c) = 1 + e + v_\ell(k)$ by Lemma 23.22(1)). By item 1, $ch' \in I_{\eta'}$ with $\eta'_t = k+1$ and $\eta'_s = -M''$ for $s \neq t$, M'' large; by item 2, $h' \in I_{\eta'} \subseteq Q_t^{k+1} R^{(t)}$. $\square$

Lemma C.19. *Let ℓ be an odd prime, F and L as in Definition 23.2, $R = \mathcal{O}_L[[X]]$ with γ_u acting $\mathcal{O}_L$-linearly by $X \mapsto (1+X)^u - 1$, $e \geq 1$, and for $\alpha = (\alpha_0, \dots, \alpha_{e-1}) \in \mathbb{Z}^e$ let $I_\alpha = \prod_{s<e} Q_s^{\alpha_s} R \subseteq R[1/\lambda_e]$; $\delta_t \in \mathbb{Z}^e$ is the t-th unit vector.*

1. *If $\mathbf{N}$ is a Wach module over F with coefficients L, $u \in \mathbb{Z}_\ell^\times$, $P \in \mathbb{Z}_\ell[Y]$ and $w \in \mathbf{N}$ with $(\gamma_{u,\mathbf{N}} - 1)w \in X\mathbf{N}$, then $P(\gamma_{u,\mathbf{N}})w - P(1)w \in X\mathbf{N}$.*

2. *Let $u' \in \mathbb{Z}_\ell^\times$ with $u' \equiv 1 \bmod \ell^e$. Then $\gamma_{u'}(I_\alpha) = I_\alpha$ and $(\gamma_{u'} - u'^{\alpha_t})(I_\alpha) \subseteq I_{\alpha+\delta_t}$ for every $t < e$ and every $\alpha \in \mathbb{Z}^e$.*

3. *Let $u \in 1 + \ell\mathbb{Z}_\ell$, $J \subset \mathbb{Z}$ finite, $t < e$, $\alpha \in \mathbb{Z}^e$ and $f \in I_\alpha$. If $\alpha_t \in J \setminus \{0\}$ then $P_{J,e}(\gamma_u) f \in I_{\alpha+\delta_t}$; if $\alpha_t = 0$ then $P_{J,e}(\gamma_u)(\gamma_u f - f) \in I_{\alpha+\delta_t}$; and for every $N \geq 0$, $\prod_{i=\alpha_t}^{\alpha_t+N-1} (\gamma_u^{\ell^e} - u^{i\ell^e}) f \in I_{\alpha+N\delta_t}$.*

Proof. **Item 1.** $\gamma_{u,\mathbf{N}}$ is a $\mathbb{Z}_\ell$-linear endomorphism of $\mathbf{N}$, and $X\mathbf{N}$ is stable under it, since $\gamma_{u,\mathbf{N}}(Xy) = \gamma_u(X)\gamma_{u,\mathbf{N}}(y)$ and $\gamma_u(X) \in X\mathbf{A}_F$ (Lemma 23.8(2)). Apply Lemma 23.22(3) with $M = \mathbf{N}$, $A = \gamma_{u,\mathbf{N}}$, $M' = X\mathbf{N}$, $f = 1$, $Q = P$.

Item 2. By Lemma 23.8(2), $\gamma_{u'}(Q_s) = Q_s v_s$ with $v_s \in \mathbb{Z}_\ell[[X]]^\times$. Let $g = \prod_{s<e} Q_s^{\alpha_s}$ and $y \in R$. Then $\gamma_{u'}(gy) = g\, v\, \gamma_{u'}(y)$ with $v = \prod_s v_s^{\alpha_s} \in R^\times$; as $\gamma_{u'}$ is bijective on R, $\gamma_{u'}(I_\alpha) = I_\alpha$, and $(\gamma_{u'} - u'^{\alpha_t})(gy) = g\,\Psi$ with $\Psi = v\gamma_{u'}(y) - u'^{\alpha_t} y \in R$. Let $x_0 = \zeta - 1$ with ζ a primitive ℓ^{t+1}-th root of unity, a root of Q_t; evaluation at x_0 is a ring homomorphism $R \to \mathcal{O}_L[\zeta]$. Since $t+1 \le e$, $u' \equiv 1 \bmod \ell^{t+1}$ and $(1+x_0)^{u'} - 1 = \zeta^{u'} - 1 = x_0$; hence $\gamma_{u'}(y)(x_0) = y(x_0)$. For $s \neq t$, $Q_s(x_0) \neq 0$ (the roots of the Q_s are the $\zeta' - 1$ with ζ' of exact order ℓ^{s+1}), so $v_s(x_0) = Q_s(x_0)/Q_s(x_0) = 1$. For $s = t$, differentiate the identity $Q_t((1+X)^{u'} - 1) = Q_t(X)v_t(X)$ and evaluate at x_0: $Q_t'(x_0)\, u'(1+x_0)^{u'-1} = Q_t'(x_0)v_t(x_0)$, and $Q_t'(x_0) \neq 0$ (simple root), $(1+x_0)^{u'-1} = \zeta^{u'-1} = 1$; so $v_t(x_0) = u'$. Therefore $\Psi(x_0) = u'^{\alpha_t} y(x_0) - u'^{\alpha_t} y(x_0) = 0$ for every root x_0 of Q_t, and by Lemma 23.8(3), $\Psi \in Q_t R$. Hence $(\gamma_{u'} - u'^{\alpha_t})(gy) \in gQ_tR = I_{\alpha+\delta_t}$.

Item 3. Put $u' = u^{\ell^e}$; since $u \equiv 1 \bmod \ell$, $u' \equiv 1 \bmod \ell^{e+1}$, and $\gamma_u^{\ell^e} = \gamma_{u'}$, $u^{i\ell^e} = u'^{\,i}$. All operators below are polynomials in γ_u, hence commute, and each preserves every I_β (item 2 for γ_u requires only $\gamma_u(Q_s) \in Q_s R^\times$, which is Lemma 23.8(2)). If $\alpha_t = i_0 \in J \setminus \{0\}$, then

$$P_{J,e}(\gamma_u) f = \Big(\prod_{i \in J \setminus \{0, i_0\}} (\gamma_{u'} - u'^{\,i}) \Big) \Big(\sum_{k < \ell^e} \gamma_u^k \Big) (\gamma_{u'} - u'^{\,i_0}) f,$$

and $(\gamma_{u'} - u'^{\,i_0}) f \in I_{\alpha+\delta_t}$ by item 2. If $\alpha_t = 0$, then $(\sum_{k<\ell^e} \gamma_u^k)(\gamma_u - 1) = \gamma_{u'} - 1 = \gamma_{u'} - u'^{\,0}$, so $P_{J,e}(\gamma_u)(\gamma_u - 1) f = \prod_{i \in J \setminus \{0\}} (\gamma_{u'} - u'^{\,i})\,(\gamma_{u'} - 1) f \in I_{\alpha+\delta_t}$ by item 2. For the last claim apply item 2 successively with $\alpha_t, \alpha_t + 1, \ldots, \alpha_t + N - 1$, the factors being applied in increasing order of i. □

Lemma C.20. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$, $R = \mathcal{O}_L[[X]]$ with γ_u ($u \in \mathbb{Z}_\ell^\times$) acting $\mathcal{O}_L$-linearly by $X \mapsto (1+X)^u - 1$ and extended to the fraction field $\mathcal{K}$ of R, and fix $u_0 \in \mathbb{Z}_\ell^\times$ with $v_\ell(u_0 - 1) = 1$; write $\gamma = \gamma_{u_0}$. Let $e \ge 1$ and $S \ge 0$ be integers, and for $s < e$ let $\epsilon_s \in \{1, -1\}$ and $b_s \ge 1$ be integers. Put*

$$\mu = \prod_{\substack{s<e \\ \epsilon_s = 1}} Q_s^{b_s+S}, \quad \delta = \prod_{\substack{s<e \\ \epsilon_s = -1}} Q_s^{b_s}, \quad \nu^+ = \prod_{\substack{s<e \\ \epsilon_s = -1}} Q_s^{b_s+S}, \quad \nu = \prod_{\substack{s<e \\ \epsilon_s = 1}} Q_s^{b_s},$$

let $J \subset \mathbb{Z}$ be a finite set containing $\{i : -b_s - S \le i < -b_s\}$ for every $s < e$ with $\epsilon_s = 1$ and $\{i : b_s \le i < b_s + S\}$ for every $s < e$ with $\epsilon_s = -1$, and let $P = P_{J,e}$ (formed with $p = \ell$, $u = u_0$). Let $f \in \mathcal{K}$ with

$$\mu f \in R \qquad \text{and} \qquad \mu\,(\gamma - 1)(f) \in X^{\ell-1}\delta R.$$

Then:

1. *$\nu\, P(\gamma)(f) \in R$;*
2. *$\nu\,(\gamma - 1)P(\gamma)(f) \in X^{\ell-1}\nu^+ R$;*
3. *if moreover $\gamma_\omega(f) = f$ for every $\omega \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$, then for every $s < e$ with $\epsilon_s = -1$ there are an integer $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with*

$$\nu\,(\ell^\kappa P(\gamma)(f) - x) \in Q_s^{b_s+S} R.$$

Proof. Define $\alpha, \beta, \alpha', \beta' \in \mathbb{Z}^e$ by

$$(\alpha_s, \beta_s, \alpha'_s, \beta'_s) = \begin{cases} (-b_s - S,\ -b_s,\ -b_s - S,\ -b_s) & \text{if } \epsilon_s = 1, \\ (0,\ 0,\ b_s,\ b_s + S) & \text{if } \epsilon_s = -1. \end{cases}$$

Then $I_\alpha = \mu^{-1}R$, $I_{\alpha'} = \mu^{-1}\delta R$, $I_\beta = \nu^{-1}R$, $I_{\beta'} = \nu^{-1}\nu^+R$. The hypotheses say $f \in I_\alpha$ and $(\gamma-1)(f) = X^{\ell-1}g$ with $g \in I_{\alpha'}$; items 1 and 2 say $P(\gamma)(f) \in I_\beta$ and $(\gamma-1)P(\gamma)(f) \in X^{\ell-1}I_{\beta'}$.

Step 0: stability. For $u \in \mathbb{Z}_\ell^\times$, $\gamma_u(Q_s) \in Q_s R^\times$ and $\gamma_u(X) \in XR^\times$ (Lemma 23.8(2)), and γ_u is bijective on R; hence $\gamma_u(I_\eta) = I_\eta$ and $\gamma_u(X^{\ell-1}I_\eta) = X^{\ell-1}I_\eta$ for every η. So every $Z(\gamma)$, $Z \in \mathbb{Z}_\ell[Y]$, maps I_η and $X^{\ell-1}I_\eta$ into themselves.

Step 1: one factor raises one level. Put $u' = u_0^{\ell^e}$. By Lemma 23.22(1), $v_\ell(u'-1) = 1+e$, so $u' \equiv 1 \bmod \ell^{e+1}$; and $\gamma^{\ell^e} = \gamma_{u'}$, $u_0^{i\ell^e} = u'^{\,i}$. Let $\eta \in \mathbb{Z}^e$ and $t < e$. Then

$$(\gamma_{u'} - u'^{\,\eta_t})(I_\eta) \subseteq I_{\eta+\mathbf{1}_t} \qquad \text{and} \qquad (\gamma_{u'} - u'^{\,\eta_t})(X^{\ell-1}I_\eta) \subseteq X^{\ell-1}I_{\eta+\mathbf{1}_t}.$$

The first inclusion is item 2 of Lemma C.19. For the second, write $\gamma_{u'}(X^{\ell-1}) = X^{\ell-1}z$ with $z \in R^\times$ (Step 0). At a root $x_0 = \zeta - 1$ of Q_t (ζ of exact order ℓ^{t+1}, $t+1 \le e$) we have $\gamma_{u'}(X)(x_0) = \zeta^{u'} - 1 = x_0 \neq 0$, so $z(x_0) = 1$; hence $z - 1 \in Q_t R$ by Lemma 23.8(3). For $h \in I_\eta$,

$$(\gamma_{u'} - u'^{\,\eta_t})(X^{\ell-1}h) = X^{\ell-1}\Big((\gamma_{u'} - u'^{\,\eta_t})(h) + (z-1)\,\gamma_{u'}(h)\Big),$$

where the first summand lies in $I_{\eta+\mathbf{1}_t}$ by the first inclusion and the second in $Q_t I_\eta = I_{\eta+\mathbf{1}_t}$ by Step 0.

Step 2: a window raises one level by its length. Let M_η stand for I_η or for $X^{\ell-1}I_\eta$ throughout. If $t < e$, $N \ge 0$ and $\{\eta_t, \eta_t+1, \dots, \eta_t+N-1\} \subseteq J \setminus \{0\}$, then $P(\gamma)(M_\eta) \subseteq M_{\eta+N\mathbf{1}_t}$. Indeed, by the definition of $P_{J,e}$,

$$P(Y) = \prod_{i=\eta_t}^{\eta_t+N-1} (Y^{\ell^e} - u_0^{i\ell^e}) \cdot P'(Y)$$

with $P' \in \mathbb{Z}_\ell[Y]$ the product of the remaining factors; $P'(\gamma)$ maps M_η into itself (Step 0), and the factors $\gamma_{u'} - u'^{\,i}$, applied in increasing order of i, map $M_{\eta+(i-\eta_t)\mathbf{1}_t}$ into $M_{\eta+(i-\eta_t+1)\mathbf{1}_t}$ by Step 1 (the t-th coordinate of $\eta + (i-\eta_t)\mathbf{1}_t$ is i). All these operators are polynomials in γ and commute.

Item 1. Let $t < e$. If $\epsilon_t = 1$, then $\{\alpha_t, \dots, \alpha_t + S - 1\} = \{-b_t - S, \dots, -b_t - 1\} \subseteq J \setminus \{0\}$, so by Step 2 (with $M = I$, $N = S$) $P(\gamma)(f) \in I_{\alpha+S\mathbf{1}_t}$, whose t-th coordinate is β_t; hence $P(\gamma)(f) \in Q_t^{\beta_t} R^{(t)}$ (item 1 of Lemma C.18, easy direction). If $\epsilon_t = -1$, then $\beta_t = \alpha_t = 0$ and $P(\gamma)(f) \in I_\alpha \subseteq Q_t^0 R^{(t)}$ by Step 0. By item 1 of Lemma C.18, $P(\gamma)(f) \in I_\beta$, that is $\nu P(\gamma)(f) \in R$.

Item 2. $(\gamma-1)P(\gamma)(f) = P(\gamma)((\gamma-1)(f)) = P(\gamma)(X^{\ell-1}g)$ with $g \in I_{\alpha'}$. Let $t < e$. The window $\{\alpha'_t, \dots, \alpha'_t + S - 1\}$ is $\{-b_t - S, \dots, -b_t - 1\}$ if $\epsilon_t = 1$ and $\{b_t, \dots, b_t + S - 1\}$ if $\epsilon_t = -1$; it lies in $J \setminus \{0\}$ (in the second case because $b_t \ge 1$). By Step 2 (with $M = X^{\ell-1}I$, $N = S$), $(\gamma-1)P(\gamma)(f) = X^{\ell-1}h$ with $h \in I_{\alpha'+S\mathbf{1}_t}$, where $h = X^{1-\ell}(\gamma-1)P(\gamma)(f) \in \mathcal{K}$ does not depend on t. The t-th coordinate of $\alpha' + S\mathbf{1}_t$ is β'_t, so $h \in Q_t^{\beta'_t} R^{(t)}$ for every t, and $h \in I_{\beta'}$ by item 1 of Lemma C.18. Thus $\nu(\gamma-1)P(\gamma)(f) = X^{\ell-1}\nu h \in X^{\ell-1}\nu^+ R$.

Item 3. Fix $s < e$ with $\epsilon_s = -1$, put $b = b_s$ and $F = P(\gamma)(f)$. For $\omega \in \mu_{\ell-1}$, $\gamma_\omega \gamma = \gamma_{\omega u_0} = \gamma\gamma_\omega$, so $\gamma_\omega(F) = P(\gamma)(\gamma_\omega f) = F$. By item 1, $F \in I_\beta \subseteq Q_s^0 R^{(s)} = R^{(s)}$ ($\beta_s = 0$). By item 2, $(\gamma-1)(F) \in X^{\ell-1}I_{\beta'} \subseteq I_{\beta'} \subseteq Q_s^{b+S} R^{(s)}$. Item 3 of Lemma C.18 (with $t = s$, $h = F$, $N = b + S$) gives $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $H = \ell^\kappa F - x \in Q_s^{b+S} R^{(s)}$. Since $\beta \le 0$, $x \in R \subseteq I_\beta$, so $H \in I_\beta$, hence $H \in Q_t^{\beta_t} R^{(t)}$ for $t \neq s$; with $H \in Q_s^{b+S} R^{(s)}$, item 1 of Lemma C.18 gives $H \in I_{\beta+(b+S)\mathbf{1}_s} = \nu^{-1} Q_s^{b+S} R$, that is $\nu(\ell^\kappa P(\gamma)(f) - x) \in Q_s^{b+S} R$. □

Proposition C.21. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N} = \mathbf{N}(T_2)$, $r = \dim_L V_2$. Let $c \in C$, $e = \mathrm{len}_c$, and $(\mathbf{n}, R)$ a low frame at c. Then there are $g_0 \le m\,e\,(e+1)$ Δ-invariant vectors $J_1, \dots, J_{g_0} \in \mathcal{K}_c^r$, each with $\Pi_c J_{i,k} \in e_c \mathbf{A}_{F,L}$ for all k, $J_{i,k} = 0$ for $k \notin R$, and Hodge-integral modulo γ, such that for every Δ-invariant $f \in \mathcal{K}_c^r$ with $\Pi_c f_k \in e_c \mathbf{A}_{F,L}$ for all k, $f_k = 0$ for $k \notin R$, and f Hodge-integral modulo γ, there is $o \in \mathcal{O}_L^{g_0}$ with $f - \sum_i o_i J_i \in X^{\ell-1}\mathcal{H}_{\mathbf{n}}$.*

Proof. Put $Z = X^{\ell-1}\mathcal{H}_{\mathbf{n}}$, let $\mathcal{M}$ be the set of Δ-invariant $f \in \mathcal{K}_c^r$ with $\Pi f_k \in \mathcal{R}$ for all k and $f_k = 0$ for $k \notin R$, and $\mathcal{M}_\gamma \subseteq \mathcal{M}$ the subset of those f that are Hodge-integral modulo γ. Both are $\mathcal{O}_L$-modules ($\mathcal{H}_{\mathbf{n}}$ is an $\mathcal{R}$-module and γ is $\mathcal{O}_L$-linear). We must find $g_0 \le m\,e\,(e+1)$ elements $J_1, \dots, J_{g_0}$ of $\mathcal{M}_\gamma$ such that every $f \in \mathcal{M}_\gamma$ lies in $\sum_i \mathcal{O}_L J_i + Z$.

Step 1: three properties of Z. (i) $X^{\ell-1}\Pi\mathcal{R}^r \subseteq Z$: for $d \in \Pi\mathcal{R}^r$, $\Pi d_k \in \mathcal{R}$, and $(d_k, \mathbf{e}_k, (H_s)_s)_k$ is a section decomposition with $\delta_e(\mathbf{e}_k) \in \varphi^{s+4}(\mathrm{Fil}^{-H_s} D_{\mathrm{cris}}(V_2))$, because every Hodge jump of V_2 at τ_{c-s} has absolute value at most H_s (Lemma C.16 (1)), so that by the remark in Definition 23.3 the filtration step $-H_s$ of the relevant component is the whole component. (ii) $\gamma_u(Z) = Z$ for $u \in \mathbb{Z}_\ell^\times$: if $\Pi h_k \in \mathcal{R}$ then $\Pi\gamma_u(h_k) = \gamma_u(\Pi h_k)\,\Pi/\gamma_u(\Pi) \in \mathcal{R}$, a section decomposition $(g_i, \mathbf{v}_i, \alpha_i)$ of h gives the decomposition $(\gamma_u(g_i), \mathbf{v}_i, \alpha_i)$ of $\gamma_u(h)$ ($\gamma_u(I_\eta) = I_\eta$), and $\gamma_u(X^{\ell-1}) \in X^{\ell-1}\mathcal{R}^\times$ (Lemma 23.8 (2)); the same holds for $\gamma_u^{-1} = \gamma_{u^{-1}}$. (iii) If $f \in \mathcal{M}$, $c \in \mathcal{O}_L \setminus \{0\}$ and $cf \in Z$, then $f \in Z$: write $cf = X^{\ell-1}h$ with $h \in \mathcal{H}_{\mathbf{n}}$ and put $h' = h/c$, so $f = X^{\ell-1}h'$. For each k, $y = \Pi h'_k$ satisfies $X^{\ell-1}y = \Pi f_k \in \mathcal{R}$ and $r_1 = cy = \Pi h_k \in \mathcal{R}$; then $X^{\ell-1}r_1 \in c\mathcal{R}$, so every coefficient of r_1 lies in $c\mathcal{O}_L$ and $y \in \mathcal{R}$. If $\ell^\kappa h$ is Hodge-graded and $\ell^j/c \in \mathcal{O}_L$, then $\ell^{\kappa+j}h' = (\ell^j/c)\ell^\kappa h$ is Hodge-graded (multiply the $\mathbf{v}_i$ by ℓ^j/c). So $h' \in \mathcal{H}_{\mathbf{n}}$ and $f \in Z$.

Step 2: $A = \mathcal{M}/(\mathcal{M} \cap Z)$ is a finitely generated torsion-free $\mathcal{O}_L$-module. Let $P_0 = X^{\ell-1}\Pi^2$, a monic polynomial congruent to $X^{\deg P_0}$ modulo ℓ (Lemma 23.8 (3)); by the Weierstrass division theorem $\mathcal{R}/P_0\mathcal{R} \cong \mathcal{O}_L[X]/(P_0)$ is free of rank $\deg P_0$ over $\mathcal{O}_L$. The map $\mathcal{M} \to \bigoplus_{k\in R} \mathcal{R}/P_0\mathcal{R}$, $f \mapsto (\Pi f_k \bmod P_0)_k$, is $\mathcal{O}_L$-linear, and its kernel consists of f with $f_k \in X^{\ell-1}\Pi\mathcal{R}$ for all k, hence lies in Z by (i). So A is a quotient of a submodule of a finitely generated module over the noetherian ring $\mathcal{O}_L$, hence finitely generated; it is torsion-free by (iii).

Step 3: the Chinese remainder vectors. For $s < e$ the polynomials $Q_s^{H_s}$ and $\Pi'_s = \prod_{t<e,\, t\neq s} Q_t^{H_t}$ have no common root (Lemma 23.8 (3)), so $A_s Q_s^{H_s} + B_s\Pi'_s = 1$ with $A_s, B_s \in L[X]$; fix $\kappa_c \ge 0$ with $\ell^{\kappa_c}A_s, \ell^{\kappa_c}B_s \in \mathcal{O}_L[X]$ for all s. Then $u_s^0 = \ell^{\kappa_c}B_s\Pi'_s \in \mathcal{R}$ satisfies $u_s^0 - \ell^{\kappa_c} \in Q_s^{H_s}\mathcal{R}$ and $u_s^0 \in Q_t^{H_t}\mathcal{R}$ for $t \neq s$. Put $u_s = (\ell-1)^{-1}\sum_{\omega\in\mu_{\ell-1}} \gamma_\omega(u_s^0)$; it is Δ-invariant and has the same two properties, since each γ_ω maps $Q_t^a\mathcal{R}$ onto itself and fixes ℓ^{κ_c}. Put $\tilde\Pi = (\ell-1)^{-1}\sum_\omega \gamma_\omega(\Pi)$. Each $\gamma_\omega(\Pi) = \Pi v_\omega$ with $v_\omega \in \mathcal{R}^\times$, and $v_\omega(0) = 1$ because γ_ω preserves constant terms and $\Pi(0) = \ell^{\sum_s H_s} \neq 0$; so $\tilde\Pi = \Pi\tilde w$ with $\tilde w(0) = 1$, $\tilde w \in \mathcal{R}^\times$, and $\tilde\Pi$ is Δ-invariant. The $N_0 = |R|(e+1) \le m\,e\,(e+1)$ vectors

$$C_{k,s} = u_s\,\mathbf{e}_k \ (k \in R,\ s < e), \qquad C_{k,e} = \tilde\Pi\,\mathbf{e}_k \ (k \in R)$$

lie in $\mathcal{M}$.

Step 4: a multiple of each $f \in \mathcal{M}_\gamma$. Let $M_0 = \max_s H_s$, $J = \{i \in \mathbb{Z} :\ -M_0 \le i < M_0\}$ and $P = P_{J,e}$ (formed with $p = \ell$, $u = u_0$); $P(1) \neq 0$ by Lemma 23.22 (2). We claim: for every $f \in \mathcal{M}_\gamma$ there is $K \ge 0$ with $\ell^K P(1) f \in \sum_{k,j} \mathcal{O}_L C_{k,j} + Z$.

(a) By Lemma 23.22 (3) there is $Q_1 \in \mathbb{Z}_\ell[Y]$ with $P(\gamma) - P(1) = Q_1(\gamma)(\gamma-1)$; as $(\gamma-1)f \in Z$ and Z is γ-stable (ii), $P(\gamma)f - P(1)f \in Z$.

(b) Fix $k \in R$ and $h = f_k$; then $h \in I_{-H}$ ($H = (H_s)_s$) and h is Δ-invariant. Put $u' = u_0^{\ell^e}$, so $\gamma^{\ell^e} = \gamma_{u'}$ and $P(\gamma) = \prod_{i\in J\setminus\{0\}}(\gamma_{u'} - u'^i)\cdot\sum_{j<\ell^e}\gamma^j$. All polynomials in γ commute and map each I_η into itself (Lemma 23.8 (2)). Let $t < e$. Since $\{-H_t, \dots, -1\} \subseteq J \setminus \{0\}$, the last clause

of item 3 of Lemma C.19 (with $\alpha = -H$, $N = H_t$), applied after the remaining factors of P, gives $F = P(\gamma)h \in I_{-H+H_t\mathbf{1}_t} \subseteq Q_t^0 R^{(t)}$ ($\mathbf{1}_t$ the t-th unit vector); by item 1 of Lemma C.18, $F \in I_0 = \mathcal{R}$. Next, $(\sum_{j<\ell^e} \gamma^j)(\gamma - 1) = \gamma_{u'} - u'^0$, so

$$(\gamma - 1)F = \prod_{i \in J} (\gamma_{u'} - u'^i)\, h,$$

and as $\{-H_t, \dots, H_t - 1\} \subseteq J$ the same clause (with $N = 2H_t$) gives $(\gamma - 1)F \in I_{-H+2H_t\mathbf{1}_t} \subseteq Q_t^{H_t} R^{(t)}$. F is Δ-invariant (γ_ω commutes with γ). If $H_t \geq 1$, item 3 of Lemma C.18 (with $N = H_t$) gives $\kappa_t \geq 0$ and $x_t \in \mathcal{O}_L$ with $\ell^{\kappa_t} F - x_t \in Q_t^{H_t} R^{(t)}$; if $H_t = 0$ put $\kappa_t = 0$, $x_t = 0$. Let $\kappa = \max_t \kappa_t$ and

$$y = \ell^{\kappa_c + \kappa} F - \sum_{t<e} \ell^{\kappa - \kappa_t} x_t\, u_t \in \mathcal{R}.$$

For each t, by the properties of the $u_{t'}$, $y \equiv \ell^{\kappa_c + \kappa - \kappa_t}(\ell^{\kappa_t} F - x_t) \equiv 0$ modulo $Q_t^{H_t} R^{(t)}$; by item 1 of Lemma C.18, $y \in I_H = \Pi\mathcal{R}$. So $y = \tilde{\Pi}\rho$ with $\rho \in \mathcal{R}$, and ρ is Δ-invariant (y, $\tilde{\Pi}$ are, $\mathcal{R}$ is a domain). The element $\rho - \rho(0) \in X\mathcal{R}$ is Δ-invariant; if non-zero with lowest term $a_j X^j$, then γ_ω multiplies that term by ω^j, so $(\ell - 1) \mid j$; hence $\rho - \rho(0) \in X^{\ell-1}\mathcal{R}$, and $y - \rho(0)\tilde{\Pi} \in X^{\ell-1}\Pi\mathcal{R}$. Thus $\ell^{K_k} P(\gamma) f_k \in \sum_{s<e} \mathcal{O}_L u_s + \mathcal{O}_L \tilde{\Pi} + X^{\ell-1}\Pi\mathcal{R}$ with $K_k = \kappa_c + \kappa$.

(c) For $k \notin R$, $f_k = 0$ and $P(\gamma) f_k = 0$. With $K = \max_{k \in R} K_k$, (b) and (i) give $\ell^K P(\gamma) f \in \sum_{k,j} \mathcal{O}_L C_{k,j} + Z$, and (a) gives the claim.

Step 5: exact generation over the principal ideal domain $\mathcal{O}_L$. Let $B \subseteq A$ be the image of $\mathcal{M}_\gamma$ and $T \subseteq A$ the image of $\sum_{k,j} \mathcal{O}_L C_{k,j}$; T is generated by N_0 elements. By Step 2, B is finitely generated and torsion-free, hence free of finite rank g_0. By Step 4, for every $b \in B$ there is $c_b = \ell^K P(1) \neq 0$ with $c_b b \in T$ (the difference of $\ell^K P(1) f$ and an element of $\sum \mathcal{O}_L C_{k,j}$ lies in $\mathcal{M} \cap Z$). Since A is torsion-free, $A \to A \otimes_{\mathcal{O}_L} L$ is injective, and $B \otimes L$, $T \otimes L$ are subspaces of $A \otimes L$ (L is flat) with $B \otimes L \subseteq T \otimes L$, as $b \otimes 1 = c_b^{-1}(c_b b \otimes 1)$. Hence $g_0 = \dim_L(B \otimes L) \leq \dim_L(T \otimes L) \leq N_0 \leq m\, e\, (e + 1)$, using $|R| \leq m\, e$. Let $b_1, \dots, b_{g_0}$ be an $\mathcal{O}_L$-basis of B and $J_i \in \mathcal{M}_\gamma$ lifts. Each J_i is Δ-invariant, has $\Pi J_{i,k} \in \mathcal{R}$, $J_{i,k} = 0$ for $k \notin R$, and is Hodge-integral modulo γ. For f as in the statement, $f \in \mathcal{M}_\gamma$, its image is $\sum_i o_i b_i$ with $o \in \mathcal{O}_L^{g_0}$, and $f - \sum_i o_i J_i \in \mathcal{M} \cap Z \subseteq X^{\ell-1}\mathcal{H}_{\mathbf{n}}$. □

Proposition C.22. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word satisfy the hypotheses of Proposition C.25; let $\nu \in \{1, 2\}$ and put $\mathbf{N} = \mathbf{N}(T_\nu)$, $r = \dim_L V_\nu$ (Hodge-integral vectors, as defined in Proposition C.11, formed for frames of $\mathbf{N}$ with $D_{\mathrm{cris}}(V_\nu)$). Let $c \in C$, $e = \mathrm{len}_c$, and $\mathbf{n}$ a Δ-invariant frame at c' of $\mathbf{N}$. Then for every Δ-invariant $f \in \mathcal{K}_c^r$ with $\Pi_c f_k \in e_c \mathbf{A}_{F,L}$ for all k that is Hodge-integral modulo γ (for $\mathbf{n}$), there is a Δ-invariant $y \in e_c \mathbf{N}[1/\lambda_\infty]$ with $(\gamma_u - 1)(y) \in X\mathbf{N}$ for all $u \in \mathbb{Z}_\ell^\times$ and $\Pi_c y \in P_e(\mathbf{N}_{c'})$ such that $\ell^{\sigma_B} f$ is an arc coordinate vector of y for $\mathbf{n}$, e, H_c, m_X.*

Proof. Write $U = P_e(\mathbf{N}_{c'})$, $\Pi = \Pi_c$, and *coordinate vector* for arc coordinate vector for $\mathbf{n}$, e, H_c, m_X. We use the calculus of Lemma C.16 for the frame $\mathbf{n}$ (for $\nu = 1$ by its item (e)), and Proposition C.23 for the same ν: (a) coordinate vectors are $e_c \mathbf{A}_{F,L}$-linear in the vector; (b) if f is a coordinate vector of y then $\gamma_u(f)$ is one of $\gamma_u(y)$, and $\gamma_u(U) = U$, $\gamma_u(\Pi) \in \Pi\, \mathbb{Z}_\ell[[X]]^\times$; (c) if 0 is a coordinate vector of y and $\Pi y \in U$, then $y \in X\mathbf{N}_c$.

Let f be as in the statement. By (R2) of Proposition C.23 there is $y_0 \in e_c \mathbf{N}[1/\lambda_\infty]$ with $\Pi y_0 \in U$ such that $\ell^{\sigma_B} f$ is a coordinate vector of y_0. Put $y = (\ell - 1)^{-1} \sum_{\delta \in \mu_{\ell-1}} \gamma_\delta(y_0)$. Then y is Δ-invariant, $\Pi y \in U$ by (b), and, as f is Δ-invariant, (a) and (b) show that $\ell^{\sigma_B} f = (\ell - 1)^{-1} \sum_\delta \gamma_\delta(\ell^{\sigma_B} f)$ is a coordinate vector of y.

The γ-condition for u_0. As f is Hodge-integral modulo γ, $(\gamma_{u_0} - 1) f = X^{\ell-1} h$ with $h \in \mathcal{H}_{\mathbf{n}}$, i.e. $\Pi h_k \in e_c \mathbf{A}_{F,L}$ for all k and $\ell^\kappa h$ is Hodge-graded for some κ. By (R1) of Proposition C.23

there is $x_h \in \mathbf{N}_c$ such that $\ell^{\sigma_B} h$ is a coordinate vector of x_h. By (a) and (b), $(\gamma_{u_0}-1)(\ell^{\sigma_B} f) = \ell^{\sigma_B} X^{\ell-1} h$ is a coordinate vector of $(\gamma_{u_0}-1)y$ and of $X^{\ell-1}x_h$, so 0 is a coordinate vector of $D = (\gamma_{u_0}-1)y - X^{\ell-1}x_h$. Moreover $\Pi D \in U$: $\Pi(\gamma_{u_0}-1)y \in U$ by (b), and $\Pi x_h \in U$ because $\Pi \mathbf{N}_c \subseteq U$ (Lemma C.16 (1)). By (c), $D \in X\mathbf{N}_c$, hence $(\gamma_{u_0}-1)y \in X\mathbf{N}$. Also $(\gamma_\delta - 1)y = 0$ for $\delta \in \mu_{\ell-1}$.

All u. Let S be the set of $u \in \mathbb{Z}_\ell^\times$ with $(\gamma_u - 1)y \in X\mathbf{N}$. Then S is a closed subgroup of $\mathbb{Z}_\ell^\times$: it is a subgroup because γ_u preserves $X\mathbf{N}$; it is closed because, writing $y = x/f'$ with $x \in \mathbf{N}$ and f' a product of the Q_s, $f'(\gamma_w - 1)y \to 0$ in $\mathbf{N}$ as $w \to 1$ (Lemma 23.29 (Gc3)) and $f'X\mathbf{N}$ is closed in $\mathbf{N}$. The set S contains $\mu_{\ell-1}$ and u_0, and u_0 generates a dense subgroup of $1 + \ell\mathbb{Z}_\ell$ ($v_\ell(u_0 - 1) = 1$, ℓ odd); so $S = \mathbb{Z}_\ell^\times = \mu_{\ell-1} \times (1 + \ell\mathbb{Z}_\ell)$. Thus y has all asserted properties. □

Proposition C.23. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; let $\nu \in \{1, 2\}$ and put $\mathbf{N} = \mathbf{N}(T_\nu)$ and $r = \dim_L V_\nu$ (Hodge-graded vectors formed with $D_{\mathrm{cris}}(V_\nu)$). Let $c \in C$, $e = \mathrm{len}_c$, and let $\mathbf{n}$ be a frame at c' of $\mathbf{N}$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$. Let $f \in \mathcal{K}_c^r$ with $\Pi_c f_k \in e_c \mathbf{A}_{F,L}$ for every k.*

(R1) Lattice vectors *If $\ell^\kappa f$ is Hodge-graded (for $\mathbf{n}$ and e) for some $\kappa \geq 0$, there is $x \in \mathbf{N}_c$ such that $\ell^{\sigma_B} f$ is an arc coordinate vector of x for $\mathbf{n}$, e, H_c and m_X.*

(R2) Pull-back vectors *There is $y \in e_c\mathbf{N}[1/\lambda_\infty]$ with $\Pi_c y \in P_e(\mathbf{N}_{c'})$ such that $\ell^{\sigma_B} f$ is an arc coordinate vector of y for $\mathbf{n}$, e, H_c and m_X.*

(R3) Sub-arcs *Let $1 \leq e_1 \leq e$, $a = c' + e_1$ and $\Pi' = \Lambda_{a,e_1}(H_c)$. Then (R1) and (R2) hold with (c, e, Π_c) replaced by (a, e_1, Π'): for $f \in \mathcal{K}_a^r$ with $\Pi' f_k \in e_a \mathbf{A}_{F,L}$ for every k there is $y \in e_a\mathbf{N}[1/\lambda_\infty]$ with $\Pi' y \in P_{e_1}(\mathbf{N}_{c'})$ such that $\ell^{\sigma_B} f$ is an arc coordinate vector of y for $\mathbf{n}$, e_1, H_c and m_X; and if $\ell^\kappa f$ is Hodge-graded (for $\mathbf{n}$ and e_1) for some $\kappa \geq 0$, then $y \in \mathbf{N}_a$.*

Proof. Write $\Pi = \Pi_c$, $R_c = e_c\mathbf{A}_{F,L}$, $U = P_e(\mathbf{N}_{c'})$, $m = m_X$, $E = 2(w + S)$ and $s(i) = s_\ell(i)$ as in Lemma 23.9; *coordinate vector* means arc coordinate vector for $\mathbf{n}$, e, H_c, m_X. We have $e \geq 1$ (Proposition C.4). Let $H_k = \sum_j h_{kj} n_j$, $h_{kj} = \sum_{i \geq 0} h_{kj,i} X^i \in e_{c'} E[[X]]$, be the horizontal sections through the frame.

Step 1: an admissible exponent. Extend $\mathbf{n}$ by frames at the other sites to an $\mathbf{A}_{F,L}$-basis of $\mathbf{N}$; the horizontal section through n_k lies in $e_{c'}\mathbf{N}_E$ (uniqueness in (Hf2) of Lemma 23.9, as $e_{c'}$ commutes with every γ_u). By (Hf3) of Lemma 23.9, $\ell^{s(i)} h_{kj,i} \in e_{c'}(\mathcal{O}_F \otimes \mathcal{O}_L)$ for all k, j, i. As s_ℓ is nondecreasing, $\kappa := s(m-1)$ is admissible and $\kappa \geq s(i)$ for $i < m$.

Step 2: the scalar divisibility. By definition $\sigma_B \geq (E + m/(\ell-1))\ell/(\ell-1)^2$, so Lemma C.15 (with $\sigma = \sigma_B$) gives, for $0 \leq i < m$, elements $a_i, b_i \in \mathbb{Z}_\ell[[X]]$ with

$$\ell^{\sigma_B} \varphi^e(X)^i = \ell^{s(i)} a_i + D\, b_i, \qquad D = (X\lambda_{e-1})^m Q_{e-1}^E.$$

Moreover $D \in X\Pi^2\, \mathbb{Z}_\ell[[X]]$: $\Pi^2 = \prod_{s<e} Q_s^{2H_c(c-s)}$; for $s = e-1$ we have $c - s = c' + 1$ and $2H_c(c'+1) = E$; for $s < e-1$ the factor Q_s^m of λ_{e-1}^m suffices, since $m = (\ell-1)(\lfloor 2h_B/(\ell-1)\rfloor + 1) > 2h_B \geq 2H_c(c-s)$; and X divides X^m.

Step 3: (R2). Let f be as in the statement. Put

$$z_k = \sum_j \sum_{i<m} \varphi^e\big(\ell^{s(i)} h_{kj,i}\big)\, a_i\, \varphi^e(n_j) \in U, \qquad u_k = \sum_j \sum_{i<m} \ell^{\kappa - s(i)} \varphi^e\big(\ell^{s(i)} h_{kj,i}\big)\, b_i\, \varphi^e(n_j) \in U,$$

using $\varphi^e(e_{c'}(\mathcal{O}_F\otimes\mathcal{O}_L))\subseteq \mathbf{A}_{F,L}$. Since $\Pi f_k\in R_c$ and Π is a product of the Q_s, $f_k\in R_c[1/Q_s : s\ge 0]$, so $y:=\sum_k f_k z_k\in e_c\mathbf{N}[1/\lambda_\infty]$, and $\Pi y=\sum_k(\Pi f_k)z_k\in U$. As $\varphi_{\mathbf{N}}$ is φ-semilinear,

$$\ell^{\sigma_B}\varphi^e\big(T_\kappa(H_k)\big)=\sum_j\sum_{i<m}\ell^{\kappa-s(i)}\varphi^e\big(\ell^{s(i)}h_{kj,i}\big)\,\ell^{\sigma_B}\varphi^e(X)^i\,\varphi^e(n_j)=\ell^\kappa z_k+D\,u_k.$$

Multiplying by Πf_k and summing over k,

$$\ell^\kappa\Pi y-\sum_k\Pi(\ell^{\sigma_B}f_k)\varphi^e(T_\kappa(H_k))=-D\sum_k(\Pi f_k)u_k\in X\Pi^2U,$$

by Step 2. Together with $\Pi(\ell^{\sigma_B}f_k)\in R_c$, this says that $\ell^{\sigma_B}f$ is a coordinate vector of y (with κ and $\kappa'=0$).

Step 4: (R1). Let $\ell^{\kappa_0}f$ be Hodge-graded and let y be as in Step 3. Multiplying the functions g_i of a section decomposition of $\ell^{\kappa_0}f$ by ℓ^{σ_B} gives a section decomposition of $\ell^{\kappa_0}(\ell^{\sigma_B}f)$ with the same $\mathbf{v}_i$ and α_i, so $\ell^{\kappa_0}(\ell^{\sigma_B}f)$ is Hodge-graded. By the membership criterion Proposition C.24 (with $t=0$ and the coordinate vector $\ell^{\sigma_B}f$ of y), $y\in\mathbf{N}_c$. So $x=y$ has the asserted property.

Step 5: (R3). Let e_1, a, Π' and f be as in (R3). Steps 1–4 go through with (c,e,Π) replaced by (a,e_1,Π'). Step 1 does not involve e. In Step 2 take $D=(X\lambda_{e_1-1})^mQ^E_{e_1-1}$ (Lemma C.15 holds for every $e_1\ge 1$); then $D\in X\Pi'^2\mathbb{Z}_\ell[[X]]$, since $\Pi'^2=\prod_{s<e_1}Q_s^{2H_c(a-s)}$, for $s=e_1-1$ the site $a-s$ is $c'+1$ with $2H_c(c'+1)=E$, and for $s<e_1-1$ the factor Q_s^m suffices as $m>2h_B\ge 2H_c(a-s)$. Step 3 is unchanged with φ^{e_1} and $U'=P_{e_1}(\mathbf{N}_{c'})$ (it gives $y=\sum_k f_kz_k\in e_a\mathbf{N}[1/\lambda_\infty]$ with $\Pi'y\in U'$), and Step 4 uses the sub-arc clause of Proposition C.24, which gives $y\in\mathbf{N}_a$. □

Proposition C.24. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1\to V_2$ ($T_1\to T_2$) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.25; let $\nu\in\{1,2\}$ and put $\mathbf{N}=\mathbf{N}(T_\nu)$. Let $c\in C$, $e=\mathrm{len}_c$, and let $\mathbf{n}$ be a frame at c' of $\mathbf{N}$, with crystalline frames formed in $D_{\mathrm{cris}}(V_\nu)$, with $\gamma_u(n_k)=n_k$ for $u\in\mu_{\ell-1}\subset\mathbb{Z}_\ell^\times$. Let $y\in e_c\mathbf{N}[1/\lambda_\infty]$ with $\Pi_c y\in P_e(\mathbf{N}_{c'})$, let $t\ge 0$, and let f be an arc coordinate vector of $\ell^t y$ for $\mathbf{n}$, e, H_c and m_X. If $\ell^\kappa f$ is Hodge-graded (for $\mathbf{n}$ and e) for some $\kappa\ge 0$, then $y\in\mathbf{N}_c$.*

Sub-arcs. *The same holds for the initial sub-arcs of the arc: let $1\le e_1\le e$, $a=c'+e_1$ and $\Pi'=\Lambda_{a,e_1}(H_c)$. If $y\in e_a\mathbf{N}[1/\lambda_\infty]$ with $\Pi' y\in P_{e_1}(\mathbf{N}_{c'})$, $t\ge 0$, f is an arc coordinate vector of $\ell^t y$ for $\mathbf{n}$, e_1, H_c and m_X, and $\ell^\kappa f$ is Hodge-graded (for $\mathbf{n}$ and e_1) for some $\kappa\ge 0$, then $y\in\mathbf{N}_a$.*

Proof. Write $c'=c-e$ (the site of the frame), $\Pi=\Pi_c=\Lambda_{c,e}(H_c)$, $m=m_X$, $D=D_{\mathrm{cris}}(V_\nu)$, $B=B^+_{\mathrm{dR}}$, and $h_s=H_c(c-s)$ for $s<e$; *coordinate vector* means arc coordinate vector for $\mathbf{n}$, e, H_c, m. We have $e\ge 1$ (Proposition C.4).

Step 1: $y\in\mathbf{N}_c[1/\lambda_e]$. Since $\varphi_{\mathbf{N}}$ maps $\mathbf{N}$ into $\mathbf{N}[1/Q]$ and $\varphi(Q_{s'})=Q_{s'+1}$, $\varphi^e_{\mathbf{N}}(\mathbf{N}_{c'})\subseteq\mathbf{N}[1/\lambda_e]$, so $P_e(\mathbf{N}_{c'})\subseteq\mathbf{N}[1/\lambda_e]$. As Π is a product of the Q_s with $s<e$, it is a unit of $\mathbf{A}_{F,L}[1/\lambda_e]$, and $y=\Pi^{-1}(\Pi y)\in\mathbf{N}[1/\lambda_e]$ (inside $\mathbf{N}[1/\lambda_\infty]$; $\mathbf{N}$ is free by (Wm1)); with $y=e_cy$, $y\in\mathbf{N}_c[1/\lambda_e]$.

Step 2: two inequalities. (a) $m\ge 2h_s$ for $s<e$: $m=(\ell-1)M>2h_B$, and $H_c\le h_B$ because $w+S\le h_B$ (if some site is thick, $h_B=b+\eta+S$ and $w\le b/20$). (b) Every Hodge jump u of V_ν at τ_x, $x=c-s$, $s<e$, satisfies $u\ge -H_c(x)$. By Lemma 24.2 (1) it suffices to take $\nu=1$. By (Ow1), $u\ge -s_x-S$ or $|u|\le\eta$. Recall $\eta<s_a$ for all a and that some site is thin, so $\eta<w\le h_B$. If $x=c'+1$, then x is thin because $c'\in C$, so $s_x\le w$ and $u\ge -(w+S)=-H_c(x)$. If $x\ne c'+1$: a thin x has $s_x+S\le w+S\le h_B$, and a thick x has $s_x+S\le b+\eta+S=h_B$ (thick sites exist then); so $u\ge -h_B=-H_c(x)$. Consequently, with $\epsilon=\epsilon_{c-s-1}$: by Definition 23.3 the filtration $\epsilon\,\mathrm{Fil}^\bullet D$ of ϵD is the Hodge filtration of V_ν at τ_{c-s}; it is decreasing and exhaustive and has no jump below $-h_s$, so $\epsilon\,\mathrm{Fil}^{-h_s}D=\epsilon D$.

Step 3: the level images of y. Fix $s < e$ and apply Lemma 23.6 with c', e, $a = c$, s, the frame $\mathbf{n}$ at c' and $(V,T) = (V_\nu, T_\nu)$; let λ_s, Λ_s, $R^+ = \epsilon(B \otimes_{\mathbb{Q}_\ell} L)$, $D_k = \varphi^{e-s-4}(d_k)$ and $\Lambda_D = \sum_k R^+ D_k$ be as there. We show $\Lambda_s(y) \in \epsilon(B \otimes_{\mathbb{Q}_\ell} V_\nu)$. *(i)* $\xi_0^{h_s}\Lambda_D \subseteq \epsilon(B \otimes V_\nu)$. By (Lm5) and Step 2, $D_k \in \epsilon D = \epsilon\,\mathrm{Fil}^{-h_s} D \subseteq t^{-h_s} B \otimes V_\nu$ (definition of Fil in Definition 23.3); as $t \in \xi_0 B^\times$, $\xi_0^{h_s} D_k \in \epsilon(B \otimes V_\nu)$, a module over R^+. *(ii) The coordinate relation.* By hypothesis there are an admissible κ, an integer $\kappa' \geq 0$ and $p \in P_e(\mathbf{N}_{c'})$ with

$$\ell^{\kappa'}\Big(\ell^{\kappa+t}\Pi y - \sum_k \Pi f_k\, \varphi^e(T_\kappa(H_k))\Big) = X\Pi^2 p.$$

By (Lm1), $\lambda_s(\Pi) = \prod_{s'<e} \lambda_s(Q_{s'})^{h_{s'}} = \xi_0^{h_s} w$ with $w \in B^\times$, and $\lambda_s(X) \in B^\times$; as $\Pi f_k \in e_c \mathbf{A}_{F,L}$, $\lambda_s(\Pi f_k) \in R^+$, so $\lambda_s(f_k) \in \xi_0^{-h_s} R^+$. By (Lm5), $\Lambda_s(\varphi^e(T_\kappa H_k)) = \ell^\kappa D_k + \xi_0^m \delta_k$ with $\delta_k \in \Lambda_D$, and $\Lambda_s(p) \in \Lambda_D$. Applying the λ_s-semilinear map Λ_s and dividing by $\ell^{\kappa+\kappa'+t}\lambda_s(\Pi)$ (invertible in $B_{\mathrm{dR}} \otimes L$),

$$\Lambda_s(y) = \ell^{-t} \sum_k \lambda_s(f_k) D_k + \ell^{-\kappa-t} \sum_k \lambda_s(f_k)\, \xi_0^m \delta_k + \ell^{-\kappa-\kappa'-t} \lambda_s(X)\lambda_s(\Pi)\Lambda_s(p).$$

The second term lies in $\xi_0^{m-h_s}\Lambda_D \subseteq \xi_0^{h_s}\Lambda_D$ (Step 2 (a)), the third in $\xi_0^{h_s}\Lambda_D$; both lie in $\epsilon(B \otimes V_\nu)$ by (i) (ℓ is a unit of B). *(iii) The Hodge-graded term.* Let $(g_i, \mathbf{v}_i, \alpha_i)_{i\in I}$ be a section decomposition of $\ell^{\kappa_0} f$ with $\delta_e(\mathbf{v}_i) \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha_i(s)} D)$ for all i (the given $\kappa \geq 0$ with $\ell^\kappa f$ Hodge-graded is called κ_0 here). Then $\ell^{\kappa_0}\sum_k \lambda_s(f_k) D_k = \sum_i \lambda_s(g_i) \sum_k v_{i,k} D_k$. The Frobenius of D is $\varphi \otimes 1$ on $B_{\mathrm{cris}} \otimes V_\nu$, hence L-linear and bijective on D, so $\sum_k v_{i,k} D_k = \varphi^{-(s+4)}(\sum_k v_{i,k}\varphi^e(d_k)) = \varphi^{-(s+4)}(\delta_e(\mathbf{v}_i)) \in \mathrm{Fil}^{-\alpha_i(s)} D \subseteq t^{-\alpha_i(s)} B \otimes V_\nu$. Write $g_i = Q^{\alpha_i} g_i'$ with $g_i' \in e_c \mathbf{A}_{F,L}$; by (Lm1), $\lambda_s(Q^{\alpha_i}) = \xi_0^{\alpha_i(s)} w_i$ with $w_i \in B^\times$ and $\lambda_s(g_i') \in R^+$. Hence $\lambda_s(g_i)\sum_k v_{i,k} D_k \in \xi_0^{\alpha_i(s)} t^{-\alpha_i(s)} R^+(B \otimes V_\nu) = \epsilon(B \otimes V_\nu)$, and the first term lies in $\epsilon(B \otimes V_\nu)$. So $\Lambda_s(y) \in \epsilon_{c-s-1}(B \otimes_{\mathbb{Q}_\ell} V_\nu)$ for every $s < e$.

Step 4: conclusion. By Step 1, $y \in \mathbf{N}_c[1/\lambda_e]$, and by Step 3 its images under all Λ_s, $s < e$, lie in $\epsilon_{c-s-1}(B \otimes V_\nu)$. The lattice criterion (Lm4) of Lemma 23.6 (with $a = c$) gives $y \in \mathbf{N}_c$.

Sub-arcs. Let e_1, a, Π', y, t, f, κ be as in the last assertion. Steps 1–4 go through with (c, e, Π) replaced by (a, e_1, Π'), for these reasons. Step 1 uses only that Π' is a product of the Q_s with $s < e_1$ and $P_{e_1}(\mathbf{N}_{c'}) \subseteq \mathbf{N}[1/\lambda_{e_1}]$. In Step 2, $h_s = H_c(a-s)$ for $s < e_1$, the sites $a - s$ ($s < e_1$) are $c'+1, \ldots, a$, and both (a) and (b) were proved for every site x with $H_c(x)$ in place of h_s (the site $c'+1$ being thin, the others bounded by h_B). Step 3 applies Lemma 23.6 with c', e_1, a and $s < e_1$, and uses $\lambda_s(\Pi') = \xi_0^{h_s} w$ with $w \in B^\times$ by (Lm1), the coordinate relation for e_1, and the section decomposition of $\ell^\kappa f$ for e_1. Step 4 applies (Lm4) with a and e_1. Hence $y \in \mathbf{N}_a$. □

C.1.3 Lifting graded sections along arcs of length one and two

Proposition C.25 lifts one graded section along an arc, according to the shape of the arc; it is used in Proposition C.10. This subsection states it and proves the cases of arcs of length one (Proposition C.26) and two (Proposition C.32). The shared tools are a lift of sections that are constant to high order at every site of the arc (Proposition C.27), a lift of sections with poles of the Hodge size at the up sites and zeros at the down sites (Lemma C.30), and lifts of filtered constants by window separation or by a Hodge gap (Lemma C.33, Lemma C.35). The lemma on the Δ-invariant variable (Lemma C.34) is used again in Section C.2.

Proposition C.25. *Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, L as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline*

lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Suppose that some site is thin, that $\epsilon_{a+1} \neq \epsilon_a$ for every a, that no three consecutive sites are all thick, that $20w \le b$, $20\eta \le b$, $20S \le b$, and that either no site is thick or $160\,\mathrm{Sg} \le b$. Put $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$, let $h_B = b + \eta + S$ if some site is thick and $h_B = w + S$ otherwise, $M = \lfloor 2h_B/(\ell-1) \rfloor + 1$ and $m_X = (\ell-1)M$. For $c \in C$ write $e = \mathrm{len}_c$, $c' = c - e$, let $H_c \colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$ be $H_c(c'+1) = w + S$ and $H_c(x) = h_B$ for $x \neq c'+1$, put $\Pi_c = \Lambda_{c,e}(H_c)$, and

$$\nu_c = \prod_{s<e,\ \epsilon_{c-s}=1} Q_s^{s_{c-s}} \ \in e_c \mathbf{A}_{F,L}.$$

Call $g \in \mathcal{K}_c$ admissible at c *if $\gamma_u(g) = g$ for $u \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$, $\nu_c g \in e_c \mathbf{A}_{F,L}$, and for every $s < e$ with $\epsilon_{c-s} = -1$ there are $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $\nu_c(\ell^\kappa g - e_c(1 \otimes x)) \in Q_s^{s_{c-s}+S} e_c \mathbf{A}_{F,L}$.*

Then there is an integer E_{arc} with $0 \le E_{\mathrm{arc}} \le 40\,\mathrm{Sg} + \eta\,\beta_{320}$ such that the following holds for every $c \in C$ (with e, c' as above). Let $\mathbf{n} = (n_k)_{k \le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \le r$ be an index with

$$\varphi^e(d_{k_0}) \in \varphi^{s+4}\big(\mathrm{Fil}^{\,s_{c-s}} D_{\mathrm{cris}}(V_2)\big) \qquad \text{for every } s < e \text{ with } \epsilon_{c-s} = 1,$$

and let g be admissible at c. Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \ge 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and the vector $\ell^{E_{\mathrm{arc}}} g\,\mathbf{e}_{k_0}$ ($\mathbf{e}_{k_0}$ the k_0-th unit vector) is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.

Proof. **Arc lengths.** Let $c \in C$; for $d \ge 1$, $c - d \in C$ means that the site $c - d + 1$ is thin, so $c - d \notin C$ means that it is thick (Ow3). If $\mathrm{len}_c \ge 4$, then $c-1, c-2, c-3 \notin C$ and the three consecutive sites $c, c-1, c-2$ are thick, which is excluded. Hence $\mathrm{len}_c \in \{1, 2, 3\}$. If $\mathrm{len}_c = 3$, the sites c and $c-1$ are thick, so some site is thick and $160\,\mathrm{Sg} \le b$ by hypothesis.

A common exponent. Let E_1, E_2 be the exponents of Proposition C.26 and Proposition C.32; if some cut has length 3, let E_3, E_4 be those of Proposition C.37 and Proposition C.39 (their extra hypothesis $160\,\mathrm{Sg} \le b$ holds by the previous paragraph), and otherwise $E_3 = E_4 = 0$. Put $E_{\mathrm{arc}} = \max(E_1, E_2, E_3, E_4)$; then $0 \le E_{\mathrm{arc}} \le 40\,\mathrm{Sg} + \eta\,\beta_{320}$.

The lifting. Let $c \in C$, $e = \mathrm{len}_c$, and $\mathbf{n}$, k_0, g as in the statement. According as $e = 1$, $e = 2$, $e = 3$ with $\epsilon_{c-2} = 1$, or $e = 3$ with $\epsilon_{c-2} = -1$, the result Proposition C.26, Proposition C.32, Proposition C.37 or Proposition C.39, with exponent E_i, gives $w_1 \in I_c$ (for $\mathbf{N}_1$), a finite product λ' of the Q_s and $z \in X\mathbf{N}_{2,c}$ with $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c \mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^{E_i} g\,\mathbf{e}_{k_0}$ an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$. Let $t = E_{\mathrm{arc}} - E_i \ge 0$. Multiplying the defining relation of arc coordinate vectors (Definition 23.3) by ℓ^t shows that $\ell^{E_{\mathrm{arc}}} g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\ell^t(\mathbf{N}(\Phi)(w_1) - z) = \mathbf{N}(\Phi)(\ell^t w_1) - \ell^t z$ (and $\Pi_c \ell^{E_{\mathrm{arc}}} g \in e_c \mathbf{A}_{F,L}$ as $\Pi_c \ell^{E_i} g$ is). Since I_c is an $\mathcal{O}_L$-module (Lemma 24.5 (Ry4)), $\ell^t w_1 \in I_c$; also $\lambda' \ell^t w_1 \in \mathbf{N}_1$, $\Pi_c \mathbf{N}(\Phi)(\ell^t w_1) \in P_e(\mathbf{N}_{2,c'})$ and $\ell^t z \in X\mathbf{N}_{2,c}$. So $\ell^t w_1$, λ', $\ell^t z$ have the asserted properties. □

Proposition C.26. *Let ℓ, F, n, L, (τ_a), $\Phi \colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25. Then there is an integer E with $0 \le E \le 40\,\mathrm{Sg} + \eta\,\beta_{320}$ such that the following holds for every $c \in C$ with $\mathrm{len}_c = 1$ (write $e = 1$). Let $\mathbf{n} = (n_k)_{k \le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \le r$ be an index with $\varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{\,s_{c-s}} D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and let g be admissible at c. Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \ge 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^E g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.*

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$ and *coordinate vector* for arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, $e = 1$, H_c, m_X.

Exponent. Let $E_C \le 6\,\mathrm{Sg}$ be the integer of Proposition C.27 and $E_N \le 6\,\mathrm{Sg}$ the integer of Lemma C.30, and put $E = \max(E_C, E_N)$; then $0 \le E \le 6\,\mathrm{Sg} \le 40\,\mathrm{Sg} + \eta\,\beta_{320}$.

Raising the exponent. If the conclusion holds for c with some $E' \le E$ in place of E (data w_1, λ', z), it holds with E: replace w_1, z by $\ell^{E-E'}w_1, \ell^{E-E'}z$; I_c is an $\mathcal{O}_L$-module ((Ry4) of Lemma 24.5), and $\ell^{E-E'}$ times a coordinate vector of y is one of $\ell^{E-E'}y$ (Lemma C.16 (a)).

Let $c \in C$ with $\mathrm{len}_c = 1$, so $c' = c - 1 \in C$ and the site $c = c' + 1$ is thin; let $\mathbf{n}$, k_0, g be as in the statement. As $e = 1$, the only $s < e$ is $s = 0$, with the site c.

Case $\epsilon_c = -1$. Then $\nu_c = 1$, so admissibility says: $\gamma_u(g) = g$ for $u \in \mu_{\ell-1}$, $g \in R_c$, and $\ell^\kappa g - e_c(1\otimes x) \in Q_0^{s_c+S}R_c$ for some $\kappa \ge 0$, $x \in \mathcal{O}_L$. These are the hypotheses of Proposition C.27 for c (with $t_0 = s_c + S$), which gives the conclusion with E_C.

Case $\epsilon_c = 1$. Then $\nu_c = Q_0^{s_c}$ and $\nu_c^+ = 1$ (no site of the arc has sign -1), so admissibility gives $\nu_c g \in \nu_c^+ R_c$; and the hypothesis on k_0 is the one of Lemma C.30. That lemma gives $w_1 \in I_c$ with $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_1(\mathbf{N}_{2,c'})$ such that $\ell^{E_N} g\,\mathbf{e}_{k_0}$ is a coordinate vector of $\mathbf{N}(\Phi)(w_1)$. With $\lambda' = 1$ (so $\lambda' w_1 = w_1 \in \mathbf{N}_1$) and $z = 0$ this is the conclusion with E_N, and raising the exponent gives it with E. □

Proposition C.27. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25. Then there is an integer E_C with $0 \le E_C \le 6\,\mathrm{Sg}$ such that the following holds for every $c \in C$ (with $e = \mathrm{len}_c$, $c' = c - e$). Let $\mathbf{n} = (n_k)_{k\le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, let $k_0 \le r$, and let $g \in e_c\mathbf{A}_{F,L}$ with $\gamma_u(g) = g$ for $u \in \mu_{\ell-1}$ such that for every $s < e$ there are $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with*

$$\ell^\kappa g - e_c(1\otimes x) \in Q_s^{t_s}\,e_c\mathbf{A}_{F,L}, \qquad t_s = s_{c-s} + S \text{ if } \epsilon_{c-s} = -1, \quad t_s = \eta \text{ if } \epsilon_{c-s} = 1.$$

Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \ge 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^{E_C} g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.

Filtered constants. *Let $c \in C$ (with $e = \mathrm{len}_c$, $c' = c - e$), let $\mathbf{n} = (n_k)_{k\le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, let $k_0 \le r$, let $\mathbf{n}^{(1)} = (n_m^{(1)})_{m\le r_1}$ ($r_1 = \dim_L V_1$) be a frame at c' of $\mathbf{N}_1$ with $\gamma_u(n_m^{(1)}) = n_m^{(1)}$ for $u \in \mu_{\ell-1}$, with crystalline frame $(d_m^{(1)})$, and let $\mu \in M_{r_1\times r}(\mathcal{O}_L)$ be the matrix of $\mathbf{N}(\Phi)$ for $\mathbf{n}^{(1)}$ and $\mathbf{n}$. Let U be a set of integers $s < e$ with $\epsilon_{c-s} = 1$, put $\nu_U = \prod_{s\in U} Q_s^{s_{c-s}}$, and for $s < e$ put $t_s = s_{c-s} + S$ if $\epsilon_{c-s} = -1$ and $t_s = \eta$ if $\epsilon_{c-s} = 1$. Let $E' \ge 0$ be an integer and $\mathbf{c} = (c_m)_{m\le r_1} \in \mathcal{O}_L^{r_1}$ with*

$$\mathbf{c}\,\mu = \ell^{E'}\mathbf{e}_{k_0}, \qquad \sum_m c_m\,\varphi^e(d_m^{(1)}) \in \varphi^{s+4}\big(\mathrm{Fil}^{\,s_{c-s}} D_{\mathrm{cris}}(V_1)\big) \quad \text{for every } s \in U,$$

and let $g \in \mathcal{K}_c$ with $\gamma_u(g) = g$ for $u \in \mu_{\ell-1}$ and $\nu_U g \in e_c\mathbf{A}_{F,L}$, such that for every $s < e$ with $s \notin U$ there are $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $\nu_U(\ell^\kappa g - e_c(1\otimes x)) \in Q_s^{t_s}e_c\mathbf{A}_{F,L}$. (For U the set of all $s < e$ with $\epsilon_{c-s} = 1$ these conditions on g say that g is admissible at c.) Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$) and a finite product λ' of the Q_s ($s \ge 0$) such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^{\sigma_B+E'} g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1)$ for $\mathbf{n}$, e, H_c and m_X.

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$, $\Pi = \Pi_c$, $\psi = \mathbf{N}(\Phi)\colon \mathbf{N}_1 \to \mathbf{N}_2$, $r_1 = \dim_L V_1$, and fix u_0 as in Proposition C.11.

Exponents. Let $r_{c''}$ ($c'' \in \mathbb{Z}/n$) be the exponents of Proposition C.6 for the surjection $\Phi\colon T_1 \to T_2$ and the window (M_a, h_a) of Lemma C.9, which contains the Hodge jumps of V_1 by

Lemma C.9 (1); by Lemma C.9 (2), $r_{c''} \le 3\,\mathrm{Sg}$ for $c'' \in C$. Put $E_C = \sigma_B + \max_{c''\in C} r_{c''}$; then $0 \le E_C \le 6\,\mathrm{Sg}$, since $\sigma_B \le 3\,\mathrm{Sg}$.

It suffices to prove the conclusion at c with some $E' \le E_C$ in place of E_C: if $\ell^{E'} g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\psi(w_1) - z$, then $\ell^{E_C} g\,\mathbf{e}_{k_0}$ is one of $\psi(\ell^{E_C-E'} w_1) - \ell^{E_C-E'} z$ (Lemma C.16 (a)), and $\ell^{E_C-E'} w_1 \in I_c$ by (Ry4) of Lemma 24.5. We take $E' = \sigma_B + r_{c'}$.

Fix $c \in C$, $e = \mathrm{len}_c$, $c' = c - e \in C$, and $\mathbf{n}$, k_0, g as in the statement.

Step 1: a frame of $\mathbf{N}_1$ and lifted constants. $\mathbf{N}_1$ is a Wach module ((Ex1) of Proposition 23.7), so by Lemma 24.15 $\mathbf{N}_{1,c'}$ has a Δ-invariant frame $\mathbf{n}^1 = (n^1_m)_{m\le r_1}$; let (d^1_m) be its crystalline frame, in $D_{\mathrm{cris}}(V_1)$. Let $\mu \in M_{r_1\times r}(\mathcal{O}_L)$ be the matrix of Lemma C.29 (1) for $f = \Phi$ and the frames $\mathbf{n}^1$, $\mathbf{n}$ at c': $\mu_{mk} = M_{mk}(0)$, where $\psi(n^1_m) = \sum_k M_{mk} n_k$. By Proposition C.6 there is $x_1 \in \mathbf{N}_{1,c'}$ with $\psi(x_1) = \ell^{r_{c'}} n_{k_0}$. Write $x_1 = \sum_m a_m n^1_m$ and $\mathbf{c} = (a_m(0))_m \in \mathcal{O}_L^{r_1}$. Comparing coordinates, $\sum_m a_m M_{mk} = \ell^{r_{c'}}\delta_{kk_0}$, and taking constant terms (a ring homomorphism $e_{c'}\mathbf{A}_{F,L} \to \mathcal{O}_L$),

$$\textstyle\sum_m \mathbf{c}_m \mu_{mk} = \ell^{r_{c'}}\delta_{kk_0} \qquad (k \le r).$$

Step 2: the coordinate vector in $\mathbf{N}_1$ is Hodge-integral modulo γ. Put $f^1 = (g\,\mathbf{c}_m)_{m\le r_1} \in \mathcal{K}_c^{r_1}$. It is Δ-invariant, and $\Pi f^1_m \in R_c$ as $g \in R_c$. By Lemma C.28 (with $K_s = t_s$), $(\gamma_{u_0} - 1)g = X^{\ell-1}h_0$ with $h_0 \in R_c$ and $\ell^\kappa h_0 \in \prod_{s<e} Q_s^{t_s} R_c$. So $(\gamma_{u_0} - 1)f^1 = X^{\ell-1}h$ with $h = (h_0\mathbf{c}_m)_m$, $\Pi h_m \in R_c$, and $\ell^\kappa h$ has the one-term section decomposition $(\ell^\kappa h_0, \mathbf{c}, \alpha)$ with $\alpha(s) = t_s \ge 0$. It is Hodge-graded: $\delta_e(\mathbf{c})$ lies in $\varepsilon_{c+3}D_{\mathrm{cris}}(V_1) = \varphi^{s+4}(\varepsilon_{c-s-1}D_{\mathrm{cris}}(V_1))$, and $\varepsilon_{c-s-1}\mathrm{Fil}^{-t_s}D_{\mathrm{cris}}(V_1) = \varepsilon_{c-s-1}D_{\mathrm{cris}}(V_1)$, because every Hodge jump of V_1 at τ_{c-s} is $\ge -t_s$ by (Ow1) of Definition 23.1 (in $[-s_{c-s} - S, -s_{c-s}] \cup [-\eta, \eta]$ if $\epsilon_{c-s} = -1$, in $[s_{c-s}, s_{c-s} + S] \cup [-\eta, \eta]$ if $\epsilon_{c-s} = 1$; $\varepsilon_{c-s-1}D_{\mathrm{cris}}$ is the τ_{c-s}-component, remark in Definition 23.3). Hence $h \in \mathcal{H}_{\mathbf{n}^1}$ and f^1 is Hodge-integral modulo γ (for $\mathbf{n}^1$).

Step 3: realisation in $\mathbf{N}_1$. By Proposition C.22 with $\nu = 1$ there is a Δ-invariant $y \in e_c\mathbf{N}_1[1/\lambda_\infty]$ with $(\gamma_u - 1)(y) \in X\mathbf{N}_1$ for all u (so $y \in I_c$, formed for $\mathbf{N}_1$) and $\Pi y \in P_e(\mathbf{N}_{1,c'})$, such that $\ell^{\sigma_B} f^1$ is an arc coordinate vector of y for $\mathbf{n}^1$, e, H_c, m_X. By definition of $\mathbf{N}_1[1/\lambda_\infty]$ there is a finite product λ' of the Q_s with $\lambda' y \in \mathbf{N}_1$.

Step 4: transport to $\mathbf{N}_2$. By Lemma C.29 (2) (with $a = c$, $H = H_c$, $m = m_X \ge 1$, and $m_X > 2h_B \ge 2H_c(c - s)$), $\Pi\psi(y) = \psi(\Pi y) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^{\sigma_B} f^1\mu$ is an arc coordinate vector of $\psi(y)$ for $\mathbf{n}$, e, H_c, m_X. By Step 1, $(\ell^{\sigma_B} f^1\mu)_k = \ell^{\sigma_B} g \sum_m \mathbf{c}_m\mu_{mk} = \ell^{\sigma_B + r_{c'}} g\,\delta_{kk_0}$, i.e. $\ell^{\sigma_B} f^1\mu = \ell^{\sigma_B + r_{c'}} g\,\mathbf{e}_{k_0}$. So $w_1 = y$, λ' and $z = 0$ have the asserted properties with the exponent $\sigma_B + r_{c'}$.

Filtered constants. Let c, $\mathbf{n}$, k_0, $\mathbf{n}^{(1)}$, μ, E', $\mathbf{c}$, g be as in that paragraph of the statement; write $\nu = \nu_U$, t_s as in the statement, and $T = \prod_{s<e,\ s\notin U} Q_s^{t_s}$. By hypothesis, $\gamma_\delta(g) = g$ for $\delta \in \mu_{\ell-1}$, $\nu g \in R_c$, and for each $s < e$ with $s \notin U$ there are $\kappa_s \ge 0$, $x_s \in \mathcal{O}_L$ and $p_s \in R_c$ with $\nu(\ell^{\kappa_s} g - x_s) = Q_s^{t_s} p_s$; let $\kappa = \max_s \kappa_s$ ($\kappa = 0$ if there is no such s).

Step F1: the γ-difference of g. Put $G = (\gamma_{u_0} - 1)(g) \in \mathcal{K}_c$. As $\mathbb{Z}_\ell^\times$ is abelian, $\gamma_\delta(G) = G$ for $\delta \in \mu_{\ell-1}$. For $u \in \mathbb{Z}_\ell^\times$ and $s \ge 0$, $\gamma_u(Q_s) = Q_s \upsilon_{u,s}$ with $\upsilon_{u,s} \in \mathbb{Z}_\ell[[X]]^\times$ (Lemma C.16 (b)); hence $\gamma_u(\nu) = \nu\upsilon_u$ with $\upsilon_u \in R_c^\times$, and $\nu G = \upsilon_{u_0}^{-1}\gamma_{u_0}(\nu g) - \nu g \in R_c$. Since $Q_s(0) = \ell \ne 0$, ν is a unit of $L[[X]]$, so $g = (\nu g)\nu^{-1}$ and G lie in $L[[X]]$, on which γ_u acts by the same substitution $X \mapsto (1+X)^u - 1$. The constant term of G is $g(0) - g(0) = 0$. If $G \ne 0$, let $a_i X^i$ ($a_i \ne 0$, $i \ge 1$) be its term of least degree and δ a generator of $\mu_{\ell-1}$; the coefficient of X^i in $\gamma_\delta(G)$ is $\delta^i a_i$, so $\delta^i = 1$ and $(\ell - 1) \mid i$. Hence $\nu G \in R_c \cap X^{\ell-1}L[[X]] = X^{\ell-1}R_c$; write $\nu G = X^{\ell-1}k$ with $k \in R_c$. For $s < e$ with $s \notin U$,

$$\ell^{\kappa_s}\nu G = \nu(\gamma_{u_0} - 1)(\nu^{-1}Q_s^{t_s}p_s) = Q_s^{t_s}(\upsilon_{u_0}^{-1}\upsilon_{u_0,s}^{t_s}\gamma_{u_0}(p_s) - p_s) \in Q_s^{t_s}R_c.$$

$R_c \cong \mathcal{O}_L[[X]]$ is a unique factorisation domain, and X and the Q_s ($s \ge 0$) are pairwise coprime in it: $Q_s = \Phi_{\ell^{s+1}}(1 + X)$ is a distinguished polynomial whose roots $\zeta - 1$ (ζ of exact order ℓ^{s+1})

are simple, so by Weierstrass preparation its prime factors in R_c are those of Q_s in $\mathcal{O}_L[X]$, and different s (and X) have no common root. Hence $\ell^\kappa \nu G \in X^{\ell-1} T R_c$ and, cancelling $X^{\ell-1}$ in the domain R_c, $\ell^\kappa k \in T R_c$. Put $h_0 = k/\nu$, so that $(\gamma_{u_0} - 1)(g) = X^{\ell-1} h_0$.

Step F2: Hodge-integral modulo γ. Put $f^1 = (g\, c_m)_{m \le r_1} \in \mathcal{K}_c^{r_1}$; it is Δ-invariant. We have $\Pi/\nu \in R_c$, i.e. $H_c(c-s) \ge s_{c-s}$ for $s \in U$: for $s = e-1$ the site $c'+1$ is thin ($c' \in C$), so $s_{c'+1} \le w \le H_c(c'+1)$; otherwise $H_c(c-s) = h_B$, and $s_{c-s} \le w \le h_B$ (thin site) or $s_{c-s} \le b + \eta \le h_B$ (thick site; then $h_B = b + \eta + S$). Hence $\Pi f^1_m = (\Pi/\nu)(\nu g) c_m \in R_c$. Next, $(\gamma_{u_0} - 1) f^1 = X^{\ell-1} h$ with $h = (h_0 c_m)_m$, $\Pi h_m = (\Pi/\nu) k\, c_m \in R_c$, and $\ell^\kappa h$ has the one-term section decomposition $(\ell^\kappa h_0, \mathbf{c}, \alpha)$ with $\alpha(s) = -s_{c-s}$ if $s \in U$ and $\alpha(s) = t_s$ if $s \notin U$, since $\ell^\kappa h_0 = \ell^\kappa k/\nu \in (T/\nu) R_c = Q^\alpha R_c$. It is Hodge-graded for $\mathbf{n}^{(1)}$: at the levels $s \in U$ this is the hypothesis on $\mathbf{c}$; at a level $s \notin U$, $\varphi^{-(s+4)}(\sum_m c_m \varphi^e(d_m^{(1)}))$ lies in the τ_{c-s}-component $\varepsilon_{c-s-1} D_{\mathrm{cris}}(V_1)$ (remark in Definition 23.3), which equals $\varepsilon_{c-s-1} \mathrm{Fil}^{-t_s} D_{\mathrm{cris}}(V_1)$ because every Hodge jump of V_1 at τ_{c-s} is $\ge -t_s$: by (Ow1) it lies in $[s_{c-s}, s_{c-s}+S] \cup [-\eta, \eta]$ if $\epsilon_{c-s} = 1$ and in $[-s_{c-s} - S, -s_{c-s}] \cup [-\eta, \eta]$ if $\epsilon_{c-s} = -1$, and $\eta < s_{c-s}$. So $h \in \mathcal{H}_{\mathbf{n}^{(1)}}$, and f^1 is Hodge-integral modulo γ (for $\mathbf{n}^{(1)}$).

Step F3: realisation and transport. By Proposition C.22 with $\nu = 1$ and the Δ-invariant frame $\mathbf{n}^{(1)}$ there is $y \in e_c \mathbf{N}_1[1/\lambda_\infty]$ with $(\gamma_u - 1)(y) \in X \mathbf{N}_1$ for all $u \in \mathbb{Z}_\ell^\times$ (so $y \in I_c$, formed for $\mathbf{N}_1$) and $\Pi y \in P_e(\mathbf{N}_{1,c'})$, such that $\ell^{\sigma_B} f^1$ is an arc coordinate vector of y for $\mathbf{n}^{(1)}$, e, H_c, m_X; let λ' be a finite product of the Q_s with $\lambda' y \in \mathbf{N}_1$. By Lemma C.29 (2) (with $m_X > 2h_B \ge 2H_c(c-s)$), $\Pi\psi(y) = \psi(\Pi y) \in P_e(\mathbf{N}_{2,c'})$ and $\ell^{\sigma_B} f^1 \mu$ is an arc coordinate vector of $\psi(y)$ for $\mathbf{n}$, e, H_c, m_X; its k-th entry is $\ell^{\sigma_B} g\, (\mathbf{c}\mu)_k = \ell^{\sigma_B + E'} g\, \delta_{kk_0}$. So $w_1 = y$ and λ' have the asserted properties. □

Lemma C.28. *Let ℓ be an odd prime, F, L, (τ_a) as in Definition 23.2, $c \in \mathbb{Z}/n$, $R = e_c \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $u_0 \in \mathbb{Z}_\ell^\times$, $e \ge 0$ and integers $K_0, \dots, K_{e-1} \ge 0$. Let $g \in R$ with $\gamma_\delta(g) = g$ for every $\delta \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$, such that for every $s < e$ there are $\kappa_s \ge 0$ and $x_s \in \mathcal{O}_L$ with $\ell^{\kappa_s} g - e_c(1 \otimes x_s) \in Q_s^{K_s} R$. Then $(\gamma_{u_0} - 1)(g) = X^{\ell-1} h_0$ with $h_0 \in R$, and $\ell^\kappa h_0 \in \prod_{s<e} Q_s^{K_s} R$ for $\kappa = \max_s \kappa_s$ ($\kappa = 0$ if $e = 0$).*

Proof. Write $G = (\gamma_{u_0} - 1)(g)$. The operators γ_u are $\mathcal{O}_L$-linear ring automorphisms of R with $\gamma_u(X) = h_u = (1+X)^u - 1 = uX + O(X^2)$, and $\gamma_{uv} = \gamma_u \gamma_v$; as $\mathbb{Z}_\ell^\times$ is abelian, $\gamma_\delta(G) = (\gamma_{u_0} - 1)(\gamma_\delta g) = G$ for $\delta \in \mu_{\ell-1}$.

Divisibility by $X^{\ell-1}$. The constant term of G is $g(0) - g(0) = 0$, as $h_{u_0}(0) = 0$. If $G \ne 0$, let $a_i X^i$ ($a_i \ne 0$, $i \ge 1$) be its term of least degree, and δ a generator of the cyclic group $\mu_{\ell-1}$. The coefficient of X^i in $\gamma_\delta(G) = G(h_\delta)$ is $\delta^i a_i$, so $\delta^i = 1$ ($\mathcal{O}_L$ is a domain), $(\ell - 1) \mid i$ and $i \ge \ell - 1$. Hence $G = X^{\ell-1} h_0$ with $h_0 \in R$.

Divisibility by $Q_s^{K_s}$. For $u \in \mathbb{Z}_\ell^\times$, $\gamma_u(Q_s) = Q_s \upsilon_{u,s}$ with a unit $\upsilon_{u,s}$ of $\mathbb{Z}_\ell[[X]]$ (Lemma C.16 (b), first assertion, a statement about $\mathbb{Z}_\ell[[X]]$ only). Write $\ell^{\kappa_s} g - x_s = Q_s^{K_s} q$ with $q \in R$ (x_s standing for $e_c(1 \otimes x_s)$, fixed by γ_{u_0}). Then

$$\ell^{\kappa_s} G = (\gamma_{u_0} - 1)(Q_s^{K_s} q) = Q_s^{K_s} (\upsilon_{u_0,s}^{K_s} \gamma_{u_0}(q) - q) \in Q_s^{K_s} R,$$

so $\ell^\kappa G \in Q_s^{K_s} R$ for every $s < e$.

Combination. $R \cong \mathcal{O}_L[[X]]$ is a regular local ring, hence a unique factorisation domain. $Q_s = \Phi_{\ell^{s+1}}(1+X)$ has the distinct simple roots $\zeta - 1$, ζ of exact order ℓ^{s+1}, so by Weierstrass preparation its prime factors in R are those of the distinguished polynomial Q_s, and they are prime to X and to the prime factors of $Q_{s'}$ for $s' \ne s$ (different roots, all in the maximal ideal of $\mathcal{O}_{\overline{L}}$). Hence for every prime element π of R, π divides at most one of $X^{\ell-1}, Q_0^{K_0}, \dots, Q_{e-1}^{K_{e-1}}$, and $v_\pi(\ell^\kappa G) \ge v_\pi(X^{\ell-1} \prod_s Q_s^{K_s})$. So $\ell^\kappa G \in X^{\ell-1} \prod_{s<e} Q_s^{K_s} R$, and cancelling $X^{\ell-1}$ in the domain R gives $\ell^\kappa h_0 \in \prod_{s<e} Q_s^{K_s} R$. □

Lemma C.29. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, let (V,T) and (V',T') be two pairs as there, of ranks $r=\dim_L V$ and $r'=\dim_L V'$, let $f\colon T\to T'$ be G_F-equivariant and $\mathcal{O}_L$-linear, and put $\mathbf{N}=\mathbf{N}(T)$, $\mathbf{N}'=\mathbf{N}(T')$, $\psi=\mathbf{N}(f)$. Fix $c\in\mathbb{Z}/n$, frames $\mathbf{n}=(n_k)_{k\le r}$ of $\mathbf{N}$ and $\mathbf{n}'=(n'_j)_{j\le r'}$ of $\mathbf{N}'$ at c, with horizontal sections H_k, H'_j and crystalline frames d_k, d'_j.*

1. *There is a unique matrix $\mu=(\mu_{kj})\in M_{r\times r'}(\mathcal{O}_L)$ with $\psi(H_k)=\sum_j \mu_{kj}H'_j$ for all k (ψ extended $E[[X]]$-linearly to $\mathbf{N}_E\to\mathbf{N}'_E$, and $\mathcal{O}_L$ acting through $e_c(1\otimes\mathcal{O}_L)$); μ_{kj} is the constant term of the n'_j-coordinate of $\psi(n_k)$, and $(1\otimes f)(d_k)=\sum_j\mu_{kj}d'_j$, where $1\otimes f\colon B_{\mathrm{cris}}\otimes_{\mathbb{Z}_\ell}T\to B_{\mathrm{cris}}\otimes_{\mathbb{Z}_\ell}T'$.*
2. *Let $e\ge 0$, $a=c+e$, $H\colon\mathbb{Z}/n\to\mathbb{Z}_{\ge 0}$, $\Pi=\Lambda_{a,e}(H)$ and $m\ge 1$ with $m\ge 2H(a-s)$ for $s<e$. Then $\psi(P_e(\mathbf{N}_c))\subseteq P_e(\mathbf{N}'_c)$, and if $g\in\mathcal{K}_a^r$ is an arc coordinate vector of $y\in\mathbf{N}[1/\lambda_\infty]$ for $\mathbf{n},e,H,m$, then $g\mu=\big(\sum_k g_k\mu_{kj}\big)_{j\le r'}$ is an arc coordinate vector of $\psi(y)$ for $\mathbf{n}',e,H,m$.*

Proof. By (Ex3) of Proposition 23.7, ψ is $\mathbf{A}_{F,L}$-linear and commutes with φ and every γ_u; so $\psi(\mathbf{N}_c)\subseteq\mathbf{N}'_c$, and its $E[[X]]$-linear extension to $\mathbf{N}_E$ (and its extension to $\mathbf{N}[1/\lambda_\infty]$) commutes with the operators $\gamma_u(h\otimes x)=(h\circ h_u)\otimes\gamma_u(x)$ (and with φ).

1. Write $\psi(n_k)=\sum_j M_{kj}n'_j$ with $M_{kj}\in e_c\mathbf{A}_{F,L}$. Extending $\mathbf{n}$, $\mathbf{n}'$ by frames at the other sites, (Hf2) of Lemma 23.9 shows that (H'_j) is an $e_cE[[X]]$-basis of $e_c\mathbf{N}'_E$, so $\psi(H_k)=\sum_j c_{kj}H'_j$ with unique $c_{kj}\in e_cE[[X]]$. As $\psi(H_k)$ and the H'_j are fixed by every γ_u, $c_{kj}\circ h_u=c_{kj}$ for every $u\in\mathbb{Z}_\ell^\times$. Take $u=1+\ell$, not a root of unity: if $c_{kj}=\sum_i a_iX^i$ had a nonzero coefficient a_i with $i\ge 1$, the least such i would give $a_iu^i=a_i$ as the coefficient of X^i (since $h_u=uX+O(X^2)$), which is impossible. So c_{kj} is a constant. Reducing modulo $X\mathbf{N}'_E$, where $H_k\equiv n_k$ and $H'_j\equiv n'_j$, gives $c_{kj}=M_{kj}(0)\in e_c(\mathcal{O}_F\otimes\mathcal{O}_L)\cong\mathcal{O}_L$; put $\mu_{kj}=c_{kj}$. For the crystalline frames: ψ maps $\mathbf{N}_R$ into $\mathbf{N}'_R$, and $\mathrm{Ev}'(\psi(W))=(1\otimes f)(\mathrm{Ev}(W))$ for $W\in\mathbf{N}_R$, because for $W=h\otimes x$ both sides equal $e(h)\cdot\varphi^3\big((\rho\otimes 1)((1\otimes f)\iota_T(x))\big)$ by (Ev3) of Lemma 23.11 and $\iota_{T'}\circ\psi=(1\otimes f)\circ\iota_T$ ((Ex3)), $1\otimes f$ being $B_{\mathrm{cris}}\otimes\mathcal{O}_L$-linear. As Ev' is linear over the constants (for $\lambda\in\mathcal{O}_L$, $e(e_c(1\otimes\lambda))$ acts as λ on $\mathrm{Ev}'(e_c\mathbf{N}'_R)$, by (Ev2)), $(1\otimes f)(d_k)=\mathrm{Ev}'(\sum_j\mu_{kj}H'_j)=\sum_j\mu_{kj}d'_j$.

2. $\psi(\varphi^e(x))=\varphi^e(\psi(x))$ and $\mathbf{A}_{F,L}$-linearity give $\psi(P_e(\mathbf{N}_c))\subseteq P_e(\mathbf{N}'_c)$. Let g be an arc coordinate vector of y with exponents (κ,κ'). Admissible exponents form an upward closed set, $T_{\kappa_1}=\ell^{\kappa_1-\kappa}T_\kappa$ for $\kappa_1\ge\kappa$, and the defining relation persists after multiplication by $\ell^{\kappa_1-\kappa}$; so we may assume κ admissible for both $\mathbf{n}$ and $\mathbf{n}'$. Applying ψ to the defining relation,

$$\ell^{\kappa'}\Big(\ell^{\kappa}\Pi\,\psi(y)-\sum_k \Pi g_k\,\varphi^e\big(\psi(T_\kappa(H_k))\big)\Big)\in X\Pi^2P_e(\mathbf{N}'_c).$$

Now $T_\kappa(H_k)-\ell^\kappa H_k\in X^m\mathbf{N}_E$ and $T_\kappa(H'_j)-\ell^\kappa H'_j\in X^m\mathbf{N}'_E$ by definition of the truncation, so by part 1

$$\delta_k:=\psi(T_\kappa(H_k))-\sum_j\mu_{kj}T_\kappa(H'_j)=\psi\big(T_\kappa(H_k)-\ell^\kappa H_k\big)-\sum_j\mu_{kj}\big(T_\kappa(H'_j)-\ell^\kappa H'_j\big)\in X^m\mathbf{N}'_E.$$

Also $\delta_k\in\mathbf{N}'_c$, since $T_\kappa(H_k)\in\mathbf{N}_c$, $T_\kappa(H'_j)\in\mathbf{N}'_c$ and μ_{kj} is integral; comparing coordinates in the basis $\mathbf{n}'$ (also an $e_cE[[X]]$-basis of $e_c\mathbf{N}'_E$), $\delta_k\in X^m\mathbf{N}'_c$. Hence $\varphi^e(\delta_k)\in\varphi^e(X)^mP_e(\mathbf{N}'_c)=(X\lambda_e)^mP_e(\mathbf{N}'_c)\subseteq X\Pi^2P_e(\mathbf{N}'_c)$, as $m\ge 1$ and $\lambda_e^m=\prod_{s<e}Q_s^m$ with $m\ge 2H(a-s)$. Since $\Pi g_k\in e_a\mathbf{A}_{F,L}$, substituting gives

$$\ell^{\kappa'}\Big(\ell^{\kappa}\Pi\,\psi(y)-\sum_j\Pi(g\mu)_j\,\varphi^e\big(T_\kappa(H'_j)\big)\Big)\in X\Pi^2P_e(\mathbf{N}'_c),$$

and $\Pi(g\mu)_j=\sum_k(\Pi g_k)\mu_{kj}\in e_a\mathbf{A}_{F,L}$. So $g\mu$ is an arc coordinate vector of $\psi(y)$. □

Lemma C.30. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25. Then there is an integer E_N with $0 \le E_N \le 6\,\mathrm{Sg}$ such that the following holds for every $c \in C$ (with $e = \mathrm{len}_c$, $c' = c - e$). Let $\mathbf{n} = (n_k)_{k \le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \le r$ be an index with $\varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}} D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and let $g \in \mathcal{K}_c$ with*

$$\nu_c\, g \in \nu_c^+\, e_c \mathbf{A}_{F,L}.$$

Then there is $w_1 \in \mathbf{N}_{1,c}$ with $w_1 \in I_c$ (formed for $\mathbf{N}_1$) and $\Pi_c\, \mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$ such that $\ell^{E_N} g\, \mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1)$ for $\mathbf{n}$, e, H_c and m_X.

Proof. Write $R_c = e_c \mathbf{A}_{F,L}$ and *coordinate vector* for arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, e, H_c, m_X.

The exponent. Let (M_a, h_a) be the window of Lemma C.9; it contains every Hodge jump of V_1 at τ_a (Lemma C.9 (1)). Let r_c ($c \in \mathbb{Z}/n$) be the exponents of Proposition C.6 for the surjection $\Phi\colon T_1 \to T_2$ and this window ($\ell \ge 11$); they depend only on the window and c, and $r_c \le 3\,\mathrm{Sg}$ for $c \in C$ by Lemma C.9 (2). Put $r^* = \max_{c \in C} r_c$. Also $\sigma_B \le 3\,\mathrm{Sg}$:

Put $E_N = r^* + \sigma_B$; then $0 \le E_N \le 6\,\mathrm{Sg}$.

The lift. Let c, $\mathbf{n}$, k_0, g be as in the statement. By definition of δ_e, $\delta_e(\mathbf{e}_{k_0}) = \varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}} D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and $\nu_c g \in \nu_c^+ R_c$. By Lemma C.31 (with $\mathbf{c} = \mathbf{e}_{k_0}$), $f = g\, \mathbf{e}_{k_0}$ satisfies $\Pi_c f_k \in R_c$ for all k and is Hodge-graded. By (R1) of Proposition C.23 there is $x_2 \in \mathbf{N}_{2,c}$ such that $\ell^{\sigma_B} f$ is a coordinate vector of x_2. By Proposition C.6 there is $x_1 \in \mathbf{N}_{1,c}$ with $\mathbf{N}(\Phi)(x_1) = \ell^{r_c} x_2$. Put $w_1 = \ell^{r^* - r_c} x_1 \in \mathbf{N}_{1,c}$, so $\mathbf{N}(\Phi)(w_1) = \ell^{r^*} x_2$. Then:

- $w_1 \in I_c$, since $(\gamma_u - 1)\mathbf{N}_1 \subseteq X\mathbf{N}_1$ by (Wm3) ($\mathbf{N}_1$ is a Wach module by (Ex1) of Proposition 23.7);
- $\Pi_c\, \mathbf{N}(\Phi)(w_1) = \ell^{r^*} \Pi_c x_2 \in \Pi_c \mathbf{N}_{2,c} \subseteq P_e(\mathbf{N}_{2,c'})$ by Lemma C.16 (1), $P_e(\mathbf{N}_{2,c'})$ being an $\mathcal{O}_L$-module;
- $\ell^{r^*} \cdot \ell^{\sigma_B} f = \ell^{E_N} g\, \mathbf{e}_{k_0}$ is a coordinate vector of $\ell^{r^*} x_2 = \mathbf{N}(\Phi)(w_1)$ by Lemma C.16 (a).

□

Lemma C.31. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N} = \mathbf{N}(T_2)$ and $r = \dim_L V_2$. Let $c \in C$, $e = \mathrm{len}_c$, let $\mathbf{n}$ be a frame at c' of $\mathbf{N}$ with crystalline frame (d_k), let $\mathbf{c} \in \mathcal{O}_L^r$ with*

$$\delta_e(\mathbf{c}) \in \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}} D_{\mathrm{cris}}(V_2)) \qquad \text{for every } s < e \text{ with } \epsilon_{c-s} = 1,$$

and let $g \in \mathcal{K}_c$ with $\nu_c g \in \nu_c^+\, e_c \mathbf{A}_{F,L}$. Then the vector $f = (g\, c_k)_{k \le r}$ (c_k acting as $e_c(1 \otimes c_k)$) satisfies $\Pi_c f_k \in e_c \mathbf{A}_{F,L}$ for every k and is Hodge-graded (for $\mathbf{n}$ and e).

Proof. Define $\alpha\colon \{0, \dots, e-1\} \to \mathbb{Z}$ by $\alpha(s) = s_{c-s} + S$ if $\epsilon_{c-s} = -1$ and $\alpha(s) = -s_{c-s}$ if $\epsilon_{c-s} = 1$. Then $Q^\alpha = \prod_{s<e} Q_s^{\alpha(s)} = \nu_c^+ / \nu_c$, so $g = Q^\alpha a$ with $a = \nu_c g / \nu_c^+ \in e_c \mathbf{A}_{F,L}$, and $(g, \mathbf{c}, \alpha)$ is a one-term section decomposition of f.

Hodge-graded. We check $\delta_e(\mathbf{c}) \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha(s)} D_{\mathrm{cris}}(V_2))$ for every $s < e$. If $\epsilon_{c-s} = 1$, then $-\alpha(s) = s_{c-s}$ and this is the hypothesis. Let $\epsilon_{c-s} = -1$, so $-\alpha(s) = -s_{c-s} - S$. By the remark in Definition 23.3, $\varphi^{-(s+4)}(\delta_e(\mathbf{c}))$ lies in $\varepsilon_{c-s-1} D_{\mathrm{cris}}(V_2)$, the component of the embedding τ_{c-s}, which is $D_{\mathrm{dR},\tau_{c-s}}(V_2)$ with the filtration $\varepsilon_{c-s-1}\mathrm{Fil}^u D_{\mathrm{cris}}(V_2) = \mathrm{Fil}^u D_{\mathrm{cris}}(V_2) \cap \varepsilon_{c-s-1} D_{\mathrm{cris}}(V_2)$ (F is unramified and V_2 crystalline, so $D_{\mathrm{dR}}(V_2) = D_{\mathrm{cris}}(V_2)$ as filtered $F \otimes_{\mathbb{Q}_\ell} L$-modules, and Fil^u is an $F \otimes L$-submodule). Every Hodge jump of V_2 at τ_{c-s} is one of V_1 (Lemma 24.2 (1)),

hence lies in $[-s_{c-s}-S,-s_{c-s}]\cup[-\eta,\eta]$ by (Ow1), hence is $\geq -s_{c-s}-S$ because $\eta < s_{c-s}$ (sizes exceed η in a weight word). The filtration is decreasing and exhaustive, so if $\mathrm{Fil}^{-s_{c-s}-S}$ were not the whole component there would be a jump $a < -s_{c-s}-S$; hence $\varepsilon_{c-s-1}\mathrm{Fil}^{-s_{c-s}-S}D_{\mathrm{cris}}(V_2) = \varepsilon_{c-s-1}D_{\mathrm{cris}}(V_2)$ and $\delta_e(\mathbf{c}) \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha(s)}D_{\mathrm{cris}}(V_2))$. So f is Hodge-graded.

Integrality. $\Pi_c = \prod_{s<e} Q_s^{H_c(c-s)}$, so $\Pi_c f_k = \prod_{s<e} Q_s^{H_c(c-s)+\alpha(s)}\, a\, e_c(1\otimes c_k)$, and it suffices that $H_c(c-s)+\alpha(s) \geq 0$ for every $s < e$. This is clear if $\epsilon_{c-s} = -1$. Let $\epsilon_{c-s} = 1$. If $s = e-1$, the site $c-s = c'+1$ is thin ($c' \in C$), so $s_{c-s} \leq w \leq w+S = H_c(c'+1)$. Otherwise $H_c(c-s) = h_B$, and $s_{c-s} \leq h_B$: a thin site has $s_{c-s} \leq w$, a thick one $s_{c-s} \leq b+\eta$ (Ow3), and $h_B = b+\eta+S$ if some site is thick, $h_B = w+S$ otherwise. Hence $\Pi_c f_k \in e_c\mathbf{A}_{F,L}$. □

Proposition C.32. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.25. Then there is an integer E with $0 \leq E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320}$ such that the following holds for every $c \in C$ with $\mathrm{len}_c = 2$ (write $e = 2$). Let $\mathbf{n} = (n_k)_{k\leq r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \leq r$ be an index with $\varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{\,s_{c-s}}D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and let g be admissible at c. Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \geq 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^E g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.*

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$, $\psi = \mathbf{N}(\Phi)$, $\beta = \beta_{320}$, and *coordinate vector* for arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, $e = 2$, H_c, m_X. Since $m_X = (\ell-1)M > 2h_B \geq 2H_c(x)$ for every site x, Lemma C.17 applies to these coordinate vectors.

Exponents. Let $E_C \leq 6\,\mathrm{Sg}$ and $E_N \leq 6\,\mathrm{Sg}$ be the integers of Proposition C.27 and Lemma C.30, and $E_0 = \max(E_C, E_N)$. Let $(M_a, h_a)_a$ be the window of Lemma C.9, so $H(a) = M_a + h_a = s_a + S + \eta$, and let $H_{\max}$, c_H and r_x ($x \in \mathbb{Z}/n$) be formed with it as in Proposition C.6 for the surjection $\Phi\colon T_1 \to T_2$; by Lemma C.9, every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$ and $r_x \leq 3\,\mathrm{Sg}$ for $x \in C$. Also $\sigma_B \leq 3\,\mathrm{Sg}$.

Put $E = \lfloor 12\,\mathrm{Sg}\rfloor + \eta\beta$; then $0 \leq E \leq 40\,\mathrm{Sg} + \eta\beta_{320}$. Below, each case gives the conclusion with an integer exponent $E'' \leq 12\,\mathrm{Sg} + \eta\beta$, hence $E'' \leq E$.

Three ways of combining.

(a) Raising. If the conclusion holds for g with an exponent $E'' \leq E$ (data w_1, λ', z), it holds with E (data $\ell^{E-E''}w_1, \lambda', \ell^{E-E''}z$): I_c is an $\mathcal{O}_L$-module (Lemma 24.5 (Ry4)), and ℓ^t times a coordinate vector of an element is one of ℓ^t times that element (Lemma C.17 item 1).

(b) Sums. If (w_j, λ'_j, z_j) give the conclusion for g_j ($j = 1, 2$) with the same exponent E'', then $(w_1+w_2, \lambda'_1\lambda'_2, z_1+z_2)$ gives it for g_1+g_2: I_c is an $\mathcal{O}_L$-module, $\lambda'_1\lambda'_2(w_1+w_2) \in \mathbf{N}_1$ as $\mathbf{N}_1$ is an $\mathbf{A}_{F,L}$-module, $P_2(\mathbf{N}_{2,c'})$ and $X\mathbf{N}_{2,c}$ are groups, and coordinate vectors add (Lemma C.17 item 1).

(c) Descent. Suppose $\ell^K g = x_2 + f_2$ with $K \geq 0$, $x_2 \in \mathcal{O}_L$ (acting as $e_c(1\otimes x_2)$) and $f_2 \in \mathcal{K}_c$ with $\nu_c f_2 \in \nu_c^+ R_c$ (ν_c^+ as in Proposition C.11). The constant $x_2 \in R_c$ is fixed by every γ_u and satisfies the hypotheses of the first part of Proposition C.27 (with $\kappa = 0$ and $x = x_2$ at every level), which gives the conclusion for x_2 with E_C. By Lemma C.30 (its hypothesis on k_0 is the one of the statement) there is $w_N \in I_c \cap \mathbf{N}_{1,c}$ with $\Pi_c\psi(w_N) \in P_2(\mathbf{N}_{2,c'})$ such that $\ell^{E_N} f_2 \mathbf{e}_{k_0}$ is a coordinate vector of $\psi(w_N)$, i.e. the conclusion for f_2 with E_N ($\lambda' = 1$, $z = 0$). By (a) (with E_0 in place of E) and (b), the conclusion holds for $\ell^K g$ with E_0, i.e. for g with $E_0 + K$.

(d) Filtered constants. By (Ex1) of Proposition 23.7, $\mathbf{N}_1$ is a Wach module, so by Lemma 24.15 $\mathbf{N}_{1,c'}$ has a frame $\mathbf{n}^{(1)} = (n_m^{(1)})_{m\leq r_1}$ fixed by γ_u, $u \in \mu_{\ell-1}$; let $(d_m^{(1)})$

be its crystalline frame and μ the matrix of ψ for $\mathbf{n}^{(1)}$ and $\mathbf{n}$ (Lemma C.29 (1)). If $\mathbf{c} \in \mathcal{O}_L^{r_1}$ and $E' \geq 0$ satisfy the hypotheses of the clause "Filtered constants" of Proposition C.27 for c, $\mathbf{n}$, k_0, $\mathbf{n}^{(1)}$ and U the set of all $s < 2$ with $\epsilon_{c-s} = 1$ (for this U the conditions on g there are admissibility), then that clause gives the conclusion for the admissible g with the exponent $\sigma_B + E'$ ($z = 0$).

The arc. Let $c \in C$ with $\mathrm{len}_c = 2$, and $\mathbf{n}$, k_0, g as in the statement. As $c - 1 \notin C$, the site c is thick; as $c' = c - 2 \in C$, the site $a := c - 1 = c' + 1$ is thin (Ow3). So some site is thick, $h = h_B = b + \eta + S$, and $s_c \leq b + \eta \leq h$, $s_a \leq w \leq h$; also $H_{\max} \leq b + 2\eta + S = h + \eta \leq 1.05\, h$ (as $20\eta \leq b$) and $c_H \leq 2 + \log_\ell(H_{\max} + 1) \leq 2 + \log_\ell(2h)$. Signs alternate, so $\epsilon_a = -\epsilon_c$. The site a is thin with the thick neighbour c, so $\beta = 1$ as soon as $|\ell s_a - b| \leq 320\, Z$, $Z = \ell\eta + \ell S + b/\ell + s_a + \ell \log_\ell(2h)$. We use $\log_\ell(2h) \leq \mathrm{Sg} - 1$ and $\mathrm{Sg} \geq 1$.

Case 1: $\epsilon_c = 1$ and $\ell(s_a + S + \eta) + \eta < s_c$. By Proposition C.6, ℓ^{r_c} is killing at c for ψ (in the sense of Lemma C.7). The hypothesis on k_0 at $s = 0$ reads $\varphi^2(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{s_c} D_{\mathrm{cris}}(V_2))$. So Lemma C.33 (with $r = r_c$ and the frames $\mathbf{n}$, $\mathbf{n}^{(1)}$) gives $\mathbf{c} \in \mathcal{O}_L^{r_1}$ with $\mathbf{c}\mu = \ell^{2\sigma_B + r_c}\mathbf{e}_{k_0}$ and $\sum_m c_m \varphi^2(d_m^{(1)}) \in \varphi^4(\mathrm{Fil}^{s_c} D_{\mathrm{cris}}(V_1))$. As $s = 0$ is the only level with $\epsilon_{c-s} = 1$, these are the hypotheses of (d) with $E' = 2\sigma_B + r_c$; the exponent is $3\sigma_B + r_c \leq 12\,\mathrm{Sg}$.

Case 2: $\epsilon_c = 1$ and $s_c \leq \ell(s_a + S + \eta) + \eta$. Here $\nu_c = Q_0^{s_c}$ and $\nu_c^+ = Q_1^y$ with $y = s_a + S \geq 1$. By admissibility $\nu_c g \in R_c$ and $\nu_c(\ell^\kappa g - x) \in Q_1^y R_c$ for some $\kappa \geq 0$, $x \in \mathcal{O}_L$. Let $K = K_\uparrow(s_c, y)$ of Lemma C.36 (Cd2) (with $s = 0$); then $Q_0^{s_c} \notin \varpi\ell^K R_c + Q_1^y R_c$, and $Q_1^y \notin \varpi R_c$ (Q_1 is a monic polynomial). So (Cd1) (with $A = \nu_c$, $N = Q_1^y$, $f = g$) gives $\ell^K g = x_2 + f_2$ with $x_2 \in \mathcal{O}_L$ and $\nu_c f_2 \in \nu_c^+ R_c$, and (c) gives the conclusion with $E_0 + K$. If $s_c < \ell y$, then $K = 0$. Otherwise $\ell y \leq s_c \leq \ell(y + \eta) + \eta < \ell(y + \eta + 1)$, so the bound of (Cd2) with $\eta + 1$ in place of η gives $K \leq \eta + 2 + \log_\ell s_c \leq \eta + 1 + \mathrm{Sg}$; and $\beta = 1$, since $\ell s_a \leq s_c - \ell S \leq b + \eta$ and $\ell s_a \geq s_c - \ell S - \ell\eta - \eta \geq b - \ell S - \ell\eta - \eta$ give $|\ell s_a - b| \leq \ell S + \ell\eta + \eta \leq 2Z$. In both cases $K \leq \eta\beta + 2\,\mathrm{Sg}$, and the exponent is at most $8\,\mathrm{Sg} + \eta\beta$.

Case 3: $\epsilon_c = -1$ and $A_a + \eta + 1 \leq s_a$, where $A_a = \lceil \sigma_a/(\ell - 1) \rceil$ and σ_a is the killing index of ψ at a (Lemma C.7). Then $\epsilon_a = 1$, and the hypothesis on k_0 at $s = 1$, $\varphi^2(d_{k_0}) \in \varphi^5(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_2))$, gives $\varphi(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_2))$, as φ is bijective on $D_{\mathrm{cris}}(V_2)$. So Lemma C.35 (for c, $a = c' + 1$, the frames $\mathbf{n}$, $\mathbf{n}^{(1)}$) gives $\mathbf{c}$ with $\mathbf{c}\mu = \ell^{2\sigma_B}\mathbf{e}_{k_0}$ and $\sum_m c_m \varphi(d_m^{(1)}) \in \varphi^4(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_1))$; applying the L-linear map φ, $\sum_m c_m \varphi^2(d_m^{(1)}) \in \varphi^5(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_1))$. As $s = 1$ is the only level with $\epsilon_{c-s} = 1$, (d) applies with $E' = 2\sigma_B$; the exponent is $3\sigma_B \leq 9\,\mathrm{Sg}$.

Case 4: $\epsilon_c = -1$ and $s_a \leq A_a + \eta$. Here $\nu_c = Q_1^y$ with $y = s_a \geq 1$ and $\nu_c^+ = Q_0^B$ with $B = s_c + S \geq 1$; by admissibility $\nu_c g \in R_c$ and $\nu_c(\ell^\kappa g - x) \in Q_0^B R_c$ for some κ, x. Let $K = K_\downarrow(y, B)$ of Lemma C.36 (Cd3) (with $s = 0$); then $Q_1^y \notin \varpi\ell^K R_c + Q_0^B R_c$, and (Cd1) (with $A = \nu_c$, $N = Q_0^B$) gives $\ell^K g = x_2 + f_2$ with $\nu_c f_2 \in \nu_c^+ R_c$; (c) gives the conclusion with $E_0 + K$. If $\ell y < B$, then $K = 0$. Otherwise $K \leq y - B/\ell + 1 + \log_\ell y$ by (Cd3). By (Ki1) of Lemma C.7 with $m = 1$ (for $\Phi\colon T_1 \to T_2$ and the window above; $a + 1 = c$), $\sigma_a \leq H(c) + c_H + 3 + H_{\max}/(\ell - 1)$, with $H(c) = s_c + S + \eta = B + \eta$; and $y \leq A_a + \eta \leq \sigma_a/(\ell - 1) + 1 + \eta$. Hence $K \leq \eta + 2.5\,\mathrm{Sg}$:

If $\eta \geq 1$ and $K > 0$, then $\beta = 1$: indeed $\ell s_a = \ell y \geq B \geq b$, and $\ell s_a \leq \sigma_a + \sigma_a/(\ell - 1) + \ell + \ell\eta$, which gives $0 \leq \ell s_a - b \leq 3Z$:

So $K \leq \eta\beta + 2.5\,\mathrm{Sg}$ in all cases, and the exponent is at most $8.5\,\mathrm{Sg} + \eta\beta$.

Conclusion. The four cases cover all $c \in C$ with $\mathrm{len}_c = 2$; each gives the conclusion with an integer exponent at most $12\,\mathrm{Sg} + \eta\beta$, hence at most E, and (a) raises it to E. □

Lemma C.33. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$ and $r_\nu = \dim_L V_\nu$. Let*

$c \in C$ with $\mathrm{len}_c = 2$ and $\epsilon_c = 1$, put $c' = c-2$, and suppose

$$\ell\,(s_{c-1} + S + \eta) + \eta < s_c.$$

Let $r \geq 0$ be an integer such that ℓ^r is killing at c for $\mathbf{N}(\Phi)$. Let $\mathbf{n} = (n_k)_{k \leq r_2}$ and $\mathbf{n}^{(1)} = (n^{(1)}_m)_{m \leq r_1}$ be frames at c' of $\mathbf{N}_2$ and $\mathbf{N}_1$, with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ and all k, with crystalline frames (d_k) and $(d^{(1)}_m)$, let $\mu \in M_{r_1 \times r_2}(\mathcal{O}_L)$ be the matrix of $\mathbf{N}(\Phi)$ for $\mathbf{n}^{(1)}$ and $\mathbf{n}$, and let $k_0 \leq r_2$ with

$$\varphi^2(d_{k_0}) \in \varphi^4\big(\mathrm{Fil}^{\,s_c} D_{\mathrm{cris}}(V_2)\big).$$

Then there is $\mathbf{c} = (c_m)_{m \leq r_1} \in \mathcal{O}_L^{r_1}$ with

$$\mathbf{c}\,\mu = \ell^{2\sigma_B + r}\mathbf{e}_{k_0} \qquad \text{and} \qquad \sum_m c_m\,\varphi^2\big(d^{(1)}_m\big) \in \varphi^4\big(\mathrm{Fil}^{\,s_c} D_{\mathrm{cris}}(V_1)\big);$$

in particular $(1 \otimes \Phi)\big(\sum_m c_m d^{(1)}_m\big) = \ell^{2\sigma_B + r} d_{k_0}$.

Proof. Write $R = e_c \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $Q = Q_0$, $b_0 = s_c$, $w' = s_{c-1}$, $y = w' + S + \eta$, and let π_0, q, ω, ω_1, R^Δ, $\mathcal{K}^\Delta$ and the average $f \mapsto \bar f$ be as in Lemma C.34. A *coordinate vector* (for $\mathbf{N}_\nu$) is an arc coordinate vector for $\mathbf{n}$ (resp. $\mathbf{n}^{(1)}$), $e = 2$, H_c and m_X. The site $c - 1 = c' + 1$ is thin ($c' \in C$) and $\epsilon_{c-1} = -1$ (signs alternate), so $w' \leq w$; $H_c(c) = h_B$, $H_c(c-1) = w + S$ and $\Pi = \Pi_c = Q^{h_B} Q_1^{w+S}$. Moreover $b_0 + S \leq h_B$ (if c is thick, $b_0 \leq b + \eta$ and $h_B = b + \eta + S$; if c is thin, $b_0 \leq w$ and $h_B \geq w + S$) and $\eta < w' \leq w$ (as $\eta < s_a$ for all a). By Lemma C.16 (1), the Hodge jumps of V_1 and V_2 at τ_x have absolute value at most $s_x + S$; by (Ow1), those of V_1 at τ_c lie in $[b_0, b_0 + S] \cup [-\eta, \eta]$ and those at τ_{c-1} in $[-w' - S, -w'] \cup [-\eta, \eta]$. Recall (Definition 23.3) that for $\mathbf{v} \in L^{r_\nu}$ the vector $\varphi^{-(s+4)}(\delta_2(\mathbf{v}))$ lies in the component $\varepsilon D_{\mathrm{cris}}(V_\nu)$ of τ_{c-s}, on which $\varepsilon\,\mathrm{Fil}^\bullet$ is the Hodge filtration at τ_{c-s}, and $\mathrm{Fil}^u D_{\mathrm{cris}}$ is stable under $F \otimes L$.

Step 1: realising the section. Put $g_2 = q^{-b_0}\varphi(q)^{w'+S} \in \mathcal{K}^\Delta$. By (Dv2), (Dv2') of Lemma C.34, $g_2 \in Q^{-b_0} Q_1^{w'+S} R$ and $\Pi g_2 \in Q^{h_B - b_0} Q_1^{w+S+w'+S} R \subseteq R$. The section decomposition $(g_2, \mathbf{e}_{k_0}, \alpha)$, $\alpha(0) = -b_0$, $\alpha(1) = w' + S$, shows that $g_2 \mathbf{e}_{k_0}$ is Hodge-graded: $\delta_2(\mathbf{e}_{k_0}) = \varphi^2(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{b_0})$ by hypothesis, and $\varphi^{-5}(\varphi^2(d_{k_0}))$ lies in the component of τ_{c-1}, where V_2 has no Hodge jump below $-(w' + S)$, so it lies in $\mathrm{Fil}^{-(w'+S)}$. By Proposition C.23 (R1) ($\nu = 2$, the $\mu_{\ell-1}$-fixed frame $\mathbf{n}$) there is $y_2 \in \mathbf{N}_{2,c}$ such that $\ell^{\sigma_B} g_2 \mathbf{e}_{k_0}$ is a coordinate vector of y_2.

Step 2: lifting and coordinates. As ℓ^r is killing at c, $\ell^r y_2 = \mathbf{N}(\Phi)(x_0)$ with $x_0 \in \mathbf{N}_{1,c}$. By Lemma C.16 (e), $\Pi x_0 \in P_2(\mathbf{N}_{1,c'})$. By Lemma C.14 (with c', $e = 2$, H_c, $m_X \geq 2H_c(x)$ and $\sigma = \sigma_B \geq (2H_c(c'+1) + m_X/(\ell-1))\ell/(\ell-1)^2)$ there is a coordinate vector f of $\ell^{\sigma_B} x_0$ with $\Pi f_m \in R$, and by Lemma 23.13 (2) there are $t, \kappa \geq 0$ and a coordinate vector f' of $\ell^t x_0$ with $\ell^\kappa f'$ Hodge-graded.

Step 3: the two congruences. By Lemma C.29 (2), $f\mu$ is a coordinate vector of $\ell^{\sigma_B + r} y_2$, as is $\ell^{2\sigma_B + r} g_2 \mathbf{e}_{k_0}$ (Lemma C.17 item 1); and $\ell^t f$, $\ell^{\sigma_B} f'$ are coordinate vectors of $\ell^{t+\sigma_B} x_0$. By Lemma C.17 item 2,

$$f\mu - \ell^{2\sigma_B + r} g_2 \mathbf{e}_{k_0} \in (X\Pi R)^{r_2}, \qquad \ell^{t+\kappa} f = \sum_i g_i \mathbf{v}_i + X\Pi \mathbf{h},$$

where $\mathbf{h} \in R^{r_1}$, $g_i \in Q^{\alpha_i(0)} Q_1^{\alpha_i(1)} R$, $\mathbf{v}_i \in \mathcal{O}_L^{r_1}$,

$$\delta_2(\mathbf{v}_i) \in \varphi^4\big(\mathrm{Fil}^{-\alpha_i(0)} D_{\mathrm{cris}}(V_1)\big) \cap \varphi^5\big(\mathrm{Fil}^{-\alpha_i(1)} D_{\mathrm{cris}}(V_1)\big)$$

($\ell^{-\sigma_B} g_i$ forming a section decomposition of $\ell^\kappa f'$).

Step 4: bounded poles. If $\mathbf{v}_i \neq 0$ then $-\alpha_i(0) \leq b_0+S$ and $-\alpha_i(1) \leq \eta$. Indeed $\varphi^{-4}\delta_2(\mathbf{v}_i)$ lies in the component of τ_c and in $\mathrm{Fil}^{-\alpha_i(0)}$, and that component of Fil^u is 0 for $u > b_0+S$ (no jump above b_0+S); likewise $\varphi^{-5}\delta_2(\mathbf{v}_i)$ lies in the component of τ_{c-1}, whose Fil^u is 0 for $u > \eta$. If either inequality failed, $\delta_2(\mathbf{v}_i) = \varphi^2(\sum_m v_{i,m} d_m^{(1)}) = 0$; as φ is bijective on $D_{\mathrm{cris}}(V_1)$ and the $d_m^{(1)}$ are linearly independent over L (Lemma 23.10 item 1), $\mathbf{v}_i = 0$. We drop the terms with $\mathbf{v}_i = 0$.

Step 5: clearing the poles. Put $\Psi = q^{b_0+S}\varphi(q)^\eta \in R^\Delta$, so $\Psi \in Q^{b_0+S}Q_1^\eta R^\times$. By Step 4, $\Psi g_i \in Q^{b_0+S+\alpha_i(0)}Q_1^{\eta+\alpha_i(1)}R \subseteq R$, and $\Psi X\Pi\mathbf{h} \in R^{r_1}$; hence $\ell^{t+\kappa}\Psi f_m \in R$. Also $\Psi f_m = G^{-1}A_m$ with $G = Q^{h_B-b_0-S}Q_1^{w+S-\eta}$ (exponents ≥ 0) and $A_m = (\Psi\Pi^{-1}G)\Pi f_m \in R$. So $\ell^{t+\kappa}A_m \in GR$; as G is a monic polynomial, R/GR is ℓ-torsion free (reduce modulo a uniformiser in the domain $(\mathcal{O}_L/\varpi)[[X]]$ and induct), so $A_m \in GR$ and $\Psi f_m \in R$.

Step 6: averaging. Put $\Phi_m = \overline{\Psi f_m} = \Psi \bar{f}_m \in R^\Delta$. Averaging the relations of Step 3 multiplied by Ψ, by (Dv3) and (Dv2') (using $\Psi g_2 = q^S\varphi(q)^y$ and $\Psi X\Pi R = XQ^{h_B+b_0+S}Q_1^{w+S+\eta}R$):

$$\Phi\mu - \ell^{2\sigma_B+r}q^S\varphi(q)^y\mathbf{e}_{k_0} \in (\mathcal{E})^{r_2}, \qquad \ell^{t+\kappa}\Phi - \sum_i \Psi\bar{g}_i\,\mathbf{v}_i \in (\mathcal{E})^{r_1},$$
$$\mathcal{E} = \pi_0 q^{h_B+b_0+S}\varphi(q)^{w+S+\eta}R^\Delta,$$

with $\Psi\bar{g}_i \in q^{b_0+S+\alpha_i(0)}\varphi(q)^{\eta+\alpha_i(1)}R^\Delta$ (both exponents ≥ 0).

Step 7: reading the coefficient of q^J, $J = S+\ell y$. In $R^\Delta = \mathcal{O}_L[[q]]$ (Lemma C.34 (Dv1)) let λ_J be the coefficient of q^J. Every element of $q^N R^\Delta$ has $\lambda_J = 0$ if $N > J$. Since $J = S+\ell y < S+b_0 \leq h_B+b_0+S$ and $\mathcal{E} \subseteq q^{h_B+b_0+S}R^\Delta$, $\lambda_J(\mathcal{E}) = 0$. By (Dv2'), $\varphi(q)^y \equiv (\sum_{j\geq\ell} a_j q^j)^y$ modulo ϖ, so $\theta := \lambda_J(q^S\varphi(q)^y)$, the coefficient of $q^{\ell y}$ in $\varphi(q)^y$, satisfies $\theta \equiv a_\ell^y$ and is a unit of $\mathcal{O}_L$. Put $\mathbf{c} = \theta^{-1}(\lambda_J(\Phi_m))_m \in \mathcal{O}_L^{r_1}$. The first relation gives $\mathbf{c}\mu = \ell^{2\sigma_B+r}\mathbf{e}_{k_0}$. The second gives $\ell^{t+\kappa}\theta\,\mathbf{c} = \sum_i \lambda_J(\Psi\bar{g}_i)\mathbf{v}_i$, where $\lambda_J(\Psi\bar{g}_i) = 0$ unless $b_0+S+\alpha_i(0) \leq J$, i.e. $-\alpha_i(0) \geq b_0-\ell y \geq \eta+1$ (hypothesis). For the remaining i, $\varphi^{-4}\delta_2(\mathbf{v}_i) \in \mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1)$, hence $z := \varphi^{-4}(\sum_m c_m\varphi^2(d_m^{(1)})) \in \mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1)$, and z lies in the component of τ_c.

Step 8: the Hodge gap. On the component of τ_c the Hodge filtration of V_1 has no jump in $[\eta+1, b_0-1]$ (by (Ow1), as recalled at the start), so its $\mathrm{Fil}^{\eta+1}$ and Fil^{b_0} agree and $z \in \mathrm{Fil}^{b_0}D_{\mathrm{cris}}(V_1)$. Finally $(1\otimes\Phi)(d_m^{(1)}) = \sum_k \mu_{mk}d_k$ (Lemma C.29 (1)) gives $(1\otimes\Phi)(\sum_m c_m d_m^{(1)}) = \ell^{2\sigma_B+r}d_{k_0}$. □

Lemma C.34. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$, $R = \mathcal{O}_L[[X]]$ with field of fractions $\mathcal{K}$, and for $u \in \mathbb{Z}_\ell^\times$ let γ_u be the $\mathcal{O}_L$-algebra automorphism of R (and of $\mathcal{K}$) with $\gamma_u(X) = (1+X)^u - 1$. Call $f \in \mathcal{K}$ Δ-*invariant *if $\gamma_\delta(f) = f$ for every $\delta \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$, write R^Δ, $\mathcal{K}^\Delta$ for the Δ-invariant elements, and put $q = \pi_0 + \ell$.*

(Dv1) Variable *The $\mathcal{O}_L$-algebra homomorphism $\mathcal{O}_L[[T]] \to R$, $T \mapsto q$, is injective with image R^Δ; so is $T \mapsto \pi_0$. Every $f \in R^\Delta$ with $f(0) = 0$ lies in $\pi_0 R^\Delta$.*

(Dv2) The ideal of Q *$q = Q\omega$ with $\omega \in R^\times$. Consequently $Q^\alpha R \cap \mathcal{K}^\Delta = q^\alpha R^\Delta$ for every $\alpha \in \mathbb{Z}$, and $XQ^N R \cap R^\Delta = \pi_0 q^N R^\Delta$ for every integer $N \geq 0$.*

(Dv2') The ideal of Q_1 *$\varphi(q)$ is Δ-invariant and $\varphi(q) = Q_1\omega_1$ with $\omega_1 = \varphi(\omega) \in R^\times$ ($Q_1 = \varphi(Q)$, φ as in Definition 23.2). For $\alpha, \beta \in \mathbb{Z}$ and integers $N, M \geq 0$: $Q^\alpha Q_1^\beta R \cap \mathcal{K}^\Delta = q^\alpha\varphi(q)^\beta R^\Delta$ and $XQ^N Q_1^M R \cap R^\Delta = \pi_0 q^N \varphi(q)^M R^\Delta$. Writing $\varphi(q) = \sum_j a_j q^j$ by (Dv1), $a_j \in \varpi\mathcal{O}_L$ for $j < \ell$ and $a_\ell \in \mathcal{O}_L^\times$ (ϖ a uniformiser of $\mathcal{O}_L$).*

(Dv3) Averaging *For $\delta \in \mu_{\ell-1}$, integers $i \geq 0$ and $\alpha, \beta \in \mathbb{Z}$, $\gamma_\delta(X^i Q^\alpha Q_1^\beta R) = X^i Q^\alpha Q_1^\beta R$. Hence the average $\bar{f} = (\ell-1)^{-1} \sum_{\delta \in \mu_{\ell-1}} \gamma_\delta(f)$ of an element $f \in X^i Q^\alpha Q_1^\beta R$ lies in $X^i Q^\alpha Q_1^\beta R \cap \mathcal{K}^\Delta$, and $\bar{f} = f$ if f is Δ-invariant.*

Proof. Write $\mathfrak{m}$ for the maximal ideal of R, ϖ for a uniformiser of $\mathcal{O}_L$ and $\bar{h}$ for the reduction of $h \in R$ modulo ϖ. We apply Lemma 23.24 with $\Delta = \mu_{\ell-1}$, so $e = 1$, $\pi_\Delta = \pi_0$ and, by (Rr3), $q_\Delta = \pi_0 + \ell = q$. By (Rr1), π_0 is Δ-invariant and $\pi_0 = X^{\ell-1} v$ with $v \in \mathbb{Z}_\ell[[X]]^\times$; hence q is Δ-invariant and $\bar{q} = X^{\ell-1}\bar{v}$ has X-adic order exactly $\ell - 1$.

A divisibility criterion. *If $h \in R$ has $\bar{h}$ of X-adic order exactly $\ell-1$ and $h(\zeta - 1) = 0$ for every primitive ℓ-th root of unity ζ, then $h \in QR^\times$.* By Weierstrass preparation $h = Pu$ with $u \in R^\times$ and $P \in \mathcal{O}_L[X]$ distinguished of degree $\ell - 1$. For each of the $\ell - 1$ elements $x = \zeta - 1$ (of positive valuation in $\mathcal{O}_{L(\zeta)}$) the value $u(x)$ is a unit, so $P(x) = 0$. Thus the monic polynomial $Q = \Phi_\ell(1 + X)$, whose roots are these $\ell - 1$ distinct elements, divides P in $L(\zeta)[X]$, hence in $\mathcal{O}_L[X]$ (division by a monic polynomial); both are monic of degree $\ell - 1$, so $P = Q$.

(Dv2). By (Rr4) of Lemma 23.24, $q = q_\Delta = Q\omega$ with $\omega = w_\Delta \in \mathbb{Z}_\ell[[X]]^\times \subseteq R^\times$. If $f \in Q^\alpha R$ is Δ-invariant, then $q^{-\alpha} f = \omega^{-\alpha} Q^{-\alpha} f \in R$ and is Δ-invariant, so $f \in q^\alpha R^\Delta$; the converse inclusion is clear. If $f \in XQ^N R \cap R^\Delta$, then $g = q^{-N} f \in XR$ is Δ-invariant with $g(0) = 0$, so $g \in \pi_0 R^\Delta$ by (Dv1); conversely $\pi_0 q^N R^\Delta \subseteq XQ^N R$ as $\pi_0 \in XR$.

(Dv2'). The ring endomorphism φ of R ($X \mapsto (1+X)^\ell - 1$, identity on $\mathcal{O}_L$) commutes with every γ_u, since both sides send $1 + X$ to $(1+X)^{\ell u}$; so $\varphi(q)$ is Δ-invariant, and $\varphi(q) = \varphi(Q)\varphi(\omega) = Q_1\omega_1$ with $\omega_1(0) = \omega(0)$ a unit. The two equalities of ideals follow as in (Dv2), dividing by the Δ-invariant element $q^\alpha \varphi(q)^\beta \in Q^\alpha Q_1^\beta R^\times$ (resp. $q^N \varphi(q)^M$) and using (Dv1). For the coefficients: reduction modulo ϖ maps $R^\Delta = \mathcal{O}_L[[q]]$ to $(\mathcal{O}_L/\varpi)[[X]]$ by $\sum_j b_j q^j \mapsto \sum_j \bar{b}_j \bar{q}^j$, and as $\bar{q} = X^{\ell-1}\bar{v}$, the X-adic order of the image is $(\ell-1)\min\{j : \bar{b}_j \neq 0\}$. For $\varphi(q) = Q_1\omega_1$ the image is $\bar{Q}_1\bar{\omega}_1$, of X-adic order $(\ell-1)\ell$: indeed $Q_1 = \sum_{i<\ell}(1+X)^{i\ell}$ and $(1+X)^\ell \equiv 1 + X^\ell$ modulo ℓ, so $\bar{Q}_1 = ((1+X^\ell)^\ell - 1)/X^\ell = X^{(\ell-1)\ell}$. Hence $\bar{a}_j = 0$ for $j < \ell$ and $\bar{a}_\ell \neq 0$.

(Dv1). By (Rr2) of Lemma 23.24, $T \mapsto \pi_0$ is injective with image R^Δ, and $R^\Delta \cap XR = \pi_0 R^\Delta$; an $f \in R^\Delta$ with $f(0) = 0$ lies in XR, hence in $\pi_0 R^\Delta$. *The variable q.* Since $\ell \in \varpi\mathcal{O}_L$, the substitutions $T \mapsto T + \ell$ and $T \mapsto T - \ell$ are mutually inverse continuous automorphisms of $\mathcal{O}_L[[T]]$; composing with $T \mapsto \pi_0$ gives the assertion for $q = \pi_0 + \ell$.

(Dv3). $\gamma_\delta(X) = (1+X)^\delta - 1 = X(\delta + X(\dots)) \in XR^\times$, as $\delta \in \mathbb{Z}_\ell^\times$. Next, $\overline{\gamma_\delta(Q)} = \gamma_\delta(\bar{Q})$ with $\bar{Q} = X^{\ell-1}$, so $\overline{\gamma_\delta(Q)}$ has X-adic order $\ell - 1$; and for $x = \zeta - 1$ as above, $\gamma_\delta(Q)(x) = Q((1+x)^\delta - 1) = \Phi_\ell(\zeta^n) = 0$ with $n \equiv \delta$, $\ell \nmid n$. By the criterion $\gamma_\delta(Q) \in QR^\times$, and applying φ (which commutes with γ_δ and maps $R^\times$ to $R^\times$), $\gamma_\delta(Q_1) \in Q_1 R^\times$. Hence $\gamma_\delta(X^i Q^\alpha Q_1^\beta) \in X^i Q^\alpha Q_1^\beta R^\times$, and $\gamma_\delta(X^i Q^\alpha Q_1^\beta R) = X^i Q^\alpha Q_1^\beta R$ (the inclusion for γ_δ and $\gamma_{\delta^{-1}}$). As $\ell - 1 \in \mathcal{O}_L^\times$, the average of $f \in X^i Q^\alpha Q_1^\beta R$ lies in $X^i Q^\alpha Q_1^\beta R$, and it is Δ-invariant because $\delta \mapsto \gamma_\delta$ is a homomorphism on the group $\mu_{\ell-1}$. □

Lemma C.35. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$ and $r_\nu = \dim_L V_\nu$. Let $c \in C$, $c' = c - \mathrm{len}_c$ and $a = c' + 1$, and suppose that $\epsilon_a = 1$ and*

$$A_a + \eta + 1 \leq s_a, \qquad A_a = \lceil \sigma_a/(\ell-1) \rceil,$$

where σ_a is the killing index of $\mathbf{N}(\Phi)$ at a (formed for $\Phi|_{T_1} : T_1 \to T_2$). Let $\mathbf{n} = (n_k)_{k \leq r_2}$ and $\mathbf{n}^{(1)} = (n_m^{(1)})_{m \leq r_1}$ be frames at c' of $\mathbf{N}_2$ and $\mathbf{N}_1$, with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ and all k, with crystalline frames (d_k) and $(d_m^{(1)})$, let $\mu \in M_{r_1 \times r_2}(\mathcal{O}_L)$ be the matrix of $\mathbf{N}(\Phi)$ for $\mathbf{n}^{(1)}$ and

$\mathbf{n}$, *and let* $k_0 \le r_2$ *with*

$$\varphi(d_{k_0}) \in \varphi^4\big(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_2)\big).$$

Then there is $\mathbf{c} = (c_m)_{m \le r_1} \in \mathcal{O}_L^{r_1}$ *with*

$$\mathbf{c}\,\mu = \ell^{2\sigma_B}\mathbf{e}_{k_0} \qquad \text{and} \qquad \sum_m c_m\,\varphi\big(d_m^{(1)}\big) \in \varphi^4\big(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_1)\big),$$

where $\mathbf{e}_{k_0}$ *is the* k_0*-th unit vector; in particular* $(1\otimes\Phi)\big(\sum_m c_m d_m^{(1)}\big) = \ell^{2\sigma_B} d_{k_0}$.

Proof. Write $R = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $\mathcal{K} = \mathcal{K}_a$, $H = H_c$, $\Pi' = \Lambda_{a,1}(H) = Q^{w+S}$ (as $H(c'+1) = w+S$), $A = A_a$, $s = s_a$, and let π_0, $q = \pi_0 + \ell$, R^Δ, $\mathcal{K}^\Delta$ and the average $f \mapsto \bar f$ be as in Lemma C.34. A *coordinate vector* (for $\mathbf{N}_\nu$) is an arc coordinate vector for the frame $\mathbf{n}$ (resp. $\mathbf{n}^{(1)}$), $e = 1$, H and m_X; this is the length-one initial sub-arc $c' \to a$ of the arc of c. We have $s \le w$ because $c'+1$ is thin ($c' \in C$), $m_X = (\ell-1)M > 2h_B \ge 2H(x)$ for every site x, and $\sigma_B \ge \big(2H(c'+1) + m_X/(\ell-1)\big)\ell/(\ell-1)^2$.

Step 1: coordinates. By Lemma C.17 (with c', $e=1$, H, m_X): coordinate vectors of one element agree modulo $X\Pi' R$ entrywise, and of is a coordinate vector of oz when f is one of z and $o \in R$.

Step 2: realising the pole. Put $g_2 = q^{-s} \in \mathcal{K}^\Delta$. By Lemma C.34 (Dv2), $q = Q\omega$ with $\omega \in R^\times$, so $\Pi' g_2 = Q^{w+S-s}\omega^{-s} \in R$, and $(g_2, \mathbf{e}_{k_0}, \alpha)$ with $\alpha(0) = -s$ is a section decomposition of $g_2\mathbf{e}_{k_0}$ with $\delta_1(\mathbf{e}_{k_0}) = \varphi(d_{k_0}) \in \varphi^4(\mathrm{Fil}^s D_{\mathrm{cris}}(V_2))$; so $g_2\mathbf{e}_{k_0}$ is Hodge-graded for $\mathbf{n}$ and $e=1$. By Proposition C.23 (R3) with $e_1 = 1$ (for $\nu = 2$ and the $\mu_{\ell-1}$-fixed frame $\mathbf{n}$) there is $y \in \mathbf{N}_{2,a}$ such that $\ell^{\sigma_B} g_2\mathbf{e}_{k_0}$ is a coordinate vector of y.

Step 3: killing the cokernel. By Lemma C.34 and Lemma 28.15 item 1, $\pi_0 = X^{\ell-1}v$ with v a unit, so by (Ki3) of Lemma C.7 π_0^A is killing at a: there is $x_0 \in \mathbf{N}_{1,a}$ with $\mathbf{N}(\Phi)(x_0) = \pi_0^A y$. By Lemma C.16 (1) every Hodge jump of V_1 at τ_a has absolute value at most $H(a)$, so by (Ex1) of Proposition 23.7 and (Wm2), $\Pi'\mathbf{N}_{1,a} = Q^{H(a)}\mathbf{N}_{1,a} \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{1,c'}) = P_1(\mathbf{N}_{1,c'})$. Hence Lemma C.14 (with $e=1$, H, m_X, $\sigma = \sigma_B$) gives a coordinate vector f of $\ell^{\sigma_B}x_0$ (for $\mathbf{N}_1$) with $\Pi' f_m \in R$, and Lemma 23.13 (2) gives $t, \kappa \ge 0$ and a coordinate vector f' of $\ell^t x_0$ with $\ell^\kappa f'$ Hodge-graded.

Step 4: the two congruences. By Lemma C.29 (2), $f\mu$ is a coordinate vector (for $\mathbf{N}_2$) of $\mathbf{N}(\Phi)(\ell^{\sigma_B}x_0) = \ell^{\sigma_B}\pi_0^A y$, and so is $\ell^{2\sigma_B}\pi_0^A g_2\mathbf{e}_{k_0}$ by Steps 1 and 2. Also $\ell^t f$ and $\ell^{\sigma_B} f'$ are coordinate vectors of $\ell^{t+\sigma_B}x_0$. By Step 1,

$$f\mu - \ell^{2\sigma_B}\pi_0^A q^{-s}\mathbf{e}_{k_0} \in (X\Pi' R)^{r_2}, \qquad \ell^{t+\kappa} f = \sum_i g_i\mathbf{v}_i + X\Pi'\mathbf{h}, \tag{C.1}$$

where $(\ell^{-\sigma_B}g_i, \mathbf{v}_i, \alpha_i)_i$ is a section decomposition of $\ell^\kappa f'$ with $\delta_1(\mathbf{v}_i) \in \varphi^4(\mathrm{Fil}^{-\alpha_i(0)} D_{\mathrm{cris}}(V_1))$, so $g_i \in Q^{\alpha_i(0)}R$, and $\mathbf{h} \in R^{r_1}$.

Step 5: averaging over Δ. Apply the average entrywise. Since π_0, q are Δ-invariant and μ, $\mathbf{v}_i$ are constant, Lemma C.34 (Dv3) turns (C.1) into the same relations for $\bar f$, $\bar g_i \in Q^{\alpha_i(0)}R \cap \mathcal{K}^\Delta$ and $\overline{X\Pi'\mathbf{h}} \in (XQ^{w+S}R \cap \mathcal{K}^\Delta)^{r_1}$, and $\bar f_m \in Q^{-(w+S)}R \cap \mathcal{K}^\Delta$. Multiply by q^{w+S} and put $\Phi_m = q^{w+S}\bar f_m$. By (Dv2), $\Phi_m \in R^\Delta$, $q^{w+S}\bar g_i \in q^{w+S+\alpha_i(0)}R^\Delta$, and the two error terms lie in $XQ^{2(w+S)}R \cap R^\Delta = \pi_0 q^{2(w+S)}R^\Delta$:

$$\Phi\mu - \ell^{2\sigma_B}(q-\ell)^A q^{w+S-s}\mathbf{e}_{k_0} \in \big(q^{2(w+S)}R^\Delta\big)^{r_2}, \qquad \ell^{t+\kappa}\Phi - \sum_i q^{w+S}\bar g_i\mathbf{v}_i \in \big(q^{2(w+S)}R^\Delta\big)^{r_1}. \tag{C.2}$$

Step 6: reading one coefficient. By (Dv1), $R^\Delta = \mathcal{O}_L[[q]]$, a subring of the field $L((q))$ of Laurent series, which also contains $q^j R^\Delta$ for $j < 0$; let λ_J be the coefficient of q^J, an L-linear

map $L((q)) \to L$ with $\lambda_J(\mathcal{O}_L[[q]]) \subseteq \mathcal{O}_L$, for

$$J = A + w + S - s.$$

Since $s \le w$ and $A < s$, $0 \le J < w + S \le 2(w + S)$, so λ_J kills $q^{2(w+S)}R^\Delta$. Put $c_m = \lambda_J(\Phi_m) \in \mathcal{O}_L$. The first relation of (C.2) gives $\mathbf{c}\mu = \ell^{2\sigma_B}\lambda_J((q-\ell)^A q^{w+S-s})\mathbf{e}_{k_0} = \ell^{2\sigma_B}\mathbf{e}_{k_0}$, as the coefficient of q^A in $(q-\ell)^A$ is 1. The second gives

$$\ell^{t+\kappa}\mathbf{c} = \sum_i \lambda_J(q^{w+S}\bar{g}_i)\mathbf{v}_i,$$

and $\lambda_J(q^{w+S}\bar{g}_i) = 0$ unless $w + S + \alpha_i(0) \le J$, i.e. $-\alpha_i(0) \ge s - A \ge \eta + 1$. For the remaining i, $\delta_1(\mathbf{v}_i) \in \varphi^4(\mathrm{Fil}^{-\alpha_i(0)}D_{\mathrm{cris}}(V_1)) \subseteq \varphi^4(\mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1))$. As δ_1 is L-linear and $\mathrm{Fil}^{\eta+1}$ is an L-subspace, $z := \varphi^{-4}(\sum_m c_m\varphi(d_m^{(1)})) \in \mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1)$.

Step 7: the Hodge gap. By Definition 23.3, z lies in the component $\varepsilon_{a-1}D_{\mathrm{cris}}(V_1)$ of the embedding τ_a, on which $\varepsilon_{a-1}\mathrm{Fil}^\bullet D_{\mathrm{cris}}(V_1)$ is the Hodge filtration of V_1 at τ_a ($\mathrm{Fil}^u D_{\mathrm{cris}}$ is stable under $F \otimes L$, so $z = \varepsilon_{a-1}z \in \varepsilon_{a-1}\mathrm{Fil}^{\eta+1}$). By (Ow1) with $\epsilon_a = 1$, the Hodge jumps of V_1 at τ_a lie in $[s, s+S] \cup [-\eta, \eta]$, so this filtration has no jump in $[\eta+1, s-1]$ and $\varepsilon_{a-1}\mathrm{Fil}^{\eta+1} = \varepsilon_{a-1}\mathrm{Fil}^s$. Hence $z \in \mathrm{Fil}^s D_{\mathrm{cris}}(V_1)$, i.e. $\sum_m c_m\varphi(d_m^{(1)}) \in \varphi^4(\mathrm{Fil}^s D_{\mathrm{cris}}(V_1))$. Finally, by Lemma C.29 (1), $(1 \otimes \Phi)(d_m^{(1)}) = \sum_k \mu_{mk}d_k$, so $(1 \otimes \Phi)(\sum_m c_m d_m^{(1)}) = \sum_k(\mathbf{c}\mu)_k d_k = \ell^{2\sigma_B}d_{k_0}$. □

Lemma C.36. *Let ℓ be a prime, L a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$ and uniformiser ϖ, $R = \mathcal{O}_L[[X]]$ and $\mathcal{K}$ its field of fractions.*

(Cd1) Descent *Let $A, N \in R$ with $N \notin \varpi R$, and let $K \ge 0$ be an integer with*

$$A \notin \varpi\ell^K R + NR.$$

Let $f \in \mathcal{K}$ with $Af \in R$, and suppose there are an integer $\kappa \ge 0$ and $x \in \mathcal{O}_L$ with $A(\ell^\kappa f - x) \in NR$. Then $\ell^K x \in \ell^\kappa\mathcal{O}_L$; with $x_2 \in \mathcal{O}_L$ defined by $\ell^\kappa x_2 = \ell^K x$ and $f_2 = \ell^K f - x_2$,

$$\ell^K f = x_2 + f_2, \qquad Af_2 \in NR.$$

Moreover, if $N' \in R$, $\kappa' \ge 0$ and $x' \in \mathcal{O}_L$ satisfy $A(\ell^{\kappa'}f - x') \in N'R$, then $A(\ell^{\kappa'}f_2 - (\ell^K x' - \ell^{\kappa'}x_2)) \in N'R$; and if γ is an $\mathcal{O}_L$-algebra automorphism of R (extended to $\mathcal{K}$) with $\gamma(f) = f$, then $\gamma(f_2) = f_2$.

(Cd2) Pole at level s, congruence at level $s+1$ *Let $s \ge 0$, $y \ge 1$ and $b \ge 0$ be integers, and put $K_\uparrow(b, y) = 0$ if $b < \ell y$, and*

$$K_\uparrow(b, y) = a - y + 1 + v_\ell\binom{a}{y-1}, \qquad a = \lceil b/\ell \rceil,$$

if $b \ge \ell y$. Then $Q_s^b \notin \varpi\ell^{K_\uparrow(b,y)}R + Q_{s+1}^y R$. If moreover $b \ge 1$ and $b < \ell(y + \eta)$ for an integer $\eta \ge 0$, then $K_\uparrow(b, y) \le \eta + 1 + \log_\ell b$.

(Cd3) Pole at level $s+1$, congruence at level s *Let $s \ge 0$ and $y, B \ge 1$ be integers, and put $K_\downarrow(y, B) = 0$ if $\ell y < B$, and*

$$K_\downarrow(y, B) = y - i_1 + v_\ell\binom{y}{i_1}, \qquad i_1 = \lceil B/\ell \rceil - 1,$$

if $B \le \ell y$. Then $Q_{s+1}^y \notin \varpi\ell^{K_\downarrow(y,B)}R + Q_s^B R$, and $K_\downarrow(y, B) \le \max(0,\, y - B/\ell + 1 + \log_\ell y)$.

Proof. Write v_ϖ for the normalised valuation of L, $e_L = v_\varpi(\ell)$, $k = \mathcal{O}_L/\varpi$, and $\bar{h} \in k[[X]]$ for the reduction of $h \in R$. We have $\varpi\ell^K R = \varpi^{e_L K+1} R$.

Three facts on R.

(i) *If $G \in R \setminus \varpi R$, $j \geq 0$ and $h \in R$ with $Gh \in \varpi^j R$, then $h \in \varpi^j R$; hence $\varpi^j h \in GR$ implies $h \in GR$.* Induction on j, the case $j = 0$ being trivial. If $Gh \in \varpi^j R$ with $j \geq 1$, then $\bar{G}\bar{h} = 0$ in the domain $k[[X]]$ with $\bar{G} \neq 0$, so $h = \varpi h'$; as R is a domain, $Gh' \in \varpi^{j-1}R$ and $h' \in \varpi^{j-1}R$ by induction. For the second assertion write $\varpi^j h = G\beta$; then $\beta = \varpi^j\beta'$ and $h = G\beta'$.

(ii) *Let $G \in \mathcal{O}_L[X]$ be a distinguished polynomial (monic, the other coefficients in $\varpi\mathcal{O}_L$) of degree $d \geq 1$. If $c \in \mathcal{O}_L$ and $c \in \varpi^j R + GR$, then $v_\varpi(c) \geq j$.* Write $c = \varpi^j\alpha + G\beta$ and, by Weierstrass division, $\alpha = Gq + r$ with $r \in \mathcal{O}_L[X]$ of degree $< d$. Then $c - \varpi^j r = G(\beta + \varpi^j q)$ is a polynomial of degree $< d$; by the uniqueness in Weierstrass division it is its own remainder, so $\beta + \varpi^j q = 0$ and $c = \varpi^j r$, whence $c = \varpi^j r(0)$ with $r(0) \in \mathcal{O}_L$.

(iii) *Q_s is a distinguished polynomial of degree $(\ell-1)\ell^s$ with $Q_s(0) = \ell$, and $Q_s^\ell = Q_{s+1} + \ell W_s$ with $W_s \in R^\times$.* Indeed $Q_s = \sum_{i=0}^{\ell-1}(1+X)^{i\ell^s} \in \mathbb{Z}[X]$ is monic of degree $(\ell-1)\ell^s$ with $Q_s(0) = \ell$; in $\mathbb{F}_\ell[X]$, $(1+X)^{\ell^s} = 1 + X^{\ell^s}$, so $Q_s \equiv \big((1+X^{\ell^s})^\ell - 1\big)/X^{\ell^s} \equiv X^{(\ell-1)\ell^s}$. Hence $Q_s^\ell \equiv X^{(\ell-1)\ell^{s+1}} \equiv Q_{s+1}$ modulo ℓ, i.e. $Q_s^\ell - Q_{s+1} = \ell W_s$ with $W_s \in \mathbb{Z}[X]$, and evaluating at 0 gives $W_s(0) = \ell^{\ell-1} - 1 \in \mathbb{Z}_\ell^\times$, so W_s is a unit of R.

An expansion bound. *Let G be as in (ii), $B \geq 1$, $0 \leq m_0 < m_1 < \cdots < m_n$ integers with $m_0 < B$, $c_i \in \mathcal{O}_L \setminus \{0\}$ and $u_i \in R^\times$, and $H = \sum_{i=0}^n c_i u_i G^{m_i}$. Let $\mu = \min\{v_\varpi(c_i) : m_i < B\}$. Then $H \notin \varpi^{\mu+1}R + G^B R$.* Suppose the contrary. Let i_0 be the least index with $m_{i_0} < B$ and $v_\varpi(c_{i_0}) = \mu$. For $i < i_0$ we have $m_i < B$ and $v_\varpi(c_i) > \mu$, so these terms lie in $\varpi^{\mu+1}R$; the terms with $m_i \geq B$ lie in $G^B R$. Hence $G^{m_{i_0}} Z \in \varpi^{\mu+1}R + G^B R$, where

$$Z = c_{i_0}u_{i_0} + \sum_{i>i_0,\ m_i<B} c_i u_i G^{m_i - m_{i_0}} \ \in \ c_{i_0}u_{i_0} + GR.$$

Write $G^{m_{i_0}} Z = \varpi^{\mu+1}\alpha + G^B\beta$. Then $G^{m_{i_0}}(Z - G^{B-m_{i_0}}\beta) \in \varpi^{\mu+1}R$, and by (i) applied m_{i_0} times ($G \notin \varpi R$ as G is monic) $Z - G^{B-m_{i_0}}\beta \in \varpi^{\mu+1}R$. As $B - m_{i_0} \geq 1$, $Z \in \varpi^{\mu+1}R + GR$, so $c_{i_0}u_{i_0} \in \varpi^{\mu+1}R + GR$ and, multiplying by $u_{i_0}^{-1}$, $c_{i_0} \in \varpi^{\mu+1}R + GR$. By (ii), $v_\varpi(c_{i_0}) \geq \mu + 1$, a contradiction.

(Cd1). Write $A(\ell^\kappa f - x) = N\beta$ with $\beta \in R$. First, $\ell^K x \in \ell^\kappa \mathcal{O}_L$: this is clear if $x = 0$. Otherwise let $a = v_\varpi(x)$, $x = \varpi^a u$ with $u \in \mathcal{O}_L^\times$, and suppose $a + e_L K < e_L\kappa$. From $\varpi^a uA = \ell^\kappa(Af) - N\beta$ and $Af \in R$ we get $\varpi^a uA = \varpi^{e_L\kappa}\alpha - N\beta$ for some $\alpha \in R$; so $N\beta \in \varpi^a R$, hence $\beta = \varpi^a\beta'$ by (i), and $uA = \varpi^{e_L\kappa - a}\alpha - N\beta'$. Thus $A \in \varpi^{e_L\kappa-a}R + NR \subseteq \varpi^{e_L K+1}R + NR = \varpi\ell^K R + NR$, as $e_L\kappa - a \geq e_L K + 1$; this contradicts the hypothesis. So $x_2 \in \mathcal{O}_L$ is defined, and $\ell^K f = x_2 + f_2$ by definition. Next,

$$\ell^\kappa(Af_2) = \ell^K\,\ell^\kappa Af - \ell^\kappa x_2 A = \ell^K A(\ell^\kappa f - x) = \ell^K N\beta \in NR,$$

and $Af_2 = \ell^K Af - x_2 A \in R$; by (i) (with $\varpi^{e_L\kappa}$ in place of ℓ^κ, which differs by a unit) $Af_2 \in NR$. For the second congruence,

$$A\big(\ell^{\kappa'} f_2 - \ell^K x' + \ell^{\kappa'} x_2\big) = A\big(\ell^{K+\kappa'} f - \ell^K x'\big) = \ell^K A(\ell^{\kappa'} f - x') \in N'R.$$

Finally $\gamma(f_2) = \ell^K\gamma(f) - \gamma(x_2) = \ell^K f - x_2 = f_2$, since γ fixes $\mathcal{O}_L$.

(Cd2). If $b < \ell y$, suppose $Q_s^b \in \varpi R + Q_{s+1}^y R$; reducing modulo ϖ and using (iii), $X^{(\ell-1)\ell^s b} \in X^{(\ell-1)\ell^{s+1}y}k[[X]]$, impossible as $(\ell-1)\ell^s b < (\ell-1)\ell^{s+1}y$. Let $b \geq \ell y$ and $a = \lceil b/\ell \rceil$, so $\ell a \geq b$

and $a \geq y$. Since $Q_s^{\ell a} = Q_s^{\ell a - b} Q_s^b$, it suffices to show $Q_s^{\ell a} \notin \varpi \ell^K R + Q_{s+1}^y R$ with $K = K_\uparrow(b, y)$. By (iii) and the binomial theorem,

$$Q_s^{\ell a} = (Q_{s+1} + \ell W_s)^a = \sum_{i=0}^{a} \binom{a}{i} \ell^{a-i} W_s^{a-i} Q_{s+1}^i.$$

Apply the expansion bound with $G = Q_{s+1}$ (distinguished by (iii)), $m_i = i$, $c_i = \binom{a}{i}\ell^{a-i} \neq 0$, $u_i = W_s^{a-i}$ and $B = y$: since $y - 1 \leq a$, $\mu \leq v_\varpi(c_{y-1}) = e_L(a - y + 1 + v_\ell\binom{a}{y-1}) = e_L K$, so $Q_s^{\ell a} \notin \varpi^{\mu+1} R + Q_{s+1}^y R \supseteq \varpi^{e_L K + 1} R + Q_{s+1}^y R$. For the bound, let $1 \leq b < \ell(y + \eta)$. If $b < \ell y$ then $K_\uparrow = 0 \leq \eta + 1 + \log_\ell b$. Otherwise $a = \lceil b/\ell \rceil \leq y + \eta$ (as $b/\ell < y + \eta$), so $a - y + 1 \leq \eta + 1$, and $1 \leq a \leq b$. By Legendre's formula $v_\ell\binom{a}{j} = \sum_{t \geq 1} (\lfloor a/\ell^t \rfloor - \lfloor j/\ell^t \rfloor - \lfloor (a-j)/\ell^t \rfloor)$ for $0 \leq j \leq a$; every summand lies in $\{0, 1\}$ and vanishes when $\ell^t > a$, so

$$v_\ell \binom{a}{j} \leq \lfloor \log_\ell a \rfloor \qquad (a \geq 1,\ 0 \leq j \leq a). \tag{C.3}$$

Hence $K_\uparrow(b, y) \leq \eta + 1 + \log_\ell a \leq \eta + 1 + \log_\ell b$.

(Cd3). If $\ell y < B$, suppose $Q_{s+1}^y \in \varpi R + Q_s^B R$; modulo ϖ this gives $X^{(\ell-1)\ell^{s+1} y} \in X^{(\ell-1)\ell^s B} k[[X]]$, impossible as $\ell y < B$. Let $B \leq \ell y$; then $i_1 = \lceil B/\ell \rceil - 1$ satisfies $0 \leq i_1 \leq y - 1$ and $\ell i_1 < B$. By (iii),

$$Q_{s+1}^y = (Q_s^\ell - \ell W_s)^y = \sum_{i=0}^{y} \binom{y}{i} (-\ell)^{y-i} W_s^{y-i} Q_s^{\ell i}.$$

Apply the expansion bound with $G = Q_s$, $m_i = \ell i$, $c_i = \binom{y}{i}(-\ell)^{y-i} \neq 0$, $u_i = W_s^{y-i}$ and B ($m_0 = 0 < B$): $\mu \leq v_\varpi(c_{i_1}) = e_L(y - i_1 + v_\ell\binom{y}{i_1}) = e_L K_\downarrow(y, B)$, which gives the assertion as in (Cd2). Since $i_1 \geq B/\ell - 1$ and, by (C.3), $v_\ell\binom{y}{i_1} \leq \log_\ell y$, we get $K_\downarrow(y, B) \leq y - B/\ell + 1 + \log_\ell y$. □

C.1.4 Lifting graded sections along arcs of length three

This subsection completes Proposition C.25 with the arcs of length three. An arc whose first site is up is treated by Proposition C.37. An arc whose first site has sign -1 (Proposition C.39) takes most of the subsection: it rests on filtered constants by a content bound (Lemma C.40) and on a scalar-multiple lift in the band case (Proposition C.41), whose proof uses a near-horizontal pull-back vector at the up site and its first-level lift (Proposition C.43, Proposition C.44), a Frobenius first lift pushed to the last site (Proposition C.48), and the resulting section vector (Proposition C.49). The lift of a Frobenius-square vector by separation of Γ-weights (Lemma C.45) and the letter condition (Lemma C.46) proved here are used again in Section C.2.

Proposition C.37. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25, and suppose $160\,\mathrm{Sg} \leq b$. Then there is an integer E with $0 \leq E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320}$ such that the following holds for every $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = 1$ (write $e = 3$). Let $\mathbf{n} = (n_k)_{k \leq r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \leq r$ be an index with $\varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{s_{c-s}} D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and let g be admissible at c. Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \geq 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^E g\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.*

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$, $\psi = \mathbf{N}(\Phi)$, $\beta = \beta_{320}$, $e = 3$, and *coordinate vector* for arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, e, H_c, m_X ($m_X > 2h_B \geq 2H_c(x)$, so Lemma C.17 applies).

Exponents and combining. Let $E_C, E_N \leq 6\,\mathrm{Sg}$ be the integers of Proposition C.27 and Lemma C.30, $E_0 = \max(E_C, E_N)$; $\sigma_B \leq 3\,\mathrm{Sg}$.

Let (M_a, h_a) be the window of Lemma C.9, $H(x) = s_x + S + \eta$, and $H_{\max}$, c_H formed with it as in Proposition C.6. Put $E = \lfloor 13\,\mathrm{Sg} \rfloor + \eta\beta \leq 40\,\mathrm{Sg} + \eta\beta_{320}$. We combine data by three rules, each a direct check: (a) if the conclusion holds for g with an exponent $E'' \leq E$ (data w_1, λ', z), it holds with E (data $\ell^{E-E''}w_1, \lambda', \ell^{E-E''}z$), because I_c is an $\mathcal{O}_L$-module (Lemma 24.5 (Ry4)) and coordinate vectors are R_c-linear (Lemma C.17 item 1); (b) data for g_1 and g_2 with the same exponent add to data for $g_1 + g_2$ (sum of the w_j and of the z_j, product of the λ'_j; Lemma C.17 item 1); (c) if $\ell^K g = x_2 + f_2$ with $x_2 \in \mathcal{O}_L$ and $\nu_c f_2 \in \nu_c^+ R_c$, the first part of Proposition C.27 for the constant x_2 (with $\kappa = 0$, $x = x_2$ at every level) and Lemma C.30 for f_2 (its hypothesis on k_0 is the one of the statement) give, by (a) and (b), the conclusion for g with the exponent $E_0 + K$.

The arc. Let $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = 1$, and $\mathbf{n}$, k_0, g as in the statement. As $c-1, c-2 \notin C$, the sites c and $c-1$ are thick; as $c' = c-3 \in C$, the site $a := c-2 = c'+1$ is thin. Signs alternate, so $\epsilon_a = 1$, $\epsilon_{c-1} = -1$, $\epsilon_c = 1$. Hence $h = h_B = b + \eta + S$, and with $b_0 = s_c \leq b + \eta$, $t = s_a$ ($\eta < t \leq w$) and $B = s_{c-1} + S$ ($b \leq B \leq h$):

$$\nu_c = Q_0^{b_0} Q_2^t, \qquad \nu_c^+ = Q_1^B.$$

By admissibility, $\gamma_\delta(g) = g$ for $\delta \in \mu_{\ell-1}$, $\nu_c g \in R_c$, and $\nu_c(\ell^\kappa g - x) \in Q_1^B R_c$ for some $\kappa \geq 0$, $x \in \mathcal{O}_L$. Also $H_{\max} \leq h + \eta \leq 1.05h$ and $c_H \leq 2 + \log_\ell(2h)$; we use $\log_\ell(2h) \leq \mathrm{Sg} - 1$, $\mathrm{Sg} \geq 1$ and $160\,\mathrm{Sg} \leq b$.

The mixed descent. Let $a_0 = \lceil b_0/\ell \rceil$, $X_0 = t - (B - a_0)/\ell + 1 + \log_\ell t$ and $K = \lceil \frac{\ell}{\ell-1} \max(0, X_0) \rceil$. Then $a_0 + K < B$:

By Lemma C.38 item 1, $\nu_c \notin \varpi\ell^K R_c + Q_1^B R_c$, and $Q_1^B \notin \varpi R_c$ (Q_1 is monic). So (Cd1) of Lemma C.36 (with $A = \nu_c$, $N = Q_1^B$, $f = g$) gives $x_2 \in \mathcal{O}_L$ and $f_2 = \ell^K g - x_2$ with $\nu_c f_2 \in \nu_c^+ R_c$.

Case 1: $A_a + \eta + 1 \leq s_a$, $A_a = \lceil \sigma_a/(\ell-1) \rceil$, σ_a the killing index of ψ at a. Let s_{fr} and h_1 be as in Lemma C.38 item 2 for (t, B, η), put $s_i = \min(K, s_{\mathrm{fr}})$ and $h_\star = \ell^{s_{\mathrm{fr}} - s_i} h_1$; so $h_\star$ is Δ-invariant, $Q_2^t h_\star \in R_c$ and $Q_2^t(\ell^{s_i} h_\star - 1) \in Q_1^B Q_0^\eta R_c$. Put $e_4 = K - s_i$, $f_a = x_2 h_\star$ and $f_3 = \ell^{e_4} g - f_a$. *The part f_3.* We have $\nu_c f_3 \in R_c$ and $\ell^{s_i}\nu_c f_3 = \nu_c(\ell^K g - x_2) - x_2 Q_0^{b_0} Q_2^t(\ell^{s_i} h_\star - 1) = \nu_c f_2 - x_2 Q_0^{b_0} Q_2^t(\ell^{s_i} h_\star - 1) \in Q_1^B R_c$. Writing $\ell^{s_i}\nu_c f_3 = Q_1^B \beta'$, the element $Q_1^B \beta'$ lies in $\ell^{s_i} R_c$; reducing modulo a uniformiser in the domain $(\mathcal{O}_L/\varpi)[[X]]$ repeatedly ($Q_1^B \notin \varpi R_c$) gives $\beta' \in \ell^{s_i} R_c$, so $\nu_c f_3 \in \nu_c^+ R_c$. By Lemma C.30 the conclusion holds for f_3 with E_N. *The part f_a (filtered constants with $U = \{2\}$).* Let $\mathbf{n}^{(1)}$ be a frame at c' of $\mathbf{N}_1$ fixed by γ_u, $u \in \mu_{\ell-1}$ (Lemma 24.15; $\mathbf{N}_1$ is a Wach module by (Ex1) of Proposition 23.7), with crystalline frame $(d_m^{(1)})$, and μ the matrix of ψ for $\mathbf{n}^{(1)}$, $\mathbf{n}$. The hypothesis on k_0 at $s = 2$ gives $\varphi(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_2))$ (φ bijective), so Lemma C.35 (for c, $a = c'+1$) gives $\mathbf{c}$ with $\mathbf{c}\mu = \ell^{2\sigma_B}\mathbf{e}_{k_0}$ and $\sum_m c_m \varphi(d_m^{(1)}) \in \varphi^4(\mathrm{Fil}^{s_a} D_{\mathrm{cris}}(V_1))$; applying the L-linear φ^2, $\sum_m c_m \varphi^3(d_m^{(1)}) \in \varphi^{2+4}(\mathrm{Fil}^{s_{c-2}} D_{\mathrm{cris}}(V_1))$. The function f_a is Δ-invariant, $\nu_{\{2\}} f_a = x_2 Q_2^t h_\star \in R_c$, and $\nu_{\{2\}}(\ell^{s_i} f_a - x_2) = x_2 Q_2^t(\ell^{s_i} h_\star - 1)$ lies in $Q_1^B R_c$ ($s = 1$, $t_1 = B$) and in $Q_0^\eta R_c$ ($s = 0$, $t_0 = \eta$). So the clause "Filtered constants" of Proposition C.27 with $U = \{2\}$, $E' = 2\sigma_B$ gives the conclusion for f_a with $3\sigma_B$. By (a), (b) with $E_1 = \max(E_N, 3\sigma_B) \leq 9\,\mathrm{Sg}$, the conclusion holds for $f_3 + f_a = \ell^{e_4} g$ with E_1, i.e. for g with $E_1 + e_4$. If $s_i = K$, $e_4 = 0$. Otherwise $s_i = s_{\mathrm{fr}} \geq t - B/\ell - \eta/\ell - 1$, and if $X_0 \leq 0$ then $K = 0$; so $e_4 \leq 3.3\,\mathrm{Sg}$:

The exponent is at most $12.3\,\mathrm{Sg}$.

Case 2: $s_a \leq A_a + \eta$**.** By (c), the conclusion holds with $E_0 + K$. By (Ki1) of Lemma C.7 with $m = 1$ (for $\Phi\colon T_1 \to T_2$ and the window above; $a+1 = c-1$), $\sigma_a \leq H(c-1) + c_H + 3 + H_{\max}/(\ell-1)$

with $H(c-1) = B + \eta$, and $t \le \sigma_a/(\ell-1) + 1 + \eta$. Hence $K \le \eta + 3.9\,\mathrm{Sg}$:

If $\eta \ge 1$ and $K > 0$, then $\beta = 1$: $X_0 > 0$ gives $\ell s_a > B - a_0 - \ell(1 + \log_\ell t)$, so $b - \ell s_a < h/\ell + 1 + \ell + \ell \log_\ell(2h) \le 2Z$, and $\ell s_a \le \sigma_a + \sigma_a/(\ell-1) + \ell + \ell\eta$ gives $\ell s_a - b \le 3Z$, where $Z = \ell\eta + \ell S + b/\ell + s_a + \ell \log_\ell(2h)$; and the thin site a has the thick neighbour $c-1$.

So $K \le \eta\beta + 3.9\,\mathrm{Sg}$, and the exponent is at most $9.9\,\mathrm{Sg} + \eta\beta$.

Conclusion. The two cases cover all $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = 1$; each gives an integer exponent at most $13\,\mathrm{Sg} + \eta\beta$, hence at most E, and (a) raises it to E. □

Lemma C.38. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$ and uniformiser ϖ, $R = \mathcal{O}_L[[X]]$ and $\mathcal{K}$ its field of fractions.*

1. Mixed pole. *Let $b_0 \ge 0$, $t \ge 1$, $B \ge 1$ and $K \ge 0$ be integers, $a = \lceil b_0/\ell \rceil$, with $a + K < B$ and $K \ge K_\downarrow(t, B - a - K)$. Then*

$$Q_0^{b_0} Q_2^t \notin \varpi\ell^K R + Q_1^B R.$$

   The hypothesis $K \ge K_\downarrow(t, B-a-K)$ holds for every integer $K \ge \frac{\ell}{\ell-1}\max(0,\ t - (B - a)/\ell + 1 + \log_\ell t)$ with $a + K < B$.

2. Fractions. *Let $t, B, \eta \ge 0$ be integers and $s_{\mathrm{fr}} = \max(0,\ \lceil t - B/\ell \rceil - \lceil \eta/\ell \rceil)$. Then $Q_2^t \in \ell^{s_{\mathrm{fr}}} R + Q_1^B Q_0^\eta R$, and there is a Δ-invariant $h \in \mathcal{K}$ with*

$$Q_2^t h \in R \qquad \text{and} \qquad Q_2^t(\ell^{s_{\mathrm{fr}}} h - 1) \in Q_1^B Q_0^\eta R.$$

Proof. Write $e_L = v_\varpi(\ell)$, so $\varpi\ell^K R = \varpi^{e_L K + 1} R$.

Two facts. (A) *For $s \ge 0$, $Q_s^\ell = Q_{s+1} + \ell W_s$ with $W_s \in R^\times$. $Q_s = \sum_{i<\ell}(1+X)^{i\ell^s} \in \mathbb{Z}[X]$* is monic of degree $(\ell-1)\ell^s$ with $Q_s(0) = \ell$; in $\mathbb{F}_\ell[X]$, $(1+X)^{\ell^s} = 1 + X^{\ell^s}$, so $Q_s \equiv X^{(\ell-1)\ell^s}$ and $Q_s^\ell \equiv X^{(\ell-1)\ell^{s+1}} \equiv Q_{s+1}$ modulo ℓ. Hence $W_s = (Q_s^\ell - Q_{s+1})/\ell \in \mathbb{Z}[X]$, and $W_s(0) = \ell^{\ell-1} - 1 \in \mathbb{Z}_\ell^\times$, so $W_s \in R^\times$. (B) *If $G \in R \setminus \varpi R$, $j \ge 0$, $y \in R$ and $Gy \in \varpi^j R$, then $y \in \varpi^j R$:* for $j \ge 1$, the reductions satisfy $\bar{G}\bar{y} = 0$ in the domain $(\mathcal{O}_L/\varpi)[[X]]$ with $\bar{G} \ne 0$, so $y = \varpi y'$ with $Gy' \in \varpi^{j-1}R$ (R is a domain), and induction on j applies. The monic polynomials Q_s^N lie in $R \setminus \varpi R$.

Item 1. Suppose $Q_0^{b_0} Q_2^t \in \varpi\ell^K R + Q_1^B R$, and put $N = a + K < B$. By (A) and the binomial theorem,

$$Q_1^N = (Q_0^\ell - \ell W_0)^N = \sum_{j=0}^{N} \binom{N}{j} Q_0^{\ell j} (-\ell W_0)^{N-j}.$$

For $j \ge a$, $Q_0^{\ell j} \in Q_0^{b_0} R$ as $\ell j \ge \ell a \ge b_0$; for $j < a$, $N - j \ge K + 1$. So $Q_1^N = Q_0^{b_0} g_1 + \ell^{K+1} g_2$ with $g_1, g_2 \in R$, and

$$Q_1^N Q_2^t = g_1\, Q_0^{b_0} Q_2^t + \ell^{K+1} g_2 Q_2^t \in \varpi\ell^K R + Q_1^B R,$$

since $\ell^{K+1} \in \varpi\ell^K R$. Write $Q_1^N Q_2^t = \varpi\ell^K \alpha + Q_1^B \beta$. Then $Q_1^N (Q_2^t - Q_1^{B-N}\beta) \in \varpi^{e_L K + 1} R$, and by (B) $Q_2^t \in \varpi\ell^K R + Q_1^{B-N} R$. Since $K \ge K_\downarrow(t, B-N)$, this contradicts (Cd3) of Lemma C.36 (with $s = 1$, $y = t$ and $B - N \ge 1$ in place of B), which gives $Q_2^t \notin \varpi\ell^{K_\downarrow(t,B-N)} R + Q_1^{B-N} R \supseteq \varpi\ell^K R + Q_1^{B-N} R$.

For the last assertion, let $x_0 = t - (B-a)/\ell + 1 + \log_\ell t$ and $K \ge \frac{\ell}{\ell-1}\max(0, x_0)$ with $a + K < B$. Then $K \ge 0$ and $K - K/\ell \ge x_0$, i.e. $K \ge t - (B - a - K)/\ell + 1 + \log_\ell t$; by (Cd3), $K_\downarrow(t, B-a-K) \le \max(0,\ t - (B-a-K)/\ell + 1 + \log_\ell t) \le K$.

Item 2. Put $\lambda = \lceil \eta/\ell \rceil$. For $j \geq 0$, (A) gives $Q_1^j = \sum_{k \leq j} \binom{j}{k} Q_0^{\ell k} (-\ell W_0)^{j-k}$; the terms with $k \geq \lambda$ lie in $Q_0^\eta R$ ($\ell k \geq \eta$), those with $k < \lambda$ in $\ell^{j-\lambda+1} R$, so

$$Q_1^j \in Q_0^\eta R + \ell^{\max(0,\, j-\lambda+1)} R.$$

By (A), $Q_2^t = \sum_{i \leq t} \binom{t}{i} (-\ell W_1)^{t-i} Q_1^{\ell i}$. A term with $\ell i < B$ lies in $\ell^{t-i} R$, and the integer $t - i$ exceeds $t - B/\ell$, so $t - i \geq \lceil t - B/\ell \rceil \geq s_{\mathrm{fr}}$ (and $t - i \geq 0$). A term with $\ell i \geq B$ lies in $\ell^{t-i} Q_1^B Q_1^{\ell i - B} R \subseteq Q_1^B Q_0^\eta R + \ell^{\, t-i+\max(0, \ell i - B - \lambda + 1)} R$, and

$$t - i + (\ell i - B - \lambda + 1) = t - B + (\ell - 1) i - \lambda + 1 \geq t - B/\ell - \lambda + 1,$$

using $i \geq B/\ell$; as the left side is an integer, it is $\geq \lceil t - B/\ell \rceil - \lambda + 1 > s_{\mathrm{fr}}$ unless $s_{\mathrm{fr}} = 0$, and $t - i \geq 0$. Hence $Q_2^t \in \ell^{s_{\mathrm{fr}}} R + Q_1^B Q_0^\eta R$. Write $Q_2^t = \ell^{s_{\mathrm{fr}}} F + Q_1^B Q_0^\eta M$ with $F, M \in R$, and put $h_0 = F/Q_2^t \in \mathcal{K}$; then $Q_2^t h_0 = F \in R$ and $Q_2^t(\ell^{s_{\mathrm{fr}}} h_0 - 1) = -Q_1^B Q_0^\eta M$. For $u \in \mathbb{Z}_\ell^\times$ and $s \geq 0$, $\gamma_u(Q_s) = Q_s \upsilon_{u,s}$ with $\upsilon_{u,s} \in \mathbb{Z}_\ell[[X]]^\times$ (Lemma C.16 (b), first assertion, a statement about $\mathbb{Z}_\ell[[X]]$). Hence for $\delta \in \mu_{\ell-1}$, $Q_2^t \gamma_\delta(h_0) = \upsilon_{\delta,2}^{-t} \gamma_\delta(F) \in R$ and $Q_2^t(\ell^{s_{\mathrm{fr}}} \gamma_\delta(h_0) - 1) = \upsilon_{\delta,2}^{-t} \gamma_\delta(Q_2^t(\ell^{s_{\mathrm{fr}}} h_0 - 1)) \in Q_1^B Q_0^\eta R$. Put $h = (\ell - 1)^{-1} \sum_{\delta \in \mu_{\ell-1}} \gamma_\delta(h_0)$ ($\ell - 1 \in \mathcal{O}_L^\times$). It is Δ-invariant, as $\mu_{\ell-1}$ is a group and $\gamma_{\delta\delta'} = \gamma_\delta \gamma_{\delta'}$, and averaging the two memberships (since $\ell^{s_{\mathrm{fr}}} h - 1 = (\ell - 1)^{-1} \sum_\delta (\ell^{s_{\mathrm{fr}}} \gamma_\delta(h_0) - 1)$) gives $Q_2^t h \in R$ and $Q_2^t(\ell^{s_{\mathrm{fr}}} h - 1) \in Q_1^B Q_0^\eta R$. □

Proposition C.39. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25, and suppose $160\,\mathrm{Sg} \leq b$. Then there is an integer E with $0 \leq E \leq 40\,\mathrm{Sg} + \eta\,\beta_{320}$ such that the following holds for every $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = -1$ (write $e = 3$). Let $\mathbf{n} = (n_k)_{k \leq r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), let $k_0 \leq r$ be an index with $\varphi^e(d_{k_0}) \in \varphi^{s+4}(\mathrm{Fil}^{\,s_{c-s}} D_{\mathrm{cris}}(V_2))$ for every $s < e$ with $\epsilon_{c-s} = 1$, and let g be admissible at c. Then there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \geq 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\, \mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^E g\, \mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.*

Proof. Write $R_c = e_c \mathbf{A}_{F,L}$, $\psi = \mathbf{N}(\Phi)$, $\beta = \beta_{320}$, $e = 3$, and *coordinate vector* for arc coordinate vector for $\mathbf{N}_2$, $\mathbf{n}$, e, H_c, m_X ($m_X > 2h_B \geq 2H_c(x)$, so Lemma C.17 applies).

Exponents and combining. Let $E_C \leq 6\,\mathrm{Sg}$ be the integer of Proposition C.27; $\sigma_B \leq 3\,\mathrm{Sg}$.

Let (M_a, h_a) be the window of Lemma C.9, $H(x) = s_x + S + \eta$, and $H_{\max}$, c_H formed with it as in Proposition C.6. Put $E = \lfloor 22\,\mathrm{Sg} \rfloor + \eta\beta \leq 40\,\mathrm{Sg} + \eta\beta_{320}$. We combine data by three rules, each a direct check: (a) if the conclusion holds for g with an exponent $E'' \leq E$ (data w_1, λ', z), it holds with E (data $\ell^{E-E''} w_1, \lambda', \ell^{E-E''} z$), because I_c is an $\mathcal{O}_L$-module (Lemma 24.5 (Ry4)) and coordinate vectors are R_c-linear (Lemma C.17 item 1); (b) data for g_1 and g_2 with the same exponent add to data for $g_1 + g_2$ (sum of the w_j and of the z_j, product of the λ'_j; Lemma C.17 item 1); (c) data for g with an exponent E'', multiplied by $u \in \mathcal{O}_L$ (the w_1 and z multiplied by u), are data for ug with the exponent E'', by the same two facts.

The arc. Let $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = -1$, and $\mathbf{n}$, k_0, g as in the statement. As $c - 1, c - 2 \notin C$, the sites c and $c - 1$ are thick; as $c' = c - 3 \in C$, the site $c - 2 = c' + 1$ is thin. Signs alternate, so $\epsilon_{c-1} = 1$, $\epsilon_c = -1$. Hence $h = h_B = b + \eta + S$, and with $b_1 = s_{c-1}$ ($b \leq b_1 \leq b + \eta$), $s_2 = s_{c-2}$ ($\eta < s_2 \leq w$) and $y = s_2 + S + \eta$, the only up level is $s = 1$ and $\nu_c = Q_1^{b_1}$. By admissibility, $\gamma_\delta(g) = g$ for $\delta \in \mu_{\ell-1}$, $Q_1^{b_1} g \in R_c$, and there are $\kappa_0, \kappa_2 \geq 0$, $x', x'' \in \mathcal{O}_L$ with

$$Q_1^{b_1}(\ell^{\kappa_0} g - x') \in Q_0^{s_c + S} R_c, \qquad Q_1^{b_1}(\ell^{\kappa_2} g - x'') \in Q_2^{s_2 + S} R_c.$$

Also $H_{\max} \le h+\eta \le 1.05h$ and $c_H \le 2+\log_\ell(2h)$; we use $h \le 1.1b$, $\log_\ell(2h) \le \mathrm{Sg}-1$, $\mathrm{Sg} \ge 1$ and $160\,\mathrm{Sg} \le b$. The hypothesis on k_0 at $s=1$ reads $\varphi^3(d_{k_0}) \in \varphi^5(\mathrm{Fil}^{b_1} D_{\mathrm{cris}}(V_2))$, i.e. $\varphi^2(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{b_1} D_{\mathrm{cris}}(V_2))$ (φ is bijective).

Case C: $\ell y \le b_1$. Let $a=c-1$, σ_a the killing index of ψ at a, $A=\lceil \sigma_a/(\ell-1)\rceil$, and

$$t = \Big\lfloor \frac{A+\eta-1+\ell(1+\log_\ell y)}{\ell-1} \Big\rfloor + 1.$$

Then $t \ge 1$ and $(\ell-1)t > A+\eta-1+\ell(1+\log_\ell y)$. By (Ki1) of Lemma C.7 with $m=1$ (for $\Phi\colon T_1 \to T_2$ and the window above; $a+1=c$), $\sigma_a \le H(c)+c_H+3+H_{\max}/(\ell-1)$ with $H(c)=s_c+S+\eta \le h+\eta$; this gives $A+\eta+t \le b_1$ and $t \le 2.3\,\mathrm{Sg}$:

Let $\mathbf{n}^{(1)}$ be a frame at c' of $\mathbf{N}_1$ fixed by γ_u, $u \in \mu_{\ell-1}$ (Lemma 24.15; $\mathbf{N}_1$ is a Wach module by (Ex1) of Proposition 23.7), with crystalline frame $(d_m^{(1)})$, and μ the matrix of ψ for $\mathbf{n}^{(1)}$, $\mathbf{n}$. By Lemma C.40 there is $\mathbf{c} \in \mathcal{O}_L^{r_1}$ with $\mathbf{c}\mu = \ell^{2\sigma_B+t}\mathbf{e}_{k_0}$ and $\sum_m c_m \varphi^2(d_m^{(1)}) \in \varphi^4(\mathrm{Fil}^{b_1} D_{\mathrm{cris}}(V_1))$; applying the L-linear φ, $\sum_m c_m \varphi^3(d_m^{(1)}) \in \varphi^{1+4}(\mathrm{Fil}^{s_{c-1}} D_{\mathrm{cris}}(V_1))$. With $U=\{1\}$ (the set of all up levels), $\nu_U = \nu_c$ and the conditions on g in the clause "Filtered constants" of Proposition C.27 are the admissibility of g. That clause with $E' = 2\sigma_B + t$ gives the conclusion for g with the exponent $3\sigma_B + t \le 11.3\,\mathrm{Sg}$ (and $z=0$), and (a) raises it to E.

Case D: $b_1 < \ell y$. *Descent at the level of the first site.* Let $K = K_\uparrow(b_1, s_2+S)$ as in (Cd2) of Lemma C.36 (with $s=1$); then $Q_1^{b_1} \notin \varpi\ell^K R_c + Q_2^{s_2+S} R_c$, and $Q_2^{s_2+S} \notin \varpi R_c$ (Q_2 is monic). So (Cd1) of Lemma C.36 (with $A = Q_1^{b_1}$, $N = Q_2^{s_2+S}$, $f=g$, $\kappa=\kappa_2$, $x=x''$) gives $x_2 \in \mathcal{O}_L$ and $f_2 = \ell^K g - x_2$ with $Q_1^{b_1} f_2 \in Q_2^{s_2+S} R_c$, $\gamma_\delta(f_2) = f_2$ for $\delta \in \mu_{\ell-1}$, and, from the congruence at level 0, $Q_1^{b_1}(\ell^{\kappa_0} f_2 - (\ell^K x' - \ell^{\kappa_0} x_2)) \in Q_0^{s_c+S} R_c$. *Bound for K.* If $b_1 < \ell(s_2+S)$ then $K=0$. Otherwise $b_1 \ge 1$ and $b_1 < \ell(s_2+S+\eta)$, so by (Cd2) $K \le \eta+1+\log_\ell b_1 \le \eta+\mathrm{Sg}$; and then $\beta=1$: the thin site $c-2$ has the thick neighbour $c-1$, and $\ell s_2 \le b_1 - \ell S \le b+\eta$, $\ell s_2 > b_1 - \ell(S+\eta) \ge b - \ell(S+\eta)$, so $|\ell s_2 - b| \le \ell\eta + \ell S \le 320(\ell\eta + \ell S + b/\ell + s_2 + \ell\log_\ell(2h))$. In both cases $K \le \eta\beta + \mathrm{Sg}$. *The two lifts.* By Proposition C.41 (its hypotheses on c, $\mathbf{n}$, k_0 are those above, and on f_2 were just checked, with $\kappa=\kappa_0$, $x_0 = \ell^K x' - \ell^{\kappa_0} x_2$) there are $e_D \le 6\,\mathrm{Sg}$, $t_3 \in \mathcal{O}_L \setminus \{0\}$ with $v_\ell(t_3) \le 14\,\mathrm{Sg}$, and data for $t_3 f_2$ with the exponent e_D. The constant $t_3 x_2 \in \mathcal{O}_L$ satisfies the hypothesis of the first part of Proposition C.27 (with $\kappa=0$, $x = t_3 x_2$ at every level), which gives data for it with the exponent E_C. By (a) and (b), with $e_0 = \max(e_D, E_C) \le 6\,\mathrm{Sg}$, there are data for $t_3 x_2 + t_3 f_2 = t_3 \ell^K g$ with the exponent e_0. *Rescaling.* Let $N = \lceil v_\ell(t_3)\rceil + K$ and $u = \ell^N/(t_3\ell^K)$; $v_\ell(u) \ge 0$, so $u \in \mathcal{O}_L$. By (c) there are data for $u\,t_3\ell^K g = \ell^N g$ with the exponent e_0, i.e. for g with the exponent $e_0 + N \le 6\,\mathrm{Sg} + 14\,\mathrm{Sg} + 1 + \eta\beta + \mathrm{Sg} \le 22\,\mathrm{Sg} + \eta\beta$, an integer; so it is at most E, and (a) raises it to E.

Conclusion. Cases C and D cover all $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = -1$, each with the exponent E. □

Lemma C.40. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25; put $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$ and $r_\nu = \dim_L V_\nu$. Let $c \in C$ with $\mathrm{len}_c = 3$ and $\epsilon_{c-2} = -1$, put $c' = c-3$, $a = c-1$, $b_1 = s_{c-1}$, $y = s_{c-2} + S + \eta$ and $A = A_a = \lceil \sigma_a/(\ell-1)\rceil$, where σ_a is the killing index of $\mathbf{N}(\Phi)$ at a, and suppose*

$$\ell\, y \le b_1.$$

Let $t \ge 1$ be an integer with

$$A+\eta+t \le b_1 \qquad \text{and} \qquad (\ell-1)\,t > A+\eta-1+\ell(1+\log_\ell y).$$

Let $\mathbf{n} = (n_k)_{k \le r_2}$ and $\mathbf{n}^{(1)} = (n_m^{(1)})_{m \le r_1}$ be frames at c' of $\mathbf{N}_2$ and $\mathbf{N}_1$, with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$ and all k, with crystalline frames (d_k) and $(d_m^{(1)})$, let $\mu \in M_{r_1 \times r_2}(\mathcal{O}_L)$ be the

matrix of $\mathbf{N}(\Phi)$ *for* $\mathbf{n}^{(1)}$ *and* $\mathbf{n}$*, and let* $k_0 \le r_2$ *with*

$$\varphi^2(d_{k_0}) \in \varphi^4\big(\mathrm{Fil}^{\,b_1} D_{\mathrm{cris}}(V_2)\big).$$

Then there is $\mathbf{c} = (c_m)_{m \le r_1} \in \mathcal{O}_L^{r_1}$ *with*

$$\mathbf{c}\,\mu = \ell^{2\sigma_B + t}\mathbf{e}_{k_0} \qquad \text{and} \qquad \sum_m c_m\,\varphi^2(d_m^{(1)}) \in \varphi^4\big(\mathrm{Fil}^{\,b_1} D_{\mathrm{cris}}(V_1)\big);$$

in particular $(1 \otimes \Phi)\big(\sum_m c_m d_m^{(1)}\big) = \ell^{2\sigma_B + t} d_{k_0}$.

Proof. Write $R = e_a \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $Q = Q_0$, $s_2 = s_{c-2}$, $H = H_c$, and let π_0, $q = \pi_0 + \ell$, ω, ω_1, R^Δ, $\mathcal{K}^\Delta$ and the average $f \mapsto \bar{f}$ be as in Lemma C.34. A *coordinate vector* (for $\mathbf{N}_\nu$) is an arc coordinate vector for $\mathbf{n}$ (resp. $\mathbf{n}^{(1)}$), $e = 2$, H and m_X: this is the initial sub-arc $c' \to c' + 2 = a$ of the arc of c, with level 0 at the site $a = c - 1$ and level 1 at the site $c - 2$; for $\mathbf{v} \in L^{r_\nu}$ the vector $\varphi^{-(s+4)}(\delta_2(\mathbf{v}))$ lies in the component $\varepsilon D_{\mathrm{cris}}(V_\nu)$ of τ_{a-s}, on which $\varepsilon\,\mathrm{Fil}^\bullet$ is the Hodge filtration at τ_{a-s} (Definition 23.3), and $\mathrm{Fil}^u D_{\mathrm{cris}}$ is stable under $F \otimes L$.

Step 0: the arc. As $c-1, c-2 \notin C$ and $c' \in C$, the sites c, $c-1$ are thick and $c - 2 = c' + 1$ is thin; signs alternate, so $\epsilon_{c-1} = 1$, $\epsilon_c = -1$. Hence $b \le b_1 \le b + \eta$, $\eta < s_2 \le w$, $h_B = b + \eta + S \ge b_1 + S$, $H(c-1) = h_B$, $H(c-2) = w + S$ and $\Pi' := \Lambda_{a,2}(H) = Q^{h_B} Q_1^{w+S}$. By (Ow1), the Hodge jumps of V_1 at τ_{c-1} lie in $[b_1, b_1 + S] \cup [-\eta, \eta]$ and those at τ_{c-2} in $[-s_2 - S, -s_2] \cup [-\eta, \eta]$; by Lemma C.16 (1) every Hodge jump of V_1, V_2 at τ_x has absolute value at most $s_x + S \le H(x)$. Also $y \ge s_2 \ge 1$, and $m_X > 2h_B \ge 2H(x)$, so Lemma C.17 applies.

Step 1: realising the section. Put $g_2 = q^{-b_1}\varphi(q)^{s_2+S} \in \mathcal{K}^\Delta$. By (Dv2), (Dv2') of Lemma C.34, $g_2 \in Q^{-b_1} Q_1^{s_2+S} R$ and $\Pi' g_2 \in Q^{h_B - b_1} Q_1^{w+S+s_2+S} R \subseteq R$. The section decomposition $(g_2, \mathbf{e}_{k_0}, \alpha)$ with $\alpha(0) = -b_1$, $\alpha(1) = s_2 + S$ shows that $g_2\mathbf{e}_{k_0}$ is Hodge-graded: $\delta_2(\mathbf{e}_{k_0}) = \varphi^2(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{b_1})$ by hypothesis, and $\varphi^{-5}(\varphi^2(d_{k_0}))$ lies in the component of τ_{c-2}, where V_2 has no Hodge jump below $-(s_2 + S)$, hence in $\mathrm{Fil}^{-(s_2+S)}$. By Proposition C.23 (R3) with $e_1 = 2$ ($\nu = 2$, the $\mu_{\ell-1}$-fixed frame $\mathbf{n}$) there is $y_2 \in \mathbf{N}_{2,a}$ such that $\ell^{\sigma_B} g_2 \mathbf{e}_{k_0}$ is a coordinate vector of y_2.

Step 2: killing the cokernel; coordinates. By Lemma 28.15 item 1, $\pi_0 = X^{\ell-1} v$ with v a unit, so by (Ki3) of Lemma C.7 π_0^A is killing at a: there is $x_0 \in \mathbf{N}_{1,a}$ with $\mathbf{N}(\Phi)(x_0) = \pi_0^A y_2$. By Step 0, $(H(x))_x$ is a window for $\mathbf{N}_1$ as in (Ex1) of Proposition 23.7, so (Wm2) gives $Q^{H(x)}\mathbf{N}_{1,x} \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{1,x-1})$ for every x; applying this at $x = a$ and, after φ (with $\varphi(Q) = Q_1$), at $x = c - 2$,

$$\Pi'\mathbf{N}_{1,a} = Q_1^{H(c-2)} Q^{H(c-1)} \mathbf{N}_{1,a} \subseteq \mathbf{A}_{F,L}\varphi\big(Q^{H(c-2)}\mathbf{N}_{1,c-2}\big) \subseteq \mathbf{A}_{F,L}\varphi^2(\mathbf{N}_{1,c'}) = P_2(\mathbf{N}_{1,c'}).$$

Hence Lemma C.14 (with c', $e = 2$, H, m_X and $\sigma = \sigma_B \ge (2H(c'+1) + m_X/(\ell-1))\ell/(\ell-1)^2$) gives a coordinate vector f of $\ell^{\sigma_B} x_0$ with $\Pi' f_m \in R$, and Lemma 23.13 (2) gives $t', \kappa \ge 0$ and a coordinate vector f' of $\ell^{t'} x_0$ with $\ell^\kappa f'$ Hodge-graded.

Step 3: the two congruences. By Lemma C.29 (2), $f\mu$ is a coordinate vector of

$$\mathbf{N}(\Phi)(\ell^{\sigma_B} x_0) = \ell^{\sigma_B}\pi_0^A y_2,$$

and so is $\ell^{2\sigma_B}\pi_0^A g_2 \mathbf{e}_{k_0}$ (Lemma C.17 item 1); $\ell^{t'} f$ and $\ell^{\sigma_B} f'$ are coordinate vectors of $\ell^{t' + \sigma_B} x_0$. By Lemma C.17 item 2,

$$f\mu - \ell^{2\sigma_B}\pi_0^A g_2 \mathbf{e}_{k_0} \in (X\Pi' R)^{r_2}, \qquad \ell^{t'+\kappa} f = \sum_i g_i \mathbf{v}_i + X\Pi'\mathbf{h},$$

where $\mathbf{h} \in R^{r_1}$, $g_i \in Q^{\alpha_i(0)}Q_1^{\alpha_i(1)}R$, $\mathbf{v}_i \in \mathcal{O}_L^{r_1}$ and

$$\delta_2(\mathbf{v}_i) \in \varphi^4(\mathrm{Fil}^{-\alpha_i(0)}D_{\mathrm{cris}}(V_1)) \cap \varphi^5(\mathrm{Fil}^{-\alpha_i(1)}D_{\mathrm{cris}}(V_1))$$

(the $\ell^{-\sigma_B}g_i$ forming a section decomposition of $\ell^\kappa f'$).

Step 4: bounded poles. If $\mathbf{v}_i \neq 0$ then $-\alpha_i(0) \leq b_1 + S$ and $-\alpha_i(1) \leq \eta$: $\varphi^{-4}\delta_2(\mathbf{v}_i)$ lies in the component of τ_{c-1}, whose Fil^u is 0 for $u > b_1 + S$, and $\varphi^{-5}\delta_2(\mathbf{v}_i)$ in the component of τ_{c-2}, whose Fil^u is 0 for $u > \eta$ (Step 0); if either inequality failed, $\varphi^2(\sum_m v_{i,m}d_m^{(1)}) = \delta_2(\mathbf{v}_i) = 0$, so $\mathbf{v}_i = 0$, as φ is bijective and the $d_m^{(1)}$ are linearly independent (Lemma 23.10 item 1). We drop the terms with $\mathbf{v}_i = 0$.

Step 5: clearing the poles. Put $\Psi = q^{b_1+S}\varphi(q)^\eta \in R^\Delta$, so $\Psi \in Q^{b_1+S}Q_1^\eta R^\times$. By Step 4, $\Psi g_i \in R$, and $\Psi X\Pi'\mathbf{h} \in R^{r_1}$; so $\ell^{t'+\kappa}\Psi f_m \in R$. Also $\Psi f_m = G^{-1}A_m$ with $G = Q^{h_B-b_1-S}Q_1^{w+S-\eta}$ (exponents ≥ 0 by Step 0) and $A_m = (\Psi\Pi'^{-1}G)\,\Pi' f_m \in R$. So $\ell^{t'+\kappa}A_m \in GR$; as G is a monic polynomial, R/GR is ℓ-torsion free (reduce modulo a uniformiser in the domain $(\mathcal{O}_L/\varpi)[[X]]$ and induct), so $A_m \in GR$ and $\Psi f_m \in R$.

Step 6: averaging. Put $\Phi_m = \overline{\Psi f_m} = \Psi\bar{f}_m \in R^\Delta$. Multiply the relations of Step 3 by Ψ and average. Since $\Psi\pi_0^A g_2 = (q-\ell)^A q^S\varphi(q)^y$, $\Psi X\Pi' R = XQ^{h_B+b_1+S}Q_1^{w+S+\eta}R$, and μ, $\mathbf{v}_i$ are constant, (Dv3) and (Dv2') give

$$\Phi\mu - \mathcal{F}\,\mathbf{e}_{k_0} \in \mathcal{E}^{r_2}, \qquad \ell^{t'+\kappa}\Phi - \sum_i \Psi\bar{g}_i\,\mathbf{v}_i \in \mathcal{E}^{r_1},$$
$$\mathcal{F} = \ell^{2\sigma_B}(q-\ell)^A q^S\varphi(q)^y,$$

with $\mathcal{E} = \pi_0 q^{h_B+b_1+S}\varphi(q)^{w+S+\eta}R^\Delta$ and $\Psi\bar{g}_i \in q^{b_1+S+\alpha_i(0)}\varphi(q)^{\eta+\alpha_i(1)}R^\Delta$ (both exponents ≥ 0).

Step 7: a coefficient of small valuation. In $R^\Delta = \mathcal{O}_L[[q]]$ (Lemma C.34 (Dv1)) let λ_j be the coefficient of q^j, and put $B_0 = b_1 + S - \eta$. We claim that $\ell^{2\sigma_B+t} \nmid \lambda_j(\mathcal{F})$ for some $j < B_0$. Suppose not. Since $\ell^{2\sigma_B}$ is a non-zero element of the domain $\mathcal{O}_L$, every coefficient λ_j, $j < B_0$, of $\mathcal{G} = (q-\ell)^A q^S\varphi(q)^y$ is divisible by ℓ^t, i.e. $\mathcal{G} \in \ell^t R^\Delta + q^{B_0}R^\Delta$. Expanding $q^{A+t-1} = ((q-\ell)+\ell)^{A+t-1}$ by the binomial theorem, the terms with ℓ^i, $i \geq t$, lie in $\ell^t\mathcal{O}_L[q]$ and the others contain $(q-\ell)^{A+t-1-i}$ with $A+t-1-i \geq A$; so $q^{A+t-1} \in (q-\ell)^A\mathcal{O}_L[q] + \ell^t\mathcal{O}_L[q]$, and hence $q^{A+t-1+S}\varphi(q)^y \in \ell^t R^\Delta + q^{B_0}R^\Delta$. Its coefficient of $q^{j+A+t-1+S}$ is $\lambda_j(\varphi(q)^y)$, so with $B = B_0 - (A+t-1+S) = b_1 - \eta - A - t + 1 \geq 1$ (hypothesis),

$$\varphi(q)^y \in \ell^t R^\Delta + q^B R^\Delta.$$

By (Dv2), (Dv2'), $\varphi(q)^y = Q_1^y\omega_1^y$ and $q^B = Q^B\omega^B$ with units ω, ω_1; multiplying by ω_1^{-y}, $Q_1^y \in \ell^t R + Q^B R \subseteq \varpi\ell^{t-1}R + Q^B R$. By (Cd3) of Lemma C.36 (with $s = 0$, $y \geq 1$, $B \geq 1$), $Q_1^y \notin \varpi\ell^K R + Q^B R$ for $K = K_\downarrow(y, B) \leq \max(0,\, y - B/\ell + 1 + \log_\ell y)$; so $t - 1 < K$, i.e. $t \leq K$. But $\ell y \leq b_1$ gives $y - B/\ell \leq (\eta + A + t - 1)/\ell$, so

$$K \leq \max\Big(0,\ \frac{\eta + A + t - 1}{\ell} + 1 + \log_\ell y\Big) < t,$$

the last inequality being $t \geq 1$ and the hypothesis $(\ell-1)t > A + \eta - 1 + \ell(1 + \log_\ell y)$. This contradiction proves the claim.

Step 8: reading the coefficient. Fix $j < B_0$ as in Step 7. As $\mathcal{O}_L$ is a discrete valuation ring and $\ell^{2\sigma_B+t} \nmid \lambda_j(\mathcal{F})$, there is $u \in \mathcal{O}_L$ with $u\,\lambda_j(\mathcal{F}) = \ell^{2\sigma_B+t}$. Every element of $q^N R^\Delta$ has $\lambda_j = 0$ if $N > j$; since $j < B_0 \leq h_B + b_1 + S$, $\lambda_j(\mathcal{E}) = 0$. Put $\mathbf{c} = u\,(\lambda_j(\Phi_m))_m \in \mathcal{O}_L^{r_1}$. The first relation of Step 6 gives $\mathbf{c}\mu = u\lambda_j(\mathcal{F})\mathbf{e}_{k_0} = \ell^{2\sigma_B+t}\mathbf{e}_{k_0}$. The second gives $\ell^{t'+\kappa}\mathbf{c} = u\sum_i \lambda_j(\Psi\bar{g}_i)\mathbf{v}_i$, and $\lambda_j(\Psi\bar{g}_i) = 0$ unless $b_1 + S + \alpha_i(0) \leq j < b_1 + S - \eta$, i.e. $-\alpha_i(0) \geq \eta + 1$.

For the remaining i, $\varphi^{-4}\delta_2(\mathbf{v}_i) \in \mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1)$; as δ_2 is L-linear and $\mathrm{Fil}^{\eta+1}$ is an L-subspace, $z := \varphi^{-4}(\sum_m c_m\varphi^2(d_m^{(1)})) \in \mathrm{Fil}^{\eta+1}D_{\mathrm{cris}}(V_1)$, and z lies in the component of τ_{c-1}.

Step 9: the Hodge gap. On the component of τ_{c-1} the Hodge filtration of V_1 has no jump in $[\eta+1, b_1-1]$ (Step 0), so there $\mathrm{Fil}^{\eta+1} = \mathrm{Fil}^{b_1}$ and $z \in \mathrm{Fil}^{b_1}D_{\mathrm{cris}}(V_1)$. Finally $(1\otimes\Phi)(d_m^{(1)}) = \sum_k \mu_{mk}d_k$ (Lemma C.29 (1)) gives $(1\otimes\Phi)(\sum_m c_m d_m^{(1)}) = \ell^{2\sigma_B+t}d_{k_0}$. □

Proposition C.41. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.25, and suppose $160\,\mathrm{Sg} \le b$. Let $c \in C$ with $\mathrm{len}_c = 3$, $\epsilon_{c-2} = -1$ and*

$$s_{c-1} < \ell\,(s_{c-2} + S + \eta)$$

(write $e = 3$, $R_c = e_c\mathbf{A}_{F,L}$). Let $\mathbf{n} = (n_k)_{k\le r}$ be a frame at c' of $\mathbf{N}_2$ with $\gamma_u(n_k) = n_k$ for $u \in \mu_{\ell-1}$, with crystalline frame (d_k), and $k_0 \le r$ with $\varphi^3(d_{k_0}) \in \varphi^5(\mathrm{Fil}^{\,s_{c-1}}D_{\mathrm{cris}}(V_2))$. Let $f_2 \in \mathcal{K}_c$ with $\gamma_u(f_2) = f_2$ for $u \in \mu_{\ell-1}$,

$$Q_1^{s_{c-1}}f_2 \in Q_2^{s_{c-2}+S}R_c,$$

and such that $Q_1^{s_{c-1}}(\ell^\kappa f_2 - e_c(1\otimes x_0)) \in Q_0^{s_c+S}R_c$ for some integer $\kappa \ge 0$ and some $x_0 \in \mathcal{O}_L$. Then there are an integer e_D with $0 \le e_D \le 6\,\mathrm{Sg}$ and $t_3 \in \mathcal{O}_L \setminus \{0\}$ with $v_\ell(t_3) \le 14\,\mathrm{Sg}$, and there are $w_1 \in I_c$ (formed for $\mathbf{N}_1$), a finite product λ' of the Q_s ($s \ge 0$) and $z \in X\mathbf{N}_{2,c}$ such that $\lambda' w_1 \in \mathbf{N}_1$, $\Pi_c\,\mathbf{N}(\Phi)(w_1) \in P_e(\mathbf{N}_{2,c'})$, and $\ell^{e_D}t_3 f_2\,\mathbf{e}_{k_0}$ is an arc coordinate vector of $\mathbf{N}(\Phi)(w_1) - z$ for $\mathbf{n}$, e, H_c and m_X.

Proof. Write $R_c = e_c\mathbf{A}_{F,L}$, $\psi = \mathbf{N}(\Phi)$, $b_1 = s_{c-1}$, $t = s_{c-2}+S$, $B = s_c + S$, and let $\kappa_0 \ge 0$, $x_0 \in \mathcal{O}_L$ be the integer and the constant of the hypothesis, so $Q_1^{b_1}f_2 \in Q_2^t R_c$ and $Q_1^{b_1}(\ell^{\kappa_0}f_2 - e_c(1\otimes x_0)) \in Q_0^B R_c$. Fix $u_0 = 1+\ell$.

The arc. Since $\mathrm{len}_c = 3$, $c-1, c-2 \notin C$ and $c' = c-3 \in C$ (Proposition C.4), so the sites c, $c-1$ are thick and $c-2 = c'+1$ is thin; hence $b \le b_1 \le b+\eta$, $b \le s_c \le b+\eta$, $h = b+\eta+S$, and $B \le h$, $b_1 \le 2h$, $t \ge 1$. Recall $\mathrm{Sg} = h/\ell^2 + (w+S+\eta)/\ell + \log_\ell(2h) + 1 \ge 1$, $\ell \ge 11$, and $\sigma_B \le 3\,\mathrm{Sg}$:

The four pieces. By Proposition C.43 there are an admissible κ and λ with its conclusion. By Proposition C.44, $s_0\lambda \in \mathbf{N}_{2,c-1}$ and there are $E \le 8\,\mathrm{Sg}$ and n_1 with $\psi(n_1) = \ell^E s_0\lambda$. By Proposition C.48 there are $\sigma_1 \le B\ell/(\ell-1)^2$, $y_1 \in P_1(\mathbf{N}_{1,c-1}) \cap I_c$ with $Q_0^B y_1 \in \mathbf{N}_{1,c}$, g_1 and κ_1 with

$$A_1 := \ell^{\kappa_1}g_1(\ell^{b_1+\kappa}\psi(y_1) - \ell^{\sigma_1+E+\sigma_B+t}\Theta) \in Q_0^B P_1, \qquad \Theta = \varphi^3(T_\kappa(H_{k_0})),\ P_1 = P_1(\mathbf{N}_{2,c-1}).$$

By Proposition C.49 (its hypothesis $s_0\lambda \in \mathbf{N}_{2,c-1}$ was just obtained), $V = f_2\varphi(\lambda) \in P_1$, $\Pi_c f_2 \in R_c$, $\varphi(\lambda) \in P_3(\mathbf{N}_{2,c'})$, $\ell^{\sigma_B}f_2\mathbf{e}_{k_0}$ is an arc coordinate vector of V, and there are g_2, κ_2 with $A_2 := \ell^{\kappa_2}g_2(\ell^{\kappa+\kappa_0}V - \ell^{\sigma_B}x_0\Theta) \in Q_0^B P_1$.

The scalar. Put $D_1 = \kappa_0 + \sigma_1 + E + t$. If $x_0 = 0$ or $v_\ell(x_0) \ge D_1 - b_1$, let $t_3 = 1$ and $B' = x_0\ell^{b_1-D_1}$ (in $\mathcal{O}_L$: if $x_0 \ne 0$, $v_\ell(B') = v_\ell(x_0) + b_1 - D_1 \ge 0$). Otherwise $x_0 \ne 0$ and $D_1 - b_1 > v_\ell(x_0) \ge 0$; let $t_3 = \ell^{D_1-b_1}/x_0$ and $B' = 1$. In both cases $t_3 \in \mathcal{O}_L \setminus \{0\}$, $B' \in \mathcal{O}_L$ and

$$t_3 x_0 \ell^{b_1} = B'\ell^{D_1}.$$

Valuation of t_3. In the first case $v_\ell(t_3) = 0$. In the second, $v_\ell(t_3) = D_1 - b_1 - v_\ell(x_0)$, and Lemma C.42 (with $f = f_2$, $\kappa = \kappa_0$; $b_1, t, B \ge 1$) gives $v_\ell(x_0) \ge \kappa_0 + t - B/(\ell(\ell-1)) - K$ with $K = K_\downarrow(b_1, B) \le \max(0,\, b_1 - B/\ell + 1 + \log_\ell b_1)$. Hence

$$v_\ell(t_3) \le \sigma_1 + E + \frac{B}{\ell(\ell-1)} + \max\Big(-b_1,\ -\frac{B}{\ell} + 1 + \log_\ell b_1\Big).$$

So $v_\ell(t_3) \le 14\,\mathrm{Sg}$.

The difference lies in the lattice at c. Let $D = t_3 V - B'\psi(y_1) \in P_1$ (ψ commutes with φ, so $\psi(P_1(\mathbf{N}_{1,c-1})) \subseteq P_1$). Expanding, and using $t_3 x_0 \ell^{b_1} = B'\ell^{D_1}$ to cancel the two multiples of $\ell^{\sigma_B}\Theta$,

$$t_3 \ell^{b_1+\kappa_1} g_1 A_2 - B'\ell^{\kappa_0+\kappa_2} g_2 A_1 = \ell^{\kappa+\kappa_0+b_1+\kappa_1+\kappa_2} g_1 g_2\, D,$$

so $\ell^k g_1 g_2 D \in Q_0^B P_1$ with $k = \kappa + \kappa_0 + b_1 + \kappa_1 + \kappa_2$. The module P_1 is free over R_c on $\varphi(n_1'), \dots, \varphi(n_r')$ for a basis (n_j') of $\mathbf{N}_{2,c-1}$: these generate it, and P_1 has rank r because it contains $Q^{h_c}\mathbf{N}_{2,c}$ by (Wm2) (window of Lemma C.9 (1), a window of $\mathbf{N}_2$ by (Ex1) of Proposition 23.7); a surjection $R_c^r \to P_1$ onto a torsion-free module of rank r is injective. Write $D = \sum_j a_j \varphi(n_j')$; then $\ell^k g_1 g_2 a_j \in Q_0^B R_c$, and $\ell^k g_1 g_2$ does not vanish at the roots of Q_0 (those of Q_s, $s \ge 1$, are other roots of unity minus 1), so $a_j \in Q_0^B R_c$ by Lemma C.18 item 2 ($e = 1$). Thus $D \in Q_0^B P_1$. At the down site c the window has $M_c = s_c + S = B$, so (Wm2) gives $Q_0^B \varphi(\mathbf{N}_{2,c-1}) \subseteq \mathbf{N}_{2,c}$ and $D \in \mathbf{N}_{2,c}$.

The lift. By Proposition C.6 (for the surjection Φ and the window of Lemma C.9) there is $x_1 \in \mathbf{N}_{1,c}$ with $\psi(x_1) = \ell^{r_c} D$, and $r_c \le 3\,\mathrm{Sg}$ by Lemma C.9 (2). Put

$$w_1 = x_1 + \ell^{r_c} B' y_1, \qquad \lambda' = Q_0^B, \qquad z = 0, \qquad e_D = r_c + \sigma_B.$$

Then $\psi(w_1) = \ell^{r_c}(D + B'\psi(y_1)) = \ell^{r_c} t_3 V$. Further: $w_1 \in I_c$, as $x_1 \in \mathbf{N}_{1,c} \subseteq I_c$ by (Wm3), $y_1 \in I_c$ and I_c is an $\mathcal{O}_L$-module (Lemma 24.5 (Ry4)); $\lambda' w_1 = Q_0^B x_1 + \ell^{r_c} B' Q_0^B y_1 \in \mathbf{N}_1$; $\Pi_c \psi(w_1) = \ell^{r_c} t_3 (\Pi_c f_2) \varphi(\lambda) \in P_3(\mathbf{N}_{2,c'})$, since $\Pi_c f_2 \in R_c$ and $\varphi(\lambda) \in P_3(\mathbf{N}_{2,c'})$; and by Lemma C.16 (a) with $o = \ell^{r_c} t_3 \in R_c$, the vector $\ell^{r_c} t_3 \cdot \ell^{\sigma_B} f_2 \mathbf{e}_{k_0} = \ell^{e_D} t_3 f_2 \mathbf{e}_{k_0}$ is an arc coordinate vector of $\psi(w_1) = \psi(w_1) - z$. Finally $0 \le e_D \le 3\,\mathrm{Sg} + 3\,\mathrm{Sg} = 6\,\mathrm{Sg}$. □

Lemma C.42. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$, v_ℓ the valuation of L with $v_\ell(\ell) = 1$, $R = \mathcal{O}_L[[X]]$ and $\mathcal{K}$ its field of fractions. Let $b_1, t, B \ge 1$ and $\kappa \ge 0$ be integers, $f \in \mathcal{K}$ and $x_0 \in \mathcal{O}_L \setminus \{0\}$ with*

$$Q_1^{b_1} f \in Q_2^t R \qquad \text{and} \qquad Q_1^{b_1}(\ell^\kappa f - x_0) \in Q_0^B R.$$

Then

$$v_\ell(x_0) \;\ge\; \kappa + t - \frac{B}{\ell(\ell-1)} - K_\downarrow(b_1, B) \;\ge\; \kappa + t - \frac{B}{\ell(\ell-1)} - \max\Big(0,\; b_1 - \frac{B}{\ell} + 1 + \log_\ell b_1\Big).$$

Proof. Let ϖ be a uniformiser of $\mathcal{O}_L$ and $e = v_\varpi(\ell)$, so that $\ell\mathcal{O}_L = \varpi^e \mathcal{O}_L$ and $v_\ell = v_\varpi / e$ on $\mathcal{O}_L$. Two facts about R: $R/\varpi R = k_L[[X]]$ is a domain, so ϖ is a prime element of R; and $Q_0 = \Phi_\ell(1+X) \equiv X^{\ell-1} \pmod{\ell}$, so $Q_0 \notin \varpi R$. Hence if ϖ^j divides $Q_0^B h$ in R then ϖ^j divides h (induction on j).

Step 1: Q_2 modulo ℓ. Put $N = \ell(\ell-1)$. As $Q_0 = ((1+X)^\ell - 1)/X$, we have $(1+X)^\ell = 1 + XQ_0$. Let $Z = (1+X)^{\ell^2} - 1 = (1+XQ_0)^\ell - 1$; since ℓ divides $\binom{\ell}{j}$ for $0 < j < \ell$, $Z \equiv (XQ_0)^\ell \pmod{\ell R}$. Further

$$Q_2 = \Phi_\ell(1+Z) = \frac{(1+Z)^\ell - 1}{Z} = \sum_{j=1}^{\ell} \binom{\ell}{j} Z^{j-1} \equiv Z^{\ell-1} \pmod{\ell R},$$

so $Q_2 \equiv (XQ_0)^N \pmod{\ell R}$, i.e. $Q_2 = \ell g + Q_0^N h$ with $g, h \in R$.

Step 2: Q_2^t modulo Q_0^B. Put $A = \max(0, t - \lceil B/N \rceil + 1)$. By the binomial theorem $Q_2^t = \sum_{i=0}^t \binom{t}{i} (Q_0^N h)^i (\ell g)^{t-i}$; a term with $Ni \ge B$ lies in $Q_0^B R$, and a term with $Ni < B$ has

$i \le \lceil B/N \rceil - 1$, so it lies in $\ell^{t-i}R \subseteq \ell^A R$. Hence $Q_2^t \in \ell^A R + Q_0^B R$. Since $\lceil B/N \rceil < B/N + 1$, in both cases of the maximum $A \ge t - B/N$.

Step 3. Write $Q_1^{b_1} f = Q_2^t U_1$ and $Q_1^{b_1}(\ell^\kappa f - x_0) = Q_0^B U_2$ with $U_1, U_2 \in R$. Then $x_0 Q_1^{b_1} = \ell^\kappa Q_2^t U_1 - Q_0^B U_2 \in \ell^{\kappa+A} R + Q_0^B R$ by Step 2. Write $x_0 = u\varpi^n$ with $u \in \mathcal{O}_L^\times$, $n \ge 0$, and put $K = K_\downarrow(b_1, B) \ge 0$. We claim $n \ge e(\kappa + A - K)$. If $n \ge e(\kappa + A)$ this is clear. Otherwise $m = e(\kappa + A) - n \ge 1$ and $u\varpi^n Q_1^{b_1} = \varpi^{n+m} g' + Q_0^B h'$ with $g', h' \in R$. Then ϖ^n divides $Q_0^B h'$, hence $h' = \varpi^n h''$ by the two facts above, and cancelling ϖ^n in the domain R gives $uQ_1^{b_1} = \varpi^m g' + Q_0^B h''$, so $Q_1^{b_1} \in \varpi^m R + Q_0^B R$. By (Cd3) of Lemma C.36 (with $s = 0$, $y = b_1$), $Q_1^{b_1} \notin \varpi \ell^K R + Q_0^B R = \varpi^{1+eK} R + Q_0^B R$. Hence $m < 1 + eK$, i.e. $m \le eK$, which is the claim.

Conclusion. $v_\ell(x_0) = n/e \ge \kappa + A - K \ge \kappa + t - B/(\ell(\ell-1)) - K$, and $K \le \max(0,\, b_1 - B/\ell + 1 + \log_\ell b_1)$ by (Cd3) of Lemma C.36. □

Proposition C.43. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$, c, the frame $\mathbf{n} = (n_k)_{k \le r}$ at $c' = c - 3$ of $\mathbf{N}_2$ and k_0 satisfy the hypotheses of Proposition C.41; let H_{k_0} be the horizontal section through n_{k_0}, $G_0 = w + S$, $u_0 \in \mathbb{Z}_\ell^\times$ with $v_\ell(u_0 - 1) = 1$, and*

$$J = \varphi(\pi_0^M(\pi_0 + \ell)^{2G_0}) \in \mathbb{Z}_\ell[[X]],$$

so that J is Δ-invariant and $J = X^{m_X} Q_0^{m_X} Q_1^{2G_0} \varepsilon$ with a unit ε of $\mathbb{Z}_\ell[[X]]$. Then there are an integer $\kappa \ge 0$ admissible for $\mathbf{n}$ and m_X, and a Δ-invariant $\lambda \in P_2(\mathbf{N}_{2,c'})$, such that $(\gamma_{u_0} - 1)\lambda = Jy$ for a Δ-invariant $y \in P_2(\mathbf{N}_{2,c'})$, and

$$\ell^{\kappa'}\big(\ell^\kappa \lambda - \ell^{\sigma_B} \varphi^2(T_\kappa(H_{k_0}))\big) \in J\, P_2(\mathbf{N}_{2,c'}) \qquad \text{for some integer } \kappa' \ge 0.$$

Proof. Write $\mathbf{N} = \mathbf{N}_2$, $R = \mathcal{O}_L[[X]]$ for a site ring, $P_e = P_e(\mathbf{N}_{c'})$, $\gamma = \gamma_{u_0}$, $H = H_{k_0}$, $n = n_{k_0}$, $m = m_X$ and $J_1 = \pi_0^M(\pi_0 + \ell)^{2G_0}$, so $J = \varphi(J_1)$.

Elementary facts. (i) By Lemma 28.15 item 1, $\pi_0 = X^{\ell-1} v$ and $\pi_0 + \ell = Qw$ with units v, w of $\mathbb{Z}_\ell[[X]]$, and π_0 is Δ-invariant, hence so is $\pi_0 + \ell$; so $J_1 = X^m Q_0^{2G_0} \varepsilon_1$ ($m = (\ell-1)M$) with the unit $\varepsilon_1 = v^M w^{2G_0}$, $J_1 = \pi_0^M(\pi_0 + \ell)^{2G_0}$ is Δ-invariant as a product of Δ-invariant elements, and $J = \varphi(J_1) = X^m Q_0^m Q_1^{2G_0} \varphi(\varepsilon_1)$ since $\varphi(X) = XQ_0$, $\varphi(Q_0) = Q_1$. By Lemma C.16 (b), $\gamma_u(J_1) \in J_1 \mathbb{Z}_\ell[[X]]^\times$ for every u. (ii) P_e is stable under every γ_u (γ_u commutes with φ by (Wm3) and preserves $\mathbf{N}$ and $\mathbf{A}_{F,L}$), and $\varphi(P_1) \subseteq P_2$ since $\varphi(a\varphi(x)) = \varphi(a)\varphi^2(x)$. (iii) P_1 is free over $e_{c'+1}\mathbf{A}_{F,L}$ on $\varphi(n_1), \dots, \varphi(n_r)$: these generate it, and P_1 contains $Q^{h_{c'+1}} \mathbf{N}_{c'+1}$ by (Wm2) (the window of Lemma C.9 (1) is a window of $\mathbf{N}$ by (Ex1) of Proposition 23.7), so it has rank r, and a surjection from a free module of rank r onto a torsion-free module of rank r is injective. (iv) Saturation: if $x \in P_1$ and $\ell^k x \in J_1 P_1$, then $x \in J_1 P_1$. Indeed, coordinatewise in the basis of (iii), $\ell^k a \in X^m Q_0^{2G_0} R$ with $a \in R$ gives $a = X^m a'$ with $a' \in R$ (compare coefficients) and $\ell^k a' \in Q_0^{2G_0} R$, hence $a' \in Q_0^{2G_0} R$ by Lemma C.18 item 2 ($e = 1$, $c = \ell^k$). (v) For $k \ge 0$, $X^k \mathbf{N}_E \cap \mathbf{N}_{c'}[1/\ell] = X^k \mathbf{N}_{c'}[1/\ell]$ and $X^k \mathbf{N}_E \cap \mathbf{N}_{c'} = X^k \mathbf{N}_{c'}$ (compare coordinates in the basis (n_j)); and $\varphi(X^m \mathbf{N}_{c'}[1/\ell]) = X^m Q_0^m \varphi(\mathbf{N}_{c'})[1/\ell] \subseteq J_1 P_1[1/\ell]$ because $m \ge 2G_0$ ($m > 2h_B \ge 2G_0$).

A relay correction. The window has $M_a \le s_a + S \le h_B$ for all a and $M_{c'+1} = s_{c-2} + S \le G_0$ (the site $c - 2 = c' + 1$ is thin with sign -1). Apply Lemma 24.5 to $\mathbf{N}$ at the site c' with $j = 1$, $G = G_0$, $g = 2G_0$, $m = m_X \ge 1 + \max_a M_a$ and $R' = m_X$; let $\sigma = \sigma_\ell(2G_0, m_X, 1)$, so $\sigma \le \sigma_B$ (compare the definitions: $\sigma_B = \lceil (2G_0 + m_X/(\ell-1))\ell/(\ell-1)^2 \rceil + 1$). By (Wm3), $n \in I_{c'}$. By (Hf2) of Lemma 23.9, $H \in n + X\mathbf{N}_E$ and $\gamma_u(H) = H$ for all u; so $n - H \in X\mathbf{N}_E$ has $(\gamma_u - 1)(n - H) = (\gamma_u - 1)(n)$, and $W_n = n - H$ by the uniqueness in (Hf1). By (Ry1) there are $\tau \in P_1$ and $V \in \mathbf{N}_{c'}[1/\ell]$ with $V - (n - H) \in X^m \mathbf{N}_E$ and $\tau - \ell^\sigma \varphi(V) \in J_1 P_1[1/\ell]$ (here

$X^m\lambda_1^{2G_0}P_1 = J_1P_1$ by (i)). Fix an integer κ admissible for $\mathbf{n}$ and m (it exists: finitely many coefficients $h_{kj,i}$, $i<m$, each in E). Put

$$\lambda_0 = \ell^{\sigma_B}\varphi(n) - \ell^{\sigma_B-\sigma}\tau \ \in P_1.$$

Approximation. First, $\lambda_0 - \ell^{\sigma_B}\varphi(n-V) = \ell^{\sigma_B-\sigma}\big(\ell^{\sigma}\varphi(V)-\tau\big) \in J_1P_1[1/\ell]$. Second, $\ell^{\kappa}(n-V) - T_\kappa(H) = -\ell^{\kappa}(V-(n-H)) + \big(\ell^{\kappa}H - T_\kappa(H)\big)$ lies in $X^m\mathbf{N}_E$ (the second term by the definition of T_κ) and in $\mathbf{N}_{c'}[1/\ell]$, hence in $X^m\mathbf{N}_{c'}[1/\ell]$ by (v), and its image under φ lies in $J_1P_1[1/\ell]$. Together, $\ell^{\kappa}\lambda_0 - \ell^{\sigma_B}\varphi(T_\kappa(H)) \in J_1P_1[1/\ell]$; as it lies in P_1, there is $\kappa'\geq 0$ with

$$A := \ell^{\kappa'}\big(\ell^{\kappa}\lambda_0 - \ell^{\sigma_B}\varphi(T_\kappa(H))\big) \in J_1P_1.$$

Δ-*average.* Put $\bar\lambda_0 = (\ell-1)^{-1}\sum_{\delta\in\mu_{\ell-1}}\gamma_\delta(\lambda_0) \in P_1$ ($\ell-1$ is a unit), which is Δ-invariant. For each δ, $\gamma_\delta(T_\kappa(H)) - T_\kappa(H) = \gamma_\delta\big(T_\kappa(H)-\ell^{\kappa}H\big) - \big(T_\kappa(H)-\ell^{\kappa}H\big) \in X^m\mathbf{N}_E \cap \mathbf{N}_{c'} = X^m\mathbf{N}_{c'}$ ($\gamma_\delta H = H$, and γ_δ preserves $X^m\mathbf{N}_E$ as $\gamma_\delta(X)\in X\mathbb{Z}_\ell[[X]]^\times$). Averaging $\gamma_\delta(A)\in J_1P_1$ (by (i), (ii)) and using (v) gives $\ell^{\kappa'}\big(\ell^{\kappa}\bar\lambda_0 - \ell^{\sigma_B}\varphi(T_\kappa(H))\big) \in J_1P_1$.

The γ-clause. Apply $\gamma-1$ to the last membership: $(\gamma-1)(J_1P_1)\subseteq J_1P_1$ by (i), (ii), and $(\gamma-1)T_\kappa(H) = (\gamma-1)\big(T_\kappa(H)-\ell^{\kappa}H\big) \in X^m\mathbf{N}_E\cap\mathbf{N}_{c'} = X^m\mathbf{N}_{c'}$, whose image under φ lies in J_1P_1 by (v); γ commutes with φ. Hence $\ell^{\kappa'+\kappa}(\gamma-1)\bar\lambda_0 \in J_1P_1$, and by (iv) $(\gamma-1)\bar\lambda_0 = J_1y_0$ with $y_0\in P_1$, unique as P_1 is torsion-free. Since γ commutes with every γ_δ, $(\gamma-1)\bar\lambda_0$ is Δ-invariant, and so is J_1; uniqueness gives $\gamma_\delta(y_0)=y_0$.

Conclusion. Put $\lambda=\varphi(\bar\lambda_0)$ and $y=\varphi(y_0)$; both lie in P_2 by (ii) and are Δ-invariant (φ commutes with γ_δ). Then $(\gamma-1)\lambda = \varphi(J_1y_0) = Jy$, and applying φ to the averaged approximation gives $\ell^{\kappa'}\big(\ell^{\kappa}\lambda - \ell^{\sigma_B}\varphi^2(T_\kappa(H))\big) \in \varphi(J_1)\varphi(P_1) \subseteq J\,P_2$. □

Proposition C.44. *Let ℓ, F, n, L, (τ_a), Φ, the weight word, c, $\mathbf{n}$, k_0, u_0 be as in Proposition C.43, and let κ and λ satisfy the conclusion of Proposition C.43. Put $b_1 = s_{c-1}$, $t = s_{c-2}+S$ and*

$$s_0 = Q_1^{t}\,Q_0^{-b_1} \in \mathcal{K}_{c-1}.$$

Then $s_0\lambda \in \mathbf{N}_{2,c-1}$, and there are an integer E with $0\leq E\leq 8\,\mathrm{Sg}$ and $n_1\in\mathbf{N}_{1,c-1}$ with

$$\mathbf{N}(\Phi)(n_1) = \ell^{E}s_0\lambda.$$

Proof. Write $\mathbf{N}=\mathbf{N}_2$, $R = e_{c-1}\mathbf{A}_{F,L}$, $b_1=s_{c-1}$, $t=s_{c-2}+S$, $G_0 = w+S$, $\varsigma=\pi_0+\ell$, $\gamma=\gamma_{u_0}$, and $T = T_\kappa(H_{k_0})$. By the conclusion of Proposition C.43 there are $\kappa'\geq 0$, $y''\in P_2(\mathbf{N}_{c'})$ and a Δ-invariant $y\in P_2(\mathbf{N}_{c'})$ with $\ell^{\kappa'}(\ell^{\kappa}\lambda - \ell^{\sigma_B}\varphi^2(T)) = Jy''$ and $(\gamma-1)\lambda = Jy$, where $J = \varphi(\pi_0)^M\varphi(\varsigma)^{2G_0} = X^{m_X}Q_0^{m_X}Q_1^{2G_0}\cdot(\text{unit})$.

The arc and the numbers. As $\mathrm{len}_c = 3$, the sites c, $c-1$ are thick and $c-2 = c'+1$ is thin, with $\epsilon_{c-1}=1$; so $b\leq b_1\leq b+\eta$, $\eta < s_{c-2}\leq w$, $h = h_B = b+\eta+S \leq 1.1b$ (as $20\eta, 20S\leq b$), $\max_a s_a \leq b+\eta$, hence $H'\leq h+\eta\leq 1.05h$, and $\mathrm{Sg} = h/\ell^2 + (w+S+\eta)/\ell + \log_\ell(2h)+1$ with $160\,\mathrm{Sg}\leq b$, $\ell\geq 11$. Put $a=\lceil a_{\mathrm{R}}\rceil$. Then:

(N1) $b_1 \geq 2a_{\mathrm{R}}+\eta+1$;

(N2) $\frac{3a_{\mathrm{R}}+S+2\eta}{\ell-1} + \log_\ell(2H') + 1 \leq 8\,\mathrm{Sg}$;

(N3) $m_X \geq a + b_1 + G_0$.

Units. By Lemma 28.15 item 1, $\pi_0 = X^{\ell-1}v$ and $\varsigma = Q_0 w$ with units v, w of $\mathbb{Z}_\ell[[X]]$, and π_0, ς are Δ-invariant; so are $\varphi(\pi_0)$, $\varphi(\varsigma)$ (φ commutes with every γ_δ). Put $u = \varphi(w)^t w^{-b_1}$, a unit, and $s = \varphi(\varsigma)^t \varsigma^{-b_1} = s_0 u$, which is Δ-invariant. Further $\varphi(\pi_0) = (XQ_0)^{\ell-1}\varphi(v) = \pi_0 \varsigma^{\ell-1}\varepsilon$ with the unit $\varepsilon = v^{-1}w^{1-\ell}\varphi(v)$, which is Δ-invariant as a quotient of Δ-invariant elements of the domain $\mathbb{Z}_\ell[[X]]$.

(a) Membership. Consider the initial sub-arc $e_1 = 2$ of the arc of c: $c' + 2 = c - 1$ and $\Pi' = \Lambda_{c-1,2}(H_c) = Q_0^{h_B} Q_1^{G_0}$ ($H_c(c-1) = h_B$, $H_c(c'+1) = w + S$). The element $s_0\lambda$ lies in $e_{c-1}\mathbf{N}[1/\lambda_\infty]$, and $\Pi' s_0\lambda = Q_0^{h_B - b_1} Q_1^{G_0+t}\lambda \in P_2(\mathbf{N}_{c'})$ since $b_1 \le h_B$. Let $f = \ell^{\sigma_B} s_0 \mathbf{e}_{k_0}$; then $\Pi' f_{k_0} = \ell^{\sigma_B} Q_0^{h_B - b_1} Q_1^{G_0+t} \in R$, and

$$\ell^{\kappa'}(\ell^\kappa \Pi' s_0\lambda - \Pi' f_{k_0}\varphi^2(T)) = \Pi' s_0\, Jy'' \in X\Pi'^2 P_2(\mathbf{N}_{c'}),$$

because $\Pi' s_0 J = X^{m_X} Q_0^{m_X + h_B - b_1} Q_1^{3G_0+t} \cdot (\text{unit})$ and $X\Pi'^2 = XQ_0^{2h_B}Q_1^{2G_0}$, with $m_X \ge 1$ and $m_X \ge h_B + b_1$ ($m_X > 2h_B$). As κ is admissible for $\mathbf{n}$ and m_X, f is an arc coordinate vector of $s_0\lambda$ for $\mathbf{n}$, 2, H_c, m_X. It is Hodge-graded, with the one-term section decomposition $(g, \mathbf{v}, \alpha) = (\ell^{\sigma_B} s_0, \mathbf{e}_{k_0}, (-b_1, t))$, $g \in Q_0^{-b_1} Q_1^t R$: here $\delta_2(\mathbf{e}_{k_0}) = \varphi^2(d_{k_0})$, and (level 0) $\varphi^2(d_{k_0}) \in \varphi^4(\mathrm{Fil}^{b_1} D_{\mathrm{cris}}(V_2))$ by the hypothesis $\varphi^3(d_{k_0}) \in \varphi^5(\mathrm{Fil}^{s_{c-1}} D_{\mathrm{cris}}(V_2))$ of Proposition C.41 (φ is bijective on $D_{\mathrm{cris}}(V_2)$); (level 1) $\varphi^{-5}(\varphi^2(d_{k_0}))$ lies in the component $\varepsilon_{c-3} D_{\mathrm{cris}}(V_2)$ of the embedding τ_{c-2} (Lemma 23.10 and the remark in Definition 23.3), on which Fil^{-t} is everything, as every Hodge jump of V_2 at τ_{c-2} is $\ge -(s_{c-2} + S) = -t$ (Lemma C.16 (1)). By the Sub-arcs paragraph of Proposition C.24 ($\nu = 2$, $e_1 = 2$, $t = 0$, $\kappa = 0$; $\mathbf{n}$ is fixed by γ_u, $u \in \mu_{\ell-1}$), $s_0\lambda \in \mathbf{N}_{c-1}$. Hence $x := s\lambda = u\, s_0\lambda \in \mathbf{N}_{c-1}$, and x is Δ-invariant (s and λ are).

(b) The γ-clause. Put $x' = \lambda \in e_{c-1}\mathbf{N}[1/\lambda_\infty]$; then $\varsigma^{b_1} x = \varphi(\varsigma)^t x'$. Since $\varphi(\pi_0)^M = \pi_0^M \varsigma^{m_X}\varepsilon^M$ ($m_X = (\ell-1)M$),

$$\varphi(\varsigma)^t(\gamma - 1)(x') = \varphi(\varsigma)^t Jy = \pi_0 \varsigma^{a+b_1} z, \qquad z = \pi_0^{M-1}\varsigma^{m_X - a - b_1}\varepsilon^M \varphi(\varsigma)^{t+2G_0} y,$$

where $M \ge 1$ and $m_X - a - b_1 \ge G_0$ by (N3). By (Ry0) of Lemma 24.5 (for $\mathbf{N}$ with the window of Lemma C.9 (1), a window by (Ex1) of Proposition 23.7; site c', $j = 2$, $G = G_0 \ge M_{c-2} = t$, $M_{c-1} = \eta$; $g = 2G_0$, $m = R = m_X$), $(Q_0Q_1)^{G_0} P_2(\mathbf{N}_{c'}) \subseteq \mathbf{N}_{c-1}$; as $\varsigma^{G_0}\varphi(\varsigma)^{G_0} = (Q_0Q_1)^{G_0} \cdot (\text{unit})$ and the remaining factors of z lie in R, $z \in \mathbf{N}_{c-1}$; and z is Δ-invariant, all its factors being so.

(c) The lift. Apply Lemma C.45 with $i = c - 1$: $\ell \ge 11$ is prime, F is unramified, (τ_a) is a Frobenius numbering, Φ is an onto map of crystalline lattices with the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ (hypotheses of Proposition C.25), $\epsilon_{c-1} = 1$ and $s_{c-1} = b_1 \ge 2a_{\mathrm{R}} + \eta + 1$ by (N1); u_0 is the element of Proposition C.43, as allowed by Lemma 28.15. With x, x' and z from (a), (b) ($s_{i-1} + S = t$, $s_i = b_1$) it gives an integer E with $0 \le E \le \frac{3a_{\mathrm{R}} + S + 2\eta}{\ell - 1} + \log_\ell(2H') + 1 \le 8\,\mathrm{Sg}$ (N2) and $y_1 \in \mathbf{N}_{1,c-1}$ with $\mathbf{N}(\Phi)(y_1) = \ell^E x$. Put $n_1 = u^{-1}y_1 \in \mathbf{N}_{1,c-1}$; by R-linearity, $\mathbf{N}(\Phi)(n_1) = \ell^E u^{-1} s\lambda = \ell^E s_0\lambda$. □

Lemma C.45. *Let $\ell \ge 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, L as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ, and*

$$a_{\mathrm{R}} = \frac{H'(2\ell - 1)}{(\ell - 1)^2} + 4 + \log_\ell(2H').$$

Let $i \in \mathbb{Z}/n$ with $\epsilon_i = 1$ and $s_i \ge 2a_{\mathrm{R}} + \eta + 1$, form π_0 and u_0 as in Lemma 28.15, and put $a = \lceil a_{\mathrm{R}} \rceil$. There is an integer E with

$$0 \le E \le \frac{3a_{\mathrm{R}} + S + 2\eta}{\ell - 1} + \log_\ell(2H') + 1$$

such that the following holds. Let $x \in \mathbf{N}(T_2)_i$ be Δ-invariant, let $x' \in e_i\mathbf{N}(T_2)[1/\lambda_\infty]$ with $(\pi_0+\ell)^{s_i}x = \varphi(\pi_0+\ell)^{\,s_{i-1}+S}x'$, and suppose that there is a Δ-invariant $z \in \mathbf{N}(T_2)_i$ with $\varphi(\pi_0+\ell)^{\,s_{i-1}+S}(\gamma_{u_0}-1)(x') = \pi_0(\pi_0+\ell)^{a+s_i}z$. Then there is a Δ-invariant $y \in \mathbf{N}(T_1)_i$ with $\mathbf{N}(\Phi)(y) = \ell^E x$.

Proof. Write $\varsigma = \pi_0 + \ell$ (local to this proof). By Lemma 28.15 (1), π_0 is Δ-invariant, $e_i\pi_0 = X^{\ell-1}v$ and $\varsigma = Q\kappa$ with units v, κ of $\mathbb{Z}_\ell[[X]]$; so ς is Δ-invariant and invertible in $\mathbf{A}_{F,L}[1/Q]$.

Step 0: numbers. Since $a_{\mathrm{R}} \geq 4$, $a \geq 1$; and $a < a_{\mathrm{R}} + 1$, so $2a + \eta < 2a_{\mathrm{R}} + \eta + 2 \leq s_i + 1$ by the hypothesis $s_i \geq 2a_{\mathrm{R}} + \eta + 1$; as all are integers, $2a + \eta \leq s_i$. Put $J_1 = \{s_i - a + 1, \dots, s_i\}$, $J_2 = \{s_i + 1, \dots, s_i + S + a\} \cup \{1 - \eta, \dots, \eta + a\}$ and

$$E = \Big\lfloor \frac{3a + S + 2\eta - 1}{\ell - 1} + \log_\ell(s_i + \eta) \Big\rfloor.$$

Then $E \geq 0$ (as $a \geq 1$ and $s_i + \eta \geq 1$), and $E \leq \frac{3a_{\mathrm{R}}+3+S+2\eta-1}{\ell-1} + \log_\ell(2H') \leq \frac{3a_{\mathrm{R}}+S+2\eta}{\ell-1} + \log_\ell(2H') + 1$, using $s_i + \eta \leq H' \leq 2H'$ and $\ell \geq 11$. By Lemma 28.15 (4) (with a, $b = s_i$, S, η; $2a + \eta \leq s_i$), $J_1 \cap J_2 = \emptyset$ and for every $j_0 \in J_1$ the integer $\sum_{j \in J_1 \setminus \{j_0\}} v_\ell(j_0 - j) + \sum_{j \in J_2} v_\ell(j_0 - j)$ is at most the real number in the floor, hence at most E.

Step 1: ς^a is killing at i for Φ. Every Hodge jump of V_1 at τ_c lies in $[-M_c, h_c]$ by (Ow1) (for $\epsilon_c = 1$ the jumps lie in $[s_c, s_c + S] \cup [-\eta, \eta] \subseteq [-\eta, s_c + S]$, for $\epsilon_c = -1$ in $[-s_c - S, -s_c] \cup [-\eta, \eta] \subseteq [-(s_c + S), \eta]$). Apply Lemma C.7 to the surjection $\Phi\colon T_1 \to T_2$ ($\ell \geq 5$) with this window: $H(c) = s_c + S + \eta \leq H'$, so $H_{\max} \leq H'$ and $c_H \leq 2 + \log_\ell(H' + 1) \leq 2 + \log_\ell(2H')$ ($H' \geq 1$). By (Ki3) with $\pi = e_i\pi_0$, $(e_i\pi_0 + \ell)^{A_i + r_i}$ is killing at i, where

$$A_i + r_i \leq \frac{H'}{\ell - 1} + 1 + \frac{H'\ell}{(\ell-1)^2} + 2 + \log_\ell(2H') = \frac{H'(2\ell - 1)}{(\ell-1)^2} + 3 + \log_\ell(2H') < a_{\mathrm{R}} \leq a.$$

As $\mathbf{N}(\Phi)(\mathbf{N}(T_1)_i)$ is an $e_i\mathbf{A}_{F,L}$-module, $e_i\varsigma^a = \varsigma^{\,a - A_i - r_i}(e_i\pi_0 + \ell)^{A_i + r_i}$ is killing at i; it is Δ-invariant.

Step 2: the letters of T_1. By Step 1 and (Ki4) (applied to $t = e_i\varsigma^a$ and x), there is $x_1 \in \mathbf{N}_1^\Delta$ with $\mathbf{N}(\Phi)(x_1) = \varsigma^a x$. Put $z_1 = \varsigma^{-a}x_1 \in e_i\mathbf{N}(T_1)[1/Q]$; it is Δ-invariant, $Q^a z_1 = \kappa^{-a}x_1 \in \mathbf{N}(T_1)$, and $\mathbf{N}(\Phi)(z_1) = x$ ($\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}[1/Q]$-linear). The Hodge jumps j of V_1 at τ_i lie in $[s_i, s_i + S] \cup [-\eta, \eta]$ (Ow1, $\epsilon_i = 1$), so $j + k \in J_2$ for $1 \leq k \leq a$. By Lemma C.46 (pair (V_1, T_1), site i, $Y = a \geq 1$, $J = J_2$), $P_{J_2}(\nabla)z_1 \in \mathbf{N}(T_1)_i$; it is Δ-invariant, being a $\mathbb{Z}_\ell$-linear combination of the $\nabla^k z_1 \in \mathbf{N}_{1,\infty}^\Delta$ (Lemma 28.15 (1)). Since $\mathbf{N}(\Phi) \circ \nabla = \nabla \circ \mathbf{N}(\Phi)$ on $\mathbf{N}_{1,\infty}^\Delta$,

$$P_{J_2}(\nabla)\,x = \mathbf{N}(\Phi)\big(P_{J_2}(\nabla)z_1\big) \in \mathbf{N}(\Phi)(\mathbf{N}_1^\Delta).$$

Step 3: the top layers. By Lemma C.47 (for the pair (V_2, T_2) at the site i, with its integers a, b, h taken as a, s_i, $s_{i-1} + S$) there is a Δ-invariant $y' \in \mathbf{N}(T_2)_i$ with $P_{J_1}(\nabla)x = \varsigma^a y'$. By Step 1 and (Ki4), $\varsigma^a y' = \mathbf{N}(\Phi)(y_1)$ with $y_1 \in \mathbf{N}_1^\Delta$. So $P_{J_1}(\nabla)x \in \mathbf{N}(\Phi)(\mathbf{N}_1^\Delta)$.

Step 4: separation. We have $x \in \mathbf{N}_2^\Delta$, the sets J_1, J_2 are finite and disjoint, E satisfies the valuation condition of Lemma 28.15 (3) (Step 0), and $P_{J_1}(\nabla)x$, $P_{J_2}(\nabla)x$ lie in $\mathbf{N}(\Phi)(\mathbf{N}_1^\Delta)$ (Steps 2, 3). By Lemma 28.15 (3), $\ell^E x = \mathbf{N}(\Phi)(y)$ for some $y \in \mathbf{N}_1^\Delta$, a Δ-invariant element of $\mathbf{N}(T_1)_i$. □

Lemma C.46. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, (V, T) a pair, $c \in \mathbb{Z}/n$, and form u_0, $c(j)$, P_J and ∇ as in Lemma 28.15 (for $T_1 = T_2 = T$). Let $Y \geq 1$ be an integer and $J \subset \mathbb{Z}$ a finite set containing $a + k$ for every Hodge jump a of V at τ_c and every integer $1 \leq k \leq Y$. If $z \in e_c\mathbf{N}(T)[1/Q]$ is Δ-invariant and $Q^Y z \in \mathbf{N}(T)$, then $P_J(\nabla)z \in \mathbf{N}(T)_c$.*

Proof. Let J_c be the set of Hodge jumps of V at τ_c (finite) and $Z = \{a+k : a \in J_c,\ 1 \le k \le Y\}$; by hypothesis $Z \subseteq J$. Let $x_1, \dots, x_m$ be an enumeration of Z without repetition, and put

$$y_0 = z, \qquad y_i = (\nabla - c(x_i))(y_{i-1}) \quad (1 \le i \le m).$$

By item 1 of Lemma 28.15, ∇ is an $\mathcal{O}_L$-linear map of $\mathbf{N}_\infty^\Delta$ into itself and $c(x_i) \in \mathbb{Z}_\ell$, so by induction every y_i lies in $\mathbf{N}_\infty^\Delta \subseteq e_c\mathbf{N}[1/Q] \subseteq e_c\mathbf{N}[1/\lambda_\infty]$ (the second inclusion because $Q = Q_0$ is among the inverted elements and $\mathbf{N}_c$ is free over the domain $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ by (Wm1), so the localisation maps are injective). By the defining property of ∇,

$$\pi_0(y_i + c(x_i)\, y_{i-1}) = \pi_0\, \nabla y_{i-1} = (\gamma_{u_0} - 1)(y_{i-1}) \qquad (1 \le i \le m),$$

and $Q^Y y_0 = Q^Y z \in \mathbf{N}$. Apply Lemma 24.8 to the pair (V, T), the site c, the finite set J_c (it contains every Hodge jump of V at τ_c), $u = u_0$ (which lies in $1 + \ell\mathbb{Z}_\ell$ since $v_\ell(u_0 - 1) = 1$; the numbers $c(x)$ of that lemma for $u = u_0$ are ours), the integer Y and the enumeration $x_1, \dots, x_m$ of $\{j + k : j \in J_c,\ 1 \le k \le Y\} = Z$: it gives $y_m \in \mathbf{N}$. As $y_m = e_c y_m$, $y_m \in e_c\mathbf{N} = \mathbf{N}_c$, and y_m is Δ-invariant, so $y_m \in \mathbf{N}^\Delta$.

The operators $\nabla - c(x)$ are polynomials in the one operator ∇ and commute, so $y_m = P_Z(\nabla)z$; since $Z \subseteq J$, $P_J = P_{J\setminus Z}\, P_Z$ and

$$P_J(\nabla)z = P_{J\setminus Z}(\nabla)(y_m).$$

By item 1 of Lemma 28.15, ∇ maps $\mathbf{N}^\Delta$ into itself; hence so does the polynomial $P_{J\setminus Z}(\nabla)$ with coefficients in $\mathbb{Z}_\ell$, and $P_J(\nabla)z \in \mathbf{N}^\Delta \subseteq \mathbf{N}(T)_c$.

Remark. No comparison of $\mathbf{N}(T)$ with Berger's Wach module is needed: Lemma 24.8 computes the action of γ_{u_0} on the pole layers directly through the de Rham expansion at the site c. Rationally, the statement for $Y = 1$ is consistent with the description of the action of Γ_1 on N_V/q in [24] (eigenvalues given by the Hodge–Tate weights), twisted by the first pole layer. □

Lemma C.47. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, (V, T) a pair, $i \in \mathbb{Z}/n$ and $a, b, h \ge 0$ integers. Form π_0, u_0, $c(j)$, P_J and ∇ as in Lemma 28.15 for $\mathbf{N}(T)$ at the site i (with $T_1 = T_2 = T$), and put $J_1 = \{b - a + 1, \dots, b\}$. Let $x \in \mathbf{N}(T)_i$ be Δ-invariant, let $x' \in e_i\mathbf{N}(T)[1/\lambda_\infty]$ with $(\pi_0 + \ell)^b x = \varphi(\pi_0 + \ell)^h x'$, and suppose that there is a Δ-invariant $z \in \mathbf{N}(T)_i$ with*

$$\varphi(\pi_0 + \ell)^h\, (\gamma_{u_0} - 1)(x') = \pi_0\, (\pi_0 + \ell)^{a+b}\, z.$$

Then there is a Δ-invariant $y \in \mathbf{N}(T)_i$ with $P_{J_1}(\nabla)\, x = (\pi_0 + \ell)^a y$.

Proof. Write $\gamma = \gamma_{u_0}$ and $\varsigma = \pi_0 + \ell$. All elements of $\mathbb{Z}_\ell[[X]]$ act on the site i through e_i. By Lemma 28.15 (1), $\pi_0 = X^{\ell-1}v$ and $\varsigma = Qw$ with units v, w of $\mathbb{Z}_\ell[[X]]$, and π_0, ς are Δ-invariant. Since $v_\ell(u_0 - 1) = 1$, $u_0 \equiv 1 \bmod \ell$. The module $\mathbf{N}(T)_i$ is free over the domain R ((Wm1)), so $e_i\mathbf{N}(T)[1/\lambda_\infty]$ is free over the domain $R[1/Q_s : s \ge 0]$ and every non-zero element of R is a non-zero-divisor on it.

Step 1: the residue map. Let ζ be a primitive ℓ-th root of unity and $\mathcal{O}' = \mathcal{O}_L \otimes_{\mathbb{Z}_\ell} \mathbb{Z}_\ell[\zeta]$, a free $\mathcal{O}_L$-module with basis $(\zeta - 1)^k$, $k < \ell - 1$; it is ℓ-torsion-free, and $\zeta - 1$ is a non-zero-divisor on it ($\mathcal{O}'$ is flat over the domain $\mathbb{Z}_\ell[\zeta]$). As $(\zeta - 1)^{\ell-1} \in \ell\mathcal{O}'$, there is a unique continuous $\mathcal{O}_L$-algebra homomorphism $\varrho\colon R \to \mathcal{O}'$ with $\varrho(X) = \zeta - 1$. Then:

1. $\ker\varrho = QR = \varsigma R$, and $\ker\varrho \cap R^\Delta = \varsigma R^\Delta$. Indeed $\varrho(Q) = \Phi_\ell(\zeta) = 0$; conversely, if $\varrho(f) = 0$, Weierstrass division by the distinguished polynomial Q of degree $\ell - 1$ gives $f = Qg + r$ with $r \in \mathcal{O}_L[X]$ of degree $< \ell - 1$, and $r(\zeta - 1) = 0$ forces $r = 0$ by the choice of basis. If moreover $f = \varsigma g'$ is Δ-invariant, then $\varsigma\gamma_\delta(g') = \gamma_\delta(f) = f = \varsigma g'$ and $g' \in R^\Delta$, R being a domain.

2. $\varrho\circ\gamma = \varrho$: both are continuous $\mathcal{O}_L$-algebra maps, and $\varrho(\gamma X) = \zeta^{u_0} - 1 = \zeta - 1$ (approximate u_0 by integers $\equiv 1 \bmod \ell$).

3. $\varrho(\varphi(f)) = f(0)$ for $f \in \mathbb{Z}_\ell[[X]]$: $\varrho \circ \varphi$ is a continuous ring map sending X to $\zeta^\ell - 1 = 0$.

4. $\varrho(\pi_0) = -\ell$, since $\varrho(\varsigma) = \varrho(Qw) = 0$.

Δ-invariant multiples of X. If $f \in XR$ is Δ-invariant and non-zero with lowest term $c_k X^k$ ($k \geq 1$), the lowest term of $\gamma_\delta(f)$ is $c_k \delta^k X^k$, so $\delta^k = 1$ for all $\delta \in \mu_{\ell-1}$, $(\ell-1) \mid k$, and $f = \pi_0 g$ with $g \in R$, Δ-invariant as above. Hence

$$(XR)^\Delta = \pi_0 R^\Delta. \qquad (1)$$

As $\gamma(X) \in XR$, γ preserves constant terms; it commutes with every γ_δ ((Wm3) on R: $\gamma_u\gamma_v = \gamma_{uv}$).

Step 2: three units. (a) For $g \in R^\Delta$, $\gamma(g) - g$ is Δ-invariant, has constant term 0 and $\varrho(\gamma g - g) = 0$ (item 2). By (1), $\gamma(g) - g = \pi_0 g_1$ with $g_1 \in R^\Delta$; then $-\ell\varrho(g_1) = 0$, so $\varrho(g_1) = 0$ and $g_1 \in \varsigma R^\Delta$ (item 1): $\gamma(g) - g = \pi_0\varsigma\tilde{g}$ with $\tilde{g} \in R^\Delta$.

(b) Let $\eta_0 = \gamma(X)/X = ((1+X)^{u_0} - 1)/X \in \mathbb{Z}_\ell[[X]]$, a unit with $\eta_0(0) = u_0$. From $Q = \varphi(X)/X$ and $\gamma\varphi = \varphi\gamma$ on $\mathbb{Z}_\ell[[X]]$ (both ring maps, equal on X): $X\eta_0\gamma(Q) = \gamma(\varphi X) = \varphi(X\eta_0) = XQ\varphi(\eta_0)$, so $\gamma(Q) = Q\varphi(\eta_0)\eta_0^{-1}$ and

$$\gamma(\varsigma) = t\,\varsigma, \qquad t = \varphi(\eta_0)\,\eta_0^{-1}\,\gamma(w)\,w^{-1} \in \mathbb{Z}_\ell[[X]]^\times.$$

The unit t is Δ-invariant ($\varsigma t = \gamma(\varsigma)$ is, and R is a domain). By item 3, $\varrho(\varphi(\eta_0)) = \eta_0(0) = u_0$; by item 2, $(\zeta - 1)\varrho(\eta_0) = \varrho(\gamma X) = \zeta - 1$, so $\varrho(\eta_0) = 1$; and $\varrho(\gamma w) = \varrho(w)$, a unit. Hence $\varrho(t) = u_0$, and $t(0) = 1$ (compare constant terms in $\gamma(\varsigma) = t\varsigma$, $\varsigma(0) = \ell$).

(c) For $k \geq 0$, $t^k - 1$ is Δ-invariant with constant term 0, so by (1) $t^k = 1 + \pi_0 T_k$ with $T_k \in R^\Delta$, and $-\ell\varrho(T_k) = u_0^k - 1$. The element $\varphi(t) \in \mathbb{Z}_\ell[[X]]$ is Δ-invariant (φ commutes with the γ_δ) and $\gamma(\varphi\varsigma) = \varphi(\gamma\varsigma) = \varphi(t)\varphi(\varsigma)$; $\varphi(t)^h - 1$ has constant term $t(0)^h - 1 = 0$, so $\varphi(t)^h = 1 + \pi_0 A$ with $A \in R^\Delta$, and $-\ell\varrho(A) = \varrho(\varphi(t))^h - 1 = t(0)^h - 1 = 0$, so $\varrho(A) = 0$.

Step 3: ∇x. Apply the semilinear γ to $\varsigma^b x = \varphi(\varsigma)^h x'$ and use the hypothesis on $(\gamma - 1)(x')$:

$$t^b\varsigma^b\gamma(x) = \varphi(t)^h\varphi(\varsigma)^h(x' + (\gamma-1)x') = \varphi(t)^h(\varsigma^b x + \pi_0\varsigma^{a+b}z).$$

Cancelling ς^b gives $t^b\gamma(x) = \varphi(t)^h(x + \pi_0\varsigma^a z)$. Insert $\gamma(x) = x + \pi_0\nabla x$, $t^b = 1 + \pi_0 T_b$, $\varphi(t)^h = 1 + \pi_0 A$, and cancel π_0:

$$\nabla x = e_1 x + \varsigma^a z_1, \qquad e_1 = t^{-b}(A - T_b) \in R^\Delta, \quad z_1 = t^{-b}\varphi(t)^h z \in \mathbf{N}^\Delta.$$

By Step 2, $\ell\varrho(e_1) = u_0^{-b}(0 + (u_0^b - 1)) = 1 - u_0^{-b} = \ell c(b)$, so $\varrho(e_1) = c(b)$ ($\mathcal{O}'$ is ℓ-torsion-free).

Step 4: two product rules. For $n \in \mathbf{N}^\Delta$ and $k \geq 0$, $\gamma(\varsigma^k n) - \varsigma^k n = \varsigma^k((t^k - 1)\gamma(n) + \pi_0\nabla n)$, so

$$\nabla(\varsigma^k n) = \varsigma^k(T_k\gamma(n) + \nabla n), \qquad T_k\gamma(n) + \nabla n \in \mathbf{N}^\Delta,$$

as γ preserves $\mathbf{N}(T)_i$ and commutes with the γ_δ, and ∇ preserves $\mathbf{N}^\Delta$ (Lemma 28.15 (1)). For $g \in R^\Delta$ and $f = \varsigma^k g$: $\gamma(f) = t^k\varsigma^k\gamma(g)$ and, by Step 2 (a), (c), $\gamma(f) - f = \varsigma^k((t^k - 1)\gamma(g) + \gamma(g) - g) = \pi_0\varsigma^k(T_k\gamma(g) + \varsigma\tilde{g})$; hence $\pi_0\nabla(fx) = (\gamma f - f)x + \pi_0\gamma(f)\nabla x$ and, by Step 3,

$$\nabla(\varsigma^k g x) = \varsigma^k(T_k\gamma(g) + \varsigma\tilde{g} + t^k\gamma(g)e_1)x + \varsigma^a \cdot \varsigma^k t^k\gamma(g)z_1.$$

Step 5: induction on the layers. For $k \geq 0$ let $\mathcal{V}_k$ be the set of $y = \varsigma^k g x + \varsigma^a n$ with $g \in R^\Delta$, $n \in \mathbf{N}^\Delta$. We claim $(\nabla - c(b-k))(\mathcal{V}_k) \subseteq \mathcal{V}_{k+1}$. For such y, Step 4 gives

$$(\nabla - c(b-k))y = \varsigma^k Y x + \varsigma^a n', \qquad Y = T_k\gamma(g) + \varsigma\tilde{g} + t^k\gamma(g)e_1 - c(b-k)g \in R^\Delta,$$

with $n' = \varsigma^k t^k \gamma(g) z_1 + T_a\gamma(n) + \nabla n - c(b-k)n \in \mathbf{N}^\Delta$. By Steps 1–3, $\varrho(\gamma g) = \varrho(g)$ and

$$\ell\varrho(Y) = \varrho(g)\big((1-u_0^k) + u_0^k(1-u_0^{-b}) - (1-u_0^{k-b})\big) = 0,$$

so $\varrho(Y) = 0$ and $Y = \varsigma Y'$ with $Y' \in R^\Delta$ (item 1). Hence $(\nabla - c(b-k))y = \varsigma^{k+1}Y'x + \varsigma^a n' \in \mathcal{V}_{k+1}$.

Conclusion. We have $x \in \mathcal{V}_0$ ($g = 1$, $n = 0$). Put $y_0 = x$ and $y_{k+1} = (\nabla - c(b-k))y_k$ for $0 \leq k < a$; by the claim $y_k \in \mathcal{V}_k$, so $y_a = \varsigma^a(gx + n)$ with $g \in R^\Delta$, $n \in \mathbf{N}^\Delta$. As $\{b - k : 0 \leq k < a\} = J_1$ and the operators $\nabla - c(j)$ are polynomials in the one $\mathcal{O}_L$-linear operator ∇ on $\mathbf{N}^\Delta$, $y_a = P_{J_1}(\nabla)x$. So $y = gx + n$ is a Δ-invariant element of $\mathbf{N}(T)_i$ with $P_{J_1}(\nabla)x = (\pi_0 + \ell)^a y$. □

Proposition C.48. *Let ℓ, F, n, L, (τ_a), Φ, the weight word, c, $\mathbf{n}$, k_0, u_0 be as in Proposition C.43, let κ and λ satisfy the conclusion of Proposition C.43, and let E and n_1 satisfy the conclusion of Proposition C.44 for these κ, λ. Put $b_1 = s_{c-1}$, $t = s_{c-2} + S$, $B = s_c + S$. Then there are an integer $\sigma_1 \geq 0$ with*

$$\sigma_1 \leq \frac{B\,\ell}{(\ell-1)^2}$$

and $y_1 \in P_1(\mathbf{N}_{1,c-1})$ with $y_1 \in I_c$ and $Q_0^B y_1 \in \mathbf{N}_{1,c}$, and there are a finite product g_1 of the Q_s with $s \geq 1$ and an integer $\kappa_1 \geq 0$ with

$$\ell^{\kappa_1} g_1\Big(\ell^{\,b_1+\kappa}\,\mathbf{N}(\Phi)(y_1) - \ell^{\,\sigma_1+E+\sigma_B+t}\,\varphi^3\big(T_\kappa(H_{k_0})\big)\Big) \in Q_0^B\,P_1(\mathbf{N}_{2,c-1}).$$

Proof. Write $\psi = \mathbf{N}(\Phi)$, $G_0 = w + S$, $T = T_\kappa(H_{k_0})$, $H = H_{k_0}$, and $\mathbf{N}_{\nu,E}$ for the module $\mathbf{N}_E$ of $\mathbf{N}_\nu$. As in Proposition C.49, $c-1$ is an up site and $c-2$, c are down sites of the arc, so the window has $M_c = s_c + S = B$, $M_{c-1} = \eta \leq G_0$, $M_{c-2} = t \leq G_0$, and $B \leq h_B < m_X$.

Conventions on $\mathbf{N}_E$. Every Q_s is a unit of $E[[X]]$ ($Q_s(0) = \ell$), so $\mathbf{N}[1/\lambda_\infty] \subseteq \mathbf{N}_E$, φ extends to a φ-semilinear map of $\mathbf{N}_E$ commuting with every γ_u and mapping $X^k\mathbf{N}_E$ into $X^k\mathbf{N}_E$ ($\varphi(X) = XQ_0$), and ψ extends $E[[X]]$-linearly, commuting with φ and the γ_u (Proposition 23.7). For a site component and $k \geq 0$, $X^k\mathbf{N}_E \cap \mathbf{N}_a = X^k\mathbf{N}_a$ (compare coordinates in a basis). Multiplication by a product of the Q_s preserves $X^k\mathbf{N}_E$.

Step 1: the horizontal section through $s_0\lambda$. By the conclusion of Proposition C.43, $\ell^\kappa\lambda - \ell^{\sigma_B}\varphi^2(T) \in \ell^{-\kappa'}JP_2(\mathbf{N}_{2,c'}) \subseteq X\mathbf{N}_{2,E}$ ($J \in X\mathbb{Z}_\ell[[X]]$), and $\varphi^2(T) - \ell^\kappa\varphi^2(H) = \varphi^2(T - \ell^\kappa H) \in \varphi^2(X^{m_X}\mathbf{N}_{2,E}) \subseteq X^{m_X}\mathbf{N}_{2,E}$. Hence $\lambda - \ell^{\sigma_B}\varphi^2(H) \in X\mathbf{N}_{2,E}$. With $s_0 = Q_1^t Q_0^{-b_1}$ (a unit of $E[[X]]$ with constant term ℓ^{t-b_1}), $s_0\lambda - \ell^{t-b_1}\lambda = (s_0 - \ell^{t-b_1})\lambda \in X\mathbf{N}_{2,E}$. So the element $\ell^{t-b_1+\sigma_B}\varphi^2(H)$, which is invariant under every γ_u (H is, and γ_u commutes with φ), lies in $s_0\lambda + X\mathbf{N}_{2,E}$; as $s_0\lambda \in \mathbf{N}_{2,c-1}$ (Proposition C.44), it is the horizontal section through $s_0\lambda$ by the uniqueness in (Hf2) of Lemma 23.9.

Step 2: the horizontal section through n_1. Let $H^{(1)}$ be the horizontal section of $\mathbf{N}_1$ through n_1 ((Hf2) for the Wach module $\mathbf{N}_1$). Then $\psi(H^{(1)})$ is γ_u-invariant and lies in $\psi(n_1) + X\mathbf{N}_{2,E} = \ell^E s_0\lambda + X\mathbf{N}_{2,E}$, so by uniqueness and Step 1

$$\ell^{b_1}\psi(H^{(1)}) = \ell^{E+t+\sigma_B}\varphi^2(H).$$

Step 3: the lift. Put $\sigma_1 = s_\ell(B-1)$; then $\sigma_1 \le (B-1)\ell/(\ell-1)^2 \le B\ell/(\ell-1)^2$ (Lemma 23.9). By (Hf3) there is $x_B \in \mathbf{N}_{1,c-1}$ with $\ell^{\sigma_1}H^{(1)} - x_B \in X^B\mathbf{N}_{1,E}$. Put $y_1 = \varphi(x_B) \in P_1(\mathbf{N}_{1,c-1})$. By (Wm2) for $\mathbf{N}_1$ with the window of Lemma C.9 ((Ex1) of Proposition 23.7), $Q^{M_c}\varphi(\mathbf{N}_{1,c-1}) \subseteq \mathbf{N}_{1,c}$, so $Q_0^B y_1 \in \mathbf{N}_{1,c}$. For every u, $(\gamma_u - 1)x_B = (\gamma_u - 1)(x_B - \ell^{\sigma_1}H^{(1)}) \in X^B\mathbf{N}_{1,E} \cap \mathbf{N}_{1,c-1} = X^B\mathbf{N}_{1,c-1}$, hence $(\gamma_u - 1)y_1 = \varphi((\gamma_u-1)x_B) \in X^B Q_0^B\varphi(\mathbf{N}_{1,c-1}) \subseteq X^B\mathbf{N}_{1,c} \subseteq X\mathbf{N}_1$ ($B \ge 1$); so $y_1 \in I_c$.

Step 4: the congruence. Let

$$D' = \ell^{b_1+\kappa}\psi(x_B) - \ell^{\sigma_1+E+t+\sigma_B}\varphi^2(T).$$

By Step 2, $\ell^{b_1+\kappa}\psi(x_B) - \ell^{\kappa+\sigma_1+E+t+\sigma_B}\varphi^2(H) = \ell^{b_1+\kappa}\psi(x_B - \ell^{\sigma_1}H^{(1)}) \in X^B\mathbf{N}_{2,E}$, and $\ell^\kappa\varphi^2(H) - \varphi^2(T) \in X^{m_X}\mathbf{N}_{2,E} \subseteq X^B\mathbf{N}_{2,E}$; so $D' \in X^B\mathbf{N}_{2,E}$. By (Ry0) of Lemma 24.5 (site c', $j=2$, $G = G_0$, $g = 2G_0$, $m = R = m_X$), $(Q_0Q_1)^{G_0}P_2(\mathbf{N}_{2,c'}) \subseteq \mathbf{N}_{2,c-1}$; as $\varphi^2(T) \in P_2(\mathbf{N}_{2,c'})$ and $\psi(x_B) \in \mathbf{N}_{2,c-1}$, we get $(Q_0Q_1)^{G_0}D' \in \mathbf{N}_{2,c-1} \cap X^B\mathbf{N}_{2,E} = X^B\mathbf{N}_{2,c-1}$. Apply φ and put $g_1 = (Q_1Q_2)^{G_0}$, $\kappa_1 = 0$:

$$g_1\Big(\ell^{b_1+\kappa}\psi(y_1) - \ell^{\sigma_1+E+\sigma_B+t}\varphi^3(T)\Big) = \varphi\big((Q_0Q_1)^{G_0}D'\big) \in X^B Q_0^B\varphi(\mathbf{N}_{2,c-1}) \subseteq Q_0^B P_1(\mathbf{N}_{2,c-1}),$$

using $\psi\circ\varphi = \varphi\circ\psi$. □

Proposition C.49. *Let ℓ, F, n, L, (τ_a), Φ, the weight word, c, $\mathbf{n}$, k_0 and f_2 satisfy the hypotheses of Proposition C.41, with $\kappa_0 \ge 0$ and $x_0 \in \mathcal{O}_L$ such that $Q_1^{s_{c-1}}(\ell^{\kappa_0}f_2 - e_c(1\otimes x_0)) \in Q_0^{s_c+S}R_c$. Let u_0 be as in Proposition C.43, let κ and λ satisfy the conclusion of Proposition C.43, and suppose $s_0\lambda \in \mathbf{N}_{2,c-1}$. Put $B = s_c + S$ and $V = f_2\,\varphi(\lambda)$. Then $\Pi_c f_2 \in R_c$, $\varphi(\lambda) \in P_3(\mathbf{N}_{2,c'})$, $V \in P_1(\mathbf{N}_{2,c-1})$, the vector $\ell^{\sigma_B}f_2\,\mathbf{e}_{k_0}$ is an arc coordinate vector of V for $\mathbf{n}$, 3, H_c and m_X, and there are a finite product g_2 of the Q_s with $s \ge 1$ and an integer $\kappa_2 \ge 0$ with*

$$\ell^{\kappa_2}g_2\Big(\ell^{\,\kappa+\kappa_0}\,V - \ell^{\sigma_B}x_0\,\varphi^3(T_\kappa(H_{k_0}))\Big) \in Q_0^B\,P_1(\mathbf{N}_{2,c-1}).$$

Proof. Write $\mathbf{N} = \mathbf{N}_2$, $R_a = e_a\mathbf{A}_{F,L}$, $b_1 = s_{c-1}$, $t = s_{c-2} + S$, $G_0 = w + S$, $T = T_\kappa(H_{k_0})$, $P_1 = P_1(\mathbf{N}_{c-1})$. The sites $c-1$ and c are thick and $c-2$ is thin (as $\mathrm{len}_c = 3$), with signs $+1$, -1, -1 at $c-1$, c, $c-2$; so $b_1 \le b + \eta \le h_B$, $B \le h_B$, $\eta < s_{c-2} \le w$, and the window has $M_{c-1} = \eta \le G_0$, $M_{c-2} = t \le G_0$.

Three facts. (i) By Lemma 28.15 item 1 and $\varphi(X) = XQ_0$, $\varphi^s(Q_0) = Q_s$: $J = X^{m_X}Q_0^{m_X}Q_1^{2G_0}\varepsilon$ and $\varphi(J) = X^{m_X}Q_0^{m_X}Q_1^{m_X}Q_2^{2G_0}\varphi(\varepsilon)$ with units $\varepsilon, \varphi(\varepsilon)$. Since $m_X > 2h_B$, $B \le h_B$ and $\Pi_c = Q_0^{h_B}Q_1^{h_B}Q_2^{G_0}$, this gives $\varphi(J) \in Q_0^B R_c$ and $\varphi(J) \in X\Pi_c^2 R_c$. (ii) By (Ry0) of Lemma 24.5 (for $\mathbf{N}$ with the window of Lemma C.9 (1), a window by (Ex1) of Proposition 23.7; site c', $j=2$, $G = G_0$, which bounds M_{c-2} and M_{c-1}, $g = 2G_0$, $m = R = m_X \ge 1 + \max_a M_a$), $(Q_0Q_1)^{G_0}P_2(\mathbf{N}_{c'}) \subseteq \mathbf{N}_{c-1}$; applying φ, $(Q_1Q_2)^{G_0}\varphi(x) \in \varphi(\mathbf{N}_{c-1}) \subseteq P_1$ for $x \in P_2(\mathbf{N}_{c'})$. (iii) $\varphi(P_e(\mathbf{N}_{c'})) \subseteq P_{e+1}(\mathbf{N}_{c'})$, since $\varphi(a\varphi^e(x)) = \varphi(a)\varphi^{e+1}(x)$.

The data. By hypothesis there are $u, u' \in R_c$ with $Q_1^{b_1}f_2 = Q_2^t u$ and $Q_1^{b_1}(\ell^{\kappa_0}f_2 - x_0) = Q_0^B u'$ (here x_0 stands for $e_c(1\otimes x_0)$). By the conclusion of Proposition C.43 there are $\kappa' \ge 0$ and $y' \in P_2(\mathbf{N}_{c'})$ with $\ell^{\kappa'}(\ell^\kappa\lambda - \ell^{\sigma_B}\varphi^2(T)) = Jy'$; applying φ,

$$\ell^{\kappa'}(\ell^\kappa\varphi(\lambda) - \ell^{\sigma_B}\varphi^3(T)) = \varphi(J)\varphi(y'), \qquad \varphi(y') \in P_3(\mathbf{N}_{c'}). \qquad (*)$$

Integrality. $\Pi_c f_2 = Q_0^{h_B}Q_1^{h_B-b_1}Q_2^{G_0+t}u \in R_c$ as $b_1 \le h_B$. $\varphi(\lambda) \in P_3(\mathbf{N}_{c'})$ by (iii). With $s_0 = Q_1^tQ_0^{-b_1}$ at the site $c-1$ we have $\varphi(s_0) = Q_2^tQ_1^{-b_1}$, so $f_2 = \varphi(s_0)u$ and $V = u\,\varphi(s_0\lambda) \in R_c\,\varphi(\mathbf{N}_{c-1}) \subseteq P_1$, as $s_0\lambda \in \mathbf{N}_{c-1}$.

Coordinates. By $(*)$, $\ell^{\kappa'}\big(\ell^{\kappa}\Pi_c V - \Pi_c\,\ell^{\sigma_B} f_2\,\varphi^3(T)\big) = (\Pi_c f_2)\,\varphi(J)\,\varphi(y') \in X\Pi_c^2 P_3(\mathbf{N}_{c'})$ by (i). As $\Pi_c \ell^{\sigma_B} f_2 \in R_c$ and κ is admissible for $\mathbf{n}$ and m_X, this is (23.1) of Definition 23.3 for $y = V$, $e = 3$, $H = H_c$, $m = m_X$ and the vector $\ell^{\sigma_B} f_2 \mathbf{e}_{k_0}$ (the sum over k has the single term $k = k_0$).

Congruence. Put $g_2 = Q_1^{b_1}(Q_1Q_2)^{G_0}$ and $\kappa_2 = \kappa'$. Since $\ell^{\kappa_0} f_2 = x_0 + Q_1^{-b_1} Q_0^B u'$, $(*)$ gives

$$\ell^{\kappa'}\big(\ell^{\kappa+\kappa_0} V - \ell^{\sigma_B} x_0 \varphi^3(T)\big) = x_0\,\varphi(J)\varphi(y') + \ell^{\kappa'+\kappa} Q_1^{-b_1} Q_0^B u'\,\varphi(\lambda).$$

Multiplying by g_2: the first term becomes $x_0 Q_1^{b_1}\varphi(J)\cdot(Q_1Q_2)^{G_0}\varphi(y') \in Q_0^B P_1$ by (i), (ii); the second becomes $\ell^{\kappa'+\kappa} Q_0^B u' \cdot (Q_1Q_2)^{G_0}\varphi(\lambda) \in Q_0^B P_1$ by (ii). Hence $\ell^{\kappa_2} g_2\big(\ell^{\kappa+\kappa_0} V - \ell^{\sigma_B} x_0 \varphi^3(T)\big) \in Q_0^B P_1$. □

Lemma C.50. *Let ℓ, F, L, (τ_a) and $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} T'' \to 0$ be as in Lemma 23.33, with $\mathbf{N}(\iota')$, $\mathbf{N}(\pi)$ extended linearly to $\mathbf{N}(\,\cdot\,)[1/\lambda_\infty]$. Let $c \in \mathbb{Z}/n$, $e \geq 0$, $a = c + e$.*

(Ae1) Left exactness $\mathbf{N}(\iota')\big(P_e(\mathbf{N}(T')_c)\big) = P_e(\mathbf{N}(T)_c) \cap \ker \mathbf{N}(\pi)$. *In particular, if $x \in \mathbf{N}(T')[1/\lambda_\infty]$ and $\mathbf{N}(\iota')(x) \in P_e(\mathbf{N}(T)_c)$, then $x \in P_e(\mathbf{N}(T')_c)$.*

(Ae2) Arc membership *Let $(M_a, h_a)_a$ be a window of V as in (Ex1) and $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$ with $H \geq h$ pointwise. If $x \in \mathbf{N}(T')[1/\lambda_\infty]$ and $\mathbf{N}(\iota')(x) \in P_e(\mathbf{N}(T)_c) + \mathbf{N}(T)_a$, then $\Lambda_{a,e}(H)\,x \in P_e(\mathbf{N}(T')_c)$.*

Proof. Write $N' = \mathbf{N}(T')$, $N = \mathbf{N}(T)$, $N'' = \mathbf{N}(T'')$, $R_b = e_b \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$.

(Ae1). By Lemma 23.33, the sequence of R_c-modules $0 \to N'_c \to N_c \to N''_c$ (maps $\mathbf{N}(\iota')$, $\mathbf{N}(\pi)$) is exact. The ring map $\varphi^e\colon R_c \to R_a$ is, under the identifications with $\mathcal{O}_L[[X]]$, the substitution $X \mapsto (1+X)^{\ell^e} - 1$; as $(1+X)^{\ell^e} - 1$ is a distinguished polynomial of degree ℓ^e, Weierstrass division shows that R_a is a free R_c-module with basis $1, X, \dots, X^{\ell^e - 1}$. So $R_a \otimes_{\varphi^e, R_c} (-)$ is exact, and $0 \to R_a \otimes N'_c \to R_a \otimes N_c \to R_a \otimes N''_c$ is exact. By Lemma 23.15(1), $g \otimes x \mapsto g\varphi^e(x)$ identifies these three modules with $P_e(N'_c)$, $P_e(N_c)$, $P_e(N''_c)$; since $\mathbf{N}(\iota')$ and $\mathbf{N}(\pi)$ are $\mathbf{A}_{F,L}$-linear and commute with φ (Ex3), the identifications carry $1 \otimes \mathbf{N}(\iota')$ and $1 \otimes \mathbf{N}(\pi)$ to the restrictions of $\mathbf{N}(\iota')$ and $\mathbf{N}(\pi)$. Hence $0 \to P_e(N'_c) \to P_e(N_c) \to P_e(N''_c)$ is exact, which is the first assertion. For the second: $\mathbf{N}(\pi)(\mathbf{N}(\iota')(x)) = 0$ (Lemma 23.33, extended to the localisation), so $\mathbf{N}(\iota')(x) = \mathbf{N}(\iota')(x')$ with $x' \in P_e(N'_c)$, and $x = x'$ because $\mathbf{N}(\iota')$ remains injective on $N'[1/\lambda_\infty]$ (localisation is exact).

(Ae2). Put $\Lambda = \Lambda_{a,e}(H) \in \mathbb{Z}_\ell[[X]]$. Then $\Lambda P_e(N_c) \subseteq P_e(N_c)$ (it is an $\mathbf{A}_{F,L}$-module) and $\Lambda N_a \subseteq P_e(N_c)$ by Lemma 23.15(2). Hence $\mathbf{N}(\iota')(\Lambda x) = \Lambda\,\mathbf{N}(\iota')(x) \in P_e(N_c)$, and (Ae1) gives $\Lambda x \in P_e(N'_c)$. □

Lemma C.51. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7; let (V', T'), (V, T) be pairs and $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} \mathcal{O}_L \to 0$ an exact sequence of G_F-equivariant $\mathcal{O}_L$-linear maps ($\mathcal{O}_L$ the trivial representation); put $\mathbf{N}' = \mathbf{N}(T')$, $\mathbf{N} = \mathbf{N}(T)$, and extend $\mathbf{N}(\iota')$ linearly to $\mathbf{N}'[1/\lambda_\infty]$. Let $c \in \mathbb{Z}/n$, $e \geq 0$, $a = c + e$, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$, $\Pi = \Lambda_{a,e}(H)$, and $m \geq 1$ an integer with $m \geq 2H(a - s)$ for $0 \leq s < e$. Let $\mathbf{n}'$, $\mathbf{n}$ be frames at c of $\mathbf{N}'$, $\mathbf{N}$, with crystalline frames (d'_k), (d_k). Let $w \in \mathbf{N}'[1/\lambda_\infty]$ with*

$$\Pi\, w \in P_e(\mathbf{N}'_c) \qquad \text{and} \qquad \mathbf{N}(\iota')(w) = p - x, \quad p \in P_e(\mathbf{N}_c),\ x \in \mathbf{N}_a.$$

Then there are $t \geq 0$ and an arc coordinate vector f of $\ell^t w$ (for $\mathbf{N}'$, $\mathbf{n}'$) that is polar and is pole-bounded by every $B = (B_s)_{s<e}$, $B_s \in \mathbb{Z}_{\geq 0} \cup \{\infty\}$, such that

$$\varphi^e\big(\varepsilon_{c+3} D_{\mathrm{cris}}(V')\big) \cap \varphi^{s+4}\big(\mathrm{Fil}^{B_s+1} D_{\mathrm{cris}}(V')\big) = 0 \qquad \text{for every } s < e \text{ with } B_s < \infty.$$

Proof. By Lemma 23.14, $\mathbf{N}'$ has (Ac1) for $\mathbf{n}'$ and $\mathbf{N}$ has (Ac2) and (Ac4) for $\mathbf{n}$, at (c,e,H,m); by Lemma 23.13 (2), $\mathbf{N}$ has (Ac3) for $\mathbf{n}$ at (c,e,H,m). Write r', r for the ranks, $D'=D_{\mathrm{cris}}(V')$, $D=D_{\mathrm{cris}}(V)$, δ'_e, δ_e for the maps of Definition 23.3 built from (d'_k), (d_k), and T'_κ, T_κ for the truncations of the horizontal sections H'_k, H_k through n'_k, n_k. For a row vector $\mathbf{v}\in\mathcal{K}_a^{r'}$ and an $r'\times r$ matrix o write $\mathbf{v}o\in\mathcal{K}_a^{r}$.

Step 0: arc coordinate vectors are linear in y. If κ is admissible, so is every $\kappa_1\geq\kappa$, and $T_{\kappa_1}(H_k)=\ell^{\kappa_1-\kappa}T_\kappa(H_k)$; multiplying the defining relation of arc coordinate vectors by $\ell^{\kappa_1-\kappa}$ shows that an arc coordinate vector for (κ,κ') is one for every $(\kappa_1,\kappa'_1)\geq(\kappa,\kappa')$. Hence (a) if f is an arc coordinate vector of y, then $\ell^u f$ is one of $\ell^u y$ ($u\geq 0$; multiply the defining relation of arc coordinate vectors by ℓ^u), and (b) if f_1, f_2 are arc coordinate vectors of y_1, y_2, then, taking common (κ,κ') and subtracting, f_1-f_2 is one of y_1-y_2. The same holds for $\mathbf{N}'$.

Step 1: the frames are compared by a constant matrix, and arc coordinate vectors are transported. $\mathbf{N}(\iota')$ is $\mathbf{A}_{F,L}$-linear, commutes with φ and the γ_u (Proposition 23.7 (Ex3)), and extends to $\mathbf{N}'_E\to\mathbf{N}_E$ commuting with the γ_u of Lemma 23.9. Write $\mathbf{N}(\iota')(n'_k)=\sum_j\mu_{kj}n_j$ with $\mu_{kj}\in e_c\mathbf{A}_{F,L}$, and let $o_{kj}\in\mathcal{O}_L$ be given by $\mu_{kj}\equiv e_c(1\otimes o_{kj})\bmod X$. The element $\mathbf{N}(\iota')(H'_k)$ is fixed by every γ_u and lies in $\mathbf{N}(\iota')(n'_k)+X\mathbf{N}_E=\sum_j o_{kj}n_j+X\mathbf{N}_E$; so does $\sum_j o_{kj}H_j$, since γ_u fixes the constants $e_c(1\otimes o_{kj})$. By the uniqueness in Lemma 23.9 (Hf2),

$$\mathbf{N}(\iota')(H'_k)=\sum_j o_{kj}H_j\qquad(k\leq r'). \tag{C.4}$$

Let κ be admissible for both frames and $\Delta_k=\mathbf{N}(\iota')(T'_\kappa(H'_k))-\sum_j o_{kj}T_\kappa(H_j)\in\mathbf{N}_c$. By the definition of truncations and (C.4), $\Delta_k=\mathbf{N}(\iota')\big(T'_\kappa(H'_k)-\ell^\kappa H'_k\big)+\sum_j o_{kj}\big(\ell^\kappa H_j-T_\kappa(H_j)\big)\in X^m\mathbf{N}_E$. In the basis $\mathbf{n}$, $\mathbf{N}_c\cap X^m\mathbf{N}_E$ consists of the vectors with coordinates in $e_c\mathbf{A}_{F,L}\cap X^m e_cE[[X]]=X^m e_c\mathbf{A}_{F,L}$, so $\Delta_k\in X^m\mathbf{N}_c$, and since $\varphi^e(X)=X\lambda_e$,

$$\varphi^e(\Delta_k)\in X^m\lambda_e^m P_e(\mathbf{N}_c)\subseteq X\Pi^2\,P_e(\mathbf{N}_c),$$

because $m\geq 1$ and $\lambda_e^m=\prod_{s<e}Q_s^m$ is divisible by $\Pi^2=\prod_{s<e}Q_s^{2H(a-s)}$ in $\mathbb{Z}_\ell[[X]]$ ($m\geq 2H(a-s)$). Now let f be an arc coordinate vector of $y'\in\mathbf{N}'[1/\lambda_\infty]$ for (κ,κ'), κ admissible for both frames (Step 0). Applying $\mathbf{N}(\iota')$ to the defining relation of arc coordinate vectors, which maps $X\Pi^2P_e(\mathbf{N}'_c)$ into $X\Pi^2P_e(\mathbf{N}_c)$, and using $\varphi^e(e_c(1\otimes o)z)=e_a(1\otimes o)\varphi^e(z)$,

$$\ell^{\kappa'}\Big(\ell^\kappa\Pi\,\mathbf{N}(\iota')(y')-\sum_j\Pi(fo)_j\,\varphi^e(T_\kappa(H_j))\Big)=\ell^{\kappa'}\sum_k\Pi f_k\,\varphi^e(\Delta_k)+\big(\text{element of }X\Pi^2P_e(\mathbf{N}_c)\big),$$

and $\Pi f_k\in e_a\mathbf{A}_{F,L}$ gives $\Pi f_k\varphi^e(\Delta_k)\in X\Pi^2P_e(\mathbf{N}_c)$. As $\Pi(fo)_j\in e_a\mathbf{A}_{F,L}$, *$fo$ is an arc coordinate vector of $\mathbf{N}(\iota')(y')$.*

Step 2: the crystalline frames are compared by the same matrix; consequences. Let $D(\iota')$ be the restriction of $1\otimes\iota'\colon B_{\mathrm{cris}}\otimes_{\mathbb{Z}_\ell}T'\to B_{\mathrm{cris}}\otimes_{\mathbb{Z}_\ell}T$ to $D'\to D$, and $D(\pi)\colon D\to D_{\mathrm{cris}}(L)$ likewise. Since $0\to T'\to T\to\mathcal{O}_L\to 0$ is split as a sequence of $\mathbb{Z}_\ell$-modules, $0\to B\otimes T'\to B\otimes T\to B\otimes\mathcal{O}_L\to 0$ is exact for every $\mathbb{Z}_\ell$-module B; the maps $1\otimes\iota'$, $1\otimes\pi$ are G_F-equivariant, $B_{\mathrm{cris}}\otimes\mathcal{O}_L$-linear and commute with $\varphi=\varphi\otimes 1$. By Lemma 23.11 (Ev3) and Proposition 23.7 (Ex3), on pure tensors $\mathrm{Ev}(g\otimes\mathbf{N}(\iota')z)=e(g)\varphi^3\big((\rho\otimes 1)((1\otimes\iota')\iota_{T'}(z))\big)=(1\otimes\iota')\mathrm{Ev}'(g\otimes z)$, so $\mathrm{Ev}\circ\mathbf{N}(\iota')=(1\otimes\iota')\circ\mathrm{Ev}'$. Also $\mathrm{Ev}(gW)=e(g)\mathrm{Ev}(W)$ for $g\in\mathbf{A}_{F,L}$, as e is a ring homomorphism; with $H_j=e_cH_j$ this gives $\mathrm{Ev}(e_c(1\otimes o)H_j)=(1\otimes o)e(e_c)\mathrm{Ev}(H_j)=o\,d_j$. Applying Ev to (C.4) ($H'_k\in\mathbf{N}'_R$ by Lemma 23.10):

$$D(\iota')(d'_k)=\sum_j o_{kj}d_j,\qquad\text{hence}\qquad D(\iota')(\delta'_e(\mathbf{v}))=\delta_e(\mathbf{v}o)\quad(\mathbf{v}\in L^{r'}). \tag{C.5}$$

(i) δ_e is injective on L^r: the d_j are L-linearly independent (Lemma 23.10 (2)) and φ^e is L-linear and injective on $B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V$ (φ is injective on B_{cris}). The same holds for δ'_e. (ii) $\mathbf{v} \mapsto \mathbf{v}o$ is injective on $L^{r'}$: if $\mathbf{v}o = 0$ then $D(\iota')(\sum_k v_k d'_k) = 0$ by (C.5), so $\sum_k v_k d'_k = 0$ and $\mathbf{v} = 0$. Hence o has rank r' over L, and there are $q \geq 0$ and an $r \times r'$ matrix P over $\mathcal{O}_L$ with $oP = \ell^q I_{r'}$.

Step 3: polar vectors of T come from T', with the filtration. Let $\mathbf{v} \in \mathcal{O}_L^r$, and suppose $\delta_e(\mathbf{v}) \in \varphi^{s_0+4}(\mathrm{Fil}^{u_0} D)$ for some $s_0 < e$ and $u_0 \geq 1$. We show: there is $\tilde{\mathbf{v}} \in L^{r'}$ with $\tilde{\mathbf{v}}o = \mathbf{v}$, and for all $s < e$, $u \in \mathbb{Z}$, if $\delta_e(\mathbf{v}) \in \varphi^{s+4}(\mathrm{Fil}^u D)$ then $\delta'_e(\tilde{\mathbf{v}}) \in \varphi^{s+4}(\mathrm{Fil}^u D')$.

First, $(t^u B_{\mathrm{dR}}^+)^{G_F} = 0$ for $u \geq 1$: if $z = t^u b$ is G_F-invariant, then $\chi_{\mathrm{cyc}}(g)^u g\theta(b) = \theta(b)$ for all g, so $\theta(b) = 0$ by Theorem B.42 (2), i.e. $z \in t^{u+1} B_{\mathrm{dR}}^+$; by induction $z \in \bigcap_k t^k B_{\mathrm{dR}}^+ = 0$ (Theorem B.40). As G_F acts trivially on L, $\mathrm{Fil}^u D_{\mathrm{cris}}(L) \subseteq (t^u B_{\mathrm{dR}}^+ \otimes_{\mathbb{Q}_\ell} L)^{G_F} = (t^u B_{\mathrm{dR}}^+)^{G_F} \otimes_{\mathbb{Q}_\ell} L = 0$ for $u \geq 1$.

Write $\delta_e(\mathbf{v}) = \varphi^{s_0+4}(z_0)$, $z_0 \in \mathrm{Fil}^{u_0} D$. Then $D(\pi)(z_0) \in \mathrm{Fil}^{u_0} D_{\mathrm{cris}}(L) = 0$, so $D(\pi)(\delta_e(\mathbf{v})) = \varphi^{s_0+4}(D(\pi)z_0) = 0$, and by exactness and G_F-equivariance $\delta_e(\mathbf{v}) = D(\iota')(y)$ with $y \in D'$. On D', a finite-dimensional $\mathbb{Q}_\ell$-space, φ is injective, hence bijective; let $y_0 = \varphi^{-e}(y)$. Then $\varphi^e(D(\iota')y_0) = \delta_e(\mathbf{v}) = \varphi^e(\sum_k v_k d_k)$, so $D(\iota')(y_0) = \sum_k v_k d_k \in \varepsilon_{c+3} D$. Write $y_0 = \sum_b \varepsilon_b y_0$ (ε_b the orthogonal idempotents of Lemma 23.10, which commute with $D(\iota')$); for $b \neq c+3$, $D(\iota')(\varepsilon_b y_0) = \varepsilon_b \sum_k v_k d_k = 0$, so $\varepsilon_b y_0 = 0$. Thus $y_0 \in \varepsilon_{c+3} D'$, which has L-basis (d'_k) by Lemma 23.10 (2): $y_0 = \sum_k \tilde{v}_k d'_k$, $y = \delta'_e(\tilde{\mathbf{v}})$, and $\delta_e(\tilde{\mathbf{v}}o) = D(\iota')(y) = \delta_e(\mathbf{v})$ by (C.5), so $\tilde{\mathbf{v}}o = \mathbf{v}$ by Step 2 (i). Finally let $\delta_e(\mathbf{v}) = \varphi^{s+4}(z_1)$ with $z_1 \in \mathrm{Fil}^u D$, and $z'_1 = \varphi^{-(s+4)}(y) \in D'$; then $\varphi^{s+4}(D(\iota')z'_1) = \varphi^{s+4}(z_1)$, so $D(\iota')(z'_1) = z_1$. Choose a $\mathbb{Q}_\ell$-basis of V extending one of $\iota'(V')$: the coordinates of $z_1 = (1 \otimes \iota')(z'_1)$ in B_{dR} lie in $\mathrm{Fil}^u B_{\mathrm{dR}}$ and are those of z'_1 on the basis of V'; so $z'_1 \in \mathrm{Fil}^u B_{\mathrm{dR}} \otimes V'$, i.e. $z'_1 \in \mathrm{Fil}^u D'$ and $\delta'_e(\tilde{\mathbf{v}}) = \varphi^{s+4}(z'_1) \in \varphi^{s+4}(\mathrm{Fil}^u D')$.

Step 4: one linear relation among the coordinates. By (Ac1) for $\mathbf{N}'$ there are t_1 and an arc coordinate vector F of $\ell^{t_1} w$; by Step 1, Fo is one of $\ell^{t_1}(p - x)$. By (Ac2) there are t_2 and an arc coordinate vector G of $\ell^{t_2} p$ with $G_j \in e_a \mathbf{A}_{F,L}$. Since $\mathbf{N}(\iota')$ is $\mathbf{A}_{F,L}$-linear and commutes with φ, it maps $P_e(\mathbf{N}'_c)$ into $P_e(\mathbf{N}_c)$; so $\Pi x = \Pi p - \mathbf{N}(\iota')(\Pi w) \in P_e(\mathbf{N}_c)$, and by (Ac3) there are t_3, κ_3 and an arc coordinate vector f^x of $\ell^{t_3} x$ with a section decomposition

$$\ell^{\kappa_3} f_j^x = \sum_{i \in I} g_i v_{i,j}, \qquad g_i \in Q^{\alpha_i} e_a \mathbf{A}_{F,L}, \quad \delta_e(\mathbf{v}_i) \in \varphi^{s+4}\big(\mathrm{Fil}^{-\alpha_i(s)} D\big) \ (s < e).$$

By Step 0, $\ell^{t_2+t_3} Fo - \ell^{t_1+t_3} G + \ell^{t_1+t_2} f^x$ is an arc coordinate vector of $\ell^{t_1+t_2+t_3}(\mathbf{N}(\iota')(w) - p + x) = 0$, so by (Ac4) there are $t_4 \geq 0$ and $\epsilon \in (X \Pi e_a \mathbf{A}_{F,L})^r$ with

$$\ell^{t_4+t_2+t_3} Fo = \epsilon + \ell^{t_4+t_1+t_3} G - \ell^{t_4+t_1+t_2} f^x. \tag{C.6}$$

Step 5: separating the polar terms. Let $I_{\mathrm{p}} = \{i \in I : \ \alpha_i(s) < 0 \text{ for some } s < e\}$. For $i \notin I_{\mathrm{p}}$, $\alpha_i \geq 0$ and $g_i \in e_a \mathbf{A}_{F,L}$. For $i \in I_{\mathrm{p}}$, Step 3 applies to $\mathbf{v}_i$ (with $u_0 = -\alpha_i(s_0) \geq 1$) and gives $\tilde{\mathbf{v}}_i \in L^{r'}$ with $\tilde{\mathbf{v}}_i o = \mathbf{v}_i$ and $\delta'_e(\tilde{\mathbf{v}}_i) \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha_i(s)} D')$ for all $s < e$. Choose $b \geq 0$ with $\mathbf{r}_i = \ell^b \tilde{\mathbf{v}}_i \in \mathcal{O}_L^{r'}$ for all $i \in I_{\mathrm{p}}$, and put

$$S_j^{\mathrm{np}} = \sum_{i \notin I_{\mathrm{p}}} g_i v_{i,j} \in e_a \mathbf{A}_{F,L}, \qquad \mathcal{P}_k = \sum_{i \in I_{\mathrm{p}}} g_i r_{i,k}, \qquad \text{so} \quad (\mathcal{P}o)_j = \ell^b\big(\ell^{\kappa_3} f_j^x - S_j^{\mathrm{np}}\big).$$

Multiplying (C.6) by ℓ^{κ_3+b} and inserting this,

$$\big(\ell^{\kappa_3+b+t_4+t_2+t_3} F + \ell^{t_4+t_1+t_2} \mathcal{P}\big) o = \mathcal{R},$$
$$\mathcal{R} = \ell^{\kappa_3+b} \epsilon + \ell^{\kappa_3+b+t_4+t_1+t_3} G - \ell^{b+t_4+t_1+t_2} S^{\mathrm{np}} \in (e_a \mathbf{A}_{F,L})^r.$$

Multiplying on the right by the matrix P of Step 2 ($oP = \ell^q I$) and putting $N_0 = q + \kappa_3 + b + t_4 + t_2 + t_3$:

$$\ell^{N_0} F = \mathcal{R}P - \ell^{q+t_4+t_1+t_2} \mathcal{P}, \qquad \mathcal{R}P \in (e_a \mathbf{A}_{F,L})^{r'}. \tag{C.7}$$

Step 6: the conclusion. Let $f = \ell^{N_0} F$; by Step 0 (a) it is an arc coordinate vector of $\ell^t w$, $t = N_0 + t_1$. By (C.7), f has the section decomposition consisting of the terms $\big((\mathcal{R}P)_k, \mathbf{e}_k, 0\big)$, $k \le r'$ ($\mathbf{e}_k$ the unit vectors), and $\big(g_i, -\ell^{q+t_4+t_1+t_2}\mathbf{r}_i, \alpha_i\big)$, $i \in I_{\mathrm{p}}$; discard the terms whose vector is 0. For the first kind $\alpha = 0$. For a term of the second kind with vector $\mathbf{v}' \neq 0$ and $s < e$ with $\alpha_i(s) < 0$: $\delta'_e(\mathbf{v}')$ is a non-zero (Step 2 (i)) L-multiple of $\delta'_e(\tilde{\mathbf{v}}_i)$, so $\delta'_e(\mathbf{v}') \in \varphi^{s+4}(\mathrm{Fil}^{-\alpha_i(s)} D')$. Hence f is polar. Let B be as in the statement and $B_s < \infty$. Since $\delta'_e(\mathbf{v}') = \varphi^e(\sum_k v'_k d'_k) \in \varphi^e(\varepsilon_{c+3} D')$ is non-zero, the hypothesis on B excludes $\delta'_e(\mathbf{v}') \in \varphi^{s+4}(\mathrm{Fil}^{B_s+1} D')$; as the filtration is decreasing, $-\alpha_i(s) \le B_s$. So the same decomposition shows that f is pole-bounded by B. $\square$

C.2 Thick alternating words

This section proves Proposition C.52, the colength bound for words of even length that are thick at every site, with signs alternating by parity; it is item 2 of the row bound Proposition 26.2. Since no site is thin, the cuts of Section C.1 are not available, and the down sites take their place. After a bounded power of ℓ and n generator steps of a free cover, every crystalline class is a sum of relay classes of Wach vectors at the down sites (Proposition C.53, Subsection C.2.1); these vectors lift along the onto map modulo X up to ℓ^e with e of order H'/ℓ^2, on a submodule reached in at most six generator steps and three length steps (Proposition C.57, Subsection C.2.2). The colength then follows from Lemma C.76.

C.2.1 Splitting of crystalline classes for thick alternating words

The subsection states Proposition C.52 and proves the splitting Proposition C.53, from unit lifts at the down sites (Proposition C.54) and a second lift with the pull-back condition (Proposition C.56). It also states the lifting result Proposition C.57, which is proved in Subsection C.2.2.

Proposition C.52. *There is an absolute constant $c_{\mathrm{C}} \ge 1$ with the following property. Let $\ell \ge 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of even degree n, L with ring of integers $\mathcal{O}_L$ as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Suppose that there is $d \in \{0,1\}$ such that, for the representatives $0 \le a < n$, $\epsilon_a = -1$ if and only if $a + d$ is even, and that, with*

$$a_{\mathrm{R}} = \frac{H'(2\ell-1)}{(\ell-1)^2} + 4 + \log_\ell(2H'),$$

every $s_a \ge 2a_{\mathrm{R}} + \eta + 1$ and every $s_a \ge (H' - \eta)/2$. Then the colength of Φ is at most

$$c_{\mathrm{C}}\Big((n+1)\, d_2\Big(\frac{H'}{\ell^2} + S + \frac{\eta}{\ell} + 1 + \log_\ell(2H')\Big) + n\, m\Big(1 + \frac{H'}{\ell} + \log_\ell(2H')\Big)\Big).$$

Proof. Put

$$B = \frac{H'}{\ell^2} + S + \frac{\eta}{\ell} + 1 + \log_\ell(2H'), \qquad \lambda = d_2 S + 2m\Big(\frac{H'+1}{\ell-1} + 1\Big),$$

let c_1 and c_4 be the absolute constants of Proposition C.53 and Proposition C.57, c_{ur} that of Proposition 24.1, and $c_{\mathrm{C}} = \max(c_1 + c_4 + 2,\ 8c_{\mathrm{ur}} + 4)$. Here $H' = \max_a s_a + S + \eta \ge 1$, since $s_a > \eta \ge 0$. Let $\mathcal{H} = H^1_f(D, T_2)$ and $\mathcal{Y} = \Phi_* H^1_f(D, T_1) \subseteq \mathcal{H}$; the colength of Φ is $\mathrm{nl}(\mathcal{H}/\mathcal{Y})$.

Step 0: down sites and windows. Let $C = \{c \in \mathbb{Z}/n :\ \epsilon_c = -1\}$. Since n is even, the parity of $a+d$ is well defined for $a \in \mathbb{Z}/n$ and changes from a to $a+1$; so by hypothesis $|C| = n/2$,

and $\epsilon_{c+1} = 1$ for every $c \in C$. Put $(M_a, h_a) = (s_a + S, \eta)$ if $\epsilon_a = -1$ and $(M_a, h_a) = (\eta, s_a + S)$ if $\epsilon_a = 1$. By (Ow1), every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$. The same holds for V_2: $\Phi(V_1)$ contains $\Phi(T_1) = T_2$, which spans V_2, so Φ is onto and $V_2 \cong V_1/\ker\Phi$; for de Rham representations the functors $V \mapsto \mathrm{gr}^i D_{\mathrm{dR}}(V)$ are exact (each is left exact, and the sum of their dimensions is $\dim V$ on de Rham representations), and they respect the decomposition along the embeddings τ_a, so the multiplicity of each Hodge jump of V_2 at τ_a is at most its multiplicity for V_1. Thus $(M_a, h_a)_a$ is a window of both V_1 and V_2 as in (Ex1), it is the window used in Proposition C.53 and Proposition C.57, and $\max_a M_a = \max_a s_a + S$ (as $s_a > \eta$), $M_{c+1} = \eta$ for $c \in C$, $\max_a(M_a + h_a) = H'$.

Step 1: a free cover. The representation V_2 is crystalline, hence de Rham, of dimension d_2 over L, and F has degree n over $\mathbb{Q}_\ell$; by Lemma 27.3, $\mathcal{H}$ is generated by $r \le (n+1)d_2$ elements. Let $P = \mathcal{O}_L^r$ and $\psi\colon P \to \mathcal{H}$ the surjection sending the standard basis to these generators.

Step 2: splitting at the down sites. By Proposition C.53 (its hypotheses are those of the present statement) there are integers $0 \le s \le c_1 B$, $g \ge \eta$, $m_{\mathrm{R}} \ge 1 + \max_a(s_a + S)$, $R \ge \max(m_{\mathrm{R}}, g)$, submodules $P = P_0 \supseteq \cdots \supseteq P_{k_0}$ with $k_0 \le n$ and each P_i/P_{i+1} generated by at most m elements, and $\mathcal{O}_L$-linear maps $w_c\colon P_{k_0} \to I_c^2$ ($c \in C$; I_c^ν and $\rho_{c,1}^\nu$ formed for $\mathbf{N}(T_\nu)$ with c, $j = 1$, $G = \eta$, g, m_{R}, R) satisfying (Vw1) and (Vw2).

Step 3: lifting at the down sites, one after the other. Enumerate $C = \{c_1, \dots, c_{n/2}\}$ and put $P^{(0)} = P_{k_0}$. For $i = 1, \dots, n/2$ apply Proposition C.57 at the down site c_i to P, the submodule $P^{(i-1)} \subseteq P_{k_0}$ and the restriction of w_{c_i} to $P^{(i-1)}$; its hypotheses hold by (Vw1). It gives an integer $0 \le e_{c_i} \le c_4 B$ and a chain from $P^{(i-1)}$ down to a submodule $P^{(i)}$ with at most 6 steps whose quotients are generated by at most m elements and at most 3 steps whose quotients have normalised length at most λ, such that for every $f \in P^{(i)}$ there are $u \in I_{c_i}^1$ and a finite product λ' of the Q_s with $\lambda' u \in \mathbf{N}(T_1)$ and $\ell^{e_{c_i}} w_{c_i}(f) - \mathbf{N}(\Phi)(u) \in X\mathbf{N}(T_2)_{c_i}$. Concatenating the chain of Step 2 with these $n/2$ chains gives submodules $P = P_0 \supseteq P_1 \supseteq \cdots \supseteq P_k = P^{(n/2)}$ and a set I of indices (the steps of Step 2 and the generator steps of Step 3) with

$$|I| \le n + 6 \cdot \tfrac{n}{2} = 4n, \qquad k - |I| \le 3 \cdot \tfrac{n}{2},$$

P_i/P_{i+1} generated by at most m elements for $i \in I$ and $\mathrm{nl}(P_i/P_{i+1}) \le \lambda$ for $i \notin I$.

Step 4: the killing exponent. Let $e^* = \max_{c \in C} e_c \le c_4 B$ and $f \in P_k$. For $c \in C$, $f \in P^{(i)}$ for the index i with $c = c_i$, so there are u_c, λ_c' as in Step 3. Apply Lemma 24.9 with $w = w_c(f) \in I_c^2$, $u = u_c \in I_c^1$, $k = e_c$ and the parameters c, $j = 1$, $G = \eta$, g, m_{R}, R: its hypotheses hold by Step 0 ($g \ge G$; $m_{\mathrm{R}} \ge 1 + \max_a M_a$ for both windows; $R \ge \max(m_{\mathrm{R}}, g)$; $M_{c+1} = \eta \le G$), and $\lambda_c' u_c \in \mathbf{N}(T_1)$. Hence $\ell^{e_c}\rho_{c,1}^2(w_c(f)) \in \mathcal{Y}$, and so $\ell^{e^*}\rho_{c,1}^2(w_c(f)) \in \mathcal{Y}$. By (Vw2), $\ell^{s+e^*}\psi(f) = \pm\sum_{c \in C} \ell^{e^*}\rho_{c,1}^2(w_c(f)) \in \mathcal{Y}$. Thus $\ell^e\psi(P_k) \subseteq \mathcal{Y}$ with $e = s + e^* \le (c_1 + c_4)B$.

Step 5: the uniform exponent. Apply Proposition 24.1 with $p = \ell$ (odd), $K = F$ (unramified), the field L (it contains $\sigma(F(\mu_\ell))$ for every embedding σ, by Definition 23.1), V_1, V_2 crystalline, the map Φ with $\Phi(T_1) = T_2$, and $a_{\tau_a}^- = M_a$, $a_{\tau_a}^+ = h_a$ (the τ_a are all the embeddings of F into L; Step 0). Then $\mathrm{wt} = H'$ and $\ell^{e'}\mathcal{H} \subseteq \mathcal{Y}$ with the integer $e' = e_{\mathrm{A}} \le c_{\mathrm{ur}}\big(2 + H'/\ell + \log_\ell(H' + 1)\big) \le 2c_{\mathrm{ur}}\big(1 + H'/\ell + \log_\ell(2H')\big)$, using $H' + 1 \le 2H'$.

Step 6: counting. Lemma C.76, applied to $\mathcal{H} \supseteq \mathcal{Y}$, the surjection ψ from the free module P of rank r, the chain and the set I of Step 3, the integers e, e' and the real λ ((Fc1), (Fc2) by Step 3, (Fc3) by Step 4, (Fc4) by Step 5), gives

$$\mathrm{nl}(\mathcal{H}/\mathcal{Y}) \le r\,e + |I|\,m\,e' + (k - |I|)\,\lambda \le (n+1)d_2(c_1 + c_4)B + 8c_{\mathrm{ur}}\,n\,m\Big(1 + \frac{H'}{\ell} + \log_\ell(2H')\Big) + \frac{3n}{2}\lambda.$$

With the side calculation, the colength is at most

$$\Big(c_1+c_4+\tfrac{3}{2}\Big)(n+1)\,d_2\,B+(8c_{\mathrm{ur}}+4)\,n\,m\Big(1+\frac{H'}{\ell}+\log_\ell(2H')\Big)$$
$$\le c_{\mathrm{C}}\Big((n+1)\,d_2\,B+n\,m\Big(1+\frac{H'}{\ell}+\log_\ell(2H')\Big)\Big),$$

which is the assertion. □

Proposition C.53. *There is an absolute constant $c_1\ge 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1\to V_2$ (with lattices T_1,T_2) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.52, let $C=\{c\in\mathbb{Z}/n:\ \epsilon_c=-1\}$ be the set of* down sites*, and put*

$$B=\frac{H'}{\ell^2}+S+\frac{\eta}{\ell}+1+\log_\ell(2H').$$

Then there are integers $0\le s\le c_1B$, $g\ge\eta$, $m_{\mathrm{R}}\ge 1+\max_a(s_a+S)$ and $R\ge\max(m_{\mathrm{R}},g)$ such that, with I_c and $\rho_{c,1}\colon I_c\to H^1(F,T_2)$ formed for $\mathbf{N}(T_2)$ with c, $j=1$, $G=\eta$, g, m_{R} (in the role of m) and R, the following holds. For every free $\mathcal{O}_L$-module P of finite rank and every $\mathcal{O}_L$-linear map $\psi\colon P\to H^1_f(F,T_2)$ there are submodules $P=P_0\supseteq P_1\supseteq\cdots\supseteq P_k$ with $k\le n$ and every P_i/P_{i+1} generated by at most m elements, and $\mathcal{O}_L$-linear maps $w_c\colon P_k\to I_c$ $(c\in C)$, such that for every $f\in P_k$:

(Vw1) *for every $c\in C$: $\gamma_\delta(w_c(f))=w_c(f)$ for all $\delta\in\mu_{\ell-1}\subseteq\mathbb{Z}_\ell^\times$, and $Q^\eta w_c(f)\in P_1(\mathbf{N}(T_2)_{c-1})$;*

(Vw2) *$\ell^s\psi(f)=\pm\sum_{c\in C}\rho_{c,1}\big(w_c(f)\big)$ in $H^1(F,T_2)$, for one of the two signs (which may depend on f).*

Proof. Let c_{U} and c_{S} be the absolute constants of Proposition C.54 and Proposition C.56, and put $c_1=c_{\mathrm{U}}+c_{\mathrm{S}}$. Let s_1 be the integer of Proposition C.54, and s_2, g, m_{R}, R the integers of Proposition C.56; put $s=s_1+s_2$. Then $0\le s\le c_{\mathrm{U}}B+c_{\mathrm{S}}B=c_1B$, and $g\ge\eta$, $m_{\mathrm{R}}\ge 1+\max_a(s_a+S)$, $R\ge\max(m_{\mathrm{R}},g)$, so I_c and $\rho_{c,1}$ are the objects of the statement. Let P and ψ be given.

Step 1: the first lift. By Proposition C.54 there are $P=P_0\supseteq\cdots\supseteq P_{k_1}$ with $k_1\le n/2$, every P_i/P_{i+1} generated by at most m elements, such that every $f\in P_{k_1}$ has property (Ul) with the exponent s_1.

Step 2: the second lift. Apply Proposition C.56 with this s_1, P, ψ and $P'=P_{k_1}$: there are $P_{k_1}=P'_0\supseteq\cdots\supseteq P'_{k_2}$ with $k_2\le n/2$, every quotient generated by at most m elements, such that every $f\in P'_{k_2}$ admits $w_c\in I_c$ $(c\in C)$ with (Sl1) and (Sl2). Put $k=k_1+k_2\le n$ and $P_{k_1+i}=P'_i$ for $0\le i\le k_2$; this is a chain $P=P_0\supseteq\cdots\supseteq P_k$ as in the statement.

Step 3: linear choice. As a submodule of the free module P of finite rank over the discrete valuation ring $\mathcal{O}_L$, P_k is free of finite rank; let $f_1,\dots,f_t$ be a basis. For each i choose, by Step 2, elements $w_c^{(i)}\in I_c$ $(c\in C)$ with (Sl1) and a sign $\sigma_i\in\{1,-1\}$ with $\ell^s\psi(f_i)=\sigma_i\sum_{c\in C}\rho_{c,1}(w_c^{(i)})$. Define $w_c\colon P_k\to I_c$ by

$$w_c\Big(\sum_i a_i f_i\Big)=\sum_i a_i\sigma_i\,w_c^{(i)}\qquad(a_i\in\mathcal{O}_L);$$

it is well defined and $\mathcal{O}_L$-linear, and takes values in I_c because I_c is an $\mathcal{O}_L$-submodule of $e_c\mathbf{N}(T_2)[1/\lambda_\infty]$ ((Ry4) of Lemma 24.5).

(Vw1). Let $f = \sum_i a_i f_i \in P_k$ and $c \in C$. The map γ_δ is semilinear over the automorphism γ_δ of $\mathbf{A}_{F,L}$, which is the identity on the coefficients $\mathcal{O}_F \otimes \mathcal{O}_L$; so γ_δ is $\mathcal{O}_L$-linear and $\gamma_\delta(w_c(f)) = \sum_i a_i \sigma_i \gamma_\delta(w_c^{(i)}) = w_c(f)$ by (Sl1). Since $P_1(\mathbf{N}(T_2)_{c-1})$ is an $\mathbf{A}_{F,L}$-submodule, $Q^\eta w_c(f) = \sum_i a_i \sigma_i Q^\eta w_c^{(i)} \in P_1(\mathbf{N}(T_2)_{c-1})$ by (Sl1).

(Vw2). By the $\mathcal{O}_L$-linearity of $\rho_{c,1}$ ((Ry4)) and of ψ, and $\sigma_i^2 = 1$,

$$\sum_{c\in C} \rho_{c,1}(w_c(f)) = \sum_i a_i \sigma_i \sum_{c\in C} \rho_{c,1}(w_c^{(i)}) = \sum_i a_i \sigma_i^2\, \ell^s \psi(f_i) = \ell^s \psi(f),$$

which is (Vw2) with the sign + for every f. □

Proposition C.54. *There is an absolute constant $c_{\mathrm{U}} \geq 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52; let C, $(M_a, h_a)_a$ and B be as in Proposition C.53, and $\varepsilon_a = (\iota \otimes \mathrm{id})(e_a) \in A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$. Then there is an integer s_1 with $0 \leq s_1 \leq c_{\mathrm{U}} B$ such that for every free $\mathcal{O}_L$-module P of finite rank and every $\mathcal{O}_L$-linear map $\psi\colon P \to H^1_f(F, T_2)$ there are submodules $P = P_0 \supseteq P_1 \supseteq \cdots \supseteq P_k$ with $k \leq n/2$ and every P_i/P_{i+1} generated by at most m elements, such that every $f \in P_k$ has the following property **(Ul)** with the exponent s_1:*

(Ul) *there are a pair (V_Y, Y) and an exact sequence $0 \to T_2 \xrightarrow{\iota'} Y \xrightarrow{\pi} \mathcal{O}_L \to 0$ of G_F-equivariant $\mathcal{O}_L$-linear maps ($\mathcal{O}_L$ the trivial representation) with $[Y] = \psi(f)$, such that every Hodge jump of V_Y at τ_a lies in $[-M_a, h_a]$ ($a \in \mathbb{Z}/n$), and for every $c \in C$ an element $x_c \in \mathbf{N}(Y)_c$ with $\gamma_\delta(x_c) = x_c$ for all $\delta \in \mu_{\ell-1} \subseteq \mathbb{Z}_\ell^\times$ and*

$$(1 \otimes \pi)\big(\iota_Y(x_c)\big) = \ell^{\,s_1} \varepsilon_c.$$

Proof. **Step 0: the killer sets and s_1.** Put $a = \lceil a_{\mathrm{R}} \rceil \geq 1$. For $b \in \mathbb{Z}/n$ let $\mathcal{X}_b$ be the set of Hodge jumps of V_2 at τ_b together with 0; for $c \in C$ let $J_c = \{x + k : \ x \in \mathcal{X}_c,\ 1 \leq k \leq a\}$ and $J_c' = J_c \setminus \{0\}$. Since $c(0) = 0$, Lemma 28.15 (2) gives $v_\ell(c(j)) = v_\ell(j)$ for $j \neq 0$, so $P_{J_c'}(0) = \prod_{j\in J_c'}(-c(j)) = \ell^{t_c} \upsilon_c$ with $\upsilon_c \in \mathbb{Z}_\ell^\times$ and $t_c = \sum_{j\in J_c'} v_\ell(j)$. Put $s_1 = \max_{c\in C} t_c$ and $c_{\mathrm{U}} = 6$. By (Ow1) and Lemma 24.2 (1), $\mathcal{X}_c \subseteq [-s_c - S, -s_c] \cup [-\eta, \eta]$, and $s_c \geq 2a_{\mathrm{R}} + \eta + 1 > a$; so $J_c \subseteq [-s_c - S + 1, -s_c + a] \cup [-\eta + 1, \eta + a]$, the first interval consisting of negative integers. Hence $0 \leq s_1 \leq c_{\mathrm{U}} B$. The Hodge jumps of V_2 at τ_c in $[-a, -1]$ lie in $[-\eta, -1]$ (as $s_c > a$), so by (Ow2)

$$\mu_c := \sum_{j=-a}^{-1} \dim_L \mathrm{gr}^j D_{\mathrm{dR},\tau_c}(V_2) \leq m. \qquad (1)$$

Step 1: one extension for all of P. Let P, ψ be given, $p_1, \ldots, p_t$ a basis of P. By Lemma 23.26, for each i there is an extension $0 \to T_2 \xrightarrow{\iota_i'} Y_i \xrightarrow{\pi_i} \mathcal{O}_L \to 0$ of pairs with $[Y_i] = \psi(p_i)$; fix $\tilde{e}_i \in Y_i$ with $\pi_i(\tilde{e}_i) = 1$ and let $\kappa_i(\sigma) = \iota_i'^{-1}(\sigma\tilde{e}_i - \tilde{e}_i)$. Let $\mathcal{Y} = (\bigoplus_i Y_i)/K$ with $K = \{(\iota_i'(t_i))_i : \sum_i t_i = 0\}$, with $\iota'\colon T_2 \to \mathcal{Y}$ induced by any ι_i' and $\pi\colon \mathcal{Y} \to P$, $(y_i) \mapsto \sum_i \pi_i(y_i) p_i$. Since K is saturated in $\bigoplus_i T_2$, which is saturated in $\bigoplus_i Y_i$, $\mathcal{Y}$ is a G_F-stable lattice in $V_{\mathcal{Y}} = \mathcal{Y} \otimes \mathbb{Q}$, a quotient of $\bigoplus_i V_{Y_i}$, hence crystalline (Theorem B.45); and $0 \to T_2 \to \mathcal{Y} \to P \to 0$ is exact, P carrying the trivial action. By exactness and strict compatibility with the filtrations of D_{dR} on de Rham representations (Fontaine), every Hodge jump of $V_{\mathcal{Y}}$, and of any extension of L by V_2, at τ_a lies in $\mathcal{X}_a$ (jumps of V_2, and 0), hence in $[-M_a, h_a]$ (Step 0 and Lemma 24.2 (1)). For $p \in P$ let $j_p\colon \mathcal{O}_L \to P$, $1 \mapsto p$, and $e_c^\circ \otimes p = \mathbf{N}(j_p)(e_c^\circ)$; by (Ex3) and Lemma 24.3, $\iota_P(e_c^\circ \otimes p) = \varepsilon_c \otimes p$, so $p \mapsto e_c^\circ \otimes p$ is $\mathcal{O}_L$-linear (ι_P is injective), and $e_c^\circ \otimes p$ is fixed by all γ_u (by (Ex2), as G_F fixes $\varepsilon_c \otimes p$). In the same way every identity between images of elements under $\mathbf{N}$ of $\mathcal{O}_L$-linear

combinations of maps is checked after ι, where $\mathbf{N}(g)$ becomes $1 \otimes g$; we use this without further mention (it gives $\mathbf{N}(g+g') = \mathbf{N}(g) + \mathbf{N}(g')$ and $\mathbf{N}(0) = 0$).

Step 2: lifts with a Q^a-pole. Let $\mathbf{N}' = \mathbf{N}(\pi)(\mathbf{N}(\mathcal{Y})) \subseteq \mathbf{N}(P)$ and $H = \max_a(M_a + h_a) = H'$. By Proposition 23.18, X^H kills $\mathbf{N}(P)/\mathbf{N}'$; $(\gamma_u - 1)\mathbf{N}(P) \subseteq X\mathbf{N}(P)$ and $(\gamma_u - 1)\mathbf{N}' = \mathbf{N}(\pi)((\gamma_u - 1)\mathbf{N}(\mathcal{Y})) \subseteq X\mathbf{N}'$ by (Wm3), and X is injective on $\mathbf{N}(P)$ (Wm1). By Lemma 23.21 (1), (2), ℓ^d kills $\mathbf{N}(P)/\mathbf{N}'$ with $d = \lfloor H\ell/(\ell-1)^2 \rfloor$; and $\pi_0^A = X^{(\ell-1)A} v^A$ kills it for $A = \lceil H/(\ell-1) \rceil$. In $q^a = \sum_{i=0}^{a} \binom{a}{i} \pi_0^i \ell^{a-i}$ every term with $i \geq A$ kills, and every term with $i < A$ has $a - i \geq a - A + 1 \geq d$, because $d + A - 1 \leq H(\frac{\ell}{(\ell-1)^2} + \frac{1}{\ell-1}) = \frac{H'(2\ell-1)}{(\ell-1)^2} \leq a_{\mathrm{R}} \leq a$. So q^a kills $\mathbf{N}(P)/\mathbf{N}'$. For $c \in C$ and each i choose $x'_{c,i} \in \mathbf{N}(\mathcal{Y})_c$ with $\mathbf{N}(\pi)(x'_{c,i}) = q^a(e_c^\circ \otimes p_i)$ and put $\tilde{x}_{c,i} = q^{-a}\mathrm{av}(x'_{c,i}) \in e_c\mathbf{N}(\mathcal{Y})[1/Q]$. Since q and $e_c^\circ \otimes p_i$ are Δ-invariant and $\mathbf{N}(\pi)$ commutes with γ_δ: $\tilde{x}_{c,i}$ is Δ-invariant, $Q^a\tilde{x}_{c,i} = w_q^{-a}\mathrm{av}(x'_{c,i}) \in \mathbf{N}(\mathcal{Y})$, and $\mathbf{N}(\pi)(\tilde{x}_{c,i}) = e_c^\circ \otimes p_i$.

Step 3: the killer. Let $y_{c,i} = P_{J'_c}(\nabla)\tilde{x}_{c,i}$, with ∇ of Lemma 28.15 (1) for $\pi\colon \mathcal{Y} \to P$ at the site c. By Lemma 28.15 (1), $y_{c,i}$ is Δ-invariant and $Q^a y_{c,i} \in \mathbf{N}(\mathcal{Y})$. Since $\mathcal{X}_c$ contains every Hodge jump of $V_{\mathcal{Y}}$ at τ_c, Lemma C.46 (with its parameter a) gives $P_{J_c}(\nabla)\tilde{x}_{c,i} \in \mathbf{N}(\mathcal{Y})_c$. If $0 \notin J_c$, then $y_{c,i} = P_{J_c}(\nabla)\tilde{x}_{c,i} \in \mathbf{N}(\mathcal{Y})$; if $0 \in J_c$, then $P_{J_c}(Z) = Z\,P_{J'_c}(Z)$ and $(\gamma_{u_0} - 1)y_{c,i} = \pi_0\nabla y_{c,i} = \pi_0 P_{J_c}(\nabla)\tilde{x}_{c,i} \in \mathbf{N}(\mathcal{Y})$. In both cases $(\gamma_{u_0} - 1)y_{c,i} \in \mathbf{N}(\mathcal{Y})$. As ∇ commutes with $\mathbf{N}(\pi)$ and $\nabla(e_c^\circ \otimes p_i) = 0$ (it solves $\pi_0\nabla x = (\gamma_{u_0} - 1)x = 0$; uniqueness),

$$\mathbf{N}(\pi)(y_{c,i}) = P_{J'_c}(0)\, e_c^\circ \otimes p_i = \ell^{t_c} v_c\, e_c^\circ \otimes p_i. \qquad (2)$$

Step 4: reference lifts and the passage. Let $N = \max_a r_a$, r_a the integers of Proposition C.6 for $\pi\colon \mathcal{Y} \to P$ and the window $(M_a, h_a)_a$ ($\ell \geq 11$). Choose $\epsilon'_{c,i} \in \mathbf{N}(\mathcal{Y})_c$ with $\mathbf{N}(\pi)(\epsilon'_{c,i}) = \ell^N e_c^\circ \otimes p_i$ and put $\epsilon_{c,i} = \mathrm{av}(\epsilon'_{c,i})$, Δ-fixed with the same image. The element $\ell^N y_{c,i} - \ell^{t_c} v_c \epsilon_{c,i} \in e_c\mathbf{N}(\mathcal{Y})[1/Q]$ has $\mathbf{N}(\pi)$-image 0 by (2), so it equals $\mathbf{N}(\iota')(u_{c,i})$ for a unique $u_{c,i} \in e_c\mathbf{N}_2[1/Q]$ (Lemma 23.33, after clearing the power of Q: all modules are free site by site). Moreover $\mathbf{N}(\iota')$ is injective on $\mathbf{N}_2[1/Q]$ and $v \in \mathbf{N}_2[1/Q]$ with $\mathbf{N}(\iota')(v) \in \mathbf{N}(\mathcal{Y})$ lies in $\mathbf{N}_2$ (if $\mathbf{N}(\iota')(v) = y \in \mathbf{N}(\mathcal{Y})$ then $\mathbf{N}(\pi)(y) = 0$, $y = \mathbf{N}(\iota')(v')$ with $v' \in \mathbf{N}_2$ by Lemma 23.33, and $v = v'$). Hence: $Q^a u_{c,i} \in \mathbf{N}_2$; $u_{c,i}$ is Δ-fixed; and $(\gamma_{u_0} - 1)u_{c,i} \in \mathbf{N}_2$, because $(\gamma_{u_0} - 1)\epsilon_{c,i} \in \mathbf{N}(\mathcal{Y})$ and $(\gamma_{u_0} - 1)y_{c,i} \in \mathbf{N}(\mathcal{Y})$ (Step 3). Define $\omega_c\colon P \to e_c\mathbf{N}_2[1/Q]$ by $\omega_c(\sum_i a_i p_i) = \sum_i a_i u_{c,i}$; it is $\mathcal{O}_L$-linear and every value satisfies (Ps1) with its parameter equal to a, (Ps2), (Ps3) of Lemma C.55 at the site c. Enumerate $C = \{c_1, \ldots, c_k\}$, $k = n/2$, put $P_0 = P$ and $P_j = \{f \in P_{j-1} : \ \omega_{c_j}(f) \in \mathbf{N}_2\}$. By Lemma C.55 for (V_2, T_2), the site c_j, its parameter equal to a and the restriction of ω_{c_j} to the finitely generated module P_{j-1}, each P_j is a submodule and P_{j-1}/P_j is generated by at most $\mu_{c_j} \leq m$ elements by (1). So $P = P_0 \supseteq \cdots \supseteq P_k$ with $k \leq n/2$, and $\omega_c(f) \in \mathbf{N}_2$ for $f \in P_k$, $c \in C$.

Step 5: integral lifts in $\mathcal{Y}$. Let $f = \sum_i a_i p_i \in P_k$ and $c \in C$, and put $y_c(f) = \sum_i a_i y_{c,i}$, $\epsilon_c(f) = \sum_i a_i \epsilon_{c,i}$. Then $\ell^N y_c(f) = \ell^{t_c} v_c \epsilon_c(f) + \mathbf{N}(\iota')(\omega_c(f)) \in \mathbf{N}(\mathcal{Y})_c$. Since $Q^a y_c(f) \in \mathbf{N}(\mathcal{Y})_c$, the saturation (3) of Lemma 23.15 (with $e = 0$, $U = \mathbf{N}(\mathcal{Y})_c$, and its f, f' equal to $1, Q^a$) gives $y_c(f) \in \mathbf{N}(\mathcal{Y})_c$. Put $X_c(f) = \ell^{s_1 - t_c} v_c^{-1} y_c(f) \in \mathbf{N}(\mathcal{Y})_c$: it is Δ-fixed and, by (2) and linearity, $\mathbf{N}(\pi)(X_c(f)) = \ell^{s_1} e_c^\circ \otimes f$.

Step 6: the extension of f and (Ul). Let $Y = \{(y, \lambda) \in \mathcal{Y} \oplus \mathcal{O}_L : \ \pi(y) = \lambda f\}$, with $\iota'_Y(t) = (\iota'(t), 0)$ and $\pi_Y(y, \lambda) = \lambda$. It is a G_F-stable lattice in a subrepresentation of the crystalline $V_{\mathcal{Y}} \oplus L$, hence a pair (Theorem B.45), and $0 \to T_2 \to Y \to \mathcal{O}_L \to 0$ is exact (π is onto). With $\tilde{e} = (\bar{y}_0, 1)$, $\bar{y}_0$ the image of $(a_i\tilde{e}_i)_i$ (so $\pi(\bar{y}_0) = f$), $\sigma\tilde{e} - \tilde{e} = (\iota'(\sum_i a_i\kappa_i(\sigma)), 0)$, so $[Y] = \sum_i a_i[Y_i] = \psi(f)$ (Lemma 23.32). The representation V_Y is an extension of L by V_2, so its Hodge jumps at τ_a lie in $[-M_a, h_a]$ (Step 1). The sequence $0 \to Y \xrightarrow{\mathrm{inc}} \mathcal{Y} \oplus \mathcal{O}_L \xrightarrow{h} P \to 0$, $h(y, \lambda) = \pi(y) - \lambda f$, is an exact sequence of lattices of pairs; by Lemma 23.33, $\ker \mathbf{N}(h) = \mathbf{N}(\mathrm{inc})(\mathbf{N}(Y))$. With ι_1, ι_2 the inclusions of the summands, the element $Z = \mathbf{N}(\iota_1)(X_c(f)) + \mathbf{N}(\iota_2)(\ell^{s_1} e_c^\circ)$ satisfies

$\mathbf{N}(h)(Z) = \mathbf{N}(\pi)(X_c(f)) - \ell^{s_1} e_c^\circ \otimes f = 0$, so $Z = \mathbf{N}(\mathrm{inc})(x_c)$ with $x_c \in \mathbf{N}(Y)$, and $x_c = e_c x_c \in \mathbf{N}(Y)_c$ ($Z = e_c Z$, $\mathbf{N}(\mathrm{inc})$ injective and $\mathbf{A}_{F,L}$-linear). It is Δ-fixed, as Z is and $\mathbf{N}(\mathrm{inc})$ is injective and commutes with γ_δ. Finally $\pi_Y = \mathrm{pr}_2 \circ \mathrm{inc}$, so $\mathbf{N}(\pi_Y)(x_c) = \mathbf{N}(\mathrm{pr}_2)(Z) = \ell^{s_1} e_c^\circ$, and by (Ex3) and Lemma 24.3, $(1 \otimes \pi_Y)(\iota_Y(x_c)) = \iota_{\mathcal{O}_L}(\ell^{s_1} e_c^\circ) = \ell^{s_1} \varepsilon_c$. This is (Ul) for f with the exponent s_1. □

Lemma C.55. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, (V, T) a pair and $\mathbf{N} = \mathbf{N}(T)$ with a window $(M_a, h_a)_a$ as in (Ex1). Let $c \in \mathbb{Z}/n$, let $k \geq 0$ be an integer, put*

$$\mu = \sum_{j=-k}^{-1} \dim_L \left(\mathrm{Fil}^j D_{\mathrm{dR},\tau_c}(V) / \mathrm{Fil}^{j+1} D_{\mathrm{dR},\tau_c}(V) \right)$$

(the number of Hodge jumps of V at τ_c in $[-k, -1]$, counted with multiplicity), and fix $u_0 \in \mathbb{Z}_\ell^\times$ with $v_\ell(u_0 - 1) = 1$. Let P be a finitely generated $\mathcal{O}_L$-module and $\omega \colon P \to e_c \mathbf{N}[1/Q]$ an $\mathcal{O}_L$-linear map such that for every $f \in P$:

(Ps1) Pole *$Q^k \omega(f) \in \mathbf{N}$;*

(Ps2) Δ-fixed *$\gamma_\delta(\omega(f)) = \omega(f)$ for every $\delta \in \mu_{\ell-1} \subseteq \mathbb{Z}_\ell^\times$;*

(Ps3) Integral defect *$(\gamma_{u_0} - 1)(\omega(f)) \in \mathbf{N}$.*

Then $P' = \{ f \in P : \ \omega(f) \in \mathbf{N} \}$ is an $\mathcal{O}_L$-submodule of P and P/P' is generated by at most μ elements.

Proof. **Step 0: level data of length one.** Let $r = \dim_L V$. Choose a frame $(n_k)_{k \leq r}$ at $c - 1$ (an $e_{c-1}\mathbf{A}_{F,L}$-basis of $\mathbf{N}_{c-1}$, which exists by (Wm1)) and arc level data of the identity map $T \to T$ with cut c, length $\mathrm{len} = 1$, $H(c) = k + h_c$ and arbitrary values of the remaining parameters (they do not enter (Lp1)–(Lp3), (Lp8)). Then $\Pi = Q_0^{H(c)} = Q^{k+h_c}$ and $W = \{ w \in \mathbf{N}[1/\lambda_\infty] : \ Q^{k+h_c} w \in P_1(\mathbf{N}_{c-1}) \}$. By Lemma 23.17, (Lp1), (Lp2) and (Lp8) hold at $s = 0$, and by Lemma 23.5 (2) with $\mathrm{len} = 1$: for $w \in W$, $w \in \mathbf{N}_c$ if and only if $\mathrm{lv}(w)$ is de Rham integral at 0. By the definition of the levels, ϵ_0 is the idempotent of the embedding τ_c, the D_k form an L-basis of $\epsilon_0 D_{\mathrm{cris}}(V)$, and $v \mapsto \sum_k v_k D_k$ maps $\mathrm{Fil}(u)$ isomorphically onto $\epsilon_0 \mathrm{Fil}^u D_{\mathrm{cris}}(V)$. Since F is unramified and V crystalline, $D_{\mathrm{cris}}(V) = D_{\mathrm{dR}}(V)$, and $\epsilon_0 D_{\mathrm{dR}}(V)$ with the induced filtration is $D_{\mathrm{dR},\tau_c}(V)$: the map $\tau_c \otimes \mathrm{id} \colon F \otimes_{\mathbb{Q}_\ell} L \to L$ is the projection onto the factor cut out by ϵ_0, so $L \otimes_{F \otimes L, \tau_c \otimes \mathrm{id}} D_{\mathrm{dR}}(V) = \epsilon_0 D_{\mathrm{dR}}(V)$ (Definition 13.7), and the filtrations correspond because each $\mathrm{Fil}^j D_{\mathrm{dR}}(V)$ is an $F \otimes L$-submodule, whose image is $\epsilon_0 \mathrm{Fil}^j D_{\mathrm{dR}}(V)$. Hence

$$\dim_L \mathrm{Fil}(-k)/\mathrm{Fil}(0) = \sum_{j=-k}^{-1} \dim_L \mathrm{gr}^j D_{\mathrm{dR},\tau_c}(V) = \mu. \tag{1}$$

Step 1: the vectors lie in the arc domain. Let $f \in P$ and $y = \omega(f)$. Since e_c commutes with Q and with γ_{u_0} ($\gamma_u(e_a) = e_a$), the elements $Q^k y$ and $z = (\gamma_{u_0} - 1)(y)$ lie in $e_c \mathbf{N}[1/Q] \cap \mathbf{N} = \mathbf{N}_c$ by (Ps1), (Ps3). By (Wm2), $Q^{h_c} \mathbf{N}_c \subseteq \mathbf{A}_{F,L} \varphi(\mathbf{N}_{c-1}) = P_1(\mathbf{N}_{c-1})$. Hence $Q^{k+h_c} y = Q^{h_c}(Q^k y) \in P_1(\mathbf{N}_{c-1})$, so $y \in W$; and every element x of $\mathbf{N}_c$ lies in W, since $Q^{k+h_c} x \in Q^k P_1(\mathbf{N}_{c-1}) \subseteq P_1(\mathbf{N}_{c-1})$. So y, $Q^k y$, $z \in W$, and the last two lie in $\mathbf{N}_c$. Moreover $y \in \mathbf{N}$ if and only if $y \in \mathbf{N}_c$, as $y = e_c y$.

Step 2: the expansion. By (Lp1), y is algebraic at level 0; write $\mathrm{lv}(y) = \sum_i a_i(f) t^i$ with $a_i(f) \in K^r$, $a_i(f) = 0$ for $i < -(k + h_c)$ (Lemma 23.17). The level map $\Lambda_0 = \varphi^{-1} \circ \iota_T$ is additive and $\Lambda_0(\lambda x) = \epsilon_0 (1 \otimes \lambda) \Lambda_0(x)$ for $\lambda \in \mathcal{O}_L$ ((Ex2)), and the D_k form a basis over $R_0 \supseteq K((t))$; so each $f \mapsto a_i(f)$ is $\mathcal{O}_L$-linear.

Step 3: the constant coefficient is in L^r. Let $\delta \in \mu_{\ell-1}$. By (Lp2) and (Ps2), $\sum_i a_i t^i = \mathrm{lv}(\gamma_\delta y) = \sum_i \delta^i \sigma_\delta(a_i) t^i$, so $\sigma_\delta(a_0) = a_0$. For $u' \in 1+\ell\mathbb{Z}_\ell$, $\sigma_{u'} = \mathrm{id}$ on K by (Lp8) at $s=0$. Every $u \in \mathbb{Z}_\ell^\times$ is $\delta u'$ with $\delta \in \mu_{\ell-1}$, $u' \in 1+\ell\mathbb{Z}_\ell$, and $\sigma_u = \sigma_\delta \circ \sigma_{u'}$ (both are induced by $g_\delta g_{u'}$, where $\chi(g_\delta)=\delta$, $\chi(g_{u'})=u'$). So a_0 is fixed by every σ_u, and $a_0 \in L^r$ by (Lp8).

Step 4: the non-constant coefficients. As $u_0 \in 1+\ell\mathbb{Z}_\ell$, $\sigma_{u_0} = \mathrm{id}$, and by (Lp2) $\mathrm{lv}(z) = \sum_i (u_0^i - 1) a_i t^i$. Since $z \in W \cap \mathbf{N}_c$, $\mathrm{lv}(z)$ is de Rham integral (Step 0): $(u_0^i-1)a_i \in K \otimes_L \mathrm{Fil}(-i)$ for every i. For $i \neq 0$, $u_0^i \neq 1$ ($1+\ell\mathbb{Z}_\ell$ is torsion free, ℓ being odd, and $u_0 \neq 1$), and $K \otimes_L \mathrm{Fil}(-i)$ is a K-submodule of K^r; so

$$a_i \in K \otimes_L \mathrm{Fil}(-i) \qquad (i \neq 0). \tag{2}$$

Step 5: the pole bounds the constant coefficient. The de Rham integral vectors at level 0 form a $K[[t]]$-submodule of $K((t))^r$: if $g = \sum_i g_i t^i$ is de Rham integral and $b = \sum_{p \geq 0} b_p t^p \in K[[t]]$, the t^i-coefficient of bg is $\sum_{p \geq 0} b_p g_{i-p}$, and $g_{i-p} \in K \otimes_L \mathrm{Fil}(p-i) \subseteq K \otimes_L \mathrm{Fil}(-i)$ since Fil is decreasing. By (Lp1), $\lambda_0(Q) = \lambda_0(Q_0) = t\,e$ with $e \in K[[t]]^\times$. As $Q^k y \in W \cap \mathbf{N}_c$, $\mathrm{lv}(Q^k y) = t^k e^k \mathrm{lv}(y)$ is de Rham integral, hence so is $t^k \mathrm{lv}(y) = e^{-k}\mathrm{lv}(Q^k y)$, i.e. $a_i \in K \otimes_L \mathrm{Fil}(-i-k)$ for all i. For an L-subspace $\mathcal{X} \subseteq L^r$ one has $(K \otimes_L \mathcal{X}) \cap L^r = \mathcal{X}$ inside $K^r = K \otimes_L L^r$ (choose an L-basis of the finite-dimensional L-algebra K containing 1 and compare the coefficients of 1). With Step 3,

$$a_0(f) \in \mathrm{Fil}(-k). \tag{3}$$

Step 6: the membership test. By Step 1 and Step 0, $\omega(f) \in \mathbf{N}$ iff $\mathrm{lv}(y)$ is de Rham integral, i.e. iff $a_i \in K \otimes_L \mathrm{Fil}(-i)$ for all i. By (2) this holds iff $a_0 \in K \otimes_L \mathrm{Fil}(0)$, and by Step 3 and Step 5 iff $a_0(f) \in \mathrm{Fil}(0)$. By (3) and Step 2,

$$\beta \colon P \to \mathrm{Fil}(-k)/\mathrm{Fil}(0), \qquad f \mapsto a_0(f) \bmod \mathrm{Fil}(0),$$

is a well-defined $\mathcal{O}_L$-linear map, and $P' = \ker \beta$. So P' is a submodule and $P/P' \cong \beta(P)$.

Step 7: the count. $\beta(P)$ is a finitely generated $\mathcal{O}_L$-submodule of the L-vector space $\mathrm{Fil}(-k)/\mathrm{Fil}(0)$, of dimension μ by (1). It is torsion free, hence free over the discrete valuation ring $\mathcal{O}_L$, and an $\mathcal{O}_L$-basis of it is L-linearly independent (clear denominators), so its rank is at most μ. Hence P/P' is generated by at most μ elements. □

Proposition C.56. *There is an absolute constant $c_{\mathrm{S}} \geq 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a \in \mathbb{Z}/n}$, $\Phi \colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, and let C, $(M_a, h_a)_a$ and B be as in Proposition C.53. Then there are integers $0 \leq s_2 \leq c_{\mathrm{S}} B$, $g \geq \eta$, $m_{\mathrm{R}} \geq 1 + \max_a(s_a + S)$ and $R \geq \max(m_{\mathrm{R}}, g)$ such that, with I_c and $\rho_{c,1} \colon I_c \to H^1(F, T_2)$ formed for $\mathbf{N}(T_2)$ with c, $j=1$, $G=\eta$, g, m_{R} (in the role of m) and R, the following holds. Let $s_1 \geq 0$ be an integer, P a free $\mathcal{O}_L$-module of finite rank, $\psi \colon P \to H^1_f(F, T_2)$ an $\mathcal{O}_L$-linear map and $P' \subseteq P$ a submodule every element of which has property (Ul) of Proposition C.54 with the exponent s_1. Then there are submodules $P' = P'_0 \supseteq P'_1 \supseteq \cdots \supseteq P'_k$ with $k \leq n/2$ and every P'_i/P'_{i+1} generated by at most m elements, such that for every $f \in P'_k$ there are $w_c \in I_c$ ($c \in C$) with*

(Sl1) *for every $c \in C$: $\gamma_\delta(w_c) = w_c$ for all $\delta \in \mu_{\ell-1} \subseteq \mathbb{Z}_\ell^\times$, and $Q^\eta w_c \in P_1\big(\mathbf{N}(T_2)_{c-1}\big)$;*

(Sl2) *$\ell^{s_1+s_2}\psi(f) = \pm \sum_{c \in C} \rho_{c,1}(w_c)$ in $H^1(F, T_2)$, for one of the two signs.*

Proof. **Step 0: the constants.** Put $c_{\mathrm{S}} = 8$, $g = \eta$, $m_{\mathrm{R}} = 1 + \max_a(s_a + S)$, $R = m_{\mathrm{R}}$, $\sigma = \sigma_\ell(g, m_{\mathrm{R}}, 1)$ and $s_2 = 2\sigma$. Since every $s_a > \eta$, $m_{\mathrm{R}} \geq g$, so $R \geq \max(m_{\mathrm{R}}, g)$, and $g \geq \eta$. Hence $0 \leq s_2 \leq 8B = c_{\mathrm{S}} B$. Let I_c, $\rho_{c,1}$ be formed for $\mathbf{N}_2$ with c, $j=1$, $G=\eta$, g, m_{R}, R.

Step 1: the configuration. By the parity hypothesis of Proposition C.52 (n even, $\epsilon_a = -1$ iff $a + d$ is even), for $c \in C$ we have $c-1, c+1 \notin C$ and $c-2 \in C$; so $\mathrm{len}_c = 2$ satisfies the condition of Proposition 24.4, and $j = 1 \le \mathrm{len}_c$. For $c \in C$, $c+1$ is an up site, so $M_{c+1} = \eta = G$, and $h_c = \eta$. By (Ow1), every Hodge jump of V_1 at τ_a lies in $[-(s_a + S), \eta]$ if $\epsilon_a = -1$ and in $[-\eta, s_a + S]$ if $\epsilon_a = 1$ (as $s_a > \eta$), hence in $[-M_a, h_a]$; by Lemma 24.2 (1) the same holds for V_2. Also $m_{\mathrm{R}} \ge \max(g, 1 + \max_a M_a)$ and $R \ge m_{\mathrm{R}}$. So for every extension Y as in (Ul), $(M_a, h_a)_a$ is a window of V_2 and of V_Y, and Proposition 24.4 applies to $0 \to T_2 \to Y \to \mathcal{O}_L \to 0$ with C, $\mathrm{len} \equiv 2$, $j = 1$, $G = \eta$, g, $m = m_{\mathrm{R}}$, R and $r = s_1$.

Step 2: units and reference lifts. Let Y, ι', π, $(x_c)_{c\in C}$ be as in (Ul). (a) By Lemma 24.3, (Ex3) and the injectivity of $\iota_{\mathcal{O}_L}$ (Proposition 23.7), $\iota_{\mathcal{O}_L}(\mathbf{N}(\pi)(x_c)) = (1 \otimes \pi)(\iota_Y(x_c)) = \ell^{s_1}\varepsilon_c = \iota_{\mathcal{O}_L}(\ell^{s_1} e_c^\circ)$, so $\mathbf{N}(\pi)(x_c) = \ell^{s_1} e_c^\circ$. Similarly $\varphi(e_a^\circ) = e_{a+1}^\circ$ (as $\iota_{\mathcal{O}_L}(\varphi e_a^\circ) = (\varphi \otimes 1)(\varepsilon_a) = (\iota \otimes \mathrm{id})(\varphi(e_a)) = \varepsilon_{a+1}$, ι commuting with φ by Lemma 23.8) and $\gamma_u(e_a^\circ) = e_a^\circ$ (by (Ex2), $\iota_{\mathcal{O}_L}(\gamma_{\chi(\sigma)} e_a^\circ) = \sigma(\varepsilon_a) = \varepsilon_a$, since G_F fixes $\iota(\mathcal{O}_F) \subseteq W(k)$ and acts trivially on $\mathcal{O}_L$). (b) Let $N = \max_a r_a$ with r_a the integers of Proposition C.6 for the window $(M_a, h_a)_a$; they depend only on ℓ and the window. By Proposition C.6 ($\ell \ge 11$), applied to π and $\ell^{N-r_a} e_a^\circ$, there is $\varepsilon'_a \in \mathbf{N}(Y)_a$ with $\mathbf{N}(\pi)(\varepsilon'_a) = \ell^N e_a^\circ$; then $\epsilon_a^Y := \mathrm{av}(\varepsilon'_a) \in \mathbf{N}(Y)_a$ is Δ-fixed and $\mathbf{N}(\pi)(\epsilon_a^Y) = \ell^N e_a^\circ$, since $\mathbf{N}(\pi)$ commutes with γ_δ and $\gamma_\delta(e_a^\circ) = e_a^\circ$.

Step 3: exactness facts. Let Y be as in (Ul). (E1) Let $\mathcal{S}$ be a multiplicative set of finite products of the Q_s. Then $\mathbf{N}(\iota')$ is injective on $\mathbf{N}_2[1/\mathcal{S}]$, its image is the kernel of $\mathbf{N}(\pi)$ on $\mathbf{N}(Y)[1/\mathcal{S}]$, and if $v \in \mathbf{N}_2[1/\mathcal{S}]$ with $\mathbf{N}(\iota')(v) \in \mathbf{N}(Y)$ then $v \in \mathbf{N}_2$. Indeed, all three modules are free over $\mathbf{A}_{F,L}$ site by site ((Wm1)), hence $\mathcal{S}$-torsion free; if $\mathbf{N}(\pi)(y/f) = 0$ then $\mathbf{N}(\pi)(y) = 0$, so $y \in \mathbf{N}(\iota')(\mathbf{N}_2)$ by Lemma 23.33; injectivity is that of Lemma 23.33 after clearing f; and if $\mathbf{N}(\iota')(v) = y \in \mathbf{N}(Y)$, then $\mathbf{N}(\pi)(y) = 0$, $y = \mathbf{N}(\iota')(v')$ with $v' \in \mathbf{N}_2$, and $v = v'$. (E2) For $c \in \mathbb{Z}/n$: if $y \in P_1(\mathbf{N}(Y)_{c-1})$ and $\mathbf{N}(\pi)(y) = 0$, then $y = \mathbf{N}(\iota')(v)$ with $v \in P_1(\mathbf{N}_{2,c-1})$. Indeed, $e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ is finite free (of rank ℓ, with basis $(1+X)^i$, $0 \le i < \ell$) over its subring $\varphi(e_{c-1}\mathbf{A}_{F,L}) = \mathcal{O}_L[[(1+X)^\ell - 1]]$ by Weierstrass division, so $R \otimes_\varphi -$ ($R = e_c\mathbf{A}_{F,L}$) is exact; applied to the exact sequence $0 \to \mathbf{N}_{2,c-1} \to \mathbf{N}(Y)_{c-1} \to \mathbf{N}(\mathcal{O}_L)_{c-1}$ (Lemma 23.33) and transported by the isomorphisms $R \otimes_\varphi \mathbf{N}_{c-1} \cong P_1(\mathbf{N}_{c-1})$ of Lemma 23.15 (1), which commute with $\mathbf{N}(\iota')$ and $\mathbf{N}(\pi)$ (these commute with φ), it gives exactness of $0 \to P_1(\mathbf{N}_{2,c-1}) \to P_1(\mathbf{N}(Y)_{c-1}) \to P_1(\mathbf{N}(\mathcal{O}_L)_{c-1})$, and the last module lies in $\mathbf{N}(\mathcal{O}_L)[1/\lambda_\infty]$.

Step 4: Δ-averaging of the class splitting. (a) *Herr classes are Δ-invariant.* Let y be a Herr vector of precision m_{R} for $\mathbf{N}_2$, $\delta \in \Delta$ and $g \in G_F$ with $\chi_{\mathrm{cyc}}(g) = \delta$. As γ_δ commutes with φ and all γ_u ((Wm3), (Gc0)) and $\gamma_\delta(X^{m_{\mathrm{R}}}\mathbf{N}_2) = X^{m_{\mathrm{R}}}\mathbf{N}_2$ ($\gamma_\delta(X) \in X\,\mathbb{Z}_\ell[[X]]^\times$), $\gamma_\delta y$ is a Herr vector and $z_u(\gamma_\delta y) = \gamma_\delta z_u(y)$ by uniqueness in Lemma 23.28. If $(\varphi \otimes 1 - 1)(b) = \iota_{T_2}(y)$, then $(\varphi \otimes 1 - 1)(gb) = g\,\iota_{T_2}(y) = \iota_{T_2}(\gamma_\delta y)$ by (Gc0). For $\sigma' \in G_F$, using $\chi_{\mathrm{cyc}}(g^{-1}\sigma' g) = \chi_{\mathrm{cyc}}(\sigma')$ and (Gc0), with $\kappa = c_{y,b}$,

$$c_{\gamma_\delta y, gb}(\sigma') = g\,\iota_{T_2}(z_{\chi(\sigma')}(y)) - (\sigma' - 1)gb = g(\kappa(g^{-1}\sigma' g) + (g^{-1}\sigma' g - 1)b) - \sigma' gb + gb = g\,\kappa(g^{-1}\sigma' g).$$

The cocycle relation gives $\kappa(\sigma' g) = \kappa(g) + g\,\kappa(g^{-1}\sigma' g)$ and $\kappa(\sigma' g) = \kappa(\sigma') + \sigma'\kappa(g)$, so $c_{\gamma_\delta y, gb}(\sigma') = \kappa(\sigma') + (\sigma' - 1)\kappa(g)$ with $\kappa(g) \in T_2$ ((Hc1)): $\mathrm{cl}(\gamma_\delta y) = \mathrm{cl}(y)$. (b) *Relay classes are Δ-invariant.* Let $w \in I_c$, let τ be a relay correction of w ((Ry1)), and let V be as in the definition of a relay correction. Since $\gamma_\delta(e_c) = e_c$ and $\gamma_\delta(Q_s) = \varphi^s(\gamma_\delta Q) \in Q_s\mathbf{A}_F^\times$ (Lemma 23.8 (2)), γ_δ preserves $e_c\mathbf{N}_2[1/\lambda_\infty]$, $\mathbf{N}_{2,c}[1/\ell]$, $P_1(\mathbf{N}_{2,c})$ and $X^{m_{\mathrm{R}}}\lambda_1^g P_1(\mathbf{N}_{2,c})[1/\ell]$; on $\mathbf{N}_{2,E}$ it commutes with every γ_u and preserves $X^k\mathbf{N}_{2,E}$ (Lemma 23.9). Hence $(\gamma_u - 1)\gamma_\delta w = \gamma_\delta(\gamma_u - 1)w \in X\mathbf{N}_2$, so $\gamma_\delta w \in I_c$; $W_{\gamma_\delta w} = \gamma_\delta W_w$ by the uniqueness in (Hf1); and $\gamma_\delta V$, $\gamma_\delta\tau$ satisfy the two conditions of a relay correction of $\gamma_\delta w$ (apply γ_δ to those for w, V, τ). By (Ry2), (Ry3) and (a), $\rho_{c,1}(\gamma_\delta w) = \mathrm{cl}(\gamma_\delta(\ell^\sigma\varphi(w) - \tau)) = \mathrm{cl}(\ell^\sigma\varphi(w) - \tau) = \rho_{c,1}(w)$. By (Ry4), $\mathrm{av}(w) \in I_c$, $\mathrm{av}(w)$ is Δ-fixed, and $\rho_{c,1}(\mathrm{av}(w)) = \rho_{c,1}(w)$. (c) *Averaged splitting.* Let Y, (x_c) be as in

(Ul). Proposition 24.4, applied with $j=1$, gives (in its statement) $\tau'_c \in P_1(\mathbf{N}_{2,c})$ and $w'_c \in I_c$ with its two identities and its class identity. Put $\tau_c = \mathrm{av}(\tau'_c) \in P_1(\mathbf{N}_{2,c})$, $w_c = \mathrm{av}(w'_c)$ and $X_c = \ell^\sigma\varphi(x_c) - \mathbf{N}(\iota')(\tau_c) = \mathrm{av}(\ell^\sigma\varphi(x_c) - \mathbf{N}(\iota')(\tau'_c))$ (x_c is Δ-fixed; $\mathbf{N}(\iota')$ and φ commute with γ_δ). Applying av to the identities of Proposition 24.4 and using (b):

$$\begin{gathered}\mathbf{N}(\iota')(w_c) = \varphi(X_{c-2}) - \ell^\sigma x_c, \qquad (\gamma_u - 1)(X_c) \in \mathbf{N}(\iota')(X^{m_{\mathrm{R}}}\mathbf{N}_2),\\ \ell^{\,s_1+2\sigma}[Y] = \sum_{c\in C}\rho_{c,1}(w_c),\end{gathered} \tag{1}$$

and w_c, τ_c, X_c are Δ-fixed.

Step 5: the vectors that must become integral. With Y, x_c, ϵ^Y_a, w_c, X_c as in Steps 2 and 4, for $c \in C$: (i) There is a unique $u_c \in e_{c+1}\mathbf{N}_2[1/Q]$ with $\mathbf{N}(\iota')(u_c) = \ell^N X_c - \ell^{s_1+\sigma}\epsilon^Y_{c+1}$, and $Q^\eta u_c \in \mathbf{N}_2$, u_c is Δ-fixed, $(\gamma_{u_0}-1)(u_c) \in \mathbf{N}_2$. Indeed $\varphi(x_c) \in e_{c+1}\mathbf{N}(Y)[1/Q]$ and $\tau_c \in Q^{-\eta}\mathbf{N}_{2,c+1}$ by (Ry0) ($G=\eta$, $\lambda_1 = Q$), so the right side lies in $e_{c+1}\mathbf{N}(Y)[1/Q]$, and by Step 2 its image under $\mathbf{N}(\pi)$ is $\ell^{N+\sigma}\varphi(\ell^{s_1}e^\circ_c) - \ell^{s_1+\sigma}\ell^N e^\circ_{c+1} = 0$; (E1) gives u_c. By (Wm2) at the up site $c+1$, $Q^\eta\varphi(x_c) \in \mathbf{N}(Y)_{c+1}$, so $Q^\eta X_c \in \mathbf{N}(Y)$ and $\mathbf{N}(\iota')(Q^\eta u_c) \in \mathbf{N}(Y)$, whence $Q^\eta u_c \in \mathbf{N}_2$ by (E1). The Δ-fixedness of u_c follows from that of X_c and ϵ^Y_{c+1} and from injectivity. Finally $(\gamma_{u_0}-1)\epsilon^Y_{c+1} \in \mathbf{N}(Y)$ ((Wm3)) has $\mathbf{N}(\pi)$-image $(\gamma_{u_0}-1)(\ell^N e^\circ_{c+1}) = 0$, so it lies in $\mathbf{N}(\iota')(\mathbf{N}_2)$ (Lemma 23.33); with (1), $\mathbf{N}(\iota')((\gamma_{u_0}-1)u_c) \in \mathbf{N}(\iota')(\mathbf{N}_2)$, and $(\gamma_{u_0}-1)u_c \in \mathbf{N}_2$ by (E1). (ii) There is $v_c \in P_1(\mathbf{N}_{2,c-1})$ with $\ell^N Q^\eta w_c = Q^\eta\varphi(u_{c-2}) + v_c$. Indeed, by (1) and (i) for $c-2 \in C$, $\mathbf{N}(\iota')(\ell^N Q^\eta w_c) = Q^\eta\varphi(\mathbf{N}(\iota')u_{c-2}) + y_c$ with $y_c = Q^\eta(\ell^{s_1+\sigma}\varphi(\epsilon^Y_{c-1}) - \ell^{N+\sigma}x_c)$. Here $\varphi(\epsilon^Y_{c-1}) \in P_1(\mathbf{N}(Y)_{c-1})$ and $Q^\eta x_c \in Q^{h_c}\mathbf{N}(Y)_c \subseteq P_1(\mathbf{N}(Y)_{c-1})$ ((Wm2), $h_c = \eta$), so $y_c \in P_1(\mathbf{N}(Y)_{c-1})$, and $\mathbf{N}(\pi)(y_c) = Q^\eta(\ell^{s_1+\sigma+N}e^\circ_c - \ell^{N+\sigma+s_1}e^\circ_c) = 0$. By (E2), $y_c = \mathbf{N}(\iota')(v_c)$ with $v_c \in P_1(\mathbf{N}_{2,c-1})$, and the identity follows from the injectivity in (E1).

Step 6: data on a basis. Let s_1, P, ψ, P' be given. As a submodule of a free module of finite rank over the discrete valuation ring $\mathcal{O}_L$, P' is free; let $f_1,\dots,f_t$ be a basis. For each i choose, by (Ul) for f_i, an extension Y_i with $[Y_i] = \psi(f_i)$ and $x^{(i)}_c$, and then by Steps 2, 4, 5 the elements $\epsilon^{(i)}_a$, $w^{(i)}_c$, $X^{(i)}_c$, $u^{(i)}_c$, $v^{(i)}_c$. For $c \in C$ define the $\mathcal{O}_L$-linear maps

$$\omega_c\colon P' \to e_{c+1}\mathbf{N}_2[1/Q], \quad \omega_c\Big(\sum_i a_i f_i\Big) = \sum_i a_i u^{(i)}_c, \qquad w_c\colon P' \to I_c, \quad w_c\Big(\sum_i a_i f_i\Big) = \sum_i a_i w^{(i)}_c$$

(I_c is an $\mathcal{O}_L$-module by (Ry4)). By Step 5 (i), and since $\mathbf{N}_2$ is an $\mathcal{O}_L$-module and γ_δ, γ_{u_0} are $\mathcal{O}_L$-linear, every $\omega_c(f)$ satisfies (Ps1) with its parameter equal to η, (Ps2) and (Ps3) of Lemma C.55 at the site $c+1$.

Step 7: the passage chain. Enumerate $C = \{c_1,\dots,c_k\}$, $k = |C| = n/2$. Put $P'_0 = P'$ and $P'_j = \{f \in P'_{j-1} :\ \omega_{c_j}(f) \in \mathbf{N}_2\}$. By Lemma C.55, applied to (V_2, T_2) with its window, the site c_j+1, its parameter equal to η, the finitely generated module P'_{j-1} and the restriction of ω_{c_j}, P'_j is a submodule and P'_{j-1}/P'_j is generated by at most $\mu_j = \sum_{i=-\eta}^{-1}\dim_L \mathrm{gr}^i D_{\mathrm{dR},\tau_{c_j+1}}(V_2) \le m$ elements, the inequality by (Ow2). So $P' = P'_0 \supseteq \cdots \supseteq P'_k$ with $k \le n/2$, and $\omega_c(f) \in \mathbf{N}_2$ for every $f \in P'_k$ and $c \in C$.

Step 8: (Sl1) and (Sl2). Let $f = \sum_i a_i f_i \in P'_k$ and put $w_c = w_c(f)$. Each $w^{(i)}_c$ is Δ-fixed, so w_c is. By Step 5 (ii), $\ell^N Q^\eta w_c = Q^\eta\varphi(\omega_{c-2}(f)) + \sum_i a_i v^{(i)}_c$. As $c-2 \in C$, $\omega_{c-2}(f) \in \mathbf{N}_2 \cap e_{c-1}\mathbf{N}_2[1/Q] = \mathbf{N}_{2,c-1}$, so $\varphi(\omega_{c-2}(f)) \in P_1(\mathbf{N}_{2,c-1})$; hence $\ell^N Q^\eta w_c \in P_1(\mathbf{N}_{2,c-1})$. Since $w_c \in e_c\mathbf{N}_2[1/\lambda_\infty]$, there is a finite product f' of the Q_s with $f'Q^\eta w_c \in \mathbf{N}_{2,c}$, so $Q^{h_c}f'Q^\eta w_c \in P_1(\mathbf{N}_{2,c-1})$ ((Wm2)), and $Q^\eta w_c$ lies in $P_1(\mathbf{N}_{2,c-1})\otimes_R \mathrm{Frac}(R)$; the saturation (3) of Lemma 23.15 (with $U = P_1(\mathbf{N}_{2,c-1})$ and its f equal to 1) gives $Q^\eta w_c \in P_1(\mathbf{N}_{2,c-1})$. This is (Sl1). By (Ry4), the linearity of ψ and (1) for each Y_i,

$$\sum_{c\in C}\rho_{c,1}(w_c) = \sum_i a_i \sum_{c\in C}\rho_{c,1}(w^{(i)}_c) = \sum_i a_i\,\ell^{\,s_1+2\sigma}\psi(f_i) = \ell^{\,s_1+s_2}\psi(f),$$

which is (Sl2) with the sign +. □

Proposition C.57. *There is an absolute constant $c_4 \geq 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, put*

$$B = \frac{H'}{\ell^2} + S + \frac{\eta}{\ell} + 1 + \log_\ell(2H'), \qquad \lambda = d_2 S + 2m\Big(\frac{H'+1}{\ell-1} + 1\Big),$$

and let $c \in \mathbb{Z}/n$ with $\epsilon_c = -1$. Write I_c^ν for the set I_c formed for $\mathbf{N}(T_\nu)$. Then there is an integer $0 \leq e \leq c_4 B$ with the following property. Let P be a free $\mathcal{O}_L$-module of finite rank, $P' \subseteq P$ a submodule and $w\colon P' \to I_c^2$ an $\mathcal{O}_L$-linear map such that for every $f \in P'$

$$\gamma_\delta(w(f)) = w(f) \ \ (\delta \in \mu_{\ell-1} \subseteq \mathbb{Z}_\ell^\times) \qquad \text{and} \qquad Q^\eta w(f) \in P_1(\mathbf{N}(T_2)_{c-1}).$$

Then there are submodules $P' = P'_0 \supseteq P'_1 \supseteq \cdots \supseteq P'_k$ and a set $J \subseteq \{0, \dots, k-1\}$ with $|J| \leq 6$ and $k - |J| \leq 3$, such that P'_i/P'_{i+1} is generated by at most m elements for $i \in J$ and $\mathrm{nl}(P'_i/P'_{i+1}) \leq \lambda$ for $i \notin J$, and such that for every $f \in P'_k$ there are $u \in I_c^1$ and a finite product λ' of the Q_s ($s \geq 0$) with $\lambda' u \in \mathbf{N}(T_1)$ and

$$\ell^e\, w(f) - \mathbf{N}(\Phi)(u) \in X\, \mathbf{N}(T_2)_c.$$

Proof. Let $c_{4,1}$ and $c_{4,2}$ be the absolute constants of Proposition C.59 and Proposition C.75, and put $c_4 = c_{4,1} + c_{4,2}$. Given the data and the down site c, let $e_2 \leq c_{4,1}B$ and $e_6 \leq c_{4,2}B$ be the integers these two statements provide, and $e = e_2 + e_6 \leq c_4 B$. Throughout, $\mathbf{N}(\Phi)$ is extended $\mathbf{A}_{F,L}$-linearly to $\mathbf{N}(T_1)[1/\lambda_\infty]$; it is additive and $\mathcal{O}_L$-linear.

First stage. Let P, P' and w be as in the statement. They satisfy the hypotheses of Proposition C.59, which gives a chain $P' = P'_0 \supseteq \cdots \supseteq P'_{k_1}$ with at most 3 steps whose quotients are generated by at most m elements and at most 1 step whose quotient has normalised length at most λ, and an $\mathcal{O}_L$-linear map $y\colon P'_{k_1} \to I_c^1$ such that for $f \in P'_{k_1}$, $\lambda'_f y(f) \in \mathbf{N}(T_1)$ for a finite product λ'_f of the Q_s, and

$$w'(f) := \ell^{e_2} w(f) - \mathbf{N}(\Phi)(y(f)) \in \mathbf{N}(T_2)_c$$

is fixed by every γ_δ, $\delta \in \mu_{\ell-1}$. The map $w'\colon P'_{k_1} \to \mathbf{N}(T_2)_c$ is $\mathcal{O}_L$-linear, as w, y and $\mathbf{N}(\Phi)$ are.

Second stage. The module P, its submodule P'_{k_1} and the map w' satisfy the hypotheses of Proposition C.75, which gives a chain $P'_{k_1} \supseteq \cdots \supseteq P'_k$ with at most 3 steps of the first kind and at most 2 of the second, such that for every $f \in P'_k$ there are $x_f \in I_c^1$ and a finite product λ''_f of the Q_s with $\lambda''_f x_f \in \mathbf{N}(T_1)$ and $\ell^{e_6} w'(f) - \mathbf{N}(\Phi)(x_f) \in X\mathbf{N}(T_2)_c$.

Assembly. The concatenated chain $P' = P'_0 \supseteq \cdots \supseteq P'_k$ has at most $3 + 3 = 6$ steps of the first kind and at most $1 + 2 = 3$ of the second. Let $f \in P'_k$ and $u = \ell^{e_6} y(f) + x_f$. By (Ry4) of Lemma 24.5, I_c^1 is an $\mathcal{O}_L$-submodule, so $u \in I_c^1$; the product $\lambda' = \lambda'_f \lambda''_f$ of the Q_s satisfies $\lambda' u = \ell^{e_6} \lambda''_f(\lambda'_f y(f)) + \lambda'_f(\lambda''_f x_f) \in \mathbf{N}(T_1)$, since $\mathbf{N}(T_1)$ is an $\mathbf{A}_{F,L}$-module. Finally

$$\ell^e w(f) - \mathbf{N}(\Phi)(u) = \ell^{e_6}\big(\ell^{e_2} w(f) - \mathbf{N}(\Phi)(y(f))\big) - \mathbf{N}(\Phi)(x_f) = \ell^{e_6} w'(f) - \mathbf{N}(\Phi)(x_f) \in X\mathbf{N}(T_2)_c.$$

□

C.2.2 Lifting at a down site

This subsection proves Proposition C.57 in two stages, after three generator steps and one length step (Proposition C.59) and after three generator steps and two length steps (Proposition C.75). The tools are the crystalline value of a Wach vector (Definition C.58) and the Frobenius-square congruence $\ell^{\sigma}\varphi^2(\pi_0)^y \in \ell^{\lceil y\ell/(\ell-1)\rceil} + \pi_0(\pi_0+\ell)^h$, with σ about $h/(\ell-1)^2$ (Lemma C.63), which enters the Frobenius-square truncations; with them Fil-filtered values from two sites back lift at an up site (Proposition C.72). The length steps are bounded by a dual length lemma at a down site (Proposition C.65), and Lemma C.76 turns generator steps, length steps and a killing exponent into a colength. The lemmas C.68 and Lemma C.69 are used again in Section C.3.

Definition C.58. Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in the existence of Wach modules over unramified fields, and $\mathbf{N} = \mathbf{N}(T)$. For $x \in \mathbf{N}$ let $H_x \in x + X\mathbf{N}_E$ be the horizontal section through x, i.e. the unique element of $x + X\mathbf{N}_E$ fixed by every γ_u, $u \in \mathbb{Z}_\ell^\times$. The **crystalline value** of x is

$$\mathrm{Cv}_T(x) = \mathrm{Ev}(H_x) \ \in \ B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T.$$

We write Cv for Cv_T when T is clear.

Proposition C.59. *There is an absolute constant $c_{4,1} \geq 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, form B and λ as in Proposition C.57, and let $c \in \mathbb{Z}/n$ with $\epsilon_c = -1$. Then there is an integer $0 \leq e_2 \leq c_{4,1}B$ with the following property. Let P be a free $\mathcal{O}_L$-module of finite rank, $P' \subseteq P$ a submodule and $w\colon P' \to I_c^2$ an $\mathcal{O}_L$-linear map such that for every $f \in P'$, $\gamma_\delta(w(f)) = w(f)$ for all $\delta \in \mu_{\ell-1} \subseteq \mathbb{Z}_\ell^\times$ and $Q^\eta w(f) \in P_1(\mathbf{N}(T_2)_{c-1})$. Then there are submodules $P' = P'_0 \supseteq P'_1 \supseteq \cdots \supseteq P'_k$, a set $J \subseteq \{0,\dots,k-1\}$ with $|J| \leq 3$ and $k - |J| \leq 1$, such that P'_i/P'_{i+1} is generated by at most m elements for $i \in J$ and $\mathrm{nl}(P'_i/P'_{i+1}) \leq \lambda$ for $i \notin J$, and an $\mathcal{O}_L$-linear map $y\colon P'_k \to I_c^1$ such that for every $f \in P'_k$: $\gamma_\delta(y(f)) = y(f)$ for $\delta \in \mu_{\ell-1}$, $\lambda' y(f) \in \mathbf{N}(T_1)$ for some finite product λ' of the Q_s ($s \geq 0$), and*

$$\ell^{e_2} w(f) - \mathbf{N}(\Phi)(y(f)) \in \mathbf{N}(T_2)_c \quad \text{and is fixed by every } \gamma_\delta,\ \delta \in \mu_{\ell-1}.$$

Proof. Put $M = s_c + S$, $h'' = s_{c-2} + S$, $q = \pi_0 + \ell$ ($q(0) = \ell$), $D = D_{\mathrm{cris}}(V_2)$, $\mathbf{N} = \mathbf{N}(T_2)$, let E be the integer of Proposition C.72 for the up site $c-1$, κ that of Proposition C.71 for c, and

$$e_2 = e_{\mathrm{H}} + \kappa - h'' = e_{\mathrm{H}} + s_\ell(k-1) + E + \sigma_{\mathrm{G}} - s_{c-1}.$$

Step 0: signs, windows, level data. As n is even and the signs alternate, $\epsilon_{c-1} = 1$, $\epsilon_{c-2} = -1$. By Lemma 24.2 (1) and (Ow1), the Hodge jumps of V_2 at τ_c lie in $[-M, -s_c] \cup [-\eta, \eta]$ and those at τ_{c-1} in $[s_{c-1}, s_{c-1}+S] \cup [-\eta, \eta]$. Fix arc level data of (V_2, T_2) with cut c, length 1, $H(c) = \eta$ and a frame at $c-1$. The level-0 expansion of an element of $e_c\mathbf{N}[1/\lambda_1]$ algebraic at level 0 is the coordinate vector of its image under $\Lambda_0 = \varphi^{-1} \circ \iota_{T_2}$ in the level frame, so it depends on the cut, the length and the frame but not on H; for such an element v we write $\Lambda_0(v) = \sum_i t^i \delta_i(v)$, $\delta_i(v) \in K_{(0)} \otimes_L \epsilon_{c-1}D$, as in Proposition C.60. For $f \in P'$, $w(f) \in W$ and, by Proposition C.60 (Ct1), $\delta_i(w(f)) = 0$ for $i < -\eta$, $\delta_i(w(f)) \in K_{(0)} \otimes_L \mathrm{Fil}^{-i}D$ for $i \neq 0$, $\delta_0(w(f)) \in \epsilon_{c-1}D$; these vectors are $\mathcal{O}_L$-linear in f.

Step 1: the constant term, linearly. The module P' is a submodule of a free module of finite rank over the principal ideal domain $\mathcal{O}_L$, hence free with a finite basis (f_j). For each j, Proposition C.60 (Ct2) gives a Δ-invariant $x_j \in \mathbf{N}_{c-2}$ with $\ell^{e_{\mathrm{H}}}\delta_0(w(f_j)) - \varphi^{-2}(\mathrm{Cv}(x_j)) \in$

$\mathrm{Fil}^{-\eta}D$. Let $\xi\colon P' \to \mathbf{N}_{c-2}^{\Delta}$ be the $\mathcal{O}_L$-linear map with $\xi(f_j) = x_j$. As Cv is $\mathcal{O}_L$-linear ((Cv1), (Cv2)) and φ^{-2} is L-linear on D, for every $f \in P'$

$$\ell^{e_{\mathrm{H}}}\delta_0(w(f)) - \varphi^{-2}\big(\mathrm{Cv}(\xi(f))\big) \in \mathrm{Fil}^{-\eta}D. \qquad (1)$$

Step 2: the dual length lemma at $c-2$. The site $c-2$ is down. With Σ_{c-2} from Proposition C.65 at $c-2$, let $P_1' = \xi^{-1}(\pi_0\mathbf{N}_{c-2}^{\Delta} + Y_{c-2} + \sum_{\Sigma_{c-2}} \mathcal{O}_L y)$ and $P_2' = \xi^{-1}(\pi_0\mathbf{N}_{c-2}^{\Delta} + Y_{c-2})$. The quotient P'/P_1' embeds in $\mathbf{N}_{c-2}^{\Delta}/(\pi_0\mathbf{N}_{c-2}^{\Delta} + Y_{c-2} + \sum_{\Sigma_{c-2}} \mathcal{O}_L y)$, so $\mathrm{nl}(P'/P_1') \le \lambda$; P_1'/P_2' embeds in a module generated by the images of the at most m elements of Σ_{c-2}, so it is generated by at most m elements.

Step 3: one Frobenius step back. Let $f \in P_2'$. Then $\xi(f) = \pi_0 n + \sum_j o_j q^{h''} g_j \varphi(x_j'')$ with $n \in \mathbf{N}_{c-2}^{\Delta}$, $o_j \in \mathcal{O}_L$, $g_j \in \mathbf{A}_{F,L}$ and $x_j'' \in \mathbf{N}_{c-3}$ Δ-invariant, each summand lying in $\mathbf{N}_{c-2}$ (Proposition C.65). By (Cv2), $\mathrm{Cv}(\pi_0 n) = 0$ ($\pi_0(0) = 0$); by (Cv4) and (Cv1), $\mathrm{Cv}(q^{h''} g_j \varphi(x_j'')) = \ell^{h''}\varphi^3(\iota_\Lambda(g_j(0)))\varphi(\mathrm{Cv}(x_j'')) = \ell^{h''}\varphi(\mathrm{Cv}(\varphi^{-1}(g_j(0))x_j''))$ (φ is bijective on Λ and ι is φ-equivariant). Hence $\mathrm{Cv}(\xi(f)) \in \ell^{h''}\varphi(\mathrm{Cv}(\mathbf{N}_{c-3}^{\Delta}))$, and $\alpha(f) = \ell^{-h''}\varphi^{-1}(\mathrm{Cv}(\xi(f)))$ defines an $\mathcal{O}_L$-linear map $\alpha\colon P_2' \to \mathrm{Cv}(\mathbf{N}_{c-3}^{\Delta}) \subseteq \epsilon_c D$ ((Cv1)), with

$$\varphi^{-2}(\mathrm{Cv}(\xi(f))) = \ell^{h''}\varphi^{-1}(\alpha(f)). \qquad (2)$$

Step 4: the Hodge condition at τ_{c-1}. We have $\varphi^{-2}(\alpha(f)) \in \epsilon_{c-2}D = D_{\mathrm{dR},\tau_{c-1}}(V_2)$. Let $\beta(f)$ be its class modulo $\epsilon_{c-2}\mathrm{Fil}^{s_{c-1}}D$ and $P_3' = P_2' \cap \ker\beta$. The target of β has L-dimension the number, with multiplicity, of Hodge jumps of V_2 at τ_{c-1} below s_{c-1}; these lie in $[-\eta,\eta]$ (Step 0, $s_{c-1} > \eta$), so by (Ow2) the dimension is at most m. The quotient P_2'/P_3' embeds in it, so it is torsion free of rank at most m, hence free and generated by at most m elements.

Step 5: realisation along Φ, linearly. The module P_3' is free; let (f_j') be a basis. For each j, $\alpha(f_j') = \mathrm{Cv}(x_j')$ for a Δ-invariant $x_j' \in \mathbf{N}_{c-3}$ (an $\mathcal{O}_L$-combination of Δ-invariant vectors), with $\varphi^{-2}(\mathrm{Cv}(x_j')) \in \mathrm{Fil}^{s_{c-1}}D$ (Step 4). By Proposition C.71 at c there is a Δ-invariant $y_j = \varphi(\tilde{y}_j)$, $\tilde{y}_j \in \mathbf{N}(T_1)_{c-1}$, with $Q^M y_j \in \mathbf{N}(T_1)_c$, $(\gamma_u - 1)y_j \in X\mathbf{N}(T_1)$ for all u, $\mathbf{N}(\Phi)(y_j)$ algebraic at level 0, and, in vector form (the level frame being an L-basis of $\epsilon_{c-1}D$), $\delta_i(\mathbf{N}(\Phi)y_j) = 0$ for $i < 0$ and for $0 < i < M$, and $\delta_0(\mathbf{N}(\Phi)y_j) = \ell^{\kappa}\varphi^{-1}(\mathrm{Cv}(x_j')) = \ell^{\kappa}\varphi^{-1}(\alpha(f_j'))$. Let $y\colon P_3' \to e_c\mathbf{N}(T_1)[1/\lambda_\infty]$ be the $\mathcal{O}_L$-linear map with $y(f_j') = y_j$. All these properties are $\mathcal{O}_L$-linear, so for every $f \in P_3'$: $y(f)$ is Δ-invariant, $Q^M y(f) \in \mathbf{N}(T_1)$ (so $\lambda' = Q_0^M$ works), $(\gamma_u - 1)y(f) \in X\mathbf{N}(T_1)$, so $y(f) \in I_c^1$; $\mathbf{N}(\Phi)(y(f))$ lies in the arc domain with $H = 0$, hence in W ($Q^\eta P_1 \subseteq P_1$); and, writing $\delta_i'(f) = \delta_i(\mathbf{N}(\Phi)(y(f)))$,

$$\delta_i'(f) = 0 \ \ (i < 0 \text{ or } 0 < i < M), \qquad \delta_0'(f) = \ell^{\kappa}\varphi^{-1}(\alpha(f)). \qquad (3)$$

Step 6: the constant term. For $f \in P_3'$, multiply (1) by ℓ^{κ} and use (2), (3): $\ell^{\kappa+e_{\mathrm{H}}}\delta_0(w(f)) - \ell^{h''}\delta_0'(f) \in \mathrm{Fil}^{-\eta}D$; dividing by $\ell^{h''}$ ($\mathrm{Fil}^{-\eta}D$ is an L-subspace),

$$\ell^{e_2}\delta_0(w(f)) - \delta_0'(f) \in \epsilon_{c-1}\mathrm{Fil}^{-\eta}D.$$

Let $\beta'(f)$ be its class in $\epsilon_{c-1}\mathrm{Fil}^{-\eta}D/\epsilon_{c-1}\mathrm{Fil}^{0}D$, and $P_4' = P_3' \cap \ker\beta'$. The target has dimension the number of Hodge jumps of V_2 at τ_c in $[-\eta,-1]$, at most m by (Ow2); as in Step 4, P_3'/P_4' is generated by at most m elements.

Step 7: membership. Let $f \in P_4'$ and $w'' = \ell^{e_2}w(f) - \mathbf{N}(\Phi)(y(f)) \in W$. Then $\Lambda_0(w'') = \sum_i t^i\big(\ell^{e_2}\delta_i(w(f)) - \delta_i'(f)\big)$, and its t^i-coefficient lies in $K_{(0)} \otimes_L \mathrm{Fil}^{-i}D$ for every i: for $i < 0$ and $0 < i < M$ by Step 0 and (3); for $i = 0$ because $f \in \ker\beta'$; for $i \ge M$ because every Hodge jump of V_2 at τ_c is $\ge -M \ge -i$, so the τ_c-component of $\mathrm{Fil}^{-i}D$ is all of $\epsilon_{c-1}D$. So $\mathrm{lv}_0(w'')$ is de Rham

integral, and by Lemma 23.5 (2) (length 1), $w'' \in \mathbf{N}(T_2)_c$. It is fixed by every γ_δ, $\delta \in \mu_{\ell-1}$: $w(f)$ and $y(f)$ are, and $\mathbf{N}(\Phi)$ commutes with the γ_u (Ex3).

Step 8: the chain and the exponent. The chain $P' = P'_0 \supseteq P'_1 \supseteq P'_2 \supseteq P'_3 \supseteq P'_4$ with $k = 4$ and $J = \{1, 2, 3\}$ ($|J| = 3$, $k - |J| = 1$) has the required properties, with y restricted to P'_4. For the exponent: by Proposition C.60, $e_{\mathrm{H}} \le (s_c+\eta)/(\ell-1)^2 + s_{c-1} + S - s_c/\ell + 3 + \log_\ell(s_{c-1}+S)$ and $e_{\mathrm{H}} \ge \sigma_{\mathrm{H}} + s_{c-1} + S + 1 - \lceil s_c/\ell \rceil$; $k = (\ell-1)\lceil M/(\ell-1)\rceil \le M + \ell - 2$, so $\lceil s_c/\ell\rceil - 1 \le \lceil M/(\ell-1)\rceil - 1 = \lfloor (k-1)/(\ell-1)\rfloor \le s_\ell(k-1) \le (k-1)\ell/(\ell-1)^2 \le M\ell/(\ell-1)^2 + 1$. Hence $e_2 \ge \sigma_{\mathrm{H}} + S + E + \sigma_{\mathrm{G}} \ge 0$, and, with $E \le (3a_{\mathrm{R}} + S + 2\eta)/(\ell-1) + \log_\ell(2H') + 1$, $\sigma_{\mathrm{G}} \le 2H'/(\ell-1)^2 + 2$, $s_c \le H'$, $s_{c-1} + S \le 2H'$, $\ell \ge 11$:

$$e_2 \le \frac{13.8\, H'}{\ell^2} + 1.21\, S + \frac{2.31\, \eta}{\ell} + 2.3 \log_\ell(2H') + 8.2 \le 14B.$$

So the statement holds with $c_{4,1} = 14$. □

Proposition C.60. *Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, let $c \in \mathbb{Z}/n$ with $\epsilon_c = -1$, $D = D_{\mathrm{cris}}(V_2)$, and put*

$$y = s_{c-1} + S, \qquad \sigma_{\mathrm{H}} = \Big\lceil \frac{s_c + \eta}{(\ell-1)^2} \Big\rceil + 1, \qquad e_{\mathrm{H}} = \sigma_{\mathrm{H}} + y + 1 - \lceil s_c/\ell \rceil + \lfloor \log_\ell y \rfloor.$$

Let $w \in I_c^2$ be Δ-invariant with $Q^\eta w \in P_1(\mathbf{N}(T_2)_{c-1})$. Fix arc level data of (V_2, T_2) with cut c, length 1, $H(c) = \eta$ and a frame at $c-1$; then $w \in W$, and writing $\mathrm{lv}_0(w) = \sum_i t^i v_i$ ($v_i \in K_{(0)}^r$) put $\delta_i = \sum_k v_{i,k} D_k^{(0)} \in K_{(0)} \otimes_L \epsilon_{c-1} D$. Then:

(Ct1) *$\delta_i = 0$ for $i < -\eta$; $\delta_i \in K_{(0)} \otimes_L \mathrm{Fil}^{-i} D$ for $i \ne 0$; and $\delta_0 \in \epsilon_{c-1} D$;*

(Ct2) *there is a Δ-invariant $x \in \mathbf{N}(T_2)_{c-2}$ with*

$$\ell^{e_{\mathrm{H}}} \delta_0 - \varphi^{-2}(\mathrm{Cv}_{T_2}(x)) \in \mathrm{Fil}^{-\eta} D.$$

Moreover $0 \le e_{\mathrm{H}} \le \dfrac{s_c + \eta}{(\ell-1)^2} + s_{c-1} + S - \dfrac{s_c}{\ell} + 3 + \log_\ell(s_{c-1} + S)$.

Proof. Put $M = s_c + S$, $q = \pi_0 + \ell$, $\mathbf{N} = \mathbf{N}(T_2)$.

Step 0: signs, windows, sizes. As n is even and the signs alternate by parity, $\epsilon_{c-1} = 1$. By Lemma 24.2 (1), (Ow1) and (Ex1), the Hodge jumps of V_2 at τ_c lie in $[-M, -s_c] \cup [-\eta, \eta]$, and $\mathbf{N}$ has window (η, y) at the up site $c-1$, so (Wm2) gives $Q^y \mathbf{N}_{c-1} \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-2})$. By the hypotheses $s_{c-1} \ge (H' - \eta)/2$ and $s_c \le H' - S - \eta$, so $s_c \le 2s_{c-1} \le \ell y$; also $y \ge s_{c-1} \ge 1$ and $s_c \ge 1$.

Step 1: the expansion, (Ct1). Here $\Pi = Q^\eta$ and $Q^\eta w \in P_1(\mathbf{N}_{c-1})$, so $w \in W$; by Lemma 23.17, w is algebraic at level 0 and $\mathrm{lv}_0(w) \in t^{-\eta} K_{(0)}[[t]]^r$, whence $\delta_i = 0$ for $i < -\eta$. For $u \in \mathbb{Z}_\ell^\times$, $(\gamma_u - 1)w \in X\mathbf{N} \cap e_c\mathbf{N}[1/\lambda_\infty] \subseteq \mathbf{N}_c$ (definition of I_c) and $(\gamma_u - 1)w \in W$ ((Lp2)); by Lemma 23.5 (2), $\mathrm{lv}_0((\gamma_u - 1)w)$ is de Rham integral, and by (Lp2) its t^i-coefficient is $u^i \sigma_u(v_i) - v_i$. Take $u = u_0$ with $v_\ell(u_0 - 1) = 1$: $\sigma_{u_0} = \mathrm{id}$ on $K_{(0)}$ by (Lp8), so $(u_0^i - 1)v_i \in K_{(0)} \otimes_L \mathrm{Fil}_0(-i)$, and $u_0^i \ne 1$ for $i \ne 0$ ($1 + \ell\mathbb{Z}_\ell$ is torsion free); hence $\delta_i \in K_{(0)} \otimes_L \mathrm{Fil}^{-i} D$ for $i \ne 0$. For $\delta \in \mu_{\ell-1}$, $\gamma_\delta w = w$ gives $\sigma_\delta(v_0) = v_0$ by (Lp2); $\sigma_u = \mathrm{id}$ for $u \in 1 + \ell\mathbb{Z}_\ell$ (Lp8), and $\sigma_{\delta u} = \sigma_\delta \sigma_u$ (both are induced by products of elements of G_F with these characters); so v_0 is fixed by every σ_u, $v_0 \in L^r$ by (Lp8), and $\delta_0 \in \epsilon_{c-1} D$.

Step 2: a Frobenius square. Put $P_c = \varphi(q)^y q^\eta$, Δ-invariant ((Dv2')), and $P = P_c w$. By (Dv2), $q^\eta w = \omega^\eta Q^\eta w \in P_1(\mathbf{N}_{c-1})$, the $\mathbf{A}_{F,L}$-span of $\varphi(\mathbf{N}_{c-1})$; for $n' \in \mathbf{N}_{c-1}$, $\varphi(q)^y \varphi(n') =$

$\varphi(q^y n')$ with $q^y n' \in Q^y \mathbf{N}_{c-1} \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-2})$ (Step 0), so $\varphi(q^y n')$ lies in the $\mathbf{A}_{F,L}$-span of $\varphi^2(\mathbf{N}_{c-2})$. Let $(e'_m)_{m\le r}$ be a Δ-invariant basis of $\mathbf{N}_{c-2}$ (Lemma 24.15). As φ is semilinear, $P = \sum_m a_m \varphi^2(e'_m)$ with $a_m \in e_c\mathbf{A}_{F,L}$; since P and the $\varphi^2(e'_m)$ are Δ-invariant and $\gamma_\delta(a\varphi^2(e'_m)) = \gamma_\delta(a)\varphi^2(e'_m)$, we may replace a_m by $(\ell-1)^{-1}\sum_{\delta\in\mu_{\ell-1}}\gamma_\delta(a_m)$; so the a_m are Δ-invariant.

Step 3: dual truncation. Apply Lemma C.62 with $i = c$, the basis (e'_m), $h = s_c + \eta$ (so $\sigma = \sigma_{\mathrm{H}}$): Δ-invariant $Z_{mk} \in e_c\mathbf{A}_{F,L}$ with $\ell^{\sigma_{\mathrm{H}}}\Lambda_0(\varphi^2(e'_m)) - \sum_k \lambda_0(Z_{mk})D_k \in t^h\Lambda_D$, $D_k = \varphi^{-2}(\mathrm{Cv}(e'_k))$. The D_k are an L-basis of $\epsilon_{c-1}D$ ((Cv3): the $\mathrm{Cv}(e'_k)$ are a basis of $\epsilon_{c+1}D$, and φ^{-2} is bijective between components). Since $\Lambda_0(aW') = \lambda_0(a)\Lambda_0(W')$ and $\lambda_0(e_c\mathbf{A}_{F,L}) \subseteq K_{(0)}[[t]] \subseteq B^+_{\mathrm{dR}} \otimes L$ ((Lp1)),

$$\ell^{\sigma_{\mathrm{H}}}\Lambda_0(P) - \sum_k \lambda_0(b_k)D_k \in t^h\Lambda_D, \qquad b_k = \sum_m a_m Z_{mk} \ \ (\Delta\text{-invariant}).$$

Step 4: coefficients modulo $\mathrm{Fil}^{-\eta}$. By (Lp1) and (Dv2), $\lambda_0(q) = tu$ with $u \in K_{(0)}[[t]]^\times$, and by (Dv2') $\lambda_0(\varphi(q)) = \lambda_0(Q_1)\lambda_0(\omega_1)$ is a unit of $K_{(0)}[[t]]$; so $\lambda_0(P_c) = \sum_j p_j t^j$ with $p_j = 0$ for $j < \eta$ and $p_\eta = \lambda_0(\varphi(q))(0)^y u(0)^\eta$ a unit of $K_{(0)}$. Since $\Lambda_0(w) = \sum_i t^i\delta_i$ and $\Lambda_0(P) = \lambda_0(P_c)\Lambda_0(w)$, the vector of Step 3 equals $\sum_k g_k D_k$ with $g_k \in K_{(0)}((t))$, and it lies in $t^h\Lambda_D = \bigoplus_k t^h R^+ D_k$ ($R^+ = \epsilon_{c-1}(B^+_{\mathrm{dR}} \otimes L)$). Hence all t^R-coefficients with $R < h = s_c + \eta$ vanish:

$$\ell^{\sigma_{\mathrm{H}}} \sum_{-\eta\le i\le R-\eta} p_{R-i}\delta_i = \sum_k \beta_{k,R}D_k, \qquad \beta_{k,R} = [t^R]\lambda_0(b_k) \qquad (R < s_c + \eta).$$

Every $i \ne 0$ occurring has $-\eta \le i < s_c$. If $i \le \eta$, $\mathrm{Fil}^{-i}D \subseteq \mathrm{Fil}^{-\eta}D$. If $\eta < i < s_c$, there are no Hodge jumps of V_2 at τ_c in $[-i, -\eta-1]$ (Step 0), so the τ_c-components (ϵ_{c-1}-components) of $\mathrm{Fil}^{-i}D$ and $\mathrm{Fil}^{-\eta}D$ agree. By (Ct1), modulo $K_{(0)} \otimes_L \epsilon_{c-1}\mathrm{Fil}^{-\eta}D$:

$$\ell^{\sigma_{\mathrm{H}}} p_R\, \delta_0 \equiv \sum_k \beta_{k,R}D_k \qquad (R < s_c + \eta). \qquad (*)$$

Step 5: coordinates. Let $\bar{D} = \epsilon_{c-1}D/\epsilon_{c-1}\mathrm{Fil}^{-\eta}D$, $\bar{D}_k$, $\bar{\delta}_0$ the images, and M' the $\mathcal{O}_L$-span of the $\bar{D}_k$; it is finitely generated and torsion free over the principal ideal domain $\mathcal{O}_L$, so free with a basis $g_1, \dots, g_p$, which is L-linearly independent; write $\bar{D}_k = \sum_j m_{kj}g_j$, $m_{kj} \in \mathcal{O}_L$. Extend (g_j) to an L-basis of $\bar{D}$; its image is a $K_{(0)}$-basis of $K_{(0)} \otimes_L \bar{D}$. By $(*)$ at $R = \eta$, $\bar{\delta}_0 = \ell^{-\sigma_{\mathrm{H}}}p_\eta^{-1}\sum_k \beta_{k,\eta}\bar{D}_k$ lies in the $K_{(0)}$-span of the g_j; as $\bar{\delta}_0 \in \bar{D}$ has coordinates in L, $\bar{\delta}_0 = \sum_j v_j g_j$ with $v_j \in L$. Inserting this in $(*)$ and comparing g_j-coordinates,

$$\ell^{\sigma_{\mathrm{H}}} v_j\, p_R = \sum_k m_{kj}\beta_{k,R} = [t^R]\lambda_0(\alpha_j), \qquad \alpha_j = \sum_k m_{kj}b_k \qquad (R < s_c + \eta),$$

that is, $\lambda_0(\alpha_j) - \theta_j\lambda_0(\varphi(q)^y q^\eta) \in t^{s_c+\eta}K_{(0)}[[t]]$ with $\theta_j = \ell^{\sigma_{\mathrm{H}}}v_j \in L$ and $\alpha_j \in e_c\mathbf{A}_{F,L}$ Δ-invariant.

Step 6: integrality, (Ct2). By Lemma C.61 with y, $b = s_c \le \ell y$ (Step 0) and η: $\ell^{h_{\mathrm{s}}}\theta_j \in \mathcal{O}_L$, $h_{\mathrm{s}} = y + 1 - \lceil s_c/\ell\rceil + \lfloor \log_\ell y\rfloor$. So $o_j = \ell^{e_{\mathrm{H}}}v_j = \ell^{h_{\mathrm{s}}}\theta_j \in \mathcal{O}_L$ and $\ell^{e_{\mathrm{H}}}\bar{\delta}_0 = \sum_j o_j g_j \in M'$, say $= \sum_k o'_k\bar{D}_k$ with $o'_k \in \mathcal{O}_L$. Put $x = \sum_k o'_k e'_k$, a Δ-invariant element of $\mathbf{N}_{c-2}$. By (Cv2) for constants and the L-linearity of φ^{-2} on D, $\varphi^{-2}(\mathrm{Cv}(x)) = \sum_k o'_k D_k$, so $\ell^{e_{\mathrm{H}}}\delta_0 - \varphi^{-2}(\mathrm{Cv}(x)) \in \epsilon_{c-1}\mathrm{Fil}^{-\eta}D \subseteq \mathrm{Fil}^{-\eta}D$.

Step 7: the exponent. We have $\sigma_{\mathrm{H}} \le (s_c+\eta)/(\ell-1)^2 + 2$ and $-\lceil s_c/\ell\rceil \le -s_c/\ell$, so $e_{\mathrm{H}} \le (s_c+\eta)/(\ell-1)^2 + s_{c-1} + S - s_c/\ell + 3 + \log_\ell(s_{c-1}+S)$; and $e_{\mathrm{H}} \ge \sigma_{\mathrm{H}} + y + 1 - \lceil s_c/\ell\rceil \ge 0$ since $s_c/\ell \le y$ (Step 0) and y is an integer, so $\lceil s_c/\ell\rceil \le y$. □

Lemma C.61. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, let $c \in \mathbb{Z}/n$, and let λ_0 and $K_{(0)}$ be the level-0 map and the level coefficient ring of arc level data with cut c (they depend*

only on c); L is a subring of $K_{(0)}$ through ϵ_0. Put $q = \pi_0 + \ell$. Let $y, b \geq 1$ and $\eta \geq 0$ be integers, and

$$K = \min(y, \lceil b/\ell \rceil - 1), \qquad h = y - K + \lfloor \log_\ell y \rfloor.$$

If $\alpha \in e_c \mathbf{A}_{F,L}$ is Δ-invariant, $\theta \in L$, and

$$\lambda_0(\alpha) - \theta\, \lambda_0(\varphi(q)^y q^\eta) \in t^{\,b+\eta} K_{(0)}[[t]],$$

then $\ell^h \theta \in \mathcal{O}_L$. If moreover $b \leq \ell y$, then $h = y + 1 - \lceil b/\ell \rceil + \lfloor \log_\ell y \rfloor \leq y - b/\ell + 1 + \log_\ell y$.

Proof. Let $R = e_c \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ and R^Δ its Δ-invariant elements.

Step 1: expansions in q. By (Dv1), $\alpha = A(q)$ for a unique $A = \sum_k a_k T^k \in \mathcal{O}_L[[T]]$; for every $N \geq 0$, writing $A = \sum_{k<N} a_k T^k + T^N A_N$ with $A_N \in \mathcal{O}_L[[T]]$ and applying the homomorphism $T \mapsto q$, we get $\alpha = \sum_{k<N} a_k q^k + q^N \alpha_N$ with $\alpha_N = A_N(q) \in R^\Delta$. The element $\varphi(q)$ is Δ-invariant (as φ commutes with the γ_δ) and lies in $\mathbb{Z}_\ell[[X]]$, so by (Dv1) for $\mathbb{Z}_\ell[[X]]$ there is $g = \sum_j g_j T^j \in \mathbb{Z}_\ell[[T]]$ with $\varphi(q) = g(q)$.

Step 2: the shape of g. (a) $g_0 = \ell$. Fix a primitive ℓ-th root of unity ζ in an algebraic closure of $\mathbb{Q}_\ell$ and let $\mathrm{ev}\colon \mathbb{Z}_\ell[[X]] \to \mathbb{Z}_\ell[\zeta]$, $f \mapsto f(\zeta - 1)$; it is a ring homomorphism, continuous for the (ℓ, X)-adic topology since $\zeta - 1$ has positive valuation. By (Dv2), $q = Q\omega$, and $\mathrm{ev}(Q) = \Phi_\ell(\zeta) = 0$ ($Q = \Phi_\ell(1 + X)$), so $\mathrm{ev}(q) = 0$ and $\mathrm{ev}(\varphi(q)) = \mathrm{ev}(g(q)) = g_0$ (the series $\sum_j g_j q^j$ converges (ℓ, X)-adically, $q(0) = \ell$). On the other hand $\varphi(q)(X) = q((1+X)^\ell - 1)$, so $\mathrm{ev}(\varphi(q)) = q(\zeta^\ell - 1) = q(0) = \pi_0(0) + \ell = \ell$, because $\pi_0(0) = \sum_{\delta \in \mu_{\ell-1}} 1 - (\ell - 1) = 0$. (b) $g \equiv T^\ell \pmod{\ell \mathbb{Z}_\ell[[T]]}$. For $f \in \mathbb{Z}_\ell[[X]]$, $\varphi(f) = f((1 + X)^\ell - 1) \equiv f(X^\ell) \equiv f^\ell$ modulo $\ell \mathbb{Z}_\ell[[X]]$ (the coefficients of f modulo ℓ lie in $\mathbb{F}_\ell$, fixed by the ℓ-th power map). Hence $(g - T^\ell)(q) = \varphi(q) - q^\ell \in \ell \mathbb{Z}_\ell[[X]]$; it is Δ-invariant, so $\ell^{-1}(g - T^\ell)(q)$ is a Δ-invariant element of $\mathbb{Z}_\ell[[X]]$, equal to $g'(q)$ with $g' \in \mathbb{Z}_\ell[[T]]$ by (Dv1); injectivity of $T \mapsto q$ gives $g - T^\ell = \ell g'$. By (a) and (b), $g = \ell G + T^\ell$ with $G \in \mathbb{Z}_\ell[[T]]$ and $G(0) = g_0/\ell = 1$. Therefore

$$g^y = \sum_{k=0}^{y} \binom{y}{k} \ell^{\,y-k} G^{\,y-k}\, T^{\ell k}. \qquad (1)$$

Step 3: comparison of coefficients. By (Lp1), $\lambda_0(Q) \in t\, K_{(0)}[[t]]^\times$ and $\lambda_0(R) \subseteq K_{(0)}[[t]]$; ω is a unit of R, so $\lambda_0(\omega)$ is a unit and $\lambda_0(q) = tu$ with $u \in K_{(0)}[[t]]^\times$. Put $N = b + \eta$ and write $g^y T^\eta = \sum_{k<N} c_k T^k + T^N r$ with $c_k \in \mathbb{Z}_\ell$, $r \in \mathbb{Z}_\ell[[T]]$, so that $\varphi(q)^y q^\eta = \sum_{k<N} c_k q^k + q^N \rho$ with $\rho = r(q) \in R^\Delta$. By Step 1,

$$\lambda_0(\alpha) - \theta \lambda_0(\varphi(q)^y q^\eta) = \sum_{k<N} (a_k - \theta c_k) u^k t^k + t^N u^N (\lambda_0(\alpha_N) - \theta \lambda_0(\rho)),$$

and the last term lies in $t^N K_{(0)}[[t]]$. So $\sum_{k<N} (a_k - \theta c_k) u^k t^k \in t^N K_{(0)}[[t]]$. By induction on $k < N$: the coefficient of t^k is $(a_k - \theta c_k) u(0)^k$ plus terms from indices $k' < k$, which vanish; $u(0)$ is a unit of $K_{(0)}$ and $K_{(0)}$ is an L-vector space, so $a_k = \theta c_k$. In particular, for $0 \leq j < b$,

$$\theta \cdot [T^j]\, g^y = \theta\, c_{\eta+j} = a_{\eta+j} \in \mathcal{O}_L. \qquad (2)$$

Step 4: a coefficient of small valuation. We have $K \geq 0$ and $\ell K < b$ (if $K = \lceil b/\ell \rceil - 1$ this is $\ell(\lceil b/\ell \rceil - 1) < b$; if $K = y < \lceil b/\ell \rceil - 1$ then $\ell y < b$). Let $\mu = \min_{0 \leq k \leq K} v_\ell\big(\binom{y}{k} \ell^{y-k}\big)$ and k_1 the least k attaining it. In (1) the terms with $k > K$ are 0 (if $K = y$) or lie in $T^{\ell \lceil b/\ell \rceil} \mathbb{Z}_\ell[[T]] \subseteq T^b \mathbb{Z}_\ell[[T]]$; so modulo T^b, $\ell^{-\mu} g^y \equiv \sum_{k \leq K} \ell^{-\mu} \binom{y}{k} \ell^{y-k} G^{y-k} T^{\ell k}$, a series with coefficients in $\mathbb{Z}_\ell$. Reduce it modulo ℓ: the terms $k < k_1$ vanish (their scalar has valuation $> \mu$),

the terms $k > k_1$ only involve T^j with $j \geq \ell k > \ell k_1$, and the term k_1 contributes to $T^{\ell k_1}$ the residue of $\ell^{-\mu}\binom{y}{k_1}\ell^{y-k_1}G(0)^{y-k_1}$, a unit ($G(0)=1$). Since $\ell k_1 \leq \ell K < b$, the coefficient $[T^{\ell k_1}]g^y$ has valuation exactly μ. By (2) with $j = \ell k_1$, $v_\ell(\theta) \geq -\mu$, so $\ell^\mu\theta \in \mathcal{O}_L$.

Step 5: the exponent. We have $\mu \leq v_\ell\big(\binom{y}{K}\big) + y - K$, and by Kummer's theorem $v_\ell\big(\binom{y}{K}\big)$ is the number of carries when K and $y-K$ are added in base ℓ; a carry out of the leading digit of y is impossible, so there are at most $\lfloor \log_\ell y \rfloor$ carries, that is, the number of base-ℓ digits of y minus 1. Hence $\mu \leq h$ and $\ell^h\theta = \ell^{h-\mu}\ell^\mu\theta \in \mathcal{O}_L$. If $b \leq \ell y$, then $\lceil b/\ell \rceil - 1 < y$, so $K = \lceil b/\ell \rceil - 1$ and $h = y + 1 - \lceil b/\ell \rceil + \lfloor \log_\ell y \rfloor \leq y + 1 - b/\ell + \log_\ell y$. □

Lemma C.62. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $D = D_{\mathrm{cris}}(V)$, $i \in \mathbb{Z}/n$, and $(e'_m)_{m\leq r}$ a basis of $\mathbf{N}_{i-2}$ over $e_{i-2}\mathbf{A}_{F,L}$ consisting of Δ-invariant vectors. Let $h \geq 1$ and $\sigma = \lceil h/(\ell-1)^2 \rceil + 1$. Let $\Lambda_0 = \varphi^{-1}\circ\iota_T$ on $\mathbf{N}[1/\lambda_2]$, $\lambda_0 = \varphi^{-1}\circ(\iota\otimes\mathrm{id})$ on $\mathbf{A}_{F,L}[1/\lambda_2]$, and $\Lambda_D = \epsilon_{i-1}(B^+_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell} L)\cdot\epsilon_{i-1}D$. Then there are Δ-invariant $Z_{mk} \in e_i\mathbf{A}_{F,L}$ $(m,k\leq r)$ such that for every m*

$$\ell^\sigma\,\Lambda_0(\varphi^2(e'_m)) - \sum_{k\leq r}\lambda_0(Z_{mk})\,\varphi^{-2}(\mathrm{Cv}(e'_k)) \in t^h\Lambda_D.$$

Proof. Put $\varsigma = \pi_0 + \ell$, $D_k = \varphi^{-2}(\mathrm{Cv}(e'_k))$, and identify $e_{i-2}E[[X]] \cong L[[X]]$, $e_i\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$.

Step 1: the basis in the horizontal frame. Let H'_k be the horizontal section through e'_k ((Hf2)); the H'_k form an $E[[X]]$-basis of $e_{i-2}\mathbf{N}_E$. Write $H'_k = \sum_m h_{km}e'_m$ with $h_{km} \in L[[X]]$; then $h \equiv I$ modulo X ($H'_k \in e'_k + X\mathbf{N}_E$), and $\ell^{s_\ell(j)}[X^j]h_{km} \in \mathcal{O}_L$ for all j by (Hf3). The h_{km} are Δ-invariant: $\gamma_\delta(H'_k)$ is fixed by every γ_u (the γ_u commute) and lies in $\gamma_\delta(e'_k)+X\mathbf{N}_E = e'_k+X\mathbf{N}_E$, so $\gamma_\delta(H'_k) = H'_k$ by the uniqueness in (Hf2); compare coordinates in the Δ-invariant basis (e'_m). The function s_ℓ is superadditive: with $J_a = \lfloor a/(\ell-1)\rfloor$, $J_a + J_b \leq J_{a+b}$, $v_\ell(J_a!) + v_\ell(J_b!) \leq v_\ell((J_a+J_b)!)$ (a binomial coefficient is an integer), and $J \mapsto J + v_\ell(J!)$ is non-decreasing; so $s_\ell(a) + s_\ell(b) \leq s_\ell(a+b)$. Hence $\mathcal{S} = \{f \in L[[X]] :\ \ell^{s_\ell(j)}[X^j]f \in \mathcal{O}_L \text{ for all } j\}$ is a subring of $L[[X]]$ (for $[X^j](fg) = \sum_{a+b=j} f_a g_b$, $\ell^{s_\ell(j)}f_a g_b = \ell^{s_\ell(j)-s_\ell(a)-s_\ell(b)}(\ell^{s_\ell(a)}f_a)(\ell^{s_\ell(b)}g_b)$), closed under X-adically convergent sums. As $I - h \in X\,M_r(\mathcal{S})$, the inverse $m = h^{-1} = \sum_{p\geq 0}(I-h)^p$ converges X-adically and lies in $M_r(\mathcal{S})$; its entries are Δ-invariant (those of h are, and γ_δ is a ring automorphism). Thus $e'_m = \sum_k m_{mk}H'_k$.

Step 2: π_0-expansions. Let $f \in \mathcal{S}$ be Δ-invariant and $K \geq 1$. If $f' \in XL[[X]]$ is Δ-invariant and $f' \neq 0$, its lowest term aX^j becomes $a\delta^j X^j$ under γ_δ ($\gamma_\delta(X) = \delta X + O(X^2)$), so $(\ell-1) \mid j$ and $j \geq \ell - 1$; as $\pi_0 = X^{\ell-1}v$ with v a unit of $\mathbb{Z}_\ell[[X]]$ and $v(0) = 1/(\ell-2)!$ ((Rr1)), $f'/\pi_0 \in L[[X]]$, and it is Δ-invariant (π_0 is). Recursively ($f_0 = f$, $b_j = f_j(0)$, $f_{j+1} = (f_j - b_j)/\pi_0$),

$$f = \sum_{j<K} b_j\pi_0^j + \pi_0^K f_K, \qquad b_j \in L,\ f_K \in L[[X]]\ \Delta\text{-invariant}.$$

Comparing coefficients of $X^{(\ell-1)j}$ in $f = \sum_{j'<j} b_{j'}\pi_0^{j'} + \pi_0^j f_j$ gives

$$b_j = v(0)^{-j}\Big([X^{(\ell-1)j}]f - \sum_{j'<j} b_{j'}[X^{(\ell-1)j}]\pi_0^{j'}\Big),$$

with $[X^{(\ell-1)j}]\pi_0^{j'} \in \mathbb{Z}_\ell$ and $v(0) \in \mathbb{Z}_\ell^\times$. By induction on j and monotonicity of s_ℓ, $\ell^{s_\ell((\ell-1)j)}b_{j'} \in \mathcal{O}_L$ for $j' \leq j$. Finally $s_\ell((\ell-1)j) = j + v_\ell(j!) \leq j + (j-1)/(\ell-1) \leq e(j)$ for $j \geq 1$ (Legendre), and both are 0 for $j = 0$; so $\ell^{e(j)}b_j \in \mathcal{O}_L$.

Step 3: the matrix Z. By Lemma C.63 choose $\alpha_j, \beta_j \in \mathcal{R}$ with $\ell^\sigma\varphi^2(\pi_0)^j = \ell^{e(j)}\alpha_j + \pi_0\varsigma^h\beta_j$ ($j \geq 0$). Let $K_0 = \lceil h/(\ell-1)\rceil \geq 1$, expand each m_{mk} by Step 2 with $K = K_0$: $m_{mk} =$

$\sum_{j<K_0} b_{mk,j}\pi_0^j + \pi_0^{K_0} f_{mk}$, and put

$$Z_{mk} = \sum_{j<K_0} (\ell^{e(j)} b_{mk,j})\alpha_j \in \mathcal{O}_L[[X]] \cong e_i \mathbf{A}_{F,L},$$

Δ-invariant since the α_j are.

Step 4: level 0. The map $\mathrm{ev}^{(1)}$ is a ring homomorphism $E[[X]] \to B^+_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$: it is $\varphi \circ \iota_\Lambda$ on coefficients followed by the substitution $X \mapsto \varphi(\mu)$, and $\theta(\varphi(\mu)) = 0$, so the substitution is continuous from the X-adic to the t-adic topology (ℓ is invertible in B^+_{dR}). On $\mathbf{A}_{F,L}$ it equals $\varphi \circ (\iota \otimes \mathrm{id}) = \lambda_0 \circ \varphi^2$ (continuous ring maps agreeing on Λ and on X, ι being φ-equivariant), and for $n \in \mathbf{N}_{i-2}$, (Ex2) gives $\Lambda_0(\varphi^2(n)) = \varphi(\iota_T(n)) = G^{(1)}(n)$ (expand n in a frame). By the definition of $G^{(1)}$ through coordinates, $G^{(1)}(fW) = \mathrm{ev}^{(1)}(f)G^{(1)}(W)$ for $f \in E[[X]]$, $W \in e_{i-2}\mathbf{N}_E$, and by Lemma 23.13 (1) with $q = 1$, $G^{(1)}(H'_k) = \varphi^{-2}(\mathrm{Ev}(H'_k)) = D_k$ ($\mathrm{Cv}(e'_k) = \mathrm{Ev}(H'_k)$ by Definition C.58). Hence, by Step 1,

$$\Lambda_0(\varphi^2(e'_m)) = G^{(1)}(e'_m) = \sum_k \mathrm{ev}^{(1)}(m_{mk})\, D_k.$$

By Steps 2 and 3, with $\mathrm{ev}^{(1)}(\pi_0^j) = \lambda_0(\varphi^2(\pi_0)^j)$,

$$\ell^\sigma \mathrm{ev}^{(1)}(m_{mk}) - \lambda_0(Z_{mk}) = \lambda_0(\varsigma)^h\, \lambda_0(\pi_0) \sum_{j<K_0} b_{mk,j}\lambda_0(\beta_j) + \ell^\sigma\, \mathrm{ev}^{(1)}(\pi_0)^{K_0}\, \mathrm{ev}^{(1)}(f_{mk}).$$

By (Lp1) for arc level data with cut i, $\lambda_0(Q) \in tK_{(0)}[[t]]$ and $\lambda_0(e_i\mathbf{A}_{F,L}) \subseteq K_{(0)}[[t]] \subseteq B^+_{\mathrm{dR}} \otimes L$; with $\varsigma = Qw$, w a unit (Lemma 28.15 (1)), the first term lies in $t^h(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L)$ ($b_{mk,j} \in L$). As $\pi_0 = X^{\ell-1}v$ and $\mathrm{ev}^{(1)}(X) = \varphi(\mu) \in \ker\theta = tB^+_{\mathrm{dR}}$, $\mathrm{ev}^{(1)}(\pi_0) \in t^{\ell-1}(B^+_{\mathrm{dR}} \otimes \mathcal{O}_L)$, so the second term lies in $t^{(\ell-1)K_0}(B^+_{\mathrm{dR}} \otimes \mathcal{O}_L) \subseteq t^h(B^+_{\mathrm{dR}} \otimes L)$. Since $\mathrm{Cv}(e'_k) \in \epsilon_{i+1}D$ (Lemma C.64 (Cv1)), $D_k \in \epsilon_{i-1}D$, and multiplying by D_k,

$$\ell^\sigma \Lambda_0(\varphi^2(e'_m)) - \sum_k \lambda_0(Z_{mk})D_k = \sum_k (\ell^\sigma \mathrm{ev}^{(1)}(m_{mk}) - \lambda_0(Z_{mk}))D_k \in t^h\Lambda_D.$$

□

Lemma C.63. *Let ℓ be an odd prime, $\mathcal{R} = \mathbb{Z}_\ell[[X]]^\Delta$ the ring of Δ-invariant elements of $\mathbb{Z}_\ell[[X]]$, $\varsigma = \pi_0 + \ell$, let $h \geq 1$ be an integer and*

$$\sigma = \Big\lceil \frac{h}{(\ell-1)^2} \Big\rceil + 1, \qquad e(y) = \Big\lceil \frac{y\,\ell}{\ell-1} \Big\rceil \quad (y \geq 0).$$

Then $\varphi^2(\pi_0) \in \mathcal{R}$ and, for every integer $y \geq 0$,

$$\ell^\sigma \varphi^2(\pi_0)^y \in \ell^{\,e(y)}\mathcal{R} + \pi_0\varsigma^h\mathcal{R}.$$

Proof. **Step 1: the ring.** The map φ commutes with every γ_δ on $\mathbb{Z}_\ell[[X]]$ (both are ring endomorphisms, and $\varphi\gamma_\delta(X) = (1+X)^{\ell\delta} - 1 = \gamma_\delta\varphi(X)$), so $\varphi(\mathcal{R}) \subseteq \mathcal{R}$; $\pi_0, \varsigma \in \mathcal{R}$ (Lemma 28.15 (1)). If $f \in \mathbb{Z}_\ell[[X]]$ and $gf \in \mathcal{R}$ for some non-zero $g \in \mathcal{R}$, then $f \in \mathcal{R}$ ($\mathbb{Z}_\ell[[X]]$ is a domain); in particular units of $\mathbb{Z}_\ell[[X]]$ lying in $\mathcal{R}$ have inverses in $\mathcal{R}$.

Step 2: $\varphi(\pi_0) = U\pi_0\varsigma^{\ell-1}$ and $\varphi(\varsigma) = \varsigma^\ell + \ell a_1$ with $U \in \mathcal{R}^\times$, $a_1 \in \mathcal{R}$. By Lemma 28.15 (1), $\pi_0 = X^{\ell-1}v$ and $\varsigma = Qw_0$ with units v, w_0; as $\varphi(X) = XQ$, $\varphi(\pi_0) = X^{\ell-1}Q^{\ell-1}\varphi(v) = \pi_0\varsigma^{\ell-1}U$ with $U = v^{-1}w_0^{1-\ell}\varphi(v)$ a unit, which lies in $\mathcal{R}$ by Step 1. Modulo ℓ, $\varphi(f)(X) =$

$f((1+X)^\ell - 1) \equiv f(X^\ell) \equiv f(X)^\ell$ for $f \in \mathbb{Z}_\ell[[X]]$ (coefficients in $\mathbb{F}_\ell$), so $\varphi(\pi_0) = \pi_0^\ell + \ell a_0$ with $a_0 \in \mathbb{Z}_\ell[[X]]$, and $a_0 \in \mathcal{R}$ by Step 1 (as $\ell a_0 \in \mathcal{R}$). From $\pi_0 = \varsigma - \ell$, $\pi_0^\ell = \varsigma^\ell - \ell d_0$ with $d_0 = -\sum_{k\ge 1} \binom{\ell}{k} \ell^{k-1}(-1)^k \varsigma^{\ell-k} \in \mathcal{R}$. Hence $\varphi(\varsigma) = \varphi(\pi_0) + \ell = \varsigma^\ell + \ell a_1$ with $a_1 = a_0 - d_0 + 1 \in \mathcal{R}$. Consequently

$$\varphi^2(\pi_0) = \varphi(U)\varphi(\pi_0)\varphi(\varsigma)^{\ell-1} = U'\pi_0 \varsigma^{\ell-1}\varphi(\varsigma)^{\ell-1}, \qquad U' = \varphi(U)U \in \mathcal{R}^\times,$$

and $\varphi^2(\pi_0) \in \mathcal{R}$.

Step 3: an inequality. Let $y \ge 1$ with $e(y) > \sigma$. Then

$$e(y) - \sigma + \Big\lfloor \frac{h-1}{\ell} \Big\rfloor \le (\ell - 1)y. \qquad (*)$$

Indeed $e(y) < y\ell/(\ell-1) + 1$ and $\sigma \ge h/(\ell-1)^2 + 1$; so $e(y) > \sigma$ gives $y\ell/(\ell-1) > h/(\ell-1)^2$, i.e. $y > h/(\ell(\ell-1))$, and the left side of $(*)$ is $< y\ell/(\ell-1) - h/(\ell-1)^2 + h/\ell$. Now

$$(\ell-1)y - \frac{y\ell}{\ell-1} = y\,\frac{\ell^2 - 3\ell + 1}{\ell - 1} > \frac{h(\ell^2 - 3\ell + 1)}{\ell(\ell-1)^2} = \frac{h}{\ell} - \frac{h}{(\ell-1)^2},$$

using $\ell^2 - 3\ell + 1 > 0$ and $(\ell-1)^2 - \ell = \ell^2 - 3\ell + 1$. So the left side of $(*)$, an integer, is $< (\ell-1)y$.

Step 4: the congruence. If $e(y) \le \sigma$ (this includes $y = 0$), then

$$\ell^\sigma \varphi^2(\pi_0)^y = \ell^{e(y)} \cdot \ell^{\sigma - e(y)} \varphi^2(\pi_0)^y \in \ell^{e(y)}\mathcal{R}.$$

Let $e(y) > \sigma$, so $y \ge 1$, and put $N = (\ell-1)y$. By Step 2,

$$\varphi^2(\pi_0)^y = U'^y \pi_0^y \varsigma^N \sum_{k=0}^{N} \binom{N}{k} \varsigma^{\ell k} \ell^{N-k} a_1^{N-k}.$$

A term with $N + \ell k \ge h$ lies in $\pi_0 \varsigma^h \mathcal{R}$ ($y \ge 1$). A term with $N + \ell k \le h - 1$ has $k \le (h-1)/\ell$, so $k \le \lfloor (h-1)/\ell \rfloor$ and, by $(*)$, $N - k \ge e(y) - \sigma$: after multiplication by ℓ^σ it lies in $\ell^{\sigma + N - k}\mathcal{R} \subseteq \ell^{e(y)}\mathcal{R}$. Summing, $\ell^\sigma \varphi^2(\pi_0)^y \in \ell^{e(y)}\mathcal{R} + \pi_0 \varsigma^h \mathcal{R}$. □

Lemma C.64. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ and a pair (V, T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $d = \dim_L V$, $D = D_{\mathrm{cris}}(V)$, and let $\varphi = \varphi \otimes 1$ on $B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T$; an element $\lambda \in \mathcal{O}_L$ acts on $B_{\mathrm{cris}} \otimes_{\mathbb{Z}_\ell} T$ through T. Then:*

(Cv1) $\mathrm{Cv}(\mathbf{N}) \subseteq D$, Cv *is additive, and* $\mathrm{Cv}(cx) = \varphi^3(\iota_\Lambda(c))\,\mathrm{Cv}(x)$ *for $c \in \Lambda$, $x \in \mathbf{N}$; in particular* Cv *is $\mathcal{O}_L$-linear and* $\mathrm{Cv}(\mathbf{N}_a) \subseteq \epsilon_{a+3} D$.

(Cv2) $\mathrm{Cv}(fx) = \varphi^3(\iota_\Lambda(f(0)))\,\mathrm{Cv}(x)$ *for $f \in \mathbf{A}_{F,L}$ with constant term $f(0) \in \Lambda$ and $x \in \mathbf{N}$; in particular* $\mathrm{Cv}(X\mathbf{N}) = 0$.

(Cv3) *For $a \in \mathbb{Z}/n$ and an $e_a\mathbf{A}_{F,L}$-basis $(n_{a,i})_{i \le d}$ of $\mathbf{N}_a$, the vectors $\mathrm{Cv}(n_{a,i})$ form an L-basis of $\epsilon_{a+3}D$, and $\mathrm{Cv}(\mathbf{N}_a) = \bigoplus_{i \le d} \mathcal{O}_L\,\mathrm{Cv}(n_{a,i})$; so $\mathrm{Cv}(\mathbf{N}_a)$ is an $\mathcal{O}_L$-lattice in $\epsilon_{a+3}D$.*

(Cv4) *If $x \in \mathbf{N}$, $\kappa \in \mathbf{A}_{F,L}$ and $\kappa\,\varphi_{\mathbf{N}}(x) \in \mathbf{N}$, then $\mathrm{Cv}(\kappa\,\varphi_{\mathbf{N}}(x)) = \varphi^3(\iota_\Lambda(\kappa(0)))\,\varphi(\mathrm{Cv}(x))$; in particular $\mathrm{Cv}(\varphi_{\mathbf{N}}(x)) = \varphi(\mathrm{Cv}(x))$ if $\varphi_{\mathbf{N}}(x) \in \mathbf{N}$. More generally, if $x_1, \dots, x_q \in \mathbf{N}$ and $\kappa_1, \dots, \kappa_q \in \mathbf{A}_{F,L}$ with $\sum_j \kappa_j \varphi_{\mathbf{N}}(x_j) \in \mathbf{N}$, then*

$$\mathrm{Cv}\Big(\sum_j \kappa_j \varphi_{\mathbf{N}}(x_j)\Big) = \sum_j \varphi^3(\iota_\Lambda(\kappa_j(0)))\,\varphi(\mathrm{Cv}(x_j)).$$

(Cv5) *For a pair (V',T') and a G_F-equivariant $\mathcal{O}_L$-linear map $f\colon T\to T'$, $\mathrm{Cv}_{T'}(\mathbf{N}(f)(x)) = (1\otimes f)(\mathrm{Cv}_T(x))$ for $x\in\mathbf{N}$.*

Proof. For $x\in\mathbf{N}$ write H_x for the horizontal section through x ((Hf2)).

Preliminaries on H_x. (i) $H_{x+y}=H_x+H_y$ and $H_{cx}=cH_x$ for $c\in\Lambda$: the right-hand sides are fixed by every γ_u (which fixes Λ) and lie in $x+y+X\mathbf{N}_E$, resp. $cx+X\mathbf{N}_E$; apply the uniqueness in (Hf2). (ii) $H_{Xy}=0$ for $y\in\mathbf{N}$, since 0 is γ_u-invariant and lies in $Xy+X\mathbf{N}_E$. (iii) $H_x\in\mathbf{N}_R$: by (Hf3) its coordinates in a basis of $\mathbf{N}$ satisfy $\ell^{s_\ell(k)}a_k\in\Lambda$, and $s_\ell(k)\le k\ell/(\ell-1)^2\le 2k$. (iv) From the defining formula (Ev3) and the multiplicativity of e (Ev2), $\mathrm{Ev}(gW)=e(g)\mathrm{Ev}(W)$ for $g\in R$, $W\in\mathbf{N}_R$, and $e(c)=\varphi^3(\iota_\Lambda(c))$ for $c\in\Lambda\subseteq\mathbf{A}_{F,L}$ (Ev2). (v) $\varphi^3(\iota_\Lambda(e_a))=\iota_\Lambda(\varphi^3(e_a))=\epsilon_{a+3}$, as ι is φ-equivariant (Lemma 23.8 (4)) and $\varphi(e_b)=e_{b+1}$.

(Cv1), (Cv2). Additivity and the formula for $c\in\Lambda$ follow from (i) and (iv); for $\lambda\in\mathcal{O}_L$, $\varphi^3(\iota_\Lambda(1\otimes\lambda))=1\otimes\lambda$, since $\iota_\Lambda=\iota|_{\mathcal{O}_F}\otimes\mathrm{id}$ and φ acts on the first factor. For $\sigma\in G_F$, (Ev3) and the invariance of H_x give $\sigma(\mathrm{Cv}(x))=\mathrm{Ev}(\gamma_{\chi_{\mathrm{cyc}}(\sigma)}H_x)=\mathrm{Cv}(x)$, so $\mathrm{Cv}(x)\in(B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)^{G_F}=D$. For $x\in\mathbf{N}_a$, $x=e_ax$ and (v) give $\mathrm{Cv}(x)=\epsilon_{a+3}\mathrm{Cv}(x)$. For $f\in\mathbf{A}_{F,L}$ write $f=f(0)+Xg$ with $g\in\mathbf{A}_{F,L}$; by (i), (ii), $H_{fx}=f(0)H_x+H_{X(gx)}=f(0)H_x$, and (iv) gives (Cv2).

(Cv3). Let $x=\sum_i f_in_{a,i}$ with $f_i\in e_a\mathbf{A}_{F,L}$. By (Cv1) and (Cv2),

$$\mathrm{Cv}(x)=\sum_i\varphi^3(\iota_\Lambda(f_i(0)))\,\mathrm{Cv}(n_{a,i}).$$

Here $f_i(0)\in e_a\Lambda$, and $e_a\Lambda=e_a(1\otimes\mathcal{O}_L)$ (under $\Lambda\cong\prod_b\mathcal{O}_L$ of Definition 23.2, $e_a(y\otimes1)=e_a(1\otimes\tau_a(y))$); so $\varphi^3(\iota_\Lambda(f_i(0)))=\epsilon_{a+3}(1\otimes\lambda_i)$ with $\lambda_i\in\mathcal{O}_L$ by (v), every $\lambda_i\in\mathcal{O}_L$ occurring (take $f_i=e_a(1\otimes\lambda_i)$). Hence $\mathrm{Cv}(\mathbf{N}_a)=\sum_i\mathcal{O}_L\,\mathrm{Cv}(n_{a,i})$. By definition $\mathrm{Cv}(n_{a,i})=\mathrm{Ev}(H_{a,i})$ with $H_{a,i}$ the horizontal section through $n_{a,i}$, and by Lemma 23.10 (2) these form a basis of $\epsilon_{a+3}D$ over $\epsilon_{a+3}(F\otimes_{\mathbb{Q}_\ell}L)\cong L$, the isomorphism being $\epsilon_{a+3}(1\otimes\lambda)\leftrightarrow\lambda$. So the sum is direct and spans $\epsilon_{a+3}D$ over L.

(Cv4). Since $\kappa\varphi_{\mathbf{N}}(e_cx)=e_{c+1}\kappa\varphi_{\mathbf{N}}(x)\in\mathbf{N}$ and both sides are additive in x, we may assume $x\in\mathbf{N}_c$. Fix bases (n_k) of $\mathbf{N}_c$ and (n'_l) of $\mathbf{N}_{c+1}$, with horizontal sections H_k, H'_l and $d_k=\mathrm{Ev}(H_k)$, $d'_l=\mathrm{Ev}(H'_l)$; write $x=\sum_k f_kn_k$ and $\kappa\varphi_{\mathbf{N}}(x)=\sum_l g_ln'_l$ with $f_k\in e_c\mathbf{A}_{F,L}$, $g_l\in e_{c+1}\mathbf{A}_{F,L}$. By (i), (ii), $H_x=\sum_k f_k(0)H_k$ and $H_{\kappa\varphi x}=\sum_l g_l(0)H'_l$.

$H_{\kappa\varphi x}=\kappa(0)\varphi(H_x)$. Extend φ semilinearly to $\mathbf{N}_E$ (Q is a unit of $E[[X]]$, as $Q(0)=\ell$). The γ_u commute with φ on $\mathbf{N}_E$ ((Wm3), and $\varphi(g)\circ h_u=\varphi(g\circ h_u)$ for $g\in E[[X]]$, both being ring maps that agree on E and on X), so $\varphi(H_x)$ is γ_u-invariant; and $H_x-x\in X\mathbf{N}_E$ gives $\varphi(H_x)-\varphi_{\mathbf{N}}(x)\in\varphi(X)\mathbf{N}_E\subseteq X\mathbf{N}_E$. As $\kappa-\kappa(0)\in X\mathbf{A}_{F,L}$, also $\kappa(0)\varphi(H_x)-\kappa\varphi_{\mathbf{N}}(x)\in X\mathbf{N}_E$, and $\kappa(0)\varphi(H_x)$ is γ_u-invariant (γ_u fixes Λ). By uniqueness in (Hf2), $\kappa(0)\varphi(H_x)=H_{\kappa\varphi x}$.

$G^{(3)}(\varphi W)=G^{(4)}(W)$ *for* $W\in e_c\mathbf{N}_E$. The map $\mathrm{ev}^{(q)}$ is the continuous ring homomorphism $E[[X]]\to B^+_{\mathrm{dR}}\otimes\mathcal{O}_L$ that is $\varphi^q\circ\iota_\Lambda$ on E and sends X to $\varphi^q(\mu)$; on $\mathbf{A}_{F,L}$ it equals $\varphi^q\circ\iota_L$ (the tails of both series beyond degree b lie in $\varphi^q(\mu)^b(A_{\mathrm{inf}}\otimes\mathcal{O}_L)$, and $\varphi^q(\mu)\in\ker\theta$ because $\theta(\varphi^q(\mu))=\theta([\varepsilon^{\ell^q}])-1=0$), hence also on $\mathbf{A}_{F,L}[1/Q]$, Q being a unit of $E[[X]]$. As $\iota_L(\varphi X)=\varphi(\mu)$ and $\iota_\Lambda\varphi=\varphi\iota_\Lambda$, the homomorphisms $\mathrm{ev}^{(3)}\circ\varphi$ and $\mathrm{ev}^{(4)}$ agree on E and on X, so $\mathrm{ev}^{(3)}\circ\varphi=\mathrm{ev}^{(4)}$. By (Wm2), $\varphi_{\mathbf{N}}(n_k)=\sum_l A_{kl}n'_l$ with $A_{kl}\in e_{c+1}\mathbf{A}_{F,L}[1/Q]$, and by (Ex2) (extended to $\mathbf{N}[1/Q]$) $\varphi(\iota_T(n_k))=\iota_T(\varphi_{\mathbf{N}}n_k)=\sum_l\iota_L(A_{kl})\iota_T(n'_l)$. For $W=\sum_k c_kn_k$,

$$\begin{aligned}G^{(3)}(\varphi W)&=\sum_l\mathrm{ev}^{(3)}\Big(\sum_k\varphi(c_k)A_{kl}\Big)\varphi^3(\iota_Tn'_l)=\sum_k\mathrm{ev}^{(4)}(c_k)\,\varphi^3\Big(\sum_l\iota_L(A_{kl})\iota_T(n'_l)\Big)\\&=\sum_k\mathrm{ev}^{(4)}(c_k)\varphi^4(\iota_Tn_k)=G^{(4)}(W).\end{aligned}$$

Conclusion. $G^{(q)}(gW) = \mathrm{ev}^{(q)}(g)G^{(q)}(W)$ for $g \in E[[X]]$ (from the definition, $\mathrm{ev}^{(q)}$ being multiplicative), and $\mathrm{ev}^{(q)}(c) = \varphi^q(\iota_\Lambda(c))$ for $c \in \Lambda$. By Lemma 23.13 (1), $G^{(3)}(H'_l) = d'_l$ and $G^{(4)}(H_k) = \varphi(d_k)$. Hence, in $B_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} T$, using (Cv3) at $c+1$ and at c and the φ-semilinearity of φ on $B_{\mathrm{cris}} \otimes T$,

$$\begin{aligned}\mathrm{Cv}(\kappa\varphi_{\mathbf{N}}x) &= \sum_l \varphi^3(\iota_\Lambda(g_l(0)))d'_l = G^{(3)}(H_{\kappa\varphi x}) = \varphi^3(\iota_\Lambda(\kappa(0)))\, G^{(3)}(\varphi H_x)\\ &= \varphi^3(\iota_\Lambda(\kappa(0)))\, G^{(4)}(H_x) = \varphi^3(\iota_\Lambda(\kappa(0)))\sum_k \varphi^4(\iota_\Lambda(f_k(0)))\varphi(d_k)\\ &= \varphi^3(\iota_\Lambda(\kappa(0)))\,\varphi(\mathrm{Cv}(x)).\end{aligned}$$

Both ends lie in $D \subseteq B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V$, and $B_{\mathrm{cris}} \to B_{\mathrm{dR}}$ is injective; so (Cv4) holds for one term. *Sums.* Let $s = \sum_j \kappa_j\varphi_{\mathbf{N}}(x_j) \in \mathbf{N}$. Since $e_{c+1}s = \sum_j \kappa_j\varphi_{\mathbf{N}}(e_c x_j) \in \mathbf{N}$ and both sides are additive over the sites, we may assume all $x_j \in \mathbf{N}_c$. As above, $\sum_j \kappa_j(0)\varphi(H_{x_j})$ is fixed by every γ_u and congruent to s modulo $X\mathbf{N}_E$, so it equals H_s; writing $s = \sum_l g_l n'_l$, $\mathrm{Cv}(s) = \sum_l \varphi^3(\iota_\Lambda(g_l(0)))d'_l = G^{(3)}(H_s) = \sum_j \varphi^3(\iota_\Lambda(\kappa_j(0)))G^{(4)}(H_{x_j}) = \sum_j \varphi^3(\iota_\Lambda(\kappa_j(0)))\varphi(\mathrm{Cv}(x_j))$, by the identities established above.

(Cv5). $\mathbf{N}(f)$ is $\mathbf{A}_{F,L}$-linear and commutes with the γ_u (Ex3); its extension $\mathbf{N}(f)\otimes\mathrm{id}\colon \mathbf{N}_E \to \mathbf{N}(T')_E$ commutes with the γ_u of Lemma 23.9 and maps $X\mathbf{N}_E$ into $X\mathbf{N}(T')_E$ and $\mathbf{N}_R$ into $\mathbf{N}(T')_R$. So $\mathbf{N}(f)(H_x)$ is γ_u-invariant in $\mathbf{N}(f)(x) + X\mathbf{N}(T')_E$, i.e. equals $H_{\mathbf{N}(f)x}$. For $g \in R$, $y \in \mathbf{N}$: $\mathrm{Ev}(g \otimes \mathbf{N}(f)y) = e(g)\varphi^3\rho(\iota_{T'}\mathbf{N}(f)y) = e(g)\varphi^3\rho((1\otimes f)\iota_T y) = (1\otimes f)\big(e(g)\varphi^3\rho(\iota_T y)\big)$, since $1\otimes f$ is $B_{\mathrm{cris}}\otimes\mathcal{O}_L$-linear and commutes with $\varphi^3\otimes 1$ and $\rho\otimes 1$. By additivity, $\mathrm{Cv}_{T'}(\mathbf{N}(f)x) = \mathrm{Ev}(\mathbf{N}(f)H_x) = (1\otimes f)\mathrm{Ev}(H_x)$. □

Proposition C.65. *Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, and let $c \in \mathbb{Z}/n$ with $\epsilon_c = -1$. Let $\mathbf{N}_c^\Delta$ be the set of Δ-invariant elements of $\mathbf{N}(T_2)_c$, and Y_c the $\mathcal{O}_L$-submodule of $e_c\mathbf{N}(T_2)[1/Q]$ generated by the elements $(\pi_0+\ell)^{s_c+S}g\,\varphi(x)$ with $g \in \mathbf{A}_{F,L}$ and $x \in \mathbf{N}(T_2)_{c-1}$ both Δ-invariant. Then $Y_c \subseteq \mathbf{N}_c^\Delta$, and there is a set $\Sigma \subseteq \mathbf{N}_c^\Delta$ with at most m elements such that*

$$\mathrm{nl}\Big(\mathbf{N}_c^\Delta \Big/ \big(\pi_0\mathbf{N}_c^\Delta + Y_c + \textstyle\sum_{y\in\Sigma}\mathcal{O}_L y\big)\Big) \le d_2 S + 2m\Big(\frac{H'+1}{\ell-1}+1\Big) = \lambda.$$

Proof. Write $M = s_c + S$, $r = d_2$, $\varsigma = \pi_0 + \ell = Qw_0$ (w_0 a unit of $\mathbb{Z}_\ell[[X]]$, Lemma 28.15 (1); ς is Δ-invariant and $w_0(0) = 1$ since $\varsigma(0) = \ell = Q(0)$), and $R = e_c\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ with its Δ-invariant elements R^Δ.

Step 0: jumps and window. By Lemma 24.2 (1) and (Ow1) ($\epsilon_c = -1$), every Hodge jump of V_2 at τ_c lies in $[-M, -s_c] \cup [-\eta, \eta]$, two disjoint intervals as $s_c > \eta$; by (Ow2) the jumps in $[-\eta, \eta]$, counted with multiplicity, number $m' \le m$. By (Ex1) with a window having $M_c = M$, (Wm2) gives $Q^M\varphi(\mathbf{N}(T_2)_{c-1}) \subseteq \mathbf{N}(T_2)_c$, hence $\varsigma^M g\varphi(x) \in \mathbf{N}(T_2)_c$ for $g \in \mathbf{A}_{F,L}$, $x \in \mathbf{N}(T_2)_{c-1}$; it is Δ-invariant when g and x are, because φ commutes with the γ_δ (Wm3). So $Y_c \subseteq \mathbf{N}_c^\Delta$.

Step 1: reduction modulo π_0. By Lemma 24.15, $\mathbf{N}(T_2)_c$ has a Δ-invariant R-basis $(e_l)_{l\le r}$; by uniqueness of coordinates, $\mathbf{N}_c^\Delta = \bigoplus_l R^\Delta e_l$. Let $\mathrm{red}\colon \mathbf{N}_c^\Delta \to \mathcal{O}_L^r$, $\sum_l f_l e_l \mapsto (f_l(0))_l$ (via $R/XR \cong \mathcal{O}_L$). It is surjective (the constants $e_c(1\otimes\lambda)$ are Δ-invariant), and its kernel is $\bigoplus_l (XR)^\Delta e_l = \pi_0\mathbf{N}_c^\Delta$, because $(XR)^\Delta = \pi_0 R^\Delta$: if $f \in XR$ is Δ-invariant with lowest term $a_i X^i$, the lowest term of $\gamma_\delta(f)$ is $a_i\delta^i X^i$, so $(\ell-1) \mid i$ and $f = \pi_0 f_1$ (π_0 is $X^{\ell-1}$ times a unit), f_1 Δ-invariant as π_0 is and R is a domain. Hence, for any Σ, the quotient in the statement is isomorphic to $\mathcal{O}_L^r/\mathrm{red}(Y_c + \sum_{y\in\Sigma}\mathcal{O}_L y)$, and if $C \in M_r(\mathcal{O}_L)$ has its columns in $\mathrm{red}(Y_c + \sum_\Sigma \mathcal{O}_L y)$

and $\det C \neq 0$, then the normalised length is at most $\mathrm{nl}(\mathcal{O}_L^r/C\mathcal{O}_L^r) = v_\ell(\det C)$ (elementary divisors over the discrete valuation ring $\mathcal{O}_L$).

Step 2: the columns. By Lemma C.66 for (V_2, T_2) at c there are a Δ-invariant basis $(e'_k)_{k\le r}$ of $\mathbf{N}(T_2)_{c-1}$ and integers j_k with $\varphi^{-3}(\mathrm{Cv}(e'_k)) \in \mathrm{Fil}^{j_k} D_{\mathrm{cris}}(V_2)$, each Hodge jump u at τ_c occurring as j_k exactly with its multiplicity. Call k *small* if $|j_k| \le \eta$ (there are m' of them) and *big* otherwise ($j_k \in [-M, -s_c]$). For big k put $\mathrm{col}_k = \varsigma^M \varphi(e'_k) \in Y_c$. For small k apply Lemma C.67 to (V_2, T_2), c, M (every jump at τ_c is $\ge -M$), $u = j_k$ and $k_0 = (\ell-1)\lceil (M+\eta)/(\ell-1)\rceil \ge M + \eta \ge M + j_k$, $k_0 \ge 1$: with $s = s_\ell(k_0 - 1)$ there is a Δ-invariant $\tilde{x}_k \in \mathbf{N}(T_2)_{c-1}$ with $\tilde{x}_k - \ell^s e'_k \in X\mathbf{N}(T_2)_{c-1}$ and $\mathrm{col}_k = \varsigma^{-j_k}\varphi(\tilde{x}_k) \in \mathbf{N}_c^\Delta$. Let $\Sigma = \{\mathrm{col}_k : \ k \text{ small}\}$, of at most $m' \le m$ elements.

Step 3: the determinant. Let $P \in M_r(R)$ with $\varsigma^M\varphi(e'_k) = \sum_l P_{lk} e_l$. By Lemma C.70 (applied with (e_l), (e'_k) and M), the matrix $P^Q = w_0^{-M} P$ of the $Q^M\varphi(e'_k)$ has $\det P^Q = vQ^w$ with $v \in R^\times$ and $w = \sum_k (M + j_k)$ (the j_k run over the jumps with multiplicity). At $X = 0$: $P(0) = P^Q(0)$ and $\det P(0) = v(0)\ell^w$ with $v(0) \in \mathcal{O}_L^\times$. For small k write $\tilde{x}_k = \sum_m z_{mk} e'_m$, $z_{mk} \in e_{c-1}\mathbf{A}_{F,L}$ with $z_{mk}(0) = \ell^s \delta_{mk} e_{c-1}$. Then $\varsigma^M\varphi(\tilde{x}_k) = \sum_l (\sum_m P_{lm}\varphi(z_{mk}))e_l$, and the coordinates $c_{lk} \in R$ of col_k satisfy $\varsigma^{M+j_k} c_{lk} = \sum_m P_{lm}\varphi(z_{mk})$ ($M + j_k \ge M - \eta > 0$). At $X = 0$, using $\varphi(z_{mk})(0) = \varphi(z_{mk}(0)) = \ell^s \delta_{mk} e_c$: $\ell^{M+j_k} c_{lk}(0) = \ell^s P_{lk}(0)$. Hence the matrix C with columns $\mathrm{red}(\mathrm{col}_k)$ is $C = P(0)\,\mathrm{diag}(d_k)$ with $d_k = 1$ for big k and $d_k = \ell^{\,s-M-j_k}$ for small k, and

$$v_\ell(\det C) = w + \sum_{k \text{ small}} (s - M - j_k) = \sum_{k \text{ big}} (M + j_k) + m's \le (r - m')S + m's,$$

since $0 \le M + j_k \le S$ for big k. In particular $\det C \neq 0$.

Step 4: the bound. Put $q = \lceil (M+\eta)/(\ell-1)\rceil$, so $k_0 - 1 = (\ell-1)q - 1$ and $J = \lfloor (k_0 - 1)/(\ell-1)\rfloor = q - 1$; by Legendre's formula $s = J + v_\ell(J!) \le J\ell/(\ell-1)$, and $J < (M+\eta)/(\ell-1) \le H'/(\ell-1)$ ($M + \eta = s_c + S + \eta \le H'$). So $s \le H'\ell/(\ell-1)^2 \le 2H'/(\ell-1) \le 2\big((H'+1)/(\ell-1) + 1\big)$. With Steps 1 and 3 and $m' \le m$, $r = d_2$, the normalised length is at most $d_2 S + 2m\big((H'+1)/(\ell-1) + 1\big) = \lambda$. □

Lemma C.66. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V, T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$ of rank r, $D = D_{\mathrm{cris}}(V)$ and $c \in \mathbb{Z}/n$. Then there are a Δ-invariant $e_{c-1}\mathbf{A}_{F,L}$-basis $(e'_k)_{k\le r}$ of $\mathbf{N}_{c-1}$ and integers $j_1, \dots, j_r$ such that*

$$\varphi^{-3}(\mathrm{Cv}(e'_k)) \in \mathrm{Fil}^{j_k} D \qquad (k \le r),$$

and for every integer u the number of k with $j_k = u$ is the multiplicity

$$\dim_L(\mathrm{Fil}^u D_{\mathrm{dR},\tau_c}(V)/\mathrm{Fil}^{u+1} D_{\mathrm{dR},\tau_c}(V))$$

of u as a Hodge jump of V at τ_c.

Proof. **The lattice.** Put $\epsilon = \epsilon_{c-1}$. By (Cv1) and (Cv3), $\mathrm{Cv}(\mathbf{N}_{c-1})$ is an $\mathcal{O}_L$-lattice in $\epsilon_{c+2}D$ (an $\mathcal{O}_L$-submodule, free with an L-basis of $\epsilon_{c+2}D$ as basis), and $\mathrm{Cv}(x) = 0$ for $x \in \mathbf{N}_{c-1}$ only if $x \in X\mathbf{N}_{c-1}$: in a basis (n_k), $\mathrm{Cv}(\sum_k f_k n_k) = \sum_k \epsilon_{c+2}(1 \otimes \lambda_k)\mathrm{Cv}(n_k)$ with $f_k(0) = e_{c-1}(1 \otimes \lambda_k)$, and the $\mathrm{Cv}(n_k)$ are L-independent. The Frobenius φ of D commutes with the action of $\mathcal{O}_L$ (which is through T) and maps $\epsilon_b D$ bijectively onto $\epsilon_{b+1}D$; so $\Lambda = \varphi^{-3}(\mathrm{Cv}(\mathbf{N}_{c-1}))$ is an $\mathcal{O}_L$-lattice in ϵD, and $\varphi^{-3} \circ \mathrm{Cv}$ induces an isomorphism $\mathbf{N}_{c-1}/X\mathbf{N}_{c-1} \cong \Lambda$. As in Definition 23.3, $\epsilon = \epsilon_{c-1}$ is the idempotent of the embedding τ_c: for $y \in \mathcal{O}_F$, $\iota(y) = \varphi(y)$ and $e_{c-1}(y \otimes 1) = e_{c-1}(1 \otimes \tau_{c-1}(y))$, so F acts on ϵD through $\tau_{c-1} \circ \varphi^{-1} = \tau_c$; hence $\epsilon D = D_{\mathrm{dR},\tau_c}(V)$ (V is crystalline, $D_{\mathrm{cris}} = D_{\mathrm{dR}}$) with the filtration $\epsilon\mathrm{Fil}^u D$.

An adapted basis of Λ. For $u \in \mathbb{Z}$ let $\Lambda_u = \Lambda \cap \epsilon \mathrm{Fil}^u D$. Each Λ_u is saturated in Λ (Λ/Λ_u embeds in $\epsilon D/\epsilon\mathrm{Fil}^u D$, hence is torsion free), so over the discrete valuation ring $\mathcal{O}_L$ it is a direct summand of Λ and of every $\Lambda_{u'}$, $u' \le u$, containing it; its rank is $\dim_L \epsilon\mathrm{Fil}^u D$ (every $v \in \epsilon\mathrm{Fil}^u D$ has $\ell^N v \in \Lambda$). The filtration is finite: $\Lambda_u = \Lambda$ for $u \ll 0$ and $\Lambda_u = 0$ for $u \gg 0$. Choosing, for u from large to small, a complement of Λ_{u+1} in Λ_u and a basis of it, we get a basis $(f_k)_{k \le r}$ of Λ and integers j_k (f_k chosen at step $u = j_k$) with $f_k \in \Lambda_{j_k} \subseteq \epsilon\mathrm{Fil}^{j_k} D$, and the number of k with $j_k = u$ is $\operatorname{rank}\Lambda_u - \operatorname{rank}\Lambda_{u+1} = \dim_L(\epsilon\mathrm{Fil}^u D/\epsilon\mathrm{Fil}^{u+1}D)$, the multiplicity of u as a Hodge jump at τ_c.

Lifting. Choose $e''_k \in \mathbf{N}_{c-1}$ with $\varphi^{-3}(\mathrm{Cv}(e''_k)) = f_k$. Their images in $\mathbf{N}_{c-1}/X\mathbf{N}_{c-1} \cong \Lambda \cong \mathcal{O}_L^r$ form a basis; as $\mathbf{N}_{c-1}$ is free of rank r over the local ring $e_{c-1}\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$ ((Wm1)), Nakayama's lemma shows that (e''_k) generates $\mathbf{N}_{c-1}$, hence is a basis (a surjective endomorphism of a finitely generated module is bijective). Put $e'_k = (\ell-1)^{-1}\sum_{\delta\in\mu_{\ell-1}} \gamma_\delta(e''_k) \in \mathbf{N}_{c-1}$ ($\ell - 1$ is a unit of $\mathbb{Z}_\ell$); it is Δ-invariant since $\gamma_{\delta'}\gamma_\delta = \gamma_{\delta'\delta}$. For $x \in \mathbf{N}$ and $\delta \in \mu_{\ell-1}$, $\gamma_\delta(H_x)$ is fixed by every γ_u (they commute) and lies in $\gamma_\delta(x) + X\mathbf{N}_E$, so $H_{\gamma_\delta x} = \gamma_\delta(H_x)$ and, by (Ev3), $\mathrm{Cv}(\gamma_\delta x) = \sigma(\mathrm{Cv}(x)) = \mathrm{Cv}(x)$ for $\sigma \in G_F$ with $\chi_{\mathrm{cyc}}(\sigma) = \delta$, as $\mathrm{Cv}(x) \in D$ is G_F-invariant. Hence $\varphi^{-3}(\mathrm{Cv}(e'_k)) = f_k \in \mathrm{Fil}^{j_k} D$, and (e'_k) is a basis of $\mathbf{N}_{c-1}$ by the same Nakayama argument. □

Lemma C.67. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $D = D_{\mathrm{cris}}(V)$, $c \in \mathbb{Z}/n$, and let $M \ge 0$, u and $k \ge 1$ be integers such that every Hodge jump of V at τ_c is at least $-M$, $(\ell-1) \mid k$ and $k \ge M + u$. Let $x \in \mathbf{N}_{c-1}$ with $\varphi^{-3}(\mathrm{Cv}(x)) \in \mathrm{Fil}^u D$. Then there is $\tilde{x} \in \mathbf{N}_{c-1}$ with $\tilde{x} - \ell^{s_\ell(k-1)}x \in X\mathbf{N}_{c-1}$ and*

$$(\pi_0 + \ell)^{-u}\,\varphi(\tilde{x}) \in \mathbf{N}_c;$$

if x is Δ-invariant, $\tilde{x}$ can be chosen Δ-invariant, and then $(\pi_0+\ell)^{-u}\varphi(\tilde{x})$ is Δ-invariant.

Proof. Write $\varsigma = \pi_0 + \ell$ and $s = s_\ell(k-1)$. By Lemma 28.15 (1), $\varsigma = Qw_0$ with w_0 a unit of $\mathbb{Z}_\ell[[X]]$, so ς is invertible in $\mathbf{A}_{F,L}[1/Q]$, and ς is Δ-invariant.

Step 1: the truncation. By (Hf3) (applied to H_x, which lies in $e_{c-1}\mathbf{N}_E$ by uniqueness in (Hf2)) there is $x_k \in \mathbf{N}$ with $\ell^s H_x - x_k \in X^k\mathbf{N}_E$; replacing x_k by $e_{c-1}x_k$ we may take $x_k \in \mathbf{N}_{c-1}$. If x is Δ-invariant, put $\tilde{x} = (\ell-1)^{-1}\sum_{\delta\in\mu_{\ell-1}}\gamma_\delta(x_k)$; otherwise $\tilde{x} = x_k$. Since every γ_δ fixes H_x and preserves $X^k\mathbf{N}_E$, in both cases $\ell^s H_x - \tilde{x} \in X^k\mathbf{N}_E$, so by (Hf3) $(\gamma_{u_0}-1)(\tilde{x}) \in X^k\mathbf{N}$ (for the u_0 fixed in Definition 23.4), and $\tilde{x} - \ell^s x \in \mathbf{N} \cap X\mathbf{N}_E = X\mathbf{N}$ (as $H_x - x \in X\mathbf{N}_E$). In the Δ-invariant case $\tilde{x}$ is Δ-invariant ($\gamma_{\delta'}\gamma_\delta = \gamma_{\delta'\delta}$), hence so is $\varsigma^{-u}\varphi(\tilde{x})$ (φ commutes with the γ_δ).

Step 2: level data. Fix arc level data for (V,T) with cut c, length 1 (so $c_0 = c-1$), $H(c) = \max(u,0)$ (and $H = 0$ elsewhere), $\Pi = Q^{H(c)}$, a frame $(n_j)_{j\le r}$ of $\mathbf{N}_{c-1}$, parameters $j = 1$, $M_{\mathrm{t}} = k/(\ell-1)$ in the role of M, $g = 0$, and arbitrary $G, S, \eta, \kappa_0, b_0$. Write $\tilde{x} - \sum_j a_j n_j \in X\mathbf{N}_{c-1}$ with $a \in \mathcal{O}_L^r$ (via $e_{c-1}\mathbf{A}_{F,L}/X \cong \mathcal{O}_L$). The element $w = \Pi^{-1}\varphi(\tilde{x})$ satisfies $\Pi w = \varphi(\tilde{x}) \in P_1(\mathbf{N}_{c-1})$, so $w \in W$, and $(\gamma_{u_0}-1)\tilde{x} \in X^{(\ell-1)M_{\mathrm{t}}}\mathbf{N}_{c-1}$ with $(\ell-1)M_{\mathrm{t}} = k \ge 0 = 3g$. By Lemma C.68 ((Lp6)), $\lambda_0(\Pi)\mathrm{lv}_0(w) - a \in t^k K_{(0)}[[t]]^r$.

Step 3: the level-0 expansion of $g = \varsigma^{-u}\varphi(\tilde{x})$. g lies in W: $\Pi g = Q^{H(c)}\varsigma^{-u}\varphi(\tilde{x})$ equals $w_0^{-u}\varphi(\tilde{x})$ if $u \ge 0$ and $\varsigma^{-u}\varphi(\tilde{x})$ if $u < 0$, an element of $\mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-1}) = P_1(\mathbf{N}_{c-1})$. As $\Lambda_0(fy) = \lambda_0(f)\Lambda_0(y)$, $\mathrm{lv}_0(g) = \lambda_0(\varsigma)^{-u}\lambda_0(\Pi)\mathrm{lv}_0(w)$. By Lemma 23.17 ((Lp1)), $\lambda_0(Q) \in tK_{(0)}[[t]]^\times$ and $\lambda_0(w_0) \in K_{(0)}[[t]]$ with $\lambda_0(w_0)\lambda_0(w_0^{-1}) = 1$, so $\lambda_0(\varsigma) = t\vartheta$ with $\vartheta \in K_{(0)}[[t]]^\times$. Hence

$$\mathrm{lv}_0(g) = t^{-u}\vartheta^{-u}(a+\rho), \qquad \rho \in t^k K_{(0)}[[t]]^r.$$

Step 4: de Rham integrality. The level frame is $D_j^{(0)} = \varphi^{-3}(\mathrm{Ev}(H_{n_j})) = \varphi^{-3}(\mathrm{Cv}(n_j))$. By (Cv1), (Cv2), $\mathrm{Cv}(\tilde{x}) = \sum_j a_j \mathrm{Cv}(n_j)$ (the a_j acting through T, which commutes with φ),

and $\mathrm{Cv}(\tilde{x}) = \ell^s \mathrm{Cv}(x)$; so $\sum_j a_j D_j^{(0)} = \ell^s \varphi^{-3}(\mathrm{Cv}(x)) \in \mathrm{Fil}^u D$, i.e. $a \in \mathrm{Fil}_0(u)$. The coefficient of t^i in $t^{-u}\vartheta^{-u}a$ is a $K_{(0)}$-multiple of a and vanishes for $i < -u$; for $i \geq -u$, $-i \leq u$ and $\mathrm{Fil}_0(u) \subseteq \mathrm{Fil}_0(-i)$ (Fil is decreasing). The coefficient of t^i in $t^{-u}\vartheta^{-u}\rho$ vanishes for $i < k-u$, and for $i \geq k-u \geq M$ we have $\mathrm{Fil}_0(-i) = L^r$: the $D_j^{(0)}$ lie in $\epsilon_0 D = \epsilon_{c-1} D = D_{\mathrm{dR},\tau_c}(V)$ (Definition 23.4: ϵ_0 is the idempotent of τ_c), whose filtration satisfies $\mathrm{Fil}^v = \epsilon_{c-1} D$ for $v \leq -M$, every Hodge jump at τ_c being $\geq -M$. So $\mathrm{lv}_0(g)$ is de Rham integral at 0, and by Lemma 23.5 (2) ((Lp3) with length 1), $g \in \mathbf{N}_c$. □

Lemma C.68. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, (V,T) a pair, $\mathbf{N} = \mathbf{N}(T)$, and fix arc level data for (V,T) (cut c, length* len*, H, frame $\mathbf{n}$ at $c_0 = c-$*len*, parameters j, M, g) with $(\ell-1)M \geq 3g$. Then (Lp6) holds: if $x \in \mathbf{N}_{c_0}$, $(\gamma_{u_0}-1)x \in X^{(\ell-1)M}\mathbf{N}_{c_0}$, $x - \sum_k a_k n_k \in X\mathbf{N}_{c_0}$ with $a \in \mathcal{O}_L^r$, and $w \in W$ with $\Pi w = \varphi^{\mathrm{len}}(x)$, then for every $s <$* len

$$\lambda_s(\Pi)\,\mathrm{lv}_s(w) - a \in t^{(\ell-1)M} K_{(s)}[[t]]^r \subseteq \lambda_s(f')\,K_{(s)}[[t]]^r, \qquad \text{so } \mathrm{lv}_s(w) - \lambda_s(\Pi)^{-1}a \in \mathcal{T}_s.$$

Proof. Put $m = (\ell-1)M$, $K = K_{(s)}$, $q =$ len $- s - 1$, and let H_k be the horizontal sections through the n_k ($E[[X]]$-basis of $e_{c_0}\mathbf{N}_E$, Lemma 23.9 (Hf2)).

Step 1: $Y = x - \sum_k a_k H_k \in X^m\mathbf{N}_E$. $Y \in X\mathbf{N}_E$, since $x - \sum_k a_k n_k \in X\mathbf{N}$ and $H_k - n_k \in X\mathbf{N}_E$; and $(\gamma_{u_0}-1)Y = (\gamma_{u_0}-1)x \in X^m\mathbf{N}_E$ (a_k is constant and H_k is γ-fixed). If $Y = X^i \sum_k y_k H_k$ with $y_k \in E[[X]]$ and $1 \leq i < m$, then, as $\gamma_{u_0}(f) = f \circ h_{u_0}$ on $E[[X]]$ with $h_{u_0}(X) \in u_0 X + X^2\mathbb{Z}_\ell[[X]]$,

$$(\gamma_{u_0}-1)Y \equiv (u_0^i - 1)X^i \sum_k y_k(0) H_k \bmod X^{i+1}\mathbf{N}_E;$$

since $u_0 \in 1 + \ell\mathbb{Z}_\ell$ is not a root of unity (ℓ odd), $u_0^i - 1 \neq 0$, so all $y_k(0) = 0$ and $Y \in X^{i+1}\mathbf{N}_E$. By induction, $Y \in X^m\mathbf{N}_E$: $Y = \sum_k y_k H_k$ with $y_k \in X^m e_{c_0} E[[X]]$.

Step 2: the level. By (Eq3) of Lemma C.69, $\lambda_s(\Pi)\Lambda_s(w) = \Lambda_s(\varphi^{\mathrm{len}}(x)) = G^{(q)}(x)$, and by Lemma 23.13 (1) and the semilinearity of $G^{(q)}$ ($G^{(q)}(gY) = \mathrm{ev}^{(q)}(g)G^{(q)}(Y)$ by its definition, $\mathrm{ev}^{(q)}$ being a ring homomorphism by (Eq1) there),

$$G^{(q)}(x) = \sum_k \mathrm{ev}^{(q)}(a_k) G^{(q)}(H_k) + \sum_k \mathrm{ev}^{(q)}(y_k) G^{(q)}(H_k) = \sum_k (a_k + \mathrm{ev}^{(q)}(y_k)) D_k^{(s)},$$

where, by (Eq3) of Lemma C.69, $\mathrm{ev}^{(q)}(a_k) = \epsilon_s a_k$ (the constant $a_k \in e_{c_0}(1 \otimes \mathcal{O}_L)$) and $\mathrm{ev}^{(q)}(y_k) \in t^m K[[t]]$ ($y_k \in X^m e_{c_0} E[[X]]$). Hence $\lambda_s(\Pi)\mathrm{lv}_s(w) - a \in t^m K[[t]]^r$.

Step 3: the truncation ideal. Since $\varphi^k(X) = X\lambda_k$, $f' = \varphi^{\mathrm{len}-j}(X^m \prod_{s'<j} Q_{s'}^{3g}) = X^m \prod_{s'<\mathrm{len}-j} Q_{s'}^m \prod_{\mathrm{len}-j\leq s'<\mathrm{len}} Q_{s'}^{3g}$. By Lemma 23.17 ((Lp1): $\lambda_s(X)$, $\lambda_s(Q_{s'})$ units for $s' \neq s$, $\lambda_s(Q_s) \in tK[[t]]^\times$), $\lambda_s(f') \in t^{e_s}K[[t]]^\times$ with $e_s = m$ if $s <$ len $- j$ and $e_s = 3g$ otherwise; in both cases $e_s \leq m$. So $t^m K[[t]]^r \subseteq \lambda_s(f')K[[t]]^r$, which is the claim. □

Lemma C.69. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $B = B_{\mathrm{dR}}^+$, $\iota_L = \iota \otimes \mathrm{id}\colon \mathbf{A}_{F,L} \to A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$, and $q \geq 0$ an integer.*

(Eq1) *$\mathrm{ev}^{(q)}\colon E[[X]] \to B \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ is a ring homomorphism, $\mathrm{ev}^{(q)}(X^m f) = \varphi^q(\mu)^m \mathrm{ev}^{(q)}(f)$ for $m \geq 0$, and $\mathrm{ev}^{(q)}(g) = (\varphi^q \otimes 1)(\iota_L(g))$ for $g \in \mathbf{A}_{F,L}[1/\ell]$.*

(Eq2) *For $c \in \mathbb{Z}/n$ and $x \in \mathbf{N}_c$, $G^{(q)}(x) = (\varphi^q \otimes 1)(\iota_T(x))$, $G^{(q)}$ formed with a frame at c.*

(Eq3) *Fix arc level data for (V,T) (cut c, length len, $c_0 = c-\mathrm{len}$), let $s < \mathrm{len}$ and $q = \mathrm{len}-s-1$. Then $\Lambda_s(\varphi^{\mathrm{len}}(x)) = G^{(q)}(x)$ for $x \in \mathbf{N}_{c_0}$, and $\lambda_s(\varphi^{\mathrm{len}}(a)) = \mathrm{ev}^{(q)}(a)$ for $a \in e_{c_0}\mathbf{A}_{F,L}[1/\ell]$. For $f = \sum_i b_i X^i \in e_{c_0}E[[X]]$ the elements $\varphi^q(\iota_\Lambda(b_i))$ lie in $\epsilon_s L \subseteq K_{(s)}$ and*

$$\mathrm{ev}^{(q)}(f) = \sum_{i\geq 0} \varphi^q(\iota_\Lambda(b_i))(\exp(\ell^q t)-1)^i \ \in K_{(s)}[[t]];$$

if moreover $f \in X^m E[[X]]$, then $\mathrm{ev}^{(q)}(f) \in t^m K_{(s)}[[t]]$.

Proof. **(Eq1).** The map $a \mapsto \varphi^q(\iota_\Lambda(a))$ is a ring homomorphism $E \to (A_{\mathrm{inf}}\otimes\mathcal{O}_L)[1/\ell] \subseteq B\otimes\mathcal{O}_L$ (ι_Λ is the restriction of $\iota\otimes\mathrm{id}$ with ℓ inverted). By Theorem B.40 (Ai1), $\theta(\varphi^q(\mu)) = \theta([\varepsilon^{\ell^q}])-1 = (\varepsilon^{\ell^q})^\sharp - 1 = 0$, so $\varphi^q(\mu)$ lies in the maximal ideal $\ker\theta = tB$ of the complete discrete valuation ring B ((Ai3)); and $B\otimes\mathcal{O}_L$ is free of finite rank over B, hence t-adically complete and separated. So the series defining $\mathrm{ev}^{(q)}$ converges, and $\mathrm{ev}^{(q)}$ is the substitution homomorphism $X \mapsto \varphi^q(\mu)$ over $a \mapsto \varphi^q(\iota_\Lambda(a))$: modulo t^b it agrees, on series and on their products, with the ring homomorphism given by the truncation at degree b, for every b. The identity for $X^m f$ is read off the series. Let $g \in \mathbf{A}_{F,L} = \Lambda[[X]]$ and $b \geq 1$, and write $g = \sum_{i<b} a_i X^i + X^b g_b$ with $a_i \in \Lambda$, $g_b \in \mathbf{A}_{F,L}$. As ι_L is a ring homomorphism equal to ι_Λ on Λ with $\iota_L(X) = \iota(X) = \mu$ (Lemma 23.8),

$$(\varphi^q\otimes 1)(\iota_L(g)) = \sum_{i<b} \varphi^q(\iota_\Lambda(a_i))\varphi^q(\mu)^i + \varphi^q(\mu)^b(\varphi^q\otimes 1)(\iota_L(g_b)) \equiv \mathrm{ev}^{(q)}(g) \bmod t^b(B\otimes\mathcal{O}_L).$$

As b is arbitrary, $\mathrm{ev}^{(q)}(g) = (\varphi^q\otimes 1)(\iota_L(g))$; for $g \in \mathbf{A}_{F,L}[1/\ell]$ multiply by a power of ℓ.

(Eq2). Let $\mathbf{n} = (n_j)$ be a frame at c, an $e_c\mathbf{A}_{F,L}$-basis of $\mathbf{N}_c$, and $x = \sum_j g_j n_j$ with $g_j \in e_c\mathbf{A}_{F,L}$. By (Ex2), $\iota_T(gy) = \iota_L(g)\iota_T(y)$ for $g \in \mathbf{A}_{F,L}$, $y \in \mathbf{N}$ ($\mathbf{A}_{F,L} = \mathbf{A}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$). Hence, by the definition of $G^{(q)}$ and (Eq1),

$$G^{(q)}(x) = \sum_j \mathrm{ev}^{(q)}(g_j)\,(\varphi^q\otimes 1)(\iota_T(n_j)) = (\varphi^q\otimes 1)\Big(\sum_j \iota_L(g_j)\iota_T(n_j)\Big) = (\varphi^q\otimes 1)(\iota_T(x)).$$

(Eq3). By (Lm2) of Lemma 23.6, applied with the site c_0 in place of its c, $e = \mathrm{len}$ and $a = c$ (its Λ_s is ours), $\Lambda_s(\varphi^{\mathrm{len}}(x)) = (\varphi^q\otimes 1)(\iota_T(x))$ for $x \in \mathbf{N}$, which is $G^{(q)}(x)$ for $x \in \mathbf{N}_{c_0}$ by (Eq2). By (Lm1) there, $\lambda_s(\varphi^{\mathrm{len}}(a)) = (\varphi^q\otimes 1)(\iota_L(a))$ for $a \in \mathbf{A}_{F,L}$, hence for $a \in \mathbf{A}_{F,L}[1/\ell]$, and this is $\mathrm{ev}^{(q)}(a)$ by (Eq1). Now let $f = \sum_i b_i X^i \in e_{c_0}E[[X]]$. Since $e_{c_0}E = e_{c_0}(1\otimes L)$ and $\iota_\Lambda(e_{c_0}) = \epsilon_{c_0}$ (Lemma 23.10), $\iota_\Lambda(b_i) \in \epsilon_{c_0}L$; as ι commutes with φ (Lemma 23.8) and $(\varphi\otimes\mathrm{id})(e_b) = e_{b+1}$ ($\tau_{b+1}\circ\varphi = \tau_b$ for the Frobenius numbering), $\varphi^q(\epsilon_{c_0}) = \epsilon_{c_0+q} = \epsilon_{c-s-1} = \epsilon_s$, so $c_i := \varphi^q(\iota_\Lambda(b_i)) \in \epsilon_s L \subseteq K_{(s)}$. In B, $[\varepsilon] = \exp(t)$ ($t = \log[\varepsilon]$), so $\varphi^q(\mu) = [\varepsilon]^{\ell^q} - 1 = \exp(\ell^q t) - 1 \in t\,\mathbb{Q}_\ell[[t]]$. Hence $(\exp(\ell^q t)-1)^i \in t^i\mathbb{Q}_\ell[[t]]$, the series $\sum_i c_i(\exp(\ell^q t)-1)^i$ defines an element of $K_{(s)}[[t]]$ (each coefficient is a finite sum), and it agrees with $\mathrm{ev}^{(q)}(f) \in R_s^+$ modulo $t^b R_s^+$ for every b, both being congruent to $\sum_{i<b} c_i(\exp(\ell^q t)-1)^i$ (the identification of Definition 23.4 maps $t^b K_{(s)}[[t]]$ into $t^b R_s^+$). As R_s^+ is t-adically separated, the two are equal. Finally, for $f = X^m f_1$, $\mathrm{ev}^{(q)}(f) = (\exp(\ell^q t)-1)^m \mathrm{ev}^{(q)}(f_1) \in t^m K_{(s)}[[t]]$ by (Eq1). □

Lemma C.70. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$ of rank $r = \dim_L V$, $a \in \mathbb{Z}/n$, and $M \geq 0$ an integer such that every Hodge jump of V at τ_a is at least $-M$. For $j \in \mathbb{Z}$ let $m_j = \dim_L(\mathrm{Fil}^j D_{\mathrm{dR},\tau_a}(V)/\mathrm{Fil}^{j+1}D_{\mathrm{dR},\tau_a}(V))$ be the multiplicity of j as a Hodge jump at τ_a. Let $(e_k)_{k\leq r}$ be an $e_a\mathbf{A}_{F,L}$-basis of $\mathbf{N}_a$ and $(e'_k)_{k\leq r}$ an $e_{a-1}\mathbf{A}_{F,L}$-basis of $\mathbf{N}_{a-1}$. Then $Q^M\varphi(e'_k) \in \mathbf{N}_a$ for every k, and the matrix $P \in M_r(e_a\mathbf{A}_{F,L})$ with $Q^M\varphi(e'_k) = \sum_m P_{mk}e_m$ satisfies*

$$\det P = v\,Q^w, \qquad v \in (e_a\mathbf{A}_{F,L})^\times, \qquad w = \sum_{j\in\mathbb{Z}}(M+j)\,m_j = rM + \sum_j j\,m_j.$$

Proof. Put $R = e_a\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, a unique factorisation domain (a regular local ring).

Step 1: $\det P$ divides a power of Q. Apply (Ex1) with the window $M_a = M$ and M_b, h_b ($b \in \mathbb{Z}/n$, h_a included) larger than all Hodge jumps. By (Wm2), $Q^M\varphi(\mathbf{N}_{a-1}) \subseteq \mathbf{N}_a$, so $P \in M_r(R)$; and $Q^{h_a}\mathbf{N}_a \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{a-1}) = \sum_k R\,\varphi(e'_k)$ (φ is semilinear), so there is $P' \in M_r(R)$ with $Q^{h_a+M}e_m = \sum_k P'_{km}Q^M\varphi(e'_k)$, i.e. $PP' = Q^{h_a+M}I$, and $\det P \cdot \det P' = Q^{r(h_a+M)}$.

Step 2: the prime factors of Q. L contains a primitive ℓ-th root of unity ζ (it contains $\sigma(F(\mu_\ell))$), and $Q = \Phi_\ell(1+X) = \prod_{k=1}^{\ell-1}\pi_k$ with $\pi_k = X - (\zeta^k - 1)$. Each π_k is prime in R ($R/\pi_k R \cong \mathcal{O}_L$), and π_k, $\pi_{k'}$ are not associate for $k \neq k'$ (their zeros $\zeta^k - 1 \neq \zeta^{k'} - 1$ in the maximal ideal of $\mathcal{O}_L$ differ). By Step 1 and unique factorisation, $\det P = v\prod_k \pi_k^{w_k}$ with $v \in R^\times$ and integers $w_k \geq 0$.

Step 3: the exponents w_k are equal. Let $u \in \mathbb{Z}_\ell^\times$ and $\gamma = \gamma_u$. With $\eta_u = \gamma(X)/X = ((1+X)^u - 1)/X$, a unit of $\mathbb{Z}_\ell[[X]]$, and $\gamma\varphi = \varphi\gamma$ on $\mathbb{Z}_\ell[[X]]$: $X\eta_u\gamma(Q) = \gamma(\varphi X) = \varphi(X\eta_u) = XQ\varphi(\eta_u)$, so $\gamma(Q) = Q\varphi(\eta_u)\eta_u^{-1}$ and $\gamma(Q)/Q$ is a unit. Let $G \in \mathrm{GL}_r(R)$, $G' \in \mathrm{GL}_r(e_{a-1}\mathbf{A}_{F,L})$ be the matrices of γ in the bases (e_m), (e'_k) (γ is bijective, with inverse $\gamma_{u^{-1}}$, by (Wm3)). Computing $\gamma(Q^M\varphi(e'_k))$ once as $\gamma(Q)^M\varphi(\gamma e'_k)$ ((Wm3)) and once from $Q^M\varphi(e'_k) = \sum_m P_{mk}e_m$ gives $G\,\gamma(P) = (\gamma(Q)/Q)^M P\,\varphi(G')$, hence

$$\det G \cdot \gamma(\det P) = (\gamma(Q)/Q)^{Mr}\ \det P \cdot \varphi(\det G'),$$

and $\gamma(\det P)$ and $\det P$ generate the same ideal of R. Now $\gamma(\pi_k) = (1+X)^u - \zeta^k$; let $k' \in \{1,\dots,\ell-1\}$ with $k'u \equiv k \bmod \ell$. Then $\gamma(\pi_k)$ vanishes at $X = \zeta^{k'} - 1$ (as $\zeta^{k'u} = \zeta^k$, u being an ℓ-adic limit of integers $\equiv u \bmod \ell$), so $\gamma(\pi_k) = \pi_{k'}g$ with $g \in R$; comparing constant terms, $-(\zeta^{k'}-1)g(0) = 1 - \zeta^k$, and both $\zeta^{k'} - 1$ and $1 - \zeta^k$ have valuation $1/(\ell-1)$, so $g(0)$ and g are units. Hence $\gamma(\det P) = \gamma(v)\prod_k \pi_{k'(k)}^{w_k} \cdot (\text{unit})$, and unique factorisation gives $w_{k'(k)} = w_k$, i.e. $w_k = w_{ku}$ (indices mod ℓ) for every u. As u runs through $\mathbb{Z}_\ell^\times$, u mod ℓ runs through $\mathbb{F}_\ell^\times$, so all w_k equal one integer w, and $\det P = vQ^w$.

Step 4: the level map at τ_a. Let $\lambda = \varphi^{-1}\circ\iota_L$ on $\mathbf{A}_{F,L}$ and $\Lambda = \varphi^{-1}\circ\iota_T$ on $\mathbf{N}$ (φ is bijective on A_{inf}). Since $\theta(\varphi^{-1}(\mu)) = \zeta_\ell - 1 \neq 0$ for the primitive root $\zeta_\ell = (\varepsilon^{1/\ell})^\sharp$, $\varphi^{-1}(\mu)$ is a unit of B^+_{dR} (Ai3), so λ takes values in $B^+_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L$ and Λ in $B^+_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} T = B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V$; by (Ex2), $\Lambda(fx) = \lambda(f)\Lambda(x)$ and $\Lambda(\varphi x) = \iota_T(x)$ for $f \in \mathbf{A}_{F,L}$, $x \in \mathbf{N}$. Further $\lambda(Q) = \varphi^{-1}(\sum_{k<\ell}[\varepsilon]^k) = \sum_{k<\ell}[\varepsilon^{1/\ell}]^k = \xi_0$, a uniformiser of B^+_{dR} with $\xi_0 B^+_{\mathrm{dR}} = tB^+_{\mathrm{dR}}$ (Ai1, Ai3). Let $\epsilon = \lambda(e_a) = \iota_\Lambda(\varphi^{-1}(e_a)) = \epsilon_{a-1}$. For $y \in \mathcal{O}_F$, $\iota(y) = \varphi(y)$ in $W(k) \subset A_{\mathrm{inf}}$ and $e_{a-1}(y\otimes 1) = e_{a-1}(1\otimes\tau_{a-1}(y))$; so on the ϵ-component $\varphi(y)\otimes 1$ acts as $1\otimes\tau_{a-1}(y)$, i.e. $F \subset B_{\mathrm{dR}}$ acts through $\tau_{a-1}\circ\varphi^{-1} = \tau_a$. Hence, for $D = D_{\mathrm{cris}}(V) = D_{\mathrm{dR}}(V)$ (V crystalline), $\epsilon D = D_{\mathrm{dR},\tau_a}(V)$ with its filtration $\epsilon\mathrm{Fil}^j D$. Put $R^+ = \epsilon(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L)$, on which ξ_0 is a non-zero-divisor and not a unit.

(i) $(\Lambda(e_m))_m$ is an R^+-basis of $\epsilon(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)$. Apply φ^{-1} to $A_{\mathrm{inf}}[1/\mu]\cdot\iota_T(\mathbf{N}) = A_{\mathrm{inf}}[1/\mu]\otimes T$ (Ex2) and extend scalars to B^+_{dR}: $B^+_{\mathrm{dR}} \otimes T$ is spanned over $B^+_{\mathrm{dR}} \otimes \mathcal{O}_L$ by Λ of an $\mathbf{A}_{F,L}$-basis of $\mathbf{N} = \bigoplus_b \mathbf{N}_b$; multiplying by $\epsilon = \lambda(e_a)$ kills $\Lambda(\mathbf{N}_b)$ for $b \neq a$ and fixes $\Lambda(e_m)$. So the r vectors $\Lambda(e_m)$ span $\epsilon(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V) = R^+ \otimes_L V$, free of rank r over R^+; a surjective endomorphism of a finitely generated module is bijective, so they form a basis.

(ii) $(\Lambda(\varphi e'_k))_k$ is an R^+-basis of $\Lambda_D = \bigoplus_i R^+ D_i^{\mathrm{ad}}$, where (D_i^{ad}) is an L-basis of ϵD adapted to the filtration: $D_i^{\mathrm{ad}} \in \epsilon\mathrm{Fil}^{j_i}D$ and $\epsilon\mathrm{Fil}^j D$ is spanned by the D_i^{ad} with $j_i \geq j$. Let H'_k be the horizontal section through e'_k and $D_k = G^{(0)}(H'_k)$, which equals $\varphi^{-3}(\mathrm{Ev}(H'_k))$ by Lemma 23.13 (1); by Lemma 23.10 (2) the $\mathrm{Ev}(H'_k)$ form an L-basis of $\epsilon_{a+2}D$, so the D_k form an L-basis of ϵD (φ maps $\epsilon_b D$ bijectively onto $\epsilon_{b+1}D$), and $\sum_k R^+ D_k = \Lambda_D$. Writing $H'_k = \sum_j h_{kj}e'_j$ with $h \equiv I \bmod X$ ((Hf2)), $D_k = \sum_j \mathrm{ev}^{(0)}(h_{kj})\,\iota_T(e'_j)$, and $\mathrm{ev}^{(0)}(h) \equiv I$ modulo ξ_0 because $\mathrm{ev}^{(0)}(X) = \mu$ and $\theta(\mu) = 0$; so $\mathrm{ev}^{(0)}(h)$ is invertible over $B^+_{\mathrm{dR}} \otimes \mathcal{O}_L$ and the $\iota_T(e'_j) = \Lambda(\varphi e'_j)$ are an R^+-basis of Λ_D (the D_k are one, being L-independent in $R^+ \otimes_L \epsilon D$).

(iii) $\epsilon(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V) = \bigoplus_i t^{-j_i} R^+ D_i^{\mathrm{ad}}$. By (Ai4) with $k=0$ and the ϵ-component ($\epsilon(B^+_{\mathrm{dR}} \otimes_F \mathrm{Fil}^j D) = R^+ \otimes_L \epsilon\mathrm{Fil}^j D$): $\epsilon(B^+_{\mathrm{dR}} \otimes V) = \sum_j t^{-j} R^+ \otimes_L \epsilon\mathrm{Fil}^j D = \bigoplus_i (\sum_{j \le j_i} t^{-j} R^+) D_i^{\mathrm{ad}} = \bigoplus_i t^{-j_i} R^+ D_i^{\mathrm{ad}}$, the sum being direct since the D_i^{ad} are independent over $R^+[1/t]$ ((Ai4)).

Step 5: $w = rM + \sum_j j\, m_j$**.** Apply Λ to $Q^M \varphi(e'_k) = \sum_m P_{mk} e_m$:

$$\xi_0^M \Lambda(\varphi e'_k) = \sum_m \lambda(P_{mk}) \Lambda(e_m).$$

By (ii) and (iii), the basis $(\Lambda(\varphi e'_k))$ is $C \cdot (D_i^{\mathrm{ad}})$ with $C \in \mathrm{GL}_r(R^+)$, $(D_i^{\mathrm{ad}}) = \mathrm{diag}(t^{j_i}) \cdot (t^{-j_i} D_i^{\mathrm{ad}})$, and $(t^{-j_i} D_i^{\mathrm{ad}}) = C' \cdot (\Lambda(e_m))$ with $C' \in \mathrm{GL}_r(R^+)$ by (i), (iii). Comparing coefficients in the basis $(\Lambda(e_m))$ and taking determinants,

$$\lambda(\det P) = \det \lambda(P) = \xi_0^{rM}\, t^{\sum_i j_i} \cdot (\text{unit of } R^+) = \xi_0^{\,rM + \sum_i j_i} \cdot (\text{unit of } R^+).$$

On the other hand $\lambda(\det P) = \lambda(v) \xi_0^w$ with $\lambda(v)$ a unit. As ξ_0 is a non-zero-divisor and not a unit of R^+, $w = rM + \sum_i j_i$. Finally $\sum_i j_i = \sum_j j \, \dim_L(\epsilon\mathrm{Fil}^j D / \epsilon\mathrm{Fil}^{j+1} D) = \sum_j j\, m_j$ (the number of i with $j_i = j$ is that dimension), and $\sum_j m_j = r$. □

Proposition C.71. *Let ℓ, F, n, L, $(\tau_a)_{a \in \mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, and let $c \in \mathbb{Z}/n$ with $\epsilon_c = -1$. Put $M = s_c + S$, $k = (\ell-1)\lceil M/(\ell-1)\rceil$, let E be the integer of Proposition C.72 for the up site $c-1$, and*

$$\kappa = s_\ell(k-1) + E + \sigma_{\mathrm{G}} + s_{c-2} + S - s_{c-1}.$$

Let $x \in \mathbf{N}(T_2)_{c-3}$ be Δ-invariant with $\varphi^{-2}(\mathrm{Cv}_{T_2}(x)) \in \mathrm{Fil}^{s_{c-1}} D_{\mathrm{cris}}(V_2)$. Then there is a Δ-invariant $\tilde{y} \in \mathbf{N}(T_1)_{c-1}$ such that $y = \varphi(\tilde{y})$ satisfies $Q^M y \in \mathbf{N}(T_1)_c$ and $(\gamma_u - 1)(y) \in X\mathbf{N}(T_1)$ for every $u \in \mathbb{Z}_\ell^\times$, and such that, for arc level data of (V_2, T_2) with cut c, length 1, $H = 0$ and any frame $(n_j)_{j \le r}$ at $c-1$, $\mathbf{N}(\Phi)(y) \in W$ and

$$\mathrm{lv}_0(\mathbf{N}(\Phi)(y)) - \ell^\kappa a \in t^M K_{(0)}[[t]]^r,$$

where $a \in L^r$ is given by $\sum_j a_j\, \varphi^{-3}(\mathrm{Cv}_{T_2}(n_j)) = \varphi^{-1}(\mathrm{Cv}_{T_2}(x))$.

Proof. **Step 0.** As n is even and the signs alternate by parity, $\epsilon_{c-1} = 1$. By Lemma 24.2 (1) and (Ow1), the Hodge jumps of V_1 and V_2 at τ_c lie in $[-M, \eta]$; by (Ex1) and (Wm2), $Q^M \varphi(\mathbf{N}(T_\nu)_{c-1}) \subseteq \mathbf{N}(T_\nu)_c$ ($\nu = 1, 2$).

Step 1: lifting at the up site $c-1$**.** By Proposition C.72 at $i = c-1$ (so $i - 2 = c - 3$), there is a Δ-invariant $y_1 \in \mathbf{N}(T_1)_{c-1}$ with $(1 \otimes \Phi)(\mathrm{Cv}_{T_1}(y_1)) = \ell^{E + \sigma_{\mathrm{G}} + s_{c-2} + S - s_{c-1}} \varphi^2(\mathrm{Cv}_{T_2}(x))$.

Step 2: truncation. Let $s = s_\ell(k-1)$. By (Hf3) there is $y_k \in \mathbf{N}(T_1)_{c-1}$ with $\ell^s H_{y_1} - y_k \in X^k \mathbf{N}(T_1)_E$ ($H_{y_1} \in e_{c-1}\mathbf{N}(T_1)_E$, replace y_k by $e_{c-1} y_k$). Put $\tilde{y} = (\ell-1)^{-1} \sum_{\delta \in \mu_{\ell-1}} \gamma_\delta(y_k)$; as the γ_δ fix H_{y_1} and preserve $X^k \mathbf{N}(T_1)_E$, also $\ell^s H_{y_1} - \tilde{y} \in X^k \mathbf{N}(T_1)_E$, so (Hf3) gives $(\gamma_u - 1)\tilde{y} \in X^k \mathbf{N}(T_1)$ for every u, and $\tilde{y} - \ell^s y_1 \in X\mathbf{N}(T_1)$. The element $\tilde{y}$ is Δ-invariant.

Step 3: $y = \varphi(\tilde{y})$**.** By Step 0, $Q^M y \in \mathbf{N}(T_1)_c$. For $u \in \mathbb{Z}_\ell^\times$, $(\gamma_u - 1)y = \varphi((\gamma_u - 1)\tilde{y}) \in \varphi(X)^k \varphi(\mathbf{N}(T_1)_{c-1}) = X^k Q^{k-M} \cdot Q^M \varphi(\mathbf{N}(T_1)_{c-1}) \subseteq X\mathbf{N}(T_1)$ ((Wm3); $k \ge M \ge 1$). The element y is Δ-invariant.

Step 4: the level-0 **expansion.** The map $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear and commutes with φ and the γ_u (Ex3); so $z := \mathbf{N}(\Phi)(\tilde{y}) \in \mathbf{N}(T_2)_{c-1}$ has $(\gamma_{u_0} - 1)z \in X^k \mathbf{N}(T_2)_{c-1}$, $z - \ell^s \mathbf{N}(\Phi)(y_1) \in X\mathbf{N}(T_2)$, and $\mathbf{N}(\Phi)(y) = \varphi(z)$. With $\Pi = 1$, $\varphi(z) \in P_1(\mathbf{N}(T_2)_{c-1})$, so $\mathbf{N}(\Phi)(y) \in W$. Take the parameters $j = 1$, $k/(\ell-1)$ in the role of M, $g = 0$ (so $(\ell-1) \cdot k/(\ell-1) = k \ge 3g$). Write

$z-\sum_j a'_j n_j \in X\mathbf{N}(T_2)_{c-1}$ with $a' \in \mathcal{O}_L^r$. By Lemma C.68 ((Lp6)), $\mathrm{lv}_0(\varphi(z))-a' \in t^k K_{(0)}[[t]]^r \subseteq t^M K_{(0)}[[t]]^r$. The level frame is $\varphi^{-3}(\mathrm{Cv}_{T_2}(n_j))$ (length 1), and by (Cv1), (Cv2), (Cv5),

$$\sum_j a'_j \varphi^{-3}(\mathrm{Cv}(n_j)) = \varphi^{-3}(\mathrm{Cv}(z)) = \ell^s \varphi^{-3}((1\otimes\Phi)\mathrm{Cv}_{T_1}(y_1)) = \ell^\kappa \varphi^{-1}(\mathrm{Cv}_{T_2}(x)),$$

so $a' = \ell^\kappa a$, the level frame being an L-basis of $\epsilon_{c-1}D_{\mathrm{cris}}(V_2)$, which contains $\varphi^{-1}(\mathrm{Cv}(x))$ ($\mathrm{Cv}(x) \in \epsilon_c D$, Lemma C.64 (Cv1)). □

Proposition C.72. *Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, let $i \in \mathbb{Z}/n$ with $\epsilon_i = 1$, and put $\sigma_{\mathrm{G}} = \lceil 2H'/(\ell-1)^2 \rceil + 1$. There is an integer E with*

$$0 \le E \le \frac{3a_{\mathrm{R}} + S + 2\eta}{\ell - 1} + \log_\ell(2H') + 1$$

such that for every Δ-invariant $y \in \mathbf{N}(T_2)_{i-2}$ with $\varphi^{-2}\big(\mathrm{Cv}_{T_2}(y)\big) \in \mathrm{Fil}^{s_i} D_{\mathrm{cris}}(V_2)$ there is a Δ-invariant $y_1 \in \mathbf{N}(T_1)_i$ with

$$(1\otimes\Phi)\big(\mathrm{Cv}_{T_1}(y_1)\big) = \ell^{\,E+\sigma_{\mathrm{G}}+s_{i-1}+S-s_i}\,\varphi^2\big(\mathrm{Cv}_{T_2}(y)\big).$$

Proof. Let E be the integer given by Lemma C.45 for the site i; it satisfies the stated bound. Let y be as in the statement. By Lemma C.73 there are Δ-invariant $x, z \in \mathbf{N}(T_2)_i$ and $x' \in e_i\mathbf{N}(T_2)[1/\lambda_\infty]$ with $(\pi_0+\ell)^{s_i}x = \varphi(\pi_0+\ell)^{s_{i-1}+S}x'$, $\varphi(\pi_0+\ell)^{s_{i-1}+S}(\gamma_{u_0}-1)(x') = \pi_0(\pi_0+\ell)^{a+s_i}z$ and $\mathrm{Cv}_{T_2}(x) = \ell^{\sigma_{\mathrm{G}}+s_{i-1}+S-s_i}\varphi^2(\mathrm{Cv}_{T_2}(y))$. These are the hypotheses of Lemma C.45 on (x, x', z), which therefore gives a Δ-invariant $y_1 \in \mathbf{N}(T_1)_i$ with $\mathbf{N}(\Phi)(y_1) = \ell^E x$. By Lemma C.64 (Cv5) and (Cv1) ($\mathcal{O}_L$-linearity),

$$(1\otimes\Phi)\big(\mathrm{Cv}_{T_1}(y_1)\big) = \mathrm{Cv}_{T_2}\big(\mathbf{N}(\Phi)(y_1)\big) = \ell^E\,\mathrm{Cv}_{T_2}(x) = \ell^{\,E+\sigma_{\mathrm{G}}+s_{i-1}+S-s_i}\,\varphi^2\big(\mathrm{Cv}_{T_2}(y)\big).$$

□

Lemma C.73. *Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1 \to V_2$ (with lattices T_1, T_2) and the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ satisfy the hypotheses of Proposition C.52, let $i \in \mathbb{Z}/n$ with $\epsilon_i = 1$, form π_0 and u_0 as in Lemma 28.15, and put*

$$a = \lceil a_{\mathrm{R}} \rceil, \qquad \sigma_{\mathrm{G}} = \Big\lceil \frac{2H'}{(\ell-1)^2} \Big\rceil + 1.$$

Let $y \in \mathbf{N}(T_2)_{i-2}$ be Δ-invariant with $\varphi^{-2}\big(\mathrm{Cv}_{T_2}(y)\big) \in \mathrm{Fil}^{s_i} D_{\mathrm{cris}}(V_2)$. Then there are Δ-invariant $x, z \in \mathbf{N}(T_2)_i$ and $x' \in e_i\mathbf{N}(T_2)[1/\lambda_\infty]$ with

$$(\pi_0+\ell)^{s_i}x = \varphi(\pi_0+\ell)^{\,s_{i-1}+S}x', \qquad \varphi(\pi_0+\ell)^{\,s_{i-1}+S}(\gamma_{u_0}-1)(x') = \pi_0(\pi_0+\ell)^{a+s_i}z,$$

$$\mathrm{Cv}_{T_2}(x) = \ell^{\,\sigma_{\mathrm{G}}+s_{i-1}+S-s_i}\,\varphi^2\big(\mathrm{Cv}_{T_2}(y)\big).$$

Here the exponent may be negative; $D_{\mathrm{cris}}(V_2)$ is an L-vector space.

Proof. Write $\varsigma = \pi_0 + \ell = Qw_0$ (w_0 a unit of $\mathbb{Z}_\ell[[X]]$, ς Δ-invariant, Lemma 28.15 (1)), $h = 2H'$, $h' = s_{i-1} + S$, $\mathbf{N} = \mathbf{N}(T_2)$, $D = D_{\mathrm{cris}}(V_2)$.

Step 0: signs and windows. As n is even and the signs alternate by parity, $\epsilon_{i-1} = -1$ and $\epsilon_{i-2} = 1$. By Lemma 24.2 (1) and (Ow1), every Hodge jump of V_2 at τ_a lies in $[-(s_a+S), \eta]$

if $\epsilon_a = -1$ and in $[-\eta, s_a + S]$ if $\epsilon_a = 1$; so by (Ex1) $\mathbf{N}$ is a Wach module with $M_{i-1} = h'$, $M_i = \eta$, and (Wm2) gives $Q^{h'}\varphi(\mathbf{N}_{i-2}) \subseteq \mathbf{N}_{i-1}$ and $Q^{\eta}\varphi(\mathbf{N}_{i-1}) \subseteq \mathbf{N}_i$. Hence $\varphi(\varsigma)^{h'}P_2(\mathbf{N}_{i-2}) \subseteq \mathbf{A}_{F,L}\varphi(\mathbf{N}_{i-1})$ and

$$\varsigma^{\eta}\varphi(\varsigma)^{h'}P_2(\mathbf{N}_{i-2}) \subseteq \mathbf{N}_i. \qquad \text{(W)}$$

Numbers: $s_i + \eta \le H'$; $a = \lceil a_{\mathrm{R}} \rceil < a_{\mathrm{R}} + 1 \le (s_i - \eta + 1)/2 \le H'$ (as $s_i \ge 2a_{\mathrm{R}} + \eta + 1$); so $h - a - s_i \ge \eta$ and $h - s_i \ge \eta$. Also $\sigma_{\mathrm{G}} = \lceil h/(\ell-1)^2 \rceil + 1$.

Step 1: the truncation. By Lemma C.74 (pair (V_2, T_2), site i, this h, $\sigma = \sigma_{\mathrm{G}}$) there is a Δ-invariant $z_0 \in P_2(\mathbf{N}_{i-2})$ with (Ft1)–(Ft3). Put $x' = z_0 \in e_i\mathbf{N}[1/\lambda_2] \subseteq e_i\mathbf{N}[1/\lambda_\infty]$ and $x = \varsigma^{-s_i}\varphi(\varsigma)^{h'}z_0 \in e_i\mathbf{N}[1/\lambda_2]$ (ς is invertible in $\mathbf{A}_{F,L}[1/Q]$). Then $\varsigma^{s_i}x = \varphi(\varsigma)^{h'}x'$, and x is Δ-invariant.

Step 2: $x \in \mathbf{N}_i$. Fix arc level data for (V_2, T_2) with cut i, length 2 ($c_0 = i-2$), $H(i) = s_i$, $H(i-1) = 0$, so $\Pi = Q^{s_i}$, a frame (e'_m) at $i-2$, and any parameters. Then $\Pi x = w_0^{-s_i}\varphi(\varsigma)^{h'}z_0 \in P_2(\mathbf{N}_{i-2})$ and $\Pi z_0 \in P_2(\mathbf{N}_{i-2})$, so $x, z_0 \in W$. The level frame is $D_m^{(s)} = \varphi^{-2-s}(\mathrm{Cv}(e'_m))$; $\epsilon_0 = \epsilon_{i-1}$ is the idempotent of τ_i and ϵ_1 that of τ_{i-1} (Definition 23.4), so Fil_0, Fil_1 read the Hodge filtrations of V_2 at τ_i, τ_{i-1}. By Lemma 23.17 ((Lp1)): $\lambda_0(Q) \in tK_{(0)}[[t]]^\times$, $\lambda_0(Q_1) \in K_{(0)}[[t]]^\times$, $\lambda_1(Q) \in K_{(1)}[[t]]^\times$, $\lambda_1(Q_1) \in tK_{(1)}[[t]]^\times$, and λ_s maps units of $e_i\mathbf{A}_{F,L}$ to units of $K_{(s)}[[t]]$; as $\varphi(\varsigma) = Q_1\varphi(w_0)$, $\lambda_0(\varsigma) = t\vartheta_0$, $\lambda_0(\varphi\varsigma) = \vartheta'_0$, $\lambda_1(\varsigma) = \vartheta_1$, $\lambda_1(\varphi\varsigma) = t\vartheta'_1$ with units ϑ.

Level 0. Let $a_y \in L^r$ with $\sum_m a_{y,m}D_m^{(0)} = \varphi^{-2}(\mathrm{Cv}(y))$. By (Ft3) (with $\Lambda_D = \bigoplus_m R_0^+ D_m^{(0)}$) and uniqueness of coordinates in the R_0-basis $(D_m^{(0)})$, $\mathrm{lv}_0(z_0) - \ell^{\sigma_{\mathrm{G}}}a_y \in K_{(0)}((t))^r \cap t^h(R_0^+)^r = t^hK_{(0)}[[t]]^r$ (if $f = \sum_{j \ge j_0} f_j t^j$ with $f_{j_0} \ne 0$, $j_0 < h$, lay in $t^hR_0^+$, then $\theta(t^{-j_0}f) = \theta(f_{j_0}) = 0$, contradicting injectivity of θ on $K_{(0)}$). Hence

$$\mathrm{lv}_0(x) = t^{-s_i}\vartheta_0^{-s_i}\vartheta_0'^{h'}\big(\ell^{\sigma_{\mathrm{G}}}a_y + t^h g\big), \qquad g \in K_{(0)}[[t]]^r.$$

The hypothesis $\varphi^{-2}(\mathrm{Cv}(y)) \in \mathrm{Fil}^{s_i}D$ says $a_y \in \mathrm{Fil}_0(s_i)$. The coefficient of t^j coming from a_y vanishes for $j < -s_i$ and is a $K_{(0)}$-multiple of $a_y \in \mathrm{Fil}_0(s_i) \subseteq \mathrm{Fil}_0(-j)$ for $j \ge -s_i$. The coefficient coming from $t^h g$ vanishes for $j < h - s_i$, and for $j \ge h - s_i \ge \eta$, $\mathrm{Fil}_0(-j) = L^r$, every jump at τ_i being $\ge -\eta$. So $\mathrm{lv}_0(x)$ is de Rham integral at 0.

Level 1. We have $\mathrm{lv}_1(x) = \vartheta_1^{-s_i}t^{h'}\vartheta_1'^{h'}\mathrm{lv}_1(z_0)$, and $\mathrm{lv}_1(z_0) \in K_{(1)}[[t]]^r$ by (Lp4) ($\lambda_1(\Pi)$ is a unit). Its coefficients of t^j vanish for $j < h'$, and for $j \ge h' = s_{i-1} + S$, $\mathrm{Fil}_1(-j) = L^r$, every jump at τ_{i-1} being $\ge -(s_{i-1} + S)$. So $\mathrm{lv}_1(x)$ is de Rham integral at 1, and by Lemma 23.5 (2) ((Lp3)), $x \in \mathbf{N}_i$.

Step 3: the Γ-defect. By (Ft1), $(\gamma_{u_0} - 1)(x') = \pi_0\varsigma^h q$ with $q \in P_2(\mathbf{N}_{i-2})$, so $\varphi(\varsigma)^{h'}(\gamma_{u_0} - 1)(x') = \pi_0\varsigma^{a+s_i}z$ with $z = \varsigma^{h-a-s_i-\eta} \cdot \varsigma^{\eta}\varphi(\varsigma)^{h'}q \in \mathbf{N}_i$ by (W) and $h - a - s_i \ge \eta$. The element z is Δ-invariant: $(\gamma_{u_0} - 1)x'$ is (γ_{u_0} commutes with the γ_δ), and z is its product with $\varphi(\varsigma)^{h'}(\pi_0\varsigma^{a+s_i})^{-1}$, a quotient of Δ-invariant elements, in the module $e_i\mathbf{N}[1/\lambda_2]$, free over a domain.

Step 4: the crystalline value. By (Ft2), $z_0 = \ell^{\sigma_{\mathrm{G}}}\varphi^2(y) + Xp$ with $p \in P_2(\mathbf{N}_{i-2})$. Put $u_1 = \varsigma^{h'}\varphi(y) \in \mathbf{N}_{i-1}$ (Step 0). Then

$$\varsigma^{s_i+\eta}x = \varsigma^{\eta}\varphi(\varsigma)^{h'}z_0 = \ell^{\sigma_{\mathrm{G}}}\varsigma^{\eta}\varphi(u_1) + X \cdot \varsigma^{\eta}\varphi(\varsigma)^{h'}p,$$

with $\varsigma^{\eta}\varphi(u_1) \in \mathbf{N}_i$ (Step 0) and $\varsigma^{\eta}\varphi(\varsigma)^{h'}p \in \mathbf{N}_i$ by (W). Apply Cv, using Lemma C.64 (Cv1), (Cv2) ($\mathrm{Cv}(X\mathbf{N}) = 0$, $\varsigma(0) = \ell$) and (Cv4) twice (with $\kappa = \varsigma^{\eta}$ at i and $\kappa = \varsigma^{h'}$ at $i-1$; $\varphi^3 \circ \iota_\Lambda$ fixes ℓ): $\ell^{s_i+\eta}\mathrm{Cv}(x) = \ell^{\sigma_{\mathrm{G}}}\ell^{\eta}\varphi(\mathrm{Cv}(u_1)) = \ell^{\sigma_{\mathrm{G}}+\eta+h'}\varphi^2(\mathrm{Cv}(y))$. Hence $\mathrm{Cv}(x) = \ell^{\sigma_{\mathrm{G}}+s_{i-1}+S-s_i}\varphi^2(\mathrm{Cv}(y))$ in the L-vector space D. □

Lemma C.74. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ and a pair (V,T) be as in Proposition 23.7, $\mathbf{N} = \mathbf{N}(T)$, $D = D_{\mathrm{cris}}(V)$, $i \in \mathbb{Z}/n$, $P_2 = P_2(\mathbf{N}_{i-2})$, $\varsigma = \pi_0 + \ell$, and let $h \ge 1$ and $\sigma = \lceil h/(\ell-1)^2 \rceil + 1$. Let*

$\Lambda_0 = \varphi^{-1} \circ \iota_T$ *on* $\mathbf{N}[1/\lambda_2]$ *(values in* $B_{\mathrm{dR}} \otimes_{\mathbb{Z}_\ell} T$*) and* $\Lambda_D = \epsilon_{i-1}(B^+_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} L) \cdot \epsilon_{i-1} D$*. For every* Δ*-invariant* $y \in \mathbf{N}_{i-2}$ *there is a* Δ*-invariant* $z \in P_2$ *with*

(Ft1) $(\gamma_u - 1)(z) \in \pi_0 \varsigma^h P_2$ *for every* $u \in \mathbb{Z}_\ell^\times$*;*

(Ft2) $z - \ell^\sigma \varphi^2(y) \in X P_2$*;*

(Ft3) $\Lambda_0(z) - \ell^\sigma \varphi^{-2}\big(\mathrm{Cv}(y)\big) \in t^h \Lambda_D$*.*

Proof. Throughout $\gamma = \gamma_u$ for a fixed $u \in \mathbb{Z}_\ell^\times$; $\gamma(X) = X\eta_u$ with η_u a unit of $\mathbb{Z}_\ell[[X]]$, so $\gamma(\pi_0)$ is π_0 times a unit ($\pi_0 = X^{\ell-1}v$, Lemma 28.15 (1)); $\varsigma = Qw_0$ with w_0 a unit, and $\gamma(Q) = Q\varphi(\eta_u)\eta_u^{-1}$ (from $Q = \varphi(X)/X$), so $\gamma(\pi_0\varsigma^h) = \pi_0\varsigma^h u_\gamma$ with u_γ a unit of $\mathbb{Z}_\ell[[X]]$.

Step 1: P_2 is free on φ^2 of a basis. By Lemma 24.15, $\mathbf{N}_{i-2}$ has a Δ-invariant basis $(e'_m)_{m \le r}$ over $e_{i-2}\mathbf{A}_{F,L}$. Since φ is semilinear, $P_2 = \sum_m R\,\varphi^2(e'_m)$ with $R = e_i\mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$. By (Wm2) at $i-1$ and i, the $R[1/\lambda_2]$-span of the $\varphi^2(e'_m)$ is $e_i\mathbf{N}[1/\lambda_2]$, free of rank r over the domain $R[1/\lambda_2]$; r generators of a free module of rank r form a basis, so the $\varphi^2(e'_m)$ are R-independent and $P_2 = \bigoplus_m R\varphi^2(e'_m)$. The map γ preserves P_2 ($\gamma(g\varphi^2(n)) = \gamma(g)\varphi^2(\gamma n)$, (Wm3)).

Step 2: the π_0-expansion of H_y. The section $H_y \in e_{i-2}\mathbf{N}_E$ is Δ-invariant ($\gamma_\delta H_y$ is horizontal through $\gamma_\delta y = y$). Write $H_y = \sum_m f_m e'_m$; the $f_m \in e_{i-2}E[[X]] \cong L[[X]]$ are Δ-invariant, and by (Hf3) the coefficient $a_{m,j}$ of X^j satisfies $\ell^{s_\ell(j)} a_{m,j} \in \mathcal{O}_L$. A Δ-invariant $f \in XL[[X]]$ is π_0 times a Δ-invariant series (lowest-degree argument: the lowest term aX^j of f becomes $a\delta^j X^j$ under γ_δ, so $(\ell-1) \mid j$). Hence, recursively, $f_m = \sum_{k<K} b_{mk}\pi_0^k + \pi_0^K f_{m,K}$ for every K, with constants $b_{mk} \in L$ and Δ-invariant $f_{m,K} \in L[[X]]$, and $b_{mk} = v(0)^{-k}\big(a_{m,(\ell-1)k} - \sum_{k'<k} b_{mk'}\,[X^{(\ell-1)k}]\pi_0^{k'}\big)$, where $[X^j]$ denotes the coefficient and the $[X^j]\pi_0^{k'}$ lie in $\mathbb{Z}_\ell$. By induction on k and monotonicity of s_ℓ, $\ell^{s_\ell((\ell-1)k)} b_{mk'} \in \mathcal{O}_L$ for $k' \le k$; and $s_\ell((\ell-1)k) = k + v_\ell(k!) \le k + (k-1)/(\ell-1) \le e(k)$ ($k \ge 1$; both are 0 for $k = 0$). Put $\hat{c}_k = \sum_m b_{mk} e'_m$, $c_k = \ell^{e(k)}\hat{c}_k \in \mathbf{N}_{i-2}$ (Δ-invariant) and $R_K = \sum_m f_{m,K} e'_m \in e_{i-2}\mathbf{N}_E$, so that

$$H_y = \sum_{k<K} \pi_0^k \hat{c}_k + \pi_0^K R_K \qquad (K \ge 0), \qquad \hat{c}_0 - y \in \mathbf{N} \cap X\mathbf{N}_E = X\mathbf{N}.$$

Step 3: the vector z. By Lemma C.63 choose, for each $k \ge 0$, $\alpha_k, \beta_k \in \mathcal{R}$ with $\ell^\sigma \varphi^2(\pi_0)^k = \ell^{e(k)}\alpha_k + \pi_0\varsigma^h\beta_k$, taking $\alpha_0 = \ell^\sigma$, $\beta_0 = 0$, and, for $(\ell-1)k \ge h$, $\alpha_k = 0$: this is possible because $\varphi(\pi_0) = \varphi(X)^{\ell-1}\varphi(v) = \pi_0\varsigma^{\ell-1}U$ with $U = v^{-1}w_0^{1-\ell}\varphi(v)$, so $\varphi^2(\pi_0) \in \pi_0\varsigma^{\ell-1}\mathcal{R}$ and $\varphi^2(\pi_0)^k \in \pi_0\varsigma^{(\ell-1)k}\mathcal{R}$ for $k \ge 1$ (the quotient lies in $\mathcal{R}$: φ commutes with every γ_δ on $\mathbb{Z}_\ell[[X]]$, as $\varphi\gamma_\delta(X) = (1+X)^{\ell\delta} - 1 = \gamma_\delta\varphi(X)$, so $\varphi(\mathcal{R}) \subseteq \mathcal{R}$ and $\varphi^2(\pi_0)^k \in \mathcal{R}$; and if $f \in \mathbb{Z}_\ell[[X]]$ and $gf \in \mathcal{R}$ for a non-zero $g \in \mathcal{R}$, here $g = \pi_0\varsigma^{(\ell-1)k}$, then $g(\gamma_\delta(f) - f) = \gamma_\delta(gf) - gf = 0$, so $\gamma_\delta(f) = f$ for every $\delta \in \Delta$, $\mathbb{Z}_\ell[[X]]$ being a domain). For $k \ge 1$, evaluating at $X = 0$ ($\pi_0(0) = 0$) gives $\ell^{e(k)}\alpha_k(0) = 0$, so $\alpha_k(0) = 0$. Let $K_0 = \lceil h/(\ell-1) \rceil$ and

$$z = \sum_{k<K_0} \alpha_k\,\varphi^2(c_k) \ \in P_2,$$

Δ-invariant ($\alpha_k \in \mathcal{R}$, φ commutes with the γ_δ). *(Ft2):* $z - \alpha_0\varphi^2(c_0) \in XP_2$ as $\alpha_k \in X\mathbb{Z}_\ell[[X]]$ for $k \ge 1$, and $\alpha_0\varphi^2(c_0) - \ell^\sigma\varphi^2(y) = \ell^\sigma\varphi^2(\hat{c}_0 - y) \in \varphi^2(X)P_2 \subseteq XP_2$.

Step 4: an integral identity. Fix $K \ge K_0$ and put $y_K = \sum_{k<K} \ell^{e(K)-e(k)}\pi_0^k c_k = \ell^{e(K)}\sum_{k<K}\pi_0^k\hat{c}_k \in \mathbf{N}_{i-2}$ (e is non-decreasing). Then

$$\begin{aligned}\ell^\sigma\varphi^2(y_K) &= \sum_{k<K} \ell^{e(K)-e(k)}\big(\ell^{e(k)}\alpha_k + \pi_0\varsigma^h\beta_k\big)\varphi^2(c_k) \\ &= \ell^{e(K)}z + \pi_0\varsigma^h p_K, \qquad p_K = \sum_{k<K} \ell^{e(K)-e(k)}\beta_k\varphi^2(c_k) \in P_2. \qquad \text{(I)}\end{aligned}$$

Step 5: (Ft1). As $\gamma H_y = H_y$, Step 2 gives $(\gamma-1)y_K = -\ell^{e(K)}(\gamma-1)(\pi_0^K R_K) = -\ell^{e(K)}\pi_0^K\big((\gamma\pi_0/\pi_0)^K\gamma(R_K)-R_K\big)$, an element of $\mathbf{N}\cap\pi_0^K\mathbf{N}_E = \mathbf{N}\cap X^{(\ell-1)K}\mathbf{N}_E = X^{(\ell-1)K}\mathbf{N} = \pi_0^K\mathbf{N}$; write $(\gamma-1)y_K = \pi_0^K m_K$, $m_K\in\mathbf{N}_{i-2}$. Apply $\gamma-1$ to (I) (γ commutes with φ):

$$\ell^{e(K)}(\gamma-1)z = \ell^\sigma\varphi^2(\pi_0)^K\varphi^2(m_K) - \pi_0\varsigma^h\big(u_\gamma\gamma(p_K)-p_K\big) = \pi_0\varsigma^h q_K,\qquad q_K\in P_2,$$

since $\varphi^2(\pi_0)^K\in\pi_0\varsigma^{(\ell-1)K}\mathcal{R}\subseteq\pi_0\varsigma^h\mathcal{R}$ ($(\ell-1)K\geq h$). In the basis of Step 1 write $(\gamma-1)z=\sum_m a_m\varphi^2(e'_m)$ and $q_K=\sum_m b_m\varphi^2(e'_m)$ ($a_m,b_m\in R$): $\ell^{e(K)}a_m=\pi_0\varsigma^h b_m$. In the unique factorisation domain $R\cong\mathcal{O}_L[[X]]$ a uniformiser ϖ of $\mathcal{O}_L$ is prime and does not divide $\pi_0\varsigma^h$ (modulo ϖ it is $X^{(\ell-1)(h+1)}$ times a unit, as $\varsigma\equiv\pi_0$ modulo ℓ); so $\ell^{e(K)}\mid b_m$, $a_m\in\pi_0\varsigma^h R$, and $(\gamma-1)z\in\pi_0\varsigma^h P_2$.

Step 6: (Ft3). Put $\epsilon=\epsilon_{i-1}$, $R^+=\epsilon(B^+_{\mathrm{dR}}\otimes L)$. For $n\in\mathbf{N}_{i-2}$, (Ex2) gives $\Lambda_0(\varphi^2 n)=\varphi(\iota_T(n))=G^{(1)}(n)$ (with $\mathrm{ev}^{(1)}=\varphi\circ\iota_L$ on $\mathbf{A}_{F,L}$, both being continuous ring maps equal on Λ and on X), and $\Lambda_0(gw)=\lambda_0(g)\Lambda_0(w)$ with $\lambda_0=\varphi^{-1}\circ\iota_L$. Let (H'_m) be the horizontal sections through (e'_m); by Lemma 23.13 (1), $G^{(1)}(H'_m)=\varphi^{-2}(\mathrm{Cv}(e'_m))=:D_m$, an L-basis of ϵD (Lemma C.64 (Cv3), φ bijective between components), so $\Lambda_D=\bigoplus_m R^+D_m$. As $e'_m=\sum_k(h^{-1})_{mk}H'_k$ with $h^{-1}\in\mathrm{GL}_r(E[[X]])$ and $\mathrm{ev}^{(1)}(E[[X]])\subseteq B^+_{\mathrm{dR}}\otimes\mathcal{O}_L$, $G^{(1)}(W)\in\Lambda_D$ for every $W\in e_{i-2}\mathbf{N}_E$, and $\Lambda_0(P_2)\subseteq\Lambda_D$. Moreover, $\theta(\mathrm{ev}^{(1)}(X))=\theta(\varphi(\mu))=0$, so $\mathrm{ev}^{(1)}(\pi_0)\in t^{\ell-1}B^+_{\mathrm{dR}}$; $\lambda_0(\varsigma)=\lambda_0(Q)\lambda_0(w_0)$ with $\lambda_0(Q)=\varphi^{-1}(\sum_{k<\ell}[\varepsilon]^k)=\xi_0\in tB^+_{\mathrm{dR}}$ (Theorem B.40 (Ai3)); and $H_y=\sum_m y_m(0)H'_m$ for $y=\sum_m y_m e'_m$ (both sides horizontal through elements congruent modulo X), so $G^{(1)}(H_y)=\sum_m\varphi(\iota_\Lambda(y_m(0)))D_m=\varphi^{-2}(\mathrm{Cv}(y))$ (Lemma C.64 (Cv2)). Apply Λ_0 to (I):

$$\ell^{e(K)}\Lambda_0(z)=\ell^\sigma G^{(1)}(y_K)-\lambda_0(\pi_0)\lambda_0(\varsigma)^h\Lambda_0(p_K),$$
$$G^{(1)}(y_K)=\ell^{e(K)}\big(G^{(1)}(H_y)-\mathrm{ev}^{(1)}(\pi_0)^K G^{(1)}(R_K)\big).$$

The last term lies in $t^{(\ell-1)K}\Lambda_D\subseteq t^h\Lambda_D$ and $\lambda_0(\pi_0)\lambda_0(\varsigma)^h\Lambda_0(p_K)\in t^h\Lambda_D$. Dividing by $\ell^{e(K)}$ (a unit of B^+_{dR}): $\Lambda_0(z)-\ell^\sigma\varphi^{-2}(\mathrm{Cv}(y))\in t^h\Lambda_D$. □

Proposition C.75. *There is an absolute constant $c_{4,2}\geq 1$ with the following property. Let ℓ, F, n, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1\to V_2$ (with lattices T_1,T_2) and the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ satisfy the hypotheses of Proposition C.52, form B and λ as in Proposition C.57, and let $c\in\mathbb{Z}/n$ with $\epsilon_c=-1$. Then there is an integer $0\leq e_6\leq c_{4,2}B$ with the following property. Let P be a free $\mathcal{O}_L$-module of finite rank, $P'\subseteq P$ a submodule and $w\colon P'\to\mathbf{N}(T_2)_c$ an $\mathcal{O}_L$-linear map with $\gamma_\delta(w(f))=w(f)$ for all $f\in P'$ and $\delta\in\mu_{\ell-1}\subseteq\mathbb{Z}_\ell^\times$. Then there are submodules $P'=P'_0\supseteq P'_1\supseteq\cdots\supseteq P'_k$ and a set $J\subseteq\{0,\dots,k-1\}$ with $|J|\leq 3$ and $k-|J|\leq 2$, such that P'_i/P'_{i+1} is generated by at most m elements for $i\in J$ and $\mathrm{nl}(P'_i/P'_{i+1})\leq\lambda$ for $i\notin J$, and such that for every $f\in P'_k$ there are $x\in I_c^1$ and a finite product λ' of the Q_s ($s\geq 0$) with $\lambda' x\in\mathbf{N}(T_1)$ and*

$$\ell^{e_6}w(f)-\mathbf{N}(\Phi)(x)\in X\,\mathbf{N}(T_2)_c.$$

Proof. Put $M=s_c+S$, $b'=s_{c-1}+S$, $h''=s_{c-2}+S$, $\varsigma=\pi_0+\ell=Qw_0$ (w_0 a unit, $\varsigma(0)=\ell$), $D=D_{\mathrm{cris}}(V_2)$, $\mathbf{N}=\mathbf{N}(T_2)$, and $e_6=E+\sigma_{\mathrm{G}}+S$ with E the integer of Proposition C.72 for the up site $c-1$.

Step 0: signs, windows, three facts. As n is even and the signs alternate, $\epsilon_{c-1}=1$, $\epsilon_{c-2}=-1$. By Lemma 24.2 (1), (Ow1) and (Ex1), $\mathbf{N}(T_\nu)$ ($\nu=1,2$) is a Wach module with window (s_a+S,η) at down sites and (η,s_a+S) at up sites; so (Wm2) gives $Q^M\varphi(\mathbf{N}(T_\nu)_{c-1})\subseteq\mathbf{N}(T_\nu)_c$, $Q^{b'}\mathbf{N}_{c-1}\subseteq\mathbf{A}_{F,L}\varphi(\mathbf{N}_{c-2})$, $Q^{h''}\varphi(\mathbf{N}_{c-3})\subseteq\mathbf{N}_{c-2}$. (F1) For a site a, $\{x\in\mathbf{N}_a^\Delta:\mathrm{Cv}(x)=0\}=\pi_0\mathbf{N}_a^\Delta$: by (Cv3), $\mathrm{Cv}(x)=0$ iff $x\in X\mathbf{N}_a$, and in a Δ-invariant basis (Lemma 24.15)

the Δ-invariant elements of $X\mathbf{N}_a$ are those with coordinates in $(XR)^\Delta = \pi_0 R^\Delta$ (lowest-degree argument, $R = e_a\mathbf{A}_{F,L}$). (F2) If a is a down site and $y \in Y_a$, then $\mathrm{Cv}(y) = \ell^{s_a+S}\varphi(\mathrm{Cv}(y'))$ for some $y' \in \mathbf{N}^\Delta_{a-1}$: write $y = \sum_j o_j \varsigma^{s_a+S} g_j \varphi(x_j)$ ($o_j \in \mathcal{O}_L$, g_j, x_j Δ-invariant); each term lies in $\mathbf{N}_a$, and by (Cv4) and (Cv1),

$$\mathrm{Cv}(\varsigma^{s_a+S} g_j \varphi(x_j)) = \ell^{s_a+S}\varphi^3(\iota_\Lambda(g_j(0)))\varphi(\mathrm{Cv}(x_j)) = \ell^{s_a+S}\varphi(\mathrm{Cv}(\varphi^{-1}(g_j(0))x_j))$$

(φ is bijective on Λ, and ι is φ-equivariant); take $y' = \sum_j o_j\varphi^{-1}(g_j(0))x_j$, Δ-invariant as the constants are. (F3) For $y_1 \in \mathbf{N}^\Delta_{c-1}$ there is $y_2 \in \mathbf{N}^\Delta_{c-2}$ with $\ell^{b'}\mathrm{Cv}(y_1) = \varphi(\mathrm{Cv}(y_2))$: with a Δ-invariant basis (e''_k) of $\mathbf{N}_{c-2}$, $\varsigma^{b'} y_1 = \sum_k g_k\varphi(e''_k)$ with $g_k \in \mathbf{A}_{F,L}$; by (Cv2) and the sum form of (Cv4), $\ell^{b'}\mathrm{Cv}(y_1) = \sum_k \varphi^3(\iota_\Lambda(g_k(0)))\varphi(\mathrm{Cv}(e''_k)) = \varphi(\mathrm{Cv}(y_2))$ with $y_2 = \sum_k \varphi^{-1}(g_k(0))e''_k$.

Step 1: the dual length lemma at c. Let Σ_c be as in Proposition C.65 at c, $P'_1 = w^{-1}(\pi_0\mathbf{N}^\Delta_c + Y_c + \sum_{\Sigma_c}\mathcal{O}_L y)$ and $P'_2 = w^{-1}(\pi_0\mathbf{N}^\Delta_c + Y_c)$ (all submodules of P are finitely generated, $\mathcal{O}_L$ being principal). The quotient P'/P'_1 embeds in $\mathbf{N}^\Delta_c/(\pi_0\mathbf{N}^\Delta_c + Y_c + \sum_{\Sigma_c}\mathcal{O}_L y)$, so $\mathrm{nl}(P'/P'_1) \le \lambda$; P'_1/P'_2 embeds in a module generated by the images of Σ_c, so it is generated by at most m elements.

Step 2: linear crystalline data. For $f \in P'_2$, $\mathrm{Cv}(w(f)) \in \ell^M\varphi(\mathrm{Cv}(\mathbf{N}^\Delta_{c-1}))$ by (F1), (F2). As φ is injective and D is torsion free, there are unique $\alpha_1(f) \in \mathrm{Cv}(\mathbf{N}^\Delta_{c-1})$ with $\ell^M\varphi(\alpha_1(f)) = \mathrm{Cv}(w(f))$ and, by (F3), $\alpha_2(f) \in \mathrm{Cv}(\mathbf{N}^\Delta_{c-2})$ with $\varphi(\alpha_2(f)) = \ell^{b'}\alpha_1(f)$; by uniqueness α_1, α_2 are $\mathcal{O}_L$-linear. By (F1), setting $\psi(f)$ equal to the class of any $y_2 \in \mathbf{N}^\Delta_{c-2}$ with $\mathrm{Cv}(y_2) = \alpha_2(f)$ gives a well-defined $\mathcal{O}_L$-linear map $\psi\colon P'_2 \to \mathbf{N}^\Delta_{c-2}/\pi_0\mathbf{N}^\Delta_{c-2}$.

Step 3: the dual length lemma at $c-2$. With Σ_{c-2} from Proposition C.65 at $c-2$, let $P'_3 = \psi^{-1}\big((\pi_0\mathbf{N}^\Delta_{c-2} + Y_{c-2} + \sum_{\Sigma_{c-2}}\mathcal{O}_L y)/\pi_0\mathbf{N}^\Delta_{c-2}\big)$ and $P'_4 = \psi^{-1}\big((\pi_0\mathbf{N}^\Delta_{c-2} + Y_{c-2})/\pi_0\mathbf{N}^\Delta_{c-2}\big)$. As in Step 1, $\mathrm{nl}(P'_2/P'_3) \le \lambda$ and P'_3/P'_4 is generated by at most m elements. For $f \in P'_4$ choose $y_2 \in Y_{c-2}$ with $\mathrm{Cv}(y_2) = \alpha_2(f)$ ((F1)); by (F2), $\alpha_2(f) = \ell^{h''}\varphi(\mathrm{Cv}(y_3))$ with $y_3 \in \mathbf{N}^\Delta_{c-3}$. Put $\alpha_3(f) = \ell^{-h''}\varphi^{-1}(\alpha_2(f))$, $\mathcal{O}_L$-linear in f, so $\alpha_3(f) = \mathrm{Cv}(y_3)$ for some Δ-invariant $y_3 = y_3(f) \in \mathbf{N}_{c-3}$.

Step 4: the Hodge condition at τ_{c-1}. We have $\varphi^{-2}(\alpha_3(f)) \in \epsilon_{c-2}D = D_{\mathrm{dR},\tau_{c-1}}(V_2)$ ($\mathrm{Cv}(\mathbf{N}_{c-3}) \subseteq \epsilon_c D$). Let $\beta(f)$ be its class modulo $\epsilon_{c-2}\mathrm{Fil}^{s_{c-1}}D$ and $P'_5 = \ker\beta \cap P'_4$. The target has L-dimension the number of Hodge jumps of V_2 at τ_{c-1} below s_{c-1}, with multiplicity; these lie in $[-\eta,\eta]$ ($\epsilon_{c-1} = 1$, (Ow1) via Lemma 24.2 (1), $s_{c-1} > \eta$), so by (Ow2) the dimension is $\le m$. The quotient P'_4/P'_5 embeds in it, so it is torsion free of rank $\le m$, hence free and generated by at most m elements.

Step 5: lifting. Let $f \in P'_5$ and $y_3 = y_3(f)$. Then $\varphi^{-2}(\mathrm{Cv}(y_3)) \in \mathrm{Fil}^{s_{c-1}}D$. By Proposition C.72 at the up site $c-1$ there is a Δ-invariant $z \in \mathbf{N}(T_1)_{c-1}$ with $(1\otimes\Phi)\mathrm{Cv}(z) = \ell^{k'}\varphi^2(\mathrm{Cv}(y_3))$, $k' = E + \sigma_{\mathrm{G}} + h'' - s_{c-1}$. Put $x = \varsigma^M\varphi(z) \in \mathbf{N}(T_1)_c$ (Step 0): $(\gamma_u - 1)x \in X\mathbf{N}(T_1)$ by (Wm3), so $x \in I^1_c$, with $\lambda' = 1$. By (Cv4), (Cv5) ($\mathbf{N}(\Phi)$ commutes with φ),

$$\mathrm{Cv}(\mathbf{N}(\Phi)x) = \ell^M\varphi((1\otimes\Phi)\mathrm{Cv}(z)) = \ell^{M+k'}\varphi^3(\mathrm{Cv}(y_3)),$$
$$\ell^{b'}\mathrm{Cv}(w(f)) = \ell^M\varphi^2(\alpha_2(f)) = \ell^{M+h''}\varphi^3(\mathrm{Cv}(y_3)).$$

Since $b' + k' = e_6 + h''$, $\ell^{h''}\big(\ell^{e_6}\mathrm{Cv}(w(f)) - \mathrm{Cv}(\mathbf{N}(\Phi)x)\big) = 0$, so $\mathrm{Cv}(\ell^{e_6}w(f) - \mathbf{N}(\Phi)x) = 0$ and, by (Cv3), $\ell^{e_6}w(f) - \mathbf{N}(\Phi)(x) \in X\mathbf{N}(T_2)_c$.

Step 6: the chain and the exponent. The chain $P' = P'_0 \supseteq \cdots \supseteq P'_5$ with $k = 5$, $J = \{1,3,4\}$ ($|J| = 3$, $k - |J| = 2$) has the required properties. Finally, with $\ell \ge 11$, $a_{\mathrm{R}} = H'(2\ell-1)/(\ell-1)^2 + 4 + \log_\ell(2H')$, $(2\ell-1)/(\ell-1)^3 \le 2/(\ell-1)^2 \le 2.42/\ell^2$ and $\ell/(\ell-1) \le 1.1$:

$$e_6 \le \frac{3a_{\mathrm{R}} + S + 2\eta}{\ell-1} + \log_\ell(2H') + 1 + \frac{2H'}{(\ell-1)^2} + 2 + S \le \frac{10H'}{\ell^2} + 2S + \frac{2.2\eta}{\ell} + 2\log_\ell(2H') + 4.2 \le 10B,$$

so the statement holds with $c_{4,2} = 10$ and $e_6 \ge 0$. □

Lemma C.76. *Let ℓ be a prime, $\mathcal{O}$ the ring of integers of a finite extension of $\mathbb{Q}_\ell$, H an $\mathcal{O}$-module, $H' \subseteq H$ a submodule, P a free $\mathcal{O}$-module of finite rank r and $\psi\colon P \to H$ a surjective $\mathcal{O}$-linear map. Let $P = P_0 \supseteq P_1 \supseteq \cdots \supseteq P_k$ be submodules, $I \subseteq \{0, \dots, k-1\}$, $m \geq 0$ and $e, e' \geq 0$ integers and $\lambda \geq 0$ a real number such that*

(Fc1) *for $i \in I$ the module P_i/P_{i+1} is generated by at most m elements;*

(Fc2) *for $i \notin I$, $\mathrm{nl}(P_i/P_{i+1}) \leq \lambda$;*

(Fc3) *$\ell^e \psi(P_k) \subseteq H'$;*

(Fc4) *$\ell^{e'} H \subseteq H'$.*

Then H/H' has finite length and

$$\mathrm{nl}(H/H') \leq r\,e + |I|\,m\,e' + (k - |I|)\,\lambda.$$

Proof. Let $Q = H/H'$, $\rho\colon P \to Q$ the composite of ψ with the quotient map (surjective), and $Q_i = \rho(P_i)$, so that $Q = Q_0 \supseteq Q_1 \supseteq \cdots \supseteq Q_k$. For $i < k$, ρ induces a surjection $P_i/P_{i+1} \to Q_i/Q_{i+1}$, because $\rho(P_{i+1}) = Q_{i+1}$.

For $i \in I$, Q_i/Q_{i+1} is generated by at most m elements by (Fc1) and is killed by $\ell^{e'}$, since $\ell^{e'} Q = 0$ by (Fc4); so it is a quotient of $(\mathcal{O}/\ell^{e'})^m$ and has length at most $m\,e'\,e_{\mathcal{O}}$. For $i \notin I$, Q_i/Q_{i+1} is a quotient of P_i/P_{i+1}, so its length is at most $\lambda\,e_{\mathcal{O}}$ by (Fc2). Finally P_k is a submodule of the free module P of rank r over the principal ideal domain $\mathcal{O}$, hence free of rank at most r; so $Q_k = \rho(P_k)$ is generated by at most r elements, and it is killed by ℓ^e by (Fc3); it has length at most $r\,e\,e_{\mathcal{O}}$.

Lengths are additive along the finite filtration $Q = Q_0 \supseteq \cdots \supseteq Q_k \supseteq 0$, so Q has finite length at most $\big(r\,e + |I|\,m\,e' + (k - |I|)\lambda\big)e_{\mathcal{O}}$; divide by $e_{\mathcal{O}}$. □

C.3 Long Frobenius orbits with isolated thick clusters

This section proves Proposition C.77, item 3 of the row bound Proposition 26.2: on a long Frobenius orbit whose thick sites form isolated clusters, the colength carries $h/(\ell-1)^{j+1}$ in place of h/ℓ. It follows from the lifting exponent Proposition C.79, with no exceptional classes. The thick sites admit a cut configuration of order j, in which the j sites after each cut are thin and each arc contains at most two thick sites (Definition C.78, Lemma C.80), and the crystalline classes lift up to the arc exponent of the configuration (Proposition C.82), which is at most $80\big(h/(\ell-1)^{j+1} + g\,\mathrm{len}_{\max} + \log_\ell h\big)$ (Lemma C.81). The arc theorem is proved from arc level data (Proposition C.84, Proposition C.106, Proposition C.107): relay vectors are killed by polynomials in γ at the target and at the source of the arc, and the constants that remain at the down levels are lifted (Proposition C.85, Proposition C.94).

Proposition C.77. *There is an absolute constant $c_{\mathrm{A}} \geq 1$ with the following property. Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, L as in Definition 23.1, $(\tau_a)_{a \in \mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Let $j \geq 1$ be an integer with $j + 1 \leq n$ and $c_{\mathrm{A}}(j+1)(G+1) \leq b$, and suppose that every thick site a satisfies one of:*

- *none of $a-1, \dots, a-j$ is thick;*

- *there is $1 \le d \le j$ such that $a-d$ is thick and none of the sites $a-k$, $1 \le k \le d+j$, $k \ne d$, is thick.*

Then the colength of Φ is at most

$$c_{\mathrm{A}}\,(n+1)\,d_2\Big(\frac{h}{(\ell-1)^{j+1}} + (G+1)(j+1) + \log_\ell h\Big).$$

Proof. Let $c_{\mathrm{E}} \ge 1$ be the absolute constant of Proposition C.79; we show that $c_{\mathrm{A}} = c_{\mathrm{E}}$ has the property. Let the data be as in the statement, with $c_{\mathrm{A}}(j+1)(G+1) \le b$. Put $D = G_F$, $H = H^1_f(D, T_2)$ and $H_1 = \Phi_* H^1_f(D, T_1)$; the colength of Φ is $\mathrm{nl}(H/H_1)$.

(i) V_2 is crystalline, hence de Rham, so by Lemma 27.3 H is generated by at most $(n+1)d_2$ elements. (ii) The hypotheses are those of Proposition C.79, which gives an integer e with $0 \le e \le c_{\mathrm{E}}(h/(\ell-1)^{j+1} + (G+1)(j+1) + \log_\ell h)$ and $\ell^e H \subseteq H_1$. (iii) By Lemma 27.14 with $g = (n+1)d_2$, this e, $Z = \emptyset$ and $e' = 0$, H/H_1 has finite length and

$$\mathrm{nl}(H/H_1) \le (n+1)\,d_2\,e \le c_{\mathrm{A}}\,(n+1)\,d_2\Big(\frac{h}{(\ell-1)^{j+1}} + (G+1)(j+1) + \log_\ell h\Big).$$

□

Definition C.78. Let $n \ge 1$ and $j \ge 1$ be integers and $\Theta \subseteq \mathbb{Z}/n$ a set (the *thick* sites; the others are *thin*).

Cut configurations. A **cut configuration of order** j for Θ is a non-empty set $\mathcal{C} \subseteq \mathbb{Z}/n$ (the *cuts*) with integers len_c ($c \in \mathcal{C}$) such that, for every $c \in \mathcal{C}$:

(Cc1) the sites $c+1, \dots, c+j$ are thin;

(Cc2) $j \le \mathrm{len}_c \le n$, $c - \mathrm{len}_c \in \mathcal{C}$, and $c - k \notin \mathcal{C}$ for $1 \le k < \mathrm{len}_c$;

(Cc3) at most two of the sites $c, c-1, \dots, c-\mathrm{len}_c+1$ (the **arc** of c) are thick.

Its **maximal length** is $\mathrm{len}_{\max} = \max_{c\in\mathcal{C}} \mathrm{len}_c$.

The arc exponent. Let moreover $\ell \ge 3$ be a prime, $g, h \ge 1$ integers, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$ a function with maximum $H_{\max}$, and $(\mathcal{C}, (\mathrm{len}_c))$ a cut configuration of order j for some Θ. Put

$$\sigma_{\mathrm{E}} = \Big\lceil \Big(3g + \frac{\lfloor (h+2g)/(\ell-1)\rfloor + 1}{\ell^{j-1}}\Big)\frac{\ell}{(\ell-1)^2} + 1\Big\rceil, \qquad c_H = \lceil 1 + \log_\ell(H_{\max}+1)\rceil, \tag{C.8}$$

$$\rho_{\mathrm{E}} = \max_{c\in\mathcal{C}}\Big(\Big\lfloor \min(\lfloor s_c\rfloor, H_{\max})\frac{\ell}{(\ell-1)^2}\Big\rfloor + c_H\Big), \qquad s_c = \sum_{a\ge 0}\frac{H(c+a+1)+c_H+3}{(\ell-1)^a}, \tag{C.9}$$

(the series converges, H being bounded). Let $\mathcal{I}(g,h)$ be the set of integer intervals $\{i \in \mathbb{Z} :\ a \le i < a+k\}$ with $a \in \mathbb{Z}$, $-2h \le a$, $0 \le k \le 3g$ and $a + k \le 2h+1$, and put

$$\kappa_{\mathrm{E}} = \max_{I_1,I_2,I_3\in\mathcal{I}(g,h)}\Big(\mathrm{len}_{\max} + \sum_{i\in(I_1\cup I_2\cup I_3)\setminus\{0\}}\big(\mathrm{len}_{\max} + 1 + v_\ell(i)\big)\Big), \tag{C.10}$$

with v_ℓ the ℓ-adic valuation. The **initial exponent** and the **arc exponent** are

$$a_{\mathrm{E}} = 2\sigma_{\mathrm{E}} + \rho_{\mathrm{E}} + 2g\,\mathrm{len}_{\max}, \qquad e_{\mathrm{E}} = 2\rho_{\mathrm{E}} + 4\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + 2\kappa_{\mathrm{E}}; \tag{C.11}$$

they depend on $(\ell, j, g, h, H, \mathcal{C}, (\mathrm{len}_c))$.

Proposition C.79. *There is an absolute constant $c_{\mathrm{E}} \geq 1$ with the following property. Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D = G_F$, L as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Let $j \geq 1$ be an integer with $j+1 \leq n$ and $c_{\mathrm{E}}(j+1)(G+1) \leq b$, and suppose that every thick site a satisfies one of:*

- *none of $a-1, \dots, a-j$ is thick;*
- *there is $1 \leq d \leq j$ such that $a-d$ is thick and none of the sites $a-k$, $1 \leq k \leq d+j$, $k \neq d$, is thick.*

Then there is an integer e with

$$0 \leq e \leq c_{\mathrm{E}}\Big(\frac{h}{(\ell-1)^{j+1}} + (G+1)(j+1) + \log_\ell h\Big) \qquad \text{and} \qquad \ell^e\, H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1).$$

Proof. We show that $c_{\mathrm{E}} = 240$ has the property. Let the data be as in the statement with $240(j+1)(G+1) \leq b$; so $b \geq 480(G+1)$ and $w, S, \eta \leq G \leq b/480$. Let Θ be the set of thick sites, and g, h_*, H as in Proposition C.82.

A cut configuration with short arcs. The hypothesis on the thick sites is (Cl1)/(Cl2) of Lemma C.80, and $j+1 \leq n$; that lemma gives a cut configuration $(\mathcal{C}, (\mathrm{len}_c))$ of order j for Θ with $\mathrm{len}_{\max} \leq 3j+1$.

The numerical input. We have $1 \leq g \leq G+1$, and $1 \leq h_* \leq h$: if $\Theta \neq \emptyset$ then $h_* = b+\eta+S = h$, and otherwise $h_* = \max(G, 1) \leq G+1 = h$. Moreover $H \leq 2h_*$ everywhere ($G \leq h_*$: if $\Theta \neq \emptyset$ because $w \leq b$, otherwise because $G \leq g$), and for $c \in \mathcal{C}$, $1 \leq k \leq j$, the site $c+k$ is thin by (Cc1), so $H(c+k) = 2G \leq 2g$. Hence Lemma C.81 applies to $(\ell, n, j, g, h_*, H, \mathcal{C}, (\mathrm{len}_c))$: with $X_* = h_*/(\ell-1)^{j+1}$ and $\Lambda_* = \log_\ell h_*$,

$$a_{\mathrm{E}} \leq 5X_* + 2g\,\mathrm{len}_{\max} + g + 2\Lambda_* + 8, \qquad e_{\mathrm{E}} \leq 80(X_* + g\,\mathrm{len}_{\max} + \Lambda_*).$$

The hypotheses (Ae1), (Ae2) of Proposition C.82. (Ae1): a thick site has $s_a \geq b > G+1 \geq g$. (Ae2) concerns two thick sites, so we may assume $\Theta \neq \emptyset$; then $h_* = b+\eta+S \leq \frac{481}{480}b \leq 2b$, and all thick sizes lie in $[b, b+\eta] \subseteq [b, 2b]$. Hence for thick $c-s$, $c-t$: $s_{c-s} \leq 2b < 11b \leq \ell s_{c-t}$ and $2s_{c-s} \leq 4b \leq \ell s_{c-t}$. It remains to show $2a_{\mathrm{E}} < s_{c-t}$, for which $a_{\mathrm{E}} < b/2$ suffices. Now $5X_* \leq 5h_*/100 \leq \frac{5\cdot 481}{48000}b < 0.051\,b$; $2g\,\mathrm{len}_{\max} + g + 8 \leq 2(G+1)(3j+1) + 9(G+1) \leq (6+\frac{9}{2})(G+1)(j+1) \leq \frac{10.5}{240}b < 0.044\,b$ (using $j+1 \geq 2$); and $2\Lambda_* \leq 2\log_{11}(2b) \leq 0.1\,b$, because $b \geq 480$, the inequality holds at $b = 480$ and $0.1\,b - 2\log_{11}(2b)$ increases for $b \geq 480$. So $a_{\mathrm{E}} < 0.2\,b < b/2$.

Conclusion. By Proposition C.82, $\ell^e H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1)$ with $e = e_{\mathrm{E}}$, an integer ≥ 0 (all terms of (C.11) are non-negative). Since $X_* \leq h/(\ell-1)^{j+1}$, $\Lambda_* \leq \log_\ell h$ and $g\,\mathrm{len}_{\max} \leq (G+1)(3j+1) \leq 3(G+1)(j+1)$,

$$e \leq 80\Big(\frac{h}{(\ell-1)^{j+1}} + 3(G+1)(j+1) + \log_\ell h\Big) \leq 240\Big(\frac{h}{(\ell-1)^{j+1}} + (G+1)(j+1) + \log_\ell h\Big).$$

□

Lemma C.80. *Let $n, j \geq 1$ be integers with $j+1 \leq n$, and $\Theta \subseteq \mathbb{Z}/n$ a set such that every $t \in \Theta$ satisfies one of:*

(Cl1) *none of $t-1, \dots, t-j$ lies in Θ;*

(Cl2) *there is* $1 \le d \le j$ *with* $t - d \in \Theta$ *such that* $t - k \notin \Theta$ *for every* $1 \le k \le d + j$ *with* $k \ne d$.

Then Θ *has a cut configuration* $(\mathcal{C}, (\mathrm{len}_c))$ *of order* j *with* $\mathrm{len}_{\max} \le 3j + 1$.

Proof. Call $e \in \Theta$ an *end* if none of $e + 1, \dots, e + j$ lies in Θ. We use two elementary facts.

Splitting a length. Every integer $N \ge j$ is a sum of integers in $[j, 2j - 1]$: write $N = qj + r$ with $q \ge 1$, $0 \le r < j$, and take $q - 1$ parts j and one part $j + r$.

Every $t \in \Theta$ *has an end among* $t, t+1, \dots, t+j$. If none of $t+1, \dots, t+j$ is in Θ, t is an end. Otherwise pick $1 \le k \le j$ with $t + k \in \Theta$; we claim $t + k$ is an end. If not, $a = t + k + k' \in \Theta$ for some $1 \le k' \le j$. As $a - k' \in \Theta$ with $k' \le j$, (Cl1) fails for a, so (Cl2) holds for a with some d; if $d \ne k'$, then $1 \le k' \le d + j$ and $a - k' \in \Theta$ contradict (Cl2), so $d = k'$. But then $a - (k + k') = t \in \Theta$ with $1 \le k + k' \le d + j$ and $k + k' \ne d$, contradicting (Cl2).

Case 1: $\Theta = \emptyset$. (Cc1) and (Cc3) hold for every choice of cuts. If $n \le 3j + 1$, take $\mathcal{C} = \{0\}$, $\mathrm{len}_0 = n$: (Cc2) holds since $j < n$, $0 - n = 0$, and $-k \ne 0$ in $\mathbb{Z}/n$ for $1 \le k < n$. If $n > 3j + 1$, split $n = d_1 + \cdots + d_r$ with parts $d_i \in [j, 2j - 1]$ ($r \ge 2$), put $p_0 = 0$, $p_i = d_1 + \cdots + d_i$, $\mathcal{C} = \{p_i \bmod n : \ 0 \le i < r\}$ and $\mathrm{len}_{p_i} = d_i$ for $1 \le i \le r$ (where $p_r \equiv p_0$). The p_i, $0 \le i < r$, are distinct modulo n since $0 \le p_i < n$; between p_{i-1} and p_i there is no other cut, so (Cc2) holds, and $\mathrm{len}_{\max} \le 2j - 1$.

Case 2: $\Theta \ne \emptyset$. By the fact above there is an end. List the ends as integers $e_1 < e_2 < \cdots < e_q$ with $e_q - e_1 < n$ (representatives of their classes along one turn of the cycle) and put $e_{q+1} = e_1 + n$; the gaps $\gamma_i = e_{i+1} - e_i$ satisfy $\gamma_i \ge 1$ and $\sum_i \gamma_i = n$. For each i consider the integer interval $(e_i, e_{i+1}]$, whose last point is an end and which contains no other end.

- *Thick sites of* $(e_i, e_{i+1}]$ *lie in* $[e_{i+1} - j, e_{i+1}]$*, and there are at most two.* Let $t \in (e_i, e_{i+1}]$ be (the class of) a thick site. By the fact above some $t + k$, $0 \le k \le j$, is an end; as $t + k > e_i$ and e_{i+1} is the first end after e_i, $t + k \ge e_{i+1}$, so $t \ge e_{i+1} - j$. If $t_1 < t_2 < t_3$ were thick sites in $[e_{i+1} - j, e_{i+1}]$, then for $a = t_3$ the site $a - (t_3 - t_2)$ is thick with $t_3 - t_2 \le j$, so (Cl2) holds with $d = t_3 - t_2$ (as in the proof of the fact above), and $a - (t_3 - t_1) = t_1$ is thick with $t_3 - t_1 \le j \le d + j$, $t_3 - t_1 \ne d$: a contradiction.

- $\gamma_i \ge j + 1$. The site e_{i+1} is thick, and $e_i + 1, \dots, e_i + j$ are thin since e_i is an end; so $e_{i+1} \notin \{e_i + 1, \dots, e_i + j\}$ (as classes), and $e_{i+1} > e_i$ gives $e_{i+1} \ge e_i + j + 1$.

Now place cuts in each interval $(e_i, e_{i+1}]$. If $\gamma_i \le 3j+1$, the only cut in it is e_{i+1}, with $\mathrm{len}_{e_{i+1}} = \gamma_i$. If $\gamma_i > 3j + 1$, then $\gamma_i - 2j - 1 \ge j$; split $\gamma_i - 2j - 1 = d_1 + \cdots + d_r$ with parts in $[j, 2j - 1]$ and take the cuts $p_k = e_i + d_1 + \cdots + d_k$ ($1 \le k \le r$, so $p_r = e_{i+1} - 2j - 1$) and e_{i+1}, with $\mathrm{len}_{p_k} = d_k$ and $\mathrm{len}_{e_{i+1}} = 2j + 1$. Let $\mathcal{C}$ be the set of classes of all cuts so placed; it contains the ends, so it is non-empty. The cuts, taken over one turn $e_1 < \cdots \le e_{q+1}$, are strictly increasing integers in $(e_1, e_1 + n]$, hence distinct modulo n, and len_c is the distance from c back to the preceding cut. So:

- (Cc2): $\mathrm{len}_c \ge j$ (parts are $\ge j$, $\gamma_i \ge j+1$, $2j+1 \ge j$), $\mathrm{len}_c \le \gamma_i \le n$, $c - \mathrm{len}_c$ is the preceding cut, and no cut lies strictly between; moreover $\mathrm{len}_c \le \max(3j + 1, 2j - 1, 2j + 1) = 3j + 1$.

- (Cc1): for an end e_{i+1} by definition of an end. For an inner cut $p_k \le e_{i+1} - 2j - 1$ of $(e_i, e_{i+1}]$, the sites $p_k + 1, \dots, p_k + j$ lie in $(e_i, e_{i+1} - j - 1]$, which contains no thick site by the first item.

- (Cc3): the arc of a cut c is the interval $(c - \mathrm{len}_c, c]$, contained in some $(e_i, e_{i+1}]$; it contains at most the (at most two) thick sites of that interval.

□

Lemma C.81. *Let $\ell \geq 11$ be a prime, $n, j, g, h \geq 1$ integers, $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$ with $H(a) \leq 2h$ for all a, and $(\mathcal{C}, (\mathrm{len}_c))$ a cut configuration of order j for some $\Theta \subseteq \mathbb{Z}/n$ such that $H(c+k) \leq 2g$ for all $c \in \mathcal{C}$ and $1 \leq k \leq j$. Put $X = h/(\ell-1)^{j+1}$ and $\Lambda = \log_\ell h$. Then*

$$a_{\mathrm{E}} \leq 5X + 2g\,\mathrm{len}_{\max} + g + 2\Lambda + 8 \qquad \text{and} \qquad e_{\mathrm{E}} \leq 80(X + g\,\mathrm{len}_{\max} + \Lambda).$$

Proof. We use repeatedly that $x \mapsto x/(x-1)^2$, $x \mapsto x/((x-1)(x-2))$ and $x \mapsto x/(x-2)$ decrease on $(2,\infty)$, so for $\ell \geq 11$: $\ell/(\ell-1)^2 \leq \frac{11}{100}$, $\ell/((\ell-1)(\ell-2)) \leq \frac{11}{90}$, $\ell/(\ell-2) \leq \frac{11}{9}$, $(\ell-1)^{j+1} \geq 100$; and $\log_\ell 2 \leq \log_{11} 2 < 0.29$, $\log_\ell 3 < 0.46$. Also $\Lambda \geq 0$ as $h \geq 1$, and $\mathrm{len}_{\max} \geq j \geq 1$ by (Cc2).

The relay exponent: $\sigma_{\mathrm{E}} \leq \frac{11}{10}X + \frac{36}{100}g + \frac{211}{100}$. Let $M = \lfloor (h+2g)/(\ell-1) \rfloor + 1 \leq (h+2g)/(\ell-1) + 1$. Then $3g\,\ell/(\ell-1)^2 \leq \frac{33}{100}g$, and

$$\frac{M\,\ell}{\ell^{j-1}(\ell-1)^2} \leq \frac{(h+2g)\,\ell^{2-j}}{(\ell-1)^3} + \frac{\ell^{2-j}}{(\ell-1)^2} = \frac{h+2g}{(\ell-1)^{j+1}}\Big(\frac{\ell}{\ell-1}\Big)^{2-j} + \frac{\ell^{2-j}}{(\ell-1)^2} \leq \frac{11}{10}\cdot\frac{h+2g}{(\ell-1)^{j+1}} + \frac{11}{100},$$

since $(\ell/(\ell-1))^{2-j} \leq \ell/(\ell-1) \leq \frac{11}{10}$ for $j \geq 1$ and $\ell^{2-j} \leq \ell$. With $2g/(\ell-1)^{j+1} \leq \frac{2}{100}g$ and $\lceil y \rceil < y+1$, (C.8) gives $\sigma_{\mathrm{E}} < \frac{33}{100}g + \frac{11}{10}X + \frac{22}{1000}g + \frac{11}{100} + 2$, which implies the claim.

The remainder exponent: $\rho_{\mathrm{E}} \leq \frac{245}{100}X + \frac{245}{1000}g + \frac{113}{100}\Lambda + \frac{313}{100}$. Since $H_{\max} \leq 2h$ and $2h+1 \leq 3h$, $c_H \leq 2 + \log_\ell(3h) \leq \frac{246}{100} + \Lambda$. Fix $c \in \mathcal{C}$. For $0 \leq a \leq j-1$ the site $c+a+1 = c+k$ has $1 \leq k \leq j$, so $H(c+a+1) \leq 2g$; for $a \geq j$, $H(c+a+1) \leq 2h$. Hence

$$s_c \leq (2g + c_H + 3)\sum_{a \geq 0}(\ell-1)^{-a} + 2h\sum_{a \geq j}(\ell-1)^{-a} = (2g + c_H + 3)\frac{\ell-1}{\ell-2} + \frac{2h}{(\ell-1)^{j-1}(\ell-2)}.$$

As $0 \leq \min(\lfloor s_c \rfloor, H_{\max}) \leq s_c$, the term of (C.9) at c is at most

$$s_c\frac{\ell}{(\ell-1)^2} + c_H \leq (2g + c_H + 3)\frac{\ell}{(\ell-1)(\ell-2)} + 2X\frac{\ell}{\ell-2} + c_H \leq \frac{22}{90}g + \frac{101}{90}c_H + \frac{33}{90} + \frac{22}{9}X.$$

Inserting the bound for c_H gives the claim.

The killer exponent: $\kappa_{\mathrm{E}} \leq \mathrm{len}_{\max} + 9g\,\mathrm{len}_{\max} + \frac{99}{10}g + 3\Lambda + \frac{87}{100}$. Let $I_1, I_2, I_3 \in \mathcal{I}(g,h)$ and $J^* = (I_1 \cup I_2 \cup I_3) \setminus \{0\}$. Each I_t has at most $3g$ elements, all in $[-2h, 2h]$ (as $a \geq -2h$ and $a + k \leq 2h+1$), so $|J^*| \leq 9g$. For one $I = I_t$ with $k \leq 3g$ elements: a non-zero i with $\ell^u \mid i$ has $\ell^u \leq |i| \leq 2h$, so only $1 \leq u \leq U = \lfloor \log_\ell(2h) \rfloor$ contribute to

$$\sum_{i \in I \setminus 0} v_\ell(i) = \sum_{u \geq 1} \#\{i \in I \setminus 0 :\ \ell^u \mid i\} \leq \sum_{u=1}^{U}\Big(\frac{k}{\ell^u} + 1\Big) \leq \frac{k}{\ell-1} + \log_\ell(2h) \leq \frac{3g}{10} + \frac{29}{100} + \Lambda,$$

a set of k consecutive integers containing at most $k/\ell^u + 1$ multiples of ℓ^u. As $v_\ell \geq 0$, $\sum_{i \in J^*} v_\ell(i) \leq \frac{9}{10}g + \frac{87}{100} + 3\Lambda$, and the bracket in (C.10) is at most $\mathrm{len}_{\max} + 9g(\mathrm{len}_{\max}+1) + \frac{9}{10}g + \frac{87}{100} + 3\Lambda$.

Assembly. By (C.11),

$$a_{\mathrm{E}} = 2\sigma_{\mathrm{E}} + \rho_{\mathrm{E}} + 2g\,\mathrm{len}_{\max} \leq \frac{465}{100}X + \frac{965}{1000}g + \frac{113}{100}\Lambda + \frac{735}{100} + 2g\,\mathrm{len}_{\max},$$

which gives the first bound. Then $e_{\mathrm{E}} = 2\rho_{\mathrm{E}} + 4\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + 2\kappa_{\mathrm{E}}$ is at most

$$\frac{186}{10}X + 22\,g\,\mathrm{len}_{\max} + 2\,\mathrm{len}_{\max} + \frac{2366}{100}g + \frac{1052}{100}\Lambda + \frac{3114}{100}.$$

Since $g, \mathrm{len}_{\max} \geq 1$, the terms $2\,\mathrm{len}_{\max}$, $23.66\,g$ and 31.14 are at most $(2 + 23.66 + 31.14)\,g\,\mathrm{len}_{\max}$, so $e_{\mathrm{E}} \leq 18.6X + 78.8\,g\,\mathrm{len}_{\max} + 10.52\Lambda \leq 80(X + g\,\mathrm{len}_{\max} + \Lambda)$. □

Proposition C.82. *Let $\ell \geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D = G_F$, L with ring of integers $\mathcal{O}_L$ as in Definition 23.1, $(\tau_a)_{a\in\mathbb{Z}/n}$ a Frobenius numbering, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Let $\Theta \subseteq \mathbb{Z}/n$ be the set of thick sites, $G = w+S+\eta$, $g = \max(G, 1)$, $h_* = b+\eta+S$ if $\Theta \neq \emptyset$ and $h_* = g$ otherwise, and $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$, $H(a) = 2h_*$ for $a \in \Theta$ and $H(a) = 2G$ for $a \notin \Theta$. Let $j \geq 1$ and let $(\mathcal{C}, (\mathrm{len}_c))$ be a cut configuration of order j for Θ; form a_{E} and e_{E} with $(\ell, j, g, h_*, H, \mathcal{C}, (\mathrm{len}_c))$. Suppose:*

(Ae1) *$s_a > g$ for every $a \in \Theta$;*

(Ae2) *for every $c \in \mathcal{C}$ and all integers $0 \leq s < t < \mathrm{len}_c$ with $c-s, c-t \in \Theta$: if $\epsilon_{c-t} = -1$ and $\epsilon_{c-s} = 1$, then $s_{c-s} < \ell\, s_{c-t}$; if $\epsilon_{c-t} = 1$ and $\epsilon_{c-s} = -1$, then $2s_{c-s} \leq \ell\, s_{c-t}$ and $2a_{\mathrm{E}} < s_{c-t}$.*

Then

$$\ell^{\,e_{\mathrm{E}}} H^1_f(D, T_2) \subseteq \Phi_* H^1_f(D, T_1).$$

Proof. We enlarge the coefficients and descend. Fix an algebraic closure of L, a primitive ℓ^n-th root of unity ζ in it, and put $L' = L(\zeta)$, with ring of integers $\mathcal{O}_{L'}$. As a finitely generated torsion-free module over the discrete valuation ring $\mathcal{O}_L$, $\mathcal{O}_{L'}$ is free; fix a basis $\beta_1, \dots, \beta_d$, $d = [L' : L]$; it is also an L-basis of L'.

Step 1: the enlarged data. $L' \supseteq L$ contains $\sigma(F(\mu_\ell))$ for every embedding σ, so L' is admissible in Definition 23.1; every $\mathbb{Q}_\ell$-embedding of F into L' lands in L, so $\tau'_a = \iota \circ \tau_a$ ($\iota\colon L \subseteq L'$) is a Frobenius numbering for L'. Put $V'_\nu = V_\nu \otimes_L L'$, $T'_\nu = T_\nu \otimes_{\mathcal{O}_L} \mathcal{O}_{L'}$ and $\Phi' = \Phi \otimes \mathrm{id}$, with D acting on the first factor. The maps

$$\theta_V\colon V_\nu^{\oplus d} \to V'_\nu, \quad (x_i)_i \mapsto \sum_i x_i \otimes \beta_i, \qquad \theta_T\colon T_\nu^{\oplus d} \to T'_\nu,$$

are D-equivariant isomorphisms of L-spaces, respectively $\mathcal{O}_L$-modules, compatible with $T_\nu \subseteq V_\nu$ and with $\Phi^{\oplus d}$ and Φ'. Hence V'_ν is crystalline as a $\mathbb{Q}_\ell$-representation (a direct sum of crystalline ones), T'_ν is a D-stable $\mathcal{O}_{L'}$-lattice in V'_ν, and $\Phi'(T'_1) = \Phi(T_1) \otimes \mathcal{O}_{L'} = T'_2$: Φ' is an onto map of crystalline lattices over F with coefficients L'.

Step 2: the weight word is unchanged. Since L' is a free L-module of finite rank with trivial D-action, taking D-invariants commutes with $- \otimes_L L'$, so $D_{\mathrm{dR}}(V'_\nu) = D_{\mathrm{dR}}(V_\nu) \otimes_L L'$ with $\mathrm{Fil}^i D_{\mathrm{dR}}(V'_\nu) = \mathrm{Fil}^i D_{\mathrm{dR}}(V_\nu) \otimes_L L'$; the idempotent of $F \otimes_{\mathbb{Q}_\ell} L'$ belonging to τ'_a is the image of the idempotent of $F \otimes_{\mathbb{Q}_\ell} L$ belonging to τ_a. Therefore $D_{\mathrm{dR},\tau'_a}(V'_\nu) = D_{\mathrm{dR},\tau_a}(V_\nu) \otimes_L L'$ as filtered spaces, and

$$\dim_{L'}(\mathrm{Fil}^i/\mathrm{Fil}^{i+1}) D_{\mathrm{dR},\tau'_a}(V'_\nu) = \dim_L(\mathrm{Fil}^i/\mathrm{Fil}^{i+1}) D_{\mathrm{dR},\tau_a}(V_\nu) \qquad (i \in \mathbb{Z}).$$

So V'_ν has at τ'_a exactly the Hodge jumps of V_ν at τ_a, with the same graded dimensions, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ is a weight word for Φ' with respect to (τ'_a): (Ow1) and (Ow2) transfer by the display, (Ow3) involves only the sizes. The thick sites, G, g, h_*, H, the cut configuration, a_{E}, e_{E}, (Ae1) and (Ae2) depend only on ℓ, n, the weight word, j and $(\mathcal{C}, (\mathrm{len}_c))$, and are the same for Φ'. Since $\zeta \in L'$, Proposition C.83 applies to Φ':

$$\ell^{\,e_{\mathrm{E}}} H^1_f(D, T'_2) \subseteq \Phi'_* H^1_f(D, T'_1).$$

Step 3: descent. Continuous cohomology commutes with finite direct sums, and $H^1_f(D, -)$ of Definition 22.2 is additive in the representation (it is the kernel of the map to $H^1(D, B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} -)$,

both functors being additive). Hence θ_V and θ_T induce isomorphisms $H^1(D,T_\nu)^{\oplus d}\cong H^1(D,T'_\nu)$ and $H^1(D,V_\nu)^{\oplus d}\cong H^1(D,V'_\nu)$ compatible with the maps from lattice to space, which carry $H^1_f(D,V_\nu)^{\oplus d}$ onto $H^1_f(D,V'_\nu)$; taking inverse images, $H^1_f(D,T_\nu)^{\oplus d}\cong H^1_f(D,T'_\nu)$, and under these isomorphisms Φ'_* is $(\Phi_*)^{\oplus d}$. Let $x\in H^1_f(D,T_2)$ and let $x'\in H^1_f(D,T'_2)$ correspond to $(x,0,\dots,0)$. By Step 2 there is $y'\in H^1_f(D,T'_1)$ with $\ell^{e_{\mathrm{E}}}x'=\Phi'_*(y')$; writing y' as $(y_1,\dots,y_d)$ with $y_i\in H^1_f(D,T_1)$ and comparing first components gives $\ell^{e_{\mathrm{E}}}x=\Phi_*(y_1)\in\Phi_*H^1_f(D,T_1)$. □

Proposition C.83. *Let $\ell\geq 11$ be a prime, F a finite unramified extension of $\mathbb{Q}_\ell$ of degree n, $D=G_F$, L with ring of integers $\mathcal{O}_L$ as in Definition 23.1, and suppose moreover that L contains a primitive ℓ^n-th root of unity. Let $(\tau_a)_{a\in\mathbb{Z}/n}$ be a Frobenius numbering, $\Phi\colon V_1\to V_2$ an onto map of crystalline lattices $T_1\to T_2$ over F with coefficients L, and $(b,w,S,\eta,m,(s_a),(\epsilon_a))$ a weight word for Φ. Let $\Theta\subseteq\mathbb{Z}/n$ be the set of thick sites, $G=w+S+\eta$, $g=\max(G,1)$, $h_*=b+\eta+S$ if $\Theta\neq\emptyset$ and $h_*=g$ otherwise, and $H\colon\mathbb{Z}/n\to\mathbb{Z}_{\geq 0}$, $H(a)=2h_*$ for $a\in\Theta$ and $H(a)=2G$ for $a\notin\Theta$. Let $j\geq 1$ and let $(\mathcal{C},(\mathrm{len}_c))$ be a cut configuration of order j for Θ; form a_{E} and e_{E} with $(\ell,j,g,h_*,H,\mathcal{C},(\mathrm{len}_c))$. Suppose:*

(Ae1) *$s_a>g$ for every $a\in\Theta$;*

(Ae2) *for every $c\in\mathcal{C}$ and all integers $0\leq s<t<\mathrm{len}_c$ with $c-s,c-t\in\Theta$: if $\epsilon_{c-t}=-1$ and $\epsilon_{c-s}=1$, then $s_{c-s}<\ell\, s_{c-t}$; if $\epsilon_{c-t}=1$ and $\epsilon_{c-s}=-1$, then $2s_{c-s}\leq\ell\, s_{c-t}$ and $2a_{\mathrm{E}}<s_{c-t}$.*

Then

$$\ell^{\,e_{\mathrm{E}}}H^1_f(D,T_2)\subseteq\Phi_*H^1_f(D,T_1).$$

Proof. We verify the hypothesis (Ae3) of Proposition C.84; its other hypotheses are those of the statement, and its conclusion is the claim.

Let $c\in\mathcal{C}$ and $\nu\in\{1,2\}$. The representation V_ν has finitely many Hodge jumps at each τ_a, so there are integers $M_a,h_a\geq 0$ with all of them in $[-M_a,h_a]$; by (Ex1), $\mathbf{N}(T_\nu)$ is a Wach module with window $(M_a,h_a)_a$, and by (Wm1) its site component at $c-\mathrm{len}_c$ is free over $e_{c-\mathrm{len}_c}\mathbf{A}_{F,L}$; a basis is a frame $\mathbf{n}^\nu$ at $c-\mathrm{len}_c$. By (Cc2), $1\leq j\leq\mathrm{len}_c\leq n$. Moreover $h_*\geq g$: if no site is thick, $h_*=g$; otherwise, for a thick site a, (Ow3) and (Ae1) give $h_*=b+\eta+S\geq s_a>g$. Hence Proposition C.107 (for the odd prime ℓ, the weight word, the cut c, the length len_c and j) applies to the frames $\mathbf{n}^1$, $\mathbf{n}^2$: the arc level data of Φ along the word at c have the arc level properties (Lp1)–(Lp8), (Lh1)–(Lh2). This is (Ae3), and Proposition C.84 gives $\ell^{e_{\mathrm{E}}}H^1_f(D,T_2)\subseteq\Phi_*H^1_f(D,T_1)$. □

Proposition C.84. *Let $\ell\geq 11$, F, n, $D=G_F$, L, $(\tau_a)_{a\in\mathbb{Z}/n}$, $\Phi\colon V_1\to V_2$ ($T_1\to T_2$), the weight word $(b,w,S,\eta,m,(s_a),(\epsilon_a))$, Θ, G, g, h_*, H, j, the cut configuration $(\mathcal{C},(\mathrm{len}_c))$, a_{E}, e_{E} and the hypotheses (Ae1), (Ae2) be as in Proposition C.83 (in particular L contains a primitive ℓ^n-th root of unity). Suppose moreover:*

(Ae3) *for every $c\in\mathcal{C}$ there are frames at $c-\mathrm{len}_c$ of $\mathbf{N}(T_1)$ and $\mathbf{N}(T_2)$ for which the arc level data of Φ along the word at the cut c of length len_c (with this j) have the arc level properties (Lp1)–(Lp8), (Lh1)–(Lh2).*

Then

$$\ell^{\,e_{\mathrm{E}}}H^1_f(D,T_2)\subseteq\Phi_*H^1_f(D,T_1).$$

Proof. We verify the hypothesis (Ae4) of Proposition C.106, whose other hypotheses are those of the statement and whose conclusion is the claim. Let $c \in \mathcal{C}$. By (Ae3) there are frames at $c - \mathrm{len}_c$ for which the arc level data of Φ along the word at the cut c of length len_c have the arc level properties. Their arc domains are the sets W_ν^c of Proposition C.106: both are defined by $\Lambda_{c,\mathrm{len}_c}(H_c)\, w \in P_{\mathrm{len}_c}(\mathbf{N}(T_\nu)_{c-\mathrm{len}_c})$ with the same function H_c of the word, and do not depend on the frames. Hence Proposition C.85 at c gives the statement of (Ae4) at c. As c was arbitrary, (Ae4) holds and Proposition C.106 gives $\ell^{e_{\mathrm{E}}} H_f^1(D, T_2) \subseteq \Phi_* H_f^1(D, T_1)$. □

Proposition C.85. *Let $\ell \geq 11$, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, a_{E} and the hypotheses (Ae1), (Ae2) be as in Proposition C.83, and form $\sigma_{\mathrm{E}}, \rho_{\mathrm{E}}, \kappa_{\mathrm{E}}$ with the same data. Let $c \in \mathcal{C}$ and suppose that for some frames at $c - \mathrm{len}_c$ the arc level data of Φ along the word at the cut c of length len_c have the arc level properties. Let W_ν ($\nu = 1, 2$) be their arc domains and*

$$I_c(T_\nu) = \{w \in e_c \mathbf{N}(T_\nu)[1/\lambda_\infty] :\ (\gamma_u - 1)(w) \in X\mathbf{N}(T_\nu) \text{ for all } u \in \mathbb{Z}_\ell^\times\}.$$

Then for every $w \in W_2 \cap I_c(T_2)$ there are $w' \in W_1 \cap I_c(T_1)$, $\epsilon \in \mathcal{O}_L^\times$ and an integer $0 \leq k \leq 2\kappa_{\mathrm{E}}$ with

$$\mathbf{N}(\Phi)(w') - \epsilon\, \ell^{\,2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}} + k}\, w \in X\, \mathbf{N}(T_2)_c.$$

Proof. Write $\mathrm{len} = \mathrm{len}_c$, $\gamma = \gamma_{u_0}$, $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$, $e_1 = 2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}}$, and let κ_s, $b_s = s_{c-s}$, $H(c-s)$ be the kinds, sizes and heights of the arc level data along the word.

Step 0: windows and parameters. Let $(M_a, h_a) = (\eta, \max(s_a + S, \eta))$ if $\epsilon_a = 1$ and $(\max(s_a + S, \eta), \eta)$ if $\epsilon_a = -1$. By (Ae1), Lemma C.102 applies: by its item 1 this is a window of V_1 and of V_2; by its items 2 and 3, $h_* \geq g$, $G, S, \eta \leq g$ ($g = \max(G, 1)$, $G = w + S + \eta$), and $b_s = s_{c-s} > g$ for every thick $c - s$. Moreover $h_{c-s} \leq H(c-s)$ for $s < \mathrm{len}$: the height $H(c-s)$ is $g + G$, $g + s_{c-s} + S$ or $g + \eta$ at a thin site, a thick site with $\epsilon_{c-s} = 1$ or a thick site with $\epsilon_{c-s} = -1$, and there h_{c-s} is at most G, equal to $s_{c-s} + S$, or equal to η (item 2). Put $E = \mathrm{len}_{\max} - 1 \geq \mathrm{len} - 1$.

Step 1: the killing sets and their valuations. Let J_2 be the set of i with $\mathrm{Nb}_s(i + g) \neq \mathrm{Nb}_s(i)$ for some $s < \mathrm{len}$, and J_1 the set of i with $\mathrm{Fil}_s^1(-i - g) \neq \mathrm{Fil}_s^1(-i)$ for some $s < \mathrm{len}$. From the kind families: a thin s contributes $[-g, -1]$, an up s contributes $[-b_s - g, -b_s - 1] \cup [-g, -1]$, a down s contributes $[-g, -1] \cup [b_s - g, b_s - 1]$. From (Lp7) for T_1 (Fil_s^1 decreasing): $\mathrm{Fil}_s^1(-i-g) \neq \mathrm{Fil}_s^1(-i)$ if and only if some jump u satisfies $-i - g \leq u \leq -i - 1$, i.e. $i \in [-u - g, -u - 1]$; jumps with $|u| \leq G$ (thin sites, and the parts $[-\eta, \eta]$, $\eta \leq G$) give subsets of $[-G - g, G - 1]$, an up site gives $[-b_s - S - g, -b_s - 1]$, a down site $[b_s - g, b_s + S - 1]$. By (Cc3) at most two sites of the arc are thick. Hence each of J_1, J_2 lies in a union $I_1 \cup I_2 \cup I_3$ of three intervals of $\mathcal{I}(g, h_*)$: the intervals above have at most $3g$ elements ($S \leq g$, $G \leq g$), start at $\geq -2h_*$ and end at $\leq 2h_*$ (for $[-G - g, G - 1]$ use $G \leq g \leq h_*$), because $b_s + S + g \leq h_* + g \leq 2h_*$ for thick s ($b_s \leq b + \eta$, $h_* = b + \eta + S$ when $\Theta \neq \emptyset$). Put $P = P_{J_2,E}$, $P' = P_{J_1,E}$. Since $u_0 \in 1 + \ell\mathbb{Z}_\ell$ with $v_\ell(u_0 - 1) = 1$ and ℓ is odd, $v_\ell(1 - u_0^m) = 1 + v_\ell(m)$ for $m \neq 0$; with $P_{J,E}(1) = \ell^E \prod_{i \in J \setminus 0}(1 - u_0^{i\ell^E})$,

$$v_\ell(P_{J,E}(1)) = E + \sum_{i \in J \setminus \{0\}} \big(1 + E + v_\ell(i)\big) \leq \mathrm{len}_{\max} + \sum_{i \in (I_1 \cup I_2 \cup I_3) \setminus \{0\}} \big(\mathrm{len}_{\max} + 1 + v_\ell(i)\big) \leq \kappa_{\mathrm{E}}.$$

Hence $P(1)P'(1) = \epsilon \ell^k$ with $\epsilon \in \mathbb{Z}_\ell^\times$ and $0 \leq k \leq 2\kappa_{\mathrm{E}}$.

Step 2: Δ-averaging. Let $w \in W_2 \cap I_c(T_2)$ and $\bar{w} = (\ell - 1)^{-1} \sum_{\delta \in \mu_{\ell-1}} \gamma_\delta(w)$. By (Lp2), $\bar{w} \in W_2$; $\gamma_\delta \bar{w} = \bar{w}$; $(\gamma_u - 1)\bar{w} = (\ell - 1)^{-1} \sum_\delta \gamma_\delta(\gamma_u - 1)w \in X\mathbf{N}_2$ (as $\gamma_\delta(X\mathbf{N}_2) \subseteq X\mathbf{N}_2$); and $\bar{w} - w = (\ell - 1)^{-1} \sum_\delta (\gamma_\delta - 1)w \in e_c X\mathbf{N}_2 = X\mathbf{N}_{2,c}$.

Step 3: killing at the target. Lemma C.86 for T_2 (window of Step 0, g, E, J_2) applied to $\bar{w}$ gives $x' = P(\gamma)\bar{w} \in W_2$, Δ-invariant, with $(\gamma_u - 1)x' \in X\mathbf{N}_2$ for all u, $x' - P(1)\bar{w} \in X\mathbf{N}_{2,c}$, and $\mathrm{lv}_s^{(2)}(x') \in L^{r_2} + \{\text{kind integral}\}$ for all $s < \mathrm{len}$.

Step 4: lifting to the source. Proposition C.92 gives $z \in W_1$ with $\mathbf{N}(\Phi)z = \ell^{e_1}x'$ and $v_s \in L^{r_1}$ with $\lambda_s(Q_s)^g(\mathrm{lv}_s^{(1)}(z) - v_s)$ de Rham integral. Replace z by $\bar{z} = (\ell-1)^{-1}\sum_\delta \gamma_\delta(z) \in W_1$: since $\mathbf{N}(\Phi)$ commutes with the γ_δ and x' is Δ-invariant, $\mathbf{N}(\Phi)\bar{z} = \ell^{e_1}x'$; by (Lp2), $\mathrm{lv}_s^{(1)}(\bar{z}) - v_s = (\ell-1)^{-1}\sum_\delta \gamma_\delta^{(s)}(\mathrm{lv}_s^{(1)}(z) - v_s)$, and $\gamma_\delta^{(s)}(\lambda_s(Q_s)^g f) = \lambda_s(\gamma_\delta Q_s)^g \gamma_\delta^{(s)}(f)$ with $\gamma_\delta(Q_s) = Q_s \cdot (\text{unit of } \mathbb{Z}_\ell[[X]])$ (Lemma 23.8), and $\gamma_\delta^{(s)}$ and multiplication by units of $K_{(s)}[[t]]$ preserve de Rham integrality (the de Rham family is increasing). Hence $\lambda_s(Q_s)^g\gamma_\delta^{(s)}(f) = \lambda_s(\text{unit})^{-g}\gamma_\delta^{(s)}(\lambda_s(Q_s)^g f)$ is de Rham integral for $f = \mathrm{lv}_s^{(1)}(z) - v_s$, using (Lp1) ($\lambda_s$ of a unit of $e_c\mathbf{A}_{F,L}$ is a unit of $K_{(s)}[[t]]$). So $\bar{z}$ has the same properties and is Δ-invariant.

Step 5: killing at the source. Item 2 of Lemma C.91 for T_1 (g, E, J_1) gives $w' = P'(\gamma)\bar{z} \in W_1$ with $(\gamma_u - 1)w' \in X\mathbf{N}_{1,c}$ for all u; as $w' \in W_1 \subseteq e_c\mathbf{N}_1[1/\lambda_\infty]$, $w' \in W_1 \cap I_c(T_1)$.

Step 6: the congruence. $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear and commutes with γ, so $\mathbf{N}(\Phi)w' = \ell^{e_1}P'(\gamma)x'$. Since $(\gamma-1)x' \in X\mathbf{N}_2$, $P'(\gamma)x' - P'(1)x' \in X\mathbf{N}_{2,c}$: write $P' = \sum_k p'_k Y^k$ with $p'_k \in \mathbb{Z}_\ell$ ($P' = P_{J_1,E}$ and $u_0 \in \mathbb{Z}_\ell$); since $\gamma(X) \in X\mathbf{A}_{F,L}$, $\gamma(X\mathbf{N}_2) \subseteq X\mathbf{N}_2$, so $(\gamma^k - 1)x' = \sum_{m<k}\gamma^m(\gamma - 1)x' \in X\mathbf{N}_2$ and $P'(\gamma)x' - P'(1)x' = \sum_k p'_k(\gamma^k - 1)x' \in X\mathbf{N}_2$; as $x' \in W_2 \subseteq e_c\mathbf{N}_2[1/\lambda_\infty]$, this difference lies in $e_cX\mathbf{N}_2 = X\mathbf{N}_{2,c}$. With Steps 2 and 3,

$$\begin{aligned}\mathbf{N}(\Phi)w' - \ell^{e_1}P'(1)P(1)\,w \\ = \ell^{e_1}\left[(P'(\gamma)x' - P'(1)x') + P'(1)(x' - P(1)\bar{w}) + P'(1)P(1)(\bar{w} - w)\right] \in X\mathbf{N}_{2,c},\end{aligned}$$

and $P'(1)P(1) = \epsilon\ell^k$ with $\epsilon \in \mathbb{Z}_\ell^\times \subseteq \mathcal{O}_L^\times$, $0 \le k \le 2\kappa_{\mathrm{E}}$ (Step 1). This is the assertion. □

Lemma C.86. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V,T) a pair, $\mathbf{N} = \mathbf{N}(T)$ with a window $(M_a, h_a)_a$ as in (Ex1), and fix arc level data for (V,T) (cut c, length* len*, H with $H(c-s) \ge h_{c-s}$ for $s <$* len*, frame, parameters G, S, η, kinds κ_s, sizes b_s) satisfying (Lp1), (Lp2), (Lp7), (Lp8) for every $s <$* len*. Let $g \ge 0$ with $G, S, \eta \le g$ and $g < b_s$ whenever κ_s is not thin, $E \ge$* len $- 1$*, and $J \subset \mathbb{Z}$ finite containing $\{i :\ \mathrm{Nb}_s(i+g) \ne \mathrm{Nb}_s(i)\}$ for every $s <$* len*; put $P = P_{J,E}$. Let $w \in W$ with $(\gamma_u - 1)(w) \in X\mathbf{N}$ for all $u \in \mathbb{Z}_\ell^\times$ and $\gamma_\delta(w) = w$ for all $\delta \in \mu_{\ell-1}$, and $x' = P(\gamma_{u_0})(w)$. Then $x' \in W$, $(\gamma_u - 1)(x') \in X\mathbf{N}$ for all u, $\gamma_\delta(x') = x'$ for all $\delta \in \mu_{\ell-1}$,*

$$x' - P(1)\,w \in X\mathbf{N}_c, \qquad \textit{and} \qquad \mathrm{lv}_s(x') \in L^r + \{\textit{kind integral vectors at } s\} \quad (s < \mathrm{len}).$$

Proof. Write $\gamma = \gamma_{u_0}$. The coefficients of P lie in $\mathbb{Z}_\ell$ ($u_0 \in \mathbb{Z}_\ell$), so x' is a $\mathbb{Z}_\ell$-linear combination of the $\gamma^k w$.

The vector x'. By (Lp2) W is γ_u-stable, and it is an $\mathbf{A}_{F,L}$-module, so $x' \in W$. Since $\gamma_u(X) = X(u + X\cdots)$, $\gamma_u(X\mathbf{N}) \subseteq X\mathbf{N}$; hence $(\gamma^k - 1)w = \sum_{m<k}\gamma^m(\gamma - 1)w \in X\mathbf{N}$, and $x' - P(1)w = \sum_k p_k(\gamma^k - 1)w \in X\mathbf{N}$ for $P = \sum_k p_k Y^k$; as $w \in W \subseteq e_c\mathbf{N}[1/\lambda_\infty]$, this difference lies in $e_cX\mathbf{N} = X\mathbf{N}_c$. The γ_u commute, so $(\gamma_u - 1)x' = P(\gamma)(\gamma_u - 1)w \in X\mathbf{N}$ and $\gamma_\delta x' = x'$.

De Rham integrality up to a constant. Fix $s <$ len. For $u \in \mathbb{Z}_\ell^\times$, $(\gamma_u - 1)w \in W \cap X\mathbf{N}_c$ (as above), so by item 3 of Lemma C.89 (with $g' = 0$, $k = 1$; its hypothesis is $H(c-s) \ge h_{c-s}$) $\mathrm{lv}_s((\gamma_u - 1)w)$ is de Rham integral, and by (Lp2) it equals $(\gamma_u^{(s)} - 1)\mathrm{lv}_s(w)$. Item 3 of Lemma C.88, with $\mathcal{X}(i) = L^r$ for all i and $\mathcal{X}'(i) = \mathrm{Fil}_s(-i)$, gives $v \in L^r$ such that $e' := \mathrm{lv}_s(w) - v$ is de Rham integral at s.

Rounding and killing. By Lemma C.90 ((Lp7) holds), $t^g e'$ is kind integral. By (Lp1), $\lambda_s(Q_s) = t\eta$ with $\eta \in K_{(s)}[[t]]^\times$, and the kind family is increasing, so $\lambda_s(Q_s)^g e' = \eta^g t^g e'$ is

kind integral (multiplication by $a = \sum_{k\geq 0} a_k t^k \in K_{(s)}[[t]]$ preserves Ξ_s of an increasing family $\mathcal{X}$: for $f = \sum_i f_i t^i \in \Xi_s(\mathcal{X})$ the t^i-coefficient of af is the finite sum $\sum_{k\geq 0} a_k f_{i-k}$, and $f_{i-k} \in K_{(s)} \otimes_L \mathcal{X}(i-k) \subseteq K_{(s)} \otimes_L \mathcal{X}(i)$, a $K_{(s)}$-subspace). By (Lp2), $\mathrm{lv}_s(w) = \mathrm{lv}_s(\gamma_\delta w) = \gamma_\delta^{(s)} \mathrm{lv}_s(w)$, so $e := \mathrm{lv}_s(w) = v + e'$ is Δ-invariant. Item 2 of Lemma C.87 (family Nb_s, $E \geq s$) gives $P(\gamma_{u_0}^{(s)})e \in L^r + \Xi_s(\mathrm{Nb}_s)$. Finally, lv_s is $\mathbb{Z}_\ell$-linear and $\mathrm{lv}_s(\gamma^k w) = (\gamma_{u_0}^{(s)})^k \mathrm{lv}_s(w)$ by (Lp2), so $\mathrm{lv}_s(x') = P(\gamma_{u_0}^{(s)})e$. □

Lemma C.87. *Fix arc level data and $s <$ len; write $K = K_{(s)}$, $\gamma_u = \gamma_u^{(s)}$ on $K((t))^r$ and $\gamma = \gamma_{u_0}$. Call $f \in K((t))^r$ Δ-invariant if $\gamma_\delta f = f$ for every $\delta \in \mu_{\ell-1} \subset \mathbb{Z}_\ell^\times$. Let $E \geq s$.*

1. *Let $\mathcal{X}' \subseteq \mathcal{X}$ be families of L-subspaces of L^r and $J \subset \mathbb{Z}$ finite with $\mathcal{X}(i) = \mathcal{X}'(i)$ for $i \notin J$. If $f \in \Xi_s(\mathcal{X})$ is Δ-invariant, there is $d \in \mathcal{X}(0)$ with $\sum_{k<\ell^E} \sigma_{u_0}^k(f^{(0)}) = \ell^E d$ and*

$$P_{J,E}(\gamma) f - P_{J,E}(1)\, d \in \Xi_s(\mathcal{X}').$$

2. *Let $\mathcal{X}$ be an increasing family ($\mathcal{X}(i) \subseteq \mathcal{X}(i+1)$), $g \geq 0$, and $J \supseteq \{i :\ \mathcal{X}(i+g) \neq \mathcal{X}(i)\}$ finite. If $e \in K((t))^r$ is Δ-invariant and $e = v + e'$ with $v \in L^r$ and $\lambda_s(Q_s)^g e' \in \Xi_s(\mathcal{X})$, then $P_{J,E}(\gamma)e \in L^r + \Xi_s(\mathcal{X})$.*

Proof. **Item 1.** By item 2 of Lemma C.88, for every i,

$$(P_{J,E}(\gamma)f)^{(i)} = \prod_{i' \in J\setminus\{0\}} (u_0^{i\ell^E} - u_0^{i'\ell^E}) \sum_{k<\ell^E} u_0^{ik} \sigma_{u_0}^k(f^{(i)}).$$

Each $K \otimes_L \mathcal{X}(i)$ is stable under the σ_u (which act on the factor K). For $i \in J\setminus\{0\}$ the coefficient is 0. For $i \notin J$, $i \neq 0$, it lies in $K \otimes \mathcal{X}(i) = K \otimes \mathcal{X}'(i)$. For $i = 0$ it is $\prod_{i'}(1 - u_0^{i'\ell^E})\, S$ with $S = \sum_{k<\ell^E} \sigma_{u_0}^k(f^{(0)}) \in K \otimes \mathcal{X}(0)$. By (Lp8), $\sigma_{u_0}^{\ell^s} = \mathrm{id}$, hence $\sigma_{u_0}^{\ell^E} = \mathrm{id}$ and $\sigma_{u_0}(S) = S$. Δ-invariance of f at t^0 reads $\sigma_\delta(f^{(0)}) = f^{(0)}$, and σ_δ commutes with σ_{u_0}, so $\sigma_\delta(S) = S$. Now σ_u depends only on u modulo ℓ^{s+1} (it acts on $\zeta_{\ell^{s+1}}$ by $\zeta \mapsto \zeta^u$ and trivially on F and L), and $\mu_{\ell-1}$ together with u_0 generates $(\mathbb{Z}/\ell^{s+1})^\times$ ($v_\ell(u_0 - 1) = 1$, so u_0 generates $(1+\ell\mathbb{Z})/(1+\ell^{s+1}\mathbb{Z})$); hence S is fixed by every σ_u. Writing $S = \sum_m \kappa_m \otimes x_m$ for an L-basis (x_m) of $\mathcal{X}(0)$, each $\kappa_m \in K$ is fixed by every σ_u, hence lies in L by (Lp8). So $S \in \mathcal{X}(0)$, and $d = \ell^{-E} S \in \mathcal{X}(0)$. Finally $P_{J,E}(1) = \ell^E \prod_{i'}(1 - u_0^{i'\ell^E})$ (item 2 of Lemma C.88), so the t^0-coefficient of $P_{J,E}(\gamma)f - P_{J,E}(1)d$ is 0, while its other coefficients are those of $P_{J,E}(\gamma)f$. Hence it lies in $\Xi_s(\mathcal{X}')$.

Item 2. By (Lp1), $\lambda_s(Q_s) = t\eta$ with $\eta \in K[[t]]^\times$. For an increasing family $\mathcal{Y}$ and $c = \sum_{k\geq 0} c_k t^k \in K[[t]]$, $f \in \Xi_s(\mathcal{Y})$ implies $cf \in \Xi_s(\mathcal{Y})$, since $(cf)^{(i)} = \sum_k c_k f^{(i-k)}$ and $K \otimes \mathcal{Y}(i-k) \subseteq K \otimes \mathcal{Y}(i)$. Hence $t^g e' = \eta^{-g} \lambda_s(Q_s)^g e' \in \Xi_s(\mathcal{X})$, i.e. $e' \in \Xi_s(\mathcal{Y})$ with $\mathcal{Y}(i) = \mathcal{X}(i+g)$. The family $\mathcal{Y}$ contains $\mathcal{X}$ ($\mathcal{X}$ increasing) and differs from it only on J. Constants are fixed by every γ_u (σ_u fixes L and $u^0 = 1$), so $e' = e - v$ is Δ-invariant. Item 1 for $(\mathcal{Y}, \mathcal{X}, J)$ gives $d \in \mathcal{Y}(0) \subseteq L^r$ with $P_{J,E}(\gamma)e' - P_{J,E}(1)d \in \Xi_s(\mathcal{X})$, and $P_{J,E}(\gamma)v = P_{J,E}(1)v$ by item 2 of Lemma C.88. Therefore $P_{J,E}(\gamma)e = P_{J,E}(1)(v+d) + \big(P_{J,E}(\gamma)e' - P_{J,E}(1)d\big) \in L^r + \Xi_s(\mathcal{X})$. □

Lemma C.88. *Fix arc level data (any pair, cut, length, frame, parameters) and $s <$ len; write $K = K_{(s)}$, $\gamma_u = \gamma_u^{(s)}$ on $K((t))^r$, $\gamma = \gamma_{u_0}$, and for $f \in K((t))^r$ let $f^{(i)} \in K^r$ be its t^i-coefficient.*

1. *For an integer $k \geq 0$: $(\gamma^k f)^{(i)} = u_0^{ik} \sigma_{u_0}^k(f^{(i)})$. If $E \geq s$, then $(\gamma^{\ell^E} f)^{(i)} = u_0^{i\ell^E} f^{(i)}$, and for a polynomial $P \in L[Y]$, $(P(\gamma^{\ell^E})f)^{(i)} = P(u_0^{i\ell^E}) f^{(i)}$.*

2. *(Killing polynomials) Let $E \geq s$, $J \subset \mathbb{Z}$ finite, and $P_{J,E}(Y) = \prod_{i' \in J \setminus \{0\}} (Y^{\ell^E} - u_0^{i'\ell^E}) \cdot \sum_{k<\ell^E} Y^k \in L[Y]$. Then*

$$(P_{J,E}(\gamma)f)^{(i)} = \prod_{i' \in J\setminus\{0\}} (u_0^{i\ell^E} - u_0^{i'\ell^E}) \sum_{k<\ell^E} u_0^{ik} \sigma_{u_0}^k(f^{(i)});$$

in particular $(P_{J,E}(\gamma)f)^{(i)} = 0$ for $i \in J \setminus \{0\}$, and $P_{J,E}(\gamma)v = P_{J,E}(1)\, v$ for a constant $v \in L^r$, with $P_{J,E}(1) = \ell^E \prod_{i' \in J\setminus\{0\}} (1 - u_0^{i'\ell^E})$.

3. *(Constants) Let $\mathcal{X}' \subseteq \mathcal{X}$ be families of L-subspaces of L^r (i.e. $\mathcal{X}'(i) \subseteq \mathcal{X}(i)$ for all i). If $f \in \Xi_s(\mathcal{X})$ and $(\gamma_u - 1)f \in \Xi_s(\mathcal{X}')$ for every $u \in \mathbb{Z}_\ell^\times$, then there is $d \in \mathcal{X}(0)$ with $f - d \in \Xi_s(\mathcal{X}')$.*

Proof. By definition $\gamma_u(\sum_i a_i t^i) = \sum_i u^i \sigma_u(a_i) t^i$ coordinatewise, and σ_u is a ring automorphism of K fixing $L = \epsilon_s L$ (by Definition 23.4 it is induced by any $g \in G_F$ with $\chi(g) = u$, which fixes F, ϵ_s and L and acts on $K = \epsilon_s(F(\zeta_{\ell^{s+1}}) \otimes_{\mathbb{Q}_\ell} L)$ through its action on $F(\zeta_{\ell^{s+1}})$; taking gh with $\chi(h) = v$ gives $\sigma_u\sigma_v = \sigma_{uv}$), so γ_u is L-linear and $\gamma_u\gamma_v = \gamma_{uv}$.

1. Induction on k gives $(\gamma^k f)^{(i)} = u_0^{ik}\sigma_{u_0}^k(f^{(i)})$. For $E \geq s$, $\sigma_{u_0}^{\ell^E} = (\sigma_{u_0}^{\ell^s})^{\ell^{E-s}} = \mathrm{id}$ by (Lp8) (Lemma 23.17), so γ^{ℓ^E} multiplies the t^i-coefficient by the scalar $u_0^{i\ell^E} \in \mathbb{Z}_\ell$; a polynomial in γ^{ℓ^E} with coefficients in L then acts on it by the value of the polynomial at that scalar.

2. $P_{J,E}(\gamma) = Q(\gamma^{\ell^E}) \circ S(\gamma)$ with $Q(Z) = \prod_{i'}(Z - u_0^{i'\ell^E})$ and $S(Y) = \sum_{k<\ell^E} Y^k$; both are L-linear and act coefficientwise by 1, which gives the formula. For $i \in J \setminus \{0\}$ the factor $i' = i$ vanishes. For a constant $v \in L^r$ only $i = 0$ occurs, σ_{u_0} fixes v, and the coefficient is $\prod_{i'}(1 - u_0^{i'\ell^E}) \cdot \ell^E v = P_{J,E}(1)v$.

3. Let $i \neq 0$. Put $u = 1 + \ell^{s+1}$; then $\sigma_u = \mathrm{id}$ (σ_u depends only on $u \bmod \ell^{s+1}$), and $u^i \neq 1$ since $u \in 1 + \ell\mathbb{Z}_\ell$ is not a root of unity (ℓ odd). So $((\gamma_u - 1)f)^{(i)} = (u^i - 1)f^{(i)} \in K \otimes_L \mathcal{X}'(i)$ gives $f^{(i)} \in K \otimes_L \mathcal{X}'(i)$. Let $i = 0$ and let $\mathcal{G}$ be the finite group of the σ_u ($u \in \mathbb{Z}_\ell^\times$), of order $N = \ell^s(\ell - 1)$, invertible in L. The hypothesis gives $\sigma(f^{(0)}) - f^{(0)} \in K \otimes_L \mathcal{X}'(0)$ for $\sigma \in \mathcal{G}$, with $\mathcal{G}$ acting on $K \otimes_L \mathcal{X}(0)$ through the first factor. Put $d = N^{-1} \sum_{\sigma\in\mathcal{G}} \sigma(f^{(0)})$. Then $d \in (K \otimes_L \mathcal{X}(0))^{\mathcal{G}} = K^{\mathcal{G}} \otimes_L \mathcal{X}(0) = \mathcal{X}(0)$ (choose an L-basis of $\mathcal{X}(0)$; $K^{\mathcal{G}} = L$ by (Lp8)), and $f^{(0)} - d = N^{-1} \sum_\sigma (f^{(0)} - \sigma(f^{(0)})) \in K \otimes_L \mathcal{X}'(0)$. Hence $f - d \in \Xi_s(\mathcal{X}')$. □

Lemma C.89. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V,T) a pair, $\mathbf{N} = \mathbf{N}(T)$ a Wach module with window $(M_a, h_a)_a$ by (Ex1), and fix arc level data for (V,T) (cut c, length $1 \leq \mathrm{len} \leq n$, H, frame). Let $g' \geq 0$ be an integer with $H(c-s) \geq g' + h_{c-s}$ for all $s < \mathrm{len}$. Then:*

1. *$\lambda_{\mathrm{len}}^{-g'} \mathbf{N}_c \subseteq W$; in particular $\mathbf{N}_c \subseteq W$;*
2. *for $x \in W$: $\lambda_{\mathrm{len}}^{g'} x \in \mathbf{N}_c$ if and only if $t^{g'} \mathrm{lv}_s(x)$ is de Rham integral at s for every $s < \mathrm{len}$;*
3. *for $x \in W$ and $k \geq 0$: $x \in X^k \mathbf{N}_c$ if and only if $X^{-k}x \in W$ and $\mathrm{lv}_s(x)$ is de Rham integral at s for every $s < \mathrm{len}$.*

Proof. Write $K = K_{(s)}$. *De Rham integrality is stable under $K[[t]]$*: if f is de Rham integral at s and $c = \sum_{j\geq 0} c_j t^j \in K[[t]]$, the t^i-coefficient of cf is $\sum_{j\geq 0} c_j f^{(i-j)} \in \sum_j K \otimes_L \mathrm{Fil}_s(-i+j) \subseteq K \otimes_L \mathrm{Fil}_s(-i)$ (Fil_s is decreasing); so multiplication by a unit of $K[[t]]$ preserves de Rham integrality in both directions. Recall from Lemma 23.17 ((Lp1)) that $\lambda_s(X) \in K[[t]]^\times$, $\lambda_s(Q_{s'}) \in K[[t]]^\times$ for $s' \neq s$ and $\lambda_s(Q_s) \in tK[[t]]^\times$, so $\lambda_s(\lambda_{\mathrm{len}}) \in tK[[t]]^\times$; and $\mathrm{lv}_s(ax) = \lambda_s(a)\mathrm{lv}_s(x)$ for $a \in e_c \mathbf{A}_{F,L}[1/\lambda_{\mathrm{len}}]$ and x algebraic at level s ($\Lambda_s(ax) = \lambda_s(a)\Lambda_s(x)$).

1. Let $y \in \mathbf{N}_c$ and $x = \lambda_{\mathrm{len}}^{-g'} y$. Define $H'' \colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$ by $H''(c-s) = H(c-s) - g'$ for $s < \mathrm{len}$ (these sites are distinct, $\mathrm{len} \leq n$) and $H''(a) = h_a$ at the other sites; then $H'' \geq h$ pointwise and, as $\lambda_{\mathrm{len}} = \prod_{s<\mathrm{len}} Q_s$, $\Pi x = \Lambda_{c,\mathrm{len}}(H'')y \in P_{\mathrm{len}}(\mathbf{N}_{c-\mathrm{len}})$ by Lemma 23.15 (2). So $x \in W$. For $g' = 0$ this is $\mathbf{N}_c \subseteq W$.

2. Let $x \in W$. Then $\lambda_{\mathrm{len}}^{g'} x \in W$ ($P_{\mathrm{len}}(\mathbf{N}_{c-\mathrm{len}})$ is an $\mathbf{A}_{F,L}$-module), and $\mathrm{lv}_s(\lambda_{\mathrm{len}}^{g'} x) = \lambda_s(\lambda_{\mathrm{len}})^{g'} \mathrm{lv}_s(x) = v\, t^{g'} \mathrm{lv}_s(x)$ with $v \in K[[t]]^\times$. By Lemma 23.5 (2), $\lambda_{\mathrm{len}}^{g'} x \in \mathbf{N}_c$ iff all $\mathrm{lv}_s(\lambda_{\mathrm{len}}^{g'} x)$ are de Rham integral, iff all $t^{g'} \mathrm{lv}_s(x)$ are.

3. If $x \in X^k \mathbf{N}_c$, then $X^{-k} x \in \mathbf{N}_c \subseteq W$ by 1, and $\mathrm{lv}_s(x) = \lambda_s(X)^k \mathrm{lv}_s(X^{-k} x)$ is de Rham integral by Lemma 23.5 (2). Conversely, if $X^{-k} x \in W$ and all $\mathrm{lv}_s(x)$ are de Rham integral, then so are the $\mathrm{lv}_s(X^{-k} x) = \lambda_s(X)^{-k} \mathrm{lv}_s(x)$, and Lemma 23.5 (2) gives $X^{-k} x \in \mathbf{N}_c$. □

Lemma C.90. *Fix arc level data for a pair (any cut, length, H, frame) with parameters G, S, η, kinds κ_s and sizes b_s, and let $g \geq 0$ be an integer with $G, S, \eta \leq g$ and $g < b_s$ whenever κ_s is not thin. Let $s < \mathrm{len}$ and suppose Fil_s satisfies (Lp7). Then for every $i \in \mathbb{Z}$*

$$\mathrm{Nb}_s(i-g) \subseteq \mathrm{Fil}_s(-i) \subseteq \mathrm{Nb}_s(i+g),$$

and consequently, for $f \in K_{(s)}((t))^r$: if f is kind integral at s, then $t^g f$ is de Rham integral at s; if f is de Rham integral at s, then $t^g f$ is kind integral at s.

Proof. Write $\mathrm{Fil} = \mathrm{Fil}_s$, $b = b_s$, and let J be its set of jumps. Since Fil is decreasing, equal to L^r for $u \ll 0$ and to 0 for $u \gg 0$, and constant between consecutive jumps: $\mathrm{Fil}(u) = L^r$ for $u \leq \min J$, $\mathrm{Fil}(u) = 0$ for $u > \max J$, and $\mathrm{Fil}(u) = \mathrm{Fil}(u')$ if no jump lies in $[u, u')$ (if $J = \emptyset$, Fil is constant, equal to L^r and to 0, so $r = 0$ and every claim is trivial). We use $u \leq u' \Rightarrow \mathrm{Fil}(u) \supseteq \mathrm{Fil}(u')$ throughout.

Thin ($J \subseteq [-G, G]$, $\mathrm{Nb}(k) = 0$ for $k < 0$, L^r for $k \geq 0$). Left: if $i - g \geq 0$ then $-i \leq -g \leq -G \leq \min J$, so $\mathrm{Fil}(-i) = L^r$. Right: if $i + g < 0$ then $-i > g \geq \max J$, so $\mathrm{Fil}(-i) = 0$.

Up ($J \subseteq [b, b+S] \cup [-\eta, \eta]$, $U = \mathrm{Fil}(b)$; $\mathrm{Nb}(k) = 0$ for $k < -b$, U for $-b \leq k < 0$, L^r for $k \geq 0$). Left: if $i - g \geq 0$, $-i \leq -g \leq -\eta \leq \min J$ and $\mathrm{Fil}(-i) = L^r$; if $-b \leq i - g < 0$, then $-i \leq b - g \leq b$ and $\mathrm{Fil}(b) \subseteq \mathrm{Fil}(-i)$. Right: if $-b \leq i + g < 0$, then $-i > g \geq \eta$; if $-i \geq b$, $\mathrm{Fil}(-i) \subseteq \mathrm{Fil}(b)$, and if $-i < b$ no jump lies in $[-i, b)$ (it would exceed η and be below b), so $\mathrm{Fil}(-i) = \mathrm{Fil}(b)$; if $i + g < -b$, then $-i > b + g \geq b + S \geq \max J$ and $\mathrm{Fil}(-i) = 0$.

Down ($J \subseteq [-b-S, -b] \cup [-\eta, \eta]$, $U = \mathrm{Fil}(-\eta)$; $\mathrm{Nb}(k) = 0$ for $k < 0$, U for $0 \leq k < b$, L^r for $k \geq b$). Left: if $i - g \geq b$, $-i \leq -b - g \leq -b - S \leq \min J$ and $\mathrm{Fil}(-i) = L^r$; if $0 \leq i - g < b$, $-i \leq -g \leq -\eta$ and $\mathrm{Fil}(-\eta) \subseteq \mathrm{Fil}(-i)$. Right: if $0 \leq i + g < b$, then $g - b < -i \leq g$; if $-i \geq -\eta$, $\mathrm{Fil}(-i) \subseteq \mathrm{Fil}(-\eta)$, and if $-i < -\eta$ no jump lies in $[-i, -\eta)$ (it would be $> g - b \geq -b$, hence not in $[-b-S, -b]$, and $< -\eta$), so $\mathrm{Fil}(-i) = \mathrm{Fil}(-\eta)$; if $i + g < 0$, then $-i > g \geq \eta \geq \max J$ ($b > 0$, so $[-b-S, -b]$ lies below 0) and $\mathrm{Fil}(-i) = 0$.

In each case the remaining instances are trivial ($\mathrm{Nb} = 0$ on the left, $\mathrm{Nb} = L^r$ on the right). Finally, the t^i-coefficient of $t^g f$ is the t^{i-g}-coefficient $f^{(i-g)}$ of f. If f is kind integral, $f^{(i-g)} \in K \otimes_L \mathrm{Nb}(i-g) \subseteq K \otimes_L \mathrm{Fil}(-i)$; if f is de Rham integral, $f^{(i-g)} \in K \otimes_L \mathrm{Fil}(-(i-g)) \subseteq K \otimes_L \mathrm{Nb}(i)$ (the right inclusion at $i - g$). □

Lemma C.91. *Let ℓ, F, L, (τ_a), (V, T), $\mathbf{N} = \mathbf{N}(T)$ with a window (M_a, h_a) and arc level data (cut c, length* len*, H with $H(c-s) \geq h_{c-s}$ for $s <$* len*) satisfying (Lp1), (Lp2), (Lp7), (Lp8) be as in Lemma C.86. Then:*

1. *$(\gamma_u - 1)(W) \subseteq XW$ for every $u \in \mathbb{Z}_\ell^\times$.*

2. *Let $g \geq 0$, $E \geq \mathrm{len} - 1$, $J \subset \mathbb{Z}$ finite containing $\{i : \mathrm{Fil}_s(-i-g) \neq \mathrm{Fil}_s(-i)\}$ for every $s < \mathrm{len}$, and $P = P_{J,E}$. Let $z \in W$ with $\gamma_\delta(z) = z$ for $\delta \in \mu_{\ell-1}$ such that for every $s < \mathrm{len}$ there is $v_s \in L^r$ with $\lambda_s(Q_s)^g(\mathrm{lv}_s(z) - v_s)$ de Rham integral at s. Then $w' = P(\gamma_{u_0})(z)$ lies in W and $(\gamma_u - 1)(w') \in X\mathbf{N}_c$ for every $u \in \mathbb{Z}_\ell^\times$.*

Proof. **Item 1.** Write $P_W = P_{\mathrm{len}}(\mathbf{N}_{c_0})$, $c_0 = c - \mathrm{len}$, and $\gamma = \gamma_u$. For $n \in \mathbf{N}_{c_0}$, $\gamma\varphi^{\mathrm{len}}(n) - \varphi^{\mathrm{len}}(n) = \varphi^{\mathrm{len}}((\gamma-1)n) \in \varphi^{\mathrm{len}}(X\mathbf{N}_{c_0})$ ((Wm3)), and $\varphi^{\mathrm{len}}(X) = X\lambda_{\mathrm{len}} \in X\mathbf{A}_{F,L}$; for $f \in \mathbf{A}_{F,L}$, $\gamma(f) - f \in X\mathbf{A}_{F,L}$. Hence $(\gamma-1)P_W \subseteq XP_W$ (using $\gamma(fp) - fp = \gamma(f)(\gamma p - p) + (\gamma f - f)p$). For each s, $\gamma(Q_s)$ vanishes at the roots of Q_s (Lemma 23.8), so $\gamma(Q_s) = Q_s v_s$ with $v_s \in \mathbb{Z}_\ell[[X]]$; at $X = 0$, $\gamma(Q_s)(0) = Q_s(0) \neq 0$, so $v_s(0) = 1$ and v_s is a unit with $v_s \equiv 1 \bmod X$. Hence $\gamma(\Pi) = \Pi v$ with $v \equiv 1 \bmod X$ a unit. For $w \in W$ put $p = \Pi w \in P_W$; then

$$\Pi(\gamma w - w) = v^{-1}\gamma(p) - p = v^{-1}(\gamma p - p) + (v^{-1} - 1)p \in XP_W,$$

so $X^{-1}(\gamma w - w) \in W$.

Item 2. By (Lp2) and item 1, $w' \in W$ and $\gamma_\delta w' = w'$. Fix $s < \mathrm{len}$ and put $e = \mathrm{lv}_s(z)$, $e' = e - v_s$; e is Δ-invariant by (Lp2). The family $\mathcal{X}(i) = \mathrm{Fil}_s(-i)$ is increasing (Fil_s is decreasing, (Lp7)), and $\lambda_s(Q_s)^g e' \in \Xi_s(\mathcal{X})$; item 2 of Lemma C.87 gives $\mathrm{lv}_s(w') = P(\gamma_{u_0}^{(s)})e \in L^r + \Xi_s(\mathcal{X})$ (using (Lp2) for $\mathrm{lv}_s(\gamma^k z)$). For $u \in \mathbb{Z}_\ell^\times$, $\gamma_u^{(s)}$ fixes L^r and maps $\Xi_s(\mathcal{X})$ into itself (it multiplies the t^i-coefficient by u^i and applies σ_u, which preserves $K_{(s)} \otimes \mathcal{X}(i)$). Hence $\mathrm{lv}_s((\gamma_u - 1)w') = (\gamma_u^{(s)} - 1)\mathrm{lv}_s(w')$ is de Rham integral at s, for every s. By item 1, $X^{-1}(\gamma_u - 1)w' \in W$, and item 3 of Lemma C.89 (with $g' = 0$, $k = 1$) gives $(\gamma_u - 1)w' \in X\mathbf{N}_c$. □

Proposition C.92. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, $\sigma_{\mathrm{E}}, \rho_{\mathrm{E}}, a_{\mathrm{E}}$, (Ae1), (Ae2), $c \in \mathcal{C}$ and the arc level data of Φ along the word at the cut c of length len_c, with the arc level properties, be as in Proposition C.85; $r_\nu = \dim_L V_\nu$. Let $x' \in W_2$ with $\gamma_\delta(x') = x'$ for $\delta \in \mu_{\ell-1}$ such that for every $s < \mathrm{len}_c$, $\mathrm{lv}_s^{(2)}(x') \in L^{r_2} + \{$kind integral vectors at $s\}$. Then there is $z \in W_1$ with*

$$\mathbf{N}(\Phi)(z) = \ell^{\,2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}}}\, x'$$

such that for every $s < \mathrm{len}_c$ there is $v_s \in L^{r_1}$ with $\lambda_s(Q_s)^g(\mathrm{lv}_s^{(1)}(z) - v_s)$ de Rham integral at s.

Proof. Write $\mathrm{len} = \mathrm{len}_c$ and $e_1 = 2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}}$, and let κ_s be the kinds of the arc level data along the word.

Step 1: kind integral vectors and constants. For each $s < \mathrm{len}$ the kind integral vectors at s form an additive group, stable under multiplication by elements of $\mathbb{Z}_\ell$: the condition is that the t^i-coefficient lies in the L-subspace $K_{(s)} \otimes_L \mathrm{Nb}_s(i)$, for every i. The same holds for de Rham integral vectors, and $\mathrm{lv}_s^{(\nu)}$ is additive and $\mathbb{Z}_\ell$-linear (Λ_s is, and the expansion in the R_s-basis $(D_k^{(s)})_k$ is unique). If κ_s is thin or up, then $\mathrm{Nb}_s(i) = L^{r_2}$ for $i \geq 0$, so every constant $v \in L^{r_2}$ (a single t^0-coefficient in $K_{(s)} \otimes_L L^{r_2}$) is kind integral at s.

Step 2: no down level. Suppose κ_s is thin or up for every $s < \mathrm{len}$. By the hypothesis and Step 1, $\mathrm{lv}_s^{(2)}(x')$ is kind integral at every $s < \mathrm{len}$. Lemma C.93 gives $z' \in W_1$ with $\mathbf{N}(\Phi)(z') = \ell^{\rho_{\mathrm{E}}} x'$ and $\lambda_s(Q_s)^g \mathrm{lv}_s^{(1)}(z')$ de Rham integral for all s. Then $z = \ell^{e_1} z' \in W_1$ satisfies $\mathbf{N}(\Phi)(z) = \ell^{e_1 + \rho_{\mathrm{E}}} x'$, and the assertion holds with $v_s = 0$.

Step 3: a down level. Suppose κ_s is down for some $s < \mathrm{len}$. Proposition C.94 gives $z_0 \in W_1$ and $v_s \in L^{r_1}$ with $\lambda_s(Q_s)^g(\mathrm{lv}_s^{(1)}(z_0) - v_s)$ de Rham integral and $\mathrm{lv}_s^{(2)}(x'')$ kind integral for every $s < \mathrm{len}$, where $x'' = \ell^{e_1} x' - \mathbf{N}(\Phi)(z_0)$. Here $x'' \in W_2$, as W_2 is an $\mathbf{A}_{F,L}$-module and

$\mathbf{N}(\Phi)(W_1) \subseteq W_2$ (Definition 23.4). Lemma C.93 applied to x'' gives $z'' \in W_1$ with $\mathbf{N}(\Phi)(z'') = \ell^{\rho_{\mathrm{E}}} x''$ and $\lambda_s(Q_s)^g \mathrm{lv}_s^{(1)}(z'')$ de Rham integral for all s. Put $z = \ell^{\rho_{\mathrm{E}}} z_0 + z'' \in W_1$. Then

$$\mathbf{N}(\Phi)(z) = \ell^{\rho_{\mathrm{E}}} \mathbf{N}(\Phi)(z_0) + \ell^{\rho_{\mathrm{E}}} \big(\ell^{e_1} x' - \mathbf{N}(\Phi)(z_0)\big) = \ell^{\,2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}}} x',$$

and, with $v_s' = \ell^{\rho_{\mathrm{E}}} v_s \in L^{r_1}$,

$$\lambda_s(Q_s)^g \big(\mathrm{lv}_s^{(1)}(z) - v_s'\big) = \ell^{\rho_{\mathrm{E}}}\, \lambda_s(Q_s)^g \big(\mathrm{lv}_s^{(1)}(z_0) - v_s\big) + \lambda_s(Q_s)^g\, \mathrm{lv}_s^{(1)}(z'')$$

is a sum of two de Rham integral vectors at s, hence de Rham integral (Step 1). This is the assertion. □

Lemma C.93. *Let $\ell \geq 11$, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word $(b, w, S, \eta, m, (s_a), (\epsilon_a))$, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$ and (Ae1) be as in Proposition C.83, and form ρ_{E} with the same data. Let $c \in \mathcal{C}$, $\mathrm{len} = \mathrm{len}_c$, and suppose that for some frames at $c - \mathrm{len}$ the arc level data of Φ along the word at the cut c of length len have the arc level properties; let W_1, W_2 be their arc domains. If $x \in W_2$ and $\mathrm{lv}_s^{(2)}(x)$ is kind integral at s for every $s < \mathrm{len}$, then there is $z \in W_1$ with*

$$\mathbf{N}(\Phi)(z) = \ell^{\,\rho_{\mathrm{E}}}\, x$$

such that $\lambda_s(Q_s)^g\, \mathrm{lv}_s^{(1)}(z)$ is de Rham integral at s for every $s < \mathrm{len}$.

Proof. Write $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$, $\lambda = \lambda_{\mathrm{len}} = \prod_{s<\mathrm{len}} Q_s$, and let κ_s, $b_s = s_{c-s}$ and $H_c(c-s)$ $(= g + G$, $g + s_{c-s} + S$, $g + \eta$ for κ_s thin, up, down) be the kinds, sizes and heights of the arc level data along the word.

Step 0: a window and the parameters. Put $(M_a, h_a) = (\eta, \max(s_a + S, \eta))$ if $\epsilon_a = 1$ and $(M_a, h_a) = (\max(s_a + S, \eta), \eta)$ if $\epsilon_a = -1$. By (Ow1) every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$, and by item 1 of Lemma 24.2 so does every Hodge jump of V_2. At a thin site $s_a \leq w$ (Definition 23.1), so $M_a, h_a \leq \max(w + S, \eta) \leq G$; at a thick site $s_a > g \geq G \geq \eta$ by (Ae1), and $s_a \leq b + \eta$ by (Ow3), so $\max(s_a + S, \eta) = s_a + S \leq h_*$. Consequently:

1. $H_c(c-s) \geq g + h_{c-s}$ for $s < \mathrm{len}$: at a thin site $h \leq G$ and $H_c = g + G$; at a thick site with $\epsilon = 1$, $h = s_{c-s} + S$ and $H_c = g + s_{c-s} + S$; with $\epsilon = -1$, $h = \eta$ and $H_c = g + \eta$;
2. $M_a + h_a \leq H(a)$ for every a: $M_a + h_a \leq 2G = H(a)$ at a thin site, and $M_a + h_a \leq h_* + \eta \leq 2h_* = H(a)$ at a thick site ($\eta \leq g < s_a \leq h_*$);
3. $G, S, \eta \leq g$ (as $g = \max(G, 1)$, $G = w + S + \eta$), and $b_s = s_{c-s} > g$ whenever κ_s is not thin (then $c - s$ is thick; (Ae1)).

Step 1: from kind integral levels to the lattice. Let $s < \mathrm{len}$. By (Lp7) for T_2 and item 3 of Step 0, Lemma C.90 applies at s: since $\mathrm{lv}_s^{(2)}(x)$ is kind integral, $t^g \mathrm{lv}_s^{(2)}(x)$ is de Rham integral at s. By item 1 of Step 0 and item 2 of Lemma C.89 for T_2 with $g' = g$ (and the window of Step 0), $y := \lambda^g x \in \mathbf{N}_{2,c}$.

Step 2: lifting. $\Phi\colon T_1 \to T_2$ is a G_F-equivariant $\mathcal{O}_L$-linear surjection and $\ell \geq 5$; by Step 0 every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$. Proposition C.6 (with $f = \Phi$, the window (M_a, h_a), the function $a \mapsto M_a + h_a$) gives $m \in \mathbf{N}_{1,c}$ with $\mathbf{N}(\Phi)(m) = \ell^{r_c} y$, where r_c is formed with $a \mapsto M_a + h_a$. By item 2 of Step 0 this function is bounded by H pointwise; the sum s_c, the maximum and c_H are monotone in the function, so $r_c \leq \rho_{\mathrm{E}}$ (definition of ρ_{E} in Definition C.78). Put $m' = \ell^{\rho_{\mathrm{E}} - r_c} m \in \mathbf{N}_{1,c}$.

Step 3: the lift z. Let $z = \lambda^{-g} m' \in e_c \mathbf{N}_1[1/\lambda_{\mathrm{len}}]$. By item 1 of Step 0 and item 1 of Lemma C.89 for T_1 with $g' = g$, $z \in W_1$. The map $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear, hence commutes with multiplication by $\lambda^{\pm g}$ on the localisation, and

$$\mathbf{N}(\Phi)(z) = \lambda^{-g} \ell^{\rho_{\mathrm{E}} - r_c} \mathbf{N}(\Phi)(m) = \lambda^{-g} \ell^{\rho_{\mathrm{E}}} \lambda^g x = \ell^{\rho_{\mathrm{E}}} x.$$

Step 4: the levels of z. Let $s < \mathrm{len}$. Since $m' \in \mathbf{N}_{1,c} \subseteq W_1$ (item 1 of Lemma C.89 with $g' = 0$), (Lp3) for T_1 shows that $\mathrm{lv}_s^{(1)}(m')$ is de Rham integral at s. The level map satisfies $\Lambda_s(aw) = \lambda_s(a)\Lambda_s(w)$, and the expansion in the R_s-basis $(D_k^{(s)})_k$ is unique, so $\mathrm{lv}_s^{(1)}(z) = \lambda_s(\lambda)^{-g}\, \mathrm{lv}_s^{(1)}(m')$ and

$$\lambda_s(Q_s)^g\, \mathrm{lv}_s^{(1)}(z) = u^{-g}\, \mathrm{lv}_s^{(1)}(m'), \qquad u = \lambda_s\Big(\prod_{s' < \mathrm{len},\, s' \neq s} Q_{s'} \Big) \in K_{(s)}[[t]]^\times$$

by (Lp1). Multiplication by an element $v = \sum_{i \geq 0} v_i t^i$ of $K_{(s)}[[t]]$ preserves de Rham integrality: Fil_s^1 is decreasing ((Lp7)), so if the t^j-coefficient f_j of f lies in $K_{(s)} \otimes_L \mathrm{Fil}_s^1(-j)$ for all j, then the t^i-coefficient $\sum_{j \leq i} v_{i-j} f_j$ of vf (a finite sum, f being a Laurent series) lies in $K_{(s)} \otimes_L \mathrm{Fil}_s^1(-i)$. Applied with $v = u^{-g}$, $\lambda_s(Q_s)^g \mathrm{lv}_s^{(1)}(z)$ is de Rham integral at s. □

Proposition C.94. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, $\sigma_{\mathrm{E}}, a_{\mathrm{E}}$, (Ae1), (Ae2), $c \in \mathcal{C}$ and the arc level data of Φ along the word at the cut c of length len_c, with the arc level properties, be as in Proposition C.92; $r_\nu = \dim_L V_\nu$. Suppose that κ_s is down for some $s < \mathrm{len}_c$. Let $x' \in W_2$ with $\gamma_\delta(x') = x'$ for $\delta \in \mu_{\ell-1}$ such that for every $s < \mathrm{len}_c$, $\mathrm{lv}_s^{(2)}(x') \in L^{r_2} + \{$kind integral vectors at $s\}$. Then there is $z_0 \in W_1$ such that for every $s < \mathrm{len}_c$:*

1. *there is $v_s \in L^{r_1}$ with $\lambda_s(Q_s)^g\big(\mathrm{lv}_s^{(1)}(z_0) - v_s\big)$ de Rham integral at s;*
2. *$\mathrm{lv}_s^{(2)}\big(\ell^{2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}}} x' - \mathbf{N}(\Phi)(z_0)\big)$ is kind integral at s.*

Proof. Write $\mathrm{len} = \mathrm{len}_c$, $\Pi = \prod_{s < \mathrm{len}} Q_s^{H(c-s)}$ (the same for $\nu = 1, 2$), $A = e_c \mathbf{A}_{F,L}$, $a = a_{\mathrm{E}}$, and let κ_s, $b_s = s_{c-s}$, $H(c-s)$, $M = \lfloor (h_* + 2g)/(\ell - 1) \rfloor + 1$ and j be the data of the arc level data along the word.

Step 0: parameters. $\sigma := \sigma_\ell(3g, (\ell-1)M, j) = \lfloor (3g + M/\ell^{j-1})\ell/(\ell-1)^2 \rfloor + 1 \leq \sigma_{\mathrm{E}}$ (Definition C.78, with $h = h_*$). By (Ae1), items 2 and 3 of Lemma C.102 apply: $h_* \geq g$; $G, S, \eta \leq g$; $b_s = s_{c-s} > g \geq 1$ for thick $c - s$; and $H(c-s) = g + b_s + S \geq b_s$ for an up level (Definition 23.4). By (Cc2) $c_0 = c - \mathrm{len} \in \mathcal{C}$ and $j \leq \mathrm{len}$, and by (Cc1) for c_0 the sites $c_0 + 1, \ldots, c_0 + j$ are thin; so Lemma C.105 applies for $\nu = 1, 2$: every truncation small vector is de Rham integral and kind integral. $\mathcal{T}_s^\nu$ is a $K_{(s)}[[t]]$-submodule (its definition is a $K_{(s)}[[t]]$-linear condition), so $o\,\mathcal{T}_s^1 \subseteq \mathcal{T}_s^2$, where o is the matrix of the level map (Lh1) of Definition 23.4. The kind and the de Rham integral vectors form additive groups stable under $\mathbb{Z}_\ell$ and, the families being increasing in i, under multiplication by $K_{(s)}[[t]]$. Finally $\rho_{\mathrm{E}} \leq a$ ($a = 2\sigma_{\mathrm{E}} + \rho_{\mathrm{E}} + 2g\,\mathrm{len}_{\max}$).

Step 1: the word. By (Cc3) at most two sites of the arc are thick, and κ_s is up or down exactly when $c - s$ is thick; by hypothesis some κ_s is down. So exactly one of the following holds: (D) one level s_1 is down, all others thin; (DD) two levels are down, all others thin; (DU) a down level s_1 and an up level $s_0 < s_1$, all others thin; (UD) a down level s_0 and an up level $s_1 > s_0$, all others thin. In case (DU), clause 1 of (Ae2) (with $s = s_0$, $t = s_1$) gives $b_{s_0} < \ell\, b_{s_1}$.

Step 2: partner of x'. By item 1 of Lemma C.95 for T_2 there is $y \in A^{r_2}$ with $\hat{y}_s - \ell^\sigma \mathrm{lv}_s^{(2)}(x') \in \mathcal{T}_s^2$ for all $s < \mathrm{len}$. By hypothesis and Step 0, $\hat{y}_s \in L^{r_2} + \{$kind integral at $s\}$ for all s.

Step 3: constants of y and their lifts. We find $\lambda, \lambda' \in \mathcal{O}_L^{r_2}$, a scalar $\theta \in A[1/\lambda_{\mathrm{len}}]$ with $\Pi\theta \in A$, and $v, v' \in \mathcal{O}_L^{r_1}$ such that, for every $s < \mathrm{len}$,

(a) $\hat{y}_s - \lambda - \lambda_s(\theta)\lambda'$ is kind integral;

(b) $ov = \ell^{2a}\lambda$, $ov' = \ell^{2a}\lambda'$;

(c) $\lambda_s(\theta)v' \in L^{r_1} + \lambda_s(Q_s)^{-g}\{\text{de Rham integral at } s\}$.

In cases (D), (DU): Lemma C.97 gives λ; put $\theta = 0$, $\lambda' = v' = 0$. In case (DD): Lemma C.98 gives $f \in Q_{s_1}^{b_{s_1}} A$ with $f - \varpi^\rho \in Q_{s_0}^{b_{s_0}} A$ and λ, λ'; put $\theta = f$. In case (UD): Lemma C.99 gives $\mathfrak{c}, \alpha, \beta$ with $P_1 = Q_{s_1}^{b_{s_1}} = \varpi^{\mathfrak{c}}\alpha + Q_{s_0}^{b_{s_0}}\beta$, λ, and $\lambda' \in U_{s_1}^{2,L} \cap \mathcal{O}_L^{r_2}$; put $\theta = \alpha/P_1$ ($\Pi\theta = \alpha\,\Pi/P_1 \in A$ as $b_{s_1} \le H(c - s_1)$). For (b): v is $\ell^{2a-\rho_{\mathrm{E}}}$ times the vector of Lemma C.101 for λ; in case (DD) v' likewise for λ'; in case (UD) $v' \in U_{s_1}^{1,L} \cap \mathcal{O}_L^{r_1}$ is given by Proposition C.103. For (c), with $\lambda_s(Q_s)^g = t^g \cdot \mathrm{unit}$ ((Lp1)) and Step 0: at a thin level, $\lambda_s(\theta) \in K[[t]]$ (for (UD) $\lambda_s(P_1)$ is a unit there), and $t^g K[[t]]v'$ is de Rham integral since $\mathrm{Fil}_s^1(u) = L^{r_1}$ for $u \le -G$ ((Lp7)) and $g \ge G$. In case (DD) at s_1: $\lambda_{s_1}(f) \in t^{b_{s_1}}K[[t]]$, and $t^{g+b_{s_1}}K[[t]]v'$ is de Rham integral ($\mathrm{Fil}_{s_1}^1(u) = L^{r_1}$ for $u \le -b_{s_1} - S$, $S \le g$); at s_0: $\lambda_{s_0}(f) \in \varpi^\rho + t^{b_{s_0}}K[[t]]$, so take the constant $\varpi^\rho v'$. In case (UD) at s_1: $\lambda_{s_1}(\theta) \in t^{-b_{s_1}}K[[t]]$ and $v' \in U_{s_1}^{1,L} = \mathrm{Fil}_{s_1}^1(b_{s_1}) \subseteq \mathrm{Fil}_{s_1}^1(u)$ for $u \le b_{s_1}$, so $t^g\lambda_{s_1}(\theta)v'$ is de Rham integral; at s_0: $\alpha/P_1 = \varpi^{-\mathfrak{c}}(1 - Q_{s_0}^{b_{s_0}}\beta/P_1)$ and $\lambda_{s_0}(P_1)$ is a unit, so $\lambda_{s_0}(\theta) \in \varpi^{-\mathfrak{c}} + t^{b_{s_0}}K[[t]]$; take the constant $\varpi^{-\mathfrak{c}}v'$ and use the down-level argument of case (DD).

Step 4: the vector z_0. Let $y_1 = \Pi(v + \theta v') \in A^{r_1}$, so $\hat{y}_{1,s} = v + \lambda_s(\theta)v'$. By item 2 of Lemma C.95 for T_1 there is $z \in W_1$ with $\mathrm{lv}_s^{(1)}(z) - \ell^\sigma \hat{y}_{1,s} \in \mathcal{T}_s^1$. Put $z_0 = \ell^{2\sigma_{\mathrm{E}} - 2\sigma} z \in W_1$.

Step 5: item 1. $\mathrm{lv}_s^{(1)}(z_0) = \ell^{2\sigma_{\mathrm{E}}-\sigma}(v + \lambda_s(\theta)v') + \tau$ with $\tau \in \mathcal{T}_s^1$; by (c) and Step 0 (truncation small vectors are de Rham integral; multiplication by $\lambda_s(Q_s)^g \in K[[t]]$ preserves this), there is $v_s \in L^{r_1}$ with $\lambda_s(Q_s)^g(\mathrm{lv}_s^{(1)}(z_0) - v_s)$ de Rham integral.

Step 6: item 2. By (Lh1), (b) and Step 0, $\mathrm{lv}_s^{(2)}(\mathbf{N}(\Phi)(z)) = o\,\mathrm{lv}_s^{(1)}(z) \in \ell^{\sigma+2a}(\lambda + \lambda_s(\theta)\lambda') + \mathcal{T}_s^2$. By Step 2, $\ell^{\sigma+2a}\ell^\sigma \mathrm{lv}_s^{(2)}(x') \in \ell^{\sigma+2a}\hat{y}_s + \mathcal{T}_s^2$. Hence

$$\mathrm{lv}_s^{(2)}\big(\ell^{2\sigma+2a}x' - \mathbf{N}(\Phi)(z)\big) \in \ell^{\sigma+2a}\big(\hat{y}_s - \lambda - \lambda_s(\theta)\lambda'\big) + \mathcal{T}_s^2,$$

which is kind integral by (a) and Step 0. Multiplying by $\ell^{2\sigma_{\mathrm{E}}-2\sigma}$: $\mathrm{lv}_s^{(2)}(\ell^{2\sigma_{\mathrm{E}}+2a}x' - \mathbf{N}(\Phi)(z_0))$ is kind integral for every $s < \mathrm{len}$. The Δ-invariance of x' is not used. □

Lemma C.95. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V,T) a pair of rank r, $\mathbf{N} = \mathbf{N}(T)$, and fix arc level data for (V,T) (cut c, length* len*, H, Π, frame $\mathbf{n}$ at $c_0 = c - \mathrm{len}$, parameters g, M, j with $1 \le j \le \mathrm{len}$). Put $\sigma = \sigma_\ell(3g, (\ell-1)M, j)$. Then:*

1. *for every $w \in W$ there is $y \in (e_c\mathbf{A}_{F,L})^r$ with $\hat{y}_s - \ell^\sigma \mathrm{lv}_s(w) \in \mathcal{T}_s$ for every $s < \mathrm{len}$;*
2. *for every $y \in (e_c\mathbf{A}_{F,L})^r$ there is $w \in W$ with $\mathrm{lv}_s(w) - \ell^\sigma\hat{y}_s \in \mathcal{T}_s$ for every $s < \mathrm{len}$.*

Proof. Put $m = (\ell-1)M$, $K = K_{(s)}$, $q_s = \mathrm{len} - s - 1 \ge 0$ for $s < \mathrm{len}$, and let $H_k = \sum_l h_{kl}n_l$ be the horizontal sections through the frame ($h_{kl} \in e_{c_0}E[[X]]$, Lemma 23.9 (Hf2)).

Step 0: denominators. Let $\mathcal{R}$ be the set of $\sum_i a_i X^i \in E[[X]]$ with $\ell^{s_\ell(i)}a_i \in \Lambda$ for all i. The function $s_\ell(i) = J + v_\ell(J!)$, $J = \lfloor i/(\ell-1)\rfloor$, is superadditive ($\lfloor a/(\ell-1)\rfloor + \lfloor b/(\ell-1)\rfloor \le \lfloor (a+b)/(\ell-1)\rfloor$, $v_\ell(J_1!) + v_\ell(J_2!) \le v_\ell((J_1+J_2)!)$, and $J \mapsto J + v_\ell(J!)$ is increasing) with $s_\ell(0) = 0$, so $\mathcal{R}$ is a subring of $E[[X]]$, closed under X-adic limits. By (Hf3) $h = (h_{kl}) \in M_r(\mathcal{R})$,

and $h \equiv 1 \bmod X$ ($H_k \in n_k + X\mathbf{N}_E$); hence $h = 1 - Z$ with $Z \in X\,M_r(\mathcal{R})$ and $h' = h^{-1} = \sum_{i\geq 0} Z^i \in M_r(\mathcal{R})$, i.e. $n_l = \sum_k h'_{lk} H_k$.

Step 1: truncated relay of one coordinate. Let $R \geq m$ and $u = \sum_i a_i X^i \in e_{c_0}\mathcal{R}$. Then

$$\ell^\sigma \varphi^j(u) = a(u) + X^m \lambda_j^{3g}\, b(u) + \ell^\sigma \varphi^j\big(X^R u_R\big), \qquad a(u) \in \mathbf{A}_{F,L},\ b(u) \in \mathbf{A}_{F,L}[1/\ell],$$

where $u_R = \sum_{i\geq R} a_i X^{i-R} \in E[[X]]$. Indeed $\varphi^j(X) = X\lambda_j$ and φ^j acts on coefficients by an automorphism of Λ, so $\ell^\sigma\varphi^j(\sum_{i<R} a_i X^i) = \sum_{i<R} \ell^\sigma\varphi^j(a_i)(X\lambda_j)^i$, and (Rt1) of Lemma 24.6 (with $3g$ in place of g; $\ell^{s_\ell(i)}\varphi^j(a_i) \in \Lambda$) writes each of these finitely many terms as an element of $\Lambda[[X]]$ plus an element of $X^m\lambda_j^{3g}\Lambda[[X]][1/\ell]$.

Step 2: levels of Frobenius pull-backs. For $Y = \sum_l c_l n_l \in e_{c_0}\mathbf{N}_E$ and $s < \mathrm{len}$, $G^{(q_s)}(Y) = \sum_l \mathrm{ev}^{(q_s)}(c_l)\varphi^{q_s}(\iota_T(n_l))$ (Lemma 23.13); for $Y \in \mathbf{N}_{c_0}$, $\Lambda_s(\varphi^{\mathrm{len}}(Y)) = G^{(q_s)}(Y)$, and $\lambda_s(\varphi^{\mathrm{len}}(a)) = \mathrm{ev}^{(q_s)}(a)$ for $a \in e_{c_0}\mathbf{A}_{F,L}[1/\ell]$ ((Eq3) of Lemma C.69, with $q = q_s$). By Lemma 23.13 (1), $G^{(q_s)}(H_k) = \varphi^{q_s-3}(d_k) = D_k^{(s)}$. Hence

$$\Lambda_s(\varphi^{\mathrm{len}}(n_l)) = \sum_k \mathrm{ev}^{(q_s)}(h'_{lk})\, D_k^{(s)},$$

so $\mathrm{lv}_s(\varphi^{\mathrm{len}}(n_l)) = (\mathrm{ev}^{(q_s)}(h'_{lk}))_k$; as $\varphi^{\mathrm{len}}(n_l) \in P_{\mathrm{len}}(\mathbf{N}_{c_0}) \subseteq W$ (Lemma C.96 item 1), this lies in $K((t))^r$ by (Lp1), and also in $(R_s^+)^r$; since $K((t)) \cap t^i R_s^+ = t^i K[[t]]$ (θ is injective on K), these coordinates lie in $K[[t]]$. Likewise, for $u \in e_{c_0}\mathcal{R}$, $\mathrm{ev}^{(q_s)}(X^R u_R) \in t^R R_s^+$ ($\mathrm{ev}^{(q)}(X) = \varphi^q(\mu) \in tB_{\mathrm{dR}}^+$), and whenever it lies in $K((t))$ it lies in $t^R K[[t]]$.

Step 3: the truncation ideal. As $\varphi^k(X) = (1+X)^{\ell^k} - 1 = X\prod_{s'<k} Q_{s'}$ and $\varphi^k(Q_{s'}) = Q_{s'+k}$,

$$f' = \varphi^{\mathrm{len}-j}(X^m\lambda_j^{3g}) = X^m \prod_{s'<\mathrm{len}-j} Q_{s'}^m \prod_{\mathrm{len}-j\leq s'<\mathrm{len}} Q_{s'}^{3g}.$$

By (Lp1) (Lemma 23.17) $\lambda_s(X)$ and $\lambda_s(Q_{s'})$ for $s' \neq s$ are units of $K[[t]]$ and $\lambda_s(Q_s) \in tK[[t]]^\times$, so $\lambda_s(f') \in t^{e_s}K[[t]]^\times$ with $e_s = m$ or $e_s = 3g$, and $e_s \leq m \leq R$ ($3g \leq m$); so $t^R K[[t]] \subseteq \lambda_s(f')K[[t]]$, and $\lambda_s(\varphi^{\mathrm{len}-j}(X^m\lambda_j^{3g}b)) = \lambda_s(f')\lambda_s(\varphi^{\mathrm{len}-j}(b)) \in \lambda_s(f')K[[t]]$ for $b \in \mathbf{A}_{F,L}[1/\ell]$ ((Lp1)). By definition, $f \in \mathcal{T}_s$ if and only if $\lambda_s(\Pi)f \in \lambda_s(f')K[[t]]^r$.

Item 1. Let $w \in W$, so $\Pi w = \sum_l y_l^0 \varphi^{\mathrm{len}}(n_l)$ with $y_l^0 \in e_c\mathbf{A}_{F,L}$ ($\mathbf{n}$ generates $\mathbf{N}_{c_0}$). By Step 2, $\lambda_s(\Pi)\mathrm{lv}_s(w)_k = \sum_l \lambda_s(y_l^0)\,\mathrm{ev}^{(q_s)}(h'_{lk})$. Apply Step 1 to $u = h'_{lk}$ and put $y_k = \sum_l \varphi^{\mathrm{len}-j}(a(h'_{lk}))\, y_l^0 \in e_c\mathbf{A}_{F,L}$. Applying $\varphi^{\mathrm{len}-j}$ to the identity of Step 1 and then λ_s (via $\mathrm{ev}^{(q_s)}$ for the last term),

$$\ell^\sigma \mathrm{ev}^{(q_s)}(h'_{lk}) = \lambda_s(\varphi^{\mathrm{len}-j}(a(h'_{lk}))) + \lambda_s(f')\lambda_s(\varphi^{\mathrm{len}-j}(b(h'_{lk}))) + \ell^\sigma \mathrm{ev}^{(q_s)}\big(X^R(h'_{lk})_R\big);$$

the first two terms lie in $K[[t]]$, hence so does the third, which therefore lies in $t^R K[[t]]$ (Step 2). Multiplying by $\lambda_s(y_l^0) \in K[[t]]$ and summing over l, $\ell^\sigma\lambda_s(\Pi)\mathrm{lv}_s(w) - \lambda_s(y) \in \lambda_s(f')K[[t]]^r$ (Step 3), i.e. $\hat{y}_s - \ell^\sigma \mathrm{lv}_s(w) \in \mathcal{T}_s$.

Item 2. Let $y \in (e_c\mathbf{A}_{F,L})^r$. Apply Step 1 to $u = h_{kl}$, put $I_k = \sum_l a(h_{kl})\varphi^j(n_l) \in P_j(\mathbf{N}_{c_0})$, and let $w = \Pi^{-1}\sum_k y_k \varphi^{\mathrm{len}-j}(I_k)$. Since $\varphi^{\mathrm{len}-j}$ maps $P_j(\mathbf{N}_{c_0})$ into $P_{\mathrm{len}}(\mathbf{N}_{c_0})$, $\Pi w \in P_{\mathrm{len}}(\mathbf{N}_{c_0})$ and $w \in W$. Since $\varphi^{\mathrm{len}-j}(I_k) = \sum_l \varphi^{\mathrm{len}-j}(a(h_{kl}))\varphi^{\mathrm{len}}(n_l)$, Step 2 gives $\mathrm{lv}_s(\varphi^{\mathrm{len}-j}(I_k)) = \sum_l \lambda_s(\varphi^{\mathrm{len}-j}(a(h_{kl})))\,\mathrm{lv}_s(\varphi^{\mathrm{len}}(n_l))$. Exactly as in item 1 (Step 1 for $u = h_{kl}$, $\varphi^{\mathrm{len}-j}$, then λ_s and $\mathrm{ev}^{(q_s)}$, which agree on φ^{len} of elements of $e_{c_0}\mathbf{A}_{F,L}[1/\ell]$), $\lambda_s(\varphi^{\mathrm{len}-j}(a(h_{kl}))) \in \ell^\sigma \mathrm{ev}^{(q_s)}(h_{kl}) + \lambda_s(f')K[[t]] + t^R K[[t]]$, where $\mathrm{ev}^{(q_s)}(h) = \mathrm{ev}^{(q_s)}(h')^{-1}$ has entries in $K[[t]]$ because $\mathrm{ev}^{(q_s)}(h') \in M_r(K[[t]])$ (Step 2) and $\mathrm{ev}^{(q_s)}(h') - 1 \in M_r(K[[t]] \cap tR_s^+) = M_r(tK[[t]])$ ($h' \equiv 1 \bmod X$); the term $\ell^\sigma\mathrm{ev}^{(q_s)}(X^R(h_{kl})_R)$ is then in $K[[t]] \cap t^R R_s^+ = t^R K[[t]]$. The coordinates $\mathrm{lv}_s(\varphi^{\mathrm{len}}(n_l)) = (\mathrm{ev}^{(q_s)}(h'_{lk'}))_{k'}$ lie in $K[[t]]$ (Step 2), and $\mathrm{ev}^{(q_s)}$ is a ring homomorphism ((Eq1) of Lemma C.69)

with $hh' = 1$, so $\sum_l \mathrm{ev}^{(q_s)}(h_{kl})\mathrm{ev}^{(q_s)}(h'_{lk'}) = \delta_{kk'}$. Hence $\mathrm{lv}_s(\varphi^{\mathrm{len}-j}(I_k)) \in \ell^\sigma e_k + \lambda_s(f')K[[t]]^r + t^R K[[t]]^r = \ell^\sigma e_k + \lambda_s(f')K[[t]]^r$ (Step 3), e_k the k-th unit vector. Therefore $\lambda_s(\Pi)\mathrm{lv}_s(w) = \sum_k \lambda_s(y_k)\,\mathrm{lv}_s(\varphi^{\mathrm{len}-j}(I_k)) \in \ell^\sigma\lambda_s(y) + \lambda_s(f')K[[t]]^r$, i.e. $\mathrm{lv}_s(w) - \ell^\sigma\hat{y}_s \in \mathcal{T}_s$. □

Lemma C.96. *Let ℓ, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ be as in Proposition 23.7, let (V',T'), (V,T), (V'',T'') be pairs with an exact sequence $0 \to T' \xrightarrow{\iota'} T \xrightarrow{\pi} T'' \to 0$ of G_F-equivariant $\mathcal{O}_L$-linear maps, and let $(M_a,h_a)_a$ be a window of V as in (Ex1). Let $c \in \mathbb{Z}/n$, $1 \le e \le n$, and $H\colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$ with $H(c-s) \ge h_{c-s}$ for $0 \le s < e$. For a pair (V°,T°) put*

$$W(T^\circ) = \{w \in \mathbf{N}(T^\circ)[1/\lambda_\infty] :\ \Lambda_{c,e}(H)\,w \in P_e(\mathbf{N}(T^\circ)_{c-e})\}.$$

Then:

1. *$W(T^\circ)$ is an $\mathbf{A}_{F,L}$-submodule of $\mathbf{N}(T^\circ)[1/\lambda_\infty]$ containing $P_e(\mathbf{N}(T^\circ)_{c-e})$;*
2. *$\mathbf{N}(T)_c \subseteq W(T)$;*
3. *if $u \in \mathbf{N}(T')[1/\lambda_\infty]$ and $\mathbf{N}(\iota')(u) \in W(T)$, then $u \in W(T')$.*

Proof. Write

$$\Lambda = \Lambda_{c,e}(H) \in \mathbb{Z}_\ell[[X]] \quad \text{and} \quad P(T^\circ) = P_e(\mathbf{N}(T^\circ)_{c-e}),$$

an $\mathbf{A}_{F,L}$-submodule of $\mathbf{N}(T^\circ)[1/\lambda_\infty]$ by definition.

Item 1. For $f \in \mathbf{A}_{F,L}$ and $w \in W(T^\circ)$, $\Lambda f w = f\Lambda w \in P(T^\circ)$; and $\Lambda P(T^\circ) \subseteq P(T^\circ)$.

Item 2. Let $H'\colon \mathbb{Z}/n \to \mathbb{Z}_{\ge 0}$ equal H at the e distinct sites $c-s$ ($0 \le s < e$; distinct as $e \le n$) and h elsewhere. Then $H' \ge h$ pointwise and $\Lambda_{c,e}(H') = \prod_{s<e} Q_s^{H(c-s)} = \Lambda$. By (Ex1), $\mathbf{N}(T)$ is a Wach module with window (M_a,h_a), and item 2 of Lemma 23.15 (with its c,e,a equal to $c-e,e,c$) gives $\Lambda\,\mathbf{N}(T)_c \subseteq P(T)$.

Item 3. Put $R_b = e_b\mathbf{A}_{F,L}$. By item 1 of Lemma 23.20 (a statement about the rings only), R_b is a free module over the subring $\varphi(R_{b-1})$ (basis $1,X,\dots,X^{\ell-1}$), and φ is injective; by transitivity R_c is free over $\varphi^e(R_{c-e})$, so R_c is flat as an R_{c-e}-module via φ^e. By Lemma 23.33 the sequence

$$0 \to \mathbf{N}(T')_{c-e} \xrightarrow{\mathbf{N}(\iota')} \mathbf{N}(T)_{c-e} \xrightarrow{\mathbf{N}(\pi)} \mathbf{N}(T'')_{c-e}$$

is exact (multiply the exact sequence of the lemma by e_{c-e}), hence so is its base change along $\varphi^e\colon R_{c-e} \to R_c$. Each $\mathbf{N}(T^\circ)$ is a Wach module for some window ((Ex1); the Hodge jumps of V° form a finite set), so by item 1 of Lemma 23.15 the base change of $\mathbf{N}(T^\circ)_{c-e}$ is identified with $P(T^\circ)$ by $g\otimes x \mapsto g\varphi^e(x)$, compatibly with $\mathbf{N}(\iota')$ and $\mathbf{N}(\pi)$, which commute with φ (Ex3). Hence

$$0 \to P(T') \xrightarrow{\mathbf{N}(\iota')} P(T) \xrightarrow{\mathbf{N}(\pi)} P(T'')$$

is exact. Now let u be as in item 3 and $v = \Lambda\mathbf{N}(\iota')(u) = \mathbf{N}(\iota')(\Lambda u) \in P(T)$. Since $\mathbf{N}(\pi)\circ\mathbf{N}(\iota') = 0$ (Lemma 23.33, extended to the localisations), $\mathbf{N}(\pi)(v) = 0$, so $v = \mathbf{N}(\iota')(p)$ with $p \in P(T')$. Finally $\mathbf{N}(\iota')$ is injective on $\mathbf{N}(T')[1/\lambda_\infty]$ (Lemma 23.33 and exactness of localisation), so $\Lambda u = p \in P(T')$, i.e. $u \in W(T')$. □

Lemma C.97. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V,T) a pair of rank r, and fix arc level data for (V,T) (cut c, length* len*, H, $\Pi = \prod_{s<\mathrm{len}} Q_s^{H(c-s)}$, frame, parameters, kinds κ_s and sizes b_s). For $y \in (e_c\mathbf{A}_{F,L})^r$ and $s <$ len put $\hat{y}_s = \lambda_s(\Pi)^{-1}\lambda_s(y) \in K_{(s)}((t))^r$. Suppose that there is $s_1 <$ len with κ_{s_1} down and $b_{s_1} \ge 1$, and that one of the following holds:*

(D) *κ_s is thin for every $s < \mathrm{len}$, $s \neq s_1$;*

(DU) *there is $s_0 < s_1$ with κ_{s_0} up, $b_{s_0} \leq H(c - s_0)$ and $b_{s_0} < \ell\, b_{s_1}$, and κ_s is thin for every $s < \mathrm{len}$, $s \notin \{s_0, s_1\}$.*

If $y \in (e_c\mathbf{A}_{F,L})^r$ and $\hat{y}_s \in L^r + \{$kind integral vectors at $s\}$ for every $s < \mathrm{len}$, then there is $\lambda \in \mathcal{O}_L^r$ such that $\hat{y}_s - \lambda$ is kind integral at s for every $s < \mathrm{len}$.

Proof. Identify $e_c\mathbf{A}_{F,L} = e_c(\mathcal{O}_F \otimes \mathcal{O}_L)[[X]]$ with $\mathcal{O}_L[[X]]$ ($e_c(\mathcal{O}_F \otimes_{\mathbb{Z}_\ell} \mathcal{O}_L) \cong \mathcal{O}_L$), and let ϖ be a uniformiser of $\mathcal{O}_L$ and k_L its residue field. By Lemma 23.17, (Lp1) and (Lp5) hold and $\lambda_s(\Pi) \in t^{H(c-s)}K_{(s)}[[t]]^\times$; in particular $\lambda_s(\Pi)$ is invertible in $K_{(s)}((t))$ and may be cancelled. Each λ_s is a ring homomorphism sending a constant $a \in \mathcal{O}_L$ to $a \in L \subseteq K_{(s)}$; hence for an $\mathcal{O}_L$-linear form $\phi\colon \mathcal{O}_L^r \to \mathcal{O}_L$, applied coordinatewise, $\lambda_s(\phi(y)) = \phi(\lambda_s(y)) = \lambda_s(\Pi)\,\phi(\hat{y}_s)$, with ϕ extended $K_{(s)}((t))$-linearly. Put $b_1 = b_{s_1}$, $U = U_{s_1}^L$, $U_\mathcal{O} = U \cap \mathcal{O}_L^r$; in case (D) put $b_0 = 0$ and let s_0 be any index (the factor $Q_{s_0}^{b_0} = 1$ below), in case (DU) $b_0 = b_{s_0}$.

Facts on $\mathcal{O}_L[[X]]$. By Lemma 23.8, $Q_s = \Phi_{\ell^{s+1}}(1 + X)$ is a monic polynomial of degree $\ell^s(\ell - 1)$ with $Q_s \equiv X^{\ell^s(\ell-1)} \bmod \ell$, hence modulo ϖ: a distinguished polynomial, and so are its powers. (F1) For a distinguished polynomial P, $\mathcal{O}_L[[X]]/(P)$ is a free $\mathcal{O}_L$-module (Weierstrass division), so $\ell^N f \in P\,\mathcal{O}_L[[X]]$ or $\varpi^N f \in P\,\mathcal{O}_L[[X]]$ implies $f \in P\,\mathcal{O}_L[[X]]$. (F2) For $s \neq s'$ and $h, h' \geq 0$, Q_s^h and $Q_{s'}^{h'}$ have no common prime factor in the unique factorisation domain $\mathcal{O}_L[[X]]$: a common prime factor is not associated to ϖ (Q_s is monic), so by Weierstrass preparation it is associated to a distinguished polynomial of positive degree whose roots in the open unit disc are common roots of $\Phi_{\ell^{s+1}}(1 + X)$ and $\Phi_{\ell^{s'+1}}(1 + X)$; there are none. Hence if f is divisible by $Q_s^{h_s}$ for each s in a finite set, it is divisible by their product.

Step 1: the constant at s_1. By hypothesis $\hat{y}_{s_1} = d + k$ with $d \in L^r$ and k kind integral at s_1: as κ_{s_1} is down, the t^i-coefficient of k is 0 for $i < 0$ and lies in $K_{(s_1)} \otimes_L U$ for $0 \leq i < b_1$. It suffices to find $\lambda \in \mathcal{O}_L^r$ with $d - \lambda \in U$. Indeed, then $\hat{y}_{s_1} - \lambda = (d - \lambda) + k$ has t^0-coefficient in $K_{(s_1)} \otimes_L U$ ($b_1 \geq 1$) and the other coefficients of k, so it is kind integral at s_1. For $s \neq s_1$ the kind is thin or up and $\mathrm{Nb}_s(i) = L^r$ for $i \geq 0$, so constants are kind integral at s; kind integral vectors form an additive group (a coefficientwise condition by subspaces), so $\hat{y}_s - \lambda$ is kind integral at s by the hypothesis.

Step 2: reduction to linear forms. The submodule $U_\mathcal{O}$ is saturated in $\mathcal{O}_L^r$, so $\mathcal{O}_L^r/U_\mathcal{O}$ is torsion free, hence free, and there is a basis $e_1, \dots, e_r$ of $\mathcal{O}_L^r$ with $e_1, \dots, e_u$ a basis of $U_\mathcal{O}$, hence an L-basis of U. Let $\phi_1, \dots, \phi_r$ be the dual coordinate forms. If $\phi_i(d) \in \mathcal{O}_L$ for $u < i \leq r$, then $\lambda = \sum_{i>u} \phi_i(d)e_i \in \mathcal{O}_L^r$ and $d - \lambda \in U$. So it suffices to show: *for every $\mathcal{O}_L$-linear form ϕ on $\mathcal{O}_L^r$ vanishing on $U_\mathcal{O}$ (hence, extended, on U), $\phi(d) \in \mathcal{O}_L$.*

Step 3: divisibility. Fix such ϕ and put $f = \phi(y) \in \mathcal{O}_L[[X]]$. For a thin s: $\hat{y}_s \in K_{(s)}[[t]]^r$ (constants and kind integral vectors have no negative powers of t), so $\lambda_s(f) \in t^{H(c-s)}K_{(s)}[[t]]$. In case (DU), at s_0: the kind family of an up level vanishes below $-b_0$, so $\hat{y}_{s_0} \in t^{-b_0}K_{(s_0)}[[t]]^r$ and $\lambda_{s_0}(f) \in t^{H(c-s_0)-b_0}K_{(s_0)}[[t]]$. At s_1: $\phi(k)$ has vanishing t^i-coefficients for $i < b_1$ (ϕ kills $K_{(s_1)} \otimes_L U$), so

$$\phi(\hat{y}_{s_1}) = \phi(d) + t^{b_1}h, \qquad h \in K_{(s_1)}[[t]],$$

and $\lambda_{s_1}(f) \in t^{H(c-s_1)}K_{(s_1)}[[t]]$. By (Lp5) and (F1), f is divisible by $Q_s^{H(c-s)}$ for $s \neq s_0$ and by $Q_{s_0}^{H(c-s_0)-b_0}$; by (F2), $f = \Pi' w$ with $w \in \mathcal{O}_L[[X]]$ and $\Pi' = \Pi\, Q_{s_0}^{-b_0} \in \mathcal{O}_L[[X]]$.

Step 4: the constant is integral. From $\lambda_{s_1}(\Pi')\lambda_{s_1}(w) = \lambda_{s_1}(f) = \lambda_{s_1}(\Pi')\lambda_{s_1}(Q_{s_0})^{b_0}(\phi(d) + t^{b_1}h)$ and the cancellation of $\lambda_{s_1}(\Pi')$ (a divisor of $\lambda_{s_1}(\Pi)$, and $\lambda_{s_1}(Q_{s_0}) \in K_{(s_1)}[[t]]$ by (Lp1)),

$$\lambda_{s_1}(w - Q_{s_0}^{b_0}\phi(d)) \in t^{b_1}K_{(s_1)}[[t]].$$

Choose $k \geq 0$ with $c_0 := \varpi^k \phi(d) \in \mathcal{O}_L$. Then $\lambda_{s_1}(\varpi^k w - Q_{s_0}^{b_0} c_0) \in t^{b_1} K_{(s_1)}[[t]]$, and (Lp5) with (F1) give $m \in \mathcal{O}_L[[X]]$ with

$$\varpi^k w - Q_{s_0}^{b_0} c_0 = Q_{s_1}^{b_1} m.$$

Suppose $\phi(d) \notin \mathcal{O}_L$, i.e. $c_0 = \varpi^e u$ with $u \in \mathcal{O}_L^\times$ and $0 \leq e < k$. Then $\varpi^e(\varpi^{k-e} w - u Q_{s_0}^{b_0}) \in Q_{s_1}^{b_1} \mathcal{O}_L[[X]]$, so by (F1) $\varpi^{k-e} w - u Q_{s_0}^{b_0} = Q_{s_1}^{b_1} m'$ with $m' \in \mathcal{O}_L[[X]]$. Reduce modulo ϖ in $k_L[[X]]$: since $k - e \geq 1$,

$$-\bar{u}\, X^{\ell^{s_0}(\ell-1)b_0} = X^{\ell^{s_1}(\ell-1)b_1}\, \bar{m}', \qquad \bar{u} \neq 0.$$

The left side has X-adic order exactly $\ell^{s_0}(\ell-1)b_0$, the right side order at least $\ell^{s_1}(\ell-1)b_1$; hence $\ell^{s_0} b_0 \geq \ell^{s_1} b_1$. In case (D), $b_0 = 0 < \ell^{s_1} b_1$; in case (DU), $s_1 \geq s_0 + 1$ gives $\ell^{s_1} b_1 \geq \ell^{s_0} \cdot \ell b_1 > \ell^{s_0} b_0$. Either way a contradiction, so $\phi(d) \in \mathcal{O}_L$. By Step 2 this gives λ, and by Step 1 the assertion. □

Lemma C.98. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V, T) a pair of rank r, and fix arc level data for (V, T) (cut c, length* len*, H, Π, frame, parameters, kinds and sizes). Identify $e_c \mathbf{A}_{F,L}$ with $\mathcal{O}_L[[X]]$, let ϖ be a uniformiser of $\mathcal{O}_L$, and suppose that there are $s_0 \neq s_1$ below* len *with $\kappa_{s_0}, \kappa_{s_1}$ down, $b_0 = b_{s_0} \geq 1$, $b_1 = b_{s_1} \geq 1$, and κ_s thin for every other $s <$* len*. Then:*

1. *the ideal $(Q_{s_0}^{b_0}, Q_{s_1}^{b_1})$ of $\mathcal{O}_L[[X]]$ meets $\mathcal{O}_L$ in $\varpi^\rho \mathcal{O}_L$ for an integer $\rho \geq 0$, and there is $f \in Q_{s_1}^{b_1} \mathcal{O}_L[[X]]$ with $f - \varpi^\rho \in Q_{s_0}^{b_0} \mathcal{O}_L[[X]]$;*
2. *for every such f and every $y \in (e_c \mathbf{A}_{F,L})^r$ with $\hat{y}_s \in L^r + \{$kind integral vectors at $s\}$ for every $s <$* len*, there are $\lambda, \lambda' \in \mathcal{O}_L^r$ such that $\hat{y}_s - \lambda - \lambda_s(f)\lambda'$ is kind integral at s for every $s <$* len*.*

Proof. Write $A = \mathcal{O}_L[[X]]$, $P_i = Q_{s_i}^{b_i}$, $U_i = U_{s_i}^L$ and $U_{i,\mathcal{O}} = U_i \cap \mathcal{O}_L^r$ $(i = 0, 1)$. We use the following facts: the Q_s are distinguished polynomials (Lemma 23.8); (F1) $A/(P)$ is $\mathcal{O}_L$-free for distinguished P (Weierstrass division), so $\varpi^N f \in PA$ implies $f \in PA$; (F2) powers of distinct Q_s are coprime in the unique factorisation domain A (a common prime factor is not associated to ϖ, as Q_s is monic, so by Weierstrass preparation it is associated to a distinguished polynomial of positive degree whose roots are common roots of $\Phi_{\ell^{s+1}}(1 + X)$ and $\Phi_{\ell^{s'+1}}(1 + X)$, and there are none); $\lambda_s(\Pi) \in t^{H(c-s)} K_{(s)}[[t]]^\times$ and (Lp1), (Lp5) hold (Lemma 23.17). For a saturated submodule $U_{\mathcal{O}} \subseteq \mathcal{O}_L^r$ fix a basis $e_1, \ldots, e_r$ of $\mathcal{O}_L^r$ whose first u members are a basis of $U_{\mathcal{O}}$, with dual forms $\phi_1, \ldots, \phi_r$; then $z \in A^r$ lies in $U_{\mathcal{O}} \otimes A + P\, A^r$ if and only if $\phi_i(z) \in PA$ for $i > u$ (write $z = \sum_i \phi_i(z) e_i$). A constant vector of $U_{\mathcal{O}} \otimes A + PA^r$ (P distinguished of positive degree) lies in $U_{\mathcal{O}}$, since a constant in PA is 0 (uniqueness of the Weierstrass remainder).

Item 1. The polynomials P_0, P_1 are distinguished without common root, so their resultant is a nonzero element of $\mathcal{O}_L$ lying in $(P_0, P_1)\mathcal{O}_L[X]$. Hence $(P_0, P_1) \cap \mathcal{O}_L$ is a nonzero ideal $\varpi^\rho \mathcal{O}_L$. Writing $\varpi^\rho = aP_0 + bP_1$ $(a, b \in A)$, $f = bP_1$ has the two properties.

Step 1: Π divides y. At a thin or down level, kind integral vectors and constants have no negative powers of t, so $\hat{y}_s \in K_{(s)}[[t]]^r$ and $\lambda_s(y_k) \in t^{H(c-s)} K_{(s)}[[t]]$ for every coordinate and every $s <$ len. By (Lp5), (F1), (F2), $y = \Pi x$ with $x \in A^r$, and $\hat{y}_s = \lambda_s(x)$ (cancellation).

Step 2: integral constants at each down level. Let $i \in \{0, 1\}$, $s = s_i$, and write $\lambda_s(x) = d_i + k_i$ with $d_i \in L^r$ and k_i kind integral: its t^j-coefficients vanish for $j < 0$ and lie in $K_{(s)} \otimes_L U_i$ for $0 \leq j < b_i$. For an $\mathcal{O}_L$-linear form ϕ vanishing on $U_{i,\mathcal{O}}$, $\lambda_s(\phi(x)) - \phi(d_i) \in t^{b_i} K_{(s)}[[t]]$; choosing k with $\varpi^k \phi(d_i) \in \mathcal{O}_L$, (Lp5) and (F1) give $\varpi^k \phi(x) - \varpi^k \phi(d_i) \in Q_s^{b_i} A$, and comparing Weierstrass remainders modulo Q_s (degree ≥ 1) shows that $\phi(d_i)$ is the constant term of the remainder of $\phi(x)$, an element of $\mathcal{O}_L$. Hence there is $\lambda_i \in \mathcal{O}_L^r$ with $d_i - \lambda_i \in U_i$: $U_{i,\mathcal{O}}$ is saturated in $\mathcal{O}_L^r$, so some basis $e_1, \ldots, e_r$ of $\mathcal{O}_L^r$ has $e_1, \ldots, e_u$ a basis of $U_{i,\mathcal{O}}$, hence an L-basis of U_i; the

dual forms ϕ'_j, $j > u$, vanish on $U_{i,\mathcal{O}}$, so $\phi'_j(d_i) \in \mathcal{O}_L$, and $\lambda_i = \sum_{j>u} \phi'_j(d_i) e_j$ works. Then $\lambda_s(x - \lambda_i) = (d_i - \lambda_i) + k_i$, so $\lambda_s(\phi_j(x - \lambda_i)) \in t^{b_i} K_{(s)}[[t]]$ for the forms ϕ_j ($j > u$) of an adapted basis of $U_{i,\mathcal{O}}$, and by (Lp5), (F1) $\phi_j(x - \lambda_i) \in P_i A$. Hence

$$x - \lambda_i \in U_{i,\mathcal{O}} \otimes A + P_i A^r \qquad (i = 0, 1).$$

Step 3: the two constants. Let $N = U_{0,\mathcal{O}} + U_{1,\mathcal{O}} \subseteq \mathcal{O}_L^r$ and $M = \mathcal{O}_L^r / N$, a finitely generated $\mathcal{O}_L$-module, and $\delta = \lambda_0 - \lambda_1$. Subtracting the two relations of Step 2, the image $\bar{\delta}$ of δ in $M \otimes_{\mathcal{O}_L} A = M[[X]]$ lies in $(P_0, P_1) \cdot M[[X]]$. We claim $M \cap (P_0, P_1) M[[X]] = \varpi^\rho M$. Decompose $M \cong \bigoplus_m \mathcal{O}_L / \varpi^{k_m}$ ($k_m \in \mathbb{Z}_{\geq 1} \cup \{\infty\}$); both sides are compatible with the decomposition, so it suffices to treat $M = \mathcal{O}_L / \varpi^k$, i.e. to show: if $c \in \mathcal{O}_L$ and $c \in I + \varpi^k A$ with $I = (P_0, P_1)$, then $c \in \varpi^{\min(\rho,k)} \mathcal{O}_L$. Suppose $c = \varpi^e u$ with u a unit and $e < \min(\rho, k)$. In $R = A/I$ we get $\varpi^e \in \varpi^k R \subseteq \varpi^{e+1} R$, so $\varpi^e(1 - \varpi r) = 0$ in R for some r; R is a quotient of the local ring A with ϖ in its maximal ideal, so $1 - \varpi r$ is a unit and $\varpi^e = 0$ in R, i.e. $\varpi^e \in I \cap \mathcal{O}_L = \varpi^\rho \mathcal{O}_L$, contradicting $e < \rho$. The inclusion $\varpi^\rho M \subseteq (P_0, P_1) M[[X]]$ is clear. Hence $\bar{\delta} \in \varpi^\rho M$: there are $\lambda' \in \mathcal{O}_L^r$, $u_0 \in U_{0,\mathcal{O}}$, $u_1 \in U_{1,\mathcal{O}}$ with $\lambda_0 - \lambda_1 = \varpi^\rho \lambda' + u_0 + u_1$. Put $\lambda = \lambda_1 + u_1 \in \mathcal{O}_L^r$.

Step 4: the levels. Let $\mu = x - \lambda - f\lambda' \in A^r$; then $\hat{y}_s - \lambda - \lambda_s(f)\lambda' = \lambda_s(\mu)$. At s_1: $\mu = (x - \lambda_1) - u_1 - f\lambda' \in U_{1,\mathcal{O}} \otimes A + P_1 A^r$, as $f \in P_1 A$. At s_0: $\mu = (x - \lambda_0) + u_0 - (f - \varpi^\rho)\lambda' \in U_{0,\mathcal{O}} \otimes A + P_0 A^r$. For $i = 0, 1$, λ_{s_i} maps $U_{i,\mathcal{O}} \otimes A$ into $K_{(s_i)}[[t]] \otimes_L U_i$ and $P_i A^r$ into $t^{b_i} K_{(s_i)}[[t]]^r$ ((Lp1): $\lambda_{s_i}(Q_{s_i}) \in t K_{(s_i)}[[t]]$), so $\lambda_{s_i}(\mu)$ has no negative powers of t and has t^j-coefficients in $K_{(s_i)} \otimes_L U_i$ for $j < b_i$: it is kind integral at s_i (down kind). At a thin level, $\lambda_s(\mu) \in K_{(s)}[[t]]^r$ is kind integral. This proves item 2. □

Lemma C.99. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V, T) a pair of rank r, and fix arc level data for (V, T) (cut c, length* len*, H, Π, frame, parameters, kinds and sizes). Identify $e_c \mathbf{A}_{F,L}$ with $A = \mathcal{O}_L[[X]]$ and let ϖ be a uniformiser of $\mathcal{O}_L$. Suppose that there are $s_0 \neq s_1$ below* len *with κ_{s_1} up, $1 \leq b_1 = b_{s_1} \leq H(c - s_1)$, κ_{s_0} down, $b_0 = b_{s_0} \geq 1$, and κ_s thin for every other $s <$* len*; put $P_i = Q_{s_i}^{b_i}$ and $U_{1,\mathcal{O}} = U_{s_1}^L \cap \mathcal{O}_L^r$. Then:*

1. *there are an integer $\mathfrak{c} \geq 0$ and $\alpha, \beta \in A$ with $P_1 = \varpi^{\mathfrak{c}} \alpha + P_0 \beta$ and $P_1 \notin (\varpi^{\mathfrak{c}+1}, P_0)$;*
2. *for all such $\mathfrak{c}, \alpha, \beta$ and every $y \in (e_c \mathbf{A}_{F,L})^r$ with $\hat{y}_s \in L^r +$ {kind integral vectors at s} for every $s <$* len*, there are $\lambda \in \mathcal{O}_L^r$ and $\lambda' \in U_{1,\mathcal{O}}$ such that*

$$\hat{y}_s - \lambda - \lambda_s(\alpha) \lambda_s(P_1)^{-1} \lambda'$$

is kind integral at s for every $s <$ len*.*

Proof. We use: (F1) $A/(P)$ is $\mathcal{O}_L$-free for a distinguished polynomial P (Weierstrass division; the Q_s and their powers are distinguished, Lemma 23.8); (F2) powers of distinct Q_s are coprime in the unique factorisation domain A (by Weierstrass preparation a common prime factor would give a common root of $\Phi_{\ell^{s+1}}(1+X)$ and $\Phi_{\ell^{s'+1}}(1+X)$, $s \neq s'$, in the open unit disc); (Lp1), (Lp5) and $\lambda_s(\Pi) \in t^{H(c-s)} K_{(s)}[[t]]^\times$ (Lemma 23.17); for a saturated $U_{\mathcal{O}} \subseteq \mathcal{O}_L^r$ with adapted basis and dual forms ϕ_j, $z \in U_{\mathcal{O}} \otimes A + PA^r$ if and only if $\phi_j(z) \in PA$ for the forms ϕ_j vanishing on $U_{\mathcal{O}}$. Multiplication by a unit of $K_{(s)}[[t]]$ preserves kind integrality, the kind families being increasing in i (as for de Rham integrality in Lemma C.93). Put $U_0 = U_{s_0}^L$, $U_1 = U_{s_1}^L$, $F_{\mathcal{O}} = U_0 \cap \mathcal{O}_L^r$, $C = U_{1,\mathcal{O}}$.

Item 1. We have $P_1 \in (\varpi^0, P_0) = A$. If $P_1 \in (\varpi^N, P_0)$ for all N, then the image of P_1 in $A/(P_0)$, a finitely generated free $\mathcal{O}_L$-module, lies in $\bigcap_N \varpi^N (A/P_0) = 0$, so $P_0 \mid P_1$, contradicting (F2) ($\deg P_0 \geq 1$). Take $\mathfrak{c}$ maximal with $P_1 \in (\varpi^{\mathfrak{c}}, P_0)$ and write $P_1 = \varpi^{\mathfrak{c}} \alpha + P_0 \beta$.

Steps 1 and 2: division and the up level. The hypotheses of Lemma C.100 hold: κ_{s_1} is up with $1 \le b_1 \le H(c-s_1)$, every other level is thin or down, and $\hat{y}_s \in L^r +$ {kind integral vectors at s} for every s. So, with $\Pi' = \Pi/P_1 \in A$, $y = \Pi' x$ with $x \in A^r$, $\hat{y}_s = \lambda_s(P_1)^{-1}\lambda_s(x)$ for every s, and $x = u + P_1 z$ with $u \in C \otimes A$, $z \in A^r$.

Step 3: the down level. Write $\hat{y}_{s_0} = d_0 + k_0$ with $d_0 \in L^r$ and k_0 kind integral (down), and choose $k \ge 0$ with $d' = \varpi^k d_0 \in \mathcal{O}_L^r$. For a form ϕ vanishing on $F_{\mathcal{O}}$: $\lambda_{s_0}(\phi(x)) = \lambda_{s_0}(P_1)(\phi(d_0) + \phi(k_0))$ and $\phi(k_0) \in t^{b_0} K_{(s_0)}[[t]]$, so by (Lp5), (F1)

$$\varpi^k \phi(x) - P_1\, \phi(d') \in P_0 A. \tag{$*$}$$

Step 4: the key divisibility. Let ϕ vanish on $F_{\mathcal{O}}$ with $\phi(C) \subseteq \varpi^n \mathcal{O}_L$, and $m = \min(n, \mathfrak{c})$. Then $\varpi^{k+m} \mid \varpi^{\mathfrak{c}}\phi(d')$. Indeed, by Step 2, $\phi(u) = \varpi^n g$ with $g \in A$, and $(*)$ reads $\varpi^{k+n} g + P_1\varpi^k\phi(z) - P_1\phi(d') \in P_0 A$. Modulo the ideal $J = (\varpi^{k+m}, P_0)$: $\varpi^{k+n} g \in J$, and $P_1\varpi^k\phi(z) = \varpi^{\mathfrak{c}+k}\alpha\phi(z) + P_0\beta\varpi^k\phi(z) \in J$; hence $P_1\phi(d') \in J$. If $\phi(d') = \varpi^e v$ with v a unit and $e + \mathfrak{c} < k + m$, then in $R = A/(P_0)$, which is ϖ-torsion free (F1), $\bar{P}_1\varpi^e \in \varpi^{k+m}R \subseteq \varpi^{e+\mathfrak{c}+1}R$, so $\bar{P}_1 \in \varpi^{\mathfrak{c}+1}R$, i.e. $P_1 \in (\varpi^{\mathfrak{c}+1}, P_0)$, a contradiction. So $e + \mathfrak{c} \ge k + m$ (or $\phi(d') = 0$).

Step 5: the constants. The submodule $F_{\mathcal{O}}$ is saturated, so $M = \mathcal{O}_L^r/F_{\mathcal{O}}$ is free; let $\bar{C}$ be the image of C. By the stacked basis theorem there are a basis $f_1, \dots, f_{m'}$ of M, an integer q and $a_1, \dots, a_q \ge 0$ with $\varpi^{a_1} f_1, \dots, \varpi^{a_q} f_q$ a basis of $\bar{C}$; let ψ_j be the dual coordinates, viewed as forms on $\mathcal{O}_L^r$ vanishing on $F_{\mathcal{O}}$. Then $\psi_j(C) = \varpi^{a_j}\mathcal{O}_L$ for $j \le q$ and $\psi_j(C) = 0$ for $j > q$. Step 4 with $n = a_j$ ($j \le q$), resp. n arbitrary ($j > q$, so $m = \mathfrak{c}$), gives: if $j > q$ or $a_j \ge \mathfrak{c}$, then $\varpi^k \mid \psi_j(d')$, and we put $\psi_j(d') = \varpi^k l_j$, $\mu_j = 0$; if $j \le q$ and $a_j < \mathfrak{c}$, then $\varpi^{\mathfrak{c}}\psi_j(d') = \varpi^{k+a_j}\mu_j$ with $\mu_j \in \mathcal{O}_L$, and we put $l_j = 0$. Let $\lambda \in \mathcal{O}_L^r$ lift $\sum_j l_j f_j$ and $\lambda' \in C$ lift $\sum_{j \le q} \mu_j \varpi^{a_j} f_j \in \bar{C}$. Comparing coordinates,

$$\varpi^{\mathfrak{c}} d' - \varpi^{k+\mathfrak{c}}\lambda - \varpi^k \lambda' \in F_{\mathcal{O}}, \qquad \text{so} \qquad \psi(\varpi^{\mathfrak{c}} d') = \varpi^{k+\mathfrak{c}}\psi(\lambda) + \varpi^k \psi(\lambda') \tag{$**$}$$

for every form ψ vanishing on $F_{\mathcal{O}}$.

Step 6: the levels. Put $\nu = x - P_1\lambda - \alpha\lambda' \in A^r$; then $\hat{y}_s - \lambda - \lambda_s(\alpha)\lambda_s(P_1)^{-1}\lambda' = \lambda_s(P_1)^{-1}\lambda_s(\nu)$. At a thin level s, $\lambda_s(P_1)$ is a unit ($s \ne s_1$, (Lp1)) and $\lambda_s(\nu) \in K_{(s)}[[t]]^r$: kind integral. At s_1: $\nu = (u - \alpha\lambda') + P_1(z - \lambda)$ with $u - \alpha\lambda' \in C \otimes A$; so $\lambda_{s_1}(P_1)^{-1}\lambda_{s_1}(\nu) \in t^{-b_1} K_{(s_1)}[[t]] \otimes_L U_1 + K_{(s_1)}[[t]]^r$, which is kind integral for the up kind (coefficients in U_1 from t^{-b_1} to t^{-1}, nothing below). At s_0: for a form ϕ vanishing on $F_{\mathcal{O}}$, by $(*)$, $(**)$ and $P_1 - \varpi^{\mathfrak{c}}\alpha = P_0\beta$,

$$\varpi^{k+\mathfrak{c}}\phi(\nu) \equiv P_1\big(\varpi^{\mathfrak{c}}\phi(d') - \varpi^{k+\mathfrak{c}}\phi(\lambda)\big) - \varpi^{k+\mathfrak{c}}\alpha\phi(\lambda') = \varpi^k\phi(\lambda')\,(P_1 - \varpi^{\mathfrak{c}}\alpha) \equiv 0 \pmod{P_0 A},$$

so $\phi(\nu) \in P_0 A$ by (F1), and $\nu \in F_{\mathcal{O}} \otimes A + P_0 A^r$. Hence $\lambda_{s_0}(\nu)$ has no negative powers and t^j-coefficients in $K_{(s_0)} \otimes_L U_0$ for $j < b_0$ ((Lp1): $\lambda_{s_0}(P_0) \in t^{b_0} K_{(s_0)}[[t]]$): it is kind integral (down), and so is its product with the unit $\lambda_{s_0}(P_1)^{-1}$. This proves item 2. □

Lemma C.100. *Let ℓ, F, L, (τ_a) be as in Proposition 23.7, (V,T) a pair of rank r, and fix arc level data for (V,T) (cut c, length* len*, H, Π, frame, parameters, kinds and sizes). Identify $e_c\mathbf{A}_{F,L}$ with $A = \mathcal{O}_L[[X]]$. Suppose that $s_1 <$* len *has κ_{s_1} up and $1 \le b_1 = b_{s_1} \le H(c - s_1)$, and that κ_s is thin or down for every $s <$* len*, $s \ne s_1$. Put $P_1 = Q_{s_1}^{b_1}$, $\Pi' = \Pi/P_1 \in A$ and $C = U_{s_1}^L \cap \mathcal{O}_L^r$. Let $y \in A^r$ with $\hat{y}_s \in L^r + \{$kind integral vectors at $s\}$ for every $s <$* len*. Then $y = \Pi' x$ with $x \in A^r$, $\hat{y}_s = \lambda_s(P_1)^{-1}\lambda_s(x)$ for every $s <$* len*, and*

$$x \in C \otimes_{\mathcal{O}_L} A + P_1 A^r.$$

Proof. We use two classical facts on A. (F1) For a distinguished polynomial $P \in A$, such as a power of some Q_s (Lemma 23.8), A/PA is a free $\mathcal{O}_L$-module (Weierstrass division); hence $\varpi^N f \in PA$ implies $f \in PA$, ϖ a uniformiser of $\mathcal{O}_L$. (F2) Powers of distinct Q_s have no common prime factor in the unique factorisation domain A: by Weierstrass preparation such a factor would give a common root of $\Phi_{\ell^{s+1}}(1+X)$ and $\Phi_{\ell^{s'+1}}(1+X)$, $s \neq s'$, in the open unit disc. By Lemma 23.17 (applied to $\Phi = \mathrm{id}_T$) the arc level data have (Lp1) and (Lp5), and $\lambda_s(\Pi) \in t^{H(c-s)} K_{(s)}[[t]]^\times$.

Division. The kind family at a thin or down level vanishes in negative degrees, and at the up level s_1 below $-b_1$; constants have no negative powers of t. So $\hat{y}_s \in K_{(s)}[[t]]^r$ for $s \neq s_1$ and $\hat{y}_{s_1} \in t^{-b_1} K_{(s_1)}[[t]]^r$. Hence, for every coordinate y_k, $\lambda_s(y_k) = \lambda_s(\Pi)\hat{y}_{s,k}$ lies in $t^{H(c-s)}K_{(s)}[[t]]$ for $s \neq s_1$ and in $t^{H(c-s_1)-b_1}K_{(s_1)}[[t]]$ for $s = s_1$. By (Lp5) and (F1), y_k is divisible by $Q_s^{H(c-s)}$ ($s \neq s_1$) and by $Q_{s_1}^{H(c-s_1)-b_1}$, and by (F2) by their product Π'. So $y = \Pi' x$ with $x \in A^r$, and $\hat{y}_s = \lambda_s(\Pi)^{-1}\lambda_s(\Pi')\lambda_s(x) = \lambda_s(P_1)^{-1}\lambda_s(x)$.

The up level. C is saturated in $\mathcal{O}_L^r$, hence a direct summand: choose a basis of $\mathcal{O}_L^r$ extending a basis of C, and let ϕ_j be the dual coordinate forms vanishing on C. A vector $z \in A^r$ lies in $C \otimes A + P_1 A^r$ if and only if $\phi_j(z) \in P_1 A$ for all these j. Now $\lambda_{s_1}(x) = \lambda_{s_1}(P_1)\hat{y}_{s_1}$ with $\lambda_{s_1}(P_1) \in t^{b_1}K_{(s_1)}[[t]]^\times$ ((Lp1)), and the t^i-coefficients of $\hat{y}_{s_1}$ with $i < 0$ lie in $K_{(s_1)} \otimes_L U_{s_1}^L$ (the constant contributes only in degree 0, and the up kind family is $U_{s_1}^L$ in degrees $-b_1 \leq i < 0$). So $\lambda_{s_1}(\phi_j(x)) \in t^{b_1}K_{(s_1)}[[t]]$, whence $\phi_j(x) \in P_1 A$ by (Lp5) and (F1). Thus $x \in C \otimes A + P_1 A^r$. □

Lemma C.101. *Let $\ell \geq 11$, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, (Ae1), ρ_{E}, $c \in \mathcal{C}$, $\mathrm{len} = \mathrm{len}_c$ and frames $\mathbf{n}^1, \mathbf{n}^2$ at $c_0 = c - \mathrm{len}$ of $\mathbf{N}(T_1)$, $\mathbf{N}(T_2)$ be as in Lemma C.93, and let $o \in M_{r_2 \times r_1}(\mathcal{O}_L)$ be the frame matrix of Φ for these frames. Then for every $v \in \mathcal{O}_L^{r_2}$ there is $v_1 \in \mathcal{O}_L^{r_1}$ with $o\, v_1 = \ell^{\rho_{\mathrm{E}}} v$.*

Proof. Write $\mathbf{N}_\nu = \mathbf{N}(T_\nu)$. By (Cc2), $c_0 \in \mathcal{C}$. By (Ae1) and items 1 and 3 of Lemma C.102, the window (M_a, h_a), which is $(\eta, \max(s_a + S, \eta))$ for $\epsilon_a = 1$ and $(\max(s_a + S, \eta), \eta)$ for $\epsilon_a = -1$, bounds the Hodge jumps of V_1, $M_a + h_a \leq H(a)$ for all a, and therefore the exponent r_{c_0} of Proposition C.6 for Φ, this window and the site c_0 satisfies $r_{c_0} \leq \rho_{\mathrm{E}}$. Indeed, r_{c_0} is formed with the function $a \mapsto M_a + h_a$, which is bounded by H pointwise; the sum s_{c_0}, the maximum and c_H of Proposition C.6 are monotone in the function; and ρ_{E} is the maximum over $\mathcal{C} \ni c_0$ of the exponent formed with H (Definition C.78). Let $v \in \mathcal{O}_L^{r_2}$ and $y = \sum_l v_l n_l^2 \in \mathbf{N}_{2,c_0}$. By Proposition C.6 there is $x \in \mathbf{N}_{1,c_0}$ with $\mathbf{N}(\Phi)(x) = \ell^{r_{c_0}} y$. As $\mathbf{n}^1$ is a basis and $e_{c_0}\mathbf{A}_{F,L}/X \cong \mathcal{O}_L$, there is $a \in \mathcal{O}_L^{r_1}$ with $x - \sum_k a_k n_k^1 \in X\mathbf{N}_{1,c_0}$. Since $\mathbf{N}(\Phi)$ is $\mathbf{A}_{F,L}$-linear, it maps $X\mathbf{N}_{1,c_0}$ into $X\mathbf{N}_{2,c_0}$, and by the definition of o,

$$\ell^{r_{c_0}} \sum_l v_l n_l^2 = \mathbf{N}(\Phi)(x) \equiv \sum_k a_k \sum_l o_{lk} n_l^2 = \sum_l (oa)_l\, n_l^2 \pmod{X\mathbf{N}_{2,c_0}}.$$

The images of the n_l^2 form an $\mathcal{O}_L$-basis of $\mathbf{N}_{2,c_0}/X\mathbf{N}_{2,c_0}$, so $oa = \ell^{r_{c_0}} v$, and $v_1 = \ell^{\rho_{\mathrm{E}} - r_{c_0}} a$ satisfies $o v_1 = \ell^{\rho_{\mathrm{E}}} v$. □

Lemma C.102. *Let ℓ, F, L, $(\tau_a)_{a \in \mathbb{Z}/n}$ be as in Proposition 23.7, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ. Let $\Theta \subseteq \mathbb{Z}/n$ be the set of thick sites, $G = w + S + \eta$, $g = \max(G, 1)$, $h_* = b + \eta + S$ if $\Theta \neq \emptyset$ and $h_* = g$ otherwise, and $H(a) = 2h_*$ for $a \in \Theta$, $H(a) = 2G$ for $a \notin \Theta$. Suppose that $s_a > g$ for every $a \in \Theta$. Put*

$$(M_a, h_a) = \begin{cases} (\eta, \max(s_a + S, \eta)) & \text{if } \epsilon_a = 1, \\ (\max(s_a + S, \eta), \eta) & \text{if } \epsilon_a = -1. \end{cases}$$

Then:

1. *for $\nu = 1, 2$ and every a, every Hodge jump of V_ν at τ_a lies in $[-M_a, h_a]$;*
2. *$G, S, \eta \le g$; at a thin site a, $M_a, h_a \le G$; at a thick site a, $\eta \le g < s_a$, $\max(s_a + S, \eta) = s_a + S \le h_*$, and $\{M_a, h_a\} = \{\eta, s_a + S\}$;*
3. *$h_* \ge g$, and $M_a \le h_*$, $h_a \le h_*$ and $M_a + h_a \le H(a)$ for every a.*

Proof. **Item 1.** Let $\epsilon_a = 1$. By (Ow1) every Hodge jump of V_1 at τ_a lies in $[s_a, s_a + S] \cup [-\eta, \eta]$; since $s_a > \eta \ge 0$, this set is contained in $[-\eta, \max(s_a + S, \eta)] = [-M_a, h_a]$. The case $\epsilon_a = -1$ is symmetric: $[-s_a - S, -s_a] \cup [-\eta, \eta] \subseteq [-\max(s_a + S, \eta), \eta]$. By item 1 of Lemma 24.2 every Hodge jump of V_2 at τ_a is one of V_1, so it lies in the same interval.

Item 2. $G = w + S + \eta$ with $w, S, \eta \ge 0$, so $S, \eta \le G \le g$. At a thin site $s_a \le w$ by (Ow3), so $\max(s_a + S, \eta) \le \max(w + S, \eta) \le G$, and the other entry of (M_a, h_a) is $\eta \le G$. At a thick site $s_a > g$ by hypothesis, so $\eta \le g < s_a \le s_a + S$ and $\max(s_a + S, \eta) = s_a + S$; by (Ow3) $s_a \le b + \eta$, so $s_a + S \le b + \eta + S = h_*$ (here $\Theta \ne \emptyset$). Then $\{M_a, h_a\} = \{\eta, s_a + S\}$ by the definition.

Item 3. If $\Theta \ne \emptyset$, a thick site a has $g < s_a \le h_*$ by item 2; otherwise $h_* = g$. At a thin site $M_a, h_a \le G \le g \le h_*$ and $M_a + h_a \le 2G = H(a)$. At a thick site $M_a, h_a \in \{\eta, s_a + S\}$ with $\eta \le g \le h_*$ and $s_a + S \le h_*$, so $M_a, h_a \le h_*$ and $M_a + h_a = \eta + s_a + S \le 2h_* = H(a)$. □

Proposition C.103. *Let ℓ, F, n, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, a_{E}, (Ae1), (Ae2), $c \in \mathcal{C}$ and the arc level data of Φ along the word at the cut c of length len_c, with the arc level properties, be as in Proposition C.94. Suppose that there are $s_0 < s_1 < \mathrm{len}_c$ with κ_{s_0} down, κ_{s_1} up, and κ_s thin for every other $s < \mathrm{len}_c$. Then for every $\lambda' \in U^{2,L}_{s_1} \cap \mathcal{O}_L^{r_2}$ there is $v' \in U^{1,L}_{s_1} \cap \mathcal{O}_L^{r_1}$ with $o\, v' = \ell^{2a_{\mathrm{E}}} \lambda'$.*

Proof. Write $\mathrm{len} = \mathrm{len}_c$, $A = e_c \mathbf{A}_{F,L} \cong \mathcal{O}_L[[X]]$, $\Pi = \prod_{s < \mathrm{len}} Q_s^{H(c-s)}$, $b_i = b_{s_i}$, $P_i = Q_{s_i}^{b_i}$, $\Pi' = \Pi / P_1 \in A$ ($b_1 \le H(c - s_1) = g + b_1 + S$), $C_\nu = U^{\nu,L}_{s_1} \cap \mathcal{O}_L^{r_\nu}$, $\sigma = \sigma_\ell(3g, (\ell - 1)M, j) \le \sigma_{\mathrm{E}}$ and $\alpha = 2\sigma + \rho_{\mathrm{E}}$. By (Ae1) and items 2 and 3 of Lemma C.102, $h_* \ge g$, $G, S, \eta \le g$ and $b_s = s_{c-s} > g$ for thick $c - s$. By (Cc2), $c_0 = c - \mathrm{len} \in \mathcal{C}$ and $j \le \mathrm{len}$, and by (Cc1) for c_0 the sites $c_0 + 1, \dots, c_0 + j$ are thin; so Lemma C.105 applies for $\nu = 1, 2$: every truncation small vector is de Rham integral and kind integral. $\mathcal{T}_s^\nu$ is a $K_{(s)}[[t]]$-submodule (its definition is a $K_{(s)}[[t]]$-linear condition), so $o\,\mathcal{T}_s^1 \subseteq \mathcal{T}_s^2$. The kind and the de Rham integral vectors form additive groups stable under $\mathbb{Z}_\ell$ and, the families being increasing in i, under multiplication by $K_{(s)}[[t]]$ (the t^i-coefficient of a product is a finite sum of coefficients of lower index).

Step 1: the core relation. Let $e \in C_2$, $\mu\colon \mathcal{O}_L^{r_2} \to \mathcal{O}_L$ an $\mathcal{O}_L$-linear form and $a \in \mathcal{O}_L$ with $\mu(o\, v) \in a\mathcal{O}_L$ for all $v \in C_1$. We show

$$\mu(e)\, \ell^\alpha \lambda^{2g} P_0 \in aA + P_1 A. \qquad (*)$$

(i) Let $y_2 = \Pi' P_0 e \in A^{r_2}$; $\hat{y}_{2,s} = \lambda_s(P_0)\lambda_s(P_1)^{-1} e$. By (Lp1) this lies in $K[[t]]e$ at a thin level, in $t^{-b_1} K[[t]]e$ at s_1 (with $e \in U^{2,L}_{s_1}$), in $t^{b_0} K[[t]]e$ at s_0: it is kind integral at every level. (ii) Item 2 of Lemma C.95 for T_2 gives $w \in W_2$ with $\mathrm{lv}_s^{(2)}(w) - \ell^\sigma \hat{y}_{2,s} \in \mathcal{T}_s^2$; so $\mathrm{lv}_s^{(2)}(w)$ is kind integral. (iii) Lemma C.93 gives $z \in W_1$ with $\mathbf{N}(\Phi)(z) = \ell^{\rho_{\mathrm{E}}} w$ and $\lambda_s(Q_s)^g \mathrm{lv}_s^{(1)}(z)$ de Rham integral. (iv) Item 1 of Lemma C.95 for T_1 gives $y_1 \in A^{r_1}$ with $\hat{y}_{1,s} - \ell^\sigma \mathrm{lv}_s^{(1)}(z) \in \mathcal{T}_s^1$. (v) Let $\delta = o\, y_1 - \ell^\alpha y_2$. By (Lh1), $\hat{\delta}_s = o\, \hat{y}_{1,s} - \ell^\alpha \hat{y}_{2,s} \in \ell^\sigma \mathrm{lv}_s^{(2)}(\mathbf{N}(\Phi) z) - \ell^{\sigma + \rho_{\mathrm{E}}} \mathrm{lv}_s^{(2)}(w) + \mathcal{T}_s^2 = \mathcal{T}_s^2$, so $\lambda_s(\delta) \in \lambda_s(f') K[[t]]^{r_2}$, and $\lambda_s(f') \in t^{e_s} K[[t]]^\times$ with $e_s = (\ell - 1)M$ for $s < \mathrm{len} - j$ and $e_s = 3g$ otherwise: as $\varphi^k(X) = (1 + X)^{\ell^k} - 1 = X \prod_{s' < k} Q_{s'}$ and $\varphi^k(Q_{s'}) = Q_{s' + k}$, $f' = X^{(\ell-1)M} \prod_{s' < \mathrm{len} - j} Q_{s'}^{(\ell-1)M} \prod_{\mathrm{len} - j \le s' < \mathrm{len}} Q_{s'}^{3g}$, and by (Lp1) (Lemma 23.17) $\lambda_s(X)$ and $\lambda_s(Q_{s'})$

for $s' \neq s$ are units of $K[[t]]$ while $\lambda_s(Q_s) \in tK[[t]]^\times$. In both cases $e_s \geq H(c-s)$: $(\ell-1)M > h_* + 2g > g + h_* \geq H(c-s)$ (as $b_s + S \leq h_*$ by (Ow3) and $G \leq g \leq h_*$), and for $s \geq \mathrm{len} - j$ the site $c-s$ is thin ((Cc1) for c_0), $H(c-s) = g + G \leq 3g$. By (Lp5) and two classical facts on A (Weierstrass division: A/PA is $\mathcal{O}_L$-free for a distinguished polynomial P, such as a power of Q_s (Lemma 23.8), so $\varpi^N f \in PA$ implies $f \in PA$; and powers of distinct Q_s have no common prime factor in the unique factorisation domain A, since by Weierstrass preparation such a factor would give a common root of $\Phi_{\ell^{s+1}}(1+X)$ and $\Phi_{\ell^{s'+1}}(1+X)$ in the open unit disc), $\delta = \Pi d$ with $d \in A^{r_2}$. (vi) Let $Y = \lambda^{2g} y_1$. Then $\hat{Y}_s = \lambda_s(\lambda)^{2g}\hat{y}_{1,s}$ with $\lambda_s(\lambda)^{2g} = t^{2g}\cdot$unit ((Lp1)); $t^{2g}\mathrm{lv}_s^{(1)}(z) = t^g \cdot (t^g \mathrm{lv}_s^{(1)}(z))$ is kind integral by Lemma C.90 (de Rham integral times t^g), and so is t^{2g} times a truncation small vector; hence $\hat{Y}_s$ is kind integral at every level. By Lemma C.100 for T_1 (κ_{s_1} up with $1 \leq b_1 \leq H(c-s_1)$, every other level thin or down, $Y \in A^{r_1}$ and $\hat{Y}_s$ kind integral, with constants 0), $Y = \Pi' x$ with $x \in C_1 \otimes A + P_1 A^{r_1}$. Since $\mu \circ o$ maps C_1 into $a\mathcal{O}_L$, $\mu(o\,Y) = \Pi'\mu(o\,x) \in \Pi'(aA + P_1 A)$. (vii) Now $\lambda^{2g}\mu(o\,y_1) = \mu(o\,Y)$ and $\mu(o\,y_1) = \ell^\alpha \mu(y_2) + \mu(\delta) = \Pi'(\ell^\alpha P_0 \mu(e) + P_1\mu(d))$. Hence $\Pi'\lambda^{2g}\ell^\alpha P_0\mu(e) \in \Pi'(aA + P_1 A)$, and cancelling $\Pi' \neq 0$ in the domain A gives $(*)$.

Step 2: the valuation bound. If $\mu(e) = 1$ in Step 1, then $(*)$ and Proposition C.104 (with $s_0 < s_1$, $b_0 \geq 1$; $2(\alpha + 2g\,\mathrm{len}) \leq 2a_\mathrm{E} < b_1$ and $2b_0 \leq \ell b_1$ by (Ae2), clause 2, since $c - s_1$ is thick with $\epsilon = 1$ and $c - s_0$ thick with $\epsilon = -1$; $\alpha + 2g\,\mathrm{len} \leq 2\sigma_\mathrm{E} + \rho_\mathrm{E} + 2g\,\mathrm{len}_{\max} = a_\mathrm{E}$) give $a \mid \ell^{2a_\mathrm{E}}$.

Step 3: the lift. C_2 is saturated in $\mathcal{O}_L^{r_2}$, hence a direct summand; let $\pi\colon \mathcal{O}_L^{r_2} \to C_2$ be a projection. By (Lh2) (Lemma 23.17), $o(C_1) \subseteq C_2$. By the stacked basis theorem there are a basis $f_1, \ldots, f_m$ of C_2, an integer $q \leq m$ and $d_1, \ldots, d_q \geq 0$ such that $\varpi^{d_1} f_1, \ldots, \varpi^{d_q} f_q$ is a basis of $o(C_1)$. Let μ_i be the i-th coordinate of π in this basis, so $\mu_i(f_i) = 1$, $\mu_i(o(C_1)) = \varpi^{d_i}\mathcal{O}_L$ for $i \leq q$ and $= 0$ for $i > q$. For $i > q$, Step 2 with $e = f_i$, $\mu = \mu_i$ and $a = \varpi^N$ gives $\varpi^N \mid \ell^{2a_\mathrm{E}}$ for every N, which is impossible; so $q = m$. For $i \leq m$, Step 2 with $a = \varpi^{d_i}$ gives $\varpi^{d_i} \mid \ell^{2a_\mathrm{E}}$, hence $\ell^{2a_\mathrm{E}} f_i \in o(C_1)$. Therefore $\ell^{2a_\mathrm{E}} C_2 \subseteq o(C_1)$: for every $\lambda' \in C_2$ there is $v' \in C_1$ with $o\,v' = \ell^{2a_\mathrm{E}}\lambda'$. □

Proposition C.104. *Let ℓ be an odd prime, L a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$, $A = \mathcal{O}_L[[X]]$, $Q_s = \Phi_{\ell^{s+1}}(1+X)$ and $\lambda_e = \prod_{s<e} Q_s$. Let $\mathrm{len} \geq 1$, $g, \alpha \geq 0$, $s_0 < s_1 < \mathrm{len}$ and $b_0 \geq 1$, $b_1 \geq 1$ be integers with*

$$2(\alpha + 2g\,\mathrm{len}) < b_1, \qquad 2b_0 \leq \ell\, b_1.$$

If $a \in \mathcal{O}_L$ and $\ell^\alpha \lambda_{\mathrm{len}}^{2g} Q_{s_0}^{b_0} \in aA + Q_{s_1}^{b_1} A$, then a divides $\ell^{2(\alpha+2g\,\mathrm{len})}$ in $\mathcal{O}_L$.

Proof. Let v be the valuation of $\mathbb{C}_\ell$ with $v(\ell) = 1$, fix $\mathcal{O}_L \subset \mathbb{C}_\ell$, put $\beta = \alpha + 2g\,\mathrm{len}$, and write $F = \ell^\alpha \lambda_{\mathrm{len}}^{2g} Q_{s_0}^{b_0}$, a polynomial. Suppose $F = aG + Q_{s_1}^{b_1} B$ with $G, B \in A$ and, for a contradiction, $v(a) > 2\beta$ (this includes $a = 0$, $v(a) = \infty$).

Roots. $Q_s = \Phi_{\ell^{s+1}}(1+X) = \prod_\zeta (X - (\zeta - 1))$ over the primitive ℓ^{s+1}-th roots of unity ζ, of degree $\ell^s(\ell-1)$ (Lemma 23.8). Fix a root $\rho = \zeta_1 - 1$ of Q_{s_1} and put $r = v(\rho) = 1/(\ell^{s_1}(\ell-1))$. For a root $\tau = \zeta' - 1$ of Q_s, $\rho - \tau = \zeta_1 - \zeta' = \zeta'(\zeta_1\zeta'^{-1} - 1)$: if $s < s_1$, $\zeta_1\zeta'^{-1}$ has order ℓ^{s_1+1} and $v(\rho - \tau) = r$; if $s > s_1$, $v(\rho - \tau) = 1/(\ell^s(\ell-1))$; if $s = s_1$, $v(\rho - \tau) \geq \min(v(\rho), v(\tau)) = r$.

Discs. For $0 < R \leq r$ let $D_R = \{x \in \mathbb{C}_\ell : \ v(x - \rho) \geq R\}$; then $v(x) \geq R > 0$ on D_R, so every $H \in \mathcal{O}_L[[X]]$ converges on D_R with $v(H(x)) \geq 0$. For a monic $Q = \prod_\tau (X - \tau)$ and $x \in D_R$, $v(Q(x)) \geq \phi_Q(R) := \sum_\tau \min(R, v(\rho - \tau))$, since $v(x - \tau) \geq \min(v(x-\rho), v(\rho - \tau))$; and if $x = \rho + y$ with $v(y) = R$ and the reduction of y/π_R (π_R a fixed element of valuation R) avoids the finitely many residues of $-(\rho - \tau)/\pi_R$ with $v(\rho - \tau) = R$, then $v(x - \tau) = \min(R, v(\rho - \tau))$ for every τ. As the residue field of $\mathbb{C}_\ell$ is infinite, one $x_R \in D_R$ achieves equality simultaneously for all roots of all the Q_s, $s < \mathrm{len}$.

The estimate. Let $R = \theta r$ with $0 < \theta \le 1$ rational and write $\phi_s = \phi_{Q_s}(R)$. By the root distances: $\phi_{s_1} = \ell^{s_1}(\ell-1)\theta r = \theta$; for $s < s_1$, $\phi_s = \ell^s(\ell-1)\theta r = \theta\ell^{s-s_1} \le 1$, in particular $\phi_{s_0} \le \theta/\ell$; for $s > s_1$, $\phi_s \le \ell^s(\ell-1)/(\ell^s(\ell-1)) = 1$. Hence at $x = x_R$,

$$v(F(x)) = \alpha + 2g\sum_{s<\mathrm{len}} \phi_s + b_0\phi_{s_0} \le \beta + \theta b_0/\ell, \qquad v(Q_{s_1}(x)^{b_1}B(x)) \ge b_1\theta, \qquad v(aG(x)) \ge v(a).$$

From $F(x) = aG(x) + Q_{s_1}(x)^{b_1}B(x)$, $v(F(x)) \ge \min(v(a), b_1\theta)$. Now $b_1 - b_0/\ell \ge b_1/2 > \beta$ (as $2b_0 \le \ell b_1$ and $2\beta < b_1$), so $\theta_0 = \beta/(b_1 - b_0/\ell) < 1$, and $\beta + \theta_0 b_0/\ell = \beta b_1/(b_1 - b_0/\ell) \le 2\beta < v(a)$. Choose a rational $\theta \in (\theta_0, 1]$ so close to θ_0 that $\beta + \theta b_0/\ell < v(a)$. Then $b_1\theta > \beta + \theta b_0/\ell$ (equivalent to $\theta(b_1 - b_0/\ell) > \beta$), so $v(F(x)) \le \beta + \theta b_0/\ell < \min(v(a), b_1\theta) \le v(F(x))$, a contradiction. Hence $v(a) \le 2\beta$, i.e. a divides $\ell^{2\beta}$ in the discrete valuation ring $\mathcal{O}_L$. □

Lemma C.105. *Let Φ, the weight word, $G = w + S + \eta$, $g = \max(G, 1)$ and h_* be as in Proposition C.107, with $h_* \ge g$; let $c \in \mathbb{Z}/n$, $1 \le j \le \mathrm{len} \le n$ with the sites $c - \mathrm{len} + 1, \dots, c - \mathrm{len} + j$ thin, and fix the arc level data of Φ along the word at the cut c of length* len *(any frames), for $\nu = 1$ or 2, with (Lp7). Then for every $s <$* len*:*

1. *every $f \in \mathcal{T}_s$ is de Rham integral and kind integral at s;*
2. *constants $v \in L^r$ satisfy $\gamma_u^{(s)}v = v$, and $\gamma_u^{(s)}$ ($u \in \mathbb{Z}_\ell^\times$) maps de Rham integral vectors to de Rham integral vectors and kind integral vectors to kind integral vectors.*

Proof. Write $K = K_{(s)}$, $H = H(c-s)$, $b_s = s_{c-s}$, $M = \lfloor (h_* + 2g)/(\ell-1) \rfloor + 1$, so $(\ell-1)M > h_* + 2g$.

1. As $\varphi^k(X) = (1+X)^{\ell^k} - 1 = X\prod_{s'<k} Q_{s'}$ and $\varphi^k(Q_{s'}) = Q_{s'+k}$,

$$f' = \varphi^{\mathrm{len}-j}(X^{(\ell-1)M}\prod_{s'<j} Q_{s'}^{3g}) = X^{(\ell-1)M}\prod_{s'<\mathrm{len}-j} Q_{s'}^{(\ell-1)M}\prod_{\mathrm{len}-j\le s'<\mathrm{len}} Q_{s'}^{3g};$$

by (Lp1) (Lemma 23.17) $\lambda_s(X)$ and $\lambda_s(Q_{s'})$ for $s' \ne s$ are units of $K[[t]]$ and $\lambda_s(Q_s) \in tK[[t]]^\times$. Hence $\lambda_s(f') \in t^eK[[t]]^\times$ with $e = (\ell-1)M$ if $s < \mathrm{len} - j$ and $e = 3g$ if $s \ge \mathrm{len} - j$; and $\lambda_s(\Pi) \in t^HK[[t]]^\times$ (Lemma 23.17). So $f \in \mathcal{T}_s$ means $f \in t^mK[[t]]^r$ with $m = e - H$, i.e. $f^{(i)} = 0$ for $i < m$. It suffices that $\mathrm{Fil}_s(-i) = L^r$ for $i \ge m$, i.e. $-m \le \min J$ (J the jumps; $\mathrm{Fil}_s(u) = L^r$ for $u \le \min J$), and $\mathrm{Nb}_s(i) = L^r$ for $i \ge m$, i.e. $m \ge 0$ (thin, up) or $m \ge b_s$ (down). By (Lp7) and (Ow3) ($b_s \le b + \eta$ at thick sites, so $b_s + S \le h_*$):

- $s \ge \mathrm{len} - j$: the site $c - s$ is thin, $H = g + G$, $e = 3g$, $m = 2g - G \ge g \ge G \ge -\min J$, and $m \ge 0$.
- $s < \mathrm{len} - j$, thin: $H = g + G$, $m > h_* + g - G \ge g \ge G \ge -\min J$.
- up: $H = g + b_s + S$, $m > h_* + g - b_s - S \ge g \ge \eta \ge -\min J$ (jumps in $[b_s, b_s + S] \cup [-\eta, \eta]$), and $m \ge 0$.
- down: $H = g + \eta$, $m > h_* + g - \eta = b + S + g \ge b_s + S + g - \eta \ge b_s + S \ge -\min J$ (jumps in $[-b_s - S, -b_s] \cup [-\eta, \eta]$; $g \ge \eta$), and $m \ge b_s$.

2. $\gamma_u^{(s)}$ multiplies the t^i-coefficient by u^i and applies σ_u coordinatewise; σ_u fixes L, so constants are fixed, and it preserves $K \otimes_L \mathcal{X}$ for every L-subspace $\mathcal{X} \subseteq L^r$ (acting on the first factor), so it preserves $\Xi_s(\mathcal{X})$ for every family $\mathcal{X}$, in particular the de Rham and kind families. □

Proposition C.106. *Let $\ell \geq 11$, F, n, $D = G_F$, L, (τ_a), $\Phi\colon V_1 \to V_2$ ($T_1 \to T_2$), the weight word, Θ, G, g, h_*, H, j, $(\mathcal{C}, (\mathrm{len}_c))$, a_{E}, e_{E} and the hypotheses (Ae1), (Ae2) be as in Proposition C.83, and form $\sigma_{\mathrm{E}}, \rho_{\mathrm{E}}, \kappa_{\mathrm{E}}$ with the same data. For $c \in \mathcal{C}$ let $H_c\colon \mathbb{Z}/n \to \mathbb{Z}_{\geq 0}$ be the function of the arc level data along the word at c ($H_c(c-s) = g + G$, $g + s_{c-s} + S$, $g + \eta$ for $c - s$ thin, thick with $\epsilon_{c-s} = 1$, thick with $\epsilon_{c-s} = -1$), and for $\nu = 1, 2$*

$$W_\nu^c = \{w \in \mathbf{N}(T_\nu)[1/\lambda_\infty] :\ \Lambda_{c,\mathrm{len}_c}(H_c)\, w \in P_{\mathrm{len}_c}(\mathbf{N}(T_\nu)_{c-\mathrm{len}_c})\},$$
$$I_c(T_\nu) = \{w \in e_c\mathbf{N}(T_\nu)[1/\lambda_\infty] :\ (\gamma_u - 1)w \in X\mathbf{N}(T_\nu)\ \forall u\}.$$

Suppose:

(Ae4) *for every $c \in \mathcal{C}$ and every $w \in W_2^c \cap I_c(T_2)$ there are $w' \in W_1^c \cap I_c(T_1)$, $\epsilon \in \mathcal{O}_L^\times$ and an integer $0 \leq k \leq 2\kappa_{\mathrm{E}}$ with $\mathbf{N}(\Phi)(w') - \epsilon\, \ell^{\,2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}} + k}\, w \in X\mathbf{N}(T_2)_c$.*

Then

$$\ell^{\,e_{\mathrm{E}}} H_f^1(D, T_2) \subseteq \Phi_* H_f^1(D, T_1).$$

Proof. Throughout, ℓ, F, L, (τ_a) satisfy the hypotheses of Proposition 23.7, and H_f^1 of a lattice is the inverse image of H_f^1 of its representation.

Step 0: a common window. Define (M_a, h_a) by $(M_a, h_a) = (\eta, \max(s_a + S, \eta))$ if $\epsilon_a = 1$ and $(M_a, h_a) = (\max(s_a + S, \eta), \eta)$ if $\epsilon_a = -1$. By (Ow1) every Hodge jump of V_1 at τ_a lies in $[-M_a, h_a]$; by item 1 of Lemma 24.2 so does every Hodge jump of V_2; and $0 \in [-M_a, h_a]$. We record: (i) $h_{c-s} \leq H_c(c-s)$ for all $c \in \mathcal{C}$, $0 \leq s < \mathrm{len}_c$: at a thin site $s_a \leq w$, so $M_a, h_a \leq \max(w + S, \eta) \leq G \leq g + G$; at a thick site with $\epsilon = 1$, $s_a > g \geq G \geq \eta$ by (Ae1), so $h_a = s_a + S \leq g + s_a + S$; with $\epsilon = -1$, $h_a = \eta \leq g + \eta$. (ii) $M_{c+s} \leq G$ for $c \in \mathcal{C}$, $1 \leq s \leq j$, as these sites are thin (Cc1). (iii) $h_* \geq g$: if $\Theta \neq \emptyset$, a thick a has $g < s_a \leq b + \eta \leq h_*$ by (Ae1), (Ow3); otherwise $h_* = g$. Hence $M_a \leq \max(G, h_*) \leq h_*$ at every site (thick: $s_a + S \leq b + \eta + S = h_*$). (iv) $M_a + h_a \leq H(a)$: at a thick site $M_a + h_a \leq h_* + \eta \leq 2h_*$; at a thin site $M_a + h_a \leq 2G$.

Step 1: the parameters. Put $M' = \lfloor (h_* + 2g)/(\ell - 1) \rfloor + 1$, $m = (\ell - 1)M'$, $R = m$ and $g' = 3g$. Then $m > h_* + 2g$, so $m \geq h_* + 2g + 1 \geq \max(3g, 1 + \max_a M_a)$ by (iii), $g' \geq G$, and $\sigma := \sigma_\ell(g', m, j) = \lfloor (3g + M'/\ell^{j-1})\ell/(\ell - 1)^2 \rfloor + 1 \leq \sigma_{\mathrm{E}}$ since $m/N_j = M'/\ell^{j-1}$ and $\lfloor y \rfloor + 1 \leq \lceil y + 1 \rceil$. With (ii) and $j \leq \mathrm{len}_c$ (Cc2), the hypotheses of Lemma 24.5 hold for $\mathbf{N}(T_1)$ and $\mathbf{N}(T_2)$ with the window (M_a, h_a) and the parameters $c \in \mathcal{C}$, j, G, g', m, R; let $\rho_{c,j}^{(\nu)}$ be the relay classes of $\mathbf{N}(T_\nu)$. Their domain is $I_c(T_\nu)$.

Step 2: the extension and its vectors x_c. Let $x \in H_f^1(D, T_2)$. By Lemma 23.26 there is an exact sequence $0 \to T_2 \xrightarrow{\iota'} T \xrightarrow{\pi} \mathcal{O}_L \to 0$ of lattices of pairs with $[T] = x$, whose Hodge jumps are 0 or jumps of V_2; so (M_a, h_a) is a window of V and of V_2. Let $c \in \mathcal{C}$. By Lemma 24.3 there is $e_c^\circ \in \mathbf{N}(\mathcal{O}_L)_c$ with $\iota_{\mathcal{O}_L}(e_c^\circ) = \varepsilon_c$. By Proposition C.6 for the surjection π, with the window (M_a, h_a) of V, there is $x_c' \in \mathbf{N}(T)_c$ with $\mathbf{N}(\pi)(x_c') = \ell^{r_c} e_c^\circ$, where r_c is formed with $H^V(a) = M_a + h_a$. As $H^V \leq H$ pointwise by (iv), and s_c, the maximum and c_H are monotone in the function, $r_c \leq \rho_{\mathrm{E}}$. Put $x_c = \ell^{\rho_{\mathrm{E}} - r_c} x_c'$; by (Ex3), $(1 \otimes \pi)(\iota_T(x_c)) = \iota_{\mathcal{O}_L}(\mathbf{N}(\pi)x_c) = \ell^{\rho_{\mathrm{E}}}\varepsilon_c$.

Step 3: splitting. Proposition 24.4 (with $T' = T_2$, $C = \mathcal{C}$, the lengths len_c, which satisfy its hypotheses by (Cc2), the window (M_a, h_a) of V_2 and V, the parameters of Step 1 and $r = \rho_{\mathrm{E}}$) gives $\tau_c' \in P_j(\mathbf{N}(T_2)_c)$ and $w_c \in I_c(T_2)$ with

$$\mathbf{N}(\iota')(w_c) = \varphi^{\mathrm{len}_c - j}(X_{c-\mathrm{len}_c}) - \ell^\sigma x_c, \qquad X_{c'} = \ell^\sigma \varphi^j(x_{c'}) - \mathbf{N}(\iota')(\tau_{c'}'),$$

and $\ell^{\rho_{\mathrm{E}} + 2\sigma} x = \sum_{c \in \mathcal{C}} \rho_{c,j}^{(2)}(w_c)$.

Step 4: $w_c \in W_2^c$**.** Apply Lemma C.96 to $0 \to T_2 \to T \to \mathcal{O}_L \to 0$ with the window (M_a, h_a) of V, $e = \mathrm{len}_c \le n$ and H_c (allowed by (i)); its $W(T_\nu)$, $W(T)$ are W_ν^c and the analogous set for T. Write $c' = c - \mathrm{len}_c$. Since $\varphi^{\mathrm{len}_c - j}\varphi^j(x_{c'}) = \varphi^{\mathrm{len}_c}(x_{c'})$ and, for $\tau'_{c'} = \sum_i f_i \varphi^j(n_i)$ ($n_i \in \mathbf{N}(T_2)_{c'}$), $\varphi^{\mathrm{len}_c - j}(\tau'_{c'}) = \sum_i \varphi^{\mathrm{len}_c - j}(f_i)\varphi^{\mathrm{len}_c}(n_i)$, while $\mathbf{N}(\iota')$ commutes with φ, we get $\varphi^{\mathrm{len}_c - j}(X_{c'}) \in P_{\mathrm{len}_c}(\mathbf{N}(T)_{c'})$. By items 1 and 2 of Lemma C.96, $\mathbf{N}(\iota')(w_c) \in W(T)$, and by item 3, $w_c \in W_2^c$. So $w_c \in W_2^c \cap I_c(T_2)$.

Step 5: lifting each relay class. By (Ae4) there are $w'_c \in W_1^c \cap I_c(T_1)$, $\epsilon_c \in \mathcal{O}_L^\times$ and $0 \le k_c \le 2\kappa_{\mathrm{E}}$ with $\mathbf{N}(\Phi)(w'_c) - \epsilon_c \ell^{e'+k_c} w_c \in X\mathbf{N}(T_2)_c$, $e' = 2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}}$. By (Ry6) for Φ, $\mathbf{N}(\Phi)(w'_c) \in I_c(T_2)$ and $\rho^{(2)}_{c,j}(\mathbf{N}(\Phi)w'_c) = \Phi_* \rho^{(1)}_{c,j}(w'_c)$; by (Ry5) and (Ry4), $\rho^{(2)}_{c,j}(\mathbf{N}(\Phi)w'_c) = \epsilon_c \ell^{e'+k_c}\rho^{(2)}_{c,j}(w_c)$. Moreover $\rho^{(1)}_{c,j}(w'_c) \in H^1_f(F, T_1)$ by (Ry7): $\Lambda_{c,\mathrm{len}_c}(H_c)w'_c \in P_{\mathrm{len}_c}(\mathbf{N}(T_1)_{c'})$, and by item 2 of Lemma 23.15 (window (M_a, h_a) of V_1) $\Lambda_{c,\mathrm{len}_c}(M)P_{\mathrm{len}_c}(\mathbf{N}(T_1)_{c'}) \subseteq \mathbf{N}(T_1)_c$, so $f w'_c \in \mathbf{N}(T_1)$ for the product $f = \Lambda_{c,\mathrm{len}_c}(M)\Lambda_{c,\mathrm{len}_c}(H_c)$ of the Q_s. Multiplying by $\epsilon_c^{-1}\ell^{2\kappa_{\mathrm{E}}-k_c}$,

$$\ell^{\,e'+2\kappa_{\mathrm{E}}}\rho^{(2)}_{c,j}(w_c) \in \Phi_* H^1_f(D, T_1).$$

Step 6: the exponent. Summing over c with Step 3, $\ell^{\rho_{\mathrm{E}}+2\sigma+e'+2\kappa_{\mathrm{E}}}x \in \Phi_* H^1_f(D, T_1)$, an $\mathcal{O}_L$-submodule. Since $\sigma \le \sigma_{\mathrm{E}}$,

$$\rho_{\mathrm{E}} + 2\sigma + 2\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + \rho_{\mathrm{E}} + 2\kappa_{\mathrm{E}} \le 2\rho_{\mathrm{E}} + 4\sigma_{\mathrm{E}} + 2a_{\mathrm{E}} + 2\kappa_{\mathrm{E}} = e_{\mathrm{E}},$$

so $\ell^{e_{\mathrm{E}}}x \in \Phi_* H^1_f(D, T_1)$. □

Proposition C.107. *Let ℓ be an odd prime, F, L, $(\tau_a)_{a\in\mathbb{Z}/n}$ as in Proposition 23.7, $\Phi\colon V_1 \to V_2$ an onto map of crystalline lattices $T_1 \to T_2$ over F with coefficients L, and $(b, w, S, \eta, m, (s_a), (\epsilon_a))$ a weight word for Φ, with $G = w + S + \eta$, $g = \max(G, 1)$, and $h_* = b + \eta + S$ if some site is thick, $h_* = g$ otherwise. Suppose $h_* \ge g$ (this holds if no site is thick, or if $s_a > g$ for every thick site a). Let $c \in \mathbb{Z}/n$, $1 \le \mathrm{len} \le n$ and $1 \le j \le \mathrm{len}$. Then for all frames $\mathbf{n}^1$, $\mathbf{n}^2$ at $c - \mathrm{len}$ of $\mathbf{N}(T_1)$, $\mathbf{N}(T_2)$, the arc level data of Φ along the word at the cut c of length* len *(with this j) have the arc level properties (Lp1)–(Lp8) and (Lh1)–(Lh2).*

Proof. (Lp1), (Lp2), (Lp4), (Lp5), (Lp8), (Lh1) and (Lh2) hold for any arc level data of Φ by Lemma 23.17 (Φ is G_F-equivariant and $\mathcal{O}_L$-linear). (Lp3) holds for $\nu = 1, 2$ by Lemma 23.5 (2), applied to the pairs (V_ν, T_ν), which are crystalline. (Lp7) is Lemma 24.2 (2). For (Lp6): along the word $M = \lfloor (h_* + 2g)/(\ell - 1) \rfloor + 1$, so $(\ell - 1)M > h_* + 2g \ge 3g$; Lemma C.68 applies to (V_ν, T_ν) and gives (Lp6). (If $s_a > g$ for every thick a and some site is thick, then for a thick a, $h_* = b + \eta + S \ge s_a > g$ by (Ow3).) □

D Technical facts on good root towers

This appendix proves the facts about good root towers that Part VI states and uses but whose proofs are long and technical. Every result it supplies is used in Part VI, at one of four places. The facts of good towers Proposition 34.2 take from it the flat determinant heights (Proposition D.65), the proportional analytic square systems (Proposition D.73) and geometric proportionality with covolumes (Proposition D.79), the identity that writes the geometric intersection numbers of the root models as covolumes of principal congruence subgroups times flag degrees (Section D.4). The Hodge-type base settings Proposition 34.35 take their existence, the base slope identity, the cusp mean bound with the corrected point heights, and positivity (Proposition D.1, Proposition D.19, Proposition D.21, Proposition D.56; Sections D.1–D.3). The existence theorem Proposition 31.14 takes nefness at primes (Gi4) (Theorem D.57), the fibre-square

identities (Fq1) (Theorem D.85) and the reference comparisons (Rh1), (Rh2), (Vl) with the wall inputs (Wd), (Wp) derived from them (Section D.6). And the torsion systems of Section 35 take the test-point facts (Proposition D.97, Section D.5).

The methods are those of Part VI: arithmetic intersection theory with log-log singular metrics and their regularisations, Hodge theory near the boundary of toroidal compactifications, integral p-adic Hodge theory of abelian schemes, and heights of points. A reader who accepts the statements just listed can read Part VI without this appendix. Apart from results of Part VI, the appendix uses one lemma of Part I (Lemma 3.5) and one of Part III (Lemma 16.27).

D.1 Base settings: existence and the slope identity

This section proves two of the four parts of the Hodge-type base settings Proposition 34.35 of Section 34: at every admissible stage and component a good tower has a base setting with regularisation limits (Proposition D.1), and the base slope identity holds (Proposition D.19). Through Proposition 34.35 and Proposition 34.2 they supply the base slope settings from which the slope at the test class (Rt6) is proved (Theorem 31.45). A base setting consists of a base variety with a Hodge-type line, log-log regularisations and cusp data (Definition 31.10, Definition 31.12, Definition 31.11); Subsection D.1.1 constructs it with its cusp weight, Subsection D.1.2 corrects and regularises the weight, and Subsection D.1.3 proves the slope identity.

D.1.1 Existence of base settings and the cusp weight

The subsection states Proposition D.1 and proves the bound for the cusp weight on which the cusp mean rests: the cusp weight of a base setting has mean at most the cusp mean constant against the Hodge measure (Lemma D.2), a lemma used again in Section D.2. The other lemmas are estimates for polarised lattices with CM action over a fundamental domain of the archimedean unitary group: the covolume of an isotropic sublattice, a scaling law for isotropic vectors, counts of short vectors, and the mean of the logarithm of the first minimum.

Proposition D.1. *Let $\mathfrak{u}$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Then for every admissible stage B and every $Z \in \mathrm{Cp}$ there is a base setting of $\mathcal{T}$ at (B, Z) (in particular its cover has the coordinate charts of (Gb1), and its Hodge-type line is integrally $\bigotimes_\tau (\det \mathcal{V}_{(\tau,-)})^\vee$ with the dual Hodge metric, (Gb2), (Gb3)) such that:*

- *(a) the limit self-intersection $\mathrm{ar}^{\mathrm{b}}(B)$ exists and the setting has regularisation limits (Mz1)–(Mz4) at B;*
- *(b) for all integers $1 \le i_1 \le i_2$ there is $t_1 > 0$ such that the first Chern form $c_1(\overline{\mathcal{M}}_{B,i_1,i_2,t})$ is semipositive on X^{b} for $0 < t \le t_1$;*
- *(c) there is $t_0 > 0$ such that $\psi_{t'} \ge \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ on $X^{\mathrm{b},\circ}$ for $0 < t' \le t_0$;*
- *(d) the setting is joined to the stage root model $\mathcal{X}_{B,Z}$;*
- *(e) the setting satisfies the hypotheses (i) and (ii) of Lemma 34.36.*

Proof. Let B be an admissible stage and $Z \in \mathrm{Cp}$; let $\mathcal{Y}_Z$ be the component of the fixed data at Z (it meets $j(\mathrm{Sh}_F)$), $Z_c = j^{-1}(\mathcal{Y}_Z)$, $S'_B = \{\ell \le B \text{ prime} : \ell \notin \mathrm{Bd}\}$ and $S = \mathrm{Bd} \cup S'_B$. By (Go5), Bd is the set of primes dividing $2\,\mathrm{disc}(E)N'$, so S contains every prime dividing $\mathrm{disc}(E)$, and $\mathrm{Bd} \cap S'_B = \varnothing$. Write c for complex conjugation on complex points of schemes over $\mathbb{Z}$.

Step 1: the cover. Proposition 33.9 for $\mathcal{Y}_c = \mathcal{Y}_Z$ and S gives a cover $f\colon \mathcal{X} \to \mathcal{Y}$ with function field Ω, projective over $\operatorname{Spec}\mathbb{Z}$, such that: the generic point of $\mathcal{X}$ maps to that of $\mathcal{Y}_Z$ and Ω is finite over $\mathbf{k}(Z_c)$; $\mathcal{X}_{\mathbb{Q}}$ is smooth and the complement Δ of the abelian locus in $\mathcal{X}_{\mathbb{Q}}$ is the support of a simple normal crossing divisor, which we take reduced; for $\ell \in S$ the ℓ^4-torsion of $G_{\mathcal{X}}$ is rational over Ω, the Hodge lattices at (S,R), $R \equiv 4$, are Hodge bundles $\mathcal{V}_s^S$, and Hodge–Tate freeness holds at every point over ℓ. The generic point of $\mathcal{X}$ lies over $\mathbb{Q}$, so $\mathcal{O}_{\mathcal{X}}$ is torsion free and $\mathcal{X}$ is flat over $\mathbb{Z}$; being proper with dense image, $\mathcal{X} \to \operatorname{Spec}\mathbb{Z}$ is surjective. $\dim \mathcal{X}_{\mathbb{Q}} = \operatorname{trdeg}_{\mathbb{Q}}\Omega = \operatorname{trdeg}_F \mathbf{k}(Z_c) = \dim \operatorname{Sh}_F = |\Phi|pq = e$ (by (Fh2) the flag bundle has dimension $|\Phi|pq$ plus the fibre dimension $|\Phi|(p(p-1)+q(q-1))/2$), so $\mathcal{X}$ has absolute dimension $e+1$. As $\mathcal{X}$ is proper over $\mathbb{Z}$ and $\operatorname{Spec}\mathcal{O}_F$, $\mathcal{Y}$ are separated over $\mathbb{Z}$, $\mathcal{X}$ is proper over $\mathcal{O}_F$ and over $\mathcal{Y}$.

Step 2: the Hodge lattices at $(\mathrm{Bd}, 4)$ *are Hodge bundles.* Put $d = \operatorname{disc}(E)$ and $A = \mathcal{O}_F[1/d]$. Let $e_s \in E \otimes_{\mathbb{Q}} F \cong \prod_{\sigma\in\operatorname{Hom}(E,F)} F$ (the isomorphism $a\otimes b \mapsto (\sigma(a)b)_\sigma$; $\sigma(E) \subseteq F$ for all σ, (Fh1)) be the idempotent of the factor σ_s ($s \mapsto \sigma_s$ is bijective onto $\operatorname{Hom}(E,F)$). The e_s lie in $\mathcal{O}_E \otimes_{\mathbb{Z}} A$: let $\omega_1,\dots,\omega_m$ be a $\mathbb{Z}$-basis of $\mathcal{O}_E$ ($m = [E:\mathbb{Q}] = |\operatorname{Hom}(E,F)|$) and $\omega_1^\vee,\dots,\omega_m^\vee$ the dual basis for the trace form, $\operatorname{Tr}_{E/\mathbb{Q}}(\omega_i^\vee\omega_j) = \delta_{ij}$, a $\mathbb{Z}$-basis of the inverse different $\mathfrak{D}_E^{-1}$. For the square matrices $M = (\sigma(\omega_j))_{\sigma,j}$ and $N = (\sigma(\omega_i^\vee))_{\sigma,i}$ the trace relations say $N^{\mathsf{T}}M = 1$, hence $MN^{\mathsf{T}} = 1$, i.e. $\sum_i \sigma'(\omega_i^\vee)\sigma(\omega_i) = \delta_{\sigma\sigma'}$; so $\sum_i \omega_i^\vee \otimes \sigma_s(\omega_i)$ maps to the unit vector at σ_s and equals e_s. The integral ideal $\mathfrak{D}_E$ has norm $|d|$ ([190, III (2.9)]) and contains its norm (which annihilates $\mathcal{O}_E/\mathfrak{D}_E$), so $d \in \mathfrak{D}_E$, $\mathfrak{D}_E^{-1} \subseteq d^{-1}\mathcal{O}_E$, and $e_s \in d^{-1}\mathcal{O}_E \otimes \mathcal{O}_F \subseteq \mathcal{O}_E \otimes A$. Let $U_2 \subseteq \mathcal{X}$ be the complement of the fibres over the primes of Bd; on U_2, d is invertible, so $\operatorname{Lie}(G_{\mathcal{X}})|_{U_2} = \bigoplus_s e_s\operatorname{Lie}(G_{\mathcal{X}})|_{U_2}$ with locally free summands (direct summands of the locally free $\operatorname{Lie}(G_{\mathcal{X}})|_{U_2}$; finitely generated projective modules over local rings are free), and $(e_s\operatorname{Lie}(G_{\mathcal{X}}))_x = e_s\operatorname{Lie}_x = \operatorname{Lie}_x \cap \operatorname{Li}_s = \mathrm{dR}_{s,x}$ (if $v \in \operatorname{Lie}_x \cap \operatorname{Li}_s$ then $v = e_s v$). Let U_1 be the complement of the fibres over the primes of S'_B. The Hodge lattice at $(\mathrm{Bd},4)$ has stalk $\mathrm{HT}_{s,x}(\ell^4) = V_{s,x}^S$ at x over $\ell \in \mathrm{Bd}$ (these x lie in U_1) and $\mathrm{dR}_{s,x}$ elsewhere; on U_1 it is given by $\mathcal{V}_s^S|_{U_1}$, on U_2 by $e_s\operatorname{Lie}(G_{\mathcal{X}})|_{U_2}$, and on $U_1\cap U_2$ both have the stalks $\mathrm{dR}_{s,x}$. Subsheaves of the constant sheaf Li_s on the integral scheme $\mathcal{X}$ with the same stalks coincide, and $U_1 \cup U_2 = \mathcal{X}$; so they glue to a locally free subsheaf $\mathcal{V}_s$ of rank $\operatorname{rk}(s)$ with the stalks of the Hodge lattice at $(\mathrm{Bd},4)$: these are Hodge bundles. On $\mathcal{X}_{\mathbb{Q}}$, $\mathcal{V}_s = \mathcal{V}_s^S = \operatorname{Lie}_s(G_{\mathcal{X}_{\mathbb{Q}}})$.

Step 3: the embedding. Let $\mathcal{L} = \bigotimes_\tau (\det \mathcal{V}_{(\tau,-)})^\vee$ and $\mathcal{L}^S = \bigotimes_\tau (\det \mathcal{V}^S_{(\tau,-)})^\vee$, invertible subsheaves of the constant sheaf on the one-dimensional Ω-space $\bigotimes_\tau (\det \operatorname{Li}_{(\tau,-)})^\vee$, equal outside the fibres over S'_B. Locally $\mathcal{L} = \mathcal{O}\lambda$, $\mathcal{L}^S = \mathcal{O}g\lambda$ with $g \in \Omega^\times$; the sheaf $\mathcal{O}g \subseteq \Omega$ does not depend on the generators, so there is an invertible subsheaf $\mathcal{O}(D) \subseteq \Omega$ with $\mathcal{O}(D)\mathcal{L} = \mathcal{L}^S$, equal to $\mathcal{O}_{\mathcal{X}}$ outside the fibres over S'_B. These fibres are pairwise disjoint and closed, so $\mathcal{O}(D) = \prod_{\ell\in S'_B} \mathcal{O}(D_\ell)$, where $\mathcal{O}(D_\ell) \subseteq \Omega$ equals $\mathcal{O}(D)$ off the fibres over $S'_B \smallsetminus \{\ell\}$ and $\mathcal{O}_{\mathcal{X}}$ off the fibre over ℓ. At x over $\ell \in S'_B$, if b_τ is a basis of $\mathcal{V}_{(\tau,-),x}$ and $b_\tau T_\tau$ one of $\mathcal{V}^S_{(\tau,-),x} = \mathrm{HT}_{(\tau,-),x}(\ell^4)$, then $(\det(b_\tau T_\tau))^\vee = (\det T_\tau)^{-1}(\det b_\tau)^\vee$, so $\mathcal{O}(D_\ell)_x = (\prod_\tau \det T_\tau)^{-1}\mathcal{O}_x$.

Fix a closed immersion $i_0\colon \mathcal{X} \to \mathbb{P}(\mathbb{Z}^{I_0})$ and $\mathcal{A} = i_0^*\mathcal{O}(1)$. By Serre's theorem ($\mathcal{X}$ projective over the noetherian ring $\mathbb{Z}$) there is $m \geq 1$ such that $\mathcal{N}_1 = \mathcal{L}\otimes\mathcal{A}^m$ and $\mathcal{N}_\ell = \mathcal{O}(D_\ell)\otimes\mathcal{A}^m$ ($\ell \in S'_B$) are generated by global sections, and finitely many suffice (the global sections form finitely generated $\mathbb{Z}$-modules). Let $K = \{0,1\} \sqcup S'_B$, $\mathcal{N}_0 = \mathcal{A}$, and for $k \in K$ let $(\sigma_{k,i})_{i\in I_k}$ be generating global sections of $\mathcal{N}_k$ (for $k=0$ the pulled-back coordinates). They define $i_k\colon \mathcal{X} \to \mathbb{P}(\mathbb{Z}^{I_k})$ with $i_k^*\mathcal{O}(1) \cong \mathcal{N}_k$, the coordinate $Y_{k,i}$ going to $\sigma_{k,i}$, and $\iota = (i_k)_k\colon \mathcal{X} \to \mathbb{P} = \prod_k \mathbb{P}(\mathbb{Z}^{I_k})$. Since $\mathrm{pr}_0 \circ \iota = i_0$ is a closed immersion and pr_0 is separated, ι is a closed immersion; put $\mathcal{X}^{\mathrm{b}} = \iota(\mathcal{X})$, which we identify with $\mathcal{X}$. With the unit vectors e_k, $a^{\mathrm{H}} = e_1 - me_0$ and $v_\ell = e_\ell - me_0$ we get isomorphisms $\alpha\colon \mathcal{O}(a^{\mathrm{H}})|_{\mathcal{X}} \to \mathcal{L}$ and $\beta_\ell\colon \mathcal{O}(v_\ell)|_{\mathcal{X}} \to \mathcal{O}(D_\ell)$. Fixing a non-zero rational section ρ_k of each $\mathcal{N}_k$, $y_{k,i} = \sigma_{k,i}/\rho_k \in \Omega$ are representing coordinates.

(Hy1) and (Gb1): $\mathcal{X}^{\mathrm{b}}$ is a closed integral subscheme of $\mathbb{P}$, flat over $\mathbb{Z}$, of absolute dimension $e+1$, with smooth generic fibre (Step 1). The map $y_{\mathbb{C}} = \iota_{\mathbb{C}}$ is a bijection from the complex points of $\mathcal{X}$ (over all embeddings of F) onto X^{b}, and a biholomorphism; put $\partial X^{\mathrm{b}} = y_{\mathbb{C}}(\Delta(\mathbb{C}))$, the image of the complex points outside the abelian locus: a closed subset, stable under c (Δ is defined over $\mathbb{Q}$), and a divisor with simple normal crossings (the base change to $\mathbb{C}$ of a simple normal crossing divisor of the smooth $\mathbb{Q}$-variety $\mathcal{X}_{\mathbb{Q}}$). The first clauses of (Gb1) are Step 1 and Step 2 ($R(\ell) = 4$ for $\ell \in S$). The rational map given by y is ι: birational onto $\mathcal{X}^{\mathrm{b}}$ and defined everywhere. Charts: for c' with $y_{c'} \neq 0$, $\mathcal{X}'_{c'} = \iota^{-1}(\prod_k D_+(Y_{k,c'_k}))$ is affine (closed in an affine scheme) with ring the image of $\mathbb{Z}[Y_{k,i}/Y_{k,c'_k}]$, which is $\mathbb{Z}[y]_{c'} \subseteq \Omega$; every point lies in some $\mathcal{X}'_{c'}$ (a coordinate of each factor does not vanish there). A point x' of $\mathcal{X}'_{c'}$ has $\mathbb{Z}[y]_{c'} \subseteq \mathcal{O}_{x'}$. Conversely, if $\mathbb{Z}[y]_{c'} \subseteq \mathcal{O}_{x'}$, the induced morphism $\operatorname{Spec}\mathcal{O}_{x'} \to \mathcal{X}'_{c'} \subseteq \mathcal{X}$ and the canonical one agree at the generic point; their equaliser is a closed subscheme of the integral scheme $\operatorname{Spec}\mathcal{O}_{x'}$ ($\mathcal{X}$ is separated) through which $\operatorname{Spec}\Omega$ factors, so its ideal vanishes in $\Omega \supseteq \mathcal{O}_{x'}$ and the two morphisms are equal: $x' \in \mathcal{X}'_{c'}$. Hence the points lying in the chart c' form the affine open $\mathcal{X}'_{c'} = \mathcal{X}_{c'}$ with ring $\mathbb{Z}[y]_{c'}$.

Step 4: Hodge data, (Hy2), (Hy3), (Gb2)–(Gb4). For $\tau \in \Phi$ let $\mathcal{E}_\tau = (\mathrm{Lie}_{(\tau,+)} \oplus \mathrm{Lie}_{(\tau,-)})(G_{\mathcal{X}_{\mathbb{Q}}})^\vee$, of rank $p+q=n$ (the pieces are direct summands of the locally free $\mathrm{Lie}(G_{\mathcal{X}_{\mathbb{Q}}})$, of the generic ranks), and $\mathcal{F}_\tau$ the annihilator of $\mathrm{Lie}_{(\tau,-)}$, of rank $p=j$; their generic fibres are those of (Gb2), and $\mathcal{E}_\tau/\mathcal{F}_\tau = \mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}_{\mathbb{Q}}})^\vee = \mathcal{V}^\vee_{(\tau,-)}|_{\mathcal{X}_{\mathbb{Q}}}$ (Step 2). At $w = y_{\mathbb{C}}(z) \in X^{\mathrm{b},\circ}$ let $h_\tau(w)$ be the metric dual to the restriction of h_z to $\mathrm{Lie}_{(\tau,+)}(G_{\mathcal{X},z}) \oplus \mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z})$, smooth in w by (Fh4); its quotient metric on $\mathcal{E}_\tau/\mathcal{F}_\tau$ is dual to $h_z|_{\mathrm{Lie}_{(\tau,-)}}$. The isomorphism of (Hy2) is $\alpha_{\mathbb{Q}}$ followed by $\mathcal{L}_{\mathbb{Q}} = \bigotimes_\tau \det(\mathcal{E}_\tau/\mathcal{F}_\tau)$. (Gb3): on the affine chart $\mathcal{X}_{c'}$ the locally free $\mathcal{V}_{(\tau,-)}$ are free on the members of a finite cover by principal opens $D(f)$, $f \in \mathbb{Z}[y]_{c'}$, with frames b_τ; there $\bigotimes_\tau(b^\vee_{\tau,1} \wedge \cdots \wedge b^\vee_{\tau,q})$ generates $\mathcal{L}$, and $\prod_k y_{k,c'_k}^{a^{\mathrm{H}}_k}$ generates $\mathcal{O}(a^{\mathrm{H}})$ on $\mathcal{X}_{c'}$, so α maps it to $u\bigotimes_\tau(b^\vee_{\tau,1} \wedge \cdots \wedge b^\vee_{\tau,q})$ with u a unit on $D(f)$. (Hy3), (Gb4): S'_B is the set S of primes of the Hodge–Tate twist (Hy3), and $g_\ell = \beta_\ell^{-1}(1)$, the rational section of $\mathcal{O}(v_\ell)|_{\mathcal{X}}$ corresponding to the rational section 1 of $\mathcal{O}(D_\ell) \subseteq \Omega$. For any chart c', $g_\ell = y_{c'}^{v_\ell} \cdot \beta_\ell(y_{c'}^{v_\ell})^{-1}$ with $\beta_\ell(y_{c'}^{v_\ell})^{-1} \in \Omega^\times = \operatorname{Frac}\mathbb{Z}[y]_{c'}$ a quotient of two multihomogeneous polynomials of equal multidegree, so g_ℓ is a quotient of multihomogeneous polynomials whose degrees differ by v_ℓ. At x over ℓ in the chart c', $\beta_\ell(y_{c'}^{v_\ell})$ generates $\mathcal{O}(D_\ell)_x = (\prod_\tau \det T_\tau)^{-1}\mathcal{O}_x$ (Step 3), i.e. equals $u(\prod_\tau \det T_\tau)^{-1}$ with $u \in \mathcal{O}_x^\times$, so $g_\ell/y_{c'}^{v_\ell} = u^{-1}\prod_\tau \det T_\tau$: this is (Gb4). At x not over ℓ, $\mathcal{O}(D_\ell)_x = \mathcal{O}_x$ and $g_\ell/y_{c'}^{v_\ell}$ is a unit, so the divisor of g_ℓ is supported in the fibre over ℓ. For this B, $S_B = S'_B$.

Step 5: auxiliary line, (Hy5), (Gb6). Let $a' = (1,\dots,1)$ and $h'(\hat{w}) = \prod_k \|\hat{w}_k\|_2$ (the ℓ^2 norm of the coordinates of the factor k), a smooth cone function of multidegree a' invariant under c. Its first Chern form $\Theta = dd^c \log h'$ on X^{b} is the sum of the pull-backs of the Fubini–Study forms of the factors, each ≥ 0, and the one of the factor 0 is positive as i_0 is an immersion: Θ is a Kähler form. Put $k^{\mathrm{A}} = 0$: for $x \in \mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$, $h_{\overline{\mathcal{A}}'}(D_x) = \sum_k h_{(\mathcal{O}(e_k),\|\cdot\|_2)}(D_x)$, and each term is ≥ 0. Indeed, let $K = \mathbf{k}(D_x)$ and $\nu\colon \operatorname{Spec}\mathcal{O}_K \to D_x$ the normalisation, finite and birational, hence surjective (its image is closed and dense). Apply Lemma 30.13 with $b=1$, $d=0$, the morphism ν and $\overline{\mathcal{H}}_1 = (\mathcal{O}(e_k), \|\cdot\|_2)|_{D_x}$: $\operatorname{Spec}\mathcal{O}_K$ (finite over $\mathbb{Z}$) and D_x (closed in $\mathbb{P}$) are integral, flat and projective over $\mathbb{Z}$ of absolute dimension 1; their generic fibres are spectra of the number field K, hence smooth over $\mathbb{Q}$; the metric is smooth (the restriction of the cone metric $\|\hat{w}_k\|_2$); and $c = [K : \mathbf{k}(D_x)] = 1$. It gives $h_{(\mathcal{O}(e_k),\|\cdot\|_2)}(D_x) = \widehat{\deg}\,\nu^*(\mathcal{O}(e_k), \|\cdot\|_2)$, where $\nu^*\mathcal{O}(e_k)$ is the pull-back of $\mathcal{O}(1)$ with its ℓ^2 metric along the extension $\operatorname{Spec}\mathcal{O}_K \to \mathbb{P}(\mathbb{Z}^{I_k})$ of $\mathrm{pr}_k(x)$. Take homogeneous coordinates $(x_i)_{i\in I_k}$ of $\mathrm{pr}_k(x)$ in K with $x_{i_0} = 1$ for some i_0. At a maximal ideal $\mathfrak{p}$ of $\mathcal{O}_K$ put $\mu_{\mathfrak{p}} = \min_i \mathrm{ord}_{\mathfrak{p}}(x_i) \leq \mathrm{ord}_{\mathfrak{p}}(x_{i_0}) = 0$; the line is generated there by

Y_j for any j with $\mathrm{ord}_{\mathfrak{p}}(x_j) = \mu_{\mathfrak{p}}$, so the rational section $Y_{i_0} = (x_{i_0}/x_j)Y_j$ has order $-\mu_{\mathfrak{p}} \geq 0$ at $\mathfrak{p}$; at an embedding $\sigma\colon K \to \mathbb{C}$, $\|Y_{i_0}\|_\sigma = |\sigma(x_{i_0})|/\|\sigma(x)\|_2 = \|\sigma(x)\|_2^{-1}$. Computing the arithmetic degree of a hermitian line bundle on $\operatorname{Spec}\mathcal{O}_K$ with the non-zero rational section Y_{i_0} gives $\widehat{\deg} = \sum_{\mathfrak{p}}(-\mu_{\mathfrak{p}})\log N\mathfrak{p} + \sum_\sigma \log\|\sigma(x)\|_2 \geq 0$, as $\|\sigma(x)\|_2 \geq |\sigma(x_{i_0})| = 1$.

Step 6: the boundary section and the cusp data. $\mathcal{O}(\Delta)$ and its canonical section s_Δ are defined over $\mathbb{Q}$; complex conjugation lifts to an antiholomorphic involution $\tilde{c}$ of the total space of $\mathcal{O}(\Delta)_{\mathbb{C}}$ over c with $\tilde{c}\circ s_\Delta = s_\Delta \circ c$. For a smooth hermitian metric $\|\cdot\|_0$, $(\frac{1}{2}(\|\cdot\|_0^2 + \|\tilde{c}(\cdot)\|_0^2))^{1/2}$ is a smooth metric invariant under $\tilde{c}$; scaling it (compactness) we get $\varsigma = s_\Delta$ with $\|\varsigma\| \leq 1$, $\|\varsigma\| \circ c = \|\varsigma\|$, zero divisor $\Delta_{\mathbb{C}}$ (reduced, simple normal crossings, support ∂X^{b}). This is hypothesis (i) of Lemma D.17; $\mathrm{rW} = e - 2\log\|\varsigma\|$ is invariant under c.

Cusp data: $O = \mathcal{O}_E$; for $w \in X^{\mathrm{b},\circ}$ let $z = y_{\mathbb{C}}^{-1}(w)$, in the abelian locus, over $\kappa\colon F \to \mathbb{C}$, and $G_z = G_{\mathcal{X},z}$. Put $\varepsilon_{w,\tau} = \kappa\circ\bar{\tau}$ (the character of $\mathcal{O}_E$ on $\mathrm{Lie}_{(\tau,-)}(G_z)$, (Fh1)), $\Lambda_w = H_1(G_z(\mathbb{C}),\mathbb{Z}) \subset \mathrm{Lie}(G_z)$ with the action ι, $\langle v, v'\rangle_w = \mathrm{Im}\, H_z(v,v')$ (alternating, integral, unimodular as the polarisation is principal, Definition 29.5), $\|v\|_w^2 = H_z(v,v)$ (positive for $v \neq 0$; $\langle v,v'\rangle_w^2 \leq |H_z(v,v')|^2 \leq \|v\|_w^2\|v'\|_w^2$), and $\lambda_{w,\tau}(v) \in \mathbb{C}^q$ the coordinates, in a fixed H_z-orthonormal basis of $\mathrm{Lie}_{(\tau,-)}(G_z)$, of the component $v_{(\tau,-)}$ of v in the decomposition (Fh1). Then $\lambda_{w,\tau}(av) = \varepsilon_{w,\tau}(a)\lambda_{w,\tau}(v)$. The pieces $\mathrm{Lie}_s(G_z)$ are pairwise H_z-orthogonal: for $u \in \mathrm{Lie}_s$, $u' \in \mathrm{Lie}_{s'}$ and $a \in \mathcal{O}_E$, the Rosati condition $H_z(\iota(a)u,u') = H_z(u,\iota(\bar{a})u')$ gives $\kappa\sigma_s(a)H_z(u,u') = \overline{\kappa\sigma_{s'}(\bar{a})}H_z(u,u') = \kappa\sigma_{s'}(a)H_z(u,u')$ (complex conjugation commutes with every embedding of the CM field E), and $\kappa\sigma_s \neq \kappa\sigma_{s'}$ for $s \neq s'$; hence $\sum_\tau|\lambda_{w,\tau}(v)|^2 = \sum_\tau H_z(v_{(\tau,-)},v_{(\tau,-)}) \leq H_z(v,v)$. Independence: let $I \subseteq \Lambda_w$ be an isotropic $\mathcal{O}_E$-submodule, $v_1,\dots,v_\rho \in I$ $\mathcal{O}_E$-linearly independent, and $I_{\mathbb{R}} \subseteq \mathrm{Lie}(G_z)$ the real span of I. If $u = iu'$ with $u,u' \in I_{\mathbb{R}}$, then $H_z(u',u') = \mathrm{Im}\, H_z(iu',u') = \mathrm{Im}\, H_z(u,u') = 0$, so $u' = 0$: $I_{\mathbb{R}} \cap iI_{\mathbb{R}} = 0$, and the $\mathcal{O}_E$-equivariant $\mathbb{C}$-linear map $\mu\colon I\otimes_{\mathbb{Z}}\mathbb{C} \to \mathrm{Lie}(G_z)$, $v\otimes a \mapsto av$, is injective ($I\otimes\mathbb{R} \cong I_{\mathbb{R}}$ as $\Lambda_w\otimes\mathbb{R} \cong \mathrm{Lie}(G_z)$). For $\sigma = \kappa\circ\bar{\tau}$, μ maps the σ-eigenspace $(I\otimes\mathbb{C})_\sigma = (I\otimes\mathbb{Q})\otimes_{E,\sigma}\mathbb{C}$ into $\mathrm{Lie}_{(\tau,-)}(G_z)$ and the σ-component of $v\otimes 1$ to $v_{(\tau,-)}$. The v_a are E-linearly independent in $I\otimes\mathbb{Q}$, so their σ-components are $\mathbb{C}$-linearly independent, hence so are the $(v_a)_{(\tau,-)}$ and the $\lambda_{w,\tau}(v_a)$. Finally fix, for every non-zero saturated isotropic $\mathcal{O}_E$-submodule I for which one exists, an $\mathcal{O}_E$-linearly independent family v^I spanning a subgroup of finite index. This gives (Hu1), the cusp weight U of (Hu2), and (Gb5) with the identity isomorphism.

Step 7: the log-log regularisations, (Hy4) and hypothesis (ii). Let $h^{\mathrm{ref}}(\hat{w}) = \|\hat{w}_1\|_2\|\hat{w}_0\|_2^{-m}$, a smooth cone function of multidegree a^{H} invariant under c; $\theta = dd^c\log h^{\mathrm{ref}}$, $\varphi = \log(h^{\mathrm{H}}/h^{\mathrm{ref}})$ on $X^{\mathrm{b},\circ}$, invariant under c by Lemma D.9, applied to the data of Steps 3–6 completed by h^{ref}, $h^{\mathrm{ref}'} = h^{\mathrm{ref}}$ and the provisional regularisations $\varphi_t = 0$, $\psi_{t'} = 0$: these data satisfy (Hy1)–(Hy5), (Hu1)–(Hu3) and (Gb1)–(Gb6) (Steps 3–6), so they form a base setting of $\mathcal{T}$ at (B,Z), and h^{H}, U do not depend on the regularisations. Put $\mathcal{M}_\tau = (\det\mathcal{V}_{(\tau,-)})^\vee$, so $\mathcal{L} = \bigotimes_\tau \mathcal{M}_\tau$. By (Gb3) and (Gb2) the metric $|\cdot|/h^{\mathrm{H}}$ corresponds under α to $\bigotimes_\tau\|\cdot\|_{\mathrm{Hdg},\tau}$ with $\|(b_{\tau,1}\wedge\cdots\wedge b_{\tau,q})^\vee\|_{\mathrm{Hdg},\tau}^2 = \det\Gamma(b_\tau)^{-1}$. Choose smooth hermitian metrics $\|\cdot\|_{\mathrm{ref},\tau}$ on $\mathcal{M}_{\tau,\mathbb{C}}$ whose tensor product corresponds to $|\cdot|/h^{\mathrm{ref}}$ (arbitrary for all τ but one, which is then determined); then $\varphi = \sum_\tau\varphi_\tau$ with $\varphi_\tau = \log\|\cdot\|_{\mathrm{ref},\tau} - \log\|\cdot\|_{\mathrm{Hdg},\tau}$. Apply Lemma 33.15, case (i), to the cover $\mathcal{X}$ of Proposition 33.9 for $\mathcal{Y}_Z$ and S, the label $s = (\tau,-)$, $j = \mathrm{rk}(s) = q$ (so $\gamma = \mathrm{id}$ and $P = X^{\mathrm{b}}$), and ς: as $\mathcal{V}^S_{(\tau,-)}$ and $\mathcal{V}_{(\tau,-)}$ agree on $\mathcal{X}_{\mathbb{Q}}$ (Step 2), its line bundle is $\mathcal{M}_{\tau,\mathbb{C}}$ with the Hodge metric $\|\cdot\|_{\mathrm{Hdg},\tau}$, and it gives that φ_τ satisfies hypotheses 1 and 2 of Theorem 33.22 on X^{b} with a constant $C_{5,\tau}$. Then φ satisfies hypothesis 1 with $C_5 = \sum_\tau C_{5,\tau}$ (φ is smooth, $h^{\mathrm{ref}}e^{\varphi}$ corresponds to the tensor product of the psh metrics $\|\cdot\|_{\mathrm{ref},\tau}e^{-\varphi_\tau}$, so its local potentials are sums of psh functions, and the bounds add). For hypothesis 2, for a point x take the charts z^τ on U^τ given for the φ_τ, a relatively compact neighbourhood U_x of x in $\bigcap_\tau U^\tau$ and $z = z^{\tau_0}|_{U_x}$; the Jacobian matrices of the changes of charts are bounded on U_x by some $c_x \geq 1$, so $\|d\varphi\|_z \leq c_x C_5 \mathrm{rW}^{C_5}\exp(\mathrm{rW}/2)$ on $U_x \cap X^{\mathrm{b},\circ}$ (as $\mathrm{rW} \geq e$). Finitely many $U_{x_1},\dots,U_{x_r}$ cover X^{b}, and hypothesis 2 holds with

$C_5' = C_5 \max_i c_{x_i}$ and the chart of a U_{x_i} containing the point. Now Theorem 33.22 on X^{b} with Θ, ς, $(\mathcal{O}(a^{\mathrm{H}})|_{X^{\mathrm{b}}}, h^{\mathrm{ref}})$, φ and C_5' gives $C \geq 1$ (enlarging C), $0 < t_0 < 1$ and $\varphi^T(t)$.

The functions $\varphi^T(t) \circ c$ have the same properties: the pointwise ones because φ and rW are invariant under c; the C^2-convergence because c preserves the compact subsets of $X^{\mathrm{b},\circ}$; and $\theta + dd^c(\varphi^T(t) \circ c) + \varepsilon(t)\Theta = -c^*(\theta + dd^c\varphi^T(t) + \varepsilon(t)\Theta) \geq 0$, since $dd^c(g \circ c) = -c^* dd^c g$ for smooth g, $\log h^{\mathrm{ref}}$ and $\log h'$ are invariant (so $c^*\theta = -\theta$, $c^*\Theta = -\Theta$), and the pull-back by the antiholomorphic c of a semipositive $(1,1)$-form is seminegative. Put $\varphi_t = \frac{1}{2}(\varphi^T(t) + \varphi^T(t) \circ c)$ for $0 < t \leq t_0$ and $\varphi_t = \varphi_{t_0}$ for $t > t_0$: smooth, invariant under c, and with all the properties (they are preserved by averaging: inequalities, the positivity of $\theta + dd^c(\cdot) + \varepsilon(t)\Theta$, limits). This is (Hy4). Shrink $t_0 \leq e^{-e}$ and put $\varepsilon(t) = C \log\log(1/t)/\log(1/t) \geq 0$, $R(t) = \log(1/t) \geq e$, $\delta(t) = t^{1/3} + C\varepsilon(t)$, $C' = \max(C, C_5')$: (R2) is $-C_5' \log \mathrm{rW} \leq \varphi \leq \varphi_t \leq C$; (R3) is $\varphi_t \leq \varphi + t^{1/3} + \varepsilon(t)$ on $\{\mathrm{rW} \leq R(t)\}$; (R4) is $\varphi_t \leq \varphi_{t'} + C\varepsilon(t') \leq \varphi_{t'} + \delta(t')$ for $t \leq t' \leq t_0$; (R5) is the C^2-convergence; and $\theta + dd^c\varphi_t + \varepsilon(t)\Theta \geq 0$. So hypothesis (ii) of Lemma D.17 holds.

Step 8: the bounded regularisations, (Hu3), clauses (b), (c). Let $h^{\mathrm{ref}'} = h^{\mathrm{ref}}$, take the φ_t of Step 7, and provisionally $\psi_{t'} = 0$. Steps 3–7 give (Hy1)–(Hy5), (Hu1)–(Hu3) and (Gb1)–(Gb6): this is a base setting of $\mathcal{T}$ at (B, Z), whose cover is proper over $\mathcal{O}_F$ (Step 1). By Lemma D.9, $\varphi' = \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ is invariant under c, and Lemma D.13 (whose hypotheses and conclusions do not involve the regularisations of the setting) gives $C_R \geq 0$, $0 < t_0' < 1$ and smooth functions $\psi_{t'}$ invariant under c with (Rw1)–(Rw3); we take them (and $\psi_{t'} = \psi_{t_0'}$ for $t' > t_0'$) as the bounded regularisations. Definition 31.11 does not restrict them, so this is again a base setting of $\mathcal{T}$ at (B, Z). (c) is the first part of (Rw2). (b): on the cone over X^{b} each g_ℓ is holomorphic without zeros (Step 4), so $\log|g_\ell|$ is pluriharmonic and $c_1(\overline{\mathcal{M}}_{B,i_1,i_2,t}) = i_2(\theta + dd^c\psi_t) + i_1\Theta \geq (i_1 - i_2 C_R/\log(1/t))\Theta \geq 0$ for $0 < t \leq t_1 = \min(t_0', \exp(-i_2 C_R/i_1))$, by (Rw1).

Step 9: clauses (a) and (e). We check the hypotheses of Lemma D.17. (i) is Step 6 and (ii) is Step 7. (iii): by Lemma D.10, near every point of the abelian locus over some κ, with holomorphic frames b_τ, $\frac{1}{2}\sum_\tau \log\det\Gamma(b_\tau) + \frac{1}{2}U \circ y_{\mathbb{C}}$ is continuous; the first sum is smooth, and $y_{\mathbb{C}}$ is a biholomorphism, so U is continuous on $X^{\mathrm{b},\circ}$. For the bound, let $x \in \partial X^{\mathrm{b}}$, a complex point of $\mathcal{X}$ over some κ, of the complex fibre $X_{\mathbb{C}} = \mathcal{X} \otimes_\kappa \mathbb{C}$ (projective, with $G' = G_{\mathcal{X}}$ and the abelian locus, case (B) of Lemma 33.16). As $\Delta_{\mathbb{C}}$ is a reduced simple normal crossing divisor, there are a neighbourhood V of x and a biholomorphic $t\colon V \to \Delta^d$ with $t(x) = 0$, $t(V \cap X^{\mathrm{b},\circ}) = \{t_1 \cdots t_a \neq 0\}$, $a \geq 1$, and (shrinking V) $\|\varsigma\| = |t_1 \cdots t_a| e^{-\chi}$ with χ smooth and bounded on V. With $L = 1 + \sum_{j \leq a} |\log|t_j||$, on $V \cap X^{\mathrm{b},\circ}$ we get $\mathrm{rW} = e + 2\sum_{j \leq a} |\log|t_j|| + 2\chi \geq 2(L-1) - 2\sup_V|\chi|$, so $L \leq c_V\,\mathrm{rW}$ for a constant $c_V \geq 1$, and $1 + \log L \leq (2 + \log c_V)\log\mathrm{rW}$ as $\mathrm{rW} \geq e$. Lemma D.16 gives C_x and a neighbourhood V_x' of x with $U \leq C_x(1 + \log L) \leq C_x(2 + \log c_V)\log\mathrm{rW}$ on $V_x' \cap X^{\mathrm{b},\circ}$. Finitely many V_x' cover the compact ∂X^{b}; on the compact complement $K' \subseteq X^{\mathrm{b},\circ}$ of their union, $U \leq \max_{K'} U \leq (\max_{K'} U)\log\mathrm{rW}$. So $U \leq C_U \log\mathrm{rW}$ on $X^{\mathrm{b},\circ}$ for some $C_U \geq 1$; enlarging C in (ii) to $\max(C', C_U)$ keeps (ii). (iv): by (Rw2), $|\psi_{t'}| \leq C_R$, and by (Rw3), $\psi_{t'} \to \varphi'$ pointwise on $X^{\mathrm{b},\circ}$.

Lemma D.17 gives that $\mathrm{ar}^{\mathrm{b}}(B)$ exists, (Mz1)–(Mz3) at B, and $\int_{X^{\mathrm{b},\circ}}(\omega^{\mathrm{H}})^e = \deg^{\mathrm{H}}$. By Lemma D.2 (an admissible B is ≥ 2), $\int_{X^{\mathrm{b},\circ}}(\omega^{\mathrm{H}})^e > 0$; so $\deg^{\mathrm{H}} \neq 0$, and Lemma D.17 gives (Mz1)–(Mz4) at B: clause (a). Clause (e) is Steps 6 and 7.

Step 10: clause (d). $\mathcal{X}$ is proper over $\operatorname{Spec}\mathbb{Z}$, $R(\ell) = 4$ for $\ell \in \mathrm{Bd} \cup S_B'$, and the Hodge lattices at $(\mathrm{Bd} \cup S_B', 4)$ are Hodge bundles (Step 1). By (Go3)(1), $\mathcal{X}_{B,Z}$ is a normal cover $f_{B,Z}$ of $\mathcal{Y}$ whose generic point maps to that of $\mathcal{Y}_Z$; it is a root model, a closed subscheme of a multiprojective space, hence proper over $\mathbb{Z}$ and over $\mathcal{Y}$. Let Ω_1 be its function field and $K_0 = \mathbf{k}(\mathcal{Y}_Z)$. As Ω is finite over K_0, $\Omega_1 \otimes_{K_0} \Omega$ is a non-zero finite Ω_1-algebra; its quotient by a maximal ideal is a field Ω'', finite over Ω_1, containing Ω_1 and Ω compatibly over K_0. Let $\mathcal{X}_0''$ be the normalisation

of $\mathcal{X}_{B,Z}$ in Ω'', finite over $\mathcal{X}_{B,Z}$ ($\mathcal{X}_{B,Z}$ is of finite type over $\mathbb{Z}$, hence excellent). The inclusion $\Omega \subseteq \Omega''$ over K_0 defines a rational map $\mathcal{X}_0'' \dashrightarrow \mathcal{X}$ over $\mathcal{Y}$; let $\Gamma \subseteq \mathcal{X}_0'' \times_{\mathcal{Y}} \mathcal{X}$ be the closure of its graph, an integral scheme with function field Ω'', and $\mathcal{X}''$ its normalisation (finite over Γ). The projection $\Gamma \to \mathcal{X}_0''$ is proper (base change of the proper $\mathcal{X} \to \mathcal{Y}$, restricted to a closed subscheme) and birational, and $\Gamma \to \mathcal{X}$ is proper (base change of the proper $\mathcal{X}_0'' \to \mathcal{Y}$). So $\phi\colon \mathcal{X}'' \to \mathcal{X}_0'' \to \mathcal{X}_{B,Z}$ and $\phi'\colon \mathcal{X}'' \to \mathcal{X}$ are proper and dominant (both map the generic point to the generic point), $\mathcal{X}''$ with $f'' = f_{B,Z} \circ \phi = f \circ \phi'$ (the two agree as Γ lies over $\mathcal{Y}$) is a normal integral scheme whose generic point maps to that of $\mathcal{Y}_Z$, with Ω'' finitely generated over K_0: a cover of $\mathcal{Y}$. So the setting is joined to the stage root model $\mathcal{X}_{B,Z}$: clause (d).

All clauses hold for the base setting constructed, which proves the proposition. □

Lemma D.2. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2, and put $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]}$. Let $B \geq 2$ be an integer, $Z \in \mathrm{Cp}$, and let a base setting of $\mathcal{T}$ at (B, Z) be given. Then $(\omega^{\mathrm{H}})^e$ is a positive measure on $X^{\mathrm{b},\circ}$ with $0 < \int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e < \infty$, U is integrable for it, and*

$$\int_{X^{\mathrm{b},\circ}} U\,(\omega^{\mathrm{H}})^e \;\leq\; |\Phi|\,q\,(6 + \log(2|\Phi|\,\mathrm{rd}_E) + \log(2|\Phi|\,q\,\mathrm{rd}_E)) \int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e.$$

Proof. Write $f_0 = |\Phi|$, so $[E:\mathbb{Q}] = 2f_0$, and $C_0 = f_0 q(6 + \log(2f_0 \mathrm{rd}_E) + \log(2f_0 q\,\mathrm{rd}_E))$. The base setting has type (Φ, n, p), so $e = |\Phi|pq$ and $j' = q$.

Step 1 (the intrinsic cusp weight). For a complex point z' of Sh_F (over any embedding of F) let $A' = G^{\mathrm{un}}_{z'}$, $\Lambda' = H_1(A'(\mathbb{C}), \mathbb{Z}) \subset \mathrm{Lie}(A')$ with its $\mathcal{O}_E$-action and $H' = H_{z'}$ (Definition 29.6, (Fh4)). For a non-zero $\mathcal{O}_E$-submodule $I \subseteq \Lambda'$ on which $\mathrm{Im}\,H'$ vanishes put $\mathrm{N}'(I) = \det\big(H'(b_i, b_k)\big)_{i,k}^{1/2}\,\mathrm{rd}_E^{-f_0\rho}$, with (b_i) a $\mathbb{Z}$-basis of I and $2f_0\rho$ the $\mathbb{Z}$-rank of I; it does not depend on the basis. Put $U'(z') = \max\big(0, \sup_I - \log \mathrm{N}'(I)\big)$, over the non-zero saturated such I. Let $\Psi_{z'}$ be the set of the embeddings by which $\mathcal{O}_E$ acts on the pieces $\mathrm{Lie}_{(\tau,-)}(A')$, $\tau \in \Phi$; it is a CM type (for z' over the embedding κ of F its members are the $\kappa \circ \sigma_{(\tau,-)} = \kappa \circ \bar\tau = \overline{\kappa \circ \tau}$, and $\{\kappa \circ \tau : \tau \in \Phi\}$ is a CM type as Φ is one and κ is injective), and each such piece has dimension q (Kottwitz condition). By Lemma D.3 applied to $(\mathrm{Lie}(A'), H', \Lambda')$ with $\Psi = \Psi_{z'}$ and $m = q$ (the hypotheses: H' is positive definite and hermitian, $\mathcal{O}_E$ preserves Λ' and $H'(ax, y) = H'(x, \bar a y)$, as $\mathrm{Im}\,H'$ is the Riemann form of a polarisation whose Rosati involution is complex conjugation, Definition 29.5 (Ud4)): for every I as above and every $\mathcal{O}_E$-independent family $v_1, \dots, v_\rho \in I$ spanning a subgroup of finite index k_v, $\mathrm{N}'(I) = k_v^{-1} \prod_\tau \det\big(H'((v_a)_{(\tau,-)}, (v_b)_{(\tau,-)})\big)_{a,b}$, the components taken in the pieces $(\tau, -)$, and

$$-\log \mathrm{N}'(I) \leq f_0 q\Big(2\max\big(0, \log \tfrac{1}{\lambda_1'}\big) + \log(2f_0 q\,\mathrm{rd}_E)\Big), \qquad \lambda_1' = \min_{0 \neq x \in \Lambda'} H'(x,x)^{1/2}. \tag{1}$$

Now let z be a complex point of the abelian locus of $\mathcal{X}$ with $w = y_{\mathbb{C}}(z) \in X^{\mathrm{b},\circ}$ and $z' = f(z)$; then $G_{\mathcal{X},z} = G^{\mathrm{un}}_{z'}$ with $H_z = H_{z'}$ (Definition 29.6, (Fh6)). Under the isomorphism $\Lambda_w \cong \Lambda'$ of (Gb5), the saturated isotropic $\mathcal{O}_E$-submodules of Λ_w correspond to those of Λ'; every non-zero one has an $\mathcal{O}_E$-independent family of finite index (a maximal $\mathcal{O}_E$-independent subset of a torsion-free finitely generated module), and $\overline{\lambda_{w,\tau}(v_a)}^{\mathsf{T}} \lambda_{w,\tau}(v_b) = H'((v_b)_{(\tau,-)}, (v_a)_{(\tau,-)})$, whose determinant is that of the complex conjugate of the positive definite matrix above. Hence $\mathrm{N}_w(I) = \mathrm{N}'(I')$ for corresponding I, I', and

$$U(w) = U'(f(z)). \tag{2}$$

Step 2 (the Hodge form). Let ω' be the first Chern form of the holomorphic line bundle $\bigotimes_{\tau\in\Phi}(\det \mathrm{Lie}_{(\tau,-)}(G^{\mathrm{un}}))^\vee$ on the complex points of Sh_F, with the metric dual to the determinant of the restriction of $h=\pi H$ (normalised as ω^{H}). Let z be a smooth complex point of $\mathcal{X}$ in the abelian locus with $y_{\mathbb{C}}(z)\in X^{\mathrm{b},\circ}$, and $D(f')$ a principal open set of a chart as in (Gb3) containing z. At complex points the Hodge lattice is the de Rham lattice, so a frame $(b_{\tau,i})$ of $\mathcal{V}_{(\tau,-)}$ on $D(f')$ is a holomorphic frame of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})=f^*\mathrm{Lie}_{(\tau,-)}(G^{\mathrm{un}})$ near z, and by (Gb3) the section $s=\prod_k y_{k,c'_k}^{a_k^{\mathrm{H}}}$ has $\|s\|=|u|\prod_\tau\|b_{\tau,1}\wedge\cdots\wedge b_{\tau,q}\|_h^{-1}$ along $y_{\mathbb{C}}$, with u a holomorphic unit. As $\log|u|^2$ is pluriharmonic,

$$y_{\mathbb{C}}^*\omega^{\mathrm{H}}=-\tfrac{1}{2\pi}i\partial\bar\partial\log(y_{\mathbb{C}}^*\|s\|^2)=f^*\omega'\quad\text{near } z. \tag{3}$$

Step 3 (from $X^{\mathrm{b},\circ}$ to Z). The rational map y is birational from $\mathcal{X}$ onto $\mathcal{X}^{\mathrm{b}}$ (Gb1), and both have dimension $e+1$, so the function field Ω of $\mathcal{X}$ has transcendence degree $e=\dim Z$ over $\mathbb{Q}$; as the generic point of $\mathcal{X}$ maps to that of $\mathcal{Y}_Z$ and Ω is finitely generated over its residue field (a cover, Definition 29.6 (Fh5)), Ω is a finite extension, of some degree $d\geq 1$, of the function field of Z. In characteristic 0 there are dense Zariski open subsets $Z^\circ\subseteq Z$ over which f is finite étale of degree d, and $\mathcal{X}^\circ\subseteq f^{-1}(Z^\circ)$ in the generic fibre of $\mathcal{X}$, smooth, mapped by y isomorphically onto an open subset of $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$. Let X, X°, $Z(\mathbb{C})$, $Z^\circ(\mathbb{C})$ be the sets of complex points (over every embedding of F). The complements of X° in X, of $y_{\mathbb{C}}(X^\circ)$ in X^{b}, of $Z^\circ(\mathbb{C})$ in $Z(\mathbb{C})$ and of $X^\circ\cap y_{\mathbb{C}}^{-1}(X^{\mathrm{b},\circ})$ in X° (the trace of the divisor ∂X^{b}) are contained in proper analytic subsets, hence are null for every smooth top form. By (Gb1), $\partial X^{\mathrm{b}}=y_{\mathbb{C}}(X\smallsetminus\text{abelian locus})$, so $y_{\mathbb{C}}^{-1}(X^{\mathrm{b},\circ})$ lies in the abelian locus, and $X^\circ\subseteq f^{-1}(Z^\circ)$ lies in it as well. On X°, f is a d-sheeted covering of $Z^\circ(\mathbb{C})$ (open in $f^{-1}(Z^\circ)(\mathbb{C})$ with null complement) and $y_{\mathbb{C}}$ a biholomorphism onto its image. So, for every Borel $\varphi\colon X^{\mathrm{b},\circ}\to[0,\infty]$ with $\varphi\circ y_{\mathbb{C}}=\varphi'\circ f$ on $X^\circ\cap y_{\mathbb{C}}^{-1}(X^{\mathrm{b},\circ})$, by change of variables and (3),

$$\int_{X^{\mathrm{b},\circ}}\varphi\,(\omega^{\mathrm{H}})^e=\int_{X^\circ\cap y_{\mathbb{C}}^{-1}(X^{\mathrm{b},\circ})}(\varphi'\circ f)\,f^*\omega'^{\,e}=d\int_{Z(\mathbb{C})}\varphi'\,\omega'^{\,e}. \tag{4}$$

By (2), (4) applies to $\varphi=U$, $\varphi'=U'$, and to $\varphi=1$, $\varphi'=1$ (once $\omega'^{\,e}\geq 0$ is shown in Step 4; then $(\omega^{\mathrm{H}})^e=y_{\mathbb{C}*}f^*\omega'^{\,e}\geq 0$ on the dense open $y_{\mathbb{C}}(X^\circ)\cap X^{\mathrm{b},\circ}$, hence everywhere on $X^{\mathrm{b},\circ}$ by continuity).

Step 4 (one piece). We have $Z(\mathbb{C})=\bigsqcup_\kappa Z_\kappa(\mathbb{C})$ over the embeddings $\kappa\colon F\to\mathbb{C}$, and by (SU6) and (SU2) of Proposition 33.35 (whose hypotheses are among those of Proposition 34.2; $p+q\geq 1$) $Z_\kappa(\mathbb{C})=u_k(\mathrm{Per}_\sigma(L_k))$ for one $k\in I_\kappa$, with u_k inducing a biholomorphism from $\Gamma_k\backslash\mathrm{Per}_\sigma(L_k)$, $\Gamma_k=\Gamma(L_k,\mathfrak{n})$, acting freely and properly discontinuously. Fix κ, k, put $L=L_k$, $\psi=\psi_k$, $\Phi'=\{\rho\colon E\to\mathbb{C}:\rho(r)=\kappa(r_{\mathbb{C}})\}=\{\kappa\circ\tau:\tau\in\Phi\}$, and let Per, G, G^1, $\omega^{\mathrm{H}}_{\mathrm{Per}}$ be the objects of Lemma 33.38 for $(L_{\mathbb{R}},\psi,\Phi')$. ($L_{\mathbb{R}}$ is free of rank n over $E\otimes\mathbb{R}$ since $L\otimes\widehat{\mathbb{Z}}\cong M\otimes\widehat{\mathbb{Z}}$, (SU2).) (a) We have $\mathrm{Per}_\sigma(L)=\mathrm{Per}$ as complex manifolds. The characteristic polynomial of $a\in\mathcal{O}_E$ on $(L_{\mathbb{R}},J)$ is $\prod_\rho(T-\rho(a))^{\delta_\rho(J)}$, $\delta_\rho(J)$ the dimension of the subspace on which a acts by $\rho(a)$; by Lemma 32.3 and the computation of $\sigma(P_a)$ in (SU4), $\sigma(P_a)=\prod_{\rho\in\Phi'}(T-\rho(a))^p(T-\bar\rho(a))^q$; for a a primitive element the $\rho(a)$ are distinct, so the determinant condition of (PU2) is exactly the dimension condition of (Pd1), and the other conditions coincide. For the complex structure: $K(J)=\ker(J+i)$, and $J\mapsto K(J)$ is holomorphic by (PU2); so $J\mapsto(K(J)\cap W_\rho)_{\rho\in\Phi'}$ is holomorphic (intersection with fixed subspaces in constant dimension q), and it is the open embedding of (Pd1); a holomorphic bijection between manifolds of the same dimension is biholomorphic. (b) We have $u_k^*\omega'=\omega^{\mathrm{H}}_{\mathrm{Per}}$. By (SU3), $u_k^*G^{\mathrm{un}}$ is $A_J=(L_{\mathbb{R}},J)/L$ with $H_1=L$ and Riemann form ψ, so the first Chern class of the polarisation is $H_J(x,y)=\psi(Jx,y)+i\psi(x,y)$, and $h=\pi H_J$; at a point over κ the piece $\mathrm{Lie}_{(\tau,-)}$ is the subspace where a acts by $\kappa(\bar\tau(a))=\overline{(\kappa\circ\tau)(a)}$, i.e. $\mathrm{Lie}_{(\kappa\circ\tau,-)}(J)$ of (Pd2), and $\tau\mapsto\kappa\circ\tau$ is a bijection $\Phi\to\Phi'$.

So the metrised line bundle defining ω' pulls back to that of Lemma 33.38 (4). By (4) of that lemma, $\omega^{\mathrm{H}}_{\mathrm{Per}}$ is G-invariant and positive definite, so $\omega'^{\,e} > 0$ on $Z_\kappa(\mathbb{C})$, and G^1 acts transitively on Per with compact stabilisers. (c) The measure. Fix $J_0 \in \mathrm{Per}$ with stabiliser K_0 in G (G preserves ψ and commutes with E, so acts on Per; K_0 preserves the definite spaces of J_0 and is compact). The push-forward of a Haar measure μ_G of G ($\cong \prod_{\rho\in\Phi'} \mathrm{U}(W_\rho)$, unimodular) along $g \mapsto gJ_0$ is a G^1-invariant Radon measure on $\mathrm{Per} = G^1/(G^1 \cap K_0)$, hence (uniqueness of invariant measures on a quotient by a compact subgroup) equals $c_2^{-1}(\omega^{\mathrm{H}}_{\mathrm{Per}})^e$ for some $c_2 > 0$. Let $F_0 \colon \mathrm{Per} \to [0,\infty]$ be Borel and invariant under the group Γ^{f} of $\mathcal{O}_E$-linear automorphisms of L preserving ψ, and $\tilde{F}_0(g) = F_0(gJ_0)$. Let $\Omega \subseteq \mathrm{Per}$ be a Borel fundamental domain of Γ_k (free and properly discontinuous action of a countable group); then $D' = \{g \in G : gJ_0 \in \Omega\}$ is a Borel fundamental domain of Γ_k acting on G by left multiplication (freeness on Per), and

$$\int_{\Gamma_k\backslash\mathrm{Per}} F_0\,(\omega^{\mathrm{H}}_{\mathrm{Per}})^e = \int_\Omega F_0\,(\omega^{\mathrm{H}}_{\mathrm{Per}})^e = c_2 \int_G \mathbf{1}_\Omega(gJ_0) F_0(gJ_0)\,d\mu_G(g) = c_2 \int_{D'} \tilde{F}_0\,d\mu_G.$$

By (SU1), Γ^{f} is the stabiliser of L in $\mathrm{U}(V_L,h_L)(E^+)$, and Γ_k is the kernel of its action on $L/\mathfrak{n}L$, of finite index i_k. With $\Gamma^{\mathrm{f}} = \bigsqcup_{l\le i_k} \Gamma_k\gamma_l$ and D a Borel fundamental domain of Γ^{f} in G (Lemma D.4), $\bigsqcup_l \gamma_l D$ is one of Γ_k (Γ^{f} acts freely on G); as the integral of a left-Γ_k-invariant function over a fundamental domain does not depend on the domain, and $\tilde{F}_0$ is left Γ^{f}-invariant and μ_G left invariant,

$$\int_{\Gamma_k\backslash\mathrm{Per}} F_0\,(\omega^{\mathrm{H}}_{\mathrm{Per}})^e = c_2\, i_k \int_D \tilde{F}_0\,d\mu_G. \tag{5}$$

(d) The bound. Here G is the group $G_\infty = \prod_v \mathrm{U}(V_v,h_v)$ of Lemma D.4 for (V_L,h_L,L) (an E-linear map preserves ψ if and only if it preserves h_L, the trace form being non-degenerate, (SU1)). The real decomposition $L_\mathbb{R} = \bigoplus_v V_v$ is ψ-orthogonal and J_0-stable (J_0 is E-linear and the idempotents of $E^+ \otimes \mathbb{R}$ are self-adjoint for ψ), and on V_v the positive quadratic form $y \mapsto \psi(J_0y,y)$ is invariant under the unit complex scalars $c \in E \otimes_{E^+,v} \mathbb{R} = \mathbb{C}$ ($\psi(J_0cy,cy) = \psi(J_0y,\bar{c}c\,y)$), so it is $h_v^+(y,y)$ for a positive definite hermitian form h_v^+ on V_v. For $g \in G$ put $J_g = gJ_0g^{-1}$ and $H_g = H_{J_g}$; then $H_g(x,x) = \psi(J_0g^{-1}x, g^{-1}x) = \|x\|_g^2$. We apply Lemma D.5 to $(\Lambda,W,h) = (L,V_L,h_L)$, $N = n$, $\Psi = \{\bar{\rho} : \rho \in \Phi'\}$, $m = q$ ($3q+1 \le n$), $\Gamma = \Gamma^{\mathrm{f}}$, $\mu = \mu_G$: (Fm1) holds as $\mathcal{O}_E$ commutes with J_g, $\mathrm{Im}\,H_g = \psi$ is integral on L, $H_g(ax,y) = H_g(x,\bar{a}y)$, and for $\rho \in \Phi'$ the subspace of $(L_\mathbb{R},J_g)$ on which a acts by $\bar{\rho}(a)$ is $\mathrm{Lie}_{(\rho,-)}(J_g)$, of dimension q ($J_g \in \mathrm{Per}$); (Fm2) holds with $\kappa = 1$; (Fm3): if $\psi(ax,y) = \mathrm{Tr}_{E/\mathbb{Q}}(r\,a\,h_L(x,y)) = 0$ for all $a \in \mathcal{O}_E$ then $h_L(x,y) = 0$. By Lemma D.8 for E there are $\mathbb{Q}$-independent $a_1,\dots,a_{2f_0} \in \mathcal{O}_E$ with $|\sigma(a_i)| \le \mathrm{vr} := \sqrt{2f_0}\,\mathrm{rd}_E$; $\mathrm{vr} \ge 1$ as $\mathrm{rd}_E \ge 1$. With $r' = \mathrm{vr}^{-1/2}$ and $\lambda_1(g) = \min_{0\ne x\in L} H_g(x,x)^{1/2}$, Lemma D.5 gives $0 < \mu_G(D) < \infty$, λ_1 Borel and positive, and $\int_D \log^+(r'/\lambda_1)\,d\mu_G \le 3\mu_G(D)$. Since $\log^+(1/\lambda_1) \le \log^+(r'/\lambda_1) + \frac{1}{2}\log\mathrm{vr}$ and $\log\mathrm{vr} \le \log(2f_0\mathrm{rd}_E)$, (1) at $u_k(J_g)$ (where $\Lambda' = L$, $H' = H_g$, $\lambda_1' = \lambda_1(g)$) gives

$$U'(u_k(J_g)) \le f_0q(2\log^+(r'/\lambda_1(g)) + \log(2f_0\mathrm{rd}_E) + \log(2f_0q\,\mathrm{rd}_E)),$$

using that the right side of (1) is ≥ 0 ($2f_0q\,\mathrm{rd}_E \ge 1$). The function $F_0 = U' \circ u_k$ is Borel on Per (a supremum over the countably many submodules $I \subseteq L$ of the continuous functions $J \mapsto -\log \mathrm{N}'(I)$, then a maximum with 0), and Γ^{f}-invariant ($\gamma \in \Gamma^{\mathrm{f}}$ is an $\mathcal{O}_E$-isometry $(L,H_J) \to (L,H_{\gamma J\gamma^{-1}})$); likewise $F_0 = 1$. Integrating over D and using (5) for both,

$$\int_{\Gamma_k\backslash\mathrm{Per}} U' \circ u_k\,(\omega^{\mathrm{H}}_{\mathrm{Per}})^e \le c_2 i_k\, C_0\,\mu_G(D) = C_0 \int_{\Gamma_k\backslash\mathrm{Per}} (\omega^{\mathrm{H}}_{\mathrm{Per}})^e,$$

and the right side is finite and positive.

Step 5 (conclusion). By (b), u_k carries $(\omega^{\mathrm{H}}_{\mathrm{Per}})^e$ on $\Gamma_k\backslash\mathrm{Per}$ to $\omega'^{\,e}$ on $Z_\kappa(\mathbb{C})$, so Step 4 gives $\int_{Z_\kappa(\mathbb{C})} U'\omega'^{\,e} \le C_0 \int_{Z_\kappa(\mathbb{C})} \omega'^{\,e}$, with $0 < \int_{Z_\kappa(\mathbb{C})} \omega'^{\,e} < \infty$, for every κ. Summing over κ and applying (4) with $\varphi = U$ and $\varphi = 1$: $\int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e = d \int_{Z(\mathbb{C})} \omega'^{\,e} \in (0,\infty)$, U is integrable, and $\int_{X^{\mathrm{b},\circ}} U(\omega^{\mathrm{H}})^e = d \int_{Z(\mathbb{C})} U'\omega'^{\,e} \le C_0 \int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e$. □

Lemma D.3. *Let E be a CM field of degree $2f$ with complex conjugation c, $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/(2f)}$, and Ψ a CM type of E (a set of f field embeddings $E \to \mathbb{C}$ containing exactly one of $\sigma, \bar\sigma = \overline{\sigma}$ for every embedding σ). Let V be a finite-dimensional complex vector space with a positive definite Hermitian form H (linear in the first variable), $\Lambda \subset V$ a lattice (a discrete subgroup spanning V over $\mathbb{R}$), and $\iota\colon \mathcal{O}_E \to \mathrm{End}_{\mathbb{C}}(V)$ a ring homomorphism with $\iota(a)\Lambda \subseteq \Lambda$ and $H(\iota(a)x, y) = H(x, \iota(c(a))y)$ for $a \in \mathcal{O}_E$, $x, y \in V$. For an embedding $\sigma\colon E \to \mathbb{C}$ let $V_\sigma = \{x : \iota(a)x = \sigma(a)x\ \forall a\}$ and $x \mapsto x_\sigma$ the projection of $V = \bigoplus_\sigma V_\sigma$ onto V_σ; suppose $\dim V_\tau = m \ge 1$ for every $\tau \in \Psi$. Put $\lambda_1 = \min\{H(\lambda,\lambda)^{1/2} : 0 \ne \lambda \in \Lambda\}$. Let $I \subseteq \Lambda$ be a non-zero $\mathcal{O}_E$-submodule with $\mathrm{Im}\, H(v,w) = 0$ for all $v, w \in I$, and let $v_1, \dots, v_\rho \in I$ be $\mathcal{O}_E$-linearly independent and span an $\mathcal{O}_E$-submodule of finite index k_v in I. Put $G_\tau = \big(H((v_a)_\tau, (v_b)_\tau)\big)_{a,b\le\rho}$ and*

$$\mathrm{N}(I) = \frac{1}{k_v} \prod_{\tau\in\Psi} \det G_\tau.$$

Then $\rho \le m$, each G_τ is positive definite, the $\mathbb{Z}$-rank of I is $2f\rho$, and for every $\mathbb{Z}$-basis $b_1, \dots, b_{2f\rho}$ of I

$$\det\big(H(b_i, b_k)\big)_{i,k} = \big(\mathrm{N}(I)\,\mathrm{rd}_E^{f\rho}\big)^2;$$

moreover

$$-\log \mathrm{N}(I) \le f\,m\,\Big(2\max\big(0, \log\tfrac{1}{\lambda_1}\big) + \log(2fm\,\mathrm{rd}_E)\Big).$$

Proof. Eigen-decomposition. Since $\mathcal{O}_E \otimes_{\mathbb{Z}} \mathbb{C} \cong \prod_{\sigma\colon E\to\mathbb{C}} \mathbb{C}$, $V = \bigoplus_\sigma V_\sigma$. If $x \in V_\sigma$, $y \in V_{\sigma'}$, then $\sigma(a)H(x,y) = H(\iota(a)x, y) = H(x, \iota(c(a))y) = \overline{\sigma'(c(a))}H(x,y) = \sigma'(a)H(x,y)$, since $\overline{\sigma'(c(a))} = \sigma'(a)$ for a CM field; so the V_σ are pairwise orthogonal and $H(x,y) = \sum_\sigma H(x_\sigma, y_\sigma)$.

Conjugate components of isotropic vectors. For $v, w \in I$ put $h_\sigma = H(v_\sigma, w_\sigma)$. For $a \in \mathcal{O}_E$, $\iota(a)v \in I$, so $\sum_\sigma \sigma(a) h_\sigma = H(\iota(a)v, w)$ is real; hence $\sum_\sigma \sigma(a)h_\sigma = \sum_\sigma \overline{\sigma(a)}\,\overline{h_\sigma} = \sum_\sigma \sigma(a)\overline{h_{\bar\sigma}}$ for all $a \in \mathcal{O}_E$. By Dedekind's independence of the distinct characters $\sigma|_{\mathcal{O}_E}$, $h_{\bar\sigma} = \overline{h_\sigma}$. In particular $G_{\bar\tau} = \overline{G_\tau}$ for $\tau \in \Psi$, with G_σ defined as G_τ for every σ.

The quadratic form on the span. The ring $E_{\mathbb{R}} = E \otimes_{\mathbb{Q}} \mathbb{R}$ acts on $V = \Lambda \otimes \mathbb{R}$, every σ extends to $E_{\mathbb{R}} \to \mathbb{C}$, and $E_{\mathbb{R}} \to \mathbb{C}^\Psi$, $e \mapsto (\tau(e))_\tau$, is an $\mathbb{R}$-isomorphism. Let $\Phi\colon E_{\mathbb{R}}^\rho \to V$, $(e_a) \mapsto \sum_a e_a v_a$. It is injective: $E^\rho \to \Lambda \otimes \mathbb{Q}$ is injective because the v_a are $\mathcal{O}_E$-independent, and tensoring with $\mathbb{R}$ over $\mathbb{Q}$ preserves injectivity. Its image is $I_{\mathbb{R}}$ (the $\mathcal{O}_E$-span of the v_a has finite index in I), on which H is real because $\mathrm{Im}\, H$ vanishes on $I \times I$ and is $\mathbb{R}$-bilinear. Since $(\Phi e)_\sigma = \sum_a \sigma(e_a)(v_a)_\sigma$, writing $u_\tau = (\tau(e_a))_a \in \mathbb{C}^\rho$ and $Q_\tau(u) = \sum_{a,b} u_a \overline{u_b}\,(G_\tau)_{ab}$ (real, as G_τ is Hermitian), the previous step gives

$$q(e) = H(\Phi e, \Phi e) = \sum_{\tau\in\Psi} \big(Q_\tau(u_\tau) + \overline{Q_\tau(u_\tau)}\big) = 2\sum_{\tau\in\Psi} Q_\tau(u_\tau).$$

As Φ is injective and H positive definite, q is positive definite; the u_τ are independent coordinates, so every Q_τ, i.e. every G_τ, is positive definite. Hence $\det G_\tau > 0$, the vectors $(v_1)_\tau, \dots, (v_\rho)_\tau$ are linearly independent in V_τ, and $\rho \le m$; also $\mathrm{N}(I) > 0$.

The Gram determinant. Use coordinates $(\mathrm{Re}\, u_\tau, \mathrm{Im}\, u_\tau)_\tau$ on $E_{\mathbb{R}}^\rho \cong \mathbb{R}^{2f\rho}$. The real symmetric matrix of the quadratic form $2Q_\tau$ on $\mathbb{C}^\rho = \mathbb{R}^{2\rho}$ has determinant $2^{2\rho}\det(G_\tau)^2$ (the realification

of a Hermitian matrix G has determinant $|\det G|^2$). The image of $\mathcal{O}_E$ in $\mathbb{C}^\Psi = \mathbb{R}^{2f}$ is a lattice of covolume $2^{-f}|\mathrm{disc}(E)|^{1/2}$ for Lebesgue measure (the standard computation of the covolume of $\mathcal{O}_E$ in its Minkowski space, E being totally imaginary), so $\mathcal{O}_E^\rho$ has covolume $2^{-f\rho}|\mathrm{disc}(E)|^{\rho/2}$. For a lattice M with $\mathbb{Z}$-basis matrix B and a form with matrix A, the Gram determinant is $\det(B^{\mathsf{T}}AB) = \mathrm{covol}(M)^2 \det A$; hence the Gram determinant of a $\mathbb{Z}$-basis of $\Phi(\mathcal{O}_E^\rho) = \sum_a \mathcal{O}_E v_a$ for H is

$$2^{-2f\rho}|\mathrm{disc}(E)|^\rho \prod_{\tau\in\Psi} 2^{2\rho}\det(G_\tau)^2 = \Big(\mathrm{rd}_E^{f\rho}\prod_{\tau\in\Psi}\det G_\tau\Big)^2,$$

using $|\mathrm{disc}(E)| = \mathrm{rd}_E^{2f}$. Passing to the overlattice I of index k_v divides the Gram determinant by k_v^2, which gives the identity; the $\mathbb{Z}$-rank of I is that of $\mathcal{O}_E^\rho$, namely $2f\rho$.

The lower bound. Put $n = 2f\rho$. The covolume of I in the Euclidean space $(I_\mathbb{R}, H)$ is $\mathrm{N}(I)\,\mathrm{rd}_E^{f\rho}$, and every non-zero vector of $I \subseteq \Lambda$ has length at least $\lambda_1 > 0$ (Λ is discrete). A ball of radius s contains a cube of side $2s/\sqrt{n}$; by Minkowski's convex body theorem, if $(2s/\sqrt{n})^n > 2^n\,\mathrm{N}(I)\,\mathrm{rd}_E^{f\rho}$ the ball contains a non-zero point of I, so $\lambda_1 \le s$. Hence $\lambda_1 \le \sqrt{n}\,(\mathrm{N}(I)\mathrm{rd}_E^{f\rho})^{1/n}$, i.e.

$$-\log \mathrm{N}(I) \le n\log\frac{\sqrt{n}}{\lambda_1} + f\rho\log \mathrm{rd}_E = f\rho\Big(2\log\frac{1}{\lambda_1} + \log(2f\rho) + \log \mathrm{rd}_E\Big).$$

Finally $\rho \le m$, $2\log\frac{1}{\lambda_1} \le 2\max(0, \log\frac{1}{\lambda_1})$ and $\log(2f\rho\,\mathrm{rd}_E) \le \log(2fm\,\mathrm{rd}_E)$ with $\log(2f\rho\,\mathrm{rd}_E) \ge 0$ ($\mathrm{rd}_E \ge 1$), which gives the bound. □

Lemma D.4. *The notation introduced here is local to this result and to the results that apply it. Let E be a CM field with complex conjugation $a \mapsto \bar a$ and maximal totally real subfield E^+, and $f = [E^+ : \mathbb{Q}]$. Let V be an E-vector space of dimension $n \ge 1$ with a nondegenerate hermitian form h (E-linear in the first variable), $\Lambda \subset V$ an $\mathcal{O}_E$-lattice (a finitely generated $\mathcal{O}_E$-submodule spanning V), and $\Gamma = \{\gamma \in \mathrm{U}(V,h)(E^+) : \gamma\Lambda = \Lambda\}$. For every real place v of E^+ fix a complex place w of E above v, let $V_v = V \otimes_{E,w} \mathbb{C}$ carry the hermitian form h_v induced by h, and fix a positive definite hermitian form h_v^+ on V_v. Put $G_\infty = \prod_v \mathrm{U}(V_v, h_v)$, in which Γ is embedded diagonally, let μ be a Haar measure on G_∞, and for $g = (g_v)_v \in G_\infty$ and $y \in V$ put*

$$\|y\|_g = \Big(\sum_v h_v^+(g_v^{-1}y,\, g_v^{-1}y)\Big)^{1/2}.$$

Let $S \subseteq \Lambda$ be a set of nonzero vectors with $h(y,y) = 0$ for all $y \in S$, such that $\gamma S = S$ for all $\gamma \in \Gamma$ and the index $[\,Ey \cap \Lambda : \mathcal{O}_E y\,]$ is bounded on S. For $t > 0$ and $g \in G_\infty$ put $c_S(t,g) = \#\{y \in S :\ \|y\|_g < t\} \in [0,\infty]$.

Then Γ is a discrete subgroup of G_∞ and has a Borel fundamental domain D (a Borel set whose translates γD, $\gamma \in \Gamma$, are pairwise disjoint and cover G_∞). For every Borel fundamental domain D of Γ the mass

$$m(t) = \int_D c_S(t,g)\,d\mu(g)$$

does not depend on D, is finite for every $t > 0$, and satisfies $m(\theta t) = \theta^{\,2f(n-1)}\,m(t)$ for all $\theta, t > 0$.

Proof. **Step 0: the group.** Let $H = \mathrm{Res}_{E^+/\mathbb{Q}}\mathrm{U}(V,h)$, a linear algebraic group over $\mathbb{Q}$ acting faithfully on the $\mathbb{Q}$-vector space V; $H(\mathbb{Q}) = \mathrm{U}(V,h)(E^+)$ and $H(\mathbb{R}) = G_\infty$, because $E \otimes_{E^+,v} \mathbb{R} \cong \mathbb{C}$ through w. The group Γ is the stabiliser in $H(\mathbb{Q})$ of the lattice Λ of V, so it is arithmetic and discrete in G_∞ by Theorem B.165(1); it is countable and acts freely on G_∞ by left multiplication. Cover G_∞ by countably many open sets $U_1, U_2, \ldots$ with $U_i \cap \gamma U_i = \emptyset$ for $\gamma \ne 1$ (possible by discreteness); then $D_0 = \bigcup_i (U_i \setminus \bigcup_{j<i} \Gamma U_j)$ is a Borel fundamental domain.

For a Borel function $\varphi \geq 0$ with $\varphi(\gamma g) = \varphi(g)$ ($\gamma \in \Gamma$) and two Borel fundamental domains D, D', left invariance of μ gives $\int_D \varphi = \sum_\gamma \int_{D\cap\gamma D'} \varphi = \sum_\gamma \int_{\gamma^{-1}D\cap D'} \varphi = \int_{D'} \varphi$. The function $c_S(t,\cdot) = \sum_{y\in S} \mathbf{1}\{g : \|y\|_g < t\}$ is a countable sum of indicators of open sets, hence Borel, and it is left Γ-invariant, since $\|y\|_{\gamma g} = \|\gamma^{-1}y\|_g$ and γ^{-1} permutes S. So $m(t)$ does not depend on D.

If $S = \emptyset$ then $m = 0$. Otherwise h is isotropic, so $n \geq 2$; let C bound the index on S.

Step 1: S is a finite union of Γ-orbits. (a) $\mathrm{U}(V,h)(E^+)$ acts transitively on the isotropic lines of V (Witt's theorem for hermitian forms), so the set of isotropic lines is $H(\mathbb{Q})/P(\mathbb{Q})$ with $P = \mathrm{Res}_{E^+/\mathbb{Q}}P'$, P' the stabiliser of one isotropic line, a parabolic E^+-subgroup of the connected reductive group $\mathrm{U}(V,h)$. By Theorem B.165(3) there are isotropic lines $\ell_1,\dots,\ell_k$ such that every isotropic line is $\gamma\ell_i$ for some $\gamma \in \Gamma$ and some i. (b) Fix $\ell = \ell_i$ and put $M = \ell \cap \Lambda$, a finitely generated torsion-free $\mathcal{O}_E$-module spanning ℓ. Choose an isotropic line ℓ' with $h(\ell,\ell') \neq 0$ (it exists as h is nondegenerate) and put $W_0 = (\ell+\ell')^\perp$, so $V = \ell \oplus \ell' \oplus W_0$. For $c \in E^\times$ let t_c act by c on ℓ, by $\bar{c}^{-1}$ on ℓ' and trivially on W_0; then $h(t_c y, t_c y') = c\,\overline{\bar{c}^{-1}}\,h(y,y') = h(y,y')$ for $y \in \ell$, $y' \in \ell'$, and the other pairings are unchanged, so $t_c \in \mathrm{U}(V,h)(E^+)$. The lattice $\Lambda' = (\ell\cap\Lambda)\oplus(\ell'\cap\Lambda)\oplus(W_0\cap\Lambda)$ has finite index in Λ; choose an integer $N \geq 1$ with $N\Lambda \subseteq \Lambda'$, and let $U' = \{c \in \mathcal{O}_E^\times : c \equiv 1 \bmod N^2\mathcal{O}_E\}$, a subgroup of finite index of $\mathcal{O}_E^\times$. For $c \in U'$ also $\bar{c}^{-1} \equiv 1 \bmod N^2\mathcal{O}_E$, so $(t_c - 1)\Lambda' \subseteq N^2\Lambda'$ and, for $\lambda \in \Lambda$, $(t_c-1)\lambda = N^{-1}(t_c-1)(N\lambda) \in N\Lambda' \subseteq \Lambda$; thus $t_c\Lambda \subseteq \Lambda$, likewise $t_{c^{-1}}\Lambda \subseteq \Lambda$, and $t_c \in \Gamma$. For $y \in S \cap \ell$ the submodule $\mathcal{O}_E y \subseteq M$ has index $d \leq C$, so it contains $dM \supseteq C!\,M$; as $M/C!\,M$ is finite, only finitely many submodules occur. If $\mathcal{O}_E y = \mathcal{O}_E y'$, then $y' = uy$ with $u \in \mathcal{O}_E^\times$ ($y' = cy$, $y = c'y'$ with $c, c' \in \mathcal{O}_E$, so $cc' = 1$). Hence $S \cap \ell$ lies in finitely many sets $\mathcal{O}_E^\times y_s$, each a finite union of sets $U'uy_s = \{t_c(uy_s) : c \in U'\}$, each contained in one Γ-orbit. (c) Every $y \in S$ spans an isotropic line, so $\gamma y \in \ell_i$ for some $\gamma \in \Gamma$ and i, and $\gamma y \in S$. By (b), $S = \Gamma y_1 \sqcup \cdots \sqcup \Gamma y_r$ for finitely many $y_j \in S$.

Step 2: unfolding. Fix $y = y_j$, let Γ_y and Q_y be the stabilisers of y in Γ and in G_∞, and for $z = (z_v) \in \prod_v V_v$ put $\|z\|_+ = (\sum_v h_v^+(z_v,z_v))^{1/2}$, so $\|y\|_g = \|g^{-1}y\|_+$. The function $\varphi(g) = \mathbf{1}\{\|g^{-1}y\|_+ < t\}$ is left Q_y-invariant. Let R be a set of representatives of $\Gamma_y\backslash\Gamma$; then $D_y = \bigcup_{\rho\in R}\rho D$ is a Borel fundamental domain of Γ_y, and

$$\int_D \sum_{y'\in\Gamma y} \mathbf{1}\{\|y'\|_g < t\}\,d\mu(g) = \sum_{\rho\in R}\int_D \varphi(\rho g)\,d\mu(g) = \sum_{\rho\in R}\int_{\rho D}\varphi\,d\mu = \int_{D_y}\varphi\,d\mu,$$

using $\|\rho^{-1}y\|_g = \|y\|_{\rho g}$, that $\rho \mapsto \rho^{-1}y$ is a bijection from R onto Γy, and left invariance of μ.

Step 3: Γ_y has finite covolume in Q_y. Let $Q_y' \subseteq \mathrm{U}(V,h)$ be the stabiliser of y, an algebraic group over E^+; Q_y is the group of real points of $\mathrm{Res}_{E^+/\mathbb{Q}}Q_y'$, and Γ_y is the stabiliser of Λ in its rational points, hence arithmetic (Theorem B.165(1)). Take $\ell = Ey$ and ℓ', W_0 as in Step 1(b). An element of Q_y' preserves $y^\perp = \ell \oplus W_0$, fixes y, acts trivially on $V/y^\perp$ (since $h(gz,y) = h(gz,gy) = h(z,y)$), and induces a unitary automorphism of $y^\perp/\ell \cong W_0$; this gives a surjection $Q_y' \to \mathrm{U}(W_0)$, split by letting $\mathrm{U}(W_0)$ act trivially on $\ell\oplus\ell'$, whose kernel acts trivially on the graded pieces of $\ell \subset y^\perp \subset V$ and is therefore unipotent, hence connected. So Q_y' is connected. A character of Q_y' defined over E^+ is trivial on the unipotent kernel, and on $\mathrm{U}(W_0)$ it factors through $\det\colon \mathrm{U}(W_0) \to \mathrm{U}(1)_{E/E^+}$ (the derived group is semisimple); the torus $\mathrm{U}(1)_{E/E^+}$ has no nontrivial E^+-character, since complex conjugation acts on its character group $\mathbb{Z}$ by -1. (If $W_0 = 0$ the quotient is trivial.) By Theorem B.165(2), applied to the restriction of scalars $\mathrm{Res}_{E^+/\mathbb{Q}}Q_y'$ as in its proof, Q_y is unimodular and every Borel fundamental domain of Γ_y in Q_y has finite measure vol_y for a fixed Haar measure μ_y of Q_y. Likewise G_∞ is unimodular ($\mathrm{U}(V,h)$ is connected and its characters factor through det in the same way).

Step 4: the orbit and its invariant measure. For each v let $O_v = \{z \in V_v : z \neq 0,\ h_v(z,z) = 0\}$ and $O = \prod_v O_v$. By Witt's theorem $\mathrm{U}(V_v,h_v)$ acts transitively on O_v, so $g \mapsto g^{-1}y$ induces a continuous bijection $Q_y\backslash G_\infty \to O$, which is a homeomorphism (the orbit

map of a transitive continuous action of a second countable locally compact group is open), and right translation by k corresponds to $z \mapsto k^{-1}z$. As G_∞ and Q_y are unimodular, $Q_y\backslash G_\infty$ carries a G_∞-invariant Radon measure $\bar\mu_y$, unique up to a positive factor, normalised so that $\int_{G_\infty} F\,d\mu = \int_{Q_y\backslash G_\infty}\int_{Q_y} F(qg)\,d\mu_y(q)\,d\bar\mu_y(g)$ for Borel $F \ge 0$; for left Q_y-invariant Borel $\varphi \ge 0$, taking $F = \mathbf{1}_{D_y}\varphi$ gives $\int_{D_y}\varphi\,d\mu = \int_{Q_y\backslash G_\infty}\varphi(g)\,\mu_y(\{q \in Q_y : qg \in D_y\})\,d\bar\mu_y(g)$, and for each g the set $\{q \in Q_y : qg \in D_y\} = Q_y \cap D_y g^{-1}$ is a Borel fundamental domain of $\Gamma_y \subseteq Q_y$ in Q_y (as D_y is one in G_∞), of measure vol_y by Step 0 applied in Q_y; hence $\int_{D_y}\varphi\,d\mu = \mathrm{vol}_y \int_{Q_y\backslash G_\infty}\varphi\,d\bar\mu_y$.

Now we build an invariant measure on O. Let $q_v(z) = h_v(z,z)$, a real quadratic form on $V_v \cong \mathbb{R}^{2n}$, and λ_v the Lebesgue measure of the euclidean structure $\mathrm{Re}\,h_v^+$. For $z \ne 0$, $dq_v(z)(u) = 2\,\mathrm{Re}\,h_v(z,u) \ne 0$ for some u, as h_v is nondegenerate; so O_v is a closed smooth hypersurface of $V_v \setminus \{0\}$. Let ν_v be the measure on O_v of the Leray form: the restriction to O_v of any $(2n-1)$-form ω, defined near a point of O_v, with $dq_v \wedge \omega = d\lambda_v$; the restriction does not depend on the choice, since two choices differ by $dq_v \wedge \beta$. Then:

- $g \in \mathrm{U}(V_v, h_v)$ preserves q_v and λ_v (g is $\mathbb{C}$-linear with $|\det g| = 1$, from $g^* h_v g = h_v$), so $g^*\omega$ is again such a form and g preserves ν_v;
- the dilation $\delta_\theta(z) = \theta z$ ($\theta > 0$) maps O_v onto itself with $\delta_\theta^* d\lambda_v = \theta^{2n} d\lambda_v$ and $\delta_\theta^* q_v = \theta^2 q_v$, so $\theta^{-2n+2}\delta_\theta^*\omega$ is such a form and $\nu_v(\delta_\theta A) = \theta^{2n-2}\nu_v(A)$;
- with $|z|_v = h_v^+(z,z)^{1/2}$, the shell $\{z \in O_v : t/2 \le |z|_v < t\}$ has compact closure in O_v, hence finite measure $c_v(t)$, and the ball $\{z \in O_v : |z|_v < t\}$ is the disjoint union of its images under $\delta_{2^{-k}}$, $k \ge 0$, so its measure is $\sum_{k\ge 0} 2^{-k(2n-2)} c_v(t) < \infty$, as $n \ge 2$.

The product $\nu = \bigotimes_v \nu_v$ is a G_∞-invariant Radon measure on O; transported to $Q_y\backslash G_\infty$ it is G_∞-invariant, so there is $c_y > 0$ with $\int_{Q_y\backslash G_\infty}\Phi(g^{-1}y)\,d\bar\mu_y(g) = c_y\int_O \Phi\,d\nu$ for Borel $\Phi \ge 0$ on O.

Step 5: conclusion. Let $B_t = \{z \in O : \|z\|_+ < t\}$. By Steps 1–4,

$$m(t) = \sum_{j=1}^r \int_{D_{y_j}} \mathbf{1}\{\|g^{-1}y_j\|_+ < t\}\,d\mu(g) = \Big(\sum_{j=1}^r \mathrm{vol}_{y_j} c_{y_j}\Big)\nu(B_t).$$

Here $\nu(B_t) \le \prod_v \nu_v\{z \in O_v : |z|_v < t\} < \infty$, and $B_{\theta t} = \prod_v \delta_\theta$ applied to B_t, so $\nu(B_{\theta t}) = \theta^{f(2n-2)}\nu(B_t)$, there being f real places. Hence $m(t) < \infty$ and $m(\theta t) = \theta^{2f(n-1)} m(t)$. □

Lemma D.5. *The notation introduced here is local to this result and to the results that apply it. Let E be a CM field of degree $2f$ with complex conjugation $a \mapsto \bar a$ and maximal totally real subfield E^+, and Ψ a CM type of E. Let Λ be a finitely generated torsion-free $\mathcal{O}_E$-module, $W = \Lambda \otimes_{\mathcal{O}_E} E \supset \Lambda$, $N = \dim_E W$, and h a nondegenerate hermitian form on W (E-linear in the first variable). Let Γ, the places v of E^+ with $W_v = W \otimes_{E,w} \mathbb{C}$, positive definite hermitian forms h_v^+, the group G_∞, a Haar measure μ and the norms $\|\cdot\|_g$ ($g \in G_\infty$) be as in Lemma D.4 for $(V,h,\Lambda) = (W,h,\Lambda)$. Let $m \ge 1$ be an integer with $3m+1 \le N$, and suppose that for every $g \in G_\infty$ a complex structure J_g and a positive definite Hermitian form H_g on $\Lambda_\mathbb{R} = \Lambda \otimes_\mathbb{Z} \mathbb{R}$ are given such that:*

(Fm1) *$(\Lambda_\mathbb{R}, J_g)$ with $H = H_g$, the lattice Λ and the action ι of $\mathcal{O}_E$ on $\Lambda_\mathbb{R}$ by the module structure satisfies the hypotheses of Lemma D.6 with this m: each $\iota(a)$ is J_g-linear, $\mathrm{Im}\,H_g(\Lambda,\Lambda) \subseteq \mathbb{Z}$, $H_g(\iota(a)x,y) = H_g(x,\iota(\bar a)y)$, and $\dim V_\tau = m$ for $\tau \in \Psi$;*

(Fm2) *there is $\kappa > 0$, independent of g, with $H_g(x,x) = \kappa\,\|x\|_g^2$ for all $g \in G_\infty$ and $x \in \Lambda$;*

(Fm3) *for $g \in G_\infty$ and $x, y \in \Lambda$: if $\mathrm{Im}\,H_g(\iota(a)x,y) = 0$ for all $a \in \mathcal{O}_E$, then $h(x,y) = 0$.*

Let $\mathrm{vr} > 0$ *be such that there are* $a_1, \dots, a_{2f} \in \mathcal{O}_E$*, linearly independent over* $\mathbb{Q}$*, with* $|\sigma(a_i)| \le \mathrm{vr}$ *for all* i *and all field embeddings* $\sigma\colon E \to \mathbb{C}$*; put* $r = \mathrm{vr}^{-1/2}$ *and* $\lambda_1(g) = \min\{H_g(x,x)^{1/2} : 0 \ne x \in \Lambda\}$*. Then every Borel fundamental domain* D *of* Γ *in* G_∞ *satisfies* $0 < \mu(D) < \infty$*, the function* λ_1 *is Borel and positive, and*

$$\int_D \log^+(r/\lambda_1(g))\, d\mu(g) \;\le\; 3\,\mu(D).$$

Proof. **Step 0: the domain.** Let $H = \mathrm{Res}_{E^+/\mathbb{Q}}\mathrm{U}(W,h)$, so $H(\mathbb{R}) = G_\infty$ and Γ is the stabiliser in $H(\mathbb{Q})$ of the lattice Λ of the $\mathbb{Q}$-vector space W, an arithmetic subgroup (Theorem B.165(1)). The group $\mathrm{U}(W,h)$ is connected, and an E^+-character of it is trivial on the semisimple derived group and so factors through $\det\colon \mathrm{U}(W,h) \to \mathrm{U}(1)_{E/E^+}$, a torus without nontrivial E^+-characters (complex conjugation acts on its character group $\mathbb{Z}$ by -1). By Theorem B.165(2) and its notation map, $\mu(D) < \infty$. Since $G_\infty = \bigcup_{\gamma\in\Gamma} \gamma D$ is a countable union and $\mu(\gamma D) = \mu(D)$, $\mu(D) > 0$.

Step 1: the counting function. Put $C = \lfloor (\mathrm{vr}\sqrt{2f})^{2f} \rfloor$ and

$$S = \{y \in \Lambda :\; y \ne 0,\; h(y,y) = 0,\; [\,Ey \cap \Lambda : \mathcal{O}_E y\,] \le C\}.$$

An element $\gamma \in \Gamma$ preserves Λ and h and maps $Ey \cap \Lambda$ onto $E\gamma y \cap \Lambda$ and $\mathcal{O}_E y$ onto $\mathcal{O}_E \gamma y$, so $\gamma S = S$. For $t > 0$ and $g \in G_\infty$ put

$$n(t,g) = \#\{y \in S :\; H_g(y,y)^{1/2} < t\} = \#\{y \in S :\; \|y\|_g < t/\sqrt{\kappa}\}$$

by (Fm2). By Lemma D.4 (with $n = N$ and the set S), $n(t,\cdot)$ is Borel and integrable on D, and $M(t) = \int_D n(t,g)\, d\mu(g)$ satisfies $M(\theta t) = \theta^{2f(N-1)} M(t)$ for $\theta, t > 0$. By (Fm2), $\lambda_1(g) = \sqrt{\kappa}\, \inf_{0\ne x\in\Lambda} \|x\|_g$ is an infimum of countably many continuous functions of g, hence upper semicontinuous and Borel; it is positive and attained by Lemma D.6, which applies by (Fm1).

Step 2: the hypotheses of Lemma D.7. We apply it to $X = D$ with the probability measure $\mu|_D/\mu(D)$, $\alpha = \lambda_1$, $a = 2fm \ge 1$, the exponent $2f(N-1)$ in place of its κ (and $2f(N-1) \ge 2f \cdot 3m = 3a$ as $N - 1 \ge 3m$), r, and n; integrability and the scaling (3) are Step 1. Fix g and write $|x| = H_g(x,x)^{1/2}$.

(1) If $t \le \lambda_1(g)$, every $y \in S$ is a nonzero vector of Λ, so $|y| \ge \lambda_1(g) \ge t$ and $n(t,g) = 0$.

(2), upper bound. If $\lambda_1(g) < t \le r$, then $n(t,g) \le \#\{x \in \Lambda : x \ne 0,\; |x| < t\} \le (3t/\lambda_1(g))^{2fm}$ by Lemma D.6(2).

(2), lower bound. Let $\lambda_1(g) < t \le r$ and $x \in \Lambda$ with $|x| = \lambda_1(g)$. As $|x| < r$, Lemma D.6(1) with $v = w = x$ and $b = 1$ gives $\mathrm{Im}\, H_g(\iota(a)x, x) = 0$ for all a, so $h(x,x) = 0$ by (Fm3). Let $M = Ex \cap \Lambda$, a free $\mathbb{Z}$-module of rank $2f$ spanning Ex; it is saturated in Λ, so $M \otimes \mathbb{R} \subseteq \Lambda_\mathbb{R}$ is a euclidean space for $|\cdot|$, in which every nonzero element of M has length at least $|x|$. By Minkowski's first theorem, $|x| \le \sqrt{2f}\,\mathrm{covol}(M)^{1/(2f)}$. The vectors $a_i x = \iota(a_i)x$ are linearly independent over $\mathbb{Z}$ ($y \mapsto yx$ is injective on E) and lie in $\mathcal{O}_E x$, and, as a acts on W_v by the scalar $w(a)$ and g_v is $\mathbb{C}$-linear,

$$|a_i x|^2 = \kappa \sum_v |w(a_i)|^2\, h_v^+(g_v^{-1}x, g_v^{-1}x) \le \mathrm{vr}^2\, \kappa\, \|x\|_g^2 = \mathrm{vr}^2 |x|^2.$$

By Hadamard's inequality, $\mathrm{covol}(\mathcal{O}_E x) \le \mathrm{covol}(\bigoplus_i \mathbb{Z} a_i x) \le \prod_i |a_i x| \le (\mathrm{vr}|x|)^{2f}$. Hence

$$[M : \mathcal{O}_E x] = \frac{\mathrm{covol}(\mathcal{O}_E x)}{\mathrm{covol}(M)} \le \frac{(\mathrm{vr}|x|)^{2f}}{(|x|/\sqrt{2f})^{2f}} = (\mathrm{vr}\sqrt{2f})^{2f},$$

and, the index being an integer, it is at most C. So $x \in S$ with $|x| < t$, and $n(t,g) \ge 1$.

Step 3: conclusion. By Lemma D.7, $\log^+(r/\lambda_1)$ is integrable on D and

$$\mu(D)^{-1}\int_D \log^+(r/\lambda_1)\,d\mu \le 3.$$

□

Lemma D.6. *Let E be a CM field of degree $2f$ with complex conjugation $a \mapsto \bar{a}$, and Ψ a CM type of E. Let V be a finite-dimensional complex vector space with a positive definite Hermitian form H (linear in the first variable), $\Lambda \subset V$ a lattice with $\operatorname{Im} H(\Lambda,\Lambda) \subseteq \mathbb{Z}$, and $\iota\colon \mathcal{O}_E \to \operatorname{End}_{\mathbb{C}}(V)$ a ring homomorphism with $\iota(a)\Lambda \subseteq \Lambda$ and $H(\iota(a)x,y) = H(x,\iota(\bar{a})y)$ for $a \in \mathcal{O}_E$, $x,y \in V$. Suppose $\dim V_\tau = m \ge 1$ for every $\tau \in \Psi$ (notation of Lemma D.3). Write $\|v\| = H(v,v)^{1/2}$ and $\lambda_1 = \min\{\|v\| : 0 \ne v \in \Lambda\}$. Let $\mathrm{vr} > 0$ be such that there are $a_1,\dots,a_{2f} \in \mathcal{O}_E$, linearly independent over $\mathbb{Q}$, with $|\sigma(a_i)| \le \mathrm{vr}$ for all i and all field embeddings $\sigma\colon E \to \mathbb{C}$, and put $r = \mathrm{vr}^{-1/2}$. Then $\lambda_1 > 0$ is attained, and:*

1. *for $v,w \in \Lambda$ with $\|v\| < r$, $\|w\| < r$ and all $a,b \in \mathcal{O}_E$, $\operatorname{Im} H(\iota(a)v,\iota(b)w) = 0$;*
2. *for $\lambda_1 < t \le r$ the set $\{v \in \Lambda : v \ne 0,\ \|v\| < t\}$ is finite and non-empty, and*

$$\#\{v \in \Lambda :\ v \ne 0,\ \|v\| < t\} \ \le\ \Big(\frac{3t}{\lambda_1}\Big)^{2fm}.$$

Proof. **Step 0: λ_1.** Λ is discrete, so the ball $\{\|v\| \le R\}$ contains finitely many points of Λ for every R; hence the minimum over the non-zero points is attained and positive.

Step 1: the action on norms. For embeddings $\sigma \ne \sigma'$ and $x \in V_\sigma$, $y \in V_{\sigma'}$, $a \in \mathcal{O}_E$: $\sigma(a)H(x,y) = H(\iota(a)x,y) = H(x,\iota(\bar{a})y) = \overline{\sigma'(\bar{a})}H(x,y) = \sigma'(a)H(x,y)$, since $\sigma'(\bar{a}) = \overline{\sigma'(a)}$ for a CM field. Choosing a with $\sigma(a) \ne \sigma'(a)$ gives $H(x,y) = 0$: the decomposition $V = \bigoplus_\sigma V_\sigma$ is H-orthogonal. Hence for $a \in \mathcal{O}_E$ and $v \in V$, $\|\iota(a)v\|^2 = \sum_\sigma |\sigma(a)|^2\|v_\sigma\|^2 \le \max_\sigma |\sigma(a)|^2\,\|v\|^2$.

Step 2: (1). Let $\|v\|,\|w\| < r$. By Cauchy–Schwarz and Step 1, $|\operatorname{Im} H(\iota(a_i)v,w)| \le \|\iota(a_i)v\|\,\|w\| \le \mathrm{vr}\,\|v\|\,\|w\| < \mathrm{vr}\,r^2 = 1$, and the value is an integer, so it is 0. Let $c \in \mathcal{O}_E$. Since the a_i form a $\mathbb{Q}$-basis of E, there are an integer $N \ge 1$ and integers n_i with $Nc = \sum_i n_i a_i$; as ι is additive and $\operatorname{Im} H$ is biadditive, $N\operatorname{Im} H(\iota(c)v,w) = \sum_i n_i \operatorname{Im} H(\iota(a_i)v,w) = 0$. For $a,b \in \mathcal{O}_E$, $\operatorname{Im} H(\iota(a)v,\iota(b)w) = \operatorname{Im} H(\iota(\bar{b}a)v,w) = 0$ by the case $c = \bar{b}a$.

Step 3: the span of the short vectors. Let $\lambda_1 < t \le r$ and $S_t = \{v \in \Lambda : v \ne 0,\ \|v\| < t\}$; it is finite by Step 0 and non-empty since it contains a vector of norm λ_1. Let I be the $\mathcal{O}_E$-submodule of Λ generated by S_t: a non-zero finitely generated torsion-free $\mathcal{O}_E$-module. By (1) and biadditivity, $\operatorname{Im} H$ vanishes on $I \times I$. A maximal $\mathcal{O}_E$-linearly independent family $v_1,\dots,v_\rho$ in I spans a submodule of finite index (for every $x \in I$ some non-zero multiple cx, $c \in \mathcal{O}_E$, lies in it, and I is finitely generated, so a non-zero integer M with MI inside it exists, and I/MI is finite). By Lemma D.3, $\rho \le m$ and I is a free $\mathbb{Z}$-module of rank $k = 2f\rho \le 2fm$.

Step 4: packing. Let W be the real span of I, of real dimension k (I is discrete in V, so a $\mathbb{Z}$-basis of I is $\mathbb{R}$-linearly independent), with the Euclidean norm $\|\cdot\|$ and its Lebesgue measure. Distinct points $u \ne u'$ of I satisfy $\|u-u'\| \ge \lambda_1$, so the open balls of radius $\lambda_1/2$ in W around the points of $S_t \cup \{0\}$ are disjoint, and they lie in the ball of radius $t + \lambda_1/2$ around 0. Comparing volumes,

$$\#S_t + 1 \le \Big(\frac{t+\lambda_1/2}{\lambda_1/2}\Big)^k = \Big(1+\frac{2t}{\lambda_1}\Big)^k \le \Big(\frac{3t}{\lambda_1}\Big)^k \le \Big(\frac{3t}{\lambda_1}\Big)^{2fm},$$

using $1 < t/\lambda_1$ for the middle inequality and $3t/\lambda_1 > 1$, $k \le 2fm$ for the last. This proves (2). □

Lemma D.7. *Let (X,μ) be a probability space, $\alpha\colon X\to(0,\infty)$ measurable, $a\ge 1$ an integer, $\kappa\ge 3a$ and $r>0$ real numbers, and let $n\colon(0,\infty)\times X\to[0,\infty)$ be a function such that $n(t,\cdot)$ is measurable and integrable for every $t>0$, and such that for all $t>0$ and $z\in X$:*

1. *$n(t,z)=0$ if $t\le\alpha(z)$;*
2. *$1\le n(t,z)\le\bigl(3t/\alpha(z)\bigr)^a$ if $\alpha(z)<t\le r$;*
3. *$M(t)=\int_X n(t,z)\,d\mu(z)$ satisfies $M(\theta t)=\theta^\kappa M(t)$ for all $\theta>0$.*

Then $M(r)\le 2\cdot 36^a$; for every $x\ge 0$

$$\mu\{z:\ \alpha(z)<e^{-x}r\}\le\min\bigl(1,\ 2\cdot 36^a e^{-\kappa x}\bigr);$$

and $\log^+(r/\alpha)$ is integrable with

$$\int_X\log^+\bigl(r/\alpha(z)\bigr)\,d\mu(z)\le 3.$$

Proof. For $t>0$ put $A(t)=\{z\in X:\ \alpha(z)<t\}$, a measurable set.

Step 1: mass of $A(t)$. Let $0<t\le r$. By (2), $n(t,z)\ge 1$ for $z\in A(t)$, and $n\ge 0$, so $\mu(A(t))\le\int_X n(t,z)\,d\mu(z)=M(t)$. By (3) with $\theta=t/r$, $M(t)=(t/r)^\kappa M(r)$. Hence

$$\mu(A(t))\le\min\bigl(1,(t/r)^\kappa M(r)\bigr)\qquad(0<t\le r).$$

Step 2: the mean at r. By (1), $n(r,z)=0$ for $z\notin A(r)$, and by (2), $n(r,z)\le(3r/\alpha(z))^a$ for $z\in A(r)$. Since $\alpha>0$, $A(r)$ is the disjoint union of the measurable shells $S_k=\{z:\ 2^{-k-1}r\le\alpha(z)<2^{-k}r\}$, $k\ge 0$. On S_k we have $(3r/\alpha)^a\le(3\cdot 2^{k+1})^a=6^a2^{ka}$, and $S_k\subseteq A(2^{-k}r)$, so by Step 1 $\mu(S_k)\le\min(1,2^{-\kappa k}M(r))$. By monotone convergence,

$$M(r)\le\sum_{k\ge 0}6^a2^{ka}\mu(S_k)\le 6^a(1+2^a)+6^aM(r)\sum_{k\ge 2}2^{(a-\kappa)k}.$$

So $M(r)\le 2\cdot 12^a+\frac12 M(r)$. As $M(r)<\infty$ ($n(r,\cdot)$ is integrable), $M(r)\le 4\cdot 12^a\le 2\cdot 36^a$, the last inequality because $2\cdot 36^a/(4\cdot 12^a)=3^a/2\ge\frac32$.

Step 3: the tail. For $x\ge 0$ put $t=e^{-x}r\le r$; Step 1 and Step 2 give $\mu(A(e^{-x}r))\le\min(1,e^{-\kappa x}M(r))\le\min(1,2\cdot 36^a e^{-\kappa x})$.

Step 4: the mean of the logarithm. The function $f=\log^+(r/\alpha)$ is measurable and non-negative, and for $x\ge 0$ we have $\{f>x\}=\{\alpha<e^{-x}r\}=A(e^{-x}r)$. By the layer-cake formula and Step 3 with $C=4\cdot 12^a\ge 1$ (Step 2),

$$\int_X f\,d\mu=\int_0^\infty\mu(A(e^{-x}r))\,dx\le\int_0^\infty\min(1,Ce^{-\kappa x})\,dx=\frac{\log C}{\kappa}+\frac{1}{\kappa}.$$

Hence f is integrable and $\int_X f\,d\mu<1.63\le 3$. □

Lemma D.8. *Let K be a number field of degree n and $\mathrm{rd}_K=|\mathrm{disc}(K)|^{1/n}$. There are $a_1,\dots,a_n\in\mathcal{O}_K$, linearly independent over $\mathbb{Q}$, such that for every i*

$$\sum_{\sigma\colon K\to\mathbb{C}}|\sigma(a_i)|^2\le n\,\mathrm{rd}_K^2;$$

in particular $\quad|\sigma(a_i)|\le\sqrt{n}\,\mathrm{rd}_K\le n\,\mathrm{rd}_K$ *for every field embedding $\sigma\colon K\to\mathbb{C}$.*

Proof. The Euclidean structure. Let $K_{\mathbb{R}} = K \otimes_{\mathbb{Q}} \mathbb{R}$; every field embedding $\sigma\colon K \to \mathbb{C}$ extends to an $\mathbb{R}$-algebra homomorphism $\sigma\colon K_{\mathbb{R}} \to \mathbb{C}$, and the map $K_{\mathbb{R}} \to \prod_\sigma \mathbb{C}$ is injective. Put

$$\langle x, y\rangle = \sum_\sigma \sigma(x)\overline{\sigma(y)} \qquad (x, y \in K_{\mathbb{R}}).$$

The terms of a real σ are real and the terms of σ and $\bar\sigma$ are complex conjugate, so $\langle\,,\rangle$ is real valued; it is $\mathbb{R}$-bilinear, symmetric and positive definite, so $(K_{\mathbb{R}}, \langle\,,\rangle)$ is a Euclidean space of dimension n, isometric to $\mathbb{R}^n$, with $\|x\|^2 = \sum_\sigma |\sigma(x)|^2$. Let c be the $\mathbb{R}$-algebra automorphism of $K_{\mathbb{R}} \cong \mathbb{R}^{r_1} \times \mathbb{C}^{r_2}$ that conjugates the complex factors; then $\sigma(c(y)) = \overline{\sigma(y)}$ for every σ, so $\langle x, y\rangle = \mathrm{Tr}_{K_{\mathbb{R}}/\mathbb{R}}(x\,c(y))$ and $\|c(y)\| = \|y\|$. The image Γ of $\mathcal{O}_K$ is a lattice in $K_{\mathbb{R}}$.

The dual lattice has minimum at least $\sqrt{n}/\mathrm{rd}_K$. Let $0 \neq y \in \Gamma^*$ and $t = c(y)$. Then $\mathrm{Tr}(xt) \in \mathbb{Z}$ for all $x \in \mathcal{O}_K$. If $\omega_1, \dots, \omega_n$ is a $\mathbb{Z}$-basis of $\mathcal{O}_K$ and $\omega_1^\vee, \dots, \omega_n^\vee \in K$ the dual basis for the (non-degenerate) trace form, then $t = \sum_j \mathrm{Tr}(\omega_j t)\,\omega_j^\vee$ by non-degeneracy of the trace form of $K_{\mathbb{R}}$; hence $t \in K$, and t lies in the inverse different $\mathfrak{d}_K^{-1} = \{u \in K : \mathrm{Tr}(u\mathcal{O}_K) \subseteq \mathbb{Z}\}$, $t \neq 0$. So $t\mathcal{O}_K = \mathfrak{d}_K^{-1}\mathfrak{a}$ with $\mathfrak{a}$ an integral ideal, and

$$\prod_\sigma |\sigma(t)| = |N_{K/\mathbb{Q}}(t)| = N(\mathfrak{d}_K)^{-1}N(\mathfrak{a}) \geq N(\mathfrak{d}_K)^{-1} = |\mathrm{disc}(K)|^{-1}.$$

By the inequality of arithmetic and geometric means,

$$\|y\|^2 = \|t\|^2 = \sum_\sigma |\sigma(t)|^2 \geq n\Big(\prod_\sigma |\sigma(t)|^2\Big)^{1/n} \geq n\,|\mathrm{disc}(K)|^{-2/n} = \frac{n}{\mathrm{rd}_K^2}.$$

Thus $\lambda_1(\Gamma^*) \geq \sqrt{n}/\mathrm{rd}_K$.

Transference. By Banaszczyk's transference theorem (W. Banaszczyk, Math. Ann. 296 (1993), 625–635) with $i = n$ (applied after an isometry $K_{\mathbb{R}} \cong \mathbb{R}^n$, which maps Γ^* to the dual of the image of Γ), $\lambda_n(\Gamma) \leq n/\lambda_1(\Gamma^*) \leq \sqrt{n}\,\mathrm{rd}_K$. As Γ is discrete, the set $\Gamma \cap \{\|v\| \leq \lambda_n(\Gamma)\}$ is finite and spans $K_{\mathbb{R}}$, so it contains n elements $a_1, \dots, a_n$ that are linearly independent over $\mathbb{R}$, hence over $\mathbb{Q}$, with $\sum_\sigma |\sigma(a_i)|^2 = \|a_i\|^2 \leq n\,\mathrm{rd}_K^2$. Each term of the sum is at most the sum, which gives $|\sigma(a_i)| \leq \sqrt{n}\,\mathrm{rd}_K$, and $\sqrt{n} \leq n$. □

D.1.2 The corrected weight: symmetry, plurisubharmonicity and regularisation

The Hodge-type metric and the cusp weight of a base setting are invariant under complex conjugation (Lemma D.9); the corrected weight is plurisubharmonic and continuous on the open part, locally bounded up to the boundary, and has bounded regularisations (Lemma D.10, Lemma D.15, Lemma D.13); and the cusp weight grows at most like $\log\log$ near the boundary (Lemma D.16). With log-log regularisation of the Hodge weight, the arithmetic intersection numbers of the regularised metrics then have limits (Lemma D.18, Lemma D.17), by the convergence of mixed Monge–Ampère integrals of Section 31. These are the regularisation limits asked for in Proposition D.1.

Lemma D.9. *Let a base setting of $\mathcal{T}$ at (B, Z) be given. Then $X^{\mathrm{b},\circ}$ is stable under complex conjugation, and for every point $\hat w$ of the affine cone over $X^{\mathrm{b},\circ}$, with image $w \in X^{\mathrm{b},\circ}$,*

$$h^{\mathrm{H}}(\bar{\hat w}) = h^{\mathrm{H}}(\hat w), \qquad U(\bar w) = U(w).$$

In particular the corrected weight $\log h^{\mathrm{H}} + \frac{1}{2}U$ is invariant under complex conjugation, and so is $\log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ on $X^{\mathrm{b},\circ}$ for every cone metric $h^{\mathrm{ref}'}$ of multidegree a^{H}.

Proof. Step 1: conjugate points of the cover. The complex points of the $\mathbb{Z}$-schemes $\mathcal{X}$ and $\mathcal{X}^{\mathrm{b}}$ carry complex conjugation $z \mapsto \bar{z} = z \circ \mathrm{Spec}(c)$, and $y_{\mathbb{C}}(\bar{z}) = \overline{y_{\mathbb{C}}(z)}$ because y is given by elements of the function field and the charts of (Gb1) are defined over $\mathbb{Z}$. If z lies over κ, then $\bar{z}$ lies over $c \circ \kappa = \bar{\kappa}$. The abelian locus $f^{-1}(j(\mathrm{Sh}_F))$ is a subscheme, so it is stable under conjugation; hence so is its complement, and by (Gb1) $\partial X^{\mathrm{b}} = y_{\mathbb{C}}(\text{complement})$ and $X^{\mathrm{b},\circ}$ are stable. Let z be in the abelian locus, $A = G_{\mathcal{X},z}$; then $G_{\mathcal{X},\bar{z}} = A^c$, and the canonical bijection $\gamma\colon A(\mathbb{C}) \to A^c(\mathbb{C})$ is an antiholomorphic isomorphism of real Lie groups. Its differential $d\gamma\colon \mathrm{Lie}(A) \to \mathrm{Lie}(A^c)$ is a $\mathbb{C}$-antilinear isomorphism with $\gamma \circ \exp = \exp \circ d\gamma$, so it maps $H_1(A(\mathbb{C}),\mathbb{Z}) = \ker \exp$ isomorphically onto $H_1(A^c(\mathbb{C}),\mathbb{Z})$. It commutes with the action of $\mathcal{O}_E$ (the endomorphisms of A^c are the base changes of those of A). If $a \in \mathcal{O}_E$ acts on $x \in \mathrm{Lie}_s(A)$ by $\kappa(\sigma_s(a))$, it acts on $d\gamma(x)$ by $\overline{\kappa(\sigma_s(a))} = \bar{\kappa}(\sigma_s(a))$, the character of $\mathcal{O}_E$ on $\mathrm{Lie}_s(A^c)$ ($\bar{z}$ lies over $\bar{\kappa}$); as both decompositions are direct sums over the labels, $d\gamma(\mathrm{Lie}_s(A)) = \mathrm{Lie}_s(A^c)$ for every label s. The polarisation of A^c is the base change of that of A; γ^* carries its line bundle to the complex conjugate of $\mathcal{L}_z$, so $E_{\bar{z}}(d\gamma x, d\gamma x') = -E_z(x,x')$ on H_1, hence on $\mathrm{Lie}(A)$ by $\mathbb{R}$-linearity, and with $i\,d\gamma(x) = d\gamma(-ix)$:

$$\begin{aligned} H_{\bar{z}}(d\gamma x, d\gamma x') &= E_{\bar{z}}(d\gamma(-ix), d\gamma x') + iE_{\bar{z}}(d\gamma x, d\gamma x') \\ &= E_z(ix, x') - iE_z(x,x') = \overline{H_z(x,x')}. \end{aligned} \tag{1}$$

Finally, for a section b of $\mathrm{Lie}(G_{\mathcal{X}})$ over an open subset of $\mathcal{X}$ containing z (hence $\bar{z}$), $b(\bar{z}) = d\gamma(b(z))$, and for a regular function u there, $u(\bar{z}) = \overline{u(z)}$.

Step 2: the Hodge-type metric. Let $w \in X^{\mathrm{b},\circ}$, z with $y_{\mathbb{C}}(z) = w$ (by (Gb1) it lies in the abelian locus), a chart c' in which z lies, and $D(f)$, the unit u and the frames $b_{\tau,i}$ of $\mathcal{V}_{(\tau,-)}$ of (Gb3) with $z \in D(f)$; at complex points of the abelian locus these frames are frames of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})$. As $D(f)$ is an open subscheme, $\bar{z} \in D(f)$, and $\bar{w} = y_{\mathbb{C}}(\bar{z})$. By Step 1 and (1), the Gram matrix $\big(h_{\bar{z}}(b_{\tau,i}(\bar{z}), b_{\tau,k}(\bar{z}))\big)$ is the complex conjugate of $\big(h_z(b_{\tau,i}(z), b_{\tau,k}(z))\big)$; both are positive definite hermitian, so their determinants are equal positive reals, and $\|b_{\tau,1} \wedge \cdots \wedge b_{\tau,q}\|_{h_{\bar{z}}}(\bar{z}) = \|b_{\tau,1} \wedge \cdots \wedge b_{\tau,q}\|_{h_z}(z)$. With $|u(\bar{z})| = |u(z)|$, (Gb3) gives $\|\sigma_{c'}\|(\bar{w}) = \|\sigma_{c'}\|(w)$ for $\sigma_{c'} = \prod_k y_{k,c'_k}^{a_k^{\mathrm{H}}}$ in the metric of the Hodge-type line. The polynomial $\sigma_{c'}$ has integer coefficients, so $|\sigma_{c'}(\bar{\hat{w}})| = |\sigma_{c'}(\hat{w})| \neq 0$ for a cone point $\hat{w}$ over w, and $h^{\mathrm{H}}(\bar{\hat{w}}) = |\sigma_{c'}(\bar{\hat{w}})|/\|\sigma_{c'}\|(\bar{w}) = h^{\mathrm{H}}(\hat{w})$.

Step 3: the cusp weight. Keep w, z over κ, A, γ. Put $\Psi = \{\kappa \circ \bar{\tau} : \tau \in \Phi\}$; it is a CM type of E, since $\kappa \circ \bar{\tau} = \overline{\kappa \circ \tau}$ (κ commutes with complex conjugation on the CM field $\tau(E)$) and $\{\kappa \circ \tau : \tau \in \Phi\}$ is a CM type (Φ is one and κ is injective), and $\mathrm{Lie}(A)_{\kappa\circ\bar{\tau}} = \mathrm{Lie}_{(\tau,-)}(A)$ has dimension $q \geq 1$. So Lemma D.3 applies to $(V,H,\Lambda,\iota) = (\mathrm{Lie}(A), H_z, H_1(A(\mathbb{C}),\mathbb{Z}), \mathcal{O}_E)$ and Ψ. Let $I \subseteq \Lambda_w$ be a non-zero saturated isotropic $\mathcal{O}_E$-submodule; it has an $\mathcal{O}_E$-linearly independent family of finite index (a maximal $\mathcal{O}_E$-linearly independent subset of the torsion-free finitely generated module I), so the fixed family v^I of (Hu1) exists. Let $I_z \subseteq H_1(A(\mathbb{C}),\mathbb{Z})$ be its image under the isomorphism of (Gb5) at w (through z); $\mathrm{Im}\, H_z$ vanishes on it. As $\lambda_{w,\tau}$ is carried to orthonormal coordinates on $\mathrm{Lie}_{(\tau,-)}(A)$, $\overline{\lambda_{w,\tau}(v_a^I)}^{\mathsf{T}} \lambda_{w,\tau}(v_b^I) = H_z\big((v_b)_{(\tau,-)}, (v_a)_{(\tau,-)}\big)$ for the images v_a of v_a^I, a hermitian matrix with the determinant of its transpose; so $\mathrm{N}_w(I)$ is the quantity $\mathrm{N}(I_z)$ of Lemma D.3, and that lemma gives, for any $\mathbb{Z}$-basis $b_1,\dots,b_{2f\rho}$ of I_z ($2f = [E:\mathbb{Q}]$, $2f\rho$ the $\mathbb{Z}$-rank of I),

$$\begin{aligned} \mathrm{N}_w(I) &= \det\big(H_z(b_i,b_k)\big)_{i,k}^{1/2}\, \mathrm{rd}_E^{-f\rho} \\ &= \det\big(\mathrm{Re}\, H_z(b_i,b_k)\big)_{i,k}^{1/2}\, \mathrm{rd}_E^{-f\rho}, \end{aligned} \tag{2}$$

the second equality because $\mathrm{Im}\, H_z = 0$ on I_z. By Step 1, $d\gamma$ is an isomorphism of $\mathcal{O}_E$-modules $H_1(A(\mathbb{C}),\mathbb{Z}) \to H_1(A^c(\mathbb{C}),\mathbb{Z})$ with $E_{\bar{z}} \circ (d\gamma \times d\gamma) = -E_z$; so it maps the non-zero saturated E_z-isotropic $\mathcal{O}_E$-submodules bijectively onto the non-zero saturated $E_{\bar{z}}$-isotropic ones, preserving

$\mathbb{Z}$-ranks, and by (1) $\operatorname{Re} H_{\bar z}(d\gamma b_i, d\gamma b_k) = \operatorname{Re} H_z(b_i, b_k)$. Composing with the isomorphisms of (Gb5) at w (through z) and at $\bar w$ (through $\bar z$) gives a bijection $I \mapsto I'$ between the non-zero saturated isotropic $\mathcal{O}_E$-submodules of Λ_w and of $\Lambda_{\bar w}$, and (2) at $\bar w$ (with $\bar z$ over $\bar\kappa$ and the CM type $\{\bar\kappa \circ \bar\tau\}$) gives $\mathrm{N}_{\bar w}(I') = \mathrm{N}_w(I)$. Hence the sets $\{-\log \mathrm{N}_w(I)\}$ and $\{-\log \mathrm{N}_{\bar w}(I')\}$ coincide, $s(\bar w) = s(w)$ and $U(\bar w) = U(w)$ by (Hu2).

Step 4. By Steps 2 and 3, $\log h^{\mathrm{H}} + \frac{1}{2}U$ is invariant under conjugation on the cone over $X^{\mathrm{b},\circ}$, and a cone metric satisfies $h^{\mathrm{ref}'}(\bar{\hat w}) = h^{\mathrm{ref}'}(\hat w)$ by definition; the difference, a function on $X^{\mathrm{b},\circ}$ (equal multidegrees), is invariant. □

Lemma D.10. *Let a base setting with cusp data be given, X the set of complex points of its cover $\mathcal{X}$ over one embedding $\kappa\colon F \to \mathbb{C}$ (as a complex manifold near the points considered), $W \subseteq X$ open, and for $\tau \in \Phi$ let b_τ be a holomorphic frame of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})^{\mathrm{an}}$ on W. Then the function*

$$u(z) = \frac{1}{2}\sum_{\tau\in\Phi} \log\det \Gamma(b_\tau(z)) + \frac{1}{2}\,U(y_{\mathbb{C}}(z))$$

is plurisubharmonic and continuous on $W \cap$ (abelian locus). (By (Gb3), u is the corrected weight $\log h^{\mathrm{H}} + \frac{1}{2}U$ read in the frame b, up to the logarithm of the modulus of a holomorphic unit.)

Proof. Both properties are local. Fix $z_0 \in W$ in the abelian locus (an open set) and a connected, simply connected open neighbourhood $W' \subseteq W$ of z_0 inside the abelian locus. Put $w_0 = y_{\mathbb{C}}(z_0)$ and $\Lambda = \Lambda_{w_0}$ with $\langle\cdot,\cdot\rangle_{w_0}$ and the families of (Hu1) at w_0, as in Lemma D.11. For $z \in W'$ let $\psi_z\colon \Lambda_w \to H_1(G_{\mathcal{X},z}(\mathbb{C}),\mathbb{Z})$ be the isomorphism of (Gb5) at $w = y_{\mathbb{C}}(z)$, and let $\phi_z\colon \Lambda \to H_1(G_{\mathcal{X},z}(\mathbb{C}),\mathbb{Z})$ ($z \in W'$) be obtained from ψ_{z_0} by parallel transport. As the $\mathcal{O}_E$-action and the Riemann form $\operatorname{Im} H_z$ of the polarisation are flat on the local system of first homology, the ϕ_z are as in Lemma D.11. Write $L(z) = \sum_{\tau\in\Phi} \log\det\Gamma(b_\tau(z))$, a continuous function ($\Gamma(b_\tau(z))$ is positive definite and smooth in z).

Step 1: the cusp weight through the flat identification. Let $z \in W'$ and $g_z = \phi_z^{-1} \circ \psi_z\colon \Lambda_w \to \Lambda$, an isomorphism of $\mathcal{O}_E$-modules carrying $\langle\cdot,\cdot\rangle_w$ to $\langle\cdot,\cdot\rangle_{w_0}$; it maps the non-zero saturated isotropic $\mathcal{O}_E$-submodules of Λ_w bijectively onto those of Λ, and the family of (Hu1) at w for I to an $\mathcal{O}_E$-linearly independent family in $g_z I$ spanning a submodule of the same index. By (Gb5), $\lambda_{w,\tau}(v)$ is the coordinate vector of $\psi_z(v)_{(\tau,-)}$ in an H_z-orthonormal basis, so $\overline{\lambda_{w,\tau}(v_a)}^{\mathsf{T}}\lambda_{w,\tau}(v_b)$ is the H_z-Gram entry of $\phi_z(g_z v_a)_{(\tau,-)}, \phi_z(g_z v_b)_{(\tau,-)}$, and $\mathrm{N}_w(I)$ is the expression defining N_z^ϕ evaluated on the family $(g_z v_a^I)_a$ of $g_z I$, which spans an $\mathcal{O}_E$-submodule of index $\iota(I)$ in $g_z I$. This expression does not depend on the family: let $v = (v_a)$, $v' = (v'_a)$ be two $\mathcal{O}_E$-linearly independent families in a saturated isotropic I' spanning $\mathcal{O}_E$-submodules M, M' of finite indices ι, ι'. Then $v' = Av$ for some $A \in \mathrm{GL}_\rho(E)$, and since E acts on $\mathrm{Lie}_{(\tau,-)}$ through $\kappa\circ\bar\tau$, the Gram matrix of the $(\tau,-)$-components of $\phi_z(v')$ is $\kappa\bar\tau(A)\,\Gamma\,\kappa\bar\tau(A)^*$ with Γ that of $\phi_z(v)$. As $\kappa\circ\bar\tau = \overline{\kappa\circ\tau}$ (κ commutes with complex conjugation on the CM field $\tau(E)$) and $\{\kappa\circ\tau : \tau\in\Phi\}$ is a CM type (Φ is one, κ is injective), $\prod_{\tau\in\Phi}|\kappa\bar\tau(\det A)|^2 = |\mathrm{N}_{E/\mathbb{Q}}(\det A)|$; and $\iota'/\iota = [M : M'] = |\mathrm{N}_{E/\mathbb{Q}}(\det A)|$ (generalised index of the free $\mathcal{O}_E$-lattices $M = \mathcal{O}_E^\rho$ and $M' = AM$; clear denominators by an integer d, using $[\mathcal{O}_E^\rho : B\mathcal{O}_E^\rho] = |\mathrm{N}_{E/\mathbb{Q}}(\det B)|$ for $B \in M_\rho(\mathcal{O}_E)$). The two factors cancel. Hence $\mathrm{N}_w(I) = \mathrm{N}_z^\phi(g_z I)$, and

$$U(w) = \max\Big(0,\ \sup_I\big(-\log \mathrm{N}_z^\phi(I)\big)\Big),$$

the supremum over the non-zero saturated isotropic I admitting a family (the others have $\mathrm{N} = 1$ and contribute 0).

Step 2: a finite maximum. By Lemma D.12 there are an open $V \ni z_0$, $V \subseteq W'$, and a finite set F with $\mathrm{N}_z^\phi(I) > 1$, i.e. $-\log \mathrm{N}_z^\phi(I) < 0$, for $z \in V$ and $I \notin F$. So on V the supremum in

Step 1 exceeds 0 only through $I \in F$, and

$$2u(z) = L(z) + U(y_{\mathbb{C}}(z)) = \max\Big(L(z),\ \max_{I\in F}\big(L(z) - \log \mathrm{N}_z^{\phi}(I)\big)\Big) \qquad (z \in V).$$

Step 3: conclusion. By Lemma D.11 (for $I = 0$ and for $I \in F$) each of the finitely many functions in this maximum is plurisubharmonic and continuous on W'. A maximum of finitely many continuous plurisubharmonic functions is continuous and plurisubharmonic. So u is plurisubharmonic and continuous on V; as z_0 was arbitrary, on $W \cap$ (abelian locus). □

Lemma D.11. *Let a base setting with cusp data be given, X the set of complex points of its cover $\mathcal{X}$ over one embedding $\kappa\colon F \to \mathbb{C}$, $W' \subseteq X$ a connected, simply connected open subset of the abelian locus, and for $\tau \in \Phi$ let b_τ be a holomorphic frame of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})^{\mathrm{an}}$ on W'. Let $w_0 \in X^{\mathrm{b},\circ}$ and write $\Lambda = \Lambda_{w_0}$, $\langle\cdot,\cdot\rangle = \langle\cdot,\cdot\rangle_{w_0}$, with the families v_a^I and the indices $\iota(I)$ of (Hu1) at w_0. Let $\phi_z\colon \Lambda \to H_1(G_{\mathcal{X},z}(\mathbb{C}),\mathbb{Z})$ $(z \in W')$ be isomorphisms of $\mathcal{O}_E$-modules carrying $\langle\cdot,\cdot\rangle$ to $\mathrm{Im}\, H_z$ and obtained from one of them by parallel transport in the local system of first homology. For a saturated isotropic $\mathcal{O}_E$-submodule $I \neq 0$ of Λ admitting the family $(v_a^I)_{a\le\rho}$ of (Hu1) put*

$$\mathrm{N}_z^{\phi}(I) = \frac{1}{\iota(I)} \prod_{\tau\in\Phi} \det\Big(H_z\big(\phi_z(v_b^I)_{(\tau,-)}, \phi_z(v_a^I)_{(\tau,-)}\big)\Big)_{a,b\le\rho},$$

where $v_{(\tau,-)}$ is the component of $v \in \mathrm{Lie}(G_{\mathcal{X},z})$ in $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z})$, and put $\mathrm{N}_z^{\phi}(0) = 1$. Then for every such I (and for $I = 0$) the function $\mathrm{N}^{\phi}(I)$ is continuous and positive on W', and

$$z \mapsto \sum_{\tau\in\Phi} \log\det\Gamma(b_\tau(z)) - \log \mathrm{N}_z^{\phi}(I)$$

is plurisubharmonic on W'.

Proof. Write $\Lambda_{\mathbb{C}} = \Lambda \otimes_{\mathbb{Z}} \mathbb{C}$, Q for the $\mathbb{C}$-bilinear extension of $\langle\cdot,\cdot\rangle$, $m = \dim \mathrm{Lie}(G_{\mathcal{X},z})$, and for a subgroup $I \subseteq \Lambda$ put $I_{\mathbb{C}} = I \otimes \mathbb{C}$ and $I^{\perp} = \{v \in \Lambda_{\mathbb{C}} : Q(v, I_{\mathbb{C}}) = 0\}$. As ϕ_z is $\mathcal{O}_E$-linear and carries $\langle\cdot,\cdot\rangle$ to $\mathrm{Im}\, H_z$, (Ud4) gives $\langle av, w\rangle = \langle v, \bar{a}w\rangle$ on Λ. Let I be 0 or a non-zero saturated isotropic $\mathcal{O}_E$-submodule with its family $v_a = v_a^I$ $(a \le \rho;\ \rho = 0$ for $I = 0)$; as $\mathcal{O}_E$ has rank $2|\Phi|$, $\dim I_{\mathbb{C}} = 2|\Phi|\rho$.

Step 1: the variation of Hodge structure of the family. Let $\beta_z\colon \Lambda_{\mathbb{C}} \to \mathrm{Lie}(G_{\mathcal{X},z})$ be the $\mathbb{C}$-linear extension of ϕ_z, where $H_1(G_{\mathcal{X},z}(\mathbb{C}),\mathbb{Z})$ is the kernel of the exponential map $\mathrm{Lie}(G_{\mathcal{X},z}) \to G_{\mathcal{X},z}(\mathbb{C})$. For $v \in \Lambda$, $z \mapsto \phi_z(v)$ is a holomorphic section of $\mathrm{Lie}(G_{\mathcal{X}})^{\mathrm{an}}$: the exponential map of the family over W' is holomorphic and a local biholomorphism, so near each point its kernel is the image of the zero section under a holomorphic local inverse, and parallel transport in the local system of first homology is the continuation of these local sections. So β is a holomorphic map $\Lambda_{\mathbb{C}} \otimes \mathcal{O}_{W'} \to \mathrm{Lie}(G_{\mathcal{X}})^{\mathrm{an}}$, surjective at every z ($\phi_z(\Lambda)$ spans Lie over $\mathbb{R}$), and $\mathcal{K}_z = \ker\beta_z$ is a holomorphic subbundle of rank m. Fix z, let J be the complex structure of $\mathrm{Lie}(G_{\mathcal{X},z})$ transported to $\Lambda_{\mathbb{R}}$ by ϕ_z and $E_0 = \langle\cdot,\cdot\rangle$ on $\Lambda_{\mathbb{R}}$; as H_z is hermitian with imaginary part E_0, $H_z(\phi_z v, \phi_z w) = E_0(Jv, w) + iE_0(v, w)$, $E_0(Jv, Jw) = E_0(v, w)$ and $E_0(Jv, w)$ is symmetric. Then

$$\mathcal{K}_z = \{v + iJv :\ v \in \Lambda_{\mathbb{R}}\}, \qquad \overline{\mathcal{K}_z} = \{v - iJv :\ v \in \Lambda_{\mathbb{R}}\}, \qquad \beta_z(v - iJv) = 2\phi_z(v),$$

$$Q(\mathcal{K}_z, \mathcal{K}_z) = 0, \qquad iQ(u, \bar{w}) = \tfrac{1}{2}H_z(\beta_z u, \beta_z w) \quad (u, w \in \overline{\mathcal{K}_z}).$$

So $\Lambda_{\mathbb{C}} = \mathcal{K}_z \oplus \overline{\mathcal{K}_z}$ with $\mathcal{K}_z$ isotropic and $iQ(u, \bar{u}) > 0$ for $0 \neq u \in \overline{\mathcal{K}_z}$: with the Weil operator C acting on $H^{a,b}$ by i^{a-b} (the convention of Theorem B.145 and Theorem B.144: the Hodge form

$Q(C\cdot,\bar{\cdot})$ is positive definite), $(\Lambda,\mathcal{K},-Q)$ is a polarised variation of Hodge structure of weight -1 on W' with $H^{-1,0}=\overline{\mathcal{K}}$, $H^{0,-1}=\mathcal{K}=F^0$ (Griffiths transversality is empty for a filtration with two steps) , its last quotient $\Lambda_{\mathbb{C}}\otimes\mathcal{O}/\mathcal{K}$ is $\mathrm{Lie}(G_{\mathcal{X}})^{\mathrm{an}}$ via β, and its Hodge metric is $iQ(u,\bar{u})$ on $\overline{\mathcal{K}}$.

Step 2: the quotient by I. (a) $I_{\mathbb{C}}\cap\overline{\mathcal{K}_z}=0=I_{\mathbb{C}}\cap\mathcal{K}_z$: for $u\in I_{\mathbb{C}}\cap\overline{\mathcal{K}_z}$, $\bar{u}\in I_{\mathbb{C}}$, so $Q(u,\bar{u})=0$ by isotropy and $u=0$ by positivity; conjugate for $\mathcal{K}_z$. (b) $\Lambda'=(I^{\perp}\cap\Lambda)/I$ is a free $\mathbb{Z}$-module (I is saturated), an $\mathcal{O}_E$-module ($I^{\perp}$ is $\mathcal{O}_E$-stable as $\langle av,w\rangle=\langle v,\bar{a}w\rangle$), with $\Lambda'_{\mathbb{C}}=I^{\perp}/I_{\mathbb{C}}$ and the non-degenerate form Q' induced by Q (as $(I^{\perp})^{\perp}=I_{\mathbb{C}}$). Put $\mathcal{K}'_z=((\mathcal{K}_z\cap I^{\perp})+I_{\mathbb{C}})/I_{\mathbb{C}}$. The map $I_{\mathbb{C}}\to\mathcal{K}_z^*$, $y\mapsto Q(y,\cdot)$, is injective (its kernel lies in $\mathcal{K}_z^{\perp}=\mathcal{K}_z$, a Lagrangian subspace, and $I_{\mathbb{C}}\cap\mathcal{K}_z=0$), so $\mathcal{K}_z\cap I^{\perp}$ has dimension $m-2|\Phi|\rho$, is a holomorphic subbundle (kernel of a holomorphic surjection of constant rank), and by (a) maps isomorphically onto $\mathcal{K}'_z$, of half the dimension $2m-4|\Phi|\rho$ of $\Lambda'_{\mathbb{C}}$. The subspace $\mathcal{K}'_z$ is Q'-isotropic. For $u\in\overline{\mathcal{K}_z}\cap I^{\perp}$ and $y\in I_{\mathbb{C}}$, $Q(u+y,\bar{u}+\bar{y})=Q(u,\bar{u})$, so $iQ'(x,\bar{x})>0$ for every $0\neq x\in\overline{\mathcal{K}'_z}$ (and $x=[u]\neq0$ iff $u\neq0$, by (a)); an $x\in\mathcal{K}'_z\cap\overline{\mathcal{K}'_z}$ has $x,\bar{x}\in\mathcal{K}'_z$, so $Q'(x,\bar{x})=0$ and $x=0$. Hence (by the same computation as in Step 1) $(\Lambda',\mathcal{K}',-Q')$ is again a polarised variation of Hodge structure of weight -1 on W', with Hodge metric $iQ'(x,\bar{x})$ on $\overline{\mathcal{K}'}$. For $I=0$ it is the variation of Step 1.

(c) Let $P_z=\beta_z(I_{\mathbb{C}})$, a holomorphic subbundle of $\mathrm{Lie}(G_{\mathcal{X}})^{\mathrm{an}}$ of rank $2|\Phi|\rho$ (β_z is injective on $I_{\mathbb{C}}$ by (a)). The map $I^{\perp}\to\mathrm{Lie}(G_{\mathcal{X},z})/P_z$, $v\mapsto\beta_z v \bmod P_z$, has kernel $I^{\perp}\cap(\mathcal{K}_z+I_{\mathbb{C}})=(\mathcal{K}_z\cap I^{\perp})+I_{\mathbb{C}}$, so it induces a holomorphic isomorphism $\Lambda'_{\mathbb{C}}/\mathcal{K}'\to\mathrm{Lie}(G_{\mathcal{X}})^{\mathrm{an}}/P$ (both of rank $m-2|\Phi|\rho$). It multiplies squared norms by 2π, for the Hodge metric on the left and the quotient metric of $h_z=\pi H_z$ on the right: let $u\in\overline{\mathcal{K}_z}\cap I^{\perp}$ and $y\in I_{\mathbb{C}}$, $y=y_1+y_2$ with $y_1\in\mathcal{K}_z$, $y_2\in\overline{\mathcal{K}_z}$, so $\beta_z y=\beta_z y_2$; then $Q(u,\bar{y}_2)=Q(u,\bar{y})-Q(u,\bar{y}_1)=0$ ($u\in I^{\perp}$, $\bar{y}\in I_{\mathbb{C}}$; $\overline{\mathcal{K}_z}$ isotropic), so $H_z(\beta_z u,\beta_z y)=0$ by Step 1. Thus $\beta_z(\overline{\mathcal{K}_z}\cap I^{\perp})$ is H_z-orthogonal to P_z, hence equal to $P_z^{\perp}$ (dimensions), and the quotient norm of $\beta_z u \bmod P_z$ is $h_z(\beta_z u,\beta_z u)=\pi H_z(\beta_z u,\beta_z u)=2\pi\, iQ'([u],[\bar{u}])$, the class $[u]\in\overline{\mathcal{K}'_z}$ representing $u \bmod \mathcal{K}'_z$.

Step 3: the pieces $(\tau,-)$. The Lie_s are mutually H_z-orthogonal: for $x\in\mathrm{Lie}_s$, $y\in\mathrm{Lie}_{s'}$, $s\neq s'$, choose $a\in\mathcal{O}_E$ with $\sigma_s(a)\neq\sigma_{s'}(a)$; applying (Ud4) to x and to ix gives $H_z(ax,y)=H_z(x,\bar{a}y)$, i.e. $\sigma_s(a)H_z(x,y)=\overline{\sigma_{s'}(\bar{a})}H_z(x,y)=\sigma_{s'}(a)H_z(x,y)$, so $H_z(x,y)=0$. As β_z is $\mathcal{O}_E$-linear, $P_z=\bigoplus_s P_{z,s}$ with $P_{z,s}=P_z\cap\mathrm{Lie}_s=\beta_z\big((I_{\mathbb{C}})_{\sigma_s}\big)$, $(I_{\mathbb{C}})_{\sigma}$ the subspace on which $\mathcal{O}_E$ acts by σ, and $\mathrm{Lie}/P=\bigoplus_s\mathrm{Lie}_s/P_s$ orthogonally, the quotient metric restricting to the quotient metric of $h_z|_{\mathrm{Lie}_s}$ on each summand. For $\tau\in\Phi$ write $V_\tau=\mathrm{Lie}_{(\tau,-)}$, $P_\tau=P_{(\tau,-)}$ and $p_{\tau,a}(z)=\phi_z(v_a)_{(\tau,-)}$, the image under β_z of the $\bar{\tau}$-component of v_a. These are holomorphic in z (components of holomorphic sections along a holomorphic direct sum) and form a basis of $P_{z,\tau}$: the v_a are an E-basis of $I\otimes\mathbb{Q}$, so their $\bar{\tau}$-components are a basis of $(I_{\mathbb{C}})_{\bar{\tau}}=I\otimes_{\mathcal{O}_E,\bar{\tau}}\mathbb{C}$, and β_z is injective on $I_{\mathbb{C}}$. Hence $\rho\le q$, and $\mathrm{N}_z^{\phi}(I)=\iota(I)^{-1}\prod_\tau\det\big(H_z(p_{\tau,b},p_{\tau,a})\big)_{a,b}$ is a product of Gram determinants of linearly independent vectors: positive, and continuous in z.

Step 4: separating the cusp. Fix τ and $k=q-\rho$. The canonical holomorphic isomorphism $\bigwedge^q V_\tau\cong\bigwedge^\rho P_\tau\otimes\bigwedge^k(V_\tau/P_\tau)$, $x_1\wedge\cdots\wedge x_\rho\wedge y_1\wedge\cdots\wedge y_k\mapsto(x_1\wedge\cdots\wedge x_\rho)\otimes(\bar{y}_1\wedge\cdots\wedge\bar{y}_k)$ ($x_i\in P_\tau$, $\bar{y}_j$ the class of y_j), is isometric for the metrics induced by h_z on V_τ and P_τ and the quotient metric on V_τ/P_τ (the y_j may be taken in $P_\tau^{\perp}$, and then the Gram matrix is block diagonal). Define c_τ by $b_{\tau,1}\wedge\cdots\wedge b_{\tau,q}=(p_{\tau,1}\wedge\cdots\wedge p_{\tau,\rho})\otimes c_\tau$: a nowhere vanishing holomorphic section of $\bigwedge^k(V_\tau/P_\tau)$ on W', as $p_{\tau,1}\wedge\cdots\wedge p_{\tau,\rho}$ is holomorphic and nowhere zero. Taking squared norms, $\det\Gamma(b_\tau)=\pi^\rho\det\big(H_z(p_{\tau,b},p_{\tau,a})\big)\,\|c_\tau\|^2$, and

$$\sum_{\tau\in\Phi}\log\det\Gamma(b_\tau(z))-\log\mathrm{N}_z^{\phi}(I)=\log\iota(I)+\rho|\Phi|\log\pi+\sum_{\tau\in\Phi}\log\|c_\tau(z)\|^2$$

(for $I=0$: $\rho=0$, $\iota=1$, $c_\tau=b_{\tau,1}\wedge\cdots\wedge b_{\tau,q}$).

Step 5: Griffiths. It suffices that each $\log\|c_\tau\|^2$ is plurisubharmonic. If $k=0$, c_τ is a nowhere vanishing holomorphic function and $\log|c_\tau|^2$ is pluriharmonic. Let $k\ge1$. By Step

3, $\bigwedge^k(V_\tau/P_\tau)$ is a holomorphic line subbundle of $\bigwedge^k(\mathrm{Lie}/P)$ with the induced metric, and by Step 2(c) $\bigwedge^k(\mathrm{Lie}/P)$ is isomorphic to $\bigwedge^k(\Lambda'_{\mathbb C}/\mathcal K')$ with squared norms multiplied by $(2\pi)^k$, the latter with the metric induced by the Hodge metric. Consider $(\bigwedge^k\Lambda', F^\bullet, (-1)^kQ'_k)$, where $(-1)^kQ'_k(x_1\wedge\cdots\wedge x_k, y_1\wedge\cdots\wedge y_k) = \det\bigl(-Q'(x_i,y_j)\bigr)$ is the form induced by the polarisation $-Q'$ of Step 2; here $F^p = \sum_{p_1+\cdots+p_k=p} F'^{p_1}\wedge\cdots\wedge F'^{p_k}$ ($F'^{-1}=\Lambda'_{\mathbb C}$, $F'^0=\mathcal K'$, $F'^1=0$) and $Q'_k(x_1\wedge\cdots\wedge x_k, y_1\wedge\cdots\wedge y_k) = \det\bigl(Q'(x_i,y_j)\bigr)$. It is a polarised variation of Hodge structure of weight $-k$ on W'.

Since $\dim\overline{\mathcal K'} = m - 2|\Phi|\rho \ge k$ (it contains a copy of V_τ/P_τ), the largest a with $F^a = \bigwedge^k\Lambda'_{\mathbb C}$ is $a=-k$; F^{-k+1} is the kernel of $\bigwedge^k\Lambda'_{\mathbb C}\to\bigwedge^k(\Lambda'_{\mathbb C}/\mathcal K')$, so the last quotient of Theorem B.144 is $\bigwedge^k(\Lambda'_{\mathbb C}/\mathcal K')$ with the metric induced by the Hodge metric of $\Lambda'_{\mathbb C}/\mathcal K'$ (on $H^{-k,0} = \bigwedge^k\overline{\mathcal K'}$ the Hodge form is the Gram determinant of $iQ'(x,\bar y)$). By Theorem B.144 on $S=W'$, the logarithm of the squared Hodge norm of the holomorphic, nowhere vanishing section c_τ is plurisubharmonic, and $\log\|c_\tau\|^2$ differs from it by the constant $k\log(2\pi)$. Summing over $\tau\in\Phi$ proves the claim. $\square$

Lemma D.12. *In the setting of Lemma D.11, every $z_0\in W'$ has an open neighbourhood $V\subseteq W'$ with a finite set F of non-zero saturated isotropic $\mathcal O_E$-submodules of Λ such that $\mathrm N_z^\phi(I)>1$ for every $z\in V$ and every non-zero saturated isotropic $\mathcal O_E$-submodule $I\notin F$ admitting a family as in (Hu1).*

Proof. For $z\in W'$ let $\gamma_z(v,w) = \operatorname{Re}H_z(\phi_z v,\phi_z w)$, a positive definite inner product on $\Lambda_{\mathbb R} = \Lambda\otimes\mathbb R$ (as $\phi_z\otimes\mathbb R$ is an $\mathbb R$-isomorphism onto $\mathrm{Lie}(G_{\mathcal X,z})$). It depends continuously on z: H_z is a smooth metric on $\mathrm{Lie}(G_{\mathcal X})^{\mathrm{an}}$, and for fixed v the vectors $\phi_z(v)$ form a holomorphic section, the exponential map of the family being a local biholomorphism whose kernel is, near each point, the image of the zero section under a holomorphic local inverse, continued by parallel transport. For a subgroup $M\subseteq\Lambda$ of rank $n\ge1$ with $\mathbb Z$-basis $e_1,\dots,e_n$ put $\mathrm{covol}_\gamma(M) = \det\bigl(\gamma(e_i,e_j)\bigr)^{1/2}$, and let D_E be the absolute value of the discriminant of E.

Step 1: the cusp norm is a covolume. We show: for every non-zero saturated isotropic $\mathcal O_E$-submodule I with a family $v_1,\dots,v_\rho$ as in (Hu1) and every $z\in W'$,

$$\mathrm N_z^\phi(I) = D_E^{-\rho/2}\,\mathrm{covol}_{\gamma_z}(I).$$

First, the Lie_s are mutually H_z-orthogonal: for $x\in\mathrm{Lie}_s$, $y\in\mathrm{Lie}_{s'}$, $s\ne s'$, pick $a\in\mathcal O_E$ with $\sigma_s(a)\ne\sigma_{s'}(a)$; (Ud4) applied to x and to ix gives $H_z(ax,y) = H_z(x,\bar a y)$, i.e. $\sigma_s(a)H_z(x,y) = \sigma_{s'}(a)H_z(x,y)$. Let $x,y\in I_{\mathbb R}$ and write x_s for the component of $\phi_z(x)$ in Lie_s. As I is an isotropic $\mathcal O_E$-module and ϕ_z carries $\langle\cdot,\cdot\rangle$ to $\operatorname{Im}H_z$, $\operatorname{Im}H_z(\phi_z(ax),\phi_z(y))=0$ for $a\in\mathcal O_E$, hence (by $\mathbb R$-linearity in a) for all $a\in E\otimes\mathbb R$:

$$\operatorname{Im}\sum_{\tau\in\Phi}\bigl(\tau(a)\,H_z(x_{(\tau,+)},y_{(\tau,+)}) + \overline{\tau(a)}\,H_z(x_{(\tau,-)},y_{(\tau,-)})\bigr) = 0.$$

As $a\mapsto(\tau(a))_{\tau\in\Phi}$ maps $E\otimes\mathbb R$ onto $\mathbb C^\Phi$, we may take $\tau(a)=1$ and then $\tau(a)=i$ at one τ and 0 at the others; this gives $H_z(x_{(\tau,+)},y_{(\tau,+)}) = \overline{H_z(x_{(\tau,-)},y_{(\tau,-)})}$, so

$$\gamma_z(x,y) = 2\sum_{\tau\in\Phi}\operatorname{Re}H_z(x_{(\tau,-)},y_{(\tau,-)}) \qquad (x,y\in I_{\mathbb R}).$$

The v_a are a basis of $I_{\mathbb R}$ over $E\otimes\mathbb R$; write $x=\sum_a x_a v_a$ ($x_a\in E\otimes\mathbb R$) and $w_{\tau,a}=\tau(x_a)$, which identifies $I_{\mathbb R}$ with $(\mathbb C^\rho)^\Phi$. With $p_{\tau,a} = \phi_z(v_a)_{(\tau,-)}$ we have $x_{(\tau,-)} = \sum_a\overline{w_{\tau,a}}\,p_{\tau,a}$, so $\gamma_z(x,x) = 2\sum_\tau\sum_{a,b}\overline{w_{\tau,a}}w_{\tau,b}\,G_\tau[a,b]$ with $G_\tau = (H_z(p_{\tau,a},p_{\tau,b}))_{a,b}$: an orthogonal sum over τ of 2 times a positive definite hermitian form on $\mathbb C^\rho$ with determinant $\det G_\tau$, whose determinant as a real quadratic form on $\mathbb R^{2\rho}$ is $(2^\rho\det G_\tau)^2$. The subgroup $M=\bigoplus_a\mathcal O_E v_a$ corresponds to $\mathcal O_E^\rho$

embedded by $(\tau)_{\tau\in\Phi}$, of covolume $(2^{-|\Phi|}D_E^{1/2})^\rho$ for Lebesgue measure on $(\mathbb{C}^\Phi)^\rho$ (Minkowski). Hence

$$\mathrm{covol}_{\gamma_z}(M) = (2^{-|\Phi|}D_E^{1/2})^\rho \prod_{\tau\in\Phi} 2^\rho \det G_\tau = D_E^{\rho/2} \prod_{\tau\in\Phi} \det G_\tau,$$

and $\mathrm{covol}_{\gamma_z}(I) = \mathrm{covol}_{\gamma_z}(M)/\iota(I)$. Since $\det G_\tau$ equals the determinant in the definition of $\mathrm{N}_z^\phi(I)$ (the transposed Gram matrix), the identity follows.

Step 2: uniform comparison. Let $B \subseteq W'$ be a compact neighbourhood of z_0 and V its interior. By continuity of $z \mapsto \gamma_z$ and compactness of B times the unit sphere of γ_{z_0}, there is $C \geq 1$ with $\gamma_z \geq C^{-1}\gamma_{z_0}$ for $z \in B$. For a subgroup of rank n the Gram determinants then satisfy $\mathrm{covol}_{\gamma_z} \geq C^{-n/2}\mathrm{covol}_{\gamma_{z_0}}$ (for positive definite forms $A \geq B$ on $\mathbb{R}^n$, $\det A \geq \det B$). With $2m' = \mathrm{rk}_{\mathbb{Z}}\Lambda$ we have $n \leq 2m'$ and $\rho \leq m'$ (as $\mathrm{rk}_{\mathbb{Z}} I = 2|\Phi|\rho \leq 2m'$). So if $z \in V$ and $\mathrm{N}_z^\phi(I) \leq 1$, then by Step 1

$$\mathrm{covol}_{\gamma_{z_0}}(I) \leq C^{m'}\,\mathrm{covol}_{\gamma_z}(I) \leq C^{m'} D_E^{\rho/2} \leq T := C^{m'} D_E^{m'/2}.$$

Step 3: finiteness. For a saturated subgroup $I \neq 0$ of rank n with $\mathbb{Z}$-basis $e_1, \ldots, e_n$, the vector $\omega_I = e_1 \wedge \cdots \wedge e_n$ of the lattice $\bigwedge^n \Lambda$ is determined by I up to sign, its norm for the inner product induced by γ_{z_0} on $\bigwedge^n \Lambda_{\mathbb{R}}$ is $\mathrm{covol}_{\gamma_{z_0}}(I)$, and $I = \{v \in \Lambda : v \wedge \omega_I = 0\}$ ($v \wedge \omega_I = 0$ iff v lies in the real span of I, and Λ meets this span in I by saturation). A lattice has only finitely many vectors of norm at most T, and n takes finitely many values. Hence the set F of non-zero saturated isotropic $\mathcal{O}_E$-submodules I admitting a family with $\mathrm{covol}_{\gamma_{z_0}}(I) \leq T$ is finite, and by Step 2, $\mathrm{N}_z^\phi(I) > 1$ for every $z \in V$ and every such $I \notin F$. □

Lemma D.13. *Let a base setting of $\mathcal{T}$ at (B, Z) be given whose cover $\mathcal{X}$ is proper over $\mathcal{O}_F$, and let $h^{\mathrm{ref}'}$ be a smooth cone function of multidegree a^{H}. Put*

$$\varphi' = \log h^{\mathrm{H}} + \tfrac{1}{2}U - \log h^{\mathrm{ref}'} \quad \text{on } X^{\mathrm{b},\circ}, \qquad \theta = dd^c \log h^{\mathrm{ref}'}, \qquad \Theta = dd^c \log h'$$

(the last two the first Chern forms on X^{b}). Then there are $C \geq 0$, $0 < t_0 < 1$ and smooth functions $\psi_{t'}$ on X^{b} $(0 < t' \leq t_0)$ such that

(Rw1) $\theta + dd^c\psi_{t'} + \frac{C}{\log(1/t')}\Theta \geq 0$ *on* X^{b};

(Rw2) $\psi_{t'} \geq \varphi'$ *on* $X^{\mathrm{b},\circ}$ *and* $|\psi_{t'}| \leq C$ *on* X^{b};

(Rw3) $\psi_{t'}(w) \to \varphi'(w)$ *as* $t' \to 0^+$, *for every* $w \in X^{\mathrm{b},\circ}$.

If moreover φ' is invariant under complex conjugation, the $\psi_{t'}$ can be chosen invariant under complex conjugation.

Proof. Let X be the set of all complex points of $\mathcal{X}$ (over every embedding $\kappa\colon F \to \mathbb{C}$, as in (Gb1)) with its analytic structure, the disjoint union over the finitely many κ of the complex points of $\mathcal{X} \otimes_{\mathcal{O}_F,\kappa} \mathbb{C}$; as $\mathcal{X}$ is proper over $\mathcal{O}_F$, each of these is compact, hence so is X, so the continuous surjection $y_{\mathbb{C}}\colon X \to X^{\mathrm{b}}$ of (Gb1) is proper. Put $Y^\circ = y_{\mathbb{C}}^{-1}(X^{\mathrm{b},\circ})$; by (Gb1) it lies in the abelian locus, and $y_{\mathbb{C}}\colon Y^\circ \to X^{\mathrm{b},\circ}$ is proper and surjective, hence a closed map and a quotient map. We check the hypotheses of Lemma D.14 for X^{b}, Θ, θ, $Z = \partial X^{\mathrm{b}}$ and $\varphi = \varphi'$: X^{b} is a compact complex manifold (Hy1); Θ is a Kähler form, being closed, real and positive (Hy5); θ is a smooth closed real $(1,1)$-form ($h^{\mathrm{ref}'}$ is smooth); ∂X^{b} is a divisor with normal crossings, a closed analytic subset with empty interior. It remains to show that φ' is bounded and locally of the form (plurisubharmonic) $-q$ with $dd^c q = \theta$.

Step 1: the corrected weight in a chart. Let $z \in X$. By (Gb1), z lies in a chart c', and by (Gb3) in a principal open subset $D(f)$ of $\mathcal{X}_{c'}$ with a unit u_f and frames b_τ of $\mathcal{V}_{(\tau,-)}$ on $D(f)$; on the abelian locus these are holomorphic frames of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})^{\mathrm{an}}$, and the polynomial $\sigma_{c'} = \prod_k y_{k,c'_k}^{a^{\mathrm{H}}_k}$ of multidegree a^{H} does not vanish at the points of $y_{\mathbb{C}}(D(f)(\mathbb{C}))$ (they lie in the chart). On the open set $\{\sigma_{c'} \neq 0\} \subseteq X^{\mathrm{b}}$ put $q_{c'} = \log h^{\mathrm{ref}'} - \log|\sigma_{c'}| = -\log\|\sigma_{c'}\|_{h^{\mathrm{ref}'}}$, a smooth function (homogeneous of degree 0 on the cone) with $dd^c q_{c'} = \theta$, since $\log|\sigma_{c'}|$ is pluriharmonic where $\sigma_{c'} \neq 0$. For $z \in D(f)(\mathbb{C}) \cap Y^\circ$ and $w = y_{\mathbb{C}}(z)$, (Gb3) gives $\|\sigma_{c'}\|_{h^{\mathrm{H}}}(w) = |u_f(z)| \prod_\tau \det\Gamma(b_\tau(z))^{-1/2}$, i.e. $\log h^{\mathrm{H}} = \log|\sigma_{c'}| - \log|u_f(z)| + \frac{1}{2}\sum_\tau \log\det\Gamma(b_\tau(z))$, and therefore

$$\varphi'(w) + q_{c'}(w) = u(z) - \log|u_f(z)|, \qquad (*)$$

with $u = \frac{1}{2}\sum_\tau \log\det\Gamma(b_\tau) + \frac{1}{2}U \circ y_{\mathbb{C}}$ the function of Lemma D.10.

Step 2: boundedness. For $x \in X$ take $D(f) \ni x$ as in Step 1. By Lemma D.15 there are an open neighbourhood W'_x of x, which we may take relatively compact in $D(f)(\mathbb{C})$ with $\overline{y_{\mathbb{C}}(W'_x)} \subseteq \{\sigma_{c'} \neq 0\}$, and C_x with $|u| \leq C_x$ on W'_x in the abelian locus; as u_f is continuous and nowhere zero on $D(f)(\mathbb{C})$ and $q_{c'}$ is continuous near $\overline{y_{\mathbb{C}}(W'_x)}$, $|\log|u_f|| + |q_{c'} \circ y_{\mathbb{C}}| \leq C'_x$ on W'_x. Finitely many W'_x cover the compact X. Every $w \in X^{\mathrm{b},\circ}$ is $y_{\mathbb{C}}(z)$ for some $z \in Y^\circ$, and z lies in one of these W'_x; by $(*)$, $|\varphi'(w)| \leq A_0 := \max_x(C_x + C'_x)$.

Step 3: continuity. By $(*)$ and the continuity of u on the abelian locus (Lemma D.10), $\varphi' \circ y_{\mathbb{C}} = u - \log|u_f| - q_{c'} \circ y_{\mathbb{C}}$ is continuous on each $D(f)(\mathbb{C}) \cap Y^\circ$, hence on Y°; as $y_{\mathbb{C}} \colon Y^\circ \to X^{\mathrm{b},\circ}$ is a quotient map, φ' is continuous on $X^{\mathrm{b},\circ}$.

Step 4: plurisubharmonicity. The map y restricts to a birational morphism of the generic fibres onto $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ (Gb1), which is an isomorphism over a dense Zariski open subset; let $A \subseteq X^{\mathrm{b}}$ be the complex points of its complement, a nowhere dense closed analytic subset. Let $w_0 \in X^{\mathrm{b},\circ}$, choose $z_0 \in y_{\mathbb{C}}^{-1}(w_0)$ and a chart c' in which z_0 lies, so $\sigma_{c'}(w_0) \neq 0$, and let $N \ni w_0$ be a connected open subset of $X^{\mathrm{b},\circ} \cap \{\sigma_{c'} \neq 0\}$. Put $v = \varphi' + q_{c'}$ on N. On $N \smallsetminus A$, v is plurisubharmonic: let $w \in N \smallsetminus A$, z its unique preimage, and c'', $D(f'')$, $u_{f''}$, frames as in Step 1 for z; then $\sigma_{c''}(w) \neq 0$, and near w, by $(*)$ for c'', $v = (u - \log|u_{f''}|) \circ y_{\mathbb{C}}^{-1} + (q_{c'} - q_{c''})$, where $q_{c'} - q_{c''} = \log|\sigma_{c''}/\sigma_{c'}|$ is pluriharmonic where both polynomials (of the same multidegree) are non-zero; here $y_{\mathbb{C}}^{-1}$ is biholomorphic onto an open subset of the manifold $X \smallsetminus y_{\mathbb{C}}^{-1}(A)$, u is plurisubharmonic there (Lemma D.10) and $\log|u_{f''}|$ is pluriharmonic. Moreover v is continuous on N (Step 3) and bounded (Step 2). By the extension theorem, $v|_{N \smallsetminus A}$ extends to a plurisubharmonic function on N whose value at $a \in A \cap N$ is $\limsup_{x \to a,\, x \notin A} v(x) = v(a)$ (A nowhere dense, v continuous). So $v = \varphi' + q_{c'}$ is plurisubharmonic on N, with $q_{c'}$ smooth and $dd^c q_{c'} = \theta$; this is the local hypothesis of Lemma D.14 with $q = q_{c'}$.

Step 5. Lemma D.14 applies with the bound A_0 of Step 2 and gives C, t_0 and smooth $\psi_{t'}$ with (B1)–(B3), which are (Rw1)–(Rw3) ($\delta(t') = C/\log(1/t')$). Complex conjugation σ of $X^{\mathrm{b}} = \mathcal{X}^{\mathrm{b}}(\mathbb{C})$ is an antiholomorphic involution with $\sigma(\partial X^{\mathrm{b}}) = \partial X^{\mathrm{b}}$ (Hy1); cone functions are invariant under conjugation, so $\log h^{\mathrm{ref}'} \circ \sigma = \log h^{\mathrm{ref}'}$ and $\log h' \circ \sigma = \log h'$, whence $\sigma^*\theta = -\theta$ and $\sigma^*\Theta = -\Theta$ ($\sigma^*\partial\bar\partial = \bar\partial\partial\sigma^*$). If $\varphi' \circ \sigma = \varphi'$, the last assertion of Lemma D.14 gives invariant $\psi_{t'}$. □

Lemma D.14. *Let X be a compact complex manifold with a Kähler form Θ, θ a smooth closed real $(1,1)$-form on X, $Z \subseteq X$ a closed analytic subset with empty interior, $X^\circ = X \smallsetminus Z$, and $\varphi \colon X^\circ \to \mathbb{R}$ a function with $|\varphi| \leq A$ such that every point of X° has an open neighbourhood W and a smooth q on W with $dd^c q = \theta$ and $q + \varphi$ plurisubharmonic on W. Then there are $C \geq 0$, $0 < t_0 < 1$ and smooth functions ψ_t on X $(0 < t \leq t_0)$ such that, with $\delta(t) = C/\log(1/t)$:*

(B1) $\theta + dd^c\psi_t + \delta(t)\Theta \geq 0$ on X;

(B2) $\varphi \le \psi_t$ *on* X° *and* $|\psi_t| \le C$ *on* X*;*

(B3) $\psi_t(x) \to \varphi(x)$ *as* $t \to 0^+$*, for every* $x \in X^\circ$*.*

If moreover $\sigma\colon X \to X$ *is an antiholomorphic involution with* $\sigma(Z) = Z$*,* $\sigma^*\theta = -\theta$*,* $\sigma^*\Theta = -\Theta$ *and* $\varphi \circ \sigma = \varphi$*, the* ψ_t *can be chosen with* $\psi_t \circ \sigma = \psi_t$*.*

Proof. Write $\ell = \log(1/t)$; we take $t \le e^{-e}$, so $\ell \ge e$ and $t \le 1/\ell$ (as $t\ell \le 1/e$).

Step 1: charts. Every $p \in X$ has holomorphic coordinates w centred at p, defined on $\{|w| < 3r_p\}$ for some $r_p > 0$, on which there are smooth q, ψ with $dd^c q = \theta$, $dd^c\psi = \Theta$ (a closed real $(1,1)$-form on a polydisc is dd^c-exact). Put $\kappa_p = w/r_p$. By compactness finitely many of these, $\kappa_j\colon U_j \to \Delta_3$ $(1 \le j \le N)$ with potentials q_j of θ, satisfy $X = \bigcup_j U_j^1$, $U_j^r = \kappa_j^{-1}(\Delta_r)$. Let Q bound $|q_j|$ on $\kappa_j^{-1}(\bar\Delta_2)$ for all j, and put $A' = A + Q$.

Step 2: extension across Z*.* On $U_j \cap X^\circ$, $q_j + \varphi$ is plurisubharmonic: near each point it differs from $q + \varphi$ of the hypothesis by the pluriharmonic function $q_j - q$ (a real function with $dd^c = 0$). The set $Z_j = \kappa_j(Z \cap U_j)$ is a closed analytic subset of Δ_3 with empty interior, hence closed and pluripolar, and $(q_j + \varphi) \circ \kappa_j^{-1}$ is bounded above near it. By the removable singularity theorem of Grauert and Remmert ([145], Ch. 2) it extends to a plurisubharmonic function u_j on Δ_3, given on Z_j by $u_j(z) = \limsup_{y \to z,\, y \notin Z_j}(q_j + \varphi)(\kappa_j^{-1}y)$. Let $\tilde\varphi = \varphi$ on X° and $\tilde\varphi(x) = \limsup_{y \to x,\, y \in X^\circ} \varphi(y)$ on Z; then $|\tilde\varphi| \le A$, $u_j = (q_j + \tilde\varphi) \circ \kappa_j^{-1}$ on Δ_3, and $|u_j| \le A'$ on Δ_2.

Step 3: local regularisation. Let $M_j(z,r) = \max_{\bar\Delta(z,r)} u_j$ for $z \in \Delta_{5/4}$, $0 < r \le 1/2$; then $-A' \le M_j(z,r) \le A'$. Let $\Lambda > 1$ and $\ell \ge 2\log(2\Lambda)$. With $a = \log(t/\Lambda) < b = \log(\Lambda t) < c = \log(1/2)$ we have $b - a = 2\log\Lambda$ and $c - b \ge \ell/2$, and the convexity of $\sigma \mapsto M_j(z, e^\sigma)$ (Lemma 33.24(P1)) gives

$$M_j(z,\Lambda t) - M_j(z, t/\Lambda) \le (b-a)\frac{M_j(z,1/2) - M_j(z,\Lambda t)}{c-b} \le \frac{8A'\log\Lambda}{\ell}. \tag{1}$$

For $t \le 1/8$ put $u_{j,t} = u_j * \rho_t$ on $\Delta_{5/4}$. By Lemma 33.24(P2) it is smooth and plurisubharmonic with $u_j \le u_{j,t} \le M_j(\cdot,t)$; by (P3), (P1) and (1) for $\Lambda = 8$,

$$u_{j,t}(z) \ge M_j(z,2t) - K_\rho(M_j(z,2t) - M_j(z,t/4)) \ge M_j(z,t) - \frac{8K_\rho A'\log 8}{\ell}. \tag{2}$$

Step 4: comparison of charts. Put $f_{t,j} = u_{j,t} \circ \kappa_j - q_j$ on $U_j^{5/4}$: smooth, with $\theta + dd^c f_{t,j} \ge 0$ since $q_j + f_{t,j} = u_{j,t} \circ \kappa_j$ is plurisubharmonic. Let Λ_0, G, t_* be the constants of Lemma 33.26 for θ, the charts κ_j and the q_j; it applies to $\tilde\varphi$, which is bounded above. Let $t_0 \le \min(e^{-e}, 1/8, t_*)$ with $\log(1/t_0) \ge 2\log(16\Lambda_0)$. For $x \in U_j^{5/4} \cap U_k^{5/4}$ and $0 < t \le t_0$, by (2) for j and k, Lemma 33.26 and (1) for $\Lambda = \Lambda_0$ (if $\Lambda_0 = 1$ the oscillation is 0),

$$|f_{t,j}(x) - f_{t,k}(x)| \le \frac{16K_\rho A'\log 8}{\ell} + \frac{8A'\log\Lambda_0}{\ell} + 2G\Lambda_0 t \le \frac{C'}{\ell} =: \delta_0(t),$$

with $C' = 16K_\rho A'\log 8 + 8A'\log\Lambda_0 + 2G\Lambda_0 + 1$, using $t \le 1/\ell$. Moreover $t \le \delta_0(t)$.

Step 5: gluing and bounds. Let K be the constant of Lemma 33.25 for (X, Θ, θ) and the charts κ_j, and let F_t be the function of Lemma 33.25(G1) for $\delta = \delta_0(t)$ and $(f_{t,j})_j$. Then F_t is smooth, $\theta + dd^c F_t + K\delta_0(t)\Theta \ge 0$, and $f_{t,j} \le F_t \le f_{t,j} + 3\delta_0(t)$ on $U_j^{5/4}$. Let $x \in X$, $x \in U_j^1$, $z = \kappa_j x$. Then

$$\tilde\varphi(x) = u_j(z) - q_j(x) \le f_{t,j}(x) \le F_t(x) \le M_j(z,t) - q_j(x) + 3\delta_0(t),$$

so $-A \le F_t \le A' + Q + 3C'$, and $\varphi \le F_t$ on X°. By (P1), $M_j(z,t) \to u_j(z)$ as $t \to 0^+$, so $F_t(x) \to \tilde{\varphi}(x)$ for every $x \in X$, in particular $F_t \to \varphi$ on X°. With $C = \max(KC', A+2Q+3C')$ and $\psi_t = F_t$, (B1)–(B3) hold.

Step 6: the involution. Put $\psi_t = \frac{1}{2}(F_t + F_t \circ \sigma)$, smooth. As σ is antiholomorphic, $\sigma^* \partial = \bar{\partial} \sigma^*$, so $dd^c(F_t \circ \sigma) = -\sigma^* dd^c F_t$ and

$$\theta + dd^c(F_t \circ \sigma) + \delta(t)\Theta = -\sigma^*\big(\theta + dd^c F_t + \delta(t)\Theta\big) \ge 0,$$

because σ^* maps a semipositive real $(1,1)$-form $\sum i\alpha_k \wedge \bar{\alpha}_k$ (α_k of type $(1,0)$) to $\sum i\beta_k \wedge \bar{\beta}_k$ with $\beta_k = \sigma^* \alpha_k$ of type $(0,1)$, which is seminegative. Averaging keeps (B1). Since $\sigma(X^\circ) = X^\circ$ and $\varphi \circ \sigma = \varphi$: $\varphi(x) = \varphi(\sigma x) \le F_t(\sigma x)$, and $F_t(\sigma x) \to \varphi(\sigma x) = \varphi(x)$; so (B2), (B3) hold for ψ_t, and $\psi_t \circ \sigma = \psi_t$. □

Lemma D.15. *Let a base setting with cusp data be given, X a complex fibre of its cover, $x \in X$, W an open neighbourhood of x and b_τ ($\tau \in \Phi$) holomorphic frames of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})^{\mathrm{an}}$ on W, and let u be as in Lemma D.10. Then there are an open neighbourhood $W' \subseteq W$ of x and $C \ge 0$ with $|u| \le C$ on $W' \cap$ (abelian locus). (By (Gb3) this says that the corrected weight minus the logarithm of a smooth reference cone function is bounded near every point of X^{b}.)*

Proof. If x lies in the abelian locus, u is continuous near x by Lemma D.10, hence bounded on a neighbourhood. Let x lie outside the abelian locus. Choose a chart $t\colon V \to \Delta^d$ at x, $V \subseteq W$, as in Lemma 33.16, with $V^* = V \cap$ (abelian locus) $= \{t_1 \cdots t_a \ne 0\}$, $a \ge 1$, and put $L = 1 + \sum_{j \le a} |\log |t_j||$ on V^*.

Upper bound. By Lemma 33.17 (applied to each frame b_τ, of q sections linearly independent at x), $\Gamma(b_\tau(z)) \le C_1 I_q$ near x, so $\frac{1}{2}\sum_\tau \log\det\Gamma(b_\tau(z)) \le \frac{1}{2}|\Phi| q \log C_1$; by Lemma D.16, $U(y_{\mathbb{C}}(z)) \le C_2(1 + \log L(z))$ near x. Hence there are $0 < r < e^{-1}$ and C_4 with $\Delta_r = \{|t_j| < r \ \forall j\} \subseteq V$ and $u \le C_4(1 + \log L)$ on $\Delta_r \cap V^*$. Fix $0 < \rho < r$; the distinguished boundary $T_\rho = \{|t_j| = \rho \ \forall j\}$ is a compact subset of V^*, so $M_\rho = \max_{T_\rho} u$ is finite (u is continuous on V^*). For $\varepsilon > 0$ the function $v_\varepsilon = u + \varepsilon \sum_{j \le a} \log|t_j|$ is plurisubharmonic on $\Delta_r \cap V^*$ (Lemma D.10; $\log|t_j|$ is pluriharmonic there), and $v_\varepsilon \le C_4(1 + \log L) - \varepsilon(L-1)$ is bounded above on $\Delta_r \cap V^*$, since $\log L = o(L)$. By the extension theorem v_ε extends to a plurisubharmonic function on Δ_r, and by the maximum principle on $\bar{\Delta}_\rho$, for $z \in \Delta_\rho \cap V^*$,

$$u(z) + \varepsilon \sum_{j \le a} \log|t_j(z)| \ \le \ \max_{T_\rho} v_\varepsilon = \max_{T_\rho} u + \varepsilon\, a \log\rho \ \le \ M_\rho.$$

Letting $\varepsilon \to 0$ gives $u \le M_\rho$ on $\Delta_\rho \cap V^*$.

Lower bound. As x is not in the abelian locus, $G_{\mathcal{X},x}$ is not abelian, so its torus part has positive dimension and the vanishing cycles I at x (Lemma 33.18) are non-zero. By (Cu), $U(y_{\mathbb{C}}(z)) \ge -\log \mathrm{N}_z(I)$ on V^*, so $u(z) \ge \frac{1}{2}\log\big(\prod_\tau \det\Gamma(b_\tau(z))/\mathrm{N}_z(I)\big)$, which by (Cn) tends to $\frac{1}{2}\log\nu'$ ($\nu' > 0$) as $z \to x$ in V^*; so u is bounded below on $V'' \cap V^*$ for a neighbourhood V'' of x. With $W' = \Delta_\rho \cap V''$ both bounds hold. □

Lemma D.16. *In this setting put $L(z) = 1 + \sum_{j=1}^a |\log|t_j(z)||$ for $z \in V^*$. Then there are $C \ge 0$ and a neighbourhood V' of x such that*

$$U(y_{\mathbb{C}}(z)) \ \le \ C\,(1 + \log L(z)) \qquad (z \in V' \cap V^*).$$

Proof. **Step 1: the cusp weight by the first minimum.** Let $z \in V^*$ and $w = y_{\mathbb{C}}(z)$. By (Gb5) of Definition 31.11 the cusp lattice Λ_w is identified with $\Lambda_z = H_1(G_{\mathcal{X},z}(\mathbb{C}),\mathbb{Z}) \subset \mathrm{Lie}(G_{\mathcal{X},z})$, $\langle\cdot,\cdot\rangle_w$ with $\mathrm{Im}\, H_z$, and the cusp norm $\mathrm{N}_w(J)$ of a non-zero saturated isotropic $\mathcal{O}_E$-submodule J with $\frac{1}{\iota(J)}\prod_\tau \det\big(H_z((v_a^J)_{\sigma_\tau},(v_b^J)_{\sigma_\tau})\big)$ (since $\overline{\lambda_{w,\tau}(v)}^{\mathsf{T}}\lambda_{w,\tau}(v') = H_z(v'_{\sigma_\tau}, v_{\sigma_\tau})$ in orthonormal coordinates, and a hermitian matrix and its transpose have the same determinant). We apply Lemma D.3 with $V = \mathrm{Lie}(G_{\mathcal{X},z})$, $H = H_z$, the lattice Λ_z, the $\mathcal{O}_E$-action (adjoint for H_z to the conjugate action, by the Rosati condition of the polarisation), $\Psi = \{\sigma_\tau : \tau \in \Phi\}$, a CM type (its members are the $\kappa\circ\bar\tau = \overline{\kappa\circ\tau}$, κ the embedding of F over which z lies, and $\{\kappa\circ\tau : \tau\in\Phi\}$ is a CM type as Φ is one and κ is injective), with $\dim V_{\sigma_\tau} = q$, and to the family v^J of index $\iota(J)$ in J. It gives $-\log \mathrm{N}_w(J) \le fq(2\max(0,\log\frac{1}{\lambda_1(z)}) + \log(2fq\,\mathrm{rd}_E))$, $\lambda_1(z)^2 = \min\{H_z(\lambda,\lambda) : 0\neq\lambda\in\Lambda_z\}$, for every such J; hence, by (Hu2),

$$U(w) \le fq\Big(2\max\big(0,\log\tfrac{1}{\lambda_1(z)}\big) + \log(2fq\,\mathrm{rd}_E)\Big).$$

Step 2: Hodge norms of lattice vectors. For $\lambda\in\Lambda_z$ (a real vector of $\Lambda_z\otimes\mathbb{C}$) write $\lambda = f_0 + g_0$ with $f_0\in\mathcal{F}_z^0$ and $g_0\in\overline{\mathcal{F}_z^0}$, the h-orthogonal complement of $\mathcal{F}_z^0$; then $g_0 = \overline{f_0}$, $h(f_0,f_0) = h(g_0,g_0)$, and λ and g_0 have the same image λ in $\mathrm{Lie}(G_{\mathcal{X},z})$, so $|\lambda|_t^2 = h(\lambda,\lambda) = 2h(g_0,g_0) = H_z(\lambda,\lambda)$. So $\lambda_1(z)^2$ is the minimum of the Hodge norms $|\lambda|_t^2$ over the non-zero integral vectors.

Step 3: the lower bound $\lambda_1(z)^2 \ge c\,L(z)^{-4}$. Identify V with Δ^d by t, put $y_j = -\log|t_j|$ and choose a neighbourhood with $|t_j|\le e^{-1}$, so $y_j\ge 1$. For each numbering $(j_1,\dots,j_a)$ the filtrations $W(\nu)$ of Theorem B.147 form a distributive family of filtrations of the constant space $H = H_{\mathbb{Z}}\otimes\mathbb{C}$, so they have a common splitting $H = \bigoplus_p U_p$ (linear algebra of distributive families); it is constant, hence a C^∞ splitting of $\widehat{\mathcal{H}}$ in the canonical frame $\tilde s$; let $\|\cdot\|$ be the hermitian norm making the frame $\tilde s$ orthonormal. As $N'_\nu = N_{j_1}+\cdots+N_{j_\nu}$ has square 0, $W(\nu)$ has at most three non-zero graded pieces, with consecutive indices $c_\nu-1, c_\nu, c_\nu+1$ for its centre $c_\nu\in\{-1,0\}$; so every index p_ν occurring is ≥ -2. Apply Theorem B.147 with $\varepsilon = \frac12$ to each of the finitely many numberings, and take the largest constant C_1 and the intersection V_1 of the neighbourhoods. For $t\in V_1\cap V^*$ choose the numbering with $y_{j_1}\le\cdots\le y_{j_a}$ (so the ratios $y_{j_\nu}/y_{j_{\nu-1}}\ge 1 > \varepsilon$); every factor of $m_p(t)$ has base ≥ 1 and exponent ≥ -2, so $m_p(t)\ge y_{j_1}^{-2}\prod_{\nu\ge2}(y_{j_\nu}/y_{j_{\nu-1}})^{-2} = y_{j_a}^{-2}\ge L(t)^{-2}$, and, with $c_2>0$ such that $\sum_p\|u_p\|^2\ge c_2\|u\|^2$ for the finitely many constant splittings,

$$|u|_t^2 \;\ge\; C_1^{-1}L(t)^{-2}\sum_p\|u_p\|^2 \;\ge\; C_1^{-1}c_2\,L(t)^{-2}\|u\|^2 \qquad (u\in\widehat{\mathcal{H}}_t).$$

Let $0\neq\lambda\in\Lambda_t$, a flat section on a slit neighbourhood; on the branch with $0\le\mathrm{Re}\,z_j<1$, $z_j = \frac{\log t_j}{2\pi i}$, $\lambda = \sum_k c_k s_k$ with $c\in\mathbb{Z}^{2g}\smallsetminus\{0\}$ in a flat $\mathbb{Z}$-basis s of $H_{\mathbb{Z}}$, and $s_k = \exp(\sum_j z_jN_j)\tilde s_k$. Since $N_iN_j = 0$ for all i,j ($N_\kappa^2=0$ for every κ and the N_j commute), $\exp(-\sum_j z_jN_j) = 1-\sum_j z_jN_j$ has operator norm at most $1+C_2\sum_j|z_j|\le C_3L(t)$ in the coordinates of $\tilde s$, as $|z_j|\le 1+y_j/(2\pi)$. Hence $\|\lambda\|\ge|c|/(C_3L(t))\ge 1/(C_3L(t))$, and

$$\lambda_1(t)^2 \;\ge\; C_1^{-1}c_2C_3^{-2}\,L(t)^{-4}.$$

Step 4. By Steps 1 and 3, on $V' = V_1$, $2\max(0,\log\frac{1}{\lambda_1}) \le \max\big(0, 4\log L + \log(C_1C_3^2/c_2)\big)$, and $U(y_{\mathbb{C}}(z))\le C(1+\log L(z))$ with $C = fq\big(4+\log^+(C_1C_3^2/c_2)+\log(2fq\,\mathrm{rd}_E)\big)$. □

Lemma D.17. *Let a Hodge-type base setting with cusp data be given; put $\Theta = dd^c\log h'$ (a Kähler form on X^{b} by (Hy5)), $\theta = dd^c\log h^{\mathrm{ref}}$ and $\varphi = \log(h^{\mathrm{H}}/h^{\mathrm{ref}})$ on $X^{\mathrm{b},\circ}$. Suppose:*

(i) *there is a holomorphic section ς of a smooth hermitian line bundle on X^{b} with $\|\varsigma\| \le 1$ whose zero divisor has simple normal crossings and support ∂X^{b}; put* $\mathrm{rW} = e - 2\log\|\varsigma\|$ *on $X^{\mathrm{b},\circ}$;*

(ii) *φ is smooth on $X^{\mathrm{b},\circ}$, and there are $C \ge 1$, $0 < t_0 < 1$ and functions $\delta, \varepsilon\colon (0,t_0] \to [0,\infty)$, $R\colon (0,t_0] \to [e,\infty)$ with $\delta(t), \varepsilon(t) \to 0$, $R(t) \to \infty$ as $t \to 0^+$, such that $u = \varphi$, $u_t = \varphi_t$ satisfy (R2)–(R5) and $\theta + dd^c\varphi_t + \varepsilon(t)\Theta \ge 0$ on X^{b} for $0 < t \le t_0$;*

(iii) *U is continuous on $X^{\mathrm{b},\circ}$ and $U \le C \log \mathrm{rW}$ there;*

(iv) *$|\psi_{t'}| \le C$ on X^{b} for small $t' > 0$, and $\psi_{t'} \to \varphi' = \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ pointwise on $X^{\mathrm{b},\circ}$ as $t' \to 0^+$.*

Then for every integer B: the limit self-intersection $\mathrm{ar}^{\mathrm{b}}(B)$ *exists and the setting has (Mz1), (Mz2), (Mz3) at B. Moreover $(\omega^{\mathrm{H}})^e$ and $U(\omega^{\mathrm{H}})^e$ are integrable on $X^{\mathrm{b},\circ}$, $\int_{X^{\mathrm{b},\circ}}(\omega^{\mathrm{H}})^e = \deg^{\mathrm{H}}$, and if $\deg^{\mathrm{H}} \ne 0$ the setting has regularisation limits (Mz1)–(Mz4) at B.*

Proof. Write $X = X^{\mathrm{b}}$, $X^\circ = X^{\mathrm{b},\circ}$; ∂X is the zero set of ς, a proper analytic subset, hence null. $X = \mathcal{X}^{\mathrm{b}}(\mathbb{C})$ for the arithmetic variety $\mathcal{X}^{\mathrm{b}}$ (closed integral in a multiprojective space, flat over $\mathbb{Z}$, of dimension $e+1$, smooth generic fibre: (Hy1)), and $e \ge 1$.

Step 0: the regularisation data. Let $I = \{\mathrm{H}, \mathrm{A}\}$ with

$$(\theta_{\mathrm{H}}, u_{\mathrm{H}}, u_{\mathrm{H},t}) = (\theta, \varphi, \varphi_t), \qquad (\theta_{\mathrm{A}}, u_{\mathrm{A}}, u_{\mathrm{A},t}) = (\Theta, 0, 0).$$

Shrinking t_0 so that $\varepsilon \le 1 \le C$ on $(0,t_0]$, (R1) holds for H by (ii), and for A as $\Theta \ge 0$; (R2)–(R5) hold by (ii), resp. trivially (as $\mathrm{rW} \ge e$). The φ_t are invariant under complex conjugation (Hy4). On the cone over X, $h^0_{\mathrm{H}} = h^{\mathrm{ref}} \prod_{\ell \in S_B} |g_\ell|$ is a smooth cone function of multidegree a^{H}_B, invariant under conjugation (h^{ref} is a cone metric and the g_ℓ are quotients of polynomials with rational coefficients), with $c_1 = \theta$; and h' is one of multidegree a' with $c_1 = \Theta$. The metric of $\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}$ is $h^0_{\mathrm{H}} e^{\varphi_t}$, that of $\overline{\mathcal{N}}_{B,i_1,i_2,t}$ is $(h^0_{\mathrm{H}})^{i_2} h'^{i_1} e^{i_2\varphi_t}$, with first Chern forms $\theta + dd^c\varphi_t$ and $i_2(\theta + dd^c\varphi_t) + i_1\Theta$. On X°, $\omega^{\mathrm{H}} = dd^c \log h^{\mathrm{H}} = \theta + dd^c\varphi$.

Step 1: mixed limits and $\mathrm{ar}^{\mathrm{b}}(B)$. For $0 \le k \le e+1$ apply Lemma D.18 with $D = e$, the data of Step 0, $\mathcal{M}_1 = \cdots = \mathcal{M}_{e+1-k} = \mathcal{O}(a^{\mathrm{H}}_B)|_{\mathcal{X}^{\mathrm{b}}}$ with h^0_{H} and $n = (1,0)$, and $\mathcal{M}_{e+2-k} = \cdots = \mathcal{M}_{e+1} = \mathcal{O}(a')|_{\mathcal{X}^{\mathrm{b}}}$ with h' and $n = (0,1)$: the limit

$$L_k = \lim_{t \to 0^+} \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{H}}^{\mathrm{b}}_{B,t})^{e+1-k} \widehat{c}_1(\overline{\mathcal{A}}')^k)$$

exists. In particular $\mathrm{ar}^{\mathrm{b}}(B) = L_0$ exists.

Step 2: (Mz1). For $1 \le i_1 \le i_2$, $c_1(\overline{\mathcal{N}}_{B,i_1,i_2,t}) = i_2(\theta + dd^c\varphi_t + \varepsilon(t)\Theta) + (i_1 - i_2\varepsilon(t))\Theta \ge 0$ as soon as $\varepsilon(t) \le i_1/i_2$, which holds for $0 < t \le t_1$ with some $t_1 > 0$ since $\varepsilon(t) \to 0$.

Step 3: (Mz3). Since $\widehat{c}_1(\overline{\mathcal{N}}_{B,i_1,i_2,t}) = i_2\widehat{c}_1(\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}) + i_1\widehat{c}_1(\overline{\mathcal{A}}')$, multilinearity gives

$$\mathrm{tN}(i_1,i_2,t) = \sum_{k=0}^{e+1} \binom{e+1}{k} \Big(\frac{i_1}{i_2}\Big)^k \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{H}}^{\mathrm{b}}_{B,t})^{e+1-k} \widehat{c}_1(\overline{\mathcal{A}}')^k)$$

$$\longrightarrow \mathrm{tN}^\infty(i_1,i_2) = \sum_{k=0}^{e+1} \binom{e+1}{k} \Big(\frac{i_1}{i_2}\Big)^k L_k.$$

With $\omega_t = \theta + dd^c\varphi_t + \frac{i_1}{i_2}\Theta$ and $\omega_\infty = \omega^{\mathrm{H}} + \frac{i_1}{i_2}\Theta$ on X°, $\omega_t^e = \sum_k \binom{e}{k}(\frac{i_1}{i_2})^k (\theta + dd^c\varphi_t)^{e-k} \wedge \Theta^k$, each term a form μ_t of Lemma 31.35 for the data of Step 0 (indices H and A), with limit form

$\mu = (\omega^{\mathrm{H}})^{e-k} \wedge \Theta^k$. By (iii), $g_t = g = \frac{1}{2}U$ is continuous with $|g| \le C \log \mathrm{rW}$ ($U \ge 0$), so Lemma 31.35(2) gives $V^{\mathrm{b}}(t) = \int_{X^\circ} \frac{1}{2}U\,\omega_t^e \to V^{\mathrm{b},\infty}(i_1,i_2) = \int_{X^\circ} \frac{1}{2}U\,\omega_\infty^e$, the latter absolutely convergent by Lemma 31.35(1) ($\frac{1}{2}U \le C \log \mathrm{rW}$). (That $V^{\mathrm{b}}(t)$ exists is shown in Step 4.)

Step 4: (Mz2). Fix $1 \le i_1 \le i_2$ and $0 < t \le t_0$ with $c_1(\overline{\mathcal{N}}_{B,i_1,i_2,t}) \ge 0$, so that ω_t^e is a positive smooth measure on the compact X, of finite mass. $V^{\mathrm{b}}(t)$ exists: $0 \le \frac{1}{2}U \le C \log \mathrm{rW}$, $\omega_t^e \le c\,\Theta^e$ for some c (a smooth top form on a compact manifold), and $(\log \mathrm{rW})\Theta^e$ is integrable by Lemma 31.35(1) (index A only). The integrand of $I(t,t')$ is $F_{t'} = \log(h^{\mathrm{ref}'}/h^{\mathrm{ref}}) + \psi_{t'} - \varphi_t$, a function on X (equal multidegrees), with $|F_{t'}| \le \max_X |\log(h^{\mathrm{ref}'}/h^{\mathrm{ref}})| + C + \max_X |\varphi_t|$ independent of t' (continuous functions on the compact X), and by (iv), on X°, $F_{t'} \to \log(h^{\mathrm{ref}'}/h^{\mathrm{ref}}) + \varphi' - \varphi_t = \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}} - \varphi_t$, the integrand of $V(t)$, which is therefore bounded by the same constant. As ∂X is null, dominated convergence gives that $V(t)$ exists and $I(t,t') \to V(t)$ as $t' \to 0^+$. Finally the integrand of $V(t)$ minus that of $V^{\mathrm{b}}(t)$ is $\varphi - \varphi_t \le 0$ by (R2), and $\omega_t^e \ge 0$, so $V(t) \le V^{\mathrm{b}}(t)$. This holds with $t_2 = t_0$.

Step 5: the Hodge mass and (Mz4). Lemma 31.35(1) with the index H taken e times gives that $(\omega^{\mathrm{H}})^e$ and $(\log \mathrm{rW})(\omega^{\mathrm{H}})^e$ are absolutely integrable on X°, hence so is $U(\omega^{\mathrm{H}})^e$ by (iii), and $\int_{X^\circ}(\omega^{\mathrm{H}})^e = \int_X \theta^e = \deg(c_1(\mathcal{O}(a^{\mathrm{H}}))^e \cap [\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}]) = \deg^{\mathrm{H}}$ (θ represents the first Chern class of $\mathcal{O}(a^{\mathrm{H}})$ on the complex points of $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$). By Step 3 with $(i_1,i_2) = (1,m)$, $\mathrm{tN}^\infty(1,m) = \sum_k \binom{e+1}{k} m^{-k} L_k \to L_0 = \mathrm{ar}^{\mathrm{b}}(B)$ as $m \to \infty$, and

$$V^{\mathrm{b},\infty}(1,m) = \sum_{k=0}^{e} \binom{e}{k} m^{-k} \int_{X^\circ} \tfrac{1}{2}U\,(\omega^{\mathrm{H}})^{e-k} \wedge \Theta^k \longrightarrow \tfrac{1}{2}\int_{X^\circ} U\,(\omega^{\mathrm{H}})^e,$$

each integral being absolutely convergent by Lemma 31.35(1) and (iii). If $\deg^{\mathrm{H}} \ne 0$, then, U being integrable for $(\omega^{\mathrm{H}})^e$, the correction mean is $\mathrm{m}^{\mathrm{b}} = \frac{1}{\deg^{\mathrm{H}}}\int_{X^\circ} U(\omega^{\mathrm{H}})^e$ (Definition 31.12), so the limit is $\frac{1}{2}\mathrm{m}^{\mathrm{b}} \deg^{\mathrm{H}}$: this is (Mz4). □

Lemma D.18. *Let $\mathcal{X}$ be an arithmetic variety (an integral scheme, projective and flat over $\mathbb{Z}$) of dimension $D+1$, $D \ge 1$, with $\mathcal{X}_{\mathbb{Q}}$ smooth, and let $X = \mathcal{X}(\mathbb{C})$ carry a Kähler form Θ and data ς, ∂X, X°, rW as in Lemma 31.35. Let I be a finite set, $0 < t_0 < 1$, and let θ_i, u_i, $u_{i,t}$ ($i \in I$, $0 < t \le t_0$) satisfy (R1)–(R5) of Lemma 31.35 for some $C \ge 1$ and functions δ, R as there, with every $u_{i,t}$ invariant under complex conjugation. Let $\mathcal{M}_1, \dots, \mathcal{M}_{D+1}$ be line bundles on $\mathcal{X}$ with smooth metrics h_k^0 invariant under complex conjugation, and $n_{k,i} \in \mathbb{Z}$ with $c_1(\mathcal{M}_k, h_k^0) = \alpha_k := \sum_{i\in I} n_{k,i}\theta_i$. Put $w_{k,t} = \sum_i n_{k,i}u_{i,t}$, $w_k = \sum_i n_{k,i}u_i$, $h_k(t) = h_k^0 e^{w_{k,t}}$ and $\alpha_k^\infty = \sum_i n_{k,i}(\theta_i + dd^c u_i)$ on X°. Then for every l the form $w_l \bigwedge_{k<l} \alpha_k^\infty \wedge \bigwedge_{k>l} \alpha_k$ is absolutely integrable on X°, and*

$$\lim_{t\to 0^+} \widehat{\deg}\Big(\prod_{k=1}^{D+1} \widehat{c}_1(\mathcal{M}_k, h_k(t))\Big) = \widehat{\deg}\Big(\prod_{k=1}^{D+1} \widehat{c}_1(\mathcal{M}_k, h_k^0)\Big) + \sum_{l=1}^{D+1} \int_{X^\circ} w_l \bigwedge_{k<l} \alpha_k^\infty \wedge \bigwedge_{k>l} \alpha_k.$$

In particular the limit exists.

Proof. Step 0: fixed forms as regularised data. For every $i \in I$ add an index i^0 with $\theta_{i^0} = \theta_i$ and $u_{i^0} = u_{i^0,t} = 0$, and let $I' = I \sqcup \{i^0 : i \in I\}$. As X is compact and Θ positive definite, there is $C_1 \ge C$ with $\theta_i + C_1\Theta \ge 0$ for all $i \in I$. Then the data indexed by I' satisfy (R1)–(R5) with C_1, δ, R: for $i \in I$, (R1) holds as $C_1\Theta - C\Theta \ge 0$ and (R2) as $C \le C_1$; for i^0, (R1) is the choice of C_1, (R2) reads $-C_1 \log \mathrm{rW} \le 0 \le 0 \le C_1$, true as $\mathrm{rW} \ge e$, and (R3)–(R5) are trivial.

Step 1: telescoping. Fix $0 < t \le t_0$ and put $\alpha_{k,t} = \sum_i n_{k,i}(\theta_i + dd^c u_{i,t}) = c_1(\mathcal{M}_k, h_k(t))$, a smooth form on X. For $0 \le l \le D+1$ let $A_l(t)$ be the arithmetic intersection number of the $\widehat{c}_1(\mathcal{M}_k, h_k(t))$ for $k \le l$ and the $\widehat{c}_1(\mathcal{M}_k, h_k^0)$ for $k > l$ (all metrics smooth and invariant

under conjugation, as the $u_{i,t}$ are); $A_0(t)$ does not depend on t, and $A_{D+1}(t)$ is the number in the statement. $A_l(t)$ and $A_{l-1}(t)$ differ only in the metric of $\mathcal{M}_l$, so by symmetry and the change-of-metric formula

$$A_l(t) - A_{l-1}(t) = \int_X w_{l,t}\ \beta_{l,t}, \qquad \beta_{l,t} = \bigwedge_{k<l} \alpha_{k,t} \wedge \bigwedge_{k>l} \alpha_k.$$

Step 2: expansion. By multilinearity, $w_{l,t}\beta_{l,t}$ is a finite sum, with integer coefficients independent of t (products of the $n_{k,i}$), of terms $u_{j,t}\,\mu_{\underline{i},t}$ with $j \in I$, $\underline{i} = (i_1, \dots, i_D) \in I'^D$ (indices in I for the factors $k < l$, indices i^0 for the factors $k > l$) and $\mu_{\underline{i},t} = \bigwedge_s(\theta_{i_s} + dd^c u_{i_s,t})$. The same expansion with $u_{j,t}, u_{i,t}$ replaced by u_j, u_i writes $w_l \bigwedge_{k<l} \alpha_k^\infty \wedge \bigwedge_{k>l} \alpha_k$ as the same combination of the terms $u_j\,\mu_{\underline{i}}$, $\mu_{\underline{i}} = \bigwedge_s(\theta_{i_s} + dd^c u_{i_s})$ on X°. The boundary ∂X, the zero set of ς, is a proper analytic subset and null, so $\int_X = \int_{X^\circ}$ for the smooth forms of Step 1.

Step 3: the limit. By (R2), $-C_1 \log \mathrm{rW} \le u_j \le u_{j,t} \le C_1 \le C_1 \log \mathrm{rW}$ on X°, so $|u_{j,t}|, |u_j| \le C_1 \log \mathrm{rW}$; by (R5), $u_{j,t} \to u_j$ uniformly on compact subsets of X°, and all are continuous there. By Lemma 31.35(1) for the data indexed by I' (with $D_v = \varnothing$), $(\log \mathrm{rW})\,\mu_{\underline{i}}$ is absolutely integrable on X°, hence so is $u_j\mu_{\underline{i}}$, which proves the integrability claim. By Lemma 31.35(2) with $g_t = u_{j,t}$, $g = u_j$, $C' = C_1$, $\int_{X^\circ} u_{j,t}\,\mu_{\underline{i},t} \to \int_{X^\circ} u_j\,\mu_{\underline{i}}$ as $t \to 0^+$. Summing the finitely many terms, $A_l(t) - A_{l-1}(t) \to \int_{X^\circ} w_l \bigwedge_{k<l} \alpha_k^\infty \wedge \bigwedge_{k>l} \alpha_k$ for every l, and $A_{D+1}(t) = A_0 + \sum_{l=1}^{D+1}(A_l(t) - A_{l-1}(t))$ converges to the stated value. □

D.1.3 The base slope identity

Proposition D.19 identifies the arithmetic degree of the test class on the root model with a slope of the base setting, which is clause (Bs1) of the base slope settings. The proof places the stage root model and a base setting joined to it on a common model (Lemma D.20) and compares the two families of metrics there with the one-model comparison of Section 31 (Lemma 31.34).

Proposition D.19. *Let* $\mathfrak{u}$, $\mathcal{Y}$ *and the root tower* $\mathcal{T}$ *of type* (Φ, n, p) *with its geometric realisation* $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ *and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2, and let* $\mathcal{T}'$ *be a root tower of type* (Φ, n, p) *with the components and the bad primes of* $\mathcal{T}$ *such that* $\widehat{\deg}'_{B,Z}(F) = \mathrm{pp}(\mathcal{X}_{B,Z}; F)$ *for every integer* $B \ge 2$, *every* $Z \in \mathrm{Cp}$ *and every* $F \in \mathcal{R}$, *where* $\widehat{\deg}'$ *are the arithmetic degrees of* $\mathcal{T}'$, *and such that* $\mathcal{T}'$ *with the geometric realisation of* $\mathcal{T}$ *has (Gi1). Let* B *be an admissible stage,* $Z \in \mathrm{Cp}$, *and let a base setting of* $\mathcal{T}$ *at* (B, Z) *be given which is joined to the stage root model, satisfies the hypotheses (i) and (ii) of Lemma 34.36, and whose limit self-intersection* $\mathrm{ar}^{\mathrm{b}}(B)$ *exists. Then* $\deg^{\mathrm{H}} > 0$, *so (Bs0) holds, and the setting satisfies the slope identity (Bs1) for* $\mathcal{T}'$ *at* (B, Z).

Proof. Let B be an admissible stage, $Z \in \mathrm{Cp}$, and fix a base setting as in the statement, with cover $\mathcal{X}$, base variety $\mathcal{X}^{\mathrm{b}}$ and $e = |\Phi|pq$. The type is (Φ, n, p), so the cut is $\kappa = p$ and $D^{\mathrm{gr}} = e$; as $q \le p$ (Definition 31.11), $n - \kappa \le \kappa$ and $\mathrm{pl} = \sum_{\tau\in\Phi} \sum_{i=p+1}^{n} x_{\tau,i}$. Let $r_0 = D - e = |\Phi|(p(p-1) + q(q-1))/2$ and write $\mathrm{fb} = \prod_{j=1}^{r_0} \ell_j$ with $\ell_j = x_{\tau_j,i'_j} - x_{\tau_j,i_j}$ the factors of the fibre class. Write $\mathcal{X}_1 = \mathcal{X}_{B,Z}$, $\delta_1 = \delta_{\mathcal{X}_1}$, $h_r(t)$ for its root metrics. The hypothesis on $\mathcal{T}'$ refers to $\mathrm{pp}(\mathcal{X}_1; \cdot)$, so $\mathcal{X}_1$ has convergent regularisation and $\mathrm{pp}(\mathcal{X}_1; F) = \lim_{t\to 0^+} \mathrm{ai}_t(\mathcal{X}_1; F)$ for every $F \in \mathcal{R}$ (a finite combination of monomials).

Step 1: $\deg^{\mathrm{H}} > 0$. By Lemma D.2, $0 < \int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e < \infty$; by Lemma 34.36 (hypotheses (i), (ii)) this integral equals $\deg^{\mathrm{H}}$. So $\deg^{\mathrm{H}} > 0$, and with the existence of $\mathrm{ar}^{\mathrm{b}}(B)$ this is (Bs0).

Step 2: the common model. Take $\widetilde{\mathcal{X}}$, p_1, e_1, β, W, λ, t_0, $\mathcal{M}_{\mathrm{pl}}$ with $h^{(1)}(t)$, $h^{(2)}(t)$ and the complex data of Lemma D.20. For $1 \le j \le r_0$ let $\mathcal{N}_j = p_1^*(\mathcal{O}(e_{(\tau_j,i'_j)} - e_{(\tau_j,i_j)})|_{\mathcal{X}_1})$ with the

metric $h_{\mathcal{N}_j}(t) = p_1^*\big(h_{(\tau_j,i'_j)}(t)/h_{(\tau_j,i_j)}(t)\big)$, and $\overline{\mathcal{N}}_j(t) = (\mathcal{N}_j, h_{\mathcal{N}_j}(t))$. By part 1 of Lemma D.20 and additivity of first Chern forms, $\mathcal{N}_j$ with $h^{(1)} = h^{(2)} = h_{\mathcal{N}_j}(t)$ satisfies hypothesis 1 of Lemma 31.34 (integer coefficients, independent of t), and hypothesis 2 with $g = 0$.

Step 3: the test class on the common model. Let $0 < t \le t_0$. Expanding $\mathrm{pl}^{e+1}\mathrm{fb}$ (homogeneous of degree $e + 1 + r_0 = D + 1$) into monomials and using multilinearity and additivity of $\widehat{c}_1$,

$$\delta_1\,\mathrm{ai}_t(\mathcal{X}_1;\mathrm{pl}^{e+1}\mathrm{fb}) = \widehat{\deg}\Big(\widehat{c}_1\big(\mathcal{O}(e_{\mathrm{pl}}), h_{\mathrm{pl}}(t)\big)^{e+1}\prod_{j=1}^{r_0}\widehat{c}_1\big(\mathcal{O}(e_{(\tau_j,i'_j)} - e_{(\tau_j,i_j)}), h_{(\tau_j,i'_j)}(t)/h_{(\tau_j,i_j)}(t)\big)\Big)$$

on $\mathcal{X}_1$, with e_{pl}, $h_{\mathrm{pl}}(t)$ as in Lemma D.20. The $D+1$ hermitian line bundles in this product have smooth metrics (cone metrics restricted to $\mathcal{X}_1$), and their pull-backs by p_1 are $(\mathcal{M}_{\mathrm{pl}}, h^{(1)}(t))$ and the $\overline{\mathcal{N}}_j(t)$. Apply Lemma 30.13 with $b = D + 1$, $d = 0$ and the morphism $p_1\colon \widetilde{\mathcal{X}}$ and $\mathcal{X}_1$ are arithmetic varieties of absolute dimension $D + 1$ with smooth generic fibres (Lemma D.20, and Lemma 31.37 for the component Z), and p_1 is surjective and generically finite of degree $e_1 = [\mathbf{k}(\widetilde{\mathcal{X}}) : \mathbf{k}(\mathcal{X}_1)]$ (Lemma D.20). Hence

$$e_1\delta_1\,\mathrm{ai}_t(\mathcal{X}_1;\mathrm{pl}^{e+1}\mathrm{fb}) = \widehat{\deg}\Big(\widehat{c}_1\big(\mathcal{M}_{\mathrm{pl}}, h^{(1)}(t)\big)^{e+1}\prod_j\widehat{c}_1\big(\overline{\mathcal{N}}_j(t)\big)\Big). \tag{A}$$

Step 4: replacement in the limit. Apply Lemma 31.34 on $\widetilde{\mathcal{X}}$ (dimension $D + 1$, smooth generic fibre) with the data of Lemma D.20, $\pi = \mathrm{id}$, $d = 1$, and the $D + 1$ line bundles $\mathcal{M}_1 = \cdots = \mathcal{M}_{e+1} = \mathcal{M}_{\mathrm{pl}}$ with the families $h^{(1)}(t)$, $h^{(2)}(t)$ (part 2 of Lemma D.20) and $\mathcal{M}_{e+1+j} = \mathcal{N}_j$ with both families equal to $h_{\mathcal{N}_j}(t)$ (Step 2). It gives

$$\lim_{t\to 0^+}\Big(\widehat{\deg}\Big(\widehat{c}_1\big(\mathcal{M}_{\mathrm{pl}}, h^{(1)}(t)\big)^{e+1}\prod_j\widehat{c}_1\big(\overline{\mathcal{N}}_j(t)\big)\Big) - \widehat{\deg}\Big(\widehat{c}_1\big(\mathcal{M}_{\mathrm{pl}}, h^{(2)}(t)\big)^{e+1}\prod_j\widehat{c}_1\big(\overline{\mathcal{N}}_j(t)\big)\Big)\Big) = 0.$$

By the definition of $h^{(2)}(t)$, λ is an isometry from $(\mathcal{M}_{\mathrm{pl}}, h^{(2)}(t))$ onto $\beta^*\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}$, so the second term is $\widehat{\deg}(\widehat{c}_1(\beta^*\overline{\mathcal{H}}^{\mathrm{b}}_{B,t})^{e+1}\prod_j\widehat{c}_1(\overline{\mathcal{N}}_j(t)))$.

Step 5: the arithmetic factor on the base. Let $\widetilde{\mathcal{X}}_\eta$ be the fibre of β over the generic point η of $\mathcal{X}^{\mathrm{b}}$, and

$$c = \deg\big(c_1(\mathcal{N}_1|_{\widetilde{\mathcal{X}}_\eta})\cdots c_1(\mathcal{N}_{r_0}|_{\widetilde{\mathcal{X}}_\eta})\cap[\widetilde{\mathcal{X}}_\eta]\big) \in \mathbb{Z},$$

which does not depend on t. Apply Lemma 30.13 with $b = e + 1$, $d = r_0$ and the morphism β: $\widetilde{\mathcal{X}}$ is an arithmetic variety of absolute dimension $D + 1 = b + d$ with smooth generic fibre and β is a morphism to $\mathcal{X}^{\mathrm{b}}$ (Lemma D.20), an arithmetic variety of absolute dimension $e + 1 = b$ with smooth generic fibre ((Hy1)); $\overline{\mathcal{H}}_1 = \cdots = \overline{\mathcal{H}}_{e+1} = \overline{\mathcal{H}}^{\mathrm{b}}_{B,t}$ has a smooth metric ((Hy4)), and $\overline{\mathcal{L}}_j = \overline{\mathcal{N}}_j(t)$ $(1 \le j \le r_0)$ have smooth metrics (pull-backs by p_1 of quotients of cone metrics). It gives

$$\widehat{\deg}\Big(\widehat{c}_1(\beta^*\overline{\mathcal{H}}^{\mathrm{b}}_{B,t})^{e+1}\prod_j\widehat{c}_1\big(\overline{\mathcal{N}}_j(t)\big)\Big) = c\,\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{H}}^{\mathrm{b}}_{B,t})^{e+1}).$$

So the second term of Step 4 tends to $c\,\mathrm{ar}^{\mathrm{b}}(B)$ as $t \to 0^+$ (the limit exists by hypothesis). With (A) and Step 4,

$$e_1\delta_1\,\mathrm{pp}(\mathcal{X}_1;\mathrm{pl}^{e+1}\mathrm{fb}) = c\,\mathrm{ar}^{\mathrm{b}}(B). \tag{Ar}$$

Step 6: the same factor on generic fibres. We first show

$$\beta_{\mathbb{Q}*}\Big(c_1(\mathcal{N}_{1,\mathbb{Q}})\cdots c_1(\mathcal{N}_{r_0,\mathbb{Q}})\cap[\widetilde{\mathcal{X}}_{\mathbb{Q}}]\Big) = c\,[\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}]. \tag{C}$$

This is Lemma 30.25 over $k=\mathbb{Q}$ for $\beta_{\mathbb{Q}}\colon \widetilde{\mathcal{X}}_{\mathbb{Q}}\to\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ and the line bundles $\mathcal{N}_{j,\mathbb{Q}}$: $\widetilde{\mathcal{X}}_{\mathbb{Q}}$ and $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ are integral projective $\mathbb{Q}$-schemes (generic fibres of arithmetic varieties) of dimensions $D=e+r_0$ and e, and the fibre of $\beta_{\mathbb{Q}}$ over the generic point of $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ is $\widetilde{\mathcal{X}}_\eta$ (as $\mathbf{k}(\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}})=\mathbf{k}(\mathcal{X}^{\mathrm{b}})$), so the factor of that lemma is the c of Step 5. Next, by multilinearity, $p_{1,\mathbb{Q}*}[\widetilde{\mathcal{X}}_{\mathbb{Q}}]=e_1[\mathcal{X}_{1,\mathbb{Q}}]$ and the projection formula for $p_{1,\mathbb{Q}}$,

$$e_1\delta_1\,\mathrm{gi}(\mathcal{X}_1;\mathrm{pl}^e\mathrm{fb})=\deg\Big(c_1(\mathcal{M}_{\mathrm{pl},\mathbb{Q}})^e\,c_1(\mathcal{N}_{1,\mathbb{Q}})\cdots c_1(\mathcal{N}_{r_0,\mathbb{Q}})\cap[\widetilde{\mathcal{X}}_{\mathbb{Q}}]\Big).$$

By λ, $\mathcal{M}_{\mathrm{pl},\mathbb{Q}}\cong\beta_{\mathbb{Q}}^*\mathcal{O}(a_B^{\mathrm{H}})$, and on $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ the sections g_ℓ ($\ell\in S'_B$) have no zeros or poles ((Hy3): their divisors lie over ℓ), so $\mathcal{O}(a_B^{\mathrm{H}})|_{\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}}\cong\mathcal{O}(a^{\mathrm{H}})|_{\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}}$. By the projection formula for the proper morphism $\beta_{\mathbb{Q}}$ [98] (Proposition 2.5(c)), the invariance of degrees under proper push-forward and (C),

$$e_1\delta_1\,\mathrm{gi}(\mathcal{X}_1;\mathrm{pl}^e\mathrm{fb})=\deg(c_1(\mathcal{O}(a^{\mathrm{H}}))^e\cap c\,[\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}])=c\,\deg^{\mathrm{H}}.$$

As $\mathrm{pl}^e\mathrm{fb}$ is homogeneous of degree D, (Gi1) for $\mathcal{T}'$ gives $\mathrm{gi}(\mathcal{X}_1;\mathrm{pl}^e\mathrm{fb})=\mathrm{vol}(Z)\deg^{\mathrm{fl}}(\mathrm{pl}^e\mathrm{fb})$, so

$$e_1\delta_1\,\mathrm{vol}(Z)\deg^{\mathrm{fl}}(\mathrm{pl}^e\mathrm{fb})=c\,\deg^{\mathrm{H}}. \tag{G}$$

Step 7: the slope identity. By Step 1, $\deg^{\mathrm{H}}>0$, so (G) gives $c=e_1\delta_1\mathrm{vol}(Z)\deg^{\mathrm{fl}}(\mathrm{pl}^e\mathrm{fb})/\deg^{\mathrm{H}}$, and (Ar), $e_1\delta_1>0$ and the hypothesis $\widehat{\deg}'_{B,Z}=\mathrm{pp}(\mathcal{X}_1;\cdot)$ give

$$\widehat{\deg}'_{B,Z}(\mathrm{pl}^{e+1}\mathrm{fb})=\mathrm{vol}(Z)\deg^{\mathrm{fl}}(\mathrm{pl}^e\mathrm{fb})\,\frac{\mathrm{ar}^{\mathrm{b}}(B)}{\deg^{\mathrm{H}}}=(D^{\mathrm{gr}}+1)\,\mathrm{vol}(Z)\deg^{\mathrm{fl}}\big(\mathrm{pl}^{D^{\mathrm{gr}}}\mathrm{fb}\big)\,\mathrm{sl}^{\mathrm{b}}(B),$$

by (31.7) and $D^{\mathrm{gr}}=e$. This is (Bs1) for $\mathcal{T}'$ at (B,Z). □

Lemma D.20. *Let $\mathfrak{u}=(E,\mathsf{H},\mathsf{U},p,q,\mathsf{L},\mathrm{Sh},F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ,n,p) with its geometric realisation $(\nu_{\mathcal{T}},(\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2, and put $D=|\Phi|\,n(n-1)/2$. Let $B\geq 2$ be an integer, $Z\in\mathrm{Cp}$, and let a base setting of $\mathcal{T}$ at (B,Z) be given which is joined to the stage root model $\mathcal{X}_{B,Z}$ and satisfies the hypotheses (i) and (ii) of Lemma 34.36. Write $h_r(t)$ ($r\in\mathrm{Rt}$) for the root metrics of $\mathcal{X}_{B,Z}$, and put*

$$e_{\mathrm{pl}}=\sum_{\tau\in\Phi}\sum_{i=p+1}^{n}e_{(\tau,i)},\qquad h_{\mathrm{pl}}(t)=\prod_{\tau\in\Phi}\prod_{i=p+1}^{n}h_{(\tau,i)}(t),$$

so that $h_{\mathrm{pl}}(t)$ is a metric on $\mathcal{O}(e_{\mathrm{pl}})|_{\mathcal{X}_{B,Z}}$. Then there are:

- *an arithmetic variety $\widetilde{\mathcal{X}}$ of absolute dimension $D+1$ with $\widetilde{\mathcal{X}}_{\mathbb{Q}}$ smooth, a surjective morphism $p_1\colon\widetilde{\mathcal{X}}\to\mathcal{X}_{B,Z}$, generically finite of some degree $e_1\geq 1$, and a surjective morphism $\beta\colon\widetilde{\mathcal{X}}\to\mathcal{X}^{\mathrm{b}}$;*
- *on the compact complex manifold $W=\widetilde{\mathcal{X}}(\mathbb{C})$ a Kähler form Θ and data ς, ∂W, W°, rW as in Lemma 31.35, with $\beta(W^\circ)\subseteq X^{\mathrm{b},\circ}$; a finite set I, a number $0<t_0<1$ and data $\theta_i,u_i,u_{i,t}$ ($i\in I$, $0<t\leq t_0$) satisfying (R1)–(R5) on (W,Θ,ς) for some $C\geq 1$ and functions δ, R;*
- *an isomorphism of line bundles $\lambda\colon p_1^*(\mathcal{O}(e_{\mathrm{pl}})|_{\mathcal{X}_{B,Z}})\to\beta^*(\mathcal{O}(a_B^{\mathrm{H}})|_{\mathcal{X}^{\mathrm{b}}})$ on $\widetilde{\mathcal{X}}$,*

such that, with $\pi=\mathrm{id}_W$, $d=1$ and $N=N'=\varnothing$ in Lemma 31.34:

1. *for every $r\in\mathrm{Rt}$ the line bundle $p_1^*(\mathcal{O}(e_r)|_{\mathcal{X}_{B,Z}})$ with $h^{(1)}(t)=h^{(2)}(t)=p_1^*h_r(t)$ ($0<t\leq t_0$) satisfies hypotheses 1 and 2 of Lemma 31.34;*

2. the line bundle $\mathcal{M}_{\mathrm{pl}} = p_1^*(\mathcal{O}(e_{\mathrm{pl}})|_{\mathcal{X}_{B,Z}})$ *with*

$$h^{(1)}(t) = p_1^* h_{\mathrm{pl}}(t), \qquad h^{(2)}(t) = \lambda^*\beta^*\Big(h^{\mathrm{ref}} e^{\varphi_t} \prod_{\ell \in S'_B} |g_\ell|\Big) \qquad (0 < t \le t_0),$$

the second being the pull-back along β*, transported by* λ*, of the metric of* $\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}$*, satisfies hypotheses 1 and 2 of Lemma 31.34;*

all these metrics being smooth and invariant under complex conjugation.

Proof. Write $\mathcal{X}_1 = \mathcal{X}_{B,Z}$, $f_1\colon \mathcal{X}_1 \to \mathcal{Y}$ for its structure map, Ω_1 for its function field, $\mathcal{A}_1$ for its abelian locus, and $\pi_Z\colon \mathcal{X}_1(\mathbb{C}) \to X_Z$ for the realisation (Go4) of its root origin. Let $f\colon \mathcal{X} \to \mathcal{Y}$ be the cover of the base setting, with function field Ω, abelian locus $\mathcal{A}_X$ and coordinates y; let C_{b}, t_{b}, δ_{b}, ε, R_{b} be the data of hypothesis (ii), ς_{b} the section of hypothesis (i), rW_{b} the corresponding function on $X^{\mathrm{b},\circ}$, $\Theta_{\mathrm{b}} = dd^c \log h'$, $\theta = dd^c \log h^{\mathrm{ref}}$ and $\varphi = \log(h^{\mathrm{H}}/h^{\mathrm{ref}})$. Let $f''\colon \mathcal{X}'' \to \mathcal{Y}$, ϕ, ϕ' be the common cover of the joined clause.

Step 1: the stage root model. By Lemma 31.37, $S_B = \mathrm{Bd} \cup S'_B$ contains every prime dividing $\mathrm{disc}(E)$; $\mathcal{X}_{1,\mathbb{Q}}$ is smooth; $\mathcal{X}_1$ carries the data (Go3)(1)–(4) of a root origin on the fixed data at Z for (S_B, R) with $R \equiv 4$; $\varphi_* = 0 = \varphi_*^T$ for Sys_Z; π_Z satisfies hypotheses 1–3 of Lemma 31.21; a point of $\mathcal{X}_1(\mathbb{C})$ lies in $\mathcal{A}_1$ if and only if its image lies in X_Z°; and on $\pi_Z^{-1}(X_Z^\circ)$

$$h^{\mathrm{ref}}_{(\tau,i)} e^{\varphi_{(\tau,i)} \circ \pi_Z} = \prod_{k \le i} (h^{\mathrm{sing}}_{(\tau,k)})^{-1} \qquad ((\tau,i) \in \mathrm{Rt}). \tag{S}$$

By (Go3)(2), $\mathcal{X}_1$ satisfies (Hp1), (Hp2) of Lemma 31.29 at $(S_B, 4)$, and its ℓ^4-torsion ($\ell \in S_B$) is defined over Ω_1.

Step 2: the base side. By the coordinate-chart clause of (Gb1), every point of $\mathcal{X}$ lies in a chart $\mathcal{X}_{c'} = \mathrm{Spec}\,\mathbb{Z}[y]_{c'}$, and on $\mathcal{X}_{c'}$ the coordinates define a morphism into the standard chart $\{\prod_k Y_{k,c'_k} \ne 0\}$ of $\mathbb{P}$; these glue to a morphism $y\colon \mathcal{X} \to \mathbb{P}$, birational onto $\mathcal{X}^{\mathrm{b}}$ by (Gb1). As $\mathcal{X}$ is proper over $\mathbb{Z}$ (joined clause) and $\mathbb{P}$ is separated, y is proper, so $y(\mathcal{X}) = \mathcal{X}^{\mathrm{b}}$. Let $T = y(\mathcal{X}_{\mathbb{Q}} \smallsetminus \mathcal{A}_X)$, a closed subset of $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ ($y_{\mathbb{Q}}$ is proper). Every complex point of T lifts to a complex point of $\mathcal{X}_{\mathbb{Q}} \smallsetminus \mathcal{A}_X$ (its fibre is a non-empty scheme of finite type over $\mathbb{C}$), so by (Gb1) $T(\mathbb{C}) = \partial X^{\mathrm{b}}$; in particular $T \ne \mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$. The Hodge lattices of $\mathcal{X}$ at $(S_B, 4)$ are Hodge bundles $\mathcal{V}_s^X$ (joined clause: $R \equiv 4$), the ℓ^4-torsion ($\ell \in S_B$) is defined over Ω and the images of the Hodge–Tate spans in the duals of the Li_s are locally free (Gb1); so $\mathcal{X}$ satisfies (Hp1), (Hp2) at $(S_B, 4)$. At a point x over no prime of S'_B the Hodge lattice at $(S_B, 4)$ is that at $(\mathrm{Bd}, 4)$, so $\mathcal{V}^X_{s,x} = \mathcal{V}_{s,x}$, $\mathcal{V}_s$ the Hodge bundle at (Bd, R) of (Gb2)–(Gb4). Let ι be the isomorphism of (Hy2) on generic fibres, which identifies rational sections of $\mathcal{O}(a^{\mathrm{H}})$ with elements of $\bigotimes_\tau \det(\mathrm{Li}^\vee_{(\tau,-)}) = \bigotimes_\tau (\det \mathrm{Li}_{(\tau,-)})^\vee$ (Gb2), and define on rational sections

$$\Lambda_X(P) = \iota\Big(P \Big/ \prod_{\ell \in S'_B} g_\ell\Big).$$

Claim: Λ_X *is an isomorphism of invertible sheaves* $y^*\mathcal{O}(a^{\mathrm{H}}_B) \to \bigotimes_\tau (\det \mathcal{V}^X_{(\tau,-)})^\vee$. Let $x \in \mathcal{X}$, c' a chart containing x, and $D(f_0) \ni x$, u, $(b_{\tau,i})_i$ as in (Gb3). Near x, $y^*\mathcal{O}(a^{\mathrm{H}}_B)$ is generated by $\sigma = \prod_k y_{k,c'_k}^{(a^{\mathrm{H}}_B)_k} = \prod_k y_{k,c'_k}^{a^{\mathrm{H}}_k} \cdot \prod_\ell y_{c'}^{v_\ell}$, and by (Gb3)

$$\Lambda_X(\sigma) = u \cdot \bigotimes_\tau (b_{\tau,1} \wedge \cdots \wedge b_{\tau,q})^\vee \cdot \prod_{\ell \in S'_B} (g_\ell / y_{c'}^{v_\ell})^{-1}.$$

For $\ell \in S'_B$ the Cartier divisor of g_ℓ is supported over ℓ (Hy3), so $g_\ell / y_{c'}^{v_\ell}$ is a unit at every point of $\mathcal{X}_{c'}$ not over ℓ. If x lies over no prime of S'_B, $\Lambda_X(\sigma)$ is a unit times a generator of

$\bigotimes_\tau(\det \mathcal{V}_{(\tau,-),x})^\vee = \bigotimes_\tau(\det \mathcal{V}^X_{(\tau,-),x})^\vee$. If x lies over $\ell_0 \in S'_B$ (then over no other prime), by (Gb4) $g_{\ell_0}/y_{c'}^{v_{\ell_0}}$ is a unit times $\prod_\tau \det T_\tau$, where a basis $(h_{\tau,i})_i$ of $\mathrm{HT}_{(\tau,-),x}(\ell_0^4) = \mathcal{V}^X_{(\tau,-),x}$ is $(b_{\tau,i})_i$ multiplied by T_τ; then $h_{\tau,1}\wedge\cdots\wedge h_{\tau,q} = \det T_\tau \cdot b_{\tau,1}\wedge\cdots\wedge b_{\tau,q}$, so $\Lambda_X(\sigma)$ is a unit times $\bigotimes_\tau(h_{\tau,1}\wedge\cdots\wedge h_{\tau,q})^\vee$, a generator of $\bigotimes_\tau(\det \mathcal{V}^X_{(\tau,-),x})^\vee$. As both sheaves are invertible subsheaves of the same constant sheaf, the claim follows. *Metric.* Let z' be a complex point of $\mathcal{A}_X$ with $w = y_{\mathbb{C}}(z') \in X^{\mathrm{b},\circ}$. The fibre of $\mathcal{V}^X_s$ at z' is $\mathrm{Lie}_s(G_{\mathcal{X},z'})$ (over $\mathbb{Q}$ the Hodge lattices are the de Rham lattices, direct summands of Lie cut out by the idempotents of $\mathcal{O}_E\otimes\mathbb{Q}$). By (Gb2), (Gb3), ι carries the metric of the Hodge-type line at w to the tensor product of the metrics dual to the determinants of $h_{z'}$ on the $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z'})$: the generator $\prod_k y_{k,c'_k}^{a^{\mathrm{H}}_k}$ has norm $|u(z')|\prod_\tau \|b_{\tau,1}(z')\wedge\cdots\wedge b_{\tau,q}(z')\|^{-1}_{h_{z'}}$, which is the dual determinant norm of its image. Since $\|P\|_{h^{\mathrm{H}}}\prod|g_\ell| = \|P/\prod_\ell g_\ell\|_{h^{\mathrm{H}}}$, the fibre of Λ_X at z' is an isometry from the metric with cone function $h^{\mathrm{H}}\prod_{\ell\in S'_B}|g_\ell|$ at w to the dual determinant Hodge metric.

Step 3: the common model. The morphism $(\phi,\phi')\colon \mathcal{X}''\to\mathcal{X}_1\times_{\mathbb{Z}}\mathcal{X}$ has proper source, so its scheme-theoretic image $\mathcal{X}_3$ is a closed integral subscheme, proper over $\mathbb{Z}$; its function field Ω_3 is the subfield of $\mathbf{k}(\mathcal{X}'')$ generated by $\phi^*\Omega_1$ and $\phi'^*\Omega$. The two morphisms $f_1\circ\mathrm{pr}_1$, $f\circ\mathrm{pr}_2\colon\mathcal{X}_3\to\mathcal{Y}$ agree after composition with $\mathcal{X}''\to\mathcal{X}_3$ ($f''=f_1\circ\phi=f\circ\phi'$); their equaliser is a closed subscheme ($\mathcal{Y}$ is separated) through which $\mathcal{X}''\to\mathcal{X}_3$ factors, hence all of $\mathcal{X}_3$. The generic points of $\mathcal{X}_1$ and $\mathcal{X}$ map to the generic point of $\mathcal{Y}_Z$; $\mathcal{X}$ has absolute dimension $e+1=|\Phi|pq+1$ ((Hy1), y birational), as has $\mathcal{Y}_Z$ (its generic fibre Z has dimension $|\Phi|pq$), so Ω is finite over $\mathbf{k}(\mathcal{Y}_Z)$, and $\Omega_3=\Omega_1\Omega$ is finite over Ω_1. By Chow's lemma there is a projective birational surjective $\mathcal{X}'_3\to\mathcal{X}_3$ with $\mathcal{X}'_3$ integral and projective over $\mathbb{Z}$; let $\mathcal{X}''_3$ be its normalisation (finite). Write $\beta_3\colon\mathcal{X}''_3\to\mathcal{X}^{\mathrm{b}}$ for the composite with $y\circ\mathrm{pr}_2$ and $\mathcal{A}_3$ for the abelian locus of $\mathcal{X}''_3$ for $f_1\circ\mathrm{pr}_1$. By Theorem B.142(A) there is a projective birational $\mathcal{R}\to\mathcal{X}''_{3,\mathbb{Q}}$ with $\mathcal{R}$ smooth and integral. Let $\mathcal{U}\subseteq\mathcal{R}$ be the preimage of the open set $\mathcal{A}_3\cap\beta_3^{-1}(\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}\smallsetminus T)$; it contains the generic point (which maps to the generic point of $j(Z)$ and of $\mathcal{X}^{\mathrm{b}}$, and $T\neq\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$), so the ideal $I_{\mathcal{R}}$ of the reduced closed set $\mathcal{R}\smallsetminus\mathcal{U}$ is non-zero. By Theorem B.142(B) there is a composite of blow-ups with smooth centres $\Pi\colon\mathcal{R}'\to\mathcal{R}$, an isomorphism over $\mathcal{U}$, with $\mathcal{R}'$ smooth and $\Pi^*I_{\mathcal{R}}$ the ideal of a simple normal crossing divisor B' with support $\mathcal{R}'\smallsetminus\Pi^{-1}(\mathcal{U})$. The composite $\mathcal{R}'\to\mathcal{X}''_{3,\mathbb{Q}}$ is projective and birational, so $\mathcal{R}'$ is a closed integral subscheme of the generic fibre of $\mathbb{P}^N_{\mathbb{Z}}\times_{\mathbb{Z}}\mathcal{X}''_3$ for some N; let $\mathcal{X}_0$ be its closure there and $\widetilde{\mathcal{X}}$ the normalisation of $\mathcal{X}_0$. Then $\widetilde{\mathcal{X}}$ is integral, normal, projective over $\mathbb{Z}$ (Hartshorne II Ex. 4.9) and flat (torsion-free), with $\widetilde{\mathcal{X}}_{\mathbb{Q}}\cong\mathcal{R}'$ ($\mathcal{R}'$ is smooth, hence normal) and function field Ω_3; so it is an arithmetic variety with smooth generic fibre, of absolute dimension $\dim\mathcal{X}_1=D+1$. Let $p_1\colon\widetilde{\mathcal{X}}\to\mathcal{X}_1$ and $p'\colon\widetilde{\mathcal{X}}\to\mathcal{X}$ be the composites with the projections, and $\beta=y\circ p'$. They are dominant and proper, hence surjective; p_1 is generically finite of degree $e_1=[\Omega_3:\Omega_1]\geq 1$. With $\widetilde{f}=f_1\circ p_1=f\circ p'$, $\widetilde{\mathcal{X}}$ is a cover of $\mathcal{Y}$, and its abelian locus $\mathcal{A}$ is $p_1^{-1}(\mathcal{A}_1)=p'^{-1}(\mathcal{A}_X)$. Moreover $\widetilde{\mathcal{X}}_{\mathbb{Q}}\smallsetminus(\mathcal{A}\cap\beta^{-1}(\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}\smallsetminus T))$ is the support of B'.

Step 4: the Hodge bundles and λ. By Steps 1 and 2 and Lemma 31.29(1), applied to p_1 and to p' (both dominant, compatible with $\widetilde{f}$, and S_B contains the primes dividing $\mathrm{disc}(E)$), the Hodge lattices of $\widetilde{\mathcal{X}}$ at $(S_B,4)$ are Hodge bundles $\widetilde{\mathcal{V}}_s=\mathcal{O}_{\widetilde{\mathcal{X}}}\mathcal{V}^1_s=\mathcal{O}_{\widetilde{\mathcal{X}}}\mathcal{V}^X_s\subseteq\widetilde{\mathrm{Li}}_s$, with $p_1^*\mathcal{V}^1_s\cong\widetilde{\mathcal{V}}_s\cong p'^*\mathcal{V}^X_s$, where $\mathcal{V}^1_s$ are those of $\mathcal{X}_1$ (both equal the Hodge lattices of the cover $\widetilde{\mathcal{X}}$). By Lemma 31.29(2) the pull-back of the integral flag of $\mathcal{X}_1$ of (Go3)(3) is an integral flag $(\widetilde{\mathcal{V}}_{s,k})_k$ of $\widetilde{\mathcal{X}}$ whose root lines are $\widetilde{\mathcal{L}}_r\cong p_1^*\mathcal{L}_r$. For a root (τ,i) with $i>p$ the label is $(\tau,-)$, the step $n+1-i$ and the sign -1 (Fh3); so, using the root sections $\varrho_r\colon\mathcal{O}(e_r)|_{\mathcal{X}_1}\to\mathcal{L}_r$ of (Go3)(3) and the canonical isomorphism $\det\widetilde{\mathcal{V}}_{(\tau,-)}\cong\bigotimes_{k=1}^q\widetilde{\mathcal{V}}_{(\tau,-),k}/\widetilde{\mathcal{V}}_{(\tau,-),k-1}$ for a full flag with locally free steps and invertible quotients,

we get an isomorphism

$$\kappa\colon p_1^*(\mathcal{O}(e_{\mathrm{pl}})|_{\mathcal{X}_1}) \xrightarrow{\otimes p_1^*\varrho_{(\tau,i)}} \bigotimes_\tau \bigotimes_{i>p} \widetilde{\mathcal{L}}_{(\tau,i)} = \bigotimes_\tau \bigotimes_{k=1}^{q} \big(\widetilde{\mathcal{V}}_{(\tau,-),k}/\widetilde{\mathcal{V}}_{(\tau,-),k-1}\big)^{-1} \cong \bigotimes_\tau (\det \widetilde{\mathcal{V}}_{(\tau,-)})^\vee.$$

On the other side $p'^*\Lambda_X$ is an isomorphism $\beta^*\mathcal{O}(a_B^{\mathrm{H}}) = p'^*y^*\mathcal{O}(a_B^{\mathrm{H}}) \to p'^*\bigotimes_\tau(\det \mathcal{V}^X_{(\tau,-)})^\vee = \bigotimes_\tau(\det \widetilde{\mathcal{V}}_{(\tau,-)})^\vee$. Put $\lambda = (p'^*\Lambda_X)^{-1}\circ\kappa$, an isomorphism of line bundles on $\widetilde{\mathcal{X}}$.

Step 5: λ is an isometry of the singular Hodge metrics on the good locus. Let $\mathcal{U}' = \mathcal{A}\cap\beta^{-1}(\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}\smallsetminus T)$ and $z\in\mathcal{U}'(\mathbb{C})$; then $p_1(z)\in\mathcal{A}_1(\mathbb{C})$, $z' = p'(z)\in\mathcal{A}_X(\mathbb{C})$, $\beta(z) = y_{\mathbb{C}}(z')\in X^{\mathrm{b},\circ}$ (as $T(\mathbb{C}) = \partial X^{\mathrm{b}}$), and $G_{\mathcal{X}_1,p_1(z)} = G_{\widetilde{\mathcal{X}},z} = G_{\mathcal{X},z'} = G^{\mathrm{un}}_{\widetilde{f}(z)}$. The fibre of $\widetilde{\mathcal{V}}_s$ at z is $\mathrm{Lie}_s(G_{\widetilde{\mathcal{X}},z})$, compatibly with the fibres of $\mathcal{V}^1_s$ at $p_1(z)$ and of $\mathcal{V}^X_s$ at z'. By (Go3)(4) and (Fh6), $p_1^*\varrho_{(\tau,i)}$ carries the metric with cone function $p_1^*h^{\mathrm{sing}}_{(\tau,i)}$ to the Hodge metric of the root line, i.e. the dual of the quotient norm of h_z on $\widetilde{\mathcal{V}}_{(\tau,-),k}/\widetilde{\mathcal{V}}_{(\tau,-),k-1}$ at z ($k = n+1-i$). For a basis $b_1,\dots,b_q$ of $\mathrm{Lie}_{(\tau,-)}(G_z)$ adapted to the flag with Gram matrix Γ, (Fh4) gives $\prod_{k=1}^q\|b_k \bmod V_{k-1}\| = \prod_k(\det\Gamma_{\le k}/\det\Gamma_{\le k-1})^{1/2} = (\det\Gamma)^{1/2} = \|b_1\wedge\cdots\wedge b_q\|$; so the fibre of κ at z carries $p_1^*h^{\mathrm{sing}}_{\mathrm{pl}}$, $h^{\mathrm{sing}}_{\mathrm{pl}} = \prod_\tau\prod_{i>p}h^{\mathrm{sing}}_{(\tau,i)}$, to the dual determinant Hodge metric. By Step 2 the fibre of $p'^*\Lambda_X$ at z carries the metric with cone function $\beta^*(h^{\mathrm{H}}\prod_\ell|g_\ell|)$ to the same metric. Hence, on $\mathcal{U}'(\mathbb{C})$,

$$p_1^*h^{\mathrm{sing}}_{\mathrm{pl}} = \lambda^*\beta^*\Big(h^{\mathrm{H}}\prod_{\ell\in S'_B}|g_\ell|\Big). \tag{1}$$

Step 6: the complex data. Put $W = \widetilde{\mathcal{X}}(\mathbb{C}) = \mathcal{R}'(\mathbb{C})$, a compact complex manifold of dimension D, Θ the restriction of a Fubini–Study form of a projective embedding of $\mathcal{R}'$, $F_1 = \pi_Z\circ p_1\colon W\to X_Z$ and $\beta_{\mathbb{C}}\colon W\to X^{\mathrm{b}}$, both holomorphic. By Step 1, $F_1^{-1}(X_Z^\circ) = \mathcal{A}(\mathbb{C})$. Let $\varsigma = F_1^*\varsigma_Z\otimes\beta^*\varsigma_{\mathrm{b}}$, a holomorphic section of the tensor product of the pulled-back hermitian line bundles, $\|\varsigma\|\le 1$; its zero set is $(W\smallsetminus\mathcal{A}(\mathbb{C}))\cup\beta^{-1}(\partial X^{\mathrm{b}}) = W\smallsetminus\mathcal{U}'(\mathbb{C})$, the support of the simple normal crossing divisor $B'_{\mathbb{C}}$, so its zero divisor ∂W has simple normal crossings. Then $W^\circ = \mathcal{U}'(\mathbb{C})$, $\beta(W^\circ)\subseteq X^{\mathrm{b},\circ}$, $F_1(W^\circ)\subseteq X_Z^\circ$, and

$$\mathrm{rW} = \mathrm{rW}_Z\circ F_1 - 2\log\|\beta^*\varsigma_{\mathrm{b}}\| \ge \mathrm{rW}_Z\circ F_1, \qquad \mathrm{rW}\ge \mathrm{rW}_{\mathrm{b}}\circ\beta \qquad \text{on } W^\circ,$$

as both logarithms are ≤ 0. *Root side.* By Lemma 31.32 applied to Sys_Z and F_1 there is $C_W\ge 1$ such that $F_1^*\theta_a$, $\varphi_a\circ F_1$, $\varphi_a^T(t)\circ F_1$ (a fundamental) satisfy (R1)–(R5) on (W,Θ,ς) with C_W, $\delta_Z(t) = t^{1/3} + (1+C_Z)\varepsilon_Z(t)$, $R_Z(t) = \log(1/t)$, $0<t\le t_1 = \min(t_Z, e^{-e})$, where ε_Z is the function $\varepsilon(t)$ of (Go1) for Sys_Z; and $F_1^*\theta_a + dd^c(\varphi_a^T(t)\circ F_1) = F_1^*\eta_a(t)$. *Base side.* Put $\theta_{\mathrm{b}} = \beta^*\theta$, $u_{\mathrm{b}} = \varphi\circ\beta$ on W° (smooth, as φ is smooth on $X^{\mathrm{b},\circ}$ by (ii)) and $u_{\mathrm{b},t} = \varphi_t\circ\beta$ on W. Choose $0<t_2\le\min(t_1,t_{\mathrm{b}})$ with $\varepsilon(t)\le 1$ and $R_{\mathrm{b}}(t)\ge e$ for $0<t\le t_2$ (possible as $\varepsilon(t)\to 0$, $R_{\mathrm{b}}(t)\to\infty$), and $C_1\ge 1$ with $\beta^*\Theta_{\mathrm{b}}\le C_1\Theta$ on W (compactness; Θ is positive definite). For $0<t\le t'\le t_2$: (R1) $\theta_{\mathrm{b}}+dd^cu_{\mathrm{b},t}+C_1\Theta\ge\beta^*(\theta+dd^c\varphi_t+\varepsilon(t)\Theta_{\mathrm{b}})\ge 0$, as pull-backs of semipositive forms are semipositive; (R2) on W°, $-C_{\mathrm{b}}\log\mathrm{rW}\le -C_{\mathrm{b}}\log(\mathrm{rW}_{\mathrm{b}}\circ\beta)\le u_{\mathrm{b}}\le u_{\mathrm{b},t}\le C_{\mathrm{b}}$; (R3) on $\{\mathrm{rW}\le R(t)\}$ with $R(t)\le R_{\mathrm{b}}(t)$ we have $\mathrm{rW}_{\mathrm{b}}\circ\beta\le R_{\mathrm{b}}(t)$, so $u_{\mathrm{b},t}\le u_{\mathrm{b}}+\delta_{\mathrm{b}}(t)$; (R4) holds pointwise; (R5) for a compact $K\subseteq W^\circ$, $\beta(K)$ is a compact subset of $X^{\mathrm{b},\circ}$, so $\varphi_t\to\varphi$ with first and second derivatives uniformly on $\beta(K)$ and, by the chain rule with the derivatives of β bounded on a compact neighbourhood of K, $u_{\mathrm{b},t}\to u_{\mathrm{b}}$ with first and second derivatives uniformly on K. *The family.* Let I be the set of fundamental indices together with one further index b, carrying $(\theta_{\mathrm{b}},u_{\mathrm{b}},u_{\mathrm{b},t})$; $t_0 = t_2$, $C = \max(C_W,C_{\mathrm{b}},C_1)$, $\delta = \max(\delta_Z,\delta_{\mathrm{b}})$, $R = \min(R_Z,R_{\mathrm{b}})$. Then $\delta(t)\to 0$, $R(t)\to\infty$, $R\ge e$, and (R1)–(R5) hold for every $i\in I$ (enlarging C and δ and shrinking R keeps them).

Step 7: hypothesis 1. Let $r = (\tau, i) \in \mathrm{Rt}$, $a = (\tau, i)$, $a^- = (\tau, i-1)$. The multidegree of r is that of a^- minus that of a, and hypotheses 2 and 3 of Lemma 31.21 for π_Z (Step 1) give $h_r(t) = h^{\mathrm{ref}}_{a^-} e^{\varphi^T_{a^-}(t)\circ\pi_Z} / h^{\mathrm{ref}}_a e^{\varphi^T_a(t)\circ\pi_Z}$ and

$$c_1\big(p_1^*\mathcal{O}(e_r), p_1^* h_r(t)\big) = F_1^*\big(\eta_{a^-}(t) - \eta_a(t)\big),$$

a combination of the forms $\theta_i + dd^c u_{i,t}$ ($i \in I$) with coefficients in $\{0, \pm 1\}$ independent of t. This is hypothesis 1 for part 1. Multiplying over $i = p+1, \dots, n$ (the product telescopes),

$$c_1\big(\mathcal{M}_{\mathrm{pl}}, p_1^* h_{\mathrm{pl}}(t)\big) = \sum_{\tau\in\Phi} F_1^*\big(\eta_{(\tau,p)}(t) - \eta_{(\tau,n)}(t)\big)$$

($p \geq 1$, so (τ, p) is a fundamental index). For $h^{(2)}(t)$: the divisor of g_ℓ lies over ℓ, so g_ℓ is a nowhere vanishing holomorphic section of $\mathcal{O}(v_\ell)$ over X^{b} and $\log|g_\ell|$ is pluriharmonic on the cone; as λ is an isomorphism of line bundles, $c_1(\mathcal{M}_{\mathrm{pl}}, h^{(2)}(t)) = \beta^* c_1(\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}) = \beta^*(\theta + dd^c\varphi_t) = \theta_{\mathrm{b}} + dd^c u_{\mathrm{b},t}$. So hypothesis 1 holds for part 2. All metrics are smooth; those of $\mathcal{X}_1$ are invariant under complex conjugation, the metric of $\overline{\mathcal{H}}^{\mathrm{b}}_{B,t}$ is, being that of a hermitian line bundle (the convention behind $\widehat{\deg}$ is fixed in Section 14), and p_1, β, λ are defined over $\mathbb{Z}$.

Step 8: hypothesis 2. In part 1 the two metrics coincide; take $g_t = 0$. In part 2, $g_t = \log(h^{(1)}(t)/h^{(2)}(t))$ is a smooth function on W. For a fundamental index a put $\Delta_a(t) = \varphi_a^T(t) - \varphi_a$ on X_Z°; by (Go1)(1),(2), $0 \leq \Delta_a(t) \leq C_Z + C_5 \log \mathrm{rW}_Z$, and by (Go1)(3), $\Delta_a(t) \to 0$ uniformly on compact subsets of X_Z°. Dividing the regularised identity (hypothesis 3 of Lemma 31.21) by (S) for (τ, n) and (τ, p) gives, on $\pi_Z^{-1}(X_Z^\circ)$, $\log\big(h_{\mathrm{pl}}(t)/h^{\mathrm{sing}}_{\mathrm{pl}}\big) = \sum_\tau \big(\Delta_{(\tau,p)}(t) - \Delta_{(\tau,n)}(t)\big)\circ\pi_Z$. On $X^{\mathrm{b},\circ}$, $\log\big(h^{\mathrm{ref}} e^{\varphi_t}/h^{\mathrm{H}}\big) = \varphi_t - \varphi$. With (1), on W°

$$g_t = \sum_{\tau\in\Phi} \big(\Delta_{(\tau,p)}(t) - \Delta_{(\tau,n)}(t)\big)\circ F_1 - (\varphi_t - \varphi)\circ\beta.$$

By (R2) for the base, $0 \leq \varphi_t - \varphi \leq C_{\mathrm{b}} + C_{\mathrm{b}} \log \mathrm{rW}_{\mathrm{b}}$; with $\mathrm{rW}_Z \circ F_1 \leq \mathrm{rW}$, $\mathrm{rW}_{\mathrm{b}} \circ \beta \leq \mathrm{rW}$ and $\log \mathrm{rW} \geq 1$ on W°, $|g_t| \leq \big(2|\Phi|(C_Z + C_5) + 2C_{\mathrm{b}}\big) \log \mathrm{rW}$ there. For a compact $K \subseteq W^\circ$, $F_1(K) \subseteq X_Z^\circ$ and $\beta(K) \subseteq X^{\mathrm{b},\circ}$ are compact, so $g_t \to 0$ uniformly on K by (Go1)(3) and (R5) for the base. This is hypothesis 2 for part 2, with $\pi = \mathrm{id}$. □

D.2 The cusp mean and corrected point heights

This section proves Proposition D.21, the third part of Proposition 34.35: the cusp mean bound (Qk1) and the corrected point heights (Qk2) of the base settings of a good tower, with $(r, L) = (\mathrm{rd}_E, L_{\mathsf{H}})$. Through Proposition 34.2 they give the clauses (Bs4) and (Bs5) used in the proof of (Rt6). The core is Lemma D.22, a lower bound for the corrected height of every algebraic point. Such a point carries a principally polarised abelian scheme with $\mathcal{O}_E$-action, and its height is bounded through the maximal slope of the Lie lattice (Subsection D.2.1), the flat saturation of the Lie eigenspaces (Subsection D.2.2), and the polarised de Rham module over the base (Subsection D.2.3). Several of these results are used again in Sections D.3, D.4 and D.6.

D.2.1 Heights of algebraic points and the height dichotomy

After the statements of Proposition D.21 and Lemma D.22, this subsection proves the bound for the maximal slope of the Lie lattice of a principally polarised abelian scheme, logarithmic in the dimension and the height (Proposition D.27); it is used again for the reference lower bound in Section D.6. The input is a lower bound for the Hodge lengths of integral tangent

vectors (Proposition D.29), proved with theta functions: a theta section of small mean-square norm (Proposition D.30), its sup norms on average over the complex places (Proposition D.32), integral spanning sections (Proposition D.33), and the order of vanishing of jets (Lemma D.35). The quoted inputs are Moret-Bailly's key formula and his models with torsion sections [181].

Proposition D.21. *There is a real number $C_{\mathrm{h}} \geq 0$ with the following property. Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2, and put $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]}$ and $L_{\mathsf{H}} = \mathrm{Re}\,(L'/L)(1, \chi_d)$, where $\mathbb{Q}(\sqrt{-d}) \subseteq E$ is the imaginary quadratic field of the host. Let B be an admissible stage, $Z \in \mathrm{Cp}$, and let a base setting of $\mathcal{T}$ at (B, Z) be given. If the setting satisfies the hypotheses (i) and (ii) of Lemma 34.36, then its cusp data have the cusp mean bound (Qk1) for $r = \mathrm{rd}_E$. If there is $t_0 > 0$ such that $\psi_{t'} \geq \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ on $X^{\mathrm{b},\circ}$ for $0 < t' \leq t_0$, then its cusp data have corrected point heights (Qk2) at B for $(r, L) = (\mathrm{rd}_E, L_{\mathsf{H}})$ and the constant C_{h}.*

Proof. Let $C_{\mathrm{h}} = C_{\mathrm{in}}$ be the constant of Lemma D.22. Let the data be as in the statement.

The root discriminant. By (Ud1), E contains $K = \mathbb{Q}(\sqrt{-d})$ with d a prime, $d \equiv 7 \pmod 8$, so $\mathrm{disc}(K) = -d$ and $d \geq 7$. From $|\mathrm{disc}(E)| = |\mathrm{disc}(K)|^{[E:K]}\,\mathrm{N}_{K/\mathbb{Q}}(\mathfrak{d}_{E/K}) \geq d^{[E:K]}$ we get $\mathrm{rd}_E \geq d^{1/2} \geq \sqrt{7} > 2$, so (Qk1) and (Qk2) are defined for $r = \mathrm{rd}_E$.

(Qk1). Suppose the setting satisfies (i) and (ii) of Lemma 34.36. An admissible B is $\geq 128 \geq 2$. By Lemma D.2, U is integrable for $(\omega^{\mathrm{H}})^e$ on $X^{\mathrm{b},\circ}$ and $\int_{X^{\mathrm{b},\circ}} U(\omega^{\mathrm{H}})^e \leq C_0 \int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e$ with $C_0 = |\Phi|\,q\,(6 + \log(2|\Phi|\mathrm{rd}_E) + \log(2|\Phi|q\,\mathrm{rd}_E)) \geq 0$. By Lemma 34.36, applied to the Hodge-type base setting underlying the given one, $\int_{X^{\mathrm{b},\circ}} (\omega^{\mathrm{H}})^e = \deg^{\mathrm{H}}$. As $j' = q$, this is (Qk1) for $r = \mathrm{rd}_E$.

(Qk2). From $q \geq 1$ and $3q + 1 \leq p + q$ we have $1 \leq q \leq p$; B admissible means $B \geq 128$, $B \geq 4|\Phi|n^2$ and $|\mathrm{Bd}| \leq B$. Let t_0 be as in the statement and $0 < t' \leq t_0$. Then $\psi_{t'} \geq \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ on $X^{\mathrm{b},\circ}$, and Lemma D.22 gives, for every $x \in \mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$ with Zariski closure D_x, $h_{\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}}(D_x) \geq -C_{\mathrm{h}}\,|\Phi|\,q\,(\log(B\,\mathrm{rd}_E) + |L_{\mathsf{H}}|)\,[\mathbf{k}(D_x) : \mathbb{Q}]$. With $j' = q$ this is (Qk2) at B for $(r, L) = (\mathrm{rd}_E, L_{\mathsf{H}})$, the constant C_{h} and this t_0. □

Lemma D.22. *There is a real number $C_{\mathrm{in}} \geq 0$ with the following property. Let $\mathfrak{u}$ be a unitary Shimura datum with $\Phi = \Phi_{\mathsf{H}}$, $n = p + q$, $1 \leq q \leq p$, put $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]}$ and $L_{\mathsf{H}} = \mathrm{Re}\,(L'/L)(1, \chi_d)$, and let a base setting of a root tower $\mathcal{T}$ at (B, Z) with cusp data be given, where $B \geq 128$, $B \geq 4|\Phi|n^2$ and $|\mathrm{Bd}| \leq B$. Let $t' > 0$ be such that $\psi_{t'} \geq \log h^{\mathrm{H}} + \frac{1}{2}U - \log h^{\mathrm{ref}'}$ on $X^{\mathrm{b},\circ}$. Then for every $x \in \mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$, with Zariski closure D_x,*

$$h_{\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}}(D_x) \;\geq\; -C_{\mathrm{in}}\,|\Phi|\,q\,\big(\log(B\,\mathrm{rd}_E) + |L_{\mathsf{H}}|\big)\,[\mathbf{k}(D_x) : \mathbb{Q}].$$

Proof. Let C_{ll} be the constant of Proposition D.29 (as in Lemma D.26) and C_{fs} that of Proposition D.36; put $C_1 = (C_{\mathrm{ll}} + \frac{1}{2})(2 + \log(3 + 2C_{\mathrm{fs}}))$ and $C_{\mathrm{in}} = C_1 + 28$, an absolute constant. Put $\Xi = \log B + \log \mathrm{rd}_E + |L_{\mathsf{H}}|$; as $B \geq 128$ and $\mathrm{rd}_E \geq 1$, $\Xi \geq \log B \geq 1$, and $\Xi = \log(B\,\mathrm{rd}_E) + |L_{\mathsf{H}}|$. Let $K = \mathbf{k}(D_x)$ and $\xi = \bar{y}^{-1}(x)$.

Step 1: the point. Let L be a number field containing K and the image of F under the homomorphism $F \to \mathbf{k}(\xi) \to \overline{\mathbb{Q}}$ (so L contains the image of every embedding of E into $\overline{\mathbb{Q}}$, as $F \supseteq \tau(E)$ for all τ). By Lemma D.24 there is $P\colon \mathrm{Spec}\,\mathcal{O}_L \to \mathcal{X}$ as in its item 2, and $\mathcal{X}$ is noetherian. Both properties of P in item 2 persist when P is composed with $\mathrm{Spec}\,\mathcal{O}_{L'} \to \mathrm{Spec}\,\mathcal{O}_L$ for a finite extension L'/L; so L may be enlarged at any point below. Put $\mathcal{A} = P^* G_{\mathcal{X}}$ and σ_τ as in Lemma D.23.

Step 2: from the corrected line to the untwisted line. By Lemma D.25 (its hypotheses: $\mathcal{X}$ locally noetherian, and P with y defined at the image of the generic point with value x and $P(\mathfrak{p})$ in a chart for every $\mathfrak{p}$), its last assertion gives

$$h_{\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}}(D_x) \geq h_{(\mathcal{O}(a^{\mathrm{H}}),h^\sharp)}(D_x) - |\Phi|\, q\,(\log B + 11)[K:\mathbb{Q}], \qquad h^\sharp = h^{\mathrm{ref}'} e^{\psi_{t'}},$$

and by hypothesis $\log h^\sharp \geq \log h^{\mathrm{H}} + \frac{1}{2}U$ on the cone over $X^{\mathrm{b},\circ}$. By its second assertion, $\sum_{\ell \leq B} c_\ell \leq \log B + 11$; for a prime $\ell > B$, $c_\ell \leq 2\log \ell/\ell < 2\log B/B$, since $\log u/u$ decreases for $u \geq e$; as $|\mathrm{Bd}| \leq B$, $\sum_{\ell \in \mathrm{Bd}} c_\ell \leq 3\log B + 11$. It therefore suffices to find Hermitian metrics ν as in Lemma D.23(i) (for L and P, possibly after enlarging L) with

$$\sum_{\tau \in \Phi} d_{\sigma_\tau}(\nu) \leq (C_1 + 2)\,|\Phi|\, q\, \Xi, \tag{$*$}$$

for then Lemma D.23(i) and the two displays give $h_{\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}}(D_x) \geq -|\Phi|\, q\,((C_1+2)\Xi + 4\log B + 22)[K:\mathbb{Q}] \geq -(C_1+28)\,|\Phi|\, q\,\Xi\,[K:\mathbb{Q}]$, using $\log B \leq \Xi$ and $1 \leq \Xi$.

Step 3: the interior case. Suppose ξ lies in the abelian locus. As $U \geq 0$, $h^\sharp \geq h^{\mathrm{H}}$ on the cone over $X^{\mathrm{b},\circ}$, so by Lemma D.23(ii) the metrics $\nu_e = h_{z_e}$ satisfy the hypothesis of (i), $\mathcal{A}$ is a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$ of relative dimension $g = |\Phi| n$ (Kottwitz condition, (Ud4)), and $d_{\sigma_\tau}(\nu) = d_{\sigma_\tau}$. We apply Proposition D.36 to $\mathcal{A}$, for each $\tau \in \Phi$, with $s_1 = \sigma_\tau$ and $s_2 = \sigma_\tau \circ c$ (c the complex conjugation of E). Its hypotheses: the Rosati involution maps $\iota(a)$ to $\iota(\bar{a})$ by the first isomorphism of (Ud4); with ρ the image of $r_{\mathbb{C}} \in K_{\mathsf{L}} \subseteq F$ in L, $\rho^2 = -d$, and for $\gamma\colon L \to k$ algebraically closed the Kottwitz condition of (Ud4) at the geometric point γ gives the eigenspace dimensions $p' = p$, $q' = q$; s_1 is injective; and for every $e\colon L \to \mathbb{C}$, $e \circ s_1$ is (the restriction of) a field embedding ψ of the CM field E, so $e \circ s_2(a) = \psi(\bar{a}) = \overline{\psi(a)}$. As $\mathrm{rk}\,\mathrm{Lie}_{s_1} + \mathrm{rk}\,\mathrm{Lie}_{s_2} = q + p$ and $1 + \log \mathrm{rd}_E + |L_{\mathsf{H}}| \leq 2\Xi$, $\sum_\tau |d_{\sigma_\tau} - d_{\sigma_\tau \circ c}| \leq 2C_{\mathrm{fs}}\, g\, \Xi$. Then Lemma D.26, with $\Psi = \{\sigma_\tau\}$, $C_{\mathrm{f}} = 2C_{\mathrm{fs}}$ (every embedding $E \to L$ lies in exactly one of Ψ, $\bar{\Psi}$; $g \leq 4|\Phi|n^2 \leq B \leq e^\Xi$), gives $\sum_\tau d_{\sigma_\tau} \leq C_1\,|\Phi|\, q\, \Xi$, which is $(*)$.

Step 4: the boundary case; the torus and the abelian part. Suppose ξ does not lie in the abelian locus. By Lemma 34.5, after enlarging L (Step 1) we have the split maximal torus T of $\mathcal{A}_L$ with $\mathcal{O}_E$-module $X = X_*(T)$ and, if $T \neq \mathcal{A}_L$, the scheme $\mathcal{B}$ and $\varphi\colon \mathcal{A} \to \mathcal{B}$, with (Ai1), (Ai2). Every z_e lies over ξ, so outside the abelian locus, and by (Gb1) and Definition 31.10 the complement of the abelian locus is near z_e a divisor with normal crossings; so Lemma 33.16 (case (B), on the complex fibre of $\mathcal{X}$ containing z_e, which is projective as $\bar{y}$ is an isomorphism onto $\mathcal{X}^{\mathrm{b}} \subseteq \mathbb{P}$) applies at z_e with a chart V_e, $V_e^* = V_e \cap$ (abelian locus), and with it Lemma 33.18 and Lemma 34.7. By Lemma 34.6 (1), (3) at the geometric points over ξ, $r_T = \dim_E(X \otimes \mathbb{Q}) \geq 1$, $\dim T = r_T[E:\mathbb{Q}]$, and, if $T \neq \mathcal{A}_L$, $\mathcal{B}_L$ satisfies the Kottwitz condition of signature $(p - r_T, q - r_T)$; in particular $r_T \leq q$, and the σ_τ-eigenspace of $\mathrm{Lie}(T)$ has dimension r_T. Fix $\mathcal{O}_E$-linearly independent $\delta_1, \ldots, \delta_{r_T} \in X$, $k = [X : \sum_a \mathcal{O}_E \delta_a]$.

Step 5: the metrics ν_e. Fix e. By Lemma 34.7 and (Ai2), $\widehat{P}_{z_e}$ maps the vanishing cycles I_e at z_e isomorphically onto $2\pi i\, X_*(T_{z_e}) = 2\pi i\, X$, $\mathcal{O}_E$-equivariantly ($\widehat{P}$ is equivariant), and $M_{z_e} = \mathrm{Lie}(G_{\mathcal{X},z_e})/\mathrm{Lie}(T_{z_e})$. Let $u_a \in I_e$ with $\widehat{P}_{z_e}(u_a) = 2\pi i\, \delta_a$; they are $\mathcal{O}_E$-linearly independent and span a subgroup of index k in I_e. Choose an ι-stable complement C_e of $\mathrm{Lie}(T_{z_e})$ (a complement in each eigenspace), and let ν_e be the Hermitian metric for which $\mathrm{Lie}(T_{z_e}) \perp C_e$, the eigenspaces of $\mathrm{Lie}(T_{z_e})$ are mutually orthogonal, on each eigenspace $\mathrm{Lie}(T_{z_e})_\sigma$ the vectors $(\delta_a)_\sigma$ are orthogonal of squared length $(4\pi)^{-1}k^{1/(r_T|\Phi|)}$, and $C_e \cong M_{z_e}$ carries πH_0. Then

$$\prod_{\tau \in \Phi} \det\big(\nu_e((\delta_a)_{\sigma_\tau}, (\delta_b)_{\sigma_\tau})\big) = k\,(4\pi)^{-r_T|\Phi|}, \qquad \prod_{\tau \in \Phi} \det\big(\nu_e((2\pi i\delta_a)_{\sigma_\tau}, (2\pi i\delta_b)_{\sigma_\tau})\big) = k\,\pi^{r_T|\Phi|},$$

and the quotient metric of ν_e on M_{z_e} (and on each eigenspace of it) is πH_0.

Step 6: the hypothesis of Lemma D.23(i) at e. For $\tau \in \Phi$ choose, by (Ce) of Lemma 33.18, a holomorphic frame

$$b_\tau = (\widehat{P}((u_1)_{\sigma_\tau}), \dots, \widehat{P}((u_{r_T})_{\sigma_\tau}), b_{\tau,r_T+1}, \dots, b_{\tau,q})$$

of $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X}})^{\mathrm{an}} = \mathrm{Lie}_{\sigma_\tau}$ near z_e (the first vectors are linearly independent at z_e; complete them), and let ς be the local generator of $\mathcal{O}(a^{\mathrm{H}})$ near w_e corresponding under θ to the dual of $\bigotimes_\tau \det b_\tau$. For $z \in V_e^*$, by (Gb3) of Definition 31.11 (the norm of the Hodge-type line is dual to the determinant of h_z on the pieces $(\tau,-)$), $\|\varsigma\|_{h^{\mathrm{H}}}(z) = \prod_\tau \det \Gamma(b_\tau(z))^{-1/2}$, Γ the πH_z-Gram matrix. The vanishing cycles I_e are non-zero ($\dim T_{z_e} > 0$), so by (Cu) of Lemma 33.18, $\mathrm{N}_z(I_e)$ may be computed with the family u, $\mathrm{N}_z(I_e) = k^{-1}\prod_\tau \det\big(H_z(\widehat{P}((u_a)_{\sigma_\tau}), \widehat{P}((u_b)_{\sigma_\tau}))\big)$, and $U \geq -\log \mathrm{N}_z(I_e)$ at $y_{\mathbb{C}}(z)$. Hence

$$\|\varsigma\|_{h^\sharp}(z) \leq \|\varsigma\|_{h^{\mathrm{H}}}(z)\, e^{-U(z)/2} \leq \Big(\frac{\prod_\tau \det \Gamma(b_\tau(z))}{\mathrm{N}_z(I_e)}\Big)^{-1/2} = \Big(k\,\pi^{r_T|\Phi|}\prod_\tau \frac{\det \Gamma(b_\tau(z))}{\det \Gamma(\widehat{P}((u)_{\sigma_\tau})(z))}\Big)^{-1/2}.$$

By (Ce) and (Cv) of Lemma 33.18, the last ratio tends, as $z \to z_e$ in V_e^*, to

$$\nu_{\sigma_\tau} = \det\big(\pi H_0(\bar b_{\tau,i}(z_e), \bar b_{\tau,l}(z_e))\big)_{i,l>r_T}.$$

Since $h^\sharp$ is a smooth cone function on all of X^{b} and V_e^* is dense near z_e,

$$\|\varsigma\|_{h^\sharp}(w_e) \leq \big(k\pi^{r_T|\Phi|}\prod_\tau \nu_{\sigma_\tau}\big)^{-1/2}.$$

On the other side, by Gram–Schmidt along $\mathrm{Lie}(T_{z_e}) \perp C_e$ and Step 5, $\det\big(\nu_e(b_{\tau,i}(z_e), b_{\tau,l}(z_e))\big) = \det\big(\nu_e((2\pi i\delta_a)_{\sigma_\tau}, (2\pi i\delta_b)_{\sigma_\tau})\big)\,\nu_{\sigma_\tau}$, using $\widehat{P}((u_a)_\sigma)(z_e) = (2\pi i\delta_a)_\sigma$; so the norm of ς for the dual of the determinant metric of ν_e is $\big(k\pi^{r_T|\Phi|}\prod_\tau \nu_{\sigma_\tau}\big)^{-1/2} \geq \|\varsigma\|_{h^\sharp}(w_e)$. This is the hypothesis of Lemma D.23(i) at e.

Step 7: the degrees. Fix τ, $s = \sigma_\tau$. Let $K_\tau = \mathrm{Lie}_s(\mathcal{A}) \cap \mathrm{Lie}(T)$, saturated in $\mathrm{Lie}_s(\mathcal{A})$ of rank r_T, and Q_τ the quotient, a projective $\mathcal{O}_L$-module of rank $q - r_T$. For the metrics induced by ν on K_τ and the quotient metrics on Q_τ, $\widehat{\deg}\,(\mathrm{Lie}_s(\mathcal{A}), \nu) = \widehat{\deg}\,K_\tau + \widehat{\deg}\,Q_\tau$. By (Ai1), $K_\tau \subseteq (X \otimes_{\mathbb{Z}} \mathcal{O}_L) \cap V_s$ in the notation of Lemma D.55, a lattice of the same rank, so $\widehat{\deg}\,K_\tau$ is at most the degree of the latter, and Lemma D.55(a) with $\Psi = \{\sigma_\tau\}$ (for every e, $\{e \circ \sigma_\tau\}$ is a CM type, as in Step 3) and $c_e = (4\pi)^{-r_T|\Phi|}$ (Step 5) gives $\sum_\tau \widehat{\deg}\,K_\tau \leq \frac{1}{2} r_T|\Phi| \log(4\pi)[L:\mathbb{Q}] \leq 2|\Phi| q\,\Xi\,[L:\mathbb{Q}]$. If $T = \mathcal{A}_L$, $Q_\tau = 0$. Otherwise $d\varphi$ maps Q_τ injectively into $\mathrm{Lie}_s(\mathcal{B})$, of the same rank $q - r_T$, and by (Ai2) and Step 5 the quotient metric is the metric of $\overline{\mathrm{Lie}}(\mathcal{B})$; so $\widehat{\deg}\,Q_\tau \leq \widehat{\deg}\,\overline{\mathrm{Lie}}_s(\mathcal{B})$. Now Step 3 applies without change to $\mathcal{B}$ in place of $\mathcal{A}$, with $(p', q') = (p - r_T, q - r_T)$ (Step 4), $g_{\mathcal{B}} = |\Phi|(n - 2r_T) \leq g$, and the Rosati condition from (Ai2) and (Cv) ($E^{\mathrm{ab}} = \mathrm{Im}\, H_0$ is $\mathcal{O}_E$-adjoint): Proposition D.36 gives $\sum_\tau |d_{\sigma_\tau}(\mathcal{B}) - d_{\sigma_\tau \circ c}(\mathcal{B})| \leq 2C_{\mathrm{fs}} g_{\mathcal{B}} \Xi$, and Lemma D.26 gives $\sum_\tau \widehat{\deg}\,\overline{\mathrm{Lie}}_{\sigma_\tau}(\mathcal{B}) \leq C_1|\Phi|(q - r_T)\,\Xi\,[L:\mathbb{Q}]$. Adding, $\sum_\tau d_{\sigma_\tau}(\nu) \leq (C_1 + 2)|\Phi| q\,\Xi$, which is $(*)$. $\square$

Lemma D.23. *Let a base setting of $\mathcal{T}$ at (B, Z) be given, and put $c_2 = 2\log 2$ and $c_\ell = \log \ell/(\ell - 1)$ for odd primes ℓ. Then the isomorphism of (Hy2) extends uniquely to an isomorphism of invertible sheaves $\theta\colon \bar y^* \mathcal{O}(a^{\mathrm{H}}) \to \bigotimes_{\tau \in \Phi} (\det \mathcal{V}_{(\tau,-)})^\vee$ on $\mathcal{X}$.*

Let $x \in \mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$, with Zariski closure D_x and residue field $K = \mathbf{k}(D_x)$, let $L \supseteq K$ be a number field and $P\colon \mathrm{Spec}\,\mathcal{O}_L \to \mathcal{X}$ a morphism as in Lemma D.24(2), and put $\mathcal{A} = P^* G_{\mathcal{X}}$, a semiabelian scheme over $\mathcal{O}_L$ with the induced $\mathcal{O}_E$-action ι. For $\tau \in \Phi$ let $\sigma_\tau\colon \mathcal{O}_E \to \mathcal{O}_L$ be $\bar\tau$ followed by the map $\mathcal{O}_F \to \mathcal{O}_L$ induced by P, and $\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}) = \{v \in \mathrm{Lie}(\mathcal{A}) : \iota(a)v = \sigma_\tau(a)v \text{ for all } a \in \mathcal{O}_E\}$. For a field embedding $e\colon L \to \mathbb{C}$ let z_e be the complex point of $\mathcal{X}$ given by e and P, and $w_e = y_{\mathbb{C}}(z_e) \in X^{\mathrm{b}}$; then $\mathrm{Lie}(\mathcal{A}) \otimes_{\mathcal{O}_L, e} \mathbb{C} = \mathrm{Lie}(G_{\mathcal{X}, z_e})$, which contains $\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z_e}) = P^*\mathcal{V}_{(\tau,-)} \otimes_{\mathcal{O}_L, e} \mathbb{C}$.

(i) (Every point.) Let $\nu = (\nu_e)_e$ be Hermitian metrics on the spaces $\mathrm{Lie}(G_{\mathcal{X},z_e})$, and $h^\sharp$ a smooth cone function of multidegree a^{H}, such that for every e the norm of $h^\sharp$ on the fibre of $\mathcal{O}(a^{\mathrm{H}})$ at w_e is at most the norm that corresponds under θ to the dual of the determinant metric of ν_e on $\bigotimes_\tau \det \mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z_e})$. Put $d_{\sigma_\tau}(\nu) = \widehat{\deg}\,(\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}),\nu)/[L:\mathbb{Q}]$, the Arakelov degree for the metrics induced by ν. Then

$$h_{(\mathcal{O}(a^{\mathrm{H}}),\,h^\sharp)|_{\mathcal{X}^{\mathrm{b}}}}(D_x) \;\geq\; -\Big(\sum_{\tau\in\Phi} d_{\sigma_\tau}(\nu) + |\Phi|\,q\sum_{\ell\in\mathrm{Bd}} c_\ell\Big)[K:\mathbb{Q}].$$

(ii) (Interior points.) Suppose that $\bar y^{-1}(x)$ lies in the abelian locus (equivalently, every complex point of $\mathcal{X}^{\mathrm{b}}$ over x lies in $X^{\mathrm{b},\circ}$). Then $\mathcal{A}$ is a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$, and for every smooth cone function $h^\sharp$ of multidegree a^{H} with $h^\sharp \geq h^{\mathrm{H}}$ on the cone over $X^{\mathrm{b},\circ}$ the hypothesis of (i) holds with $\nu_e = h_{z_e}$, the metric of $\overline{\mathrm{Lie}}(\mathcal{A})$ at e. Hence, with $d_{\sigma_\tau} = \widehat{\deg}\,\overline{\mathrm{Lie}}_{\sigma_\tau}(\mathcal{A})/[L:\mathbb{Q}]$,

$$h_{(\mathcal{O}(a^{\mathrm{H}}),\,h^\sharp)|_{\mathcal{X}^{\mathrm{b}}}}(D_x) \;\geq\; -\Big(\sum_{\tau\in\Phi} d_{\sigma_\tau} + |\Phi|\,q\sum_{\ell\in\mathrm{Bd}} c_\ell\Big)[K:\mathbb{Q}].$$

Proof. **Step 0: the extension θ.** By (Gb3), on every member $D(f)$ of the finite covers of the charts $\mathcal{X}_{c'}$, which cover $\mathcal{X}$ by (Gb1), the generator $\prod_k y_{k,c'_k}^{a_k^{\mathrm{H}}}$ of $\bar y^*\mathcal{O}(a^{\mathrm{H}})$ corresponds under the isomorphism of (Hy2) to a unit times a generator of $\bigotimes_\tau(\det \mathcal{V}_{(\tau,-)})^\vee$. Hence that isomorphism extends to an isomorphism θ of invertible sheaves on $\mathcal{X}$; it is unique, as $\mathcal{X}$ is integral and the abelian locus is dense.

Step 1: the point and the line at P. Write ξ for the image under P of the generic point of $\operatorname{Spec}\mathcal{O}_L$, so that $\tilde x = \bar y\circ P\colon \operatorname{Spec}\mathcal{O}_L \to \mathcal{X}^{\mathrm{b}}$ extends x. As $\tilde x$ factors through the normalisation of D_x, $[L:K]\,h_{(\mathcal{O}(a^{\mathrm{H}}),h^\sharp)}(D_x) = \widehat{\deg}\,\tilde x^*(\mathcal{O}(a^{\mathrm{H}}),h^\sharp)$. The scheme $\mathcal{A} = P^*G_{\mathcal{X}} = P^*f^*G_{\mathcal{Y}}$ is semiabelian over $\mathcal{O}_L$ with $\mathcal{O}_E$-action and a cubical line bundle (Definition 29.6, (Fh5)), and $\mathrm{Lie}(\mathcal{A}) = P^*\mathrm{Lie}(G_{\mathcal{X}})$, since the Lie algebra commutes with base change; in particular $\mathrm{Lie}(\mathcal{A})\otimes_{\mathcal{O}_L,e}\mathbb{C} = \mathrm{Lie}(G_{\mathcal{X},z_e})$. Pulling back θ gives $\tilde x^*\mathcal{O}(a^{\mathrm{H}}) \cong \bigotimes_\tau(\det M_\tau)^\vee$ with $M_\tau = P^*\mathcal{V}_{(\tau,-)}$, a projective $\mathcal{O}_L$-module of rank q, and $M_\tau\otimes_{\mathcal{O}_L,e}\mathbb{C} = \mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z_e})$ by (Gb2). Under the hypothesis of (i), $\|\cdot\|_{h^\sharp}$ is at every e at most the norm of $\bigotimes_\tau(\det\overline{M}_\tau)^\vee$, where $\overline{M}_\tau$ carries the metrics induced by ν; computing both degrees with one rational section,

$$\widehat{\deg}\,\tilde x^*(\mathcal{O}(a^{\mathrm{H}}),h^\sharp) \;\geq\; \sum_{\tau\in\Phi}\widehat{\deg}\,(\det\overline{M}_\tau)^\vee = -\sum_{\tau\in\Phi}\widehat{\deg}\,\overline{M}_\tau.$$

Step 2: M_τ inside the Lie lattice. The stalk $\mathcal{V}_{(\tau,-),\xi}$ is $\mathrm{dR}_{(\tau,-),\xi} = \mathrm{Lie}_\xi \cap \mathrm{Li}_{(\tau,-)}$ (ξ lies over no prime). Since $\mathbb{Q}\subseteq\mathcal{O}_\xi$, $\mathcal{O}_E\otimes\mathcal{O}_\xi$ is a product of copies of $\mathcal{O}_\xi$ indexed by the embeddings, so $\mathrm{Lie}_\xi = \bigoplus_s \mathrm{dR}_{s,\xi}$ and $\mathcal{V}_{(\tau,-),\xi}\otimes\mathbf{k}(\xi)\to\mathrm{Lie}(G_{\mathcal{X},\xi})$ is injective with image the $\bar\tau$-eigenspace. Hence the map $M_\tau\to M_\tau\otimes L = \mathcal{V}_{(\tau,-),\xi}\otimes_{\mathcal{O}_\xi}L\to\mathrm{Lie}_\xi\otimes_{\mathcal{O}_\xi}L = \mathrm{Lie}(\mathcal{A}_L)$ is injective (M_τ is torsion free), and its image (again written M_τ) is a lattice in the σ_τ-eigenspace $\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}_L)$, because $\iota(a)$ acts on $\mathcal{V}_{(\tau,-)}$ by $\bar\tau(a)$ and both have dimension q. For a maximal ideal $\mathfrak{p}$ the localisation $(M_\tau)_\mathfrak{p}$ is the image of $\mathcal{V}_{(\tau,-),P(\mathfrak{p})}\otimes\mathcal{O}_{L,\mathfrak{p}}$ under $P^\sharp$, and $\mathrm{Lie}_{\sigma_\tau}(\mathcal{A})_\mathfrak{p} = \mathrm{Lie}(\mathcal{A})_\mathfrak{p}\cap\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}_L)$. Let $\mathfrak{p}$ be a maximal ideal of $\mathcal{O}_L$ over the prime p and $x' = P(\mathfrak{p})$, a point over p (in the abelian locus or not).

- If $p\notin\mathrm{Bd}$, then $\mathcal{V}_{(\tau,-),x'} = \mathrm{dR}_{(\tau,-),x'}\subseteq\mathrm{Lie}_{x'}$, so $(M_\tau)_\mathfrak{p}\subseteq\mathrm{Lie}_{\sigma_\tau}(\mathcal{A})_\mathfrak{p}$.

- If $p=\ell\in\mathrm{Bd}$, then $\mathcal{V}_{(\tau,-),x'}=\mathrm{HT}_{(\tau,-),x'}(\ell^{R(\ell)})$. We apply Lemma 35.32 at x' with $p=\ell$, $R=R(\ell)$: $\mathcal{X}$ is noetherian by Lemma D.24(1); the $\ell^{R(\ell)}$-torsion of $G_{\mathcal{X}}$ is rational over Ω and $\mathrm{ht}_{x'}$ is free of rank $\dim \mathrm{Li}$ at every point over ℓ by (Gb1) (Hodge–Tate freeness); that lemma does not require $G_{\mathcal{X}}$ to be abelian at x'. Its part (3) gives $\varpi_\ell\,\mathcal{V}_{(\tau,-),x'}\subseteq \mathrm{dR}_{(\tau,-),x'}$, so $P^\sharp(\varpi_\ell)(M_\tau)_{\mathfrak{p}}\subseteq \mathrm{Lie}_{\sigma_\tau}(\mathcal{A})_{\mathfrak{p}}$. Moreover $P^\sharp(\zeta)$ is a primitive ℓ-th root of unity in L for odd ℓ, so $-\log|P^\sharp(\varpi_\ell)|_{\mathfrak{p}}=[L_{\mathfrak{p}}:\mathbb{Q}_\ell]\,\frac{\log\ell}{\ell-1}$, and $-\log|4|_{\mathfrak{p}}=[L_{\mathfrak{p}}:\mathbb{Q}_2]\,2\log 2$ for $\ell=2$; in both cases this is $[L_{\mathfrak{p}}:\mathbb{Q}_\ell]\,c_\ell$.

Let $N_\tau\subseteq \mathrm{Lie}_{\sigma_\tau}(\mathcal{A}_L)$ be the $\mathcal{O}_L$-lattice equal to $\mathrm{Lie}_{\sigma_\tau}(\mathcal{A})_{\mathfrak{p}}$ at $\mathfrak{p}$ not over Bd and to

$$P^\sharp(\varpi_\ell)^{-1}\mathrm{Lie}_{\sigma_\tau}(\mathcal{A})_{\mathfrak{p}}$$

at $\mathfrak{p}$ over $\ell\in\mathrm{Bd}$, with the metrics induced by ν. Then $M_\tau\subseteq N_\tau$ have the same rank and metrics, so $\widehat{\deg}\,\overline{M}_\tau=\widehat{\deg}\,\overline{N}_\tau-\log\#(N_\tau/M_\tau)\le\widehat{\deg}\,\overline{N}_\tau$, and

$$\widehat{\deg}\,\overline{N}_\tau=\widehat{\deg}\,(\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}),\nu)+q\sum_{\ell\in\mathrm{Bd}}\sum_{\mathfrak{p}\mid\ell}-\log|P^\sharp(\varpi_\ell)|_{\mathfrak{p}}=\widehat{\deg}\,(\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}),\nu)+q\,[L:\mathbb{Q}]\sum_{\ell\in\mathrm{Bd}}c_\ell,$$

using $\sum_{\mathfrak{p}\mid\ell}[L_{\mathfrak{p}}:\mathbb{Q}_\ell]=[L:\mathbb{Q}]$ and that multiplying a rank-q lattice at $\mathfrak{p}$ by π^{-1}, $|\pi|_{\mathfrak{p}}<1$, raises its degree by $-q\log|\pi|_{\mathfrak{p}}$.

Step 3: conclusion of (i). By Steps 1 and 2,

$$[L:K]\,h_{(\mathcal{O}(a^{\mathrm{H}}),h^\sharp)}(D_x)\ge-\sum_{\tau\in\Phi}\widehat{\deg}\,(\mathrm{Lie}_{\sigma_\tau}(\mathcal{A}),\nu)-|\Phi|\,q\,[L:\mathbb{Q}]\sum_{\ell\in\mathrm{Bd}}c_\ell;$$

dividing by $[L:K]$ and using $[L:\mathbb{Q}]/[L:K]=[K:\mathbb{Q}]$ gives (i).

Step 4: (ii). Suppose $\bar y^{-1}(x)$ lies in the abelian locus. Then $\xi=\bar y^{-1}(x)$, and the generic fibre of $\mathcal{A}$ is the base change of the fibre of $G_{\mathcal{X}}$ at ξ, which lies over $j(\mathrm{Sh}_F)$, so it is an abelian variety with ample, principally polarising line bundle (Definition 29.5); so $\mathcal{A}$ is as in Definition 31.6. The equivalence in the hypothesis: by (Gb1) ∂X^{b} is the image under $y_{\mathbb{C}}=\bar y_{\mathbb{C}}$ of the complex points of $\mathcal{X}$ outside the abelian locus, $\bar y$ is an isomorphism, and a complex point over ξ lies in the abelian locus if and only if ξ does. Every z_e lies over ξ, hence in the abelian locus, and $w_e\in X^{\mathrm{b},\circ}$. By (Gb2), (Gb3) and the convention $\|\sigma\|=|\sigma|/h$, the metric given by h^{H} at w_e is, under θ, the dual of the determinant of h_{z_e} on $\bigotimes_\tau\det\mathrm{Lie}_{(\tau,-)}(G_{\mathcal{X},z_e})$. Since $h^\sharp\ge h^{\mathrm{H}}$ there, $\|\cdot\|_{h^\sharp}\le\|\cdot\|_{h^{\mathrm{H}}}$ at w_e, which is the hypothesis of (i) for $\nu_e=h_{z_e}=\pi H_{z_e}$, the metric of $\overline{\mathrm{Lie}}(\mathcal{A})$ at e (Definition 31.6). Then $d_{\sigma_\tau}(\nu)=d_{\sigma_\tau}$, and (i) gives (ii). □

Lemma D.24. *Let a base setting of $\mathcal{T}$ at (B,Z) be given, with cover $\mathcal{X}$, function field Ω and representing coordinates y. For an index c' with $y_{c'}\neq0$ let $\mathbb{Z}[y]_{c'}$, the points lying in the chart c' and the affine open subset $\mathcal{X}_{c'}$ be as in the coordinate-chart clause of (Gb1). Then:*

1. *there is a unique isomorphism of schemes $\bar y\colon\mathcal{X}\to\mathcal{X}^{\mathrm{b}}$ that induces on function fields the identification of $\mathbf{k}(\mathcal{X}^{\mathrm{b}})$ with Ω given by y; it maps $\mathcal{X}_{c'}$ onto $\mathcal{X}^{\mathrm{b}}\cap\{Y_{c'}\neq0\}$, where $Y_{c'}=\prod_k Y_{k,c'_k}$ in the multihomogeneous coordinates Y of $\mathbb{P}$. In particular $\mathcal{X}$ is of finite type over $\mathbb{Z}$, hence noetherian, and the rational map y is defined at every point of $\mathcal{X}$;*
2. *for every $x\in\mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$, with Zariski closure D_x and residue field $K_x=\mathbf{k}(D_x)$, and every number field $L\supseteq K_x$, there is a morphism $P\colon\operatorname{Spec}\mathcal{O}_L\to\mathcal{X}$ such that y is defined at the image of the generic point and sends it to x, and such that for every maximal ideal $\mathfrak{p}$ of $\mathcal{O}_L$ the image $P(\mathfrak{p})$ lies in some chart.*

So every algebraic point of $\mathcal{X}^{\mathrm{b}}$ satisfies the lifting hypothesis of Lemma D.25, with $L=K_x$.

Proof. **Step 1: the charts of $\mathcal{X}^{\mathrm{b}}$.** For an index c' write $\mathbb{A}_{c'} = \{Y_{c'} \neq 0\} = \operatorname{Spec} \mathbb{Z}[Y_{k,i}/Y_{k,c'_k}]$ for the standard affine chart of $\mathbb{P}$ and $\mathcal{X}^{\mathrm{b}}_{c'} = \mathcal{X}^{\mathrm{b}} \cap \mathbb{A}_{c'}$, an open subset of the integral scheme $\mathcal{X}^{\mathrm{b}}$. If $y_{c'} = 0$ in Ω, the generic point of $\mathcal{X}^{\mathrm{b}}$ is not in $\mathbb{A}_{c'}$, so the open set $\mathcal{X}^{\mathrm{b}}_{c'}$ contains no generic point and is empty. If $y_{c'} \neq 0$, then $\mathcal{X}^{\mathrm{b}}_{c'}$ is a non-empty closed integral subscheme of $\mathbb{A}_{c'}$ whose generic point is the Ω-point $Y_{k,i}/Y_{k,c'_k} \mapsto y_{k,i}/y_{k,c'_k}$; its ideal is therefore the kernel of the evaluation $\mathbb{Z}[Y_{k,i}/Y_{k,c'_k}] \to \Omega$ (a function on an integral affine scheme vanishes if and only if it vanishes at the generic point), and $\mathcal{X}^{\mathrm{b}}_{c'} = \operatorname{Spec} \mathbb{Z}[y]_{c'}$. The sets $\mathbb{A}_{c'}$ cover $\mathbb{P}$, so the $\mathcal{X}^{\mathrm{b}}_{c'}$ with $y_{c'} \neq 0$ cover $\mathcal{X}^{\mathrm{b}}$.

Step 2: the isomorphism. For $y_{c'} \neq 0$ the affine open subscheme $\mathcal{X}_{c'}$ has ring $\mathbb{Z}[y]_{c'}$ by the coordinate-chart clause of (Gb1), so the identity of $\mathbb{Z}[y]_{c'}$ gives an isomorphism $\bar{y}_{c'} \colon \mathcal{X}_{c'} \to \mathcal{X}^{\mathrm{b}}_{c'}$, which induces the identity of Ω on function fields. On $\mathcal{X}_{c'} \cap \mathcal{X}_{c''}$ the two morphisms $\bar{y}_{c'}, \bar{y}_{c''}$ to the separated scheme $\mathcal{X}^{\mathrm{b}}$ agree at the generic point (both send it to the generic point of $\mathcal{X}^{\mathrm{b}}$ by the identity of Ω); since $\mathcal{X}^{\mathrm{b}}$ is of finite type over $\mathbb{Z}$ they agree on a non-empty open subset, and two morphisms from a reduced scheme to a separated scheme that agree on a dense open subset are equal. By the coordinate-chart clause of (Gb1) every point lies in some chart, so the $\mathcal{X}_{c'}$ cover $\mathcal{X}$, so the $\bar{y}_{c'}$ glue to a morphism $\bar{y} \colon \mathcal{X} \to \mathcal{X}^{\mathrm{b}}$. We have $\bar{y}^{-1}(\mathcal{X}^{\mathrm{b}}_{c'}) = \mathcal{X}_{c'}$: the inclusion $\supseteq$ holds by construction, and if $\bar{y}(x') \in \mathcal{X}^{\mathrm{b}}_{c'}$ then $\mathbb{Z}[y]_{c'} \subseteq \mathcal{O}_{\mathcal{X}^{\mathrm{b}},\bar{y}(x')}$, and the local homomorphism $\bar{y}^\sharp$, which is the inclusion of subrings of Ω, gives $\mathbb{Z}[y]_{c'} \subseteq \mathcal{O}_{\mathcal{X},x'}$, i.e. $x' \in \mathcal{X}_{c'}$. So over each member $\mathcal{X}^{\mathrm{b}}_{c'}$ of an open cover of $\mathcal{X}^{\mathrm{b}}$ the morphism $\bar{y}$ restricts to the isomorphism $\bar{y}_{c'}$; hence $\bar{y}$ is an isomorphism. Uniqueness: a morphism inducing the identity of Ω agrees with $\bar{y}$ at the generic point, hence everywhere, by the argument above. Since $\mathcal{X}^{\mathrm{b}}$ is of finite type over $\mathbb{Z}$, so is $\mathcal{X}$; and y is defined at every point, being the composite of $\bar{y}$ with the inclusion $\mathcal{X}^{\mathrm{b}} \subseteq \mathbb{P}$.

Step 3: integral points of $\mathcal{X}^{\mathrm{b}}$. Let x and $L \supseteq K_x$ be given; x defines a morphism $\operatorname{Spec} L \to \mathcal{X}^{\mathrm{b}}$, with multihomogeneous coordinates $w = (w_{k,i})$, $w_{k,i} \in L$, not all zero in each factor k. For c' with $w_{c'} = \prod_k w_{k,c'_k} \neq 0$ put $\mathcal{O}_L[w]_{c'} = \mathcal{O}_L[\, w_{k,i}/w_{k,c'_k} \,] \subseteq L$. Let T be the finite set of maximal ideals $\mathfrak{p}$ with $|w_{k,i}/w_{k,c'_k}|_{\mathfrak{p}} > 1$ for some (k,i). Since the class group of L is finite, there is $s \in \mathcal{O}_L \smallsetminus \{0\}$ whose prime divisors are exactly the members of T (take s generating $(\prod_{\mathfrak{p} \in T} \mathfrak{p})^h$, h the class number). Both $\mathcal{O}_L[w]_{c'}$ and $\mathcal{O}_L[1/s]$ are rings between $\mathcal{O}_L$ and L, hence each is the intersection of the $\mathcal{O}_{L,\mathfrak{p}}$ containing it; a maximal ideal $\mathfrak{p}$ has $\mathcal{O}_{L,\mathfrak{p}} \supseteq \mathcal{O}_L[w]_{c'}$ if and only if $\mathfrak{p} \notin T$, if and only if $\mathcal{O}_{L,\mathfrak{p}} \supseteq \mathcal{O}_L[1/s]$. So $\mathcal{O}_L[w]_{c'} = \mathcal{O}_L[1/s]$, and $V_{c'} = \operatorname{Spec} \mathcal{O}_L[w]_{c'}$ is the open subset $D(s)$ of $\operatorname{Spec} \mathcal{O}_L$: the generic point and the maximal ideals not in T. Since x lies in $\mathcal{X}^{\mathrm{b}}_{c'} = \operatorname{Spec} \mathbb{Z}[y]_{c'}$, the ring homomorphism $\mathbb{Z}[y]_{c'} \to L$ of x sends $y_{k,i}/y_{k,c'_k}$ to $w_{k,i}/w_{k,c'_k}$ and takes values in $\mathcal{O}_L[w]_{c'}$; this gives a morphism $\tilde{x}_{c'} \colon V_{c'} \to \mathcal{X}^{\mathrm{b}}_{c'}$ extending x. Every maximal ideal $\mathfrak{p}$ lies in some $V_{c'}$: choose, for every k, c'_k with $|w_{k,c'_k}|_{\mathfrak{p}} = \max_i |w_{k,i}|_{\mathfrak{p}}$. On overlaps the $\tilde{x}_{c'}$ agree at the generic point, hence agree (as in Step 2: $\operatorname{Spec} \mathcal{O}_L$ is reduced and $\mathcal{X}^{\mathrm{b}}$ separated). They glue to $\tilde{x} \colon \operatorname{Spec} \mathcal{O}_L \to \mathcal{X}^{\mathrm{b}}$ extending x, with $\tilde{x}(\mathfrak{p}) \in \mathcal{X}^{\mathrm{b}}_{c'}$ whenever $\mathfrak{p} \in V_{c'}$.

Step 4: conclusion. Put $P = \bar{y}^{-1} \circ \tilde{x}$. The generic point of $\operatorname{Spec} \mathcal{O}_L$ goes to $\bar{y}^{-1}(x)$, where y is defined (Step 2) with value $\bar{y}(\bar{y}^{-1}(x)) = x$. For a maximal ideal $\mathfrak{p}$ and c' with $\mathfrak{p} \in V_{c'}$, $\tilde{x}(\mathfrak{p}) \in \mathcal{X}^{\mathrm{b}}_{c'}$, so $P(\mathfrak{p}) \in \bar{y}^{-1}(\mathcal{X}^{\mathrm{b}}_{c'}) = \mathcal{X}_{c'}$ by Step 2: $P(\mathfrak{p})$ lies in the chart c'. With $L = K_x$ this is the hypothesis of Lemma D.25, whose remaining hypothesis ($\mathcal{X}$ locally noetherian) holds by item 1 (Step 2). □

Lemma D.25. *Let a base setting of $\mathcal{T}$ at (B, Z) be given, with cover $\mathcal{X}$, and suppose that $\mathcal{X}$ is locally noetherian. A point x' of $\mathcal{X}$ lies in a chart c' as in the coordinate-chart clause of (Gb1), that is, $y_{k,i}/y_{k,c'_k} \in \mathcal{O}_{\mathcal{X},x'}$ for all (k,i). Let $x \in \mathcal{X}^{\mathrm{b}}(\overline{\mathbb{Q}})$ with Zariski closure D_x and residue field $K = \mathbf{k}(D_x)$, and suppose that there are a number field $L \supseteq K$ and a morphism $P \colon \operatorname{Spec} \mathcal{O}_L \to \mathcal{X}$ such that the rational map y is defined at the image of the generic point and sends it to x, and such that for every maximal ideal $\mathfrak{p}$ of $\mathcal{O}_L$ the image $x_{\mathfrak{p}} \in \mathcal{X}$ of $\mathfrak{p}$ lies in some chart. Put $c_2 = 2 \log 2$ and $c_\ell = \log \ell/(\ell - 1)$ for odd primes ℓ. Then for every multidegree a*

and every smooth cone function h of multidegree a,

$$-|\Phi|\,q\Big(\sum_{\ell\in S'_B} c_\ell\Big)[K:\mathbb{Q}] \;\le\; h_{(\mathcal{O}(a+\sum_{\ell\in S'_B} v_\ell),\, h\prod_{\ell\in S'_B}|g_\ell|)}(D_x) - h_{(\mathcal{O}(a),h)}(D_x) \;\le\; 0,$$

the line bundles being restricted to $\mathcal{X}^{\mathrm{b}}$; and

$$\sum_{\ell\in S'_B} c_\ell \;\le\; \sum_{\ell\le B} c_\ell \;\le\; \log B + 11.$$

In particular, for a base setting with cusp data, every $t'>0$ and x as above, $h_{\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}}(D_x) \ge h_{(\mathcal{O}(a^{\mathrm{H}}),\, h^{\mathrm{ref}'}e^{\psi_{t'}})}(D_x) - |\Phi|\,q\,(\log B+11)\,[K:\mathbb{Q}]$.

Proof. **Step 1: heights at x by local terms.** Let $(\mathcal{O}(b),h_b)$ be a line bundle of $\mathbb{P}$ with a smooth cone function, restricted to $\mathcal{X}^{\mathrm{b}}$. The L-point x extends uniquely to $\tilde{x}\colon \operatorname{Spec}\mathcal{O}_L\to\mathcal{X}^{\mathrm{b}}$, since $\mathbb{P}$ is proper, and $\tilde{x}$ factors through the normalisation of D_x, so $[L:K]\,h_{(\mathcal{O}(b),h_b)}(D_x) = \widehat{\deg}\,\tilde{x}^*(\mathcal{O}(b),h_b)$. Let σ be a quotient of multihomogeneous polynomials of multidegree difference b which is defined and non-zero at x. At a maximal ideal $\mathfrak{p}$, choose c with $|y_{k,c_k}(x)|_{\mathfrak{p}} = \max_i|y_{k,i}(x)|_{\mathfrak{p}}$ for every k; then $\tilde{x}$ maps $\operatorname{Spec}\mathcal{O}_{L,\mathfrak{p}}$ into the standard affine chart $\{y_c\neq 0\}$ of $\mathbb{P}$, on which the monomial $y_c^b=\prod_k y_{k,c_k}^{b_k}$ generates $\mathcal{O}(b)$. Hence

$$[L:K]\,h_{(\mathcal{O}(b),h_b)}(D_x) = \sum_{\mathfrak{p}} -\log\Big|\frac{\sigma}{y_c^b}(x)\Big|_{\mathfrak{p}} + \sum_{e\colon L\to\mathbb{C}} -\log\frac{|\sigma(e(x))|}{h_b(e(x))},$$

and the $\mathfrak{p}$-term does not depend on the choice of a maximising c. **Step 2: the difference.** Apply Step 1 to $(\mathcal{O}(a),h)$ with σ and to the twisted bundle with the section $\sigma\prod_\ell g_\ell$, which is defined and non-zero at x since the divisors of the g_ℓ are vertical. At the archimedean places $|\sigma\prod g_\ell|/(h\prod|g_\ell|)=|\sigma|/h$, so these terms cancel. Since max over monomials of multidegree $a+\sum v_\ell$ is attained at the same c for all multidegrees,

$$[L:K]\,\big(h_{\mathrm{tw}}(D_x)-h(D_x)\big) = \sum_{\ell\in S'_B}\sum_{\mathfrak{p}} -\log|f_{\ell,\mathfrak{p}}(x)|_{\mathfrak{p}},\qquad f_{\ell,\mathfrak{p}} = g_\ell/y_{c(\mathfrak{p})}^{v_\ell},$$

with $c(\mathfrak{p})$ any maximising index at $\mathfrak{p}$. **Step 3: $\mathfrak{p}\nmid\ell$.** On $\mathcal{X}^{\mathrm{b}}\cap\{y_c\neq0\}$ the rational function $f_{\ell,\mathfrak{p}}$ is a local equation of the Cartier divisor $\operatorname{div}(g_\ell)$, which is supported over ℓ; so it is a unit at every point of this chart not over ℓ. The closed point of $\tilde{x}$ at $\mathfrak{p}$ lies over $p\neq\ell$; hence $|f_{\ell,\mathfrak{p}}(x)|_{\mathfrak{p}}=1$. **Step 4: $\mathfrak{p}\mid\ell$, $\ell\in S'_B$.** By hypothesis $x_{\mathfrak{p}}=P(\mathfrak{p})$ lies in a chart c'. The local homomorphism $P^\sharp\colon\mathcal{O}_{\mathcal{X},x_{\mathfrak{p}}}\to\mathcal{O}_{L,\mathfrak{p}}$ sends $y_{k,i}/y_{k,c'_k}$ to its value at x (the map y is defined at the generic point of P with image x), so $|y_{k,i}(x)/y_{k,c'_k}(x)|_{\mathfrak{p}}\le1$ and c' is maximising at $\mathfrak{p}$; take $c(\mathfrak{p})=c'$. The point $x_{\mathfrak{p}}$ lies over ℓ and in the chart c', so by (Gb4) $f_{\ell,\mathfrak{p}}=u\prod_{\tau\in\Phi}\det T_\tau$ with $u\in\mathcal{O}^\times_{\mathcal{X},x_{\mathfrak{p}}}$, where T_τ is the matrix of a basis of $\mathrm{HT}_{(\tau,-),x_{\mathfrak{p}}}(\ell^{R(\ell)})$ in a basis of $\mathcal{V}_{(\tau,-),x_{\mathfrak{p}}}$, a $q\times q$ matrix over Ω. Since $\ell\notin\mathrm{Bd}$, $\mathcal{V}_{(\tau,-),x_{\mathfrak{p}}}=\mathrm{dR}_{(\tau,-),x_{\mathfrak{p}}}$ by (Fh5). We apply Lemma 35.32 with $p=\ell$, $R=R(\ell)$ at $x_{\mathfrak{p}}$: $\mathcal{X}$ is a locally noetherian cover; every $\ell^{R(\ell)}$-torsion point of $G_{\mathcal{X}}$ over an algebraic closure of Ω is defined over Ω by (Gb1); and $\mathrm{ht}_{x_{\mathfrak{p}}}$ is locally free, hence free, of rank $g=\dim\mathrm{Li}$ by the Hodge–Tate freeness of (Gb1). It gives $\varpi_\ell\in\mathcal{O}_{\mathcal{X},x_{\mathfrak{p}}}$, $\mathrm{dR}_{(\tau,-)}\subseteq\mathrm{HT}_{(\tau,-)}(\ell^{R(\ell)})$ and $\varpi_\ell\,\mathrm{HT}_{(\tau,-)}(\ell^{R(\ell)})\subseteq\mathrm{dR}_{(\tau,-)}$ at $x_{\mathfrak{p}}$. The first inclusion says that T_τ^{-1} has entries in $\mathcal{O}_{\mathcal{X},x_{\mathfrak{p}}}$, the second that $\varpi_\ell T_\tau$ has. Hence

$$f_{\ell,\mathfrak{p}}^{-1}\in\mathcal{O}_{\mathcal{X},x_{\mathfrak{p}}},\qquad \varpi_\ell^{q|\Phi|}f_{\ell,\mathfrak{p}}\in\mathcal{O}_{\mathcal{X},x_{\mathfrak{p}}}.$$

Apply $P^\sharp$. The image ζ' of the primitive ℓ-th root of unity ζ of Lemma 35.32 satisfies $\Phi_\ell(\zeta')=0$ for the ℓ-th cyclotomic polynomial, and $\Phi_\ell(1)=\ell\neq0$ in L, so ζ' is a primitive ℓ-th root of

unity and $P^\sharp(\varpi_\ell) \neq 0$, with $-\log|P^\sharp(\varpi_\ell)|_{\mathfrak{p}} = [L_{\mathfrak{p}} : \mathbb{Q}_\ell]\, c_\ell$ (for ℓ odd, $\zeta' - 1$ has ℓ-adic valuation $1/(\ell-1)$; for $\ell = 2$, $\varpi_2 = 4$). Both images are integral and their product is $P^\sharp(\varpi_\ell)^{q|\Phi|} \neq 0$; and $P^\sharp(f_{\ell,\mathfrak{p}}) = f_{\ell,\mathfrak{p}}(x)$. Therefore

$$-q|\Phi|\,[L_{\mathfrak{p}} : \mathbb{Q}_\ell]\, c_\ell \;\leq\; -\log|f_{\ell,\mathfrak{p}}(x)|_{\mathfrak{p}} \;\leq\; 0.$$

Step 5: summation. Summing Step 4 over $\mathfrak{p} \mid \ell$ ($\sum_{\mathfrak{p}|\ell}[L_{\mathfrak{p}} : \mathbb{Q}_\ell] = [L : \mathbb{Q}]$), Step 3 over the other $\mathfrak{p}$, and then over $\ell \in S'_B$, Step 2 gives $-q|\Phi|\,[L : \mathbb{Q}] \sum_{\ell \in S'_B} c_\ell \leq [L : K](h_{\mathrm{tw}}(D_x) - h(D_x)) \leq 0$; divide by $[L : K]$, using $[L : \mathbb{Q}]/[L : K] = [K : \mathbb{Q}]$. **Step 6: the sum over primes.** Write $c_\ell = \sum_{m \geq 1} \log \ell/\ell^m$ for odd ℓ and $c_2 = \log 2 + \sum_{m \geq 1} \log 2/2^m$. Splitting at $\ell^m \leq B$,

$$\sum_{\ell \leq B} c_\ell \leq \log 2 + \sum_{n \leq B} \frac{\Lambda(n)}{n} + \sum_{\ell \leq B} \log \ell \sum_{m:\ \ell^m > B} \ell^{-m}.$$

For $\ell \leq B$ let m_0 be least with $\ell^{m_0} > B$; then $\sum_{m \geq m_0} \ell^{-m} = \ell^{-m_0}\ell/(\ell-1) \leq 2/B$, so the last sum is at most $(2/B)\sum_{n \leq B} \Lambda(n) \leq 6$ by Lemma 3.5(2), and the middle sum is at most $\log B + 3 + \log 2$ by Lemma 3.5(3). Hence $\sum_{\ell \leq B} c_\ell \leq \log B + 9 + 2\log 2 \leq \log B + 11$, and $S'_B \subseteq \{\ell \leq B\}$. **Step 7: the corrected line.** By Definition 31.12, $\overline{\mathcal{H}}^{\mathrm{c}}_{B,t'}$ is the twisted bundle of the lemma for $a = a^{\mathrm{H}}$ and the smooth cone function $h = h^{\mathrm{ref}'} e^{\psi_{t'}}$ (with $S_B = S'_B$), so the last assertion is the lower inequality together with Step 6. □

Lemma D.26. *Let E be a CM field with complex conjugation c, L a number field containing the image of every field embedding $E \to \overline{\mathbb{Q}}$ of E into an algebraic closure of L, and $\mathcal{A}$ a principally polarised abelian scheme with $\mathcal{O}_E$-action ι over $\mathcal{O}_L$ of relative dimension g. For a field embedding $\sigma\colon E \to L$ put*

$$\mathrm{Lie}_\sigma(\mathcal{A}) = \{x \in \mathrm{Lie}(\mathcal{A}) :\ \iota(a)x = \sigma(a)x \text{ for all } a \in \mathcal{O}_E\}, \qquad d_\sigma = \frac{\widehat{\deg}\,\overline{\mathrm{Lie}}_\sigma(\mathcal{A})}{[L : \mathbb{Q}]}, \qquad \bar\sigma = \sigma \circ c.$$

Let Ψ be a set of embeddings $E \to L$ such that every embedding $E \to L$ lies in exactly one of Ψ and $\bar\Psi = \{\bar\sigma : \sigma \in \Psi\}$, and put $r_\Psi = \sum_{\sigma \in \Psi} \mathrm{rk}\,\mathrm{Lie}_\sigma(\mathcal{A})$. Let $C_{\mathrm{f}} \geq 0$ and $\Xi \geq 1$ be real numbers with

$$g \leq e^\Xi \qquad \text{and} \qquad \sum_{\sigma \in \Psi} |d_\sigma - d_{\bar\sigma}| \leq C_{\mathrm{f}}\, g\, \Xi.$$

Then

$$\sum_{\sigma \in \Psi} d_\sigma \;\leq\; (C_{\mathrm{ll}} + \tfrac{1}{2})(2 + \log(3 + C_{\mathrm{f}}))\, r_\Psi\, \Xi.$$

Proof. Write $V = \overline{\mathrm{Lie}}(\mathcal{A})$, $\widehat{\mu}_{\max} = \widehat{\mu}_{\max}(V)$, $h = -\widehat{\deg}(V)/[L : \mathbb{Q}]$, so that $h^+(\mathcal{A}) = \max(h, 0)$, and put $x = \sum_{\sigma \in \Psi} d_\sigma$, $y = \sum_{\sigma \in \Psi} d_{\bar\sigma}$, $C_{\mathrm{s}} = C_{\mathrm{ll}} + \frac{1}{2} \geq 0$.

The eigen-submodules have total degree at most that of V: $x + y \leq -h$. Since L contains all conjugates of E, $\mathcal{O}_E \otimes_{\mathbb{Z}} L \cong \prod_{\sigma\colon E \to L} L$ by $a \otimes b \mapsto (\sigma(a)b)_\sigma$, and the corresponding idempotents decompose $\mathrm{Lie}(\mathcal{A}) \otimes_{\mathcal{O}_L} L = \bigoplus_\sigma W_\sigma$ with W_σ the σ-eigenspace of ι. As $\mathrm{Lie}(\mathcal{A})$ is torsion-free, $\mathrm{Lie}_\sigma(\mathcal{A}) = \mathrm{Lie}(\mathcal{A}) \cap W_\sigma$, a saturated submodule whose L-span is W_σ (every $w \in W_\sigma$ has a non-zero integer multiple in $\mathrm{Lie}(\mathcal{A})$). Hence $M = \sum_\sigma \mathrm{Lie}_\sigma(\mathcal{A})$, the sum over all embeddings $\sigma\colon E \to L$, i.e. over $\Psi \sqcup \bar\Psi$, is a direct sum and a submodule of $\mathrm{Lie}(\mathcal{A})$ of full rank g, so $\mathrm{Lie}(\mathcal{A})/M$ is finite and $\widehat{\deg}\,\overline{M} = \widehat{\deg}\,V - \log\#(\mathrm{Lie}(\mathcal{A})/M) \leq \widehat{\deg}\,V$, $\overline{M}$ with the induced norms. For a direct sum $M = M_1 \oplus M_2$ of projective $\mathcal{O}_L$-modules with norms induced from one Hermitian norm at each complex place, $\det M = \det M_1 \otimes \det M_2$, and at every complex place the norm of $s_1 \wedge s_2$ ($s_i \in \det M_i \otimes \mathbb{C}$) is at most $\|s_1\|\,\|s_2\|$ by Fischer's inequality for the Gram matrix of the

union of bases (the determinant of a positive definite block matrix is at most the product of the determinants of its diagonal blocks); hence $\widehat{\deg}\,\overline{M} \geq \widehat{\deg}\,\overline{M}_1 + \widehat{\deg}\,\overline{M}_2$. By induction over the summands,

$$[L:\mathbb{Q}]\,(x+y) = \sum_{\sigma} \widehat{\deg}\,\overline{\mathrm{Lie}}_\sigma(\mathcal{A}) \leq \widehat{\deg}\,\overline{M} \leq \widehat{\deg}\,V = -[L:\mathbb{Q}]\,h.$$

The conjugate degrees nearly agree: $x - y \leq C_{\mathrm{f}} g \Xi$. Indeed $x - y = \sum_{\sigma\in\Psi}(d_\sigma - d_{\bar\sigma}) \leq \sum_{\sigma\in\Psi} |d_\sigma - d_{\bar\sigma}| \leq C_{\mathrm{f}} g \Xi$ by hypothesis.

Case $h \geq C_{\mathrm{f}} g \Xi$ (large height). Adding the two inequalities, $2x \leq -h + C_{\mathrm{f}} g \Xi \leq 0$, so $x \leq 0$, which is at most the right-hand side of the claim (all its factors are ≥ 0).

Case $h < C_{\mathrm{f}} g \Xi$ (small height). Then $\max(h,0) \leq C_{\mathrm{f}} g \Xi$, and since $g \geq 1$, $\Xi \geq 1$, so $g\Xi \geq 1$,

$$2 + g + h^+(\mathcal{A}) \leq 2g\Xi + g\Xi + C_{\mathrm{f}} g \Xi = (3 + C_{\mathrm{f}})\, g\, \Xi.$$

With $\log g \leq \Xi$ and $\log \Xi \leq \Xi$ this gives $\log(2+g+h^+(\mathcal{A})) \leq \log(3+C_{\mathrm{f}}) + 2\Xi \leq (2+\log(3+C_{\mathrm{f}}))\Xi$. By the logarithmic slope bound Proposition D.27,

$$\widehat{\mu}_{\max} \leq \mu^*, \qquad \mu^* = C_{\mathrm{s}}(2 + \log(3 + C_{\mathrm{f}}))\Xi \ \geq 0.$$

For $\sigma \in \Psi$ with $\mathrm{Lie}_\sigma(\mathcal{A}) \neq 0$, the normalised slope of $\overline{\mathrm{Lie}}_\sigma(\mathcal{A})$ is at most $\widehat{\mu}_{\max}$ by the definition of the maximal slope, so $d_\sigma \leq \mathrm{rk}\,\mathrm{Lie}_\sigma(\mathcal{A})\,\widehat{\mu}_{\max} \leq \mathrm{rk}\,\mathrm{Lie}_\sigma(\mathcal{A})\,\mu^*$ (using $\widehat{\mu}_{\max} \leq \mu^*$ and $\mathrm{rk} \geq 0$); for $\mathrm{Lie}_\sigma(\mathcal{A}) = 0$ both sides vanish. Summing over Ψ gives $x \leq r_\Psi\, \mu^*$, the claim.

Remark on the use of the slope bound. Only the second case uses Proposition D.27, and only there is it essential that the bound is logarithmic in the height: a bound linear in h^+ would give $x \leq C\, r_\Psi\, g\, \Xi$ instead. □

Proposition D.27. *For every CM field E, every number field L and every principally polarised abelian scheme $\mathcal{A}$ with $\mathcal{O}_E$-action over $\mathcal{O}_L$ of relative dimension g,*

$$\widehat{\mu}_{\max}\big(\overline{\mathrm{Lie}}(\mathcal{A})\big) \ \leq \ (C_{\mathrm{ll}} + \tfrac{1}{2}) \log\big(2 + g + h^+(\mathcal{A})\big).$$

Proof. Write $\overline{M} = \overline{\mathrm{Lie}}(\mathcal{A})$ and $Y = \log(2+g+h^+(\mathcal{A}))$. It suffices to show $\widehat{\mu}(\overline{F}) \leq C_{\mathrm{ll}} Y + \frac{1}{2}\log r + \varepsilon$ for every non-zero submodule $F \subseteq M$ of rank r and every $\varepsilon > 0$, since $r \leq g$ gives $\frac{1}{2}\log r \leq \frac{1}{2} Y$.

A large line in F. By Zhang's absolute Siegel lemma [276] (Theorem B.136, applied to the Hermitian lattice $\overline{F}$ of rank $r \geq 1$ over $\mathcal{O}_L$) there are a finite extension K'/L and $0 \neq v \in F \otimes_{\mathcal{O}_L} K'$ such that the rank-one Hermitian lattice $\overline{N} = \overline{F}_{K'}(v) = K'v \cap (F \otimes_{\mathcal{O}_L} \mathcal{O}_{K'})$ satisfies $\widehat{\mu}(\overline{N}) \geq \widehat{\mu}(\overline{F}) - \frac{1}{2}(H_r - 1) - \varepsilon$. Since $H_r - 1 = \sum_{k=2}^{r} \frac{1}{k} \leq \int_1^r \frac{dt}{t} = \log r$,

$$\widehat{\mu}(\overline{N}) \geq \widehat{\mu}(\overline{F}) - \tfrac{1}{2}\log r - \varepsilon. \tag{D.1}$$

Making the line free. Let K'' be the Hilbert class field of K'. By the principal ideal theorem every ideal of $\mathcal{O}_{K'}$ becomes principal in $\mathcal{O}_{K''}$, so the projective rank-one module $N \otimes_{\mathcal{O}_{K'}} \mathcal{O}_{K''}$ (isomorphic to an ideal of $\mathcal{O}_{K'}$ extended to $\mathcal{O}_{K''}$) is free; let y be a generator. With the norms $\|\cdot\|_{\sigma''} = \|\cdot\|_{\sigma''|_{K'}}$, the normalised slope does not change under the extension $\mathcal{O}_{K'} \to \mathcal{O}_{K''}$ (the Arakelov degree is multiplied by $[K'' : K']$, as is $[K' : \mathbb{Q}]$), and for a free Hermitian lattice of rank one $\widehat{\deg} = -\sum_{\sigma''} \log \|y\|_{\sigma''}$. Hence

$$\widehat{\mu}(\overline{N}) = -\frac{1}{[K'':\mathbb{Q}]} \sum_{\sigma'' :\, K'' \to \mathbb{C}} \log \|y\|_{\sigma''}.$$

The length bound after base change. Let $\mathcal{A}'' = \mathcal{A} \times_{\mathcal{O}_L} \mathcal{O}_{K''}$. It is a semiabelian scheme over $\mathcal{O}_{K''}$ with the induced $\mathcal{O}_E$-action and the pulled-back rigidified symmetric cubical line bundle, ample on the generic fibre $A_{K''}$ (an abelian variety of dimension g) with the base-changed principal polarisation; so $\mathcal{A}''$ is a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_{K''}$. Since $\mathcal{A}$ is smooth, its Lie algebra commutes with base change, $\mathrm{Lie}(\mathcal{A}'') = \mathrm{Lie}(\mathcal{A}) \otimes_{\mathcal{O}_L} \mathcal{O}_{K''}$, and for $\sigma'' \colon K'' \to \mathbb{C}$ the complex torus, period lattice and Riemann form of $A_{K'',\sigma''}$ are those of $A_{\sigma''|_L}$, so the Hodge norm at σ'' is the Hodge norm at $\sigma''|_L$. Hence $\overline{\mathrm{Lie}}(\mathcal{A}'') = \overline{M} \otimes_{\mathcal{O}_L} \mathcal{O}_{K''}$ as Hermitian lattices, and by the invariance of the normalised degree $h^+(\mathcal{A}'') = h^+(\mathcal{A})$. The vector y lies in $N \otimes \mathcal{O}_{K''} \subseteq F \otimes \mathcal{O}_{K''} \subseteq \mathrm{Lie}(\mathcal{A}'')$ and is non-zero. By Proposition D.29 for $\mathcal{A}''$ and y,

$$\widehat{\mu}(\overline{N}) = -\frac{1}{[K'' : \mathbb{Q}]} \sum_{\sigma''} \log \|y\|_{\sigma''} \le C_{\mathrm{ll}} \log\bigl(2 + g + h^+(\mathcal{A}'')\bigr) = C_{\mathrm{ll}} Y.$$

Conclusion. With (D.1), $\widehat{\mu}(\overline{F}) \le C_{\mathrm{ll}} Y + \frac{1}{2}\log r + \varepsilon$. Letting $\varepsilon \to 0$ and taking the supremum over F gives $\widehat{\mu}_{\max}(\overline{M}) \le C_{\mathrm{ll}} Y + \frac{1}{2}\log g \le (C_{\mathrm{ll}} + \frac{1}{2}) Y$. □

Definition D.28. Let $(\mathcal{A}, \mathcal{L}_{\mathcal{A}}, r)$ be a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$, of relative dimension g, and $\sigma \colon L \to \mathbb{C}$. Write $\mathcal{L}_\sigma$ for the line bundle on A_σ obtained from $\mathcal{L}_{\mathcal{A}}|_A$ by base change along σ, $r_\sigma \in \mathcal{L}_\sigma(0)$ for the rigidification, $\mathrm{Lie}(A_\sigma) = \mathrm{Lie}(\mathcal{A}) \otimes_{\mathcal{O}_L,\sigma} \mathbb{C}$, x_σ for the image of $x \in \mathrm{Lie}(\mathcal{A})$, and $\pi_\sigma \colon \mathrm{Lie}(A_\sigma) \to A_\sigma(\mathbb{C})$ for the exponential map, with kernel Π_σ.

Theta trivialisation. The **theta trivialisation** $\vartheta_{\mathcal{A},\sigma}$ is the nowhere vanishing holomorphic section of $\pi_\sigma^* \mathcal{L}_\sigma$ on $\mathrm{Lie}(A_\sigma)$ with $\vartheta_{\mathcal{A},\sigma}(0) = r_\sigma$ and

$$\vartheta_{\mathcal{A},\sigma}(w + l) = \Bigl(\alpha_\sigma(l) \exp\bigl(\pi H_\sigma(w,l) + \tfrac{\pi}{2} H_\sigma(l,l)\bigr)\Bigr)^{-1} \vartheta_{\mathcal{A},\sigma}(w) \qquad (w \in \mathrm{Lie}(A_\sigma),\ l \in \Pi_\sigma) \quad \text{(D.2)}$$

in the fibre $\mathcal{L}_\sigma(\pi_\sigma(w))$, where $(H_\sigma, \alpha_\sigma)$ are the Appell–Humbert data of $\mathcal{L}_\sigma$ (the Hermitian form of $\mathcal{L}_\sigma$ is H_σ, since its imaginary part on Π_σ is the Riemann form of the principal polarisation, and $\alpha_\sigma \colon \Pi_\sigma \to \mathbb{C}^\times$ is a semicharacter for it).

Theta functions and canonical norms. For $n \ge 1$ and $s \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes n})$ the **theta function** of s is the entire function θ_s on $\mathrm{Lie}(A_\sigma)$ with $\pi_\sigma^* s = \theta_s \, \vartheta_{\mathcal{A},\sigma}^{\otimes n}$, and the **canonical norm** of s at $\pi_\sigma(w)$ is

$$\|s\|(\pi_\sigma(w)) = |\theta_s(w)| \exp\bigl(-\tfrac{\pi n}{2} H_\sigma(w,w)\bigr), \qquad \text{(D.3)}$$

which does not depend on the choice of w by (D.2). Put $\|s\|_{\sup,\sigma} = \sup_{A_\sigma(\mathbb{C})} \|s\|$ and $\|s\|_{L^2,\sigma} = \bigl(\int_{A_\sigma(\mathbb{C})} \|s\|^2 \, d\mu_\sigma\bigr)^{1/2}$, with μ_σ the Haar probability measure. For $s \in H^0(\mathcal{A}, \mathcal{L}_{\mathcal{A}}^{\otimes n})$ or $s \in H^0(A, \mathcal{L}_{\mathcal{A}}|_A^{\otimes n})$ these are taken for its image $s_\sigma \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes n})$.

Jets along a tangent vector. For $v \in \mathrm{Lie}(A_\sigma)$ and $k \ge 0$ put $\partial_v^k \theta_s(0) = \frac{d^k}{d\tau^k} \theta_s(\tau v)\big|_{\tau=0}$ ($\tau \in \mathbb{C}$).

Proposition D.29. *There is an absolute constant $C_{\mathrm{ll}} \ge 0$ such that for every CM field E, every number field L, every principally polarised abelian scheme $\mathcal{A}$ with $\mathcal{O}_E$-action over $\mathcal{O}_L$, of relative dimension g, and every $0 \ne x \in \mathrm{Lie}(\mathcal{A})$*

$$-\frac{1}{[L : \mathbb{Q}]} \sum_{\sigma \colon L \to \mathbb{C}} \log \|x\|_\sigma \ \le\ C_{\mathrm{ll}} \log\bigl(2 + g + h^+(\mathcal{A})\bigr).$$

Proof. Write $h = h^+(\mathcal{A})$, $Y = 2 + g + h \ge 3$, and for a number field $K \supseteq L$ and a function f on the embeddings $K \to \mathbb{C}$, $\mathrm{mean}_K f = \frac{1}{[K:\mathbb{Q}]} \sum_{\sigma \colon K \to \mathbb{C}} f(\sigma)$. We show the bound with

$$C_{\mathrm{ll}} = 6 + \tfrac{1}{2}\log 27 + C_{\mathrm{key}} + C_{\sup}\bigl(1 + \log(1 + C_{\mathrm{key}})\bigr).$$

Step 0: base change. For a finite extension K/L the base change $\mathcal{A}_K$ is a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_K$; $\mathrm{Lie}(\mathcal{A}_K) = \mathrm{Lie}(\mathcal{A}) \otimes_{\mathcal{O}_L} \mathcal{O}_K$, and at $\sigma\colon K \to \mathbb{C}$ the complex torus, lattice, Riemann form, line bundle and rigidification of $\mathcal{A}_K$ are those of $\mathcal{A}$ at $\sigma|_L$. Hence the Hodge norms, theta functions and canonical norms at σ are those at $\sigma|_L$, $h^+(\mathcal{A}_K) = h$, and, each $\sigma_0\colon L \to \mathbb{C}$ having $[K : L]$ extensions, $\mathrm{mean}_K \log \|x \otimes 1\| = \mathrm{mean}_L \log \|x\|$.

Step 1: the sections. By Proposition D.30 there are L_1/L and $\theta \in H^0(\mathcal{A}_{L_1}, \mathcal{L})$, non-zero on the generic fibre and lying in the Moret-Bailly lattice (Definition 34.8), with $\mathrm{mean}_{L_1} \log \|\theta\|_{L^2} \le \Phi := h/2 + C_{\mathrm{key}} g$ (Step 0 for h). Both Proposition D.32 and Proposition D.33 below are applied to this θ on $\mathcal{A}_{L_1}$, and their hypothesis that θ lies in the Moret-Bailly lattice is this clause. Put $M_\sigma = \|\theta\|_{\sup,\sigma}$, positive since θ_{θ_σ} is a non-zero entire function; by Proposition D.32 ($\Phi \ge 0$),

$$\mathrm{mean}_{L_1} \log M \le \Phi + C_{\sup}\, g \log(2 + g + \Phi). \tag{D.4}$$

Let K_0 be the least even integer with $K_0 \ge 2 + g^2 + h$, $m = 3K_0$ (even, as K_0 is), $n' = 3K_0^2$ and $n = m^2 = 3n'$. By Proposition D.33 (for the even integer $m \ge 2$) there are $L_2 \supseteq L_1$ and $s_1, \dots, s_r \in H^0(\mathcal{A}_{L_2}, \mathcal{L}^{\otimes n})$, $r = m^{2g}$, with $\|s_j\|_{\sup,\sigma} \le M'_\sigma := M_{\sigma|_{L_1}}$ that span $H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes n})$ for every $\sigma\colon L_2 \to \mathbb{C}$. Write $\mathcal{A}_2 = \mathcal{A}_{L_2}$, $x_2 = x \otimes 1 \in \mathrm{Lie}(\mathcal{A}_2)$, $d = [L_2 : \mathbb{Q}]$ and $\ell_\sigma = \|x_2\|_\sigma$; $\ell_\sigma > 0$ because $\mathrm{Lie}(\mathcal{A}_2)$ is projective, so $x_{2,\sigma} \ne 0$, and H_σ is positive definite.

Step 2: the jet filtration. Let j_k be the maps of Lemma D.34 for $\mathcal{A}_2$, x_2 and n. For $c \in L_2^r$ put $s_c = \sum_j c_j s_j$ and $J_k(c) = j_k(s_c)$; let $E_0 = L_2^r$, $E_i = \{c : J_k(c) = 0 \ (k < i)\}$, and $\phi_i = J_i|_{E_i}$, so $E_{i+1} = \ker \phi_i$. For $\sigma\colon L_2 \to \mathbb{C}$ write $E_{i,\sigma} = E_i \otimes_\sigma \mathbb{C} \subseteq \mathbb{C}^r$ and $\phi_{i,\sigma}$; these are cut out by the $J_{k,\sigma}$. By Lemma D.34(2), for $c \in \mathbb{C}^r$: $c \in E_{i,\sigma}$ if and only if $\partial^k \theta_{s_c}(0) = 0$ for $k < i$, and then $\phi_{i,\sigma}(c) = \partial^i \theta_{s_c}(0)$, where ∂ is taken along $x_{2,\sigma}$ and $s_c = \sum_j c_j s_{j,\sigma}$.

Step 3: every step has rank one up to n'. Let $0 \le i \le n'$ and fix σ. By Lemma D.35 ($v = x_{2,\sigma} \ne 0$, $n' \ge 1$) there is $s \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes 3n'})$ with $\partial^k \theta_s(0) = 0$ for $k < i$ and $\partial^i \theta_s(0) \ne 0$. As $3n' = n$, the spanning property gives $s = s_c$ for some $c \in \mathbb{C}^r$; by Step 2, $c \in E_{i,\sigma}$ and $\phi_{i,\sigma}(c) \ne 0$. So $\phi_i \ne 0$, and $\dim E_i - \dim E_{i+1} = 1$ for $0 \le i \le n'$.

Step 4: the archimedean bound. Let $c \in E_{i,\sigma}$ and $F(\tau) = \theta_{s_c}(\tau x_{2,\sigma}) = \sum_j c_j \theta_{s_j}(\tau x_{2,\sigma})$. By the definition of the canonical norm (Definition D.28), $|\theta_{s_j}(w)| = \|s_j\|(\pi_\sigma(w)) e^{\pi n H_\sigma(w,w)/2} \le M'_\sigma e^{\pi n H_\sigma(w,w)/2}$, and $\pi H_\sigma(\tau x_2, \tau x_2) = |\tau|^2 \ell_\sigma^2$; by Cauchy–Schwarz, with $|c|^2 = \sum_j |c_j|^2$,

$$|F(\tau)| \le \sqrt{r}\, M'_\sigma\, |c|\, \exp(n\ell_\sigma^2 |\tau|^2/2) \qquad (\tau \in \mathbb{C}).$$

Cauchy's estimate on $|\tau| = R$ gives $|F^{(i)}(0)| \le i!\, R^{-i} \max_{|\tau|=R} |F|$. For $i = 0$ this gives $|F(0)| \le \sqrt{r} M'_\sigma |c|$ ($R \to 0$). For $1 \le i \le n'$ take $R^2 = i/(n\ell_\sigma^2)$ and use $i! \le i^i$, $i \le n'$:

$$|\phi_{i,\sigma}(c)| \le i! \Big(\frac{n\ell_\sigma^2}{i}\Big)^{i/2} e^{i/2} \sqrt{r} M'_\sigma |c| \le A_i(\sigma)\, |c|, \qquad A_i(\sigma) := (enn')^{i/2} \ell_\sigma^i \sqrt{r}\, M'_\sigma \quad (0 \le i \le n'). \tag{D.5}$$

Step 5: the slope inequality along the filtration. Let $\overline{\Lambda} = \mathcal{O}_{L_2}^r$ with the norms $|c|_\sigma = (\sum_j |\sigma(c_j)|^2)^{1/2}$; $\widehat{\deg}\, \overline{\Lambda} = 0$. Put $\Lambda_i = \Lambda \cap E_i$, saturated with $\Lambda_i \otimes L_2 = E_i$, and $Q_i = \Lambda_i/\Lambda_{i+1}$ ($0 \le i \le n'$), projective of rank one by Step 3, with the quotient norms of $\overline{\Lambda}_i$. Additivity of degrees gives

$$0 = \widehat{\deg}\, \overline{\Lambda} = \sum_{i=0}^{n'} \widehat{\deg}\, \overline{Q}_i + \widehat{\deg}\, \overline{\Lambda}_{n'+1} \le \sum_{i=0}^{n'} \widehat{\deg}\, \overline{Q}_i.$$

For $c \in \Lambda_i$ the section s_c lies in $H^0(\mathcal{A}_2, \mathcal{L}^{\otimes n})$ and $J_k(c) = 0$ for $k < i$, so $\phi_i(c) \in \mathcal{O}_{L_2}$ by Lemma D.34(1). Hence ϕ_i induces $\psi_i\colon Q_i \to \mathcal{O}_{L_2}$, non-zero by Step 3 and therefore injective. For

$y \in Q_i \otimes_\sigma \mathbb{C}$ and any lift $c \in E_{i,\sigma}$, $\psi_{i,\sigma}(y) = \phi_{i,\sigma}(c)$ since $\phi_{i,\sigma}$ vanishes on $E_{i+1,\sigma}$; minimising (D.5) over the lifts, $|\psi_{i,\sigma}(y)| \le A_i(\sigma)\|y\|_\sigma$. For $0 \neq y \in Q_i$: $\#(Q_i/\mathcal{O}_{L_2} y) = \#\big(\psi_i(Q_i)/\psi_i(y)\mathcal{O}_{L_2}\big) \le |N_{L_2/\mathbb{Q}}(\psi_i(y))| = \prod_\sigma |\sigma\psi_i(y)|$ and $\log\|y\|_\sigma \ge \log|\sigma\psi_i(y)| - \log A_i(\sigma)$, so $\widehat{\deg}\,\overline{Q}_i \le \sum_\sigma \log A_i(\sigma)$. Therefore

$$0 \le \sum_{i=0}^{n'} \sum_{\sigma\colon L_2 \to \mathbb{C}} \log A_i(\sigma). \tag{D.6}$$

Step 6: the numbers. With $S_\ell = \sum_\sigma \log \ell_\sigma$, $S_M = \sum_\sigma \log M'_\sigma$, $B = (enn')^{1/2}$ and $T = \sqrt{r} = m^g$, the right side of (D.6) is $\frac{n'(n'+1)}{2}(d\log B + S_\ell) + (n'+1)(d\log T + S_M)$. Dividing by $dn'(n'+1)/2$ and using Step 0 ($S_\ell/d = \mathrm{mean}_L \log\|x\|$), $S_M/d = \mathrm{mean}_{L_1} \log M$ and (D.4):

$$-\mathrm{mean}_L \log\|x\| \le \tfrac{1}{2}\log(enn') + \frac{2}{n'}\Big(g\log m + \Phi + C_{\mathrm{sup}}\, g \log(2+g+\Phi)\Big).$$

Now $2+g^2+h \le K_0 \le 4+g^2+h \le Y^2$ (the last since $Y^2 = (2+g+h)^2 \ge 4+g^2+h$), so $K_0 \ge g$ and $K_0 \ge h$. Each term: $\frac{1}{2}\log(enn') = \frac{1}{2}\log(27eK_0^4) \le \frac{1}{2}(1+\log 27) + 4\log Y$; $\frac{2}{n'} g\log m = \frac{2g\log(3K_0)}{3K_0^2} \le \frac{2g}{K_0} \le \frac{2g}{2+g^2} \le 1$; $\frac{2}{n'}\Phi = \frac{h+2C_{\mathrm{key}}g}{3K_0^2} \le \frac{1}{3} + C_{\mathrm{key}}$; and, as $2 \le 2+g+\Phi \le (1+C_{\mathrm{key}})Y$ and $g \le K_0^2$, $\frac{2}{n'} C_{\mathrm{sup}} g\log(2+g+\Phi) \le C_{\mathrm{sup}}\big(\log(1+C_{\mathrm{key}}) + \log Y\big)$. Since $\log Y \ge \log 3 \ge 1$, the sum of these is at most $C_{\mathrm{ll}} \log Y$. □

Proposition D.30. *There is an absolute constant $C_{\mathrm{key}} \ge 0$ such that for every CM field E, every number field L and every principally polarised abelian scheme $(\mathcal{A}, \mathcal{L}_\mathcal{A}, r)$ with $\mathcal{O}_E$-action over $\mathcal{O}_L$ of relative dimension g there are a finite extension L'/L and a section $\theta \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'})$ of the base change $\mathcal{A}'$ of $\mathcal{A}$ to $\mathcal{O}_{L'}$, non-zero on the generic fibre and lying in the Moret-Bailly lattice, with*

$$\frac{1}{[L':\mathbb{Q}]} \sum_{\sigma'\colon L' \to \mathbb{C}} \log\|\theta\|_{L^2,\sigma'} \;\le\; \frac{h^+(\mathcal{A})}{2} + C_{\mathrm{key}}\, g.$$

Proof. We prove the statement with $C_{\mathrm{key}} = \frac{1}{4}\log(2\pi)$. Let $(\mathcal{A}, \mathcal{L}_\mathcal{A}, r)$ be given over $\mathcal{O}_L$, of relative dimension $g \ge 1$, and put $A = \mathcal{A}_L$, $L_A = \mathcal{L}_\mathcal{A}|_A$: a symmetric ample line bundle defining a principal polarisation. Write $r_0 \in e^*\mathcal{L}_\mathcal{A}$ for the generator with $r(r_0) = 1$; its image in $\mathcal{L}_\sigma(0)$ is the rigidification r_σ.

Step 1: the key formula after a field extension. Apply Theorem B.137 to $K_0 = L$ and (A, L_A): it gives $K \supseteq L$, $\pi\colon \mathcal{G} \to \mathrm{Spec}\,\mathcal{O}_K$, $\mathcal{M}$, $\varphi\colon \mathcal{M}|_{\mathcal{G}_K} \cong L_A \otimes_L K$ and the cubist metrics. The $\mathcal{O}_K$-module $E = H^0(\mathcal{G}, \mathcal{M})$ is projective of rank one (the theorem with $K' = K$), hence isomorphic to a fractional ideal $\mathfrak{a}$ of K. Let L' be the Hilbert class field of K; by the principal ideal theorem (Furtwängler) $\mathfrak{a}\mathcal{O}_{L'}$ is principal. Since $\mathcal{O}_{L'}$ is flat over $\mathcal{O}_K$ and $\mathcal{G}$ is quasi-compact and separated, flat base change gives $E' = H^0(\mathcal{G}', \mathcal{M}') = E \otimes_{\mathcal{O}_K} \mathcal{O}_{L'} \cong \mathfrak{a}\mathcal{O}_{L'}$, a free $\mathcal{O}_{L'}$-module of rank one; let θ_0 be a generator. For a free Hermitian lattice of rank one with generator θ_0 one has $\widehat{\deg}\,\overline{E'} = -\sum_{\sigma'} \log\|\theta_0\|_{L^2,\sigma'}$, so Theorem B.137 (with $K' = L'$) gives

$$\frac{1}{[L':\mathbb{Q}]} \sum_{\sigma'\colon L' \to \mathbb{C}} \log\|\theta_0\|_{L^2,\sigma'} = \frac{1}{2}\, h_F(A) + \frac{g}{4}\log(2\pi), \tag{D.7}$$

where $\|\cdot\|_{L^2,\sigma'}$ is formed with the cubist metric. As $E' \otimes L' = H^0(A_{L'}, \mathcal{M}|_{A_{L'}})$ and $\theta_0 \neq 0$, the image of θ_0 on the generic fibre is non-zero.

Step 2: a Moret-Bailly model over $\mathcal{O}_{L'}$. By Theorem B.137 the pull-back $\varepsilon^*\mathcal{M}$ with the cubist metrics is isometric to $\mathcal{O}_K$ with the trivial metrics; let u_0 be the generator of norm 1 at every place and u its base change, a generator of $\varepsilon^*\mathcal{M}'$ of norm 1 at every $\sigma'\colon L' \to \mathbb{C}$. The

isomorphism $\varphi' = \varphi \otimes L'$ maps u to $a\,(r_0 \otimes 1)$ for some $a \in L'^{\times}$; put $\psi = a^{-1}\varphi'$, so $\psi(u) = r_0 \otimes 1$. Then $(\mathcal{G}', i', \mathcal{M}', (\|\cdot\|_{\sigma'})_{\sigma'}, \psi, u)$, with $i'\colon \mathcal{G}'_{L'} \cong A_{L'}$ the base change of the isomorphism of Theorem B.137, is a Moret-Bailly model of $(A_{L'}, L_A \otimes L', r_0 \otimes 1, \varnothing)$ over $\mathcal{O}_{L'}$: (Mb1) and (Mb2) hold by Theorem B.137 and base change (smoothness, separatedness, finite type, the structure of the fibres, the cubical structure and its trivialisation of norm 1 are preserved); (Mb3) holds by construction; (Mb4) is empty; (Mb5) holds for the base change of the finite flat subscheme of Theorem B.137 with generic fibre $A[2]$. Rescaling φ' by the constant a^{-1} does not change (D.7), which concerns θ_0 and the cubist metric only.

Step 3: the section θ. Let $\mathcal{A}'$ be the base change of $\mathcal{A}$ to $\mathcal{O}_{L'}$ and apply Lemma D.31 (with $K = L'$, $F = \varnothing$, $N = 1$) to the model of Step 2 and $s = \theta_0$: $\theta = \theta_0^{\flat}$ lies in $H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'})$, its restriction to $A_{L'}$ is $\psi(\theta_0|_{\mathcal{G}'_{L'}})$ transported by i', which is non-zero by Step 1, and $\|\theta\|_{L^2,\sigma'} = \|\theta_0\|_{L^2,\sigma'}$ for every σ'. By definition of the Moret-Bailly lattice of the model of Step 2, this restriction lies in that lattice, so θ lies in the Moret-Bailly lattice (Definition 34.8 with $K = L'$).

Step 4: the Faltings height and the Lie lattice. Compute $h_F(A)$ with the semiabelian model $\mathcal{S} = \mathcal{A}$ over $\mathcal{O}_L$. Since $e^*\Omega^1_{\mathcal{A}/\mathcal{O}_L}$ is the dual of $\mathrm{Lie}(\mathcal{A}) = e^*T_{\mathcal{A}/\mathcal{O}_L}$, $\omega_{\mathcal{A}} = e^*\Omega^g = \det(\mathrm{Lie}(\mathcal{A}))^{\vee}$. Compare the metrics at $\sigma\colon L \to \mathbb{C}$: let $e_1, \dots, e_g$ be an orthonormal basis of $\mathrm{Lie}(A_\sigma)$ for H_σ, $z_1, \dots, z_g$ the dual coordinates and $\alpha = dz_1 \wedge \cdots \wedge dz_g$. Then $i^{g^2}\alpha \wedge \overline{\alpha} = 2^g\, d\lambda$, with λ the Lebesgue measure of the Euclidean structure $\mathrm{Re}\, H_\sigma$:

The covolume of Π_σ for H_σ equals $\chi(A, L_A) = 1$ ([46, 2.1.2]: the covolume of the period lattice for the Hermitian form of the Riemann form of L is $\chi(A, L)$; here the polarisation is principal). Hence $\|\alpha\|_\sigma^2 = 2^g/(2\pi)^g = \pi^{-g}$ in Deligne's normalisation. For the norm πH_σ on $\mathrm{Lie}(A_\sigma)$ the vectors $e_k/\sqrt{\pi}$ are orthonormal, and the dual norm of α on $\det \mathrm{Lie}(A_\sigma)$ is $|\alpha(e_1/\sqrt{\pi} \wedge \cdots \wedge e_g/\sqrt{\pi})| = \pi^{-g/2}$. So $\overline{\omega}_{\mathcal{A}} \cong \det(\overline{\mathrm{Lie}}(\mathcal{A}))^{\vee}$ isometrically, and

$$h_F(A) = \frac{\widehat{\deg}\,\overline{\omega}_{\mathcal{A}}}{[L:\mathbb{Q}]} = -\frac{\widehat{\deg}\,\overline{\mathrm{Lie}}(\mathcal{A})}{[L:\mathbb{Q}]} \le h^+(\mathcal{A}).$$

Conclusion. The scheme $\mathcal{A}'$ is the base change of $\mathcal{A}$ to $\mathcal{O}_{L'}$, $\theta \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'})$ is non-zero on the generic fibre and lies in the Moret-Bailly lattice (Step 3), and by Step 3, (D.7) and Step 4,

$$\frac{1}{[L':\mathbb{Q}]} \sum_{\sigma'} \log \|\theta\|_{L^2,\sigma'} = \frac{1}{2}\, h_F(A) + \frac{g}{4}\log(2\pi) \le \frac{h^+(\mathcal{A})}{2} + C_{\mathrm{key}}\, g.$$

□

Lemma D.31. *Let $(\mathcal{A}, \mathcal{L}_{\mathcal{A}}, r)$ be a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$, $A = \mathcal{A}_L$, and $r_0 \in \mathcal{L}_{\mathcal{A}}(0)$ the generator with $r(r_0) = 1$. Let K/L be a finite extension, $\mathcal{A}_K$ the base change of $\mathcal{A}$ to $\mathcal{O}_K$, $F \subseteq A(K)$ finite, and $(\mathcal{G}, i, \mathcal{M}, (\|\cdot\|_\sigma)_\sigma, \varphi, u, (\varepsilon_P)_{P\in F})$ a Moret-Bailly model of $(A_K, \mathcal{L}_{\mathcal{A}}|_{A_K}, r_0 \otimes 1, F)$ over $\mathcal{O}_K$; let $\mathcal{G}^0 \subseteq \mathcal{G}$ be its identity component. Then:*

1. *there is an isomorphism of group schemes $j\colon \mathcal{A}_K \to \mathcal{G}^0$ with $i \circ j_K = \mathrm{id}_{A_K}$;*
2. *for every integer $N \ge 1$ there is an isomorphism of line bundles $\psi_N\colon j^*(\mathcal{M}^{\otimes N}|_{\mathcal{G}^0}) \to \mathcal{L}_{\mathcal{A}_K}^{\otimes N}$ on $\mathcal{A}_K$ whose restriction to the generic fibre is $\varphi^{\otimes N}$ (transported by $j_K = i^{-1}$), and for every $\sigma\colon K \to \mathbb{C}$ it carries the N-th power of the cubist metric $\|\cdot\|_\sigma$ to the canonical norm on $\mathcal{L}_\sigma^{\otimes N}$;*
3. *consequently, for $s \in H^0(\mathcal{G}, \mathcal{M}^{\otimes N})$ the section $s^{\flat} = \psi_N(j^*(s|_{\mathcal{G}^0}))$ lies in $H^0(\mathcal{A}_K, \mathcal{L}_{\mathcal{A}_K}^{\otimes N})$, its restriction to A_K is $\varphi^{\otimes N}(s|_{\mathcal{G}_K})$ transported by i, and for every σ the canonical norm of $s^{\flat}$ at each point of $A_\sigma(\mathbb{C})$ equals the cubist norm of s at the corresponding point of $\mathcal{G}_\sigma(\mathbb{C})$; in particular $\|s^{\flat}\|_{\sup,\sigma}$ and $\|s^{\flat}\|_{L^2,\sigma}$ are the sup and L^2 norms of s for the cubist metric.*

Proof. (1). The identity component $\mathcal{G}^0$ is the open subgroup scheme whose fibres are the identity components of the fibres of $\mathcal{G}$ (SGA 3, Exp. VI_B, 3.10, for smooth group schemes); its fibres are connected extensions of abelian varieties by tori, so it is a semiabelian scheme over $\mathcal{O}_K$, with generic fibre $\mathcal{G}_K$ (connected, being an abelian variety by i). The base change $\mathcal{A}_K$ is a semiabelian scheme with generic fibre A_K. A semiabelian scheme over a Dedekind scheme whose generic fibre is an abelian variety is the identity component of the Néron model of that abelian variety ([227], Exp. IX; [45], §7.4). Applying this to $\mathcal{A}_K$ and to $\mathcal{G}^0$ (with generic fibre identified with A_K by i), both are identified with the identity component of the Néron model of A_K, compatibly with the generic fibres; this gives j with $i \circ j_K = \mathrm{id}$.

(2), the integral isomorphism. Write $\mathcal{N} = j^*(\mathcal{M}^{\otimes N}|_{\mathcal{G}^0})$. On the generic fibre, $(i^{-1})^*\varphi^{\otimes N}$ is an isomorphism $\mathcal{N}|_{A_K} \to \mathcal{L}_{\mathcal{A}}^{\otimes N}|_{A_K}$; regard it as a rational section ψ of $\mathcal{N}^\vee \otimes \mathcal{L}_{\mathcal{A}_K}^{\otimes N}$ on $\mathcal{A}_K$, regular and nowhere zero on the generic fibre. The scheme $\mathcal{A}_K$ is regular (smooth over the Dedekind ring $\mathcal{O}_K$) and its closed fibres are smooth and connected, hence irreducible; so the divisor of ψ is a combination of closed fibres: $\mathrm{div}(\psi) = \pi^*\Delta$ for a divisor Δ on $\operatorname{Spec}\mathcal{O}_K$, $\pi\colon \mathcal{A}_K \to \operatorname{Spec}\mathcal{O}_K$ the structure map. Pulling back along the unit section e (with $\pi \circ e = \mathrm{id}$), $\mathrm{div}(e^*\psi) = \Delta$. Now $j \circ e = \varepsilon$, so $e^*\mathcal{N} = \varepsilon^*\mathcal{M}^{\otimes N}$ is generated by $u^{\otimes N}$, and $e^*\psi(u^{\otimes N}) = \varphi(u)^{\otimes N} = (r_0 \otimes 1)^{\otimes N}$ by (Mb3), which generates $e^*\mathcal{L}_{\mathcal{A}_K}^{\otimes N}$ because r is an isomorphism $e^*\mathcal{L}_{\mathcal{A}} \cong \mathcal{O}$. Hence $e^*\psi$ maps a generator to a generator, $\Delta = 0$, and ψ is a nowhere vanishing regular section, i.e. an isomorphism $\psi_N\colon \mathcal{N} \to \mathcal{L}_{\mathcal{A}_K}^{\otimes N}$ with $e^*\psi_N(u^{\otimes N}) = (r_0 \otimes 1)^{\otimes N}$.

(2), the metrics. Fix $\sigma\colon K \to \mathbb{C}$ and write $X = A_\sigma(\mathbb{C})$, identified with $\mathcal{G}_\sigma(\mathbb{C})$ by i. Let $\|\cdot\|'$ be the metric on $\mathcal{L}_\sigma^{\otimes N}$ obtained from the N-th power of the cubist metric through ψ_N, and $\|\cdot\|$ the canonical norm. Both curvature forms are translation invariant:

- for $\|\cdot\|'$: let ω be the curvature form of the cubist metric on $\mathcal{M}_\sigma$ (that of $\|\cdot\|'$ is $N\omega$). The cubical trivialisation of $\Theta(\mathcal{M})_\sigma$ is holomorphic, nowhere zero and of norm 1, so the curvature of $\Theta(\mathcal{M})_\sigma$ with the induced metric vanishes: $\sum_{\varnothing \neq I \subseteq \{1,2,3\}} (-1)^{|I|+1} m_I^*\omega = 0$ on X^3. Pull this identity back along $X^2 \to X^3$, $(x,y) \mapsto (x,y,c)$, for fixed $c \in X$; pull-backs along constant maps vanish, so with $D_c = t_c^*\omega - \omega$ one gets $m^*D_c = p_1^*D_c + p_2^*D_c$ on X^2 (m the addition, p_1, p_2 the projections). Restricting to $X \times \{y\}$ gives $t_y^*D_c = D_c$ for every y: D_c is translation invariant. It is also exact, since t_c is homotopic to the identity. A translation-invariant form on a complex torus has constant coefficients, hence is harmonic for a flat metric, and an exact harmonic form is 0; so $t_c^*\omega = \omega$ for every c.
- for $\|\cdot\|$: on $\mathrm{Lie}(A_\sigma)$, for a local holomorphic section s, $-\log\|s\|^2 = -\log|\theta_s|^2 + \pi N H_\sigma(w,w)$ with θ_s holomorphic, so the curvature form is $\frac{i}{2\pi}\partial\bar\partial\big(\pi N H_\sigma(w,w)\big)$, which has constant coefficients.

The function $f = \|\cdot\|'/\|\cdot\|$ is smooth and positive on X, and $dd^c \log f$ is the difference of the two curvature forms. Both represent $c_1(\mathcal{L}_\sigma^{\otimes N})$ and are translation invariant, hence harmonic; cohomologous harmonic forms are equal, so $dd^c \log f = 0$, $\log f$ is pluriharmonic on the compact connected manifold X and therefore constant (maximum principle). At the origin, $\|(r_\sigma)^{\otimes N}\|' = \|u\|_\sigma^N = 1$ by (Mb3), and $\|(r_\sigma)^{\otimes N}\| = |\theta_s(0)| = 1$ for a local section s with $s(0) = r_\sigma^{\otimes N}$, since $\vartheta_{\mathcal{A},\sigma}(0) = r_\sigma$. Hence $f \equiv 1$.

(3). $s|_{\mathcal{G}^0}$ is a section of $\mathcal{M}^{\otimes N}$ over $\mathcal{G}^0$, so $s^\flat$ is a global section of $\mathcal{L}_{\mathcal{A}_K}^{\otimes N}$ over $\mathcal{A}_K$; on the generic fibre $\mathcal{G}_K^0 = \mathcal{G}_K$ and ψ_N is $\varphi^{\otimes N}$, which gives the restriction. The equality of the pointwise norms is (2), and the sup and L^2 norms follow, the Haar probability measures corresponding under the group isomorphism i_σ. □

Proposition D.32. *There is an absolute constant $C_{\sup} \geq 0$ such that for every CM field E, every number field L, every principally polarised abelian scheme $(\mathcal{A}, \mathcal{L}_{\mathcal{A}}, r)$ with $\mathcal{O}_E$-action over*

$\mathcal{O}_L$ of relative dimension g, every $\theta \in H^0(\mathcal{A}, \mathcal{L}_\mathcal{A})$ non-zero on the generic fibre and lying in the Moret-Bailly lattice, and every real $\Phi \geq 0$ with $\frac{1}{[L:\mathbb{Q}]} \sum_\sigma \log \|\theta\|_{L^2,\sigma} \leq \Phi$,

$$\frac{1}{[L:\mathbb{Q}]} \sum_{\sigma\colon L \to \mathbb{C}} \log \|\theta\|_{\sup,\sigma} \;\leq\; \Phi + C_{\sup}\, g \log(2 + g + \Phi).$$

Proof. We prove the statement with $C_{\sup} = 4$. Let θ and Φ be as in the statement, $A = \mathcal{A}_L$, r_0 the generator of $e^*\mathcal{L}_\mathcal{A}$ with $r(r_0) = 1$, and $b_\sigma = \|\theta\|_{L^2,\sigma}$; $b_\sigma > 0$ and $\|\theta\|_{\sup,\sigma} < \infty$ since θ_{θ_σ} is a non-zero entire function and the canonical norm is continuous on the compact $A_\sigma(\mathbb{C})$. For a finite extension K'/L and a function f of the embeddings $L \to \mathbb{C}$, the mean over $\sigma'\colon K' \to \mathbb{C}$ of $f(\sigma'|_L)$ equals the mean over $\sigma\colon L \to \mathbb{C}$ of $f(\sigma)$, each σ having $[K' : L]$ extensions; the canonical norms of θ at σ' are those at $\sigma'|_L$.

Step 1: $h_F(A) \leq 2\Phi - \frac{g}{2}\log(2\pi)$. As θ lies in the Moret-Bailly lattice, there are a finite extension K/L and a Moret-Bailly model $\mathfrak{M}$ of $(A_K, L_A \otimes K, r_0 \otimes 1, \varnothing)$ over $\mathcal{O}_K$ whose lattice Λ contains $\theta|_{A_K}$, where $L_A = \mathcal{L}_\mathcal{A}|_A$. Apply Theorem B.137 to $K_0 = L$ and (A, L_A); it gives a field $K_1 \supseteq L$ and data $(\mathcal{G}_1, \mathcal{M}_1, \varphi_1)$ with cubist metrics and a finite flat subscheme with generic fibre $A[2]$. Let K' be a finite extension of L containing (copies of) K and K_1. By Theorem B.133 (2), the base change $\mathfrak{M}'$ of $\mathfrak{M}$ to $\mathcal{O}_{K'}$ is a Moret-Bailly model with lattice $\Lambda \otimes \mathcal{O}_{K'} \ni \theta|_{A_{K'}}$. On the other side, by Theorem B.137 $\varepsilon^*\mathcal{M}_1$ with the cubist metrics is isometric to $\mathcal{O}_{K_1}$ with the trivial metrics; let u be the base change to $\mathcal{O}_{K'}$ of its generator of norm one, write $\varphi_1 \otimes K'(u) = a\,(r_0 \otimes 1)$ with $a \in K'^\times$, and put $\psi = a^{-1}(\varphi_1 \otimes K')$. The base changes $\mathcal{G}_1'$, $\mathcal{M}_1'$ of $\mathcal{G}_1$, $\mathcal{M}_1$, with the base-changed isomorphism of generic fibres, cubist metrics and finite flat subscheme, together with (ψ, u), satisfy (Mb1), (Mb2), (Mb5) (these properties are preserved by base change) and (Mb3) (by construction), (Mb4) being empty: they form a Moret-Bailly model $\mathfrak{M}_1'$ of $(A_{K'}, L_A \otimes K', r_0 \otimes 1, \varnothing)$ over $\mathcal{O}_{K'}$, whose lattice is $\psi(E')$ with $E' = H^0(\mathcal{G}_1', \mathcal{M}_1')$. By Theorem B.133 (3) the two lattices coincide, so $\theta|_{A_{K'}} = \psi(t|_{\mathcal{G}'_{1,K'}})$ for some $0 \neq t \in E'$. By Lemma D.31 (3) for $\mathfrak{M}_1'$ and $N = 1$, $\|\theta\|_{L^2,\sigma'}$ equals the L^2 norm of t for the cubist metric, for every $\sigma'\colon K' \to \mathbb{C}$. By Theorem B.137 (with its K' our K', rescaling φ_1 not affecting E' and its norms),

$$[K' : \mathbb{Q}]\Big(-\frac{1}{2}h_F(A) - \frac{g}{4}\log(2\pi)\Big) = \widehat{\deg}\,\overline{E'} = \log \#(E'/\mathcal{O}_{K'}t) - \sum_{\sigma'} \log \|\theta\|_{L^2,\sigma'} \geq -[K' : \mathbb{Q}]\,\Phi,$$

using the remark on means and the hypothesis on Φ. This is the claim.

Step 2: the sup norm at one place. Fix $\sigma\colon L \to \mathbb{C}$; write $V = \mathrm{Lie}(A_\sigma)$, $H = H_\sigma$, $\Pi = \Pi_\sigma$, $\rho = \rho_\sigma = \min_{0 \neq l \in \Pi} H(l,l)^{1/2}$, θ_σ for the theta function of θ at σ and $N(w) = |\theta_\sigma(w)| e^{-\frac{\pi}{2}H(w,w)}$, the canonical norm of θ at $\pi_\sigma(w)$. Let λ be the Lebesgue measure of the Euclidean structure $\mathrm{Re}\,H$ on $V \cong \mathbb{R}^{2g}$. The covolume of Π for λ is $\chi(A, L_A) = 1$ ([46, 2.1.2]; the polarisation is principal), so the Haar probability measure of $A_\sigma(\mathbb{C})$ is the image of λ restricted to a fundamental domain, and for every measurable $B \subseteq V$ on which π_σ is injective and every $w_0 \in V$, $\int_B N(w_0 + w)^2\, d\lambda(w) \leq b_\sigma^2$. Fix $w_0 \in V$ and put $f(w) = \theta_\sigma(w_0 + w)\exp\big(-\pi H(w, w_0) - \frac{\pi}{2}H(w_0, w_0)\big)$, an entire function ($H$ is $\mathbb{C}$-linear in its first argument). From $H(w_0 + w, w_0 + w) = H(w,w) + 2\,\mathrm{Re}\,H(w, w_0) + H(w_0, w_0)$,

$$|f(w)| = N(w_0 + w)\, e^{\frac{\pi}{2}H(w,w)}.$$

Let $R = \frac{1}{2}\min(\rho, 1)$ and $B_R = \{w : H(w,w) < R^2\}$. Since $|f|^2$ is plurisubharmonic, hence subharmonic on $\mathbb{R}^{2g}$, it satisfies the sub-mean-value inequality on B_R. If $w, w' \in B_R$ and $w - w' \in \Pi$, then $H(w - w', w - w')^{1/2} < 2R \leq \rho$, so $w = w'$: π_σ is injective on $w_0 + B_R$. With

$\lambda(B_R) = \pi^g R^{2g}/g!$:

$$N(w_0)^2 = |f(0)|^2 \le \frac{1}{\lambda(B_R)} \int_{B_R} N(w_0+w)^2 e^{\pi H(w,w)}\, d\lambda(w) \le \frac{g!\, e^{\pi R^2}}{\pi^g R^{2g}}\, b_\sigma^2.$$

Taking the supremum over w_0 and using $\log g! \le g \log g$, $\pi R^2/2 \le \pi/8 < 1$, $\pi^{-g} \le 1$ and $\log(1/R) = \log 2 + \frac{1}{2}\log\max(1,\rho^{-2}) \le \log 2 + \frac{1}{2}\log(1+\rho^{-2})$:

$$\log \|\theta\|_{\sup,\sigma} \le \log b_\sigma + 1 + \frac{g}{2}\log g + g\log 2 + \frac{g}{2}\log(1+\rho_\sigma^{-2}). \tag{D.8}$$

Step 3: the mean over the places. By Theorem B.138 for A over L with $\varepsilon = \frac{1}{2}$ (the forms H_σ there are ours), $\frac{\pi}{12}\,\mathrm{mean}_\sigma \rho_\sigma^{-2} \le h_F(A) - \frac{g}{2}\log\pi + \frac{g}{2}\log(4\pi^2) = h_F(A) + \frac{g}{2}\log(4\pi)$, and by Step 1

$$\mathrm{mean}_\sigma\, \rho_\sigma^{-2} \le \frac{12}{\pi}\Big(2\Phi + \frac{g}{2}\log 2\Big) \le \frac{24}{\pi}\Phi + \frac{6}{\pi}g.$$

Average (D.8) over σ, use $\mathrm{mean}_\sigma \log b_\sigma \le \Phi$ and Jensen's inequality for the concave log:

$$\mathrm{mean}_\sigma \log(1+\rho_\sigma^{-2}) \le \log(1+\mathrm{mean}_\sigma \rho_\sigma^{-2}) \le \log\big(8(2+g+\Phi)\big) \le 3\log(2+g+\Phi),$$

the last step since $\log 8 \le 2\log 3 \le 2\log(2+g+\Phi)$. With $Y = \log(2+g+\Phi) \ge \log 3 \ge 1$, $\log g \le Y$ and $\log 2 \le Y$:

$$\mathrm{mean}_\sigma \log \|\theta\|_{\sup,\sigma} \le \Phi + gY + \frac{g}{2}Y + gY + \frac{3g}{2}Y = \Phi + 4g\log(2+g+\Phi).$$

□

Proposition D.33. *Let E be a CM field, L a number field, $(\mathcal{A}, \mathcal{L}_\mathcal{A}, r)$ a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$ of relative dimension g, $\theta \in H^0(\mathcal{A}, \mathcal{L}_\mathcal{A})$ non-zero on the generic fibre and lying in the Moret-Bailly lattice, and $(M_\sigma)_{\sigma\colon L\to\mathbb{C}}$ positive reals with $\|\theta\|_{\sup,\sigma} \le M_\sigma$ for every σ. For every even integer $m \ge 2$ there are a finite extension L'/L and sections $s_1, \dots, s_{m^{2g}} \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'}^{\otimes m^2})$ of the base change $\mathcal{A}'$ of $\mathcal{A}$ to $\mathcal{O}_{L'}$ such that for every $\sigma'\colon L' \to \mathbb{C}$*

$$\|s_j\|_{\sup,\sigma'} \le M_{\sigma'|_L} \quad (1 \le j \le m^{2g}),$$

and the images of $s_1, \dots, s_{m^{2g}}$ span $H^0(A'_{\sigma'}, \mathcal{L}_{\sigma'}^{\otimes m^2})$ over $\mathbb{C}$.

Proof. Write $A = \mathcal{A}_L$, $L_A = \mathcal{L}_\mathcal{A}|_A$, $r_0 \in \mathcal{L}_\mathcal{A}(0)$ for the generator with $r(r_0) = 1$, and, for a finite extension K/L, θ_K for the restriction of θ to A_K. By Definition 31.6, A is an abelian variety of dimension $g \ge 1$ and L_A is symmetric, ample and defines a principal polarisation. Fix an even integer $m \ge 2$.

Step 1: one model carrying θ and the torsion sections. As θ lies in the Moret-Bailly lattice, there are a finite extension K/L and a Moret-Bailly model $\mathfrak{M}$ of $(A_K, L_A \otimes K, r_0 \otimes 1, \varnothing)$ over $\mathcal{O}_K$ whose Moret-Bailly lattice Λ contains θ_K. By Theorem B.133 (1), applied with L in place of the base field, to A, L_A, $r_0 \ne 0$ and the even integer $r = m \ge 2$ (its hypotheses are those just listed), there are a finite extension K_1/L with $A[m^2] \subseteq A(K_1)$ and a Moret-Bailly model $\mathfrak{M}_1$ of $(A_{K_1}, L_A \otimes K_1, r_0 \otimes 1, A[m^2](K_1))$ over $\mathcal{O}_{K_1}$. Let L' be a finite extension of L containing K and K_1 (a compositum). Then $A[m^2](L') = A[m^2](K_1)$, all m^2-torsion being K_1-rational. By Theorem B.133 (2), the base change $\mathfrak{M}_{L'}$ of $\mathfrak{M}$ is a Moret-Bailly model of $(A_{L'}, L_A \otimes L', r_0 \otimes 1, \varnothing)$ with Moret-Bailly lattice $\Lambda \otimes_{\mathcal{O}_K} \mathcal{O}_{L'}$, which contains $\theta_{L'} = \theta_K \otimes 1$; and the base change

$$\mathfrak{M}' = (\mathcal{G}, i, \mathcal{M}, (\|\cdot\|_{\sigma'})_{\sigma'}, \varphi, u, (\varepsilon_x)_{x \in A[m^2](L')})$$

of $\mathfrak{M}_1$ is a Moret-Bailly model of $(A_{L'}, L_A \otimes L', r_0 \otimes 1, A[m^2](L'))$ over $\mathcal{O}_{L'}$. Forgetting the sections ε_x, the data of $\mathfrak{M}'$ form a Moret-Bailly model of $(A_{L'}, L_A \otimes L', r_0 \otimes 1, \varnothing)$ (condition (Mb4) is empty for $F = \varnothing$, the others are unchanged), with the same Moret-Bailly lattice. By Theorem B.133 (3) this lattice equals that of $\mathfrak{M}_{L'}$, so it contains $\theta_{L'}$: there is $s_0 \in H^0(\mathcal{G}, \mathcal{M})$ with $\varphi(s_0|_{\mathcal{G}_{L'}}) \circ i^{-1} = \theta_{L'}$.

Step 2: the norm of s_0. Let $\mathcal{A}'$ be the base change of $\mathcal{A}$ to $\mathcal{O}_{L'}$. Apply Lemma D.31 to $\mathcal{A}$, the extension L'/L, the finite set $F = A[m^2](L') \subseteq A(L')$ and the model $\mathfrak{M}'$: for every $N \geq 1$ and $s \in H^0(\mathcal{G}, \mathcal{M}^{\otimes N})$ it gives $s^\flat \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'}^{\otimes N})$ whose restriction to $A_{L'}$ is $\varphi^{\otimes N}(s|_{\mathcal{G}_{L'}})$ transported by i, and whose canonical norm at each point $i(y)$ of $A_{\sigma'}(\mathbb{C})$ equals the cubist norm $\|s\|_{\sigma'}(y)$, for every $\sigma' \colon L' \to \mathbb{C}$ and $y \in \mathcal{G}_{\sigma'}(\mathbb{C})$. For $N = 1$ and $s = s_0$, the sections $s_0^\flat$ and $\theta \otimes 1 \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'})$ have the same restriction $\theta_{L'}$ to the generic fibre; since $\mathcal{A}'$ is flat over $\mathcal{O}_{L'}$, restriction to the generic fibre is injective on $H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'})$, so $s_0^\flat = \theta \otimes 1$. The complex torus, the Hermitian form, the line bundle and the rigidification of $\mathcal{A}'$ at σ' are those of $\mathcal{A}$ at $\sigma'|_L$, hence so are the theta trivialisation and the canonical norms (Definition D.28). Therefore, for every σ' and $y \in \mathcal{G}_{\sigma'}(\mathbb{C})$,

$$\|s_0\|_{\sigma'}(y) = \|\theta \otimes 1\|(i(y)) \leq \|\theta\|_{\sup, \sigma'|_L} \leq M_{\sigma'|_L}. \tag{D.9}$$

Step 3: the translates. Let j, i_x and ψ_x ($x \in A[m^2](L')$) be the isomorphisms and maps of Theorem B.133 (4) for the model $\mathfrak{M}'$ and $r = m$, and let $\Sigma \subseteq A[m^2](L')$ be a set of representatives of $A[m^2]/A[m]$; it has $m^{4g}/m^{2g} = m^{2g}$ elements. Since $[m]$, t_{ε_x}, j and i_x are defined over $\mathcal{G}$, $\psi_x(s_0) = i_x(t_{\varepsilon_x}^* j([m]^* s_0)) \in H^0(\mathcal{G}, \mathcal{M}^{\otimes m^2})$, and its restriction to $\mathcal{G}_{L'}$ is $\psi_x(s_0|_{\mathcal{G}_{L'}})$. Put $s_x = \psi_x(s_0)^\flat \in H^0(\mathcal{A}', \mathcal{L}_{\mathcal{A}'}^{\otimes m^2})$ (Step 2 with $N = m^2$) for $x \in \Sigma$, and number them $s_1, \ldots, s_{m^{2g}}$.

Step 4: the sup norms. Fix σ' and $y \in \mathcal{G}_{\sigma'}(\mathbb{C})$, and write ε_x also for the point $\varepsilon_x(\sigma') \in \mathcal{G}_{\sigma'}(\mathbb{C})$. The metric on $t_{\varepsilon_x}^* \mathcal{M}^{\otimes m^2}$ is the pull-back metric, and that on $[m]^*\mathcal{M}$ the pull-back of the cubist metric; as i_x and j are isometric (Theorem B.133 (4)),

$$\|\psi_x(s_0)\|_{\sigma'}(y) = \big\|j([m]^* s_0)\big\|_{\sigma'}(y + \varepsilon_x) = \|[m]^* s_0\|_{\sigma'}(y + \varepsilon_x) = \|s_0\|_{\sigma'}(my + m\varepsilon_x) \leq M_{\sigma'|_L}$$

by (D.9). By Step 2 the canonical norm of s_x at $i(y)$ is $\|\psi_x(s_0)\|_{\sigma'}(y)$; as y runs over $\mathcal{G}_{\sigma'}(\mathbb{C})$, $i(y)$ runs over $A_{\sigma'}(\mathbb{C})$, so $\|s_x\|_{\sup, \sigma'} \leq M_{\sigma'|_L}$.

Step 5: spanning. The maps φ and i identify $H^0(\mathcal{G}_{L'}, \mathcal{M}_{L'})$ with $H^0(A_{L'}, L_A \otimes L')$, which is one-dimensional and contains $\theta_{L'} \neq 0$ (θ is non-zero on the generic fibre); hence $H^0(\mathcal{G}_{L'}, \mathcal{M}_{L'}) = L'\, s_0|_{\mathcal{G}_{L'}}$. By Theorem B.133 (4), $(c_x s_0|_{\mathcal{G}_{L'}})_{x \in \Sigma} \mapsto \sum_{x \in \Sigma} c_x \psi_x(s_0|_{\mathcal{G}_{L'}})$ ($c_x \in L'$) is an isomorphism onto $H^0(\mathcal{G}_{L'}, \mathcal{M}_{L'}^{\otimes m^2})$, so the $\psi_x(s_0)|_{\mathcal{G}_{L'}}$, $x \in \Sigma$, form an L'-basis of it. Applying the isomorphisms $\varphi^{\otimes m^2}$ and i, the restrictions of the s_x to $A_{L'}$ (Step 2) form an L'-basis of $H^0(A_{L'}, L_A^{\otimes m^2} \otimes L')$. By flat base change along σ', $H^0(A_{\sigma'}, \mathcal{L}_{\sigma'}^{\otimes m^2}) = H^0(A_{L'}, L_A^{\otimes m^2} \otimes L') \otimes_{L', \sigma'} \mathbb{C}$, so the images of $s_1, \ldots, s_{m^{2g}}$ form a $\mathbb{C}$-basis of $H^0(A_{\sigma'}, \mathcal{L}_{\sigma'}^{\otimes m^2})$; in particular they span it. □

Lemma D.34. *Let $(\mathcal{A}, \mathcal{L}_{\mathcal{A}}, r)$ be a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$, $x \in \mathrm{Lie}(\mathcal{A})$ and $n \geq 1$; put $W_n = H^0(A, \mathcal{L}_{\mathcal{A}}|_A^{\otimes n})$. There are L-linear maps $j_k \colon W_n \to L$ ($k \geq 0$) such that:*

1. *if $s \in H^0(\mathcal{A}, \mathcal{L}_{\mathcal{A}}^{\otimes n})$, $i \geq 0$ and $j_k(s) = 0$ for all $k < i$, then $j_i(s) \in \mathcal{O}_L$;*
2. *for every $\sigma \colon L \to \mathbb{C}$, every $s \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes n}) = W_n \otimes_{L, \sigma} \mathbb{C}$ and every $i \geq 0$, with $j_{k,\sigma} = j_k \otimes_\sigma \mathbb{C}$: $j_{k,\sigma}(s) = 0$ for all $k < i$ if and only if $\partial_{x_\sigma}^k \theta_s(0) = 0$ for all $k < i$, and in that case $j_{i,\sigma}(s) = \partial_{x_\sigma}^i \theta_s(0)$.*

Proof. Let X be the invariant vector field on $\mathcal{A}$ with value x along the unit section e; it is a global section of $T_{\mathcal{A}/\mathcal{O}_L}$, i.e. an $\mathcal{O}_L$-derivation of $\mathcal{O}_\mathcal{A}$, and its restriction to A is the invariant vector field of x_L.

Definition of the jets. Since $\mathcal{L}_\mathcal{A}|_A$ is invertible near 0, there is a section ϵ of it on an open neighbourhood of 0 in A generating it there, and after scaling $\epsilon(0) = r$. For $s \in W_n$ the quotient s/ϵ^n is regular at 0; put $j_k(s) = (X^k(s/\epsilon^n))(0) \in L$. These maps are L-linear.

Item 2. Fix σ. The vector field X_σ on $A_\sigma(\mathbb{C})$ is invariant with value x_σ at 0, and its integral curve through 0 is $\tau \mapsto \pi_\sigma(\tau x_\sigma)$; by invariance $\frac{d}{d\tau}\varphi(\pi_\sigma(\tau x_\sigma)) = (X_\sigma\varphi)(\pi_\sigma(\tau x_\sigma))$ for holomorphic φ near 0, hence by induction $(X_\sigma^k\varphi)(0) = \frac{d^k}{d\tau^k}\varphi(\pi_\sigma(\tau x_\sigma))|_{\tau=0}$. So $j_{k,\sigma}(s) = F^{(k)}(0)$ for $F(\tau) = (s/\epsilon^n)(\pi_\sigma(\tau x_\sigma))$. Near 0 write $\pi_\sigma^*\epsilon = \eta\,\vartheta$ with η holomorphic and $\eta(0) = 1$ (both equal r_σ at 0). Then $\pi_\sigma^* s = \theta_s \vartheta^{\otimes n} = ((s/\epsilon^n)\circ\pi_\sigma)\eta^n\vartheta^{\otimes n}$, so $\theta_s(\tau x_\sigma) = F(\tau)U(\tau)$ with $U(\tau) = \eta(\tau x_\sigma)^n$ holomorphic near 0 and $U(0) = 1$. If $F^{(k)}(0) = 0$ for $k < i$, the Leibniz rule gives $(FU)^{(k)}(0) = 0$ for $k < i$ and $(FU)^{(i)}(0) = F^{(i)}(0)U(0) = F^{(i)}(0)$; conversely, if $(FU)^{(k)}(0) = 0$ for $k < i$, the same argument applied to $F = (FU)\cdot U^{-1}$ gives $F^{(k)}(0) = 0$ for $k < i$. This is item 2.

Item 1. Let $\mathfrak{p}$ be a maximal ideal of $\mathcal{O}_L$, $R = \mathcal{O}_{L,\mathfrak{p}}$, and $P = e(\mathfrak{p}) \in \mathcal{A}$. Choose a generator $\epsilon_\mathfrak{p}$ of $\mathcal{L}_\mathcal{A}$ on an open neighbourhood $N_\mathfrak{p}$ of P. Open sets are stable under generisation, so $N_\mathfrak{p}$ contains the image of $\operatorname{Spec} R$ under e, and $e^*\epsilon_\mathfrak{p}$ generates $e^*\mathcal{L}_\mathcal{A} \otimes R \cong R$; after multiplying by a unit of R, $e^*\epsilon_\mathfrak{p} = r$. For $s \in H^0(\mathcal{A}, \mathcal{L}_\mathcal{A}^{\otimes n})$ we have $s/\epsilon_\mathfrak{p}^n \in \mathcal{O}_{\mathcal{A},P}$, hence $X^a(s/\epsilon_\mathfrak{p}^n) \in \mathcal{O}_{\mathcal{A},P}$, and

$$j_a^\mathfrak{p}(s) := e^*\big(X^a(s/\epsilon_\mathfrak{p}^n)\big) \in R \qquad (a \geq 0);$$

its image in L is $(X^a(s/\epsilon_\mathfrak{p}^n))(0)$ computed on A. Near 0 in A, $\epsilon = \beta\,\epsilon_\mathfrak{p}$ with β regular and invertible at 0, $\beta(0) = 1$. Then $s/\epsilon^n = (s/\epsilon_\mathfrak{p}^n)\,\beta^{-n}$ and the Leibniz rule for the derivation X gives

$$j_k(s) = j_k^\mathfrak{p}(s) + \sum_{a<k} \binom{k}{a} j_a^\mathfrak{p}(s)\,(X^{k-a}\beta^{-n})(0).$$

If $j_k(s) = 0$ for $k < i$, induction on $k < i$ gives $j_k^\mathfrak{p}(s) = 0$ for $k < i$, and then $j_i(s) = j_i^\mathfrak{p}(s) \in R$. As this holds for every $\mathfrak{p}$, $j_i(s) \in \bigcap_\mathfrak{p} \mathcal{O}_{L,\mathfrak{p}} = \mathcal{O}_L$. □

Lemma D.35. *Let $(\mathcal{A}, \mathcal{L}_\mathcal{A}, r)$ be a principally polarised abelian scheme with $\mathcal{O}_E$-action over $\mathcal{O}_L$, $\sigma\colon L \to \mathbb{C}$, $0 \neq v \in \operatorname{Lie}(A_\sigma)$, and let $n' \geq 1$ and $0 \leq i \leq n'$ be integers. Then there is $s \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes 3n'})$ with*

$$\partial_v^k\theta_s(0) = 0 \quad (0 \leq k < i), \qquad \partial_v^i\theta_s(0) \neq 0.$$

Proof. The line bundle $\mathcal{L}_\sigma$ is ample, being the base change of the ample $\mathcal{L}_\mathcal{A}|_A$ along the field embedding σ. By Lefschetz's theorem [32] (Theorem B.122), $\mathcal{L}_\sigma^{\otimes 3}$ is very ample, so its complete linear system defines a closed embedding j of A_σ; in particular it is base point free and dj is injective on the tangent space $T_0A_\sigma = \operatorname{Lie}(A_\sigma)$.

Two sections. Choose $s_0 \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes 3})$ with $s_0(0) \neq 0$. On the open set $\{s_0 \neq 0\}$ the functions s/s_0 ($s \in H^0(\mathcal{L}_\sigma^{\otimes 3})$) are the affine coordinates of j, so injectivity of dj at 0 gives s with $d(s/s_0)_0(v) \neq 0$; then $s_1 = s - (s/s_0)(0)\,s_0$ satisfies $s_1(0) = 0$ and $d(s_1/s_0)_0(v) = d(s/s_0)_0(v) \neq 0$.

Translation to theta functions. Write $\pi_\sigma^* s_a = \theta_a\vartheta^{\otimes 3}$ ($a = 0, 1$). As ϑ vanishes nowhere, $\theta_0(0) \neq 0$, $\theta_1(0) = 0$, and near 0 we have $(s_1/s_0)\circ\pi_\sigma = \theta_1/\theta_0$. The exponential map π_σ is a local biholomorphism at 0 with differential the identity of $\operatorname{Lie}(A_\sigma)$, so $d(\theta_1/\theta_0)_0(v) = d(s_1/s_0)_0(v) \neq 0$. For $f(\tau) = \theta_1(\tau v)$ and $u(\tau) = \theta_0(\tau v)$ this gives $f(0) = 0$, $u(0) \neq 0$ and, since $f(0) = 0$, $f'(0) = u(0)\,\frac{d}{d\tau}(f/u)(0) = u(0)\,d(\theta_1/\theta_0)_0(v) \neq 0$.

The section. Put $s = s_1^{\otimes i} \otimes s_0^{\otimes(n'-i)} \in H^0(A_\sigma, \mathcal{L}_\sigma^{\otimes 3n'})$. Then $\pi_\sigma^* s = \theta_1^i \theta_0^{n'-i} \vartheta^{\otimes 3n'}$, so $\theta_s = \theta_1^i \theta_0^{n'-i}$ and $\theta_s(\tau v) = f(\tau)^i u(\tau)^{n'-i} = \tau^i q(\tau)$ with q entire and $q(0) = f'(0)^i u(0)^{n'-i} \neq 0$. Hence $\partial_v^k \theta_s(0) = 0$ for $k < i$ and $\partial_v^i \theta_s(0) = i!\, q(0) \neq 0$. □

D.2.2 Flat saturation and flat generators of the determinant line

Flat saturation (Proposition D.36) says that the complex-conjugate Lie eigenspaces of an abelian variety of unitary signature have nearly equal degrees, with an error controlled by rd_E and L_{H}; it is an input of Lemma D.22. The proof realises the abelian variety as a point of a unitary Shimura variety (Proposition D.37) and evaluates a generator of the τ-determinant line there, which is a flat generator with archimedean and ℓ-adic norms (Proposition D.38, Proposition D.39), so that its flat height is given by Theorem 34.20. Proposition D.38 is used again in Section D.4.

Proposition D.36. *There is a real number $C_{\mathrm{fs}} \geq 0$ with the following property. Let E be a CM field with complex conjugation c and a CM host $\mathsf{H} = (d, r, r_{\mathbb{C}})$, put $\mathrm{rd}_E = |\mathrm{disc}(E)|^{1/[E:\mathbb{Q}]}$ and $L_{\mathsf{H}} = \mathrm{Re}\,(L'/L)(1, \chi_d)$, let L be a number field and $\mathcal{A}$ a principally polarised abelian scheme with $\mathcal{O}_E$-action ι over $\mathcal{O}_L$, with generic fibre A, such that the Rosati involution of the principal polarisation of A maps $\iota(a)$ to $\iota(c(a))$ for $a \in \mathcal{O}_E$. Suppose that there are $\rho \in L$ with $\rho^2 = -d$ and integers $p', q' \geq 0$ such that for every algebraically closed field k, every ring homomorphism $\gamma\colon L \to k$ and every ring homomorphism $\sigma\colon \mathcal{O}_E \to k$, the σ-eigenspace $\{x : \iota(a)x = \sigma(a)x \ \forall a \in \mathcal{O}_E\}$ of $\mathrm{Lie}(A) \otimes_{L,\gamma} k$ has dimension p' if $\sigma(r) = \gamma(\rho)$ and dimension q' otherwise. Let $s_1, s_2\colon \mathcal{O}_E \to \mathcal{O}_L$ be ring homomorphisms with s_1 injective and $e \circ s_2 = \overline{e \circ s_1}$ for every field embedding $e\colon L \to \mathbb{C}$. For $i = 1, 2$ put $\mathrm{Lie}_{s_i}(\mathcal{A}) = \{x \in \mathrm{Lie}(\mathcal{A}) : \iota(a)x = s_i(a)x \ \forall a \in \mathcal{O}_E\}$ and $d_{s_i} = \widehat{\deg}\,\overline{\mathrm{Lie}}_{s_i}(\mathcal{A})/[L : \mathbb{Q}]$. Then*

$$|d_{s_1} - d_{s_2}| \ \leq \ C_{\mathrm{fs}}\,(\mathrm{rk}\,\mathrm{Lie}_{s_1}(\mathcal{A}) + \mathrm{rk}\,\mathrm{Lie}_{s_2}(\mathcal{A}))\,(1 + \log \mathrm{rd}_E + |L_{\mathsf{H}}|).$$

Proof. We prove the bound with $C_{\mathrm{fs}} = \frac{3}{2}$. Write $\mathrm{rk}_i = \mathrm{rk}\,\mathrm{Lie}_{s_i}(\mathcal{A})$.

Step 1: the labels. As $r^2 = -d$ in $\mathcal{O}_E$, $s_1(r)^2 = -d = \rho^2$ in the field L, so $s_1(r) = \pm\rho$. If $s_1(r) = -\rho$, then for every $e\colon L \to \mathbb{C}$, $e(s_2(r)) = \overline{e(s_1(r))} = -\overline{e(\rho)} = e(\rho)$, because $e(\rho)^2 = -d$ makes $e(\rho)$ purely imaginary; so $s_2(r) = \rho$, and s_2 is injective (as $e \circ s_2 = \overline{e \circ s_1}$). The hypotheses and the conclusion are symmetric in (s_1, s_2), so we may assume $s_1(r) = \rho$. By the signature hypothesis (for $k = \overline{L}$, and since $\mathrm{Lie}_{s_i}(\mathcal{A}) \otimes_{\mathcal{O}_L} L$ is the s_i-eigenspace of $\mathrm{Lie}(A)$), $\mathrm{rk}_1 = p'$ and $\mathrm{rk}_2 = q'$ ($s_2(r) = -\rho \neq \rho$). If $p' + q' = 0$ both lattices are zero and there is nothing to prove; let $p' + q' \geq 1$.

Step 2: the moduli point. By Proposition D.37 there are a unitary Shimura datum $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p', q', \mathsf{L}, \mathrm{Sh}, F)$ with level good at every prime and split components, an integral model $(\mathcal{Y}, j, G_{\mathcal{Y}}, \iota_{\mathcal{Y}}, \mathcal{L}_{\mathcal{Y}})$ over $\mathcal{O}_F$, a finite extension $K \supseteq L$ with $\beta\colon F \to K$, $\beta(r_{\mathbb{C}}) = \rho$, and $y \in \mathrm{Sh}_F(K)$ with an $\mathcal{O}_E$-linear, polarisation-compatible isomorphism $G_y \cong A \otimes_L K$. The maps $\beta \circ \sigma$, $\sigma \in \mathrm{Hom}(E, F)$, are $[E : \mathbb{Q}]$ distinct embeddings $E \to K$ (F contains every conjugate of E), hence all of them; so $s_1 = \beta \circ \tau$ on $\mathcal{O}_E$ for a unique $\tau \in \mathrm{Hom}(E, F)$, and $\beta(\tau(r)) = s_1(r) = \rho = \beta(r_{\mathbb{C}})$ gives $\tau(r) = r_{\mathbb{C}}$, i.e. $\tau \in \Phi_{\mathsf{H}}$ and $\sigma_{(\tau,+)} = \tau$. For $e'\colon K \to \mathbb{C}$ extending $e\colon L \to \mathbb{C}$, $e' \circ \beta$ restricted to the CM field $\tau(E)$ commutes with complex conjugation, so $e'(\beta(\bar\tau(a))) = \overline{e'(\beta(\tau(a)))} = \overline{e(s_1(a))} = e(s_2(a))$; hence $s_2 = \beta \circ \sigma_{(\tau,-)}$.

Step 3: the flat generator. The point $j(y)$ lies in an irreducible component $\mathcal{Y}'$ of $\mathcal{Y}$ meeting $j(\mathrm{Sh}_F)$; put $U = j^{-1}(\mathcal{Y}' \times_{\mathcal{O}_F} F)$, so $y \in U(K)$. By Proposition D.38 (components split, level good at every prime, $n = p' + q' \geq 1$), for a nowhere vanishing section ξ of $\det \mathrm{Lie}_{(\tau,+)} \otimes (\det \mathrm{Lie}_{(\tau,-)})^{-1}$ on $\mathcal{Y}'_F$ the frame function φ_ξ on the connected component U is a flat generator

over a connected component Y of $U(\mathbb{C})$ with some constants (e,c), and has archimedean norms N_s at every $s\colon F\to\mathbb{C}$ and ℓ-adic norms N_κ at every $\kappa\colon F\to\mathbb{C}_\ell$, every ℓ.

Step 4: the product formula. Let $\mathcal{G}=\mathcal{A}\times_{\mathcal{O}_L}\mathcal{O}_K$, a semiabelian scheme over $\mathcal{O}_K$ with $\mathcal{O}_E$-action whose generic fibre is identified with G_y. Its eigen-submodules $\mathcal{L}_\pm$ for $\beta\circ\sigma_{(\tau,\pm)}=s_1,s_2$ are $\mathrm{Lie}_{s_1}(\mathcal{A})\otimes_{\mathcal{O}_L}\mathcal{O}_K$ and $\mathrm{Lie}_{s_2}(\mathcal{A})\otimes_{\mathcal{O}_L}\mathcal{O}_K$ (kernels of finitely many $\mathcal{O}_L$-linear maps commute with the flat base change). As the isomorphism respects the principal polarisations, the Hodge inner product $h_{y^t}=\pi H_{y^t}$ at $t\colon K\to\mathbb{C}$ is the norm $\pi H_{t|_L}$ of the Lie lattice $\overline{\mathrm{Lie}}(\mathcal{A})$ (Definition 31.6). The arithmetic degree of a Hermitian lattice is multiplied by $[K:L]$ under base change to $\mathcal{O}_K$, so $d_{s_i}=\widehat{\deg}\,\overline{\mathcal{L}}_\pm/[K:\mathbb{Q}]$. Lemma D.54, applied to $\mathfrak{u}$, τ, U, φ_ξ, K, β, y and $\mathcal{G}$, gives

$$d_{s_1}-d_{s_2}=-\frac{1}{[F:\mathbb{Q}]}\Big(\sum_s N_s+\sum_\ell\sum_\kappa N_\kappa\Big)=h^{\mathrm{fl}}(\varphi_\xi),$$

the flat height of (Fd1) in Theorem 34.20.

Step 5: the bound. By (Fd3) of Theorem 34.20, applied to φ_ξ (a flat generator over Y with all local norms, U a union of connected components),

$$|d_{s_1}-d_{s_2}|=|h^{\mathrm{fl}}(\varphi_\xi)|\le n\Big(\frac{3}{2}\log\mathrm{rd}_E+\frac{|L_{\mathsf{H}}|}{2}\Big)\le\frac{3}{2}\,(\mathrm{rk}_1+\mathrm{rk}_2)(1+\log\mathrm{rd}_E+|L_{\mathsf{H}}|),$$

since $n=p'+q'=\mathrm{rk}_1+\mathrm{rk}_2$ and $\log\mathrm{rd}_E\ge0$. This is the claim with $C_{\mathrm{fs}}=\frac{3}{2}$. □

Proposition D.37. *Let E be a CM field unramified over its maximal totally real subfield at every finite place, with complex conjugation c and a CM host $\mathsf{H}=(d,r,r_{\mathbb{C}})$; let L be a number field and $\mathcal{A}$ a principally polarised abelian scheme with $\mathcal{O}_E$-action ι over $\mathcal{O}_L$, with generic fibre A, such that the Rosati involution of the principal polarisation of A maps $\iota(a)$ to $\iota(c(a))$. Suppose that there are $\rho\in L$ with $\rho^2=-d$ and integers $p',q'\ge0$ with $p'+q'\ge1$ such that for every algebraically closed field k, every ring homomorphism $\gamma\colon L\to k$ and every ring homomorphism $\sigma\colon\mathcal{O}_E\to k$, the σ-eigenspace of $\mathrm{Lie}(A)\otimes_{L,\gamma}k$ has dimension p' if $\sigma(r)=\gamma(\rho)$ and q' otherwise. Then there are a unitary Shimura datum $\mathfrak{u}=(E,\mathsf{H},\mathsf{U},p',q',\mathsf{L},\mathrm{Sh},F)$ whose level is good at every prime and whose components split, an integral model $(\mathcal{Y},j,G_{\mathcal{Y}},\iota_{\mathcal{Y}},\mathcal{L}_{\mathcal{Y}})$ of Sh over $\mathcal{O}_F$, a finite extension K of L with a field embedding $\beta\colon F\to K$ such that $\beta(r_{\mathbb{C}})=\rho$, and a point $y\in\mathrm{Sh}_F(K)$ (an F-morphism $\mathrm{Spec}\,K\to\mathrm{Sh}_F$ through β), together with an $\mathcal{O}_E$-linear isomorphism of the fibre G_y of the universal abelian scheme with $A\otimes_L K$ that carries the principal polarisation of G_y to that of $A\otimes_L K$.*

Proof. Put $n=p'+q'$ and $g=\dim A$.

Step 1: the unitary datum. The elements $\pm\rho$ are the roots of T^2+d in L, and every embedding of L into $\mathbb{C}$ sends ρ to $\pm r_{\mathbb{C}}$, its complex conjugate to the other sign; so there is $\sigma\colon L\to\mathbb{C}$ with $\sigma(\rho)=r_{\mathbb{C}}$. Write $A_\sigma(\mathbb{C})=\mathrm{Lie}(A_\sigma)/M$, $M=H_1(A_\sigma(\mathbb{C}),\mathbb{Z})$, with the $\mathcal{O}_E$-action ι and the Riemann form $\langle\,,\rangle$ of the principal polarisation: a perfect alternating $\mathbb{Z}$-pairing on M with $\langle Jx,Jy\rangle=\langle x,y\rangle$ and $\langle Jx,x\rangle>0$ for $x\ne0$, where J is multiplication by i on $M_{\mathbb{R}}=\mathrm{Lie}(A_\sigma)$, and $\langle ax,y\rangle=\langle x,\bar a y\rangle$ by the Rosati hypothesis. The lattice M is a finitely generated torsion-free, hence projective, $\mathcal{O}_E$-module. By the signature hypothesis (with $k=\mathbb{C}$, $\gamma=\sigma$), the τ-eigenspace of $\mathrm{Lie}(A_\sigma)$ has dimension p' for $\tau\in\Phi_{\mathsf{H}}$ ($\tau(r)=r_{\mathbb{C}}=\sigma(\rho)$) and q' for $\tau\notin\Phi_{\mathsf{H}}$, and $\mathrm{Lie}(A_\sigma)$ is their sum ($E\otimes\mathbb{C}$ is split); so $g=\frac12[E:\mathbb{Q}]n$, M has $\mathcal{O}_E$-rank n, and for $a\in\mathcal{O}_E$ the $\mathbb{C}$-trace of a on $(M_{\mathbb{R}},J)$ is $t(a)=\sum_{\tau\in\Phi_{\mathsf{H}}}(p'\tau(a)+q'\overline{\tau(a)})$; hence the $\mathbb{R}$-traces of a and of Ja on $M_{\mathbb{R}}$ are $2\,\mathrm{Re}\,t(a)$ and $2\,\mathrm{Re}(i\,t(a))=-2\,\mathrm{Im}\,t(a)$. So $\mathsf{U}=(M,\langle\,,\rangle)$ is a unitary datum of signature (p',q') for H (Ud2), and $\det_{\mathbb{C}}(T-\iota(a)\mid\mathrm{Lie}(A_\sigma))=P_a(T)$, the polynomial of Theorem B.105 for $(E,M,\langle\,,\rangle,J)$.

Step 2: the level. The field $\mathbb{Q}(\sqrt{-d})$ has infinitely many split primes (Dirichlet); choose two distinct split primes $p_1, p_2 \geq 3$ and put $N = p_1 p_2$. As $-d \equiv 1 \pmod 4$, $\mathbb{Z}[w_0]$ is the ring of integers of $\mathbb{Q}(\sqrt{-d}) \subseteq E$ and $p_i = \mathfrak{q}_i \bar{\mathfrak{q}}_i$ with $\mathfrak{q}_i + \bar{\mathfrak{q}}_i = \mathbb{Z}[w_0]$. Put $\mathfrak{n} = \mathfrak{q}_1 \mathfrak{q}_2 \mathcal{O}_E$: it is generated by $\mathfrak{n} \cap \mathbb{Z}[w_0] \supseteq \mathfrak{q}_1 \mathfrak{q}_2$, $\mathfrak{n}\bar{\mathfrak{n}} = N\mathcal{O}_E$ and $\mathfrak{n} + \bar{\mathfrak{n}} = \mathcal{O}_E$. The level $\mathsf{L} = (N, \mathfrak{n}, 1)$ is good at every prime ($N/\ell^{v_\ell(N)} \in \{N, p_1, p_2\}$ is ≥ 3), and $K_{\mathsf{L}} = \mathbb{Q}(r_{\mathbb{C}})$.

Step 3: the moduli scheme and the point. By Proposition 32.10 (E unramified over E^+, level good at every prime, $A = 1$) there is a moduli scheme Sh of type (U, L); by Proposition 32.9 there is a finite étale surjection $\theta \circ \varpi \colon \mathcal{M}_N \to \mathrm{Sh}$ from the full-level scheme of Theorem B.105 (base changed to K_{L}) under which o^{un} pulls back to $(A^{\mathrm{un}}, \iota, \mathcal{L}_{\phi_{\mathrm{pol}}}, \eta, 0)$, whose cubical line bundle has the universal principal polarisation ϕ_{pol}. Let $K_0 \supseteq L$ be a finite extension containing the coordinates of all points of $A[N]$ over an algebraic closure, a primitive N-th root of unity, and regard K_0 as a K_{L}-algebra by $r_{\mathbb{C}} \mapsto \rho$. Fix an embedding $\sigma_0 \colon K_0 \to \mathbb{C}$ extending σ. Through σ_0, $A[m](\overline{K_0}) \cong A_\sigma(\mathbb{C})[m] = \frac{1}{m}M/M \cong M/mM$ for all m, $\mathcal{O}_E$-linearly, and the Weil pairing of the principal polarisation is $\zeta_m^{\langle x, y\rangle}$ for the compatible system $\zeta_m = e^{\epsilon 2\pi i/m}$, with a sign $\epsilon \in \{\pm 1\}$ fixed by the normalisation of e_m. Taking α_N the resulting isomorphism $M/NM \cong A[N]$ over K_0, $\nu_N(1) = \sigma_0^{-1}(\zeta_N)$ and, for $N \mid m$, the analogous (α_m, ν_m) over the finite extension of K_0 generated by the m-torsion and μ_m (finite étale surjective over $\operatorname{Spec} K_0$), the tuple $(A_{K_0}, \phi, \iota, \alpha_N, \nu_N)$ is an object of the functor of Theorem B.105 over K_0: $\phi\iota(a) = \iota(\bar{a})^\vee \phi$ is the Rosati hypothesis, and $\det(T - \iota(a) \mid \mathrm{Lie}(A_{K_0})) = P_a(T)$ because P_a has coefficients in $F_{\mathrm{ref}} \subseteq K_{\mathsf{L}}$ (Lemma 32.3), read in K_0 through $r_{\mathbb{C}} \mapsto \rho$, and the two polynomials agree after the injective σ_0, which sends ρ back to $r_{\mathbb{C}}$ (Step 1). It gives $y' \in \mathcal{M}_N(K_0)$, and $y_0 = \theta \circ \varpi \circ y' \in \mathrm{Sh}(K_0)$ with $G_{y_0} \cong A_{K_0}$, $\mathcal{O}_E$-linearly and compatibly with the principal polarisations.

Step 4: the coefficient field. Let $F_0 \subset \mathbb{C}$ be a coefficient field for L (e.g. the Galois closure of E adjoined $e^{2\pi i/N}$ and $r_{\mathbb{C}}$). The scheme Sh_{F_0} is smooth of finite type; for each of its finitely many irreducible components Z_i let $F_i \subseteq \mathbf{k}(Z_i)$ be the (finite) algebraic closure of F_0, and let $F \subset \mathbb{C}$ be a finite Galois extension of $\mathbb{Q}$ containing F_0 and an image over F_0 of every F_i. Then F is a coefficient field, and the components of Sh_F split: every component of Sh_F is a component of some $Z_i \times_{F_0} F$, whose components correspond to the factors F of $F_i \otimes_{F_0} F$ and have function fields $\mathbf{k}(Z_i) \otimes_{F_i} F$; as $\mathbf{k}(Z_i)$ is separable over F_i (characteristic 0) with F_i algebraically closed in it, $\mathbf{k}(Z_i)$ is regular over F_i, so $\mathbf{k}(Z_i) \otimes_{F_i} F$ is a field in which F is algebraically closed. Choose a finite extension K of K_0 with an embedding $\beta \colon F \to K$ extending the K_{L}-structure ($\beta(r_{\mathbb{C}}) = \rho$): take K generated over K_0 by a root of a primitive element of F over K_{L}. The point y_0 and β give $y \in \mathrm{Sh}_F(K) = (\mathrm{Sh} \times_{K_{\mathsf{L}}} F)(K)$ over β, with $G_y \cong A \otimes_L K$ as in Step 3. The datum $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p', q', \mathsf{L}, \mathrm{Sh}, F)$ is a unitary Shimura datum with level good at every prime and split components.

Step 5: the integral model. By Proposition 32.1 ($n \geq 1$, level good at every prime, $A = 1$) there is an integral model of Sh over $\mathcal{O}_F$ (with uniformised degenerations). □

Proposition D.38. *Let $\mathfrak{u}$ be a unitary Shimura datum with $n = p + q \geq 1$ whose components split, let $(\mathcal{Y}, j, G_{\mathcal{Y}}, \iota_{\mathcal{Y}}, \mathcal{L}_{\mathcal{Y}})$ be an integral model of* Sh *over $\mathcal{O}_F$, let $\mathcal{Y}'$ be an irreducible component of $\mathcal{Y}$ meeting $j(\mathrm{Sh}_F)$, $\mathcal{Y}'_F = \mathcal{Y}' \times_{\mathcal{O}_F} F$, $G' = G_{\mathcal{Y}} \times_{\mathcal{Y}} \mathcal{Y}'_F$ with the induced $\mathcal{O}_E$-action, $U = j^{-1}(\mathcal{Y}'_F) \subseteq \mathrm{Sh}_F$, and $\tau \in \Phi_{\mathsf{H}}$. Put*

$$\mathcal{D} = \det \mathrm{Lie}_{(\tau,+)}(G') \otimes \left(\det \mathrm{Lie}_{(\tau,-)}(G')\right)^{-1}.$$

Then $\mathcal{D}$ is invertible and has a global section on $\mathcal{Y}'_F$ that vanishes at no point of $\mathcal{Y}'_F$. For such a section ξ, a field k with an embedding $F \to k$, $y \in U(k)$ and a frame (v, w) at y, define $\varphi_\xi(y; v, w) \in k^\times$ by

$$\xi(j(y)) = \varphi_\xi(y; v, w)\,(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1},$$

the fibre of $\mathcal{D}$ at $j(y)$ being identified with $\det \mathrm{Lie}_{(\tau,+)}(G_y) \otimes (\det \mathrm{Lie}_{(\tau,-)}(G_y))^{-1}$ through the isomorphism of j^*G' with the universal abelian scheme. Then for every such ξ:

1. *U is a connected component of Sh_F, φ_ξ is a frame function on U, and every global section of $\mathcal{D}$ on $\mathcal{Y}'_F$ that vanishes at no point is $x\xi$ for some $x \in F^\times$;*
2. *for every connected component Y of $U(\mathbb{C})$ and every $z_0 \in Y$ there are $\mathcal{O}_E$-linearly independent $e \in \Lambda^n_{z_0}$ and $c \in \mathbb{C}^\times$ such that φ_ξ is a flat generator over Y with constants (e, c);*
3. *φ_ξ has an archimedean norm N_s at every embedding $s\colon F \to \mathbb{C}$;*
4. *for every prime ℓ, φ_ξ has an ℓ-adic norm N_κ at every ring homomorphism $\kappa\colon F \to \mathbb{C}_\ell$.*

Proof. Existence. By Proposition 34.16, $\mathcal{D}$ is invertible and has a global section vanishing at no point. Fix such a ξ.

Clause 1. As $\mathcal{Y}$ is normal, its irreducible components are pairwise disjoint, so $\mathcal{Y}'$ is open and closed in $\mathcal{Y}$, integral, normal and projective over $\mathcal{O}_F$; hence X_F is open and closed in $\mathcal{Y} \times_{\mathcal{O}_F} F$, and it is integral, normal and projective over F. So $U = j^{-1}(X_F)$ is open and closed in Sh_F, and it is irreducible, being identified by j with the dense open subset $X_F \cap j(\mathrm{Sh}_F)$ of X_F; a non-empty irreducible open and closed subset is a connected component. For $y \in U(k)$, $\xi(j(y))$ is a non-zero element of the one-dimensional k-vector space $\det \mathrm{Lie}_{(\tau,+)}(G_y) \otimes (\det \mathrm{Lie}_{(\tau,-)}(G_y))^{-1}$, of which $(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1}$ is a basis, so $\varphi_\xi(y; v, w) \in k^\times$ is well defined. Since $(Av)_1 \wedge \cdots \wedge (Av)_p = \det A\,(v_1 \wedge \cdots \wedge v_p)$ and likewise for Bw,

$$\varphi_\xi(y; Av, Bw)\,\frac{\det A}{\det B} = \varphi_\xi(y; v, w),$$

which is the frame law of (Yf2); compatibility with a field homomorphism $f\colon k \to k'$ holds because the fibre of ξ at the induced point is the image of $\xi(j(y))$ under f and the wedge of (f_*v, f_*w) is the image of the wedge of (v, w). So φ_ξ is a frame function on U. If ξ' is another global section of $\mathcal{D}$ vanishing at no point, then $\xi' = h\xi$ with $h \in H^0(X_F, \mathcal{O}_{X_F})^\times$. As X_F is proper and integral over F, $H^0(X_F, \mathcal{O}_{X_F})$ is a field, finite over F and contained in the function field $\mathbf{k}(X_F) = \mathbf{k}(U)$. The components split and U is a component of Sh_F, so F is algebraically closed in $\mathbf{k}(U)$ (Ud6); hence $H^0(X_F, \mathcal{O}_{X_F}) = F$ and $h \in F^\times$.

The comparison at an embedding $s\colon F \to \mathbb{C}$. The scheme U is smooth over F (Ud5) and integral, and F is algebraically closed in $\mathbf{k}(U)$; as F has characteristic zero, $U \otimes_{F,s} \mathbb{C}$ is an irreducible smooth complex variety, so the complex manifold $Y_s = U^s(\mathbb{C})$ of points of U over s is connected. Let Φ be a function as in Lemma 33.21 for (U, s, Y_s), and let X_s be the connected component of $(X_F \otimes_{F,s} \mathbb{C})^{\mathrm{an}}$ containing Y_s. By Lemma 34.17, X_s is a compact connected normal complex space and there is a nowhere vanishing holomorphic section ϑ of $(\mathcal{D} \otimes_{F,s} \mathbb{C})^{\mathrm{an}}$ on X_s with $\vartheta(z) = \Phi(z; v, w)\,(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1}$ for $z \in Y_s$. The analytification ξ_s of $\xi \otimes_{F,s} 1$ also vanishes nowhere on X_s, so $\xi_s = \kappa_s \vartheta$ with κ_s a nowhere vanishing holomorphic function on X_s; a holomorphic function on a compact connected complex space is constant (maximum principle), so $\kappa_s \in \mathbb{C}^\times$. Comparing coefficients of $(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1}$ at $z \in Y_s$,

$$\varphi_\xi(z; v, w) = \kappa_s\,\Phi(z; v, w) \qquad (z \in Y_s,\ (v, w) \text{ a frame at } z).$$

Clause 3. By clause 3 of Lemma 33.21 there is $c_s > 0$ with $|\Phi(z; v, w)|^2 \det \Gamma(v)(\det \Gamma(w))^{-1} = c_s$ for all $z \in Y_s$ and all frames. Every $y \in U(\mathbb{C})$ over s lies in Y_s, so

$$\log|\varphi_\xi(y; v, w)| + \tfrac{1}{2}\log\det\Gamma(v) - \tfrac{1}{2}\log\det\Gamma(w) = \log|\kappa_s| + \tfrac{1}{2}\log c_s$$

for all such y and all frames: $N_s = \log|\kappa_s| + \frac{1}{2}\log c_s$ is an archimedean norm of φ_ξ at s.

Clause 2. Let s be the inclusion; then $Y_s = U(\mathbb{C})$ is its only connected component Y. Let $z_0 \in Y$. The lattice Λ_{z_0} has $\mathbb{Z}$-rank $2\dim G_{z_0} = [E:\mathbb{Q}]\,n$ (Kottwitz condition of (Ud4)) and is an $\mathcal{O}_E$-module, so $\Lambda_{z_0}\otimes\mathbb{Q}$ is an E-vector space of dimension n and contains n E-linearly independent elements, which may be taken in Λ_{z_0}; let e be such a tuple ($\mathcal{O}_E$-linearly independent). Clause 4 of Lemma 33.21 gives $c \in \mathbb{C}^\times$ with $\Phi(z;v,w)\det\binom{C}{R} = c$ for all $z,\gamma,(v,w),C,B,R$ as in (Yf4); hence $\varphi_\xi(z;v,w)\det\binom{C}{R} = \kappa_s c$, and φ_ξ is a flat generator over Y with constants $(e,\kappa_s c)$.

Clause 4. This is Proposition D.39, whose hypotheses (components split, ξ vanishing nowhere) hold; it does not need the level to be good at any prime. □

Proposition D.39. *Let $\mathfrak{u}$ be a unitary Shimura datum with $n = p+q \geq 1$ whose components split, let $(\mathcal{Y}, j, G_{\mathcal{Y}}, \iota_{\mathcal{Y}}, \mathcal{L}_{\mathcal{Y}})$ be an integral model of* Sh *over $\mathcal{O}_F$, $\mathcal{Y}'$ an irreducible component of $\mathcal{Y}$ meeting $j(\mathrm{Sh}_F)$, $G' = G_{\mathcal{Y}} \times_{\mathcal{Y}} \mathcal{Y}'_F$, $U = j^{-1}(\mathcal{Y}'_F)$, $\tau \in \Phi_{\mathsf{H}}$, and ξ a global section of $\det\mathrm{Lie}_{(\tau,+)}(G') \otimes (\det\mathrm{Lie}_{(\tau,-)}(G'))^{-1}$ on $\mathcal{Y}'_F$ vanishing at no point. Let φ_ξ be the frame function on U with $\xi(j(y)) = \varphi_\xi(y;v,w)\,(v_1\wedge\cdots\wedge v_p)\otimes(w_1\wedge\cdots\wedge w_q)^{-1}$ for every field k with an embedding $F \to k$, $y \in U(k)$ and frame (v,w) at y. Then for every prime ℓ and every ring homomorphism $\kappa\colon F \to \mathbb{C}_\ell$, φ_ξ has an ℓ-adic norm at κ.*

Proof. Fix ℓ and $\kappa\colon F \to \mathbb{C}_\ell$; let $\mathfrak{l} = \{x \in \mathcal{O}_F : |\kappa(x)| < 1\}$, a maximal ideal over ℓ, $\mathcal{O} = \mathcal{O}_{F,\mathfrak{l}}$ the localisation, a discrete valuation ring with $|\kappa| \leq 1$ on $\mathcal{O}$, and $\pi \in \mathcal{O}_F$ a uniformiser of $\mathcal{O}$. To avoid a clash with the open immersion j, the map called j in (Yf3) is written λ below.

Step 1: the model over $\mathcal{O}$. The irreducible components of the normal noetherian scheme $\mathcal{Y}$ are disjoint, so $\mathcal{Y}'$ is open and closed in $\mathcal{Y}$: a normal integral scheme, projective and flat over $\mathcal{O}_F$. Put $X = \mathcal{Y}' \times_{\mathcal{O}_F} \mathcal{O}$, whose points are those of $\mathcal{Y}'$ over $\mathfrak{l}$ or over no prime, with the same local rings: X is normal, integral, proper and flat over $\mathcal{O}$, with generic fibre $X_K = \mathcal{Y}'_F$ and special fibre X_s, non-empty since $X \to \operatorname{Spec}\mathcal{O}$ is proper and dominant. As $\mathcal{Y}'$ meets the dense open set $j(\mathrm{Sh}_F)$ of $\mathcal{Y}\times F$, the generic point of X lies in $j(U)$ and $G_X = G_{\mathcal{Y}}|_X$ has abelian generic fibre. Let v be an ℓ-adic place with $F\cap\mathcal{O}_v = \mathcal{O}$ (extend the valuation of $\mathcal{O}$ to $\mathbb{C}$). Then $\mathcal{O}_{F,v} = \mathcal{O}$, and $\mathcal{Y}\times_{\mathcal{O}_F}\mathcal{O}$ with the restrictions of j, $G_{\mathcal{Y}}$, $\iota_{\mathcal{Y}}$, $\mathcal{L}_{\mathcal{Y}}$ is an integral model of Sh over $\mathcal{O}_{F,v}$: normality, projectivity and flatness are preserved by the localisation, and the generic fibre, j and the abelian locus are unchanged. By Lemma D.53, the semiabelian structure $(G_X,\iota,\mathcal{L})$ satisfies (PF).

Step 2: the special fibre is connected. $A = H^0(X,\mathcal{O}_X)$ is a finite $\mathcal{O}$-algebra and a domain, and by flat base change $A\otimes_{\mathcal{O}} F = H^0(\mathcal{Y}'_F,\mathcal{O})$, a finite F-algebra inside the function field of $\mathcal{Y}'_F$, which is $\mathbf{k}(Z)$ for the component Z of Sh_F with $j(Z)$ dense in $\mathcal{Y}'_F$. Its elements are algebraic over F, and F is algebraically closed in $\mathbf{k}(Z)$ (components split), so $A\otimes F = F$; A, integral over the integrally closed $\mathcal{O}$ and inside F, is $\mathcal{O}$. By Zariski's connectedness theorem [82, 4.3.1] the fibres of $X \to \operatorname{Spec}\mathcal{O}$ are connected; in particular X_s is.

Step 3: the line bundle. By Steps 1 and 2, Corollary D.41 applies to $(G_X,\iota,\mathcal{L})$ over X (a point of residue characteristic ℓ exists), with $\tau\colon \mathcal{O}_E \to \mathcal{O}_F \subseteq \Gamma(X,\mathcal{O}_X)$: $\mathcal{H} = \mathrm{H}^\natural(G_X,\mathcal{L})$ is locally free of rank $n' = 2g/[E:\mathbb{Q}]$ over $\mathcal{O}_E\otimes\mathcal{O}_X$ and $\mathcal{D}_X = \det\mathcal{H}_\tau$ is an invertible sheaf on X; by its (iii) on X_K, $\mathcal{D}_X|_{X_K} \cong \det\mathrm{Lie}_{(\tau,+)}(G') \otimes (\det\mathrm{Lie}_{(\tau,-)}(G'))^{-1}$, by an isomorphism compatible with pull-back to points. Let σ_0 be the section of $\mathcal{D}_X|_{X_K}$ corresponding to ξ, a rational section of $\mathcal{D}_X$ generating it at every point of X_K.

Step 4: degree 0 on the curves of X_s. Let $C \subseteq X_s$ be an integral closed subscheme of dimension one and $\nu\colon \tilde{C} \to C$ its normalisation, an integral normal curve, proper and hence projective over $\kappa(\mathfrak{l})$, of characteristic ℓ; let $c\colon \tilde{C} \to X$ be the composite. By Corollary D.41 (ii), $c^*\mathcal{H}_\tau$ is the quotient H_σ of $H = c^*\mathcal{H}$ for $\sigma = c^*\tau$, and by Corollary D.51 (ii) (its hypotheses

are those of Step 1) it is a vector bundle of degree 0. Hence $\deg \nu^*(\mathcal{D}_X|_C) = \deg c^*\mathcal{D}_X = \deg\det H_\sigma = 0$.

Step 5: constant vertical order. By Steps 1, 2 and 4, Lemma D.50 applies to X, $\mathcal{D}_X$, σ_0 and π: there are $M \geq 1$ and $a \in \mathbb{Z}$ such that $\theta = \sigma_0^M \pi^{-a}$ generates $\mathcal{D}_X^{\otimes M}$ at every point of X.

Step 6: evaluation at an integral frame. Let V, k, λ, β, $y \in U(k)$, $\mathcal{G}$ and the integral frame (v, w) be as in (Yf3), with $\lambda \circ \beta = \kappa$. Then $\beta(\mathcal{O}) \subseteq V$, and $\beta(\pi) \in \mathfrak{m}_V$. By properness of X over $\mathcal{O}$ (valuative criterion), the point $j(y)\colon \operatorname{Spec} k \to X_K$ extends to $z\colon \operatorname{Spec} V \to X$. The semiabelian schemes z^*G_X and $\mathcal{G}$ over V have generic fibres identified $\mathcal{O}_E$-linearly with G_y ((Ud7) and the datum of (Yf3)); by Theorem B.104 (normal base $\operatorname{Spec} V$, dense open $\operatorname{Spec} k$) this identification and its inverse extend to homomorphisms, mutually inverse and $\mathcal{O}_E$-linear by the uniqueness of extensions. So $\operatorname{Lie}(\mathcal{G}) \cong \operatorname{Lie}(z^*G_X) =: L$, and v, w are V-bases of $L[\sigma]$ and $L[\bar\sigma]$, where $\sigma = \beta\circ\tau$, $\bar\sigma = \beta\circ\bar\tau$, in the notation of Lemma D.49. Put $N = z^*\mathcal{H} = \mathrm{H}^\natural(z^*G_X, z^*\mathcal{L})$ (Lemma D.44 (6)): free of rank n' over $\mathcal{O}_E \otimes V$, with the equivariant Hodge sequence $0 \to L^\vee \to N \to L \to 0$, a acting on $L^\vee$ by $\operatorname{Lie}(\iota(\bar a))^\vee$ (Lemma D.43 (2), Lemma D.44 (4)), and $N_\sigma = z^*\mathcal{H}_\tau$, $\det N_\sigma = z^*\mathcal{D}_X$ (Corollary D.41 (ii)). The hypotheses of Lemma D.49 hold: k has characteristic 0, V residue characteristic ℓ, the $[E:\mathbb{Q}]$ embeddings $E \to k$ are the $\beta\circ\tau'$, $\tau' \in \operatorname{Hom}(E,F)$, and they map $\mathcal{O}_E$ into $\beta(\mathcal{O}_F) \subseteq V$; and $r_{\beta\tau'} = p$ if $\tau' \in \Phi_{\mathsf{H}}$, q otherwise (Kottwitz condition at y, as $L \otimes k = \operatorname{Lie}(G_y)$). In particular $n' = p + q = n$.

Let b be a V-basis of N_σ. As $z^*\theta$ generates $(\det N_\sigma)^{\otimes M}$, $z^*\theta = u\,(b_1 \wedge \cdots \wedge b_n)^{\otimes M}$ with $u \in V^\times$. Writing the generic value $z^*\sigma_0 = c\, b_1 \wedge \cdots \wedge b_n$ with $c \in k^\times$, we get $c^M = u\,\beta(\pi)^a$, so $\log|\lambda(c)| = \frac{a}{M}\log|\kappa(\pi)|$ ($|\lambda(u)| = 1$ as $V = \{|\lambda| \leq 1\}$). On the other hand, the identification of Step 3 at $j(y)$ is the one of Corollary D.41 (iii) over k, which is the exact sequence of Lemma D.49; it carries $\xi(j(y)) = \varphi_\xi(y; v, w)\,(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1}$ to $\varphi_\xi(y; v, w)\, w_1^* \wedge \cdots \wedge w_q^* \wedge \tilde v_1 \wedge \cdots \wedge \tilde v_p = \varphi_\xi(y; v, w)\,\delta\, b_1 \wedge \cdots \wedge b_n$, with δ as in Lemma D.49. Hence $\varphi_\xi(y; v, w) = c/\delta$.

Step 7: the norm. The absolute value $|\lambda(\cdot)|$ on k has valuation ring V, so $\log|\lambda(x)|$ is a negative multiple of the valuation $v(x)$, and by Lemma D.49

$$\log|\lambda(\delta)| = \sum_{s \in S_\sigma,\ s \neq \sigma} r_s \log|\lambda(s(\varpi) - \sigma(\varpi))| = \sum_{\tau' \in T_\kappa} r_{\tau'} \log|\kappa(\tau'(\varpi) - \tau(\varpi))|,$$

where $\varpi \in \mathcal{O}_E$ is a uniformiser at the prime $\{a \in \mathcal{O}_E :\ |\kappa(\tau(a))| < 1\}$, T_κ is the set of $\tau' \in \operatorname{Hom}(E,F)$, $\tau' \neq \tau$, with $|\kappa(\tau'(a) - \tau(a))| < 1$ for all $a \in \mathcal{O}_E$, and $r_{\tau'} = p$ for $\tau' \in \Phi_{\mathsf{H}}$, q otherwise (for $s = \beta\tau'$, $\lambda(s(x)) = \kappa(\tau'(x))$, and $s(a) - \sigma(a) \in \mathfrak{m}_V$ iff $|\kappa(\tau'(a) - \tau(a))| < 1$). Therefore

$$\log|\lambda(\varphi_\xi(y; v, w))| = \frac{a}{M}\log|\kappa(\pi)| - \sum_{\tau' \in T_\kappa} r_{\tau'} \log|\kappa(\tau'(\varpi) - \tau(\varpi))|,$$

a number that depends only on κ (through $\mathfrak{l}$, X, M, a, π, ϖ), not on $(V, \lambda, \beta, y, \mathcal{G}, v, w)$. It is the ℓ-adic norm N_κ of φ_ξ at κ. The second term vanishes when ℓ is unramified in E.

Remark. No condition on the level is used; the splitting of the components is used in Step 2. □

D.2.3 The polarised de Rham module over the base

The subsection develops the polarised vector extension and the polarised de Rham module of a semiabelian scheme with a rigidified cubical line bundle (Definition D.40). Its main results are that the module is locally free over $\mathcal{O}_E$ on the base (Corollary D.41) and that on every complete curve in a fibre of positive characteristic it has $\mathcal{O}_E$-equivariant Hodge and conjugate sequences and is locally free over $\mathcal{O}_E$ (Corollary D.42). The second is the input of the weighted flag inequality behind nefness at primes in Section D.3; the vertical orders along fibres (Lemma D.50) are used for flat determinants in Section D.4.

Definition D.40. Let S be a scheme, $G \to S$ a semiabelian scheme of relative dimension g with unit section e, and $\mathcal{L}$ a rigidified line bundle on G with a cubical structure. Write $\mathcal{L}_x = x^*\mathcal{L}$ for $x \in G(T)$, T an S-scheme, and $\Lambda_{(x,y)} = (x,y)^*\Lambda(\mathcal{L}) = \mathcal{L}_{x+y} \otimes \mathcal{L}_x^{-1} \otimes \mathcal{L}_y^{-1}$. Let $\omega_G = e^*\Omega^1_{G/S}$, $\mathrm{Lie}(G) = \mathcal{H}om(\omega_G, \mathcal{O}_S)$, and let $G_1 \subset G$ be the first infinitesimal neighbourhood of e (ideal $\mathcal{I}^2$, $\mathcal{I}$ the ideal of e), so that $\mathcal{O}_{G_1} = \mathcal{O}_S \oplus \omega_G$.

Canonical structures of Λ. The rigidification $\mathcal{L}_0 \cong \mathcal{O}$ gives canonical trivialisations of $\Lambda_{(x,0)}$ and $\Lambda_{(0,y)}$; the equality $\Lambda_{(x,y)} = \Lambda_{(y,x)}$ (commutativity of G) is the **symmetry**; and since $\Lambda_{(x+x',y)} \otimes \Lambda_{(x,y)}^{-1} \otimes \Lambda_{(x',y)}^{-1} = \Theta(\mathcal{L})_{(x,x',y)}$, the cubical structure gives the **partial composition** $\Lambda_{(x,y)} \otimes \Lambda_{(x',y)} \cong \Lambda_{(x+x',y)}$.

The polarised vector extension. The polarised vector extension $E^\natural(G,\mathcal{L})$ is the functor on S-schemes T whose T-points are the pairs (x,t) of $x \in G(T)$ and a trivialisation t of the line bundle $(x \circ \mathrm{pr}_1, \mathrm{pr}_2)^*\Lambda(\mathcal{L})$ on $T \times_S G_1$ that equals the canonical trivialisation of $\Lambda_{(x,0)}$ on $T \times_S \{e\}$, with the composition $(x,t)\cdot(x',t') = (x+x', t\cdot t')$, $t\cdot t'$ the image of $t \otimes t'$ under the partial composition. The forgetful map $(x,t) \mapsto x$ is the **projection** $E^\natural(G,\mathcal{L}) \to G$; its kernel consists of the trivialisations $u \cdot t_0$ of $\Lambda_{(0,\cdot)}|_{T\times G_1}$, t_0 the canonical one and $u = 1+\eta$ with $\eta \in \Gamma(T, \omega_G \otimes \mathcal{O}_T)$.

The polarised de Rham module. For an open $U \subseteq S$ let $U[\varepsilon] = U \times \operatorname{Spec}\mathbb{Z}[\varepsilon]/(\varepsilon^2)$. The **polarised de Rham module** $\mathrm{H}^\natural(G,\mathcal{L})$ is the Lie algebra of $E^\natural(G,\mathcal{L})$: the sheaf $U \mapsto \ker(E^\natural(G,\mathcal{L})(U[\varepsilon]) \to E^\natural(G,\mathcal{L})(U))$, an $\mathcal{O}_S$-module with $c \in \mathcal{O}(U)$ acting through $\varepsilon \mapsto c\varepsilon$. Its **Hodge maps** are

$$\omega_G \to \mathrm{H}^\natural(G,\mathcal{L}), \quad \eta \mapsto (0, (1+\varepsilon\eta)t_0), \qquad \mathrm{H}^\natural(G,\mathcal{L}) \to \mathrm{Lie}(G), \quad (v,t) \mapsto v.$$

Pairing. For sections $h = (v,t)$ over $U[\varepsilon]$ and $h' = (v',t')$ over $U[\varepsilon']$ of $\mathrm{H}^\natural(G,\mathcal{L})$, work over $U[\varepsilon,\varepsilon'] = U \times \operatorname{Spec}\mathbb{Z}[\varepsilon,\varepsilon']/(\varepsilon^2, \varepsilon'^2)$: v' is a point of G_1, so $t(v')$ trivialises $\Lambda_{(v,v')}$, and likewise $t'(v)$ trivialises $\Lambda_{(v',v)} = \Lambda_{(v,v')}$. The **pairing** $\langle h, h'\rangle \in \mathcal{O}(U)$ is defined by

$$t'(v) = \bigl(1 + \varepsilon\varepsilon'\langle h, h'\rangle\bigr)\, t(v'). \tag{D.10}$$

Endomorphism actions. Let $\iota\colon \mathcal{O} \to \mathrm{End}_S(G)$ be a ring homomorphism from a ring $\mathcal{O}$ with an involution $a \mapsto \bar a$. An **adjunction system** for $(G,\iota,\mathcal{L})$ is a family $\epsilon = (\epsilon_a)_{a\in\mathcal{O}}$ of isomorphisms of line bundles $\epsilon_a\colon (\iota(a),1)^*\Lambda(\mathcal{L}) \to (1,\iota(\bar a))^*\Lambda(\mathcal{L})$ on $G \times_S G$ that are the identity on $G \times_S \{e\}$ and on $\{e\} \times_S G$ under the canonical trivialisations. Given one, $a \in \mathcal{O}$ acts on $E^\natural(G,\mathcal{L})$ by

$$a\cdot(x,t) = \bigl(\iota(a)x,\ \epsilon_a^{-1}((1\times\iota(\bar a)|_{G_1})^*t)\bigr),$$

where $\iota(\bar a)$ maps G_1 into G_1; $\rho^\natural(a)$ denotes the induced endomorphism of $\mathrm{H}^\natural(G,\mathcal{L})$.

Conjugate map. Suppose $p\mathcal{O}_S = 0$ for a prime p, with absolute Frobenius F_S, and that $E^\natural(G,\mathcal{L})$ is represented by a commutative group scheme flat over S. Its Verschiebung $V\colon E^\natural(G,\mathcal{L})^{(p)} \to E^\natural(G,\mathcal{L})$ induces on Lie algebras the **conjugate map**

$$\tilde\alpha = \mathrm{Lie}(V)\colon F_S^*\mathrm{H}^\natural(G,\mathcal{L}) \to \mathrm{H}^\natural(G,\mathcal{L}).$$

Corollary D.41. *Let E be a CM field with complex conjugation $a \mapsto \bar a$, $\mathcal{X}$ a normal integral noetherian scheme with a point of positive residue characteristic, and $(G,\iota,\mathcal{L})$ a semiabelian structure over $\mathcal{X}$ of relative dimension g, with abelian generic fibre, satisfying (PF). Let $H = \mathrm{H}^\natural(G,\mathcal{L})$, with $a \in \mathcal{O}_E$ acting by $\rho^\natural(a)$. Then $[E:\mathbb{Q}]$ divides $2g$; put $n = 2g/[E:\mathbb{Q}]$.*

(i) H is locally free of rank n as a module over $\mathcal{O}_E \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{X}}$.

(ii) *For every ring homomorphism $\tau\colon \mathcal{O}_E \to \Gamma(\mathcal{X},\mathcal{O}_\mathcal{X})$, the quotient $H_\tau = H/\sum_{a\in\mathcal{O}_E}(\rho^\natural(a) - \tau(a))H$ is locally free of rank n over $\mathcal{O}_\mathcal{X}$, so $\det H_\tau$ is an invertible sheaf; for every morphism $c\colon \mathcal{X}' \to \mathcal{X}$, c^*H_τ is the $c^*\tau$-quotient of $c^*H = \mathrm{H}^\natural(G_{\mathcal{X}'},\mathcal{L}_{\mathcal{X}'})$ with the action $c^*\rho^\natural$.*

(iii) *Let $U \subseteq \mathcal{X}$ be open with $\mathbb{Q} \subseteq \Gamma(U,\mathcal{O}_U)$, τ as in (ii), $\bar\tau(a) = \tau(\bar a)$, and for $s \in \{\tau,\bar\tau\}$ let $\mathrm{Lie}[s] \subseteq \mathrm{Lie}(G)|_U$ be the subsheaf of sections x with $\mathrm{Lie}(\iota(a))x = s(a)x$ for all a. Then $\mathrm{Lie}[\tau]$ and $\mathrm{Lie}[\bar\tau]$ are locally direct summands of $\mathrm{Lie}(G)|_U$, and the Hodge maps induce an exact sequence*

$$0 \to \mathrm{Lie}[\bar\tau]^\vee \to H_\tau|_U \to \mathrm{Lie}[\tau] \to 0,$$

in which the first map sends λ to the class of any $\eta \in \omega_G$ with $\eta|_{\mathrm{Lie}[\bar\tau]} = \lambda$ and the second is induced by the projection $H \to \mathrm{Lie}(G)$. Hence $\det H_\tau|_U \cong \det \mathrm{Lie}[\tau] \otimes (\det \mathrm{Lie}[\bar\tau])^{-1}$, the isomorphism sending $(w_1^* \wedge \cdots \wedge w_q^*) \wedge (\tilde v_1 \wedge \cdots \wedge \tilde v_p)$ to $(v_1 \wedge \cdots \wedge v_p) \otimes (w_1 \wedge \cdots \wedge w_q)^{-1}$ for local bases v of $\mathrm{Lie}[\tau]$ and w of $\mathrm{Lie}[\bar\tau]$, the dual basis w^* and lifts $\tilde v_i \in H_\tau$ of v_i.

Proof. For a point z write $H(z) = H \otimes \kappa(z)$ and $A_z = \mathcal{O}_E \otimes_\mathbb{Z} \kappa(z)$.

Step 1: points of positive characteristic. Let z have residue characteristic $p > 0$ and let k be an algebraic closure of $\kappa(z)$. By Lemma D.44 (6), $H(z) \otimes_{\kappa(z)} k = \mathrm{H}^\natural(G_k,\mathcal{L}_k)$ with the action defined by the pulled-back adjunction system, and by (PF) at z the hypotheses of Lemma D.45 hold for $(G_k,\iota,\mathcal{L}_k)$; by its (1), $H(z)\otimes k$ is free over $A_z \otimes_{\kappa(z)} k$, of some rank r, and $r[E:\mathbb{Q}] = \dim_k H(z)\otimes k = 2g$. So $[E:\mathbb{Q}] \mid 2g$ and $r = n$. Write $A_z = \prod_i A_i$ with A_i local Artinian; $A_z \to A_z \otimes k$ is faithfully flat and $H(z)\otimes_{A_z}(A_z\otimes k) = H(z)\otimes k$ is flat over $A_z\otimes k$, so $H(z)$ is flat, hence projective, over A_z, and each $H(z)_i = H(z)\otimes_{A_z} A_i$ is free over the local ring A_i, of rank n since $H(z)_i \otimes k$ is free of rank n over $A_i \otimes k \neq 0$. Thus $H(z) \cong A_z^n$. Lift a basis to $h_1,\dots,h_n$ in the stalk H_z; the map $(\mathcal{O}_E\otimes\mathcal{O}_{\mathcal{X},z})^n \to H_z$, $(b_m) \mapsto \sum_m \rho^\natural(b_m)h_m$, is surjective by Nakayama's lemma, and both sides are free $\mathcal{O}_{\mathcal{X},z}$-modules of rank $n[E:\mathbb{Q}] = 2g$, so it is an isomorphism; it extends to an isomorphism over an open neighbourhood of z.

Step 2: points of characteristic 0. By hypothesis there is a point of positive characteristic; the generic point η of the integral scheme $\mathcal{X}$ lies in the neighbourhood of Step 1, so $H(\eta) \cong (E\otimes_\mathbb{Q}\kappa(\eta))^n$. Let z have residue characteristic 0, and let $a \in \mathcal{O}_E$ generate E over $\mathbb{Q}$, with minimal polynomial $P \in \mathbb{Q}[T]$ (separable, of degree $[E:\mathbb{Q}]$). The characteristic polynomial $\chi \in \mathcal{O}_{\mathcal{X},z}[T]$ of $\rho^\natural(a)$ on the free $\mathcal{O}_{\mathcal{X},z}$-module H_z equals P^n in $\kappa(\eta)[T]$ (on $E\otimes\kappa(\eta) = \kappa(\eta)[T]/(P)$ the characteristic polynomial of a is P), hence in $\mathcal{O}_{\mathcal{X},z}[T] \subseteq \kappa(\eta)[T]$, and so the characteristic polynomial of a on $H(z)$ is P^n. Write $P = f_1\cdots f_t$ with $f_i \in \kappa(z)[T]$ irreducible, distinct (P separable); then $A_z = \prod_i L_i$, $L_i = \kappa(z)[T]/(f_i)$, $H(z) \cong \prod_i L_i^{m_i}$, and the characteristic polynomial of a on it is $\prod_i f_i^{m_i} = \prod_i f_i^n$; so $m_i = n$ for all i and $H(z) \cong A_z^n$. The Nakayama argument of Step 1 gives freeness of rank n near z. This proves (i).

(ii). Locally $H \cong (\mathcal{O}_E\otimes\mathcal{O}_\mathcal{X})^n$, and $(\mathcal{O}_E\otimes\mathcal{O}_\mathcal{X})/\sum_a(a\otimes 1 - 1\otimes\tau(a)) = \mathcal{O}_\mathcal{X}$; so $H_\tau \cong \mathcal{O}_\mathcal{X}^n$ locally. The quotient is a cokernel, and pull-back is right exact, so c^*H_τ is the $c^*\tau$-quotient of c^*H, which is $\mathrm{H}^\natural(G_{\mathcal{X}'},\mathcal{L}_{\mathcal{X}'})$ with the action $c^*\rho^\natural$ by Lemma D.44 (6).

(iii). Over U, $E\otimes_\mathbb{Q}\Gamma(U,\mathcal{O})$ contains the idempotent e_τ, image under $1\otimes\tau$ of the separability idempotent of $E\otimes_\mathbb{Q}E$; it satisfies $(a\otimes 1)e_\tau = \tau(a)e_\tau$ and $\mu_\tau(e_\tau) = 1$, where $\mu_\tau(a\otimes c) = \tau(a)c$, and $\ker\mu_\tau = (1-e_\tau)$. Therefore, for every $E\otimes\mathcal{O}_U$-module M, we have $M/\sum_a(a-\tau(a))M = M/(1-e_\tau)M \cong e_\tau M = \{m :\ am = \tau(a)m\ \forall a\}$, and $M \mapsto e_\tau M$ is exact. Applied to the equivariant Hodge sequence (Lemma D.44 (4)) this gives the exact sequence $0 \to e_\tau\omega_G \to e_\tau H \cong H_\tau \to e_\tau\mathrm{Lie}(G) \to 0$, with $e_\tau\mathrm{Lie}(G) = \mathrm{Lie}[\tau]$ a direct summand of $\mathrm{Lie}(G)|_U$; likewise $\mathrm{Lie}[\bar\tau] = e_{\bar\tau}\mathrm{Lie}(G)$. On $\omega_G = \mathrm{Lie}(G)^\vee$ the element $\sum_i a_i\otimes c_i$ acts by the transpose of $\sum_i c_i\mathrm{Lie}(\iota(\bar a_i))$, so e_τ acts by the transpose of $\bar e_\tau$, the image of e_τ under $a\otimes c \mapsto \bar a\otimes c$. Hence $e_\tau\omega_G$ is the image of the transpose of the projection $e_{\bar\tau}$, i.e. restriction to $\mathrm{Lie}[\bar\tau]$ identifies $e_\tau\omega_G$ with $\mathrm{Lie}[\bar\tau]^\vee$, and the

class in H_τ of $\eta \in \omega_G$ is that of $e_\tau \eta$, which depends only on $\eta|_{\mathrm{Lie}[\bar\tau]}$. The determinant of a short exact sequence of locally free sheaves gives $\det H_\tau|_U \cong \det \mathrm{Lie}[\bar\tau]^\vee \otimes \det \mathrm{Lie}[\tau]$, with the stated effect on local bases, and $\det(\mathrm{Lie}[\bar\tau]^\vee) = (\det \mathrm{Lie}[\bar\tau])^{-1}$ via $w_1^* \wedge \cdots \wedge w_q^* \mapsto (w_1 \wedge \cdots \wedge w_q)^{-1}$. □

Corollary D.42. *Let E be a CM field with complex conjugation $a \mapsto \bar a$, $\mathcal{X}$ a normal integral noetherian scheme and $(G, \iota, \mathcal{L})$ a semiabelian structure over $\mathcal{X}$ whose fibre at the generic point of $\mathcal{X}$ is an abelian variety, and such that*

(PF) for every point $z \in \mathcal{X}$ of positive residue characteristic and an algebraic closure k of $\kappa(z)$, there are an exact sequence $0 \to T \to G_k \xrightarrow{q} B \to 0$ of a torus T and an abelian variety B over k and a line bundle $\mathcal{M}$ on B defining a principal polarisation, with $\mathcal{L}|_{G_k} \cong q^*\mathcal{M}$.

Then $(G, \iota, \mathcal{L})$ has exactly one adjunction system ϵ, and $a \mapsto \rho^\natural(a)$ is a ring homomorphism $\mathcal{O}_E \to \mathrm{End}(\mathrm{H}^\natural(G, \mathcal{L}))$. Let p be a prime, κ a field of characteristic p, C an integral normal projective curve over κ with absolute Frobenius F, and $c\colon C \to \mathcal{X}$ a morphism. Put $L = c^*\mathrm{Lie}(G)$ with $\mathcal{O}_E$ acting by $\rho_L(a) = c^*\mathrm{Lie}(\iota(a))$, $L^\vee = c^*\omega_G$ with a acting by $\rho_L(\bar a)^\vee$, and $H = c^*\mathrm{H}^\natural(G, \mathcal{L})$ with $\rho_H(a) = c^*\rho^\natural(a)$. Then L, $L^\vee$, H are vector bundles on C of ranks g, g, $2g$, and:

(i) the pulled-back Hodge maps form an $\mathcal{O}_E$-equivariant exact sequence $0 \to L^\vee \to H \to L \to 0$;

(ii) $E^\natural(G_C, \mathcal{L}_C)$ is represented by a smooth commutative group scheme over C, $\tilde\alpha$ vanishes on $F^*L^\vee$, and the map $\alpha\colon F^*L \to H$ it induces fits into an $\mathcal{O}_E$-equivariant exact sequence $0 \to F^*L \xrightarrow{\alpha} H \to F^*(L^\vee) \to 0$, the outer terms carrying $a \mapsto F^*(\rho_L(a))$ and $a \mapsto F^*(\rho_L(\bar a)^\vee)$;

(iii) H is locally free as a module over $\mathcal{O}_E \otimes_{\mathbb{Z}} \mathcal{O}_C$.

In particular $(L^\vee, L, H)$ satisfies hypotheses (a) and (b) of Lemma D.52 (with $M_0 = L^\vee$, $M_1 = L$, $K = E$), and (L, H) satisfies the hypotheses of Lemma D.63 and of Lemma D.62.

Proof. **The action and the pull-back.** As $\mathcal{X}$ is normal integral noetherian with abelian generic fibre, $(G, \iota, \mathcal{L})$ has exactly one adjunction system ϵ and $\rho^\natural$ is a ring homomorphism ((1), (2) of Lemma D.44). By (6) of Lemma D.44 and (1), (2) of Lemma D.43, $H = c^*\mathrm{H}^\natural(G, \mathcal{L}) = \mathrm{H}^\natural(G_C, \mathcal{L}_C)$ with the action $c^*\rho^\natural$ defined by the adjunction system $c^*\epsilon$, with the pulled-back Hodge maps and pairing; $E^\natural(G_C, \mathcal{L}_C)$ is a smooth commutative group scheme over C, and L, $L^\vee$, H are vector bundles of ranks g, g, $2g$. Since $p\mathcal{O}_C = 0$, the conjugate map of $(G_C, \mathcal{L}_C)$ is defined, vanishes on $F^*L^\vee$ and induces $\alpha\colon F^*L \to H$ ((4) of Lemma D.43).

(i). The sequence $0 \to L^\vee \to H \to L \to 0$ is exact by (2) of Lemma D.43 over C, and equivariant for the stated actions by (4) of Lemma D.44 over C.

Pointwise input. Let $P \in C$ be a closed point, $z = c(P)$, and k an algebraic closure of $\kappa(P)$; it contains an algebraic closure of $\kappa(z)$, and the data of (PF) at z base change to k (an extension of G_k by a torus with abelian quotient B_k, and $\mathcal{L}_k \cong q^*\mathcal{M}_k$ with $\phi_{\mathcal{M}_k}$ an isomorphism). By (6) of Lemma D.44, the fibre of $(H, c^*\rho^\natural, \langle\,,\rangle, \alpha)$ at P, base changed to k, is $(\mathrm{H}^\natural(G_k, \mathcal{L}_k), \rho^\natural, \langle\,,\rangle, \alpha)$ for the pulled-back adjunction system. By Lemma D.45: (a) $H \otimes k$ is free over $\mathcal{O}_E \otimes k$; (b) $\alpha \otimes k$ is injective; (c) $\langle \alpha u, \alpha u' \rangle = 0$ on $F^*L \otimes k$.

(ii). By (b), $\alpha(P)\colon (F^*L)(P) \to H(P)$ is injective at every closed point P (injectivity descends along the field extension $\kappa(P) \to k$). A map of vector bundles on C that is injective on the fibres at all closed points is injective with locally free cokernel (locally a basis of F^*L maps to part of a basis of H by Nakayama's lemma); so $\alpha(F^*L)$ is a subbundle of rank g. The section $(u, u') \mapsto \langle \alpha u, \alpha u' \rangle$ of $(F^*L)^\vee \otimes (F^*L)^\vee$ vanishes in the fibre at every closed point by (c), hence vanishes (C is reduced). Define $\beta\colon H \to (F^*L)^\vee = F^*(L^\vee)$ by $\beta(h)(u) = \langle \alpha u, h \rangle$. Since

the pairing identifies H with $H^\vee$ ((3) of Lemma D.43) and α is a subbundle, β is surjective and $\ker\beta$ is a subbundle of rank $2g-g=g$. By isotropy $\alpha(F^*L)\subseteq\ker\beta$; a subbundle of H of rank g contained in a subbundle of rank g is locally a direct summand of it of full rank, so $\alpha(F^*L)=\ker\beta$ and $0\to F^*L\xrightarrow{\alpha}H\xrightarrow{\beta}F^*(L^\vee)\to 0$ is exact. Equivariance: $\rho_H(a)\circ\alpha=\alpha\circ F^*\rho_L(a)$ by (5) of Lemma D.44; and by (3) of Lemma D.44 (applied to $\bar a$),

$$\beta(\rho_H(a)h)(u)=\langle\alpha u,\rho_H(a)h\rangle=\langle\rho_H(\bar a)\alpha u,h\rangle=\langle\alpha(F^*\rho_L(\bar a)u),h\rangle=\big(F^*(\rho_L(\bar a)^\vee)\beta(h)\big)(u),$$

so β is equivariant for $a\mapsto F^*(\rho_L(\bar a)^\vee)$ on $F^*(L^\vee)$.

(iii). Let P be a closed point, $A_P=\mathcal{O}_E\otimes_{\mathbb{Z}}\kappa(P)=\prod_i A_i$ with A_i local Artinian. By (a), $H(P)\otimes_{\kappa(P)}k\cong(A_P\otimes k)^r$ for some r. Each factor $H(P)_i$ becomes free of rank r over the faithfully flat extension $A_i\otimes k$ of A_i; so it is flat over the local Artinian ring A_i, hence free, necessarily of rank r. Thus $H(P)$ is free of rank r over A_P, and $r[E:\mathbb{Q}]=\dim_{\kappa(P)}H(P)=2g$. Lift a basis to $v_1,\dots,v_r$ in the stalk H_P; the map $(\mathcal{O}_E\otimes\mathcal{O}_{C,P})^r\to H_P$, $(b_j)\mapsto\sum b_jv_j$, is surjective by Nakayama's lemma and is a surjection of free $\mathcal{O}_{C,P}$-modules of the same rank $2g$, hence an isomorphism; it extends to an isomorphism over an open neighbourhood of P. These neighbourhoods cover C.

Consequences. Items (i) and (ii) are hypothesis (a) of Lemma D.52 with $M_0=L^\vee$, $M_1=L$ (the outer terms of the second sequence carrying F^* of the actions on M_1 and M_0), and (iii) is its hypothesis (b). Items (i) and (ii) are the two equivariant exact sequences of Lemma D.63 ($\mathcal{O}_E$ acting on $L^\vee$ by $a\mapsto\rho_L(\bar a)^\vee$). Item (i) and the injectivity of α give the hypotheses of Lemma D.62. □

Lemma D.43. *Let S be a scheme, $G\to S$ a semiabelian scheme of relative dimension g and $\mathcal{L}$ a rigidified line bundle on G with a cubical structure. Let $W(\omega_G)$ be the vector group $T\mapsto\Gamma(T,\omega_G\otimes_{\mathcal{O}_S}\mathcal{O}_T)$.*

1. *$W(\omega_G)$ acts on $E^\natural(G,\mathcal{L})$ over G by $\eta\cdot(x,t)=(x,(1+\eta)t)$, making the projection $E^\natural(G,\mathcal{L})\to G$ a torsor under $W(\omega_G)\times_S G$, trivial locally on G for the Zariski topology. Hence $E^\natural(G,\mathcal{L})$ is represented by a smooth commutative group scheme over S, and $0\to W(\omega_G)\to E^\natural(G,\mathcal{L})\to G\to 0$ is exact, with $\eta\mapsto(0,(1+\eta)t_0)$ the first map. Its formation commutes with every base change $S'\to S$.*

2. *$\mathrm{H}^\natural(G,\mathcal{L})$ is a locally free $\mathcal{O}_S$-module of rank $2g$, the Hodge maps form an exact sequence $0\to\omega_G\to\mathrm{H}^\natural(G,\mathcal{L})\to\mathrm{Lie}(G)\to 0$, and the formation of $\mathrm{H}^\natural(G,\mathcal{L})$ and of this sequence commutes with base change.*

3. *The pairing $\langle\,,\rangle$ is a well-defined $\mathcal{O}_S$-bilinear pairing on $\mathrm{H}^\natural(G,\mathcal{L})$ inducing an isomorphism $\mathrm{H}^\natural(G,\mathcal{L})\to\mathrm{H}^\natural(G,\mathcal{L})^\vee$; for $\eta\in\omega_G$ and $h=(v,t)$, $\langle h,(0,(1+\varepsilon'\eta)t_0)\rangle=\eta(v)$.*

4. *If $p\mathcal{O}_S=0$ for a prime p, then $\tilde\alpha$ vanishes on $F_S^*\omega_G\subseteq F_S^*\mathrm{H}^\natural(G,\mathcal{L})$, so it induces*

$$\alpha\colon F_S^*\mathrm{Lie}(G)\to\mathrm{H}^\natural(G,\mathcal{L}),$$

and the composite of α with $\mathrm{H}^\natural(G,\mathcal{L})\to\mathrm{Lie}(G)$ is the map

$$\mathrm{Lie}(V_G)\colon F_S^*\mathrm{Lie}(G)=\mathrm{Lie}(G^{(p)})\to\mathrm{Lie}(G).$$

Proof. The cubical structure of the rigidified line bundle $\mathcal{L}$ makes $\Lambda(\mathcal{L})$ a symmetric biextension of $G\times_S G$ by $\mathbb{G}_m$ whose two partial compositions are associative and commutative, compatible with each other, with the symmetry and with the canonical trivialisations along $G\times\{e\}$ and

$\{e\} \times G$ (Moret-Bailly, Pinceaux de variétés abéliennes, Astérisque 129, Ch. I, 2.5; Breen, Fonctions thêta et théorème du cube, LNM 980, §2). For an S-scheme T write $T[\omega] = T \times_S G_1 = \mathrm{Spec}_T(\mathcal{O}_T \oplus \omega_T)$, $\omega_T = \omega_G \otimes \mathcal{O}_T$; it is a square-zero thickening of T.

(1) Torsor and group structure. Let $x \in G(T)$ and $N = (x \circ \mathrm{pr}_1, \mathrm{pr}_2)^*\Lambda(\mathcal{L})$ on $T[\omega]$. Two trivialisations t, t' of N agreeing on $T \times \{e\}$ differ by a unit u of $\mathcal{O}_T \oplus \omega_T$ with image 1 in $\mathcal{O}_T$, that is $u = 1 + \eta$ with $\eta \in \Gamma(T, \omega_T)$; conversely $(1+\eta)t$ is again such a trivialisation. So $W(\omega_G)(T)$ acts simply transitively on the fibre of $E^\natural(G, \mathcal{L})(T) \to G(T)$ over x whenever this fibre is non-empty. It is non-empty locally on T: a point of T has an affine neighbourhood $\mathrm{Spec}\, A$ with A local after localising, $A \oplus \Gamma(\omega_T)$ is then local, so N is trivial near the point; if t trivialises N there, $t|_{T\times\{e\}} = c\, t_{\mathrm{can}}$ with $c \in \mathcal{O}_T^\times$, and $c^{-1}t$ agrees with the canonical trivialisation. Applied to the universal point $x = \mathrm{id}_G$ ($T = G$) this shows that $E^\natural(G, \mathcal{L}) \to G$ is a $W(\omega_G)$-torsor trivial on a Zariski cover of G; hence it is represented by a scheme locally isomorphic over G to $G \times_S W(\omega_G)$, which is smooth over S ($W(\omega_G)$ is locally an affine space $\mathbb{A}^g_S$). The composition of Definition D.40 is defined because the partial composition maps the canonical trivialisations at (x, e) and (x', e) to that at $(x+x', e)$; it is associative and commutative because the first partial composition is, its unit is $(0, t_0)$ (t_0 the canonical trivialisation of $\Lambda_{(0,\cdot)}$, which is neutral for the first partial composition), and (x, t) has the inverse $(-x, t^{-1})$, t^{-1} read through $\Lambda_{(x,y)} \otimes \Lambda_{(-x,y)} \cong \Lambda_{(0,y)} \overset{t_0}{\cong} \mathcal{O}$. On the fibre over 0 the composition is $(0, (1+\eta)t_0) \cdot (0, (1+\eta')t_0) = (0, (1+\eta)(1+\eta')t_0) = (0, (1+\eta+\eta')t_0)$ since $\eta\eta' = 0$ in $\mathcal{O}_T \oplus \omega_T$; so $\eta \mapsto (0, (1+\eta)t_0)$ is an injective homomorphism $W(\omega_G) \to E^\natural$ onto the kernel of the projection, and the projection is surjective as a map of Zariski sheaves by the local existence above. The action of $W(\omega_G)$ is translation by this subgroup, because $(x, t) \cdot (0, (1+\eta)t_0) = (x, (1+\eta)t)$ (t_0 neutral). All constructions are pull-backs of $\Lambda(\mathcal{L})$, G_1 and ω_G, which commute with base change.

(2) The Lie algebra. $E^\natural(G, \mathcal{L})$ is smooth over S, so its Lie algebra is locally free with formation commuting with base change, and the exact sequence of smooth group schemes in (1) gives an exact sequence of Lie algebras $0 \to \mathrm{Lie}\, W(\omega_G) \to \mathrm{H}^\natural \to \mathrm{Lie}(G) \to 0$: left exactness is that of kernels; surjectivity holds because $E^\natural \to G$ has a section over a Zariski neighbourhood of e in G (local triviality of the torsor), whose differential at e splits the sequence. Finally $\mathrm{Lie}\, W(\omega_G) = \omega_G$ via $\eta \mapsto \varepsilon\eta$, which is the first Hodge map $\eta \mapsto (0, (1+\varepsilon\eta)t_0)$; so the rank is $g + g = 2g$.

(3) The pairing. Work locally on S. On $S[\omega] \times_S G_1 = G_1 \times_S G_1 = \mathrm{Spec}(\mathcal{O}_S \oplus \omega_G \oplus \omega_G \oplus \omega_G \otimes \omega_G)$ choose, by the argument of (1), a trivialisation s of $\Lambda(\mathcal{L})$ that agrees with the canonical trivialisations on $G_1 \times \{e\}$ and $\{e\} \times G_1$ (first trivialise, then divide by the unit $c(1 + \eta_1 \otimes 1)(1 + 1 \otimes \eta_2)$ measuring the defect on the two axes, which agree at (e, e)). Pulling back by the symmetry, $s(y, x) = (1+\sigma)s(x, y)$ with $\sigma \in \omega_G \otimes \omega_G$, since the defect is a unit equal to 1 on both axes. Let $h = (v, t) \in \mathrm{H}^\natural(U)$, so $v \in \mathrm{Lie}(G)(U)$ is a point of G_1 over $U[\varepsilon]$ and t trivialises $\Lambda_{(v,\cdot)}$ on $U[\varepsilon][\omega]$ with value t_0 modulo ε. As $s(v, \cdot)$ is another trivialisation with the same properties, (1) gives a unique $w \in \omega_G(U)$ with $t = (1 + \varepsilon w)s(v, \cdot)$; the map $h \mapsto (v, w)$ is an isomorphism $\mathrm{H}^\natural|_U \cong \mathrm{Lie}(G)|_U \oplus \omega_G|_U$ of $\mathcal{O}_U$-modules (both sides have the structure induced by $\varepsilon \mapsto c\varepsilon$). For $h' = (v', t')$, $t' = (1 + \varepsilon' w')s(v', \cdot)$, evaluate at the points of G_1: a function $w \in \omega_G$ takes the value $\varepsilon' w(v')$ at v', and σ takes the value $\varepsilon\varepsilon'\sigma(v, v')$ at (v, v'). Hence

$$t'(v) = (1 + \varepsilon\varepsilon' w'(v))\, s(v', v) = (1 + \varepsilon\varepsilon' w'(v))(1 + \varepsilon\varepsilon'\sigma(v, v'))\, s(v, v'),$$
$$t(v') = (1 + \varepsilon\varepsilon' w(v'))\, s(v, v'),$$

so (D.10) holds with the unique value

$$\langle h, h' \rangle = w'(v) - w(v') + \sigma(v, v').$$

This is $\mathcal{O}_U$-bilinear, and in the decomposition $\mathrm{Lie} \oplus \omega$ it has the block matrix $\begin{pmatrix} \sigma & -1 \\ 1 & 0 \end{pmatrix}$ with respect to the duality of $\mathrm{Lie}(G)$ and ω_G, which is invertible; so $h \mapsto \langle h, \cdot \rangle$ is an isomorphism onto the dual. For $h' = (0, (1 + \varepsilon'\eta)t_0)$ we have $v' = 0$, $w' = \eta$ (as $s(0, \cdot) = t_0$), and $\langle h, h' \rangle = \eta(v)$.

(4) The conjugate map. For a commutative group scheme X flat over S with $p\mathcal{O}_S = 0$, the Verschiebung $V_X \colon X^{(p)} \to X$ is functorial in X and satisfies $V_X \circ F_{X/S} = [p]_X$ (SGA 3, Exp. VII$_\mathrm{A}$, 4.3). For $X = W(\omega_G)$, locally $\mathbb{G}_a^g$, $[p] = 0$ and $F_{X/S}$ is faithfully flat, so $V_{W(\omega_G)} = 0$. Functoriality for the inclusion $i \colon W(\omega_G) \to E^\natural$ gives $V_{E^\natural} \circ i^{(p)} = i \circ V_{W(\omega_G)} = 0$, so $\tilde{\alpha} = \mathrm{Lie}(V_{E^\natural})$ vanishes on $\mathrm{Lie}(W(\omega_G)^{(p)}) = F_S^*\omega_G$ and induces α on $F_S^*\mathrm{H}^\natural / F_S^*\omega_G = F_S^*\mathrm{Lie}(G)$ by (2) (pull-back by F_S is right exact and preserves the locally split sequence). Functoriality for the projection $\pi \colon E^\natural \to G$ gives $\pi \circ V_{E^\natural} = V_G \circ \pi^{(p)}$, whence the last claim on Lie algebras. □

Lemma D.44. *Let E be a CM field with complex conjugation $a \mapsto \bar{a}$, S a normal integral noetherian scheme with generic point η, and $(G, \iota, \mathcal{L})$ a semiabelian structure over S with G_η an abelian variety.*

1. *$(G, \iota, \mathcal{L})$ has exactly one adjunction system ϵ.*
2. *With ϵ, every $a \in \mathcal{O}_E$ acts on $E^\natural(G, \mathcal{L})$ by a group endomorphism, and $a \mapsto \rho^\natural(a)$ is a ring homomorphism $\mathcal{O}_E \to \mathrm{End}_{\mathcal{O}_S}(\mathrm{H}^\natural(G, \mathcal{L}))$.*
3. *$\langle \rho^\natural(a)h, h' \rangle = \langle h, \rho^\natural(\bar{a})h' \rangle$ for all a and all sections h, h'.*
4. *The Hodge maps are $\mathcal{O}_E$-equivariant when a acts on ω_G by $\mathrm{Lie}(\iota(\bar{a}))^\vee$ and on $\mathrm{Lie}(G)$ by $\mathrm{Lie}(\iota(a))$.*
5. *If $p\mathcal{O}_S = 0$ for a prime p, then $\rho^\natural(a) \circ \alpha = \alpha \circ F_S^*\mathrm{Lie}(\iota(a))$ for all a.*
6. *For every morphism $c \colon S' \to S$, $c^*\epsilon$ is an adjunction system for the pull-back $(G_{S'}, \iota_{S'}, \mathcal{L}_{S'})$, and with it $\mathrm{H}^\natural(G_{S'}, \mathcal{L}_{S'}) = c^*\mathrm{H}^\natural(G, \mathcal{L})$ with the action $c^*\rho^\natural$, the pulled-back Hodge maps, pairing and (if $p\mathcal{O}_{S'} = 0$) conjugate map; (3), (4), (5) hold over S'.*

Proof. The rigidified line bundle $\mathcal{L}$ is symmetric with a cubical structure (Definition 31.2), so $\Lambda(\mathcal{L})$ is a symmetric biextension of $G \times_S G$ by $\mathbb{G}_m$ whose two partial compositions are associative and commutative, compatible with each other, with the symmetry and with the canonical trivialisations along $G \times \{e\}$ and $\{e\} \times G$ ([181, Ch. I, 2.5]; [51, §2]). These are the partial compositions, symmetry and canonical trivialisations used below.

Units. Let $n \geq 1$ and $X = G^n = G \times_S \cdots \times_S G$. Then X is smooth over S with geometrically integral fibres (smooth connected group schemes over fields), flat over the integral scheme S, so every irreducible component of X dominates S and meets X_η, which is irreducible; and X is normal. Hence X is integral and $\Gamma(X, \mathcal{O}_X) \subseteq \Gamma(X_\eta, \mathcal{O}) = \kappa(\eta)$, the last equality because $X_\eta = G_\eta^n$ is a proper geometrically integral $\kappa(\eta)$-variety. So every unit u on X is constant along the fibres of $X \to S$: $u = u(e)$, the pull-back of its value along the unit section, a unit of $\mathcal{O}(S)$. Consequently: *two isomorphisms between the same two line bundles on G^n that agree along the unit section are equal.* This is the uniqueness principle used below; in each application both isomorphisms are composites of partial compositions, symmetries and the ϵ_a, all of which are the canonical identifications at the unit section, so they agree there.

(1) By the definition of a semiabelian structure there is an isomorphism $\varphi_a \colon (\iota(a), 1)^*\Lambda(\mathcal{L}) \to (1, \iota(\bar{a}))^*\Lambda(\mathcal{L})$. Its restrictions to $G \times \{e\}$ and $\{e\} \times G$, read through the canonical trivialisations, are units of $\mathcal{O}(G)$, hence equal to the constant $c = \varphi_a(e, e) \in \mathcal{O}(S)^\times$ by the Units step ($n = 1$).

So $\epsilon_a = c^{-1}\varphi_a$ is the identity on both axes. Two such differ by a unit on G^2 equal to 1 at (e,e), which is 1. Hence ϵ exists and is unique.

(2) Compatibilities of ϵ. By the uniqueness principle on G^2 or G^3, for $a, b \in \mathcal{O}_E$ and points x, x', y:

(c1) $\epsilon_1 = \mathrm{id}$ and $\epsilon_{ab} = \epsilon_b(x, \bar{a}y) \circ \epsilon_a(bx, y)$ as maps $\Lambda_{(abx,y)} \to \Lambda_{(x,\overline{ab}y)}$;

(c2) ϵ_a commutes with the first partial composition: $\Lambda_{(ax,y)} \otimes \Lambda_{(ax',y)} \to \Lambda_{(a(x+x'),y)} \xrightarrow{\epsilon_a} \Lambda_{(x+x',\bar{a}y)}$ equals $\epsilon_a \otimes \epsilon_a$ followed by the first partial composition;

(c3) ϵ_{a+b} composed with the first partial composition $\Lambda_{(ax,y)} \otimes \Lambda_{(bx,y)} \to \Lambda_{((a+b)x,y)}$ equals $\epsilon_a \otimes \epsilon_b$ followed by the second partial composition $\Lambda_{(x,\bar{a}y)} \otimes \Lambda_{(x,\bar{b}y)} \to \Lambda_{(x,\overline{(a+b)}y)}$;

(c4) with sym the symmetry, $\epsilon_{\bar{a}} \circ \mathrm{sym} \circ \epsilon_a = \mathrm{sym}$ as maps $\Lambda_{(ax,z)} \to \Lambda_{(z,ax)}$.

By (c2) the action $a \cdot (x,t) = (ax, \epsilon_a^{-1}(t(\bar{a}\,\cdot)))$ is a group endomorphism of $E^\natural$, and by (c1) 1 acts trivially and $(ab)\cdot = a \cdot (b\cdot)$: indeed $a \cdot (b \cdot (x,t)) = (abx, \epsilon_a(bx,\cdot)^{-1}\epsilon_b(x,\bar{a}\,\cdot)^{-1}t(\bar{b}\bar{a}\,\cdot))$. For additivity let $(x,t) \in E^\natural(T)$. Extend t, locally on T, to a trivialisation $\tilde{t}$ of $\Lambda_{(x,\cdot)}$ on an open neighbourhood U of the unit section in G_T, equal to the canonical one at e. The unit $D(y_1,y_2) = \tilde{t}(y_1+y_2)/(\tilde{t}(y_1)\cdot\tilde{t}(y_2))$ (product by the second partial composition) on a neighbourhood of (e,e) in G_T^2 is 1 on both axes, so $D-1$ lies in the product of the ideals of $\{e\}\times G$ and $G \times \{e\}$ (locally G is smooth and the two ideals are generated by complementary parts of a regular sequence). Along $G_1 \to G^2$, $y \mapsto (\bar{a}y, \bar{b}y)$, both ideals pull back into the ideal of e in G_1, whose square is 0; so $t((\bar{a}+\bar{b})y) = t(\bar{a}y)\cdot t(\bar{b}y)$ for $y \in G_1$. With (c3) this gives $(a+b)\cdot(x,t) = a\cdot(x,t)\cdot b\cdot(x,t)$ in the group $E^\natural$. Taking Lie algebras, $\rho^\natural$ is a ring homomorphism.

(3) Let $h = (v,t)$ over $U[\varepsilon]$, $h' = (v',t')$ over $U[\varepsilon']$, and put $A = t(\bar{a}v') \in \Lambda_{(v,\bar{a}v')}$, $B = t'(av) \in \Lambda_{(v',av)}$. By the definitions, $\rho^\natural(a)h = (av, \epsilon_a^{-1}t(\bar{a}\,\cdot))$ and $\rho^\natural(\bar{a})h' = (\bar{a}v', \epsilon_{\bar{a}}^{-1}t'(a\,\cdot))$, so (D.10) reads

$$\mathrm{sym}(B) = (1+\varepsilon\varepsilon' c_1)\,\epsilon_a^{-1}(A), \qquad \epsilon_{\bar{a}}^{-1}(B) = (1+\varepsilon\varepsilon' c_2)\,\mathrm{sym}(A),$$

with $c_1 = \langle \rho^\natural(a)h, h'\rangle$ and $c_2 = \langle h, \rho^\natural(\bar{a})h'\rangle$. By (c4), $\mathrm{sym}\circ\epsilon_a\circ\mathrm{sym} = \epsilon_{\bar{a}}^{-1}$; applying $\mathrm{sym}\circ\epsilon_a$ to the first equation gives $\epsilon_{\bar{a}}^{-1}(B) = (1+\varepsilon\varepsilon' c_1)\mathrm{sym}(A)$, so $c_1 = c_2$.

(4) For $\eta \in \omega_G$, $\rho^\natural(a)(0,(1+\varepsilon\eta)t_0) = (0, \epsilon_a^{-1}((1+\varepsilon\eta(\bar{a}\,\cdot))t_0)) = (0,(1+\varepsilon\,\iota(\bar{a})^*\eta)t_0)$, because ϵ_a is the identity on $\{e\}\times G$ and t_0 is canonical; and $\iota(\bar{a})^*$ on $\omega_G = e^*\Omega^1$ is $\mathrm{Lie}(\iota(\bar{a}))^\vee$. The projection $(v,t) \mapsto v$ carries the action to $v \mapsto \iota(a)v$, i.e. $\mathrm{Lie}(\iota(a))$.

(5) The Verschiebung is functorial for the endomorphism $a\cdot$ of $E^\natural$ ([226, Exp. VII$_\mathrm{A}$, 4.3]), so $\rho^\natural(a)\circ\tilde{\alpha} = \tilde{\alpha}\circ F_S^*\rho^\natural(a)$; restricted to $F_S^*\mathrm{Lie}(G)$ through (4) and (4) of Lemma D.43 this is the claim.

(6) The conditions defining an adjunction system (isomorphism of the pulled-back line bundles, identity on the axes) are preserved by pull-back, and all constructions of Definition D.40 are pull-backs (Lemma D.43, (1), (2)). The proofs of (3)–(5) use only the identities (c1)–(c4), which pull back, and Lemma D.43. □

Lemma D.45. *Let E be a CM field with complex conjugation $a \mapsto \bar{a}$, k an algebraically closed field of characteristic $p > 0$, G a semiabelian variety over k with a ring homomorphism $\iota\colon \mathcal{O}_E \to \mathrm{End}_k(G)$, $\mathcal{L}$ a rigidified line bundle on G with a cubical structure, and ϵ an adjunction system for $(G,\iota,\mathcal{L})$. Suppose there are an exact sequence $0 \to T \to G \xrightarrow{q} B \to 0$ with T a torus and B an abelian variety, and a line bundle $\mathcal{M}$ on B whose polarisation $\phi_\mathcal{M}$ is an isomorphism, with $\mathcal{L} \cong q^*\mathcal{M}$. Then:*

1. $\mathrm{H}^\natural(G,\mathcal{L})$, *with a acting by* $\rho^\natural(a)$, *is a free* $\mathcal{O}_E\otimes_{\mathbb{Z}}k$*-module;*

2. $\alpha\colon F_k^*\mathrm{Lie}(G)\to\mathrm{H}^\natural(G,\mathcal{L})$ *is injective;*

3. $\langle\alpha(u),\alpha(u')\rangle=0$ *for all* $u,u'\in F_k^*\mathrm{Lie}(G)$.

Proof. Write $R=\mathcal{O}_E\otimes_{\mathbb{Z}}k$, a finite k-algebra, hence semilocal. We use Rosenlicht's theorem: on a connected smooth algebraic group X over k every unit is $c\chi$ with $c\in k^\times$ and $\chi\in\mathrm{Hom}(X,\mathbb{G}_m)$. For $X=X_1\times\cdots\times X_n$ ($n\geq 2$) a unit equal to 1 on each locus $\{x_i=e\}$ is therefore 1 (writing it as $c\prod\chi_i(x_i)$ and restricting to these loci).

Step 1: $\Lambda(\mathcal{L})=(q\times q)^*\Lambda(\mathcal{M})$ as biextensions. Give $\mathcal{M}$ a rigidification and its cubical structure, and scale the isomorphism $\mathcal{L}\cong q^*\mathcal{M}$ by a constant so that it respects the rigidifications. The cubical structure of $\mathcal{L}$ and the pull-back of that of $\mathcal{M}$ are two trivialisations of $\Theta(\mathcal{L})$ on G^3 that agree with the canonical trivialisation (given by the rigidification) on each locus $\{x_i=e\}$; their ratio is a unit on G^3 equal to 1 there, hence 1. So the induced isomorphism $\Lambda(\mathcal{L})\cong(q\times q)^*\Lambda(\mathcal{M})$ respects the partial compositions, the symmetry and the canonical trivialisations; we use it as an identification.

Step 2: actions on T and B. For $a\in\mathcal{O}_E$, $q(\iota(a)(T))$ is a torus in the abelian variety B (image of a torus), hence trivial; so $\iota(a)T\subseteq T$, and ι induces ring homomorphisms $\iota_T\colon\mathcal{O}_E\to\mathrm{End}(T)$, $\iota_B\colon\mathcal{O}_E\to\mathrm{End}(B)$ with $q\circ\iota(a)=\iota_B(a)\circ q$.

Step 3: ϵ descends to B. For $a\in\mathcal{O}_E$ the source and target of ϵ_a are the pull-backs along $q\times q$ of $N_1=(\iota_B(a),1)^*\Lambda(\mathcal{M})$ and $N_2=(1,\iota_B(\bar a))^*\Lambda(\mathcal{M})$, and so carry the canonical $T\times T$-linearisations of pull-backs. Comparing ϵ_a at $(x+s,y+s')$ with ϵ_a at (x,y) through these linearisations gives a unit u on $T\times T\times G\times G$, with $u=1$ where $s=s'=e$; and $u(s,e,x,e)=1=u(e,s',e,y)$, because ϵ_a is the identity on $G\times\{e\}$ and on $\{e\}\times G$, where both bundles are canonically trivial compatibly with the linearisations. Writing $u=c\,\chi(s)\chi'(s')\chi_1(x)\chi_2(y)$ these three facts force $u=1$. So ϵ_a is invariant under the $T\times T$-torsor $q\times q\colon G\times G\to B\times B$, and by faithfully flat descent it is the pull-back of an isomorphism $\epsilon_{B,a}\colon N_1\to N_2$, the identity on both axes: $\epsilon_B=(\epsilon_{B,a})_a$ is an adjunction system for $(B,\iota_B,\mathcal{M})$.

Step 4: the subgroup E'. Let $E'=G\times_B E^\natural(B,\mathcal{M})$ and $j\colon E'\to E^\natural(G,\mathcal{L})$, $j(x,(qx,t'))=(x,t'\circ q)$, where $t'\circ q$ is the pull-back of t' along $1\times q|_{G_1}\colon\{x\}\times G_1\to\{qx\}\times B_1$ (Step 1). The map $q|_{G_1}$ corresponds to $\mathcal{O}_{B_1}=k\oplus\omega_B\to k\oplus\omega_G$, injective because $0\to\omega_B\to\omega_G\to\omega_T\to 0$ is exact (dual of $0\to\mathrm{Lie}\,T\to\mathrm{Lie}\,G\to\mathrm{Lie}\,B\to 0$); so pull-back of trivialisations along it is injective and j is injective. It is a homomorphism (Step 1: partial compositions correspond) and $\mathcal{O}_E$-equivariant for the actions defined by ϵ and by ϵ_B on the second factor (ι on the first), by Step 3 and $q\circ\iota(\bar a)=\iota_B(\bar a)\circ q$. Over each x, j is equivariant for $W(\omega_B)\subseteq W(\omega_G)$. Hence on Lie algebras, with $\mathrm{H}^\natural_G=\mathrm{H}^\natural(G,\mathcal{L})$, $\mathrm{H}^\natural_B=\mathrm{H}^\natural(B,\mathcal{M})$, there are $\mathcal{O}_E$-equivariant exact sequences

$$0\to\mathrm{Lie}\,T\to\mathrm{Lie}\,E'\xrightarrow{\pi}\mathrm{H}^\natural_B\to 0,\qquad 0\to\mathrm{Lie}\,E'\xrightarrow{dj}\mathrm{H}^\natural_G\to\omega_T\to 0.$$

The first is exact because $E'\to E^\natural(B,\mathcal{M})$ is smooth surjective with kernel $T\times\{0\}$. The second is exact because dj is injective, $dj(\mathrm{Lie}\,E')\cap\omega_G=\omega_B$ (the fibres over 0), so $\omega_T=\omega_G/\omega_B$ injects into the cokernel, and dimensions agree: $\dim\mathrm{Lie}\,E'=\dim T+2\dim B$ and $\dim\mathrm{H}^\natural_G=2\dim G$ by (2) of Lemma D.43. Here $\mathcal{O}_E$ acts on $\mathrm{Lie}\,T$ by $\mathrm{Lie}\,\iota_T(a)$, on $\mathrm{H}^\natural_B$ by $\rho^\natural_B(a)$ (from ϵ_B) and on ω_T by $\iota_T(\bar a)^*$ (as on ω_G, (4) of Lemma D.44 whose proof of (4) uses only that ϵ_a is the identity on $\{e\}\times G$).

Step 5: freeness (1). T is split (k algebraically closed), and $\mathrm{Lie}\,T=X_*(T)\otimes_{\mathbb{Z}}k$ equivariantly, $X_*(T)$ the cocharacter group with $\mathcal{O}_E$ acting through ι_T. A nonzero $a\in\mathcal{O}_E$ divides the nonzero integer $N_{E/\mathbb{Q}}(a)$ in $\mathcal{O}_E$, which acts injectively on the free $\mathbb{Z}$-module $X_*(T)$; so $X_*(T)$ is a

finitely generated torsion-free, hence projective, $\mathcal{O}_E$-module, isomorphic to $\mathcal{O}_E^{r-1} \oplus \mathfrak{a}$ for an ideal $\mathfrak{a}$ (Steinitz). Then $\mathfrak{a} \otimes_{\mathbb{Z}} k$ is an invertible module over the semilocal ring R, hence free, and $\operatorname{Lie} T$ is free over R. Its k-dual ω_T with the transposed action is free: $\operatorname{Hom}_k(R,k) \cong \operatorname{Hom}_{\mathbb{Z}}(\mathcal{O}_E,\mathbb{Z}) \otimes k$ is invertible (inverse different), hence free of rank one over R; and composing an action with the ring automorphism $a \otimes c \mapsto \bar{a} \otimes c$ of R preserves freeness. By (iii) of Lemma D.46 (for ϵ_B), θ identifies $\mathrm{H}^\natural_B$ with $H^1_{\mathrm{dR}}(B/k)$ on which a acts by $\iota_B(\bar{a})^*$; by Rapoport's lemma (Rapoport, Compositio Math. 36 (1978), Lemme 1.3;) $H^1_{\mathrm{dR}}(B/k)$ is free over R for $a \mapsto \iota_B(a)^*$, hence also for $a \mapsto \iota_B(\bar{a})^*$. Extensions of free (projective) R-modules split, so the two sequences of Step 4 give that $\mathrm{H}^\natural_G$ is free.

Step 6: injectivity (2). By (4) of Lemma D.43, α is induced by $\tilde{\alpha} = \operatorname{Lie}(V_{E^\natural})$. Since $\operatorname{Lie} E' \to \operatorname{Lie} G$ is surjective, $F_k^*\operatorname{Lie} G$ is the image of $F_k^*\operatorname{Lie} E'$, and by functoriality of the Verschiebung for j, $\alpha(F_k^*\operatorname{Lie} G) = dj(\operatorname{Lie}(V_{E'})(F_k^*\operatorname{Lie} E')) \subseteq dj(\operatorname{Lie} E')$. Functoriality for $T \to E'$, $s \mapsto (s,(0,t_0))$, shows that α restricted to $F_k^*\operatorname{Lie} T$ is $\operatorname{Lie}(V_T)$, an isomorphism onto $\operatorname{Lie} T$: for $T \cong \mathbb{G}_m^r$, $F_{T/k}$ is identified with $[p]$ under $T^{(p)} = T$, and $V_T \circ F_{T/k} = [p]$ with $F_{T/k}$ an epimorphism gives $V_T = \mathrm{id}$. Functoriality for $E' \to E^\natural(B,\mathcal{M})$ shows $\pi \circ \alpha = \alpha_B \circ F_k^*\operatorname{Lie}(q)$. Now α_B is injective: by (i), (ii) of Lemma D.46, $\theta \circ \alpha_B$ is $F^*_{B/k}$ restricted to $F_k^* H^1_{\mathrm{dR}}(B/k)/F_k^*\omega_B = F_k^* R^1 f_* \mathcal{O}_B$, which is injective by Lemma D.48. In the diagram with exact rows $0 \to F_k^*\operatorname{Lie} T \to F_k^*\operatorname{Lie} G \to F_k^*\operatorname{Lie} B \to 0$ and $0 \to \operatorname{Lie} T \to \operatorname{Lie} E' \to \mathrm{H}^\natural_B \to 0$ and vertical maps $\operatorname{Lie}(V_T)$ (bijective), α, α_B (injective), α is injective.

Step 7: isotropy (3). For $h, h' \in \operatorname{Lie} E'$, $\langle dj(h), dj(h')\rangle = \langle \pi h, \pi h'\rangle_B$: if $\pi h = (qv,t)$ and $\pi h' = (qv',t')$ then $dj(h) = (v, t\circ q)$, $dj(h') = (v', t' \circ q)$, and $(t' \circ q)(v) = t'(qv)$, $(t \circ q)(v') = t(qv')$ in $\Lambda(\mathcal{L})_{(v,v')} = \Lambda(\mathcal{M})_{(qv,qv')}$ with the same symmetry (Step 1), so (D.10) gives the same scalar. As $\alpha(F_k^*\operatorname{Lie} G) \subseteq dj(\operatorname{Lie} E')$ (Step 6), $\langle \alpha u, \alpha u'\rangle = \langle \alpha_B(qu), \alpha_B(qu')\rangle_B = 0$ by Lemma D.47 (for B and $\mathcal{M}$). □

Lemma D.46. *Let $f\colon A \to S$ be an abelian scheme of relative dimension g and $\mathcal{L}$ a rigidified line bundle on A with a cubical structure whose polarisation $\phi_{\mathcal{L}}\colon A \to A^\vee$ is an isomorphism. Then there is an isomorphism of $\mathcal{O}_S$-modules $\theta\colon \mathrm{H}^\natural(A,\mathcal{L}) \to H^1_{\mathrm{dR}}(A/S)$, compatible with base change in S, such that:*

(i) θ is the identity on $\omega_{A/S}$ (embedded by the Hodge map, resp. by the Hodge sequence), and induces on the quotients the isomorphism $\lambda_A \circ \operatorname{Lie}(\phi_{\mathcal{L}})\colon \operatorname{Lie}(A/S) \to R^1 f_* \mathcal{O}_A$;

(ii) if $p\mathcal{O}_S = 0$ for a prime p, with $F_{A/S}\colon A \to A^{(p)}$ the relative Frobenius and $H^1_{\mathrm{dR}}(A^{(p)}/S) = F_S^* H^1_{\mathrm{dR}}(A/S)$, then $\theta \circ \tilde{\alpha} = F^*_{A/S} \circ F_S^* \theta$;

(iii) if $\iota\colon \mathcal{O} \to \operatorname{End}_S(A)$ is a ring homomorphism from a commutative ring with involution $a \mapsto \bar{a}$, and ϵ is an adjunction system for $(A,\iota,\mathcal{L})$, then $\theta \circ \rho^\natural(a) = \iota(\bar{a})^* \circ \theta$ for every $a \in \mathcal{O}$.

Proof. Write $\operatorname{Extrig}(A) = \operatorname{Extrig}(A, \mathbb{G}_m)$, $W(\omega_A)$ for the vector group of $\omega_A = \omega_{A/S}$, and $E^\natural = E^\natural(A,\mathcal{L})$. For a homomorphism $u\colon A \to B$ of abelian schemes, u maps A_1 into B_1, and $u^\#\colon \operatorname{Extrig}(B) \to \operatorname{Extrig}(A)$ denotes pull-back of rigidified extensions along u; it induces on $\underline{\operatorname{Ext}}^1(-,\mathbb{G}_m) = \underline{\operatorname{Pic}}^0$ the pull-back of line bundles, that is the transpose $u^\vee$ (by (b) of Theorem B.125). We use: (U) a unit on $A_T \times_T A_T$ (T an S-scheme) that equals 1 on $A_T \times \{e\}$ is 1, because $A \times_S A$ is an abelian scheme, so its units over T come from T ((a) of Theorem B.125).

Step 1: the rigidified extension attached to a point of $E^\natural$. By the biextension axioms of $\Lambda(\mathcal{L})$ (Moret-Bailly, Pinceaux de variétés abéliennes, Astérisque 129, Ch. I, 2.5), for $x \in A(T)$ the line bundle $M_x = (x \circ \mathrm{pr}_1, \mathrm{pr}_2)^*\Lambda(\mathcal{L})$ on A_T, $y \mapsto \Lambda_{(x,y)}$, with the partial composition in the

second variable (the partial composition of Definition D.40 transported by the symmetry) and the canonical trivialisation of $\Lambda_{(x,0)}$, makes its $\mathbb{G}_m$-torsor $M_x^\times$ an extension of A_T by $\mathbb{G}_m$; the first partial composition $c\colon M_x \otimes M_{x'} \cong M_{x+x'}$ is compatible with the second, that is, it is an isomorphism of extensions from the contracted product $M_x^\times \wedge M_{x'}^\times$ (the Baer sum) onto $M_{x+x'}^\times$. For $(x,t) \in E^\natural(T)$, t trivialises M_x on $(A_T)_1$ and equals the canonical trivialisation at e: it is a morphism of T-pointed T-schemes $(A_T)_1 \to M_x^\times$ lifting the inclusion, a rigidification. Put

$$\Psi_{\mathcal{L}}(x,t) = \text{the class of } (M_x^\times, t) \in \mathrm{Extrig}(A)(T).$$

Step 2: $\Psi_{\mathcal{L}}$ is an isomorphism of group schemes, compatible with base change. It is a homomorphism: $(x,t)\cdot(x',t') = (x+x', t\cdot t')$ with $t\cdot t' = c(t\otimes t')$, and c is an isomorphism of extensions carrying the rigidification $t\otimes t'$ of the Baer sum to $t\cdot t'$. On the subgroups $W(\omega_A)$: $\Psi_{\mathcal{L}}(0,(1+\eta)t_0)$ is the trivial extension (M_0 trivialised by t_0) with the rigidification $1+\eta$, which is the image of η under the first map of (b) of Theorem B.125; so $\Psi_{\mathcal{L}}$ is the identity of $W(\omega_A)$. On the quotients: $M_x \cong t_x^*\mathcal{L}\otimes\mathcal{L}^{-1}\otimes f_T^*\mathcal{L}_x^{-1}$, whose class in $\underline{\mathrm{Pic}}^0(A)(T) = A^\vee(T)$ is $\phi_{\mathcal{L}}(x)$ by the definition of $\phi_{\mathcal{L}}$; by (b) of Theorem B.125 the projection $\mathrm{Extrig}(A) \to \underline{\mathrm{Ext}}^1(A,\mathbb{G}_m) = A^\vee$ sends $\Psi_{\mathcal{L}}(x,t)$ to the class of M_x, so $\Psi_{\mathcal{L}}$ induces $\phi_{\mathcal{L}}$ on the quotients. The rows $0\to W(\omega_A)\to E^\natural \to A\to 0$ (Lemma D.43 (1)) and $0\to W(\omega_A)\to \mathrm{Extrig}(A)\to A^\vee\to 0$ ((b)) are exact and $\phi_{\mathcal{L}}$ is an isomorphism, so $\Psi_{\mathcal{L}}$ is an isomorphism of sheaves, hence of the representing smooth group schemes. It is formed by pull-backs, so it commutes with base change in S.

Step 3: the de Rham isomorphism μ_A and its naturality. For S affine let

$$\mu_A\colon \mathrm{Lie}\,\mathrm{Extrig}(A) \to H^1_{\mathrm{dR}}(A/S)$$

be the isomorphism of (g) of Theorem B.125: a rigidified extension (E,r) of $A_{S[\varepsilon]}$ reducing to the trivial one receives the unique connection ∇ of (e) (over $S[\varepsilon]$), the class of the line bundle with connection $(\mathcal{L}_E,\nabla)$ in $\mathbb{H}^1(\Omega^{\bullet\times}_{A_{S[\varepsilon]}/S[\varepsilon]})$ lies in the kernel of reduction, and (f) identifies that kernel with $H^1_{\mathrm{dR}}(A/S)$. (N) For a homomorphism $u\colon A\to B$, $\mu_A\circ\mathrm{Lie}(u^\#) = u^*\circ\mu_B$: u maps $A_1\to B_1$ and $\Delta^1(A)\to\Delta^1(B)$ compatibly with the two maps τ, so $u^*\nabla$ is an integrable connection on $u^\#E$, compatible with the group structure, whose pull-back by τ carries the unit section to u^*r; by the uniqueness in (e) it is the connection of $u^\#(E,r)$, and Čech classes and the split sequence of (f) commute with pull-back along u. (BC) For a morphism $S'\to S$ of affine schemes, $\mu_{A_{S'}}$ is the base change of μ_A (same uniqueness argument, with (c) and (d) of Theorem B.125). By (BC) for affine opens, the μ glue to an isomorphism μ_A over any S, satisfying (N) and (BC).

Step 4: θ. Put $\theta = \mu_A\circ\mathrm{Lie}(\Psi_{\mathcal{L}})\colon \mathrm{H}^\natural(A,\mathcal{L}) \to H^1_{\mathrm{dR}}(A/S)$, an isomorphism of $\mathcal{O}_S$-modules by Steps 2 and 3, compatible with base change in S by Step 2 and (BC).

(i). Let η be a section of ω_A over an affine open U. By Step 2, $\mathrm{Lie}(\Psi_{\mathcal{L}})$ maps the Hodge image $(0,(1+\varepsilon\eta)t_0)$ to the trivial extension over $U[\varepsilon]$ with the rigidification $1+\varepsilon\eta$. By (e), the corresponding connection on the trivial torsor is given by the unit $1+w$ with $\tau^*w = \varepsilon\eta$, that is $w = \varepsilon\tilde\eta$ where $\tilde\eta\in\Gamma(A_U,\Omega^1)$ is the form with $\tau^*\tilde\eta = e^*\tilde\eta = \eta$; its connection form is $\varepsilon\tilde\eta$ and its transition functions are 1. Under the split sequence of (f) (in degree 1, $w\mapsto\varepsilon w$) this class is the class of $(0,\tilde\eta)$, the image of $\tilde\eta\in H^0(A,\Omega^1) = \mathbb{H}^1(\Omega^{\geq 1})$ in H^1_{dR}, which is the image of η under the first map of the Hodge sequence ($\omega_{A/S} = f_*\Omega^1_{A/S} \cong e^*\Omega^1_{A/S}$). So θ is the identity on $\omega_{A/S}$. On the quotients, the second Hodge map $(v,t)\mapsto v$ corresponds under $\Psi_{\mathcal{L}}$ to $\mathrm{Lie}\,\mathrm{Extrig}(A)\to\mathrm{Lie}(A^\vee)$, which induces $\mathrm{Lie}(\phi_{\mathcal{L}})$ (Step 2); and by (f), (g) the projection $H^1_{\mathrm{dR}}(A/S)\to R^1f_*\mathcal{O}_A$ (forgetting the connection forms) corresponds to $\mathrm{Lie}(E^\natural)\to\mathrm{Lie}(A^\vee)\cong\mathrm{Lie}(\underline{\mathrm{Pic}}(A))\cong R^1f_*\mathcal{O}_A$, the last map sending a line bundle on $A_{U[\varepsilon]}$ with transition functions $1+\varepsilon g_{ij}$ to the class of (g_{ij}) (degree 0 of the split sequence), which is λ_A. Hence θ induces $\lambda_A\circ\mathrm{Lie}(\phi_{\mathcal{L}})$ on the quotients.

(ii). Let $p\mathcal{O}_S = 0$. By (c), $\mathrm{Extrig}(A)^{(p)} = \mathrm{Extrig}(A^{(p)})$, and $(A^\vee)^{(p)} = (A^{(p)})^\vee$. We show $V_{\mathrm{Extrig}(A)} = F^\#_{A/S}$ as homomorphisms $\mathrm{Extrig}(A^{(p)})\to\mathrm{Extrig}(A)$. Both are compatible with the

projections to $A^\vee$: by functoriality of the Verschiebung (SGA 3, Exp. VII$_\mathrm{A}$, 4.3) the first induces $V_{A^\vee/S}$, the second induces $F^\vee_{A/S}$, and $F^\vee_{A/S} = V_{A^\vee/S}$ (the transpose of the relative Frobenius is the Verschiebung of the dual; Mumford, Abelian varieties, §15). Both vanish on $W(\omega_{A^{(p)}})$: the Verschiebung of the vector group W is 0 (since $V_W \circ F_{W/S} = [p]_W = 0$ and $F_{W/S}$ is faithfully flat, W being locally $\mathbb{G}_a^g$), and $F_{A/S}$ maps A_1 into the unit section of $A^{(p)}$ (the ideal of the unit section of $A^{(p)}$ is generated locally by the $g \otimes 1$ with g in the ideal $\mathcal{I}$ of e, and $F^*_{A/S}(g \otimes 1) = g^p \in \mathcal{I}^2$), so $F^\#_{A/S}$ pulls every rigidification of the trivial extension back to the trivial one. Hence the difference $V_{\mathrm{Extrig}(A)} - F^\#_{A/S}$ is a homomorphism into $W(\omega_A)$ vanishing on $W(\omega_{A^{(p)}})$, so it factors through a homomorphism $(A^{(p)})^\vee \to W(\omega_A)$, which is 0 by (a). Now $\Psi_\mathcal{L}$ is an isomorphism, so $\Psi_\mathcal{L} \circ V_{E^\natural} = V_{\mathrm{Extrig}(A)} \circ \Psi^{(p)}_\mathcal{L}$, and $\Psi^{(p)}_\mathcal{L} = \Psi_{\mathcal{L}^{(p)}}$ under $E^\natural(A,\mathcal{L})^{(p)} = E^\natural(A^{(p)}, \mathcal{L}^{(p)})$ (Step 2, Lemma D.43 (1)). Taking Lie algebras and using (N) for $u = F_{A/S}$ and (BC) for F_S (with $H^1_\mathrm{dR}(A^{(p)}/S) = F_S^* H^1_\mathrm{dR}(A/S)$, Theorem B.124 (i)):

$$\theta \circ \tilde\alpha = \mu_A \circ \mathrm{Lie}(F^\#_{A/S}) \circ \mathrm{Lie}(\Psi_{\mathcal{L}^{(p)}}) = F^*_{A/S} \circ \mu_{A^{(p)}} \circ \mathrm{Lie}(\Psi_{\mathcal{L}^{(p)}}) = F^*_{A/S} \circ F_S^* \theta.$$

(iii). Let $a \in \mathcal{O}$, $b = \iota(\bar a)$, $(x,t) \in E^\natural(T)$. Restricted to $\{x\} \times A_T$, ϵ_a is an isomorphism of line bundles $\epsilon_{a,x} \colon M_{\iota(a)x} \to b^* M_x$ (as $\Lambda_{(x,by)} = (b^* M_x)_y$), equal to the identity at $y = e$ under the canonical trivialisations. It respects the extension structures: the defect between $\epsilon_{a,x}$ composed with the composition of $M_{\iota(a)x}$ and the composition of b^*M_x composed with $\epsilon_{a,x} \otimes \epsilon_{a,x}$ is a unit on $A_T \times_T A_T$ equal to 1 on $A_T \times \{e\}$, hence 1 by (U). Since b is a homomorphism, b^*M_x with the pulled-back composition is the extension $b^\# M_x^\times$, and $(1 \times b|_{A_1})^* t$ is the pulled-back rigidification. So $\epsilon_{a,x}$ is an isomorphism of rigidified extensions from $(M^\times_{\iota(a)x}, \epsilon_a^{-1}((1\times b|_{A_1})^* t))$ to $b^\#(M_x^\times, t)$, that is $\Psi_\mathcal{L}(a \cdot (x,t)) = \iota(\bar a)^\# \Psi_\mathcal{L}(x,t)$. Taking Lie algebras and using (N) for $u = \iota(\bar a)$: $\theta \circ \rho^\natural(a) = \mu_A \circ \mathrm{Lie}(\iota(\bar a)^\#) \circ \mathrm{Lie}(\Psi_\mathcal{L}) = \iota(\bar a)^* \circ \theta$. □

Lemma D.47. *Let p be a prime, S a scheme with $p\mathcal{O}_S = 0$ and absolute Frobenius F_S, $f \colon A \to S$ an abelian scheme, and $\mathcal{L}$ a rigidified line bundle on A with a cubical structure. Then $\langle \alpha(u), \alpha(u') \rangle = 0$ for all sections u, u' of $F_S^* \mathrm{Lie}(A)$.*

Proof. **Notation.** Put $A' = A^{(p)} = A \times_{S,F_S} S$ with the pulled-back rigidified line bundle $\mathcal{L}'$ and cubical structure, $\Lambda = \Lambda(\mathcal{L})$ on $A \times_S A$, $\Lambda' = \Lambda(\mathcal{L}')$ on $A' \times_S A'$, $F = F_{A/S} \colon A \to A'$, $V = V_{A/S} \colon A' \to A$, $E = E^\natural(A,\mathcal{L})$, $E' = E^\natural(A',\mathcal{L}') = E^{(p)}$ (Lemma D.43 (1)), and $\pi \colon E \to A$, $\pi' \colon E' \to A'$ the projections. Let c be the partial composition of Λ (first variable), ς the symmetry, $c^\mathrm{t} = \varsigma \circ c \circ (\varsigma \otimes \varsigma)$ the partial composition in the second variable, can the canonical trivialisations of $\Lambda_{(x,0)}$ and $\Lambda_{(0,y)}$ (they agree on $\Lambda_{(0,0)}$ and ς preserves them), and $c', \varsigma', c'^\mathrm{t}, \mathrm{can}'$ the same for Λ'. We use:

(B) Λ is a symmetric biextension of $A \times_S A$ by $\mathbb{G}_m$ (Moret-Bailly [181], Ch. I, 2.5): c, c^t are associative, commutative and compatible, and can is a unit for both; for $x \in A(T)$, $\Lambda^\times_{(x,\cdot)}$ with c^t is an extension of A_T by $\mathbb{G}_m$ with unit section can; likewise after pull-back along homomorphisms. Iteration gives isomorphisms $c_p \colon \Lambda^{\otimes p}_{(x,y)} \to \Lambda_{(px,y)}$ and $c_p^\mathrm{t} \colon \Lambda^{\otimes p}_{(x,y)} \to \Lambda_{(x,py)}$ mapping $\mathrm{can}^{\otimes p}$ to can.

(R) If $X \to S$ is an abelian scheme (here: a fibre product over S of copies of A and A') and T an S-scheme, a unit on X_T equal to 1 along the unit section is 1, because by (a) it is the pull-back of a unit on T.

(FV) Let X be a commutative group scheme flat over a scheme T with $p\mathcal{O}_T = 0$. Then $V_{X/T} \circ F_{X/T} = [p]_X$, $F_{X/T} \circ V_{X/T} = [p]_{X^{(p)}}$, and V is functorial in X (SGA 3, Exp. VII$_\mathrm{A}$, 4.3).

If $x \in X(R)$, R a T-algebra, reduces to the unit modulo an ideal J with $j^p = 0$ for all $j \in J$, then $F_{X/T}(x)$ is the unit, since $F_{X/T}(x)^*(g \otimes 1) = (x^*g)^p = 0$ for g in the ideal of the unit section and the $g \otimes 1$ generate the ideal of the unit section of $X^{(p)}$; hence $x^p = V_{X/T}(F_{X/T}(x))$ is the unit. The same computation shows that F maps A_1 (where $J = \mathcal{I}/\mathcal{I}^2$) into the unit section of A'.

(Fl) F is an epimorphism in the category of S-schemes, being faithfully flat and quasi-compact (fpqc descent of morphisms): it is finite and surjective (F^* makes $\mathcal{O}_A$ integral over $\mathcal{O}_{A'}$, and F is a universal homeomorphism), and flat by the fibrewise criterion of flatness (EGA IV_3, 11.3.10), since on each fibre it is a finite surjective morphism of regular schemes of the same dimension (EGA IV_2, 6.1.5).

Step 1: $(V \times 1)^*\Lambda \cong (1 \times F)^*\Lambda'$. Let $N_1 = (V \times 1)^*\Lambda$ and $N_2 = (1 \times F)^*\Lambda'$ on $A' \times_S A$. We show there is an isomorphism $\gamma\colon N_1 \to N_2$ of line bundles which maps can to can$'$ along $A' \times \{e\}$ and is compatible with the first partial compositions c (at (Vy_1, Vy_2, z)) and c' (at (y_1, y_2, Fz)). For $y \in A'(T)$, $N_{1,y} = \Lambda_{(Vy,\cdot)}$ with c^{t} and $N_{2,y} = F^*\Lambda'_{(y,\cdot)}$ with the pull-back of c'^{t} are extensions of A_T by $\mathbb{G}_m$ (B); by (b) their classes define morphisms $\xi_1, \xi_2\colon A' \to A^\vee$. For $x \in A(T)$: $N_{1,Fx} = \Lambda_{(px,\cdot)} \cong \Lambda^{\otimes p}_{(x,\cdot)}$ by $V \circ F = [p]_A$ and c_p; and $N_{2,Fx}$ is the restriction of $(F \times F)^*\Lambda' = \Lambda(F^*\mathcal{L}')$ (F is a homomorphism) to $\{x\} \times A_T$, where $F^*\mathcal{L}' \cong \mathcal{L}^{\otimes p}$ (the pull-back of $\mathcal{L}$ along the absolute Frobenius of A, by $\ell \mapsto \ell^{\otimes p}$), so $N_{2,Fx} \cong \Lambda^{\otimes p}_{(x,\cdot)}$ as well. By (b) the class of an extension depends only on its line bundle, so $\xi_1 \circ F = \xi_2 \circ F$, and $\xi_1 = \xi_2$ by (Fl). Hence (for $T = A'$, $y = \mathrm{id}$) the extensions N_1 and N_2 of $A_{A'}$ by $\mathbb{G}_m$ are isomorphic locally on A'. Two isomorphisms of extensions differ by a homomorphism $A_T \to \mathbb{G}_m$, a unit equal to 1 along the unit section, hence 1 by (R); so the local isomorphisms are unique and glue to an isomorphism of extensions $\gamma\colon N_1 \to N_2$. It maps the unit section can to the unit section can$'$ (note $F(e) = e$). The two isomorphisms $\gamma \circ c$ and $c' \circ (\gamma \otimes \gamma)$ from $N_{1,(y_1,z)} \otimes N_{1,(y_2,z)}$ to $N_{2,(y_1+y_2,z)}$ differ by a unit on $A' \times_S A' \times_S A$ that is 1 at the unit section (all maps send can to can$'$ there), hence 1 by (R).

Step 2: a homomorphism $\sigma\colon A' \to E$ lifting V. Let $y \in A'(T)$. By (FV), F maps $(A_T)_1$ into the unit section, so N_2 restricted to $\{y\} \times (A_T)_1$ is the pull-back of $\Lambda'_{(y,e)}$ and is trivialised by can$'$. Put $t_y = \gamma^{-1}(\mathrm{can}')$ there: a trivialisation of $\Lambda_{(Vy,\cdot)}$ on $T \times_S A_1$, equal to can at e (Step 1). So $\sigma(y) = (Vy, t_y) \in E(T)$; this is functorial in T, hence a morphism $\sigma\colon A' \to E$ with $\pi \circ \sigma = V$. It is a homomorphism: $t_{y_1} \cdot t_{y_2} = c(t_{y_1} \otimes t_{y_2}) = \gamma^{-1}(c'(\mathrm{can}' \otimes \mathrm{can}')) = \gamma^{-1}(\mathrm{can}') = t_{y_1+y_2}$ by Step 1 and (B).

Step 3: $V_E = \sigma \circ \pi'$, hence $\alpha = \mathrm{Lie}(\sigma)$. Both are homomorphisms $E' \to E$. By functoriality of V (FV) for π, $\pi \circ V_E = V \circ \pi' = \pi \circ \sigma \circ \pi'$. On $W(\omega_{A'}) = W(\omega_A)^{(p)} \subset E'$: V_E restricts to $i \circ V_{W(\omega_A)} = 0$ (i the inclusion; $V_{W(\omega_A)} \circ F_{W(\omega_A)/S} = [p] = 0$ with $F_{W(\omega_A)/S}$ faithfully flat, $W(\omega_A)$ being locally $\mathbb{G}_a^g$), and $\sigma \circ \pi'$ restricts to 0. So $d = V_E - \sigma \circ \pi'$ takes values in $\ker \pi = W(\omega_A)$ and vanishes on $W(\omega_{A'})$; as $E' \to A'$ is an epimorphism with kernel $W(\omega_{A'})$ (Lemma D.43 (1)), d factors through a homomorphism $A' \to W(\omega_A)$, which is 0 by (a). Thus $V_E = \sigma \circ \pi'$ and $\tilde{\alpha} = \mathrm{Lie}(V_E) = \mathrm{Lie}(\sigma) \circ \mathrm{Lie}(\pi')$. Since $\mathrm{Lie}(\pi')$ is the pull-back by F_S of the second Hodge map of $\mathrm{H}^\natural(A, \mathcal{L})$ (Lemma D.43 (2), base change), the map α of (4) of Lemma D.43 is $\mathrm{Lie}(\sigma)\colon \mathrm{Lie}(A') = F_S^*\mathrm{Lie}(A) \to \mathrm{H}^\natural(A, \mathcal{L})$. Concretely, for an open $U \subseteq S$ and $u \in \mathrm{Lie}(A')(U) = \ker(A'(U[\varepsilon]) \to A'(U))$, $\alpha(u) = \sigma(u) = (Vu, t_u)$.

Step 4: two isomorphisms $(V \times V)^*\Lambda \to \Lambda'^{\otimes p}$ agree. On $A' \times_S A'$ let $Q = (V \times V)^*\Lambda$, so $Q_{(y,y')} = \Lambda_{(Vy,Vy')}$, and note γ at (y, Vy') maps it to $\Lambda'_{(y,FVy')} = \Lambda'_{(y,py')}$ by (FV). Define

$$\Gamma_1 = (c'^{\mathrm{t}}_p)^{-1} \circ \gamma_{(y,Vy')}\colon Q_{(y,y')} \to \Lambda'^{\otimes p}_{(y,y')}, \qquad \Gamma_2 = \varsigma'^{\otimes p} \circ (c'^{\mathrm{t}}_p)^{-1} \circ \gamma_{(y',Vy)} \circ \varsigma\colon Q_{(y,y')} \to \Lambda'^{\otimes p}_{(y,y')},$$

where in Γ_2 the symmetry ς maps $\Lambda_{(Vy,Vy')}$ to $\Lambda_{(Vy',Vy)}$, γ maps this to $\Lambda'_{(y',py)}$, and $(c_p'^{\mathrm{t}})^{-1}$ maps that to $\Lambda'^{\otimes p}_{(y',y)}$. Both are isomorphisms of line bundles on $A' \times_S A'$, and at (e,e) both send can to $\mathrm{can}'^{\otimes p}$ (Step 1, (B), and ς, ς' preserve the canonical trivialisations). So $\Gamma_2 \circ \Gamma_1^{-1}$ is a unit on $A' \times_S A'$ equal to 1 at the unit section, and $\Gamma_1 = \Gamma_2 =: \Gamma$ by (R).

Step 5: p-th powers of first-order trivialisations. Let $U \subseteq S$ be an affine open, $R = \mathcal{O}(U)[\varepsilon,\varepsilon']$ with $\varepsilon^2 = \varepsilon'^2 = 0$, and $u \in A'(U[\varepsilon])$, $u' \in A'(U[\varepsilon'])$ reducing to e. Then $pu' = e$ and $pu = e$ by (FV) ($[p] = V \circ F$ and $F(u') = e$, with $J = (\varepsilon')$). The R-module $\Lambda'_{(u,u')}$ is invertible and reduces modulo the nilpotent ideal $(\varepsilon,\varepsilon')$ to $\Lambda'_{(e,e)} \cong \mathcal{O}(U)$, so it is free, and every lift of a generator modulo (ε') (resp. (ε)) is a generator.

(P1) If w generates $\Lambda'_{(u,u')}$ and $w \equiv \mathrm{can}'_{(u,e)}$ modulo ε', then $c_p'^{\mathrm{t}}(w^{\otimes p}) = \mathrm{can}'_{(u,e)}$. Indeed, let X be the $\mathbb{G}_m$-torsor of $\Lambda'_{(u,\cdot)}$ on $A'_{U[\varepsilon]}$, a commutative group scheme over $U[\varepsilon]$ under c'^{t} with unit $\mathrm{can}'_{(u,e)}$ (B), smooth as a $\mathbb{G}_m$-torsor over an abelian scheme. The point $x = (u', w) \in X(R)$ reduces to the unit modulo $J = (\varepsilon')$, and $j^p = 0$ for $j \in J$; by (FV) x^p is the unit, and $x^p = (pu', c_p'^{\mathrm{t}}(w^{\otimes p}))$.

(P2) Symmetrically (exchange ε and ε', u and u'), if $\tilde{w}$ generates $\Lambda'_{(u',u)}$ and $\tilde{w} \equiv \mathrm{can}'_{(u',e)}$ modulo ε, then $c_p'^{\mathrm{t}}(\tilde{w}^{\otimes p}) = \mathrm{can}'_{(u',e)}$.

(P3) Two generators w_1, w_2 of $\Lambda'_{(u,u')}$ that both reduce to $\mathrm{can}'_{(e,e)}$ modulo $(\varepsilon,\varepsilon')$ have $w_1^{\otimes p} = w_2^{\otimes p}$: $w_2 = \zeta w_1$ with $\zeta = 1 + \varepsilon a + \varepsilon' b + \varepsilon\varepsilon' c$, and $\zeta^p = 1$, since $p\mathcal{O}_U = 0$, $(\varepsilon a + \varepsilon' b + \varepsilon\varepsilon' c)^2 = 2ab\,\varepsilon\varepsilon'$ and the cube is 0 (for $p = 2$, $\zeta^2 = 1 + 2ab\,\varepsilon\varepsilon' = 1$).

The generators w of (P1) and $\varsigma'(\tilde{w})$, $\tilde{w}$ as in (P2), both reduce to $\mathrm{can}'_{(e,e)}$ modulo $(\varepsilon,\varepsilon')$, so by (P3)

$$\text{(P4)} \qquad w^{\otimes p} = \varsigma'(\tilde{w})^{\otimes p} = \varsigma'^{\otimes p}(\tilde{w}^{\otimes p}).$$

Step 6: conclusion. Let u, u' be sections of $F_S^*\mathrm{Lie}(A) = \mathrm{Lie}(A')$ over U, read as in Step 5, and put $h = \alpha(u) = (v, t_u)$, $h' = \alpha(u') = (v', t_{u'})$ with $v = Vu$, $v' = Vu'$ (Step 3); v' is a point of A_1 with $Fv' = FVu' = pu' = e$, and likewise $Fv = e$. By the definition of t_u (Step 2), $\gamma(t_u(v')) = \mathrm{can}'_{(u,e)}$, so by (P1)

$$\Gamma_1\big(t_u(v')\big) = (c_p'^{\mathrm{t}})^{-1}(\mathrm{can}'_{(u,e)}) = w^{\otimes p}.$$

Likewise $\gamma(t_{u'}(v)) = \mathrm{can}'_{(u',e)}$, so by (P2) and (P4)

$$\Gamma_2\big(\varsigma(t_{u'}(v))\big) = \varsigma'^{\otimes p}\big((c_p'^{\mathrm{t}})^{-1}(\mathrm{can}'_{(u',e)})\big) = \varsigma'^{\otimes p}(\tilde{w}^{\otimes p}) = w^{\otimes p}.$$

As $\Gamma_1 = \Gamma_2$ is an isomorphism (Step 4), $\varsigma(t_{u'}(v)) = t_u(v')$ in $\Lambda_{(v,v')}$. This is (D.10) with $\langle h, h'\rangle = 0$. The pairing is $\mathcal{O}_S$-bilinear and local on S, so $\langle \alpha(u), \alpha(u')\rangle = 0$ for all sections u, u'. □

Lemma D.48. *Let p be a prime, S a scheme with $p\mathcal{O}_S = 0$ and absolute Frobenius F_S, $f\colon A \to S$ an abelian scheme, and $F_{A/S}\colon A \to A^{(p)} = A \times_{S,F_S} S$ the relative Frobenius. Identify $H^1_{\mathrm{dR}}(A^{(p)}/S) = F_S^* H^1_{\mathrm{dR}}(A/S)$, $\omega_{A^{(p)}/S} = F_S^*\omega_{A/S}$ and $R^1 f_*^{(p)}\mathcal{O}_{A^{(p)}} = F_S^* R^1 f_*\mathcal{O}_A$ by base change. Then the pull-back*

$$F_{A/S}^*\colon F_S^* H^1_{\mathrm{dR}}(A/S) \to H^1_{\mathrm{dR}}(A/S)$$

is the composite of the Hodge projection $F_S^* H^1_{\mathrm{dR}}(A/S) \to F_S^* R^1 f_*\mathcal{O}_A$ (the second map of (ii) for $A^{(p)}$) and the first map $F_S^* R^1 f_*\mathcal{O}_A \to H^1_{\mathrm{dR}}(A/S)$ of the conjugate sequence (iii). In particular $\ker F_{A/S}^* = F_S^*\omega_{A/S}$, and $F_{A/S}^*$ maps $F_S^* R^1 f_*\mathcal{O}_A$ isomorphically onto the first term of the conjugate sequence.

Proof. Write $\pi\colon A^{(p)} \to S$ and $F = F_{A/S}$, a finite (hence affine) morphism. The complex $F_*\Omega^\bullet_{A/S}$ is a complex of $\mathcal{O}_{A^{(p)}}$-modules with $\mathcal{O}_{A^{(p)}}$-linear differential, and pull-back of forms is a map of complexes $F^*\colon \Omega^\bullet_{A^{(p)}/S} \to F_*\Omega^\bullet_{A/S}$ computing $F^*_{A/S}$ on H^1_{dR} after $R^1\pi_*$ (as F is affine, $R^1\pi_*(F_*\Omega^\bullet_{A/S}) = H^1_{\mathrm{dR}}(A/S)$).

F^* factors through $\mathcal{O}[0]$. Locally $\Omega^1_{A^{(p)}/S}$ is generated by the differentials $d(g\otimes 1)$ of functions g on A, and $F^*(g\otimes 1) = g^p$, so $F^*d(g\otimes 1) = d(g^p) = pg^{p-1}dg = 0$. Hence F^* vanishes on $\Omega^{\geq 1}$ and factors as

$$\Omega^\bullet_{A^{(p)}/S} \longrightarrow \mathcal{O}_{A^{(p)}}[0] \xrightarrow{c} F_*\Omega^\bullet_{A/S}, \qquad c(h) = F^*h,$$

where the first arrow is the quotient by the subcomplex $\Omega^{\geq 1}$ and c is a map of complexes because $d(F^*h) = 0$ (as just shown, F^*h is locally a sum of p-th powers times functions of S).

The two factors. Applying $R^1\pi_*$, the first arrow gives the Hodge projection $H^1_{\mathrm{dR}}(A^{(p)}/S) \to R^1\pi_*\mathcal{O}_{A^{(p)}}$, which by (ii) and (i) for $A^{(p)}$ is surjective with kernel $\omega_{A^{(p)}/S} = F_S^*\omega_{A/S}$. For the second, c identifies $\mathcal{O}_{A^{(p)}}$ with the sheaf $\mathcal{H}^0(F_*\Omega^\bullet_{A/S})$ (the Cartier isomorphism in degree 0, Katz, Nilpotent connections and the monodromy theorem, Theorem 7.2), and the conjugate spectral sequence of Katz, Theorem 7.4, is the spectral sequence of hypercohomology of $F_*\Omega^\bullet_{A/S}$ for its canonical filtration, $E_2^{a,b} = R^a\pi_*\mathcal{H}^b(F_*\Omega^\bullet_{A/S})$; its edge map $E_2^{1,0} \to H^1_{\mathrm{dR}}(A/S)$ is induced by the inclusion $\mathcal{H}^0[0] = \tau_{\leq 0}F_*\Omega^\bullet \to F_*\Omega^\bullet$, that is, by c. By (iii) of Theorem B.124 this edge map $F_S^*R^1f_*\mathcal{O}_A = R^1\pi_*\mathcal{O}_{A^{(p)}} \to H^1_{\mathrm{dR}}(A/S)$ is the injective first map of the conjugate sequence.

Conclusion. $F^*_{A/S}$ is the surjection with kernel $F_S^*\omega_{A/S}$ followed by the injection onto the first term of the conjugate sequence; both claims follow. □

Lemma D.49. *Let E be a number field with an automorphism $a \mapsto \bar a$ of order dividing 2, V a discrete valuation ring with valuation v, maximal ideal $\mathfrak{m}$, fraction field k of characteristic 0 and residue field of characteristic $\ell > 0$, such that there are $[E:\mathbb{Q}]$ field embeddings $E \to k$ and $s(\mathcal{O}_E) \subseteq V$ for each of them. For an embedding $\sigma\colon E \to k$ put $\bar\sigma(a) = \sigma(\bar a)$, let S_σ be the set of embeddings s with $s(a) - \sigma(a) \in \mathfrak{m}$ for all $a \in \mathcal{O}_E$, and let $\varpi_\sigma \in \mathcal{O}_E$ be a uniformiser of $\mathcal{O}_E$ at the prime $\mathcal{O}_E \cap \sigma^{-1}(\mathfrak{m})$. Let L be a free V-module of finite rank with a ring homomorphism $\rho_L\colon \mathcal{O}_E \to \mathrm{End}_V(L)$, $r_s = \dim_k\{x \in L\otimes k :\ \rho_L(a)x = s(a)x\ \forall a\}$ for each embedding s, and $L^\vee = \mathrm{Hom}_V(L,V)$ with a acting by $\rho_L(\bar a)^\vee$. Let N be a module over $\mathcal{O}_E\otimes_{\mathbb{Z}} V$, free of rank n, with an $\mathcal{O}_E$-equivariant exact sequence $0 \to L^\vee \to N \to L \to 0$ of V-modules. For a V-module M with $\mathcal{O}_E$-action write $M_\sigma = M/\sum_a(a - \sigma(a))M$ and $M[\sigma] = \{x \in M :\ ax = \sigma(a)x\ \forall a\}$. Let $v_1,\dots,v_p$ be a V-basis of $L[\sigma]$, $w_1,\dots,w_q$ a V-basis of $L[\bar\sigma]$, $w_1^*,\dots,w_q^*$ the dual basis of $(L[\bar\sigma]\otimes k)^\vee$, and $\tilde v_i \in N_\sigma \otimes k$ lifts of v_i; regard $w_j^* \in N_\sigma\otimes k$ through the exact sequence*

$$0 \to (L[\bar\sigma]\otimes k)^\vee \to N_\sigma \otimes k \to L[\sigma]\otimes k \to 0$$

induced by the given one (the first map: restriction of functionals, inverted). Then N_σ is free of rank $p+q = n$ over V, and for a V-basis b of N_σ the element $\delta \in k^\times$ with $w_1^*\wedge\cdots\wedge w_q^*\wedge\tilde v_1\wedge\cdots\wedge\tilde v_p = \delta\, b_1\wedge\cdots\wedge b_n$ satisfies

$$v(\delta) = \sum_{s\in S_\sigma,\ s\neq\sigma} r_s\, v\big(s(\varpi_\sigma) - \sigma(\varpi_\sigma)\big).$$

In particular $v(\delta) = 0$ if the prime $\mathcal{O}_E\cap\sigma^{-1}(\mathfrak{m})$ is unramified over ℓ.

Proof. **Conventions.** A *lattice* in a finite-dimensional k-space W is a finitely generated V-submodule spanning W; it is free (V is a principal ideal domain). For lattices Λ,Λ' in W let

$[\Lambda' : \Lambda] = v(\det g)$, g the matrix of a basis of Λ in a basis of Λ'; it is independent of the bases, $[\Lambda'' : \Lambda] = [\Lambda'' : \Lambda'] + [\Lambda' : \Lambda]$, $[\Lambda' : \Lambda]$ is the length of Λ'/Λ if $\Lambda \subseteq \Lambda'$, and if $W_1 \subseteq W$ is a subspace with $\Lambda \cap W_1$, $\Lambda' \cap W_1$ lattices in W_1 then $[\Lambda' : \Lambda] = [\Lambda' \cap W_1 : \Lambda \cap W_1] + [\bar{\Lambda}' : \bar{\Lambda}]$, bars denoting images in W/W_1 (block-triangular matrices). For a finitely generated V-module Q let $t(Q)$ be the length of its torsion submodule.

Step 1: reduction to complete V. Let $\hat{V}$ be the completion, $\hat{k}$ its fraction field. $V \to \hat{V}$ is faithfully flat, so base change preserves the freeness of N over $\mathcal{O}_E \otimes \hat{V}$, the exact sequence, the kernels $L[\sigma]$, $L[\bar{\sigma}]$ (kernels commute with flat base change), the quotient N_σ (a cokernel), the dimensions r_s, δ, v, $\mathfrak{m}$-congruences and S_σ. So we may assume V complete.

Step 2: the factor of σ. Let $\mathfrak{p} = \mathcal{O}_E \cap \sigma^{-1}(\mathfrak{m})$, $E_\mathfrak{p}$ the completion, $O_0 \subseteq \mathcal{O}_{E_\mathfrak{p}}$ the ring of integers of its maximal unramified subextension, of degree f over $\mathbb{Z}_\ell$, e the ramification index, and ζ a root of unity of order prime to ℓ with $O_0 = \mathbb{Z}_\ell[\zeta]$. *The embeddings.* An embedding $s\colon E \to k$ maps $\mathcal{O}_E$ into V, so it is continuous for the $\mathfrak{p}_s$-adic topology, $\mathfrak{p}_s = \mathcal{O}_E \cap s^{-1}(\mathfrak{m})$, and extends ($k$ is complete) to a $\mathbb{Q}_\ell$-embedding $E_{\mathfrak{p}_s} \to k$; distinct s give distinct extensions, E being dense in $E_{\mathfrak{p}_s}$. Since $E_{\mathfrak{p}'}$ has at most $[E_{\mathfrak{p}'} : \mathbb{Q}_\ell]$ embeddings into k over $\mathbb{Q}_\ell$ and $\sum_{\mathfrak{p}'|\ell} [E_{\mathfrak{p}'} : \mathbb{Q}_\ell] = [E : \mathbb{Q}]$ is the number of the s, every $\mathbb{Q}_\ell$-embedding $E_\mathfrak{p} \to k$ comes from exactly one s, and there are ef of them. As $\mathbb{Q}_\ell(\zeta)$ has at most f embeddings into k and each has at most $[E_\mathfrak{p} : \mathbb{Q}_\ell(\zeta)] = e$ extensions to $E_\mathfrak{p}$, each of the f embeddings of $\mathbb{Q}_\ell(\zeta)$ occurs, with exactly e extensions; these take e distinct values at ϖ_σ, an embedding of $E_\mathfrak{p} = \mathbb{Q}_\ell(\zeta, \varpi_\sigma)$ being determined by its values at ζ and ϖ_σ. All these values are integral over $\mathbb{Z}_\ell$, hence lie in V. Then $\mathcal{O}_E \otimes_\mathbb{Z} V = \prod_{\mathfrak{p}'|\ell} \mathcal{O}_{E_{\mathfrak{p}'}} \otimes_{\mathbb{Z}_\ell} V$ (V is a complete $\mathbb{Z}_\ell$-algebra); the minimal polynomial g of ζ over $\mathbb{Z}_\ell$ is separable modulo ℓ; its roots in V (images of ζ under the embeddings) are distinct modulo $\mathfrak{m}$, so $O_0 \otimes V = V[x]/(g) \cong V^f$ by the Chinese remainder theorem. As $\mathcal{O}_{E_\mathfrak{p}} = O_0[\varpi_\sigma]$ with ϖ_σ a root of an Eisenstein polynomial over O_0 of degree e, the factor R_σ of $\mathcal{O}_E \otimes V$ on which $\mu_\sigma\colon a \otimes c \mapsto \sigma(a)c$ is non-zero is $R_\sigma = V[t]/(P)$, $t = \varpi_\sigma \otimes 1$, $P = \prod_{s \in S}(t - s(\varpi_\sigma))$, where S is the set of the e embeddings s inducing $\mathfrak{p}$ and the same embedding of O_0 as σ; these are exactly the s with $s(a) \equiv \sigma(a) \bmod \mathfrak{m}$ for all $a \in \mathcal{O}_E$ (same prime and same map on the residue field O_0/ℓ), so $S = S_\sigma$, and the roots $s(\varpi_\sigma)$ are distinct. Let $\varepsilon \in \mathcal{O}_E \otimes V$ be the idempotent of R_σ and $\pi_s = s(\varpi_\sigma)$. Then $\ker \mu_\sigma$ is generated by $1 - \varepsilon$ and $\varepsilon(t - \pi_\sigma)$.

Step 3: a formula for one module. Let M be a free V-module of finite rank with an $\mathcal{O}_E$-action, $d_s = \dim_k(M \otimes k)[s]$, $M' = \varepsilon M$, $T = t - \pi_\sigma$ on M'. By Step 2, $M_\sigma = M'/TM'$. On $M'_k = M' \otimes k$, t acts semisimply with eigenvalues π_s ($s \in S_\sigma$, distinct roots of P) and $M'_k = \bigoplus_{s \in S_\sigma} M_k[s]$; so $M[\sigma] = \ker(T|_{M'})$. Let e_σ be the projection of M'_k onto $M_k[\sigma]$ along $Y = \bigoplus_{s \neq \sigma} M_k[s] = T(M'_k)$, $e_\sigma M = e_\sigma(M')$, $A = M[\sigma]$, $B = M' \cap Y$. We claim

$$[e_\sigma M : A] + t(M_\sigma) = \sum_{s \in S_\sigma,\ s \neq \sigma} d_s\, v(\pi_s - \pi_\sigma). \tag{$*$}$$

The map $M' \to e_\sigma M$, $m \mapsto e_\sigma m$, is onto with kernel B, and m maps into A if and only if $m - e_\sigma m \in M' \cap Y = B$; so $e_\sigma M/A \cong M'/(A \oplus B)$. Next $TM' \subseteq B$, M'/B is torsion-free of rank $d_\sigma = \operatorname{rank} M'/TM'$, so the torsion of $M_\sigma = M'/TM'$ is B/TM'. T maps M' onto TM' with kernel A and is injective on B, so $M'/(A \oplus B) \cong TM'/TB$. Hence the left side of ($*$) is $\operatorname{length}(TM'/TB) + \operatorname{length}(B/TM') = [B : TB] = v(\det(T|_Y)) = \sum_{s \neq \sigma} d_s v(\pi_s - \pi_\sigma)$.

Step 4: N_σ. $N \cong (\mathcal{O}_E \otimes V)^n$ and $(\mathcal{O}_E \otimes V)_\sigma = V$, so $N_\sigma \cong V^n$; it has no torsion, so $N_\sigma \to N_\sigma \otimes k = e_\sigma N_k$ is injective with image $e_\sigma N$. Write $K \subseteq N$ for the image of $L^\vee$, so $K_k \cong L_k^\vee$ and $L = N/K$. The exact sequence of the statement is e_σ applied to $0 \to K_k \to N_k \to L_k \to 0$: $e_\sigma L_k = L_k[\sigma]$, and a acts on $K_k = L_k^\vee$ by transposes of $\rho_L(\bar{a})$, so $e_\sigma K_k$ consists of the functionals supported on $L_k[\bar{\sigma}]$ (on $L_k[s]$, $\rho_L(\bar{a}) = s(\bar{a})$, and $s(\bar{a}) = \sigma(a)$ for all a if and only if $s = \bar{\sigma}$), i.e. $e_\sigma K_k \cong L_k[\bar{\sigma}]^\vee$ by restriction. Rank count: $n = r_\sigma + r_{\bar{\sigma}} = p + q$.

Step 5: the index. Let Λ be the lattice spanned by w^* and $\tilde{v}$ in $e_\sigma N_k$; then $v(\delta) = [e_\sigma N : \Lambda]$, independent of the lifts $\tilde{v}_i$ (another choice changes the basis by a unipotent matrix). Filter by $W_1 = e_\sigma K_k$. Images in $e_\sigma N_k/W_1 = L_k[\sigma]$: that of Λ is $L[\sigma]$, that of $e_\sigma N$ is $e_\sigma L$ (projection commutes with $N \to L$). Intersections with W_1: $\Lambda \cap W_1$ is spanned by w^*, which is $e_\sigma K$: restriction to the direct summand $L[\bar{\sigma}] = L \cap L_k[\bar{\sigma}]$ of L maps $L^\vee$ onto $L[\bar{\sigma}]^\vee$. And $e_\sigma N \cap W_1 = K'$, the kernel of $e_\sigma N \to e_\sigma L$. Hence

$$v(\delta) = [K' : e_\sigma K] + [e_\sigma L : L[\sigma]].$$

Right exactness of $M \mapsto M_\sigma$ gives the exact sequence $K_\sigma \to N_\sigma \to L_\sigma \to 0$; the image of K_σ in $N_\sigma = e_\sigma N$ is $e_\sigma K$, and $e_\sigma N \to e_\sigma L$ is $N_\sigma \to L_\sigma$ followed by the quotient by the torsion of L_σ. So K' is the preimage of the torsion of L_σ, and $K'/e_\sigma K$ is isomorphic to that torsion: $[K' : e_\sigma K] = t(L_\sigma)$. By $(*)$ for $M = L$, $v(\delta) = t(L_\sigma) + [e_\sigma L : L[\sigma]] = \sum_{s \in S_\sigma, s \neq \sigma} r_s \, v(\pi_s - \pi_\sigma)$. If $\mathfrak{p}$ is unramified over ℓ, $e = 1$, $S_\sigma = \{\sigma\}$ and the sum is empty. □

Lemma D.50. *Let $\mathcal{O}$ be a discrete valuation ring with uniformiser ϖ, fraction field K and residue field κ, and let X be a normal integral scheme with a proper morphism $X \to \operatorname{Spec} \mathcal{O}$ whose image contains the generic point; put $X_K = X \times_{\mathcal{O}} K$ and $X_s = X \times_{\mathcal{O}} \kappa$, and suppose that X_s is connected. Let $\mathcal{L}$ be an invertible sheaf on X of degree 0 on every curve of X_s: for every integral closed subscheme $C \subseteq X_s$ of dimension one, with normalisation $\nu\colon \tilde{C} \to C$ (a normal integral curve, proper over κ), $\deg \nu^* \mathcal{L} = 0$; this holds for instance if $\mathcal{L}|_{X_s} \cong \mathcal{O}_{X_s}$. Let σ be a non-zero rational section of $\mathcal{L}$ (an element of the stalk at the generic point) that generates $\mathcal{L}$ at every point of X_K. Then there are integers $M \geq 1$ and a such that $\sigma^M \varpi^{-a}$ generates $\mathcal{L}^{\otimes M}$ at every point of X.*

Proof. **Step 1: the components of the special fibre.** X is of finite type over the noetherian ring $\mathcal{O}$, hence noetherian. As X is integral and dominates $\operatorname{Spec} \mathcal{O}$, ϖ is a non-zero element of the function field, and X_s is the closed subset $V(\varpi)$. If $X_s = \varnothing$, every point lies in X_K and $M = 1$, $a = 0$ will do; assume $X_s \neq \varnothing$. Let $X_1, \dots, X_t$ be the irreducible components of X_s (finitely many), with generic points $\xi_1, \dots, \xi_t$. By Krull's principal ideal theorem each ξ_i has codimension one in X, so $\mathcal{O}_{X,\xi_i}$ is a normal noetherian local domain of dimension one, a discrete valuation ring with valuation v_i. Trivialise $\mathcal{L}$ at ξ_i and let $n_i \in \mathbb{Z}$ be the valuation of σ in this trivialisation (independent of the choice), and $m_i = v_i(\varpi) \geq 1$.

Step 2: the choice of M and a. Choose j with $n_j/m_j = \min_i n_i/m_i$, and put $M = m_1 \cdots m_t$ and $a = n_j \prod_{i \neq j} m_i$, so that $a/M = n_j/m_j$. Let $\theta = \sigma^M \varpi^{-a}$, a rational section of $\mathcal{L}^{\otimes M}$. Its order at ξ_i is $M n_i - a m_i = M m_i (\frac{n_i}{m_i} - \frac{n_j}{m_j}) \geq 0$, with equality for $i = j$. Every point of codimension one of X either lies in X_K, where σ generates and ϖ is a unit, so that θ has order 0 there, or is one of the ξ_i. Hence θ has non-negative order at every point of codimension one. Since X is normal and noetherian, a rational function with non-negative order at every point of codimension one through x lies in $\mathcal{O}_{X,x}$ (the local ring is the intersection of its localisations at height-one primes); applied in local trivialisations, θ is a global section of $\mathcal{L}^{\otimes M}$, and it generates $\mathcal{L}^{\otimes M}$ at x as soon as its order is 0 at every point of codimension one through x.

Step 3: all orders vanish. Let I be the set of indices i such that the order of θ at ξ_i is positive. It therefore suffices to show that I is empty. Put $Z = \bigcup_{i \in I} X_i$. First, θ fails to generate $\mathcal{L}^{\otimes M}$ exactly at the points of Z. Indeed, let $y \in X_i$ with $i \in I$; in a trivialisation of $\mathcal{L}^{\otimes M}$ near y, θ is an element $h \in \mathcal{O}_{X,y}$ with $v_i(h) > 0$; as ξ_i specialises to y, $\mathcal{O}_{X,\xi_i}$ is the localisation of $\mathcal{O}_{X,y}$ at the prime $\mathfrak{p}_i$ of ξ_i, and $v_i(h) > 0$ means $h \in \mathfrak{p}_i \mathcal{O}_{X,\xi_i} \cap \mathcal{O}_{X,y} = \mathfrak{p}_i \subseteq \mathfrak{m}_y$, so θ vanishes at y. If $y \notin Z$, the points of codimension one through y are points of X_K and generic points $\xi_{i'}$ with $i' \notin I$, at which θ has order 0, so θ generates at y by Step 2.

Suppose now $I \neq \varnothing$. Its complement J contains j. The closed sets Z and $Z' = \bigcup_{i' \in J} X_{i'}$ are non-empty and cover the connected space X_s, so $Z \cap Z'$ is a non-empty closed subset of X_s; as X_s is of finite type over κ, $Z \cap Z'$ contains a closed point x of X_s, and $x \in X_{i'}$ for some $i' \in J$.

A curve through x not inside Z. Give $X_{i'}$ its reduced structure, an integral scheme of finite type over κ in which x is a closed point, and let $A = \mathcal{O}_{X_{i'},x}$, a noetherian local domain with maximal ideal $\mathfrak{m}$, and $\mathfrak{a} \subseteq A$ the ideal of the reduced closed subscheme $Z \cap X_{i'}$ at x. The generic point $\xi_{i'}$ is not in Z (the X_i are distinct irreducible components and $i' \notin I$), so $\mathfrak{a} \neq 0$; choose $0 \neq g \in \mathfrak{a}$; then $g \in \mathfrak{m}$ as $x \in Z$, and $d = \dim A \geq 1$ as $x \neq \xi_{i'}$. Since A is a domain and $g \neq 0$, every chain of primes containing g extends by the prime 0, so $\dim A/gA \leq d-1$, and $\dim A/gA \geq d-1$ by Krull's height theorem; hence $\dim A/gA = d-1$. Choose $g_1, \ldots, g_{d-1} \in \mathfrak{m}$ whose images form a system of parameters of A/gA, and put $\mathfrak{b} = (g_1, \ldots, g_{d-1})$; then $\dim A/(\mathfrak{b}+gA) = 0$. By Krull's height theorem $\dim A/\mathfrak{b} \geq d-(d-1) = 1$, and $\dim A/\mathfrak{b} \leq \dim A/(\mathfrak{b}+gA)+1 = 1$ (again by Krull's principal ideal theorem, now in $A/\mathfrak{b}$). Let P be a prime of A minimal over $\mathfrak{b}$ with $\dim A/P = 1$. If $g \in P$, then $P \supseteq \mathfrak{b} + gA$ and $\dim A/P \leq 0$; so $g \notin P$. Let C be the closure in $X_{i'}$ of the point corresponding to P, with its reduced structure: an integral closed subscheme of X_s containing x, with $\dim \mathcal{O}_{C,x} = \dim A/P = 1$, hence of dimension one (C is integral of finite type over κ and x is a closed point). Its generic point η_C is not in Z, because $g \in \mathfrak{a}$ and $g \notin P$.

The degree. Let $\nu\colon \tilde{C} \to C$ be the normalisation, finite and surjective (C is of finite type over a field), and θ_C the pull-back of θ, a global section of $\nu^*\mathcal{L}^{\otimes M}$. At the generic point of $\tilde{C}$, which maps to $\eta_C \notin Z$, θ_C generates; so $\theta_C \neq 0$ and its divisor is effective. Let $\tilde{x} \in \nu^{-1}(x)$, a closed point of $\tilde{C}$; as θ vanishes at $x \in Z$, θ_C vanishes at $\tilde{x}$. Hence $M \deg \nu^*\mathcal{L} = \deg \nu^*\mathcal{L}^{\otimes M} \geq [\kappa(\tilde{x}) : \kappa] \operatorname{ord}_{\tilde{x}}(\theta_C) > 0$, contradicting $\deg \nu^*\mathcal{L} = 0$. (If $\mathcal{L}|_{X_s} \cong \mathcal{O}_{X_s}$, then $\nu^*\mathcal{L} \cong \mathcal{O}_{\tilde{C}}$ has degree 0, which is the instance named in the statement.) Hence $I = \varnothing$, every order of θ at a point of codimension one is 0, and by Step 2 $\theta = \sigma^M \varpi^{-a}$ generates $\mathcal{L}^{\otimes M}$ everywhere. □

Corollary D.51. *Let E be a CM field, $\mathcal{X}$ a normal integral noetherian scheme and $(G, \iota, \mathcal{L})$ a semiabelian structure over $\mathcal{X}$ with abelian generic fibre satisfying (PF). Let p be a prime, κ a field of characteristic p, C an integral normal projective curve over κ, $c\colon C \to \mathcal{X}$ a morphism and $H = c^*\mathrm{H}^\natural(G, \mathcal{L})$ with $\rho_H = c^*\rho^\natural$. Then:*

(i) for every finite field $k \subseteq \Gamma(C, \mathcal{O}_C)$ and every idempotent e of $k \otimes_{\mathbb{Z}} \mathcal{O}_E$ we have $\deg eH = 0$;

(ii) for every ring homomorphism $\sigma\colon \mathcal{O}_E \to \Gamma(C, \mathcal{O}_C)$ the quotient $H_\sigma = H/\sum_a (\rho_H(a) - \sigma(a))H$ is a vector bundle on C with $\deg H_\sigma = 0$.

Proof. By Corollary D.42 applied to c, with $L = c^*\mathrm{Lie}(G)$ and $L^\vee = c^*\omega_G$ (actions as there), (i) and (ii) there give $\mathcal{O}_E$-equivariant exact sequences $0 \to L^\vee \to H \to L \to 0$ and $0 \to F^*L \to H \to F^*(L^\vee) \to 0$, the outer terms of the second carrying F^* of the actions on L and $L^\vee$: this is hypothesis (a) of Lemma D.52 with $K = E$, $M_0 = L^\vee$, $M_1 = L$. Item (iii) there is hypothesis (b). So (i) and (ii) of Lemma D.52 give the two claims. □

Lemma D.52. *Let p be a prime, κ a field of characteristic p, C an integral normal projective curve over κ with absolute Frobenius $F\colon C \to C$, and K a number field with ring of integers $\mathcal{O}_K$. For a vector bundle V on C, an $\mathcal{O}_K$-action on V is a ring homomorphism $\rho_V\colon \mathcal{O}_K \to \mathrm{End}_{\mathcal{O}_C}(V)$; then F^*V carries the $\mathcal{O}_K$-action $a \mapsto F^*(\rho_V(a))$. Let H, M_0, M_1 be vector bundles on C with $\mathcal{O}_K$-actions such that*

(a) there are $\mathcal{O}_K$-equivariant exact sequences of $\mathcal{O}_C$-modules

$$0 \to M_0 \to H \to M_1 \to 0, \qquad 0 \to F^*M_1 \to H \to F^*M_0 \to 0.$$

Then:

(i) for every finite field $k \subseteq \Gamma(C, \mathcal{O}_C)$ and every idempotent e of $k \otimes_{\mathbb{Z}} \mathcal{O}_K$, acting on H by $c \otimes a \mapsto c\,\rho_H(a)$, the image eH is a vector bundle and $\deg eH = 0$;

(ii) if moreover

(b) H is locally free as a module over $\mathcal{O}_K \otimes_{\mathbb{Z}} \mathcal{O}_C$,

then for every ring homomorphism $\sigma\colon \mathcal{O}_K \to \Gamma(C, \mathcal{O}_C)$ the quotient

$$H_\sigma = H \Big/ \sum_{a \in \mathcal{O}_K} (\rho_H(a) - \sigma(a))H$$

is a vector bundle on C and $\deg H_\sigma = 0$.

Proof. Degrees are taken over κ; recall $\deg W = \deg \det W$ and that deg is additive in short exact sequences of vector bundles.

The twisted algebra. Let $k \subseteq \Gamma(C, \mathcal{O}_C)$ be a finite field, $|k| = p^f$, and let $A = k \otimes_{\mathbb{Z}} \mathcal{O}_K$, a finite commutative k-algebra, and $\varphi = \mathrm{Frob}_k \otimes \mathrm{id}$, a ring automorphism of A with $\varphi^f = \mathrm{id}$. For a vector bundle V with $\mathcal{O}_K$-action, A acts on V by $\rho_V(c \otimes a) = c\,\rho_V(a)$ ($c \in k$ acting as a global function). The maps in (a) are $\mathcal{O}_C$-linear and $\mathcal{O}_K$-equivariant, hence A-equivariant.

Frobenius twist of the action. For V with $\mathcal{O}_K$-action and $y \in A$,

$$\rho_{F^*V}(\varphi(y)) = F^*(\rho_V(y)). \tag{D.11}$$

Both sides are additive in y; for $y = c \otimes a$, F^* of multiplication by the function c is multiplication by c^p, so $F^*(c\rho_V(a)) = c^p F^*(\rho_V(a)) = \rho_{F^*V}(c^p \otimes a)$.

Images of idempotents. For an idempotent $e \in A$ put $eV = \rho_V(e)V$. Then $V = eV \oplus (1-e)V$, so eV is a vector bundle; an A-equivariant exact sequence is the direct sum of its e-part and its $(1-e)$-part, so its e-part $0 \to eV' \to eV \to eV'' \to 0$ is exact. Applying F^* to $V = eV \oplus (1-e)V$ and using (D.11), $F^*(eV) = \varphi(e)F^*V$.

Degree zero of the idempotent parts. For every vector bundle W, $\det F^*W = F^* \det W \cong (\det W)^{\otimes p}$, so $\deg F^*W = p \deg W$. Let $e \in A$ be idempotent; so is $\varphi(e)$. The e-part of the first sequence of (a) and the $\varphi(e)$-part of the second give

$$\deg eH = \deg eM_0 + \deg eM_1, \qquad \deg \varphi(e)H = \deg F^*(eM_1) + \deg F^*(eM_0) = p \deg eH.$$

By induction $\deg \varphi^j(e)H = p^j \deg eH$ for all $j \geq 0$; for $j = f$, $\varphi^f(e) = e$ gives $(p^f - 1)\deg eH = 0$, so

$$\deg eH = 0 \quad \text{for every idempotent } e \in A. \tag{D.12}$$

This is (i).

From the idempotent to the σ-quotient: proof of (ii). The ring $\Gamma(C, \mathcal{O}_C)$ is a field (C is integral and proper over κ), so $\sigma(\mathcal{O}_K) \cong \mathcal{O}_K / \ker \sigma$ is a domain; $p \in \ker \sigma$ and $\mathcal{O}_K/p$ is finite, so $k := \sigma(\mathcal{O}_K)$ is a finite field contained in $\Gamma(C, \mathcal{O}_C)$; take A and φ for this k. Let $\sigma_A\colon A \to k$, $c \otimes a \mapsto c\sigma(a)$, a surjective k-algebra homomorphism with kernel $\mathfrak{m}$, a maximal ideal. Modulo the elements $1 \otimes a - \sigma(a) \otimes 1$ every $c \otimes a$ is congruent to $c\sigma(a) \otimes 1$, so these elements generate $\mathfrak{m}$ and $\mathfrak{m}H = \sum_a (\rho_H(a) - \sigma(a))H$, i.e. $H_\sigma = H/\mathfrak{m}H$. The Artinian ring A is the product of its localisations at its maximal ideals ([12, Theorem 8.7]); let e be the idempotent with $eA \cong A_{\mathfrak{m}}$. Then $1 - e \in \mathfrak{m}$, eA is local with maximal ideal $\mathfrak{n} = e\mathfrak{m}$ and residue field k, and $\mathfrak{n}^N = 0$ for

some N. Put $\mathfrak{n}^0 = eA$. As $(1-e)H = (1-e)^2H \subset \mathfrak{m}H$, we have $\mathfrak{m}H = \mathfrak{n}H \oplus (1-e)H$ and $H_\sigma = eH/\mathfrak{n}H$.

Since $k \subset \Gamma(C, \mathcal{O}_C)$, $\mathcal{O}_K \otimes_{\mathbb{Z}} \mathcal{O}_C = A \otimes_k \mathcal{O}_C$, so by (b) every point of C has an open neighbourhood U with $H|_U \cong (A \otimes_k \mathcal{O}_U)^r$ as $A \otimes_k \mathcal{O}_U$-modules ($r$ is constant as C is connected). Then $\mathfrak{n}^i H|_U \cong (\mathfrak{n}^i \otimes_k \mathcal{O}_U)^r$, since $\mathcal{O}_U$ is flat over k. For $0 \le i < N$ multiplication gives a well-defined $\mathcal{O}_C$-linear map

$$\mu_i \colon (\mathfrak{n}^i/\mathfrak{n}^{i+1}) \otimes_k H_\sigma \to \mathfrak{n}^i H/\mathfrak{n}^{i+1}H$$

(it kills $\mathfrak{n}^i \otimes \mathfrak{n}H$, and for $i \ge 1$ also $\mathfrak{n}^i \otimes (1-e)H$, because $\mathfrak{n}^i(1-e) = 0$), and on U it is the isomorphism $(\mathfrak{n}^i/\mathfrak{n}^{i+1}) \otimes_k \mathcal{O}_U^r \to ((\mathfrak{n}^i/\mathfrak{n}^{i+1}) \otimes_k \mathcal{O}_U)^r$. Hence $H_\sigma|_U \cong \mathcal{O}_U^r$, so H_σ is a vector bundle of rank r, and $eH = \mathfrak{n}^0 H \supset \mathfrak{n}^1 H \supset \cdots \supset \mathfrak{n}^N H = 0$ is a filtration by vector bundles with graded pieces $\mathfrak{n}^i H/\mathfrak{n}^{i+1}H \cong H_\sigma^{\oplus d_i}$, $d_i = \dim_k \mathfrak{n}^i/\mathfrak{n}^{i+1}$. By additivity and (D.12),

$$0 = \deg eH = \Big(\sum_{i<N} d_i\Big) \deg H_\sigma = (\dim_k eA) \deg H_\sigma,$$

and $\dim_k eA \ge 1$, so $\deg H_\sigma = 0$. □

Lemma D.53. *Let $(\mathcal{Y}, j, G_\mathcal{Y}, \iota_\mathcal{Y}, \mathcal{L}_\mathcal{Y})$ be either an integral model of $\mathrm{Sh}_{\mathsf{L}'}$ over $\mathcal{O}_{F',v}$ for an ℓ-adic place v, or a global integral model of Sh over $\mathcal{O}_F$. Then for every point $z \in \mathcal{Y}$ of positive residue characteristic and every algebraically closed field k containing $\kappa(z)$ there are an exact sequence $0 \to T \to G_{\mathcal{Y},k} \xrightarrow{q} B \to 0$ of a torus T and an abelian variety B over k and a line bundle $\mathcal{M}$ on B whose polarisation $\phi_\mathcal{M}$ is an isomorphism, with $\mathcal{L}_\mathcal{Y}|_{G_{\mathcal{Y},k}} \cong q^*\mathcal{M}$.*

Proof. **Local models.** Let $\mathcal{Y}$ be an integral model over $O = \mathcal{O}_{F',v}$ and $z \in \mathcal{Y}$. Put $\mathcal{O} = \mathcal{O}_{\mathcal{Y},z}$, a normal local domain ($\mathcal{Y}$ is normal), essentially of finite type over the excellent ring O, hence excellent; its completion $\widehat{\mathcal{O}}$ is therefore normal, hence a domain, and of characteristic 0 since $\mathcal{O} \subseteq \widehat{\mathcal{O}}$ and $\mathcal{Y}$ is flat over O. By (Gl2) (Lemma 32.13) there is a finite separable extension $k' = \kappa(z)[t]/(f)$ over which $G_{\mathcal{Y},z}$ is an extension of an abelian variety by a split torus. Lift f to a monic $\tilde{f} \in \widehat{\mathcal{O}}[t]$ and put $R = \widehat{\mathcal{O}}[t]/(\tilde{f})$: it is finite étale over $\widehat{\mathcal{O}}$ (the discriminant is a unit), local with residue field k' (f irreducible), complete (finite over a complete local ring), normal (étale over a normal ring), hence a complete noetherian normal local domain of characteristic 0. Let $\xi \colon \operatorname{Spec} R \to \mathcal{Y}$ be the composite map; it sends the closed point to z. Its generic point maps to the generic point of the unique irreducible component of $\mathcal{Y}$ through z (R is flat over $\mathcal{O}$), which lies in $\mathcal{Y} \otimes F'$ (flatness over O) and hence in the dense open $j(\mathrm{Sh}_{\mathsf{L}',F'})$, where $G_\mathcal{Y}$ is abelian by (Ud7). The torus part of $\xi^* G_\mathcal{Y}$ over the residue field k' is split. So (Gl3) (Proposition 32.14) applies: $\xi^*(G_\mathcal{Y}, \iota_\mathcal{Y}, \mathcal{L}_\mathcal{Y})$ is uniformised by degeneration data $(B_R, \mathcal{L}_{B_R}, \iota_B, X, c, \psi)$ over $(R, \mathfrak{m}_R)$, where $\mathcal{L}_{B_R}$ is a line bundle on the abelian scheme B_R defining a principal polarisation. Uniformisation for $e = 0$ identifies $G_{\mathcal{Y},z} \otimes_{\kappa(z)} k'$ with the reduction $\widetilde{G}_{k'}$ of the Raynaud extension, an extension $0 \to T_{k'} \to \widetilde{G}_{k'} \xrightarrow{\pi} B_{k'} \to 0$ of $B_{k'} = B_R \otimes k'$ by the split torus with character group X, and $\mathcal{L}_\mathcal{Y} \otimes k'$ with $\pi^*(\mathcal{L}_{B_R} \otimes k')$. For an algebraically closed $k \supseteq \kappa(z)$ choose a $\kappa(z)$-embedding $k' \to k$ ($k'/\kappa(z)$ is finite separable) and base change: $T = T_k$, $B = B_k$, $q = \pi_k$, $\mathcal{M} = \mathcal{L}_{B_R} \otimes k$, whose polarisation is the base change of an isomorphism, hence an isomorphism.

Global models. Let $\mathcal{Y}$ be global over $\mathcal{O}_F$ and $z \in \mathcal{Y}$ of residue characteristic $\ell > 0$, lying over the prime $\mathfrak{p}$ of $\mathcal{O}_F$. Extending the valuation of $\mathcal{O}_{F,\mathfrak{p}}$ to $\mathbb{C}_\ell$ gives an ℓ-adic place v with $\mathcal{O}_{F,v} = \mathcal{O}_{F,\mathfrak{p}}$, and z is a point of $\mathcal{Y} \otimes \mathcal{O}_{F,v}$. By (Gl9) there are $f \colon \mathcal{Y} \otimes \mathcal{O}_{F,v} \to \mathcal{Y}^v_{\mathsf{L},F}$ and a morphism over f of semiabelian structures, i.e. an isomorphism $G_\mathcal{Y} \otimes \mathcal{O}_{F,v} \cong f^* G_{\mathcal{Y}^v}$ carrying $f^*\mathcal{L}_{\mathcal{Y}^v}$ to $\mathcal{L}_\mathcal{Y}$. A field $k \supseteq \kappa(z)$ contains $\kappa(f(z))$, and the claim at z is the claim at $f(z)$ for the local model $\mathcal{Y}^v_{\mathsf{L},F}$ over $\mathcal{O}_{F,v}$, proved above. □

Lemma D.54. *Let $\mathfrak{u}$ be a unitary Shimura datum, $\tau \in \Phi_{\mathsf{H}}$, $U \subseteq \mathrm{Sh}_F$ a union of connected components and φ a frame function on U which has an archimedean norm N_s at every embedding $s\colon F \to \mathbb{C}$ and an ℓ-adic norm N_κ at every ring homomorphism $\kappa\colon F \to \mathbb{C}_\ell$, for every prime ℓ. Let K be a number field with an embedding $\beta\colon F \to K$, $y \in U(K)$, and suppose that there are a semiabelian scheme $\mathcal{G}$ over $\mathcal{O}_K$ (for instance an abelian scheme) with an action $\iota_{\mathcal{G}}\colon \mathcal{O}_E \to \mathrm{End}(\mathcal{G})$ and an $\mathcal{O}_E$-linear isomorphism of its generic fibre with G_y. For $\pm$ let $\mathcal{L}_\pm = \{x \in \mathrm{Lie}(\mathcal{G}) : \iota_{\mathcal{G}}(a)x = \beta(\sigma_{(\tau,\pm)}(a))x \ \forall a \in \mathcal{O}_E\}$, a projective $\mathcal{O}_K$-module whose generic fibre is $\mathrm{Lie}_{(\tau,\pm)}(G_y)$, with the Hermitian norms $\|x\|_t^2 = h_{y^t}(x,x)$ at every embedding $t\colon K \to \mathbb{C}$ (y^t the complex point induced by t), and $d_\pm = \widehat{\deg}\,\overline{\mathcal{L}}_\pm/[K:\mathbb{Q}]$. Then $N_\kappa = 0$ for all κ above all but finitely many primes ℓ, and*

$$d_+ - d_- = -\frac{1}{[F:\mathbb{Q}]}\Big(\sum_{s\colon F\to\mathbb{C}} N_s + \sum_{\ell} \sum_{\kappa\colon F\to\mathbb{C}_\ell} N_\kappa\Big).$$

Proof. Degrees by local norms. For a projective $\mathcal{O}_K$-module M of rank r with Hermitian norms and a non-zero $e \in \det M \otimes K$, define at a ring homomorphism $j\colon K \to \mathbb{C}_\ell$ with valuation ring $V_j = \{a \in K : |j(a)| \le 1\}$ (a discrete valuation ring, the localisation of $\mathcal{O}_K$ at the prime $\mathfrak{p}_j = \{|j(a)| < 1\}$) the number $\log\|e\|_j = \log|j(c)|$, where $e = c\,e_0$ with e_0 a V_j-basis of $\det M \otimes V_j$ ($c \in K^\times$, well defined as basis changes are units of V_j). The $[K_\mathfrak{p} : \mathbb{Q}_\ell]$ homomorphisms j inducing $\mathfrak{p}$ each give $\log|j(c)| = -v_\mathfrak{p}(c)\log N\mathfrak{p}/[K_\mathfrak{p}:\mathbb{Q}_\ell]$, so the usual formula for the arithmetic degree reads

$$\widehat{\deg}\,\overline{M} = -\sum_{t\colon K\to\mathbb{C}} \log\|e\|_t - \sum_{\ell}\sum_{j\colon K\to\mathbb{C}_\ell} \log\|e\|_j,$$

with finitely many non-zero finite terms, independent of e by the product formula.

Local values of φ. Fix a frame (v,w) at y, v a K-basis of $\mathcal{L}_+ \otimes K = \mathrm{Lie}_{(\tau,+)}(G_y)$ and w of $\mathcal{L}_- \otimes K$, and put $e_+ = v_1 \wedge \cdots \wedge v_p$, $e_- = w_1 \wedge \cdots \wedge w_q$, $x = \varphi(y; v, w) \in K^\times$ (Yf2).

- At $j\colon K \to \mathbb{C}_\ell$, put $\kappa = j \circ \beta$. Base change of $\mathcal{G}$ to V_j is a semiabelian scheme over V_j with $\mathcal{O}_E$-action and generic fibre G_y, and its eigen-submodules of the Lie algebra are $\mathcal{L}_\pm \otimes V_j$ (kernels of finitely many $\mathcal{O}_K$-linear maps $\iota_{\mathcal{G}}(a) - \beta(\sigma_{(\tau,\pm)}(a))$, a in a $\mathbb{Z}$-basis of $\mathcal{O}_E$, commute with the flat base change $\mathcal{O}_K \to V_j$); they are free over the discrete valuation ring V_j. Choose V_j-bases $v' = Av$, $w' = Bw$ ($A \in \mathrm{GL}_p(K)$, $B \in \mathrm{GL}_q(K)$); (v', w') is an integral frame (Yf3), so $\log|j(\varphi(y; v', w'))| = N_\kappa$. By (Yf2), $\varphi(y; v', w')\det A = x \det B$, and $e_+ = (\det A)^{-1}(v_1' \wedge \cdots \wedge v_p')$, so $\log\|e_+\|_j = -\log|j(\det A)|$, $\log\|e_-\|_j = -\log|j(\det B)|$. Hence
$$\log|j(x)| = N_{j\circ\beta} + \log\|e_-\|_j - \log\|e_+\|_j.$$
- At $t\colon K \to \mathbb{C}$, put $s = t \circ \beta$. By (Yf2) applied to t, $t(x) = \varphi(y^t; t_*v, t_*w)$, and by (Yf3), with $\det\Gamma(t_*v) = \|e_+\|_t^2$ and $\det\Gamma(t_*w) = \|e_-\|_t^2$ (Gram determinants for h_{y^t}),
$$\log|t(x)| = N_s + \log\|e_-\|_t - \log\|e_+\|_t.$$

Finiteness. For all but finitely many $\mathfrak{p}$, x is a unit at $\mathfrak{p}$ and v, w are V_j-bases ($A = 1$, $B = 1$ possible), so $N_{j\circ\beta} = \log|j(x)| = 0$; every $\kappa\colon F \to \mathbb{C}_\ell$ is of the form $j \circ \beta$ (extend κ to K, $\mathbb{C}_\ell$ being algebraically closed), and N_κ does not depend on the extension. So $N_\kappa = 0$ above all but finitely many ℓ.

Product formula. Summing over all $t\colon K \to \mathbb{C}$ and all $j\colon K \to \mathbb{C}_\ell$, all ℓ, the left-hand sides add to $\sum_t \log|t(x)| + \sum_\ell \sum_j \log|j(x)| = 0$. Every $s\colon F \to \mathbb{C}$ has exactly $[K : \beta F]$ extensions t,

and every $\kappa\colon F \to \mathbb{C}_\ell$ exactly $[K:\beta F]$ extensions j. With the formula for the degree applied to $\overline{\mathcal{L}}_+$ and $\overline{\mathcal{L}}_-$,

$$0 = [K:\beta F]\Big(\sum_s N_s + \sum_\ell \sum_\kappa N_\kappa\Big) + \widehat{\deg}\,\overline{\mathcal{L}}_+ - \widehat{\deg}\,\overline{\mathcal{L}}_-.$$

Dividing by $[K:\mathbb{Q}] = [K:\beta F][F:\mathbb{Q}]$ gives the claim. □

Lemma D.55. *The notation introduced here is local to this result and to the results that apply it. Let E be a CM field of degree $2f$, L a number field containing the image of every field embedding of E into an algebraic closure of L, and Ψ a set of f ring homomorphisms $\mathcal{O}_E \to \mathcal{O}_L$ such that for every field embedding $e\colon L \to \mathbb{C}$ the set $\{e \circ s :\ s \in \Psi\}$ contains exactly one of $\psi, \bar\psi$ for every embedding $\psi\colon E \to \mathbb{C}$. Let X be a finitely generated torsion-free $\mathcal{O}_E$-module with $r = \dim_E(X \otimes \mathbb{Q}) \geq 1$, put $V = X \otimes_{\mathbb{Z}} L$ and $M = X \otimes_{\mathbb{Z}} \mathcal{O}_L \subseteq V$, with $\mathcal{O}_E$ acting through X, and for a ring homomorphism $s\colon \mathcal{O}_E \to \mathcal{O}_L$ let $V_s = \{v \in V :\ av = s(a)v \text{ for all } a \in \mathcal{O}_E\}$ and $v \mapsto v_s$ the projection of $V = \bigoplus_s V_s$ onto V_s.*

(a) Let $\delta_1, \dots, \delta_r \in X$ be $\mathcal{O}_E$-linearly independent, $k = [X : \sum_a \mathcal{O}_E\delta_a]$, and for every $e\colon L \to \mathbb{C}$ let ν_e be a Hermitian metric on $V \otimes_{L,e} \mathbb{C}$ and $c_e > 0$ with

$$\prod_{s\in\Psi} \det\big(\nu_e((\delta_a)_s, (\delta_b)_s)\big)_{a,b\leq r} = k\,c_e.$$

Then the $\mathcal{O}_L$-modules $K_s = M \cap V_s$ ($s \in \Psi$), with the metrics induced by ν, satisfy

$$\sum_{s\in\Psi} \widehat{\deg}\,(K_s, \nu) \ \leq\ -\frac{1}{2} \sum_{e\colon L\to\mathbb{C}} \log c_e.$$

(b) The quantity $k^{-1}\prod_{s\in\Psi}\det\big(\nu_e((\delta_a)_s,(\delta_b)_s)\big)_{a,b}$ does not depend on the choice of the $\mathcal{O}_E$-linearly independent family $\delta_1, \dots, \delta_r$ in X.

Proof. **The eigen-decomposition.** As L contains the image of every embedding of E, $E \otimes_{\mathbb{Q}} L \cong \prod_s L$ over the $2f$ ring homomorphisms $s\colon \mathcal{O}_E \to \mathcal{O}_L$ (equivalently the field embeddings $E \to L$), so $V = (X \otimes \mathbb{Q}) \otimes_E (E \otimes_{\mathbb{Q}} L) = \bigoplus_s V_s$ with $V_s = X \otimes_{\mathcal{O}_E,s} L$ of dimension r, and the projection $v \mapsto v_s$ maps $x \otimes \lambda$ ($x \in X$, $\lambda \in L$) to $x \otimes_s \lambda$. Since X is finitely generated and torsion-free over the Dedekind ring $\mathcal{O}_E$, it is projective, so $M_s = X \otimes_{\mathcal{O}_E,s} \mathcal{O}_L$ is a projective $\mathcal{O}_L$-module of rank r and maps injectively into $X \otimes_{\mathcal{O}_E,s} L = V_s$; we identify it with its image, which is the image of M under $v \mapsto v_s$.

(a). Fix $s \in \Psi$. If $v \in K_s = M \cap V_s$, then $v = v_s \in M_s$; so $K_s \subseteq M_s$. Since M spans V over L and $M \cap V_s \supseteq \varpi M_s$ for a non-zero integer ϖ annihilating the cokernel of $M \to \bigoplus_s M_s$ (both are lattices in V), K_s has rank r, and with the same metrics

$$\widehat{\deg}\,(K_s, \nu) = \widehat{\deg}\,(M_s, \nu) - \log \#(M_s/K_s) \leq \widehat{\deg}\,(M_s, \nu).$$

Put $X_\delta = \sum_a \mathcal{O}_E\delta_a$, free with basis $\delta_1, \dots, \delta_r$, and $D_s = X_\delta \otimes_{\mathcal{O}_E,s} \mathcal{O}_L = \bigoplus_a \mathcal{O}_L(\delta_a)_s \subseteq M_s$. The ring $\mathcal{O}_L$ is torsion-free, hence flat, over $\mathcal{O}_E$ via s, so $M_s/D_s \cong (X/X_\delta) \otimes_{\mathcal{O}_E,s} \mathcal{O}_L$. The finite $\mathcal{O}_E$-module X/X_δ of order k has a composition series with factors $\mathcal{O}_E/\mathfrak{p}$, and $(\mathcal{O}_E/\mathfrak{p}) \otimes_{\mathcal{O}_E,s} \mathcal{O}_L = \mathcal{O}_L/\mathfrak{p}\mathcal{O}_L$ has order $\mathrm{N}\mathfrak{p}^{[L:s(E)]}$; by flatness the orders multiply, so $\#(M_s/D_s) = k^{[L:E]}$. By the formula for $\widehat{\deg}$ with the basis $(\delta_a)_s$,

$$\widehat{\deg}\,(M_s, \nu) = [L:E]\log k - \frac{1}{2}\sum_e \log\det\big(\nu_e((\delta_a)_s,(\delta_b)_s)\big)_{a,b}.$$

Summing over the f elements of Ψ and using the hypothesis,

$$\sum_{s\in\Psi}\widehat{\deg}\,(K_s,\nu)\le f[L:E]\log k-\frac12\sum_e\bigl(\log k+\log c_e\bigr)=-\frac12\sum_e\log c_e,$$

since $\sum_e 1=[L:\mathbb{Q}]=2f[L:E]$.

(b). Let $\delta'_1,\dots,\delta'_r$ be another $\mathcal{O}_E$-linearly independent family in X, with $k'=[X:X_{\delta'}]$. Both families are E-bases of $X\otimes\mathbb{Q}$, so $\delta'_a=\sum_b A_{ab}\delta_b$ with $A\in\mathrm{GL}_r(E)$, and $(\delta'_a)_s=\sum_b s(A_{ab})(\delta_b)_s$. Hence $\det\bigl(\nu_e((\delta'_a)_s,(\delta'_b)_s)\bigr)=|e(s(\det A))|^2\det\bigl(\nu_e((\delta_a)_s,(\delta_b)_s)\bigr)$, and as $\{e\circ s: s\in\Psi\}$ is a CM type, $\prod_{s\in\Psi}|e(s(\det A))|^2=\prod_\psi|\psi(\det A)|=|\mathrm{N}_{E/\mathbb{Q}}(\det A)|$, the product over all embeddings $\psi\colon E\to\mathbb{C}$. On the other side, $X_{\delta'}$ is the image of X_δ under the E-linear map with matrix A in the basis δ, whose determinant as a $\mathbb{Q}$-linear map is $\mathrm{N}_{E/\mathbb{Q}}(\det A)$; comparing covolumes of the lattices X_δ, $X_{\delta'}$ of $X\otimes\mathbb{R}$, $k'=k\,|\mathrm{N}_{E/\mathbb{Q}}(\det A)|$. The two factors cancel. □

D.3 Positivity and nefness at primes

This section proves nefness at primes (Gi4) for good towers (Theorem D.57), used in the proof of Proposition 31.14 for (Gt2), and the ampleness and vertical nefness of the perturbed bundles of the base settings (Proposition D.56), the last part of Proposition 34.35. At the primes of S_B nefness comes from the full flags of a trivial bundle of Section 35 (Proposition 35.66); at the other primes it comes from a Frobenius slope estimate and a weighted flag inequality for the Lie algebra pulled back to a curve in characteristic p (Proposition D.58, Corollary D.61), which rest on the polarised de Rham module of Section D.2.

Proposition D.56. *Let $\mathfrak{u}$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ,n,p) with its geometric realisation and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Let B be an admissible stage, $Z\in\mathrm{Cp}$, and let a base setting of $\mathcal{T}$ at (B,Z) be given which is joined to the stage root model. Then for all integers $1\le i_1\le i_2$ and every $t>0$ the line bundle $\mathcal{M}_{B,i_1,i_2,t,\mathbb{Q}}$ on $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ is ample, and $\deg(\mathcal{M}_{B,i_1,i_2,t}|_\Gamma)\ge0$ for every closed integral curve $\Gamma\subseteq\mathcal{X}^{\mathrm{b}}$ contained in a fibre of $\mathcal{X}^{\mathrm{b}}\to\operatorname{Spec}\mathbb{Z}$.*

Proof. Write $\mathcal{L}_{\mathcal{X}}=\bigotimes_{\tau\in\Phi}(\det\mathcal{V}^{S_B}_{(\tau,-)})^\vee$ on $\mathcal{X}$ and $\mathcal{L}_{B,Z}=\bigotimes_\tau(\det\mathcal{V}^{B,Z}_{(\tau,-)})^\vee$ on $\mathcal{X}_{B,Z}$, the Hodge bundles at $(S_B,4)$ of the two covers. Since $\mathcal{M}_{B,i_1,i_2,t}=\mathcal{O}(i_2a^{\mathrm{H}}_B+i_1a')|_{\mathcal{X}^{\mathrm{b}}}$ does not depend on t, and $\mathcal{O}(a')$, $a'=(1,\dots,1)$ (Gb6), is very ample on the multiprojective space, hence ample on $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$ and of degree ≥0 on every closed integral curve, it suffices to show: $\deg\mathcal{O}(a^{\mathrm{H}}_B)|_\Gamma\ge0$ for every closed integral curve $\Gamma\subseteq\mathcal{X}^{\mathrm{b}}$ that lies in a fibre over a prime or in $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$. Then $i_2a^{\mathrm{H}}_B$ is nef on the fibres and on $\mathcal{X}^{\mathrm{b}}_{\mathbb{Q}}$, and $\mathcal{M}_{B,i_1,i_2,t,\mathbb{Q}}$, nef plus $i_1\ge1$ times ample, is ample.

Step 1: the cover is the base variety. Every point of $\mathcal{X}$ lies in a chart c', and $\mathcal{X}_{c'}$ is affine with ring $\mathbb{Z}[y]_{c'}$ (Gb1), a quotient of the coordinate ring of the standard affine open $U_{c'}=\{Y_{c'}\ne0\}$ of the multiprojective space; so y is a morphism on $\mathcal{X}$ and $\mathcal{X}_{c'}\to U_{c'}$ is a closed immersion. If $y(x')\in U_{c'}$, the ratios $y_{k,i}/y_{k,c'_k}$ are regular at x', so $x'\in\mathcal{X}_{c'}$; hence $y^{-1}(U_{c'})=\mathcal{X}_{c'}$ and y is an immersion. As $\mathcal{X}$ is proper over $\mathbb{Z}$, it is a closed immersion, and its image is closed, integral and contains the image of the generic point, which is dense in $\mathcal{X}^{\mathrm{b}}$ (y is birational onto $\mathcal{X}^{\mathrm{b}}$); so $y\colon\mathcal{X}\to\mathcal{X}^{\mathrm{b}}$ is an isomorphism, compatible with the fibres over primes and the generic fibres. We identify $\mathcal{X}=\mathcal{X}^{\mathrm{b}}$.

Step 2: the twisted Hodge-type line is $\mathcal{L}_{\mathcal{X}}$. Let x be a point of $\mathcal{X}$, c' a chart and $D(f)\ni x$ as in (Gb3). By (Gb3) the isomorphism of (Hy2) maps the generator $y_{c'}^{a^{\mathrm{H}}}=\prod_k y_{k,c'_k}^{a^{\mathrm{H}}_k}$ of $\mathcal{O}(a^{\mathrm{H}})$ on $D(f)$ to a generator of $\bigotimes_\tau(\det\mathcal{V}_{(\tau,-)})^\vee$ ($\mathcal{V}$ the Hodge bundles at (Bd,R)). Compose with multiplication by $\prod_{\ell\in S'_B}g_\ell^{-1}$, a rational isomorphism $\mathcal{O}(a^{\mathrm{H}}_B)\to\mathcal{O}(a^{\mathrm{H}})$ (S_B of (Hy3) is S'_B here,

(Gb4)). It sends the generator $y_{c'}^{a_B^{\mathrm{H}}} = y_{c'}^{a^{\mathrm{H}}} \prod_\ell y_{c'}^{v_\ell}$ to $y_{c'}^{a^{\mathrm{H}}} \prod_\ell (g_\ell / y_{c'}^{v_\ell})^{-1}$. If x lies over no $\ell \in S'_B$, each $g_\ell / y_{c'}^{v_\ell}$ is a unit at x (its divisor lies over ℓ), and $\mathcal{V}^{S_B}_{(\tau,-),x} = \mathcal{V}_{(\tau,-),x}$; if x lies over $\ell \in S'_B$, then by (Gb4) $g_\ell / y_{c'}^{v_\ell}$ is a unit times $\prod_\tau \det T_\tau$, the others are units, and a generator of $\bigotimes_\tau (\det \mathcal{V}_{(\tau,-),x})^\vee$ times $\prod_\tau (\det T_\tau)^{-1}$ generates $\bigotimes_\tau (\det \mathcal{V}^{S_B}_{(\tau,-),x})^\vee$ ($\mathcal{V}^{S_B}_{(\tau,-),x} = \mathrm{HT}_{(\tau,-),x}(\ell^4)$ has the basis T_τ times a basis of $\mathcal{V}_{(\tau,-),x}$). So the composite rational isomorphism $\mathcal{O}(a_B^{\mathrm{H}})|_{\mathcal{X}} \to \bigotimes_\tau (\det \mathrm{Li}_{(\tau,-)})^\vee$ maps local generators to local generators of $\mathcal{L}_{\mathcal{X}}$ at every point: $\mathcal{O}(a_B^{\mathrm{H}})|_{\mathcal{X}} \cong \mathcal{L}_{\mathcal{X}}$.

Step 3: the root model. On $\mathcal{X}_{B,Z}$ the integral flag of (Go3)(3) gives, for $s = (\tau, -)$, $\det \mathcal{V}_s^{B,Z} \cong \bigotimes_{k=1}^{q} \mathcal{V}_{s,k}^{B,Z} / \mathcal{V}_{s,k-1}^{B,Z}$ (determinants are multiplicative in exact sequences of locally free sheaves), and by (Fh3) the roots (τ, i) with $i > p$ have label $(\tau, -)$, step $n + 1 - i$ and sign -1, so $\bigotimes_{i>p} \mathcal{L}_{(\tau,i)} \cong (\det \mathcal{V}^{B,Z}_{(\tau,-)})^{-1}$. With the root sections, $\mathcal{L}_{B,Z} \cong \mathcal{O}(E_-)|_{\mathcal{X}_{B,Z}}$, $E_- = \sum_\tau \sum_{i>p} e_{(\tau,i)}$. Let μ_- be the weight with $\mu_-(\tau, i) = 0$ for $i \le p$ and -1 for $i > p$: it is dominant, and $\sum_r c(\mu_-, 0)_r e_r = E_-$, $c(\mu_-, 0)_* = 0$.

(a) Vertical curves. Let $W \subseteq \mathcal{X}_{B,Z} \otimes \mathbb{F}_\ell$ be a closed integral curve. If $\ell \le B$ or $\ell \in \mathrm{Bd}$, (Gi4) applies to μ_-; otherwise $\ell > B \ge 4|\Phi| n^2$, so $(\ell - 2)(\mu_-(a, p) - \mu_-(a, p + 1)) = \ell - 2 \ge 4|\Phi| = 4|\Phi| \|\mu_-\|_\infty$ and μ_- is above the nef threshold at ℓ. By Theorem D.57, $c(\mu_-, 0)$ is nef at ℓ: $\deg \mathcal{L}_{B,Z}|_W = \sum_r c(\mu_-, 0)_r \deg \mathcal{O}(e_r)|_W \ge 0$.

(b) Curves of the generic fibre. Let ρ be the weight $\rho(\tau, i) = -i$ and $\nu = \nu_{\mathcal{T}}$. For $0 < \delta \le 1$ and $0 < s \le \delta / (2\|\nu\|_\infty + 1)$ the weight $\lambda = \mu_- + \delta\rho$ has $\|\lambda\|_1 \le A := |\Phi|(q + n^2)$, and $\lambda_s = \lambda - s\nu$ is dominant (consecutive differences $\ge \delta - 2s\|\nu\|_\infty > 0$). By Lemma 31.24 there is $s_0 > 0$, depending on A only, such that $c(\lambda_s, s)$ is semipositive at $t(s)$ on $\mathcal{X}_{B,Z}$ for such $s \le s_0$: the function $\sum_r c(\lambda_s, s)_r \log h_r(t(s))$ is plurisubharmonic along the cone over $\mathcal{X}_{B,Z}(\mathbb{C})$. Let W be a closed integral curve of $\mathcal{X}_{B,Z} \otimes \mathbb{Q}$ and $\widetilde{W}$ the normalisation of $W(\mathbb{C})$; the pull-back to $\widetilde{W}$ of the smooth form $\sum_r c(\lambda_s, s)_r c_1(\mathcal{O}(e_r), h_r(t(s)))$ is semipositive (its local potentials are restrictions of the plurisubharmonic function above along holomorphic maps into the cone with Zariski tangent derivative), so $\sum_r c(\lambda_s, s)_r \deg \mathcal{O}(e_r)|_W \ge 0$. Letting $s \to 0^+$ and then $\delta \to 0^+$, $c(\lambda_s, s) \to c(\mu_-, 0)$ and $\deg \mathcal{L}_{B,Z}|_W \ge 0$.

Step 4: the common cover. The Hodge lattices of $\mathcal{X}$ and of $\mathcal{X}_{B,Z}$ at $(S_B, 4)$ are Hodge bundles (joined; (Go3)(2)), their Hodge–Tate spans have free images in the duals of the Li_s ((Gb1); (Go3)(2)), and $S_B \supseteq \mathrm{Bd}$ contains every prime dividing $\mathrm{disc}(E)$ ((Go5)). By Lemma 31.29(1), applied to ϕ and to ϕ', the Hodge lattices of $\mathcal{X}''$ at $(S_B, 4)$ form Hodge bundles $\mathcal{V}''_s$ with $\phi^* \mathcal{V}_s^{B,Z} \cong \mathcal{V}''_s \cong \phi'^* \mathcal{V}_s^{S_B}$; hence $\phi'^* \mathcal{L}_{\mathcal{X}} \cong \phi^* \mathcal{L}_{B,Z}$.

Step 5: descent. Let $\Gamma \subseteq \mathcal{X}$ be a closed integral curve in the fibre over a prime ℓ or in $\mathcal{X}_{\mathbb{Q}}$. As ϕ' is proper and dominant, it is surjective; a closed point of the generic fibre of $\phi'^{-1}(\Gamma) \to \Gamma$ has a closure $\Gamma'' \subseteq \mathcal{X}''$, a closed integral curve mapping finitely onto Γ, in the same fibre over $\operatorname{Spec} \mathbb{Z}$. By Steps 2 and 4, $[\mathbf{k}(\Gamma'') : \mathbf{k}(\Gamma)] \deg \mathcal{O}(a_B^{\mathrm{H}})|_\Gamma = \deg \phi'^* \mathcal{L}_{\mathcal{X}}|_{\Gamma''} = \deg \phi^* \mathcal{L}_{B,Z}|_{\Gamma''}$. The image $\phi(\Gamma'')$ lies in the corresponding fibre of $\mathcal{X}_{B,Z}$ (ϕ is compatible with the maps to $\mathcal{Y}$) and is a point or a closed integral curve W; in the first case the pull-back of $\mathcal{L}_{B,Z}$ to Γ'' is trivial and the degree is 0, in the second it is $[\mathbf{k}(\Gamma'') : \mathbf{k}(W)] \deg \mathcal{L}_{B,Z}|_W \ge 0$ by Step 3. Hence $\deg \mathcal{O}(a_B^{\mathrm{H}})|_\Gamma \ge 0$, which proves the claim and the proposition. □

Theorem D.57. *Let $\mathfrak{u}$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Then the realised tower has the nefness at primes (Gi4).*

Proof. Fix $B \ge 2$, $c \in \mathrm{Cp}$, a prime ℓ and a dominant weight μ such that $\ell \le B$, or $\ell \in \mathrm{Bd}$, or μ is above the nef threshold at ℓ; let $\mathcal{X} = \mathcal{X}_{B,c}$. By (Go5) the good origin contains a root origin of $\mathcal{X}$ on the fixed data at c, and $\mathcal{X} \subseteq \mathbb{P}$ is projective over $\mathbb{Z}$. We must show

$\sum_r c(\mu,0)_r \deg(\mathcal{O}(e_r)|_W) \geq 0$ for every integral closed curve $W \subseteq \mathcal{X}_{\mathbb{F}_\ell}$.

Case $\ell \notin S_B$. Then $\ell > B$ and $\ell \notin \mathrm{Bd}$, so by hypothesis μ is above the nef threshold at ℓ, i.e. $4|\Phi|\|\mu\|_\infty \leq (\ell-2)(\mu_{a,p} - \mu_{a,p+1})$ for every a (the cut of a tower of type (Φ,n,p) is $\kappa = p$), and Proposition D.58 gives that $c(\mu,0)$ is nef at ℓ.

Case $\ell \in S_B$. Fix $\tau \in \Phi$ and an integral closed curve $W \subseteq \mathcal{X}_{\mathbb{F}_\ell} = \mathcal{X}_\ell$; W is proper over $\mathbb{F}_\ell$. Write $d_i = \deg(\mathcal{O}(e_{(\tau,i)})|_W)$ and $D_k = d_1 + \cdots + d_k$. Let $(\mathcal{U}_{\tau,k})_k$ be the chain of Proposition 35.66 and $\nu\colon \widetilde{W} \to W \hookrightarrow \mathcal{X}_\ell$ the normalisation of W composed with the inclusion. As the quotients $\mathcal{U}_{\tau,k}/\mathcal{U}_{\tau,k-1}$ are locally free, pulling back preserves the exact sequences, so $\nu^*\mathcal{U}_{\tau,k} \subseteq \mathcal{O}_{\widetilde{W}}^n$ is a locally free submodule of rank k with locally free quotient, and $\det \nu^*\mathcal{U}_{\tau,k} \cong \bigotimes_{i\leq k} \nu^*\mathcal{O}(e_{(\tau,i)})$. Since $\nu^*\mathcal{U}_{\tau,k}$ is locally a direct summand of $\mathcal{O}_{\widetilde{W}}^n$, the induced map $\det \nu^*\mathcal{U}_{\tau,k} \to \bigwedge^k \mathcal{O}_{\widetilde{W}}^n \cong \mathcal{O}_{\widetilde{W}}^{\binom{n}{k}}$ is injective, so one of its $\binom{n}{k}$ coordinates is a non-zero map $\det \nu^*\mathcal{U}_{\tau,k} \to \mathcal{O}_{\widetilde{W}}$, i.e. a non-zero global section of $(\det \nu^*\mathcal{U}_{\tau,k})^{-1}$. Hence $-D_k = \deg_{\widetilde{W}}(\det \nu^*\mathcal{U}_{\tau,k})^{-1} \geq 0$, i.e. $D_k \leq 0$ for $1 \leq k \leq n$; for $k = n$, $\det \nu^*\mathcal{U}_{\tau,n} = \det \mathcal{O}_{\widetilde{W}}^n$ is trivial, so $D_n = 0$. As μ is dominant, $\mu_{\tau,k} - \mu_{\tau,k+1} \geq 0$, and by summation by parts

$$\sum_{i=1}^{n} \mu_{\tau,i}\, d_i = \sum_{k=1}^{n-1} (\mu_{\tau,k} - \mu_{\tau,k+1})\, D_k + \mu_{\tau,n} D_n \leq 0.$$

Summing over τ and using $c(\mu,0)_{(\tau,i)} = -\mu_{\tau,i}$, $c(\mu,0)_* = 0$: $\sum_r c(\mu,0)_r \deg(\mathcal{O}(e_r)|_W) = -\sum_\tau \sum_i \mu_{\tau,i} d_i \geq 0$.

In both cases $c(\mu,0)$ is nef at ℓ on $\mathcal{X}_{B,c}$, which is (Gi4). □

Proposition D.58. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ,n,p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,c}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Let $B \geq 2$, $c \in \mathrm{Cp}$, let ℓ be a prime with $\ell \notin S_B$, and let μ be a dominant weight above the nef threshold at ℓ, i.e. $4|\Phi|\,\|\mu\|_\infty \leq (\ell-2)(\mu_{a,p} - \mu_{a,p+1})$ for every $a \in \Phi$. Then $c(\mu,0)$ is nef at ℓ on $\mathcal{X}_{B,c}$.*

Proof. Write $\mathcal{X} = \mathcal{X}_{B,c}$, $n = p+q$, and let $\ell \notin S_B$ and μ be as in the statement. By definition we must show $\sum_{r \in \mathrm{Rt}^+} c(\mu,0)_r \deg(\mathcal{O}(e_r)|_W) \geq 0$ for every integral closed curve $W \subseteq \mathcal{X}_{\mathbb{F}_\ell}$; as $c(\mu,0)_* = 0$ and $c(\mu,0)_{a,i} = -\mu_{a,i}$, this is

$$\sum_{\tau \in \Phi} \sum_{i=1}^{n} \mu_{\tau,i} \deg(\mathcal{O}(e_{(\tau,i)})|_W) \leq 0. \tag{D.13}$$

The setting at ℓ. The good origin contains a tower origin, so Bd is the set of primes dividing $2\,\mathrm{disc}(E)\,N'$ (Go5) and $\mathrm{Bd} \subseteq S_B$; hence $\ell > 2$, and every prime dividing $\mathrm{disc}(E)$ lies in S_B. The scheme $\mathcal{X} \subseteq \mathbb{P}$ is projective over $\mathbb{Z}$, so W is projective over $\mathbb{F}_\ell$; let $\nu\colon C \to \mathcal{X}$ be its normalisation composed with the inclusion, an integral normal projective curve over a finite field, and recall $\deg(\mathcal{N}|_W) = \deg \nu^*\mathcal{N}$ for a line bundle $\mathcal{N}$. By (Go3)(3) the root line $\mathcal{L}_r$ of the integral flag of the Hodge bundles is isomorphic to $\mathcal{O}(e_r)|_{\mathcal{X}}$, so $\deg(\mathcal{O}(e_r)|_W) = \deg \nu^*\mathcal{L}_r$.

The tie. Lemma D.59 applies ($\mathcal{X}$ carries a root origin, $\ell \notin S_B$, the primes dividing $\mathrm{disc}(E)$ lie in S_B). It gives a finite field $k \subseteq \Gamma(C, \mathcal{O}_C)$ with $k \otimes \mathcal{O}_E \cong k^\Sigma$, the bijection $s \mapsto \tilde{\sigma}_s$ from the labels onto Σ, and with $L = \mathrm{Lie}(G_C) = \nu^*\mathrm{Lie}(G_{\mathcal{X}})$: $\nu^*\mathcal{V}_s = L_{\tilde{\sigma}_s}$ and full flags $W_{\tau,i} = \nu^*\mathcal{V}_{(\tau,+),i}$ $(0 \leq i \leq p)$ of $L_{\tilde{\sigma}_{(\tau,+)}}$ and $V_{\tau,i} = \nu^*\mathcal{V}_{(\tau,-),i}$ $(0 \leq i \leq q)$ of $L_{\tilde{\sigma}_{(\tau,-)}}$, with, by (Fh3),

$$\deg \nu^*\mathcal{L}_{(\tau,i)} = \deg W_{\tau,i} - \deg W_{\tau,i-1}\ (i \leq p), \qquad \deg \nu^*\mathcal{L}_{(\tau,i)} = -\big(\deg V_{\tau,n+1-i} - \deg V_{\tau,n-i}\big)\ (i > p).$$

Put $T = \{\tilde{\sigma}_{(\tau,+)} : \tau \in \Phi\}$; since $\tilde{\sigma}_{(\tau,-)} = \tilde{\sigma}_{(\tau,+)} \circ {}^-$, $\Sigma = T \sqcup \bar{T}$ and $|T| = |\Phi|$.

The weighted flag inequality. The scheme $\mathcal{X}$ is normal, integral and noetherian, and $(G_{\mathcal{X}}, \iota_{\mathcal{X}}, \mathcal{L}_{\mathcal{X}})$, pulled back from $\mathcal{Y}$, is a semiabelian structure whose generic fibre is abelian (the generic point of $\mathcal{X}$ maps into $j(\mathrm{Sh}_F)$, where $G_{\mathcal{Y}}$ is abelian, (Ud7)); it satisfies (PF) by Lemma D.60. So Corollary D.61 applies to $\nu\colon C \to \mathcal{X}$ with the prime $\ell > 2$: the weighted flag inequality (ii) of Lemma D.63 holds for L, with $j = p$, $q = q$, the subsheaves $W_{\tau,i}$, $V_{\tau,i}$ above (indexed by $\tilde\sigma_{(\tau,+)} \in T$; $W_{\tau,0} = V_{\tau,0} = 0$, $W_{\tau,p} = L_{\tilde\sigma_{(\tau,+)}}$, $V_{\tau,q} = L_{\overline{\tilde\sigma_{(\tau,+)}}}$), the weights $\mu_{\tau,1} \geq \cdots \geq \mu_{\tau,n}$ (μ is dominant), $M = \|\mu\|_\infty$ and $g = \min_\tau(\mu_{\tau,p} - \mu_{\tau,p+1})$: the threshold of the lemma, $4|T|M \leq (\ell-2)g$, is the hypothesis $4|\Phi|\,\|\mu\|_\infty \leq (\ell-2)(\mu_{a,p} - \mu_{a,p+1})$ for every a. The inequality reads

$$\sum_{\tau\in\Phi}\Big(\sum_{i=1}^{p}\mu_{\tau,i}(\deg W_{\tau,i} - \deg W_{\tau,i-1}) + \sum_{i'=1}^{q}\mu_{\tau,n+1-i'}\big(\deg V_{\tau,i'-1} - \deg V_{\tau,i'}\big)\Big) \leq 0.$$

With $i = n+1-i'$ the second inner sum is

$$\sum_{i=p+1}^{n}\mu_{\tau,i}(\deg V_{\tau,n-i} - \deg V_{\tau,n+1-i}) = \sum_{i>p}\mu_{\tau,i}\deg\nu^*\mathcal{L}_{(\tau,i)},$$

and the first is $\sum_{i\leq p}\mu_{\tau,i}\deg\nu^*\mathcal{L}_{(\tau,i)}$. So the left side is the left side of (D.13), which is therefore ≤ 0: $c(\mu,0)$ is nef at ℓ on $\mathcal{X}$. □

Lemma D.59. *Let* $\mathfrak{u}$, $\mathcal{Y}$, *a root tower* $\mathcal{T}$ *with geometric realisation,* $B \geq 2$ *and* $c \in \mathrm{Cp}$ *be such that* $\mathcal{X} = \mathcal{X}_{B,c}$ *carries a root origin (Go3), with Hodge bundles* $\mathcal{V}_s$ *at* (S_B, R), *an integral flag* $(\mathcal{V}_{s,j})_j$ *of them and root lines* $\mathcal{L}_r$; *suppose every prime dividing* $\mathrm{disc}(E)$ *lies in* S_B. *Let* $\ell \notin S_B$ *be a prime,* $W \subseteq \mathcal{X} \otimes \mathbb{F}_\ell$ *an integral closed subscheme of dimension one, proper over a field,* $\nu\colon C \to \mathcal{X}$ *the normalisation of* W *composed with the inclusion,* $G_C = \nu^*G_{\mathcal{X}}$ *with its* $\mathcal{O}_E$*-action and* $\mathrm{Lie}(G_C)$. *Then:*

(i) W *lies over one closed point* v *of* $\mathrm{Spec}\,\mathcal{O}_F$, *and* $k = \kappa(v) \subseteq \Gamma(C,\mathcal{O}_C)$; *with* $\Sigma = \mathrm{Hom}(\mathcal{O}_E, k)$, *the map* $k \otimes_{\mathbb{Z}} \mathcal{O}_E \to k^\Sigma$, $\lambda\otimes a \mapsto (\lambda\, t(a))_t$, *is bijective, and* $s \mapsto \tilde\sigma_s = (\sigma_s \bmod v)$ *is a bijection from the labels onto* Σ *with* $\tilde\sigma_{(\tau,-)} = \tilde\sigma_{(\tau,+)} \circ {}^-$;

(ii) for every label s, $\nu^*\mathcal{V}_s = e_{\tilde\sigma_s}\mathrm{Lie}(G_C)$ *as subbundles of* $\mathrm{Lie}(G_C)$, *where* $e_t \in k\otimes\mathcal{O}_E$ *is the idempotent of* $t \in \Sigma$;

(iii) $(\nu^*\mathcal{V}_{s,j})_j$ *is a full flag of* $e_{\tilde\sigma_s}\mathrm{Lie}(G_C)$, *and for every root* r,

$$\nu^*\mathcal{L}_r = \big(\nu^*\mathcal{V}_{s(r),\mathrm{st}(r)}/\nu^*\mathcal{V}_{s(r),\mathrm{st}(r)-1}\big)^{\otimes \mathrm{sg}(r)}.$$

Proof. **(i).** The image of W in $\mathrm{Spec}\,\mathcal{O}_F$ is irreducible and lies in the finite fibre over ℓ, so it is one closed point v; the structure map gives $\kappa(v) \to \Gamma(W,\mathcal{O}_W) \to \Gamma(C,\mathcal{O}_C)$. Let $\omega_1,\dots,\omega_d$ be a $\mathbb{Z}$-basis of $\mathcal{O}_E$, $d = [E:\mathbb{Q}]$. The labels s give the d embeddings $\sigma_s\colon E \to F$ (Fh1), and $\det(\sigma_s(\omega_i))^2 = \mathrm{disc}(E)$, which is prime to ℓ (every prime dividing it is in S_B) and hence a unit in $\mathcal{O}_{F,v}$. Reducing modulo v, the matrix $(\tilde\sigma_s(\omega_i))$ is invertible over k; so the $\tilde\sigma_s$ are pairwise distinct (d distinct elements of Σ, which has at most $\dim_k(k\otimes\mathcal{O}_E) = d$ elements: a bijection), and $k\otimes\mathcal{O}_E \to k^\Sigma$ is a k-linear map between d-dimensional spaces with invertible matrix in the bases $(1\otimes\omega_i)$ and the unit vectors, hence bijective. Finally, $\sigma_{(\tau,-)} = \bar\tau = \tau\circ{}^-$ by (Fh1).

The idempotents at points over ℓ. Let $x \in \mathcal{X}$ lie over ℓ. Its residue field has characteristic ℓ, so $\operatorname{disc}(E)$ is a unit in $\mathcal{O}_x \supseteq \mathcal{O}_F$, and by the same determinant $\mathcal{O}_E \otimes \mathcal{O}_x \to \prod_s \mathcal{O}_x$, $a \otimes b \mapsto (\sigma_s(a)b)_s$, is an isomorphism; let $e_s \in \mathcal{O}_E \otimes \mathcal{O}_x$ be its idempotents. On $\mathrm{Li} = \mathrm{Lie}(G_{\mathcal{X},\Omega})$, e_s is the projection onto Li_s. As $G_{\mathcal{X}}$ is smooth, $\mathrm{Lie}(G_{\mathcal{X}})$ is locally free and $\mathcal{X}$ integral, so $\mathrm{Lie}(G_{\mathcal{X}})_x \to \mathrm{Li}$ is injective with image Lie_x; it is an $\mathcal{O}_E \otimes \mathcal{O}_x$-module, so $\mathrm{Lie}_x = \bigoplus_s e_s\mathrm{Lie}_x$ and $e_s\mathrm{Lie}_x = \mathrm{Lie}_x \cap \mathrm{Li}_s = \mathrm{dR}_{s,x}$ (if $y \in \mathrm{Lie}_x \cap \mathrm{Li}_s$ then $y = e_s y$). As $\ell \notin S_B$, the Hodge lattice at x is $V_{s,x}^{S_B} = \mathrm{dR}_{s,x}$ (Fh5). Hence the stalks at x of the coherent subsheaves $\mathcal{V}_s$ and $e_s\mathrm{Lie}(G_{\mathcal{X}})$ of the constant sheaf Li_s coincide (the latter is defined on the open set where $\operatorname{disc}(E)$ is invertible); finitely many local generators of each lie in the other at x, hence on a neighbourhood of x. So $\mathcal{V}_s = e_s\mathrm{Lie}(G_{\mathcal{X}})$ on an open set $U \supseteq \mathcal{X} \otimes \mathbb{F}_\ell$.

(ii). The morphism ν factors through U. The formation of Lie of a smooth group scheme commutes with base change, so $\nu^*\mathrm{Lie}(G_{\mathcal{X}}) = \mathrm{Lie}(G_C)$ compatibly with $\mathcal{O}_E$, and e_s maps to the idempotent of $k \otimes \mathcal{O}_E$ whose $\tilde{\sigma}_{s'}$-component is the reduction of $\delta_{ss'}$, i.e. to $e_{\tilde{\sigma}_s}$. Pulling back the decomposition $\mathrm{Lie}(G_{\mathcal{X}})|_U = \bigoplus_s e_s\mathrm{Lie}(G_{\mathcal{X}})|_U$ gives $\nu^*\mathcal{V}_s = \nu^*(e_s\mathrm{Lie}(G_{\mathcal{X}})) = e_{\tilde{\sigma}_s}\mathrm{Lie}(G_C)$, a direct summand.

(iii). An integral flag is a chain of locally free submodules with invertible step quotients (Fh2), i.e. of subbundles; pull-back preserves the exact sequences

$$0 \to \mathcal{V}_{s,j-1} \to \mathcal{V}_{s,j} \to \mathcal{V}_{s,j}/\mathcal{V}_{s,j-1} \to 0$$

of vector bundles, so $(\nu^*\mathcal{V}_{s,j})_j$ is a full flag of $\nu^*\mathcal{V}_s$ with step quotients $\nu^*(\mathcal{V}_{s,j}/\mathcal{V}_{s,j-1})$, and ν^* commutes with tensor powers and duals of line bundles; this is the formula for $\nu^*\mathcal{L}_r$ by (Fh3). □

Lemma D.60. *Let $\mathcal{Y}$ be an integral model of* Sh *over $\mathcal{O}_F$ with uniformised degenerations and $f\colon \mathcal{X} \to \mathcal{Y}$ a cover, with the pulled-back semiabelian structure $(G_{\mathcal{X}}, \iota_{\mathcal{X}}, \mathcal{L}_{\mathcal{X}})$. Then for every point $z \in \mathcal{X}$ of positive residue characteristic and every algebraically closed field $k \supseteq \kappa(z)$ there are an exact sequence $0 \to T \to G_{\mathcal{X},k} \xrightarrow{q} B \to 0$ of a torus T and an abelian variety B over k and a line bundle $\mathcal{M}$ on B whose polarisation $\phi_{\mathcal{M}}$ is an isomorphism, with $\mathcal{L}_{\mathcal{X}}|_{G_{\mathcal{X},k}} \cong q^*\mathcal{M}$.*

Proof. Let $z \in \mathcal{X}$ have residue characteristic $\ell > 0$ and let $k \supseteq \kappa(z)$ be algebraically closed. Then $y = f(z) \in \mathcal{Y}$ has residue characteristic ℓ and $\kappa(y) \subseteq \kappa(z) \subseteq k$; let $\mathfrak{p}$ be the prime of $\mathcal{O}_F$ below y. Extending the valuation of $\mathcal{O}_{F,\mathfrak{p}}$ to $\mathbb{C}_\ell$ gives an ℓ-adic place v with $\mathcal{O}_{F,v} = \mathcal{O}_{F,\mathfrak{p}}$, and y is a point of $\mathcal{Y} \otimes_{\mathcal{O}_F} \mathcal{O}_{F,v}$. By (Ug1) there is an integral model $\mathcal{Y}^v$ of Sh over $\mathcal{O}_{F,v}$, and by (Ug2) a morphism $f_v\colon \mathcal{Y} \otimes \mathcal{O}_{F,v} \to \mathcal{Y}^v$ with a morphism over f_v of semiabelian structures, i.e. an isomorphism $G_{\mathcal{Y}} \otimes \mathcal{O}_{F,v} \cong f_v^*G_{\mathcal{Y}^v}$ compatible with the $\mathcal{O}_E$-actions and carrying $f_v^*\mathcal{L}_{\mathcal{Y}^v}$ to $\mathcal{L}_{\mathcal{Y}}$. The point $f_v(y)$ has residue characteristic ℓ and $\kappa(f_v(y)) \subseteq \kappa(y) \subseteq k$, so the local case of Lemma D.53 (an integral model over $\mathcal{O}_{F,v}$, with $F' = F$ and $\mathsf{L}' = \mathsf{L}$) gives $0 \to T \to G_{\mathcal{Y}^v,k} \xrightarrow{q} B \to 0$ and $\mathcal{M}$ with $\phi_{\mathcal{M}}$ an isomorphism and $\mathcal{L}_{\mathcal{Y}^v}|_{G_{\mathcal{Y}^v,k}} \cong q^*\mathcal{M}$. The fibres over k satisfy $G_{\mathcal{X},k} = G_{\mathcal{Y},k} \cong G_{\mathcal{Y}^v,k}$ (base change along $\operatorname{Spec} k \to \mathcal{X} \to \mathcal{Y} \to \mathcal{Y}^v$) with $\mathcal{L}_{\mathcal{X}}|_{G_{\mathcal{X},k}} \cong \mathcal{L}_{\mathcal{Y}^v}|_{G_{\mathcal{Y}^v,k}}$; transporting T, q and $\mathcal{M}$ along this isomorphism gives the claim. □

Corollary D.61. *Let E be a CM field, $\mathcal{X}$ a normal integral noetherian scheme and $(G, \iota, \mathcal{L})$ a semiabelian structure over $\mathcal{X}$ with abelian generic fibre satisfying (PF). Let $p > 2$ be a prime, κ a field of characteristic p, C an integral normal projective curve over κ, $c\colon C \to \mathcal{X}$ a morphism, and $L = c^*\mathrm{Lie}(G)$ with $\rho_L(a) = c^*\mathrm{Lie}(\iota(a))$. Then the degrees of the subsheaves of L have a maximum $P \geq 0$ with $(p-2)P \leq -\deg L$, and for every finite field $k \subseteq \Gamma(C, \mathcal{O}_C)$ and every T as in Lemma D.63 (with $K = E$ and complex conjugation as involution), $\deg L_\tau = \deg L_{\bar{\tau}}$ for $\tau \in T$ and the weighted flag inequality (ii) of Lemma D.63 holds for L.*

Proof. By (i) and (ii) of Corollary D.42, applied to c, the bundles L, $L^\vee = c^*\omega_G$ (with a acting by $\rho_L(\bar a)^\vee$) and $H = c^*\mathrm{H}^\natural(G,\mathcal{L})$ (with $c^*\rho^\natural$) form $\mathcal{O}_E$-equivariant exact sequences $0 \to L^\vee \to H \to L \to 0$ and $0 \to F^*L \xrightarrow{\alpha} H \to F^*(L^\vee) \to 0$, the outer terms of the second carrying F^* of the actions on L and $L^\vee$. The first sequence and the injective map α are (a), (b) of Lemma D.62, which gives $P \geq 0$ and $(p-2)P \leq \deg L^\vee = -\deg L$. The two sequences are the hypotheses of Lemma D.63 with $K = E$, which gives $\deg L_\tau = \deg L_{\bar\tau}$ and the weighted flag inequality. □

Lemma D.62. *Let $p > 2$ be a prime, κ a field of characteristic p, C an integral normal projective curve over κ with absolute Frobenius $F\colon C \to C$, and L, H vector bundles on C. Suppose that*

(a) there is an exact sequence of $\mathcal{O}_C$-modules

$$0 \to L^\vee \to H \to L \to 0,$$

where $L^\vee = \mathcal{H}om_{\mathcal{O}_C}(L, \mathcal{O}_C)$;

(b) there is an $\mathcal{O}_C$-linear map $\alpha\colon F^*L \to H$ which is injective at the generic point of C.

Then the degrees of the subsheaves of L have a maximum $P \geq 0$, and

$$(p-2)\,P \leq \deg L^\vee.$$

In particular $\deg L^\vee \geq 0$, and $(p-2)\deg U \leq \deg L^\vee$ for every subsheaf $U \subseteq L$.

Proof. Degrees are over κ. The degrees of the subsheaves of a vector bundle on C are bounded above (existence of the Harder–Narasimhan filtration), and the zero subsheaf has degree 0; let $P \geq 0$ be the maximum and $U_0 \subseteq L$ a subsheaf with $\deg U_0 = P$. Its saturation contains it with torsion quotient, so has degree $\geq P$; hence we may take U_0 saturated, i.e. L/U_0 locally free and U_0 locally a direct summand of L.

The Frobenius image. As U_0 is locally a direct summand, $F^*U_0 \to F^*L$ is injective, and $\deg F^*U_0 = \deg\det F^*U_0 = \deg(\det U_0)^{\otimes p} = pP$. The composite $F^*U_0 \to F^*L \xrightarrow{\alpha} H$ is injective at the generic point by (b), hence injective (its kernel is a torsion subsheaf of the vector bundle F^*U_0). Let $V \subseteq H$ be its image; $V \cong F^*U_0$, so $\deg V = pP$.

Splitting V along (a). Let $V_1 = V \cap L^\vee$ and $V_2 \subseteq L$ the image of V in L; then $0 \to V_1 \to V \to V_2 \to 0$ is exact, so $\deg V = \deg V_1 + \deg V_2$, and $\deg V_2 \leq P$ by the choice of P. Let V_1' be the saturation of V_1 in $L^\vee$ and $Q = L^\vee/V_1'$, a vector bundle. Dualising $L^\vee \to Q \to 0$ gives an injection $Q^\vee \to L^{\vee\vee} = L$, so $-\deg Q = \deg Q^\vee \leq P$, and

$$\deg V_1 \leq \deg V_1' = \deg L^\vee - \deg Q \leq \deg L^\vee + P.$$

Conclusion. $pP = \deg V \leq \deg L^\vee + 2P$, i.e. $(p-2)P \leq \deg L^\vee$. As $p > 2$ and $P \geq 0$, $\deg L^\vee \geq 0$, and for a subsheaf $U \subseteq L$, $(p-2)\deg U \leq (p-2)P \leq \deg L^\vee$. □

Lemma D.63. *Let $p > 2$ be a prime, κ a field of characteristic p, C an integral normal projective curve over κ with absolute Frobenius F, K a number field with ring of integers $\mathcal{O}_K$ and a ring involution $a \mapsto \bar a$ of $\mathcal{O}_K$. Let L and H be vector bundles on C with $\mathcal{O}_K$-actions ρ_L, ρ_H; let $\mathcal{O}_K$ act on $L^\vee$ by $a \mapsto \rho_L(\bar a)^\vee$. Suppose there are $\mathcal{O}_K$-equivariant exact sequences*

$$0 \to L^\vee \to H \to L \to 0, \qquad 0 \to F^*L \to H \to F^*(L^\vee) \to 0.$$

Let $k \subseteq \Gamma(C, \mathcal{O}_C)$ be a finite field such that, with Σ the set of ring homomorphisms $\mathcal{O}_K \to k$, the map $k \otimes_{\mathbb{Z}} \mathcal{O}_K \to k^\Sigma$, $c \otimes a \mapsto (c\,s(a))_s$, is bijective; for $s \in \Sigma$ let $e_s \in k \otimes \mathcal{O}_K$ be the idempotent mapping to the s-th unit vector, $L_s = e_s L$ (acting by $c \otimes a \mapsto c\rho_L(a)$) and $\bar s = s \circ {}^-$. Let $T \subseteq \Sigma$ with $\Sigma = T \sqcup \{\bar\tau : \tau \in T\}$.

(i) $\deg L_\tau = \deg L_{\bar\tau}$ *for every* $\tau \in T$.

(ii) Let $j, q \geq 1$*; for each* $\tau \in T$ *let* $W_{\tau,0}, \dots, W_{\tau,j}$ *and* $V_{\tau,0}, \dots, V_{\tau,q}$ *be subsheaves of* L *with* $W_{\tau,0} = V_{\tau,0} = 0$*,* $W_{\tau,j} = L_\tau$*,* $V_{\tau,q} = L_{\bar\tau}$*, and let* $\mu_{\tau,1} \geq \mu_{\tau,2} \geq \cdots \geq \mu_{\tau,j+q}$ *be real numbers. Let* $M, g \in \mathbb{R}$ *with* $|\mu_{\tau,i}| \leq M$ *and* $g \leq \mu_{\tau,j} - \mu_{\tau,j+1}$ *for all* τ, i*, and*

$$4\,|T|\,M \leq (p-2)\,g.$$

Then

$$\sum_{\tau\in T}\Big(\sum_{i=1}^{j}\mu_{\tau,i}\big(\deg W_{\tau,i} - \deg W_{\tau,i-1}\big) + \sum_{i=1}^{q}\mu_{\tau,j+q+1-i}\big(\deg V_{\tau,i-1} - \deg V_{\tau,i}\big)\Big) \leq 0.$$

Proof. Write $A = k\otimes_{\mathbb{Z}}\mathcal{O}_K \cong k^{\Sigma}$; for a vector bundle V with $\mathcal{O}_K$-action, A acts by $c\otimes a \mapsto c\rho_V(a)$, $V = \bigoplus_s e_s V$, and the e_s-part of an equivariant exact sequence is exact.

The pieces of $L^\vee$. Since $a \mapsto \bar a$ is an involution, $(1\otimes{}^-)(e_s) = e_{\bar s}$: for $s' \in \Sigma$, $s'_A((1\otimes{}^-)e_s) = (s'\circ{}^-)_A(e_s)$ is 1 if $s'\circ{}^- = s$, i.e. $s' = \bar s$, and 0 otherwise. The action of $c\otimes a$ on $L^\vee$ is $c\rho_L(\bar a)^\vee = \rho_L(c\otimes\bar a)^\vee$, so e_s acts on $L^\vee$ as $\rho_L(e_{\bar s})^\vee$, whose image is $(e_{\bar s}L)^\vee = L^\vee_{\bar s}$ (dualise $L = e_{\bar s}L \oplus (1-e_{\bar s})L$).

(i). The sequences of the statement are (a) of Lemma D.52 with $M_0 = L^\vee$, $M_1 = L$, so $\deg e_\tau H = 0$ by (i) there. The e_τ-part of the first sequence is $0 \to L^\vee_{\bar\tau} \to e_\tau H \to L_\tau \to 0$, hence $0 = -\deg L_{\bar\tau} + \deg L_\tau$.

The slope bound. The first sequence is (a) of Lemma D.62, and the first map of the second sequence is an injective $\mathcal{O}_C$-linear map $F^*L \to H$, which is (b) there. So the degrees of subsheaves of L have a maximum $P \geq 0$ and

$$(p-2)P \leq \deg L^\vee = -\deg L. \tag{D.14}$$

By (i), with $D_\tau = \deg L_\tau$, $\deg L = \sum_{s\in\Sigma}\deg L_s = \sum_{\tau\in T}(\deg L_\tau + \deg L_{\bar\tau}) = 2\sum_\tau D_\tau$.

(ii): Abel summation for one τ. If $T = \emptyset$ there is nothing to prove; otherwise $M \geq |\mu_{\tau,1}| \geq 0$, so $(p-2)g \geq 4|T|M \geq 0$ and $g \geq 0$. Fix τ; write $\mu_i = \mu_{\tau,i}$, $w_i = \deg W_{\tau,i}$, $v_i = \deg V_{\tau,i}$, so $w_0 = v_0 = 0$, $w_j = D_\tau$, $v_q = \deg L_{\bar\tau} = D_\tau$ by (i), and $w_i, v_i \leq P$. Summation by parts gives

$$\sum_{i=1}^{j}\mu_i(w_i - w_{i-1}) = \mu_j D_\tau + \sum_{i=1}^{j-1}(\mu_i - \mu_{i+1})w_i \leq \mu_j D_\tau + (\mu_1 - \mu_j)P,$$

and, with $\nu_i = \mu_{j+q+1-i}$ (so $\nu_1 \leq \cdots \leq \nu_q = \mu_{j+1}$),

$$\sum_{i=1}^{q}\nu_i(v_{i-1} - v_i) = -\nu_q D_\tau + \sum_{i=1}^{q-1}(\nu_{i+1} - \nu_i)v_i \leq -\mu_{j+1}D_\tau + (\mu_{j+1} - \mu_{j+q})P,$$

since all the coefficients $\mu_i - \mu_{i+1}$, $\nu_{i+1} - \nu_i$ are ≥ 0. Let $G = \mu_j - \mu_{j+1} \geq g$ and S_τ the sum of the two left sides. Then

$$S_\tau \leq GD_\tau + (\mu_1 - \mu_{j+q} - G)P = gD_\tau + (G-g)(D_\tau - P) + (\mu_1 - \mu_{j+q} - g)P \leq gD_\tau + 2MP,$$

because $(G-g) \geq 0$ and $D_\tau - P \leq 0$ (L_τ is a subsheaf of L), $\mu_1 - \mu_{j+q} \leq 2M$, and $gP \geq 0$.

(ii): summing over τ. By the last two displays and (D.14),

$$\begin{aligned}\sum_{\tau\in T} S_\tau &\leq g\sum_\tau D_\tau + 2|T|MP = -\tfrac{g}{2}\deg L^\vee + \tfrac{1}{2}\,(4|T|M)\,P\\ &\leq -\tfrac{g}{2}\deg L^\vee + \tfrac{1}{2}(p-2)gP \leq -\tfrac{g}{2}\deg L^\vee + \tfrac{g}{2}\deg L^\vee = 0,\end{aligned}$$

using $4|T|M \leq (p-2)g$, $P \geq 0$ and $g \geq 0$. The constant 4 is $2\cdot 2$: one factor 2 from $\deg L = 2\sum_\tau D_\tau$, one from the two boundary terms μ_1 and μ_{j+q} of the Abel summation. □

D.4 Flat determinants, square systems and covolumes

This section proves four statements used in Part VI. Three are facts of good towers in Proposition 34.2: the base determinant heights are flat heights of flat generators up to bad-prime terms (Proposition D.65, Subsection D.4.1), which gives (Db); good towers have proportional analytic square systems (Proposition D.73); and they have geometric proportionality with covolumes (Vp) (Proposition D.79, Subsection D.4.2). The fourth is the fibre-square identities (Fq1) (Theorem D.85, Subsection D.4.3), used in the proof of Proposition 31.14 for (Gt4). (Vp) is the place where covolumes enter the volumes of the towers: the geometric intersection numbers of the root models are sums of covolumes of principal congruence subgroups of lattices in one genus, times flag degrees.

D.4.1 Base determinant heights as flat heights

Proposition D.65 follows from flat determinant lines on the stage-two root models, whose heights split into a flat height and local terms (Proposition D.66). The flat height is computed by Theorem 34.20; the local terms are controlled because the flat generator has constant order along the fibre over every prime of the constant field (Proposition D.67), and its order at a point over a prime is compared with its ℓ-adic norm (Proposition D.69). The comparison uses the Hodge–Tate sandwich of Section 35, and the vertical orders use the full flags of a trivial bundle from the same section.

Definition D.64. Let $\mathcal{X} \subseteq \mathbb{P}$ be a root model of type (Φ, n), and write $\widehat{\mathcal{X}} \subseteq \widehat{\mathbb{C}}$ for the affine cone over $\mathcal{X}(\mathbb{C})$. For a cone metric h of multidegree e, $c_1(h)$ denotes the first Chern form of the Hermitian line $(\mathcal{O}(e), h)|_{\mathcal{X}}$ on $\mathcal{X}(\mathbb{C})$ (for $h = h_r(t)$: $c_1(\overline{\mathcal{L}}_r(t))$).

(Dl1) Flat lines. Let $e_A \in \mathbb{Z}^K$, let h_A be a cone metric of multidegree e_A, and put $\overline{\mathcal{A}} = (\mathcal{O}(e_A), h_A)|_{\mathcal{X}}$. Let F be a number field. The line $\overline{\mathcal{A}}$ is **flat over** F if the structure morphism $\mathcal{X} \to \operatorname{Spec}\mathbb{Z}$ factors through $\operatorname{Spec}\mathcal{O}_F$, and there are an integer $M \geq 1$, multihomogeneous polynomials f, g with integer coefficients, of multidegrees d_f, d_g with $d_f - d_g = Me_A$, neither vanishing identically on $\mathcal{X}$, such that the rational section f/g of $\mathcal{O}(Me_A)|_{\mathcal{X}}$ generates $\mathcal{O}(Me_A)|_{\mathcal{X}}$ at every point of $\mathcal{X}$ (it has neither zeros nor poles), and positive real numbers κ_s $(s\colon F \to \mathbb{C})$ with $\kappa_{\bar{s}} = \kappa_s$ and

$$|f(z)| = \bigl(\kappa_s\, h_A(z)\bigr)^M\, |g(z)| \qquad \text{for every } z \in \widehat{\mathcal{X}} \text{ over a point of } \mathcal{X}(\mathbb{C}) \text{ lying over } s.$$

Equivalently, the section f/g has the constant norm κ_s^M on the part of $\mathcal{X}(\mathbb{C})$ over s. The **height** of $\overline{\mathcal{A}}$ (with these data) is

$$\operatorname{ht}(\overline{\mathcal{A}}) = -\frac{1}{[F:\mathbb{Q}]} \sum_{s\colon F \to \mathbb{C}} \log \kappa_s.$$

(Dl2) Flat determinant lines. Let $a \in \Phi$. A **flat determinant line of $\mathcal{X}$ at** a is a line $\overline{\mathcal{A}} = (\mathcal{O}(e_A), h_A)|_{\mathcal{X}}$ flat over some number field, with data as in (Dl1), such that $e_A = \sum_{i=1}^{n} e_{(a,i)}$, together with functions $v_t\colon \widehat{\mathbb{C}} \to \mathbb{R}$ $(t > 0)$, smooth and invariant under $(\lambda_k) \in (\mathbb{C}^\times)^K$, such that

$$\prod_{i=1}^{n} h_{(a,i)}(t)(z) = h_A(z)\, e^{-v_t(z)} \qquad (t > 0,\ z \in \widehat{\mathcal{X}}),$$

and, for all roots $r_1, \dots, r_D \in \mathrm{Rt}$,

$$\lim_{t \to 0^+} \int_{\mathcal{X}(\mathbb{C})} v_t\, c_1(\overline{\mathcal{L}}_{r_1}(t)) \wedge \cdots \wedge c_1(\overline{\mathcal{L}}_{r_D}(t)) = 0.$$

Its height is the height of $\overline{\mathcal{A}}$.

Proposition D.65. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2 (so every $\mathcal{X}_{B,Z}$ has convergent regularisation, by Theorem 31.20). Let $\mathcal{T}'$ be a root tower of type (Φ, n, p) with the components and the bad primes of $\mathcal{T}$ such that $\widehat{\deg}'_{2,Z}(F) = \mathrm{pp}(\mathcal{X}_{2,Z}; F)$ for every $Z \in \mathrm{Cp}$ and every $F \in \mathcal{R}$, where $\widehat{\deg}'$ are the arithmetic degrees of $\mathcal{T}'$, and such that $\mathcal{T}'$ with the geometric realisation of $\mathcal{T}$ has (Gi1). Then $\mathfrak{u}$ and $\mathcal{T}'$ satisfy the hypotheses 1–3 of Lemma 34.19: for every $Z \in \mathrm{Cp}$ and every $a \in \Phi$ there are a base determinant height $\mathrm{hf}(Z, a)$ with the stage-two degree identity 1, a flat generator with all its norms as in 2, and real numbers d_ℓ, v_ℓ ($\ell \in \mathrm{Bd}$) as in 3.*

Proof. Here $\Phi = \Phi_{\mathsf{H}}$ and $n = p + q$ (Proposition 34.2). Write $\mathrm{vol}'(Z)$ for the volumes of $\mathcal{T}'$. Fix $Z \in \mathrm{Cp}$ and $a \in \Phi$, and put $\mathcal{X} = \mathcal{X}_{2,Z}$. By Proposition D.66 there are U, Y, z_0, a flat generator φ over Y for $\tau = a$ with constants (e, c) and all its norms N_s, N_κ, a flat determinant line $\overline{\mathcal{A}}$ of $\mathcal{X}$ at a, and real numbers d_ℓ ($\ell \in \mathrm{Bd}$) as in its items 1–3. Put $\mathrm{hf}(Z, a) = \mathrm{ht}(\overline{\mathcal{A}})$.

Hypothesis 1. $\mathcal{X}$ has convergent regularisation by Theorem 31.20. Let $Q \in \mathcal{R}$ be homogeneous of degree D. Then $\mathrm{ps}_{a,1} Q \in \mathcal{R}$, and by the hypothesis on $\mathcal{T}'$, by Lemma D.72, and by (Gi1) for $\mathcal{T}'$ with the geometric realisation of $\mathcal{T}$,

$$\widehat{\deg}'_{2,Z}(\mathrm{ps}_{a,1} Q) = \mathrm{pp}(\mathcal{X}; \mathrm{ps}_{a,1} Q) = \mathrm{ht}(\overline{\mathcal{A}})\, \mathrm{gi}(\mathcal{X}; Q) = \mathrm{hf}(Z, a)\, \mathrm{vol}'(Z)\, \deg^{\mathrm{fl}}(Q).$$

Hypothesis 2. $\tau = a \in \Phi_{\mathsf{H}}$, U, Y, z_0 and φ with its norms are as required (item 1 of Proposition D.66).

Hypothesis 3. For $\ell \in \mathrm{Bd}$ put $v_\ell = w_\ell / ([E : \mathbb{Q}] \log \ell)$. The different $\mathfrak{d}_E$ is an integral ideal, and every ring homomorphism $j \colon E \to \mathbb{C}_\ell$ maps $\mathcal{O}_E$ into the closed unit ball, so $|\mathfrak{d}_E|_j \le 1$, $w_\ell \ge 0$ and $v_\ell \ge 0$. Item 3 of Proposition D.66 gives $|d_\ell| \le n\bigl(c_\ell \log \ell + \frac{w_\ell}{[E:\mathbb{Q}]}\bigr) = (n\, c_\ell + n\, v_\ell) \log \ell$ and the decomposition of $\mathrm{hf}(Z, a) = \mathrm{ht}(\overline{\mathcal{A}})$ required in 3. It remains to bound $\sum_{\ell \in \mathrm{Bd}} v_\ell \log \ell = \frac{1}{[E:\mathbb{Q}]} \sum_{\ell \in \mathrm{Bd}} w_\ell$. For a prime $\mathfrak{P}$ of E above ℓ, with ramification index $e_{\mathfrak{P}}$ and residue degree $f_{\mathfrak{P}}$, exactly $e_{\mathfrak{P}} f_{\mathfrak{P}}$ homomorphisms $j \colon E \to \mathbb{C}_\ell$ induce $\mathfrak{P}$, and for each of them $|\mathfrak{d}_E|_j = \ell^{-v_{\mathfrak{P}}(\mathfrak{d}_E)/e_{\mathfrak{P}}}$, since $\mathfrak{d}_E$ is dense in $\mathfrak{d}_E \mathcal{O}_{E_{\mathfrak{P}}} = \mathfrak{P}^{v_{\mathfrak{P}}(\mathfrak{d}_E)} \mathcal{O}_{E_{\mathfrak{P}}}$. Hence w_ℓ is the logarithm of the ℓ-part of the absolute norm $\mathrm{N}(\mathfrak{d}_E)$:

All w_ℓ are ≥ 0 and $\mathrm{N}(\mathfrak{d}_E) = |\mathrm{disc}(E)|$ (Dedekind), so

$$\sum_{\ell \in \mathrm{Bd}} v_\ell \log \ell \le \frac{1}{[E : \mathbb{Q}]} \sum_{\ell} w_\ell = \frac{\log |\mathrm{disc}(E)|}{[E : \mathbb{Q}]} = \log \mathrm{rd}_E.$$

So $\mathrm{hf}(Z, a)$, φ with its norms, and d_ℓ, v_ℓ ($\ell \in \mathrm{Bd}$) satisfy hypotheses 1–3 of Lemma 34.19 at (Z, a). As Z and a were arbitrary, this proves the proposition. □

Proposition D.66. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. For a prime ℓ put $c_2 = 2$, $c_\ell = \frac{1}{\ell - 1}$ if $\ell \ge 3$, and $w_\ell = -\sum_{j \colon E \to \mathbb{C}_\ell} \log |\mathfrak{d}_E|_j$. Then for every $Z \in \mathrm{Cp}$ and every $a \in \Phi$ there are:*

1. *a union $U \subseteq \mathrm{Sh}_F$ of connected components, a connected component Y of $U(\mathbb{C})$, $z_0 \in Y$, and a flat generator φ over Y for $\tau = a$ with constants (e, c) that has an archimedean norm N_s at every embedding $s \colon F \to \mathbb{C}$ and an ℓ-adic norm N_κ at every ring homomorphism $\kappa \colon F \to \mathbb{C}_\ell$, for every prime ℓ;*

2. *a flat determinant line* $\overline{\mathcal{A}}$ *of the root model* $\mathcal{X}_{2,Z}$ *at* a*;*

3. *real numbers* d_ℓ *(*$\ell \in \mathrm{Bd}$*) with* $|d_\ell| \le n\big(c_\ell \log \ell + \frac{w_\ell}{[E:\mathbb{Q}]}\big)$ *and*

$$\mathrm{ht}(\overline{\mathcal{A}}) = -\frac{1}{[F:\mathbb{Q}]}\Big(\sum_{s\colon F\to\mathbb{C}} N_s + \sum_{\ell}\sum_{\kappa\colon F\to\mathbb{C}_\ell} N_\kappa\Big) + \sum_{\ell\in\mathrm{Bd}} d_\ell$$

(the sum over all primes ℓ *has finitely many non-zero terms, by Theorem 34.20).*

Proof. Fix $Z \in \mathrm{Cp}$ (we write $c = Z$) and $a \in \Phi$, and put $\mathcal{X} = \mathcal{X}_{2,c}$ with function field Ω and representing coordinates y, $e_A = \sum_{i=1}^n e_{(a,i)}$, and $\mathcal{D}_{\mathcal{X}} = \det \mathcal{V}_{(a,+)} \otimes (\det \mathcal{V}_{(a,-)})^{-1}$.

Step 1: clause 1. By (Go2), $\mathcal{Y}_c$ is an irreducible component of $\mathcal{Y}$ meeting $j(\mathrm{Sh}_F)$. By Proposition D.38 (components split, level good at every prime, $n \ge 1$) there is a nowhere vanishing section ξ of $\det \mathrm{Lie}_{(a,+)} \otimes (\det \mathrm{Lie}_{(a,-)})^{-1}$ on $\mathcal{Y}_c \times_{\mathcal{O}_F} F$; with $U = Z_c$, a connected component of Sh_F, any connected component Y of $U(\mathbb{C})$ and $z_0 \in Y$, the frame function $\varphi = \varphi_\xi$ is a flat generator over Y for $\tau = a$ with constants (e, c) and has archimedean norms N_s at every $s\colon F \to \mathbb{C}$ and ℓ-adic norms N_κ at every $\kappa\colon F \to \mathbb{C}_\ell$, every ℓ. By (Fd1) of Theorem 34.20, $N_\kappa = 0$ above all but finitely many ℓ. Two facts on these norms. (i) $N_{\bar s} = N_s$: complex conjugation carries $U(\mathbb{C})$ over s to $U(\mathbb{C})$ over $\bar s$, frames to frames, φ to $\overline{\varphi}$ (ξ is defined over F, (Yf2)) and the Hodge forms to their conjugates, so the Gram determinants are unchanged. (ii) N_κ depends only on the prime $\mathfrak{l}$ of $\mathcal{O}_F$ induced by κ, by Lemma D.70, for every $\mathfrak{l}$ at which data of (Yf3) exist; they exist at every $\mathfrak{l}$, at the points z of Step 6 (the base change of $G_{\mathcal{X}}$ along z with bases of its free Lie eigenmodules); write $N_{\mathfrak{l}}$.

Step 2: the rational section. By (Fh3), (Fh6) and the root sections (Go3)(3), $\mathcal{D}_{\mathcal{X}} \cong \bigotimes_i \mathcal{L}_{(a,i)}$ and $P \mapsto \varrho_A P(y)$, $\varrho_A = \prod_i \varrho_{(a,i)}$, is an isomorphism $\mathcal{O}(e_A)|_{\mathcal{X}} \to \mathcal{D}_{\mathcal{X}}$; at every complex point z of the abelian locus and every cone point $\tilde z$ over it, (Go3)(4) and the Gram-determinant formula of (Fh4) give $\|\varrho_A P(y)\|^{\mathrm{Hdg}}(z) = |P(\tilde z)|/\prod_i h^{\mathrm{sing}}_{(a,i)}(\tilde z)$, the Hodge norm of $\mathcal{D}_{\mathcal{X}}$ being the product of the step-quotient norms. Write $u_\xi = \varrho_A \theta$ with $\theta \in \Omega^\times$ and $\theta = F_0(y)/G_0(y)$ for multihomogeneous F_0, G_0 with integer coefficients and $\deg F_0 - \deg G_0 = e_A$ (the elements of Ω are ratios of polynomials in y of equal multidegree; multiply by a monomial of multidegree e_A).

Step 3: the vertical orders. By Proposition D.67 ($\mathrm{Bd} = S_2$ contains every prime dividing $\mathrm{disc}(E)$), $\mathcal{X} \to \mathrm{Spec}\,\mathbb{Z}$ factors through $\mathrm{Spec}\,\mathcal{O}_{F'}$ with connected fibres, u_ξ generates $\mathcal{D}_{\mathcal{X}}$ at every point over no prime, and for each maximal ideal $\mathfrak{p}$ of $\mathcal{O}_{F'}$ with a uniformiser $\pi_\mathfrak{p} \in F'$ there are $M_\mathfrak{p} \ge 1$, $a_\mathfrak{p}$ with $u_\xi^{M_\mathfrak{p}} \pi_\mathfrak{p}^{-a_\mathfrak{p}}$ generating $\mathcal{D}_{\mathcal{X}}^{\otimes M_\mathfrak{p}}$ at every point over $\mathfrak{p}$; $r_\mathfrak{p} = a_\mathfrak{p}/M_\mathfrak{p}$ is the common ratio of the order of u_ξ and of $\pi_\mathfrak{p}$ along the components of the fibre, hence independent of choices. The closed set where u_ξ does not generate $\mathcal{D}_{\mathcal{X}}$ lies over no point of characteristic 0; its image in $\mathrm{Spec}\,\mathcal{O}_{F'}$ is closed ($\mathcal{X}$ is proper) and misses the generic point, hence is a finite set P_0, and $r_\mathfrak{p} = 0$ for $\mathfrak{p} \notin P_0$ (then $M_\mathfrak{p} = 1$, $a_\mathfrak{p} = 0$ will do). Let h be the class number of F', $M' = \prod_{\mathfrak{p}\in P_0} M_\mathfrak{p}$, $M = hM'$; then $Mr_\mathfrak{p} = h\,(M'/M_\mathfrak{p})a_\mathfrak{p} \in h\mathbb{Z}$, so $\prod_{\mathfrak{p}\in P_0} \mathfrak{p}^{Mr_\mathfrak{p}}$ is the h-th power of a fractional ideal, hence principal, $= (\alpha)$ with $\alpha \in F'^\times$. The rational section $u_\xi^M \alpha^{-1}$ of $\mathcal{D}_{\mathcal{X}}^{\otimes M}$ generates at every point: over $\mathfrak{p} \in P_0$ it is the $(M/M_\mathfrak{p})$-th power of $u_\xi^{M_\mathfrak{p}} \pi_\mathfrak{p}^{-a_\mathfrak{p}}$ times $\pi_\mathfrak{p}^{Mr_\mathfrak{p}} \alpha^{-1}$, a unit of $\mathcal{O}_{F',\mathfrak{p}}$; over $\mathfrak{p} \notin P_0$ and over no prime, u_ξ generates and α is a unit. Write $\alpha = A_0(y)/B_0(y)$ with A_0, B_0 multihomogeneous of equal multidegree with integer coefficients, and put $f = F_0^M B_0$, $g = G_0^M A_0$. Then f, g have integer coefficients, $\deg f - \deg g = Me_A$, neither vanishes on $\mathcal{X}$, and the rational section f/g of $\mathcal{O}(Me_A)|_{\mathcal{X}}$, which corresponds to $u_\xi^M \alpha^{-1}$ under the M-th power of the isomorphism of Step 2, generates $\mathcal{O}(Me_A)|_{\mathcal{X}}$ at every point.

Step 4: the metric and (Dl1). For $s\colon F' \to \mathbb{C}$ put $\kappa_s = |s(\alpha)|^{-1/M} e^{N_{s|_F}}$; then $\kappa_{\bar s} = \kappa_s$ by (i). At a cone point $\tilde z$ over a point of $\mathcal{X}(\mathbb{C})$ over s, choose integer multihomogeneous

f', g' with $f'/g' = f/g$ in Ω and $g'(\tilde z) \neq 0$ (possible as f/g generates); then $f'(\tilde z) \neq 0$ and $h_A(\tilde z) = \kappa_s^{-1}(|f'(\tilde z)|/|g'(\tilde z)|)^{1/M}$ is independent of the choice (two choices agree on a dense open set), smooth, positive, homogeneous of multidegree e_A and invariant under conjugation; extend $\log(h_A/h_0)$, for the smooth cone metric $h_0(z) = \prod_k \|z_k\|^{e_{A,k}}$, from the closed submanifold $\mathcal{X}(\mathbb{C})$ ($\mathcal{X} \otimes \mathbb{Q}$ is smooth) to a smooth conjugation-invariant function on $\prod_k \mathbb{P}(\mathbb{C}^{I_k})$, which makes h_A a cone metric of multidegree e_A. By construction $|f(\tilde z)| = (\kappa_s h_A(\tilde z))^M |g(\tilde z)|$ at every cone point over s, so $\overline{\mathcal{A}} = (\mathcal{O}(e_A), h_A)|_{\mathcal{X}}$ is flat over F' (Dl1). At a complex point z of the abelian locus over s, with y^s the induced point of U over $s|_F$: u_ξ at z is $\xi(j(y^s))$, of Hodge norm $|\varphi(y^s; v, w)| \det \Gamma(v)^{1/2} \det \Gamma(w)^{-1/2} = e^{N_{s|_F}}$ (Yf3); by Step 2,

$$\frac{|f(\tilde z)|}{|g(\tilde z)| \prod_i h^{\mathrm{sing}}_{(a,i)}(\tilde z)^M} = \|u_\xi^M \alpha^{-1}\|^{\mathrm{Hdg}}(z) = \frac{e^{M N_{s|_F}}}{|s(\alpha)|},$$

so $h_A = \prod_i h^{\mathrm{sing}}_{(a,i)}$ at all cone points over the abelian locus.

Step 5: (Dl2), clause 2. By Lemma D.71 (root origin of $\mathcal{X}$ realised on $\mathcal{X}(\mathbb{C})$ without resolution, h_A as just shown), $v_t = \log h_A - \sum_i \log h_{(a,i)}(t)$ is smooth and invariant, $\prod_i h_{(a,i)}(t) = h_A e^{-v_t}$, and the limits of (Dl2) vanish. So $\overline{\mathcal{A}}$ with these data is a flat determinant line of $\mathcal{X}_{2,Z}$ at a.

Step 6: the height. By (Dl1) and the product formula $\sum_s \log|s(\alpha)| = \sum_{\mathfrak{p}} v_{\mathfrak{p}}(\alpha) \log N\mathfrak{p} = M \sum_{\mathfrak{p}} r_{\mathfrak{p}} \log N\mathfrak{p}$, and since every $s_0 \colon F \to \mathbb{C}$ has $[F' : F]$ extensions to F',

$$\mathrm{ht}(\overline{\mathcal{A}}) = -\frac{1}{[F' : \mathbb{Q}]} \sum_s \log \kappa_s = -\frac{1}{[F : \mathbb{Q}]} \sum_{s_0} N_{s_0} + \frac{1}{[F' : \mathbb{Q}]} \sum_{\mathfrak{p}} r_{\mathfrak{p}} \log N\mathfrak{p}.$$

Fix a prime ℓ and $\mathfrak{p} \mid \ell$ with ramification index $e_{\mathfrak{p}}$ and residue degree $f_{\mathfrak{p}}$ over ℓ. The fibre of $\mathcal{X}$ over $\mathfrak{p}$ is non-empty ($\mathcal{X} \to \operatorname{Spec} \mathcal{O}_{F'}$ is proper and dominant, hence surjective) and the regular locus contains the generic points of its components (normality), so it has a regular closed point x; by Lemma D.68, applied with Δ the closed set of points mapping outside the open locus of $\mathcal{Y}$ over which $G_{\mathcal{Y}}$ is abelian, there is a point $z \colon \operatorname{Spec} \mathcal{O}_{k,\mathfrak{P}} \to \mathcal{X}$ with centre x whose generic point lies in the abelian locus ((Ud7)), with $\vartheta \colon k \to \mathbb{C}_\ell$; $\vartheta|_{F'}$ induces $\mathfrak{p}$, so $\log|\vartheta(\pi_{\mathfrak{p}})| = -\log \ell / e_{\mathfrak{p}}$, and $\kappa = \vartheta \circ \beta$ induces $\mathfrak{l} = \mathfrak{p} \cap \mathcal{O}_F$. At x, $u_\xi^{M_{\mathfrak{p}}} \pi_{\mathfrak{p}}^{-a_{\mathfrak{p}}}$ is a unit times a generator. Put $\delta_{\mathfrak{p}} = N_{\mathfrak{l}} + r_{\mathfrak{p}} \log \ell / e_{\mathfrak{p}}$. Proposition D.69 gives: $\delta_{\mathfrak{p}} = 0$ if $\ell \notin \mathrm{Bd}$ (then $\ell \notin S_2$ and $\ell \nmid \mathrm{disc}(E)$); and if $\ell \in \mathrm{Bd}$, for every non-zero $d \in \mathfrak{d}_E$, $|\delta_{\mathfrak{p}}| \leq n(c_\ell \log \ell - \log|\kappa(a(d))|)$. Choose d with $|\kappa(a(d))| = |\mathfrak{d}_E|_{\kappa \circ a}$ (the supremum in Definition 33.13 is attained: the values are a discrete set of powers of ℓ bounded by 1). As E is Galois over $\mathbb{Q}$, any two embeddings $j, j' \colon E \to \mathbb{C}_\ell$ satisfy $j' = j \circ \gamma$ with $\gamma \in \mathrm{Gal}(E/\mathbb{Q})$, and $\gamma(\mathfrak{d}_E) = \mathfrak{d}_E$, so $|\mathfrak{d}_E|_j$ does not depend on j and $-\log|\mathfrak{d}_E|_{\kappa \circ a} = w_\ell / [E : \mathbb{Q}]$. Hence $|\delta_{\mathfrak{p}}| \leq n(c_\ell \log \ell + w_\ell / [E : \mathbb{Q}])$ for $\ell \in \mathrm{Bd}$. Now $r_{\mathfrak{p}} \log N\mathfrak{p} = r_{\mathfrak{p}} f_{\mathfrak{p}} \log \ell = e_{\mathfrak{p}} f_{\mathfrak{p}} (\delta_{\mathfrak{p}} - N_{\mathfrak{l}})$. The ring homomorphisms $F \to \mathbb{C}_\ell$ inducing $\mathfrak{l}$ number $[F_{\mathfrak{l}} : \mathbb{Q}_\ell]$, all with the norm $N_{\mathfrak{l}}$ by (ii), and $\sum_{\mathfrak{p} \mid \mathfrak{l}} e_{\mathfrak{p}} f_{\mathfrak{p}} = [F' : F]\,[F_{\mathfrak{l}} : \mathbb{Q}_\ell]$; so

$$\frac{1}{[F' : \mathbb{Q}]} \sum_{\mathfrak{p} \mid \ell} r_{\mathfrak{p}} \log N\mathfrak{p} = -\frac{1}{[F : \mathbb{Q}]} \sum_{\kappa \colon F \to \mathbb{C}_\ell} N_\kappa + d_\ell, \qquad d_\ell = \frac{1}{[F' : \mathbb{Q}]} \sum_{\mathfrak{p} \mid \ell} e_{\mathfrak{p}} f_{\mathfrak{p}}\, \delta_{\mathfrak{p}}.$$

For $\ell \notin \mathrm{Bd}$, $d_\ell = 0$; for $\ell \in \mathrm{Bd}$, as $\sum_{\mathfrak{p} \mid \ell} e_{\mathfrak{p}} f_{\mathfrak{p}} = [F' : \mathbb{Q}]$, $|d_\ell| \leq n(c_\ell \log \ell + w_\ell / [E : \mathbb{Q}])$. Summing over ℓ (finitely many non-zero terms: $r_{\mathfrak{p}} = 0$ off P_0, and $N_\kappa = 0$ above almost all ℓ) gives the formula of clause 3. □

Proposition D.67. *Let $\mathfrak{u}$, $\mathcal{Y}$, $\mathcal{T}$, B, c, $\mathcal{X} = \mathcal{X}_{B,c}$ with its root origin, τ, ξ and u_ξ be as in Proposition D.69, suppose moreover that the level L is good at every prime and that every prime*

dividing $\operatorname{disc}(E)$ *lies in* S_B*, and put* $\mathcal{D}_{\mathcal{X}} = \det \mathcal{V}_{(\tau,+)} \otimes (\det \mathcal{V}_{(\tau,-)})^{-1}$*, an invertible sheaf on* $\mathcal{X}$ *whose stalk at the generic point contains* u_ξ*. Let* F' *be the algebraic closure of* $\mathbb{Q}$ *in* Ω*. Then* F' *is a number field,* $\mathcal{O}_{F'} = H^0(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$*, the fibres of* $\mathcal{X} \to \operatorname{Spec} \mathcal{O}_{F'}$ *are connected, and for every maximal ideal* $\mathfrak{p}$ *of* $\mathcal{O}_{F'}$ *and every* $\pi \in F'$ *of* $\mathfrak{p}$*-adic valuation one there are integers* $M \geq 1$ *and* a *such that* $u_\xi^M \pi^{-a}$ *generates* $\mathcal{D}_{\mathcal{X}}^{\otimes M}$ *at every point of* $\mathcal{X}$ *over* $\mathfrak{p}$*, and at every point over no prime.*

Proof. **Step 1: the constant field.** $\mathcal{X}$ is proper over $\mathbb{Z}$, so $A = H^0(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a finite $\mathbb{Z}$-algebra; it is a domain contained in Ω, and integrally closed in its fraction field because $\mathcal{X}$ is normal. Every $\alpha \in F'$ has a non-zero integer multiple $N\alpha$ integral over $\mathbb{Z}$, hence over every local ring of $\mathcal{X}$, hence in every local ring (normality), so $N\alpha \in A$. Thus $\operatorname{Frac}(A) = F'$, F' is finite over $\mathbb{Q}$, and A, integrally closed and finite over $\mathbb{Z}$, is $\mathcal{O}_{F'}$. The morphism $g\colon \mathcal{X} \to \operatorname{Spec} \mathcal{O}_{F'}$ is proper with $g_*\mathcal{O}_{\mathcal{X}} = \mathcal{O}_{\operatorname{Spec} \mathcal{O}_{F'}}$, so its fibres are connected by Zariski's connectedness theorem (EGA III, 4.3.1). Fix $\mathfrak{p}$ over the prime ℓ and π as in the statement; put $\mathcal{O} = \mathcal{O}_{F',\mathfrak{p}}$ and $X = \mathcal{X} \times_{\mathcal{O}_{F'}} \mathcal{O}$, a normal integral scheme, proper over $\mathcal{O}$, dominating $\operatorname{Spec} \mathcal{O}$, with connected special fibre X_s (the fibre of g over $\mathfrak{p}$). Its points are the points of $\mathcal{X}$ over $\mathfrak{p}$ and those over no prime, and π is a uniformiser of $\mathcal{O}$.

Step 2: the generic fibre. Let x be a point of $\mathcal{X}$ over no prime. By (Fh5) the stalk of $\mathcal{V}_s$ at x is $\mathrm{dR}_{s,x} = \mathrm{Lie}_x \cap \mathrm{Li}_s$; since $F \subseteq \mathcal{O}_x$ contains every conjugate of E, the idempotents of $E \otimes_{\mathbb{Q}} F = \prod_{\mathrm{Hom}(E,F)} F$ make it the direct summand $\mathrm{Lie}_s(G_{\mathcal{X}})_x$, and $\mathrm{Lie}_s(G_{\mathcal{X}}) = f^*\mathrm{Lie}_s(G_{\mathcal{Y}})$ near x. The image $f(x)$ lies in $\mathcal{Y}_c \times_{\mathcal{O}_F} F$ (it is a specialisation of the generic point of $\mathcal{Y}_c$ over no prime), so $\mathcal{D}_{\mathcal{X},x} = (f^*\mathcal{D})_x$ with $\mathcal{D}$ as in Proposition D.69, and u_ξ is the germ of $f^*\xi$, which generates there because ξ vanishes nowhere. So u_ξ generates $\mathcal{D}_{\mathcal{X}}$ at every point over no prime; in particular its order at every point of codimension one over no prime is 0, and the last assertion holds for every M and a (π is a unit there).

Step 3: the case $\ell \in S_B$. By (Fh3), (Fh6) and the determinant of a full flag, $\mathcal{D}_{\mathcal{X}} \cong \bigotimes_{i=1}^n \mathcal{L}_{(\tau,i)}$ (the roots (τ,i) with $i \leq p$ give the step quotients of the integral flag of $\mathcal{V}_{(\tau,+)}$, those with $i > p$ the inverses of the step quotients of $\mathcal{V}_{(\tau,-)}$), and by the root sections of (Go3)(3), $\mathcal{L}_{(\tau,i)} \cong \mathcal{O}(e_{(\tau,i)})|_{\mathcal{X}}$. By Proposition 35.66, on $\mathcal{X}_\ell = \mathcal{X} \times \operatorname{Spec} \mathbb{F}_\ell$ the sheaves $\mathcal{O}(e_{(\tau,i)})|_{\mathcal{X}_\ell}$ are the graded pieces of a full flag of $\mathcal{O}_{\mathcal{X}_\ell}^n$, so their tensor product is $\det \mathcal{O}_{\mathcal{X}_\ell}^n \cong \mathcal{O}_{\mathcal{X}_\ell}$. As $\ell \in \mathfrak{p}$, X_s is a closed subscheme of $\mathcal{X}_\ell$, and $\mathcal{D}_{\mathcal{X}}|_{X_s} \cong \mathcal{O}_{X_s}$. By Step 2, u_ξ generates $\mathcal{D}_{\mathcal{X}}$ on the generic fibre of X. Lemma D.50, applied to X, $\mathcal{L} = \mathcal{D}_{\mathcal{X}}|_X$, $\sigma = u_\xi$ and the uniformiser π, gives the integers M, a.

Step 4: the case $\ell \notin S_B$: orders at the components. Then $\ell \nmid \operatorname{disc}(E)$ by hypothesis. $X_s = V(\pi)$; let $X_1, \dots, X_t$ be its irreducible components, with generic points ξ_i of codimension one (Krull), local rings that are discrete valuation rings (normality) with valuations v_i, $m_i = v_i(\pi) \geq 1$, and n_i the order of u_ξ at ξ_i in a trivialisation of $\mathcal{D}_{\mathcal{X}}$. Fix i. The regular locus of $\mathcal{X}$ is open ($\mathcal{X}$ is of finite type over $\mathbb{Z}$, hence excellent) and contains ξ_i (normal schemes are regular in codimension one), so $W_i = X_i \cap \mathrm{Reg}(\mathcal{X}) \smallsetminus \bigcup_{k \neq i} X_k$ is a non-empty open subset of X_i; let $x \in W_i$ be a closed point (it exists, X_i being of finite type over a finite field). Near x the only codimension-one points through x are ξ_i and points over no prime (points over another prime of $\mathcal{O}_{F'}$ do not specialise to x); as $\mathcal{O}_{\mathcal{X},x}$ is regular, hence factorial, $u_\xi^{m_i}\pi^{-n_i}$, whose order is $m_in_i - n_im_i = 0$ at ξ_i and 0 at the other height-one primes of $\mathcal{O}_{\mathcal{X},x}$ (Step 2, and π is a unit over no prime), generates $\mathcal{D}_{\mathcal{X}}^{\otimes m_i}$ at x. Let $\Delta \subseteq \mathcal{X}$ be the closed set of points whose image under f lies outside the open locus of $\mathcal{Y}$ over which $G_{\mathcal{Y}}$ is abelian; it does not contain the generic point of $\mathcal{X}$, whose image lies in $j(\mathrm{Sh}_F)$. By Lemma D.68 there are a number field k, a maximal ideal $\mathfrak{P}$ of $\mathcal{O}_k$ over ℓ, a morphism $z\colon \operatorname{Spec} \mathcal{O}_{k,\mathfrak{P}} \to \mathcal{X}$ with closed point x and generic point $\eta \notin \Delta$ over no prime, and $\vartheta\colon k \to \mathbb{C}_\ell$ with $\mathcal{O}_{k,\mathfrak{P}} = \{|\vartheta| \leq 1\}$. By (Ud7), $f(\eta) \in j(\mathrm{Sh}_F)$: η lies in the abelian locus. Let $\kappa = \vartheta \circ \beta$ as in Proposition D.69; by Proposition D.38(4) (components split, level good at every prime), φ_ξ has an ℓ-adic norm N_κ at κ. Proposition D.69(1), with $V = \mathcal{O}_{k,\mathfrak{P}}$,

$m = m_i$, $\nu = n_i$ and π, gives $\frac{n_i}{m_i}\log|\vartheta(\pi_z)| = N_\kappa$, π_z the image of π in k.

Step 5: independence of i. The composite $\mathcal{O}_{F'} \to \mathcal{O}_{\mathcal{X},x} \to \mathcal{O}_{k,\mathfrak{P}}$ maps $\mathfrak{p}$ into $\mathfrak{P}$, so $\vartheta|_{F'}$ induces $\mathfrak{p}$ and $\log|\vartheta(\pi_z)| = -\frac{\log\ell}{e_\mathfrak{p}}$, $e_\mathfrak{p}$ the ramification index of $\mathfrak{p}$ over ℓ, independent of i. Likewise κ induces on F the prime $\mathfrak{l} = \mathfrak{p} \cap \mathcal{O}_F$ for every i, and N_κ depends only on $\mathfrak{l}$ by Lemma D.70 (all these norms exist by Proposition D.38(4), and data of (Yf3) exist at the point z: the base change of $G_\mathcal{X}$ along z with bases of its free Lie eigenmodules). Hence $r = n_i/m_i = -e_\mathfrak{p}N_\kappa/\log\ell$ is the same rational number for all i.

Step 6: conclusion for $\ell \notin S_B$. Put $M = m_1 \cdots m_t$ and $a = rM \in \mathbb{Z}$ ($rM = n_1\prod_{k\neq 1} m_k$). The rational section $\theta = u_\xi^M \pi^{-a}$ of $\mathcal{D}_\mathcal{X}^{\otimes M}$ has order $Mn_i - am_i = 0$ at every ξ_i and order 0 at every point of codimension one over no prime (Step 2). A point x' of $\mathcal{X}$ over $\mathfrak{p}$ lies in X, and every height-one prime of $\mathcal{O}_{\mathcal{X},x'}$ is one of these; since the local ring of a normal noetherian domain is the intersection of its localisations at height-one primes, θ and θ^{-1} are regular at x' in a trivialisation, i.e. θ generates $\mathcal{D}_\mathcal{X}^{\otimes M}$ at x'. □

Lemma D.68. *Let X be an integral scheme of finite type over $\mathbb{Z}$ whose function field has characteristic 0, let $\Delta \subseteq X$ be a closed subset not containing the generic point of X, let ℓ be a prime and x a closed point of X with $\ell \in \mathfrak{m}_x$ at which X is regular. Then there are a number field k, a maximal ideal $\mathfrak{P}$ of $\mathcal{O}_k$ over ℓ and a morphism $z\colon \operatorname{Spec}\mathcal{O}_{k,\mathfrak{P}} \to X$ that maps the closed point to x and the generic point to a point of $X \smallsetminus \Delta$ lying over no prime. For every field homomorphism $\vartheta\colon k \to \mathbb{C}_\ell$ inducing $\mathfrak{P}$ (such ϑ exist), $\mathcal{O}_{k,\mathfrak{P}} = \{a \in k : |\vartheta(a)| \leq 1\}$.*

Proof. Let $A = \mathcal{O}_{X,x}$, a regular local ring with maximal ideal $\mathfrak{m}$, of dimension d. As the function field has characteristic 0, $\ell \neq 0$ in A; as $\ell \in \mathfrak{m}$, $d \geq 1$. Let $I \subseteq A$ be the ideal of Δ near x (so that a prime $\mathfrak{q}$ of A is a point of Δ iff $I \subseteq \mathfrak{q}$); $I \neq 0$ because Δ does not contain the generic point. Put $J = \ell I \neq 0$; as A is a domain, $\dim A/J \leq d-1$.

Step 1: parameters. We choose $t_1, \ldots, t_{d-1} \in \mathfrak{m}$ whose images in $\mathfrak{m}/\mathfrak{m}^2$ are linearly independent and with $\dim A/(J + (t_1, \ldots, t_i)) \leq d-1-i$ for $0 \leq i \leq d-1$. Suppose $t_1, \ldots, t_{i-1}$ chosen ($i \leq d-1$) and let $Q_1, \ldots, Q_s$ be the minimal primes of $J + (t_1, \ldots, t_{i-1})$ different from $\mathfrak{m}$. The ideal $\mathfrak{m}^2 + (t_1, \ldots, t_{i-1})$ does not contain $\mathfrak{m}$, since $\dim \mathfrak{m}/\mathfrak{m}^2 = d > i-1$, and no Q_j contains $\mathfrak{m}$. By prime avoidance (all ideals but one prime), there is $t_i \in \mathfrak{m}$ outside $\mathfrak{m}^2 + (t_1, \ldots, t_{i-1})$ and outside every Q_j. Then t_i lies in no minimal prime of $J + (t_1, \ldots, t_{i-1})$ of dimension ≥ 1, so $\dim A/(J + (t_1, \ldots, t_i)) \leq \max(0, \dim A/(J + (t_1, \ldots, t_{i-1})) - 1) \leq d-1-i$. After $d-1$ steps, $J + (t_1, \ldots, t_{d-1})$ is $\mathfrak{m}$-primary.

Step 2: the curve. Since $t_1, \ldots, t_{d-1}$ is part of a regular system of parameters of the regular local ring A, $\mathfrak{q} = (t_1, \ldots, t_{d-1})$ is prime and $V = A/\mathfrak{q}$ is a regular local ring of dimension 1, a discrete valuation ring. If $\ell \in \mathfrak{q}$ or $I \subseteq \mathfrak{q}$, then $J \subseteq \mathfrak{q}$ and $J + (t_1, \ldots, t_{d-1}) \subseteq \mathfrak{q} \neq \mathfrak{m}$ would not be $\mathfrak{m}$-primary; so $\ell \notin \mathfrak{q}$ and $I \not\subseteq \mathfrak{q}$. Let $\eta \in X$ be the point corresponding to $\mathfrak{q}$; then $\eta \notin \Delta$, and η lies over no prime: $\ell \neq 0$ in V, and a prime $p \neq \ell$ is a unit in A (both p and ℓ in $\mathfrak{m}$ would give $1 \in \mathfrak{m}$). Let k be the fraction field of V, the residue field of η, a field of characteristic 0. The closure C of η in X is integral, of finite type over $\mathbb{Z}$, of dimension 1 ($\dim \mathcal{O}_{C,x} = \dim V = 1$ and x is a closed point of X of finite type over $\mathbb{Z}$) and dominates $\operatorname{Spec}\mathbb{Z}$; so its generic fibre over $\mathbb{Q}$ has dimension 0 and k is a finite extension of $\mathbb{Q}$, a number field. The discrete valuation ring $V \subset k$ contains $\mathbb{Z}$, hence its integral closure $\mathcal{O}_k$, and so $V = \mathcal{O}_{k,\mathfrak{P}}$ for $\mathfrak{P} = \mathfrak{m}_V \cap \mathcal{O}_k$, which lies over ℓ as $\ell \in \mathfrak{m}_V$. Let z be the composite $\operatorname{Spec} V \to \operatorname{Spec} A \to X$; it maps the closed point to x and the generic point to η.

Step 3: the embedding. The completion $k_\mathfrak{P}$ is a finite extension of $\mathbb{Q}_\ell$, so it embeds over $\mathbb{Q}_\ell$ into $\mathbb{C}_\ell$; the composite $\vartheta\colon k \to \mathbb{C}_\ell$ induces $\mathfrak{P}$. For any such ϑ, $|\vartheta(\cdot)|$ is an absolute value on k whose valuation ring is the localisation of $\mathcal{O}_k$ at $\mathfrak{P}$, i.e. $\{a \in k : |\vartheta(a)| \leq 1\} = \mathcal{O}_{k,\mathfrak{P}}$. □

Proposition D.69. *Let $\mathfrak{u}$ be a unitary Shimura datum with $n = p + q$, $p, q \geq 1$, whose components split, $\mathcal{Y}$ an integral model of* Sh *over $\mathcal{O}_F$, $\mathcal{T}$ a root tower of type $(\Phi_{\mathsf{H}}, n, p)$ with a geometric realisation, $B \geq 2$, $c \in \mathrm{Cp}$, and let $\mathcal{X} = \mathcal{X}_{B,c}$ carry a root origin on fixed data at c, with cover $f\colon \mathcal{X} \to \mathcal{Y}$, function field Ω and Hodge bundles $\mathcal{V}_s$ at (S_B, R). Let $\tau \in \Phi_{\mathsf{H}}$, let ξ be a global section, vanishing at no point, of $\mathcal{D} = \det \mathrm{Lie}_{(\tau,+)}(G') \otimes (\det \mathrm{Lie}_{(\tau,-)}(G'))^{-1}$ on $\mathcal{Y}_c \times_{\mathcal{O}_F} F$ (G' the restriction of $G_{\mathcal{Y}}$), with frame function φ_ξ on Z_c, and let*

$$u_\xi \in \det \mathrm{Li}_{(\tau,+)} \otimes_\Omega \left(\det \mathrm{Li}_{(\tau,-)}\right)^{-1}$$

be the value of ξ at the generic point of $\mathcal{Y}_c$, transported to Ω along f (the generic point of $\mathcal{X}$ maps to that of $\mathcal{Y}_c$, and $G_{\mathcal{X}} = f^*G_{\mathcal{Y}}$). Let ℓ be a prime, V a discrete valuation ring with fraction field k, $\vartheta\colon k \to \mathbb{C}_\ell$ a field homomorphism with $V = \{a \in k : |\vartheta(a)| \leq 1\}$, and $z\colon \operatorname{Spec} V \to \mathcal{X}$ a morphism whose generic point maps into the abelian locus; let x_0 be the image of the closed point (it lies over ℓ), $\beta\colon F \to k$ the homomorphism induced by $\mathcal{O}_F \to \mathcal{O}_{\mathcal{X},x_0} \to V$, $\kappa = \vartheta \circ \beta$, and suppose that φ_ξ has an ℓ-adic norm N_κ at κ. Let $b^+ = (b_1^+, \dots, b_p^+)$ and $b^- = (b_1^-, \dots, b_q^-)$ be bases of the free $\mathcal{O}_{\mathcal{X},x_0}$-modules $\mathcal{V}_{(\tau,+),x_0}$ and $\mathcal{V}_{(\tau,-),x_0}$, and $a \in \Omega^\times$ with $u_\xi = a\,(b_1^+ \wedge \cdots \wedge b_p^+) \otimes (b_1^- \wedge \cdots \wedge b_q^-)^{-1}$. Suppose that there are integers $m \geq 1$ and ν and an element $\pi \in \Omega^\times$ algebraic over $\mathbb{Q}$ with $a^m \pi^{-\nu} \in \mathcal{O}_{\mathcal{X},x_0}^\times$; π is a unit at the image η of the generic point of Spec V*, and we write $\kappa(\pi)$ for ϑ of its image under $\mathcal{O}_{\mathcal{X},\eta} \to k$ (for $\pi \in F^\times$ this is $\kappa(\pi)$ in the previous sense). Put $c_2 = 2$ and $c_\ell = \frac{1}{\ell - 1}$ for $\ell \geq 3$. Then:*

1. *if $\ell \notin S_B$ and $\ell \nmid \operatorname{disc}(E)$, then $\frac{\nu}{m} \log |\kappa(\pi)| = N_\kappa$;*
2. *if $\ell \in S_B$, then for every non-zero $d \in \mathfrak{d}_E$*

$$\left|\frac{\nu}{m} \log |\kappa(\pi)| - N_\kappa\right| \leq n(c_\ell \log \ell - \log |\kappa(\tau(d))|).$$

Proof. **Step 0: notation.** Write $\mathcal{O} = \mathcal{O}_{\mathcal{X},x_0}$ and $z^\sharp\colon \mathcal{O} \to V$ for the local homomorphism given by z. As $|\vartheta(\ell)| < 1$, ℓ lies in the maximal ideal of V, hence in that of $\mathcal{O}$: x_0 lies over ℓ. Let $\eta \in \mathcal{X}$ be the image of the generic point of $\operatorname{Spec} V$, a generalisation of x_0, so $\mathcal{O} \subseteq \mathcal{O}_\eta \subseteq \Omega$, and let $z_\eta^\sharp\colon \mathcal{O}_\eta \to k$ be the induced homomorphism, which extends $z^\sharp$. The point η lies in the abelian locus $f^{-1}(j(\mathrm{Sh}_F))$, hence in characteristic 0: every prime is a unit in $\mathcal{O}_\eta$, so $F = \mathcal{O}_F \otimes \mathbb{Q} \subseteq \mathcal{O}_\eta$. Since $\operatorname{Spec} k$ is reduced and j is an immersion whose image contains $f(\eta)$, the k-point $f \circ z$ at the generic point is $j \circ y$ for a unique $y \in Z_c(k)$ (F-morphisms through β), and $G_y = y^*G^{\mathrm{un}}$ is identified $\mathcal{O}_E$-linearly with the fibre of $G_{\mathcal{X}} = f^*G_{\mathcal{Y}}$ at η base changed to k. Put $\mathcal{G} = z^*G_{\mathcal{X}}$, a semiabelian scheme over V with $\mathcal{O}_E$-action whose generic fibre is G_y. As $\mathrm{Lie}(G_{\mathcal{X}})$ is locally free and formation of Lie commutes with base change, $\mathrm{Lie}(\mathcal{G}) = \mathrm{Lie}_{x_0} \otimes_{\mathcal{O}} V$ inside $\mathrm{Lie}(G_y) = \mathrm{Lie}_\eta \otimes_{\mathcal{O}_\eta} k$; for $e \in \mathrm{Lie}_\eta$ write z^*e for its image in $\mathrm{Lie}(G_y)$, so that z^* maps Lie_{x_0} into $\mathrm{Lie}(\mathcal{G})$. For a label s put

$$I_s = \mathrm{Lie}(\mathcal{G}) \cap \mathrm{Lie}_s(G_y),$$

the V-module $\mathrm{Lie}_s(\mathcal{G})$ of (Yf3) for $s = (\tau, \pm)$. It is saturated in the free V-module $\mathrm{Lie}(\mathcal{G})$ and spans $\mathrm{Lie}_s(G_y)$, so it is free of rank $\dim_k \mathrm{Lie}_s(G_y) = \mathrm{rk}(s)$ (Kottwitz condition).

Step 1: the pulled-back Hodge lattices. The basis $b^\pm$ of the stalk $\mathcal{V}_{(\tau,\pm),x_0}$ of the locally free sheaf $\mathcal{V}_{(\tau,\pm)}$ is a basis of $\mathcal{V}_{(\tau,\pm),\eta} = \mathcal{V}_{(\tau,\pm),x_0} \otimes_{\mathcal{O}} \mathcal{O}_\eta$. The point η lies over no prime, so $\mathcal{V}_{s,\eta} = \mathrm{dR}_{s,\eta} = \mathrm{Lie}_\eta \cap \mathrm{Li}_s$. As $F \subseteq \mathcal{O}_\eta$ contains every conjugate of E, $E \otimes_{\mathbb{Q}} F = \prod_{\sigma \in \mathrm{Hom}(E,F)} F$ supplies idempotents ϵ_σ acting on Lie_η with $\mathrm{Lie}_\eta \cap \mathrm{Li}_s = \epsilon_{\sigma_s}\mathrm{Lie}_\eta$, a direct summand; its base change to k is $\epsilon_{\sigma_s}\mathrm{Lie}(G_y) = \mathrm{Lie}_s(G_y)$. Hence $z^*b^\pm$ is a k-basis of $\mathrm{Lie}_{(\tau,\pm)}(G_y)$, that is, a frame at y (Yf1). Let Λ_s be the V-span of $z^*\mathcal{V}_{s,x_0}$ in $\mathrm{Lie}_s(G_y)$; for $s = (\tau, \pm)$ it is free with basis $z^*b^\pm$.

Step 2: the value of φ_ξ in the Hodge frame. Put $\theta = a^m\pi^{-\nu} \in \mathcal{O}^\times$. As π and π^{-1} are algebraic over $\mathbb{Q} \subseteq \mathcal{O}_\eta$, they are integral over $\mathcal{O}_\eta$ after multiplication by suitable non-zero integers, which are units of $\mathcal{O}_\eta$; so they lie in the normal domain $\mathcal{O}_\eta$, and $\pi \in \mathcal{O}_\eta^\times$. Hence $a^m \in \mathcal{O}_\eta^\times$; so a and a^{-1} are integral over the normal domain $\mathcal{O}_\eta$ ($\mathcal{X}$ is normal by (Go3)(1)), and $a \in \mathcal{O}_\eta^\times$. Near η (on the part of the abelian locus over no prime), $\mathcal{V}_s = \mathrm{Lie}_s(G_\mathcal{X}) = f^*\mathrm{Lie}_s(G')$ by Step 1 and the base change of the idempotents, so $\det \mathcal{V}_{(\tau,+)} \otimes (\det \mathcal{V}_{(\tau,-)})^{-1}$ and $f^*\mathcal{D}$ have the same stalk at η; the section $f^*\xi$ and u_ξ agree at the generic point, hence u_ξ is the germ of $f^*\xi$ at η, and its image at η base changed to k is $\xi(j(y))$ (the fibre of $\mathcal{D}$ at $j(y)$ being identified with $\det \mathrm{Lie}_{(\tau,+)}(G_y) \otimes (\det \mathrm{Lie}_{(\tau,-)}(G_y))^{-1}$ as in Proposition D.38). Applying $z_\eta^\sharp$ to $u_\xi = a\,(\wedge b^+) \otimes (\wedge b^-)^{-1}$ gives

$$\varphi_\xi(y; z^*b^+, z^*b^-) = a_z, \qquad a_z = z_\eta^\sharp(a), \qquad a_z^m = z^\sharp(\theta)\,\pi_z^\nu, \qquad \pi_z = z_\eta^\sharp(\pi), \quad \vartheta(\pi_z) = \kappa(\pi).$$

As $z^\sharp(\theta) \in V^\times$, $|\vartheta(z^\sharp(\theta))| = 1$, and therefore

$$\log|\vartheta(a_z)| = \frac{\nu}{m}\log|\kappa(\pi)|.$$

Step 3: comparison with an integral frame. Let (v, w) be an integral frame of $\mathcal{G}$: bases of $I_{(\tau,+)}$ and $I_{(\tau,-)}$ (Step 0). Write $v = M_+\, z^*b^+$ and $w = M_-\, z^*b^-$ with $M_+ \in \mathrm{GL}_p(k)$, $M_- \in \mathrm{GL}_q(k)$. By the frame law (Yf2), $\varphi_\xi(y; v, w)\det M_+ = \varphi_\xi(y; z^*b^+, z^*b^-)\det M_-$. The data $(V, k, \vartheta, \beta, y, \mathcal{G}, (v, w))$ satisfy the conditions of (Yf3) ($\vartheta \circ \beta = \kappa$, $\mathcal{G}$ semiabelian over V with an $\mathcal{O}_E$-linear isomorphism of its generic fibre with G_y, and Z_c a connected component of Sh_F on which φ_ξ is a frame function by Proposition D.38(1)), so $\log|\vartheta(\varphi_\xi(y; v, w))| = N_\kappa$. With Step 2,

$$N_\kappa - \frac{\nu}{m}\log|\kappa(\pi)| = \log|\vartheta(\det M_-)| - \log|\vartheta(\det M_+)| \qquad (*).$$

Step 4: clause 1. Let $\ell \notin S_B$ and $\ell \nmid \mathrm{disc}(E)$. Then $\mathcal{V}_{s,x_0} = \mathrm{dR}_{s,x_0} = \mathrm{Lie}_{x_0} \cap \mathrm{Li}_s$. Every prime dividing $\mathrm{disc}(E)$ is different from ℓ, hence a unit in $\mathcal{O}$ (it is coprime to ℓ, which lies in the maximal ideal). The $\mathcal{O}_F$-linear map $\mathcal{O}_E \otimes_\mathbb{Z} \mathcal{O}_F \to \prod_{\sigma\in\mathrm{Hom}(E,F)} \mathcal{O}_F$, $a \otimes b \mapsto (\sigma(a)b)_\sigma$, between free modules of rank $[E : \mathbb{Q}]$, has determinant whose square is $\pm\mathrm{disc}(E)$; so after base change to $\mathcal{O}$ it is an isomorphism, and $\mathcal{O}_E \otimes \mathcal{O}$ contains idempotents ϵ_σ with $(a \otimes 1)\epsilon_\sigma = \sigma(a)\epsilon_\sigma$ and $\sum_\sigma \epsilon_\sigma = 1$. They act on Lie_{x_0}, on $\mathrm{Lie}(\mathcal{G})$ and on $\mathrm{Lie}(G_y)$ compatibly with z^*, and ϵ_{σ_s} is the projection of $\mathrm{Lie}(G_y)$ onto $\mathrm{Lie}_s(G_y)$ along the other eigenspaces. Hence $\mathrm{Lie}_{x_0} \cap \mathrm{Li}_s = \epsilon_{\sigma_s}\mathrm{Lie}_{x_0}$ and $I_s = \epsilon_{\sigma_s}\mathrm{Lie}(\mathcal{G})$, and

$$\Lambda_s = V \cdot z^*(\epsilon_{\sigma_s}\mathrm{Lie}_{x_0}) = \epsilon_{\sigma_s}(\mathrm{Lie}_{x_0} \otimes_\mathcal{O} V) = I_s.$$

So $z^*b^\pm$ and (v, w) are bases of the same V-modules, $M_\pm \in \mathrm{GL}(V)$, $|\vartheta(\det M_\pm)| = 1$, and $(*)$ gives clause 1.

Step 5: clause 2, the lower inclusion. Let $\ell \in S_B$, $R = R(\ell)$. By Lemma 35.32, applied to the locally noetherian cover $\mathcal{X}$ (a closed subscheme of a multiprojective space over $\mathbb{Z}$) at x_0 with $p = \ell$ (its last assertion: $\mathcal{X}$ carries a root origin and $\ell \in S_B$), $\varpi_\ell \in \mathcal{O}$, and with $\mathcal{V}_{s,x_0} = \mathrm{HT}_{s,x_0}(\ell^R)$:

$$\varpi_\ell\,\tau(d)\,\mathcal{V}_{(\tau,+),x_0} \subseteq \mathrm{dR}_{(\tau,+),x_0}, \qquad \varpi_\ell\,\mathcal{V}_{(\tau,-),x_0} \subseteq \mathrm{dR}_{(\tau,-),x_0} \qquad (d \in \mathfrak{d}_E),$$

using $\sigma_{(\tau,+)} = \tau$. As $\mathrm{dR}_{s,x_0} \subseteq \mathrm{Lie}_{x_0}$ and z^* maps Lie_{x_0} into $\mathrm{Lie}(\mathcal{G})$ and $\mathrm{Li}_s \cap \mathrm{Lie}_\eta$ into $\mathrm{Lie}_s(G_y)$, $z^*\mathrm{dR}_{s,x_0} \subseteq I_s$. Put $\varpi = z^\sharp(\varpi_\ell)$; then $\varpi\,\beta(\tau(d))\,\Lambda_{(\tau,+)} \subseteq I_{(\tau,+)}$ and $\varpi\,\Lambda_{(\tau,-)} \subseteq I_{(\tau,-)}$. The value of ϖ: for $\ell = 2$, $\varpi = 4$ and $-\log|\vartheta(\varpi)| = 2\log 2$; for ℓ odd, $\varpi = \zeta' - 1$ with $\zeta' = z_\eta^\sharp(\zeta)$ a root of the ℓ-th cyclotomic polynomial Φ_ℓ in k, and $\zeta' \neq 1$ since $\Phi_\ell(1) = \ell \neq 0$ in k; so $\vartheta(\zeta')$ is a primitive ℓ-th root of unity in $\mathbb{C}_\ell$ and $-\log|\vartheta(\varpi)| = \frac{\log\ell}{\ell-1}$. In both cases $-\log|\vartheta(\varpi)| = c_\ell\log\ell$.

Step 6: clause 2, the upper inclusion $I_s \subseteq \Lambda_s$. Let $s = (\tau, \pm)$ and $r = \mathrm{rk}(s)$. By (Go3)(2) the image h_s of $\mathrm{ht}_{x_0} \subseteq \omega_{x_0}$ under restriction to Li_s is a free $\mathcal{O}$-module of rank $r = \dim_\Omega \mathrm{Li}_s$; choose $w_1, \dots, w_r \in \mathrm{ht}_{x_0}$ whose restrictions $h_1, \dots, h_r$ form a basis of h_s, hence an Ω-basis of the dual of Li_s, and let $e_1, \dots, e_r \in \mathrm{Li}_s$ be the dual basis. For $e \in \mathrm{Li}_s$, $e = \sum_i h_i(e) e_i$, so $\mathrm{HT}'_{s,x_0} = \{e \in \mathrm{Li}_s : h(e) \in \mathcal{O} \text{ for all } h \in h_s\} = \bigoplus_i \mathcal{O} e_i$. Moreover $\mathrm{HT}'_{s,x_0} \subseteq \mathcal{V}_{s,x_0}$: for $s = (\tau, -)$ they are equal, and for $s = (\tau, +)$, if $e \in \mathrm{HT}'_{s,x_0}$ and $d \in \mathfrak{d}_E \subseteq \mathcal{O}_E$, then $\tau(d) \in \mathcal{O}_F$ maps into $\mathcal{O}$ and $\tau(d)e \in \mathrm{HT}'_{s,x_0}$, so $e \in \mathrm{HT}_{s,x_0}(\ell^R)$. In particular $e_i \in \mathcal{V}_{s,x_0} \subseteq \mathrm{Lie}_\eta$ (Step 1). Each $w_i \in \omega_{x_0} = \mathrm{Hom}_{\mathcal{O}}(\mathrm{Lie}_{x_0}, \mathcal{O})$ induces $z^* w_i = w_i \otimes V \in \mathrm{Hom}_V(\mathrm{Lie}(\mathcal{G}), V)$, extended k-linearly to $\mathrm{Lie}(G_y)$; it is also the base change of $w_i \otimes \mathcal{O}_\eta \in \mathrm{Hom}(\mathrm{Lie}_\eta, \mathcal{O}_\eta)$, so $(z^* w_i)(z^* e_j) = z_\eta^\sharp(w_i(e_j)) = z_\eta^\sharp(h_i(e_j)) = \delta_{ij}$. Thus $z^* e_1, \dots, z^* e_r$ is a k-basis of the r-dimensional space $\mathrm{Lie}_s(G_y)$ with dual functionals $z^* w_i$, and every $e \in I_s$ satisfies $e = \sum_i (z^* w_i)(e)\, z^* e_i$ with $(z^* w_i)(e) \in V$, because $e \in \mathrm{Lie}(\mathcal{G})$. Hence $I_s \subseteq V \cdot z^* \mathrm{HT}'_{s,x_0} \subseteq \Lambda_s$.

Step 7: clause 2, the determinants. By Step 6, $v \in I^p_{(\tau,+)} \subseteq \Lambda^p_{(\tau,+)}$, so M_+ has entries in V and $|\vartheta(\det M_+)| \le 1$. Let $d \in \mathfrak{d}_E$ be non-zero and $\delta = \varpi\, \beta(\tau(d))$; $\delta \neq 0$ as $\varpi \neq 0$ (Step 5) and $\tau(d) \neq 0$. By Step 5, $\delta\, z^* b^+ = N_+ v$ with $N_+ \in \mathrm{M}_p(V)$; then $\delta \cdot 1_p = N_+ M_+$, so $\delta^p = \det N_+ \det M_+$ and $|\vartheta(\det M_+)| \ge |\vartheta(\delta)|^p$. In the same way $|\vartheta(\varpi)|^q \le |\vartheta(\det M_-)| \le 1$. Since $\tau(d)$ is integral over $\mathbb{Z}$, $-\log|\kappa(\tau(d))| \ge 0$, and by Step 5 $-\log|\vartheta(\delta)| = c_\ell \log \ell - \log|\kappa(\tau(d))|$. Therefore, by $(*)$,

$$-q\, c_\ell \log \ell \;\le\; N_\kappa - \frac{\nu}{m} \log|\kappa(\pi)| \;\le\; p(c_\ell \log \ell - \log|\kappa(\tau(d))|),$$

and both bounds are at most $n(c_\ell \log \ell - \log|\kappa(\tau(d))|)$ in absolute value. This is clause 2. □

Lemma D.70. *Let $\mathfrak{u}$ be a unitary Shimura datum, $\tau \in \Phi_{\mathsf{H}}$, $U \subseteq \mathrm{Sh}_F$ a union of connected components and φ a frame function on U. Let ℓ be a prime and $\kappa, \kappa' \colon F \to \mathbb{C}_\ell$ ring homomorphisms inducing the same prime $\mathfrak{l}$ of $\mathcal{O}_F$. Suppose that φ has ℓ-adic norms N_κ at κ and $N_{\kappa'}$ at κ', and that there is at least one tuple $(V, k, j, \beta, y, \mathcal{G}, (v, w))$ as in (Yf3) with $j \circ \beta = \kappa$ (a discrete valuation ring with fraction field k, $j \colon k \to \mathbb{C}_\ell$ with valuation ring V, $y \in U(k)$ over β, a semiabelian model $\mathcal{G}$ of G_y over V with $\mathcal{O}_E$-action and an integral frame). Then $N_\kappa = N_{\kappa'}$.*

Proof. The homomorphisms κ, κ' extend by continuity to embeddings over $\mathbb{Q}_\ell$ of the completion $F_{\mathfrak{l}}$, a finite extension of $\mathbb{Q}_\ell$, into $\overline{\mathbb{Q}}_\ell \subset \mathbb{C}_\ell$. Two such embeddings differ by an element of $\mathrm{Gal}(\overline{\mathbb{Q}}_\ell / \mathbb{Q}_\ell)$; it preserves $|\cdot|$ (uniqueness of the extension of the absolute value) and so extends by continuity to an automorphism γ of $\mathbb{C}_\ell$ with $|\gamma(x)| = |x|$ for all x and $\kappa' = \gamma \circ \kappa$. Let $(V, k, j, \beta, y, \mathcal{G}, (v, w))$ be a tuple as in the statement. Then $(V, k, \gamma \circ j, \beta, y, \mathcal{G}, (v, w))$ satisfies the conditions of (Yf3) for κ': $\{a \in k : |\gamma(j(a))| \le 1\} = \{a : |j(a)| \le 1\} = V$ and $\gamma \circ j \circ \beta = \kappa'$. Hence $N_{\kappa'} = \log|\gamma(j(\varphi(y; v, w)))| = \log|j(\varphi(y; v, w))| = N_\kappa$. □

Lemma D.71. *Let $\mathcal{X} = \mathcal{X}_{B,c}$ carry a root origin on fixed data at c, with a realisation $\pi \colon \mathcal{X}(\mathbb{C}) \to X_c^{\mathrm{an}}$ of Sys_c defined on $\mathcal{X}(\mathbb{C})$ itself, $\mathcal{X} \otimes \mathbb{Q}$ being smooth. Let $a \in \Phi$, $e_A = \sum_{i=1}^n e_{(a,i)}$, and let h_A be a cone metric of multidegree e_A with $h_A(\tilde z) = \prod_{i=1}^n h_{(a,i)}^{\mathrm{sing}}(\tilde z)$ at every point $\tilde z$ of the affine cone over a complex point of the abelian locus. For $t > 0$ put $v_t = \log h_A - \sum_{i=1}^n \log h_{(a,i)}(t)$ on the affine cone $\widehat{\mathbb{C}}$. Then v_t is smooth and invariant under $(\mathbb{C}^\times)^K$, $\prod_i h_{(a,i)}(t) = h_A e^{-v_t}$, and for all roots $r_1, \dots, r_D$*

$$\lim_{t \to 0^+} \int_{\mathcal{X}(\mathbb{C})} v_t\, c_1(\overline{\mathcal{L}}_{r_1}(t)) \wedge \cdots \wedge c_1(\overline{\mathcal{L}}_{r_D}(t)) = 0.$$

Proof. **Step 1: v_t.** h_A and $\prod_i h_{(a,i)}(t)$ are smooth, positive and homogeneous of the same multidegree e_A, so their logarithmic difference is smooth and invariant under $(\mathbb{C}^\times)^K$, and $\prod_i h_{(a,i)}(t) = h_A e^{-v_t}$ by definition.

Step 2: v_t through the realisation. For a fundamental index $b = (\sigma, i)$ write $H_{(\sigma,i)}(t) = \prod_{k \le i} h_{(\sigma,k)}(t)$ and $H_{(\sigma,0)} = 1$. By (Go4), for $0 < t \le t_0$, $H_{(\sigma,i)}(t)^{-1} = h^{\mathrm{ref}}_{(\sigma,i)} e^{\varphi^T_{(\sigma,i)}(t) \circ \pi}$ at the cone points of $\mathcal{X}$, and on cone points over $\pi^{-1}(X^\circ)$, which by (Go4) is the set of complex points of the abelian locus, $h^{\mathrm{ref}}_{(\sigma,i)} e^{\varphi_{(\sigma,i)} \circ \pi} = \prod_{k \le i} (h^{\mathrm{sing}}_{(\sigma,k)})^{-1}$. Dividing the two identities for $(\sigma, i) = (a, n)$ and using the hypothesis on h_A,

$$v_t = \log \frac{\prod_i h^{\mathrm{sing}}_{(a,i)}}{\prod_i h_{(a,i)}(t)} = g_t \circ \pi, \qquad g_t = \varphi^T_{(a,n)}(t) - \varphi_{(a,n)} \text{ on } X^\circ \qquad (0 < t \le t_0)$$

at all cone points over $\pi^{-1}(X^\circ)$ (here v_t, being $(\mathbb{C}^\times)^K$-invariant, is read as a function on $\mathcal{X}(\mathbb{C})$).

Step 3: the root forms. By (Go4) the metric of the fundamental index b with cone function $H_b(t)^{-1}$ is the pull-back by π of $(\mathcal{M}_b, h^{\mathrm{ref}}_b e^{\varphi^T_b(t)})$, whose Chern form is $\Omega_b(t) = \theta_b + dd^c \varphi^T_b(t)$, θ_b the Chern form of $(\mathcal{M}_b, h^{\mathrm{ref}}_b)$; put $\Omega_{(\sigma,0)}(t) = 0$. Since $h_{(\sigma,k)}(t) = H_{(\sigma,k)}(t)/H_{(\sigma,k-1)}(t)$, the root line $\overline{\mathcal{L}}_{(\sigma,k)}(t)$ is the fundamental line of $(\sigma, k-1)$ tensored with the inverse of that of (σ, k), and

$$c_1(\overline{\mathcal{L}}_{(\sigma,k)}(t)) = \pi^*\big(\Omega_{(\sigma,k-1)}(t) - \Omega_{(\sigma,k)}(t)\big) \qquad (0 < t \le t_0).$$

Expanding the product by multilinearity, $\bigwedge_j c_1(\overline{\mathcal{L}}_{r_j}(t))$ is a signed sum of at most 2^D forms $\pi^*\mu_t$, $\mu_t = \bigwedge_{j=1}^D \Omega_{b_j}(t)$ for fundamental indices $b_j = (\sigma_j, i_j)$ with $i_j \ge 1$ (terms containing some $\Omega_{(\sigma,0)} = 0$ vanish). It suffices to show $\int_{\mathcal{X}(\mathbb{C})} v_t \, \pi^*\mu_t \to 0$ for each such μ_t.

Step 4: transfer to X. The complement of $\pi^{-1}(X^\circ)$ in $\mathcal{X}(\mathbb{C})$ is the set of complex points outside the abelian locus, a proper closed analytic subset, hence of measure zero; so is the preimage $\pi^{-1}(\Sigma)$ of the exceptional analytic subset $\Sigma \subset X$ of (Go4), and Σ itself. Off these sets π is a local biholomorphism with exactly $\deg_{B,c}$ preimages over every point. By Step 2 and the change of variables for such a covering,

$$\int_{\mathcal{X}(\mathbb{C})} v_t \, \pi^*\mu_t = \deg_{B,c} \int_{X^\circ} g_t \, \mu_t \qquad (0 < t \le t_0),$$

the right side being absolutely convergent because $|g_t| \le C'' \log \mathrm{rW}$ (Step 5) and $\log \mathrm{rW}$ is integrable against the smooth form μ_t (it is a sum of terms $\log(-\log|z_k|^2)$ plus a bounded function in local coordinates adapted to ∂X).

Step 5: the convergence. Apply Lemma 31.35 to X, Θ, ς, with $v = 1$ a section of the trivial bundle ($D_v = \varnothing$, $G = 0$), I the fundamental indices (σ, i), $i \ge 1$, θ_b, $u_b = \varphi_b$, $u_{b,t} = \varphi^T_b(t)$, $t_0' = \min(t_0, e^{-e})$, $\delta(t) = t^{1/3} + (1 + C)\varepsilon(t)$, $R(t) = \log(1/t)$ (so $R(t) \ge e$ and δ, R tend to 0 and ∞), and the constant $C''' = \max(C_5, C, \sup_{0<t\le t_0'} \varepsilon(t), 1)$. Its hypotheses are (Go1): (R1) is the plurisubharmonicity of $h^{\mathrm{ref}}_b e^{\varphi^T_b(t)}$ twisted by $\varepsilon(t)\Theta$, i.e. $\Omega_b(t) + \varepsilon(t)\Theta \ge 0$; (R2) is $-C_5 \log \mathrm{rW} \le \varphi_b \le \varphi^T_b(t) \le C$; (R3) is $\varphi^T_b(t) \le \varphi_b + t^{1/3} + \varepsilon(t)$ where $\mathrm{rW} \le \log(1/t)$; (R4) is $\varphi^T_b(t) \le \varphi^T_b(t') + C\varepsilon(t')$; (R5) is (Go1)(3). The functions g_t are continuous on X° with $0 \le g_t \le C + C_5 \log \mathrm{rW} \le (C + C_5) \log \mathrm{rW}$ (as $\log \mathrm{rW} \ge 1$), and $g_t \to 0$ uniformly on compact subsets of X° by (Go1)(3). By Lemma 31.35(2) with $g = 0$, $\int_{X^\circ} g_t \, \mu_t \to 0$, and by Steps 3 and 4 the limit of the statement is 0. □

Lemma D.72. *Let $\mathcal{X}$ be a root model of type (Φ, n) with convergent regularisation, let $a \in \Phi$, and let $\overline{\mathcal{A}}$ be a flat determinant line of $\mathcal{X}$ at a, of height $\mathrm{ht}(\overline{\mathcal{A}})$. Then*

$$\mathrm{pp}(\mathcal{X}; \mathrm{ps}_{a,1} Q) = \mathrm{ht}(\overline{\mathcal{A}}) \, \mathrm{gi}(\mathcal{X}; Q)$$

for every $Q \in \mathcal{R}$ homogeneous of degree D.

Proof. Both sides are linear in Q, so it suffices to take a monomial $Q = x_{r_1}\cdots x_{r_D}$ with roots $r_1,\dots,r_D \in \mathrm{Rt}$. Take the data of (Dl1) and (Dl2) for $\overline{\mathcal{A}}$: the number field F, M, f, g, (κ_s), h_A and (v_t). Fix $t>0$ and write $c_1^Q(t) = c_1(\overline{\mathcal{L}}_{r_1}(t)) \wedge \cdots \wedge c_1(\overline{\mathcal{L}}_{r_D}(t))$ and $\widehat{c}^{\,Q}(t) = \widehat{c}_1(\overline{\mathcal{L}}_{r_1}(t))\cdots\widehat{c}_1(\overline{\mathcal{L}}_{r_D}(t))$.

Step 1: the product line. No factor of $\mathrm{ps}_{a,1}Q$ is the auxiliary variable, so by (29.2) and the additivity of $\widehat{c}_1$ under tensor products,

$$\mathrm{ai}_t(\mathcal{X};\mathrm{ps}_{a,1}Q) = \frac{1}{\delta_{\mathcal{X}}}\sum_{i=1}^{n}\widehat{\deg}\big(\widehat{c}_1(\overline{\mathcal{L}}_{(a,i)}(t))\,\widehat{c}^{\,Q}(t)\big) = \frac{1}{\delta_{\mathcal{X}}}\widehat{\deg}\big(\widehat{c}_1(\overline{\mathcal{B}}_t)\,\widehat{c}^{\,Q}(t)\big),$$

where $\overline{\mathcal{B}}_t = \bigotimes_i \overline{\mathcal{L}}_{(a,i)}(t) = (\mathcal{O}(e_A), \prod_i h_{(a,i)}(t))|_{\mathcal{X}}$, using $e_A = \sum_i e_{(a,i)}$ (Dl2).

Step 2: the section f/g. Choose any cone metric h_g of multidegree d_g (a product of powers of Fubini–Study cone functions) and put $h_f = (\prod_i h_{(a,i)}(t))^M h_g$, a cone metric of multidegree $Me_A + d_g = d_f$. Then $\overline{\mathcal{B}}_t^{\otimes M} \cong (\mathcal{O}(d_f),h_f)\otimes(\mathcal{O}(d_g),h_g)^{\otimes -1}$ isometrically on $\mathcal{X}$, so by multilinearity $M\,\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{B}}_t)\widehat{c}^{\,Q}(t))$ is the difference of the intersection numbers of $(\mathcal{O}(d_f),h_f)$ and of $(\mathcal{O}(d_g),h_g)$ against $\widehat{c}^{\,Q}(t)$. The global sections f and g do not vanish identically on the integral scheme $\mathcal{X}$, so their divisors meet $\mathcal{X}$ properly, and Lemma 30.17 (on the regular ambient $\mathbb{P}$ of $\mathcal{X}$, with $\mathcal{Z}=\mathcal{X}$; all bundles here are restrictions of cone metrics, i.e. smooth metrics on $\mathbb{P}$) applies to both: the height of $\mathcal{X}$ is the contribution of the Weil divisor of the section (horizontal heights and $\log p$ times vertical degrees) minus $\int_{\mathcal{X}(\mathbb{C})}\log\|s\|\,c_1\wedge\cdots\wedge c_1$. Since f/g generates $\mathcal{O}(Me_A)|_{\mathcal{X}}$ at every point, $\mathrm{div}(f)=\mathrm{div}(g)$ as Cartier divisors on $\mathcal{X}$, so the two Weil divisors coincide and the two divisor contributions cancel. With $\log\|f\|_{h_f}-\log\|g\|_{h_g} = \log|f|-\log|g|-M\sum_i\log h_{(a,i)}(t)$ we get

$$M\,\widehat{\deg}\big(\widehat{c}_1(\overline{\mathcal{B}}_t)\,\widehat{c}^{\,Q}(t)\big) = -\int_{\mathcal{X}(\mathbb{C})}\Big(\log\frac{|f|}{|g|} - M\sum_{i=1}^{n}\log h_{(a,i)}(t)\Big)c_1^Q(t),$$

the integrand being a function on $\mathcal{X}(\mathbb{C})$ (it is invariant under the scaling of the cone, as $d_f-d_g = Me_A$).

Step 3: the integrand. $\mathcal{X}(\mathbb{C}) = \bigsqcup_{s\colon F\to\mathbb{C}}\mathcal{X}_s(\mathbb{C})$ with $\mathcal{X}_s = \mathcal{X}\otimes_{\mathcal{O}_F,s}\mathbb{C}$, as $\mathcal{X}\to\operatorname{Spec}\mathbb{Z}$ factors through $\operatorname{Spec}\mathcal{O}_F$. On $\mathcal{X}_s(\mathbb{C})$, by (Dl1) and (Dl2),

$$\log\frac{|f|}{|g|} - M\sum_i\log h_{(a,i)}(t) = M\log\kappa_s + M\log h_A - M\big(\log h_A - v_t\big) = M\log\kappa_s + Mv_t.$$

Hence

$$\widehat{\deg}\big(\widehat{c}_1(\overline{\mathcal{B}}_t)\,\widehat{c}^{\,Q}(t)\big) = -\sum_s\log\kappa_s\int_{\mathcal{X}_s(\mathbb{C})}c_1^Q(t) - \int_{\mathcal{X}(\mathbb{C})}v_t\,c_1^Q(t).$$

Step 4: the geometric degrees. The integral of the Chern forms of smooth metrics over $\mathcal{X}_s(\mathbb{C})$ is the intersection number $g_s = \deg(c_1(\mathcal{O}(e_{r_1}))\cdots c_1(\mathcal{O}(e_{r_D}))\cap[\mathcal{X}_s])$, independent of t. The schemes $\mathcal{X}_s$ are the base changes of the F-variety $\mathcal{X}_F$ along the embeddings s, which are permuted transitively by the automorphisms of $\mathbb{C}$, and the bundles $\mathcal{O}(e_r)$ are defined over $\mathbb{Z}$; so $g_s = g$ does not depend on s, and $[F:\mathbb{Q}]\,g = \sum_s g_s = \deg(c_1(\mathcal{O}(e_{r_1}))\cdots c_1(\mathcal{O}(e_{r_D}))\cap[\mathcal{X}_{\mathbb{Q}}]) = \delta_{\mathcal{X}}\,\mathrm{gi}(\mathcal{X};Q)$. Therefore, by Steps 1–3 and the definition of $\mathrm{ht}(\overline{\mathcal{A}})$ in (Dl1),

$$\mathrm{ai}_t(\mathcal{X};\mathrm{ps}_{a,1}Q) = \mathrm{ht}(\overline{\mathcal{A}})\,\mathrm{gi}(\mathcal{X};Q) - \frac{1}{\delta_{\mathcal{X}}}\int_{\mathcal{X}(\mathbb{C})}v_t\,c_1^Q(t).$$

Step 5: the limit. As $t\to 0^+$ the last integral tends to 0 by (Dl2), and $\mathrm{ai}_t(\mathcal{X};\mathrm{ps}_{a,1}Q)\to\mathrm{pp}(\mathcal{X};\mathrm{ps}_{a,1}Q)$ because $\mathcal{X}$ has convergent regularisation (Definition 30.1; $\mathrm{ps}_{a,1}Q$ is a sum of monomials of $\mathcal{R}^+$). This gives the identity for monomials, hence for all Q. □

D.4.2 Proportional square systems and covolumes

Flag models carry analytic square systems for every Levi reflection (Proposition D.74), and with the comparison of root origins of Section 31 this gives Proposition D.73. Geometric proportionality with covolumes Proposition D.79 has two halves: the geometric intersection forms of the root models are proportional to the flag degree (Proposition D.80), by a flag-volume identity (Lemma D.81) and the Weyl proportionality of Section 33 (Proposition D.82); and the geometric volumes are sums of covolumes of principal congruence subgroups of lattices in one genus (Proposition D.83), computed through the complex uniformisation of the moduli scheme.

Proposition D.73. *Let $\mathfrak{u}$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Then the realised tower (whose root models have convergent regularisation by Theorem 31.20) has proportional analytic square systems: for every integer $B \geq 2$, every $Z \in \mathrm{Cp}$ and every Levi reflection s there are a root model $\mathcal{X}'$ of type (Φ, n) with convergent regularisation and a real number $m > 0$ with $\mathrm{pp}(\mathcal{X}';\cdot) = m\,\mathrm{pp}(\mathcal{X}_{B,Z};\cdot)$ and $\mathrm{gi}(\mathcal{X}';\cdot) = m\,\mathrm{gi}(\mathcal{X}_{B,Z};\cdot)$ on $\mathcal{R}$, and a square system for s on $\mathcal{X}'$ with (Fx5), (Fx6), (Fx7) and an analytic square system.*

Proof. Let $B \geq 2$, $Z \in \mathrm{Cp}$ and s a Levi reflection; write $c = Z$, $\mathcal{X} = \mathcal{X}_{B,Z}$, and let $\mathcal{Y}_c$ be the component of $\mathcal{Y}$ of the fixed data at c (Go2), (Go5). The hypotheses of Proposition 34.2 include that $\mathcal{Y}$ has uniformised degenerations and $p, q \geq 1$ ($q \geq 1$ and $p \geq 2q+1$).

Step 1: the flag model. The set S_B contains Bd, the primes dividing $2\,\mathrm{disc}(E)\,N'$ (Go5), hence every prime dividing $\mathrm{disc}(E)$. By Proposition D.74 for the fixed data at c and $S = S_B$ there is a root model $\mathcal{X}'$ of type (Φ, n) with clauses 1–3 there; by clause 3 it carries, for the given s, a square system with (Fx5), (Fx6), (Fx7) and an analytic square system.

Step 2: $\mathcal{X}$ satisfies the hypotheses of Proposition 31.27 for (S_B, R) with $R(\ell) = 4$. This is Lemma 31.37 (with Sys_c, $d = \deg_{B,c}$ and the realisation π of (Go4)).

Step 3: the comparison. By Step 1, clauses 1 and 2 of Proposition D.74, $\mathcal{X}'$ satisfies the same hypotheses for the same fixed data and the same (S_B, R). The set S_B contains every prime dividing $\mathrm{disc}(E)$ (Step 1). By Proposition 31.27 with $S = S_B$, $\mathcal{X}_1 = \mathcal{X}'$, $\mathcal{X}_2 = \mathcal{X}$, $c_1 = c_2 = c$ and the identity twist ($g = \mathrm{id}$, $\mathrm{tw} = \mathrm{id}$, $\psi = \mathrm{id}$, so $\sigma_g = \mathrm{id}$ and tw_F maps Z_c onto itself), both have convergent regularisation and, by its parts 1 and 2, $\mathrm{pp}(\mathcal{X}';F) = \mathrm{pp}(\mathcal{X};F)$, $\mathrm{gi}(\mathcal{X}';F) = \mathrm{gi}(\mathcal{X};F)$ for every $F \in \mathcal{R}$. Hence $\mathcal{X}'$ with the factor $m = 1$ and the square system of Step 1 is a proportional square model of $\mathcal{X}$ for s (Definition 31.9). As B, Z and s were arbitrary, the realised tower has proportional analytic square systems. □

Proposition D.74. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$ be a unitary Shimura datum with $p, q \geq 1$, $\Phi = \Phi_{\mathsf{H}}$, $n = p + q$, let $\mathcal{Y}$ be an integral model of* Sh *over $\mathcal{O}_F$ with uniformised degenerations, let fixed data at an irreducible component $\mathcal{Y}_c$ of $\mathcal{Y}$ be given, and let S be a finite set of primes containing every prime dividing* $\mathrm{disc}(E)$. *Then there is a root model $\mathcal{X}'$ of type (Φ, n) such that:*

1. *$\mathcal{X}'_{\mathbb{Q}}$ is smooth, and $\mathcal{X}'$ carries the data (Go3)(1)–(4) of a root origin on the fixed data at c for S with $R(\ell) = 4$ for every $\ell \in S$;*

2. *there are an analytic system* Sys' *(Go1) with $\varphi_* = 0 = \varphi_*^T$ and a holomorphic map $\pi' \colon \mathcal{X}'(\mathbb{C}) \to X^{\mathrm{an}\prime}$ satisfying hypotheses 1–3 of Lemma 31.21 for some integer $d \geq 1$, such that a point of $\mathcal{X}'(\mathbb{C})$ lies in the abelian locus if and only if its image lies in the open part $X^{\circ\prime}$, and on $\pi'^{-1}(X^{\circ\prime})$ the singular weights are the Hodge metric: $h^{\mathrm{ref}}_{(\tau,i)} e^{\varphi_{(\tau,i)} \circ \pi'} = \prod_{k \leq i} (h^{\mathrm{sing}}_{(\tau,k)})^{-1}$ for $(\tau, i) \in \mathrm{Rt}$;*

3. *for every Levi reflection s there is a square system for s on $\mathcal{X}'$ with open parts and limit metrics (Fx5), fibre charts with (Fx6) and (Fx7), and an analytic square system (Sw1)–(Sw3).*

Proof. Let $\mathcal{X}^{\mathrm{b}}$ be a Hodge base for $\mathcal{Y}_c$ and S (Proposition 33.9; it needs only that S contains the primes dividing $\mathrm{disc}(E)$), and $\mathcal{X}'$ the flag bundle of its Hodge bundles with the multiprojective immersion and the data of (Go3)(1)–(4) of Lemma 33.8, made a root model of type (Φ, n) by Proposition 33.12, item 1.

Clause 1. $\mathcal{X}'_{\mathbb{Q}}$ is smooth by Lemma 33.8, item 1, and Lemma 33.8, item 2, gives the data of (Go3)(1)–(4) on the fixed data at c for S with $R(\ell) = 4$ for every $\ell \in S$ (with $\delta_{\mathcal{X}'} = [F : \mathbb{Q}]\deg$, as fixed in Proposition 33.12).

Clause 2. Proposition 33.12, item 2, gives the analytic system Sys' with $\varphi_* = 0 = \varphi_*^T$ and $\pi' = \mathrm{id}\colon \mathcal{X}'(\mathbb{C}) \to X^{\mathrm{an}\prime} = \mathcal{X}'(\mathbb{C})$ satisfying hypotheses 1–3 of Lemma 31.21 with $d = 1$; its open part $X^{\circ\prime}$ is the abelian locus, so a point lies in the abelian locus if and only if its image lies in $X^{\circ\prime}$; and on $\pi'^{-1}(X^{\circ\prime})$, $h^{\mathrm{ref}}_{(\tau,i)} e^{\varphi_{(\tau,i)} \circ \pi'} = \prod_{k \le i} (h^{\mathrm{sing}}_{(\tau,k)})^{-1}$.

Clause 3. Let $s = s_{\tau,i}$ be a Levi reflection and $(k_0, \mathcal{X}^{(2)}, g, h)$ as in Lemma D.75: it satisfies (Fx2) and (Fx3), and $(e_\Xi)_{k_0} = -2$. The factor k_0 is the Plücker factor $k_{s',j}$ with $s' = (\tau, +)$, $j = i$ if $i < p$ and $s' = (\tau, -)$, $j = n - i$ if $i > p$, and $\{r_1, r_2\} = \{(\tau, i), (\tau, i+1)\}$ is the set of the roots of label s' and steps j, $j+1$ (by (Fh3) of Definition 29.6: for $i < p$ both roots have label $(\tau, +)$ and steps i, $i+1$; for $i > p$ label $(\tau, -)$ and steps $n+1-i$, $n-i$). By Proposition 33.12, item 3, for every $t > 0$ the cone metrics $h_r(t)$, $r \notin \{r_1, r_2\}$, and $h_{r_1}(t) h_{r_2}(t)$ are from the base at k_0. So (Fx1) holds, and $(k_0, \mathcal{X}^{(2)}, g, h)$ is a square system for s on $\mathcal{X}'$. By Proposition D.76 it has open parts and limit metrics (Fx5), fibre charts with (Fx6) and (Fx7), and an analytic square system (Sw1)–(Sw3). One root model $\mathcal{X}'$ serves all Levi reflections. □

Lemma D.75. *In the situation of Lemma 33.8, let $s_{\tau,i}$ be a Levi reflection, and let $k_0 = k_{(\tau,+),i}$ if $i < p$ and $k_0 = k_{(\tau,-),n-i}$ if $i > p$. Then:*

1. *$(e_\Xi)_{k_0} = -2$, $(e_{r_1} + e_{r_2})_{k_0} = 0$, and $(e_r)_{k_0} = 0$ for every root $r \notin \{r_1, r_2\}$;*
2. *there are a closed integral subscheme $\mathcal{X}^{(2)} \subseteq \mathbb{P}^{(2)} = \mathbb{P} \times \mathbb{P}(\mathbb{Z}^{I_{k_0}})$ and multihomogeneous polynomials g, h with integer coefficients in the coordinates of $\mathbb{P}^{(2)}$ satisfying (Fx2) and (Fx3) for $\mathcal{X}'$, $s_{\tau,i}$ and k_0; here $\mathcal{X}^{(2)}$ is the image of $\mathcal{X}' \times_{\beta_{s,j}} \mathcal{X}'$ under the map*

$$(x, x'') \mapsto (x, \text{the } k_0\text{-coordinates of } x''),$$

Δ is the image of the diagonal, and g/h is a 2×2 minor of the k_0-coordinates of the two points divided by a rational section pulled back from $\mathcal{X}'_{s,j}$ (with s, j the label and step of k_0); more precisely, $g = (z_{k_0,a} z'_b - z_{k_0,b} z'_a) H(z)$ and $h = G(z)$ for some $a, b \in I_{k_0}$ and multihomogeneous G, H in the coordinates of $\mathbb{P}$ with $\deg G - \deg H = e_\delta := 2e_{\mathcal{H}} - d_{s,j-1} - d_{s,j+1}$ ($e_{\mathcal{H}}$, $d_{s,k}$ the base and fundamental multidegrees of that Plücker datum, whose fundamental root sections $P \mapsto \varrho_{s,k} P(y) w_{s,k}\colon \mathcal{O}(d_{s,k})|_{\mathcal{X}'} \to \wedge^k \mathcal{V}'_{s,k}$ are isomorphisms by Lemma 33.8(d)), such that under these root sections and $F \mapsto F(y)\colon \mathcal{O}(e_{\mathcal{H}})|_{\mathcal{X}'} \to \beta^* \mathcal{H}^m$ the rational section G/H of $\mathcal{O}(e_\delta)|_{\mathcal{X}'}$ is the section δ^{loc} of $(\wedge^{j-1} \mathcal{V}'_{s,j-1})^{-1} \otimes (\wedge^{j+1} \mathcal{V}'_{s,j+1})^{-1} \otimes \beta^* \mathcal{H}^{2m}$, $\gamma \otimes \gamma' \mapsto \det\big(\sigma_{s,j,c}(\gamma \wedge u_l)\big)_{l=1,2;\, c=a,b}$ for $\gamma' = \gamma \wedge u_1 \wedge u_2$, with $\sigma_{s,j,\cdot}$ the sections of the Plücker datum defining the factor k_0.

Proof. Write (s, j) for the label and step of k_0: $s = (\tau, +)$, $j = i$ if $i < p$; $s = (\tau, -)$, $j = n - i$ if $i > p$. In both cases $1 \le j < \mathrm{rk}(s)$, and $\{r_1, r_2\}$ is the set of the two roots of label s with steps

j and $j+1$: for $i<p$, $\mathrm{st}(r_1)=j$, $\mathrm{st}(r_2)=j+1$, signs $+1$; for $i>p$, $\mathrm{st}(r_1)=n+1-i=j+1$, $\mathrm{st}(r_2)=j$, signs -1.

Item 1. By Lemma 33.8(c), $(e_r)_{k_0}=0$ for $r\notin\{r_1,r_2\}$, and for $i<p$: $(e_{r_1})_{k_0}=-1$, $(e_{r_2})_{k_0}=1$; for $i>p$: $(e_{r_1})_{k_0}=\mathrm{sg}=-1$, $(e_{r_2})_{k_0}=-\mathrm{sg}=1$. In both cases $(e_\Xi)_{k_0}=-2$ and $(e_{r_1}+e_{r_2})_{k_0}=0$. Moreover, with $e^\flat$ denoting e with its k_0-entry replaced by 0, both cases give

$$e_\Xi^\flat = 2e_{\mathcal{H}} - d_{s,j-1} - d_{s,j+1} \tag{XI}$$

.

The fibre square. Let $Q=\mathcal{V}'_{s,j+1}/\mathcal{V}'_{s,j-1}$, pulled back from $\mathcal{X}'_{s,j}$, locally free of rank 2; $\beta_{s,j}$ is the bundle of lines of Q (Lemma 33.8(b)). Let $\mathcal{X}''=\mathcal{X}'\times_{\mathcal{X}'_{s,j}}\mathcal{X}'$ with projections $\mathrm{pr}_0,\mathrm{pr}_1$; via pr_0 it is the bundle of lines of pr_0^*Q over $\mathcal{X}'$, so it is integral, normal, projective over $\mathbb{Z}$, flat over $\mathbb{Z}$, of absolute dimension $D+2$. The composite of $w\wedge\cdot\colon\wedge^{j-1}\mathcal{V}'_{s,j-1}\otimes Q\to\wedge^j\mathcal{V}_s$ (injective with locally free cokernel) and of the map $\wedge^j\mathcal{V}_s\to(\mathcal{H}^m)^{I_{k_0}}$ dual to the surjection given by the $\sigma_{s,j,\cdot}$ is injective with locally free cokernel; so the k_0-component embeds the bundle of lines of Q linearly, and $\mathcal{X}''\to\mathcal{X}'\times\mathbb{P}(\mathbb{Z}^{I_{k_0}})$, $(x,x'')\mapsto(x,\iota_{k_0}(x''))$, is a closed immersion over $\mathcal{X}'$. Composed with the closed immersion of $\mathcal{X}'$ it gives a closed immersion $\mathcal{X}''\to\mathbb{P}^{(2)}$; let $\mathcal{X}^{(2)}$ be its image. By Lemma 33.8(a), all coordinates of x'' outside k_0 equal those of x, so $q_1(\mathcal{X}^{(2)})$ is the image of pr_1, i.e. $\mathcal{X}'$; and $q_0(\mathcal{X}^{(2)})=\mathcal{X}'$. The fibre of q_0 over the generic point of $\mathcal{X}'$ is the image of the fibre of $\beta_{s,j}$ through it, a line by Lemma 33.8(b). This is (Fx2).

The diagonal and the minor. Let $\Delta\subseteq\mathcal{X}^{(2)}$ be the image of the diagonal section of pr_0: closed, integral, of absolute dimension $D+1$, and on it z' and z_{k_0} are the same point of $\mathbb{P}(\mathbb{Z}^{I_{k_0}})$, so the minors $z_{k_0,a}z'_b-z_{k_0,b}z'_a$ vanish. Over a point of $\mathcal{X}'_{s,j}$ choose local bases: by the injectivity above and since the $\sigma_{s,j,\cdot}$ span every fibre of the dual, at the generic point the vectors $(\sigma_{s,j,a}(w_{s,j-1}\wedge v))_{a\in I_{k_0}}$, $v\in\{v_{s,j},v_{s,j+1}\}$, are linearly independent; fix $a,b\in I_{k_0}$ with

$$\delta=\det\begin{pmatrix}\sigma_{s,j,a}(w_{s,j-1}\wedge v_{s,j}) & \sigma_{s,j,b}(w_{s,j-1}\wedge v_{s,j})\\ \sigma_{s,j,a}(w_{s,j-1}\wedge v_{s,j+1}) & \sigma_{s,j,b}(w_{s,j-1}\wedge v_{s,j+1})\end{pmatrix}\neq 0$$

in Ω' (the values lie in $\mathcal{H}^m\otimes\Omega'=\Omega'$). The same determinant, formed with local generators, is the section δ^{loc} of $N=(\wedge^{j-1}\mathcal{V}'_{s,j-1})^{-2}\otimes(\det Q)^{-1}\otimes\mathcal{H}^{2m}=(\wedge^{j-1}\mathcal{V}'_{s,j-1})^{-1}\otimes(\wedge^{j+1}\mathcal{V}'_{s,j+1})^{-1}\otimes\mathcal{H}^{2m}$ given by the determinant of the map $\wedge^{j-1}\mathcal{V}'_{s,j-1}\otimes Q\to(\mathcal{H}^m)^2$ through the coordinates a,b; it is pulled back from $\mathcal{X}'_{s,j}$. Through the fundamental root sections (isomorphisms by Lemma 33.8(d)) and $F\mapsto F(y)$, an isomorphism $\mathcal{O}(e_{\mathcal{H}})|_{\mathcal{X}'}\to\beta^*\mathcal{H}^m$ (the base factors of Definition 33.7), $N\cong\mathcal{O}(e_\delta)|_{\mathcal{X}'}$ with $e_\delta=2e_{\mathcal{H}}-d_{s,j-1}-d_{s,j+1}$, and δ^{loc} corresponds to the rational section $c\,\delta$ of $\mathcal{O}(e_\delta)$ for a constant $c\in\Omega'^{\times}$ (a product of the $\varrho_{s,k}^{\pm1}$). Every element of Ω' is a quotient of multihomogeneous integer polynomials of equal multidegree evaluated at the representing coordinates, so $c\,\delta=G(y)/H(y)$ with G,H multihomogeneous, $\deg G-\deg H=e_\delta$, $G(y),H(y)\neq0$; then the divisor of the rational section G/H of $\mathcal{O}(e_\delta)|_{\mathcal{X}'}$ is $\mathrm{div}(\delta^{\mathrm{loc}})$. Put

$$g=(z_{k_0,a}z'_b-z_{k_0,b}z'_a)\,H(z),\qquad h=G(z),$$

polynomials in the coordinates of $\mathbb{P}^{(2)}$ (G, H in the coordinates of the first factor).

The divisor identity. Let μ be the restriction of the minor to $\mathcal{X}''$, a section of $q_0^*\mathcal{O}(\mathbf{1}_{k_0})\otimes\mathcal{O}(1)_{\mathrm{last}}$. At a point (x,x'') over a point of $\mathcal{X}'_{s,j}$, with x, x'' the lines ℓ, ℓ'' of Q and w a local generator of $\wedge^{j-1}\mathcal{V}'_{s,j-1}$, the k_0-coordinates of x and x'' are the values of the $\sigma_{s,j,\cdot}$ on $w\wedge u$, $w\wedge u''$ for generators u of ℓ, u'' of ℓ''; so μ corresponds to $(w\otimes u)\otimes(w\otimes u'')\mapsto\delta^{\mathrm{loc}}\cdot(u\wedge u'')$, where $u\wedge u''$ is the canonical section of $\ell^{-1}\otimes\ell''^{-1}\otimes\det Q$ (multiplicativity of 2×2 determinants). Locally over $\mathcal{X}'_{s,j}$, with Q free on f_1,f_2 and affine fibre coordinates $\ell=\langle f_1+tf_2\rangle$, $\ell''=\langle f_1+t''f_2\rangle$,

$u \wedge u'' = (t''-t) f_1 \wedge f_2$ (and likewise at $t=\infty$), whose divisor is the diagonal, reduced. Hence, as Cartier (equivalently Weil, $\mathcal{X}''$ being normal) divisors on $\mathcal{X}'' \cong \mathcal{X}^{(2)}$,

$$\begin{aligned}\operatorname{div}(\mu) &= [\Delta] + q_0^*\operatorname{div}(\delta^{\mathrm{loc}}),\\ \operatorname{div}(g|_{\mathcal{X}^{(2)}}) &= [\Delta] + q_0^*\operatorname{div}(\delta^{\mathrm{loc}}) + q_0^*\operatorname{div}(H),\\ \operatorname{div}(h|_{\mathcal{X}^{(2)}}) &= q_0^*\operatorname{div}(G) = q_0^*\operatorname{div}(\delta^{\mathrm{loc}}) + q_0^*\operatorname{div}(H),\end{aligned}$$

so $\operatorname{div}(g|_{\mathcal{X}^{(2)}}) = \operatorname{div}(h|_{\mathcal{X}^{(2)}}) + [\Delta]$; neither g nor h vanishes identically on $\mathcal{X}^{(2)}$. Degrees: $\deg g - \deg h = (\mathbf{1}_{k_0} - e_\delta,\, 1) \in \mathbb{Z}^K \times \mathbb{Z}$, while $q_0^* e_\Xi + q_1^* e_\Xi = (e_\Xi + e_\Xi^\flat, (e_\Xi)_{k_0}) = (2e_\Xi^\flat - 2\cdot\mathbf{1}_{k_0}, -2)$ by item 1; by (XI), $e_\delta = e_\Xi^\flat$, so $2(\deg g - \deg h) = -(q_0^* e_\Xi + q_1^* e_\Xi)$. This is (Fx3). □

Proposition D.76. *In the situation of Proposition 33.12, let s be a Levi reflection and $(k_0, \mathcal{X}^{(2)}, g, h)$ the square system for s of Lemma D.75 on the root model $\mathcal{X}'$ of Proposition 33.12, item 1. Then, with X° the abelian locus of $\mathcal{X}'(\mathbb{C})$, $W^\circ = q_0^{-1}(X^\circ) \cap \mathcal{X}^{(2)}(\mathbb{C})$ and the limit metrics $h_r(0) = h_r^{\mathrm{sing}}$ on the cone over X° ($r \in \mathrm{Rt}$), the square system has open parts and limit metrics (Fx5), fibre charts with (Fx6) and (Fx7), and an analytic square system (Sw1)–(Sw3).*

Proof. Put $X = \mathcal{X}'(\mathbb{C})$ and $W = \mathcal{X}^{(2)}(\mathbb{C})$.

(Fx5)–(Fx7). By Lemma D.77, X°, W° and the limit metrics $h_r(0) = h_r^{\mathrm{sing}}$ satisfy (Fx5), and there are fibre charts satisfying (Fx6) and (Fx7).

Compact models and (Sw2). By Lemma D.78, item 1, $(X, \Theta', \varsigma, \mathrm{id}, 1)$ is a compact model of X° with $X \smallsetminus \partial X = X^\circ$, $(W, \Theta_W, q_0^*\varsigma, \mathrm{id}, 1)$ is a compact model of W°, and $p_j = q_j|_W$ $(j = 0, 1)$ satisfy (Sw2).

(Sw1). Let Λ be the set of fundamental indices of Sys', a finite set, and for $\lambda \in \Lambda$ put $\gamma_\lambda = \theta_\lambda$, $f_\lambda = \varphi_\lambda$ on X° and $f_{\lambda,t} = \varphi_\lambda^T(t)$ on X $(0 < t \le t_1)$, where $t_1 = \min(t_0, e^{-e}) \in (0,1)$. By Lemma D.78, item 2, these families satisfy (R1)–(R5) on (X, Θ', ς) for some constant ≥ 1 and the functions δ, R of that item. For a root $r = (\tau, i)$ and $\lambda \in \Lambda$ put $b_{r,\lambda} = -1$ if $\lambda = (\tau, i)$, $b_{r,\lambda} = 1$ if $i \ge 2$ and $\lambda = (\tau, i-1)$, and $b_{r,\lambda} = 0$ otherwise (both (τ, i) and, for $i \ge 2$, $(\tau, i-1)$ are fundamental indices, as $a(r)$ is one for every root). Then $\sum_\lambda b_{r,\lambda}\gamma_\lambda = \theta_{a(r)^-} - \theta_{a(r)}$, $\sum_\lambda b_{r,\lambda} f_\lambda = \varphi_{a(r)^-} - \varphi_{a(r)}$ and $\sum_\lambda b_{r,\lambda} f_{\lambda,t} = \varphi_{a(r)^-}^T(t) - \varphi_{a(r)}^T(t)$, with the convention $\theta_{(\tau,0)} = 0$, $\varphi_{(\tau,0)} = \varphi_{(\tau,0)}^T = 0$: these are the forms and functions θ_r, u_r, $u_{r,t}$ of Lemma D.78. By its item 2, $\omega_{r,t} = \theta_r + dd^c u_{r,t}$ on X for $0 < t \le t_1$ and $\omega_{r,0} = \theta_r + dd^c u_r$ on X°, which is $\widetilde{X}^\circ \cap \varrho_X^{-1}(X^\circ)$ for $\varrho_X = \mathrm{id}$. This is (Sw1) with t_1 in place of t_0.

(Sw3). Lemma D.78, item 3, gives a holomorphic section v of a smooth hermitian line bundle on W and $\kappa_v \in \mathbb{R}$ with $\|v\| \le 1$, reduced zero divisor $\Delta(\mathbb{C})$ with no component in $\partial W = q_0^{-1}(\partial X)$ and $\Delta(\mathbb{C}) + (\partial W)_{\mathrm{red}}$ of simple normal crossings, and the identities of (Sw3) for the $u_{r,t}$, u_r above, $p_j = q_j$ and $\varrho_W = \mathrm{id}$, for $0 < t \le t_1$ and for $t = 0$.

So the compact models, p_0, p_1, v and κ_v form an analytic square system (Sw1)–(Sw3) for the square system. □

Lemma D.77. *In the situation of Lemma D.75, let $s_{\tau,i}$ be a Levi reflection with square system $(k_0, \mathcal{X}^{(2)}, g, h)$, (s, j) the label and step of k_0, $X = \mathcal{X}'(\mathbb{C})$, $W = \mathcal{X}^{(2)}(\mathbb{C})$, X° the abelian locus of X, $W^\circ = q_0^{-1}(X^\circ) \cap W$, and $h_r(0) = h_r^{\mathrm{sing}}$ on the affine cone over X° ($r \in \mathrm{Rt}$). Then X°, W° and the $h_r(0)$ satisfy (Fx5), and there are fibre charts $(U_n, B_n, G_n, (\alpha_{n,\beta})_\beta, \Phi_n, \Phi_n^{(2)})_{n\ge1}$ satisfying (Fx6) and (Fx7). Here $G_n(y)$ is the Hodge Gram matrix of a holomorphic frame of the rank-two bundle $\mathcal{V}'_{s,j+1}/\mathcal{V}'_{s,j-1}$ with its quotient Hodge metric, and $\Phi_n(z,y)$ is the flag whose step j is the line spanned by the first frame vector plus z times the second.*

Proof. **The Hodge metric of the ξ-line.** In both cases ($i < p$, signs $+1$, $\mathrm{st}(r_1) = j$, $\mathrm{st}(r_2) = j+1$; $i > p$, signs -1, $\mathrm{st}(r_1) = j+1$, $\mathrm{st}(r_2) = j$; by (Fh3) of Definition 29.6, since $r_1 = (\tau, i)$, $r_2 = (\tau, i+1)$ and $i \neq p$) the ξ-line is

$$\Xi = \mathcal{L}_{r_1} \otimes \mathcal{L}_{r_2}^{-1} = (\wedge^j \mathcal{V}'_{s,j})^{\otimes 2} \otimes (\wedge^{j-1} \mathcal{V}'_{s,j-1})^{-1} \otimes (\wedge^{j+1} \mathcal{V}'_{s,j+1})^{-1},$$

isometrically for the Hodge metrics, with $\varrho_\Xi := \varrho_{r_1}/\varrho_{r_2} = \varrho_{s,j}^2/(\varrho_{s,j-1}\varrho_{s,j+1})$ and $\lambda_{r_1}/\lambda_{r_2} = w_{s,j}^2/(w_{s,j-1}w_{s,j+1})$. By (Go3)(4) and multiplicativity, for every rational section $R = A/B$ of $\mathcal{O}(e_\Xi)$ (A, B multihomogeneous) and every cone point $\tilde{x}$ over $x \in X^\circ$ with $A(\tilde{x})B(\tilde{x}) \neq 0$,

$$\log h_\Xi(0)(\tilde{x}) = \log|R(\tilde{x})| - \log\|\varrho_\Xi R(y)\lambda_{r_1}\lambda_{r_2}^{-1}\|^{\mathrm{Hdg}}(x), \tag{HX}$$

and likewise for every root line and for $\mathcal{L}_{r_1} \otimes \mathcal{L}_{r_2}$ with $h_{r_1}(0)h_{r_2}(0)$.

(Fx5). X is a complex manifold ($\mathcal{X}'_{\mathbb{Q}}$ smooth, Lemma 33.8, item 1) and $W \cong \mathcal{X}''(\mathbb{C})$ is a $\mathbb{P}^1$-bundle over X (Lemma D.75), so all points are smooth; $X^\circ = \beta^{-1}$ of the abelian locus of the base is open, hence so is W°. A point of W° is a pair of flags with the same image in $\mathcal{X}'_{s,j}$, hence in $\mathcal{X}^{\mathrm{b}}$; so $q_1(W^\circ) \subseteq X^\circ$, and $q_0(W^\circ) \subseteq X^\circ$ by definition. On the cone over X°, $h_r^{\mathrm{sing}}(\tilde{x}) = |P(\tilde{x})|/\|\varrho_r P(y)\lambda_r\|^{\mathrm{Hdg}}(x)$ for a local section P with $P(\tilde{x}) \neq 0$ (this is (Go3)(4), which holds by Lemma 33.8, item 2, read at a section P with $P(\tilde{x}) \neq 0$, so that $\varrho_r P(y)\lambda_r$ generates $\mathcal{L}_r$ at x by (Go3)(3)): a quotient of a positive smooth function and the norm of a holomorphic nowhere-vanishing section in the Hodge metric, smooth on the abelian locus by (Fh4); so $h_r(0)$ is positive and C^∞, and it has multidegree e_r (Definition 29.7, (Go3)): $h_r(0)((\lambda_k z_k)_k) = \prod_k |\lambda_k|^{e_{r,k}} h_r(0)(z)$.

The charts. $\mathcal{X}'_{s,j}(\mathbb{C})$ is a complex manifold of dimension $D-1$ ($\beta_{s,j}$ is a $\mathbb{P}^1$-bundle, Lemma 33.8(b)), and its abelian part $Y^\circ = \beta_{s,j}(X^\circ)$ is open and second countable. Choose countably many holomorphic charts $\kappa_n \colon U_n \to Y^\circ$ ($U_n \subseteq \mathbb{C}^{D-1}$ open, κ_n biholomorphic onto an open set) covering Y°, so small that on $\kappa_n(U_n)$ the bundle Q has a holomorphic frame $f_{n,1}, f_{n,2}$ and $\wedge^{j-1}\mathcal{V}'_{s,j-1}$ a holomorphic generator γ_n (both bundles are pulled back from $\mathcal{X}'_{s,j}$), and put $B_n = \kappa_n^{-1}(\kappa_n(U_n) \smallsetminus \bigcup_{m<n} \kappa_m(U_m))$, a Borel set. Let $u(z,y) = f_{n,1}(y) + z f_{n,2}(y)$ and let $\Phi_n(z,y)$ be the point of X over $\kappa_n(y)$ whose step j is the preimage in step $j+1$ of the line $\mathbb{C}u(z,y) \subseteq Q_{\kappa_n(y)}$; $\Phi_n^{(2)}(z_0,z_1,y)$ the image in W of $(\Phi_n(z_0,y), \Phi_n(z_1,y)) \in \mathcal{X}''(\mathbb{C})$. In the trivialisation of $\mathbb{P}(Q)$ by the frame these are the standard affine charts $z \mapsto [1:z]$ of $\mathbb{P}^1$, resp. of $\mathbb{P}^1 \times \mathbb{P}^1$, times κ_n: holomorphic, injective, with invertible differential, hence biholomorphic onto open subsets, contained in X°, resp. W°. By construction $q_0\Phi_n^{(2)}(z_0,z_1,y) = \Phi_n(z_0,y)$, and $q_1\Phi_n^{(2)}(z_0,z_1,y) = \Phi_n(z_1,y)$ because all coordinates of $\Phi_n(z_1,y)$ outside k_0 equal those of $\Phi_n(z_0,y)$ (Lemma 33.8(a)). The sets $\kappa_n(B_n)$ partition Y°, so the sets $\Phi_n(\mathbb{C} \times B_n) = \beta_{s,j}^{-1}(\kappa_n(B_n)) \smallsetminus \{\text{step } j = \text{line of } f_{n,2}\}$ are pairwise disjoint and cover X° up to the union of countably many pieces of the closed complex hypersurfaces $\{\text{step } j = \text{line of } f_{n,2}\}$ over $\kappa_n(U_n)$, a null set; likewise for W° with two hypersurfaces per chart. Let $G_n(y)$ be the Hermitian matrix with $u^* G_n(y) u = |u_1 f_{n,1}(y) + u_2 f_{n,2}(y)|_Q^2$ ($u \in \mathbb{C}^2$): positive definite and C^∞ in y (the Hodge metric is smooth on the abelian locus), so that by polarisation $|u_0^* G_n(y) u_1| = |\langle u(z_0,y), u(z_1,y)\rangle_Q|$ for $u_l = (1, z_l)^{\mathsf{T}}$, and $\det G_n(y) = |f_{n,1} \wedge f_{n,2}|_Q^2$.

(Fx6), the ξ-potential. Over $\mathbb{C} \times U_n$ the section $\tau = (\gamma_n \wedge u)^{\otimes 2} \otimes \gamma_n^{-1} \otimes (\gamma_n \wedge f_{n,1} \wedge f_{n,2})^{-1}$ of Ξ (pulled back by Φ_n) is holomorphic and nowhere zero, and by the norm relations for Gram determinants ($\|w \wedge u\| = \|w\|\,|u|_Q$ and $\|w \wedge u \wedge u'\| = \|w\|\,|u \wedge u'|_Q$)

$$\log\|\tau\|^{\mathrm{Hdg}} = 2\log|u|_Q - \log|f_{n,1} \wedge f_{n,2}|_Q = \log\big(u(z)^* G_n(y) u(z)\big) - \tfrac{1}{2}\log\det G_n(y) = -\mathrm{xp}_{G_n(y)}(z),$$

with $u(z) = (1,z)^{\mathsf{T}}$. Let $\tilde{\Phi}$ be a local holomorphic lift of Φ_n to the affine cone near (z^0, y^0), and $R = A/B$ a rational section of $\mathcal{O}(e_\Xi)$ with $A(\tilde{\Phi})B(\tilde{\Phi}) \neq 0$ near this point (a monomial in

coordinates non-zero at the point). Then $\varrho_\Xi R(y)\lambda_{r_1}\lambda_{r_2}^{-1}$ is a holomorphic generator of Ξ near the point ((Go3)(3)), so equals $\phi\tau$ with ϕ holomorphic and nowhere zero, and by (HX)

$$\log h_\Xi(0)\circ\tilde\Phi - \mathrm{xp}_{G_n(y)}(z) = \log|R(\tilde\Phi)| - \log|\phi|,$$

the real part of a logarithm of a nowhere-vanishing holomorphic function: pluriharmonic.

(Fx6), the base lines. For $r\notin\{r_1,r_2\}$ the root line $\mathcal{L}_r$ and its Hodge metric are built from steps other than step j of s, and $\mathcal{L}_{r_1}\otimes\mathcal{L}_{r_2} = (\wedge^{j+1}\mathcal{V}'_{s,j+1}\otimes(\wedge^{j-1}\mathcal{V}'_{s,j-1})^{-1})^{\pm1}$ with the product of the Hodge metrics; so for every $\beta\in\mathrm{Rt}_s^{\mathrm{b}}$ the Hermitian line $\overline{\mathcal{L}}_\beta$ is pulled back by $\beta_{s,j}$ from $\mathcal{X}'_{s,j}$ (over the abelian part). Shrinking the charts we may assume it has a holomorphic generator $\epsilon_{n,\beta}$ on $\kappa_n(U_n)$; put $\alpha_{n,\beta}(y) = -\log\|\epsilon_{n,\beta}(\kappa_n(y))\|^{\mathrm{Hdg}}$, a C^∞ function. As above, the root section of a monomial R is $\phi_\beta\,\epsilon_{n,\beta}$ with ϕ_β holomorphic nowhere zero, and (HX) for β gives $\log h_\beta(0)\circ\tilde\Phi - \alpha_{n,\beta}(y) = \log|R(\tilde\Phi)| - \log|\phi_\beta|$, pluriharmonic. This completes (Fx6).

(Fx7). Let $y\in U_n$, $z_0\neq z_1$ with $gh\neq0$ at $\Phi_n^{(2)}(z_0,z_1,y)$; write $x=\Phi_n(z_0,y)$, $u_l=u(z_l,y)$, $w=\gamma_n(\kappa_n(y))$, $\omega_l = w\wedge u_l\in\wedge^j V_j$ at $\Phi_n(z_l,y)$. Fix a monomial E of multidegree $e_{\mathcal{H}}$ in the base coordinates not vanishing at x and a base cone point $\tilde b$; write $\sigma_{s,j,c}(\omega_l) = s_c^{(l)}E(y)(x)$ ($s_c^{(l)}\in\mathbb{C}$, $c\in I_{k_0}$). As G_0 is invariant under the scalings of the cone, we may evaluate it at the lift $\tilde x$ with base coordinates $\tilde b$ and k_0-coordinates $(s_c^{(0)})_c$, and $\tilde x_1$ the same with $(s_c^{(1)})_c$ (the lift of q_1). Take c with $s_c^{(l)}\neq0$ and the section $P_j = E/Y_{k_0,c}$ of $\mathcal{O}(d_{s,j})$: its fundamental root section is the vector $\gamma\in\wedge^jV_j$ with $\sigma_{s,j,c}(\gamma)=E(y)$, i.e. $\omega_l/s_c^{(l)}$, so $|P_j(\tilde x_l)|/\|\gamma\| = |E(\tilde b)|/\|\omega_l\|$. Fix also sections $P_{j\pm1}$ of $\mathcal{O}(d_{s,j\pm1})$ (free of k_0) not vanishing at x, with fundamental root sections $\gamma_{j\pm1}$. Applying (HX) to $R=P_j^2/(P_{j-1}P_{j+1})$ at $\tilde x_0$ and $\tilde x_1$:

$$\log h_\Xi(0)(\tilde x_l) = 2\log|E(\tilde b)| - 2\log\|\omega_l\| - \log\frac{|P_{j-1}P_{j+1}(\tilde b)|}{\|\gamma_{j-1}\|\,\|\gamma_{j+1}\|}\qquad(l=0,1).$$

By the normalisation of Lemma D.75, $g=\min\cdot H$, $h=G$ with G/H the section δ^{loc} under the root sections; with $\gamma_{j-1}=\mu' w$ and $w\wedge u_0\wedge u_1=\mu\gamma_{j+1}$, bilinearity of the 2×2 determinant gives $\min(\tilde x_0,\tilde x_1) = s_a^{(0)}s_b^{(1)} - s_b^{(0)}s_a^{(1)} = \delta^{\mathrm{loc}}(w\otimes w\wedge u_0\wedge u_1)/E(y)^2$ and $\delta^{\mathrm{loc}}(\gamma_{j-1}\otimes\gamma_{j+1}) = \frac{G(\tilde b)}{H(\tilde b)}\cdot\frac{P_{j-1}P_{j+1}(\tilde b)}{E(\tilde b)^2}E(y)^2$. Hence

$$\log|g/h|(\tilde x_0,\tilde x_1) = \log(\|w\|\,\|w\wedge u_0\wedge u_1\|) + \log\frac{|P_{j-1}P_{j+1}(\tilde b)|}{\|\gamma_{j-1}\|\,\|\gamma_{j+1}\|} - 2\log|E(\tilde b)|$$

. Adding $\frac12\log h_\Xi(0)(\tilde x_0)+\frac12\log h_\Xi(0)(\tilde x_1)$, the terms in E and $P_{j\pm1}$ cancel and

$$\begin{aligned} G_0(\Phi_n^{(2)}(z_0,z_1,y)) &= \log\frac{\|w\|\,\|w\wedge u_0\wedge u_1\|}{\|w\wedge u_0\|\,\|w\wedge u_1\|} = \log\frac{|u_0\wedge u_1|_Q}{|u_0|_Q\,|u_1|_Q}\\ &= \tfrac12\log\Big(1-\frac{|\langle u_0,u_1\rangle_Q|^2}{|u_0|_Q^2|u_1|_Q^2}\Big) = \mathrm{ls}_{G_n(y)}(z_0,z_1)\end{aligned}$$

(Gram determinant of two vectors), using $|u_l|_Q^2 = u_l^*G_n(y)u_l$ and $|\langle u_0,u_1\rangle_Q| = |u_0^*G_n(y)u_1|$. This is (Fx7). □

Lemma D.78. *In the situation of Lemma D.77, on the flag model of Lemma 33.8, in either of its cases (i) and (ii), with the data of Proposition 33.12 in the same case, put $X=\mathcal{X}'(\mathbb{C})$, $W=\mathcal{X}^{(2)}(\mathbb{C})$, and for a root $r=(\tau,i)$ write $a(r)=(\tau,i)$, $a(r)^-=(\tau,i-1)$ (with $\theta_{(\tau,0)}=0$, $\varphi_{(\tau,0)}=\varphi^T_{(\tau,0)}=0$), $\theta_r=\theta_{a(r)^-}-\theta_{a(r)}$, $u_r=\varphi_{a(r)^-}-\varphi_{a(r)}$, $u_{r,t}=\varphi^T_{a(r)^-}(t)-\varphi^T_{a(r)}(t)$. Then:*

1. *$(X, \Theta', \varsigma, \mathrm{id}, 1)$ is a compact model of X°, and $(W, \Theta_W, q_0^*\varsigma, \mathrm{id}, 1)$, for any Kähler form Θ_W on W, is a compact model of W°, with $\mathrm{rW}_W = \mathrm{rW}_X \circ q_0 = \mathrm{rW}_X \circ q_1$ on W°; with $p_j = q_j|_W$ (Sw2) holds;*

2. *with $t_1 = \min(t_0, e^{-e})$, $\delta(t) = t^{1/3} + (1+C)\varepsilon(t)$, $R(t) = \log(1/t)$, the families $(\theta_a, \varphi_a, (\varphi_a^T(t))_{0<t\le t_1})$, a running over the fundamental indices, satisfy (R1)–(R5) on (X, Θ', ς) for some constant; and for every root r, $\omega_{r,t} = \theta_r + dd^c u_{r,t}$ on X $(0 < t \le t_1)$ and $\omega_{r,0} = \theta_r + dd^c u_r$ on X°;*

3. *there are a holomorphic section v of a smooth hermitian line bundle on W and $\kappa_v \in \mathbb{R}$ such that $\|v\| \le 1$, the zero divisor of v is the reduced smooth divisor $\Delta(\mathbb{C})$, no component of it lies in $q_0^{-1}(\partial X)$, $\Delta(\mathbb{C}) + q_0^{-1}(\partial X)_{\mathrm{red}}$ has simple normal crossings, and the identities of (Sw3) hold with these $u_{r,t}$, u_r, $p_j = q_j$ and $\varrho_W = \mathrm{id}$, for $0 < t \le t_1$ and for $t = 0$.*

Proof. **Item 1.** X is a compact complex manifold ($\mathcal{X}'_{\mathbb{Q}}$ smooth and projective) with the Kähler form Θ', and ς is the section of Proposition 33.12 (pulled back from the base, $\|\varsigma\| \le 1$, simple normal crossing zero divisor with support the complement of X°). With $\varrho_X = \mathrm{id}$, $d_X = 1$ and $N = N' = \varnothing$ (no singular points) the covering condition is trivial and $\varrho_X^{-1}(X^\circ) = X \smallsetminus \partial X$. $W \cong \mathcal{X}''(\mathbb{C})$ is a $\mathbb{P}^1$-bundle over X via q_0 (Lemma D.75), a projective manifold, so it carries a Kähler form Θ_W; q_0 is a submersion, so the zero divisor of $q_0^*\varsigma$ (with the pulled-back metric, $\|q_0^*\varsigma\| \le 1$) is the pull-back of a simple normal crossing divisor by a submersion, again one (local coordinates pull back to part of a coordinate system), with complement $q_0^{-1}(X^\circ) = W^\circ$. As ς and its metric are pulled back from the base and q_0, q_1 agree after projection to the base, $\|\varsigma\| \circ q_0 = \|\varsigma\| \circ q_1$, so $\mathrm{rW}_W = \mathrm{rW}_X \circ q_j$ on W° and $q_j(W^\circ) \subseteq X^\circ$ (Lemma D.77, (Fx5)). This gives the compact models and (Sw2) with equality.

Item 2. Lemma 31.32 with $F = \mathrm{id}_X$ (so $\mathrm{rW} \circ F = \mathrm{rW}$) gives (R1)–(R5) for the families of the fundamental indices with δ, R, t_1, and $\theta_a + dd^c\varphi_a^T(t) = \eta_a(t) = c_1(\mathcal{M}_a, h_a^{\mathrm{ref}} e^{\varphi_a^T(t)})$. By hypothesis 3 of Lemma 31.21 in Proposition 33.12, item 2, $\prod_{k\le i} h_{(\tau,k)}(t)^{-1} = h^{\mathrm{ref}}_{(\tau,i)} e^{\varphi^T_{(\tau,i)}(t)}$ for $0 < t \le t_0$, so $h_r(t) = h^{\mathrm{ref}}_{a(r)^-} e^{\varphi^T_{a(r)^-}(t)} / (h^{\mathrm{ref}}_{a(r)} e^{\varphi^T_{a(r)}(t)})$ and $\omega_{r,t} = \eta_{a(r)^-}(t) - \eta_{a(r)}(t) = \theta_r + dd^c u_{r,t}$ (first Chern forms are additive under tensor products). On X°, item 2 of Proposition 33.12 gives $\prod_{k\le i}(h^{\mathrm{sing}}_{(\tau,k)})^{-1} = h^{\mathrm{ref}}_{(\tau,i)} e^{\varphi_{(\tau,i)}}$, so in the same way $\omega_{r,0} = \frac{i}{\pi}\partial\bar\partial \log h_r^{\mathrm{sing}} = \theta_r + dd^c u_r$ (the normalisation of dd^c is the one for which $c_1(\mathcal{M}, he^\varphi) = c_1(\mathcal{M}, h) + dd^c\varphi$, as in Lemma 31.32).

Item 3. Let $h^{\mathrm{ref}}_\Xi = \frac{h^{\mathrm{ref}}_{a(r_1)^-} h^{\mathrm{ref}}_{a(r_2)}}{h^{\mathrm{ref}}_{a(r_1)} h^{\mathrm{ref}}_{a(r_2)^-}}$, a smooth positive cone function of multidegree e_Ξ; by item 2, $\log h_\Xi(t) = \log h^{\mathrm{ref}}_\Xi + u_{r_1,t} - u_{r_2,t}$ for $0 < t \le t_1$ on the cone over X, and the same with $u_{r_1} - u_{r_2}$ for $t = 0$ over X°. Let $\mathcal{M} = \mathcal{O}(\deg g - \deg h)|_W$ with the smooth metric $\|P\|_0 = |P|\,(h^{\mathrm{ref}}_\Xi \circ q_0 \cdot h^{\mathrm{ref}}_\Xi \circ q_1)^{1/2}$ on the cone (the exponent of the multidegree matches: $2(\deg g - \deg h) = -(q_0^* e_\Xi + q_1^* e_\Xi)$ by (Fx3)). Since $\mathrm{div}(g|_W) = \mathrm{div}(h|_W) + [\Delta]$ ((Fx3), on the smooth complex points), g/h is a holomorphic section of $\mathcal{M}$ with zero divisor $\Delta(\mathbb{C})$, reduced. Put $\kappa_v = \log\max(1, \max_W \|g/h\|_0)$ (W compact), $\|\cdot\| = e^{-\kappa_v}\|\cdot\|_0$ and $v = g/h$: then $\|v\| \le 1$ and $\frac12 \log\|v\|^2 + \kappa_v = \log|g| - \log|h| + \frac12 \sum_j \log h^{\mathrm{ref}}_\Xi \circ q_j$, so by (31.4)

$$G_t = \tfrac12 \log\|v\|^2 + \kappa_v + \tfrac12 \sum_{j=0,1} (u_{r_1,t} - u_{r_2,t}) \circ q_j$$

off $\Delta \cup \{gh = 0\}$ for $0 < t \le t_1$, and the same with $u_{r_1} - u_{r_2}$ on W° for $t = 0$. $\Delta(\mathbb{C})$ is the image of the diagonal section of the $\mathbb{P}^1$-bundle $q_0 \colon W \to X$: a smooth hypersurface meeting every fibre transversally in one point; near any of its points, in a trivialisation $W \supseteq U \times \mathbb{P}^1$ with $\Delta = \{w = \phi(x)\}$, the functions $(x, w - \phi(x))$ form coordinates in which $q_0^{-1}(\partial X) = \{x_1 \cdots x_{m'} = 0\}$ and

$\Delta = \{w - \phi(x) = 0\}$: simple normal crossings. Each component of $\Delta(\mathbb{C})$ maps isomorphically onto a component of X by q_0, which is not contained in ∂X, so it is not contained in $q_0^{-1}(\partial X)$. $\square$

Proposition D.79. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Then the realised tower has geometric proportionality with covolumes (Vp) over E.*

Proof. By Proposition D.83, applied to the same data, there are a hermitian space (V, h) over E of dimension n, indefinite at some real place of E^+, a neat non-zero ideal $\mathfrak{a}$ of $\mathcal{O}_E$, an integer $m \geq 1$, a real number $c_0 > 0$ and, for every $Z \in \mathrm{Cp}$, lattices $\Lambda_{Z,1}, \dots, \Lambda_{Z,m}$ of V, all of them in one genus, such that

$$c_0\,(-1)^D\,\mathrm{gi}(\mathcal{X}_{2,Z}; x^\delta) = \sum_{i=1}^{m} \mu_\infty\big(\Gamma(\Lambda_{Z,i}, \mathfrak{a})\backslash G^1_\infty(V)\big) \qquad (Z \in \mathrm{Cp}). \tag{1}$$

These are data as required in (Vu): one space of dimension n indefinite at some real place, one neat ideal, one m, one c_0, and lattices in one genus. We show that they satisfy the identity of (Vp). Let $B \geq 2$ be an integer, $Z \in \mathrm{Cp}$ and $F \in \mathcal{R}$ homogeneous of degree D. By Proposition D.80, applied to the same data,

$$\mathrm{gi}(\mathcal{X}_{B,Z}; F) = (-1)^D\,\mathrm{gi}(\mathcal{X}_{2,Z}; x^\delta)\,\deg^{\mathrm{fl}}(F).$$

Multiplying by c_0 and inserting (1),

$$c_0\,\mathrm{gi}(\mathcal{X}_{B,Z}; F) = \big(c_0\,(-1)^D\,\mathrm{gi}(\mathcal{X}_{2,Z}; x^\delta)\big)\deg^{\mathrm{fl}}(F) = \Big(\sum_{i=1}^{m} \mu_\infty\big(\Gamma(\Lambda_{Z,i}, \mathfrak{a})\backslash G^1_\infty(V)\big)\Big)\deg^{\mathrm{fl}}(F),$$

which is the identity of (Vp) for (B, Z, F). Since B, Z and F were arbitrary and the data $(V, h), \mathfrak{a}, m, c_0, (\Lambda_{Z,i})$ do not depend on them, the realised tower has geometric proportionality with covolumes (Vp) over E. $\square$

Proposition D.80. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2, and put $x^\delta = \prod_{a\in\Phi}\prod_{i=1}^{n} x_{a,i}^{n-i} \in \mathcal{R}$, a monomial of degree D with $\deg^{\mathrm{fl}}(x^\delta) = (-1)^D$. Then for every integer $B \geq 2$, every $Z \in \mathrm{Cp}$ and every $F \in \mathcal{R}$ homogeneous of degree D,*

$$\mathrm{gi}(\mathcal{X}_{B,Z}; F) = (-1)^D\,\mathrm{gi}(\mathcal{X}_{2,Z}; x^\delta)\,\deg^{\mathrm{fl}}(F).$$

Proof. Fix $c \in \mathrm{Cp}$; here $[F : \mathbb{Q}]$ refers to the field F of $\mathfrak{u}$, and F as an argument is the polynomial.

Step 1 (the geometric degrees as one integral). By Lemma D.81, for every integer $B \geq 2$ and every $F \in \mathcal{R}$ homogeneous of degree D,

$$\mathrm{gi}(\mathcal{X}_{B,c}; F) = \frac{1}{[F : \mathbb{Q}]} \int_{X_c^{\mathrm{an}}} F(\xi); \tag{1}$$

the right-hand side does not depend on B.

Step 2 (proportionality). By Proposition D.82 there is a real v_c with $\int_{X_c^{\mathrm{an}}} F(\xi) = v_c \deg^{\mathrm{fl}}(F)$ for all $F \in \mathcal{R}$ homogeneous of degree D. With (1), $\mathrm{gi}(\mathcal{X}_{B,c}; F) = \frac{v_c}{[F:\mathbb{Q}]}\deg^{\mathrm{fl}}(F)$ for every $B \geq 2$ and every such F. For $F = x^\delta$: in (21.1) the coefficient $[x^{\delta\circ w}]x^\delta$ is 1 if $\delta \circ w = \delta$

and 0 otherwise, and $\delta \circ w = \delta$ forces $w = \mathrm{id}$ because $i \mapsto n-i$ is injective; so $\deg^{\mathrm{fl}}(x^\delta) = (-1)^D$, and $B = 2$ gives $\frac{v_c}{[F:\mathbb{Q}]} = (-1)^D \mathrm{gi}(\mathcal{X}_{2,c}; x^\delta)$. Substituting,

$$\mathrm{gi}(\mathcal{X}_{B,c}; F) = (-1)^D \, \mathrm{gi}(\mathcal{X}_{2,c}; x^\delta) \, \deg^{\mathrm{fl}}(F)$$

for every $B \geq 2$, every $c = Z \in \mathrm{Cp}$ and every $F \in \mathcal{R}$ homogeneous of degree D. □

Lemma D.81. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. For $c \in \mathrm{Cp}$ and $1 \leq i \leq n$, $\tau \in \Phi$, put*

$$\xi_{\tau,i} = c_1(\mathcal{M}_{(\tau,i-1)}, h^{\mathrm{ref}}_{(\tau,i-1)}) - c_1(\mathcal{M}_{(\tau,i)}, h^{\mathrm{ref}}_{(\tau,i)})$$

on the compact complex manifold X_c^{an} of Sys_c (the first term omitted for $i = 1$), and let $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})$ be the complex manifold of all complex points of the F-scheme $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}$ (over every embedding of F into $\mathbb{C}$), with the forms $\omega_r = c_1(\mathcal{L}_r, \|\cdot\|^{\mathrm{Hdg}})$ for the roots r. For $G \in \mathcal{R}$ homogeneous of degree D let $G(\xi)$ and $G(\omega)$ be the $2D$-forms obtained by substituting $\xi_{\tau,i}$, respectively $\omega_{(\tau,i)}$, for $x_{\tau,i}$. Then for every integer $B \geq 2$, every $c \in \mathrm{Cp}$ and every $G \in \mathcal{R}$ homogeneous of degree D, the form $G(\omega)$ is integrable on $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})$ and

$$[F : \mathbb{Q}] \, \mathrm{gi}(\mathcal{X}_{B,c}; G) = \int_{X_c^{\mathrm{an}}} G(\xi) = \int_{\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})} G(\omega).$$

In particular, with $x^\delta = \prod_{\tau \in \Phi} \prod_{i=1}^{n} x_{\tau,i}^{n-i}$ and $\nu = (-1)^D x^\delta(\omega)$, one has

$$[F : \mathbb{Q}] \, (-1)^D \, \mathrm{gi}(\mathcal{X}_{2,c}; x^\delta) = \int_{\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})} \nu$$

for every $c \in \mathrm{Cp}$.

Proof. Let $B \geq 2$ and $c \in \mathrm{Cp}$. The good origin contains a root origin of $\mathcal{X}_{B,c}$ on the fixed data at c for S_B, and by its clause (smooth) $\mathcal{X}_{B,c} \otimes \mathbb{Q}$ is smooth. So Lemma 33.29, applied to the fixed data at c, $S = S_B$ and $\mathcal{X} = \mathcal{X}_{B,c}$, gives for every $G \in \mathcal{R}$ homogeneous of degree D the integrability of $G(\omega)$ on $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})$ and the displayed identity. The last assertion is the case $B = 2$, $G = (-1)^D x^\delta$, by linearity of gi. □

Proposition D.82. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. For $c \in \mathrm{Cp}$ let Sys_c be the analytic system of the fixed data at c, with compact complex manifold X_c^{an} of dimension D and, for each fundamental index a, the smooth hermitian line bundle $(\mathcal{M}_a, h_a^{\mathrm{ref}})$. For $\tau \in \Phi$ and $1 \leq i \leq n$ put*

$$\xi_{\tau,i} = c_1(\mathcal{M}_{(\tau,i-1)}, h^{\mathrm{ref}}_{(\tau,i-1)}) - c_1(\mathcal{M}_{(\tau,i)}, h^{\mathrm{ref}}_{(\tau,i)}),$$

a real closed $(1,1)$-form on X_c^{an}, where the first term is omitted for $i = 1$; for $G \in \mathcal{R}$ homogeneous of degree D let $G(\xi)$ be the $2D$-form obtained by substituting $\xi_{\tau,i}$ for $x_{\tau,i}$ (well defined, since forms of even degree commute). Then for every $c \in \mathrm{Cp}$ there is a real number v_c such that

$$\int_{X_c^{\mathrm{an}}} G(\xi) = v_c \, \deg^{\mathrm{fl}}(G) \qquad \text{for every } G \in \mathcal{R} \text{ homogeneous of degree } D.$$

Proof. Fix $c \in \mathrm{Cp}$ and write $M_c = \mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})$, the complex manifold of all complex points of $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}$ (over every embedding of F), an open and closed subset of the manifold M of Proposition 33.31.

Step 1 (the integral over the flag bundle). By Lemma D.81 (with $B = 2$), for every $G \in \mathcal{R}$ homogeneous of degree D the form $G(\omega)$ is integrable on M_c and

$$\int_{X_c^{\mathrm{an}}} G(\xi) = \int_{M_c} G(\omega). \tag{1}$$

Step 2 (pointwise proportionality). Let $G_0 = (-1)^D x^\delta$ with $x^\delta = \prod_{\tau\in\Phi}\prod_{i=1}^n x_{\tau,i}^{n-i}$. In (21.1) only $w = \mathrm{id}$ contributes to $\deg^{\mathrm{fl}}(x^\delta)$, since $i \mapsto n-i$ is injective, so $\deg^{\mathrm{fl}}(G_0) = 1$. By Proposition 33.31, at every $y \in M_c$, $G(\omega)_y = \deg^{\mathrm{fl}}(G)\,\nu_y$ for every G; with $G = G_0$ this gives $\nu_y = G_0(\omega)_y$, hence

$$G(\omega) = \deg^{\mathrm{fl}}(G)\, G_0(\omega) \quad \text{on } M_c.$$

Step 3 (conclusion). Integrating over M_c (both sides integrable by Step 1) and using (1) for G and for G_0,

$$\int_{X_c^{\mathrm{an}}} G(\xi) = \deg^{\mathrm{fl}}(G)\int_{M_c} G_0(\omega) = \deg^{\mathrm{fl}}(G)\int_{X_c^{\mathrm{an}}} G_0(\xi),$$

so $v_c = \int_{X_c^{\mathrm{an}}} G_0(\xi)$ has the required property. □

Proposition D.83. *Let $\mathfrak{u} = (E, \mathsf{H}, \mathsf{U}, p, q, \mathsf{L}, \mathrm{Sh}, F)$, $\mathcal{Y}$ and the root tower $\mathcal{T}$ of type (Φ, n, p) with its geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ and its good origin immersive at level four satisfy the hypotheses of Proposition 34.2. Then there are a hermitian space (V, h) over E of dimension n, indefinite at some real place of E^+, a neat non-zero ideal $\mathfrak{a}$ of $\mathcal{O}_E$, an integer $m \geq 1$, a real number $c_0 > 0$ and, for every $Z \in \mathrm{Cp}$, lattices $\Lambda_{Z,1}, \dots, \Lambda_{Z,m}$ of V, all of them (over all Z and i) in one genus, such that for every $Z \in \mathrm{Cp}$*

$$c_0\,(-1)^D\,\mathrm{gi}(\mathcal{X}_{2,Z}; x^\delta) = \sum_{i=1}^m \mu_\infty(\Gamma(\Lambda_{Z,i}, \mathfrak{a})\backslash G_\infty^1(V)).$$

Proof. Put $\Phi'_\kappa = \{\rho\colon E \to \mathbb{C} :\ \rho(r) = \kappa(r_{\mathbb{C}})\}$ for a field embedding $\kappa\colon F \to \mathbb{C}$; it is Φ if $\varepsilon_\kappa = 1$ and $\overline{\Phi}$ if $\varepsilon_\kappa = -1$, and $\kappa \circ \tau \in \Phi'_\kappa$ for $\tau \in \Phi$ (as $\tau(r) = r_{\mathbb{C}}$). Let $\nu^{\mathrm{Fl}} = (-1)^D x^\delta(\omega)$ on $\mathrm{Fl}_{\mathfrak{u}}(\mathbb{C})$, ω_r the Hodge Chern forms of the root lines.

Step 1 (reduction to the flag bundle). By Lemma D.81, for every $c \in \mathrm{Cp}$,

$$[F:\mathbb{Q}]\,(-1)^D\,\mathrm{gi}(\mathcal{X}_{2,c}; x^\delta) = \int_{\mathrm{Fl}_{\mathfrak{u}}|_{Z_c}(\mathbb{C})} \nu^{\mathrm{Fl}} = \sum_{\kappa\colon F\to\mathbb{C}} \int_{\mathrm{Fl}_{\mathfrak{u}}|_{Z_c,\kappa}} \nu^{\mathrm{Fl}}, \tag{1}$$

where $\mathrm{Fl}_{\mathfrak{u}}|_{Z_c,\kappa}$ is the open and closed set of complex points over κ, i.e. the flag bundle over the complex points of $Z_c \otimes_{F,\kappa} \mathbb{C}$.

Step 2 (one piece). Fix c and κ, and let $k = k(c,\kappa) \in I_\kappa$ be the index with $u_k(\mathrm{Per}_\sigma(L_k))$ the complex points of $Z_c \otimes_{F,\kappa} \mathbb{C}$ (SU6). By Lemma 33.34 (for $Z = Z_c$; the level is good at every prime with $A = 1$ and the components split),

$$\int_{\mathrm{Fl}_{\mathfrak{u}}|_{Z_c,\kappa}} \nu^{\mathrm{Fl}} = \mu_{\nu,k}(\Gamma_k\backslash G_k^1), \tag{2}$$

with $\Gamma_k = \Gamma(L_k, \mathfrak{n})$, and G_k^1 and $\mu_{\nu,k}$ the group and Haar measure of Lemma 33.38 for $(L_{k,\mathbb{R}}, \psi_k, \Phi'_\kappa)$.

Step 3 (one space, one genus, one measure). Fix an embedding κ_0 and $c_1 \in \mathrm{Cp}$, put $k_0 = k(c_1, \kappa_0)$, $V = L_{k_0} \otimes \mathbb{Q}$ and $h = \varepsilon_{\kappa_0} h_{k_0}$. By (SU4) the form $\varepsilon_\kappa h_k$ has, at every real place of E^+, the same signature (q and p, or p and q, depending only on the sign of $\operatorname{Im} r_{\mathbb{C}}$) for all κ and k; as $p, q \geq 1$, (V, h) is indefinite at every real place. Since $\psi_k = \operatorname{Tr}_{E/\mathbb{Q}}(r\, h_k) = \operatorname{Tr}_{E/\mathbb{Q}}\big((\varepsilon_\kappa r)(\varepsilon_\kappa h_k)\big)$ is perfect on L_k, $L_k = \{x : \operatorname{Tr}(\varepsilon_\kappa r\, \varepsilon_\kappa h_k(x, L_k)) \subseteq \mathbb{Z}\}$. The element $\xi = \varepsilon_\kappa r$ satisfies $\bar\xi = -\xi$ ($r^2 = -d < 0$ at every embedding) and $\xi \mathcal{O}_E = r\mathcal{O}_E$, and E/E^+ is unramified at every finite place (by the definition of unitary Shimura data). By Lemma D.84 (with $\xi' = \varepsilon_{\kappa_0} r$, $\Lambda' = L_{k_0}$) there is an E-linear isometry $g_{\kappa,k} \colon (L_k \otimes \mathbb{Q}, \varepsilon_\kappa h_k) \to (V, h)$, and all the lattices $g_{\kappa,k} L_k$ lie in one genus with L_{k_0}, hence in one genus. For $c \in \mathrm{Cp}$ and κ put $\Lambda_{c,\kappa} = g_{\kappa,k(c,\kappa)} L_{k(c,\kappa)}$. As $\mathrm{U}(\varepsilon h) = \mathrm{U}(h)$ and an E-linear map preserves ψ_k if and only if it preserves h_k ((SU1); over $\mathbb{R}$ likewise, the trace form being non-degenerate), conjugation by $g = g_{\kappa,k}$ maps $\Gamma(L_k, \mathfrak{n})$ onto $\Gamma(\Lambda_{c,\kappa}, \mathfrak{n})$ (31.2) and G^1_k onto $G^1_\infty(V)$, which is the group G^1 of the lemma for $(V_{\mathbb{R}}, \psi_V, \Phi'_{\kappa_0})$, $\psi_V = \operatorname{Tr}(\varepsilon_{\kappa_0} r\, h)$. Now $\psi_V(gx, gy) = \varepsilon_{\kappa_0}\varepsilon_\kappa\, \psi_k(x, y)$, and $\Phi'_{\kappa_0} = \Phi'_\kappa$ if $\varepsilon_{\kappa_0}\varepsilon_\kappa = 1$, $= \overline{\Phi'_\kappa}$ otherwise; so by Lemma 33.38 (3) conjugation by g carries $\mu_{\nu,k}$ to the one Haar measure μ_ν of $(V_{\mathbb{R}}, \psi_V, \Phi'_{\kappa_0})$ on $G^1_\infty(V)$. Write $\mu_\nu = c'\mu_\infty$ with $c' > 0$. With (2),

$$\int_{\mathrm{Fl_u}|_{Z_{c,\kappa}}} \nu^{\mathrm{Fl}} = c'\, \mu_\infty\big(\Gamma(\Lambda_{c,\kappa}, \mathfrak{n}) \backslash G^1_\infty(V)\big).$$

Step 4 (conclusion). Put $\mathfrak{a} = \mathfrak{n}$ (neat, (SU5), non-zero), $m = [F : \mathbb{Q}]$, index the embeddings κ by $1 \leq i \leq m$, put $\Lambda_{c,i} = \Lambda_{c,\kappa_i}$ and $c_0 = [F : \mathbb{Q}]/c' > 0$. Summing over κ in (1) and dividing by c',

$$c_0\, (-1)^D\, \mathrm{gi}(\mathcal{X}_{2,c}; x^\delta) = \sum_{i=1}^{m} \mu_\infty\big(\Gamma(\Lambda_{c,i}, \mathfrak{a}) \backslash G^1_\infty(V)\big) \qquad (c \in \mathrm{Cp}),$$

with (V, h) of dimension n, indefinite at some real place, and all $\Lambda_{c,i}$ lattices of V in one genus; none of $V, h, \mathfrak{a}, m, c_0$ depends on c. □

Lemma D.84. *Let E be a CM field with maximal totally real subfield E^+ such that E/E^+ is unramified at every finite place. Let $\xi, \xi' \in E^\times$ with $\bar\xi = -\xi$, $\bar\xi' = -\xi'$ and $\xi\mathcal{O}_E = \xi'\mathcal{O}_E$. Let (V, h) and (V', h') be hermitian spaces over E of the same dimension such that at every real place w of E^+ the hermitian forms $h \otimes_{E^+,w} \mathbb{R}$ and $h' \otimes_{E^+,w} \mathbb{R}$ have the same signature, and let $\Lambda \subseteq V$, $\Lambda' \subseteq V'$ be lattices with*

$$\Lambda = \{x \in V :\ \operatorname{Tr}_{E/\mathbb{Q}}(\xi h(x, \Lambda)) \subseteq \mathbb{Z}\}, \qquad \Lambda' = \{x \in V' :\ \operatorname{Tr}_{E/\mathbb{Q}}(\xi' h'(x, \Lambda')) \subseteq \mathbb{Z}\}.$$

Then there is an E-linear isometry $g \colon (V, h) \to (V', h')$, and for every such g the lattices $g\Lambda$ and Λ' of V' lie in one genus.

Proof. **The trace condition is a scaled hermitian duality.** For $x \in V$, $h(x, \Lambda)$ is an $\mathcal{O}_E$-submodule of E (as $h(x, ay) = \bar a h(x, y)$), so by the definition of the inverse different

$$\operatorname{Tr}_{E/\mathbb{Q}}(\xi h(x, \Lambda)) \subseteq \mathbb{Z} \quad \text{if and only if} \quad h(x, \Lambda) \subseteq \mathfrak{c} := \xi^{-1}\mathfrak{D}^{-1}.$$

The same holds for Λ' with the same $\mathfrak{c}$, since $\xi'\mathcal{O}_E = \xi\mathcal{O}_E$. Thus

$$\Lambda = \{x \in V :\ h(x, \Lambda) \subseteq \mathfrak{c}\}, \qquad \Lambda' = \{x \in V' :\ h'(x, \Lambda') \subseteq \mathfrak{c}\}.$$

The ideal $\mathfrak{c}$ is stable under complex conjugation ($\bar\xi = -\xi$, and $\mathfrak{D}$ is stable under every automorphism of E).

Local form at a finite place. Let v be a finite place of E^+. As E/E^+ is unramified at v, either E_v is the unramified quadratic extension of F_v, and then a uniformiser ϖ_v of F_v is one of E_v, or $E_v \cong F_v \times F_v$ with conjugation exchanging the factors. In both cases the conjugation-stable fractional ideal $\mathfrak{c}R_v$ equals $c_v R_v$ for some $c_v \in F_v^\times$ (a power of ϖ_v; in the split case the two exponents agree by stability). The form $k_v = c_v^{-1} h_v$ is hermitian since $c_v \in F_v$. Taking the completion at v of the description of Λ above (the dual of a finitely generated module commutes with the flat base change $\mathcal{O}_{E^+} \to \mathcal{O}_v$, and $\mathfrak{c} \otimes \mathcal{O}_v = c_v R_v$) gives

$$\Lambda_v = \{x \in V_v : \ k_v(x, \Lambda_v) \subseteq R_v\},$$

that is, Λ_v is a self-dual R_v-lattice for k_v in the sense of Lemma 16.27, and likewise Λ'_v for $k'_v = c_v^{-1} h'_v$.

Determinants are local norms. R_v is a semilocal Dedekind domain, hence a principal ideal domain, so Λ_v is free over R_v; in a basis of Λ_v the Gram matrix of k_v is invertible over R_v (self-duality), and its determinant is conjugation-invariant, hence lies in $R_v^\times \cap F_v = \mathcal{O}_v^\times$. Fix E-bases (e_i) of V and (e'_i) of V' and put $G = (h(e_j, e_i))_{i,j}$, $G' = (h'(e'_j, e'_i))_{i,j}$, so that $\bar{x}^\top G y = h(\sum_j y_j e_j, \sum_i x_i e_i)$; G and G' are non-degenerate hermitian matrices, $\det G, \det G' \in E^{+\times}$, and a change of basis multiplies the determinant by an element $z\bar{z}$, $z \in E^\times$. Put $\delta = \det G' / \det G \in E^{+\times}$. Comparing with bases of Λ_v and Λ'_v,

$$\det G \in c_v^n \, u_v \, N(E_v^\times), \qquad \det G' \in c_v^n \, u'_v \, N(E_v^\times), \qquad u_v, u'_v \in \mathcal{O}_v^\times,$$

($n = \dim V$, N the norm of E_v/F_v), so $\delta \in \mathcal{O}_v^\times N(E_v^\times) = N(E_v^\times)$: every unit of F_v is a norm from E_v (unramified: Serre, *Local fields*, Ch. V, §2; split: $N(a,b) = ab$). At a real place w the sign of $w(\det G)$ is $(-1)^{s_w}$ with s_w the number of negative eigenvalues of $h \otimes_w \mathbb{R}$, and likewise for G'; equal signatures give $w(\delta) > 0$, a norm from $\mathbb{C}$. Write $E = E^+(\sqrt{\delta_0})$ with $\delta_0 \in E^+$; the norms from E (resp. E_v, $E \otimes_w \mathbb{R}$) are the elements $a^2 - \delta_0 b^2$. By the Hasse norm theorem (Theorem B.27, applied to δ_0 and $x = \delta$) $\delta = z\bar{z}$ with $z \in E^\times$.

Isometry. For every embedding $\tau\colon E \to \mathbb{C}$ the matrices $\tau(G)$ and $\tau(G')$ have the signature of h, resp. h', at the real place below τ (for the conjugate embedding the matrix is conjugated, with the same signature), so they agree. By Landherr's theorem (Theorem B.28) there is $\gamma \in \mathrm{GL}_n(E)$ with $\bar{x}^\top \bar{\gamma}^\top G \gamma y = \bar{x}^\top G' y$; then the E-linear map g with $g(\sum_i y_i e'_i) = \sum_i (\gamma y)_i e_i$ is an isometry $(V', h') \to (V, h)$, and its inverse is an isometry $(V, h) \to (V', h')$.

One genus. Let $g\colon (V,h) \to (V',h')$ be any isometry. Then $g\Lambda = \{x \in V' : \ h'(x, g\Lambda) \subseteq \mathfrak{c}\}$, so by the local form above both $(g\Lambda)_v = g\Lambda_v$ and Λ'_v are self-dual R_v-lattices for the hermitian form $k'_v = c_v^{-1} h'_v$ on V'_v, for every finite place v. By Lemma 16.27 there is an E_v-linear g_v preserving k'_v, hence h'_v, with $g_v(g\Lambda)_v = \Lambda'_v$; that is, $g_v \in \mathrm{U}(V')(F_v)$. So $g\Lambda$ and Λ' lie in one genus. □

D.4.3 The fibre-square identities

Theorem D.85 derives the fibre-square identities (Fq1) of the root models from proportional square systems. The compact-dual side is Theorem D.87: the Fubini–Study height of the flag scheme satisfies the fibre-square identities with the sphere moments $\kappa_k = \frac{1}{2}\sum_{i<k} \frac{1}{2i+1}$ (Fq2). The model side passes to the limit of the square integrals (Theorem D.92), using the square convergence (Fx8) from an analytic square system (Theorem D.95) and the convergence of mixed Monge–Ampère integrals.

Theorem D.85. *Let $\mathcal{T}$ be a root tower of type (Φ, n, κ) with a geometric realisation whose root models have convergent regularisation and which has proportional analytic square systems. Then*

for every integer $B \geq 2$, every $Z \in \mathrm{Cp}$ and every Levi reflection s, the pair

$$(\mathrm{pp}(\mathcal{X}_{B,Z};\cdot)|_{\mathcal{R}}, \mathrm{gi}(\mathcal{X}_{B,Z};\cdot)|_{\mathcal{R}})$$

satisfies the fibre-square identities for s with the sphere moments $\mathrm{sph} = (\mathrm{sph}_k)_{k\geq 1}$, $\mathrm{sph}_k = \frac{1}{2}\sum_{j=0}^{k-1} \frac{1}{2j+1}$*; that is, the realised tower has (Fq1). If moreover $\mathcal{T}$ has the Fubini–Study compact dual (Fs), then the realised tower has the fibre-square identities (Fq1), (Fq2).*

Proof. Fix $B \geq 2$, $Z \in \mathrm{Cp}$ and a Levi reflection s. By hypothesis $\mathcal{X}_{B,Z}$ has a proportional square model for s: a root model $\mathcal{X}'$ of type (Φ, n) with convergent regularisation, a real number $m > 0$ with $\mathrm{pp}(\mathcal{X}';F) = m\,\mathrm{pp}(\mathcal{X}_{B,Z};F)$ and $\mathrm{gi}(\mathcal{X}';F) = m\,\mathrm{gi}(\mathcal{X}_{B,Z};F)$ for $F \in \mathcal{R}$, and a square system $(k_0, \mathcal{X}'^{(2)}, g, h)$ for s on $\mathcal{X}'$ with (Fx5), (Fx6), (Fx7) which carries an analytic square system. By Theorem D.95 this square system has analytic square data (Fx5)–(Fx8), and by Theorem D.92 it has the square limit (Fx4).

The identities on $\mathcal{X}'$. Since $\mathcal{X}'$ has convergent regularisation, $\mathrm{ai}_t(\mathcal{X}';x^a) \to \mathrm{pp}(\mathcal{X}';x^a)$ for every monomial $x^a \in \mathcal{R}^+$, and by linearity $\mathrm{ai}_t(\mathcal{X}';F) \to \mathrm{pp}(\mathcal{X}';F)$ as $t \to 0^+$ for every $F \in \mathcal{R}$. Let c be an s-invariant weight.

For $F = \mathrm{lr}(c)^{D+1}$: by Lemma D.86, applied to the square system on $\mathcal{X}'$, $\mathrm{ai}_t(\mathcal{X}';F) = 0$ for every $t > 0$, hence $\mathrm{pp}(\mathcal{X}';F) = 0$.

For $1 \leq k \leq (D+1)/2$ and $F = \xi_s^{2k}\mathrm{lr}(c)^{D+1-2k}$: by Lemma D.86, $\mathrm{ai}_t(\mathcal{X}';F) = I_t(k,c)/\delta_{\mathcal{X}'}$ for every $t > 0$, where $I_t(k,c)$ is the square integral of the square system on $\mathcal{X}'$; by (Fx4) the right side tends to $-2\,\mathrm{sph}_k\,\mathrm{gi}(\mathcal{X}';\xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k})$ ($\delta_{\mathcal{X}'} \geq 1$). Hence

$$\mathrm{pp}(\mathcal{X}';\xi_s^{2k}\mathrm{lr}(c)^{D+1-2k}) = -2\,\mathrm{sph}_k\,\mathrm{gi}(\mathcal{X}';\xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k}).$$

So the pair $(\mathrm{pp}(\mathcal{X}';\cdot)|_{\mathcal{R}}, \mathrm{gi}(\mathcal{X}';\cdot)|_{\mathcal{R}})$ satisfies the identities (30.1) for s with moments sph.

Carrying over. $\mathcal{X}_{B,Z}$ and $\mathcal{X}'$ are root models of type (Φ, n) with convergent regularisation, proportional with the factor $m > 0$ on $\mathcal{R}$; by Lemma D.96 the pair $(\mathrm{pp}(\mathcal{X}_{B,Z};\cdot)|_{\mathcal{R}}, \mathrm{gi}(\mathcal{X}_{B,Z};\cdot)|_{\mathcal{R}})$ satisfies the fibre-square identities for s with moments sph. As B, Z and s were arbitrary, this is (Fq1).

If $\mathcal{T}$ has (Fs), then $h^{\mathrm{cd}} = h^{\mathrm{FS}}_{\Phi,n}$ and Theorem D.87 gives the identities for $(h^{\mathrm{cd}}, \deg^{\mathrm{fl}})$ with its numbers κ_k, which are the sph_k; this is (Fq2), and with (Fq1) the second assertion. □

Lemma D.86. *Let $\mathcal{X}$ be a root model of type (Φ, n), s a Levi reflection and $(k_0, \mathcal{X}^{(2)}, g, h)$ a square system for s on $\mathcal{X}$. Then for every $t > 0$, every s-invariant weight c and every integer $1 \leq k \leq (D+1)/2$,*

$$\mathrm{ai}_t(\mathcal{X};\mathrm{lr}(c)^{D+1}) = 0, \qquad \delta_{\mathcal{X}}\,\mathrm{ai}_t(\mathcal{X};\xi_s^{2k}\,\mathrm{lr}(c)^{D+1-2k}) = I_t(k,c).$$

Proof. Fix $t > 0$ and k, write $m = D+1-2k$, $\mathbb{P} = \prod_{k' \in K} \mathbb{P}(\mathbb{Z}^{I_{k'}})$ for the ambient space of $\mathcal{X}$, $r_1 = (\tau, i)$, $r_2 = (\tau, i+1)$ for $s = s_{\tau,i}$, and $\overline{\Xi} = \overline{\Xi}(t)$. We use heights of cycles of the regular arithmetic varieties $\mathbb{P}$, $\mathbb{P}^{(2)}$ and $\mathbb{P}' = \prod_{k' \neq k_0} \mathbb{P}(\mathbb{Z}^{I_{k'}})$ with respect to Hermitian line bundles with smooth metrics on them (Section 14, Lemma 29.26); all cycles $\mathcal{Z}$ below $(\mathcal{X}, \mathcal{X}^{(2)}, \Delta)$ are integral and flat over $\mathbb{Z}$. The numbers $\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{M}}_0)\cdots\widehat{c}_1(\overline{\mathcal{M}}_p) \mid \mathcal{Z})$ for an integral closed subscheme $\mathcal{Z}$ of absolute dimension $p+1$ are symmetric and multilinear; for a non-zero rational section σ of $\mathcal{M}_0|_{\mathcal{Z}}$ whose Weil divisor $\mathrm{div}\,\sigma$ has no component in a fibre over a prime, Lemma 30.17 gives the *inductive formula*

$$\begin{aligned}\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{M}}_0)\cdots\widehat{c}_1(\overline{\mathcal{M}}_p) \mid \mathcal{Z}) &= \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{M}}_1)\cdots\widehat{c}_1(\overline{\mathcal{M}}_p) \mid \mathrm{div}\,\sigma) \\ &\quad - \int_{\mathcal{Z}(\mathbb{C})} \log\|\sigma\|\, c_1(\overline{\mathcal{M}}_1)\wedge\cdots\wedge c_1(\overline{\mathcal{M}}_p)\end{aligned} \tag{D.15}$$

with $\log\|\sigma\|$ integrable (the vertical sum of Lemma 30.17 is empty); and for a morphism f of such ambient varieties, Lemma 30.18 with $d = 0$ (part (1) if $\dim f(\mathcal{Z}) = \dim \mathcal{Z}$, with $c = \deg(\mathcal{Z}/f(\mathcal{Z}))$, part (2) otherwise) gives the *projection formula* $\widehat{\deg}(\prod \widehat{c}_1(f^*\overline{\mathcal{M}}_j) \mid \mathcal{Z}) = \widehat{\deg}(\prod \widehat{c}_1(\overline{\mathcal{M}}_j) \mid f_*[\mathcal{Z}])$, where $f_*[\mathcal{Z}] = \deg(\mathcal{Z}/f(\mathcal{Z}))[f(\mathcal{Z})]$ if $\dim f(\mathcal{Z}) = \dim \mathcal{Z}$ and $f_*[\mathcal{Z}] = 0$ otherwise. By (29.2) and multilinearity, $\delta_{\mathcal{X}}\mathrm{ai}_t(\mathcal{X}; F) = \widehat{\deg}(F(\widehat{c}_1(\overline{\mathcal{L}}(t))) \mid \mathcal{X})$ for $F \in \mathcal{R}$ homogeneous of degree $D+1$, where x_r is replaced by $\widehat{c}_1(\overline{\mathcal{L}}_r(t))$; in particular ξ_s is replaced by $\widehat{c}_1(\overline{\Xi})$.

Step 1: reduction to integral weights. The s-invariant weights form a real vector space V_s with the lattice $V_s \cap \mathbb{Z}^{\mathrm{Rt}}$ of full rank. Both sides of each identity are polynomial functions of $c \in V_s$: the left sides by multilinearity, the right side because $\omega_{c,t}$ is linear in c and each integral in (31.5) is a finite multilinear expression in the forms $c_1(\overline{\mathcal{L}}_r(t))$. A polynomial vanishing on a lattice of full rank vanishes identically, so it suffices to treat $c \in V_s \cap \mathbb{Z}^{\mathrm{Rt}}$. For such c let $\overline{\mathcal{A}} = \bigotimes_r \overline{\mathcal{L}}_r(t)^{\otimes(-c_r)}$, of multidegree $e_A = -\sum_r c_r e_r$ and cone function $h_A = \prod_r h_r(t)^{-c_r}$; then $c_1(\overline{\mathcal{A}}) = \omega_{c,t}$ and $\mathrm{lr}(c)$ is replaced by $\widehat{c}_1(\overline{\mathcal{A}})$.

Step 2: $\overline{\mathcal{A}}$ comes from the base. Since $c_{r_1} = c_{r_2}$, $h_A = (h_{r_1}(t)h_{r_2}(t))^{-c_{r_1}} \prod_{r \neq r_1, r_2} h_r(t)^{-c_r}$ is a product of powers of functions that come from the base at k_0 by (Fx1), so h_A comes from the base at k_0. So $(e_A)_{k_0} = 0$, $\overline{\mathcal{A}} = \mathrm{pr}^*\overline{\mathcal{A}}'$ for the projection $\mathrm{pr}\colon \mathbb{P} \to \mathbb{P}'$ and the Hermitian line bundle $\overline{\mathcal{A}}'$ on $\mathbb{P}'$ with the induced multidegree and cone function, and, since $\mathrm{pr} \circ q_0 = \mathrm{pr} \circ q_1$, $q_0^*\overline{\mathcal{A}} = q_1^*\overline{\mathcal{A}}$ on $\mathbb{P}^{(2)}$.

Step 3: $\mathrm{pr}(\mathcal{X})$ has absolute dimension at most D, and the first identity. Let $\mathcal{X}' = \mathrm{pr}(\mathcal{X})$, an integral closed subscheme of $\mathbb{P}'$, and $e = \dim \mathcal{X} - \dim \mathcal{X}'$. There is a dense open $V' \subseteq \mathcal{X}'$ over which all fibres of $\mathcal{X} \to \mathcal{X}'$ have dimension e. A point (z, z') of $\mathcal{X}^{(2)}$ has $q_0(z,z') \in \mathcal{X}$, $q_1(z,z') \in \mathcal{X}$ and $\mathrm{pr}\, q_0(z,z') = \mathrm{pr}\, q_1(z,z')$, so the fibre of $\mathcal{X}^{(2)} \to \mathcal{X}'$ over $y \in V'$ embeds into $\mathcal{X}_y \times \mathcal{X}_y$ and has dimension $\leq 2e$. As $\mathcal{X}^{(2)} \to \mathcal{X} \to \mathcal{X}'$ is surjective (Fx2), $\mathcal{X}^{(2)}$ dominates $\mathcal{X}'$, and the dimension of an integral scheme of finite type over $\mathbb{Z}$ dominating $\mathcal{X}'$ is at most $\dim \mathcal{X}'$ plus the dimension of its generic fibre. Hence $D + 2 \leq \dim \mathcal{X}' + 2e = 2(D+1) - \dim \mathcal{X}'$, i.e. $\dim \mathcal{X}' \leq D < \dim \mathcal{X}$. By the projection formula for pr, $\delta_{\mathcal{X}}\mathrm{ai}_t(\mathcal{X}; \mathrm{lr}(c)^{D+1}) = \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{A}}')^{D+1} \mid \mathrm{pr}_*[\mathcal{X}]) = 0$. This is the first identity.

Step 4: the diagonal maps birationally onto $\mathcal{X}$. Let Δ be as in (Fx3). On Δ the coordinates z_{k_0} and z' are proportional, so $q_0|_\Delta = q_1|_\Delta =: q_\Delta$. For every point x of $\mathcal{X}$ the fibre $q_\Delta^{-1}(x)$ lies in $\{(x, z') : z' \text{ proportional to } x_{k_0}\}$, a single point; so q_Δ is quasi-finite and proper, its image is closed of dimension $\dim \Delta = D+1$, hence equal to $\mathcal{X}$. Over the generic point η of $\mathcal{X}$, the fibre Δ_η is a non-empty integral closed subscheme of $(\mathcal{X}^{(2)})_\eta \cap \{z' \wedge z_{k_0} = 0\}$; by (Fx2) the first is a linear subspace of $\mathbb{P}(\mathbf{k}(\eta)^{I_{k_0}})$, and the minors with z_{k_0} fixed are linear forms in z' cutting out the reduced $\mathbf{k}(\eta)$-point $[z_{k_0}]$. The intersection is a linear subspace contained in a point, hence equals $\operatorname{Spec}\mathbf{k}(\eta)$, and so does Δ_η. Thus $\mathbf{k}(\Delta) = \mathbf{k}(\mathcal{X})$, q_Δ is birational, and $(q_0)_*[\Delta] = [\mathcal{X}]$.

Step 5: the inductive formula on the fibre square. On $\mathcal{X}^{(2)}$ put $\overline{\mathcal{X}}_0 = q_0^*\overline{\Xi}$, $\overline{\mathcal{X}}_1 = q_1^*\overline{\Xi}$, $\overline{\mathcal{A}}_0 = q_0^*\overline{\mathcal{A}} = q_1^*\overline{\mathcal{A}}$ (Step 2), and let $\overline{\mathcal{N}}$ be $\mathcal{O}(\deg g - \deg h)$ with cone function $(h_\Xi(t) \circ q_0 \cdot h_\Xi(t) \circ q_1)^{-1/2}$, smooth and positive. By (Fx3), $\overline{\mathcal{N}}^{\otimes 2} \cong (\overline{\mathcal{X}}_0 \otimes \overline{\mathcal{X}}_1)^{\otimes -1}$ isometrically (equal multidegrees and cone functions), so $2\widehat{c}_1(\overline{\mathcal{N}}) = -\widehat{c}_1(\overline{\mathcal{X}}_0) - \widehat{c}_1(\overline{\mathcal{X}}_1)$. The rational section $\sigma = g/h$ of $\mathcal{N}$ on $\mathcal{X}^{(2)}$ has $\operatorname{div}\sigma = [\Delta]$ (Fx3) and $\log\|\sigma\| = G_t$ (31.4). For $\alpha + \beta = 2k+1$ put

$$U(\alpha, \beta) = \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{X}}_0)^\alpha \widehat{c}_1(\overline{\mathcal{X}}_1)^\beta \widehat{c}_1(\overline{\mathcal{A}}_0)^m \mid \mathcal{X}^{(2)}),$$

and for $0 \leq a \leq 2k$ let $J_a = \int_{\mathcal{X}^{(2)}(\mathbb{C})} G_t\, q_0^*\omega_{\Xi,t}^a \wedge q_1^*\omega_{\Xi,t}^{2k-a} \wedge q_0^*\omega_{c,t}^m$, so that $I_t(k,c) = \sum_a (-1)^a J_a$. The inductive formula (D.15) with $\overline{\mathcal{M}}_0 = \overline{\mathcal{N}}$, the section σ, a copies of $\overline{\mathcal{X}}_0$, $2k-a$ copies of $\overline{\mathcal{X}}_1$ and m copies of $\overline{\mathcal{A}}_0$ gives

$$-\tfrac{1}{2}(U(a+1, 2k-a) + U(a, 2k-a+1)) = \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{X}}_0)^a \widehat{c}_1(\overline{\mathcal{X}}_1)^{2k-a} \widehat{c}_1(\overline{\mathcal{A}}_0)^m \mid \Delta) - J_a.$$

On Δ the three bundles are $q_\Delta^*\overline{\Xi}$, $q_\Delta^*\overline{\Xi}$, $q_\Delta^*\overline{\mathcal{A}}$ (Step 4), so by the projection formula and $(q_0)_*[\Delta] = [\mathcal{X}]$ the degree on Δ equals $\widehat{\deg}(\widehat{c}_1(\overline{\Xi})^{2k}\widehat{c}_1(\overline{\mathcal{A}})^m \mid \mathcal{X}) = \delta_{\mathcal{X}} A$ with $A = \mathrm{ai}_t(\mathcal{X}; \xi_s^{2k}\mathrm{lr}(c)^m)$, independently of a. Hence

$$U(a+1, 2k-a) + U(a, 2k-a+1) = -2\delta_{\mathcal{X}} A + 2J_a \qquad (0 \le a \le 2k). \tag{D.16}$$

Step 6: the end terms vanish. $U(2k+1, 0) = \widehat{\deg}(q_0^*(\widehat{c}_1(\overline{\Xi})^{2k+1}\widehat{c}_1(\overline{\mathcal{A}})^m) \mid \mathcal{X}^{(2)}) = 0$ by the projection formula for q_0, since $\dim q_0(\mathcal{X}^{(2)}) = \dim \mathcal{X} < \dim \mathcal{X}^{(2)}$; likewise $U(0, 2k+1) = 0$ for q_1, using $\overline{\mathcal{A}}_0 = q_1^*\overline{\mathcal{A}}$.

Step 7: alternating summation. Write $U_a = U(a, 2k+1-a)$ for $0 \le a \le 2k+1$, so that the left side of (D.16) is $U_{a+1} + U_a$. Multiplying (D.16) by $(-1)^a$ and summing over $0 \le a \le 2k$, the left side telescopes to $U_0 + U_{2k+1} = 0$ (Step 6), while $\sum_{a=0}^{2k}(-1)^a = 1$. So $0 = -2\delta_{\mathcal{X}} A + 2\sum_a (-1)^a J_a = -2\delta_{\mathcal{X}} A + 2I_t(k, c)$, which is the second identity. □

Theorem D.87. *Let Φ be a non-empty finite set, $n \ge 2$, and put $\kappa_k = \frac{1}{2}\sum_{i=0}^{k-1} \frac{1}{2i+1}$ for $k \ge 1$ (the **sphere moments**; $\kappa_1 = \frac{1}{2}$, $\kappa_2 = \frac{2}{3}$). For every $\tau \in \Phi$ and every $1 \le i \le n-1$, with $s = s_{\tau,i}$ and $\xi_s = x_{\tau,i} - x_{\tau,i+1}$, and for every weight c with $c_{\tau,i} = c_{\tau,i+1}$,*

$$h^{\mathrm{FS}}_{\Phi,n}(\mathrm{lr}(c)^{D+1}) = 0,$$
$$h^{\mathrm{FS}}_{\Phi,n}(\xi_s^{2k}\,\mathrm{lr}(c)^{D+1-2k}) = -2\,\kappa_k\,\deg^{\mathrm{fl}}(\xi_s^{2k-1}\,\mathrm{lr}(c)^{D+1-2k}) \quad (1 \le k \le (D+1)/2).$$

In particular the pair $(h^{\mathrm{FS}}_{\Phi,n}, \deg^{\mathrm{fl}})$ satisfies the fibre-square identities for every Levi reflection with moments $(\kappa_k)_{k\ge1}$, and every root tower with the Fubini–Study compact dual (Fs) has (Fq2) with these moments.

Proof. Fix τ, i, $s = s_{\tau,i}$, an s-invariant weight c, and write $\mathrm{Fl} = \mathrm{Fl}_{\Phi,n}$, $m_k = D + 1 - 2k$.

Step 1: the $\mathbb{P}^1$-bundle. By Lemma 30.26(2), Fl is the smooth projective $\mathbb{Z}$-scheme of Φ-tuples of complete flags $0 = \mathcal{U}_{a,0} \subset \mathcal{U}_{a,1} \subset \cdots \subset \mathcal{U}_{a,n} = \mathcal{O}^n$ of locally split subbundles ($\mathrm{rk}\,\mathcal{U}_{a,j} = j$), embedded by the Plücker coordinates of its steps. On $\mathcal{O}^n$ put the standard Hermitian metric and on every $\mathcal{U}_{a,j}$ the induced one. The Plücker embedding of the factor $k = (a, j)$ restricts $\mathcal{O}(-1)$ to $\wedge^j\mathcal{U}_{a,j} \subseteq \wedge^j\mathcal{O}^n$, and the Fubini–Study metric of $\mathcal{O}(-1)$ is the restriction of the standard norm of $\wedge^j\mathbb{C}^n$, i.e. the determinant metric of $\mathcal{U}_{a,j}$. So, with $\hat{s}_k = \widehat{c}_1(\mathcal{O}(1_k), h^{\mathrm{FS}}_{1_k})|_{\mathrm{Fl}}$ (the class of the line $\mathcal{O}(1)$ of the factor k with its Fubini–Study metric, restricted to Fl),

$$\hat{s}_{(a,j)} = -\widehat{c}_1(\det \overline{\mathcal{U}}_{a,j}) \quad (1 \le j \le n-1), \qquad \hat{s}_{(a,0)} = \hat{s}_{(a,n)} = 0$$

($\det\mathcal{U}_{a,n} = \det\mathcal{O}^n$ has the section $e_1 \wedge \cdots \wedge e_n$ of norm 1). Let $\mathcal{Y}$ be the smooth projective $\mathbb{Z}$-scheme of Φ-tuples of flags of the same kind with the step (τ, i) omitted, embedded by the Plücker coordinates of the remaining steps $k \ne (\tau, i)$; it is a regular arithmetic variety of absolute dimension D, and the forgetful morphism $p\colon \mathrm{Fl} \to \mathcal{Y}$ is the restriction of the projection forgetting the factor (τ, i), so that $\hat{s}_k = p^*\hat{s}'_k$ for $k \ne (\tau, i)$, $\hat{s}'_k$ the Fubini–Study class of the factor k on $\mathcal{Y}$. Let $W = \mathcal{U}_{\tau,i+1}/\mathcal{U}_{\tau,i-1}$ on $\mathcal{Y}$, of rank 2, with the quotient metric h. A step $\mathcal{U}_{\tau,i}$ between $\mathcal{U}_{\tau,i-1}$ and $\mathcal{U}_{\tau,i+1}$ with locally free quotients is the same as a locally split line $\mathcal{S} = \mathcal{U}_{\tau,i}/\mathcal{U}_{\tau,i-1} \subseteq W$; hence p identifies Fl with $\pi\colon \mathbb{P}(W) \to \mathcal{Y}$, the tautological line being $\mathcal{S}$. Its metric induced from W is the quotient metric of $\mathcal{U}_{\tau,i}/\mathcal{U}_{\tau,i-1}$ (both are the metric of $\mathcal{U}_{\tau,i} \cap \mathcal{U}_{\tau,i-1}^{\perp}$ at complex points).

Step 2: the classes. For Hermitian bundles $V' \subseteq V$ with induced and quotient metrics, $\det V \cong \det V' \otimes \det(V/V')$ isometrically; $\widehat{c}_1$ is additive on tensor products of Hermitian line bundles and vanishes on $(\mathcal{O}, |\cdot|)$ ((GC3) of Lemma D.90), so $\widehat{c}_1(\overline{L}^\vee) = -\widehat{c}_1(\overline{L})$. Moreover $\widehat{c}_1(\overline{W}) = \widehat{c}_1(\det\overline{W})$ by Lemma D.91: $\mathcal{Y}$ is a regular arithmetic variety, $\mathcal{Y}(\mathbb{C})$ is a product of partial flag manifolds, hence connected, and the section $P\colon \mathrm{Spec}\,\mathbb{Z} \to \mathcal{Y}$ given by the standard

flags ($\mathcal{U}_{a,j} = \mathbb{Z}e_1 \oplus \cdots \oplus \mathbb{Z}e_j$ for the steps $(a,j) \neq (\tau,i)$) has $P^*\overline{W} = (\mathbb{Z}e_1 \oplus \cdots \oplus \mathbb{Z}e_{i+1})/(\mathbb{Z}e_1 \oplus \cdots \oplus \mathbb{Z}e_{i-1})$ with the quotient metric, the orthogonal sum of the images of $\mathbb{Z}e_i$ and $\mathbb{Z}e_{i+1}$, each of norm 1. Hence $\hat{\zeta} = \widehat{c}_1(\overline{\mathcal{S}}^\vee) = \hat{s}_{(\tau,i)} - \hat{s}_{(\tau,i-1)}$ and $\widehat{c}_1(\overline{W}) = \hat{s}'_{(\tau,i-1)} - \hat{s}'_{(\tau,i+1)}$ (pulled back), so

$$\hat{\theta} = 2\hat{\zeta} + p^*\widehat{c}_1(\overline{W}) = 2\hat{s}_{(\tau,i)} - \hat{s}_{(\tau,i-1)} - \hat{s}_{(\tau,i+1)}.$$

Put $\hat{y}_r = -\widehat{c}_1(\overline{\mathcal{X}}_r^{\mathrm{FS}}) = \hat{s}_{(a,j-1)} - \hat{s}_{(a,j)}$ for $r = (a,j)$ ($\overline{\mathcal{X}}_r^{\mathrm{FS}} = (\mathcal{O}(e_r^{\mathrm{Fl}}), h_{e_r^{\mathrm{Fl}}}^{\mathrm{FS}})|_{\mathrm{Fl}}$ with $e^{\mathrm{Fl}}_{(a,j)} = 1_{(a,j)} - 1_{(a,j-1)}$, the indices 0 and n omitted, and $h_e^{\mathrm{FS}} = \prod_k h_{1_k}^{\mathrm{FS}e_k}$, Definition 29.11). By (29.7) and multilinearity, $h^{\mathrm{FS}}_{\Phi,n}(F) = \widehat{\deg}(F(\hat{y}))$ for F homogeneous of degree $D+1$, $F(\hat{y})$ obtained by substituting $\hat{y}_r$ for x_r. Now $\xi_s(\hat{y}) = \hat{y}_{\tau,i} - \hat{y}_{\tau,i+1} = -\hat{\theta}$, and in $\mathrm{lr}(c)(\hat{y}) = -\sum_r c_r \hat{y}_r$ the two roots $(\tau,i),(\tau,i+1)$ contribute $-c_{\tau,i}(\hat{s}_{(\tau,i-1)} - \hat{s}_{(\tau,i+1)})$ while every other $\hat{y}_r$ involves only classes $\hat{s}_k$ with $k \neq (\tau,i)$. Hence $\mathrm{lr}(c)(\hat{y}) = p^*\hat{\eta}_c$ with $\hat{\eta}_c = \sum_{k\neq(\tau,i)} b_k \hat{s}'_k$ for real numbers b_k depending on c, and $\omega(\hat{\eta}_c) = \omega_c := \sum_k b_k \omega'_k$ with ω'_k the Fubini–Study forms. Expanding $\hat{\eta}_c^m$ multinomially into monomials x in the $\hat{s}'_k$ (rational classes) with real coefficients, and applying linearity to each, the numbers below are real-multilinear in the b_k.

Step 3: the arithmetic side. For $k=0$: $h^{\mathrm{FS}}_{\Phi,n}(\mathrm{lr}(c)^{D+1}) = \widehat{\deg}((p^*\hat{\eta}_c)^{D+1}) = 0$. Indeed, by the expansion above it suffices that $\widehat{\deg}(p^*\hat{s}'_{k_1}\cdots p^*\hat{s}'_{k_{D+1}}) = 0$ for all indices $k_1,\dots,k_{D+1} \neq (\tau,i)$. Since p is a morphism of regular arithmetic varieties with smooth generic fibre (Step 1), p^* is a ring homomorphism on $\widehat{\mathrm{CH}}^*(\cdot)_{\mathbb{Q}}$ ((GA1) of Lemma D.89), so this product is $p^*(x)$ with $x = \hat{s}'_{k_1}\cdots\hat{s}'_{k_{D+1}} \in \widehat{\mathrm{CH}}^{D+1}(\mathcal{Y})_{\mathbb{Q}}$. This group is 0: $\widehat{\mathrm{CH}}^{D+1}(\mathcal{Y})$ is a quotient of the group of pairs (Z,g) of a cycle Z of codimension $D+1$ on $\mathcal{Y}$ and a real current g of type (D,D) on $\mathcal{Y}(\mathbb{C})$ ([110], 3.3.3 and 3.3.4); $Z=0$ because the integral scheme $\mathcal{Y}$ has dimension D, so that no local ring of $\mathcal{Y}$ has Krull dimension $D+1$, and $g=0$ because $\mathcal{Y}(\mathbb{C})$ is a complex manifold of dimension $D-1$. Hence $x=0$ and $p^*(x)=0$. For $1 \le k \le (D+1)/2$, by (D.18) applied to each monomial ($\mathcal{Y}$ has absolute dimension $d+1$ with $d=D-1$, and $m_k = d+2-2k$):

$$h^{\mathrm{FS}}_{\Phi,n}(\xi_s^{2k}\mathrm{lr}(c)^{m_k}) = \widehat{\deg}(\hat{\theta}^{2k}\cdot p^*\hat{\eta}_c^{m_k}) = \frac{c_k}{2}\,I_k, \qquad I_k := \int_{\mathcal{Y}(\mathbb{C})} \Delta_h^{k-1} \wedge \omega_c^{m_k}.$$

Step 4: the geometric side. By Lemma 30.22, $\deg^{\mathrm{fl}}(G) = \deg(G(y)\cap[\mathrm{Fl}_{\mathbb{Q}}])$ for G of degree D, with $y_r = c_1(\mathcal{O}(-e_r^{\mathrm{Fl}}))$ the images of $\hat{y}_r$ in $\mathrm{CH}^1(\mathrm{Fl}_{\mathbb{Q}})$. The identities of Step 2 hold for these images: $\xi_s(y) = -\theta$ and $\mathrm{lr}(c)(y) = p^*\eta_c$. By the projection formula and the last assertion of Lemma D.88,

$$\deg^{\mathrm{fl}}(\xi_s^{2k-1}\mathrm{lr}(c)^{m_k}) = -\deg(p_*(\theta^{2k-1})\,\eta_c^{m_k}\cap[\mathcal{Y}_{\mathbb{Q}}]) = -2\deg(\Delta^{k-1}\eta_c^{m_k}\cap[\mathcal{Y}_{\mathbb{Q}}]) = -2\,I_k,$$

the last equality by Chern–Weil theory on the compact Kähler manifold $\mathcal{Y}(\mathbb{C})$: $c_i(W,h)$ and ω'_k represent $c_i(W_{\mathbb{C}})$ and $c_1(\mathcal{O}(1_k))$, and the degree of a zero-cycle class does not change under the extension $\mathbb{Q}\subseteq\mathbb{C}$.

Step 5. Since $c_k = 8\kappa_k$, $h^{\mathrm{FS}}_{\Phi,n}(\xi_s^{2k}\mathrm{lr}(c)^{m_k}) = 4\kappa_k I_k = -2\kappa_k \deg^{\mathrm{fl}}(\xi_s^{2k-1}\mathrm{lr}(c)^{m_k})$. For a root tower with (Fs), $h^{\mathrm{cd}} = h^{\mathrm{FS}}_{\Phi,n}$, so this is (Fq2) with moments (κ_k). The moments coincide with the closed form of the sphere-moment integrals of the fibre square computed in computer check C7, listed in Appendix B. □

Lemma D.88. *Let $\mathcal{Y}$ be a regular arithmetic variety over $\mathbb{Z}$ of absolute dimension $d+1$, $\overline{W} = (W,h)$ a Hermitian vector bundle of rank 2 on $\mathcal{Y}$, $\pi\colon \mathbb{P}(W) \to \mathcal{Y}$ the bundle of lines, $\overline{\mathcal{S}} \subseteq \pi^*\overline{W}$ the tautological line with the induced metric and $\hat{\zeta} = \widehat{c}_1(\overline{\mathcal{S}}^\vee)$. Put*

$$\hat{\theta} = 2\hat{\zeta} + \pi^*\widehat{c}_1(\overline{W}), \qquad \widehat{\Delta} = \widehat{c}_1(\overline{W})^2 - 4\widehat{c}_2(\overline{W}),$$

$$\Delta_h = c_1(W,h)^2 - 4c_2(W,h), \qquad c_k = 4\sum_{i=0}^{k-1}\frac{1}{2i+1}.$$

Then, in $\widehat{\mathrm{CH}}^*(\mathcal{Y})_{\mathbb{Q}}$,

$$\pi_*(\hat\theta^{\,0}) = 0, \qquad \pi_*(\hat\theta^{\,2k}) = a(c_k\,\Delta_h^{k-1}) \quad (k\ge 1), \qquad \pi_*(\hat\theta^{\,2k+1}) = 2\,\widehat{\Delta}^{\,k} \quad (k\ge 0). \tag{D.17}$$

Consequently, for $k\ge 1$ *and every* $x\in \widehat{\mathrm{CH}}^{\,d+2-2k}(\mathcal{Y})_{\mathbb{Q}}$,

$$\widehat{\deg}(\hat\theta^{\,2k}\cdot\pi^*x) = \frac{c_k}{2}\int_{\mathcal{Y}(\mathbb{C})}\Delta_h^{k-1}\wedge\omega(x), \tag{D.18}$$

and on the generic fibres, with $\theta = 2c_1(\mathcal{S}_{\mathbb{Q}}^\vee)+\pi^*c_1(W_{\mathbb{Q}})$ *and* $\Delta = c_1(W_{\mathbb{Q}})^2-4c_2(W_{\mathbb{Q}})$, $\pi_*(\theta^{2k-1}) = 2\Delta^{k-1}$ *in* $\mathrm{CH}^{2k-2}(\mathcal{Y}_{\mathbb{Q}})_{\mathbb{Q}}$ *for* $k\ge 1$.

Proof. Let $A=\mathbb{Q}[\mathsf{c}_1,\mathsf{c}_2]$ be the polynomial ring in two indeterminates and define $\mathsf{s}_m\in A$ by $\sum_m \mathsf{s}_m t^m = (1+\mathsf{c}_1t+\mathsf{c}_2t^2)^{-1}$ in $A[[t]]$; for $N\ge 0$ put

$$P_N=\sum_{j=1}^{N}\binom{N}{j}2^j\,\mathsf{s}_{j-1}\,\mathsf{c}_1^{N-j}, \qquad M_n=\sum_{p+q=n}\frac{\mathsf{s}_p\mathsf{s}_q}{q+1}, \qquad \Psi_N=\sum_{j=2}^{N}\binom{N}{j}2^j\,\mathsf{c}_1^{N-j}M_{j-2}.$$

Then $\hat s_m=\mathsf{s}_m(\widehat{c}_1(\overline{W}),\widehat{c}_2(\overline{W}))$ in the commutative ring $\widehat{\mathrm{CH}}^*(\mathcal{Y})_{\mathbb{Q}}$, $s'_m=\mathsf{s}_m(c_1(W,h),c_2(W,h))$ in the commutative algebra of even forms, and $-R_m=M_{m-1}(c_1(W,h),c_2(W,h))$ for $m\ge 1$.

The arithmetic intersection theory used along π and along the structure morphisms to $\operatorname{Spec}\mathbb{Z}$ is Lemma D.89: $\mathcal{Y}$ and $\mathbb{P}(W)$ are regular, flat and projective over $\mathbb{Z}$, and π is smooth of relative dimension 1. The numerical projection formula Proposition B.129 would not suffice: in (D.18) the $2k\ge 2$ factors $\hat\theta$ are not pulled back from $\mathcal{Y}$. The arithmetic Chern classes $\widehat{c}_1(\overline{W})$, $\widehat{c}_2(\overline{W})$ and their forms and cycles are those of Lemma D.90. *Step 1: reduction to two polynomial identities.* Since $\widehat{\mathrm{CH}}^*(\mathbb{P}(W))_{\mathbb{Q}}$ is commutative (GA1), $\hat\theta^N=\sum_{j=0}^N\binom{N}{j}2^j\hat\zeta^{\,j}\cdot\pi^*\widehat{c}_1(\overline{W})^{N-j}$. By the projection formula (GA2), $\pi_*(\hat\zeta^{\,j}\cdot\pi^*y)=\pi_*(\hat\zeta^{\,j})\cdot y$; $\pi_*(1)=0$ because π has relative dimension one and $\widehat{\mathrm{CH}}^{-1}=0$; for $j\ge 1$, $\pi_*(\hat\zeta^{\,j})=\hat s_{j-1}-a(R_{j-1})$ by Theorem B.139; and $a(R)\cdot\widehat{c}_1(\overline{W})^{N-j}=a(R\wedge c_1(W,h)^{N-j})$ by (GA3), since $\omega(\widehat{c}_1(\overline{W}))=c_1(W,h)$ by (GC2). Hence

$$\pi_*(\hat\theta^N)=P_N\big(\widehat{c}_1(\overline{W}),\widehat{c}_2(\overline{W})\big)+a\Big(\Psi_N\big(c_1(W,h),c_2(W,h)\big)\Big) \tag{D.19}$$

($R_0=0$ removes $j=1$ from the secondary sum). It remains to show, in A,

$$P_{2k}=0,\quad P_{2k+1}=2(\mathsf{c}_1^2-4\mathsf{c}_2)^k,\quad \Psi_{2k+1}=0\ (k\ge 0),\qquad \Psi_{2k}=c_k(\mathsf{c}_1^2-4\mathsf{c}_2)^{k-1}\ (k\ge 1),\quad \Psi_0=0. \tag{D.20}$$

Step 2: generating functions. Embed A in $L=\mathbb{Q}(\alpha,\beta)$ by $\mathsf{c}_1=-(\alpha+\beta)$, $\mathsf{c}_2=\alpha\beta$, and put $\delta=\alpha-\beta$, so $\mathsf{c}_1^2-4\mathsf{c}_2=\delta^2$ and $S(t):=\sum\mathsf{s}_mt^m=((1-\alpha t)(1-\beta t))^{-1}$. In $L[[y]]$, for any sequence (A_j) and $B\in L$, exchanging the order of summation gives $\sum_N y^N\sum_j\binom{N}{j}A_jB^{N-j}=\frac{1}{1-By}\sum_j A_jY^j$ with $Y=\frac{y}{1-By}$; take $B=\mathsf{c}_1$. Then

$$1-2\alpha Y=\frac{1-\delta y}{1-\mathsf{c}_1y}, \qquad 1-2\beta Y=\frac{1+\delta y}{1-\mathsf{c}_1y}.$$

For P: $A_j=2^j\mathsf{s}_{j-1}$ $(j\ge 1)$, $A_0=0$, so $\sum_N P_Ny^N=\frac{2Y\,S(2Y)}{1-\mathsf{c}_1y}=\frac{2y}{1-\delta^2y^2}$. For Ψ: $\sum_n M_nt^n=S(t)\sum_q\mathsf{s}_q\frac{t^q}{q+1}$, and since $\mathsf{s}_{m-1}=\frac{\alpha^m-\beta^m}{\alpha-\beta}$, $\sum_q\mathsf{s}_q\frac{t^q}{q+1}=\frac{1}{\delta t}\sum_{m\ge1}\frac{(\alpha^m-\beta^m)t^m}{m}=\frac{1}{\delta t}\Lambda(t)$ with $\Lambda(t)=\log\frac{1-\beta t}{1-\alpha t}$ (formal logarithm). With $A_j=2^jM_{j-2}$ $(j\ge 2)$,

$$\sum_N\Psi_Ny^N=\frac{4Y^2}{1-\mathsf{c}_1y}\cdot\frac{\Lambda(2Y)}{2\delta Y(1-2\alpha Y)(1-2\beta Y)}=\frac{2y}{\delta(1-\delta^2y^2)}\log\frac{1+\delta y}{1-\delta y}.$$

Since $\log\frac{1+x}{1-x} = 2\sum_{i\geq 0}\frac{x^{2i+1}}{2i+1}$ and $\frac{1}{1-x^2} = \sum_i x^{2i}$, the Cauchy product with $x = \delta y$ gives $\sum_N \Psi_N y^N = \sum_{k\geq 1} c_k \delta^{2k-2} y^{2k}$, and $\sum_N P_N y^N = \sum_k 2\delta^{2k} y^{2k+1}$. Comparing coefficients gives (D.20) in L, hence in $A \subseteq L$. (The symbolic steps and the coefficients for $N \leq 60$ have been checked independently by computer: computer check C8, listed in Appendix B.) With (D.19) this proves (D.17).

Step 3: the consequences. By (GA5) for π, the projection formula (GA2), (D.17), (GA3) and (GA5) for $\mathcal{Y}$, $\widehat{\deg}(\hat\theta^{2k}\cdot\pi^*x) = \widehat{\deg}(\pi_*(\hat\theta^{2k})\cdot x) = \widehat{\deg}(a(c_k\Delta_h^{k-1})\cdot x) = \widehat{\deg}\, a(c_k\Delta_h^{k-1}\wedge\omega(x)) = \frac{c_k}{2}\int_{\mathcal{Y}(\mathbb{C})}\Delta_h^{k-1}\wedge\omega(x)$, which is (D.18). The map $\zeta\colon \widehat{\mathrm{CH}}^* \to \mathrm{CH}^*$ forgetting the Green current is a ring homomorphism commuting with π_* and kills $a(\cdot)$ ((GA1), (GA2)), and it sends $\widehat{c}_i(\overline{W})$ to $c_i(W)$ and $\hat\zeta$ to $c_1(\mathcal{S}^\vee)$ ((GC2), in ranks 2 and 1); followed by restriction to the open generic fibres (flat pull-back, which commutes with proper push-forward), it turns $\pi_*(\hat\theta^{2k-1}) = 2\widehat{\Delta}^{k-1}$ into $\pi_*(\theta^{2k-1}) = 2\Delta^{k-1}$. □

Lemma D.89. *Let X and Y be regular arithmetic varieties over $\mathbb{Z}$ and $f\colon X\to Y$ a morphism of relative dimension e whose generic fibre $f_\mathbb{Q}$ is smooth. Then:*

(GA1) *$\widehat{\mathrm{CH}}^*(X)_\mathbb{Q}$ is a commutative and associative $\mathbb{Q}$-algebra with unit; $\zeta\colon \widehat{\mathrm{CH}}^*(X)_\mathbb{Q} \to \mathrm{CH}^*(X)_\mathbb{Q}$ is a ring homomorphism with $\zeta\circ a = 0$; f^* is a ring homomorphism with $\zeta\circ f^* = f^*\circ\zeta$.*

(GA2) *The push-forward $f_*\colon \widehat{\mathrm{CH}}^p(X)_\mathbb{Q} \to \widehat{\mathrm{CH}}^{p-e}(Y)_\mathbb{Q}$ of Gillet and Soulé satisfies $(g\circ f)_* = g_*\circ f_*$ for every further such morphism $g\colon Y\to Y'$, $\zeta\circ f_* = f_*\circ\zeta$, $\omega(f_*x) = \int_f\omega(x)$, and $f_*(f^*(y)\cdot x) = y\cdot f_*(x)$ for $x\in\widehat{\mathrm{CH}}^*(X)_\mathbb{Q}$, $y\in\widehat{\mathrm{CH}}^*(Y)_\mathbb{Q}$.*

(GA3) *$a(\eta)\cdot x = a(\eta\wedge\omega(x))$ for η as above and $x\in\widehat{\mathrm{CH}}^q(X)_\mathbb{Q}$.*

(GA4) *$f_*(a(\eta)) = a\big(\int_f\eta\big)$, which is 0 if $p-1<e$.*

(GA5) *If X has absolute dimension $d+1$ and $\widehat{\deg}\colon \widehat{\mathrm{CH}}^{d+1}(X)_\mathbb{Q}\to\mathbb{R}$ is the push-forward along the structure morphism $X\to\operatorname{Spec}\mathbb{Z}$ followed by the arithmetic degree on $\widehat{\mathrm{CH}}^1(\operatorname{Spec}\mathbb{Z})$, then $\widehat{\deg}(f_*x) = \widehat{\deg}(x)$ for $x\in\widehat{\mathrm{CH}}^{d+1}(X)_\mathbb{Q}$, and $\widehat{\deg}\, a(\eta) = \frac12\int_{X(\mathbb{C})}\eta$ for η of type (d,d).*

Proof. In this proof a and ω without further comment on a class of $\widehat{\mathrm{CH}}^p(\cdot,\mathcal{D}_{\log})$ are those of [106], and a, ω on $\widehat{\mathrm{CH}}^p(\cdot)$ those of Gillet and Soulé.

Step 0: the hypotheses of Proposition B.140 hold, and $f_\# = f_!$ on smooth forms. X and Y are regular, flat and projective over $\mathbb{Z}$, so they are arithmetic varieties in the sense of Proposition B.140, and $X_\mathbb{R}$, $Y_\mathbb{R}$ are projective. f is proper (X is proper over $\mathbb{Z}$ and Y is separated), of relative dimension e between integral schemes, and $f_\mathbb{R}$ is smooth (base change of $f_\mathbb{Q}$) and proper between proper varieties; so (BK3) applies to f. The structure morphism $X\to\operatorname{Spec}\mathbb{Z}$ also satisfies the hypotheses of (BK3): its generic fibre $X_\mathbb{Q}$ is a regular scheme of finite type over the perfect field $\mathbb{Q}$, hence smooth. Since $X(\mathbb{C})$ is compact, it is its only compactification with normal crossing boundary (empty boundary); hence the forms with logarithmic singularities at infinity on $X(\mathbb{C})$ are all smooth forms, and in the construction of (BK3) over $U = Y(\mathbb{C})$ the only $\overline{Y}$ is $Y(\mathbb{C})$ with $D=\emptyset$, so that $\mathcal{F}(Y,p) = \mathcal{D}(E_{X(\mathbb{C})},p)$ and u is the identity on global sections. Therefore $f_\# = v\circ u^{-1} = f_! = (2\pi i)^{-e}\int_f$ on global smooth forms.

Step 1: the dictionary. For η as in the statement put $x_\eta = (2\pi i)^{p-1}\eta$. It has type $(p-1,p-1)$, lies in $(2\pi i)^{p-1}$ times the real forms, and $F_\infty^* x_\eta = (-1)^{p-1}x_\eta = \overline{x_\eta}$; so x_η defines a class $\widetilde{x}_\eta\in\widetilde{\mathcal{D}}^{2p-1}_{\log}(X,p)$, and $\eta\mapsto\widetilde{x}_\eta$ respects $\operatorname{Im}\partial+\operatorname{Im}\bar\partial$. By the formula for a, $\mathrm{a}(\widetilde{x}_\eta) = [0,(2\partial\bar\partial x_\eta, -\widetilde{x}_\eta)]$,

so by (BK4) $\Psi(\mathrm{a}(\widetilde{x}_\eta))$ is the class of $(0,g)$ with $g=-2(2\pi i)^{d-p+1}[x_\eta]_X$, d the relative dimension of X, i.e.

$$g(\varphi)=-2(2\pi i)^{d-p+1}(2\pi i)^{-d}\int_{X(\mathbb{C})}\varphi\wedge(2\pi i)^{p-1}\eta=-2\int_{X(\mathbb{C})}\varphi\wedge\eta,$$

the current of the form -2η. Hence, for every p,

$$a(\eta)=\Psi\big(\mathrm{a}(-\tfrac{1}{2}\widetilde{x}_\eta)\big),\qquad \omega(\Psi(\alpha))=(2\pi i)^{-p}\,\omega(\alpha),\qquad \zeta(\Psi(\alpha))=\zeta(\alpha) \tag{D.21}$$

for $\alpha\in\widehat{\mathrm{CH}}^p(X,\mathcal{D}_{\log})$: the second is the last assertion of (BK4) (the Green current of $\Psi(\alpha)$ satisfies $dd^c g+\delta=[(2\pi i)^{-p}\omega_y]$), the third holds because Ψ does not change the cycle.

Step 2: (GA1) and (GA2). By (BK4) and Step 0, Ψ_X and Ψ_Y are isomorphisms compatible with products, pull-backs and push-forwards; in particular the push-forward of Gillet and Soulé is $f_*=\Psi_Y\circ f_*\circ\Psi_X^{-1}$ with the f_* of (BK3). Transporting (BK1) and (BK2) by Ψ, with the third identity of (D.21), gives (GA1) except $\zeta\circ a=0$, which holds because $a(\eta)$ is represented by the zero cycle. Transporting (BK3) gives functoriality, $\zeta\circ f_*=f_*\circ\zeta$, and $f_*(f^*(y)\cdot x)=y\cdot f_*(x)$ (with commutativity from (GA1)). For $\alpha\in\widehat{\mathrm{CH}}^p(X,\mathcal{D}_{\log})$, by (D.21), (BK3) and Step 0,

$$\omega(f_*\Psi\alpha)=(2\pi i)^{-(p-e)}\omega(f_*\alpha)=(2\pi i)^{-(p-e)}(2\pi i)^{-e}\int_f\omega(\alpha)=\int_f\omega(\Psi\alpha).$$

Step 3: (GA3). By linearity it suffices to take $x=\Psi[z,\mathfrak{g}_z]$ with z a q-codimensional cycle and $\mathfrak{g}_z=(\omega_z,\widetilde{g}_z)$ a Green form. Put $\xi=-\frac{1}{2}\widetilde{x}_\eta$. The zero cycle and z intersect properly in the generic fibre, so by (BK1) $\mathrm{a}(\xi)\cdot[z,\mathfrak{g}_z]$ is the class of $((0,\mathrm{a}(\xi)*\mathfrak{g}_z),0)$ with $\mathrm{a}(\xi)*\mathfrak{g}_z=\widetilde{\mathrm{a}(\xi\wedge\omega_z)}$; that is, $\mathrm{a}(\xi)\cdot[z,\mathfrak{g}_z]=\widetilde{\mathrm{a}(\xi\wedge\omega_z)}$. By (D.21), $\omega_z=(2\pi i)^q\omega(x)$, so $\xi\wedge\omega_z=-\frac{1}{2}(2\pi i)^{p+q-1}\eta\wedge\omega(x)=-\frac{1}{2}x_{\eta\wedge\omega(x)}$, where $\eta\wedge\omega(x)$ is real of type $(p+q-1,p+q-1)$ with $F^*_\infty=(-1)^{p+q-1}$ (as $F^*_\infty\omega(x)=(-1)^q\omega(x)$). Applying Ψ, compatible with products, and (D.21) in degree $p+q$:

$$a(\eta)\cdot x=\Psi\big(\mathrm{a}(\xi)\cdot[z,\mathfrak{g}_z]\big)=\Psi\big(\mathrm{a}(-\tfrac{1}{2}\widetilde{x}_{\eta\wedge\omega(x)})\big)=a(\eta\wedge\omega(x)).$$

Step 4: (GA4). By (D.21), Step 2, (BK3) and Step 0,

$$f_*a(\eta)=\Psi_Y\big(f_*\mathrm{a}(-\tfrac{1}{2}\widetilde{x}_\eta)\big)=\Psi_Y\big(\mathrm{a}(f_\#(-\tfrac{1}{2}\widetilde{x}_\eta))\big)=\Psi_Y\big(\mathrm{a}(-\tfrac{1}{2}(2\pi i)^{p-1-e}\textstyle\int_f\eta)\big)=a\big(\int_f\eta\big),$$

the last equality by (D.21) on Y in degree $p-e$, since $\int_f\eta$ is real of type $(p-1-e,p-1-e)$ and $(2\pi i)^{p-1-e}\int_f\eta=x_{\int_f\eta}$. A form of negative type is 0.

Step 5: (GA5). The structure morphism of X is that of Y composed with f, so (GA2) gives $\widehat{\deg}(f_*x)=\widehat{\deg}(x)$. Let η be of type (d,d), so $a(\eta)\in\widehat{\mathrm{CH}}^{d+1}(X)$, and let $c=\int_{X(\mathbb{C})}\eta\in\mathbb{R}$. By (GA4) for the structure morphism ($e=d$), the push-forward of $a(\eta)$ to $S=\operatorname{Spec}\mathbb{Z}$ is $a(c)$. On S ($p=1$, relative dimension 0) (D.21) gives $a(c)=\Psi(\mathrm{a}(-\frac{c}{2}))$, and $\mathrm{a}(-\frac{c}{2})=[0,(0,\frac{c}{2})]$ because $S(\mathbb{C})$ is a point, which carries no forms of type $(1,1)$. By (BK5), $\widehat{\deg}\,a(c)=\widehat{\deg}[0,(0,\frac{c}{2})]=\frac{c}{2}$. Hence $\widehat{\deg}\,a(\eta)=\frac{1}{2}\int_{X(\mathbb{C})}\eta$. (On S, (D.21) reads $\Psi\circ\mathrm{a}=a\circ(-2)$, in accordance with the sign and the factor 2 in (BK5).) □

Lemma D.90. *Let Y be a regular arithmetic variety over $\mathbb{Z}$ and $\overline{W}=(W,h)$ a hermitian vector bundle of rank n on Y (smooth metric on W_∞ over $Y(\mathbb{C})$, invariant under complex conjugation). For $k\geq 0$ let $\widehat{c}_k(\overline{W})\in\widehat{\mathrm{CH}}^k(Y)$ be the k-th arithmetic Chern class of Gillet and Soulé, and let $c_k(W,h)$ be the Chern forms: in a local frame with matrix H of h and curvature matrix $K=\bar\partial(\partial H\cdot H^{-1})$,*

$$\sum_{k\geq 0}c_k(W,h)\,t^k=\det\Big(1+t\,\tfrac{i}{2\pi}K\Big).$$

Then:

(GC1) *$f^*\widehat{c}_k(\overline{W}) = \widehat{c}_k(f^*\overline{W})$ for every morphism $f\colon X \to Y$ of regular arithmetic varieties over $\mathbb{Z}$.*

(GC2) *$\omega(\widehat{c}_k(\overline{W})) = c_k(W,h)$ and $\zeta(\widehat{c}_k(\overline{W})) = c_k(W) \in \mathrm{CH}^k(Y)$.*

(GC3) *If $\overline{W}$ is an orthogonal direct sum of hermitian line bundles $\overline{L}_1,\dots,\overline{L}_n$, then $\widehat{c}_k(\overline{W}) = e_k(\widehat{c}_1(\overline{L}_1),\dots,\widehat{c}_1(\overline{L}_n))$ in $\widehat{\mathrm{CH}}^*(Y)_{\mathbb{Q}}$, e_k the elementary symmetric polynomial. For hermitian line bundles, $\widehat{c}_1(\overline{L}\otimes\overline{M}) = \widehat{c}_1(\overline{L}) + \widehat{c}_1(\overline{M})$, and $\widehat{c}_1(\mathcal{O}_Y, |\cdot|) = 0$.*

(GC4) *If $x \in \widehat{\mathrm{CH}}^1(Y)$ satisfies $\zeta(x) = 0$ and $\omega(x) = 0$, then $x = a(c)$ for a real function c on $Y(\mathbb{C})$ that is constant on each connected component and invariant under complex conjugation.*

(GC5) *$f^*a(\eta) = a(f^*\eta)$ for f as in (GC1) and η as in Lemma D.89.*

Proof. Step 0: hypotheses. Y and X are regular, flat and projective over $\mathbb{Z}$, so Proposition B.141 and Proposition B.140 apply to them, $Y_{\mathbb{R}}$ is projective, and the map $\Psi_0\colon \widehat{\mathrm{CH}}^p(Y,\mathcal{D}_{\log}) \to \widehat{\mathrm{CH}}^p(Y)$ of (BK4) is an isomorphism compatible with products and pull-backs.

Step 1: the dictionary for Ψ. First for Ψ_0. By the last assertion of (BK4), for $\alpha = [y,(\omega_y,\widetilde{g}_y)]$ the Green current of $\Psi_0(\alpha)$ satisfies $dd^c g + \delta_y = (2\pi i)^{-p}\omega_y$ and the cycle is unchanged, so $\omega(\Psi_0\alpha) = (2\pi i)^{-p}\omega(\alpha)$ and $\zeta(\Psi_0\alpha) = \zeta(\alpha)$. Since $\mathrm{a}(\widetilde{x}_\eta) = [0,(-\mathrm{d}_{\mathcal{D}}x_\eta, -\widetilde{x}_\eta)]$, $\Psi_0(\mathrm{a}(\widetilde{x}_\eta))$ is the class of $(0,g)$ with $g(\varphi) = -2(2\pi i)^{d-p+1}(2\pi i)^{-d}\int_{Y(\mathbb{C})}\varphi\wedge(2\pi i)^{p-1}\eta = -2\int_{Y(\mathbb{C})}\varphi\wedge\eta$, i.e. $a(\eta) = \Psi_0(\mathrm{a}(-\frac{1}{2}\widetilde{x}_\eta))$ (d the relative dimension). Now the map ι of (BC1) is induced by an inclusion of complexes, so it sends the class of $[y,(\omega_y,\widetilde{g}_y)]$ to the class of the same pair; hence $\omega\circ\iota = \omega$, $\zeta\circ\iota = \zeta$, $\iota\circ\mathrm{a} = \mathrm{a}$, and, since Ψ of (BC2) and Ψ_0 are given by the same formula on pairs, $\Psi\circ\iota = \Psi_0$. As ι is surjective, the same identities hold for Ψ: for $\beta \in \widehat{\mathrm{CH}}^p(Y,\mathcal{D}_{\mathrm{ls}})$,

$$\omega(\Psi\beta) = (2\pi i)^{-p}\omega(\beta), \qquad \zeta(\Psi\beta) = \zeta(\beta), \qquad a(\eta) = \Psi\big(\mathrm{a}(-\tfrac{1}{2}\widetilde{x}_\eta)\big).$$

By (BC3)(5), $\widehat{c}_k(\overline{W}) = \Psi(\widehat{c}_k^{\mathrm{BKK}}(\overline{W}))$.

Step 2: (GC1), (GC3). Ψ is compatible with pull-backs and products (BC2), so (BC3)(1) gives (GC1), and (BC3)(2), (3) give the first two assertions of (GC3) (in $\widehat{\mathrm{CH}}^*_{\mathbb{Q}}$, where products of $\widehat{c}_1$ live). Since $\mathcal{O}_Y\otimes\mathcal{O}_Y \cong \mathcal{O}_Y$, $1\otimes 1 \mapsto 1$, is an isometry for the standard metrics, additivity gives $\widehat{c}_1(\mathcal{O}_Y,|\cdot|) = 2\,\widehat{c}_1(\mathcal{O}_Y,|\cdot|)$, hence 0.

Step 3: (GC2). By Step 1 and (BC3)(4), $\omega(\widehat{c}_k(\overline{W})) = (2\pi i)^{-k}e_k(-K) = e_k(-\frac{1}{2\pi i}K) = e_k(\frac{i}{2\pi}K) = c_k(W,h)$, because e_k (evaluated on a matrix of even forms as the invariant polynomial) is homogeneous of degree k and $-\frac{1}{2\pi i} = \frac{i}{2\pi}$. By Step 1 and (BC4), $\zeta(\widehat{c}_k(\overline{W})) = \zeta(\widehat{c}_k^{\mathrm{BKK}}(\overline{W})) = c_k(W)$.

Step 4: (GC4). Put $\beta = \Psi^{-1}(x) \in \widehat{\mathrm{CH}}^1(Y,\mathcal{D}_{\mathrm{l,ll}})$. By Step 1, $\zeta(\beta) = 0$ and $\omega(\beta) = 2\pi i\,\omega(x) = 0$, so by (BC5) $\beta = \mathrm{a}(\widetilde{u})$ with $\widetilde{u}$ the class of a $\mathrm{d}_{\mathcal{D}}$-closed element u of degree $2p-1 = 1$ for $p = 1$. As the boundary is empty and $Y(\mathbb{C})$ is compact, the elements of this degree are the smooth real functions u on $Y(\mathbb{C})$ with $F_\infty^* u = u$ (the description of $\widetilde{\mathcal{D}}^{2p-1}(X,p)$ in Proposition B.140 with $p = 1$; nothing is divided out in degree $(0,0)$), and $\mathrm{d}_{\mathcal{D}}u = -2\partial\bar\partial u$. So $\partial\bar\partial u = 0$: u is pluriharmonic, hence harmonic in local holomorphic coordinates, and by the maximum principle constant on each connected component of the compact manifold $Y(\mathbb{C})$. By Step 1 with $p = 1$ ($x_\eta = \eta$), $x = \Psi(\mathrm{a}(\widetilde{u})) = a(-2u)$; take $c = -2u$. (This agrees with [110], Theorem 3.3.5 (ii), where the kernel of $(\zeta,-\omega)$ in degree 1 is $a(H^{0,0}(Y_{\mathbb{R}}))$.)

Step 5: (GC5). Let η be of type $(p-1,p-1)$. By Step 1 on Y, $a(\eta) = \Psi_0(\mathrm{a}(-\frac{1}{2}\widetilde{x}_\eta))$; Ψ_0 commutes with pull-backs and $f^*\circ\mathrm{a} = \mathrm{a}\circ f^*$ (BK2), and $f^*x_\eta = x_{f^*\eta}$. Hence $f^*a(\eta) =$

$\Psi_0(\mathrm{a}(-\frac{1}{2}\widetilde{x}_{f^*\eta})) = a(f^*\eta)$ by Step 1 on X (Step 1 holds for every regular arithmetic variety over $\mathbb{Z}$). $\square$

Lemma D.91. *Let Y be a regular arithmetic variety over $\mathbb{Z}$ with $Y(\mathbb{C})$ connected, and $\overline{W}$ a hermitian vector bundle of rank n on Y. Suppose there is a section $P\colon \operatorname{Spec}\mathbb{Z} \to Y$ such that $P^*\overline{W}$ is isometric to an orthogonal direct sum of hermitian line bundles. Then $\widehat{c}_1(\overline{W}) = \widehat{c}_1(\det\overline{W})$ in $\widehat{\mathrm{CH}}^1(Y)_{\mathbb{Q}}$.*

Proof. Put $\delta = \widehat{c}_1(\det\overline{W}) - \widehat{c}_1(\overline{W})$.

Step 1: $\delta = a(c)$ for a real constant c. By (GC2), $\zeta(\delta) = c_1(\det W) - c_1(W) = 0$ in $\mathrm{CH}^1(Y)$, the first Chern class of a vector bundle being that of its determinant. In a local frame of W_∞ with matrix H, the induced frame of $\det W_\infty$ has norm squared $\det H$, and by Jacobi's formula $\partial \log\det H = \operatorname{tr}(\partial H \cdot H^{-1})$; hence the curvature of $\det\overline{W}$ is $\bar\partial\operatorname{tr}(\partial H\cdot H^{-1}) = \operatorname{tr} K$ and, by (GC2), $\omega(\delta) = \frac{i}{2\pi}\operatorname{tr} K - \frac{i}{2\pi}\operatorname{tr} K = 0$. By (GC4), $\delta = a(c)$ with c locally constant on $Y(\mathbb{C})$, hence a real constant since $Y(\mathbb{C})$ is connected.

Step 2: $P^*\delta = 0$. Write $P^*\overline{W} \cong \overline{L}_1 \oplus \cdots \oplus \overline{L}_n$ orthogonally. Then $\det P^*\overline{W} \cong \overline{L}_1 \otimes \cdots \otimes \overline{L}_n$ isometrically (the determinant of an orthonormal basis is a unit vector), and $P^*\det\overline{W} = \det P^*\overline{W}$ with the determinant metrics. By (GC1) and (GC3),

$$P^*\delta = \widehat{c}_1(\det P^*\overline{W}) - \widehat{c}_1(P^*\overline{W}) = \sum_j \widehat{c}_1(\overline{L}_j) - \sum_j \widehat{c}_1(\overline{L}_j) = 0.$$

Step 3: $c = 0$. By (GC5), $P^*a(c) = a(c)$ in $\widehat{\mathrm{CH}}^1(\operatorname{Spec}\mathbb{Z})$, the pull-back of a constant function to the point $\operatorname{Spec}\mathbb{Z}(\mathbb{C})$ being the same constant; by (GA5) with $d = 0$, $\widehat{\deg}\, a(c) = \frac{c}{2}$. By Step 2, $\frac{c}{2} = \widehat{\deg}(P^*\delta) = 0$. Hence $\delta = a(0) = 0$. $\square$

Theorem D.92. *Let $(k_0, \mathcal{X}^{(2)}, g, h)$ be a square system for a Levi reflection s on a root model $\mathcal{X}$ of type (Φ, n) which has analytic square data (Fx5)–(Fx8). Then the square system has the square limit (Fx4): for every s-invariant weight c and every integer $1 \le k \le (D+1)/2$,*

$$\lim_{t\to 0^+} I_t(k,c) = -2\operatorname{sph}_k \delta_{\mathcal{X}}\, \mathrm{gi}(\mathcal{X}; \xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k}).$$

Proof. Fix c and k, put $m = D+1-2k$ and $d = D-1$, so that $m = d+2-2k$ and $U_n \subseteq \mathbb{C}^d$. By (Fx8)(1), $\lim_{t\to0^+} I_t(k,c) = I_0(k,c)$; we compute $I_0(k,c)$.

Step 1: the integrands in the fibre charts. Fix n. For $\beta \in \mathrm{Rt}_s^{\mathrm{b}}$ the pluriharmonic differences in (Fx6) are killed by $\partial\bar\partial$, so on $\mathbb{C}\times U_n$

$$\Phi_n^*\omega_{\Xi,0} = \xi := \tfrac{i}{\pi}\partial\bar\partial\operatorname{xp}_{G_n(y)}(z), \qquad \Phi_n^*\omega_{c,0} = \eta_n := \tfrac{i}{\pi}\partial\bar\partial\alpha_{n,c}(y),$$
$$\alpha_{n,c} = -c_{r_1}\alpha_{n,r_{12}} - \sum_{r\neq r_1,r_2} c_r\alpha_{n,r},$$

using $c_{r_1} = c_{r_2}$ (s-invariance), so that $-\sum_r c_r\log h_r(0) = -c_{r_1}\log h_{r_{12}}(0) - \sum_{r\neq r_1,r_2} c_r\log h_r(0)$. By the compatibilities $q_j\circ\Phi_n^{(2)}(z_0,z_1,y) = \Phi_n(z_j,y)$, $(\Phi_n^{(2)})^*q_j^*\omega_{\Xi,0} = \xi_j := \frac{i}{\pi}\partial\bar\partial\operatorname{xp}_{G_n(y)}(z_j)$ and $(\Phi_n^{(2)})^*q_0^*\omega_{c,0} = \eta_n$ (pulled back to $\mathbb{C}^2\times U_n$). By (Fx7), $G_0\circ\Phi_n^{(2)} = \mathrm{ls}_{G_n(y)}(z_0,z_1)$ off the null set where $z_0 = z_1$ or $gh = 0$. These are the data of Lemma D.93 for $(U_n, G_n, \alpha_{n,c})$; write $\Omega_k^{(n)}$, $\Omega_k'^{(n)}$ for its forms.

Step 2: I_0 as a sum over fibre charts. For $0 \le a \le 2k$ let F_a be the integrand of (Fx8)(1), absolutely integrable on W°. By (Fx6) W° is, up to a null set, the disjoint union of the open-chart images $\Phi_n^{(2)}(\mathbb{C}^2 \times B_n)$, and a biholomorphism preserves the complex orientation, so by countable additivity and the change of variables formula

$$\int_{W^\circ} F_a = \sum_{n\ge1} \int_{\mathbb{C}^2\times B_n} (\Phi_n^{(2)})^* F_a = \sum_{n\ge1} \int_{\mathbb{C}^2\times B_n} \mathrm{ls}_{G_n(y)}(z_0,z_1)\, \xi_0^a \wedge \xi_1^{2k-a} \wedge \eta_n^m,$$

with $\sum_n \int_{\mathbb{C}^2\times B_n} |(\Phi_n^{(2)})^* F_a| = \int_{W^\circ} |F_a| < \infty$. Hence $I_0(k,c) = \sum_n \int_{\mathbb{C}^2\times B_n} \mathrm{ls}\,\Omega_k^{(n)}$, the series converging absolutely. Likewise, by (Fx8)(2) and (Fx6) for X°,

$$\int_{X^\circ} \omega_{\Xi,0}^{2k-1} \wedge \omega_{c,0}^m = \sum_{n\ge1} \int_{\mathbb{C}\times B_n} \Omega_k'^{(n)}, \qquad \text{absolutely convergent.}$$

Step 3: fibre-local evaluation. Exhaust U_n by compact sets $K_{n,1} \subseteq K_{n,2} \subseteq \cdots$ and put $B_{n,j} = B_n \cap (K_{n,j} \smallsetminus K_{n,j-1})$ ($K_{n,0} = \varnothing$): Borel sets with compact closure in U_n, disjoint, with union B_n. By Lemma D.93, $\int_{\mathbb{C}^2\times B_{n,j}} \mathrm{ls}\,\Omega_k^{(n)} = -2\,\mathrm{sph}_k \int_{\mathbb{C}\times B_{n,j}} \Omega_k'^{(n)}$ for all n, j. Summing over j and n (both sides absolutely convergent by Step 2, since $|\mathrm{ls}\,\Omega_k^{(n)}| \le \sum_a |(\Phi_n^{(2)})^* F_a|$) gives

$$I_0(k,c) = -2\,\mathrm{sph}_k \int_{X^\circ} \omega_{\Xi,0}^{2k-1} \wedge \omega_{c,0}^m = -2\,\mathrm{sph}_k\, \delta_{\mathcal{X}}\, \mathrm{gi}(\mathcal{X}; \xi_s^{2k-1} \mathrm{lr}(c)^m)$$

by (Fx8)(2). With $\lim_{t\to0^+} I_t(k,c) = I_0(k,c)$ this is (Fx4). □

Lemma D.93. *Let $d \ge 0$, $U \subseteq \mathbb{C}^d$ open, $G\colon U \to \mathrm{M}_2(\mathbb{C})$ of class C^2 with $G(y)$ positive definite Hermitian for all y, and $\alpha\colon U \to \mathbb{R}$ of class C^2. Write $u(z) = (1,z)^{\mathsf T}$, $\mathrm{xp}_G(y,z) = \mathrm{xp}_{G(y)}(z)$ and $\mathrm{ls}_G(y,z_0,z_1) = \mathrm{ls}_{G(y)}(z_0,z_1)$ for $y \in U$, $z, z_0, z_1 \in \mathbb{C}$, $z_0 \ne z_1$. On $\mathbb{C}\times U$ with coordinates (z,y) let $\xi = \frac{i}{\pi}\partial\bar\partial\,\mathrm{xp}_G$; on $\mathbb{C}^2\times U$ with coordinates (z_0,z_1,y) let $\xi_j = \frac{i}{\pi}\partial\bar\partial(\mathrm{xp}_G(y,z_j))$ ($j = 0,1$); on both let $\beta = \frac{i}{\pi}\partial\bar\partial\alpha(y)$. Let $k \ge 1$ with $m = d+2-2k \ge 0$, and*

$$\Omega_k = \sum_{a=0}^{2k} (-1)^a\, \xi_0^a \wedge \xi_1^{2k-a} \wedge \beta^m, \qquad \Omega_k' = \xi^{2k-1} \wedge \beta^m,$$

continuous forms of top degree on $\mathbb{C}^2\times U$ and on $\mathbb{C}\times U$. Then for every Borel set $B \subseteq U$ with compact closure in U, $\mathrm{ls}_G\,\Omega_k$ is absolutely integrable on $\mathbb{C}^2\times B$, Ω_k' is absolutely integrable on $\mathbb{C}\times B$, and

$$\int_{\mathbb{C}^2\times B} \mathrm{ls}_G\,\Omega_k = -2\,\mathrm{sph}_k \int_{\mathbb{C}\times B} \Omega_k'. \tag{D.22}$$

Moreover the same relation holds between the fibre integrals over $\mathbb{C}^2\times\{y\}$ and $\mathbb{C}\times\{y\}$ (integration of the coefficient of the fibre volume), as continuous (d,d)-forms in $y \in U$.

Proof. Step 1: extension to $\mathbb{P}^1$, integrability, reduction to fibres. Let $w = 1/z$ near $z = \infty$; since $u(z) = z\,v(w)$ with $v(w) = (w,1)^{\mathsf T}$, $\mathrm{xp}_G(y,z) = -\log|z|^2 - \log\big(v(w)^* G(y) v(w)\big) + \frac12 \log\det G(y)$, where $-\log|z|^2$ is pluriharmonic and the rest is C^2 in (w,y). So ξ, ξ_j extend to continuous forms on $\mathbb{P}^1\times U$, $\mathbb{P}^1\times\mathbb{P}^1\times U$, and $\Omega_k = f\,\mathrm{v}$, $\Omega_k' = f'\,\mathrm{v}'$ with f, f' continuous and v, v' the products of the Fubini–Study area forms $\omega_1 = \frac{i}{2\pi}\frac{dz\wedge d\bar z}{(1+|z|^2)^2}$ (of total mass 1) of the $\mathbb{P}^1$ factors with Lebesgue measure on U. The quantity under the logarithm in ls_G depends only on the lines $[v_0], [v_1]$ through $v_j = u(z_j)$ and equals $\det G(y)\,|\det(v_0,v_1)|^2 / \big((v_0^* G v_0)(v_1^* G v_1)\big)$ (Lagrange's identity for the Hermitian form $G(y)$). For y in a compact $K \subset U$ the eigenvalues of $G(y)$ lie in a fixed interval $[c_K, C_K] \subset (0,\infty)$, so $|\mathrm{ls}_G(y,z_0,z_1) - \ell(z_0,z_1)| \le C_K'$ with $\ell = \frac12 \log \frac{|\det(v_0,v_1)|^2}{|v_0|^2|v_1|^2}$, which is

$L(\langle n(z_0), n(z_1)\rangle)$ for the Bloch map n of Step 4 (by (D.23) below) and hence $\omega_1 \otimes \omega_1$-integrable on $\mathbb{P}^1 \times \mathbb{P}^1$ (Lemma D.94, as $n_*\omega_1 = \sigma$). Hence $\mathrm{ls}_G\Omega_k$ and Ω'_k are absolutely integrable on $\mathbb{C}^2 \times B$ and $\mathbb{C} \times B$ (the points at infinity and the diagonal are null sets), and by Fubini (D.22) follows from the fibrewise relation. It remains to prove the latter at a fixed $y_0 \in U$.

Step 2: holomorphic change of frame. Let $V \subseteq U$ be an open neighbourhood of y_0 and $M\colon V \to \mathrm{GL}_2(\mathbb{C})$ holomorphic; put $G' = M^*GM$ (C^2, positive definite). Where $\lambda(z,y) := (M(y)^{-1}u(z))_1 \neq 0$ put $T(z,y) = (M(y)^{-1}u(z))_2/\lambda(z,y)$, so that $M(y)^{-1}u(z) = \lambda(z,y)\,u(T(z,y))$. Then $u^*Gu = |\lambda|^2\,u(T)^*G'u(T)$ and $\det G = |\det M|^{-2}\det G'$, so

$$\mathrm{xp}_G(y,z) = \mathrm{xp}_{G'}(y, T(z,y)) - \log|\lambda(z,y)|^2 - \log|\det M(y)|,$$
$$\mathrm{ls}_G(y,z_0,z_1) = \mathrm{ls}_{G'}(y, T(z_0,y), T(z_1,y)),$$

the correction being pluriharmonic. For each y, $\lambda(\cdot,y)$ is a non-zero affine function, and $z \mapsto T(z,y)$ is a Möbius transformation (biholomorphic between complements of at most one point). The maps $\Psi(z_0,z_1,y) = (T(z_0,y), T(z_1,y), y)$ and $\psi(z,y) = (T(z,y),y)$ are holomorphic and fibre-preserving, so, writing $\xi[G']$, $\xi_j[G']$, $\Omega_k[G']$, $\Omega'_k[G']$ for the forms built from G' on V, $\xi_j = \Psi^*\xi_j[G']$, $\xi = \psi^*\xi[G']$, $\beta = \Psi^*\beta = \psi^*\beta$, hence $\mathrm{ls}_G\Omega_k = \Psi^*(\mathrm{ls}_{G'}\Omega_k[G'])$ and $\Omega'_k = \psi^*(\Omega'_k[G'])$. The real Jacobian of Ψ at (z,y) is $|\det \partial_{(z_0,z_1)}(T(z_0,y),T(z_1,y))|^2$ (block triangular with the identity on the base), so by the change of variables formula for the fibre map the fibre integrals at y of a top form and of its pull-back by Ψ (resp. ψ) agree. Hence the fibrewise relation at y_0 for G is equivalent to that for G'.

Step 3: a normal frame. Choose $C \in \mathrm{GL}_2(\mathbb{C})$ with $C^*G(y_0)C = I$, let $G_1 = C^*GC$, $H_j = \frac{\partial G_1}{\partial y_j}(y_0)$, and $M(y) = C(I - \sum_j H_j(y_j - y_{0,j}))$, invertible near y_0. As G_1 is Hermitian, $\frac{\partial G_1}{\partial \bar y_j}(y_0) = H_j^*$, and $G' = M^*GM = I + o(|y-y_0|)$:

By Step 2 we may assume $y_0 = 0$, $G(0) = I$ and $dG(0) = 0$.

Step 4: the forms over $y_0 = 0$. Let $h(z,y) = u(z)^*G(y)u(z)$, so $h(z,0) = 1 + |z|^2$. Fibre part: $\frac{i}{\pi}\partial_z\bar\partial_z(-\log h)(z,0) = -2\omega_1(z)$. Mixed part: $\partial_{\bar y_l}h(z,0) = u^*\partial_{\bar y_l}G(0)u = 0$ for all z, hence $\partial_z\partial_{\bar y_l}h(z,0) = 0$ and $\partial_z\partial_{\bar y_l}\log h = h^{-1}\partial_z\partial_{\bar y_l}h - h^{-2}\partial_z h\,\partial_{\bar y_l}h$ vanishes at $y=0$; likewise $\partial_{\bar z}\partial_{y_l}$; and $\log\det G$ does not depend on z. Base part: $\partial_{y_j}\partial_{\bar y_l}\log h(z,0) = u^*\partial_{y_j}\partial_{\bar y_l}G(0)u/|u|^2$ and $\partial_{y_j}\partial_{\bar y_l}\log\det G(0) = \mathrm{tr}\,\partial_{y_j}\partial_{\bar y_l}G(0)$ (Jacobi's formula, $G(0)=I$, $dG(0)=0$). Let $\Theta = \frac{i}{\pi}\sum_{j,l}\partial_{y_j}\partial_{\bar y_l}G(0)\,dy_j\wedge d\bar y_l$, a 2×2 matrix of $(1,1)$-forms at 0, and $b_i = \frac12\mathrm{tr}(\sigma_i\Theta)$ for the Pauli matrices $\sigma_1 = \begin{pmatrix}0&1\\1&0\end{pmatrix}$, $\sigma_2 = \begin{pmatrix}0&-i\\i&0\end{pmatrix}$, $\sigma_3 = \begin{pmatrix}1&0\\0&-1\end{pmatrix}$; these are real $(1,1)$-forms (G is Hermitian) and $\Theta - \frac12(\mathrm{tr}\,\Theta)I = \sum_i b_i\sigma_i$. With the Bloch map $n(z) = (u^*\sigma_i u/|u|^2)_i = \frac{(2\,\mathrm{Re}\,z,\,2\,\mathrm{Im}\,z,\,1-|z|^2)}{1+|z|^2} \in S^2$ (inverse stereographic projection, so $n_*\omega_1 = \sigma$) we get, at every point over 0,

$$\xi = -2\,\omega_1(z) - \langle n(z), b\rangle, \qquad \xi_j = -2\,\omega_1(z_j) - \langle n(z_j), b\rangle, \qquad \beta = \beta(0),$$

all of even degree, hence commuting. Moreover, for $G(0) = I$,

$$1 - \frac{|u(z_0)^*u(z_1)|^2}{|u(z_0)|^2|u(z_1)|^2} = \frac{1 - \langle n(z_0), n(z_1)\rangle}{2}, \qquad \text{so} \qquad \mathrm{ls}_G(0,z_0,z_1) = L(\langle n(z_0), n(z_1)\rangle). \quad \text{(D.23)}$$

Step 5: evaluation over 0. Since $\omega_1(z_j)\wedge\omega_1(z_j) = 0$ and the fibre integral over $\mathbb{C}^2$ only sees the components containing $\omega_1(z_0)\wedge\omega_1(z_1)$, the fibre integral of $\xi_0^a\xi_1^{2k-a}\beta^m$ against a function $F(z_0,z_1)$ is that of $4\,a(2k-a)\,F\,\omega_1(z_0)\wedge\omega_1(z_1)\wedge\langle n(z_0),b\rangle^{a-1}\langle n(z_1),b\rangle^{2k-1-a}\wedge\beta^m$ (the sign is $(-2)^2(-1)^{2k-2} = 4$; it is 0 for $a \in \{0, 2k\}$). With (D.23), $n_*\omega_1 = \sigma$ and (D.24), applied in the commutative algebra of even-degree forms at 0, the fibre integral of $\mathrm{ls}_G\Omega_k$ over 0 is

$$4\iint L(\langle n_0, n_1\rangle)\,Q_k\big(\langle n_0, b\rangle, \langle n_1, b\rangle\big)\,d\sigma\,d\sigma\wedge\beta^m = 4\,\mathrm{sph}_k\,(b\cdot b)^{k-1}\wedge\beta^m.$$

Likewise the fibre integral of $\Omega'_k = \xi^{2k-1}\beta^m$ over 0 is $(2k-1)(-2)\int\langle n,b\rangle^{2k-2}d\sigma\wedge\beta^m = -2\,(b\cdot b)^{k-1}\wedge\beta^m$ by (D.25). So the first is $-2\,\mathrm{sph}_k$ times the second, which is the fibrewise relation. Both fibre integrals are continuous in y (Step 1 and dominated convergence).

□

Lemma D.94. *Let σ be the rotation-invariant probability measure on the unit sphere $S^2\subset\mathbb{R}^3$, let $L(t)=\frac12\log\frac{1-t}{2}$ for $-1\le t<1$, and for an integer $k\ge1$ let*

$$P_k(u,v)=\sum_{a=0}^{2k}(-1)^a\,u^a v^{2k-a},\qquad Q_k=\frac{\partial^2 P_k}{\partial u\,\partial v}=\sum_{a=1}^{2k-1}(-1)^a\,a(2k-a)\,u^{a-1}v^{2k-1-a}.$$

Let A be a commutative $\mathbb{R}$-algebra, $b=(b_1,b_2,b_3)\in A^3$, $\langle n,b\rangle=\sum_i n_ib_i$ for $n\in S^2$ and $b\cdot b=\sum_i b_i^2$; integrals of A-valued polynomial expressions in n are taken coefficientwise in the monomials of b. Then $(n_1,n_2)\mapsto L(\langle n_1,n_2\rangle)$ is integrable on $S^2\times S^2$, and

$$\int_{S^2}\int_{S^2}L(\langle n_1,n_2\rangle)\,Q_k(\langle n_1,b\rangle,\langle n_2,b\rangle)\,d\sigma(n_1)\,d\sigma(n_2)=\mathrm{sph}_k\,(b\cdot b)^{k-1},\tag{D.24}$$

$$\int_{S^2}\langle n,b\rangle^{2j}\,d\sigma(n)=\frac{(b\cdot b)^j}{2j+1},\qquad\int_{S^2}\langle n,b\rangle^{2j+1}\,d\sigma(n)=0\qquad(j\ge0).\tag{D.25}$$

Proof. Step 0: Archimedes, and integrability. For a unit vector e, the push-forward of σ under $n\mapsto\langle n,e\rangle$ is the uniform probability measure $\frac12\,dx$ on $[-1,1]$, and in the cylindrical coordinates $n=(\sqrt{1-x^2}\cos\theta,\sqrt{1-x^2}\sin\theta,x)$ around $e=(0,0,1)$ one has $d\sigma=\frac{1}{4\pi}\,dx\,d\theta$ (Archimedes). Hence, for fixed n_1, $\int|L(\langle n_1,n_2\rangle)|\,d\sigma(n_2)=\frac12\int_{-1}^1|L(t)|\,dt<\infty$, independently of n_1, and $L(\langle n_1,n_2\rangle)$ is integrable on $S^2\times S^2$ by Tonelli; the factors $Q_k(\cdots)$ are bounded on $S^2\times S^2$ coefficientwise. Also $\int\langle n,e\rangle^j d\sigma=\frac12\int_{-1}^1x^j dx$, which is $\frac{1}{j+1}$ for j even and 0 for j odd.

Step 1: reduction to $A=\mathbb{R}$ and $b=e$. For integers $j,l\ge0$ let

$$F_{j,l}(b)=\iint L(\langle n_1,n_2\rangle)\langle n_1,b\rangle^j\langle n_2,b\rangle^l\,d\sigma\,d\sigma,\qquad H_j(b)=\int\langle n,b\rangle^j d\sigma;$$

expanding the powers, these are homogeneous polynomials in $\mathbb{R}[b_1,b_2,b_3]$ of degrees $j+l$ and j, and the left sides of (D.24), (D.25) are their images under the ring homomorphism $\mathbb{R}[b_1,b_2,b_3]\to A$ sending b_i to the given elements. Since $\sigma\otimes\sigma$ and $\langle n_1,n_2\rangle$ are invariant under $(n_1,n_2)\mapsto(Rn_1,Rn_2)$ for $R\in\mathrm{O}(3)$, $F_{j,l}(R^{\mathsf T}b)=F_{j,l}(b)$, and likewise for H_j. An $\mathrm{O}(3)$-invariant homogeneous polynomial f of degree N satisfies $f(b)=|b|^Nf(e)$ for real $b\neq0$; if N is odd then $f(-b)=f(b)=-f(b)$, so $f=0$; if N is even then $f-f(e)\,(b\cdot b)^{N/2}$ vanishes on $\mathbb{R}^3$, hence is the zero polynomial. Applied to H_j with the values of Step 0 this gives (D.25); applied to $\sum_a(-1)^a a(2k-a)F_{a-1,2k-1-a}$ (degree $2k-2$) it reduces (D.24) to the real number

$$S_k:=\iint L(\langle n_1,n_2\rangle)\,Q_k(x_1,x_2)\,d\sigma(n_1)\,d\sigma(n_2),\qquad x_i=\langle n_i,e\rangle,$$

and we must show $S_k=\mathrm{sph}_k$.

Step 2: the azimuthal average. In the coordinates of Step 0, $\langle n_1,n_2\rangle=x_1x_2+B\cos(\theta_1-\theta_2)$ with $B=\sqrt{(1-x_1^2)(1-x_2^2)}$. By Fubini (Step 0), $S_k=\frac14\int_{-1}^1\int_{-1}^1K(x_1,x_2)\,Q_k(x_1,x_2)\,dx_1\,dx_2$ with $K(x,y)=\frac{1}{2\pi}\int_0^{2\pi}L(xy+B\cos\varphi)\,d\varphi$ (replacing φ by $\varphi+\pi$ changes the sign of the cosine). For $x,y\in(-1,1)$ put $A_0=1-xy>0$; then $A_0\ge B\ge0$ and $A_0^2-B^2=(x-y)^2$, and the classical mean value $\frac{1}{2\pi}\int_0^{2\pi}\log(A_0-B\cos\varphi)\,d\varphi=\log\frac{A_0+\sqrt{A_0^2-B^2}}{2}$ (Jensen's formula for

$|\alpha-\beta e^{i\varphi}|^2$ with $A_0=|\alpha|^2+|\beta|^2$, $B=2|\alpha\beta|$) gives, with $M=\max(x,y)$, $m=\min(x,y)$ and $A_0+|x-y|=(1+M)(1-m)$,

$$K(x,y)=\tfrac12\Big(\log\tfrac{(1+M)(1-m)}{2}-\log 2\Big)=\tfrac12\big(a(M)+c(m)\big),\qquad a(s)=\log\tfrac{1+s}{2},\quad c(s)=\log\tfrac{1-s}{2}.$$

Step 3: integration by parts. Let P be a real polynomial in two variables with $P(-x,-y)=P(x,y)$ and write $P_{xy}=\partial_x\partial_y P$. Since $a(1)=0$, $a(M)=-\int_{-1}^{1}\frac{\mathbf{1}[s>M]}{1+s}\,ds$, and since $c(-1)=0$, $c(m)=-\int_{-1}^{1}\frac{\mathbf{1}[s<m]}{1-s}\,ds$. Fubini applies, because $\iint_{x,y<s}|P_{xy}|\le\|P_{xy}\|_\infty(1+s)^2$ and $\iint_{x,y>s}|P_{xy}|\le\|P_{xy}\|_\infty(1-s)^2$; and $\iint_{x,y<s}P_{xy}=\Delta(s):=P(s,s)-P(s,-1)-P(-1,s)+P(-1,-1)$. Hence

$$\iint a(M)P_{xy}=-\int_{-1}^{1}\frac{\Delta(s)}{1+s}\,ds,$$
$$\iint c(m)P_{xy}=-\int_{-1}^{1}\frac{P(1,1)-P(1,s)-P(s,1)+P(s,s)}{1-s}\,ds=-\int_{-1}^{1}\frac{\Delta(s')}{1+s'}\,ds',$$

the last by $s=-s'$ and $P(-x,-y)=P(x,y)$. So $\iint K\,P_{xy}=-\int_{-1}^{1}\Delta(s)\,(1+s)^{-1}\,ds$.

Step 4: the bracket for P_k. P_k is homogeneous of degree $2k$, so the symmetry holds, and $P_k(s,s)=s^{2k}\sum_a(-1)^a=s^{2k}$, $P_k(s,-1)=P_k(-1,s)=\sum_{i=0}^{2k}s^i$, $P_k(-1,-1)=1$. Hence

$$\Delta(s)=1+s^{2k}-2\sum_{i=0}^{2k}s^i=-(1+s)\sum_{i=0}^{2k-1}s^i$$

and $\iint K\,Q_k=\int_{-1}^{1}\sum_{i=0}^{2k-1}s^i\,ds=\sum_{j=0}^{k-1}\frac{2}{2j+1}$. Therefore $S_k=\frac14\sum_{j<k}\frac{2}{2j+1}=\mathrm{sph}_k$.

The case $k=1$ directly. $Q_1=-1$, so

$$S_1=-\iint L\,d\sigma\,d\sigma=-\frac12\int_{-1}^{1}\frac12\log\frac{1-t}{2}\,dt=-\frac12\int_0^1\log w\,dw=\frac12=\mathrm{sph}_1.$$

Computer checks. Computer check C9, listed in Appendix B, evaluates S_k exactly in rational arithmetic for $1\le k\le 12$ by two methods sharing no step with each other: the double integral of Step 2 against Q_k monomial by monomial (without Steps 3, 4), and the Funk–Hecke expansion of L in Legendre polynomials on $S^2\times S^2$ (without Step 2), plus a direct quadrature of the original integral for $k\le 3$; all agree with sph_k. Computer check C7, also listed in Appendix B, proves the same values by generating functions in the grouping $y(x^{2k}-y^{2k})/(x+y)$, which differs from P_k by $-x^{2k}$ and has the same mixed derivative up to sign. □

Theorem D.95. *Let $(k_0,\mathcal{X}^{(2)},g,h)$ be a square system for a Levi reflection s on a root model $\mathcal{X}$ of type (Φ,n), with open parts X°, W° and positive functions $h_r(0)$ satisfying (Fx5), which carries an analytic square system. Then the square convergence (Fx8) holds. Consequently, if fibre charts with (Fx6) and (Fx7) are also given, the square system has analytic square data (Fx5)–(Fx8); in particular, the square system of a proportional square model (as in Definition 31.9) has analytic square data (Fx5)–(Fx8).*

Proof. Fix an s-invariant weight c and $1\le k\le(D+1)/2$, put $m=D+1-2k$, and let $(\widetilde X,\dots,d_X)$, $(\widetilde W,\dots,d_W)$, p_0,p_1, v, κ_v be the analytic square system, with Λ, $b_{r,\lambda}$, γ_λ, f_λ, $f_{\lambda,t}$, $\theta_r,u_r,u_{r,t}$, C,δ,R,t_0 as in (Sw1), $\bar b=\max_{r\in\mathrm{Rt}}\sum_{\lambda\in\Lambda}|b_{r,\lambda}|$, and N_X,N_X',N_W,N_W' the null sets of the two compact models.

Step 1: the pulled-back families on $\widetilde W$. For $\lambda\in\Lambda$ and $j\in\{0,1\}$ put $\gamma_{\lambda,j}=p_j^*\gamma_\lambda$, $f_{\lambda,j}=f_\lambda\circ p_j$ on $\widetilde W^\circ$ (defined as $p_j(\widetilde W^\circ)\subseteq\widetilde X^\circ$ by (Sw2)) and $f_{\lambda,j,t}=f_{\lambda,t}\circ p_j$ on $\widetilde W$. These families, indexed by

$\Lambda\times\{0,1\}$, satisfy (R1)–(R5) on $(\widetilde{W},\Theta_W,\varsigma_W)$ with the constant $C_W = C\,c_p$, where $c_p\ge 1$ is such that $p_j^*\Theta_X \le c_p\Theta_W$ for $j=0,1$ ($\widetilde{W}$ compact), and the same δ, R: (R1) $\gamma_{\lambda,j}+dd^c f_{\lambda,j,t}+C_W\Theta_W \ge p_j^*(\gamma_\lambda + dd^c f_{\lambda,t} + C\Theta_X)\ge 0$; (R2) on $\widetilde{W}^\circ$, $-C_W\log\mathrm{rW}_W \le -C\log(\mathrm{rW}_X\circ p_j)\le f_{\lambda,j}\le f_{\lambda,j,t}\le C\le C_W$ by (Sw2); (R3) $\{y\in\widetilde{W}^\circ : \mathrm{rW}_W(y)\le R(t)\}\subseteq p_j^{-1}\{x\in\widetilde{X}^\circ : \mathrm{rW}_X(x)\le R(t)\}$ by (Sw2); (R4) is pulled back; (R5) a compact $K\subseteq\widetilde{W}^\circ$ has compact image $p_j(K)\subseteq\widetilde{X}^\circ$, and by the chain rule the derivatives of order ≤ 2 of $f_{\lambda,t}\circ p_j$ on K are polynomials in those of $f_{\lambda,t}$ on $p_j(K)$ with coefficients the derivatives of p_j, bounded on K. For $r\in\mathrm{Rt}$ put $\theta_{r,j}=p_j^*\theta_r=\sum_\lambda b_{r,\lambda}\gamma_{\lambda,j}$, $u_{r,j}=u_r\circ p_j=\sum_\lambda b_{r,\lambda}f_{\lambda,j}$ on $\widetilde{W}^\circ$ and $u_{r,j,t}=u_{r,t}\circ p_j=\sum_\lambda b_{r,\lambda}f_{\lambda,j,t}$ on $\widetilde{W}$. By (R2) and $\log\mathrm{rW}_W\ge 1$, $|f_{\lambda,j,t}|\le C_W\log\mathrm{rW}_W$ on $\widetilde{W}^\circ$, hence $|u_{r,j,t}|\le\bar b\,C_W\log\mathrm{rW}_W$ there.

Step 2: the integrands. Write $\theta_{\Xi,j}=\theta_{r_1,j}-\theta_{r_2,j}$, $u_{\Xi,j,t}=u_{r_1,j,t}-u_{r_2,j,t}$, $\theta_c=-\sum_r c_r\theta_{r,0}$, $u_{c,t}=-\sum_r c_r u_{r,0,t}$, and the same without t for the limits. By definition $\omega_{\Xi,t}=\omega_{r_1,t}-\omega_{r_2,t}$ and $\omega_{c,t}=-\sum_r c_r\omega_{r,t}$, also for $t=0$ (with the notation $\omega_{r,t}$ of Definition 31.9). Since $q_j\circ\varrho_W=\varrho_X\circ p_j$ (Sw2), (Sw1) gives on $\widetilde{W}$, for $0<t\le t_0$,

$$\varrho_W^*q_j^*\omega_{\Xi,t}=\theta_{\Xi,j}+dd^cu_{\Xi,j,t},\qquad \varrho_W^*q_0^*\omega_{c,t}=\theta_c+dd^cu_{c,t},$$

and the same identities at $t=0$ on $\widetilde{W}^\circ\setminus N_W$: there $\varrho_W(y)\in W^\circ$ (compact model), $q_j(\varrho_W(y))\in X^\circ$ (Fx5) and $p_j(y)\in\widetilde{X}^\circ\cap\varrho_X^{-1}(X^\circ)$. For $0\le a\le 2k$ let $F_{a,t}=G_t\,q_0^*\omega_{\Xi,t}^a\wedge q_1^*\omega_{\Xi,t}^{2k-a}\wedge q_0^*\omega_{c,t}^m$ ($0\le t\le t_0$) and

$$\mu_t^{(a)}=(\theta_{\Xi,0}+dd^cu_{\Xi,0,t})^a\wedge(\theta_{\Xi,1}+dd^cu_{\Xi,1,t})^{2k-a}\wedge(\theta_c+dd^cu_{c,t})^m,$$

and $\mu^{(a)}$ the same with the limits $u_\cdot$ on $\widetilde{W}^\circ$. Expanding multilinearly, $\mu_t^{(a)}$ and $\mu^{(a)}$ are the same finite real combination of products $\bigwedge_{l=1}^{D+1}(\gamma_{i_l}+dd^cf_{i_l,t})$, resp. of their limits $\bigwedge_{l=1}^{D+1}(\gamma_{i_l}+dd^cf_{i_l})$, with $i_l\in\Lambda\times\{0,1\}$: each factor $\theta_{r,j}+dd^cu_{r,j,t}$ equals $\sum_\lambda b_{r,\lambda}(\gamma_{\lambda,j}+dd^cf_{\lambda,j,t})$, and likewise for the limits. By (Sw3),

$$\varrho_W^*F_{a,t}=\big(\tfrac12\log\|v\|^2+\kappa_v+g_t\big)\mu_t^{(a)},\qquad g_t=\tfrac12\sum_{j=0,1}u_{\Xi,j,t},$$

on $\widetilde{W}\setminus(D_v\cup\varrho_W^{-1}\{gh=0\})$ for $0<t\le t_0$, and with $g_0=\frac12\sum_j u_{\Xi,j}$ and $\mu^{(a)}$ on $\widetilde{W}^\circ\setminus(N_W\cup D_v\cup\varrho_W^{-1}\{gh=0\})$ for $t=0$. The removed sets are null: D_v is a proper analytic subset; g and h do not vanish identically on the integral scheme $\mathcal{X}^{(2)}$ (Fx3), so $\{gh=0\}$ is a proper analytic subset of $\mathcal{X}^{(2)}(\mathbb{C})$, null, and its preimage under the covering $\widetilde{W}\setminus N_W\to\mathcal{X}^{(2)}(\mathbb{C})\setminus N'_W$ is null.

Step 3: (Fx8)(1). By Step 1, $|\kappa_v+g_t|\le(|\kappa_v|+2\bar b\,C_W)\log\mathrm{rW}_W$ on $\widetilde{W}^\circ$ (g_t is half a sum of four terms $\pm u_{r,j,t}$, each of absolute value at most $\bar b\,C_W\log\mathrm{rW}_W$, and $\log\mathrm{rW}_W\ge 1$), and $\kappa_v+g_t\to\kappa_v+g_0$ uniformly on compact subsets of $\widetilde{W}^\circ$ by (R5). Lemma 31.35, applied on $\widetilde{W}$ (dimension $D+1$) with Θ_W, ς_W, the section v and the families of Step 1, gives for each product in the expansion of $\mu_t^{(a)}$: (1) absolute integrability of $(\log\mathrm{rW}_W-\log\|v\|^2)$ times the limit product on $\widetilde{W}^\circ\setminus D_v$, (2) convergence of the integrals against κ_v+g_t, (3) convergence of the integrals against $-\log\|v\|^2$. By linearity, $\varrho_W^*F_{a,0}$ is absolutely integrable on $\widetilde{W}^\circ$ and $\int_{\widetilde{W}}\varrho_W^*F_{a,t}\to\int_{\widetilde{W}^\circ}\varrho_W^*F_{a,0}$ as $t\to0^+$. By the change of variables along the d_W-sheeted covering $\widetilde{W}\setminus N_W\to\mathcal{X}^{(2)}(\mathbb{C})\setminus N'_W$, which maps $\widetilde{W}^\circ\setminus N_W=\varrho_W^{-1}(W^\circ\setminus N'_W)$ onto $W^\circ\setminus N'_W$: $F_{a,0}$ is absolutely integrable on W° with $\int_{W^\circ}F_{a,0}=d_W^{-1}\int_{\widetilde{W}^\circ}\varrho_W^*F_{a,0}$, and $\int_{\mathcal{X}^{(2)}(\mathbb{C})}F_{a,t}=d_W^{-1}\int_{\widetilde{W}}\varrho_W^*F_{a,t}$ for $t>0$ (the integrals in (31.5) are over the regular locus off $\{gh=0\}$; N'_W is null). Taking the alternating sum over a, $I_t(k,c)\to I_0(k,c)$. This is (Fx8)(1).

Step 4: (Fx8)(2). On $\widetilde{X}$ put $\theta_\Xi=\theta_{r_1}-\theta_{r_2}$, $\theta'_c=-\sum_r c_r\theta_r$ and similarly $u_{\Xi,t}, u'_{c,t}$ and the limits. By (Sw1), $\varrho_X^*(\omega_{\Xi,t}^{2k-1}\wedge\omega_{c,t}^m)=\mu_{X,t}:=(\theta_\Xi+dd^cu_{\Xi,t})^{2k-1}\wedge(\theta'_c+dd^cu'_{c,t})^m$ on $\widetilde{X}$

and $\varrho_X^*(\omega_{\Xi,0}^{2k-1}\wedge\omega_{c,0}^m)=\mu_X$ (the limit) on $\widetilde{X}^\circ\smallsetminus N_X$. Lemma 31.35(1) on $\widetilde{X}$ (dimension D, $v=1$, $D_v=\varnothing$), applied to each product of the multilinear expansion in the factors $\gamma_\lambda+dd^cf_{\lambda,t}$ ($\lambda\in\Lambda$), resp. their limits, with the families $(\gamma_\lambda,f_\lambda,(f_{\lambda,t})_t)_{\lambda\in\Lambda}$ of (Sw1), shows that μ_X is absolutely integrable on $\widetilde{X}^\circ$ with $\int_{\widetilde{X}^\circ}\mu_X=\int_{\widetilde{X}}\theta_\Xi^{2k-1}\wedge\theta_c'^m$, and by Stokes' theorem on $\widetilde{X}$ this equals $\int_{\widetilde{X}}\mu_{X,t}$ for every $0<t\le t_0$. By the change of variables along the d_X-sheeted covering $\widetilde{X}\smallsetminus N_X\to\mathcal{X}(\mathbb{C})\smallsetminus N_X'$ (with $\varrho_X^{-1}(X^\circ\smallsetminus N_X')=\widetilde{X}^\circ\smallsetminus N_X$),

$$\int_{X^\circ}\omega_{\Xi,0}^{2k-1}\wedge\omega_{c,0}^m=\frac{1}{d_X}\int_{\widetilde{X}^\circ}\mu_X=\frac{1}{d_X}\int_{\widetilde{X}}\mu_{X,t}=\int_{\mathcal{X}(\mathbb{C})_{\mathrm{reg}}}\omega_{\Xi,t}^{2k-1}\wedge\omega_{c,t}^m,$$

the left side absolutely convergent. Expanding

$$\omega_{\Xi,t}=c_1(\overline{\mathcal{L}}_{r_1}(t))-c_1(\overline{\mathcal{L}}_{r_2}(t))\quad\text{and}\quad\omega_{c,t}=-\sum_r c_rc_1(\overline{\mathcal{L}}_r(t)),$$

Lelong's theorem with Chern–Weil theory on each irreducible component of the projective variety $\mathcal{X}(\mathbb{C})$ (the complex points of $\mathcal{X}_{\mathbb{Q}}$; degrees are invariant under the flat base change $\mathbb{Q}\to\mathbb{C}$) gives for every monomial $\int_{\mathcal{X}(\mathbb{C})_{\mathrm{reg}}}c_1(\overline{\mathcal{L}}_{r_1'}(t))\wedge\cdots\wedge c_1(\overline{\mathcal{L}}_{r_D'}(t))=\deg\bigl(c_1(\mathcal{O}(e_{r_1'}))\cdots c_1(\mathcal{O}(e_{r_D'}))\cap[\mathcal{X}_{\mathbb{Q}}]\bigr)=\delta_{\mathcal{X}}\,\mathrm{gi}(\mathcal{X};x_{r_1'}\cdots x_{r_D'})$ ($r_l'\in\mathrm{Rt}$). As $\xi_s=x_{r_1}-x_{r_2}$ and $\mathrm{lr}(c)=-\sum_r c_rx_r$, summing gives $\int_{X^\circ}\omega_{\Xi,0}^{2k-1}\wedge\omega_{c,0}^m=\delta_{\mathcal{X}}\,\mathrm{gi}(\mathcal{X};\xi_s^{2k-1}\mathrm{lr}(c)^m)$. This is (Fx8)(2).

The consequences are the definitions of analytic square data and of a proportional square model, whose square system has (Fx5), (Fx6), (Fx7) and carries an analytic square system. □

Lemma D.96. *Let $\mathcal{X}$ and $\mathcal{X}'$ be root models of type (Φ,n) with convergent regularisation, and let $m>0$ be a real number with*

$$\mathrm{pp}(\mathcal{X}';F)=m\,\mathrm{pp}(\mathcal{X};F)\quad\textit{and}\quad\mathrm{gi}(\mathcal{X}';F)=m\,\mathrm{gi}(\mathcal{X};F)\qquad\textit{for every } F\in\mathcal{R}.$$

Let s be a Levi reflection and $\mu=(\mu_k)_{k\ge1}$ real numbers. If the pair $\bigl(\mathrm{pp}(\mathcal{X}';\cdot)|_{\mathcal{R}},\mathrm{gi}(\mathcal{X}';\cdot)|_{\mathcal{R}}\bigr)$ satisfies the fibre-square identities for s with moments μ, then so does the pair $\bigl(\mathrm{pp}(\mathcal{X};\cdot)|_{\mathcal{R}},\mathrm{gi}(\mathcal{X};\cdot)|_{\mathcal{R}}\bigr)$.

Proof. Let c be an s-invariant weight. The elements $\mathrm{lr}(c)^{D+1}$, $\xi_s^{2k}\mathrm{lr}(c)^{D+1-2k}$ and $\xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k}$ ($1\le k\le(D+1)/2$) lie in $\mathcal{R}$. By the identities for $\mathcal{X}'$ and the hypothesis,

$$m\,\mathrm{pp}(\mathcal{X};\mathrm{lr}(c)^{D+1})=\mathrm{pp}(\mathcal{X}';\mathrm{lr}(c)^{D+1})=0,$$

and for $1\le k\le(D+1)/2$

$$\begin{aligned}m\,\mathrm{pp}(\mathcal{X};\xi_s^{2k}\mathrm{lr}(c)^{D+1-2k})&=\mathrm{pp}(\mathcal{X}';\xi_s^{2k}\mathrm{lr}(c)^{D+1-2k})\\&=-2\mu_k\,\mathrm{gi}(\mathcal{X}';\xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k})\\&=-2\mu_k\,m\,\mathrm{gi}(\mathcal{X};\xi_s^{2k-1}\mathrm{lr}(c)^{D+1-2k}).\end{aligned}$$

Dividing by $m\neq0$ gives the identities (30.1) for the pair of $\mathcal{X}$. □

D.5 Torsion systems: the test-point facts

This section proves the test-point facts Proposition D.97 for torsion-regular systems with Hodge–Tate lattice families, used in Section 35 for the existence of pre-admissible torsion systems with test-point conditions (Proposition 35.23). Subsection D.5.1 shows that at a test point the Hopf orders are stable and tight, with the abelian-factor target, and that the reduction is good or Mumford-degenerate (Proposition D.99); Subsection D.5.2 proves the Hodge–Tate facts at test points (Proposition D.110).

D.5.1 Stable tight Hopf orders at test points

The subsection states Proposition D.97 and proves its algebraic part. At a test point the torsion function orders are base changes of a complete local order, and the reduction is good or Mumford-degenerate (Proposition D.99); the orders are stable tight Hopf orders and abelian factors (Proposition D.98); and the cotangent maps kill products, are equivariant, satisfy the kernel clause, and detect the square of the augmentation ideal (Lemma D.107, Lemma D.108, Proposition D.109).

Proposition D.97. *Let $\mathcal{T}$, $\mathcal{Y}$, E, c, $2 \le B_0 \le B$, $\mathcal{X} \subseteq \mathbb{P}$, $p \in S(B_0, B)$ and λ be as in Proposition 35.11, $\mathcal{T}$ of type (Φ, n, κ). Let $\mathfrak{T} = (\mathcal{O}', \mathcal{X}', \pi, (\mathcal{A}_{\mathfrak{P}}, \theta))$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$, $R \ge 4$ an integer as in Definition 35.22, $w \in \mathcal{O}'$ with $w^{p-1} = u\,p$ for a unit u, and for every $a \in \Phi$ let $\beta, \bar{\beta}$ be bases and $(U_\nu, \iota_\nu, h_\nu)_\nu$ a Hodge–Tate atlas for $(\mathfrak{T}, (a, +), \beta, \bar{\beta})$ whose Hodge–Tate lattice family satisfies (Hm1), (Hm2), (Hm4) and (Hm5) of Proposition 35.24. Then every point $\mathfrak{q}$ of $\mathcal{X}'$ of codimension one at which p is not a unit is the first entry of a test point $(\mathfrak{q}, C, \iota_C)$ such that:*

1. *(Ox3) holds at $(\mathfrak{q}, C, \iota_C)$;*
2. *for every $a \in \Phi$, with $s = (a, +)$, $m = m_{\mathfrak{P}_s}$ and the eigen flag H_i, J_i of H as in (Hm2), (F0)–(F2) hold for the $\mathcal{O}_C$-spans of the stalks at $\mathfrak{q}$ of the Hodge–Tate lattice family of a, and $\mathcal{O}_C J_{i,\mathfrak{q}} = \mathcal{O}_C\,\mathcal{O}_{\mathcal{X}'}(-\mathrm{Ec}_{s,i})_{\mathfrak{q}}$ in C for $1 \le i \le m$.*

Proof. Let $\mathfrak{q}$ be a point of $\mathcal{X}'$ of codimension one at which p is not a unit, and let $(\mathfrak{q}, C, \iota_C)$ be the test point given by Proposition D.110. By Proposition D.98 (which holds at every test point of the torsion-regular pre-admissible system $\mathfrak{T}$), for every prime $\mathfrak{P} \mid p$ the order $\mathcal{A}_{\mathfrak{P},C}$ is an $\mathbb{F}_{\mathfrak{P}}$-stable tight Hopf order on $\Gamma_{\mathfrak{P}}$ and an abelian factor; by Lemma D.107 and Lemma D.108 (both at every test point) the three cotangent conditions of (Ox3) hold for every label u. Together these are (Ox3) at $(\mathfrak{q}, C, \iota_C)$, which is (1). Part (2) is the conclusion of Proposition D.110 at the same test point. □

Proposition D.98. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97 and $(\mathfrak{q}, C, \iota_C)$ a test point. Then for every prime $\mathfrak{P} \mid p$ of $\mathcal{O}_E$, $\mathcal{A}_{\mathfrak{P},C}$ is an $\mathbb{F}_{\mathfrak{P}}$-stable tight Hopf order on $\Gamma_{\mathfrak{P}}$ and an abelian factor.*

Proof. Let $h\colon \widehat{R} \to \mathcal{O}_C$, $\widehat{G}$ and $N = \prod_{\mathfrak{P}'} \Gamma_{\mathfrak{P}'}$ be as in Proposition D.99, and $M = \mathrm{Ord}(\widehat{G}[p])_h = \boxtimes_{\mathfrak{P}'} \mathcal{A}_{\mathfrak{P}',C}$ (its part (1)).

Step 1: M is a tight Hopf order on N and an abelian factor. If $\widehat{G}$ carries degeneration data as in Proposition D.99(2), Proposition D.101 applies ($\widehat{R}$ is a complete discrete valuation ring of characteristic 0, h is injective, $\widehat{G}_{\widehat{K}}$ is principally polarised, $\widehat{G}[p]$ is flat, quasi-finite, separated, of finite presentation, with constant generic fibre of points N): M is a tight abelian factor (tightness includes being a Hopf order). Otherwise $\widehat{G}$ is an abelian scheme with a principal polarisation, so $\mathcal{B} = \widehat{G} \otimes_{\widehat{R},h} \mathcal{O}_C$ is a principally polarised abelian scheme over $\mathcal{O}_C$. The group scheme $\widehat{G}[p]$ is finite and locally free, hence affine; its $\widehat{K}$-points are $\widehat{R}$-points (their coordinates are integral over the normal domain $\widehat{R}$), so translations by points of N are automorphisms and the functions given by global sections of $\mathcal{O}_{\widehat{G}[p]}$ lie in $\mathrm{Ord}(\widehat{G}[p])$; conversely local sections are determined by their values at the points of the reduced constant generic fibre ($\mathcal{O}_{\widehat{G}[p]}$ is $\widehat{R}$-torsion free), so the local sections defining a regular function glue. Hence $\mathrm{Ord}(\widehat{G}[p])$ is the image of $\Gamma(\widehat{G}[p], \mathcal{O})$, and by base change of affine schemes $M = M_{\mathcal{B}}$ with $N = N_{\mathcal{B}}$. By Lemma D.105 M is a tight Hopf order, and it is an abelian factor with $\iota = \rho = \mathrm{id}$.

Step 2: the factor at $\mathfrak{P}$ is a Hopf order and an abelian factor. Fix $\mathfrak{P}$, write $N = \Gamma_{\mathfrak{P}} \times N'$, $M = \mathcal{A}_{\mathfrak{P},C} \boxtimes M'$, and let $\mathcal{A}'$, $\iota\colon N \to N_{\mathcal{A}'}$, ρ be data exhibiting M as an abelian factor. Let $\iota_{\mathfrak{P}}\colon \Gamma_{\mathfrak{P}} \to N$, $x \mapsto (x,0)$, and $\rho_{\mathfrak{P}}\colon N \to \Gamma_{\mathfrak{P}}$ the projection. Every element of $\mathcal{A}_{\mathfrak{P},C}$ and of M' takes values in $\mathcal{O}_C$ ($\mathcal{A}_{\mathfrak{P}} \subseteq \mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O})$), and $1 \in M'$; for a pure tensor $f \boxtimes f'$, $(f \boxtimes f') \circ \iota_{\mathfrak{P}} = f'(0) f$ and $(f \boxtimes f') \circ \iota_{\mathfrak{P}} \rho_{\mathfrak{P}} = f \boxtimes f'(0) 1 \in M$. Hence $\{g \circ \iota_{\mathfrak{P}} :\ g \in M\} = \mathcal{A}_{\mathfrak{P},C}$ and $M \circ \iota_{\mathfrak{P}} \rho_{\mathfrak{P}} \subseteq M$. Put $\iota'' = \iota \circ \iota_{\mathfrak{P}}$, $\rho'' = \rho_{\mathfrak{P}} \circ \rho$; then $\rho'' \iota'' = \mathrm{id}$, $\{g \circ \iota'' :\ g \in M_{\mathcal{A}'}\} = \{m \circ \iota_{\mathfrak{P}} :\ m \in M\} = \mathcal{A}_{\mathfrak{P},C}$, and for $g \in M_{\mathcal{A}'}$, $g \circ \iota'' \rho'' = ((g \circ \iota) \circ \iota_{\mathfrak{P}} \rho_{\mathfrak{P}}) \circ \rho$; here $(g \circ \iota) \circ \iota_{\mathfrak{P}} \rho_{\mathfrak{P}} \in M$, so it equals $g' \circ \iota$ for some $g' \in M_{\mathcal{A}'}$, and $g' \circ \iota\rho \in M_{\mathcal{A}'}$. So $\mathcal{A}_{\mathfrak{P},C}$ is an abelian factor. It is a Hopf order: it is the $\mathcal{O}_C$-span of the free module $\mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ whose basis is a C-basis of $\mathrm{Map}(\Gamma_{\mathfrak{P}}, C)$ (Ox2), it is an algebra containing 1, and for $f = g \circ \iota''$ the functions $f(x+y) = g(\iota''x + \iota''y)$ and $f(-x)$ are expressed through the comultiplication and antipode of the Hopf order $M_{\mathcal{A}'}$ (Lemma D.105 is not needed here: $M_{\mathcal{A}'}$ is the function algebra of the finite group scheme $\mathcal{A}'[p]$) as sums of products $g_1(\iota''x) g_2(\iota''y)$ with $g_i \circ \iota'' \in \mathcal{A}_{\mathfrak{P},C}$. The same argument applied to N' shows that M' is a Hopf order.

Step 3: tightness. By Steps 1 and 2 and Lemma D.106 (with $B_1 = \mathcal{A}_{\mathfrak{P},C}$, $B_2 = M'$), $\mathcal{A}_{\mathfrak{P},C}$ is tight.

Step 4: $\mathbb{F}_{\mathfrak{P}}$-stability. Let $a \in \mathbb{F}_{\mathfrak{P}}$ and $\tilde{a} \in \mathcal{O}_E$ a lift. The endomorphism $[\tilde{a}]$ of $G'[\mathfrak{P}]$ acts on $\Gamma_{\mathfrak{P}}$ as multiplication by a. If f is regular on $G'[\mathfrak{P}] \times U$, given near a point by a section s, then $f(a\,\cdot)$ is given near any preimage point by $[\tilde{a}]^* s$; and the translates of $f(a\,\cdot)$ are $f(t' + a\,\cdot)$, again of this form. So the generators of $\mathrm{Ord}(G'[\mathfrak{P}] \times U)$ and hence $\mathcal{A}_{\mathfrak{P}}(U)$ (Definition 35.22(Hf1)) are stable under $f \mapsto f(a\,\cdot)$, and so are the stalk at $\mathfrak{q}$ and its $\mathcal{O}_C$-span $\mathcal{A}_{\mathfrak{P},C}$. □

Proposition D.99. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97, with function field Ω', and $(\mathfrak{q}, C, \iota_C)$ a test point. Put $R_{\mathfrak{q}} = \mathcal{O}_{\mathcal{X}',\mathfrak{q}}$. Then there are a complete discrete valuation ring $\widehat{R}$ of characteristic 0 with fraction field $\widehat{K}$, a ring homomorphism $g\colon R_{\mathfrak{q}} \to \widehat{R}$ and an injective homomorphism $h\colon \widehat{R} \to \mathcal{O}_C$ with $h \circ g = \iota_C|_{R_{\mathfrak{q}}}$ such that, with $\widehat{G} = G' \times_{\mathcal{X}'} \mathrm{Spec}\, \widehat{R}$ (through g): $\widehat{G}_{\widehat{K}}$ is a principally polarised abelian variety; $\widehat{G}[p]$ is flat, quasi-finite, separated and of finite presentation over $\widehat{R}$ with constant generic fibre whose group of points is $N = G'[p](\Omega') = \bigoplus_{\mathfrak{P}|p} \Gamma_{\mathfrak{P}}$;*

1. *under $N = \prod_{\mathfrak{P}|p} \Gamma_{\mathfrak{P}}$, $\mathrm{Ord}(\widehat{G}[p])_h = \boxtimes_{\mathfrak{P}|p} \mathcal{A}_{\mathfrak{P},C}$;*
2. *either $\widehat{G}$ is an abelian scheme over $\widehat{R}$ to which the principal polarisation of $\widehat{G}_{\widehat{K}}$ extends, or $\widehat{G}$ carries principally polarised split degeneration data satisfying (D1)–(D4) for which it is a uniformisation.*

Proof. As in the setting of Proposition D.97, p is unramified in E. Write $\iota = \iota_C$.

Step 1: the ring $\widehat{R}$ and the maps g, h. $R_{\mathfrak{q}}$ is a discrete valuation ring ($\mathcal{X}'$ is normal, $\mathfrak{q}$ has codimension one) with fraction field Ω'; let π_0 be a uniformiser and R_0 its completion, a complete discrete valuation ring, faithfully flat over $R_{\mathfrak{q}}$, so $R_{\mathfrak{q}} \subseteq R_0$. Since $\iota^{-1}(\mathcal{O}_C) = R_{\mathfrak{q}}$, every $x \in \mathfrak{m}_{\mathfrak{q}}$ has $x^{-1} \notin R_{\mathfrak{q}}$, hence $|\iota(x)| < 1$; with $\rho = |\iota(\pi_0)| < 1$, $|\iota(y)| \le \rho^n$ for $y \in \mathfrak{m}_{\mathfrak{q}}^n$, and units u of $R_{\mathfrak{q}}$ have $|\iota(u)| = 1$. So $\iota|_{R_{\mathfrak{q}}}$ is uniformly continuous for the $\mathfrak{m}_{\mathfrak{q}}$-adic topology, and as $\mathcal{O}_C$ is complete it extends uniquely to a continuous ring homomorphism $h_0\colon R_0 \to \mathcal{O}_C$. It is injective: a non-zero $x \in R_0$ is $u\pi_0^n$ with $u \in R_0^\times$, and $u \equiv u_0 \bmod \pi_0 R_0$ for some $u_0 \in R_{\mathfrak{q}}^\times$ (equal residue fields), so $|h_0(u)| = |\iota(u_0)| = 1$ and $h_0(x) \neq 0$. In particular R_0 has characteristic 0. Let κ be the residue field of R_0. The fibre of G' at the closed point of $\mathrm{Spec}\, R_0$ is a semiabelian variety over κ (Step 2 below), an extension of an abelian variety by a torus; a torus over a field splits over a finite separable extension, so there is a finite separable extension $\kappa' = \kappa(\bar{a})$ over which this torus splits, $\bar{a}$ a root of a separable irreducible monic $\bar{f} \in \kappa[x]$. Let $f \in R_0[x]$ be a monic lift

and $\widehat{R} = R_0[x]/(f)$: since $\bar{f}$ is irreducible and separable, $\widehat{R}$ is a complete discrete valuation ring, finite and étale over R_0, with uniformiser π_0, residue field κ' and fraction field $\widehat{K} = \widehat{K_0}[x]/(f)$ (unramified extensions of complete discrete valuation rings; f is irreducible over R_0 as $\bar{f}$ is, hence over $\mathrm{Frac}(R_0) = \widehat{K_0}$ by Gauss's lemma). As C is algebraically closed, f^{h_0} has a root $\alpha \in C$, integral over $h_0(R_0) \subseteq \mathcal{O}_C$, so $\alpha \in \mathcal{O}_C$ ($\mathcal{O}_C$ is integrally closed). Let $h\colon \widehat{R} \to \mathcal{O}_C$ extend h_0 by $x \mapsto \alpha$, and $g\colon R_{\mathfrak{q}} \subseteq R_0 \subseteq \widehat{R}$. Then $h \circ g = \iota|_{R_{\mathfrak{q}}}$; $\ker h$ is a prime of $\widehat{R}$ over $\ker h_0 = 0$, so $\ker h = 0$ by incomparability for the integral extension $R_0 \subseteq \widehat{R}$. $\widehat{R}$ is a complete noetherian normal local domain of characteristic 0, and g is injective, so it extends to a field embedding $\Omega' \to \widehat{K}$ through which we regard the Ω'-points x_t of G' as $\widehat{K}$-points.

Step 2: the group $\widehat{G}$. By (Fh5) the generic point of $\mathcal{X}'$ (a cover through $f \circ \pi$ in the notation there) maps to a point of $j(\mathrm{Sh}_F)$. By (Ud7), $(G_{\mathcal{Y}}, \iota_{\mathcal{Y}}, \mathcal{L}_{\mathcal{Y}})$ is a semiabelian structure whose restriction along j is the triple of the universal object, so (Ud4) it is an abelian scheme there with $\mathcal{L}_{\mathcal{Y}}$ relatively ample and $\phi_{\mathcal{L}_{\mathcal{Y}}}$ a principal polarisation. Its pull-back $(\widehat{G}, \iota_{\widehat{G}}, \widehat{\mathcal{L}})$ to $\operatorname{Spec}\widehat{R}$ (through $G' = \pi^* G_{\mathcal{X}}$ and g) is a semiabelian structure over $\widehat{R}$; as g is injective, the generic point of $\operatorname{Spec}\widehat{R}$ maps to the generic point of $\mathcal{X}'$, so $\widehat{G}_{\widehat{K}}$ is an abelian variety, $\widehat{\mathcal{L}}|_{\widehat{G}_{\widehat{K}}}$ is ample and $\phi_{\widehat{\mathcal{L}}_{\widehat{K}}}$ is a principal polarisation. By Lemma 35.30(1) (over the complete noetherian normal local domain $\widehat{R}$, whose maximal ideal contains p as $p \in \mathfrak{m}_{\mathfrak{q}}$), $\widehat{G}[p] = \prod_{\mathfrak{P}|p} \widehat{G}[\mathfrak{P}]$ with each factor quasi-finite and flat; $\widehat{G}[p]$ is a closed subgroup scheme of the separated $\widehat{R}$-scheme of finite type $\widehat{G}$, hence separated and of finite presentation. By (Ts3), $G'[\mathfrak{P}]_{\Omega'} = G_{\mathcal{X}}[\mathfrak{P}] \times_{\Omega} \Omega'$ is constant with points $\Gamma_{\mathfrak{P}}$, so $\widehat{G}[p]_{\widehat{K}} = G'[p]_{\Omega'} \otimes_{\Omega'} \widehat{K}$ is reduced and constant with group of points $N = \bigoplus_{\mathfrak{P}} \Gamma_{\mathfrak{P}} = \prod_{\mathfrak{P}} \Gamma_{\mathfrak{P}}$. So $\widehat{G}[p]$ and each $\widehat{G}[\mathfrak{P}]$ are as in Definition 35.21 over $\widehat{R}$, with $T = N$, resp. $T = \Gamma_{\mathfrak{P}}$.

Step 3: clause (1). Let $U = \operatorname{Spec} R_U$ be an affine open neighbourhood of $\mathfrak{q}$ in $\mathcal{X}'$ and $h_1\colon R_U \to R_{\mathfrak{q}} \to \widehat{R}$. By (Hf1), $\mathcal{A}_{\mathfrak{P}}(U) = \mathrm{Ord}(G'[\mathfrak{P}]_U)$. Apply Lemma 35.28(3) to h_1 (R_U is a noetherian integrally closed domain with fraction field Ω', $\widehat{R}$ a noetherian domain), with $B = \Omega'$, $h_B\colon \Omega' \to \widehat{K}$ the embedding of Step 1 and $\sigma_t = x_t$: the base change $\widehat{G}[\mathfrak{P}]$ with the induced points is as in Definition 35.21 with the same $T = \Gamma_{\mathfrak{P}}$ (Step 2). Hence $\mathrm{Ord}(\widehat{G}[\mathfrak{P}])$ is the $\widehat{R}$-span of $\{h_1 \circ f :\ f \in \mathcal{A}_{\mathfrak{P}}(U)\}$. By Lemma D.100(2) over the discrete valuation ring $\widehat{R}$, applied to the product $\widehat{G}[p] = \prod_{\mathfrak{P}} \widehat{G}[\mathfrak{P}]$ (its points are the tuples of points, matching $N = \prod_{\mathfrak{P}} \Gamma_{\mathfrak{P}}$), $\mathrm{Ord}(\widehat{G}[p])$ is the $\widehat{R}$-span of the functions $(z_{\mathfrak{P}}) \mapsto \prod_{\mathfrak{P}} a_{\mathfrak{P}}(z_{\mathfrak{P}})$, $a_{\mathfrak{P}} \in \mathrm{Ord}(\widehat{G}[\mathfrak{P}])$, hence the $\widehat{R}$-span of the products of the functions $h_1 \circ f_{\mathfrak{P}}$, $f_{\mathfrak{P}} \in \mathcal{A}_{\mathfrak{P}}(U)$. As $h \circ h_1 = \iota|_{R_U}$, $\mathrm{Ord}(\widehat{G}[p])_h$ is the $\mathcal{O}_C$-span of the products $\prod_{\mathfrak{P}} \iota \circ f_{\mathfrak{P}}(z_{\mathfrak{P}})$, $f_{\mathfrak{P}} \in \mathcal{A}_{\mathfrak{P}}(U)$. On the other hand $\mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ is the $R_{\mathfrak{q}}$-span of $\mathcal{A}_{\mathfrak{P}}(U)$ ($\mathcal{A}_{\mathfrak{P}}$ is quasi-coherent, (Ts3)), so by (Ox2) $\mathcal{A}_{\mathfrak{P},C}$ is the $\mathcal{O}_C$-span of $\{\iota \circ f :\ f \in \mathcal{A}_{\mathfrak{P}}(U)\}$, and $\boxtimes_{\mathfrak{P}} \mathcal{A}_{\mathfrak{P},C}$, the $\mathcal{O}_C$-span of the products of elements of the factors, is the $\mathcal{O}_C$-span of the same products (expand the products of $\mathcal{O}_C$-combinations). This is (1).

Step 4: clause (2). The closed fibre of $\widehat{G}$ is the base change to κ' of the closed fibre of G'_{R_0}, an extension of an abelian variety by a torus that is split over κ' (Step 1). (a) If this torus is trivial, all fibres of $\widehat{G}$ ($\operatorname{Spec}\widehat{R}$ has two points) are abelian varieties, so the semiabelian scheme $\widehat{G}$ is an abelian scheme (Faltings–Chai, Ch. I, Remark 2.8; Lan, Remark 3.3.1.8). Let $\widehat{G}^\vee$ be its dual and $\lambda = \phi_{\widehat{\mathcal{L}}}\colon \widehat{G} \to \widehat{G}^\vee$, a symmetric homomorphism whose generic fibre is the principal polarisation $\phi_{\widehat{\mathcal{L}}_{\widehat{K}}}$. By Theorem B.104 ($\operatorname{Spec}\widehat{R}$ is noetherian and normal, its generic point is a dense open subscheme, abelian schemes are semiabelian) the inverse of $\lambda_{\widehat{K}}$ extends to a homomorphism $\mu\colon \widehat{G}^\vee \to \widehat{G}$, and $\mu\lambda$, $\lambda\mu$ extend identities, so they are identities by the uniqueness in Theorem B.104: λ is an isomorphism. By Theorem B.126 ($\operatorname{Spec}\widehat{R}$ is connected and λ is a polarisation at the generic point) λ is a polarisation, hence a principal polarisation of $\widehat{G}$ extending that of $\widehat{G}_{\widehat{K}}$: the first alternative of (2). (b) Otherwise, Proposition 32.15 applies

to the semiabelian structure $(\widehat{G}, \iota_{\widehat{G}}, \widehat{\mathcal{L}})$ over $\widehat{R}$: its hypothesis (1) holds by Step 2 and (2) by the choice of κ'. So $(\widehat{G}, \iota_{\widehat{G}}, \widehat{\mathcal{L}})$ is uniformised by degeneration data $\mathfrak{D} = (B, \mathcal{L}_B, \iota_B, X, c, \psi)$ with $\mathcal{O}_E$-structure over $(\widehat{R}, \mathfrak{m})$. Forgetting the $\mathcal{O}_E$-structure, these are principally polarised split degeneration data $(P, \mathcal{L}, X, c, \psi) = (B, \mathcal{L}_B, X, c, \psi)$ satisfying (D1)–(D4) of Proposition D.101, clause by clause: (D1) B is an abelian scheme and $\mathcal{L}_B$ a rigidified symmetric cubical relatively ample line bundle of principal polarisation; (D2) X is free of finite rank and $c\colon X \to B(\widehat{R})$ a homomorphism; (D3) the $\psi(\chi)$ are nowhere-zero sections, i.e. trivialisations, of $c(\chi)^*\mathcal{L}_B^{-1}$ over $\widehat{K}$, with $\psi(-\chi) = \psi(\chi)$ under the symmetry and τ bimultiplicative; (D4) for $\chi \neq 0$, $\psi(\chi)$ is a section over $\widehat{R}$ of $\mathfrak{m} \cdot c(\chi)^*\mathcal{L}_B^{-1}$, i.e. has values in $\mathfrak{m}$ in every local trivialisation, and for every n only finitely many $\psi(\chi)$ fail to lie in $\mathfrak{m}^n c(\chi)^*\mathcal{L}_B^{-1}$. $\widehat{G}$ is a uniformisation as there: for every $e \geq 0$ the identification of $\widehat{G} \otimes \widehat{R}/\mathfrak{m}^{e+1}$ with $\widetilde{G} \otimes \widehat{R}/\mathfrak{m}^{e+1}$, $\widetilde{G}$ the extension of B by the split torus T_X with character group X given by c, compatible in e, gives the exact sequences $1 \to T_X \to \widehat{G} \otimes \widehat{R}/\mathfrak{m}^{e+1} \to B \otimes \widehat{R}/\mathfrak{m}^{e+1} \to 0$; the identification of $\widehat{\mathcal{L}} \otimes \widehat{R}/\mathfrak{m}^{e+1}$ with the pull-back of $\mathcal{L}_B$, compatible with rigidifications, symmetries and cubical structures, gives the compatible cubical rigidified line bundles; and $\widehat{G}_{\widehat{K}}$ carries the principal polarisation of $\widehat{\mathcal{L}}_{\widehat{K}}$. Finally $\widehat{G}$ is smooth, separated and commutative with $\widehat{G}_{\widehat{K}}$ the principally polarised abelian variety of Step 2: the second alternative of (2). □

Lemma D.100. *Let R be a noetherian domain with fraction field K.*

1. ***Characterisation.*** *Let Γ, T and $(x_t)_{t\in T}$ be as in Definition 35.21, and let $A \subseteq \operatorname{Map}(T, R)$ be an R-subalgebra with $\varphi_t(A) \subseteq A$ for every $t \in T$. Suppose there is an R-morphism $j\colon \Gamma \to \operatorname{Spec} A$ which is an open immersion, satisfies $j \circ x_t = \operatorname{ev}_t$ for every $t \in T$, and whose image has covering translates:* $\operatorname{Spec} A = \bigcup_{t\in T} \tau_t(j(\Gamma))$. *Then $A = \operatorname{Ord}(\Gamma)$.*

2. ***Products.*** *Let R be in addition integrally closed, and let Γ_1, Γ_2 with groups T_1, T_2 and points $(x_t^{(1)})_{t\in T_1}$, $(x_t^{(2)})_{t\in T_2}$ be as in Definition 35.21. Then $\Gamma = \Gamma_1 \times_R \Gamma_2$ with $T = T_1 \times T_2$ and $x_{(t_1,t_2)} = (x_{t_1}^{(1)}, x_{t_2}^{(2)})$ is as in Definition 35.21,* $\operatorname{Ord}(\Gamma)$ *is the R-span of the functions $(t_1, t_2) \mapsto a(t_1)\, b(t_2)$ with $a \in \operatorname{Ord}(\Gamma_1)$, $b \in \operatorname{Ord}(\Gamma_2)$, and the map $\operatorname{Ord}(\Gamma_1) \otimes_R \operatorname{Ord}(\Gamma_2) \to \operatorname{Ord}(\Gamma)$ sending $a \otimes b$ to this function is an isomorphism of R-algebras. By induction the same holds for finite products $\Gamma_1 \times_R \cdots \times_R \Gamma_k$.*

Proof. **Proof of (1).** Put $X = \operatorname{Spec} A$ and $V = j(\Gamma)$, an open subset. Since $\varphi_t \circ \varphi_{-t} = \mathrm{id}$, $\varphi_t(A) = A$ and τ_t is an automorphism; as $\varphi_s \circ \varphi_t = \varphi_{s+t}$, $\tau_t \circ \tau_s = \tau_{s+t}$, so $\tau_{-t} = \tau_t^{-1}$. The composite of $\operatorname{ev}_s\colon \operatorname{Spec} K \to X$ with τ_t corresponds to the ring map $\operatorname{ev}_s \circ \varphi_t = \operatorname{ev}_{s+t}$, so $\tau_t \circ \operatorname{ev}_s = \operatorname{ev}_{s+t}$. For $a \in A$ its value at ev_s is $a(s)$.

Step 1 (sections are determined by their values). Let $W \subseteq X$ be open, $\sigma \in \mathcal{O}_X(W)$ with $\sigma(\operatorname{ev}_t) = 0$ for every t with $\operatorname{ev}_t \in W$. We show $\sigma = 0$. Cover W by basic open sets $D(a)$, $a \in A$. For $a \in A$, $\operatorname{ev}_t \in D(a)$ if and only if $a(t) \neq 0$, and localisation at a is exact, so $\mathcal{O}_X(D(a)) = A_a \to \operatorname{Map}(T, K)_a$ is injective; since a is a unit in the factors t with $a(t) \neq 0$ and zero in the others, $\operatorname{Map}(T, K)_a = \prod_{t:\, a(t)\neq 0} K$, and the t-th coordinate of the image of an element is its value at ev_t. Hence $\sigma|_{D(a)} = 0$ for every a with $D(a) \subseteq W$, and $\sigma = 0$.

Step 2 ($A \subseteq \operatorname{Ord}(\Gamma)$). Let $f \in A$ and $t' \in T$. Then $\varphi_{t'} f \in A$, and $s = j^*(\varphi_{t'} f) \in \mathcal{O}_\Gamma(\Gamma)$ has $s(x_t) = (\varphi_{t'} f)(\operatorname{ev}_t) = f(t' + t)$ for every t, because $j \circ x_t = \operatorname{ev}_t$. So every translate of $f\colon T \to R$ is regular on Γ (with the neighbourhood $U = \Gamma$ at every point), and f is one of the generators of $\operatorname{Ord}(\Gamma)$.

Step 3 ($\operatorname{Ord}(\Gamma) \subseteq A$). As A is an R-subalgebra, it suffices to show that every $g\colon T \to R$ all of whose translates are regular on Γ lies in A. Let $t' \in T$ and $P \in \tau_{t'}(V)$; then $\tau_{-t'}(P) = j(\gamma)$

for a point γ of Γ. As $\varphi_{t'}g$ is regular on Γ, there are an open $U \ni \gamma$ and $s \in \mathcal{O}_\Gamma(U)$ with $s(x_u) = g(t'+u)$ whenever $x_u \in U$. Since j is an open immersion, $W' = j(U)$ is open in X and $\sigma' = (j|_U^{-1})^* s \in \mathcal{O}_X(W')$; as j is injective and $j(x_u) = \mathrm{ev}_u$, we have $\mathrm{ev}_u \in W'$ if and only if $x_u \in U$, and then $\sigma'(\mathrm{ev}_u) = s(x_u) = g(t'+u)$. Put $W = \tau_{-t'}^{-1}(W') = \tau_{t'}(W')$, an open neighbourhood of P, and $\sigma = \tau_{-t'}^* \sigma' \in \mathcal{O}_X(W)$. For $\mathrm{ev}_v \in W$ we have $\tau_{-t'} \circ \mathrm{ev}_v = \mathrm{ev}_{v-t'} \in W'$ and $\sigma(\mathrm{ev}_v) = \sigma'(\mathrm{ev}_{v-t'}) = g(v)$. Since the sets $\tau_{t'}(V)$, $t' \in T$, cover X, we obtain an open cover $X = \bigcup_i W_i$ with sections $\sigma_i \in \mathcal{O}_X(W_i)$ satisfying $\sigma_i(\mathrm{ev}_v) = g(v)$ whenever $\mathrm{ev}_v \in W_i$. On $W_i \cap W_k$ the difference $\sigma_i - \sigma_k$ has all values 0, so vanishes by Step 1. The σ_i glue to $a \in \mathcal{O}_X(X) = A$, and every ev_v lies in some W_i, so $a(v) = g(v)$ for all v: $g = a \in A$. With Step 2, $A = \mathrm{Ord}(\Gamma)$.

Proof of (2). Γ is a commutative group scheme which is flat, quasi-finite, separated and of finite presentation over R (these properties are stable under base change and composition). Its generic fibre is $\Gamma_{1,K} \times_K \Gamma_{2,K} = (\bigsqcup_{T_1} \operatorname{Spec} K) \times_K (\bigsqcup_{T_2} \operatorname{Spec} K) = \bigsqcup_{T_1 \times T_2} \operatorname{Spec} K$, reduced, with points exactly the $x_{(t_1,t_2)}$, and $(t_1,t_2) \mapsto x_{(t_1,t_2)}$ is an injective homomorphism. So Γ is as in Definition 35.21.

Put $A_i = \mathrm{Ord}(\Gamma_i)$. By Lemma 35.28(1), A_i is a finitely generated projective R-module, stable under every φ_t, $t \in T_i$, with $d_i A_i^{\mathrm{full}} \subseteq A_i \subseteq A_i^{\mathrm{full}}$ for some $d_i \neq 0$, where $A_i^{\mathrm{full}} = \mathrm{Map}(T_i, R)$; hence $A_i \otimes_R K = \mathrm{Map}(T_i, K)$. By Lemma 35.28(2) there is an open immersion $j_i \colon \Gamma_i \to \operatorname{Spec} A_i$ with $j_i \circ x_t^{(i)} = \mathrm{ev}_t$ and $\operatorname{Spec} A_i = \bigcup_{t \in T_i} \tau_t(j_i(\Gamma_i))$.

Let $\mu \colon A_1 \otimes_R A_2 \to \mathrm{Map}(T, R)$, $\mu(a \otimes b)(t_1,t_2) = a(t_1)b(t_2)$, a homomorphism of R-algebras, and $A = \mu(A_1 \otimes_R A_2)$, the span in the statement. The module $A_1 \otimes_R A_2$ is projective, hence torsion free, so it embeds into $(A_1 \otimes_R A_2) \otimes_R K = \mathrm{Map}(T_1, K) \otimes_K \mathrm{Map}(T_2, K)$, and the latter maps isomorphically onto $\mathrm{Map}(T, K)$ (bases of indicator functions); so μ is injective and $\mu \colon A_1 \otimes_R A_2 \to A$ is an isomorphism of R-algebras. For $t = (t_1,t_2)$, $\varphi_t \mu(a \otimes b) = \mu(\varphi_{t_1} a \otimes \varphi_{t_2} b)$, so $\varphi_t(A) \subseteq A$, and under $\operatorname{Spec} \mu$, which identifies $\operatorname{Spec} A$ with $\operatorname{Spec} A_1 \times_R \operatorname{Spec} A_2$, τ_t corresponds to $\tau_{t_1} \times \tau_{t_2}$ and ev_t to $(\mathrm{ev}_{t_1}, \mathrm{ev}_{t_2})$ (as $\mathrm{ev}_t \circ \mu(a \otimes b) = a(t_1)b(t_2)$).

Let $j = j_1 \times j_2 \colon \Gamma \to \operatorname{Spec} A_1 \times_R \operatorname{Spec} A_2 = \operatorname{Spec} A$. It is an open immersion (the composite of the base changes $j_1 \times \mathrm{id}$ and $\mathrm{id} \times j_2$ of open immersions), $j \circ x_t = (\mathrm{ev}_{t_1}, \mathrm{ev}_{t_2}) = \mathrm{ev}_t$, and $j(\Gamma) = \mathrm{pr}_1^{-1}(V_1) \cap \mathrm{pr}_2^{-1}(V_2)$ with $V_i = j_i(\Gamma_i)$. Covering translates: for a point P of $\operatorname{Spec} A$ choose t_i with $\mathrm{pr}_i(P) \in \tau_{t_i}(V_i)$; then $P \in \mathrm{pr}_1^{-1}(\tau_{t_1} V_1) \cap \mathrm{pr}_2^{-1}(\tau_{t_2} V_2) = (\tau_{t_1} \times \tau_{t_2})(\mathrm{pr}_1^{-1}(V_1) \cap \mathrm{pr}_2^{-1}(V_2)) = \tau_{(t_1,t_2)}(j(\Gamma))$, because $\mathrm{pr}_i \circ (\tau_{t_1} \times \tau_{t_2}) = \tau_{t_i} \circ \mathrm{pr}_i$ and $\tau_{t_1} \times \tau_{t_2}$ is bijective. By (1), $\mathrm{Ord}(\Gamma) = A$, which is the assertion. For k factors apply this to $(\Gamma_1 \times \cdots \times \Gamma_{k-1}) \times \Gamma_k$, the first factor being as in Definition 35.21 by the first paragraph. □

Proposition D.101. *Let p be a prime and C, $\mathcal{O}_C$, v as in Definition 35.18. Let R be a complete discrete valuation ring of characteristic 0 with maximal ideal $\mathfrak{m}$ and fraction field K, and $h \colon R \to \mathcal{O}_C$ an injective homomorphism. Let A be a principally polarised abelian variety over K and G a smooth separated commutative group scheme over R with $G_K \cong A$, given together with principally polarised split degeneration data $(P, \mathcal{L}, X, c, \psi)$ in the sense of [87, Ch. II–III]:*

(D1) *a principally polarised abelian scheme P over R with a symmetric, rigidified, cubical relatively ample line bundle $\mathcal{L}$;*

(D2) *a free abelian group X of finite rank and a homomorphism $c \colon X \to P(R)$;*

(D3) *trivialisations $\psi(\chi)$ of $c(\chi)^* \mathcal{L}^{-1}$ over K ($\chi \in X$) with $\psi(-\chi) = \psi(\chi)$ under the symmetry of $\mathcal{L}$, whose associated trivialisations $\tau(\chi,\chi') = \psi(\chi+\chi')\psi(\chi)^{-1}\psi(\chi')^{-1}$ of the biextension are bimultiplicative;*

(D4) *positivity: for $\chi \neq 0$, $\psi(\chi)$ is a section with values in $\mathfrak{m}$ (in every local trivialisation of $c(\chi)^* \mathcal{L}^{-1}$ over R), and for every n only finitely many $\psi(\chi)$ fail to have values in $\mathfrak{m}^n$;*

and for which G is a uniformisation: for every $e \geq 0$, an exact sequence $1 \to T_X \to G \otimes R/\mathfrak{m}^{e+1} \to P \otimes R/\mathfrak{m}^{e+1} \to 0$ with T_X the split torus with character group X, compatible in e, with cubical rigidified line bundles on G and P compatible with these sequences and with the polarisation of A. Assume that $G[p]$ is flat, quasi-finite and separated over R, and that $A[p]$ is constant over K with group of points N. Then $M = \mathrm{Ord}(G[p])_h \subseteq \mathrm{Map}(N, C)$, the base change along h of the regular-translate order of $G[p]$ (Definition 35.21, with $T = N$), is an abelian factor, and it is tight.

Proof. Let N_t, N_a, N_e, e and $\mu(N_t)$ be as given by Proposition D.102, $r_t = \dim_{\mathbb{F}_p} N_t$, $r_e = \dim_{\mathbb{F}_p} N_e$, $r = \max(r_t, r_e)$, and $P_C = P \otimes_{R,h} \mathcal{O}_C$. We transport functions along e and write $M \circ e = \{f \circ e : \ f \in M\}$.

Step 1: $M \circ e = \mu_C(N_t) \boxtimes M_{P_C} \boxtimes \mathrm{Map}(N_e, \mathcal{O}_C)$, where $\mu_C(N_t)$ is the $\mathcal{O}_C$-span of the homomorphisms $N_t \to \mathcal{O}_C^\times$. By Proposition D.102(3), $M \circ e$ is the $\mathcal{O}_C$-span of the products $(h \circ a) \boxtimes (h \circ b) \boxtimes (h \circ c')$, so it suffices to identify the three spans. (a) By Proposition D.102(2) the homomorphisms $N_t \to R^\times$ span $\mathrm{Map}(N_t, K)$ over K; homomorphisms being linearly independent (Dedekind), there are at least $|N_t|$ of them; composed with the injective h they are distinct homomorphisms $N_t \to \mathcal{O}_C^\times$, of which there are exactly $|N_t|$ ($N_t \cong (\mathbb{Z}/p)^{r_t}$ and $\mu_p(C)$ is cyclic of order p). Hence the $\mathcal{O}_C$-span of $h \circ \mu(N_t)$ is $\mu_C(N_t)$ (a product of characters is a character). (b) $P[p]$ is finite and locally free over R, so affine; its K-points are R-points (their coordinates are integral over the normal domain R), so translations by points of N_a are automorphisms of $P[p]$ and every function given by a global section of $\mathcal{O}_{P[p]}$ lies in $\mathrm{Ord}(P[p])$. Conversely, sections of $\mathcal{O}_{P[p]}$ over an open set are determined by their values at the points of the generic fibre ($\mathcal{O}_{P[p]}$ is R-torsion free and the generic fibre is reduced and constant by Proposition D.102(1)), so the local sections defining a function regular on $P[p]$ glue to a global section. Hence $\mathrm{Ord}(P[p])$ is the image of $\Gamma(P[p], \mathcal{O})$ under evaluation; as $\Gamma(P[p]_{\mathcal{O}_C}, \mathcal{O}) = \Gamma(P[p], \mathcal{O}) \otimes_{R,h} \mathcal{O}_C$ and $N_a = P[p](K) = P_C[p](\mathcal{O}_C)$ (both of order $|N_a|$), the $\mathcal{O}_C$-span of $h \circ \mathrm{Ord}(P[p])$ is M_{P_C}. (c) The span of $h \circ \mathrm{Map}(N_e, R)$ is $\mathrm{Map}(N_e, \mathcal{O}_C)$.

Step 2: the abelian scheme. Let E and $x \colon \mathbb{Z}/p \times \mathbb{Z}/p \to N_E$ be as in Lemma D.104, and $\mathcal{A} = P_C \times E^r$, principally polarised by the product of the principal polarisations of P_C (D1) and of E, and admitting a relatively ample line bundle. Then $N_{\mathcal{A}} = N_{P_C} \times N_E^r$ and, as $\mathcal{A}[p] = P_C[p] \times E[p]^r$ and the ring of global sections of a product of affine schemes is the tensor product of the rings of global sections, $M_{\mathcal{A}} = M_{P_C} \boxtimes M_E^{\boxtimes r}$. Fix isomorphisms $N_t \cong (\mathbb{Z}/p)^{r_t}$, $N_e \cong (\mathbb{Z}/p)^{r_e}$ and extend coordinate vectors by zeros to length r. Define $\iota \colon N \to N_{\mathcal{A}}$ by $\iota(e(z_t, z_a, z_e)) = (z_a, (x(u_k, w_k))_{k \leq r})$, u, w the extended coordinates of z_t, z_e, and $\rho \colon N_{\mathcal{A}} \to N$ by $\rho(y, (x(u_k, w_k))_k) = e((u_k)_{k \leq r_t}, y, (w_k)_{k \leq r_e})$. These are homomorphisms with $\rho \circ \iota = \mathrm{id}_N$.

Step 3: M is an abelian factor. By Lemma D.104, $M_E \circ x = \mu_C(\mathbb{Z}/p) \boxtimes \mathrm{Map}(\mathbb{Z}/p, \mathcal{O}_C)$. For a pure tensor $g = g_0 \boxtimes \bigotimes_k (\alpha_k \boxtimes \gamma_k)$ ($g_0 \in M_{P_C}$, $\alpha_k \in \mu_C(\mathbb{Z}/p)$, $\gamma_k \in \mathrm{Map}(\mathbb{Z}/p, \mathcal{O}_C)$, transported along x), $g \circ \iota \circ e$ is the product of $g_0(z_a)$, of $\prod_{k \leq r_t} \alpha_k(u_k)$ (a character of N_t), of $\prod_{k \leq r_e} \gamma_k(w_k)$, and of the constants $\alpha_k(0), \gamma_k(0) \in \mathcal{O}_C$ for the remaining indices; since the characters of N_t are exactly the products of characters of the coordinates, Step 1 gives $\{g \circ \iota : \ g \in M_{\mathcal{A}}\} = M$. Likewise $g \circ \iota \circ \rho$ is the pure tensor in which the factors at the unused coordinates are replaced by their values at 0, which lies in $M_{\mathcal{A}}$. So M is an abelian factor (Af3).

Step 4: M is tight. Reorder the coordinates of $N_{\mathcal{A}}$ as $N \times N_c$, $N_c = (\mathbb{Z}/p)^{r-r_t} \times (\mathbb{Z}/p)^{r-r_e}$ (the unused coordinates), via ι and the inclusion of N_c. By Steps 1–3, $M_{\mathcal{A}}$ becomes $M \boxtimes M_c$ with $M_c = \mu_C(\mathbb{Z}/p)^{\boxtimes(r-r_t)} \boxtimes \mathrm{Map}(\mathbb{Z}/p, \mathcal{O}_C)^{\boxtimes(r-r_e)}$. Here M is a Hopf order on N (Step 1 and Lemma D.106: $\mu_C(N_t)$ is spanned by the columns of the invertible character table, closed under products, with $\chi(x+y) = \chi(x)\chi(y)$ and $\chi(-x) = \chi(x)^{-1}$; M_{P_C} by Lemma D.105; $\mathrm{Map}(N_e, \mathcal{O}_C)$ trivially), and so is M_c. By Lemma D.105, $M_{\mathcal{A}}$ is tight on $N_{\mathcal{A}}$; tightness is preserved by the group isomorphism reordering the coordinates (all quantities of (Ho3) are transported), so $M \boxtimes M_c$ is

tight, and by Lemma D.106 M is tight. □

Proposition D.102. *Let p be a prime, R a complete discrete valuation ring of characteristic 0 with maximal ideal $\mathfrak{m}$ and fraction field K, A a principally polarised abelian variety over K, and G a smooth separated commutative group scheme over R with $G_K \cong A$, given with degeneration data $(P, \mathcal{L}, X, c, \psi)$ satisfying (D1)–(D4) of Proposition D.101 for which G is a uniformisation (as there). Assume that $G[p]$ is flat, quasi-finite, separated and of finite presentation over R and that $A[p]$ is constant over K, with group of points N. Then there are finite abelian groups N_t, N_a, N_e killed by p and a group isomorphism $e\colon N_t \times N_a \times N_e \to N$ such that:*

1. *$P[p]_K$ is constant and $N_a = P[p](K)$;*
2. *the R-subalgebra $\mu(N_t) \subseteq \mathrm{Map}(N_t, R)$ generated by the homomorphisms $N_t \to R^\times$ contains $d\,\mathrm{Map}(N_t, R)$ for some $d \in R \smallsetminus \{0\}$;*
3. *$\{f \circ e :\ f \in \mathrm{Ord}(G[p])\}$ is the R-span of the functions $(z_t, z_a, z_e) \mapsto a(z_t)\, b(z_a)\, c'(z_e)$ with $a \in \mu(N_t)$, $b \in \mathrm{Ord}(P[p])$ (formed with $T = N_a$) and $c' \in \mathrm{Map}(N_e, R)$.*

Proof. Let π_R be a uniformiser of R, κ its residue field, $\Gamma = G[p]$, and let $t \mapsto x_t$, $t \in N$, be the points of Γ_K; N is killed by p.

Step 1: G is semiabelian and its Raynaud extension is an extension of P by T_X. $\operatorname{Spec} R$ has two points. $G_K \cong A$ is an abelian variety, and by the uniformisation with $e = 0$, G_κ is an extension of the abelian variety P_κ by the split torus $T_{X,\kappa}$; so the smooth separated commutative group scheme G is semiabelian, with abelian generic fibre, and its closed fibre is an extension of an abelian variety by a split torus. Let $0 \to T \to \widetilde{G} \to A' \to 0$ be its Raynaud extension (Theorem B.109(1)). The compatible system of the sequences $1 \to T_X \to G \otimes R/\mathfrak{m}^{e+1} \to P \otimes R/\mathfrak{m}^{e+1} \to 0$ gives a formal subtorus T_X^{for} of G^{for} lifting the torus of G_κ with quotient P^{for}; by uniqueness of formal tori lifting a torus it is T^{for}, so $T \cong T_X$, and $A'^{\mathrm{for}} = G^{\mathrm{for}}/T^{\mathrm{for}} \cong P^{\mathrm{for}}$ algebraises to an isomorphism $A' \cong P$ of abelian schemes. So $\widetilde{G}$ is an extension $0 \to T_X \to \widetilde{G} \xrightarrow{\varpi} P \to 0$ over R, defined by some homomorphism $c_0\colon X \to P^\vee(R)$.

Step 2: the finite part. R is complete, hence henselian, and Γ is quasi-finite and separated, so $\Gamma = \Gamma^f \sqcup \Gamma^r$ with Γ^f the finite part, an open and closed subgroup scheme, finite and flat, and Γ^r open and closed with empty closed fibre. So Γ^r lies in the generic fibre $\Gamma_K = \bigsqcup_t \{x_t\}$: it is the open subscheme $\{x_t :\ t \notin N^f\}$, each point $\operatorname{Spec} K$, where $N^f = \{t :\ x_t \in \Gamma^f\}$, a subgroup of N. By Theorem B.119(1) (with $m = p$), $\Gamma^f = G[p]^f \cong \widetilde{G}[p]$ as group schemes. Hence $\widetilde{G}[p]_K \cong \Gamma^f_K$ is constant (an open and closed subgroup of the constant Γ_K) with group of points N^f. By Lemma D.103 (R is a discrete valuation ring, $\widetilde{G}$ the extension defined by c_0) there is an isomorphism $\widetilde{G}[p] \cong T_X[p] \times_R P[p]$, the identity on $T_X[p]$ and compatible with the projections to $P[p]$. Composing, we obtain an isomorphism of group schemes $\phi\colon T_X[p] \times_R P[p] \to \Gamma^f$. Its generic fibre identifies the constant group Γ^f_K with $T_X[p]_K \times P[p]_K$, so both factors are constant over K.

Step 3: the groups and the isomorphism e; clause (1). Put $N_t = T_X[p](K)$ and $N_a = P[p](K)$, finite abelian groups killed by p; $P[p]_K$ is constant (Step 2), which is (1). ϕ induces a group isomorphism $N_t \times N_a \to N^f$, $(z_t, z_a) \mapsto \phi(z_t, z_a)$. Choose a complement N_e of the $\mathbb{F}_p$-subspace N^f of N and put $e(z_t, z_a, z_e) = \phi(z_t, z_a) + z_e$; $e\colon N_t \times N_a \times N_e \to N$ is a group isomorphism.

Step 4: clause (2). If $X = 0$ then $N_t = 0$ and (2) holds with $d = 1$. Otherwise $T_X[p] = \mathrm{Hom}(X, \mu_p)$ is constant over K, so $\mu_p(\bar{K}) \subseteq K$, and these roots of unity are integral, so lie in $R^\times$. $T_X[p] = \operatorname{Spec} R[X/pX]$, and $N_t = \mathrm{Hom}(X/pX, \mu_p(K))$; for $\chi \in X/pX$ the function $z \mapsto z(\chi)$ is a homomorphism $N_t \to R^\times$, and these are $|N_t|$ distinct characters, i.e. all characters

of $N_t \cong (\mathbb{Z}/p)^r$ with values in $\mu_p(K)$. By orthogonality, $\sum_\chi \chi(z) = |N_t|$ if $z = 0$ and 0 otherwise, so for $z_0 \in N_t$ the function $|N_t|\,\delta_{z_0} = \sum_\chi \chi(z_0)^{-1}\chi$ lies in $\mu(N_t)$. Hence $d\,\mathrm{Map}(N_t, R) \subseteq \mu(N_t)$ with $d = |N_t| \neq 0$ (R has characteristic 0). Moreover, since a product of characters is a character, $\mu(N_t)$ is the R-span of the characters, and it is the image of $\mathcal{O}(T_X[p]) = R[X/pX]$ under evaluation at the points $z \in N_t$.

Step 5: functions on Γ^f. The scheme $P[p]$ is finite and flat over R with reduced constant generic fibre; $\mathcal{O}(P[p])$ is torsion free, so evaluation at the points of N_a embeds it into $\mathrm{Map}(N_a, K)$, and its values are integral over R, hence in R. Let $A_P \subseteq \mathrm{Map}(N_a, R)$ be its image. Each K-point of $P[p]$ extends to an R-point (finite over the normal R), so translations by N_a are automorphisms of $P[p]$ and A_P is translation stable; taking for j the isomorphism $P[p] \to \operatorname{Spec} A_P$ (an open immersion with $j \circ x_z = \mathrm{ev}_z$, whose single translate covers), Lemma D.100(1) gives $A_P = \mathrm{Ord}(P[p])$. As $\Gamma^f \cong T_X[p] \times_R P[p]$ via ϕ and the ring of functions of a fibre product of affine schemes is the tensor product of the rings of functions, evaluation at the points $\phi(z_t, z_a)$ maps $\mathcal{O}(\Gamma^f)$ onto

$$B^f = \mu(N_t) \boxtimes \mathrm{Ord}(P[p]) \subseteq \mathrm{Map}(N_t \times N_a, R),$$

the R-span of the functions $a(z_t)b(z_a)$ (Steps 4 and 5); it is injective (Γ^f is flat with reduced constant generic fibre), so $\mathcal{O}(\Gamma^f) \cong B^f$ and $\Gamma^f \cong \operatorname{Spec} B^f$, with $x_{\phi(z_t,z_a)}$ corresponding to evaluation at (z_t, z_a).

Step 6: clause (3). Let $\mathcal{A} \subseteq \mathrm{Map}(N, R)$ be the set of f with $f \circ e$ in the R-span of the functions $a(z_t)b(z_a)c'(z_e)$, $a \in \mu(N_t)$, $b \in \mathrm{Ord}(P[p])$, $c' \in \mathrm{Map}(N_e, R)$; equivalently (expand c' in indicator functions of points of N_e), $f \in \mathcal{A}$ iff $f_{z_e}\colon (z_t, z_a) \mapsto f(e(z_t, z_a, z_e))$ lies in B^f for every $z_e \in N_e$. So $f \mapsto (f_{z_e})_{z_e}$ is an isomorphism of R-algebras $\mathcal{A} \to \prod_{z_e \in N_e} B^f$, and $\operatorname{Spec}\mathcal{A}$ is the disjoint union of the open and closed subschemes $V_{z_e} \cong \operatorname{Spec} B^f$. We verify the hypotheses of Lemma D.100(1) for Γ and $\mathcal{A}$.

(a) $\mathcal{A}$ is an R-subalgebra of $\mathrm{Map}(N, R)$, stable under every φ_t: for $t = e(w_t, w_a, w_e)$, $(\varphi_t f) \circ e(z_t, z_a, z_e) = f \circ e(w_t + z_t, w_a + z_a, w_e + z_e)$, and $\mu(N_t)$, $\mathrm{Ord}(P[p])$ (Step 5: the image of $\mathcal{O}(P[p])$, stable under translations) and $\mathrm{Map}(N_e, R)$ are translation stable ($\chi(w + z) = \chi(w)\chi(z)$ for characters).

(b) The morphism j. On Γ^f let j be $\Gamma^f \cong \operatorname{Spec} B^f = V_0 \subseteq \operatorname{Spec}\mathcal{A}$ (Step 5), induced by $f \mapsto f_0$; for $t = \phi(z_t, z_a) \in N^f$, $j \circ x_t$ is the K-point $f \mapsto f_0(z_t, z_a) = f(t)$, i.e. ev_t. On Γ^r let j send the open point $x_t = \operatorname{Spec} K$ ($t \notin N^f$) to ev_t. Since $d\,\mathrm{Map}(N_t, R) \subseteq \mu(N_t)$ and $\mathrm{Ord}(P[p]) \otimes K = \mathrm{Map}(N_a, K)$ ($\mathcal{O}(P[p]) \otimes K = \mathcal{O}(P[p]_K)$), $\mathcal{A} \otimes_R K = \mathrm{Map}(N, K)$; so the generic fibre of $\operatorname{Spec}\mathcal{A}$, the open subset where π_R is invertible, is the disjoint union of the points ev_t, $t \in N$, each open with residue field K. For $t \notin N^f$, $t = e(z_t, z_a, z_e)$ with $z_e \neq 0$, so $\mathrm{ev}_t \in V_{z_e}$ is disjoint from $V_0 = j(\Gamma^f)$, and $x_t \to \{\mathrm{ev}_t\}$ is an isomorphism onto an open subscheme. Thus j is an R-morphism and an open immersion (a disjoint union of open immersions with pairwise disjoint open images), with $j \circ x_t = \mathrm{ev}_t$ for all $t \in N$.

(c) Covering translates. For $w_e \in N_e$ and $t = e(0, 0, w_e)$, $(\varphi_t f)_{z_e} = f_{z_e + w_e}$, so τ_t maps V_{z_e} onto $V_{z_e + w_e}$ (a prime $\{f : f_{z_e} \in Q\}$ of V_{z_e} goes to φ_t^{-1} of it, $\{f : f_{z_e + w_e} \in Q\}$); hence $\tau_t(V_0) = V_{w_e}$, and the translates $\tau_t(V_0)$, $t \in e(0, 0, N_e)$, are all the V_{z_e}, and they cover $\operatorname{Spec}\mathcal{A}$.

By Lemma D.100(1), $\mathrm{Ord}(G[p]) = \mathcal{A}$, which is (3). □

Lemma D.103. *Let R be a discrete valuation ring with fraction field K, p a prime, P an abelian scheme over R, X a free abelian group of finite rank, T_X the split torus over R with character group X, and $0 \to T_X \to \widetilde{G} \xrightarrow{\varpi} P \to 0$ the extension defined by a homomorphism $c\colon X \to P^\vee(R)$ (for $\chi \in X$, the push-out along $\chi\colon T_X \to \mathbb{G}_m$ is the extension of P by $\mathbb{G}_m$ with class $c(\chi)$). Suppose that $\widetilde{G}[p]_K$ is a constant group scheme. Then there is a homomorphism*

$c'\colon X \to P^\vee(R)$ *with* $c = pc'$*, and an isomorphism of group schemes over* R

$$\widetilde{G}[p] \;\cong\; T_X[p] \times_R P[p]$$

which restricts to the identity on $T_X[p]$ *and under which* $\varpi|_{\widetilde{G}[p]}$ *is the second projection. In particular there is a homomorphism of group schemes* $s\colon P[p] \to \widetilde{G}[p]$ *with* $\varpi \circ s = \mathrm{id}$.

Proof. Step 1: $c(\chi) \in pP^\vee(R)$ *for every* $\chi \in X$. Since $[p]$ is an fppf epimorphism on T_X and on P, the snake lemma gives an exact sequence $0 \to T_X[p] \to \widetilde{G}[p] \to P[p] \to 0$. Over K the three terms are constant ($\widetilde{G}[p]_K$ is, hence so are its subgroup and quotient), so $\widetilde{G}[p](K) \to P[p](K)$ is a surjection of $\mathbb{F}_p$-vector spaces and has a linear section, which defines a homomorphism of constant group schemes $\sigma\colon P[p]_K \to \widetilde{G}[p]_K$ with $\varpi\sigma = \mathrm{id}$. Fix $\chi \in X$ and let $u\colon \widetilde{G} \to E_\chi$ be the push-out along χ, an extension $0 \to \mathbb{G}_m \to E_\chi \to P \to 0$ of class $c(\chi)$. Then $u \circ \sigma$ splits the restriction $E_\chi|_{P[p]} = E_\chi \times_P P[p]$ of E_χ to $P[p]$ over K. Apply $\mathrm{Hom}_K(-, \mathbb{G}_m)$ to $0 \to P[p]_K \to P_K \xrightarrow{p} P_K \to 0$: the exact sequence

$$\mathrm{Ext}^1_K(P_K, \mathbb{G}_m) \xrightarrow{[p]^*} \mathrm{Ext}^1_K(P_K, \mathbb{G}_m) \xrightarrow{\mathrm{res}} \mathrm{Ext}^1_K(P[p]_K, \mathbb{G}_m)$$

with $[p]^*$ multiplication by p shows that $c(\chi)_K \in pP^\vee(K)$. As $P^\vee$ is proper and separated over the discrete valuation ring R, $P^\vee(R) \to P^\vee(K)$ is bijective, so $c(\chi) = p\, d_\chi$ with $d_\chi \in P^\vee(R)$.

Step 2: c' *and a second description of* $\widetilde{G}$. Choose a basis $\chi_1, \dots, \chi_r$ of X and let $c'\colon X \to P^\vee(R)$ be the homomorphism with $c'(\chi_i) = d_{\chi_i}$; then $pc' = c$ on the basis, hence on X. Let $\widetilde{G}'$ be the extension of P by T_X defined by c', and $\widetilde{G}'' = \widetilde{G}' \times_{P,[p]} P$ its pull-back along $[p]_P$, an extension of P by T_X with class $[p]^*c' = pc' = c$. Two extensions with the same class are isomorphic, and the isomorphism is unique because $\mathrm{Hom}_R(P, T_X) = 0$; so $\widetilde{G} \cong \widetilde{G}''$ as extensions.

Step 3: the p*-torsion of* $\widetilde{G}''$. A point of $\widetilde{G}''$ (with values in any R-scheme) is a pair (g', z) with $g' \in \widetilde{G}'$, $z \in P$, $\varpi'(g') = pz$; its image in P is z, and T_X embeds as $t \mapsto (t, 0)$. Such a pair is killed by p if and only if $pg' = 0$ and $pz = 0$; then $\varpi'(g') = pz = 0$, so $g' \in T_X$, and $pg' = 0$ gives $g' \in T_X[p]$. Conversely every (t, z) with $t \in T_X[p]$, $z \in P[p]$ is a point of $\widetilde{G}''[p]$ ($\varpi'(t) = 0 = pz$). Hence $(t, z) \mapsto (t, z)$ is an isomorphism of group schemes $T_X[p] \times_R P[p] \to \widetilde{G}''[p]$, the identity on $T_X[p]$ and compatible with the projections to $P[p]$. Transporting along $\widetilde{G} \cong \widetilde{G}''$ gives the assertion, and $s(z) = (0, z)$. □

Lemma D.104. *Let* p *be a prime,* C *and* $\mathcal{O}_C$ *as in Definition 35.18, and* $\zeta \in \mathcal{O}_C$ *a primitive* p*-th root of unity. There are an elliptic curve* E *over* $\mathcal{O}_C$ *(a principally polarised abelian scheme of relative dimension one) and a group isomorphism* $x\colon \mathbb{Z}/p \times \mathbb{Z}/p \to N_E$ *such that* $\{f \circ x :\ f \in M_E\}$ *is the* $\mathcal{O}_C$*-span of the functions* $(a, b) \mapsto \zeta^{ka}\, c'(b)$*,* $k \in \mathbb{Z}/p$*,* $c' \in \mathrm{Map}(\mathbb{Z}/p, \mathcal{O}_C)$.

Proof. Step 1: an ordinary curve. Since $\lfloor p/12 \rfloor + 2 < p$ for $p \geq 5$, and $j = 1 \neq 0$ for $p = 2, 3$, there is $j_0 \in \mathbb{F}_p$ which is not supersingular; let E_0 be an elliptic curve over $\mathbb{F}_p$ with $j(E_0) = j_0$, given by a Weierstrass equation. Lifting its coefficients to $\mathbb{Z}_p$ gives a Weierstrass equation whose discriminant is a unit, i.e. an elliptic curve E_1 over $\mathbb{Z}_p$ with special fibre E_0. As $\mathcal{O}_C$ is complete with $|p| < 1$, it is a $\mathbb{Z}_p$-algebra; put $E = E_1 \otimes_{\mathbb{Z}_p} \mathcal{O}_C$, an elliptic curve over $\mathcal{O}_C$, principally polarised by its origin.

Step 2: the connected–étale sequence. $E[p]$ is finite flat of order p^2 over $\mathcal{O}_C$, a henselian local ring with algebraically closed residue field k (as C is algebraically closed). In the sequence (ii), $E[p]^{\mathrm{et}}$ has order $|E_0[p](k)| = p$ (ordinary), so it is the constant group $\mathbb{Z}/p$, and $E[p]^0$ has order p. By (iii), Cartier duality turns the sequence into $0 \to (\mathbb{Z}/p)^D \to E[p] \to (E[p]^0)^D \to 0$; $(\mathbb{Z}/p)^D = \mu_p$ is connected (its special fibre is infinitesimal), so $\mu_p \subseteq E[p]^0$, and both have order p: $E[p]^0 = \mu_p$.

Step 3: the splitting. $E[p](\mathcal{O}_C) = E[p](C)$ has p^2 elements (valuative criterion, $E[p]$ finite), and $\mu_p(\mathcal{O}_C)$ has p elements; so the image of $E[p](\mathcal{O}_C) \to (\mathbb{Z}/p)(\mathcal{O}_C) = \mathbb{Z}/p$ has p elements and contains 1. A point $Q \in E[p](\mathcal{O}_C)$ over 1 defines a homomorphism $\mathbb{Z}/p \to E[p]$, $1 \mapsto Q$, splitting the sequence: $E[p] \cong \mu_p \times \mathbb{Z}/p$.

Step 4: the function module. Hence $\Gamma(E[p], \mathcal{O}) \cong \mathcal{O}_C[t]/(t^p - 1) \otimes_{\mathcal{O}_C} \mathrm{Map}(\mathbb{Z}/p, \mathcal{O}_C)$, and with $x(a, b) = (\zeta^a, b)$ the evaluation sends $t^k \otimes c'$ to $(a, b) \mapsto \zeta^{ka} c'(b)$. So $\{f \circ x : \ f \in M_E\}$ is the stated span, and x is a group isomorphism onto $N_E = \mu_p(\mathcal{O}_C) \times \mathbb{Z}/p$. □

Lemma D.105. *Let C and $\mathcal{O}_C$ be as in Definition 35.18 and P a principally polarised abelian scheme over $\mathcal{O}_C$. Then M_P is a tight Hopf order on N_P.*

Proof. Let $B = M_P$ and $N = N_P$. *B is a Hopf order on N.* $\Gamma(P[p], \mathcal{O})$ is free of rank p^{2g} over the local ring $\mathcal{O}_C$ and its generic fibre is the constant group scheme on N, so evaluation at the points is injective and identifies $\Gamma(P[p], \mathcal{O}) \otimes C$ with $\mathrm{Map}(N, C)$: B is spanned by the columns of a matrix in $\mathrm{GL}_N(C)$. It contains 1 and is closed under products, and the group law and the inverse of $P[p]$ give the comultiplication and antipode axioms of (Ho2).

The four quantities. The augmentation ideal I_B is the ideal of the unit section, so $I_B/I_B^2 = \omega_{P[p]} \cong (\mathcal{O}_C/p)^g$ has normalised length g. By Lemma 35.47, Q_B has a normalised length and $2\,\mathrm{colen}(B) \le (p-1)|N|\,\mathrm{len}_C(Q_B)$; by Proposition 35.54, $(p-1)\mathrm{len}_C(Q_B) \le g$; by Lemma 35.49, $|N|\,\mathrm{len}_C(I_B/I_B^2) \le 2\,\mathrm{colen}(B)$. Hence

$$2\,\mathrm{colen}(B) \le (p-1)|N|\,\mathrm{len}_C(Q_B) \le |N|\,g = |N|\,\mathrm{len}_C(I_B/I_B^2) \le 2\,\mathrm{colen}(B),$$

all are equalities, and the two identities of (Ho3) hold: B is tight. □

Lemma D.106. *Let N_1, N_2 be finite abelian groups with $pN_1 = pN_2 = 0$, B_i a Hopf order on N_i ($i = 1, 2$), and $B_1 \boxtimes B_2 \subseteq \mathrm{Map}(N_1 \times N_2, C)$ the $\mathcal{O}_C$-span of the functions $(x_1, x_2) \mapsto f_1(x_1) f_2(x_2)$, $f_i \in B_i$. Then $B = B_1 \boxtimes B_2$ is a Hopf order on $N = N_1 \times N_2$,*

$$\mathrm{colen}(B) = |N_2|\,\mathrm{colen}(B_1) + |N_1|\,\mathrm{colen}(B_2),$$
$$\mathrm{len}_C(I_B/I_B^2) = \sum_i \mathrm{len}_C(I_{B_i}/I_{B_i}^2), \qquad \mathrm{len}_C(Q_B) = \sum_i \mathrm{len}_C(Q_{B_i}),$$

and if B is tight, then B_1 and B_2 are tight.

Proof. Step 1: B is a Hopf order and $B \cong B_1 \otimes_{\mathcal{O}_C} B_2$. Let $E_i \in \mathrm{GL}_{N_i}(C)$ have columns $f_{i,1}, \dots$ spanning B_i; the functions $f_{1,k} \boxtimes f_{2,l}$ are the columns of the Kronecker product $E_1 \otimes E_2 \in \mathrm{GL}_N(C)$, so they are linearly independent and span B, and $f_1 \otimes f_2 \mapsto f_1 \boxtimes f_2$ is an isomorphism $B_1 \otimes B_2 \to B$. B contains $1 = 1 \boxtimes 1$, is closed under products (products of pure tensors are pure tensors), and for $g = f_1 \boxtimes f_2$ the function $((x_1, x_2), (y_1, y_2)) \mapsto f_1(x_1 + y_1) f_2(x_2 + y_2)$ is a sum of products $(g_1 \boxtimes g_2)(x_1, x_2)\,(g_1' \boxtimes g_2')(y_1, y_2)$ by the comultiplication axiom for B_1 and B_2; $x \mapsto g(-x)$ is $f_1(-\cdot) \boxtimes f_2(-\cdot) \in B$. Since $\det(E_1 \otimes E_2) = \det(E_1)^{|N_2|} \det(E_2)^{|N_1|}$, the colength formula holds.

Step 2: the cotangent modules. Each $f \in B_i$ is integral over $\mathcal{O}_C$ (B_i is a finite $\mathcal{O}_C$-algebra), so its values are integral over $\mathcal{O}_C$ and lie in $\mathcal{O}_C$; hence $B_i = \mathcal{O}_C 1 \oplus I_i$ with $I_i = I_{B_i}$ ($f = f(0)1 + (f - f(0)1)$). By Step 1,

$$B = \mathcal{O}_C \oplus (I_1 \boxtimes 1) \oplus (1 \boxtimes I_2) \oplus (I_1 \boxtimes I_2), \qquad I_B = (I_1 \boxtimes 1) \oplus (1 \boxtimes I_2) \oplus (I_1 \boxtimes I_2).$$

Multiplying the summands pairwise, $I_B^2 = (I_1^2 \boxtimes 1) \oplus (1 \boxtimes I_2^2) \oplus (I_1 \boxtimes I_2)$ (the cross products $(a \boxtimes 1)(1 \boxtimes b) = a \boxtimes b$ give all of $I_1 \boxtimes I_2$, and every product involving $I_1 \boxtimes I_2$ lies in it). Hence $I_B/I_B^2 \cong I_1/I_1^2 \oplus I_2/I_2^2$ and the normalised lengths add.

Step 3: the almost-additive cokernels. For $f\colon N \to C$ almost additive, $f(x_1,x_2) - f(x_1,0) - f(0,x_2) \in p\mathcal{O}_C$, $f(\cdot,0)$ and $f(0,\cdot)$ are almost additive, and $f(0) \in p\mathcal{O}_C$ (from $x = y = 0$). So $\mathrm{Lin}(N) = \mathrm{Lin}(N_1)\circ\mathrm{pr}_1 + \mathrm{Lin}(N_2)\circ\mathrm{pr}_2 + p\,\mathrm{Map}(N,\mathcal{O}_C)$. If moreover $f \in B$, write $f = \sum_k f_{1,k} \boxtimes f_{2,k}$; then $f(\cdot,0) = \sum_k f_{2,k}(0) f_{1,k} \in B_1$ and likewise $f(0,\cdot) \in B_2$; conversely $a_1\circ\mathrm{pr}_1 = a_1 \boxtimes 1 \in B$. Hence $\mathrm{AF}(B) + p\,\mathrm{Map}(N,\mathcal{O}_C) = \mathrm{AF}(B_1)\circ\mathrm{pr}_1 + \mathrm{AF}(B_2)\circ\mathrm{pr}_2 + p\,\mathrm{Map}(N,\mathcal{O}_C)$. The map $\mathrm{Lin}(N_1)\oplus\mathrm{Lin}(N_2) \to Q_B$, $(f_1,f_2) \mapsto f_1\circ\mathrm{pr}_1 + f_2\circ\mathrm{pr}_2$, is therefore onto; if $f_1\circ\mathrm{pr}_1 + f_2\circ\mathrm{pr}_2 = a_1\circ\mathrm{pr}_1 + a_2\circ\mathrm{pr}_2 + ph$ with $a_i \in \mathrm{AF}(B_i)$, evaluation at $(x_1,0)$ gives $f_1 - a_1 \in p\,\mathrm{Map}(N_1,\mathcal{O}_C)$ (as $f_2(0), a_2(0) \in p\mathcal{O}_C$), and symmetrically. So $Q_B \cong Q_{B_1} \oplus Q_{B_2}$ and the normalised lengths add.

Step 4: tightness passes to the factors. By Lemma 35.47, $2\,\mathrm{colen}(B_i) \le (p-1)|N_i|\,\mathrm{len}_C(Q_{B_i})$; multiplying by $|N_{3-i}|$ and adding, with Steps 1 and 3, $2\,\mathrm{colen}(B) \le (p-1)|N|\,\mathrm{len}_C(Q_B)$, with equality only if both inequalities are equalities. By Lemma 35.49, $|N_i|\,\mathrm{len}_C(I_{B_i}/I_{B_i}^2) \le 2\,\mathrm{colen}(B_i)$; multiplying by $|N_{3-i}|$ and adding, with Steps 1 and 2, $|N|\,\mathrm{len}_C(I_B/I_B^2) \le 2\,\mathrm{colen}(B)$, with equality only if both are equalities. If B is tight, both outer relations are equalities, hence so are the four inequalities for B_1, B_2, which are the identities of (Ho3) for B_1 and B_2. □

Lemma D.107. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X},p,\lambda)$ as in Proposition D.97, $(\mathfrak{q},C,\iota_C)$ a test point, u a label and $\mathfrak{P} = \mathfrak{P}_u$. Then $\theta_{u,C}(gh) = 0$ for $g,h \in \mathcal{I}_{\mathfrak{P},C}$, and $\theta_{u,C}(x \mapsto g(ax)) = \chi_u(a)\,\theta_{u,C}(g)$ for $a \in \mathbb{F}_{\mathfrak{P}}$ and $g \in \mathcal{I}_{\mathfrak{P},C}$.*

Proof. The prime p is unramified in E ($p \notin \mathrm{Bd}$). Let $\widehat{W}$ be the completion of $\mathcal{O}_{E,(\mathfrak{P})}$ (maximal ideal $p\widehat{W}$), $\omega\colon \mathbb{F}_{\mathfrak{P}} \to \widehat{W}$ the Teichmüller map and $\hat{\sigma}_u\colon \widehat{W} \to \widehat{\mathcal{O}'}$ the continuous extension of σ_u ($\sigma_u^{-1}(\mathfrak{m}_{\mathcal{O}'}) = \mathfrak{P}$). Then $\hat{\sigma}_u \circ \omega = \chi_u$: both vanish at 0, take values in the roots of unity of order dividing $|\mathbb{F}_{\mathfrak{P}}| - 1$ (which lie in $\mathcal{O}'$ by (Ts1)) elsewhere, and agree modulo $\mathfrak{m}_{\mathcal{O}'}$, where reduction is injective on such roots of unity. Both identities are $\mathcal{O}_C$-(bi)linear in g,h, and $\mathcal{I}_{\mathfrak{P},C}$ is the $\mathcal{O}_C$-span of the stalk $\mathcal{I}_{\mathfrak{P},\mathfrak{q}}$ (Ox2); so it suffices to prove them for g,h in $\mathcal{I}_{\mathfrak{P}}(U)$, U an affine open neighbourhood of $\mathfrak{q}$, with θ_u in place of $\theta_{u,C}$. Let $\tilde{g},\tilde{h}$ be regular functions near the unit section e of $G'[\mathfrak{P}]\times U$ with values g,h, as in (Hf1).

Products. $\tilde{g}\tilde{h}$ has values gh, and $d(\tilde{g}\tilde{h}) = \tilde{g}\,d\tilde{h} + \tilde{h}\,d\tilde{g}$. The function $\tilde{g}\circ e$ on U has value $g(0) = 0$ at the generic point, so it is 0 ($\mathcal{O}(U) \subseteq \Omega'$); likewise $\tilde{h}\circ e = 0$. Hence $e^*d(\tilde{g}\tilde{h}) = 0$ and $\theta_u(gh) = 0$.

Equivariance. Let $a \in \mathbb{F}_{\mathfrak{P}}$. As $\mathcal{O}_E$ is dense in $\widehat{W}$, choose $\tilde{a} \in \mathcal{O}_E$ with $\tilde{a} - \omega(a) \in p\widehat{W}$; then $\tilde{a} \equiv a$ modulo $\mathfrak{P}$, so the endomorphism $[\tilde{a}]$ of $G'[\mathfrak{P}]$ acts on $\Gamma_{\mathfrak{P}}$ as multiplication by a, and $\sigma_u(\tilde{a}) - \chi_u(a) = \hat{\sigma}_u(\tilde{a} - \omega(a)) \in p\widehat{\mathcal{O}'} \cap \mathcal{O}' = p\,\mathcal{O}'$. The function $[\tilde{a}]^*\tilde{g}$ is regular near e ($[\tilde{a}]\circ e = e$) with values $x \mapsto g(ax)$, and $e^*d([\tilde{a}]^*\tilde{g}) = [\tilde{a}]^*(e^*d\tilde{g})$, where $[\tilde{a}]^*$ on $e^*\Omega^1_{G'[\mathfrak{P}]/\mathcal{X}'} = \omega_{G'}/\mathfrak{P}\,\omega_{G'}$ is induced by the action of $\tilde{a}$ on $\omega_{G'}$, which is multiplication by $\sigma_u(\tilde{a})$ on ω_u. Taking σ_u-isotypic components, $\theta_u(g(a\,\cdot)) = \sigma_u(\tilde{a})\,\theta_u(g) = \chi_u(a)\,\theta_u(g)$ in $\omega_u/p\,\omega_u$. □

Lemma D.108. *Let $\mathfrak{T}$, $(\mathfrak{q},C,\iota_C)$ be as in Proposition D.109, u a label and $\mathfrak{P} = \mathfrak{P}_u$. Every $g \in \mathcal{I}_{\mathfrak{P},C}$ with $g(ax) = \chi_u(a)g(x)$ for all $a \in \mathbb{F}_{\mathfrak{P}}$, $x \in \Gamma_{\mathfrak{P}}$, and $\theta_{u,C}(g) = 0$ lies in the $\mathcal{O}_C$-span of the products of two elements of $\mathcal{I}_{\mathfrak{P},C}$.*

Proof. Let u' be a label with $\mathfrak{P}_{u'} = \mathfrak{P}$, $u' \neq u$. The embeddings σ with $\sigma^{-1}(\mathfrak{m}_{\mathcal{O}'}) = \mathfrak{P}$ number $[E_{\mathfrak{P}} : \mathbb{Q}_p] = f = [\mathbb{F}_{\mathfrak{P}} : \mathbb{F}_p]$ (p is unramified in E), and $\sigma_u \circ \mathrm{Frob}_p^k$, $0 \le k < f$, are f distinct such embeddings; so $\sigma_{u'} = \sigma_u \circ \mathrm{Frob}_p^k$ with $0 < k < f$, and $\chi_{u'} = \chi_u^{p^k}$ (reduce modulo $\mathfrak{m}_{\mathcal{O}'}$, as in Definition 35.7). As χ_u is injective on $\mathbb{F}_{\mathfrak{P}}^\times$ (its reduction is $a \mapsto \sigma_u(\tilde{a})$ modulo $\mathfrak{m}_{\mathcal{O}'}$, an embedding of fields), and $a \mapsto a^{p^k}$ is not the identity of $\mathbb{F}_{\mathfrak{P}}$, there is $a \in \mathbb{F}_{\mathfrak{P}}^\times$ with $\chi_{u'}(a) \neq \chi_u(a)$; both are roots of unity of order prime to p, distinct modulo $\mathfrak{m}_{\mathcal{O}'}$, so $\chi_u(a) - \chi_{u'}(a)$ is a unit. By

Lemma D.107 and the eigen property,

$$\chi_u(a)\,\theta_{u',C}(g) = \theta_{u',C}(x \mapsto g(ax)) = \chi_{u'}(a)\,\theta_{u',C}(g),$$

hence $\theta_{u',C}(g) = 0$. With $\theta_{u,C}(g) = 0$, the hypothesis of Proposition D.109 holds, and g lies in the span of products. □

Proposition D.109. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97, $(\mathfrak{q}, C, \iota_C)$ a test point and $\mathfrak{P} \mid p$ a prime of $\mathcal{O}_E$. If $g \in \mathcal{I}_{\mathfrak{P},C}$ and $\theta_{u,C}(g) = 0$ for every label u with $\mathfrak{P}_u = \mathfrak{P}$, then g lies in the $\mathcal{O}_C$-span of the products of two elements of $\mathcal{I}_{\mathfrak{P},C}$.*

Proof. As in the setting of Proposition D.97, p is unramified in E. Let $U_{\mathfrak{P}}$ be the set of labels u with $\mathfrak{P}_u = \mathfrak{P}$, $q = q_{\mathfrak{P}}$, $N = \Gamma_{\mathfrak{P}}$, and $R = R_{\mathfrak{q}}$: a discrete valuation ring ($\mathcal{X}'$ is normal and $\mathfrak{q}$ has codimension one) whose maximal ideal contains p, with fraction field Ω'.

Step 0: ranks. By (Ud6) F contains $\tau(E)$ for every embedding τ, and $F \subseteq F'$. The map $\mathcal{O}_E \otimes_{\mathbb{Z}} \mathcal{O}' \to \prod_{\sigma \in \mathrm{Hom}(E,F)} \mathcal{O}'$, $a \otimes x \mapsto (\sigma(a)x)_\sigma$, is a map of free $\mathcal{O}'$-modules of rank $[E : \mathbb{Q}]$ whose determinant (in an integral basis of $\mathcal{O}_E$) has square the discriminant of E, a unit in $\mathcal{O}'$ because p is unramified in E and every other prime is invertible in $\mathcal{O}'$; so it is an isomorphism. Hence the locally free $\mathcal{O}_E \otimes \mathcal{O}_{\mathcal{X}'}$-module $\omega_{G'} = \pi^*\omega_{G_{\mathcal{X}}}$ is the direct sum of its eigensubsheaves ω_u over all labels u (the labels correspond bijectively to $\mathrm{Hom}(E, F)$), and each ω_u is locally free. Put $d_{\mathfrak{P}} = \sum_{u \in U_{\mathfrak{P}}} \mathrm{rk}\,\omega_u$. By (Hf1), $\omega_{G'}/\mathfrak{P}\omega_{G'} = \bigoplus_{u \in U_{\mathfrak{P}}} \omega_u/p\,\omega_u$, so its stalk at $\mathfrak{q}$ is a free R/pR-module of rank $d_{\mathfrak{P}}$.

Step 1: the order commutes with flat base change. Let $S \to S'$ be a flat homomorphism of noetherian domains with fraction fields L, L' such that $L \otimes_S S' = L'$, and let H over S, the finite group T and the points $x_t \in H(L)$ be as in Definition 35.21; then $H_{S'}$ satisfies the same hypotheses with the same T and points. For an open $V \subseteq H$ the map $\mathcal{O}(V) \to \mathcal{O}(V_L)$ is injective (H is flat over the domain S), and V_L is the disjoint union of the points $x_t \in V$, each $\mathrm{Spec}\,L$; so sections over V are determined by their values at these points, local sections with prescribed values glue, and $f\colon T \to S$ is regular on H if and only if $f \in \mathrm{Reg}(H) = \mathrm{ev}(\mathcal{O}(H)) \cap \mathrm{Map}(T, S)$, where $\mathrm{ev}\colon \mathcal{O}(H) \to \mathrm{Map}(T, L)$ is the injective evaluation map. Flat base change gives $\mathcal{O}(H_{S'}) = \mathcal{O}(H) \otimes_S S'$ (H is quasi-compact and separated), and $\mathrm{Map}(T, L) \otimes_S S' = \mathrm{Map}(T, L')$. As S' is flat, intersections of submodules of $\mathrm{Map}(T, L)$ commute with $- \otimes_S S'$, so $\mathrm{Reg}(H_{S'}) = S'\,\mathrm{Reg}(H)$ (the S'-span in $\mathrm{Map}(T, L')$). The set of f all of whose translates are regular is the finite intersection $\bigcap_{t'} \tau_{t'}^{-1}\mathrm{Reg}(H)$, $\tau_{t'} f = f(t' + \cdot)$; it is an S-subalgebra (sums, products and translates of regular functions are regular, constants are regular), hence equal to $\mathrm{Ord}(H)$, and the same argument gives $\mathrm{Ord}(H_{S'}) = S'\,\mathrm{Ord}(H) \cong S' \otimes_S \mathrm{Ord}(H)$.

Let U be an affine open neighbourhood of $\mathfrak{q}$. By (Hf1), $\mathcal{A}_{\mathfrak{P}}(U) = \mathrm{Ord}(G'[\mathfrak{P}] \times_{\mathcal{X}'} U)$, and $\mathcal{A}_{\mathfrak{P}}$ is quasi-coherent (locally free by (Ts3)); by Step 1 for $\mathcal{O}(U) \to R$, $\mathcal{A}_{\mathfrak{P},\mathfrak{q}} = \mathrm{Ord}(G'[\mathfrak{P}]_R)$. Let $\widehat{R}$ be the completion of R, a complete discrete valuation ring with fraction field $\widehat{K} = \Omega' \otimes_R \widehat{R}$, faithfully flat over R. By Step 1, $\mathcal{O} := \mathrm{Ord}(\Gamma) \cong \widehat{R} \otimes_R \mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ for $\Gamma = G'[\mathfrak{P}]_{\widehat{R}}$.

Step 2: the order over $\widehat{R}$ and its cotangent module. By (Fh5) the generic point of $\mathcal{X}'$ (a cover through $f \circ \pi$) maps to a point of $j(\mathrm{Sh}_F)$, over which $G_{\mathcal{Y}}$ is abelian (Ud7); so $G'_{\widehat{R}}$ is a semiabelian scheme with abelian generic fibre and $\mathcal{O}_E$-action over the complete noetherian normal local domain $\widehat{R}$, whose maximal ideal contains p. By Lemma 35.30, Γ is quasi-finite and flat, its finite part $W = \Gamma^f$ is a finite locally free subgroup scheme, and $\omega_W \cong \omega_{G'_{\widehat{R}}}/\mathfrak{P}\,\omega_{G'_{\widehat{R}}} = (\omega_{G'}/\mathfrak{P}\omega_{G'})_{\mathfrak{q}} \otimes_R \widehat{R}$, free of rank $d_{\mathfrak{P}}$ over $\widehat{R}/p\widehat{R}$ (Step 0). By definition of the finite part over the henselian ring $\widehat{R}$ (EGA IV$_4$ 18.5.11; Stacks Project, Tag 04GG), $\Gamma = W \sqcup \Gamma'$ with Γ' open and closed and without points over the closed point. As $\mathrm{Spec}\,\widehat{R}$ has two points, Γ' is an open

subscheme of $\Gamma_{\widehat{K}}$, the constant scheme with points x_t, $t \in N$ (Ts3). Let $N^f = \{t : \ x_t \in W\}$, a subgroup, and $B_W = \mathcal{O}(W)$, finite free over $\widehat{R}$.

1. Each x_t, $t \in N^f$, extends to an $\widehat{R}$-point y_t of W: the image of B_W under x_t^* is integral over the normal ring $\widehat{R}$. So evaluation $\rho\colon B_W \to \mathrm{Map}(N^f, \widehat{R})$ is defined, injective (as in Step 1), and $\rho(B_W)$ is stable under $b \mapsto b(t' + \cdot)$ for $t' \in N^f$ (translation by $y_{t'}$ is an automorphism of W).

2. A function $f\colon N \to \widehat{R}$ is regular on Γ if and only if $f|_{N^f} \in \rho(B_W)$: near points of W use W itself (open) and gluing as in Step 1; the points of Γ' are open points $\operatorname{Spec}\widehat{K}$, on which every value is regular.

3. Hence $\mathcal{O} = \{f : \ f(t' + \cdot)|_{N^f} \in \rho(B_W) \text{ for all } t' \in N\}$. With coset representatives $t_1 = 0, t_2, \ldots, t_k$ of N^f in N, $f \mapsto (f(t_j + \cdot)|_{N^f})_j$ is an isomorphism of $\widehat{R}$-algebras $\mathcal{O} \to \rho(B_W)^k$ (surjective: by (1) the condition for $t' \in t_j + N^f$ follows from that for t_j), under which $f \mapsto f(0)$ is evaluation at 0 in the first factor.

4. So $I_{\mathcal{O}} = \{f \in \mathcal{O} : \ f(0) = 0\}$ corresponds to $I_W \times B_W^{k-1}$, I_W the augmentation ideal of the unit section, and $I_{\mathcal{O}}^2$ to $I_W^2 \times B_W^{k-1}$ (each factor $j \geq 2$ contains its unit idempotent, which lies in $I_{\mathcal{O}}$). Therefore $I_{\mathcal{O}}/I_{\mathcal{O}}^2 \cong I_W/I_W^2 \cong e^*\Omega^1_{W/\widehat{R}} = \omega_W \cong (\widehat{R}/p\widehat{R})^{d_{\mathfrak{P}}}$.

Step 3: descent to R and base change to $\mathcal{O}_C$. Write $\mathcal{A}_{\mathfrak{P},\mathfrak{q}} = R \cdot 1 \oplus \mathcal{I}_{\mathfrak{P},\mathfrak{q}}$ and $M = \mathcal{I}_{\mathfrak{P},\mathfrak{q}}/\mathcal{I}^2_{\mathfrak{P},\mathfrak{q}}$. Under $\mathcal{O} \cong \widehat{R} \otimes_R \mathcal{A}_{\mathfrak{P},\mathfrak{q}}$, $I_{\mathcal{O}} = \widehat{R} \otimes \mathcal{I}_{\mathfrak{P},\mathfrak{q}}$ and $I_{\mathcal{O}}^2$ is the image of $\widehat{R} \otimes \mathcal{I}^2_{\mathfrak{P},\mathfrak{q}}$; by right exactness $\widehat{R} \otimes_R M \cong (\widehat{R}/p\widehat{R})^{d_{\mathfrak{P}}}$. By faithful flatness $pM = 0$, and as $R/pR \to \widehat{R}/p\widehat{R}$ is an isomorphism, $M \cong \widehat{R} \otimes_R M \cong (R/pR)^{d_{\mathfrak{P}}}$. By (Ox2), $\mathcal{A}_{\mathfrak{P},C} = \mathcal{O}_C \otimes_R \mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ and $\mathcal{I}_{\mathfrak{P},C} = \mathcal{O}_C \otimes_R \mathcal{I}_{\mathfrak{P},\mathfrak{q}}$; the span of products is the image of $\mathcal{O}_C \otimes \mathcal{I}^2_{\mathfrak{P},\mathfrak{q}}$, so $\mathcal{I}_{\mathfrak{P},C}/\mathcal{I}^2_{\mathfrak{P},C} \cong \mathcal{O}_C \otimes_R M \cong (\mathcal{O}_C/p\mathcal{O}_C)^{d_{\mathfrak{P}}}$, where $\mathcal{I}^2_{\mathfrak{P},C}$ denotes the $\mathcal{O}_C$-span of the products of two elements of $\mathcal{I}_{\mathfrak{P},C}$.

Step 4: the cotangent maps at the labels over $\mathfrak{P}$ are jointly onto. Let $\Omega_{\mathfrak{P}} = \bigoplus_{u \in U_{\mathfrak{P}}} \mathcal{O}_C \otimes_R (\omega_u/p\,\omega_u)_{\mathfrak{q}} \cong (\mathcal{O}_C/p\mathcal{O}_C)^{d_{\mathfrak{P}}}$ (Step 0) and $\theta_{\mathfrak{P}} = (\theta_{u,C})_{u \in U_{\mathfrak{P}}}\colon \mathcal{I}_{\mathfrak{P},C} \to \Omega_{\mathfrak{P}}$. By Lemma D.107, $\theta_{\mathfrak{P}}$ vanishes on $\mathcal{I}^2_{\mathfrak{P},C}$. Each $\theta_{u,C}$ is onto: θ_u is onto by (Ts3), hence so is its stalk at $\mathfrak{q}$, and $\mathcal{O}_C \otimes_R -$ is right exact. Let $u \neq u'$ in $U_{\mathfrak{P}}$. The embeddings σ with $\sigma^{-1}(\mathfrak{m}_{\mathcal{O}'}) = \mathfrak{P}$ number $[E_{\mathfrak{P}} : \mathbb{Q}_p] = f = [\mathbb{F}_{\mathfrak{P}} : \mathbb{F}_p]$ (p unramified), and $\sigma_u \circ \mathrm{Frob}_p^k$, $0 \leq k < f$, are f distinct ones, so $\sigma_{u'} = \sigma_u \circ \mathrm{Frob}_p^k$ with $0 < k < f$ and $\chi_{u'} = \chi_u^{p^k}$; as χ_u is injective on $\mathbb{F}_{\mathfrak{P}}^\times$ (its reduction is a field embedding) and $a \mapsto a^{p^k}$ is not the identity of $\mathbb{F}_{\mathfrak{P}}$, the homomorphism $\psi = \chi_u^{-1}\chi_{u'}\colon \mathbb{F}_{\mathfrak{P}}^\times \to \mathcal{O}'^\times$ is non-trivial, and $\sum_{a \in \mathbb{F}_{\mathfrak{P}}^\times} \psi(a) = 0$ (multiply by $\psi(b) \neq 1$; $\mathcal{O}'$ is a domain). For $g \in \mathcal{I}_{\mathfrak{P},C}$ put

$$e_u(g)(x) = \frac{1}{q-1} \sum_{a \in \mathbb{F}_{\mathfrak{P}}^\times} \chi_u(a)^{-1} g(ax);$$

$q - 1$ is prime to p, and $e_u(g) \in \mathcal{I}_{\mathfrak{P},C}$ because $\mathcal{A}_{\mathfrak{P},C}$ is $\mathbb{F}_{\mathfrak{P}}$-stable (Proposition D.98). By Lemma D.107, $\theta_{u',C}(e_u(g)) = \frac{1}{q-1} \sum_a \chi_u(a)^{-1}\chi_{u'}(a)\, \theta_{u',C}(g)$, which is $\theta_{u,C}(g)$ for $u' = u$ and 0 for $u' \neq u$. Given $(w_u)_u \in \Omega_{\mathfrak{P}}$, choose g_u with $\theta_{u,C}(g_u) = w_u$; then $\theta_{\mathfrak{P}}\big(\sum_u e_u(g_u)\big) = (w_u)_u$.

Step 5: conclusion. By Steps 3 and 4, $\theta_{\mathfrak{P}}$ induces a surjective $\mathcal{O}_C/p\mathcal{O}_C$-linear map $\bar{\theta}$ from $\mathcal{I}_{\mathfrak{P},C}/\mathcal{I}^2_{\mathfrak{P},C}$ to $\Omega_{\mathfrak{P}}$, between free modules of the same rank $d_{\mathfrak{P}}$ over the local ring $\mathcal{O}_C/p\mathcal{O}_C$. It splits, as the target is free; its kernel K is a direct summand, hence finitely generated, and comparing dimensions after tensoring with the residue field gives $K \otimes k = 0$, so $K = 0$ by Nakayama's lemma. Hence $\bar{\theta}$ is injective: if $g \in \mathcal{I}_{\mathfrak{P},C}$ and $\theta_{u,C}(g) = 0$ for every $u \in U_{\mathfrak{P}}$, then $g \in \mathcal{I}^2_{\mathfrak{P},C}$, the $\mathcal{O}_C$-span of the products of two elements of $\mathcal{I}_{\mathfrak{P},C}$. □

D.5.2 Hodge–Tate comparison at test points

Proposition D.110 gives the Hodge–Tate facts at test points: every point of codimension one at which p is not a unit is the first entry of a test point at which the Hodge–Tate conditions of Proposition D.97 hold. The lemmas compute the Hodge–Tate and Weil matrices of the p-torsion at such a point (Lemma D.114), place the Weil pairing in the tensor square of the test-point order (Lemma D.115), and derive the flag conditions from the flag theorem for tight Hopf orders of Section 35 (Lemma D.122).

Proposition D.110. *Let $\mathcal{T}, \dots, \lambda$, $\mathfrak{T}$, R, w and, for every $a \in \Phi$, $\beta, \bar{\beta}$ and the Hodge–Tate atlas $(U_\nu, \iota_\nu, h_\nu)_\nu$ be as in the hypotheses of Proposition D.97. Then every point $\mathfrak{q}$ of $\mathcal{X}'$ of codimension one at which p is not a unit is the first entry of a test point $(\mathfrak{q}, C, \iota_C)$ such that:*

1. *for every $a \in \Phi$, with $s = (a, +)$, (F0)–(F2) hold for the $\mathcal{O}_C$-spans of the stalks at $\mathfrak{q}$ of the Hodge–Tate lattice family of a, and $\mathcal{O}_C J_{i,\mathfrak{q}} = \mathcal{O}_C\, \mathcal{O}_{\mathcal{X}'}(-\mathrm{Ec}_{s,i})_{\mathfrak{q}}$ for $1 \le i \le m_{\mathfrak{P}_s}$.*

Proof. Let $\mathfrak{q}$ be a point of $\mathcal{X}'$ of codimension one at which p is not a unit, and let $(\mathfrak{q}, C, \iota_C)$ be the test point given by Proposition D.111. For every $a \in \Phi$, with $s = (a, +)$, that proposition gives (F1), (F2) for the $\mathcal{O}_C$-spans of the stalks at $\mathfrak{q}$ of the Hodge–Tate lattice family of a, and Lemma D.122 (at every test point, with the same hypotheses) gives $\mathcal{O}_C J_{i,\mathfrak{q}} = \mathcal{O}_C\, \mathcal{O}_{\mathcal{X}'}(-\mathrm{Ec}_{s,i})_{\mathfrak{q}}$ for $1 \le i \le m_{\mathfrak{P}_s}$. (F0) for these spans, $\mathcal{O}_C H_{\mathfrak{q}} \subseteq w^{-1}\mathcal{O}_C T_{\mathfrak{q}}$, holds at every test point by Lemma D.121, whose hypotheses are those of Proposition D.97 ($\mathfrak{T}$ torsion-regular and pre-admissible, $w^{p-1} = u\,p$ with $u \in \mathcal{O}'^{\times}$). □

Proposition D.111. *Let $\mathcal{T}, \dots, \lambda$, $\mathfrak{T}$, R, w and, for every $a \in \Phi$, $\beta, \bar{\beta}$ and the Hodge–Tate atlas $(U_\nu, \iota_\nu, h_\nu)_\nu$ be as in the hypotheses of Proposition D.97. Then every point $\mathfrak{q}$ of $\mathcal{X}'$ of codimension one at which p is not a unit is the first entry of a test point $(\mathfrak{q}, C, \iota_C)$ such that for every $a \in \Phi$, with $s = (a, +)$: (F1) and (F2) hold for the $\mathcal{O}_C$-spans of the stalks at $\mathfrak{q}$ of the Hodge–Tate lattice family of a (with K, I formed from the spans of $\Gamma_{\mathfrak{q}}$, $\Delta_{\mathfrak{q}}$, $H_{\mathfrak{q}}$).*

Proof. Let $\mathfrak{q}$ be a point of $\mathcal{X}'$ of codimension one with $p \notin \mathcal{O}_{\mathfrak{q}}^{\times}$, and $R_{\mathfrak{q}} = \mathcal{O}_{\mathcal{X}',\mathfrak{q}}$.

Step 0: the test point. Let C, $\mathcal{O}_C$ be as in Definition 35.37 for the cover $\mathcal{X}'$ at $\mathfrak{q}$ (with $\ell = p$, $N = p^R$): C is the completion of an algebraic closure of $\widehat{K} = \mathrm{Frac}(\widehat{\mathcal{O}}_{\mathfrak{q}})$, with the fixed embedding of an algebraic closure of Ω' over $\Omega' \subseteq \widehat{K}$, and let $\iota_C \colon \Omega' \to C$ be its restriction. C is algebraically closed of characteristic 0, complete, and $|p| < 1$ as $p \in \mathfrak{m}_{\mathfrak{q}}$. The absolute value of C restricts to that of the complete discretely valued field $\widehat{K}$, so $\mathcal{O}_C \cap \widehat{K} = \widehat{\mathcal{O}}_{\mathfrak{q}}$, and $\widehat{\mathcal{O}}_{\mathfrak{q}} \cap \Omega' = R_{\mathfrak{q}}$. Hence $\iota_C^{-1}(\mathcal{O}_C) = R_{\mathfrak{q}}$ and $(\mathfrak{q}, C, \iota_C)$ is a test point (Ox1). We prove (F1), (F2) at it for every $a \in \Phi$.

Step 1: data. Fix $a \in \Phi$, $s = (a, +)$, $\bar{s} = (a, -)$, $\kappa = \mathrm{rk}(s)$, $\mathfrak{P} = \mathfrak{P}_s$, $m = m_{\mathfrak{P}}$, $\sigma = \sigma_s$, the atlas $(U_\nu, \iota_\nu, h_\nu)_\nu$ of the hypothesis with its points y, and ν with $\mathfrak{q} \in U_\nu$; write $(\iota, h) = (\iota_\nu, h_\nu)$, with forms $\eta_1, \dots, \eta_m$, and also for the C-linear extensions. Fix (ϖ_k), (ϖ_k^*), I, $x_{(l,k)}$, $\mathbf{P}$, $\mathbf{J}$ as in Lemma D.117. Let $\zeta \in \Omega'$ be the primitive p^R-th root of unity of (Hm5) and ε, g_{lj}, $\mathbf{E}_\varepsilon$ as in Lemma D.119; choose the compatible system of Definition 35.37 with $\zeta_{p^R} = \zeta$ (successive p-th roots above level R, $\zeta_{p^k} = \zeta^{p^{R-k}}$ below), so $\zeta_p = \zeta^{p^{R-1}}$. Let $g = \dim \mathrm{Lie}(G'_{\Omega'})$, $w_1, \dots, w_g$ an $R_{\mathfrak{q}}$-basis of $\omega_{\mathfrak{q}}$, and Λ, $\bar{\Lambda}$ as in Lemma D.119.

Step 2: the Hodge–Tate and Weil matrices. By Lemma D.114 (cover $\mathcal{X}'$, point $\mathfrak{q}$, the basis $(x_j)_{j \in I}$ of N from Lemma D.117, the basis (w_i)) there are $\mathbf{h} \in M_{g \times I}(\mathcal{O}_C)$, $\mathbf{e} \in \mathrm{GL}_I(\mathbb{Z}_p)$, $\mathbf{e}_0 \in M_I(\mathbb{Z})$ with (1)–(3) there. Moreover $\mathbf{e} - \mathbf{E}_\varepsilon \in p\, M_I(\mathbb{Z}_p)$: for $j = (l, k)$, j' in I put $\tilde{x}_j = \varpi_k y_l$,

so $x_j = p^{R-1}\tilde{x}_j$; then

$$\zeta_p^{(\mathbf{e}_0)_{jj'}} = e_p(x_j, x_{j'}) = e_{p^R}(\tilde{x}_j, x_{j'}) = e_{p^R}(\tilde{x}_j, \tilde{x}_{j'})^{p^{R-1}} = \zeta_p^{\varepsilon(\tilde{x}_j, \tilde{x}_{j'})},$$

so $(\mathbf{e}_0)_{jj'} \equiv (\mathbf{E}_\varepsilon)_{jj'}$ modulo p, and $\mathbf{e} \equiv \mathbf{e}_0$ modulo p.

Step 3: B is a tight Hopf order on N. By Proposition D.98 each $\mathcal{A}_{\mathfrak{P}',C}$ is a tight Hopf order on $\Gamma_{\mathfrak{P}'}$. Applying Lemma D.106 to the factors one at a time, B is a Hopf order on $N = \bigoplus_{\mathfrak{P}'} \Gamma_{\mathfrak{P}'}$, and tightness passes from two tight factors B_1, B_2 on N_1, N_2 to $B_1 \boxtimes B_2$ by its additivity formulas:

$$\begin{aligned} |N|(p-1)\mathrm{len}_C(Q_B) &= |N_2| \cdot |N_1|(p-1)\mathrm{len}_C(Q_{B_1}) + |N_1| \cdot |N_2|(p-1)\mathrm{len}_C(Q_{B_2}) \\ &= 2|N_2|\mathrm{colen}(B_1) + 2|N_1|\mathrm{colen}(B_2) = 2\,\mathrm{colen}(B), \end{aligned}$$

and in the same way $|N|\,\mathrm{len}_C(I_B/I_B^2) = 2\,\mathrm{colen}(B)$.

Step 4: the almost-additive lattice of B. Identify N with $\mathbb{F}_p^I$ by $x \mapsto \hat{x}$. We apply Lemma D.112 with B (Step 3), the primitive p-th root of unity $\zeta_C = \iota_C(\zeta_p)$, the matrices $\mathbf{h}, \mathbf{e}, \mathbf{e}_0$ (Step 2: $\mathbf{e}^\mathsf{T} = -\mathbf{e}$, $\mathbf{h}\mathbf{e}^{-1}\mathbf{h}^\mathsf{T} = 0$, $\mathbf{e} - \mathbf{e}_0 \in pM_I(\mathbb{Z}_p)$, $\mathbf{e} \in \mathrm{GL}_I(\mathcal{O}_C)$), and D the map of Lemma D.116(1) followed by the isomorphism $\mathcal{O}_C \otimes (\omega_\mathfrak{q}/p\,\omega_\mathfrak{q}) \cong (\mathcal{O}_C/p)^g$ of the basis (w_i). (Wb1): by Lemma D.115(1) for the polarisation $\phi_\mathcal{L}$ of $G'_{\Omega'}$, $(z, z') \mapsto \iota_C(e_p(z, z'))$ lies in the $\mathcal{O}_C$-span of the $f \otimes f'$, $f, f' \in B$, and $\iota_C(e_p(z, z')) = \zeta_C^{\hat{z}^\mathsf{T}\mathbf{e}_0\hat{z}'}$ by Lemma D.114(1). (Wb2) is Lemma D.116(1). (Wb3): for $x \in N$ choose $y' \in G'(\Omega')[p^R]$ with $p^{R-1}y' = x$ ($G'(\Omega')[p^R] \cong (\mathbb{Z}/p^R)^{2g}$) and a Hodge–Tate value v' of y' at $\mathfrak{q}$ (Lemma 31.30(1)); the character $\chi_x = \iota_C(e_p(x, \cdot))$ is that of Lemma D.116, and by Lemma D.116(2) and Lemma D.114(3), $D(\chi_x) = [v'] \bmod p = \mathbf{h}\hat{x} \bmod p$. The lattice $\mathrm{af}(B)$ of Lemma D.112 equals $\mathrm{af}(B)$ of Lemma D.117: if $\lambda_l = f + pf'$ with $f \in B$, then f is almost additive because λ_l is $(\widehat{x + x'} - \hat{x} - \hat{x}' \in p\mathbb{Z}^I)$, so $f \in \mathrm{AF}(B)$. Hence Lemma D.112(1)–(6) hold for $\mathrm{af}(B)$, with $c = \sum_{k=1}^{p-1}(-1)^{k-1}(\zeta_C - 1)^k/k$, $v(c) = \frac{1}{p-1} = v(w)$.

Step 5: the lattices at $\mathfrak{q}$. Every integer prime to p is a unit of $R_\mathfrak{q}$, so the discriminant of E is, and $\sigma_t(\mathcal{O}_E) \subseteq \mathcal{O}' \subseteq R_\mathfrak{q}$ for every label t; the idempotents of $\mathcal{O}_E \otimes R_\mathfrak{q} \cong \prod_t R_\mathfrak{q}$ (Fh1) split the free module $\mathrm{Lie}_\mathfrak{q}$ as $\bigoplus_t(\mathrm{Lie}_\mathfrak{q} \cap \mathrm{Li}_t)$, so $\mathrm{dR}_{s,\mathfrak{q}}$ and $\mathrm{dR}_{\bar{s},\mathfrak{q}}$ are free direct summands of $\mathrm{Lie}_\mathfrak{q}$; the same holds over a neighbourhood of $\mathfrak{q}$ on which the discriminant is invertible. A germ in $\mathrm{Lie}_\mathfrak{q}$ is a section of $\mathrm{Lie}(G')$ near $\mathfrak{q}$, so the stalks of the sheaves of (Hf2) are $\mathrm{lie}_\mathfrak{q} = \{c : \sum_k c_k\beta_k \in \mathrm{dR}_{s,\mathfrak{q}}\}$ and $\bar{\mathrm{l}}_\mathfrak{q} = \{c : \sum_k c_k\bar{\beta}_k \in \mathrm{dR}_{\bar{s},\mathfrak{q}}\}$, and, $\bar{\mathrm{l}}$ being locally free near $\mathfrak{q}$, $\omega_\mathfrak{q}$ is the dual lattice of $\bar{\mathrm{l}}_\mathfrak{q}$. Write X_C for the $\mathcal{O}_C$-span of a stalk $X_\mathfrak{q}$.

1. $\mathrm{lie}_C = \{a \in C^\kappa : \Lambda a \in \mathcal{O}_C^g\}$. For $a \in C^\kappa$ and $A = \sum_k a_k\beta_k$: as $\mathrm{dR}_{s,\mathfrak{q}}$ is a direct summand of $\mathrm{Lie}_\mathfrak{q}$, $A \in \mathcal{O}_C\mathrm{dR}_{s,\mathfrak{q}}$ iff $A \in \mathcal{O}_C\mathrm{Lie}_\mathfrak{q}$ iff $w_i(A) \in \mathcal{O}_C$ for all i ((w_i) is the dual basis of a basis of $\mathrm{Lie}_\mathfrak{q}$), i.e. iff $\Lambda a \in \mathcal{O}_C^g$.

2. $\omega_C = \bar{\Lambda}^\mathsf{T}\mathcal{O}_C^g$. The dual lattice of $\bar{\mathrm{l}}_\mathfrak{q}$ is $\{(\varphi(\bar{\beta}_r))_r : \varphi \in \mathrm{Hom}_{R_\mathfrak{q}}(\mathrm{dR}_{\bar{s},\mathfrak{q}}, R_\mathfrak{q})\}$ (to c corresponds $\varphi(\sum_r c'_r\bar{\beta}_r) = c \cdot c'$), every such φ is the restriction of some $\eta = \sum_i u_i w_i \in \omega_\mathfrak{q}$ (direct summand), and $(\eta(\bar{\beta}_r))_r = \bar{\Lambda}^\mathsf{T}u$. So $\omega_\mathfrak{q} = \bar{\Lambda}^\mathsf{T}R_\mathfrak{q}^g$.

3. By (Hm1), $\mathrm{lie}_C \subseteq W_C$, $wW_C \subseteq \mathrm{lie}_C$, $\omega'_C \subseteq \omega_C$ and $\mathcal{O}_C^m = T_C \subseteq H_C$; by Lemma D.121, $H_C \subseteq w^{-1}\mathcal{O}_C^m$ (F0); by Lemma D.117(4), $H_C = \{u \in C^m :\ l\mathbf{J}u \in \mathcal{O}_C \text{ for all } l \in \mathrm{af}(B)\}$.

Step 6: $\iota^{-1}(\mathcal{O}_C^m) = W_C$. By (Hm4) at $\mathfrak{q}$, $\iota(W_\mathfrak{q}) \subseteq R_\mathfrak{q}^m$ and $W_\mathfrak{q}/wW_\mathfrak{q} \to R_\mathfrak{q}^m/wR_\mathfrak{q}^m$ is injective. $W_\mathfrak{q}$ is free (Hm1), so $W_C = \mathcal{O}_C \otimes W_\mathfrak{q}$, and by flatness $\iota(W_C) \subseteq \mathcal{O}_C^m$ and $W_C \cap \iota^{-1}(w\mathcal{O}_C^m) = wW_C$. Let $a \in C^\kappa$ with $\iota(a) \in \mathcal{O}_C^m$. As W_C has a C-basis of C^κ as $\mathcal{O}_C$-basis and $v(w) > 0$, $w^k a \in W_C$ for some $k \geq 0$; take k minimal. If $k \geq 1$, then $\iota(w^k a) = w^k\iota(a) \in w\mathcal{O}_C^m$, so $w^k a \in wW_C$ and $w^{k-1}a \in W_C$, against minimality. So $a \in W_C$.

Step 7: the images of H_C. We apply Lemma D.120 with AF = af(B), $\mathbf{h}$, $\mathbf{e}$, c, w, $\mathbf{P}$, $\mathbf{J}$, $r=\kappa$, $r'=n-\kappa$, Λ, $\bar\Lambda$, $W=W_C$ and the maps h, ι. Its hypotheses: (1)–(5) are Lemma D.112(1), (2), (3), (4), (6) (Step 4); $\mathbf{PJ}=\mathbf{1}$ and the stability of af(B) are Lemma D.117(1), (3); its H is H_C and its lie is lie$_C$ (Step 5); lie$_C\subseteq W_C$, $wW_C\subseteq$ lie$_C$ (Step 5). (6): the column of $\mathbf{P}$ of index (l,k) is $\sigma(\varpi_k)e_l$, so this is Lemma D.119(1), whose hypothesis on $\mathbf{h}$ is Lemma D.114(3). (7) is Step 6. (8): let $a\in W_\mathfrak{q}$. Then $w\sum_k a_k\beta_k\in \mathrm{dR}_{s,\mathfrak{q}}\subseteq \mathrm{Lie}_\mathfrak{q}$ ($W\subseteq w^{-1}$lie, Step 5), $\iota(a)\in R^m_\mathfrak{q}$ (Hm4), and a is a section of W over an open $U'\subseteq U_\nu$ containing $\mathfrak{q}$, so (Hm5) gives $\sum_l \iota(a)_l g_{lj}-\eta_j(\sum_k a_k\beta_k)\in p^{R-2}R_\mathfrak{q}$; as $R\geq 4$, Lemma D.119(2) gives $\mathbf{E}_\varepsilon\mathbf{J}\iota(a)+\mathbf{h}^\mathsf{T}\Lambda a\in w\mathcal{O}_C^I$, and $(\mathbf{e}-\mathbf{E}_\varepsilon)\mathbf{J}\iota(a)\in p\,\mathcal{O}_C^I\subseteq w\mathcal{O}_C^I$ by Step 2. Both sides being $\mathcal{O}_C$-linear in a, (8) holds on W_C. Therefore

$$h(H_C)=\bar\Lambda^\mathsf{T}\mathcal{O}_C^g=\omega_C,\qquad \iota^{-1}(H_C)=w^{-1}\mathrm{lie}_C.$$

Step 8: (F1) and (F2). By (Hm4) the stalks of the graphs at $\mathfrak{q}$ are $\Gamma_\mathfrak{q}=\{(c,d): wc\in W_\mathfrak{q},\ d-\iota(c)\in R^m_\mathfrak{q}\}$ and $\Delta_\mathfrak{q}=\{(d,e): wd\in R^m_\mathfrak{q},\ e-h(d)\in\omega'_\mathfrak{q}\}$. The C-linear automorphism $(c,d)\mapsto(wc,d-\iota(c))$ maps $\Gamma_\mathfrak{q}$ onto $W_\mathfrak{q}\oplus R^m_\mathfrak{q}$, so $\mathcal{O}_C\Gamma_\mathfrak{q}=\{(c,d): wc\in W_C,\ d-\iota(c)\in\mathcal{O}_C^m\}$, and likewise $\mathcal{O}_C\Delta_\mathfrak{q}=\{(d,e): wd\in\mathcal{O}_C^m,\ e-h(d)\in\omega'_C\}$. With K and I formed from these spans and H_C: since $\mathcal{O}_C^m\subseteq H_C$, $K=\{c:\ wc\in W_C,\ \iota(c)\in H_C\}$; and if $\iota(c)\in H_C\subseteq w^{-1}\mathcal{O}_C^m$, then $\iota(wc)\in\mathcal{O}_C^m$ and $wc\in W_C$ by Step 6. So $K=\iota^{-1}(H_C)=w^{-1}\mathrm{lie}_C$ by Step 7: this is (F1). By (F0), $wd\in\mathcal{O}_C^m$ for every $d\in H_C$, so $I=h(H_C)+\omega'_C=\omega_C+\omega'_C=\omega_C$ by Step 7 and $\omega'_C\subseteq\omega_C$: this is (F2). □

Lemma D.112. *Let p be an odd prime, $g\geq 1$ and $N=\mathbb{F}_p^{2g}$. For $z\in N$ let $\hat z\in\{0,\dots,p-1\}^{2g}\subseteq\mathcal{O}_C^{2g}$ be its representative; for a row vector $l\in\mathcal{O}_C^{2g}$ let $\lambda_l(z)=l\hat z$, and put*

$$\mathrm{af}(B)=\{l:\ \lambda_l\in\mathrm{AF}(B)+p\,\mathrm{Map}(N,\mathcal{O}_C)\}.$$

Let B be a tight Hopf order on N, $\zeta\in C$ a primitive p-th root of unity and $c=\sum_{k=1}^{p-1}(-1)^{k-1}(\zeta-1)^k/k$. Let $\mathbf{h}\in M_{g\times 2g}(\mathcal{O}_C)$, $\mathbf{e}\in\mathrm{GL}_{2g}(\mathcal{O}_C)$ with $\mathbf{e}^\mathsf{T}=-\mathbf{e}$ and $\mathbf{h}\,\mathbf{e}^{-1}\mathbf{h}^\mathsf{T}=0$, and $\mathbf{e}_0\in M_{2g}(\mathbb{Z})$ with $\mathbf{e}-\mathbf{e}_0\in pM_{2g}(\mathcal{O}_C)$. Assume:

(Wb1) *the function $K(z,z')=\zeta^{\hat z^\mathsf{T}\mathbf{e}_0\hat z'}$ on $N\times N$ lies in the $\mathcal{O}_C$-span of the functions $(z,z')\mapsto f(z)f'(z')$, $f,f'\in B$ (so each $\chi_x=K(x,\cdot)$, $x\in N$, lies in B: if $K=\sum_i f_i\otimes f'_i$ then $\chi_x=\sum_i f_i(x)f'_i$ with $f_i(x)\in\mathcal{O}_C$);*

(Wb2) *$D\colon B\to(\mathcal{O}_C/p)^g$ is a surjective $\mathcal{O}_C$-linear derivation at the origin: $D(ff')=f(0)D(f')+f'(0)D(f)$;*

(Wb3) *$D(\chi_x)=\mathbf{h}\hat x \bmod p$ for every $x\in N$.*

Then $v(c)=\frac{1}{p-1}$, and:

1. *$c\,l\in\mathrm{af}(B)$ for every row vector $l\in\mathcal{O}_C^{2g}$;*
2. *every row of $\mathbf{h}$ lies in af(B);*
3. *if $y\in\mathcal{O}_C^{2g}$ and $y^\mathsf{T}\mathbf{e}\in\mathrm{af}(B)$, then $\mathbf{h}y\in c\,\mathcal{O}_C^g$;*
4. *for every $u\in\mathcal{O}_C^g$ there is $y\in\mathcal{O}_C^{2g}$ with $y^\mathsf{T}\mathbf{e}\in\mathrm{af}(B)$ and $\mathbf{h}y-cu\in p\,\mathcal{O}_C^g$;*
5. *if $y_1,\dots,y_g$ are as in (4) for the unit vectors $u=e_1,\dots,e_g$, then af(B) is the $\mathcal{O}_C$-span of the rows of $\mathbf{h}$ and of $y_1^\mathsf{T}\mathbf{e},\dots,y_g^\mathsf{T}\mathbf{e}$;*
6. *for every $u\in\mathcal{O}_C^g$ there is $x\in C^{2g}$ with $lx\in\mathcal{O}_C$ for all $l\in\mathrm{af}(B)$ and $\mathbf{h}x=u$.*

Proof. The elements of B take values in $\mathcal{O}_C$ by Lemma 35.48 (B is a Hopf order). Write $L(X) = \sum_{k=1}^{p-1}(-1)^{k-1}X^k/k \in \mathbb{Z}_{(p)}[X]$, so $c = L(\zeta - 1)$, and put $\kappa = 1 + \frac{1}{p-1}$. Since p is odd, $\frac{1}{p-1} < 1$.

Step 0: $v(c) = \frac{1}{p-1}$, and $p = cs$ with $v(s) > 0$. $v(\zeta - 1) = \frac{1}{p-1}$ and for $2 \le k \le p-1$, $v((\zeta-1)^k/k) = \frac{k}{p-1} > \frac{1}{p-1}$. So $v(c) = \frac{1}{p-1}$ and $s = p/c$ has $v(s) = 1 - \frac{1}{p-1} > 0$.

Step 1: the truncated logarithm. (a) If $a, b \in \mathcal{O}_C$ have valuation $\ge \frac{1}{p-1}$, then $v\big(L(a+b+ab) - L(a) - L(b)\big) \ge \kappa$. Indeed $P(S,T) = L(S+T+ST) - L(S) - L(T) \in \mathbb{Z}_{(p)}[S,T]$, and in $\mathbb{Q}[[S,T]]$ its part of total degree $< p$ equals that of $\log((1+S)(1+T)) - \log(1+S) - \log(1+T) = 0$, because $L(X)$ and $\log(1+X)$ agree up to degree $p-1$ and $(S+T+ST)^k$ has no monomial of degree $< k$; so every monomial of P has degree $\ge p$ and $v(P(a,b)) \ge \frac{p}{p-1} = \kappa$. (b) By induction on $a \ge 0$, applying (a) to $\zeta^a - 1$ and $\zeta - 1$: $v\big(L(\zeta^a - 1) - ac\big) \ge \kappa$ for every integer $a \ge 0$; as ζ^a and $ac \bmod pc$ depend only on $a \bmod p$ ($v(pc) = \kappa$), this holds for all $a \in \mathbb{Z}$. (c) For $f \in B$, $L(f-1) = \sum_{k=1}^{p-1}(-1)^{k-1}(f-1)^k/k \in B$ ($1/k \in \mathcal{O}_C$, B is an algebra with 1). (d) $D(1) = D(1 \cdot 1) = 2D(1)$, so $D(1) = 0$; if $f(0) = 1$ then $D((f-1)^k) = 0$ for $k \ge 2$ (Leibniz, $(f-1)(0) = 0$), so $D(L(f-1)) = D(f)$.

Step 2: the functions $T(y)$. For $1 \le m \le 2g$ let e_m be the m-th unit vector of N; $\chi_{e_m}(z) = \zeta^{(\mathbf{e}_0\hat{z})_m}$ lies in B by (Wb1), with $\chi_{e_m}(0) = 1$. For $y \in \mathcal{O}_C^{2g}$ put $T(y) = \sum_m y_m\, L(\chi_{e_m} - 1) \in B$ (Step 1(c)). By Step 1(d) and (Wb3), $D(T(y)) = \sum_m y_m \mathbf{h} e_m = \mathbf{h}y \bmod p$. By Step 1(b) with $a = (\mathbf{e}_0\hat{z})_m$, and $y^{\mathsf{T}}\mathbf{e}_0\hat{z} - y^{\mathsf{T}}\mathbf{e}\hat{z} \in p\,\mathcal{O}_C$,

$$v\big(T(y)(z) - c\,\lambda_{y^{\mathsf{T}}\mathbf{e}}(z)\big) \ge \kappa \qquad \text{for all } z \in N.$$

Step 3: proof of (1). Let l be a row vector and $y = (l\mathbf{e}^{-1})^{\mathsf{T}}$, so $y^{\mathsf{T}}\mathbf{e} = l$. By Step 2, $T(y) - c\lambda_l \in p\,\mathrm{Map}(N, \mathcal{O}_C)$ ($\kappa \ge 1$). λ_l is almost additive ($\widehat{z+z'} - \hat{z} - \hat{z}' \in p\mathbb{Z}^{2g}$), hence so is $T(y)$, and $T(y) \in \mathrm{AF}(B)$; so $cl \in \mathrm{af}(B)$.

Step 4: the hypothesis of Lemma D.113. By (Ho3) equality holds in its displayed hypothesis; $v(c) = \frac{1}{p-1}$ (Step 0); and $c\,\mathrm{Lin}(N) \subseteq \mathrm{AF}(B) + p\,\mathrm{Map}(N, \mathcal{O}_C)$: an almost-additive λ satisfies $\lambda - \lambda_l \in p\,\mathrm{Map}(N, \mathcal{O}_C)$ for $l = (\lambda(e_1), \dots, \lambda(e_{2g}))$ (almost additivity, $\lambda(\hat{z}_1 e_1 + \dots)$ expanded), and $c\lambda_l \in \mathrm{AF}(B) + p\,\mathrm{Map}$ by Step 3. With $W = (\mathcal{O}_C/p)^g$, Lemma D.113 applies to D.

Step 5: the key congruence. If $f \in \mathrm{AF}(B)$, $y \in \mathcal{O}_C^{2g}$ and $f - \lambda_{y^{\mathsf{T}}\mathbf{e}} \in p\,\mathrm{Map}(N, \mathcal{O}_C)$, then $\mathbf{h}y \equiv c\,D(f) \pmod p$. Indeed $(T(y) - cf)(z) = \big(T(y)(z) - c\lambda_{y^{\mathsf{T}}\mathbf{e}}(z)\big) - c\big(f(z) - \lambda_{y^{\mathsf{T}}\mathbf{e}}(z)\big)$ has valuation $\ge \kappa$ (Step 2; $v(cp) = \kappa$), so $D(T(y) - cf) = 0$ by Lemma D.113(ii), and $D(T(y)) = \mathbf{h}y \bmod p$ (Step 2).

Step 6: proof of (2). Fix $k \le g$ and write $K = \sum_i f_i \otimes f_i'$ with $f_i, f_i' \in B$ (Wb1). Choose $r_i \in \mathcal{O}_C$ lifting the k-th coordinate of $D(f_i')$ and put $F = \sum_i r_i f_i \in B$. For $x \in N$, $\chi_x = \sum_i f_i(x) f_i'$, so by (Wb3) $F(x) = \sum_i r_i f_i(x) \equiv D(\chi_x)_k \equiv (\mathbf{h}\hat{x})_k = \lambda_{\mathbf{h}_k}(x) \pmod p$, $\mathbf{h}_k$ the k-th row. Hence F is almost additive, $F \in \mathrm{AF}(B)$ and $\mathbf{h}_k \in \mathrm{af}(B)$.

Step 7: proof of (3). If $y^{\mathsf{T}}\mathbf{e} \in \mathrm{af}(B)$, there is $f \in \mathrm{AF}(B)$ with $f - \lambda_{y^{\mathsf{T}}\mathbf{e}} \in p\,\mathrm{Map}$. By Step 5, $\mathbf{h}y = cu + pw$ with $u, w \in \mathcal{O}_C^g$ (u a lift of $D(f)$), so $\mathbf{h}y = c(u + sw) \in c\,\mathcal{O}_C^g$ (Step 0).

Step 8: proof of (4). By (Wb2) there is $f \in B$ with $D(f) = u \bmod p$, and by Lemma D.113(i) there are $g_j \in \mathrm{AF}(B)$, $a_j \in \mathcal{O}_C$ with $D(f) = \sum_j a_j D(g_j)$. Then $F = \sum_j a_j g_j \in \mathrm{AF}(B)$, $D(F) = u \bmod p$, and $F - \lambda_l \in p\,\mathrm{Map}$ for $l = (F(e_1), \dots, F(e_{2g}))$ (as in Step 4). Put $y = (l\mathbf{e}^{-1})^{\mathsf{T}}$: $y^{\mathsf{T}}\mathbf{e} = l \in \mathrm{af}(B)$, and Step 5 gives $\mathbf{h}y \equiv cu \pmod p$.

Step 9: proof of (5). Let Y be the $2g \times g$ matrix with columns y_k and $\Phi \in M_{2g}(\mathcal{O}_C)$ the matrix with rows those of $\mathbf{h}$ followed by those of $Y^{\mathsf{T}}\mathbf{e}$; Λ its row span. By (2) and the choice of the y_k, $\Lambda \subseteq \mathrm{af}(B)$. By (4), $\mathbf{h}Y = c\,\mathbf{1}_g + pU = c(\mathbf{1}_g + sU)$ with $U \in M_g(\mathcal{O}_C)$. Using $\mathbf{e}^{\mathsf{T}} = -\mathbf{e}$

and $\mathbf{h}\mathbf{e}^{-1}\mathbf{h}^{\mathsf{T}} = 0$,

$$\Phi\,\mathbf{e}^{-1}\Phi^{\mathsf{T}} = \begin{pmatrix} \mathbf{h}\mathbf{e}^{-1}\mathbf{h}^{\mathsf{T}} & \mathbf{h}\mathbf{e}^{-1}\mathbf{e}^{\mathsf{T}}Y \\ Y^{\mathsf{T}}\mathbf{e}\mathbf{e}^{-1}\mathbf{h}^{\mathsf{T}} & Y^{\mathsf{T}}\mathbf{e}\mathbf{e}^{-1}\mathbf{e}^{\mathsf{T}}Y \end{pmatrix} = \begin{pmatrix} 0 & -\mathbf{h}Y \\ (\mathbf{h}Y)^{\mathsf{T}} & -Y^{\mathsf{T}}\mathbf{e}Y \end{pmatrix},$$

whose determinant is $\pm\det(\mathbf{h}Y)^2$ (block anti-triangular). As $\det\mathbf{e} \in \mathcal{O}_C^\times$ and $\det(\mathbf{1}_g + sU) \equiv 1 \pmod s$ is a unit ($v(s) > 0$), $2v(\det\Phi) = 2v(\det\mathbf{h}Y) = 2g\,v(c)$, so $v(\det\Phi) = \frac{g}{p-1}$ and $\mathrm{len}_C(\mathcal{O}_C^{2g}/\Lambda) = \frac{g}{p-1}$.

On the other side, $l \mapsto \lambda_l \bmod p$ maps $\mathcal{O}_C^{2g}$ onto the module V of additive maps $N \to \mathcal{O}_C/p$ with kernel $p\,\mathcal{O}_C^{2g}$, and $\mathrm{af}(B)$ is the preimage of the image M of $\mathrm{AF}(B)$; so $\mathcal{O}_C^{2g}/\mathrm{af}(B) \cong V/M \cong Q_B$, which has a normalised length (Lemma 35.47). The map $f \mapsto D(f - f(0)) = D(f)$ (Step 1(d)) shows $D(I_B) = D(B) = (\mathcal{O}_C/p)^g$, and D vanishes on I_B^2 (Leibniz), so I_B/I_B^2 maps onto $(\mathcal{O}_C/p)^g$ and $\mathrm{len}_C(I_B/I_B^2) \geq g$. The two equations of (Ho3) give $(p-1)\mathrm{len}_C(Q_B) = \mathrm{len}_C(I_B/I_B^2) \geq g$. Since $\mathcal{O}_C^{2g}/\Lambda \to \mathcal{O}_C^{2g}/\mathrm{af}(B)$ is onto with kernel $\mathrm{af}(B)/\Lambda$,

$$\tfrac{g}{p-1} = \mathrm{len}_C(\mathcal{O}_C^{2g}/\Lambda) = \mathrm{len}_C(Q_B) + \mathrm{len}_C(\mathrm{af}(B)/\Lambda) \geq \tfrac{g}{p-1} + \mathrm{len}_C(\mathrm{af}(B)/\Lambda),$$

so $\mathrm{af}(B)/\Lambda$ has length 0 and is zero: $\mathrm{af}(B) = \Lambda$.

Step 10: proof of (6). $\det\Phi \neq 0$ (Step 9). Given u, let $b \in \mathcal{O}_C^{2g}$ be u followed by g zeros and $x = \Phi^{-1}b \in C^{2g}$. The first g entries of $\Phi x = b$ give $\mathbf{h}x = u$. Every $l \in \mathrm{af}(B) = \Lambda$ is $l = a\Phi$ with a a row vector over $\mathcal{O}_C$, so $lx = ab \in \mathcal{O}_C$. □

Lemma D.113. *Let N be a finite-dimensional $\mathbb{F}_p$-vector space, $n = \dim N$, and B a Hopf order on N with*

$$(p-1)\,|N|\,\mathrm{len}_C(Q_B) = 2\,\mathrm{colen}(B)$$

(for instance a tight Hopf order). Let $c \in \mathcal{O}_C$ with $v(c) = 1/(p-1)$ and $c\,\mathrm{Lin}(N) \subseteq \mathrm{AF}(B) + p\,\mathrm{Map}(N, \mathcal{O}_C)$. Let W be an $\mathcal{O}_C$-module with $pW = 0$ and $D\colon B \to W$ an $\mathcal{O}_C$-linear derivation at the origin, that is $D(fh) = f(0)\,D(h) + h(0)\,D(f)$ for all $f, h \in B$. Then:

(i) there are $g_1, \ldots, g_n \in \mathrm{AF}(B)$ such that $D(B)$ is the $\mathcal{O}_C$-span of $D(g_1), \ldots, D(g_n)$;

(ii) $D(f) = 0$ for every $f \in B$ with $v(f(x)) \geq 1 + \frac{1}{p-1}$ for all $x \in N$.

Proof. The elements of B take values in $\mathcal{O}_C$ (Lemma 35.48; B is a Hopf order), so $f(0) \in \mathcal{O}_C$ for $f \in B$. By hypothesis equality holds in Lemma 35.47; take $g_j = \varepsilon_j\tilde{\lambda}_j \in \mathrm{AF}(B)$ ($\varepsilon_j \mid p$, $1 \leq j \leq n$) as there, so that the $\tilde{\lambda}^d$ form a basis of $\mathrm{Map}(N, \mathcal{O}_C)$ (its (i)), the image M of $\mathrm{AF}(B)$ in $V = \mathrm{Lin}(N)/p\,\mathrm{Map}(N, \mathcal{O}_C)$ is $\bigoplus_j \bar{\varepsilon}_j(\mathcal{O}_C/p)\lambda_j$ with (λ_j) a basis of V (its (ii)), and the $g^d = \prod_j g_j^{d_j}$, $d \in \{0, \ldots, p-1\}^n$, form a basis of B (its (iii)). Write $e_j \in \{0, \ldots, p-1\}^n$ for the j-th unit vector, $|d| = \sum_j d_j$.

Step 1: $g_j(0) \in p\,\mathcal{O}_C$. Almost additivity at $x = y = 0$ gives $g_j(0) - 2g_j(0) \in p\,\mathcal{O}_C$.

Step 2: $D(g^d) = 0$ unless $d = e_j$ for some j. For $d = 0$: $D(1) = D(1 \cdot 1) = 2D(1)$, so $D(1) = 0$. If $|d| \geq 2$, choose j with $d_j \geq 1$ and put $d' = d - e_j$, so $|d'| \geq 1$ and $g^d = g_j\,g^{d'}$. Then $g^{d'}(0)$ is a product of values $g_i(0)$, at least one factor, all in $\mathcal{O}_C$ and in $p\,\mathcal{O}_C$ by Step 1, so $g^{d'}(0) \in p\,\mathcal{O}_C$. Hence $D(g^d) = g_j(0)D(g^{d'}) + g^{d'}(0)D(g_j) \in pW = 0$.

Proof of (i). Every $f \in B$ is $f = \sum_d a_d g^d$ with $a_d \in \mathcal{O}_C$ (basis (iii)); by Step 2 and linearity $D(f) = \sum_j a_{e_j} D(g_j)$, and conversely each $D(g_j) \in D(B)$.

Step 3: $v(\varepsilon_j) \leq \frac{1}{p-1}$. $\tilde{\lambda}_j \in \mathrm{Lin}(N)$ (its reduction λ_j is additive, and any lift of an additive map to $\mathcal{O}_C$ is almost additive), so $c\tilde{\lambda}_j \in \mathrm{AF}(B) + p\,\mathrm{Map}(N, \mathcal{O}_C)$ and $\bar{c}\lambda_j \in M$. Comparing

coefficients of λ_j in the basis (λ_k) of V: $c = \varepsilon_j a + pb$ with $a, b \in \mathcal{O}_C$. If $p = 2$ then $v(\varepsilon_j) \le v(p) = 1 = v(c)$. If $p > 2$ then $v(c) < 1$, and $v(\varepsilon_j) > v(c)$ would give $v(c) \ge \min(v(\varepsilon_j), 1) > v(c)$; so $v(\varepsilon_j) \le v(c) = \frac{1}{p-1}$.

Proof of (ii). Let $f = \sum_d a_d g^d \in B$ with $v(f(x)) \ge 1 + \frac{1}{p-1}$ for all x. Then $f = \sum_d b_d \tilde{\lambda}^d$ with $b_d = a_d \prod_j \varepsilon_j^{d_j}$. The matrix $U = (\tilde{\lambda}^d(x))_{x,d}$ lies in $\mathrm{GL}_{|N|}(\mathcal{O}_C)$ by (i) of Lemma 35.47, so the vector $(b_d)_d = U^{-1}(f(x))_x$ has entries of valuation $\ge 1 + \frac{1}{p-1}$. For $d = e_j$, $b_{e_j} = a_{e_j}\varepsilon_j$ and Step 3 give $v(a_{e_j}) \ge 1 + \frac{1}{p-1} - v(\varepsilon_j) \ge 1$, so $a_{e_j} \in p\,\mathcal{O}_C$. By the formula in the proof of (i), $D(f) = \sum_j a_{e_j} D(g_j) \in pW = 0$. □

Lemma D.114. *Let $\mathfrak{T} = (\mathcal{O}', \mathcal{X}', \pi, (\mathcal{A}_{\mathfrak{P}}, \theta))$ be a pre-admissible torsion system, $G' = \pi^* G_{\mathcal{X}}$ with function field Ω' of $\mathcal{X}'$, R as in Definition 35.22, $g = \dim_{\Omega'} \mathrm{Lie}(G'_{\Omega'})$, and q a point of $\mathcal{X}'$ of codimension one with $p \notin \mathcal{O}_q^\times$; let C, $\mathcal{O}_C$, T_p, e be as in Definition 35.37 for the cover $\mathcal{X}'$ at q. Let $x_1, \dots, x_{2g}$ be an $\mathbb{F}_p$-basis of $N_p = G'(\Omega')[p]$ and $w_1, \dots, w_g$ an $\mathcal{O}_q$-basis of ω_q; for $x \in N_p$ let $\hat{x} \in \{0, \dots, p-1\}^{2g}$ be its coordinate vector, and for $w \in \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C$ let $[w] \in \mathcal{O}_C^g$ be its coordinate vector. Then there are $\mathbf{h} \in M_{g \times 2g}(\mathcal{O}_C)$, $\mathbf{e} \in \mathrm{GL}_{2g}(\mathbb{Z}_p)$ and $\mathbf{e}_0 \in M_{2g}(\mathbb{Z})$ such that:*

1. *$\mathbf{e}^{\mathsf{T}} = -\mathbf{e}$, $\mathbf{e} - \mathbf{e}_0 \in p\,M_{2g}(\mathbb{Z}_p)$, and $e_p(x, x') = \zeta_p^{\hat{x}^{\mathsf{T}} \mathbf{e}_0 \hat{x}'}$ for all $x, x' \in N_p$;*
2. *$\mathbf{h}\,\mathbf{e}^{-1}\mathbf{h}^{\mathsf{T}} = 0$;*
3. *for every $x \in N_p$, every $y \in G'(\Omega')[p^R]$ with $p^{R-1}y = x$ and every Hodge–Tate value w of y at q: $[w] - \mathbf{h}\hat{x} \in p\,\mathcal{O}_C^g$.*

Proof. Step 1: a lift. By Lemma 35.39 if $G' \times_{\mathcal{X}'} \operatorname{Spec} \mathcal{O}_q$ is an abelian scheme and by Proposition 35.41 otherwise (their hypotheses are those of Definition 35.37, which hold for the cover $\mathcal{X}'$ at q), there is a Hodge–Tate isotropic lift $\beta\colon T_p \to \omega_q \otimes_{\mathcal{O}_q} \mathcal{O}_C$ at q, with sign ϵ as in (Iz2).

Step 2: the Weil matrix. T_p is free of rank $2g$ over $\mathbb{Z}_p$ and $Y \mapsto Y_{(1)}$ induces $T_p/pT_p \cong N_p$; choose $Y_m \in T_p$ with $(Y_m)_{(1)} = x_m$, a $\mathbb{Z}_p$-basis by Nakayama. Put $\mathbf{e} = (e(Y_m, Y_{m'}))_{m,m'} \in M_{2g}(\mathbb{Z}_p)$, alternating as e is, and let $\mathbf{e}_0 \in M_{2g}(\mathbb{Z})$ have entries in $\{0, \dots, p-1\}$ congruent to those of $\mathbf{e}$ modulo p. For $x, x' \in N_p$, bilinearity and $e_p(x_m, x_{m'}) = \zeta_p^{e(Y_m, Y_{m'})}$ give $e_p(x, x') = \zeta_p^{\hat{x}^{\mathsf{T}} \mathbf{e}_0 \hat{x}'}$; this is (1) once $\mathbf{e}$ is invertible. As e_p is perfect, $\mathbf{e} \bmod p$ is invertible, so $\det \mathbf{e} \in \mathbb{Z}_p^\times$ and $\mathbf{e} \in \mathrm{GL}_{2g}(\mathbb{Z}_p)$.

Step 3: the Hodge–Tate matrix and (2). Let $\mathbf{h}$ be the matrix whose m-th column is $[\epsilon\beta(Y_m)]$. The basis (y'_k) with $e(Y_j, y'_k) = \delta_{jk}$ is $y'_k = \sum_l (\mathbf{e}^{-1})_{lk} Y_l$ (indeed $\sum_l \mathbf{e}_{jl}(\mathbf{e}^{-1})_{lk} = \delta_{jk}$). By (Iz3) with the basis (Y_j) and $\mathbb{Z}_p$-linearity of β,

$$0 = \sum_j \beta(Y_j) \otimes \beta(y'_j) = \sum_{j,l} (\mathbf{e}^{-1})_{lj}\, \beta(Y_j) \otimes \beta(Y_l) \quad \text{in } (\omega_q \otimes \omega_q) \otimes \mathcal{O}_C.$$

In the basis $w_k \otimes w_{k'}$ the (k, k') coefficient, multiplied by $\epsilon^2 = 1$, is $\sum_{j,l} \mathbf{h}_{kj}(\mathbf{e}^{-1})_{lj}\mathbf{h}_{k'l} = \left(\mathbf{h}(\mathbf{e}^{-1})^{\mathsf{T}}\mathbf{h}^{\mathsf{T}}\right)_{kk'}$. As $(\mathbf{e}^{-1})^{\mathsf{T}} = (\mathbf{e}^{\mathsf{T}})^{-1} = -\mathbf{e}^{-1}$, this is (2).

Step 4: additivity of Hodge–Tate values. If w_1, w_2 are Hodge–Tate values at q of $y_1, y_2 \in G'(\Omega')[p^R]$, then $w_1 + w_2$ is one of $y_1 + y_2$. Let ϕ_1, ϕ_2 be regular functions as in (Fh5); on the intersection of their domains $\phi_1\phi_2(g) = e_{p^R}(y_1, g)e_{p^R}(y_2, g) = e_{p^R}(y_1 + y_2, g)$. The function ϕ_i pulled back along the unit section is regular near q and equals $e_{p^R}(y_i, 0) = 1$ at the generic point, so it is 1; hence $d(\phi_1\phi_2) = d\phi_1 + d\phi_2$ on Lie_q, and $w_1 + w_2$ satisfies the congruence of (Fh5) for $y_1 + y_2$.

Step 5: (3). Let x, y, w be as in (3) and $Y = \sum_m \hat{x}_m Y_m \in T_p$, so $Y_{(1)} = x$ and $\epsilon\beta(Y)$ has coordinates $\mathbf{h}\hat{x}$. As $p^{R-1}Y_{(R)} = Y_{(1)} = x = p^{R-1}y$, $t = y - Y_{(R)}$ is killed by p^{R-1}, hence

$t = pt'$ with $t' \in G'(\Omega')[p^R]$ ($G'(\Omega')[p^R] \cong (\mathbb{Z}/p^R)^{2g}$). By Lemma 31.30(1) there are Hodge–Tate values w' of $Y_{(R)}$ and w'' of t' at q, and by Step 4 $w' + pw''$ is a Hodge–Tate value of y; by Lemma 31.30(1) again $w - w' - pw'' \in p^R\omega_q$. By (Iz2), $\epsilon\beta(Y) - w' \in p^R(\omega_q \otimes \mathcal{O}_C)$. Hence $[w] - \mathbf{h}\hat{x} = [w - w' - pw''] + [w' - \epsilon\beta(Y)] + p[w''] \in p\,\mathcal{O}_C^g$. □

Lemma D.115. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97, with p odd and function field Ω' of $\mathcal{X}'$, and let $(\mathfrak{q}, C, \iota_C)$ be a test point. Put $N = G'(\Omega')[p] = \bigoplus_{\mathfrak{P}|p} \Gamma_{\mathfrak{P}}$ and*

$$B = \boxtimes_{\mathfrak{P}|p} \mathcal{A}_{\mathfrak{P},C} \subseteq \mathrm{Map}(N, C),$$

the $\mathcal{O}_C$-span of the functions $z \mapsto \prod_{\mathfrak{P}|p} f_{\mathfrak{P}}(z_{\mathfrak{P}})$, $f_{\mathfrak{P}} \in \mathcal{A}_{\mathfrak{P},C}$, where $z_{\mathfrak{P}}$ is the $\Gamma_{\mathfrak{P}}$-component of z. Let ϕ be a polarisation of the abelian variety $G'_{\Omega'}$ and $e_p = e_p^{\phi}\colon N \times N \to \mu_p(\Omega')$ its Weil pairing. Then:

1. *the function $K(z, z') = \iota_C(e_p(z, z'))$ on $N \times N$ lies in the $\mathcal{O}_C$-span of the functions $(z, z') \mapsto f(z)f'(z')$ with $f, f' \in B$;*
2. *for every $x \in N$ the function $\chi_x = K(x, \cdot)$ lies in B, and for every prime $\mathfrak{P} \mid p$ of $\mathcal{O}_E$ its restriction to $\Gamma_{\mathfrak{P}}$ lies in $\mathcal{A}_{\mathfrak{P},C}$.*

Proof. **Setting.** Let $\widehat{R}$, $\widehat{K}$, $g\colon R_{\mathfrak{q}} \to \widehat{R}$, $h\colon \widehat{R} \to \mathcal{O}_C$ and $\widehat{G} = G' \times_{\mathcal{X}'} \operatorname{Spec} \widehat{R}$ be as in Proposition D.99. Since $h \circ g = \iota_C|_{R_{\mathfrak{q}}}$ is injective, g is injective and extends to a field embedding $g\colon \Omega' \to \widehat{K}$; so $A := \widehat{G}_{\widehat{K}} = G'_{\Omega'} \otimes_{\Omega'} \widehat{K}$ is an abelian variety, polarised by the base change $\phi_{\widehat{K}}$ of ϕ. $\widehat{G}$ is a semiabelian scheme over $\widehat{R}$ (base change of the semiabelian scheme G'), with abelian generic fibre. By Proposition D.99, $\widehat{G}[p]$ is flat, quasi-finite, separated and of finite presentation over $\widehat{R}$, with constant generic fibre whose points x_t ($t \in N$) are the images of the points of N; this is the situation of Definition 35.21 over the noetherian integrally closed domain $\widehat{R}$ with $T = N$. Put $\mathrm{Ord}_1 = \mathrm{Ord}(\widehat{G}[p]) \subseteq \mathrm{Map}(N, \widehat{R})$. The Weil pairing commutes with base change, so $e_p^{\phi_{\widehat{K}}}(x_t, x_{t'}) = g(e_p(t, t'))$ for $t, t' \in N$. These values are p-th roots of unity in $\widehat{K}$, integral over $\mathbb{Z}$, hence in the normal ring $\widehat{R}$. Define $F\colon N \times N \to \widehat{R}$ by $F(t, t') = g(e_p(t, t'))$. As e_p is bilinear, for $a \in N$ the maps $\psi_a = F(\cdot, a)$ and $\psi'_a = F(a, \cdot)$ are homomorphisms $N \to \mu_p(\widehat{K})$.

Step 1: F is the restriction of a global unit on $\widehat{G}[p] \times \widehat{G}[p]$. Let $\mathcal{P}$ be the Poincaré bundle on $A \times A^\vee$, $\mathcal{M} = (1, \phi_{\widehat{K}})^*\mathcal{P}$, rigidified at the origin, and $\mathcal{L} = \mathcal{M}^{\otimes p}$ with its cubical structure. Then $\phi_{\mathcal{L}} = p\,\phi_{\mathcal{M}} = 2p\,\phi_{\widehat{K}}$, so $K(\mathcal{L}) = \ker(2p\,\phi_{\widehat{K}})$ is finite and contains $A[p]$. $\widehat{R}$ is a complete discrete valuation ring, hence a complete noetherian normal local domain and regular. By Theorem B.119(2), applied to $S = \operatorname{Spec} \widehat{R}$, the semiabelian scheme $\widehat{G}$ and $\mathcal{L}$, the schematic closure K_S of $K(\mathcal{L})$ in $\widehat{G}$ is a closed subgroup scheme, flat and quasi-finite over S, and there is a pairing $e_S^{\mathcal{L}}\colon K_S \times_S K_S \to \mathbb{G}_{m,S}$ extending $e^{\mathcal{L}}$. Now $\widehat{G}[p]$ is closed in $\widehat{G}$ (the kernel of $[p]$ on a separated group scheme) and flat over $\widehat{R}$; so its structure sheaf has no $\widehat{R}$-torsion and $\widehat{G}[p]$ is the schematic closure in $\widehat{G}$ of its generic fibre $A[p]$. Since K_S is a closed subscheme of $\widehat{G}$ containing $A[p] \subseteq K(\mathcal{L})$, we get $\widehat{G}[p] \subseteq K_S$. Let $\Gamma = \widehat{G}[p] \times_S \widehat{G}[p]$ and $u \in \mathcal{O}(\Gamma)^\times$ the restriction of $e_S^{\mathcal{L}}$; then $u(x_t, x_{t'}) = e^{\mathcal{L}}(x_t, x_{t'})$. For $x, y \in A[p]$,

$$e^{\mathcal{L}}(x, y) = e_p(x, \phi_{\mathcal{M}}(y))^{\epsilon} = e_p(x, 2\phi_{\widehat{K}}(y))^{\epsilon} = e_p^{\phi_{\widehat{K}}}(x, y)^{2\epsilon}.$$

As p is odd, $s = u^{\epsilon(p+1)/2} \in \mathcal{O}(\Gamma)^\times$ satisfies $s(x_t, x_{t'}) = e_p^{\phi_{\widehat{K}}}(x_t, x_{t'})^{p+1} = F(t, t')$ for all $t, t' \in N$.

Step 2: homomorphisms $N \to \mu_p(\widehat{K})$ lie in Ord_1. By Lemma 35.28(1), Ord_1 is a finitely generated projective $\widehat{R}$-module with $d\,\mathrm{Map}(N, \widehat{R}) \subseteq \mathrm{Ord}_1$ for some $d \neq 0$, and $\operatorname{Spec} \mathrm{Ord}_1$

is a finite flat commutative group scheme with group law induced by the addition of N: its comultiplication sends f to $(t,t')\mapsto f(t+t')$, an element of $\mathrm{Ord}_1\otimes_{\widehat R}\mathrm{Ord}_1\subseteq\mathrm{Map}(N\times N,\widehat K)$ (the inclusion because Ord_1 is flat and $\widehat K\otimes\mathrm{Ord}_1=\mathrm{Map}(N,\widehat K)$), and its counit is $f\mapsto f(0)$. The dual $\mathrm{Ord}_1^\vee=\mathrm{Hom}_{\widehat R}(\mathrm{Ord}_1,\widehat R)$, with the product dual to the comultiplication and the counit as unit, is a commutative $\widehat R$-algebra, finitely generated as a module (Cartier duality). Let $\psi\colon N\to\mu_p(\widehat K)$ be a homomorphism. In $\mathrm{Map}(N,\widehat K)=\widehat K\otimes\mathrm{Ord}_1$ it satisfies $\psi(t+t')=\psi(t)\psi(t')$ and $\psi(0)=1$, so $\ell\mapsto\ell(\psi)$ is a homomorphism of $\widehat K$-algebras $\widehat K\otimes\mathrm{Ord}_1^\vee\to\widehat K$: $(\ell\ell')(\psi)=(\ell\otimes\ell')((t,t')\mapsto\psi(t)\psi(t'))=\ell(\psi)\ell'(\psi)$ and the unit takes the value $\psi(0)=1$. Every $\ell\in\mathrm{Ord}_1^\vee$ is integral over $\widehat R$, so $\ell(\psi)\in\widehat K$ is integral over $\widehat R$ and lies in $\widehat R$. Hence $\ell\mapsto\ell(\psi)$ restricts to an element of $\mathrm{Hom}_{\widehat R}(\mathrm{Ord}_1^\vee,\widehat R)$, which is evaluation at some $f\in\mathrm{Ord}_1$ (a finitely generated projective module is reflexive). Then $\ell(f)=\ell(\psi)$ for every $\ell\in\mathrm{Ord}_1^\vee$; these ℓ span the $\widehat K$-dual of $\mathrm{Map}(N,\widehat K)$, so $\psi=f\in\mathrm{Ord}_1$.

Step 3: $F\in\mathrm{Ord}(\Gamma)$ and its splitting. By Lemma D.100(2), Γ with $T=N\times N$ and the points $(x_t,x_{t'})$ is as in Definition 35.21. The functions regular on a group scheme as in Definition 35.21 form an $\widehat R$-subalgebra of the maps on its group of points (near a point, intersect the two neighbourhoods and add or multiply the two sections); hence every element of Ord_1, a product of sums of regular generators, is regular on $\widehat G[p]$, and for $f\in\mathrm{Ord}_1$ the functions $(t,t')\mapsto f(t)$ and $(t,t')\mapsto f(t')$ are regular on Γ (pull back the local sections along the two projections $\Gamma\to\widehat G[p]$). By Step 1, F is regular on Γ (the global section s). For $(a,b)\in N\times N$, bilinearity gives

$$F(t+a,t'+b)=F(a,b)\,F(t,t')\,\psi_b(t)\,\psi'_a(t'),$$

and $\psi_b,\psi'_a\in\mathrm{Ord}_1$ by Step 2. So every translate of F is a product of functions regular on Γ, hence regular, and $F\in\mathrm{Ord}(\Gamma)$ by definition. By Lemma D.100(2) there are $a_i,b_i\in\mathrm{Ord}_1$ $(1\le i\le r)$ with $F(t,t')=\sum_i a_i(t)b_i(t')$ for all $t,t'\in N$.

Step 4: transport to C. Applying h and using $h\circ g=\iota_C$ on Ω' (both are field embeddings extending $h\circ g=\iota_C|_{R_\mathfrak q}$, and Ω' is the fraction field of $R_\mathfrak q$),

$$K(z,z')=\iota_C(e_p(z,z'))=h(F(z,z'))=\sum_i(h\circ a_i)(z)\,(h\circ b_i)(z'),$$

and $h\circ a_i,h\circ b_i\in\mathrm{Ord}(\widehat G[p])_h=B$ by Proposition D.99(1), under the identification $N=\prod_{\mathfrak P|p}\Gamma_\mathfrak P$ used there. This is (1).

(2) With the decomposition of Step 4, $\chi_x=\sum_i(h\circ a_i)(x)\,(h\circ b_i)$ with coefficients $(h\circ a_i)(x)\in h(\widehat R)\subseteq\mathcal O_C$, so $\chi_x\in B$. Every element of $\mathcal A_{\mathfrak P',C}$ takes values in $\mathcal O_C$ (it is an $\mathcal O_C$-combination of functions with values in $\iota_C(R_\mathfrak q)\subseteq\mathcal O_C$, (Ox2)). The restriction to $\Gamma_\mathfrak P$ (all other components 0) of a generator $z\mapsto\prod_{\mathfrak P'}f_{\mathfrak P'}(z_{\mathfrak P'})$ of B is $\big(\prod_{\mathfrak P'\ne\mathfrak P}f_{\mathfrak P'}(0)\big)f_\mathfrak P\in\mathcal A_{\mathfrak P,C}$; so restriction maps B into $\mathcal A_{\mathfrak P,C}$, and $\chi_x|_{\Gamma_\mathfrak P}\in\mathcal A_{\mathfrak P,C}$.

The argument does not distinguish good and degenerate reduction at $\mathfrak q$: it uses only that $\widehat G$ is semiabelian with abelian generic fibre and part (1) of Proposition D.99. □

Lemma D.116. *Let $\mathfrak T$ be a torsion-regular pre-admissible torsion system for $(\mathcal X,p,\lambda)$ as in Proposition D.97, with p odd, function field Ω' of $\mathcal X'$ and R as in Definition 35.22, let $(\mathfrak q,C,\iota_C)$ be a test point, and let $N=G'(\Omega')[p]$ and $B\subseteq\mathrm{Map}(N,C)$ be as in Lemma D.115. Let e_p, e_{p^R} be the Weil pairings of the polarisation of the cubical line bundle of G' (as in (Fh5)), and for $x\in N$ let $\chi_x\colon N\to C$, $z\mapsto\iota_C(e_p(x,z))$. Put $\Omega_C=\mathcal O_C\otimes_{R_\mathfrak q}(\omega_\mathfrak q/p\,\omega_\mathfrak q)$, and for $f\in B$ and a prime $\mathfrak P\mid p$ of $\mathcal O_E$ let $f|_\mathfrak P$ be the restriction of f to $\Gamma_\mathfrak P\subseteq N$. Then:*

1. *$\omega_\mathfrak q=\bigoplus_u\omega_{u,\mathfrak q}$ (all labels u), so $\Omega_C=\bigoplus_u\mathcal O_C\otimes_{R_\mathfrak q}(\omega_u/p\,\omega_u)_\mathfrak q$; for $f\in B$, $f|_\mathfrak P-f(0)\in\mathcal I_{\mathfrak P,C}$;*

and

$$D(f)=\sum_{\mathfrak{P}\mid p}\ \sum_{u\colon\,\mathfrak{P}_u=\mathfrak{P}}\theta_{u,C}(f|_{\mathfrak{P}}-f(0))$$

defines a surjective $\mathcal{O}_C$-linear map $D\colon B\to\Omega_C$ with $D(ff')=f(0)D(f')+f'(0)D(f)$ for $f,f'\in B$;

2. *for every $x\in N$, every $y\in G'(\Omega')[p^R]$ with $p^{R-1}y=x$ and every Hodge–Tate value $w\in\omega_{\mathfrak{q}}$ of y at $\mathfrak{q}$: $\chi_x\in B$ and $D(\chi_x)=1\otimes(w \bmod p\,\omega_{\mathfrak{q}})$.*

Proof. **Step 0: eigen decomposition of $\omega_{\mathfrak{q}}$.** G' is the pull-back of $G_{\mathcal{X}}$, $\mathrm{Lie}(G')$ is locally free, so $\mathrm{Lie}_{\mathfrak{q}}=\mathrm{Lie}(G')_{\mathfrak{q}}$ and $\omega_{\mathfrak{q}}=\mathrm{Hom}(\mathrm{Lie}_{\mathfrak{q}},R_{\mathfrak{q}})$ is the stalk of $\omega_{G'}=\pi^*\omega_{G_{\mathcal{X}}}$. Since the discriminant of E is a unit in $R_{\mathfrak{q}}$, $\mathcal{O}_E\otimes R_{\mathfrak{q}}\to\prod_{\sigma\in\mathrm{Hom}(E,F)}R_{\mathfrak{q}}$, $a\otimes r\mapsto(\sigma(a)r)_\sigma$, is an isomorphism, and as $u\mapsto\sigma_u$ is a bijection onto $\mathrm{Hom}(E,F)$, $\omega_{\mathfrak{q}}=\bigoplus_u\omega_{u,\mathfrak{q}}$. On $\omega_{u,\mathfrak{q}}$ the ideal $\mathfrak{P}$ acts through $\sigma_u(\mathfrak{P})R_{\mathfrak{q}}$, which is $pR_{\mathfrak{q}}$ if $\mathfrak{P}_u=\mathfrak{P}$ ($\sigma_u(\mathfrak{P})\mathcal{O}'=p\mathcal{O}'$, as $p\mathcal{O}_E=\mathfrak{P}\mathfrak{P}''$ with $\sigma_u(\mathfrak{P}'')\not\subseteq\mathfrak{m}_{\mathcal{O}'}$) and $R_{\mathfrak{q}}$ otherwise ($\sigma_u(\mathfrak{P})\not\subseteq\mathfrak{m}_{\mathcal{O}'}$). Hence $\omega_{\mathfrak{q}}/\mathfrak{P}\omega_{\mathfrak{q}}=\bigoplus_{\mathfrak{P}_u=\mathfrak{P}}(\omega_u/p\,\omega_u)_{\mathfrak{q}}$, the decomposition into σ_u-isotypic components used in (Hf1) of Definition 35.22.

Step 1: D is well defined. Every element of $\mathcal{A}_{\mathfrak{P}',C}$ has values in $\mathcal{O}_C$ ((Ox2): an $\mathcal{O}_C$-combination of functions with values in $\iota_C(R_{\mathfrak{q}})$). For a generator $f(z)=\prod_{\mathfrak{P}'}f_{\mathfrak{P}'}(z_{\mathfrak{P}'})$ of B, $f|_{\mathfrak{P}}=(\prod_{\mathfrak{P}'\neq\mathfrak{P}}f_{\mathfrak{P}'}(0))f_{\mathfrak{P}}\in\mathcal{A}_{\mathfrak{P},C}$; by linearity $f|_{\mathfrak{P}}\in\mathcal{A}_{\mathfrak{P},C}$ for all $f\in B$, and since $1\in\mathcal{A}_{\mathfrak{P},C}$ and $f(0)\in\mathcal{O}_C$, $f|_{\mathfrak{P}}-f(0)\in\mathcal{I}_{\mathfrak{P},C}$. So D is an $\mathcal{O}_C$-linear map $B\to\Omega_C$.

Step 2: Leibniz rule at the origin. For $f,f'\in B$ put $g=f|_{\mathfrak{P}}-f(0)$, $g'=f'|_{\mathfrak{P}}-f'(0)$, both in $\mathcal{I}_{\mathfrak{P},C}$. Then

$$(ff')|_{\mathfrak{P}}-(ff')(0)=gg'+f(0)\,g'+f'(0)\,g,$$

and $\theta_{u,C}(gg')=0$ by Lemma D.107. Summing over $\mathfrak{P}$ and u gives $D(ff')=f(0)D(f')+f'(0)D(f)$.

Step 3: D is onto. Fix $\mathfrak{P}$. For $g\in\mathcal{A}_{\mathfrak{P},C}$ the function $f(z)=g(z_{\mathfrak{P}})$ lies in B (take $f_{\mathfrak{P}'}=1$ for $\mathfrak{P}'\neq\mathfrak{P}$), with $f|_{\mathfrak{P}'}-f(0)=0$ for $\mathfrak{P}'\neq\mathfrak{P}$ and $f|_{\mathfrak{P}}-f(0)=g-g(0)$; so $D(f)=\sum_{\mathfrak{P}_u=\mathfrak{P}}\theta_{u,C}(g-g(0))$. It therefore suffices to show that $(\theta_{u,C})_{\mathfrak{P}_u=\mathfrak{P}}\colon\mathcal{I}_{\mathfrak{P},C}\to\bigoplus_{\mathfrak{P}_u=\mathfrak{P}}\mathcal{O}_C\otimes(\omega_u/p\,\omega_u)_{\mathfrak{q}}$ is onto. Each θ_u is onto by (Ts3), hence so is its stalk at $\mathfrak{q}$ and its $\mathcal{O}_C$-linear extension $\theta_{u,C}$ (Ox2). The characters $\chi_u|_{\mathbb{F}_{\mathfrak{P}}^\times}$ ($\mathfrak{P}_u=\mathfrak{P}$) are homomorphisms to $\mathcal{O}'^\times$ and pairwise distinct: if $\chi_u=\chi_{u'}$, then $\sigma_u(a)\equiv\sigma_{u'}(a)$ modulo $\mathfrak{m}_{\mathcal{O}'}$ for all $a\in\mathcal{O}_E$; writing $\sigma_{u'}=\sigma_u\circ\gamma$ with $\gamma\in\mathrm{Gal}(E/\mathbb{Q})$, $\gamma(a)-a\in\sigma_u^{-1}(\mathfrak{m}_{\mathcal{O}'})=\mathfrak{P}$ for all a, so γ lies in the inertia group of $\mathfrak{P}$, which is trivial, and $u=u'$. By Proposition D.98, $\mathcal{A}_{\mathfrak{P},C}$ is $\mathbb{F}_{\mathfrak{P}}$-stable; $q_{\mathfrak{P}}-1$ is prime to p, a unit of $\mathcal{O}_C$. For $g\in\mathcal{I}_{\mathfrak{P},C}$ put

$$\varepsilon_u(g)=\frac{1}{q_{\mathfrak{P}}-1}\sum_{a\in\mathbb{F}_{\mathfrak{P}}^\times}\chi_u(a)^{-1}\,g(a\,\cdot)\in\mathcal{I}_{\mathfrak{P},C}.$$

By Lemma D.107, $\theta_{u',C}(\varepsilon_u(g))=\frac{1}{q_{\mathfrak{P}}-1}\sum_a\chi_u(a)^{-1}\chi_{u'}(a)\,\theta_{u',C}(g)$, which is $\theta_{u,C}(g)$ if $u'=u$ and 0 otherwise. Given $t_u\in\mathcal{O}_C\otimes(\omega_u/p\,\omega_u)_{\mathfrak{q}}$, choose $g_u\in\mathcal{I}_{\mathfrak{P},C}$ with $\theta_{u,C}(g_u)=t_u$; then $g=\sum_u\varepsilon_u(g_u)$ has $\theta_{u,C}(g)=t_u$ for every u with $\mathfrak{P}_u=\mathfrak{P}$. With Step 0 ($\Omega_C$ is the direct sum over $\mathfrak{P}$ of these targets), D is onto.

Step 4: the value on Weil characters. By Lemma D.115(2) (with the polarisation of the cubical line bundle), $\chi_x\in B$ and $\chi_x|_{\mathfrak{P}}\in\mathcal{A}_{\mathfrak{P},C}$; also $\chi_x(0)=1$. The values of $\chi_x|_{\mathfrak{P}}$ lie in $\iota_C(\Omega')$. By the remark in (Ox2), an $R_{\mathfrak{q}}$-basis (a_j) of $\mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ is an Ω'-basis of $\mathrm{Map}(\Gamma_{\mathfrak{P}},\Omega')$ and a C-basis of $\mathrm{Map}(\Gamma_{\mathfrak{P}},C)$; so the coordinates of $\chi_x|_{\mathfrak{P}}$ lie in $\mathcal{O}_C\cap\iota_C(\Omega')=\iota_C(R_{\mathfrak{q}})$ (Ox1), and $g_{\mathfrak{P}}:=\chi_x|_{\mathfrak{P}}-1$, read in Ω', lies in $\mathcal{I}_{\mathfrak{P},\mathfrak{q}}$. Then $\theta_{u,C}(g_{\mathfrak{P}})=1\otimes\theta_u(g_{\mathfrak{P}})$ with the stalk of θ_u at $\mathfrak{q}$.

Let ϕ be the regular function of (Fh5) for the Hodge–Tate value w of y: defined on an open neighbourhood V of the unit point over $\mathfrak{q}$ in G', with $\phi(z) = e_{p^R}(y,z)$ for all $z \in G'(k)[p^R]$ ($k \supseteq \Omega'$ algebraically closed) and $w(v) \equiv d\phi(v)$ modulo $p^R R_{\mathfrak{q}}$ for $v \in \mathrm{Lie}_{\mathfrak{q}}$. Choose an affine open $U \ni \mathfrak{q}$ with $e(U) \subseteq V$ (e the unit section) and $g_{\mathfrak{P}} \in \mathcal{I}_{\mathfrak{P}}(U)$. Then $W = V \cap (G'[\mathfrak{P}] \times_{\mathcal{X}'} U)$ is an open neighbourhood of the unit section of $G'[\mathfrak{P}] \times_{\mathcal{X}'} U$, and $\tilde{g} = (\phi - 1)|_W$ is regular on W. At a point $z \in \Gamma_{\mathfrak{P}} \subseteq G'(\Omega')[p]$ lying in W,

$$\tilde{g}(z) = e_{p^R}(y,z) - 1 = e_p(p^{R-1}y, z) - 1 = e_p(x,z) - 1 = g_{\mathfrak{P}}(z).$$

By (Hf1), $\theta_u(g_{\mathfrak{P}})$ is the σ_u-component of the class of $e^*d\tilde{g}$ in $e^*\Omega^1_{G'[\mathfrak{P}]/\mathcal{X}'} = \omega_{G'}/\mathfrak{P}\,\omega_{G'}$, and $e^*d\tilde{g}$ is the image of $e^*d\phi \in \omega_{G'}(U)$ under restriction of differentials along $G'[\mathfrak{P}] \subseteq G'$. At $\mathfrak{q}$, $e^*d\phi$ is the form $v \mapsto d\phi(v)$ on $\mathrm{Lie}_{\mathfrak{q}}$, so $e^*d\phi - w \in p^R\omega_{\mathfrak{q}}$ ($\mathrm{Lie}_{\mathfrak{q}}$ is free). Writing $w = \sum_u w_u$ with $w_u \in \omega_{u,\mathfrak{q}}$ (Step 0), we get $\theta_u(g_{\mathfrak{P}}) = w_u \bmod p\,\omega_{u,\mathfrak{q}}$ for every u with $\mathfrak{P}_u = \mathfrak{P}$. Summing,

$$D(\chi_x) = \sum_{\mathfrak{P}} \sum_{\mathfrak{P}_u = \mathfrak{P}} 1 \otimes (w_u \bmod p) = 1 \otimes (w \bmod p\,\omega_{\mathfrak{q}}).$$

□

Lemma D.117. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97, with p odd, function field Ω' of $\mathcal{X}'$ and R as in Definition 35.22; let $(\mathfrak{q}, C, \iota_C)$ be a test point and $N = G'(\Omega')[p]$, $B = \boxtimes_{\mathfrak{P}'|p}\mathcal{A}_{\mathfrak{P}',C}$ as in Lemma D.115. Let $a \in \Phi$, $s = (a,+)$, $\mathfrak{P} = \mathfrak{P}_s$, $m = m_{\mathfrak{P}}$, $\sigma = \sigma_s$, let $y = (y_1, \dots, y_m)$ be points for $(\mathfrak{T}, s)$, $(\varpi_k)_{1 \le k \le d}$ a $\mathbb{Z}$-basis of $\mathcal{O}_E$ and $(\varpi_k^*)_k$ its dual basis for the trace form, $\mathrm{Tr}(\varpi_k \varpi_{k'}^*) = \delta_{kk'}$. Put $I = \{1, \dots, m\} \times \{1, \dots, d\}$ and $x_{(l,k)} = \varpi_k\, p^{R-1} y_l$. Then $(x_j)_{j \in I}$ is an $\mathbb{F}_p$-basis of N; with coordinate vectors $\hat{x}$ and $\mathrm{af}(B)$ formed for this basis, and the matrices $\mathbf{P} \in M_{m \times I}(C)$, $\mathbf{J} \in M_{I \times m}(C)$,*

$$\mathbf{P}_{i,(l,k)} = \delta_{il}\,\sigma(\varpi_k), \qquad \mathbf{J}_{(l,k),i} = \delta_{li}\,\sigma(\varpi_k^*),$$

the following hold.

1. *The entries of $\mathbf{P}$ and $\mathbf{J}$ lie in $\mathcal{O}_C$, and $\mathbf{PJ} = \mathbf{1}_m$.*
2. *For $\alpha \in \mathcal{O}_E$ with image ξ in $\mathbb{F}_{\mathfrak{P}}$, $\chi_s(\xi) - \sigma(\alpha) \in p\,\mathcal{O}_C$. For $x \in N$ with $\Gamma_{\mathfrak{P}}$-component $\sum_i \xi_i b_i$ and $1 \le i \le m$, $(\mathbf{P}\hat{x})_i - \chi_s(\xi_i) \in p\,\mathcal{O}_C$.*
3. *$l\mathbf{JP} \in \mathrm{af}(B)$ for every $l \in \mathrm{af}(B)$.*
4. *With $\mathrm{af}_C = \{c \in C^m : \ell_c \in \mathcal{A}_{\mathfrak{P},C} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_C)\}$, the $\mathcal{O}_C$-spans in C^m of the stalks at $\mathfrak{q}$ satisfy $\mathcal{O}_C\,\mathrm{af}_{\mathfrak{q}} = \mathrm{af}_C$ and*

   $$\mathcal{O}_C H_{\mathfrak{q}} = \{u \in C^m : c \cdot u \in \mathcal{O}_C \text{ for all } c \in \mathrm{af}_C\} = \{u \in C^m : l\mathbf{J}u \in \mathcal{O}_C \text{ for all } l \in \mathrm{af}(B)\}.$$

Proof. **The basis.** By (Hf4), $G'(\Omega')[p^R]$ is free over $\mathcal{O}_E/p^R$ with basis $y_1, \dots, y_m$. Its p-torsion is $N = p^{R-1}G'(\Omega')[p^R]$, free over $\mathcal{O}_E/p$ with basis $p^{R-1}y_1, \dots, p^{R-1}y_m$ (multiplication by p^{R-1} induces $\mathcal{O}_E/p \cong p^{R-1}\mathcal{O}_E/p^R\mathcal{O}_E$). As the ϖ_k reduce to an $\mathbb{F}_p$-basis of $\mathcal{O}_E/p$, the $x_{(l,k)}$ form an $\mathbb{F}_p$-basis of N.

Proof of (1). $\sigma(\varpi_k) \in \mathcal{O}' \subseteq \mathcal{O}_C$. The ϖ_k^* span the inverse different $\mathfrak{d}^{-1}$; since $d_E = \pm N(\mathfrak{d}) \in \mathfrak{d}$, $d_E\varpi_k^* \in \mathcal{O}_E$, so $\sigma(\varpi_k^*) \in d_E^{-1}\mathcal{O}' \subseteq \mathcal{O}_C$. Let $\tau_1, \dots, \tau_d$ be the embeddings of E into an algebraic closure and $A = (\tau_i(\varpi_k))_{i,k}$, $A^* = (\tau_i(\varpi_k^*))_{i,k}$. Then $(A^{\mathsf{T}}A^*)_{kk'} = \mathrm{Tr}(\varpi_k\varpi_{k'}^*) = \delta_{kk'}$, so $A^*A^{\mathsf{T}} = \mathbf{1}$, and its diagonal entries give $\tau_i(\sum_k \varpi_k\varpi_k^*) = 1$, i.e. $\sum_k \varpi_k\varpi_k^* = 1$. Hence $(\mathbf{PJ})_{ij} = \sum_{(l,k)} \delta_{il}\delta_{lj}\sigma(\varpi_k)\sigma(\varpi_k^*) = \delta_{ij}\,\sigma(\sum_k \varpi_k\varpi_k^*) = \delta_{ij}$.

Proof of (2). Write $q = q_{\mathfrak{P}}$. As p is unramified, $p\mathcal{O}_E = \mathfrak{P}\mathfrak{P}''$ with $\mathfrak{P}''$ prime to $\mathfrak{P}$, and $\sigma(\mathfrak{P}'') \not\subseteq \mathfrak{m}_{\mathcal{O}'}$ (as $\sigma^{-1}(\mathfrak{m}_{\mathcal{O}'}) = \mathfrak{P}$), so $\sigma(\mathfrak{P})\mathcal{O}' = p\mathcal{O}'$. If $\xi = 0$, then $\alpha \in \mathfrak{P}$ and $\sigma(\alpha) \in p\mathcal{O}'$, while $\chi_s(0) = 0$. If $\xi \neq 0$, put $v = \sigma(\alpha)$; from $\alpha^q - \alpha \in \mathfrak{P}$ we get $v^q - v \in p\mathcal{O}'$, and by induction $v^{q^{k+1}} - v^{q^k} \in p^{k+1}\mathcal{O}'$ (if $v^{q^k} = v^{q^{k-1}} + p^k r$, raise to the q-th power: all binomial terms but the first are divisible by p^{k+1}). So $\tau = \lim_k v^{q^k}$ exists in the complete ring $\mathcal{O}_C$, $\tau - v \in p\mathcal{O}_C$ ($p\mathcal{O}_C$ is closed), $\tau^q = \tau$ and $\tau \not\equiv 0$ modulo $\mathfrak{m}_C$, so τ is a $(q-1)$-th root of unity congruent to $\sigma(\alpha)$ modulo $\mathfrak{m}_C$. Distinct $(q-1)$-th roots of unity are distinct modulo $\mathfrak{m}_C$ ($p \nmid q-1$), so $\tau = \chi_s(\xi)$, which gives the first claim.

For $x \in N$ put $\alpha_l = \sum_k \hat{x}_{(l,k)}\varpi_k \in \mathcal{O}_E$; then $x = \sum_l \alpha_l\, p^{R-1} y_l$ and $(\mathbf{P}\hat{x})_i = \sum_k \sigma(\varpi_k)\hat{x}_{(i,k)} = \sigma(\alpha_i)$. The decomposition $N = \bigoplus_{\mathfrak{P}'} \Gamma_{\mathfrak{P}'}$ is stable under $\mathcal{O}_E$, which acts on $\Gamma_{\mathfrak{P}}$ through $\mathbb{F}_{\mathfrak{P}} = \mathcal{O}_E/\mathfrak{P}$, and the $\Gamma_{\mathfrak{P}}$-component of $p^{R-1}y_l$ is b_l (Hf4). So ξ_i is the image of α_i, and $(\mathbf{P}\hat{x})_i - \chi_s(\xi_i) = \sigma(\alpha_i) - \chi_s(\xi_i) \in p\,\mathcal{O}_C$.

Proof of (3). First, $f \circ [\alpha] \in B$ for $f \in B$ and $\alpha \in \mathcal{O}_E$ ($[\alpha]$ the action on N): on a generator $z \mapsto \prod_{\mathfrak{P}'} f_{\mathfrak{P}'}(z_{\mathfrak{P}'})$ of B, $(\alpha z)_{\mathfrak{P}'} = \bar{\alpha} z_{\mathfrak{P}'}$ with $\bar{\alpha}$ the image of α in $\mathbb{F}_{\mathfrak{P}'}$, and $\mathcal{A}_{\mathfrak{P}',C}$ is $\mathbb{F}_{\mathfrak{P}'}$-stable (Proposition D.98). For $\alpha \in \mathcal{O}_E$ let $\mathbf{M}(\alpha) \in M_I(\mathbb{Z})$, $\mathbf{M}(\alpha)_{(l',t),(l,k)} = \delta_{ll'} c_t(\alpha\varpi_k)$. Since $\alpha x = \sum_{l,k} \hat{x}_{(l,k)}\alpha\varpi_k\, p^{R-1} y_l = \sum_{l,t}\big(\sum_k c_t(\alpha\varpi_k)\hat{x}_{(l,k)}\big)x_{(l,t)}$, we have $\widehat{\alpha x} \equiv \mathbf{M}(\alpha)\hat{x}$ modulo $p\mathbb{Z}^I$. Let $l \in \mathrm{af}(B)$, $\lambda_l = f + pg$ with $f \in B$. For $x \in N$, l being integral,

$$\lambda_{l\mathbf{M}(\alpha)}(x) = l\,\mathbf{M}(\alpha)\hat{x} \equiv l\,\widehat{\alpha x} = f(\alpha x) + p\,g(\alpha x) \equiv f(\alpha x) \pmod{p\,\mathcal{O}_C},$$

so $l\mathbf{M}(\alpha) \in \mathrm{af}(B)$. Finally $\mathbf{JP} = \sum_t \sigma(\varpi_t^*)\mathbf{M}(\varpi_t)$: the $((l,k),(l',k'))$ entry of the right side is $\delta_{ll'}\sigma\big(\sum_t \mathrm{Tr}(\varpi_t\varpi_{k'}\varpi_k^*)\varpi_t^*\big) = \delta_{ll'}\sigma(\varpi_{k'}\varpi_k^*)$, which is the entry of $\mathbf{JP}$. As $\mathrm{af}(B)$ is an $\mathcal{O}_C$-module and $\sigma(\varpi_t^*) \in \mathcal{O}_C$ by (1), $l\mathbf{JP} = \sum_t \sigma(\varpi_t^*)\, l\mathbf{M}(\varpi_t) \in \mathrm{af}(B)$.

Proof of (4). Let $\mathcal{M} = \mathcal{A}_{\mathfrak{P}} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_{\mathcal{X}'})$, a quasi-coherent subsheaf of $\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_{\mathcal{X}'})$, and $\ell\colon c \mapsto \ell_c$, an injective Ω'-linear map $V_H \to \mathrm{Map}(\Gamma_{\mathfrak{P}}, \Omega')$ ($\ell_c(b_i) = c_i$) with $\ell(\mathcal{O}'^m) \subseteq \mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O})$. By definition $\mathrm{af} = \ell^{-1}(\mathcal{M})$ sectionwise, so $\mathrm{af}_{\mathfrak{q}} = \ell^{-1}(\mathcal{M}_{\mathfrak{q}})$; evaluation at the b_i gives $p\,\mathcal{O}'^m \subseteq \mathrm{af} \subseteq \mathcal{O}'^m$. Hence af is the kernel of $\mathcal{O}'^m \to \mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O})/\mathcal{M}$, a coherent sheaf, and $\mathrm{af}_{\mathfrak{q}}$ is free of rank m over the discrete valuation ring $R_{\mathfrak{q}}$. The dual lattice H is $\mathcal{H}om(\mathrm{af}, \mathcal{O})$ realised in V_H by the dot product (as $\Omega'\mathrm{af} = V_H$), and $\mathcal{H}om$ of a coherent sheaf commutes with stalks; so $H_{\mathfrak{q}}$ is the dual lattice of $\mathrm{af}_{\mathfrak{q}}$.

$\mathcal{O}_C$ is torsion-free, hence flat, over $R_{\mathfrak{q}}$. Tensoring the exact sequence $0 \to \mathrm{af}_{\mathfrak{q}} \xrightarrow{\ell} \mathcal{M}_{\mathfrak{q}} \to \mathrm{Map}(\Gamma_{\mathfrak{P}}, \Omega')/\ell(V_H)$ with $\mathcal{O}_C$, and using that an $R_{\mathfrak{q}}$-basis of $\mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ is a C-basis of $\mathrm{Map}(\Gamma_{\mathfrak{P}}, C)$ (remark in (Ox2)), gives $\mathcal{O}_C\mathrm{af}_{\mathfrak{q}} = \{c \in C'^m :\ \ell_c \in \mathcal{O}_C\mathcal{M}_{\mathfrak{q}}\}$ with $\mathcal{O}_C\mathcal{M}_{\mathfrak{q}} = \mathcal{A}_{\mathfrak{P},C} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_C)$; this is af_C. A basis of $\mathrm{af}_{\mathfrak{q}}$ is an $\mathcal{O}_C$-basis of af_C, and its dual basis is an $R_{\mathfrak{q}}$-basis of $H_{\mathfrak{q}}$ and an $\mathcal{O}_C$-basis of the dual lattice of af_C; so $\mathcal{O}_C H_{\mathfrak{q}}$ is the dual lattice of af_C. This is the first equality.

For the second apply Lemma D.118 with $M = B$ (whose elements take values in $\mathcal{O}_C$, being $\mathcal{O}_C$-combinations of products of elements of the $\mathcal{A}_{\mathfrak{P}',C}$, which do by (Ox2)), the basis (x_j), $\mathbb{F} = \mathbb{F}_{\mathfrak{P}}$, $\Gamma = \Gamma_{\mathfrak{P}}$ with the basis (b_i), i the inclusion, π the projection onto the $\Gamma_{\mathfrak{P}}$-component, $\chi = \chi_s$, $P = \mathbf{P}$, $J = \mathbf{J}$. Its hypotheses: $\pi \circ i = \mathrm{id}$; for $f \in B$, $f \circ i \circ \pi\colon z \mapsto f(z_{\mathfrak{P}})$ lies in B (on a generator it is $\prod_{\mathfrak{P}' \neq \mathfrak{P}} f_{\mathfrak{P}'}(0) \cdot f_{\mathfrak{P}}(z_{\mathfrak{P}})$); $M_\Gamma = \{f|_{\Gamma_{\mathfrak{P}}} : f \in B\} = \mathcal{A}_{\mathfrak{P},C}$ (a generator restricts to $\prod_{\mathfrak{P}' \neq \mathfrak{P}} f_{\mathfrak{P}'}(0) \cdot f_{\mathfrak{P}}$, and $g \in \mathcal{A}_{\mathfrak{P},C}$ is the restriction of $z \mapsto g(z_{\mathfrak{P}}) \in B$), so its af_Γ is af_C and its H_Γ is the dual lattice of af_C; $\chi_s(0) = 0$, $\chi_s(1) = 1$; $\mathbf{PJ} = \mathbf{1}$ by (1); the congruence by (2); the stability by (3). Lemma D.118(2) is the second equality. □

Lemma D.118. *Let p be a prime, N a finite-dimensional $\mathbb{F}_p$-vector space with a basis $(x_j)_{j\in I}$, and for $x \in N$ let $\hat{x} \in \{0,\dots,p-1\}^I$ be its coordinate vector. Let $M \subseteq \mathrm{Map}(N, \mathcal{O}_C)$ be an $\mathcal{O}_C$-submodule and, with $\lambda_l(x) = l\hat{x}$ for $l \in \mathcal{O}_C^I$,*

$$\mathrm{af}(M) = \{l \in \mathcal{O}_C^I :\ \lambda_l \in M + p\,\mathrm{Map}(N, \mathcal{O}_C)\}.$$

Let $\mathbb{F}$ be a finite field of characteristic p, Γ an $\mathbb{F}$-vector space with a basis $b_1,\dots,b_m$, and $i\colon \Gamma \to N$, $\pi\colon N \to \Gamma$ additive maps with $\pi \circ i = \mathrm{id}_\Gamma$ such that $f \circ i \circ \pi \in M$ for every $f \in M$. Put $M_\Gamma = \{f \circ i :\ f \in M\}$. Let $\chi\colon \mathbb{F} \to \mathcal{O}_C$ be a map with $\chi(0) = 0$, $\chi(1) = 1$; for $c \in C^m$ let $\ell_c(y) = \sum_k c_k \chi(y_k)$ for $y = \sum_k y_k b_k \in \Gamma$, and put

$$\mathrm{af}_\Gamma = \{c \in C^m :\ \ell_c \in M_\Gamma + p\,\mathrm{Map}(\Gamma, \mathcal{O}_C)\}, \qquad H_\Gamma = \{u \in C^m :\ c \cdot u \in \mathcal{O}_C \text{ for all } c \in \mathrm{af}_\Gamma\}.$$

Let $P \in M_{m\times I}(\mathcal{O}_C)$ and $J \in M_{I\times m}(\mathcal{O}_C)$ with $PJ = \mathbf{1}_m$, such that

$$(P\hat{x})_k - \chi(\pi(x)_k) \in p\,\mathcal{O}_C \quad (x \in N,\ 1 \le k \le m), \qquad lJP \in \mathrm{af}(M) \quad (l \in \mathrm{af}(M)),$$

where $\pi(x) = \sum_k \pi(x)_k b_k$. Then:

1. *$\mathrm{af}_\Gamma \subseteq \mathcal{O}_C^m$, and for $l \in \mathcal{O}_C^m$: $l \in \mathrm{af}_\Gamma$ if and only if $lP \in \mathrm{af}(M)$;*
2. *$H_\Gamma = \{u \in C^m :\ lJu \in \mathcal{O}_C \text{ for all } l \in \mathrm{af}(M)\}$.*

Proof. A congruence. For $l \in \mathcal{O}_C^m$ and $x \in N$,

$$\lambda_{lP}(x) - \ell_l(\pi(x)) = \sum_k l_k((P\hat{x})_k - \chi(\pi(x)_k)) \in p\,\mathcal{O}_C,$$

since $\lambda_{lP}(x) = lP\hat{x}$ and the l_k are integral.

Proof of (1). Let $c \in \mathrm{af}_\Gamma$, $\ell_c = g \circ i + pf$ with $g \in M$, $f \in \mathrm{Map}(\Gamma, \mathcal{O}_C)$. Since $\chi(0) = 0$ and $\chi(1) = 1$, $\ell_c(b_k) = c_k$, and $g(i(b_k)) \in \mathcal{O}_C$; so $c_k \in \mathcal{O}_C$. This proves $\mathrm{af}_\Gamma \subseteq \mathcal{O}_C^m$.

Let $l \in \mathrm{af}_\Gamma$ and write $\ell_l = g \circ i + pf$ as above. Then $G = g \circ i \circ \pi \in M$, and for $x \in N$ the congruence gives $\lambda_{lP}(x) \equiv \ell_l(\pi(x)) = G(x) + pf(\pi(x)) \equiv G(x)$ modulo $p\,\mathcal{O}_C$. So $\lambda_{lP} \in M + p\,\mathrm{Map}(N, \mathcal{O}_C)$ and $lP \in \mathrm{af}(M)$.

Conversely let $l \in \mathcal{O}_C^m$ with $lP \in \mathrm{af}(M)$, $\lambda_{lP} = g + pf$ with $g \in M$. For $y \in \Gamma$, $\pi(i(y)) = y$, so the congruence at $x = i(y)$ gives $\ell_l(y) \equiv \lambda_{lP}(i(y)) = g(i(y)) + pf(i(y)) \equiv g(i(y))$ modulo $p\,\mathcal{O}_C$. Hence $\ell_l - g \circ i \in p\,\mathrm{Map}(\Gamma, \mathcal{O}_C)$, $g \circ i \in M_\Gamma$, and $l \in \mathrm{af}_\Gamma$.

Proof of (2). Let $u \in H_\Gamma$ and $l \in \mathrm{af}(M)$. Then $lJ \in \mathcal{O}_C^m$ and $(lJ)P = lJP \in \mathrm{af}(M)$, so $lJ \in \mathrm{af}_\Gamma$ by (1), and $lJu = (lJ) \cdot u \in \mathcal{O}_C$. Conversely let $u \in C^m$ with $lJu \in \mathcal{O}_C$ for all $l \in \mathrm{af}(M)$, and let $c \in \mathrm{af}_\Gamma$. By (1), $c \in \mathcal{O}_C^m$ and $cP \in \mathrm{af}(M)$, so $c \cdot u = cPJu = (cP)Ju \in \mathcal{O}_C$. Hence $u \in H_\Gamma$. □

Lemma D.119. *Let $\mathfrak{T}$, p (odd), Ω', R, the test point $(\mathfrak{q}, C, \iota_C)$, $a \in \Phi$, $s = (a,+)$, $\bar{s} = (a,-)$, $\kappa = \mathrm{rk}(s)$, $\mathfrak{P} = \mathfrak{P}_s$, $m = m_{\mathfrak{P}}$, $\sigma = \sigma_s$, the points $y = (y_1,\dots,y_m)$, (ϖ_k), (ϖ_k^*), I, $x_{(l,k)}$ and $\mathbf{J}$ be as in Lemma D.117, and assume $R \ge 3$. Let $w \in \mathcal{O}'$ with $w^{p-1} = up$, $u \in \mathcal{O}'^\times$, bases $\beta, \bar{\beta}$ as in Definition 35.22, and (ι, h) a Hodge–Tate chart for $(\mathfrak{T}, s, \beta, \bar{\beta})$ over an open $U \ni \mathfrak{q}$ with points y and forms $\eta_1,\dots,\eta_m$; ι, h also denote their C-linear extensions, and $e_1,\dots,e_m$ is the standard basis of C^m. Let $g = \dim_{\Omega'} \mathrm{Lie}(G'_{\Omega'})$, $w_1,\dots,w_g$ an $R_{\mathfrak{q}}$-basis of $\omega_{\mathfrak{q}}$ (extended Ω'-linearly to $\mathrm{Lie}(G'_{\Omega'})$), $[v] \in C^g$ the coordinate vector of $v \in \omega_{\mathfrak{q}} \otimes C$, and $\Lambda \in M_{g\times\kappa}(\Omega')$, $\bar{\Lambda} \in M_{g\times(n-\kappa)}(\Omega')$ the matrices with entries $\Lambda_{ik} = w_i(\beta_k)$, $\bar{\Lambda}_{ik} = w_i(\bar{\beta}_k)$. Let $\mathbf{h} \in M_{g\times I}(\mathcal{O}_C)$ be such that $[v] - \mathbf{h}\hat{x} \in p\,\mathcal{O}_C^g$ for every $x \in N$, every $y' \in G'(\Omega')[p^R]$ with $p^{R-1}y' = x$ and every Hodge–Tate value v of y' at $\mathfrak{q}$. Let $\zeta \in \Omega'$ be a primitive p^R-th root of unity, $e_{p^R}(y', y'') = \zeta^{\varepsilon(y',y'')}$ the Weil pairing of the polarisation on $G'(\Omega')[p^R]$ with $\varepsilon(y', y'') \in \{0,\dots,p^R - 1\}$, and put*

$$\mathbf{E}_\varepsilon = \big(\varepsilon(\varpi_k y_l, \varpi_{k'} y_{l'})\big)_{(l,k),(l',k')\in I} \in M_I(\mathbb{Z}), \qquad g_{lj} = \sum_k \sigma(\varpi_k^*)\,\varepsilon(\varpi_k y_l, y_j).$$

Then:

1. *for every* $(l,k)\in I$, *with* $\mathbf{h}_{(l,k)}$ *the column of* $\mathbf{h}$ *of index* (l,k): $\bar\Lambda^{\mathsf T}\mathbf{h}_{(l,k)}-\sigma(\varpi_k)\,h(e_l)\in p\,\bar\Lambda^{\mathsf T}\mathcal{O}_C^{g}$;
2. *for every* $c\in V_L$ *with* $w\sum_k c_k\beta_k\in\mathrm{Lie}_{\mathfrak q}$, $\iota(c)\in R_{\mathfrak q}^{m}$ *and* $\sum_l \iota(c)_l\,g_{lj}-\eta_j\big(\sum_k c_k\beta_k\big)\in p^{R-2}R_{\mathfrak q}$ *for* $1\le j\le m$:
$$\mathbf{E}_\varepsilon\mathbf{J}\,\iota(c)+\mathbf{h}^{\mathsf T}\Lambda c\in w\,\mathcal{O}_C^{I}.$$

Proof. **Step 1: Hodge–Tate values of ϖy_j.** Let $\alpha\in\mathcal{O}_E$ and $1\le j\le m$. By (Hf4) the restriction of η_j to $\mathrm{Lie}_{\mathfrak q}$ is a Hodge–Tate value of y_j at $\mathfrak q$: there is a regular function ϕ on an open neighbourhood V of the unit point over $\mathfrak q$ with $\phi(z)=e_{p^R}(y_j,z)$ for $z\in G'(k)[p^R]$ ($k\supseteq\Omega'$ algebraically closed) and $d\phi(t)\equiv\eta_j(t)$ modulo $p^RR_{\mathfrak q}$ for $t\in\mathrm{Lie}_{\mathfrak q}$. Then $\phi\circ\iota(\bar\alpha)$ is regular on the open neighbourhood $\iota(\bar\alpha)^{-1}(V)$ of the unit point over $\mathfrak q$, and by the Rosati condition $\phi(\iota(\bar\alpha)z)=e_{p^R}(y_j,\bar\alpha z)=e_{p^R}(\alpha y_j,z)$; its differential is $t\mapsto d\phi(\mathrm{Lie}(\iota(\bar\alpha))t)\equiv\eta_j(\mathrm{Lie}(\iota(\bar\alpha))t)$ modulo $p^RR_{\mathfrak q}$. So $v_{j,\alpha}:=\eta_j\circ\mathrm{Lie}(\iota(\bar\alpha))$, restricted to $\mathrm{Lie}_{\mathfrak q}$, is a Hodge–Tate value of αy_j at $\mathfrak q$. Since $p^{R-1}(\varpi_k y_j)=x_{(j,k)}$, whose coordinate vector is the unit vector of index (j,k), the hypothesis on $\mathbf{h}$ gives
$$[v_{j,\varpi_k}]-\mathbf{h}_{(j,k)}\in p\,\mathcal{O}_C^{g}. \tag{D.26}$$

Step 2: proof of (1). For $v\in\omega_{\mathfrak q}\otimes C$, $v=\sum_i[v]_iw_i$ and so $\bar\Lambda^{\mathsf T}[v]=(v(\bar\beta_r))_r$. By Step 1 with $\alpha=\varpi_k$, and as $\mathrm{Lie}(\iota(\bar\varpi_k))$ acts on $\mathrm{Li}_{\bar s}$ by $\sigma_{\bar s}(\bar\varpi_k)=\sigma(\varpi_k)$,
$$\bar\Lambda^{\mathsf T}[v_{l,\varpi_k}]=\big(\eta_l(\sigma(\varpi_k)\bar\beta_r)\big)_r=\sigma(\varpi_k)\,(\eta_l(\bar\beta_r))_r=\sigma(\varpi_k)\,h(e_l)$$
by the definition of the forms of a chart. Applying $\bar\Lambda^{\mathsf T}$ to (D.26) (with $j=l$) gives (1).

Step 3: the Hodge–Tate side of (2). Let c be as in (2), $A=\sum_k c_k\beta_k\in\mathrm{Li}_s$, so $wA\in\mathrm{Lie}_{\mathfrak q}$, and fix $(j,k')\in I$. By (D.26), $\mathbf{h}_{(j,k')}=[v_{j,\varpi_{k'}}]-p\,r$ with $r\in\mathcal{O}_C^{g}$, hence
$$(\mathbf{h}^{\mathsf T}\Lambda c)_{(j,k')}=\sum_i(\mathbf{h}_{(j,k')})_i\,w_i(A)=v_{j,\varpi_{k'}}(A)-\frac{p}{w}\sum_i r_i\,w_i(wA).$$
The last sum lies in $\mathcal{O}_C$ ($w_i(wA)\in R_{\mathfrak q}$), so the last term lies in $w\mathcal{O}_C$. As $\mathrm{Lie}(\iota(\bar\varpi_{k'}))$ acts on Li_s by $\sigma(\bar\varpi_{k'})$, $v_{j,\varpi_{k'}}(A)=\sigma(\bar\varpi_{k'})\eta_j(A)$, and by the hypothesis on c, $\eta_j(A)-\sum_l\iota(c)_lg_{lj}\in p^{R-2}R_{\mathfrak q}\subseteq p\,\mathcal{O}_C$ ($R\ge3$). Therefore
$$(\mathbf{h}^{\mathsf T}\Lambda c)_{(j,k')}\equiv\sigma(\bar\varpi_{k'})\sum_l\iota(c)_l\,g_{lj}\pmod{w\,\mathcal{O}_C}.$$

Step 4: the Weil side of (2). The Weil pairing e_{p^R} is bilinear and alternating and satisfies the Rosati condition $e_{p^R}(\alpha y',y'')=e_{p^R}(y',\bar\alpha y'')$; so modulo p^R, ε is biadditive, $\varepsilon(y',y'')\equiv-\varepsilon(y'',y')$ and $\varepsilon(y',\alpha y'')\equiv\varepsilon(\bar\alpha y',y'')$. Hence
$$\varepsilon(\varpi_{k'}y_j,\varpi_ky_l)\equiv-\varepsilon(\varpi_ky_l,\varpi_{k'}y_j)\equiv-\varepsilon(\bar\varpi_{k'}\varpi_ky_l,y_j)\equiv-\sum_t c_t(\bar\varpi_{k'}\varpi_k)\,\varepsilon(\varpi_ty_l,y_j)\pmod{p^R}.$$
Moreover $\sum_k\sigma(\varpi_k^*)c_t(\bar\varpi_{k'}\varpi_k)=\sigma\big(\sum_k\mathrm{Tr}(\bar\varpi_{k'}\varpi_t^*\varpi_k)\varpi_k^*\big)=\sigma(\bar\varpi_{k'}\varpi_t^*)$. Since $(\mathbf{J}\iota(c))_{(l,k)}=\sigma(\varpi_k^*)\iota(c)_l$ with $\iota(c)_l\in R_{\mathfrak q}$,
$$\begin{aligned}(\mathbf{E}_\varepsilon\mathbf{J}\iota(c))_{(j,k')}&=\sum_{l,k}\varepsilon(\varpi_{k'}y_j,\varpi_ky_l)\,\sigma(\varpi_k^*)\,\iota(c)_l\\&\equiv-\sigma(\bar\varpi_{k'})\sum_l\iota(c)_l\sum_t\sigma(\varpi_t^*)\varepsilon(\varpi_ty_l,y_j)=-\sigma(\bar\varpi_{k'})\sum_l\iota(c)_l\,g_{lj}\end{aligned}$$
modulo $p^R\mathcal{O}_C$. Adding Step 3 gives (2). □

Lemma D.120. *Let p be an odd prime and $w, c \in \mathcal{O}_C$ with $v(w) = v(c) = \frac{1}{p-1}$. Let I be a finite set, $g, m, r, r' \geq 0$ integers, $\mathrm{AF} \subseteq \mathcal{O}_C^I$ an $\mathcal{O}_C$-submodule of row vectors, $\mathbf{h} \in M_{g\times I}(\mathcal{O}_C)$ and $\mathbf{e} \in \mathrm{GL}_I(\mathcal{O}_C)$, such that:*

1. *$c\,l \in \mathrm{AF}$ for every $l \in \mathcal{O}_C^I$;*
2. *every row of $\mathbf{h}$ lies in AF;*
3. *if $y \in \mathcal{O}_C^I$ and $y^{\mathsf{T}}\mathbf{e} \in \mathrm{AF}$, then $\mathbf{h}y \in c\,\mathcal{O}_C^g$;*
4. *for every $u \in \mathcal{O}_C^g$ there is $y \in \mathcal{O}_C^I$ with $y^{\mathsf{T}}\mathbf{e} \in \mathrm{AF}$ and $\mathbf{h}y - cu \in p\,\mathcal{O}_C^g$;*
5. *for every $u \in \mathcal{O}_C^g$ there is $x \in C^I$ with $lx \in \mathcal{O}_C$ for all $l \in \mathrm{AF}$ and $\mathbf{h}x = u$.*

Let $\mathbf{P} \in M_{m\times I}(\mathcal{O}_C)$, $\mathbf{J} \in M_{I\times m}(\mathcal{O}_C)$ with $\mathbf{PJ} = \mathbf{1}_m$ and $l\mathbf{JP} \in \mathrm{AF}$ for every $l \in \mathrm{AF}$, and put $H = \{u \in C^m : \ l\mathbf{J}u \in \mathcal{O}_C \text{ for all } l \in \mathrm{AF}\}$. Let $\Lambda \in M_{g\times r}(C)$, $\bar{\Lambda} \in M_{g\times r'}(C)$, $\mathrm{lie} = \{a \in C^r : \Lambda a \in \mathcal{O}_C^g\}$, and $W \subseteq C^r$ an $\mathcal{O}_C$-submodule with $\mathrm{lie} \subseteq W$ and $wW \subseteq \mathrm{lie}$. Let $h\colon C^m \to C^{r'}$ and $\iota\colon C^r \to C^m$ be C-linear maps such that:

6. *$\bar{\Lambda}^{\mathsf{T}}\mathbf{h} - h(\mathbf{P}) \in p\,\bar{\Lambda}^{\mathsf{T}} M_{g\times I}(\mathcal{O}_C)$;*
7. *$\iota^{-1}(\mathcal{O}_C^m) = W$;*
8. *$\mathbf{eJ}\iota(a) + \mathbf{h}^{\mathsf{T}}\Lambda a \in w\,\mathcal{O}_C^I$ for every $a \in W$.*

Then $h(H) = \bar{\Lambda}^{\mathsf{T}}\mathcal{O}_C^g$ and $\iota^{-1}(H) = w^{-1}\mathrm{lie}$.

Proof. Put $t = p/w$. Then $v(t) = 1 - \frac{1}{p-1}$, and as $p \geq 3$, $\frac{1}{p-1} \leq v(t) < 1$: so $t \in w\,\mathcal{O}_C \cap \mathfrak{m}_C$. H is an $\mathcal{O}_C$-submodule of C^m.

Step 0: denominators of the dual. If $x \in C^I$ and $lx \in \mathcal{O}_C$ for all $l \in \mathrm{AF}$, then $wx \in \mathcal{O}_C^I$. Indeed, by (1) the row c times the unit row of index j lies in AF, so $cx_j \in \mathcal{O}_C$ and $v(x_j) \geq -v(c) = -v(w)$.

Step 1: the key identity. If $x \in C^I$ with $wx \in \mathcal{O}_C^I$, then $h(\mathbf{P}x) = \bar{\Lambda}^{\mathsf{T}}(\mathbf{h}x - tu')$ for some $u' \in \mathcal{O}_C^g$. Indeed, by (6), $h(\mathbf{P}_j) = \bar{\Lambda}^{\mathsf{T}}(\mathbf{h}_j - pU_j)$ with $U_j \in \mathcal{O}_C^g$ for every column index $j \in I$, so

$$h(\mathbf{P}x) = \sum_j x_j\, h(\mathbf{P}_j) = \bar{\Lambda}^{\mathsf{T}}\Big(\mathbf{h}x - t\sum_j (wx_j)U_j\Big),$$

and $u' = \sum_j (wx_j)U_j \in \mathcal{O}_C^g$.

Step 2: $h(H) \subseteq \bar{\Lambda}^{\mathsf{T}}\mathcal{O}_C^g$. Let $u_0 \in H$ and $x = \mathbf{J}u_0$. Then $lx \in \mathcal{O}_C$ for $l \in \mathrm{AF}$, so $wx \in \mathcal{O}_C^I$ (Step 0), and $\mathbf{P}x = u_0$. By Step 1, $h(u_0) = \bar{\Lambda}^{\mathsf{T}}(\mathbf{h}x - tu')$, and $(\mathbf{h}x)_k = \mathbf{h}_k\mathbf{J}u_0 \in \mathcal{O}_C$ for each row $\mathbf{h}_k$ of $\mathbf{h}$, by (2) and $u_0 \in H$. So $h(u_0) \in \bar{\Lambda}^{\mathsf{T}}\mathcal{O}_C^g$.

Step 3: $\bar{\Lambda}^{\mathsf{T}}\mathcal{O}_C^g \subseteq h(H)$. Let $N' = \{u \in \mathcal{O}_C^g : \ \bar{\Lambda}^{\mathsf{T}}u \in h(H)\}$, an $\mathcal{O}_C$-submodule. Let $u \in \mathcal{O}_C^g$ and x as in (5). By Step 0, $wx \in \mathcal{O}_C^I$; and $\mathbf{P}x \in H$, since $l\mathbf{J}(\mathbf{P}x) = (l\mathbf{JP})x \in \mathcal{O}_C$ for $l \in \mathrm{AF}$. By Step 1, $h(\mathbf{P}x) = \bar{\Lambda}^{\mathsf{T}}(u - tu')$ with $u' \in \mathcal{O}_C^g$, so $u - tu' \in N'$. Hence $\mathcal{O}_C^g = N' + t\,\mathcal{O}_C^g$ with $t \in \mathfrak{m}_C$, and $N' = \mathcal{O}_C^g$ by Nakayama's lemma. So $\bar{\Lambda}^{\mathsf{T}}u \in h(H)$ for every $u \in \mathcal{O}_C^g$.

Step 4: an equivalence. Let $a \in C^r$ with $wa \in W$ and $y \in \mathcal{O}_C^I$. Then

$$y^{\mathsf{T}}\mathbf{eJ}\iota(a) \in \mathcal{O}_C \iff (\mathbf{h}y)^{\mathsf{T}}\Lambda(wa) \in w\,\mathcal{O}_C.$$

Indeed, by (8) for wa, $\mathbf{eJ}\iota(wa) = -\mathbf{h}^{\mathsf{T}}\Lambda(wa) + wz$ with $z \in \mathcal{O}_C^I$, so $w\,y^{\mathsf{T}}\mathbf{eJ}\iota(a) = -(\mathbf{h}y)^{\mathsf{T}}\Lambda(wa) + w\,y^{\mathsf{T}}z$ with $y^{\mathsf{T}}z \in \mathcal{O}_C$.

Step 5: $\iota^{-1}(H) \subseteq w^{-1}\mathrm{lie}$. Let $a \in C^r$ with $\iota(a) \in H$. For $1 \le k \le m$ the row $c\,\mathbf{P}_k$ ($\mathbf{P}_k$ the k-th row of $\mathbf{P}$) lies in AF by (1), and $c\,\mathbf{P}_k\mathbf{J}\iota(a) = c\,\iota(a)_k$ as $\mathbf{PJ} = \mathbf{1}$; so $c\,\iota(a)_k \in \mathcal{O}_C$, $w\iota(a) \in \mathcal{O}_C^m$, and $wa \in W$ by (7). Let $u \in \mathcal{O}_C^g$ and y as in (4), $\mathbf{h}y = cu + pu''$ with $u'' \in \mathcal{O}_C^g$. As $y^{\mathsf{T}}\mathbf{e} \in \mathrm{AF}$ and $\iota(a) \in H$, $y^{\mathsf{T}}\mathbf{e}\mathbf{J}\iota(a) \in \mathcal{O}_C$, so by Step 4

$$(\mathbf{h}y)^{\mathsf{T}}\Lambda(wa) = c\,u^{\mathsf{T}}\Lambda(wa) + t\,u''^{\mathsf{T}}\Lambda(w\cdot wa) \in w\,\mathcal{O}_C.$$

Since $w \cdot wa \in wW \subseteq \mathrm{lie}$, $\Lambda(w\cdot wa) \in \mathcal{O}_C^g$ and the second term lies in $t\,\mathcal{O}_C \subseteq w\,\mathcal{O}_C$. So $c\,u^{\mathsf{T}}\Lambda(wa) \in w\,\mathcal{O}_C$, i.e. $u^{\mathsf{T}}\Lambda(wa) \in \mathcal{O}_C$. As u is arbitrary, $\Lambda(wa) \in \mathcal{O}_C^g$: $wa \in \mathrm{lie}$.

Step 6: $w^{-1}\mathrm{lie} \subseteq \iota^{-1}(H)$. Let $wa \in \mathrm{lie}$; then $wa \in W$. Let $l \in \mathrm{AF}$ and $y = (l\mathbf{e}^{-1})^{\mathsf{T}} \in \mathcal{O}_C^I$, so $y^{\mathsf{T}}\mathbf{e} = l \in \mathrm{AF}$ and $\mathbf{h}y = cu$ with $u \in \mathcal{O}_C^g$ by (3). Then $(\mathbf{h}y)^{\mathsf{T}}\Lambda(wa) = c\,u^{\mathsf{T}}\Lambda(wa) \in c\,\mathcal{O}_C = w\,\mathcal{O}_C$, and Step 4 gives $l\mathbf{J}\iota(a) = y^{\mathsf{T}}\mathbf{e}\mathbf{J}\iota(a) \in \mathcal{O}_C$. So $\iota(a) \in H$. □

Lemma D.121. *Let $\mathfrak{T}$ be a torsion-regular pre-admissible torsion system for $(\mathcal{X}, p, \lambda)$ as in Proposition D.97, $w \in \mathcal{O}'$ with $w^{p-1} = u\,p$, $u \in \mathcal{O}'^{\times}$, $a \in \Phi$, $s = (a, +)$, $\mathfrak{P} = \mathfrak{P}_s$, $m = m_{\mathfrak{P}}$, and let $(\mathfrak{q}, C, \iota_C)$ be a test point. Then the $\mathcal{O}_C$-spans in C^m of the stalks at $\mathfrak{q}$ satisfy $\mathcal{O}_C H_{\mathfrak{q}} \subseteq w^{-1}\mathcal{O}_C T_{\mathfrak{q}} = w^{-1}\mathcal{O}_C^m$.*

Proof. **Step 1: reduction to $we_i \in \mathrm{af}_C$.** Put $\mathcal{M} = \mathcal{A}_{\mathfrak{P}} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O})$; then $\mathrm{af} = \ell^{-1}(\mathcal{M})$, where $\ell\colon V_H \to \mathrm{Map}(\Gamma_{\mathfrak{P}}, \Omega')$, $c \mapsto \ell_c$, is linear and injective ($\ell_c(b_i) = c_i$ as $\chi_s(1) = 1$, $\chi_s(0) = 0$). af is the kernel of $\mathcal{M} \to \mathrm{Map}/\ell(V_H)$ pulled back by ℓ, a coherent sheaf, so its stalk is $\mathrm{af}_{\mathfrak{q}} = \ell^{-1}(\mathcal{M}_{\mathfrak{q}})$ and $H_{\mathfrak{q}}$ is the dual lattice of $\mathrm{af}_{\mathfrak{q}}$; both are free of rank m ($p\,\mathcal{O}^m \subseteq \mathrm{af} \subseteq \mathcal{O}^m$, as $\ell(p\mathcal{O}^m) \subseteq p\,\mathrm{Map}$ and $\ell_c(b_i) = c_i$). By flatness of $\mathcal{O}_C$ over $R_{\mathfrak{q}}$, tensoring the exact sequence $0 \to \mathcal{M}_{\mathfrak{q}} \cap \ell(V_H) \to \mathcal{M}_{\mathfrak{q}} \to \mathrm{Map}(\Gamma_{\mathfrak{P}}, \Omega')/\ell(V_H)$ gives $\mathcal{O}_C\mathrm{af}_{\mathfrak{q}} = \mathrm{af}_C := \{c \in C^m : \ell_c \in \mathcal{M}_C\}$ with $\mathcal{M}_C = \mathcal{O}_C\mathcal{M}_{\mathfrak{q}} = \mathcal{A}_{\mathfrak{P},C} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_C)$, and $\mathcal{O}_C H_{\mathfrak{q}}$ is the dual lattice of af_C (dual bases). Dualising, it suffices to show $w\,\mathcal{O}_C^m \subseteq \mathrm{af}_C$, i.e. that the function $x \mapsto \ell_{we_i}(x) = w\,\chi_s(x_i)$ ($x = \sum_j x_j b_j$) lies in $\mathcal{M}_C$ for every i.

Step 2: the Teichmüller character modulo p. Let $a \in \mathbb{F}_{\mathfrak{P}}$ and $\tilde{a} \in \mathcal{O}_E$ any lift. Then $\chi_s(a) - \sigma_s(\tilde{a}) \in p\,\mathcal{O}_C$. Indeed, $p\mathcal{O}_E = \mathfrak{P}\mathfrak{P}''$ with $\mathfrak{P}''$ prime to $\mathfrak{P}$, $\sigma_s(\mathfrak{P}'') \not\subseteq \mathfrak{m}_{\mathcal{O}'}$, so $\sigma_s(\mathfrak{P})\mathcal{O}' = p\mathcal{O}'$. If $a = 0$, $\tilde{a} \in \mathfrak{P}$ and $\sigma_s(\tilde{a}) \in p\mathcal{O}'$. If $a \neq 0$, $v = \sigma_s(\tilde{a})$ satisfies $v^q - v \in \sigma_s(\mathfrak{P})\mathcal{O}' = p\mathcal{O}'$ ($q = q_{\mathfrak{P}}$, $\tilde{a}^q \equiv \tilde{a}$ modulo $\mathfrak{P}$); by induction $v^{q^{k+1}} - v^{q^k} \in p^{k+1}\mathcal{O}'$, so $\tau = \lim_k v^{q^k}$ exists in the complete ring $\mathcal{O}_C$, $\tau - v \in p\mathcal{O}_C$ ($p\mathcal{O}_C$ is closed) and $\tau^q = \tau$, $\tau \neq 0$. Thus τ is a $(q-1)$-th root of unity congruent to $\sigma_s(\tilde{a})$ modulo $\mathfrak{m}_C$; as $(q-1)$-th roots of unity are distinct modulo $\mathfrak{m}_C$ ($p \nmid q-1$), $\tau = \chi_s(a)$.

Step 3: characters lie in $\mathcal{A}_{\mathfrak{P},C}$. By Proposition D.98, $\mathcal{A}_{\mathfrak{P},C}$ is an abelian factor: there are an abelian scheme A over $\mathcal{O}_C$ and homomorphisms $\iota\colon \Gamma_{\mathfrak{P}} \to N_A$, $\rho\colon N_A \to \Gamma_{\mathfrak{P}}$ with $\rho\iota = \mathrm{id}$ and $\mathcal{A}_{\mathfrak{P},C} = \{g \circ \iota : g \in M_A\}$ (Definition 35.17). Let $\psi\colon \Gamma_{\mathfrak{P}} \to \mu_p(C)$ be a homomorphism. $A[p]$ is finite locally free over $\mathcal{O}_C$, and $N_A = A[p](\mathcal{O}_C) = A[p](C)$ (valuative criterion). The homomorphism $\psi \circ \rho\colon A[p](C) \to \mu_p(C) \subseteq C^{\times}$ is a C-point of the Cartier dual $A[p]^D$, which is finite over $\mathcal{O}_C$, so it extends to an $\mathcal{O}_C$-point, i.e. to a homomorphism $A[p] \to \mathbb{G}_{m,\mathcal{O}_C}$; its coordinate is a function $a_\psi \in \Gamma(A[p], \mathcal{O})$ with $x^* a_\psi = \psi(\rho(x))$ for $x \in N_A$. So $\psi \circ \rho \in M_A$ and $\psi = (\psi \circ \rho) \circ \iota \in \mathcal{A}_{\mathfrak{P},C}$.

Step 4: $w\chi_s(x_i) \in \mathcal{M}_C$. Let $\theta_1, \dots, \theta_f \in \mathcal{O}_E$ lift an $\mathbb{F}_p$-basis $\bar{\theta}_1, \dots, \bar{\theta}_f$ of $\mathbb{F}_{\mathfrak{P}}$, and $r_k\colon \mathbb{F}_{\mathfrak{P}} \to \mathbb{F}_p$ the coordinate functionals. For $a \in \mathbb{F}_{\mathfrak{P}}$, $\sum_k \widetilde{r_k(a)}\theta_k$ is a lift of a ($\tilde{}$ the representative in $\{0, \dots, p-1\}$), so by Step 2

$$w\,\chi_s(x_i) \equiv \sum_{k=1}^{f} \sigma_s(\theta_k)\,w\,\widetilde{r_k(x_i)} \pmod{p\,\mathcal{O}_C} \qquad (x \in \Gamma_{\mathfrak{P}}).$$

Let $\zeta \in \mathcal{O}'$ be a primitive p-th root of unity; since $(\zeta-1)^{p-1} \in \widetilde{p\,\mathbb{Z}[\zeta]^\times}$ and $w^{p-1} = up$, $w/(\zeta-1)$ is a unit of $\mathcal{O}_C$. By Lemma 35.56 (with $K = C$, $\mathcal{O} = \mathcal{O}_C$), $w\, r_k(x_i) = \sum_j c_j \zeta^{j\, r_k(x_i)}$ with $c_j \in \mathcal{O}_C$, and $x \mapsto \zeta^{j\, r_k(x_i)}$ is a homomorphism $\Gamma_{\mathfrak{P}} \to \mu_p$ ($x \mapsto r_k(x_i)$ is additive), which lies in $\mathcal{A}_{\mathfrak{P},C}$ by Step 3. As $\sigma_s(\theta_k) \in \mathcal{O}' \subseteq \mathcal{O}_C$, the function $x \mapsto w\chi_s(x_i)$ lies in $\mathcal{A}_{\mathfrak{P},C} + p\,\mathrm{Map}(\Gamma_{\mathfrak{P}}, \mathcal{O}_C) = \mathcal{M}_C$. By Step 1 this proves the claim. □

Lemma D.122. *Let $\mathcal{T}, \dots, \lambda$, $\mathfrak{T}$, R, w and, for every $a \in \Phi$, $\beta, \bar\beta$ and the Hodge–Tate atlas be as in the hypotheses of Proposition D.97. Then at every test point $(\mathfrak{q}, C, \iota_C)$ of $\mathfrak{T}$, for every $a \in \Phi$, with $s = (a, +)$,*

$$\mathcal{O}_C J_{i,\mathfrak{q}} = \mathcal{O}_C\, \mathcal{O}_{\mathcal{X}'}(-\mathrm{Ec}_{s,i})_{\mathfrak{q}} \quad \text{in } C, \qquad 1 \le i \le m_{\mathfrak{P}_s}.$$

Proof. Fix a, $s = (a,+)$, $\mathfrak{P} = \mathfrak{P}_s$, $m = m_{\mathfrak{P}}$, $N = \Gamma_{\mathfrak{P}}$ with the basis $b_1, \dots, b_m$ of (Ts4), $N_i = \Gamma_{\mathfrak{P},i}$, $\chi = \chi_s$ and $B = \mathcal{A}_{\mathfrak{P},C}$; regard $\Omega' \subseteq C$ through ι_C. $R_{\mathfrak{q}}$ is a discrete valuation ring with fraction field Ω', and $\mathcal{O}_C$ is torsion free, hence flat, over it, with $\Omega' \otimes_{R_{\mathfrak{q}}} \mathcal{O}_C = C$. All stalks below are finitely generated torsion-free, hence free, $R_{\mathfrak{q}}$-modules, and for submodules of a finite-dimensional Ω'-vector space the formation of intersections, kernels and images commutes with $- \otimes_{R_{\mathfrak{q}}} \mathcal{O}_C$ (flatness).

Step 1: χ is fundamental. Let $q = |\mathbb{F}_{\mathfrak{P}}|$, $a', b' \in \mathbb{F}_{\mathfrak{P}}$, $y = \chi(a'+b')$ and $z = \chi(a') + \chi(b')$. As $\chi(x)^q = \chi(x)$ for all x and the binomial coefficients $\binom{q}{k}$, $0 < k < q$, are divisible by p, $z^q \equiv z \pmod{p\mathcal{O}_C}$; and $z \equiv y \pmod{\mathfrak{m}_C}$ by (Ts1). With $e = z - y \in \mathfrak{m}_C$, $z^q - z \equiv y^q - y + e^q - e = e(e^{q-1}-1) \pmod{p\mathcal{O}_C}$, and $e^{q-1}-1$ is a unit; so $e \in p\mathcal{O}_C$. Hence χ is a fundamental character.

Step 2: the flag conditions. By Proposition D.98, B is an $\mathbb{F}_{\mathfrak{P}}$-stable tight Hopf order on N and an abelian factor; by Proposition 35.43 it has the generation property at every N_i. By Theorem 35.58 and Step 1, $(B, (b_i))$ satisfies the flag conditions for χ; in particular there are $c_i \in \mathcal{O}_C \smallsetminus \{0\}$ with $\mathrm{Xr}_{\chi,i}(B) = \mathrm{Ad}_{\chi,i}(B) = c_i\mathcal{O}_C$ $(1 \le i \le m)$.

Step 3: the divisor side. The stalk $\mathcal{O}(\mathrm{Ec}_{s,i})_{\mathfrak{q}}$ is the kernel of the $R_{\mathfrak{q}}$-linear map $\Omega' \to \mathrm{Map}(N_i, \Omega')/\mathcal{A}_{\mathfrak{P},i,\mathfrak{q}}$, $c \mapsto c\,\xi_{s,i}$, where $\mathcal{A}_{\mathfrak{P},i,\mathfrak{q}}$ is the restriction of $\mathcal{A}_{\mathfrak{P},\mathfrak{q}}$ to N_i; it is invertible, $= e\,R_{\mathfrak{q}}$ with $e \in \Omega'^{\times}$. A basis of the free module $\mathcal{A}_{\mathfrak{P},i,\mathfrak{q}}$ is an Ω'-basis of $\mathrm{Map}(N_i, \Omega')$ (by (Ts3), $p^N\mathrm{Map} \subseteq \mathcal{A}_{\mathfrak{P}}$), hence a C-basis of $\mathrm{Map}(N_i, C)$, so $\mathcal{A}_{\mathfrak{P},i,\mathfrak{q}} \otimes \mathcal{O}_C$ is its $\mathcal{O}_C$-span, which is $B|_{N_i}$ (Ox2). Tensoring the kernel with $\mathcal{O}_C$: $e\,\mathcal{O}_C = \{c \in C : c\,\xi_{s,i} \in B|_{N_i}\}$. Since $\xi_{s,i}(\alpha b_i + k) = \chi(\alpha)$ for $\alpha \in \mathbb{F}_{\mathfrak{P}}$, $k \in N_{i-1}$, the right side is $\mathrm{Xr}_{\chi,i}(B) = c_i\mathcal{O}_C$. Hence $\mathcal{O}_C\,\mathcal{O}(-\mathrm{Ec}_{s,i})_{\mathfrak{q}} = e^{-1}\mathcal{O}_C = c_i^{-1}\mathcal{O}_C$.

Step 4: the lattice af *at the test point.* Since $\mathcal{A}_{\mathfrak{P}} + p\,\mathrm{Map}(N, \mathcal{O}) \subseteq \mathrm{Map}(N, \mathcal{O})$ and $\ell_c(b_j) = c_j$, $\mathrm{af}_{\mathfrak{q}}$ is the kernel of $R_{\mathfrak{q}}^m \to \mathrm{Map}(N, R_{\mathfrak{q}})/(\mathcal{A}_{\mathfrak{P},\mathfrak{q}} + p\,\mathrm{Map}(N, R_{\mathfrak{q}}))$, $c \mapsto \ell_c$; so $L := \mathcal{O}_C\,\mathrm{af}_{\mathfrak{q}} = \{c \in \mathcal{O}_C^m : \ell_c \in B + p\,\mathrm{Map}(N, \mathcal{O}_C)\}$, a free $\mathcal{O}_C$-module of rank m with $p\mathcal{O}_C^m \subseteq L \subseteq \mathcal{O}_C^m$. Let A_i be the image of $L \cap (0^{i-1} \oplus C^{m-i+1})$ under the i-th coordinate. Claim: $A_i = \mathrm{Ad}_{\chi,i}(B)$. If $c \in L$ with $c_1 = \dots = c_{i-1} = 0$, write $\ell_c = g + ph$ with $g \in B$, $h \in \mathrm{Map}(N, \mathcal{O}_C)$; ℓ_c is additive modulo p (Step 1) and $\ell_c(\alpha x) = \chi(\alpha)\ell_c(x)$, so g is almost additive with $g(\alpha x) - \chi(\alpha)g(x) \in p\mathcal{O}_C$, $g(N_{i-1}) \subseteq p\mathcal{O}_C$ (ℓ_c vanishes on N_{i-1}) and $g(b_i) - c_i \in p\mathcal{O}_C$: so $c_i \in \mathrm{Ad}_{\chi,i}(B)$. Conversely, for $c \in \mathrm{Ad}_{\chi,i}(B)$ with its g, put $c'_j = g(b_j) \in \mathcal{O}_C$; then $g(\sum_j x_j b_j) \equiv \sum_j \chi(x_j)c'_j = \ell_{c'}(x) \pmod p$, so $\ell_{c'} \in B + p\,\mathrm{Map}$ and $c' \in L$, with $c'_j \in p\mathcal{O}_C$ for $j < i$ and $c'_i \equiv c \pmod p$; as $p\mathcal{O}_C^m \subseteq L$, $c' - \sum_{j<i} c'_j e_j + (c - c'_i)e_i \in L \cap (0^{i-1} \oplus C^{m-i+1})$ has i-th coordinate c. So $A_i = c_i\mathcal{O}_C$ (Step 2).

Step 5: duality. Choose $v_i \in L \cap (0^{i-1} \oplus C^{m-i+1})$ with i-th coordinate c_i. By descending induction on i, every $x \in L \cap (0^{i-1} \oplus C^{m-i+1})$ is an $\mathcal{O}_C$-combination of $v_i, \dots, v_m$ (subtract $(x_i/c_i)v_i$, $x_i/c_i \in \mathcal{O}_C$); so the matrix V with columns $v_1, \dots, v_m$, lower triangular with diagonal $c_1, \dots, c_m$, has columns forming a basis of L. H is the dual of af and $\mathrm{af}_{\mathfrak{q}}$ is free, so $\mathcal{O}_C H_{\mathfrak{q}} = \{d \in$

$C^m : d\cdot c \in \mathcal{O}_C\ \forall c \in L\}$, whose basis is the rows $r_1, \dots, r_m$ of V^{-1}; V^{-1} is lower triangular with diagonal c_i^{-1}, so $r_i \in C^i \oplus 0$ with i-th coordinate c_i^{-1}. Hence $\mathcal{O}_C H_{i,\mathfrak{q}} = \mathcal{O}_C H_{\mathfrak{q}} \cap (C^i \oplus 0)$ (flat base change of the intersection) is spanned by $r_1, \dots, r_i$, and its image under the i-th coordinate is $\mathcal{O}_C J_{i,\mathfrak{q}} = c_i^{-1}\mathcal{O}_C$. With Step 3 this is the assertion. □

D.6 Reference comparisons

This section proves five results used in the proof of Proposition 31.14 for (Gt4). A realised tower with a good origin, (Gi2) and (Gi4) is compared with fixed reference models: it has the reference link (Vl) (Theorem D.126) and the comparison of heights (Rh1) against the frozen reference models (Theorem D.123), both through joint reference models (Lemma D.124). Lie fibre data of the reference models give the reference lower bound (Rh2) (Theorem D.127), through the maximal slope of the Lie lattice of Section D.2. From these, the wall inputs follow: the monomial bound (Wd) from (Vl) (Theorem D.129), and the heights of points (Wp) from (Rh1) and (Rh2) (Theorem D.131).

Theorem D.123. *Let $\mathcal{T}$ be a root tower of type (Φ, n, p) with a geometric realisation and a good origin over an integral model of a unitary Shimura datum, and assume (Gi2) and (Gi4). For $c \in \mathrm{Cp}$ let $\mathcal{X}_c^{\mathrm{fr}}$ be the frozen reference model of Definition 34.1. Then the realised tower satisfies (Rh1) with the reference models $\mathcal{X}_c^{\mathrm{fr}}$: there are $C_{\mathrm{Rh}} \geq 1$ and $s_{\mathrm{Rh}} \in (0,1]$ such that for every $B \geq 2$ and $c \in \mathrm{Cp}$ there are an arithmetic variety $\mathcal{J}$ of absolute dimension $D+1$ and surjective morphisms $q\colon \mathcal{J} \to \mathcal{X}_{B,c}$, $q^{\mathrm{ref}}\colon \mathcal{J} \to \mathcal{X}_c^{\mathrm{fr}}$ with*

$$-C_{\mathrm{Rh}}\big(\log B + \log(1/s) + 1\big) \leq h_{c(\mu,s),t(s)}\big(q(W)\big) - h^{\mathrm{fr}}_{c(\mu,s),1}\big(q^{\mathrm{ref}}(W)\big) \leq C_{\mathrm{Rh}}(\log B + 1)$$

for every point W of $\mathcal{J}$, every dominant weight μ with $\|\mu\|_\infty \leq 2$ and every $0 < s \leq s_{\mathrm{Rh}}$.

Proof. Write $k_c = k_c^A$; all root models below carry the normalising integer k_c, so $c(\mu,s)$ is the same vector on each. For $c \in \mathrm{Cp}$ every connected component of X_c^{an} meets the dense open set X_c°; choose $R_c \geq e$ such that every component contains a point of X_c° with $\mathrm{rW} \leq R_c$, and put $t_1 = \min_c \min(t_0, e^{-R_c})$ (finitely many c; the constants of the systems are fixed) and $s_{\mathrm{Rh}} \in (0,1]$ with $t(s_{\mathrm{Rh}}) \leq t_1$. As $\log(1/t) \geq R_c \geq e$ on $(0,t_1]$, ε is continuous there and tends to 0, so $C_\varepsilon = \sup_{0<t\leq t_1} \varepsilon(t)$ is finite.

Step 1: the correspondence. Fix B, c and let $\mathcal{J} = \widetilde{\mathcal{X}}$, $q = \mathrm{pr}_1$, $q^{\mathrm{ref}} = \mathrm{pr}_0$ from Lemma D.124; on $\mathcal{J}$ consider the pulled-back root models $\widetilde{\mathcal{X}}$ (stage lines $\overline{\mathcal{L}}_r(t)$) and $\widetilde{\mathcal{X}}'$ (reference lines $\overline{\mathcal{L}}'_r(t)$). For a point W of $\mathcal{J}$, $q(W)$ and $q^{\mathrm{ref}}(W)$ are points, $\deg W_{\mathbb{Q}} = \deg(W/q(W)) \deg q(W)_{\mathbb{Q}}$, and by Lemma 30.13 (with $b=1$, $d=0$ and β the surjections $W \to q(W)$ and $W \to q^{\mathrm{ref}}(W)$ of arithmetic varieties of absolute dimension 1, whose generic fibres, spectra of number fields, are smooth over $\mathbb{Q}$; the metrics on the finite sets $q(W)(\mathbb{C})$ and $q^{\mathrm{ref}}(W)(\mathbb{C})$ are smooth; $c = \deg(W/q(W))$, resp. $\deg(W/q^{\mathrm{ref}}(W))$) $h_{c,t}(q(W))$ equals the height of W for the lines $\overline{\mathcal{L}}_r(t)$, and $h^{\mathrm{fr}}_{c,1}(q^{\mathrm{ref}}(W))$ the height of W for the lines $\overline{\mathcal{L}}'_r(t_0)$. Write $\widehat{h}_W(\cdot) = \widehat{\deg}(\widehat{c}_1(\cdot)\cdot[W])/\deg W_{\mathbb{Q}}$. Then, for $c = c(\mu,s)$ and $t = t(s) \leq t_1$, the difference to be bounded is $\Sigma_{\mathrm{fin}} + \Sigma_\infty$ with

$$\Sigma_{\mathrm{fin}} = \sum_{r\in \mathrm{Rt}^+} c_r\big(\widehat{h}_W(\overline{\mathcal{L}}_r(t)) - \widehat{h}_W(\overline{\mathcal{L}}'_r(t))\big), \qquad \Sigma_\infty = \sum_{r\in \mathrm{Rt}^+} c_r\big(\widehat{h}_W(\overline{\mathcal{L}}'_r(t)) - \widehat{h}_W(\overline{\mathcal{L}}'_r(t_0))\big).$$

Step 2: the finite places. Let $r \in \mathrm{Rt}^+$ and let f_r, g_r be the polynomials of the vertical closeness (Jr3), (Jr4), with exponents α_ℓ ($\alpha = 0$ for $r = *$). The rational section $\sigma = f_r/g_r$ of $\overline{\mathcal{L}}_r(t) \otimes \overline{\mathcal{L}}'_r(t)^{-1}$ has norm 1 on $\mathcal{J}(\mathbb{C})$ and vertical divisor, so it is regular and non-zero at the generic point of W. Let $\nu_W\colon \operatorname{Spec} \mathcal{O}_{\mathbf{k}(W)} \to W$ be the normalisation of W, a surjection of arithmetic

varieties of absolute dimension 1 with smooth generic fibres and $c = 1$; by Lemma 30.13 ($b = 1$, $d = 0$, $\beta = \nu_W$; the metrics on the finite set $W(\mathbb{C})$ are smooth) the height of W for a Hermitian line bundle $\overline{N}$ on $\mathcal{J}$ is the Arakelov degree of $\nu_W^*\overline{N}$ (this is also used in Step 3). For $\overline{N} = \overline{\mathcal{L}}_r(t) \otimes \overline{\mathcal{L}}'_r(t)^{-1}$, computed with σ (of norm 1), this gives $\deg W_{\mathbb{Q}}(\widehat{h}_W(\overline{\mathcal{L}}_r(t)) - \widehat{h}_W(\overline{\mathcal{L}}'_r(t))) = \sum_w \operatorname{ord}_w(\sigma|_W)\log \#\kappa(w)$, the sum over the closed points w of $\operatorname{Spec}\mathcal{O}_{\mathbf{k}(W)}$, the normalisation of W. Let w be a closed point of the normalisation of W, over the point $x \in \mathcal{J}$ and the prime ℓ. Choose monomials m_f, m_g of the multidegrees of f_r, g_r in coordinates non-zero at x and put $\phi = (f_r/m_f)/(g_r/m_g) \in \Omega^\times$; m_f/m_g generates the line at x, so $\operatorname{ord}_w(\sigma|_W) = \operatorname{ord}_w(\phi)$, and $\operatorname{ord}_{W'}(\phi) = \operatorname{ord}_{W'}(f_r) - \operatorname{ord}_{W'}(g_r)$ for every prime divisor W' through x; these are horizontal or lie over ℓ. If $\ell \notin S_B$, all these orders vanish, so $\phi^{\pm 1} \in \mathcal{O}_x$ by normality and $\operatorname{ord}_w(\phi) = 0$. If $\ell \in S_B$, take an integer $N \geq 1$ with $N\alpha_\ell \in \mathbb{Z}$: $\phi^{\pm N}\ell^{N\alpha_\ell}$ has non-negative order along every prime divisor through x, so lies in $\mathcal{O}_x$, and its image in the valuation ring of w gives $|\operatorname{ord}_w(\phi)| \leq \alpha_\ell \operatorname{ord}_w(\ell)$. Summing,

$$|\widehat{h}_W(\overline{\mathcal{L}}_r(t)) - \widehat{h}_W(\overline{\mathcal{L}}'_r(t))| \leq \frac{1}{\deg W_{\mathbb{Q}}} \sum_{\ell \in S_B} \alpha_\ell \sum_{w|\ell} \operatorname{ord}_w(\ell)\log \#\kappa(w) = \sum_{\ell \in S_B} \alpha_\ell \log \ell \leq C_{\mathrm{Vl}} \log B$$

by (Vl5) in Theorem D.126 (which has the same S_B and α), and the difference is 0 for $r = *$. As $|c_r| \leq 2$ for roots, $|\Sigma_{\mathrm{fin}}| \leq 2|\Phi| n\, C_{\mathrm{Vl}} \log B$.

Step 3: the archimedean places. Changing a metric changes the height by the logarithm of the ratio of cone functions at the $\deg W_{\mathbb{Q}}$ complex points of W, so Σ_∞ is the average over $x \in W(\mathbb{C})$ of $\Psi(x) = \sum_r c_r \log(h_r^0(t)/h_r^0(t_0))(z_x)$, z_x a cone point over $\mathrm{pr}_0(x)$; the auxiliary metric does not depend on t. By (Go4), for a fundamental index $a = (\tau, i)$, $\sum_{j \leq i} \log(h^0_{(\tau,j)}(t)/h^0_{(\tau,j)}(t_0)) = -\Delta_a \circ \pi_0$ with $\Delta_a = \varphi_a^T(t) - \varphi_a^T(t_0)$, so with $\Delta_{(\tau,0)} = 0$ and summation by parts ($c_{\tau,i} = -\mu_{\tau,i}$)

$$\Psi = \sum_{\tau \in \Phi} \Big(\sum_{i<n} (\mu_{\tau,i} - \mu_{\tau,i+1})\, \Delta_{(\tau,i)} + \mu_{\tau,n}\, \Delta_{(\tau,n)} \Big) \circ \pi_0.$$

By (Go1)(2), $\Delta_a \leq C\varepsilon(t_0)$ and $\Delta_a \geq -C\log\log(1/t) - 2C$. For $a = (\tau, n)$, the clause (flat) makes the metrics $h_a^{\mathrm{ref}} e^{\varphi_a^T(t)}$ and $h_a^{\mathrm{ref}} e^{\varphi_a^T(t_1)}$ both of pluriharmonic local potentials, so $\varphi_a^T(t) - \varphi_a^T(t_1)$ is pluriharmonic on the compact manifold X_c^{an}, hence constant on each component; at a point of X_c° with $\mathrm{rW} \leq R_c \leq \log(1/t_1) \leq \log(1/t)$, (Go1)(2) gives $0 \leq \varphi_a^T(t') - \varphi_a \leq t'^{1/3} + \varepsilon(t')$ for $t' \in \{t, t_1\}$, so $|\varphi_a^T(t) - \varphi_a^T(t_1)| \leq 2 + 2C_\varepsilon$ everywhere. With C_7 the maximum of the continuous function $|\varphi_a^T(t_1) - \varphi_a^T(t_0)|$ on X_c^{an}, $|\Delta_{(\tau,n)}| \leq 2 + 2C_\varepsilon + C_7 =: C_{\mathrm{det}}$. Since $\|\mu\|_\infty \leq 2$, the gaps lie in $[0,4]$ and $|\mu_{\tau,n}| \leq 2$; with $\log\log(1/t(s)) = 2\log(1/s)$,

$$-|\Phi|\big(4(n-1)(2C\log(1/s) + 2C) + 2C_{\mathrm{det}}\big) \leq \Psi \leq |\Phi|\big(4(n-1)C|\varepsilon(t_0)| + 2C_{\mathrm{det}}\big).$$

Conclusion. Taking for C_{Rh} the maximum over $c \in \mathrm{Cp}$ of 1, $2|\Phi|nC_{\mathrm{Vl}} + |\Phi|(8(n-1)C + 8(n-1)C + 2C_{\mathrm{det}})$ and $|\Phi|(4(n-1)C|\varepsilon(t_0)| + 2C_{\mathrm{det}}) + 2|\Phi|nC_{\mathrm{Vl}}$ (constants of Sys_c), both inequalities of (Rh1) follow from $\Sigma_{\mathrm{fin}} + \Sigma_\infty$, Steps 2 and 3. □

Lemma D.124. *Let $\mathcal{T}$ be a root tower of type (Φ, n, p) with a geometric realisation and a good origin over an integral model $\mathcal{Y}$ of a unitary Shimura datum with CM field E. Let $B \geq 2$ and $c \in \mathrm{Cp}$; write $\mathcal{X}_1 = \mathcal{X}_{B,c} \subseteq \mathbb{P}_1 = \prod_{k \in K_1} \mathbb{P}(\mathbb{Z}^{I_k})$ and $\mathcal{X}_0 = \mathcal{X}_c^{\mathrm{ref}} \subseteq \mathbb{P}_0 = \prod_{k \in K_0} \mathbb{P}(\mathbb{Z}^{I_k})$ ($K_0 \cap K_1 = \varnothing$), with root origins on the fixed data at c (function fields Ω_i, embeddings g_i, root sections ϱ_r^i, maps f_i, multidegrees e_r^i, e_*^i, metrics $h_r^i(t), h_*^i$, realisations π_i), and let t_0 be the constant of Sys_c. Put $\alpha_\ell = e_\ell + 2v_\ell(\operatorname{disc} E)$ for $\ell \in S_B$. Then there are a finite set I_2 and a closed integral subscheme $\widetilde{\mathcal{X}} \subseteq \widetilde{\mathbb{P}} = \mathbb{P}(\mathbb{Z}^{I_2}) \times \mathbb{P}_1 \times \mathbb{P}_0$, flat over $\mathbb{Z}$ of absolute dimension $D + 1$, such that, writing a point of the affine cone as $z = (z_2, z_1, z_0)$:*

(Jr1) *$\widetilde{\mathcal{X}}$ is normal; the projections restrict to surjective morphisms $\mathrm{pr}_i\colon \widetilde{\mathcal{X}} \to \mathcal{X}_i$; pr_1 is birational, pr_0 is generically finite of degree $\deg_{B,c}$; $f_1 \circ \mathrm{pr}_1 = f_0 \circ \mathrm{pr}_0$, and the induced field embeddings satisfy $\iota_1 g_1 = \iota_0 g_0$;*

(Jr2) *$\pi_1 \circ \mathrm{pr}_1 = \pi_0 \circ \mathrm{pr}_0$ on $\widetilde{\mathcal{X}}(\mathbb{C})$;*

(Jr3) *for every root r and every $0 < t \le t_0$, the Hermitian line bundles $(\mathcal{O}(0, e_r^1, 0), h_r^1(t)(z_1))|_{\widetilde{\mathcal{X}}}$ and $(\mathcal{O}(0, 0, e_r^0), h_r^0(t)(z_0))|_{\widetilde{\mathcal{X}}}$ are vertically close over (S_B, α);*

(Jr4) *the auxiliary lines $(\mathcal{O}(0, e_*^1, 0), h_*^1(z_1))|_{\widetilde{\mathcal{X}}}$ and $(\mathcal{O}(0, 0, e_*^0), h_*^0(z_0))|_{\widetilde{\mathcal{X}}}$ are vertically close over $(S_B, 0)$.*

Proof. Step 1: the common field and the closure. As $g_0\colon \Omega_c \to \Omega_0$ is an isomorphism, $\iota = g_1 \circ g_0^{-1}\colon \Omega_0 \to \Omega_1 =: \Omega$ is a field embedding with $\iota g_0 = g_1$. Put $y = (y^1, \iota(y^0))$ (coordinates of $\mathbb{P}_1 \times \mathbb{P}_0$). The multihomogeneous G with $G(y) = 0$ generate a multihomogeneous prime $\mathfrak{q}$ (kernel of a ring map to a field on multihomogeneous elements) containing no coordinate that is non-zero at y; let $\mathcal{X}^{\mathrm{cl}} \subseteq \mathbb{P}_1 \times \mathbb{P}_0$ be the integral closed subscheme it defines. Its function field is generated by the coordinate ratios; the ratios of y^1 already generate Ω and those of $\iota(y^0)$ lie in Ω, so it is Ω. If G vanishes on $\mathcal{X}_1$ (resp. $\mathcal{X}_0$) then $G(y^1) = 0$ (resp. $G(\iota y^0) = \iota G(y^0) = 0$), so $\mathcal{X}^{\mathrm{cl}} \subseteq \mathcal{X}_1 \times \mathcal{X}_0$; the projection to $\mathcal{X}_1$ induces the identity of Ω (birational), the projection to $\mathcal{X}_0$ induces ι, of degree $[\Omega : \iota\Omega_0] = [\Omega : g_1\Omega_c] = \deg_{B,c}$. As Ω has characteristic 0, $\mathcal{X}^{\mathrm{cl}}$ is flat over $\mathbb{Z}$, of absolute dimension $\mathrm{trdeg}_{\mathbb{Q}}\Omega + 1 = D + 1$. The maps $f_1 \circ \mathrm{pr}_1$, $f_0 \circ \mathrm{pr}_0$ to the separated scheme $\mathcal{Y}$ both induce $\mathbf{k}(\mathcal{Y}_c) \to \Omega$ through $g_1 = \iota g_0$, so they agree at the generic point, hence on the reduced scheme $\mathcal{X}^{\mathrm{cl}}$.

Step 2: normalisation; (Jr1). The normalisation $\widetilde{\mathcal{X}} \to \mathcal{X}^{\mathrm{cl}}$ is finite, so $\widetilde{\mathcal{X}}$ embeds as a closed subscheme of $\mathbb{P}(\mathbb{Z}^{I_2}) \times \mathcal{X}^{\mathrm{cl}} \subseteq \widetilde{\mathbb{P}}$ over $\mathcal{X}^{\mathrm{cl}}$ for a finite set I_2; it is normal, integral, flat over $\mathbb{Z}$, of absolute dimension $D + 1$, with function field Ω. The projections pr_i are projective, hence proper, and dominant, hence surjective; pr_1 is birational, pr_0 generically finite of degree $\deg_{B,c}$, $f_1\mathrm{pr}_1 = f_0\mathrm{pr}_0$ by Step 1, and $\iota_1 = \mathrm{id}$, $\iota_0 = \iota$ satisfy $\iota_1 g_1 = \iota_0 g_0$. Being normal, integral, locally noetherian and mapping to $\mathcal{Y}$ through $\mathcal{X}_1$, $\widetilde{\mathcal{X}}$ is a cover in the same sense as $\mathcal{X}_1$, with $G_{\widetilde{\mathcal{X}}} = \mathrm{pr}_i^* G_{\mathcal{X}_i}$.

Step 3: (Jr2). Identify $I_{k_0^1}$ and $I_{k_0^0}$ with $\{0, \dots, m\}$ by the bijections of the root origins. The two morphisms $\widetilde{\mathcal{X}} \to \mathbb{P}^m_{\mathbb{Z}}$ given by the factors k_0^1 and k_0^0 have coordinate ratios $g_1(y_j^c/y_{j'}^c)$ and $\iota g_0(y_j^c/y_{j'}^c)$, which are equal; so they agree on a dense open set, hence everywhere. In particular the multihomogeneous polynomials $Y_{k_0^1,a}Y_{k_0^0,b} - Y_{k_0^1,b}Y_{k_0^0,a}$ vanish on $\widetilde{\mathcal{X}}$, and at every cone point z the vectors z_{1,k_0^1} and z_{0,k_0^0} are proportional. For $x \in \widetilde{\mathcal{X}}(\mathbb{C})$, $\pi_1(\mathrm{pr}_1 x)$ and $\pi_0(\mathrm{pr}_0 x)$ therefore have proportional images under pt_c, so they are equal.

Step 4: (Jr4). Choose j with $y_j^c \neq 0$ and put $f_* = Y_{k_0^1,j}$, $g_* = Y_{k_0^0,j}$; then $\deg f_* - \deg g_* = (0, e_*^1, 0) - (0, 0, e_*^0)$ (e_*^i is the unit vector at k_0^i), and neither vanishes on $\widetilde{\mathcal{X}}$. At a cone point z write $z_{1,k_0^1} = \lambda z_{0,k_0^0}$ ($\lambda \in \mathbb{C}^\times$, Step 3); as $h_*^i(z) = h_c(z_{i,k_0^i})$ and h_c is homogeneous of degree one in absolute value, $|f_*(z)|h_*^0(z_0) = |\lambda||z_{0,k_0^0,j}|h_c(z_{0,k_0^0}) = |g_*(z)|h_*^1(z_1)$. For a prime divisor W choose j' with $Y_{k_0^1,j'}$ not identically zero on W; by Step 3 neither is $Y_{k_0^0,j'}$, and $\mathrm{ord}_W(f_*) = \mathrm{ord}_W(g_1(y_j^c/y_{j'}^c)) = \mathrm{ord}_W(g_*)$.

Step 5: the polynomials for a root r. Put $d = (0, e_r^1, -e_r^0)$. For each $k \in K_1 \sqcup K_0$ choose j_k with $y_{k,j_k} \neq 0$, let $M_1 = \prod_k Y_{k,j_k}^{\max(d_k,0)}$, $M_2 = \prod_k Y_{k,j_k}^{\max(-d_k,0)}$; the element $\iota(\varrho_r^0)M_2(y)/(\varrho_r^1 M_1(y)) \in \Omega^\times$ is a rational function in the coordinate ratios, so it equals $G(y)/H(y)$ with $G, H \in \mathbb{Z}[Y_1, Y_0]$ multihomogeneous of equal multidegree, $H(y) \neq 0$. Put $f_r = GM_1$, $g_r = HM_2$: $\deg f_r - \deg g_r =$

d and

$$f_r(y)/g_r(y) = \iota(\varrho_r^0)/\varrho_r^1 \neq 0.$$

Step 6: orders. Let W be a prime divisor of $\widetilde{\mathcal{X}}$, $x_i = \mathrm{pr}_i(W)$. For each $k \in K_i$ choose c_k' with $Y_{k,c_k'}$ non-zero at x_i; by (Go3)(3) the stalk of $\mathcal{L}_r^i$ at x_i is generated by $\varrho_r^i m^i(y^i)$, $m^i = \prod_{k\in K_i} Y_{k,c_k'}^{e^i_{r,k}}$, and the coordinates $Y_{k,c_k'}$ do not vanish identically on W. With the monomials m_f, m_g in these coordinates of multidegrees $\deg f_r, \deg g_r$ (so $m_f/m_g = m^1/m^0$), the definition of ord_W gives

$$\mathrm{ord}_W(f_r) - \mathrm{ord}_W(g_r) = \mathrm{ord}_W\Big(\frac{f_r(y)}{g_r(y)} \cdot \frac{\iota(m^0(y^0))}{m^1(y^1)}\Big) = -\mathrm{ord}_W(u),$$

where $\varrho_r^1 m^1(y^1) = u \cdot \iota(\varrho_r^0 m^0(y^0))$ compares generators of $\Lambda^1_{r,W}$ and $\Lambda^0_{r,W}$ in the notation of Lemma D.125. That lemma applies to $\widetilde{\mathcal{X}} \to \mathcal{X}_i$: $\mathcal{X}_1$ has Hodge bundles at (S_B, R) with rational torsion and free Hodge–Tate spans over S_B ((Go3)(2)); $\mathcal{X}_0$ has the de Rham Hodge bundles ($S = \varnothing$); the generic flags are g_1 and g_0 of the universal flag ((Go3)(3)), so they coincide after $\iota_1 g_1 = \iota_0 g_0$. Hence $\mathrm{ord}_W(f_r) = \mathrm{ord}_W(g_r)$ if W is horizontal; if W lies over ℓ, $|\mathrm{ord}_W(f_r) - \mathrm{ord}_W(g_r)| \le (e_\ell[\ell \in S_B] + 2v_\ell(\mathrm{disc}E))\mathrm{ord}_W(\ell)$, which is $\alpha_\ell \mathrm{ord}_W(\ell)$ for $\ell \in S_B$ and 0 for $\ell \notin S_B$, since every prime dividing $\mathrm{disc}\, E$ lies in $\mathrm{Bd} \subseteq S_B$ ((Go5)).

Step 7: metrics. Let $r = (\tau, k)$ and put $a_j = (\tau, j)$, with a_0 the trivial index ($h^{\mathrm{ref}}_{a_0} = 1$, $\varphi_{a_0} = \varphi^T_{a_0} = 0$). By (Go4), on $\mathcal{X}_i$ and $0 < t \le t_0$, $\prod_{j\le k} h^i_{(\tau,j)}(t) = (h^{\mathrm{ref}}_{a_k} e^{\varphi^T_{a_k}(t)\circ\pi_i})^{-1}$ on the whole cone and $\prod_{j\le k} h^{i,\mathrm{sing}}_{(\tau,j)} = (h^{\mathrm{ref}}_{a_k} e^{\varphi_{a_k}\circ\pi_i})^{-1}$ on the cone over $\pi_i^{-1}(X_c^\circ)$. Dividing the identities for k and $k-1$, on the cone over $\pi_i^{-1}(X_c^\circ)$

$$h_r^i(t) = h_r^{i,\mathrm{sing}} \cdot \exp\big(-(\psi_{a_k}(t) - \psi_{a_{k-1}}(t)) \circ \pi_i\big), \qquad \psi_a(t) = \varphi_a^T(t) - \varphi_a \text{ on } X_c^\circ.$$

By (Jr2) the exponential factor is the same function Ξ_t on the cone over $U = (\pi_1 \mathrm{pr}_1)^{-1}(X_c^\circ)$ for $i = 0, 1$; U is the abelian locus of $\widetilde{\mathcal{X}}$ (through either $\mathcal{X}_i$), the complement of a proper Zariski closed subset defined over $\mathbb{Q}$, hence dense. Let $x \in U$ and z a cone point over x with $f_r(z)g_r(z) \neq 0$. Choose a Laurent monomial Q of multidegree $(0, e_r^1, 0) - \deg f_r$ in coordinates non-zero at z, and put $\xi = \varrho_r^1 f_r(y)Q(y) = \iota(\varrho_r^0) g_r(y)Q(y)$, an element of the root line Λ_r regular at x. Its Hodge norm at x (that of the root line of $G_{\widetilde{\mathcal{X}},x}$ for the common flag) is computed through $\mathcal{X}_1$ as follows: let m^1 be a Laurent monomial of multidegree e_r^1 in coordinates of $\mathbb{P}_1$ non-zero at z_1; then $\xi = (f_r Q/m^1)(y) \cdot \varrho_r^1 m^1(y^1)$, the first factor is a rational function of multidegree zero, regular at x with value $f_r(z)Q(z)/m^1(z_1)$, and (Go3)(4) gives $\|\varrho_r^1 m^1(y^1)\|^{\mathrm{Hdg}} = |m^1(z_1)|/h_r^{1,\mathrm{sing}}(z_1)$ at $\mathrm{pr}_1(x)$; so $\|\xi\|^{\mathrm{Hdg}}(x) = |f_r(z)Q(z)|/h_r^{1,\mathrm{sing}}(z_1)$. In the same way, through $\mathcal{X}_0$ and a Laurent monomial of multidegree e_r^0 in coordinates of $\mathbb{P}_0$, $\|\xi\|^{\mathrm{Hdg}}(x) = |g_r(z)Q(z)|/h_r^{0,\mathrm{sing}}(z_0)$. Hence $|f_r(z)|h_r^{0,\mathrm{sing}}(z_0) = |g_r(z)|h_r^{1,\mathrm{sing}}(z_1)$, and multiplying by $\Xi_t(z)$, $|f_r(z)|h_r^0(t)(z_0) = |g_r(z)|h_r^1(t)(z_1)$. Both sides are continuous on the affine cone over $\widetilde{\mathcal{X}}(\mathbb{C})$ and the points used are dense there, so the identity holds everywhere. With Step 6 this is (Jr3). □

Lemma D.125. *Let $\mathcal{Y}$ be an integral model of a unitary Shimura datum with CM field E. For $i \in \{0,1\}$ let $\mathcal{X}_i$ be a locally noetherian cover of $\mathcal{Y}$ with function field Ω_i, structure map f_i, a finite set S_i of primes with integers $R_i(\ell) \ge 1$ ($\ell \in S_i$) such that every $\ell^{R_i(\ell)}$-torsion point of $G_{\mathcal{X}_i}$ over an algebraic closure of Ω_i is defined over Ω_i, Hodge bundles $\mathcal{V}_s^i$ at (S_i, R_i) and an integral flag of them with root lines $\mathcal{L}_r^i$. Assume that* ht_x *is a free $\mathcal{O}_x$-module of rank* $\dim \mathrm{Li}$ *at every point x of $\mathcal{X}_i$ over every $\ell \in S_i$. Let $\widetilde{\mathcal{X}}$ be a locally noetherian cover of $\mathcal{Y}$ with function field $\widetilde{\Omega}$ and dominant morphisms $\mathrm{pr}_i\colon \widetilde{\mathcal{X}} \to \mathcal{X}_i$ with $f_0 \circ \mathrm{pr}_0 = f_1 \circ \mathrm{pr}_1$, inducing $\iota_i\colon \Omega_i \to \widetilde{\Omega}$, such that for every label s the flags ι_0(flag of $\mathcal{V}_s^0$)$\otimes\widetilde{\Omega}$ and ι_1(flag of $\mathcal{V}_s^1$)$\otimes\widetilde{\Omega}$ of $\mathrm{Li}_s(\widetilde{\Omega})$ coincide. For a root*

r let Λ_r be the corresponding root line of this flag (a one-dimensional $\widetilde{\Omega}$-space) and, for a point w of $\widetilde{\mathcal{X}}$, $\Lambda^i_{r,w} = \mathcal{O}_w \cdot \iota_i(\mathcal{L}^i_{r,\mathrm{pr}_i(w)}) \subseteq \Lambda_r$. For p prime put $e_p = 2$ if $p = 2$ and $e_p = \frac{1}{p-1}$ otherwise. Let W be a point of $\widetilde{\mathcal{X}}$ whose local ring is a discrete valuation ring, with normalised valuation ord_W. Then $\Lambda^0_{r,W}$ and $\Lambda^1_{r,W}$ are free of rank one, $\Lambda^1_{r,W} = u\,\Lambda^0_{r,W}$ for some $u \in \widetilde{\Omega}^\times$, and:

1. *if W lies over no prime, then $\mathrm{ord}_W(u) = 0$;*
2. *if W lies over the prime p, then*

$$|\mathrm{ord}_W(u)| \le \Big(e_p\,([p \in S_0] + [p \in S_1]) + 2\,v_p(\mathrm{disc}\,E)\Big)\,\mathrm{ord}_W(p),$$

where $[p \in S_i]$ is 1 if $p \in S_i$ and 0 otherwise.

Proof. Write $\mathcal{O} = \mathcal{O}_W$, $v = \mathrm{ord}_W$, $x_i = \mathrm{pr}_i(W)$, and identify Ω_i with its image under ι_i. Fix the label $s = s(r)$ and $k = \mathrm{st}(r)$; let $(\Lambda_{s,j})_j$ be the common flag of $\mathrm{Li}_s(\widetilde{\Omega})$.

Step 1: idempotents with denominators in the different. Let $\Sigma = \mathrm{Hom}(E,F)$ and $\varepsilon_\sigma = \sum_j \omega_j^\vee \otimes \sigma(\omega_j) \in E \otimes_{\mathbb{Q}} F$ for $\sigma \in \Sigma$. Under $E \otimes F \cong \prod_{\tau\in\Sigma} F$, $a \otimes b \mapsto (\tau(a)b)_\tau$, the τ-component of ε_σ is $\sum_j \tau(\omega_j^\vee)\sigma(\omega_j) = \delta_{\tau\sigma}$ (the matrices $(\tau(\omega_j))$ and $(\tau(\omega_j^\vee))$ are inverse transposes of each other, by $\mathrm{Tr}(\omega_j\omega_{j'}^\vee) = \delta_{jj'}$). So ε_σ is the idempotent cutting out the σ-eigenspace, and $(d\otimes 1)\varepsilon_\sigma \in \mathcal{O}_E \otimes \mathcal{O}_F$ for every $d \in \mathfrak{d}_E$, since $\omega_j^\vee \in \mathfrak{d}_E^{-1}$. Let y be a point of a cover $\mathcal{X}'$ with a dominant map $\mathrm{pr}'\colon \widetilde{\mathcal{X}} \to \mathcal{X}'$ through which $W \mapsto y$ ($\mathcal{X}'$ one of $\mathcal{X}_0, \mathcal{X}_1$). Then $\mathrm{Lie}_W = \mathcal{O}\,\mathrm{Lie}_y$ (the Lie algebra of $G_{\widetilde{\mathcal{X}}} = \mathrm{pr}'^* G_{\mathcal{X}'}$ is the pull-back). Let δ be an element of least valuation among the $\sigma_s(d)$, $d \in \mathfrak{d}_E$ (a finite set of generators suffices). We claim

$$(*) \qquad \mathcal{O}\,\mathrm{dR}_{s,y} \subseteq \mathrm{dR}_{s,W} \subseteq \delta^{-1}\mathcal{O}\,\mathrm{dR}_{s,y}.$$

The first inclusion is clear. If $e \in \mathrm{dR}_{s,W} = \mathrm{Lie}_W \cap \mathrm{Li}_s$, write $e = \sum_j a_j l_j$ with $a_j \in \mathcal{O}$, $l_j \in \mathrm{Lie}_y$; for $d \in \mathfrak{d}_E$, $(d\otimes 1)\varepsilon_{\sigma_s}$ acts on Li through ι and the scalars, preserves Lie_y (an $\mathcal{O}_E \otimes \mathcal{O}_y$-module), maps Li into Li_s, and acts on Li_s as $\sigma_s(d)$. Hence $\sigma_s(d)e = \sum_j a_j (d\otimes 1)\varepsilon_{\sigma_s} l_j \in \mathcal{O}\,\mathrm{dR}_{s,y}$, and with $\sigma_s(d) = \delta$ the claim follows. If W lies over no prime, $\mathcal{O} \supseteq \mathbb{Q}$ and δ divides the non-zero integer $\mathrm{N}(d)$ in $\mathcal{O}$, so $v(\delta) = 0$. If W lies over p, then $v \circ \sigma_s$ restricted to E is $v(p)\,v_{\mathfrak{p}}/e_{\mathfrak{p}}$ for the prime $\mathfrak{p} \mid p$ of E it defines (ramification index $e_{\mathfrak{p}}$, residue degree $f_{\mathfrak{p}}$), so $v(\delta) = v(p)\,v_{\mathfrak{p}}(\mathfrak{d}_E)/e_{\mathfrak{p}} \le v(p)\,f_{\mathfrak{p}} v_{\mathfrak{p}}(\mathfrak{d}_E) \le v(p)\,v_p(\mathrm{disc}\,E)$, as $\mathfrak{p}^{f_{\mathfrak{p}} v_{\mathfrak{p}}(\mathfrak{d}_E)}$ divides the norm $|\mathrm{disc}\,E|$.

Step 2: the Hodge lattices against $\mathrm{dR}_{s,W}$. Put $c_i = \varpi_p\delta$ if W lies over $p \in S_i$ and $c_i = 1$ otherwise. We claim

$$(**) \qquad \mathcal{O}\,\mathrm{dR}_{s,x_i} \subseteq \mathcal{O}\,V^{S_i}_{s,x_i} \subseteq c_i^{-1}\mathcal{O}\,\mathrm{dR}_{s,x_i}.$$

If x_i lies over no prime of S_i (in particular if W lies over no prime of S_i: x_i lies over p whenever W does, $\mathcal{O}_{x_i} \to \mathcal{O}$ being local), $V^{S_i}_{s,x_i} = \mathrm{dR}_{s,x_i}$. If x_i lies over $p \in S_i$ (then so does W, as p is a non-unit of $\mathcal{O}_{x_i}$ mapping into the maximal ideal of $\mathcal{O}$), $V^{S_i}_{s,x_i} = \mathrm{HT}_{s,x_i}(p^{R_i(p)})$ and Lemma 35.32(3) gives $\mathrm{dR} \subseteq \mathrm{HT}$ and $\varpi_p\sigma_s(d)\mathrm{HT} \subseteq \mathrm{dR}$ at x_i for all $d \in \mathfrak{d}_E$ (for $s = (\tau, -)$ even without $\sigma_s(d)$, and $\sigma_s(d) \in \mathcal{O}_{x_i}$), in particular for d with $\sigma_s(d) = \delta$; apply $\mathcal{O}\cdot$. Combining with $(*)$ for $y = x_i$: with $N_i = \mathcal{O}V^{S_i}_{s,x_i}$ and $D = \mathrm{dR}_{s,W}$,

$$\delta\,D \subseteq N_i \subseteq c_i^{-1}D.$$

Step 3: root lines. The flag of $\mathcal{V}^i_s$ at x_i consists of direct summands with free quotients: $V^{S_i}_{s,x_i} = V^i_k \oplus Q_k$ with $V^i_k = V^{S_i}_{s,x_i} \cap \Lambda_{s,k}$ (saturation) for each k. Hence $N_i \cap \Lambda_{s,k} = \mathcal{O}V^i_k$, and the image $\ell_k(N_i)$ of $N_i \cap \Lambda_{s,k}$ in $\Lambda_{s,k}/\Lambda_{s,k-1}$ is $\mathcal{O}\cdot(V^i_k/V^i_{k-1})$. So $\Lambda^i_{r,W} = \ell_k(N_i)^{\otimes \mathrm{sg}(r)}$, a finitely generated torsion-free, hence free, $\mathcal{O}$-module of rank one. Inclusions $M \subseteq aM'$ of lattices in

$\mathrm{Li}_s(\widetilde{\Omega})$ give $\ell_k(M) \subseteq a\,\ell_k(M')$. From Step 2, $\ell_k(N_1) \subseteq c_1^{-1}\ell_k(D) \subseteq c_1^{-1}\delta^{-1}\ell_k(N_0)$ and $\ell_k(N_0) \subseteq c_0^{-1}\ell_k(D) \subseteq c_0^{-1}\delta^{-1}\ell_k(N_1)$. Writing $\ell_k(N_1) = u'\ell_k(N_0)$, this says $-v(c_1\delta) \le v(u') \le v(c_0\delta)$, and $u = u'^{\,\mathrm{sg}(r)}$, so $|v(u)| \le v(\delta) + \max(v(c_0), v(c_1)) \le v(\delta) + v(c_0) + v(c_1)$.

Conclusion. If W lies over no prime, $v(\delta) = 0$ and $c_0 = c_1 = 1$, so $v(u) = 0$. If W lies over p: $v(\delta) \le v_p(\mathrm{disc}E)\,v(p)$, and $v(c_i) = v(\varpi_p) + v(\delta) \le e_p\,v(p) + v_p(\mathrm{disc}E)\,v(p)$ if $p \in S_i$ ($v(\zeta - 1) = v(p)/(p-1)$, $v(4) = 2v(2)$), $v(c_i) = 0$ otherwise. Hence $|v(u)| \le v(\delta) + \max(v(c_0), v(c_1)) \le 2v(\delta) + e_p\,v(p)\,\max([p \in S_0], [p \in S_1])$, which is at most $(e_p([p \in S_0] + [p \in S_1]) + 2v_p(\mathrm{disc}E))v(p)$. □

Theorem D.126. *Let $\mathcal{T}$ be a root tower of type (Φ, n, p) with a geometric realisation and a good origin over an integral model of a unitary Shimura datum with CM field E, and assume that the realised tower has the geometric inputs (Gi2) and (Gi4). Then every reference model $\mathcal{X}_c^{\mathrm{ref}}$ ($c \in \mathrm{Cp}$) has convergent regularisation, and the realised tower has the reference link (Vl) with $\mathrm{pp}_c^{\mathrm{ref}} = \mathrm{pp}(\mathcal{X}_c^{\mathrm{ref}}; \cdot)$, with $S = S_B$ and $\alpha_\ell = e_\ell + 2v_\ell(\mathrm{disc}\,E)$ ($\ell \in S_B$) at every stage B, with t_0 the constant of Sys_c, and with*

$$C_{\mathrm{Vl}} = 1 + \frac{1}{\log 2}\Big(3 + 3\log 2 + \sum_{\ell \in \mathrm{Bd}} e_\ell \log \ell + 2\log|\mathrm{disc}\,E|\Big).$$

Proof. Fix $c \in \mathrm{Cp}$ and write $\mathcal{X}_0 = \mathcal{X}_c^{\mathrm{ref}} \subseteq \mathbb{P}_0 = \prod_{k \in K_0} \mathbb{P}(\mathbb{Z}^{I_k})$ with multidegrees e_r^0 ($r \in \mathrm{Rt}^+$), $\delta_0 = [F : \mathbb{Q}]$ and $k_0 = k_c^A$ ((Go3)(1), (Go3)(5), degree one). For a fundamental index $a = (\tau, i)$ put $f_a^0 = -\sum_{j \le i} e^0_{(\tau,j)}$, and let $n_c \ge 0$ be an integer with $e^0_{r,k} + n_c \ge 0$ for all $r \in \mathrm{Rt}^+$, $k \in K_0$; let $\mathbf{1} \in \mathbb{Z}^{K_0}$ be the vector of ones and $e_H^0 = \sum_a f_a^0 + n_c\mathbf{1}$. Let $M_c^{\mathrm{ref}} \ge 0$ be the maximum of 0 and of the numbers $\deg(c_1(\mathcal{O}(\epsilon_1)) \cdots c_1(\mathcal{O}(\epsilon_D)) \cap [\mathcal{X}_{0,\mathbb{Q}}])/\delta_0$ over $\epsilon_1, \dots, \epsilon_D \in \{e_H^0\} \cup \{e_r^0 + e_H^0 : r \in \mathrm{Rt}^+\}$. These depend on c only.

Step 1: the two root models at a stage. Let $B \ge 2$, $\mathcal{X}_1 = \mathcal{X}_{B,c} \subseteq \mathbb{P}_1$ with multidegrees e_r^1, metrics $h_r^1(t), h_*^1$, $\delta_1 = [F : \mathbb{Q}]\deg_{B,c}$, $k_1 = k_c^A$, and let $\widetilde{\mathcal{X}} \subseteq \widetilde{\mathbb{P}}$ be as in Lemma D.124. Define root models on $\widetilde{\mathcal{X}}$ with $k = k_c^A$, $\delta = \delta_1$: $\widetilde{\mathcal{X}}$ with multidegrees $(0, e_r^1, 0)$, metrics $h_r^1(t)(z_1)$ for all $t > 0$ and $h_*^1(z_1)$; $\widetilde{\mathcal{X}}'$ with multidegrees $(0, 0, e_r^0)$, metrics $h_r^0(t)(z_0)$, $h_*^0(z_0)$. Each such function is smooth, positive, conjugation invariant and multihomogeneous of the stated multidegree on the punctured product, hence a cone metric. Put $f_a^1 = -\sum_{j \le i} e^1_{(\tau,j)}$ and

$$e_H = \sum_a (0, f_a^1, 0) + n_c(0, 0, \mathbf{1}) \in \mathbb{Z}^{\widetilde{K}}.$$

By Lemma 30.18 (1) with $d = 0$ for the projections of $\widetilde{\mathbb{P}}$ to $\mathbb{P}_1$ and to $\mathbb{P}_0$ and $\mathcal{Z} = \widetilde{\mathcal{X}}$, as pr_1 is surjective and birational ($c = 1$) and pr_0 is surjective of degree $\deg_{B,c} = \delta_1/\delta_0$ ($c = \deg_{B,c}$) (Lemma D.124 (Jr1)),

$$\mathrm{ai}_t(\widetilde{\mathcal{X}}; \cdot) = \mathrm{ai}_t(\mathcal{X}_1; \cdot), \qquad \mathrm{ai}_t(\widetilde{\mathcal{X}}'; \cdot) = \mathrm{ai}_t(\mathcal{X}_0; \cdot) \qquad (t > 0),$$

and likewise for the geometric degrees of pulled-back line bundles on $\widetilde{\mathcal{X}}_{\mathbb{Q}}$ (factor $\deg_{B,c}$ for pr_0).

Step 2: (Vl2) and the vertical classes. (Vl2) is (Jr3) and (Jr4) of Lemma D.124 (closeness over $(S_B, 0)$ implies closeness over (S_B, α)). For $r \in \mathrm{Rt}^+$ let f_r, g_r be the polynomials of vertical closeness; f_r/g_r is a rational section of $\mathcal{O}(e_r - e_r')$ on $\widetilde{\mathcal{X}}$ whose divisor $\mathcal{D}_r$ has order 0 along every horizontal prime divisor, i.e. is vertical, and whose norm is 1 on $\widetilde{\mathcal{X}}(\mathbb{C})$ for $0 < t \le t_0$. Hence, for these t, $\overline{\mathcal{N}}_r(t) = \overline{\mathcal{L}}_r(t) \otimes \overline{\mathcal{L}}_r'(t)^{\otimes -1}$, the restriction of a Hermitian line bundle with smooth metric on $\widetilde{\mathbb{P}}$, has the rational section f_r/g_r of norm 1 with vertical Weil divisor $\mathcal{D}_r =$

$\sum_W \mathrm{ord}_W(f_r/g_r)[W]$. On $\widetilde{\mathcal{X}}_{\mathbb{Q}}$, which is normal, f_r/g_r is a nowhere vanishing regular section, so $\mathcal{O}(e_r) \cong \mathcal{O}(e'_r)$ there.

Step 3: (Vl1). By (Gi2) $\mathcal{X}_1$, hence $\widetilde{\mathcal{X}}$ (Step 1), has convergent regularisation. For a monomial $x_{r_1} \cdots x_{r_{D+1}}$ and $0 < t \le t_0$, replacing the lines one at a time and using multilinearity,

$$\delta k^{\#}\big(\mathrm{ai}_t(\widetilde{\mathcal{X}}; x^m) - \mathrm{ai}_t(\widetilde{\mathcal{X}}'; x^m)\big) = \sum_{j=1}^{D+1} \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}}'_{r_1}(t)) \cdots \widehat{c}_1(\overline{\mathcal{L}}'_{r_{j-1}}(t))\, \widehat{c}_1(\overline{\mathcal{N}}_{r_j}(t)) \\ \widehat{c}_1(\overline{\mathcal{L}}_{r_{j+1}}(t)) \cdots \widehat{c}_1(\overline{\mathcal{L}}_{r_{D+1}}(t))),$$

and by Lemma 30.17 (on the regular $\widetilde{\mathbb{P}}$, $\mathcal{Z} = \widetilde{\mathcal{X}}$, $\overline{\mathcal{M}}_0 = \overline{\mathcal{N}}_{r_j}(t)$, $\sigma = f_{r_j}/g_{r_j}$: no horizontal components, $\log\|\sigma\| = 0$) each term equals $\sum_p \log p \sum_{W \subseteq \widetilde{\mathcal{X}}_{\mathbb{F}_p}} \mathrm{ord}_W(f_{r_j}/g_{r_j})$ times the degree on W of the first Chern classes of the other D line bundles, a sum of geometric intersection numbers independent of t. Hence $\widetilde{\mathcal{X}}'$, and by Step 1 $\mathcal{X}_0$, has convergent regularisation, and $\mathrm{pp}(\widetilde{\mathcal{X}}; \cdot) = \mathrm{pp}(\mathcal{X}_{B,c}; \cdot)$, $\mathrm{pp}(\widetilde{\mathcal{X}}'; \cdot) = \mathrm{pp}(\mathcal{X}_c^{\mathrm{ref}}; \cdot) = \mathrm{pp}_c^{\mathrm{ref}}$, which does not depend on B.

Step 4: (Vl3). Let $\ell \in S_B$. For a fundamental index $a = (\tau, i)$, the weight μ with $\mu_{\tau,j} = 1$ for $j \le i$ and 0 otherwise is dominant, and $c(\mu, 0)$ has entries $-\mu$ on the roots and 0 at $*$; as $\ell \le B$ or $\ell \in \mathrm{Bd}$, (Gi4) gives $\deg(\mathcal{O}(f_a^1)|_{W'}) \ge 0$ for every integral curve $W' \subseteq \mathcal{X}_{1,\mathbb{F}_\ell}$. For an integral curve $W \subseteq \widetilde{\mathcal{X}}_{\mathbb{F}_\ell}$, $\mathrm{pr}_1(W)$ is a point or a curve W', and $\deg(\mathrm{pr}_1^*\mathcal{O}(f_a^1)|_W)$ is 0 or $\deg(W \to W')\deg(\mathcal{O}(f_a^1)|_{W'}) \ge 0$. A multidegree with non-negative entries has non-negative degree on every curve. Now, with $f^1_{(\tau,0)} = 0$, the root multidegree is $e^1_{(\tau,i)} = f^1_{(\tau,i-1)} - f^1_{(\tau,i)}$, so

$$(0, e^1_{(\tau,i)}, 0) + e_H = (0, f^1_{(\tau,i-1)}, 0) + \sum_{a \ne (\tau,i)} (0, f_a^1, 0) + n_c(0, 0, \mathbf{1}),$$

a sum of classes of non-negative degree on W; likewise e_H, $(0, e^1_*, 0) + e_H$ ($e^1_* \ge 0$) and $(0, 0, e^0_r + n_c\mathbf{1}) + \sum_a (0, f^1_a, 0) = (0, 0, e^0_r) + e_H$ ($e^0_r + n_c\mathbf{1} \ge 0$). This is (Vl3).

Step 5: (Vl4). By Step 2, on $\widetilde{\mathcal{X}}_{\mathbb{Q}}$ the line bundles $\mathcal{O}(0, e^1_r, 0)$ and $\mathcal{O}(0, 0, e^0_r)$ are isomorphic for every $r \in \mathrm{Rt}^+$, hence so are $\mathcal{O}(0, f^1_a, 0)$ and $\mathcal{O}(0, 0, f^0_a)$, $\mathcal{O}(e_H)$ and $\mathcal{O}(0, 0, e^0_H)$, and $\mathcal{O}(e_r + e_H)$ and $\mathcal{O}(0, 0, e^0_r + e^0_H)$. These are pull-backs along pr_0, which is generically finite of degree $\deg_{B,c}$ on generic fibres; so every intersection number in (Vl4) equals $\deg_{B,c}$ times the corresponding number on $\mathcal{X}_{0,\mathbb{Q}}$, which is at most $\delta_0 M_c^{\mathrm{ref}}$. Hence it is at most $\deg_{B,c}\delta_0 M_c^{\mathrm{ref}} = M_c^{\mathrm{ref}}\delta$.

Step 6: (Vl5). As $2 \in S_B$, $e_2 = 2$, and Bd contains every prime dividing $\mathrm{disc}\, E$,

$$\sum_{\ell \in S_B} \alpha_\ell \log \ell \le 2\log 2 + \sum_{3 \le \ell \le B} \frac{\log \ell}{\ell - 1} + \sum_{\ell \in \mathrm{Bd}} e_\ell \log \ell + 2\log|\mathrm{disc}\, E|.$$

Since $\frac{\log \ell}{\ell-1} = \frac{\log \ell}{\ell} + \frac{\log \ell}{\ell(\ell-1)} \le \frac{\log \ell}{\ell} + \frac{2\log \ell}{\ell^2}$ and $x \mapsto \log x/x^2$ is decreasing for $x \ge 2$, $\sum_{m \ge 3} \frac{2\log m}{m^2} \le 2\int_2^\infty \frac{\log x}{x^2}\, dx = 1 + \log 2$; with Mertens' bound, $\sum_{3 \le \ell \le B} \frac{\log \ell}{\ell-1} \le \log B + 3 + \log 2$. So the sum is at most $\log B + 3 + 3\log 2 + \sum_{\mathrm{Bd}} e_\ell \log \ell + 2\log|\mathrm{disc} E| \le C_{\mathrm{Vl}} \log B$, using $1 \le \log B/\log 2$. □

Theorem D.127. *Let $\mathcal{T}$ be a root tower of type (Φ, n, κ) with $1 \le \kappa \le n-1$ and a geometric realisation, and let $\mathcal{X}_Z^{\mathrm{ref}}$ ($Z \in \mathrm{Cp}$) be root models of type (Φ, n) that have Lie fibre data. Then there is $C_0 \ge 1$ such that for every $C \ge C_0$, every $Z \in \mathrm{Cp}$ and every point W of $\mathcal{X}_Z^{\mathrm{ref}}$, with $x = h^{\mathrm{ref}}_{c(0,1),1}(W)$:*

$$x \ge -C \qquad \text{and}$$
$$h^{\mathrm{ref}}_{c(\mu,0),1}(W) \ge -C\log(2 + C + x) - C \quad \text{for every dominant weight } \mu \text{ with } \|\mu\|_\infty \le 2.$$

In particular the clause (Rh2) holds for these reference models with any constant $C_{\mathrm{Rh}} \ge C_0$.

Proof. Since Cp is finite it suffices to find C_0 for one Z; fix Z and write $\mathcal{X} = \mathcal{X}_Z^{\mathrm{ref}} \subseteq \mathbb{P} = \prod_{k\in K}\mathbb{P}(\mathbb{Z}^{I_k})$, $k_{\mathcal{X}}$ its normalising integer, $\mathbf{1} = (1,\dots,1) \in \mathbb{Z}^K$, and $h_{\mathbf{1}}(z) = \prod_k \|z_k\|$ (Euclidean norms), a cone metric of multidegree $\mathbf{1}$. For a point W, $x = \widehat{h}_W(\overline{\mathcal{L}}_*)/k_{\mathcal{X}}$, and $h^{\mathrm{ref}}_{c(\mu,0),1}(W) = -\sum_{a,i}\mu_{a,i}\,\widehat{h}_W(\overline{\mathcal{L}}_{(a,i)}(1))$ because $c(\mu,0)_* = 0$. For $f \in \mathbb{Z}^K$ and a cone metric h of multidegree f write $\widehat{h}_W(f,h) = \widehat{\deg}(\widehat{c}_1((\mathcal{O}(f),h)|_{\mathcal{X}})\cdot[W])/\deg W_{\mathbb{Q}}$; it is additive under tensor products (products of cone functions).

Step 1: heights of sections. Let $s \in H^0(\mathcal{X},\mathcal{O}(f)|_{\mathcal{X}})$ not vanish at the closed point $W_{\mathbb{Q}}$. The point W is integral, finite and flat over $\mathbb{Z}$, so $W = \operatorname{Spec} R$ for an order R in the residue field of $W_{\mathbb{Q}}$, with $\deg W_{\mathbb{Q}}$ complex points; by Lemma 30.17 with $m = 0$ (ambient the regular $\mathbb{P}$, $\mathcal{Z} = W$, $\sigma = s|_W$; W has no horizontal prime divisors) $\widehat{\deg}(\overline{\mathcal{O}(f)}\cdot[W]) = \sum_p \log p \sum_{w\in W_{\mathbb{F}_p}} \operatorname{ord}_w(s|_W)\,[\mathbf{k}(w):\mathbb{F}_p] - \sum_{w\in W(\mathbb{C})}\log\|s\|(w)$. The first term is ≥ 0, as $s|_W$ is a regular section, so all its orders are ≥ 0, and $\|s\|$ is continuous on the compact space $\mathcal{X}(\mathbb{C})$. Hence

$$\widehat{h}_W(f,h) \geq -\log\sup_{\mathcal{X}(\mathbb{C})}\|s\|_h. \tag{D.27}$$

Consequences. (a) If $f \geq 0$ componentwise, choose for each k an index j_k with z_{k,j_k} non-zero at $W_{\mathbb{Q}}$; the monomial $\prod_k z_{k,j_k}^{f_k}$ is a section of $\mathcal{O}(f)$ non-zero at $W_{\mathbb{Q}}$. As there are finitely many monomials of multidegree f, (D.27) gives $\widehat{h}_W(f,h) \geq -c(f,h)$ with $c(f,h)$ independent of W. (b) By (Lx1) and Serre's theorem there is $m \geq 1$ such that $\mathcal{O}(me_* - \mathbf{1})|_{\mathcal{X}_{\mathbb{Q}}}$ is globally generated; since $\mathcal{X}$ is flat over $\mathbb{Z}$, $H^0(\mathcal{X},\mathcal{O}(me_*-\mathbf{1})|_{\mathcal{X}})\otimes\mathbb{Q} = H^0(\mathcal{X}_{\mathbb{Q}},\mathcal{O}(me_*-\mathbf{1}))$, so integer multiples of finitely many generating sections are sections $s_1,\dots,s_l$ over $\mathcal{X}$ without common zero on $\mathcal{X}_{\mathbb{Q}}$. Applying (D.27) to the metric $h_*^m/h_{\mathbf{1}}$ and an s_i non-zero at $W_{\mathbb{Q}}$: $mk_{\mathcal{X}}x - \widehat{h}_W(\mathbf{1},h_{\mathbf{1}}) \geq -c_1$ with c_1 independent of W. With (a) for $f = \mathbf{1}$: $mk_{\mathcal{X}}x \geq -c_1 - c(\mathbf{1},h_{\mathbf{1}})$, so

$$x \geq -c_2, \qquad \widehat{h}_W(\mathbf{1},h_{\mathbf{1}}) \leq mk_{\mathcal{X}}x + c_1. \tag{D.28}$$

Step 2: root heights are dominated by x. Let $r \in \mathrm{Rt}$. Write $e_r = f^+ - f^-$ with $f^\pm \geq 0$ and choose an integer $N \geq 1$ with $f^\pm \leq N\mathbf{1}$. Put $\eta^- = \prod_k \|z_k\|^{f_k^-}$ and $\eta^+ = h_r(1)\,\eta^-$, cone metrics of multidegrees f^- and $e_r + f^- = f^+$, so that $\widehat{h}_W(\overline{\mathcal{L}}_r(1)) = \widehat{h}_W(f^+,\eta^+) - \widehat{h}_W(f^-,\eta^-)$. For $0 \leq f \leq N\mathbf{1}$ and a cone metric h_f of multidegree f, additivity, (a) for $N\mathbf{1}-f$ and (D.28) give $-c(f,h_f) \leq \widehat{h}_W(f,h_f) = N\widehat{h}_W(\mathbf{1},h_{\mathbf{1}}) - \widehat{h}_W(N\mathbf{1}-f, h_{\mathbf{1}}^N/h_f) \leq N(mk_{\mathcal{X}}x + c_1) + c(N\mathbf{1}-f, h_{\mathbf{1}}^N/h_f)$. Since $x + c_2 \geq 0$, there is $C_5 \geq c_2 + 1$, independent of W, with

$$|\widehat{h}_W(\overline{\mathcal{L}}_r(1))| \leq C_5\,y \quad (r \in \mathrm{Rt}), \qquad y := x + C_5 \geq 1. \tag{D.29}$$

Step 3: the Lie fibre. Fix a point W and take L, the Lie fibre $\overline{V}$ and the data (a), (b) of (Lx2); write $g_{a,i} = \widehat{h}_W(\overline{\mathcal{L}}_{(a,i)}(1))$ and $C' = C_{\mathrm{Lx}} \geq 1$. By (Lx2)(a), $|\sum_{i\leq\kappa} g_{a,i} - d_{a,\kappa}| \leq \kappa C'$ and $|\sum_{j\leq n-\kappa} g_{a,n+1-j} + d'_{a,n-\kappa}| \leq (n-\kappa)C'$ (telescoping); with (Lx3),

$$|d_{a,\kappa} - d'_{a,n-\kappa}| \leq (n+1)C', \qquad -d_{a,\kappa} - d'_{a,n-\kappa} \leq \sum_{i=1}^n |g_{a,i}| + nC' \leq n(C_5 y + C'). \tag{D.30}$$

The $2|\Phi|$ pieces $F_{a,\kappa}\otimes L$, $S_{a,n-\kappa}\otimes L$ are pairwise orthogonal and span $V\otimes_{\mathcal{O}_L} L$, so they are independent and $N = \bigoplus_a (F_{a,\kappa}\oplus S_{a,n-\kappa})$ is a submodule of finite index in V, of rank $g = |\Phi|n$, whose induced norms are the orthogonal sums. The Arakelov degree is additive on orthogonal direct sums and $\widehat{\deg}\,\overline{V} = \widehat{\deg}\,\overline{N} + \log\#(V/N) \geq \widehat{\deg}\,\overline{N}$; with (D.30),

$$\max\Big(-\frac{\widehat{\deg}\,\overline{V}}{[L:\mathbb{Q}]},0\Big) \leq \max\Big(0,\ -\sum_a (d_{a,\kappa} + d'_{a,n-\kappa})\Big) \leq |\Phi|\,n\,(C_5 y + C').$$

By (Lx2)(b), the hypotheses (1), (2) of Lemma D.128 hold for $\overline{V}$ with the constant $C' \geq 1$. With $C_{\mathrm{sb}} = C_{\mathrm{ll}} + \frac{1}{2}$ and $C_6 = 2 + |\Phi| n\big(1 + C_5 + C' + \frac{1}{2}\log C'\big)$, so that $2 + g + \frac{g}{2}\log C' + \max(-\widehat{\deg}\,\overline{V}/[L:\mathbb{Q}], 0) \leq C_6 y$ as $y \geq 1$, Lemma D.128 gives

$$M := \max(\widehat{\mu}_{\max}(\overline{V}), 0) \leq C_{\mathrm{sb}}\big(\log C_6 + \log y\big) + \tfrac{1}{2}\log C'. \tag{D.31}$$

Step 4: summation by parts. Let μ be dominant with $\|\mu\|_\infty \leq 2$ and fix a; drop the index a. Write $g_i = (d_i - d_{i-1}) + \epsilon_i$ $(i \leq \kappa)$ and $g_{n+1-j} = -(d'_j - d'_{j-1}) + \epsilon'_j$ $(j \leq n - \kappa)$ with $|\epsilon_i|, |\epsilon'_j| \leq C'$. Abel summation with $d_0 = d'_0 = 0$ gives

$$-\sum_{i=1}^{n} \mu_i g_i = -\sum_{i=1}^{\kappa-1} (\mu_i - \mu_{i+1}) d_i - \sum_{j=1}^{n-\kappa-1} (\mu_{n-j} - \mu_{n+1-j}) d'_j - (\mu_\kappa - \mu_{\kappa+1}) d_\kappa - \mu_{\kappa+1}(d_\kappa - d'_{n-\kappa}) + R,$$

with $|R| \leq \sum_i |\mu_i| C' \leq 2nC'$. The coefficients $\mu_i - \mu_{i+1}$ that occur are distinct gaps of a non-increasing sequence, so they are ≥ 0 and sum to at most $\mu_1 - \mu_n \leq 4$. Each $d_i = i\,\widehat{\mu}(\overline{F}_i) \leq nM$ and $d'_j \leq nM$, by the definition of the maximal slope (F_i, S_j are non-zero submodules). With (D.30),

$$-\sum_{i=1}^{n} \mu_{a,i} g_{a,i} \geq -4nM - 2(n+1)C' - 2nC'.$$

Summing over $a \in \Phi$ and inserting (D.31):

$$h^{\mathrm{ref}}_{c(\mu,0),1}(W) \geq -4|\Phi| n C_{\mathrm{sb}} \log(x + C_5) - \big(4|\Phi| n C_{\mathrm{sb}} \log C_6 + 2|\Phi| n \log C' + |\Phi|(4n+2)C'\big).$$

Step 5: the constant. Let $C_0 \geq 1$ be at least c_2, $4|\Phi| n C_{\mathrm{sb}}$, $4|\Phi| n C_{\mathrm{sb}} \log C_6 + 2|\Phi| n \log C' + |\Phi|(4n+2)C'$ and $C_5 - 2$ (all independent of W). For $C \geq C_0$: $x \geq -c_2 \geq -C$ by (D.28); $x + C_5 \leq 2 + C + x$ and $2 + C + x \geq 2$, so $\log(x + C_5) \leq \log(2 + C + x)$ with both logarithms positive; hence $h^{\mathrm{ref}}_{c(\mu,0),1}(W) \geq -C\log(2 + C + x) - C$. Taking the maximum of C_0 over the finitely many Z proves the theorem. □

Lemma D.128. *Let L be a number field, $\overline{V} = (V, (\|\cdot\|_{V,\sigma})_\sigma)$ a Hermitian lattice over $\mathcal{O}_L$ of rank $g \geq 1$, and $C \geq 1$. For $\sigma\colon L \to \mathbb{C}$ write $V_\sigma = V \otimes_{\mathcal{O}_L,\sigma} \mathbb{C}$. Assume:*

1. *there are $0 \leq r \leq g$ and elements $\varepsilon_1, \dots, \varepsilon_r \in V$, linearly independent over $\mathcal{O}_L$, spanning a submodule U, with*

$$C^{-1}\sum_{b=1}^{r} |w_b|^2 \;\leq\; \Big\|\sum_{b=1}^{r} w_b \varepsilon_b\Big\|^2_{V,\sigma} \;\leq\; C\sum_{b=1}^{r} |w_b|^2 \qquad (\sigma\colon L \to \mathbb{C},\ w \in \mathbb{C}^r);$$

2. *either $U = V$, or there are a CM field E, a principally polarised abelian scheme $\mathcal{A}$ with $\mathcal{O}_E$-action over $\mathcal{O}_L$ and an $\mathcal{O}_L$-linear map $\phi\colon V \to \mathrm{Lie}(\mathcal{A})$ with $\ker\phi = U$, $\mathrm{Lie}(\mathcal{A})/\phi(V)$ finite, and $\|\phi_\sigma(x)\|^2_\sigma \leq C\,\|x\|^2_{V,\sigma}$ for every σ and $x \in V_\sigma$, where $\phi_\sigma = \phi \otimes_\sigma \mathbb{C}$.*

Then

$$\widehat{\mu}_{\max}(\overline{V}) \;\leq\; \big(C_{\mathrm{ll}} + \tfrac{1}{2}\big)\log\Big(2 + g + \tfrac{g}{2}\log C + \max\Big(-\frac{\widehat{\deg}\,\overline{V}}{[L:\mathbb{Q}]}, 0\Big)\Big) + \tfrac{1}{2}\log C.$$

Proof. Write $n_L = [L:\mathbb{Q}]$. We use four standard facts on Hermitian lattices over $\mathcal{O}_L$ (Bost's normalisation, as in [48]). (F1) If M has rank s and $m_1, \dots, m_s \in M$ are linearly independent, then $\widehat{\deg}\,\overline{M} = \log\#(M/(\mathcal{O}_L m_1 + \cdots + \mathcal{O}_L m_s)) - \sum_\sigma \log\|m_1 \wedge \cdots \wedge m_s\|_\sigma$, the norm on $\bigwedge^s M_\sigma$ being the Gram determinant: $\|m_1 \wedge \cdots \wedge m_s\|^2_\sigma = \det(\langle m_a, m_b\rangle_\sigma)$. (F2) If $M' \subseteq M$ has the same

rank and the induced norms, $\widehat{\deg}\,\overline{M} = \widehat{\deg}\,\overline{M'} + \log\#(M/M')$. (F3) If $N \subseteq M$ is saturated, with the induced norms on N and the quotient norms $\|y\|_\sigma = \min\{\|x\|_\sigma : x \mapsto y\}$ on $(M/N)_\sigma = M_\sigma/N_\sigma$, then $\widehat{\deg}\,\overline{M} = \widehat{\deg}\,\overline{N} + \widehat{\deg}\,\overline{M/N}$. (F4) If $\psi\colon M \to M''$ is an injective $\mathcal{O}_L$-linear map of Hermitian lattices, M of rank s, with $\|\psi_\sigma(x)\|_\sigma \le \lambda\|x\|_\sigma$ for all σ, x ($\lambda > 0$), then $\widehat{\deg}\,\overline{\psi(M)} \ge \widehat{\deg}\,\overline{M} - s\,n_L\log\lambda$, $\psi(M)$ with the norms induced from $\overline{M''}$. Indeed, by (F1) applied to m_a and $\psi(m_a)$ (the index term is the same, ψ being an isomorphism $M \to \psi(M)$), it suffices that the Gram matrices satisfy $G'' \le \lambda^2 G$ as Hermitian forms, which gives $\det G'' \le \lambda^{2s}\det G$ by monotonicity of the determinant on positive definite matrices.

Step 1: the torus lattice. Give U the norms induced from $\overline{V}$, and let $\overline{U}_0$ be U with the norms $\|\sum_b w_b\varepsilon_b\|_{0,\sigma}^2 = \sum_b |w_b|^2$. Every non-zero submodule $M \subseteq U$ satisfies $\widehat{\deg}_{\overline{U}_0}(M) \le 0$: let $s = \operatorname{rk} M$, choose linearly independent $m_1,\dots,m_s \in M$ and write $\omega = m_1\wedge\cdots\wedge m_s = \sum_{|I|=s} c_I\varepsilon_I$ in $\bigwedge^s U = \bigoplus_I \mathcal{O}_L\varepsilon_I$, with $c_I \in \mathcal{O}_L$ the $s\times s$ minors; the ε_I are orthonormal for the norm induced by $\|\cdot\|_{0,\sigma}$ (Cauchy–Binet), so $\|\omega\|_{0,\sigma} \ge |\sigma(c_J)|$ for a fixed J with $c_J \ne 0$. The map $\bigwedge^s M \to \mathcal{O}_L$, coefficient of ε_J, is injective (rank one, torsion free, non-zero on ω), and $\#(M/\sum_a \mathcal{O}_L m_a) = \#(\bigwedge^s M/\mathcal{O}_L\omega)$ (the index ideal of $\sum_a \mathcal{O}_L m_a$ in M is that of $\mathcal{O}_L\omega$ in $\bigwedge^s M$), so this index is at most $\#(\mathcal{O}_L/c_J\mathcal{O}_L) = |N_{L/\mathbb{Q}}(c_J)|$. By (F1), $\widehat{\deg}_{\overline{U}_0}(M) \le \log|N_{L/\mathbb{Q}}(c_J)| - \sum_\sigma \log|\sigma(c_J)| = 0$. By (1), $\|x\|_{0,\sigma} \le C^{1/2}\|x\|_{V,\sigma}$ and $\|x\|_{V,\sigma} \le C^{1/2}\|x\|_{0,\sigma}$; (F4) for the identity maps gives $\widehat{\deg}_{\overline{U}}(M) \le \widehat{\deg}_{\overline{U}_0}(M) + \frac{s}{2}n_L\log C \le \frac{s}{2}n_L\log C$, and, as $\widehat{\deg}\,\overline{U}_0 = 0$ by (F1) for the basis ε, $\widehat{\deg}\,\overline{U} \ge -\frac{r}{2}n_L\log C$. Hence

$$\widehat{\mu}_{\max}(\overline{U}) \le \tfrac{1}{2}\log C \quad (r \ge 1), \qquad \widehat{\deg}\,\overline{U} \le \tfrac{r}{2}\,n_L\log C. \tag{D.32}$$

If $U = V$, then $\widehat{\mu}_{\max}(\overline{V}) \le \frac{1}{2}\log C$, which is at most the right-hand side because $C_{\mathrm{ll}} \ge 0$ and the logarithm there is at least $\log 2 > 0$. From now on $U \ne V$, and $\mathcal{A}$, ϕ are as in (2).

Step 2: the abelian quotient. Put $Q = V/U$ with projection p. Since $\ker\phi = U$, ϕ induces an injection $\bar\phi\colon Q \to \operatorname{Lie}(\mathcal{A})$ with image $\phi(V)$ of finite index; so Q is torsion free, hence projective, U is saturated in V, and $g' := \operatorname{rk} Q = \operatorname{rk}\operatorname{Lie}(\mathcal{A})$ is the relative dimension of $\mathcal{A}$, with $r + g' = g$. Give Q the quotient norms of $\overline{V}$. As Q is projective, $U_\sigma = \ker(V_\sigma \to Q_\sigma)$, and ϕ_σ vanishes on U_σ; so for $x \in V_\sigma$ and every $u \in U_\sigma$, $\|\bar\phi_\sigma(p_\sigma x)\|_\sigma = \|\phi_\sigma(x+u)\|_\sigma \le C^{1/2}\|x+u\|_{V,\sigma}$, and minimising over u,

$$\|\bar\phi_\sigma(y)\|_\sigma \le C^{1/2}\|y\|_{Q,\sigma} \qquad (y \in Q_\sigma).$$

For a non-zero submodule $M \subseteq Q$ of rank s, (F4) for $\bar\phi|_M$ gives $\widehat{\mu}(\overline{M}) \le \widehat{\mu}(\overline{\bar\phi(M)}) + \frac{1}{2}\log C \le \widehat{\mu}_{\max}(\overline{\operatorname{Lie}}(\mathcal{A})) + \frac{1}{2}\log C$; and (F4) for $\bar\phi$ with (F2) for $\phi(V) \subseteq \operatorname{Lie}(\mathcal{A})$ gives $\widehat{\deg}\,\overline{Q} \le \widehat{\deg}\,\overline{\phi(V)} + \frac{g'}{2}n_L\log C \le \widehat{\deg}\,\overline{\operatorname{Lie}}(\mathcal{A}) + \frac{g'}{2}n_L\log C$. Thus

$$\widehat{\mu}_{\max}(\overline{Q}) \le \widehat{\mu}_{\max}(\overline{\operatorname{Lie}}(\mathcal{A})) + \tfrac{1}{2}\log C, \qquad \widehat{\deg}\,\overline{Q} \le \widehat{\deg}\,\overline{\operatorname{Lie}}(\mathcal{A}) + \tfrac{g'}{2}\,n_L\log C. \tag{D.33}$$

Step 3: the maximal slope of an extension. We show

$$\widehat{\mu}_{\max}(\overline{V}) \le \max\bigl(\widehat{\mu}_{\max}(\overline{U}), \widehat{\mu}_{\max}(\overline{Q})\bigr),$$

the first term omitted if $r = 0$; this holds exactly, for the induced norms on U and the quotient norms on Q. Let $M \subseteq V$ be a non-zero submodule of rank s, $M_1 = M \cap U$ of rank s_1, and $M_2 = p(M) \cong M/M_1$ of rank $s_2 = s - s_1$; M_1 is saturated in M since M/M_1 embeds in the torsion free Q. Give M the norms induced from $\overline{V}$. By (F3), $\widehat{\deg}\,\overline{M} = \widehat{\deg}\,\overline{M_1} + \widehat{\deg}\,\overline{M/M_1}$, where M_1 carries the norms induced from $\overline{U}$ and M/M_1 the quotient norms of $\overline{M}$. For $x \in M_\sigma$, the quotient norm of its class is $\min_{y\in(M_1)_\sigma}\|x+y\|_{V,\sigma} \ge \min_{u\in U_\sigma}\|x+u\|_{V,\sigma} = \|p_\sigma x\|_{Q,\sigma}$, since $(M_1)_\sigma \subseteq U_\sigma$. So the isomorphism $M/M_1 \to M_2$ does not increase norms, and (F4)

with $\lambda = 1$ gives $\widehat{\deg}\,\overline{M/M_1} \le \widehat{\deg}\,\overline{M_2}$, M_2 with the norms induced from $\overline{Q}$. Hence $\widehat{\deg}\,\overline{M} \le n_L\big(s_1\widehat{\mu}_{\max}(\overline{U}) + s_2\widehat{\mu}_{\max}(\overline{Q})\big)$ (a term with $s_i = 0$ is 0), and dividing by $n_L s$ proves the claim.

Step 4: the height of the abelian part. By (F3) for $U \subseteq V$, (D.32) and (D.33), $\widehat{\deg}\,\overline{V} = \widehat{\deg}\,\overline{U} + \widehat{\deg}\,\overline{Q} \le \widehat{\deg}\,\overline{\mathrm{Lie}}(\mathcal{A}) + \frac{g}{2} n_L \log C$. Hence $-\widehat{\deg}\,\overline{\mathrm{Lie}}(\mathcal{A})/n_L \le -\widehat{\deg}\,\overline{V}/n_L + \frac{g}{2}\log C$ and, as $\log C \ge 0$,

$$h^+(\mathcal{A}) \le \max\Big(-\frac{\widehat{\deg}\,\overline{V}}{n_L}, 0\Big) + \frac{g}{2}\log C.$$

Step 5: conclusion. By Proposition D.27 for $\mathcal{A}$ (relative dimension $g' \le g$) and Step 4,

$$\begin{aligned}\widehat{\mu}_{\max}(\overline{\mathrm{Lie}}(\mathcal{A})) &\le (C_{\mathrm{ll}} + \tfrac{1}{2})\log(2 + g' + h^+(\mathcal{A})) \\ &\le (C_{\mathrm{ll}} + \tfrac{1}{2})\log\Big(2 + g + \tfrac{g}{2}\log C + \max\Big(-\frac{\widehat{\deg}\,\overline{V}}{n_L}, 0\Big)\Big) =: \Lambda.\end{aligned}$$

By Step 3, (D.32) and (D.33), $\widehat{\mu}_{\max}(\overline{V}) \le \max(\frac{1}{2}\log C,\ \Lambda + \frac{1}{2}\log C) = \Lambda + \frac{1}{2}\log C$, since $\Lambda \ge 0$. □

Theorem D.129. *Let $\mathcal{T}$ be a root tower of type (Φ, n, κ) with a geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ whose root models have convergent regularisation, and assume that the realised tower has the reference link (Vl). For $Z \in \mathrm{Cp}$ let A_Z be the maximum of $|\mathrm{pp}_Z^{\mathrm{ref}}(x^m)|$ over the monomials $x^m \in \mathcal{R}^+$ of degree $D+1$. Then the realised tower has the monomial bound (Wd), with the constant*

$$C = \max_{Z\in\mathrm{Cp}}\Big(\frac{A_Z}{\log 2} + (D+1)\,2^D M_Z^{\mathrm{ref}}\,C_{\mathrm{Vl}}\Big).$$

Proof. Fix an integer $B \ge 2$, $Z \in \mathrm{Cp}$ and a monomial $x^m \in \mathcal{R}^+$. If x^m has degree $\ne D+1$, then $\mathrm{ai}_t(\mathcal{X}_{B,Z}; x^m) = 0$ for every t, hence $\mathrm{pp}(\mathcal{X}_{B,Z}; x^m) = 0$ and there is nothing to prove. Let $x^m = x_{r_1}\cdots x_{r_{D+1}}$ with $r_j \in \mathrm{Rt}^+$, and take $\widetilde{\mathcal{X}}$, $\widetilde{\mathcal{X}}'$, k, δ, S, α, e_H, t_0 as in (Vl) for (B, Z).

Comparison at a fixed regularisation parameter. Let $0 < t \le t_0$. Apply Lemma D.130 on $\widetilde{\mathcal{X}}$ to $\overline{\mathcal{L}}_j = \overline{\mathcal{L}}_{r_j}(t)$, the lines of $\widetilde{\mathcal{X}}$, and $\overline{\mathcal{L}}'_j = \overline{\mathcal{L}}'_{r_j}(t)$, those of $\widetilde{\mathcal{X}}'$ (for $r_j = *$ the auxiliary lines), with $M = M_Z^{\mathrm{ref}}\delta$. Its hypotheses hold: $\overline{\mathcal{L}}_j$ and $\overline{\mathcal{L}}'_j$ are vertically close over (S, α) by (Vl2); hypothesis 1 holds by (Vl3), since $e_{r_j} + e_H$ and $e'_{r_j} + e_H$ belong to the sets listed there; hypothesis 2 holds by (Vl4). Dividing the resulting inequality by $\delta k^{\#\{j:\, r_j = *\}} \ge \delta$ and using (29.2) for both root models (they have the same normalising integers) and (Vl5),

$$|\mathrm{ai}_t(\widetilde{\mathcal{X}}; x^m) - \mathrm{ai}_t(\widetilde{\mathcal{X}}'; x^m)| \le (D+1)\,2^D M_Z^{\mathrm{ref}} \sum_{p\in S}\alpha_p \log p \le (D+1)\,2^D M_Z^{\mathrm{ref}}\,C_{\mathrm{Vl}}\log B.$$

Limit. Both models have convergent regularisation, so letting $t \to 0^+$ and using (Vl1),

$$|\mathrm{pp}(\mathcal{X}_{B,Z}; x^m) - \mathrm{pp}_Z^{\mathrm{ref}}(x^m)| = |\mathrm{pp}(\widetilde{\mathcal{X}}; x^m) - \mathrm{pp}(\widetilde{\mathcal{X}}'; x^m)| \le (D+1)\,2^D M_Z^{\mathrm{ref}}\,C_{\mathrm{Vl}}\log B.$$

Conclusion. Since $B \ge 2$, $A_Z \le (A_Z/\log 2)\log B$, so

$$|\mathrm{pp}(\mathcal{X}_{B,Z}; x^m)| \le A_Z + (D+1)\,2^D M_Z^{\mathrm{ref}}\,C_{\mathrm{Vl}}\log B \le C\log B,$$

which is (Wd); C is finite because Cp is finite. □

Lemma D.130. *Let $\mathcal{X} \subseteq \mathbb{P} = \prod_{k\in K} \mathbb{P}(\mathbb{Z}^{I_k})$ be a closed integral subscheme, flat over $\mathbb{Z}$, of absolute dimension $D+1$ with $D \geq 0$. Let S be a finite set of primes, $\alpha_p \geq 0$ for $p \in S$, and $M \geq 0$. For $1 \leq j \leq D+1$ let $\overline{\mathcal{L}}_j = (\mathcal{O}(e_j), h_j)|_{\mathcal{X}}$ and $\overline{\mathcal{L}}'_j = (\mathcal{O}(e'_j), h'_j)|_{\mathcal{X}}$ be Hermitian line bundles given by cone metrics such that $\overline{\mathcal{L}}_j$ and $\overline{\mathcal{L}}'_j$ are vertically close over (S, α). Let $e_H \in \mathbb{Z}^K$ be such that*

1. *for every $p \in S$, every integral closed curve $W \subseteq \mathcal{X}_{\mathbb{F}_p}$ and every $f \in \{e_H\} \cup \{e_j + e_H,\ e'_j + e_H :\ 1 \leq j \leq D+1\}$, $\deg(\mathcal{O}(f)|_W) \geq 0$;*
2. *$\deg(c_1(\mathcal{O}(f_1)) \cdots c_1(\mathcal{O}(f_D)) \cap [\mathcal{X}_{\mathbb{Q}}]) \leq M$ for all $f_1, \ldots, f_D \in \{e_H\} \cup \{e_j + e_H :\ 1 \leq j \leq D+1\}$.*

Then

$$\left|\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}}_1) \cdots \widehat{c}_1(\overline{\mathcal{L}}_{D+1})) - \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}}'_1) \cdots \widehat{c}_1(\overline{\mathcal{L}}'_{D+1}))\right| \leq (D+1)\, 2^D M \sum_{p\in S} \alpha_p \log p.$$

Proof. **Step 1: the comparison sections.** For each j choose f_j, g_j as in the definition of vertical closeness and put $\sigma_j = f_j/g_j$, a non-zero rational section of $\mathcal{L}_j \otimes \mathcal{L}_j'^{-1} = \mathcal{O}(e_j - e'_j)|_{\mathcal{X}}$ (by (31.3), $d_{f_j} - d_{g_j} = e_j - e'_j$). The metric of $\overline{\mathcal{L}}_j \otimes \overline{\mathcal{L}}_j'^{-1}$ has cone function h_j/h'_j, so on the affine cone over $\mathcal{X}(\mathbb{C})$, wherever $g_j \neq 0$,

$$\|\sigma_j\| = \frac{|f_j|}{|g_j|} \cdot \frac{h'_j}{h_j} = 1$$

by (31.3). The Weil divisor of σ_j is $[\operatorname{div}\sigma_j] = \sum_W \big(\operatorname{ord}_W(f_j) - \operatorname{ord}_W(g_j)\big)[W]$, the sum over prime divisors W of $\mathcal{X}$ (Fulton, *Intersection theory*, §1.2, §2.1). By vertical closeness only prime divisors $W \subseteq \mathcal{X}_{\mathbb{F}_p}$ with $p \in S$ occur, with coefficients $a_{j,W}$ satisfying

$$|a_{j,W}| \leq \alpha_p \operatorname{ord}_W(p) \qquad (W \subseteq \mathcal{X}_{\mathbb{F}_p},\ p \in S). \tag{D.34}$$

Step 2: telescoping. For $1 \leq j \leq D+1$ let $\overline{\mathcal{A}}^{(j)} = (\overline{\mathcal{L}}'_1, \ldots, \overline{\mathcal{L}}'_{j-1}, \overline{\mathcal{L}}_{j+1}, \ldots, \overline{\mathcal{L}}_{D+1})$, a list of D Hermitian line bundles, and write $\widehat{c}_1(\overline{\mathcal{A}}^{(j)})$ for the product of their arithmetic first Chern classes. Since $\widehat{\deg}$ of a product of $D+1$ arithmetic first Chern classes is symmetric and $\widehat{c}_1$ is additive in tensor products,

$$\Delta := \widehat{\deg}\Big(\prod_j \widehat{c}_1(\overline{\mathcal{L}}_j)\Big) - \widehat{\deg}\Big(\prod_j \widehat{c}_1(\overline{\mathcal{L}}'_j)\Big) = \sum_{j=1}^{D+1} \widehat{\deg}\Big(\widehat{c}_1(\overline{\mathcal{A}}^{(j)}) \cdot \widehat{c}_1(\overline{\mathcal{L}}_j \otimes \overline{\mathcal{L}}_j'^{-1})\Big).$$

Step 3: each term is a sum of vertical degrees. By Lemma 30.17 (ambient $\mathbb{P}$, $\mathcal{Z} = \mathcal{X}$, integral and flat over $\mathbb{Z}$): for restrictions $\overline{\mathcal{M}}_1, \ldots, \overline{\mathcal{M}}_D, \overline{\mathcal{N}}$ to $\mathcal{X}$ of Hermitian line bundles with smooth metrics on $\mathbb{P}$ and a non-zero rational section σ of $\mathcal{N}$ on $\mathcal{X}$,

$$\widehat{\deg}(\widehat{c}_1(\overline{\mathcal{M}}_1) \cdots \widehat{c}_1(\overline{\mathcal{M}}_D) \cdot \widehat{c}_1(\overline{\mathcal{N}})) = h_{\overline{\mathcal{M}}_1, \ldots, \overline{\mathcal{M}}_D}([\operatorname{div}\sigma]) - \int_{\mathcal{X}(\mathbb{C})} \log\|\sigma\|\, c_1(\overline{\mathcal{M}}_1) \wedge \cdots \wedge c_1(\overline{\mathcal{M}}_D),$$

where the horizontal components of $[\operatorname{div}\sigma]$ contribute their heights and a vertical prime divisor $W \subseteq \mathcal{X}_{\mathbb{F}_p}$ contributes $\log p \cdot \deg(c_1(\mathcal{M}_1|_W) \cdots c_1(\mathcal{M}_D|_W) \cap [W])$ times its multiplicity (the two

sums of Lemma 30.17). Apply this with $\overline{\mathcal{N}} = \overline{\mathcal{L}}_j \otimes \overline{\mathcal{L}}_j'^{-1}$ and $\sigma = \sigma_j$: the integral vanishes because $\log\|\sigma_j\| = 0$, and Step 1 gives

$$\widehat{\deg}\Big(\widehat{c}_1(\overline{\mathcal{A}}^{(j)}) \cdot \widehat{c}_1(\overline{\mathcal{L}}_j \otimes \overline{\mathcal{L}}_j'^{-1})\Big) = \sum_{p \in S} \log p \sum_{W \subseteq \mathcal{X}_{\mathbb{F}_p}} a_{j,W}\, \deg\Big(\prod_{i=1}^{D} c_1(\mathcal{A}_i^{(j)}) \cap [W]\Big). \tag{D.35}$$

Step 4: the degree on one vertical prime divisor. Fix j, $p \in S$ and a prime divisor $W \subseteq \mathcal{X}_{\mathbb{F}_p}$; W is a projective scheme over $\mathbb{F}_p$ of dimension D. Each $\mathcal{A}_i^{(j)}$ is $\mathcal{O}(g_i)|_{\mathcal{X}}$ with $g_i \in \{e_l, e_l'\}$; put $N_i = g_i + e_H$, so $\mathcal{O}(g_i) = \mathcal{O}(N_i) \otimes \mathcal{O}(e_H)^{-1}$ and $N_i \in \{e_l + e_H,\ e_l' + e_H\}$. Expanding multilinearly,

$$\deg\Big(\prod_{i=1}^{D} c_1(\mathcal{O}(g_i)) \cap [W]\Big) = \sum_{I \subseteq \{1,\dots,D\}} (-1)^{D-|I|}\, d_I(W),$$
$$d_I(W) = \deg\Big(\prod_{i \in I} c_1(\mathcal{O}(N_i))\, c_1(\mathcal{O}(e_H))^{D-|I|} \cap [W]\Big).$$

By hypothesis 1 the restrictions of $\mathcal{O}(N_i)$ and $\mathcal{O}(e_H)$ to W have non-negative degree on every integral curve in W, i.e. they are nef on W, so by Kleiman's theorem every $d_I(W) \geq 0$. Hence

$$\Big|\deg\Big(\prod_{i} c_1(\mathcal{A}_i^{(j)}) \cap [W]\Big)\Big| \leq \sum_{I} d_I(W). \tag{D.36}$$

Step 5: summing over the fibre. Since $\mathcal{X}$ is integral and flat over $\mathbb{Z}$, p is a non-zero-divisor on $\mathcal{X}$, every irreducible component of $\mathcal{X}_{\mathbb{F}_p}$ is a prime divisor of $\mathcal{X}$ (Krull), and the cycle of the fibre is $[\mathcal{X}_{\mathbb{F}_p}] = \sum_{W \subseteq \mathcal{X}_{\mathbb{F}_p}} \mathrm{ord}_W(p)[W]$. The scheme $\mathcal{X} \times_{\mathbb{Z}} \mathbb{Z}_{(p)}$ is flat and projective over the discrete valuation ring $\mathbb{Z}_{(p)}$, so by conservation of number (Fulton, *Intersection theory*, Proposition 10.2)

$$\sum_{W \subseteq \mathcal{X}_{\mathbb{F}_p}} \mathrm{ord}_W(p)\, d_I(W) = \deg\Big(\prod_{i \in I} c_1(\mathcal{O}(N_i))\, c_1(\mathcal{O}(e_H))^{D-|I|} \cap [\mathcal{X}_{\mathbb{Q}}]\Big).$$

On the generic fibre, $c_1(\mathcal{O}(e_l')) \cap \gamma = c_1(\mathcal{O}(e_l)) \cap \gamma$ for every cycle class γ of $\mathcal{X}_{\mathbb{Q}}$: the section σ_l of $\mathcal{O}(e_l - e_l')$ has order $\mathrm{ord}_W(f_l) - \mathrm{ord}_W(g_l) = 0$ along every prime divisor W of $\mathcal{X}$ not contained in a fibre, and these are exactly the closures of the prime divisors of $\mathcal{X}_{\mathbb{Q}}$, with the same local rings; so $c_1(\mathcal{O}(e_l - e_l')) \cap [\mathcal{X}_{\mathbb{Q}}] = [\mathrm{div}(\sigma_l|_{\mathcal{X}_{\mathbb{Q}}})] = 0$, and the same holds after capping with further first Chern classes since these commute (Fulton, Proposition 2.5). Replacing each $e_l' + e_H$ by $e_l + e_H$, hypothesis 2 bounds the right side by M. With (D.34) and (D.36),

$$\sum_{W \subseteq \mathcal{X}_{\mathbb{F}_p}} |a_{j,W}| \,\Big|\deg\Big(\prod_{i} c_1(\mathcal{A}_i^{(j)}) \cap [W]\Big)\Big| \leq \alpha_p \sum_{I} \sum_{W} \mathrm{ord}_W(p)\, d_I(W) \leq \alpha_p\, 2^D M.$$

Step 6: conclusion. By Step 2, (D.35) and Step 5,

$$|\Delta| \leq \sum_{j=1}^{D+1} \sum_{p \in S} \log p \cdot \alpha_p\, 2^D M = (D+1)\, 2^D M \sum_{p \in S} \alpha_p \log p.$$

□

Theorem D.131. *Let $\mathcal{T}$ be a root tower of type (Φ, n, κ) with a geometric realisation $(\nu_{\mathcal{T}}, (\mathcal{X}_{B,Z}))$ whose root models have convergent regularisation, and assume that the realised*

tower has the reference comparison (Rh1), (Rh2). Then it has the heights of points (Wp). More precisely, for $c_0 > 0$ one may take

$$\theta_0 = \min\Big(s_{\mathrm{Rh}},\ \frac{1}{2\|\nu_{\mathcal{T}}\|_\infty + 1},\ \Big(\frac{c_0}{2\|\nu_{\mathcal{T}}\|_\infty + 1}\Big)^{1/2}\Big),$$

$C = \max(C_a, C_b)$ *with* $C_a = 2C_{\mathrm{Rh}} + (C_{\mathrm{Rh}} \log C_{\mathrm{Rh}} + 2C_{\mathrm{Rh}} + 2)/\log 2$ *and* $C_b = C_{\mathrm{Rh}} + \big((2|\Phi|n + 1)\max_Z D_Z + C_{\mathrm{Rh}}\big)/\log 2$, *where* D_Z *is a constant of Lemma D.132 for* $\mathcal{X}_Z^{\mathrm{ref}}$ *and its lines* $\overline{\mathcal{L}}_r(1)$, $r \in \mathrm{Rt}^+$.

Proof. Fix $c_0 > 0$, θ_0 as stated, an integer $B \geq 2$, $Z \in \mathrm{Cp}$, $\theta \in (0, \theta_0]$ with $s = \theta^2$ rational, and a (c_0, θ)-spaced weight λ with rational entries; write $\mathcal{X} = \mathcal{X}_{B,Z}$ and $\lambda_s = \lambda - s\nu$. Take $\mathcal{J}$, q, q^{ref} as in (Rh1) for (B, Z).

Step 0: the perturbed weight is admissible in (Rh). Since $\theta \leq \theta_0 \leq s_{\mathrm{Rh}} \leq 1$, $0 < s \leq \theta \leq s_{\mathrm{Rh}} \leq 1$. Next $\|\lambda_s\|_\infty \leq 1 + \theta^2\|\nu\|_\infty \leq 1 + \theta\|\nu\|_\infty \leq \frac{3}{2}$. For $i \neq \kappa$, $(\lambda_s)_{a,i} - (\lambda_s)_{a,i+1} \geq c_0 - 2\theta^2\|\nu\|_\infty \geq c_0 - \theta^2(2\|\nu\|_\infty + 1) \geq 0$; at the cut, $(\lambda_s)_{a,\kappa} - (\lambda_s)_{a,\kappa+1} \geq \theta - 2\theta^2\|\nu\|_\infty = \theta(1 - 2\theta\|\nu\|_\infty) > 0$. So λ_s is dominant with $\|\lambda_s\|_\infty \leq 2$, and (Rh1) applies to $\mu = \lambda_s$ and s. Also $c(\lambda_s, s) = c(\lambda_s, 0) + s\,c(0, 1)$ on each model, and $h_{c,t}(W)$ is linear in c by (30.2).

Step 1: points lift along surjective morphisms. Let $g\colon \mathcal{J} \to \mathcal{Y}$ be a surjective morphism of arithmetic varieties and W a point of $\mathcal{Y}$. The generic point η of W is a closed point of $\mathcal{Y}_{\mathbb{Q}}$. The fibre $g^{-1}(\eta)$ is non-empty and of finite type over $\mathbf{k}(\eta)$; let y be a closed point of it. Then $\mathbf{k}(y)$ is finite over $\mathbf{k}(\eta)$, hence over $\mathbb{Q}$, so y is a closed point of $\mathcal{J}_{\mathbb{Q}}$; its closure W' in $\mathcal{J}$ is integral, flat over $\mathbb{Z}$ (its generic point lies over $\mathbb{Q}$), of absolute dimension $1 + \mathrm{trdeg}_{\mathbb{Q}}\mathbf{k}(y) = 1$, i.e. a point of $\mathcal{J}$. As g is proper, $g(W')$ is closed and irreducible with generic point $g(y) = \eta$, so $g(W') = W$.

Step 2: the lower bound (a). Let W be a point of $\mathcal{X}$. By Step 1 there is a point W' of $\mathcal{J}$ with $q(W') = W$; put $W^{\mathrm{ref}} = q^{\mathrm{ref}}(W')$ and $x = h^{\mathrm{ref}}_{c(0,1),1}(W^{\mathrm{ref}})$. By (Rh1), Step 0 and (Rh2),

$$\begin{aligned} h_{c(\lambda_s,s),t(s)}(W) &\geq h^{\mathrm{ref}}_{c(\lambda_s,0),1}(W^{\mathrm{ref}}) + s\,x - C(\log B + \log(1/s) + 1) \\ &\geq -C\log y - C + s(y - 2 - C) - C(\log B + \log(1/s) + 1), \end{aligned}$$

with $y = 2 + C + x \geq 2$ (as $x \geq -C$). The function $y \mapsto sy - C\log y$ on $(0, \infty)$ has its minimum at $y = C/s$, so $sy - C\log y \geq C - C\log C - C\log(1/s)$; also $s(2 + C) \leq 2 + C$. Hence

$$\begin{aligned} h_{c(\lambda_s,s),t(s)}(W) &\geq -C\log B - 2C\log(1/s) - (C\log C + 2C + 2) \\ &\geq -C_a\big(\log B + \log(1/s)\big) = -C_a\log(B/s), \end{aligned}$$

using $C \geq 1$ (so $C\log C \geq 0$), $\log B \geq \log 2$ and $\log(1/s) \geq 0$.

Step 3: the dense set (b). By Lemma D.132 applied to $\mathcal{X}_Z^{\mathrm{ref}}$ and the lines $\overline{\mathcal{L}}_r(1)$, $r \in \mathrm{Rt}^+$, of the reference model, there is a Zariski dense set F^{ref} of points of $\mathcal{X}_Z^{\mathrm{ref}}$ on which all these heights are at most D_Z in absolute value. For $W^{\mathrm{ref}} \in F^{\mathrm{ref}}$, by (30.2),

$$h^{\mathrm{ref}}_{c(\lambda_s,s),1}(W^{\mathrm{ref}}) \leq \|c(\lambda_s, s)\|_1 D_Z \leq \big(\|\lambda_s\|_1 + s\big)D_Z \leq (2|\Phi|n + 1)D_Z.$$

For each $W^{\mathrm{ref}} \in F^{\mathrm{ref}}$ choose, by Step 1, a point W' of $\mathcal{J}$ with $q^{\mathrm{ref}}(W') = W^{\mathrm{ref}}$; let $F_{\mathcal{J}}$ be the set of these W' and $F = \{q(W') : W' \in F_{\mathcal{J}}\}$, a set of points of $\mathcal{X}$. By (Rh1), for $W' \in F_{\mathcal{J}}$,

$$h_{c(\lambda_s,s),t(s)}(q(W')) \leq (2|\Phi|n + 1)D_Z + C(\log B + 1) \leq C_b \log B.$$

$F_{\mathcal{J}}$ is dense in $\mathcal{J}$. Let $\mathcal{Y} \subseteq \mathcal{J}$ be closed and contain every $W' \in F_{\mathcal{J}}$. Then $q^{\mathrm{ref}}(\mathcal{Y})$ is closed (q^{ref} is proper) and contains every member of F^{ref}, so it is $\mathcal{X}_Z^{\mathrm{ref}}$. Some irreducible component

$\mathcal{Y}_0$ of $\mathcal{Y}$ maps onto $\mathcal{X}_Z^{\mathrm{ref}}$; it dominates $\operatorname{Spec}\mathbb{Z}$, and its function field contains that of $\mathcal{X}_Z^{\mathrm{ref}}$, so $\dim\mathcal{Y}_0 = 1+\operatorname{trdeg}_{\mathbb{Q}}\mathbf{k}(\mathcal{Y}_0) \geq 1+\operatorname{trdeg}_{\mathbb{Q}}\mathbf{k}(\mathcal{X}_Z^{\mathrm{ref}}) = D+1 = \dim\mathcal{J}$. As $\mathcal{J}$ is irreducible, $\mathcal{Y}_0 = \mathcal{J}$ as sets. *F is Zariski dense in $\mathcal{X}$.* Let $\mathcal{Y}' \subseteq \mathcal{X}$ be a closed subscheme containing every member of F. Then $q^{-1}(\mathcal{Y}')$ contains every $W' \in F_{\mathcal{J}}$, hence equals $\mathcal{J}$ as a set, so the underlying set of $\mathcal{Y}'$ contains $q(\mathcal{J}) = \mathcal{X}$; as $\mathcal{X}$ is reduced, $\mathcal{Y}' = \mathcal{X}$.

With $C = \max(C_a, C_b)$, Steps 2 and 3 are (a) and (b) of (Wp). □

Lemma D.132. *Let $\mathcal{X} \subseteq \mathbb{P} = \prod_{k\in K}\mathbb{P}(\mathbb{Z}^{I_k})$ be a closed integral subscheme, flat over $\mathbb{Z}$, of absolute dimension $d+1$, and let $\overline{\mathcal{L}}_j = (\mathcal{O}(e_j), h_j)|_{\mathcal{X}}$, $j \in J$, be finitely many Hermitian line bundles given by cone metrics. For a point W of $\mathcal{X}$ put $h_{\overline{\mathcal{L}}_j}(W) = \widehat{\deg}(\widehat{c}_1(\overline{\mathcal{L}}_j)\cdot[W])/\deg W_{\mathbb{Q}}$. Then there are $C \geq 0$ and a Zariski dense set F of points of $\mathcal{X}$ with $|h_{\overline{\mathcal{L}}_j}(W)| \leq C$ for every $W \in F$ and every $j \in J$.*

Proof. **Step 1: heights of points by local terms.** Let W be a point of $\mathcal{X}$. Its generic point u is a closed point of $\mathcal{X}_{\mathbb{Q}}$ ($W_{\mathbb{Q}}$ is non-empty and of dimension 0), and $\deg W_{\mathbb{Q}} = [\mathbf{k}(u):\mathbb{Q}]$. Let $L \supseteq \mathbf{k}(u)$ be a number field and $z = (z_k)_k$, $z_k \in L^{I_k}\smallsetminus\{0\}$, multihomogeneous coordinates of u. For a cone metric h of multidegree e, the definition of the height of a point for the Hermitian line bundle $(\mathcal{O}(e),h)$ (whose integral structure at the finite places is that of $\mathcal{O}(e)$ on $\mathbb{P}$) together with the product formula gives the standard expression ([48], §3)

$$h_{(\mathcal{O}(e),h)}(W) = \frac{1}{[L:\mathbb{Q}]}\Big(\sum_{v\text{ finite}}\sum_k e_k \log\max_i |z_{k,i}|_v + \sum_{\sigma\colon L\to\mathbb{C}} \log h(\sigma z)\Big), \tag{D.37}$$

independent of L and of the coordinates.

Step 2: reduction to standard heights. For $k \in K$ put

$$h_k^{\mathrm{st}}(W) = \frac{1}{[L:\mathbb{Q}]}\Big(\sum_{v\text{ finite}} \log\max_i |z_{k,i}|_v + \sum_{\sigma}\log\max_i|\sigma(z_{k,i})|\Big) \geq 0,$$

the inequality by the product formula applied to a non-zero coordinate z_{k,i_0}. For a cone metric h_j of multidegree e_j, the function $\psi_j(z) = \log h_j(z) - \sum_k e_{j,k}\log\max_i|z_{k,i}|$ is continuous on $\widehat{\mathbb{C}} = \prod_k(\mathbb{C}^{I_k}\smallsetminus\{0\})$ and invariant under $z_k \mapsto \lambda_k z_k$, $\lambda_k \in \mathbb{C}^\times$; so it is bounded, $|\psi_j| \leq m_j$, by its values on the compact set $\{\max_i|z_{k,i}| = 1\ \forall k\}$. By (D.37),

$$\Big|h_{\overline{\mathcal{L}}_j}(W) - \sum_k e_{j,k}h_k^{\mathrm{st}}(W)\Big| \leq m_j, \qquad \text{so} \qquad |h_{\overline{\mathcal{L}}_j}(W)| \leq \Big(\sum_k|e_{j,k}|\Big)\max_k h_k^{\mathrm{st}}(W) + m_j. \tag{D.38}$$

It therefore suffices to find C_0 and a Zariski dense set F of points with $h_k^{\mathrm{st}}(W) \leq C_0$ for all k; then $C = \max_j((\sum_k|e_{j,k}|)C_0 + m_j)$.

Step 3: a finite projection. The scheme $\mathcal{X}_{\mathbb{Q}}$ is integral, of dimension d, and dense in $\mathcal{X}$ (flatness). For each k choose $i_k \in I_k$ such that z_{k,i_k} does not vanish identically on $\mathcal{X}_{\mathbb{Q}}$ (if all coordinates of a block vanished identically, $\mathcal{X}_{\mathbb{Q}}$ would be empty). Then $U = \mathcal{X}_{\mathbb{Q}} \cap \{\prod_k z_{k,i_k} \neq 0\}$ is a non-empty open affine subscheme of $\mathcal{X}_{\mathbb{Q}}$ with coordinate ring A, an integral domain of dimension d generated over $\mathbb{Q}$ by the functions $y_{k,i} = z_{k,i}/z_{k,i_k}$. By Noether normalisation there are $y_1',\dots,y_d' \in A$, algebraically independent over $\mathbb{Q}$, such that A is finite over $R = \mathbb{Q}[y_1',\dots,y_d']$. Every generator $y_{k,i}$ is then a root of a monic polynomial

$$P_{k,i}(T) = T^{m_{k,i}} + \sum_{l<m_{k,i}} a_{k,i,l}(y_1',\dots,y_d')\,T^l, \qquad a_{k,i,l} \in \mathbb{Q}[Y_1,\dots,Y_d].$$

Let $N \geq 1$ be a common denominator of all coefficients of all $a_{k,i,l}$, and B_0 the maximum over (k,i,l) of the sum of the absolute values of the coefficients of $a_{k,i,l}$. The morphism $\varphi =$

$(y'_1,\dots,y'_d)\colon U\to \mathbb{A}^d_{\mathbb{Q}}$ is finite, hence closed, and surjective, since $R\to A$ is an injective integral extension (lying over).

Step 4: the points. Let $\mathcal{T}\subseteq \mathbb{A}^d_{\mathbb{Q}}$ be the set of closed points whose coordinates (in $\overline{\mathbb{Q}}$, up to conjugation) are all roots of unity. The set $\mathcal{T}$ is Zariski dense in $\mathbb{A}^d_{\mathbb{Q}}$: a polynomial vanishing on $\mu_\infty^d\subseteq\overline{\mathbb{Q}}^d$ is zero, by induction on d, since μ_∞ is infinite. For each $\tau\in\mathcal{T}$ choose a closed point $u_\tau\in U$ with $\varphi(u_\tau)=\tau$; it is a closed point of $\mathcal{X}_{\mathbb{Q}}$ (its residue field is finite over $\mathbb{Q}$), and its closure W_τ in $\mathcal{X}$ is a point of $\mathcal{X}$. Put $F=\{W_\tau:\tau\in\mathcal{T}\}$.

F is Zariski dense. Let $\mathcal{Y}\subseteq\mathcal{X}$ be a closed subscheme containing every W_τ. Then $\mathcal{Y}\cap U$ is closed in U and contains every u_τ, so the closed set $\varphi(\mathcal{Y}\cap U)$ contains $\mathcal{T}$, hence equals $\mathbb{A}^d_{\mathbb{Q}}$; thus $\dim(\mathcal{Y}\cap U)\geq d=\dim U$ (a finite morphism does not raise dimension), and since U is irreducible, $\mathcal{Y}\cap U$ contains U as a set. So the underlying set of $\mathcal{Y}$ contains the closure of U, which is $\mathcal{X}$; as $\mathcal{X}$ is reduced, $\mathcal{Y}=\mathcal{X}$.

Heights. Let $\tau\in\mathcal{T}$, L a number field containing $\mathbf{k}(u_\tau)$, and take the coordinates $z_{k,i}=y_{k,i}(u_\tau)$ (so $z_{k,i_k}=1$). Each $\eta=z_{k,i}$ is a root of $T^m+\sum_{l<m}a_l(\zeta)T^l$, $a_l=a_{k,i,l}$, where $\zeta=(y'_1(u_\tau),\dots,y'_d(u_\tau))$ consists of roots of unity.

- At a finite place v: $|\zeta_i|_v=1$ and the coefficients of a_l lie in $N^{-1}\mathbb{Z}$, so $|a_l(\zeta)|_v\leq|N|_v^{-1}$ by the ultrametric inequality. If $|\eta|_v>|N|_v^{-1}$ (≥ 1), then $|a_l(\zeta)\eta^l|_v<|\eta|_v^{l+1}\leq|\eta^m|_v$ for every $l<m$, contradicting $\eta^m=-\sum_l a_l(\zeta)\eta^l$. So $\max_i|z_{k,i}|_v\leq|N|_v^{-1}$.
- At an embedding σ: $|\sigma(a_l(\zeta))|\leq B_0$. If $|\sigma\eta|>1+B_0$, then $|\sigma\eta|^m\leq B_0\sum_{l<m}|\sigma\eta|^l<B_0|\sigma\eta|^m/(|\sigma\eta|-1)<|\sigma\eta|^m$, a contradiction. So $\max_i|\sigma(z_{k,i})|\leq 1+B_0$.

By the product formula $\sum_{v\text{ finite}}\log|N|_v^{-1}=[L:\mathbb{Q}]\log N$, hence $h_k^{\mathrm{st}}(W_\tau)\leq\log N+\log(1+B_0)=:C_0$ for every k. Step 2 finishes the proof. □

E Hecke ideals, patching and Taylor–Wiles levels

This appendix contains the automorphic side of the Hecke realisation: Hida theory for ordinary forms on definite unitary groups with a type at an auxiliary place, and patching in the manner of Taylor and Wiles [254] at the one-dimensional points of the polarised ordinary determinant ring. It is written for a rank-n Hecke datum (Definition 50.1), so that it serves both the auxiliary fields of Part IX, in ranks two and three, and the links of the symplectic case, in rank four. It proves five statements of the main text. Proposition E.1, the existence of a Hecke ideal of zero-monodromy type with classical level modules at every Taylor–Wiles level; Proposition E.25, the automorphy, with the witness conditions, of the irreducible points of the classical ideal with a parallel inertial weight; and Proposition E.32, $R=T$ for such ideals at patchable curve points and along thick chains. These three are used in Proposition 50.11 (Section 50) and in Theorem 53.10 (Section 53). The other two, Lemma E.27 on twist stability and Lemma E.29 on purity at arithmetic points, are used only in Theorem 53.10. The proofs cite from the main text only four lemmas: Lemma 49.25, Lemma 50.13, Lemma 50.24 and Lemma 53.25.

The appendix has five sections. Section E.1 constructs the Hecke ideals of zero-monodromy type from Geraghty's ordinary Hecke algebras [105], through the Galois representations of their points, local–global compatibility, base change from the definite unitary group and the control of the level, and proves automorphy and purity at their classical points. Section E.2 proves Proposition E.32 from abstract patching and from the existence of patching systems (Proposition E.39); the latter rests on the choice of Taylor–Wiles places and elements, on a map from patched tuples to the eigenvalue algebra, and on the results of the next three sections. Section E.3 realises a

determinant over a Taylor–Wiles level as a representation, through Cayley–Hamilton quotients in the sense of Chenevier [66], and proves the Galois clause of a patching system. Section E.4 proves the Selmer bounds at the levels: the first-order dual Selmer bound (B1), by Selmer counts at the levels with the Greenberg–Wiles formula (Proposition E.100), and the obstruction bound (B2). Section E.5 constructs the patched ring and shows that classical levels give automorphic patching data. The arguments follow the standard pattern of patching. Two features shape the details: patching is done at curve points of a residually reducible determinant ring, and the level modules are cut out by types of zero monodromy.

E.1 Hecke ideals of zero-monodromy type

This section proves the Hida-theoretic statements of the appendix. The first, Proposition E.1, gives for every rank-n Hecke datum with trivial wild values a Hecke ideal of zero-monodromy type of the universal polarised ordinary determinant ring which, if proper, has classical levels; it is used in Proposition 50.11 and in Theorem 53.10. The second, Proposition E.25, says that the irreducible points of the classical ideal with a parallel inertial weight are automorphic of conjugate self-dual type with the witness conditions, and has the same two consumers. The section also proves the twist stability and the purity of the ideals cut out by an ordinary Hecke algebra of a type (Lemma E.27, Lemma E.29), which Theorem 53.10 uses. The ideals come from the ordinary Hecke algebras of definite unitary groups of Geraghty [105], taken with a type of zero monodromy at the places of St; the determinant ring maps onto them through a Galois determinant (Lemma E.16).

E.1.1 Existence of Hecke ideals of zero-monodromy type

This subsection proves Proposition E.1 from Proposition E.2. When the determinant ring has a classical ordinary point, the ordinary Hecke algebra of a zero-monodromy type at St receives the universal determinant ring, and the kernel of the surjection, taken at fixed torsion values, is a Hecke ideal of zero-monodromy type. Its classical level modules at the Taylor–Wiles levels come from the Λ-adic typed forms of Subsection E.1.4. Integral zero-monodromy types with prescribed inertial characters exist for a finite product of groups GL_n of p-adic fields (Lemma E.3).

Proposition E.1. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$ whose wild values are trivial ($\xi_{v,a} = 1$ for all $v \in S_\ell$ and $1 \le a \le n$), κ a twist for $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$. Then B_n^{po} has a Hecke ideal J of zero-monodromy type for ι and κ which, if $J \neq B_n^{\mathrm{po}}$, has classical levels. Moreover, if B_n^{po} has a classical ordinary point for ι and κ, J may be taken of the form given in Proposition E.2 (for $B = B_n^{\mathrm{po}}$): $J = \ker\theta$ with $\theta\colon B_n^{\mathrm{po}} \to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}_0$ the surjection of (Gd2) of Lemma E.16 for a type datum $((V_v),\tau)$, $\mathfrak{m}$, χ_0, $\mathfrak{a}_0$ and $\mathcal{C}_{\chi_0}$ as described there.*

Proof. By Proposition E.2 (its hypotheses are those of this statement), B has a Hecke ideal of zero-monodromy type. If B has no classical ordinary point for ι and κ, take $J = B$; there is nothing more to show. Otherwise take J of the form given in Proposition E.2: a type datum $((V_v)_{v\in\mathrm{St}},\tau)$ over $\mathscr{H}$ of principal congruence level c satisfying (Zt), a maximal ideal $\mathfrak{m}$ of $\mathbb{T}_\tau$ with $\mathbb{T}_\tau/\mathfrak{m} = \mathbb{F}$ satisfying (Mx), the homomorphism $\chi_0\colon \Delta_\ell \to \mathcal{O}'^{\times}$ with $\chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))$, $\mathbb{T} = \mathbb{T}_{\tau,\mathfrak{m}}$, $\mathfrak{a}_0 = \mathfrak{a}_{\chi_0} \subseteq \mathbb{T}$, $T = \mathbb{T}/\mathfrak{a}_0$, $M = (e_\mathfrak{m} N_\tau)^{\chi_0} = e_\mathfrak{m} N_\tau / \sum_{\delta\in\Delta_\ell}(\langle\delta\rangle - \chi_0(\delta)) e_\mathfrak{m} N_\tau$ ($e_\mathfrak{m}$ the idempotent of $\mathbb{T}_\tau$ for $\mathfrak{m}$), free of finite rank over Λ_1 and faithful over T by (Zm1), and the surjection $\theta\colon B \to T$ of (Gd2) of Lemma E.16 ($Q = \varnothing$, $\mathfrak{a} = \mathfrak{a}_0$, $\mathcal{C} = \mathcal{C}_{\chi_0}$, which is non-empty with $\bigcap_{y\in\mathcal{C}_{\chi_0}} \ker y = \mathfrak{a}_0$ by (Zp4), as $\mathfrak{a}_0 \neq \mathbb{T}$), with $J = \ker\theta$; so the hypotheses of Lemma E.16

hold for $\mathscr{H}$, κ, B, c and this type datum. By (Gd2) ($Q = \varnothing$), for all w, $v \in S_\ell$, $1 \le j \le n$ and $z \in \mathcal{O}_{L_{\tilde{v}}}^\times$, with $\chi(\mathrm{Frob}_w) = (\mathrm{N}w)^{-1}$:

$$\begin{gathered} T_w^{(j)} = f_j(\mathrm{Frob}_w), \quad f_j(g) = \chi(g)^{j(j-1)/2}\kappa(g)^j\,\theta(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(g)))\ (g \in G_L); \\ \langle d_j(z)\rangle = (\chi^{j-1}\kappa)(\mathrm{Art}(z))\,\theta(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(z))), \end{gathered} \tag{$*$}$$

and the identity for $U_{\tilde{v}}^{(j)}$ stated there. Each $f_j\colon G_L \to T$ is continuous (D^{u}, θ, χ, κ are continuous) and constant on conjugacy classes.

Step 1: the Taylor–Wiles base. Let $v \in S_\ell$ and $d_v = [L_v^+ : \mathbb{Q}_\ell]$. The principal units U^1 of L_v^+ are isomorphic to $\mu_{\ell^\infty}(L_v^+) \times \mathbb{Z}_\ell^{d_v}$ ([190], Chapter II, (5.7)); their open subgroup $1 + \ell\mathcal{O}_{L_v^+}$ contains no non-trivial root of unity ((Wf1) of Lemma E.20; ℓ is odd), so it is a torsion-free finitely generated $\mathbb{Z}_\ell$-module of rank d_v, hence free of rank d_v. Choose a $\mathbb{Z}_\ell$-basis of each $1+\ell\mathcal{O}_{L_v^+}$ and enumerate the triples (v, a, z) with $v \in S_\ell$, $1 \le a \le n$ and z in the chosen basis at v as (v_k, a_k, z_k), $1 \le k \le \sum_v nd_v = n[L^+ : \mathbb{Q}] = D$. Then the $u_k = d_{a_k}(z_k)$ form a $\mathbb{Z}_\ell$-basis of $T_n(\ell^1) = \prod_{v\in S_\ell}(1 + \ell\mathcal{O}_{L_v^+})^n$, so $\varepsilon\colon \Lambda_D \to \Lambda_1$, $X_k \mapsto [u_k] - 1$, is an isomorphism of $\mathcal{O}'$-algebras. Put $\gamma_k = \mathrm{Art}(z_k) \in I_{v_k}$ and $c_k = (\chi^{a_k-1}\kappa)(\gamma_k) \in \mathcal{O}'^\times$. As γ_k lies in the image of the pro-ℓ group $1 + \ell\mathcal{O}_{L_{v_k}^+}$, every character of finite order prime to ℓ kills it, so $\bar{c}_k = 1 = \bar{\chi}_{a_k}(\gamma_k)$ and $\mathbf{w} = (v_k, a_k, \gamma_k, c_k)_k$ is a family of weight variables. By ($*$), $\theta(\lambda_B(X_k)) = c_k\theta(\psi_{v_k,a_k}^{\mathrm{d}}(\gamma_k)) - 1 = \langle u_k\rangle - 1$, i.e. $\theta \circ \lambda_B = \langle\cdot\rangle \circ \varepsilon$, $\langle\cdot\rangle\colon \Lambda_1 \to T$ the diamond map.

Let $M^* = \mathrm{Hom}_{\Lambda_1}(M, \Lambda_1)$ with $t \in T$ acting by $\phi \mapsto \phi \circ t$, a B-module through θ. It is free of finite rank over Λ_1, and the transposed diamond operator $\langle u\rangle$ is multiplication by $[u]$ (ϕ is Λ_1-linear); so through λ_B the Λ_D-module M^* is M^* with its Λ_1-structure transported by ε, free of finite rank. T acts faithfully on M^*: if $\phi \circ t = 0$ for all ϕ, then $tm = 0$ for all $m \in M$ (M is free), so $t = 0$ by (Zm1). Hence $\mathrm{Ann}_B(M^*) = \theta^{-1}(0) = J$, and $(\mathbf{w}, M^*)$ satisfies (Hl1): it is a Taylor–Wiles base for J.

Fix now $Q = \{v_1, \dots, v_q\}$ and $\bar{w}_j$, w_j as in Definition 53.9; Q is disjoint from T_L and its places split in L. Through ι_{w_j}, G_Q, K_Q, Iw_Q, $\mathrm{Iw}_{1,Q}$ are identified with subgroups of $\prod_{v\in Q}\mathbb{G}_L(L_v^+)$, and Lemma E.22 applies to $((V_v), \tau)$ and Q; write $N(K') = N_\tau(K')$, $\mathbb{T}(K') = \mathbb{T}_\tau(K')$ and $\mathbb{T}_1 = \mathbb{T}(\mathrm{Iw}_{1,Q})$. Since $\mathbb{T}^{\mathrm{ord}}(V(K'))$ is the Λ^+-algebra generated by the operators and $\Lambda^+ = \bigoplus_u \Lambda_1[u]$ (u over representatives of $T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)/T_n(\ell^1)$, $[u]$ acting as $\langle u\rangle$), every element of $\mathbb{T}(K')$ is a finite Λ_1-linear combination of monomials in the operators. $N(K_Q) = N_\tau$ (the level at K_Q is V), and $\mathbb{T}(K_Q) \subseteq \mathbb{T}_\tau$ is the Λ^+-subalgebra generated by the operators away from $T_L \cup Q$.

Step 2: $\mathbb{T}(K_Q)$ maps onto T. Let $T'' \subseteq T$ be the image of $e_{\mathfrak{m}}\mathbb{T}(K_Q) \subseteq \mathbb{T}$, a Λ_1-submodule of the finite Λ_1-module T, hence closed. It contains the images of the topological generators of T ((Gd0)) except possibly $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ for w above Q. For such w, by the Chebotarev density theorem there are places w_i above split places outside $T_L \cup Q$ and Frobenius elements $\mathrm{Frob}_{w_i} \to \mathrm{Frob}_w$ in G_L (G_L is metrisable, and every conjugacy class of every finite quotient contains Frobenius elements of such places); by ($*$) and continuity, $e_{\mathfrak{m}}T_w^{(j)} = \lim_i f_j(\mathrm{Frob}_{w_i}) = \lim_i e_{\mathfrak{m}}T_{w_i}^{(j)} \in T''$. T is integral over T'' (it is finite over the image of Λ_1, which lies in T''), so a unit of T lying in T'' is a unit of T'', and $(T_w^{(n)})^{-1} \in T''$. Hence $T'' = T$. Let $\mathfrak{m}' = \{t \in \mathbb{T}(K_Q) : e_{\mathfrak{m}}t \in \mathfrak{m}_{\mathbb{T}}\} = \mathfrak{m} \cap \mathbb{T}(K_Q)$, a maximal ideal with residue field $\mathbb{F}$.

Step 3: $\mathfrak{m}$ is the only maximal ideal of $\mathbb{T}_\tau$ above $\mathfrak{m}'$. Let $\mathfrak{n}$ be one. $\mathbb{T}_{\tau,\mathfrak{n}}$ is a non-zero direct factor of $\mathbb{T}_\tau$, finite and torsion-free over Λ_1 ((Gd0)), so $\Lambda_1 \to \mathbb{T}_{\tau,\mathfrak{n}}$ is injective and integral; for a dominant weight λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$ there is a prime of $\mathbb{T}_{\tau,\mathfrak{n}}$ above $\mathfrak{P}_{\lambda,1}$ (lying over), with quotient a domain finite over $\Lambda_1/\mathfrak{P}_{\lambda,1} \subseteq \overline{\mathbb{Q}}_\ell$, hence a point y of $\mathbb{T}_\tau$ through $\mathbb{T}_{\tau,\mathfrak{n}}$ with $y(\mathfrak{P}_{\lambda,1}) = 0$. By Lemma E.11 ($Q = \varnothing$, $\alpha = 1$, $r = 1$) and (Gy5)(i) there is a continuous semisimple $r_\pi\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, unramified above every w up to semisimplification, with $r_\pi(\mathrm{Frob}_w)$ of characteristic

polynomial $P_{y,w}$. Its image is compact, so it stabilises a lattice over the ring of integers of a finite extension of $\mathbb{Q}_\ell$; let $\bar r$ be the semisimplified reduction, a continuous representation over $\overline{\mathbb{F}}_\ell$ whose characteristic polynomial at Frob_w is the reduction of $P_{y,w}$, i.e. is computed from the images of the $T_w^{(j)}$ in $\mathbb{T}_\tau/\mathfrak{n}$. For w above a place outside $T_L \cup Q$, $T_w^{(j)} \in \mathbb{T}(K_Q)$ and $\mathfrak{n} \cap \mathbb{T}(K_Q) = \mathfrak{m}' \subseteq \mathfrak{m}$, so by (Mx) this polynomial is $\prod_a (X - (\bar\chi_a \bar\kappa)(\mathrm{Frob}_w))$. The characteristic polynomials of $\bar r$ and of $\bigoplus_a \bar\chi_a\bar\kappa$ are locally constant functions on G_L agreeing on a dense set, hence everywhere; at Frob_w for w above Q this gives $(\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} \equiv e_j((\bar\chi_a\bar\kappa)(\mathrm{Frob}_w))_a$ modulo $\mathfrak{n}$, the same value as modulo $\mathfrak{m}$ ((Mx)). So the residue maps of $\mathfrak{n}$ and $\mathfrak{m}$ agree on all topological generators of $\mathbb{T}_\tau$, with values in $\mathbb{F}$; being continuous with discrete image, they are equal, and $\mathfrak{n} = \mathfrak{m}$. Consequently the idempotent $e_{\mathfrak{m}'}$ of the semilocal ring $\mathbb{T}(K_Q)$ for $\mathfrak{m}'$, an idempotent of $\mathbb{T}_\tau$ that is 1 exactly modulo the maximal ideals above $\mathfrak{m}'$, equals $e_{\mathfrak{m}}$.

Step 4: the Hecke algebra at level $\mathrm{Iw}_{1,Q}$ *and its determinant.* By (Sm1), the map $p = p_{\mathrm{Iw}_{1,Q}K_Q} \colon N(\mathrm{Iw}_{1,Q}) \to N_\tau$ is surjective and commutes with the operators, so an element of $\mathbb{T}_1$ (a Λ_1-combination of monomials acting as 0 on $N(\mathrm{Iw}_{1,Q})$ acts as 0 on N_τ) induces an endomorphism of N_τ: a surjective homomorphism $s \colon \mathbb{T}_1 \to \mathbb{T}(K_Q)$ sending each operator to itself. Let $\mathfrak{m}_Q = s^{-1}(\mathfrak{m}')$, e_Q its idempotent, $T_Q = e_Q\mathbb{T}_1 = \mathbb{T}_{1,\mathfrak{m}_Q}$. Then $s(e_Q) = e_{\mathfrak{m}'} = e_{\mathfrak{m}}$ (Step 3), and $s_Q \colon T_Q \to T$, $t \mapsto e_{\mathfrak{m}} s(t) \bmod \mathfrak{a}_0$, is a surjective local homomorphism (Step 2) sending each operator to its image in T. $\mathbb{T}_1/\mathfrak{m}_Q = \mathbb{F}$, and $\mathfrak{m}_Q$ satisfies (Mx) (the congruences of (Mx) involve only operators, and hold in T). Apply Lemma E.17 at level $K' = \mathrm{Iw}_{1,Q}$ (with (Zt)) to $\mathfrak{m}_Q$ and χ_0, and let $\mathfrak{a}_0^Q \subseteq T_Q$ and $\mathcal{C}_{\chi_0}^Q$ be the ideal and the set of (Zp4) there. For $y \in \mathcal{C}_{\chi_0}$ (a point of $\mathbb{T}$ killing $\mathfrak{a}_0$, i.e. of T), $y \circ s_Q$ is a point of T_Q with $y(s_Q(\langle\delta\rangle)) = y(\langle\delta\rangle) = \chi_0(\delta)$ for $\delta \in \Delta_\ell$, so it kills $\mathfrak{a}_0^Q$ by (Zp4). As $\mathcal{C}_{\chi_0}$ is non-empty with $\bigcap_{y\in\mathcal{C}_{\chi_0}} \ker y = \mathfrak{a}_0$, this gives $\mathfrak{a}_0^Q \neq T_Q$ and $s_Q(\mathfrak{a}_0^Q) = 0$; so s_Q induces a surjective local homomorphism $T_Q/\mathfrak{a}_0^Q \to T$. From now on T_Q denotes $e_Q\mathbb{T}_1/\mathfrak{a}_0^Q$ and s_Q this surjection; it still sends each operator to its image in T. By (Zp4), $\mathcal{C}_{\chi_0}^Q$ is non-empty with $\bigcap_{y\in\mathcal{C}_{\chi_0}^Q} \ker y = \mathfrak{a}_0^Q$; its points satisfy (i), (ii) of (Gd2) ((Zp1), (Zp2)) and (iii): $y(\langle d_j(\zeta)\rangle) = \chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))\,\xi_{v,j}(g_\zeta)$, the wild values being trivial. By (Gd2) of Lemma E.16 at level $\mathrm{Iw}_{1,Q}$ with $\mathfrak{a} = \mathfrak{a}_0^Q$ and $\mathcal{C} = \mathcal{C}_{\chi_0}^Q$, there are a continuous T_Q-valued determinant D^Q of dimension n on $\Gamma^{0,Q}$ and continuous characters $\psi_{v,j}^\flat \colon D_v \to T_Q^\times$ with (Od1)–(Od3) for π^Q, the reductions $\bar D_n$, $\bar\chi_j$, and $\chi_{D^Q}(\pi^Q(\mathrm{Frob}_w)) = \sum_j (-1)^j \kappa(\mathrm{Frob}_w)^{-j} (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j}$ for w outside $T_L \cup Q$, $\psi_{v,j}^\flat(\mathrm{Art}(z)) = (\chi^{j-1}\kappa)(\mathrm{Art}(z))^{-1}\langle d_j(z)\rangle$ and the analogous identity at $\mathrm{Art}(\varpi_{\tilde v})$.

Step 5: compatibility over T. For w outside $T_L \cup Q$, applying s_Q to $\chi_{D^Q}(\pi^Q(\mathrm{Frob}_w))$ gives, by $(*)$ and $\pi_{\mathscr{H}} = h^Q \circ \pi^Q$, the polynomial $\theta(\chi_{D^{\mathrm{u}}}(h^Q(\pi^Q(\mathrm{Frob}_w))))$. The determinants $s_Q \circ D^Q$ and $\theta \circ D^{\mathrm{u}} \circ h^Q$ on $\Gamma^{0,Q}$ are continuous and the $\pi^Q(\mathrm{Frob}_w)$ are dense in $\Gamma^{0,Q} = \pi^Q(G_L)$ (Chebotarev), so their characteristic polynomials agree everywhere, and $s_Q \circ D^Q = \theta \circ D^{\mathrm{u}} \circ h^Q$ by (Ch1). Likewise $s_Q \circ \psi_{v,j}^\flat$ and $\theta \circ \psi_{v,j}^{\mathrm{d}}$ agree on $\mathrm{Art}(\mathcal{O}_{L_{\tilde v}}^\times)$ and at $\mathrm{Art}(\varpi_{\tilde v})$ ($(*)$ and the identity for $U_{\tilde v}^{(j)}$), hence on D_v (both continuous, trivial on the closed commutator subgroup, and the image of Art is dense in D_v^{ab}).

Step 6: the ring R *and the map* β. Let $R = \{(a,b) \in T_Q \times B : s_Q(a) = \theta(b)\}$. Since s_Q and θ are surjective, $T_Q \times B = R \cdot (1,0) + R \cdot (0,1)$ (for (a,b) choose b' with $\theta(b') = s_Q(a)$ and a'' with $s_Q(a'') = \theta(b)$; then $(a,b) = (a,b')(1,0) + (a'',b)(0,1)$), so the Noetherian ring $T_Q \times B$ is finite over R, and R is Noetherian (Eakin–Nagata). $R \to T \to \mathbb{F}$ is surjective, and an element (a,b) outside its kernel has a, b units, with $(a^{-1}, b^{-1}) \in R$; so R is local with residue field $\mathbb{F}$. $(T_Q \times B)/\mathfrak{m}_R(T_Q \times B)$ is finite over $\mathbb{F}$, so $\mathfrak{m}_R(T_Q \times B)$ is an ideal of definition of the complete semilocal ring $T_Q \times B$; by Artin–Rees the subspace topology on R is the $\mathfrak{m}_R$-adic one, and R, closed in $T_Q \times B$ (compact), is complete: $R \in \mathrm{CNL}_{\mathcal{O}'}$. By Step 5, for every $\gamma \in \Gamma^{0,Q}$ the pair $(\chi_{D^Q}(\gamma), \chi_{D^{\mathrm{u}}}(h^Q(\gamma)))$ lies in $R[X]$; by (Ch4) (with $R \subseteq T_Q \times B$ and the determinants D^Q,

$D^{\mathrm{u}}\circ h^Q$) there is a continuous R-valued determinant D_R of dimension n on $\Gamma^{0,Q}$ with base changes D^Q and $D^{\mathrm{u}}\circ h^Q$. Put $\psi_{R,v,a}=(\psi^\flat_{v,a},\psi^{\mathrm{d}}_{v,a})\colon D_v\to R^\times$ (Step 5), continuous. Both components reduce to $\bar D_n$, resp. $\bar\chi_a$. (Od1) and (Od2) for $(D_R,(\psi_{R,v,a}))$ and π^Q: the relevant elements of R (coefficients of $\chi_{D_R}(\pi^Q(cg^{-1}c))-\chi_{D_R}(\pi^Q(g))$, traces $\mathrm{tr}_{D_R}(\gamma\prod_a(\pi^Q(g_a)-\psi_{R,v,a}(g_a)))$) map to 0 in T_Q by Step 4 and in B by (Od1), (Od2) for D^{u} composed with h^Q ($h^Q\circ\pi^Q=\pi_{\mathscr{H}}$; traces commute with base change), and $R\to T_Q\times B$ is injective. (Od3): for $g\in\mu_v$, $\psi^\flat_{v,a}(g)=1$ in T_Q ((Od3) in Step 4) and $\psi^{\mathrm{d}}_{v,a}(g)=1$ in B ((Od3) for B), the wild values being trivial; so $\psi_{R,v,a}(g)=1=\xi_{v,a}(g)$. Let $\beta\colon R\to B$ be the second projection: $\beta\circ D_R=D^{\mathrm{u}}\circ h^Q$ and $\beta\circ\psi_{R,v,a}=\psi^{\mathrm{d}}_{v,a}$. The first projection $\mathrm{pr}_1\colon R\to T_Q$ satisfies $s_Q\circ\mathrm{pr}_1=\theta\circ\beta$.

Step 7: the module P. Let $P'=\sum_{g\in G_Q}\rho(g)\,j_{\mathrm{Iw}_{1,Q}}(N^*(\mathrm{Iw}_{1,Q}))\subseteq P_\infty$. For $t\in\mathbb{T}_1$ written as $\sum_i\mu_i m_i$ ($\mu_i\in\Lambda_1$, m_i monomials in the operators) let t act on P' as $\sum_i\mu_i m_i$ acting on P_∞. This is well defined: if $\sum_i\mu_i m_i=0$ in $\mathbb{T}_1$, it kills $N(\mathrm{Iw}_{1,Q})$, hence (transposing) $j_{\mathrm{Iw}_{1,Q}}(N^*(\mathrm{Iw}_{1,Q}))$, hence each $\rho(g)j_{\mathrm{Iw}_{1,Q}}(N^*(\mathrm{Iw}_{1,Q}))$, as the operators and Λ_1 commute with ρ ((Sm2)). So P' is a $\mathbb{T}_1$-module on which $\mathbb{T}_1$ commutes with ρ. Let P be the submodule of e_QP' killed by the ideal $\mathfrak{a}_0^Q$ of $e_Q\mathbb{T}_1$: a module over $e_Q\mathbb{T}_1/\mathfrak{a}_0^Q=T_Q$, an R-module through pr_1, and stable under ρ, which commutes with $\mathbb{T}_1$. Let $\kappa_Q\colon G_Q\to\mathcal{O}'^\times$, $(g_j)_j\mapsto\prod_j\kappa(\mathrm{Art}_{w_j}(\det g_j))^{-1}$, with κ restricted to $D_{\bar w_j}\subseteq G_L$ (v_j splits) and Art_{w_j} the local Artin map of L_{w_j} normalised as in Theorem B.91; κ is unramified above w_j (Definition 50.1, (Rd7)), so κ_Q is trivial on $K_Q\supseteq\mathrm{Iw}_Q$. Let G_Q act on P by $\rho_P(g)=\kappa_Q(g)\rho(g)$, an R-linear action (e_Q commutes with ρ) with the same invariants under subgroups of K_Q as ρ. Through λ_R, Λ_D acts on P as Λ_1 does, transported by ε: $\mathrm{pr}_1(\lambda_R(X_k))=c_k\psi^\flat_{v_k,a_k}(\gamma_k)-1=\langle u_k\rangle-1$ (Step 4), and $\langle u\rangle$ acts on P_∞ as $[u]$.

(Hl2). $P'^{\mathrm{Iw}_{1,Q}}=j_{\mathrm{Iw}_{1,Q}}(N^*(\mathrm{Iw}_{1,Q}))=P_\infty^{\mathrm{Iw}_{1,Q}}$ by (Sm2), so $(e_QP')^{\mathrm{Iw}_{1,Q}}=e_QP_\infty^{\mathrm{Iw}_{1,Q}}$ (e_Q is an idempotent commuting with ρ), which $j_{\mathrm{Iw}_{1,Q}}$ identifies with the Λ_1-dual of $X=e_QN(\mathrm{Iw}_{1,Q})$ (a linear form on the direct summand X extends uniquely by 0), $t\in e_Q\mathbb{T}_1$ acting by $\phi\mapsto\phi\circ t$. A form is killed by $\mathfrak{a}_0^Q$ if and only if it vanishes on $\mathfrak{a}_0^QX$, and $\mathfrak{a}_0^QX=\sum_\delta(\langle\delta\rangle-\chi_0(\delta))X$: it contains the right side as $\langle\delta\rangle-\chi_0(\delta)\in\mathfrak{a}_0^Q$, and is contained in it as $\mathfrak{a}_0^Q$ kills X^{χ_0} ((Zp5) at level $\mathrm{Iw}_{1,Q}$). So $P^{\mathrm{Iw}_{1,Q}}\cong\mathrm{Hom}_{\Lambda_1}(X^{\chi_0},\Lambda_1)$, compatibly with Δ_Q. By (Wf3) of Lemma E.20 for $K''=\mathrm{Iw}_{1,Q}$ normal in $K'=\mathrm{Iw}_Q$, with quotient the ℓ-group Δ_Q, $\mathrm{Hom}_{\Lambda_1}(N(\mathrm{Iw}_{1,Q})^{\chi_0},\Lambda_1)$ is a free $\Lambda_1[\Delta_Q]$-module of finite rank; e_Q commutes with Δ_Q and with the diamond operators, so $P^{\mathrm{Iw}_{1,Q}}$ is isomorphic to a direct summand of it, finitely generated and projective over $\Lambda_1[\Delta_Q]\cong\Lambda_D[\Delta_Q]$ (through ε), and finitely generated over Λ_D.

(Hl3). $j_{K_Q}(N^*(K_Q))=j_{\mathrm{Iw}_{1,Q}}(p^*(N^*(K_Q)))\subseteq P'$, so $P'^{K_Q}=j_{K_Q}(N_\tau^*)$ by (Sm2), $N_\tau^*=\mathrm{Hom}_{\Lambda_1}(N_\tau,\Lambda_1)$. As p commutes with the operators, $t\in\mathbb{T}_1$ acts on N_τ^* by $\phi\mapsto\phi\circ s(t)$; hence $(e_QP')^{K_Q}=e_QP'^{K_Q}=j_{K_Q}(\{\phi\circ e_{\mathfrak{m}}:\phi\in N_\tau^*\})$ (Step 4: $s(e_Q)=e_{\mathfrak{m}}$), which restriction identifies with $\mathrm{Hom}_{\Lambda_1}(e_{\mathfrak{m}}N_\tau,\Lambda_1)$ (a linear form on the direct summand $e_{\mathfrak{m}}N_\tau$ extends uniquely by 0 on $(1-e_{\mathfrak{m}})N_\tau$), $t\in e_Q\mathbb{T}_1$ acting through $e_{\mathfrak{m}}s(t)$. The forms killed by $\mathfrak{a}_0^Q$ are those vanishing on $e_{\mathfrak{m}}s(\mathfrak{a}_0^Q)N_\tau$, a module containing $\sum_\delta(\langle\delta\rangle-\chi_0(\delta))e_{\mathfrak{m}}N_\tau$ (s fixes the operators) and contained in $\mathfrak{a}_0e_{\mathfrak{m}}N_\tau$ ($e_{\mathfrak{m}}s(\mathfrak{a}_0^Q)\subseteq\mathfrak{a}_0$, Step 4), which equals the former as $\mathfrak{a}_0$ kills M ((Zm1)). So restriction gives a bijective additive map $e\colon P^{K_Q}\to M^*$. For $t\in R$ and $x=j_{K_Q}(\phi\circ e_{\mathfrak{m}})$, tx corresponds to $\phi\circ e_{\mathfrak{m}}s(\tilde t)$, $\tilde t\in e_Q\mathbb{T}_1$ a lift of $\mathrm{pr}_1(t)$, which on the T-module M is $\phi\circ s_Q(\mathrm{pr}_1(t))=\phi\circ\theta(\beta(t))$, so $e(tx)=\beta(t)e(x)$.

Step 8: (Hl4). Let $z\in P$, $z\neq0$. Apply Lemma E.23 to $x=z$: it gives λ, π, y, Y, π_Y and sp with (Ls1)–(Ls4). For $t=\sum_i\mu_im_i\in\mathbb{T}_1$ put $\theta_0(t)=\sum_i y(\mu_i)\prod y(\text{factors of }m_i)$. By (Ls2), $\mathrm{sp}(tz')=\theta_0(t)\mathrm{sp}(z')$ for $z'\in P'$; in particular $\theta_0(t)$ does not depend on the expression of t (a vanishing expression acts as 0 on $P'\ni z$, and $\mathrm{sp}(z)\neq0$ by (Ls1)), and $\theta_0\colon\mathbb{T}_1\to\overline{\mathbb{Q}}_\ell$ is a homomorphism of $\mathcal{O}'$-algebras (compare $\mathrm{sp}(tt'z)$, $\mathrm{sp}((t+t')z)$ with $\mathrm{sp}(z)$). From $z=e_Qz$, $\theta_0(e_Q)=1$, and from $\mathfrak{a}_0^Qz=0$ ($z\in P$) and $\mathrm{sp}(z)\neq0$, $\theta_0(\mathfrak{a}_0^Q)=0$; so θ_0 factors through

T_Q; and $\theta_0(\langle u\rangle) = (w_0\lambda)(u)^{-1}$ on $T_n(\ell^1)$, so $\theta_0(\mathfrak{P}_{\lambda,1}) = 0$ (renormalised structure) and θ_0 is a regular point of T_Q. Put $\vartheta = \theta_0 \circ \mathrm{pr}_1 \colon R \to \overline{\mathbb{Q}}_\ell$. By (Zp1) at level $\mathrm{Iw}_{1,Q}$, $\tilde{r}_{\theta_0} = r_{\theta_0} \otimes \kappa^{-1}$ is trivial on N^Q; let r be the continuous representation of $\Gamma^{0,Q}$ with $r \circ \pi^Q = \tilde{r}_{\theta_0}$. The determinants $\det \circ r$ and $\vartheta \circ D_R = \theta_0 \circ D^Q$ are continuous with the same characteristic polynomial $\theta_0\big(\sum_j (-1)^j \kappa(\mathrm{Frob}_w)^{-j} (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j}\big)$ at the dense elements $\pi^Q(\mathrm{Frob}_w)$, w outside $T_L \cup Q$; so they are equal ((Ch1)). By (Ls2) and (Gy5)(i), r_π is continuous and semisimple with characteristic polynomial $P_{\theta_0,w}$ at these Frob_w, as is r_{θ_0}; so $r_\pi \cong r_{\theta_0}$ (Chebotarev, Brauer–Nesbitt) and $r \circ \pi^Q \cong r_\pi \otimes \kappa^{-1}$.

Let $Y_{\mathbb{C}} = Y \otimes_{\overline{\mathbb{Q}}_\ell, \iota} \mathbb{C}$ with G_Q acting by $\iota(\kappa_Q(g))\,\pi_Y(g) \otimes 1$, $\mathrm{sp}_{\mathbb{C}}(m) = \mathrm{sp}(m) \otimes 1$ for $m \in P$, and $\sigma_j = (\iota\pi_{v_j} \circ \iota_{w_j}^{-1}) \otimes (\iota \circ \kappa^{-1} \circ \mathrm{Art}_{w_j} \circ \det)$, an irreducible smooth representation of $\mathrm{GL}_n(L_{w_j})$. Then $\mathrm{sp}_{\mathbb{C}}(tm) = \iota(\vartheta(t))\mathrm{sp}_{\mathbb{C}}(m)$ for $t \in R$ (Step 7: R acts through pr_1), $\mathrm{sp}_{\mathbb{C}}(\rho_P(g)m) = \iota(\kappa_Q(g))\pi_Y(g)\mathrm{sp}(m) \otimes 1$ by (Ls3), and by (Ls4), twisting source and target by the same character, $Y_{\mathbb{C}}$ is spanned by the images of the $\mathrm{GL}_n(L_{w_j})$-equivariant maps $\sigma_j \to Y_{\mathbb{C}}$. By (Ug2) of Lemma E.8 at v_j (split, not above ℓ; $[L^+ : \mathbb{Q}] \geq 2$ by (Gd0)) and the compatibility of rec with twists by characters ($\mathrm{rec}(\sigma \otimes (\eta \circ \det)) = \mathrm{rec}(\sigma) \otimes \mathrm{rec}(\eta)$, $\mathrm{rec}(\eta) = \eta \circ \mathrm{Art}^{-1}$ on GL_1, Theorem B.92),

$$\mathrm{rec}\big(\sigma_j \otimes |\det|^{(1-n)/2}\big) \cong \iota\,\mathrm{WD}\big(r_\pi|_{G_{L_{w_j}}}\big)^{F\text{-}ss} \otimes \iota\kappa^{-1} \cong \iota\,\mathrm{WD}\big(r \circ \pi^Q|_{D_{\bar{w}_j}}\big)^{F\text{-}ss},$$

unconditionally. So $(\vartheta, r, Y_{\mathbb{C}}, \cdot, \mathrm{sp}_{\mathbb{C}}, (\sigma_j)_j)$ is a level point with $\mathrm{sp}_{\mathbb{C}}(z) \neq 0$: the level points for ι separate P.

Hence $(R, D_R, (\psi_{R,v,a}), \beta, P, \rho_P)$ is a classical level module at Q for the Taylor–Wiles base $(\mathbf{w}, M^*)$; as Q was arbitrary, J has classical levels. □

Proposition E.2. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ whose wild values are trivial ($\xi_{v,a} = 1$ for all $v \in S_\ell$ and $1 \leq a \leq n$), κ a twist for $\mathscr{H}$, $\iota \colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$. Then B has a Hecke ideal of zero-monodromy type for ι and κ. Moreover, if B has a classical ordinary point for ι and κ, it may be taken of the following form: $J = \ker\theta$, with $T = \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}_0$, λ_T the diamond map $[u] \mapsto \langle u\rangle$ followed by the projection, $M = N_{\tau,\mathfrak{m}}/\sum_{\delta\in\Delta_\ell}(\langle\delta\rangle - \chi_0(\delta))N_{\tau,\mathfrak{m}}$ and $f = \theta$, where $((V_v)_{v\in\mathrm{St}}, \tau)$ is a type datum over $\mathscr{H}$ with V_v the kernel of reduction modulo ϖ_v^c for an integer c as in Proposition E.5, satisfying (Zt) for ι and κ; $\mathfrak{m}$ is a maximal ideal of $\mathbb{T}_\tau$ with $\mathbb{T}_\tau/\mathfrak{m}$ the residue field of $\mathcal{O}$, satisfying (Mx); $\chi_0 \colon \Delta_\ell \to \mathcal{O}^\times$ is the homomorphism with $\chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))$ for $v \in S_\ell$, $1 \leq j \leq n$ and every ℓ-power root of unity $\zeta \in L_{\tilde{v}}$; $\mathfrak{a}_0 = \mathfrak{a}_{\chi_0}$ and $\mathcal{C}_{\chi_0}$ are as in (Zp4) for $\mathbb{T}_{\tau,\mathfrak{m}}$; and $\theta \colon B \to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}_0$ is the surjection of (Gd2) ($Q = \varnothing$, $\mathfrak{a} = \mathfrak{a}_0$, $\mathcal{C} = \mathcal{C}_{\chi_0}$). If moreover the reduction $\bar{\omega}$ of χ_{cyc} is non-trivial on D_v for every $v \in S_\ell$, then $\Delta_\ell = \{1\}$, $\mathfrak{a}_0 = 0$, $T = \mathbb{T}_{\tau,\mathfrak{m}}$ and $M = N_{\tau,\mathfrak{m}}$.*

Proof. If B has no classical ordinary point for ι and κ, then $J = B$ is a Hecke ideal of zero-monodromy type by definition. Assume from now on that there is one.

Step 1: the type. For $v \in \mathrm{St}$ let $\tilde{v}$ be the fixed place of L above v; $L_{\tilde{v}} = L_v^+$ is a finite extension of $\mathbb{Q}_p$ for the prime p below v, $p \neq \ell$. For $1 \leq a \leq n$ let $\chi_{v,a} = ([\bar{\chi}_a]\kappa)|_{I_{L_{\tilde{v}}}}$: a character of finite order with values in $\mathcal{O}^\times$ ($\bar{\chi}_a$ has finite order, and $\kappa^{m'}$ is trivial on $I_{L_{\tilde{v}}}$ by (Rd7)), the restriction of the continuous character $[\bar{\chi}_a]\kappa$ of $G_{L_{\tilde{v}}} \supseteq W_{L_{\tilde{v}}}$. By Lemma E.3 (with $F_v = L_{\tilde{v}}$, $v \in \mathrm{St}$) there are open normal subgroups $V_v' \subseteq \mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}}})$ and a finite free $\mathcal{O}$-module τ_0 with an action of $\prod_v \mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}}})/V_v'$ such that $\mathrm{Hom}_K(\tau_0 \otimes_{\mathcal{O},\iota} \mathbb{C}, \bigotimes_v \sigma_v) \neq 0$ if and only if every σ_v has zero monodromy and inertia $(\chi_{v,a})_a$ ($K = \prod_{v\in\mathrm{St}} \mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}}})$). Let c be an integer as in Proposition E.5, so large that the kernel of reduction modulo ϖ_v^c of $\mathbb{G}_L(\mathcal{O}_{L_v^+}) \cong \mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}}})$ (through $\iota_{\tilde{v}}$) lies in V_v' for every $v \in \mathrm{St}$ (the V_v' are open; the condition on c in Proposition E.5

persists when c grows). Let V_v be that kernel, $H = \prod_v \mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v$, through which τ_0 is a representation, and $\tau = \tau_0^\vee$. Then $((V_v), \tau)$ is a type datum over $\mathscr{H}$ with principal congruence level c; (Zc) holds for τ_0 (the direction "if"), and (Zt) holds for τ: if $\mathrm{Hom}_H(\tau^\vee \otimes \overline{\mathbb{Q}}_\ell, \bigotimes_v \pi_v^{V_v}) \neq 0$, then, as $\tau^\vee \cong \tau_0$, transporting by ι gives $\mathrm{Hom}_K(\tau_0 \otimes_{\mathcal{O},\iota} \mathbb{C}, \bigotimes_v \iota\pi_v \circ \iota_{\tilde{v}}^{-1}) \neq 0$, and the direction "only if" gives zero monodromy and inertia $\bigoplus_a \iota \circ \chi_{v,a}$ for every $\mathrm{rec}(\iota\pi_v \circ \iota_{\tilde{v}}^{-1})$.

Step 2: the maximal ideal. For a classical ordinary point x, with $\tilde{r}_x$ as in (Cy1), let y_x be the point of $\mathbb{T}_\tau$ given by Lemma E.4. By (Gd0), y_x takes values in the ring of integers of a finite extension of $\mathbb{Q}_\ell$; let $\bar{y}_x$ be its reduction, a continuous homomorphism to $\overline{\mathbb{F}}_\ell$. On the topological generators of $\mathbb{T}_\tau$ ((Gd0)) its values lie in $\mathbb{F}$ and do not depend on x: $(\mathrm{N}w)^{j(j-1)/2}\bar{y}_x(T_w^{(j)})$ is the reduction of the j-th elementary symmetric function of the eigenvalues of $(\tilde{r}_x \circ \pi_{\mathscr{H}} \otimes \kappa)(\mathrm{Frob}_w)$, i.e. $e_j((\bar{\chi}_a\bar{\kappa})(\mathrm{Frob}_w))_a$, because $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}_x$ reduces to $\bar{D}_n$ and $\mathrm{N}w$ is prime to ℓ; $\bar{y}_x(\langle d_j(z)\rangle)$ and $\bar{y}_x(U_{\tilde{v}}^{(j)})/\bar{y}_x(U_{\tilde{v}}^{(j-1)})$ are the reductions of $\phi_{v,j} = \chi^{j-1}\kappa(x \circ \psi_{v,j}^{\mathrm{d}})$ at $\mathrm{Art}(z)$ and $\mathrm{Art}(\varpi_{\tilde{v}})$, i.e. the values of $\bar{\chi}^{j-1}\bar{\kappa}\bar{\chi}_j$, as $x \circ \psi_{v,j}^{\mathrm{d}} \equiv \bar{\chi}_j$. Hence $\bar{y}_x = \bar{y}$ is independent of x, its image is $\mathbb{F}$, $\mathfrak{m} = \ker \bar{y}$ is a maximal ideal with $\mathbb{T}_\tau/\mathfrak{m} = \mathbb{F}$ satisfying (Mx), and every y_x factors through $\mathbb{T}_{\tau,\mathfrak{m}}$ (it is local onto its image).

Step 3: T, M and (Zm1). Write $\mathbb{T} = \mathbb{T}_{\tau,\mathfrak{m}}$ and $N = N_{\tau,\mathfrak{m}}$. By (Gd0), $\mathbb{T}$ is a complete Noetherian local $\mathcal{O}$-algebra with residue field $\mathbb{F}$, finite and torsion-free over Λ_1 (diamond structure); it is reduced (Lemma E.18). $\mathbb{T}_\tau$ is the product of its localisations at its finitely many maximal ideals; with the corresponding idempotent $e_\mathfrak{m}$, which commutes with the diamond operators, $N = e_\mathfrak{m}N_\tau$ is a direct summand of N_τ, and $\mathbb{T} = e_\mathfrak{m}\mathbb{T}_\tau$ acts faithfully on N (if $tN = 0$ for $t = e_\mathfrak{m}t$, then $tN_\tau = tN = 0$, so $t = 0$, $\mathbb{T}_\tau$ acting faithfully on N_τ). By (Zp5) of Lemma E.17 ($Q = \varnothing$, $\chi = \chi_0$; it applies by Steps 1 and 2), $M = N/\sum_\delta(\langle\delta\rangle - \chi_0(\delta))N$ is free of finite rank over Λ_1, and its annihilator in $\mathbb{T}$ is $\mathfrak{a}_0$. Put $T = \mathbb{T}/\mathfrak{a}_0$ and let λ_T be the diamond map followed by the projection. By Step 4, $\mathfrak{a}_0 \neq \mathbb{T}$, so $T \in \mathrm{CNL}_\mathcal{O}$. So M is a faithful T-module, free of finite rank over Λ_1 through λ_T: (Zm1).

Step 4: the surjection f and (Zm2). By Step 1 and Step 2, Lemma E.17 applies to $((V_v), \tau)$ and $\mathfrak{m}$. Let x be a classical ordinary point and y_x the point of $\mathbb{T}$ of Step 2. For $v \in S_\ell$, $1 \leq j \leq n$ and an ℓ-power root of unity $\zeta \in L_{\tilde{v}}$, Lemma E.4 gives $y_x(\langle d_j(\zeta)\rangle) = (\chi^{j-1}\kappa)(g_\zeta)\, x(\psi_{v,j}^{\mathrm{d}}(g_\zeta)) = \kappa(\mathrm{Art}(\zeta)) = \chi_0(d_j(\zeta))$: the values of these continuous characters of D_v at $\mathrm{Art}(\zeta)$ are their values at g_ζ; $g_\zeta \in \mu_v$ and $\chi(g_\zeta) = 1$ by (Wv1) of Lemma 50.24; and $x(\psi_{v,j}^{\mathrm{d}}(g_\zeta)) = \xi_{v,j}(g_\zeta) = 1$ by (Od3), the wild values being trivial. As Δ_ℓ is generated by the $d_j(\zeta)$, the first assertion of (Zp4) gives $y_x(\mathfrak{a}_0) = 0$; so $\mathfrak{a}_0 \neq \mathbb{T}$, and by the second assertion $\mathcal{C}_{\chi_0}$ is non-empty with $\bigcap_{y \in \mathcal{C}_{\chi_0}} \ker y = \mathfrak{a}_0$. Every $y \in \mathcal{C}_{\chi_0} \subseteq \mathcal{C}$ ($\mathcal{C}$ the regular points of trivial nebentypus) satisfies (i) and (ii) of (Gd2) ((Zp1), (Zp2)), and (iii): $y(\langle d_j(\zeta)\rangle) = \chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))\,\xi_{v,j}(g_\zeta)$. By (Gd2) of Lemma E.16 with $\mathfrak{a} = \mathfrak{a}_0$, $\mathcal{C} = \mathcal{C}_{\chi_0}$, $A = T$, there is a surjective homomorphism of $\mathcal{O}$-algebras $f = \theta\colon B \to T$ with the identities stated there. Put $J = \ker f$. For $v \in S_\ell$, $1 \leq j \leq n$ and $z \in 1 + \ell\mathcal{O}_{L_v^+}$, with $g_z = \mathrm{Art}(z) \in I_v$, these identities give $\lambda_T([d_j(z)]) = \langle d_j(z)\rangle = (\chi^{j-1}\kappa)(g_z) f(\psi_{v,j}^{\mathrm{d}}(g_z))$: (Zm2).

Step 5: (Zm3). Let $y\colon T \to \overline{\mathbb{Q}}_\ell$ be a homomorphism of $\mathcal{O}$-algebras with $y(\lambda_T([u])) = (w_0\lambda)(u)^{-1}$ on $T_n(\ell^1)$ for a dominant λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$, and with ρ_y absolutely irreducible. By (Gd0) y is continuous, i.e. a point (identified with the point $\mathbb{T} \to T \to \overline{\mathbb{Q}}_\ell$ of $\mathbb{T}$, which kills $\mathfrak{a}_0$), and $y(\mathfrak{P}_{\lambda,1}) = 0$ (renormalised structure), so y is regular. Put $\rho' = \rho_y \circ \pi_{\mathscr{H}} \otimes \kappa$, absolutely irreducible as $\pi_{\mathscr{H}}(G_L) = \Gamma^0_{\mathscr{H}}$. For every w, the inertia groups above w lie in $N_{\mathscr{H}}$ (Rd4) and κ is unramified above w (Rd7), so ρ' is unramified above w; applying y to the first identity of (Gd2), the characteristic polynomial of $\rho'(\mathrm{Frob}_w) = \kappa(\mathrm{Frob}_w)\rho_y(\pi_{\mathscr{H}}(\mathrm{Frob}_w))$ is $P_{y,w}$. By (Hx2) of Proposition E.5 (for points of $\mathbb{T}_\tau$ through Lemma E.15), ρ' is automorphic of conjugate self-dual type for ι. Let r_y be as in (Hx1); it is semisimple with characteristic polynomials $P_{y,w}$, so $r_y \cong \rho'$ (Chebotarev, Brauer–Nesbitt), and r_y is absolutely irreducible; by (Hx1)(iii), $r_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\psi_{v,j}^y)_j$ for $v \in S_\ell$. Applying y to the second and third identities of

(Gd2), the continuous characters $y\circ f\circ\psi^{\mathrm{d}}_{v,j}$ and $\chi^{1-j}\kappa^{-1}\psi^{y}_{v,j}$ agree on $\mathrm{Art}(\mathcal{O}^\times_{L_{\tilde v}})$ and at $\mathrm{Art}(\varpi_{\tilde v})$, hence on D_v (dense image of Art). So $\rho_y\circ\pi_{\mathscr{H}}\cong r_y\otimes\kappa^{-1}$ is triangular on D_v with diagonal $(y\circ f\circ\psi^{\mathrm{d}}_{v,a})_a$.

Step 6: (Zm4). Let x be a classical ordinary point and y_x the point of $\mathbb{T}$ of Step 2; it kills $\mathfrak{a}_0$ (Step 4), so it is a point of T. The tuples $(x\circ D^{\mathrm{u}},(x\circ\psi^{\mathrm{d}}_{v,a}))$ and $(y_x\circ f\circ D^{\mathrm{u}},(y_x\circ f\circ\psi^{\mathrm{d}}_{v,a}))$ coincide: by the first identity of (Gd2) and Lemma E.4, $y_x(f(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w))))=\kappa(\mathrm{Frob}_w)^{-j}(\mathrm{N}w)^{j(j-1)/2}y_x(T^{(j)}_w)$ is the j-th elementary symmetric function of the eigenvalues of $\tilde r_x(\pi_{\mathscr{H}}(\mathrm{Frob}_w))$, i.e. $x(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w)))$ (Cy1); both determinants are continuous, the $\pi_{\mathscr{H}}(\mathrm{Frob}_w)$ are dense in $\Gamma^0_{\mathscr{H}}$ (Chebotarev), so their characteristic polynomials agree everywhere and the determinants are equal by (Ch1); and by the other identities of (Gd2) and Lemma E.4, $y_x\circ f\circ\psi^{\mathrm{d}}_{v,j}$ and $x\circ\psi^{\mathrm{d}}_{v,j}=(\chi^{j-1}\kappa)^{-1}\phi_{v,j}$ agree on $\mathrm{Art}(\mathcal{O}^\times_{L_{\tilde v}})$ and at $\mathrm{Art}(\varpi_{\tilde v})$, hence everywhere. By (Gd0), $x(B)$ and $y_x(T)$ are $\mathcal{O}$-orders in finite extensions of $\mathbb{Q}_\ell$, with residue field $\mathbb{F}$; the $\mathcal{O}$-algebra $R\subseteq\overline{\mathbb{Q}}_\ell$ they generate is finite over $\mathcal{O}$, a domain, hence local and complete, with residue field generated by elements of $\mathbb{F}$, so $R\in\mathrm{CNL}_{\mathcal{O}}$. Both x and $y_x\circ f$ are morphisms $B\to R$ classifying the same polarised ordinary determinant, so $x=y_x\circ f$ by the uniqueness in the universal property, and $x(J)=0$.

Hence $J=\ker f$, with T, λ_T, M, f, is a Hecke ideal of zero-monodromy type for ι and κ. It has the form described in the statement: the type datum satisfies (Zt) (Step 1), $\mathfrak{m}$ satisfies (Mx) (Step 2), T, λ_T and M are as stated (Step 3), and $f=\theta$ for $\mathfrak{a}=\mathfrak{a}_0$ and $\mathcal{C}=\mathcal{C}_{\chi_0}$ (Step 4).

Finally, suppose $\bar\omega|_{D_v}\neq1$ for every $v\in S_\ell$. As $\bar\omega$ is the character by which G_{L^+} acts on the ℓ-th roots of unity, L^+_v contains no primitive ℓ-th root of unity, so $\mu_{\ell^\infty}(L^+_v)=1$ and $\Delta_\ell=\{1\}$; then $M=N$, and $\mathfrak{a}_0$ is the intersection of all minimal primes of the reduced ring $\mathbb{T}$, which is 0. □

Lemma E.3. *Let $\mathcal{O}$ be a coefficient ring, $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism, $n\geq1$, and $F_1,\dots,F_s$ finite extensions of $\mathbb{Q}_{p_1},\dots,\mathbb{Q}_{p_s}$ (primes p_k). For $1\leq k\leq s$ and $1\leq a\leq n$ let $\chi_{k,a}\colon I_{F_k}\to\mathcal{O}^\times$ be a character of finite order which is the restriction of a continuous character of W_{F_k}. Put $K_k=\mathrm{GL}_n(\mathcal{O}_{F_k})$ and $K=\prod_k K_k$. For an irreducible smooth representation π_k of $\mathrm{GL}_n(F_k)$ over $\mathbb{C}$ say that π_k **has zero monodromy and inertia** $(\chi_{k,a})_a$ if $\mathrm{rec}(\pi_k)|_{I_{F_k}}\cong\bigoplus_a\iota\circ\chi_{k,a}$ and $N=0$ on $\mathrm{rec}(\pi_k)$. Then there are open normal subgroups $V_k\subseteq K_k$ and a finite free $\mathcal{O}$-module τ_0 with an $\mathcal{O}$-linear action of $H=\prod_k K_k/V_k$ such that for all irreducible smooth representations π_k of $\mathrm{GL}_n(F_k)$ over $\mathbb{C}$ $(1\leq k\leq s)$:*

$$\mathrm{Hom}_K\Big(\tau_0\otimes_{\mathcal{O},\iota}\mathbb{C},\ \bigotimes_k\pi_k\Big)\neq0\iff\text{every }\pi_k\text{ has zero monodromy and inertia }(\chi_{k,a})_a.$$

Proof. Write $\mathrm{Z}_k(\pi_k)$ for the condition "π_k has zero monodromy and inertia $(\chi_{k,a})_a$".

Step 1: one factor over $\mathbb{C}$. Each $\iota\circ\chi_{k,a}$ has finite image, so its kernel is open in I_{F_k}, and it extends to W_{F_k}; hence $\bigoplus_a\iota\circ\chi_{k,a}$ is an inertial type. By Theorem B.166 there is an irreducible smooth finite-dimensional representation ξ_k of K_k over $\mathbb{C}$ such that for every irreducible smooth π_k: $\mathrm{Hom}_{K_k}(\xi_k,\pi_k)\neq0$ if and only if $\mathrm{Z}_k(\pi_k)$. As K_k is compact and ξ_k smooth and finite-dimensional, $V_k=\ker\xi_k$ is an open normal subgroup; put $Q_k=K_k/V_k$, a finite group. For $\sigma\in\mathrm{Aut}(\mathbb{C})$, ξ_k^σ is irreducible with the same kernel V_k (its matrix entries are the σ-images of those of ξ_k in a basis).

Step 2: conjugation by $\mathrm{Aut}(\mathbb{C}/\iota(E))$ preserves the condition. Let $\sigma\in\mathrm{Aut}(\mathbb{C})$ fix $\iota(E)$ pointwise and let π_k be irreducible smooth. Twisting by $|\det|^s$ $(s\in\frac12\mathbb{Z})$ or by any unramified character changes rec by an unramified character, which is trivial on I_{F_k} and does not change N; and $(\pi_k\otimes|\det|^{(1-n)/2})^\sigma=\pi_k^\sigma\otimes\chi$ with $\chi=\sigma\circ|\det|^{(1-n)/2}$ unramified. Hence, by Theorem B.93,

$\mathrm{rec}(\pi_k^\sigma)|_{I_{F_k}} \cong \sigma(\mathrm{rec}(\pi_k))|_{I_{F_k}}$ and the monodromy of $\mathrm{rec}(\pi_k^\sigma)$ is 0 if and only if that of $\mathrm{rec}(\pi_k)$ is. Since the values of $\iota\circ\chi_{k,a}$ lie in $\iota(E)$, $\sigma(\bigoplus_a \iota\circ\chi_{k,a}) \cong \bigoplus_a \iota\circ\chi_{k,a}$. So $\mathrm{Z}_k(\pi_k)$ implies $\mathrm{Z}_k(\pi_k^\sigma)$, and applying this to σ^{-1} and π_k^σ gives the converse. Moreover $\mathrm{Hom}_{K_k}(\xi_k^\sigma, \pi_k) \neq 0$ if and only if $\mathrm{Hom}_{K_k}(\xi_k, \pi_k^{\sigma^{-1}}) \neq 0$ (apply $-\otimes_{\mathbb{C},\sigma^{-1}}\mathbb{C}$ to a K_k-map), so by Step 1 and the above, $\mathrm{Hom}_{K_k}(\xi_k^\sigma, \pi_k) \neq 0$ if and only if $\mathrm{Z}_k(\pi_k)$.

Step 3: an E-rational model. Let ψ_k be the character of ξ_k and $e_k = \frac{\dim\xi_k}{|Q_k|}\sum_{g\in Q_k}\psi_k(g^{-1})g \in \mathbb{C}[Q_k]$ its central primitive idempotent. The values of ψ_k lie in $\mathbb{Q}(\zeta_{h_k})$, $h_k = |Q_k|$; let $E' = \iota(E)(\zeta_{h_k}) \subseteq \mathbb{C}$, a finite Galois extension of $\iota(E)$ with group Γ. Every $\gamma\in\Gamma$ extends to some $\sigma \in \mathrm{Aut}(\mathbb{C}/\iota(E))$ ($\mathbb{C}$ is algebraically closed), and $\gamma(e_k)$ is the central primitive idempotent of ξ_k^σ, whose character is $\sigma\circ\psi_k$. Let f_k be the sum of the distinct elements of $\{\gamma(e_k) : \gamma\in\Gamma\}$. Distinct central primitive idempotents are orthogonal, so f_k is a central idempotent; it is Γ-invariant, so its coefficients lie in the fixed field $\iota(E)$ of Γ. Let $f_k' \in E[Q_k]$ be its preimage under ι. By Wedderburn theory, $\mathbb{C}[Q_k]f_k \cong \bigoplus_{\xi'} \xi'^{\oplus\dim\xi_k}$ as left $\mathbb{C}[Q_k]$-modules, ξ' running over the distinct representations ξ_k^σ, σ as above (finitely many: one for each element of the orbit); and $(E[Q_k]f_k')\otimes_{E,\iota}\mathbb{C} = \mathbb{C}[Q_k]f_k$.

Step 4: a lattice. Let $\tau_k = \mathcal{O}[Q_k]f_k' \subseteq E[Q_k]f_k'$. It is an $\mathcal{O}$-submodule stable under left multiplication by Q_k, finitely generated (the image of $\mathcal{O}[Q_k]$ under $x\mapsto xf_k'$) and torsion-free, hence free of finite rank over the discrete valuation ring $\mathcal{O}$; it spans $E[Q_k]f_k'$ over E (as $\ell^m f_k' \in \mathcal{O}[Q_k]$ for large m and $E[Q_k]f_k' = E\cdot\mathcal{O}[Q_k]f_k'$). So $\tau_k\otimes_{\mathcal{O},\iota}\mathbb{C} \cong \bigoplus_{\xi'}\xi'^{\oplus\dim\xi_k}$ as K_k-representations, ξ' as in Step 3.

Step 5: the product. Let $\tau_0 = \bigotimes_k \tau_k$ (tensor product over $\mathcal{O}$), finite free over $\mathcal{O}$, with $H = \prod_k Q_k$ acting factorwise. Then $\tau_0\otimes_{\mathcal{O},\iota}\mathbb{C}$ is a direct sum of copies of the representations $\bigotimes_k \xi_k'$ of K, ξ_k' running over the conjugates of Step 3, each tuple occurring. For smooth representations A_k of the compact groups K_k over $\mathbb{C}$, $(\bigotimes_k A_k)^K = \bigotimes_k A_k^{K_k}$: the averaging projector of K_k onto $A_k^{K_k}$ (averaging over a finite quotient through which K_k acts on a given vector) acts on the tensor product as the identity on the other factors, and $(A\otimes B)^{K_1\times K_2} = ((A\otimes B)^{K_1})^{K_2} = (A^{K_1}\otimes B)^{K_2} = A^{K_1}\otimes B^{K_2}$. With $A_k = \mathrm{Hom}_{\mathbb{C}}(\xi_k', \pi_k) = \xi_k'^\vee\otimes\pi_k$ (ξ_k' finite-dimensional) this gives $\mathrm{Hom}_K(\bigotimes_k\xi_k', \bigotimes_k\pi_k) \cong \bigotimes_k \mathrm{Hom}_{K_k}(\xi_k', \pi_k)$, which is non-zero if and only if every factor is non-zero. By Step 2 the factor for $\xi_k' = \xi_k^\sigma$ is non-zero if and only if $\mathrm{Z}_k(\pi_k)$, independently of σ. Hence $\mathrm{Hom}_K(\tau_0\otimes_{\mathcal{O},\iota}\mathbb{C}, \bigotimes_k\pi_k) \neq 0$ if and only if $\mathrm{Z}_k(\pi_k)$ for every k; and τ_0 is a representation of $H = \prod_k K_k/V_k$ by construction. □

E.1.2 The ordinary Hecke algebra at principal congruence level

This subsection proves Proposition E.5: at principal congruence level at St the points of the ordinary Hecke algebra carry Galois representations, the irreducible points are automorphic, and the ordinary lines at the places above ℓ are read off from the eigenvalues of the U- and diamond operators (Lemma E.6). The inputs are Hida's control theorem in Geraghty's form, local–global compatibility, including Thorne's for ordinary representations [256], and base change from the definite unitary group with its cuspidality and descent statements (Proposition E.7, Proposition E.9, Lemma E.8). Classical ordinary points of the determinant ring give points of the Hecke algebra of zero-monodromy type (Lemma E.4), and Geraghty's torus algebra is finite free over the rational weight algebra (Lemma E.10).

Lemma E.4. *Let $\mathscr{H}$ over $\mathcal{O}'$, κ, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ and c be as in Lemma E.16, $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism, V_v ($v\in\mathrm{St}$) the kernel of reduction modulo ϖ_v^c, $H = \prod_{v\in\mathrm{St}}\mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v$, identified through $\iota_{\tilde v}$ with a quotient of $K = \prod_{v\in\mathrm{St}}\mathrm{GL}_n(\mathcal{O}_{L_{\tilde v}})$, and τ_0 a finite free $\mathcal{O}'$-module with an $\mathcal{O}'$-linear action of H such that*

(Zc) $\mathrm{Hom}_K(\tau_0 \otimes_{\mathcal{O}',\iota} \mathbb{C}, \bigotimes_{v\in \mathrm{St}} \sigma_v) \neq 0$ *for all irreducible smooth representations* σ_v *of* $\mathrm{GL}_n(L_{\tilde{v}})$ *over* $\mathbb{C}$ *such that every* σ_v *has zero monodromy and inertia* $((\bar{\chi}_a]\kappa)|_{I_{L_{\tilde{v}}}})_{1\le a\le n}$.

Let $\tau = \tau_0^\vee = \mathrm{Hom}_{\mathcal{O}'}(\tau_0, \mathcal{O}')$ *with the contragredient action. Then for every classical ordinary point* x *of* B_n^{po} *for* ι *and* κ*, with* $\tilde{r}$ *as in (Cy1), there is a point* y *of* $\mathbb{T}_\tau$ *such that:* $y(\mathfrak{P}_{\lambda,\alpha}) = 0$ *for a dominant weight* λ *and a character* α *of finite order; for every* w*,* $P_{y,w}$ *is the characteristic polynomial of* $(\tilde{r}\circ\pi_{\mathscr{H}}\otimes\kappa)(\mathrm{Frob}_w)$*; and for every* $v\in S_\ell$*,* $1\le j\le n$ *and* $z\in\mathcal{O}_{L_{\tilde{v}}}^\times$*,* $y(\langle d_j(z)\rangle) = \phi_{v,j}(\mathrm{Art}(z))$ *and* $y(U_{\tilde{v}}^{(j)}) = y(U_{\tilde{v}}^{(j-1)})\,\phi_{v,j}(\mathrm{Art}(\varpi_{\tilde{v}}))$*, with* $\phi_{v,j} = \chi_{\mathrm{cyc}}^{j-1}\kappa\,(x\circ\psi_{v,j}^{\mathrm{d}})$ *and* $U_{\tilde{v}}^{(0)} = 1$.

Proof. Step 1: the point of $\mathbb{T}^{\mathrm{ord}}(V)$ *and its weight.* By (Hx3) of Proposition E.5 there is a point y_0 of $\mathbb{T}^{\mathrm{ord}}(V)$ with the stated values of $P_{y_0,w}$, $y_0(\langle d_j(z)\rangle)$ and $y_0(U_{\tilde{v}}^{(j)})$. Fix $v\in S_\ell$ and j. By (Cy4), $x\circ\psi_{v,j}^{\mathrm{d}}$ is de Rham with τ'-Hodge–Tate weights $h_{\tau',j}$ (integers, strictly decreasing in j); a de Rham character of D_v is Hodge–Tate, hence locally algebraic ([220]): $x\circ\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(z)) = \prod_{\tau'}\tau'(z)^{h_{\tau',j}}$ for z in an open subgroup of $\mathcal{O}_{L_{\tilde{v}}}^\times$ (with Art sending uniformisers to geometric Frobenius, a character equal to $\mathrm{Art}(z)\mapsto\prod\tau'(z)^{a_{\tau'}}$ near 1 has τ'-weight $a_{\tau'}$; $\chi(\mathrm{Art}(z)) = \prod_{\tau'}\tau'(z)$ on units); likewise $\kappa(\mathrm{Art}(z)) = \prod_{\tau'}\tau'(z)^{m_{\tau'}}$ near 1 (κ is algebraic). Put $\lambda_{\tau',n+1-j} = -(j-1) - m_{\tau'} - h_{\tau',j}$. Then $u\mapsto y_0(\langle u\rangle)(w_0\lambda)(u)$ is a continuous character of $T_n(\ell^1)$ trivial on an open subgroup , i.e. a character α of finite order, and $y_0(\mathfrak{P}_{\lambda,\alpha}) = 0$ for the renormalised structure, $u\mapsto(w_0\nu)^{-1}(u)\langle u\rangle$. λ is dominant: $\lambda_{\tau',n-j} - \lambda_{\tau',n+1-j} = h_{\tau',j} - h_{\tau',j+1} - 1 \ge 0$. Choose $b\ge 1$ with $T_n(\ell^b)\subseteq\ker\alpha$; by construction $y_0(\langle u\rangle) = \alpha(u)(w_0\lambda)(u)^{-1}$ for $u\in T_n(\ell^1)$.

Step 2: an automorphic representation with the type. By Lemma E.11 for the type datum $((V_v),\mathcal{O}'[H])$ and y_0, there are an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$, unramified with $T_w^{(j)}$-eigenvalues $y_0(T_w^{(j)})$ at every split $v\notin T_L$, and a non-zero $f\in\pi\cap S_\lambda^{\mathrm{ord}}(V(\ell^{Eb,Eb}),\alpha,\overline{\mathbb{Q}}_\ell)$, E the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ, which is a joint eigenvector, with eigencharacter y_0, of the operators assigned by (Gy7)(c). By (Gy5)(i), r_π is semisimple with characteristic polynomial $P_{y_0,w}$ at Frob_w for all w, as is $r\otimes\kappa$, which is absolutely irreducible (Cy1); by the Chebotarev density theorem and the Brauer–Nesbitt theorem, $r_\pi\cong r\otimes\kappa$. Let $v\in\mathrm{St}$, $I = I_{\bar{w}}\cap G_L$ for a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above $\tilde{v}$, the inertia group of $L_{\tilde{v}}$, and $I' = \{s\in I : \bar{\chi}_a(s) = 1\ (1\le a\le n)\}\subseteq N_{\mathscr{H}}$. Then $r(I') = 1$, so $r|_I$ factors through the finite group I/I', which embeds into $(\mathbb{F}^\times)^n$ through the $\bar{\chi}_a$ and so has order prime to ℓ; hence $r|_I\cong\bigoplus_a\psi_a$ with characters ψ_a of order prime to ℓ. The reduction of r has semisimplification with the characteristic polynomials of $\bigoplus_a\bar{\chi}_a$ ($x\circ D^{\mathrm{u}}$ reduces to $\bar{D}_n$), so the reductions of the ψ_a are the $\bar{\chi}_a|_I$ up to order, and a character of order prime to ℓ is the Teichmüller lift of its reduction: $r|_I\cong\bigoplus_a[\bar{\chi}_a]|_I$. As $\kappa|_I$ has finite order (Rd7), $(r\otimes\kappa)|_I\cong\bigoplus_a([\bar{\chi}_a]\kappa)|_I$ has finite image, so by (Wd1) $\mathrm{WD}(r_\pi|_{G_{L_{\tilde{v}}}})$ has monodromy 0 ($\exp(t_\ell(\sigma)N) = 1$ on an open subgroup forces $N = 0$) and inertia $r_\pi|_I$; Frobenius-semisimplification changes neither. By (Ug2) (applicable by (Gd0)), $\mathrm{rec}(\iota\pi_v\circ\iota_{\tilde{v}}^{-1}\otimes|\det|^{(1-n)/2})$, and hence its unramified twist $\mathrm{rec}(\iota\pi_v\circ\iota_{\tilde{v}}^{-1})$, has zero monodromy and inertia $(([\bar{\chi}_a]\kappa)|_I)_a$. By (Zc), $\mathrm{Hom}_K(\tau_0\otimes_{\mathcal{O}',\iota}\mathbb{C},\bigotimes_{v\in\mathrm{St}}\iota\pi_v\circ\iota_{\tilde{v}}^{-1})\neq 0$; as τ_0 is trivial on $\prod_v V_v$, the image of such a map lies in the $\prod_v V_v$-invariants, and transporting by ι^{-1}, $\mathrm{Hom}_H(\tau_0\otimes\overline{\mathbb{Q}}_\ell,\bigotimes_{v\in\mathrm{St}}\pi_v^{V_v})\neq 0$.

Step 3: y_0 factors through $\mathbb{T}_\tau$. By Lemma E.14 (with τ, λ, α, y_0, π and f of Step 2 and Eb in place of its r, which is allowed as $T_n(\ell^{Eb})\subseteq T_n(\ell^b)\subseteq\ker\alpha$; $\tau^\vee = \tau_0$), $y_0 = y\circ q$ for a point y of $\mathbb{T}_\tau$. As q sends each operator to the operator of the same name and respects the Λ_1-structures, y has the values of y_0 on $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u\rangle$, and $y(\mathfrak{P}_{\lambda,\alpha}) = 0$. □

Proposition E.5. *Let* $\mathscr{H} = (n, L, c, (\bar{v}), \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a))$ *over* $\mathcal{O}'$*,* κ *and* $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ *be as in the hypotheses of Proposition E.26. For* $v\mid\ell$*,* $1\le j\le n$ *and* $z\in\mathcal{O}_{L_{\tilde{v}}}^\times$ *let* $d_j(z)\in T_n(\mathcal{O}_{L_v^+})$ *correspond under* $\iota_{\tilde{v}}$ *to the diagonal matrix with* z *in position* j *and* 1 *elsewhere, and identify* D_v *with the decomposition group of* $G_{L_{\tilde{v}}}$ *through* $\bar{v}$*. Give* $\mathbb{T}_\tau$ *the renormalised* Λ_1*-structure*

$u \mapsto (w_0\nu)^{-1}(u)\langle u\rangle$ *and, for a dominant weight* λ *and a character* α *of* $T_n(\ell^1)$ *of finite order, let* $\mathfrak{P}_{\lambda,\alpha} \subsetneq \Lambda_1$ *be as in (Gy3). A* point *of* $\mathbb{T}_\tau$ *is a continuous homomorphism of* $\mathcal{O}'$*-algebras* $y\colon \mathbb{T}_\tau \to \overline{\mathbb{Q}}_\ell$*; its* Hecke polynomial *at a place* w *of* L *above a place* $v \notin T_L$ *of* L^+ *split in* L *is* $P_{y,w}(X) = \sum_{j=0}^n (-1)^j (\mathrm{N}w)^{j(j-1)/2} y(T_w^{(j)}) X^{n-j}$ *(*$T_w^{(0)} = 1$*). Fix an integer* $c \geq 1$ *such that* $\bar\chi_1(\mathrm{Art}_{L_w}(z)) = \cdots = \bar\chi_n(\mathrm{Art}_{L_w}(z)) = \kappa(\mathrm{Art}_{L_w}(z)) = 1$ *for every place* w *of* L *above a place of* St *and every* $z \in 1 + \varpi_w^c \mathcal{O}_{L_w}$ *(it exists: the* $\bar\chi_a$ *have finite order and* κ *has finite order on these inertia groups by (Rd7)). Let* $((V_v)_{v\in \mathrm{St}}, \tau)$ *be the type datum with* V_v *the kernel of reduction* $\mathbb{G}_L(\mathcal{O}_{L_v^+}) \to \mathbb{G}_L(\mathcal{O}_{L_v^+}/\varpi_v^c)$ *and* $\tau = \mathcal{O}'[H]$ *with* H *acting by left multiplication, and* V *its level. Then:*

(Hx1) *for every point* y *of* $\mathbb{T}_\tau$ *with* $y(\mathfrak{P}_{\lambda,1}) = 0$ *for a regular dominant weight* λ *(as in (Gy6)) there is a continuous semisimple* $r_y\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ *such that (i) for every* w *as above, the semisimplification of the restriction of* r_y *to a decomposition group above* w *is unramified and* $r_y(\mathrm{Frob}_w)$ *has characteristic polynomial* $P_{y,w}$*; (ii)* $r_y^c \cong r_y^\vee \chi_{\mathrm{cyc}}^{1-n}$*; (iii) if* r_y *is absolutely irreducible, then for every* $v \mid \ell$*,* $r_y|_{D_v}$ *is triangular with diagonal* $(\chi_{\mathrm{cyc}}^{1-j}\psi_{v,j}^y)_{1\leq j\leq n}$*, where* $\psi_{v,j}^y$ *is the character of* D_v *with* $\psi_{v,j}^y(\mathrm{Art}_{L_{\tilde v}}(z)) = y(\langle d_j(z)\rangle)$ *for* $z \in \mathcal{O}_{L_{\tilde v}}^\times$ *and* $\psi_{v,j}^y(\mathrm{Art}_{L_{\tilde v}}(\varpi_{\tilde v})) = y(U_{\tilde v}^{(j)})/y(U_{\tilde v}^{(j-1)})$ *(*$U_{\tilde v}^{(0)} = 1$*);*

(Hx2) *for every point* y *of* $\mathbb{T}_\tau$ *with* $y(\mathfrak{P}_{\lambda,\alpha}) = 0$ *for a dominant weight* λ *and a character* α *of finite order, every absolutely irreducible continuous* $\rho\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ *such that, for every* w *as above, the restriction of* ρ *to a decomposition group above* w *has unramified semisimplification and* $\rho(\mathrm{Frob}_w)$ *has characteristic polynomial* $P_{y,w}$*, is automorphic of conjugate self-dual type for* ι*;*

(Hx3) *for every classical ordinary point* x *of* B_n^{po} *for* ι *and* κ*, with* $\tilde r$ *as in (Cy1), there is a point* y *of* $\mathbb{T}_\tau$ *such that: for every* w *as above,* $P_{y,w}$ *is the characteristic polynomial of* $(\tilde r \circ \pi_{\mathscr{H}} \otimes \kappa)(\mathrm{Frob}_w)$*; and for every* $v \mid \ell$*,* $1 \leq j \leq n$ *and* $z \in \mathcal{O}_{L_{\tilde v}}^\times$*,*

$$y(\langle d_j(z)\rangle) = \phi_{v,j}(\mathrm{Art}_{L_{\tilde v}}(z)), \qquad y(U_{\tilde v}^{(j)}) = y(U_{\tilde v}^{(j-1)})\, \phi_{v,j}(\mathrm{Art}_{L_{\tilde v}}(\varpi_{\tilde v})),$$
$$\phi_{v,j} = \chi_{\mathrm{cyc}}^{j-1}\, \kappa\, (x \circ \psi_{v,j}^{\mathrm{d}}),$$

with $U_{\tilde v}^{(0)} = 1$*.*

Proof. Step 0: the setting. V_v is open and normal in $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ and τ is finite free, so $((V_v), \tau)$ is a type datum. Evaluation at 1 is an isomorphism $N_\tau = \mathrm{Hom}_{\mathcal{O}'[H]}(\mathcal{O}'[H], \mathcal{S}_V) \to \mathcal{S}_V$ compatible with $\mathbb{T}^{\mathrm{ord}}(V)$, so $\mathbb{T} = \mathbb{T}^{\mathrm{ord}}(V)$. The hypotheses of Theorem B.91 hold for $F = L$, $\mathbb{G} = \mathbb{G}_L$, $T = T_L$, $U = V$, $b_0 = 1$: L is imaginary CM with the places above ℓ split (Rd2); $\mathcal{O}' \supseteq \tau'(\mathcal{O}_L)$ for all embeddings τ'; $\mathbb{G}_L$ comes from $X \mapsto {}^tX^c$ and the order $\mathrm{M}_n(\mathcal{O}_L)$, is compact at the real places, and is quasi-split at every finite place (split places: GL_n; the other places are unramified by (Rd2), where the Hermitian form $\sum x_i\bar x_i$ of discriminant 1 is quasi-split, for n even because $(-1)^{n/2}$ is a unit, hence a norm), and $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ is hyperspecial at the inert places (unimodular form over the unramified extension); the places of T_L split (Rd2); $V_v = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ at $v \in S_\ell$ and at the split $v \notin T_L$; $V(\ell^{1,1})$ is sufficiently small, its component at v_0 being $1 + p\,\mathrm{M}_n(\mathcal{O}_{L_{\tilde v_0}})$, p odd and unramified in L, which has no non-trivial element of finite order . For (Gy4) and Proposition E.7: L/L^+ is unramified at all finite places (Rd2), and hence $[L^+ : \mathbb{Q}] \geq 2$: if $L^+ = \mathbb{Q}$, then L is an imaginary quadratic field, whose discriminant has absolute value at least 3, so some prime ramifies in $L/\mathbb{Q} = L/L^+$. The operators $U_{\tilde v}^{(j)}$ are units of $\mathbb{T}$: $\mathbb{T}$ is finite over Λ_1 (Qh2), so semilocal, and an element of a maximal ideal $\mathfrak{n}$ acts nilpotently on $\mathcal{S}_V/\mathfrak{n}\mathcal{S}_V \neq 0$

(Nakayama, faithfulness), while $U_{\tilde v}^{(j)}$ is invertible on the ordinary module. A point y has values in the ring of integers of a finite extension of $\mathbb{Q}_\ell$ ($\mathbb{T}/\ker y$ is finite over $\mathcal{O}'$), so $y(U_{\tilde v}^{(j)})$ is an ℓ-adic unit.

Step 1: a point gives an ordinary eigenform. Let y be a point with $y(\mathfrak{P}_{\lambda,\alpha}) = 0$, λ dominant, and $r \geq 1$ with $T_n(\mathfrak{l}^r) \subseteq \ker\alpha$ (such r exist by (Qh1)). As y kills $\mathfrak{P}_{\lambda,\alpha}\mathbb{T}$ and $\overline{\mathbb{Q}}_\ell$ is reduced, (Qh3) factors y as $y_\lambda \circ s$, with s the surjection of (Qh3) and y_λ a homomorphism from the finite commutative $\mathcal{K}'$-algebra $\mathbb{T}_\lambda = \mathbb{T}_\lambda^{\mathrm{ord}}(V(\ell^{r,r}), \alpha, \mathcal{K}')$, which acts faithfully on the finite-dimensional space $S = S_\lambda^{\mathrm{ord}}(V(\ell^{r,r}), \alpha, \mathcal{K}')$. The localisation of $S \otimes_{\mathcal{K}'} \overline{\mathbb{Q}}_\ell$ at $\ker(y_\lambda \otimes 1)$ is non-zero (faithfulness), so it contains a common eigenvector $f \neq 0$ of the commuting operators of $\mathbb{T}_\lambda$ with eigencharacter y_λ; f is a form of weight λ and level $V(\ell^{r,r})$ with coefficients in $\overline{\mathbb{Q}}_\ell$, i.e. $f \in S_\lambda(\overline{\mathbb{Q}}_\ell)^{V(\ell^{r,r})}$. Let W be the $\mathbb{G}_L(\mathbb{A}_{L^+}^\infty)$-subrepresentation generated by f and π an irreducible quotient of W (W is finitely generated); π is an irreducible constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$, the image $\bar f$ of f in $\pi^{V(\ell^{r,r})}$ is non-zero, and $\bar f$ is an eigenvector of the Hecke operators of level $V(\ell^{r,r})$ with the same eigenvalues as f (they are defined on the invariants of every smooth representation, compatibly with equivariant maps). By (Gy7)(c): $T_w^{(j)}\bar f = y(T_w^{(j)})\bar f$, $U_{\lambda,\varpi_{\tilde v}}^{(j)}\bar f = y(U_{\tilde v}^{(j)})\bar f$ and $\langle u\rangle \bar f = (w_0\lambda)(u)\, y(\langle u\rangle)\bar f$; in particular $\langle d_j(z)\rangle \bar f = \prod_{\tau'} \tau'(z)^{\lambda_{\tau',n+1-j}}\, y(\langle d_j(z)\rangle)\bar f$, τ' running over the embeddings inducing $\tilde v$. Write r_π for the representation of (Gy5).

Step 2: (Hx1)(i), (ii). Let y be as in (Hx1); apply Step 1 with $\alpha = 1$ and $r = r_0$, the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ ($T_n(\mathfrak{l}^{r_0}) \subseteq T_n(\ell^1)$ by (Qh1)), and put $r_y = r_\pi$, continuous and semisimple. For $w \mid v$ as above, $V_v = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ and $\pi = \otimes' \pi_{v'}$ (Flath) has $\pi^{V(\ell^{r_0,r_0})} \ni \bar f \neq 0$, so π_v is unramified, $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L_v^+})}$ is a line, and $T_w^{(j)}$ acts on it by $y(T_w^{(j)})$; (Gy5)(i) gives (i), and (Gy5)(ii) gives (ii) ($\varepsilon = \chi$).

Step 3: (Hx2). Let y, λ, α, ρ be as in (Hx2) and π as in Step 1; as in Step 2, r_π is semisimple and $r_\pi(\mathrm{Frob}_w)$ has characteristic polynomial $P_{y,w}$ for every w. The Frobenius elements at the places w (all but finitely many places of degree one over $\mathbb{Q}$ of L lie above split places of L^+) are dense in G_L (Chebotarev), so ρ and r_π have the same characteristic polynomials everywhere (continuity) and $\rho \cong r_\pi$ (Brauer–Nesbitt, both semisimple). So r_π is absolutely irreducible and (Bc1) gives a regular algebraic conjugate self-dual cuspidal Π of weight $\iota\lambda$ with $r_\iota(\Pi) \cong r_\pi \cong \rho$. At every place w' of L not above ℓ where Π is unramified, (To1) gives $\mathrm{WD}(\rho|_{G_{L_{w'}}})^{\text{F-ss}} \cong \mathrm{rec}^T(\iota^{-1}\Pi_{w'})$, unramified with $N = 0$; if $\Pi_{w'}$ is a subquotient of the unramified principal series of $\chi_1 \otimes \cdots \otimes \chi_n$, then ρ is unramified at w' and the eigenvalues of $\rho(\mathrm{Frob}_{w'})$ are $\chi_i(\varpi_{w'})(\mathrm{N}w')^{(n-1)/2}$; $\mathrm{Frob}_{w'}$ is the inverse of an arithmetic Frobenius, so $\rho \leftrightarrow_\iota \Pi$ in the sense fixed in Section 13.

Step 4: (Hx1)(iii). Let y, λ be as in (Hx1) with r_y absolutely irreducible, and π, $\bar f$ as in Step 2. By Step 3 (with $\rho = r_y$, $\alpha = 1$) and (Bc1), Π is cuspidal of weight $\iota\lambda$, $r_\iota(\Pi) \cong r_y$, and $\pi_v \cong \iota^{-1}\Pi_{\tilde v} \circ \iota_{\tilde v}$ for $v \mid \ell$ (v splits, (Rd2)). Fix $v \mid \ell$. Under $\pi^{V(\ell^{r_0,r_0})} = \pi_v^{\mathrm{Iw}(\tilde v^{r_0,r_0})} \otimes (\pi^v)^{V^v(\ell^{r_0,r_0})}$ the operators $U_{\lambda,\varpi_{\tilde v}}^{(j)}$ and $\langle d_j(z)\rangle$ act on the first factor; as $\bar f$ is a common eigenvector, the joint eigenspace $E \subseteq \pi_v^{\mathrm{Iw}(\tilde v^{r_0,r_0})}$ with the eigenvalues of Step 1 satisfies $\bar f \in E \otimes (\pi^v)^{V^v(\ell^{r_0,r_0})}$, so $E \neq 0$. A non-zero $x \in E \subseteq (\iota^{-1}\Pi_{\tilde v})^{\mathrm{Iw}(\varpi_{\tilde v}^{r_0,r_0})}$ ($b = r_0$ in (Ol1)) satisfies the hypotheses of (Ol1) with $u_j = y(U_{\tilde v}^{(j)})$ (units, Step 0) and $e_j(z) = \prod_{\tau'} \tau'(z)^{\lambda_{\tau',n+1-j}} y(\langle d_j(z)\rangle)$. By (Ol1), $r_y|_{D_v}$ is triangular with diagonal θ_j, $\theta_j(\mathrm{Art}(z)) = \chi(\mathrm{Art}(z))^{1-j} y(\langle d_j(z)\rangle)$ and $\theta_j(\mathrm{Art}(\varpi_{\tilde v})) = \chi(\mathrm{Art}(\varpi_{\tilde v}))^{1-j} y(U_{\tilde v}^{(j)})/y(U_{\tilde v}^{(j-1)})$; as $L_{\tilde v}^\times = \mathcal{O}^\times \times \varpi_{\tilde v}^{\mathbb{Z}}$ and Art has dense image, $\theta_j = \chi^{1-j}\psi_{v,j}^y$.

Step 5: (Hx3). Let x be classical, with $\tilde r$ and Π as in (Cy1), (Cy2), and $r = \tilde r \circ \pi_{\mathscr{H}}$. (a) $r \otimes \kappa$ is absolutely irreducible (Cy1) and $r \otimes \kappa \leftrightarrow_\iota \Pi$; by (To1) and the computation of Step 3, $r_\iota(\Pi)$ has the same Frobenius characteristic polynomials at almost all places, so $r_\iota(\Pi) \cong r \otimes \kappa$ (Chebotarev, Brauer–Nesbitt). Let λ be the weight of Π (Π of weight $\iota\lambda$). (b) Inertia away

from ℓ: for a place $w' \nmid \ell$ of L and $s \in I_{w'}$ with $\bar\chi_a(s) = 1$ for all a, $s \in N_{\mathscr{H}}$, so $r(s) = 1$; with (Rd7), $(r \otimes \kappa)|_{I_{w'}}$ factors through a finite abelian quotient, so $\mathrm{WD}((r \otimes \kappa)|_{G_{L_{w'}}})$ has $N = 0$ and its inertia representation is $(r \otimes \kappa)|_{I_{w'}}$, a sum of characters; if w' lies above a place of L^+ not in $S_\ell \cup \mathrm{St}$, the $\bar\chi_a$ are trivial on $I_{w'}$ (Rd4), so $I_{w'} \subseteq N_{\mathscr{H}}$, and with (Rd7) $r \otimes \kappa$ is unramified at w'; if w' lies above St, these characters are trivial on $\mathrm{Art}(1 + \varpi_{w'}^c \mathcal{O})$ by the choice of c. (c) Unramified places: for $w' \nmid \ell$ above a place of L^+ not in $S_\ell \cup \mathrm{St}$ (in particular above v_0, above the split $v \notin T_L$ and above the inert places, as the places of $S_\ell \cup \mathrm{St}$ split by (Rd2)), $\mathrm{rec}^T(\iota^{-1}\Pi_{w'})$ is unramified with $N = 0$ by (b) and (To1), so $\Pi_{w'}$ is unramified (the local Langlands correspondence matches unramified representations with unramified Weil–Deligne representations with $N = 0$). (d) The places of St: for w' above $v \in \mathrm{St}$, (Bg3) (for the polarizable Π, $r_{\ell,\iota}(\Pi) \cong r_\iota(\Pi)$, $U = 1 + \varpi_{w'}^c \mathcal{O}$) shows that $\sigma = \iota^{-1}\Pi_{w'}$ is a subquotient of a principal series of characters trivial on U; its Jacquet module σ_{N_n} is non-zero with semisimplification a sum of characters $\xi^s \delta_{B_n}^{1/2}$, all trivial on $T_n(\varpi_{w'}^c)$ (Bernstein–Zelevinsky; δ_{B_n} is trivial on units), so the compact group $T_n(\varpi_{w'}^c)$ acts trivially on σ_{N_n} (its smooth representations are semisimple); by (Gy7)(a) with $b = c$, $\sigma^{\mathrm{Iw}(\varpi_{w'}^{c,c})} \neq 0$, and $\mathrm{Iw}(\varpi_{w'}^{c,c})$ contains the kernel of reduction modulo $\varpi_{w'}^c$, so σ has non-zero vectors fixed by $\iota_{\tilde v}(V_v)$. (e) The places above ℓ: for $v \mid \ell$, $r \otimes \kappa$ is triangular on D_v with diagonal $\theta_j = \kappa\,(x \circ \psi_{v,j}^{\mathrm{d}})$ (Cy3), and the Hodge–Tate weights of the θ_j are strictly decreasing in j in the normalisation fixed in Section 13 (Cy4) (κ shifts all of them equally), i.e. strictly increasing in that of (To1). By (Ol2) at $\tilde v$, Π is ι-ordinary at $\tilde v$, and a non-zero $x_v \in (\iota^{-1}\Pi_{\tilde v})^{\mathrm{ord}}$, which lies in $(\iota^{-1}\Pi_{\tilde v})^{\mathrm{Iw}(\varpi_{\tilde v}^{b,b})}$ for some b, is an eigenvector of $U_{\lambda,\varpi_{\tilde v}}^{(j)}$ with eigenvalue $\prod_{a \le j} \phi_{v,a}(\mathrm{Art}(\varpi_{\tilde v}))$ and of $d_j(z)$ with eigenvalue $\phi_{v,j}(\mathrm{Art}(z)) \prod_{\tau'} \tau'(z)^{\lambda_{\tau',n-j+1}}$ ($\varepsilon^{j-1}\theta_j = \phi_{v,j}$). (f) Descent and the point: by (Gy4) and (Bc2) there are a dominant λ' and an irreducible constituent π of $S_{\lambda'}(\overline{\mathbb{Q}}_\ell)$ with $\pi_v \cong \iota^{-1}\Pi_w \circ \iota_w$ at the split v and $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L_v^+})} \neq 0$ at the inert v (where Π is unramified by (c)). By (Gy5)(i) and (c), r_π and $r_\iota(\Pi)$ have the same Frobenius characteristic polynomials at almost all split places, so $r_\pi \cong r_\iota(\Pi)$, and comparing Hodge–Tate weights ((Gy5)(iv), (To1)) gives $\lambda' = \lambda$. Choose b (and $r_1 \ge b$) such that the x_v of (e) are fixed by $\mathrm{Iw}(\varpi_{\tilde v}^{b,b})$ for all $v \mid \ell$, and let $f = \otimes_{v'} f_{v'} \in \pi$ with $f_v = x_v$ ($v \mid \ell$), f_v fixed by V_v for $v \in \mathrm{St}$ (by (d)), f_{v_0} and f_v for the split $v \notin T_L$ spherical (by (c)), and f_v fixed by $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ at the inert v. Then $f \in \pi^{V(\ell^{b,b})}$ is a common eigenvector of the $T_w^{(j)}$ (with the eigenvalues determined by the unramified Π_w), of the $U_{\lambda,\varpi_{\tilde v}}^{(j)}$ (unit eigenvalues) and of the diamond operators; the diamond eigenvalues on $T_n(\ell^1)$ form a character α of finite order (the e_j are smooth), trivial on $T_n(\ell^{r_1})$ for r_1 large. Taking $V(\ell^{r_1,r_1})$-invariants is exact, so the eigencharacter of f on the commutative Hecke algebra of level $V(\ell^{r_1,r_1})$ occurs in $S_\lambda(\overline{\mathbb{Q}}_\ell)^{V(\ell^{r_1,r_1})}$, in its ordinary part with $T_n(\ell^1)$ acting by α, and gives a homomorphism $\mathbb{T}_\lambda^{\mathrm{ord}}(V(\ell^{r_1,r_1}), \alpha, \mathcal{K}') \to \overline{\mathbb{Q}}_\ell$; composed with the surjection of (Qh3) it is a point y of $\mathbb{T}$ with $y(\mathfrak{P}_{\lambda,\alpha}) = 0$. By (Gy7)(c): $y(T_w^{(j)})$ is the eigenvalue of $T_w^{(j)}$ on f, so $P_{y,w}$ is the characteristic polynomial of $r_\pi(\mathrm{Frob}_w)$ (Gy5)(i), i.e. of $(r \otimes \kappa)(\mathrm{Frob}_w)$; $y(U_{\tilde v}^{(j)}) = \prod_{a \le j} \phi_{v,a}(\mathrm{Art}(\varpi_{\tilde v}))$, which is the second identity; and $y(\langle d_j(z)\rangle) = (w_0\lambda)(d_j(z))^{-1}\phi_{v,j}(\mathrm{Art}(z)) \prod_{\tau'} \tau'(z)^{\lambda_{\tau',n-j+1}} = \phi_{v,j}(\mathrm{Art}(z))$, as $(w_0\lambda)(d_j(z)) = \prod_{\tau'} \tau'(z)^{\lambda_{\tau',n+1-j}}$. □

Lemma E.6. *Let F be an imaginary CM field, $n \ge 2$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, $\lambda = (\lambda_\tau)$ dominant (as in Theorem B.94) and Π a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ of weight $\iota\lambda$. Let $w \mid \ell$ be a place of F, ϖ a uniformiser of F_w, τ run over the embeddings $F_w \to \overline{\mathbb{Q}}_\ell$, $\sigma = \iota^{-1}\Pi_w$, $r = r_\iota(\Pi)|_{G_{F_w}}$, and for $z \in \mathcal{O}_{F_w}^\times$ let $d_j(z)$ be the diagonal matrix with z in position j and 1 elsewhere.*

(Ol1) *Suppose that there are $b \ge 1$ and $0 \neq x \in \sigma^{\mathrm{Iw}(\varpi^{b,b})}$ which is an eigenvector of every $U_{\lambda,\varpi}^{(j)}$ with an ℓ-adic unit eigenvalue u_j and of every $d_j(z)$ with eigenvalue $e_j(z)$. Put*

$u_0 = 1$. *Then r is conjugate to an upper triangular representation with diagonal characters $\theta_1, \dots, \theta_n$ (in this order), where θ_j has τ-Hodge–Tate weight $\lambda_{\tau,n-j+1} + j - 1$ and*

$$\theta_j(\mathrm{Art}(z)) = \varepsilon(\mathrm{Art}(z))^{1-j}\, e_j(z) \prod_\tau \tau(z)^{-\lambda_{\tau,n-j+1}} \quad (z \in \mathcal{O}_{F_w}^\times),$$
$$\theta_j(\mathrm{Art}(\varpi)) = \varepsilon(\mathrm{Art}(\varpi))^{1-j}\, \frac{u_j}{u_{j-1}}.$$

(Ol2) *Conversely, suppose that r is conjugate to an upper triangular representation with diagonal characters $\theta_1, \dots, \theta_n$ (in this order) whose τ-Hodge–Tate weights are strictly increasing in j for every τ. Then Π is ι-ordinary at w, and every non-zero x in $(\iota^{-1}\Pi_w)^{\mathrm{ord}}$ is an eigenvector of $U^{(j)}_{\lambda,\varpi}$ with eigenvalue $\prod_{a=1}^j (\varepsilon^{a-1}\theta_a)(\mathrm{Art}(\varpi))$ and of $d_j(z)$ with eigenvalue $(\varepsilon^{j-1}\theta_j)(\mathrm{Art}(z)) \prod_\tau \tau(z)^{\lambda_{\tau,n-j+1}}$, for all j and $z \in \mathcal{O}_{F_w}^\times$.*

Proof. Three classical facts. (F1) ([27, 2.12], the geometric lemma; exactness of the Jacquet functor) $I(\chi)_{N_n}$ has semisimplification $\bigoplus_{s\in S_n} \chi^s\delta^{1/2}$, $\chi^s(t) = \chi(s^{-1}ts)$; if σ is irreducible and μ is an irreducible quotient of $\sigma_{N_n} \neq 0$ (a character, $T_n(F_w)$ being abelian), Frobenius reciprocity embeds σ into $I(\mu\delta^{-1/2})$; for $s \in S_n$, $I(\chi)$ and $I(\chi^s)$ have the same irreducible subquotients. (F2) (Fontaine; as used in the proof of Corollary 2.7.8 of [105]) a de Rham character θ of G_{F_w} with τ-Hodge–Tate weights h_τ satisfies: $x \mapsto \theta(\mathrm{Art}(x)) \prod_\tau \tau(x)^{h_\tau}$ is a smooth character of $F_w^\times$, equal to $\mathrm{WD}(\theta)$; conversely a character equal to $\prod_\tau \tau^{-h_\tau} \circ \mathrm{Art}^{-1}$ on an open subgroup of inertia and de Rham has these weights. (F3) (Lubin–Tate) $\varepsilon(\mathrm{Art}(x)) = \mathrm{N}_{F_w/\mathbb{Q}_\ell}(x)\,|x|_w$, so $\varepsilon(\mathrm{Art}(z)) = \prod_\tau \tau(z)$ for units and $\varepsilon(\mathrm{Art}(\varpi)) = q^{-1}\prod_\tau \tau(\varpi)$.

Step 1: the Weil–Deligne representation of a triangular r. If r is triangular with diagonal (θ_j), the θ_j are de Rham (subquotients of the de Rham r, (To1)), D_{pst} is exact, and the semisimplification of the Weil group representation of $\mathrm{WD}(r)$ is $\bigoplus_j \mathrm{WD}(\theta_j)$. Moreover Π is polarizable (conjugate self-dual) and $r \cong r_{\ell,\iota}(\Pi)|_{G_{F_w}}$ (both global representations are semisimple with the same Frobenius characteristic polynomials at almost all places by (To1) and (Bg1)), so (Bg3) with $U = \{1\}$ and (Bg5) apply: σ is a subquotient of $I(\xi)$ for characters ξ_i with $\iota^{-1}\xi_i = \lambda_i\,|\cdot|_w^{(n-1)/2}$, where $\lambda_1, \dots, \lambda_n$ are the characters of the semisimplified $\mathrm{WD}(r)$.

Step 2: (Ol1). Let x, u_j, e_j be as in (Ol1) and $u^{(j)} = \prod_\tau \prod_{i\le j} \tau(\varpi)^{\lambda_{\tau,n-i+1}} u_j$, the eigenvalue of $U^{(j)}_\varpi$ on x, non-zero. By (Gy7)(a) with $c = b$, the image $\bar{x}$ of x in σ_{N_n} is non-zero; it is an eigenvector of $T_n(\mathcal{O}_{F_w})$ (generated by the $d_j(z)$) with eigenvalues $e_j(z)$ and of $\sigma_{N_n}(\alpha^{(j)}_\varpi)$ with eigenvalue $\delta(\alpha^{(j)}_\varpi)u^{(j)}$; as $T_n(F_w)$ is generated by $T_n(\mathcal{O}_{F_w})$ and the $\alpha^{(j)}_\varpi$, $\bar{x}$ spans a $T_n(F_w)$-stable line with character μ, which is a constituent of σ_{N_n}. Since $\sigma_{N_n} \neq 0$, (F1) gives χ with σ a subquotient of $I(\chi)$, then $\mu = \chi^s\delta^{1/2}$ for some s, and σ is a subquotient of $I(\chi')$ with $\chi' = \mu\delta^{-1/2}$. Here $\chi'_j|_{\mathcal{O}^\times} = e_j$ (δ is trivial on units) and, as $\delta^{1/2}(\alpha^{(j)}_\varpi) = q^{-j(n-j)/2}$,

$$\chi'_j(\varpi) = \frac{\mu(\alpha^{(j)}_\varpi)\,\delta^{-1/2}(\alpha^{(j)}_\varpi)}{\mu(\alpha^{(j-1)}_\varpi)\,\delta^{-1/2}(\alpha^{(j-1)}_\varpi)} = q^{-\frac{n-1}{2}}\, q^{j-1} \prod_\tau \tau(\varpi)^{\lambda_{\tau,n-j+1}}\, \frac{u_j}{u_{j-1}}.$$

As the u_j are units,

$$v_\ell(\chi'_j(\varpi)) = \frac{1}{e}\sum_\tau (\lambda_{\tau,n+1-j} - \frac{n-1}{2} + j - 1).$$

By (To2), Π is ι-ordinary at w with tuple (χ'_j), and by (To3) r is triangular with diagonal (θ_j), $\theta_j(\mathrm{Art}(z)) = e_j(z)\prod_\tau \tau(z)^{-(\lambda_{\tau,n-j+1}+j-1)}$, which is the first formula by (F3); by (F2) θ_j has

weights $h_{\tau,j} = \lambda_{\tau,n-j+1} + j - 1$, strictly increasing in j. By Step 1 the multisets $\{\mathrm{WD}(\theta_j)\}$ and $\{\lambda_i\}$ coincide, and σ is a subquotient of both $I(\xi)$ and $I(\chi')$; two principal series sharing an irreducible subquotient have the same cuspidal support ([27, Theorem 2.9]), so $\{\iota^{-1}\xi_i\} = \{\chi'_j\}$ and $\{\mathrm{WD}(\theta_j)\} = \{\chi'_j|\cdot|_w^{(1-n)/2}\}$. At ϖ: $v_\ell(\mathrm{WD}(\theta_j)(\varpi)) = \frac{1}{e}\sum_\tau h_{\tau,j}$ by (F2) ($\theta_j(\mathrm{Art}(\varpi))$ is a unit, G_{F_w} being compact), and $v_\ell(\chi'_i(\varpi)q^{(n-1)/2}) = \frac{1}{e}\sum_\tau h_{\tau,i}$; both are strictly increasing, so the bijection between the two multisets matches j with j: $\mathrm{WD}(\theta_j) = \chi'_j|\cdot|_w^{(1-n)/2}$. Evaluating at ϖ with (F2): $\theta_j(\mathrm{Art}(\varpi))\prod_\tau \tau(\varpi)^{h_{\tau,j}} = \chi'_j(\varpi)q^{(n-1)/2} = q^{j-1}\prod_\tau \tau(\varpi)^{\lambda_{\tau,n-j+1}}u_j/u_{j-1}$, i.e. $\theta_j(\mathrm{Art}(\varpi)) = (q^{-1}\prod_\tau \tau(\varpi))^{1-j}u_j/u_{j-1} = \varepsilon(\mathrm{Art}(\varpi))^{1-j}u_j/u_{j-1}$ by (F3).

Step 3: (Ol2). The multiset of τ-Hodge–Tate weights of r is $\{\lambda_{\tau,n}, \lambda_{\tau,n-1}+1, \dots, \lambda_{\tau,1}+n-1\}$ (To1), listed increasingly; as the weights of the θ_j are strictly increasing in j, θ_j has weight $h_{\tau,j} = \lambda_{\tau,n-j+1} + j - 1$. By Step 1, σ is a subquotient of $I(\chi'')$ with $\chi''_j = \mathrm{WD}(\theta_j)|\cdot|_w^{(n-1)/2}$ (order the ξ_i by the bijection with the $\mathrm{WD}(\theta_j)$; reordering does not change the subquotients, (F1)), and $v_\ell(\chi''_j(\varpi)) = \frac{1}{e}\sum_\tau h_{\tau,j} - \frac{(n-1)f}{2} = \frac{1}{e}\sum_\tau(\lambda_{\tau,n+1-j} - \frac{n-1}{2} + j - 1)$. By (To2), Π is ι-ordinary at w, so by (Gy7)(b) $(\iota^{-1}\Pi_w)^{\mathrm{ord}}$ is a line, contained in $\sigma^{\mathrm{Iw}(\varpi^{b,b})}$ for some b. The $U^{(j)}_{\lambda,\varpi}$ commute with each other and the $d_j(z)$ commute with them ($d_j(z)$ normalises $N_n(\mathcal{O})$, $\mathrm{Iw}(\varpi^{b,b})$ and commutes with $\alpha^{(i)}_\varpi$), so all of them preserve the ordinary part, which is a line: a non-zero x in it is a common eigenvector, the U-eigenvalues u_j being units. By Step 2, r is triangular with a diagonal (θ'_j) given by the formulas of (Ol1) and with weights $h_{\tau,j}$. The diagonal characters of a triangular representation are its Jordan–Hölder factors, so $\{\theta'_j\} = \{\theta_j\}$ as multisets; as θ'_j and θ_j both have weights $h_{\tau,j}$, pairwise distinct in j, $\theta'_j = \theta_j$. Solving the formulas of (Ol1) for $e_j(z)$ and u_j/u_{j-1} gives the eigenvalues claimed in (Ol2). □

Proposition E.7. *Let ℓ, $n \geq 2$, F, F^+, $\mathcal{O}$, $\mathbb{G}$ be as in Theorem B.91, with $[F^+ : \mathbb{Q}] \geq 2$, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism.*

(Bc1) *Let λ be a dominant weight for $\mathbb{G}$ and π an irreducible constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ such that r_π is absolutely irreducible. Then there is a regular algebraic conjugate self-dual cuspidal automorphic representation Π of $\mathrm{GL}_n(\mathbb{A}_F)$ of weight $\iota\lambda$ such that $\pi_v \cong \iota^{-1}\Pi_w \circ \iota_w$ for every finite place v of F^+ which splits as ww^c in F, and $r_\pi \cong r_\iota(\Pi)$.*

Proof. Step 1: the decomposition. The hypotheses of Lemma E.8 hold (ℓ, n, F, F^+, $\mathbb{G}$ as in Theorem B.91, $[F^+ : \mathbb{Q}] \geq 2$, ι, λ dominant, π an irreducible constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$). By its clause (Ug1) there are $r \geq 1$, integers $k_i, m_i \geq 1$ with $\sum_i k_i m_i = n$ and unitary cuspidal automorphic representations τ_i of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$ with $\tau_i^c \cong \tau_i^\vee$ such that, with $s_i = \frac{m_i-1}{2} - \frac{n-k_i}{2}$, each $\tau'_i = \tau_i \otimes |\det|^{s_i}$ is regular algebraic, cuspidal and polarizable, and, for $\Pi = \mathrm{Sp}(\tau_1, k_1)\boxplus\cdots\boxplus\mathrm{Sp}(\tau_r, k_r)$: (i) $\Pi_w \cong \iota\pi_v \circ \iota_w^{-1}$ at every finite place v of F^+ split as ww^c in F; (ii) $r_\pi \cong \bigoplus_{i=1}^r \bigoplus_{a=0}^{k_i-1} r_{\ell,\iota}(\tau'_i)\otimes\varepsilon^{-a}$.

Step 2: only one summand. Every summand in (ii) is non-zero (of dimension $m_i \geq 1$) and r_π is absolutely irreducible, so the double sum has exactly one term: $r = 1$ and $k_1 = 1$. Then $m_1 = n$, $s_1 = \frac{n-1}{2} - \frac{n-1}{2} = 0$, $\tau'_1 = \tau_1$, and $\Pi = \mathrm{Sp}(\tau_1, 1) = \tau_1$ (for $k = 1$ the parabolic subgroup of type (m_1) is the whole group, and the induction in (Mw1) is τ_1 itself). Hence Π is a cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ which is regular algebraic (as $\tau'_1 = \Pi$) and conjugate self-dual ($\Pi^c \cong \Pi^\vee$), and $r_\pi \cong \rho_1$ with $\rho_1 = r_{\ell,\iota}(\Pi)$.

Step 3: $r_\pi \cong r_\iota(\Pi)$. Let $w \nmid \ell$ be a place of F at which Π is unramified. By (Bg1) for $\Pi = \tau'_1$ ($m_1 = n$, $s_1 = 0$), ι carries the characteristic polynomial of $\rho_1(\mathrm{Frob}_w)$ to $\prod_{\alpha\in\alpha_w(\Pi)}(X - q_w^{(n-1)/2}\alpha)$. By (To1), $\mathrm{WD}(r_\iota(\Pi)|_{G_{F_w}})^{\text{F-ss}} \cong \mathrm{rec}(\iota^{-1}\Pi_w \otimes |\det|^{(1-n)/2})$, an unramified representation on which Frob_w has the eigenvalues $q_w^{(n-1)/2}\alpha$, $\alpha \in \alpha_w(\Pi)$ (after ι); Frobenius-

semisimplification keeps the characteristic polynomial, so $r_\iota(\Pi)(\mathrm{Frob}_w)$ has the same characteristic polynomial as $\rho_1(\mathrm{Frob}_w)$. These Frobenius elements are dense in G_F (Chebotarev), so the characteristic polynomials of $r_\iota(\Pi)$ and $\rho_1 \cong r_\pi$ agree on G_F by continuity, and by the Brauer–Nesbitt theorem the semisimplification of $r_\iota(\Pi)$ is isomorphic to r_π. As r_π is irreducible, $r_\iota(\Pi)$ has a single composition factor, so $r_\iota(\Pi) \cong r_\pi$.

Step 4: the weight. Let $\iota\mu$ be the weight of Π (it exists as Π is regular algebraic). For every embedding $\tau\colon F \to \overline{\mathbb{Q}}_\ell$, (To1) gives the τ-Hodge–Tate weights $\mu_{\tau,n-j+1} + j - 1$ $(1 \le j \le n)$ of $r_\iota(\Pi)$ and (Gy5)(iv) gives those of r_π as $\lambda_{\tau,n-j+1} + j - 1$, both with ε of weight -1; by Step 3 the two multisets agree, and both lists are strictly increasing in j, so $\mu_\tau = \lambda_\tau$ and Π has weight $\iota\lambda$.

Step 5: the local components. For v split as ww^c, Step 1(i) gives $\Pi_w \cong \iota\pi_v \circ \iota_w^{-1}$, i.e. $\pi_v \cong \iota^{-1}\Pi_w \circ \iota_w$. □

Lemma E.8. *Let ℓ, $n \ge 2$, F, F^+, $\mathcal{O}$, $\mathbb{G}$ be as in Theorem B.91, with $[F^+ : \mathbb{Q}] \ge 2$; let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism, λ a dominant weight for $\mathbb{G}$ and π an irreducible constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$.*

(Ug1) *There are $r \ge 1$, integers $k_i, m_i \ge 1$ $(1 \le i \le r)$ with $\sum_i k_i m_i = n$, and unitary cuspidal automorphic representations τ_i of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$ with $\tau_i^c \cong \tau_i^\vee$, such that, with $s_i = \frac{m_i-1}{2} - \frac{n-k_i}{2}$, each $\tau_i' = \tau_i \otimes |\det|^{s_i}$ is regular algebraic, cuspidal and polarizable, and, with $\Pi = \mathrm{Sp}(\tau_1, k_1) \boxplus \cdots \boxplus \mathrm{Sp}(\tau_r, k_r)$:*

1. *$\Pi_w \cong \iota\pi_v \circ \iota_w^{-1}$ for every finite place v of F^+ which splits as ww^c in F;*
2. *$r_\pi \cong \bigoplus_{i=1}^r \bigoplus_{a=0}^{k_i-1} r_{\ell,\iota}(\tau_i') \otimes \varepsilon^{-a}$.*

(Ug2) *For every finite place $v \nmid \ell$ of F^+ which splits as ww^c in F,*

$$\iota\,\mathrm{WD}\big(r_\pi|_{G_{F_w}}\big)^{F\text{-}ss} \cong \mathrm{rec}_{F_w}\big(\iota\pi_v \circ \iota_w^{-1} \otimes |\det|^{(1-n)/2}\big).$$

(Ug3) *In particular, for such v and w: if $\mathrm{rec}_{F_w}(\iota\pi_v \circ \iota_w^{-1})$ has monodromy 0, then $\mathrm{WD}(r_\pi|_{G_{F_w}})$ has monodromy 0.*

Proof. Step 1: the automorphic representation of $\mathbb{G}$. By [105], Lemma 2.2.5 (with no places carrying a character), $S_\lambda(\overline{\mathbb{Q}}_\ell) \otimes_{\overline{\mathbb{Q}}_{\ell,\iota}} \mathbb{C} \cong \mathrm{Hom}_{\mathbb{G}(F^+\otimes\mathbb{R})}(\xi_{\lambda,\iota}^\vee, \mathcal{A})$ as $\mathbb{G}(\mathbb{A}_{F^+}^\infty)$-modules, where $\mathcal{A}$ is the space of automorphic forms on $\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+})$ and $\xi_{\lambda,\iota}$ the irreducible representation of the compact group $\mathbb{G}(F^+ \otimes \mathbb{R})$ defined by λ through ι. Hence $\sigma = \xi_{\lambda,\iota}^\vee \otimes \iota\pi$ is an irreducible automorphic representation of $\mathbb{G}(\mathbb{A}_{F^+})$ with $\sigma_v \cong \iota\pi_v$ at the finite places. As $\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+})$ is compact, σ lies in the discrete spectrum; σ_∞, an irreducible representation of a compact group, is a discrete series representation; and Labesse's property $(*)$ holds for σ because $\mathbb{G}(F^+ \otimes \mathbb{R})$ is compact (the last sentence of Theorem B.96; [153], the remark before Corollaire 5.3).

Step 2: weak base change. $\mathbb{G}$ is a unitary group in n variables for F/F^+, an inner form of the quasi-split one, F^+ is totally real of degree ≥ 2 and F is totally imaginary. By Theorem B.96 ([153], Corollaire 5.3; its F, E, U are our F^+, F, $\mathbb{G}$, the infinity component is a discrete series as $\mathbb{G}(F^+ \otimes \mathbb{R})$ is compact, and property $(*)$ holds for the same reason), there are a partition $n = n_1 + \cdots + n_r$ and automorphic representations $\Pi_1, \ldots, \Pi_r$ of $\mathrm{GL}_{n_i}(\mathbb{A}_F)$ in the discrete spectrum which are conjugate self-dual, $\Pi_i^\vee \cong \Pi_i^c$, such that the isobaric sum $\Pi = \Pi_1 \boxplus \cdots \boxplus \Pi_r$ is a weak base change of σ and: (1) at every finite place v of F^+ which splits as ww^c in F, $\Pi_w \cong \sigma_v \circ \iota_w^{-1}$; (2) Π_∞ is cohomological for an algebraic coefficient system W, so by Wigner's

lemma Π_∞ has the infinitesimal character of $W^\vee$, and at every complex place of F the exponents (p_j), (q_j) of Π are each n pairwise distinct elements of $\frac{n-1}{2}+\mathbb{Z}$.

Step 3: the discrete summands. By (Mw1), $\Pi_i \cong \mathrm{Sp}(\tau_i, k_i)$ for some $k_i \geq 1$ with $m_i = n_i/k_i \in \mathbb{Z}$ and a unitary cuspidal automorphic representation τ_i of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$; so Π is the isobaric sum of (Ug1), and (Ug1)(i) is Step 2(1) with $\sigma_v \cong \iota\pi_v$. At every finite place w at which τ_i is unramified, $\Pi_{i,w}$ is unramified with

$$\alpha_w(\Pi_i) = \bigsqcup_{a=0}^{k_i-1} q_w^{a-(k_i-1)/2}\,\alpha_w(\tau_i), \tag{E.1}$$

(by (Mw2) for $r=1$, $\mathrm{rec}(\Pi_{i,w}) = \bigoplus_a \mathrm{rec}(\tau_{i,w}) \otimes \mathrm{rec}(|\cdot|^{(k_i-1)/2-a})$ is a sum of unramified characters with monodromy 0; by (Ln6) and (Ln1) of Theorem B.92 and the bijectivity of rec, the representation with this parameter is the unramified Langlands quotient of the corresponding unramified characters, whose Satake parameters are their values at a uniformiser), and at every complex place the exponents of Π_i are those of τ_i shifted by $\frac{k_i-1}{2}-a$, $0 \leq a \leq k_i-1$ (both p and q, since $|z|_{\mathbb{C}} = z\bar{z}$). The exponents and Satake parameters of the isobaric sum Π are the unions of those of the Π_i.

Step 4: the twisted cuspidal pieces have Galois representations. (i) $\tau_i^c \cong \tau_i^\vee$: at almost all w, $\alpha_w(\Pi_i^\vee) = \alpha_w(\Pi_i)^{-1}$ and $\alpha_w(\Pi_i^c) = \alpha_{w^c}(\Pi_i)$, so by (E.1), with $t_a = a - \frac{k_i-1}{2}$ running over a set symmetric about 0, the families $(\tau_i^\vee|\det|^{t_a})_a$ and $(\tau_i^c|\det|^{t_a})_a$ have the same unions of Satake parameters at almost all places. By Theorem B.97 there is a bijection s with $\tau_i^\vee|\det|^{t_a} \cong \tau_i^c|\det|^{t_{s(a)}}$; comparing absolute values of the (unitary) central characters gives $t_a = t_{s(a)}$, so $\tau_i^\vee \cong \tau_i^c$. (ii) By Steps 2(2) and 3, the numbers $p + \frac{k_i-1}{2} - a$, for p an exponent of τ_i at a complex place and $0 \leq a < k_i$, lie in $\frac{n-1}{2}+\mathbb{Z}$ and are pairwise distinct; so the exponents of τ_i lie in $\frac{n-k_i}{2}+\mathbb{Z}$ and are pairwise distinct, and those of τ_i', shifted by s_i, are pairwise distinct elements of $\frac{m_i-1}{2}+\mathbb{Z}$ (likewise for q): τ_i' is regular algebraic and cuspidal. (iii) $\tau_i'^c \cong \tau_i^\vee|\det|^{s_i} = \tau_i'^\vee \otimes (\chi_i \circ \mathrm{N}_{F/F^+} \circ \det)$ with $\chi_i = |\cdot|_{\mathbb{A}_{F^+}}^{2s_i}$, trivial on -1 at every infinite place; so τ_i' is polarizable. Let $\rho_i = r_{\ell,\iota}(\tau_i')\colon G_F \to \mathrm{GL}_{m_i}(\overline{\mathbb{Q}}_\ell)$ (Theorem B.62); by (Bg1), at every $w \nmid \ell$ where τ_i is unramified, ι carries the characteristic polynomial of $\rho_i(\mathrm{Frob}_w)$ to $\prod_{\beta\in\alpha_w(\tau_i)}(X - q_w^{(m_i-1)/2-s_i}\beta)$.

Step 5: (Ug1)(ii). Let Σ be the set of places $w \nmid \ell$ of F above places v of F^+ split in F such that π_v is unramified and all $\tau_{i,w}$ are unramified; it contains all but finitely many places of F of degree one over F^+. For $w \in \Sigma$, (Ug1)(i) and (Gy5)(i) show that the characteristic polynomial of $r_\pi(\mathrm{Frob}_w)$ is carried by ι to $\prod_{\alpha\in\alpha_w(\Pi)}(X - q_w^{(n-1)/2}\alpha)$.

By (E.1), $q_w^{(n-1)/2}\alpha_w(\Pi) = \bigsqcup_i \bigsqcup_{a=0}^{k_i-1} q_w^{(n-1)/2+a-(k_i-1)/2}\alpha_w(\tau_i)$, and $\frac{n-1}{2} + a - \frac{k_i-1}{2} = \frac{m_i-1}{2} - s_i + a$. Since $\varepsilon^{-a}(\mathrm{Frob}_w) = q_w^a$, the semisimple representations r_π and $\rho = \bigoplus_i \bigoplus_{a=0}^{k_i-1} \rho_i \otimes \varepsilon^{-a}$ have the same characteristic polynomials at the Frobenius elements of all $w \in \Sigma$. These are dense in G_F (Chebotarev; the places of degree two over F^+ have density 0), so the characteristic polynomials agree on G_F by continuity, and $r_\pi \cong \rho$ by the Brauer–Nesbitt theorem.

Step 6: (Ug2). Let $v \nmid \ell$ split as ww^c and $K = F_w$, with W_K its Weil group. Isomorphic representations have isomorphic Weil–Deligne representations, and WD and Frobenius-semisimplification commute with direct sums and with twisting by a character of G_K trivial on inertia. As $w \nmid \ell$, $\varepsilon|_{G_K}$ is unramified with $\varepsilon(\mathrm{Art}_K(\varpi)) = q_w^{-1} = |\varpi|$ for a uniformiser ϖ ($\mathrm{Art}_K(\varpi)$ a geometric Frobenius), so $\varepsilon|_{W_K} = \mathrm{rec}_K(|\cdot|)$ by (Ln1). By (Ug1)(ii), (Bg7) applied

to τ'_i (of rank m_i) and (Ln2),

$$\iota\,\mathrm{WD}(r_\pi|_{G_K})^{F\text{-}ss} \cong \bigoplus_{i=1}^{r}\bigoplus_{a=0}^{k_i-1} \mathrm{rec}_K\big(\tau'_{i,w}\otimes|\det|^{(1-m_i)/2}\big)\otimes\mathrm{rec}_K(|\cdot|^{-a})$$
$$\cong \bigoplus_{i=1}^{r}\bigoplus_{a=0}^{k_i-1} \mathrm{rec}_K(\tau_{i,w})\otimes\mathrm{rec}_K\big(|\cdot|^{s_i+(1-m_i)/2-a}\big).$$

So the right side is $\big(\bigoplus_{i,a}\mathrm{rec}_K(\tau_{i,w})\otimes\mathrm{rec}_K(|\cdot|^{(k_i-1)/2-a})\big)\otimes\mathrm{rec}_K(|\cdot|^{(1-n)/2})$, which by (B.1) of (Mw2) is $\mathrm{rec}_K(\Pi_w)\otimes\mathrm{rec}_K(|\cdot|^{(1-n)/2}) = \mathrm{rec}_K(\Pi_w\otimes|\det|^{(1-n)/2})$ (Ln2), and $\Pi_w\cong\iota\pi_v\circ\iota_w^{-1}$ by (Ug1)(i).

Step 7: (Ug3). Frobenius-semisimplification does not change the monodromy operator, and by (Ln2) $\mathrm{rec}_K(\sigma'\otimes|\det|^{(1-n)/2}) = \mathrm{rec}_K(\sigma')\otimes\mathrm{rec}_K(|\cdot|^{(1-n)/2})$ has the monodromy operator of $\mathrm{rec}_K(\sigma')$. So by (Ug2) the monodromy of $\mathrm{WD}(r_\pi|_{G_K})$ is conjugate (after ι) to that of $\mathrm{rec}_K(\iota\pi_v\circ\iota_w^{-1})$, which is 0 by hypothesis. □

Proposition E.9. *Let ℓ, $n\geq 2$, F, F^+, $\mathcal{O}$, $\mathbb{G}$ be as in Theorem B.91, with F/F^+ unramified at all finite places, $[F^+:\mathbb{Q}]\geq 2$, and $\mathbb{G}(\mathcal{O}_{F_v^+})$ a hyperspecial maximal compact subgroup of $\mathbb{G}(F_v^+)$ for every finite place v of F^+ inert in F; let $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ be an isomorphism.*

(Bc2) *For every regular algebraic conjugate self-dual cuspidal automorphic representation Π of $\mathrm{GL}_n(\mathbb{A}_F)$, the irreducible constituent π of (Gy4) can be chosen such that, moreover, $\pi_v^{\mathbb{G}(\mathcal{O}_{F_v^+})}\neq 0$ for every place v of F^+ inert in F at which Π is unramified.*

Proof. Let Π be a regular algebraic conjugate self-dual cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, and let $\mathcal{V}$ be the set of finite places v of F^+ inert in F at which Π is unramified; for $v\in\mathcal{V}$ let w be the place of F above v and $K_v=\mathbb{G}(\mathcal{O}_{F_v^+})$, hyperspecial by hypothesis. We follow the proof of [153], Théorème 5.4, and [105], Proposition 2.2.7, which deduces (Gy4) from it, keeping track of the test function at the places of $\mathcal{V}$.

Step 1: the setting of Labesse, §5. F^+ is totally real of degree ≥ 2, F/F^+ is totally imaginary and unramified at all finite places, and $U=\mathbb{G}_{F^+}$ is an inner form of the quasi-split unitary group U^*, quasi-split at every finite place (hypothesis of Theorem B.91), with $U(F^+\otimes\mathbb{R})$ compact. So the standing hypotheses of [153], §5.2, hold, and property $(*)$ holds for every discrete automorphic σ of U (remark before Corollaire 5.3: U_∞ compact). Π is cuspidal, θ-invariant ($\Pi^c\cong\Pi^\vee$) and cohomological at infinity (regular algebraic).

Step 2: the refined identity for associated pairs. Let $f=\bigotimes_v f_v\in C_c^\infty(U(\mathbb{A}_{F^+}))$ with f_∞ a pseudo-coefficient of the discrete series σ_∞ of the proof of Théorème 5.4 (for compact U_∞: a multiple of the conjugate of the character of an irreducible representation σ_∞, so $\mathrm{tr}\,\sigma'_\infty(f_\infty)\neq 0$ if and only if $\sigma'_\infty\cong\sigma_\infty$), and let $\varphi=\bigotimes_v\varphi_v$ be a function on $\tilde{G}(\mathbb{A}_{F^+})$ such that f_v and φ_v are associated (stable base change transfer) at every place, φ_∞ the Lefschetz function of that proof. Théorème 5.1 of loc. cit. (whose proof uses of $\tilde{f}^{U^*}=\varphi$ only that it is a stable base change transfer of f: §4.8, formula 4.12) and the separation of Hecke eigensystems in the proof of Théorème 5.4, where the classification of Jacquet–Shalika and Proposition 4.9 show that for the cuspidal Π no endoscopic group $H\neq U^*$ contributes, give the refined identity

$$\sum_{\sigma'} m(\sigma')\,\mathrm{tr}\,\sigma'(f)=\mathrm{tr}\,\tilde{\Pi}(\varphi),$$

the sum over the discrete automorphic representations σ' of U whose Hecke eigenvalues agree with those determined by Π at almost all places, $m(\sigma')\geq 1$ their multiplicities. Writing the

global intertwining operator of $\tilde{\Pi}$ as a non-zero multiple of the tensor product of local ones, normalised at the places where Π is unramified to fix the vectors invariant under the hyperspecial subgroup used ([153], before Lemme 4.8), $\operatorname{tr}\tilde{\Pi}(\varphi) = C\prod_v \operatorname{tr}\tilde{\Pi}_v(\varphi_v)$ with $C \neq 0$.

Step 3: the unit at the places of $\mathcal{V}$. Let $v \in \mathcal{V}$. U_v is unramified (quasi-split and split by the unramified extension F_w), K_v is the stabiliser of a hyperspecial point x of its building, and the stabiliser K'_w of x in $U(F_w) \cong \mathrm{GL}_n(F_w)$ is a θ-stable hyperspecial maximal compact subgroup. By Kottwitz's base change fundamental lemma for unit elements [149] (unramified group, unramified extension), 1_{K_v} and $\varphi_v^\circ = 1_{K'_w} \rtimes \theta$ are associated. Π_w is unramified; K'_w is $\mathrm{GL}_n(F_w)$-conjugate to $\mathrm{GL}_n(\mathcal{O}_{F_w})$, so $\Pi_w^{K'_w}$ is a line, preserved by the normalised intertwining operator A_w (as $\theta(K'_w) = K'_w$), on which A_w acts by a sign ($A_w^2 = 1$). Hence $\operatorname{tr}\tilde{\Pi}_w(\varphi_v^\circ) = \pm\operatorname{vol}(K'_w) \neq 0$.

Step 4: a test function with non-zero right side. By the proof of Théorème 5.4 the right side of Step 2 is not identically zero: there are associated f^0, φ^0 as in Step 2 with $\prod_v \operatorname{tr}\tilde{\Pi}_v(\varphi_v^0) \neq 0$. As $f^0 \in C_c^\infty(U(\mathbb{A}_{F^+}))$, $f_v^0 = 1_{K_v}$ for all but finitely many $v \in \mathcal{V}$; and we may take $\varphi_v^0 = \varphi_v^\circ$ there (Step 3). Let f, φ be obtained by replacing f_v^0, φ_v^0 by $1_{K_v}, \varphi_v^\circ$ at the finitely many remaining $v \in \mathcal{V}$; they are associated, and by Step 3 the product of local traces stays non-zero. So $\sum_{\sigma'} m(\sigma')\operatorname{tr}\sigma'(f) \neq 0$, and some σ' in the sum has $\operatorname{tr}\sigma'_\infty(f_\infty) \neq 0$, i.e. $\sigma'_\infty \cong \sigma_\infty$, and $\operatorname{tr}\sigma'_v(1_{K_v}) = \operatorname{vol}(K_v)\dim\sigma_v'^{K_v} \neq 0$ for every $v \in \mathcal{V}$.

Step 5: σ' has the properties of (Gy4). σ' satisfies $(*)$ (Step 1), so by [153], Corollaire 5.3, it has a weak base change $\pi' = \pi_1 \boxplus \cdots \boxplus \pi_r$, the correspondence $\sigma'_v \mapsto \pi'_v$ being local base change at the split places, compatible with infinitesimal characters at the archimedean places. As σ' has the Hecke eigenvalues of Π at almost all places, π' and Π agree at almost all places, so $\pi' = \Pi$ by the classification of Jacquet–Shalika (Π cuspidal). Hence, as in the deduction of [105], Proposition 2.2.7, from Labesse's Corollaire 5.3: $\sigma'_v \cong \Pi_w \circ \iota_w$ at every finite v split as ww^c, and σ'_∞ is the irreducible algebraic representation $\xi_\lambda^\vee$ with the infinitesimal character of Π_∞ (for the compact U_∞ an irreducible representation is determined by its infinitesimal character), for the dominant weight λ of (Gy4). By Lemma 2.2.5 of [105], $\iota^{-1}\sigma'_f$ is an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$; it has the properties of (Gy4), and $\pi_v^{\mathbb{G}(\mathcal{O}_{F_v^+})} \neq 0$ for every $v \in \mathcal{V}$ by Step 4. This is (Bc2). □

Lemma E.10. *Let the data be as in Theorem B.91. For $v \in S_\ell$ let e_v be the ramification index of $F_v^+/\mathbb{Q}_\ell$, and $e_{\max} = \max_{v\in S_\ell} e_v$.*

(Qh1) *For every $b \geq 1$, $T_n(\mathfrak{l}^{be_{\max}}) \subseteq T_n(\ell^b) \subseteq T_n(\mathfrak{l}^b)$; the index $[T_n(\mathfrak{l}^b) : T_n(\ell^b)]$ is a power of ℓ, equal to 1 for every b if ℓ is unramified in F^+; and $\Lambda_b^{\mathfrak{l}}$ is a free Λ_b-module with basis any set of representatives of $T_n(\mathfrak{l}^b)/T_n(\ell^b)$.*

Suppose now that $b_0 \geq 1$ and $U(\ell^{b_0,b_0})$ is sufficiently small.

(Qh2) *$\mathcal{S}$ is a free Λ_{b_0}-module of finite rank, $\mathbb{T}^{\mathrm{ord}}(U)$ is commutative and finite as a Λ_{b_0}-module, and, if $\mathcal{S} \neq 0$, $\Lambda_{b_0} \to \mathbb{T}^{\mathrm{ord}}(U)$ is injective.*

(Qh3) *Let λ be a dominant weight, $\alpha\colon T_n(\ell^1) \to \overline{\mathbb{Q}}_\ell^\times$ a character of finite order and $r \geq 1$ with $T_n(\mathfrak{l}^r) \subseteq \ker\alpha$ (so $T_n(\mathfrak{l}^r) \subseteq T_n(\ell^1)$; if $T_n(\ell^{r_0}) \subseteq \ker\alpha$, then $r = e_{\max}r_0$ will do). The characters $\alpha'\colon T_n(\mathfrak{l}) \to \overline{\mathbb{Q}}_\ell^\times$ with $\alpha'|_{T_n(\ell^1)} = \alpha$ are $[T_n(\mathfrak{l}) : T_n(\ell^1)]$ in number, of finite order and trivial on $T_n(\mathfrak{l}^r)$, and the primes $\mathfrak{P}_{\lambda,\alpha'}^{\mathfrak{l}}$ of $\Lambda_1^{\mathfrak{l}}$ lie over $\mathfrak{P} = \mathfrak{P}_{\lambda,\alpha}$. Let $\mathcal{K}'$ be the fraction field of $\Lambda_1/\mathfrak{P}$. Then the action on $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K}')$ induces a surjection of finite $\mathcal{K}'$-algebras*

$$\mathbb{T}^{\mathrm{ord}}(U) \otimes_{\Lambda_1} (\Lambda_1)_{\mathfrak{P}}/\mathfrak{P} \longrightarrow \mathbb{T}_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K}'),$$

and its kernel is nilpotent.

(Qh4) *In (Qh3), suppose moreover that $\mathcal{O}$ contains the values of every character α' of $T_n(\mathfrak{l})$ with $\alpha'|_{T_n(\ell^1)} = \alpha$ (if ℓ is unramified in F^+: the values of α). Then $\Lambda_1/\mathfrak{P} = \mathcal{O}$, $\mathcal{K}' = \mathcal{K}$, and there is an isomorphism of $\mathcal{K}$-vector spaces*

$$\mathcal{S}_{\mathfrak{P}}/\mathfrak{P}\mathcal{S}_{\mathfrak{P}} \cong \mathrm{Hom}_{\mathcal{K}}(S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}), \alpha, \mathcal{K}), \mathcal{K}) \qquad (\mathcal{S}_{\mathfrak{P}} = \mathcal{S} \otimes_{\Lambda_1} (\Lambda_1)_{\mathfrak{P}})$$

which carries the action of $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ on the left to the transposes of the operators assigned to them by (Gy7)(c) on the right, and which is equivariant for right translation by every element g as in (Gk3).

Proof. Write $G = T_n(\mathfrak{l})$, $H = T_n(\ell^1)$, $N_r = T_n(\mathfrak{l}^r)$, $\mathbb{T} = \mathbb{T}^{\mathrm{ord}}(U)$, and for $v \in S_\ell$ let ϖ_v be a uniformiser of $\mathcal{O}_v = \mathcal{O}_{F_v^+}$, so that $\ell\mathcal{O}_v = \varpi_v^{e_v}\mathcal{O}_v$.

Step 1: (Qh1). $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) = \prod_{v\in S_\ell} T_n(\mathcal{O}_v)$, and by the Chinese remainder theorem $\mathcal{O}_{F^+}/\mathfrak{l}^b = \prod_v \mathcal{O}_v/\varpi_v^b$ and $\mathcal{O}_{F^+}/\ell^b = \prod_v \mathcal{O}_v/\varpi_v^{be_v}$. Hence

$$T_n(\mathfrak{l}^b) = \prod_{v\in S_\ell} (1 + \varpi_v^b\mathcal{O}_v)^n, \qquad T_n(\ell^b) = \prod_{v\in S_\ell} (1 + \varpi_v^{be_v}\mathcal{O}_v)^n,$$

and $b \le be_v \le be_{\max}$ gives the inclusions; if all $e_v = 1$ the two groups coincide. The quotient is finite and filtered by the groups $(1 + \varpi_v^i\mathcal{O}_v)/(1 + \varpi_v^{i+1}\mathcal{O}_v) \cong \mathcal{O}_v/\varpi_v$ $(i \ge 1)$, of characteristic ℓ, so its order is a power of ℓ. Let $G_b = T_n(\mathfrak{l}^b)$, $H_b = T_n(\ell^b)$ and R a set of representatives of G_b/H_b. The open subgroups $N \subseteq H_b$ are cofinal among the open subgroups of G_b and normal (G_b is abelian); for each, $\mathcal{O}[G_b/N]$ is a free $\mathcal{O}[H_b/N]$-module with basis the image of R, compatibly with the transition maps. Finite direct sums commute with inverse limits, so $\Lambda_b^{\mathfrak{l}} = \varprojlim_N \mathcal{O}[G_b/N] = \bigoplus_{g\in R} g\,\Lambda_b$.

Step 2: (Qh2). By (Gy1), $\mathcal{S} \cong (\Lambda_{b_0}^{\mathfrak{l}})^m$, which is free of rank $m[G_{b_0} : H_{b_0}]$ over Λ_{b_0} by (Qh1). By (Gy2), $\mathbb{T}$ is commutative and finite over $\Lambda_{b_0}^{\mathfrak{l}}$, which is finite over Λ_{b_0} by (Qh1), and, if $\mathcal{S} \neq 0$, $\Lambda_{b_0}^{\mathfrak{l}} \to \mathbb{T}$ is injective; its restriction to the subring Λ_{b_0} (a direct summand, taking $1 \in R$) is the structure map of Λ_{b_0}, hence injective. In particular $\mathbb{T}$ is finite over $\Lambda_1 \supseteq \Lambda_{b_0}$.

Step 3: the extensions of α. The characters $w_0\nu$ and $w_0\lambda$ are defined on all of $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell)$ with values in $\mathcal{O}^\times$. Put $\chi = \alpha\,(w_0\nu)^{-1}(w_0\lambda)^{-1}$ on H and let $\psi\colon \Lambda_1 \to \overline{\mathbb{Q}}_\ell$ be the induced homomorphism, with kernel $\mathfrak{P}$; so $\mathcal{K}' = \mathrm{Frac}\,\psi(\Lambda_1) \subseteq \overline{\mathbb{Q}}_\ell$, and $\mathcal{K}'$ contains the values of α. Let X be the set of characters $\alpha'\colon G \to \overline{\mathbb{Q}}_\ell^\times$ with $\alpha'|_H = \alpha$. Each $\alpha' \in X$ is trivial on $N_r \subseteq \ker\alpha$, so it factors through the finite group G/N_r and has finite order. As $\overline{\mathbb{Q}}_\ell^\times$ is divisible, α (a character of H/N_r) extends to G/N_r, and the extensions form a principal homogeneous set under the character group of G/H, which has $[G : H]$ elements (G/H finite abelian, $\overline{\mathbb{Q}}_\ell$ algebraically closed of characteristic 0); so $|X| = [G : H]$. For $\alpha' \in X$ let $\chi_{\alpha'} = \alpha'(w_0\nu)^{-1}(w_0\lambda)^{-1}$ on G and $\psi_{\alpha'}\colon \Lambda_1^{\mathfrak{l}} \to \overline{\mathbb{Q}}_\ell$ the induced homomorphism; its kernel is $\mathfrak{P}_{\lambda,\alpha'}^{\mathfrak{l}}$ and $\psi_{\alpha'}|_{\Lambda_1} = \psi$, so $\mathfrak{P}_{\lambda,\alpha'}^{\mathfrak{l}}$ lies over $\mathfrak{P}$.

Step 4: the fibre of $\Lambda_1^{\mathfrak{l}}$ over $\mathfrak{P}$ splits. Let $L \subseteq \overline{\mathbb{Q}}_\ell$ be a finite extension of $\mathcal{K}'$ containing the values of every $\alpha' \in X$ (finitely many roots of unity), a Λ_1-algebra through ψ. Let R be a set of representatives of G/H. By (Qh1) ($b = 1$), $\psi_{\alpha'}(\Lambda_1^{\mathfrak{l}}) = \sum_{g\in R} \chi_{\alpha'}(g)\psi(\Lambda_1) \subseteq L$, and $\Lambda_1^{\mathfrak{l}} \otimes_{\Lambda_1} L$ has L-basis R. The homomorphism of L-algebras

$$\Phi\colon \Lambda_1^{\mathfrak{l}} \otimes_{\Lambda_1} L \to L^X, \qquad x \otimes c \mapsto \big(c\,\psi_{\alpha'}(x)\big)_{\alpha'\in X},$$

is an isomorphism: fixing $\alpha'_0 \in X$, every $\alpha' \in X$ is $\alpha'_0\theta$ with θ a character of G/H, so the matrix of Φ in the basis R is $\big(\theta(g)\big)_{\theta,g} \cdot \mathrm{diag}\big(\chi_{\alpha'_0}(g)\big)_{g\in R}$, a product of the character table of

G/H (invertible by the orthogonality relations) and an invertible diagonal matrix, and both sides have dimension $|X| = [G : H]$. Consequently

$$\mathbb{T} \otimes_{\Lambda_1} L \cong \mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}} (\Lambda_1^\mathfrak{t} \otimes_{\Lambda_1} L) \cong \prod_{\alpha' \in X} \mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}, \psi_{\alpha'}} L, \qquad (*)$$

the factor of α' being the quotient on which $\Lambda_1^\mathfrak{t}$ acts through $\psi_{\alpha'}$; and $\mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}, \psi_{\alpha'}} L = (\mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}} \mathcal{K}'_{\alpha'}) \otimes_{\mathcal{K}'_{\alpha'}} L$, where $\mathcal{K}'_{\alpha'} = \operatorname{Frac} \psi_{\alpha'}(\Lambda_1^\mathfrak{t}) = (\Lambda_1^\mathfrak{t})_{\mathfrak{P}'}/\mathfrak{P}'$, $\mathfrak{P}' = \mathfrak{P}^\mathfrak{t}_{\lambda,\alpha'}$.

Step 5: the forms split in the same way. Let $W = S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, L)$. For $u \in N_r$ the components of u at S_ℓ are diagonal and $\equiv 1$ modulo ϖ_v^r, so $u \in U(\ell^{r,r})$ and the operator $\langle u \rangle = [U(\ell^{r,r}) u U(\ell^{r,r})]$ of weight λ is $f \mapsto u \cdot f = f$ (the invariance defining $S_\lambda(U(\ell^{r,r}), L)$ in (Gk4)). The operators $\langle u \rangle$ commute with all operators of weight λ ([105], Lemma 2.3.3), so they preserve W, on which H acts through α. Thus W is a module over $A = L[G/N_r] \otimes_{L[H/N_r],\alpha} L$, and $A \cong L^X$ by $x \otimes c \mapsto (c\,\alpha'(x))_{\alpha'}$ (the argument of Step 4, with α' in place of $\chi_{\alpha'}$). Its primitive idempotents $e_{\alpha'}$ are L-linear combinations of the $\langle u \rangle$, and

$$W = \bigoplus_{\alpha' \in X} e_{\alpha'} W, \qquad e_{\alpha'} W = S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha', L).$$

As the $e_{\alpha'}$ lie in the commutative algebra $\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, L)$, restriction to the summands gives $\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, L) = \prod_{\alpha' \in X} \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha', L)$. By (Gy7)(c), $u \in G$, as an element of $\Lambda_1^\mathfrak{t}$ with the renormalised structure, acts on $S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha', L)$ by $(w_0\nu)^{-1}(u)(w_0\lambda)(u)^{-1}\alpha'(u) = \chi_{\alpha'}(u)$, i.e. $\Lambda_1^\mathfrak{t}$ acts through $\psi_{\alpha'}$; so the decomposition $(*)$ and this one correspond to each other.

Step 6: (Qh3) after extending scalars to L. For a field $M \supseteq \mathcal{O}$ containing the values of a character β of G or of H and an extension $L \supseteq M$, $S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \beta, L) = S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \beta, M) \otimes_M L$ (the forms are functions on a finite set with values in $M_\lambda \otimes M$, and the ordinary part and the β-part are cut out by operators defined over M), and $\mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \beta, L) = \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \beta, M) \otimes_M L$ (the L-span of the products of the operators). For $\alpha' \in X$, (Gy3) applies (α' of finite order, $N_r \subseteq \ker \alpha'$): $\mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}} \mathcal{K}'_{\alpha'} \to \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha', \mathcal{K}'_{\alpha'})$ is surjective with nilpotent kernel. Extending scalars to L is exact and keeps a nilpotent ideal nilpotent, so $\mathbb{T} \otimes_{\Lambda_1^\mathfrak{t}, \psi_{\alpha'}} L \to \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha', L)$ is surjective with nilpotent kernel. By $(*)$ and Step 5, the map $s_L \colon \mathbb{T} \otimes_{\Lambda_1} L \to \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, L)$ induced by the action is the product of these maps over X, hence surjective with nilpotent kernel.

Step 7: (Qh3). $(\Lambda_1)_\mathfrak{P}/\mathfrak{P} = \mathcal{K}'$, and Λ_1 acts on $S^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, \mathcal{K}')$ through ψ (by (Gy7)(c), $u \in H$ acts by $\chi(u)$), so the action induces $s \colon \mathbb{T} \otimes_{\Lambda_1} \mathcal{K}' \to \mathbb{T}^{\mathrm{ord}}_\lambda(U(\ell^{r,r}), \alpha, \mathcal{K}')$, and $s \otimes_{\mathcal{K}'} L = s_L$ by Step 6. Both sides are finite over $\mathcal{K}'$ (Step 2). As L is faithfully flat over $\mathcal{K}'$, s is surjective; $\mathbb{T} \otimes_{\Lambda_1} \mathcal{K}' \to \mathbb{T} \otimes_{\Lambda_1} L$ is injective and $\ker(s) \otimes L = \ker(s_L)$ is nilpotent, so every element of $\ker s$ is nilpotent; $\ker s$ is a finitely generated ideal of a commutative ring, hence nilpotent.

Step 8: (Qh4). By hypothesis every $\alpha' \in X$, hence also $\alpha = \alpha'|_H$, and so χ and every $\chi_{\alpha'}$, take values in $\mathcal{O}$. The image $\psi(\Lambda_1)$ is compact, contains $\mathcal{O}$ and lies in the closure of the $\mathcal{O}$-span of the values of χ; so $\psi(\Lambda_1) = \mathcal{O} = \psi_{\alpha'}(\Lambda_1^\mathfrak{t})$, $\Lambda_1/\mathfrak{P} = \mathcal{O}$, $\mathcal{K}' = \mathcal{K} = \mathcal{K}'_{\alpha'}$, and Steps 4 and 5 apply with $L = \mathcal{K}$. The isomorphism Φ (with $L = \mathcal{K}$) gives

$$\mathcal{S}_\mathfrak{P}/\mathfrak{P}\mathcal{S}_\mathfrak{P} = \mathcal{S} \otimes_{\Lambda_1} \mathcal{K} \cong \bigoplus_{\alpha' \in X} \mathcal{S} \otimes_{\Lambda_1^\mathfrak{t}, \psi_{\alpha'}} \mathcal{K} = \bigoplus_{\alpha' \in X} \mathcal{S}_{\mathfrak{P}'}/\mathfrak{P}'\mathcal{S}_{\mathfrak{P}'} \qquad (\mathfrak{P}' = \mathfrak{P}^\mathfrak{t}_{\lambda,\alpha'}),$$

a decomposition into summands stable under the $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ and the right translations g of (Gk3), all of which commute with the action of $\Lambda_1^\mathfrak{t}$ (for g: the diamond operators are right translations by elements supported at S_ℓ, where g is trivial). By (Gk3) for each α' (values in

$\mathcal{O}$, $N_r \subseteq \ker\alpha'$), the summand of α' is isomorphic to $\mathrm{Hom}_{\mathcal{K}}(S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}),\alpha',\mathcal{K}),\mathcal{K})$, compatibly with these operators as stated there. Summing over X and using $S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}),\alpha,\mathcal{K}) = \bigoplus_{\alpha'} S_\lambda^{\mathrm{ord}}(U(\ell^{r,r}),\alpha',\mathcal{K})$, a decomposition stable under the same operators (Step 5), gives the isomorphism of (Qh4) with its compatibilities. □

E.1.3 Points of ordinary Hecke algebras of a type

This subsection describes the points of the ordinary Hecke algebra of a type, from which the Hecke ideals of Subsection E.1.1 are cut out. Its points at classical weights come from automorphic representations whose components at St contain the dual type, and such eigenforms give points (Lemma E.11, Lemma E.14). It is a quotient of the full ordinary Hecke algebra (Lemma E.15), it is reduced (Lemma E.18), and it receives the universal determinant ring through a Galois determinant (Lemma E.16). At zero-monodromy type the Galois representations of regular points are level-free (Lemma E.17). The lemmas on ordinary forms at levels shrunk away from ℓ, projective over the weight algebra and free over the torsion diamonds (Lemma E.12, Lemma E.20, Lemma E.21), are the module-theoretic input of the Taylor–Wiles levels.

Lemma E.11. *Let $((V_v)_{v\in\mathrm{St}},\tau)$ be a type datum, and let Q and $K'=(K'_v)_{v\in Q}$ be a finite set of places and open subgroups as in the levels at auxiliary places of Definition 50.8. Here $Q=\varnothing$ is allowed; if $Q\neq\varnothing$, the type datum is over a rank-n Hecke datum. Let $V=V(K')$ be its level at K', $N=N_\tau(K')$, $\mathbb{T}=\mathbb{T}_\tau(K')$ (for $Q=\varnothing$: V, N_τ, $\mathbb{T}_\tau$) and $H=\prod_{v\in\mathrm{St}}\mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v$; let $\tau^\vee=\mathrm{Hom}_{\mathcal{O}}(\tau,\mathcal{O})$ with the contragredient action of H. Let E be the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ, $\mathfrak{l}$ and $T_n(\mathfrak{l})\supseteq T_n(\ell^1)$ as in Theorem B.91. Let λ be a dominant weight, $\alpha\colon T_n(\ell^1)\to\mathcal{O}^\times$ a character of finite order such that $\mathcal{O}$ contains the values of every character of $T_n(\mathfrak{l})$ whose restriction to $T_n(\ell^1)$ is α (no condition if ℓ is unramified in L^+), $r\geq 1$ with $T_n(\ell^r)\subseteq\ker\alpha$, and $y\colon\mathbb{T}\to\overline{\mathbb{Q}}_\ell$ a homomorphism of $\mathcal{O}$-algebras with $y(\mathfrak{P}_{\lambda,\alpha})=0$. If the type datum is over a rank-n Hecke datum, α may more generally be a character $T_n(\ell^1)\to\overline{\mathbb{Q}}_\ell^\times$ of finite order (with r as before and $\mathfrak{P}_{\lambda,\alpha}$ the kernel of the homomorphism $\Lambda_1\to\overline{\mathbb{Q}}_\ell$ induced by $\alpha\,(w_0\nu)^{-1}(w_0\lambda)^{-1}$, as in (Gy3)), provided y satisfies, besides $y(\mathfrak{P}_{\lambda,\alpha})=0$, $y(\langle u\rangle)=\alpha(u)\,(w_0\lambda)(u)^{-1}$ for all $u\in T_n(\ell^1)$. Then there are an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ and an embedding $\pi\subseteq S_\lambda(\overline{\mathbb{Q}}_\ell)$ such that:*

1. $\mathrm{Hom}_H\big(\tau^\vee\otimes_{\mathcal{O}}\overline{\mathbb{Q}}_\ell,\ \bigotimes_{v\in\mathrm{St}}\pi_v^{V_v}\big)\neq 0$;
2. *for every place $v\notin T_L\cup Q$ of L^+ split in L, π_v is unramified, and for every place $w\mid v$ of L the eigenvalue of $T_w^{(j)}$ on $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L_v^+})}$ is $y(T_w^{(j)})$;*
3. *there is a non-zero $f\in\pi\cap S_\lambda^{\mathrm{ord}}(V(\ell^{Er,Er}),\alpha,\overline{\mathbb{Q}}_\ell)$ on which the operators assigned by (Gy7)(c) to $T_w^{(j)}$, $U_{\tilde v}^{(j)}$ and $\langle u\rangle$ act by the scalars $y(T_w^{(j)})$, $y(U_{\tilde v}^{(j)})$, $y(\langle u\rangle)$.*

Proof. Put $r'=Er$; by (Qh1), $T_n(\mathfrak{l}^{r'})\subseteq T_n(\ell^r)\subseteq\ker\alpha$.

Step 0: reduction to coefficients containing the values of the extensions of α. If $\mathcal{O}$ contains the values of every character of $T_n(\mathfrak{l})$ extending α there is nothing to do. Otherwise the type datum is over a rank-n Hecke datum $\mathscr{H}$ over $\mathcal{O}$; let $\mathcal{O}''\supseteq\mathcal{O}$ be the ring of integers of a finite extension of $\mathcal{O}[1/\ell]$ in $\overline{\mathbb{Q}}_\ell$ containing the values of every character of $T_n(\mathfrak{l})$ extending α (finitely many roots of unity: they are characters of $T_n(\mathfrak{l})/T_n(\mathfrak{l}^{r'})$), free of finite rank over $\mathcal{O}$. By Lemma E.13, $\mathscr{H}''$ (the datum with coefficients $\mathcal{O}''$) is a rank-n Hecke datum, $((V_v),\tau''=\tau\otimes_{\mathcal{O}}\mathcal{O}'')$ a type datum over it, and $N''=N\otimes_{\mathcal{O}}\mathcal{O}''$, $\mathbb{T}''=\mathbb{T}\otimes_{\mathcal{O}}\mathcal{O}''$, $\Lambda_1''=\Lambda_1\otimes_{\mathcal{O}}\mathcal{O}''$, compatibly with the

operators and with H. Let $y'' = y \otimes (\mathcal{O}'' \subseteq \overline{\mathbb{Q}}_\ell)\colon \mathbb{T}'' \to \overline{\mathbb{Q}}_\ell$ and χ the homomorphism $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$ induced by $\alpha(w_0\nu)^{-1}(w_0\lambda)^{-1}$, with image $R_0 \cong \Lambda_1/\mathfrak{P}_{\lambda,\alpha}$. As y kills $\mathfrak{P}_{\lambda,\alpha}$, $y|_{\Lambda_1} = \sigma \circ \chi$ for a homomorphism of $\mathcal{O}$-algebras $\sigma\colon R_0 \to \overline{\mathbb{Q}}_\ell$; by the second hypothesis on y, σ is the identity on the generators $\chi(u)$ of R_0, so $y|_{\Lambda_1} = \chi$. Hence $y''|_{\Lambda_1''} = \chi \otimes \mathrm{id}$ is the homomorphism induced by the same character on Λ_1'', and y'' kills its kernel $\mathfrak{P}''_{\lambda,\alpha}$. The case of values in the coefficient ring, applied to $\mathscr{H}''$, $((V_v), \tau'')$ and y'', gives π with (i)–(iii) for y''; these are (i)–(iii) for y, since $\tau''^\vee \otimes_{\mathcal{O}''} \overline{\mathbb{Q}}_\ell = \tau^\vee \otimes_{\mathcal{O}} \overline{\mathbb{Q}}_\ell$, $y''(t \otimes 1) = y(t)$, and $S_\lambda(\overline{\mathbb{Q}}_\ell)$ and $S^{\mathrm{ord}}_\lambda(V(\ell^{r',r'}), \alpha, \overline{\mathbb{Q}}_\ell)$ do not depend on the coefficient ring. We assume from now on that $\mathcal{O}$ contains the values of every character of $T_n(\mathfrak{l})$ extending α, in particular those of α. Write $\Lambda = \Lambda_1$ with the renormalised structure, $\mathfrak{P} = \mathfrak{P}_{\lambda,\alpha}$, $\mathcal{K} = \mathcal{O}[1/\ell]$, and $W = S^{\mathrm{ord}}_\lambda(V(\ell^{r',r'}), \alpha, \mathcal{K})$.

Step 1: the setting of Lemma E.12. Let $U \supseteq V$ be the group with $U_v = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ for $v \in \mathrm{St}$ and $U_v = V_v$ otherwise. Then U is as in Theorem B.91 ($F = L$, $T = T_L \cup Q$, all of whose places split in L), V_v is open normal in U_v for every v and equal to it for $v \in S_\ell$ and $v \notin T_L \cup Q$, and $U/V = H$; take $G_1 = H$, $G_2 = 1$, $b_0 = 1$: $U(\ell^{1,1})$ is sufficiently small, as its component at v_0 is the kernel of reduction modulo p of $\mathbb{G}_L(\mathcal{O}_{L_{v_0}^+}) \cong \mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}_0}})$, p odd and unramified in L (Definition 50.8), which contains no non-trivial element of finite order . Here $\mathcal{S}' = \mathcal{S}_V$. By (Yp2) $\mathcal{S}_V$ is a direct summand of $\Lambda[H]^m$ for some m, and by (Yp3) $N = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_V)$ is free of finite rank over Λ (for the diamond structure, hence for the renormalised one, which differs by an automorphism of Λ).

Step 2: the fibre of N at $\mathfrak{P}$. Let $\Lambda \to A$ be a homomorphism to a commutative ring. For $\Lambda[H]$ itself, $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, \Lambda[H]) \otimes_\Lambda A \cong \Lambda \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O}) \otimes_\Lambda A \cong \mathrm{Hom}_{\mathcal{O}[H]}(\tau, A[H])$, by the isomorphism $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R \otimes_{\mathcal{O}} \mathcal{O}[H]) \cong R \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O})$ for every $\mathcal{O}$-algebra R, given by $f \mapsto \epsilon \circ f$ with $\epsilon\colon R \otimes \mathcal{O}[H] \to R$ the coefficient of 1, with inverse $\varphi \mapsto (t \mapsto \sum_{h \in H} \varphi(h^{-1}t)\, h)$ (a direct check; τ is finite free over $\mathcal{O}$ and $\mathcal{O}[H]$ is free over $\mathcal{O}$ with basis H). Both sides are additive, so the natural map $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_V) \otimes_\Lambda A \to \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_V \otimes_\Lambda A)$ is an isomorphism for the direct summand $\mathcal{S}_V$ of $\Lambda[H]^m$. Take $A = \Lambda_{\mathfrak{P}}/\mathfrak{P}\Lambda_{\mathfrak{P}} = \mathcal{K}$ ($\Lambda/\mathfrak{P} = \mathcal{O}$). By (Qh4) for $U = V$, $b_0 = 1$ and the level r' (applicable: $T_n(\mathfrak{l}^{r'}) \subseteq \ker \alpha$, $\mathcal{O}$ contains the values of the extensions of α, V is as in Theorem B.91, and, for the equivariance of (Gk3), the elements of $\prod_{v \in \mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})$ have trivial components at S_ℓ and normalise every $V(\ell^{c,c})$), $\mathcal{S}_V \otimes_\Lambda \mathcal{K} \cong W^* := \mathrm{Hom}_{\mathcal{K}}(W, \mathcal{K})$, compatibly with H and with the Hecke operators (acting on W^* by the transposes of the operators of (Gy7)(c)). Hence

$$N_{\mathfrak{P}}/\mathfrak{P}N_{\mathfrak{P}} \cong \mathrm{Hom}_{\mathcal{K}[H]}(\tau \otimes_{\mathcal{O}} \mathcal{K}, W^*),$$

compatibly with the action of $\mathbb{T}^{\mathrm{ord}}(V)$.

Step 3: y is an eigensystem on this fibre. $\mathbb{T}$ acts faithfully on N, which is free of rank d over Λ; localisation is exact, so $\mathbb{T}_{\mathfrak{P}} = \mathbb{T} \otimes_\Lambda \Lambda_{\mathfrak{P}}$ acts faithfully on $N_{\mathfrak{P}}$. If $t \in \mathbb{T}_{\mathfrak{P}}$ acts by 0 on $N_{\mathfrak{P}}/\mathfrak{P}N_{\mathfrak{P}}$, its matrix in a $\Lambda_{\mathfrak{P}}$-basis has entries in $\mathfrak{P}\Lambda_{\mathfrak{P}}$, so its characteristic polynomial is $X^d + \sum_{i<d} c_i X^i$ with $c_i \in \mathfrak{P}\Lambda_{\mathfrak{P}}$, and by Cayley–Hamilton $t^d \in \mathfrak{P}\mathbb{T}_{\mathfrak{P}}$. So the kernel of $\mathbb{T}_{\mathfrak{P}}/\mathfrak{P}\mathbb{T}_{\mathfrak{P}} \to \mathrm{End}_{\mathcal{K}}(N_{\mathfrak{P}}/\mathfrak{P}N_{\mathfrak{P}})$ is nil. The restriction of y to Λ has kernel exactly $\mathfrak{P}$ (it factors through $\Lambda/\mathfrak{P} = \mathcal{O} \subseteq \overline{\mathbb{Q}}_\ell$), so y extends to $\mathbb{T}_{\mathfrak{P}}$, kills $\mathfrak{P}\mathbb{T}_{\mathfrak{P}}$ and every nilpotent element, and so factors through the image $\mathcal{A}$ of $\mathbb{T}_{\mathfrak{P}}$ in $\mathrm{End}_{\mathcal{K}}(N_{\mathfrak{P}}/\mathfrak{P}N_{\mathfrak{P}})$, a finite commutative $\mathcal{K}$-algebra. Let $X = (N_{\mathfrak{P}}/\mathfrak{P}N_{\mathfrak{P}}) \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell$, on which $\mathcal{A} \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell$ acts faithfully; X is the direct sum of the generalised eigenspaces of $\mathcal{A} \otimes \overline{\mathbb{Q}}_\ell$ for its characters, each non-zero; the character induced by y is one of them, so there is $0 \neq \xi \in X$ with $t\xi = y(t)\xi$ for all $t \in \mathbb{T}^{\mathrm{ord}}(V)$.

Step 4: the automorphic representation. By Step 2, ξ is a non-zero H-map $\tau \otimes \overline{\mathbb{Q}}_\ell \to W^*_{\overline{\mathbb{Q}}_\ell}$, $W_{\overline{\mathbb{Q}}_\ell} = W \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell = S^{\mathrm{ord}}_\lambda(V(\ell^{r',r'}), \alpha, \overline{\mathbb{Q}}_\ell)$, with image in the subspace of $W^*_{\overline{\mathbb{Q}}_\ell}$ on which every t acts (by transpose) as $y(t)$. Let $W_y \subseteq W_{\overline{\mathbb{Q}}_\ell}$ be the joint generalised eigenspace of the commuting operators of (Gy7)(c) for the eigenvalues $y(t)$; $W_{\overline{\mathbb{Q}}_\ell} = W_y \oplus W'$ with W' the sum of the other

generalised eigenspaces, both H-stable (H commutes with the Hecke operators, (Yp1)), and the y-eigenvectors of the transposes vanish on W'. So $\mathrm{Hom}_H(\tau\otimes\overline{\mathbb{Q}}_\ell, W_y^*)\neq 0$, and as H is finite and $\overline{\mathbb{Q}}_\ell$ has characteristic 0, $\mathrm{Hom}_H(\tau\otimes\overline{\mathbb{Q}}_\ell, W_y^*)\cong \mathrm{Hom}_H(W_y, (\tau\otimes\overline{\mathbb{Q}}_\ell)^*)$, so W_y has an irreducible H-constituent occurring in $\tau^\vee\otimes\overline{\mathbb{Q}}_\ell$. The space $S_\lambda(\overline{\mathbb{Q}}_\ell)$ is a semisimple admissible $\mathbb{G}_L(\mathbb{A}_{L^+}^\infty)$-module ([105], §2.2), the sum of its isotypic components $S_\lambda[\pi]$; $W_{\overline{\mathbb{Q}}_\ell}$ and W_y are cut out of the $V(\ell^{r',r'})$-invariants by Hecke operators (the ordinary idempotent, the projection to the α-part, generalised eigenprojections), which preserve each $S_\lambda[\pi]^{V(\ell^{r',r'})}$, as does H. So $W_y=\bigoplus_\pi(W_y\cap S_\lambda[\pi])$, and some π has $W_y\cap S_\lambda[\pi]\neq 0$ with an H-constituent occurring in $\tau^\vee\otimes\overline{\mathbb{Q}}_\ell$. As an H-module $S_\lambda[\pi]^{V(\ell^{r',r'})}$ is a sum of copies of $\bigotimes_{v\in\mathrm{St}}\pi_v^{V_v}$, which gives (i). On $S_\lambda[\pi]^{V(\ell^{r',r'})}\cong \pi^{V(\ell^{r',r'})}\otimes_{\overline{\mathbb{Q}}_\ell}\overline{\mathbb{Q}}_\ell^{m_\pi}$ (m_π the multiplicity of π) the operators act through π, so $W_y\cap S_\lambda[\pi]$ contains a joint eigenvector f for the commuting operators with the eigenvalues $y(t)$, which may be taken in one copy of π; this is (iii). For $v\notin T_L\cup Q$ split, $V_v=\mathbb{G}_L(\mathcal{O}_{L_v^+})$ and $\pi^{V(\ell^{r',r'})}\neq 0$, so π_v is unramified, its spherical line is $\pi_v^{V_v}$, and $T_w^{(j)}$ (assigned to itself by (Gy7)(c)) acts on it by the eigenvalue $y(T_w^{(j)})$ of f: (ii). □

Lemma E.12. *Let ℓ, n, F, F^+, $\mathcal{O}$, $\mathbb{G}$, T be as in Theorem B.91, and let $U=\prod_v U_v\supseteq U'=\prod_v U_v'$ be compact open subgroups of $\mathbb{G}(\mathbb{A}_{F^+}^\infty)$ such that U is as in Theorem B.91, U_v' is an open normal subgroup of U_v for every v, and $U_v'=U_v$ for every $v\in S_\ell$ and every $v\notin T$. Put $\Gamma=U/U'$ and suppose $\Gamma=G_1\times G_2$ for subgroups G_1, G_2. Let $b_0\geq 1$ be such that $U(\ell^{b_0,b_0})$ is sufficiently small, $\Lambda=\Lambda_{b_0}$, and let $\mathcal{S}'$, resp. $\mathcal{S}$, be the Pontryagin dual of $S^{\mathrm{ord}}(U'(\ell^\infty),\mathcal{K}/\mathcal{O})$, resp. $S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})$, with Λ^+ acting through the diamond operators and Γ acting on $\mathcal{S}'$ dually to right translation. Then:*

(Yp1) *U' is as in Theorem B.91; the action of Γ on $\mathcal{S}'$ is well defined and commutes with Λ^+ and with the operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ (w above a place $v\notin T$ split in F) and $U_{\tilde{v}}^{(j)}$ ($v\in S_\ell$);*

(Yp2) *$\mathcal{S}'$ is a finitely generated projective $\Lambda[\Gamma]$-module;*

(Yp3) *for every finite free $\mathcal{O}$-module τ with an $\mathcal{O}$-linear action of G_1, $\mathrm{Hom}_{\mathcal{O}[G_1]}(\tau,\mathcal{S}')$ is a finitely generated projective $\Lambda[G_2]$-module, and a free one if G_2 is an ℓ-group (for instance trivial);*

(Yp4) *the dual of the inclusion $S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})\subseteq S^{\mathrm{ord}}(U'(\ell^\infty),\mathcal{K}/\mathcal{O})$ induces an isomorphism of Λ^+-modules $\mathcal{S}'_\Gamma\to\mathcal{S}$ from the Γ-coinvariants, compatible with the operators of (Yp1).*

Proof. Write $\mathbb{F}$ for the residue field of $\mathcal{O}$, ϖ for a uniformiser, $\mathfrak{m}_\Lambda$ for the maximal ideal of Λ; for $v\in S_\ell$ let ϖ_v be a uniformiser of $\mathcal{O}_{F_v^+}$; let $\Lambda^{\mathfrak{l}}=\Lambda_{b_0}^{\mathfrak{l}}$, which contains Λ by (Qh1), $\mathfrak{a}\subseteq\Lambda^{\mathfrak{l}}$ its augmentation ideal (the kernel of $\Lambda^{\mathfrak{l}}\to\mathcal{O}$, $[u]\mapsto 1$) and $\mathfrak{m}=\mathfrak{a}+\varpi\Lambda^{\mathfrak{l}}$, the maximal ideal of the noetherian complete local ring $\Lambda^{\mathfrak{l}}$ (by the Chinese remainder theorem $T_n(\mathfrak{l}^{b_0})=\prod_{v\in S_\ell}(1+\varpi_v^{b_0}\mathcal{O}_{F_v^+})^n$, a finitely generated abelian pro-ℓ group); and for an $\mathcal{O}$-module A and $1\leq b\leq c$ put $U'(\ell^{b,c})=\prod_{v\notin S_\ell}U_v'\times\prod_{v\in S_\ell}U(\ell^{b,c})_v$.

Step 1: (Yp1) and the levels. $U_v'=U_v$ is $\mathbb{G}(\mathcal{O}_{F_v^+})$ for $v\in S_\ell$ and for $v\notin T$ split in F, so U' is as in Theorem B.91, and $U'(\ell^{b,c})$ is the group $U'(\ell^{b,c})$ defined there. As the components of U and U' agree at S_ℓ and U_v' is normal in U_v, $U'(\ell^{b,c})$ is normal in $U(\ell^{b,c})$ and the inclusion $\prod_{v\notin S_\ell}U_v\to U(\ell^{b,c})$ induces an isomorphism $\Gamma\to U(\ell^{b,c})/U'(\ell^{b,c})$ for all $b\leq c$. Hence for $f\in S(U'(\ell^{b,c}),A)$ and $g\in\prod_{v\notin S_\ell}U_v$ the function $x\mapsto f(xg)$ is again right $U'(\ell^{b,c})$-invariant and depends only on gU'; this is the action of Γ, compatible with the inclusions between levels. The

operators $\langle u\rangle$ and $U_{\tilde v}^{(j)}$ are double coset operators supported at the places of S_ℓ, and $T_w^{(j)}$ at a place $v\notin T$; since Γ acts through the components at the places of $T\setminus S_\ell$, they commute with it. So the ordinary idempotent e (the limit of $P^{m!}$, P the product of the $U_{\tilde v}^{(j)}$, on each finite level) commutes with Γ, and Γ acts on $S^{\mathrm{ord}}(U'(\ell^\infty),\mathcal{K}/\mathcal{O})=\varinjlim_c S^{\mathrm{ord}}(U'(\ell^{c,c}),\mathcal{K}/\mathcal{O})$ and dually on $\mathcal{S}'$, commuting with the operators listed. This is (Yp1).

Step 2: the fibre of $\mathcal{S}'$ at the augmentation ideal. Let $M=S^{\mathrm{ord}}(U'(\ell^\infty),\mathcal{K}/\mathcal{O})$, so $\mathcal{S}'=M^\vee$. The diamond operator $\langle u\rangle$, $u\in T_n(\mathfrak{l}^{b_0})$, acts on $S(U'(\ell^{c,c}),A)$ by right translation by u in the components at S_ℓ (u normalises $U'(\ell^{c,c})$). The group $\mathrm{Iw}(\tilde v^{b,c})$ consists of the matrices of $\mathrm{GL}_n(\mathcal{O}_{F_v^+})$ that are upper triangular modulo ϖ_v^c and unipotent modulo ϖ_v^b ([105], §2.1); reduction of the diagonal modulo ϖ_v^c is a homomorphism $\mathrm{Iw}(\tilde v^{0,c})\to T_n(\mathcal{O}_{F_v^+}/\varpi_v^c)$ with kernel $\mathrm{Iw}(\tilde v^{c,c})$, and $\mathrm{Iw}(\tilde v^{b_0,c})$ is the preimage of the image of $(1+\varpi_v^{b_0}\mathcal{O}_{F_v^+})^n$. As the components of U' at S_ℓ are those of U, $U'(\ell^{b_0,c})=U'(\ell^{c,c})\,T_n(\mathfrak{l}^{b_0})$. Since e commutes with the diamond operators ([105], Lemma 2.3.3), the $T_n(\mathfrak{l}^{b_0})$-invariants of $S^{\mathrm{ord}}(U'(\ell^{c,c}),\mathcal{K}/\mathcal{O})$ are $S^{\mathrm{ord}}(U'(\ell^{b_0,c}),\mathcal{K}/\mathcal{O})$, which is $S^{\mathrm{ord}}(U'(\ell^{b_0,b_0}),\mathcal{K}/\mathcal{O})$ by (Gk2) for U'. Taking the union over c, $M^{T_n(\mathfrak{l}^{b_0})}=S^{\mathrm{ord}}(U'(\ell^{b_0,b_0}),\mathcal{K}/\mathcal{O})$. Let $u_1,\dots,u_k$ generate $T_n(\mathfrak{l}^{b_0})$ topologically. The ideal J of $\Lambda^{\mathfrak{l}}$ generated by the $[u_i]-1$ is $\mathfrak{a}$.

If $m\in M$ is killed by the $[u_i]-1$, its stabiliser in $T_n(\mathfrak{l}^{b_0})$ is a subgroup that is open (m has a finite level $U'(\ell^{c,c})$, so it is fixed by $T_n(\mathfrak{l}^c)$), hence closed, and contains the u_i, so it is all of $T_n(\mathfrak{l}^{b_0})$; so $M[\mathfrak{a}]=M^{T_n(\mathfrak{l}^{b_0})}=S^{\mathrm{ord}}(U'(\ell^{b_0,b_0}),\mathcal{K}/\mathcal{O})$. The set $X=\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+}^\infty)/U'(\ell^{b_0,b_0})$ is finite ($\mathbb{G}(F^+\otimes\mathbb{R})$ is compact), so $S(U'(\ell^{b_0,b_0}),A)=\mathcal{O}^X\otimes_{\mathcal{O}}A$, with e acting as $e\otimes 1$; hence $M[\mathfrak{a}]=L\otimes_{\mathcal{O}}\mathcal{K}/\mathcal{O}$ with $L=S^{\mathrm{ord}}(U'(\ell^{b_0,b_0}),\mathcal{O})=e\,\mathcal{O}^X$, a finite free $\mathcal{O}$-module. As $\mathfrak{a}$ is finitely generated, $M[\mathfrak{a}]$ is the kernel of a map $M\to M^k$, and duality gives

$$\mathcal{S}'/\mathfrak{a}\mathcal{S}'\cong(M[\mathfrak{a}])^\vee\cong\mathrm{Hom}_{\mathcal{O}}(L,\mathcal{O})=:D,$$

Γ-equivariantly (Γ acting on D contragrediently).

Step 3: D is projective over $\mathcal{O}[\Gamma]$. $U(\ell^{b_0,b_0})$ is sufficiently small, its components at S_ℓ lie in $\mathbb{G}(\mathcal{O}_{F_v^+})$, and $U'(\ell^{b_0,b_0})$ is an open normal subgroup with quotient Γ (Step 1). By (Gk1), $\mathcal{O}^X=S(U'(\ell^{b_0,b_0}),\mathcal{O})$ is a finite free $\mathcal{O}[\Gamma]$-module, and $L=e\,\mathcal{O}^X$ is a direct summand as e commutes with Γ; so L is finitely generated projective over $\mathcal{O}[\Gamma]$. The $\mathcal{O}$-dual of $\mathcal{O}[\Gamma]$ with the contragredient action is isomorphic to $\mathcal{O}[\Gamma]$ (the dual basis (δ_g) is permuted simply transitively), and $\mathrm{Hom}_{\mathcal{O}}(-,\mathcal{O})$ preserves finite direct sums and summands; so D is finitely generated projective over $\mathcal{O}[\Gamma]$, and $D/\varpi D$ over $\mathbb{F}[\Gamma]$.

Step 4: (Yp2). By (Gy1) applied to U' ($U'(\ell^{b_0,b_0})\subseteq U(\ell^{b_0,b_0})$ is sufficiently small), $\mathcal{S}'$ is a free $\Lambda^{\mathfrak{l}}$-module of finite rank. Let $R^{\mathfrak{l}}=\Lambda^{\mathfrak{l}}[\Gamma]$, a free $\Lambda^{\mathfrak{l}}$-module of finite rank with $R^{\mathfrak{l}}/\mathfrak{m}R^{\mathfrak{l}}=\mathbb{F}[\Gamma]$; the actions of $\Lambda^{\mathfrak{l}}\subseteq\Lambda^+$ and of Γ on $\mathcal{S}'$ commute (Step 1), so $\mathcal{S}'$ is an $R^{\mathfrak{l}}$-module. Since $\mathfrak{m}=\mathfrak{a}+\varpi\Lambda^{\mathfrak{l}}$, Step 2 gives $\mathcal{S}'/\mathfrak{m}\mathcal{S}'\cong D/\varpi D$, a finitely generated projective $\mathbb{F}[\Gamma]$-module: $D/\varpi D\cong\mathbb{F}[\Gamma]^r\varepsilon_0$ for some r and an idempotent matrix $\varepsilon_0\in\mathrm{M}_r(\mathbb{F}[\Gamma])$ (acting on row vectors). The ring $\mathrm{M}_r(R^{\mathfrak{l}})$ is complete for the topology of the two-sided ideal $\mathrm{M}_r(\mathfrak{m}R^{\mathfrak{l}})$ ($R^{\mathfrak{l}}$ is finite over the $\mathfrak{m}$-adically complete ring $\Lambda^{\mathfrak{l}}$), so ε_0 lifts to an idempotent $\varepsilon\in\mathrm{M}_r(R^{\mathfrak{l}})$ (lifting of idempotents modulo an ideal for which the ring is complete). Then $P=(R^{\mathfrak{l}})^r\varepsilon$ is a finitely generated projective $R^{\mathfrak{l}}$-module with an isomorphism $P/\mathfrak{m}P\cong\mathcal{S}'/\mathfrak{m}\mathcal{S}'$, and as P is projective the composite $P\to P/\mathfrak{m}P\cong\mathcal{S}'/\mathfrak{m}\mathcal{S}'$ lifts to an $R^{\mathfrak{l}}$-linear $\phi\colon P\to\mathcal{S}'$. Its image I satisfies $I+\mathfrak{m}\mathcal{S}'=\mathcal{S}'$, so ϕ is surjective by Nakayama's lemma over $\Lambda^{\mathfrak{l}}$ ($\mathcal{S}'$ is finitely generated over $\Lambda^{\mathfrak{l}}$). Let $K=\ker\phi$. Since $\mathcal{S}'$ is $\Lambda^{\mathfrak{l}}$-free, $\mathrm{Tor}_1^{\Lambda^{\mathfrak{l}}}(\mathcal{S}',\mathbb{F})=0$, so $0\to K/\mathfrak{m}K\to P/\mathfrak{m}P\to\mathcal{S}'/\mathfrak{m}\mathcal{S}'\to 0$ is exact; the last map is the chosen isomorphism, so $K/\mathfrak{m}K=0$, and K, a submodule of the finitely generated module P over the noetherian ring $\Lambda^{\mathfrak{l}}$, is finitely generated, hence $K=0$. So $\mathcal{S}'\cong P$ is finitely generated projective over $R^{\mathfrak{l}}$. Finally let $R=\Lambda[\Gamma]$. By (Qh1), $\Lambda^{\mathfrak{l}}$ is a free Λ-module of finite rank $[T_n(\mathfrak{l}^{b_0}):T_n(\ell^{b_0})]$, so $R^{\mathfrak{l}}=\Lambda^{\mathfrak{l}}\otimes_\Lambda R$ is a free R-module of the same rank. $\mathcal{S}'$ is a direct

summand of some $(R^{\mathfrak{l}})^{m'}$ as an $R^{\mathfrak{l}}$-module, hence as an R-module, so it is a direct summand of a free R-module of finite rank: $\mathcal{S}'$ is finitely generated projective over $R = \Lambda[\Gamma]$. This is (Yp2).

Step 5: (Yp3). Write $R = \Lambda[G_2] \otimes_{\mathcal{O}} \mathcal{O}[G_1]$, with $\Lambda[G_2]$ acting on the first factor and G_1 by left multiplication on the second; the two actions commute. As $\Lambda[G_2]$ is flat over $\mathcal{O}$ and τ is finitely presented over $\mathcal{O}[G_1]$,

$$\mathrm{Hom}_{\mathcal{O}[G_1]}(\tau, R) \cong \Lambda[G_2] \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}[G_1]}(\tau, \mathcal{O}[G_1]) \cong \Lambda[G_2] \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O}),$$

the second isomorphism being $f \mapsto \epsilon \circ f$ with ϵ the coefficient of 1, with inverse $\varphi \mapsto (t \mapsto \sum_{g \in G_1} \varphi(g^{-1}t)\, g)$. So $\mathrm{Hom}_{\mathcal{O}[G_1]}(\tau, R)$ is a free $\Lambda[G_2]$-module of finite rank. By Step 4, $\mathcal{S}'$ is a direct summand of R^m for some m, as R-modules, so $\mathrm{Hom}_{\mathcal{O}[G_1]}(\tau, \mathcal{S}')$ is a direct summand of $\mathrm{Hom}_{\mathcal{O}[G_1]}(\tau, R)^m$ as $\Lambda[G_2]$-modules: finitely generated projective. If G_2 is an ℓ-group, $\Lambda[G_2]$ is a local ring: it is finite over the complete local ring Λ, so each of its maximal ideals contains $\mathfrak{m}_\Lambda \Lambda[G_2]$, and $\mathbb{F}[G_2]$ is local ($\mathbb{F}$ has characteristic ℓ); a finitely generated projective module over a local ring is free.

Step 6: (Yp4). For every c, a function in $S(U'(\ell^{c,c}), \mathcal{K}/\mathcal{O})$ is right $U(\ell^{c,c})$-invariant if and only if it is Γ-invariant (Step 1), so $S(U(\ell^{c,c}), \mathcal{K}/\mathcal{O}) = S(U'(\ell^{c,c}), \mathcal{K}/\mathcal{O})^\Gamma$, and the same holds for the ordinary parts since e commutes with Γ and the two idempotents agree on $S(U(\ell^{c,c}), \mathcal{K}/\mathcal{O})$ (the $U_{\tilde{v}}^{(j)}$ act there by the same double cosets). Invariants of the finite group Γ commute with filtered direct limits, so $S^{\mathrm{ord}}(U(\ell^\infty), \mathcal{K}/\mathcal{O}) = M^\Gamma$. Dualising the exact sequence $0 \to M^\Gamma \to M \to \prod_{g \in \Gamma} M$, $m \mapsto (gm - m)_g$, gives $(M^\Gamma)^\vee = \mathcal{S}'/\sum_g (g-1)\mathcal{S}' = \mathcal{S}'_\Gamma$, the isomorphism being induced by the dual of the inclusion. It is Λ^+-linear and commutes with the operators of (Yp1), which commute with Γ and preserve M^Γ. □

Lemma E.13. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $((V_v)_{v \in \mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$, Q, K' as in the levels at auxiliary places ($Q = \varnothing$ allowed), and $\mathcal{O}'' \supseteq \mathcal{O}$ the ring of integers of a finite extension of $\mathcal{O}[1/\ell]$ in $\overline{\mathbb{Q}}_\ell$. Let $\mathscr{H}''$ be $\mathscr{H}$ with the residual characters composed with $\mathbb{F}_{\mathcal{O}} \subseteq \mathbb{F}_{\mathcal{O}''}$ and the wild values composed with $\mathcal{O}^\times \subseteq \mathcal{O}''^\times$, and $\tau'' = \tau \otimes_{\mathcal{O}} \mathcal{O}''$. Then $\mathscr{H}''$ is a rank-n Hecke datum over $\mathcal{O}''$, $((V_v), \tau'')$ is a type datum over it with the same group H and the same levels, and, writing $''$ for the objects over $\mathcal{O}''$, there are isomorphisms*

$$\mathcal{S}''_{V(K')} \cong \mathcal{S}_{V(K')} \otimes_{\mathcal{O}} \mathcal{O}'', \qquad N''_{\tau''}(K') \cong N_\tau(K') \otimes_{\mathcal{O}} \mathcal{O}'',$$
$$\mathbb{T}''_{\tau''}(K') \cong \mathbb{T}_\tau(K') \otimes_{\mathcal{O}} \mathcal{O}'', \qquad \Lambda''_1 = \Lambda_1 \otimes_{\mathcal{O}} \mathcal{O}'',$$

compatible with the action of H and carrying each operator $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ to the operator of the same name tensored with $\mathcal{O}''$.

Proof. $\mathcal{O}''$ is a finitely generated torsion-free module over the discrete valuation ring $\mathcal{O}$, hence free of finite rank d; so $- \otimes_{\mathcal{O}} \mathcal{O}''$ is exact and commutes with $\mathrm{Hom}_{\mathcal{O}}$ out of any module into a finite direct sum.

The datum. Of the conditions of Definition 50.1 only (Rd1) and (Rd6) involve the coefficient ring: $\tau(\mathcal{O}_L) \subseteq \mathcal{O} \subseteq \mathcal{O}''$, and the reduction of χ_{cyc} modulo $\mathfrak{m}_{\mathcal{O}''}$ is that modulo $\mathfrak{m}_{\mathcal{O}}$ followed by the injection $\mathbb{F}_{\mathcal{O}} \to \mathbb{F}_{\mathcal{O}''}$, so it is non-trivial on $D_{\bar{v}_0} \cap G_L$; (Rd10) holds as the wild values are unchanged as elements. A type datum is a family of open normal subgroups and a finite free module with an action of H; τ'' is finite free over $\mathcal{O}''$ with the induced action.

The forms. For an $\mathcal{O}$-module M and a compact open U', $S(U', M)$ is additive in M, so the natural map $S(U', M) \otimes_{\mathcal{O}} \mathcal{O}'' \to S(U', M \otimes_{\mathcal{O}} \mathcal{O}'')$ is an isomorphism (through $\mathcal{O}'' \cong \mathcal{O}^d$), compatible with right translations and hence with the Hecke and diamond operators, the operators $U_{\tilde{v}}^{(j)}$ and H; the ordinary parts correspond, being images of an idempotent which is a limit

of polynomials in these operators. Take $M = \mathcal{K}/\mathcal{O}$, for which $M \otimes_{\mathcal{O}} \mathcal{O}'' = \mathcal{K}''/\mathcal{O}''$, and pass to the direct limit over the levels $V(K')(\ell^{c,c})$: the ordinary forms X'' of level $V(K')(\ell^\infty)$ with coefficients in $\mathcal{K}''/\mathcal{O}''$ are $X \otimes_{\mathcal{O}} \mathcal{O}''$, X those with coefficients in $\mathcal{K}/\mathcal{O}$. Their Pontryagin dual over $\mathcal{O}''$ is

$$\mathrm{Hom}_{\mathcal{O}''}(X \otimes_{\mathcal{O}} \mathcal{O}'', \mathcal{K}''/\mathcal{O}'') \cong \mathrm{Hom}_{\mathcal{O}}(X, (\mathcal{K}/\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}'') \cong \mathrm{Hom}_{\mathcal{O}}(X, \mathcal{K}/\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}''$$

(adjunction; then $(\mathcal{K}/\mathcal{O}) \otimes_{\mathcal{O}} \mathcal{O}'' \cong (\mathcal{K}/\mathcal{O})^d$), i.e. $\mathcal{S}_{V(K')} \otimes_{\mathcal{O}} \mathcal{O}''$, with the dual operators. Likewise $\Lambda_1'' = \mathcal{O}''[[T_n(\ell^1)]] = \Lambda_1 \otimes_{\mathcal{O}} \mathcal{O}''$ and $\Lambda''^+ = \Lambda^+ \otimes_{\mathcal{O}} \mathcal{O}''$ ($\mathcal{O}''$ finite free), acting through the diamond operators.

N and $\mathbb{T}$. $N''_{\tau''}(K') = \mathrm{Hom}_{\mathcal{O}''[H]}(\tau \otimes_{\mathcal{O}} \mathcal{O}'', \mathcal{S}_{V(K')} \otimes_{\mathcal{O}} \mathcal{O}'') = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}_{V(K')} \otimes_{\mathcal{O}} \mathcal{O}'') = N_\tau(K') \otimes_{\mathcal{O}} \mathcal{O}''$ (adjunction; $\mathcal{S}_{V(K')} \otimes_{\mathcal{O}} \mathcal{O}'' \cong \mathcal{S}^d_{V(K')}$ as $\mathcal{O}[H]$-modules). The algebra $\mathbb{T}''^{\mathrm{ord}}(V(K'))$ is the Λ''^+-subalgebra of $\mathrm{End}_{\mathcal{O}''}(\mathcal{S}''_{V(K')})$ generated by the operators of the same names, i.e. the image of $\mathbb{T}^{\mathrm{ord}}(V(K')) \otimes_{\mathcal{O}} \mathcal{O}''$; and $\mathbb{T}''_{\tau''}(K')$ is its image in $\mathrm{End}_{\mathcal{O}''}(N_\tau(K') \otimes_{\mathcal{O}} \mathcal{O}'')$, i.e. the image of $\mathbb{T}^{\mathrm{ord}}(V(K')) \otimes_{\mathcal{O}} \mathcal{O}''$ there. The map $\mathrm{End}_{\mathcal{O}}(N) \otimes_{\mathcal{O}} \mathcal{O}'' \to \mathrm{End}_{\mathcal{O}''}(N \otimes_{\mathcal{O}} \mathcal{O}'')$ ($N = N_\tau(K')$) is injective (in a basis $e_1, \dots, e_d$ of $\mathcal{O}''$, $\sum_i \phi_i \otimes e_i$ sends $m \otimes 1$ to $\sum_i \phi_i(m) \otimes e_i$), and the image of $\mathbb{T}^{\mathrm{ord}}(V(K'))$ in $\mathrm{End}_{\mathcal{O}}(N)$ is $\mathbb{T}_\tau(K')$; by exactness of $- \otimes_{\mathcal{O}} \mathcal{O}''$ the image of $\mathbb{T}^{\mathrm{ord}}(V(K')) \otimes_{\mathcal{O}} \mathcal{O}''$ is $\mathbb{T}_\tau(K') \otimes_{\mathcal{O}} \mathcal{O}''$. □

Lemma E.14. *Let $\mathscr{H}$ over $\mathcal{O}'$, κ, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ and c be as in Lemma E.16, V_v ($v \in \mathrm{St}$) the kernel of reduction modulo ϖ_v^c, $H = \prod_{v \in \mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v$, τ a finite free $\mathcal{O}'$-module with an $\mathcal{O}'$-linear action of H, $\tau^\vee = \mathrm{Hom}_{\mathcal{O}'}(\tau, \mathcal{O}')$, and $q\colon \mathbb{T}_{\mathcal{O}'[H]} \to \mathbb{T}_\tau$ the surjection of Lemma E.15. Let λ be a dominant weight, $\alpha\colon T_n(\ell^1) \to \overline{\mathbb{Q}}_\ell^\times$ a character of finite order, $r \geq 1$ with $T_n(\ell^r) \subseteq \ker \alpha$, and y_0 a point of $\mathbb{T}_{\mathcal{O}'[H]}$ with $y_0(\mathfrak{P}_{\lambda,\alpha}) = 0$ and $y_0(\langle u \rangle) = \alpha(u)(w_0\lambda)(u)^{-1}$ for $u \in T_n(\ell^1)$. Suppose that there are an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ with $\mathrm{Hom}_H(\tau^\vee \otimes_{\mathcal{O}'} \overline{\mathbb{Q}}_\ell, \bigotimes_{v \in \mathrm{St}} \pi_v^{V_v}) \neq 0$ and a non-zero $f \in \pi \cap S_\lambda^{\mathrm{ord}}(V(\ell^{r,r}), \alpha, \overline{\mathbb{Q}}_\ell)$ on which every operator assigned by (Gy7)(c) to an element t among the $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ acts by $y_0(t)$. Then $y_0 = y \circ q$ for a point y of $\mathbb{T}_\tau$.*

Proof. Let E be the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ and $r' = Er$; by (Qh1), $T_n(\mathfrak{l}^{r'}) \subseteq T_n(\ell^r) \subseteq \ker \alpha$. As $V(\ell^{r',r'}) \subseteq V(\ell^{r,r})$ and the inclusion of the forms of level $V(\ell^{r,r})$ into those of level $V(\ell^{r',r'})$ commutes with the operators of (Gy7)(c) ([105], Lemma 2.3.3), hence with the ordinary and α-projectors, $f \in \pi \cap S_\lambda^{\mathrm{ord}}(V(\ell^{r',r'}), \alpha, \overline{\mathbb{Q}}_\ell)$, with the same eigenvalues.

Step 0: values of the extensions of α in $\mathcal{O}'$. If $\mathcal{O}'$ does not contain the values of every character of $T_n(\mathfrak{l})$ extending α, let $\mathcal{O}'' \supseteq \mathcal{O}'$ be the ring of integers of a finite extension of $\mathcal{O}'[1/\ell]$ containing them (finitely many roots of unity). By Lemma E.13, over $\mathcal{O}''$ the Hecke algebras are $\mathbb{T}_{\mathcal{O}'[H]} \otimes_{\mathcal{O}'} \mathcal{O}''$ and $\mathbb{T}_\tau \otimes_{\mathcal{O}'} \mathcal{O}''$ (as $\mathcal{O}''[H] = \mathcal{O}'[H] \otimes \mathcal{O}''$), the surjection of Lemma E.15 over $\mathcal{O}''$ is $q \otimes \mathrm{id}$ (both send each operator to the operator of the same name), and $\Lambda_1'' = \Lambda_1 \otimes_{\mathcal{O}'} \mathcal{O}''$; the hypotheses on π and f do not involve the coefficient ring ($\tau''^\vee \otimes_{\mathcal{O}''} \overline{\mathbb{Q}}_\ell = \tau^\vee \otimes_{\mathcal{O}'} \overline{\mathbb{Q}}_\ell$). Put $y_0'' = y_0 \otimes (\mathcal{O}'' \subseteq \overline{\mathbb{Q}}_\ell)$. As y_0 kills $\mathfrak{P}_{\lambda,\alpha}$, its restriction to Λ_1 is $\sigma \circ \chi_0$, χ_0 the homomorphism induced by $\alpha(w_0\nu)^{-1}(w_0\lambda)^{-1}$ and σ an $\mathcal{O}'$-algebra homomorphism on its image, which is the identity on the generators by the hypothesis on $y_0(\langle u \rangle)$; so $y_0|_{\Lambda_1} = \chi_0$, $y_0''|_{\Lambda_1''} = \chi_0 \otimes \mathrm{id}$, and y_0'' kills $\mathfrak{P}''_{\lambda,\alpha}$. If the case of values in the coefficient ring gives $y_0'' = y'' \circ (q \otimes \mathrm{id})$, then $y = y''|_{\mathbb{T}_\tau \otimes 1}$ is a point of $\mathbb{T}_\tau$ with $y_0 = y \circ q$. So assume that $\mathcal{O}'$ contains the values of every character of $T_n(\mathfrak{l})$ extending α, in particular those of α.

Step 1: the fibre of N_τ. Put $\Lambda = \Lambda_1$ (renormalised structure), $\mathfrak{P} = \mathfrak{P}_{\lambda,\alpha}$, $\mathcal{K} = \mathcal{O}'[1/\ell] = \Lambda_{\mathfrak{P}}/\mathfrak{P}\Lambda_{\mathfrak{P}}$ and $W = S_\lambda^{\mathrm{ord}}(V(\ell^{r',r'}), \alpha, \mathcal{K})$. By (Gd0) and Lemma E.12 for $U = V^{\mathrm{St}} \supseteq U' = V$, $\Gamma = G_1 = H$, $G_2 = 1$, $b_0 = 1$: (Yp1) the action of H on $\mathcal{S}_V$ commutes with the Hecke operators, and (Yp2) $\mathcal{S}_V$ is a direct summand of $\Lambda[H]^m$ for some m. For an $\mathcal{O}'$-algebra R and a finite

free $\mathcal{O}'$-module τ' with an action of H, $\varphi \mapsto \epsilon \circ \varphi$ (ϵ the coefficient of 1) is an isomorphism $\mathrm{Hom}_{\mathcal{O}'[H]}(\tau', R[H]) \to R \otimes_{\mathcal{O}'} \mathrm{Hom}_{\mathcal{O}'}(\tau', \mathcal{O}')$ with inverse $\psi \mapsto (t \mapsto \sum_{h\in H} \psi(h^{-1}t)h)$; so for every homomorphism $\Lambda \to A$ the natural map $\mathrm{Hom}_{\mathcal{O}'[H]}(\tau', \Lambda[H]) \otimes_\Lambda A \to \mathrm{Hom}_{\mathcal{O}'[H]}(\tau', A[H])$ is an isomorphism, and by additivity the same holds for the direct summand $\mathcal{S}_V$. With $A = \mathcal{K}$ and (Qh4) for $U = V$, $b_0 = 1$ and the level r' (applicable: $T_n(\mathfrak{l}^{r'}) \subseteq \ker \alpha$ and $\mathcal{O}'$ contains the values of the extensions of α; for the equivariance of (Gk3), the elements of $\prod_{v\in \mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})$ have trivial components at S_ℓ and normalise every $V(\ell^{c',c'})$), for $\tau' = \tau$ and $\tau' = \mathcal{O}'[H]$:

$$N_{\tau'} \otimes_\Lambda \mathcal{K} \cong \mathrm{Hom}_{\mathcal{K}[H]}(\tau' \otimes \mathcal{K}, W^*), \qquad W^* = \mathrm{Hom}_{\mathcal{K}}(W, \mathcal{K}),$$

compatibly with the Hecke operators, which act on the right through the transposes of the operators of (Gy7)(c).

Step 2: y_0 factors through q. Let $W_{\overline{\mathbb{Q}}_\ell} = W \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell = S^{\mathrm{ord}}_\lambda(V(\ell^{r',r'}), \alpha, \overline{\mathbb{Q}}_\ell)$, W_0 its joint generalised eigenspace for the eigencharacter y_0 of the operators of (Gy7)(c), and W' the sum of the others; both are H-stable (Yp1). The copy of π containing f has $\pi^{V(\ell^{r',r'})} = (\bigotimes_{v\in \mathrm{St}} \pi_v^{V_v}) \otimes X$, with H acting on the first factor and the operators of (Gy7)(c), which involve no place of St, on the second; as $f \neq 0$ is a joint eigenvector, X contains a non-zero joint eigenvector e with eigencharacter y_0, which is ordinary with $T_n(\ell^1)$ acting through α (the ordinary and α-projectors are given by these operators), and $(\bigotimes_{v\in \mathrm{St}} \pi_v^{V_v}) \otimes e \subseteq W_0$. By hypothesis W_0 has an H-constituent occurring in $\tau^\vee \otimes \overline{\mathbb{Q}}_\ell$, so ($H$ finite, characteristic 0) $Z = \mathrm{Hom}_H(\tau \otimes \overline{\mathbb{Q}}_\ell, W_0^*) \cong \mathrm{Hom}_H(W_0, \tau^\vee \otimes \overline{\mathbb{Q}}_\ell) \neq 0$. By Step 1, Z is a subspace of $N_\tau \otimes_\Lambda \overline{\mathbb{Q}}_\ell$ ($W^*_{\overline{\mathbb{Q}}_\ell} = W_0^* \oplus W'^*$), stable under the Hecke operators, on which every element t of $\mathbb{T}_{\mathcal{O}'[H]}$ acts, through q, with the single eigenvalue $y_0(t)$. If $q(t) = 0$, then t acts by 0 on N_τ, hence on Z, so $y_0(t) = 0$. Hence $y_0 = y \circ q$ for a homomorphism of $\mathcal{O}'$-algebras $y\colon \mathbb{T}_\tau \to \overline{\mathbb{Q}}_\ell$, continuous because q is a continuous surjection of compact spaces, hence a quotient map. □

Lemma E.15. *Let $\mathscr{H}$ over $\mathcal{O}'$, κ and $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be as in the hypotheses of Proposition E.26, let c be an integer as in Proposition E.5, V_v ($v \in \mathrm{St}$) the kernel of reduction $\mathbb{G}_L(\mathcal{O}_{L_v^+}) \to \mathbb{G}_L(\mathcal{O}_{L_v^+}/\varpi_v^c)$, V the level and $H = \prod_{v\in\mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})/V_v$. Let τ_0 be a finite free $\mathcal{O}'$-module with an $\mathcal{O}'$-linear action of H, and $\tau = \mathcal{O}'[H]$ (left multiplication). Then there is a surjective homomorphism of Λ^+-algebras $q\colon \mathbb{T}_\tau \to \mathbb{T}_{\tau_0}$ sending $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde{v}}^{(j)}$ and $\langle u\rangle$ to the operators of the same names; for every point y of $\mathbb{T}_{\tau_0}$, $y \circ q$ is a point of $\mathbb{T}_\tau$ with the same values on these operators; and (Hx1), (Hx2) of Proposition E.5 hold for the points of $\mathbb{T}_{\tau_0}$ (with $P_{y,w}$ and $\psi_{v,j}^y$ defined by the same formulas).*

Proof. Both type data have the same level V, hence the same $\mathcal{S}_V$ and the same $\mathbb{T}^{\mathrm{ord}}(V) \subseteq \mathrm{End}_{\mathcal{O}'}(\mathcal{S}_V)$. Evaluation at $1 \in \mathcal{O}'[H]$ is an isomorphism $N_\tau = \mathrm{Hom}_{\mathcal{O}'[H]}(\mathcal{O}'[H], \mathcal{S}_V) \to \mathcal{S}_V$, equivariant for $\mathbb{T}^{\mathrm{ord}}(V)$ (which commutes with H); so the image of $\mathbb{T}^{\mathrm{ord}}(V)$ in $\mathrm{End}_{\mathcal{O}'}(N_\tau)$ is $\mathbb{T}^{\mathrm{ord}}(V)$ itself: $\mathbb{T}_\tau = \mathbb{T}^{\mathrm{ord}}(V)$. By definition $\mathbb{T}_{\tau_0}$ is the image of $\mathbb{T}^{\mathrm{ord}}(V)$ in $\mathrm{End}_{\mathcal{O}'}(N_{\tau_0})$ under its action on $N_{\tau_0} = \mathrm{Hom}_{\mathcal{O}'[H]}(\tau_0, \mathcal{S}_V)$ through $\mathcal{S}_V$; let q be this restriction map. It is a surjective homomorphism of Λ^+-algebras sending each generator to the operator of the same name, and it respects the renormalised Λ_1-structures, which are defined from the $\langle u\rangle$. Both algebras are finite over Λ_1 ((Qh2) of Lemma E.10 for $\mathbb{T}^{\mathrm{ord}}(V)$, and $\mathbb{T}_{\tau_0}$ is a quotient), so q is continuous for their Λ_1-adic topologies, and for a point y of $\mathbb{T}_{\tau_0}$ the composite $y \circ q$ is a continuous homomorphism of $\mathcal{O}'$-algebras, i.e. a point of $\mathbb{T}_\tau$; it kills $\mathfrak{P}_{\lambda,\alpha}$ if and only if y does, and $y \circ q$ and y take the same values on $T_w^{(j)}$, $U_{\tilde{v}}^{(j)}$, $\langle u\rangle$. The statements (Hx1) and (Hx2) for a point depend only on these values ($P_{y,w}$ through $y(T_w^{(j)})$, $\psi_{v,j}^y$ through $y(\langle d_j(z)\rangle)$ and $y(U_{\tilde{v}}^{(j)})$) and on the condition $y(\mathfrak{P}_{\lambda,\alpha}) = 0$; so they hold for y because they hold for $y \circ q$ by Proposition E.5. □

Lemma E.16. *Let $\mathscr{H}$ over $\mathcal{O}'$, κ and $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be as in the hypotheses of Proposition E.26, $\mathbb{F}$ the residue field of $\mathcal{O}'$, c an integer as in Proposition E.5, and $((V_v)_{v\in\mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$ with V_v the kernel of reduction $\mathbb{G}_L(\mathcal{O}_{L_v^+}) \to \mathbb{G}_L(\mathcal{O}_{L_v^+}/\varpi_v^c)$ for $v \in \mathrm{St}$ (and τ arbitrary). Let Q and K' be as in the levels at auxiliary places of Definition 50.8 ($Q = \varnothing$ allowed); in this statement and its proof V, N_τ and $\mathbb{T}_\tau$ denote $V(K')$, $N_\tau(K')$ and $\mathbb{T}_\tau(K')$. Let $\mathfrak{m}$ be a maximal ideal of $\mathbb{T}_\tau$ with $\mathbb{T}_\tau/\mathfrak{m} = \mathbb{F}$ such that in $\mathbb{F}$, for all w, $1 \le j \le n$, $v \in S_\ell$ and $z \in \mathcal{O}_{L_{\tilde{v}}}^\times$:*

(Mx) $(\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} \equiv e_j\big((\bar{\chi}_a\bar{\kappa})(\mathrm{Frob}_w)\big)_{1\le a\le n}$, $\langle d_j(z)\rangle \equiv (\bar{\chi}^{j-1}\bar{\kappa}\bar{\chi}_j)(\mathrm{Art}(z))$ *and* $U_{\tilde{v}}^{(j)} \equiv U_{\tilde{v}}^{(j-1)}\,(\bar{\chi}^{j-1}\bar{\kappa}\bar{\chi}_j)(\mathrm{Art}(\varpi_{\tilde{v}}))$ *modulo* $\mathfrak{m}$ *(e_j the j-th elementary symmetric function, bars denoting reductions, $U_{\tilde{v}}^{(0)} = 1$).*

(Gd0) $[L^+ : \mathbb{Q}] \ge 2$*; the hypotheses of Theorem B.91 hold for $F = L$, $\mathbb{G} = \mathbb{G}_L$, $T = T_L \cup Q$, $b_0 = 1$ and $U = V$, the level of the type datum, as well as for $U = V^{\mathrm{St}}$, the group with $V_v^{\mathrm{St}} = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ for $v \in \mathrm{St}$ and $V_v^{\mathrm{St}} = V_v$ otherwise; $\mathbb{T}_\tau$ is commutative, finite and torsion-free over Λ_1 (for the diamond structure and for the renormalised one); the $U_{\tilde{v}}^{(j)}$ are units of $\mathbb{T}_\tau$; and $\mathbb{T}_\tau$ is topologically generated over $\mathcal{O}'$ by the $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde{v}}^{(j)}$ and $\langle u\rangle$, $u \in T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)$. Every homomorphism of $\mathcal{O}'$-algebras from B_n^{po}, from $\mathbb{T}_\tau$, or from a quotient of either, to $\overline{\mathbb{Q}}_\ell$ has image in the ring of integers of a finite extension of $\mathbb{Q}_\ell$, is local onto its image, and is continuous; its image is an $\mathcal{O}'$-order, finite over $\mathcal{O}'$.*

Call a point y of $\mathbb{T}_{\tau,\mathfrak{m}}$ ***regular*** *if $y(\mathfrak{P}_{\lambda,1}) = 0$ for a dominant weight λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$ for all embeddings τ' and all j; for such y let r_y be, if $Q = \varnothing$, as in (Hx1) of Proposition E.5 (through Lemma E.15), and in general the representation r_π of (Gy5) for an irreducible constituent π given by Lemma E.11 for y (level K', $\alpha = 1$, $r = 1$): a continuous semisimple representation of G_L, well defined up to isomorphism, with $r_y(\mathrm{Frob}_w)$ of characteristic polynomial $P_{y,w}$ for every w and $r_y^c \cong r_y^\vee \chi^{1-n}$ (the two definitions agree if $Q = \varnothing$); put $\tilde{r}_y = r_y \otimes \kappa^{-1}$. Let $\mathfrak{a}$ be an ideal of $\mathbb{T}_{\tau,\mathfrak{m}}$, $A = \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}$, and $\mathcal{C}$ a non-empty set of regular points with $\bigcap_{y\in\mathcal{C}} \ker y = \mathfrak{a}$.*

(Gd1) *There is a continuous A-valued determinant D^{H} of dimension n on G_L with $y \circ D^{\mathrm{H}} = \det \circ r_y$ for every $y \in \mathcal{C}$; for every w, $\chi_{D^{\mathrm{H}}}(\mathrm{Frob}_w) = \sum_{j=0}^n (-1)^j (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j}$ in $A[X]$; and for every point y of A and every continuous $\rho\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that, for every w, ρ is unramified above w and $\rho(\mathrm{Frob}_w)$ has characteristic polynomial $P_{y,w}$, $y \circ D^{\mathrm{H}} = \det \circ \rho$.*

(Gd2) *Suppose moreover that for every $y \in \mathcal{C}$: (i) $\tilde{r}_y$ is trivial on N^Q, (ii) for every $v \in S_\ell$, $r_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\psi_{v,j}^y)_{1\le j\le n}$, and (iii) for every $v \in S_\ell$, $1 \le j \le n$ and every ℓ-power root of unity $\zeta \in L_{\tilde{v}}$, $y(\langle d_j(\zeta)\rangle) = \kappa(\mathrm{Art}(\zeta))\,\xi_{v,j}(g_\zeta)$, with $\xi_{v,j}$ the wild values of $\mathscr{H}$ and g_ζ as in Lemma 50.24 (by (Wv2) of Lemma 50.24, (iii) is empty at every v with $\bar{\omega}|_{D_v} \ne 1$: there $\zeta = 1$ only). Then $A \in \mathrm{CNL}_{\mathcal{O}'}$; there are a continuous A-valued determinant D^Q of dimension n on $\Gamma^{0,Q}$ and continuous characters $\psi_{v,j}^\flat\colon D_v \to A^\times$ ($v \in S_\ell$, $1 \le j \le n$) satisfying (Od1), (Od2) and (Od3) of Definition 50.2 with π^Q, $\Gamma^{0,Q}$ in place of π, Γ^0, with D^Q reducing to $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$ and $\psi_{v,j}^\flat \equiv \bar{\chi}_j$ modulo $\mathfrak{m}_A$, such that for all w, $v \in S_\ell$, $1 \le j \le n$, $z \in \mathcal{O}_{L_{\tilde{v}}}^\times$ and $y \in \mathcal{C}$: $\chi_{D^Q}(\pi^Q(\mathrm{Frob}_w)) = \sum_{j=0}^n (-1)^j \kappa(\mathrm{Frob}_w)^{-j} (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j}$, $\psi_{v,j}^\flat(\mathrm{Art}(z)) = (\chi^{j-1}\kappa)(\mathrm{Art}(z))^{-1}\langle d_j(z)\rangle$, $\psi_{v,j}^\flat(\mathrm{Art}(\varpi_{\tilde{v}})) = (\chi^{j-1}\kappa)(\mathrm{Art}(\varpi_{\tilde{v}}))^{-1} U_{\tilde{v}}^{(j)} (U_{\tilde{v}}^{(j-1)})^{-1}$, $y \circ D^Q = \det \circ \tilde{r}_y^Q$ and $y \circ \psi_{v,j}^\flat = \chi^{1-j}\kappa^{-1}\psi_{v,j}^y$, where $\tilde{r}_y^Q$ is the representation of $\Gamma^{0,Q}$ with $\tilde{r}_y^Q \circ \pi^Q = \tilde{r}_y$. If $Q = \varnothing$, there is moreover a surjective homomorphism of $\mathcal{O}'$-algebras $\theta\colon B_n^{\mathrm{po}} \to A$ such*

that, in A, for all w, $1 \le j \le n$, $v \in S_\ell$ and $z \in \mathcal{O}_{L_{\tilde v}}^\times$,

$$(\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} = \kappa(\mathrm{Frob}_w)^j\, \theta\big(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w))\big),$$
$$\langle d_j(z)\rangle = (\chi^{j-1}\kappa)(\mathrm{Art}(z))\, \theta\big(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(z))\big),$$
$$U_{\tilde v}^{(j)} = U_{\tilde v}^{(j-1)}\, (\chi^{j-1}\kappa)(\mathrm{Art}(\varpi_{\tilde v}))\, \theta\big(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(\varpi_{\tilde v}))\big),$$

and, for every $y \in \mathcal{C}$, $y \circ \theta \circ D^{\mathrm{u}} = \det \circ \tilde r'_y$ and $y \circ \theta \circ \psi_{v,j}^{\mathrm{d}} = \chi^{1-j}\kappa^{-1}\psi_{v,j}^{y}$, where $\tilde r'_y$ is the representation of $\Gamma^0_{\mathscr{H}}$ with $\tilde r'_y \circ \pi_{\mathscr{H}} = \tilde r_y$.

Proof. Step 0: points are continuous. Let R be a complete Noetherian semilocal $\mathcal{O}'$-algebra, finite over a complete Noetherian local ring with finite residue field, and $y\colon R \to \overline{\mathbb{Q}}_\ell$ a homomorphism of $\mathcal{O}'$-algebras. Then $R/\ker y$ is a complete Noetherian local domain (a complete semilocal domain is local) of characteristic 0 whose fraction field is algebraic over $\mathrm{Frac}(\mathcal{O}')$, so it has dimension one and is finite over $\mathcal{O}'$ (complete Nakayama), and $y(R)$ is an order in a finite extension E of $\mathbb{Q}_\ell$, contained in $\mathcal{O}_E$; y is local onto its image, hence continuous. This applies to B (a complete Noetherian local ring), to $\mathbb{T}$ and to their quotients, by Step 1; it is the last sentence of (Gd0).

Step 1: (Gd0), and finiteness. Let V be the level of the type datum. L/L^+ is unramified at all finite places (Rd2), so $[L^+ : \mathbb{Q}] \ge 2$: if $L^+ = \mathbb{Q}$, then L is imaginary quadratic, its discriminant has absolute value at least 3, and some prime ramifies in $L/\mathbb{Q}$. The hypotheses of Theorem B.91 hold for $F = L$, $\mathbb{G} = \mathbb{G}_L$, $T = T_L \cup Q$, $b_0 = 1$ and $U = V$ or $U = V^{\mathrm{St}}$ (the two differ only at St, which plays no role below): L is imaginary CM and the places above ℓ split by (Rd2); $\mathcal{O}' \supseteq \tau'(\mathcal{O}_L)$ for every embedding τ' by (Rd1); $\mathbb{G}_L$ comes from the involution $X \mapsto {}^tX^c$ and the order $\mathrm{M}_n(\mathcal{O}_L)$, is compact at the real places (positive definite form) and quasi-split at every finite place (split places: GL_n; the non-split places are unramified in L by (Rd2), where the form $\sum x_i\bar x_i$ of discriminant 1 is quasi-split, for n even because $(-1)^{n/2}$ is a unit, hence a norm from the unramified quadratic extension); the places of T_L split (Rd2), those of Q by assumption; $V_v = \mathbb{G}_L(\mathcal{O}_{L_v^+})$ for $v \in S_\ell$ and for $v \notin T_L \cup Q$; and $V(\ell^{1,1})$ is sufficiently small, its component at v_0 being $1 + p\,\mathrm{M}_n(\mathcal{O}_{L_{\tilde v_0}})$ with p odd and $L_{\tilde v_0}/\mathbb{Q}_p$ unramified (Rd3), which has no non-trivial element of finite order . By (Qh2) (with $b_0 = 1$), $\mathbb{T}^{\mathrm{ord}}(V)$ is commutative and finite over Λ_1, and $\mathcal{S}_V$ is free of finite rank over Λ_1, so $N_\tau \subseteq \mathrm{Hom}_{\mathcal{O}'}(\tau, \mathcal{S}_V) \cong \mathcal{S}_V^{\mathrm{rk}\,\tau}$ is torsion-free and finitely generated over Λ_1, and $\mathbb{T}$, acting faithfully on N_τ, is torsion-free over Λ_1 (if $0 \ne \mu \in \Lambda_1$ and $\mu t = 0$, then $\mu(tm) = 0$, so $tm = 0$ for all $m \in N_\tau$, and $t = 0$). So $\mathbb{T}$ is a commutative, finite, torsion-free Λ_1-algebra (for the diamond structure, hence for the renormalised one, which differs by the automorphism $[u] \mapsto (w_0\nu)^{-1}(u)[u]$ of Λ_1), complete and semilocal, the product of its finitely many localisations at maximal ideals; so $\mathbb{T}_{\mathfrak{m}}$ and A are complete Noetherian local $\mathcal{O}'$-algebras, finite over Λ_1, compact. The operators $U_{\tilde v}^{(j)}$ are units of $\mathbb{T}$: they are invertible on the ordinary module $\mathcal{S}_V$ and hence on N_τ, and an element of $\mathbb{T}$ lying in a maximal ideal $\mathfrak{n}$ acts nilpotently on $N_{\tau,\mathfrak{n}}/\mathfrak{n}N_{\tau,\mathfrak{n}}$, which is non-zero by Nakayama and the faithfulness of $\mathbb{T}_{\mathfrak{n}}$ on $N_{\tau,\mathfrak{n}}$ (N_τ is finitely generated over Λ_1 as $\mathcal{S}_V$ is, by (Qh2)). Finally $\mathbb{T}$ is topologically generated over $\mathcal{O}'$ by the images of the $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde v}^{(j)}$ and $\langle u\rangle$, $u \in T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)$: the $\mathcal{O}'$-algebra they generate is dense in the Λ^+-algebra they generate, $\mathcal{O}'[T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)]$ being dense in Λ^+ and $\mathbb{T}$ being finite over Λ_1; the same holds for the direct factor $\mathbb{T}_{\mathfrak{m}}$ and its quotient A.

Step 2: (Gd1). First the representations r_y of a regular point y, with λ. By Lemma E.11 (level K', $\alpha = 1$, $r = 1$) there is an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ with π_v unramified, with $T_w^{(j)}$-eigenvalues $y(T_w^{(j)})$, at every split $v \notin T_L \cup Q$; by (Gy5)(i),(ii), r_π is continuous and semisimple, its restriction above w has unramified semisimplification, $r_\pi(\mathrm{Frob}_w)$ has characteristic polynomial $P_{y,w}$, and $r_\pi^c \cong r_\pi^\vee \chi^{1-n}$. Two continuous semisimple representations of G_L

with the same characteristic polynomials at all Frob_w are isomorphic (the Frob_w are dense by the Chebotarev density theorem; Brauer–Nesbitt), so r_y is well defined up to isomorphism, and for $Q = \varnothing$ it agrees with the r_y of (Hx1), which is semisimple with the same characteristic polynomials ((Hx1)(i)). In every case r_y has the properties (i) and (ii) of (Hx1), the only ones used below. For $y \in \mathcal{C}$, r_y is continuous on the compact group G_L, so after conjugation it takes values in $\mathrm{GL}_n(\mathcal{O}_{E_y})$ for a finite extension E_y of $\mathbb{Q}_\ell$ (its image is a compact subgroup of $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, hence by the Baire category theorem contained in $\mathrm{GL}_n(E)$ for some finite E, and it stabilises an $\mathcal{O}_E$-lattice); enlarging E_y we may assume $y(A) \subseteq \mathcal{O}_{E_y}$ (Step 0). By (Hx1)(i), for every w the characteristic polynomial of $r_y(\mathrm{Frob}_w)$ is $P_{y,w}$, the image under y of $P_w = \sum_j (-1)^j (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j} \in A[X]$; this does not depend on the choice of Frob_w, r_y being unramified above w ((Hx1)(i): the semisimplification of the restriction is unramified, and the characteristic polynomial of an element depends only on the semisimplification). The map $A \to \prod_{y\in\mathcal{C}} \mathcal{O}_{E_y}$ is injective (as $\bigcap_{y\in\mathcal{C}} \ker y = \mathfrak{a}$) and continuous (Step 0), A is compact (Step 1), and the Frobenius elements Frob_w are dense in G_L by the Chebotarev density theorem (the places w have density one). By (Ch4) there is a continuous A-valued determinant D^{H} of dimension n on G_L with $y \circ D^{\mathrm{H}} = \det \circ r_y$ for all $y \in \mathcal{C}$; and $\chi_{D^{\mathrm{H}}}(\mathrm{Frob}_w) = P_w$, both having the same image under the injective map $A[X] \to \prod_y \mathcal{O}_{E_y}[X]$. Let y be any point of A and ρ as in (Gd1). Then $\det \circ \rho$ and $y \circ D^{\mathrm{H}}$ are continuous determinants with the same characteristic polynomial $y(P_w)$ at every Frob_w; by continuity the characteristic polynomials agree on all of G_L, and by (Ch1) the determinants are equal.

Step 3: the determinant on $\Gamma^{0,Q}$. Assume the hypotheses of (Gd2), and write $\tilde{r}'_y = \tilde{r}^Q_y$. For $y \in \mathcal{C}$, $\tilde{r}_y = r_y \otimes \kappa^{-1}$ is trivial on N^Q by (i), so $\tilde{r}_y = \tilde{r}'_y \circ \pi^Q$ with $\tilde{r}'_y$ continuous on $\Gamma^{0,Q}$ ($\pi^Q \colon G_L \to \Gamma^{0,Q}$ is a quotient map of profinite groups), with values in $\mathrm{GL}_n(\mathcal{O}_{E_y})$ after enlarging E_y to contain the values of κ. For every w, the inertia groups above w lie in N^Q (the $\bar{\chi}_a$ are trivial on them by (Rd4), and w lies above no place of Q) and κ is unramified above w (Rd7), so $\pi^Q(\mathrm{Frob}_w)$ and $\kappa(\mathrm{Frob}_w) \in \mathcal{O}'^{\times}$ are well defined, and the characteristic polynomial of $\tilde{r}'_y(\pi^Q(\mathrm{Frob}_w)) = \kappa(\mathrm{Frob}_w)^{-1} r_y(\mathrm{Frob}_w)$ is the image under y of $\tilde{P}_w = \sum_j (-1)^j \kappa(\mathrm{Frob}_w)^{-j} (\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} X^{n-j} \in A[X]$. The elements $\pi^Q(\mathrm{Frob}_w)$ are dense in $\Gamma^{0,Q} = \pi^Q(G_L)$. By (Ch4), as in Step 2, there is a continuous A-valued determinant D of dimension n on $\Gamma^{0,Q}$ with $y \circ D = \det \circ \tilde{r}'_y$ for $y \in \mathcal{C}$ and $\chi_D(\pi^Q(\mathrm{Frob}_w)) = \tilde{P}_w$.

Step 4: the characters at ℓ. For $v \in S_\ell$ and $1 \le j \le n$ let $\psi^A_{v,j} \colon D_v \to A^\times$ be the continuous character with $\psi^A_{v,j}(\mathrm{Art}(z)) = \langle d_j(z) \rangle$ for $z \in \mathcal{O}^\times_{L_{\tilde{v}}}$ and $\psi^A_{v,j}(\mathrm{Art}(\varpi_{\tilde{v}})) = U^{(j)}_{\tilde{v}} (U^{(j-1)}_{\tilde{v}})^{-1}$ (well defined: D_v is identified with $G_{L_{\tilde{v}}}$, D_v^{ab} is the profinite completion of $L^\times_{\tilde{v}} = \mathcal{O}^\times_{L_{\tilde{v}}} \times \varpi^{\mathbb{Z}}_{\tilde{v}}$, the diamond map is continuous, the $U^{(j)}_{\tilde{v}}$ are units (Step 1), and $k \mapsto t^k$ extends continuously to $\widehat{\mathbb{Z}}$ for $t \in A^\times$, $A^\times$ being profinite). Put $\psi^\flat_{v,j} = \chi^{1-j} \kappa^{-1} \psi^A_{v,j}$. For $y \in \mathcal{C}$, $y \circ \psi^A_{v,j} = \psi^y_{v,j}$, both being continuous with the same values on the dense image of Art.

Step 5: a polarised ordinary determinant to A. (Od1): for $y \in \mathcal{C}$, by (Hx1)(ii) and (Rd7) ($\kappa\kappa^c = \chi^{1-n}$), $\tilde{r}^c_y = r^c_y \otimes (\kappa^c)^{-1} \cong r^\vee_y \chi^{1-n} (\kappa^c)^{-1} = r^\vee_y \otimes \kappa = \tilde{r}^\vee_y$, so $\tilde{r}_y(cg^{-1}c)$ and ${}^t\tilde{r}_y(g)$ have the same characteristic polynomial for $g \in G_L$: the coefficients of $\chi_D(\pi^Q(cg^{-1}c)) - \chi_D(\pi^Q(g))$ vanish at every $y \in \mathcal{C}$, hence are 0. (Od2): for $y \in \mathcal{C}$ and $v \in S_\ell$, by (ii) $r_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\psi^y_{v,j})_j$, so $\tilde{r}_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\kappa^{-1}\psi^y_{v,j})_j = (y \circ \psi^\flat_{v,j})_j$, and by (Fg1) (with $C = \overline{\mathbb{Q}}_\ell$) $\prod_{a=1}^n \big(\tilde{r}_y(g_a) - y(\psi^\flat_{v,a}(g_a))\big) = 0$ for $g_1, \dots, g_n \in D_v$. As $y \circ \mathrm{tr}_D = \mathrm{tr} \circ \tilde{r}'_y$ on $A[\Gamma^{0,Q}]$ (traces commute with base change), y kills $\mathrm{tr}_D(\gamma \prod_a (\pi^Q(g_a) - \psi^\flat_{v,a}(g_a)))$ for all $\gamma \in \Gamma^{0,Q}$, which is therefore 0. Reductions: $A/\mathfrak{m}_A = \mathbb{F}$; by (Mx) the reduction of $\tilde{P}_w$ is $\prod_a (X - \bar{\chi}_a(\mathrm{Frob}_w))$ ($\bar{\kappa}$ cancels), the characteristic polynomial of $\bar{D}_n$ at $\pi^Q(\mathrm{Frob}_w)$; the two continuous $\mathbb{F}$-valued determinants $D \bmod \mathfrak{m}_A$ and $\bar{D}_n$ (here $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$ on $\Gamma^{0,Q}$; the

$\bar\chi_a$ factor through it as $N^Q \subseteq N_{\mathscr H}$) have the same characteristic polynomials on a dense set, hence everywhere ($\mathbb F$ is discrete), and are equal by (Ch1). By (Mx), $\psi^A_{v,j} \equiv \bar\chi^{j-1}\bar\kappa\bar\chi_j$ on the dense image of Art, so $\psi^\flat_{v,j} \equiv \bar\chi_j$ modulo $\mathfrak m_A$. A is a complete Noetherian local $\mathcal O'$-algebra with residue field $\mathbb F$ (Step 1), i.e. $A \in \mathrm{CNL}_{\mathcal O'}$. So $D^Q = D$ and the $\psi^\flat_{v,j}$ have the properties stated in (Gd2) before θ, the identities having been shown in Steps 3 and 4. (Od3): let $v \in S_\ell$, $1 \le j \le n$ and $\zeta \in L_{\tilde v}$ an ℓ-power root of unity. As ζ is a unit and g_ζ has image $\mathrm{Art}(\zeta)$ in D^{ab}_v, $\psi^\flat_{v,j}(g_\zeta) = \chi(g_\zeta)^{1-j}\kappa(\mathrm{Art}(\zeta))^{-1}\langle d_j(\zeta)\rangle = \kappa(\mathrm{Art}(\zeta))^{-1}\langle d_j(\zeta)\rangle$, since $\chi(g_\zeta) = 1$ by (Wv1) of Lemma 50.24. By (iii), every $y \in \mathcal C$ maps $\psi^\flat_{v,j}(g_\zeta) - \xi_{v,j}(g_\zeta)$ to 0, so this element of A is 0 ($\bigcap_{y\in\mathcal C}\ker y = 0$ in A). By (Wv1) of Lemma 50.24 for the continuous homomorphism $\psi^\flat_{v,j}\colon D_v \to A^\times$, $\psi^\flat_{v,j}(g)$ is the image of $\xi_{v,j}(g)$ for every $g \in \mu_v$: (Od3). If $Q = \varnothing$, $(D, (\psi^\flat_{v,j}))$ is therefore a polarised ordinary determinant of rank n over $\mathscr H$ to A ((Od1)–(Od3)); let $\theta\colon B \to A$ classify it.

Step 6: the identities ($Q = \varnothing$). $\theta \circ D^{\mathrm u} = D$ and $\theta \circ \psi^{\mathrm d}_{v,j} = \psi^\flat_{v,j}$. The coefficient of X^{n-j} in $\chi_D(\pi^Q(\mathrm{Frob}_w)) = \tilde P_w$ gives $\theta(\Lambda_j(D^{\mathrm u})(\pi^Q(\mathrm{Frob}_w))) = \kappa(\mathrm{Frob}_w)^{-j}(\mathrm N w)^{j(j-1)/2}T^{(j)}_w$; the definition of $\psi^\flat$ gives the identities for $\langle d_j(z)\rangle$ and $U^{(j)}_{\tilde v}$; and for $y \in \mathcal C$, $y\circ\theta\circ D^{\mathrm u} = y\circ D = \det\circ\tilde r'_y$ and $y\circ\theta\circ\psi^{\mathrm d}_{v,j} = \chi^{1-j}\kappa^{-1}\psi^y_{v,j}$ (Step 4).

Step 7: θ is surjective ($Q = \varnothing$). $\theta(B) \cong B/\ker\theta$ is a local subring of A, compact and hence closed. By Step 6, with $\mathrm N w$ a power of a prime $\ne \ell$ and $\kappa(\mathrm{Frob}_w) \in \mathcal O'^\times$, every $T^{(j)}_w$ lies in $\theta(B)$; $T^{(n)}_w$ is a unit of A, so it does not lie in $\theta(\mathfrak m_B) \subseteq \mathfrak m_A$, and it is a unit of the local ring $\theta(B)$, whence $(T^{(n)}_w)^{-1} \in \theta(B)$. Again by Step 6, $\langle d_j(z)\rangle \in \theta(B)$ (as $(\chi^{j-1}\kappa)(\mathrm{Art}(z)) \in \mathcal O'^\times$), so $\langle u\rangle \in \theta(B)$ for every $u \in T_n(\mathcal O_{L^+}\otimes\mathbb Z_\ell) = \prod_{v\in S_\ell} T_n(\mathcal O_{L^+_v})$, each such u being a finite product of elements $d_j(z)$; and by induction on j, $U^{(j)}_{\tilde v} \in \theta(B)$. By the last sentence of Step 1, $\theta(B) = A$. □

Lemma E.17. *Let $\mathscr H$ over $\mathcal O'$ (residue field $\mathbb F$), κ and c be as in Lemma E.16, let $\iota\colon \overline{\mathbb Q}_\ell \to \mathbb C$ be an isomorphism, let $((V_v)_{v\in\mathrm{St}}, \tau)$ be a type datum over $\mathscr H$ with V_v the kernel of reduction modulo ϖ_v^c ($v \in \mathrm{St}$), and let Q, K' be as in the levels at auxiliary places of Definition 50.8. Here $Q = \varnothing$ is allowed; as in Lemma E.16, $\mathbb T_\tau$ denotes $\mathbb T_\tau(K')$, and w denotes a place above a split place outside $T_L \cup Q$. Suppose that*

- **(Zt)** *for every dominant weight λ, every irreducible constituent π of $S_\lambda(\overline{\mathbb Q}_\ell)$ with $\mathrm{Hom}_H(\tau^\vee \otimes_{\mathcal O'} \overline{\mathbb Q}_\ell, \bigotimes_{v\in\mathrm{St}} \pi_v^{V_v}) \ne 0$ ($\tau^\vee = \mathrm{Hom}_{\mathcal O'}(\tau, \mathcal O')$) and every $v \in \mathrm{St}$, the Weil–Deligne representation $\mathrm{rec}(\iota\pi_v \circ \iota_{\tilde v}^{-1})$ has monodromy 0 and its restriction to the inertia group of $L_{\tilde v}$ is isomorphic to $\bigoplus_{a=1}^n \iota\circ([\bar\chi_a]\kappa)$.*

Let $\mathfrak m$ be a maximal ideal of $\mathbb T_\tau$ with $\mathbb T_\tau/\mathfrak m = \mathbb F$ satisfying (Mx), and let $\mathcal C$ be the set of points y of $\mathbb T_{\tau,\mathfrak m}$ for which there is a dominant weight λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$ for all τ', j and $y(\langle u\rangle) = (w_0\lambda)(u)^{-1}$ for every $u \in T_n(\mathcal O_{L^+}\otimes\mathbb Z_\ell)$ (regular points of trivial nebentypus). Then:

- **(Zp1)** *every regular point y of $\mathbb T_{\tau,\mathfrak m}$ satisfies (i) of (Gd2): $\tilde r_y = r_y \otimes \kappa^{-1}$ is trivial on N^Q (Definition 53.8; $N^\varnothing = N_{\mathscr H}$);*
- **(Zp2)** *every $y \in \mathcal C$ is regular and satisfies (ii) of (Gd2): for $v \in S_\ell$, $r_y|_{D_v}$ is triangular with diagonal $(\chi_{\mathrm{cyc}}^{1-j}\psi^y_{v,j})_{1\le j\le n}$;*
- **(Zp3)** *$\bigcap_{y\in\mathcal C}\ker y = 0$ in $\mathbb T_{\tau,\mathfrak m}$;*
- **(Zp4)** *let Δ_ℓ be the group of elements of ℓ-power order of $T_n(\mathcal O_{L^+}\otimes\mathbb Z_\ell)$, $\chi\colon \Delta_\ell \to \mathcal O'^\times$ a homomorphism, $\mathfrak a_\chi$ the intersection of the minimal prime ideals P of $\mathbb T_{\tau,\mathfrak m}$ with $\langle\delta\rangle - \chi(\delta) \in P$ for all $\delta \in \Delta_\ell$ ($\mathfrak a_\chi = \mathbb T_{\tau,\mathfrak m}$ if there is none), and $\mathcal C_\chi = \{y \in \mathcal C : y(\langle\delta\rangle) = \chi(\delta)$ for all $\delta \in$*

$\Delta_\ell\}$. *Then every point y of $\mathbb{T}_{\tau,\mathfrak{m}}$ with $y(\langle\delta\rangle)=\chi(\delta)$ for all $\delta\in\Delta_\ell$ satisfies $y(\mathfrak{a}_\chi)=0$, and $\bigcap_{y\in\mathcal{C}_\chi}\ker y=\mathfrak{a}_\chi$;*

(Zp5) *with Δ_ℓ, χ and $\mathfrak{a}_\chi$ as in (Zp4), let $N=e_\mathfrak{m}N_\tau(K')$ ($e_\mathfrak{m}$ the idempotent of $\mathbb{T}_\tau$ for $\mathfrak{m}$) and $N^\chi=N/\sum_{\delta\in\Delta_\ell}(\langle\delta\rangle-\chi(\delta))N$. Then N^χ is a free Λ_1-module of finite rank ($\Lambda_1=\mathcal{O}'[[T_n(\ell^1)]]$, diamond structure), and its annihilator in $\mathbb{T}_{\tau,\mathfrak{m}}$ is $\mathfrak{a}_\chi$.*

Proof. Step 0: the automorphic representation of a regular point. Let y be a point of $\mathbb{T}$ with $y(\mathfrak{P}_{\lambda,1})=0$ for a dominant λ. By Lemma E.11 (level K', $\alpha=1$, $r=1$) there is an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ with $\mathrm{Hom}_H(\tau^\vee\otimes\overline{\mathbb{Q}}_\ell,\bigotimes_{v\in\mathrm{St}}\pi_v^{V_v})\neq0$, π_v unramified with $T_w^{(j)}$-eigenvalues $y(T_w^{(j)})$ at every split $v\notin T_L\cup Q$, and a non-zero $f\in\pi\cap S_\lambda^{\mathrm{ord}}(V(\ell^{E,E}),1,\overline{\mathbb{Q}}_\ell)$ (E the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ) on which the operators assigned by (Gy7)(c) to $U_{\tilde v}^{(j)}$ and $\langle u\rangle$ act by $y(U_{\tilde v}^{(j)})$ and $y(\langle u\rangle)$. By (Gy5)(i), r_π is semisimple with characteristic polynomial $P_{y,w}$ at Frob_w for all w; so is r_y (its definition in Lemma E.16); by the Chebotarev density theorem and the Brauer–Nesbitt theorem, $r_y\cong r_\pi$ if λ is regular. Also $[L^+:\mathbb{Q}]\geq2$ (Lemma E.16, (Gd0)), so Lemma E.8 applies to π. Let $\tilde r=r_\pi\otimes\kappa^{-1}$. Its residual semisimplification has the characteristic polynomials of $\bigoplus_a\bar\chi_a$: by (Mx) they agree at every Frob_w, hence (continuity, Chebotarev) at every $g\in G_L$.

Step 1: (Zp1). Let y be regular and π, $\tilde r$ as in Step 0; $\tilde r_y\cong\tilde r$, so $K=\ker\tilde r_y\cap G_L$ is a closed normal subgroup of G_L with $cKc=K$, as $\tilde r^c\cong\tilde r^\vee$ ((Gy5)(ii) and (Rd7): $\tilde r^c=r_\pi^c\otimes(\kappa^c)^{-1}\cong r_\pi^\vee\chi^{1-n}(\kappa^c)^{-1}=r_\pi^\vee\otimes\kappa$). As $G_{L^+}=G_L\cup cG_L$, K is normal in G_{L^+}, and it suffices to show $s\in K$ for every generator $s\in I_{\bar w}\cap G_L$ of N^Q ($\bar w$ above neither ℓ nor a place of Q, $\bar\chi_a(s)=1$ for all a). The place of L^+ below $\bar w$ is unramified in L (Rd2). Since K is normal in G_L and $cKc=K$, and $c(I_{\bar w}\cap G_L)c=I_{c\bar w}\cap G_L$ with $\bar\chi_a(csc)=\bar\chi_{n+1-a}(s)^{-1}$ (Rd5), we may replace $\bar w$ by any G_{L^+}-conjugate; for a split place we may thus assume that $\bar w$ lies above the fixed place $\tilde v$ of L (or any chosen place w above v). Let $I'=\{s\in I_{\bar w}\cap G_L:\bar\chi_a(s)=1\ (1\leq a\leq n)\}$, $D'=D_{\bar w}\cap G_L$, the absolute Galois group of the completion L_w, q its residue cardinality, and $\Phi\in D'$ a lift of geometric Frobenius. (a) $v\notin T_L$ inert in L: $V_v=\mathbb{G}_L(\mathcal{O}_{L_v^+})$ is hyperspecial ($\mathbb{G}_L$ is reductive over $\mathcal{O}_{L_v^+}$, L/L^+ being unramified at v and the Hermitian form of unit discriminant) and $\pi_v^{V_v}\neq0$, as $\pi^{V(\ell^{E,E})}\ni f\neq0$; by (Gy5)(iii) r_π is unramified above v, and κ is unramified there (Rd7). (b) $v\notin T_L\cup Q$ split: π_v is unramified, so $\mathrm{rec}(\iota\pi_v\circ\iota_w^{-1}\otimes|\det|^{(1-n)/2})$ is unramified with monodromy 0; by (Ug2), $\mathrm{WD}(r_\pi|_{D'})^{F\text{-}ss}$ has monodromy 0 and is trivial on inertia, so by (Wd1) $r_\pi(\sigma)=\rho(\sigma)=1$ for σ in inertia ($N=0$, and Frobenius-semisimplification does not change ρ on inertia); κ is unramified (Rd7). (c) $v\in\mathrm{St}$, $w=\tilde v$: by (Zt), $\mathrm{rec}(\iota\pi_v\circ\iota_{\tilde v}^{-1})$, and hence its unramified twist by $|\det|^{(1-n)/2}$, has monodromy 0 and inertia $\bigoplus_a\iota\circ([\bar\chi_a]\kappa)$; by (Ug2) and (Wd1), $r_\pi|_{I_{\bar w}}\cong\bigoplus_a[\bar\chi_a]\kappa$, so $\tilde r|_{I_{\bar w}}\cong\bigoplus_a[\bar\chi_a]$, which is trivial on I' (a Teichmüller lift is trivial where the character is). (d) $v=v_0$, $\bar w=\bar v_0$ (allowed by the reduction above): by (Rd6) all $\bar\chi_a$ agree on D', so all eigenvalues of $\tilde r(\Phi)$ have one and the same reduction $\bar\alpha$ (Step 0), and $q\not\equiv1\bmod\ell$, $\bar\omega$ being unramified at v_0 ($p\neq\ell$) and non-trivial on D'. Let $(\rho,N)=\mathrm{WD}(r_\pi|_{D'})$. If $N\neq0$, then by (38.5), with $\rho(\Phi)=r_\pi(\Phi)$ by (Wd1) (indeed $\rho(\Phi)N=q^{-1}N\rho(\Phi)$ maps the generalised β-eigenspace into the generalised $q^{-1}\beta$-eigenspace, and some generalised eigenvector is not killed by N), $r_\pi(\Phi)$, and hence $\tilde r(\Phi)$, has two eigenvalues of ratio q, whose reductions differ by the factor $q\not\equiv1$: a contradiction. So $N=0$, $\tilde r(\sigma)=\rho(\sigma)\kappa(\sigma)^{-1}$ on inertia (Wd1), and $\tilde r(I')$ is finite. Every eigenvalue of $\tilde r(s)$, $s\in I'$, is a root of unity reducing to 1 (the residual semisimplification is $\bigoplus_a\bar\chi_a$, trivial on I'), hence of ℓ-power order, and $\tilde r(s)$ is semisimple; so $\tilde r(I')$ is a finite ℓ-group. As I' is open normal in D' and its maximal pro-ℓ quotient is a quotient of $t_\ell(I')\subseteq\mathbb{Z}_\ell(1)$ (t_ℓ the ℓ-part of the tame character; wild inertia is pro-p), $\tilde r(I')=\langle\tilde r(s_0)\rangle$ for some $s_0\in I'$, and $\tilde r(\Phi s_0\Phi^{-1})=\tilde r(s_0)^{q^{-1}}$ ($t_\ell(\Phi s\Phi^{-1})=q^{-1}t_\ell(s)$). Suppose $\tilde r(s_0)$ has an

eigenvalue $\mu \neq 1$, of order ℓ^k, $k \geq 1$, with eigenspace W_μ. Then $\tilde{r}(\Phi)W_\mu = W_{\mu^q}$; the orbit $\mu, \mu^q, \mu^{q^2}, \ldots$ has length d equal to the order of q in $(\mathbb{Z}/\ell^k)^\times$, which has a prime divisor $e \neq \ell$ ($q \not\equiv 1 \bmod \ell$, and the order of q modulo ℓ divides $\ell - 1$). On $W = \bigoplus_{i<d} W_{\mu^{q^i}}$, $\tilde{r}(\Phi)$ permutes the summands cyclically, so its characteristic polynomial there is $\det(X^d - \tilde{r}(\Phi)^d|_{W_\mu})$, and with every eigenvalue γ also $\zeta_e\gamma$ is an eigenvalue (ζ_e a primitive e-th root of unity). As $\zeta_e \not\equiv 1$ modulo the maximal ideal ($e \neq \ell$), two eigenvalues of $\tilde{r}(\Phi)$ have different reductions: a contradiction. So $\tilde{r}(s_0) = 1$ and $\tilde{r}(I') = 1$. In all cases $s \in K$.

Step 2: (Zp2). Let $y \in \mathcal{C}$ with λ. Then $y(\mathfrak{P}_{\lambda,1}) = 0$, since for $u \in \mathbb{X}_1$

$$y((w_0\nu)^{-1}(u)\langle u\rangle) = (w_0\nu)^{-1}(u)(w_0\lambda)^{-1}(u),$$

so y is regular. Take π, f as in Step 0. The operator assigned by (Gy7)(c) to $\langle u\rangle$ is $(w_0\lambda)(u)^{-1}\langle u\rangle_\lambda$ ($\langle u\rangle_\lambda$ the action on forms of weight λ), so $\langle u\rangle_\lambda f = (w_0\lambda)(u)y(\langle u\rangle)f = f$ for all $u \in \mathbb{X}$. In particular $T_n(\mathfrak{l}) \subseteq \mathbb{X}$ ($\mathfrak{l}$ the product of the places above ℓ, as in Theorem B.91) acts trivially on f, so f has level $V(\ell^{1,1})$ by the last sentence of Lemma E.21 ($U = V$, $s = 1$, $c = E$, $A = \overline{\mathbb{Q}}_\ell$, α trivial). Since $V(\ell^{0,1}) = V(\ell^{1,1}) \cdot \mathbb{X}$ (at each $v \in S_\ell$, $\mathrm{Iw}(\tilde{v}^{0,1}) = \mathrm{Iw}(\tilde{v}^{1,1})\, T_n(\mathcal{O}_{L_{\tilde{v}}})$: a matrix upper triangular modulo $\varpi_{\tilde{v}}$ is a diagonal unit matrix times one that is unipotent modulo $\varpi_{\tilde{v}}$), f is fixed by $V(\ell^{0,1})$: $\pi^{V(\ell^{0,1})} \cap S^{\mathrm{ord}}_\lambda(V(\ell^{0,1}), \overline{\mathbb{Q}}_\ell) \ni f \neq 0$ (after scaling, f has coefficients in a finite extension of $\mathcal{O}'$). This is the line of (Gy6); it contains f, on which $U^{(j)}_{\lambda,\varpi_{\tilde{v}}}$ (the operator assigned to $U^{(j)}_{\tilde{v}}$ by (Gy7)(c)) acts by $y(U^{(j)}_{\tilde{v}})$, so the eigenvalues $u^{(j)}$ of (Gy6) are the $y(U^{(j)}_{\tilde{v}})$. By (Gy6) (with $U = V$, λ regular), $r_\pi|_{G_{L_{\tilde{v}}}}$ is conjugate to an upper triangular representation with diagonal $(\varepsilon^{1-j}\psi_{\tilde{v},j})_j$, where

$$\psi_{\tilde{v},j}(\mathrm{Art}(x)) = \prod_{\tau'} \tau'(x)^{-\lambda_{\tau',n-j+1}} = (w_0\lambda)(d_j(x))^{-1} = y(\langle d_j(x)\rangle) = \psi^y_{v,j}(\mathrm{Art}(x))$$

for $x \in \mathcal{O}^\times_{L_{\tilde{v}}}$, and $\psi_{\tilde{v},j}(\mathrm{Art}(\varpi_{\tilde{v}})) = y(U^{(j)}_{\tilde{v}})/y(U^{(j-1)}_{\tilde{v}}) = \psi^y_{v,j}(\mathrm{Art}(\varpi_{\tilde{v}}))$. As $\varepsilon = \chi$ and $r_y \cong r_\pi$ (Step 0), $r_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\psi^y_{v,j})_j$.

Step 3: (Zp3), through a given minimal prime. We show: for every minimal prime P of $\mathbb{T}$ and every $t \in \mathbb{T} \setminus P$ there is $y \in \mathcal{C}$ with $y(P) = 0$ and $y(t) \neq 0$. As $\mathbb{T}$ is reduced, every $t \neq 0$ lies outside some minimal prime, so this gives (Zp3). $\mathbb{T}$ is reduced (Lemma E.18) and finite and torsion-free over Λ_1 with the diamond structure ((Gd0)). We may enlarge $\mathcal{O}'$ to contain the e-th roots of unity, e the order of the torsion subgroup Δ of $\mathbb{X}$: $\mathbb{T} \otimes_{\mathcal{O}'} \mathcal{O}''$ is again reduced (it embeds in $\mathbb{T} \otimes \mathcal{K}''$, reduced as a base change of the reduced $\mathbb{T} \otimes \mathcal{K}'$ along a separable field extension) and has the same points, and an element of $\mathbb{T}$ is 0 if it is 0 in $\mathbb{T} \otimes \mathcal{O}''$ (flatness). Let P be a minimal prime of the original $\mathbb{T}$ and $t \notin P$. The ring $\mathbb{T} \otimes \mathcal{O}''$ is integral over $\mathbb{T}$ and contains it, so some prime lies over P; one that is minimal among the primes lying over P is a minimal prime of $\mathbb{T} \otimes \mathcal{O}''$ (a prime contained in it lies over a prime contained in P, hence over P), and it does not contain t; we rename it P. Non-zero elements of Λ_1 are non-zero-divisors on $\mathbb{T}$ and minimal primes consist of zero-divisors, so $\Lambda_1 \to \mathbb{T}/P$ is injective; $\Lambda_1 \cong \mathcal{O}'[[X_1, \ldots, X_{N_0}]]$ is a normal domain ($\mathbb{X}_1 \cong \mathbb{Z}_\ell^{N_0}$: it is torsion-free as ℓ is odd), so the minimal polynomial of $t \bmod P$ over $\mathrm{Frac}(\Lambda_1)$ has coefficients in Λ_1 and constant term $c_0 \neq 0$. Each $\langle\delta\rangle$, $\delta \in \Delta$, is a root in the domain $\mathbb{T}/P \supseteq \mathcal{O}'$ of $X^e - 1 = \prod_{\zeta\in\mu_e(\mathcal{O}')}(X - \zeta)$, so $\langle\delta\rangle \equiv \varepsilon_P(\delta) \bmod P$ for a character $\varepsilon_P\colon \Delta \to \mu_e(\mathcal{O}')$. Write $\mathbb{X} = \Delta \times F'$ with $F' \cong \mathbb{Z}_\ell^{N_0}$ ($\mathbb{X} = \prod_{v\in S_\ell}(\mathcal{O}^\times_{L_v^+})^n$, a finitely generated $\mathbb{Z}_\ell$-module times a finite group); then $\Lambda^+ = \mathcal{O}'[\Delta] \otimes_{\mathcal{O}'} \mathcal{O}'[[F']]$, and the kernel $\mathfrak{q}_P$ of $\varepsilon_P \otimes \mathrm{id}\colon \Lambda^+ \to \mathcal{O}'[[F']]$ is contained in $P \cap \Lambda^+$; as $\Lambda^+/\mathfrak{q}_P \cong \mathcal{O}'[[F']]$ is a domain of the same dimension as $\Lambda^+/(P \cap \Lambda^+)$ (both finite over Λ_1 and containing it), $\mathfrak{q}_P = P \cap \Lambda^+$. For a dominant λ, the homomorphism $\phi_\lambda\colon \Lambda^+ \to \overline{\mathbb{Q}}_\ell$, $[u] \mapsto (w_0\lambda)(u)^{-1}$, kills $\mathfrak{q}_P$ if $(w_0\lambda)^{-1}|_\Delta = \varepsilon_P$.

Let $\mathcal{L}$ be the set of dominant λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$ and $(w_0\lambda)^{-1}|_\Delta = \varepsilon_P$. For each $v \in S_\ell$ fix an embedding τ_v of L_v^+; $\Delta = \prod_v \mu(L_v^+)^n$ with $\mu(L_v^+)$ cyclic of order e_v, on which τ_v is a faithful character; so $(w_0\lambda)^{-1}|_\Delta = \varepsilon_P$ holds as soon as each $\lambda_{\tau_v,i}$ lies in a prescribed class modulo e_v and $\lambda_{\tau',i} \equiv 0 \bmod e_v$ for the other embeddings τ' of L_v^+. Put $k(\lambda)_{\tau',j} = -\lambda_{\tau',n+1-j}$, so that $\phi_\lambda|_{\Lambda_1}$ has kernel $\mathfrak{P}_{k(\lambda)}$ in the notation of Lemma 50.13 ($F^+ = L^+$; $\mathcal{O}' \supseteq \tau'(\mathcal{O}_{L^+})$ by (Rd1)). Write $e_v = \ell^{a_v} e_v'$ with $\ell \nmid e_v'$ and $M = \prod_v e_v'$. The closure of $\{k(\lambda) : \lambda \in \mathcal{L}\}$ contains the open set Ω of $k \in (\mathbb{Z}_\ell^n)^I$ satisfying the congruences modulo ℓ^{a_v} imposed by $\mathcal{L}$: given $k^* \in \Omega \cap (\mathbb{Z}^n)^I$ and $e'' \geq \max_v a_v$, choose integers $\lambda_{\tau',i} \equiv -k^*_{\tau',n+1-i} \bmod \ell^{e''}$ and in the prescribed classes modulo M (Chinese remainder theorem; the conditions modulo ℓ^{a_v} are compatible as $k^* \in \Omega$), then add $\ell^{e''} MA(n-i)$ to $\lambda_{\tau',i}$ with A large: $\lambda \in \mathcal{L}$ and $k(\lambda) \equiv k^* \bmod \ell^{e''}$. By Lemma 50.13, $c_0 \notin \mathfrak{P}_{k(\lambda)}$ for some $\lambda \in \mathcal{L}$. As $\mathbb{T}/P$ is integral over $\Lambda^+/\mathfrak{q}_P$ (finite over Λ_1), lying over gives $y\colon \mathbb{T}/P \to \overline{\mathbb{Q}}_\ell$ extending ϕ_λ (its restriction to $\mathbb{T}$ is an $\mathcal{O}'$-algebra homomorphism from a quotient of $\mathbb{T}_\tau$ to $\overline{\mathbb{Q}}_\ell$, hence continuous by the last sentence of (Gd0) of Lemma E.16: it is a point, and $y \in \mathcal{C}$); $y(t)$ is a root of the image of the minimal polynomial, whose constant term $y(c_0) \neq 0$, so $y(t) \neq 0$; and y kills the original minimal prime.

Step 4: (Zp4). Let y be a point of $\mathbb{T}$ with $y(\langle\delta\rangle) = \chi(\delta)$ for all $\delta \in \Delta_\ell$. Its kernel is a prime ideal, so it contains a minimal prime P of $\mathbb{T}$. For $\delta \in \Delta_\ell$ of order ℓ^k, $t = \langle\delta\rangle$ satisfies $t^{\ell^k} = 1$ and $y(t) = \chi(\delta) \in \mathcal{O}'$, so (Wv3) of Lemma 50.24 (with $R = \mathbb{T}$) gives $\langle\delta\rangle - \chi(\delta) \in P$. Hence P is one of the primes whose intersection is $\mathfrak{a}_\chi$, and $y(\mathfrak{a}_\chi) = 0$; in particular $\mathfrak{a}_\chi \subseteq \bigcap_{y \in \mathcal{C}_\chi} \ker y$. Conversely, let $t \notin \mathfrak{a}_\chi$. Then there is a minimal prime P with $\langle\delta\rangle - \chi(\delta) \in P$ for all $\delta \in \Delta_\ell$ and $t \notin P$, and Step 3 gives $y \in \mathcal{C}$ with $y(P) = 0$ and $y(t) \neq 0$; then $y(\langle\delta\rangle) = \chi(\delta)$ for all δ, so $y \in \mathcal{C}_\chi$ and $t \notin \bigcap_{y \in \mathcal{C}_\chi} \ker y$. (If there is no such P, then $\mathfrak{a}_\chi = \mathbb{T}$, $\mathcal{C}_\chi$ is empty by the first assertion, and both sides are $\mathbb{T}$.)

Step 5: (Zp5). $\mathbb{T} = e_\mathfrak{m}\mathbb{T}_\tau$ acts faithfully on N (if $tN = 0$ for $t = e_\mathfrak{m} t$, then $tN_\tau(K') = 0$, so $t = 0$, $\mathbb{T}_\tau$ being a ring of endomorphisms of $N_\tau(K')$). By (Wf2) of Lemma E.20 (with $K'' = K'$), $N_\tau(K')$ is free of finite rank over $\Lambda_1[\Delta_\ell]$, a local ring ((Wf1)); $e_\mathfrak{m}$ commutes with the diamond operators, so N is a direct summand, finitely generated projective, hence free: $N \cong \Lambda_1[\Delta_\ell]^k$, and $N^\chi = N \otimes_{\mathcal{O}'[\Delta_\ell]} \mathcal{O}'$ ($\mathcal{O}'[\Delta_\ell] \to \mathcal{O}'$ given by χ) is free of rank k over Λ_1. $\Lambda_1 \cong \mathcal{O}'[[X_1, \ldots, X_{N_0}]]$ is a domain ($T_n(\ell^1)$ is torsion-free by (Wf1)); let Φ be its fraction field. Non-zero elements of Λ_1 are non-zero-divisors on $\mathbb{T}$ ((Gd0)), N and N^χ, so these embed in $\mathbb{T}_\Phi = \mathbb{T} \otimes_{\Lambda_1} \Phi$, N_Φ and N^χ_Φ, and $t \in \mathbb{T}$ kills N^χ if and only if it kills N^χ_Φ. $\mathbb{T}$ is reduced (Lemma E.18), so $\mathbb{T}_\Phi$ is reduced and finite over Φ, hence a finite product of fields; its prime ideals are the $P\mathbb{T}_\Phi$ for the primes P of $\mathbb{T}$ with $P \cap \Lambda_1 = 0$, which are exactly the minimal primes of $\mathbb{T}$ (a minimal prime consists of zero-divisors; if $P' \subseteq P$ and $P \cap \Lambda_1 = 0$, then $P' = P$ by incomparability for the integral extension $\Lambda_1 \subseteq \mathbb{T}$). So $\mathbb{T}_\Phi = \prod_P k(P)$ over the minimal primes, $k(P)$ the fraction field of $\mathbb{T}/P$, with idempotents ε_P; $N_\Phi = \bigoplus_P \varepsilon_P N_\Phi$, and every $\varepsilon_P N_\Phi \neq 0$, as $\mathbb{T}_\Phi$ acts faithfully on N_Φ. For $\delta \in \Delta_\ell$, $\langle\delta\rangle - \chi(\delta)$ acts on $\varepsilon_P N_\Phi$ through its image in $k(P)$: by 0 if $\langle\delta\rangle - \chi(\delta) \in P$, invertibly otherwise. Hence $N^\chi_\Phi = \bigoplus_{P \in \mathcal{P}_\chi} \varepsilon_P N_\Phi$, $\mathcal{P}_\chi$ the set of minimal primes containing every $\langle\delta\rangle - \chi(\delta)$, and $t \in \mathbb{T}$ kills N^χ_Φ if and only if $\varepsilon_P t = 0$, i.e. $t \in P$, for every $P \in \mathcal{P}_\chi$. So the annihilator of N^χ is $\bigcap_{P \in \mathcal{P}_\chi} P = \mathfrak{a}_\chi$. □

Lemma E.18. *Let $((V_v)_{v \in \mathrm{St}}, \tau)$ be a type datum (over a rank-n Hecke datum $\mathscr{H}$ over $\mathcal{O}$, or over L), and let Q and K' be as in the levels at auxiliary places of Definition 50.8; here $Q = \varnothing$ is allowed, and $Q \neq \varnothing$ occurs only over $\mathscr{H}$. Then the ordinary Hecke algebra $\mathbb{T}_\tau(K')$ of type τ at level K' (for $Q = \varnothing$: $\mathbb{T}_\tau$) is reduced; hence so is its localisation $\mathbb{T}_{\tau,\mathfrak{m}}$ at every maximal ideal $\mathfrak{m}$.*

Proof. Write V, N_τ, $\mathbb{T}^{\mathrm{ord}}(V)$, $\mathbb{T}_\tau$ for $V(K')$, $N_\tau(K')$, $\mathbb{T}^{\mathrm{ord}}(V(K'))$, $\mathbb{T}_\tau(K')$, $\mathbb{G} = \mathbb{G}_L$, $\mathcal{K} = \mathcal{O}[1/\ell]$, and for $c \geq 1$ put $U_c = V(\ell^{c,c})$ and $X_c = \mathbb{G}(L^+)\backslash\mathbb{G}(\mathbb{A}^\infty_{L^+})/U_c$, a finite set ($\mathbb{G}(L^+ \otimes \mathbb{R})$ is compact).

Step 1: finite levels. In trivial weight a form of level U_c with coefficients in an $\mathcal{O}$-module A is a function $X_c \to A$, so $S(U_c, \mathcal{K}/\mathcal{O}) = S(U_c, \mathcal{O}) \otimes_{\mathcal{O}} \mathcal{K}/\mathcal{O}$ with $S(U_c, \mathcal{O})$ finite free. Let P_c be the product of the operators $U_{\tilde{v}}^{(j)}$ ($v \in S_\ell$, $1 \le j \le n$) on $S(U_c, \mathcal{O})$ and $e_c = \lim_m P_c^{m!}$, the idempotent of the finite $\mathcal{O}$-algebra $\mathcal{O}[P_c]$ cutting out the part on which P_c, equivalently every $U_{\tilde{v}}^{(j)}$, is invertible. Then $M_c = e_c S(U_c, \mathcal{O})$ is finite free, $S^{\mathrm{ord}}(U_c, \mathcal{K}/\mathcal{O}) = M_c \otimes_{\mathcal{O}} \mathcal{K}/\mathcal{O}$ (the ordinary part of a torsion module $M \otimes \mathcal{K}/\mathcal{O}$ is $eM \otimes \mathcal{K}/\mathcal{O}$, since e commutes with $\otimes$ and $U^{(j)}$ is invertible on $(1-e)M \otimes \ell^{-k}\mathcal{O}/\mathcal{O}$ only if this module is 0), and $S^{\mathrm{ord}}(V(\ell^\infty), \mathcal{K}/\mathcal{O}) = \bigcup_c M_c \otimes \mathcal{K}/\mathcal{O}$. All the operators $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ ($u \in T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)$, acting through the finite quotient $T_n(\mathcal{O}_{L^+}/\ell^c)$) and the action of H preserve M_c, and the operators commute with H. Let $A_c \subseteq \mathrm{End}_{\mathcal{O}}(M_c)$ be the $\mathcal{O}$-algebra they generate (commutative, [105], Lemma 2.3.3); it is a finite $\mathcal{O}$-module, hence closed, so the image of $\mathbb{T}^{\mathrm{ord}}(V)$ (the closure of the algebra generated by the same operators over $\mathcal{O}[T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)]$) acting on M_c lies in A_c.

Step 2: A_c acts semisimply on $M_c \otimes \overline{\mathbb{Q}}_\ell$. Transport by ι to $\mathbb{C}$. By [105], Lemma 2.2.5 (trivial weight), $\varinjlim_U S(U, \mathbb{C})$ is the space of automorphic forms on $\mathbb{G}(L^+)\backslash\mathbb{G}(\mathbb{A}_{L^+})$ with trivial archimedean type, a semisimple admissible $\mathbb{G}(\mathbb{A}_{L^+}^\infty)$-module; so $S(U_c, \mathbb{C}) = \bigoplus_\sigma m(\sigma)\, \sigma^{U_c}$ over irreducible $\sigma = \bigotimes_v' \sigma_v$ with finite multiplicities, and $\sigma^{U_c} = \bigotimes_v \sigma_v^{U_{c,v}}$. On each summand $T_w^{(j)}$ acts on the line $\sigma_v^{\mathbb{G}(\mathcal{O}_{L_v^+})}$ ($w \mid v \notin T_L \cup Q$) by a scalar, and $U_{\tilde{v}}^{(j)}$, $\langle u \rangle$ act on the factor $\sigma_v^{\mathrm{Iw}(\tilde{v}^{c,c})}$, $v \in S_\ell$; the operators $U_{\tilde{v}}^{(j)}$ preserve the lattice, so their eigenvalues are ℓ-adic integers (after ι^{-1}), e_c is the projection onto the sum of the generalised eigenspaces of P_c with unit eigenvalues, and $e_c\sigma^{U_c} = \bigotimes_{v \in S_\ell} (\sigma_v^{\mathrm{Iw}(\tilde{v}^{c,c})})^{\mathrm{ord}} \otimes \bigotimes_{v \notin S_\ell} \sigma_v^{U_{c,v}}$, where for $v \in S_\ell$ the ordinary part is the sum of the joint generalised eigenspaces of the $U_{\tilde{v}}^{(j)}$ with unit eigenvalues. For $v \in S_\ell$, $K = L_{\tilde{v}}$ with uniformiser ϖ and the irreducible smooth representation $\sigma' = \sigma_v \circ \iota_{\tilde{v}}^{-1}$ of $\mathrm{GL}_n(K)$, the operators $U_\varpi^{(j)}$ and $\sigma'(u)$, $u \in T_n(\mathcal{O}_K)$, act semisimply on $Y = (\sigma'^{\mathrm{Iw}(\varpi^{c,c})})^{\mathrm{ord}}$ by Lemma E.19; so all generators of A_c are diagonalisable and commute, and $M_c \otimes \overline{\mathbb{Q}}_\ell$ is the direct sum of the joint eigenspaces of A_c.

Step 3: $\mathbb{T}_\tau$ is reduced. By Pontryagin duality ($\mathrm{Hom}_{\mathcal{O}}(M \otimes \mathcal{K}/\mathcal{O}, \mathcal{K}/\mathcal{O}) = \mathrm{Hom}_{\mathcal{O}}(M, \mathcal{O})$ for M finite free), restriction to the submodules $M_c \otimes \mathcal{K}/\mathcal{O}$, whose union is $S^{\mathrm{ord}}(V(\ell^\infty), \mathcal{K}/\mathcal{O})$, gives an injective map $\mathcal{S}_V \to \prod_c M_c^*$, $M_c^* = \mathrm{Hom}_{\mathcal{O}}(M_c, \mathcal{O})$, equivariant for H and for $\mathbb{T}^{\mathrm{ord}}(V)$ (acting on M_c^* by transposes). Applying the left exact functor $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ gives an injective $\mathbb{T}^{\mathrm{ord}}(V)$-map $N_\tau \to \prod_c N_c$, $N_c = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, M_c^*)$, a finite free $\mathcal{O}$-module; let $N_c' \subseteq N_c$ be the image of N_τ, a $\mathbb{T}^{\mathrm{ord}}(V)$-stable submodule. By Step 2, $M_c^* \otimes \overline{\mathbb{Q}}_\ell$ is the direct sum of the joint eigenspaces E_χ of the transposes of A_c (dual basis), each H-stable (the actions commute), so $N_c \otimes \overline{\mathbb{Q}}_\ell = \bigoplus_\chi \mathrm{Hom}_H(\tau \otimes \overline{\mathbb{Q}}_\ell, E_\chi)$, on whose summands every $t \in \mathbb{T}^{\mathrm{ord}}(V)$ acts by the scalar $\chi(t)$ (Step 1: t acts on M_c through A_c). Now let $t \in \mathbb{T}^{\mathrm{ord}}(V)$ act nilpotently on N_τ, $t^k N_\tau = 0$. Then t^k kills N_c'; $N_c' \otimes \overline{\mathbb{Q}}_\ell$ is a sum of its intersections with the summands above (a submodule stable under a commuting family of diagonalisable operators), on each of which t acts by a scalar $\chi(t)$ with $\chi(t)^k = 0$; so t kills $N_c' \otimes \overline{\mathbb{Q}}_\ell$, hence the torsion-free N_c'. Thus the image of tN_τ in every N_c is 0, and $tN_\tau = 0$. As $\mathbb{T}_\tau$ is the image of $\mathbb{T}^{\mathrm{ord}}(V)$ in $\mathrm{End}_{\mathcal{O}}(N_\tau)$, every nilpotent element of $\mathbb{T}_\tau$ is 0. A localisation of a reduced ring is reduced. □

Lemma E.19. *Let K be a finite extension of $\mathbb{Q}_\ell$ with uniformiser ϖ, $n \ge 1$, $c \ge 1$, and σ' an irreducible smooth representation of $\mathrm{GL}_n(K)$ on a $\overline{\mathbb{Q}}_\ell$-vector space. Let $c_0 = 0, c_1, \dots, c_n$ be rational numbers such that $c_j - c_{j-1}$ is non-decreasing in j (for instance all $c_j = 0$), and let $Y \subseteq \sigma'^{\mathrm{Iw}(\varpi^{c,c})}$ be the sum of the joint generalised eigenspaces of the commuting operators $U_\varpi^{(1)}, \dots, U_\varpi^{(n)}$ whose eigenvalues $e_1, \dots, e_n$ satisfy $v_\ell(e_j) = c_j$ for all j (v_ℓ the valuation of $\overline{\mathbb{Q}}_\ell$ with $v_\ell(\ell) = 1$). For $c_j = 0$ for all j, Y is the **ordinary part**. Then the operators $U_\varpi^{(j)}$ ($1 \le j \le n$) and $\sigma'(u)$ ($u \in T_n(\mathcal{O}_K)$) act semisimply on Y, and every joint eigenspace of this*

commuting family on Y has dimension at most one.

Proof. Write $\alpha^{(j)} = \alpha_\varpi^{(j)}$ and let $j\colon \sigma'^{\mathrm{Iw}(\varpi^{c,c})} \to X = (\sigma'_{N_n})^{T_n(\varpi^c)}$ be the map of (Gy7)(a). By (Gy7)(a), j is $T_n(\mathcal{O}_K)$-equivariant with $j \circ U_\varpi^{(j)} = \delta_B(\alpha^{(j)})^{-1}\sigma'_{N_n}(\alpha^{(j)}) \circ j$, and its kernel is the part on which some $U_\varpi^{(j)}$ is not invertible. Y is stable under the $U_\varpi^{(j)}$ and under $T_n(\mathcal{O}_K)$ (which commutes with them), the $U_\varpi^{(j)}$ are invertible on Y (their eigenvalues there have finite valuation, so are non-zero), so $Y \cap \ker j = 0$ and $j|_Y$ is injective and intertwines the actions of the $U_\varpi^{(j)}$ with those of $\delta_B(\alpha^{(j)})^{-1}\sigma'_{N_n}(\alpha^{(j)})$, and of $T_n(\mathcal{O}_K)$. X is a finite-dimensional direct summand of σ'_{N_n} stable under $T_n(K)$ (averaging over $T_n(\varpi^c)$; σ'_{N_n} is admissible), hence the direct sum of its joint generalised eigenspaces X_ψ for characters ψ of $T_n(K)$. As $T_n(K)$ is generated by $T_n(\mathcal{O}_K)$ and the $\alpha^{(j)}$, $j(Y)$ is $T_n(K)$-stable, hence the sum of its intersections with the X_ψ, and only ψ with $v_\ell(\delta_B(\alpha^{(j)})^{-1}\psi(\alpha^{(j)})) = c_j$ for every j (call such ψ *of slope* c) occur. A character ψ of $T_n(K)$ is determined by its values on $T_n(\mathcal{O}_K)$ and on the $\alpha^{(j)}$. It therefore suffices to show $\dim X_\psi \le 1$ for ψ of slope c: then $T_n(K)$ acts on X_ψ by ψ, $Y \cong j(Y)$ is a direct sum of lines on which the $U_\varpi^{(j)}$ and $T_n(\mathcal{O}_K)$ act by scalars, and distinct lines carry distinct characters ψ, hence distinct joint eigencharacters.

Let ψ be of slope c with $X_\psi \neq 0$ and $\psi_i(x) = \psi(\mathrm{diag}(1,\dots,x,\dots,1))$ (x in place i). Since $\delta_B(\alpha^{(j)}) = q^{-j(n-j)}$ and $\psi(\alpha^{(j)}) = \prod_{i\le j}\psi_i(\varpi)$, the slope condition gives $v_\ell(\psi_1(\varpi)\cdots\psi_j(\varpi)) = -fj(n-j) + c_j$ for all j, so

$$v_\ell(\psi_j(\varpi)) = -f\big(j(n-j) - (j-1)(n-j+1)\big) + (c_j - c_{j-1}) = -f(n+1-2j) + (c_j - c_{j-1});$$

put $\xi = \delta_B^{-1/2}\psi$, so $v_\ell(\xi_i(\varpi)) = -\frac{f}{2}(n+1-2i) + (c_i - c_{i-1})$, strictly increasing in i as $f > 0$ and $c_i - c_{i-1}$ is non-decreasing, and the ξ_i are pairwise distinct characters of $K^\times$. As $X_\psi \neq 0$, the $T_n(K)$-module σ'_{N_n} has the quotient ψ (a non-zero linear form on X_ψ vanishing on the images of the nilpotent operators $\sigma'_{N_n}(t) - \psi(t)$, composed with the projection onto X_ψ), so by Frobenius reciprocity ([27], Proposition 2.3) σ' embeds in the normalised induction $I(\xi) = \text{n-Ind}_B^{\mathrm{GL}_n(K)}(\xi_1 \otimes \cdots \otimes \xi_n)$. The Jacquet functor is exact, and the semisimplification of $I(\xi)_{N_n}$ is $\bigoplus_{w\in S_n} \delta_B^{1/2}\, w(\xi)$ ([27, 2.12], the geometric lemma). As the ξ_i are pairwise distinct, $w(\xi) = \xi$ only for $w = 1$, so $\psi = \delta_B^{1/2}\xi$ occurs in $I(\xi)_{N_n}$, hence in σ'_{N_n}, with multiplicity at most one; thus the generalised eigenspace of $T_n(K)$ on σ'_{N_n} for ψ, which contains X_ψ, has dimension at most one. □

Lemma E.20. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, $((V_v)_{v\in\mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$, Q a finite set of places of L^+ split in L and not in T_L, and $K'' = \prod_{v\in Q} K''_v \subseteq K' = \prod_{v\in Q} K'_v$ compact open subgroups of $\prod_{v\in Q}\mathbb{G}_L(L_v^+)$ with K''_v normal in K'_v for every $v \in Q$, such that $\Gamma = K'/K''$ is an ℓ-group (for instance $K'' = K'$). Let Γ act on $N_\tau(K'')$ through $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ applied to the action on $\mathcal{S}_{V(K'')}$ dual to right translation by K'. Let Δ be the set of elements of ℓ-power order of $T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)$. Then:*

(Wf1) *Δ is a finite subgroup and $\Delta \cap T_n(\ell^1) = \{1\}$; so $(\delta, u) \mapsto \delta u$ is an isomorphism of $\Delta \times T_n(\ell^1)$ onto an open subgroup of $T_n(\mathcal{O}_{L^+} \otimes \mathbb{Z}_\ell)$, and $\Lambda_1[\Delta\times\Gamma] = \mathcal{O}[[\Delta \times T_n(\ell^1) \times \Gamma]]$ acts on $N_\tau(K'')$ through the diamond operators and the action of Γ, which commute.*

(Wf2) *$N_\tau(K'')$ is a free $\Lambda_1[\Delta\times\Gamma]$-module of finite rank.*

(Wf3) *Let $\chi\colon \Delta \to \mathcal{O}^\times$ be a homomorphism, let*

$$N^\chi = N_\tau(K'')/\sum_{\delta\in\Delta}(\langle\delta\rangle - \chi(\delta))N_\tau(K''),$$

and let Γ *act on* $\mathrm{Hom}_{\Lambda_1}(N^\chi,\Lambda_1)$ *by* $\phi\mapsto\phi\circ\gamma^{-1}$. *Then* N^χ *and* $\mathrm{Hom}_{\Lambda_1}(N^\chi,\Lambda_1)$ *are free* $\Lambda_1[\Gamma]$*-modules of the same finite rank, and composition with the projection identifies* $\mathrm{Hom}_{\Lambda_1}(N^\chi,\Lambda_1)$ *with*

$$\{\phi\in\mathrm{Hom}_{\Lambda_1}(N_\tau(K''),\Lambda_1):\phi\circ\langle\delta\rangle=\chi(\delta)\phi\ \textit{for all}\ \delta\in\Delta\}.$$

Proof. Write ϖ for a uniformiser and $\mathbb{F}$ for the residue field of $\mathcal{O}$. For $v\in S_\ell$ let $\mathcal{O}_v$ be the ring of integers of L_v^+, ϖ_v a uniformiser, k_v the residue field and e_v the ramification index over $\mathbb{Q}_\ell$; through $\tilde v$ we have $L_{\tilde v}=L_v^+$ and $T_n(\mathcal{O}_{L^+}\otimes\mathbb{Z}_\ell)=\prod_{v\in S_\ell}T_n(\mathcal{O}_v)$, diagonal in $\prod_{v\in S_\ell}\mathrm{GL}_n(\mathcal{O}_{L_{\tilde v}})$. By [105], §2.1, $\mathrm{Iw}(\tilde v^{b,c})$ $(0\le b\le c)$ is the group of matrices of $\mathrm{GL}_n(\mathcal{O}_v)$ that are upper triangular modulo ϖ_v^c and unipotent modulo ϖ_v^b. For $b\ge1$ put

$$\Sigma_b=\prod_{v\in S_\ell}(1+\varpi_v^b\mathcal{O}_v)^n\subseteq T_n(\mathcal{O}_{L^+}\otimes\mathbb{Z}_\ell),\qquad \Sigma=\Sigma_1,$$
$$\Lambda'=\mathcal{O}[[\Sigma]],\qquad \mathfrak{a}_b=\ker(\Lambda'\to\mathcal{O}[\Sigma/\Sigma_b]),$$

and let $\mathfrak{m}'=\mathfrak{a}_1+\varpi\Lambda'$, the maximal ideal of Λ'.

Step 1: (Wf1) and the rings. Let $v\in S_\ell$. As $k_v^\times$ has order prime to ℓ, an element of $\mathcal{O}_v^\times$ of ℓ-power order lies in $1+\varpi_v\mathcal{O}_v$. If $\zeta\in L_v^+$ has order ℓ^k, $k\ge1$, then $v(\zeta-1)=e_v/(\ell^{k-1}(\ell-1))\le e_v/(\ell-1)<e_v=v(\ell)$, because $\ell\ge3$ (Definition 50.1); so $\zeta\notin1+\ell\mathcal{O}_v$. Hence $\Delta=\prod_{v\in S_\ell}\mu_{\ell^\infty}(L_v^+)^n$ is a finite group (a local field has finitely many roots of unity), $\Delta\subseteq\Sigma$, and $\Delta\cap T_n(\ell^1)=\{1\}$. The group is abelian, so $(\delta,u)\mapsto\delta u$ is an injective homomorphism; its image $\Sigma^\circ=\Delta\,T_n(\ell^1)$ contains the open subgroup $T_n(\ell^1)$, so it is open, of finite index in Σ. Each $1+\varpi_v\mathcal{O}_v$ is a finitely generated $\mathbb{Z}_\ell$-module (the logarithm maps $1+\varpi_v^b\mathcal{O}_v$ isomorphically onto $\varpi_v^b\mathcal{O}_v$ for large b), so $\Sigma\cong\Sigma_{\mathrm{tors}}\times\mathbb{Z}_\ell^d$ and $\Lambda'\cong\mathcal{O}[\Sigma_{\mathrm{tors}}][[X_1,\dots,X_d]]$ is noetherian; Σ is pro-ℓ, since $(1+\varpi_v^b\mathcal{O}_v)/(1+\varpi_v^{b+1}\mathcal{O}_v)\cong k_v$. So $\Sigma\times\Gamma$ is pro-ℓ and $\Lambda'[\Gamma]=\mathcal{O}[[\Sigma\times\Gamma]]$ is a local ring: modulo ϖ each $\mathcal{O}[\Sigma/\Sigma_b\times\Gamma]$ is the group algebra of a finite ℓ-group over a field of characteristic ℓ. Finally $\Lambda'[\Gamma]$ is a free $\Lambda_1[\Delta\times\Gamma]=\mathcal{O}[[\Sigma^\circ\times\Gamma]]$-module with basis a set of representatives of Σ/Σ°: this holds for $\mathcal{O}[\Sigma/\Sigma_b\times\Gamma]$ over $\mathcal{O}[\Sigma^\circ/\Sigma_b\times\Gamma]$ for every b with $\Sigma_b\subseteq\Sigma^\circ$, compatibly in b, and passes to the inverse limit. The diamond operators commute with each other and with the action of Γ (supported at Q, while $\langle u\rangle$ is supported at S_ℓ), which gives (Wf1).

Step 2: the levels. Let U be the group with components $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ at $v\in\mathrm{St}$, K_v' at $v\in Q$, and those of the level V elsewhere, and $U'=V(K'')$. Both are as in Theorem B.91 with $F=L$, $\mathbb{G}=\mathbb{G}_L$, $T=T_L\cup Q$ (all places of T split in L; the components at S_ℓ and at the split places outside T are hyperspecial). U_v' is normal in U_v for every v, and $U_v=U_v'$ for $v\notin\mathrm{St}\cup Q$. For $1\le b\le c$, $U(\ell^{b,c})$ and $U'(\ell^{b,c})$ are sufficiently small: their component at $v_0\notin\mathrm{St}\cup Q\cup S_\ell$ is the kernel of reduction modulo p of $\mathrm{GL}_n(\mathcal{O}_{L_{\tilde v_0}})$, p odd and unramified in L (Definition 50.8), which has no element of finite order other than 1.

Reduction of the diagonal modulo ϖ_v^c is a homomorphism $\mathrm{Iw}(\tilde v^{0,c})\to T_n(\mathcal{O}_v/\varpi_v^c)$ with kernel $\mathrm{Iw}(\tilde v^{c,c})$, and $\mathrm{Iw}(\tilde v^{b,c})$ is the preimage of the image of $(1+\varpi_v^b\mathcal{O}_v)^n$. Hence $U'(\ell^{c,c})$ is normal in $U(\ell^{1,c})$, $U'(\ell^{b,c})=U'(\ell^{c,c})\,\Sigma_b$, and the inclusions of Σ (at the places of S_ℓ) and of $\prod_{v\notin S_\ell}U_v$ induce an isomorphism

$$G_c:=(\Sigma/\Sigma_c)\times H\times\Gamma\ \xrightarrow{\sim}\ U(\ell^{1,c})/U'(\ell^{c,c}).$$

For $u\in T_n(\mathcal{O}_{L^+}\otimes\mathbb{Z}_\ell)$, which normalises every $\mathrm{Iw}(\tilde v^{c,c})$, the diamond operator

$$\langle u\rangle=[U'(\ell^{c,c})\,u\,U'(\ell^{c,c})]$$

of [105], §2.3, acts on $S(U'(\ell^{c,c}),A)$ by $f\mapsto f(\cdot\,u)$. So, with Σ_b acting through diamond operators, $S(U'(\ell^{c,c}),A)^{\Sigma_b}=S(U'(\ell^{b,c}),A)$.

Step 3: the invariants of the ordinary forms. Let $1 \le b \le c$. The operators $U_{\tilde{v}}^{(j)}$ on the levels $U'(\ell^{b,c})$ and $U'(\ell^{c,c})$ are the double coset operators of the same elements $\alpha_{\varpi_{\tilde{v}}}^{(j)}$, for which one set of coset representatives serves all levels $U'(\ell^{b',c'})$ with $c' > 0$ ([105], proof of Lemma 2.5.2); so the operators of level (b,c) are the restrictions of those of level (c,c), and so are the ordinary idempotents. The Hecke algebra of a finite level is commutative ([105], Lemma 2.3.3), so e commutes with the diamond operators, and Step 2 gives $S^{\mathrm{ord}}(U'(\ell^{c,c}),A)^{\Sigma_b} = S^{\mathrm{ord}}(U'(\ell^{b,c}),A)$, which is $S^{\mathrm{ord}}(U'(\ell^{b,b}),A)$ by (Gk2) for U'. Let $M = S^{\mathrm{ord}}(U'(\ell^{\infty}),\mathcal{K}/\mathcal{O}) = \bigcup_c S^{\mathrm{ord}}(U'(\ell^{c,c}),\mathcal{K}/\mathcal{O})$, so that $\mathcal{S}' := \mathcal{S}_{V(K'')} = M^{\vee}$. Taking the union over $c \ge b$,

$$M^{\Sigma_b} = S^{\mathrm{ord}}(U'(\ell^{b,b}),\mathcal{K}/\mathcal{O}).$$

Every element of M is fixed by some Σ_c, so M is a discrete Λ'-module. Let $u_1,\dots,u_k$ generate Σ_b topologically. The ideal J of Λ' generated by the $[u_i]-1$ equals $\mathfrak{a}_b$.

So $M[\mathfrak{a}_b] = M^{\Sigma_b}$, the kernel of $M \to M^k$, $m \mapsto (([u_i]-1)m)_i$. Duality gives $\mathcal{S}'/\mathfrak{a}_b\mathcal{S}' \cong (M^{\Sigma_b})^{\vee}$. The set $X_b = \mathbb{G}_L(L^+)\backslash\mathbb{G}_L(\mathbb{A}_{L^+}^{\infty})/U'(\ell^{b,b})$ is finite ($\mathbb{G}_L(L^+\otimes\mathbb{R})$ is compact), so $S(U'(\ell^{b,b}),A) = \mathcal{O}^{X_b}\otimes_{\mathcal{O}} A$ with e acting as $e\otimes 1$; thus $M^{\Sigma_b} = L_b\otimes_{\mathcal{O}}\mathcal{K}/\mathcal{O}$ with $L_b = e\,\mathcal{O}^{X_b}$ finite free over $\mathcal{O}$, and

$$\mathcal{S}'/\mathfrak{a}_b\mathcal{S}' \cong D_b := \mathrm{Hom}_{\mathcal{O}}(L_b,\mathcal{O}),$$

equivariantly for G_b (Σ/Σ_b through the diamond operators, H and Γ by right translation, acting on D_b contragrediently).

Step 4: D_b is projective over $\mathcal{O}[G_b]$. By (Gk1) for the sufficiently small group $U(\ell^{1,b})$, whose components at S_ℓ lie in $\mathrm{GL}_n(\mathcal{O}_v)$, and its open normal subgroup $U'(\ell^{b,b})$ (Step 2), $\mathcal{O}^{X_b} = S(U'(\ell^{b,b}),\mathcal{O})$ is a finite free $\mathcal{O}[G_b]$-module, G_b acting by right translation, which on Σ/Σ_b is the action of the diamond operators (Step 2). The idempotent e commutes with G_b (Step 3 for Σ/Σ_b; H and Γ act at places outside S_ℓ, where the $U_{\tilde{v}}^{(j)}$ are supported), so L_b is a direct summand of $\mathcal{O}^{X_b}$, finitely generated projective over $\mathcal{O}[G_b]$. The $\mathcal{O}$-dual of $\mathcal{O}[G_b]$ with the contragredient action is isomorphic to $\mathcal{O}[G_b]$ (the dual basis (δ_g) is permuted simply transitively), and $\mathrm{Hom}_{\mathcal{O}}(-,\mathcal{O})$ preserves finite direct sums and summands; so D_b is finitely generated projective over $\mathcal{O}[G_b]$.

Step 5: $\mathcal{S}'$ is free over Λ'. $\mathcal{O}[G_b]$ is free over $\mathcal{O}[\Sigma/\Sigma_b]$, a local ring, so D_b is free over $\mathcal{O}[\Sigma/\Sigma_b]$, of some rank r_b. Since $\mathfrak{a}_b \subseteq \mathfrak{a}_1$ and $\Lambda'/\mathfrak{a}_1 = \mathcal{O}$, $D_b/\mathfrak{a}_1 D_b \cong \mathcal{S}'/\mathfrak{a}_1\mathcal{S}' \cong D_1$, so $r_b = r := \mathrm{rank}_{\mathcal{O}} D_1$ for every b. By (Gy1) for U' with $b_0 = 1$ ($U'(\ell^{1,1})$ is sufficiently small), $\mathcal{S}'$ is finitely generated over $\Lambda_1 \subseteq \Lambda'$, hence over Λ'. As $\mathcal{S}'/\mathfrak{m}'\mathcal{S}' \cong D_1/\varpi D_1$ has dimension r over $\mathbb{F}$, Nakayama's lemma gives a surjection $\varphi\colon \Lambda'^{r} \to \mathcal{S}'$. For every b, φ induces a surjection $(\Lambda'/\mathfrak{a}_b)^r \to \mathcal{S}'/\mathfrak{a}_b\mathcal{S}' \cong (\Lambda'/\mathfrak{a}_b)^r$ between free modules of the same finite rank over a commutative ring, which is therefore an isomorphism; so $\ker\varphi \subseteq \mathfrak{a}_b\Lambda'^{r}$ for every b, and $\bigcap_b \mathfrak{a}_b = 0$ ($\Lambda' = \varprojlim_b \mathcal{O}[\Sigma/\Sigma_b]$). Hence $\mathcal{S}'$ is free of rank r over Λ'.

Step 6: $\mathcal{S}'$ is projective over $R = \Lambda'[H\times\Gamma]$. R is a free Λ'-module of finite rank and $R/\mathfrak{m}'R = \mathbb{F}[H\times\Gamma]$. By Steps 3 and 4 ($b=1$, $G_1 = H\times\Gamma$), $\mathcal{S}'/\mathfrak{m}'\mathcal{S}' \cong D_1/\varpi D_1$ is a finitely generated projective $\mathbb{F}[H\times\Gamma]$-module: $D_1/\varpi D_1 \cong \mathbb{F}[H\times\Gamma]^s\varepsilon_0$ for an idempotent matrix $\varepsilon_0 \in \mathrm{M}_s(\mathbb{F}[H\times\Gamma])$ acting on row vectors. $\mathrm{M}_s(R)$ is complete for the topology of the two-sided ideal $\mathrm{M}_s(\mathfrak{m}'R)$ (R is finite over the $\mathfrak{m}'$-adically complete ring Λ'), so ε_0 lifts to an idempotent $\varepsilon \in \mathrm{M}_s(R)$. Then $P = R^s\varepsilon$ is finitely generated projective over R with $P/\mathfrak{m}'P \cong \mathcal{S}'/\mathfrak{m}'\mathcal{S}'$, and the composite $P \to P/\mathfrak{m}'P \cong \mathcal{S}'/\mathfrak{m}'\mathcal{S}'$ lifts to an R-linear $\psi\colon P \to \mathcal{S}'$. Its image I satisfies $I + \mathfrak{m}'\mathcal{S}' = \mathcal{S}'$, so ψ is surjective (Nakayama over Λ'). Let $K = \ker\psi$. As $\mathcal{S}'$ is free over Λ' (Step 5), $\mathrm{Tor}_1^{\Lambda'}(\mathcal{S}',\mathbb{F}) = 0$, so $0 \to K/\mathfrak{m}'K \to P/\mathfrak{m}'P \to \mathcal{S}'/\mathfrak{m}'\mathcal{S}' \to 0$ is exact; the last map is an isomorphism, so $K/\mathfrak{m}'K = 0$, and K, a submodule of a finitely generated module over the noetherian ring Λ', is finitely generated, hence $K = 0$. So $\mathcal{S}' \cong P$ is a direct summand of R^s as an R-module.

Step 7: (Wf2). Write $R = \Lambda'[\Gamma] \otimes_{\mathcal{O}} \mathcal{O}[H]$, with $\Lambda'[\Gamma]$ acting on the first factor and H by left multiplication on the second. As $\Lambda'[\Gamma]$ is flat over $\mathcal{O}$ and τ is finite free over $\mathcal{O}$, $f \mapsto \epsilon \circ f$ (ϵ the coefficient of $1 \in H$) is an isomorphism of $\Lambda'[\Gamma]$-modules

$$\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R) \cong \Lambda'[\Gamma] \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O}),$$

with inverse $\varphi \mapsto (t \mapsto \sum_{h \in H} \varphi(h^{-1}t)\, h)$; so $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R)$ is free of finite rank over $\Lambda'[\Gamma]$. The functor $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ is additive, so by Step 6 $N_\tau(K'') = \mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{S}')$ is a direct summand of $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R)^s$ as a $\Lambda'[\Gamma]$-module: finitely generated projective, hence free, $\Lambda'[\Gamma]$ being local (Step 1). Since $\Lambda'[\Gamma]$ is free of finite rank over $\Lambda_1[\Delta \times \Gamma]$ (Step 1), whose action is the restriction of that of $\Lambda'[\Gamma]$, $N_\tau(K'')$ is free of finite rank over $\Lambda_1[\Delta \times \Gamma]$.

Step 8: (Wf3). Let $N = N_\tau(K'') \cong \Lambda_1[\Delta \times \Gamma]^k$ (Step 7). Then $N^\chi = N \otimes_{\mathcal{O}[\Delta]} \mathcal{O}$, $\mathcal{O}[\Delta] \to \mathcal{O}$ given by χ, is isomorphic to $(\Lambda_1[\Delta \times \Gamma] \otimes_{\mathcal{O}[\Delta]} \mathcal{O})^k = \Lambda_1[\Gamma]^k$ as a $\Lambda_1[\Gamma]$-module. A Λ_1-linear $\phi\colon N \to \Lambda_1$ factors through N^χ if and only if it kills every $(\langle\delta\rangle - \chi(\delta))x$, i.e. $\phi \circ \langle\delta\rangle = \chi(\delta)\phi$ for all $\delta \in \Delta$; this is the identification stated. Finally $\mathrm{Hom}_{\Lambda_1}(\Lambda_1[\Gamma], \Lambda_1)$, with γ acting by $\phi \mapsto \phi \circ \gamma^{-1}$, is free of rank one over $\Lambda_1[\Gamma]$, since $\delta_g \circ \gamma^{-1} = \delta_{\gamma g}$ for the dual basis $(\delta_g)_{g \in \Gamma}$; as $\mathrm{Hom}_{\Lambda_1}(-, \Lambda_1)$ preserves finite direct sums, $\mathrm{Hom}_{\Lambda_1}(N^\chi, \Lambda_1) \cong \Lambda_1[\Gamma]^k$. □

Lemma E.21. *Let the data be as in Theorem B.91, λ a dominant weight, $1 \le s \le c$ integers, $\mathcal{O}'' \supseteq \mathcal{O}$ the ring of integers of a finite extension of $\mathcal{O}[1/\ell]$ in $\overline{\mathbb{Q}}_\ell$, and $f \in S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \mathcal{O}''[1/\ell])$ with $\langle u\rangle f = f$ for every $u \in T_n(\mathfrak{l}^s)$. Then $f \in S_\lambda^{\mathrm{ord}}(U(\ell^{s,s}), \mathcal{O}''[1/\ell])$. Consequently, for a field $A \supseteq \mathcal{O}$ of characteristic 0 and a character α of finite order of $T_n(\mathfrak{l})$ with values in A and $T_n(\mathfrak{l}^s) \subseteq \ker\alpha$, the inclusion $S_\lambda^{\mathrm{ord}}(U(\ell^{s,s}), \alpha, A) \subseteq S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \alpha, A)$ is an equality.*

Proof. Write $\mathcal{K}'' = \mathcal{O}''[1/\ell]$ and ϖ'' for a uniformiser of $\mathcal{O}''$. The space $S_\lambda(U(\ell^{c,c}), \mathcal{K}'')$ consists of functions on the finite set $\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}_{F^+}^\infty)/U(\ell^{c,c})$ (with values in $M_\lambda \otimes \mathcal{K}''$, subject to the invariance of (Gk4)), so after multiplying f by a power of ϖ'' we may assume $f \in S_\lambda(U(\ell^{c,c}), \mathcal{O}'')$; the hypotheses and the conclusion are unchanged.

Step 1: f lies in the ordinary part over $\mathcal{O}''$. The ordinary idempotent e of (Gk4) is an idempotent endomorphism of the finite free $\mathcal{O}''$-module $S = S_\lambda(U(\ell^{c,c}), \mathcal{O}'')$, so $S = eS \oplus (1-e)S$ and $S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \mathcal{K}'') = eS \otimes \mathcal{K}''$. As $f \in S$ and $(1-e)f = 0$ in $S \otimes \mathcal{K}''$, the component of f in the torsion-free module $(1-e)S$ vanishes, so $f \in eS = S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \mathcal{O}'')$.

Step 2: reduction modulo ϖ''^k. Let $k \ge 1$ and f_k the image of $\varpi''^{-k} f$ in $S_\lambda(U(\ell^{c,c}), \varpi''^{-k}\mathcal{O}''/\mathcal{O}'')$ (reduce the values of $\varpi''^{-k}f$ modulo $M_\lambda \otimes \mathcal{O}''$; the invariance under $U(\ell^{c,c})$ is preserved). The reduction map commutes with the operators of weight λ (they are given by the same double coset formulas), hence with $e = \lim_r U(\ell)^{r!}$, so $f_k = ef_k$ is ordinary, and $\langle u\rangle f_k = f_k$ for $u \in T_n(\mathfrak{l}^s)$. Its image in $S_\lambda^{\mathrm{ord}}(U(\ell^\infty), \mathcal{K}''/\mathcal{O}'')$ is therefore fixed by the $\langle u\rangle$, $u \in T_n(\mathfrak{l}^s)$, and by (Gk4)(b) (with $b = s$) it lies in $S_\lambda^{\mathrm{ord}}(U(\ell^{s,s}), \mathcal{K}''/\mathcal{O}'')$: f_k is invariant under $U(\ell^{s,s})$, i.e. $\xi_\lambda(g_{S_\ell}) f_k(xg) = f_k(x)$ for all $g \in U(\ell^{s,s})$ and x.

Step 3: conclusion. For $g \in U(\ell^{s,s})$ and x, the element $\xi_\lambda(g_{S_\ell}) f(xg) - f(x)$ of $M_\lambda \otimes \mathcal{O}''$ lies in $\varpi''^k(M_\lambda \otimes \mathcal{O}'')$ for every k by Step 2, hence is 0 ($M_\lambda \otimes \mathcal{O}''$ is finite free over $\mathcal{O}''$). So $f \in S_\lambda(U(\ell^{s,s}), \mathcal{O}'')$, and it is ordinary there: the inclusion of levels commutes with the operators $U^{(j)}_{\lambda, \varpi_{\bar v}}$ ([105], Lemma 2.3.3), hence with e. For the last sentence: if $f \in S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \alpha, A)$, then f has coefficients in a finitely generated subfield, and writing f in a basis of A over $\mathcal{K}''$, where $\mathcal{K}''$ is a finite extension of $\mathcal{K}$ containing the values of α such that f is a finite sum $\sum a_i f_i$ with $f_i \in S_\lambda^{\mathrm{ord}}(U(\ell^{c,c}), \alpha, \mathcal{K}'')$ and $a_i \in A$ linearly independent over $\mathcal{K}''$ (the ordinary part and the α-part are cut out by operators defined over $\mathcal{K}''$), each f_i satisfies $\langle u\rangle f_i = \alpha(u) f_i = f_i$ for $u \in T_n(\mathfrak{l}^s)$, so f_i, hence f, has level $U(\ell^{s,s})$. □

E.1.4 Λ-adic typed forms of all levels

This subsection constructs the Λ-adic typed forms of all levels at a finite set of split places, a smooth module whose invariants are the forms of finite level (Lemma E.22), and shows that the classical points of weight λ separate them (Lemma E.23). With module-level classicality, natural in the level away from ℓ (Lemma E.24), they give the classical level modules of Proposition E.1. The separation uses the density of algebraic weights from the main text (Lemma 50.13).

Lemma E.22. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, $((V_v)_{v\in\mathrm{St}},\tau)$ a type datum over $\mathscr{H}$ and Q a finite set of places of L^+ split in L and not in T_L. Put $G_Q=\prod_{v\in Q}\mathbb{G}_L(L_v^+)$, let $\mathcal{U}$ be the set of compact open subgroups $K'=\prod_{v\in Q}K'_v$ of G_Q, $\Lambda=\Lambda_1$ (diamond structure), and for $K'\in\mathcal{U}$ put $N(K')=N_\tau(K')$ and $N^*(K')=\mathrm{Hom}_\Lambda(N(K'),\Lambda)$. The* operators *are the $T_w^{(j)}$, $(T_w^{(n)})^{-1}$ (w above a place $v\notin T_L\cup Q$ split in L), $U_{\tilde v}^{(j)}$ ($v\in S_\ell$) and $\langle u\rangle$ ($u\in T_n(\mathcal{O}_{L^+}\otimes\mathbb{Z}_\ell)$); they act on every $N(K')$, and on $N^*(K')$ by transposition. Then:*

(Sm1) *$N(K')$ is free of finite rank over Λ. For $K''\subseteq K'$ in $\mathcal{U}$, the map $p_{K''K'}\colon N(K'')\to N(K')$ obtained by applying $\mathrm{Hom}_{\mathcal{O}[H]}(\tau,-)$ to the Pontryagin dual of the inclusion*

$$S^{\mathrm{ord}}(V(K')(\ell^\infty),\mathcal{K}/\mathcal{O})\subseteq S^{\mathrm{ord}}(V(K'')(\ell^\infty),\mathcal{K}/\mathcal{O})$$

is surjective and commutes with the operators; if K'' is normal in K', then $p_{K''K'}$ induces an isomorphism $N(K'')_{K'/K''}\to N(K')$ from the coinvariants for the action of K'/K'' dual to right translation.

(Sm2) *There are a Λ-module P_∞, injective Λ-linear maps $j_{K'}\colon N^*(K')\to P_\infty$ ($K'\in\mathcal{U}$) with $j_{K''}\circ p^*_{K''K'}=j_{K'}$ for $K''\subseteq K'$ and $P_\infty=\bigcup_{K'}j_{K'}(N^*(K'))$, a Λ-linear action ρ of G_Q on P_∞ and an action of the operators on P_∞, commuting with ρ and compatible with every $j_{K'}$, such that $P_\infty^{K'}=j_{K'}(N^*(K'))$ for every $K'\in\mathcal{U}$, and such that $\rho(g)\circ j_{K'}=j_{gK'g^{-1}}\circ a_g^*$ for $g\in G_Q$ and $K'\in\mathcal{U}$, where right translation $r_g\colon f\mapsto f(\cdot\,g)$ maps $S^{\mathrm{ord}}(V(K')(\ell^\infty),\mathcal{K}/\mathcal{O})$ onto $S^{\mathrm{ord}}(V(gK'g^{-1})(\ell^\infty),\mathcal{K}/\mathcal{O})$ and $a_g\colon N(gK'g^{-1})\to N(K')$ is obtained by applying $\mathrm{Hom}_{\mathcal{O}[H]}(\tau,-)$ to the Pontryagin dual of r_g.*

(Sm3) *If $K''\subseteq K'$ in $\mathcal{U}$ and K'' is normal in K', then $P_\infty^{K''}$, with the action of K'/K'' induced by ρ, is a finitely generated projective $\Lambda[K'/K'']$-module, and a free one if K'/K'' is an ℓ-group.*

Proof. For $K'\in\mathcal{U}$ let $V^{\mathrm{St}}(K')\supseteq V(K')$ be the group with components $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ at $v\in\mathrm{St}$ and those of $V(K')$ elsewhere. Both are as in Theorem B.91 with $F=L$, $\mathbb{G}=\mathbb{G}_L$, $T=T_L\cup Q$ (all places of T split in L; the components at S_ℓ and at split places outside T are hyperspecial; any compact open components are allowed at T), and $V^{\mathrm{St}}(K')(\ell^{1,1})$ is sufficiently small, its component at v_0 being the kernel of reduction modulo p of $\mathrm{GL}_n(\mathcal{O}_{L_{\tilde v_0}})$, p odd and unramified in L (Definition 50.8), which has no non-trivial element of finite order .

Step 1: (Sm1). By (Yp3) for $U=V^{\mathrm{St}}(K')\supseteq U'=V(K')$, $\Gamma=G_1=H$, $G_2=1$, $b_0=1$, $N(K')$ is free of finite rank over Λ. Let $K''\subseteq K'$ be normal and $\Gamma=K'/K''$. Apply Lemma E.12 to $U=V^{\mathrm{St}}(K')\supseteq U'=V(K'')$ (componentwise normal, equal outside $\mathrm{St}\cup Q$), with $U/U'=H\times\Gamma$, $G_1=H$, $G_2=\Gamma$: by (Yp1) the action of $H\times\Gamma$ on $\mathcal{S}'=\mathcal{S}_{V(K'')}$ commutes with the operators, and by (Yp2) $\mathcal{S}'$ is a direct summand of R^m for some m, $R=\Lambda[H\times\Gamma]$. Apply Lemma E.12 also to $U=V(K')\supseteq U'=V(K'')$, with quotient Γ: by (Yp4) the dual of the inclusion induces an isomorphism $\mathcal{S}'_\Gamma\to\mathcal{S}_{V(K')}$ compatible with the operators; it is H-equivariant, the inclusion of forms commuting with right translation at St. For R itself,

write $R = \Lambda[\Gamma] \otimes_{\mathcal{O}} \mathcal{O}[H]$; the map $f \mapsto \epsilon \circ f$, ϵ the coefficient of $1 \in H$, is an isomorphism $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R) \cong \Lambda[\Gamma] \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O})$ with inverse $\varphi \mapsto (t \mapsto \sum_{h \in H} \varphi(h^{-1}t)\, h)$ (a direct check; τ is finite free over $\mathcal{O}$), Γ-equivariant for Γ acting on the factor $\Lambda[\Gamma]$; this shows that the natural map $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, R)_\Gamma \to \mathrm{Hom}_{\mathcal{O}[H]}(\tau, R_\Gamma)$ is an isomorphism: both sides are $\Lambda \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O})$, $R_\Gamma = \Lambda[H]$. Both functors are additive, so the natural map is an isomorphism for the direct summand $\mathcal{S}'$ of R^m; composing with $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ of the isomorphism of (Yp4) gives $N(K'')_\Gamma \cong N(K')$, induced by $p_{K''K'}$, which is therefore surjective. For arbitrary $K'' \subseteq K'$ in $\mathcal{U}$, the intersection K''' of the finitely many K'-conjugates of K'' (K'' has finite index in K') lies in $\mathcal{U}$ and is normal in K'; as inclusions of forms compose, $p_{K''K'} \circ p_{K'''K''} = p_{K'''K'}$, which is surjective, so $p_{K''K'}$ is surjective. The operators are the same double coset operators at all levels at Q (they involve no place of Q), so they commute with the inclusions of forms, hence with every $p_{K''K'}$.

Step 2: the limit. Order $\mathcal{U}$ by reverse inclusion; it is directed ($K' \cap K'' \in \mathcal{U}$). The transposes $p^*_{K''K'} \colon N^*(K') \to N^*(K'')$ are injective ($p_{K''K'}$ is surjective) and compatible ($p_{K'''K'} = p_{K''K'} \circ p_{K'''K''}$). Let P_∞ be the direct limit and $j_{K'}$ the canonical maps, which are injective; P_∞ is their union. The operators act on each $N^*(K')$ by transposition, compatibly with the p^* (Step 1), hence on P_∞.

Step 3: the action of G_Q. For $g \in G_Q$ and $K' \in \mathcal{U}$, right translation $f \mapsto f(\cdot\, g)$ maps forms of level $V(K')(\ell^{c,c})$ bijectively to forms of level $V(gK'g^{-1})(\ell^{c,c})$ (g has trivial components outside Q); it commutes with the operators and the ordinary idempotent (supported outside Q), with right translation at St and with the inclusions of forms between levels at Q. Dualising and applying $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ gives Λ-linear isomorphisms $a_g \colon N(gK'g^{-1}) \to N(K')$, compatible with the operators and with the maps p; from $(f(\cdot\, g))(\cdot\, h) = f(\cdot\, hg)$ one gets $a_{hg} = a_g \circ a_h$, so the transposes $a_g^* \colon N^*(K') \to N^*(gK'g^{-1})$ satisfy $a^*_{hg} = a^*_h \circ a^*_g$. Put $\rho(g) = a^*_g$ on $j_{K'}(N^*(K'))$; by the compatibility with the p^* this defines a Λ-linear map of P_∞, and $\rho(h)\rho(g) = \rho(hg)$, $\rho(1) = 1$: an action of G_Q commuting with the operators. If $g \in K'$, right translation by g is the identity on forms of level $V(K')$, so $\rho(g)$ fixes $j_{K'}(N^*(K'))$: $j_{K'}(N^*(K')) \subseteq P_\infty^{K'}$. Conversely let $x \in P_\infty^{K'}$. Then $x \in j_{K'''}(N^*(K'''))$ for some $K''' \in \mathcal{U}$, and replacing K''' by the intersection of the K'-conjugates of $K''' \cap K'$ we may take $K'' = K'''$ normal in K'. For $\gamma \in K'$, $\rho(\gamma)$ acts on $N^*(K'')$ as the transpose of a_γ, which is the action of $\Gamma = K'/K''$ dual to right translation in (Sm1); so $x = j_{K''}(\phi)$ with $\phi \circ a_\gamma = \phi$ for all γ, i.e. ϕ factors through $N(K'')_\Gamma \cong N(K')$ (Step 1): $\phi = p^*_{K''K'}(\psi)$ with $\psi \in N^*(K')$, and $x = j_{K'}(\psi)$. This proves (Sm2).

Step 4: (Sm3). By (Yp3) for $U = V^{\mathrm{St}}(K') \supseteq U' = V(K'')$, $G_1 = H$, $G_2 = \Gamma = K'/K''$ (Step 1), $X = N(K'')$ is a finitely generated projective $\Lambda[\Gamma]$-module, free if Γ is an ℓ-group, Γ acting through the a_γ. By (Sm2) and Step 3, $P_\infty^{K''} \cong N^*(K'') = \mathrm{Hom}_\Lambda(X, \Lambda)$ with γ acting by $\phi \mapsto \phi \circ a_\gamma$. For $X = \Lambda[\Gamma]$ this module is free of rank one: the dual basis (δ_γ) of the basis Γ is permuted simply transitively. The functor $\mathrm{Hom}_\Lambda(-, \Lambda)$ preserves finite direct sums and direct summands, so $N^*(K'')$ is finitely generated projective over $\Lambda[\Gamma]$, and free if X is. □

Lemma E.23. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, $((V_v)_{v \in \mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$, Q a finite set of places of L^+ split in L and not in T_L, and P_∞, ρ as in Lemma E.22. Let $x \in P_\infty$, $x \neq 0$. Then there are a dominant weight λ with $\lambda_{\tau',j} > \lambda_{\tau',j+1}$ for all embeddings τ' and all j, an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$, a homomorphism of $\mathcal{O}$-algebras $y \colon \Lambda \to \overline{\mathbb{Q}}_\ell$, values $y(t) \in \overline{\mathbb{Q}}_\ell$ for the operators t, a $\overline{\mathbb{Q}}_\ell$-vector space Y with a representation π_Y of G_Q and an additive map $\mathrm{sp} \colon P_\infty \to Y$ such that:*

(Ls1) $\mathrm{sp}(x) \neq 0$;

(Ls2) $\mathrm{sp}(\mu z) = y(\mu)\,\mathrm{sp}(z)$ *and* $\mathrm{sp}(tz) = y(t)\,\mathrm{sp}(z)$ *for $\mu \in \Lambda$, every operator t and $z \in P_\infty$;* $y([u]) = y(\langle u \rangle) = (w_0\lambda)(u)^{-1}$ *for $u \in T_n(\ell^1)$; and for every place $v \notin T_L \cup Q$ of L^+ split*

in L, π_v is unramified and $y(T_w^{(j)})$ is the eigenvalue of $T_w^{(j)}$ on $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L_v^+})}$ for every place $w \mid v$ of L;

(Ls3) $\mathrm{sp}(\rho(g)z) = \pi_Y(g)\,\mathrm{sp}(z)$ *for $g \in G_Q$ and $z \in P_\infty$;*

(Ls4) *for every $v \in Q$, Y is spanned by the images of the $\mathbb{G}_L(L_v^+)$-equivariant linear maps $\pi_v \to Y$, $\mathbb{G}_L(L_v^+)$ acting on Y through the factor of G_Q at v.*

Proof. Step 0: the levels. For $K' \in \mathcal{U}$ the group $V(K')$ is as in Theorem B.91 with $T = T_L \cup Q$ (all places of T split in L by (Rd2) and the choice of Q; the components at S_ℓ and at the split places outside T are hyperspecial), and $V(K')(\ell^{1,1})$ is sufficiently small: its component at v_0 is the kernel of reduction modulo p of $\mathrm{GL}_n(\mathcal{O}_{L_{\tilde{v}_0}})$, p odd and unramified in L (Rd3), which has no non-trivial element of finite order . Write $S_{K'}$, $W_{K'}$, $\Phi_{K'}$ for the objects of Lemma E.24 for $U = V(K')$ (with λ chosen in Step 1); all $V(K')$ have the same components at S_ℓ. The group $V^{\mathrm{St}}(K')$ with components $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ at $v \in \mathrm{St}$ and those of $V(K')$ elsewhere is as in Theorem B.91, contains $V(K')$ as a componentwise normal subgroup with quotient H, equal at S_ℓ and outside T; so by (Yp2) ($b_0 = 1$) $S_{K'}$ is a finitely generated projective $\Lambda[H]$-module.

Step 1: the weight. By (Sm2), $x = j_K(\phi)$ for some $K \in \mathcal{U}$ and $\phi \in N^*(K)$, $\phi \neq 0$; by (Sm1) $N(K)$ is Λ-free, so $\phi(m) \neq 0$ for some $m \in N(K)$. Let I be the set of embeddings $L^+ \to \overline{\mathbb{Q}}_\ell$; restriction is a bijection from the embeddings τ of L inducing the places $\tilde{v}$ onto I ($L_{\tilde{v}} = L_v^+$), and for $u \in T_n(\ell^1)$, $(w_0\lambda)(u)^{-1} = \prod_\tau \prod_j \tau(u_j)^{-\lambda_{\tau,n+1-j}} = \chi_k(u)$ with $k_{\tau|_{L^+},j} = -\lambda_{\tau,n+1-j}$; so $\mathfrak{p}_\lambda = \mathfrak{P}_k$, and $\lambda \mapsto k$ is a bijection from the dominant weights with $\lambda_{\tau,j} > \lambda_{\tau,j+1}$ for all τ, j onto the set $\mathcal{K}_0$ of $k \in (\mathbb{Z}^n)^I$ strictly decreasing in j for every $\tau' \in I$. The closure of $\mathcal{K}_0$ in $(\mathbb{Z}_\ell^n)^I$ is everything: for $a \in (\mathbb{Z}^n)^I$ and $e \geq 1$, $a + M\ell^e(n+1-j)_{\tau',j} \in \mathcal{K}_0$ for every large integer M. As ℓ is odd and $\mathcal{O} \supseteq \tau(\mathcal{O}_L)$ (Rd1), Lemma 50.13 gives $\bigcap_{k\in\mathcal{K}_0} \mathfrak{P}_k = 0$, so there is such a λ with $\phi(m) \notin \mathfrak{p}_\lambda$. Fix it, write $\mathfrak{p} = \mathfrak{p}_\lambda$ and $y_0 \colon \Lambda \to \Lambda/\mathfrak{p} = \mathcal{O}$.

Step 2: one level. Let $K' \in \mathcal{U}$. The natural map $N(K') \otimes_\Lambda \Lambda/\mathfrak{p} \to \mathrm{Hom}_{\mathcal{O}[H]}(\tau, S_{K'}/\mathfrak{p}S_{K'})$ is an isomorphism: for $R = \Lambda[H]$, $f \mapsto \epsilon \circ f$ (ϵ the coefficient of $1 \in H$) gives isomorphisms $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, \Lambda[H]) \cong \Lambda \otimes_{\mathcal{O}} \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O})$ and $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, \mathcal{O}[H]) \cong \mathrm{Hom}_{\mathcal{O}}(\tau, \mathcal{O})$ (inverse $\varphi \mapsto (t \mapsto \sum_h \varphi(h^{-1}t)h)$), compatible with $R \to R/\mathfrak{p}R = \mathcal{O}[H]$; so the map is an isomorphism for R, hence for finite sums and direct summands (both sides are additive), hence for $S_{K'}$ (Step 0). H acts on $S_{K'}$ dually to right translation by elements h with components in $\prod_{v\in\mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})$, which normalise $V(K')$ and have trivial components at S_ℓ and outside T; so by (Wn3) with $g = h$, $\Phi_{K'}$ is H-equivariant, H acting on $W_{K'}^*$ by the transposes of right translation. Tensoring with $\mathcal{K}$ (τ is finite free) and applying $\Phi_{K'}$ gives an isomorphism

$$\beta_{K'} \colon N(K') \otimes_\Lambda \Lambda/\mathfrak{p} \otimes_{\mathcal{O}} \mathcal{K} \cong \mathrm{Hom}_{\mathcal{K}[H]}(\tau_{\mathcal{K}}, W_{K'}^*) = \left((\tau_{\mathcal{K}} \otimes_{\mathcal{K}} W_{K'})_H\right)^*,$$

$\tau_{\mathcal{K}} = \tau \otimes \mathcal{K}$, H acting diagonally; the last identification is natural for H-equivariant maps of W. Put $Y_{K'} = (\tau_{\mathcal{K}} \otimes W_{K'})_H$, finite-dimensional. Since $N(K')$ is free of finite rank, $N^*(K') \otimes_\Lambda \Lambda/\mathfrak{p} \otimes \mathcal{K}$ is the $\mathcal{K}$-dual of the left side, hence $\cong Y_{K'}^{**} = Y_{K'}$ by the transpose of $\beta_{K'}$. Let $\mathrm{sp}_{K'} \colon N^*(K') \to Y_{K'}$ be reduction followed by this isomorphism: $\mathrm{sp}_{K'}(\psi)$ is the element of $Y_{K'}$ whose pairing with $\beta_{K'}(n \otimes 1)$ is $y_0(\psi(n))$, for $n \in N(K')$.

Step 3: all levels. Let $K'' \subseteq K'$ in $\mathcal{U}$; forms of level $V(K')$ are forms of level $V(K'')$, giving an H-equivariant inclusion $\iota \colon W_{K'} \subseteq W_{K''}$. By (Wn2), and since $p_{K''K'}$ is $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$ of the dual of the inclusion of forms of trivial weight, $\beta_{K'} \circ (p_{K''K'} \otimes 1) = \mathrm{Hom}_H(\tau_{\mathcal{K}}, \iota^t) \circ \beta_{K''}$, and $\mathrm{Hom}_H(\tau_{\mathcal{K}}, \iota^t)$ is the transpose of $(1 \otimes \iota)_H \colon Y_{K'} \to Y_{K''}$. Transposing, $\mathrm{sp}_{K''} \circ p_{K''K'}^* = (1 \otimes \iota)_H \circ \mathrm{sp}_{K'}$. Let $W_\infty = \bigcup_{K'} W_{K'}$ (a directed union: $K' \cap K'' \in \mathcal{U}$) and $Y_\infty = (\tau_{\mathcal{K}} \otimes W_\infty)_H = \varinjlim Y_{K'}$; the maps $Y_{K'} \to Y_\infty$ are injective, H-coinvariants being exact in characteristic 0 (averaging

identifies them with invariants). By (Sm2) ($P_\infty = \bigcup j_{K'}(N^*(K'))$, $j_{K''} \circ p^*_{K''K'} = j_{K'}$, the j injective) there is a unique additive map $\mathrm{sp}_\infty \colon P_\infty \to Y_\infty$ with $\mathrm{sp}_\infty(j_{K'}(\psi)) = \mathrm{sp}_{K'}(\psi)$: if $j_{K'}(\psi) = j_{K''}(\psi'')$, both agree in $N^*(K''')$ for $K''' = K' \cap K''$, and the compatibility gives the same image.

Step 4: the operators. For an operator t let t_λ be $T^{(j)}_w$, $(T^{(n)}_w)^{-1}$, $U^{(j)}_{\lambda,\varpi_{\tilde v}}$, resp. $(w_0\lambda)(u)^{-1}\langle u\rangle$ of weight λ, for $t = T^{(j)}_w$, $(T^{(n)}_w)^{-1}$, $U^{(j)}_{\tilde v}$, $\langle u\rangle$. These commute with H and with ι (double cosets at places outside $\mathrm{St} \cup Q$, with the same components for all $V(K')$) and preserve every $W_{K'}$. By (Wn1), $\beta_{K'}$ carries the action of t on $N(K')$ to composition with t^t_λ, i.e. to the transpose of $(1 \otimes t_\lambda)_H$ on $Y_{K'}$; as t acts on $N^*(K')$ by $\psi \mapsto \psi \circ t$, $\mathrm{sp}_{K'}(t\psi) = (1 \otimes t_\lambda)\mathrm{sp}_{K'}(\psi)$. As $\mathrm{sp}_{K'}$ factors through $- \otimes_\Lambda \Lambda/\mathfrak{p}$, $\mathrm{sp}_{K'}(\mu\psi) = y_0(\mu)\mathrm{sp}_{K'}(\psi)$ for $\mu \in \Lambda$. Hence $\mathrm{sp}_\infty(tz) = (1 \otimes t_\lambda)\mathrm{sp}_\infty(z)$ and $\mathrm{sp}_\infty(\mu z) = y_0(\mu)\mathrm{sp}_\infty(z)$.

Step 5: the group G_Q. Let $g \in G_Q$, $K' \in \mathcal{U}$. g has trivial components outside $Q \subseteq T$, so by (Wn3) right translation r_g maps $W_{K'}$ onto $W_{gK'g^{-1}}$, commutes with H, and $\Phi_{K'} \circ (a'_g \otimes 1) = r^t_g \circ \Phi_{gK'g^{-1}}$, a'_g the dual of r_g on forms of trivial weight; applying $\mathrm{Hom}_{\mathcal{O}[H]}(\tau, -)$, $\beta_{K'} \circ (a_g \otimes 1)$ is $\beta_{gK'g^{-1}}$ followed by composition with r^t_g, the transpose of $(1 \otimes r_g)_H \colon Y_{K'} \to Y_{gK'g^{-1}}$. Transposing, $\mathrm{sp}_{gK'g^{-1}} \circ a^*_g = (1 \otimes r_g)_H \circ \mathrm{sp}_{K'}$. By (Sm2), $\rho(g) \circ j_{K'} = j_{gK'g^{-1}} \circ a^*_g$; so $\mathrm{sp}_\infty(\rho(g)z) = \pi_\infty(g)\mathrm{sp}_\infty(z)$ with $\pi_\infty(g) = (1 \otimes r_g)_H$ on Y_∞, a representation of G_Q ($r_h r_g = r_{hg}$).

Step 6: decomposition. Put $\overline{W} = W_\infty \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell$, $\overline{Y} = Y_\infty \otimes_{\mathcal{K}} \overline{\mathbb{Q}}_\ell = (\tau_{\overline{\mathbb{Q}}_\ell} \otimes \overline{W})_H$, into which Y_∞ injects. Let E be as in Lemma E.24. By (Gk4)(a) ($\overline{\mathbb{Q}}_\ell$ is flat over $\mathcal{O}$, and invariants under $T_n(\ell^1)$, which acts on the forms of level $V(K')(\ell^{E,E})$ through a finite quotient, are the kernel of a finite family of differences $\langle u\rangle - 1$, so they commute with flat base change), $W_{K'} \otimes \overline{\mathbb{Q}}_\ell$ is the subspace of $e\,S_\lambda(V(K')(\ell^{E,E}), \overline{\mathbb{Q}}_\ell)$ fixed by the $\langle u\rangle$, $u \in T_n(\ell^1)$, and $e\,S_\lambda(V(K')(\ell^{E,E}), \overline{\mathbb{Q}}_\ell)$ is the sum of the joint generalised eigenspaces of the $U^{(j)}_{\lambda,\varpi_{\tilde v}}$ on $S_\lambda(V(K')(\ell^{E,E}), \overline{\mathbb{Q}}_\ell)$ with ℓ-adic unit eigenvalues . Let $K^Q = \prod_{v \notin Q} V(\ell^{E,E})_v$, the components of every $V(K')(\ell^{E,E})$ outside Q. By (Gk4)(d), $S_\lambda(\overline{\mathbb{Q}}_\ell)$ is a semisimple admissible representation of $\mathbb{G}_L(\mathbb{A}^\infty_{L^+})$; its K^Q-invariants are

$$\bigcup_{K'} S_\lambda(V(K')(\ell^{E,E}), \overline{\mathbb{Q}}_\ell)$$

(a vector is fixed by some compact open subgroup, which contains $K' \times K''$ with $K' \in \mathcal{U}$ and K'' open in $\prod_{v \notin Q} \mathbb{G}_L(L^+_v)$; so a K^Q-invariant vector is fixed by $V(K')(\ell^{E,E}) = K' \times K^Q$), G_Q acts on them by r_g, and the operators act as double coset operators of this representation at the places of S_ℓ and outside $T_L \cup Q$. Hence $\overline{W}$ is the subspace fixed by the $\langle u\rangle$, $u \in T_n(\ell^1)$, of the sum of the generalised eigenspaces with unit eigenvalues of the $U^{(j)}_{\lambda,\varpi_{\tilde v}}$ on $S_\lambda(\overline{\mathbb{Q}}_\ell)^{K^Q}$.

Write $S_\lambda(\overline{\mathbb{Q}}_\ell) = \bigoplus_\pi S[\pi]$ with $S[\pi] \cong \pi \otimes M_\pi$, π over the isomorphism classes of irreducible constituents and M_π a multiplicity space (finite-dimensional by admissibility). By Flath's tensor product theorem, $\pi \cong \bigotimes'_v \pi_v$, so $\pi^{K^Q} \cong \pi_Q \otimes X_\pi \otimes R_\pi$ with $\pi_Q = \bigotimes_{v \in Q} \pi_v$ (on which G_Q acts), $X_\pi = \bigotimes_{v \in S_\ell} \pi_v^{\mathrm{Iw}(\tilde v^{E,E})}$ and $R_\pi = \bigotimes_{v \notin Q \cup S_\ell} \pi_v^{V_v}$ (finite-dimensional, H acting through the factors at St). For $v \notin T_L \cup Q$ split, $T^{(j)}_w$ acts on R_π through $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L^+_v})}$, which is 0 or a line (the spherical vectors of an irreducible admissible representation of $\mathrm{GL}_n(L_w)$); so if $R_\pi \neq 0$, π_v is unramified and $T^{(j)}_w$ acts on R_π by its eigenvalue $t^{(j)}_w(\pi)$ on $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L^+_v})}$. The $U^{(j)}_{\lambda,\varpi_{\tilde v}} = (w_0\lambda)(\alpha^{(j)}_{\varpi_{\tilde v}})^{-1} U^{(j)}_{\varpi_{\tilde v}}$ ((Gy7)(c)) and $\langle u\rangle$ act on X_π factorwise. For $v \in S_\ell$ let $c_{v,j} = v_\ell\big((w_0\lambda)(\alpha^{(j)}_{\varpi_{\tilde v}})\big) = v_\ell(\varpi_{\tilde v}) \sum_{i \le j} \sum_\tau \lambda_{\tau,n+1-i}$ (τ over the embeddings inducing $\tilde v$); $c_{v,j} - c_{v,j-1} = v_\ell(\varpi_{\tilde v}) \sum_\tau \lambda_{\tau,n+1-j}$ is non-decreasing in j (λ_τ is decreasing). The unit-eigenvalue part of $\pi_v^{\mathrm{Iw}(\tilde v^{E,E})}$ for the $U^{(j)}_{\lambda,\varpi_{\tilde v}}$ is the part X_v of Lemma E.19 for $K = L_{\tilde v}$, $c = E$, slopes $c_{v,j}$, $\sigma' = \pi_v$ (through $\iota_{\tilde v}$); by that lemma the $U^{(j)}_{\varpi_{\tilde v}}$ and $T_n(\mathcal{O}_{L_{\tilde v}})$ act semisimply on X_v with joint eigenspaces

of dimension at most one. The unit-eigenvalue part of X_π is $\bigotimes_v X_v$, hence the direct sum of lines X_χ on which the operators $U^{(j)}_{\lambda,\varpi_{\tilde v}}$ and $\langle u\rangle$ act through a character χ, distinct lines carrying distinct χ; its subspace fixed by the $\langle u\rangle$, $u \in T_n(\ell^1)$, is the sum of the lines X_χ with $\chi(\langle u\rangle) = 1$ for all $u \in T_n(\ell^1)$, and only these χ occur below. Therefore

$$\overline{W} = \bigoplus_{\pi,\chi} W[\pi,\chi], \qquad W[\pi,\chi] \cong \pi_Q \otimes X_\chi \otimes R_\pi \otimes M_\pi,$$

each part stable under G_Q and H, every t_λ acting on $W[\pi,\chi]$ by a scalar $y_{\pi,\chi}(t_\lambda)$ ($t^{(j)}_w(\pi)$ for $T^{(j)}_w$, and χ for the operators at S_ℓ); and $\overline{Y} = \bigoplus_{\pi,\chi}(\tau_{\overline{\mathbb{Q}}_\ell} \otimes W[\pi,\chi])_H$.

Step 7: the specialisation. $\mathrm{sp}_\infty(x) = \mathrm{sp}_K(\phi)$ pairs with $\beta_K(m \otimes 1)$ to $y_0(\phi(m)) \neq 0$ (Step 1), so it is non-zero, and so is its image in $\overline{Y}$. Choose (π,χ) for which the component of this image is non-zero, put $Y = (\tau_{\overline{\mathbb{Q}}_\ell} \otimes W[\pi,\chi])_H$, sp the composite of sp_∞, $Y_\infty \to \overline{Y}$ and the projection to Y, $\pi_Y(g) = (1 \otimes r_g)_H|_Y$, $y = y_0$ on Λ (followed by $\mathcal{O} \subseteq \overline{\mathbb{Q}}_\ell$) and $y(t) = y_{\pi,\chi}(t_\lambda)$ for the operators. (Ls1) holds by the choice. (Ls2): by Step 4 and Step 6, $\mathrm{sp}(\mu z) = y(\mu)\mathrm{sp}(z)$ and $\mathrm{sp}(tz) = y(t)\mathrm{sp}(z)$ (the projection commutes with the t_λ); for $u \in T_n(\ell^1)$, $y([u]) = y_0([u]) = (w_0\lambda)(u)^{-1}$, and $\langle u\rangle$ of weight λ is trivial on $W_{K'}$ (definition of $W_{K'}$ in Lemma E.24), hence on $\overline{W}$ and on every $W[\pi,\chi]$, so $y(\langle u\rangle) = (w_0\lambda)(u)^{-1}$; $Y \neq 0$ forces $R_\pi \neq 0$, so for $v \notin T_L \cup Q$ split, π_v is unramified and $y(T^{(j)}_w) = t^{(j)}_w(\pi)$. (Ls3): Step 5, the parts being G_Q-stable. (Ls4): H acts trivially on π_Q, so $Y \cong \pi_Q \otimes (\tau_{\overline{\mathbb{Q}}_\ell} \otimes X_\chi \otimes R_\pi \otimes M_\pi)_H$ with G_Q acting on π_Q; for $v \in Q$, $\pi_Q = \pi_v \otimes \pi_{Q\smallsetminus\{v\}}$, and the maps $a \mapsto a \otimes b$ (b in the remaining factors) are $\mathbb{G}_L(L^+_v)$-equivariant from π_v to Y and their images span Y. □

Lemma E.24. *Let ℓ, n, F, F^+, $\mathcal{O}$, $\mathbb{G}$ and T be as in Theorem B.91, $\mathcal{K} = \mathcal{O}[1/\ell]$, λ a dominant weight for $\mathbb{G}$, and $\mathfrak{p}_\lambda \subseteq \Lambda_1$ the kernel of the homomorphism of $\mathcal{O}$-algebras $\Lambda_1 \to \mathcal{O}$, $[u] \mapsto (w_0\lambda)(u)^{-1}$. For every U as in Theorem B.91 such that $U(\ell^{1,1})$ is sufficiently small, let S_U be the Pontryagin dual of $S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})$, with Λ_1 acting through the diamond operators and the operators acting dually, let E be the largest ramification index of $F^+_v/\mathbb{Q}_\ell$ over the places $v \in S_\ell$, and*

$$W_U = \{f \in S^{\mathrm{ord}}_\lambda(U(\ell^{E,E}),\mathcal{K}) : \langle u\rangle f = f \text{ for all } u \in T_n(\ell^1)\},$$

$\langle u\rangle$ the operator of weight λ (if ℓ is unramified in F^+, then $E = 1$ and $W_U = S^{\mathrm{ord}}_\lambda(U(\ell^{1,1}),\mathcal{K})$). Then there are $\mathcal{K}$-linear isomorphisms

$$\Phi_U \colon (S_U/\mathfrak{p}_\lambda S_U) \otimes_{\mathcal{O}} \mathcal{K} \longrightarrow \mathrm{Hom}_{\mathcal{K}}(W_U,\mathcal{K})$$

such that:

(Wn1) *Φ_U carries $T^{(j)}_w$, $(T^{(n)}_w)^{-1}$, $U^{(j)}_{\tilde v}$ and $\langle u\rangle$ ($u \in T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell)$) to the transposes of the operators $T^{(j)}_w$, $(T^{(n)}_w)^{-1}$, $U^{(j)}_{\lambda,\varpi_{\tilde v}}$ and $(w_0\lambda)(u)^{-1}\langle u\rangle$ of weight λ on W_U;*

(Wn2) *if $U' \subseteq U$ are two such groups with $U'_v = U_v$ for every $v \in S_\ell$, then $W_U \subseteq W_{U'}$ and $\Phi_U \circ (p \otimes 1) = r \circ \Phi_{U'}$, where $p \colon S_{U'}/\mathfrak{p}_\lambda S_{U'} \to S_U/\mathfrak{p}_\lambda S_U$ is induced by the dual of the inclusion $S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O}) \subseteq S^{\mathrm{ord}}(U'(\ell^\infty),\mathcal{K}/\mathcal{O})$ and r is the restriction of linear forms to W_U;*

(Wn3) *if $g \in \mathbb{G}(\mathbb{A}^\infty_{F^+})$ has $g_v = 1$ for every $v \in S_\ell$ and every $v \notin T$ split in F, and $U_g = gUg^{-1}$, then U_g is again such a group, right translation $r_g \colon f \mapsto f(\cdot\, g)$ maps $S^{\mathrm{ord}}(U(\ell^\infty),\mathcal{K}/\mathcal{O})$ onto $S^{\mathrm{ord}}(U_g(\ell^\infty),\mathcal{K}/\mathcal{O})$ and W_U onto W_{U_g}, and $\Phi_U \circ (a_g \otimes 1) = r^t_g \circ \Phi_{U_g}$, where $a_g \colon S_{U_g}/\mathfrak{p}_\lambda S_{U_g} \to S_U/\mathfrak{p}_\lambda S_U$ is induced by the dual of r_g and $r^t_g(\phi) = \phi \circ r_g|_{W_U}$.*

Proof. Fix U as in the statement and write $M_U = S^{\mathrm{ord}}(U(\ell^\infty), \mathcal{K}/\mathcal{O})$, $M_{\lambda,U} = S^{\mathrm{ord}}_\lambda(U(\ell^\infty), \mathcal{K}/\mathcal{O})$, $Z_U = S_\lambda(U(\ell^{E,E}), \mathcal{O})$ (E as in the statement); $\chi = w_0\lambda$ is a continuous character $T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell) \to \mathcal{O}^\times$ ($\mathcal{O}$ contains the images of all embeddings of F).

Step 1: the fibre at $\mathfrak{p}_\lambda$. The continuous $\mathcal{O}$-algebra automorphism θ of Λ_1 with $\theta([u]) = \chi(u)[u]$ ($u \in T_n(\ell^1)$) satisfies $\mathrm{aug} \circ \theta^{-1}([u]) = \chi(u)^{-1}$, so $\mathfrak{p}_\lambda = \theta(\mathfrak{a})$, $\mathfrak{a}$ the augmentation ideal, which is generated by the elements $[u] - 1$; hence $\mathfrak{p}_\lambda$ is generated by the elements $[u] - \chi(u)^{-1}$, and, Λ_1 being noetherian, by finitely many of them, $x_1, \dots, x_k$. For a discrete Λ_1-module M let $M[\mathfrak{p}_\lambda]$ be the submodule killed by $\mathfrak{p}_\lambda$, i.e. the m with $\langle u\rangle m = \chi(u)^{-1}m$ for all $u \in T_n(\ell^1)$. It is the kernel of $M \to M^k$, $m \mapsto (x_i m)_i$, so dualising gives an isomorphism $M^\vee/\mathfrak{p}_\lambda M^\vee \cong (M[\mathfrak{p}_\lambda])^\vee$, natural for Λ_1-linear maps $M \to M'$. For $M = M_U$: $S_U/\mathfrak{p}_\lambda S_U \cong (M_U[\mathfrak{p}_\lambda])^\vee$.

Step 2: passage to weight λ. Let $M^\flat_{\lambda,U}$ be the submodule of $M_{\lambda,U}$ fixed by all $\langle u\rangle$, $u \in T_n(\ell^1)$. By (Gk4)(c), λ_* maps $M^\flat_{\lambda,U}$ isomorphically onto $M_U[\mathfrak{p}_\lambda]$: if $\langle u\rangle f = f$ then $\langle u\rangle\lambda_*(f) = \chi(u)^{-1}\lambda_*(\langle u\rangle f) = \chi(u)^{-1}\lambda_*(f)$; conversely if $\lambda_*(f) \in M_U[\mathfrak{p}_\lambda]$ then $\lambda_*(\langle u\rangle f) = \chi(u)\langle u\rangle\lambda_*(f) = \lambda_*(f)$, so $\langle u\rangle f = f$ as λ_* is injective. Let $\mathfrak{l}$ and $T_n(\mathfrak{l}^b)$ be as in (Gk4)(b). By (Qh1) of Lemma E.10 (with $b = 1$), $T_n(\mathfrak{l}^E) \subseteq T_n(\ell^1)$. By (Gk4)(b) with $b = E$, the submodule of $M_{\lambda,U}$ fixed by the $\langle u\rangle$, $u \in T_n(\mathfrak{l}^E)$, is $S^{\mathrm{ord}}_\lambda(U(\ell^{E,E}), \mathcal{K}/\mathcal{O})$, compatibly with the operators; hence $M^\flat_{\lambda,U}$ is the submodule of $S^{\mathrm{ord}}_\lambda(U(\ell^{E,E}), \mathcal{K}/\mathcal{O})$ fixed by the $\langle u\rangle$, $u \in T_n(\ell^1)$. On forms of level $U(\ell^{E,E})$ the operator $\langle u\rangle$ of weight λ, $u \in T_n(\mathcal{O}_{F^+} \otimes \mathbb{Z}_\ell)$ (placed at the components of S_ℓ; it normalises $U(\ell^{E,E})$), is $f \mapsto \xi_\lambda(u)f(\cdot\, u)$, which is the identity for $u \in T_n(\mathfrak{l}^E) \subseteq U(\ell^{E,E})$ by the invariance defining $S_\lambda(U(\ell^{E,E}), A)$. So $T_n(\ell^1)$ acts on the forms of level $U(\ell^{E,E})$ through the finite abelian group $\Delta = T_n(\ell^1)/T_n(\mathfrak{l}^E)$, and $M^\flat_{\lambda,U} = S^{\mathrm{ord}}_\lambda(U(\ell^{E,E}), \mathcal{K}/\mathcal{O})^\Delta$.

Step 3: integral structure. Z_U is a finitely generated torsion-free, hence free, $\mathcal{O}$-module (evaluation at representatives of the finite set $\mathbb{G}(F^+)\backslash\mathbb{G}(\mathbb{A}^\infty_{F^+})/U(\ell^{E,E})$ embeds it in a finite sum of copies of M_λ). By (Gk4)(a) ($U(\ell^{E,E}) \subseteq U(\ell^{1,1})$ is sufficiently small), $S_\lambda(U(\ell^{E,E}), \mathcal{K}/\mathcal{O}) = Z_U \otimes_{\mathcal{O}} \mathcal{K}/\mathcal{O}$; the operators, given on both sides by the same finite sums of translates, act as $t \otimes 1$, so the ordinary idempotent acts as $e \otimes 1$, and $S^{\mathrm{ord}}_\lambda(U(\ell^{E,E}), \mathcal{K}/\mathcal{O}) = L'_U \otimes_{\mathcal{O}} \mathcal{K}/\mathcal{O}$ with $L'_U = eZ_U$ a direct summand of Z_U, finite free. The group Δ acts on Z_U through the operators $\langle u\rangle$, which commute with e ([105], Lemma 2.3.3), so it preserves L'_U. Let $L_U = (L'_U)^\Delta$. It is saturated in L'_U (if $x \in L'_U$ and $\varpi x \in L_U$, then $\varpi(\delta x - x) = 0$, so $\delta x = x$ for $\delta \in \Delta$), so L'_U/L_U is finitely generated and torsion-free, hence free, and L_U is a direct summand of L'_U, finite free. Invariants under the finite group Δ are the kernel of $x \mapsto (\delta x - x)_{\delta\in\Delta}$ and $\mathcal{K}$ is flat over $\mathcal{O}$, so $W_U = (L'_U \otimes_{\mathcal{O}} \mathcal{K})^\Delta = L_U \otimes_{\mathcal{O}} \mathcal{K}$. As L_U is a direct summand of L'_U, the map $L_U \otimes \mathcal{K}/\mathcal{O} \to L'_U \otimes \mathcal{K}/\mathcal{O}$ is injective, with image in $M^\flat_{\lambda,U} = (L'_U \otimes \mathcal{K}/\mathcal{O})^\Delta$ (Step 2); its cokernel C_U in $M^\flat_{\lambda,U}$ is finite: the Δ-invariants of $0 \to L'_U \to L'_U \otimes \mathcal{K} \to L'_U \otimes \mathcal{K}/\mathcal{O} \to 0$ give an exact sequence $L_U \otimes \mathcal{K} \to (L'_U \otimes \mathcal{K}/\mathcal{O})^\Delta \to H^1(\Delta, L'_U)$ in which the image of the first map is $L_U \otimes \mathcal{K}/\mathcal{O}$, and $H^1(\Delta, L'_U)$ is a subquotient of the finitely generated $\mathcal{O}$-module of maps $\Delta \to L'_U$ and is killed by $|\Delta|$, hence finite. Dualising $0 \to L_U \otimes \mathcal{K}/\mathcal{O} \to M^\flat_{\lambda,U} \to C_U \to 0$ and tensoring with $\mathcal{K}$, which kills the finite module $C_U^\vee$, the restriction $(M^\flat_{\lambda,U})^\vee \otimes_{\mathcal{O}} \mathcal{K} \to (L_U \otimes \mathcal{K}/\mathcal{O})^\vee \otimes_{\mathcal{O}} \mathcal{K}$ is an isomorphism. For a finite free $\mathcal{O}$-module L there are isomorphisms, natural in L,

$$(L \otimes_{\mathcal{O}} \mathcal{K}/\mathcal{O})^\vee \cong \mathrm{Hom}_{\mathcal{O}}(L, \mathrm{End}_{\mathcal{O}}(\mathcal{K}/\mathcal{O})) = \mathrm{Hom}_{\mathcal{O}}(L, \mathcal{O}),$$
$$\mathrm{Hom}_{\mathcal{O}}(L, \mathcal{O}) \otimes_{\mathcal{O}} \mathcal{K} \cong \mathrm{Hom}_{\mathcal{K}}(L \otimes_{\mathcal{O}} \mathcal{K}, \mathcal{K})$$

($\mathrm{End}_{\mathcal{O}}(\mathcal{K}/\mathcal{O}) = \mathcal{O}$, $\mathcal{O}$ being complete; the second is the base change of linear forms on a free module of finite rank).

Definition of Φ_U. Φ_U is the composite of the isomorphism of Step 1 tensored with $\mathcal{K}$, the dual of the inverse of the isomorphism $\lambda_*\colon M^\flat_{\lambda,U} \to M_U[\mathfrak{p}_\lambda]$ of Step 2 tensored with $\mathcal{K}$, the restriction isomorphism $(M^\flat_{\lambda,U})^\vee \otimes \mathcal{K} \to (L_U \otimes \mathcal{K}/\mathcal{O})^\vee \otimes \mathcal{K}$ of Step 3, and the isomorphisms of

Step 3 for $L = L_U$. It is a $\mathcal{K}$-linear isomorphism.

(Wn1). By (Gy2) the operators on M_U commute with each other and with Λ_1, so they preserve $M_U[\mathfrak{p}_\lambda]$, and Step 1 transports the dual action on $S_U/\mathfrak{p}_\lambda S_U$ to the dual of the action on $M_U[\mathfrak{p}_\lambda]$. By (Gk4)(c), λ_* intertwines $T_w^{(j)}$ with $T_w^{(j)}$, $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$ with $U_{\tilde{v}}^{(j)}$, and $\chi(u)^{-1}\langle u\rangle$ (weight λ) with $\langle u\rangle$ (trivial weight); these operators of weight λ commute with the $\langle u\rangle$ ([105], Lemma 2.3.3), so preserve $M_{\lambda,U}^\flat$, L'_U and L_U; by (Gk4)(b) they act on $M_{\lambda,U}^\flat \subseteq S_\lambda^{\mathrm{ord}}(U(\ell^{E,E}), \mathcal{K}/\mathcal{O})$ as on the forms of level $U(\ell^{E,E})$, so the inclusion $L_U \otimes \mathcal{K}/\mathcal{O} \subseteq M_{\lambda,U}^\flat$ intertwines $t|_{L_U} \otimes 1$ with them, and the restriction isomorphism of Step 3 carries the dual of their action to the dual of $t|_{L_U} \otimes 1$. The isomorphisms of Step 3 are natural in L, so they carry the dual of $t|_{L_U} \otimes 1$ to the transpose of $t|_{L_U} \otimes 1$ on W_U. Inverses correspond to inverses. This is (Wn1).

(Wn2). U' and U have the same components at S_ℓ and at the split places outside T, and $U'(\ell^{b,c}) \subseteq U(\ell^{b,c})$; so forms of level $U(\ell^{b,c})$ are forms of level $U'(\ell^{b,c})$, giving inclusions ι of all the spaces above, for every coefficient module. Each operator $T_w^{(j)}$, $U_{\lambda,\varpi_{\tilde{v}}}^{(j)}$, $\langle u\rangle$ is a double coset operator $[U''\alpha U'']$ with α supported at one place v_0 (a split place outside T, or a place of S_ℓ), where $U''_{v_0} = U'_{v_0}$; writing $U''_{v_0}\alpha U''_{v_0} = \coprod_i x_i \alpha U''_{v_0}$ with $x_i \in U''_{v_0}$, we get $U''\alpha U'' = \coprod_i x_i\alpha U''$ for both levels with the same x_i, and the operator is $f \mapsto \sum_i \xi_\lambda((x_i\alpha)_{S_\ell}) f(\cdot\, x_i\alpha)$ (up to the same scalar) on both; hence ι commutes with all operators, with the ordinary idempotents, with direct limits over c, and with λ_*, which is composition with ϵ_λ on the values. So ι maps M_U into $M_{U'}$ Λ_1-linearly, $M_{\lambda,U}^\flat$ into $M_{\lambda,U'}^\flat$, L'_U into $L'_{U'}$, L_U into $L_{U'}$ and W_U into $W_{U'}$ (the groups Δ for U and U' are the same, and ι commutes with the $\langle u\rangle$), and all squares formed with the maps of Steps 1–3 commute. Each map in the definition of Φ is natural for these maps (Step 1 for Λ_1-linear maps, Step 2 because $\iota \circ \lambda_* = \lambda_* \circ \iota$, the restriction of Step 3 because ι maps $L_U \otimes \mathcal{K}/\mathcal{O}$ into $L_{U'} \otimes \mathcal{K}/\mathcal{O}$, Step 3 for $\mathcal{O}$-linear maps $L_U \to L_{U'}$); dualising reverses the arrows, the dual of $\iota\colon M_U \to M_{U'}$ induces p and the transpose of $\iota|_{W_U}$ is r. Hence $\Phi_U \circ (p \otimes 1) = r \circ \Phi_{U'}$.

(Wn3). $(U_g)_v = U_v$ for $v \in S_\ell$ and for $v \notin T$ split in F, so U_g is as in Theorem B.91, $U_g(\ell^{b,c}) = gU(\ell^{b,c})g^{-1}$, and $U_g(\ell^{1,1})$ is sufficiently small (its projection to $\mathbb{G}(F_v^+)$ is conjugate to that of $U(\ell^{1,1})$). If f has level $U(\ell^{b,c})$ and $u = gu'g^{-1}$ with $u' \in U(\ell^{b,c})$, then $u_{S_\ell} = u'_{S_\ell}$ and $\xi_\lambda(u_{S_\ell})(r_g f)(xu) = \xi_\lambda(u'_{S_\ell}) f(xgu') = f(xg)$; so r_g maps forms of level $U(\ell^{b,c})$ bijectively (inverse $r_{g^{-1}}$) onto forms of level $U_g(\ell^{b,c})$, for every coefficient module. For a double coset operator as in the proof of (Wn2), supported at v_0 with $g_{v_0} = 1$, the elements $x_i\alpha$ commute with g and the decomposition at v_0 is the same for both levels, so r_g commutes with it: $\sum_i \xi_\lambda((x_i\alpha)_{S_\ell}) f(xgx_i\alpha) = \sum_i \xi_\lambda((x_i\alpha)_{S_\ell}) f(xx_i\alpha g)$. Also r_g commutes with λ_* (values against arguments) and with direct limits. The argument of (Wn2), with r_g in place of ι, gives $\Phi_U \circ (a_g \otimes 1) = r_g^t \circ \Phi_{U_g}$. □

E.1.5 Automorphy and purity at points of the classical ideal

This subsection proves Proposition E.25, the automorphy with the witness conditions of the irreducible points of the classical ideal with a parallel inertial weight, which Proposition 50.11 and Theorem 53.10 use. The classical ideal is the kernel of a Galois determinant onto the irreducible-type quotient of an ordinary Hecke algebra of a type (Proposition E.26), and the witness conditions come from Lemma 53.25. The subsection also proves the two properties of ideals cut out by such Hecke algebras that Theorem 53.10 needs: stability under twists (Lemma E.27, with the criterion Lemma E.28) and purity at arithmetic points (Lemma E.29).

Proposition E.25. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, κ a twist for $\mathscr{H}$, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, and $(\psi_{v,a}^\circ)$ an inertial weight for $\mathscr{H}$ such that for every $v \in S_\ell$ and $1 \le a, b \le n$ there is an integer h_{ab} with $\psi_{v,a}^\circ(\psi_{v,b}^\circ)^{-1}\chi_{\mathrm{cyc}}^{-h_{ab}}$ trivial on an open subgroup of I_v. Let A be an integral test ring over $\mathcal{O}'$,*

$\rho\colon \Gamma^0_{\mathscr{H}} \to \mathrm{GL}_n(A)$ *a homomorphism such that* $\rho_L = \rho \circ \pi_{\mathscr{H}}|_{G_L}$ *is continuous and irreducible over* $\overline{\mathbb{Q}}_\ell$*, and* $y\colon B_n^{\mathrm{po}} \to A$ *a homomorphism of* $\mathcal{O}'$*-algebras with* $y \circ D^{\mathrm{u}} = \det \circ \rho$*,* $y(\psi^{\mathrm{d}}_{v,a}(g)) = \psi^{\circ}_{v,a}(g)$ *for all* $v \in S_\ell$*,* $1 \le a \le n$ *and* $g \in I_v$*, and* $y(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$*. Then* $\rho_L \otimes \kappa$ *is automorphic of conjugate self-dual type for* ι *and satisfies the witness conditions.*

Proof. The integral test ring A is a subring of $\overline{\mathbb{Q}}_\ell$; let $y'\colon B \to \overline{\mathbb{Q}}_\ell$ be y followed by the inclusion. As $y'(1) = 1$ and $y'(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$, $\mathcal{J}_\kappa^{\mathrm{cl}} \neq B$, so Proposition E.26 provides (Hz3); its hypotheses hold for the inertial weight $(\psi^{\circ}_{v,a})$: $y'(\psi^{\mathrm{d}}_{v,a}(g)) = \psi^{\circ}_{v,a}(g)$ for $g \in I_v$, and $y' \circ D^{\mathrm{u}} = \det \circ \rho$ with ρ, viewed over $\overline{\mathbb{Q}}_\ell$, continuous ($\Gamma$ carries the quotient topology of $\pi|_{G_L}$) and absolutely irreducible (because ρ_L is irreducible over $\overline{\mathbb{Q}}_\ell$ and $\pi(G_L) = \Gamma$). So y' is a classical ordinary point: there are $\tilde{r}\colon \Gamma \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, $r = \tilde{r} \circ \pi$ continuous, and a regular algebraic conjugate self-dual cuspidal Π with (Cy1)–(Cy3).

Step 1: $\rho_L \cong r$*, hence automorphy.* By (Cy1), $\det \circ \rho = y' \circ D^{\mathrm{u}} = \det \circ \tilde{r}$ as $\overline{\mathbb{Q}}_\ell$-valued determinants on Γ. $\rho \otimes \overline{\mathbb{Q}}_\ell$ is irreducible because ρ_L is and $\pi(G_L) = \Gamma$. The semisimplification $\tilde{r}^{\mathrm{ss}}$ has the same determinant as $\tilde{r}$ (characteristic polynomials only depend on it), so by the uniqueness in (Ch3), $\tilde{r}^{\mathrm{ss}} \cong \rho$ is irreducible; then $\tilde{r}$ has no proper invariant subspace, $\tilde{r} = \tilde{r}^{\mathrm{ss}} \cong \rho$, and $\rho_L \cong r$. By (Cy2), $\rho_L \otimes \kappa \cong r \otimes \kappa \leftrightarrow_\iota \Pi$, so $\rho_L \otimes \kappa$ is automorphic of conjugate self-dual type for ι.

Step 2: (Qw1) for $r' = \rho_L \otimes \kappa$*.* Let $w \nmid \ell$ be a finite place of L, $\bar{w} \mid w$, $D = D_{\bar{w}} \cap G_L$, $I = I_{\bar{w}} \cap G_L$, and $\bar{\chi} = (\bar{\chi}_1, \dots, \bar{\chi}_n)\colon G_L \to (\mathbb{F}^\times_{\mathcal{O}'})^n$. Every $s \in I$ with $\bar{\chi}(s) = 1$ lies in $N_{\mathscr{H}}$, so $\rho_L|_I$ factors through the finite abelian group $A_I = \bar{\chi}(I) \subseteq A_D = \bar{\chi}(D)$; hence $\rho_L|_I$ has finite image and is conjugate to $\mathrm{diag}(\phi_i \circ \bar{\chi})$ for characters ϕ_i of A_I. Extend each ϕ_i to a character ϕ_i' of A_D (characters of finite abelian groups extend from subgroups) and put $\Psi_i' = \phi_i' \circ \bar{\chi}|_D$. The continuous character κ has finite image on I (on an open subgroup of I it is $\exp(t_\ell(\cdot)N)$ with N a nilpotent 1×1 matrix, i.e. trivial). So $r'(I)$ is finite and $r'|_I$ is conjugate to $\mathrm{diag}(\Psi_i'\kappa|_I)$ with characters $\Psi_i'\kappa|_D$ of D.

Step 3: the polarisation of ρ*.* The map $\rho^\sharp\colon \Gamma \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, $\gamma \mapsto {}^t\rho(\pi(c)\gamma^{-1}\pi(c))$, is a homomorphism, irreducible because ρ is. For $g \in G_L$, (Od1) for the polarised ordinary determinant $(y' \circ D^{\mathrm{u}}, (y' \circ \psi^{\mathrm{d}}_{v,a}))$ says that $\rho(\pi(cg^{-1}c))$, hence $\rho^\sharp(\pi(g))$, has the same characteristic polynomial as $\rho(\pi(g))$. Two irreducible representations of Γ over the algebraically closed field $\overline{\mathbb{Q}}_\ell$ of characteristic 0 with the same characteristic polynomials are isomorphic (Brauer–Nesbitt), so there is $P \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with $\rho(\pi(cg^{-1}c)) = {}^t(P\rho(\pi(g))P^{-1})$ for all $g \in G_L$.

Step 4: (Qw2) for r'*.* Let $u \in S_\ell$, with the place $\bar{u}$ of $\mathscr{H}$ and $D_u = D_{\bar{u}} \cap G_{L^+} \subseteq G_L$ ((Rd2): u splits in L). By (Cy3) and Step 1, ρ_L is triangular on D_u with diagonal $(y' \circ \psi^{\mathrm{d}}_{u,a})_a$, whose restrictions to I_u are the $\psi^{\circ}_{u,a}$. Every place of $\overline{\mathbb{Q}}$ above a place of L above u is $h\bar{u}$ or $ch\bar{u}$ with $h \in G_L$ (as $G_{L^+} = G_L \cup cG_L$), with decomposition groups in G_L equal to hD_uh^{-1}, resp. $chD_uh^{-1}c$, and inertia groups hI_uh^{-1}, resp. $chI_uh^{-1}c$. On $D' = hD_uh^{-1}$, ρ_L is triangular with diagonal $(\kappa_a)_a$, $\kappa_a(s) = y'(\psi^{\mathrm{d}}_{u,a}(h^{-1}sh))$. Let $Z \in \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ conjugate $\rho_L|_{D'}$ to upper triangular form. For $s \in D'$, $X = Z\rho_L(s^{-1})Z^{-1}$ is upper triangular with diagonal $(\kappa_a(s)^{-1})_a$, and by Step 3 $\rho_L(csc) = {}^t(P\rho_L(s^{-1})P^{-1})$ is conjugate to ${}^tX$ by a matrix independent of s, and $J_n\,{}^tX\,J_n$ (J_n the antidiagonal matrix of ones) is upper triangular with diagonal $(\kappa_{n+1-a}(s)^{-1})_a$; so ρ_L is triangular on $cD'c$ with diagonal $(csc \mapsto \kappa_{n+1-a}(s)^{-1})_a$. Twisting by κ multiplies every diagonal character by κ and does not change their ratios. By hypothesis, $\psi^{\circ}_{u,a}(\psi^{\circ}_{u,b})^{-1}\chi_{\mathrm{cyc}}^{-h_{ab}}$ is trivial on an open subgroup U_{ab} of I_u; since $\chi_{\mathrm{cyc}}(h^{-1}sh) = \chi_{\mathrm{cyc}}(s) = \chi_{\mathrm{cyc}}(csc)$, on D' the character $\kappa_a\kappa_b^{-1}\chi_{\mathrm{cyc}}^{-h_{ab}}$ is trivial on $hU_{ab}h^{-1}$, and on $cD'c$ the ratio of the a-th and b-th diagonal characters times $\chi_{\mathrm{cyc}}^{-h_{n+1-b,n+1-a}}$ is trivial on $chU_{n+1-b,n+1-a}h^{-1}c$, open subgroups of the respective inertia groups. This is (Qw2).

Step 5. r' is irreducible, $n \ge 2$, automorphic of conjugate self-dual type (Step 1), and satisfies

(Qw1), (Qw2); by Lemma 53.25 it satisfies the witness conditions. □

Proposition E.26. *Let $\mathscr{H} = (n, L, c, (\bar v)_{v\in S_\ell}, \mathrm{St}, v_0, \bar v_0, (\bar\chi_a)_{1\le a\le n})$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, κ a twist for $\mathscr{H}$, and $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$. Then $\mathcal{J}_\kappa^{\mathrm{cl}} = B_n^{\mathrm{po}}$, or there are a type datum $((V_v)_{v\in\mathrm{St}}, \tau)$ over $\mathscr{H}$, a maximal ideal $\mathfrak{m}$ of $\mathbb{T}_\tau$, an ideal $\mathfrak{a}$ of $\mathbb{T}_{\tau,\mathfrak{m}}$ which is the intersection of a non-empty set of minimal prime ideals of $\mathbb{T}_{\tau,\mathfrak{m}}$, and a surjective homomorphism of $\mathcal{O}'$-algebras $\theta\colon B_n^{\mathrm{po}} \to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}$ such that*

(Hz1) $\ker\theta = \mathcal{J}_\kappa^{\mathrm{cl}}$;

(Hz2) *for every $u \in T_n(\ell^1)$, $\langle u\rangle - 1$ lies in the ideal of $\mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}$ generated by $\mathfrak{m}_{\mathcal{O}'}$ and the elements $\theta(\psi^{\mathrm{d}}_{v,a}(g)) - 1$ with $v \in S_\ell$, $1 \le a \le n$, $g \in I_v$ and $\bar\chi_b(g) = 1$ for $1 \le b \le n$;*

(Hz3) *for every inertial weight $(\psi^\circ_{v,a})$ for $\mathscr{H}$, every homomorphism of $\mathcal{O}'$-algebras $y\colon B_n^{\mathrm{po}} \to \overline{\mathbb{Q}}_\ell$ with $y(\mathcal{J}_\kappa^{\mathrm{cl}}) = 0$, $y(\psi^{\mathrm{d}}_{v,a}(g)) = \psi^\circ_{v,a}(g)$ for all $v \in S_\ell$, $1 \le a \le n$ and $g \in I_v$, and $y \circ D^{\mathrm{u}} = \det\circ\rho$ for a continuous absolutely irreducible representation $\rho\colon \Gamma^0_{\mathscr{H}} \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, is a classical ordinary point for ι and κ.*

Proof. Step 1: the setting. Let $((V_v), \tau)$ be the type datum of Proposition E.5, V its level, $\mathbb{T} = \mathbb{T}_\tau$. By (Gd0) of Lemma E.16, $\mathbb{T}$ is commutative, finite and torsion-free over Λ_1 (for the diamond and the renormalised structures), the product of its localisations at its finitely many maximal ideals, topologically generated by the $T_w^{(j)}$, $(T_w^{(n)})^{-1}$, $U_{\tilde v}^{(j)}$ and $\langle u\rangle$; the $U_{\tilde v}^{(j)}$ are units; and every homomorphism of $\mathcal{O}'$-algebras from B, from $\mathbb{T}$ or from a quotient of either to $\overline{\mathbb{Q}}_\ell$ is continuous, local onto its image, with image an $\mathcal{O}'$-order in a finite extension of $\mathbb{Q}_\ell$. Also $[L^+ : \mathbb{Q}] \ge 2$ ((Gd0)).

Step 2: the maximal ideal. If there is no classical ordinary point, $\mathcal{J} = B$ and we are done. Otherwise, for every classical ordinary point x let $\tilde r_x$ be as in (Cy1) and y_x the point of $\mathbb{T}$ of (Hx3). The reduction $\bar y_x$ of y_x (Step 1) takes on the topological generators of $\mathbb{T}$ over $\mathcal{O}'$ values independent of x and lying in $\mathbb{F}$: on $T_w^{(j)}$ the reductions of $(\mathrm{N}w)^{-j(j-1)/2}$ times the coefficients of the characteristic polynomial of $(\tilde r_x \otimes \kappa)(\mathrm{Frob}_w)$, i.e. those of $\bar D_n \otimes \bar\kappa$ ($x\circ D^{\mathrm{u}}$ reduces to $\bar D_n$, and $\kappa(G_L) \subseteq \mathcal{O}'^\times$); on $\langle d_j(z)\rangle$ and $U_{\tilde v}^{(j)}$ the reductions of the $\phi_{v,j}$, i.e. of $\chi^{j-1}\kappa\bar\chi_j$. Hence $\mathfrak{m} = \ker\bar y_x$ is one maximal ideal for all x, $\mathbb{T}/\mathfrak{m} = \mathbb{F}$, and every y_x factors through $\mathbb{T}_\mathfrak{m} = \mathbb{T}_{\tau,\mathfrak{m}}$.

Step 3: regular points are dense on every component. Call a point y of $\mathbb{T}_\mathfrak{m}$ *regular* if $y(\mathfrak{P}_{\lambda,1}) = 0$ for a regular dominant λ with $\lambda_{\tau,j} > \lambda_{\tau,j+1}$ for all τ, j. Claim: for every minimal prime P of $\mathbb{T}_\mathfrak{m}$ and every $f \notin P$ there is a regular y with $y(P) = 0 \ne y(f)$. Indeed, $\Lambda_1 \to \mathbb{T}_\mathfrak{m}/P$ is injective (non-zero elements of Λ_1 are non-zero-divisors by Step 1, and a minimal prime consists of zero-divisors), and $\mathbb{T}_\mathfrak{m}/P$ is a domain finite over the normal domain $\Lambda_1 \cong \mathcal{O}'[[X_1, \dots, X_N]]$; the minimal polynomial of f mod P over $\mathrm{Frac}(\Lambda_1)$ has coefficients in Λ_1 and a non-zero constant term c_0. The kernel of $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$ induced by $(w_0\nu)^{-1}(w_0\lambda)^{-1}$ is $\mathfrak{P}_{k(\lambda)}$ in the notation of Lemma 50.13 with $k(\lambda)_{\tau,j} = -(j-1) - \lambda_{\tau,n+1-j}$; the set of $k(\lambda)$, λ as above, is dense in $(\mathbb{Z}_\ell^n)^I$ (given k^* and e', choose λ with $k(\lambda) \equiv k^* \bmod \ell^{e'}$ and add $\ell^{e'}A(n-i)$ to $\lambda_{\tau,i}$ for large A). By Lemma 50.13 ($F^+ = L^+$; $\mathcal{O}' \supseteq \tau(\mathcal{O}_{L^+})$ by (Rd1)), $c_0 \notin \mathfrak{P}_{k(\lambda)}$ for some such λ. By lying over there is $y\colon \mathbb{T}_\mathfrak{m}/P \to \overline{\mathbb{Q}}_\ell$ extending $\Lambda_1/\mathfrak{P}_{k(\lambda)} \to \overline{\mathbb{Q}}_\ell$; $y(f)$ is a root of the image of the minimal polynomial, whose constant term $y(c_0) \ne 0$, so $y(f) \ne 0$. Consequently the intersection of the kernels of the regular points is the nilradical $\mathfrak{n}$ of $\mathbb{T}_\mathfrak{m}$.

Step 4: the Galois determinant and the components of irreducible type. For a regular y let r_y be as in (Hx1). The maximal ideal $\mathfrak{m}$ satisfies (Mx) of Lemma E.16 (Step 2), and by Step 3 the regular points separate $\mathbb{T}_\mathfrak{m}/\mathfrak{n}$. By (Gd1) of Lemma E.16 (with $\mathfrak{a} = \mathfrak{n}$ and $\mathcal{C}$ the set of

regular points) there is a continuous $\mathbb{T}_{\mathfrak{m}}/\mathfrak{n}$-valued determinant D^{H} of dimension n on G_L with $y \circ D^{\mathrm{H}} = \det \circ r_y$ for all regular y, and $y \circ D^{\mathrm{H}} = \det \circ \rho$ for every point y of $\mathbb{T}_{\mathfrak{m}}$ (it kills $\mathfrak{n}$) and every continuous $\rho\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ unramified above every w with characteristic polynomial $P_{y,w}$ at Frob_w. For a minimal prime P let ρ_P be the semisimple representation over an algebraic closure Ω_P of $\mathrm{Frac}(\mathbb{T}_{\mathfrak{m}}/P)$ with determinant D^{H} mod P (Ch3), and let $\mathcal{P}$ be the set of minimal primes P contained in $\ker y_x$ for some classical ordinary point x. By (P2) below, ρ_P is absolutely irreducible for $P \in \mathcal{P}$, because $y_x \circ D^{\mathrm{H}} = \det(\tilde{r}_x \circ \pi_{\mathscr{H}} \otimes \kappa)$ (by (Hx3) and the remark above) is the determinant of an absolutely irreducible representation (Cy1).

(P1) For a minimal prime P with ρ_P absolutely irreducible (in particular for $P \in \mathcal{P}$) there is $g_P \notin P$ such that r_y is absolutely irreducible for every regular y with $y(P) = 0 \neq y(g_P)$: by Burnside choose $\gamma_1, \dots, \gamma_{n^2} \in G_L$ with $\rho_P(\gamma_i)$ a basis of $\mathrm{M}_n(\Omega_P)$ and let g_P lift $\det(\mathrm{tr}_{D^{\mathrm{H}}}(\gamma_i\gamma_j)) \bmod P = \det(\mathrm{tr}\,\rho_P(\gamma_i\gamma_j)) \neq 0$; if $y(g_P) \neq 0$, the $r_y(\gamma_i)$ are linearly independent, span $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$, and r_y has no invariant proper subspace.

(P2) For a minimal prime P with ρ_P not absolutely irreducible and every point y with $y(P) = 0$, the semisimple representation with determinant $y \circ D^{\mathrm{H}}$ is reducible: $\rho_P = \rho_1 \oplus \rho_2$ with $\dim \rho_i \geq 1$; the coefficients of the characteristic polynomials of ρ_i are roots-sums of monic polynomials over $\mathbb{T}_{\mathfrak{m}}/P$, hence lie in the integral closure R_P of $\mathbb{T}_{\mathfrak{m}}/P$ in Ω_P, so by (Ch1) $\det \rho_i$ is the base change of an R_P-valued determinant D_i; y extends to $\tilde{y}\colon R_P \to \overline{\mathbb{Q}}_\ell$ (lying over), and $y \circ D^{\mathrm{H}} = (\tilde{y} \circ D_1)(\tilde{y} \circ D_2)$ is, by (Ch3), the determinant of a direct sum of representations of dimensions $\dim \rho_1$, $\dim \rho_2$.

Let $\mathfrak{a} = \bigcap_{P \in \mathcal{P}} P$ and $A = \mathbb{T}_{\mathfrak{m}}/\mathfrak{a}$. For a classical x, $\ker y_x$ contains a minimal prime, which lies in $\mathcal{P}$. So $\mathcal{P} \neq \varnothing$ and $y_x(\mathfrak{a}) = 0$ for every classical x.

(P3) (Invariance under $N_{\mathscr{H}}$ on the components through classical points.) Let $P \in \mathcal{P}$, $P \subseteq \ker y_x$, $R = \mathbb{T}_{\mathfrak{m}}/P$, D_P the determinant D^{H} mod P twisted by κ^{-1} (as for $D^\flat$ in Step 5), w' a place of L not above ℓ, $I_{w'} \subseteq D_{w'}$ inertia and decomposition groups at a place of $\overline{\mathbb{Q}}$ above it, $I' = \{s \in I_{w'} : \bar{\chi}_a(s) = 1 \ (1 \leq a \leq n)\}$, $q = \mathrm{N}w'$ and $\Phi \in D_{w'}$ a lift of a Frobenius. Then $\chi_{D_P}(gs) = \chi_{D_P}(g)$ in $R[t]$ for all $g \in G_L$, $s \in I'$. Proof. (a) For every regular y with $y(P) = 0$, $\tilde{r}_y = r_y \otimes \kappa^{-1}$ has residual semisimplification with determinant $\bar{D}_n$ (Step 2), i.e. $\bigoplus_a \bar{\chi}_a$, trivial on I'; so $\tilde{r}_y(I')$ lies in a pro-ℓ group (the preimage of a unipotent group for a stable lattice), $\tilde{r}_y|_{I'}$ factors through the maximal pro-ℓ quotient of I', which is a quotient of $t_\ell(I') \subseteq \mathbb{Z}_\ell(1)$ (t_ℓ the ℓ-part of the tame character; wild inertia is pro-p), and I' is normal in $D_{w'}$, with $t_\ell(\Phi s \Phi^{-1}) = q^{\pm 1} t_\ell(s)$. Hence for $s \in I'$ the multiset of eigenvalues of $\tilde{r}_y(s)$ is stable under $\mu \mapsto \mu^{q^{\pm 1}}$, and every eigenvalue satisfies $\mu^Q = 1$, $Q = \prod_{k=1}^n (q^k - 1)$. (b) Let $c_i \in R$ be the coefficients of $\chi_{D_P}(s)$ and $F_i \in \mathbb{Z}[T]$ the monic polynomial whose roots are the i-th coefficients of the polynomials $\prod_{k=1}^n (X - \mu_k)$, $\mu_k^Q = 1$ (a Galois-stable finite set of algebraic integers). By (a), $F_i(c_i)$ vanishes at all regular y with $y(P) = 0$, which separate R (Step 3), so $F_i(c_i) = 0$ and c_i is algebraic over $\mathbb{Q}$; let m_i be its minimal polynomial. As $s \in N_{\mathscr{H}}$, $y_x(\chi_{D_P}(s)) = \det(X - \tilde{r}_x(\pi_{\mathscr{H}}(s))) = (X-1)^n$, so m_i has the rational root $y_x(c_i)$ and $c_i = y_x(c_i)$: $\chi_{D_P}(s) = (X-1)^n$, and $\tilde{r}_y(s)$ is unipotent at every regular y with $y(P) = 0$. (c) Let $\delta \in R$ be the symmetric expression $\prod_{i \neq j}(\alpha_i - q\alpha_j)$ in the roots α_i of $\chi_{D_P}(\Phi)$, a polynomial in its coefficients. The representation $r_{y_x} = \tilde{r}_x \circ \pi_{\mathscr{H}} \otimes \kappa$ is absolutely irreducible and attached to the cuspidal Π of (Cy2), hence isomorphic to $r_{\ell,\iota}(\Pi)$ (Theorem B.62, (Bg1), Chebotarev); it has finite image on $I_{w'}$ (it kills $I' \subseteq N_{\mathscr{H}}$ up to κ, which has finite order there by (Rd7)), so its Weil–Deligne representation at w' has $N = 0$ and, being pure (Theorem B.90: by (Pv2) $N = 0$ forces $V = \mathrm{gr}_k$), all eigenvalues of $r_{y_x}(\Phi)$ have the same absolute value under every embedding into $\mathbb{C}$; as $q > 1$, $y_x(\delta) \neq 0$

(the twist by $\kappa(\Phi)$ does not change ratios). (d) Let y be regular with $y(P) = 0 \neq y(g_P\delta)$; such y separate R (Step 3, applied to $fg_P\delta$). Then r_y is absolutely irreducible (P1), so by (Hx2) and (Hx1)(i) it is automorphic of conjugate self-dual type, $r_y \cong r_{\ell,\iota}(\Pi_y)$ for a regular algebraic conjugate self-dual cuspidal Π_y, and its Weil–Deligne representation (ρ, N) at w' is pure. If $N \neq 0$, then, N mapping each generalised eigenspace of $\rho(\Phi)$ for an eigenvalue α into the one for $q^{\pm1}\alpha$ (the monodromy relation), $\rho(\Phi)$ has eigenvalues α and $q^{\pm1}\alpha$; for an ordering of the eigenvalues along these chains N is block nilpotent, so $r_y(\Phi)$, which differs from $\rho(\Phi)$ by a factor $\exp(cN)$, has the same eigenvalues, and $y(\delta) = 0$, a contradiction. So $N = 0$, r_y is trivial on an open subgroup of $I_{w'}$, and $\tilde{r}_y(s)$ ($s \in I'$) is unipotent of finite order, i.e. 1. Hence $\chi_{D_P}(gs) - \chi_{D_P}(g)$ vanishes at all such y, so it is 0.

Step 5: the Hecke determinant over A, and θ. Let $\mathcal{C}$ be the set of regular y with $y(P) = 0 \neq y(g_P)$ for some $P \in \mathcal{P}$. The points in $\mathcal{C}$ separate A: if $f \notin \mathfrak{a}$, then $f \notin P$ for some $P \in \mathcal{P}$, $fg_P \notin P$, and Step 3 gives a regular y with $y(P) = 0 \neq y(f)y(g_P)$. Let $D^\flat$ be D^{H} mod $\mathfrak{a}$ twisted by κ^{-1} (composed with the ring automorphism $g \mapsto \kappa(g)^{-1}g$ of $A[G_L]$), so $y \circ D^\flat = \det \circ \tilde{r}_y$ with $\tilde{r}_y := r_y \otimes \kappa^{-1}$. The elements $s \in I_{\bar{v}} \cap G_L$, $\bar{v} \nmid \ell$, with $\bar{\chi}_a(s) = 1$ for all a form a set stable under conjugation by G_{L^+} (by G_L, as the $\bar{\chi}_a$ are characters; by c, as $\bar{\chi}_a(csc) = \bar{\chi}_{n+1-a}(s)^{-1}$ by (Rd5)), which therefore generates $N_{\mathscr{H}}$ as a closed subgroup. By (P3), $\chi_{D^\flat}(gs) = \chi_{D^\flat}(g)$ for $g \in G_L$ and such s, in $\prod_{P\in\mathcal{P}}(\mathbb{T}_{\mathfrak{m}}/P)[t]$, into which $A[t]$ embeds; the set of $s \in G_L$ with this property for all g is a closed subgroup (continuity; $\chi(gs_1s_2) = \chi(gs_1) = \chi(g)$, and $\chi(gs^{-1}) = \chi(gs^{-1}s)$), so it contains $N_{\mathscr{H}}$. For $y \in \mathcal{C}$ and $s \in N_{\mathscr{H}}$, then $\mathrm{tr}(\tilde{r}_y(g)(\tilde{r}_y(s) - 1)) = 0$ for all g; $\tilde{r}_y$ is absolutely irreducible (P1), so the $\tilde{r}_y(g)$ span $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ (Burnside) and $\tilde{r}_y(s) = 1$: $\tilde{r}_y = \tilde{r}'_y \circ \pi_{\mathscr{H}}$ with $\tilde{r}'_y$ continuous on $\Gamma^0_{\mathscr{H}}$. So $\tilde{r}_y$ is trivial on $N_{\mathscr{H}}$ for every $y \in \mathcal{C}$; and, r_y being absolutely irreducible (P1), by (Hx1)(iii) $r_y|_{D_v}$ is triangular with diagonal $(\chi^{1-j}\psi^y_{v,j})_j$ for $v \mid \ell$. Finally (iii) of (Gd2) of Lemma E.16 holds for every $y \in \mathcal{C}$: let $v \in S_\ell$, $1 \leq j \leq n$, $\zeta \in L_{\tilde{v}}$ an ℓ-power root of unity, say $\zeta^{\ell^k} = 1$, and $t = \langle d_j(\zeta)\rangle \in \mathbb{T}_{\mathfrak{m}}$; as $u \mapsto \langle u\rangle$ is a homomorphism, $t^{\ell^k} = 1$. Let $P \in \mathcal{P}$ with $y(P) = 0$ and x classical with $P \subseteq \ker y_x$. By (Hx3), $y_x(\langle d_j(z)\rangle) = \phi_{v,j}(\mathrm{Art}(z)) = (\chi^{j-1}\kappa)(\mathrm{Art}(z))\, x(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z)))$ for units z (as in Step 6). The universal tuple satisfies (Od3), so $x(\psi^{\mathrm{d}}_{v,j}(g_\zeta)) = \xi_{v,j}(g_\zeta)$, and $\chi(g_\zeta) = 1$ by (Wv1) of Lemma 50.24; hence $y_x(t) = \kappa(\mathrm{Art}(\zeta))\,\xi_{v,j}(g_\zeta) \in \mathcal{O}'$. By (Wv3) of Lemma 50.24 (with $R = \mathbb{T}_{\mathfrak{m}}$ and the points y_x, y, which both kill the prime P), $y(t) = y_x(t) = \kappa(\mathrm{Art}(\zeta))\,\xi_{v,j}(g_\zeta)$. Thus (i), (ii) and (iii) of (Gd2) of Lemma E.16 hold for $\mathfrak{a}$ and $\mathcal{C}$, and $\mathfrak{m}$ satisfies (Mx) (Step 2): $A \in \mathrm{CNL}_{\mathcal{O}'}$, and there is a surjective homomorphism of $\mathcal{O}'$-algebras $\theta\colon B \to A$ with the identities of (Gd2); in particular $y \circ \theta \circ D^{\mathrm{u}} = \det \circ \tilde{r}'_y$ and $y \circ \theta \circ \psi^{\mathrm{d}}_{v,j} = \chi^{1-j}\kappa^{-1}\psi^y_{v,j}$ for $y \in \mathcal{C}$.

Step 6: (Hz1). ($\mathcal{J} \subseteq \ker\theta$.) Let $y \in \mathcal{C}$ and $x_y = y \circ \theta$. With $\tilde{r}'_y$ as in (Gd2) (Step 5): (Cy1) $x_y \circ D^{\mathrm{u}} = \det \circ \tilde{r}'_y$, $\tilde{r}'_y$ absolutely irreducible; (Cy2) $\tilde{r}'_y \circ \pi_{\mathscr{H}} \otimes \kappa = r_y$ is absolutely irreducible, unramified with characteristic polynomial $P_{y,w}$ at Frob_w, and $y(\mathfrak{P}_{\lambda,1}) = 0$ with λ dominant, so by (Hx2) $r_y \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal Π; (Cy3) by (Gd2), $x_y \circ \psi^{\mathrm{d}}_{v,j} = \chi^{1-j}\kappa^{-1}\psi^y_{v,j}$, the diagonal of the triangular $\tilde{r}'_y \circ \pi_{\mathscr{H}}|_{D_v} = (r_y \otimes \kappa^{-1})|_{D_v}$ (Step 5); (Cy4) for z in $1 + \ell\mathcal{O}_{L_{\tilde{v}}}$, $y(\langle d_j(z)\rangle) = (w_0\lambda)^{-1}(d_j(z)) = \prod_\tau \tau(z)^{-\lambda_{\tau,n+1-j}}$ (as $(w_0\nu)^{-1}(u)y(\langle u\rangle) = (w_0\nu)^{-1}(w_0\lambda)^{-1}(u)$ on $T_n(\ell^1)$), and $\kappa(\mathrm{Art}(z)) = \prod_\tau \tau(z)^{m_\tau}$ on an open subgroup (κ algebraic), so $x_y \circ \psi^{\mathrm{d}}_{v,j}$ has τ-Hodge–Tate weight $h_{\tau,j} = (1-j) - m_\tau - \lambda_{\tau,n+1-j}$ and $h_{\tau,j} - h_{\tau,j+1} = 1 + \lambda_{\tau,n-j} - \lambda_{\tau,n+1-j} \geq 1$. So x_y is a classical ordinary point, and for $b \in \mathcal{J}$, $y(\theta(b)) = x_y(b) = 0$ for all $y \in \mathcal{C}$, whence $\theta(b) = 0$. ($\ker\theta \subseteq \mathcal{J}$.) Let x be classical. By Step 4, y_x induces $y'_x\colon A \to \overline{\mathbb{Q}}_\ell$, and $y'_x \circ \theta$ and x classify the same polarised ordinary determinant: by the first identity of (Gd2) and (Hx3), $y'_x \circ \theta \circ D^{\mathrm{u}}$ and $x \circ D^{\mathrm{u}} = \det \circ \tilde{r}_x$ have the same characteristic polynomial at every $\pi_{\mathscr{H}}(\mathrm{Frob}_w)$, a dense set (Chebotarev), so they are equal (continuity, (Ch1)); and by the other identities of (Gd2) and (Hx3), $y'_x \circ \theta \circ \psi^{\mathrm{d}}_{v,j}$ and $\chi^{1-j}\kappa^{-1}\phi_{v,j} = x \circ \psi^{\mathrm{d}}_{v,j}$ agree on the dense image of Art, hence everywhere. By Step 1 both $x(B)$ and $y'_x(A)$ are orders in a finite extension E; the

$\mathcal{O}'$-algebra $R \subseteq \mathcal{O}_E$ they generate is finite over $\mathcal{O}'$, a local domain with residue field $\mathbb{F}$ (generated by residues in $\mathbb{F}$), so $R \in \mathrm{CNL}_{\mathcal{O}'}$, and uniqueness in the universal property gives $x = y'_x \circ \theta$. Hence $x(\ker\theta) = 0$ for every classical x.

Step 7: (Hz2). Let $v \mid \ell$, $z \in 1 + \ell\mathcal{O}_{L_{\tilde{v}}}$, $g = \mathrm{Art}(z) \in I_v$. As $\mathrm{Art}(1+\ell\mathcal{O})$ is pro-ℓ and the $\bar{\chi}_b$ have order prime to ℓ, $\bar{\chi}_b(g) = 1$ for all b, and $(\chi^{j-1}\kappa)(g) = 1 + \mu$ with $\mu \in \mathfrak{m}_{\mathcal{O}'}$ (a continuous character of a pro-ℓ group into $\mathcal{O}'^{\times}$ lands in $1+\mathfrak{m}_{\mathcal{O}'}$). By (Gd2), $\langle d_j(z)\rangle - 1 = (1+\mu)\big(\theta(\psi^{\mathrm{d}}_{v,j}(g)) - 1\big) + \mu$. Every $u \in T_n(\ell^1)$ is a finite product of such $d_j(z)$, and $\langle uu'\rangle - 1 = \langle u\rangle(\langle u'\rangle - 1) + (\langle u\rangle - 1)$.

Step 8: (Hz3), and the weight normalisation. Let $(\psi^{\circ}_{v,a})$ be an inertial weight, $\phi_{v,a}$ de Rham characters for it as in (Rd8), $h_{\tau,a}$ their τ-Hodge–Tate weights (integers, strictly decreasing in a), and y, ρ as in (Hz3). By (Hz1), $y = y' \circ \theta$ with $y' \colon A \to \overline{\mathbb{Q}}_\ell$; let y'' be the point $\mathbb{T} \to \mathbb{T}_{\mathfrak{m}} \to A \to \overline{\mathbb{Q}}_\ell$. For $v \mid \ell$: a de Rham character of D_v is Hodge–Tate, hence locally algebraic [220]: there are integers b_τ with $\phi_{v,j}(\mathrm{Art}(z)) = \prod_\tau \tau(z)^{b_\tau}$ for z in an open subgroup of $\mathcal{O}^{\times}_{L_{\tilde{v}}}$, and $b_\tau = h_{\tau,j}$ by the remark on Hodge–Tate weights at the start of this proof. So for z in an open subgroup of $1 + \ell\mathcal{O}_{L_{\tilde{v}}}$: $y(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))) = \psi^{\circ}_{v,j}(\mathrm{Art}(z)) = \prod_\tau \tau(z)^{h_{\tau,j}}$, $\kappa(\mathrm{Art}(z)) = \prod_\tau \tau(z)^{m_\tau}$, and by (Gd2)

$$y''(\langle d_j(z)\rangle) = (\chi^{j-1}\kappa)(\mathrm{Art}(z))\, y(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))) = \prod_\tau \tau(z)^{(j-1)+m_\tau+h_{\tau,j}}.$$

Put $\lambda_{\tau,n+1-j} = -(j-1) - m_\tau - h_{\tau,j}$. Then $u \mapsto (w_0\nu)^{-1}(u)\, y''(\langle u\rangle)$ and $(w_0\nu)^{-1}(w_0\lambda)^{-1}$ agree on an open subgroup of $T_n(\ell^1)$, so their ratio α has finite order and $y''(\mathfrak{P}_{\lambda,\alpha}) = 0$. *Dominance.* $\lambda_{\tau,n-j} - \lambda_{\tau,n+1-j} = h_{\tau,j} - h_{\tau,j+1} - 1 \geq 0$, as the $h_{\tau,a}$ are strictly decreasing integers; so $\lambda_{\tau,1} \geq \cdots \geq \lambda_{\tau,n}$. Let $\rho' = \rho \circ \pi_{\mathscr{H}} \otimes \kappa$, continuous and absolutely irreducible ($\pi_{\mathscr{H}}(G_L) = \Gamma^0_{\mathscr{H}}$). It is unramified above every w (w lies above a place of L^+ not in $T_L \supseteq S_\ell \cup \mathrm{St}$, so inertia there lies in $N_{\mathscr{H}}$ by (Rd4); κ by (Rd7)), and, by the first identity of (Gd2) under y' and $y \circ D^{\mathrm{u}} = \det\rho$, $\rho'(\mathrm{Frob}_w)$ has characteristic polynomial $P_{y'',w}$. By (Hx2), $\rho' \leftrightarrow_\iota \Pi$ for a regular algebraic conjugate self-dual cuspidal Π: (Cy2) with $\tilde{r} = \rho$; (Cy1) holds by hypothesis. (Cy3): for $\gamma \in \Gamma^0_{\mathscr{H}}$ and $g_1, \ldots, g_n \in D_v$, (Od2) under y gives $\mathrm{tr}\big(\rho(\gamma)X\big) = 0$ with $X = \prod_a (\rho(\pi_{\mathscr{H}}(g_a)) - y(\psi^{\mathrm{d}}_{v,a}(g_a)))$; $\rho(\Gamma^0_{\mathscr{H}})$ spans $\mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ (Burnside) and the trace form is non-degenerate, so $X = 0$. The flag is obtained from this vanishing and the regularity of Π, without an element of D_v separating the residual characters. Write $V = \overline{\mathbb{Q}}_\ell^n$, $r = \rho \circ \pi_{\mathscr{H}}$ and $\psi_a = y \circ \psi^{\mathrm{d}}_{v,a} \colon D_v \to \overline{\mathbb{Q}}_\ell^{\times}$, and let $S_a \subseteq \mathrm{M}_n(\overline{\mathbb{Q}}_\ell)$ be the linear span of the $r(g) - \psi_a(g)$, $g \in D_v$. As $X = 0$ for all $g_1, \ldots, g_n \in D_v$, multilinearity gives $S_1 S_2 \cdots S_n = 0$. Each S_a is stable under left multiplication by $r(D_v)$, as $r(g)(r(g') - \psi_a(g')) = (r(gg') - \psi_a(gg')) - \psi_a(g')(r(g) - \psi_a(g))$ (ψ_a is a character). For $0 \leq k \leq n$ let $W_k = S_{k+1} \cdots S_n V$ be the span of the images (so $W_n = V$, $W_0 = 0$ and $W_{k-1} = S_k W_k$). By the stability, each W_k is $r(D_v)$-stable; hence $S_k W_k \subseteq W_k$, i.e. $W_{k-1} \subseteq W_k$, and $(r(g) - \psi_k(g))W_k \subseteq W_{k-1}$, so D_v acts on W_k/W_{k-1} by the scalar $\psi_k(g)$. Put $m_k = \dim W_k/W_{k-1}$; then $\sum_{k=1}^n m_k = n$. The W_k are also stable under $\rho'|_{D_v}$, D_v acting on W_k/W_{k-1} by $\psi_k\kappa$. Now ρ' is absolutely irreducible and $\rho' \leftrightarrow_\iota \Pi$, so $\rho' \cong r_{\ell,\iota}(\Pi)$ by (Bg1) of Theorem B.62 (Π conjugate self-dual is polarizable with $\chi = 1$), the Chebotarev density theorem and the Brauer–Nesbitt theorem. Through $\bar{v}$, $D_v = D_{\bar{v}} \cap G_L$ is the absolute Galois group of $L_{\tilde{v}} = L_v^+$, so by (Bg2) $\rho'|_{D_v}$ is de Rham, in particular Hodge–Tate, and for each embedding τ its n τ-Hodge–Tate weights are pairwise distinct, the infinitesimal character of the regular algebraic Π being regular. Subquotients of Hodge–Tate representations are Hodge–Tate, and the τ-Hodge–Tate weights, with multiplicity, are additive in short exact sequences of them (D_{HT} is exact on Hodge–Tate representations [52]). Hence the τ-Hodge–Tate weights of $\rho'|_{D_v}$ are those of the characters $\psi_k\kappa$, each counted m_k times; as they are pairwise distinct, $m_k \leq 1$ for every k, and $\sum_k m_k = n$ gives $m_k = 1$ for all k. Choosing $e_k \in W_k \smallsetminus W_{k-1}$, the basis $(e_1, \ldots, e_n)$ of V puts every $r(g)$, $g \in D_v$, in upper triangular form with diagonal $(\psi_1(g), \ldots, \psi_n(g))$: $\rho \circ \pi_{\mathscr{H}}$ is triangular on D_v with diagonal $(y \circ \psi^{\mathrm{d}}_{v,a})_a$. (Cy4): $y \circ \psi^{\mathrm{d}}_{v,a}$ and $\phi_{v,a}$ agree on I_v, so their ratio is

unramified, hence crystalline of Hodge–Tate weight 0; so $y\circ\psi^{\mathrm{d}}_{v,a}$ is de Rham with τ-Hodge–Tate weights $h_{\tau,a}$, strictly decreasing in a. So y is a classical ordinary point. □

Lemma E.27. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$ with trivial wild values, κ a twist for $\mathscr{H}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, c an integer as in Proposition E.5, $((V_v)_{v\in\mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$ with V_v the kernel of reduction modulo ϖ_v^c satisfying (Zt) for ι and κ, $\mathfrak{m}$ a maximal ideal of $\mathbb{T}_\tau$ with residue field $\mathbb{F}_{\mathcal{O}'}$ satisfying (Mx), $\chi_0\colon \Delta_\ell \to \mathcal{O}'^\times$ the homomorphism with $\chi_0(d_j(\zeta)) = \kappa(\mathrm{Art}(\zeta))$ for $v\in S_\ell$, $1\le j\le n$ and ℓ-power roots of unity $\zeta\in L_{\tilde{v}}$, $\mathfrak{a}_0 = \mathfrak{a}_{\chi_0}$ and $\mathcal{C}_{\chi_0}$ as in (Zp4) for $\mathbb{T}_{\tau,\mathfrak{m}}$, and $\theta\colon B\to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}_0$ a surjective homomorphism of $\mathcal{O}'$-algebras satisfying, for all w, $1\le j\le n$, $v\in S_\ell$ and $z\in\mathcal{O}^\times_{L_{\tilde{v}}}$, the three identities of (Gd2) of Lemma E.16:*

$$(\mathrm{N}w)^{j(j-1)/2}T^{(j)}_w = \kappa(\mathrm{Frob}_w)^j\theta(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w))),$$
$$\langle d_j(z)\rangle = (\chi_{\mathrm{cyc}}^{j-1}\kappa)(\mathrm{Art}(z))\theta(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))),$$
$$U^{(j)}_{\tilde{v}} = U^{(j-1)}_{\tilde{v}}(\chi_{\mathrm{cyc}}^{j-1}\kappa)(\mathrm{Art}(\varpi_{\tilde{v}}))\theta(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(\varpi_{\tilde{v}}))).$$

Then $J=\ker\theta$ is stable under twists: $\tau_\beta(J)\subseteq J$ for every admissible continuous homomorphism $\beta\colon\Gamma^0_{\mathscr{H}}\to B^\times$ with $\beta\equiv 1$ modulo $\mathfrak{m}_B$.

Proof. By Lemma E.28 it suffices to give a set $\mathcal{X}$ with (Ts1), (Ts2).

Step 1: the set $\mathcal{X}$ and (Ts1). By (Zp4) every $y\in\mathcal{C}_{\chi_0}$ kills $\mathfrak{a}_0$; let $\bar{y}$ be the induced point of A and $x_y=\bar{y}\circ\theta$. Put $\mathcal{X}=\{x_y : y\in\mathcal{C}_{\chi_0}\}$; by (Gd0) each x_y is continuous with values in the ring of integers of a finite extension of $\mathbb{Q}_\ell$. Each x_y kills J; conversely, if $x_y(b)=0$ for all y, then $\theta(b)$ lies in the image in A of $\bigcap_{y\in\mathcal{C}_{\chi_0}}\ker y=\mathfrak{a}_0$ (Zp4), so $\theta(b)=0$: (Ts1).

Step 2: an eigenform for y. Fix $y\in\mathcal{C}_{\chi_0}$, with regular λ and $y(\langle u\rangle)=(w_0\lambda)(u)^{-1}$ on $T_n(\mathcal{O}_{L^+}\otimes\mathbb{Z}_\ell)$, and let $y^\natural$ be its composite with $\mathbb{T}_\tau\to\mathbb{T}_{\tau,\mathfrak{m}}$; then $y^\natural(\mathfrak{P}_{\lambda,1})=0$. By Lemma E.11 ($Q=\varnothing$, $\alpha=1$, $r=1$) there are an irreducible constituent π_y of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ with $\mathrm{Hom}_H(\tau^\vee\otimes\overline{\mathbb{Q}}_\ell, \bigotimes_{v\in\mathrm{St}}\pi_{y,v}^{V_v})\neq 0$ and a non-zero $f\in\pi_y\cap S^{\mathrm{ord}}_\lambda(V(\ell^{E,E}),1,\overline{\mathbb{Q}}_\ell)$, E the maximal ramification index of $L^+/\mathbb{Q}$ at the places above ℓ, on which the operators assigned by (Gy7)(c) to $T^{(j)}_w$, $U^{(j)}_{\tilde{v}}$, $\langle u\rangle$ act by $y^\natural$ of these.

Step 3: the twisting character. Let $\beta'\colon\Gamma^0_{\mathscr{H}}\to\overline{\mathbb{Q}}_\ell^\times$ be admissible, continuous, of finite ℓ-power order, $\beta=\beta'\circ\pi|_{G_L}$, and $\xi\colon\mathbb{A}_L^\times/L^\times\to\overline{\mathbb{Q}}_\ell^\times$, $\xi(z)=\beta(\mathrm{Art}_L(z))^{-1}$, continuous of finite ℓ-power order. Anti-invariance gives $\xi(z^c)=\xi(z)^{-1}$; on $\mathbb{A}_{L^+}^\times$ ($z^c=z$) this gives $\xi^2=1$, so ξ is trivial there (ℓ odd). Its archimedean component is a finite-order character of the connected group $(L\otimes\mathbb{R})^\times$, hence trivial. Let U_1 be the norm-one torus of L/L^+. The map $z\mapsto z/z^c$ from $\mathbb{A}_L^\times$ to $U_1(\mathbb{A}_{L^+})$ has kernel $\mathbb{A}_{L^+}^\times$ and is surjective (Hilbert 90 at every place, and integrally at the finite places, all unramified in L by (Rd2)), and $U_1(L^+)=\{a/a^c : a\in L^\times\}$; so $\psi(z/z^c)=\xi(z)$ defines a continuous character ψ of $U_1(\mathbb{A}_{L^+})$ of finite order, trivial on $U_1(L^+)$ and on $U_1(L^+\otimes\mathbb{R})$; let ψ^∞ be its restriction to $U_1(\mathbb{A}_{L^+}^\infty)$, trivial on $U_1(L^+)$. At a place v of L^+ split as ww^c, $U_1(L^+_v)\cong L^\times_w$ by the projection, and $\psi_v=\xi_w$. The character β is trivial on the inertia groups above $\mathrm{St}\cup\{v_0\}$ (admissibility) and above the places of L^+ not in $S_\ell\cup\mathrm{St}$ (these inertia elements lie in $N_{\mathscr{H}}$ by (Rd4), which π kills); so ξ_w is unramified for $w\nmid\ell$, and ψ_v is trivial on $U_1(\mathcal{O}_{L^+_v})$ for $v\notin S_\ell$. For $v\in S_\ell$ and $\zeta\in L_{\tilde{v}}$ an ℓ-power root of unity, $\xi_{\tilde{v}}(\zeta)=\beta(\mathrm{Art}_{L_{\tilde{v}}}(\zeta))^{-1}=1$: the image of $\mathrm{Art}_{L_{\tilde{v}}}(\zeta)$ in D_v^{ab} is that of an element of μ_v ((Wv1) of Lemma 50.24), on which β' is trivial. Moreover $\xi_{\tilde{v}}(x)=\beta(\mathrm{Art}(x))$ for $x\in L^\times_{\tilde{v}}$, and $\xi_w(\varpi_w)=\beta(\mathrm{Frob}_w)$ (Frob_w geometric).

Step 4: the twisted eigenform. For $h\in S_\lambda(\overline{\mathbb{Q}}_\ell)$ put $h^\psi(x)=\psi^\infty(\det x)h(x)$ ($\det x\in U_1(\mathbb{A}_{L^+}^\infty)$). As $\psi^\infty\circ\det$ is trivial on $\mathbb{G}_L(L^+)$ and on an open subgroup of $\mathbb{G}_L(\mathbb{A}_{L^+}^\infty)$, $h^\psi\in S_\lambda(\overline{\mathbb{Q}}_\ell)$, and $g\cdot(h^\psi)=\psi^\infty(\det g)(g\cdot h)^\psi$; so $h\mapsto h^\psi$ carries π_y onto an irreducible constituent π'. If a

double coset operator $\sum_i \xi_\lambda(\cdot)(\cdot)g_i$ has $\psi^\infty(\det g_i) = e$ for all i, it acts on h^ψ as e times its action on h, transported. Hence, choosing $r' \geq E$ so large that $\xi_{\tilde{v}}$ is trivial on $1 + \varpi_{\tilde{v}}^{r'}\mathcal{O}_{L_{\tilde{v}}}$ for $v \in S_\ell$ (so that $\psi^\infty \circ \det$ is trivial on $V(\ell^{r',r'})$, whose matrices at S_ℓ are unipotent modulo $\varpi^{r'}$, and on V_v, $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ away from S_ℓ), f^ψ is non-zero, fixed by $V(\ell^{r',r'})$, and is a joint eigenvector of the operators of (Gy7)(c) with: eigenvalue $\xi_w(\varpi_w)^j y^\natural(T_w^{(j)})$ for $T_w^{(j)}$ (its cosets have determinant in $\varpi_w^j\mathcal{O}_w^\times$); $\xi_{\tilde{v}}(\varpi_{\tilde{v}})^j y^\natural(U_{\tilde{v}}^{(j)})$ for $U_{\tilde{v}}^{(j)}$ (determinant $\varpi_{\tilde{v}}^j$ times units in $1 + \varpi^{r'}$), a unit, so f^ψ is ordinary; and $\xi_{\tilde{v}}(\det u)y^\natural(\langle u\rangle)$ for $\langle u\rangle$. So $f^\psi \in S_\lambda^{\mathrm{ord}}(V(\ell^{r',r'}), \alpha', \overline{\mathbb{Q}}_\ell)$ with $\alpha'(u) = \xi(\det u)$ on $T_n(\ell^1)$, of finite order. For $h \in \prod_{v\in \mathrm{St}} \mathbb{G}_L(\mathcal{O}_{L_v^+})$, $\psi^\infty(\det h) = 1$, so $\pi_v'^{V_v} = \pi_{y,v}^{V_v}$ as representations of $\mathbb{G}_L(\mathcal{O}_{L_v^+})$ ($v \in \mathrm{St}$), and $\mathrm{Hom}_H(\tau^\vee \otimes \overline{\mathbb{Q}}_\ell, \bigotimes_{v\in\mathrm{St}} \pi_v'^{V_v}) \neq 0$.

Step 5: the twisted point of $\mathbb{T}_\tau$. Let $\mathcal{K}'$ be the field generated over $\mathcal{O}'[1/\ell]$ by the values of the character inducing $\mathfrak{P}_{\lambda,\alpha'}$. The forms of weight λ and level $V(\ell^{r',r'})$ with coefficients in $\overline{\mathbb{Q}}_\ell$ are the base change of those with coefficients in $\mathcal{K}'$ (solutions of the same $\mathcal{K}'$-linear equations), compatibly with the operators, the ordinary projector and the α'-part; so the eigencharacter of f^ψ is a homomorphism $\mathbb{T}_\lambda^{\mathrm{ord}}(V(\ell^{r',r'}), \alpha', \mathcal{K}') \to \overline{\mathbb{Q}}_\ell$, and its composite with the surjection of (Qh3) ($U = V$, $b_0 = 1$, applicable by (Gd0); $T_n(\mathfrak{l}^{r'}) \subseteq T_n(\ell^1)$ by (Qh1) as $r' \geq E$, and $T_n(\mathfrak{l}^{r'}) \subseteq \ker\alpha'$, the components at S_ℓ of its elements being $\equiv 1$ modulo $\varpi^{r'}$, so that their determinants lie in $1 + \varpi_{\tilde{v}}^{r'}\mathcal{O}_{L_{\tilde{v}}}$, where $\xi_{\tilde{v}}$ is trivial) is a homomorphism y_0' on $\mathbb{T}^{\mathrm{ord}}(V)$, which is $\mathbb{T}_{\mathcal{O}'[H]}$ ($N_{\mathcal{O}'[H]} = \mathcal{S}_V$ by evaluation at 1), continuous by (Gd0), with the eigenvalues of Step 4 on the operators ((Gy7)(c)), $y_0'(\mathfrak{P}_{\lambda,\alpha'}) = 0$ and $y_0'(\langle u\rangle) = \alpha'(u)(w_0\lambda)(u)^{-1}$ on $T_n(\ell^1)$. By Lemma E.14 (with π', f^ψ, λ, α', r'), $y_0' = y' \circ q$ for a point y' of $\mathbb{T}_\tau$ with the same values on the operators. The values of y' and $y^\natural$ on the topological generators of $\mathbb{T}_\tau$ ((Gd0)) differ by ℓ-power roots of unity, which are $\equiv 1$ in the residue field, so $\ker\bar{y}' = \ker\bar{y}^\natural = \mathfrak{m}$ and y' factors through $\mathbb{T}_{\tau,\mathfrak{m}}$ (it is local onto its image, (Gd0)). For $\delta = d_j(\zeta) \in \Delta_\ell$, $y'(\langle\delta\rangle) = \xi_{\tilde{v}}(\zeta)y(\langle\delta\rangle) = \chi_0(\delta)$ by Step 3, and Δ_ℓ is generated by such δ; so by (Zp4) y' kills $\mathfrak{a}_0$ and induces a point $\bar{y}'$ of A.

Step 6: (Ts2). $\bar{y}'\circ\theta$ and $(x_y)_{\beta'}$ classify the same polarised ordinary determinant. By the first identity under $\bar{y}'$, the j-th coefficient of the characteristic polynomial of $\bar{y}' \circ \theta \circ D^{\mathrm{u}}$ at $\pi(\mathrm{Frob}_w)$ is $\kappa(\mathrm{Frob}_w)^{-j}(\mathrm{N}w)^{j(j-1)/2}\xi_w(\varpi_w)^j y(T_w^{(j)}) = \beta'(\pi(\mathrm{Frob}_w))^j x_y(\Lambda_j(D^{\mathrm{u}})(\pi(\mathrm{Frob}_w)))$, which is that of $(x_y \circ D^{\mathrm{u}})_{\beta'}$ ($\Lambda_j(D_{\beta'})(\gamma) = \beta'(\gamma)^j\Lambda_j(D)(\gamma)$ by homogeneity). These elements are dense in $\Gamma^0_{\mathscr{H}}$ (Chebotarev), so the characteristic polynomials agree everywhere by continuity and the determinants are equal by (Ch1). By the second and third identities, $\bar{y}'(\theta(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(x)))) = \xi_{\tilde{v}}(x)\, x_y(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(x))) = \beta'(\pi(\mathrm{Art}(x)))\, x_y(\psi_{v,j}^{\mathrm{d}}(\mathrm{Art}(x)))$ for $x \in \mathcal{O}_{L_{\tilde{v}}}^\times$ and $x = \varpi_{\tilde{v}}$, hence on the dense image of Art, hence on D_v. Both are morphisms to the $\mathcal{O}'$-algebra $R \subseteq \overline{\mathbb{Q}}_\ell$ generated by their images, which is finite over $\mathcal{O}'$ (Gd0), a local domain with residue field $\mathbb{F}_{\mathcal{O}'}$, so in $\mathrm{CNL}_{\mathcal{O}'}$; by uniqueness $(x_y)_{\beta'} = \bar{y}' \circ \theta$, which kills J: (Ts2). □

Lemma E.28. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, $(B, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, and $\Gamma = \Gamma^0_{\mathscr{H}}$, $\pi = \pi_{\mathscr{H}}$. For a commutative ring R and a homomorphism $\beta\colon \Gamma \to R^\times$ let ϕ_β be the R-algebra automorphism of $R[\Gamma]$ with $\gamma \mapsto \beta(\gamma)\gamma$, and for an R-valued determinant D on Γ put $D_\beta = D \circ \phi_\beta$. Call β **admissible** if $\beta(\pi(csc)) = \beta(\pi(s))^{-1}$ for $s \in G_L$, β is trivial on $\pi(I_{\bar{w}} \cap G_L)$ for every place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a place in $\mathrm{St} \cup \{v_0\}$, and β is trivial on μ_v for every $v \in S_\ell$. Let $J \subseteq B$ be an ideal and $\mathcal{X}$ a set of homomorphisms of $\mathcal{O}'$-algebras $x\colon B \to \overline{\mathbb{Q}}_\ell$, each continuous with image in the ring of integers of a finite extension of $\mathbb{Q}_\ell$, such that:*

(Ts1) $J = \bigcap_{x\in\mathcal{X}} \ker x$;

(Ts2) *for every $x \in \mathcal{X}$ and every admissible continuous character $\beta'\colon \Gamma \to \overline{\mathbb{Q}}_\ell^\times$ of finite ℓ-power order, the homomorphism $x_{\beta'}\colon B \to \overline{\mathbb{Q}}_\ell$ classifying $((x \circ D^{\mathrm{u}})_{\beta'}, (\beta'|_{D_v} \cdot x \circ \psi_{v,a}^{\mathrm{d}}))$ (it exists, by the first paragraph of the proof) satisfies $x_{\beta'}(J) = 0$.*

Then for every admissible continuous homomorphism $\beta\colon \Gamma \to B^\times$ with $\beta \equiv 1$ modulo $\mathfrak{m}_B$, the tuple $(D^{\mathrm{u}}_\beta, (\beta|_{D_v}\psi^{\mathrm{d}}_{v,a}))$ is a polarised ordinary determinant to B, and the morphism $\tau_\beta\colon B \to B$ of $\mathrm{CNL}_{\mathcal{O}'}$ classifying it satisfies $\tau_\beta(J) \subseteq J$.

Proof. Twisting preserves polarised ordinary determinants. Let $A \in \mathrm{CNL}_{\mathcal{O}'}$, $(D, (\psi_{v,a}))$ a polarised ordinary determinant to A and $\beta\colon \Gamma \to A^\times$ an admissible continuous homomorphism with $\beta \equiv 1$ modulo $\mathfrak{m}_A$. Then $(D_\beta, (\beta|_{D_v}\psi_{v,a}))$ is one: D_β is a continuous determinant of dimension n with the reduction of D, as $\beta \equiv 1$, and $\beta|_{D_v}\psi_{v,a} \equiv \bar{\chi}_a$. For $\gamma \in \Gamma$, $\chi_{D_\beta}(\gamma)(X) = D(X - \beta(\gamma)\gamma) = \beta(\gamma)^n\chi_D(\gamma)(\beta(\gamma)^{-1}X)$ (homogeneity of degree n). (Od1): for $g \in G_L$, anti-invariance with $s = g^{-1}$ gives $\beta(\pi(cg^{-1}c)) = \beta(\pi(g))$, and (Od1) for D gives $\chi_D(\pi(cg^{-1}c)) = \chi_D(\pi(g))$; so $\chi_{D_\beta}(\pi(cg^{-1}c)) = \chi_{D_\beta}(\pi(g))$. (Od2): $\mathrm{tr}_{D_\beta} = \mathrm{tr}_D \circ \phi_\beta$, and $\phi_\beta(\gamma\prod_a(\pi(g_a) - \beta(\pi(g_a))\psi_{v,a}(g_a))) = \beta(\gamma)\prod_a \beta(\pi(g_a)) \cdot \gamma\prod_a(\pi(g_a) - \psi_{v,a}(g_a))$, whose D-trace vanishes by (Od2) for D. (Od3): β is trivial on μ_v. If $f\colon A \to A'$ is a morphism of $\mathrm{CNL}_{\mathcal{O}'}$, then $f \circ (D_\beta) = (f \circ D)_{f\circ\beta}$.

In particular τ_β exists ($A = B$). For $x \in \mathcal{X}$ and β' as in (Ts2), let E be a finite extension of $\mathbb{Q}_\ell$ containing $x(B)$ and the values of β', and $R \subseteq \mathcal{O}_E$ the $\mathcal{O}'$-algebra generated by them: finite over $\mathcal{O}'$, a local domain, complete, with residue field $\mathbb{F}_{\mathcal{O}'}$ (generated by the residues of $x(B)$, which lie in $\mathbb{F}_{\mathcal{O}'}$ as x is local onto its image, and of ℓ-power roots of unity, which are 1); so $R \in \mathrm{CNL}_{\mathcal{O}'}$, $\beta' \equiv 1$ modulo $\mathfrak{m}_R$, and the twisted tuple of x is a polarised ordinary determinant to R, classified by $x_{\beta'}$.

Fix β as in the conclusion, $b \in J$ and $N \geq 0$; put $I = \mathfrak{m}_B^{N+1}$ and $\bar{B} = B/I$, a finite ring in $\mathrm{CNL}_{\mathcal{O}'}$.

Step 1: a finite ℓ-group. The reduction $\bar{\beta}\colon \Gamma \to \bar{B}^\times$ is continuous into a finite group; let $Q = \bar{\beta}(\Gamma)$, $q\colon \Gamma \to Q$ the induced surjection (open kernel) and $j\colon Q \to \bar{B}^\times$ the inclusion. Q is an ℓ-group: if $t \in \mathfrak{m}_B$ then $(1+t)^{\ell^k} - 1 \in \mathfrak{m}_B^{k+1}$ for all k, as $\ell \in \mathfrak{m}_B$, so every element of Q has order dividing ℓ^N. As β is admissible, so is q (the conditions are on kernels and on $q(\pi(csc)) = q(\pi(s))^{-1}$).

Step 2: the universal finite twist. $B[Q]$ is finite free over B; its quotient by $\mathfrak{m}_B B[Q]$ is $\mathbb{F}[Q]$ ($\mathbb{F} = \mathbb{F}_{\mathcal{O}'}$), local because Q is an ℓ-group, so $B[Q]$ is a complete Noetherian local $\mathcal{O}'$-algebra with residue field $\mathbb{F}$, in $\mathrm{CNL}_{\mathcal{O}'}$. The homomorphism $\gamma \mapsto [q(\gamma)] \in B[Q]^\times$ is continuous (locally constant), admissible, and $\equiv 1$ modulo the maximal ideal. By the first paragraph (with $A = B[Q]$ and the base change of the universal tuple along $B \to B[Q]$) there is a morphism $\mathrm{tw}\colon B \to B[Q]$ of $\mathrm{CNL}_{\mathcal{O}'}$ classifying the twisted tuple. Write $\mathrm{tw}(b) = \sum_{g\in Q} c_g[g]$ with $c_g \in B$.

Step 3: Fourier inversion. Let $x \in \mathcal{X}$ and $\chi\colon Q \to \overline{\mathbb{Q}}_\ell^\times$ a character; $\beta' = \chi \circ q$ is continuous, admissible, of finite ℓ-power order. Let R be as in the first paragraph for x and β', and $e\colon B[Q] \to R$, $\sum_g b_g[g] \mapsto \sum_g x(b_g)\chi(g)$, a morphism of $\mathrm{CNL}_{\mathcal{O}'}$. By the base change rule, $e \circ \mathrm{tw}$ classifies $((x \circ D^{\mathrm{u}})_{\beta'}, (\beta'|_{D_v} \cdot x \circ \psi^{\mathrm{d}}_{v,a}))$, so $e \circ \mathrm{tw} = x_{\beta'}$ by uniqueness, and (Ts2) gives $\sum_g x(c_g)\chi(g) = x_{\beta'}(b) = 0$. This holds for all characters χ of the finite abelian group Q, which span the space of functions $Q \to \overline{\mathbb{Q}}_\ell$ (there are $|Q|$ of them, linearly independent by Dedekind–Artin, as $\overline{\mathbb{Q}}_\ell$ is algebraically closed of characteristic 0); so $x(c_g) = 0$ for every g. As $x \in \mathcal{X}$ was arbitrary, (Ts1) gives $c_g \in J$ for all g.

Step 4: back to β. Let $s\colon B[Q] \to \bar{B}$, $\sum_g b_g[g] \mapsto \sum_g \bar{b}_g\, j(g)$, a morphism of $\mathrm{CNL}_{\mathcal{O}'}$. By the base change rule, $s \circ \mathrm{tw}$ and the composite of τ_β with $B \to \bar{B}$ both classify $((\bar{D}^{\mathrm{u}})_{\bar{\beta}}, (\bar{\beta}|_{D_v}\bar{\psi}^{\mathrm{d}}_{v,a}))$, bars denoting reduction modulo I ($j \circ q = \bar{\beta}$). By uniqueness they are equal, so $\tau_\beta(b) \equiv \sum_g c_g\, \tilde{j}(g)$ modulo I for lifts $\tilde{j}(g) \in B$, and $\tau_\beta(b) \in J + \mathfrak{m}_B^{N+1}$.

Step 5: Krull. N was arbitrary, and $\bigcap_N (J + \mathfrak{m}_B^{N+1}) = J$ by the Krull intersection theorem in the Noetherian local ring B/J. So $\tau_\beta(b) \in J$. □

Lemma E.29. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$ with residue field $\mathbb{F}$, κ a twist for $\mathscr{H}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, c an integer as in Proposition E.5, $((V_v)_{v\in \mathrm{St}}, \tau)$ a type datum over $\mathscr{H}$ with V_v the kernel of reduction $\mathbb{G}_L(\mathcal{O}_{L_v^+}) \to \mathbb{G}_L(\mathcal{O}_{L_v^+}/\varpi_v^c)$, $\mathfrak{m}$ a maximal ideal of $\mathbb{T}_\tau$ with $\mathbb{T}_\tau/\mathfrak{m} = \mathbb{F}$ satisfying (Mx), $\mathfrak{a}$ an ideal of $\mathbb{T}_{\tau,\mathfrak{m}}$, and $\theta\colon B \to \mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}$ a surjective homomorphism of $\mathcal{O}'$-algebras such that in $\mathbb{T}_{\tau,\mathfrak{m}}/\mathfrak{a}$, for all w, $1 \le j \le n$, $v \in S_\ell$ and $z \in \mathcal{O}^\times_{L_{\tilde{v}}}$,*

$$(\mathrm{N}w)^{j(j-1)/2} T_w^{(j)} = \kappa(\mathrm{Frob}_w)^j\, \theta(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w))),$$
$$\langle d_j(z)\rangle = (\chi_{\mathrm{cyc}}^{j-1}\kappa)(\mathrm{Art}(z))\, \theta(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))).$$

Let $J = \ker\theta$. Let $y\colon B \to \overline{\mathbb{Q}}_\ell$ be a homomorphism of $\mathcal{O}'$-algebras with $y(J) = 0$ for which there are integers $h_{v,a,\varsigma}$ ($v \in S_\ell$, $1 \le a \le n$, ς a continuous field embedding $L_v^+ \to \overline{\mathbb{Q}}_\ell$), strictly increasing in a for every v and ς, such that $y(\psi^{\mathrm{d}}_{v,a}(\sigma)) = \prod_\varsigma \varsigma(u_\sigma)^{h_{v,a,\varsigma}}$ for all σ in an open subgroup of I_v, where $u_\sigma \in \mathcal{O}^\times_{L_v^+}$ is the unit with $\mathrm{Art}_{L_v^+}(u_\sigma)$ equal to the image of σ in D_v^{ab}. Then there are a continuous semisimple representation $\rho\colon G_L \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with $\det\circ\rho = y\circ D^{\mathrm{u}}\circ\pi_{\mathscr{H}}|_{G_L}$, an integer $k \ge 1$, integers $d_i, m_i \ge 1$ and continuous representations $\rho_i'\colon G_L \to \mathrm{GL}_{d_i}(\overline{\mathbb{Q}}_\ell)$ ($1 \le i \le k$) such that

$$\det(X - \rho(g)) = \prod_{i=1}^{k}\prod_{j=0}^{m_i-1} \det(X - \chi_{\mathrm{cyc}}(g)^{-j}\rho_i'(g)) \qquad (g \in G_L),$$

and, if $m_i = 1$ for all i, then for all but finitely many finite places w' of L the representation ρ is unramified at w' and any two eigenvalues α, α' of $\rho(\mathrm{Frob}_{w'})$ satisfy $|\iota(\alpha)| < \mathrm{N}w'\,|\iota(\alpha')|$.

Proof. Step 1: the point of the Hecke algebra. As θ is surjective and $y(\ker\theta) = 0$, $y = y'\circ\theta$ for a homomorphism of $\mathcal{O}'$-algebras $y'\colon A \to \overline{\mathbb{Q}}_\ell$. Let $y''\colon \mathbb{T}_\tau \to \overline{\mathbb{Q}}_\ell$ be the composite of $\mathbb{T}_\tau \to \mathbb{T}_{\tau,\mathfrak{m}} \to A$ with y', and $y_0\colon \mathbb{T}^{\mathrm{ord}}(V) \to \overline{\mathbb{Q}}_\ell$ its composite with the surjection $\mathbb{T}^{\mathrm{ord}}(V) \to \mathbb{T}_\tau$ (Definition 50.8). By (Gd0) of Lemma E.16 (whose hypotheses are those made here), $[L^+ : \mathbb{Q}] \ge 2$, the hypotheses of Theorem B.91 hold for $U = V$ and $b_0 = 1$, and y, y', y'' are continuous with values in the ring of integers of a finite extension of $\mathbb{Q}_\ell$.

Step 2: the weight. Let $v \in S_\ell$. The map Art of Proposition E.5 and $\mathrm{Art}_{L_v^+}$ differ by inversion: $\mathrm{Art}(x) = \mathrm{Art}_{L_v^+}(x^{-1})$ in D_v^{ab}. $\mathrm{Art}_{L_v^+}$ maps $\mathcal{O}^\times_{L_v^+}$ homeomorphically onto the image of I_v in D_v^{ab}, so there is an open subgroup $U_v \subseteq 1 + \ell\mathcal{O}_{L_v^+}$ such that, for $z \in U_v$, $\mathrm{Art}(z)$ is the image of an element σ of the open subgroup of the hypothesis, with $u_\sigma = z^{-1}$; hence $y(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))) = \prod_\varsigma \varsigma(z)^{-h_{v,j,\varsigma}}$. With this normalisation $\chi(\mathrm{Art}(z)) = \prod_\varsigma \varsigma(z)$ for units z (Lubin–Tate theory), and, as κ corresponds to an algebraic Hecke character, there are integers $b_{v,\varsigma}$ with $\kappa(\mathrm{Art}(z)) = \prod_\varsigma \varsigma(z)^{b_{v,\varsigma}}$ for z in an open subgroup of $\mathcal{O}^\times_{L_v^+}$ ([220], Chapter II); shrink U_v accordingly. The second identity of the hypothesis, under y', gives for $z \in U_v$ and $1 \le j \le n$

$$y''(\langle d_j(z)\rangle) = (\chi^{j-1}\kappa)(\mathrm{Art}(z))\, y(\psi^{\mathrm{d}}_{v,j}(\mathrm{Art}(z))) = \prod_\varsigma \varsigma(z)^{(j-1)+b_{v,\varsigma}-h_{v,j,\varsigma}}.$$

Let λ be the weight with $\lambda_{\varsigma,n+1-j} = h_{v,j,\varsigma} - (j-1) - b_{v,\varsigma}$ at the embeddings ς inducing $\tilde{v}$, $v \in S_\ell$ (the components at the conjugate embeddings being determined by these, as for every weight of $\mathbb{G}_L$). It is dominant: $\lambda_{\varsigma,n-j} - \lambda_{\varsigma,n+1-j} = h_{v,j+1,\varsigma} - h_{v,j,\varsigma} - 1 \ge 0$, the $h_{v,a,\varsigma}$ being strictly increasing integers in a. Put $\alpha(u) = y''(\langle u\rangle)\,(w_0\lambda)(u)$ for $u \in T_n(\ell^1)$, a continuous character ($u \mapsto \langle u\rangle$ and $w_0\lambda$ are homomorphisms). So α is trivial on the subgroup generated by the $d_j(z)$, $z \in U_v$, $v \in S_\ell$, which is open in $T_n(\ell^1) = \prod_{v\in S_\ell}\prod_j d_j(1 + \ell\mathcal{O}_{L_v^+})$; hence α has finite order, and $T_n(\ell^r) \subseteq \ker\alpha$ for some $r \ge 1$. In the renormalised structure, $y_0([u]) = (w_0\nu)^{-1}(u)\, y''(\langle u\rangle) =$

$\alpha(u)(w_0\nu)^{-1}(u)(w_0\lambda)^{-1}(u)$ for $u \in T_n(\ell^1)$. The restriction of y_0 to Λ_1 and the homomorphism $\Lambda_1 \to \overline{\mathbb{Q}}_\ell$ induced by the character $\alpha(w_0\nu)^{-1}(w_0\lambda)^{-1}$ are continuous homomorphisms of $\mathcal{O}'$-algebras (Step 1) which agree on the group elements, whose $\mathcal{O}'$-span is dense in Λ_1; so they are equal, and $y_0(\mathfrak{P}_{\lambda,\alpha}) = 0$.

Step 3: an automorphic representation. By Step 2, y'' kills $\mathfrak{P}_{\lambda,\alpha}$ (the renormalised structure of $\mathbb{T}^{\mathrm{ord}}(V)$ maps onto that of $\mathbb{T}_\tau$) and $y''(\langle u\rangle) = \alpha(u)(w_0\lambda)(u)^{-1}$ for $u \in T_n(\ell^1)$, with α of finite order, $T_n(\ell^r) \subseteq \ker\alpha$ and λ dominant. The type datum is over the rank-n Hecke datum $\mathscr{H}$, so Lemma E.11 ($Q = \varnothing$; α with values in $\overline{\mathbb{Q}}_\ell^\times$) gives an irreducible constituent π of $S_\lambda(\overline{\mathbb{Q}}_\ell)$ such that, for every split $v \notin T_L$, π_v is unramified and $T_w^{(j)}$ acts on $\pi_v^{\mathbb{G}_L(\mathcal{O}_{L_v^+})}$ by $t_w^{(j)} = y''(T_w^{(j)})$ (its clause (ii)).

Step 4: ρ. Let r_π be as in (Gy5) and $\rho = r_\pi \otimes \kappa^{-1}$, a continuous semisimple representation of G_L. For every w, (Gy5)(i) and Step 3 give that r_π is unramified above w with $\det(X - r_\pi(\mathrm{Frob}_w)) = \sum_j (-1)^j (\mathrm{N}w)^{j(j-1)/2} y''(T_w^{(j)}) X^{n-j}$; by the first identity of the hypothesis under y' this is $\sum_j (-1)^j \kappa(\mathrm{Frob}_w)^j y(\Lambda_j(D^{\mathrm{u}})(\pi_{\mathscr{H}}(\mathrm{Frob}_w)))X^{n-j}$, so $\rho(\mathrm{Frob}_w)$ has the characteristic polynomial of the $\overline{\mathbb{Q}}_\ell$-valued determinant $y \circ D^{\mathrm{u}} \circ \pi_{\mathscr{H}}|_{G_L}$ at Frob_w. Both $\det\circ\rho$ and this determinant are continuous determinants of dimension n on G_L; the Frob_w are dense in G_L (Chebotarev: the places of L of degree one over L^+ have density one), so their characteristic polynomials agree on G_L by continuity, and they are equal by (Ch1) of Theorem B.83.

Step 5: the decomposition. By (Ug1) of Lemma E.8 ($[L^+ : \mathbb{Q}] \geq 2$ by Step 1; λ dominant; π a constituent of $S_\lambda(\overline{\mathbb{Q}}_\ell)$) there are $k \geq 1$, integers $k_i, d_i \geq 1$ with $\sum_i k_i d_i = n$ and unitary cuspidal automorphic representations σ_i of $\mathrm{GL}_{d_i}(\mathbb{A}_L)$ (called τ_i, with m_i in place of d_i, there) such that $\sigma_i' = \sigma_i \otimes |\det|^{s_i}$, $s_i = \frac{d_i-1}{2} - \frac{n-k_i}{2}$, is regular algebraic, cuspidal and polarizable and $r_\pi \cong \bigoplus_i \bigoplus_{a=0}^{k_i-1} r_{\ell,\iota}(\sigma_i') \otimes \varepsilon^{-a}$, with $\varepsilon = \chi$. Put $m_i = k_i$ and $\rho_i' = r_{\ell,\iota}(\sigma_i') \otimes \kappa^{-1}$, continuous of dimension d_i. Then $\rho \cong \bigoplus_i \bigoplus_{j=0}^{m_i-1} \rho_i' \otimes \chi^{-j}$, and the characteristic polynomial of a direct sum is the product of those of the summands: the displayed identity holds.

Step 6: the eigenvalues when all $m_i = 1$. Then $s_i = \frac{d_i-n}{2}$ and $\rho \cong \bigoplus_i r_{\ell,\iota}(\sigma_i') \otimes \kappa^{-1}$. Let w' be a finite place of L not above ℓ, not above a place of St, at which every σ_i is unramified; all but finitely many places are such. Then κ is unramified at w' ((Rd7) of Definition 50.1), $\sigma_{i,w'}'$ is unramified with Satake parameters $q_{w'}^{-s_i}\beta$, β running over those of $\sigma_{i,w'}$, and by (Bg1) of Theorem B.62 (for the polarizable σ_i' of rank d_i), $r_{\ell,\iota}(\sigma_i')$ is unramified at w' and the eigenvalues of a geometric Frobenius on it are carried by ι to the numbers $q_{w'}^{(d_i-1)/2-s_i}\beta = q_{w'}^{(n-1)/2}\beta$. The central character of the unitary σ_i is unitary, so (Js2) of Theorem B.60 gives $q_{w'}^{-1/2} < |\beta| < q_{w'}^{1/2}$. So ρ is unramified at w', and every eigenvalue α of $\rho(\Phi)$, Φ a geometric Frobenius at w', satisfies $C\, q_{w'}^{(n-2)/2} < |\iota(\alpha)| < C\, q_{w'}^{n/2}$ with $C = |\iota\kappa(\Phi)|^{-1} > 0$ independent of α. For two eigenvalues, $|\iota(\alpha)| < Cq_{w'}^{n/2} = q_{w'} \cdot Cq_{w'}^{(n-2)/2} < q_{w'}|\iota(\alpha')|$. The eigenvalues of an arithmetic Frobenius are the inverses of these, and the condition, required for all ordered pairs, is unchanged under inversion ($|\alpha^{-1}| < q|\alpha'^{-1}|$ is $|\alpha'| < q|\alpha|$). □

E.2 Patching at curve points

This section proves Proposition E.32: a Hecke ideal of zero-monodromy type which, if proper, has classical levels has $R = T$ at patchable curve points and along thick chains; Proposition 50.11 and Theorem 53.10 use it. The method is patching in the manner of Taylor and Wiles [254], carried out at one-dimensional points of the determinant ring. The proof combines abstract patching (Proposition E.33) with the existence of patching systems (Proposition E.39); the latter takes the Galois clause from Section E.3, the dual Selmer bound from Section E.4 and the patched ring and the automorphic patching data from Section E.5.

E.2.1 Patching at curve points and abstract patching

This subsection defines abstract patching towers and patching systems along curve points (Definition E.30, Definition E.31) and proves Proposition E.32 from the existence of patching systems, Proposition E.39. The abstract input is Proposition E.33: it describes the patched module over the patching ring and its fibre, and controls the dimension of its support at the primes that avoid the isogeny element.

Definition E.30. Let Λ be a complete Noetherian local ring with maximal ideal $\mathfrak{m}_\Lambda$ and finite residue field, let $s \geq 0$ be an integer and $S = \Lambda[[y_1, \dots, y_s]]$. For integers $k, j \geq 1$ put

$$\mathfrak{c}_{k,j} = (y_1, \dots, y_s)^k + \mathfrak{m}_\Lambda^j S \subseteq S. \tag{E.2}$$

An **abstract patching tower** over S is a tuple $(R, \beta, X, f, I, e, (M_N)_{N\geq 1}, \mathcal{U})$ consisting of a Noetherian local ring R with maximal ideal $\mathfrak{m}_R$, a ring homomorphism $\beta\colon S \to R$, an R-module X, an element $f \in R$, an ideal $I \subseteq R$, an integer $e \geq 1$, R-modules M_N ($N \geq 1$) and a non-principal ultrafilter $\mathcal{U}$ on the set of positive integers (one containing no finite set), such that the following hold, where every R-module is regarded as an S-module through β:

(Tow0) X is a finitely generated free Λ-module, and $\beta(y_i)X = 0$ for $1 \leq i \leq s$;

(Tow1) for all $k, j \geq 1$, the set of N such that $M_N/\mathfrak{c}_{k,j}M_N$ is a free $S/\mathfrak{c}_{k,j}$-module of finite rank belongs to $\mathcal{U}$ (the rank may depend on N, k and j);

(Tow2) for every $j \geq 1$, the set of N for which there are R-linear maps $\varphi\colon X/\mathfrak{m}_\Lambda^j X \to M_N/\mathfrak{c}_{1,j}M_N$ and $\psi\colon M_N/\mathfrak{c}_{1,j}M_N \to X/\mathfrak{m}_\Lambda^j X$ with $\psi\circ\varphi$ and $\varphi\circ\psi$ both equal to multiplication by f belongs to $\mathcal{U}$;

(Tow3) I is generated by a finite set G such that for every $g \in G$ and every $j \geq 1$, the set of N for which there is $a \in R$ with $(fg)^e - a \in \mathfrak{m}_R^j$ and $aM_N = 0$ belongs to $\mathcal{U}$.

Here $\mathfrak{c}_{k,j}M_N$ means $\beta(\mathfrak{c}_{k,j})M_N$; by (Tow0), $\mathfrak{c}_{1,j}X = \mathfrak{m}_\Lambda^j X$. The integer s is the **number of patching variables** of the tower, f its **isogeny element** and I its **relation ideal**. The ideal of R generated by $\beta(y_1), \dots, \beta(y_s)$ is denoted $\mathfrak{y}$, and the $\mathfrak{y}$-adic completion of the localisation $R_f = R[1/f]$ is called the **patching ring** R' of the tower:

$$R' = \varprojlim_k R_f/\mathfrak{y}^k R_f, \qquad \iota\colon R \to R_f \to R' \text{ the natural homomorphism.} \tag{E.3}$$

Definition E.31. Let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be a universal polarised ordinary determinant of rank n over a residual setting $(n, L, c, \Gamma, \Gamma^0, \dots)$ (over a rank-n Hecke datum, or over a CM field L), with v_0 as in Definition 50.9. Write $B = B_n^{\mathrm{po}}$, and let $\mathcal{O}$ be the coefficient ring over which B is an algebra. Let $J \subseteq B$ be an ideal, $h \geq 0$, and $x_0, \dots, x_h$ curve points of B with homomorphisms $f_i\colon B \to A_{k_i} = k_i[[T]]$.

Eigenvalue algebras. Let $q \geq 0$, $\sigma_1, \dots, \sigma_q \in \Gamma^0$ and $\tilde{u}_{j,i} \in \mathcal{O}$ ($1 \leq j \leq q$, $1 \leq i \leq n$) with $\chi_{D^{\mathrm{u}}}(\sigma_j) \equiv \prod_{i=1}^n (X - \tilde{u}_{j,i})$ modulo $\mathfrak{m}_B$ for every j, and let $\mathcal{O}_1$ be a complete discrete valuation ring that is a free $\mathcal{O}$-module of finite rank, unramified over $\mathcal{O}$ (that is, $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathfrak{m}_{\mathcal{O}_1}$). With a variable z put

$$C_0 = B[[z]][[Z_{j,i} : 1 \leq j \leq q,\ 1 \leq i \leq n]] \Big/ \Big(\text{the coefficients of } \textstyle\prod_{i=1}^n (X - \tilde{u}_{j,i} - Z_{j,i}) - \chi_{D^{\mathrm{u}}}(\sigma_j)(X),\ 1 \leq j \leq q\Big),$$

and let $u_{j,i} \in C_0$ be the class of $\tilde{u}_{j,i} + Z_{j,i}$, so that $\prod_{i=1}^{n}(X - u_{j,i}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(X)$ in $C_0[X]$. The **eigenvalue algebra** of $(\mathcal{O}_1, (\sigma_j), (\tilde{u}_{j,i}))$ is $C = \mathcal{O}_1 \otimes_{\mathcal{O}} C_0$, with $u\colon B \to C$, $u(b) = 1 \otimes b$. Through $\mathcal{O}_1 \otimes_{\mathcal{O}} (B[[z]] \to C_0)$ it is an algebra over $C_1 = (\mathcal{O}_1 \otimes_{\mathcal{O}} B)[[z]]$, which equals $\mathcal{O}_1 \otimes_{\mathcal{O}} B[[z]]$ as $\mathcal{O}_1$ is a free $\mathcal{O}$-module of finite rank; z and $u_{j,i}$ also denote their images in C. For $q = 0$, $C = C_1$.

A **patching system** for J along $(x_0, \dots, x_h)$ is a tuple $(\mathcal{T}, d, C, u, \pi)$ of an abstract patching tower $\mathcal{T} = (R, \beta, X, f_{\mathcal{T}}, I, e, (M_N)_{N \geq 1}, \mathcal{U})$ over some $S = \Lambda[[y_1, \dots, y_s]]$, an integer $d \geq 0$, the eigenvalue algebra C, with u, of some $(\mathcal{O}_1, (\sigma_j)_{1 \leq j \leq q}, (\tilde{u}_{j,i}))$ as above such that the residue field of $\mathcal{O}_1$ has cardinality $|k_i|$ for every i (so the k_i have one common cardinality), and a surjective ring homomorphism $\pi\colon R \to C$. A **surjective lift** of f_i is a surjective ring homomorphism $f'\colon C \to A_{k_i}$ with $f' \circ u = f_i$ and $f'(z) = T$; its kernel is a prime ideal of C (as $C/\ker f' \cong A_{k_i}$ is a domain) with $u^{-1}(\ker f') = \ker f_i$. The tuple is required to satisfy the following, where a prime ideal of R is called **stable for the system** if it is contained in $\pi^{-1}(P'')$ for some prime ideal P'' of C with $u^{-1}(P'')$ a stable prime of B:

(Sys0) for every i and every j, the polynomial obtained from $\chi_{D^{\mathrm{u}}}(\sigma_j)$ by applying f_i to its coefficients is a product of n monic polynomials of degree 1 in $A_{k_i}[X]$;

(Sys1) $\pi(\beta(y_i)) = 0$ for $1 \leq i \leq s$;

(Sys2) for every prime ideal P of C: $\mathrm{Ann}_R(X) \subseteq \pi^{-1}(P)$ if and only if $J \subseteq u^{-1}(P)$;

(Sys3) for every i and every surjective lift f' of f_i, the prime $\mathfrak{q} = \pi^{-1}(\ker f')$ satisfies $f_{\mathcal{T}} \notin \mathfrak{q}$, and $\Lambda_{\mathfrak{p}}$ is a regular local ring of dimension d for $\mathfrak{p} = \{a \in \Lambda : \beta(a) \in \mathfrak{q}\}$;

(Sys4) for every i, every surjective lift f' of f_i, $\mathfrak{q} = \pi^{-1}(\ker f')$ and $\hat{A}$ the completion of $R_{\mathfrak{q}}$ at its maximal ideal: if $\hat{Z}, \hat{Q}$ are prime ideals of $\hat{A}$ such that $I\hat{A} \subseteq \hat{Z}$, the preimage of $\hat{Z}$ in R is stable for the system, $\dim \hat{A}/\hat{Z} \geq d + s$, and the preimage of $\hat{Q}$ in R is $\pi^{-1}(P')$ for a prime ideal P' of C with $u^{-1}(P')$ stable or thick, then $\hat{Z} \subseteq \hat{Q}$.

Proposition E.32. *Let $\mathscr{H} = (n, L, c, (\bar{v})_{v \in S_\ell}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1 \leq a \leq n})$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, κ a twist for $\mathscr{H}$, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism and J a Hecke ideal of zero-monodromy type for ι and κ which, if $J \neq B_n^{\mathrm{po}}$, has classical levels. Then J has $R = T$ at patchable curve points and $R = T$ along thick chains (for v_0, with the place $\bar{v}_0$).*

Proof. Write $B = B_n^{\mathrm{po}}$ and $\mathcal{J} = J$. If $\mathcal{J} = B$ both properties hold vacuously: no curve point f (a homomorphism onto a subring of $A_k \neq 0$) has $B \subseteq \ker f$, and no prime contains B. Assume $\mathcal{J} \neq B$, so $\mathcal{J}$ has classical levels and Proposition E.39 applies to it. For $\gamma \in \Gamma^0_{\mathscr{H}}$ let $\mathrm{Tr}(\gamma) \in B$ be the coefficient $\Lambda_1(\gamma)$ of $\chi_{D^{\mathrm{u}}}(\gamma)$ in the notation of (Ch1); its image under a homomorphism to a field F over which the base change of D^{u} is $\det \circ r$ is $\mathrm{tr}\, r(\gamma)$.

Step 1: stability passes to smaller primes. Let $\mathfrak{q} \subseteq \mathfrak{q}'$ be primes of B with $\mathfrak{q}'$ stable, and r' irreducible over $K' = \bar{\kappa}(\mathfrak{q}')$ with $D_{\mathfrak{q}'} = \det \circ r'$. By Burnside's theorem the K'-span of $r'(\Gamma^0_{\mathscr{H}})$ is $\mathrm{M}_n(K')$; choose $g_1, \dots, g_{n^2} \in \Gamma^0_{\mathscr{H}}$ with $(r'(g_a))_a$ a basis, and put $\delta = \det\big(\mathrm{Tr}(g_a g_b)\big)_{a,b} \in B$. Its image in K' is the Gram determinant of the basis $(r'(g_a))$ for the trace form $(Y, Y') \mapsto \mathrm{tr}(YY')$, which is non-degenerate on $\mathrm{M}_n(K')$ (its matrix in the basis of elementary matrices is a permutation matrix); so $\delta \notin \mathfrak{q}'$, hence $\delta \notin \mathfrak{q}$. By (Ch3), $D_{\mathfrak{q}} = \det \circ r$ for a semisimple r over $K = \bar{\kappa}(\mathfrak{q})$; the image of δ in K is $\det(\mathrm{tr}(r(g_a)r(g_b))) \neq 0$, so the $r(g_a)$ are linearly independent and span $\mathrm{M}_n(K)$. A proper non-zero r-stable subspace of K^n would be stable under all of $\mathrm{M}_n(K)$; so r is irreducible and $\mathfrak{q}$ is stable.

Step 2: the kernel at a point of irreducible type is stable. Let x be a curve point of irreducible type, with finite field k, representation ρ and homomorphism f. f embeds $B/\ker f$ into A_k,

hence $\kappa(\ker f)$ into F_k; fix an algebraic closure $\bar\kappa(\ker f) \subseteq \bar F_k$. By (Ch3), $D_{\ker f} = \det \circ r$ with r semisimple over $\bar\kappa(\ker f)$. Its base change to $\bar F_k$ is $\det \circ (r \otimes \bar F_k)$, and also the base change of $f \circ D^{\mathrm{u}} = \det \circ \rho$, i.e. $\det \circ (\rho \otimes \bar F_k)$. Both representations are semisimple (r is a sum of irreducibles over an algebraically closed field, which stay irreducible over $\bar F_k$; $\rho \otimes \bar F_k$ is irreducible, already on Γ'). By the uniqueness in (Ch3), $r \otimes \bar F_k \cong \rho \otimes \bar F_k$ is irreducible, hence so is r: $\ker f$ is stable.

Step 3: the chain lemma. Let $J \subseteq B$ be an ideal, $x_0, \dots, x_h$ curve points with homomorphisms $f_0, \dots, f_h$, and $(\mathcal{T}, d, C, u, \pi)$ a patching system for J along $(x_0, \dots, x_h)$, $\mathcal{T} = (R, \beta, X, f_{\mathcal{T}}, I, \dots)$ over $S = \Lambda[[y_1, \dots, y_s]]$, with patching ring R', $\iota\colon R \to R'$, and M_∞ the finitely generated R'-module of Proposition E.33; let $\mathcal{P}$ be the set of primes Q of R with $f_{\mathcal{T}} \notin Q$ and $\beta(y_1), \dots, \beta(y_s) \in Q$, and for $Q \in \mathcal{P}$ recall from (Pat0) that QR' is a prime of R' with $\iota^{-1}(QR') = Q$. Let $\mathfrak{e}_1, \dots, \mathfrak{e}_h$ be thick primes with $\mathfrak{e}_i \subseteq \ker f_{i-1} \cap \ker f_i$ and $\mathfrak{t}$ a stable prime with $J \subseteq \mathfrak{t} \subseteq \ker f_0$. We show: every prime $\mathfrak{q} \subseteq \ker f_h$ of B that is stable or thick contains J. (a) *Primes of C.* By Definition E.31, $C = \mathcal{O}_1 \otimes_{\mathcal{O}} C_0$ is the eigenvalue algebra of some $(\mathcal{O}_1, (\sigma_j)_{1 \le j \le q}, (\tilde u_{j,i}))$, where $\mathcal{O}_1$ is a complete discrete valuation ring, finite free and unramified over $\mathcal{O}$, with residue field of cardinality $|k_i|$ for all i; it is an algebra over $C_1 = B_1[[z]]$, $B_1 = \mathcal{O}_1 \otimes_{\mathcal{O}} B$, through a homomorphism $\iota\colon C_1 \to C$ with $\iota(z) = z$, and $u = \iota \circ u_1$ for $u_1\colon B \to C_1$, $u_1(b) = 1 \otimes b$. *Primes of the base C_1.* As $\mathcal{O}_1$ is a free $\mathcal{O}$-module of finite positive rank, B_1 is a free B-module of finite positive rank; so B_1 is integral over B (lying over and going-up hold) and flat over B (going-down holds). Choose a prime $\tilde P_0$ of B_1 over $\ker f_0$; for $i = 1, \dots, h$ choose by going-down $\tilde E_i \subseteq \tilde P_{i-1}$ over $\mathfrak{e}_i$ (as $\mathfrak{e}_i \subseteq \ker f_{i-1}$) and by going-up $\tilde P_i \supseteq \tilde E_i$ over $\ker f_i$ (as $\mathfrak{e}_i \subseteq \ker f_i$). By going-down choose $\tilde P_{\mathfrak{t}} \subseteq \tilde P_0$ over $\mathfrak{t}$ and $\tilde Q \subseteq \tilde P_h$ over $\mathfrak{q}$. For an ideal $\mathfrak{a}$ of B_1 let $\mathfrak{a}[[z]] \subseteq C_1$ be the set of power series with all coefficients in $\mathfrak{a}$, the kernel of $B_1[[z]] \to (B_1/\mathfrak{a})[[z]]$; for $\mathfrak{a}$ prime, $(B_1/\mathfrak{a})[[z]]$ is a domain, so $\mathfrak{a}[[z]]$ is a prime of C_1 with $\mathfrak{a}[[z]] \cap B_1 = \mathfrak{a}$, hence $u_1^{-1}(\mathfrak{a}[[z]])$ is the contraction of $\mathfrak{a}$ to B; and $\mathfrak{a} \subseteq \mathfrak{b}$ implies $\mathfrak{a}[[z]] \subseteq \mathfrak{b}[[z]]$. By Lemma E.64 (for f_i, $\mathcal{O}' = \mathcal{O}_1$, and the prime $\tilde P_i$, which contracts to $\ker f_i$) there is a surjective ring homomorphism $g_i\colon C_1 \to A_{k_i}$ with $g_i \circ u_1 = f_i$, $g_i(z) = T$ and $\ker g_i \cap B_1 = \tilde P_i$. Every power series $g = \sum_m c_m z^m$ with all $c_m \in \tilde P_i$ lies in $\ker g_i$: for each N, $g = \sum_{m<N} c_m z^m + z^N g_N$ with $g_N \in C_1$, so $g_i(g) = T^N g_i(g_N) \in T^N A_{k_i}$, and $\bigcap_N T^N A_{k_i} = 0$. So $\tilde P_i[[z]] \subseteq \ker g_i$. Put $P_i^1 = \ker g_i$, $E_i^1 = \tilde E_i[[z]]$, $P_{\mathfrak{t}}^1 = \tilde P_{\mathfrak{t}}[[z]]$, $Q^1 = \tilde Q[[z]]$, primes of C_1. Then $E_i^1 \subseteq \tilde P_{i-1}[[z]] \subseteq P_{i-1}^1$, $E_i^1 \subseteq \tilde P_i[[z]] \subseteq P_i^1$, $P_{\mathfrak{t}}^1 \subseteq P_0^1$, $Q^1 \subseteq P_h^1$, and $u_1^{-1}(P_i^1) = \ker f_i$, $u_1^{-1}(E_i^1) = \mathfrak{e}_i$, $u_1^{-1}(P_{\mathfrak{t}}^1) = \mathfrak{t}$, $u_1^{-1}(Q^1) = \mathfrak{q}$. *Passage to C.* We show: $(*)$ ι is injective, C is integral and flat over C_1, and every prime P of C with $\iota^{-1}(P) = P_i^1$ is $\ker f'$ for a surjective lift f' of f_i with $f' \circ \iota = g_i$. If $q = 0$, then $C = C_1$, ι is the identity and $f' = g_i$ does it ($g_i \circ u_1 = f_i$, $g_i(z) = T$). Let $q \ge 1$. The ring $B[[z]]$ is a complete Noetherian local $\mathcal{O}$-algebra with residue field $\mathbb{F}_{\mathcal{O}}$, and $\chi_{D^{\mathrm{u}}}(\sigma_j) \equiv \prod_i (X - \tilde u_{j,i})$ modulo $\mathfrak{m}_B \subseteq \mathfrak{m}_{B[[z]]}$; by Lemma E.59 (with $A = B[[z]]$, $P_j = \chi_{D^{\mathrm{u}}}(\sigma_j)$), C_0 is a local ring and a free $B[[z]]$-module of finite rank $r \ge 1$. Hence C is a free C_1-module of rank r; so ι is injective (an element of C_1 killing a non-zero free module is 0), C is integral over C_1 (lying over and going-up hold) and flat over C_1 (going-down holds). The maximal ideal of C_0 is generated by $\mathfrak{m}_{B[[z]]}$ and the $Z_{j,i}$ (C_0 is a quotient of $B[[z]][[Z_{j,i}]]$), so $\bar C = C_0/\mathfrak{m}_{B[[z]]}C_0$ is a finite-dimensional local $\mathbb{F}_{\mathcal{O}}$-algebra whose maximal ideal, generated by the images of the $Z_{j,i}$, is nilpotent, say of exponent t; so $\bar C$ is spanned by the images of the monomials in the $Z_{j,i}$ of degree less than t, and by Nakayama's lemma (C_0 is a finite module over the local ring $B[[z]]$) these finitely many monomials generate C_0 as a $B[[z]]$-module. As $Z_{j,i} = u_{j,i} - \tilde u_{j,i}$ with $\tilde u_{j,i} \in \mathcal{O}$, C is generated as a C_1-module by finitely many products of the $u_{j,i}$. Each $u_{j,i}$ is a root of ιp_j, where $p_j \in C_1[X]$ is the image of $\chi_{D^{\mathrm{u}}}(\sigma_j)$ under u_1, since $\prod_i (X - u_{j,i}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(X)$ in $C[X]$; and $g_i p_j$ is the image of $\chi_{D^{\mathrm{u}}}(\sigma_j)$ under $g_i \circ u_1 = f_i$, a product of monic polynomials of degree 1 in $A_{k_i}[X]$ by (Sys0). By Lemma E.65 (with $w = (u_{j,i})_{j,i}$, $A = A_{k_i}$, the domain, and $g = g_i$, surjective), every prime P of C with $\iota^{-1}(P) = P_i^1$ is the kernel of a surjective ring homomorphism $f'\colon C \to A_{k_i}$ with $f' \circ \iota = g_i$; then $f' \circ u = g_i \circ u_1 = f_i$ and $f'(z) = g_i(z) = T$, so f' is a surjective lift of f_i. This

proves $(*)$. Now choose by lying over a prime P_0 of C with $\iota^{-1}(P_0) = P_0^1$; for $i = 1, \dots, h$ choose by going-down $E_i \subseteq P_{i-1}$ with $\iota^{-1}(E_i) = E_i^1$ (as $E_i^1 \subseteq P_{i-1}^1$) and by going-up $P_i \supseteq E_i$ with $\iota^{-1}(P_i) = P_i^1$ (as $E_i^1 \subseteq P_i^1$); by going-down choose $P_{\mathfrak{t}} \subseteq P_0$ over $P_{\mathfrak{t}}^1$ and $Q \subseteq P_h$ over Q^1. By $(*)$, $P_i = \ker f_i'$ for a surjective lift f_i' of f_i. Then $E_i \subseteq P_{i-1} \cap P_i$, $P_{\mathfrak{t}} \subseteq P_0$, $Q \subseteq P_h$, and, as $u = \iota \circ u_1$, $u^{-1}(P_i) = \ker f_i$, $u^{-1}(E_i) = \mathfrak{e}_i$, $u^{-1}(P_{\mathfrak{t}}) = \mathfrak{t}$, $u^{-1}(Q) = \mathfrak{q}$. Put $\mathfrak{q}_i = \pi^{-1}(P_i)$. As π is surjective, preimages of primes of C are primes of R, and they contain $\beta(y_1), \dots, \beta(y_s)$ by (Sys1). By (Sys3) for the surjective lift f_i', $f_{\mathcal{T}} \notin \mathfrak{q}_i$; hence $\pi^{-1}(P') \in \mathcal{P}$ for every prime P' of C contained in some P_i. (b) *A minimal prime of the support.* Put $\tau = \pi^{-1}(P_{\mathfrak{t}}) \in \mathcal{P}$. As $J \subseteq \mathfrak{t} = u^{-1}(P_{\mathfrak{t}})$, (Sys2) gives $\mathrm{Ann}_R(X) \subseteq \tau$, so $\tau R' \in \mathrm{Supp}_{R'}(M_\infty)$ by (Pat3). As M_∞ is finitely generated over the Noetherian ring R', $\mathrm{Supp}_{R'}(M_\infty) = V(\mathrm{Ann}_{R'}(M_\infty))$; let $Z \subseteq \tau R'$ be a prime of R' minimal in it. Then $\iota^{-1}(Z) \subseteq \iota^{-1}(\tau R') = \tau = \pi^{-1}(P_{\mathfrak{t}})$ with $u^{-1}(P_{\mathfrak{t}}) = \mathfrak{t}$ stable, so every prime of R contained in $\iota^{-1}(Z)$ is stable for the system. Also $Z \subseteq \mathfrak{q}_0 R'$, as $\tau \subseteq \mathfrak{q}_0$. (c) *The key inclusion.* Suppose $Z \subseteq \mathfrak{q}_i R'$ for some i, and let $P' \subseteq P_i$ be a prime of C with $u^{-1}(P')$ stable or thick; put $\varphi = \pi^{-1}(P') \in \mathcal{P}$, so $\varphi R' \subseteq \mathfrak{q}_i R'$. We show $Z \subseteq \varphi R'$. Since $\mathfrak{q}_i R' \supseteq Z \supseteq \mathrm{Ann}_{R'}(M_\infty)$, (Pat3) gives $\mathrm{Ann}_R(X) \subseteq \mathfrak{q}_i$; with (a) and (Sys3), the hypotheses of (Pat4) hold at $\mathfrak{q}_i$ with the integer d of the system. Let $\hat{A}$ be the completion of $R'_{\mathfrak{q}_i R'}$, identified by (Pat0) with the completion of $R_{\mathfrak{q}_i}$ compatibly with the maps from R, and let $\hat{Z}$ be a prime of $\hat{A}$ minimal over $Z\hat{A}$. By (Pat4), $\hat{Z}$ lies over Z and is minimal in $\mathrm{Supp}(M_\infty \otimes_{R'} \hat{A})$, hence $I\hat{A} \subseteq \hat{Z}$ and $\dim \hat{A}/\hat{Z} \geq d + s$; its preimage in R is $\iota^{-1}(Z)$, stable for the system by (b). As $\hat{A}$ is faithfully flat over $R'_{\mathfrak{q}_i R'}$, there is a prime $\hat{Q}$ of $\hat{A}$ lying over $\varphi R'_{\mathfrak{q}_i R'}$; its preimage in R' is $\varphi R'$ and in R is $\varphi = \pi^{-1}(P')$. By (Sys4) for the point x_i and the surjective lift f_i' (so $\mathfrak{q} = \pi^{-1}(\ker f_i') = \mathfrak{q}_i$), $\hat{Z} \subseteq \hat{Q}$; taking preimages in R', $Z \subseteq \varphi R'$. (d) *Along the chain.* By induction $Z \subseteq \mathfrak{q}_i R'$ for all i: the case $i = 0$ is (b); if $Z \subseteq \mathfrak{q}_{i-1} R'$, apply (c) with $P' = E_i \subseteq P_{i-1}$, $u^{-1}(E_i) = \mathfrak{e}_i$ thick: $Z \subseteq \pi^{-1}(E_i)R' \subseteq \pi^{-1}(P_i)R' = \mathfrak{q}_i R'$. (e) *The conclusion.* Apply (c) with $i = h$ and $P' = Q \subseteq P_h$, $u^{-1}(Q) = \mathfrak{q}$ stable or thick: $Z \subseteq \varphi R'$ for $\varphi = \pi^{-1}(Q) \in \mathcal{P}$. Then $\varphi R' \in \mathrm{Supp}_{R'}(M_\infty)$, so (Pat3) gives $\mathrm{Ann}_R(X) \subseteq \varphi$, and (Sys2) gives $J \subseteq u^{-1}(Q) = \mathfrak{q}$.

Step 4: $R = T$ at patchable curve points. Let x be a patchable curve point of irreducible type, with homomorphism f, with $\mathcal{J} \subseteq \ker f$. By Step 2, $\ker f$ is stable, and by Step 1 every prime $\mathfrak{q} \subseteq \ker f$ is stable. By Proposition E.39 (with $h = 0$, $x_0 = x$; its hypotheses are among those of the present statement) there are a curve point x' with homomorphism f' such that $\ker f' = \ker f$ and a patching system for $\mathcal{J}$ along (x'). Step 3 with $h = 0$, the point x' and $\mathfrak{t} = \ker f = \ker f'$ (stable, and $\mathcal{J} \subseteq \ker f$) gives $\mathcal{J} \subseteq \mathfrak{q}$ for every prime $\mathfrak{q} \subseteq \ker f' = \ker f$ that is stable; by the above, these are all primes $\mathfrak{q} \subseteq \ker f$.

Step 5: $R = T$ along thick chains. Let $x_0, \dots, x_h$ be patchable curve points of endoscopic type with homomorphisms $f_0, \dots, f_h$, thick primes $\mathfrak{e}_i \subseteq \ker f_{i-1} \cap \ker f_i$ and a stable prime $\mathfrak{t}$ with $\mathcal{J} \subseteq \mathfrak{t} \subseteq \ker f_0$. By Proposition E.39 there are curve points $x_0', \dots, x_h'$ with homomorphisms $f_0', \dots, f_h'$ such that $\ker f_i' = \ker f_i$ for every i, and a patching system for $\mathcal{J}$ along $(x_0', \dots, x_h')$. The hypotheses of Step 3 involve only the kernels: $\mathfrak{e}_i \subseteq \ker f_{i-1}' \cap \ker f_i'$ and $\mathcal{J} \subseteq \mathfrak{t} \subseteq \ker f_0'$. So Step 3, applied to $x_0', \dots, x_h'$, shows that every prime $\mathfrak{q} \subseteq \ker f_h' = \ker f_h$ that is stable or thick contains $\mathcal{J}$. □

Proposition E.33. *Let $(R, \beta, X, f, I, e, (M_N)_{N \geq 1}, \mathcal{U})$ be an abstract patching tower over $S = \Lambda[[y_1, \dots, y_s]]$, with patching ring R' and $\iota\colon R \to R'$. For a multi-index $\alpha \in \mathbb{Z}_{\geq 0}^s$ write $|\alpha| = \sum_i \alpha_i$ and $y^\alpha = \prod_i \iota(\beta(y_i))^{\alpha_i} \in R'$, and let $\mathcal{P}$ be the set of prime ideals Q of R with $f \notin Q$ and $\mathfrak{y} \subseteq Q$. Then R' is a Noetherian ring, and there is a finitely generated R'-module M_∞ with the following properties.*

(Pat0) *For $Q \in \mathcal{P}$, QR' is a prime ideal of R' with $\iota^{-1}(QR') = Q$, and $Q \mapsto QR'$ is a bijection from $\mathcal{P}$ onto the set of prime ideals of R' containing $\mathfrak{y}R'$. For $Q \in \mathcal{P}$, the homomorphism*

$R_Q \to R'_{QR'}$ induced by ι induces an isomorphism of their completions at the maximal ideals.

(Pat1) *$R'/\mathfrak{y}R' \cong R_f/\mathfrak{y}R_f$, and $M_\infty/\mathfrak{y}M_\infty \cong X \otimes_R R_f$ as modules over this ring. For every $k \geq 0$ the map*

$$\bigoplus_{|\alpha|=k} M_\infty/\mathfrak{y}M_\infty \longrightarrow \mathfrak{y}^k M_\infty/\mathfrak{y}^{k+1}M_\infty, \qquad (w_\alpha)_\alpha \longmapsto \textstyle\sum_\alpha y^\alpha w_\alpha,$$

is an isomorphism.

(Pat2) *For every $g \in I$ there is $t \geq 1$ with $\iota(g)^t M_\infty = 0$.*

(Pat3) *For every $Q \in \mathcal{P}$: $QR' \in \operatorname{Supp}_{R'}(M_\infty)$ if and only if $\operatorname{Ann}_R(X) \subseteq Q$.*

(Pat4) *Let $\mathfrak{q} \in \mathcal{P}$ with $\operatorname{Ann}_R(X) \subseteq \mathfrak{q}$, such that for $\mathfrak{p} = \{a \in \Lambda : \beta(a) \in \mathfrak{q}\}$ the local ring $\Lambda_\mathfrak{p}$ is regular of dimension d. Let A be either $R'_{\mathfrak{q}R'}$ or its completion $\hat{A}$ at its maximal ideal (by (Pat0), $\hat{A}$ is the completion of $R_\mathfrak{q}$), and $M_A = M_\infty \otimes_{R'} A$. Then $M_A \neq 0$, $\operatorname{depth}_A(M_A) \geq d + s$, and every prime ideal P of A that is minimal in $\operatorname{Supp}_A(M_A)$ satisfies $\iota(I)A \subseteq P$ and $\dim A/P \geq d + s$. Moreover, if $Z \subseteq \mathfrak{q}R'$ is a prime ideal of R' minimal in $\operatorname{Supp}_{R'}(M_\infty)$, then every prime ideal of $\hat{A}$ minimal over $Z\hat{A}$ lies over Z and is minimal in $\operatorname{Supp}_{\hat{A}}(M_\infty \otimes_{R'} \hat{A})$.*

Proof. Here AM refers to [12] and Mat to [166]. Write $S_{k,j} = S/\mathfrak{c}_{k,j}$ and, for a family $(Z_N)_{N\geq 1}$ of sets, $\prod_\mathcal{U} Z_N$ for its ultraproduct (sequences, defined on a member of $\mathcal{U}$, modulo agreement on a member of $\mathcal{U}$). For α a multi-index, y^α also denotes $\prod_i y_i^{\alpha_i} \in S$; its action on an R-module is through β.

Step 0: finiteness. Each $\Lambda/\mathfrak{m}_\Lambda^j$ is finite (the residue field is finite). The ring

$$S_{k,j} \cong (\Lambda/\mathfrak{m}_\Lambda^j)[y_1, \ldots, y_s]/(y_1, \ldots, y_s)^k$$

is a finite local ring, free over $\Lambda/\mathfrak{m}_\Lambda^j$ on the monomials of degree $< k$, and $X/\mathfrak{m}_\Lambda^j X$ is finite by (Tow0). A finitely generated R-module that is a finite set has finite length, and a module of length λ over the local ring R is killed by $\mathfrak{m}_R^\lambda$; so for every j there is $c_j \geq 1$ with

$$\mathfrak{m}_R^{c_j}\,(X/\mathfrak{m}_\Lambda^j X) = 0. \tag{E.4}$$

(X is a finitely generated R-module: a Λ-basis generates it, Λ acting through β.)

Step 1: facts on ultraproducts. Let (Z_N) be R-modules. (U1) $\prod_\mathcal{U} Z_N$ is an R-module componentwise; ultraproducts of R-linear maps are R-linear, and an ultraproduct of sequences $Z'_N \to Z_N \to Z''_N$ that are exact for $\mathcal{U}$-almost all N is exact. Ultraproducts commute with finite direct sums. (U2) If Z is a finite R-module and $Z_N = Z$ for $\mathcal{U}$-almost all N, the diagonal map $Z \to \prod_\mathcal{U} Z_N$ is bijective: a sequence with values in a finite set is constant on a member of $\mathcal{U}$. (U3) If $J = (g_1, \ldots, g_m)$ is a finitely generated ideal of R, or of S acting through β, then $\prod_\mathcal{U} Z_N \to \prod_\mathcal{U}(Z_N/JZ_N)$ is surjective with kernel $J\prod_\mathcal{U} Z_N$, and $\prod_\mathcal{U}(JZ_N) = J\prod_\mathcal{U} Z_N$: a class (z_N) has $z_N \in JZ_N$ for $\mathcal{U}$-almost all N iff $z_N = \sum_i g_i w_{i,N}$ there, i.e. iff $(z_N) = \sum_i g_i(w_{i,N})$.

Step 2: the finite levels. Put $P_{k,j} = \prod_\mathcal{U} M_N/\mathfrak{c}_{k,j}M_N$, an R-module killed by $\mathfrak{c}_{k,j}$. (a) For $k \leq k'$, $j \leq j'$ the reductions induce an R-linear surjection $P_{k',j'} \to P_{k,j}$ with kernel $\mathfrak{c}_{k,j}P_{k',j'}$, by (U3) applied to $Z_N = M_N/\mathfrak{c}_{k',j'}M_N$. (b) *The monomial isomorphism.* Let $k, j \geq 1$. For an R-module Y put $\bar{Y} = Y/\mathfrak{c}_{k+1,j}Y$; the map $\mu_Y\colon \bigoplus_{|\alpha|=k} Y/\mathfrak{c}_{1,j}Y \to \bar{Y}$, $(w_\alpha) \mapsto \sum_\alpha y^\alpha \tilde{w}_\alpha$ ($\tilde{w}_\alpha$ any lift) is well defined, since $y^\alpha \mathfrak{c}_{1,j} \subseteq (y)^{k+1} + \mathfrak{m}_\Lambda^j S \subseteq \mathfrak{c}_{k+1,j}$, and its image is $\mathfrak{y}^k\bar{Y}$. If $\bar{Y}$ is

a free $S_{k+1,j}$-module, μ_Y is injective: for $\bar{Y} = S_{k+1,j}$ it is the map $\bigoplus_{|\alpha|=k} \Lambda/\mathfrak{m}_\Lambda^j \to S_{k+1,j}$, $(a_\alpha) \mapsto \sum a_\alpha y^\alpha$, injective by Step 0, and the free case is a direct sum of copies. By (Tow1) and (U1), (U3), the ultraproduct $\mu_{k,j}\colon \bigoplus_{|\alpha|=k} P_{1,j} \to P_{k+1,j}$ of the μ_{M_N} is injective with image $\mathfrak{y}^k P_{k+1,j}$. By (a), the kernel of $P_{k+1,j} \to P_{k,j}$ is $\mathfrak{c}_{k,j} P_{k+1,j} = \mathfrak{y}^k P_{k+1,j}$, as $\mathfrak{m}_\Lambda^j S \subseteq \mathfrak{c}_{k+1,j}$ kills $P_{k+1,j}$. So

$$0 \to \bigoplus_{|\alpha|=k} P_{1,j} \xrightarrow{\mu_{k,j}} P_{k+1,j} \to P_{k,j} \to 0 \tag{E.5}$$

is exact, compatibly with the reductions in j. (c) *Uniform annihilation.* Let $k, j \geq 1$ and $g \in G$ (the generating set of (Tow3)). For N in the member of $\mathcal{U}$ given by (Tow2) at level j, $f(M_N/\mathfrak{c}_{1,j}M_N) = \varphi\psi(M_N/\mathfrak{c}_{1,j}M_N) \subseteq \varphi(X/\mathfrak{m}_\Lambda^j X)$ is killed by $\mathfrak{m}_R^{c_j}$ (E.4), φ being R-linear. Let $\bar{M} = M_N/\mathfrak{c}_{k,j}M_N$. Then $\mathfrak{y}^k\bar{M} = 0$, and for $0 \leq i < k$ the quotient $\mathfrak{y}^i\bar{M}/\mathfrak{y}^{i+1}\bar{M}$ is the image of $\bigoplus_{|\alpha|=i} M_N/\mathfrak{c}_{1,j}M_N$ under $(w_\alpha) \mapsto \sum y^\alpha \tilde{w}_\alpha$ (well defined because $\mathfrak{m}_\Lambda^j \bar{M} = 0$); so $f\mathfrak{m}_R^{c_j}$ kills each of these k quotients and $f^k\mathfrak{m}_R^{kc_j}\bar{M} = 0$. By (Tow3) with exponent kc_j, for $\mathcal{U}$-almost all N there is a_N with $(fg)^e - a_N \in \mathfrak{m}_R^{kc_j}$ and $a_N M_N = 0$; then $f^k(fg)^e z = f^k((fg)^e - a_N)z = 0$ for $z \in \bar{M}$. Hence

$$f^k(fg)^e P_{k,j} = 0 \qquad (g \in G,\ k, j \geq 1). \tag{E.6}$$

Step 3: compatible comparison maps. For $j \geq 1$ let $W_j \in \mathcal{U}$ be the set of (Tow2) at level j, and $W_j' = W_1 \cap \cdots \cap W_j \cap \{N : N \geq j\} \in \mathcal{U}$. For $N \in W_1'$ put $j(N) = \max\{j : N \in W_j'\}$ (finite, as $N \in W_j'$ forces $j \leq N$), and choose (φ_N, ψ_N) as in (Tow2) at level $j(N)$. For $j \leq j(N)$, φ_N maps $\mathfrak{m}_\Lambda^j(X/\mathfrak{m}_\Lambda^{j(N)}X)$ into $\mathfrak{m}_\Lambda^j(M_N/\mathfrak{c}_{1,j(N)}M_N)$ and ψ_N maps $\mathfrak{c}_{1,j}(M_N/\mathfrak{c}_{1,j(N)}M_N)$ into $\mathfrak{c}_{1,j}(X/\mathfrak{m}_\Lambda^{j(N)}X) = \mathfrak{m}_\Lambda^j(X/\mathfrak{m}_\Lambda^{j(N)}X)$ (Tow0); since $\mathfrak{c}_{1,j} = \mathfrak{c}_{1,j(N)} + \mathfrak{m}_\Lambda^j S$, they induce R-linear maps $\varphi_{N,j}\colon X/\mathfrak{m}_\Lambda^j X \to M_N/\mathfrak{c}_{1,j}M_N$ and $\psi_{N,j}$ back, with both composites f and compatible with reduction in j. Since $N \in W_j'$ implies $j(N) \geq j$, these are defined for $N \in W_j'$. Let $\Phi_j\colon X/\mathfrak{m}_\Lambda^j X \to P_{1,j}$ be the diagonal bijection of (U2) followed by $\prod_{\mathcal{U}} \varphi_{N,j}$, and $\Psi_j\colon P_{1,j} \to X/\mathfrak{m}_\Lambda^j X$ be $\prod_{\mathcal{U}} \psi_{N,j}$ followed by the inverse of that bijection. They are R-linear (U1), $\Psi_j\Phi_j = f$, $\Phi_j\Psi_j = f$, and they are compatible with the maps of Step 2(a) and the reductions of X.

Step 4: limits over j. Put $U_k = \varprojlim_j P_{k,j}$ along the surjections of Step 2(a). The exact sequences (E.5) form an inverse system in j whose left terms have surjective transition maps, so the limit is exact (AM, Proposition 10.2):

$$0 \to \bigoplus_{|\alpha|=k} U_1 \xrightarrow{\mu_k} U_{k+1} \to U_k \to 0,$$

where $\mu_k((w_\alpha)) = \sum y^\alpha \tilde{w}_\alpha$ with lifts $\tilde{w}_\alpha \in U_{k+1}$ (these exist: by induction on k, $U_{k+1} \to U_1$ is surjective). Hence $U_{k+1} \to U_k$ is surjective with kernel $\mathfrak{y}^k U_{k+1} = \mu_k(\bigoplus U_1)$, μ_k is injective, $\mathfrak{y}^k U_k = 0$, and by (E.6) $f^k(fg)^e U_k = 0$ for $g \in G$. As $X \cong \Lambda^\rho$ with Λ complete, $X = \varprojlim_j X/\mathfrak{m}_\Lambda^j X$, and the limits of Step 3 are R-linear maps

$$\Phi\colon X \to U_1, \qquad \Psi\colon U_1 \to X, \qquad \Psi\Phi = f, \quad \Phi\Psi = f. \tag{E.7}$$

Step 5: inverting f; the patched module, (Pat1) and (Pat2). Put $V_k = U_k \otimes_R R_f$. Localisation is exact, so $0 \to \bigoplus_{|\alpha|=k} V_1 \to V_{k+1} \to V_k \to 0$ is exact with first map the monomial map and image $\mathfrak{y}^k V_{k+1}$; thus $V_{k+1}/\mathfrak{y}^k V_{k+1} \cong V_k$, and $\mathfrak{y}^k V_k = 0$. By (E.7), $\Phi \otimes R_f\colon X \otimes_R R_f \to V_1$ is an isomorphism with inverse $f^{-1}(\Psi \otimes R_f)$. Put $M_\infty = \varprojlim_k V_k$; it is a module over $\varprojlim_k R_f/\mathfrak{y}^k R_f = R'$. By [242, Lemma 10.98.2], applied over R_f to the finitely generated ideal $\mathfrak{y}R_f$, $M_\infty/\mathfrak{y}^k M_\infty \cong V_k$ for all k and M_∞ is $\mathfrak{y}$-adically complete. The ring R_f is Noetherian, so R' is Noetherian, $\mathfrak{y}R'$-adically complete, and $R'/\mathfrak{y}^k R' \cong R_f/\mathfrak{y}^k R_f$ (AM, Proposition 10.15, Theorem 10.26). Hence $M_\infty/\mathfrak{y}M_\infty \cong V_1 \cong X \otimes_R R_f$, and $\mathfrak{y}^k M_\infty/\mathfrak{y}^{k+1}M_\infty = \ker(V_{k+1} \to V_k)$ is

the injective image of $\bigoplus_{|\alpha|=k} V_1$ under the monomial map: this is (Pat1). The module $X \otimes_R R_f$ is finitely generated over R_f; choose $g_1, \dots, g_t \in M_\infty$ whose images generate $M_\infty/\mathfrak{y}M_\infty$. As R' is $\mathfrak{y}R'$-adically complete and M_∞ is $\mathfrak{y}$-adically separated, the g_i generate M_∞ (Mat, Theorem 8.4): M_∞ is a finitely generated R'-module. For $g \in G$, $f^{k+e} g^e U_k = 0$ and f is a unit of R_f, so $\iota(g)^e V_k = 0$ for all k and $\iota(g)^e M_\infty = 0$. For $g = \sum_{h \in G} c_h h \in I$ and $t = |G|(e-1)+1$, every monomial of $(\sum_h c_h h)^t$ is divisible by some h^e, so $\iota(g)^t M_\infty = 0$: this is (Pat2).

Step 6: primes and completions, (Pat0). By $R'/\mathfrak{y}R' \cong R_f/\mathfrak{y}R_f$, the prime ideals of R' containing $\mathfrak{y}R'$ correspond bijectively to the prime ideals of R_f containing $\mathfrak{y}R_f$, hence to $\mathcal{P}$. The prime corresponding to $Q \in \mathcal{P}$ is the preimage of $QR_f/\mathfrak{y}R_f$, i.e. $QR' + \mathfrak{y}R' = QR'$, and its preimage in R is the preimage of QR_f, which is Q. For $t \geq 1$, $\mathfrak{y}^t \subseteq Q^t$, so $R'/Q^tR' \cong R_f/Q^tR_f$ compatibly with ι; localising at QR', resp. QR_f, gives $R'_{QR'}/Q^tR'_{QR'} \cong R_Q/Q^tR_Q$. The maximal ideal of $R'_{QR'}$ is $QR'_{QR'}$, so passing to the limit over t gives the isomorphism of completions.

Step 7: (Pat3). For a finitely generated module M over a Noetherian ring and an ideal J, $\mathrm{Supp}(M/JM) = \mathrm{Supp}(M) \cap V(J)$. With $J = \mathfrak{y}R' \subseteq QR'$: $QR' \in \mathrm{Supp}_{R'}(M_\infty)$ iff $(M_\infty/\mathfrak{y}M_\infty)_{QR'} \neq 0$. By (Pat1) and Step 6 this localisation is the localisation of $X \otimes_R R_f$ at QR_f, i.e. X_Q. As X is a finitely generated R-module, $X_Q \neq 0$ iff $\mathrm{Ann}_R(X) \subseteq Q$.

Step 8: depth, (Pat4). Let $\mathfrak{q}, \mathfrak{p}, d$ be as in (Pat4), $\mathfrak{q}' = \mathfrak{q}R'$, $A_0 = R'_{\mathfrak{q}'}$ and $M_0 = (M_\infty)_{\mathfrak{q}'}$, a finitely generated module over the Noetherian local ring A_0; the elements $\iota\beta(y_i)$ lie in its maximal ideal. Localisation is exact, so the isomorphisms of (Pat1) localise: the sequence $\iota\beta(y_1), \dots, \iota\beta(y_s)$ is M_0-quasi-regular. The modules $M_0/(\iota\beta(y_1), \dots, \iota\beta(y_i))M_0$ are finitely generated over A_0, hence separated for the $\mathfrak{y}$-adic topology (Krull's intersection theorem), so the sequence is M_0-regular (Mat, Theorem 16.3). By Step 7, $M_0/\mathfrak{y}M_0 \cong X_{\mathfrak{q}}$, a non-zero module as $\mathrm{Ann}_R(X) \subseteq \mathfrak{q}$. Choose $z_1, \dots, z_d \in \mathfrak{p}$ whose images form a regular system of parameters of $\Lambda_{\mathfrak{p}}$; a regular local ring is Cohen–Macaulay, so $z_1, \dots, z_d$ is regular on $\Lambda_{\mathfrak{p}}$, hence on $X \otimes_\Lambda \Lambda_{\mathfrak{p}} \cong \Lambda_{\mathfrak{p}}^\rho$. As $\beta(\Lambda \smallsetminus \mathfrak{p}) \subseteq R \smallsetminus \mathfrak{q}$, the module $X_{\mathfrak{q}}$ is a localisation of $X \otimes_\Lambda \Lambda_{\mathfrak{p}}$, so multiplication by z_i is injective on $X_{\mathfrak{q}}/(z_1, \dots, z_{i-1})X_{\mathfrak{q}}$; and $X_{\mathfrak{q}}/(z)X_{\mathfrak{q}} \neq 0$ by Nakayama's lemma, as $\beta(z_i) \in \mathfrak{q}$. So $\iota\beta(y_1), \dots, \iota\beta(y_s), \iota\beta(z_1), \dots, \iota\beta(z_d)$ is an M_0-regular sequence in the maximal ideal of A_0, $M_0 \neq 0$ and $\mathrm{depth}_{A_0}(M_0) \geq d + s$. The completion $\hat{A}$ is faithfully flat over A_0, so tensoring preserves the injectivity of each multiplication map and the non-vanishing of the last quotient; the same holds for $A = \hat{A}$, $M_{\hat{A}} = M_0 \otimes_{A_0} \hat{A}$. Let P be minimal in $\mathrm{Supp}_A(M_A)$. Then P is an associated prime of M_A, and $\dim A/P \geq \mathrm{depth}_A(M_A) \geq d + s$ (Mat, Theorem 17.2). For $g \in I$, (Pat2) gives $\iota(g)^t \in \mathrm{Ann}_A(M_A) \subseteq P$, so $\iota(g) \in P$. Finally let $Z \subseteq \mathfrak{q}'$ be minimal in $\mathrm{Supp}_{R'}(M_\infty)$; then ZA_0 is minimal in $\mathrm{Supp}(M_0)$. Let $\hat{Z}$ be minimal over $Z\hat{A}$. If $\hat{Z} \cap A_0 \neq ZA_0$, going-down for the flat extension $A_0 \to \hat{A}$ gives $\hat{Z}' \subsetneq \hat{Z}$ lying over ZA_0, so $Z\hat{A} \subseteq \hat{Z}' \subsetneq \hat{Z}$, a contradiction; so $\hat{Z}$ lies over Z. For a finitely generated A_0-module M and a prime P' of $\hat{A}$ over P'', $(M \otimes \hat{A})_{P'} = M_{P''} \otimes \hat{A}_{P'}$ with $\hat{A}_{P'}$ faithfully flat over $(A_0)_{P''}$; so $\mathrm{Supp}(M \otimes \hat{A})$ is the preimage of $\mathrm{Supp}(M)$. Hence $\hat{Z} \in \mathrm{Supp}(M_{\hat{A}})$, and a prime $P' \subsetneq \hat{Z}$ of this support would lie over a prime of $\mathrm{Supp}(M_0)$ contained in ZA_0, i.e. over ZA_0, so $P' \supseteq Z\hat{A}$, contradicting the minimality of $\hat{Z}$ over $Z\hat{A}$. □

E.2.2 Existence of patching systems

This subsection proves Proposition E.39: patching systems exist for ideals with classical levels along extensions of patchable curve points. It defines the Selmer data of a framed curve point, the Selmer sets at the levels with the bounds (B1), (B2) and the conditions (K1)–(K3), automorphic patching data, their patched tower data, and realisations over a level (Definition E.34, Definition E.35, Definition E.36, Definition E.37, Definition E.38). The limit over the Taylor–Wiles levels is taken through ultrafilter limits of quotients of a finitely generated profinite group

(Lemma E.43, Lemma E.44, Lemma E.42). Cocycles with values in finite ℓ-groups vanish on the pro-ℓ kernel (Lemma E.45), and at the primes of the patched ring that are stable for the system the reducibility ideal of a realisation is not contained in the prime (Lemma E.46, Lemma E.47).

Definition E.34. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, write $\Gamma = \Gamma_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $\pi = \pi_{\mathscr{H}}$, $\bar{c} = \pi(c)$, and let $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ be a curve point of B_n^{po} that is normalised of shape $(a, n-a)$, $A = A_k$. For a commutative A-algebra X let $\mathrm{Ev}_a(X) \subseteq \mathrm{M}_n(X)$ be the matrices whose (i,j) entry vanishes unless i, j lie in the same block $\{1,\dots,a\}$ or $\{a{+}1,\dots,n\}$, and $\mathrm{Od}_a(X)$ those whose (i,j) entry vanishes unless i, j lie in different blocks (so $\mathrm{Od}_n(X) = 0$). For $v \in S_\ell$, $\mu_v \subseteq D_v$ is as in Definition 50.1.

(Sd1) Framed points. A **frame** of x is a pair $((w_v)_{v\in S_\ell}, (I_u^x)_{u\in \mathrm{St}})$ of matrices $w_v \in \mathrm{GL}_n(A)$, each of whose columns has its non-zero entries in one block, such that $w_v^{-1}\rho(\pi(g))w_v$ is upper triangular with diagonal $(\psi_{v,1}(g),\dots,\psi_{v,n}(g))$ for $g \in D_v$, and of closed subgroups $I_u^x \subseteq \pi(I_{\bar{u}} \cap G_L)$ ($\bar{u}$ a place of $\overline{\mathbb{Q}}$ above u) on which ρ is trivial. Together with a frame, x is a **framed point**; it satisfies **(Np3)** if it satisfies (Pj2) of Definition 50.9, and **(Np4)** if 0 is the only $Z \in \mathrm{M}_n(A)$ with $\chi_{\mathrm{cyc}}(\gamma)\rho(\gamma)Z = Z\rho(\gamma)$ for all $\gamma \in \Delta_0$.

(Sd2) Ordinary Selmer cocycles. The A-module $Z^1_{\mathrm{ord}}(x)$ consists of the maps $z\colon \Gamma^0 \to \mathrm{Od}_a(A)$ such that: every entry of z is continuous for the T-adic topology; $z(\gamma\gamma') = z(\gamma) + \rho(\gamma)z(\gamma')\rho(\gamma)^{-1}$; $z(\bar{c}\gamma\bar{c}) = -{}^t z(\gamma)$; z vanishes on every I_u^x; and for every $v \in S_\ell$ there is $Y_v \in \mathrm{Od}_a(A)$ such that, for $g \in D_v$ and $z_v(g) = w_v^{-1}(z(\pi g) - \rho(\pi g)Y_v\rho(\pi g)^{-1} + Y_v)w_v$, the matrix $z_v(g)$ is upper triangular, with zero diagonal when $g \in \mu_v$. The **coboundaries** are $\mathrm{Bd}(x) = \{\gamma \mapsto \rho(\gamma)Y\rho(\gamma)^{-1} - Y :\ Y \in \mathrm{Od}_a(A),\ {}^tY = -Y\} \subseteq Z^1_{\mathrm{ord}}(x)$. A **Selmer basis** of x is a family $\kappa = (\kappa_1,\dots,\kappa_g)$ in $Z^1_{\mathrm{ord}}(x)$ such that $\sum_j c_j\kappa_j \in \mathrm{Bd}(x)$ with $c \in A^g$ forces $c = 0$, and for every $z \in Z^1_{\mathrm{ord}}(x)$ there are $s \geq 0$ and $c \in A^g$ with $T^s z - \sum_j c_j\kappa_j \in \mathrm{Bd}(x)$.

(Sd3) Paired dual numbers and the first-order deformation. For $g \geq 0$ and a commutative A-algebra X, the ring of **paired dual numbers** is $\mathrm{PD}_g(X) = X \oplus \bigoplus_{j=1}^g X\epsilon_j \oplus \bigoplus_{j=1}^g X\epsilon'_j \oplus X\eta$ with $\epsilon_i\epsilon'_j = \delta_{ij}\eta$ and all other products of two of $\epsilon_1,\dots,\epsilon_g,\epsilon'_1,\dots,\epsilon'_g,\eta$ equal to 0. Let $\mathrm{PB}_a \subseteq \mathrm{M}_n(\mathrm{PD}_g(A))$ be the matrices whose same-block entries lie in $A\eta$ and whose different-block entries lie in $\bigoplus_j A\epsilon'_j$. For a Selmer basis κ put $\rho_1(\gamma) = \big(1 + \sum_j \epsilon_j\kappa_j(\gamma)\big)\rho(\gamma) \in \mathrm{GL}_n(\mathrm{PD}_g(A))$.

(Sd4) Twisted dual cocycles and detecting sets. $\mathrm{TwZ}(x,\kappa)$ is the set of maps $z\colon \Gamma^0 \to \mathrm{PB}_a$ with T-adically continuous entries such that $z(\gamma\gamma') = z(\gamma) + \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma)z(\gamma')\rho_1(\gamma)^{-1}$ and $z(\bar{c}\gamma\bar{c}) = -\chi_{\mathrm{cyc}}(\bar{c})\,{}^t z(\gamma)$; $\mathrm{TwB}(x,\kappa)$ is the set of the maps $\gamma \mapsto \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma)Y\rho_1(\gamma)^{-1} - Y$ with $Y \in \mathrm{PB}_a$, $-\chi_{\mathrm{cyc}}(\bar{c})\,{}^tY = Y$. For $\sigma \in \Gamma^0$ and $z \in \mathrm{TwZ}(x,\kappa)$ let $\ell_\sigma(z) \in A$ be the η-coefficient of $\mathrm{tr}\big(z(\sigma)\rho_1(\sigma)\big)$. A subset $\Sigma \subseteq \Gamma^0$ **detects** (x,κ) if every $z \in \mathrm{TwZ}(x,\kappa)$ with $\ell_\sigma(z) = 0$ for all $\sigma \in \Sigma$ satisfies $T^s z \in \mathrm{TwB}(x,\kappa)$ for some $s \geq 0$.

Definition E.35. Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, $\bar{c} = \pi(c)$, and x a framed normalised curve point of shape $(a, n-a)$ with frame $((w_v)_{v\in S_\ell}, (I_u^x)_{u\in\mathrm{St}})$.

(Lv) Levels. A **level** over $\mathscr{H}$ is a tuple $\mathbf{V} = (\Gamma_1, h, c_1, (\phi_{1,v})_{v\in S_\ell}, (I_{1,u})_{u\in\mathrm{St}})$ of a profinite group Γ_1, a continuous surjective homomorphism $h\colon \Gamma_1 \to \Gamma$, an element $c_1 \in \Gamma_1$ with $c_1^2 = 1$ and $h(c_1) = \bar{c}$, continuous homomorphisms $\phi_{1,v}\colon D_v \to \Gamma_1^0 := h^{-1}(\Gamma^0)$ with $h \circ \phi_{1,v} = \pi|_{D_v}$, and closed subgroups $I_{1,u} \subseteq \Gamma_1^0$ with $h(I_{1,u}) = I_u^x$. The **base level** is $(\Gamma, \mathrm{id}, \bar{c}, (\pi|_{D_v}), (I_u^x))$. For a Taylor–Wiles datum and $N \geq 1$, the **level** N is $\mathbf{V}_N = (\Gamma_N, h_N, \pi^{Q_N}(c), (\pi^{Q_N}|_{D_v}), (I_{N,u})_u)$ with $I_{N,u} = \pi^{Q_N}\big(I_{\bar{u}} \cap G_L \cap \pi^{-1}(I_u^x)\big)$, $\bar{u}$ the place of the frame; then $h_N(I_{N,u}) = I_u^x$ since $h_N \circ \pi^{Q_N} = \pi$ and $I_u^x \subseteq \pi(I_{\bar{u}} \cap G_L)$. (If $I_u^x = \{1\}$, then $I_{\bar{u}} \cap G_L \cap N_{\mathscr{H}}$ consists of inertia elements killed by all $\bar{\chi}_a$, which are trivial in Γ^{Q_N}, so $I_{N,u} = \{1\}$.)

(Sc) Selmer cocycles at a level. Let $\mathbf{V}$ be a level, R a commutative A-algebra, $V \subseteq \mathrm{M}_n(R)$ an A-submodule, $\varrho\colon \Gamma_1^0 \to \mathrm{GL}_n(R)$ a homomorphism and $u_v \in \mathrm{GL}_n(R)$ ($v \in S_\ell$). The

set $\mathrm{Sel}_{\mathbf{V}}(\varrho,u,V)$ consists of the maps $z\colon \Gamma_1^0\to V$ such that: every entry of z is continuous for the topology of R defined by the ideal TR; $z(\gamma\gamma')=z(\gamma)+\varrho(\gamma)z(\gamma')\varrho(\gamma)^{-1}$; $z(c_1\gamma c_1)=-{}^t z(\gamma)$; z vanishes on every $I_{1,u}$; and for every $v\in S_\ell$ there is $Y_v\in V$ such that for all $g\in D_v$ the matrix $u_v^{-1}(z(\phi_{1,v}g)-\varrho(\phi_{1,v}g)Y_v\varrho(\phi_{1,v}g)^{-1}+Y_v)u_v$ has zero entries below the diagonal, and zero diagonal entries if $g\in\mu_v$. The set $\mathrm{Bd}_{\mathbf{V}}(\varrho,V)$ consists of the maps $\gamma\mapsto\varrho(\gamma)Y\varrho(\gamma)^{-1}-Y$ with $Y\in V$, ${}^tY=-Y$.

(Ss) The six Selmer sets. Let κ be a Selmer basis of x together with **local witnesses** $Y_{j,v}\in\mathrm{Od}_a(A)$ for κ_j at v (as in (Sd2) of Definition E.34). For a commutative A-algebra X, let $\mathrm{PW}_a^1(X)$ (resp. $\mathrm{PW}_a^2(X)$) $\subseteq \mathrm{M}_n(\mathrm{PD}_g(X))$ be the matrices whose same-block entries lie in $X\cdot 1$ (resp. $\bigoplus_j X\epsilon'_j$) and whose different-block entries lie in $\bigoplus_j X\epsilon_j$ (resp. $X\eta$); put $w_v^1=(1-\sum_j\epsilon_jY_{j,v})w_v\in\mathrm{GL}_n(\mathrm{PD}_g(X))$. With $\rho_X=\rho\circ h$ (entries mapped to X) and $\rho_{1,X}=\rho_1\circ h$ (entries mapped to $\mathrm{PD}_g(X)$):

$$\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(X)=\mathrm{Sel}_{\mathbf{V}}(\rho_X,w,\mathrm{Ev}_a(X)),\quad \mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}}(X)=\mathrm{Sel}_{\mathbf{V}}(\rho_X,w,\mathrm{Od}_a(X)),$$
$$\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(X)=\mathrm{Bd}_{\mathbf{V}}(\rho_X,\mathrm{Od}_a(X)),\quad \mathrm{Sel}^1_{\mathbf{V}}(X)=\mathrm{Sel}_{\mathbf{V}}(\rho_{1,X},w^1,\mathrm{PW}_a^1(X)),$$
$$\mathrm{Bd}^1_{\mathbf{V}}(X)=\mathrm{Bd}_{\mathbf{V}}(\rho_{1,X},\mathrm{PW}_a^1(X)),\quad \mathrm{Sel}^2_{\mathbf{V}}(X)=\mathrm{Sel}_{\mathbf{V}}(\rho_{1,X},w^1,\mathrm{PW}_a^2(X)).$$

Write $A_m=A/T^mA$ ($m\geq 1$).

(Bd) Bounds along a Taylor–Wiles datum (levels $\mathbf{V}_N$), for an integer $D_0\geq 0$:

(B1) there is $C\geq 0$ such that for every $m\geq 1$ there is N_0 with: for $N\geq N_0$, $\mathrm{Sel}^1_{\mathbf{V}_N}(A_m)$ is finite and $\#\mathrm{Sel}^1_{\mathbf{V}_N}(A_m)\leq\#\mathrm{Bd}^1_{\mathbf{V}_N}(A_m)\cdot(\#k)^{mD_0+C}$;

(B2) there is $C\geq 0$ such that for every $m\geq 1$ there is N_0 with: for $N\geq N_0$ and every family $(z_{i,j})_{0\leq i\leq g,\,1\leq j\leq g}$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}_N}(A_m)$ there are $c_0,\dots,c_g\in A$, one of them a unit, and $\Psi\in\mathrm{Sel}^2_{\mathbf{V}_N}(A_m)$ such that, for all j and γ, the ϵ'_j-coefficient of $\Psi(\gamma)$ is $T^C\sum_i c_iz_{i,j}(\gamma)$.

(Kd) Conditions at one level V (with $X=A$), for an integer $D_0\geq 0$:

(K1) if $z_1,\dots,z_e\in\mathrm{Sel}^1_{\mathbf{V}}(A)$ and $\sum_i c_iz_i\in\mathrm{Bd}^1_{\mathbf{V}}(A)$ with $c\in A^e$ forces $c=0$, then $e\leq D_0$;

(K2) for every family $(z_{i,j})_{0\leq i\leq g,\,1\leq j\leq g}$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(A)$ there are $c\in A^{g+1}\smallsetminus\{0\}$ and $\Psi\in\mathrm{Sel}^2_{\mathbf{V}}(A)$ such that the ϵ'_j-coefficient of $\Psi(\gamma)$ is $\sum_i c_iz_{i,j}(\gamma)$ for all j, γ;

(K3) for every $z\in\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}}(A)$ there are $s\geq 0$ and $c\in A^g$ with $T^sz-\sum_j c_j(\kappa_j\circ h)\in\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(A)$.

Definition E.36. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B,D^{\mathrm{u}},(\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $J\subseteq B$ an ideal and $\mathcal{D}$ a Taylor–Wiles datum of size q for $\mathscr{H}$ (notation of Definition 53.8; $\Gamma_N^0=\pi^{Q_N}(G_L)$). Put $D=n[L^+:\mathbb{Q}]$.

Auxiliary rings and elements. Put $S_\infty=\Lambda_D[[Y_{j,i}:1\leq j\leq q,\ 1\leq i\leq n]]$; for $a=(a_j)\in\mathbb{N}^q$, $\mathfrak{d}_a\subseteq S_\infty$ is the ideal generated by the $(1+Y_{j,i})^{\ell^{a_j}}-1$. For $N\geq 1$ and $\tilde u=(\tilde u_{j,i})\in\mathcal{O}^{q\times n}$, the **eigenvalue algebra** is

$$\mathrm{Sp}_N=B[[Z_{j,i}]]/(\text{the coefficients of }\textstyle\prod_{i=1}^n(X-\tilde u_{j,i}-Z_{j,i})-\chi_{D^{\mathrm{u}}}(h_N(\Phi_{N,j}))(X),\ 1\leq j\leq q),$$

a B-algebra, with $u_{j,i}\in\mathrm{Sp}_N$ the class of $\tilde u_{j,i}+Z_{j,i}$. For a commutative ring R, a group G, $\phi,t\in G$, $U=(U_i)\in R^n$, $1\leq i\leq n$ and $y\in R$, put in $R[G]$

$$q_1(\phi,U)=\prod_{k=1}^n(\phi-U_k),\qquad q_2(\phi,t,U,i,y)=\Big(\prod_{k\neq i}(\phi-U_k)\Big)(t-1-y)$$

(ordered products, k increasing), and for $U=(U_{j,i})\in R^{q\times n}$ and integers (m_j)

$$f_m(U)=\prod_{j=1}^{q}\prod_{i=1}^{n}\prod_{i'\neq i}(U_{j,i}-U_{j,i'})(U_{j,i}-m_jU_{j,i'})\in R.$$

Automorphic patching data. Automorphic patching data for J along $\mathcal{D}$ consist of a Taylor–Wiles base $(\mathbf{w},M)$ for J with weight map λ_B; elements $\tilde{u}_{j,i}\in\mathcal{O}$ with $\tilde{u}_{j,i}\equiv\bar{\chi}_i(\sigma_j)$ modulo $\mathfrak{m}_{\mathcal{O}}$; an integer $e\geq 1$; and for every $N\geq 1$: $R_N\in\mathrm{CNL}_{\mathcal{O}}$ with a polarised ordinary determinant $(D_N,(\psi_{N,v,a}))$ of rank n on Γ_N^0 to R_N (as in Definition 53.9); a homomorphism of $\mathcal{O}$-algebras $s_N\colon S_\infty\to R_N$; elements $U_{N,j,i}\in R_N$; an R_N-module M_N with integers $a_{N,j}\geq N$ and $\mathrm{rk}_N\geq 0$; a homomorphism of $\mathcal{O}$-algebras $\theta_N\colon R_N\to\mathrm{Sp}_N$; and additive maps $\varphi_N\colon\mathrm{Sp}_N\otimes_B M\to X_N$, $\psi_N\colon X_N\to\mathrm{Sp}_N\otimes_B M$, where $X_N=M_N/(s_N(Y_{j,i}))_{j,i}M_N$; such that, writing $f=f_{(q_{N,j})_j}$:

(Ha1) $s_N(X_k)=c_k\psi_{N,v_k,a_k}(\gamma_k)-1$ for the weight variables $\mathbf{w}=(v_k,a_k,\gamma_k,c_k)$, and $U_{N,j,i}-\tilde{u}_{j,i}\in\mathfrak{m}_{R_N}$;

(Ha2) there is an additive bijection $M_N\to(S_\infty/\mathfrak{d}_{a_N})^{\mathrm{rk}_N}$ carrying $s_N(z)m$ to z times the image of m;

(Ha3) $\theta_N\circ D_N$ is the base change to Sp_N of $D^{\mathrm{u}}\circ h_N$, $\theta_N\circ\psi_{N,v,a}=\psi^{\mathrm{d}}_{v,a}$ (in Sp_N), $\theta_N(s_N(z))=\lambda_B(z_0)$ where $z_0\in\Lambda_D$ is z modulo the $Y_{j,i}$, and $\theta_N(U_{N,j,i})=u_{j,i}$;

(Ha4) $\varphi_N(\theta_N(t)z)=t\varphi_N(z)$, $\psi_N(tx)=\theta_N(t)\psi_N(x)$, $\varphi_N\psi_N(x)=f(U_N)x$ and $\psi_N\varphi_N(z)=\theta_N(f(U_N))z$;

(Ha5) for all j, i and $g\in\Gamma_N^0$,

$$\big(f(U_N)\,\mathrm{tr}_{D_N}(g\,q_1(\Phi_{N,j},U_{N,j}))\big)^eM_N=0,$$
$$\big(f(U_N)\,\mathrm{tr}_{D_N}(g\,q_2(\Phi_{N,j},\mathrm{T}_{N,j},U_{N,j},i,s_N(Y_{j,i})))\big)^eM_N=0.$$

Definition E.37. Setting. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B,D^{\mathrm{u}},(\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $J\subseteq B$ an ideal, $D=n[L^+:\mathbb{Q}]$, $\mathcal{D}$ a Taylor–Wiles datum of size q for $\mathscr{H}$ with H and $\sigma_1,\dots,\sigma_q$, and automorphic patching data for J along $\mathcal{D}$ with Taylor–Wiles base $(\mathbf{w},M)$, $\mathbf{w}=(v_k,a_k,\gamma_k,c_k)_{1\leq k\leq D}$, elements $\tilde{u}_{j,i}$, exponent e and, for $N\geq 1$, $(R_N,D_N,(\psi_{N,v,a}),s_N,(U_{N,j,i}),M_N,\dots)$. Let $\mathcal{O}_1$ be a complete discrete valuation ring which is a free $\mathcal{O}$-module of finite rank with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1=\mathfrak{m}_{\mathcal{O}_1}$. Let $(\Pi,(\pi_N),\mathcal{U},\bar{\theta},c_\infty,(\Phi_j),(\mathrm{T}_j),(F_w))$ be as in the conclusion of Lemma E.42 for $\mathcal{D}$, $\bar{\Gamma}^0\subseteq\bar{\Gamma}$ the image of $\Gamma^0_{\mathscr{H}}$, $\bar{H}\subseteq\bar{\Gamma}$ the image of H, $P^0=\pi_\infty^{-1}(\bar{\theta}^{-1}(\bar{\Gamma}^0))$, and fix $\tilde{c}\in\Pi$ with $\pi_\infty(\tilde{c})=c_\infty$. By Lemma E.62 (the $\bar{\chi}_a$ are trivial on H by (Tg1)) D^{u} is the composite of a unique determinant $\bar{D}^{\mathrm{u}}$ on $\bar{\Gamma}^0$ with the projection.

Eigenvalue algebra. Recall from Definition E.31 (where C_0^{sp} is written C_0): with a variable z,

$$C_0^{\mathrm{sp}}=B[[z]][[Z_{j,i}:1\leq j\leq q,\ 1\leq i\leq n]]\Big/\Big(\text{the coefficients of }\textstyle\prod_{i=1}^n(X-\tilde{u}_{j,i}-Z_{j,i})-\chi_{D^{\mathrm{u}}}(\sigma_j)(X),\ 1\leq j\leq q\Big),$$

with $u_{j,i}\in C_0^{\mathrm{sp}}$ the class of $\tilde{u}_{j,i}+Z_{j,i}$; it lies in $\mathrm{CNL}_{\mathcal{O}}$ (the relations reduce to 0 modulo $(\mathfrak{m}_B,z,Z_{j,i})$, since $\tilde{u}_{j,i}\equiv\bar{\chi}_i(\sigma_j)$). Then $C^{\mathrm{sp}}=\mathcal{O}_1\otimes_{\mathcal{O}}C_0^{\mathrm{sp}}$, with $u\colon B\to C^{\mathrm{sp}}$, $u(b)=1\otimes b$, is the eigenvalue algebra of $(\mathcal{O}_1,(\sigma_j)_{1\leq j\leq q},(\tilde{u}_{j,i}))$ in the sense of Definition E.31, the **eigenvalue**

algebra of the data (the congruence $\chi_{D^{\mathrm{u}}}(\sigma_j) \equiv \prod_i (X - \tilde{u}_{j,i})$ modulo $\mathfrak{m}_B$ required there holds, as D^{u} reduces to $\bar{D}_n$ and $\tilde{u}_{j,i} \equiv \bar{\chi}_i(\sigma_j)$).

The ring and the Iwasawa map. Let $t^{\mathrm{u}} = (D^{\mathrm{t}}, (\psi^{\mathrm{t}}_{v,a}), s^{\mathrm{t}}, (U^{\mathrm{t}}_{j,i}), (y^{\mathrm{t}}_{j,i}))$ be the universal patched tuple to R_{tup} (formed with $\mathcal{D}$, the limit objects above and the $\tilde{u}_{j,i}$), and $R = \mathcal{O}_1 \otimes_{\mathcal{O}} R_{\mathrm{tup}}$. Let $\Lambda = \mathcal{O}_1[[X_0, X_1, \dots, X_D]]$, $S = \Lambda[[y_{j,i} : 1 \le j \le q,\ 1 \le i \le n]]$, and $\beta \colon S \to R$ the continuous homomorphism of $\mathcal{O}_1$-algebras with

$$\beta(X_0) = s^{\mathrm{t}}, \qquad \beta(X_k) = c_k \psi^{\mathrm{t}}_{v_k,a_k}(\gamma_k) - 1 \ (1 \le k \le D), \qquad \beta(y_{j,i}) = y^{\mathrm{t}}_{j,i}.$$

The map to the eigenvalue algebra. The map $\pi \colon R \to C^{\mathrm{sp}}$ is $\mathrm{id}_{\mathcal{O}_1} \otimes \pi_0$, where $\pi_0 \colon R_{\mathrm{tup}} \to C^{\mathrm{sp}}_0$ is the morphism of $\mathrm{CNL}_{\mathcal{O}}$ carrying t^{u} to the patched tuple $(\bar{D}^{\mathrm{u}} \circ \bar{\theta} \circ \pi_\infty|_{P^0}, (\psi^{\mathrm{d}}_{v,a}), z, (u_{j,i}), (0))$ (determinant and characters base changed along $B \to C^{\mathrm{sp}}_0$; the characters take the wild values on μ_v by (Od3) of Definition 50.2 for $(D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$).

Relation ideal. With D^{t} extended to R, the **relations** are the following elements of R, for $h \in P^0$:

(Wv1) (kernel) $\mathrm{tr}_{D^{\mathrm{t}}}(h(k-1))$ for $k \in \ker \pi_\infty$;

(Wv2) (polarisation) $\Lambda_i(D^{\mathrm{t}})(\tilde{c} g^{-1} \tilde{c}^{-1}) - \Lambda_i(D^{\mathrm{t}})(g)$ for $g \in P^0$ and $1 \le i \le n$;

(Wv3) (ordinary condition) $\mathrm{tr}_{D^{\mathrm{t}}}(h \prod_{a=1}^{n} (g'_a - \psi^{\mathrm{t}}_{v,a}(g_a)))$ (product with a increasing) for $v \in S_\ell$, $g_1, \dots, g_n \in D_v$ and $g'_a \in P^0$ with $\pi_\infty(g'_a) = F_v(g_a)$;

(Wv4) (inertia at the Steinberg places) $\mathrm{tr}_{D^{\mathrm{t}}}(h(g' - 1))$ for $u \in \mathrm{St}$, $g \in D_u \cap I_{\bar{u}} \cap G_L$ with $\bar{\chi}_a(g) = 1$ for $1 \le a \le n$, and $g' \in P^0$ with $\pi_\infty(g') = F_u(g)$;

(Wv5) (first Taylor–Wiles relation) $\mathrm{tr}_{D^{\mathrm{t}}}(h\, q_1(\phi, U^{\mathrm{t}}_j))$ for $1 \le j \le q$ and $\phi \in P^0$ with $\pi_\infty(\phi) = \Phi_j$, where $U^{\mathrm{t}}_j = (U^{\mathrm{t}}_{j,i})_i$;

(Wv6) (second Taylor–Wiles relation) $\mathrm{tr}_{D^{\mathrm{t}}}(h\, q_2(\phi, \tau, U^{\mathrm{t}}_j, i, y^{\mathrm{t}}_{j,i}))$ for $1 \le j \le q$, $1 \le i \le n$ and $\phi, \tau \in P^0$ with $\pi_\infty(\phi) = \Phi_j$, $\pi_\infty(\tau) = \mathrm{T}_j$.

The **relation ideal** $I \subseteq R$ is the ideal generated by all relations, and the **isogeny element** is $f = f_{(1,\dots,1)}(U^{\mathrm{t}}) = \prod_{j=1}^{q} \prod_{i \ne i'} (U^{\mathrm{t}}_{j,i} - U^{\mathrm{t}}_{j,i'})^2 \in R$.

Modules. Put $X = C^{\mathrm{sp}} \otimes_B M$, an R-module through π. Let $\mathcal{N}_0$ be the set of $N \ge 1$ such that $\bar{h}_N(\pi_N(g))\bar{H} = \bar{\theta}(\pi_\infty(g))\bar{H}$ for all $g \in \Pi$; it belongs to $\mathcal{U}$ by (L1)(ii) of Lemma E.42. For $N \in \mathcal{N}_0$, π_N maps P^0 into the image $\bar{\Gamma}^0_N$ of Γ^0_N in $\bar{\Gamma}_N$, and $\rho_N \colon R \to \mathcal{O}_1 \otimes_{\mathcal{O}} R_N[[z]]$ is $\mathrm{id}_{\mathcal{O}_1} \otimes \rho^0_N$, where $\rho^0_N \colon R_{\mathrm{tup}} \to R_N[[z]]$ is the morphism of $\mathrm{CNL}_{\mathcal{O}}$ carrying t^{u} to the patched tuple $(\bar{D}_N \circ \pi_N|_{P^0}, (\psi_{N,v,a}), z, (U_{N,j,i}), (s_N(Y_{j,i})))$ (base changed along $R_N \to R_N[[z]]$; the characters take the wild values on μ_v by (Od3) for $(D_N, (\psi_{N,v,a}))$, as in Definition 53.9); the **level module** at N is $M^\natural_N = \mathcal{O}_1 \otimes_{\mathcal{O}} (R_N[[z]] \otimes_{R_N} M_N)$, an R-module through ρ_N. For $N \notin \mathcal{N}_0$ put $M^\natural_N = 0$.

The tuple $(R, \beta, X, f, I, e + 1, (M^\natural_N)_{N \ge 1}, \mathcal{U})$ over S, together with π, C^{sp} and $u \colon B \to C^{\mathrm{sp}}$, are the **patched tower data** of the automorphic patching data (for $\mathcal{O}_1$, the limit objects and $\tilde{c}$).

Definition E.38. Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$ with $\ell \ne 2$, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed normalised curve point of shape $(a, n-a)$ with frame $((w_v), (I^x_u))$, $A = k[[T]]$, $F = F_k$ its fraction field, $\kappa = (\kappa_1, \dots, \kappa_g)$ a Selmer basis of x with local witnesses, and $\mathbf{V} = (\Gamma_1, h, c_1, (\phi_{1,v}), (I_{1,u}))$ a level over $\mathscr{H}$. Write $\gamma^* = c_1 \gamma^{-1} c_1$ for $\gamma \in \Gamma^0_1$, and extend $\gamma \mapsto \gamma^*$ to a linear anti-involution of every group ring $R[\Gamma^0_1]$.

(Bf) Bounded maps over F. A map z from Γ^0_1 to $\mathrm{M}_n(F)$ or to $\mathrm{M}_n(\mathrm{PD}_g(F))$ is **bounded** if there is $s \ge 0$ such that all coordinates of all entries of $T^s z$ lie in A and are continuous for

the T-adic topology of A. For $\bullet \in \{\mathrm{ev}, \mathrm{od}, 1, 2\}$ let $\mathrm{Sel}^{\bullet,\mathrm{b}}_{\mathbf{V}}(F)$ be the set of bounded elements of $\mathrm{Sel}^{\bullet}_{\mathbf{V}}(F)$ (over F, the topology defined by $TF = F$ is the indiscrete one, so boundedness is the only continuity condition). A g-tuple $(z_1, \dots, z_g)$ of maps $\Gamma_1^0 \to \mathrm{M}_n(F)$ **lifts** if there is $\Psi \in \mathrm{Sel}^{2,\mathrm{b}}_{\mathbf{V}}(F)$ whose ϵ'_j-coefficient is z_j for every j.

(Vr) Realisations. Let $\mathcal{O}_1$ be a complete discrete valuation ring which is an $\mathcal{O}$-algebra, free of finite rank as an $\mathcal{O}$-module, with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathfrak{m}_{\mathcal{O}_1}$ (for instance $\mathcal{O}_1 = \mathcal{O}$). A **realisation of x over V with coefficient ring** $\mathcal{O}_1$ is a tuple $\mathfrak{R} = (B, D, (\hat{\psi}_{v,i}), (\phi_j, \tau_j, U_{j,i}, y_{j,i}), s, f_1, \hat{B}, \lambda, \mathcal{O}', \mathcal{A}, N, \nu)$ ($v \in S_\ell$, $1 \le i \le n$, $1 \le j \le q$ for some $q \ge 0$) such that:

(Vr1) *Global ring.* Γ_1^0 satisfies Mazur's condition Φ_ℓ (Theorem B.71); B is a complete Noetherian local $\mathcal{O}_1$-algebra with residue field finite over that of $\mathcal{O}_1$; D is a continuous determinant of dimension n on $B[\Gamma_1^0]$; $\hat{\psi}_{v,i}\colon D_v \to B^\times$ are continuous characters whose values on μ_v (Definition E.34) lie in the image of $\mathcal{O} \to B$; $f_1\colon B \to A$ is a surjective homomorphism of $\mathcal{O}$-algebras with $f_1 \circ D = \det \circ (\rho \circ h)$ and $f_1 \circ \hat{\psi}_{v,i} = \psi_{v,i}$; $s \in B$ with $f_1(s) = T$.

(Vr2) *Taylor–Wiles elements.* $\phi_j, \tau_j \in \Gamma_1^0$ with $\phi_j\tau_j = \tau_j\phi_j$, $h(\tau_j) = 1$; $U_{j,i}, y_{j,i} \in B$ with $f_1(y_{j,i}) = 0$, the $f_1(U_{j,1}), \dots, f_1(U_{j,n})$ pairwise distinct and $\det(X - \rho(h(\phi_j))) = \prod_i (X - f_1(U_{j,i}))$; and B is topologically generated as an $\mathcal{O}_1$-algebra by s, the $U_{j,i}$, $y_{j,i}$, the values $\hat{\psi}_{v,i}(g)$ and the coefficients of the characteristic polynomials $\chi_D(\gamma)$, $\gamma \in \Gamma_1^0$.

(Vr3) *Relation ideal.* $\mathcal{I}_1 \subseteq B[\Gamma_1^0]$ is the intersection over $k \ge 1$ and the open normal subgroups $H' \subseteq \Gamma_1^0$ of the two-sided ideals generated by: the Cayley–Hamilton ideal of D; $\mathfrak{m}_B^k \cdot 1$; $h' - 1$ ($h' \in H'$); and the following elements together with their images under *: $\prod_{i=1}^n (\phi_{1,v}(g_i) - \hat{\psi}_{v,i}(g_i))$ ($v \in S_\ell$, $g_i \in D_v$, $i = 1$ on the left); $\gamma - 1$ ($\gamma \in I_{1,u}$, $u \in \mathrm{St}$); $\prod_{i=1}^n (\phi_j - U_{j,i})$; $\prod_{k \ne i} (\phi_j - U_{j,k}) \cdot (\tau_j - 1 - y_{j,i})$ (products in increasing order of the index).

(Vr4) *Completion and coefficients.* $\hat{B}$ is the completion of $B_{\ker f_1}$ at its maximal ideal $\hat{\mathfrak{m}}$, and $\lambda\colon \hat{B} \to F$ is the ring homomorphism extending f_1, with $\ker\lambda = \hat{\mathfrak{m}}$. The ring $\mathcal{O}'$ is a complete discrete valuation ring with maximal ideal $\mathfrak{m}_{\mathcal{O}'}$ and a ring homomorphism $\iota\colon \mathcal{O}' \to \hat{B}$ making $\hat{B}$ a complete Noetherian local $\mathcal{O}'$-algebra, such that $\lambda \circ \iota$ is surjective onto F, the image of $\mathcal{O}_1 \to \hat{B}$ (hence that of $\mathcal{O}$) lies in $\iota(\mathcal{O}')$, the image of s lies in $\iota(\mathcal{O}')$, and every $a \in A$ is $f_1(b)$ for some $b \in B$ whose image in $\hat{B}$ lies in $\iota(\mathcal{O}')$.

(Vr5) *Coefficient algebra.* $\mathcal{A}$ is a commutative ring containing $\hat{B}$ as a subring, finitely generated as a $\hat{B}$-module, with a $\hat{B}$-submodule N such that $\mathcal{A} = \hat{B} \cdot 1 \oplus N$, $yy' \in \hat{\mathfrak{m}} \cdot 1$ for $y, y' \in N$, and $N = 0$ if $a = n$.

(Vr6) *The realisation.* $\nu\colon \Gamma_1^0 \to \mathrm{M}_n(\mathcal{A})$ is multiplicative with $\nu(1) = 1$; its B-linear extension to $B[\Gamma_1^0]$ (through $B \to \hat{B} \subseteq \mathcal{A}$) vanishes on $\mathcal{I}_1$; the $\hat{B}$-span of $\nu(\Gamma_1^0)$ is the set of matrices with entries in $\hat{B} \cdot 1$ at the positions in one block and in N at the other positions; $\nu(\gamma^*) = {}^t\nu(\gamma)$; the base change of D to $\mathcal{A}$ is $\det \circ \nu$; and if $\nu(\gamma)_{ij} - b \cdot 1 \in N$ with $b \in \hat{B}$, then $\lambda(b) = \rho(h(\gamma))_{ij}$.

(Vr7) *Thickness.* Every prime ideal Q of $\hat{B}$ such that $\kappa[\Gamma_1^0]$ modulo the two-sided ideal generated by the image of $\mathcal{I}_1$ is not semisimple, for some homomorphism $\hat{B} \to \kappa$ to a field with kernel Q, contains $\mathrm{Ann}_{\hat{B}}(N)$.

(Vr8) *Continuity.* There is a finitely generated B-submodule $\mathcal{P}_0 \subseteq \mathrm{M}_n(\mathcal{A})$ containing $\nu(\Gamma_1^0)$ such that for every $j \ge 1$ there is an open normal subgroup $V_j \subseteq \Gamma_1^0$ with $\nu(\gamma v) - \nu(\gamma) \in \mathfrak{m}_B^j \mathcal{P}_0$ for $\gamma \in \Gamma_1^0$, $v \in V_j$.

A **realisation of x over $\mathbf{V}$** is a realisation of x over $\mathbf{V}$ with coefficient ring some $\mathcal{O}_1$ as above.

(Tg) Tangent and test spaces. For a realisation put $\mathfrak{a} = \iota(\mathfrak{m}_{\mathcal{O}'})\hat{B} + \hat{\mathfrak{m}}^2 + \mathrm{ired}(N)$, where $\mathrm{ired}(N) \subseteq \hat{B}$ is the ideal generated by the b with $yy' = b \cdot 1$ for some $y, y' \in N$. For $y \in \mathcal{A}$ let $\mathrm{pr}_0(y) \in \hat{B}$ and $\mathrm{pr}_1(y) \in N$ be its components. Let

- Tp be the F-vector space of additive maps $\alpha\colon \hat{B} \to F$ with $\alpha(bb') = \lambda(b)\alpha(b') + \lambda(b')\alpha(b)$, $\alpha \circ \iota = 0$ and $\alpha(\mathrm{ired}(N)) = 0$;
- La be the F-vector space of additive maps $\mu\colon N \to F$ with $\mu(by) = \lambda(b)\mu(y)$ ($b \in \hat{B}$, $y \in N$);
- Ph be the F-vector space of additive maps $\Phi\colon N \to F$ with $\Phi(\iota(o)y) = \lambda(\iota(o))\Phi(y)$ ($o \in \mathcal{O}'$) and $\Phi(\mathfrak{a}N) = 0$;

and, for additive $\alpha\colon \hat{B} \to F$ and $\mu\colon N \to F$, the **first-order maps** $\Gamma_1^0 \to \mathrm{M}_n(F)$

$$\mathrm{al}(\alpha)(\gamma) = \big(\alpha(\mathrm{pr}_0(\nu(\gamma)_{ij}))\big)_{ij}\,\rho(h(\gamma))^{-1}, \qquad \mathrm{la}(\mu)(\gamma) = \big(\mu(\mathrm{pr}_1(\nu(\gamma)_{ij}))\big)_{ij}\,\rho(h(\gamma))^{-1}.$$

A family $(m_1, \dots, m_g)$ in N is **dual to** κ if $\mathrm{la}(\mu) - \sum_j \mu(m_j)\,(\kappa_j \circ h) \in \mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(F)$ for every $\mu \in \mathrm{La}$.

Proposition E.39. *Let $\mathscr{H} = (n, L, c, (\bar{v})_{v\in S_\ell}, \mathrm{St}, v_0, \bar{v}_0, (\bar{\chi}_a)_{1\le a\le n})$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}'$, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, and $J \neq B_n^{\mathrm{po}}$ an ideal of B_n^{po} which has classical levels. Let $h \ge 0$, and $x_0, \dots, x_h$ patchable curve points of B_n^{po} (for v_0, with the place $\bar{v}_0$) with homomorphisms $f_i\colon B_n^{\mathrm{po}} \to A_{k_i}$, either all of irreducible type or all of endoscopic type. Then there are curve points $x'_0, \dots, x'_h$ of B_n^{po} with homomorphisms $f'_i\colon B_n^{\mathrm{po}} \to A_{k'_i}$, over finite fields $k'_0, \dots, k'_h$ of one common cardinality, such that $\ker f'_i = \ker f_i$ for $0 \le i \le h$, and a patching system for J along $(x'_0, \dots, x'_h)$.*

Proof. Write $\mathcal{O} = \mathcal{O}'$, $B = B_n^{\mathrm{po}}$, $\mathbb{F}_{\mathcal{O}}$ for the residue field of $\mathcal{O}$, $\delta = n[L^+ : \mathbb{Q}]$ (written D in Definition E.37), and $x_i = (k_i, \rho_i, P_i, (\psi_{i,v,b}), f_i)$. Recall ℓ is odd.

Step 1: normalised points. Fix i. If x_i is of irreducible type, Proposition E.54 gives a finite field $k''_i \supseteq k_i$, an injective local homomorphism of $\mathcal{O}$-algebras $j_i\colon A_{k_i} \to A_{k''_i}$ making $A_{k''_i}$ a finite A_{k_i}-module, and a framed curve point $y_i = (k''_i, \rho''_i, 1_n, (\psi''_{i,v,b}), g_i)$, normalised of shape $(a_i, n - a_i)$ with $a_i = n$ by (Nm4); if x_i is of endoscopic type, Proposition E.53 gives the same with $1 \le a_i < n$. In both cases (Nm1)–(Nm3) hold: $g_i = j_i \circ f_i$ and $\det \circ \rho''_i = j_i \circ \det \circ \rho_i$; y_i satisfies (Pj1), (Np3) and (Np4); and y_i is spanning.

Step 2: Taylor–Wiles elements, the datum, and the extended points. By Proposition E.48, $\Gamma_{\mathscr{H}}$ satisfies Φ_ℓ. The points $y_0, \dots, y_h$ are spanning framed curve points, each normalised of some shape and satisfying (Np3); so Proposition E.50 gives $q \ge 0$, $\sigma_1, \dots, \sigma_q \in \Gamma'$ and, for each i, an extension $x'_i = (k'_i, \rho'_i, 1_n, (\psi'_{i,v,b}), f'_i)$ of y_i along some $j'_i\colon A_{k''_i} \to A_{k'_i}$, with $|k'_0| = \cdots = |k'_h|$, a Selmer basis κ'_i of x'_i such that $\{\sigma_1, \dots, \sigma_q\}$ detects (x'_i, κ'_i), and pairwise distinct $\alpha_{i,j,1}, \dots, \alpha_{i,j,n} \in A_{k'_i}$ with $\det(X - \rho'_i(\sigma_j)) = \prod_b (X - \alpha_{i,j,b})$. By Proposition E.48 there is a Taylor–Wiles datum $\mathcal{D}$ of size q for $\mathscr{H}$ with elements $\sigma_1, \dots, \sigma_q$; let H be its open normal subgroup. Then $(\alpha_{i,j,b})$ are eigenvalue data of x'_i along $\mathcal{D}$. Put $\lambda_i = j'_i \circ j_i\colon A_{k_i} \to A_{k'_i}$, an injective local homomorphism of $\mathcal{O}$-algebras making $A_{k'_i}$ a finite A_{k_i}-module. Then $f'_i = j'_i \circ g_i = \lambda_i \circ f_i$, so $\ker f'_i = \ker f_i$ as λ_i is injective. By the definition of an extension, x'_i is a spanning framed curve point normalised of shape $(a_i, n - a_i)$, and by (Et2) of Lemma E.41 it satisfies (Pj1) and (Np4), with $\det \circ \rho'_i = j'_i \circ \det \circ \rho''_i = \lambda_i \circ \det \circ \rho_i$. By (Et1) of Lemma E.41 (applied to x_i, λ_i and x'_i; x_i is patchable, and $a_i = n$ for irreducible type, $a_i < n$ for endoscopic type), x'_i is a patchable curve point of irreducible type if $a_i = n$ and of endoscopic type if $a_i < n$. Each $\kappa'_{i,j} \in Z^1_{\mathrm{ord}}(x'_i)$

has, for every $v \in S_\ell$, a matrix Y_v as in (Sd2); choosing these, κ'_i is a Selmer basis with local witnesses.

Step 3: $\rho'_i(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$. Fix i, write $A = A_{k'_i}$ and $\bar{c} = \pi_{\mathscr{H}}(c)$, so $\bar{c}^2 = 1$. The preimage under f'_i of the maximal ideal TA is a prime ideal of B with $B/f_i'^{-1}(TA)$ a subring of the finite field k'_i, hence a field; so it is the maximal ideal $\mathfrak{m}_B$, and $f'_i(\mathfrak{m}_B) \subseteq TA$. As $f'_i \circ D^{\mathrm{u}} = \det \circ \rho'_i$ and D^{u} reduces to $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$ modulo $\mathfrak{m}_B$, the characteristic polynomial of $\rho'_i(\gamma)$ modulo T is $\prod_a (X - \bar{\chi}_a(\gamma))$. For $h \in H$, (Tg1) gives $h \in \Gamma^0_{\mathscr{H}}$ and $\bar{\chi}_a(h) = 1$, so $\rho'_i(h)$ modulo T is unipotent; with $\ell^w \geq n$, $(\rho'_i(h) \bmod T)^{\ell^w} - 1 = (\rho'_i(h) \bmod T - 1)^{\ell^w} = 0$ in characteristic ℓ. For $m \geq 1$ let K_m be the set of $\gamma \in \Gamma^0_{\mathscr{H}}$ with $\rho'_i(\gamma) \equiv 1$ modulo T^m: an open normal subgroup of $\Gamma^0_{\mathscr{H}}$ (ρ'_i is continuous and $\mathrm{GL}_n(A/T^m A)$ is finite), and normal in $\Gamma_{\mathscr{H}} = \Gamma^0_{\mathscr{H}} \cup \bar{c}\Gamma^0_{\mathscr{H}}$, since for $\gamma \in K_m$, $\bar{c}\gamma\bar{c} = (\gamma^{-1})^*$ and $\rho'_i((\gamma^{-1})^*) = {}^t\rho'_i(\gamma^{-1}) \equiv 1$ (x'_i is normalised). For $h \in H$, $\rho'_i(h)^{\ell^w}$ lies modulo T^m in the kernel of $\mathrm{GL}_n(A/T^m A) \to \mathrm{GL}_n(k'_i)$, a group of order $|k'_i|^{n^2(m-1)}$, a power of ℓ; so $h^{\ell^{w'}} \in K_m$ for some w'. By the definition of PL (Definition 53.8, with $G = \Gamma_{\mathscr{H}}$), $\mathrm{PL}(H) \subseteq K_m$ for every m; so $\rho'_i(\gamma) \equiv 1$ modulo every T^m, i.e. $\rho'_i(\gamma) = 1$, for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$.

Step 4: the patched tower. J has classical levels, so Proposition E.136 gives automorphic patching data for J along $\mathcal{D}$ with exponent $e = n!$, with elements $\tilde{u}_{j,i} \in \mathcal{O}$. As k'_0 contains $\mathbb{F}_{\mathcal{O}}$, $|k'_0| = |\mathbb{F}_{\mathcal{O}}|^r$ for some $r \geq 1$; let $\mathcal{O}_1$ be an unramified extension of $\mathcal{O}$ of degree r: a complete discrete valuation ring, free of rank r over $\mathcal{O}$, with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathfrak{m}_{\mathcal{O}_1}$ and residue field of cardinality $|k'_i|$ for every i. Let $(\Pi, (\pi_N), \mathcal{U}, \bar{\theta}, c_\infty, (\Phi_j), (\mathrm{T}_j), (F_w))$ be limit objects for $\mathcal{D}$ as in Lemma E.42, fix $\tilde{c} \in \Pi$ with $\pi_\infty(\tilde{c}) = c_\infty$, and let $(R, \beta, X, f, I, e+1, (M_N^\natural), \mathcal{U})$ over $S = \Lambda[[y_{j,i}]]$, C^{sp}, u and π be the patched tower data (Definition E.37). By Proposition E.57, $\mathcal{T} = (R, \beta, X, f, I, e+1, (M_N^\natural), \mathcal{U})$ is an abstract patching tower over S with $s = nq$ patching variables $y_{j,i}$. By Definition E.37, C^{sp} with u is the eigenvalue algebra of $(\mathcal{O}_1, (\sigma_j), (\tilde{u}_{j,i}))$, and the residue field of $\mathcal{O}_1$ has cardinality $|k'_i|$ for every i. By Lemma E.40, B is topologically generated as an $\mathcal{O}$-algebra by the coefficients of the $\chi_{D^{\mathrm{u}}}(\gamma)$, $\gamma \in \Gamma^0_{\mathscr{H}}$, and the values $\psi^{\mathrm{d}}_{v,a}(g)$; so Proposition E.56 and Proposition E.134 apply to these data. Put $d = 1 + \delta$. We show that $(\mathcal{T}, d, C^{\mathrm{sp}}, u, \pi)$ is a patching system for J along $(x'_0, \dots, x'_h)$; the curve points x'_i have homomorphisms $f'_i \colon B \to A_{k'_i}$ over fields of one cardinality with $\ker f'_i = \ker f_i$ (Step 2), which then proves the statement.

Step 5: (Sys0)–(Sys3). π is surjective and $\pi(\beta(y_{j,i})) = 0$ for all j, i by (Wz1) of Proposition E.56: this is (Sys1). (Sys2) is (Wz2). (Sys0): for every i and j, applying f'_i to the coefficients of $\chi_{D^{\mathrm{u}}}(\sigma_j)$ gives $\chi_{f'_i \circ D^{\mathrm{u}}}(\sigma_j) = \chi_{\det \circ \rho'_i}(\sigma_j) = \det(X - \rho'_i(\sigma_j)) = \prod_b (X - \alpha_{i,j,b})$, a product of monic polynomials of degree 1 in $A_{k'_i}[X]$. (Sys3): let f' be a surjective lift of f'_i, i.e. a surjective ring homomorphism $f' \colon C^{\mathrm{sp}} \to A_{k'_i}$ with $f' \circ u = f'_i$ and $f'(z) = T$. The curve point x'_i has eigenvalue data along $\mathcal{D}$ and $|k'_i|$ is the residue cardinality of $\mathcal{O}_1$; so (Wz3) gives, for $\mathfrak{q} = \pi^{-1}(\ker f')$, $f \notin \mathfrak{q}$ and $\Lambda_{\mathfrak{p}}$ regular local of dimension $1 + \delta = d$ for $\mathfrak{p} = \{a \in \Lambda : \beta(a) \in \mathfrak{q}\}$.

Step 6: (Sys4). Fix i and a surjective lift f' of f'_i. We apply Corollary E.66 to the tuple $(\mathcal{T}, d, C^{\mathrm{sp}}, u, \pi)$ (which has the form required there), i, f', the point $x = x'_i$ of shape $(a_i, n - a_i)$ over $A = A_{k'_i}$, $\kappa = \kappa'_i$ and $\mathcal{D}$, and check its hypotheses. (i) $\pi(I) = 0$ by (Wz1); the $\bar{\chi}_a$ are pairwise distinct by (Rd4). (ii) x'_i is of irreducible type if $a_i = n$ and of endoscopic type if $a_i < n$ (Step 2). (iii) The hypotheses of Proposition E.97 (those of Proposition E.119 and more): $\mathcal{O}$ is a discrete valuation ring; x'_i is a framed curve point normalised of shape $(a_i, n - a_i)$, κ'_i a Selmer basis with local witnesses, and x'_i has eigenvalue data along $\mathcal{D}$ (Step 2); $\rho'_i(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$ (Step 3); x'_i satisfies (Pj1) and (Np4) and is spanning (Step 2); $\{\sigma_1, \dots, \sigma_q\}$ detects (x'_i, κ'_i) (Step 2). (iv) $\delta + nq \leq d + s - 1$: here $d + s - 1 = \delta + nq$. (v) The limit objects of Step 4 are as in the conclusion of Lemma E.42; let $\mathbf{V}_\infty$ be the limit level formed from them. (vi) Data on R/I: by Proposition E.134 (its hypotheses: $\ell \neq 2$; the data of Step 4; B topologically generated; x'_i

framed normalised with $|k_i'|$ the residue cardinality of $\mathcal{O}_1$ and with eigenvalue data along $\mathcal{D}$; κ_i' with local witnesses satisfying all hypotheses of Proposition E.97 by (iii); the surjective lift f'), R/I carries D, $(\hat{\psi}_{v,i})$, $(\phi_j, \tau_j, U_{j,i}, y_{j,i})$ and s such that, with $f_1 = f' \circ \bar{\pi}$, the clauses of (Vr1), (Vr2) concerning them hold over $\mathbf{V}_\infty$ for $\mathcal{O}_1$ (In2), and (Lv1), (Lv2) hold over $\mathbf{V}_\infty$ (In3). (vii) (Gl1), (Gl2) for every realisation $\mathfrak{R}$ of x_i' over $\mathbf{V}_\infty$ with coefficient ring $\mathcal{O}_1$ and these data (global ring R/I, determinant D, characters, Taylor–Wiles elements and s of (vi)): if $a_i < n$ and $\hat{Z}'$ is a prime of $\hat{B}$ whose preimage in R is stable for the system, i.e. contained in $\pi^{-1}(P'')$ for a prime P'' of C^{sp} with $u^{-1}(P'')$ stable, then $\mathrm{ired}(N) \not\subseteq \hat{Z}'$ by Lemma E.46: this is (Gl1). For a prime $\hat{Q}'$ of $\hat{B}$ whose preimage in R is $\pi^{-1}(P')$, Lemma E.133 gives (Tk1), which is the first half of (Gl2), and (Tk2), which gives the second half with κ an algebraic closure of the fraction field of $\hat{B}/\hat{Q}'$ and the natural homomorphism $\hat{B} \to \kappa$ with kernel $\hat{Q}'$. So Corollary E.66 gives the conclusion of (Sys4) for i and f'. As i and f' were arbitrary, (Sys4) holds, and $(\mathcal{T}, d, C^{\mathrm{sp}}, u, \pi)$ is a patching system for J along $(x_0', \dots, x_h')$. □

Lemma E.40. *Let $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ be a universal polarised ordinary determinant of rank n over a residual setting $(n, L, c, \Gamma, \Gamma^0, \pi, (D_v \supseteq I_v)_{v\in S_\ell}, (\bar{\chi}_a))$ over a coefficient ring $\mathcal{O}$, $B = B_n^{\mathrm{po}}$, and let $A \subseteq B$ be the $\mathcal{O}$-subalgebra generated by the elements $\Lambda_i(D^{\mathrm{u}})(\gamma)$ ($\gamma \in \Gamma^0$, $1 \le i \le n$) and $\psi_{v,a}^{\mathrm{d}}(g)$ ($v \in S_\ell$, $1 \le a \le n$, $g \in D_v$). Then $B = A + \mathfrak{m}_B^N$ for every $N \ge 1$; that is, B is topologically generated as an $\mathcal{O}$-algebra by these elements.*

Proof. Write $F = \mathbb{F}_{\mathcal{O}}$, $\mathfrak{m} = \mathfrak{m}_B$, $r\colon B \to F$ the residue map, and ϖ a uniformiser of $\mathcal{O}$. Every $b \in B$ has $r(b) = r(\tilde{b})$ for some $\tilde{b} \in \mathcal{O}$ (the residue field of B is F); so $B = \mathcal{O} + \mathfrak{m}$, and in particular $B = A + \mathfrak{m}$. Let $T \subseteq \mathfrak{m}$ be the set of elements $a - \tilde{a}$ with a one of the generators of A listed in the statement and $\tilde{a} \in \mathcal{O}$ with $r(a) = r(\tilde{a})$, together with $\varpi \cdot 1$. Then $T \subseteq A \cap \mathfrak{m}$.

Step 1: $\mathfrak{m} = TB + \mathfrak{m}^2$. Put $\mathfrak{n} = TB + \mathfrak{m}^2 \subseteq \mathfrak{m}$, an ideal containing ϖB, so $\mathfrak{m}/\mathfrak{n}$ is an F-vector space. Suppose $\mathfrak{n} \neq \mathfrak{m}$ and choose an F-linear $\delta_0\colon \mathfrak{m}/\mathfrak{n} \to F$ which is not zero; let $\delta\colon \mathfrak{m} \to F$ be its composite with the projection. Let $F[\epsilon] = F \oplus F\epsilon$, $\epsilon^2 = 0$, an object of $\mathrm{CNL}_{\mathcal{O}}$. Define $\phi_0, \phi_\delta\colon B \to F[\epsilon]$ by $\phi_0(b) = r(b)$ and $\phi_\delta(b) = r(b) + \delta(b - \tilde{b})\epsilon$, where $\tilde{b} \in \mathcal{O}$ is any element with $r(\tilde{b}) = r(b)$. This does not depend on $\tilde{b}$: two choices differ by an element of $\mathfrak{m}_{\mathcal{O}} = \varpi\mathcal{O}$, whose image lies in $\varpi B \subseteq \mathfrak{n}$. The map ϕ_δ is additive and $\mathcal{O}$-linear (δ is $\mathcal{O}$-linear, $\mathcal{O}$ acting on F through its residue field, since $\varpi\mathfrak{m} \subseteq \mathfrak{n}$), $\phi_\delta(1) = 1$, and it is multiplicative:

Both are local homomorphisms of $\mathcal{O}$-algebras, i.e. morphisms of $\mathrm{CNL}_{\mathcal{O}}$, and they differ: for $b \in \mathfrak{m}$ with $\delta(b) \neq 0$ (take $\tilde{b} = 0$), $\phi_\delta(b) = \delta(b)\epsilon \neq 0 = \phi_0(b)$. For $\phi \in \{\phi_0, \phi_\delta\}$ the base change $(\phi \circ D^{\mathrm{u}}, (\phi \circ \psi_{v,a}^{\mathrm{d}}))$ is a polarised ordinary determinant of rank n to $F[\epsilon]$: continuity, the residual conditions and the identities (Od1)–(Od3) are preserved by base change along a morphism of $\mathrm{CNL}_{\mathcal{O}}$ (the characteristic polynomial and the trace of the base change are the images of those of D^{u}, and ϕ is an $\mathcal{O}$-algebra map). On the generators of A the two maps agree: for a a generator, $\phi_0(a) = r(a)$ and $\phi_\delta(a) = r(a) + \delta(a - \tilde{a})\epsilon = r(a)$, as $a - \tilde{a} \in T \subseteq \ker\delta$. Hence $\chi_{\phi_0 \circ D^{\mathrm{u}}}(\gamma) = \chi_{\phi_\delta \circ D^{\mathrm{u}}}(\gamma)$ for all $\gamma \in \Gamma^0$ (their coefficients are the images of the $\Lambda_i(D^{\mathrm{u}})(\gamma)$), so $\phi_0 \circ D^{\mathrm{u}} = \phi_\delta \circ D^{\mathrm{u}}$ by (Ch1) of Theorem B.83; and $\phi_0 \circ \psi_{v,a}^{\mathrm{d}} = \phi_\delta \circ \psi_{v,a}^{\mathrm{d}}$. By the uniqueness in the universal property of B (Definition 50.2), $\phi_0 = \phi_\delta$, a contradiction. So $\mathfrak{m} = TB + \mathfrak{m}^2$.

Step 2: approximation. We show $B = A + \mathfrak{m}^N$ by induction on N; $N = 1$ was shown. Assume $B = A + \mathfrak{m}^N$. The ideal $\mathfrak{m}^N$ is generated by the products $b_1 \cdots b_N$ with $b_k \in \mathfrak{m}$; writing each $b_k \in TB + \mathfrak{m}^2$ and expanding, $\mathfrak{m}^N \subseteq T^N B + \mathfrak{m}^{N+1}$, where T^N is the set of products of N elements of T. For $t \in T^N$ and $b \in B = A + \mathfrak{m}$, write $b = a + m$; then $tb = ta + tm$ with $ta \in A$ (as $T \subseteq A$) and $tm \in \mathfrak{m}^{N+1}$ (as $T \subseteq \mathfrak{m}$). So $\mathfrak{m}^N \subseteq A + \mathfrak{m}^{N+1}$ and $B = A + \mathfrak{m}^N \subseteq A + \mathfrak{m}^{N+1}$. □

Lemma E.41. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ and B the ring of a universal polarised ordinary determinant over $\mathscr{H}$.*

(Et1) *Let $x = (k, \rho, P, (\psi_{v,b}), f)$ be a patchable curve point of B, $j\colon A_k \to A_{k'}$ an injective local homomorphism of $\mathcal{O}$-algebras making $A_{k'}$ a finite A_k-module, and $x' = (k', \rho', 1_n, (\psi'_{v,b}), f')$ a curve point of B, normalised of shape $(a, n-a)$, satisfying (Pj1) and (Np4), with $\det\circ\rho' = j\circ\det\circ\rho$ as determinants on $\Gamma^0_{\mathscr{H}}$. If x is of irreducible type and $a = n$, then x' is a patchable curve point of irreducible type. If x is of endoscopic type and $a < n$, then x' is a patchable curve point of endoscopic type.*

(Et2) *Let x' be a framed curve point of B, normalised of some shape, satisfying (Pj1) and (Np4). Then every extension of x' satisfies (Pj1) and (Np4), and $\det\circ\rho'' = j'\circ\det\circ\rho'$ for the extension x'' along j', with representation ρ''.*

Proof. (Et1), patchability. x' is a curve point satisfying (Pj1) by hypothesis. As j is injective and local between the domains A_k, $A_{k'}$, it extends to an embedding $F_k \to F_{k'}$, again written j; as $A_{k'}$ is a finite A_k-module, $F_{k'}$ is a finite extension of $j(F_k)$. For $\gamma \in \Gamma^0_{\mathscr{H}}$ the characteristic polynomial of $\rho'(\gamma)$ is the image under j of that of $\rho(\gamma)$, as $\det\circ\rho' = j\circ\det\circ\rho$. (Pj2): an open subset of $\Gamma^0_{\mathscr{H}}$ meeting Γ' contains, by (Pj2) for x, some $\sigma \in \Gamma'$ whose characteristic polynomial for ρ is separable over F_k, i.e. has non-zero discriminant; its image under the field embedding j has the image discriminant, non-zero, so the characteristic polynomial of $\rho'(\sigma)$ is separable over $F_{k'}$. (Pj3): if $X \in \mathrm{M}_n(F_{k'})$ satisfies $\chi_{\mathrm{cyc}}(\gamma)\rho'(\gamma)X = X\rho'(\gamma)$ for $\gamma \in \Delta_0$, then for s large $T^sX \in \mathrm{M}_n(A_{k'})$ satisfies the same identities, so $T^sX = 0$ by (Np4) and $X = 0$.

(Et1), types. Let Ω be an algebraic closure of $F_{k'}$; since $F_{k'}$ is algebraic over $j(F_k)$, Ω is also an algebraic closure of F_k (through j), and we use it as $\bar{F}_k$ and $\bar{F}_{k'}$. Put $V = \rho \otimes \Omega$ and $V' = \rho' \otimes \Omega$, restricted to Γ'. Their determinants on Γ' agree. The direct sum of the Jordan–Hölder constituents of a finite-dimensional representation (its semisimplification) has the same determinant (in a basis adapted to a composition series the matrices are block upper triangular); by the uniqueness in (Ch3), applied to the group Γ', the semisimplifications of V and V' are isomorphic, i.e. V and V' have the same Jordan–Hölder constituents with multiplicities. Irreducible type ($a = n$): V is irreducible, so V' has exactly one constituent and is irreducible; x' is of irreducible type. Endoscopic type ($a < n$): let Q, r_1, r_2, P_1, P_2 be as in the definition for x. Then $V \cong (r_1 \oplus r_2) \otimes \Omega|_{\Gamma'}$ has exactly two constituents $r_1 \otimes \Omega|_{\Gamma'}$, $r_2 \otimes \Omega|_{\Gamma'}$, and these are not isomorphic: an isomorphism would be a non-zero $Y \in \mathrm{M}_{b\times a}(\Omega)$ (with $a = b$) such that $Yr_1(\sigma) = r_2(\sigma)Y$ for $\sigma \in \Gamma'$, which the definition excludes. As x' is normalised of shape $(a, n-a)$ with $a < n$, $\rho' = \mathrm{diag}(r'_1, r'_2)$ with blocks r'_1, r'_2 of sizes $a, n-a \geq 1$, and the constituents of V' are those of $r'_1 \otimes \Omega|_{\Gamma'}$ together with those of $r'_2 \otimes \Omega|_{\Gamma'}$. Each of the two contributes at least one and together there are exactly two; so $r'_1 \otimes \Omega|_{\Gamma'}$ and $r'_2 \otimes \Omega|_{\Gamma'}$ are irreducible and are the two non-isomorphic constituents. By Schur's lemma, 0 is the only $Y \in \mathrm{M}_{(n-a)\times a}(\Omega)$ with $Yr'_1(\sigma) = r'_2(\sigma)Y$ for all $\sigma \in \Gamma'$. Since x' is normalised, $\rho'(\gamma^*) = {}^t\rho'(\gamma)$, so $r'_i(\gamma^*) = {}^t r'_i(\gamma)$, which is the polarisation condition with $P_i = 1$; with $Q = 1_n$ the definition of endoscopic type holds for x' (over $F_{k'}$).

(Et2). Let x'' be the extension of $x' = (k', \rho', 1_n, (\psi'_{v,b}), f')$ along $j'\colon A_{k'} \to A_{k''}$, so $\rho'' = j'\circ\rho'$, $\psi''_{v,b} = j' \circ \psi'_{v,b}$, and $\det\circ\rho'' = j' \circ \det\circ\rho'$. (Pj1): j' is an injective homomorphism of $\mathcal{O}$-algebras and $\chi_{\mathrm{cyc}}|_{D_v}$ takes values in $\mathcal{O}^\times$, so $j' \circ \psi'_{v,a} \neq j' \circ \psi'_{v,b}$ and $j' \circ \psi'_{v,a} \neq (j' \circ \psi'_{v,b})\chi_{\mathrm{cyc}}|_{D_v}$ whenever the same holds without j'. (Np4): $A_{k''}$ is a finitely generated module over the discrete valuation ring $A_{k'}$ (through j'), torsion-free as j' is injective and $A_{k''}$ is a domain; so it is free, with a basis $e_1, \ldots, e_m$. Write $Z \in \mathrm{M}_n(A_{k''})$ as $Z = \sum_r j'(Z_r)e_r$ with $Z_r \in \mathrm{M}_n(A_{k'})$. Since $\rho''(\gamma) = j'(\rho'(\gamma))$ and $\chi_{\mathrm{cyc}}(\gamma) \in \mathcal{O}^\times$, the identity $\chi_{\mathrm{cyc}}(\gamma)\rho''(\gamma)Z = Z\rho''(\gamma)$ for $\gamma \in \Delta_0$ holds if and only if $\chi_{\mathrm{cyc}}(\gamma)\rho'(\gamma)Z_r = Z_r\rho'(\gamma)$ for every r; by (Np4) for x' all $Z_r = 0$, so $Z = 0$. □

Lemma E.42. *Let a Taylor–Wiles datum of size q for a rank-n Hecke datum $\mathscr{H}$ be given.*

Put $\bar\Gamma = \Gamma_{\mathscr H}/\mathrm{PL}(H)$, $\bar\Gamma_N = \Gamma_N/\mathrm{PL}(H_N)$, *let* $\bar h_N\colon \bar\Gamma_N \to \bar\Gamma$ *be induced by* h_N, *and write* $\bar x$ *for images in these quotients. For* $w \in S_\ell \cup \mathrm{St}$ *let* D_w *be the decomposition group* ($D_{\bar u} \cap G_{L^+}$ *for* $u \in \mathrm{St}$) *and* $\bar\phi_{N,w}\colon D_w \to \bar\Gamma_N$ *the map induced by* π^{Q_N}. *Then there are a topologically finitely generated profinite group* Π, *continuous surjections* $\pi_N\colon \Pi \to \bar\Gamma_N$, *a non-principal ultrafilter* $\mathcal U$ *on* $\mathbb N$ *(giving* $\bar\Gamma_\infty = \Pi/K_\infty$ *and* π_∞ *as in Lemma E.43), a continuous surjection* $\bar\theta\colon \bar\Gamma_\infty \to \bar\Gamma$, *elements* $c_\infty, \Phi_j, \mathrm{T}_j \in \bar\Gamma_\infty$ *and continuous homomorphisms* $F_w\colon D_w \to \bar\Gamma_\infty$ *such that:*

Proof. Construction. By Lemma E.44 every $\bar\Gamma_N$ is topologically generated by $d = r+s$ elements; let Π be the free profinite group on d generators and π_N a continuous homomorphism sending the free generators to such generators (onto: its image is closed and dense). Let $\mathcal U$ be a non-principal ultrafilter, and K_∞, π_∞ as in Lemma E.43. The maps $\theta_N = \bar h_N \circ \pi_N\colon \Pi \to \bar\Gamma$ are onto and kill $\ker\pi_N$; by (U3) they have a $\mathcal U$-limit θ, onto and killing K_∞, which induces $\bar\theta$. In particular $\bar\Gamma$ is topologically finitely generated. Choose lifts $\tilde c_N, \tilde\phi_{N,j}, \tilde t_{N,j} \in \Pi$ of $\bar c_N, \bar\Phi_{N,j}, \bar{\mathrm{T}}_{N,j}$, let $\tilde c, \tilde\phi_j, \tilde t_j$ be their $\mathcal U$-limits (U2), and $c_\infty, \Phi_j, \mathrm{T}_j$ their images. For w, let $D'_w = D_w \cap \pi_{\mathscr H}^{-1}(H)$ (open normal in D_w) and P_w the kernel of the map from D'_w onto its maximal pro-ℓ quotient (closed, characteristic in D'_w, so normal in D_w). Since $\bar\phi_{N,w}(D'_w) \subseteq \bar H_N$, a pro-$\ell$ group (Lemma E.45 (Pl1)), $\bar\phi_{N,w}(P_w) = 1$. $D_w \subseteq G_L$ satisfies Φ_ℓ (Tg6), so D'_w/P_w is a pro-ℓ group with finitely many continuous homomorphisms to $\mathbb Z/\ell$, hence topologically finitely generated (Burnside basis theorem, as in Lemma E.44), and so is D_w/P_w (add coset representatives). (U4) gives F_w.

(L1). (i) is (U1), (ii) is (U3), (iii) is (U2) and (iv) is (U4); a finite intersection of sets in $\mathcal U$ is in $\mathcal U$.

(L2). Fix an open normal subgroup Y of $\bar\Gamma$ and put $V = \theta^{-1}(Y)$. For $\mathcal U$-many N, $\theta \equiv \theta_N \bmod Y$ and $\tilde c \in \tilde c_N V$, so $\theta(\tilde c) \equiv \theta(\tilde c_N) \equiv \theta_N(\tilde c_N) = \bar c \bmod Y$; similarly $\theta(\tilde t_j) \equiv \bar h_N(\bar{\mathrm{T}}_{N,j}) = 1$ (Tg4) and $\theta(\tilde\phi_j) \equiv \bar h_N(\bar\Phi_{N,j}) \bmod Y$, while $\bar h_N(\bar\Phi_{N,j}) \equiv \bar\sigma_j \bmod Y$ for all large N by (Tg3) (the preimage of Y in $\Gamma_{\mathscr H}$ is open normal and contains $\mathrm{PL}(H)$), hence for $\mathcal U$-many N ($\mathcal U$ is non-principal). As Y is arbitrary, $\bar\theta(c_\infty) = \bar c$, $\bar\theta(\mathrm{T}_j) = 1$, $\bar\theta(\Phi_j) = \bar\sigma_j$. The $\mathcal U$-limit of $\tilde c_N^2 \in \ker\pi_N$ is $\tilde c^2$, so $\tilde c^2 \in K_\infty$ by (U2): $c_\infty^2 = 1$. For $y \in D_w$ and g, g' as in (iv) for V: $\theta(g') \equiv \theta(g) \equiv \theta_N(g) = \bar h_N\bar\phi_{N,w}(y) = \overline{\pi_{\mathscr H}(y)} \bmod Y$; so $\bar\theta F_w(y) = \overline{\pi_{\mathscr H}(y)}$.

Commuting. Fix an open normal subgroup V of Π, and let ℓ^a be the largest power of ℓ dividing $\#(\Pi/V)$. In $\bar\Gamma_N$, (Tg4) gives $\bar\Phi_{N,j}^{-1}\bar{\mathrm{T}}_{N,j}\bar\Phi_{N,j} = \bar{\mathrm{T}}_{N,j}^{q_{N,j}}$, and $\bar{\mathrm{T}}_{N,j} \in \bar H_N$ (as $h_N(\mathrm{T}_{N,j}) = 1 \in H$). The image of $\bar H_N$ in $\bar\Gamma_N/\pi_N(V)$, a quotient of Π/V, is an ℓ-group of order dividing ℓ^a; as $\ell^N \mid q_{N,j} - 1$ (Tg2), for $N \ge a$ we get $\bar{\mathrm{T}}_{N,j}^{q_{N,j}-1} \in \pi_N(V)$, so $\tilde\phi_{N,j}^{-1}\tilde t_{N,j}\tilde\phi_{N,j}\tilde t_{N,j}^{-1} \in (\ker\pi_N)V$. For $\mathcal U$-many N ($N \ge a$, (i), and $\tilde\phi_j \in \tilde\phi_{N,j}V$, $\tilde t_j \in \tilde t_{N,j}V$) this gives $\tilde\phi_j^{-1}\tilde t_j\tilde\phi_j\tilde t_j^{-1} \in K_\infty V$. As V is arbitrary and K_∞ is closed, $\Phi_j\mathrm{T}_j = \mathrm{T}_j\Phi_j$.

The kernel. Let $R \subseteq \Pi$ be the closure of $\langle\langle \tilde t_1, \dots, \tilde t_q\rangle\rangle K_\infty$; we show $\ker\theta = R$, which gives the last claim. $R \subseteq \ker\theta$ by the above. In $\bar\Gamma_N$, $\ker\bar h_N$ is the closed normal subgroup generated by the $\bar{\mathrm{T}}_{N,j}$ ((Tg4); the generators from $\mathrm{PL}(H_N)$ are trivial there), so for every open normal V, $(\ker\theta_N)V = \langle\langle \tilde t_{N,j}\rangle\rangle(\ker\pi_N)V$, which for $\mathcal U$-many N equals $\langle\langle\tilde t_j\rangle\rangle K_\infty V = RV$. Hence $[\bar\Gamma : \theta_N(V)] = [\Pi : (\ker\theta_N)V] = [\Pi : RV]$ for $\mathcal U$-many N; as $\bar\Gamma$ is topologically finitely generated,

it has finitely many open subgroups of this index, so $\theta_N(V) = Y_V$ for one Y_V and $\mathcal{U}$-many N. Let $x \in \ker\theta$. For $\mathcal{U}$-many N, $\theta_N(x) \in Y_V = \theta_N(V)$ (by (ii) with $Y = Y_V$), so $x \in (\ker\theta_N)V = RV$. Hence $x \in \bigcap_V RV = R$. □

Lemma E.43. *Let Π be a topologically finitely generated profinite group, $(\Gamma_N)_{N\geq 1}$ profinite groups with continuous surjections $\pi_N\colon \Pi \to \Gamma_N$, and $\mathcal{U}$ an ultrafilter on $\mathbb{N}$. For an open normal subgroup V of Π, the subgroup $(\ker\pi_N)V$ takes only finitely many values; let W_V be the one with $\{N :\ (\ker\pi_N)V = W_V\} \in \mathcal{U}$, and put $K_\infty = \bigcap_V W_V$, $\bar\Gamma_\infty = \Pi/K_\infty$, $\pi_\infty\colon \Pi \to \bar\Gamma_\infty$. Then:*

(U1) *K_∞ is a closed normal subgroup, and $K_\infty V = W_V$ for every open normal V; so $\{N : (\ker\pi_N)V = (\ker\pi_\infty)V\} \in \mathcal{U}$;*

(U2) *for every sequence (g_N) in Π there is $g \in \Pi$ with $\{N :\ g_N \in gV\} \in \mathcal{U}$ for every open normal V (a $\mathcal{U}$-limit); if $g_N \in \ker\pi_N$ for $\mathcal{U}$-many N, then $g \in K_\infty$;*

(U3) *for every profinite group Q and continuous homomorphisms $\theta_N\colon \Pi \to Q$ there is a continuous homomorphism $\theta\colon \Pi \to Q$ with $\{N :\ \theta_N \equiv \theta \bmod Y\} \in \mathcal{U}$ for every open normal Y of Q; if every θ_N is onto, so is θ; if $\theta_N(\ker\pi_N) = 1$ for $\mathcal{U}$-many N, then $\theta(K_\infty) = 1$;*

(U4) *for every profinite group Y, closed normal subgroup $P \subseteq Y$ with Y/P topologically finitely generated, and continuous homomorphisms $f_N\colon Y \to \Gamma_N$ with $f_N(P) = 1$, there is a continuous homomorphism $F\colon Y \to \bar\Gamma_\infty$ with $F(P) = 1$ such that for every open normal V of Π, for $\mathcal{U}$-many N: for every $y \in Y$ there are $g, g' \in \Pi$ with $\pi_N(g) = f_N(y)$, $\pi_\infty(g') = F(y)$ and $g^{-1}g' \in V$.*

Proof. A topologically finitely generated profinite group has only finitely many continuous homomorphisms to a given finite group (they are determined by the images of finitely many generators). In particular Π/V is finite and the subgroups $(\ker\pi_N)V \supseteq V$ correspond to subgroups of Π/V; as $\mathcal{U}$ is an ultrafilter, exactly one value occurs on a set in $\mathcal{U}$. If $V' \subseteq V$, then $(\ker\pi_N)V'V = (\ker\pi_N)V$, so $W_{V'}V = W_V$ (intersect the two sets in $\mathcal{U}$).

(U1) K_∞ is an intersection of closed normal subgroups. We have $K_\infty V \subseteq W_V$. Let $x \in W_V$. For open normal $V' \subseteq V$, $x \in W_{V'}V$, so the closed set $xV \cap W_{V'}$ is non-empty; these sets decrease as V' decreases and every finite family of them contains the one for the intersection of the V'; by compactness some w lies in all of them, i.e. $w \in xV \cap \bigcap_{V'\subseteq V} W_{V'}$, and $\bigcap_{V'\subseteq V} W_{V'} = K_\infty$ (for arbitrary V'', $W_{V''} \supseteq W_{V''\cap V}$). So $x \in K_\infty V$.

(U2) The $\mathcal{U}$-limit exists in the compact Hausdorff space Π: the images of g_N in each finite Π/V have a $\mathcal{U}$-limit, compatible in V. If $g_N \in \ker\pi_N$ for $\mathcal{U}$-many N, then for each V and $\mathcal{U}$-many N, $g \in g_N V \subseteq (\ker\pi_N)V = W_V$; so $g \in K_\infty$.

(U3) For each open normal Y of Q the composites $\Pi \to Q/Y$ lie in a finite set, so one of them, θ_Y, occurs for $\mathcal{U}$-many N; the θ_Y are compatible and define $\theta\colon \Pi \to \varprojlim Q/Y = Q$. If all θ_N are onto, every θ_Y is onto, hence $\theta(\Pi)$, compact and dense, is Q. If $\theta_N(\ker\pi_N) = 1$ for $\mathcal{U}$-many N: given Y, let $V = \theta^{-1}(Y)$ (open normal); for $\mathcal{U}$-many N we have $\theta_N \equiv \theta \bmod Y$, $\theta_N(\ker\pi_N) = 1$ and $(\ker\pi_N)V = K_\infty V$, so for $k \in K_\infty$, $k = k'v$ with $\pi_N(k') = 1$, and $\theta(k) \equiv \theta_N(k')\theta_N(v) \equiv \theta(v) \equiv 1 \bmod Y$. Hence $\theta(K_\infty) = 1$.

(U4) Let $y_1, \dots, y_t \in Y$ have images generating Y/P topologically, let $\hat F_t$ be the free profinite group on $x_1, \dots, x_t$ and $\epsilon\colon \hat F_t \to Y/P$, $x_i \mapsto y_i P$, which is onto; let $R = \ker\epsilon$. Choose $g_{i,N} \in \Pi$ with $\pi_N(g_{i,N}) = f_N(y_i)$, let g_i be their $\mathcal{U}$-limits (U2), and let $\Psi_N, \Psi\colon \hat F_t \to \Pi$ be the homomorphisms with $x_i \mapsto g_{i,N}$, resp. g_i. For each open normal V, $\Psi_N \equiv \Psi \bmod V$ for $\mathcal{U}$-many N (the generators agree modulo V). For $w \in R$, $\pi_N\Psi_N(w) = \bar f_N(\epsilon(w)) = 1$ ($\bar f_N$ induced on Y/P), so

$\Psi(w) \in (\ker \pi_N)V = W_V$ for $\mathcal{U}$-many N, hence $\Psi(w) \in K_\infty$. So $\pi_\infty \circ \Psi$ kills R and induces a continuous $\bar{F}\colon Y/P \to \bar{\Gamma}_\infty$; put $F(y) = \bar{F}(yP)$. Given V, for $\mathcal{U}$-many N with $\Psi_N \equiv \Psi \bmod V$: for $y \in Y$ choose w with $\epsilon(w) = yP$ and take $g = \Psi_N(w)$, $g' = \Psi(w)$; then $\pi_N(g) = f_N(y)$, $\pi_\infty(g') = F(y)$ and $g^{-1}g' \in V$. □

Lemma E.44. *Let a Taylor–Wiles datum for a rank-n Hecke datum $\mathscr{H}$ be given, with H, b and the levels Γ_N, $H_N = h_N^{-1}(H)$. Put $\bar{\Gamma}_N = \Gamma_N/\mathrm{PL}(H_N)$ and $\bar{H}_N = H_N/\mathrm{PL}(H_N)$, let r be the largest integer with $\ell^r \le b$, and put $s = [\Gamma_{\mathscr{H}} : H]$. Then for every N, $\bar{H}_N$ is a pro-ℓ group topologically generated by r elements, and $\bar{\Gamma}_N$ is topologically generated by $r + s$ elements.*

Proof. By Lemma E.45 (Pl1) (with $G = \Gamma_N$ and the open normal subgroup H_N), $\mathrm{PL}(H_N)$ is a closed normal subgroup of Γ_N contained in H_N and $\bar{H}_N$ is pro-ℓ. Every continuous homomorphism $\bar{H}_N \to \mathbb{Z}/\ell$ comes from one of H_N, and there are at most b of these (Tg5). The Frattini quotient $\bar{H}_N/\Phi(\bar{H}_N)$ of the pro-ℓ group $\bar{H}_N$ is an $\mathbb{F}_\ell$-vector space whose dual is $\mathrm{Hom}(\bar{H}_N, \mathbb{Z}/\ell)$, so it has dimension at most r; by the Burnside basis theorem for pro-ℓ groups (a subset generates topologically iff its image generates the Frattini quotient), $\bar{H}_N$ is topologically generated by r elements. Since h_N is onto and $H_N = h_N^{-1}(H)$, $\bar{\Gamma}_N/\bar{H}_N \cong \Gamma_N/H_N \cong \Gamma_{\mathscr{H}}/H$ has order s; adding representatives of the s cosets to r generators of $\bar{H}_N$ gives $r+s$ topological generators of $\bar{\Gamma}_N$. □

Lemma E.45. *Let ℓ be a prime, G a profinite group and $H \subseteq G$ an open normal subgroup. Then:*

(Pl1) $\mathrm{PL}(H)$ *is a closed normal subgroup of G contained in H, equal to the intersection of the open normal subgroups of H of ℓ-power index; in particular $H/\mathrm{PL}(H)$ is a pro-ℓ group;*

(Pl2) *if $\Gamma' \subseteq G$ is a subgroup containing H, M a finite abelian group of ℓ-power order with an action of Γ' that is trivial on $\mathrm{PL}(H)$, and $z\colon \Gamma' \to M$ a continuous map with $z(\gamma\gamma') = z(\gamma) + \gamma z(\gamma')$, then z vanishes on $\mathrm{PL}(H)$;*

(Pl3) *if $h\colon G' \to G$ is a continuous surjective homomorphism of profinite groups, then*

$$h(\mathrm{PL}(h^{-1}(H))) \subseteq \mathrm{PL}(H).$$

Proof. Let $\mathcal{U}$ be the set of open normal subgroups U of G such that every $x \in H$ has some $x^{\ell^e} \in U$; thus $\mathrm{PL}(H) = \bigcap \mathcal{U}$, a closed normal subgroup of G. For $U \in \mathcal{U}$ every element of the finite group $H/(H \cap U)$ has ℓ-power order, so (Cauchy) $[H : H \cap U]$ is a power of ℓ.

(Pl1). Let N be an open normal subgroup of H of ℓ-power index. As H is open and normal in G, the conjugates gNg^{-1} ($g \in G$) are finitely many open normal subgroups of H of the same index; their intersection N_G is open, normal in G, contained in N, and H/N_G embeds into $\prod H/gNg^{-1}$, an ℓ-group; so $N_G \in \mathcal{U}$. Conversely, for $U \in \mathcal{U}$, $U \cap H$ is an open normal subgroup of H of ℓ-power index. Hence $\mathcal{U}$ contains members inside H, so $\mathrm{PL}(H) \subseteq H$, and $\mathrm{PL}(H) = \bigcap_{U\in\mathcal{U}}(U \cap H)$ is the intersection of the open normal subgroups of H of ℓ-power index. The quotients of $H/\mathrm{PL}(H)$ by the images of these subgroups are ℓ-groups and these images form a basis of open neighbourhoods of 1, so $H/\mathrm{PL}(H)$ is pro-ℓ.

(Pl2). Write $P = \mathrm{PL}(H) \subseteq H \subseteq \Gamma'$. As P acts trivially on M, $z|_P$ is a homomorphism. For $x \in H$, $y \in P$, since $xyx^{-1} \in P$ acts trivially and $z(x) + x\,z(x^{-1}) = z(1) = 0$,

$$z(xyx^{-1}) = z(x) + x\,z(y) + xy\,z(x^{-1}) = z(x) + x\,z(y) + (xyx^{-1})\,x\,z(x^{-1}) = x\,z(y).$$

So $K = \ker(z|_P)$ is normal in H; it is closed (z continuous, M discrete), and P/K embeds into M, a finite ℓ-group. We show that every open normal subgroup $W \supseteq K$ of H has ℓ-power index.

Let $\bar H = H/K$, $\bar P = P/K$ (a finite normal ℓ-subgroup), $\bar W = W/K$, and choose an open normal subgroup $\bar N$ of $\bar H$ with $\bar N \cap \bar P = \{1\}$ (the open normal subgroups of the profinite group $\bar H$ form a basis at 1, and $\bar P$ is finite). Then

$$[\bar H : \bar N \cap \bar W] = [\bar H : (\bar N \cap \bar W)\bar P] \cdot [(\bar N \cap \bar W)\bar P : \bar N \cap \bar W],$$

where the first factor is the index of an open subgroup of $\bar H/\bar P \cong H/P$, a pro-ℓ group by (Pl1), hence a power of ℓ (an open subgroup of a pro-ℓ group contains an open normal subgroup of ℓ-power index), and the second factor equals $\#\bar P$ because $\bar P \cap \bar N \cap \bar W = \{1\}$. So $[H : W] = [\bar H : \bar W]$ divides a power of ℓ. As K is closed and normal in the profinite group H, K is the intersection of the open normal subgroups W of H containing it; each has ℓ-power index and therefore contains P by (Pl1). Hence $K = P$, i.e. z vanishes on P.

(Pl3). Let $H' = h^{-1}(H)$, open and normal in G'. For $U \in \mathcal{U}$, $h^{-1}(U)$ is open and normal in G', and every $x \in H'$ has $h(x)^{\ell^e} \in U$ for some e, i.e. $x^{\ell^e} \in h^{-1}(U)$. So $\mathrm{PL}(H') \subseteq \bigcap_{U\in\mathcal{U}} h^{-1}(U) = h^{-1}(\mathrm{PL}(H))$. □

Lemma E.46. *In the situation of Proposition E.134, let x have shape $(a, n-a)$ with $a < n$, and let $\mathfrak{R}$ be a realisation of x over $\mathbf{V}_\infty$ whose global ring and determinant are R/I and the determinant D of Proposition E.134. Let $\hat Z'$ be a prime ideal of $\hat B$ whose preimage $\mathfrak{z}$ in R (along $R \to R/I \to \hat B$) is contained in $\pi^{-1}(P'')$ for a prime ideal P'' of C^{sp} such that $u^{-1}(P'')$ is a stable prime of B. Then* $\mathrm{ired}(N) \not\subseteq \hat Z'$.

Proof. Step 1: a discriminant criterion. Let A be a commutative ring, G a group, D' an A-valued determinant of dimension n on G, $\mathfrak{p}$ a prime ideal of A and $\bar\kappa$ an algebraic closure of the fraction field of $A/\mathfrak{p}$. We show: the base change $D'_{\bar\kappa}$ of D' to $\bar\kappa$ is $\det\circ r$ for an irreducible $r\colon G \to \mathrm{GL}_n(\bar\kappa)$ if and only if there are $g_1, \dots, g_{n^2} \in G$ with $\delta = \det\big(\mathrm{tr}_{D'}(g_i g_j)\big)_{i,j} \notin \mathfrak{p}$. By (Ch3) of Theorem B.83, $D'_{\bar\kappa} = \det\circ r$ for some representation r, and the image of $\mathrm{tr}_{D'}(g)$ in $\bar\kappa$ is $\mathrm{tr}\, r(g)$; so the image of δ is $\det\big(\mathrm{tr}(r(g_i)r(g_j))\big)$. If r is irreducible, the $\bar\kappa$-span of $r(G)$ is $\mathrm{M}_n(\bar\kappa)$ (Burnside), so some $r(g_1), \dots, r(g_{n^2})$ form a basis, and as the trace form $(X, Y) \mapsto \mathrm{tr}(XY)$ on $\mathrm{M}_n(\bar\kappa)$ is non-degenerate, the image of δ is non-zero, i.e. $\delta \notin \mathfrak{p}$. Conversely, if the image of δ is non-zero, the $r(g_i)$ are linearly independent (a linear relation among them is a relation among the rows of the Gram matrix), so they span $\mathrm{M}_n(\bar\kappa)$; a non-zero proper $r(G)$-stable subspace would be stable under $\mathrm{M}_n(\bar\kappa)$, which is impossible, so r is irreducible.

Step 2: irreducibility at $\hat Z'$. Put $\mathfrak{Q} = u^{-1}(P'')$, a stable prime of B: the base change of D^{u} to an algebraic closure of the residue field of $\mathfrak{Q}$ is $\det\circ r$ with r irreducible on $\Gamma^0_{\mathscr{H}}$. By Step 1 there are $\gamma_1, \dots, \gamma_{n^2} \in \Gamma^0_{\mathscr{H}}$ with $\delta_0 = \det(\mathrm{tr}_{D^{\mathrm{u}}}(\gamma_i\gamma_j)) \notin \mathfrak{Q}$. As h maps $\Gamma^0_\infty = h^{-1}(\Gamma^0_{\mathscr{H}})$ onto $\Gamma^0_{\mathscr{H}}$, choose $e_i \in \Gamma^0_\infty$ with $h(e_i) = \gamma_i$, and put $\delta = \det(\mathrm{tr}_D(e_ie_j)) \in R/I$. By (In1) of Proposition E.134, applied to e_ie_j (whose image under h is $\gamma_i\gamma_j$), $\bar\pi$ carries the coefficients of the characteristic polynomial of D at e_ie_j to those of D^{u} at $\gamma_i\gamma_j$, base changed along u; in particular $\bar\pi(\mathrm{tr}_D(e_ie_j)) = u(\mathrm{tr}_{D^{\mathrm{u}}}(\gamma_i\gamma_j))$, hence $\bar\pi(\delta) = u(\delta_0) \notin P''$, since $u^{-1}(P'') = \mathfrak{Q} \not\ni \delta_0$. So $\delta \notin \bar\pi^{-1}(P'') = \pi^{-1}(P'')/I$, and a fortiori $\delta \notin \mathfrak{z}/I$, which is the preimage of $\hat Z'$ in R/I. Hence the image of δ in $\hat B$ is not in $\hat Z'$. The base change $D_{\hat B}$ of D along $R/I \to \hat B$ has $\mathrm{tr}_{D_{\hat B}}(e_ie_j)$ equal to the image of $\mathrm{tr}_D(e_ie_j)$; by Step 1, applied to $D_{\hat B}$ and $\hat Z'$, the base change of D along $R/I \to \hat B \to \bar\kappa$, with $\bar\kappa$ an algebraic closure of the fraction field of $\hat B/\hat Z'$, is $\det\circ r'$ for an irreducible $r'\colon \Gamma^0_\infty \to \mathrm{GL}_n(\bar\kappa)$.

Step 3. By Lemma E.47, applied to $\mathfrak{R}$ (of shape $(a, n-a)$ with $a < n$) and $\hat Q = \hat Z'$, $\mathrm{ired}(N) \not\subseteq \hat Z'$. □

Lemma E.47. *Let $\mathfrak{R}$ be a realisation of a framed normalised curve point x of shape $(a, n-a)$ with $a < n$ over a level $\mathbf{V}$, $\hat Q$ a prime ideal of $\hat B$ and $\bar\kappa$ an algebraic closure of the fraction field*

of $\hat{B}/\hat{Q}$. If the base change of D along $B \to \hat{B} \to \bar{\kappa}$ is $\det \circ r$ for an irreducible homomorphism $r\colon \Gamma_1^0 \to \mathrm{GL}_n(\bar{\kappa})$, then $\mathrm{ired}(N) \not\subseteq \hat{Q}$.

Proof. Suppose $\mathrm{ired}(N) \subseteq \hat{Q}$; let $\varphi\colon \hat{B} \to \bar{\kappa}$ be the homomorphism with kernel $\hat{Q}$, $\mathcal{A}_{\bar{\kappa}} = \mathcal{A} \otimes_{\hat{B}} \bar{\kappa} = \bar{\kappa} \cdot 1 \oplus N_{\bar{\kappa}}$ with $N_{\bar{\kappa}}$ the image of $N \otimes_{\hat{B}} \bar{\kappa}$ (the decomposition $\mathcal{A} = \hat{B} \cdot 1 \oplus N$ of (Vr5) is one of $\hat{B}$-modules, so it survives base change and $\bar{\kappa} \to \mathcal{A}_{\bar{\kappa}}$ is injective). For $y, y' \in N$ we have $yy' = b \cdot 1$ with $b \in \mathrm{ired}(N) \subseteq \hat{Q}$, so the product of any two elements of $N_{\bar{\kappa}}$ is 0, and the same holds for the image N_T of $N_{\bar{\kappa}} \otimes T$ in $\mathcal{A}_{\bar{\kappa}} \otimes_{\bar{\kappa}} T$ for every commutative $\bar{\kappa}$-algebra T.

By (Vr6) every $\nu(\gamma)$ has entries in $\hat{B} \cdot 1$ at the positions (i,j) in one block and in N at the others, so its image $\nu_{\bar{\kappa}}(\gamma)$ in $\mathrm{M}_n(\mathcal{A}_{\bar{\kappa}})$ is $\begin{pmatrix} P(\gamma) & X(\gamma) \\ Y(\gamma) & S(\gamma) \end{pmatrix}$ with $P(\gamma) \in \mathrm{M}_a(\bar{\kappa})$, $S(\gamma) \in \mathrm{M}_{n-a}(\bar{\kappa})$ and $X(\gamma), Y(\gamma)$ with entries in $N_{\bar{\kappa}}$. Since ν is multiplicative, $P(\gamma\gamma') = P(\gamma)P(\gamma') + X(\gamma)Y(\gamma') = P(\gamma)P(\gamma')$ (the entries of $X(\gamma)Y(\gamma')$ are sums of products of two elements of $N_{\bar{\kappa}}$), likewise $S(\gamma\gamma') = S(\gamma)S(\gamma')$, and $P(1) = 1$, $S(1) = 1$; so P, S are homomorphisms into $\mathrm{GL}_a(\bar{\kappa})$, $\mathrm{GL}_{n-a}(\bar{\kappa})$.

For a commutative $\bar{\kappa}$-algebra T, $t_b \in T$ and $\gamma_b \in \Gamma_1^0$, the matrix $M = \sum_b t_b \nu_{\bar{\kappa}}(\gamma_b)$ has the same block shape, with off-diagonal blocks in N_T. In the Leibniz expansion of $\det M$, a permutation sending some index of the first block to the second also sends some index of the second block to the first, so its term contains at least two factors from N_T and vanishes. Hence $\det M = \det(\sum_b t_b P(\gamma_b)) \det(\sum_b t_b S(\gamma_b))$. By (Vr6) the base change of D to $\mathcal{A}$ is $\det \circ \nu$, so its further base change to $\mathcal{A}_{\bar{\kappa}}$ is $\det \circ \nu_{\bar{\kappa}} = \det \circ (P \oplus S)$. In particular, for every γ the characteristic polynomials of the base change $D_{\bar{\kappa}}$ of D to $\bar{\kappa}$ and of $(P \oplus S)(\gamma)$ coincide after the injection $\bar{\kappa}[X] \to \mathcal{A}_{\bar{\kappa}}[X]$, hence in $\bar{\kappa}[X]$, and by Theorem B.83 (Ch1) $D_{\bar{\kappa}} = \det \circ (P \oplus S)$. Let $P^{\mathrm{ss}}, S^{\mathrm{ss}}$ be the semisimplifications; the characteristic polynomial of a representation is the product of those of its Jordan–Hölder factors, so by (Ch1) again $\det \circ (P \oplus S) = \det \circ (P^{\mathrm{ss}} \oplus S^{\mathrm{ss}})$. Thus $\det \circ r = \det \circ (P^{\mathrm{ss}} \oplus S^{\mathrm{ss}})$ with both representations semisimple (r is irreducible), and (Ch3) gives $r \cong P^{\mathrm{ss}} \oplus S^{\mathrm{ss}}$. But $a \geq 1$ and $n - a \geq 1$, so the right side has at least two irreducible summands, while r is irreducible: a contradiction. Hence $\mathrm{ired}(N) \not\subseteq \hat{Q}$. □

E.2.3 Choice of Taylor–Wiles places and elements

This subsection chooses the auxiliary data of the patching argument, used in Proposition E.39. Taylor–Wiles places exist whose Frobenius elements approximate prescribed elements of the cyclotomic kernel (Proposition E.48), by a Chebotarev argument with places of absolute degree one (Lemma E.49). Taylor–Wiles elements that detect all points of a chain exist after a common finite extension (Proposition E.50), because dense subsets of the cyclotomic kernel detect the twisted dual cocycles (Proposition E.51) and Selmer bases with finite detection exist (Proposition E.52). Patchable curve points of endoscopic and of irreducible type can be normalised over finite extensions of the curve (Proposition E.53, Proposition E.54, Lemma E.55).

Proposition E.48. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$. Then $\Gamma_{\mathscr{H}}$ satisfies Φ_ℓ, and for every $q \geq 0$ and all $\sigma_1, \dots, \sigma_q \in \Gamma'$ there is a Taylor–Wiles datum of size q for $\mathscr{H}$ whose elements are $\sigma_1, \dots, \sigma_q$.*

Proof. Write $\Gamma = \Gamma_{\mathscr{H}}$, $\pi = \pi_{\mathscr{H}}$, $S = S_\ell \cup \mathrm{St} \cup \{v_0\}$.

Step 0: the levels are quotients of Galois groups with restricted ramification. Let Q be a finite set of places as in Definition 53.8. For a finite place $\bar{w} \nmid \ell$ of $\overline{\mathbb{Q}}$ above a place of L^+ outside $\mathrm{St} \cup Q$ (and outside S_ℓ), $I_{\bar{w}} \subseteq G_L$ (L/L^+ is unramified at finite places, (Rd2)) and every $\bar{\chi}_a$ is trivial on $I_{\bar{w}}$ by (Rd4); so $I_{\bar{w}} \subseteq N^Q$. Hence Γ^Q is a quotient of the Galois group $G_{L^+, S_\ell \cup \mathrm{St} \cup Q}$ of the

maximal extension of L^+ unramified outside $S_\ell \cup \mathrm{St} \cup Q$ and the infinite places, which satisfies Φ_ℓ by (2) of Theorem B.71. A quotient of a group satisfying Φ_ℓ satisfies it (open subgroups pull back to open subgroups, and homomorphisms to $\mathbb{Z}/\ell$ inflate injectively). So every Γ^Q, in particular $\Gamma = \Gamma^\varnothing$, satisfies Φ_ℓ. This is the first assertion.

Step 1: H and a basis at $\mathrm{PL}(H)$. Define H by (Tg1). $\Gamma^0_{\mathscr{H}}$ has index 2; the $\bar\chi_a$ and $\chi_{\mathrm{cyc}} \bmod \ell$ are continuous with finite image; and $\bigcap_a \ker \bar\chi_a$ is stable under conjugation by $\pi(c)$ by (Rd5). So H is an open normal subgroup of Γ. Γ, a quotient of G_{L^+}, has only countably many open subgroups (they correspond to finite extensions of L^+ inside $\overline{\mathbb{Q}}$); let $U_1, U_2, \dots$ enumerate the open normal subgroups U of Γ such that every $h \in H$ has some $h^{\ell^e} \in U$ (repeat the last one if there are finitely many; $U = H$ is one of them), and put $W_N = H \cap U_1 \cap \cdots \cap U_N$. The W_N are open, normal, decreasing, contained in H, and $\bigcap_N W_N = H \cap \mathrm{PL}(H) = \mathrm{PL}(H)$ (as $\mathrm{PL}(H) \subseteq H$). If $V \supseteq \mathrm{PL}(H)$ is open, then $\Gamma \smallsetminus V$ is compact and covered by the increasing open sets $\Gamma \smallsetminus W_N$, so $W_N \subseteq V$ for N large.

Step 2: the places. Fix $N \geq 1$ and lifts $g_j \in G_L$ of σ_j^{-1} ($\sigma_j \in \Gamma' \subseteq \pi(G_L)$). Let $U'_N = \pi^{-1}(W_N) \cap \ker(\chi_{\mathrm{cyc}} \bmod \ell^N) \cap G_L$, an open normal subgroup of G_L. For $j = 1, \dots, q$ in turn, apply Lemma E.49 with $F = L$, $U = U'_N$, $g = g_j$ and the finite set of places of L above S, above ℓ, or above one of $v_{N,1}, \dots, v_{N,j-1}$: it gives a place w of L of absolute degree one, unramified over $\mathbb{Q}$, outside that set, a place $\bar w_{N,j}$ above it and an arithmetic Frobenius $\sigma \in D_{\bar w_{N,j}}$ with $I_{\bar w_{N,j}} \subseteq U'_N$ and $\sigma g_j^{-1} \in U'_N$. Put $w_{N,j} = w$, $v_{N,j} = w|_{L^+}$, $\phi_{N,j} = \sigma^{-1} \in D_{\bar w_{N,j}} \cap G_L$. As $f(w \mid p) = 1$ and L/L^+ is unramified at w, $v_{N,j}$ splits in L; it is not in S, not above ℓ, and different from the earlier $v_{N,j'}$. $q_{N,j} = \mathrm{N}w$, and $\chi_{\mathrm{cyc}}(\sigma) = \mathrm{N}w$ in $\mathbb{Z}_\ell^\times$ (σ acts on ℓ-power roots of unity as an arithmetic Frobenius); since $\sigma \in g_j U'_N$ and $\chi_{\mathrm{cyc}}(g_j) = \chi_{\mathrm{cyc}}(\sigma_j)^{-1} = 1$, $q_{N,j} \equiv 1 \bmod \ell^N$. Choose $\tau_{N,j} \in I_{\bar w_{N,j}}$ mapping to a topological generator of the maximal pro-ℓ quotient $I_{\bar w_{N,j}}/K_{N,j} \cong \mathbb{Z}_\ell(1)$; then $I_{\bar w_{N,j}}$ is the closed subgroup generated by $\tau_{N,j}$ and $K_{N,j}$. This is (Tg2).

Step 3: (Tg3). $\pi(\sigma) \in \pi(g_j) W_N = \sigma_j^{-1} W_N$, so $\pi(\phi_{N,j}) = \eta^{-1}\sigma_j$ for some $\eta \in W_N$ and $h_N(\Phi_{N,j})\sigma_j^{-1} = \pi(\phi_{N,j})\sigma_j^{-1} = \eta^{-1} \in W_N \subseteq H$. By Step 1, for $V \supseteq \mathrm{PL}(H)$ open normal, $W_N \subseteq V$ for N large.

Step 4: inertia at the new places lies in H_N, and its ℓ'-part in $\mathrm{PL}(H_N)$. Every place $\bar w$ above some $v_{N,j}$ is $g\bar w_{N,j}$ with $g \in G_{L^+}$, and $I_{\bar w} = g I_{\bar w_{N,j}} g^{-1} \subseteq G_L$ is in $N_{\mathscr{H}}$ by (Rd4) (the $\bar\chi_a$ are trivial on it, $v_{N,j} \notin S_\ell \cup \mathrm{St}$). So $h_N(\pi^{Q_N}(I_{\bar w})) = 1$, in particular $\pi^{Q_N}(I_{\bar w}) \subseteq H_N$ and $h_N(\mathrm{T}_{N,j}) = 1$. Let $x \in I_{\bar w}$ map to 1 in the maximal pro-ℓ quotient of $I_{\bar w}$, and U an open normal subgroup of Γ_N such that every element of H_N has an ℓ-power in U. The image of $I_{\bar w}$ in the finite group $H_N/(H_N \cap U)$ is an ℓ-group, hence a quotient of the maximal pro-ℓ quotient of $I_{\bar w}$, so $\pi^{Q_N}(x) \in U$. Hence $\pi^{Q_N}(x) \in \mathrm{PL}(H_N)$.

Step 5: (Tg4). In $I_{\bar w_{N,j}}/K_{N,j} \cong \mathbb{Z}_\ell(1)$ the arithmetic Frobenius $\sigma = \phi_{N,j}^{-1}$ acts by multiplication by $q_{N,j}$, so $\tau_{N,j}^{-q_{N,j}} \phi_{N,j}^{-1} \tau_{N,j} \phi_{N,j} \in K_{N,j}$ (an element of $I_{\bar w_{N,j}}$, as σ normalises inertia), and by Step 4 its image $\mathrm{T}_{N,j}^{-q_{N,j}} \Phi_{N,j}^{-1} \mathrm{T}_{N,j} \Phi_{N,j}$ lies in $\mathrm{PL}(H_N)$. $\ker h_N$ is the image of $N_{\mathscr{H}}$ in Γ_N; the generators of $N_{\mathscr{H}}$ at places outside Q_N lie in N^{Q_N}, so $\ker h_N$ is the closed normal subgroup generated by the images of $I_{\bar w}$, $\bar w$ above Q_N (on which all $\bar\chi_a$ are trivial). Each such image is $\pi^{Q_N}(g)\, \pi^{Q_N}(I_{\bar w_{N,j}})\, \pi^{Q_N}(g)^{-1}$, contained in the closure of the subgroup generated by the conjugate of $\mathrm{T}_{N,j}$ and $\pi^{Q_N}(g K_{N,j} g^{-1}) \subseteq \mathrm{PL}(H_N)$ (Step 4). $\mathrm{PL}(H_N)$ is normal (an intersection of normal subgroups); so $\ker h_N$ lies in the closure of the subgroup generated by $\mathrm{PL}(H_N)$ and the conjugates of $\mathrm{T}_{N,1}, \dots, \mathrm{T}_{N,q}$.

Step 6: (Tg5). H and H_N are open in groups satisfying Φ_ℓ (Step 0), so their sets of homomorphisms to $\mathbb{Z}/\ell$ are finite. Let $m = [\Gamma : H] = [\Gamma_N : H_N]$ and $r_1, \dots, r_m$ coset representatives of H_N in Γ_N. Let $\psi, \psi' \colon H_N \to \mathbb{Z}/\ell$ agree on the mq elements $r_i \mathrm{T}_{N,j} r_i^{-1}$, and

put $\delta = \psi - \psi'$. (i) δ vanishes on $\mathrm{PL}(H_N)$: the intersection U of the Γ_N-conjugates of $\ker\delta$ (finitely many, as H_N is open and normal) is open and normal in Γ_N, and H_N/U embeds into a product of copies of $\mathbb{Z}/\ell$, so every element of H_N has its ℓ-th power in U; thus $\mathrm{PL}(H_N) \subseteq U \subseteq \ker\delta$. (ii) δ vanishes on all conjugates $g\mathrm{T}_{N,j}g^{-1}$, $g = r_i h$ with $h \in H_N$: $\delta(r_i h \mathrm{T} h^{-1} r_i^{-1}) = \delta\big((r_i h r_i^{-1})(r_i \mathrm{T} r_i^{-1})(r_i h r_i^{-1})^{-1}\big) = \delta(r_i \mathrm{T} r_i^{-1}) = 0$, as $\mathbb{Z}/\ell$ is abelian and $\mathrm{T} \in \ker h_N \subseteq H_N$. As $\ker\delta$ is closed, (i), (ii) and Step 5 give $\ker h_N \subseteq \ker\delta$, so δ is inflated from a homomorphism $H = H_N/\ker h_N \to \mathbb{Z}/\ell$. Hence the number of homomorphisms $H_N \to \mathbb{Z}/\ell$ is at most $b = \#\mathrm{Hom}(H, \mathbb{Z}/\ell) \cdot \ell^{mq}$, independent of N.

Step 7: (Tg6). $D_v \cap G_L$ ($v \in S_\ell$) and $D_{\bar{u}} \cap G_L$ ($u \in \mathrm{St}$; u splits in L by (Rd2)) are absolute Galois groups of local fields, which satisfy Φ_ℓ by the classical fact recalled above.

So H, the σ_j, b and the places, Frobenius and tame elements of Steps 2–3 form a Taylor–Wiles datum of size q with elements $\sigma_1, \ldots, \sigma_q$. □

Lemma E.49. *Let F be a number field, $\overline{F}$ an algebraic closure, $G_F = \mathrm{Gal}(\overline{F}/F)$, $U \subseteq G_F$ an open normal subgroup, $g \in G_F$ and S a finite set of finite places of F. Then the set of finite places $v \notin S$ of F such that*

1. *v has absolute degree one and is unramified over $\mathbb{Q}$: if p is the prime below v, then $f(v \mid p) = e(v \mid p) = 1$;*
2. *there are a place $\bar{v}$ of $\overline{F}$ above v and an element σ of the decomposition group $D_{\bar{v}} \subseteq G_F$ which induces the arithmetic Frobenius $x \mapsto x^{\mathrm{N}v}$ on the residue field of $\bar{v}$, such that $I_{\bar{v}} \subseteq U$ and $\sigma g^{-1} \in U$*

has Dirichlet density $\#C/[G_F : U]$, where C is the conjugacy class of gU in G_F/U. In particular it is infinite. Equivalently, for a finite Galois extension L/F inside $\overline{F}$ and $h \in \mathrm{Gal}(L/F)$, there are infinitely many finite places $v \notin S$ with $f(v \mid p) = e(v \mid p) = 1$, unramified in L, with a place w of L above v whose Frobenius Frob_w is h.

Proof. The two forms are equivalent. Put $L = \overline{F}^U$, a finite Galois extension of F, so that restriction identifies G_F/U with $\mathrm{Gal}(L/F)$. For a place $\bar{v}$ of $\overline{F}$ with restriction w to L, restriction maps $D_{\bar{v}}$ onto D_w and $I_{\bar{v}}$ onto I_w, and an element of $D_{\bar{v}}$ inducing the arithmetic Frobenius on the residue field of $\bar{v}$ maps to an element inducing it on the residue field of w. So $I_{\bar{v}} \subseteq U$ says exactly that v is unramified in L, and then $\sigma g^{-1} \in U$ says exactly that $\mathrm{Frob}_w = gU$. Conversely, given w with $\mathrm{Frob}_w = h$ and v unramified in L, any $\bar{v}$ above w and any $\sigma \in D_{\bar{v}}$ inducing the arithmetic Frobenius satisfy 2 with g any lift of h. It therefore suffices to prove the density statement for L/F and $h = gU$, with C the conjugacy class of h.

The places with Frobenius conjugate to h have density $\#C/[L : F]$. Let P_C be the set of finite places of F, unramified in L, at which the Frobenius conjugacy class is C. By Chebotarev's density theorem, P_C has Dirichlet density $\#C/[L : F] > 0$. At a place $v \in P_C$ some place w of L above v has $\mathrm{Frob}_w = h$: if $\mathrm{Frob}_{w_0} = \tau h \tau^{-1}$ for one place w_0 above v and some $\tau \in \mathrm{Gal}(L/F)$, then $w = \tau^{-1} w_0$ has

$$\mathrm{Frob}_{\tau^{-1} w_0} = \tau^{-1} \mathrm{Frob}_{w_0} \tau = h.$$

The excluded places have density zero. Let Z be the union of three sets: S; the finitely many places that ramify in L or lie above a prime dividing the discriminant of F (these contain all v with $e(v \mid p) > 1$); and the set Z_2 of places with $f(v \mid p) \geq 2$. A finite set has density zero. For Z_2: every $v \in Z_2$ has $\mathrm{N}v \geq p^2$, and at most $[F : \mathbb{Q}]$ places lie above each prime p. Hence, for real $s > 1$,

$$\sum_{v \in Z_2} \mathrm{N}v^{-s} \leq [F : \mathbb{Q}] \sum_p p^{-2s} \leq [F : \mathbb{Q}]\, \zeta(2),$$

which stays bounded as $s \to 1^+$, while $\log \frac{1}{s-1} \to \infty$. So Z_2, and hence Z, has Dirichlet density zero.

Conclusion. Let M be the set in the statement. By the equivalence and the previous step, every place of $P_C \setminus Z$ lies in M. Conversely, condition 2 forces $v \in P_C$. So $P_C \setminus Z \subseteq M \subseteq P_C$, and M has the density of $P_C \setminus Z$ once the latter exists. For $s > 1$,

$$\sum_{v \in P_C \setminus Z} \mathrm{N}v^{-s} = \sum_{v \in P_C} \mathrm{N}v^{-s} - \sum_{v \in P_C \cap Z} \mathrm{N}v^{-s},$$

and the last sum is at most $\sum_{v \in Z} \mathrm{N}v^{-s} = o(\log \frac{1}{s-1})$. So $P_C \setminus Z$ has Dirichlet density $\#C/[L : F] > 0$. Since $M \setminus (P_C \setminus Z) \subseteq P_C \cap Z$, the same estimate shows that M has this density too. A set of positive Dirichlet density is infinite, because every finite set has density zero. □

Proposition E.50. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell \neq 2$ and $\Gamma_{\mathscr{H}}$ satisfying Φ_ℓ, and let $x_0, \dots, x_h$ be spanning framed curve points of a universal polarised ordinary determinant over $\mathscr{H}$, each normalised of some shape, each satisfying (Np3). Then there are $q \geq 0$, elements $\sigma_1, \dots, \sigma_q \in \Gamma'$ and, for $0 \leq i \leq h$, an extension $x_i' = (k_i', \rho_i', 1_n, (\psi_{i,v,b}'), f_i')$ of x_i, with $|k_0'| = \cdots = |k_h'|$, a Selmer basis κ_i' of x_i' such that $\{\sigma_1, \dots, \sigma_q\}$ detects (x_i', κ_i'), and pairwise distinct $\alpha_{i,j,1}, \dots, \alpha_{i,j,n} \in A_{k_i'}$ with $\det(X - \rho_i'(\sigma_j)) = \prod_{b=1}^n (X - \alpha_{i,j,b})$ for $1 \leq j \leq q$.*

Proof. Write $x_i = (k_i, \rho_i, 1_n, (\psi_{i,v,b}), f_i)$ and $A_i = A_{k_i}$, $F_i = F_{k_i}$.

Step 1: separable elements are dense in Γ'. For $\sigma \in \Gamma^0_{\mathscr{H}}$ let $\delta_i(\sigma) \in A_i$ be the discriminant of the monic polynomial $\det(X - \rho_i(\sigma))$; it is a polynomial with integer coefficients in the entries of $\rho_i(\sigma)$, and $\det(X - \rho_i(\sigma))$ is separable over F_i if and only if $\delta_i(\sigma) \neq 0$. The entries of ρ_i are continuous for the T-adic topology of A_i (Definition 50.9), so δ_i is continuous; as A_i is T-adically separated, $\{0\}$ is closed and $S_i = \{\sigma : \delta_i(\sigma) \neq 0\}$ is open in $\Gamma^0_{\mathscr{H}}$. Put $S = \Gamma' \cap S_0 \cap \cdots \cap S_h$. Let $\sigma \in \Gamma'$ and U an open neighbourhood of σ. Put $U_0 = U$; if U_i is open and meets Γ', (Np3) (that is, (Pj2)) for x_i gives $\tau \in U_i \cap \Gamma' \cap S_i$, and $U_{i+1} = U_i \cap S_i$ is open and meets Γ' (it contains τ). Then $U_{h+1} \cap \Gamma' \subseteq U \cap S$ is non-empty. So the closure of S contains Γ', and $S \subseteq \Gamma'$.

Step 2: a finite detecting set. By (Cf1) of Proposition E.52 each x_i has a Selmer basis κ_i. By Proposition E.51, S detects (x_i, κ_i); by (Cf2) some finite $T_i \subseteq S$ detects (x_i, κ_i). Let $\{\sigma_1, \dots, \sigma_q\} = T_0 \cup \cdots \cup T_h \subseteq S \subseteq \Gamma'$. Detection is inherited by larger sets (a cocycle with $\ell_\sigma(z) = 0$ on the larger set has it on the smaller one), so $\{\sigma_1, \dots, \sigma_q\}$ detects every (x_i, κ_i).

Step 3: a common extension. Every σ_j lies in S, so $\det(X - \rho_i(\sigma_j))$ is separable over F_i for all i, j. (Cf3) applied to $(x_i, \kappa_i, \sigma_1, \dots, \sigma_q)$ gives $d_i \geq 1$; put $D = d_0 d_1 \cdots d_h$, a multiple of every d_i. (Cf3) with this D gives, for each i, an extension x_i' of x_i with $|k_i'| = \ell^D$, a Selmer basis κ_i' of x_i' detected by $\{\sigma_1, \dots, \sigma_q\}$, and the pairwise distinct roots $\alpha_{i,j,b}$; the residue fields all have ℓ^D elements. □

Proposition E.51. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell \neq 2$, and $x = (k, \rho, 1_n, (\psi_{v,b}), f)$ a framed curve point of a universal polarised ordinary determinant over $\mathscr{H}$, normalised of shape $(a, n-a)$, such that for every $Z \in \mathrm{Ev}_a(A_k)$ some $T^s Z$ lies in the A_k-span of $\rho(\Gamma')$. Then for every Selmer basis κ of x and every subset $\Sigma \subseteq \Gamma'$ whose closure contains Γ', Σ detects (x, κ).*

Proof. Write $A = A_k$, $F = \mathrm{Frac}(A)$, $G = \Gamma^0_{\mathscr{H}}$, $G' = \Gamma'$, $\bar{c} = \pi_{\mathscr{H}}(c)$, $b = n - a$, $\chi = \chi_{\mathrm{cyc}}$ with values in $\mathbb{F}_\ell^\times \subseteq A^\times$ (A has characteristic ℓ). Let $z \in \mathrm{TwZ}(x, \kappa)$ with $\ell_\sigma(z) = 0$ for $\sigma \in \Sigma$. Put $E_0 = \mathrm{Ev}_a(F) \cong \mathrm{M}_a(F) \times \mathrm{M}_b(F)$, $N = \bigoplus_j \epsilon_j \mathrm{Od}_a(F)$, $E_1 = E_0 \oplus N$ and $P = \mathrm{PB}_a \otimes_A F = \eta E_0 \oplus \bigoplus_k \epsilon_k' \mathrm{Od}_a(F)$, inside $\mathrm{M}_n(\mathrm{PD}_g(F))$. As $\epsilon_i \epsilon_j = 0$, $\epsilon_i \epsilon_k' = \delta_{ik}\eta$ and $\eta\epsilon = \eta\epsilon' = 0$, and $\mathrm{Ev} \cdot \mathrm{Od}, \mathrm{Od} \cdot \mathrm{Ev} \subseteq \mathrm{Od}$, $\mathrm{Od} \cdot \mathrm{Od} \subseteq \mathrm{Ev}$: E_1 is an algebra with $N^2 = 0$, P is an E_1-bimodule,

$\rho_1(G) \subseteq E_1$, and $\langle p, e\rangle = (\eta\text{-coefficient of } \mathrm{tr}(pe))$ is a perfect pairing $P \times E_1 \to F$ (for $p = \eta P_0 + \sum_k \epsilon'_k P_k$, $e = e_0 + \sum_j \epsilon_j Y_j$ it is $\mathrm{tr}(P_0 e_0) + \sum_k \mathrm{tr}(P_k Y_k)$). Write $\gamma \star p = \chi(\gamma)\rho_1(\gamma) p \rho_1(\gamma)^{-1}$, so $z(\gamma\gamma') = z(\gamma) + \gamma \star z(\gamma')$, $z(\gamma^{-1}) = -\gamma^{-1} \star z(\gamma)$.

Step 0: vanishing on G'. $\sigma \mapsto \ell_\sigma(z)$ is a polynomial in the entries of $z(\sigma)$ and $\rho_1(\sigma)$, hence T-adically continuous; its zero set is closed and contains Σ, hence G'.

Step 1: a derivation on the group algebra. For $\sigma \in G'$ put $\zeta(\sigma) = z(\sigma)\rho_1(\sigma) \in P$. As $\chi = 1$ on G', $\zeta(\sigma\tau) = \zeta(\sigma)\rho_1(\tau) + \rho_1(\sigma)\zeta(\tau)$. Extend ρ_1 to an algebra homomorphism $F[G'] \to E_1$ and ζ linearly: $\zeta(uv) = \zeta(u)\rho_1(v) + \rho_1(u)\zeta(v)$, and $\langle \zeta(u), 1\rangle = 0$ for all u by Step 0.

Step 2: $\rho_1(F[G']) = E_1$. Let $R = \rho_1(F[G'])$. Its image under $e \mapsto e_0$ is $\rho(F[G']) = E_0$ (the spanning hypothesis, after inverting T), with kernel $R \cap N$; as $N^2 = 0$, $R \cap N$ is an E_0-sub-bimodule of $N \cong \mathrm{M}_{a\times b}(F)^g \oplus \mathrm{M}_{b\times a}(F)^g$, whose two corner bimodules are simple, non-isomorphic, with endomorphisms F; so $R \cap N = U \otimes \mathrm{M}_{a\times b} \oplus U' \otimes \mathrm{M}_{b\times a}$ for subspaces $U, U' \subseteq F^g$. Suppose $U \neq F^g$ and choose $c \in F^g \smallsetminus \{0\}$ with $\sum_j c_j u_j = 0$ for $u \in U$. Let $p\colon E_1 \to \mathrm{M}_{a\times b}(F)$ send $e_0 + \sum_j \epsilon_j Y_j$ to the (a,b)-corner of $\sum_j c_j Y_j$; it vanishes on $R \cap N$, so $p|_R = L(e_0)$ for a linear $L\colon E_0 \to \mathrm{M}_{a\times b}(F)$, and multiplicativity of R gives $L(ee') = e_{aa}L(e') + L(e)e'_{bb}$. So L is a derivation into a bimodule of the separable algebra E_0, hence inner: $L(e) = e_{aa}X - Xe_{bb}$ with $X \in \mathrm{M}_{a\times b}(F)$. At $e = \rho_1(\sigma)$, $\sigma \in G'$: the (a,b)-corner of $\kappa_c = \sum_j c_j \kappa_j$ is $\rho_{aa}(\sigma) X \rho_{bb}(\sigma)^{-1} - X$. By (Sd2), $\kappa_c(\bar c \gamma \bar c) = -{}^t\kappa_c(\gamma)$, and $\rho(\bar c\gamma\bar c) = {}^t\rho(\gamma)^{-1}$ (normalised point); $\bar c$ normalises G'; transposing exchanges the corners, so the (b,a)-corner of $\kappa_c(\sigma)$ is $\rho_{bb}(\sigma)(-{}^tX)\rho_{aa}(\sigma)^{-1} + {}^tX$. Hence $\delta = \kappa_c - dY$, with $Y \in \mathrm{Od}_a(F)$ having corners X, $-{}^tX$ (so ${}^tY = -Y$) and $dY(\gamma) = \rho(\gamma)Y\rho(\gamma)^{-1} - Y$, is a cocycle of G vanishing on the normal subgroup G'; then $\delta(\gamma) = \delta(\gamma \cdot \gamma^{-1}\sigma\gamma) = \delta(\sigma\gamma) = \rho(\sigma)\delta(\gamma)\rho(\sigma)^{-1}$ for $\sigma \in G'$, so $\delta(\gamma)$ commutes with E_0, and an element of $\mathrm{Od}_a(F)$ commuting with E_0 is 0. So $\sum_j (T^s c_j)\kappa_j = d(T^s Y) \in \mathrm{Bd}(x)$ for s with $T^s c \in A^g$, $T^s Y \in \mathrm{Od}_a(A)$, contradicting the independence of a Selmer basis. So $U = F^g$, and likewise (exchanging the corners) $U' = F^g$: $R \supseteq N$ and $R = E_1$.

Step 3: ζ factors through ρ_1. If $\rho_1(u) = 0$, then for all v, $\langle \zeta(u), \rho_1(v)\rangle = \langle \zeta(u)\rho_1(v), 1\rangle = \langle \zeta(uv), 1\rangle = 0$; by Step 2 and perfectness, $\zeta(u) = 0$. So $\zeta = D \circ \rho_1$ for a linear $D\colon E_1 \to P$ with $D(ee') = D(e)e' + eD(e')$. For $\gamma \in G$ and $\sigma \in G'$, $\sigma' = \gamma\sigma\gamma^{-1} \in G'$ and the cocycle identities give $z(\sigma') = \gamma \star z(\sigma) + z(\gamma) - \rho_1(\sigma')z(\gamma)\rho_1(\sigma')^{-1}$, hence, with $\mathrm{Ad}_\gamma(e) = \rho_1(\gamma)e\rho_1(\gamma)^{-1}$ and by linearity,

$$D(\mathrm{Ad}_\gamma e) = \chi(\gamma)\mathrm{Ad}_\gamma(D(e)) + z(\gamma)\mathrm{Ad}_\gamma(e) - \mathrm{Ad}_\gamma(e)z(\gamma) \qquad (e \in E_1). \tag{$*$}$$

Step 4: z is a coboundary over F. E_0 is separable, so there is $Y_1 \in P$ with $D(e) = eY_1 - Y_1 e$ for $e \in E_0$. Put $z'(\gamma) = z(\gamma) - (\gamma \star Y_1 - Y_1)$, a cocycle, with $z'(\sigma)\rho_1(\sigma) = D'(\rho_1(\sigma))$ on G' for $D'(e) = D(e) - (eY_1 - Y_1 e)$; D' satisfies Step 3 and $(*)$ with z', and $D'|_{E_0} = 0$. Then $D'|_N$ is a map of E_0-bimodules $N \to P$; it has no component in ηE_0 (no non-zero bimodule map from a corner $\mathrm{M}_{a\times b}$ or $\mathrm{M}_{b\times a}$ to the diagonal blocks), so by Schur $D'(\epsilon_j Y) = \sum_k \epsilon'_k M_{jk}(Y)$ with M_{jk} acting by a scalar on each corner. By (Rd6) there is $g \in G$ with $\chi(g) \neq 1$ in $\mathbb{F}_\ell$. Apply $(*)$ to $e = \epsilon_j Y$: $\mathrm{Ad}_g(\epsilon_j Y) = \epsilon_j \rho(g) Y \rho(g)^{-1}$; the commutator term lies in ηE_0; comparing ϵ'-parts, $\rho(g)M_{jk}(Y)\rho(g)^{-1} = \chi(g)\rho(g)M_{jk}(Y)\rho(g)^{-1}$ (M_{jk} commutes with conjugation by the block diagonal $\rho(g)$), so $M_{jk} = 0$. Thus $D' = 0$ and $z' = 0$ on G'. As in Step 2, $z'(\gamma)$ then commutes with $\rho_1(G')$, i.e. with E_1; the elements of P commuting with E_1 are ηw with w in the centre Z_0 of E_0, on which Ad is trivial. So $z'(\gamma) = \eta s(\gamma)$, $s(\gamma\gamma') = s(\gamma) + \chi(\gamma)s(\gamma')$, and comparing $s(\gamma g) = s(g\gamma)$ gives $s(\gamma) = \chi(\gamma)w - w$ with $w = -(1 - \chi(g))^{-1}s(g) \in Z_0$. Hence $z = dY_2$ for $Y_2 = Y_1 + \eta w \in P$, where $dY_2(\gamma) = \gamma \star Y_2 - Y_2$.

Step 5: symmetry and integrality. Let $\theta(p) = -\chi(\bar c)\,{}^t p$ on P (an involution, as $\chi(\bar c)^2 = 1$). By (Sd2) and normalisation, $\rho_1(\bar c\gamma\bar c) = {}^t\rho_1(\gamma)^{-1}$, and a direct computation gives $\theta(dY_2(\gamma)) = (d\,\theta(Y_2))(\bar c\gamma\bar c)$; as $z(\bar c\gamma\bar c) = \theta(z(\gamma))$ by (Sd4), $z = d\,\theta(Y_2)$ too, so $z = dY_3$ with $Y_3 = \frac{1}{2}(Y_2 + \theta(Y_2))$ ($\ell \neq 2$), $\theta(Y_3) = Y_3$. Choose s with $T^s Y_3 \in \mathrm{PB}_a$; then $T^s z = d(T^s Y_3) \in \mathrm{TwB}(x, \kappa)$. □

Proposition E.52. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell \neq 2$ and $\Gamma_{\mathscr{H}}$ satisfying Φ_ℓ. Call a framed curve point $x = (k, \rho, 1_n, (\psi_{v,b}), f)$ of a universal polarised ordinary determinant over $\mathscr{H}$, normalised of shape $(a, n-a)$, **spanning** if for every $Z \in \mathrm{Ev}_a(A_k)$ some $T^s Z$ lies in the A_k-span of $\rho(\Gamma')$; an **extension** of x along an injective local homomorphism $j\colon A_k \to A_{k'}$ of $\mathcal{O}$-algebras making $A_{k'}$ a finite A_k-module is a spanning framed point $(k', j\circ\rho, 1_n, (j\circ\psi_{v,b}), j\circ f)$, normalised of shape $(a, n-a)$. Let x be spanning. Then:*

(Cf1) *x has a Selmer basis;*

(Cf2) *for every Selmer basis κ of x and every $\Sigma \subseteq \Gamma^0_{\mathscr{H}}$ that detects (x,κ), some finite subset of Σ detects (x,κ);*

(Cf3) *for every Selmer basis κ of x and all $\sigma_1, \dots, \sigma_q \in \Gamma^0_{\mathscr{H}}$ such that $\{\sigma_1, \dots, \sigma_q\}$ detects (x,κ) and every $\det(X - \rho(\sigma_j))$ is separable over F_k, there is an integer $d \geq 1$ such that for every multiple $D \geq 1$ of d there are an extension x' of x along some $j\colon A_k \to A_{k'}$ with $|k'| = \ell^D$, a Selmer basis κ' of x' such that $\{\sigma_1, \dots, \sigma_q\}$ detects (x', κ'), and pairwise distinct $\alpha_{j',1}, \dots, \alpha_{j',n} \in A_{k'}$ with $\det(X - j(\rho(\sigma_{j'}))) = \prod_i (X - \alpha_{j',i})$ for $1 \leq j' \leq q$.*

Proof. Write $A = A_k$, $F = F_k$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$; Γ^0 is open in $\Gamma_{\mathscr{H}}$, so it satisfies Φ_ℓ.

Step 1: continuous cocycles form a finitely generated module. Let V be a free A-module of finite rank with an A-linear action of Γ^0, continuous for the T-adic topology, and $Z^1(V)$ the A-module of T-adically continuous maps $z\colon \Gamma^0 \to V$ with $z(\gamma\gamma') = z(\gamma) + \gamma z(\gamma')$. The kernel Γ_1 of the action on V/TV is open. A cocycle with values in the finite group V/TV is, on Γ_1, a continuous homomorphism to $V/TV \cong (\mathbb{Z}/\ell)^N$ ($\ell = \mathrm{char}\, k$), of which there are finitely many by Φ_ℓ; and two cocycles with the same restriction to Γ_1 differ by a map that is constant on the finitely many cosets of Γ_1. So the cocycles with values in V/TV form a finite set. The kernel of reduction $Z^1(V) \to Z^1(V/TV)$ is $TZ^1(V)$ (T is a non-zero-divisor on V, and z/T is again a continuous cocycle); so $Z^1(V)/TZ^1(V)$ is finite-dimensional. $Z^1(V)$ is T-adically separated ($T^m Z^1(V)$ consists of cocycles with values in $T^m V$, and $\bigcap_m T^m V = 0$) and complete (a T-adic Cauchy sequence converges uniformly on Γ^0; the limit is a continuous cocycle). By topological Nakayama, $Z^1(V)$ is finitely generated; so is every A-submodule. Moreover $Z^1(V)$ is torsion-free.

Step 2: (Cf1). Take $V = \mathrm{Od}_a(A)$ with $\gamma \cdot Y = \rho(\gamma) Y \rho(\gamma)^{-1}$ (ρ is block diagonal, so V is stable). $Z^1_{\mathrm{ord}}(x)$ and $\mathrm{Bd}(x)$ are A-submodules of $Z^1(V)$ (all conditions of (Sd2) are A-linear in $(z, (Y_v))$), so $M = Z^1_{\mathrm{ord}}(x)/\mathrm{Bd}(x)$ is finitely generated and $M \otimes_A F$ is finite-dimensional. Choose $\kappa_1, \dots, \kappa_g \in Z^1_{\mathrm{ord}}(x)$ whose classes form an F-basis of $M \otimes_A F$ (multiply representatives by powers of T). If $\sum_j c_j \kappa_j \in \mathrm{Bd}(x)$ with $c \in A^g$, then $\sum_j c_j [\kappa_j] = 0$ in $M \otimes F$, so $c = 0$. For $z \in Z^1_{\mathrm{ord}}(x)$ write $[z] = \sum_j c'_j [\kappa_j]$ in $M \otimes F$, choose s with $c = T^s c' \in A^g$; then $T^s z - \sum_j c_j \kappa_j$ has torsion class in M, so $T^{s'}(T^s z - \sum_j c_j \kappa_j) \in \mathrm{Bd}(x)$ for some s'. So κ is a Selmer basis.

Step 3: (Cf2). Let $W = \mathrm{PB}_a$ with $\gamma \cdot Y = \chi_{\mathrm{cyc}}(\gamma) \rho_1(\gamma) Y \rho_1(\gamma)^{-1}$; W is stable (ρ is block diagonal, the κ_j have values in Od_a, and $\epsilon_j \epsilon'_j = \eta$ while all other products of $\epsilon, \epsilon', \eta$ vanish, so the conjugate of an element of PB_a has its same-block part in $A\eta$ and its different-block part in $\bigoplus_j A\epsilon'_j$), free of finite rank over A, with continuous action. $\mathrm{TwZ}(x,\kappa)$ is an A-submodule of $Z^1(W)$, hence finitely generated and torsion-free (Step 1), and the ℓ_σ are A-linear. For $\Sigma' \subseteq \Sigma$ put $K_{\Sigma'} = \{z \in \mathrm{TwZ} : \ell_\sigma(z) = 0 \ \forall \sigma \in \Sigma'\}$. Among finite $\Sigma_0 \subseteq \Sigma$ choose one with $\dim_F(K_{\Sigma_0} \otimes F)$ minimal. Let $z \in K_{\Sigma_0}$ and $\sigma \in \Sigma$. $K_{\Sigma_0 \cup \{\sigma\}} \otimes F \subseteq K_{\Sigma_0} \otimes F$ (localisation is exact) has the same dimension, so they are equal; hence $T^s z \in K_{\Sigma_0 \cup \{\sigma\}}$ for some s (TwZ is torsion-free), so $T^s \ell_\sigma(z) = 0$ and $\ell_\sigma(z) = 0$. So $K_{\Sigma_0} = K_\Sigma$, and as Σ detects, every $z \in K_{\Sigma_0}$ has $T^s z \in \mathrm{TwB}(x,\kappa)$: Σ_0 detects (x,κ).

Step 4: (Cf3). Let E/F be a splitting field of $\prod_j \det(X-\rho(\sigma_j))$, a finite separable extension. The integral closure A_E of A in E is a complete discrete valuation ring, finite and free over A, with finite residue field $k_E \supseteq k$; put $d = \log_\ell |k_E|$. Let $D \geq 1$ be a multiple of d, $k' \supseteq k_E$ the field with ℓ^D elements and $A' = k' \otimes_{k_E} A_E$, again a complete discrete valuation ring (unramified extension), finite free over A, with residue field k'; by Cohen, $A' \cong k'[[T']]$ for a uniformiser T', and $j\colon A \to A'$ is injective, local and finite. Fix an A-basis $e_1, \dots, e_r$ of A'. The roots of each $\det(X-\rho(\sigma_j))$ are integral over A and lie in E, hence in A', and are pairwise distinct by separability. Put $x' = (k', j\circ\rho, 1_n, (j\circ\psi_{v,b}), j\circ f)$ with frame $(j(w_v)), (I_u^x)$: it is a curve point normalised of shape $(a, n-a)$, framed, and spanning: $Z' \in \mathrm{Ev}_a(A')$ is $\sum_i e_i Z_i$ with $Z_i \in \mathrm{Ev}_a(A)$, and $j(T)$ is a unit times a power of T'. For every module V of Step 1 and its base change $V' = V \otimes_A A' = \bigoplus_i e_i V$ (with the action through j), a map $z' = \sum_i e_i z_i$ is a continuous cocycle (resp. satisfies the linear conditions of (Sd2), resp. of (Sd4)) if and only if every z_i is; so $Z^1_{\mathrm{ord}}(x') = \bigoplus_i e_i Z^1_{\mathrm{ord}}(x)$, $\mathrm{Bd}(x') = \bigoplus_i e_i \mathrm{Bd}(x)$, and with $\kappa'_j = j\circ\kappa_j$ (so $\rho'_1 = j\circ\rho_1$): $\mathrm{TwZ}(x',\kappa') = \bigoplus_i e_i \mathrm{TwZ}(x,\kappa)$, $\mathrm{TwB}(x',\kappa') = \bigoplus_i e_i \mathrm{TwB}(x,\kappa)$ and $\ell'_\sigma(\sum_i e_i z_i) = \sum_i e_i \ell_\sigma(z_i)$. Expanding coefficients in the basis (e_i), the two conditions of a Selmer basis for κ' follow componentwise from those for κ, and if $\ell'_{\sigma_j}(z') = 0$ for all j, then $\ell_{\sigma_j}(z_i) = 0$ for all i, j, so $T^s z_i \in \mathrm{TwB}(x,\kappa)$ for a common s, and $T^s z' \in \mathrm{TwB}(x',\kappa')$ (and T^s is a unit times a power of T'). So x', κ' and the roots have the properties of (Cf3), with $|k'| = \ell^D$. □

Proposition E.53. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell \neq 2$, and $x = (k, \rho, P, (\psi_{v,b}), f)$ a patchable curve point of endoscopic type of a universal polarised ordinary determinant over $\mathscr{H}$. Then there are a finite field $k' \supseteq k$, an injective local homomorphism of $\mathcal{O}$-algebras $j\colon A_k \to A_{k'}$ making $A_{k'}$ a finite A_k-module, an integer $1 \leq a < n$ and a framed curve point $x' = (k', \rho', 1_n, (\psi'_{v,b}), f')$, normalised of shape $(a, n-a)$, with (Nm1), (Nm2) and (Nm3) of Proposition E.54.*

Proof. Write $A = A_k$, $F = F_k$, $\varpi = T \in A$, and give $V = F^n$ the symmetric bilinear form $\langle v, w\rangle = {}^t v P w$; it is non-degenerate, and $\langle A^n, A^n\rangle \subseteq A$ as $P \in \mathrm{GL}_n(A)$. From $\rho(\gamma^*) = P^{-1}\,{}^t\rho(\gamma) P$ we get ${}^t\rho(\gamma)P = P\rho(\gamma^*)$, that is, the adjunction identity

$$\langle \rho(\gamma)v, w\rangle = \langle v, \rho(\gamma^*)w\rangle \qquad (\gamma \in \Gamma^0,\ v, w \in V).$$

Step 1: the two blocks are orthogonal. Let $a, b \geq 1$, $a+b = n$, Q, r_1, r_2, P_1, P_2 be as in the definition of endoscopic type. Put $\rho_Q(\gamma) = Q\rho(\gamma)Q^{-1} = \mathrm{diag}(r_1(\gamma), r_2(\gamma))$ and $P_Q = {}^t Q^{-1} P Q^{-1}$, a symmetric matrix in $\mathrm{GL}_n(F)$. Then $P_Q \rho_Q(\gamma^*) = {}^t\rho_Q(\gamma) P_Q$ Write $P_Q = \begin{pmatrix} X & Y \\ {}^t Y & W \end{pmatrix}$ with X of size $a\times a$ and Y of size $a\times b$. The upper right block of the identity reads $Y r_2(\gamma^*) = {}^t r_1(\gamma) Y$. Inserting $r_2(\gamma^*) = P_2^{-1}\,{}^t r_2(\gamma) P_2$ and multiplying by P_2^{-1} on the right gives $(YP_2^{-1})\,{}^t r_2(\gamma) = {}^t r_1(\gamma)(YP_2^{-1})$; transposing, $Y_0 = {}^t(YP_2^{-1}) \in \mathrm{M}_{b\times a}(F)$ satisfies $Y_0 r_1(\gamma) = r_2(\gamma) Y_0$ for all $\gamma \in \Gamma^0$, in particular for $\gamma \in \Gamma'$. By the last condition of endoscopic type $Y_0 = 0$, so $Y = 0$ and $P_Q = \mathrm{diag}(X, W)$ with X, W invertible. Put $V_1 = Q^{-1}(F^a \oplus 0)$ and $V_2 = Q^{-1}(0 \oplus F^b)$. They are $\rho(\Gamma^0)$-stable, $V = V_1 \oplus V_2$, and as $\langle Q^{-1}x, Q^{-1}y\rangle = {}^t x P_Q y$, $\langle V_1, V_2\rangle = 0$ and the form is non-degenerate on each V_i.

Step 2: an almost self-dual stable lattice in each block. Fix $i \in \{1, 2\}$. A lattice in V_i is a finitely generated A-submodule spanning V_i; it is stable if $\rho(\gamma)M \subseteq M$ for all $\gamma \in \Gamma^0$; its dual is $M^\vee = \{v \in V_i : \langle v, M\rangle \subseteq A\}$, again a lattice (the dual basis of a basis of M is a basis of $M^\vee$, by non-degeneracy). If M is stable so is $M^\vee$: for $v \in M^\vee$, $m \in M$, $\langle \rho(\gamma)v, m\rangle = \langle v, \rho(\gamma^*)m\rangle \in A$ as $\gamma^* \in \Gamma^0$. If $M \subseteq M'$ then $M'^\vee \subseteq M^\vee$. The module $M_0 = A^n \cap V_i$ is a stable lattice (finitely generated as a submodule of A^n; spanning, as $\varpi^N v \in A^n$ for $v \in V_i$ and N large) with $\langle M_0, M_0\rangle \subseteq A$, i.e. $M_0 \subseteq M_0^\vee$. Let $\mathcal{M}$ be the set of stable lattices M with $M_0 \subseteq M \subseteq M^\vee$.

It contains M_0, and each of its members satisfies $M_0 \subseteq M \subseteq M^\vee \subseteq M_0^\vee$; as $M_0^\vee/M_0$ has finite length and k is finite, $M_0^\vee/M_0$ is finite, so $\mathcal{M}$ is finite and has a member M_i maximal for inclusion. Let $r \geq 0$ be least with $\varpi^r M_i^\vee \subseteq M_i$, and suppose $r \geq 2$. Then $N = M_i + \varpi^{r-1} M_i^\vee$ is a stable lattice containing M_i, strictly by minimality of r. For $x, y \in M_i^\vee$ we have $\langle \varpi^r x, y\rangle \in \langle M_i, M_i^\vee\rangle \subseteq A$, so $\langle \varpi^{r-1}x, \varpi^{r-1}y\rangle \in \varpi^{r-2}A \subseteq A$; together with $\langle M_i, M_i\rangle \subseteq A$ and $\langle M_i, \varpi^{r-1}M_i^\vee\rangle \subseteq A$ this gives $N \subseteq N^\vee$, so $N \in \mathcal{M}$, contradicting maximality. Hence

$$\varpi M_i^\vee \subseteq M_i \subseteq M_i^\vee.$$

Step 3: orthogonal bases. Let U be a finite-dimensional F-vector space with a non-degenerate symmetric bilinear form and $M \subseteq U$ a lattice with $\langle M, M\rangle \subseteq A$. Then M has an A-basis of pairwise orthogonal vectors. Induction on $\dim U$, the case 0 being empty: let μ be the least valuation of $\langle x, y\rangle$, $x, y \in M$ (finite, as the form is non-zero on the spanning set M). As $2\langle x, y\rangle = \langle x+y, x+y\rangle - \langle x, x\rangle - \langle y, y\rangle$ and $2 \in A^\times$ ($\ell \neq 2$), there is $e \in M$ with $\langle e, e\rangle$ of valuation μ. For $x \in M$, $c_x = \langle x, e\rangle/\langle e, e\rangle \in A$ by minimality of μ, and $x - c_x e \in M_e = \{y \in M : \langle y, e\rangle = 0\}$; so $M = Ae \oplus M_e$, and M_e is a lattice in $e^\perp$ (finitely generated as the image of M under $x \mapsto x - c_x e$; spanning, as $\varpi^N u \in M \cap e^\perp = M_e$ for $u \in e^\perp$ and N large), on which the form is non-degenerate since $U = Fe \oplus e^\perp$ orthogonally. Induction applies to M_e. Apply this to $M_i \subseteq V_i$: there is a basis $e_1, \ldots, e_m$ of M_i with $\langle e_p, e_q\rangle = 0$ for $p \neq q$ and $\langle e_p, e_p\rangle = u_p \varpi^{m_p}$, $u_p \in A^\times$, $m_p \geq 0$. The dual basis is $(u_p^{-1}\varpi^{-m_p} e_p)_p$, so $M_i^\vee$ has basis $(\varpi^{-m_p} e_p)_p$, and $\varpi M_i^\vee \subseteq M_i$ gives $m_p \in \{0, 1\}$.

Step 4: a unimodular stable lattice after adjoining a square root of ϖ. Let k' be the quadratic extension of k; every element of k is a square in k' (the squares of the cyclic group $k'^\times$ form its subgroup of index 2, of order $(|k|-1)(|k|+1)/2$, divisible by $|k|-1$ as $|k|$ is odd, so it contains $k^\times$). Let $A' = A_{k'} = k'[[T]]$, $\varpi' = T \in A'$, $F' = F_{k'}$, and $j\colon A \to A'$ the homomorphism of k-algebras with $j(\varpi) = \varpi'^2$. It is an injective local homomorphism of $\mathcal{O}$-algebras ($\mathcal{O}$ acts through $\mathbb{F}_\mathcal{O} \subseteq k$), and A' is a free $j(A)$-module with basis $(\epsilon \varpi'^e)$, ϵ in a k-basis of k', $e \in \{0, 1\}$; so A' is a finite A-module. Extend j to $F \to F'$, regard $V \subseteq F'^n = V'$ through j, extend the form F'-bilinearly (its matrix is $j(P)$), and put $V_i' = F'V_i$; then $V' = V_1' \oplus V_2'$ orthogonally. Let M_i' be the A'-span of $\{e_p : m_p = 0\} \cup \{\varpi'^{-1} e_p : m_p = 1\}$. As $\varpi'^{-1} e_p = \varpi' \cdot \varpi^{-1} e_p$, $M_i' = A'M_i + \varpi' A' M_i^\vee$, which is stable under $\rho(\Gamma^0)$ (the entries of $\rho(\gamma)$ lie in $j(A) \subseteq A'$, and M_i, $M_i^\vee$ are stable). Its basis vectors are pairwise orthogonal, with $\langle e_p, e_p\rangle = j(u_p)$ if $m_p = 0$ and $\langle \varpi'^{-1} e_p, \varpi'^{-1} e_p\rangle = \varpi'^{-2} j(u_p \varpi) = j(u_p)$ if $m_p = 1$. Write $j(u_p) = c(1 + \varpi' y)$ with $c \in k^\times$, $y \in A'$; $c = d^2$ with $d \in k'$, and $1 + \varpi' y = h^2$ with $h \in A'$ by Hensel's lemma ($X^2 - (1 + \varpi' y)$ has the simple root 1 modulo ϖ', as $2 \in k'^\times$). Dividing each basis vector by $s_p = dh \in A'^\times$ gives an A'-basis $f_1^{(i)}, \ldots, f_{\dim V_i}^{(i)}$ of M_i' with $\langle f_p^{(i)}, f_q^{(i)}\rangle = \delta_{pq}$.

Step 5: the point x'. Let $S \in \mathrm{GL}_n(F')$ be the inverse of the matrix whose columns are $f_1^{(1)}, \ldots, f_a^{(1)}, f_1^{(2)}, \ldots, f_b^{(2)}$, and $\rho'(\gamma) = S\, j(\rho(\gamma))\, S^{-1}$, the matrix of $\rho(\gamma)$ in this basis of V'. As V_1', V_2' are stable, $\rho'(\gamma)$ is block diagonal with blocks of sizes a, $n-a$ ($a = \dim V_1$, $1 \leq a < n$); as M_1', M_2' are stable, its entries lie in A', and so do those of $\rho'(\gamma)^{-1} = \rho'(\gamma^{-1})$: $\rho'(\gamma) \in \mathrm{GL}_n(A')$. By Steps 1 and 4 the Gram matrix of the basis is 1_n, i.e. ${}^tS^{-1} j(P) S^{-1} = 1_n$, so $j(P) = {}^tSS$ and

$$\rho'(\gamma^*) = S\, j(P)^{-1}\, {}^t j(\rho(\gamma))\, j(P)\, S^{-1} = S\, S^{-1}\, {}^tS^{-1}\, {}^t j(\rho(\gamma))\, {}^tS\, S\, S^{-1} = {}^t\rho'(\gamma).$$

The entries of ρ' are fixed F'-linear combinations of those of $j \circ \rho$, hence continuous for the ϖ'-adic topology ($j(\varpi^N A) \subseteq \varpi'^{2N} A'$). Put $\psi'_{v,b} = j \circ \psi_{v,b}$ and $f' = j \circ f$. For $\gamma_1, \ldots, \gamma_m \in \Gamma^0$ and indeterminates $y_1, \ldots, y_m$, $\det(\sum_p y_p \rho'(\gamma_p)) = j(\det(\sum_p y_p \rho(\gamma_p)))$ in $F'[y]$, both sides lying in $A'[y]$; specialising the y_p in any A'-algebra shows that the determinant of ρ' is the base change along j of the determinant of ρ, so $f' \circ D^{\mathrm{u}} = j \circ (f \circ D^{\mathrm{u}}) = \det \circ \rho'$.

Step 6: frames. Fix $v \in S_\ell$. There is $h \in \mathrm{GL}_n(F)$ with $h\rho(\pi(g))h^{-1}$ upper triangular with diagonal $(\psi_{v,1}(g), \ldots, \psi_{v,n}(g))$ for $g \in D_v$. Let $U_c \subseteq V'$ ($0 \leq c \leq n$) be the F'-span of the first

c columns of $j(h)^{-1}$: a flag of $\rho(\pi(D_v))$-stable subspaces on whose quotient U_c/U_{c-1} the group D_v acts by $\psi'_{v,c}$. By (Pj1) for x the characters $\psi_{v,1},\dots,\psi_{v,n}$ are pairwise distinct, hence so are the $\psi'_{v,c}$ (j is injective); by the Jordan–Hölder theorem each occurs exactly once among the composition factors of the D_v-module V', and these are the composition factors of V'_1 together with those of V'_2. (a) Every D_v-stable subspace $U\subseteq V'$ satisfies $U=(U\cap V'_1)\oplus(U\cap V'_2)$. Let p_1,p_2 be the projections of $V'=V'_1\oplus V'_2$ (they commute with D_v). The map $p_1(U)\to p_2(U)/(U\cap V'_2)$, $p_1(u)\mapsto p_2(u)$ mod $U\cap V'_2$, is well defined (if $p_1(u)=p_1(u')$ then $u-u'=p_2(u)-p_2(u')\in U\cap V'_2$), D_v-equivariant and surjective, with kernel $U\cap V'_1$ (if $p_2(u)\in U$ then $p_1(u)=u-p_2(u)\in U$). So $p_1(U)/(U\cap V'_1)\cong p_2(U)/(U\cap V'_2)$ is a subquotient both of V'_1 and of V'_2; if it were non-zero, one of its composition factors would occur twice in V'. Hence $p_1(U)\subseteq U$, so also $p_2(U)\subseteq U$, and $U=p_1(U)\oplus p_2(U)$ with $p_i(U)=U\cap V'_i$. (b) Let $d_{i,c}=\dim(U_c\cap V'_i)$. By (a) $d_{1,c}+d_{2,c}=c$, and both are non-decreasing in c, so for each $1\le c\le n$ exactly one $\beta(c)\in\{1,2\}$ has $d_{\beta(c),c}=d_{\beta(c),c-1}+1$. The modules $N_{i,c}=U_c\cap M'_i$ satisfy $N_{i,c-1}=N_{i,c}\cap U_{c-1}$, so $N_{i,c}/N_{i,c-1}$ is finitely generated and torsion-free of rank $d_{i,c}-d_{i,c-1}$, hence free of rank 0 or 1. Choose $u_c\in N_{\beta(c),c}$ mapping to a generator of $N_{\beta(c),c}/N_{\beta(c),c-1}$. By induction on c, the $u_{c'}$ with $c'\le c$ and $\beta(c')=i$ form a basis of $N_{i,c}$; as $N_{i,n}=M'_i$, $(u_1,\dots,u_n)$ is an A'-basis of $M'_1\oplus M'_2$. Let $w_v\in\mathrm{M}_n(A')$ have as c-th column the coordinates of u_c in the basis $(f^{(1)},f^{(2)})$; it lies in $\mathrm{GL}_n(A')$ (as $M'_1\oplus M'_2$ has the basis $(f^{(1)},f^{(2)})$), and its c-th column has its non-zero entries in the block $\beta(c)$. For $g\in D_v$, $\rho(\pi(g))u_c-\psi'_{v,c}(g)u_c$ lies in U_{c-1} and in $M'_1\oplus M'_2$, hence by (a) in $(U_{c-1}\cap M'_1)\oplus(U_{c-1}\cap M'_2)=N_{1,c-1}\oplus N_{2,c-1}$, the span of $u_1,\dots,u_{c-1}$. So $w_v^{-1}\rho'(\pi(g))w_v$ is upper triangular with diagonal $(\psi'_{v,1}(g),\dots,\psi'_{v,n}(g))$. With $I_u^{x'}=\{1\}$ for $u\in\mathrm{St}$, $((w_v)_v,(I_u^{x'})_u)$ is a frame. In particular $\rho'\circ\pi$ is triangular over F' on each D_v with diagonal $(\psi'_{v,c})_c$, so by Step 5 $x'=(k',\rho',1_n,(\psi'_{v,b}),f')$ is a curve point, normalised of shape $(a,n-a)$, and framed.

Step 7: (Nm1)–(Nm3). (Nm1) holds by construction and Step 5. (Pj1) for x': $\psi'=j\circ\psi$ with j injective, and $j\circ\chi_{\mathrm{cyc}}|_{D_v}=\chi_{\mathrm{cyc}}|_{D_v}$ as χ_{cyc} takes values in the image of $\mathcal{O}^\times$ and j is a map of $\mathcal{O}$-algebras. (Np3): the characteristic polynomial of $\rho'(\sigma)$ is the image under j of that of $\rho(\sigma)$, and a polynomial separable over F stays separable over F'; so (Pj2) for x gives (Pj2) for x'. (Np4): let $Z\in\mathrm{M}_n(A')$ with $\chi_{\mathrm{cyc}}(\gamma)\rho'(\gamma)Z=Z\rho'(\gamma)$ for $\gamma\in\Delta_0$. Then $Z_S=S^{-1}ZS$ satisfies $\chi_{\mathrm{cyc}}(\gamma)j(\rho(\gamma))Z_S=Z_Sj(\rho(\gamma))$; writing $Z_S=\sum_q\epsilon_q j(Z_q)$ with (ϵ_q) a basis of F' over $j(F)$ and $Z_q\in\mathrm{M}_n(F)$, each Z_q satisfies the same relation for ρ (the entries of $\rho(\gamma)$ and $\chi_{\mathrm{cyc}}(\gamma)$ lie in F), so $Z_q=0$ by (Pj3) for x, and $Z=0$. (Nm3): $\rho'(\gamma)=(Sj(Q)^{-1})\,\mathrm{diag}(j(r_1(\gamma)),j(r_2(\gamma)))\,(Sj(Q)^{-1})^{-1}$, and $Sj(Q)^{-1}$ maps $F'^a\oplus 0=j(Q)(V'_1)$ onto $S(V'_1)=F'^a\oplus 0$ and $0\oplus F'^{n-a}=j(Q)(V'_2)$ onto $S(V'_2)=0\oplus F'^{n-a}$; so $Sj(Q)^{-1}=\mathrm{diag}(S_1,S_2)$ and $\rho'(\gamma)=\mathrm{diag}(r'_1(\gamma),r'_2(\gamma))$ with $r'_i=S_i\,j(r_i)\,S_i^{-1}$. Let $\bar F$ be an algebraic closure of F'. Then r'_1, r'_2 are irreducible over $\bar F$ on Γ', and 0 is the only $Y\in\mathrm{M}_{(n-a)\times a}(\bar F)$ with $Yr'_1(\sigma)=r'_2(\sigma)Y$ on Γ' (for such Y, $S_2^{-1}YS_1$ intertwines r_1 and r_2). Let $E\subseteq\mathrm{M}_a(\bar F)\times\mathrm{M}_{n-a}(\bar F)$ be the $\bar F$-span of $\{(r'_1(\sigma),r'_2(\sigma)):\sigma\in\Gamma'\}$, a subalgebra whose two projections p_1, p_2 are onto by Burnside's theorem. $K=E\cap(\mathrm{M}_a\times 0)$ is stable under left multiplication by E, so $p_1(K)$ is a two-sided ideal of $\mathrm{M}_a(\bar F)$. If $p_1(K)=\mathrm{M}_a(\bar F)$, then $\mathrm{M}_a\times 0\subseteq E$ and, p_2 being onto, $E=\mathrm{M}_a(\bar F)\times\mathrm{M}_{n-a}(\bar F)$. If $p_1(K)=0$, then $p_2|_E$ is injective, $p_1\circ(p_2|_E)^{-1}\colon\mathrm{M}_{n-a}(\bar F)\to\mathrm{M}_a(\bar F)$ is a surjective algebra homomorphism, injective as its source is simple, so $a=n-a$ and by Skolem–Noether it is $Z\mapsto Y^{-1}ZY$ for some invertible Y; then $Yr'_1(\sigma)=r'_2(\sigma)Y$ on Γ' with $Y\neq 0$, which is excluded. So $\dim_{\bar F}E=a^2+(n-a)^2$. The F'-span of $\rho'(\Gamma')$ lies in $\mathrm{Ev}_a(F')$ and has the same dimension as E (the rank of a family of vectors does not change under field extension), so it is $\mathrm{Ev}_a(F')$. Choose $\sigma_1,\dots,\sigma_N\in\Gamma'$ with $\rho'(\sigma_q)$ an F'-basis of $\mathrm{Ev}_a(F')$; each elementary matrix in Ev_a is an F'-combination of them, and clearing denominators gives $s\ge 0$ with $\varpi'^s\mathrm{Ev}_a(A')$ contained in the A'-span of $\rho'(\Gamma')$. This is (Nm3), ϖ' being the variable T of $A_{k'}$. □

Proposition E.54. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell\neq 2$,*

$(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ *a universal polarised ordinary determinant over* $\mathscr{H}$*, and* $x = (k, \rho, P, (\psi_{v,a}), f)$ *a patchable curve point of* B_n^{po} *of irreducible or of endoscopic type. Then there are a finite field* $k' \supseteq k$*, an injective local homomorphism of* $\mathcal{O}$*-algebras* $j\colon A_k \to A_{k'}$ *making* $A_{k'}$ *a finite* A_k*-module, an integer* $1 \le a \le n$ *and a framed curve point* $x' = (k', \rho', 1_n, (\psi'_{v,a}), f')$*, normalised of shape* $(a, n-a)$*, such that:*

(Nm1) $f' = j \circ f$ *and* $\psi'_{v,b} = j \circ \psi_{v,b}$ *for all* $v \in S_\ell$*,* $1 \le b \le n$*; in particular* $\det \circ \rho' = j \circ \det \circ \rho$*;*

(Nm2) x' *satisfies (Pj1), (Np3) and (Np4);*

(Nm3) *for every* $Z \in \mathrm{Ev}_a(A_{k'})$ *there is* $s \ge 0$ *such that* $T^s Z$ *lies in the* $A_{k'}$*-span of* $\rho'(\Gamma')$*;*

(Nm4) *if* x *is of irreducible type, then* $a = n$*.*

Proof. If x is of irreducible type, Lemma E.55 gives k', j (the inclusion $k[[T]] \subseteq k'[[T]]$, injective, local, and finite as $[k' : k] < \infty$) and x' with (Nm1)–(Nm4) and $a = n$. If x is of endoscopic type, Proposition E.53 gives k', j, $1 \le a < n$ and x' with (Nm1)–(Nm3); (Nm4) is void, as x is not of irreducible type (the two types exclude each other: at a point of endoscopic type $\rho \otimes \bar{F}_k$ restricted to Γ' is conjugate to a block-diagonal representation with blocks of sizes $a, b \ge 1$, so it is reducible). □

Lemma E.55. *Let* $\mathscr{H}$ *be a rank-n Hecke datum over a coefficient ring* $\mathcal{O}$ *with* $\ell \ne 2$*, and* $x = (k, \rho, P, (\psi_{v,a}), f)$ *a patchable curve point of irreducible type of a universal polarised ordinary determinant over* $\mathscr{H}$*. Then there are a finite field* $k' \supseteq k$ *with* $[k' : k] \le 2^n$*, and, with* $j\colon k[[T]] \to k'[[T]]$ *the inclusion, a framed curve point* $x' = (k', \rho', 1_n, (j \circ \psi_{v,a}), j \circ f)$*, normalised of shape* $(n, 0)$*, with (Nm1)–(Nm4) of Proposition E.54; moreover* $\rho' = S\rho S^{-1}$ *for some* $S \in \mathrm{GL}_n(k'[[T]])$*.*

Proof. Write $A = k[[T]]$, $F = k((T))$. $P \in \mathrm{GL}_n(A)$ is symmetric and $2 \in A^\times$, so $P = {}^t S_0 \,\mathrm{diag}(u_1, \dots, u_n)\, S_0$ with $S_0 \in \mathrm{GL}_n(A)$, $u_i \in A^\times$. Write $u_i = c_i(1 + Tm_i)$, $c_i \in k^\times$; $1 + Tm_i$ has a square root in A (Hensel, $\ell \ne 2$), and c_i has one in the field k' obtained by adjoining square roots of $c_1, \dots, c_n$ ($[k' : k] \le 2^n$). So $\mathrm{diag}(u_i) = {}^t R\, R$ with R diagonal in $\mathrm{GL}_n(A')$, $A' = k'[[T]]$; put $S = RS_0$, so $P = {}^t S S$, and $\rho'(\gamma) = S\rho(\gamma)S^{-1} \in \mathrm{GL}_n(A')$. Then $\rho'(\gamma^*) = SP^{-1}\,{}^t\rho(\gamma) P S^{-1} = SS^{-1}\,{}^t S^{-1}\,{}^t\rho(\gamma)\,{}^t S S\, S^{-1} = {}^t\rho'(\gamma)$; the entries of ρ' are T-adically continuous; $\det \circ \rho' = \det \circ \rho$, so $j \circ f$ and $j \circ \psi_{v,a}$ make x' a curve point once it is triangular on each D_v, which follows from the frame below; it is normalised of shape $(n, 0)$ with $P' = 1_n$.

Frames. For $v \in S_\ell$ there is $h \in \mathrm{GL}_n(F)$ with $h\rho(\pi g)h^{-1}$ upper triangular with diagonal $(\psi_{v,1}(g), \dots, \psi_{v,n}(g))$ for $g \in D_v$; the subspaces $V_i \subseteq F'^n$ ($F' = k'((T))$) spanned by the first i columns of Sh^{-1} form a $\rho'(\pi(D_v))$-stable flag on whose i-th graded piece D_v acts by $\psi_{v,i}$. The modules $M_i = V_i \cap A'^n$ are saturated, hence direct summands, and $\rho'(\pi(D_v))$-stable (ρ' has entries in A'); choosing a basis $w_1, \dots, w_n$ of A'^n with $M_i = \langle w_1, \dots, w_i \rangle$, $w_v = (w_1 | \cdots | w_n) \in \mathrm{GL}_n(A')$ has $w_v^{-1}\rho'(\pi g) w_v$ upper triangular with diagonal $(\psi_{v,i}(g))_i$. With $I_u^{x'} = \{1\}$ this is a frame (the column condition is empty for $a = n$).

(Nm1)–(Nm4). (Nm1) holds by construction and (Nm4) with $a = n$. (Pj1) for x': j is injective. (Np3): $\det(X - \rho'(\sigma)) = \det(X - \rho(\sigma))$, separable over F hence over F', so (Pj2) for x gives it for x'. (Np4): if $Z \in \mathrm{M}_n(A')$ satisfies $\chi_{\mathrm{cyc}}(\gamma)\rho'(\gamma)Z = Z\rho'(\gamma)$ on Δ_0, write $S^{-1}ZS = \sum_i e_i Z_i$ with (e_i) a k-basis of k' (an F-basis of F') and $Z_i \in \mathrm{M}_n(F)$; each Z_i satisfies the same relation for ρ, so $Z_i = 0$ by (Pj3) and $Z = 0$. (Nm3): $\rho \otimes \bar{F}$ is irreducible on Γ', so by Burnside the $\bar{F}$-span of $\rho(\Gamma')$ is $\mathrm{M}_n(\bar{F})$, hence the F'-span of $\rho'(\Gamma')$ is $\mathrm{M}_n(F')$; the A'-span Λ of $\rho'(\Gamma')$ is a submodule of $\mathrm{M}_n(A')$ of full rank, finitely generated (A' is Noetherian), so $T^s \mathrm{M}_n(A') \subseteq \Lambda$ for some s. □

E.2.4 The map from patched tuples to the eigenvalue algebra

This subsection proves Proposition E.56: the ring of patched tuples maps onto the eigenvalue algebra, the map kills the patching variables and the relations, and it detects the support. The patched tuples carry an abstract patching tower with nq patching variables (Proposition E.57) and form a universal ring on the patched group (Proposition E.60). The determinants of automorphic patching data factor through the pro-ℓ reduced levels (Corollary E.61, Lemma E.62), and the comparison with the level modules holds up to the isogeny element (Lemma E.58, Lemma E.63). Proposition E.56 is used in Proposition E.39 and in the construction of the patched ring, Proposition E.134.

Proposition E.56. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, and let automorphic patching data for an ideal $J \subseteq B$ along a Taylor–Wiles datum $\mathcal{D}$ of size q, $\mathcal{O}_1$, limit objects and $\tilde{c}$ be given as in Definition E.37, with patched tower data $(R, \beta, X, f, I, e+1, (M_N^\natural), \mathcal{U})$, eigenvalue algebra C^{sp}, $u\colon B \to C^{\mathrm{sp}}$ and $\pi\colon R \to C^{\mathrm{sp}}$. Assume that B is topologically generated as an $\mathcal{O}$-algebra by the coefficients of the polynomials $\chi_{D^{\mathrm{u}}}(\gamma)$, $\gamma \in \Gamma^0_{\mathscr{H}}$, and the values $\psi^{\mathrm{d}}_{v,a}(g)$, $v \in S_\ell$, $g \in D_v$. Then:*

(Wz1) *π is surjective, $\pi(\beta(y_{j,i})) = 0$ for all j, i, and $\pi(I) = 0$;*

(Wz2) *for every prime ideal P of C^{sp}: $\mathrm{Ann}_R(X) \subseteq \pi^{-1}(P)$ if and only if $J \subseteq u^{-1}(P)$;*

(Wz3) *let x be a curve point of B with homomorphism $f_x\colon B \to A_k$, $|k| = |\mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1}|$, which has eigenvalue data along $\mathcal{D}$, and let $f'\colon C^{\mathrm{sp}} \to A_k$ be a surjective ring homomorphism with $f' \circ u = f_x$ and $f'(z) = T$. Then $\mathfrak{q} = \pi^{-1}(\ker f')$ is a prime ideal of R with $f \notin \mathfrak{q}$, and for $\mathfrak{p} = \{a \in \Lambda : \beta(a) \in \mathfrak{q}\}$ the ring $\Lambda_{\mathfrak{p}}$ is regular local of dimension $1 + n[L^+ : \mathbb{Q}]$.*

Proof. Write $A = C_0^{\mathrm{sp}}$. By definition of π_0, for $x \in R_{\mathrm{tup}}[P^0]$, $\pi_0(\mathrm{tr}_{D^{\mathrm{t}}}(x)) = \mathrm{tr}_{\bar{D}^{\mathrm{u}}_A}(\bar{x})$ and $\pi_0(\Lambda_i(D^{\mathrm{t}})(g)) = \Lambda_i(\bar{D}^{\mathrm{u}}_A)(\bar{\theta}\pi_\infty(g))$, where $\bar{D}^{\mathrm{u}}_A$ is the base change of $\bar{D}^{\mathrm{u}}$ to A and $\bar{x}$ is the image of x under π_0 on coefficients and $\bar{\theta} \circ \pi_\infty$ on P^0; also $\pi_0(\psi^{\mathrm{t}}_{v,a}) = \psi^{\mathrm{d}}_{v,a}$, $\pi_0(s^{\mathrm{t}}) = z$, $\pi_0(U^{\mathrm{t}}_{j,i}) = u_{j,i}$, $\pi_0(y^{\mathrm{t}}_{j,i}) = 0$.

(Wz1). $\pi(\beta(y_{j,i})) = \pi(y^{\mathrm{t}}_{j,i}) = 0$. *Surjectivity.* $\bar{\theta} \circ \pi_\infty$ maps P^0 onto $\bar{\Gamma}^0$ (π_∞, $\bar{\theta}$ are onto and P^0 is a full preimage), so the image of π_0 contains the coefficients of all $\chi_{D^{\mathrm{u}}}(\gamma)$, $\gamma \in \Gamma^0_{\mathscr{H}}$, the values $\psi^{\mathrm{d}}_{v,a}(g)$, z and $Z_{j,i} = u_{j,i} - \tilde{u}_{j,i}$. By hypothesis and continuity of $B \to A$, the closure of the $\mathcal{O}$-algebra they generate contains B, z and the $Z_{j,i}$, hence is A: the image of π_0 is dense. As $\mathfrak{m}_A^2$ is open, $R_{\mathrm{tup}} \to A/\mathfrak{m}_A^2$ is onto, so $\mathfrak{m}_A = \mathfrak{m}_{R_{\mathrm{tup}}}A + \mathfrak{m}_A^2$ and, by Nakayama, $\mathfrak{m}_A = \mathfrak{m}_{R_{\mathrm{tup}}}A$. So A is separated for the $\mathfrak{m}_{R_{\mathrm{tup}}}$-adic topology and $A/\mathfrak{m}_{R_{\mathrm{tup}}}A = \mathbb{F}$ is generated by 1; by [166, Theorem 8.4], A is generated by 1 as an R_{tup}-module, i.e. π_0 is onto, and so is $\pi = \mathrm{id}_{\mathcal{O}_1} \otimes \pi_0$. *The relations.* It suffices that π_0 kills each relation of (Wv1)–(Wv6) (formed in R_{tup}). Let $\bar{h}$ be the image of h. (Wv1): $k \in \ker \pi_\infty$ maps to 1, so $h(k-1) \mapsto \bar{h}(1-1) = 0$. (Wv2): choose $g_0 \in G_L$ whose image in $\bar{\Gamma}^0$ is $\bar{\theta}\pi_\infty(g)$. By (L2), $\bar{\theta}(c_\infty) = \bar{c}$, so $\tilde{c}g^{-1}\tilde{c}^{-1}$ maps to the image of $cg_0^{-1}c^{-1} = cg_0^{-1}c$ ($c^2 = 1$); (Od1) for D^{u} gives equal characteristic polynomials, hence $\Lambda_i(\bar{D}^{\mathrm{u}}_A)$ agrees on the two images. (Wv3): by (L2), $\bar{\theta} \circ F_v$ is the map $D_v \to \bar{\Gamma}$ induced by $\pi_{\mathscr{H}}$, so g'_a maps to the image of g_a, and the image of the relation is $\mathrm{tr}(\bar{h}\prod_a(\pi(g_a) - \psi^{\mathrm{d}}_{v,a}(g_a)))$, which is 0 by (Od2). (Wv4): $g \in I_{\bar{u}} \cap G_L$ with all $\bar{\chi}_a(g) = 1$ at $u \in \mathrm{St}$ (not above ℓ) lies in $N_{\mathscr{H}}$, so $\pi_{\mathscr{H}}(g) = 1$ and, by (L2), g' maps to 1; the relation maps to 0 as in (Wv1). (Wv5): ϕ maps to $\bar{\theta}(\Phi_j) = \bar{\sigma}_j$ by (L2), and in $A[X]$, $\prod_k(X - u_{j,k}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(X)$ by definition of A. So the relation maps to $\mathrm{tr}(\bar{h}\,\chi(\bar{\sigma}_j)(\bar{\sigma}_j))$ with $\chi = \chi_{\bar{D}^{\mathrm{u}}_A}$; $\chi(\bar{\sigma}_j)(\bar{\sigma}_j)$ lies in the Cayley–Hamilton ideal, contained in $\ker(\bar{D}^{\mathrm{u}}_A)$ by Theorem B.88, and the trace vanishes on the two-sided ideal $\ker(\bar{D}^{\mathrm{u}}_A)$. (Wv6): τ maps to $\bar{\theta}(\mathrm{T}_j) = 1$ by (L2) and $y^{\mathrm{t}}_{j,i} \mapsto 0$, so the factor $\tau - 1 - y^{\mathrm{t}}_{j,i}$ maps to 0.

(Wz2). As R acts on X through the surjection π, $\mathrm{Ann}_R(X) = \pi^{-1}(\mathrm{Ann}_{C^{\mathrm{sp}}}(X))$, so $\mathrm{Ann}_R(X) \subseteq \pi^{-1}(P)$ if and only if $\mathrm{Ann}_{C^{\mathrm{sp}}}(X) \subseteq P$, i.e. $P \in \mathrm{Supp}(X)$ ($X = C^{\mathrm{sp}} \otimes_B M$ is finite over C^{sp}, M being finite over B as in Proposition E.57). Put $\mathfrak{p}_B = u^{-1}(P)$. Then $X_P = C^{\mathrm{sp}}_P \otimes_{B_{\mathfrak{p}_B}} M_{\mathfrak{p}_B}$; if $M_{\mathfrak{p}_B} \neq 0$, Nakayama gives $M_{\mathfrak{p}_B} \otimes \kappa(\mathfrak{p}_B) \neq 0$ and $X_P \otimes \kappa(P) = (M_{\mathfrak{p}_B} \otimes \kappa(\mathfrak{p}_B)) \otimes_{\kappa(\mathfrak{p}_B)} \kappa(P) \neq 0$; if $M_{\mathfrak{p}_B} = 0$ then $X_P = 0$. So $P \in \mathrm{Supp}(X)$ if and only if $\mathfrak{p}_B \in \mathrm{Supp}_B(M) = V(\mathrm{Ann}_B(M))$, which by (Hl1) holds if and only if $J \subseteq \mathfrak{p}_B$.

(Wz3). $\ker f'$ is prime (A_k is a domain) and π is onto, so $\mathfrak{q}$ is prime. Let $(\alpha_{j,i})$ be the eigenvalue data of x: $\det(X - \rho(\sigma_j)) = \prod_i (X - \alpha_{j,i})$ with $\alpha_{j,1}, \dots, \alpha_{j,n}$ pairwise distinct. As $f_x \circ D^{\mathrm{u}} = \det \circ \rho$ and $f' \circ u = f_x$, applying f' to $\prod_i (X - u_{j,i}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(X)$ gives $\prod_i (X - f'(u_{j,i})) = \prod_i (X - \alpha_{j,i})$ in $A_k[X]$; A_k being a domain, $(f'(u_{j,i}))_i$ is a permutation of $(\alpha_{j,i})_i$. Hence $f'(\pi(f)) = \prod_j \prod_{i \neq i'} (f'(u_{j,i}) - f'(u_{j,i'}))^2 \neq 0$, i.e. $f \notin \mathfrak{q}$. Next, $\phi = f' \circ \pi \circ \beta|_\Lambda \colon \Lambda \to A_k$ is a local homomorphism (composite of continuous local maps and a surjection of local rings) with $\phi(X_0) = f'(z) = T$; its residue map $\mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1} \to k$ is an injection of finite fields of the same cardinality, hence bijective. So $\mathfrak{m}_\Lambda A_k \supseteq T A_k = \mathfrak{m}_{A_k}$, hence $\mathfrak{m}_\Lambda A_k = \mathfrak{m}_{A_k}$ and $A_k/\mathfrak{m}_\Lambda A_k = k$ is generated by 1 over Λ; A_k is $\mathfrak{m}_\Lambda$-adically separated, so by [166, Theorem 8.4] ϕ is onto, and $\Lambda/\mathfrak{p} \cong A_k$ ($\mathfrak{p} = \ker \phi$) has dimension 1. $\Lambda = \mathcal{O}_1[[X_0, \dots, X_D]]$ is regular local of dimension $D + 2$, so $\Lambda_{\mathfrak{p}}$ is regular of dimension $\mathrm{ht}\,\mathfrak{p} = (D+2) - 1 = 1 + D = 1 + n[L^+ : \mathbb{Q}]$. □

Proposition E.57. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, and let automorphic patching data with exponent e for an ideal J along a Taylor–Wiles datum of size q, $\mathcal{O}_1$, limit objects and $\tilde{c}$ be given as in Definition E.37, with patched tower data $(R, \beta, X, f, I, e+1, (M_N^\natural)_{N \geq 1}, \mathcal{U})$ over $S = \Lambda[[y_{j,i} : 1 \leq j \leq q,\ 1 \leq i \leq n]]$. Then this tuple is an abstract patching tower over S, with nq patching variables. Moreover the eigenvalue algebra C_0^{sp} is a free $B[[z]]$-module of finite positive rank.*

Proof. Step 0: the ring. $R_{\mathrm{tup}} \in \mathrm{CNL}_{\mathcal{O}}$ by Proposition E.60, with residue field $\mathbb{F} = \mathcal{O}/\mathfrak{m}_{\mathcal{O}}$. $R = \mathcal{O}_1 \otimes_{\mathcal{O}} R_{\mathrm{tup}}$ is a free R_{tup}-module of finite rank, hence Noetherian and integral over R_{tup}; every maximal ideal of R therefore contracts to $\mathfrak{m}_{R_{\mathrm{tup}}}$ and contains $\mathfrak{m}_{R_{\mathrm{tup}}} R$, and $R/\mathfrak{m}_{R_{\mathrm{tup}}} R = \mathcal{O}_1/\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1$ is a field because $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathfrak{m}_{\mathcal{O}_1}$. So R is a Noetherian local ring with $\mathfrak{m}_R = \mathfrak{m}_{R_{\mathrm{tup}}} R$. Λ is a complete Noetherian local ring with finite residue field $\mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1}$, $e + 1 \geq 1$, and $\mathcal{U}$ is a non-principal ultrafilter by Lemma E.42; it contains the complement of every finite set.

Step 1: C_0^{sp} is free of finite positive rank over $A = B[[z]]$. A is a complete Noetherian local $\mathcal{O}$-algebra with residue field $\mathbb{F}$, $C_0^{\mathrm{sp}} = \mathrm{Sp}_A(P)$ for $P_j = \chi_{D^{\mathrm{u}}}(\sigma_j)$ in the notation of Lemma E.59, and $P_j \equiv \prod_i (X - \bar{\chi}_i(\sigma_j)) \equiv \prod_i (X - \tilde{u}_{j,i})$ modulo $\mathfrak{m}_A$ (the reduction of D^{u} is $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$). By Lemma E.59, C_0^{sp} is free over A of some rank $r_0 \geq 1$.

Step 2: (Tow0). The Λ-module structure of X is through $\pi \circ \beta$, and by the definition of π_0: $\pi(\beta(X_0)) = z$, $\pi(\beta(X_k)) = c_k \psi^{\mathrm{d}}_{v_k, a_k}(\gamma_k) - 1 = \lambda_B(X_k) \in B$ (the weight map of $(\psi^{\mathrm{d}}_{v,a})$), and $\pi(\beta(y_{j,i})) = 0$. So $\beta(y_{j,i}) X = 0$. By (Hl1), $M \cong \Lambda_D^m$ as Λ_D-modules through λ_B; M is finitely generated over Λ_D, hence over B, hence finitely presented over the Noetherian ring B, and $B[[z]] \otimes_B M \cong M[[z]]$ (true for finite free M; both sides are right exact in M, as $M \mapsto M[[z]]$ is exact). Hence, with a basis of C_0^{sp} over A from Step 1,

$$X = \mathcal{O}_1 \otimes_{\mathcal{O}} (C_0^{\mathrm{sp}} \otimes_A M[[z]]) \cong \mathcal{O}_1 \otimes_{\mathcal{O}} M[[z]]^{r_0} \cong (\mathcal{O}_1 \otimes_{\mathcal{O}} \Lambda_D[[z]])^{r_0 m} = \Lambda^{r_0 m},$$

the isomorphisms being A-linear, so Λ_D-linear through λ_B and with X_0 acting as z; X is a free Λ-module of rank $r_0 m$.

Step 3: (Tow1). Let $k, j \geq 1$ and $N \in \mathcal{N}_0$. By (Ha2), M_N is finitely generated over S_∞ through s_N, hence over R_N, and $R_N[[z]] \otimes_{R_N} M_N \cong M_N[[z]]$ as in Step 2. S acts on $M_N^\natural$ through $\rho_N \circ \beta$: $X_0 \mapsto z$, $X_k \mapsto c_k \psi_{N, v_k, a_k}(\gamma_k) - 1 = s_N(X_k)$ by (Ha1), $y_{j,i} \mapsto s_N(Y_{j,i})$. So

(Ha2) gives an isomorphism of S-modules $M_N^\natural \cong \mathcal{O}_1 \otimes_{\mathcal{O}} ((S_\infty/\mathfrak{d}_{a_N})[[z]])^{\mathrm{rk}_N} = (S/\mathfrak{d}_{a_N}S)^{\mathrm{rk}_N}$, where $S_\infty[[z]]$ is identified with $\mathcal{O}[[X_0,\dots,X_D]][[y_{j,i}]]$ by $z = X_0$, $Y_{j,i} = y_{j,i}$. If $a_N \geq k+j$, then $\mathfrak{d}_{a_N}S \subseteq \mathfrak{c}_{k,j}$: $(1+y_{j,i})^{\ell^a} - 1 = \sum_{m\geq 1}\binom{\ell^a}{m} y_{j,i}^m$, the terms with $m \geq k$ lie in $(y)^k$, and for $1 \leq m < k$, $v_\ell\binom{\ell^a}{m} = a - v_\ell(m) \geq a-k \geq j$, so these terms lie in $\ell^j S \subseteq \mathfrak{m}_\Lambda^j S$. Hence $M_N^\natural/\mathfrak{c}_{k,j}M_N^\natural \cong (S/\mathfrak{c}_{k,j})^{\mathrm{rk}_N}$ is free of finite rank for every $N \in \mathcal{N}_0$ with $N \geq k+j$ (as $a_N \geq N$). This set belongs to $\mathcal{U}$ ($\mathcal{N}_0 \in \mathcal{U}$, and the finite set $\{N < k+j\}$ does not).

Step 4: (Tow2). This is Lemma E.58.

Step 5: (Tow3). I is generated by the set of relations (Wv1)–(Wv6); as R is Noetherian, a finite subset G of relations generates I. For each $g \in G$ and $j \geq 1$, Lemma E.63 gives the required set in $\mathcal{U}$ with exponent $e+1$.

The patching variables are the $y_{j,i}$, $1 \leq j \leq q$, $1 \leq i \leq n$: there are nq of them. □

Lemma E.58. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ and let automorphic patching data, $\mathcal{O}_1$, limit objects and $\tilde{c}$ be given as in Definition E.37, with patched tower data $(R,\beta,X,f,I,e+1,(M_N^\natural)_{N\geq 1},\mathcal{U})$ over $S = \Lambda[[y_{j,i}]]$. Then for every $j \geq 1$ the set of N for which there are R-linear maps*

$$\varphi\colon X/\mathfrak{m}_\Lambda^j X \to M_N^\natural/\mathfrak{c}_{1,j}M_N^\natural, \qquad \psi\colon M_N^\natural/\mathfrak{c}_{1,j}M_N^\natural \to X/\mathfrak{m}_\Lambda^j X$$

with $\psi\circ\varphi$ and $\varphi\circ\psi$ both equal to multiplication by f belongs to $\mathcal{U}$.

Proof. Fix $j \geq 1$. Put $P_{j'}^\infty = \chi_{D^{\mathrm{u}}}(\sigma_{j'})$ and $P_{j'}^N = \chi_{D^{\mathrm{u}}}(h_N(\Phi_{N,j'}))$; then $\mathrm{Sp}_N = \mathrm{Sp}_B(P^N)$, and we put $\mathrm{Sp}_\infty = \mathrm{Sp}_B(P^\infty)$, so that $C_0^{\mathrm{sp}} = \mathrm{Sp}_\infty[[z]]$. By (Tg3), $h_N(\Phi_{N,j'})\sigma_{j'}^{-1} \in H$, on which the $\bar{\chi}_a$ are trivial; so all P^N and P^∞ have the same reduction modulo $\mathfrak{m}_B$, and by Lemma E.59 Sp_N and Sp_∞ are free B-modules of one rank $r_0 \geq 1$. Let $M \cong \Lambda_D^m$ by (Hl1), $\Lambda' = \Lambda_D[[z]]$, and for a B-algebra Sp free of rank r_0 let $W(\mathrm{Sp}) = (\mathrm{Sp}\otimes_B M)[[z]]/\mathfrak{m}_{\Lambda'}^j(\mathrm{Sp}\otimes_B M)[[z]]$, Λ_D acting through λ_B and z by multiplication. Then $X/\mathfrak{m}_\Lambda^j X = \mathcal{O}_1 \otimes_{\mathcal{O}} W(\mathrm{Sp}_\infty)$ (as $\mathfrak{m}_\Lambda = \mathfrak{m}_{\Lambda'}\Lambda$, $\mathcal{O}_1$ being flat and unramified over $\mathcal{O}$), and $M_N^\natural/\mathfrak{c}_{1,j}M_N^\natural = \mathcal{O}_1 \otimes_{\mathcal{O}} W_N$ with $W_N = X_N[[z]]/\mathfrak{m}_{\Lambda'}^j X_N[[z]]$, Λ_D acting through s_N ($N \in \mathcal{N}_0$).

Step 1: a uniform exponent. Let $e_j = |\Lambda_D/\mathfrak{m}_{\Lambda_D}^j|^{r_0 m}$. For Sp as above, $Q = (\mathrm{Sp}\otimes_B M)/\mathfrak{m}_{\Lambda_D}^j(\mathrm{Sp}\otimes_B M)$ is a B-module (Λ_D acts through B) with $\mathrm{Sp}\otimes_B M \cong M^{r_0} \cong \Lambda_D^{r_0 m}$ over Λ_D, so $|Q| = e_j$. In the chain $Q \supseteq \mathfrak{m}_B Q \supseteq \mathfrak{m}_B^2 Q \supseteq \dots$, equality $\mathfrak{m}_B^k Q = \mathfrak{m}_B^{k+1}Q$ forces $\mathfrak{m}_B^k Q = 0$ (Nakayama), so the chain reaches 0 after at most $|Q|$ steps: $\mathfrak{m}_B^{e_j}(\mathrm{Sp}\otimes_B M) \subseteq \mathfrak{m}_{\Lambda_D}^j(\mathrm{Sp}\otimes_B M)$. Hence $\mathfrak{m}_B^{e_j}$ kills $W(\mathrm{Sp})$, and $W(\mathrm{Sp})$ depends only on $\mathrm{Sp}/\mathfrak{m}_B^{e_j}\mathrm{Sp}$.

Step 2: the set of N. $B/\mathfrak{m}_B^{e_j}$ is finite and $\bar{D}^{\mathrm{u}}$ is continuous on the compact group $\bar{\Gamma}^0$, so there is an open normal subgroup $\bar{V}$ of $\bar{\Gamma}$ with $\Lambda_i(\bar{D}^{\mathrm{u}})(\gamma v) - \Lambda_i(\bar{D}^{\mathrm{u}})(\gamma) \in \mathfrak{m}_B^{e_j}$ for all $\gamma \in \bar{\Gamma}^0$, $v \in \bar{V}\cap\bar{\Gamma}^0$, $1 \leq i \leq n$; let $V \subseteq \Gamma_{\mathscr{H}}$ be its preimage (open normal, containing $\mathrm{PL}(H)$). Let $\mathcal{N}_2$ be the set of $N \in \mathcal{N}_0$ with $N \geq j$, $h_N(\Phi_{N,j'})\sigma_{j'}^{-1} \in V$ for all j' (true for large N by (Tg3)), and $\bar{h}_N(\pi_N(g))\bar{V} = \bar{\theta}(\pi_\infty(g))\bar{V}$ for all $g \in \Pi$ ((L1)(ii)). Then $\mathcal{N}_2 \in \mathcal{U}$. Fix $N \in \mathcal{N}_2$.

Step 3: identification of the eigenvalue algebras. The coefficients of $P_{j'}^N$ and $P_{j'}^\infty$ are $\Lambda_i(\bar{D}^{\mathrm{u}})$ at elements of $\bar{\Gamma}^0$ differing by an element of $\bar{V}$, so $P^N \equiv P^\infty$ modulo $\mathfrak{m}_B^{e_j}$. Hence the identity of $B[[Z_{j',i}]]$ induces a B-algebra isomorphism $\iota\colon \mathrm{Sp}_N/\mathfrak{m}_B^{e_j} \to \mathrm{Sp}_\infty/\mathfrak{m}_B^{e_j}$ with $\iota(u_{j',i}) = u_{j',i}$, and (Step 1) a ι-semilinear bijection $W(\mathrm{Sp}_N) \to W(\mathrm{Sp}_\infty)$, also denoted ι.

Step 4: π_0 through level N. Let $\theta_N^z\colon R_N[[z]] \to \mathrm{Sp}_N[[z]]$ be θ_N on coefficients, and $\vartheta = \iota\circ\theta_N^z\circ\rho_N^0\colon R_{\mathrm{tup}} \to (\mathrm{Sp}_\infty/\mathfrak{m}_B^{e_j})[[z]]$, a morphism of $\mathrm{CNL}_{\mathcal{O}}$, as is the reduction $\bar{\pi}_0$ of π_0. We compare the images of t^{u}. By (Ha3): $s^{\mathrm{t}} \mapsto z$ under both; $U_{j',i}^{\mathrm{t}} \mapsto \iota(\theta_N(U_{N,j',i})) = u_{j',i}$; $y_{j',i}^{\mathrm{t}} \mapsto \theta_N(s_N(Y_{j',i})) = \lambda_B(0) = 0$; $\psi_{v,a}^{\mathrm{t}} \mapsto \theta_N\circ\psi_{N,v,a} = \psi_{v,a}^{\mathrm{d}}$. For the determinants it suffices

by (Ch1) to compare characteristic polynomials at $g \in P^0$: write $\pi_N(g) = p_N(\gamma)$, $\gamma \in \Gamma_N^0$; by (Ha3), $\theta_N(\Lambda_i(\bar{D}_N)(\pi_N(g))) = \theta_N(\Lambda_i(D_N)(\gamma)) = \Lambda_i(D^{\mathrm{u}})(h_N(\gamma)) = \Lambda_i(\bar{D}^{\mathrm{u}})(\bar{h}_N(\pi_N(g)))$, while π_0 gives $\Lambda_i(\bar{D}^{\mathrm{u}})(\bar{\theta}(\pi_\infty(g)))$; these agree modulo $\mathfrak{m}_B^{e_j}$ by the choice of $\mathcal{N}_2$. By the uniqueness in Proposition E.60, $\vartheta = \bar{\pi}_0$.

Step 5: the maps. Extend φ_N, ψ_N coefficientwise in z to $\Phi\colon (\mathrm{Sp}_N \otimes_B M)[[z]] \to X_N[[z]]$ and Ψ back; by (Ha4), $\Phi(\theta_N^z(t)\xi) = t\Phi(\xi)$, $\Psi(tx) = \theta_N^z(t)\Psi(x)$ for $t \in R_N[[z]]$ (each coefficient is a finite sum), $\Phi\Psi = f_{(q_{N,j'})}(U_N)$ and $\Psi\Phi = \theta_N(f_{(q_{N,j'})}(U_N))$. For $\lambda \in \Lambda_D$, $\lambda_B(\lambda) = \theta_N(s_N(\lambda))$ by (Ha3), so $\Phi(\lambda\xi) = s_N(\lambda)\Phi(\xi)$ and $\Psi(s_N(\lambda)x) = \lambda\Psi(x)$; with z-linearity, Φ and Ψ respect the submodules $\mathfrak{m}_{\Lambda'}^j(\cdot)$ and induce $\bar{\Phi}\colon W(\mathrm{Sp}_N) \to W_N$, $\bar{\Psi}\colon W_N \to W(\mathrm{Sp}_N)$. Put $\varphi = \mathrm{id}_{\mathcal{O}_1} \otimes (\bar{\Phi} \circ \iota^{-1})$ and $\psi = \mathrm{id}_{\mathcal{O}_1} \otimes (\iota \circ \bar{\Psi})$. R-linearity: for $r \in R_{\mathrm{tup}}$, $\pi_0(r)$ acts on $W(\mathrm{Sp}_\infty)$ through $\bar{\pi}_0(r) = \vartheta(r) = \iota(\theta_N^z(\rho_N^0(r)))$ (Step 1, Step 4), so $\varphi(\pi_0(r)\xi) = \bar{\Phi}(\theta_N^z(\rho_N^0(r))\iota^{-1}\xi) = \rho_N^0(r)\varphi(\xi)$, and likewise $\psi(\rho_N^0(r)x) = \vartheta(r)\psi(x) = \pi_0(r)\psi(x)$; both extend $\mathcal{O}_1$-linearly to R. Composites: $\varphi\psi$ is multiplication by $f_{(q_{N,j'})}(U_N) = \rho_N^0(f_{(q_{N,j'})}(U^{\mathrm{t}}))$, which differs from $\rho_N^0(f)$ by an element of $\ell^N R_N$ (each factor changes by $(q_{N,j'} - 1)U_{N,j',i'}$, (Tg2)); as $N \geq j$ and $\ell^j \in \mathfrak{m}_{\Lambda_D}^j$ kills W_N, $\varphi\psi = f$. Similarly $\psi\varphi$ is multiplication by $\iota(\theta_N(f_{(q_{N,j'})}(U_N))) = f_{(q_{N,j'})}(u) \equiv f_{(1)}(u) = \pi_0(f)$ modulo ℓ^N, and ℓ^j kills $W(\mathrm{Sp}_\infty)$; so $\psi\varphi = f$. This holds for every $N \in \mathcal{N}_2 \in \mathcal{U}$. □

Lemma E.59. *Let $\mathcal{O}$ be a complete discrete valuation ring with finite residue field $\mathbb{F}$, A a complete Noetherian local $\mathcal{O}$-algebra with residue field $\mathbb{F}$, $n, q \geq 1$, $P_1, \dots, P_q \in A[X]$ monic of degree n, and $\tilde{u}_{j,i} \in \mathcal{O}$ ($1 \leq j \leq q$, $1 \leq i \leq n$) with $P_j \equiv \prod_{i=1}^n (X - \tilde{u}_{j,i})$ modulo $\mathfrak{m}_A$. Put*

$$\mathrm{Sp}_A(P) = A[[Z_{j,i}]] \Big/ \Big(\text{the coefficients of } \textstyle\prod_{i=1}^n (X - \tilde{u}_{j,i} - Z_{j,i}) - P_j(X),\ 1 \leq j \leq q\Big).$$

Then $\mathrm{Sp}_A(P)$ is a local ring with residue field $\mathbb{F}$ and a free A-module of finite rank $r \geq 1$, and r depends only on the reductions $\bar{P}_j \in \mathbb{F}[X]$ and the $\tilde{u}_{j,i}$ modulo $\mathfrak{m}_{\mathcal{O}}$.

Proof. Let $\mathrm{Spl} = A[V_{j,i}]/(\text{coefficients of } \prod_i (X - V_{j,i}) - P_j(X),\ 1 \leq j \leq q)$, the tensor product over A of the universal splitting algebras of the P_j; it is free of rank $(n!)^q$ over A. By hypothesis $V_{j,i} \mapsto \tilde{u}_{j,i} \bmod \mathfrak{m}_{\mathcal{O}}$ defines a surjection $\mathrm{Spl} \to \mathbb{F}$ (it kills the relations, which reduce to those of $\bar{P}_j = \prod_i (X - \bar{u}_{j,i})$); let $\mathfrak{n}_0$ be its kernel, a maximal ideal. As A is complete local and Spl finite over A, $\mathrm{Spl} = \prod_{\mathfrak{n}} \mathrm{Spl}_{\mathfrak{n}}$; so $\mathrm{Spl}_{\mathfrak{n}_0} \neq 0$ is a direct summand of a free A-module of finite rank, hence free of finite rank $r \geq 1$, and $r = \dim_{\mathbb{F}}(\mathrm{Spl}/\mathfrak{m}_A\mathrm{Spl})_{\bar{\mathfrak{n}}_0}$ depends only on $\mathrm{Spl}/\mathfrak{m}_A\mathrm{Spl}$ (the splitting algebra of the $\bar{P}_j$ over $\mathbb{F}$) and the point $\bar{u}$.

$\mathrm{Spl}_{\mathfrak{n}_0}$ is finite over A, hence $\mathfrak{m}_A$-adically complete; for its maximal ideal $\mathfrak{n}$, $\mathfrak{n}^s \subseteq \mathfrak{m}_A\mathrm{Spl}_{\mathfrak{n}_0} \subseteq \mathfrak{n}$ for some s (the quotient by $\mathfrak{m}_A$ is Artinian local), so it is $\mathfrak{n}$-adically complete. Hence $A[Z_{j,i}] \to \mathrm{Spl}_{\mathfrak{n}_0}$, $Z_{j,i} \mapsto V_{j,i} - \tilde{u}_{j,i} \in \mathfrak{n}$, extends continuously to $A[[Z_{j,i}]]$, kills the defining relations of $\mathrm{Sp}_A(P)$ and gives $\alpha\colon \mathrm{Sp}_A(P) \to \mathrm{Spl}_{\mathfrak{n}_0}$. $\mathrm{Sp}_A(P)$ is a quotient of the local ring $A[[Z_{j,i}]]$ by an ideal contained in $(\mathfrak{m}_A, Z_{j,i})$ (the relations reduce to 0 modulo it), so it is local with residue field $\mathbb{F}$ and complete. $V_{j,i} \mapsto \tilde{u}_{j,i} + Z_{j,i}$ defines $\mathrm{Spl} \to \mathrm{Sp}_A(P)$, whose composite with the residue map has kernel $\mathfrak{n}_0$; elements outside $\mathfrak{n}_0$ go to units, so it factors through $\gamma\colon \mathrm{Spl}_{\mathfrak{n}_0} \to \mathrm{Sp}_A(P)$. $\gamma \circ \alpha$ is a local homomorphism of complete Noetherian local rings fixing A and the $Z_{j,i}$, hence continuous and the identity on a dense subring, hence the identity; $\alpha \circ \gamma$ is the identity on the image of Spl, hence on its localisation. So $\mathrm{Sp}_A(P) \cong \mathrm{Spl}_{\mathfrak{n}_0}$. □

Proposition E.60. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $\mathcal{D}$ a Taylor–Wiles datum of size q for $\mathscr{H}$ with $H, \sigma_1, \dots, \sigma_q$, $(\Pi, (\pi_N), \mathcal{U}, \bar{\theta}, c_\infty, (\Phi_j), (\mathrm{T}_j), (F_w))$ as in the conclusion of Lemma E.42, $\bar{\Gamma}_\infty^0 = \bar{\theta}^{-1}(\overline{\Gamma_{\mathscr{H}}^0})$ ($\overline{\Gamma_{\mathscr{H}}^0}$ the image of $\Gamma_{\mathscr{H}}^0$ in $\bar{\Gamma}$) and $P^0 = \pi_\infty^{-1}(\bar{\Gamma}_\infty^0)$, and $\tilde{u}_{j,i} \in \mathcal{O}$ ($1 \leq j \leq q$, $1 \leq i \leq n$) with $\tilde{u}_{j,i} \equiv \bar{\chi}_i(\sigma_j)$ modulo $\mathfrak{m}_{\mathcal{O}}$. Since the $\bar{\chi}_a$ are trivial on $H \supseteq \mathrm{PL}(H)$, $\bar{D}_n$ defines a determinant $\bar{D}_n \circ \bar{\theta} \circ \pi_\infty$ on P^0. For $A \in \mathrm{CNL}_{\mathcal{O}}$, a* ***patched***

tuple *to A is $(D, (\psi_{v,a}), s, (U_{j,i}), (y_{j,i}))$ with D a continuous A-valued determinant of dimension n on P^0 whose reduction modulo $\mathfrak{m}_A$ is $\bar{D}_n \circ \bar{\theta} \circ \pi_\infty$, continuous homomorphisms $\psi_{v,a} \colon D_v \to A^\times$ with $\psi_{v,a} \equiv \bar{\chi}_a$ modulo $\mathfrak{m}_A$ and $\psi_{v,a}(g)$ equal to the image of $\xi_{v,a}(g)$ in A for $g \in \mu_v$ ($v \in S_\ell$, $1 \le a \le n$), $s \in \mathfrak{m}_A$, $U_{j,i} \in A$ with $U_{j,i} - \tilde{u}_{j,i} \in \mathfrak{m}_A$, and $y_{j,i} \in \mathfrak{m}_A$. Then there are $R_{\mathrm{tup}} \in \mathrm{CNL}_{\mathcal{O}}$ and a patched tuple t^{u} to R_{tup} such that for every $A \in \mathrm{CNL}_{\mathcal{O}}$ and every patched tuple t to A there is exactly one morphism $R_{\mathrm{tup}} \to A$ of $\mathrm{CNL}_{\mathcal{O}}$ carrying t^{u} to t (componentwise base change).*

Proof. Step 1: finiteness. P^0 is open in Π ($\bar{\Gamma}^0_\infty$ has index at most 2 in $\bar{\Gamma}_\infty$, and π_∞, $\bar{\theta}$ are continuous), and Π is topologically finitely generated (Lemma E.42). An open subgroup of a topologically finitely generated profinite group is topologically finitely generated, and a topologically finitely generated profinite group has only finitely many open subgroups of each index; so every open subgroup of P^0 has only finitely many continuous homomorphisms to $\mathbb{Z}/\ell$, i.e. P^0 satisfies Φ_ℓ. Each D_v ($v \in S_\ell$) lies in G_L and satisfies Φ_ℓ by (Tg6) of Definition 53.8.

Step 2: the factors. By (Ch2) applied to P^0 and $\bar{D} = \bar{D}_n \circ \bar{\theta} \circ \pi_\infty$ (continuous, as π_∞ and $\bar{\theta}$ are), there is a universal continuous determinant $D(\bar{D})$ on P^0 with values in a profinite local $W(k)$-algebra $A(\bar{D})$ with residue field k, Noetherian by Step 1. Put $A_{\det} = A(\bar{D}) \otimes_{W(k)} \mathcal{O}$, finite over $A(\bar{D})$, hence a complete Noetherian local $\mathcal{O}$-algebra with residue field k, with the base-changed determinant. For $A \in \mathrm{CNL}_{\mathcal{O}}$, morphisms $A_{\det} \to A$ of $\mathrm{CNL}_{\mathcal{O}}$ correspond to $W(k)$-algebra homomorphisms $A(\bar{D}) \to A$ that are local, and these are continuous (a local homomorphism of complete Noetherian local rings is continuous for the adic topologies, and $A(\bar{D})$ carries its profinite, here adic, topology); so $A_{\det}$ represents the functor $A \mapsto \{$continuous A-valued determinants of dimension n on P^0 lifting $\bar{D}\}$ on $\mathrm{CNL}_{\mathcal{O}}$. In the same way, (Ch2) with $n = 1$ applied to D_v and $\bar{\chi}_a|_{D_v}$ gives $A_{v,a} \in \mathrm{CNL}_{\mathcal{O}}$ representing continuous determinants of dimension 1 on D_v lifting $\bar{\chi}_a$; a determinant of dimension 1 on a group G' is the same as a homomorphism $G' \to A^\times$ (a multiplicative homogeneous polynomial law of degree 1 on $A[G']$ is an A-algebra homomorphism $A[G'] \to A$), and continuity corresponds, so $A_{v,a}$ represents the continuous lifts $\psi_{v,a} \colon D_v \to A^\times$ of $\bar{\chi}_a$. Let $\psi^{\mathrm{u}}_{v,a}$ be the universal lift and $\mathfrak{a}_{v,a} \subseteq A_{v,a}$ the ideal generated by the $\psi^{\mathrm{u}}_{v,a}(g) - \xi_{v,a}(g)$, $g \in \mu_v$. It lies in $\mathfrak{m}_{A_{v,a}}$: for $g \in \mu_v$ there is e with $g^{\ell^e} \in \overline{[D_v, D_v]}$, so $\xi_{v,a}(g)^{\ell^e} = 1$ by (Rd10) and $\bar{\chi}_a(g)^{\ell^e} = 1$ ($\bar{\chi}_a$ is a continuous character to an abelian group, trivial on $\overline{[D_v, D_v]}$); as $\#\mathbb{F}^\times_{\mathcal{O}}$ is prime to ℓ, both $\bar{\chi}_a(g)$ and the reduction of $\xi_{v,a}(g)$ equal 1, so $\psi^{\mathrm{u}}_{v,a}(g) - \xi_{v,a}(g) \in \mathfrak{m}_{A_{v,a}}$. Hence $A'_{v,a} = A_{v,a}/\mathfrak{a}_{v,a} \in \mathrm{CNL}_{\mathcal{O}}$ (every ideal of a Noetherian complete local ring is closed), and a morphism $A'_{v,a} \to A$ is a morphism $A_{v,a} \to A$ killing $\mathfrak{a}_{v,a}$, i.e. the classified lift takes the values $\xi_{v,a}(g)$ on μ_v. So $A'_{v,a}$ represents the continuous lifts of $\bar{\chi}_a$ that agree with $\xi_{v,a}$ on μ_v. Finally $\mathcal{O}[[s, Z_{j,i}, y_{j,i}]]$ represents the triples $(s, (Z_{j,i}), (y_{j,i}))$ of elements of $\mathfrak{m}_A$, and $U_{j,i} = \tilde{u}_{j,i} + Z_{j,i}$ is a bijection onto the families with $U_{j,i} - \tilde{u}_{j,i} \in \mathfrak{m}_A$.

Step 3: the product. The completed tensor product over $\mathcal{O}$ of finitely many objects of $\mathrm{CNL}_{\mathcal{O}}$ is in $\mathrm{CNL}_{\mathcal{O}}$ and is their coproduct there. So $R_{\mathrm{tup}} = A_{\det} \widehat{\otimes}_{\mathcal{O}} \widehat{\bigotimes}_{v,a} A'_{v,a} \widehat{\otimes}_{\mathcal{O}} \mathcal{O}[[s, Z_{j,i}, y_{j,i}]]$ with the tuple t^{u} formed by the images of the universal objects represents patched tuples: a morphism $R_{\mathrm{tup}} \to A$ is the same as a family of morphisms from the factors, i.e. a patched tuple to A, and it carries t^{u} to that tuple by construction; uniqueness holds because the images of the universal objects generate the factors topologically and morphisms of $\mathrm{CNL}_{\mathcal{O}}$ are continuous. □

Corollary E.61. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $J \subseteq B$ an ideal, $\mathcal{D}$ a Taylor–Wiles datum for $\mathscr{H}$ with H, and automorphic patching data for J along $\mathcal{D}$ with determinants D_N on Γ^0_N to R_N. Then for every N, $\mathrm{PL}(H_N)$ is a closed subgroup of Γ^0_N, normal in Γ_N, and there is a unique continuous R_N-valued determinant $\bar{D}_N$ of dimension n on $\Gamma^0_N/\mathrm{PL}(H_N)$ with $D_N = \bar{D}_N \circ p_N$, $p_N \colon R_N[\Gamma^0_N] \to R_N[\Gamma^0_N/\mathrm{PL}(H_N)]$ the natural map; in particular $\mathrm{tr}_{D_N}(x) =$*

$\mathrm{tr}_{\bar{D}_N}(p_N(x))$ *for all* $x \in R_N[\Gamma_N^0]$.

Proof. Apply Lemma E.62 with $\Gamma = \Gamma_N$, $\Gamma^0 = \Gamma_N^0$, $H = H_N$, $A = R_N$, $D = D_N$ and $\bar{\rho} = \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n) \circ h_N$ on Γ_N^0 (with values in $\mathrm{GL}_n(\mathbb{F}_{\mathcal{O}})$, continuous and semisimple, a sum of characters). The hypotheses hold: (a) $\Gamma_N^0 = \pi^{Q_N}(G_L)$ is open of index at most 2, hence normal, in Γ_N. (b) $H_N = h_N^{-1}(H)$ is open and normal in Γ_N (H is open and normal in $\Gamma_{\mathscr{H}}$). (c) $H_N \subseteq \Gamma_N^0$: by (Tg1) $H \subseteq \Gamma_{\mathscr{H}}^0 = h_N(\Gamma_N^0)$, so $H_N \subseteq \Gamma_N^0 \ker h_N$; and $\ker h_N = \pi^{Q_N}(N_{\mathscr{H}}) \subseteq \pi^{Q_N}(G_L) = \Gamma_N^0$, since $N_{\mathscr{H}}$ is the closed normal subgroup of G_{L^+} generated by elements of the closed normal subgroup G_L. (d) $H_N \subseteq \ker \bar{\rho}$: $\bar{\chi}_a(h_N(H_N)) = \bar{\chi}_a(H) = 1$ by (Tg1). (e) By Definition E.36 (polarised ordinary determinants on Γ_N^0 as in Definition 53.9) the reduction of D_N is $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$, i.e. $\det \circ \bar{\rho}$. The lemma gives $\bar{D}_N$, unique as p_N is surjective. The trace is a coefficient of the characteristic polynomial $D_N(X - x) = \bar{D}_N(X - p_N(x))$. □

Lemma E.62. *Let $\mathcal{O}$ be a coefficient ring with residue field k, Γ a profinite group, $\Gamma^0 \subseteq \Gamma$ an open normal subgroup, $H \subseteq \Gamma^0$ a subgroup that is open and normal in Γ, $\bar{\rho}\colon \Gamma^0 \to \mathrm{GL}_n(k)$ a continuous semisimple representation with $H \subseteq \ker \bar{\rho}$, $A \in \mathrm{CNL}_{\mathcal{O}}$, and D a continuous A-valued determinant of dimension n on Γ^0 whose reduction modulo $\mathfrak{m}_A$ is $\det \circ \bar{\rho}$. Then $\mathrm{PL}(H)$ (taken in Γ) is a closed subgroup of H, normal in Γ, and there is a unique continuous A-valued determinant D' of dimension n on $\Gamma^0/\mathrm{PL}(H)$ such that D is the composite of D' with the map $A[\Gamma^0] \to A[\Gamma^0/\mathrm{PL}(H)]$.*

Proof. Step 1: $\mathrm{PL}(H)$. It is an intersection of open normal subgroups of Γ, hence closed and normal in Γ; $U = H$ is one of them (every $h \in H$ lies in H), so $\mathrm{PL}(H) \subseteq H$. Let $N \subseteq H$ be a closed subgroup, normal in Γ, with H/N pro-ℓ. For every open normal subgroup $U \supseteq N$ of Γ, HU/U is a finite quotient of H/N, hence an ℓ-group, so every $h \in H$ has an ℓ-power in U; therefore $\mathrm{PL}(H) \subseteq \bigcap_U U = N$ (in a profinite group a closed normal subgroup is the intersection of the open normal subgroups containing it).

Step 2: comparison with Chenevier's subgroup. Let H_0 be the smallest closed normal subgroup of Γ^0 contained in $\ker \bar{\rho}$ with $\ker \bar{\rho}/H_0$ pro-ℓ. $H \cap H_0$ is closed and normal in Γ^0, and $H/(H \cap H_0)$ embeds into $\ker \bar{\rho}/H_0$, so it is pro-ℓ. Let $N = \bigcap_g g(H \cap H_0)g^{-1}$, g running over representatives of the finite group Γ/Γ^0: a closed subgroup of H, normal in Γ (H is normal in Γ), and H/N embeds into $\prod_g H/g(H \cap H_0)g^{-1} \cong \prod_g H/(H \cap H_0)$, so it is pro-$\ell$. By Step 1, $\mathrm{PL}(H) \subseteq N \subseteq H_0$.

Step 3: factorisation. A is a profinite local $W(k)$-algebra with residue field k (an object of $\mathrm{CNL}_{\mathcal{O}}$, through $W(k) \to \mathcal{O}$), and $\bar{\rho}$ is defined over k, so Theorem B.99 applies to $G = \Gamma^0$: $D = D'' \circ p_0$ for a determinant D'' on Γ^0/H_0, $p_0\colon A[\Gamma^0] \to A[\Gamma^0/H_0]$. As $\mathrm{PL}(H) \subseteq H_0$, p_0 factors as $A[\Gamma^0] \xrightarrow{p} A[\Gamma^0/\mathrm{PL}(H)] \xrightarrow{p'} A[\Gamma^0/H_0]$; put $D' = D'' \circ p'$, a determinant of dimension n with $D' \circ p = D$. Continuity: continuity of a determinant in the sense of [66] is the continuity of the finitely many coefficient maps $(g_1, \dots, g_m) \mapsto$ (coefficients of $D(t_1 g_1 + \cdots + t_m g_m)$) on G^m, for every m. For D' these maps on $(\Gamma^0/\mathrm{PL}(H))^m$, composed with the quotient map $(\Gamma^0)^m \to (\Gamma^0/\mathrm{PL}(H))^m$, are those of D, hence continuous; as this quotient map is a continuous open surjection, they are continuous. Uniqueness: p is surjective. □

Lemma E.63. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ and let automorphic patching data with exponent e, $\mathcal{O}_1$, limit objects and $\tilde{c}$ be given as in Definition E.37, with patched tower data $(R, \beta, X, f, I, e+1, (M_N^\natural)_{N \geq 1}, \mathcal{U})$. Then for every relation $g \in R$ (any element listed in (Wv1)–(Wv6)) and every $j \geq 1$, the set of N for which there is $a \in R$ with*

$$(fg)^{e+1} - a \in \mathfrak{m}_R^j \qquad \text{and} \qquad aM_N^\natural = 0$$

belongs to $\mathcal{U}$.

Proof. Fix $j \geq 1$. Write $\mathfrak{m} = \mathfrak{m}_R$; then $\ell \in \mathfrak{m}$. For $N \in \mathcal{N}_0$, by definition of ρ_N: $\rho_N(\Lambda_i(D^{\mathrm{t}})(g)) = \Lambda_i(\bar{D}_N)(\pi_N(g))$ and $\rho_N(\mathrm{tr}_{D^{\mathrm{t}}}(x)) = \mathrm{tr}_{\bar{D}_N}(\pi_N(x))$ for $g \in P^0$, $x \in R_{\mathrm{tup}}[P^0]$ (π_N applied to group elements, ρ_N^0 to coefficients), $\rho_N(\psi^{\mathrm{t}}_{v,a}) = \psi_{N,v,a}$, $\rho_N(U^{\mathrm{t}}_{j',i}) = U_{N,j',i}$, $\rho_N(y^{\mathrm{t}}_{j',i}) = s_N(Y_{j',i})$; and $\mathrm{tr}_{D_N} = \mathrm{tr}_{\bar{D}_N} \circ p_N$, $\Lambda_i(D_N) = \Lambda_i(\bar{D}_N) \circ p_N$ by Corollary E.61. All elements below are taken in R_{tup} and then in R.

Step 1: uniform continuity. P^0 is an open normal subgroup of Π (the preimage of the subgroup $\bar{\Gamma}^0$ of index at most 2). D^{t} is continuous, $R_{\mathrm{tup}}/\mathfrak{m}^j$ is finite and discrete, and P^0 is compact, so the maps $g \mapsto \Lambda_i(D^{\mathrm{t}})(g) \bmod \mathfrak{m}^j$ ($1 \leq i \leq n$) are uniformly locally constant: there is an open normal subgroup V of Π with $V \subseteq P^0$ and $\Lambda_i(D^{\mathrm{t}})(gv) - \Lambda_i(D^{\mathrm{t}})(g) \in \mathfrak{m}^j$ for all $g \in P^0$, $v \in V$, i. As $\mathrm{tr} = \Lambda_1$ is linear, $\mathrm{tr}_{D^{\mathrm{t}}}(x) - \mathrm{tr}_{D^{\mathrm{t}}}(x') \in \mathfrak{m}^j$ whenever x' arises from $x \in R_{\mathrm{tup}}[P^0]$ by replacing, in a product expression, factors $g \in P^0$ by elements of gV: indeed $agvb = agb\,(b^{-1}vb)$ with $b^{-1}vb \in V$ for $a, b \in P^0$, and one expands multilinearly.

Step 2: lifting to level N. Let $\mathcal{N}_1$ be the set of $N \in \mathcal{N}_0$ with $N \geq j$ for which (L1)(i), (iii), (iv) hold for V (and $Y = \bar{\Gamma}$); it belongs to $\mathcal{U}$. Claim: for $N \in \mathcal{N}_1$, if $g_0, g'' \in \Pi$ with $g_0^{-1}g'' \in V$ and $g' \in g'' \ker \pi_\infty$, there is $g_N \in g_0 \ker \pi_N$ with $g_N^{-1}g' \in V$. Indeed $g' = g''k$ with $k \in \ker \pi_\infty \subseteq (\ker \pi_N)V$ by (L1)(i); write $k = k_N v'$ and put $g_N = g_0 k_N$; then $g_N^{-1}g' = k_N^{-1}(g_0^{-1}g'')k_N\, v' \in V$. Applied with (L1)(iii), (iv) this gives, for $N \in \mathcal{N}_1$: (a) for $g' \in \ker \pi_\infty$ (take $g_0 = g'' = 1$) some $g_N \in \ker \pi_N \cap g'V$; (b) for g' with $\pi_\infty(g') = F_w(y)$, $w \in S_\ell \cup \mathrm{St}$, $y \in D_w$, some $g_N \in g'V$ with $\pi_N(g_N) = \bar{\phi}_{N,w}(y)$ (take g_0, g'' from (L1)(iv)); (c) for g' with $\pi_\infty(g') = \Phi_j$, resp. T_j, resp. c_∞, some $g_N \in g'V$ with $\pi_N(g_N) = \bar{\Phi}_{N,j}$, resp. $\bar{\mathrm{T}}_{N,j}$, resp. $\bar{c}_N$ (take $g'' = \tilde{\phi}_j, \tilde{t}_j, \tilde{c}'$ from (L1)(iii), whose image is $\bar{\Phi}_{N,j}\pi_N(v)$ etc., and $g_0 = g''v^{-1}$). Elements of $g'V$ lie in P^0 when g' does.

Step 3: each relation. Let r be a relation and $N \in \mathcal{N}_1$. Replace each element g' of P^0 (or $\tilde{c}$) occurring in r with a prescribed image under π_∞ by the element g_N of Step 2; call the result r_N. By Step 1, $r - r_N \in \mathfrak{m}^j$ (for (Wv2) note $c'g^{-1}c'^{-1} = \tilde{c}g^{-1}\tilde{c}^{-1} \cdot v''$ with $v'' \in V$ when $c' \in \tilde{c}V$, V being normal). Then: (Wv1), (Wv4): the replaced element lies in $\ker \pi_N$ (in (Wv4) because $g \in I_{\bar{u}} \cap G_L$ with all $\bar{\chi}_a(g) = 1$ lies in N^{Q_N} ($u \in \mathrm{St}$ is not above ℓ and not in Q_N), so $\bar{\phi}_{N,u}(g) = 1$); hence $\rho_N(r_N) = \mathrm{tr}_{\bar{D}_N}(\pi_N(h)(1-1)) = 0$. (Wv2): $\rho_N(r_N) = \Lambda_i(\bar{D}_N)(\bar{c}_N\bar{g}^{-1}\bar{c}_N^{-1}) - \Lambda_i(\bar{D}_N)(\bar{g})$ with $\bar{g} = \pi_N(g) \in \bar{\Gamma}_N^0$; choosing $g_1 \in G_L$ with $p_N(\pi^{Q_N}(g_1)) = \bar{g}$ and using $c^2 = 1$, this is 0 by (Od1) for D_N. (Wv3): $\rho_N(r_N) = \mathrm{tr}_{\bar{D}_N}(\pi_N(h)\prod_a(\bar{\phi}_{N,v}(g_a) - \psi_{N,v,a}(g_a))) = 0$ by (Od2) for D_N (lift $\pi_N(h)$ to Γ_N^0). In these cases put $a = (fr_N)^{e+1}$: $\rho_N(a) = 0$, so $aM_N^\natural = 0$, and $(fr)^{e+1} - a \in \mathfrak{m}^j$ as $fr - fr_N \in \mathfrak{m}^j$. (Wv5), (Wv6): let $f_N = f_{(q_{N,j'})_{j'}}(U^{\mathrm{t}})$. Each factor of f differs from the corresponding factor of f_N by $(q_{N,j'} - 1)U^{\mathrm{t}}_{j',i'} \in \ell^N R$ ((Tg2)), so $f - f_N \in \ell^N R \subseteq \mathfrak{m}^j$. $\rho_N(f_N r_N) = f(U_N)\,\mathrm{tr}_{\bar{D}_N}(\pi_N(h)\, q_1(\bar{\Phi}_{N,j}, U_{N,j}))$, resp. with $q_2(\bar{\Phi}_{N,j}, \bar{\mathrm{T}}_{N,j}, U_{N,j}, i, s_N(Y_{j,i}))$, an element of R_N whose e-th power kills M_N by (Ha5) (applied to a lift of $\pi_N(h)$ to Γ_N^0). Put $a = (f_N r_N)^{e+1}$: $\rho_N(a)$ kills $R_N[[z]] \otimes_{R_N} M_N$, so $aM_N^\natural = 0$, and $fr - f_N r_N = (f - f_N)r + f_N(r - r_N) \in \mathfrak{m}^j$, whence $(fr)^{e+1} - a \in \mathfrak{m}^j$. In all cases the required a exists for every $N \in \mathcal{N}_1 \in \mathcal{U}$. □

Lemma E.64. *Let $\mathcal{O}$ be a complete discrete valuation ring with finite residue field $\mathbb{F}_\mathcal{O}$, B a commutative $\mathcal{O}$-algebra, $k \supseteq \mathbb{F}_\mathcal{O}$ a finite field and $f\colon B \to k[[T]]$ a homomorphism of $\mathcal{O}$-algebras (with $\mathcal{O} \to \mathbb{F}_\mathcal{O} \subseteq k \subseteq k[[T]]$). Let $\mathcal{O}'$ be a complete discrete valuation ring that is a finite free $\mathcal{O}$-algebra, unramified over $\mathcal{O}$ (a uniformiser of $\mathcal{O}$ generates its maximal ideal), with residue field of cardinality $|k|$. Then for every prime $\mathfrak{Q}$ of $\mathcal{O}' \otimes_\mathcal{O} B$ with $\{b \in B : 1 \otimes b \in \mathfrak{Q}\} = \ker f$ there is a homomorphism of rings*

$$f'\colon \tilde{B} = (\mathcal{O}' \otimes_\mathcal{O} B)[[z]] \longrightarrow k[[T]]$$

with: $f'(1 \otimes b) = f(b)$ for $b \in B$; $f'(z) = T$; $\{y \in \mathcal{O}' \otimes_\mathcal{O} B : f'(y) = 0\} = \mathfrak{Q}$; f' surjective; and $f'|_{\mathcal{O}'}$ followed by reduction modulo T is a surjection $\mathcal{O}' \to k$.

Proof. Let $d = [k : \mathbb{F}_{\mathcal{O}}]$ and $\bar{P} \in \mathbb{F}_{\mathcal{O}}[X]$ the minimal polynomial of a generator $\bar{\beta}$ of k over $\mathbb{F}_{\mathcal{O}}$; it is irreducible of degree d and separable ($\mathbb{F}_{\mathcal{O}}$ is perfect). Let $P \in \mathcal{O}[X]$ be a monic lift of $\bar{P}$.

Step 0: $\mathcal{O}' \cong \mathcal{O}[X]/(P)$ as $\mathcal{O}$-algebras. Let k' be the residue field of $\mathcal{O}'$. As $\mathfrak{m}_{\mathcal{O}}\mathcal{O}'$ is the maximal ideal of $\mathcal{O}'$, $k' = \mathcal{O}'/\mathfrak{m}_{\mathcal{O}}\mathcal{O}'$; if $\mathcal{O}'$ is free of rank r over $\mathcal{O}$, then $\dim_{\mathbb{F}_{\mathcal{O}}} k' = r$, and $|k'| = |k|$ gives $r = d$. The fields k and k' contain $\mathbb{F}_{\mathcal{O}}$ and have the same cardinality q; each is a splitting field of $X^q - X$ over $\mathbb{F}_{\mathcal{O}}$, so they are isomorphic over $\mathbb{F}_{\mathcal{O}}$. Hence $\bar{P}$ has a root $\bar{\beta}' \in k'$, simple as $\bar{P}$ is separable, and $k' = \mathbb{F}_{\mathcal{O}}(\bar{\beta}')$ (both have degree d over $\mathbb{F}_{\mathcal{O}}$). By Hensel's lemma in the complete local ring $\mathcal{O}'$ there is $\beta' \in \mathcal{O}'$ with $P(\beta') = 0$ reducing to $\bar{\beta}'$. The $\mathcal{O}$-algebra map $\iota_0 \colon \mathcal{O}[X]/(P) \to \mathcal{O}'$, $X \mapsto \beta'$, is surjective modulo $\mathfrak{m}_{\mathcal{O}}\mathcal{O}'$ (its image there contains $\mathbb{F}_{\mathcal{O}}[\bar{\beta}'] = k'$), hence surjective by Nakayama's lemma, $\mathcal{O}'$ being a finitely generated $\mathcal{O}$-module. As $\mathcal{O}'$ is free, ι_0 splits as a map of $\mathcal{O}$-modules: $\mathcal{O}[X]/(P) \cong \mathcal{O}' \oplus K$ with $K = \ker \iota_0$ finitely generated. Both $\mathcal{O}[X]/(P)$ (basis $1, X, \dots, X^{d-1}$, as P is monic) and $\mathcal{O}'$ are free of rank d, so reduction modulo $\mathfrak{m}_{\mathcal{O}}$ gives $K/\mathfrak{m}_{\mathcal{O}}K = 0$, and $K = 0$ by Nakayama's lemma. So we may and do assume $\mathcal{O}' = \mathcal{O}[X]/(P)$.

Step 1: the extensions of f. $\mathcal{O}' \otimes_{\mathcal{O}} B = B[X]/(P)$. Let $P^f \in k[[T]][X]$ be the image of P under $\mathcal{O} \to k[[T]]$; modulo T it is $\bar{P}$ (viewed in $k[X]$), which splits over k into d distinct linear factors (the conjugates of $\bar{\beta}$). By Hensel's lemma over the complete local ring $k[[T]]$, $P^f = \prod_{i=1}^{d}(X - \beta_i)$ with $\beta_i \in k[[T]]$ lifting the distinct roots $\bar{\beta}_i$ of $\bar{P}$. The ring homomorphisms $\varphi \colon B[X]/(P) \to k[[T]]$ with $\varphi(b) = f(b)$ are exactly $\varphi_i \colon X \mapsto \beta_i$, $1 \le i \le d$.

Step 2: every prime over $\ker f$ is a kernel $\ker \varphi_i$. Let $R_0 = f(B) \cong B/\ker f$, a domain inside $k[[T]]$, with fraction field $K_0 \subseteq F_k = k((T))$. Primes of $B[X]/(P)$ contracting to $\ker f$ correspond to primes of $R_0[X]/(P)$ contracting to 0, hence (localising at $R_0 \setminus \{0\}$) to primes of $K_0[X]/(P)$, i.e. to the monic irreducible factors g of P over K_0, the prime being the contraction of (g). Over F_k, $P = \prod_i (X - \beta_i)$, so $g(\beta_i) = 0$ for some i. The kernel of φ_i on $R_0[X]/(P)$ meets R_0 only in 0 (as $R_0 \subseteq k[[T]]$), and its extension to $K_0[X]/(P)$ is the kernel of $X \mapsto \beta_i$, $K_0[X]/(P) \to F_k$, which is (g) since g is the minimal polynomial of β_i over K_0. Hence $\ker \varphi_i$ is the prime attached to g. So for the given $\mathfrak{Q}$ there is i with $\ker \varphi_i = \mathfrak{Q}$.

Step 3: f'. Define $f'(\sum_{m \ge 0} c_m z^m) = \sum_{m \ge 0} \varphi_i(c_m) T^m$; the right side is a well-defined element of $k[[T]]$ (the coefficient of T^N involves only $\varphi_i(c_0), \dots, \varphi_i(c_N)$), and f' is a ring homomorphism (multiplication of power series is compatible term by term). Then $f'(1 \otimes b) = f(b)$, $f'(z) = T$, and on constants $f' = \varphi_i$, whose kernel is $\mathfrak{Q}$.

Step 4: surjectivity. Let $R_1 = \varphi_i(\mathcal{O}') \subseteq k[[T]]$. Its image modulo T contains $\bar{\beta}_i$ and $\mathbb{F}_{\mathcal{O}}$, hence is $\mathbb{F}_{\mathcal{O}}(\bar{\beta}_i) = k$; so $\mathcal{O}' \to k$ is onto. Given $y \in k[[T]]$, choose inductively $o_m \in \mathcal{O}'$ with $y - \sum_{m<N} \varphi_i(o_m) T^m \in T^N k[[T]]$ for all N (if $y_N = T^{-N}(y - \sum_{m<N} \varphi_i(o_m) T^m)$, take o_N with $\varphi_i(o_N) \equiv y_N \bmod T$). Then $y = f'(\sum_m (o_m \otimes 1) z^m)$. □

Lemma E.65. *Let $\iota \colon C_1 \to C$ be a homomorphism of commutative rings, $w_1, \dots, w_m \in C$ and $p_1, \dots, p_m \in C_1[X]$ with $(\iota p_k)(w_k) = 0$ for every k, where $\iota p_k \in C[X]$ is obtained by applying ι to the coefficients, and suppose that C is generated as a C_1-module by finitely many products of the w_k (the empty product 1 included). Let $g \colon C_1 \to A$ be a surjective ring homomorphism onto a domain A such that for every k the polynomial $gp_k \in A[X]$ obtained by applying g to the coefficients is $\prod_l (X - a_{k,l})$ for some $a_{k,l} \in A$. Then for every prime ideal P of C with $\iota^{-1}(P) = \ker g$ there is a surjective ring homomorphism $f' \colon C \to A$ with $f' \circ \iota = g$ and $\ker f' = P$.*

Proof. Let $\varphi \colon C \to C/P$ be the quotient map. As g is surjective and $\ker g = \iota^{-1}(P) = \ker(\varphi \circ \iota)$, there is a unique ring homomorphism $\psi \colon A \to C/P$ with $\psi \circ g = \varphi \circ \iota$, and it is injective: $\psi(g(c)) = 0$ if and only if $\iota(c) \in P$, if and only if $c \in \ker g$.

For each k, applying φ to $(\iota p_k)(w_k) = 0$ gives $((\varphi \circ \iota)p_k)(\varphi(w_k)) = 0$, and $(\varphi \circ \iota)p_k = (\psi \circ g)p_k = \prod_l (X - \psi(a_{k,l}))$. So $\prod_l (\varphi(w_k) - \psi(a_{k,l})) = 0$ in the domain C/P, and $\varphi(w_k) = \psi(a_{k,l})$ for some l; thus $\varphi(w_k) \in \psi(A)$ for every k, and so $\varphi(\mu) \in \psi(A)$ for every product μ of the w_k, $\psi(A)$ being a subring. By hypothesis every $c \in C$ is $c = \sum_t \iota(c_t)\mu_t$ with $c_t \in C_1$ and μ_t products of the w_k; hence $\varphi(c) = \sum_t \psi(g(c_t))\varphi(\mu_t) \in \psi(A)$. So ψ is bijective (φ is onto). Put $f' = \psi^{-1} \circ \varphi$: it is a surjective ring homomorphism with $\ker f' = \ker \varphi = P$ and $f' \circ \iota = \psi^{-1} \circ \psi \circ g = g$. □

E.3 Realisations over Taylor–Wiles levels and the Galois clause

This section proves the Galois clause (Sys4) of a patching system at a surjective lift from the patched ring's determinant on the limit level, Corollary E.66, which Proposition E.39 uses. A determinant over a level is first realised as a representation, through the Cayley–Hamilton quotient of the group algebra in the sense of Chenevier [66] (Proposition E.67); the Selmer conditions (K1)–(K3) at the level then give the Galois clause (Proposition E.78). Three lemmas on Cayley–Hamilton quotients are used again for the patched ring in Section E.5 (Lemma E.69, Lemma E.70, Lemma E.71).

E.3.1 Realisations over a level and the Galois clause

This subsection proves Corollary E.66 from Proposition E.78, the dual Selmer bound Proposition E.97, the patched level Proposition E.94 and the existence of realisations Proposition E.67. A realisation rests on the finiteness of the closed Cayley–Hamilton quotient of a determinant that is residually a sum of distinct characters (Lemma E.69), on its anti-involution (Lemma E.70), and on its realisation in matrices over a nilpotent extension at points of block type (Lemma E.72). For an orthogonal, block-diagonally full residual representation the quotient has symmetric matrix units and is realised in matrices (Proposition E.73, Proposition E.74, Lemma E.75).

Corollary E.66. *Let $\mathscr{H}$, $B = B_n^{\mathrm{po}}$, J, $x_0, \dots, x_h$, a tuple $(\mathcal{T}, d, C, u, \pi)$ for J along them as in Proposition E.78 (as in the definition of a patching system, not required to satisfy (Sys0)–(Sys4)) with ring R, relation ideal I and $S = \Lambda[[y_1, \dots, y_s]]$, where C is the eigenvalue algebra of $(\mathcal{O}_1, (\sigma_j), (\tilde{u}_{j,i}))$, i, a surjective lift f' of f_i, $\mathfrak{q} = \pi^{-1}(\ker f')$ and $\hat{A}$ be as in Proposition E.78; assume $\pi(I) = 0$, let $\bar{\pi}\colon R/I \to C$ be the induced homomorphism, and let the $\bar{\chi}_a$ be pairwise distinct. Let x be a framed normalised curve point of shape $(a, n-a)$ with $A = A_{k_i}$, of irreducible type if $a = n$ and of endoscopic type if $a < n$, κ a Selmer basis of x with local witnesses, and a Taylor–Wiles datum of size q such that all hypotheses of Proposition E.97 hold (among them (Pj1), (Np4) and the span condition, as supplied by Proposition E.54), and assume $n[L^+ : \mathbb{Q}] + nq \le d + s - 1$. Let limit objects for this Taylor–Wiles datum be given as in the conclusion of Lemma E.42, and let $\mathbf{V}_\infty$ be the limit level formed from them (Proposition E.94). Suppose that R/I carries $(D, (\hat{\psi}_{v,i}), (\phi'_j, \tau'_j, U_{j,i}, y_{j,i}), s')$ such that, with $f_1 = f' \circ \bar{\pi}$, the clauses of (Vr1), (Vr2) concerning them hold over $\mathbf{V}_\infty$ for the coefficient ring $\mathcal{O}_1$, and (Lv1), (Lv2) hold over $\mathbf{V}_\infty$, and that (Gl1), (Gl2) hold for every realisation of x over $\mathbf{V}_\infty$ with coefficient ring $\mathcal{O}_1$ and these data. Then the conclusion of (Sys4) holds for i and f'.*

Proof. By Proposition E.94, $\mathbf{V}_\infty$ is a level over $\mathscr{H}$; by its (P3), (K1) holds at $\mathbf{V}_\infty$ with $D_0 = n[L^+ : \mathbb{Q}] + nq \le d + s - 1$, and (K2), (K3) hold; by its (P4), Γ_∞^0 satisfies Φ_ℓ. The point x satisfies (Pj1) (a hypothesis of Proposition E.97). The residue field of $\mathcal{O}_1$ has exactly $|k_i|$ elements, as required of a patching system in Definition E.31, and $\mathcal{O}_1$ is a complete discrete valuation ring, free of finite rank over $\mathcal{O}$ with $\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathfrak{m}_{\mathcal{O}_1}$, as in (Vr) of Definition E.38. So Proposition E.67 applies to x, $\mathbf{V}_\infty$, $\mathcal{O}_1$ and the data on R/I, and gives a realisation of x over $\mathbf{V}_\infty$ with coefficient ring $\mathcal{O}_1$, global ring R/I and $f_1 = f' \circ \bar{\pi}$. By hypothesis it satisfies (Gl1) and (Gl2); x satisfies

(Pj1) and the span condition (for every $Z \in \mathrm{Ev}_a(A)$ some $T^r Z$ lies in the A-span of $\rho(\Gamma')$), both hypotheses of Proposition E.97; and $\pi(I) = 0$. So Proposition E.78 gives the conclusion of (Sys4) for i and f'. □

Proposition E.67. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$ with $\ell \neq 2$ and the $\bar{\chi}_a$ pairwise distinct, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed normalised curve point of shape $(a, n-a)$ satisfying (Pj1), of irreducible type if $a = n$ and of endoscopic type if $a < n$, $\mathbf{V}$ a level over $\mathscr{H}$ with Γ_1^0 satisfying Φ_ℓ, and $\mathcal{O}_1$ a complete discrete valuation ring as in (Vr) of Definition E.38 whose residue field has exactly $|k|$ elements. Let $(B, D, (\hat{\psi}_{v,i}), (\phi_j, \tau_j, U_{j,i}, y_{j,i}), s, f_1)$ satisfy the clauses of (Vr1) and (Vr2) that concern them, for the coefficient ring $\mathcal{O}_1$, and assume:*

(Lv1) *$\chi_D(\gamma^*) = \chi_D(\gamma)$ for all $\gamma \in \Gamma_1^0$;*

(Lv2) *$\mathrm{tr}_D(\gamma z) = 0$ for all $\gamma \in \Gamma_1^0$ and every element z listed in the last item of (Vr3) (the ordinary products at $v \in S_\ell$, the elements $\gamma' - 1$ with $\gamma' \in I_{1,u}$, the two kinds of Taylor–Wiles elements, and their images under *).*

Then there are $\hat{B}, \lambda, \mathcal{O}', \iota, \mathcal{A}, N, \nu$ such that $(B, D, (\hat{\psi}_{v,i}), (\phi_j, \tau_j, U_{j,i}, y_{j,i}), s, f_1, \hat{B}, \lambda, \mathcal{O}', \mathcal{A}, N, \nu)$ is a realisation of x over $\mathbf{V}$ with coefficient ring $\mathcal{O}_1$.

Proof. The proof applies Lemma E.72 to B, the ring $\hat{B}$ and λ of Step 0, $f = f_1$, the group Γ_1^0 with $\gamma^* = c_1 \gamma^{-1} c_1$, the determinant D, the set $\mathcal{S}$ of Step 0 and $\rho_1 = \rho \circ h$; Steps 0–4 check its hypotheses. Write $\Gamma_1' = h^{-1}(\Gamma') \cap \Gamma_1^0$ and $\mathfrak{p} = \ker f_1$.

Step 0: the rings and the residual determinant. B is complete Noetherian local with finite residue field k_B of characteristic $\ell \neq 2$ (Vr1). The composite $\mathcal{O}_1 \to B \xrightarrow{f_1} A$ kills $\mathfrak{m}_{\mathcal{O}_1} = \mathfrak{m}_{\mathcal{O}} \mathcal{O}_1$, since f_1 is a homomorphism of $\mathcal{O}$-algebras and $\mathcal{O}$ acts on A through $\mathbb{F}_{\mathcal{O}} \subseteq k$; so it factors through the finite field $\mathbb{F}_{\mathcal{O}_1}$, whose non-zero elements are roots of unity of order prime to ℓ. Such a root of unity $\zeta \in A^\times$ lies in k: write $\zeta = \zeta_0(1 + Tg)$ with $\zeta_0 \in k^\times$, $g \in A$; if $g \neq 0$ and T^d is the lowest power of T in Tg, then $(1 + Tg)^m = 1$ with $\ell \nmid m$ (for m a multiple of the orders of ζ and ζ_0) has lowest term $mT^d(\cdot) \neq 0$, a contradiction. Hence f_1 makes k an $\mathcal{O}_1$-algebra through a field embedding $\mathbb{F}_{\mathcal{O}_1} \to k$, which is onto as both fields have $|k|$ elements, and f_1 is a homomorphism of $\mathcal{O}_1$-algebras for this structure on A. By Lemma E.68, applied with $\mathcal{O}_1$ in place of $\mathcal{O}$, there are $\hat{B}$, λ with $\ker \lambda = \hat{\mathfrak{m}}$ and $\lambda(\hat{B}) = F$, and $\mathcal{O}'$, ι with all requirements of (Vr4) for the coefficient ring $\mathcal{O}_1$; 2 is invertible in $\hat{B}$. The base change of D along $B \to k_B \to k$ equals that of $f_1 \circ D = \det \circ \rho_1$ modulo T, i.e. $\det \circ \mathrm{diag}(\bar{\chi}_1 \circ h, \ldots, \bar{\chi}_n \circ h)$ (the reduction of ρ modulo T has this determinant, as x is a curve point over $\mathscr{H}$); since $k_B \to k$ is injective and the $\bar{\chi}_a$ take values in the residue field of $\mathcal{O}$, (Ch1) gives that the base change of D to k_B is $\det \circ \mathrm{diag}(\bar{\chi}_a \circ h)$. The characters $\bar{\chi}_a \circ h$ of Γ_1^0 are continuous and pairwise distinct ($h(\Gamma_1^0) = \Gamma^0$), and Γ_1^0 satisfies Φ_ℓ, so by (F0) the spaces $Z^1(\bar{\chi}_a \circ h, \bar{\chi}_b \circ h)$ are finite-dimensional. Let $\mathcal{S} \subseteq B[\Gamma_1^0]$ be the set of elements listed in the last item of (Vr3) (with their images under *); then $\mathcal{I}_1$ is the ideal $\bar{J}$ of Lemma E.69 formed from $(B, \Gamma_1^0, D, \mathcal{S})$, and $\mathcal{S}^* = \mathcal{S}$.

Step 1: $\mathcal{S} \subseteq \ker(D)$ and the involution. $\Gamma_1^0 = h^{-1}(\Gamma^0)$ is normal in Γ_1 and $c_1^2 = 1$, so $\gamma \mapsto \gamma^* = c_1 \gamma^{-1} c_1$ is a continuous anti-automorphism of Γ_1^0 of order 2, and $\chi_D(\gamma^*) = \chi_D(\gamma)$ by (Lv1). By (Q2) (with $\mathcal{S} = \varnothing$, $\eta = 1$) $\mathrm{tr}_D(y^*) = \mathrm{tr}_D(y)$ for $y \in B[\Gamma_1^0]$. By (Lv2) and (Kt2), every element of $\mathcal{S}$ lies in $\ker(D)$.

Step 2: the setting of Lemma E.72. B is complete Noetherian local with finite residue field of characteristic $\ell \neq 2$; $\hat{B}$ is complete Noetherian local with $\ker \lambda = \hat{\mathfrak{m}}$, $\lambda(\hat{B}) = F$ and $\lambda|_B = f_1$ (Step 0); Γ_1^0 satisfies Φ_ℓ (hypothesis) and * is a continuous anti-automorphism of order 2 (Step 1); D is continuous (Vr1), with base change to k_B equal to $\det \circ \mathrm{diag}(\bar{\chi}_a \circ h)$, pairwise distinct (Step 0), and $\chi_D(\gamma^*) = \chi_D(\gamma)$ (Lv1); $\mathcal{S} \subseteq \ker(D)$, $\mathcal{S}^* = \mathcal{S}$ (Steps 0, 1), and $\mathcal{I}_1$ is the ideal $\bar{J}$

formed from $(B, \Gamma_1^0, D, \mathcal{S})$ (Step 0). The homomorphism $\rho_1 = \rho \circ h \colon \Gamma_1^0 \to \mathrm{GL}_n(A)$ is T-adically continuous (ρ is, and h is continuous), block diagonal with blocks of sizes a, $n-a$ if $a < n$ (x is normalised), and satisfies $f_1 \circ D = \det \circ \rho_1$ (Step 0) and $\rho_1(\gamma^*) = {}^t\rho_1(\gamma)$ (as $\rho(h(\gamma^*)) = {}^t\rho(h(\gamma))$, x being normalised and $h(c_1) = \bar{c}$). By (Ab1) of Lemma E.72, with J the two-sided ideal of $\hat{B}[\Gamma_1^0]$ generated by the image of $\mathcal{I}_1$, $E = \hat{B}[\Gamma_1^0]/J$ and ι the projection: E is a finitely generated $\hat{B}$-module with a Cayley–Hamilton determinant D_E, $D_E \circ \iota$ the base change of D; $(yy')^* = y'^* y^*$, $J^* = J$, $\mathrm{tr}_{D_E} \circ \iota \circ {}^* = \mathrm{tr}_{D_E} \circ \iota$; and the image P_0 of $B[\Gamma_1^0]$ in E is a finitely generated B-module with $\iota(\gamma v) - \iota(\gamma) \in \mathfrak{m}_B^j P_0$ for v in an open normal V_j.

Step 3: $\rho_f(\mathcal{S}) = 0$. Let $\rho_f \colon B[\Gamma_1^0] \to \mathrm{M}_n(A)$, $\sum b_\gamma \gamma \mapsto \sum f_1(b_\gamma)\rho_1(\gamma)$. It kills the ordinary products: $\rho_1 \circ \phi_{1,v} = \rho \circ \pi|_{D_v}$ is triangular over F with diagonal $(\psi_{v,1}, \dots, \psi_{v,n}) = (f_1 \circ \hat{\psi}_{v,i})_i$, so in a basis of F^n, with flag $V_0 \subset V_1 \subset \cdots \subset V_n$, in which every $\rho_1(\phi_{1,v}(g))$ is upper triangular with that diagonal, $N_b = \rho_1(\phi_{1,v}(g_b)) - f_1(\hat{\psi}_{v,b}(g_b))$ maps V_b into V_{b-1}, and the image $N_1 N_2 \cdots N_n$ of an ordinary product maps V_n to $V_0 = 0$. It kills $\gamma' - 1$ for $\gamma' \in I_{1,u}$, since $\rho_1(\gamma') = \rho(h(\gamma'))$ with $h(\gamma') \in I_u^x$, on which ρ is trivial. It kills $\prod_i(\phi_j - U_{j,i})$, whose image $\prod_i(\rho(h(\phi_j)) - f_1(U_{j,i}))$ is the characteristic polynomial of $\rho(h(\phi_j))$ evaluated at that matrix (Vr2), hence 0. It kills $\prod_{k \neq i}(\phi_j - U_{j,k})(\tau_j - 1 - y_{j,i})$, whose last factor maps to $\rho(1) - 1 - 0 = 0$ ($h(\tau_j) = 1$, $f_1(y_{j,i}) = 0$). As $\rho_1(\gamma^*) = {}^t\rho_1(\gamma)$ (Step 2), $\rho_f(y^*) = {}^t\rho_f(y)$, so ρ_f also kills the images under * of these elements. Hence $\rho_f(\mathcal{S}) = 0$.

Step 4: the span, and the residual representation of E. Let $\bar{F}$ be an algebraic closure of F; recall $h(\Gamma_1') = \Gamma'$ and $\rho_1 = \rho \circ h$. If $a = n$, $\rho \otimes \bar{F}$ is irreducible on Γ' (x of irreducible type), hence $\rho_1 \otimes \bar{F}$ is irreducible on Γ_1'. If $a < n$, let Q, r_1, r_2 be as in the definition of endoscopic type for x; then $Q\rho_1(\sigma)Q^{-1} = \mathrm{diag}(r_1(h(\sigma)), r_2(h(\sigma)))$ for $\sigma \in \Gamma_1'$, the $r_i \circ h$ are irreducible over $\bar{F}$ on Γ_1', and a matrix Y with $Yr_1(h(\sigma)) = r_2(h(\sigma))Y$ for all $\sigma \in \Gamma_1'$ satisfies the same relation on Γ', hence is 0. So (Ab0) of Lemma E.72 with $\Gamma'' = \Gamma_1'$ gives that the F-span of $\rho_1(\Gamma_1^0)$ is $\mathrm{M}_n(F)$ if $a = n$ and the block-diagonal matrices $\mathrm{M}_n^{(a)}(F)$ if $a < n$. By (Ab2) and Step 3, there is a homomorphism of $\hat{B}$-algebras $r \colon E \to \mathrm{M}_n(F)$ with $r(\iota(\gamma)) = \rho_1(\gamma)$, the image of $D_E(t - z)$ the characteristic polynomial of $r(z)$, $r(\iota(y^*)) = r(\iota(y))^T$ and $r(E) = \mathrm{M}_n^{(a)}(F)$.

Step 5: the realisation. By (Ab3) of Lemma E.72 (2 is invertible in $\hat{B}$ by Step 0; the span by Step 4) there are $\mathcal{A}$, N, ν with the properties listed there, and these give: (Vr5) ($\mathcal{A} = \hat{B} \cdot 1 \oplus N$, $NN \subseteq \hat{\mathfrak{m}} \cdot 1$, $N = 0$ if $a = n$); (Vr6) (ν vanishes on J, so its B-linear extension vanishes on $\mathcal{I}_1$; the span; $\nu(\gamma^*) = {}^t\nu(\gamma)$; $D_{\mathcal{A}} = \det \circ \nu$; and $\lambda(b) = r(\iota(\gamma))_{ij} = \rho(h(\gamma))_{ij}$ when $\nu(\gamma)_{ij} - b \cdot 1 \in N$); (Vr7) from its clause on the primes with a non-semisimple quotient; and (Vr8) with $\mathcal{P}_0 = \bar{\nu}(P_0)$ from its last clause. (Vr1)–(Vr4) hold by hypothesis and Step 0. So the tuple is a realisation of x over $\mathbf{V}$ with coefficient ring $\mathcal{O}_1$. □

Lemma E.68. *Let $\mathcal{O}$ be a complete discrete valuation ring with uniformiser ϖ and residue field $k_{\mathcal{O}}$, B a complete Noetherian local $\mathcal{O}$-algebra (the structure map local), k a field with a surjective ring homomorphism $\mathcal{O} \to k$, $A = k[[T]]$ with fraction field F (an $\mathcal{O}$-algebra through $\mathcal{O} \to k$), $f_1 \colon B \to A$ a surjective homomorphism of $\mathcal{O}$-algebras and $s \in B$ with $f_1(s) = T$. Let $\hat{B}$ be the completion of $B_{\ker f_1}$ at its maximal ideal $\hat{\mathfrak{m}}$. Then:*

(Cd1) *there is a unique ring homomorphism $\lambda \colon \hat{B} \to F$ whose composite with $B \to \hat{B}$ is f_1 followed by $A \subseteq F$, and $\ker \lambda = \hat{\mathfrak{m}}$;*

(Cd2) *the ϖ-adic completion $\mathcal{O}'$ of the localisation $\mathcal{O}[[X]]_{(\varpi)}$ is a complete discrete valuation ring with maximal ideal $\varpi\mathcal{O}'$, and there is a local ring homomorphism $\iota \colon \mathcal{O}' \to \hat{B}$ extending $\mathcal{O} \to \hat{B}$ with $\iota(X) = s$, such that $\lambda \circ \iota$ is surjective onto F and every $a \in A$ is $f_1(b)$ for some $b \in B$ whose image in $\hat{B}$ lies in $\iota(\mathcal{O}')$.*

In particular $(\hat{B}, \lambda, \mathcal{O}', \iota)$ satisfy (Vr4) of Definition E.38 when $\mathcal{O}$ is the coefficient ring and B, f_1, s are the global ring, point and element of a realisation and the residue field of $\mathcal{O}$ maps onto k.

Proof. (Cd1). $\mathfrak{p} = \ker f_1$ is prime and $B/\mathfrak{p} \cong A$, so $B_\mathfrak{p}/\mathfrak{p}B_\mathfrak{p} \cong F$; since $\hat{B}/\hat{\mathfrak{m}} = B_\mathfrak{p}/\mathfrak{p}B_\mathfrak{p}$, the projection $\hat{B} \to \hat{B}/\hat{\mathfrak{m}} \cong F$ is a homomorphism λ with kernel $\hat{\mathfrak{m}}$ whose composite with $B \to \hat{B}$ is f_1. A homomorphism λ' with this property agrees with λ on the image of $B_\mathfrak{p}$ (the elements of $B \setminus \mathfrak{p}$ go to units), hence kills $\hat{\mathfrak{m}} = \mathfrak{p}\hat{B}$ (as $f_1(\mathfrak{p}) = 0$) and agrees with λ on $\hat{B} = \mathrm{im}(B_\mathfrak{p}) + \hat{\mathfrak{m}}$.

(Cd2). $\mathcal{O}[[X]]$ is a regular local ring of dimension 2, hence a unique factorisation domain, and ϖ is a prime element; so $\mathcal{O}[[X]]_{(\varpi)}$ is a discrete valuation ring with uniformiser ϖ and residue field $\mathrm{Frac}(k_\mathcal{O}[[X]]) = k_\mathcal{O}((X))$, and its ϖ-adic completion $\mathcal{O}'$ is a complete discrete valuation ring with maximal ideal $\varpi\mathcal{O}'$ and the same residue field. Since $f_1(s) = T$ lies in the maximal ideal of A and $f_1^{-1}(\mathfrak{m}_A)$ is the maximal ideal $\mathfrak{m}_B$, $s \in \mathfrak{m}_B$; as B is complete and $\mathcal{O} \to B$ is local, there is a continuous $\mathcal{O}$-algebra homomorphism $\varphi_0 \colon \mathcal{O}[[X]] \to B$ with $\varphi_0(X) = s$, $\varphi_0(\sum o_i X^i) = \sum o_i s^i$. If $g \in \mathcal{O}[[X]] \setminus \varpi\mathcal{O}[[X]]$, then $f_1(\varphi_0(g)) = \bar{g}(T)$, where $\bar{g} \in k[[X]]$ is the image of g under the reduction $\mathcal{O} \to k$ (continuity of f_1: $f_1(\mathfrak{m}_B^j) \subseteq \mathfrak{m}_A^j$). Because $\mathcal{O} \to k$ is surjective with kernel $\varpi\mathcal{O}$ (its kernel is a maximal ideal), $k = k_\mathcal{O}$ and $\bar{g} \neq 0$; so $\varphi_0(g) \notin \mathfrak{p}$ and its image in $\hat{B}$ is a unit. Thus φ_0 extends to $\mathcal{O}[[X]]_{(\varpi)} \to \hat{B}$; it maps $\varpi^m\mathcal{O}[[X]]_{(\varpi)}$ into $\hat{\mathfrak{m}}^m$ ($\varpi \in \mathfrak{p}$ since $f_1(\varpi) = 0$), and $\hat{B}$ is $\hat{\mathfrak{m}}$-adically complete and separated, so it extends continuously to $\iota \colon \mathcal{O}' \to \hat{B}$, which is local and extends $\mathcal{O} \to \hat{B}$, with $\iota(X) = s$. $\lambda \circ \iota$ kills ϖ and sends X to T, so it induces $k((X)) \to F = k((T))$, $X \mapsto T$, which is surjective (an isomorphism). Finally let $a = \sum_i a_i T^i \in A$; choose $o_i \in \mathcal{O}$ lifting a_i and put $b = \varphi_0(\sum_i o_i X^i) = \sum_i o_i s^i \in B$. Then $f_1(b) = \sum_i a_i T^i = a$ (continuity of f_1), and the image of b in $\hat{B}$ is $\iota(\sum_i o_i X^i) \in \iota(\mathcal{O}')$.

For the last sentence: (Vr4) asks for λ with kernel $\hat{\mathfrak{m}}$ extending f_1 (Cd1), a complete discrete valuation ring $\mathcal{O}'$ with ι making $\hat{B}$ a complete Noetherian local $\mathcal{O}'$-algebra ($\hat{B}$ is the completion of a Noetherian local ring and ι is local), $\lambda \circ \iota$ onto F, the image of $\mathcal{O}$ and of s in $\iota(\mathcal{O}')$, and the lifting property of A: all given by (Cd2). □

Lemma E.69. *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}$ and finite residue field k of characteristic $\ell \neq 2$, Γ a profinite group, $n \geq 1$, and D a B-valued determinant of dimension n on Γ. Let $\bar{\chi}_1, \dots, \bar{\chi}_n \colon \Gamma \to k^\times$ be pairwise distinct continuous characters such that the base change of D to k is $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$. For $a \neq b$ let $Z^1(\bar{\chi}_a, \bar{\chi}_b)$ be the k-vector space of locally constant maps $\alpha \colon \Gamma \to k$ with*

$$\alpha(gg') = \bar{\chi}_a(g)\,\alpha(g') + \alpha(g)\,\bar{\chi}_b(g') \qquad (g, g' \in \Gamma).$$

Let $\mathrm{CH}(D) \subseteq B[\Gamma]$ be the set of coefficients, in $B[\Gamma]$, of the elements $\chi_{D'}(y)(y) \in B[t_1, \dots, t_m][\Gamma]$, where $m \geq 1$, $y = \sum_{i=1}^m t_i y_i$ with $y_i \in B[\Gamma]$, and D' is the base change of D to $B[t_1, \dots, t_m]$. Let $\mathcal{S} \subseteq B[\Gamma]$ be any subset. For $N \geq 1$ and an open normal subgroup H of Γ let $J_{N,H}$ be the two-sided ideal of $B[\Gamma]$ generated by $\mathrm{CH}(D) \cup \mathcal{S} \cup \mathfrak{m}^N \cdot 1 \cup \{h - 1 : h \in H\}$; put

$$\bar{J} = \bigcap_{N \geq 1,\ H} J_{N,H}, \qquad E = B[\Gamma]/\bar{J},$$

and let $\iota \colon B[\Gamma] \to E$ be the projection.

(F0) *If Γ satisfies Φ_ℓ, then $Z^1(\bar{\chi}_a, \bar{\chi}_b)$ is finite-dimensional for all $a \neq b$.*

(F1) *Let $h \geq 0$ be an integer with $\dim_k Z^1(\bar{\chi}_a, \bar{\chi}_b) \leq h$ for all $a \neq b$, and $c = n + \sum_{p=1}^{n-1} \binom{n(n-1)h}{p}$. There are $\gamma_1, \dots, \gamma_c \in \Gamma$ such that $\iota(\gamma_1), \dots, \iota(\gamma_c)$ generate E as a B-module; in particular E is a finitely generated B-module.*

(F2) *Under the hypothesis of (F1), for every $N \geq 1$ there is an open normal subgroup V_N of Γ with $\iota(\gamma v) - \iota(\gamma) \in \mathfrak{m}^N E$ for all $\gamma \in \Gamma$ and $v \in V_N$.*

(F3) *Under the hypothesis of (F1), the natural map $E \to \varprojlim_{N,H} B[\Gamma]/J_{N,H}$ is bijective.*

Proof. Write $E_{N,H} = B[\Gamma]/J_{N,H}$. As $\mathfrak{m}^N \cdot 1$ and $h - 1$ ($h \in H$) lie in $J_{N,H}$, $E_{N,H}$ is spanned over $B/\mathfrak{m}^N$ by the images of a set of representatives of the finite group Γ/H; $B/\mathfrak{m}^N$ is finite (each $\mathfrak{m}^j/\mathfrak{m}^{j+1}$ is a finite-dimensional k-vector space), so $E_{N,H}$ is a finite set. If $N' \geq N$ and $H' \subseteq H$ then $J_{N',H'} \subseteq J_{N,H}$, so $E_{N',H'} \to E_{N,H}$ is surjective. Let $H_\chi = \bigcap_a \ker \bar{\chi}_a$, an open normal subgroup ($k^\times$ is finite and discrete), and let $\bar{D}$ be the base change of D to k.

Step 1: (F0). Let $\alpha \in Z^1(\bar{\chi}_a, \bar{\chi}_b)$. On H_χ the cocycle relation reads $\alpha(gg') = \alpha(g') + \alpha(g)$, so $\alpha|_{H_\chi}$ is a continuous homomorphism $H_\chi \to (k, +)$; and $\alpha(g\gamma) = \bar{\chi}_a(g)\alpha(\gamma) + \alpha(g)$ for $g \in \Gamma$, $\gamma \in H_\chi$. Hence, for a set $\mathcal{R}$ of representatives of Γ/H_χ, the k-linear map $\alpha \mapsto (\alpha|_{H_\chi}, (\alpha(r))_{r\in\mathcal{R}})$ into $\mathrm{Hom}_{\mathrm{cont}}(H_\chi, k) \times k^{\mathcal{R}}$ is injective. As $(k, +) \cong \mathbb{F}_\ell^f$, $\mathrm{Hom}_{\mathrm{cont}}(H_\chi, k) \cong \mathrm{Hom}_{\mathrm{cont}}(H_\chi, \mathbb{F}_\ell)^f$ is finite under Φ_ℓ; so $Z^1(\bar{\chi}_a, \bar{\chi}_b)$ is finite-dimensional.

Step 2: the residual algebra has dimension at most c. Fix an open normal subgroup $H \subseteq H_\chi$, let $\mathrm{CH}(\bar{D}) \subseteq k[\Gamma]$ be defined as $\mathrm{CH}(D)$ with $\bar{D}$ in place of D, I_H the two-sided ideal generated by $\mathrm{CH}(\bar{D}) \cup \{h - 1 : h \in H\}$, $C = k[\Gamma]/I_H$, and $\bar{g}$ the image of $g \in \Gamma$ in C. We show $\dim_k C \leq c$.

(a) Let $\bar{\rho}\colon k[\Gamma] \to k^n$ be the k-algebra homomorphism (k^n with componentwise product) with $\bar{\rho}(g) = (\bar{\chi}_1(g), \ldots, \bar{\chi}_n(g))$, with components $\bar{\rho}_a$, extended linearly over every commutative k-algebra T. Since $\bar{D} = \det \circ \mathrm{diag}(\bar{\chi}_1, \ldots, \bar{\chi}_n)$, the base change $\bar{D}_T$ is the polynomial law $y \mapsto \prod_a \bar{\rho}_a(y)$, so

$$\chi_{\bar{D}_T}(y)(X) = \prod_{a=1}^{n} (X - \bar{\rho}_a(y)) \qquad (y \in T[\Gamma]).$$

For $y = \sum_i t_i y_i$ the a-th component of $\bar{\rho}(\chi_{\bar{D}'}(y)(y))$ is $\prod_b(\bar{\rho}_a(y) - \bar{\rho}_b(y)) = 0$; comparing coefficients, $\bar{\rho}$ kills $\mathrm{CH}(\bar{D})$. It kills $h - 1$ for $h \in H \subseteq H_\chi$. So $\bar{\rho}$ induces $\bar{\rho}_C\colon C \to k^n$, which is surjective: pairwise distinct characters $\Gamma \to k^\times$ are linearly independent over k (Dedekind), so the vectors $\bar{\rho}(g)$ span k^n. Let $K = \ker \bar{\rho}_C$ and $\varepsilon_1, \ldots, \varepsilon_n$ the standard idempotents of k^n.

(b) Every $x \in K$ satisfies $x^n = 0$: for a lift $\tilde{x} \in k[\Gamma]$, $\bar{\rho}(t\tilde{x}) = 0$, so $\chi_{\bar{D}'}(t\tilde{x})(X) = X^n$ over $k[t]$ and $\chi_{\bar{D}'}(t\tilde{x})(t\tilde{x}) = t^n\tilde{x}^n$; its coefficient $\tilde{x}^n$ lies in $\mathrm{CH}(\bar{D})$. Consequently $K \subseteq \mathrm{rad}(C)$: for $x \in K$ and $y \in C$, $yx \in K$ is nilpotent, so $1 - yx$ is invertible.

(c) C is finite-dimensional, hence integral over the henselian local ring k, in which 2 is invertible. By Theorem B.100 (with $\tau = \mathrm{id}$, $I = K$, and the orthogonal idempotents of $C/K \cong k^n$ corresponding to $\varepsilon_1, \ldots, \varepsilon_n$) there are orthogonal idempotents $e_1, \ldots, e_n \in C$ with $\bar{\rho}_C(e_a) = \varepsilon_a$. The idempotent $f = 1 - \sum_a e_a$ lies in K, so $f = f^n = 0$ by (b): $\sum_a e_a = 1$.

(d) $e_aCe_a = ke_a$. Let first $z \in e_aCe_a \cap K$, with lifts $\tilde{e}, \tilde{z} \in k[\Gamma]$ of e_a, z, and $y = t\tilde{e} + s\tilde{z} \in k[t, s][\Gamma]$. Then $\bar{\rho}(y) = t\varepsilon_a$, so $\chi_{\bar{D}'}(y)(X) = X^{n-1}(X - t)$, and the coefficients of $\chi_{\bar{D}'}(y)(y)$ lie in $\mathrm{CH}(\bar{D})$: with $u = te_a + sz \in C[t, s]$, $u^{n-1}(u - t) = 0$. If $n \geq 2$, $u^{n-1}e_a = u^{n-1}$ gives $u^{n-1}(u - t) = s\,u^{n-1}z$, whose coefficient of $t^{n-1}s$ is $e_az = z$; if $n = 1$, $e_a = 1$ and $u - t = sz$. In both cases $z = 0$. Now for $x \in e_aCe_a$, $\bar{\rho}_C(x) = \varepsilon_a\bar{\rho}_C(x)\varepsilon_a = \lambda\varepsilon_a$ for some $\lambda \in k$, and $x - \lambda e_a \in e_aCe_a \cap K = 0$. Applying $\bar{\rho}_C$ also gives $e_a\bar{g}e_a = \bar{\chi}_a(g)e_a$ for $g \in \Gamma$.

(e) Put $A_{ab} = e_aCe_b$, so $C = \bigoplus_{a,b} A_{ab}$ by (c). For $a \neq b$, $\bar{\rho}_C(A_{ab}) = \varepsilon_a k^n \varepsilon_b = 0$, so $A_{ab} \subseteq K$, while $\bar{\rho}_C$ is injective on $\bigoplus_a A_{aa} = \bigoplus_a ke_a$. Hence $K = \mathcal{N} := \bigoplus_{a\neq b} A_{ab}$, a two-sided ideal with $\mathcal{N} \cap A_{aa} = 0$. As C is spanned by the $\bar{g}$, A_{ab} is spanned by the $e_a\bar{g}e_b$, $g \in \Gamma$.

(f) For $a \neq b$ put $A'_{ab} = \sum_{d\notin\{a,b\}} A_{ad}A_{db}$. A product $x_1 \cdots x_r$ with $x_q \in A_{a_qb_q}$, $a_q \neq b_q$, vanishes unless $b_q = a_{q+1}$ for all $q < r$, and then lies in $\mathcal{N} \cap A_{a_1b_r}$. For $r = 2$ this gives $\mathcal{N}^2 = \bigoplus_{a\neq b} A'_{ab}$, hence $\mathcal{N}/\mathcal{N}^2 \cong \bigoplus_{a\neq b} A_{ab}/A'_{ab}$. For $r = n$ the $n + 1$ indices $a_1, \ldots, a_n, b_n$

take at most n values, so $a_q = a_{q'}$ for some $q < q'$ or $a_q = b_n$ for some q; the corresponding subproduct $x_q \cdots x_{q'-1}$, resp. $x_q \cdots x_n$, lies in $\mathcal{N} \cap A_{a_q a_q} = 0$. Hence $\mathcal{N}^n = 0$.

(g) $\dim_k A_{ab}/A'_{ab} \le h$ for $a \ne b$. For a k-linear form λ on A_{ab} vanishing on A'_{ab} put $\alpha_\lambda(g) = \lambda(e_a \bar{g} e_b)$. Using $\sum_d e_d = 1$ and (d),

$$e_a \overline{gg'} e_b = \sum_d e_a \bar{g} e_d \, \bar{g}' e_b \in \bar{\chi}_a(g)\, e_a \bar{g}' e_b + \bar{\chi}_b(g')\, e_a \bar{g} e_b + A'_{ab},$$

so $\alpha_\lambda(gg') = \bar{\chi}_a(g)\alpha_\lambda(g') + \alpha_\lambda(g)\bar{\chi}_b(g')$; α_λ is constant on cosets of H, hence locally constant. Thus $\lambda \mapsto \alpha_\lambda$ is a k-linear map $\mathrm{Hom}_k(A_{ab}/A'_{ab}, k) \to Z^1(\bar{\chi}_a, \bar{\chi}_b)$, injective because the $e_a \bar{g} e_b$ span A_{ab}.

(h) By (f) and (g), $\dim_k \mathcal{N}/\mathcal{N}^2 \le n(n-1)h$. Choose a subspace $V \subseteq \mathcal{N}$ of dimension at most $n(n-1)h$ with $\mathcal{N} = V + \mathcal{N}^2$; by induction $\mathcal{N}^p = V^p + \mathcal{N}^{p+1}$, so $\dim_k \mathcal{N}^p/\mathcal{N}^{p+1} \le (n(n-1)h)^p$, and $\mathcal{N}^n = 0$ gives $\dim_k C = n + \dim_k \mathcal{N} \le c$. As C is spanned by the $\bar{g}$, there are $g_1, \dots, g_c \in \Gamma$ (repetitions allowed) whose images span C.

Step 3: generators at each level. Let $N \ge 1$, H open normal, and $H' = H \cap H_\chi$. Formation of $\chi_{D'}(y)(y)$ commutes with the base change $B \to k$, and every element of $k[\Gamma]$ lifts to $B[\Gamma]$; so the image of $\mathrm{CH}(D)$ in $k[\Gamma]$ is $\mathrm{CH}(\bar{D})$, and $E_{N,H'}/\mathfrak{m}E_{N,H'} = k[\Gamma]/(\text{image of } J_{N,H'})$ is a quotient of the algebra C of Step 2 for H'. The images of $g_1, \dots, g_c$ of Step 2 (for H') span it; by Nakayama's lemma over $B/\mathfrak{m}^N$ they generate the finitely generated module $E_{N,H'}$, hence its quotient $E_{N,H}$. So the set $T_{N,H} \subseteq \Gamma^c$ of tuples whose images generate $E_{N,H}$ as a B-module is non-empty.

Step 4: one tuple for all levels. The image of γ in $E_{N,H}$ depends only on γH, so $T_{N,H}$ is a union of cosets of the open subgroup H^c of Γ^c, hence closed. If $N' \ge N$ and $H' \subseteq H$, then $T_{N',H'} \subseteq T_{N,H}$; so finitely many of the sets T_{N_i,H_i} contain $T_{\max_i N_i, \bigcap_i H_i} \ne \varnothing$. By compactness of Γ^c there is $(\gamma_1, \dots, \gamma_c) \in \bigcap_{N,H} T_{N,H}$.

Step 5: (F1) and (F3). Let $\hat{E} = \varprojlim E_{N,H}$ over the pairs (N, H), directed by $N' \ge N$, $H' \subseteq H$, with the inverse limit topology of the finite discrete sets $E_{N,H}$: a compact Hausdorff space in which the sets $\{x' : x'_{N,H} = x_{N,H}\}$ form a basis of neighbourhoods of x. The map $\hat{\iota}\colon B[\Gamma] \to \hat{E}$ has kernel $\bar{J}$, so $E \to \hat{E}$ is injective. $B \cong \varprojlim B/\mathfrak{m}^N$ is compact. The map $\theta\colon B^c \to \hat{E}$, $\theta(b) = \hat{\iota}(\sum_i b_i \gamma_i)$, is continuous (its component in $E_{N,H}$ depends only on b modulo $\mathfrak{m}^N$), so $\theta(B^c)$ is compact, hence closed; by Step 4 its image in every $E_{N,H}$ is everything, so it meets every basic neighbourhood of every point: $\theta(B^c) = \hat{E}$. As $\theta(B^c) \subseteq \hat{\iota}(B[\Gamma]) \subseteq \hat{E}$, $E \to \hat{E}$ is bijective, which is (F3), and every element of E is $\sum_i b_i \iota(\gamma_i)$, which is (F1).

Step 6: (F2). Give E the topology of $\hat{E}$. The map $\psi\colon B^c \to E$, $b \mapsto \sum_i b_i \iota(\gamma_i)$, is a continuous surjective homomorphism of compact Hausdorff groups; the induced continuous bijection $B^c/\ker\psi \to E$ from a compact space onto a Hausdorff space is a homeomorphism, so ψ is open and $\mathfrak{m}^N E = \psi((\mathfrak{m}^N)^c)$ is open in E. The map $\Gamma \to E$, $\gamma \mapsto \iota(\gamma)$, is continuous (its components are constant on cosets of H). Since $\mathfrak{m}^N E$, the image of $\mathfrak{m}^N B[\Gamma]$, is a two-sided ideal, $U = \{v \in \Gamma : \iota(v) - 1 \in \mathfrak{m}^N E\}$ is a subgroup (the elements whose image in $E/\mathfrak{m}^N E$ is 1), and it is open as the preimage of the open set $1 + \mathfrak{m}^N E$. Being open in the compact group Γ, U has finite index, and the intersection V_N of its finitely many conjugates is an open normal subgroup. For $v \in V_N$, $\iota(\gamma v) - \iota(\gamma) = \iota(\gamma)(\iota(v) - 1) \in \mathfrak{m}^N E$. □

Lemma E.70. *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}$, Γ a profinite group, $n \ge 1$ and D a B-valued determinant of dimension n on Γ such that the maps $\Gamma \to B$, $g \mapsto \Lambda_i(g)$ $(1 \le i \le n)$, are continuous for the $\mathfrak{m}$-adic topology. Let $\mathcal{S} \subseteq \ker(D)$, and let $J_{N,H}$, $\bar{J}$, $E = B[\Gamma]/\bar{J}$ and ι be formed from $(B, \Gamma, D, \mathcal{S})$ as in Lemma E.69. For a commutative B-algebra B' let $J' \subseteq B'[\Gamma]$ be the two-sided ideal generated by the image of $\bar{J}$, $E' = B'[\Gamma]/J'$ and*

$\iota'\colon B'[\Gamma] \to E'$ *the projection.*

(Q1) *$\bar{J} \subseteq \ker(D)$, and there is a determinant D_E of dimension n on E with $D = D_E \circ \iota$. For every commutative B-algebra B', $E' = E \otimes_B B'$, and the base change $D_{E'}$ of D_E to E' is a Cayley–Hamilton determinant of dimension n with $D_{E'} \circ \iota'$ the base change of D to B'; if E is a finitely generated B-module, E' is a finitely generated B'-module.*

(Q2) *Let $\gamma \mapsto \gamma^*$ be a continuous anti-automorphism of Γ with $\gamma^{**} = \gamma$, and $\eta\colon \Gamma \to B^\times$ a character, continuous for the $\mathfrak{m}$-adic topology, with $\eta(\gamma^*)\eta(\gamma) = 1$ and $\chi_D(\eta(\gamma)\gamma^*) = \chi_D(\gamma)$ for all $\gamma \in \Gamma$. For a commutative B-algebra B' let $y \mapsto y^*$ be the B'-linear map $B'[\Gamma] \to B'[\Gamma]$ with $\gamma \mapsto \eta(\gamma)\gamma^*$. If $\mathcal{S}^* \subseteq \bar{J}$, then $(yy')^* = y'^* y^*$, $y^{**} = y$, $J'^* = J'$ and $\operatorname{tr}_{D_{E'}}(\iota'(y^*)) = \operatorname{tr}_{D_{E'}}(\iota'(y))$ for all $y, y' \in B'[\Gamma]$.*

Proof. For $N \geq 1$ let D_N be the base change of D to $B/\mathfrak{m}^N$. For a commutative $B/\mathfrak{m}^N$-algebra T, $(D_N)_T = D_T$, so the image of $\ker(D)$ in $(B/\mathfrak{m}^N)[\Gamma]$ lies in $\ker(D_N)$.

Step 1: a level for each N. Each Λ_i followed by $B \to B/\mathfrak{m}^N$ is a continuous map from the profinite group Γ to a discrete set, hence constant on the cosets of some open normal subgroup; let H_N be an open normal subgroup with $\Lambda_i(gh) \equiv \Lambda_i(g) \bmod \mathfrak{m}^N$ for all $g \in \Gamma$, $h \in H_N$, $1 \leq i \leq n$.

Step 2: $h - 1 \in \ker(D_N)$ for $h \in H_N$. Let T be a commutative $B/\mathfrak{m}^N$-algebra and $r' = \sum_{k=1}^m c_k g_k \in T[\Gamma]$. Over $P = B[u, x_1, \ldots, x_m, y_1, \ldots, y_m]$ consider

$$X = u \cdot 1 + \sum_k x_k\, h g_k + \sum_k y_k\, g_k, \qquad X' = u \cdot 1 + \sum_k x_k\, g_k + \sum_k y_k\, g_k.$$

By (Ch1), $D_P(X) = \Lambda_n(X)$ and $D_P(X')$ are the same integer polynomial, depending only on n and $2m+1$, evaluated at the elements $\Lambda_j(w)$ for w running over the finite products of the families $(1, hg_1, \ldots, hg_m, g_1, \ldots, g_m)$ and $(1, g_1, \ldots, g_m, g_1, \ldots, g_m)$ respectively. Corresponding products w, w' satisfy $w \in w' H_N$ (H_N is normal), so $\Lambda_j(w) \equiv \Lambda_j(w') \bmod \mathfrak{m}^N$ and $D_P(X) \equiv D_P(X')$ coefficientwise modulo $\mathfrak{m}^N$. Specialising $u \mapsto 1$, $x_k \mapsto c_k$, $y_k \mapsto -c_k$ into T gives $D_T(1 + (h-1)r') = D_T(1) = 1$. By the definition of $\ker(D_N)$ and (Ck1) (the right-hand version), $h - 1 \in \ker(D_N)$.

Step 3: $\bar{J} \subseteq \ker(D)$. The generators of J_{N,H_N} map into $\ker(D_N)$: $\mathrm{CH}(D) \subseteq \ker(D)$ by (Ck2) and $\mathcal{S} \subseteq \ker(D)$; $\mathfrak{m}^N \cdot 1$ maps to 0; and the remaining generators by Step 2. As $\ker(D_N)$ is a two-sided ideal (Ck1), the image of $J_{N,H_N} \supseteq \bar{J}$ lies in $\ker(D_N)$. Let $y \in \bar{J}$, T a commutative B-algebra and $r' = \sum_k c_k g_k \in T[\Gamma]$. Put $P = B[x_1, \ldots, x_m]$ and $z = \sum_k x_k g_k$. The image of $D_P(1 + yz)$ in $(B/\mathfrak{m}^N)[x_1, \ldots, x_m]$ is $(D_N)(1 + \bar{y}\bar{z}) = 1$ for every N, so every coefficient of $D_P(1 + yz) - 1$ lies in $\bigcap_N \mathfrak{m}^N = 0$ (Krull's intersection theorem). Specialising $x_k \mapsto c_k$ gives $D_T(1 + yr') = 1$; so $y \in \ker(D)$.

Step 4: (Q1). By (Ck1), $D = \tilde{D} \circ \pi$ for the projection $\pi\colon B[\Gamma] \to B[\Gamma]/\ker(D)$; as $\bar{J} \subseteq \ker(D)$, $D_E = \tilde{D} \circ (E \to B[\Gamma]/\ker(D))$ is a determinant of dimension n with $D = D_E \circ \iota$. Right exactness of $\otimes_B B'$ gives $E \otimes_B B' = B'[\Gamma]/J'$, and finite generation passes to E'. Let A' be a commutative B'-algebra and $x \in E' \otimes_{B'} A' = E \otimes_B A'$, the image of $\sum_{i=1}^m a_i \otimes y_i$ with $a_i \in A'$, $y_i \in B[\Gamma]$. Over $P = B[t_1, \ldots, t_m]$ put $y = \sum_i t_i y_i$ and write $\chi_{D_P}(y)(y) = \sum_\beta t^\beta c_\beta$ with $c_\beta \in \mathrm{CH}(D) \subseteq \bar{J}$. Since $D = D_E \circ \iota$ and polynomial laws are compatible with the specialisation $P \to A'$, $t_i \mapsto a_i$, the element $\chi_{D_{E'}}(x)(x)$ is the image of $\chi_{D_P}(y)(y)$, i.e. $\sum_\beta a^\beta \iota(c_\beta) = 0$. So $D_{E'}$ is Cayley–Hamilton; $D_{E'} \circ \iota'$ is the base change of $D_E \circ \iota = D$.

Step 5: the involution and D. On Γ, $(\gamma\gamma')^* \mapsto \eta(\gamma\gamma')\gamma'^*\gamma^* = (\eta(\gamma')\gamma'^*)(\eta(\gamma)\gamma^*)$ and $\gamma \mapsto \eta(\gamma)\eta(\gamma^*)\gamma^{**} = \gamma$ under two applications; by linearity $(yy')^* = y'^* y^*$ and $y^{**} = y$ on every $B'[\Gamma]$.

The polynomial law $y \mapsto D(y^*)$ (extended linearly over every T) is multiplicative ($D((yy')^*) = D(y'^*)D(y^*)$, T being commutative) and homogeneous of degree n, so it is a determinant of dimension n on Γ, with characteristic polynomial $D(X - \eta(\gamma)\gamma^*) = \chi_D(\eta(\gamma)\gamma^*) = \chi_D(\gamma)$ at $\gamma \in \Gamma$. By (Ch1) it equals D. Hence, for generic $y = \sum_i t_i y_i$, $\chi_{D_P}(y^*) = \chi_{D_P}(y)$ and, $*$ being P-linear and anti-multiplicative, $(\chi_{D_P}(y)(y))^* = \chi_{D_P}(y^*)(y^*)$ with $y^* = \sum_i t_i y_i^*$ generic again: $\mathrm{CH}(D)^* \subseteq \mathrm{CH}(D)$.

Step 6: $\bar{J}^* = \bar{J}$ and (Q2). Let $N \geq 1$ and H open normal. As $\gamma \mapsto \gamma^*$ is a homeomorphism and an anti-automorphism, H^* is an open normal subgroup; η followed by $B^\times \to (B/\mathfrak{m}^N)^\times$ has open kernel. Choose an open normal $H' \subseteq H^*$ inside that kernel. For $h \in H'$, $(h-1)^* = (\eta(h)-1)h^* + (h^*-1) \in \mathfrak{m}^N B[\Gamma] + \{h''-1 : h'' \in H\}$; $(\mathfrak{m}^N \cdot 1)^* = \mathfrak{m}^N \cdot 1$; $\mathrm{CH}(D)^* \subseteq \mathrm{CH}(D)$ (Step 5); $\mathcal{S}^* \subseteq \bar{J} \subseteq J_{N,H}$. An anti-automorphism maps the two-sided ideal generated by a set onto the two-sided ideal generated by its image, so $J^*_{N,H'} \subseteq J_{N,H}$, and $\bar{J}^* \subseteq \bigcap_{N,H} J_{N,H} = \bar{J}$; with $** = \mathrm{id}$, $\bar{J}^* = \bar{J}$. The B'-linear extension maps the image of $\bar{J}$ onto itself, hence $J'^* = J'$. Finally $\mathrm{tr}_{D_{E'}}(\iota'(y))$ is minus the coefficient of X^{n-1} in $D_{B'}(X-y)$, and $D_{B'}(X-y^*) = D_{B'}((X-y)^*) = D_{B'}(X-y)$ by Step 5; so $\mathrm{tr}_{D_{E'}}(\iota'(y^*)) = \mathrm{tr}_{D_{E'}}(\iota'(y))$. □

Lemma E.71. (Kt1) *Let A be a commutative ring with $\mathrm{Spec}(A)$ connected, R an A-algebra, $D\colon R \to A$ a Cayley–Hamilton determinant of dimension $n \geq 1$, and $e_1, \ldots, e_n \in R$ orthogonal idempotents with $\sum_a e_a = 1$ and $D(1 + Xe_a) = 1 + X$ in $A[X]$ for every a. Then $\ker(D) = \{x \in R : \mathrm{tr}_D(yx) = 0$ for all $y \in R\}$.*

(Kt2) *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}$ and finite residue field k of characteristic $\neq 2$, Γ a profinite group, $n \geq 1$, and D a B-valued determinant of dimension n on Γ such that $g \mapsto \Lambda_i(g)$ is continuous for the $\mathfrak{m}$-adic topology ($1 \leq i \leq n$) and the base change of D to k is $\det \circ \mathrm{diag}(\bar{\chi}_1, \ldots, \bar{\chi}_n)$ for pairwise distinct continuous characters $\bar{\chi}_a\colon \Gamma \to k^\times$ with $Z^1(\bar{\chi}_a, \bar{\chi}_b)$ finite-dimensional for all $a \neq b$. Then for $y \in B[\Gamma]$: $y \in \ker(D)$ if and only if $\mathrm{tr}_D(gy) = 0$ for all $g \in \Gamma$.*

Proof. Two general facts. For a determinant D of dimension n and $z \in R \otimes_A T$, $D_T(1+tz) = \sum_{i=0}^n \Lambda_i(z)t^i$, so the coefficient of t is $\mathrm{tr}_D(z)$.

By (Am1), $D(1+tuv) = D(1+tvu)$, hence $\mathrm{tr}_D(uv) = \mathrm{tr}_D(vu)$.

(Kt1), the inclusion $\subseteq$. If $x \in \ker(D)$ and $y \in R$, then $yx \in \ker(D)$ (Ck1), so $D(1+tyx) = 1$ and $\mathrm{tr}_D(yx) = 0$.

(Kt1), corners. Let T be a polynomial ring $A[x_1, \ldots, x_m]$; $\mathrm{Spec}(T)$ is connected (the idempotents of $A[x_1, \ldots, x_m]$ are those of A), and D_T is Cayley–Hamilton. Fix a and $e = e_a$. By (Cd1) for $(R \otimes_A T, D_T)$, $D_T((1-e)+Ye) = D_{1-e}(1-e)\, D_e(Ye) = Y^{r(e)}$, and with $Y = 1+X$ the hypothesis gives $(1+X)^{r(e)} = 1+X$, so $r(e) = 1$. By (Cd1) and (Cd2), D_e is a Cayley–Hamilton determinant of dimension 1 on $e(R \otimes T)e$, so every $w \in e(R \otimes T)e$ equals λe with $\lambda \in T$; then $D_T(X-w) = D_T((X-\lambda)e + X(1-e)) = (X-\lambda)X^{n-1}$, so $\lambda = \mathrm{tr}_{D_T}(w)$. Hence, for $z \in R \otimes_A T$,

$$eze = \mathrm{tr}_{D_T}(eze)\, e = \mathrm{tr}_{D_T}(ze)\, e.$$

(Kt1), the inclusion $\supseteq$. Let $x \in R$ with $\mathrm{tr}_D(yx) = 0$ for all $y \in R$; by T-linearity of tr_{D_T}, $\mathrm{tr}_{D_T}(hx) = 0$ for $h \in R \otimes_A T$. For $h \in R \otimes_A T$, (Am1) and the corner formula give

$$D_T(1 + hxe_a) = D_T(1 + (hxe_a)e_a) = D_T(1 + e_a hxe_a) = D_T\big(1 + \mathrm{tr}_{D_T}(e_a hx)\, e_a\big) = D_T(1) = 1.$$

Every $h' \in R \otimes_A T'$, for any commutative A-algebra T', is the image of some $h = \sum_k x_k \otimes r_k$ under a homomorphism $A[x_1, \ldots, x_m] \to T'$, and $D_{T'}(1 + h'xe_a)$ is the image of $D_T(1 + hxe_a) = 1$. So $xe_a \in \ker(D)$ for every a, and $x = \sum_a xe_a \in \ker(D)$ (Ck1).

(Kt2). If $y \in \ker(D)$ then $\mathrm{tr}_D(gy) = 0$ by the first inclusion. Conversely, let $E_0 = B[\Gamma]/\bar{J}_0$ be the quotient of Lemma E.69 for $\mathcal{S} = \varnothing$, with projection ι_0. By (Q1) of Lemma E.70, $\bar{J}_0 \subseteq \ker(D)$ and $D = D_0 \circ \iota_0$ for a Cayley–Hamilton determinant D_0 on E_0; by (F1) E_0 is a finitely generated B-module.

Residual map. Let $\bar{\rho}\colon B[\Gamma] \to k^n$ be the ring homomorphism with $\bar{\rho}(bg) = \bar{b}\,(\bar{\chi}_1(g), \dots, \bar{\chi}_n(g))$. If $x \in \ker(D)$, its image $\bar{x} \in k[\Gamma]$ lies in the kernel of the base change $\bar{D} = \det \circ \mathrm{diag}(\bar{\chi}_a)$, so $1 = \bar{D}(1 + t\bar{x}) = \prod_a (1 + t\bar{\rho}_a(x))$ in $k[t]$, i.e. $\bar{\rho}(x) = 0$. Hence $\bar{\rho}$ factors through a surjection $\bar{\rho}_0\colon E_0 \to k^n$ (surjective since distinct characters are linearly independent); its kernel K_0 contains $\mathfrak{m}E_0$.

The inclusion $K_0 \subseteq \mathrm{rad}(E_0)$. For $u \in K_0$ the image of $\chi_{D_0}(u)(X)$ in $k[X]$ is $\prod_a (X - \bar{\rho}_{0,a}(u)) = X^n$, so by the Cayley–Hamilton property $u^n = -\sum_{i \geq 1} (-1)^i \Lambda_i(u) u^{n-i} \in \mathfrak{m}E_0$. As E_0 is a finitely generated module over the complete ring B, it is $\mathfrak{m}$-adically complete, and $1 - w$ is invertible for $w \in \mathfrak{m}E_0$ (inverse $\sum_j w^j$, $w^j \in \mathfrak{m}^j E_0$). So $1 - u^n = (1 - u)(1 + u + \cdots + u^{n-1})$ shows $1 - u$ invertible. Applied to $u = yx$ ($x \in K_0$, $y \in E_0$, K_0 an ideal), $K_0 \subseteq \mathrm{rad}(E_0)$.

Idempotents. The ring B is henselian with 2 invertible and E_0 is integral over B; by Theorem B.100 (with $\tau = \mathrm{id}$, $I = K_0$) there are orthogonal idempotents $e_1, \dots, e_n \in E_0$ with $\bar{\rho}_0(e_a)$ the a-th standard idempotent. The idempotent $f = 1 - \sum_a e_a$ lies in $\mathrm{rad}(E_0)$, so $1 - f$ is invertible and $f = 0$ from $f(1 - f) = 0$. By (Cd1) (as in the corner step, $\mathrm{Spec}(B)$ connected), $D_0(1 + Xe_a) = (1 + X)^{r(e_a)}$, whose image in $k[X]$ is $\bar{D}(1 + X\bar{e}_a) = \prod_b (1 + X\bar{\rho}_{0,b}(e_a)) = 1 + X$; so $D_0(1 + Xe_a) = 1 + X$.

Conclusion. By (Kt1) for $(E_0, D_0, (e_a))$, $\ker(D_0) = \{z : \mathrm{tr}_{D_0}(wz) = 0 \ \forall w \in E_0\}$. If $\mathrm{tr}_D(gy) = 0$ for all $g \in \Gamma$, then $\mathrm{tr}_{D_0}(\iota_0(w)\iota_0(y)) = \mathrm{tr}_D(wy) = 0$ for all $w \in B[\Gamma]$ by linearity, so $\iota_0(y) \in \ker(D_0)$; and $D_T(1 + yr') = D_{0,T}(1 + \iota_0(y)\iota_0(r')) = 1$ for all T and r', i.e. $y \in \ker(D)$. □

Lemma E.72. *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}_B$ and finite residue field k_B of characteristic $\ell \neq 2$; k a finite field, $A = k[[T]]$, $F = \mathrm{Frac}(A)$ and $f\colon B \to A$ a ring homomorphism; $\hat{B}$ a complete Noetherian local ring with maximal ideal $\hat{\mathfrak{m}}$, a ring homomorphism $B \to \hat{B}$, and a ring homomorphism $\lambda\colon \hat{B} \to F$ with kernel $\hat{\mathfrak{m}}$, image F, and restriction to B equal to f followed by $A \subseteq F$. Let Γ^0 be a profinite group satisfying Φ_ℓ, $\gamma \mapsto \gamma^*$ a continuous anti-automorphism of Γ^0 with $\gamma^{**} = \gamma$, extended B-linearly (and $\hat{B}$-linearly) to the group rings, $n \geq 1$, $1 \leq a \leq n$, and D a B-valued determinant of dimension n on Γ^0 with $g \mapsto \Lambda_i(g)$ continuous for the $\mathfrak{m}_B$-adic topology, whose base change to k_B is $\det \circ \mathrm{diag}(\bar{\chi}_1, \dots, \bar{\chi}_n)$ for pairwise distinct continuous characters $\bar{\chi}_b\colon \Gamma^0 \to k_B^\times$, and with $\chi_D(\gamma^*) = \chi_D(\gamma)$ for $\gamma \in \Gamma^0$. Let $\mathcal{S} \subseteq \ker(D)$ with $\mathcal{S}^* = \mathcal{S}$, $\mathcal{I} = \bar{J}$ the ideal formed from $(B, \Gamma^0, D, \mathcal{S})$, J the two-sided ideal of $\hat{B}[\Gamma^0]$ generated by the image of $\mathcal{I}$, $E = \hat{B}[\Gamma^0]/J$ and $\iota\colon \hat{B}[\Gamma^0] \to E$ the projection. Let $\rho\colon \Gamma^0 \to \mathrm{GL}_n(A)$ be a homomorphism, continuous for the T-adic topology, and $\rho_f\colon B[\Gamma^0] \to \mathrm{M}_n(A)$, $\sum b_\gamma \gamma \mapsto \sum f(b_\gamma)\rho(\gamma)$, such that $f \circ D = \det \circ \rho$, $\rho(\gamma^*) = {}^t\rho(\gamma)$ for $\gamma \in \Gamma^0$, $\rho_f(\mathcal{S}) = 0$, and, if $a < n$, every $\rho(\gamma)$ is block diagonal with diagonal blocks of sizes a and $n - a$. Let $\mathrm{M}_n^{(a)}(F)$ be the set of matrices in $\mathrm{M}_n(F)$ whose entry at (i, j) vanishes unless i, j are in the same block. Then:*

(Ab0) *(a criterion for the span) let $\bar{F}$ be an algebraic closure of F and $\Gamma'' \subseteq \Gamma^0$ a subgroup. If $a = n$ and $\rho \otimes \bar{F}$ restricted to Γ'' is irreducible, the F-span of $\rho(\Gamma^0)$ is $\mathrm{M}_n(F)$. If $a < n$ and there are $Q \in \mathrm{GL}_n(\bar{F})$, integers $a', b' \geq 1$ with $a' + b' = n$ and homomorphisms $r_1\colon \Gamma'' \to \mathrm{GL}_{a'}(\bar{F})$, $r_2\colon \Gamma'' \to \mathrm{GL}_{b'}(\bar{F})$ with $Q\rho(\sigma)Q^{-1} = \mathrm{diag}(r_1(\sigma), r_2(\sigma))$ for $\sigma \in \Gamma''$, r_1 and r_2 irreducible, and 0 the only $Y \in \mathrm{M}_{b' \times a'}(\bar{F})$ with $Yr_1(\sigma) = r_2(\sigma)Y$ for all $\sigma \in \Gamma''$, then the F-span of $\rho(\Gamma^0)$ is $\mathrm{M}_n^{(a)}(F)$;*

(Ab1) *E is a finitely generated $\hat{B}$-module carrying a Cayley–Hamilton determinant D_E of*

dimension n with $D_E \circ \iota$ the base change of D to $\hat{B}$; $(yy')^* = y'^* y^*$, $J^* = J$ and $\mathrm{tr}_{D_E}(\iota(y^*)) = \mathrm{tr}_{D_E}(\iota(y))$ for $y, y' \in \hat{B}[\Gamma^0]$; the image P_0 of $B[\Gamma^0]$ in E is a finitely generated B-module, and for every $j \geq 1$ there is an open normal subgroup V_j of Γ^0 with $\iota(\gamma v) - \iota(\gamma) \in \mathfrak{m}_B^j P_0$ for $\gamma \in \Gamma^0$, $v \in V_j$;

(Ab2) *if the F-span of $\rho(\Gamma^0)$ is $\mathrm{M}_n^{(a)}(F)$ (for instance by (Ab0)), there is a homomorphism of $\hat{B}$-algebras $r\colon E \to \mathrm{M}_n(F)$ ($\hat{B}$ acting through λ) with $r(\iota(\gamma)) = \rho(\gamma)$, such that the image of $D_E(t - z)$ in $F[t]$ is the characteristic polynomial of $r(z)$ for $z \in E$, $r(\iota(y^*)) = r(\iota(y))^T$, and $r(E) = \mathrm{M}_n^{(a)}(F)$;*

(Ab3) *if the F-span of $\rho(\Gamma^0)$ is $\mathrm{M}_n^{(a)}(F)$ and 2 is invertible in $\hat{B}$, there are a commutative ring $\mathcal{A}$ containing $\hat{B}$ as a subring and finitely generated as a $\hat{B}$-module, a $\hat{B}$-submodule $N \subseteq \mathcal{A}$ with $\mathcal{A} = \hat{B} \cdot 1 \oplus N$, $xy \in \hat{\mathfrak{m}} \cdot 1$ for $x, y \in N$ and $N = 0$ if $a = n$, and a homomorphism of $\hat{B}$-algebras $\nu\colon \hat{B}[\Gamma^0] \to \mathrm{M}_n(\mathcal{A})$ with: $\nu(J) = 0$, and the $\hat{B}$-span of $\nu(\Gamma^0)$ is the set of matrices with entries in $\hat{B} \cdot 1$ at positions in the same block and in N elsewhere; $\nu(y^*) = \nu(y)^T$; the base change of D to $\mathcal{A}$ is $\det \circ \nu$ (for every commutative $\mathcal{A}$-algebra T', $D_{T'}(\sum_b t_b \gamma_b) = \det(\sum_b t_b \nu(\gamma_b))$); if $\gamma \in \Gamma^0$, $b \in \hat{B}$ and $\nu(\gamma)_{ij} - b \cdot 1 \in N$, then $\lambda(b) = \rho(\gamma)_{ij}$; every prime ideal Q of $\hat{B}$ such that $\kappa[\Gamma^0]$ modulo the two-sided ideal generated by the image of $\mathcal{I}$ is not semisimple, for some homomorphism $\hat{B} \to \kappa$ to a field with kernel Q, contains $\mathrm{Ann}_{\hat{B}}(N)$; and $\nu = \bar{\nu} \circ \iota$ for a homomorphism of $\hat{B}$-algebras $\bar{\nu}\colon E \to \mathrm{M}_n(\mathcal{A})$, so that $\mathcal{P}_0 = \bar{\nu}(P_0)$ is a finitely generated B-module containing $\nu(\Gamma^0)$ with $\nu(\gamma v) - \nu(\gamma) \in \mathfrak{m}_B^j \mathcal{P}_0$ for $\gamma \in \Gamma^0$, $v \in V_j$.*

Proof. Step 0: (Ab0). The F-span of $\rho(\Gamma^0)$ contains that of $\rho(\Gamma'')$, and the dimension of a span does not change under extension of the field to $\bar{F}$. If $a = n$, Burnside's theorem gives that the $\bar{F}$-span of $\rho(\Gamma'')$ is $\mathrm{M}_n(\bar{F})$, so the F-span of $\rho(\Gamma^0)$ is $\mathrm{M}_n(F)$. Let $a < n$ and $V = \bar{F}^n$ with the action of Γ'' through ρ. Through Q, V is the direct sum of simple $\bar{F}[\Gamma'']$-modules of dimensions a' and b' (afforded by r_1, r_2), which are not isomorphic (an isomorphism would be a non-zero Y with $Y r_1(\sigma) = r_2(\sigma) Y$, after transposing the roles if $a' = b'$; if $a' \neq b'$ they differ in dimension). The submodules $\bar{F}^a \oplus 0$ and $0 \oplus \bar{F}^{n-a}$ (ρ is block diagonal) are direct sums of simple submodules isomorphic to these two, of dimension $< n$, hence simple; so the blocks ρ_1, ρ_2 of ρ are irreducible on Γ'' over $\bar{F}$ and not isomorphic. By Schur's lemma the commutant of the $\bar{F}$-span $\mathcal{B}$ of $\{\mathrm{diag}(\rho_1(\sigma), \rho_2(\sigma)) : \sigma \in \Gamma''\}$ in $\mathrm{End}(V)$ is $\bar{F} \times \bar{F}$, and the density theorem gives $\mathcal{B} = \mathrm{M}_a(\bar{F}) \times \mathrm{M}_{n-a}(\bar{F})$, of dimension $a^2 + (n-a)^2$. Hence the F-span of $\rho(\Gamma^0)$, contained in $\mathrm{M}_n^{(a)}(F)$ (ρ is block diagonal), has dimension $a^2 + (n-a)^2$ and equals it.

Step 1: (Ab1). Since Γ^0 satisfies Φ_ℓ, (F0) shows that all $Z^1(\bar{\chi}_b, \bar{\chi}_{b'})$ ($b \neq b'$) are finite-dimensional. Let $E_B = B[\Gamma^0]/\mathcal{I}$ with projection ι_B. By (F1) and (F2), E_B is a finitely generated B-module and for every j there is an open normal subgroup V_j with $\iota_B(\gamma v) - \iota_B(\gamma) \in \mathfrak{m}_B^j E_B$. By (Q1) with $B' = \hat{B}$ (here $\mathcal{S} \subseteq \ker(D)$ and D is continuous), $E = E_B \otimes_B \hat{B}$ is a finitely generated $\hat{B}$-module with a Cayley–Hamilton determinant D_E such that $D_E \circ \iota$ is the base change of D. By (Q2) with $\eta = 1$ (the hypothesis $\chi_D(\gamma^*) = \chi_D(\gamma)$ is given, and $\mathcal{S}^* = \mathcal{S} \subseteq \mathcal{I}$), $(yy')^* = y'^* y^*$, $J^* = J$ and $\mathrm{tr}_{D_E} \circ \iota \circ {}^* = \mathrm{tr}_{D_E} \circ \iota$. The image P_0 of $B[\Gamma^0]$ in E is the image of $E_B \to E$, $e \mapsto e \otimes 1$, a finitely generated B-module, and $\iota(\gamma v) - \iota(\gamma) = (\iota_B(\gamma v) - \iota_B(\gamma)) \otimes 1 \in \mathfrak{m}_B^j P_0$.

Step 2: ρ_f kills $\mathcal{I}$. (i) ρ_f kills $\mathrm{CH}(D)$: for $y = \sum_i t_i y_i$ the image of $\chi_{D'}(y)(y)$ is $\chi(\rho_f(y))(\rho_f(y))$, with χ the characteristic polynomial of the matrix $\rho_f(y)$ over $A[t_1, \ldots, t_m]$ (as $f \circ D = \det \circ \rho$), which is 0 by the Cayley–Hamilton theorem; so ρ_f kills all its coefficients. (ii) $\rho_f(\mathcal{S}) = 0$ by hypothesis. (iii) A ring homomorphism from the local ring B to A followed by $A \to k$ has maximal kernel, so $f(\mathfrak{m}_B) \subseteq TA$ and $f(\mathfrak{m}_B^j) \subseteq T^j A$. For $j \geq 1$,

$H_j = \{\gamma \in \Gamma^0 : \rho(\gamma) \equiv 1 \bmod T^j\}$ is an open normal subgroup (ρ is T-adically continuous). Every $y \in \mathcal{I}$ lies in the two-sided ideal generated by $\mathrm{CH}(D) \cup \mathcal{S} \cup \mathfrak{m}_B^j \cdot 1 \cup \{h - 1 : h \in H_j\}$, whose generators ρ_f maps into the two-sided ideal $T^j \mathrm{M}_n(A)$; so $\rho_f(y) \in \bigcap_j T^j \mathrm{M}_n(A) = 0$.

Step 3: (Ab2). By Step 2, ρ_f factors through E_B, and $r(e \otimes \hat{b}) = \lambda(\hat{b})\rho_f(e)$ is a well-defined homomorphism of $\hat{B}$-algebras $E = E_B \otimes_B \hat{B} \to \mathrm{M}_n(F)$, since λ restricted to B is f; $r(\iota(\gamma)) = \rho(\gamma)$. The base change of D along $B \to \hat{B} \xrightarrow{\lambda} F$ is $\det \circ \rho$ (base-changed to F), so for $z = \iota(y)$ the image of $D_E(t - z)$ is $\det(t - r(z))$. From $\rho(\gamma^*) = {}^t\rho(\gamma)$, $r(\iota(y^*)) = r(\iota(y))^T$. As E is generated over $\hat{B}$ by $\iota(\Gamma^0)$ and $\lambda(\hat{B}) = F$, $r(E)$ is the F-span of $\rho(\Gamma^0)$, which is $\mathrm{M}_n^{(a)}(F)$ by the hypothesis of (Ab2).

Step 4: (Ab3). Apply Proposition E.73 to $(\hat{B}, F, \lambda)$ ($\hat{B}$ complete Noetherian local with 2 invertible, $\ker\lambda = \hat{\mathfrak{m}}$), the group Γ^0, n, a, the image of $\mathcal{I}$ in $\hat{B}[\Gamma^0]$ as generating set (so that the two-sided ideal it generates is J), the map * and r: (R1), (R2) are (Ab1) and (R3) is (Ab2), whose hypothesis is part of that of (Ab3). This gives $\mathcal{A}$, N, ν with (G1)–(G5). (G1) is the first clause of (Ab3), (G2) the second, (G3) (for the base change $D_E \circ \iota$ of D to $\hat{B}$) the third, (G4) with $y = \gamma$ and $r(\iota(\gamma)) = \rho(\gamma)$ the fourth, and (G5) the fifth ($\kappa[\Gamma^0]$ modulo the ideal generated by the image of $\mathcal{I}$ is the ring of (G5)). By (G1), ν vanishes on J, so $\nu = \bar{\nu} \circ \iota$ with $\bar{\nu}$ a homomorphism of $\hat{B}$-algebras, in particular B-linear; $\mathcal{P}_0 = \bar{\nu}(P_0)$ is a finitely generated B-module containing $\bar{\nu}(\iota(\Gamma^0)) = \nu(\Gamma^0)$, and $\nu(\gamma v) - \nu(\gamma) = \bar{\nu}(\iota(\gamma v) - \iota(\gamma)) \in \bar{\nu}(\mathfrak{m}_B^j P_0) = \mathfrak{m}_B^j \mathcal{P}_0$ by (Ab1). □

Proposition E.73. *Let B be a complete Noetherian local ring with maximal ideal $\mathfrak{m}$ in which 2 is invertible, F a field and $\lambda\colon B \to F$ a ring homomorphism with kernel $\mathfrak{m}$. Let Γ be a group, $n \geq 1$ and $1 \leq a \leq n$; we say that $i, j \in \{1, \dots, n\}$ are in the same block if $i, j \leq a$ or $i, j > a$. Let $\mathcal{I} \subseteq B[\Gamma]$ be a subset, J the two-sided ideal generated by $\mathcal{I}$, $E = B[\Gamma]/J$ and $\iota\colon B[\Gamma] \to E$ the projection. Assume:*

(R1) *E is a finitely generated B-module carrying a Cayley–Hamilton determinant $D_E\colon E \to B$ of dimension n; write* tr *for its trace and $D = D_E \circ \iota$;*

(R2) *$y \mapsto y^*$ is a B-linear map $B[\Gamma] \to B[\Gamma]$ with $(yy')^* = y'^* y^*$, $y^{**} = y$, $J^* = J$ and $\mathrm{tr}(\iota(y^*)) = \mathrm{tr}(\iota(y))$;*

(R3) *$r\colon E \to \mathrm{M}_n(F)$ is a homomorphism of B-algebras such that the image of $D_E(t - z)$ in $F[t]$ is the characteristic polynomial of $r(z)$ for all $z \in E$, $r(\iota(y^*)) = r(\iota(y))^T$ for all y, and $r(E)$ is the set of matrices whose entry at (i, j) vanishes unless i, j are in the same block;*

(R4) *(only for (G6)) Γ is a topological group and for every $j \geq 1$ there is an open normal subgroup V_j of Γ with $\iota(\gamma v) - \iota(\gamma) \in \mathfrak{m}^j E$ for all $\gamma \in \Gamma$, $v \in V_j$.*

Then there are a commutative ring $\mathcal{A}$ containing B as a subring and finitely generated as a B-module, a B-submodule $N \subseteq \mathcal{A}$ with $\mathcal{A} = B \cdot 1 \oplus N$, $xy \in \mathfrak{m} \cdot 1$ for all $x, y \in N$ and $N = 0$ if $a = n$, and a homomorphism of B-algebras $\nu\colon B[\Gamma] \to \mathrm{M}_n(\mathcal{A})$ such that:

(G1) *$\nu(J) = 0$, and the B-span of $\nu(\Gamma)$ is the set of matrices with entries in $B \cdot 1$ at the positions (i, j) in the same block and in N at the other positions;*

(G2) *$\nu(y^*) = \nu(y)^T$ for all $y \in B[\Gamma]$;*

(G3) *D followed by $B \to \mathcal{A}$ equals $\det \circ \nu$: for every commutative $\mathcal{A}$-algebra T, $t_1, \dots, t_m \in T$ and $\gamma_1, \dots, \gamma_m \in \Gamma$, $D_T(\sum_s t_s \gamma_s) = \det(\sum_s t_s \nu(\gamma_s))$;*

(G4) *if $y \in B[\Gamma]$, $b \in B$ and $\nu(y)_{ij} - b \cdot 1 \in N$, then $\lambda(b) = r(\iota(y))_{ij}$;*

(G5) *every prime ideal Q of B such that $\kappa[\Gamma]/\langle f(\mathcal{I})\rangle$ is not semisimple for some homomorphism $f\colon B \to \kappa$ to a field with $\ker f = Q$ contains $\mathrm{Ann}_B(N)$;*

(G6) *under (R4), with $\mathcal{P} \subseteq \mathrm{M}_n(\mathcal{A})$ the finitely generated B-module of matrices described in (G1): $\nu(\Gamma) \subseteq \mathcal{P}$, and $\nu(\gamma v) - \nu(\gamma) \in \mathfrak{m}^j\mathcal{P}$ for all $j \geq 1$, $\gamma \in \Gamma$, $v \in V_j$.*

Proof. Step 1: the involution and the trace on E. Since $J^* = J$, $*$ induces a B-linear map on E, again written $*$, with $(zz')^* = z'^*z^*$, $z^{**} = z$ and $\mathrm{tr}(z^*) = \mathrm{tr}(z)$ by (R2). For $z, z' \in E$, (Am1) over $B[t]$ gives $D_E(1-tzz') = D_E(1-tz'z)$; comparing the coefficients of t gives $\mathrm{tr}(zz') = \mathrm{tr}(z'z)$. Also $r(z^*) = r(z)^T$ by (R3), as ι is surjective.

Step 2: symmetric matrix units. B is henselian, $2 \in B^\times$, E is finite over B and D_E is Cayley–Hamilton, and r satisfies the hypotheses of Proposition E.74 (its image contains the block-diagonal matrices by (R3)). So there are $e_i, x_i \in E$ $(1 \leq i \leq n)$ satisfying (U1)–(U3) for tr, $*$ and the map o with $o(i) = 1$ for $i \leq a$, $o(i) = n$ for $i > a$, with $r(e_i) = E_{ii}$, $r(x_i) = E_{o(i)i}$ and $D_E(1 + te_i) = 1 + t$. Here $o(i) = o(j)$ if and only if i, j are in the same block, and $o(\{1, \dots, n\}) = \{1\}$ if $a = n$, $= \{1, n\}$ with $1 \neq n$ if $a < n$.

Step 3: the realisation. Lemma E.75 with $I = \{1, \dots, n\}$, $p = 1$ and (if $a < n$) $q = n$ gives the commutative ring $\mathcal{A} = B \oplus N$ (with $N = 0$ if $a = n$), finite over B, containing B via $b \mapsto (b, 0)$, with $\mathcal{A} = B \cdot 1 \oplus N$ and $nn' = \langle n, n'\rangle \cdot 1$, and the injective B-algebra homomorphism $\varphi\colon E \to \mathrm{M}_n(\mathcal{A})$. Its part (3) applies to r: $r(z^*) = r(z)^T$, $r(x_i) = E_{o(i)i}$, and $r(z)_{ij} = 0$ when $o(i) \neq o(j)$ by (R3). Hence $\lambda(\langle n, n'\rangle) = 0$, i.e. $nn' \in \mathfrak{m} \cdot 1$ for $n, n' \in N$. Put $\nu = \varphi \circ \iota$.

Step 4: (G1), (G2), (G4). $\nu(J) = \varphi(\iota(J)) = 0$. The B-span of $\nu(\Gamma)$ is φ of the B-span of $\iota(\Gamma)$, which is $\varphi(E)$ since Γ spans $B[\Gamma]$ and ι is onto; by Lemma E.75 (2) this is the set of matrices described in (G1). (G2): $\nu(y^*) = \varphi(\iota(y)^*) = \varphi(\iota(y))^T$ by Lemma E.75 (2). (G4): if $\nu(y)_{ij} = (b', n)$ with $(b', n) - (b, 0) \in N$, then $b' = b$, and $\lambda(b) = r(\iota(y))_{ij}$ by Lemma E.75 (3).

Step 5: (G3). By (U1), (U2) ($e_iEe_i = Be_i$) and $D_E(1 + te_i) = 1 + t$, Lemma E.76 applies to D_E, the e_i, $S = \mathcal{A}$ and φ (with $\varphi(e_i) = E_{ii}$ by Lemma E.75 (2)): $D_{E,T}(\sum_a t_a \otimes z_a) = \det(\sum_a t_a \varphi(z_a))$ for every commutative $\mathcal{A}$-algebra T. With $z_a = \iota(\gamma_a)$, and $D_T = D_{E,T} \circ (\mathrm{id}_T \otimes \iota)$ by definition of D, this is (G3).

Step 6: (G5). $E \cong B[\Gamma]/\langle\mathcal{I}\rangle$, so Lemma E.77 gives $\mathrm{Ann}_B(N) \subseteq Q$ for every such Q.

Step 7: (G6). By Lemma E.75 (2), $\varphi(E) = \mathcal{P}$, which is finitely generated over B as E is. Hence $\nu(\Gamma) \subseteq \mathcal{P}$, and, φ being B-linear, $\nu(\gamma v) - \nu(\gamma) = \varphi(\iota(\gamma v) - \iota(\gamma)) \in \varphi(\mathfrak{m}^j E) = \mathfrak{m}^j\mathcal{P}$ for $v \in V_j$. □

Proposition E.74. *Let B be a henselian local ring with maximal ideal $\mathfrak{m}_B$ in which 2 is invertible, E a B-algebra which is finitely generated as a B-module, $D\colon E \to B$ a Cayley–Hamilton determinant of dimension $n \geq 1$ with trace* tr*, and $y \mapsto y^*$ a B-linear map $E \to E$ with $(yy')^* = y'^*y^*$, $y^{**} = y$, $\mathrm{tr}(y^*) = \mathrm{tr}(y)$ and $\mathrm{tr}(yy') = \mathrm{tr}(y'y)$ for all $y, y' \in E$. Let F be a field, $\lambda\colon B \to F$ a ring homomorphism with kernel $\mathfrak{m}_B$, and $r\colon E \to \mathrm{M}_n(F)$ a homomorphism of B-algebras such that for all $y \in E$ the image of $D(t - y)$ in $F[t]$ is the characteristic polynomial of $r(y)$ and $r(y^*) = r(y)^T$. Let $1 \leq a \leq n$, assume that every matrix in $\mathrm{M}_n(F)$ whose entries at (i, j) vanish whenever exactly one of i, j is $\leq a$ lies in $r(E)$, and let $o\colon \{1, \dots, n\} \to \{1, \dots, n\}$ be $o(i) = 1$ for $i \leq a$ and $o(i) = n$ for $i > a$. Then there are $e_1, \dots, e_n, x_1, \dots, x_n \in E$ satisfying (U1)–(U3) for* tr*, $*$ and o, with $r(e_i) = E_{ii}$, $r(x_i) = E_{o(i)i}$ and $D(1 + te_i) = 1 + t$ in $B[t]$ for every i.*

Proof. Step 1: $\ker r \subseteq \mathrm{rad}(E)$. Let $u \in \ker r$. The image of $D(t - u) = t^n + \sum_{k<n} c_k t^k$ in $F[t]$ is the characteristic polynomial of 0, so all $c_k \in \ker\lambda = \mathfrak{m}_B$, and the Cayley–Hamilton identity

$u^n + \sum_k c_k u^k = 0$ gives $u^n \in \mathfrak{m}_B E$. Now let $y \in \ker r$ and $z \in E$; then $u = zy \in \ker r$, so $1+u$ is invertible modulo $\mathfrak{m}_B E$ (its inverse there is $\sum_{k<n}(-u)^k$), hence invertible in E because $\mathfrak{m}_B E \subseteq \operatorname{rad}(E)$. As $1+zy$ is invertible for all z, $y \in \operatorname{rad}(E)$.

Step 2: orthogonal idempotents fixed by $*$. Since $r(y^*) = r(y)^T$, the two-sided ideal $\ker r$ is stable under $*$, and r induces an injective homomorphism $\bar{r}\colon E/\ker r \to \mathrm{M}_n(F)$. The diagonal matrix units lie in $r(E)$ by hypothesis; let $\epsilon_i \in E/\ker r$ with $\bar{r}(\epsilon_i) = E_{ii}$. The ϵ_i are orthogonal idempotents ($\bar{r}$ is injective), and $\epsilon_i^* = \epsilon_i$ since $\bar{r}(\epsilon_i^*) = E_{ii}^T = E_{ii}$. As E is finite, hence integral, over B, Theorem B.100 (with $S = E$, $\tau = *$, $I = \ker r$, Step 1) gives orthogonal idempotents e_i lifting ϵ_i with $\{e_1, \dots, e_n\}$ stable under $*$. If $e_i^* = e_j$, then $E_{jj} = r(e_j) = r(e_i)^T = E_{ii}$, so $j = i$: $e_i^* = e_i$. The idempotent $f = 1 - \sum_i e_i$ satisfies $r(f) = 0$, so $f \in \operatorname{rad}(E)$; then $1-f$ is invertible and $(1-f)f = 0$, so $f = 0$. Thus (U1), $e_i^* = e_i$ and $r(e_i) = E_{ii}$ hold.

Step 3: rank-one corners. By (Cd1) of Theorem B.102 ($\operatorname{Spec}(B)$ is connected as B is local), D_{e_i} is a Cayley–Hamilton determinant on $e_i E e_i$ of some dimension s_i, and D restricted to $e_iEe_i \oplus (1-e_i)E(1-e_i)$ is $D_{e_i}D_{1-e_i}$, with $\dim D_{1-e_i} = n - s_i$. Since $t - e_i = (t-1)e_i + t(1-e_i)$ and $D_{e_i}(e_i) = D(1) = 1$, homogeneity gives

$$D(t-e_i) = (t-1)^{s_i}\, t^{n-s_i}, \qquad D(1+te_i) = D_{e_i}((1+t)e_i)\, D_{1-e_i}(1-e_i) = (1+t)^{s_i}.$$

The image of $D(t-e_i)$ in $F[t]$ is the characteristic polynomial $(t-1)t^{n-1}$ of E_{ii}, so $s_i = 1$ by unique factorisation in $F[t]$. Hence $D(1+te_i) = 1+t$, and $\operatorname{tr}(e_i) = 1$ (minus the coefficient of t^{n-1} in $(t-1)t^{n-1}$). By (Cd2), $B \to e_iEe_i$, $b \mapsto be_i$, is an isomorphism, so $e_iEe_i = Be_i$, and every $w \in e_iEe_i$ equals $\operatorname{tr}(w)e_i$ (write $w = be_i$; then $\operatorname{tr}(w) = b$). This proves (U2).

Step 4: the elements x_i. For i with $o(i) = i$ (that is, $i \in \{1,n\} \cap o(\{1,\dots,n\})$) put $x_i = e_i$. For the other i, the indices $o(i)$ and i lie in the same block, so $E_{o(i)i} \in r(E)$; choose y_i with $r(y_i) = E_{o(i)i}$ and put $z_i = e_{o(i)} y_i e_i$, so that $r(z_i) = E_{o(i)o(i)}E_{o(i)i}E_{ii} = E_{o(i)i}$. As $z_i^* = e_i y_i^* e_{o(i)}$, we have $z_i^* z_i \in e_iEe_i$ and $z_i z_i^* \in e_{o(i)}Ee_{o(i)}$, so by Step 3

$$z_i^* z_i = c_i e_i, \qquad z_i z_i^* = \operatorname{tr}(z_i z_i^*)e_{o(i)} = c_i e_{o(i)}, \qquad c_i = \operatorname{tr}(z_i^* z_i) \in B.$$

Applying r to the first identity, $\lambda(c_i)E_{ii} = E_{i\,o(i)}E_{o(i)i} = E_{ii}$, so $\lambda(c_i) = 1$. The polynomial $X^2 - c_i$ has the simple root 1 modulo $\mathfrak{m}_B$ (its derivative there is $2 \neq 0$), so by Hensel's lemma there is $u_i \in B$ with $u_i^2 = c_i$ and $\lambda(u_i) = 1$; u_i is a unit. Put $x_i = u_i^{-1} z_i$. Then $x_i^* x_i = c_i^{-1} z_i^* z_i = e_i$, $x_i x_i^* = e_{o(i)}$, $e_{o(i)} x_i e_i = x_i$ and $r(x_i) = E_{o(i)i}$. For $i = o(i)$ these hold trivially for $x_i = e_i$, and $x_{o(i)} = e_{o(i)}$ for every i since $o(o(i)) = o(i)$. This proves (U3). □

Lemma E.75. *Let B be a commutative ring and E a B-algebra, with a B-linear map $y \mapsto y^*$ of E to itself such that $(yy')^* = y'^* y^*$ and $y^{**} = y$, and a B-linear map $\operatorname{tr}\colon E \to B$ such that $\operatorname{tr}(yy') = \operatorname{tr}(y'y)$ and $\operatorname{tr}(y^*) = \operatorname{tr}(y)$. Let I be a finite set, $o\colon I \to I$ a map with $o \circ o = o$, and $(e_i)_{i\in I}$, $(x_i)_{i\in I}$ elements of E such that for all $i, j \in I$:*

(U1) *$e_i e_j = \delta_{ij} e_i$ and $\sum_{i\in I} e_i = 1$;*

(U2) *$e_i^* = e_i$, $\operatorname{tr}(e_i) = 1$, and $e_iEe_i = Be_i$;*

(U3) *$e_{o(i)} x_i e_i = x_i$, $x_{o(i)} = e_{o(i)}$, $x_i x_i^* = e_{o(i)}$ and $x_i^* x_i = e_i$.*

Assume that $o(I) = \{p\}$ or $o(I) = \{p,q\}$ with $p \neq q$. Put $N = 0$ in the first case and $N = e_pEe_q$ in the second, and $\langle n, n'\rangle = \operatorname{tr}(n\, n'^*)$ for $n, n' \in N$. Then:

1. *The B-module $\mathcal{A} = B \oplus N$ with the product*

$$(b,n)(b',n') = (bb' + \langle n, n'\rangle,\ bn' + b'n) \tag{E.8}$$

is a commutative ring with unit $(1,0)$*;* $b \mapsto (b,0)$ *is an injective ring homomorphism* $B \to \mathcal{A}$*, through which* $\mathcal{A} = B \cdot 1 \oplus N$ *as* B*-modules, and* $nn' = \langle n, n' \rangle \cdot 1$ *for* $n, n' \in N$*. If* E *is a finitely generated* B*-module, so is* $\mathcal{A}$*.*

2. *For* $z \in E$ *put* $\theta(z) = (\mathrm{tr}(z),\ e_p(z + z^*)e_q) \in \mathcal{A}$ *(with second component* 0 *if* $N = 0$*). The map* $\varphi\colon E \to \mathrm{M}_I(\mathcal{A})$*,*

$$\varphi(y)_{ij} = \theta(x_i\, y\, x_j^*) \qquad (i, j \in I), \tag{E.9}$$

is an injective homomorphism of B*-algebras with* $\varphi(y^*) = \varphi(y)^T$*,* $\varphi(e_i)$ *the matrix unit at* (i,i)*, and* $\sum_i \varphi(y)_{ii} = \mathrm{tr}(y) \cdot 1$*; its image is the set of matrices* (a_{ij}) *with* $a_{ij} \in B \cdot 1$ *if* $o(i) = o(j)$ *and* $a_{ij} \in N$ *if* $o(i) \neq o(j)$*.*

3. *Let* F *be a commutative* B*-algebra with structure map* $\lambda\colon B \to F$ *and* $r\colon E \to \mathrm{M}_I(F)$ *a homomorphism of* B*-algebras with* $r(y^*) = r(y)^T$*,* $r(x_i)$ *the matrix unit at* $(o(i), i)$*, and* $r(y)_{ij} = 0$ *whenever* $o(i) \neq o(j)$*. If* $\varphi(y)_{ij} = (b, n)$*, then* $\lambda(b) = r(y)_{ij}$*. Moreover* $\lambda(\langle n, n' \rangle) = 0$ *for all* $n, n' \in N$*.*

Proof. Step 0: elementary facts. (a) For $z \in e_i E e_i$ we have $z = \mathrm{tr}(z)e_i$: by (U2), $z = se_i$ with $s \in B$, and $\mathrm{tr}(z) = s\,\mathrm{tr}(e_i) = s$. (b) For $i \neq j$ and $z \in e_i E e_j$, $\mathrm{tr}(z) = \mathrm{tr}(e_i \cdot z e_j) = \mathrm{tr}(z e_j e_i) = 0$ by (U1). (c) $(e_a z e_b)^* = e_b z^* e_a$ by (U2), so $*$ maps C_{ab} onto C_{ba}. (d) By (U3), $x_i = x_i e_i$ and $x_j^* = e_j x_j^*$; hence $x_i x_j^* = x_i e_i e_j x_j^* = 0$ for $i \neq j$, and $x_i x_i^* = e_{o(i)}$. (e) For $y \in E$ put $w_{ij}(y) = x_i y x_j^*$; by (U3) and (c), $w_{ij}(y) \in C_{o(i)o(j)}$.

Step 1: part (1). If $N = 0$ there is nothing to prove ($\mathcal{A} = B$). Let $N = C_{pq}$. The form $\langle \cdot, \cdot \rangle$ is B-bilinear, and symmetric: $\langle n, n' \rangle = \mathrm{tr}((nn'^*)^*) = \mathrm{tr}(n'n^*) = \langle n', n \rangle$. For $n, n', n'' \in N$,

$$\langle n, n' \rangle n'' = \langle n', n'' \rangle n. \tag{E.10}$$

Indeed $nn'^* \in C_{pq}C_{qp} \subseteq C_{pp}$, so $nn'^* = \langle n, n' \rangle e_p$ by (a), and $n'^* n'' \in C_{qq}$, so $n'^* n'' = \mathrm{tr}(n'^* n'')e_q$ with $\mathrm{tr}(n'^* n'') = \mathrm{tr}(n'' n'^*) = \langle n'', n' \rangle = \langle n', n'' \rangle$; hence $\langle n, n' \rangle n'' = \langle n, n' \rangle e_p n'' = nn'^* n'' = n\langle n', n'' \rangle e_q = \langle n', n'' \rangle n$. The product (E.8) is B-bilinear, commutative by symmetry, and $(1,0)$ is a unit. Associativity: expanding both sides,

the first components agree and the second agree by (E.10). So $\mathcal{A}$ is a commutative ring; $b \mapsto (b,0)$ is an injective ring homomorphism, the B-module structure of $\mathcal{A}$ is $b(b', n) = (bb', bn)$, so $\mathcal{A} = B \cdot 1 \oplus N$, and $(0,n)(0,n') = (\langle n, n' \rangle, 0)$. Finally N is the image of E under $z \mapsto e_p z e_q$, so it is finitely generated when E is.

Step 2: values of θ *on the corners.* For $z \in C_{aa}$: $\theta(z) = (\mathrm{tr}(z), 0)$, since $e_p z e_q = e_p e_a z e_a e_q = 0$ and likewise for $z^* \in C_{aa}$ ($p \neq q$). For $z \in C_{pq}$: $\theta(z) = (0, z)$, by (b) and $e_p z^* e_q \in e_p C_{qp} e_q = 0$. For $z \in C_{qp}$: $\theta(z) = (0, z^*)$ similarly. (If $N = 0$, only the first case occurs.) In particular θ restricted to C_{ab} is injective: on C_{aa} by (a), on C_{pq} trivially, on C_{qp} since $*$ is injective. Also $\theta(z^*) = \theta(z)$ for all $z \in E$, as $\mathrm{tr}(z^*) = \mathrm{tr}(z)$ and $z^* + z^{**} = z + z^*$.

Step 3: $\theta(zz') = \theta(z)\theta(z')$ *for* $z \in C_{ab}$*,* $z' \in C_{bc}$*,* $a, b, c \in o(I)$*.* If $a = b$, then $z = se_a$ with $s = \mathrm{tr}(z)$, $zz' = sz'$ and $\theta(z) = (s, 0)$, so both sides are $s\theta(z')$; similarly if $b = c$. Otherwise $a \neq b$ and $b \neq c$, so $a = c$ and $\{a, b\} = \{p, q\}$, and $zz' \in C_{aa}$, $\theta(zz') = (\mathrm{tr}(zz'), 0)$. If $(a,b) = (p,q)$: $\theta(z)\theta(z') = (0,z)(0,z'^*) = (\mathrm{tr}(zz'), 0)$. If $(a,b) = (q,p)$: $\theta(z)\theta(z') = (0,z^*)(0,z') = (\mathrm{tr}(z^* z'^*), 0) = (\mathrm{tr}((z'z)^*), 0) = (\mathrm{tr}(z'z), 0) = (\mathrm{tr}(zz'), 0)$.

Step 4: φ *is a* B*-algebra homomorphism.* B-linearity is clear. By (U1) and (U3), $w_{ij}(yy') = x_i y(\sum_k e_k) y' x_j^* = \sum_k x_i y x_k^* x_k y' x_j^* = \sum_k w_{ik}(y) w_{kj}(y')$, with $w_{ik}(y) \in C_{o(i)o(k)}$, $w_{kj}(y') \in C_{o(k)o(j)}$. By additivity of θ and Step 3, $\varphi(yy')_{ij} = \sum_k \varphi(y)_{ik}\varphi(y')_{kj}$. By (d), $w_{ij}(1) = \delta_{ij} e_{o(i)}$, so $\varphi(1)$ is the identity matrix; likewise $w_{kl}(e_i) = x_k e_i x_l^* = \delta_{ki}\delta_{li} e_{o(i)}$ gives $\varphi(e_i)$ the matrix unit at (i,i).

Step 5: transpose and trace. $w_{ij}(y^*) = x_i y^* x_j^* = (x_j y x_i^*)^* = w_{ji}(y)^*$, so $\varphi(y^*)_{ij} = \theta(w_{ji}(y)^*) = \theta(w_{ji}(y)) = \varphi(y)_{ji}$ by Step 2. For the trace, $w_{ii}(y) \in C_{o(i)o(i)}$, so $\varphi(y)_{ii} = (\mathrm{tr}(x_i y x_i^*), 0)$ and $\mathrm{tr}(x_i y x_i^*) = \mathrm{tr}(y x_i^* x_i) = \mathrm{tr}(y e_i)$; summing over i gives $\mathrm{tr}(y)$ by (U1).

Step 6: injectivity and image. By (U3), $x_i^* w_{ij}(y) x_j = e_i y e_j$, so

$$y = \sum_{i,j} x_i^*\, w_{ij}(y)\, x_j. \tag{E.11}$$

If $\varphi(y) = 0$, then $w_{ij}(y) = 0$ for all i, j by the injectivity in Step 2, and $y = 0$ by (E.11). By Step 2, $\varphi(y)_{ij} \in \theta(C_{o(i)o(j)})$, which is $B \cdot 1$ if $o(i) = o(j)$ and N otherwise. Conversely let (a_{ij}) be a matrix of that shape. Choose $w_{ij} \in C_{o(i)o(j)}$ with $\theta(w_{ij}) = a_{ij}$: $w_{ij} = s e_{o(i)}$ if $a_{ij} = (s, 0)$ and $o(i) = o(j)$; $w_{ij} = n$ if $a_{ij} = (0, n)$ and $(o(i), o(j)) = (p, q)$; $w_{ij} = n^*$ if $a_{ij} = (0, n)$ and $(o(i), o(j)) = (q, p)$. Put $y = \sum_{i,j} x_i^* w_{ij} x_j$. By (d), $w_{kl}(y) = \sum_{i,j} (x_k x_i^*) w_{ij} (x_j x_l^*) = e_{o(k)} w_{kl} e_{o(l)} = w_{kl}$, so $\varphi(y) = (a_{ij})$.

Step 7: part (3). Write E_{ab} for the matrix units of $\mathrm{M}_I(F)$. By hypothesis $r(e_{o(k)}) = r(x_{o(k)}) = E_{o(k)o(k)}$ (as $o(o(k)) = o(k)$) and $r(x_j^*) = r(x_j)^T = E_{j\,o(j)}$. Let $\varphi(y)_{ij} = (b, n)$, so $b = \mathrm{tr}(w)$ for $w = w_{ij}(y) \in C_{o(i)o(j)}$. If $o(i) \neq o(j)$, then $b = 0$ by (b) and $r(y)_{ij} = 0$ by hypothesis. If $o(i) = o(j) = a$, then $w = b e_a$ by (a), so $r(w) = \lambda(b) E_{aa}$, while $r(w) = E_{ai}\, r(y)\, E_{ja} = r(y)_{ij} E_{aa}$; comparing the entries at (a, a) gives $\lambda(b) = r(y)_{ij}$. Finally let $N \neq 0$ and $n, n' \in N = C_{pq}$. Then $r(n) = r(e_p) r(n) r(e_q) = E_{pp} r(n) E_{qq} = r(n)_{pq} E_{pq} = 0$, since $o(p) = p \neq q = o(q)$. As $n n'^* = \langle n, n' \rangle e_p$ (Step 1), $\lambda(\langle n, n' \rangle) E_{pp} = r(n) r(n')^T = 0$, so $\lambda(\langle n, n' \rangle) = 0$. □

Lemma E.76. *Let A be a commutative ring, E an A-algebra, $D\colon E \to A$ a determinant of dimension $n \geq 1$, and $e_1, \dots, e_n \in E$ orthogonal idempotents with $\sum_i e_i = 1$, $e_i E e_i = A e_i$ and $D(1 + t e_i) = 1 + t$ in $A[t]$ for every i. Let S be a commutative A-algebra and $\varphi\colon E \to \mathrm{M}_n(S)$ a homomorphism of A-algebras with $\varphi(e_i) = E_{ii}$ for every i. Then for every commutative S-algebra T, all $m \geq 1$, $t_1, \dots, t_m \in T$ and $x_1, \dots, x_m \in E$,*

$$D_T\Big(\sum_{a=1}^{m} t_a \otimes x_a\Big) = \det\Big(\sum_{a=1}^{m} t_a\, \varphi(x_a)\Big) \quad \text{in } T,$$

where D_T is the value of D on $T \otimes_A E$ and $\varphi(x_a)$ is mapped to $\mathrm{M}_n(T)$; that is, D followed by $A \to S$ equals $\det \circ \varphi$ as S-valued determinants on E.

Proof. Let P_1 be D followed by $A \to S$ and $P_2 = \det \circ \varphi$; both are S-valued determinants of dimension n on E (multiplicative, homogeneous of degree n), and we write $\Lambda_l^{(1)}, \Lambda_l^{(2)}$ for their coefficients as in Theorem B.101. By homogeneity, $P(u - tw) = \sum_l (-1)^l \Lambda_l(w) t^l u^{n-l}$ in $S[t, u]$ for either law P, so $P(1 - tw) = \sum_l (-1)^l \Lambda_l(w) t^l$ determines all $\Lambda_l(w)$, and $P(w) = \Lambda_n(w)$.

Step 1: a spanning monoid. Let $\mathcal{M} = \{1\} \cup \bigcup_{i,j} e_i E e_j$. It is closed under multiplication ($e_i E e_j \cdot e_k E e_l$ is $0 \in e_i E e_l$ if $j \neq k$ and lies in $e_i E e_l$ if $j = k$), and it spans E as an A-module, since $y = \sum_{i,j} e_i y e_j$.

Step 2: the coefficients agree on $\mathcal{M}$. For $w = 1$: $P(1 - t) = (1 - t)^n P(1) = (1 - t)^n$ for both laws. For $w \in e_i E e_j$ with $i \neq j$: $w = (e_i w) e_j$, so by (Am1) over $A[t]$, $P(1 - tw) = P(1 - e_j\, t e_i w) = P(1 - t\, e_j e_i w) = P(1) = 1$ for both laws. For $w \in e_i E e_i$: $w = a e_i$ with $a \in A$; applying the A-algebra map $A[t] \to A[t]$, $t \mapsto -at$, to $D(1 + t e_i) = 1 + t$ gives $P_1(1 - tw) = 1 - at$, while $P_2(1 - tw) = \det(1 - ta E_{ii}) = 1 - at$. In all cases $\Lambda_l^{(1)}(w) = \Lambda_l^{(2)}(w)$ for every l.

Step 3: conclusion. Let T, t_a, x_a be as in the statement. By Step 1 write $x_a = \sum_{k=1}^{K} c_{ak} w_k$ with $c_{ak} \in A$, $w_k \in \mathcal{M}$; then $\sum_a t_a \otimes x_a = \sum_k s_k \otimes w_k$ with $s_k = \sum_a c_{ak} t_a \in T$. By naturality under $S[u_1, \dots, u_K] \to T$, $u_k \mapsto s_k$, it suffices to prove $P_1(\sum_k u_k w_k) = P_2(\sum_k u_k w_k)$ in $S[u_1, \dots, u_K]$. Both sides are $\Lambda_n(\sum_k u_k w_k)$, which by (Am2) is the same integral polynomial

$P_{K,n}$ evaluated at the u_k and at the $\Lambda_j(w)$ for the finite products w of the w_k. These products lie in $\mathcal{M}$ by Step 1, so the arguments coincide by Step 2, and so do the values. □

Lemma E.77. *In the setting of Lemma E.75, let $f\colon B \to \kappa$ be a ring homomorphism to a field and assume that $f(s) \neq 0$ for some $s \in \mathrm{Ann}_B(N)$. Then $\kappa \otimes_B E$ is isomorphic, as a κ-algebra, to $\prod_{c\in o(I)} \mathrm{M}_{|o^{-1}(c)|}(\kappa)$; in particular it is semisimple. Consequently, if Γ is a group, $\mathcal{I} \subseteq B[\Gamma]$ a subset, $E \cong B[\Gamma]/\langle\mathcal{I}\rangle$ as B-algebras ($\langle\mathcal{I}\rangle$ the two-sided ideal generated by $\mathcal{I}$), and Q a prime ideal of B such that $\kappa[\Gamma]/\langle f(\mathcal{I})\rangle$ is not semisimple for some homomorphism $f\colon B \to \kappa$ to a field with $\ker f = Q$, then $\mathrm{Ann}_B(N) \subseteq Q$.*

Proof. Step 1: $\kappa \otimes_B N = 0$ and $\kappa \otimes_B \mathcal{A} \cong \kappa$. For $c \in \kappa$ and $n \in N$, $c \otimes n = cf(s)^{-1}f(s) \otimes n = cf(s)^{-1} \otimes sn = 0$. Hence $\kappa \otimes_B \mathcal{A} = \kappa \otimes_B (B \cdot 1 \oplus N) = \kappa \otimes 1$, and the ring homomorphism $\kappa \to \kappa \otimes_B \mathcal{A}$ is an isomorphism.

Step 2: the splitting. Let $\mathrm{Blk} \subseteq \mathrm{M}_I(\mathcal{A})$ be the set of matrices with entries in $B \cdot 1$ at (i,j) with $o(i) = o(j)$ and in N at the other positions; by Lemma E.75 (2), $\varphi\colon E \to \mathrm{Blk}$ is a B-algebra isomorphism. As a B-module, $\mathrm{M}_I(\mathcal{A}) = \mathrm{Blk} \oplus \mathrm{Blk}'$, where Blk' consists of the matrices with entries in N at (i,j) with $o(i) = o(j)$ and in $B \cdot 1$ elsewhere; so $\kappa \otimes \varphi\colon \kappa \otimes_B E \to \kappa \otimes_B \mathrm{M}_I(\mathcal{A}) = \mathrm{M}_I(\kappa \otimes_B \mathcal{A}) = \mathrm{M}_I(\kappa)$ is an injective homomorphism of κ-algebras. Its image is $\kappa \otimes_B \mathrm{Blk}$, which by Step 1 is the set of matrices in $\mathrm{M}_I(\kappa)$ vanishing at the positions (i,j) with $o(i) \neq o(j)$, i.e. $\prod_{c\in o(I)} \mathrm{M}_{|o^{-1}(c)|}(\kappa)$ after ordering I by blocks. A finite product of matrix algebras over a field is semisimple.

Step 3: the consequence. Suppose $s \in \mathrm{Ann}_B(N) \setminus Q$ and $\ker f = Q$; then $f(s) \neq 0$ and $\kappa \otimes_B E$ is semisimple by Step 2. Now $\kappa \otimes_B E \cong \kappa \otimes_B B[\Gamma]/\langle\mathcal{I}\rangle \cong \kappa[\Gamma]/\langle f(\mathcal{I})\rangle$ (right exactness of $\kappa \otimes_B -$ applied to $\langle\mathcal{I}\rangle \to B[\Gamma] \to E \to 0$, the image of $\kappa \otimes \langle\mathcal{I}\rangle$ in $\kappa[\Gamma]$ being the two-sided ideal generated by $f(\mathcal{I})$). So $\kappa[\Gamma]/\langle f(\mathcal{I})\rangle$ is semisimple, a contradiction. Hence $\mathrm{Ann}_B(N) \subseteq Q$. □

Proposition E.78. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell \neq 2$, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant over $\mathscr{H}$, $B = B_n^{\mathrm{po}}$, $J \subseteq B$ an ideal, $x_0, \dots, x_h$ curve points of B with homomorphisms $f_i\colon B \to A_{k_i}$, and $(\mathcal{T}, d, C, u, \pi)$ a tuple as in the definition of a patching system for J along $(x_0, \dots, x_h)$ in Definition E.31 (an abstract patching tower $\mathcal{T}$, an integer $d \geq 0$, an eigenvalue algebra C with u whose coefficient ring $\mathcal{O}_1$ has residue field of cardinality $|k_i|$ for every i, and a surjective ring homomorphism $\pi\colon R \to C$), which is not required to satisfy (Sys0)–(Sys4); surjective lifts and primes stable for the system are defined for such a tuple as there. Fix i, a surjective lift f' of f_i, $\mathfrak{q} = \pi^{-1}(\ker f')$ and the completion $\hat{A}$ of $R_{\mathfrak{q}}$ at its maximal ideal. Let C be the eigenvalue algebra of $(\mathcal{O}_1, (\sigma_j), (\tilde{u}_{j,i}))$. Assume $\pi(I) = 0$, and let $\bar{\pi}\colon R/I \to C$ be the induced homomorphism. Suppose there are a framed normalised curve point x of shape $(a, n-a)$ with $A = A_{k_i}$ and representation ρ that satisfies (Pj1) and such that for every $Z \in \mathrm{Ev}_a(A)$ there is $r \geq 0$ with $T^r Z$ in the A-span of $\rho(\Gamma')$, a Selmer basis κ of x with local witnesses, a level $\mathbf{V}$ over $\mathscr{H}$ at which (K1) holds with an integer $D_0 \leq d + s - 1$ and (K2), (K3) hold, and a realisation $\mathfrak{R}$ of x over $\mathbf{V}$ with coefficient ring $\mathcal{O}_1$ whose global ring is R/I, with $f_1 = f' \circ \bar{\pi}$, such that (prime ideals of $\hat{B}$ are pulled back to R along $R \to R/I \to \hat{B}$):*

(Gl1) *if $a < n$, then $\mathrm{ired}(N) \not\subseteq \hat{Z}'$ for every prime $\hat{Z}'$ of $\hat{B}$ whose preimage in R is stable for the system;*

(Gl2) *let $\hat{Q}'$ be a prime of $\hat{B}$ whose preimage in R is $\pi^{-1}(P')$ for a prime P' of C; if $a < n$ and $u^{-1}(P')$ is stable, then $\mathrm{ired}(N) \not\subseteq \hat{Q}'$; if $u^{-1}(P')$ is thick, then $\kappa[\Gamma_1^0]$ modulo the two-sided ideal generated by the image of $\mathcal{I}_1$ is not semisimple for some homomorphism $\hat{B} \to \kappa$ to a field with kernel $\hat{Q}'$.*

Then the conclusion of (Sys4) holds for i and f': if $\hat{Z},\hat{Q}$ are prime ideals of $\hat{A}$ such that $I\hat{A}\subseteq\hat{Z}$, the preimage of $\hat{Z}$ in R is stable for the system, $\dim\hat{A}/\hat{Z}\geq d+s$, and the preimage of $\hat{Q}$ in R is $\pi^{-1}(P')$ for a prime ideal P' of C with $u^{-1}(P')$ stable or thick, then $\hat{Z}\subseteq\hat{Q}$.

Proof. Reduction to $\hat{B}$. As $\pi(I)=0$, every ideal $\pi^{-1}(P)$, P a prime ideal of C, contains I; in particular $I\subseteq\mathfrak{q}$, and $\ker f_1=\bar{\pi}^{-1}(\ker f')=\mathfrak{q}/I$. The ring R of an abstract patching tower is a Noetherian local ring (Definition E.30), so $R_{\mathfrak{q}}$ is a Noetherian local ring and completion at its maximal ideal is exact on finitely generated $R_{\mathfrak{q}}$-modules. Since $(R/I)_{\mathfrak{q}/I}=R_{\mathfrak{q}}/IR_{\mathfrak{q}}$, the completion $\hat{B}$ of $(R/I)_{\ker f_1}$ at its maximal ideal is $\hat{A}/I\hat{A}$, compatibly with the maps from R. Let $\hat{Z},\hat{Q}$ be as in the conclusion. Then $I\hat{A}\subseteq\hat{Z}$ by hypothesis, and $I\hat{A}\subseteq\hat{Q}$ because the preimage $\pi^{-1}(P')$ of $\hat{Q}$ in R contains I. So $\hat{Z}'=\hat{Z}/I\hat{A}$ and $\hat{Q}'=\hat{Q}/I\hat{A}$ are prime ideals of $\hat{B}$ whose preimages in R are those of $\hat{Z}$ and $\hat{Q}$, and $\dim\hat{B}/\hat{Z}'=\dim\hat{A}/\hat{Z}\geq d+s\geq 1+D_0$. It suffices to show $\hat{Z}'\subseteq\hat{Q}'$: then $\hat{Z}$, the preimage of $\hat{Z}'$ in $\hat{A}$, lies in $\hat{Q}$, the preimage of $\hat{Q}'$.

Presentation. By Proposition E.79 (its hypotheses (Pj1) and the span condition on x are hypotheses here) there are $X_1,\dots,X_{D_0}\in\hat{\mathfrak{m}}$ (the maximal ideal of $\hat{B}$), $m_1,\dots,m_g\in N$ generating N and $c_{ij,a}\in\mathcal{O}'$ such that $(\mathcal{O}',\hat{B},\mathcal{A},N)$ and these elements satisfy all hypotheses of Lemma E.80 except those on the primes; in particular $\hat{B}$ is a complete Noetherian local ring, $\iota\colon\mathcal{O}'\to\hat{B}$ is a local homomorphism inducing a surjection of residue fields, and $\hat{\mathfrak{m}}=(X_1,\dots,X_{D_0})\hat{B}+\mathfrak{a}$ with $\mathfrak{a}=\iota(\mathfrak{m}_{\mathcal{O}'})\hat{B}+\hat{\mathfrak{m}}^2+\operatorname{ired}(N)$.

Case $a=n$. Then $N=0$ by (Vr5), so $\operatorname{ired}(N)=0$ and $\hat{\mathfrak{m}}=(X_1,\dots,X_{D_0})\hat{B}+\iota(\mathfrak{m}_{\mathcal{O}'})\hat{B}+\hat{\mathfrak{m}}^2$. This is the generation hypothesis of Lemma E.81 with $D=D_0$ (for $\mathcal{O}'\to\hat{B}$), and $\hat{Z}'$ is a prime with $\dim\hat{B}/\hat{Z}'\geq 1+D_0$; so Lemma E.81 gives $\hat{Z}'=0\subseteq\hat{Q}'$.

Case $a<n$. We apply Lemma E.80 to $(\mathcal{O}',\hat{B},\mathcal{A},N)$, the elements above, $Z=\hat{Z}'$ and $Q=\hat{Q}'$. $\dim\hat{B}/\hat{Z}'\geq 1+D_0$, and $\operatorname{ired}(N)\not\subseteq\hat{Z}'$ by (Gl1), as the preimage of $\hat{Z}'$ in R is stable for the system. For $\hat{Q}'$, whose preimage in R is $\pi^{-1}(P')$: if $u^{-1}(P')$ is stable, $\operatorname{ired}(N)\not\subseteq\hat{Q}'$ by (Gl2); if it is thick, (Gl2) gives a homomorphism $\hat{B}\to\kappa$ with kernel $\hat{Q}'$ for which $\kappa[\Gamma_1^0]$ modulo the ideal generated by $\mathcal{I}_1$ is not semisimple, and (Vr7) of the realisation gives $\operatorname{Ann}_{\hat{B}}(N)\subseteq\hat{Q}'$. So all hypotheses of Lemma E.80 hold and $\hat{Z}'\subseteq\hat{Q}'$. □

E.3.2 Presentations at realised points and deformation steps

This subsection proves Proposition E.79: at a realised point the Selmer conditions (K1)–(K3) at a level give the hypotheses of the cotangent lemma E.80, from which Proposition E.78 concludes. Its inputs come from a deformation analysis of a realisation at first and second order (Lemma E.85): the first-order maps are polarised cocycles with values in the even or odd block matrices (Lemma E.87), they are bounded (Lemma E.88), a tangent vector whose first-order map is a coboundary vanishes (Lemma E.91), and the first-order maps of the derivations of a functional lift to second order (Lemma E.93).

Proposition E.79. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell\neq 2$, x a framed normalised curve point of shape $(a,n-a)$ satisfying (Pj1) and such that for every $Z\in\mathrm{Ev}_a(A)$ there is $r\geq 0$ with T^rZ in the A-span of $\rho(\Gamma')$, $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis of x with local witnesses, $\mathbf{V}$ a level over $\mathscr{H}$ at which (K1) (with an integer $D_0\geq 0$), (K2) and (K3) hold, and $\mathfrak{R}$ a realisation of x over $\mathbf{V}$. Then there are $X_1,\dots,X_{D_0}\in\hat{\mathfrak{m}}$, $m_1,\dots,m_g\in N$ generating N as a $\hat{B}$-module, and $c_{ij,a}\in\mathcal{O}'$ $(1\leq i,j\leq g,\ 1\leq a\leq D_0)$ such that the g^2 vectors $(c_{ij,a}\bmod\mathfrak{m}_{\mathcal{O}'})_a\in(\mathcal{O}'/\mathfrak{m}_{\mathcal{O}'})^{D_0}$ are linearly independent, and, with $\ell_{ij}=\sum_a\iota(c_{ij,a})X_a$,*

$$\hat{\mathfrak{m}}=(X_1,\dots,X_{D_0})\hat{B}+\mathfrak{a},\qquad\sum_{j=1}^{g}\ell_{ij}\,m_j\in\mathfrak{a}N\quad(1\leq i\leq g).$$

In particular $(\mathcal{O}', \hat{B}, \mathcal{A}, N)$ *with these elements satisfy all hypotheses of Lemma E.80 except those on the primes* Z, Q.

Proof. The point x satisfies (Pj1) and the span condition, so Lemma E.85 applies to x, κ, $\mathbf{V}$ and $\mathfrak{R}$. Write $\bar{o} = \lambda(\iota(o))$ for $o \in \mathcal{O}'$. Since $\lambda \circ \iota \colon \mathcal{O}' \to F$ is a surjective ring homomorphism onto a field, its kernel is the maximal ideal $\mathfrak{m}_{\mathcal{O}'}$, so $o \mapsto \bar{o}$ induces an isomorphism $\mathcal{O}'/\mathfrak{m}_{\mathcal{O}'} \cong F$; and $\hat{B} = \iota(\mathcal{O}') + \hat{\mathfrak{m}}$ because $\ker\lambda = \hat{\mathfrak{m}}$. As $yy' \in \hat{\mathfrak{m}} \cdot 1$ for $y, y' \in N$, $\mathrm{ired}(N) \subseteq \hat{\mathfrak{m}}$, hence $\mathfrak{a} \subseteq \hat{\mathfrak{m}}$; and $\hat{\mathfrak{m}}^2 \subseteq \mathfrak{a}$, so $\hat{\mathfrak{m}}/\mathfrak{a}$ is a vector space over $\hat{B}/\hat{\mathfrak{m}} \cong F$ (via λ), finite-dimensional since $\hat{\mathfrak{m}}$ is a finitely generated ideal of the Noetherian ring $\hat{B}$.

Step 1: bounded forms of (K1)–(K3). Let z be a bounded element of one of the Selmer sets over F with local witnesses Y_v. Choosing s so large that $T^s z$ has T-adically continuous entries (coordinates) in A and $T^s Y_v$ has entries in A for the finitely many $v \in S_\ell$, $T^s z$ lies in the corresponding Selmer set over A (all defining conditions of Definition E.35 (Sc) are F-linear in $(z, (Y_v))$, and ρ_A, w_v, w_v^1 have entries in A, resp. $\mathrm{PD}_g(A)$); conversely the Selmer sets over A lie in those over F, and all sets over F are F-vector spaces (each condition is F-linear and boundedness is preserved, as $c = c'T^{-r}$ with $c' \in A$). Finitely many bounded elements admit a common s. Hence: ($\mathrm{K1^b}$) if $z_1, \dots, z_e \in \mathrm{Sel}^{1,\mathrm{b}}_{\mathbf{V}}(F)$ are independent modulo $\mathrm{Bd}^1_{\mathbf{V}}(F)$ then $e \le D_0$: the $T^s z_i \in \mathrm{Sel}^1_{\mathbf{V}}(A)$ satisfy the hypothesis of (K1), since $\sum_i c_i T^s z_i \in \mathrm{Bd}^1_{\mathbf{V}}(A) \subseteq \mathrm{Bd}^1_{\mathbf{V}}(F)$ with $c \in A^e$ forces $c_i T^s = 0$. ($\mathrm{K2^b}$) for every family $(z_{i,j})_{0\le i\le g, 1\le j\le g}$ in $\mathrm{Sel}^{\mathrm{ev},\mathrm{b}}_{\mathbf{V}}(F)$ there is $c \in F^{g+1} \smallsetminus \{0\}$ such that $(\sum_i c_i z_{i,j})_j$ lifts: apply (K2) to $(T^s z_{i,j})$ to get $c \in A^{g+1} \smallsetminus \{0\}$ and $\Psi \in \mathrm{Sel}^2_{\mathbf{V}}(A)$, and take $T^s c$ and Ψ (bounded). ($\mathrm{K3^b}$) for $z \in \mathrm{Sel}^{\mathrm{od},\mathrm{b}}_{\mathbf{V}}(F)$ there is $c \in F^g$ with $z - \sum_j c_j(\kappa_j \circ h) \in \mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(F)$: by (K3) $T^{s'}T^s z - \sum_j c'_j(\kappa_j \circ h) \in \mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(A)$, and we divide by $T^{s+s'}$.

Step 2: cotangent duality. Every $\alpha \in \mathrm{Tp}$ vanishes on $\hat{\mathfrak{m}}^2$ (as $\lambda(\hat{\mathfrak{m}}) = 0$), on $\iota(\mathfrak{m}_{\mathcal{O}'})\hat{B}$ (as $\alpha(\iota(o)b) = \bar{o}\,\alpha(b) + \lambda(b)\alpha(\iota(o)) = \bar{o}\,\alpha(b)$) and on $\mathrm{ired}(N)$, hence on $\mathfrak{a}$, and $\alpha(bx) = \lambda(b)\alpha(x)$ for $x \in \hat{\mathfrak{m}}$. So restriction gives an F-linear map $r \colon \mathrm{Tp} \to \mathrm{Hom}_F(\hat{\mathfrak{m}}/\mathfrak{a}, F)$; it is injective since $\hat{B} = \iota(\mathcal{O}') + \hat{\mathfrak{m}}$ and $\alpha \circ \iota = 0$. It is surjective: for ξ put $\alpha(\iota(o) + x) = \xi(x \bmod \mathfrak{a})$; this is well defined, since $\iota(o)+x = \iota(o')+x'$ gives $\iota(o-o') \in \hat{\mathfrak{m}}$, so $o - o' \in \mathfrak{m}_{\mathcal{O}'}$ and $x' - x = \iota(o-o') \in \mathfrak{a}$; it is additive, kills $\iota(\mathcal{O}')$ and $\mathrm{ired}(N) \subseteq \mathfrak{a}$, and from $(\iota(o)+x)(\iota(o')+x') = \iota(oo') + \iota(o)x' + \iota(o')x + xx'$ with $xx' \in \mathfrak{a}$ it satisfies the derivation rule. Hence Tp is finite-dimensional; by duality of finite-dimensional spaces: (T1) if $b \in \hat{\mathfrak{m}}$ and $\alpha(b) = 0$ for all $\alpha \in \mathrm{Tp}$, then $b \in \mathfrak{a}$; (T2) every F-linear functional on Tp is $\alpha \mapsto \alpha(b)$ for some $b \in \hat{\mathfrak{m}}$.

Step 3: separation by Ph. N is a finitely generated $\hat{B}$-module (a direct summand of the finite $\hat{B}$-module $\mathcal{A}$), so $N/\mathfrak{a}N$ is a finitely generated module over $\hat{B}/\mathfrak{a}$, which is finite-dimensional over F by the filtration $\hat{B} \supseteq \hat{\mathfrak{m}} \supseteq \mathfrak{a}$; through ι, $\mathfrak{m}_{\mathcal{O}'}$ acts by 0, so $N/\mathfrak{a}N$ is a finite-dimensional vector space over $\mathcal{O}'/\mathfrak{m}_{\mathcal{O}'} \cong F$. If $y \in N \smallsetminus \mathfrak{a}N$, a linear functional on it, nonzero on the class of y and transported along $\mathcal{O}'/\mathfrak{m}_{\mathcal{O}'} \cong F$, gives $\Phi \in \mathrm{Ph}$ with $\Phi(y) \neq 0$. So: (T3) $y \in N$ with $\Phi(y) = 0$ for all $\Phi \in \mathrm{Ph}$ lies in $\mathfrak{a}N$.

Step 4: the space of lifting tuples. The map $\alpha \mapsto \mathrm{al}(\alpha)$ is F-linear in α (it is defined entrywise by α, then multiplied by $\rho(h(\gamma))^{-1}$). The set of lifting g-tuples is an F-subspace: $\mathrm{Sel}^{2,\mathrm{b}}_{\mathbf{V}}(F)$ is one (Step 1) and the ϵ'_j-coefficient is F-linear. Hence $U = \{(\alpha_1, \dots, \alpha_g) \in \mathrm{Tp}^g : (\mathrm{al}(\alpha_1), \dots, \mathrm{al}(\alpha_g)) \text{ lifts}\}$ is an F-subspace of Tp^g. (A) Any $g+1$ elements $\alpha^{(0)}, \dots, \alpha^{(g)}$ of Tp^g have a nontrivial combination in U: by Lemma E.85 (Df1) the $\mathrm{al}(\alpha_j^{(i)})$ lie in $\mathrm{Sel}^{\mathrm{ev},\mathrm{b}}_{\mathbf{V}}(F)$, ($\mathrm{K2^b}$) gives $c \neq 0$ with $(\sum_i c_i \mathrm{al}(\alpha_j^{(i)}))_j = (\mathrm{al}(\sum_i c_i \alpha_j^{(i)}))_j$ lifting. Consequently $\dim_F \mathrm{Tp}^g/U \le g$. (B) Let $W = \{\alpha \in \mathrm{Tp} : \ \iota_j(\alpha) \in U \text{ for all } j\}$, $\iota_j(\alpha)$ the tuple with j-th entry α and all others 0, and $e = \dim W$. Applying Lemma E.85 (Df2), whose hypothesis is ($\mathrm{K1^b}$), to a basis of W gives $e + g^2 \le D_0$.

Step 5: linear algebra. Let $U^\perp \subseteq (\mathrm{Tp}^*)^g$ be the annihilator of U (a tuple $(\omega_1, \dots, \omega_g)$

acting by $\sum_j \omega_j(\alpha_j)$); $\dim U^\perp = \dim \mathrm{Tp}^g/U \le g$ by (A). Choose $\omega^{(1)},\dots,\omega^{(g)}$ spanning $U^\perp$ (repetitions or zeros allowed). As $U = (U^\perp)^\perp$, $\iota_j(\alpha) \in U$ iff $\omega_j^{(i)}(\alpha) = 0$ for all i; so W is the common kernel of the g^2 functionals $\omega_j^{(i)}$ and its annihilator $W^\perp \subseteq \mathrm{Tp}^*$ is their span. Choose $\beta_1,\dots,\beta_e \in \mathrm{Tp}^*$ whose restrictions form a basis of W^*; then $\{\omega_j^{(i)}\} \cup \{\beta_b\}$ spans Tp^* (for $\omega \in \mathrm{Tp}^*$ write $\omega|_W = \sum r_b\beta_b|_W$; then $\omega - \sum r_b\beta_b \in W^\perp$). Index $\{1,\dots,D_0\}$ so that its first g^2 elements are the pairs (i,j) and the next e are $1,\dots,e$ (possible by (B)); put $\bar X_{(i,j)} = \omega_j^{(i)}$, $\bar X_{g^2+b} = \beta_b$, $\bar X_a = 0$ for the remaining a, and let $\bar c_{ij} \in F^{D_0}$ be the unit vector at the index (i,j). Then the $\bar X_a$ span Tp^*, the $\bar c_{ij}$ are linearly independent, and for $(\alpha_j) \in U$ and every i: $\sum_j \sum_a \bar c_{ij,a}\bar X_a(\alpha_j) = \sum_j \omega_j^{(i)}(\alpha_j) = 0$.

Step 6: lifting to $\hat B$ and $\mathcal{O}'$. By (T2) choose $X_a \in \hat{\mathfrak{m}}$ with $\alpha(X_a) = \bar X_a(\alpha)$ for all $\alpha \in \mathrm{Tp}$, and choose $c_{ij,a} \in \mathcal{O}'$ with $\overline{c_{ij,a}} = \bar c_{ij,a}$. Under $\mathcal{O}'/\mathfrak{m}_{\mathcal{O}'} \cong F$ the vectors $(c_{ij,a} \bmod \mathfrak{m}_{\mathcal{O}'})_a$ correspond to the $\bar c_{ij}$, so they are independent. For $\alpha \in \mathrm{Tp}$, $o \in \mathcal{O}'$, $x \in \hat{\mathfrak{m}}$ we have $\alpha(\iota(o)x) = \bar o\,\alpha(x)$ (derivation rule, $\lambda(x) = 0$, $\alpha \circ \iota = 0$).

Step 7: $\hat{\mathfrak{m}} = (X_1,\dots,X_{D_0})\hat B + \mathfrak{a}$. The inclusion $\supseteq$ is clear. Let $b \in \hat{\mathfrak{m}}$. The functional $\alpha \mapsto \alpha(b)$ is $\sum_a r_a\bar X_a$ for some $r_a \in F$ (the $\bar X_a$ span); choose $o_a \in \mathcal{O}'$ with $\bar o_a = r_a$. Then $b' = b - \sum_a \iota(o_a)X_a \in \hat{\mathfrak{m}}$ and $\alpha(b') = \alpha(b) - \sum_a r_a\bar X_a(\alpha) = 0$ for all α by Step 6, so $b' \in \mathfrak{a}$ by (T1).

Step 8: generators of N and the relations. By Lemma E.83, whose hypotheses (Dg1), (Dg2), (Dg3) are Lemma E.85 (Df1), (K3^{b}) and Lemma E.84, there is a family $(m_1,\dots,m_g)$ in N dual to κ that generates N. Fix i and put $y_i = \sum_j \ell_{ij}m_j$; by (T3) it suffices that $\Phi(y_i) = 0$ for every $\Phi \in \mathrm{Ph}$. By Lemma E.85 (Df3) there are $\alpha_1,\dots,\alpha_g \in \mathrm{Tp}$ with $\alpha_j(b) = \Phi(bm_j) - \lambda(b)\Phi(m_j)$ and $(\alpha_j)_j \in U$. Since $\ell_{ij} \in \hat{\mathfrak{m}}$, $\Phi(\ell_{ij}m_j) = \alpha_j(\ell_{ij}) = \sum_a \bar c_{ij,a}\,\alpha_j(X_a) = \sum_a \bar c_{ij,a}\bar X_a(\alpha_j)$ by Step 6, and so $\Phi(y_i) = \sum_j \sum_a \bar c_{ij,a}\bar X_a(\alpha_j) = 0$ by Step 5.

Finally, $\hat B$ is a complete Noetherian local ring and ι is a local homomorphism inducing a surjection of residue fields ((Vr4); $\iota(\mathfrak{m}_{\mathcal{O}'}) \subseteq \hat{\mathfrak{m}}$ because $\lambda \circ \iota$ kills $\mathfrak{m}_{\mathcal{O}'}$), $\mathcal{A} = \hat B \cdot 1 \oplus N$ with $yy' \in \hat{\mathfrak{m}} \cdot 1$ (Vr5), and $\mathfrak{a}$ is the ideal of Lemma E.80 for $(\mathcal{O}', \hat B, N)$; so all hypotheses of that lemma other than those on Z, Q hold. □

Lemma E.80. *Let $\mathcal{O}$ be a complete discrete valuation ring with maximal ideal $\mathfrak{m}_{\mathcal{O}}$ and residue field k, and B a complete Noetherian local ring with maximal ideal $\mathfrak{m}_B$ together with a local ring homomorphism $\mathcal{O} \to B$ inducing a surjection $k \to B/\mathfrak{m}_B$. Let A be a ring containing B as a subring and finitely generated as a B-module, and $N \subseteq A$ a B-submodule with $A = B \oplus N$ as B-modules and $xy \in \mathfrak{m}_B$ for all $x, y \in N$. Let* $\mathrm{ired}(N) \subseteq B$ *be the ideal generated by the products xy with $x, y \in N$, and put*

$$\mathfrak{a} = \mathfrak{m}_{\mathcal{O}}B + \mathfrak{m}_B^2 + \mathrm{ired}(N).$$

Let $D_0, g \ge 0$, $X_1,\dots,X_{D_0} \in \mathfrak{m}_B$, $m_1,\dots,m_g \in N$ generating N as a B-module, and $c_{ij,a} \in \mathcal{O}$ ($1 \le i,j \le g$, $1 \le a \le D_0$) such that the g^2 vectors $(c_{ij,a} \bmod \mathfrak{m}_{\mathcal{O}})_{1\le a\le D_0} \in k^{D_0}$ are linearly independent over k. Put $\ell_{ij} = \sum_a c_{ij,a}X_a$ and assume

$$\mathfrak{m}_B = (X_1,\dots,X_{D_0})B + \mathfrak{a}, \qquad \sum_{j=1}^{g} \ell_{ij}\, m_j \in \mathfrak{a}N \quad (1 \le i \le g). \tag{E.12}$$

Let Z, Q be prime ideals of B with $\dim B/Z \ge 1 + D_0$ *and* $\mathrm{ired}(N) \not\subseteq Z$, *and such that* $\mathrm{ired}(N) \not\subseteq Q$ *or* $\mathrm{Ann}_B(N) \subseteq Q$. *Then $Z \subseteq Q$.*

Proof. Since $g = 0$ forces $N = 0$ and $\mathrm{ired}(N) = 0 \subseteq Z$, we have $g \ge 1$.

Step 1: A is a complete Noetherian local ring with maximal ideal $\mathfrak{m}_A = \mathfrak{m}_B + N$ and residue field $B/\mathfrak{m}_B$, and $\operatorname{ired}(N)A \subseteq \mathfrak{m}_A^2$. Write $a \in A$ as $a = b + n$ ($b \in B$, $n \in N$). The set $\mathfrak{m}_B + N$ is an ideal of A: it is additive, and $(b' + n')(b + n) = (b'b + n'n) + (b'n + bn')$ with $n'n \in \mathfrak{m}_B$ whenever $b \in \mathfrak{m}_B$. It does not contain 1: $1 = b + n$ with $b \in \mathfrak{m}_B$ gives $n = 1 - b \in B \cap N = 0$ and $b = 1$. If $b \notin \mathfrak{m}_B$, then $(b + n)(b - n) = b^2 - n^2$ with $n^2 \in \mathfrak{m}_B$ is a unit of B, so $b + n$ is a unit. Hence A is local with $\mathfrak{m}_A = \mathfrak{m}_B + N$, and $A/\mathfrak{m}_A = B/\mathfrak{m}_B$. A is Noetherian, being finite over B. As $N \cdot N \subseteq \mathfrak{m}_B$, $\mathfrak{m}_A^2 \subseteq \mathfrak{m}_B A \subseteq \mathfrak{m}_A$, so the $\mathfrak{m}_A$-adic and $\mathfrak{m}_B A$-adic topologies agree and A is complete ([166, Theorem 8.7]). Finally each generator xy of $\operatorname{ired}(N)$ is a product of two elements of $N \subseteq \mathfrak{m}_A$.

Step 2: a surjection from a power series ring. Let $P = \mathcal{O}[[x_1, \dots, x_{D_0}, y_1, \dots, y_g]]$, a regular local ring of dimension $1 + D_0 + g$ whose cotangent space $\mathfrak{m}_P/\mathfrak{m}_P^2$ has the k-basis $\bar{\varpi}, \bar{x}_a, \bar{y}_j$. By (E.12) and Step 1, $\mathfrak{m}_B \subseteq (X_1, \dots, X_{D_0})A + \mathfrak{m}_{\mathcal{O}} A + \mathfrak{m}_A^2$ and $N \subseteq (m_1, \dots, m_g)A$, so

$$\mathfrak{m}_A = (X_1, \dots, X_{D_0}, m_1, \dots, m_g)A + \mathfrak{m}_{\mathcal{O}} A + \mathfrak{m}_A^2.$$

By Lemma E.81 (its first assertion, for A and these $D_0 + g$ elements), the $\mathcal{O}$-algebra homomorphism $\Phi\colon P \to A$ with $\Phi(x_a) = X_a$, $\Phi(y_j) = m_j$ exists and is surjective. Hence $\Phi(\mathfrak{m}_P) = \mathfrak{m}_A$ and $\Phi(\varpi P + \mathfrak{m}_P^2) = \varpi A + \mathfrak{m}_A^2$.

Step 3: lifting the relations. The module $\mathfrak{a}N$ consists of the sums $\sum_j w_j m_j$ with $w_j \in \mathfrak{a}$ (write each element of N in terms of the m_j). So by (E.12) there are $w_{ij} \in \mathfrak{a}$ with $\sum_j \ell_{ij} m_j = \sum_j w_{ij} m_j$; put $\zeta_{ij} = \ell_{ij} - w_{ij} \in B$ and $\zeta = (\zeta_{ij})$, so that

$$\sum_{j=1}^{g} \zeta_{ij}\, m_j = 0 \quad (1 \le i \le g). \tag{E.13}$$

By Step 1, $\mathfrak{a}A \subseteq \varpi A + \mathfrak{m}_A^2$, so there are $v_{ij} \in \varpi P + \mathfrak{m}_P^2$ with $\Phi(v_{ij}) = w_{ij}$. Put $z_{ij} = \sum_a c_{ij,a} x_a - v_{ij} \in \mathfrak{m}_P$ and $z = (z_{ij})$. Then $\Phi(z_{ij}) = \zeta_{ij}$, $\Phi(\det z) = \det \zeta$, and by (E.13) the ideal $I \subseteq P$ generated by the entries of zy, $y = (y_1, \dots, y_g)^T$, lies in $\ker \Phi$.

Step 4: the z_{ij} and y_j are independent in the cotangent space of P. Writing $v_{ij} = \varpi u_{ij} + s_{ij}$ with $s_{ij} \in \mathfrak{m}_P^2$, the image of z_{ij} in $\mathfrak{m}_P/\mathfrak{m}_P^2$ is $\sum_a \bar{c}_{ij,a} \bar{x}_a - \bar{u}_{ij} \bar{\varpi}$, where bars denote residues in k. In a vanishing combination $\sum \alpha_{ij} \bar{z}_{ij} + \sum \beta_j \bar{y}_j = 0$, the coefficient of $\bar{x}_a$ gives $\sum_{i,j} \alpha_{ij} \bar{c}_{ij,a} = 0$ for every a, so all $\alpha_{ij} = 0$ by the linear independence of the g^2 vectors, and then all $\beta_j = 0$.

Step 5: $\det \zeta \in Q$. By Cramer's rule and (E.13), $\det(\zeta) m_k = \sum_i \operatorname{adj}(\zeta)_{ki} \sum_j \zeta_{ij} m_j = 0$ for every k, so $\det \zeta \in \operatorname{Ann}_B(N)$. If $\operatorname{Ann}_B(N) \subseteq Q$ we are done. Otherwise $\operatorname{ired}(N) \not\subseteq Q$, so $xy \notin Q$ for some $x, y \in N$; then $\det(\zeta)\, xy = (\det(\zeta)x)y = 0$ in B, whence $\det \zeta \in Q$.

Step 6: primes of A. The extension $B \subseteq A$ is integral. Choose primes Z', Q' of A with $Z' \cap B = Z$ and $Q' \cap B = Q$ (lying over, [166, Theorem 9.3]). Then $\dim A/Z' = \dim B/Z \ge 1 + D_0$. Some m_j is not in Z': otherwise $N \subseteq Z'$, so $xy \in Z' \cap B = Z$ for all $x, y \in N$ and $\operatorname{ired}(N) \subseteq Z$. And $\det \zeta \in Q \subseteq Q'$ by Step 5.

Step 7: conclusion. Let $\hat{Z} = \Phi^{-1}(Z')$ and $\hat{Q} = \Phi^{-1}(Q')$, primes of P. Since Φ is surjective, $P/\hat{Z} \cong A/Z'$, so $\dim P/\hat{Z} \ge 1 + D_0 = \dim P - g$; $I \subseteq \ker \Phi \subseteq \hat{Z}$; and $y_j \notin \hat{Z}$ for the j of Step 6, as $\Phi(y_j) = m_j \notin Z'$. Also $I \subseteq \hat{Q}$ and $\det z \in \hat{Q}$, since $\Phi(\det z) = \det \zeta \in Q'$. By Step 4, Lemma E.82 applies to the regular local ring P, the matrix z and the vector y; its part (3) gives $\hat{Z} \subseteq \hat{Q}$. Applying the surjection Φ, $Z' = \Phi(\hat{Z}) \subseteq \Phi(\hat{Q}) = Q'$, and $Z = Z' \cap B \subseteq Q' \cap B = Q$. □

Lemma E.81. *Let $\mathcal{O}$ be a complete discrete valuation ring with maximal ideal $\mathfrak{m}_{\mathcal{O}}$, and B a complete Noetherian local ring with maximal ideal $\mathfrak{m}_B$ together with a local ring homomorphism $\mathcal{O} \to B$ inducing a surjection $\mathcal{O}/\mathfrak{m}_{\mathcal{O}} \to B/\mathfrak{m}_B$. Let $D \ge 0$ and $X_1, \dots, X_D \in \mathfrak{m}_B$ with*

$$\mathfrak{m}_B = (X_1, \dots, X_D)B + \mathfrak{m}_{\mathcal{O}} B + \mathfrak{m}_B^2. \tag{E.14}$$

Then the $\mathcal{O}$-algebra homomorphism $F\colon \mathcal{O}[[x_1,\dots,x_D]] \to B$ with $F(x_a) = X_a$ exists and is surjective. If moreover Z is a prime ideal of B with $\dim B/Z \geq 1+D$, then F is an isomorphism, B is a domain and $Z = 0$; in particular $Z \subseteq Q$ for every prime ideal Q of B.

Proof. Put $P = \mathcal{O}[[x_1,\dots,x_D]]$, a Noetherian local domain with maximal ideal $\mathfrak{m}_P = \mathfrak{m}_{\mathcal{O}}P + (x_1,\dots,x_D)$ and $\dim P = 1 + D$: with ϖ a uniformiser of $\mathcal{O}$, $\mathfrak{m}_P = (\varpi, x_1,\dots,x_D)$ gives $\dim P \leq 1+D$ by Krull's height theorem, and $(0) \subsetneq (x_1) \subsetneq (x_1,x_2) \subsetneq \cdots \subsetneq (x_1,\dots,x_D) \subsetneq \mathfrak{m}_P$ is a chain of primes of length $1+D$ (the quotients $\mathcal{O}[[x_{i+1},\dots,x_D]]$ are domains).

Existence of F. For a power series $\sum_\alpha c_\alpha x^\alpha$ ($c_\alpha \in \mathcal{O}$) the terms $c_\alpha X^\alpha$ lie in $\mathfrak{m}_B^{|\alpha|}$, so the series $\sum_\alpha c_\alpha X^\alpha$ converges in the $\mathfrak{m}_B$-adically complete ring B; this defines an $\mathcal{O}$-algebra homomorphism F with $F(x_a) = X_a$, multiplicativity holding on the truncations modulo $\mathfrak{m}_B^k$ for every k.

Surjectivity. Put $I = (X_1,\dots,X_D)B + \mathfrak{m}_{\mathcal{O}}B = F(\mathfrak{m}_P)B$. By (E.14), $\mathfrak{m}_B = I + \mathfrak{m}_B^2$, so the finitely generated B-module $\mathfrak{m}_B/I$ satisfies $\mathfrak{m}_B(\mathfrak{m}_B/I) = \mathfrak{m}_B/I$ and vanishes by Nakayama's lemma: $\mathfrak{m}_P B = I = \mathfrak{m}_B$. Regard B as a P-module through F. Then $\mathfrak{m}_P^k B = \mathfrak{m}_B^k$ for all k, so B is separated for the $\mathfrak{m}_P$-adic topology (Krull's intersection theorem), and $B/\mathfrak{m}_P B = B/\mathfrak{m}_B$ is generated over $P/\mathfrak{m}_P = \mathcal{O}/\mathfrak{m}_{\mathcal{O}}$ by the image of 1, as $\mathcal{O}/\mathfrak{m}_{\mathcal{O}} \to B/\mathfrak{m}_B$ is surjective. As P is $\mathfrak{m}_P$-adically complete, [166, Theorem 8.4] shows that 1 generates B as a P-module, i.e. F is surjective.

Dimension. Let $K = \ker F$, so $B \cong P/K$. If $K \neq 0$, every chain $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_r$ of primes of B is the image of a chain of primes of P containing K, and $(0) \subsetneq F^{-1}(\mathfrak{p}_0)$ since P is a domain; so $\dim B \leq \dim P - 1 = D$. Likewise, if B is a domain and $Z \neq 0$, a chain of primes of B/Z extends at the bottom by $(0) \subsetneq Z$, so $\dim B/Z \leq \dim B - 1$. Now let Z be a prime of B with $\dim B/Z \geq 1+D$. Since $\dim B/Z \leq \dim B$, the first observation gives $K = 0$: F is an isomorphism and B is a domain of dimension $1+D$. The second gives $Z = 0$, and then $Z \subseteq Q$ for every prime Q. □

Lemma E.82. *Let P be a regular local ring with maximal ideal $\mathfrak{m}_P$, let $g \geq 1$, and let $z = (z_{ij})_{1\leq i,j\leq g}$ be a $g \times g$ matrix and $m = (m_1,\dots,m_g)^T$ a column vector with entries in $\mathfrak{m}_P$ such that the g^2+g elements z_{ij}, m_j have linearly independent images in $\mathfrak{m}_P/\mathfrak{m}_P^2$. Let $I \subseteq P$ be the ideal generated by the g entries $\sum_j z_{ij}m_j$ of zm, and put $J = I + (\det z)P$. Then:*

1. *there is a prime ideal K of P with $J \subseteq K$ such that $K \subseteq Q$ for every prime ideal Q of P containing J;*
2. *$\dim P/I \leq \dim P - g$; in particular $\dim P/K \leq \dim P - g$;*
3. *if Z is a prime ideal of P with $I \subseteq Z$, $m_j \notin Z$ for some j, and $\dim P/Z \geq \dim P - g$, then $Z = K$; in particular $Z \subseteq Q$ for every prime ideal Q of P containing J.*

Proof. Theorem numbers in this proof refer to [166].

Step 0: a prime containing I and missing some m_j contains $\det z$. By Cramer's rule $\operatorname{adj}(z)(zm) = \det(z)\,m$, so $\det(z)m_j \in I$ for every j; if $Z \supseteq I$ is prime and $m_j \notin Z$, then $\det z \in Z$.

Step 1: the chart ideals and the primes K_c. Fix $c \in \{1,\dots,g\}$. Let $\Lambda_c = P[\lambda_j : j \neq c]$ be the polynomial ring in $g-1$ variables over P, put $\lambda_c = 1$ and $\lambda = (\lambda_1,\dots,\lambda_g)^T$, and let $C_c \subseteq \Lambda_c$ be the ideal generated by

$$r_i = \sum_{j=1}^{g} z_{ij}\lambda_j \quad (1 \leq i \leq g), \qquad s_j = m_j - \lambda_j m_c \quad (j \neq c). \tag{E.15}$$

The ideal $M_c = \mathfrak{m}_P \Lambda_c$ is prime, as $\Lambda_c/M_c \cong k[\lambda_j : j \neq c]$, and $C_c \subseteq M_c$ since all z_{ij}, m_j lie in $\mathfrak{m}_P$. Put

$$K_c = \{f \in P : \ sf \in C_c \text{ for some } s \in \Lambda_c \setminus M_c\},$$

the preimage of $C_c(\Lambda_c)_{M_c}$ under $P \to (\Lambda_c)_{M_c}$.

Claim A: for every prime $\mathfrak{Q}$ of Λ_c with $M_c \subseteq \mathfrak{Q}$, the ideal $C_c(\Lambda_c)_{\mathfrak{Q}}$ is prime. Put $L = (\Lambda_c)_{\mathfrak{Q}}$, a Noetherian local ring with residue field κ. The homomorphism $P \to L$ is flat (Λ_c is free over P) and local, and its closed fibre $L/\mathfrak{m}_P L$ is the localisation of $k[\lambda_j : j \neq c]$ at the prime $\mathfrak{Q}/M_c$, a regular local ring (Theorem 19.5) of some dimension e. Let $x_1, \dots, x_d$ generate $\mathfrak{m}_P$ and let $h_1, \dots, h_e \in \mathfrak{Q}L$ lift a regular system of parameters of the fibre. Then $\mathfrak{Q}L = \mathfrak{m}_P L + (h_1, \dots, h_e)$ is generated by $d+e$ elements, while $\dim L = d + e$ by Theorem 15.1. Hence L is regular and the images of $x_1, \dots, x_d, h_1, \dots, h_e$ form a κ-basis of $\mathfrak{Q}L/\mathfrak{Q}^2 L$; in particular the κ-linear map $\iota\colon (\mathfrak{m}_P/\mathfrak{m}_P^2) \otimes_k \kappa \to \mathfrak{Q}L/\mathfrak{Q}^2 L$ induced by inclusion is injective. For $a \in \Lambda_c$ and $x \in \mathfrak{m}_P$ the image of ax is $\bar{a}\,\iota(\bar{x})$, with $\bar{a}$ the image of a in κ; so the images of the generators (E.15) are

$$\iota(\bar{z}_{ic}) + \sum_{j \neq c} \bar{\lambda}_j \, \iota(\bar{z}_{ij}) \quad (1 \leq i \leq g), \qquad \iota(\bar{m}_j) - \bar{\lambda}_j \, \iota(\bar{m}_c) \quad (j \neq c).$$

The vectors $\iota(\bar{z}_{ij})$, $\iota(\bar{m}_j)$ are κ-linearly independent, and in a vanishing linear combination of these $2g-1$ images the coefficient of the image of r_i is the coefficient of $\iota(\bar{z}_{ic})$, and that of the image of s_j is the coefficient of $\iota(\bar{m}_j)$; so the $2g-1$ images are linearly independent. By Theorems 14.2 and 14.3, $L/C_c L$ is a regular local ring, hence a domain, and Claim A follows.

Taking $\mathfrak{Q} = M_c$ in Claim A, K_c is the preimage of a prime ideal, hence prime. Moreover $J \subseteq K_c$, indeed $J \subseteq C_c \cap P$: since the c-th entry of $m - m_c\lambda$ is 0,

$$\sum_j z_{ij} m_j = m_c \, r_i + \sum_{j \neq c} z_{ij} s_j \in C_c, \qquad \det z = \det(z)\lambda_c = \sum_k \operatorname{adj}(z)_{ck} \, r_k \in C_c,$$

the second by Cramer's rule $\operatorname{adj}(z)\, z\lambda = \det(z)\lambda$.

Step 2: a transfer criterion. Let Q be a prime ideal of P, V a local ring with maximal ideal $\mathfrak{m}_V$, and $\pi\colon P \to V$ a ring homomorphism with $\ker \pi = Q$ and $\pi(\mathfrak{m}_P) \subseteq \mathfrak{m}_V$. Suppose that for some c there is $l \in V^g$ with $l_c = 1$, $\pi(z)\, l = 0$ and $\pi(m_j) = l_j \, \pi(m_c)$ for all j. Then $K_c \subseteq Q$. Indeed, let $\psi\colon \Lambda_c \to V$ be the extension of π with $\psi(\lambda_j) = l_j$ $(j \neq c)$. Then $\psi(r_i) = (\pi(z)l)_i = 0$ and $\psi(s_j) = \pi(m_j) - l_j \pi(m_c) = 0$, so $C_c \subseteq \ker \psi$; and $\mathfrak{Q} = \psi^{-1}(\mathfrak{m}_V)$ is a prime containing M_c. Let $f \in K_c$, with $s \in \Lambda_c \setminus M_c$ and $sf \in C_c$. By Claim A, $C_c(\Lambda_c)_{\mathfrak{Q}}$ is prime and contains sf. If it contained s, then $ts \in C_c \subseteq M_c$ for some $t \in \Lambda_c \setminus \mathfrak{Q}$, and $t \notin M_c$, $s \notin M_c$ contradict the primality of M_c. So $tf \in C_c$ for some $t \in \Lambda_c \setminus \mathfrak{Q}$; then $\psi(t)\pi(f) = \psi(tf) = 0$ with $\psi(t) \notin \mathfrak{m}_V$ a unit, so $\pi(f) = 0$ and $f \in Q$.

Step 3: the primes K_c do not depend on c. Let $c, c' \in \{1, \dots, g\}$. By Claim A, $D = (\Lambda_{c'})_{M_{c'}}/C_{c'}(\Lambda_{c'})_{M_{c'}}$ is a local domain, and the natural map $\pi\colon P \to D$ has kernel $K_{c'}$ and maps $\mathfrak{m}_P$ into the maximal ideal. The residue field of D is $k(\lambda_j : j \neq c')$, in which the images of the λ_j are non-zero; so every λ_j is a unit of D. Put $l = \lambda_c^{-1}\lambda \in D^g$. Then $l_c = 1$; $\pi(z)\, l = \lambda_c^{-1}(r_1, \dots, r_g)^T = 0$ in D; and since $s_j \in C_{c'}$, $\pi(m_j) = \lambda_j \pi(m_{c'})$ for all j, so $\pi(m_j) = l_j \lambda_c \pi(m_{c'}) = l_j \pi(m_c)$. Step 2 gives $K_c \subseteq K_{c'}$. By symmetry $K_c = K_{c'}$; put $K = K_1$.

Step 4: proof of (1). K is prime and contains J by Step 1. Let $Q \supseteq J$ be prime, F the fraction field of P/Q, and V a valuation ring of F with $P/Q \subseteq V$ and $\mathfrak{m}_V \cap P/Q = \mathfrak{m}_P/Q$ (Theorem 10.2); let $\pi\colon P \to P/Q \subseteq V$ and v the valuation of V. Then $\ker \pi = Q$, $\pi(\mathfrak{m}_P) \subseteq \mathfrak{m}_V$, and $\bar{z} = \pi(z)$, $\bar{m} = \pi(m)$ satisfy $\bar{z}\bar{m} = 0$ and $\det \bar{z} = 0$, as $J \subseteq Q$. If $\bar{m} \neq 0$, choose c with $\bar{m}_c \neq 0$ and $v(\bar{m}_c) \leq v(\bar{m}_j)$ for all j with $\bar{m}_j \neq 0$; then $l = \bar{m}_c^{-1}\bar{m} \in V^g$ has $l_c = 1$, $\bar{z}l = 0$ and $\bar{m}_j = l_j \bar{m}_c$. If $\bar{m} = 0$, choose $u \in F^g \setminus \{0\}$ with $\bar{z}u = 0$ (possible as $\det \bar{z} = 0$), and c with

$u_c \neq 0$ of least valuation among the non-zero entries; then $l = u_c^{-1}u \in V^g$ has $l_c = 1$, $\bar{z}l = 0$ and $\bar{m}_j = 0 = l_j\bar{m}_c$. In both cases Step 2 and Step 3 give $K = K_c \subseteq Q$.

Step 5: proof of (2). As the images of the z_{ij} and m_j are linearly independent in the d-dimensional k-space $\mathfrak{m}_P/\mathfrak{m}_P^2$, there are $t_1, \dots, t_e \in \mathfrak{m}_P$, $e = d - g^2 - g$, such that the images of the z_{ij}, m_j, t_a form a basis; by Nakayama's lemma these d elements generate $\mathfrak{m}_P$. Let σ be the family of the $d - g$ elements $t_1, \dots, t_e$, z_{ij} $(i \neq j)$ and $z_{ii} - m_i$ $(1 \leq i \leq g)$. Together with $m_1, \dots, m_g$ they generate the same ideal $\mathfrak{m}_P$, so they form a regular system of parameters, and by Theorem 14.2 $P' = P/(\sigma)$ is a regular local ring of dimension g whose maximal ideal is generated by the images $m_1', \dots, m_g'$ of the m_j. In P' the matrix z becomes the diagonal matrix with entries $m_1', \dots, m_g'$, so $IP' = (m_1'^2, \dots, m_g'^2)$; this ideal contains every monomial of degree $2g - 1$ in the m_j', hence a power of the maximal ideal of P', and $\dim P/(I + (\sigma)) = \dim P'/IP' = 0$. Theorem 13.6, applied to the local ring P/I and the images of the $d - g$ elements of σ, gives $\dim P/I \leq d - g$. As $I \subseteq K$, $\dim P/K \leq \dim P/I \leq d - g$.

Step 6: proof of (3). By Step 0, $\det z \in Z$, so $J \subseteq Z$ and $K \subseteq Z$ by (1). If $K \neq Z$, a chain of primes of length $\dim P/Z$ in P/Z lifts to a chain of primes of P starting at Z, and prefixing $K \subsetneq Z$ gives $\dim P/K \geq \dim P/Z + 1 \geq d - g + 1$, contradicting (2) (all dimensions are finite as P is Noetherian local). Hence $Z = K$, and $Z \subseteq Q$ for every prime $Q \supseteq J$ by (1). □

Lemma E.83. *Let $\mathfrak{R}$ be a realisation of a framed normalised curve point x over a level $\mathbf{V}$, and $\kappa = (\kappa_1, \dots, \kappa_g)$ a Selmer basis of x with local witnesses. Assume:*

(Dg1) *for every $\mu \in \mathrm{La}$, $\mathrm{la}(\mu) \in \mathrm{Sel}_{\mathbf{V}}^{\mathrm{od,b}}(F)$;*

(Dg2) *for every $z \in \mathrm{Sel}_{\mathbf{V}}^{\mathrm{od,b}}(F)$ there is $c \in F^g$ with $z - \sum_j c_j(\kappa_j \circ h) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$;*

(Dg3) *if $\mu \in \mathrm{La}$ and $\mathrm{la}(\mu) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$, then $\mu = 0$.*

Then there is a family $(m_1, \dots, m_g)$ in N that is dual to κ and generates N as a $\hat{B}$-module.

Proof. Step 1: La *is the dual of $N/\hat{\mathfrak{m}}N$.* N is a finitely generated $\hat{B}$-module (a direct summand of $\mathcal{A}$, (Vr5)), so $\bar{N} = N/\hat{\mathfrak{m}}N$ is a finite-dimensional vector space over $\hat{B}/\hat{\mathfrak{m}}$, which λ identifies with F. An additive $\mu\colon N \to F$ with $\mu(by) = \lambda(b)\mu(y)$ kills $\hat{\mathfrak{m}}N$ and induces an F-linear functional on $\bar{N}$, and conversely; so $\mathrm{La} \cong \mathrm{Hom}_F(\bar{N}, F)$. Hence La is finite-dimensional, and every F-linear functional on La is $\mu \mapsto \mu(y)$ for some $y \in N$.

Step 2: the coefficient map. The maps $\kappa_j \circ h$ are linearly independent over F modulo $\mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$: if $\sum_j c_j(\kappa_j \circ h)(\gamma) = \rho(h\gamma)Y\rho(h\gamma)^{-1} - Y$ with $Y \in \mathrm{Od}_a(F)$, ${}^tY = -Y$, choose s with $T^s c_j \in A$ and $T^sY \in \mathrm{Od}_a(A)$; as h is onto, $\sum_j T^s c_j \kappa_j \in \mathrm{Bd}(x)$, so $T^s c = 0$ by the definition of a Selmer basis, and $c = 0$. Hence by (Dg1) and (Dg2), for each $\mu \in \mathrm{La}$ there is exactly one $c(\mu) \in F^g$ with $\mathrm{la}(\mu) - \sum_j c_j(\mu)(\kappa_j \circ h) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$. As $\mu \mapsto \mathrm{la}(\mu)$ is F-linear and $\mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$ is an F-subspace, uniqueness makes $c\colon \mathrm{La} \to F^g$ linear; it is injective, since $c(\mu) = 0$ means $\mathrm{la}(\mu) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$, so $\mu = 0$ by (Dg3).

Step 3: the generators. By Step 1, for each j there is $m_j \in N$ with $\mu(m_j) = c_j(\mu)$ for all $\mu \in \mathrm{La}$; then $\mathrm{la}(\mu) - \sum_j \mu(m_j)(\kappa_j \circ h) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$, i.e. (m_j) is dual to κ. If the images of the m_j did not span $\bar{N}$, some nonzero $\mu \in \mathrm{La} \cong \bar{N}^*$ would vanish on all m_j, so $c(\mu) = 0$ and $\mu = 0$ by Step 2, a contradiction. So the m_j span $N/\hat{\mathfrak{m}}N$, and by Nakayama's lemma (N finitely generated over the local ring $\hat{B}$) they generate N. □

Lemma E.84. *Let $\mathfrak{R}$ be a realisation of a framed normalised curve point x over a level $\mathbf{V}$. If $\mu \in \mathrm{La}$ and $\mathrm{la}(\mu) \in \mathrm{Bd}_{\mathbf{V}}^{\mathrm{od}}(F)$, then $\mu = 0$.*

Proof. Let $F[\varepsilon]=F[X]/(X^2)$ and define $\theta\colon \mathcal{A}=\hat{B}\cdot 1\oplus N\to F[\varepsilon]$ by $\theta(b\cdot 1+y)=\lambda(b)+\varepsilon\mu(y)$. It is additive, and multiplicative: for $y,y'\in N$ write $yy'=c\cdot 1$ with $c\in \mathrm{ired}(N)\subseteq\hat{\mathfrak{m}}$; then $(b+y)(b'+y')=(bb'+c)\cdot 1+(by'+b'y)$, and θ of this is $\lambda(b)\lambda(b')+\varepsilon(\lambda(b)\mu(y')+\lambda(b')\mu(y))=\theta(b+y)\theta(b'+y')$, using $\lambda(c)=0$ and $\mu\in\mathrm{La}$. Apply θ entrywise to matrices. Write $\rho_1=\rho\circ h$; by (Vr6), $\lambda(\mathrm{pr}_0(\nu(\gamma)_{ij}))=\rho_1(\gamma)_{ij}$, so

$$\theta(\nu(\gamma))=\rho_1(\gamma)+\varepsilon\,\mathrm{la}(\mu)(\gamma)\rho_1(\gamma)\qquad(\gamma\in\Gamma_1^0).$$

Suppose $\mathrm{la}(\mu)(\gamma)=\rho_1(\gamma)Y\rho_1(\gamma)^{-1}-Y$ for all γ, with $Y\in\mathrm{Od}_a(F)$. Then $\theta(\nu(\gamma))=\rho_1(\gamma)+\varepsilon(\rho_1(\gamma)Y-Y\rho_1(\gamma))=U\rho_1(\gamma)U^{-1}$ with $U=1-\varepsilon Y$, $U^{-1}=1+\varepsilon Y$. Let $y\in N$ and (i,j) a position in different blocks. By (Vr6) the matrix yE_{ij} (entry y at (i,j), zero elsewhere) is $\sum_k b_k\nu(\gamma_k)$ for some $b_k\in\hat{B}$, $\gamma_k\in\Gamma_1^0$. Applying θ: $\varepsilon\mu(y)E_{ij}=\sum_k\lambda(b_k)U\rho_1(\gamma_k)U^{-1}=UMU^{-1}$ with $M=\sum_k\lambda(b_k)\rho_1(\gamma_k)\in\mathrm{M}_n(F)$. Comparing the components free of ε (that of $UMU^{-1}=M+\varepsilon(\dots)$ is M, that of the left side is 0) gives $M=0$, so $\varepsilon\mu(y)E_{ij}=0$ and $\mu(y)=0$. As y was arbitrary, $\mu=0$. (If $a=n$, then $N=0$ and there is nothing to prove.) □

Lemma E.85. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell\neq 2$, $x=(k,\rho,1_n,(\psi_{v,b}),f)$ a framed normalised curve point of shape $(a,n-a)$ with frame $((w_v),(I_u^x))$, satisfying (Pj1) and such that for every $Z\in\mathrm{Ev}_a(A)$ there is $r\geq 0$ with T^rZ in the A-span of $\rho(\Gamma')$, $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis of x with local witnesses, $\mathbf{V}$ a level over $\mathscr{H}$ and $\mathfrak{R}$ a realisation of x over $\mathbf{V}$. Then:*

(Df1) *for every $\alpha\in\mathrm{Tp}$ the map $\mathrm{al}(\alpha)$ satisfies, at every $v\in S_\ell$, the local condition of Definition E.35 (Sc) for $(\rho_F,w,\mathrm{Ev}_a(F))$ (with a witness $Y_v\in\mathrm{Ev}_a(F)$); for every $\mu\in\mathrm{La}$ the map $\mathrm{la}(\mu)$ satisfies the local conditions for $(\rho_F,w,\mathrm{Od}_a(F))$. Together with Lemma E.87 and Lemma E.88, this gives $\mathrm{al}(\alpha)\in\mathrm{Sel}_{\mathbf{V}}^{\mathrm{ev,b}}(F)$ and $\mathrm{la}(\mu)\in\mathrm{Sel}_{\mathbf{V}}^{\mathrm{od,b}}(F)$.*

(Df2) *Let $D_0\geq 0$ be such that $e\leq D_0$ whenever $z_1,\dots,z_e\in\mathrm{Sel}_{\mathbf{V}}^{1,\mathrm{b}}(F)$ and $\sum_i c_iz_i\in\mathrm{Bd}_{\mathbf{V}}^1(F)$ with $c\in F^e$ forces $c=0$. If $\alpha_1,\dots,\alpha_e\in\mathrm{Tp}$ are linearly independent over F and, for all i and j, the g-tuple with j-th entry $\mathrm{al}(\alpha_i)$ and all other entries 0 lifts, then $e+g^2\leq D_0$.*

(Df3) *If $(m_1,\dots,m_g)$ in N is dual to κ, then for every $\Phi\in\mathrm{Ph}$ there are $\alpha_1,\dots,\alpha_g\in\mathrm{Tp}$ with $\alpha_j(b)=\Phi(bm_j)-\lambda(b)\Phi(m_j)$ for all $b\in\hat{B}$ and j, such that $(\mathrm{al}(\alpha_1),\dots,\mathrm{al}(\alpha_g))$ lifts.*

Proof. Notation. $\rho_F=\rho\circ h$, a homomorphism $\Gamma_1^0\to\mathrm{GL}_n(A)\subseteq\mathrm{GL}_n(F)$. For $v\in S_\ell$ and $g\in D_v$ write $\phi g=\phi_{1,v}(g)$; as $h\circ\phi_{1,v}=\pi|_{D_v}$, $\rho_F(\phi g)=\rho(\pi g)$, and by the frame $T_g=w_v^{-1}\rho(\pi g)w_v$ is upper triangular with diagonal $(\psi_{v,1}(g),\dots,\psi_{v,n}(g))$. Let $J=\mathrm{diag}(1_a,-1_{n-a})$, so $JXJ=X$ for $X\in\mathrm{Ev}_a(F)$ and $JXJ=-X$ for $X\in\mathrm{Od}_a(F)$. As x is normalised of shape $(a,n-a)$, $\rho(\gamma)\in\mathrm{Ev}_a(A)$, hence $J\rho_F(\gamma)J=\rho_F(\gamma)$. Since each column of w_v has its non-zero entries in one block, $Jw_v=w_vE_v$ for a diagonal matrix E_v with entries ±1. The field F has characteristic $\ell\neq 2$, so 2 is invertible in F.

(Df1). Let $\alpha\in\mathrm{Tp}$, $\mu\in\mathrm{La}$, and $F[\varepsilon]=F\oplus F\varepsilon$ with $\varepsilon^2=0$. Using $\mathcal{A}=\hat{B}\cdot 1\oplus N$ ((Vr5)) define $\theta_\alpha,\theta_\mu\colon\mathcal{A}\to F[\varepsilon]$ by

$$\theta_\alpha(b\cdot 1+y)=\lambda(b)+\varepsilon\,\alpha(b),\qquad\theta_\mu(b\cdot 1+y)=\lambda(b)+\varepsilon\,\mu(y)\qquad(b\in\hat{B},\ y\in N).$$

Both are ring homomorphisms. They are additive and send 1 to 1. For $y,y'\in N$, (Vr5) gives $yy'=c\cdot 1$ with $c\in\mathrm{ired}(N)\subseteq\hat{\mathfrak{m}}$, so $\lambda(c)=0$, and $\alpha(c)=0$ by the definition of Tp. Hence $(b\cdot1+y)(b'\cdot1+y')=(bb'+c)\cdot1+(by'+b'y)$ is sent by θ_α to $\lambda(b)\lambda(b')+\varepsilon(\lambda(b)\alpha(b')+\lambda(b')\alpha(b))$ (derivation rule), and by θ_μ to $\lambda(b)\lambda(b')+\varepsilon(\lambda(b)\mu(y')+\lambda(b')\mu(y))$ ($\mu(by')=\lambda(b)\mu(y')$); these are the products of the images.

Let (θ, z) be $(\theta_\alpha, \mathrm{al}(\alpha))$ or $(\theta_\mu, \mathrm{la}(\mu))$, and $u(\gamma) = \theta(\nu(\gamma))$ (entrywise). By the last clause of (Vr6), $\lambda(\mathrm{pr}_0(\nu(\gamma)_{pq})) = \rho_F(\gamma)_{pq}$, so by the definition of al and la in Definition E.38

$$u(\gamma) = \big(1 + \varepsilon\, z(\gamma)\big)\rho_F(\gamma) \qquad (\gamma \in \Gamma_1^0),$$

and u is a homomorphism $\Gamma_1^0 \to \mathrm{GL}_n(F[\varepsilon])$, as ν is multiplicative with $\nu(1) = 1$ and θ is a ring homomorphism.

Fix $v \in S_\ell$. For $g \in D_v$ put $r_0(g) = T_g$, $r_1(g) = w_v^{-1} u(\phi g) w_v$, $\vartheta_{0,i} = \psi_{v,i}$ and $\vartheta_{1,i} = \theta \circ \hat{\psi}_{v,i}$ (with $\hat{\psi}_{v,i}(g) \in B$ mapped to $\hat{B} \cdot 1 \subseteq \mathcal{A}$). These are homomorphisms on D_v, and $r_1(g) - r_0(g) = \varepsilon\, w_v^{-1} z(\phi g) \rho_F(\phi g) w_v$ has entries in $F\varepsilon$. Since λ extends f_1 ((Vr4)) and $f_1 \circ \hat{\psi}_{v,i} = \psi_{v,i}$ ((Vr1)),

$$\vartheta_{1,i}(g) = \psi_{v,i}(g) + \varepsilon\, \alpha(\hat{\psi}_{v,i}(g)) \ \text{ for } \theta = \theta_\alpha, \qquad \vartheta_{1,i}(g) = \psi_{v,i}(g) \ \text{ for } \theta = \theta_\mu.$$

We apply Lemma E.86 with $R = F[\varepsilon]$, $R \to F$ the constant part (its kernel $F\varepsilon$ consists of nilpotent elements), $\mathfrak{n} = F\varepsilon$ (so $\mathfrak{n}^2 = 0$), $H = D_v$ and the data above; $r_1 - r_0$ and $\vartheta_{1,i} - \vartheta_{0,i}$ take values in $\mathfrak{n}$. Hypothesis 1 is the triangularity of T_g. Hypothesis 2: the residues of the $\vartheta_{0,i}$ are the characters $\psi_{v,i} \colon D_v \to A^\times \subseteq F^\times$, pairwise distinct by (Pj1). Hypothesis 3: for $g_1, \dots, g_n \in D_v$ the element $\prod_{i=1}^n (\phi_{1,v}(g_i) - \hat{\psi}_{v,i}(g_i))$ (increasing order) lies in $\mathcal{I}_1$ by (Vr3); the B-linear extension of ν to $B[\Gamma_1^0]$ is a ring homomorphism ($\mathcal{A}$ is commutative) vanishing on $\mathcal{I}_1$ ((Vr6)), so $\prod_i (\nu(\phi g_i) - \hat{\psi}_{v,i}(g_i)) = 0$ in $\mathrm{M}_n(\mathcal{A})$; applying θ entrywise and conjugating by w_v gives $\prod_i (r_1(g_i) - \vartheta_{1,i}(g_i)) = 0$. Hence there is $Y \in \mathrm{M}_n(F\varepsilon)$, which we write $Y = \varepsilon\, w_v^{-1} Y' w_v$ with $Y' \in \mathrm{M}_n(F)$, such that $r_1(g) r_0(g)^{-1} - 1 - (r_0(g) Y r_0(g)^{-1} - Y)$ is upper triangular with i-th diagonal entry $(\vartheta_{1,i}(g) - \psi_{v,i}(g))\psi_{v,i}(g)^{-1}$ for every $g \in D_v$. As $r_1(g) r_0(g)^{-1} - 1 = \varepsilon\, w_v^{-1} z(\phi g) w_v$ and $r_0(g) Y r_0(g)^{-1} - Y = \varepsilon\, w_v^{-1} (\rho_F(\phi g) Y' \rho_F(\phi g)^{-1} - Y') w_v$, comparing ε-coefficients gives: for every $g \in D_v$ the matrix

$$L_g(Y') = w_v^{-1} (z(\phi g) - \rho_F(\phi g) Y' \rho_F(\phi g)^{-1} + Y') w_v$$

is upper triangular with i-th diagonal entry $\delta_i(g)$, where $\delta_i(g) = \alpha(\hat{\psi}_{v,i}(g))\psi_{v,i}(g)^{-1}$ if $z = \mathrm{al}(\alpha)$ and $\delta_i(g) = 0$ if $z = \mathrm{la}(\mu)$. If $g \in \mu_v$, then $\hat{\psi}_{v,i}(g)$ lies in the image of $\mathcal{O} \to B$ ((Vr1)), whose image in $\hat{B}$ lies in $\iota(\mathcal{O}')$ ((Vr4)), and $\alpha \circ \iota = 0$; so $\delta_i(g) = 0$ for $g \in \mu_v$ in both cases.

It remains to replace Y' by a witness of the right block shape. Let $\mathcal{Z}$ be the set of $Y'' \in \mathrm{M}_n(F)$ such that for every $g \in D_v$ the matrix $L_g(Y'')$ (same formula) is upper triangular with diagonal $(\delta_i(g))_i$; it is an affine subspace of $\mathrm{M}_n(F)$ (L_g is affine in Y'') containing Y'. Put $\varsigma = 1$ if $z = \mathrm{al}(\alpha)$ and $\varsigma = -1$ if $z = \mathrm{la}(\mu)$; by Lemma E.87 z takes values in $\mathrm{Ev}_a(F)$, resp. $\mathrm{Od}_a(F)$, so $Jz(\gamma)J = \varsigma z(\gamma)$. Using $J\rho_F J = \rho_F$ and $w_v^{-1} J = E_v w_v^{-1}$, $J w_v = w_v E_v$ (recall $J^2 = 1$, $E_v^2 = 1$),

$$L_g(\varsigma J Y'' J) = \varsigma\, w_v^{-1} J (z(\phi g) - \rho_F(\phi g) Y'' \rho_F(\phi g)^{-1} + Y'') J w_v = \varsigma\, E_v\, L_g(Y'')\, E_v.$$

Conjugation by the diagonal sign matrix E_v preserves upper triangularity and the diagonal entries, and for $\varsigma = -1$ the prescribed diagonal is 0. Hence $\mathcal{Z}$ is stable under the affine involution $Y'' \mapsto \varsigma J Y'' J$, and $Y_v = \frac{1}{2}(Y' + \varsigma J Y' J) \in \mathcal{Z}$. Since $J Y_v J = \varsigma Y_v$, $Y_v \in \mathrm{Ev}_a(F)$ if $z = \mathrm{al}(\alpha)$ and $Y_v \in \mathrm{Od}_a(F)$ if $z = \mathrm{la}(\mu)$. The statement $Y_v \in \mathcal{Z}$ is exactly the local condition at v of Definition E.35 (Sc) for $(\rho_F, w, \mathrm{Ev}_a(F))$, resp. $(\rho_F, w, \mathrm{Od}_a(F))$, with witness Y_v. This proves the first two assertions of (Df1).

For the last sentence of (Df1): by Lemma E.87, $\mathrm{al}(\alpha)$ and $\mathrm{la}(\mu)$ take values in $\mathrm{Ev}_a(F)$, resp. $\mathrm{Od}_a(F)$, satisfy the cocycle rule for ρ_F and $z(c_1 \gamma c_1) = -{}^t z(\gamma)$, and vanish on every $I_{1,u}$; continuity for the topology of F defined by $TF = F$ is automatic (that topology is indiscrete); with the local conditions just proved, $\mathrm{al}(\alpha) \in \mathrm{Sel}_{\mathbf{V}}^{\mathrm{ev}}(F)$ and $\mathrm{la}(\mu) \in \mathrm{Sel}_{\mathbf{V}}^{\mathrm{od}}(F)$; both are bounded by Lemma E.88.

(Df2). Let D_0 and $\alpha_1,\dots,\alpha_e$ be as in (Df2). By (Df1), $\mathrm{al}(\alpha_i)\in \mathrm{Sel}^{\mathrm{ev,b}}_{\mathbf{V}}(F)$ for every i. So all hypotheses of Lemma E.89 hold ($\ell\neq 2$; x satisfies (Pj1) and the span condition; κ, $\mathbf{V}$, $\mathfrak{R}$, D_0 as there; the α_i independent, with $\mathrm{al}(\alpha_i)$ even bounded Selmer maps whose single-entry g-tuples lift), and it gives $e+g^2\le D_0$.

(Df3). Let $(m_1,\dots,m_g)$ be dual to κ and $\Phi\in\mathrm{Ph}$, and put $\alpha_j(b)=\Phi(bm_j)-\lambda(b)\Phi(m_j)$. By Lemma E.93 (whose hypotheses are $\ell\neq 2$, (Pj1) for x, and κ, $\mathbf{V}$, $\mathfrak{R}$, (m_j) as here) $\alpha_j\in\mathrm{Tp}$ for every j and $(\mathrm{al}(\alpha_1),\dots,\mathrm{al}(\alpha_g))$ lifts. □

Lemma E.86. *Let R be a commutative ring with a surjective ring homomorphism $R\to K$, $t\mapsto \bar t$, onto a field K whose kernel consists of nilpotent elements, $\mathfrak{n}\subseteq R$ an ideal with $\mathfrak{n}^2=0$, H a group, $n\ge 1$, $r_0,r_1\colon H\to \mathrm{GL}_n(R)$ homomorphisms with $r_1(g)-r_0(g)\in \mathrm{M}_n(\mathfrak{n})$, and $\vartheta_{0,i},\vartheta_{1,i}\colon H\to R^\times$ $(1\le i\le n)$ homomorphisms with $\vartheta_{1,i}(g)-\vartheta_{0,i}(g)\in\mathfrak{n}$, for all $g\in H$. Suppose:*

1. *every $r_0(g)$ is upper triangular with diagonal $(\vartheta_{0,1}(g),\dots,\vartheta_{0,n}(g))$;*
2. *for $i\neq j$ the characters $g\mapsto\overline{\vartheta_{0,i}(g)}$ and $g\mapsto\overline{\vartheta_{0,j}(g)}$ of H are distinct;*
3. *for all $g_1,\dots,g_n\in H$,*

$$\big(r_1(g_1)-\vartheta_{1,1}(g_1)\big)\big(r_1(g_2)-\vartheta_{1,2}(g_2)\big)\cdots\big(r_1(g_n)-\vartheta_{1,n}(g_n)\big)=0.$$

Then there is $Y\in\mathrm{M}_n(\mathfrak{n})$ such that for every $g\in H$ the matrix

$$r_1(g)r_0(g)^{-1}-1-\big(r_0(g)Yr_0(g)^{-1}-Y\big)$$

is upper triangular with i-th diagonal entry $(\vartheta_{1,i}(g)-\vartheta_{0,i}(g))\vartheta_{0,i}(g)^{-1}$ $(1\le i\le n)$.

Proof. Write $e_1,\dots,e_n$ for the standard basis of R^n and extend $r_0,r_1,\vartheta_{0,i},\vartheta_{1,i}$ R-linearly to the group ring $R[H]$. Since $r_1(x)-\vartheta_{1,i}(x)=\sum_g a_g(r_1(g)-\vartheta_{1,i}(g))$ for $x=\sum_g a_g g$, hypothesis 3 extends by multilinearity to all $x_1,\dots,x_n\in R[H]$. Likewise 1 gives that $r_0(x)$ is upper triangular with diagonal $(\vartheta_{0,1}(x),\dots,\vartheta_{0,n}(x))$ for $x\in R[H]$.

Step 1: separating elements. The R-linear map $R[H]\to R^n$, $x\mapsto(\vartheta_{0,k}(x))_k$, is surjective. Indeed, by 2 and Artin's theorem on the linear independence of distinct characters $H\to K^\times$, the map $K[H]\to K^n$, $x\mapsto(\overline{\vartheta_{0,k}}(x))_k$, is surjective (a non-zero linear form on K^n vanishing on its image would give a linear relation among the characters), so the image M' of $R[H]$ satisfies $M'+\mathfrak{m}R^n=R^n$, $\mathfrak{m}$ the kernel of $R\to K$; $\mathfrak{m}$ lies in the Jacobson radical of R ($1+t$ is a unit for nilpotent t), and Nakayama's lemma gives $M'=R^n$. Fix $x^{(i)}\in R[H]$ with $\vartheta_{0,k}(x^{(i)})=\delta_{ik}$; then also $\vartheta_{1,k}(x^{(i)})-\delta_{ik}\in\mathfrak{n}$.

Step 2: uniqueness of eigenvectors. We show: if $n\ge 2$ and $u\in R^n$ has $u_1=0$ and $r_1(g)u=\vartheta_{1,1}(g)u$ for all $g\in H$, then $u=0$. Let Z be an R-module and $u\in Z^n$ with $u_1=0$ and $r_0(g)u=\vartheta_{0,1}(g)u$ for all g, where matrices over R act on Z^n in the obvious way. If $u\neq 0$, let p be the largest index with $u_p\neq 0$; then $p\ge 2$, and the p-th coordinate of $r_0(x^{(p)})u-\vartheta_{0,1}(x^{(p)})u=0$ is, as $r_0(x^{(p)})$ is upper triangular, $(\vartheta_{0,p}(x^{(p)})-\vartheta_{0,1}(x^{(p)}))u_p=u_p$, a contradiction; so $u=0$. Apply this first to $Z=R/\mathfrak{n}$ and the image of the given u (modulo $\mathfrak{n}$, $r_1\equiv r_0$ and $\vartheta_{1,1}\equiv\vartheta_{0,1}$): so $u\in\mathfrak{n}^n$. Then $(r_1(g)-r_0(g))u=0$ and $(\vartheta_{1,1}(g)-\vartheta_{0,1}(g))u=0$ as $\mathfrak{n}^2=0$, and the same argument with $Z=R$ gives $u=0$.

Step 3: a triangularising basis. We show by induction on n: there is $V\in\mathrm{GL}_n(R)$ with $V-1\in\mathrm{M}_n(\mathfrak{n})$ such that $V^{-1}r_1(g)V$ is upper triangular with diagonal $(\vartheta_{1,1}(g),\dots,\vartheta_{1,n}(g))$ for all g. For $n=1$, hypothesis 3 says $r_1=\vartheta_{1,1}$; take $V=1$. Let $n\ge 2$. For $x_2,\dots,x_n\in R[H]$ put $P(x_2,\dots,x_n)=\prod_{k=2}^{n}(r_1(x_k)-\vartheta_{1,k}(x_k))$ (ordered product). By 3 (with $x_1=g$),

the image of $P(x_2,\dots,x_n)$ lies in $E_1=\{m\in R^n : r_1(g)m=\vartheta_{1,1}(g)m \text{ for all } g\}$. Let $v_1=P(x^{(1)},\dots,x^{(1)})e_1\in E_1$. Modulo $\mathfrak{n}$, $P(x^{(1)},\dots,x^{(1)})\equiv\prod_{k\geq 2}(r_0(x^{(1)})-\vartheta_{0,k}(x^{(1)}))=r_0(x^{(1)})^{n-1}$, and $r_0(x^{(1)})e_1=\vartheta_{0,1}(x^{(1)})e_1=e_1$; hence $v_1-e_1\in\mathfrak{n}^n$. In particular the first coordinate of v_1 is a unit, and $E_1=Rv_1$: for $m\in E_1$, $m-tv_1$ with $t=m_1(v_1)_1^{-1}$ lies in E_1 and has first coordinate 0, so it vanishes by Step 2. Let V_1 be the matrix with columns $v_1,e_2,\dots,e_n$; $V_1-1\in \mathrm{M}_n(\mathfrak{n})$, so V_1 is invertible. As $v_1\in E_1$, $V_1^{-1}r_1(g)V_1=\begin{pmatrix}\vartheta_{1,1}(g) & *\\ 0 & s_1(g)\end{pmatrix}$ with a homomorphism $s_1\colon H\to \mathrm{GL}_{n-1}(R)$. Let $s_0(g)$ be the lower right $(n-1)\times(n-1)$ block of $r_0(g)$, a homomorphism by 1, upper triangular with diagonal $(\vartheta_{0,2}(g),\dots,\vartheta_{0,n}(g))$; since $V_1\equiv 1$ modulo $\mathfrak{n}$, $s_1(g)-s_0(g)\in\mathrm{M}_{n-1}(\mathfrak{n})$. For $x_2,\dots,x_n\in R[H]$ the matrix $V_1^{-1}P(x_2,\dots,x_n)V_1$ is block upper triangular with lower right block $\prod_{k\geq 2}(s_1(x_k)-\vartheta_{1,k}(x_k))$, and its image lies in $V_1^{-1}E_1=Re_1$, so its rows $2,\dots,n$ vanish and so does that block. Hence $(s_0,s_1,(\vartheta_{0,k},\vartheta_{1,k})_{k\geq 2})$ satisfies the hypotheses with $n-1$, and induction gives V' for it. Then $V=V_1\,\mathrm{diag}(1,V')$ has the required properties.

Step 4: the matrix Y. Write $V=1+Y_0$ with $Y_0\in\mathrm{M}_n(\mathfrak{n})$; then $V^{-1}=1-Y_0$, and, using $\mathfrak{n}^2=0$ and $r_1(g)-r_0(g)\in\mathrm{M}_n(\mathfrak{n})$,

$$V^{-1}r_1(g)V=r_1(g)+r_0(g)Y_0-Y_0r_0(g)=(1+c(g)+r_0(g)Y_0r_0(g)^{-1}-Y_0)r_0(g),$$

where $c(g)=r_1(g)r_0(g)^{-1}-1$. Put $Y=-Y_0$ and $c'(g)=c(g)-(r_0(g)Yr_0(g)^{-1}-Y)$. Then $1+c'(g)=(V^{-1}r_1(g)V)\,r_0(g)^{-1}$ is a product of upper triangular matrices with diagonals $(\vartheta_{1,i}(g))_i$ and $(\vartheta_{0,i}(g)^{-1})_i$, so $c'(g)$ is upper triangular with i-th diagonal entry $\vartheta_{1,i}(g)\vartheta_{0,i}(g)^{-1}-1$. □

Lemma E.87. *Let $\mathfrak{R}$ be a realisation of x over $\mathbf{V}$, $\alpha\in\mathrm{Tp}$, $\mu\in\mathrm{La}$, and write $\rho_1(\gamma)=\rho(h(\gamma))$. Then $z=\mathrm{al}(\alpha)$ takes values in $\mathrm{Ev}_a(F)$, $z'=\mathrm{la}(\mu)$ takes values in $\mathrm{Od}_a(F)$, and each $w\in\{z,z'\}$ satisfies: $w(\gamma\gamma')=w(\gamma)+\rho_1(\gamma)w(\gamma')\rho_1(\gamma)^{-1}$ and $w(c_1\gamma c_1)=-{}^tw(\gamma)$ for $\gamma,\gamma'\in\Gamma_1^0$, and w vanishes on every $I_{1,u}$. Moreover $\alpha\mapsto\mathrm{al}(\alpha)$ and $\mu\mapsto\mathrm{la}(\mu)$ are F-linear.*

Proof. Write $\nu(\gamma)_{ij}=b_{ij}(\gamma)\cdot 1+n_{ij}(\gamma)$ with $b_{ij}(\gamma)=\mathrm{pr}_0(\nu(\gamma)_{ij})\in\hat{B}$ and $n_{ij}(\gamma)=\mathrm{pr}_1(\nu(\gamma)_{ij})\in N$. By (Vr6), $n_{ij}=0$ when i,j lie in one block and $b_{ij}=0$ otherwise, and $\lambda(b_{ij}(\gamma))=\rho_1(\gamma)_{ij}$ (for i,j in different blocks, $\nu(\gamma)_{ij}-0\cdot 1\in N$, so $\rho_1(\gamma)_{ij}=0$, as ρ is block diagonal). Put $\beta(\gamma)=(\alpha(b_{ij}(\gamma)))_{ij}$ and $\beta'(\gamma)=(\mu(n_{ij}(\gamma)))_{ij}$; so $z=\beta\rho_1^{-1}$, $z'=\beta'\rho_1^{-1}$. As $\rho_1(\gamma)$ is block diagonal, z has the block shape of β (in $\mathrm{Ev}_a(F)$) and z' that of β' (in $\mathrm{Od}_a(F)$). Linearity follows from the definitions.

Product rule. For γ,γ' and i,j in one block, $\nu(\gamma\gamma')_{ij}=\sum_k b_{ik}(\gamma)b_{kj}(\gamma')\cdot 1+\sum_k n_{ik}(\gamma)n_{kj}(\gamma')$, the first sum over k in that block and the second over k in the other; the second sum lies in $\mathrm{ired}(N)\cdot 1$. Since α kills $\mathrm{ired}(N)$ and is a derivation over λ, $\alpha(b_{ij}(\gamma\gamma'))=\sum_k(\rho_1(\gamma)_{ik}\alpha(b_{kj}(\gamma'))+\alpha(b_{ik}(\gamma))\rho_1(\gamma')_{kj})$, i.e. $\beta(\gamma\gamma')=\rho_1(\gamma)\beta(\gamma')+\beta(\gamma)\rho_1(\gamma')$ (both sides vanish at positions in different blocks). For i,j in different blocks, $n_{ij}(\gamma\gamma')=\sum_k b_{ik}(\gamma)n_{kj}(\gamma')+\sum_k n_{ik}(\gamma)b_{kj}(\gamma')$, and $\mu(by)=\lambda(b)\mu(y)$ gives $\beta'(\gamma\gamma')=\rho_1(\gamma)\beta'(\gamma')+\beta'(\gamma)\rho_1(\gamma')$. Multiplying on the right by $\rho_1(\gamma\gamma')^{-1}=\rho_1(\gamma')^{-1}\rho_1(\gamma)^{-1}$ gives the cocycle identity for $w=z,z'$. Also $\nu(1)=1$ gives $\beta(1)=(\alpha(\delta_{ij}))=0$ ($\alpha(1)=\alpha(1\cdot 1)=2\alpha(1)$) and $\beta'(1)=0$, so $w(1)=0$ and $\rho_1(\gamma)w(\gamma^{-1})\rho_1(\gamma)^{-1}=-w(\gamma)$.

Polarisation. By (Vr6), $\nu(\gamma^*)={}^t\nu(\gamma)$ with $\gamma^*=c_1\gamma^{-1}c_1$, so $\beta(\gamma^*)={}^t\beta(\gamma)$, $\beta'(\gamma^*)={}^t\beta'(\gamma)$; and $\rho_1(\gamma^*)=\rho(\bar{c}\,h(\gamma)^{-1}\bar{c})={}^t\rho_1(\gamma)$ (x normalised, $h(c_1)=\bar{c}$). Hence

$$w(\gamma^*)={}^t(\rho_1(\gamma)^{-1}w(\gamma)\rho_1(\gamma)).$$

Applying this to γ^{-1}, for which $(\gamma^{-1})^*=c_1\gamma c_1$, and using the last identity of the previous paragraph: $w(c_1\gamma c_1)={}^t(\rho_1(\gamma)w(\gamma^{-1})\rho_1(\gamma)^{-1})=-{}^tw(\gamma)$.

Frame inertia. For $\gamma' \in I_{1,u}$, $\gamma' - 1 \in \mathcal{I}_1$ by (Vr3), so $\nu(\gamma') = 1$ by (Vr6); hence $\beta(\gamma') = \beta'(\gamma') = 0$ and $w(\gamma') = 0$. □

Lemma E.88. *Let $\mathfrak{R}$ be a realisation of x over a level $\mathbf{V}$. For every $\alpha \in \mathrm{Tp}$ and $\mu \in \mathrm{La}$ the maps $\mathrm{al}(\alpha)$ and $\mathrm{la}(\mu)$ are bounded.*

Proof. We use Cohen's structure theorem: a complete Noetherian local ring of characteristic ℓ with residue field k_0 is a quotient of $k_0[[x_1, \dots, x_m]]$ for some m.

Write $\rho_1 = \rho \circ h$; its entries and those of ρ_1^{-1} lie in A and are T-adically continuous. Let $\beta(\gamma) = (\alpha(\mathrm{pr}_0(\nu(\gamma)_{ij})))_{ij}$ and $\beta'(\gamma) = (\mu(\mathrm{pr}_1(\nu(\gamma)_{ij})))_{ij}$, so $\mathrm{al}(\alpha) = \beta\rho_1^{-1}$, $\mathrm{la}(\mu) = \beta'\rho_1^{-1}$; it suffices to find s such that the entries of $T^s\beta$, $T^s\beta'$ lie in A and are continuous. Let $\alpha_B = \alpha \circ (B \to \hat{B})$; it is additive, kills the image of $\mathcal{O}$, and $\alpha_B(bb') = f_1(b)\alpha_B(b') + f_1(b')\alpha_B(b)$.

Step 1: $\alpha_B(B) \subseteq T^{-s_0}A$ for some s_0, and $\alpha_B(\mathfrak{m}_B^j) \subseteq T^{j-1-s_0}A$ for $j \geq 1$. As $\ell = 0$ in F, $\alpha_B(\ell b) = f_1(\ell)\alpha_B(b) + f_1(b)\alpha_B(\ell) = 0$, and $\alpha_B(c^\ell) = \ell f_1(c)^{\ell-1}\alpha_B(c) = 0$. The ring $\bar{B} = B/\ell B$ is complete Noetherian local of characteristic ℓ with finite (hence perfect) residue field k_0; by Cohen's theorem it is a quotient of $k_0[[x_1, \dots, x_m]]$, which is generated as a module over its subring of ℓ-th powers $k_0[[x_1^\ell, \dots, x_m^\ell]]$ by the monomials x^e with $0 \leq e_i < \ell$. Choose $u_e \in B$ mapping to the images of these monomials. Then every $b \in B$ is $\sum_e c_e^\ell u_e + \ell b'$ with $c_e, b' \in B$, and $\alpha_B(b) = \sum_e f_1(c_e)^\ell \alpha_B(u_e)$. So $\alpha_B(B)$ lies in the A-module generated by the finitely many $\alpha_B(u_e) \in F$, hence in $T^{-s_0}A$ for some s_0. For $x_1, \dots, x_j \in \mathfrak{m}_B$, $\alpha_B(x_1 \cdots x_j) = \sum_i (\prod_{k \neq i} f_1(x_k))\alpha_B(x_i) \in T^{j-1}T^{-s_0}A$, as $f_1(\mathfrak{m}_B) \subseteq TA$; sums of such products give the second claim.

Step 2: bounds. By (Vr8), $\nu(\Gamma_1^0) \subseteq \mathcal{P}_0 = \sum_{k=1}^r BP_k$ for some $P_k \in \mathrm{M}_n(\mathcal{A})$. Let $p_{k,ij} = \mathrm{pr}_0((P_k)_{ij}) \in \hat{B}$ and $q_{k,ij} = \mathrm{pr}_1((P_k)_{ij}) \in N$, and choose s_1 with $T^{s_1}\lambda(p_{k,ij})$, $T^{s_1}\alpha(p_{k,ij})$, $T^{s_1}\mu(q_{k,ij})$ in A for all k, i, j (finitely many elements of F). For $P = \sum_k b_k P_k \in \mathcal{P}_0$ ($b_k \in B$), as $\mathrm{pr}_0, \mathrm{pr}_1$ are $\hat{B}$-linear,

$$\alpha(\mathrm{pr}_0(P_{ij})) = \sum_k (f_1(b_k)\alpha(p_{k,ij}) + \lambda(p_{k,ij})\alpha_B(b_k)), \qquad \mu(\mathrm{pr}_1(P_{ij})) = \sum_k f_1(b_k)\mu(q_{k,ij}).$$

With $s = s_0 + s_1 + 1$, Step 1 shows that these lie in $T^{-s}A$ for all $P \in \mathcal{P}_0$, and in $T^{j-1-s}A$ if all $b_k \in \mathfrak{m}_B^j$ (then $f_1(b_k) \in T^j A$). Hence the entries of $T^s\beta(\gamma)$, $T^s\beta'(\gamma)$ lie in A, and for $v \in V_j$ of (Vr8), $\nu(\gamma v) - \nu(\gamma) \in \mathfrak{m}_B^j \mathcal{P}_0$ gives $T^s(\beta(\gamma v) - \beta(\gamma))$, $T^s(\beta'(\gamma v) - \beta'(\gamma)) \in T^{j-1}\mathrm{M}_n(A)$: the entries are T-adically continuous. □

Lemma E.89. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell \neq 2$ and x a framed normalised curve point of shape $(a, n-a)$ satisfying (Pj1) and such that for every $Z \in \mathrm{Ev}_a(A)$ there is $s \geq 0$ with $T^s Z$ in the A-span of $\rho(\Gamma')$. Let $\kappa = (\kappa_1, \dots, \kappa_g)$ be a Selmer basis of x with local witnesses, $\mathbf{V}$ a level over $\mathscr{H}$, $\mathfrak{R}$ a realisation of x over $\mathbf{V}$, and $D_0 \geq 0$ an integer such that $e \leq D_0$ whenever $z_1, \dots, z_e \in \mathrm{Sel}_{\mathbf{V}}^{1,\mathrm{b}}(F)$ and $\sum_i c_i z_i \in \mathrm{Bd}_{\mathbf{V}}^1(F)$ with $c \in F^e$ forces $c = 0$. If $\alpha_1, \dots, \alpha_e \in \mathrm{Tp}$ are linearly independent over F, $\mathrm{al}(\alpha_i) \in \mathrm{Sel}_{\mathbf{V}}^{\mathrm{ev},\mathrm{b}}(F)$ for every i, and for all i and j the g-tuple with j-th entry $\mathrm{al}(\alpha_i)$ and all other entries 0 lifts, then $e + g^2 \leq D_0$.*

Proof. Write $\rho_F = \rho \circ h$, $\rho_{1,F} = (1 + \sum_k \epsilon_k(\kappa_k \circ h))\rho_F$, and for a matrix M over $\mathrm{PD}_g(F)$ let M_0 and M_{ϵ_k} be its matrices of components in $F \cdot 1$ and $F\epsilon_k$. The map $M \mapsto M_0$ is a ring homomorphism on matrices over $F \oplus \bigoplus_k F\epsilon_k$, and $(\rho_{1,F})_0 = \rho_F$.

The $e + g^2$ maps. For $1 \leq i \leq e$, Lemma E.90 applied to $z = \mathrm{al}(\alpha_i)$ gives $y_i \in \mathrm{Sel}_{\mathbf{V}}^{1,\mathrm{b}}(F)$ with $(y_i)_0 = \mathrm{al}(\alpha_i)$. For $1 \leq p, m \leq g$ put $\omega_{p,m}(\gamma) = \epsilon_m \kappa_p(h(\gamma))$. Then $\omega_{p,m} \in \mathrm{Sel}_{\mathbf{V}}^{1,\mathrm{b}}(F)$: its values lie in $\mathrm{PW}_a^1(F)$ as κ_p takes values in $\mathrm{Od}_a(A)$; since $\epsilon_m\epsilon_k = 0$, conjugation by $\rho_{1,F}(\gamma)$ acts on $\epsilon_m \mathrm{M}_n(F)$ as conjugation by $\rho_F(\gamma)$, so the cocycle identity for $\rho_{1,F}$ is that of κ_p for

ρ composed with the homomorphism h; polarisation follows from $h(c_1\gamma c_1) = \bar{c}\,h(\gamma)\bar{c}$ and that of κ_p; $\omega_{p,m}$ vanishes on $I_{1,u}$ as $h(I_{1,u}) = I_u^x$; at $v \in S_\ell$ the element $\epsilon_m Y_{p,v} \in \mathrm{PW}_a^1(F)$ ($Y_{p,v}$ the local witness of κ_p) is a witness, because, again as $\epsilon_m\epsilon_k = 0$, the local matrix equals $\epsilon_m\, w_v^{-1}(\kappa_p(\pi g) - \rho(\pi g)Y_{p,v}\rho(\pi g)^{-1} + Y_{p,v})w_v$, which is upper triangular with zero diagonal for $g \in \mu_v$ by (Sd2) of Definition E.34; and it is bounded with exponent 0, its coordinates being T-adically continuous entries of $\kappa_p \circ h$.

Independence modulo $\mathrm{Bd}^1_{\mathbf{V}}(F)$. Let $c \in F^e$, $d \in F^{g\times g}$ and $Y \in \mathrm{PW}_a^1(F)$ with ${}^tY = -Y$ be such that

$$\sum_i c_i y_i(\gamma) + \sum_{p,m} d_{p,m}\omega_{p,m}(\gamma) = \rho_{1,F}(\gamma)Y\rho_{1,F}(\gamma)^{-1} - Y \qquad (\gamma \in \Gamma_1^0).$$

Taking constant parts, $\sum_i c_i\,\mathrm{al}(\alpha_i)(\gamma) = \rho_F(\gamma)Y_0\rho_F(\gamma)^{-1} - Y_0$. By F-linearity of al (Lemma E.87) the left side is $\mathrm{al}(\sum_i c_i\alpha_i)$, so Lemma E.91 gives $\sum_i c_i\alpha_i = 0$, and $c = 0$ by independence. Hence Y_0 commutes with $\rho_F(\Gamma_1^0) = \rho(\Gamma^0)$ (h maps $\Gamma_1^0 = h^{-1}(\Gamma^0)$ onto Γ^0). Moreover $Y_0 \in \mathrm{Ev}_a(F)$ (same-block entries of PW_a^1 lie in $F\cdot 1$, different-block entries in $\bigoplus_k F\epsilon_k$) and ${}^tY_0 = -Y_0$. We show $Y_0 = 0$. Its diagonal entries satisfy $2(Y_0)_{pp} = 0$, and $2 \neq 0$ in F as $\ell \neq 2$. Let $p \neq q$ lie in the same block. The elementary matrix E_{pp} lies in $\mathrm{Ev}_a(A)$, so for some s, T^sE_{pp} is an A-linear combination of elements of $\rho(\Gamma') \subseteq \rho(\Gamma^0)$ and commutes with Y_0; the (p,q) entry of $T^s(E_{pp}Y_0 - Y_0E_{pp}) = 0$ is $T^s(Y_0)_{pq}$, so $(Y_0)_{pq} = 0$. Entries in different blocks vanish as $Y_0 \in \mathrm{Ev}_a(F)$.

Now $Y = \sum_k \epsilon_k Y_{\epsilon_k}$ with $Y_{\epsilon_k} \in \mathrm{Od}_a(F)$ and ${}^tY_{\epsilon_k} = -Y_{\epsilon_k}$, and as $\epsilon_k\epsilon_{k'} = 0$, $\rho_{1,F}(\gamma)Y\rho_{1,F}(\gamma)^{-1} = \sum_k \epsilon_k\rho_F(\gamma)Y_{\epsilon_k}\rho_F(\gamma)^{-1}$. Since $c = 0$ and the $\omega_{p,m}$ have constant part 0, comparing ϵ_m-components gives, for each m,

$$\sum_p d_{p,m}\,\kappa_p(h(\gamma)) = \rho_F(\gamma)Y_{\epsilon_m}\rho_F(\gamma)^{-1} - Y_{\epsilon_m} \qquad (\gamma \in \Gamma_1^0).$$

Choose $0 \neq t \in A$ with $td_{p,m} \in A$ for all p and $tY_{\epsilon_m} \in \mathrm{Od}_a(A)$. As $h(\Gamma_1^0) = \Gamma^0$, $\sum_p td_{p,m}\kappa_p$ is the map $\gamma' \mapsto \rho(\gamma')(tY_{\epsilon_m})\rho(\gamma')^{-1} - tY_{\epsilon_m}$ on Γ^0, an element of $\mathrm{Bd}(x)$ (as ${}^t(tY_{\epsilon_m}) = -tY_{\epsilon_m}$); by the definition of a Selmer basis $td_{p,m} = 0$ for all p, so $d = 0$.

Thus the $e+g^2$ elements $y_1,\dots,y_e$, $\omega_{p,m}$ of $\mathrm{Sel}^{1,\mathrm{b}}_{\mathbf{V}}(F)$ satisfy the hypothesis defining D_0, and $e + g^2 \leq D_0$. □

Lemma E.90. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell \neq 2$, x a framed normalised curve point of shape $(a, n-a)$ satisfying (Pj1), $\kappa = (\kappa_1,\dots,\kappa_g)$ a Selmer basis of x with local witnesses, and $\mathbf{V}$ a level over $\mathscr{H}$. Let $z \in \mathrm{Sel}^{\mathrm{ev},\mathrm{b}}_{\mathbf{V}}(F)$ be such that, for every $1 \leq j \leq g$, the g-tuple with j-th entry z and all other entries 0 lifts. Then there is $y \in \mathrm{Sel}^{1,\mathrm{b}}_{\mathbf{V}}(F)$ such that, for every $\gamma \in \Gamma_1^0$, the component in $F\cdot 1$ of each entry of $y(\gamma)$ (for the decomposition $\mathrm{PD}_g(F) = F \oplus \bigoplus_j F\epsilon_j \oplus \bigoplus_j F\epsilon'_j \oplus F\eta$) is the corresponding entry of $z(\gamma)$.*

Proof. Write $\mathrm{PD} = \mathrm{PD}_g(F)$ and, for $u \in \mathrm{PD}$, $u = u_0 + \sum_i u_{\epsilon_i}\epsilon_i + \sum_i u_{\epsilon'_i}\epsilon'_i + u_\eta\eta$; the same subscripts on a matrix over PD denote the matrices of components. Let $\mathrm{S} = F \oplus \bigoplus_i F\epsilon_i$, a subring of PD (as $\epsilon_i\epsilon_k = 0$), and $\mathrm{E} = \bigoplus_i F\epsilon'_i \oplus F\eta$, an ideal of S-modules with $\mathrm{S\,E} \subseteq \mathrm{E}$; $u \mapsto u_0$ is a ring homomorphism $\mathrm{S} \to F$. Two facts on these rings are used throughout.

(i) For $u \in \mathrm{S}$, $\epsilon'_j u = u_0\epsilon'_j + u_{\epsilon_j}\eta$. Hence $u \in \mathrm{S}$ is 0 if and only if $u_0 = 0$ and $\epsilon'_j u = 0$ for all j.

(ii) For $S_1, S_2 \in \mathrm{M}_n(\mathrm{S})$ and $M \in \mathrm{M}_n(\mathrm{E})$, $(S_1MS_2)_{\epsilon'_i} = (S_1)_0 M_{\epsilon'_i}(S_2)_0$, since $\epsilon_k\epsilon'_i \in F\eta$ and $\eta\,\mathrm{E} = 0$.

Write $\rho_F = \rho \circ h$ and $\rho_{1,F} = \rho_1 \circ h = (1 + \sum_k \epsilon_k(\kappa_k \circ h))\rho_F$, with values in $\mathrm{GL}_n(\mathrm{S})$, inverse $\rho_F^{-1}(1 - \sum_k \epsilon_k(\kappa_k \circ h))$ and constant part ρ_F. For $v \in S_\ell$ let $Y_{k,v} \in \mathrm{Od}_a(A)$ be the given local witness of κ_k; then $w_v^1 = (1 - \sum_k \epsilon_k Y_{k,v})w_v \in \mathrm{GL}_n(\mathrm{S})$ with inverse $w_v^{-1}(1 + \sum_k \epsilon_k Y_{k,v})$ and constant part w_v. For $g \in D_v$ write $\phi g = \phi_{1,v}(g)$; as $h \circ \phi_{1,v} = \pi|_{D_v}$, $\rho_F(\phi g) = \rho(\pi g)$, and $T_g = w_v^{-1}\rho(\pi g)w_v$ is upper triangular with diagonal $(\psi_{v,1}(g), \dots, \psi_{v,n}(g))$ (the frame). On F and PD the ideal generated by T is the whole ring, so the continuity condition in the Selmer sets over F is void.

Construction of y. For each j choose $\Psi_j \in \mathrm{Sel}_{\mathbf{V}}^{2,\mathrm{b}}(F)$ whose ϵ_i'-coefficient is z for $i = j$ and 0 for $i \neq j$. Its values lie in $\mathrm{PW}_a^2(F) \subseteq \mathrm{M}_n(\mathrm{E})$, so $\Psi_j(\gamma) = \epsilon_j' z(\gamma) + \eta\, \Psi_j(\gamma)_\eta$ with $\Psi_j(\gamma)_\eta \in \mathrm{Od}_a(F)$. Put

$$y(\gamma) = z(\gamma) + \sum_{j=1}^{g} \epsilon_j\, \Psi_j(\gamma)_\eta \qquad (\gamma \in \Gamma_1^0).$$

As $z(\gamma) \in \mathrm{Ev}_a(F)$, $y(\gamma) \in \mathrm{PW}_a^1(F) \subseteq \mathrm{M}_n(\mathrm{S})$, $y(\gamma)_0 = z(\gamma)$, and by (i)

$$\epsilon_j'\, y(\gamma) = \Psi_j(\gamma) \qquad (1 \le j \le g,\ \gamma \in \Gamma_1^0). \qquad (*)$$

y is bounded: its coordinates are those of z and of the Ψ_j, all bounded, and finitely many bounded maps admit a common exponent.

Cocycle, polarisation and inertia conditions. The two sides of

$$y(\gamma\gamma') = y(\gamma) + \rho_{1,F}(\gamma) y(\gamma') \rho_{1,F}(\gamma)^{-1}$$

lie in $\mathrm{M}_n(\mathrm{S})$. Their constant parts agree because z is a cocycle for ρ_F, and their products with ϵ_j' agree by $(*)$ because Ψ_j is a cocycle for $\rho_{1,F}$ (ϵ_j' is central). By (i), applied entrywise, they are equal. In the same way $y(c_1\gamma c_1) = -{}^t y(\gamma)$ and $y|_{I_{1,u}} = 0$ follow from the corresponding properties of z and of the Ψ_j.

Local condition at $v \in S_\ell$: the discrepancy of the witnesses is triangular. Let $Y_v \in \mathrm{Ev}_a(F)$ be a witness for z and $Y^{(j)} \in \mathrm{PW}_a^2(F)$ one for Ψ_j. The ϵ_i'-components $P_{j,i} = Y^{(j)}_{\epsilon_i'}$ lie in $\mathrm{Ev}_a(F)$, and $Y_\eta^{(j)} \in \mathrm{Od}_a(F)$. Put $Q_{j,i} = P_{j,i} - \delta_{ij} Y_v \in \mathrm{Ev}_a(F)$. By (ii), the ϵ_i'-component of the local matrix $(w_v^1)^{-1}(\Psi_j(\phi g) - \rho_{1,F}(\phi g) Y^{(j)} \rho_{1,F}(\phi g)^{-1} + Y^{(j)}) w_v^1$ is $w_v^{-1}(\delta_{ij} z(\phi g) - \rho_F(\phi g) P_{j,i} \rho_F(\phi g)^{-1} + P_{j,i}) w_v$, which therefore has zero entries below the diagonal; subtracting δ_{ij} times the local matrix of z, the matrix $T_g Q' T_g^{-1} - Q'$ with $Q' = w_v^{-1} Q_{j,i} w_v$ is upper triangular for all $g \in D_v$, hence so is $T_g Q' - Q' T_g$ (multiply on the right by T_g). We show $Q'_{pq} = 0$ for $p > q$ by induction on $(n - p) + q$. If $p > q$ and the claim holds for smaller values, then $(T_g Q')_{pq} = \sum_{k \ge p} (T_g)_{pk} Q'_{kq} = \psi_{v,p}(g) Q'_{pq}$ and $(Q' T_g)_{pq} = \sum_{k \le q} Q'_{pk} (T_g)_{kq} = Q'_{pq} \psi_{v,q}(g)$, so $(\psi_{v,p}(g) - \psi_{v,q}(g)) Q'_{pq} = 0$ for all g; by (Pj1) some g has $\psi_{v,p}(g) \neq \psi_{v,q}(g)$, and $Q'_{pq} = 0$. Thus $C_j' = \sum_i \epsilon_i' w_v^{-1} Q_{j,i} w_v$ is upper triangular.

Local condition at v: the witness of y. Put $C_j = w_v^1 C_j' (w_v^1)^{-1}$. Expanding, $C_j = \sum_i \epsilon_i' Q_{j,i} + \eta \sum_k (Q_{j,k} Y_{k,v} - Y_{k,v} Q_{j,k})$; as $\mathrm{Ev}_a \cdot \mathrm{Od}_a$ and $\mathrm{Od}_a \cdot \mathrm{Ev}_a$ lie in Od_a, $C_j \in \mathrm{PW}_a^2(F)$ with $(C_j)_{\epsilon_i'} = Q_{j,i}$. Let

$$Y' = Y_v + \sum_j \epsilon_j\, Y_\eta^{(j)} \in \mathrm{PW}_a^1(F); \qquad \text{then} \qquad \epsilon_j' Y' = Y^{(j)} - C_j$$

by (i) (the ϵ_i'-components of both sides are $\delta_{ij} Y_v = P_{j,i} - Q_{j,i}$, the η-components $Y_\eta^{(j)}$). For $g \in D_v$ let $M_g = (w_v^1)^{-1}(y(\phi g) - \rho_{1,F}(\phi g) Y' \rho_{1,F}(\phi g)^{-1} + Y') w_v^1 \in \mathrm{M}_n(\mathrm{S})$ and $B_g = (w_v^1)^{-1} \rho_{1,F}(\phi g) w_v^1$. Its constant part is the local matrix $w_v^{-1}(z(\phi g) - \rho_F(\phi g) Y_v \rho_F(\phi g)^{-1} + Y_v) w_v$ of z, which vanishes below the diagonal, and on the diagonal when $g \in \mu_v$. By $(*)$,

$$\epsilon_j' M_g = (w_v^1)^{-1}(\Psi_j(\phi g) - \rho_{1,F}(\phi g) Y^{(j)} \rho_{1,F}(\phi g)^{-1} + Y^{(j)}) w_v^1 + (B_g C_j' B_g^{-1} - C_j').$$

The first summand is the local matrix of Ψ_j: zero below the diagonal, and on it when $g \in \mu_v$. B_g is upper triangular: its constant part is T_g, and its ϵ_k-component is $w_v^{-1}(\kappa_k(\pi g) - \rho(\pi g)Y_{k,v}\rho(\pi g)^{-1} + Y_{k,v})w_v \cdot T_g$, a product of upper triangular matrices by the local condition on κ_k with witness $Y_{k,v}$ (Definition E.34 (Sd2)). Likewise $B_g^{-1} = B_{g^{-1}}$ is upper triangular, and $(B_g)_{pp}(B_g^{-1})_{pp} = 1$ for all p (the entries commute). Hence $B_g C_j' B_g^{-1}$ is upper triangular with diagonal entries $(B_g)_{pp}(C_j')_{pp}(B_g^{-1})_{pp} = (C_j')_{pp}$, and the second summand is upper triangular with zero diagonal. By (i), applied entrywise, M_g has zero entries below the diagonal for every $g \in D_v$, and zero diagonal entries for $g \in \mu_v$. So Y' is a witness for y at v.

Hence $y \in \mathrm{Sel}_{\mathbf{V}}(\rho_{1,F}, w^1, \mathrm{PW}_a^1(F)) = \mathrm{Sel}_{\mathbf{V}}^1(F)$, y is bounded, and its constant part is z. $\square$

Lemma E.91. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell \neq 2$, x a framed normalised curve point of shape $(a, n-a)$ satisfying (Pj1), $\mathbf{V}$ a level over $\mathscr{H}$ and $\mathfrak{R}$ a realisation of x over $\mathbf{V}$. Let $\alpha \in \mathrm{Tp}$, and suppose there is $Y \in \mathrm{M}_n(F)$ with*

$$\mathrm{al}(\alpha)(\gamma) = \rho(h(\gamma))\, Y\, \rho(h(\gamma))^{-1} - Y \qquad \textit{for all } \gamma \in \Gamma_1^0.$$

Then $\alpha = 0$.

Proof. Write $\rho_1(\gamma) = \rho(h(\gamma))$ for $\gamma \in \Gamma_1^0$, $\hat{b}$ for the image of $b \in B$ under $B \to B_{\ker f_1} \to \hat{B}$, and $P = \ker f_1$; by (Vr4), $\lambda(\hat{b}) = f_1(b) \in A \subseteq F$. Of (Pj1) only the first half is used: $\psi_{v,b} \neq \psi_{v,b'}$ for $b \neq b'$.

Step 1: a dual-number specialisation of the realisation. Let $F[\varepsilon] = F[X]/(X^2)$ and $\theta\colon \mathcal{A} = \hat{B}\cdot 1 \oplus N \to F[\varepsilon]$, $\theta(c\cdot 1 + y) = \lambda(c) + \varepsilon\alpha(c)$. It is a ring homomorphism: it is additive with $\theta(1) = 1$; for $y, y' \in N$ we have $yy' = c_0 \cdot 1$ with $c_0 \in \mathrm{ired}(N) \subseteq \hat{\mathfrak{m}}$ (by (Vr5)), so $\lambda(c_0) = 0$ and $\alpha(c_0) = 0$ (as $\alpha \in \mathrm{Tp}$), and the derivation rule of α gives $\theta((c+y)(c'+y')) = \lambda(cc') + \varepsilon\alpha(cc') = \theta(c+y)\theta(c'+y')$. Apply θ entrywise to matrices. By (Vr6), $\lambda(\mathrm{pr}_0(\nu(\gamma)_{ij})) = \rho_1(\gamma)_{ij}$, so by the definition of al and the hypothesis

$$\begin{aligned}\theta(\nu(\gamma)) = \rho_1(\gamma) + \varepsilon\,\mathrm{al}(\alpha)(\gamma)\rho_1(\gamma) &= \rho_1(\gamma) + \varepsilon(\rho_1(\gamma)Y - Y\rho_1(\gamma)) \\ &= W\rho_1(\gamma)W^{-1}, \qquad W = 1 - \varepsilon Y,\ W^{-1} = 1 + \varepsilon Y.\end{aligned}$$

Put $\delta(b) = \alpha(\hat{b})$ for $b \in B$. Then δ is additive, $\delta(bb') = f_1(b)\delta(b') + f_1(b')\delta(b)$, and δ vanishes on the image of the coefficient ring $\mathcal{O}_1$ of the realisation (by (Vr4) this image lies in $\iota(\mathcal{O}')$, and $\alpha \circ \iota = 0$). Let $\Theta\colon B[\Gamma_1^0] \to \mathrm{M}_n(F[\varepsilon])$ be θ composed with the B-linear extension of ν; it is a ring homomorphism (ν is multiplicative with $\nu(1) = 1$), $\Theta(b) = f_1(b) + \varepsilon\delta(b)$ for $b \in B$, $\Theta(\gamma) = W\rho_1(\gamma)W^{-1}$, and $\Theta(\mathcal{I}_1) = 0$ by (Vr6). Each element listed in (Vr3) lies in every ideal of the intersection defining $\mathcal{I}_1$, hence in $\mathcal{I}_1$, and is killed by Θ.

Step 2: δ vanishes on the generators of B listed in (Vr2).

- s: $\hat{s} \in \iota(\mathcal{O}')$ by (Vr4), so $\delta(s) = 0$.
- Coefficients of $\chi_D(\gamma)$, $\gamma \in \Gamma_1^0$: by (Vr6) the base change of D to $\mathcal{A}$ is $\det \circ \nu$, so the images in $\hat{B} \cdot 1$ of the coefficients c of $\chi_D(\gamma)$ are the coefficients of $\det(X - \nu(\gamma))$. Applying the ring homomorphism θ coefficientwise, the elements $f_1(c) + \varepsilon\delta(c)$ are the coefficients of $\det(X - W\rho_1(\gamma)W^{-1}) = \det(X - \rho_1(\gamma)) \in F[X]$; comparing ε-components, $\delta(c) = 0$.
- $\hat{\psi}_{v,b_0}(g)$, $v \in S_\ell$, $1 \leq b_0 \leq n$, $g \in D_v$: write $\tilde{\psi}_b(g') = \psi_{v,b}(g') + \varepsilon\beta_b(g')$ with $\beta_b(g') = \delta(\hat{\psi}_{v,b}(g'))$ (by (Vr1), $f_1 \circ \hat{\psi}_{v,b} = \psi_{v,b}$). For $g_1, \ldots, g_n \in D_v$, Θ kills $\prod_{b=1}^n(\phi_{1,v}(g_b) - \hat{\psi}_{v,b}(g_b))$; conjugating by W, $\prod_b(\rho_1(\phi_{1,v}g_b) - \tilde{\psi}_b(g_b)) = 0$. Since $h \circ \phi_{1,v} = \pi|_{D_v}$, $\rho_1(\phi_{1,v}g') = \rho(\pi g')$, and by the frame $w_v^{-1}\rho(\pi g')w_v$ is upper triangular with diagonal $(\psi_{v,1}(g'), \ldots, \psi_{v,n}(g'))$.

Conjugating by w_v, a product of upper triangular matrices vanishes; its (b_0,b_0) entry is $\prod_b(\psi_{v,b_0}(g_b)-\psi_{v,b}(g_b)-\varepsilon\beta_b(g_b))=0$. Take $g_{b_0}=g$ and, for $b\neq b_0$, $g_b\in D_v$ with $\psi_{v,b_0}(g_b)\neq\psi_{v,b}(g_b)$ (by (Pj1)). The factor $b=b_0$ is $-\varepsilon\beta_{b_0}(g)$, the others are $u_b+\varepsilon(\cdot)$ with $u_b\in F^\times$, so as $\varepsilon^2=0$ the entry is $-\varepsilon\beta_{b_0}(g)\prod_{b\neq b_0}u_b$, and $\beta_{b_0}(g)=0$.

- $U_{j,i}$ and $y_{j,i}$: fix j and put $u_i=f_1(U_{j,i})$. By (Vr2) the u_i are pairwise distinct and are the roots of $\det(X-\rho_1(\phi_j))$, so there is $Q\in\mathrm{GL}_n(F)$ with $Q^{-1}\rho_1(\phi_j)Q=\mathrm{diag}(u_1,\dots,u_n)$. Θ kills $\prod_i(\phi_j-U_{j,i})$; conjugating by W and then by Q, the diagonal matrix

$$\prod_i(\mathrm{diag}(u_1,\dots,u_n)-u_i-\varepsilon\delta(U_{j,i}))$$

vanishes, and its i_0-th entry is $-\varepsilon\delta(U_{j,i_0})\prod_{i\neq i_0}(u_{i_0}-u_i)$; so $\delta(U_{j,i_0})=0$ for all i_0, i.e. $\Theta(U_{j,i})=u_i$. Next, $\Theta(\tau_j)=W\rho_1(\tau_j)W^{-1}=1$ as $h(\tau_j)=1$, and $\Theta(y_{j,i})=\varepsilon\delta(y_{j,i})$ as $f_1(y_{j,i})=0$. So Θ applied to $\prod_{k\neq i}(\phi_j-U_{j,k})\cdot(\tau_j-1-y_{j,i})$ gives $-\varepsilon\delta(y_{j,i})\,W\prod_{k\neq i}(\rho_1(\phi_j)-u_k)W^{-1}=0$. Conjugating by W and Q, the i-th diagonal entry is $-\varepsilon\delta(y_{j,i})\prod_{k\neq i}(u_i-u_k)$, so $\delta(y_{j,i})=0$.

Step 3: $\delta=0$ on B. Let $B_0\subseteq B$ be the $\mathcal{O}_1$-subalgebra generated by the elements of (Vr2). The set $\{b:\delta(b)=0\}$ contains the image of $\mathcal{O}_1$ and, by the derivation rule, is closed under sums and products; by Step 2, $\delta(B_0)=0$. As B_0 is dense, $B=B_0+\mathfrak{m}_B^r$ for every $r\geq 1$. By Lemma E.92 there is $s_0\geq 0$ with $\delta(\mathfrak{m}_B^r)\subseteq T^{r-1-s_0}A$ for all $r\geq 1$. Given $b\in B$ and $r\geq 1$, write $b=b_0+b_r$ with $b_0\in B_0$, $b_r\in\mathfrak{m}_B^r$; then $\delta(b)=\delta(b_r)\in T^{r-1-s_0}A$. As $\bigcap_r T^{r-1-s_0}A=0$, $\delta(b)=0$.

Step 4: $\alpha=0$. For $b\in B$ and $t\in B\smallsetminus P$, the image e of b/t in $\hat{B}$ satisfies $\hat{b}=\hat{t}\,e$, so $0=\alpha(\hat{b})=\lambda(\hat{t})\alpha(e)+\lambda(e)\alpha(\hat{t})=f_1(t)\alpha(e)$, and $f_1(t)\neq 0$; thus α vanishes on the image of B_P. Since $\hat{B}$ is the completion of B_P at its maximal ideal, $\hat{B}=(\text{image of }B_P)+\hat{\mathfrak{m}}^2$; and $\alpha(\hat{\mathfrak{m}}^2)=0$, because $\alpha(xx')=\lambda(x)\alpha(x')+\lambda(x')\alpha(x)=0$ for $x,x'\in\hat{\mathfrak{m}}=\ker\lambda$. Hence $\alpha=0$. □

Lemma E.92. *Let $\mathfrak{R}$ be a realisation of a framed normalised curve point x over a level $\mathbf{V}$, and write $\hat{b}$ for the image of $b\in B$ in $\hat{B}$. For every $\alpha\in\mathrm{Tp}$ there is $s_0\geq 0$ such that $\alpha(\hat{b})\in T^{-s_0}A$ for all $b\in B$ and $\alpha(\hat{b})\in T^{j-1-s_0}A$ for all $j\geq 1$ and $b\in\mathfrak{m}_B^j$.*

Proof. Put $\delta(b)=\alpha(\hat{b})$ ($b\in B$). Since $\lambda(\hat{b})=f_1(b)$ (by (Vr4)) and α satisfies the derivation rule, δ is additive with $\delta(bb')=f_1(b)\delta(b')+f_1(b')\delta(b)$. The kernel $P=\ker f_1$ is finitely generated, $P=(p_1,\dots,p_t)$, as B is Noetherian. Given $b\in B$, (Vr4) gives $b'\in B$ with $f_1(b')=f_1(b)$ and $\hat{b}'\in\iota(\mathcal{O}')$, so $\delta(b')=0$ as $\alpha\circ\iota=0$; writing $b-b'=\sum_i c_ip_i$ with $c_i\in B$, $\delta(b)=\sum_i(f_1(c_i)\delta(p_i)+f_1(p_i)\delta(c_i))=\sum_i f_1(c_i)\delta(p_i)$. So $\delta(B)$ lies in the finitely generated A-submodule $\sum_i A\,\delta(p_i)$ of F, hence in $T^{-s_0}A$ for some $s_0\geq 0$. Next, $f_1(\mathfrak{m}_B)\subseteq TA$: $f_1(\mathfrak{m}_B)$ is an ideal of A (f_1 is onto), and it is proper, since $f_1(x)=1$ with $x\in\mathfrak{m}_B$ would give $f_1(1-x)=0$ for the unit $1-x$. For $x_1,\dots,x_j\in\mathfrak{m}_B$, $\delta(x_1\cdots x_j)=\sum_i(\prod_{l\neq i}f_1(x_l))\delta(x_i)\in T^{j-1}T^{-s_0}A$, and every element of $\mathfrak{m}_B^j$ is a finite sum of such products. □

Lemma E.93. *Let $\mathscr{H}$ be a rank-n Hecke datum with $\ell\neq 2$, x a framed normalised curve point of shape $(a,n-a)$ satisfying (Pj1), $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis of x with local witnesses, $\mathbf{V}$ a level over $\mathscr{H}$, $\mathfrak{R}$ a realisation of x over $\mathbf{V}$, and $(m_1,\dots,m_g)$ a family in N dual to κ. Let $\Phi\in\mathrm{Ph}$ and, for $1\leq j\leq g$, $\alpha_j\colon\hat{B}\to F$, $\alpha_j(b)=\Phi(bm_j)-\lambda(b)\Phi(m_j)$. Then $\alpha_j\in\mathrm{Tp}$ for every j, and $(\mathrm{al}(\alpha_1),\dots,\mathrm{al}(\alpha_g))$ lifts.*

Proof. Notation. $\rho_F=\rho\circ h$; $\rho_{1,F}=\rho_1\circ h=(1+\sum_j\epsilon_j(\kappa_j\circ h))\rho_F$, a homomorphism into $\mathrm{GL}_n(\mathrm{PD}_g(F))$ (κ_j are cocycles and $\epsilon_i\epsilon_j=0$); $\gamma^*=c_1\gamma^{-1}c_1$; $\phi g=\phi_{1,v}(g)$ for $g\in D_v$, so

$\rho_F(\phi g) = \rho(\pi g)$, and $T_g = w_v^{-1}\rho(\pi g)w_v$ is upper triangular with diagonal $(\psi_{v,i}(g))_i$; $\hat{b}$ is the image of $b \in B$ in $\hat{B}$; $Y_{j,v} \in \mathrm{Od}_a(A)$ the local witnesses of κ_j; $J = \mathrm{diag}(1_a, -1_{n-a})$, so $JXJ = X$ for $X \in \mathrm{Ev}_a$ and $JXJ = -X$ for $X \in \mathrm{Od}_a$. Two facts on matrices: (F1) since each column of w_v has its non-zero entries in one block, $Jw_v = w_vE_v$ for a diagonal matrix E_v with entries ± 1, and $w_v^{-1}Xw_v$ has zero diagonal for $X \in \mathrm{Od}_a(F)$ (Xw_ve_p lies in the block other than that of w_ve_p, which is spanned by the w_ve_q with $q \neq p$); (F2) $\rho(\gamma^*) = {}^t\rho(\gamma)$ (normalised point), and for each j, from $\kappa_j(\bar{c}\delta\bar{c}) = -{}^t\kappa_j(\delta)$ and the cocycle rule, $\kappa_j(\delta^*) = -{}^t\kappa_j(\delta^{-1}) = {}^t\rho(\delta)\,{}^t\kappa_j(\delta)\,{}^t\rho(\delta)^{-1}$; hence $\rho_{1,F}(\gamma^*) = {}^t\rho_{1,F}(\gamma)$.

Step 1: derivations attached to Φ. For $y \in N$ let $D(y)(b) = \Phi(by) - \lambda(b)\Phi(y)$ ($b \in \hat{B}$), so $\alpha_j = D(m_j)$. We show $D(y) \in \mathrm{Tp}$. Additivity is clear, and $D(y)(\iota(o)) = 0$ as $\Phi \in \mathrm{Ph}$. Every $b \in \hat{B}$ is $\iota(o) + q$ with $q \in \hat{\mathfrak{m}}$ ((Vr4): $\lambda \circ \iota$ is onto, $\ker\lambda = \hat{\mathfrak{m}}$), and $\Phi(\iota(o)y') = \lambda(\iota(o))\Phi(y')$, $\Phi(\hat{\mathfrak{m}}^2N) = 0$ (as $\hat{\mathfrak{m}}^2 \subseteq \mathfrak{a}$). For $b = \iota(o) + q$, $b' = \iota(o') + q'$ this gives $D(y)(bb') = \lambda(\iota o)\Phi(q'y) + \lambda(\iota o')\Phi(qy) = \lambda(b)D(y)(b') + \lambda(b')D(y)(b)$. For $c \in \mathrm{ired}(N) \subseteq \mathfrak{a} \cap \hat{\mathfrak{m}}$, $D(y)(c) = 0$. So $D(y) \in \mathrm{Tp}$. Moreover D is additive in y, and $D(cy) = \lambda(c)D(y)$ for $c \in \hat{B}$ (rewrite the derivation rule for $D(y)$ at (b, c)). Hence D vanishes on $\hat{\mathfrak{m}}N$; as N is a finitely generated $\hat{B}$-module ((Vr5)), the F-span W of $D(N)$ is finite-dimensional. Let $\beta_1, \dots, \beta_e$ be a basis of W and define $\mu_k \colon N \to F$ by $D(y) = \sum_k \mu_k(y)\beta_k$; then $\mu_k \in \mathrm{La}$, and

$$\Phi(by) = \lambda(b)\Phi(y) + \sum_{k=1}^{e} \beta_k(b)\mu_k(y) \qquad (b \in \hat{B},\ y \in N). \tag{$\star$}$$

Put $c_{kj} = \mu_k(m_j)$; then $\alpha_j = \sum_k c_{kj}\beta_k$, so $\mathrm{al}(\alpha_j) = \sum_k c_{kj}A_k$ with $A_k = \mathrm{al}(\beta_k)$ (Lemma E.87).

Step 2: the test deformation. Let $\theta \colon \mathcal{A} \to \mathrm{PD}_e(F)$, $\theta(b \cdot 1 + y) = \lambda(b) + \sum_k \epsilon'_k\beta_k(b) + \sum_k \epsilon_k\mu_k(y) + \eta\,\Phi(y)$. It is a ring homomorphism: for $y, y' \in N$, $yy' = c \cdot 1$ with $c \in \mathrm{ired}(N)$, killed by λ and the β_k; $\theta(y)\theta(y') = 0$; and the η-component of $\theta(b)\theta(y')$ is $\sum_k \beta_k(b)\mu_k(y')$, which by $(\star)$ is the η-component $\Phi(by') - \lambda(b)\Phi(y')$ needed, the other components matching by the derivation rule and $\mu_k \in \mathrm{La}$. Let $u(\gamma) = \theta(\nu(\gamma))$. By (Vr6), u is a homomorphism $\Gamma_1^0 \to \mathrm{GL}_n(\mathrm{PD}_e(F))$ and

$$u(\gamma) = \Big(1 + \sum_k \epsilon_k\,\mathrm{la}(\mu_k)(\gamma) + \sum_k \epsilon'_kA_k(\gamma) + \eta\,\Xi(\gamma)\Big)\rho_F(\gamma), \qquad \Xi(\gamma) = \big(\Phi(\mathrm{pr}_1(\nu(\gamma)_{pq}))\big)_{pq}\rho_F(\gamma)^{-1}.$$

Further: (U1) $u(\gamma^*) = {}^tu(\gamma)$ ((Vr6)); (U2) $u(\gamma) = 1$ for $\gamma \in I_{1,u}$ ($\gamma - 1 \in \mathcal{I}_1$); (U3) for $v \in S_\ell$ and $g_1, \dots, g_n \in D_v$, $\prod_i(u(\phi g_i) - \vartheta_{v,i}(g_i)) = 0$ with the homomorphisms $\vartheta_{v,i} = \theta \circ \hat{\psi}_{v,i} \colon D_v \to \mathrm{PD}_e(F)^\times$ (the ordinary elements of (Vr3) lie in $\mathcal{I}_1$); here $\vartheta_{v,i}(g) = \psi_{v,i}(g) + \sum_k \epsilon'_k\beta_k(\hat{\psi}_{v,i}(g))$, and $\vartheta_{v,i}(g) = \psi_{v,i}(g)$ for $g \in \mu_v$, since then $\hat{\psi}_{v,i}(g)$ lies in the image of $\mathcal{O}$ ((Vr1)), hence in $\iota(\mathcal{O}')$ ((Vr4)), where the β_k vanish; (U4) let σ_e be the ring automorphism of $\mathrm{PD}_e(F)$ with $\epsilon_k \mapsto -\epsilon_k$, $\epsilon'_k \mapsto \epsilon'_k$, $\eta \mapsto -\eta$, and $\tau_e(X) = J\sigma_e(X)J$ on matrices; by the shape clause of (Vr6) (entries in $\hat{B} \cdot 1$ at same-block positions, in N at the others), $\tau_e(u(\gamma)) = u(\gamma)$.

Step 3: conjugation. As (m_j) is dual to κ, $\mathrm{la}(\mu_k) = K_k + \rho_FZ_k\rho_F^{-1} - Z_k$ with $K_k = \sum_j c_{kj}(\kappa_j \circ h)$, $Z_k \in \mathrm{Od}_a(F)$, ${}^tZ_k = -Z_k$. Let $G = 1 + \sum_k \epsilon_kZ_k$; then $G^{-1} = 1 - \sum_k \epsilon_kZ_k = {}^tG$ and $\tau_e(G) = G$. Put $u'(\gamma) = Gu(\gamma)G^{-1}$. Expanding (only $\epsilon_k\epsilon'_k = \eta$ survives among products),

$$u'(\gamma) = \Big(1 + \sum_k \epsilon_kK_k(\gamma) + \sum_k \epsilon'_kA_k(\gamma) + \eta\,\Xi'(\gamma)\Big)\rho_F(\gamma), \qquad \Xi' = \Xi + \sum_k \big(Z_kA_k - A_k\rho_FZ_k\rho_F^{-1}\big).$$

u' is a homomorphism satisfying (U1) (as ${}^tG = G^{-1}$), (U2), (U3) (the $\vartheta_{v,i}$ are scalars) and $\tau_e(u') = u'$.

Step 4: transfer to $\mathrm{PD}_g(F)$. Let $\mathrm{PD}' = F \oplus \bigoplus_{j=1}^{g} F\tilde{\epsilon}_j \oplus \bigoplus_{k=1}^{e} F\tilde{\epsilon}'_k \oplus F\tilde{\eta}$ with $\tilde{\epsilon}_j\tilde{\epsilon}'_k = c_{kj}\tilde{\eta}$ and all other products of two of $\tilde{\epsilon}_j, \tilde{\epsilon}'_k, \tilde{\eta}$ zero, a commutative F-algebra. The F-linear maps

$\omega_e\colon \mathrm{PD}' \to \mathrm{PD}_e(F)$, $\tilde\epsilon_j \mapsto \sum_k c_{kj}\epsilon_k$, $\tilde\epsilon'_k \mapsto \epsilon'_k$, $\tilde\eta \mapsto \eta$, and $\omega_g\colon \mathrm{PD}' \to \mathrm{PD}_g(F)$, $\tilde\epsilon_j \mapsto \epsilon_j$, $\tilde\epsilon'_k \mapsto \sum_j c_{kj}\epsilon'_j$, $\tilde\eta \mapsto \eta$, fixing F, are ring homomorphisms (both send $\tilde\epsilon_j\tilde\epsilon'_k$ to $c_{kj}\eta$). Let $\mathfrak{n}' = \bigoplus_k F\tilde\epsilon'_k \oplus F\tilde\eta$; ω_e maps $\mathfrak{n}'$ isomorphically onto $\mathfrak{n}_e = \bigoplus_k F\epsilon'_k \oplus F\eta$. Hence:

(P) a matrix over PD' whose components in F and in the $F\tilde\epsilon_j$ vanish and whose image under ω_e is 0 is 0.

Let σ' be the automorphism of PD' with $\tilde\epsilon_j \mapsto -\tilde\epsilon_j$, $\tilde\epsilon'_k \mapsto \tilde\epsilon'_k$, $\tilde\eta \mapsto -\tilde\eta$, $\tau'(X) = J\sigma'(X)J$, and σ_g, τ_g likewise on $\mathrm{PD}_g(F)$; ω_e, ω_g intertwine them. Put

$$\tilde u(\gamma) = \Big(1 + \sum_j \tilde\epsilon_j \kappa_j(h\gamma) + \sum_k \tilde\epsilon'_k A_k(\gamma) + \tilde\eta\, \Xi'(\gamma)\Big)\rho_F(\gamma), \qquad \text{so } \omega_e(\tilde u) = u'.$$

$\tilde u$ is a homomorphism: in $\tilde u(\gamma\gamma') - \tilde u(\gamma)\tilde u(\gamma')$ the F-component vanishes (ρ_F is a homomorphism), the $\tilde\epsilon_j$-component is $(\kappa_j(h\gamma\gamma') - \kappa_j(h\gamma) - \rho(h\gamma)\kappa_j(h\gamma')\rho(h\gamma)^{-1})\rho_F(\gamma\gamma') = 0$, and the image under ω_e is 0 as u' is a homomorphism; apply (P). In the same way (P), (F2), (U1)–(U2) for u', $\kappa_j \in \mathrm{Od}_a$ and $\tau_e(u') = u'$ give $\tilde u(\gamma^*) = {}^t\tilde u(\gamma)$, $\tilde u = 1$ on $I_{1,u}$ (ρ is trivial on $I_u^x = h(I_{1,u})$ and κ_j vanishes there), and $\tau'(\tilde u) = \tilde u$. Let $u'' = \omega_g(\tilde u)$. Then u'' is a homomorphism with $u''(\gamma^*) = {}^t u''(\gamma)$, $u'' = 1$ on $I_{1,u}$, $\tau_g(u'') = u''$, and

$$u''(\gamma) = \Big(1 + \sum_j \epsilon_j \kappa_j(h\gamma) + \sum_j \epsilon'_j\, \mathrm{al}(\alpha_j)(\gamma) + \eta\, \Xi'(\gamma)\Big)\rho_F(\gamma),$$

using $\sum_k c_{kj}A_k = \mathrm{al}(\alpha_j)$ (Step 1).

Step 5: the lift Ψ. Let $\mathrm{E} = \bigoplus_j F\epsilon'_j \oplus F\eta \subseteq \mathrm{PD}_g(F)$, an ideal with $\mathrm{E}^2 = 0$, and $\Psi(\gamma) = u''(\gamma)\rho_{1,F}(\gamma)^{-1} - 1$. Since $\rho_{1,F}^{-1} = \rho_F^{-1}(1 - \sum_j \epsilon_j\kappa_j \circ h)$,

$$\Psi(\gamma) = \sum_j \epsilon'_j\, \mathrm{al}(\alpha_j)(\gamma) + \eta\Big(\Xi'(\gamma) - \sum_j \mathrm{al}(\alpha_j)(\gamma)\,\kappa_j(h\gamma)\Big) \in \mathrm{M}_n(\mathrm{E}),$$

so the ϵ'_j-coefficient of Ψ is $\mathrm{al}(\alpha_j)$. From $u''(\gamma\gamma') = u''(\gamma)u''(\gamma')$ and $\mathrm{E}^2 = 0$: $\Psi(\gamma\gamma') = \Psi(\gamma) + \rho_{1,F}(\gamma)\Psi(\gamma')\rho_{1,F}(\gamma)^{-1}$. From $u''(\gamma^*) = {}^t u''(\gamma)$ and (F2): $\Psi(\gamma^*) = {}^t\rho_{1,F}(\gamma)\,{}^t\Psi(\gamma)\,{}^t\rho_{1,F}(\gamma)^{-1}$; applied to γ^{-1} (note $c_1\gamma c_1 = (\gamma^{-1})^*$) together with $\Psi(\gamma^{-1}) = -\rho_{1,F}(\gamma)^{-1}\Psi(\gamma)\rho_{1,F}(\gamma)$, this gives $\Psi(c_1\gamma c_1) = -{}^t\Psi(\gamma)$. Ψ vanishes on $I_{1,u}$. As τ_g fixes u'' and $\rho_{1,F}$, it fixes Ψ; the τ_g-fixed elements of $\mathrm{M}_n(\mathrm{E})$ are those with same-block entries in $\bigoplus_j F\epsilon'_j$ and different-block entries in $F\eta$, i.e. $\mathrm{PW}_a^2(F)$. Over $\mathrm{PD}_g(F)$ the ideal generated by T is the whole ring, so continuity is void.

Step 6: Ψ is bounded. The maps $\mathrm{al}(\alpha_j)$ are bounded (Lemma E.88), and so are $\kappa_j \circ h$, $\rho_F^{\pm1}$ (entries in A, continuous) and the constants Z_k; products and sums of bounded maps are bounded. It remains to bound $\gamma \mapsto (\Phi(\mathrm{pr}_1(\nu(\gamma)_{pq})))_{pq}$. By (Vr8), $\nu(\Gamma_1^0) \subseteq \mathcal{P}_0 = \sum_r BP_r$ (finitely many P_r). For $P = \sum_r b_r P_r$ with $b_r \in B$ and $q_r = \mathrm{pr}_1((P_r)_{pq})$, $(\star)$ gives $\Phi(\mathrm{pr}_1(P_{pq})) = \sum_r (f_1(b_r)\Phi(q_r) + \sum_k \beta_k(\hat b_r)\mu_k(q_r))$. By Lemma E.92 (for each β_k) there is s such that these values lie in $T^{-s}A$ for all $P \in \mathcal{P}_0$, and in $T^{j-1-s}A$ when all $b_r \in \mathfrak{m}_B^j$ (then $f_1(b_r) \in T^jA$). As $\nu(\gamma\upsilon) - \nu(\gamma) \in \mathfrak{m}_B^j\mathcal{P}_0$ for $\upsilon \in V_j$ ((Vr8)), T^s times these entries lie in A and are T-adically continuous.

Step 7: the local condition at $v \in S_\ell$. Let $\tilde w = (1 - \sum_j \tilde\epsilon_j Y_{j,v})w_v$, so $\omega_g(\tilde w) = w_v^1$ and $w^e := \omega_e(\tilde w) = (1 - \sum_k \epsilon_k Y_k^e)w_v$ with $Y_k^e = \sum_j c_{kj}Y_{j,v}$. For $g \in D_v$ let $r_0(g) = (w^e)^{-1}(1 + \sum_k \epsilon_k K_k(\phi g))\rho_F(\phi g)w^e$ and $r_1(g) = (w^e)^{-1}u'(\phi g)w^e$, homomorphisms $D_v \to \mathrm{GL}_n(\mathrm{PD}_e(F))$ with $r_1 - r_0 \in \mathrm{M}_n(\mathfrak{n}_e)$. Expanding, $r_0(g) = T_g + \sum_k \epsilon_k M_k(g)T_g$ with $M_k(g) = \sum_j c_{kj}\, w_v^{-1}(\kappa_j(\pi g) - \rho(\pi g)Y_{j,v}\rho(\pi g)^{-1} + Y_{j,v})w_v$, upper triangular by (Sd2) of Definition E.34 and with zero diagonal by (F1) (the bracket lies in $\mathrm{Od}_a(F)$); so $r_0(g)$ is upper

triangular with diagonal $(\psi_{v,i}(g))_i$. Apply Lemma E.86 with $R = \mathrm{PD}_e(F)$, $R \to F$ the constant part (kernel nilpotent), $\mathfrak{n} = \mathfrak{n}_e$, the group D_v, r_0, r_1, $\vartheta_{0,i} = \psi_{v,i}$ and $\vartheta_{1,i} = \vartheta_{v,i}$: hypothesis 1 was just shown, 2 is (Pj1), 3 is (U3) for u' conjugated by w^e. It gives $Y_e \in \mathrm{M}_n(\mathfrak{n}_e)$ such that $X(g) = r_1(g)r_0(g)^{-1} - 1 - (r_0(g)Y_e r_0(g)^{-1} - Y_e)$ is upper triangular with diagonal entries $d_i(g) = (\vartheta_{v,i}(g) - \psi_{v,i}(g))\psi_{v,i}(g)^{-1} \in \mathfrak{n}_e$, and $d_i(g) = 0$ for $g \in \mu_v$ by (U3). Let $\tilde{Y} \in \mathrm{M}_n(\mathfrak{n}')$ with $\omega_e(\tilde{Y}) = Y_e$, $\tilde{r}_0(g) = \tilde{w}^{-1}(1+\sum_j \tilde{\epsilon}_j\kappa_j(\pi g))\rho_F(\phi g)\tilde{w}$, $\tilde{r}_1(g) = \tilde{w}^{-1}\tilde{u}(\phi g)\tilde{w}$, and $\tilde{X}(g)$ the analogue of $X(g)$; its entries lie in $\mathfrak{n}'$ (as $\tilde{u} \equiv (1 + \sum_j \tilde{\epsilon}_j\kappa_j \circ h)\rho_F$ modulo $\mathfrak{n}'$) and $\omega_e(\tilde{X}(g)) = X(g)$, so $\tilde{X}(g)$ is upper triangular with diagonal entries $\tilde{d}_i(g) = (\omega_e|_{\mathfrak{n}'})^{-1}(d_i(g))$, zero for $g \in \mu_v$. Applying ω_g and putting $Y^\flat = w_v^1\,\omega_g(\tilde{Y})\,(w_v^1)^{-1} \in \mathrm{M}_n(\mathrm{E})$,

$$\omega_g(\tilde{X}(g)) = (w_v^1)^{-1}\big(\Psi(\phi g) - \rho_{1,F}(\phi g)Y^\flat\rho_{1,F}(\phi g)^{-1} + Y^\flat\big)w_v^1$$

is upper triangular with diagonal entries $\omega_g(\tilde{d}_i(g)) \in \bigoplus_j F\epsilon'_j$, zero for $g \in \mu_v$ (indeed $d_i(g) = \sum_k \epsilon'_k\beta_k(\hat{\psi}_{v,i}(g))\psi_{v,i}(g)^{-1}$ has no η-component, so $\tilde{d}_i(g) \in \bigoplus_k F\bar{\epsilon}'_k$, which ω_g maps into $\bigoplus_j F\epsilon'_j$; this is what makes the prescribed diagonal entries fixed by σ_g below). The set $\mathcal{Z}$ of $Y \in \mathrm{M}_n(\mathrm{E})$ for which, for all $g \in D_v$, $(w_v^1)^{-1}(\Psi(\phi g) - \rho_{1,F}(\phi g)Y\rho_{1,F}(\phi g)^{-1} + Y)w_v^1$ is upper triangular with these diagonal entries is an affine subspace containing $Y^\flat$. It is τ_g-stable: τ_g fixes Ψ, $\rho_{1,F}$ and the elements of $\bigoplus_j F\epsilon'_j$, and $\tau_g(w_v^1) = (1-\sum_j \epsilon_j Y_{j,v})Jw_vJ = w_v^1E_vJ$ by (F1) and $JY_{j,v}J = -Y_{j,v}$, so $\tau_g((w_v^1)^{-1}Mw_v^1) = (E_vJ)(w_v^1)^{-1}\tau_g(M)w_v^1(E_vJ)$ with E_vJ diagonal of entries ±1, which preserves triangularity and diagonal entries. As 2 is invertible, $\frac{1}{2}(Y^\flat + \tau_g(Y^\flat)) \in \mathcal{Z}$ is τ_g-fixed, hence lies in $\mathrm{PW}_a^2(F)$; it is a witness for Ψ at v.

Hence $\Psi \in \mathrm{Sel}_{\mathbf{V}}^{2,\mathrm{b}}(F)$ with ϵ'_j-coefficient $\mathrm{al}(\alpha_j)$ for every j: the tuple $(\mathrm{al}(\alpha_1), \dots, \mathrm{al}(\alpha_g))$ lifts. □

E.4 Selmer bounds at the Taylor–Wiles levels

This section proves the two Selmer bounds along a Taylor–Wiles datum, the first-order dual Selmer bound (B1) (Proposition E.97) and the obstruction bound (B2) (Proposition E.119), and from them the conditions (K1)–(K3) at the patched level (Proposition E.94). Proposition E.97 is used in Proposition E.39 and Corollary E.66; Proposition E.94 is used in Corollary E.66 and Proposition E.134. The bounds come from Selmer counts at the levels, with the Greenberg–Wiles formula (Proposition E.100) and Mazur's finiteness condition for the Galois groups of a Hecke datum (Lemma E.116).

E.4.1 The patched level and the first-order dual Selmer bound

This subsection proves Proposition E.94 and Proposition E.97. The dual Selmer bound compares the c-symmetric cocycles at a level (Proposition E.98) with the local and global bounds for the modules of first-order matrices (Proposition E.105), using local Tate duality; the Greenberg–Wiles inequality at the levels is Proposition E.99, the ordinary local condition above ℓ has the expected size (Lemma E.111), and local conditions of Steinberg type are the unramified ones and are self-dual (Lemma E.103). The patched level is a limit of the levels, on whose pro-ℓ kernels the Selmer cocycles vanish (Lemma E.95, Lemma E.96); its conditions (K1)–(K3) follow from (B1), (B2) and the lemmas of Subsection E.4.2. The lemma E.116 is used again in Section E.5.

Proposition E.94. *Let $\mathscr{H}$, $\mathcal{O}$, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ with frame $((w_v), (I_u^x))$, κ with local witnesses, and a Taylor–Wiles datum of size q (with H, $\sigma_1, \dots, \sigma_q$) satisfy all hypotheses of Proposition E.97, and let $(\Pi, (\pi_N), \mathcal{U}, \bar{\theta}, c_\infty, (\Phi_j), (\mathrm{T}_j), (F_w))$ be limit objects for this Taylor–Wiles datum as in the conclusion of Lemma E.42. Put*

$$\Gamma_\infty = \{(g,\gamma) \in \bar{\Gamma}_\infty \times \Gamma_{\mathscr{H}} :\ \bar{\theta}(g) = \bar{\gamma}\}, \qquad h(g,\gamma) = \gamma, \qquad c'_\infty = (c_\infty, \pi_{\mathscr{H}}(c)),$$

*($\bar\gamma$ the image of γ in $\bar\Gamma$), $\phi_{\infty,v}(y) = (F_v(y), \pi_{\mathscr H}(y))$ for $v \in S_\ell$ and $y \in D_v$, $I_{\infty,u} = \{(F_u(y), \pi_{\mathscr H}(y)) : \ y \in I_{\bar u} \cap G_L \cap \pi_{\mathscr H}^{-1}(I_u^x)\}$ for $u \in \mathrm{St}$, $\phi_j = (\Phi_j, \sigma_j)$, $\tau_j = (\mathrm{T}_j, 1)$ ($1 \le j \le q$) and $P_1 = \{1\} \times \mathrm{PL}(H)$. Then $\mathbf{V}_\infty = (\Gamma_\infty, h, c'_\infty, (\phi_{\infty,v}), (I_{\infty,u}))$ is a level over $\mathscr H$, the **limit level formed from these limit objects**; $\phi_j, \tau_j \in \Gamma_\infty^0$; P_1 is a closed normal subgroup of Γ_∞ contained in Γ_∞^0; and:*

(P1) *$h(\phi_j) = \sigma_j$, $h(\tau_j) = 1$, $\phi_j\tau_j = \tau_j\phi_j$, and $\ker h$ is the closure of the subgroup generated by the conjugates of $\tau_1, \dots, \tau_q$;*

(P2) *Γ_∞/P_1 is topologically finitely generated, $h(P_1) = \mathrm{PL}(H)$, and every element of each of the six Selmer sets of $\mathbf{V}_\infty$ over A and over every A_m vanishes on P_1;*

(P3) *(K1) with $D_0 = n[L^+ : \mathbb{Q}] + nq$, (K2) and (K3) hold at $\mathbf{V}_\infty$;*

(P4) *Γ_∞ and Γ_∞^0 satisfy Φ_ℓ.*

Proof. Let Π, π_N, $\mathcal{U}$, $\bar\Gamma_\infty = \Pi/K_\infty$, π_∞, $\bar\theta$, c_∞, Φ_j, T_j, F_w be the given limit objects, $\theta = \bar\theta \circ \pi_\infty$, and let the notation $\bar\Gamma, \bar\Gamma_N, \bar h_N, \theta_N = \bar h_N \circ \pi_N, \bar\phi_{N,w}$ be as in Lemma E.42; $\bar\Gamma^0$ is the image of $\Gamma^0_{\mathscr H}$.

The level. Γ_∞ is a closed subgroup of $\bar\Gamma_\infty \times \Gamma_{\mathscr H}$, and h is onto as $\bar\theta$ is. $c'_\infty \in \Gamma_\infty$ is an involution with $h(c'_\infty) = \pi_{\mathscr H}(c)$, by (L2) ($c_\infty^2 = 1$, $\bar\theta(c_\infty) = \bar c$). $\phi_{\infty,v}$ ($v \in S_\ell$) is a continuous homomorphism into Γ_∞^0 with $h \circ \phi_{\infty,v} = \pi_{\mathscr H}|_{D_v}$, by (L2) ($\bar\theta \circ F_v = \overline{\pi_{\mathscr H}}|_{D_v}$). For $u \in \mathrm{St}$ put $J'_u = I_{\bar u} \cap G_L \cap \pi_{\mathscr H}^{-1}(I_u^x)$, a closed subgroup of D_u; then $I_{\infty,u} = \{(F_u(y), \pi_{\mathscr H}(y)) : \ y \in J'_u\}$ is a closed subgroup of Γ_∞^0 (it lies in Γ_∞ by (L2)) with $h(I_{\infty,u}) = I_u^x$ (as $I_u^x \subseteq \pi_{\mathscr H}(I_{\bar u} \cap G_L)$). So $\mathbf{V}_\infty$ is a level. $P_1 = \{1\} \times \mathrm{PL}(H)$ lies in Γ_∞ (as $\bar\theta(1) = 1$ is the image of $\mathrm{PL}(H)$ in $\bar\Gamma$), in Γ_∞^0 since $\mathrm{PL}(H) \subseteq H \subseteq \Gamma^0_{\mathscr H}$, and is closed and normal in Γ_∞ as $\mathrm{PL}(H)$ is closed and normal in $\Gamma_{\mathscr H}$.

(P1). By (L2), $\phi_j, \tau_j \in \Gamma_\infty$, $h(\phi_j) = \sigma_j$, $h(\tau_j) = 1$, and they commute. $\ker h = \ker\bar\theta \times \{1\}$, and conjugation by (g, γ) maps $(\mathrm{T}_j, 1)$ to $(g\mathrm{T}_j g^{-1}, 1)$; so by (L2) $\ker h$ is the closure of the subgroup generated by the conjugates of the τ_j.

(P2). The first projection $\Gamma_\infty \to \bar\Gamma_\infty$ is onto with kernel P_1, and $\bar\Gamma_\infty$ is a quotient of Π. ρ and the κ_j are trivial on $\mathrm{PL}(H)$ (hypothesis and Lemma E.96 (Pv1)), and $\chi_{\mathrm{cyc}} \equiv 1 \bmod \ell$ on H (Tg1); so P_1 acts trivially on all coefficient modules. Over A_m the coefficient modules are finite and killed by ℓ, so Lemma E.95 (with $E = \Gamma_\infty$, $G = \Gamma_{\mathscr H}$, $E' = \Gamma_\infty^0$) shows that every Selmer cocycle vanishes on P_1; over A all reductions modulo T^m vanish there, hence so does the cocycle.

Transfer. Fix m. Let $\mathcal{M}$ be the finitely many modules $\mathrm{PW}^1_a(A_m)$, $\mathrm{PW}^2_a(A_m)$, $\mathrm{Ev}_a(A_m)$, $\mathrm{Od}_a(A_m)$; $\bar\Gamma^0$ acts on each through $(\rho_1, \chi_{\mathrm{cyc}})$ modulo (T^m, ℓ), which factors through $\bar\Gamma^0$ by the above; let $Y_0 \subseteq \bar\Gamma^0$ be an open normal subgroup of $\bar\Gamma$ acting trivially on all of them and contained in $\bar H = H/\mathrm{PL}(H)$. Let $X = \theta^{-1}(Y_0)$, open normal in Π, hence topologically finitely generated, and let V be the closure of $X^\ell[X, X]$: open (as X/V is a finitely generated elementary abelian ℓ-group) and normal in Π (characteristic in X). Let $\Pi^0 = \theta^{-1}(\bar\Gamma^0)$. By (L1) and (L2), for $\mathcal{U}$-many N: $(\ker\pi_N)V = K_\infty V$; $\theta_N \equiv \theta \bmod Y_0$, so $\pi_N^{-1}(\bar\Gamma_N^0) = \Pi^0$ and Π^0 acts on each $M \in \mathcal{M}$ in the same way through θ_N and through θ, with X acting trivially; the lifts of $\bar c_N$ and of c_∞ can be chosen congruent modulo V; and (iv) of (L1) holds for V. Fix such N. By Lemma E.96 (Pv2), every element of a Selmer set of $\mathbf{V}_N$ over A_m vanishes on $\mathrm{PL}(H_N)$, hence is $\bar z \circ$ (projection) for a cocycle $\bar z$ on $\bar\Gamma_N^0$; by (P2) every element of a Selmer set of $\mathbf{V}_\infty$ over A_m is $\bar z \circ$ (first projection) for a cocycle $\bar z$ on $\bar\Gamma_\infty^0$. In both cases $\tilde z = \bar z \circ \pi_N$, resp. $\bar z \circ \pi_\infty$, is a cocycle of Π^0 for the common action; its restriction to X is a homomorphism into a group of exponent ℓ, so it vanishes on V, and as V acts trivially, $\tilde z$ is constant on cosets of $(\ker\pi_N)V = K_\infty V$. Thus both Selmer sets are

identified, via $\bar z \mapsto \tilde z$, with sets of cocycles of the finite group $\Pi^0/K_\infty V$. These sets coincide: the polarisation conditions use conjugation by lifts of $\bar c_N$, resp. c_∞, which agree modulo $K_\infty V$; the conditions at $u \in \mathrm{St}$ (vanishing on $\bar\phi_{N,u}(J'_u)$, resp. $F_u(J'_u)$) and at $v \in S_\ell$ (the witness conditions on the values at $\bar\phi_{N,v}(y)$, resp. $F_v(y)$, with the same matrix $\rho_1(\pi_{\mathscr H} y)$) agree because by (iv) these values are values of $\tilde z$ at elements congruent modulo V. The coboundaries Bd^1 correspond as well (same action). Hence, for $\mathcal U$-many N, there are bijections $\mathrm{Sel}^*_{\mathbf V_N}(A_m) \to \mathrm{Sel}^*_{\mathbf V_\infty}(A_m)$ $(* = 1, \mathrm{ev}, 2)$ mapping Bd^1 onto Bd^1 and compatible with taking ϵ'_j-coefficients and with A-linear combinations.

(P3). By Proposition E.97, (B1) holds with $D_0 = n[L^+ : \mathbb Q] + nq$ and some C; for given m choose N in the $\mathcal U$-set above with $N \geq N_0(m)$ ($\mathcal U$ is non-principal): $\mathrm{Sel}^1_{\mathbf V_\infty}(A_m)$ is finite with $\#\mathrm{Sel}^1_{\mathbf V_\infty}(A_m) \leq \#\mathrm{Bd}^1_{\mathbf V_\infty}(A_m)(\#k)^{mD_0+C}$. By Proposition E.119 (whose hypotheses are among those of Proposition E.97), (B2) holds with some C; transporting a family $(z_{i,j})$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf V_\infty}(A_m)$ to such a level N, applying (B2) and transporting Ψ back gives the hypothesis of Lemma E.130 at $\mathbf V_\infty$. With (P2), Lemma E.129 gives (K1) and Lemma E.130 gives (K2). The characteristic polynomial of $\rho(\sigma_j)$ has the pairwise distinct roots $\alpha_{j,i} \in A$ (eigenvalue data), so (P1) and Lemma E.131 give (K3).

(P4). We apply Lemma E.132 to $G_1 = \bar\Gamma_\infty$ (a quotient of Π, hence topologically finitely generated), $G_2 = \Gamma_{\mathscr H}$ (which satisfies Φ_ℓ by Lemma E.116), $\bar G = \bar\Gamma = \Gamma_{\mathscr H}/\mathrm{PL}(H)$, $\theta = \bar\theta$, q the projection, and $\bar G_0 = \bar H = H/\mathrm{PL}(H)$, open in $\bar\Gamma$. It remains to see that $H^2(V, \mathbb Z/\ell)$ is finite for every open subgroup V of $\bar H$. Let K, K_*, E be the fixed fields in $\overline{\mathbb Q}$ of $N_{\mathscr H}$, $\pi^{-1}_{\mathscr H}(H)$, $\pi^{-1}_{\mathscr H}(\mathrm{PL}(H))$, so $K_* \subseteq E \subseteq K$, $K_* \supseteq L$ (as $H \subseteq \Gamma^0_{\mathscr H}$) and $\bar H = \mathrm{Gal}(E/K_*)$. (i) *$E$ is the maximal pro-ℓ extension of K_* inside K.* For an open normal U of $\Gamma_{\mathscr H}$ as in the definition of $\mathrm{PL}(H)$, $H/(H \cap U)$ is a finite group of ℓ-power exponent, hence an ℓ-group, and $U = H$ is allowed, so $\mathrm{PL}(H) \subseteq H$ and $\bar H$ is pro-ℓ. Conversely, if $W \subseteq H$ is open normal in H with H/W an ℓ-group, its core $W' = \bigcap_g gWg^{-1}$ (finitely many conjugates, all in H as H is normal) is open normal in $\Gamma_{\mathscr H}$ and H/W' embeds into a product of ℓ-groups, so $\mathrm{PL}(H) \subseteq W' \subseteq W$. (ii) *$E/K_*$ is unramified at the finite places not above ℓ.* Let $\bar w \nmid \ell$ and $s \in I_{\bar w} \cap G_{K_*}$; then $s \in G_L$, each $\bar\chi_a(s)$ lies in the multiplicative group of a finite field of characteristic ℓ, so for some m prime to ℓ all $\bar\chi_a(s^m) = 1$ and $s^m \in N_{\mathscr H}$ acts trivially on $K \supseteq E$; the image of s in the pro-ℓ group $\mathrm{Gal}(E/K_*)$ has order dividing m, hence is trivial. (iii) *$E = M$, the maximal pro-ℓ extension of K_* unramified at the finite places not above ℓ.* M is Galois over L^+ (K_* is, H being normal). A generator $s \in I_{\bar w} \cap G_L$ ($\bar w \nmid \ell$, $\bar\chi_a(s) = 1$) of $N_{\mathscr H}$ fixes $K \supseteq K_*$, so its image in $\mathrm{Gal}(M/L^+)$ lies in the inertia group of $\bar w$ in $\mathrm{Gal}(M/K_*)$, which is trivial; hence $N_{\mathscr H}$ fixes M, $M \subseteq K$, and $M \subseteq E$ by (i); $E \subseteq M$ by (i) and (ii). (iv) Let $V = \mathrm{Gal}(E/K'')$ be open in $\bar H$, K''/K_* finite inside E, and S the set of places of K'' above ℓ. E/K'' is pro-ℓ and unramified outside S, so $E \subseteq K''_S(\ell)$. Conversely the Galois closure $\tilde N$ of $K''_S(\ell)$ over K_* is the compositum of the fields $\sigma(K''_S(\ell)) = \sigma(K'')_S(\ell)$ with $\sigma(K'') \subseteq E$; each $\sigma(K'')_S(\ell)E/E$ is Galois pro-ℓ, so $\tilde N/E$ is pro-ℓ, $\tilde N/K_*$ is pro-ℓ (an extension of pro-ℓ groups) and unramified at the finite places not above ℓ; so $\tilde N \subseteq M = E$. Hence $V = G_S(\ell)$ for K'', and $H^2(V, \mathbb Z/\ell)$ is finite by Theorem B.38. So Lemma E.132 applies: Γ_∞ satisfies Φ_ℓ, and so does its open subgroup $\Gamma^0_\infty = h^{-1}(\Gamma^0_{\mathscr H})$ (open subgroups of Γ^0_∞ are open in Γ_∞). □

Lemma E.95. *Let ℓ be a prime, G a profinite group, $H \subseteq G$ an open normal subgroup, E a profinite group with a continuous surjective homomorphism $h\colon E \to G$, and $P_1 \subseteq h^{-1}(H)$ a closed normal subgroup of E such that $h|_{P_1}$ is injective and $h(P_1) = \mathrm{PL}(H)$. Let $E' \subseteq E$ be a subgroup containing $h^{-1}(H)$, M a finite abelian group of ℓ-power order with an action of E' that is trivial on P_1, and $z\colon E' \to M$ a continuous map with $z(\gamma\gamma') = z(\gamma) + \gamma z(\gamma')$. Then z vanishes on P_1. In particular, for $E = E_0 \times_{G/\mathrm{PL}(H)} G$ (fibre product over a continuous surjection $E_0 \to G/\mathrm{PL}(H)$, with h the second projection), this applies to $P_1 = \{1\} \times \mathrm{PL}(H)$.*

Proof. Write $P = \mathrm{PL}(H)$. As P_1 acts trivially, $f = z|_{P_1}$ is a continuous homomorphism, and for $g \in E'$, $p \in P_1$: $z(gpg^{-1}) = z(g) + g\,z(p) + gp\,z(g^{-1}) = g\,z(p)$ (using $z(g^{-1}) = -g^{-1}z(g)$ and $gp\,z(g^{-1}) = g\,z(g^{-1})$). Let $f' = f \circ (h|_{P_1})^{-1} \colon P \to M$, a continuous homomorphism ($h|_{P_1}$ is a continuous bijection of compact spaces, hence a homeomorphism). For $\eta \in H$ choose $g \in h^{-1}(\eta) \subseteq E'$; then $gP_1g^{-1} = P_1$ and $f'(\eta q \eta^{-1}) = g \cdot f'(q)$ for $q \in P$, so $N = \ker f'$ is a closed subgroup of P normalised by H, i.e. normal in H. The group H/N is an extension of H/P by P/N; H/P is pro-ℓ (Lemma E.45 (Pl1)) and P/N embeds in M, a finite ℓ-group; hence H/N is pro-ℓ. So N is the intersection of the open normal subgroups of H containing it, each of ℓ-power index, and therefore $N \supseteq P$ by (Pl1). So $f' = 0$ and z vanishes on P_1. For the fibre product, $\{1\} \times P$ is closed and normal, lies in $h^{-1}(H)$, and the second projection maps it bijectively onto P. □

Lemma E.96. *Let $\mathscr{H}$ be a rank-n Hecke datum, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed normalised curve point of shape $(a, n-a)$ and $\kappa = (\kappa_1, \dots, \kappa_g)$ a Selmer basis of x with local witnesses. Fix a Taylor–Wiles datum with open normal subgroup $H \subseteq \Gamma_{\mathscr{H}}$, and assume that $\rho(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$. Put $H_N = h_N^{-1}(H)$. Then:*

(Pv1) $\mathrm{PL}(H) \subseteq H \subseteq \Gamma^0_{\mathscr{H}}$, *and $\kappa_j(\gamma) = 0$ and $\rho_1(\gamma) = 1$ for $\gamma \in \mathrm{PL}(H)$;*

(Pv2) *for every $N \geq 1$, $h_N(\mathrm{PL}(H_N)) \subseteq \mathrm{PL}(H)$, and for $X = A$ and for $X = A_m$ ($m \geq 1$) every element of $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}_N}(X)$, $\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(X)$, $\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_N}(X)$, $\mathrm{Sel}^{1}_{\mathbf{V}_N}(X)$, $\mathrm{Bd}^{1}_{\mathbf{V}_N}(X)$, $\mathrm{Sel}^{2}_{\mathbf{V}_N}(X)$ vanishes on $\mathrm{PL}(H_N)$; the same holds at the base level with $\mathrm{PL}(H)$.*

Proof. (Pv1). $H \subseteq \Gamma^0_{\mathscr{H}}$ by (Tg1), and $\mathrm{PL}(H) \subseteq H$ by Lemma E.45 (Pl1); so $\rho = 1$ on $\mathrm{PL}(H)$. Fix j and $m \geq 1$. The map $\kappa_j \bmod T^m \colon \Gamma^0_{\mathscr{H}} \to \mathrm{Od}_a(A_m)$ is continuous (its entries are T-adically continuous and A_m is discrete) and a cocycle for the action $\gamma \cdot Z = \rho(\gamma) Z \rho(\gamma)^{-1}$; $\mathrm{Od}_a(A_m)$ is finite of order a power of $\#k$, hence of ℓ, and $\mathrm{PL}(H)$ acts trivially. By Lemma E.45 (Pl2) (with $G = \Gamma_{\mathscr{H}}$, $\Gamma' = \Gamma^0_{\mathscr{H}}$), $\kappa_j \equiv 0 \bmod T^m$ on $\mathrm{PL}(H)$ for every m, so $\kappa_j = 0$ there, and $\rho_1 = (1 + \sum_j \epsilon_j \kappa_j)\rho = 1$ there.

(Pv2). H is open and normal in $\Gamma_{\mathscr{H}}$ and h_N is a continuous surjection, so $h_N(\mathrm{PL}(H_N)) \subseteq \mathrm{PL}(H)$ by (Pl3); also $H_N \subseteq h_N^{-1}(\Gamma^0_{\mathscr{H}}) = \Gamma^0_N$ is open and normal in Γ_N. Hence on $\mathrm{PL}(H_N)$ the maps $\rho \circ h_N$ and $\rho_1 \circ h_N$ are trivial, so $\mathrm{PL}(H_N)$ acts trivially on the matrix modules $\mathrm{Ev}_a(X)$, $\mathrm{Od}_a(X)$, $\mathrm{PW}^1_a(X)$, $\mathrm{PW}^2_a(X)$ by conjugation. A coboundary $\gamma \mapsto \varrho(\gamma) Y \varrho(\gamma)^{-1} - Y$ vanishes where ϱ is trivial; this treats $\mathrm{Bd}^{\mathrm{od}}$ and Bd^1. Let z be an element of one of the four sets of cocycles. For $X = A_m$ the module is finite of ℓ-power order and z is continuous (discrete topology), so (Pl2) (with $G = \Gamma_N$, $\Gamma' = \Gamma^0_N$, H_N) gives $z = 0$ on $\mathrm{PL}(H_N)$. For $X = A$, $z \bmod T^m$ is such a cocycle for $X = A_m$ (entries continuous, values reduced), so it vanishes on $\mathrm{PL}(H_N)$ for every m, hence so does z. The base level is the case $h = \mathrm{id}$, $\Gamma_1 = \Gamma_{\mathscr{H}}$, with (Pv1). □

Proposition E.97. *Let $\mathscr{H}$, $\mathcal{O}$ (a discrete valuation ring), $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$, κ with local witnesses, and a Taylor–Wiles datum of size q (with H and $\sigma_1, \dots, \sigma_q$) along which x has eigenvalue data be as in Proposition E.119, with $\rho(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$. Assume moreover that x satisfies (Np4) and (Pj1) of Definition 50.9, that for every $Z \in \mathrm{Ev}_a(A_k)$ some $T^s Z$ lies in the A_k-span of $\rho(\Gamma')$ (Γ' as in Definition 50.9), and that $\{\sigma_1, \dots, \sigma_q\}$ detects (x, κ). Then (B1) holds for x, κ and the levels $\mathbf{V}_N$ of the datum, with $D_0 = n[L^+ : \mathbb{Q}] + nq$.*

Proof. Write $K = \#k$, $d = [L^+ : \mathbb{Q}]$, and let $M_{N,m}$, $M'_{N,m}$, $b_{N,m}$, Zb_v, ν and the constants c_1', C_v, C_q, c_0, c_2 be as in Proposition E.105 (the action on $M_{N,m}$ is that of Lemma E.107 (Rf2)). Put $C = c_1' + c_2 + \sum_{v \in S_\ell} C_v + qC_q + c_0$; it does not depend on m or N. Fix $m \geq 1$ and let N_0

be an integer at least as large as each of the integers N_0 given by (Bs3) for $j = 1, \dots, q$ and by (Bs6) for this m. Let $N \geq N_0$ and write $M = M_{N,m}$, $M' = M'_{N,m}$.

Step 1: the setting of Proposition E.98. Take $Q = Q_N$ and $T = S_\ell \cup \mathrm{St} \cup Q_N \cup \{v_0\}$, so $T^\circ = \{v_0\}$: by (Tg2) the $v_{N,j}$ lie outside $S_\ell \cup \mathrm{St} \cup \{v_0\}$, are not above ℓ and split in L; v_0 splits in L by (Rd2). Then $\Gamma^{Q_N} = \Gamma_N$ and $\Gamma^{0,Q_N} = \pi^{Q_N}(G_L) = h_N^{-1}(\Gamma^0_{\mathscr{H}})$ (as $\ker h_N = \pi^{Q_N}(N_{\mathscr{H}})$ and $N_{\mathscr{H}} \subseteq G_L$), and $\iota_v = \pi^{Q_N}|_{D_v}$ is the map $\phi_{N,v}$ of the level $\mathbf{V}_N$. By Lemma E.107 (Rf2) and (Bs0), M, M', $b_{N,m}$ satisfy the hypotheses of Proposition E.98 (M is killed by ℓ, as $\mathrm{char}\, k = \ell$). Take the local conditions $\mathcal{L}_v = B^1(D_v, M) + \mathrm{Zb}_v$ ($v \in S_\ell$), $\mathcal{L}_u = Z^1_{J_{\bar{u}}}(M)$ ($u \in \mathrm{St}$), $\mathcal{L}_w = Z^1(D_w, M)$ ($w \in Q_N \cup \{v_0\}$).

Step 2: $\mathrm{Sel}^1_{\mathbf{V}_N}(A_m) \subseteq \mathrm{Sel}$ *and* $\mathrm{Bd}^1_{\mathbf{V}_N}(A_m) = \mathrm{Bd}$ (the sets of Proposition E.98). Let $z \in \mathrm{Sel}^1_{\mathbf{V}_N}(A_m)$. The T-adic topology of A_m is discrete, so z is continuous; it is a cocycle for the action on M restricted to Γ^0_N, and $z(c_N \gamma c_N) = -{}^t z(\gamma) = c_N \cdot z(\gamma)$. For $v \in S_\ell$, with the witness $Y_v \in \mathrm{PW}^1_a(A_m)$ of (Sc) in Definition E.35, the cocycle $g \mapsto z(\iota_v g) - (\iota_v(g) \cdot Y_v - Y_v)$ lies in Zb_v, so $z \circ \iota_v \in \mathcal{L}_v$. For $u \in \mathrm{St}$, $J_{\bar{u}} \subseteq N^{Q_N}$, so $\pi^{Q_N}(J_{\bar{u}}) = \{1\}$ and $z \circ \iota_u$ vanishes on $J_{\bar{u}}$. Hence $z \in \mathrm{Sel}$. The coboundaries agree since ${}^t Y = -Y$ means $c_N \cdot Y = Y$.

Step 3: the local factors. By (Bs2), $\#\mathcal{L}_v \leq \#M \cdot K^{m(n+\nu)d_v + C_v}$. For $u \in \mathrm{St}$, Lemma E.102 (Lb2), (Lb3) give the hypotheses of Lemma E.104, and (Ur1) gives $\#\mathcal{L}_u = \#M$. For $w \in Q_N \cup \{v_0\}$ ($w \nmid \ell$), Theorem B.29 (4) and (2) give

$$\begin{aligned} \#Z^1(D_w, M) &= \#H^1(D_w, M) \cdot \frac{\#M}{\#H^0(D_w, M)} = \#M \cdot \#H^2(D_w, M) \\ &= \#M \cdot \#H^0(D_w, M^\vee) = \#M \cdot \#H^0(D_w, M'), \end{aligned}$$

using the isomorphism $\phi\colon M' \to M^\vee$, $\phi(m') = b_{N,m}(\cdot, m')$: it is injective by non-degeneracy in M', so $\#M' \leq \#M^\vee = \#M$, symmetrically $\#M \leq \#M'$, so ϕ is bijective; and it is Γ_N-equivariant, $(\gamma\phi(m'))(m) = \gamma\, b_{N,m}(\gamma^{-1}m, m') = b_{N,m}(m, \gamma m')$, hence D_w-equivariant through ι_w; so $\#\mathcal{L}_{v_{N,j}} \leq \#M \cdot K^{mn+C_q}$ by (Bs3) and $\#\mathcal{L}_{v_0} \leq \#M \cdot K^{c_0}$ by (Bs4). As $\sum_{v \in S_\ell} d_v = d$,

$$\prod_{w \in T} \#\mathcal{L}_w \leq (\#M)^{\#T} \cdot K^{m(n+\nu)d + mnq + \sum_v C_v + qC_q + c_0}.$$

Step 4: conclusion. The places with full condition include Q_N, so $Z^1_{\mathcal{L},*}$ is contained in the set of (Bs6) and $\#Z^1_{\mathcal{L},*} \leq \#B^1(\Gamma_N, M') \cdot K^{c_2}$. By (Bs1) $\#H^0(\Gamma_N, M) \leq K^{c_1'}$, and by Lemma E.107 (Rf3) (each c_i is an involution outside Γ^0_N, as complex conjugation acts non-trivially on the CM field L) $\prod_{i=1}^d \#M^{c_i=1} \geq K^{m\nu d}$. Inserting these and Step 3 into Proposition E.98 and cancelling $\#B^1(\Gamma_N, M') \cdot (\#M)^{\#T}$:

$$\#\mathrm{Sel} \cdot K^{m\nu d} \leq \#\mathrm{Bd} \cdot K^{m(n+\nu)d + mnq + C}, \qquad \text{i.e.} \qquad \#\mathrm{Sel} \leq \#\mathrm{Bd} \cdot K^{m(nd+nq)+C}.$$

With Step 2, $\mathrm{Sel}^1_{\mathbf{V}_N}(A_m)$ is finite and $\#\mathrm{Sel}^1_{\mathbf{V}_N}(A_m) \leq \#\mathrm{Bd}^1_{\mathbf{V}_N}(A_m) \cdot (\#k)^{mD_0 + C}$ with $D_0 = n[L^+ : \mathbb{Q}] + nq$, for all $N \geq N_0$. This is (B1). □

Proposition E.98. *Let $\mathscr{H}$, Q, T, $(D_w, \iota_w)_{w \in T}$, $c_1, \dots, c_d$ be as in Proposition E.99, and assume that every place of T° splits in L. Put $\bar{c} = \pi^Q(c)$. Let M be a finite abelian group killed by ℓ with a continuous action of Γ^Q, M' a finite abelian group with a continuous action of Γ^Q, and $b\colon M \times M' \to \mu_\ell$ a bi-additive map with $b(\gamma m, \gamma m') = \gamma\, b(m, m')$ (Γ^Q acting on μ_ℓ through χ_{cyc}) that is non-degenerate on both sides. Let $(\mathcal{L}_w)_{w \in T}$ be local conditions for M as in Proposition E.99, and define $Z^1_{\mathcal{L},*}$ there with M' in place of $M^\vee$. Put*

$$\begin{aligned} \mathrm{Sel} = \{ z\colon \Gamma^{0,Q} \to M \text{ continuous} :\ & z(\gamma\gamma') = z(\gamma) + \gamma z(\gamma'), \\ & z(\bar{c}\gamma\bar{c}) = \bar{c}\, z(\gamma),\ z \circ \iota_w \in \mathcal{L}_w\ (w \in T)\}, \\ \mathrm{Bd} = \{ \gamma \mapsto \gamma Y - Y\ (\gamma \in \Gamma^{0,Q}) :\ & Y \in M,\ \bar{c}Y = Y \}. \end{aligned}$$

Then the maps ι_w take values in $\Gamma^{0,Q}$, Sel *is finite,* $\mathrm{Bd} \subseteq \mathrm{Sel}$*, and*

$$\#\mathrm{Sel}\cdot\#B^1(\Gamma^Q,M')\cdot(\#M)^{\#T}\cdot\prod_{i=1}^{d}\#\{m\in M:\ c_i m=m\}\ \le\ \#\mathrm{Bd}\cdot\#H^0(\Gamma^Q,M)\cdot\#Z^1_{\mathcal{L},*}\cdot\prod_{w\in T}\#\mathcal{L}_w.$$

Proof. Write $\Gamma=\Gamma^Q$, $\Gamma^0=\Gamma^{0,Q}$.

Step 0: the groups. $N^Q\subseteq G_L$, so $\Gamma/\Gamma^0\cong G_{L^+}/G_L$ has order 2, Γ^0 is open, $\bar c\notin\Gamma^0$ and $\bar c^2=1$; so $\Gamma=\Gamma^0\sqcup\Gamma^0\bar c$. Every $w\in T$ splits in L (by (Rd2) for $S_\ell\cup\mathrm{St}$, by assumption for Q and T°), so $D_w\subseteq G_L$ and $\iota_w(D_w)\subseteq\Gamma^0$.

Step 1: $M'\cong M^\vee$. The map $\phi\colon M'\to M^\vee$, $\phi(m')=b(\cdot,m')$, is injective (non-degeneracy in M'), so $\#M'\le\#M^\vee=\#M$; symmetrically $\#M\le\#M'$; hence ϕ is bijective. It is Γ-equivariant: $(\gamma\phi(m'))(m)=\gamma\,b(\gamma^{-1}m,m')=b(m,\gamma m')$. So ϕ carries $B^1(\Gamma,M')$, $B^1(D_w,M')$ and $Z^1_{\mathcal{L},*}$ (for M') bijectively onto the same objects for $M^\vee$.

Step 2: Sel *is the set of cocycles in $Z^1_{\mathcal{L}}$ vanishing at $\bar c$.* For $z\in\mathrm{Sel}$ define $\hat z\colon\Gamma\to M$ by $\hat z(\gamma)=\hat z(\gamma\bar c)=z(\gamma)$ $(\gamma\in\Gamma^0)$. It is continuous, and a cocycle: for $\gamma,\gamma'\in\Gamma^0$,

$$\hat z(\gamma\bar c\,\gamma')=z(\gamma\cdot\bar c\gamma'\bar c)=z(\gamma)+\gamma\bar c\,z(\gamma')=\hat z(\gamma\bar c)+\gamma\bar c\,\hat z(\gamma'),$$

and the cases $\hat z(\gamma\gamma'\bar c)$, $\hat z(\gamma\bar c\gamma'\bar c)$ reduce to the same identities. Its restrictions through ι_w are those of z. Conversely the restriction to Γ^0 of a cocycle $\hat z\in Z^1_{\mathcal{L}}$ (of Proposition E.99) with $\hat z(\bar c)=0$ lies in Sel, since $\hat z(\bar c\gamma\bar c)=\hat z(\bar c)+\bar c\,\hat z(\gamma)+\bar c\gamma\,\hat z(\bar c)=\bar c\,\hat z(\gamma)$. So $\mathrm{Sel}\cong\ker\bigl(e\colon Z^1_{\mathcal{L}}\to M,\ \hat z\mapsto\hat z(\bar c)\bigr)$, which is finite by Proposition E.99.

Step 3: the image of e. From $\hat z(\bar c^2)=0$, e takes values in $M^-=\{m:\bar cm=-m\}$. For $Y\in M$ the coboundary $\gamma\mapsto\gamma Y-Y$ lies in $Z^1_{\mathcal{L}}$ (each $\mathcal{L}_w\supseteq B^1(D_w,M)$) and has e-value $\bar cY-Y$; for $m\in M^-$ and $Y=-m/2$ (ℓ odd) this is m. So e maps onto M^-. As ℓ is odd, $M=M^+\oplus M^-$ with $M^+=\{m:\bar cm=m\}$, hence

$$\#\mathrm{Sel}\cdot\#M=\#Z^1_{\mathcal{L}}\cdot\#M^+.$$

Step 4: the coboundaries. $Y\mapsto(\gamma\mapsto\gamma Y-Y)$ maps M^+ onto Bd with kernel $\{Y\in M^+:\gamma Y=Y\ (\gamma\in\Gamma^0)\}=H^0(\Gamma,M)$, so $\#\mathrm{Bd}\cdot\#H^0(\Gamma,M)=\#M^+$. By Step 2 (for $\hat z$ a coboundary of $Y\in M^+$, $e(\hat z)=0$) $\mathrm{Bd}\subseteq\mathrm{Sel}$.

Step 5: conclusion. By Proposition E.99 and Step 1,

$$\#Z^1_{\mathcal{L}}\cdot\#B^1(\Gamma,M')\cdot(\#M)^{\#T}\cdot\prod_i\#M^{c_i=1}\le\#M\cdot\#Z^1_{\mathcal{L},*}\cdot\prod_w\#\mathcal{L}_w.$$

Multiply by $\#M^+$. On the left insert $\#Z^1_{\mathcal{L}}\#M^+=\#\mathrm{Sel}\,\#M$ (Step 3), on the right insert $\#M^+=\#\mathrm{Bd}\,\#H^0(\Gamma,M)$ (Step 4), and cancel $\#M$. □

Proposition E.99. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, Q and $T\supseteq S_\ell\cup\mathrm{St}\cup Q$ as in Lemma E.102, $T^\circ=T\smallsetminus(S_\ell\cup\mathrm{St}\cup Q)$, and $d=[L^+:\mathbb{Q}]$. For each $w\in T$ fix a place $\bar w$ of $\overline{\mathbb{Q}}$ above w, put $D_w=D_{\bar w}\cap G_{L^+}$ and $\iota_w=\pi^Q|_{D_w}\colon D_w\to\Gamma^Q$; let $c_1,\dots,c_d\in\Gamma^Q$ be the images of complex conjugations at the d real places of L^+, one for each place. Let M be a finite abelian group killed by ℓ with a continuous action of Γ^Q, and $M^\vee=\mathrm{Hom}(M,\mu_\ell)$ with $\gamma\phi=\gamma\circ\phi\circ\gamma^{-1}$, Γ^Q acting on μ_ℓ through χ_{cyc}. Let $(\mathcal{L}_w)_{w\in T}$ be subgroups $B^1(D_w,M)\subseteq\mathcal{L}_w\subseteq Z^1(D_w,M)$ (for the action through ι_w) with $\mathcal{L}_u=Z^1_{J_{\bar u}}(M)$ for $u\in\mathrm{St}$ and $\mathcal{L}_t=Z^1(D_t,M)$ for $t\in T^\circ$. Put*

$$Z^1_{\mathcal{L}}=\{z\in Z^1(\Gamma^Q,M):\ z\circ\iota_w\in\mathcal{L}_w\ (w\in T)\},$$
$$Z^1_{\mathcal{L},*}=\{y\in Z^1(\Gamma^Q,M^\vee):\ y\circ\iota_w\in B^1(D_w,M^\vee)\ \text{whenever}\ \mathcal{L}_w=Z^1(D_w,M)\}.$$

Then $Z^1(\Gamma^Q, M)$ and $Z^1(\Gamma^Q, M^\vee)$ are finite and

$$\#Z^1_{\mathcal{L}} \cdot \#B^1(\Gamma^Q, M^\vee) \cdot (\#M)^{\#T} \cdot \prod_{i=1}^{d} \#\{m \in M : \ c_i m = m\} \ \le \ \#M \cdot \#Z^1_{\mathcal{L},*} \cdot \prod_{w \in T} \#\mathcal{L}_w.$$

Proof. Write $F = L^+$ (totally real), $G = G_{F,T_\infty}$ with $T_\infty = T \cup \{\text{archimedean places}\}$, $p\colon G \to \Gamma^Q$ the surjection of Lemma E.102 (Lb1), and regard M, $M^\vee$ as G-modules through p; this is the module $M^\vee$ of Proposition E.100 with $r = 1$, since G acts on μ_ℓ through χ_{cyc}. The map $D_w \to \Gamma^Q$ factors through G, so the local groups $H^i(F_w, \cdot)$ of Proposition E.100 are those of ι_w. Recall ℓ is odd (Definition 50.1).

Step 1: finiteness and passage to G. By Proposition E.101 (Pk1), $H^1(G, M)$ and $H^1(G, M^\vee)$ are finite, and B^1 is a quotient of the finite module, so $Z^1(G, M)$, $Z^1(G, M^\vee)$ are finite; by Lemma E.102 (Lb3) $z \mapsto z \circ p$ embeds $Z^1(\Gamma^Q, \cdot)$ into them, with $B^1(\Gamma^Q, \cdot) \cong B^1(G, \cdot)$ and $H^0(\Gamma^Q, \cdot) = H^0(G, \cdot)$. Let $Z^1_{\mathcal{L}}(G) = \{z \in Z^1(G, M) : \ z|_{D_w} \in \mathcal{L}_w \ (w \in T)\}$; then $z \mapsto z \circ p$ maps $Z^1_{\mathcal{L}}$ injectively into $Z^1_{\mathcal{L}}(G)$, so $\#Z^1_{\mathcal{L}} \le \#Z^1_{\mathcal{L}}(G)$.

Step 2: the local conditions. Put $L_w = \mathcal{L}_w / B^1(D_w, M) \subseteq H^1(F_w, M)$, so $\#L_w = \#\mathcal{L}_w \cdot \#H^0(F_w, M)/\#M$ (as $\#B^1(D_w, M) = \#M/\#H^0(F_w, M)$). For $u \in \mathrm{St}$, Lemma E.102 (Lb2), (Lb3) give the hypotheses of Lemma E.103 for $J = J_{\bar{u}}$, so $L_u = H^1_{J_{\bar{u}}}(M)$ and $L_u^\perp = H^1_{J_{\bar{u}}}(M^\vee)$ by (St2). For w with $\mathcal{L}_w = Z^1(D_w, M)$, $L_w = H^1(F_w, M)$ and $L_w^\perp = 0$ by Theorem B.29 (2).

Step 3: Greenberg–Wiles. Since every $\mathcal{L}_w$ contains $B^1(D_w, M)$, $Z^1_{\mathcal{L}}(G)$ is the full preimage of the Selmer group $H^1_L(M)$ of Proposition E.100 and contains $B^1(G, M)$; so $\#Z^1_{\mathcal{L}}(G) = \#H^1_L(M) \cdot \#M/\#H^0(G, M)$. Let $Z^1_{L^\perp}(G) \subseteq Z^1(G, M^\vee)$ be the preimage of $H^1_{L^\perp}(M^\vee)$; $\#Z^1_{L^\perp}(G) = \#H^1_{L^\perp}(M^\vee) \cdot \#B^1(G, M^\vee)$. Proposition E.100 for F, $S = T_\infty$, $r = 1$ (the archimedean places are the d real places, with $H^0 = M^{c_i=1}$) reads, after inserting $\#L_w$,

$$\#H^1_L(M) \cdot \#H^0(G, M^\vee) \cdot \prod_{i=1}^{d} \#M^{c_i=1} \cdot (\#M)^{\#T} = \#H^1_{L^\perp}(M^\vee) \cdot \#H^0(G, M) \cdot \prod_{w \in T} \#\mathcal{L}_w.$$

Multiplying by $\#M \cdot \#B^1(G, M^\vee)/\#H^0(G, M)$ and dropping the factor $\#H^0(G, M^\vee) \ge 1$:

$$\#Z^1_{\mathcal{L}}(G) \cdot \#B^1(G, M^\vee) \cdot (\#M)^{\#T} \cdot \prod_{i} \#M^{c_i=1} \le \#M \cdot \#Z^1_{L^\perp}(G) \cdot \prod_{w \in T} \#\mathcal{L}_w.$$

Step 4: the dual cocycles come from Γ^Q. Let $y \in Z^1_{L^\perp}(G)$. For $u \in \mathrm{St}$, $[y|_{D_u}] \in L_u^\perp = H^1_{J_{\bar{u}}}(M^\vee)$, so y vanishes on $J_{\bar{u}}$ by Lemma E.103 (St1) for $M^\vee$. For $t \in T^\circ$, $L_t^\perp = 0$, so $y|_{D_t}$ is a coboundary $g \mapsto gm - m$; it vanishes on $I_{\bar{t}} \cap G_{L^+}$, which acts trivially on M (Lb3) and on μ_ℓ ($t \nmid \ell$), hence on $M^\vee$. By (Lb3) for $M^\vee$, $y = y_0 \circ p$ with $y_0 \in Z^1(\Gamma^Q, M^\vee)$, and where $\mathcal{L}_w = Z^1(D_w, M)$, $y_0 \circ \iota_w = y|_{D_w} \in B^1(D_w, M^\vee)$ as $L_w^\perp = 0$. So $y \mapsto y_0$ embeds $Z^1_{L^\perp}(G)$ into $Z^1_{\mathcal{L},*}$, and $\#Z^1_{L^\perp}(G) \le \#Z^1_{\mathcal{L},*}$.

Combining Steps 1, 3, 4 with $\#B^1(G, M^\vee) = \#B^1(\Gamma^Q, M^\vee)$ gives the inequality. □

Proposition E.100. *Let F be a number field and ℓ a prime; assume that ℓ is odd or that F has no real place. Let S be a finite set of places of F containing the places above ℓ and the archimedean places, $S_f \subseteq S$ its finite places, $r \ge 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of $G_{F,S}$. For $v \in S_f$ let*

$$\langle\ ,\ \rangle_v\colon H^1(F_v, M) \times H^1(F_v, M^\vee) \to H^2(F_v, \mu_{\ell^r}) \xrightarrow{\mathrm{inv}_v} \mathbb{Q}/\mathbb{Z}$$

be the cup product pairing. A ***family of local conditions*** *for M is a family $\mathcal{L} = (L_v)_{v\in S_f}$ of subgroups $L_v \subseteq H^1(F_v, M)$; its* ***dual family*** *is $\mathcal{L}^\perp = (L_v^\perp)_{v\in S_f}$, $L_v^\perp \subseteq H^1(F_v, M^\vee)$ the annihilator of L_v under $\langle\ ,\ \rangle_v$; the* ***Selmer groups*** *are*

$$H^1_{\mathcal{L}}(M) = \{x \in H^1(G_{F,S}, M) :\ \mathrm{res}_v(x) \in L_v \text{ for all } v \in S_f\},$$
$$H^1_{\mathcal{L}^\perp}(M^\vee) = \{y \in H^1(G_{F,S}, M^\vee) :\ \mathrm{res}_v(y) \in L_v^\perp \text{ for all } v \in S_f\}.$$

Then $H^1_{\mathcal{L}}(M)$ and $H^1_{\mathcal{L}^\perp}(M^\vee)$ are finite and

$$\#H^1_{\mathcal{L}}(M)\cdot\#H^0(G_{F,S}, M^\vee)\cdot\prod_{v\in S}\#H^0(F_v, M) = \#H^1_{\mathcal{L}^\perp}(M^\vee)\cdot\#H^0(G_{F,S}, M)\cdot\prod_{v\in S_f}\#L_v,$$

where the product on the left runs over all places of S, the archimedean ones included ($H^0(F_v, M)$ is the subgroup fixed by a complex conjugation at a real place v, and M at a complex place).

Proof. Write $H^i(M) = H^i(G_{F,S}, M)$, $P^i(M) = \prod_{v\in S_f} H^i(F_v, M)$, and let $\lambda^i_M\colon H^i(M) \to P^i(M)$ be the product of the restriction maps. Since S contains the places above ℓ and the archimedean places, the extension $F(\mu_{\ell^r})/F$ is unramified outside S, so μ_{ℓ^r} is a $G_{F,S}$-module, and so is $M^\vee$, a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with continuous action; $(M^\vee)^\vee = M$ canonically. The hypothesis that ℓ is odd or F has no real place is the standing hypothesis of Theorem B.37 and of Theorem B.39, so both apply to M and to $M^\vee$; Theorem B.29 holds for every prime ℓ. All groups below are finite: $H^i(M)$, $H^i(M^\vee)$ by Theorem B.37, item 1, and the local groups by Theorem B.29, item 1.

Step 1: the archimedean places drop out. Let v be an archimedean place; $\mathrm{Gal}(\mathbb{C}/F_v)$ has order 1 or 2. If ℓ is odd, M and $M^\vee$ have odd order, so every Tate cohomology group $\hat H^i(F_v, M)$, $\hat H^i(F_v, M^\vee)$ is killed by the order of the group, which divides 2, and by ℓ^r, hence vanishes. If F has no real place, v is complex, $\mathrm{Gal}(\mathbb{C}/F_v)$ is trivial, and every Tate cohomology group of the trivial group vanishes. In either case $H^i(F_v, M) = \hat H^i(F_v, M) = 0$ and $H^i(F_v, M^\vee) = 0$ for $i \geq 1$; hence $\mathrm{Sha}^i_S(F, M) = \ker\lambda^i_M$ and $\mathrm{Sha}^i_S(F, M^\vee) = \ker\lambda^i_{M^\vee}$ for $i = 1, 2$. The Poitou–Tate nine-term sequence of Theorem B.39, item 3, for M has its local terms the products over S_f. By Theorem B.29, item 2, the sum of the pairings $\langle\ ,\ \rangle_v$ is a perfect pairing $P^1(M)\times P^1(M^\vee) \to \mathbb{Q}/\mathbb{Z}$. The part

$$H^1(M) \xrightarrow{\lambda^1_M} P^1(M) \xrightarrow{\beta} H^1(M^\vee)^* \to H^2(M) \xrightarrow{\lambda^2_M} P^2(M) \to H^0(M^\vee)^* \to 0$$

of that sequence is exact, where $\beta(x)(y) = \sum_{v\in S_f}\langle x_v, \mathrm{res}_v(y)\rangle_v$ (the dual of $\lambda^1_{M^\vee}$ composed with local duality). Exactness at $P^1(M)$ says $\mathrm{im}\,\lambda^1_M = \ker\beta = (\mathrm{im}\,\lambda^1_{M^\vee})^\perp$; as the pairing is perfect, also $(\mathrm{im}\,\lambda^1_M)^\perp = \mathrm{im}\,\lambda^1_{M^\vee}$. Exactness at $P^2(M)$ gives $\#\mathrm{im}\,\lambda^2_M = \#P^2(M)/\#H^0(M^\vee)$, hence

$$\#\mathrm{Sha}^2_S(F, M) = \#\ker\lambda^2_M = \frac{\#H^2(M)\,\#H^0(M^\vee)}{\#P^2(M)}. \tag{E.16}$$

Step 2: the local part of the Selmer groups. Put $A = \mathrm{im}\,\lambda^1_M$, $A' = \mathrm{im}\,\lambda^1_{M^\vee} = A^\perp$, $\Lambda = \prod_v L_v \subseteq P^1(M)$, so that $\Lambda^\perp = \prod_v L_v^\perp$. By definition $H^1_{\mathcal{L}}(M) = (\lambda^1_M)^{-1}(\Lambda)$ and $H^1_{\mathcal{L}^\perp}(M^\vee) = (\lambda^1_{M^\vee})^{-1}(\Lambda^\perp)$, so, by Step 1,

$$\#H^1_{\mathcal{L}}(M) = \#\mathrm{Sha}^1_S(F, M)\,\#(A\cap\Lambda),$$
$$\#H^1_{\mathcal{L}^\perp}(M^\vee) = \#\mathrm{Sha}^1_S(F, M^\vee)\,\#(A^\perp\cap\Lambda^\perp).$$

For subgroups of a finite group with a perfect pairing, $A^\perp \cap \Lambda^\perp = (A+\Lambda)^\perp$ has order

$$\#P^1(M)/\#(A+\Lambda) = \#P^1(M)\,\#(A\cap\Lambda)/(\#A\,\#\Lambda).$$

With $\#A = \#H^1(M)/\#\mathrm{Sha}^1_S(F,M)$ this gives

$$\frac{\#H^1_{\mathcal{L}}(M)}{\#H^1_{\mathcal{L}^\perp}(M^\vee)} = \frac{\#H^1(M)\,\#\Lambda}{\#\mathrm{Sha}^1_S(F,M^\vee)\,\#P^1(M)}.$$

Step 3: Sha duality and the Euler characteristics. By Theorem B.39, item 2, applied to $M^\vee$ (whose dual is M), $\#\mathrm{Sha}^1_S(F,M^\vee) = \#\mathrm{Sha}^2_S(F,M)$, given by (E.16). By Theorem B.29, item 4, $\#H^1(F_v,M) = \#H^0(F_v,M)\,\#H^2(F_v,M)\,(\#M)^{[F_v:\mathbb{Q}_\ell]}$ for $v \mid \ell$ and without the last factor otherwise; since $\sum_{v|\ell}[F_v:\mathbb{Q}_\ell] = [F:\mathbb{Q}]$,

$$\#P^1(M) = \#P^0(M)\,\#P^2(M)\,(\#M)^{[F:\mathbb{Q}]}.$$

By Theorem B.37, item 2,

$$\#H^1(M)/\#H^2(M) = \#H^0(M)\prod_{v|\infty}|\#M|_v/\#H^0(F_v,M),$$

and $\prod_{v|\infty}|\#M|_v = (\#M)^{r_1+2r_2} = (\#M)^{[F:\mathbb{Q}]}$, where r_1, r_2 are the numbers of real and complex places ($r_1 = 0$ when F has no real place). Substituting,

$$\begin{aligned}\frac{\#H^1_{\mathcal{L}}(M)}{\#H^1_{\mathcal{L}^\perp}(M^\vee)} &= \frac{\#H^1(M)\,\#P^2(M)\,\#\Lambda}{\#H^2(M)\,\#H^0(M^\vee)\,\#P^0(M)\,\#P^2(M)\,(\#M)^{[F:\mathbb{Q}]}}\\ &= \frac{\#H^0(M)\,\prod_{v\in S_f}\#L_v}{\#H^0(M^\vee)\,\#P^0(M)\,\prod_{v|\infty}\#H^0(F_v,M)},\end{aligned}$$

and $\#P^0(M)\prod_{v|\infty}\#H^0(F_v,M) = \prod_{v\in S}\#H^0(F_v,M)$. Clearing denominators gives the assertion. □

Proposition E.101. *Let F be a totally real number field of degree $d=[F:\mathbb{Q}]$, ℓ an odd prime, S a finite set of places of F containing the places above ℓ and the archimedean places, S_f its finite places, and $G = G_{F,S}$. For each real place u of F let $c_u \in G$ be the image of a complex conjugation at u. By an ℓ-**module** of a profinite group we mean a finite abelian group killed by ℓ with a continuous action. Then:*

(Pk1) *for every ℓ-module M of G, $H^i(G,M)$ is finite for all i and zero for $i\geq 3$; and for every surjective homomorphism $M\to M'$ of ℓ-modules of G, the induced map $H^2(G,M)\to H^2(G,M')$ is surjective;*

(Pk2) *for every $v\in S_f$ and every ℓ-module M of G_{F_v}, $H^i(F_v,M)$ is finite for all i and zero for $i\geq 3$, $H^2(F_v,\cdot)$ is surjective on surjections of ℓ-modules, and $\#H^1(F_v,M) = \#H^0(F_v,M)\,\#H^2(F_v,M)\,(\#M)^{d_v}$ with $d_v=[F_v:\mathbb{Q}_\ell]$ if $v\mid\ell$ and $d_v=0$ otherwise;*

(Pk3) *$c_u^2=1$; if $L\subseteq\overline{\mathbb{Q}}$ is a CM field with $L^+=F$, unramified over F outside S, then c_u acts non-trivially on L; and for every ℓ-module M of G,*

$$\#H^0(G,M)\,\#H^2(G,M)\,(\#M)^d = \#H^1(G,M)\prod_{u\ \text{real}}\#M^{c_u=1};$$

(Pk4) *for every ℓ-module M of G, every subset $T \subseteq S_f$ and every family of surjective G_{F_v}-equivariant homomorphisms $M \to Q_v$ onto ℓ-modules Q_v of G_{F_v} ($v \in T$), the cokernel of*

$$H^2(G, M) \longrightarrow \bigoplus_{v \in T} H^2(F_v, Q_v)$$

(restriction followed by push-forward) has order at most $\#\mathrm{Hom}_G(M, \mu_\ell)$.

Proof. An ℓ-module is a finite $\mathbb{Z}/\ell\mathbb{Z}$-module, so the results used below apply with $r = 1$.

(Pk1). Finiteness is Theorem B.37, item 1. Let $F' = F(\mu_\ell)$. It is totally imaginary (it contains a primitive ℓ-th root of unity, which is not real as ℓ is odd), Galois over F of degree e dividing $\ell - 1$, and unramified outside the places above ℓ; so F' lies in the maximal extension F_S of F unramified outside S and $G' = \mathrm{Gal}(F_S/F')$ is an open normal subgroup of G of index e, equal to $G_{F',S'}$ for the set S' of places of F' above S (every extension of F' inside F_S is unramified outside S', and conversely an extension of F' unramified outside S' is unramified outside S over F). By Theorem B.34, item 3, $H^i(G', M) = 0$ for $i \geq 3$. Corestriction after restriction is multiplication by e on $H^i(G, M)$, which is bijective since e is prime to ℓ and $H^i(G, M)$ is killed by ℓ; hence restriction $H^i(G, M) \to H^i(G', M) = 0$ is injective and $H^i(G, M) = 0$ for $i \geq 3$. For a surjection $M \to M'$ with kernel K (an ℓ-module), the long exact sequence gives $H^2(G, M) \to H^2(G, M') \to H^3(G, K) = 0$.

(Pk2). Finiteness, vanishing for $i \geq 3$ and the Euler characteristic are Theorem B.29, items 1 and 4 (with $[F_v : \mathbb{Q}_\ell] = d_v$ for $v \mid \ell$). Right exactness of H^2 follows from the vanishing of H^3 as in (Pk1).

(Pk3). c_u is the image of an element of order 2, so $c_u^2 = 1$. A CM field L is totally imaginary, so a complex conjugation at any embedding acts non-trivially on it. By Theorem B.37, item 2 (ℓ odd), with $H^0(F_u, M) = M^{c_u=1}$ and $|\#M|_u = \#M$ at the d real places u (and no complex places), $\#H^0(G, M)\,\#H^2(G, M)/\#H^1(G, M) = \prod_u \#M^{c_u=1}/(\#M)^d$, which is the assertion.

(Pk4). Let $\lambda\colon H^2(G, M) \to P^2 = \bigoplus_{v \in S_f} H^2(F_v, M)$ be the restriction and $q\colon P^2 \to \bigoplus_{v \in T} H^2(F_v, Q_v)$ the projection to the components in T followed by the push-forwards; q is surjective by (Pk2). The map of the statement is $q \circ \lambda$, so its cokernel is a quotient of $P^2/\mathrm{im}\,\lambda$ (as q is onto). By Theorem B.37, item 3 (ℓ odd), $P^2/\mathrm{im}\,\lambda \cong H^0(G, M^\vee)^*$, of order $\#H^0(G, M^\vee) = \#\mathrm{Hom}_G(M, \mu_\ell)$. □

Lemma E.102. *Let $\mathscr{H}$ be a rank-n Hecke datum over $\mathcal{O}$, Q a finite set of places of L^+ outside $S_\ell \cup \mathrm{St} \cup \{v_0\}$, not above ℓ and split in L, and T a finite set of finite places of L^+ containing $S_\ell \cup \mathrm{St} \cup Q$; write $T_\infty = T \cup \{\text{archimedean places}\}$ and $T^\circ = T \smallsetminus (S_\ell \cup \mathrm{St} \cup Q)$. For a place $\bar{w}$ of $\overline{\mathbb{Q}}$ above a finite place of L^+ put $J_{\bar{w}} = \{s \in I_{\bar{w}} \cap G_L :\ \bar{\chi}_a(s) = 1\ (1 \leq a \leq n)\}$. Then:*

(Lb1) *π^Q factors as $G_{L^+} \to G_{L^+,T_\infty} \xrightarrow{p} \Gamma^Q$ with p a continuous surjection, and $\ker p$ is the closed normal subgroup of G_{L^+,T_∞} generated by the images of $J_{\bar{u}}$ ($u \in \mathrm{St}$) and of $I_{\bar{t}} \cap G_{L^+}$ ($t \in T^\circ$), for any one choice of places $\bar{u}$ above u and $\bar{t}$ above t;*

(Lb2) *for $u \in \mathrm{St}$ and $\bar{u}$ above u, the decomposition group $D_{\bar{u}} \cap G_{L^+}$ of L^+ at u lies in G_L, and $J_{\bar{u}}$ is a closed subgroup of its inertia group $I_{\bar{u}} \cap G_{L^+}$, normal in $D_{\bar{u}} \cap G_{L^+}$, of finite index prime to ℓ; and for $t \in T^\circ$, $I_{\bar{t}} \cap G_{L^+} = I_{\bar{t}} \cap G_L = J_{\bar{t}}$;*

(Lb3) *for every discrete abelian group M with a continuous action of Γ^Q, regarded as a G_{L^+,T_∞}-module through p, the subgroups $J_{\bar{u}}$ ($u \in \mathrm{St}$) and $I_{\bar{t}}$ ($t \in T^\circ$) act trivially on M, $H^0(\Gamma^Q, M) = H^0(G_{L^+,T_\infty}, M)$, and $z \mapsto z \circ p$ is a bijection from $Z^1(\Gamma^Q, M)$ onto*

$$\{z \in Z^1(G_{L^+,T_\infty}, M) :\ z \text{ vanishes on the images of } J_{\bar{u}}\ (u \in \mathrm{St}) \text{ and of } I_{\bar{t}} \cap G_{L^+}\ (t \in T^\circ)\},$$

mapping $B^1(\Gamma^Q, M)$ onto $B^1(G_{L^+,T_\infty}, M)$.

Proof. Write $G = G_{L^+}$, $\bar{G} = G_{L^+,T_\infty}$ and $\Sigma = \{s \in G_L : \bar{\chi}_a(s) = 1 \ (1 \le a \le n)\}$. By (Rd5) and the remark in Definition 50.1 that the kernels of the $\bar{\chi}_a$ jointly are stable under G_L- and c-conjugation, Σ is a closed normal subgroup of $G = G_L \cup cG_L$. For $g \in G$ and a place $\bar{w}$, $gI_{\bar{w}}g^{-1} = I_{g\bar{w}}$, hence $gJ_{\bar{w}}g^{-1} = J_{g\bar{w}}$; and G acts transitively on the places of $\overline{\mathbb{Q}}$ above a given place of L^+.

Inertia outside $S_\ell \cup \mathrm{St} \cup Q$ lies in N^Q. Let $\bar{w}$ lie above a finite place $w \notin S_\ell \cup \mathrm{St} \cup Q$ of L^+; $w \nmid \ell$ as S_ℓ contains all places above ℓ. By (Rd2) L/L^+ is unramified at w, so $I_{\bar{w}} \cap G$ acts trivially on L, i.e. $I_{\bar{w}} \cap G = I_{\bar{w}} \cap G_L$; by (Rd4) every $\bar{\chi}_a$ is trivial on it. So $I_{\bar{w}} \cap G = J_{\bar{w}}$ consists of generators of N^Q (the place $\bar{w}$ is above neither ℓ nor Q). This proves the last assertion of (Lb2).

(Lb1). The kernel of $G \to \bar{G}$ is the closed normal subgroup generated by the inertia groups $I_{\bar{w}} \cap G$ at places $\bar{w}$ above finite places outside T (its fixed field is the maximal extension of L^+ unramified outside T_∞). By the previous paragraph it lies in N^Q, so π^Q factors through a continuous surjection $p\colon \bar{G} \to \Gamma^Q$, and $\ker p$ is the image of N^Q in $\bar{G}$. The image of the closed normal subgroup generated by a set X under a continuous surjection of profinite groups is the closed normal subgroup generated by the image of X (the image of a closure is closed by compactness and contained in the closure of the image). The generators of N^Q are the elements of $J_{\bar{w}}$ for $\bar{w}$ above neither ℓ nor Q; those above places outside T map to 1; for $\bar{w}$ above $t \in T^\circ$, $J_{\bar{w}} = I_{\bar{w}} \cap G$ by the previous paragraph; the remaining ones lie above St. By the conjugation rule and transitivity, one place above each u and each t suffices.

(Lb2). By (Rd2) u splits in L, so $D_{\bar{u}} \cap G$ fixes L, i.e. lies in G_L. Hence $J_{\bar{u}} = (I_{\bar{u}} \cap G) \cap \Sigma$ is closed and normal in $D_{\bar{u}} \cap G$ (both $I_{\bar{u}} \cap G$ and $\Sigma \cap D_{\bar{u}}$ are normal there). The map $s \mapsto (\bar{\chi}_a(s))_a$ embeds $(I_{\bar{u}} \cap G)/J_{\bar{u}}$ into $(\mathbb{F}_{\mathcal{O}}^\times)^n$, a finite group of order prime to ℓ.

(Lb3). $J_{\bar{u}}$ and $I_{\bar{t}} \cap G = J_{\bar{t}}$ map into $\ker p$ (they generate part of N^Q), so they act trivially on M; and H^0 agrees because p is surjective. Let $K = \ker p$. For $z \in Z^1(\bar{G}, M)$, K acts trivially, so $z|_K$ is a homomorphism, and for $g \in \bar{G}$, $x \in K$:

$$z(gxg^{-1}) = z(g) + g\,z(x) + gx\,z(g^{-1}) = z(g) + g\,z(x) + (gxg^{-1})\,g\,z(g^{-1}) = g\,z(x),$$

since gxg^{-1} acts trivially and $z(g) + g\,z(g^{-1}) = z(1) = 0$. Hence if z vanishes on the images of the $J_{\bar{u}}$ and $I_{\bar{t}} \cap G$, it vanishes on their conjugates, on the subgroup they generate and, being continuous with values in a discrete group, on its closure K (by (Lb1)). A cocycle vanishing on K satisfies $z(gx) = z(g) + g\,z(x) = z(g)$ for $x \in K$, so $z = z_0 \circ p$ for a unique map z_0 on Γ^Q, which is a continuous cocycle (Γ^Q carries the quotient topology). Conversely $z_0 \circ p$ vanishes on K. Coboundaries $g \mapsto gm - m$ correspond to each other. □

Lemma E.103. *Let F be a number field, v a finite place of F whose residue characteristic differs from the prime ℓ, $D = G_{F_v}$, $I = I_v \subseteq D$, and $J \subseteq I$ a closed subgroup, normal in D, of finite index in I prime to ℓ. Let M be a finite abelian group killed by ℓ with a continuous action of D that is trivial on J. Then:*

(St1) *for $z \in Z^1(D, M)$, the class $[z]$ lies in $H^1_J(M)$ if and only if $z|_J = 0$; and $H^1_J(M) = H^1_{\mathrm{ur}}(F_v, M)$ as subgroups of $H^1(F_v, M)$, of order $\#H^0(F_v, M)$;*

(St2) *J acts trivially on $M^\vee$, and $H^1_J(M)$ and $H^1_J(M^\vee)$ are exact annihilators of each other under the cup product pairing $H^1(F_v, M) \times H^1(F_v, M^\vee) \to H^2(F_v, \mu_\ell) \cong \mathbb{Z}/\ell\mathbb{Z}$.*

Proof. (St1). By Lemma E.104 (Ur1), $B^1(D,M) \subseteq Z^1_J(M)$, so $H^1_J(M)$ is a subgroup of $H^1(F_v,M)$ of order $\#H^0(F_v,M)$. A coboundary $g \mapsto gm - m$ vanishes on J since J acts trivially on M; hence if $z = z' + b$ with $z' \in Z^1_J(M)$ and $b \in B^1(D,M)$, then $z|_J = 0$; the converse is the definition. As J acts trivially, $H^1(J,M) = \mathrm{Hom}_{\mathrm{cont}}(J,M)$ and the restriction of $[z]$ is $z|_J$; so

$$H^1_J(M) = \ker\bigl(\mathrm{res}^D_J \colon H^1(D,M) \to H^1(J,M)\bigr).$$

Now $\mathrm{res}^D_J = \mathrm{res}^I_J \circ \mathrm{res}^D_I$, and res^I_J is injective on $H^1(I,M)$: J is normal in I, so by the inflation–restriction sequence its kernel is $H^1(I/J, M^J) = H^1(I/J,M)$, which is killed by the order $[I:J]$ of the finite group I/J and by ℓ, hence is zero as $\ell \nmid [I:J]$. Therefore $\ker \mathrm{res}^D_J = \ker \mathrm{res}^D_I = H^1_{\mathrm{ur}}(F_v,M)$.

(St2), triviality on $M^\vee$. As the residue characteristic of v is not ℓ, $F_v(\mu_\ell)/F_v$ is unramified, so I acts trivially on μ_ℓ. For $g \in J$ and $\phi \in M^\vee$, $(g\phi)(m) = g\,\phi(g^{-1}m) = \phi(m)$. So (St1) applies to the finite group $M^\vee$, killed by ℓ: $H^1_J(M^\vee) = H^1_{\mathrm{ur}}(F_v, M^\vee)$, of order $\#H^0(F_v,M^\vee)$.

Orthogonality. Let $x \in H^1_{\mathrm{ur}}(F_v,M)$, $y \in H^1_{\mathrm{ur}}(F_v,M^\vee)$. By the inflation–restriction sequence for $I \trianglelefteq D$, $x = \inf(x_0)$ and $y = \inf(y_0)$ with $x_0 \in H^1(D/I, M^I)$, $y_0 \in H^1(D/I, (M^\vee)^I)$. Cup products commute with inflation, so $x \cup y = \inf(x_0 \cup y_0)$ with $x_0 \cup y_0 \in H^2(D/I, \mu_\ell)$ for the pairing $M^I \times (M^\vee)^I \to \mu_\ell$. The group $D/I \cong \hat{\mathbb{Z}}$ has cohomological dimension 1 ([222], I.3.2, II.1), so $H^2(D/I,\mu_\ell) = 0$ and $x \cup y = 0$. Hence $H^1_{\mathrm{ur}}(F_v,M^\vee) \subseteq H^1_{\mathrm{ur}}(F_v,M)^\perp$.

Equality by counting. By Theorem B.29 (2) the pairing on H^1 is perfect, so $\#H^1(F_v,M^\vee) = \#H^1(F_v,M)$ and

$$\begin{aligned}\#H^1_{\mathrm{ur}}(F_v,M)^\perp &= \frac{\#H^1(F_v,M)}{\#H^1_{\mathrm{ur}}(F_v,M)} = \frac{\#H^1(F_v,M)}{\#H^0(F_v,M)} \\ &= \#H^2(F_v,M) = \#H^0(F_v,M^\vee) = \#H^1_{\mathrm{ur}}(F_v,M^\vee),\end{aligned}$$

using (St1) for M, Theorem B.29 (4) for $v \nmid \ell$, Theorem B.29 (2) with $i = 0$, and (St1) for $M^\vee$. So $H^1_{\mathrm{ur}}(F_v,M)^\perp = H^1_{\mathrm{ur}}(F_v,M^\vee)$; as the pairing is perfect, also $H^1_{\mathrm{ur}}(F_v,M^\vee)^\perp = H^1_{\mathrm{ur}}(F_v,M)$. With (St1) for M and $M^\vee$ this is (St2). □

Lemma E.104. *Let K be a non-archimedean local field whose residue characteristic p differs from the prime ℓ, $D = G_K$, $I \subseteq D$ its inertia subgroup, and $J \subseteq I$ a closed subgroup, normal in D, of finite index in I prime to ℓ. For a finite abelian group M killed by ℓ with a continuous action of D that is trivial on J, put $Z^1_J(M) = \{z \in Z^1(D,M) : z|_J = 0\}$ and $H^1_J(M) = Z^1_J(M)/B^1(D,M)$. Then:*

(Ur1) *$B^1(D,M) \subseteq Z^1_J(M)$, $\#Z^1_J(M) = \#M$ and $\#H^1_J(M) = \#H^0(D,M)$;*

(Ur2) *for every surjective D-equivariant homomorphism $M \to M'$ onto a module M' of the same kind, every $z' \in Z^1_J(M')$ is the image of some $z \in Z^1_J(M)$.*

Proof. Let $\Phi \in D$ be a lift of Frobenius; $D/I \cong \widehat{\mathbb{Z}}$, topologically generated by the image of Φ. Put $\bar{D} = D/J$ and $P = I/J$, a finite normal subgroup of $\bar{D}$ of order prime to ℓ with $\bar{D}/P = D/I$.

(Ur1). Coboundaries $g \mapsto gx - x$ vanish on J, which acts trivially. Let $z \in Z^1_J(M)$ and $m = \#P$. Since z vanishes on J, $z|_I$ factors through P; summing $z(gh) = z(g) + gz(h)$ over $h \in P$ gives $mz(g) = \sum_h z(h) - g\sum_h z(h)$ for $g \in I$, so $z(g) = gx - x$ on I with $x = -m^{-1}\sum_{h\in P} z(h)$ (m is invertible on M). Hence restriction maps $Z^1_J(M)$ onto $B^1(I,M)$ (onto because $B^1(D,M) \subseteq Z^1_J(M)$ restricts onto $B^1(I,M)$), and $\#B^1(I,M) = \#M/\#M^I$. The kernel consists of the cocycles vanishing on I; for such z and $h \in I$, $z(hg) = hz(g)$ and $z(hg) = z(g \cdot g^{-1}hg) = z(g)$, so z takes values in M^I and is a cocycle of D/I. The map $z \mapsto z(\Phi)$ from these cocycles to M^I is

injective (a continuous cocycle vanishing on I and at Φ vanishes on the dense subgroup generated by I and Φ) and onto: for $x \in M^I$, if Φ acts on M^I with order e, the function $k \mapsto \sum_{0\le i<k} \Phi^i x$ on $k \ge 0$ depends only on k modulo $e\ell$ (the sum of $e\ell$ consecutive terms is $\ell \sum_{i<e} \Phi^i x = 0$), hence extends to a continuous cocycle of $\widehat{\mathbb{Z}} = D/I$ with value x at Φ. So $\#Z^1_J(M) = \#M^I \cdot \#M/\#M^I = \#M$, and $\#H^1_J(M) = \#M/\#B^1(D,M) = \#M/(\#M/\#M^D) = \#M^D$.

(Ur2). Let K' be the kernel of $M \to M'$, an ℓ-module of $\bar{D}$. By standard facts of the cohomology of profinite groups [222, I.2.2, I.3.3, I.3.4], $Z^1_J(\cdot) = Z^1(\bar{D}, \cdot)$, and $H^2(\bar{D}, K') \cong H^2(\bar{D}/P, K'^P) = H^2(\widehat{\mathbb{Z}}, K'^P) = 0$. The long exact sequence of $\bar{D}$-cohomology shows that $H^1(\bar{D}, M) \to H^1(\bar{D}, M')$ is onto. So for $z' \in Z^1(\bar{D}, M')$ there are $z_0 \in Z^1(\bar{D}, M)$ and $x' \in M'$ with $z'(g) = \bar{z}_0(g) + gx' - x'$, $\bar{z}_0$ the image of z_0; lifting x' to $x \in M$, $z = z_0 + (g \mapsto gx - x)$ lies in $Z^1(\bar{D}, M) = Z^1_J(M)$ and maps to z'. □

Proposition E.105. *Let $\mathscr{H}$, $\mathcal{O}$ (a discrete valuation ring), x, κ with local witnesses $Y_{j,v}$, and a Taylor–Wiles datum of size q (with H, $\sigma_1, \dots, \sigma_q$) along which x has eigenvalue data be as in Proposition E.97, with $\rho(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$, x satisfying (Np4) and (Pj1) of Definition 50.9, for every $Z \in \mathrm{Ev}_a(A)$ some $T^s Z$ in the A-span of $\rho(\Gamma')$ (Γ' as in Definition 50.9), and $\{\sigma_1, \dots, \sigma_q\}$ detecting (x, κ). Put $K = \#k$, $d = [L^+ : \mathbb{Q}]$, $\nu = \binom{a}{2} + \binom{n-a}{2} + g\,a(n-a)$, $A_m = A/T^m A$, $c_N = \pi^{Q_N}(c)$, $\Gamma^0_N = h_N^{-1}(\Gamma^0_{\mathscr{H}})$. Let $\mathrm{PB}_a(A_m) \subseteq \mathrm{M}_n(\mathrm{PD}_g(A_m))$ be the matrices whose same-block entries lie in $A_m\eta$ and whose different-block entries lie in $\bigoplus_j A_m\epsilon'_j$. For $N, m \ge 1$ let $M_{N,m} = \mathrm{PW}^1_a(A_m)$ and $M'_{N,m} = \mathrm{PB}_a(A_m)$ with*

$$\gamma \cdot Z = \rho_1(h_N\gamma) Z \rho_1(h_N\gamma)^{-1}, \quad c_N \cdot Z = -{}^t Z;$$
$$\gamma \cdot Y = \chi_{\mathrm{cyc}}(\gamma)\rho_1(h_N\gamma) Y \rho_1(h_N\gamma)^{-1}, \quad c_N \cdot Y = -\chi_{\mathrm{cyc}}(c)\,{}^t Y$$

($\gamma \in \Gamma^0_N$; entries of ρ_1 and values of χ_{cyc} mapped to $\mathrm{PD}_g(A_m)$). For $v \in S_\ell$ let Zb_v be the set of cocycles $\beta \in Z^1(D_v, M_{N,m})$ (action through ι_v) such that $(w^1_v)^{-1}\beta(g)w^1_v$ is upper triangular for all $g \in D_v$, with zero diagonal for $g \in \mu_v$. Then:

(Bs0) *the formulas for $M'_{N,m}$ define a continuous action of Γ_N on the finite group $M'_{N,m}$ (for $M_{N,m}$ this is Lemma E.107 (Rf2)), and there is a bi-additive map $b_{N,m}\colon M_{N,m} \times M'_{N,m} \to \mu_\ell$, non-degenerate on both sides, with $b_{N,m}(\gamma Z, \gamma Y) = \gamma\, b_{N,m}(Z, Y)$ for $\gamma \in \Gamma_N$;*

(Bs1) *there is $c'_1 \ge 0$ with $\#H^0(\Gamma_N, M_{N,m}) \le K^{c'_1}$ for all N, m;*

(Bs2) *for $v \in S_\ell$ there is $C_v \ge 0$ with $\#(B^1(D_v, M_{N,m}) + \mathrm{Zb}_v) \le \#M_{N,m} \cdot K^{m(n+\nu)d_v + C_v}$ for all N, m;*

(Bs3) *there is $C_q \ge 0$ such that for all m and j there is N_0 with $\#H^0(D_{v_{N,j}}, M'_{N,m}) \le K^{mn+C_q}$ for $N \ge N_0$ (local groups at $\bar{w}_{N,j}$);*

(Bs4) *there is $c_0 \ge 0$ with $\#H^0(D_{v_0}, M'_{N,m}) \le K^{c_0}$ for all N, m (local group at $\bar{v}_0$);*

(Bs6) *there is $c_2 \ge 0$ such that for every m there is N_0 such that for $N \ge N_0$ the set of $y \in Z^1(\Gamma_N, M'_{N,m})$ with $y \circ \iota_{v_{N,j}} \in B^1(D_{v_{N,j}}, M'_{N,m})$ for $1 \le j \le q$ has at most $\#B^1(\Gamma_N, M'_{N,m}) \cdot K^{c_2}$ elements.*

Proof. Each item is a lemma proved separately. (Bs0) is Lemma E.106. (Bs1) is (H1) of Lemma E.109 ($H^0(\Gamma_N, M_{N,m})$ is the set of elements fixed by Γ_N), which uses the spanning hypothesis. (Bs2) is the second inequality of Lemma E.111, which uses (Pj1). (Bs3) and (Bs4) are (H3) and (H4) of Lemma E.109 (the local invariants are the elements fixed by $\iota(D_{v_{N,j}})$, resp. $\iota(D_{v_0})$); (H4) uses (Np4). (Bs6) is Lemma E.113, which uses that $\{\sigma_1, \dots, \sigma_q\}$ detects (x, κ) and that ρ is trivial on $\Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$. □

Lemma E.106. *Let $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ be a curve point normalised of shape $(a, n-a)$ over a rank-n Hecke datum $\mathscr{H}$, κ a Selmer basis of x, and a Taylor–Wiles datum; let $N, m \geq 1$. Then the formulas $\gamma \cdot Y = \chi_{\mathrm{cyc}}(\gamma)\rho_1(h_N\gamma)Y\rho_1(h_N\gamma)^{-1}$ ($\gamma \in \Gamma_N^0$) and $c_N \cdot Y = -\chi_{\mathrm{cyc}}(c)\,{}^tY$ define a continuous action of Γ_N on the finite group $M'_{N,m}$. Fix a primitive ℓ-th root of unity ζ and put $\tau(y) = \mathrm{Tr}_{k/\mathbb{F}_\ell}(y_{m-1})$ for $y = \sum_{i<m} y_i T^i \in A_m$. Then*

$$b_{N,m}(Z,Y) = \zeta^{\tau(e(Z,Y))}, \qquad e(Z,Y) = \textit{the } \eta\textit{-coefficient of } \mathrm{tr}(ZY) \in A_m,$$

is a bi-additive map $M_{N,m} \times M'_{N,m} \to \mu_\ell$, non-degenerate on both sides, with $b_{N,m}(\gamma Z, \gamma Y) = \gamma\, b_{N,m}(Z,Y)$ for $\gamma \in \Gamma_N$ (Γ_N acting on $M_{N,m}$ as in Lemma E.107 (Rf2) and on μ_ℓ through χ_{cyc}). In particular (Bs0) of Proposition E.105 holds.

Proof. Write $M = M_{N,m}$, $M' = M'_{N,m}$; values of χ_{cyc} are taken in $\mathbb{F}_\ell \subseteq A_m$. Every $Y \in M'$ is $Y = \eta Y_0 + \sum_j \epsilon'_j Y_j$ with $Y_0 \in \mathrm{Ev}_a(A_m)$, $Y_j \in \mathrm{Od}_a(A_m)$.

The action. For $\gamma \in \Gamma^0_{\mathscr{H}}$ Lemma E.108 gives $\rho_1(\gamma)Y\rho_1(\gamma)^{-1} = \eta\big(\rho Y_0\rho^{-1} + \sum_j [\kappa_j(\gamma), \rho Y_j \rho^{-1}]\big) + \sum_j \epsilon'_j \rho Y_j \rho^{-1}$ ($\rho = \rho(\gamma)$), which lies in M': ρ is block diagonal, so $\rho Y_0 \rho^{-1} \in \mathrm{Ev}_a$, $\rho Y_j \rho^{-1} \in \mathrm{Od}_a$, and $[\mathrm{Od}_a, \mathrm{Od}_a] \subseteq \mathrm{Ev}_a$. Also ${}^tM' = M'$. As ρ_1 and χ_{cyc} are homomorphisms (Lemma E.107 (Rf1)), the formula defines an action of Γ_N^0. For $\gamma \in \Gamma_N^0$, $\gamma' = h_N\gamma$, using $\chi_{\mathrm{cyc}}(c)^2 = 1$, $\chi_{\mathrm{cyc}}(c_N\gamma c_N) = \chi_{\mathrm{cyc}}(\gamma)$ and $\rho_1(\bar{c}\gamma'\bar{c}) = {}^t\rho_1(\gamma')^{-1}$ ((Rf1)):

$$c_N \cdot (\gamma \cdot (c_N \cdot Y)) = \chi_{\mathrm{cyc}}(\gamma)\,{}^t\big(\rho_1(\gamma')\,{}^tY\rho_1(\gamma')^{-1}\big) = \chi_{\mathrm{cyc}}(\gamma)\,{}^t\rho_1(\gamma')^{-1}Y\,{}^t\rho_1(\gamma') = (c_N\gamma c_N)\cdot Y,$$

and $c_N \cdot (c_N \cdot Y) = Y$. Since Γ_N^0 has index 2 in Γ_N and $c_N^2 = 1$, $c_N \notin \Gamma_N^0$, these identities say exactly that $\gamma \mapsto (\cdot)$ on Γ_N^0 and $c_N\gamma \mapsto c_N \cdot (\gamma\cdot\,)$ define an action of Γ_N (the same argument as for (Rf2)). It is continuous: on Γ_N^0 it factors through h_N and the reduction of $(\rho_1, \chi_{\mathrm{cyc}})$ modulo (T^m, ℓ), a continuous homomorphism to a finite group (ρ and the κ_j have T-adically continuous entries), and Γ_N^0 is open.

The form τ. $\tau\colon A_m \to \mathbb{F}_\ell$ is $\mathbb{F}_\ell$-linear, and if $y \neq 0$ there is z with $\tau(yz) \neq 0$: if i is minimal with $y_i \neq 0$, take $z = cT^{m-1-i}$ with $c \in k$ and $\mathrm{Tr}_{k/\mathbb{F}_\ell}(y_i c) \neq 0$ (the trace form of the separable extension $k/\mathbb{F}_\ell$ is non-degenerate). The same holds for A_m^g with $(y,z) \mapsto \tau(\sum_t y_t z_t)$.

Bi-additivity and non-degeneracy. e is bi-additive, so $b_{N,m}$ is. For a matrix unit E_{ji} and $y \in \mathrm{PD}_g(A_m)$, $\mathrm{tr}(ZE_{ji}y) = Z_{ij}y$. Let $Z \in M$ with $b_{N,m}(Z,\cdot) = 1$. If i,j lie in the same block, $Z_{ij} \in A_m$ and $E_{ji}\eta y' \in M'$ for $y' \in A_m$, with $e(Z, E_{ji}\eta y') = Z_{ij}y'$; so $\tau(Z_{ij}y') = 0$ for all y' and $Z_{ij} = 0$. If they lie in different blocks, $Z_{ij} = \sum_t z_t\epsilon_t$ and $E_{ji}\sum_t y'_t\epsilon'_t \in M'$ with $e = \sum_t z_t y'_t$ ($\epsilon_t\epsilon'_s = \delta_{ts}\eta$); so all $z_t = 0$. Hence $Z = 0$. Symmetrically (using $\mathrm{tr}(ZY) = \mathrm{tr}(YZ)$ and the matrix units E_{ji} in M with entries in A_m or $\bigoplus_t A_m\epsilon_t$), $b_{N,m}(\cdot, Y) = 1$ forces $Y = 0$.

Equivariance. For $\gamma \in \Gamma_N^0$ with $r = \rho_1(h_N\gamma)$: $\mathrm{tr}\big(rZr^{-1} \cdot \chi_{\mathrm{cyc}}(\gamma) rYr^{-1}\big) = \chi_{\mathrm{cyc}}(\gamma)\mathrm{tr}(ZY)$, so $e(\gamma Z, \gamma Y) = \chi_{\mathrm{cyc}}(\gamma)e(Z,Y)$ and $b_{N,m}(\gamma Z, \gamma Y) = \zeta^{\chi_{\mathrm{cyc}}(\gamma)\tau(e(Z,Y))} = \gamma\, b_{N,m}(Z,Y)$ (τ is $\mathbb{F}_\ell$-linear). For c_N: $\mathrm{tr}\big((-{}^tZ)(-\chi_{\mathrm{cyc}}(c)\,{}^tY)\big) = \chi_{\mathrm{cyc}}(c)\mathrm{tr}({}^t(YZ)) = \chi_{\mathrm{cyc}}(c)\mathrm{tr}(ZY)$, so again $b_{N,m}(c_N Z, c_N Y) = c_N\, b_{N,m}(Z,Y)$. As Γ_N is generated by Γ_N^0 and c_N, equivariance holds for all of Γ_N. □

Lemma E.107. *Let $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ be a curve point normalised of shape $(a, n-a)$ over a rank-n Hecke datum $\mathscr{H}$, $\kappa = (\kappa_1, \ldots, \kappa_g)$ a Selmer basis of x and $\bar{c} = \pi_{\mathscr{H}}(c)$. Fix a Taylor–Wiles datum and let $N, m \geq 1$, $c_N = \pi^{Q_N}(c)$, $\Gamma_N^0 = h_N^{-1}(\Gamma^0_{\mathscr{H}})$, $M = \mathrm{PW}^1_a(A_m)$, and $\nu = \binom{a}{2} + \binom{n-a}{2} + g\,a(n-a)$. Then:*

(Rf1) *$\rho_1(\gamma\gamma') = \rho_1(\gamma)\rho_1(\gamma')$ and $\rho_1(\bar{c}\gamma\bar{c}) = {}^t\rho_1(\gamma)^{-1}$ for $\gamma, \gamma' \in \Gamma^0_{\mathscr{H}}$, and $\rho_1(\gamma)M\rho_1(\gamma)^{-1} = M$ (entries mapped to $\mathrm{PD}_g(A_m)$);*

(Rf2) *$\gamma \cdot Z = \rho_1(h_N\gamma) Z \rho_1(h_N\gamma)^{-1}$ ($\gamma \in \Gamma_N^0$) and $c_N \cdot Z = -{}^tZ$ define a continuous action of Γ_N on the finite group M;*

(Rf3) *for every $c' \in \Gamma_N \smallsetminus \Gamma_N^0$ with $c'^2 = 1$, $\#\{Z \in M : \ c' \cdot Z = Z\} \geq (\#k)^{m\nu}$.*

Proof. (Rf1). Write $\kappa_\epsilon = \sum_j \epsilon_j \kappa_j$; products of two ϵ's vanish. The cocycle rule $\kappa_\epsilon(\gamma\gamma') = \kappa_\epsilon(\gamma) + \rho(\gamma)\kappa_\epsilon(\gamma')\rho(\gamma)^{-1}$ gives

$$(1+\kappa_\epsilon(\gamma))\rho(\gamma)(1+\kappa_\epsilon(\gamma'))\rho(\gamma') = (1+\kappa_\epsilon(\gamma)+\rho(\gamma)\kappa_\epsilon(\gamma')\rho(\gamma)^{-1})\rho(\gamma\gamma') = \rho_1(\gamma\gamma').$$

As x is normalised, $\rho(\gamma^*) = {}^t\rho(\gamma)$, i.e. $\rho(\bar c\gamma\bar c) = {}^t\rho(\gamma^{-1}) = {}^t\rho(\gamma)^{-1}$; with $\kappa_j(\bar c\gamma\bar c) = -{}^t\kappa_j(\gamma)$ (Definition E.34 (Sd2)),

$$\rho_1(\bar c\gamma\bar c) = (1 - {}^t\kappa_\epsilon(\gamma))\,{}^t\rho(\gamma)^{-1} = \big({}^t\rho(\gamma)(1+{}^t\kappa_\epsilon(\gamma))\big)^{-1} = {}^t\rho_1(\gamma)^{-1}.$$

For the last claim: if $a < n$, $\rho(\gamma)$ is block diagonal and $\kappa_j(\gamma) \in \mathrm{Od}_a(A)$, so in $\rho_1(\gamma) = \rho(\gamma) + \sum_j \epsilon_j\kappa_j(\gamma)\rho(\gamma)$ the second term has different-block entries in $\bigoplus_j A\epsilon_j$ and zero same-block entries. For $Z \in M$ (same-block entries in A_m, different-block entries in $\bigoplus_j A_m\epsilon_j$), $\rho(\gamma)Z$ and $Z\rho(\gamma)$ have the same pattern, and $\epsilon_j\kappa_j(\gamma)\rho(\gamma)Z$, $Z\epsilon_j\kappa_j(\gamma)\rho(\gamma)$ have different-block entries in $A_m\epsilon_j$ and same-block entries in the span of products $\epsilon_j\epsilon_{j'} = 0$. So $\rho_1(\gamma)M \subseteq M$, $M\rho_1(\gamma) \subseteq M$, and the same for $\rho_1(\gamma)^{-1} = \rho_1(\gamma^{-1})$. If $a = n$, $\mathrm{Od}_n = 0$ and $\rho_1 = \rho$. Hence $\rho_1(\gamma)M\rho_1(\gamma)^{-1} = M$.

(Rf2). $\Gamma_N = \Gamma_N^0 \sqcup \Gamma_N^0 c_N$ with $c_N^2 = 1$ and $h_N(c_N) = \bar c$. By (Rf1), $\gamma \mapsto \rho_1(h_N\gamma)$ is a homomorphism and conjugation by it preserves M; transposition preserves M (its pattern is symmetric). The rule $(\gamma c_N^\varepsilon)\cdot Z = \gamma\cdot(c_N^\varepsilon \cdot Z)$ therefore defines an action provided $c_N\cdot(c_N\cdot Z) = Z$, which is clear, and $c_N \cdot (\gamma \cdot Z) = (c_N\gamma c_N)\cdot(c_N\cdot Z)$, which reads, with $S = \rho_1(h_N\gamma)$ and $\rho_1(\bar c\, h_N(\gamma)\, \bar c) = {}^tS^{-1}$ from (Rf1),

$$-{}^t(SZS^{-1}) = -{}^tS^{-1}\,{}^tZ\,{}^tS = {}^tS^{-1}(-{}^tZ)\,{}^tS.$$

The action is continuous: $\rho_1 \bmod T^m$ is locally constant (the entries of ρ and κ_j are T-adically continuous), h_N is continuous and Γ_N^0 is open.

(Rf3). Put $g = c'c_N \in \Gamma_N^0$ (both c' and c_N lie in the non-trivial coset of Γ_N^0). From $c'^2 = c_N^2 = 1$, $c_Ngc_N = c_Nc' = g^{-1}$, so by (Rf1) $S := \rho_1(h_Ng)$ satisfies $S^{-1} = \rho_1(h_Ng^{-1}) = \rho_1(\bar c\, h_N(g)\, \bar c) = {}^tS^{-1}$, i.e. ${}^tS = S$. Since $c' = gc_N$, $c'\cdot Z = S(-{}^tZ)S^{-1}$. For $Y \in M$ with ${}^tY = -Y$, $Z = SY$ lies in M by (Rf1) and

$$c'\cdot Z = -S\,{}^tY\,{}^tS\,S^{-1} = SY = Z.$$

$Y \mapsto SY$ is injective, so $\#M^{c'=1}$ is at least the number of $Y \in M$ with ${}^tY = -Y$. Such Y has zero diagonal (ℓ odd) and is determined by its entries above the diagonal, which are arbitrary in A_m for the $\binom{a}{2} + \binom{n-a}{2}$ same-block positions and arbitrary in $\bigoplus_{j=1}^g A_m\epsilon_j$ for the $a(n-a)$ different-block positions; as $\#A_m = (\#k)^m$, their number is $(\#k)^{m\nu}$. □

Lemma E.108. *Let x be a normalised curve point, $\kappa = (\kappa_1, \dots, \kappa_g)$ a Selmer basis of x, X a commutative A-algebra and $\gamma \in \Gamma^0$; write $\rho = \rho(\gamma)$, $\kappa_j = \kappa_j(\gamma)$ (entries mapped to X). For $Z_0, Z_1, \dots, Z_g, Y_0, Y_1, \dots, Y_g \in \mathrm{M}_n(X)$,*

$$\rho_1(\gamma)\Big(Z_0 + \sum_j \epsilon_j Z_j\Big)\rho_1(\gamma)^{-1} = \rho Z_0\rho^{-1} + \sum_j \epsilon_j(\rho Z_j\rho^{-1} + [\kappa_j, \rho Z_0\rho^{-1}]),$$

$$\rho_1(\gamma)\Big(\eta Y_0 + \sum_j \epsilon'_j Y_j\Big)\rho_1(\gamma)^{-1} = \eta\Big(\rho Y_0\rho^{-1} + \sum_j [\kappa_j, \rho Y_j\rho^{-1}]\Big) + \sum_j \epsilon'_j \rho Y_j\rho^{-1}.$$

Proof. Put $E=\sum_j \epsilon_j\kappa_j$, so $\rho_1(\gamma)=(1+E)\rho$ and, as $\epsilon_i\epsilon_j=0$ gives $E^2=0$, $\rho_1(\gamma)^{-1}=\rho^{-1}(1-E)$. For $W\in \mathrm{M}_n(\mathrm{PD}_g(X))$, $\rho_1 W\rho_1^{-1}=(1+E)W'(1-E)=W'+EW'-W'E-EW'E$ with $W'=\rho W\rho^{-1}$; the scalars $\epsilon_j,\epsilon'_j,\eta$ are central. In PD_g, $\epsilon_i\epsilon_j=0$, $\epsilon_i\epsilon'_j=\delta_{ij}\eta$ and $\epsilon_i\eta=0$. For $W=Z_0+\sum_j\epsilon_jZ_j$: $EW'=\sum_j\epsilon_j\kappa_j\rho Z_0\rho^{-1}$, $W'E=\sum_j\epsilon_j\rho Z_0\rho^{-1}\kappa_j$, $EW'E=0$, which gives the first identity. For $W=\eta Y_0+\sum_j\epsilon'_jY_j$: $EW'=\eta\sum_j\kappa_j\rho Y_j\rho^{-1}$, $W'E=\eta\sum_j\rho Y_j\rho^{-1}\kappa_j$, and $EW'E=0$ (every term contains $\epsilon_i\eta$ or $\epsilon_i\epsilon_k$ with a further factor ϵ), which gives the second. □

Lemma E.109. *Let $\mathscr{H}$ be a rank-n Hecke datum, x a framed normalised curve point of shape $(a,n-a)$, $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis of x, and a Taylor–Wiles datum of size q (with H, $\sigma_1,\dots,\sigma_q$) along which x has eigenvalue data; assume $\rho(\gamma)=1$ for $\gamma\in\Gamma^0_{\mathscr{H}}\cap\mathrm{PL}(H)$. For a subset S of Γ_N write M^S for the elements of $M=M_{N,m}$ or $M=M'_{N,m}$ fixed by every element of S under the formulas of Proposition E.105. Take $D_{v_0}=D_{\bar v_0}\cap G_{L^+}$ and $D_{v_{N,j}}=D_{\bar w_{N,j}}\cap G_{L^+}$, with $\iota=\pi^{Q_N}$ on them.*

(H1) *If for every $Z\in\mathrm{Ev}_a(A)$ some T^sZ lies in the A-span of $\rho(\Gamma')$, then there is $c'_1\ge0$ with $\#M_{N,m}^{\Gamma_N}\le K^{c'_1}$ for all $N,m\ge1$.*

(H3) *There is $C_q\ge0$ such that for all $m\ge1$ and $1\le j\le q$ there is N_0 with $\#(M'_{N,m})^{\iota(D_{v_{N,j}})}\le K^{mn+C_q}$ for all $N\ge N_0$.*

(H4) *If x satisfies (Np4), there is $c_0\ge0$ with $\#(M'_{N,m})^{\iota(D_{v_0})}\le K^{c_0}$ for all $N,m\ge1$.*

Proof. Write $\Gamma^0=\Gamma^0_{\mathscr{H}}$ and, for $\gamma\in\Gamma^0$, $E(\gamma)=\sum_j\epsilon_j\kappa_j(\gamma)$, so $\rho_1(\gamma)=(1+E(\gamma))\rho(\gamma)$ and, as $\epsilon_i\epsilon_j=0$, $\rho_1(\gamma)^{-1}=\rho(\gamma)^{-1}(1-E(\gamma))$. For a commutative A-algebra X every $Z\in\mathrm{PW}^1_a(X)$ is uniquely $Z=Z_0+\sum_j\epsilon_jZ_j$ with $Z_0\in\mathrm{Ev}_a(X)$, $Z_j\in\mathrm{Od}_a(X)$, and every $Y\in\mathrm{PB}_a(X)$ is uniquely $Y=\eta Y_0+\sum_j\epsilon'_jY_j$ with $Y_0\in\mathrm{Ev}_a(X)$, $Y_j\in\mathrm{Od}_a(X)$. By Lemma E.108, writing $\rho=\rho(\gamma)$, $\kappa_j=\kappa_j(\gamma)$:

$$\begin{aligned}\rho_1Z\rho_1^{-1}&=\rho Z_0\rho^{-1}+\sum_j\epsilon_j\big(\rho Z_j\rho^{-1}+[\kappa_j,\rho Z_0\rho^{-1}]\big),\\ \rho_1Y\rho_1^{-1}&=\eta\Big(\rho Y_0\rho^{-1}+\sum_j[\kappa_j,\rho Y_j\rho^{-1}]\Big)+\sum_j\epsilon'_j\rho Y_j\rho^{-1}.\end{aligned}\tag{1}$$

The modules $P_1=\mathrm{PW}^1_a(A)$ and $P_2=\mathrm{PB}_a(A)$ are free of finite rank over A, with $P_1/T^mP_1=M_{N,m}$, $P_2/T^mP_2=M'_{N,m}$ and $P_i\otimes_AF=\mathrm{PW}^1_a(F)$, $\mathrm{PB}_a(F)$. For $\gamma\in\Gamma^0$ and $e\in\mathbb{Z}$ the maps $Z\mapsto e\rho_1(\gamma)Z\rho_1(\gamma)^{-1}-Z$ and $Z\mapsto-{}^tZ-Z$ are A-linear maps into the free module $\mathrm{M}_n(\mathrm{PD}_g(A))$, and the action formulas of Proposition E.105 on $M_{N,m}$, $M'_{N,m}$ are their reductions modulo T^m (with γ replaced by $h_N\gamma$ and e by the image of χ_{cyc}). Each item is proved by applying Lemma E.110 to a family of such maps that does not depend on N (in (H3): for $N\ge N_0$).

(H1). $\Gamma^0_N=h_N^{-1}(\Gamma^0)$ has index 2 in Γ_N and $c_N\notin\Gamma^0_N$, so Γ_N is generated by Γ^0_N and c_N, and since h_N is surjective, $M_{N,m}^{\Gamma_N}$ is the common kernel modulo T^m of the maps $\varphi_\gamma(Z)=\rho_1(\gamma)Z\rho_1(\gamma)^{-1}-Z$ ($\gamma\in\Gamma^0$) and $\varphi_c(Z)=-{}^tZ-Z$ on P_1; this family does not depend on N. By Lemma E.110 it suffices to show that 0 is the only $Z\in P_1$ killed by all of them. Let Z be such. By (1), $\rho(\gamma)Z_0=Z_0\rho(\gamma)$ for $\gamma\in\Gamma^0$, so Z_0 commutes with the A-span of $\rho(\Gamma')$. For each i the elementary matrix E_{ii} lies in $\mathrm{Ev}_a(A)$, so some T^sE_{ii} lies in that span, $T^s(E_{ii}Z_0-Z_0E_{ii})=0$, and as A is a domain, Z_0 commutes with every E_{ii}: Z_0 is diagonal. From $\varphi_c(Z)=0$, ${}^tZ_0=-Z_0$, so $2Z_0=0$ and $Z_0=0$ (ℓ is odd, so $2\in A^\times$). Then (1) gives $\rho(\gamma)Z_j=Z_j\rho(\gamma)$ for all $\gamma\in\Gamma^0$, and the same argument shows that Z_j is diagonal; as $Z_j\in\mathrm{Od}_a(A)$ has zero diagonal, $Z_j=0$. So $Z=0$, and Lemma E.110 gives c'_1.

(H4). By (Rd2) v_0 splits in L, so $D_{v_0} \subseteq G_L$, $\iota(D_{v_0}) \subseteq \pi^{Q_N}(G_L) = \Gamma_N^0$, and $h_N(\iota(g)) = \pi_{\mathscr{H}}(g)$ for $g \in D_{v_0}$; moreover $\pi_{\mathscr{H}}(D_{v_0}) = \Delta_0$. Hence $(M'_{N,m})^{\iota(D_{v_0})}$ is the common kernel modulo T^m of the maps $\psi_\delta(Y) = \chi_{\mathrm{cyc}}(\delta)\rho_1(\delta)Y\rho_1(\delta)^{-1} - Y$ ($\delta \in \Delta_0$) on P_2, independent of N. Let $Y \in P_2$ be killed by all ψ_δ. By (1), the ϵ'_j-component gives $\chi_{\mathrm{cyc}}(\delta)\rho(\delta)Y_j = Y_j\rho(\delta)$ for all $\delta \in \Delta_0$, so $Y_j = 0$ by (Np4); then the η-component gives $\chi_{\mathrm{cyc}}(\delta)\rho(\delta)Y_0 = Y_0\rho(\delta)$, so $Y_0 = 0$ by (Np4). By Lemma E.110 (with $r = 0$) there is c_0 as stated.

(H3). Fix j and m. By (Tg2) $v_{N,j}$ splits in L, so $D_{v_{N,j}} \subseteq G_L$; it contains $\phi_{N,j}$, and $\iota(\phi_{N,j}) = \Phi_{N,j} \in \Gamma_N^0$. Since $\phi_{N,j}^{-1}$ is a Frobenius element for the norm $q_{N,j} \equiv 1 \bmod \ell^N$, $\chi_{\mathrm{cyc}}(\phi_{N,j}) \equiv 1 \bmod \ell$, so its image in k is 1. Hence every element of $(M'_{N,m})^{\iota(D_{v_{N,j}})}$ is fixed by $Y \mapsto r_m(h_N\Phi_{N,j})Y r_m(h_N\Phi_{N,j})^{-1}$, where $r_m(\gamma)$ is $\rho_1(\gamma)$ with entries reduced modulo T^m.

Approximation. $r_m\colon \Gamma^0 \to \mathrm{GL}_n(\mathrm{PD}_g(A_m))$ is a homomorphism (Lemma E.107 (Rf1)) into a finite group, and it is continuous because the entries of ρ and of the κ_i are T-adically continuous (the definition of curve points and (Sd2)). So $U_m = \ker r_m$ is open in Γ^0, hence in $\Gamma_{\mathscr{H}}$, and $U_m \supseteq \mathrm{PL}(H)$ by Lemma E.96 (Pv1). The intersection V of the finitely many conjugates of U_m in $\Gamma_{\mathscr{H}}$ is an open normal subgroup, and $V \supseteq \mathrm{PL}(H)$ since $\mathrm{PL}(H)$, an intersection of normal subgroups, is normal. By (Tg3) there is N_0 with $h_N(\Phi_{N,j})\sigma_j^{-1} \in V \subseteq U_m$ for $N \geq N_0$; as $h_N(\Phi_{N,j}) \in \Gamma^0$ and $\sigma_j \in \Gamma' \subseteq \Gamma^0$, $r_m(h_N\Phi_{N,j}) = r_m(\sigma_j)$ for $N \geq N_0$. So for $N \geq N_0$, $(M'_{N,m})^{\iota(D_{v_{N,j}})}$ lies in the kernel modulo T^m of the single map $\psi(Y) = \rho_1(\sigma_j)Y\rho_1(\sigma_j)^{-1} - Y$ on P_2, which depends neither on N nor on m.

The rank. Let $W \subseteq \mathrm{PB}_a(F)$ be the kernel of $\psi \otimes F$ and $P = \rho(\sigma_j) = \mathrm{diag}(P'_1, P'_2)$ (block diagonal, x being normalised). The characteristic polynomials f_1, f_2 of P'_1, P'_2 have product $\prod_i (X - \alpha_{j,i})$ with the $\alpha_{j,i} \in A$ pairwise distinct, so they have no common root, and $f_1(P'_2) = \prod_{f_1(\alpha)=0}(P'_2 - \alpha)$ is invertible over F. If $B \in \mathrm{M}_{a\times(n-a)}(F)$ and $P'_1B = BP'_2$, then $0 = f_1(P'_1)B = Bf_1(P'_2)$ (Cayley–Hamilton), so $B = 0$; likewise $P'_2C = CP'_1$ forces $C = 0$. Hence every matrix over F commuting with P lies in $\mathrm{Ev}_a(F)$, and no non-zero element of $\mathrm{Od}_a(F)$ commutes with P. Now let $Y \in W$. By (1) the ϵ'_j-components give $PY_iP^{-1} = Y_i$ with $Y_i \in \mathrm{Od}_a(F)$, so $Y_i = 0$; then the η-component gives $PY_0 = Y_0P$. Conversely every ηY_0 with Y_0 in the centraliser of P in $\mathrm{M}_n(F)$ lies in W. As P has n distinct eigenvalues in F, it is diagonalisable over F and its centraliser has dimension n. So $\dim_F W = n$, and Lemma E.110 gives $C_{(j)}$ with $\#(M'_{N,m})^{\iota(D_{v_{N,j}})} \leq K^{mn+C_{(j)}}$ for $N \geq N_0$. Take $C_q = \max_j C_{(j)}$. □

Lemma E.110. *Let k be a finite field, $K = \#k$, $A = k[[T]]$ with fraction field F, and $A_m = A/T^mA$ ($m \geq 1$). Let P be a free A-module of finite rank and $(\varphi_i)_{i\in I}$ a family, over an arbitrary index set I, of A-linear maps $\varphi_i\colon P \to P_i$ into free A-modules of finite rank. Let $W = \bigcap_{i\in I} \ker(\varphi_i \otimes F) \subseteq P \otimes_A F$ and $r = \dim_F W$. Then there is $C \geq 0$ such that for every $m \geq 1$*

$$\#\{x \in P/T^mP :\ (\varphi_i \otimes A_m)(x) = 0 \text{ for all } i \in I\} \ \leq\ K^{mr+C}.$$

Moreover $r = 0$ if and only if 0 is the only $x \in P$ with $\varphi_i(x) = 0$ for all $i \in I$.

Proof. The subspaces $\bigcap_{i\in I_0} \ker(\varphi_i \otimes F)$, $I_0 \subseteq I$ finite, of the finite-dimensional space $P \otimes_A F$ have a minimal element; it is contained in each $\ker(\varphi_i \otimes F)$ (otherwise adding i makes it smaller), so it equals W. Fix such a finite $I_0 = \{i_1, \dots, i_s\}$ and put $\Phi = (\varphi_{i_1}, \dots, \varphi_{i_s})\colon P \to P' = \bigoplus_{t=1}^s P_{i_t}$, an A-linear map between free modules of finite ranks p and p' with $\ker(\Phi \otimes F) = W$, so $\Phi \otimes F$ has rank $p - r$.

A is a discrete valuation ring with uniformiser T. By the Smith normal form over a principal ideal domain there are bases $e_1, \dots, e_p$ of P and $f_1, \dots, f_{p'}$ of P' and integers $b_1, \dots, b_{p-r} \geq 0$ with $\Phi(e_i) = T^{b_i} f_i$ for $i \leq p - r$ and $\Phi(e_i) = 0$ for $i > p - r$ (the number of non-zero invariant

factors is the rank of $\Phi\otimes F$, and every non-zero element of A is a unit times a power of T). Put $C=\sum_{i\le p-r} b_i$.

Let $m\ge 1$. Reducing modulo T^m, we have $P/T^mP=\bigoplus_i A_m\bar e_i$ and

$$(\Phi\otimes A_m)\Big(\sum_i x_i\bar e_i\Big)=\sum_{i\le p-r} T^{b_i}x_i\bar f_i,$$

with the $\bar f_i$ a basis of P'/T^mP'. So $\ker(\Phi\otimes A_m)$ consists of the $\sum_i x_i\bar e_i$ with $T^{b_i}x_i=0$ in A_m for $i\le p-r$, i.e. $x_i\in T^{\max(m-b_i,0)}A_m$, a group of order $K^{\min(b_i,m)}$, and $x_i\in A_m$ arbitrary for $i>p-r$. Hence

$$\#\ker(\Phi\otimes A_m)=K^{mr}\prod_{i\le p-r}K^{\min(b_i,m)}\le K^{mr+C}.$$

The set of the statement is contained in $\ker(\Phi\otimes A_m)$, which proves the bound.

For the last assertion: $\bigcap_i\ker\varphi_i=W\cap P$ (an element of P is killed by φ_i if and only if it is killed by $\varphi_i\otimes F$, as P_i is torsion free). If $w\in W$ is non-zero, then $T^sw\in P$ for some $s\ge 0$ and $T^sw\in W\cap P$ is non-zero. So $W=0$ if and only if $W\cap P=0$. □

Lemma E.111. *Let $\mathscr{H}$ be a rank-n Hecke datum, x a framed normalised curve point of shape $(a,n-a)$ satisfying (Pj1), $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis of x with local witnesses $Y_{j,v}$, and a Taylor–Wiles datum. Let $v\in S_\ell$, with D_v acting on $M_{N,m}$ through $\pi^{Q_N}|_{D_v}$. Then there is $C_v\ge 0$ such that for all $N,m\ge 1$*

$$\#\mathrm{Zb}_v\le K^{m(n+\nu)(d_v+1)+C_v}\qquad\text{and}\qquad\#\big(B^1(D_v,M_{N,m})+\mathrm{Zb}_v\big)\le\#M_{N,m}\cdot K^{m(n+\nu)d_v+C_v}.$$

Proof. Fix N,m, write $M=M_{N,m}$, $w=w_v$, $w^1=w_v^1$, $\psi_i=\psi_{v,i}$, $\pi=\pi_{\mathscr{H}}$. As $D_v\subseteq G_L$ and $h_N\circ\pi^{Q_N}=\pi$, $g\in D_v$ acts on M by $Z\mapsto\rho_1(\pi g)Z\rho_1(\pi g)^{-1}$ (entries reduced modulo T^m).

Step 1: the frame turns the blocks into types. With the types $\mathrm{ty}(i)$ of the columns of w, Lemma E.112 gives $w^{-1}\mathrm{Ev}_a(X)w=\mathrm{Ev}_{\mathrm{ty}}(X)$ and $w^{-1}\mathrm{Od}_a(X)w=\mathrm{Od}_{\mathrm{ty}}(X)$ for every commutative A-algebra X, exactly a indices having type 1. Conjugation by $1-\sum_j\epsilon_jY_{j,v}$ ($Y_{j,v}\in\mathrm{Od}_a(A)$) maps $Z_0+\sum_j\epsilon_jZ_j$ to $Z_0+\sum_j\epsilon_j(Z_j-[Y_{j,v},Z_0])$, an automorphism of $\mathrm{PW}^1_a(A_m)$ since $[\mathrm{Od}_a,\mathrm{Ev}_a]\subseteq\mathrm{Od}_a$. Hence $Z\mapsto Z'=(w^1)^{-1}Zw^1$ is an isomorphism of M onto $M^w=\{Z_0+\sum_j\epsilon_jZ_j:\ Z_0\in\mathrm{Ev}_{\mathrm{ty}}(A_m),\ Z_j\in\mathrm{Od}_{\mathrm{ty}}(A_m)\}$, carrying the action to $Z'\mapsto R(g)Z'R(g)^{-1}$ with $R(g)=(w^1)^{-1}\rho_1(\pi g)w^1$.

Step 2: $R(g)$ is upper triangular with diagonal $(\psi_1(g),\dots,\psi_n(g))$. Using $\epsilon_i\epsilon_j=0$,

$$R(g)=w^{-1}\Big(1+\sum_j\epsilon_j\big(\kappa_j(\pi g)+Y_{j,v}-\rho(\pi g)Y_{j,v}\rho(\pi g)^{-1}\big)\Big)\rho(\pi g)w=\Big(1+\sum_j\epsilon_ju_j(g)\Big)b(g),$$

with $b(g)=w^{-1}\rho(\pi g)w$ upper triangular with diagonal $(\psi_i(g))$ (the frame, (Sd1)) and $u_j(g)=w^{-1}(\kappa_j(\pi g)+Y_{j,v}-\rho(\pi g)Y_{j,v}\rho(\pi g)^{-1})w$, upper triangular because $Y_{j,v}$ is a local witness for κ_j ((Sd2)), and in $\mathrm{Od}_{\mathrm{ty}}(A)$ by Step 1 ($\rho(\pi g)$ is block diagonal), so with zero diagonal. Hence $R(g)$ is upper triangular with $R(g)_{ii}=\psi_i(g)$.

Step 3: the upper triangular part. Let $U\subseteq M^w$ be the upper triangular elements. Its entries are: on the diagonal, arbitrary elements of A_m (n entries; the Z_j have zero diagonal); at (i,j), $i<j$, arbitrary elements of A_m if $\mathrm{ty}(i)=\mathrm{ty}(j)$ ($\binom{a}{2}+\binom{n-a}{2}$ pairs) and of $\bigoplus_t A_m\epsilon_t$ otherwise ($a(n-a)$ pairs). So $\#U=K^{m(n+\nu)}$. U is stable under the action. For $h\ge 0$ let $U_h\subseteq U$ be the elements whose entries of height $j-i<h$ vanish. For upper triangular R and Z', $(RZ'R^{-1})_{ij}=\sum_{i\le i'\le j'\le j}R_{ii'}Z'_{i'j'}(R^{-1})_{j'j}$ involves only entries of height $\le j-i$, and its term

with $(i',j')=(i,j)$ is $R_{ii}Z'_{ij}R_{jj}^{-1}$. Hence each U_h is stable, and $U_h/U_{h+1}\cong\bigoplus_{j-i=h}X_{ij}$, where X_{ij} ($=A_m$ or A_m^g) carries the action of g by multiplication by $\theta_{ij}(g)=\psi_i(g)\psi_j(g)^{-1}$.

Step 4: counting Zb_v. The isomorphism of Step 1 maps Zb_v onto the set Zb' of cocycles $\beta'\in Z^1(D_v,U)$ whose diagonal vanishes on μ_v. From $0\to U_{h+1}\to U_h\to U_h/U_{h+1}\to 0$ we get $\#Z^1(D_v,U_h)\le\#Z^1(D_v,U_{h+1})\cdot\#Z^1(D_v,U_h/U_{h+1})$, and the image of Zb' in $Z^1(D_v,U_0/U_1)$ (trivial action, $\theta_{ii}=1$) consists of n-tuples of continuous homomorphisms $D_v\to A_m$ vanishing on μ_v. Hence

$$\#\mathrm{Zb}_v\le\left(\#\mathrm{Hom}_{\mu_v}(D_v,A_m)\right)^n\prod_{i<j}\#Z^1(D_v,X_{ij}).$$

(a) A continuous homomorphism $D_v\to A_m$ (A_m is killed by ℓ) vanishing on μ_v factors through $D_v^{\mathrm{ab}}/\mu_v^{\mathrm{ab}}\otimes\mathbb{F}_\ell$, with μ_v^{ab} the elements of ℓ-power order. By local class field theory D_v^{ab} is the profinite completion of $(L_v^+)^\times\cong\mathbb{Z}\times\mu_{q_v-1}\times\mu_{\ell^\infty}(L_v^+)\times\mathbb{Z}_\ell^{d_v}$ (structure of the units of a local field), whose elements of ℓ-power order form the finite group $\mu_{\ell^\infty}(L_v^+)$; the quotient is $\hat{\mathbb{Z}}\times\mu_{q_v-1}\times\mathbb{Z}_\ell^{d_v}$, with maximal elementary abelian ℓ-quotient $(\mathbb{Z}/\ell)^{1+d_v}$. So $\#\mathrm{Hom}_{\mu_v}(D_v,A_m)=(\#A_m)^{1+d_v}=K^{m(1+d_v)}$.

(b) Let $i<j$ and $X=X_{ij}$, of order K^{mr} with $r\in\{1,g\}$. By Theorem B.29 (4) (with $v\mid\ell$, $[L_v^+:\mathbb{Q}_\ell]=d_v$) and $\#B^1=\#X/\#H^0$, $\#Z^1(D_v,X)=\#H^2(D_v,X)\cdot(\#X)^{d_v+1}$, and by Theorem B.29 (2) $\#H^2(D_v,X)=\#H^0(D_v,X^\vee)$, the number of additive maps $f\colon X\to\mu_\ell$ with $f(\theta_{ij}(g)y)=\chi_{\mathrm{cyc}}(g)f(y)$, i.e. vanishing on $I\cdot X$ with $I\subseteq A$ the ideal generated by the $\theta_{ij}(g)-\chi_{\mathrm{cyc}}(g)$, $g\in D_v$ (values of χ_{cyc} in $\mathbb{F}_\ell\subseteq A$). By (Pj1), $\psi_i\ne\psi_j\chi_{\mathrm{cyc}}|_{D_v}$, so $I\ne 0$ and $I=T^{e_{ij}}A$ for some $e_{ij}\ge 0$ independent of N,m; f factors through $X/T^{e_{ij}}X$, of order at most $K^{re_{ij}}$, and $\#H^2\le K^{ge_{ij}}$. So $\#Z^1(D_v,X_{ij})\le K^{mr(d_v+1)+ge_{ij}}$.

Multiplying, with $\sum_{i<j}r_{ij}=\nu$ and $C_v=g\sum_{i<j}e_{ij}$: $\#\mathrm{Zb}_v\le K^{m(n+\nu)(d_v+1)+C_v}$.

Step 5: adding the coboundaries. For $Y'\in U$ the coboundary $g\mapsto R(g)Y'R(g)^{-1}-Y'$ is upper triangular with diagonal entries $\psi_iY'_{ii}\psi_i^{-1}-Y'_{ii}=0$; so the coboundaries of the elements of $(w^1)U(w^1)^{-1}\subseteq M$ lie in $B^1(D_v,M)\cap\mathrm{Zb}_v$, and they form a group of order at least $\#U/\#H^0(D_v,M)$. As $\#B^1(D_v,M)=\#M/\#H^0(D_v,M)$,

$$\begin{aligned}\#(B^1+\mathrm{Zb}_v)&=\frac{\#B^1\cdot\#\mathrm{Zb}_v}{\#(B^1\cap\mathrm{Zb}_v)}\le\frac{\#M}{\#H^0}\cdot\#\mathrm{Zb}_v\cdot\frac{\#H^0}{\#U}\\&\le\#M\cdot K^{m(n+\nu)(d_v+1)+C_v-m(n+\nu)}=\#M\cdot K^{m(n+\nu)d_v+C_v}.\end{aligned}$$

□

Lemma E.112. *Let x be a framed normalised curve point of shape $(a,n-a)$, $v\in S_\ell$ and $w=w_v$. For $1\le i\le n$ let $\mathrm{ty}(i)\in\{1,2\}$ be the block (1 for $\{1,\dots,a\}$, 2 for $\{a+1,\dots,n\}$) containing the non-zero entries of the i-th column of w. Then exactly a indices have type 1, and for every commutative A-algebra X*

$$w^{-1}\mathrm{Ev}_a(X)w=\mathrm{Ev}_{\mathrm{ty}}(X),\qquad w^{-1}\mathrm{Od}_a(X)w=\mathrm{Od}_{\mathrm{ty}}(X),$$

where $\mathrm{Ev}_{\mathrm{ty}}(X)$, resp. $\mathrm{Od}_{\mathrm{ty}}(X)$, is the set of matrices in $\mathrm{M}_n(X)$ whose (i,j) entry vanishes unless $\mathrm{ty}(i)=\mathrm{ty}(j)$, resp. unless $\mathrm{ty}(i)\ne\mathrm{ty}(j)$. In particular every element of $w^{-1}\mathrm{Od}_a(X)w$ has zero diagonal.

Proof. Every column of w is non-zero ($w\in\mathrm{GL}_n(A)$) and has its non-zero entries in one block by (Sd1), so ty is well defined. Let $B_1=\bigoplus_{i\le a}Ae_i$, $B_2=\bigoplus_{i>a}Ae_i$ and $E_t=\bigoplus_{\mathrm{ty}(i)=t}Ae_i$. Then $w(E_t)\subseteq B_t$, and since w is invertible and $A^n=E_1\oplus E_2=B_1\oplus B_2$, $w(E_t)=B_t$; comparing ranks, exactly a indices have type 1. The same holds after base change to X. A

matrix $Z \in \mathrm{M}_n(X)$ lies in $\mathrm{Ev}_a(X)$ iff it maps $B_1 \otimes X$ and $B_2 \otimes X$ into themselves, iff $w^{-1}Zw$ maps $E_1 \otimes X$ and $E_2 \otimes X$ into themselves, iff $w^{-1}Zw \in \mathrm{Ev}_{\mathrm{ty}}(X)$; and $Z \in \mathrm{Od}_a(X)$ iff Z maps $B_1 \otimes X$ into $B_2 \otimes X$ and $B_2 \otimes X$ into $B_1 \otimes X$, iff $w^{-1}Zw$ exchanges $E_1 \otimes X$ and $E_2 \otimes X$, iff $w^{-1}Zw \in \mathrm{Od}_{\mathrm{ty}}(X)$. A diagonal position (i,i) has $\mathrm{ty}(i) = \mathrm{ty}(i)$, so elements of $\mathrm{Od}_{\mathrm{ty}}(X)$ have zero diagonal. □

Lemma E.113. *Let $\mathscr{H}$ be a rank-n Hecke datum, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed curve point normalised of shape $(a, n-a)$, κ a Selmer basis of x, and a Taylor–Wiles datum of size q (with H and $\sigma_1, \dots, \sigma_q$) such that $\rho(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr{H}} \cap \mathrm{PL}(H)$ and $\{\sigma_1, \dots, \sigma_q\}$ detects (x, κ). Take $D_{v_{N,j}} = D_{\bar{w}_{N,j}} \cap G_{L^+}$ acting through $\iota_{N,j} = \pi^{Q_N}|_{D_{v_{N,j}}}$. Then there is $c_2 \geq 0$ such that for every $m \geq 1$ there is N_0 with: for $N \geq N_0$,*

$$\#\{y \in Z^1(\Gamma_N, M'_{N,m}) :\ y \circ \iota_{N,j} \in B^1(D_{v_{N,j}}, M'_{N,m})\ (1 \leq j \leq q)\} \ \leq\ \#B^1(\Gamma_N, M'_{N,m}) \cdot K^{c_2}.$$

This is (Bs6) of Proposition E.105.

Proof. Let TwZ_m, TwB_m, ℓ_σ be as in Lemma E.114, and let c_2 be the constant C given there for $\Sigma = \{\sigma_1, \dots, \sigma_q\} \subseteq \Gamma'$. Fix m. Write $\Gamma = \Gamma_{\mathscr{H}}$, $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $r_m(\gamma)$ for $\rho_1(\gamma)$ with entries reduced modulo T^m, and $\bar{\chi}(\gamma) \in \mathbb{F}_\ell$ for the reduction of $\chi_{\mathrm{cyc}}(\gamma)$.

Step 0: choice of N_0. Γ^0 acts continuously on the finite group $\mathrm{PB}_a(A_m)$ by $\gamma \cdot Y = \bar{\chi}(\gamma) r_m(\gamma) Y r_m(\gamma)^{-1}$; let $U' \subseteq \Gamma^0$ be the kernel of this action and of r_m, an open subgroup. It contains $\mathrm{PL}(H)$: $\mathrm{PL}(H) \subseteq H$, $\rho_1 = 1$ on $\mathrm{PL}(H)$ (Lemma E.96 (Pv1)) and $\bar{\chi} = 1$ on H (Tg1). TwZ_m is finite by Lemma E.118: its elements are locally constant maps satisfying the cocycle identity for this continuous action of Γ^0 by group automorphisms on the finite group $\mathrm{PB}_a(A_m)$, which is killed by ℓ (A_m is a k-algebra and k has characteristic ℓ), and Γ^0 satisfies Φ_ℓ by Lemma E.116. Each $z \in \mathrm{TwZ}_m$ restricts to a continuous homomorphism on U', with open kernel U_z, and z vanishes on $\mathrm{PL}(H)$ by Lemma E.45 (Pl2) (with $G = \Gamma$, the subgroup $\Gamma^0 \supseteq H$, and $\mathrm{PL}(H)$ acting trivially). Let V be the intersection of the conjugates in Γ of $U' \cap \bigcap_z U_z$: an open normal subgroup of Γ containing the normal subgroup $\mathrm{PL}(H)$. By (Tg3) there is N_0 with $h_N(\Phi_{N,j})\sigma_j^{-1} \in V$ for all j and $N \geq N_0$. For such N, $u = h_N(\Phi_{N,j})\sigma_j^{-1}$ lies in $V \subseteq U'$, so

$$r_m(h_N \Phi_{N,j}) = r_m(\sigma_j), \qquad z(h_N \Phi_{N,j}) = z(u) + u \cdot z(\sigma_j) = z(\sigma_j) \quad (z \in \mathrm{TwZ}_m). \tag{1}$$

Moreover $\bar{\chi}(\Phi_{N,j}) = 1$, since $\phi_{N,j}^{-1}$ is a Frobenius element for the norm $q_{N,j} \equiv 1 \bmod \ell^N$ (Tg2).

Now let $N \geq N_0$, $M' = M'_{N,m}$, let Z be the set in the statement, $B^1 = B^1(\Gamma_N, M')$, $Z^c = \{y \in Z :\ y(c_N) = 0\}$, $B^c = \{b \in B^1 :\ b(c_N) = 0\}$.

Step 1: removing c_N. Z is a group containing B^1 (a coboundary restricts to a coboundary). For $y \in Z^1(\Gamma_N, M')$, $0 = y(c_N^2) = y(c_N) + c_N \cdot y(c_N)$, so $y(c_N) \in M'^{-} = \{Y :\ c_N \cdot Y = -Y\}$. As ℓ is odd, for $Y \in M'^{-}$ the coboundary b_Y of Y has $b_Y(c_N) = -2Y$, so $Y \mapsto b_Y(c_N)$ maps M'^{-} onto M'^{-}. Hence $y \mapsto y(c_N)$ maps both Z and B^1 onto M'^{-}, with kernels Z^c and B^c, and

$$\#Z \cdot \#B^c = \#Z^c \cdot \#B^1. \tag{2}$$

Step 2: descent to Γ^0. Let $y \in Z^c$. Elements of $\ker h_N$ act trivially on M' (the action of Γ^0_N factors through h_N, and χ_{cyc} factors through Γ), and so do the elements of $\mathrm{PL}(H_N)$ (as $h_N(\mathrm{PL}(H_N)) \subseteq \mathrm{PL}(H)$ by Lemma E.45 (Pl3), where $\rho_1 = 1$ and $\bar{\chi} = 1$). Let W be the closure of the subgroup generated by $\mathrm{PL}(H_N)$ and the conjugates of $\mathrm{T}_{N,1}, \dots, \mathrm{T}_{N,q}$; it acts trivially, so $y|_W$ is a continuous homomorphism, and $y(g\gamma g^{-1}) = y(g) + g \cdot y(\gamma) + g\gamma \cdot y(g^{-1}) = g \cdot y(\gamma)$ for γ acting trivially (using $y(g^{-1}) = -g^{-1}y(g)$). By hypothesis there is Y_j with $y(\iota_{N,j}g) = \iota_{N,j}(g) \cdot Y_j - Y_j$ for $g \in D_{v_{N,j}}$; with $g = \tau_{N,j}$, $\mathrm{T}_{N,j} \in \ker h_N$ (Tg4) acts trivially, so $y(\mathrm{T}_{N,j}) = 0$, and y vanishes on

all conjugates of the $\mathrm{T}_{N,j}$. By Lemma E.45 (Pl2) (with $G = \Gamma_N$ and the open normal subgroup H_N), y vanishes on $\mathrm{PL}(H_N)$. So the homomorphism $y|_W$ vanishes on a set of topological generators of W, hence on W, and $W \supseteq \ker h_N$ by (Tg4). Then $y(g\gamma) = y(g) + g \cdot y(\gamma) = y(g)$ for $\gamma \in \ker h_N$, and $\Psi(y)\colon \Gamma^0 \to \mathrm{PB}_a(A_m)$, $\Psi(y)(h_N g) = y(g)$ ($g \in \Gamma^0_N$), is well defined. It is locally constant (h_N is a continuous surjection of profinite groups, hence open), it satisfies the twisted cocycle identity because y does and $h_N\gamma$ acts through $\bar\chi(h_N\gamma) r_m(h_N\gamma)$, and, as $y(c_N) = 0$, $y(c_N g c_N) = c_N \cdot (y(g) + g \cdot y(c_N)) = -\chi_{\mathrm{cyc}}(c)\, {}^t y(g)$ with $h_N(c_N g c_N) = \bar c\, h_N(g)\, \bar c$. So $\Psi(y) \in \mathrm{TwZ}_m$.

Step 3: $\ell_{\sigma_j}(\Psi(y)) = 0$. By (1), the definition of Ψ and $\bar\chi(\Phi_{N,j}) = 1$,

$$\Psi(y)(\sigma_j) = \Psi(y)(h_N \Phi_{N,j}) = y(\Phi_{N,j}) = \Phi_{N,j} \cdot Y_j - Y_j = r_m(\sigma_j) Y_j r_m(\sigma_j)^{-1} - Y_j,$$

so $\mathrm{tr}(\Psi(y)(\sigma_j) r_m(\sigma_j)) = \mathrm{tr}(r_m(\sigma_j) Y_j) - \mathrm{tr}(Y_j r_m(\sigma_j)) = 0$.

Step 4: Ψ is injective on Z^c. $\Psi(y)$ determines y on Γ^0_N, and $y(c_N g) = y(c_N) + c_N \cdot y(g) = c_N \cdot y(g)$; as $\Gamma_N = \Gamma^0_N \cup c_N \Gamma^0_N$, y is determined.

Step 5: $\#\mathrm{TwB}_m \le \#B^c$. If $Y \in \mathrm{PB}_a(A_m)$ and $-\chi_{\mathrm{cyc}}(c)\, {}^t Y = Y$, i.e. $c_N \cdot Y = Y$, its coboundary b_Y over Γ_N lies in $B^c \subseteq Z^c$ and $\Psi(b_Y)$ is the element $\gamma \mapsto \bar\chi(\gamma) r_m(\gamma) Y r_m(\gamma)^{-1} - Y$ of TwB_m. So $\mathrm{TwB}_m \subseteq \Psi(B^c)$.

Conclusion. By Steps 2–4 and Lemma E.114, $\#Z^c \le \#\{z \in \mathrm{TwZ}_m :\ \ell_{\sigma_j}(z) = 0\ (j \le q)\} \le \#\mathrm{TwB}_m \cdot K^{c_2} \le \#B^c \cdot K^{c_2}$ (Step 5), and by (2), $\#Z = \#B^1 \cdot \#Z^c / \#B^c \le \#B^1 \cdot K^{c_2}$. □

Lemma E.114. *Let $\mathscr{H}$ be a rank-n Hecke datum, x a curve point normalised of shape $(a, n-a)$, κ a Selmer basis of x, $\bar c = \pi_{\mathscr{H}}(c)$, $K = \#k$, and $\Sigma \subseteq \Gamma'$ a finite set detecting (x, κ). For $m \ge 1$ let TwZ_m be the set of locally constant maps $z\colon \Gamma^0_{\mathscr{H}} \to \mathrm{PB}_a(A_m)$ (the matrices in $\mathrm{M}_n(\mathrm{PD}_g(A_m))$ with same-block entries in $A_m\eta$ and different-block entries in $\bigoplus_j A_m \epsilon'_j$) such that $z(\gamma\gamma') = z(\gamma) + \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma) z(\gamma') \rho_1(\gamma)^{-1}$ and $z(\bar c \gamma \bar c) = -\chi_{\mathrm{cyc}}(\bar c)\, {}^t z(\gamma)$ (entries of ρ_1 and values of χ_{cyc} mapped to $\mathrm{PD}_g(A_m)$); let TwB_m be the set of the maps $\gamma \mapsto \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma) Y \rho_1(\gamma)^{-1} - Y$ with $Y \in \mathrm{PB}_a(A_m)$, $-\chi_{\mathrm{cyc}}(\bar c)\, {}^t Y = Y$; and for $\sigma \in \Gamma^0_{\mathscr{H}}$ let $\ell_\sigma(z) \in A_m$ be the η-coefficient of $\mathrm{tr}(z(\sigma)\rho_1(\sigma))$. Then there is $C \ge 0$ such that for all $m \ge 1$*

$$\#\{z \in \mathrm{TwZ}_m :\ \ell_\sigma(z) = 0 \text{ for all } \sigma \in \Sigma\} \ \le\ \#\mathrm{TwB}_m \cdot K^C.$$

Proof. Write $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $P = \mathrm{M}_n(\mathrm{PD}_g(A))$, a free A-module of finite rank, and $\mathrm{PB}_a = \mathrm{PB}_a(A) \subseteq P$, a direct summand spanned by coordinates, so P/PB_a is free and

$$(P/\mathrm{PB}_a) \otimes A_m = \mathrm{M}_n(\mathrm{PD}_g(A_m))/\mathrm{PB}_a(A_m).$$

We apply Lemma E.115.

The modules. Let $\mathcal{C}$ be the A-module of maps $f\colon \Gamma^0 \to P$ whose reductions modulo every T^N are locally constant (T-adically continuous maps). By Lemma E.117, item 1, $\mathcal{C}$ has no T-torsion and is T-adically separated and complete. Let $Y = \prod_{(\gamma,\gamma')} P \times \prod_\gamma P \times \prod_\gamma P/\mathrm{PB}_a \times A^\Sigma$, a product of free modules of finite rank, hence without T-torsion and separated, and

$$\Phi(f) = \Big(\big(f(\gamma\gamma') - f(\gamma) - \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma) f(\gamma') \rho_1(\gamma)^{-1}\big),\ \big(f(\bar c\gamma\bar c) + \chi_{\mathrm{cyc}}(\bar c)\, {}^t f(\gamma)\big),\ \big(f(\gamma) \bmod \mathrm{PB}_a\big),\ \big(\ell_\sigma(f)\big)_{\sigma\in\Sigma} \Big),$$

with $\ell_\sigma(f)$ the η-coefficient of $\mathrm{tr}(f(\sigma)\rho_1(\sigma))$. Φ is A-linear and $\ker\Phi = \{z \in \mathrm{TwZ}(x,\kappa) :\ \ell_\sigma(z) = 0\ (\sigma \in \Sigma)\}$.

B. Let $B = \mathrm{TwB}(x,\kappa)$. Each $b_Y(\gamma) = \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma)Y\rho_1(\gamma)^{-1} - Y$ with $Y \in \mathrm{PB}_a$, $-\chi_{\mathrm{cyc}}(\bar{c})^t Y = Y$, is T-adically continuous, takes values in PB_a (Lemma E.106), satisfies the cocycle identity, and $b_Y(\bar{c}\gamma\bar{c}) = \chi_{\mathrm{cyc}}(\gamma)\,{}^t\rho_1(\gamma)^{-1}Y\,{}^t\rho_1(\gamma) - Y = -\chi_{\mathrm{cyc}}(\bar{c})\,{}^t b_Y(\gamma)$ by Lemma E.107 (Rf1) and ${}^tY = -\chi_{\mathrm{cyc}}(\bar{c})Y$. For $\sigma \in \Sigma \subseteq \Gamma'$, $\chi_{\mathrm{cyc}}(\sigma) = 1$ and $\mathrm{tr}(b_Y(\sigma)\rho_1(\sigma)) = \mathrm{tr}(\rho_1(\sigma)Y) - \mathrm{tr}(Y\rho_1(\sigma)) = 0$. So $B \subseteq \ker\Phi$, and since Σ detects (x,κ), every element of $\ker\Phi$ has a multiple $T^s z$ in B.

Reduction modulo T^m. Let $X_m = \Phi^{-1}(T^mY)$ and $Z_m = \{z \in \mathrm{TwZ}_m : \ell_\sigma(z) = 0\ (\sigma \in \Sigma)\}$. The map $f \mapsto \bar{f}$ (reduction of values modulo T^m) sends X_m into Z_m, since $\Phi(f) \in T^mY$ says exactly that $\bar{f}$ satisfies the defining conditions of Z_m. It is onto: by Lemma E.117, item 2, every $z \in Z_m$ has a lift $f \in \mathcal{C}$, and $\Phi(f) \in T^mY$ because $\Phi(f)$ modulo T^mY depends only on $\bar{f} = z$. Its kernel is $X_m \cap T^m\mathcal{C} = T^m\mathcal{C}$ (Lemma E.117, item 2). Hence $\#(X_m/T^m\mathcal{C}) = \#Z_m$. Likewise $(B + T^m\mathcal{C})/T^m\mathcal{C}$ is the set of reductions of elements of B, contained in TwB_m (reduce Y).

Finiteness of $X_1/T\mathcal{C} \cong Z_1$. The formula $\gamma \cdot Y = \chi_{\mathrm{cyc}}(\gamma)\rho_1(\gamma)Y\rho_1(\gamma)^{-1}$ is a continuous action of Γ^0 by group automorphisms on the finite group $\mathrm{PB}_a(k)$ (killed by ℓ), the elements of Z_1 are locally constant maps satisfying the cocycle identity for this action, and Γ^0 satisfies Φ_ℓ by Lemma E.116; so Z_1 is finite by Lemma E.118.

By Lemma E.115 there is e with $\#Z_m = \#(X_m/T^m\mathcal{C}) \le \#((B + T^m\mathcal{C})/T^m\mathcal{C}) \cdot K^e \le \#\mathrm{TwB}_m \cdot K^e$ for all m. Take $C = e$. □

Lemma E.115. *Let k be a finite field, $K = \#k$, $A = k[[T]]$. Let C be an A-module without T-torsion that is T-adically separated and complete, Y an A-module without T-torsion that is T-adically separated, $\Phi\colon C \to Y$ an A-linear map, and $B \subseteq \ker\Phi$ a submodule such that every $f \in \ker\Phi$ has some $T^s f \in B$. For $m \ge 1$ put $X_m = \Phi^{-1}(T^mY)$. If X_1/TC is finite, there is $e \ge 0$ such that for all $m \ge 1$*

$$\#(X_m/T^mC) \;\le\; \#((B + T^mC)/T^mC) \cdot K^e.$$

Proof. Write $\mathcal{K} = \ker\Phi$ and $I = \Phi(C) \subseteq Y$.

Step 1: two intersections. $\mathcal{K} \cap T^mC = T^m\mathcal{K}$ and $X_m \cap TC = TX_{m-1}$ ($X_0 = C$): if $f = T^m g$ with $\Phi(f) = 0$, then $T^m\Phi(g) = 0$ and $\Phi(g) = 0$; if $f = Tg$ with $\Phi(f) \in T^mY$, then $\Phi(g) \in T^{m-1}Y$ (Y has no T-torsion). Since C has no T-torsion, $TX_{m-1}/T^mC \cong X_{m-1}/T^{m-1}C$, so the exact sequence $0 \to TX_{m-1}/T^mC \to X_m/T^mC \to X_1/TC$ gives $\#(X_m/T^mC) \le \#(X_1/TC)^m$ by induction.

Step 2: $\mathcal{K}$ is free of finite rank r and $T^s\mathcal{K} \subseteq B$ for some s. $\mathcal{K}/T\mathcal{K} = \mathcal{K}/(\mathcal{K} \cap TC)$ embeds in X_1/TC, so it is finite. $\mathcal{K}$ is complete for its T-adic filtration, which by Step 1 is induced from C: a Cauchy sequence (f_i) in $\mathcal{K}$ has a limit $f \in C$, and $\Phi(f) = \Phi(f - f_i) \in T^iY$ for all large i, so $\Phi(f) \in \bigcap_i T^iY = 0$. Let $k_1, \dots, k_r \in \mathcal{K}$ lift a k-basis of $\mathcal{K}/T\mathcal{K}$. For $f \in \mathcal{K}$, write successively $f = \sum_i a_i^{(0)}k_i + Tf_1$, $f_1 = \sum_i a_i^{(1)}k_i + Tf_2$, … with $a_i^{(j)} \in A$ and $f_j \in \mathcal{K}$; then $f - \sum_i(\sum_{j<J} T^j a_i^{(j)})k_i \in T^J\mathcal{K}$ for every J, and as A is complete and $\mathcal{K}$ separated, $f = \sum_i(\sum_j T^j a_i^{(j)})k_i$. So $\mathcal{K}$ is finitely generated, and being torsion free over the discrete valuation ring A, it is free; its rank is $r = \dim_k \mathcal{K}/T\mathcal{K}$. Choosing s_i with $T^{s_i}k_i \in B$ and $s = \max_i s_i$, $T^s\mathcal{K} \subseteq B$.

Step 3: the image is closed with bounded defect. Let $S = \{y \in Y : T^j y \in I \text{ for some } j\}/I$ and $S[T^j]$ its elements killed by T^j. The map $X_1 \to S[T]$, $f \mapsto [y]$ where $\Phi(f) = Ty$, is well defined (y is unique), onto, and kills TC; so $S[T]$ is finite. Multiplication by T^{j-1} embeds $S[T^j]/S[T^{j-1}]$ in $S[T]$, so every $S[T^j]$ is finite. We claim $S[T^{c+1}] = S[T^c]$ for some c. Otherwise the subgroups $D_j = T^{j-1}S[T^j] \subseteq S[T]$ are all non-zero; they decrease, so they are eventually

equal to some $D \neq 0$; fix $0 \neq s_1 \in D$. The sets $E_j = \{x \in S[T^j] : T^{j-1}x = s_1\}$ are finite and, for large j, non-empty, and $x \mapsto Tx$ maps E_{j+1} to E_j; by König's lemma there are $s_j \in E_j$ with $Ts_{j+1} = s_j$ for all j. Choose $y_j \in Y$ representing s_j; then $Ty_{j+1} = y_j + i_j$ with $i_j \in I$, and $u_j = T^j y_j \in I$ satisfies $u_{j+1} = u_j + T^j i_j$. Choose $f_1, g_j \in C$ with $\Phi(f_1) = u_1$ and $\Phi(g_j) = i_j$, and put $F_J = f_1 + \sum_{j<J} T^j g_j$, so $\Phi(F_J) = u_J$. By completeness the series $\sum_{j \geq J} T^{j-J} g_j$ converge in C; so (F_J) has a limit f with $f - F_J \in T^J C$, and $\Phi(f) - u_J = \Phi(f - F_J) \in T^J I$. Hence $\Phi(f) = T^J(y_J + h_J)$ with $h_J \in I$, for every J, so $\Phi(f) \in \bigcap_J T^J Y = 0$; then $T^J(y_J + h_J) = 0$ gives $y_J = -h_J \in I$, i.e. $s_J = 0$, and $s_1 = T^{J-1} s_J = 0$, a contradiction. So $S[T^{c+1}] = S[T^c]$, and then $S[T^j] = S[T^c]$ for all $j \geq c$ (if $T^{c+2}x = 0$ then $Tx \in S[T^{c+1}] = S[T^c]$, so $x \in S[T^{c+1}]$; induct). As S is the union of the $S[T^j]$, $T^c S = 0$. Consequently $I \cap T^m Y \subseteq T^{m-c} I$ for $m \geq c$: if $u = T^m y \in I$, then $[y] \in S$, so $T^c y \in I$ and $u = T^{m-c}(T^c y)$.

Step 4: the count. Let $m \geq c$ and $f \in X_m$. By Step 3, $\Phi(f) = T^{m-c}\Phi(g)$ with $g \in C$, and $\Phi(g) \in T^c Y$ (Y has no T-torsion), so $g \in X_c$ and $f - T^{m-c} g \in \mathcal{K}$. Hence $X_m = \mathcal{K} + T^{m-c} X_c$ (the inclusion $\supseteq$ is clear), and

$$\#(X_m/T^m C) \leq \#((\mathcal{K}+T^m C)/T^m C) \cdot \#((T^{m-c}X_c + T^m C)/T^m C) \leq \#(\mathcal{K}/T^m\mathcal{K}) \cdot \#(X_c/T^c C),$$

using $(\mathcal{K} + T^m C)/T^m C \cong \mathcal{K}/(\mathcal{K} \cap T^m C) = \mathcal{K}/T^m\mathcal{K}$ (Step 1) and the surjection $X_c/T^c C \to (T^{m-c}X_c + T^m C)/T^m C$, $g \mapsto T^{m-c} g$. By Step 2, $\#(\mathcal{K}/T^m\mathcal{K}) = K^{mr}$, while $(B + T^m C)/T^m C \cong B/(B \cap T^m\mathcal{K})$ contains the image of $T^s\mathcal{K}$, of order $\#(T^s\mathcal{K}/T^m\mathcal{K}) = K^{(m-s)r}$ when $m \geq s$; so in all cases $\#(\mathcal{K}/T^m\mathcal{K}) \leq \#((B + T^m C)/T^m C) \cdot K^{sr}$. With Step 1, $\#(X_c/T^c C) \leq \#(X_1/TC)^c$, and for $m < c$, $\#(X_m/T^m C) \leq \#(X_1/TC)^c$. Choosing e with $K^e \geq K^{sr} \cdot \#(X_1/TC)^c$ proves the bound for all $m \geq 1$. □

Lemma E.116. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$. Then $\Gamma_{\mathscr{H}}$ and $\Gamma^0_{\mathscr{H}}$ satisfy Mazur's condition Φ_ℓ.*

Proof. Let $K \in \{L^+, L\}$, so that $\Gamma_K := \pi_{\mathscr{H}}(G_K)$ is $\Gamma_{\mathscr{H}}$ or $\Gamma^0_{\mathscr{H}}$; since $N_{\mathscr{H}} \subseteq G_L \subseteq G_K$ (Definition 50.1), $\Gamma_K = G_K/N_{\mathscr{H}}$ as profinite groups. Let $\Gamma' \subseteq \Gamma_K$ be open and $G' \subseteq G_K$ its preimage, an open subgroup containing $N_{\mathscr{H}}$; so $G' = G_{K'}$ for a finite extension K' of K inside $\overline{\mathbb{Q}}$, and $\Gamma' = G_{K'}/N_{\mathscr{H}}$. Composition with the projection identifies $\mathrm{Hom}_{\mathrm{cont}}(\Gamma', \mathbb{F}_\ell)$ with the continuous homomorphisms $\phi\colon G_{K'} \to \mathbb{F}_\ell$ trivial on $N_{\mathscr{H}}$.

Let S' be the set of places of K' above the places of L^+ in $S_\ell \cup \mathrm{St}$ and above ∞; it is finite. Let w be a finite place of K' not in S' and $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above w; the inertia group of $G_{K'}$ at $\bar{w}$ is $I_{\bar{w}} \cap G_{K'}$. The place of L^+ below w is finite and not in $S_\ell \cup \mathrm{St}$, so $\bar{w} \nmid \ell$ and, by (Rd4), every $\bar{\chi}_a$ is trivial on $I_{\bar{w}} \cap G_L$; hence every element of $I_{\bar{w}} \cap G_L$ is one of the generators of $N_{\mathscr{H}}$, and $I_{\bar{w}} \cap G_{K'} \subseteq I_{\bar{w}} \cap G_L \subseteq N_{\mathscr{H}}$; here $I_{\bar{w}} \cap G_{K'} \subseteq I_{\bar{w}} \cap G_L$ because $G_{K'} \subseteq G_L$ if $K = L$, and because $I_{\bar{w}} \cap G_{L^+} \subseteq G_L$ if $K = L^+$ (L/L^+ is unramified at every finite place, (Rd2)). So ϕ is trivial on the inertia groups of $G_{K'}$ at all finite places outside S', i.e. ϕ factors through $G_{K',S'}$, which satisfies Φ_ℓ by Theorem B.71, item 2; hence the ϕ form a subset of the finite set $\mathrm{Hom}_{\mathrm{cont}}(G_{K',S'}, \mathbb{F}_\ell)$. So $\mathrm{Hom}_{\mathrm{cont}}(\Gamma', \mathbb{F}_\ell)$ is finite for every open Γ', for both groups. □

Lemma E.117. *Let k be a finite field, $A = k[[T]]$, P a free A-module of finite rank and G a profinite group. Let $C(G, P)$ be the A-module of maps $f\colon G \to P$ whose reduction modulo T^N is locally constant for every $N \geq 1$. Then:*

1. *$C(G, P)$ has no T-torsion and is T-adically separated and complete;*
2. *for every $m \geq 1$, reduction of values modulo T^m is an A-linear map from $C(G, P)$ onto the set of locally constant maps $G \to P/T^m P$, with kernel $T^m C(G, P)$.*

Proof. Write $C = C(G,P)$. As $P \cong A^r$, P has no T-torsion, $\bigcap_N T^N P = 0$, and P is T-adically complete.

Item 1. If $Tf = 0$, every value $f(\gamma)$ is killed by T, so $f = 0$. If $f \in \bigcap_N T^N C$, its values lie in $\bigcap_N T^N P = 0$. First a remark used twice: if $f \in C$ has all values in $T^i P$, then $g = f/T^i$ (defined value by value, P having no T-torsion) lies in C, since the reduction of g modulo T^N is determined by the reduction of f modulo T^{N+i}, which is locally constant; so $f = T^i g \in T^i C$. Now let (f_i) be a sequence in C with $f_{i+1} - f_i \in T^i C$ for all i. For each γ, $(f_i(\gamma))$ is Cauchy in P; let $f(\gamma)$ be its limit. For $i \geq N$, $f(\gamma) \equiv f_N(\gamma) \bmod T^N$, so the reduction of f modulo T^N equals that of f_N and is locally constant: $f \in C$. Moreover $f - f_i$ has values in $T^i P$, so $f - f_i \in T^i C$ by the remark. Hence C is complete.

Item 2. The reduction $f \mapsto \bar{f}$ is A-linear and $\bar{f}$ is locally constant by definition of C. It is onto: given a locally constant $z\colon G \to P/T^m P$ and a set-theoretic section $s\colon P/T^m P \to P$ of the reduction, $f = s \circ z$ is locally constant (it takes the finitely many values of s on the image of z, on the open fibres of z), hence lies in C, and $\bar{f} = z$. Its kernel contains $T^m C$; conversely, if $\bar{f} = 0$, f has values in $T^m P$, so $f \in T^m C$ by the remark in Item 1. □

Lemma E.118. *Let ℓ be a prime, G a profinite group satisfying Mazur's condition Φ_ℓ, and M a finite abelian group with $\ell M = 0$ on which G acts by group automorphisms, continuously for the discrete topology of M. Then the set of locally constant maps $z\colon G \to M$ with*

$$z(\gamma\gamma') = z(\gamma) + \gamma \cdot z(\gamma') \qquad (\gamma, \gamma' \in G)$$

is finite.

Proof. As M is finite and discrete and the action is continuous, the kernel U of $G \to \mathrm{Aut}(M)$ is the intersection of the finitely many open stabilisers of the elements of M, an open normal subgroup of G. Let z be a map as in the statement. For $u, u' \in U$, $z(uu') = z(u) + u \cdot z(u') = z(u) + z(u')$, so $z|_U$ is a continuous homomorphism $U \to M$. Fix an isomorphism $M \cong (\mathbb{Z}/\ell)^d$ of groups ($\ell M = 0$); then $z|_U$ is given by d continuous homomorphisms $U \to \mathbb{F}_\ell$, and as U is open, $\mathrm{Hom}_{\mathrm{cont}}(U, \mathbb{F}_\ell)$ is finite by Φ_ℓ. So $z|_U$ takes at most $(\#\mathrm{Hom}_{\mathrm{cont}}(U, \mathbb{F}_\ell))^d$ values. Let $\gamma_1, \dots, \gamma_r$ be representatives of the finitely many cosets $U\gamma_i$ of U in G. For $u \in U$, $z(u\gamma_i) = z(u) + u \cdot z(\gamma_i) = z(u) + z(\gamma_i)$, so z is determined by $z|_U$ and $z(\gamma_1), \dots, z(\gamma_r) \in M$. Hence there are at most $(\#\mathrm{Hom}_{\mathrm{cont}}(U, \mathbb{F}_\ell))^d \, (\#M)^r$ such maps. □

E.4.2 The obstruction bound

This subsection proves the obstruction bound (B2), Proposition E.119, from a bound for the number of generators of the obstruction modules at the levels (Proposition E.120). The obstruction classes of first-order even Selmer families lie in the odd-block obstruction module (Lemma E.122), which has at most g generators up to a bounded factor at every Taylor–Wiles level (Lemma E.123); the reason is that odd-block Selmer cocycles at the levels are base-level cocycles up to a bounded factor (Lemma E.126, Lemma E.127). The subsection ends with the conditions (K1)–(K3) at a level, from the truncated Selmer and span bounds and from tame generators of the kernel (Lemma E.129, Lemma E.130, Lemma E.131), which Proposition E.94 uses.

Proposition E.119. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ that is a discrete valuation ring, $(B_n^{\mathrm{po}}, D^{\mathrm{u}}, (\psi_{v,a}^{\mathrm{d}}))$ a universal polarised ordinary determinant over $\mathscr{H}$, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed curve point of B_n^{po} normalised of shape $(a, n-a)$, κ a Selmer basis of x with local witnesses, and a Taylor–Wiles datum for $\mathscr{H}$ (with open subgroup H*

and elements $\sigma_1,\dots,\sigma_q$) along which x has eigenvalue data. Assume $\rho(\gamma)=1$ for every $\gamma\in\Gamma^0_{\mathscr{H}}\cap \mathrm{PL}(H)$, that x satisfies (Pj1) of Definition 50.9, and that for every $Z\in \mathrm{Ev}_a(A_k)$ some T^sZ lies in the A_k-span of $\rho(\Gamma')$ (Γ' as in Definition 50.9). Then (B2) holds for x, κ and the levels $\mathbf{V}_N$ of the datum.

Proof. Let C be the constant of Proposition E.120; we show (B2) with this C. Fix $m\ge 1$, let N_0 be as in Proposition E.120, let $N\ge N_0$, and let $(z_{i,j})_{0\le i\le g,\,1\le j\le g}$ be a family in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}_N}(A_m)$. Let $H=H_{N,m}$ and $\xi_0,\dots,\xi_g\in H$ be as in (Ob1), (Ob2) of Proposition E.120.

$A=k[[T]]$ is a discrete valuation ring with uniformiser T and residue field k, and H is a finite A-module with $T^mH=0$ and $\#(H/T^eH)\le(\#k)^{ge+C}$ for $0\le e\le m$ (Ob1). By Lemma E.128 there are $c_0,\dots,c_g\in A$, one of them a unit, with $\sum_i(T^Cc_i)\xi_i=T^C\sum_i c_i\xi_i=0$. By (Ob2) applied to $(T^Cc_i)_i$ there is $\Psi\in\mathrm{Sel}^2_{\mathbf{V}_N}(A_m)$ whose ϵ'_j-coefficient of $\Psi(\gamma)$ is $\sum_i T^Cc_iz_{i,j}(\gamma)=T^C\sum_i c_iz_{i,j}(\gamma)$ for all j and γ. This is (B2). □

Proposition E.120. *Let $\mathscr{H}$, $\mathcal{O}$, $(B_n^{\mathrm{po}},D^{\mathrm{u}},(\psi^{\mathrm{d}}_{v,a}))$, $x=(k,\rho,1_n,(\psi_{v,a}),f)$, $\kappa=(\kappa_1,\dots,\kappa_g)$ with local witnesses, and a Taylor–Wiles datum (with H and $\sigma_1,\dots,\sigma_q$) along which x has eigenvalue data be as in Proposition E.119, with $\rho(\gamma)=1$ for $\gamma\in\Gamma^0_{\mathscr{H}}\cap\mathrm{PL}(H)$, x satisfying (Pj1) of Definition 50.9, and for every $Z\in\mathrm{Ev}_a(A)$ some T^sZ in the A-span of $\rho(\Gamma')$ (Γ' as in Definition 50.9). Then there is $C\ge0$ such that for every $m\ge1$ there is N_0 such that for every $N\ge N_0$ there is a finite A-module $H_{N,m}$ with:*

(Ob1) *$T^mH_{N,m}=0$ and $\#(H_{N,m}/T^eH_{N,m})\le(\#k)^{ge+C}$ for $0\le e\le m$;*

(Ob2) *for every family $(z_{i,j})_{0\le i\le g,\,1\le j\le g}$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}_N}(A_m)$ there are $\xi_0,\dots,\xi_g\in H_{N,m}$ such that for every $c\in A^{g+1}$ with $\sum_i c_i\xi_i=0$ there is $\Psi\in\mathrm{Sel}^2_{\mathbf{V}_N}(A_m)$ whose ϵ'_j-coefficient of $\Psi(\gamma)$ is $\sum_i c_iz_{i,j}(\gamma)$ for all j and γ.*

Proof. Take $H_{N,m}$ to be the obstruction module of the Selmer data $\mathcal{D}_{N,m}$ of Lemma E.122 (the odd-block module $\mathrm{Od}_a(A_m)$ over G_{L^+,T_∞}, $T=S_\ell\cup\mathrm{St}\cup Q_N$, with the ordinary quotients at S_ℓ and vanishing on J_u at St), and C, N_0 as in Lemma E.123. For $N\ge N_0$, Lemma E.123 gives (Ob1): $H_{N,m}$ is a finite A-module, $T^mH_{N,m}=0$ and $\#(H_{N,m}/T^eH_{N,m})\le(\#k)^{ge+C}$ for $0\le e\le m$; and Lemma E.122 gives (Ob2). □

Definition E.121. Let A be a commutative ring and G a profinite group. **Selmer data** $\mathcal{D}$ over G consist of a finite A-module M with a continuous A-linear action of G (M discrete) and a finite family, indexed by $w\in W$, of: a profinite group G_w with a continuous homomorphism $\phi_w\colon G_w\to G$; a finite A-module Q_w with a continuous A-linear action of G_w; a surjective A-linear map $\pi_w\colon M\to Q_w$ with $\pi_w(\phi_w(g)m)=g\,\pi_w(m)$; and an A-submodule L_w with $B^1(G_w,Q_w)\subseteq L_w\subseteq Z^1(G_w,Q_w)$ (the **local condition**). For a cochain x of G with values in M write $\pi_w\phi_w^*x$ for the cochain $(g_1,\dots,g_i)\mapsto\pi_w(x(\phi_wg_1,\dots,\phi_wg_i))$ of G_w.

The **Selmer cocycles** are $Z^1_{\mathcal{D}}=\{z\in Z^1(G,M):\ \pi_w\phi_w^*z\in L_w\text{ for all }w\}$, and the **Selmer group** is $H^1_{\mathcal{D}}=Z^1_{\mathcal{D}}/B^1(G,M)$. The **obstruction module** is $H^2_{\mathcal{D}}=Z^2_{\mathcal{D}}/B^2_{\mathcal{D}}$, where

$$Z^2_{\mathcal{D}}=\Big\{(a,(b_w)_{w\in W}):\ a\in Z^2(G,M),\ b_w\in C^1(G_w,Q_w),\ db_w=\pi_w\phi_w^*a\text{ for all }w\Big\},$$

$$B^2_{\mathcal{D}}=\Big\{(dx,(\pi_w\phi_w^*x+\lambda_w)_w):\ x\in C^1(G,M),\ \lambda_w\in L_w\Big\}.$$

($B^2_{\mathcal{D}}\subseteq Z^2_{\mathcal{D}}$ since $d(\pi_w\phi_w^*x)=\pi_w\phi_w^*dx$ and $d\lambda_w=0$.) Both $H^1_{\mathcal{D}}$ and $H^2_{\mathcal{D}}$ are A-modules; they are the first and second cohomology of the Selmer complex of M with the local conditions (L_w).

Lemma E.122. *Let $\mathscr{H}$ be a rank-n Hecke datum, $x=(k,\rho,1_n,(\psi_{v,a}),f)$ a framed curve point normalised of shape $(a,n-a)$, $\kappa=(\kappa_1,\dots,\kappa_g)$ a Selmer basis with local witnesses $X_{j,v}=Y_{j,v}\in\mathrm{Od}_a(A)$, and a Taylor–Wiles datum; let $N,m\geq 1$, $c_N=\pi^{Q_N}(c)$, $\Gamma_N^0=h_N^{-1}(\Gamma^0_{\mathscr{H}})$. Let $T=S_\ell\cup\mathrm{St}\cup Q_N$, $G=G_{L^+,T_\infty}$ with the continuous surjection $p\colon G\to\Gamma_N$ of Lemma E.102 (Lb1) (for $Q=Q_N$; here $T^\circ=\varnothing$), and for a decomposition group $D\subseteq G_{L^+}$ let $\phi_D\colon D\to G$ be the restriction of $G_{L^+}\to G$, so $p\circ\phi_D=\pi^{Q_N}|_D$. Let $\mathcal{D}_{N,m}$ be the Selmer data over G (with A acting through A_m) given by: $M=\mathrm{Od}_a(A_m)$, on which G acts through p by $\gamma\cdot P=\rho(h_N\gamma)P\rho(h_N\gamma)^{-1}$ ($\gamma\in\Gamma_N^0$) and $c_N\cdot P=-{}^tP$; for $v\in S_\ell$: $G_v=D_v$, $\phi_v=\phi_{D_v}$, $Q_v=M/F_v$ with $F_v=\{P: w_v^{-1}Pw_v$ upper triangular$\}$, π_v the projection, $L_v=B^1(D_v,Q_v)$; for $u\in\mathrm{St}$, with $\bar u$ the place of the frame: $G_u=D_{\bar u}\cap G_{L^+}$, $\phi_u=\phi_{G_u}$, $Q_u=M$, $\pi_u=\mathrm{id}$, and L_u the cocycles vanishing on J_u, the closed normal subgroup of G_u generated by $I_{\bar u}\cap G_L\cap\pi_{\mathscr{H}}^{-1}(I_u^x)$. Put $H_{N,m}=H^2_{\mathcal{D}_{N,m}}$. Then for every family $(z_{i,j})_{0\leq i\leq g,\,1\leq j\leq g}$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}_N}(A_m)$ there are $\xi_0,\dots,\xi_g\in H_{N,m}$ such that for every $c\in A^{g+1}$ with $\sum_i c_i\xi_i=0$ there is $\Psi\in\mathrm{Sel}^2_{\mathbf{V}_N}(A_m)$ such that the ϵ'_j-coefficient of $\Psi(\gamma)$ is $\sum_i c_iz_{i,j}(\gamma)$ for all j and γ. This is (Ob2) of Proposition E.120 for $H_{N,m}$.*

Proof. Throughout, Γ_N acts on $\mathrm{Ev}_a(A_m)$ and $\mathrm{Od}_a(A_m)$ by the same formulas as on M (an action as in Lemma E.107 (Rf2), with ρ in place of ρ_1), ρ and κ_j are evaluated at $h_N\gamma$, and $\pi=\pi_{\mathscr{H}}$. For $X\in\mathrm{Od}_a$, $Y\in\mathrm{Ev}_a$ the bracket $[X,Y]=XY-YX$ lies in Od_a and is Γ_N-equivariant: for Γ_N^0 this is conjugation, and $[-{}^tX,-{}^tY]={}^tX{}^tY-{}^tY{}^tX=-{}^t[X,Y]$.

Step 0: extension to Γ_N. A cocycle z on Γ_N^0 with $z(c_N\gamma c_N)=c_N\cdot z(\gamma)$ extends uniquely to a cocycle $\tilde z$ on Γ_N with $\tilde z(c_N)=0$, namely $\tilde z(c_N\gamma)=c_N\cdot z(\gamma)$ (direct check of the cocycle identity in the four cases). This applies to $\kappa_j\circ h_N$ (into $\mathrm{Od}_a(A_m)$) and to the $z_{i,j}$ (into $\mathrm{Ev}_a(A_m)$), by (Sd2) and (Sc). For cocycles κ,P (into Od_a, Ev_a) put $(\kappa\cup P)(\gamma,\gamma')=[\kappa(\gamma),\gamma\cdot P(\gamma')]$; by equivariance of the bracket this is a continuous 2-cocycle. Cochains of Γ_N are regarded as cochains of G through p (inflation, which preserves cocycles and the identities below), and for g in a decomposition group we write ϕ_wg also for $p(\phi_wg)=\pi^{Q_N}(g)$. For X, Y fixed and cocycles P, κ one checks directly (with d as in Section 13, $(dy)(\gamma,\gamma')=\gamma y(\gamma')-y(\gamma\gamma')+y(\gamma)$):

$$d\big([X,P(\cdot)]\big)=(dX)\cup P,\qquad d\big([\kappa(\cdot),(\cdot)\,Y]\big)=-\kappa\cup dY,\qquad d\big([X,Y]\big)(\gamma)=[\gamma X,\gamma Y]-[X,Y]. \tag{1}$$

Step 1: the classes. Fix i, write $P_{i,j}=\tilde z_{i,j}$, $a_i=\sum_j\tilde\kappa_j\cup P_{i,j}$. For $v\in S_\ell$ and each j choose a witness $Y_{i,j,v}\in\mathrm{Ev}_a(A_m)$ for $z_{i,j}$ at v, and put, for $g\in D_v$ (acting through ϕ_v), $\kappa'_j(g)=\kappa_j(\pi g)-(gX_{j,v}-X_{j,v})$ and $Q_{i,j}(g)=z_{i,j}(\phi_vg)-(gY_{i,j,v}-Y_{i,j,v})$; both are cocycles of D_v with values in F_v (the witness conditions), and D_v preserves F_v and $[F_v\cap\mathrm{Od}_a,\{w_v\text{-upper triangular}\}\cap\mathrm{Ev}_a]\subseteq F_v$, because $w_v^{-1}\rho(\pi g)w_v$ is upper triangular ((Sd1)). Using (1) twice, on D_v:

$$\phi_v^*a_i=\sum_j\kappa'_j\cup Q_{i,j}+d\,\beta_{i,v},\qquad \beta_{i,v}(g)=\sum_j\big([X_{j,v},z_{i,j}(\phi_vg)]-[\kappa'_j(g),\,gY_{i,j,v}]\big),$$

and $\kappa'_j\cup Q_{i,j}$ has values in F_v. Put $b_{i,v}=\pi_v\circ\beta_{i,v}$; then $db_{i,v}=\pi_v\phi_v^*a_i$. For $u\in\mathrm{St}$: $p(\phi_u(J_u))$ lies in the closed normal subgroup of Γ_N^0 generated by $I_{N,u}$; its elements act trivially on M and $\mathrm{Ev}_a(A_m)$ (ρ is trivial on $I_u^x=h_N(I_{N,u})$), and $\tilde\kappa_j$, $P_{i,j}$ vanish on them (they vanish on $I_{N,u}$, by (Sd2) and (Sc), and a cocycle vanishing on a trivially acting element vanishes on its conjugates, $z(huh^{-1})=h\cdot z(u)$, and by continuity on the closure). Hence $\phi_u^*a_i(\gamma j,\gamma' j')=\phi_u^*a_i(\gamma,\gamma')$ for $j,j'\in J_u$, i.e. $\phi_u^*a_i$ is inflated from a 2-cocycle $\bar a_i$ of G_u/J_u with values in M (J_u acting trivially). $G_u\subseteq G_L$ by (Rd2); $G_u/(I_{\bar u}\cap G_u)\cong\hat{\mathbb{Z}}$, and $(I_{\bar u}\cap G_u)/J_u$ is a quotient of $\pi(I_{\bar u}\cap G_L)/I_u^x$, a finite group of order prime to ℓ (inertia elements on which all $\bar\chi_a$ are trivial lie in $N_{\mathscr{H}}$, so $\pi(I_{\bar u}\cap G_L)$ embeds in a product of copies of $\mathbb{F}_{\mathcal{O}}^\times$). By the Hochschild–Serre spectral sequence (the finite normal subgroup has order prime to ℓ, M is an ℓ-group) and $H^2(\hat{\mathbb{Z}},M')=0$ for finite M',

$H^2(G_u/J_u, M) = 0$. So $\bar a_i = d\bar b_i$ with $\bar b_i(1) = \bar a_i(1,1) = 0$; its inflation $b_{i,u}$ satisfies $db_{i,u} = \phi_u^* a_i$ and vanishes on J_u. Let ξ_i be the class of $(a_i, (b_{i,w})_w) \in Z^2_{\mathcal{D}_{N,m}}$.

Step 2: a relation gives Ψ. Let $c \in A^{g+1}$ with $\sum_i c_i\xi_i = 0$; put $P_j = \sum_i c_i P_{i,j}$, $Y^\flat_{j,v} = \sum_i c_i Y_{i,j,v}$ (a witness for P_j, the witness conditions being linear), $a = \sum_i c_i a_i = \sum_j \tilde\kappa_j \cup P_j$, $b_w = \sum_i c_i b_{i,w}$. By definition of $B^2_{\mathcal D}$ there are $x \in C^1(G, M)$ and $\lambda_w \in L_w$ with $a = dx$ (a inflated to G) and $b_w = \pi_w\phi_w^* x + \lambda_w$. *Descent to Γ_N.* Elements of $\ker p$ act trivially on M, and a vanishes when one argument lies in $\ker p$; so $dx = a$ gives $x(\gamma k) = x(\gamma) + \gamma\cdot x(k)$ and $x(k\gamma) = x(k) + x(\gamma)$, hence $x(\gamma k\gamma^{-1}) = \gamma\cdot x(k)$, for $k \in \ker p$: $x|_{\ker p}$ is a continuous homomorphism compatible with conjugation. At $u \in \mathrm{St}$, b_u and λ_u vanish on J_u, so x vanishes on $\phi_u(J_u)$, which contains the image of $J_{\bar u} = \{s \in I_{\bar u} \cap G_L :\ \bar\chi_a(s) = 1\ (1 \le a \le n)\}$ (as $J_{\bar u} \subseteq N_{\mathscr H}$, $\pi_{\mathscr H}(J_{\bar u}) = 1 \subseteq I^x_u$). By Lemma E.102 (Lb1) (with $T^\circ = \varnothing$), $\ker p$ is the closed normal subgroup generated by these images; so x vanishes on $\ker p$, $x(\gamma k) = x(\gamma)$, and $x = \bar x \circ p$ with $\bar x \in C^1(\Gamma_N, M)$ continuous (p is open), $d\bar x = a$ on Γ_N and $b_w = \pi_w\phi_w^*\bar x + \lambda_w$. Let $y = -\bar x$, so $dy = -a$ on Γ_N. As $\tilde\kappa_j(c_N) = P_j(c_N) = 0$, $a(c_N, \cdot) = a(\cdot, c_N) = 0$ and $a(1,1) = 0$; so $y(1) = 0$ and $c_N\cdot y(c_N) = -y(c_N)$. With $Y^* = y(c_N)/2$ (ℓ odd) let $y' = y + dY^*$; then $y'(c_N) = 0$, $dy' = -a$, and evaluating $dy' = -a$ at (γ, c_N) and $(c_N, \gamma c_N)$ gives $y'(c_N\gamma c_N) = c_N\cdot y'(\gamma) = -{}^t y'(\gamma)$. Moreover $\pi_w\phi_w^* y' + b_w = \lambda_w + d(\pi_w Y^*) \in L_w$. Define $\Psi(\gamma) = \sum_j \epsilon'_j P_j(\gamma) + \eta\, y'(\gamma)$ for $\gamma \in \Gamma^0_N$, a continuous map into $\mathrm{PW}^2_a(A_m)$.

Cocycle and c. By Lemma E.108 (second identity; an element of PW^2_a is $\eta Y_0 + \sum_j \epsilon'_j Y_j$ with $Y_0 \in \mathrm{Od}_a$, $Y_j \in \mathrm{Ev}_a$), $\rho_1\Psi(\gamma')\rho_1^{-1} = \sum_j \epsilon'_j\gamma\cdot P_j(\gamma') + \eta\big(\gamma\cdot y'(\gamma') + \sum_j[\kappa_j(\gamma), \gamma\cdot P_j(\gamma')]\big)$ ($\rho_1 = \rho_1(h_N\gamma)$); so the cocycle identity for Ψ is the cocycle identity for the P_j together with $dy' = -a$. The c_N-condition holds for the P_j and for y'.

Steinberg places. On J_u: $b_u = 0$ and $\lambda_u = 0$, and dY^* vanishes on the trivially acting $p(\phi_u(J_u))$; so y' vanishes on $p(\phi_u(J_u)) \supseteq \pi^{Q_N}(I_{\bar u} \cap G_L \cap \pi^{-1}(I^x_u)) = I_{N,u}$. The P_j vanish on $I_{N,u}$. So Ψ vanishes on $I_{N,u}$.

Places above ℓ. Let $v \in S_\ell$, $X_j = X_{j,v}$, $Y_j = Y^\flat_{j,v}$. As $\pi_v\phi_v^* y' + b_v \in B^1(D_v, Q_v)$, there is $Y' \in M$ with $\pi_v\big(y'(\phi_v g) + \beta_v(g) - (gY' - Y')\big) = 0$, where $\beta_v = \sum_i c_i\beta_{i,v}$, i.e. $\beta_v(g) = \sum_j([X_j, P_j(\phi_v g)] - [\kappa'_j(g), gY_j])$. Put $Y_0 = Y' - \sum_j[X_j, Y_j] \in \mathrm{Od}_a(A_m)$ and $Y_v = \sum_j \epsilon'_j Y_j + \eta Y_0 \in \mathrm{PW}^2_a(A_m)$. With $w^1_v = (1 - \sum_j \epsilon_j X_j)w_v$ and $(w^1_v)^{-1} = w_v^{-1}(1 + \sum_j \epsilon_j X_j)$, for $R = \Psi(\phi_v g) - \rho_1 Y_v \rho_1^{-1} + Y_v$ one finds

$$(w^1_v)^{-1} R w^1_v = w_v^{-1}\Big(\sum_j \epsilon'_j R_j + \eta\big(R_0 + \sum_j [X_j, R_j]\big)\Big)w_v,$$

with $R_j = P_j(\phi_v g) - (gY_j - Y_j)$ and $R_0 = y'(\phi_v g) - (gY_0 - Y_0) - \sum_j[\kappa_j(\pi g), gY_j]$. Each $w_v^{-1}R_j w_v$ is upper triangular with zero diagonal for $g \in \mu_v$ (Y_j is a witness for P_j). By (1) and $\kappa_j - \kappa'_j = dX_j$,

$$\begin{aligned} R_0 + \sum_j [X_j, R_j] &= y'(\phi_v g) + \beta_v(g) - (gY' - Y') + \Big(d\sum_j [X_j, Y_j]\Big)(g) \\ &\quad - \sum_j \big([gX_j - X_j, gY_j] + [X_j, gY_j - Y_j]\big), \end{aligned}$$

and the last two terms cancel by the third identity in (1). So $R_0 + \sum_j[X_j, R_j] \in F_v$: its w_v-conjugate is upper triangular, and it lies in Od_a, whose w_v-conjugates have zero diagonal (Lemma E.112). Hence Y_v is a local witness for Ψ at v in the sense of (Sc) of Definition E.35.

Therefore $\Psi \in \mathrm{Sel}^2_{\mathbf V_N}(A_m)$, and its ϵ'_j-coefficient is $P_j = \sum_i c_i z_{i,j}$ on Γ^0_N. □

Lemma E.123. *Let $\mathscr H$, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$, κ with local witnesses and a Taylor–Wiles datum of size q (with H, $\sigma_1, \dots, \sigma_q$) along which x has eigenvalue data be as in Lemma E.122. Assume that $\rho(\gamma) = 1$ for $\gamma \in \Gamma^0_{\mathscr H} \cap \mathrm{PL}(H)$, that x satisfies (Pj1), and that for every $Z \in \mathrm{Ev}_a(A)$*

some T^sZ lies in the A-span of $\rho(\Gamma')$. Let $K = \#k$. Then there is $C \geq 0$ such that for every $m \geq 1$ there is N_0 such that for all $N \geq N_0$: $H_{N,m}$ is a finite A-module, $T^m H_{N,m} = 0$, and $\#(H_{N,m}/T^e H_{N,m}) \leq K^{ge+C}$ for $0 \leq e \leq m$. This is (Ob1) of Proposition E.120 for $H_{N,m}$.

Proof. Let C_0 (Lemma E.127), C_n (Lemma E.126), C_d, C_h (Lemma E.125 (Od1), (Od2)) be the constants given there, and $C = C_0 + C_n + \#S_\ell \cdot C_h + 2C_d$. Fix m and let N_0 be at least the integers N_0 of Lemma E.126 for $e = 1, \dots, m$. Let $N \geq N_0$. For $1 \leq e \leq m$ let $\mathcal{D}_e$ be the Selmer data of Lemma E.122 with A_e in place of A_m (so $\mathcal{D}_m = \mathcal{D}_{N,m}$), $M_e = \mathrm{Od}_a(A_e)$, over $G = G_{L^+,T_\infty}$, $T = S_\ell \cup \mathrm{St} \cup Q_N$. They are admissible in the sense of Lemma E.124 with $F = L^+$, $S = T_\infty$, $W = S_\ell \cup \mathrm{St}$: M_e is killed by ℓ; the places $v \in S_\ell$ are of type (i); the places $u \in \mathrm{St}$ are of type (ii) with J_u: J_u contains $J_{\bar{u}}$ of Lemma E.102, lies in the inertia group of G_u, is normal in G_u, and has finite index prime to ℓ there because $J_{\bar{u}}$ has (Lemma E.102 (Lb2)); it acts trivially on M_e.

Step 1: $\#H^2_{\mathcal{D}_e} \leq K^{ge+C-C_d}$. We evaluate the factors of Lemma E.124 (Sc1). (a) In the w_v-frame (Lemma E.112: $w_v^{-1}\mathrm{Od}_a(A_e)w_v = \mathrm{Od}_{\mathrm{ty}}(A_e)$), M_e is the set of matrices with entries in A_e at the positions (i,j) of different types, and F_v its upper triangular part; positions of different types come in pairs $(i,j),(j,i)$, so $\#Q_v = \#M_e/\#F_v = (\#M_e)^{1/2}$. (b) Let c_u be a complex conjugation; its image c' in Γ_N is an involution outside Γ_N^0 (Proposition E.101 (Pk3)), $c' = c_N\gamma$ with $\gamma \in \Gamma_N^0$, acting by $P \mapsto -{}^t(RPR^{-1})$, $R = \rho(h_N\gamma)$. From $c'^2 = 1$ and $\rho(\bar{c}\gamma'\bar{c}) = {}^t\rho(\gamma')^{-1}$ (Lemma E.107 (Rf1)) we get $R = {}^tR$; then $P \mapsto RP$ is a bijection of M_e (R is block diagonal) carrying the action of c' to $Q \mapsto -{}^tQ$, whose fixed points $\left(\begin{smallmatrix} 0 & B \\ -{}^tB & 0 \end{smallmatrix}\right)$ number $(\#M_e)^{1/2}$. With $\sum_v d_v = d$, (a) and (b) give $\prod_v (\#Q_v)^{d_v} \prod_u \#M_e^{c_u=1} = (\#M_e)^d$. (c) $\#H^0(G_v, Q_v) \leq K^{C_h}$ by (Od2), and $\#\mathrm{Hom}_G(M_e, \mu_\ell) \leq K^{C_d}$ by (Od1) (G acts through p and h_N; an equivariant map is invariant under the elements mapping into Γ', where $\chi_{\mathrm{cyc}} = 1$). (d) $H^1_{\mathcal{D}_e}$: a Selmer cocycle vanishes on $\phi_u(J_u) \supseteq$ the images of $J_{\bar{u}}$, so by Lemma E.102 (Lb3) it is inflated from a unique cocycle $\bar{z}$ of Γ_N, coboundaries corresponding to coboundaries; the local conditions say that $\bar{z}(\pi^{Q_N} g) - (gY - Y) \in F_v$ for some $Y \in M_e$ ($g \in D_v$; lift a primitive in Q_v) and that $\bar{z}$ vanishes on $I_{N,u}$ (equivalently on $p(\phi_u(J_u))$, generated as a closed normal subgroup by $I_{N,u}$, which acts trivially). Every class has a representative with $\bar{z}(c_N) = 0$: as $c_N^2 = 1$, $0 = \bar{z}(c_N^2) = \bar{z}(c_N) + c_N \cdot \bar{z}(c_N)$, so $X = \bar{z}(c_N)$ satisfies $c_N \cdot X = -X$; as ℓ is odd and $\ell M_e = 0$, $Y = -X/2 \in M_e$ is defined, and its coboundary $b_Y(g) = g \cdot Y - Y$ has $b_Y(c_N) = -2Y = X$; b_Y satisfies the local conditions (with witness Y at $v \in S_\ell$; it vanishes on $I_{N,u}$, which acts trivially), so $\bar{z} - b_Y$ represents the same class and vanishes at c_N. Two such representatives differ by a coboundary b_Y with $0 = b_Y(c_N) = c_N \cdot Y - Y$, and c_N acts by $Y \mapsto -{}^tY$ (the action of c' in (b) with $\gamma = 1$), so the representative is unique up to coboundaries of Y with ${}^tY = -Y$; and the restrictions to Γ_N^0 of such $\bar{z}$ are exactly the elements of $\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$. Hence $\#H^1_{\mathcal{D}_e} = \#\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)/\#\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$. The coboundaries at level N are those of the base level composed with h_N (onto), so $\#\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_N}(A_e) = \#\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$, and by Lemma E.126 and Lemma E.127, $\#H^1_{\mathcal{D}_e} \leq K^{ge+C_0+C_n}$. Inserting (a)–(d) and $\#H^0(G, M_e) \geq 1$ in (Sc1): $\#H^2_{\mathcal{D}_e} \leq K^{ge+C_0+C_n+\#S_\ell C_h+C_d}$.

Step 2: (Ob1). $H = H_{N,m} = H^2_{\mathcal{D}_m}$ is finite (Sc1) and an A_m-module, so $T^m H = 0$. For $e = 0$ the bound is trivial and for $e = m$ it is Step 1. Let $1 \leq e < m$. Reduction $g\colon M_m \to M_e$ and $r\colon M_m \to M_{m-e}$, and $u\colon M_{m-e} \to M_m$, $y \mapsto T^e\tilde{y}$ ($\tilde{y}$ any lift), are maps of Selmer data (all maps are entrywise in the w_v-frames, so they respect the F_v and the Q_v), with $u \circ r = T^e$, and the sequences $0 \to M_{m-e} \xrightarrow{u} M_m \xrightarrow{g} M_e \to 0$ and $0 \to T^{m-e}M_m \to M_m \xrightarrow{r} M_{m-e} \to 0$, together with the induced sequences of the Q_v, are exact (entrywise from $0 \to A_{m-e} \to A_m \to A_e \to 0$). So $T^e H = u_* r_*(H) \subseteq u_* H^2_{\mathcal{D}_{m-e}} = \ker g_*$ by (Sc2), and

$$\#(H/T^eH) = \#(H/\ker g_*) \cdot \#(\ker g_*/T^eH) \leq \#H^2_{\mathcal{D}_e} \cdot \#\mathrm{coker}(r_*),$$

as $\ker g_*/T^eH$ is a quotient of $H^2_{\mathcal{D}_{m-e}}/r_*(H)$. By (Sc2), $\#\mathrm{coker}(r_*) \le \#\mathrm{Hom}_G(T^{m-e}M_m, \mu_\ell)$, and $T^{m-e}M_m \cong M_e$ as G-modules (multiplication by T^{m-e}), so this is at most K^{C_d} by (Od1). With Step 1, $\#(H/T^eH) \le K^{ge+C}$. □

Lemma E.124. *Let F be a totally real number field, $d = [F:\mathbb{Q}]$, ℓ an odd prime, S a finite set of places of F containing those above ℓ and the archimedean ones, $G = G_{F,S}$, and $W \subseteq S$ a set of finite places. Call Selmer data $\mathcal{D}$ over G **admissible** if M is an ℓ-module of G, the index set is W, $G_w = G_{F_w}$ with ϕ_w the natural map, each Q_w is an ℓ-module, and for each w either (i) $L_w = B^1(G_w, Q_w)$, or (ii) $w \nmid \ell$, $Q_w = M$, $\pi_w = \mathrm{id}$ and $L_w = Z^1_{J_w}(M)$ for a closed subgroup J_w of the inertia group of G_w, normal in G_w, of finite index prime to ℓ there, acting trivially on M.*

(Sc1) *For admissible $\mathcal{D}$, $H^1_{\mathcal{D}}$ and $H^2_{\mathcal{D}}$ are finite and*

$$\#H^2_{\mathcal{D}} \le \#H^1_{\mathcal{D}} \cdot \prod_{w \text{ of type (i)}} \#H^0(G_w, Q_w)\,(\#Q_w)^{d_w} \cdot \frac{\prod_{u \text{ real}} \#M^{c_u=1}}{\#H^0(G,M)\,(\#M)^d} \cdot \#\mathrm{Hom}_G(M, \mu_\ell).$$

(Sc2) *Let $\mathcal{D}_K, \mathcal{D}_M, \mathcal{D}_{M'}$ be admissible Selmer data with the same W, types and J_w, and A-linear maps $K \to M \to M'$ and $Q_w(K) \to Q_w(M) \to Q_w(M')$ compatible with the actions and the π_w, forming short exact sequences $0 \to K \to M \to M' \to 0$ and $0 \to Q_w(K) \to Q_w(M) \to Q_w(M') \to 0$. Then the induced sequence $H^2_{\mathcal{D}_K} \to H^2_{\mathcal{D}_M} \to H^2_{\mathcal{D}_{M'}}$ is exact, and the cokernel of $H^2_{\mathcal{D}_M} \to H^2_{\mathcal{D}_{M'}}$ has order at most $\#\mathrm{Hom}_G(K, \mu_\ell)$.*

Proof. Maps of Selmer data (compatible maps $M \to M'$, $Q_w \to Q'_w$) map $Z^2_{\mathcal{D}}$, $B^2_{\mathcal{D}}$ to the corresponding sets, so they induce maps on $H^1_{\mathcal{D}}$, $H^2_{\mathcal{D}}$. Write $\bar{L}_w = L_w/B^1(G_w, Q_w) \subseteq H^1(G_w, Q_w)$.

(Sc1). Consider

$$H^1(G,M) \xrightarrow{\mathrm{loc}^1} \bigoplus_w H^1(G_w, Q_w)/\bar{L}_w \xrightarrow{\delta} H^2_{\mathcal{D}} \xrightarrow{\alpha} H^2(G,M) \xrightarrow{\mathrm{loc}^2} \bigoplus_w H^2(G_w, Q_w),$$

with loc^i induced by $\pi_w\phi_w^*$ (restriction followed by push-forward), $\delta((y_w))$ the class of $(0,(y_w))$ for cocycles y_w, and α the class of the first component. These are well defined ($B^1 \subseteq L_w$; $(0,(\lambda_w)) \in B^2_{\mathcal{D}}$ for $\lambda_w \in L_w$; $(dx,\dots) \mapsto 0$). Exactness: $\delta(\mathrm{loc}^1 z)$ is the class of $(0, \pi_w\phi_w^* z) = (dz, \pi_w\phi_w^* z) \in B^2_{\mathcal{D}}$; conversely $(0,(y_w)) = (dx, (\pi_w\phi_w^* x + \lambda_w))$ forces $x \in Z^1(G,M)$ and $y_w \equiv \pi_w\phi_w^* x \bmod L_w$. If α of the class of $(a,(b_w))$ vanishes, $a = dx$, and $(a,(b_w)) - (dx, (\pi_w\phi_w^* x)) = (0, (b_w - \pi_w\phi_w^* x))$ with $b_w - \pi_w\phi_w^* x$ a cocycle; and $\alpha\delta = 0$. Finally $[a] \in \ker \mathrm{loc}^2$ iff $\pi_w\phi_w^* a = db_w$ for some b_w, i.e. iff a is the first component of an element of $Z^2_{\mathcal{D}}$. All groups in the sequence are finite by Proposition E.101 (Pk1), (Pk2), hence $H^2_{\mathcal{D}}$ is finite, and so is $H^1_{\mathcal{D}} = \ker \mathrm{loc}^1$. Counting orders,

$$\begin{aligned}\#H^2_{\mathcal{D}} &= \#\mathrm{coker}\,\mathrm{loc}^1 \cdot \#\ker \mathrm{loc}^2 \\ &= \frac{\#H^1_{\mathcal{D}} \prod_w \#(H^1(G_w,Q_w)/\bar{L}_w)}{\#H^1(G,M)} \\ &\quad \cdot \frac{\#H^2(G,M) \cdot \#\mathrm{coker}\,\mathrm{loc}^2}{\prod_w \#H^2(G_w,Q_w)}.\end{aligned}$$

By (Pk3), $\#H^2(G,M)/\#H^1(G,M) = \prod_u \#M^{c_u=1}/(\#H^0(G,M)(\#M)^d)$; by (Pk4) (with the subset W), $\#\mathrm{coker}\,\mathrm{loc}^2 \le \#\mathrm{Hom}_G(M, \mu_\ell)$. For w of type (i), $\bar{L}_w = 0$ and, by (Pk2),

$$\#H^1(G_w,Q_w)/\#H^2(G_w,Q_w) = \#H^0(G_w,Q_w)(\#Q_w)^{d_w}.$$

For w of type (ii), $\#\bar{L}_w = \#H^0(G_w, M)$ by Lemma E.104 (Ur1) (applied to the local field F_w, $D = G_w$, $J = J_w$), and $\#H^1(G_w, M) = \#H^0(G_w, M)\#H^2(G_w, M)$ by (Pk2) ($d_w = 0$); so the factor of w is 1. This gives the bound.

(Sc2). Write $f\colon M \to M'$, and f also for the induced maps. *Lifting local conditions:* every element of $L_w(M')$ is the image of an element of $L_w(M)$: for type (i) because $Q_w(M) \to Q_w(M')$ is onto, for type (ii) by Lemma E.104 (Ur2). Continuous cochains with values in M' or $Q_w(M')$ lift to continuous cochains (compose with a set-theoretic section of the finite surjection).

Exactness in the middle. The composite $H^2_{\mathcal{D}_K} \to H^2_{\mathcal{D}_{M'}}$ is zero. If $(a, (b_w)) \in Z^2_{\mathcal{D}_M}$ maps into $B^2_{\mathcal{D}_{M'}}$, say to $(dx', (\pi_w\phi_w^* x' + \lambda'_w))$, lift x' to x and λ'_w to $\lambda_w \in L_w(M)$; then $(a, (b_w)) - (dx, (\pi_w\phi_w^* x + \lambda_w))$ has components with values in K and $Q_w(K)$, so it lies in $Z^2_{\mathcal{D}_K}$.

The cokernel. Let

$$\mathrm{loc}^2_K\colon H^2(G, K) \to \bigoplus_w H^2(G_w, Q_w(K))$$

be the map defined as in (Sc1); by (Pk4), $\#\mathrm{coker}\,\mathrm{loc}^2_K \le \#\mathrm{Hom}_G(K, \mu_\ell)$. We define a homomorphism $\Theta\colon Z^2_{\mathcal{D}_{M'}} \to \mathrm{coker}\,\mathrm{loc}^2_K$. Given $(a', (b'_w))$: by (Pk1) $H^2(G, M) \to H^2(G, M')$ is onto, so $a' = f(a_0) + dx'$ with $a_0 \in Z^2(G, M)$; let $\beta_w \in C^1(G_w, Q_w(M))$ lift $b'_w - \pi_w\phi_w^* x'$; then $e_w = d\beta_w - \pi_w\phi_w^* a_0$ is a continuous 2-cocycle with values in $Q_w(K)$ (its image is $db'_w - \pi_w\phi_w^*(a' - dx') - d\pi_w\phi_w^* x' = 0$). Let $\Theta(a', (b'_w))$ be the class of $([e_w])_w$. Independence of the choices: if $a_0^\sharp, x'^\sharp, \beta_w^\sharp$ are other choices, then $f(a_0 - a_0^\sharp) = d(x'^\sharp - x')$; lifting $x'^\sharp - x'$ to x'', $k = a_0 - a_0^\sharp - dx'' \in Z^2(G, K)$, and $\beta_w^\sharp = \beta_w - \pi_w\phi_w^* x'' + \gamma_w$ with γ_w a 1-cochain into $Q_w(K)$; so $e_w^\sharp = e_w + d\gamma_w + \pi_w\phi_w^* k$, and the classes differ by $\mathrm{loc}^2_K[k]$. Using sums of choices for sums, Θ is additive. Θ vanishes on $B^2_{\mathcal{D}_{M'}}$: for $(dx', (\pi_w\phi_w^* x' + \lambda'_w))$ take $a_0 = 0$ and β_w a lift of λ'_w in $L_w(M)$, a cocycle, so $e_w = 0$. It vanishes on the image of $Z^2_{\mathcal{D}_M}$ (take $x' = 0$ and the given lifts: $e_w = 0$). Conversely if $\Theta(a', (b'_w)) = 0$, then $e_w = \pi_w\phi_w^* k + d\gamma_w$ with $k \in Z^2(G, K)$, $\gamma_w \in C^1(G_w, Q_w(K))$, and $(a_0 + k, (\beta_w - \gamma_w)) \in Z^2_{\mathcal{D}_M}$ (as $d(\beta_w - \gamma_w) = \pi_w\phi_w^*(a_0 + k)$) maps to $(a' - dx', (b'_w - \pi_w\phi_w^* x'))$, which is in the class of $(a', (b'_w))$. So Θ induces an injection of the cokernel of $H^2_{\mathcal{D}_M} \to H^2_{\mathcal{D}_{M'}}$ into $\mathrm{coker}\,\mathrm{loc}^2_K$. □

Lemma E.125. *Let $\mathscr{H}$ be a rank-n Hecke datum, x a framed curve point normalised of shape $(a, n-a)$, $\pi = \pi_{\mathscr{H}}$ and $K = \#k$. For $e \ge 1$ let $\Gamma^0_{\mathscr{H}}$ act on $\mathrm{Od}_a(A_e)$ by $\gamma \cdot P = \rho(\gamma)P\rho(\gamma)^{-1}$ and D_v ($v \in S_\ell$) by $g \cdot P = \rho(\pi g)P\rho(\pi g)^{-1}$; let $F_v(A_e) = \{P \in \mathrm{Od}_a(A_e) : w_v^{-1}Pw_v$ upper triangular$\}$.*

(Od1) *If for every $Z \in \mathrm{Ev}_a(A)$ some $T^s Z$ lies in the A-span of $\rho(\Gamma')$, then there is $C_d \ge 0$ such that for every $e \ge 1$ the number of additive maps $f\colon \mathrm{Od}_a(A_e) \to \mu_\ell$ with $f(\gamma\cdot P) = f(P)$ for all $\gamma \in \Gamma'$ and P is at most K^{C_d}. (In particular this bounds the maps with $f(\gamma\cdot P) = \gamma f(P)$ for γ in any group acting through $\Gamma^0_{\mathscr{H}} \supseteq \Gamma'$ and on μ_ℓ through χ_{cyc}, as $\chi_{\mathrm{cyc}} = 1$ on Γ'.)*

(Od2) *If x satisfies (Pj1), then $F_v(A_e)$ is D_v-stable and there is $C_h \ge 0$ with*

$$\#H^0(D_v, \mathrm{Od}_a(A_e)/F_v(A_e)) \le K^{C_h}$$

for all $e \ge 1$ and $v \in S_\ell$.

Proof. (Od1). Let $\tau\colon A_e \to \mathbb{F}_\ell$ be the non-degenerate form of Lemma E.106 (trace of the top coefficient) and ζ a primitive ℓ-th root of unity. For $Y \in \mathrm{Od}_a(A_e)$ put $f_Y(P) = \zeta^{\tau(\mathrm{tr}(PY))}$. Every additive $f\colon \mathrm{Od}_a(A_e) \to \mu_\ell$ is f_Y for exactly one Y: for the matrix units, $\mathrm{tr}(P \cdot E_{ji}y) = P_{ij}y$, and $E_{ji} \in \mathrm{Od}_a$ exactly when P_{ij} is an entry of Od_a; so $Y \mapsto f_Y$ is injective by non-degeneracy of τ, and both sides have $\#\mathrm{Od}_a(A_e)$ elements ($\mathrm{Od}_a(A_e)$ is an $\mathbb{F}_\ell$-vector space and $\mu_\ell \cong \mathbb{F}_\ell$).

Now $f_Y(\gamma\cdot P)=f_Y(P)$ for all P iff $\tau(\mathrm{tr}(P(\rho^{-1}Y\rho-Y)))=0$ for all $P\in \mathrm{Od}_a(A_e)$ ($\rho=\rho(\gamma)$), iff $\rho^{-1}Y\rho=Y$, because $\rho^{-1}Y\rho-Y\in\mathrm{Od}_a(A_e)$ (ρ is block diagonal) and the pairing is non-degenerate. So the maps in question correspond to the $Y\in\mathrm{Od}_a(A_e)$ with $\rho(\gamma)Y=Y\rho(\gamma)$ for all $\gamma\in\Gamma'$: the common kernel modulo T^e of the A-linear maps $Y\mapsto\rho(\gamma)Y-Y\rho(\gamma)$ on $\mathrm{Od}_a(A)$. Over A this common kernel is 0: such a Y commutes with the A-span of $\rho(\Gamma')$; for each i the matrix unit E_{ii} lies in $\mathrm{Ev}_a(A)$, so by the hypothesis of (Od1) some T^sE_{ii} lies in that span, $T^s(E_{ii}Y-YE_{ii})=0$, and, A being a domain, Y commutes with every E_{ii}, so it is diagonal, and a diagonal element of $\mathrm{Od}_a(A)$ is 0. By Lemma E.110 there is C_d as stated.

(Od2). Write $w=w_v$, $b(g)=w^{-1}\rho(\pi g)w$, upper triangular with diagonal $(\psi_{v,1}(g),\dots,\psi_{v,n}(g))$ by (Sd1). By Lemma E.112, $P\mapsto w^{-1}Pw$ maps $\mathrm{Od}_a(A_e)$ onto $\mathrm{Od}_{\mathrm{ty}}(A_e)$ (entries (i,j) with $\mathrm{ty}(i)\neq\mathrm{ty}(j)$; zero diagonal), carrying $F_v(A_e)$ onto its upper triangular elements and the action to $P'\mapsto b(g)P'b(g)^{-1}$. As $b(g)$ is upper triangular, F_v is stable, and the quotient is identified with the strictly lower triangular part Λ of $\mathrm{Od}_{\mathrm{ty}}(A_e)$ with the induced action. For upper triangular b, $(bP'b^{-1})_{ij}=\sum_{i'\geq i,\ j'\leq j}b_{ii'}P'_{i'j'}(b^{-1})_{j'j}$ involves only entries of depth $i'-j'\geq i-j$, and its term $(i',j')=(i,j)$ is $\psi_i\psi_j^{-1}P'_{ij}$. Hence the subgroups $\Lambda_h\subseteq\Lambda$ of classes with all entries of depth $>h$ zero are stable, and $\Lambda_h/\Lambda_{h-1}\cong\bigoplus_{i-j=h,\ \mathrm{ty}(i)\neq\mathrm{ty}(j)}A_e$ with g acting on the (i,j) summand by $\theta_{ij}(g)=\psi_i(g)\psi_j(g)^{-1}$. By left exactness of invariants, $\#H^0(D_v,\Lambda)\leq\prod_{i>j}\#H^0(D_v,A_e(\theta_{ij}))$. For $i\neq j$, (Pj1) gives $\theta_{ij}\neq1$, so the ideal of A generated by the $\theta_{ij}(g)-1$ is $T^{e_{ij}}A$ for some $e_{ij}\geq0$ independent of e, and $H^0(D_v,A_e(\theta_{ij}))=\{y\in A_e:\ T^{e_{ij}}y=0\}$ has at most $K^{e_{ij}}$ elements. Take $C_h=\max_v\sum_{i>j}e_{ij}$. □

Lemma E.126. *Let $\mathscr{H}$ be a rank-n Hecke datum, $x=(k,\rho,1_n,(\psi_{v,a}),f)$ a framed curve point normalised of shape $(a,n-a)$ and $K=\#k$. Fix a Taylor–Wiles datum of size q (with H, $\sigma_1,\dots,\sigma_q$) along which x has eigenvalue data, and assume that $\rho(\gamma)=1$ for $\gamma\in\Gamma^0_{\mathscr{H}}\cap\mathrm{PL}(H)$. Let $\mathbf{V}_0$ be the base level. Then there is $C_n\geq0$ such that for every $e\geq1$ there is N_0 with*

$$\#\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)\ \leq\ \#\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)\cdot K^{C_n}\qquad(N\geq N_0),$$

and every $z\in\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$ vanishing at $\mathrm{T}_{N,1},\dots,\mathrm{T}_{N,q}$ is $z_0\circ h_N$ for a unique $z_0\in\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$.

Proof. Write $\Gamma^0=\Gamma^0_{\mathscr{H}}$, $\Gamma^0_N=h_N^{-1}(\Gamma^0)$, and let Γ^0_N act on $\mathrm{Od}_a(A_e)$ by $\gamma\cdot P=\rho(h_N\gamma)P\rho(h_N\gamma)^{-1}$; elements of Γ^0_N in $\ker h_N$ or in $\mathrm{PL}(H_N)$ act trivially (for the latter, $h_N(\mathrm{PL}(H_N))\subseteq\mathrm{PL}(H)\subseteq\Gamma^0$ by Lemma E.45 (Pl1), (Pl3), and $\rho=1$ there). $\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$ is a group of cocycles $z\colon\Gamma^0_N\to\mathrm{Od}_a(A_e)$, killed by ℓ, with $z(c_N\gamma c_N)=-{}^tz(\gamma)$, $c_N=\pi^{Q_N}(c)$.

Step 1: the bounded part. For each j let $P_j=\rho(\sigma_j)=\mathrm{diag}(P'_j,P''_j)$. The characteristic polynomials f'_j, f''_j of P'_j, P''_j have product $\prod_i(X-\alpha_{j,i})$ with the $\alpha_{j,i}\in A$ pairwise distinct (eigenvalue data), so they have no common root and $f'_j(P''_j)=\prod_{f'_j(\alpha)=0}(P''_j-\alpha)$ is invertible over F. If $B\in\mathrm{M}_{a\times(n-a)}(F)$ and $P'_jB=BP''_j$, then $0=f'_j(P'_j)B=Bf'_j(P''_j)$ (Cayley–Hamilton), so $B=0$; likewise $P''_jC=CP'_j$ with $C\in\mathrm{M}_{(n-a)\times a}(F)$ forces $C=0$. Hence no non-zero element of $\mathrm{Od}_a(F)$ commutes with P_j; so by Lemma E.110 there is b_j with $\#\{P\in\mathrm{Od}_a(A_e):\ P_jP=PP_j\}\leq K^{b_j}$ for all e. Put $C_n=\sum_jb_j$. Fix e. We choose N_0. Let $U\subseteq\Gamma^0$ be the kernel of $\gamma\mapsto\rho(\gamma)\bmod T^e$, an open normal subgroup of Γ^0 (ρ is continuous for the T-adic topology), and $V=U\cap\bar cU\bar c^{-1}$ with $\bar c=\pi_{\mathscr{H}}(c)$; as $\Gamma_{\mathscr{H}}=\Gamma^0\cup\bar c\,\Gamma^0$, V is an open normal subgroup of $\Gamma_{\mathscr{H}}$. It contains $\mathrm{PL}(H)$: H is one of the open normal subgroups whose intersection defines $\mathrm{PL}(H)$, so $\mathrm{PL}(H)\subseteq H\subseteq\Gamma^0$ (Tg1), hence $\rho=1$ on $\mathrm{PL}(H)$ by hypothesis and $\mathrm{PL}(H)\subseteq U$; and $\mathrm{PL}(H)$, an intersection of normal subgroups, is normal in $\Gamma_{\mathscr{H}}$, so $\mathrm{PL}(H)=\bar c\,\mathrm{PL}(H)\bar c^{-1}\subseteq\bar cU\bar c^{-1}$. By (Tg3), applied to V for each of the finitely many j, there is N_0 with $u_{N,j}=h_N(\Phi_{N,j})\sigma_j^{-1}\in V$ for all j and $N\geq N_0$. As $\sigma_j\in\Gamma'\subseteq\Gamma^0$ and $u_{N,j}\in U$, $\rho(h_N\Phi_{N,j})=\rho(u_{N,j})\rho(\sigma_j)\equiv\rho(\sigma_j)\bmod T^e$ for all j and $N\geq N_0$. Let $N\geq N_0$, $z\in\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$, $\mathrm{T}=\mathrm{T}_{N,j}$, $\Phi=\Phi_{N,j}$. As T acts trivially,

$z(\mathrm{T}^k) = kz(\mathrm{T})$ and $z(\Phi^{-1}\mathrm{T}\Phi) = \Phi^{-1}\cdot z(\mathrm{T})$ (for u acting trivially, $z(gug^{-1}) = g\cdot z(u)$). By (Tg4), $\mathrm{T}^{-q_{N,j}}\Phi^{-1}\mathrm{T}\Phi \in \mathrm{PL}(H_N)$, and z vanishes on $\mathrm{PL}(H_N)$ by Lemma E.45 (Pl2) (applied to $G = \Gamma_N$, the open normal subgroup $H_N \subseteq \Gamma_N^0$); so $0 = -q_{N,j}z(\mathrm{T}) + \Phi^{-1}\cdot z(\mathrm{T})$, and as $q_{N,j} \equiv 1 \bmod \ell$ (Tg2) and $\ell z(\mathrm{T}) = 0$, $\Phi\cdot z(\mathrm{T}) = z(\mathrm{T})$, i.e. $z(\mathrm{T}_{N,j})$ commutes with $\rho(\sigma_j)$ modulo T^e. Hence $z \mapsto (z(\mathrm{T}_{N,j}))_j$ is a homomorphism from $\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_N}(A_e)$ to a group of order at most K^{C_n}.

Step 2: the kernel descends. Let z vanish at all $\mathrm{T}_{N,j}$. Then z vanishes on every conjugate $g\mathrm{T}_{N,j}g^{-1}$: for $g \in \Gamma_N^0$ it equals $g\cdot z(\mathrm{T}_{N,j}) = 0$, and for $g = c_N g_0$ it is $-{}^t z(g_0\mathrm{T}_{N,j}g_0^{-1}) = 0$. It vanishes on $\mathrm{PL}(H_N)$ (Step 1). The closed subgroup W generated by these elements lies in Γ_N^0 (normal, containing H_N) and acts trivially, so $z|_W$ is a continuous homomorphism vanishing on generators, hence $z|_W = 0$; by (Tg4) $\ker h_N \subseteq W$. So $z(g\gamma) = z(g)$ for $\gamma \in \ker h_N$, and $z = z_0 \circ h_N$ for a unique map $z_0\colon \Gamma^0 \to \mathrm{Od}_a(A_e)$ (h_N is onto), locally constant since h_N is open. z_0 lies in $\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$: the cocycle and $\bar c$-identities descend ($h_N(c_N) = \bar c$); z_0 vanishes on $I_u^x = h_N(I_{N,u})$; and for $v \in S_\ell$, $z(\pi^{Q_N}g) = z_0(\pi_{\mathscr{H}}g)$ for $g \in D_v$ (as $h_N \circ \pi^{Q_N} = \pi_{\mathscr{H}}$), so the local witnesses of z serve for z_0. Conversely $z_0 \mapsto z_0 \circ h_N$ is injective. Hence the kernel of the homomorphism of Step 1 has at most $\#\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$ elements, and the bound follows. □

Lemma E.127. *Let $\mathscr{H}$ be a rank-n Hecke datum, $x = (k, \rho, 1_n, (\psi_{v,a}), f)$ a framed curve point normalised of shape $(a, n-a)$ with a Selmer basis $\kappa = (\kappa_1, \dots, \kappa_g)$, $\mathbf{V}_0$ the base level and $K = \#k$. Then there is $C_0 \geq 0$ such that for all $e \geq 1$*

$$\#\mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e) \;\leq\; \#\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)\cdot K^{ge+C_0}.$$

Proof. Write $\Gamma^0 = \Gamma^0_{\mathscr{H}}$, $\pi = \pi_{\mathscr{H}}$, $\bar c = \pi(c)$, $\mathrm{Sel}_e = \mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$, $\mathrm{Bd}_e = \mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}_0}(A_e)$. We apply Lemma E.115, carrying the local witnesses along as extra coordinates.

The modules. Let $C' = C \times \mathrm{Od}_a(A)^{S_\ell}$, where C is the A-module of T-adically continuous maps $f\colon \Gamma^0 \to \mathrm{Od}_a(A)$; by Lemma E.117, item 1 ($\mathrm{Od}_a(A)$ is a free A-module of finite rank), C has no T-torsion and is T-adically separated and complete, hence so is C', its product with a free A-module of finite rank. For $v \in S_\ell$ and $X \in \mathrm{M}_n(A)$ let $\lambda_v(X)$ be the family of the entries of $w_v^{-1}Xw_v$ strictly below the diagonal. Let Y be the product, over pairs (γ, γ'), elements γ, places $u \in \mathrm{St}$ with $\gamma \in I_u^x$, and pairs (v, g) with $v \in S_\ell$, $g \in D_v$, of copies of $\mathrm{M}_n(A)$ or of $A^{n(n-1)/2}$, and let $\Phi(f, (Y_v))$ have the components

$$f(\gamma\gamma') - f(\gamma) - \rho(\gamma)f(\gamma')\rho(\gamma)^{-1}, \quad f(\bar c\gamma\bar c) + {}^t f(\gamma), \quad f(\gamma)\ (\gamma \in I_u^x),$$
$$\lambda_v(f(\pi g) - \rho(\pi g)Y_v\rho(\pi g)^{-1} + Y_v).$$

Y has no T-torsion and is separated, Φ is A-linear, and, since $w_v^{-1}\mathrm{Od}_a w_v$ has zero diagonal (Lemma E.112), $\ker\Phi$ is the set of pairs $(z, (Y_v))$ with $z \in Z^1_{\mathrm{ord}}(x)$ and (Y_v) a family of local witnesses for z; likewise $X_e = \Phi^{-1}(T^eY)$ reduces onto the set of pairs $(\bar z, (\bar Y_v))$ with $\bar z \in \mathrm{Sel}_e$ and $(\bar Y_v)$ a family of witnesses for $\bar z$ in $\mathrm{Od}_a(A_e)$ (lift $\bar z$ to $f \in C$ by Lemma E.117, item 2, and each $\bar Y_v$ to any $Y_v \in \mathrm{Od}_a(A)$; $\Phi(f, (Y_v))$ modulo T^eY depends only on the reductions), with kernel T^eC' (Lemma E.117, item 2, for the first component).

The count of pairs. Let W_e be the set of families $(\bar Y_v)$ with $\lambda_v(\bar Y_v - \rho(\pi g)\bar Y_v\rho(\pi g)^{-1}) = 0$ for all v, g (the witnesses of $\bar z = 0$), a group. The witnesses of any $\bar z \in \mathrm{Sel}_e$ form a coset of W_e. Hence $\#(X_e/T^eC') = \#\mathrm{Sel}_e \cdot \#W_e$.

B. Let $R \subseteq Z^1_{\mathrm{ord}}(x)$ be $\sum_j A\kappa_j + \mathrm{Bd}(x)$ and $B = \{(z, (Y_v)) \in \ker\Phi :\ z \in R\}$. By the definition of a Selmer basis ((Sd2)), every $z \in Z^1_{\mathrm{ord}}(x)$ has $T^s z \in R$, so every element of $\ker\Phi$ has a multiple $T^s(z, (Y_v)) \in B$. The reduction of B modulo T^e consists of pairs $(\bar z, (\bar Y_v))$ with $\bar z \in \bar R_e$, the reduction of R, and $(\bar Y_v)$ a witness family of $\bar z$; so $\#((B + T^eC')/T^eC') \leq \#\bar R_e \cdot \#W_e$.

Moreover $\bar{R}_e \subseteq \sum_j A_e\bar{\kappa}_j + \mathrm{Bd}_e$ (a coboundary of a skew $Y \in \mathrm{Od}_a(A)$ reduces to the coboundary of a skew element of $\mathrm{Od}_a(A_e)$), so $\#\bar{R}_e \le K^{ge}\cdot\#\mathrm{Bd}_e$.

Finiteness of X_1/TC'. $\#(X_1/TC') = \#\mathrm{Sel}_1\cdot\#W_1$; $W_1 \subseteq \mathrm{Od}_a(k)^{S_\ell}$ is finite, and Sel_1 is a set of locally constant maps $\Gamma^0 \to \mathrm{Od}_a(k) \subseteq \mathrm{M}_n(k)$ satisfying the cocycle identity for the continuous action $\gamma\cdot X = \bar{\rho}(\gamma)X\bar{\rho}(\gamma)^{-1}$ ($\bar{\rho}$ the reduction of ρ modulo T) of Γ^0 on the finite group $\mathrm{M}_n(k)$, killed by ℓ; as Γ^0 satisfies Φ_ℓ (Lemma E.116), Sel_1 is finite by Lemma E.118.

By Lemma E.115 there is C_0 with $\#\mathrm{Sel}_e\cdot\#W_e \le \#\bar{R}_e\cdot\#W_e\cdot K^{C_0} \le K^{ge}\cdot\#\mathrm{Bd}_e\cdot\#W_e\cdot K^{C_0}$ for all e; cancelling $\#W_e$ gives the claim. □

Lemma E.128. *Let A be a discrete valuation ring with uniformiser t and finite residue field of cardinality q_A, let $g, C, m \ge 0$ be integers, and let H be a finite A-module with $t^m H = 0$ and*

$$\#(H/t^eH) \le q_A^{ge+C} \qquad \text{for all integers } 0 \le e \le m.$$

Then for all $\xi_0,\dots,\xi_g \in H$ there are $c_0,\dots,c_g \in A$, at least one of them a unit, with $t^C\sum_{i=0}^g c_i\xi_i = 0$.

Proof. If $m \le C$, take all $c_i = 1$: $t^CH = 0$. Let $m \ge C+1$, put $e = C+1 \le m$, and suppose, for a contradiction, that $t^C\sum_i c_i\xi_i \ne 0$ whenever some c_i is a unit. Let $\varphi\colon A^{g+1} \to H$, $\varphi(c) = \sum_i c_i\xi_i$, and $N = \varphi(A^{g+1})$.

Step 1: if $\varphi(d) = t^e\varphi(d_0)$ with $d, d_0 \in A^{g+1}$, then $d \in t^eA^{g+1}$. We show $d \in t^kA^{g+1}$ by induction on $k \le e$; $k = 0$ is clear. Let $k < e$ and $d = t^kd'$. If some d'_{i_0} is a unit, put $d'' = d' - t^{e-k}d_0$; then d''_{i_0} is a unit ($e - k \ge 1$) and $t^k\varphi(d'') = \varphi(d) - t^e\varphi(d_0) = 0$, so $t^C\varphi(d'') = t^{C-k}t^k\varphi(d'') = 0$ (as $k \le C$), contrary to the assumption. So t divides every d'_i and $d \in t^{k+1}A^{g+1}$.

Step 2: counting. By Step 1, the map $(A/t^eA)^{g+1} \to N/t^eN$ induced by φ is injective, so $\#(N/t^eN) \ge (\#A/t^eA)^{g+1} = q_A^{e(g+1)}$ (the successive quotients $t^iA/t^{i+1}A$ have q_A elements). For a finite A-module P, multiplication by t^e has kernel $P[t^e]$ and cokernel P/t^eP of the same cardinality. Hence

$$q_A^{e(g+1)} \le \#(N/t^eN) = \#N[t^e] \le \#H[t^e] = \#(H/t^eH) \le q_A^{ge+C} < q_A^{ge+e},$$

as $e > C$ and $q_A \ge 2$: a contradiction. □

Lemma E.129. *Let x be a framed normalised curve point of shape $(a, n-a)$ over a rank-n Hecke datum, and let a Selmer basis $\kappa = (\kappa_1,\dots,\kappa_g)$ of x with local witnesses and a level $\mathbf{V} = (\Gamma_1, h, c_1, (\phi_{1,v}), (I_{1,u}))$ be given. Let $P_1 \subseteq \Gamma_1^0$ be a closed normal subgroup of Γ_1 such that Γ_1/P_1 is topologically finitely generated, $\rho(h(P_1)) = 1$, $\kappa_j(h(P_1)) = 0$ for all j, and every element of $\mathrm{Sel}^1_{\mathbf{V}}(A)$ and of every $\mathrm{Sel}^1_{\mathbf{V}}(A_m)$ vanishes on P_1 (for instance $P_1 = \{1\}$ when Γ_1 is topologically finitely generated). Let $D_0 \ge 0$, and assume that there is $C' \ge 0$ such that for every $m \ge 1$ the set $\mathrm{Sel}^1_{\mathbf{V}}(A_m)$ is finite and $\#\mathrm{Sel}^1_{\mathbf{V}}(A_m) \le \#\mathrm{Bd}^1_{\mathbf{V}}(A_m)\cdot(\#k)^{mD_0+C'}$. Then (K1) holds at $\mathbf{V}$: if $z_1,\dots,z_e \in \mathrm{Sel}^1_{\mathbf{V}}(A)$ are such that $\sum_i c_iz_i \in \mathrm{Bd}^1_{\mathbf{V}}(A)$ with $c \in A^e$ forces $c = 0$, then $e \le D_0$.*

Proof. Write $\varrho_1 = \rho_1\circ h$ on Γ_1^0 (entries in $\mathrm{PD}_g(A)$) and, for $R = A$ or A_m, $d_R(Y)$ for the map $\gamma \mapsto \varrho_1(\gamma)Y\varrho_1(\gamma)^{-1} - Y$. Recall that 2 is invertible in A (ℓ odd), and $\rho(\bar{c}\gamma\bar{c}) = {}^t\rho(\gamma)^{-1}$ (normalised point, $\gamma^* = \bar{c}\gamma^{-1}\bar{c}$).

Step 0: the sets are A-modules and $\mathrm{Bd}^1 \subseteq \mathrm{Sel}^1$. The conditions defining $\mathrm{Sel}_{\mathbf{V}}(\varrho, u, V)$ in Definition E.35 are A-linear in z (the local witnesses add), so $\mathrm{Sel}^1_{\mathbf{V}}(R)$ and $\mathrm{Bd}^1_{\mathbf{V}}(R)$ are A-submodules. Let $Y \in \mathrm{PW}^1_a(R)$ with ${}^tY = -Y$. $d_R(Y)$ has values in $\mathrm{PW}^1_a(R)$ (conjugation

by $\varrho_1(\gamma)$, block diagonal plus ϵ-terms in the off-diagonal blocks, preserves PW^1_a), is continuous and a cocycle; the local condition holds with witness $Y_v = Y$; and since $\kappa_j(\bar{c}\gamma\bar{c}) = -{}^t\kappa_j(\gamma)$, $\varrho_1(c_1\gamma c_1) = (1 - \sum_j \epsilon_j {}^t\kappa_j(h\gamma))^t\rho(h\gamma)^{-1} = {}^t\varrho_1(\gamma)^{-1}$, whence $d_R(Y)(c_1\gamma c_1) = {}^t\varrho_1(\gamma)^{-1}Y^t\varrho_1(\gamma) - Y = -{}^t(d_R(Y)(\gamma))$. So $\mathrm{Bd}^1_{\mathbf{V}}(R) \subseteq \mathrm{Sel}^1_{\mathbf{V}}(R)$. Reduction modulo T^m (entrywise, with the same local witnesses reduced) maps $\mathrm{Sel}^1_{\mathbf{V}}(A)$ into $\mathrm{Sel}^1_{\mathbf{V}}(A_m)$; write $\bar{z}$ for the reduction.

Step 1: a uniform bound on coefficients. Let $z_1, \dots, z_e$ be as in the statement. We show: there is $C \geq 0$ such that for all $m \geq 0$ and $c \in A^e$ with $\sum_i c_i\bar{z}_i \in \mathrm{Bd}^1_{\mathbf{V}}(A_m)$, every c_i lies in $T^{m-C}A$ (read as A for $m \leq C$). The open subgroup Γ_1^0/P_1 of index 2 of the topologically finitely generated group Γ_1/P_1 is topologically finitely generated (Schreier's lemma: if $s_1, \dots, s_r$ generate a dense subgroup, the Schreier generators for the cosets $1, c_1$ generate a dense subgroup of the index-2 subgroup); let $t_1, \dots, t_p \in \Gamma_1^0$ map to such generators. P_1 acts trivially ($\varrho_1 = 1$ on P_1), so a cocycle vanishing on P_1 satisfies $z(\gamma p) = z(\gamma)$ and induces a cocycle of Γ_1^0/P_1; coboundaries vanish on P_1 too. Hence a cocycle with T-adically continuous entries vanishing on P_1 is determined by its values at $t_1, \dots, t_p$: two such cocycles agreeing there agree on the subgroup of Γ_1^0/P_1 generated by the images (cocycle rule) and, being continuous into a Hausdorff space, on its closure. Let $M' = \mathrm{M}_n(\mathrm{PD}_g(A))^p$, a finitely generated free A-module, $V_0 = \{Y \in \mathrm{PW}^1_a(A) : {}^tY = -Y\}$, and

$$\Phi\colon A^e \oplus V_0 \to M', \qquad (c, Y) \mapsto \Big(\sum_i c_i z_i(t_k) - d_A(Y)(t_k)\Big)_{1 \leq k \leq p}.$$

If $\Phi(c, Y) = 0$, then $\sum_i c_i z_i = d_A(Y) \in \mathrm{Bd}^1_{\mathbf{V}}(A)$ by the remark just made, hence $c = 0$: each coordinate function c_i vanishes on $\ker\Phi$. By the Artin–Rees lemma [166, Thm. 8.5] for the submodule $P = \Phi(A^e \oplus V_0)$ of M' and $I = TA$ there is C with $P \cap T^{m+C}M' \subseteq T^mP$. Now let $\sum_i c_i\bar{z}_i = d_{A_m}(\bar{Y})$ with $\bar{Y} \in \mathrm{PW}^1_a(A_m)$, ${}^t\bar{Y} = -\bar{Y}$, $m \geq C$. Lift $\bar{Y}$ to $Y \in V_0$: lift each coordinate (in A_m) of the entries $\bar{Y}_{ij}$, $i < j$, to A, put $Y_{ji} = -Y_{ij}$ for $i < j$ (the positions (i, j) and (j, i) are both same-block or both different-block), and $Y_{ii} = 0$ (the diagonal entries of $\bar{Y}$ vanish since $2\bar{Y}_{ii} = 0$ and 2 is invertible). Then $\Phi(c, Y) \in P \cap T^mM' \subseteq T^{m-C}P$, so $\Phi(c, Y) = \Phi(c', Y')$ with $c' \in T^{m-C}A^e$; $(c - c', Y - Y') \in \ker\Phi$ gives $c = c' \in T^{m-C}A^e$.

Step 2: counting. Let $m \geq C$, $S_m = \mathrm{Sel}^1_{\mathbf{V}}(A_m)$, $B_m = \mathrm{Bd}^1_{\mathbf{V}}(A_m) \subseteq S_m$ (finite, nonempty), and fix a set-theoretic section σ of $A \to A/T^{m-C}A$. The map $B_m \times (A/T^{m-C}A)^e \to S_m$, $(b, \bar{c}) \mapsto b + \sum_i \sigma(\bar{c}_i)\bar{z}_i$, is injective: equal images give $\sum_i(\sigma(\bar{c}_i) - \sigma(\bar{c}'_i))\bar{z}_i = b' - b \in B_m$, so $\sigma(\bar{c}_i) - \sigma(\bar{c}'_i) \in T^{m-C}A$ by Step 1, i.e. $\bar{c} = \bar{c}'$, and then $b = b'$. As $\#(A/T^{m-C}A) = (\#k)^{m-C}$,

$$\#B_m\,(\#k)^{(m-C)e} \leq \#S_m \leq \#B_m\,(\#k)^{mD_0+C'}, \qquad \text{so} \qquad (m-C)e \leq mD_0 + C' \quad (m \geq C).$$

If $e \geq D_0 + 1$, then $(m - C)(D_0 + 1) \leq mD_0 + C'$, i.e. $m \leq C(D_0 + 1) + C'$, which fails for large m. Hence $e \leq D_0$. □

Lemma E.130. *Let x be a framed normalised curve point over a rank-n Hecke datum, and let a Selmer basis $\kappa = (\kappa_1, \dots, \kappa_g)$ of x with local witnesses and a level $\mathbf{V}$ be given. Let $P_1 \subseteq \Gamma_1^0$ be a closed normal subgroup of Γ_1 such that Γ_1/P_1 is topologically finitely generated, $\rho(h(P_1)) = 1$, $\kappa_j(h(P_1)) = 0$ for all j, and every element of $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(R)$ and $\mathrm{Sel}^2_{\mathbf{V}}(R)$, $R = A$ or A_m, vanishes on P_1 (for instance $P_1 = \{1\}$ when Γ_1 is topologically finitely generated). Assume that there is $C \geq 0$ such that for every $m \geq 1$ and every family $(z_{i,j})_{0 \leq i \leq g,\, 1 \leq j \leq g}$ in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(A_m)$ there are $c \in A^{g+1}$ with some $c_i \in A^\times$ and $\Psi \in \mathrm{Sel}^2_{\mathbf{V}}(A_m)$ such that the ϵ'_j-coefficient of $\Psi(\gamma)$ is $T^C \sum_i c_i z_{i,j}(\gamma)$ for all j, γ. Then (K2) holds at $\mathbf{V}$.*

Proof. Reduction modulo T^m (entrywise, with reduced local witnesses) maps $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(A_{m'})$ to $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(A_m)$ and $\mathrm{Sel}^2_{\mathbf{V}}(A_{m'})$ to $\mathrm{Sel}^2_{\mathbf{V}}(A_m)$ for $m' \geq m$ (with $A_{m'} = A$ allowed); write $\bar{\Psi}^{(m)}$ for reductions.

Step 1: finiteness. The subgroup $\Gamma^0 = \pi(G_L)$ has index at most 2 in Γ, so $\Gamma_1^0 = h^{-1}(\Gamma^0)$ has index at most 2 in Γ_1, and $H = \Gamma_1^0/P_1$ is a closed, hence open, subgroup of finite index of the topologically finitely generated profinite group Γ_1/P_1. If D is a finitely generated dense subgroup of Γ_1/P_1, then $D \cap H$ has finite index in D, so is finitely generated (Schreier's lemma), and is dense in H as H is open. Let $t_1, \dots, t_p \in \Gamma_1^0$ map to generators of $D \cap H$. Since $\rho(h(P_1)) = 1$ and $\kappa_j(h(P_1)) = 0$, the homomorphism $\rho_1 \circ h$, $\rho_1(\gamma) = (1 + \sum_j \epsilon_j \kappa_j(\gamma))\rho(\gamma)$, is trivial on P_1. Let $z \in \mathrm{Sel}^2_{\mathbf{V}}(A_m)$; it vanishes on P_1, so the cocycle rule gives $z(\gamma p) = z(\gamma) = z(p\gamma)$ for $p \in P_1$, and z factors through H. By the cocycle rule its values on the subgroup generated by the images of the t_k are determined by $z(t_1), \dots, z(t_p)$, and since the entries of z are continuous (locally constant, T being nilpotent in A_m), z is determined on the closure H. The values $z(t_k)$ lie in the finite set $\mathrm{M}_n(\mathrm{PD}_g(A_m))$ (k is finite). So $\mathrm{Sel}^2_{\mathbf{V}}(A_m)$ is finite.

Step 2: closedness. Let $\Psi\colon \Gamma_1^0 \to \mathrm{PW}^2_a(A)$ be a map with $\bar\Psi^{(m)} \in \mathrm{Sel}^2_{\mathbf{V}}(A_m)$ for every m. Each entry coordinate of $\bar\Psi^{(m)}$ is locally constant (T is nilpotent in A_m), so the entries of Ψ are continuous into $A = \varprojlim A_m$. The cocycle rule, the polarisation rule and the vanishing on the $I_{1,u}$ hold modulo every T^m, hence hold, as $\bigcap_m T^m A = 0$. For $v \in S_\ell$ let $W_m \subseteq \mathrm{PW}^2_a(A_m)$ be the set of local witnesses of $\bar\Psi^{(m)}$ at v: it is non-empty and finite, and reduction maps W_{m+1} into W_m. An inverse system of non-empty finite sets has non-empty inverse limit; an element $(Y_m)_m$ defines $Y_v \in \mathrm{PW}^2_a(A)$ whose reductions are witnesses, and the conditions on Y_v (vanishing of certain entries of a matrix depending polynomially on Y_v) hold modulo every T^m, hence over A. So $\Psi \in \mathrm{Sel}^2_{\mathbf{V}}(A)$.

Step 3: the limit. Let $(z_{i,j})$ be a family in $\mathrm{Sel}^{\mathrm{ev}}_{\mathbf{V}}(A)$. For every $m \geq 1$ apply the hypothesis to the reductions $\bar z^{(m)}_{i,j}$: there are $c^{(m)} \in A^{g+1}$ with $c^{(m)}_{i(m)} \in A^\times$ and $\Psi_m \in \mathrm{Sel}^2_{\mathbf{V}}(A_m)$ with ϵ'_j-coefficient $T^C \sum_i c^{(m)}_i \bar z^{(m)}_{i,j}$. Choose i_0 with $i(m) = i_0$ for m in an infinite set M_0. As A^{g+1} is compact and metrisable (k is finite), there are an infinite $M_1 \subseteq M_0$ and $c \in A^{g+1}$ with $c^{(m)} \to c$ along M_1; since $A^\times = A \smallsetminus TA$ is closed, $c_{i_0} \in A^\times$, so $c \neq 0$. By Step 1 and induction on $j \geq 1$ there are infinite sets $M_1 \supseteq M_2 \supseteq \cdots$ and $\psi_j \in \mathrm{Sel}^2_{\mathbf{V}}(A_j)$ with $\bar\Psi^{(j)}_m = \psi_j$ for all $m \in M_j$, $m \geq j$ (finitely many values: some value is taken infinitely often). Then $\bar\psi^{(j)}_{j+1} = \psi_j$, so the ψ_j define a map $\Psi\colon \Gamma_1^0 \to \mathrm{PW}^2_a(A)$ with $\bar\Psi^{(j)} = \psi_j$, and $\Psi \in \mathrm{Sel}^2_{\mathbf{V}}(A)$ by Step 2. For $j \geq 1$ choose $m \in M_j$, $m \geq j$, with $c^{(m)} \equiv c$ modulo T^j (possible as $M_j \subseteq M_1$ is infinite). Modulo T^j, the $\epsilon'_{j'}$-coefficient of $\Psi(\gamma)$ is that of $\Psi_m(\gamma)$, i.e. $T^C \sum_i c^{(m)}_i z_{i,j'}(\gamma) \equiv T^C \sum_i c_i z_{i,j'}(\gamma)$. As this holds for every j, the $\epsilon'_{j'}$-coefficient of $\Psi(\gamma)$ equals $\sum_i c'_i z_{i,j'}(\gamma)$ with $c' = T^C c$, and $c' \neq 0$ since A is a domain. This is (K2). □

Lemma E.131. *Let x be a framed normalised curve point of shape $(a, n-a)$ over a rank-n Hecke datum, κ a Selmer basis of x with local witnesses, and $\mathbf{V}$ a level. Let $\sigma_1, \dots, \sigma_q \in \Gamma^0$ be such that the characteristic polynomial of $\rho(\sigma_j)$ is $\prod_{i=1}^n (X - \alpha_{j,i})$ with $\alpha_{j,1}, \dots, \alpha_{j,n} \in A$ pairwise distinct, and let $\phi_j, \tau_j \in \Gamma_1^0$ with $h(\phi_j) = \sigma_j$, $h(\tau_j) = 1$ and $\phi_j\tau_j = \tau_j\phi_j$ $(1 \leq j \leq q)$. Assume that $\ker h$ is the closure of the subgroup of Γ_1 generated by the conjugates $g\tau_j g^{-1}$, $g \in \Gamma_1$, $1 \leq j \leq q$. Then (K3) holds at $\mathbf{V}$: for every $z \in \mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}}(A)$ there are $s \geq 0$ and $c \in A^g$ with $T^s z - \sum_j c_j(\kappa_j \circ h) \in \mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(A)$.*

Proof. Write $\varrho = \rho \circ h$ on Γ_1^0; $\rho(\gamma)$ is block diagonal for $\gamma \in \Gamma^0$ (shape $(a, n-a)$). If $a = n$ then $\mathrm{Od}_a = 0$, $z = 0$ and there is nothing to prove; let $a < n$. Fix $z \in \mathrm{Sel}^{\mathrm{od}}_{\mathbf{V}}(A)$ (the frame w as local matrices).

Step 1: $z(\tau_j) = 0$. By the cocycle rule and $\varrho(\tau_j) = 1$, $z(\phi_j\tau_j) = z(\phi_j) + \rho(\sigma_j) z(\tau_j) \rho(\sigma_j)^{-1}$ and $z(\tau_j\phi_j) = z(\tau_j) + z(\phi_j)$; as $\phi_j\tau_j = \tau_j\phi_j$, $Z = z(\tau_j) \in \mathrm{Od}_a(A)$ commutes with $M = \rho(\sigma_j) =$

$\mathrm{diag}(M_1, M_2)$, M_1 of size a. Writing $Z = \begin{pmatrix} 0 & Z_{12} \\ Z_{21} & 0 \end{pmatrix}$, this says $M_1 Z_{12} = Z_{12} M_2$ and $M_2 Z_{21} = Z_{21} M_1$, hence $P(M_1) Z_{12} = Z_{12} P(M_2)$ and $P(M_2) Z_{21} = Z_{21} P(M_1)$ for every polynomial P. The characteristic polynomials P_1, P_2 of M_1, M_2 have product $\prod_i (X - \alpha_{j,i})$ with distinct roots, so they have no common root and are coprime in $F_k[X]$, $F_k = \mathrm{Frac}(A)$: $uP_1 + vP_2 = 1$ with $u, v \in F_k[X]$. By Cayley–Hamilton, $0 = P_1(M_1) Z_{12} = Z_{12} P_1(M_2)$, and $u(M_2) P_1(M_2) = 1 - v(M_2) P_2(M_2) = 1$, so $P_1(M_2)$ is invertible over F_k and $Z_{12} = 0$; symmetrically $Z_{21} = 0$ (use P_2). So $z(\tau_j) = 0$.

Step 2: z vanishes on $\ker h$. We have $\ker h \subseteq \Gamma_1^0$. For $\gamma, \gamma' \in \ker h$, $z(\gamma\gamma') = z(\gamma) + z(\gamma')$ and $z(\gamma^{-1}) = -z(\gamma)$ (cocycle rule with $\varrho(\gamma) = 1$), so $K_z = \{\gamma \in \ker h : z(\gamma) = 0\}$ is a subgroup; it is closed, since the entries of z are continuous for the T-adic topology of A, which is Hausdorff. For $g \in \Gamma_1^0$, $z(g \tau_j g^{-1}) = z(g) + \varrho(g)\big(z(\tau_j) + z(g^{-1})\big)\varrho(g)^{-1} = z(g) + \varrho(g) z(g^{-1}) \varrho(g)^{-1} = z(gg^{-1}) = 0$ by Step 1. For $g \notin \Gamma_1^0$ write $g = c_1 g'$ with $g' \in \Gamma_1^0$ (as $h(c_1) = \bar{c} \notin \Gamma^0$, Γ_1^0 has index 2 and $c_1 \notin \Gamma_1^0$); then $g \tau_j g^{-1} = c_1 (g' \tau_j g'^{-1}) c_1$ and $z(c_1 \gamma c_1) = -{}^t z(\gamma)$ gives 0. So K_z contains all conjugates of the τ_j, hence their closed span $\ker h$.

Step 3: descent to the base level. For $\gamma \in \Gamma_1^0$ and $\kappa' \in \ker h$, $z(\gamma\kappa') = z(\gamma) + \varrho(\gamma) z(\kappa') \varrho(\gamma)^{-1} = z(\gamma)$; as h maps Γ_1^0 onto Γ^0, there is a unique map $y \colon \Gamma^0 \to \mathrm{Od}_a(A)$ with $z = y \circ h$. Since $h \colon \Gamma_1^0 \to \Gamma^0$ is a continuous surjection of compact Hausdorff spaces, it is a quotient map, so the entries of y are T-adically continuous. The cocycle rule for y and ρ follows from that of z; $y(\bar{c}\gamma\bar{c}) = z(c_1 \gamma' c_1) = -{}^t z(\gamma') = -{}^t y(\gamma)$ for $h(\gamma') = \gamma$; y vanishes on $I_u^x = h(I_{1,u})$; and for $v \in S_\ell$ and $g \in D_v$, $z(\phi_{1,v} g) = y(\pi g)$ and $\varrho(\phi_{1,v} g) = \rho(\pi g)$ because $h \circ \phi_{1,v} = \pi|_{D_v}$, so the local witness Y_v of z is one for y. Hence $y \in Z^1_{\mathrm{ord}}(x)$.

Step 4. As κ is a Selmer basis, there are $s \geq 0$, $c \in A^g$ and $Y \in \mathrm{Od}_a(A)$ with ${}^t Y = -Y$ such that $T^s y(\gamma) - \sum_j c_j \kappa_j(\gamma) = \rho(\gamma) Y \rho(\gamma)^{-1} - Y$ for $\gamma \in \Gamma^0$. Composing with h, $T^s z - \sum_j c_j (\kappa_j \circ h)$ is $\gamma \mapsto \varrho(\gamma) Y \varrho(\gamma)^{-1} - Y$, an element of $\mathrm{Bd}^{\mathrm{od}}_{\mathbf{V}}(A)$. □

Lemma E.132. *Let ℓ be a prime, G_1, G_2, $\bar{G}$ profinite groups and $\theta \colon G_1 \to \bar{G}$, $q \colon G_2 \to \bar{G}$ surjective homomorphisms, and let $\Gamma = G_1 \times_{\bar{G}} G_2 = \{(a, b) : \theta(a) = q(b)\}$. Assume that G_1 and G_2 satisfy Φ_ℓ and that there is an open subgroup $\bar{G}_0$ of $\bar{G}$ such that $H^2(V, \mathbb{Z}/\ell)$ is finite for every open subgroup V of $\bar{G}$ contained in $\bar{G}_0$. Then Γ satisfies Φ_ℓ. The hypothesis Φ_ℓ on G_1 holds in particular if G_1 is topologically finitely generated.*

Proof. We use the following classical facts. A surjective homomorphism of profinite groups is open. For a closed normal subgroup P of a profinite group E the five-term inflation–restriction sequence

$$0 \to H^1(E/P, \mathbb{Z}/\ell) \to H^1(E, \mathbb{Z}/\ell) \to H^1(P, \mathbb{Z}/\ell)^E \to H^2(E/P, \mathbb{Z}/\ell)$$

is exact (e.g. Neukirch–Schmidt–Wingberg, Cohomology of Number Fields, Prop. 1.6.7). Moreover $H^1(E, \mathbb{Z}/\ell) = \mathrm{Hom}(E, \mathbb{Z}/\ell)$, and an open subgroup of a topologically finitely generated profinite group is topologically finitely generated.

Let $U \subseteq \Gamma$ be open. There are open normal subgroups $W_1 \subseteq G_1$, $W_2 \subseteq G_2$ with $U_0 = \Gamma \cap (W_1 \times W_2) \subseteq U$, and shrinking W_2 we may assume $W_2 \subseteq q^{-1}(\bar{G}_0)$ (an open subgroup of G_2 contains an open normal one); U_0 is open and normal in Γ. A homomorphism $U \to \mathbb{Z}/\ell$ vanishing on U_0 factors through the finite group U/U_0, so the restriction map $\mathrm{Hom}(U, \mathbb{Z}/\ell) \to \mathrm{Hom}(U_0, \mathbb{Z}/\ell)$ has finite fibres, and it suffices to show that $\mathrm{Hom}(U_0, \mathbb{Z}/\ell)$ is finite.

The first projection maps U_0 onto $V_1 = W_1 \cap \theta^{-1}(q(W_2))$, which is open in G_1 (q is open), with kernel $\{1\} \times P'$, $P' = W_2 \cap \ker q$. The second projection maps U_0 onto $L = W_2 \cap q^{-1}(\theta(W_1))$, open in G_2; $P' = L \cap \ker q$ is normal in L and $L/P' \cong q(L)$, an open subgroup of $\bar{G}$. Conjugation by $(a, b) \in U_0$ acts on $\{1\} \times P'$ as conjugation by b on P', so $H^1(P', \mathbb{Z}/\ell)^{U_0} = H^1(P', \mathbb{Z}/\ell)^L$.

The five-term sequence for $\{1\} \times P' \subseteq U_0$ gives an exact sequence

$$0 \to \mathrm{Hom}(V_1, \mathbb{Z}/\ell) \to \mathrm{Hom}(U_0, \mathbb{Z}/\ell) \to H^1(P', \mathbb{Z}/\ell)^L,$$

and the one for $P' \subseteq L$ gives an exact sequence $\mathrm{Hom}(L, \mathbb{Z}/\ell) \to H^1(P', \mathbb{Z}/\ell)^L \to H^2(q(L), \mathbb{Z}/\ell)$. Here $\mathrm{Hom}(V_1, \mathbb{Z}/\ell)$ and $\mathrm{Hom}(L, \mathbb{Z}/\ell)$ are finite by Φ_ℓ for G_1 and G_2, and $H^2(q(L), \mathbb{Z}/\ell)$ is finite by hypothesis, as $q(L) \subseteq q(W_2) \subseteq \bar{G}_0$ is open in $\bar{G}$; hence $H^1(P', \mathbb{Z}/\ell)^L$ is finite, and so is $\mathrm{Hom}(U_0, \mathbb{Z}/\ell)$.

If G_1 is topologically finitely generated, so is each of its open subgroups V, and $\mathrm{Hom}(V, \mathbb{Z}/\ell)$ is finite (a homomorphism is determined by its values on finitely many generators); so G_1 satisfies Φ_ℓ. □

E.5 The patched ring and automorphic patching data

This section proves the remaining inputs of Proposition E.39. Proposition E.134 says that the patched ring modulo its relation ideal carries a polarised ordinary determinant on the limit level group with the Taylor–Wiles data; with it, at thick primes under the patched ring the relation quotient of a realisation is not semisimple (Lemma E.133). Proposition E.136 says that classical levels give automorphic patching data along every Taylor–Wiles datum. It is proved through operator modules with the local relations at every Taylor–Wiles level (Definition E.135, Proposition E.137, Proposition E.142): at a Taylor–Wiles place the U-eigencharacters on Iwahori invariants determine the Frobenius eigenvalues and the tame action (Lemma E.140), up to a Vandermonde-type element (Lemma E.139, Lemma E.141).

Lemma E.133. *In the situation of Proposition E.134, let $\mathfrak{R}$ be a realisation of x (of shape $(a, n-a)$) over $\mathbf{V}_\infty$ whose global ring, determinant, characters, Taylor–Wiles elements and s are those of Proposition E.134, and let $\hat{Q}'$ be a prime ideal of $\hat{B}$ whose preimage in R is $\pi^{-1}(P')$ for a prime ideal P' of C^{sp}. Then (Gl2) of Proposition E.78 holds for $\hat{Q}'$:*

(Tk1) *if $a < n$ and $u^{-1}(P')$ is stable, then* $\mathrm{ired}(N) \not\subseteq \hat{Q}'$*;*

(Tk2) *if $u^{-1}(P')$ is thick, then for an algebraic closure κ of the fraction field of $\hat{B}/\hat{Q}'$ and the natural homomorphism $\hat{B} \to \kappa$ (with kernel $\hat{Q}'$), $\kappa[\Gamma_\infty^0]$ modulo the two-sided ideal generated by the image of $\mathcal{I}_1$ is not semisimple.*

Proof. (Tk1). The preimage $\pi^{-1}(P')$ of $\hat{Q}'$ in R is contained in $\pi^{-1}(P')$, and $u^{-1}(P')$ is stable; so Lemma E.46 (with $P'' = P'$) gives $\mathrm{ired}(N) \not\subseteq \hat{Q}'$.

(Tk2). Put $\mathfrak{Q} = u^{-1}(P')$, $\bar{C} = C^{\mathrm{sp}}/P'$ and let $\mathfrak{m}_{\bar{C}}$ be its maximal ideal; $\bar{C}$ is a Noetherian local domain (C^{sp} is a complete Noetherian local ring). Let $\varrho\colon R/I \to \bar{C}$ be $\bar{\pi}$ followed by the projection; it is onto with kernel $\pi^{-1}(P')/I$, which is the preimage of $\hat{Q}'$ in R/I. So ϱ induces an embedding $\bar{C} \to \hat{B}/\hat{Q}' \subseteq \kappa$ through which $R/I \to \hat{B} \to \kappa$ factors, and u induces $B/\mathfrak{Q} \to \bar{C}$; let $K \subseteq \kappa$ be the algebraic closure of the fraction field of $B/\mathfrak{Q}$ in κ, an algebraic closure of it.

Step 1: the residual algebra. $\mathcal{I}$ is the ideal $\bar{J}$ of Lemma E.69 formed from $(B, \Gamma^0_{\mathscr{H}}, D^{\mathrm{u}}, \mathcal{S})$, $\mathcal{S}$ the ordinary products and their images under *. B is a complete Noetherian local ring with finite residue field of characteristic $\ell \neq 2$, the base change of D^{u} to the residue field is $\det \circ \mathrm{diag}(\bar{\chi}_a)$ with pairwise distinct $\bar{\chi}_a$, and $\Gamma^0_{\mathscr{H}}$ satisfies Φ_ℓ, being open in $\Gamma_{\mathscr{H}}$, which does by Lemma E.116. By (F0)–(F2) of Lemma E.69, $E_B = B[\Gamma^0_{\mathscr{H}}]/\mathcal{I}$ is a finitely generated B-module, and for every $j \geq 1$ there is an open normal $V_j \subseteq \Gamma^0_{\mathscr{H}}$ with $\iota_B(\gamma v) - \iota_B(\gamma) \in \mathfrak{m}_B^j E_B$ (ι_B the projection). By the definition of thickness, $E_K = K[\Gamma^0_{\mathscr{H}}]/(\text{ideal generated by the image of } \mathcal{I}) = E_B \otimes_B K$ is not semisimple; it is finite-dimensional over K.

Step 2: a map on the realisation's group algebra. Let $M = E_B \otimes_B \bar{C}$ (through $B \to \bar{C}$), a $\bar{C}$-algebra, finitely generated as a $\bar{C}$-module, and $\Psi\colon (R/I)[\Gamma^0_\infty] \to M$ the ring homomorphism $\sum b_g g \mapsto \sum \varrho(b_g)\,\iota_B(h(g)) \otimes 1$. We show $\Psi(\mathcal{I}_1) = 0$. Recall that $\mathcal{I}_1$ is the intersection over $j \geq 1$ and open normal $H' \subseteq \Gamma^0_\infty$ of the two-sided ideals $J^1_{j,H'}$ generated by $\mathrm{CH}(D)$, $\mathfrak{m}^j_{R/I} \cdot 1$, $h' - 1$ ($h' \in H'$) and the elements listed in (Vr3) with their images under *. Fix j and take $H' = h^{-1}(V_j) \cap \Gamma^0_\infty$. Images of the generators:

- $h' - 1$, $h' \in H'$: $\iota_B(h(h')) - 1 \in \mathfrak{m}^j_B E_B$, so $\Psi(h' - 1) \in \mathfrak{m}^j_{\bar{C}} M$; and $\Psi(\mathfrak{m}^j_{R/I}) \subseteq \mathfrak{m}^j_{\bar{C}} M$, as ϱ is a local homomorphism.
- Ordinary products: $h \circ \phi_{\infty,v} = \pi_{\mathscr{H}}|_{D_v}$ and $\varrho(\hat{\psi}_{v,a}(g))$ is the image of $\psi^{\mathrm{d}}_{v,a}(g)$ (definition of π_0 in Definition E.37), so Ψ maps $\prod_a(\phi_{\infty,v}(g_a) - \hat{\psi}_{v,a}(g_a))$ to the image of $\prod_a(\pi_{\mathscr{H}}(g_a) - \psi^{\mathrm{d}}_{v,a}(g_a)) \in \mathcal{S} \subseteq \mathcal{I}$, i.e. to 0. As $h(c'_\infty) = \pi_{\mathscr{H}}(c)$, $h(\gamma^*) = h(\gamma)^*$, so Ψ commutes with * and the images under * also go to 0 ($\mathcal{S}^* \subseteq \mathcal{S}$).
- Frame inertia: let $\gamma' = (F_u(y), \pi_{\mathscr{H}}(y)) \in I_{\infty,u}$ with $y \in I_{\bar{u}} \cap G_L$ and $\pi_{\mathscr{H}}(y) \in I^x_u$. As ρ is trivial on I^x_u (frame), $\det(X - \rho(\pi_{\mathscr{H}} y)) = (X-1)^n$; its reduction modulo T is $\prod_a(X - \bar{\chi}_a(y))$, since $f_x \circ D^{\mathrm{u}} = \det \circ \rho$ and D^{u} reduces to $\det \circ \mathrm{diag}(\bar{\chi}_a)$. So all $\bar{\chi}_a(y) = 1$, y is one of the generators of $N_{\mathscr{H}}$ ($u \nmid \ell$), and $h(\gamma') = \pi_{\mathscr{H}}(y) = 1$: $\Psi(\gamma' - 1) = 0$; likewise for the images under *.
- Taylor–Wiles elements: $h(\phi_j) = \sigma_j$ and $\varrho(U_{j,i})$ is the image of $u_{j,i}$, so $\Psi(\prod_i(\phi_j - U_{j,i}))$ is the image of $\prod_i(\sigma_j - u_{j,i}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(\sigma_j)$ (in $\bar{C}[\Gamma^0_{\mathscr{H}}]$, by the definition of the eigenvalue algebra), which is the image of an element of $\mathrm{CH}(D^{\mathrm{u}}) \subseteq \mathcal{I}$ ($m = 1$, $y_1 = \sigma_j$); so it is 0. $h(\tau_j) = 1$ and $\varrho(y_{j,i}) = 0$, so the factor $\tau_j - 1 - y_{j,i}$, and with it the second Taylor–Wiles element, maps to 0. The images under * follow as above.
- $\mathrm{CH}(D)$: let $y_1, \ldots, y_m \in (R/I)[\Gamma^0_\infty]$ and write $\Psi_0(y_i) = \sum_g a_{ig} g \in \bar{C}[\Gamma^0_{\mathscr{H}}]$ for the image under ϱ on coefficients and h on the group. By (In1) of Proposition E.134 and (Ch1) of Theorem B.83, the base change of D along ϱ is the base change of D^{u} along $B \to \bar{C}$ composed with h; so Ψ maps the coefficients of $\chi_{D'}(\sum t_i y_i)(\sum t_i y_i)$ to the images in M of the coefficients of $\chi(\sum_g s_g g)(\sum_g s_g g)$, χ the characteristic polynomial of D^{u} over $B[s_g]$, specialised at $s_g = \sum_i t_i a_{ig}$; those coefficients lie in $\mathrm{CH}(D^{\mathrm{u}}) \subseteq \mathcal{I}$, so the images are $\bar{C}$-linear combinations of images of elements of $\mathcal{I}$, i.e. 0.

Since $\mathfrak{m}^j_{\bar{C}} M$ is a two-sided ideal of M ($\bar{C}$ is central), $\Psi(J^1_{j,H'}) \subseteq \mathfrak{m}^j_{\bar{C}} M$, hence $\Psi(\mathcal{I}_1) \subseteq \bigcap_j \mathfrak{m}^j_{\bar{C}} M = 0$ by Krull's intersection theorem for the finitely generated module M over the Noetherian local ring $\bar{C}$.

Step 3: non-semisimplicity. Tensoring Ψ with κ over $\bar{C}$ gives a ring homomorphism $\kappa[\Gamma^0_\infty] \to M \otimes_{\bar{C}} \kappa = E_B \otimes_B \kappa = E_K \otimes_K \kappa$ (coefficients through $R/I \to \hat{B} \to \kappa$, which factors through ϱ), which kills the image of $\mathcal{I}_1$ by Step 2 and is onto, since h maps Γ^0_∞ onto $\Gamma^0_{\mathscr{H}}$ and E_B is spanned by the image of $\Gamma^0_{\mathscr{H}}$. The finite-dimensional K-algebra E_K is not semisimple, so its Jacobson radical $\mathfrak{r}$ is a non-zero nilpotent two-sided ideal; $\mathfrak{r} \otimes_K \kappa$ is a non-zero nilpotent two-sided ideal of $E_K \otimes_K \kappa$, which is therefore not semisimple. A quotient of a semisimple ring is semisimple; so $\kappa[\Gamma^0_\infty]$ modulo the two-sided ideal generated by the image of $\mathcal{I}_1$, which maps onto $E_K \otimes_K \kappa$, is not semisimple. □

Proposition E.134. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$ with $\ell \neq 2$, and let automorphic patching data for an ideal $J \subseteq B$ along a Taylor–Wiles datum $\mathcal{D}$ of size q (with H and $\sigma_1, \ldots, \sigma_q$), $\mathcal{O}_1$, limit objects $(\Pi, (\pi_N), \mathcal{U}, \bar{\theta}, c_\infty, (\Phi_j), (\mathrm{T}_j), (F_w))$ and $\tilde{c}$ be given as in Definition E.37, with patched tower data $(R, \beta, X, f, I, e+1, (M^\natural_N), \mathcal{U})$, C^{sp}, u and π. Assume*

that B is topologically generated as an $\mathcal{O}$-algebra by the coefficients of the polynomials $\chi_{D^{\mathrm{u}}}(\gamma)$, $\gamma \in \Gamma^0_{\mathscr{H}}$, and the values $\psi^{\mathrm{d}}_{v,a}(g)$, $v \in S_\ell$, $g \in D_v$. Let $x = (k, \rho, 1_n, (\psi_{v,a}), f_x)$ be a framed normalised curve point of B with $|k| = |\mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1}|$ which has eigenvalue data along $\mathcal{D}$, κ a Selmer basis of x with local witnesses such that x, κ and $\mathcal{D}$ satisfy all hypotheses of Proposition E.97, $f' \colon C^{\mathrm{sp}} \to A_k$ a surjective ring homomorphism with $f' \circ u = f_x$ and $f'(z) = T$, and $\mathbf{V}_\infty$ the limit level formed from the given limit objects. Then $\pi(I) = 0$; let $\bar\pi \colon R/I \to C^{\mathrm{sp}}$ be the induced homomorphism, $f_1 = f' \circ \bar\pi$, and write b_I for the image of $b \in R$ in R/I. Then:

(In1) *the base change D_I of D^{t} to R/I is $\bar D \circ \pi_\infty$ for a unique continuous R/I-valued determinant $\bar D$ of dimension n on $\bar\Gamma^0_\infty = \pi_\infty(P^0)$; put $D = \bar D \circ p_1$ on Γ^0_∞, where $p_1(g,\gamma) = g$; then $\bar\pi(\Lambda_i(D)(g,\gamma)) = u(\Lambda_i(D^{\mathrm{u}})(\gamma))$ for $(g,\gamma) \in \Gamma^0_\infty$ and $1 \le i \le n$;*

(In2) *with $\hat\psi_{v,i} = (\psi^{\mathrm{t}}_{v,i})_I$, $U_{j,i} = (U^{\mathrm{t}}_{j,i})_I$, $y_{j,i} = (y^{\mathrm{t}}_{j,i})_I$ and $s = (s^{\mathrm{t}})_I$, the tuple $(R/I, D, (\hat\psi_{v,i}), (\phi_j, \tau_j, U_{j,i}, y_{j,i}), s, f_1)$ satisfies, for the coefficient ring $\mathcal{O}_1$ and the level $\mathbf{V}_\infty$, all clauses of (Vr1) and (Vr2) that concern it;*

(In3) *(Lv1) and (Lv2) hold for D over $\mathbf{V}_\infty$.*

Proof. By (Wz1) of Proposition E.56, π is onto and $\pi(I) = 0$; so $\bar\pi$ is defined and onto, and f_1 is onto. By its definition in Definition E.37 (π_0 carries the universal patched tuple $t^{\mathrm{u}} = (D^{\mathrm{t}}, (\psi^{\mathrm{t}}_{v,a}), s^{\mathrm{t}}, (U^{\mathrm{t}}_{j,i}), (y^{\mathrm{t}}_{j,i}))$ to $(\bar D^{\mathrm{u}} \circ \bar\theta \circ \pi_\infty|_{P^0}, (\psi^{\mathrm{d}}_{v,a}), z, (u_{j,i}), (0)))$, π_0 carries $\Lambda_i(D^{\mathrm{t}})(g)$ to $\Lambda_i(\bar D^{\mathrm{u}})(\bar\theta\pi_\infty(g))$ (base changed to C^{sp}_0), $\psi^{\mathrm{t}}_{v,a}$ to $\psi^{\mathrm{d}}_{v,a}$, s^{t} to z, $U^{\mathrm{t}}_{j,i}$ to $u_{j,i}$ and $y^{\mathrm{t}}_{j,i}$ to 0.

Step 0: the ring. $R_{\mathrm{tup}} \in \mathrm{CNL}_{\mathcal{O}}$ and $\mathcal{O}_1$ is free of finite rank over $\mathcal{O}$, so $R = \mathcal{O}_1 \otimes_{\mathcal{O}} R_{\mathrm{tup}}$ is a finite R_{tup}-algebra, hence complete and Noetherian, and $R/\mathfrak{m}_{R_{\mathrm{tup}}}R = \mathcal{O}_1/\mathfrak{m}_{\mathcal{O}}\mathcal{O}_1 = \mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1}$ is a field; so R, and with it R/I, is a complete Noetherian local $\mathcal{O}_1$-algebra with residue field $\mathcal{O}_1/\mathfrak{m}_{\mathcal{O}_1}$. f_1 is a homomorphism of $\mathcal{O}$-algebras: π is $\mathcal{O}_1$-linear and f' is $\mathcal{O}$-linear, as $f' \circ u = f_x$ is.

Step 1: (In1). $\bar\Gamma^0$ (the image of $\Gamma^0_{\mathscr{H}}$) has index at most 2 in $\bar\Gamma$, so P^0 is open in the topologically finitely generated group Π and is itself topologically finitely generated. D_I is continuous, and its reduction modulo the maximal ideal is $\det \circ \mathrm{diag}(\bar\chi_a \circ \bar\theta \circ \pi_\infty)$ (patched tuple; $\bar D_n = \det \circ \mathrm{diag}(\bar\chi_a)$), with the characters $\bar\chi_a \circ \bar\theta \circ \pi_\infty$ of P^0 pairwise distinct ($\bar\theta \circ \pi_\infty$ maps P^0 onto $\bar\Gamma^0$, through which the pairwise distinct $\bar\chi_a$ factor). For continuous characters χ, χ' of a topologically finitely generated group into the residue field, a continuous cocycle in $Z^1(\chi, \chi')$ is determined by its values on a finite set of topological generators, so $Z^1(\chi, \chi')$ is finite-dimensional. As $\ell \ne 2$, (Kt2) applies to D_I on P^0: an element $y \in (R/I)[P^0]$ lies in $\ker(D_I)$ as soon as $\mathrm{tr}_{D_I}(gy) = 0$ for all $g \in P^0$. For $k \in \ker \pi_\infty$ (contained in P^0), the relations (Wv1) lie in I, so $\mathrm{tr}_{D_I}(g(k-1)) = 0$ for all $g \in P^0$, and $k - 1 \in \ker(D_I)$. The two-sided ideal generated by these $k-1$ is the kernel of $(R/I)[P^0] \to (R/I)[\pi_\infty(P^0)]$, and it lies in the two-sided ideal $\ker(D_I)$; by (Ck1), D_I factors through $(R/I)[P^0]/\ker(D_I)$, hence through $(R/I)[\pi_\infty(P^0)]$: $D_I = \bar D \circ \pi_\infty$ for a determinant $\bar D$ of dimension n, unique as π_∞ is onto. Its coefficient maps $\Lambda_i(\bar D)$ are continuous, because $\Lambda_i(\bar D) \circ \pi_\infty = \Lambda_i(D_I)$ is and $\pi_\infty|_{P^0}$ is a continuous surjection of compact groups (a quotient map). Since π_∞ is onto, $\pi_\infty(P^0) = \bar\theta^{-1}(\bar\Gamma^0) = \bar\Gamma^0_\infty$. Finally $p_1 \colon \Gamma^0_\infty \to \bar\Gamma^0_\infty$ is a continuous homomorphism, onto: for $g \in \bar\Gamma^0_\infty$ choose $\gamma \in \Gamma^0_{\mathscr{H}}$ with image $\bar\theta(g)$; then $(g,\gamma) \in \Gamma^0_\infty$. So $D = \bar D \circ p_1$ is a continuous determinant of dimension n on Γ^0_∞, and for $(g,\gamma) \in \Gamma^0_\infty$ and any $\tilde g \in P^0$ with $\pi_\infty(\tilde g) = g$, $\Lambda_i(D)(g,\gamma) = \Lambda_i(D^{\mathrm{t}})(\tilde g)_I$.

For $(g,\gamma) \in \Gamma^0_\infty$, $\bar\theta(g)$ is the image $\bar\gamma$ of γ in $\bar\Gamma$ and $D^{\mathrm{u}} = \bar D^{\mathrm{u}} \circ (\text{projection})$, so by the definition of π_0, $\bar\pi(\Lambda_i(D)(g,\gamma)) = \pi(\Lambda_i(D^{\mathrm{t}})(\tilde g)) = u(\Lambda_i(\bar D^{\mathrm{u}})(\bar\gamma)) = u(\Lambda_i(D^{\mathrm{u}})(\gamma))$.

Step 2: (Vr1). R/I is as required by Step 0; D is a continuous determinant of dimension n on $(R/I)[\Gamma^0_\infty]$ by Step 1; the $\hat\psi_{v,i}$ are continuous characters $D_v \to (R/I)^\times$; f_1 is a surjective

homomorphism of $\mathcal{O}$-algebras (Step 0). $f_1(s) = f'(\pi(s^{\mathrm{t}})) = f'(z) = T$. $f_1 \circ \hat{\psi}_{v,i} = f' \circ u \circ \psi^{\mathrm{d}}_{v,i} = f_x \circ \psi^{\mathrm{d}}_{v,i} = \psi_{v,i}$, as x is a curve point. For $(g,\gamma) \in \Gamma^0_\infty$ and $\tilde{g}$ as above, $\bar{\theta}(g)$ is the image $\bar{\gamma}$ of γ, and $D^{\mathrm{u}} = \bar{D}^{\mathrm{u}} \circ$ (projection); so

$$f_1(\Lambda_i(D)(g,\gamma)) = f'(\pi(\Lambda_i(D^{\mathrm{t}})(\tilde{g}))) = f'(u(\Lambda_i(D^{\mathrm{u}})(\gamma))) = f_x(\Lambda_i(D^{\mathrm{u}})(\gamma)) = \Lambda_i(\det \circ \rho)(\gamma),$$

the last because $f_x \circ D^{\mathrm{u}} = \det \circ \rho$. As $h(g,\gamma) = \gamma$, the determinants $f_1 \circ D$ and $\det \circ (\rho \circ h)$ on Γ^0_∞ have the same characteristic polynomials at every element, hence are equal by (Ch1). The clause Φ_ℓ of (Vr1) concerns the level: it is (P4) of Proposition E.94. Finally, for $g \in \mu_v$, $\psi^{\mathrm{t}}_{v,i}(g)$ is the image in R_{tup} of the wild value $\xi_{v,i}(g) \in \mathcal{O}$ (t^{u} is a patched tuple, Proposition E.60), so $\hat{\psi}_{v,i}(g)$ lies in the image of $\mathcal{O} \to R/I$.

Step 3: (Vr2). By (P1) of Proposition E.94, $\phi_j, \tau_j \in \Gamma^0_\infty$ commute and $h(\tau_j) = 1$, $h(\phi_j) = \sigma_j$. $f_1(y_{j,i}) = f'(0) = 0$. Applying f' to the identity $\prod_i (X - u_{j,i}) = \chi_{D^{\mathrm{u}}}(\sigma_j)(X)$ of $C^{\mathrm{sp}}[X]$ (definition of the eigenvalue algebra) and using $f' \circ u = f_x$ and $f_x \circ D^{\mathrm{u}} = \det \circ \rho$ gives $\prod_i (X - f_1(U_{j,i})) = \det(X - \rho(\sigma_j)) = \det(X - \rho(h(\phi_j)))$. By the eigenvalue data, this polynomial is $\prod_i (X - \alpha_{j,i})$ with pairwise distinct $\alpha_{j,i} \in A_k$; A_k being a domain, $(f_1(U_{j,i}))_i$ is a permutation of $(\alpha_{j,i})_i$, so pairwise distinct. *Generation.* Let $R' \subseteq R_{\mathrm{tup}}$ be the closure of the $\mathcal{O}$-subalgebra generated by the $\Lambda_i(D^{\mathrm{t}})(g)$ ($g \in P^0$), the $\psi^{\mathrm{t}}_{v,a}(g)$, s^{t}, the $U^{\mathrm{t}}_{j,i}$ and the $y^{\mathrm{t}}_{j,i}$. Fix $m \geq 1$, let $\varpi_m \colon R_{\mathrm{tup}} \to R_{\mathrm{tup}}/\mathfrak{m}^m$ ($\mathfrak{m}$ the maximal ideal) and $R'_m = \varpi_m(R')$, a finite local $\mathcal{O}$-algebra with residue field $\mathcal{O}/\mathfrak{m}_{\mathcal{O}}$, hence in $\mathrm{CNL}_{\mathcal{O}}$. By (Ch1), $\varpi_m \circ D^{\mathrm{t}}$ is the base change of a determinant D'_m with values in the subring generated by its coefficients, which lies in R'_m; D'_m is continuous (R'_m is finite and the Λ_i are locally constant) and lifts $\bar{D}_n \circ \bar{\theta} \circ \pi_\infty$, and the other components of $\varpi_m(t^{\mathrm{u}})$ lie in R'_m with the required congruences. So $\varpi_m(t^{\mathrm{u}})$ is (the base change of) a patched tuple to R'_m, and Proposition E.60 gives a morphism $\varphi \colon R_{\mathrm{tup}} \to R'_m$ carrying t^{u} to it. The composite of φ with $R'_m \subseteq R_{\mathrm{tup}}/\mathfrak{m}^m$ and the projection ϖ_m both carry t^{u} to $\varpi_m(t^{\mathrm{u}})$ (for the determinants: equal characteristic polynomials, (Ch1)); by uniqueness they coincide, so $\varpi_m(R_{\mathrm{tup}}) \subseteq R'_m$, i.e. $R' + \mathfrak{m}^m = R_{\mathrm{tup}}$. As R' is closed, $R' = R_{\mathrm{tup}}$. Hence $R = \mathcal{O}_1 \otimes_{\mathcal{O}} R_{\mathrm{tup}}$, and R/I, are topologically generated as $\mathcal{O}_1$-algebras by the images of these elements. By Step 1 the images of the $\Lambda_i(D^{\mathrm{t}})(\tilde{g})$, $\tilde{g} \in P^0$, are the coefficients of the $\chi_D(\gamma)$, $\gamma \in \Gamma^0_\infty$ (every $\tilde{g}$ maps to $\pi_\infty(\tilde{g}) = p_1(\gamma)$ for some $\gamma \in \Gamma^0_\infty$, p_1 being onto); the other images are s, $U_{j,i}$, $y_{j,i}$ and the values $\hat{\psi}_{v,i}(g)$. This is the generation clause of (Vr2).

Step 4: (In3). Write $\gamma^* = c'_\infty \gamma^{-1} c'_\infty$ on Γ^0_∞ (a normal subgroup of Γ_∞, as $h^{-1}(\Gamma^0_{\mathscr{H}})$). For $\gamma \in \Gamma^0_\infty$ the pushforward of $y \in (R/I)[\Gamma^0_\infty]$ along p_1 is written $p_{1*}y$; $\mathrm{tr}_D(y) = \mathrm{tr}_{\bar{D}}(p_{1*}y)$, and for $w \in R[P^0]$ with image w_I in $(R/I)[P^0]$, $\mathrm{tr}_{\bar{D}}(\pi_{\infty *} w_I) = \mathrm{tr}_{D^{\mathrm{t}}}(w)_I$. (Lv1). Let $\gamma \in \Gamma^0_\infty$ and $g \in P^0$ with $\pi_\infty(g) = p_1(\gamma)$. As $p_1(c'_\infty) = c_\infty = \pi_\infty(\tilde{c})$ and $c'^2_\infty = 1$, $p_1(\gamma^*) = \pi_\infty(\tilde{c} g^{-1} \tilde{c}^{-1})$, and $\tilde{c} g^{-1} \tilde{c}^{-1} \in P^0$ (P^0 is normal in Π, as $\bar{\Gamma}^0$ is normal in $\bar{\Gamma}$). By Step 1 and (Wv2), $\Lambda_i(D)(\gamma^*) = \Lambda_i(D^{\mathrm{t}})(\tilde{c} g^{-1} \tilde{c}^{-1})_I = \Lambda_i(D^{\mathrm{t}})(g)_I = \Lambda_i(D)(\gamma)$ for all i; so $\chi_D(\gamma^*) = \chi_D(\gamma)$. (Lv2) for the listed elements themselves. Let $\gamma \in \Gamma^0_\infty$ and $h_0 \in P^0$ with $\pi_\infty(h_0) = p_1(\gamma)$.

- Ordinary products, $v \in S_\ell$, $g_1, \ldots, g_n \in D_v$: $p_1(\phi_{\infty,v}(g_a)) = F_v(g_a)$; choose $g'_a \in P^0$ with $\pi_\infty(g'_a) = F_v(g_a)$ ($F_v(g_a) \in \bar{\Gamma}^0_\infty$ by (L2), as $D_v \subseteq G_L$). Then $p_{1*}(\gamma \prod_a (\phi_{\infty,v}(g_a) - \hat{\psi}_{v,a}(g_a))) = \pi_{\infty *}(h_0 \prod_a (g'_a - \psi^{\mathrm{t}}_{v,a}(g_a)))_I$, whose trace is the image of a relation (Wv3), hence 0.

- Inertia, $u \in \mathrm{St}$, $\gamma' = (F_u(y), \pi_{\mathscr{H}}(y)) \in I_{\infty,u}$ with $y \in I_{\bar{u}} \cap G_L$, $\pi_{\mathscr{H}}(y) \in I^x_u$. Then $y \in D_u$, and $\bar{\chi}_a(y) = 1$ for all a: ρ is trivial on I^x_u (frame), so $\det(X - \rho(\pi_{\mathscr{H}} y)) = (X-1)^n$, whose reduction modulo T is $\prod_a (X - \bar{\chi}_a(y))$ (the reduction of $f_x \circ D^{\mathrm{u}}$ is $\bar{D}_n$). With $g' \in P^0$, $\pi_\infty(g') = F_u(y)$, the trace of $\gamma(\gamma' - 1)$ is the image of the relation (Wv4) for h_0, g, g' with $g = y$, hence 0.

- Taylor–Wiles elements: $p_1(\phi_j) = \Phi_j$ and $p_1(\tau_j) = \mathrm{T}_j$ lie in $\bar{\Gamma}^0_\infty$ by (L2); with $\phi, \tau \in P^0$ lifting them, the traces of $\gamma \prod_k (\phi_j - U_{j,k})$ and $\gamma \prod_{k \neq i} (\phi_j - U_{j,k})(\tau_j - 1 - y_{j,i})$ are the images of the relations (Wv5) and (Wv6) (q_1, q_2 of Definition E.36 are these products), hence 0.

(Lv2) for the images under *. By (Lv1), (Q2) of Lemma E.70 applies to $(R/I, \Gamma^0_\infty, D)$ with $\mathcal{S} = \varnothing$, $\eta = 1$ and $B' = R/I$, and with (Q1) gives $\mathrm{tr}_D(y^*) = \mathrm{tr}_D(y)$ and $(yy')^* = y'^* y^*$, $y^{**} = y$ for $y, y' \in (R/I)[\Gamma^0_\infty]$. Also $\mathrm{tr}_D(gy) = \mathrm{tr}_D(yg)$ for $g \in \Gamma^0_\infty$: by multiplicativity $D(g^{-1}y'g) = D(y')$ for every y' after any base change, so $\chi_D(g^{-1}(gy)g) = \chi_D(gy)$. For a listed z and $\gamma \in \Gamma^0_\infty$: $\mathrm{tr}_D(\gamma z^*) = \mathrm{tr}_D((\gamma z^*)^*) = \mathrm{tr}_D(z\gamma^*) = \mathrm{tr}_D(\gamma^* z) = 0$ by the case already proved. □

Definition E.135. Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $J \subseteq B$ an ideal, $(\mathbf{w}, M)$ a Taylor–Wiles base for J with weight variables $\mathbf{w} = (v_k, a_k, \gamma_k, c_k)_k$, $\mathcal{D}$ a Taylor–Wiles datum of size q for $\mathscr{H}$, $N \geq 1$ and $e \geq 1$. Put $D = n[L^+ : \mathbb{Q}]$. For a commutative ring R write $R[U] = R[U_{j,i}]$ and $R[U, Y] = R[U_{j,i}, Y_{j,i}]$ ($1 \leq j \leq q$, $1 \leq i \leq n$), $f = f_{(q_{N,j})_j}(U) \in R[U]$, and let $\mathrm{Sp}^{\mathrm{pol}}_N = B[U]/I_N$, where I_N is the ideal generated by the coefficients of $\prod_{i=1}^n (X - U_{j,i}) - \chi_{D^{\mathrm{u}}}(h_N(\Phi_{N,j}))(X)$, $1 \leq j \leq q$.

An **operator module at level** N (for J, the base and the datum) consists of $R \in \mathrm{CNL}_{\mathcal{O}}$ with a polarised ordinary determinant $(D_R, (\psi_{R,v,a}))$ of rank n on Γ^0_N to R; R-modules M_1, M_{w}; homomorphisms of R-algebras $\mathrm{act}_1 \colon R[U, Y] \to \mathrm{End}_R(M_1)$ and $\mathrm{act}_{\mathrm{w}} \colon R[U] \to \mathrm{End}_R(M_{\mathrm{w}})$; integers $a_j \geq N$; a homomorphism of $\mathcal{O}$-algebras $\beta \colon R \to B$; and an R-linear map $\mathrm{tr} \colon M_1 \to M_{\mathrm{w}}$, such that, with Λ_D acting on R through $X_k \mapsto c_k \psi_{R,v_k,a_k}(\gamma_k) - 1$ and $\Delta_a = \prod_{j,i} \mathbb{Z}/\ell^{a_j}$:

(Op1) $\beta \circ D_R$ is the base change of $D^{\mathrm{u}} \circ h_N$ and $\beta \circ \psi_{R,v,a} = \psi^{\mathrm{d}}_{v,a}$;

(Op2) M_1 is finitely generated over Λ_D;

(Op3) there is an action of Δ_a on M_1 by Λ_D-linear maps in which the generator of the factor (j, i) acts as $1 + \mathrm{act}_1(Y_{j,i})$, and M_1 is a projective $\Lambda_D[\Delta_a]$-module;

(Op4) tr is surjective with kernel $\sum_{j,i} \mathrm{act}_1(Y_{j,i}) M_1$, and $\mathrm{tr} \circ \mathrm{act}_1(U_{j,i}) = \mathrm{act}_{\mathrm{w}}(U_{j,i}) \circ \mathrm{tr}$.

It **satisfies the relations with exponent** e if moreover:

(Op5) there are additive maps $\varphi \colon \mathrm{Sp}^{\mathrm{pol}}_N \otimes_B M \to M_{\mathrm{w}}$ and $\psi \colon M_{\mathrm{w}} \to \mathrm{Sp}^{\mathrm{pol}}_N \otimes_B M$ with $\varphi(\beta(t)z) = \mathrm{act}_{\mathrm{w}}(t)\varphi(z)$ and $\psi(\mathrm{act}_{\mathrm{w}}(t)x) = \beta(t)\psi(x)$ for $t \in R[U]$ ($\beta(t)$ the image in $\mathrm{Sp}^{\mathrm{pol}}_N$ of t with β applied to its coefficients), $\varphi\psi = \mathrm{act}_{\mathrm{w}}(f)$ and $\psi\varphi = \beta(f)$;

(Op6) for all j and $g \in \Gamma^0_N$: $\mathrm{act}_1\big((f \cdot \mathrm{tr}_{D_R}(g\, q_1(\Phi_{N,j}, U_j)))^e\big) = 0$, the trace of D_R base-changed to $R[U, Y]$;

(Op7) for all j, i and $g \in \Gamma^0_N$: $\mathrm{act}_1\big((f \cdot \mathrm{tr}_{D_R}(g\, q_2(\Phi_{N,j}, \mathrm{T}_{N,j}, U_j, i, Y_{j,i})))^e\big) = 0$.

Here $U_j = (U_{j,1}, \ldots, U_{j,n})$.

Proposition E.136. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B^{\mathrm{po}}_n, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, and $J \subseteq B^{\mathrm{po}}_n$ an ideal with classical levels. Then for every Taylor–Wiles datum $\mathcal{D}$ for $\mathscr{H}$ there are automorphic patching data for J along $\mathcal{D}$, with exponent $e = n!$.*

Proof. Let $\mathcal{D}$ be a Taylor–Wiles datum of size q for $\mathscr{H}$, with $\sigma_1, \ldots, \sigma_q$. As J has classical levels, there is a Taylor–Wiles base $(\mathbf{w}, M)$ for J, with weight map λ_B, as in the definition of

classical levels (Definition 53.9). The values $\bar{\chi}_i(\sigma_j)$ lie in the residue field $\mathbb{F}_{\mathcal{O}}$, and $\mathcal{O} \to \mathbb{F}_{\mathcal{O}}$ is surjective, so there are $\tilde{u}_{j,i} \in \mathcal{O}$ with $\tilde{u}_{j,i} \equiv \bar{\chi}_i(\sigma_j)$ modulo $\mathfrak{m}_{\mathcal{O}}$. Put $e = n!$. For every $N \geq 1$, Proposition E.137 gives an operator module at level N (for J, $(\mathbf{w}, M)$ and $\mathcal{D}$) satisfying the relations with exponent $n!$, and Proposition E.142 turns it into R_N, $(D_N, (\psi_{N,v,a}))$, s_N, $(U_{N,j,i})$, M_N, $(a_{N,j})$, rk_N, θ_N, φ_N, ψ_N satisfying (Ha1)–(Ha5) at N for these $\tilde{u}$ and e. Together with $(\mathbf{w}, M)$, $\tilde{u}$ and e these are automorphic patching data for J along $\mathcal{D}$ with exponent $n!$ (Definition E.36). □

Proposition E.137. *Let $\mathscr{H}$ be a rank-n Hecke datum over a coefficient ring $\mathcal{O}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$ a universal polarised ordinary determinant of rank n over $\mathscr{H}$, $J \subseteq B$ an ideal with classical levels, and $(\mathbf{w}, M)$ a Taylor–Wiles base for J as in the definition of classical levels. Then for every Taylor–Wiles datum $\mathcal{D}$ for $\mathscr{H}$ and every $N \geq 1$ there is an operator module at level N (for J, $(\mathbf{w}, M)$ and $\mathcal{D}$) which satisfies the relations with exponent $n!$.*

Proof. Fix the datum $\mathcal{D}$ of size q and $N \geq 1$; write $Q = Q_N$, $w_j = w_{N,j}$, $K_j = L_{w_j}$ with residue field k_j of order $q_j = q_{N,j}$, $G_j = \mathrm{GL}_n(K_j)$, $\Phi_j = \Phi_{N,j}$, $\mathrm{T}_j = \mathrm{T}_{N,j}$. By (Tg2) the places of Q satisfy the conditions of the level groups in Definition 53.9, so, since $(\mathbf{w}, M)$ is a Taylor–Wiles base for J as in the definition of classical levels, there is a classical level module $(R, D_R, (\psi_{R,v,a}), \beta, P, \rho)$ at Q (with the places $\bar{w}_{N,j}$), and an isomorphism ι for which the level points separate P (Hl4). The operator module is built from it.

Local choices. Identify G_{K_j} with the decomposition group $D_{\bar{w}_{N,j}} \cap G_L$. By (Tg2) $\phi_{N,j}$ is a lift of geometric Frobenius, so (as recalled in Lemma E.140) there is a unique uniformiser ϖ_j of K_j with $\mathrm{Art}_{K_j}(\varpi_j) = \phi_{N,j}|_{K_j^{\mathrm{ab}}}$; $\tau_{N,j}$ lies in inertia and its image generates the maximal pro-ℓ quotient of inertia, and $\delta_j \in \mathcal{O}_{K_j}^{\times}$ is the element with $\mathrm{Art}_{K_j}(\delta_j) = \tau_{N,j}|_{K_j^{\mathrm{ab}}}$; its residue generates $k_j^{\times}$ together with the subgroup $C_{0,j}$ of elements of order prime to ℓ. Each q_j is prime to ℓ ($w_j \nmid \ell$), hence a unit of $\mathcal{O}$ and of R.

The modules and operators ((Op1)–(Op4)). Take R, $(D_R, (\psi_{R,v,a}))$ and β from the level module: (Op1) is the condition $\beta \circ D_R = D^{\mathrm{u}} \circ h^Q$, $h^Q = h_N$, $\beta \circ \psi_{R,v,a} = \psi^{\mathrm{d}}_{v,a}$ of Definition 53.9. Put $M_1 = P^{\mathrm{Iw}_{1,Q}}$ and $M_{\mathrm{w}} = P^{\mathrm{Iw}_Q}$; (Op2) is part of (Hl2). For each j apply (Si1) of Lemma E.138 with $\Lambda = R$ to the $R[G_j]$-module $P^{(j)} = P^{\prod_{j' \neq j} \mathrm{Iw}_{1,j'}}$ (on which G_j acts, as G_j commutes with $G_{j'}$), for $C = C_{0,j}$ and for $C = k_j^{\times}$: this gives $\theta_{1,j}$ on $(P^{(j)})^{\mathrm{Iw}(C_{0,j})} = M_1$ and, by restriction (last clause of (Si1)), $\theta_{\mathrm{w},j}$ on M_{w}. The $\theta_{1,j}(t)$, $\theta_{1,j'}(t')$ commute: for $j = j'$ by (Si1); for $j \neq j'$ because the action of $G_{j'}$ commutes with the double coset operators at j, hence with their inverses. Define $\mathrm{act}_1(U_{j,i}) = q_j^{i-1}\theta_{1,j}(e_i(\varpi_j))$, $\mathrm{act}_1(Y_{j,i}) = \theta_{1,j}(e_i(\delta_j)) - 1$ and $\mathrm{act}_{\mathrm{w}}(U_{j,i}) = q_j^{i-1}\theta_{\mathrm{w},j}(e_i(\varpi_j))$; these are commuting R-linear maps, so act_1, $\mathrm{act}_{\mathrm{w}}$ are homomorphisms of R-algebras. Let $a_j = v_\ell(q_j - 1)$; by (Tg2) $q_j \equiv 1 \bmod \ell^N$, so $a_j \geq N$. As $k_j^{\times}$ is cyclic of order $q_j - 1$, $k_j^{\times}(\ell)$ is cyclic of order ℓ^{a_j} and is generated by the image of the residue of δ_j; hence $\Delta_Q \cong \prod_j (k_j^{\times}(\ell))^n \cong \Delta_a$, the generator of the factor (j,i) corresponding to the class of $\mathrm{diag}(e_i(\delta_j)) \in \mathrm{Iw}_Q$ at j. By (Si1) this class acts on M_1 as $\theta_{1,j}(e_i(\delta_j)) = 1 + \mathrm{act}_1(Y_{j,i})$; the action is R-linear, hence Λ_D-linear, and M_1 is a projective $\Lambda_D[\Delta_a]$-module by (Hl2): (Op3). Let $\mathrm{tr}\colon M_1 \to M_{\mathrm{w}}$, $\mathrm{tr}(m) = \sum_{\gamma \in \Delta_Q} \gamma m$, the norm, with values in $M_1^{\Delta_Q} = M_{\mathrm{w}}$. For a free $\Lambda_D[\Delta_a]$-module the norm is surjective onto the invariants with kernel the augmentation ideal times the module (for $\Lambda_D[\Delta_a]$ itself: invariants $\Lambda_D \cdot \sum_\gamma \gamma$, kernel of multiplication by $\sum_\gamma \gamma$ the augmentation ideal); both properties pass to direct summands, so to the projective module M_1. The augmentation ideal is generated by the $\gamma - 1$ for the generators γ of Δ_a, so $\ker \mathrm{tr} = \sum_{j,i} \mathrm{act}_1(Y_{j,i}) M_1$. Finally, $\theta_{1,j}(t)$ commutes with the action of the diagonal units (commutative image in (Si1)), which represent Δ_Q, and restricts to $\theta_{\mathrm{w},j}(t)$ on M_{w}; so $\mathrm{tr}(\mathrm{act}_1(U_{j,i})m) = \mathrm{act}_1(U_{j,i})\mathrm{tr}(m) = \mathrm{act}_{\mathrm{w}}(U_{j,i})\mathrm{tr}(m)$: (Op4).

Transport to level points. Let $(\theta, r, Y, \pi, \mathrm{sp}, (\sigma_j))$ be a level point for ι and $c = \iota \circ \theta\colon R \to \mathbb{C}$.

Since sp is additive, c-semilinear and G_Q-equivariant, it maps P^H into Y^H for every subgroup H and commutes with every double coset operator; applying (Si1) with $\Lambda = \mathbb{C}$ to the $\mathbb{C}[G_j]$-module Y (for $C = C_{0,j}$, $k_j^\times$), and writing $\theta(t) = [t_1][t_2]^{-1}$ with t_1, t_2 dominant, sp intertwines $\theta_{1,j}(t)$, $\theta_{\mathrm{w},j}(t)$ with the corresponding operators $\theta^Y_{1,j}(t)$, $\theta^Y_{\mathrm{w},j}(t)$. Hence for $H \in R[U,Y]$ and $m \in M_1$: $\mathrm{sp}(\mathrm{act}_1(H)m) = H^c(U^Y, Y^Y)\,\mathrm{sp}(m)$, where H^c has c applied to its coefficients and $U^Y_{j,i}$, $Y^Y_{j,i}$ are the analogous operators on Y; likewise for act_w. Let $r_j = r \circ \pi^Q|_{G_{K_j}}$; the level point condition at j is the hypothesis of Lemma E.140 and of Lemma E.139 on (σ_j, r_j), with $\Phi = \phi_{N,j}$, $\tau = \tau_{N,j}$, $\varpi = \varpi_j$, $\delta = \delta_j$. Since $\theta \circ D_R = \det \circ r$, $c(\chi_{D_R}(x))$ is the characteristic polynomial of $\imath r(x)$ and $c(\mathrm{tr}_{D_R}(x)) = \mathrm{tr}(\imath r(x))$ for x in the group algebra, also after base change to $R[U,Y]$ (the trace is linear). Finally, for $y \in Y^{H_j}$ with $H_j \subseteq G_j$ compact open, y is a finite sum $\sum_s h_s(x_s)$ with G_j-maps $h_s\colon \sigma_j \to Y$ (the images span Y), and averaging over H_j (each x_s is fixed by an open subgroup) gives $y = \sum_s h_s(x'_s)$ with $x'_s \in \sigma_j^{H_j}$; the h_s commute with the operators at j.

(Op6), (Op7) with exponent $n!$. Let $g \in \Gamma^0_N$, $f = f_{(q_j)_j}(U)$, and $\Xi = \mathrm{tr}_{D_R}(g\, q_1(\Phi_j, U_j))$ or $\mathrm{tr}_{D_R}(g\, q_2(\Phi_j, \mathrm{T}_j, U_j, i, Y_{j,i}))$. Write $f = f_j \cdot f'$ with $f_j = \prod_i \prod_{i' \neq i}(U_{j,i} - U_{j,i'})(U_{j,i} - q_j U_{j,i'})$; then $(f\Xi)^{n!} = f'^{n!}(f_j\Xi)^{n!}$ in the commutative ring $R[U,Y]$. For $m \in M_1$ and a level point, $y = \mathrm{sp}(m) \in Y^{\mathrm{Iw}(C_{0,j})}$, and the operator $((f_j\Xi)^{n!})^c$ (in the $U^Y_{j,\bullet}$, $Y^Y_{j,\bullet}$) acting on y is, on each $h_s(x'_s)$ ($x'_s \in \sigma_j^{\mathrm{Iw}(C_{0,j})}$), h_s of the operator $(f\,\Xi_1(A))^{n!}$, resp. $(f\,\Xi_{2,i}(A))^{n!}$, of Lemma E.139 for σ_j, r_j and $A = \imath r(g)$ (by the previous paragraph, c turns Ξ into $\mathrm{tr}(\imath r(g)\prod_k(\imath r_j(\phi_{N,j}) - U^Y_{j,k}))$, resp. the corresponding $\Xi_{2,i}$, as $\imath r(\Phi_j) = \imath r_j(\phi_{N,j})$, $\imath r(\mathrm{T}_j) = \imath r_j(\tau_{N,j})$); by (Ln1) it is 0. So $\mathrm{sp}(\mathrm{act}_1((f\Xi)^{n!})m) = (f'^{n!})^c\,((f_j\Xi)^{n!})^c\,\mathrm{sp}(m) = 0$ for every level point, and $\mathrm{act}_1((f\Xi)^{n!})m = 0$ by (Hl4).

(Op5). Apply Lemma E.141 with $h = q$, the K_j, $\Lambda = R$, $V = P$, B, β, the base module M, $\iota_M = e^{-1}\colon M \to P^{K_Q}$ for the bijection e of (Hl3) (so $\iota_M(\beta(t)m) = t\iota_M(m)$), $P_j = \chi_{D^\mathrm{u}}(h_N(\Phi_j))$ (monic of degree n), $g \in \mathbb{Z}[U]$ with $f_{(q_j)} = g\prod_j N_{q_j}(U_{j,\bullet})$ (each factor $U_{j,i'} - q_j U_{j,i}$, $i < i'$, of N_{q_j} is one of the factors of $f_{(q_j)}$). Its hypotheses hold: the q_j are units of R; multiplication by a non-zero integer k is injective on P, since $k\,m = 0$ gives $k\,\mathrm{sp}(m) = 0$ in the complex space Y for every level point, so $m = 0$ by (Hl4); its operators $U_{j,i}$ on P^{Iw_Q} are the $\mathrm{act}_\mathrm{w}(U_{j,i})$; $\mathrm{Sp} = \mathrm{Sp}^{\mathrm{pol}}_N$; and the symmetric-function hypothesis holds: for $v \in P^{K_Q}$ and a level point, $\mathrm{sp}(v) \in Y^{\mathrm{GL}_n(\mathcal{O}_{K_j})}$ is a sum of $h_s(x'_s)$ with x'_s spherical in σ_j, and by (Ln2) of Lemma E.139 $e_k(U^Y_{j,\bullet})$ acts on it by $(-1)^k$ times the coefficient of X^{n-k} in $\det(X - \imath r_j(\phi_{N,j})) = c(\chi_{D_R}(\Phi_j))$; by separation, $e_k(\mathrm{act}_\mathrm{w}(U_{j,\bullet}))v = (-1)^k\chi_{D_R}(\Phi_j)_{n-k}\,v$, and applying e, as $\beta(\chi_{D_R}(\Phi_j)) = \chi_{D^\mathrm{u}}(h_N(\Phi_j))$ by (Op1), $e_k(U_{j,\bullet})\iota_M(m) = \iota_M((-1)^k c_{j,n-k}m)$ with $P_j = \sum_r c_{j,r}X^r$. The maps φ, ψ of Lemma E.141 (with $u = \mathrm{act}_\mathrm{w}$, $\bar\beta(t)$ the image of t with β applied to its coefficients) are those of (Op5) for $f = f_{(q_{N,j})_j}$.

Thus $(R, \ldots, \mathrm{tr})$ is an operator module at level N satisfying the relations with exponent $n!$. □

Lemma E.138. *Let K be a finite extension of $\mathbb{Q}_p$ with ring of integers $\mathcal{O}_K$, uniformiser ϖ and residue field k of order q; let $G = \mathrm{GL}_n(K)$, $K_0 = \mathrm{GL}_n(\mathcal{O}_K)$, and for a subgroup $C \subseteq k^\times$ let $\mathrm{Iw}(C) \subseteq K_0$ be the group of matrices that are upper triangular modulo ϖ with diagonal entries modulo ϖ in C; $\mathrm{Iw} = \mathrm{Iw}(k^\times)$. Identify $T = (K^\times)^n$ with the diagonal matrices, call $t \in T$ dominant if $v(t_1) \geq \cdots \geq v(t_n)$, and let $e_i(x) \in T$ have x in place i and 1 elsewhere. Let Λ be a commutative ring and V a Λ-module with a Λ-linear action of G. Assume $q \in \Lambda^\times$. For dominant t let $[t]_C$ be the endomorphism $v \mapsto \sum_{g \in \mathrm{Iw}(C)t\mathrm{Iw}(C)/\mathrm{Iw}(C)} gv$ of $V^{\mathrm{Iw}(C)}$, and let $E\colon V^{\mathrm{Iw}} \to V^{\mathrm{Iw}}$, $Ev = \sum_{g \in K_0/\mathrm{Iw}} gv$.*

(Si1) *For every C there is a unique homomorphism θ_C from T to the group of Λ-linear automorphisms of $V^{\mathrm{Iw}(C)}$ with $\theta_C(t) = [t]_C$ for every dominant t. Its image is commutative; $\theta_C(t)$ is the action of t for $t \in (\mathcal{O}_K^\times)^n$; and for $C \subseteq C'$ the restriction of $\theta_C(t)$ to $V^{\mathrm{Iw}(C')}$*

is $\theta_{C'}(t)$.

Let $U_i = q^{i-1}\theta_{k^\times}(e_i(\varpi))$ $(1 \le i \le n)$, *let* $u\colon \Lambda[X_1,\dots,X_n] \to \mathrm{End}_\Lambda(V^{\mathrm{Iw}})$ *be the homomorphism with* $u(X_i) = U_i$, *and in* $\Lambda[X_1,\dots,X_n]$ *put*

$$\Delta = \prod_{i<j}(X_j - X_i), \qquad N_q = \prod_{i<j}(X_j - qX_i), \qquad \mathrm{dd}(x) = \Delta^{-1}\sum_{w\in S_n}\mathrm{sgn}(w)\,w(x),$$

S_n *permuting the variables* ($\sum_w \mathrm{sgn}(w)w(x)$ *is divisible by* Δ, *and* $\mathrm{dd}(x)$ *is symmetric).*

(Si2) $E \circ u(z) = u(z) \circ E$ *for every symmetric* $z \in \Lambda[X_1,\dots,X_n]$.

(Si3) *There are* $m \ge 1$ *and* $a_1,\dots,a_m, c_1,\dots,c_m \in \mathbb{Z}[X_1,\dots,X_n]$ *with* $\sum_{k=1}^m a_k\, w(c_k) = \Delta$ *for* $w = 1$ *and* $= 0$ *for* $w \in S_n \setminus \{1\}$; *and for any such families* $\sum_{k=1}^m u(a_k)\circ E \circ u(c_k) = u(N_q)$.

(Si4) *If multiplication by the integer* $[K_0 : \mathrm{Iw}]$ *is injective on* V, *then* $u(z)V^{K_0} \subseteq V^{K_0}$ *for every symmetric* z, *and* $E(u(y)v) = u(\mathrm{dd}(N_q y))v$ *for every* $y \in \Lambda[X_1,\dots,X_n]$ *and* $v \in V^{K_0}$.

Proof. **Step 1 (dominant double cosets).** Let $t \in T^+$. Gaussian elimination (all pivots are units) gives $\mathrm{Iw}(C) = N^+ T_C N_1^-$. For $n^- \in N_1^-$ the entry (i,j), $i > j$, of $t^{-1}n^-t$ is that of n^- times $t_i^{-1}t_j$, of valuation $\ge v(t_j) - v(t_i) \ge 0$, so $t^{-1}N_1^- t \subseteq N_1^-$; and $T_C t = tT_C$. Hence $\mathrm{Iw}(C)t\mathrm{Iw}(C) = N^+ t\,\mathrm{Iw}(C)$. Likewise $tN^+t^{-1} \subseteq N^+$. For $x, x' \in N^+$, $xt\mathrm{Iw}(C) = x't\mathrm{Iw}(C)$ iff $t^{-1}x^{-1}x't \in \mathrm{Iw}(C)$, i.e. (this matrix being upper unitriangular, and $\mathrm{Iw}(C)$ meeting the upper unitriangular group of G in N^+) iff $x^{-1}x' \in tN^+t^{-1}$. Therefore, for $v \in V^{\mathrm{Iw}(C)}$,

$$(1) \qquad [t]_C v = \sum_{x \in N^+/tN^+t^{-1}} x\,t\,v,$$

each summand depending only on the coset of x (as $tN^+t^{-1}tv = tN^+v = tv$). The right side of (1) does not involve C, and $|N^+/tN^+t^{-1}| = q^{\sum_{i<j}(v(t_i)-v(t_j))}$.

Step 2 (products). Let $t, t' \in T^+$. Then $N^+ \supseteq tN^+t^{-1} \supseteq tt'N^+(tt')^{-1}$, and $(x,x') \mapsto x \cdot tx't^{-1}$ induces a bijection $N^+/tN^+t^{-1} \times N^+/t'N^+t'^{-1} \to N^+/tt'N^+(tt')^{-1}$ (representatives of a subgroup chain; conjugation by t maps $N^+/t'N^+t'^{-1}$ onto $tN^+t^{-1}/tt'N^+(tt')^{-1}$). By (1), $[t]_C[t']_C v = \sum_{x,x'} x\,(tx't^{-1})\,tt'v = [tt']_C v$. So $t \mapsto [t]_C$ is a homomorphism of monoids $T^+ \to \mathrm{End}_\Lambda(V^{\mathrm{Iw}(C)})$ with commuting values. For $\tau \in T(\mathcal{O}_K) \subseteq T^+$ the index in (1) is 1 and $[\tau]_C v = \tau v$; for the scalar matrix $\varpi^r 1_n$ ($r \in \mathbb{Z}$, dominant) likewise $[\varpi^r 1_n]_C v = \varpi^r v$. Both are invertible.

Step 3 (quadratic relation on V^{Iw_1}). Fix $1 \le a < n$, let s be the permutation matrix of $s_a = (a\ a{+}1)$, $u_y = 1 + yE_{a,a+1}$ ($y \in \mathcal{O}_K$), and for $y \in \mathcal{O}_K^\times$ let $d_y \in T(\mathcal{O}_K)$ have entries $-y^{-1}, y$ in places $a, a+1$ and 1 elsewhere. Let $[s]$ be the endomorphism $v \mapsto \sum_{g \in \mathrm{Iw}_1 s \mathrm{Iw}_1/\mathrm{Iw}_1} gv$ of V^{Iw_1}. Since $s^{-1}N_1^- s \subseteq 1 + \varpi M_n(\mathcal{O}_K) \subseteq \mathrm{Iw}_1$, $s^{-1}T_{\{1\}}s = T_{\{1\}}$, and $N^+ = \{u_y\} \cdot N'$ with $N' = \{x \in N^+ : x_{a,a+1} = 0\}$ (the kernel of the homomorphism $x \mapsto x_{a,a+1}$) and $s^{-1}N's \subseteq N^+$, we get $\mathrm{Iw}_1 s \mathrm{Iw}_1 = \bigsqcup_{y \in R_k} u_y s \mathrm{Iw}_1$ (and $u_y s\mathrm{Iw}_1 = u_{y'}s\mathrm{Iw}_1$ iff $s^{-1}u_{y'-y}s = 1 + (y'-y)E_{a+1,a} \in \mathrm{Iw}_1$ iff $y \equiv y'$). Thus $[s]v = \sum_{y\in R_k} u_y s v$, and $u_z s v$ depends only on z modulo ϖ. Now

$$[s]^2 v = \sum_{y,y' \in R_k} u_y s u_{y'} s v.$$

For $y' = 0$, $s^2 = 1$ and the terms sum to $\sum_y u_y v = qv$. For $y' \ne 0$, in the block $(a, a+1)$, $s u_{y'} s = u_{y'^{-1}} d_{y'} s u_{y'^{-1}}$, and $u_{y'^{-1}} \in \mathrm{Iw}_1$ fixes v, so $u_y s u_{y'} s v = u_{y + y'^{-1}} d_{y'} s v$.

As y runs over R_k, $y+y'^{-1}$ runs over representatives of k; and $u_z d_{y'} = d_{y'} u_{-y'^2 z}$, $-y'^2 z$ again running over representatives. Hence $\sum_y u_y s u_{y'} s v = d_{y'}[s]v$, and

$$[s]^2 = q + c\,[s], \qquad c = \sum_{y \in R_k \setminus \{0\}} d_y$$

as endomorphisms of V^{Iw_1} ($T(\mathcal{O}_K)$ normalises Iw_1, and d_y acts on V^{Iw_1} through y modulo ϖ, as $T_{\{1\}} \subseteq \mathrm{Iw}_1$). Further $s d_y s^{-1} = d_{-y^{-1}}$, so by the same reindexing $[s] d_y v = d_{-y^{-1}}[s]v$; as $y \mapsto -y^{-1}$ permutes $k^\times$, $[s]c = c[s]$. Therefore $([s]-c)[s] = [s]([s]-c) = q$, and $[s]$ is invertible with inverse $q^{-1}([s]-c)$, q being a unit of Λ.

Step 4 (invertibility of $[t]_C$). The ring $\mathcal{H}^{(1)}$ of Theorem B.168 acts on V^{Iw_1} by $h \cdot v = \sum_{g \in G/\mathrm{Iw}_1} h(g)\, gv$. The action is through a ring homomorphism, by the convolution formula

$$(h * h')(g) = \sum_{g' \in G/\mathrm{Iw}_1} h(g') h'(g'^{-1} g),$$

and T_g acts by $v \mapsto \sum_{g' \in \mathrm{Iw}_1 g \mathrm{Iw}_1/\mathrm{Iw}_1} g' v$; so T_s acts as $[s]$ and T_t as $[t]_{\{1\}}$ for $t \in T^+$. Let $1 \le m < n$, $\alpha_m = \mathrm{diag}(\varpi 1_m, 1_{n-m})$, $\Pi = \begin{pmatrix} 0 & 1_{n-1} \\ \varpi & 0 \end{pmatrix}$ and $w_m = \begin{pmatrix} 0 & 1_m \\ 1_{n-m} & 0 \end{pmatrix}$, the permutation matrix of the permutation $j \mapsto j+m$ ($j \le n-m$), $j \mapsto j-n+m$ ($j > n-m$), which has $m(n-m)$ inversions. Then $\alpha_m = w_m \Pi^m$, and Π normalises Iw and every $\mathrm{Iw}(C)$.

Lengths in the sense of Theorem B.168: $\ell(\alpha_m) = m(n-m)$ by Step 1 (for $C = k^\times$); $\ell(\Pi^m) = 0$; and $\ell(w)$ is the number of inversions for a permutation matrix w, since Iw is the inverse image of the upper triangular group $B(k)$ under reduction $K_0 \to \mathrm{GL}_n(k)$, so that $\mathrm{Iw} w \mathrm{Iw}/\mathrm{Iw} \cong B(k) w B(k)/B(k)$, of order $q^{\#\mathrm{inversions}(w)}$ (Bruhat decomposition of $\mathrm{GL}_n(k)$). Choose a reduced word $w_m = s_{a_1} \cdots s_{a_r}$, $r = m(n-m)$. Applying Theorem B.168 repeatedly (the lengths add at each step), $T_{\alpha_m} = T_{s_{a_1}} \cdots T_{s_{a_r}} T_{\Pi^m}$, so on V^{Iw_1}

$$[\alpha_m]_{\{1\}} = [s_{a_1}] \cdots [s_{a_r}] \circ (v \mapsto \Pi^m v),$$

a composite of automorphisms (Step 3). Every $t \in T^+$ is $t = \tau \cdot \varpi^{\lambda_n} 1_n \cdot \prod_{m<n} \alpha_m^{\lambda_m - \lambda_{m+1}}$ with $\tau \in T(\mathcal{O}_K)$, $\lambda_i = v(t_i)$, all factors in T^+; by Step 2, $[t]_{\{1\}}$ is invertible. Now $\mathrm{Iw}(C) = \mathrm{Iw}_1 T_C$ (divide $g \in \mathrm{Iw}(C)$ by its diagonal), so $V^{\mathrm{Iw}(C)}$ is the set of T_C-fixed vectors of V^{Iw_1}, and $[t]_C$ is the restriction of $[t]_{\{1\}}$ by (1). By Step 2, $[t]_{\{1\}}$ commutes with the action of $T(\mathcal{O}_K) = \{[\tau]_{\{1\}}\}$, hence so does its inverse, which therefore maps $V^{\mathrm{Iw}(C)}$ into itself. So $[t]_C$ is an automorphism of $V^{\mathrm{Iw}(C)}$, and for $C \subseteq C'$ the inverse of $[t]_C$ restricts to that of $[t]_{C'}$.

Step 5 (proof of (Si1)). Every $t \in T$ is $t_1 t_2^{-1}$ with $t_1, t_2 \in T^+$ (take $t_2 = \mathrm{diag}(\varpi^{M(n-1)}, \varpi^{M(n-2)}, \ldots, 1)$ with $M \ge \max_i |v(t_{i+1}) - v(t_i)|$ and $t_1 = t t_2$). Put $\theta_C(t_1 t_2^{-1}) = [t_1]_C [t_2]_C^{-1}$. This is well defined: $t_1 t_2^{-1} = t_1' t_2'^{-1}$ gives $t_1 t_2' = t_1' t_2$, so $[t_1]_C [t_2']_C = [t_1']_C [t_2]_C$ (Step 2), and the operators commute. It is a homomorphism with commutative image extending $t \mapsto [t]_C$ on T^+, and it is the only one, since any such homomorphism takes these values on $t_1 t_2^{-1}$. On $T(\mathcal{O}_K)$ it is the action (Step 2). For $C \subseteq C'$, $V^{\mathrm{Iw}(C')} \subseteq V^{\mathrm{Iw}(C)}$ and $[t_i]_C$ and $[t_i]_C^{-1}$ restrict to $[t_i]_{C'}$ and $[t_i]_{C'}^{-1}$ (Steps 1, 4), so $\theta_C(t)$ restricts to $\theta_{C'}(t)$.

Step 6 (the integral Iwahori–Hecke ring). Let $\mathcal{H}$ be the algebra of Theorem B.167, $R = \mathbb{Z}[1/q] \subseteq \mathbb{C}$, and $\mathcal{H}_R \subseteq \mathcal{H}$ the R-span of the T_g; it is a subring, the structure constants $(T_g * T_{g'})(x) = \#\{y \in \mathrm{Iw} g \mathrm{Iw}/\mathrm{Iw} : y^{-1} x \in \mathrm{Iw} g' \mathrm{Iw}\}$ being integers. As $q \in \Lambda^\times$, Λ is an R-algebra and $\rho_V(h)v = \sum_{x \in G/\mathrm{Iw}} h(x)\, xv$ defines a ring homomorphism $\rho_V \colon \mathcal{H}_R \to \mathrm{End}_\Lambda(V^{\mathrm{Iw}})$, with $\rho_V(T_t) = [t]_{k^\times}$ for $t \in T^+$. By the Bruhat decomposition $\mathrm{GL}_n(k) = \bigsqcup_{w \in S_n} B(k) w B(k)$, $K_0 = \bigsqcup_w \mathrm{Iw} w \mathrm{Iw}$, so $\mathbf{1}_{K_0} = \sum_{w \in S_n} T_w \in \mathcal{H}_R$ and $\rho_V(\mathbf{1}_{K_0}) = E$.

Apply Steps 1–5 to the module $V' = C_c(G/\mathrm{Iw}, R)$ (finitely supported functions on G/Iw, G acting by $(gf)(x) = f(g^{-1}x)$). Then $V'^{\mathrm{Iw}} = \mathcal{H}_R$ and $[t]_{k^\times}$ is left multiplication by T_t.

Its inverse L commutes with right multiplications (as T_t* does), so $y = L(\mathbf{1}_{\mathrm{Iw}})$ satisfies $T_t * y = \mathbf{1}_{\mathrm{Iw}}$ and $y * T_t = L(T_t) = \mathbf{1}_{\mathrm{Iw}}$: $T_t \in \mathcal{H}_R^\times$. As in Step 5 we get a homomorphism $\theta\colon T \to \mathcal{H}_R^\times$, $t_1 t_2^{-1} \mapsto T_{t_1} T_{t_2}^{-1}$, and $\rho_V \circ \theta = \theta_{k^\times}$ by the uniqueness in (Si1). In $\mathcal{H}$, (IH2) gives $\theta(\varpi^\lambda) = q^{\langle\rho,\lambda\rangle}\Theta_\lambda$ for dominant λ, hence for all $\lambda \in \mathbb{Z}^n$ (both sides are homomorphisms in λ). Put $\tilde{X}_i = q^{i-1}\theta(\varpi^{e_i}) \in \mathcal{H}_R$; since $\langle\rho, e_i\rangle = \frac{n+1-2i}{2}$, $\tilde{X}_i = \kappa\,\Theta_{e_i}$ with $\kappa = q^{(n-1)/2}$. The $\tilde{X}_i$ commute, $\rho_V(\tilde{X}_i) = U_i$, and for $y \in \mathbb{Z}[X_1, \dots, X_n]$, $\rho_V(y(\tilde{X})) = u(y)$. Let $A = \mathbb{C}[x_1^{\pm 1}, \dots, x_n^{\pm 1}]$ be the group algebra of $\mathbb{Z}^n$ (x^μ for μ), with S_n acting by $w(x_i) = x_{w(i)}$, as on exponents in (IH3); for a polynomial y put $y^\flat = y(\kappa x_1, \dots, \kappa x_n) \in A$. Then $y(\tilde{X}) = \Theta(y^\flat)$.

Step 7 (the polynomial representation). By (IH1), $T_{s_a}\mathbf{1}_{K_0} = q\mathbf{1}_{K_0}$, hence $T_w\mathbf{1}_{K_0} = q^{\ell(w)}\mathbf{1}_{K_0}$.

So $\iota\colon A \to \mathcal{H}$, $x \mapsto \Theta(x)\mathbf{1}_{K_0} = \sum_{\mu,w} x_\mu \Theta_\mu T_w$, is injective (basis in (IH2)) with image $\mathcal{H}\mathbf{1}_{K_0}$ ($\mathcal{H}$ is spanned by the $\Theta_\mu T_w$). Thus $\mathcal{H}$ acts on A by $h\cdot x = \iota^{-1}(h\iota(x))$: $\Theta(f)$ acts as multiplication by f, $\mathbf{1}_{K_0}\Theta(x)\mathbf{1}_{K_0} = \iota(\mathbf{1}_{K_0} \cdot x)$, and by (IH3) and $T_{s_a}\mathbf{1}_{K_0} = q\mathbf{1}_{K_0}$, T_{s_a} acts as

$$D_a x = q\, s_a(x) + (1-q)\frac{s_a(x) - x}{1 - x_{a+1}x_a^{-1}} = \frac{q-1}{1 - x_{a+1}x_a^{-1}}\, x + \frac{1 - q x_{a+1}x_a^{-1}}{1 - x_{a+1}x_a^{-1}}\, s_a(x)$$

(here $x^{-\alpha^\vee} = x_{a+1}x_a^{-1}$). Let $\mathcal{K}$ be the fraction field of A and $\mathcal{K}[S_n]$ the twisted group ring (elements $\sum_w f_w w$, acting on $\mathcal{K}$ by $x \mapsto \sum_w f_w w(x)$, with $wf = w(f)w$). An element of $\mathcal{K}[S_n]$ vanishing on A vanishes on $\mathcal{K}$ (write an element of $\mathcal{K}$ as x/d with $x \in A$ and d an S_n-invariant element of A, by multiplying a denominator by its conjugates), hence is 0 by Dedekind's independence of the distinct automorphisms w of $\mathcal{K}$. So $D_a = A_a + B_a s_a$ in $\mathcal{K}[S_n]$ with $B_a = (1 - qx_{a+1}x_a^{-1})/(1 - x_{a+1}x_a^{-1}) \neq 0$, and by (IH1) T_w acts as $D_w = D_{a_1} \cdots D_{a_r}$ for a reduced word $w = s_{a_1} \cdots s_{a_r}$. Expanding the product, the group elements that occur are products of subwords, of length $\le r$, and only the full subword has length r; so

$$D_w = \beta_w\, w + \sum_{\ell(v) < \ell(w)} f_{w,v}\, v, \qquad \beta_w = B_{a_1}\, s_{a_1}(B_{a_2}) \cdots (s_{a_1} \cdots s_{a_{r-1}})(B_{a_r}) \neq 0. \tag{2}$$

For the longest element w_0 ($w_0(i) = n+1-i$, the only element of length $n(n-1)/2$) the coroots $s_{a_1} \cdots s_{a_{j-1}}(e_{a_j} - e_{a_j+1})$, $1 \le j \le r$, are the $e_i - e_{i'}$, $i < i'$, each once ([49, Ch. VI, §1.6, Cor. 2]), so $\beta_{w_0} = \prod_{i<i'}(x_i - qx_{i'})/(x_i - x_{i'})$.

Step 8 (faithfulness). If $h \in \mathcal{H}$ acts as 0 on A then $h = 0$. Indeed $h = \sum_w \Theta(f_w)T_w$ by (IH2) and acts as $\sum_w f_w D_w$, which is 0 in $\mathcal{K}[S_n]$ (Step 7). If some $f_w \neq 0$, choose such w of maximal length; by (2) the coefficient of w in $\sum_v f_v D_v$ is $f_w\beta_w \neq 0$, a contradiction.

Step 9 (the symmetriser). $\mathbf{1}_{K_0}$ acts as $\mathcal{S} = \sum_w D_w$, and $T_{s_a}\mathbf{1}_{K_0} = q\mathbf{1}_{K_0}$ gives $D_a\mathcal{S}x = q\mathcal{S}x$ for $x \in A$. For $z \in A$, $D_a z - qz = (s_a(z) - z)\,\frac{1 - qx_{a+1}x_a^{-1}}{1 - x_{a+1}x_a^{-1}}$, so $D_a z = qz$ iff $s_a(z) = z$.

Hence $\mathcal{S}x$ is S_n-invariant for every $x \in A$, i.e. $s_a\mathcal{S} = \mathcal{S}$ in $\mathcal{K}[S_n]$. Writing $\mathcal{S} = \sum_v g_v v$, this reads $g_{s_a v} = s_a(g_v)$, so $g_v = v(g_1)$. By (2) only D_{w_0} contributes to the coefficient of w_0: $g_{w_0} = \beta_{w_0}$, so $g_1 = w_0(\beta_{w_0}) = \prod_{i<i'}(x_{i'} - qx_i)/(x_{i'} - x_i) = N_q/\Delta$ (in the variables x). Thus $\mathcal{S}x = \sum_v v(xN_q/\Delta) = \Delta^{-1}\sum_v \mathrm{sgn}(v)v(N_q x)$, as $v(\Delta) = \mathrm{sgn}(v)\Delta$; for a polynomial x this is $\mathrm{dd}(N_q x)$. Since N_q and Δ are homogeneous of the same degree, $\mathrm{dd}(N_q y^\flat) = (\mathrm{dd}(N_q y))^\flat$. With Step 6 this gives, for every $y \in \mathbb{C}[X_1, \dots, X_n]$ (in particular in $\mathcal{H}_R$ for $y \in \mathbb{Z}[X_1, \dots, X_n]$),

$$\mathbf{1}_{K_0}\, y(\tilde{X})\, \mathbf{1}_{K_0} = (\mathrm{dd}(N_q y))(\tilde{X})\, \mathbf{1}_{K_0}. \tag{3}$$

Step 10 (proof of (Si2)). A symmetric $z \in \Lambda[X_1, \dots, X_n]$ is a Λ-combination of orbit sums m_μ of monomials, so it suffices to take $z = m_\mu$, homogeneous of degree d with integer coefficients.

Then $z(\tilde{X}) = \Theta(\kappa^d m_\mu(x))$ is central in $\mathcal{H}$ by (IH4), so commutes with $\mathbf{1}_{K_0}$; applying ρ_V gives $u(z)E = Eu(z)$.

Step 11 (proof of (Si3)). Existence: expand $F = \prod_{i<j}(X_j - Y_i) = \sum_{k=1}^{m} a_k(X)c_k(Y)$ as a sum of products of monomials. Then $\sum_k a_k w(c_k) = \prod_{i<j}(X_j - X_{w(i)})$; for $w = 1$ this is Δ; for $w \neq 1$ let i be least with $w(i) \neq i$: then $w(i) > i$ and the factor with $j = w(i)$ vanishes. Now let a_k, c_k be any such families. For every polynomial y (over any coefficient ring),

$$\sum_k a_k \,\mathrm{dd}(c_k y) = y, \tag{4}$$

since $\Delta \sum_k a_k \mathrm{dd}(c_k y) = \sum_w \mathrm{sgn}(w) w(y) \sum_k a_k w(c_k) = \Delta y$ and Δ is a non-zero-divisor. Let $h = \sum_k a_k(\tilde{X})\mathbf{1}_{K_0} c_k(\tilde{X}) - N_q(\tilde{X}) \in \mathcal{H}_R$. For $y \in \mathbb{C}[X_1, \dots, X_n]$, by (3) and (4) with $N_q y$ in place of y,

$$h\,\iota(y^\flat) = h\,y(\tilde{X})\mathbf{1}_{K_0} = \Big(\sum_k a_k \,\mathrm{dd}(c_k N_q y) - N_q y\Big)(\tilde{X})\,\mathbf{1}_{K_0} = 0.$$

As $y \mapsto y^\flat$ is onto the polynomials of A, h kills $\iota(x)$ for every polynomial x; a general $x \in A$ is $(x_1 \cdots x_n)^{-M} x'$ with x' a polynomial, and $\Theta((x_1 \cdots x_n)^{-M})$ is central (IH4), so $h\iota(x) = \Theta((x_1 \cdots x_n)^{-M}) h\iota(x') = 0$. By Step 8, $h = 0$; applying ρ_V gives $\sum_k u(a_k)Eu(c_k) = u(N_q)$.

Step 12 (proof of (Si4)). For $v \in V^{K_0}$, $Ev = [K_0 : \mathrm{Iw}]v$, and $Ew \in V^{K_0}$ for every $w \in V^{\mathrm{Iw}}$. Let z be symmetric; by (Si2), $[K_0 : \mathrm{Iw}]u(z)v = u(z)Ev = Eu(z)v \in V^{K_0}$, so for $g \in K_0$, $[K_0 : \mathrm{Iw}](gu(z)v - u(z)v) = 0$, whence $gu(z)v = u(z)v$ by the injectivity hypothesis. For $y \in \mathbb{Z}[X_1, \dots, X_n]$, applying ρ_V to (3) gives $Eu(y)E = u(\mathrm{dd}(N_q y))E$, so $[K_0 : \mathrm{Iw}]Eu(y)v = [K_0 : \mathrm{Iw}]u(\mathrm{dd}(N_q y))v$, and cancelling, $E(u(y)v) = u(\mathrm{dd}(N_q y))v$. Both sides are Λ-linear in y (dd is, by uniqueness of the quotient by the non-zero-divisor Δ), so the identity holds for all $y \in \Lambda[X_1, \dots, X_n]$. □

Lemma E.139. *Let ℓ, K, q, ϖ, C_0, Φ, τ, δ be as in Lemma E.140, σ an irreducible smooth representation of $\mathrm{GL}_n(K)$ on a complex vector space, and $r\colon G_K \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ continuous such that, if $\mathrm{rec}(\sigma \otimes |\det|^{(1-n)/2})$ has monodromy 0 and is trivial on the commutator subgroup of the Weil group, it is isomorphic to the Frobenius-semisimplification $\mathrm{WD}(r)^{F\text{-}ss}$ (as in Lemma E.140) of the Weil–Deligne representation of r transported by ι. Put $F = \iota r(\Phi)$, $T = \iota r(\tau)$, $\theta_1 = \theta_{C_0}$ and $\theta = \theta_{k^\times}$ (for $\Lambda = \mathbb{C}$, $V = \sigma$), and on $\sigma^{\mathrm{Iw}(C_0)}$ the commuting operators $U_i = q^{i-1}\theta_1(e_i(\varpi))$, $Y_i = \theta_1(e_i(\delta)) - 1$ ($1 \le i \le n$), and $f = \prod_i \prod_{i' \neq i}(U_i - U_{i'})(U_i - qU_{i'})$. For a matrix $A \in \mathrm{M}_n(\mathbb{C})$ and $1 \le i \le n$ let $\Xi_1(A)$ and $\Xi_{2,i}(A)$ be the operators on $\sigma^{\mathrm{Iw}(C_0)}$ obtained by substituting the U_k, Y_k into the polynomials*

$$\mathrm{tr}\Big(A \prod_{k=1}^{n}(F - U_k)\Big), \qquad \mathrm{tr}\Big(A\Big(\prod_{k \neq i}(F - U_k)\Big)(T - 1 - Y_i)\Big) \in \mathbb{C}[U_1, \dots, U_n, Y_1, \dots, Y_n]$$

(the U_k, Y_i being scalars for the matrix product). Then:

(Ln1) $(f\,\Xi_1(A))^{n!} = 0$ *and* $(f\,\Xi_{2,i}(A))^{n!} = 0$ *for every A and i;*

(Ln2) *for every $v \in \sigma^{\mathrm{GL}_n(\mathcal{O}_K)}$ and $0 \le k \le n$, $e_k(q^0\theta(e_1(\varpi)), \dots, q^{n-1}\theta(e_n(\varpi)))v = (-1)^k c_{n-k} v$, where $\det(X - F) = \sum_r c_r X^r$ and e_k is the k-th elementary symmetric polynomial.*

Proof. The dimension of $W = \sigma^{\mathrm{Iw}(C_0)}$ is at most $n!$. Let $\mathrm{Iw}_p \subseteq \mathrm{Iw}(C_0)$ be the matrices upper triangular and unipotent modulo ϖ and $j\colon \sigma^{\mathrm{Iw}_p} \to (\sigma_N)^{T(\varpi)}$ the map of (Gy7)(a) (σ is

admissible, being irreducible smooth). For $t = \alpha^{(m)} = \mathrm{diag}(\varpi 1_m, 1_{n-m})$ the Iwahori factorisation $\mathrm{Iw}(C_0) = N(\mathcal{O}_K)T_{C_0}\bar{N}(\varpi\mathcal{O}_K)$ and $t^{-1}\bar{N}(\varpi\mathcal{O}_K)t \subseteq \bar{N}(\varpi\mathcal{O}_K)$ give $\mathrm{Iw}(C_0)t\,\mathrm{Iw}(C_0) = N(\mathcal{O}_K)t\,\mathrm{Iw}(C_0)$, so $\theta_1(t)$ is the restriction to W of $U_\varpi^{(m)} = [N(\mathcal{O}_K)tN(\mathcal{O}_K)]$ on σ^{Iw_p}. These restrictions are invertible on W by (Si1), so $W \cap \ker j$, a subspace stable under the $U_\varpi^{(m)}$ on which they are invertible, is 0 by (Gy7)(a). Hence $\dim W \leq \dim(\sigma_N)^{T(\varpi)} < \infty$. If $W \neq 0$, then $X = (\sigma_N)^{T(\varpi)}$ is a non-zero finite-dimensional T-stable direct summand of σ_N (averaging over $T(\varpi)$), so the commutative family T has a common eigenvector of the dual of X, i.e. a non-zero T-map $\sigma_N \to X \to \chi'$ to a character; by Frobenius reciprocity ([27], Proposition 2.3) σ embeds into $I(\xi)$ for some characters $\xi = (\xi_1, \ldots, \xi_n)$, so $\dim W \leq \dim I(\xi)^{\mathrm{Iw}(C_0)}$. A function in $I(\xi)^{\mathrm{Iw}(C_0)}$ is determined by its values on representatives of $B\backslash \mathrm{GL}_n(K)/\mathrm{Iw}(C_0)$, and there are $n!$ of them: by the Iwasawa decomposition $\mathrm{GL}_n(K) = B\,\mathrm{GL}_n(\mathcal{O}_K)$ these double cosets are those of $B(k)\backslash \mathrm{GL}_n(k)/B_{C_0}(k)$ ($B_{C_0}(k)$ the upper triangular matrices with diagonal in C_0), and $B(k)wB(k) = B(k)w\,N(k) \subseteq B(k)wB_{C_0}(k)$ (as $wT(k)w^{-1} = T(k)$) with the Bruhat decomposition show that these are the $n!$ cosets $B(k)wB_{C_0}(k)$, $w \in S_n$. So $\dim W \leq n!$.

Generalised eigenspaces. The group $T(1 + \varpi\mathcal{O}_K)$ of diagonal matrices $\equiv 1$ modulo ϖ lies in $\mathrm{Iw}(C_0)$ and acts trivially on W, so θ_1 factors through the finitely generated abelian group $T/T(1 + \varpi\mathcal{O}_K)$, and $W = \bigoplus_\chi W_\chi$, the sum over the characters χ of T for which the joint generalised eigenspace W_χ of the $\theta_1(t)$ for the eigenvalues $\chi(t)$ is non-zero. Fix such χ, put $\alpha_i = q^{i-1}\chi(e_i(\varpi))$ and $d_\chi = \dim W_\chi \leq n!$. The operators $\theta_1(t) - \chi(t)$ on W_χ commute and are nilpotent; in a common basis they are strictly upper triangular, so the ideal $\mathfrak{n}$ they generate in the commutative algebra $\mathcal{A}$ generated by $\theta_1(T)$ on W_χ satisfies $\mathfrak{n}^{d_\chi} = 0$. Every polynomial $P(U_1, \ldots, U_n, Y_1, \ldots, Y_n)$ acts on W_χ as $P(\alpha_1, \ldots, \alpha_n, \chi(e_1(\delta)) - 1, \ldots, \chi(e_n(\delta)) - 1)$ plus an element of $\mathfrak{n}$, since $U_i - \alpha_i = q^{i-1}(\theta_1(e_i(\varpi)) - \chi(e_i(\varpi)))$ and $Y_i - (\chi(e_i(\delta)) - 1)$ lie in $\mathfrak{n}$.

Proof of (Ln1). It suffices to prove it on each W_χ. Suppose first that α is generic ($\alpha_i \neq \alpha_{i'}$, $\alpha_i \neq q\alpha_{i'}$ for $i \neq i'$). By Lemma E.140 (1), applied to σ, $C = C_0$, θ_1 (which equals $[t]$ on dominant t by (Si1)) and χ, $\det(X - F) = \prod_k(X - \alpha_k)$, so $\prod_k(F - \alpha_k) = 0$ by Cayley–Hamilton and the scalar value of $\Xi_1(A)$ is $\mathrm{tr}(A \cdot 0) = 0$; by Lemma E.140 (2), $\big(\prod_{k\neq i}(F - \alpha_k)\big)(T - \chi(e_i(\delta))) = 0$, so the scalar value of $\Xi_{2,i}(A)$ is 0. Hence $\Xi_1(A)$, $\Xi_{2,i}(A)$ lie in $\mathfrak{n}$ on W_χ. If α is not generic, the scalar value of f, namely $\prod_i \prod_{i'\neq i}(\alpha_i - \alpha_{i'})(\alpha_i - q\alpha_{i'})$, is 0, so $f \in \mathfrak{n}$ on W_χ. In either case $f\,\Xi$ ($\Xi = \Xi_1(A)$ or $\Xi_{2,i}(A)$) lies in $\mathfrak{n}$, so $(f\,\Xi)^{n!} = 0$ on W_χ as $n! \geq d_\chi$.

Proof of (Ln2). Let $v \in \sigma^{\mathrm{GL}_n(\mathcal{O}_K)}$, $v \neq 0$; then $\sigma^{\mathrm{GL}_n(\mathcal{O}_K)}$ is the line $\mathbb{C}v$ (irreducible spherical representations have a one-dimensional space of spherical vectors, by the commutativity of the spherical Hecke algebra). Put $U_i^\circ = q^{i-1}\theta(e_i(\varpi))$ on $W^\circ = \sigma^{\mathrm{Iw}}$ and $z = e_k(U_1^\circ, \ldots, U_n^\circ)$. By (Si4) of Lemma E.138 (σ is a complex vector space, so multiplication by $[\mathrm{GL}_n(\mathcal{O}_K) : \mathrm{Iw}]$ is injective) z preserves $\mathbb{C}v$, so $zv = \lambda v$ for some $\lambda \in \mathbb{C}$. Decompose $W^\circ = \bigoplus_\chi W_\chi^\circ$ into joint generalised eigenspaces of θ as above and choose χ with non-zero component v_χ of v; as z preserves each W_χ°, $zv_\chi = \lambda v_\chi$, and z acts on W_χ° as $e_k(\alpha_1, \ldots, \alpha_n)$ plus a nilpotent operator ($\alpha_i = q^{i-1}\chi(e_i(\varpi))$), so $\lambda = e_k(\alpha_1, \ldots, \alpha_n)$. By Lemma E.140 (1) (with $C = k^\times$; σ has a non-zero $\mathrm{GL}_n(\mathcal{O}_K)$-fixed vector), $\prod_i(X - \alpha_i) = \det(X - F)$, whence $e_k(\alpha) = (-1)^k c_{n-k}$. □

Lemma E.140. *Let ℓ be a prime, K a finite extension of $\mathbb{Q}_p$ with $p \neq \ell$, $\mathcal{O}_K$, k, $q = |k|$ and a uniformiser ϖ; let $C_0 \subseteq k^\times$ be the subgroup of elements of order prime to ℓ. For a subgroup $C_0 \subseteq C \subseteq k^\times$ let $\mathrm{Iw}(C) \subseteq \mathrm{GL}_n(\mathcal{O}_K)$ be the group of matrices that are upper triangular modulo ϖ with diagonal entries modulo ϖ in C. For $t = (t_1, \ldots, t_n) \in (K^\times)^n$ with $v(t_1) \geq \cdots \geq v(t_n)$ let $[t]$ be the double coset operator $[\mathrm{Iw}(C)\,\mathrm{diag}(t)\,\mathrm{Iw}(C)]$ on $\sigma^{\mathrm{Iw}(C)}$, for an irreducible smooth representation σ of $\mathrm{GL}_n(K)$ on a complex vector space. For $x \in K^\times$ and $1 \leq i \leq n$ let $e_i(x) \in (K^\times)^n$ have x in place i and 1 elsewhere.*

Let σ be such a representation, θ a homomorphism from $(K^\times)^n$ to the group of units of

$\mathrm{End}(\sigma^{\mathrm{Iw}(C)})$ *with* $\theta(t)=[t]$ *whenever* $v(t_1)\geq\cdots\geq v(t_n)$, *and* $\chi\colon (K^\times)^n\to\mathbb{C}^\times$ *a character such that the joint generalised eigenspace of the* $\theta(t)$ *for the eigenvalues* $\chi(t)$ *is non-zero. Call* α generic *if* $\alpha_i\neq\alpha_j$ *and* $\alpha_i\neq q\alpha_j$ *for all* $i\neq j$. *Then:*

1. *if* σ *has a non-zero* $\mathrm{GL}_n(\mathcal{O}_K)$*-fixed vector or* α *is generic, the characteristic polynomial of* $\iota(r(\Phi))$ *is* $\prod_{i=1}^n(X-\alpha_i)$*;*

2. *if* α *is generic, then for every* i: $\Big(\prod_{i'\neq i}(\iota r(\Phi)-\alpha_{i'})\Big)(\iota r(\tau)-\chi(e_i(\delta)))=0$.

Proof. Write $G=\mathrm{GL}_n(K)$, $\mathrm{Iw}_1\subseteq\mathrm{GL}_n(\mathcal{O}_K)$ for the matrices upper triangular and unipotent modulo ϖ, $W=\sigma^{\mathrm{Iw}(C)}\subseteq\sigma^{\mathrm{Iw}_1}$, $\chi_i(x)=\chi(e_i(x))$ for $x\in K^\times$, and $W_\chi\neq 0$ for the joint generalised eigenspace of the hypothesis. As σ is irreducible smooth it is admissible [27], so σ^{Iw_1} is finite-dimensional. Call $t\in T$ dominant if $v(t_1)\geq\cdots\geq v(t_n)$, and put $\alpha^{(j)}=\mathrm{diag}(\varpi 1_j,1_{n-j})$.

Step 1: the Hecke operators on W. For dominant t, $tN(\mathcal{O}_K)t^{-1}\subseteq N(\mathcal{O}_K)$ and $t^{-1}\bar{N}(\varpi\mathcal{O}_K)t\subseteq\bar{N}(\varpi\mathcal{O}_K)$ (the entry (i,j) is multiplied by t_i/t_j, resp. $t_i^{-1}t_j$, of valuation ≥ 0 for $i<j$, resp. $i>j$). With the Iwahori decomposition $\mathrm{Iw}(C)=N(\mathcal{O}_K)T_C\bar{N}(\varpi\mathcal{O}_K)$ (T_C the diagonal matrices of $\mathrm{Iw}(C)$, which commute with t) this gives $\mathrm{Iw}(C)t\,\mathrm{Iw}(C)=N(\mathcal{O}_K)t\,\mathrm{Iw}(C)$, so $[t]w=\sum_{u\in N(\mathcal{O}_K)/tN(\mathcal{O}_K)t^{-1}}\sigma(ut)w$ for $w\in W$; the same computation for Iw_1 shows that $\theta(\alpha^{(j)})=[\alpha^{(j)}]$ is the restriction to W of the operator $U_\varpi^{(j)}=[N(\mathcal{O}_K)\alpha^{(j)}N(\mathcal{O}_K)]$ of (Gy7)(a) on σ^{Iw_1}. For $u\in T(\mathcal{O}_K)$ (dominant, normalising $\mathrm{Iw}(C)$), $\theta(u)=\sigma(u)|_W$. Every $t\in T$ is $u\prod_{j<n}(\alpha^{(j)})^{m_j}\cdot(\alpha^{(n)})^{m_n}$ with $u\in T(\mathcal{O}_K)$, $m_j\geq 0$ for $j<n$ and $m_n\in\mathbb{Z}$, and θ is a homomorphism.

Step 2: an exponent of the Jacquet module. Let $j\colon\sigma^{\mathrm{Iw}_1}\to(\sigma_N)^{T(\varpi)}$ be the map of (Gy7)(a) ($T(\varpi)$ the diagonal matrices $\equiv 1 \bmod\varpi$). It is $T(\mathcal{O}_K)$-equivariant and

$$j\circ U_\varpi^{(j)}=\delta_B(\alpha^{(j)})^{-1}\sigma_N(\alpha^{(j)})\circ j.$$

By Step 1 and multiplicativity (δ_B is trivial on $T(\mathcal{O}_K)$ and on the central $\alpha^{(n)}$; for $m_n<0$ invert the relation for $\alpha^{(n)}$, both sides being invertible), $j\circ\theta(t)=\delta_B(t)^{-1}\sigma_N(t)\circ j$ on W for all $t\in T$. The restriction of j to W is injective: W is stable under the $U_\varpi^{(j)}$, which act on it invertibly (as $\theta(\alpha^{(j)})$, units of $\mathrm{End}(W)$), while by (Gy7)(a) the kernel of j is the part of σ^{Iw_1} on which some $U_\varpi^{(j)}$ acts non-invertibly; so $W\cap\ker j$, a subspace stable under the $U_\varpi^{(j)}$ on which they are invertible, is 0. Let $X=(\sigma_N)^{T(\varpi)}$, the image of j, finite-dimensional and T-stable (T is commutative); averaging over the compact open subgroup $T(\varpi)$ is a T-equivariant projection of σ_N onto X, so X is a T-equivariant direct summand of σ_N. If $w\in W_\chi$ and $(\theta(t)-\chi(t))^m w=0$, then $(\sigma_N(t)-\delta_B(t)\chi(t))^m j(w)=0$; hence the joint generalised eigenspace $X_{\delta_B\chi}$ of T on X for the character $\delta_B\chi$ contains $j(W_\chi)\neq 0$. It is a direct summand of X (decomposition of a finite-dimensional space under a commuting family into joint generalised eigenspaces), and on it the operators $\sigma_N(t)-\delta_B(t)\chi(t)$ are commuting nilpotents, so their

images span a proper subspace Y'; any non-zero linear form on $X_{\delta_{B\chi}}/Y'$ gives a non-zero T-equivariant map $\sigma_N \to X \to X_{\delta_{B\chi}} \to \delta_{B\chi}$. By Frobenius reciprocity for normalised induction ([27, Proposition 2.3]: $\mathrm{Hom}_G(\sigma, I(\xi)) \cong \mathrm{Hom}_T(\sigma_N, \delta_B^{1/2}\xi)$), with $\xi = \delta_B^{1/2}\chi$, there is a non-zero, hence injective (σ irreducible), G-map $\sigma \to I(\xi_1, \dots, \xi_n)$. Since $\delta_B^{1/2}(t) = \prod_i |t_i|^{(n+1-2i)/2}$,

$$\xi_i = \chi_i\,|\cdot|^{(n+1-2i)/2}, \qquad \xi_i(\varpi)\,q^{(n-1)/2} = q^{\,i-1}\chi_i(\varpi) = \alpha_i, \qquad \xi_i(\delta) = \chi_i(\delta) = \chi(e_i(\delta)).$$

In particular the cuspidal support of σ is the multiset $\{\xi_1, \dots, \xi_n\}$ (it is unique: [27, Theorem 2.9]).

Step 3: rec *of* σ. (Generic case.) Suppose α generic. If $\xi_j = \xi_i|\cdot|$ for some $i \neq j$, then $\xi_j(\varpi) = q^{-1}\xi_i(\varpi)$, and since $\xi_m(\varpi) = q^{-(n-1)/2}\alpha_m$ for every m by the display, $\alpha_i = q\alpha_j$; this is excluded by genericity. So no two members of the cuspidal support are linked. By Zelevinsky's classification [275] σ is the Langlands quotient of a multisegment whose segments have union the cuspidal support; a segment of length ≥ 2 contains ρ and $\rho|\cdot|$, two linked members, so all segments are the singletons $\{\xi_i\}$, and by (Ln6), (Ln1) of Theorem B.92 (the singleton segment $\{\xi_i\}$ has $Q(\{\xi_i\}) = \xi_i$), $\mathrm{rec}(\sigma) = \bigoplus_i \xi_i \circ \mathrm{Art}_K^{-1}$, a sum of characters, with $N = 0$. (Spherical case.) If $\sigma^{\mathrm{GL}_n(\mathcal{O}_K)} \neq 0$, then $I(\xi)^{\mathrm{GL}_n(\mathcal{O}_K)} \neq 0$; by the Iwasawa decomposition $G = B\,\mathrm{GL}_n(\mathcal{O}_K)$ a non-zero fixed function is determined by its value at 1 and forces $\delta_B^{1/2}\xi$ to be trivial on $T(\mathcal{O}_K)$, i.e. every ξ_i is unramified. Then σ is the spherical constituent of the unramified principal series $I(\xi)$, and $\mathrm{rec}(\sigma) = \bigoplus_i \xi_i \circ \mathrm{Art}_K^{-1}$ with $N = 0$ (compatibility of rec with the Satake parametrisation of spherical representations, [121]). In both cases, by (Ln2) and (Ln1) for $\chi = |\cdot|^{(1-n)/2}$, $\mathrm{rec}(\sigma \otimes |\det|^{(1-n)/2}) = \bigoplus_i \psi_i$ with $\psi_i = (\xi_i|\cdot|^{(1-n)/2}) \circ \mathrm{Art}_K^{-1}$, which has monodromy 0 and is trivial on the commutator subgroup of the Weil group.

Step 4: the Galois side. By the hypothesis on r, $\mathrm{WD}(r)^{F\text{-}ss}$ transported by ι is $\bigoplus_i \psi_i$, with monodromy 0. Frobenius-semisimplification does not change the monodromy, so $\mathrm{WD}(r)$ has monodromy 0 and is $(\overline{\mathbb{Q}}_\ell^{\,n}, r|_{W_K}, 0)$ by (Wd1) of Definition 38.12; computing its Frobenius-semisimplification with the Frobenius lift Φ, it is $(\overline{\mathbb{Q}}_\ell^{\,n}, \rho_s, 0)$ with $\rho_s(\Phi^m\sigma) = r(\Phi)_s^m r(\sigma)$ ($m \in \mathbb{Z}$, $\sigma \in I_K$), $r(\Phi)_s$ the semisimple part of $r(\Phi)$. So there is a basis in which

$$\iota\rho_s(g) = \mathrm{diag}(\psi_1(g), \dots, \psi_n(g))$$

for g in the Weil group; in particular $\iota r(\Phi)_s = \mathrm{diag}(\psi_i(\Phi))$ and, as $\tau \in I_K$, $\iota r(\tau) = \mathrm{diag}(\psi_i(\tau))$. As $\mathrm{Art}_K^{-1}(\Phi|_{K^{\mathrm{ab}}}) = \varpi$ and $\mathrm{Art}_K^{-1}(\tau|_{K^{\mathrm{ab}}}) = \delta$, the display gives $\psi_i(\Phi) = \xi_i(\varpi)q^{(n-1)/2} = \alpha_i$ and $\psi_i(\tau) = \xi_i(\delta) = \chi(e_i(\delta))$. Hence (1): $r(\Phi)$ and its semisimple part have the same characteristic polynomial, so that of $\iota r(\Phi)$ is $\prod_i(X - \alpha_i)$. For (2), α is generic, so the α_i are pairwise distinct; $\iota r(\Phi)$ has n distinct eigenvalues, hence is semisimple and equals $\iota r(\Phi)_s = \mathrm{diag}(\alpha_i)$ in this basis, while $\iota r(\tau) = \mathrm{diag}(\chi(e_i(\delta)))$. In this basis the matrix $\big(\prod_{i' \neq i}(\iota r(\Phi) - \alpha_{i'})\big)(\iota r(\tau) - \chi(e_i(\delta)))$ is diagonal with m-th entry $\prod_{i' \neq i}(\alpha_m - \alpha_{i'}) \cdot (\chi(e_m(\delta)) - \chi(e_i(\delta)))$, which vanishes for $m \neq i$ (the factor $i' = m$) and for $m = i$ (the last factor). □

Lemma E.141. *Let $h \geq 0$ and $n \geq 1$. For $1 \leq j \leq h$ let K_j be a finite extension of some $\mathbb{Q}_{p_j}$ with residue field of order q_j, $G_j = \mathrm{GL}_n(K_j) \supseteq K_{0,j} = \mathrm{GL}_n(\mathcal{O}_{K_j}) \supseteq \mathrm{Iw}_j$ (upper triangular modulo the maximal ideal), and $G = \prod_j G_j \supseteq K_0 = \prod_j K_{0,j} \supseteq \mathrm{Iw} = \prod_j \mathrm{Iw}_j$. Let Λ be a commutative ring in which every q_j is a unit, and V a Λ-module with a Λ-linear action of G on which multiplication by every non-zero integer is injective. For each j let $U_{j,1}, \dots, U_{j,n}$ be the operators U_i of Lemma E.138 for K_j and the $\Lambda[G_j]$-module $V^{\prod_{j' \neq j} \mathrm{Iw}_{j'}}$; they act on V^{Iw}, and all $U_{j,i}$ commute, so that $u\colon \Lambda[U] = \Lambda[U_{j,i}]_{j,i} \to \mathrm{End}_\Lambda(V^{\mathrm{Iw}})$ is defined. Let B be a commutative ring, $\beta\colon \Lambda \to B$ a ring homomorphism, M a B-module, $\iota\colon M \to V^{K_0}$ an additive bijection with $\iota(\beta(t)m) = t\,\iota(m)$, and $P_1, \dots, P_h \in B[X]$ monic of degree n such that, for all j, $0 \leq k \leq n$ and*

$m \in M$,

$$e_k(U_{j,1},\dots,U_{j,n})\,\iota(m) = \iota((-1)^k c_{j,n-k}\,m), \qquad P_j = \textstyle\sum_r c_{j,r}X^r,$$

e_k the k-th elementary symmetric polynomial. Let $\mathrm{Sp} = B[U]/I$, *I the ideal generated by the coefficients of* $\prod_{i=1}^n (X - U_{j,i}) - P_j(X)$, $1 \le j \le h$, *and for* $t \in \Lambda[U]$ *let* $\bar\beta(t) \in \mathrm{Sp}$ *be the class of t with β applied to its coefficients. Let* $g \in \mathbb{Z}[U]$ *and* $f = g \cdot \prod_{j=1}^h N_{q_j}(U_{j,1},\dots,U_{j,n})$. *Then there are additive maps* $\varphi\colon \mathrm{Sp} \otimes_B M \to V^{\mathrm{Iw}}$ *and* $\psi\colon V^{\mathrm{Iw}} \to \mathrm{Sp} \otimes_B M$ *such that for all* $t \in \Lambda[U]$, $z \in \mathrm{Sp} \otimes_B M$, $x \in V^{\mathrm{Iw}}$*:*

$$\varphi(\bar\beta(t)z) = u(t)\varphi(z), \quad \psi(u(t)x) = \bar\beta(t)\psi(x), \quad \varphi(\psi(x)) = u(f)x, \quad \psi(\varphi(z)) = \bar\beta(f)z.$$

Proof. Operators at different places commute. For j fixed write $V_j = V^{\prod_{j'\neq j} \mathrm{Iw}_{j'}}$; it is G_j-stable, $V_j^{\mathrm{Iw}_j} = V^{\mathrm{Iw}}$, and $U_{j,i}$, $E_j\colon v \mapsto \sum_{g \in K_{0,j}/\mathrm{Iw}_j} gv$ are endomorphisms of V^{Iw}. The action of $G_{j'}$, $j' \neq j$, commutes with that of G_j, hence with E_j and with the double coset operators at j; it therefore commutes with $\theta_{k_j^\times}(t)$ for dominant t and with their inverses, so with all $U_{j,i}$. As $U_{j',i'}$ and $E_{j'}$ are built from the action of $G_{j'}$ in the same way, all $U_{j,i}$, E_j ($1 \le j \le h$) commute with each other on V^{Iw}, except that E_j need not commute with $U_{j,i}$. Moreover $E_1 \cdots E_h$ maps V^{Iw} into V^{K_0}. Write $u_j\colon \Lambda[X_1,\dots,X_n] \to \mathrm{End}_\Lambda(V^{\mathrm{Iw}})$, $X_i \mapsto U_{j,i}$. Since multiplication by $[K_{0,j} : \mathrm{Iw}_j]$ is injective on $V_j \subseteq V$, (Si4) applies to V_j: for symmetric z, $u_j(z)$ preserves $V_j^{K_{0,j}}$, and $E_j u_j(y)v = u_j(\mathrm{dd}(N_{q_j}y))v$ for $v \in V_j^{K_{0,j}}$. For $v \in V^{K_0}$ the vector $u_j(z)v$ (z symmetric) is again fixed by $K_{0,j'}$ for $j' \neq j$ (commutation), so $u_j(z)V^{K_0} \subseteq V^{K_0}$.

Symmetric functions. Every symmetric $z \in \Lambda[X_1,\dots,X_n]$ is $Z(e_1,\dots,e_n)$ for a polynomial Z over Λ; put $\sigma_j(z) = Z^\beta(-c_{j,n-1}, c_{j,n-2},\dots,(-1)^n c_{j,0}) \in B$, Z^β having β applied to its coefficients. By the hypothesis and the semilinearity of ι, $u_j(z)\iota(m) = \iota(\sigma_j(z)m)$; and in Sp, where $\prod_i (X - U_{j,i}) = P_j$, i.e. $e_k(U_{j,\bullet}) = (-1)^k c_{j,n-k}$, the class $\bar\beta(z(U_{j,\bullet}))$ equals $\sigma_j(z)\cdot 1$. Let $\mathrm{tr} = \iota^{-1} \circ E_1 \cdots E_h\colon V^{\mathrm{Iw}} \to M$; it is additive with $\mathrm{tr}(tx) = \beta(t)\mathrm{tr}(x)$ for $t \in \Lambda$, and by (Si2) for the V_j and the commutation above, $\mathrm{tr}(u_j(z)x) = \sigma_j(z)\mathrm{tr}(x)$ for symmetric z.

Dual families. Fix $a_1,\dots,a_r, c_1,\dots,c_r \in \mathbb{Z}[X_1,\dots,X_n]$ as in (Si3). Applying w to the relation for w^{-1} gives $\sum_k c_k\, w(a_k) = \Delta$ for $w = 1$ and 0 otherwise, so the two families play symmetric roles. For every $y \in \Lambda[X_1,\dots,X_n]$,

$$\text{(E)} \qquad \sum_k a_k\,\mathrm{dd}(c_k y) = y, \qquad \sum_k c_k\,\mathrm{dd}(a_k y) = y:$$

indeed $\Delta \sum_k a_k \mathrm{dd}(c_k y) = \sum_w \mathrm{sgn}(w) w(y) \sum_k a_k w(c_k) = \Delta y$, and Δ, a product of the non-zero-divisors $X_{i'} - X_i$, can be cancelled; the second identity is the first for the exchanged families. For a multi-index $\kappa = (\kappa_1,\dots,\kappa_h) \in \{1,\dots,r\}^h$ put $a_\kappa = \prod_j a_{\kappa_j}(U_{j,\bullet})$ and $c_\kappa = \prod_j c_{\kappa_j}(U_{j,\bullet})$ in $\mathbb{Z}[U]$.

Construction of φ. The map $B[U] \times M \to V^{\mathrm{Iw}}$, $(\sum_\epsilon b_\epsilon U^\epsilon, m) \mapsto \sum_\epsilon u(U^\epsilon)\iota(b_\epsilon m)$ (monomials U^ϵ) is biadditive and B-balanced, and sends $(\bar t\, x, m)$ to $u(t)$ of the image of (x,m) for $t \in \Lambda[U]$, $\bar t$ its image in $B[U]$ (as $\iota(\beta(\lambda)bm) = \lambda\iota(bm)$). It vanishes on $(U^\epsilon \cdot r, m)$ for $r = (-1)^k e_k(U_{j,\bullet}) - c_{j,n-k}$, the coefficient of X^{n-k} in $\prod_i (X - U_{j,i}) - P_j$: the image is $u(U^\epsilon)\big((-1)^k u(e_k(U_{j,\bullet}))\iota(m) - \iota(c_{j,n-k}m)\big) = 0$ by the hypothesis. Hence it vanishes on $I \times M$ and induces φ on $\mathrm{Sp} \otimes_B M$ with $\varphi(1 \otimes m) = \iota(m)$ and $\varphi(\bar\beta(t)z) = u(t)\varphi(z)$.

Construction of ψ and its semilinearity. Put $\psi(x) = \sum_\kappa \bar\beta(a_\kappa) \otimes \mathrm{tr}(u(c_\kappa)x)$. It is additive and $\psi(\lambda x) = \beta(\lambda)\psi(x)$ for $\lambda \in \Lambda$. Since $\psi(u(tt')x) = \psi(u(t)u(t')x)$, it suffices to show $\psi(u_j(y)x) = \bar\beta(y(U_{j,\bullet}))\psi(x)$ for one j and $y \in \Lambda[X_1,\dots,X_n]$. By the second identity of (E) with $c_{\kappa_j} y$ in place

of y, $u(c_\kappa)u_j(y) = \sum_l u(c_{\kappa[l]})\,u_j(\mathrm{dd}(a_l c_{\kappa_j} y))$, where $\kappa[l]$ is κ with κ_j replaced by l. As $\mathrm{dd}(\cdot)$ is symmetric, tr turns $u_j(\mathrm{dd}(\cdot))$ into $\sigma_j(\mathrm{dd}(\cdot)) \in B$, which passes through $\otimes_B$ and becomes the class of $\mathrm{dd}(\cdot)(U_{j,\bullet})$ in Sp. Thus

$$\psi(u_j(y)x) = \sum_{\kappa'} \Big(\sum_k \bar\beta(a_{\kappa'[k]})\,\bar\beta\big(\mathrm{dd}(a_{\kappa'_j} c_k y)(U_{j,\bullet})\big)\Big) \otimes \mathrm{tr}(u(c_{\kappa'})x),$$

and, writing $a' = \prod_{j'' \neq j} a_{\kappa'_{j''}}(U_{j'',\bullet})$ (so that $a_{\kappa'[k]} = a'\,a_k(U_{j,\bullet})$), the inner sum is

$$\bar\beta(a') \cdot \bar\beta\big(\sum_k a_k \mathrm{dd}(c_k\, y\, a_{\kappa'_j})(U_{j,\bullet})\big) = \bar\beta\big(y(U_{j,\bullet})\, a_{\kappa'}\big)$$

by the first identity of (E). So $\psi(u_j(y)x) = \bar\beta(y(U_{j,\bullet}))\psi(x)$.

The two composites for $g = 1$. For $x \in V^{\mathrm{Iw}}$, using commutation of the operators at different places and (Si3) at each place (for the module V_j),

$$\varphi(\psi(x)) = \sum_\kappa u(a_\kappa)\,E_1 \cdots E_h\, u(c_\kappa)x = \prod_{j=1}^{h} \Big(\sum_k u_j(a_k) E_j u_j(c_k) \Big) x = \prod_j u_j(N_{q_j})x.$$

For $z = \bar\beta(y) \otimes m$ with $y = \prod_j y_j(U_{j,\bullet})$, $y_j \in \Lambda[X_1, \ldots, X_n]$ (such elements span $\mathrm{Sp} \otimes_B M$ additively, together with B-multiples which pass to m), $\varphi(z) = u(y)\iota(m)$, and by (Si4) applied successively at $j = h, h-1, \ldots, 1$ (each step leaves a vector of V^{K_0}, by the first paragraph),

$$E_1 \cdots E_h\, u(c_\kappa y)\iota(m) = \prod_j u_j\big(\mathrm{dd}(N_{q_j} c_{\kappa_j} y_j)\big)\iota(m) = \iota\Big(\prod_j \sigma_j\big(\mathrm{dd}(N_{q_j} c_{\kappa_j} y_j)\big) m \Big).$$

Hence $\psi(\varphi(z)) = \sum_\kappa \bar\beta(a_\kappa) \prod_j \bar\beta\big(\mathrm{dd}(N_{q_j} c_{\kappa_j} y_j)(U_{j,\bullet})\big) \otimes m = \prod_j \bar\beta\Big(\sum_k a_k\, \mathrm{dd}(c_k N_{q_j} y_j)\Big)(U_{j,\bullet}) \otimes m = \bar\beta(\prod_j N_{q_j})z$ by (E).

General g. Replace φ by $\varphi'(z) = \varphi(\bar\beta(g)z)$: it has the same semilinearity (Sp is commutative), $\varphi'\psi = u(g)\varphi\psi = u(f)$ and $\psi\varphi' = \bar\beta(g)\bar\beta(\prod_j N_{q_j}) = \bar\beta(f)$. □

Proposition E.142. *Let $\mathscr{H}$, $\mathcal{O}$, $(B, D^{\mathrm{u}}, (\psi^{\mathrm{d}}_{v,a}))$, J, a Taylor–Wiles base $(\mathbf{w}, M)$ for J with weight map λ_B, a Taylor–Wiles datum $\mathcal{D}$ of size q, $N \geq 1$ and $e \geq 1$ be as in Definition E.135, and let $\tilde u_{j,i} \in \mathcal{O}$ with $\tilde u_{j,i} \equiv \bar\chi_i(\sigma_j)$ modulo $\mathfrak{m}_{\mathcal{O}}$. If there is an operator module at level N satisfying the relations with exponent e, then there are R_N, $(D_N, (\psi_{N,v,a}))$, s_N, $(U_{N,j,i})$, M_N, $(a_{N,j})$, rk_N, θ_N, φ_N, ψ_N as in the clause "for every $N \geq 1$" of Definition E.36 (for these $\tilde u$ and e) satisfying (Ha1)–(Ha5) at this N.*

Proof. Step 0: Λ_D-linearity. Λ_D acts on R through $\lambda_R\colon X_k \mapsto c_k\psi_{R,v_k,a_k}(\gamma_k) - 1$, and $\beta \circ \lambda_R = \lambda_B$ by (Op1) (both are continuous and agree on the X_k). Hence, taking $t \in \lambda_R(\Lambda_D) \subseteq R[U]$ in (Op5), φ and ψ are Λ_D-linear, Λ_D acting on $\mathrm{Sp}^{\mathrm{pol}}_N \otimes_B M$ through B and on M_{w} through R. All modules below are finite over Λ_D: M_1 by (Op2), M_{w} as a quotient of it (Op4), $\mathrm{Sp}^{\mathrm{pol}}_N \otimes_B M$ as $\mathrm{Sp}^{\mathrm{pol}}_N$ is a finite free B-module (generic splitting algebra of monic polynomials) and M is finite over Λ_D. A Λ_D-linear map sends $\mathfrak{m}^k_{\Lambda_D}$ times its source into $\mathfrak{m}^k_{\Lambda_D}$ times its target, and in a finite Λ_D-module $\bigcap_k \mathfrak{m}^k_{\Lambda_D}(\cdot) = 0$.

Step 1: the ring. Let $R_N = R[[Z_{j,i}, Y_{j,i}]] \in \mathrm{CNL}_{\mathcal{O}}$, $U_{N,j,i} = \tilde u_{j,i} + Z_{j,i}$, $(D_N, (\psi_{N,v,a}))$ the base change of $(D_R, (\psi_{R,v,a}))$ (base change preserves (Od1), (Od2), (Od3) and the residual conditions), $s_N\colon S_\infty \to R_N$ the continuous $\mathcal{O}$-algebra map with $X_k \mapsto c_k\psi_{N,v_k,a_k}(\gamma_k) - 1$ and $Y_{j,i} \mapsto Y_{j,i}$, and $a_{N,j} = a_j \geq N$. Then (Ha1) holds.

Step 2: the module and (Ha2). Let T_1 be the image of $R[U,Y]$ in $\mathrm{End}_{\Lambda_D}(M_1)$, a finite commutative Λ_D-algebra, hence the product of its localisations at its finitely many maximal ideals. By (Op3), $(1+Y_{j,i})^{\ell^{a_j}} = 1$ in T_1, so $Y_{j,i}$ lies in every maximal ideal (in a field of characteristic ℓ this equation forces $Y_{j,i}=0$). Let $e_1 \in T_1$ be the idempotent of the maximal ideal generated by $\mathfrak{m}_R$, the $U_{j,i}-\tilde{u}_{j,i}$ and the $Y_{j,i}$ ($e_1=0$ if they generate T_1), and $M_N = e_1 M_1$. On M_N these generators act through the maximal ideal of the finite local Λ_D-algebra e_1T_1, hence topologically nilpotently, and M_N is $\mathfrak{m}_{\Lambda_D}$-adically complete; so the action of $R[U,Y]$ on M_N extends uniquely to a continuous action of R_N (power series in $Z=U-\tilde{u}$ and Y). The action of Δ_a commutes with e_1, so M_N is a direct summand of the projective $\Lambda_D[\Delta_a]$-module M_1, hence projective and finitely generated. The map $\Lambda_D[\Delta_a] \to S_\infty/\mathfrak{d}_a$ sending the generator of the factor (j,i) to $1+Y_{j,i}$ is an isomorphism: it is well defined, and by Weierstrass division in each variable $S_\infty/\mathfrak{d}_a$ is free over Λ_D on the monomials $\prod Y_{j,i}^{b_{j,i}}$, $b_{j,i} < \ell^{a_j}$, which are triangular combinations of the images of the group elements. This ring is local (Δ_a is an ℓ-group, Λ_D local of residue characteristic ℓ), so M_N is free of some rank rk_N; through s_N the S_∞-action on M_N is this one. This is (Ha2).

Step 3: X_N. For $t \in R[U,Y]$, $\mathrm{tr}\circ \mathrm{act}_1(t) = \mathrm{act}_{\mathrm{w}}(\bar{t})\circ \mathrm{tr}$, $\bar{t}$ the image under $Y \mapsto 0$ (Op4). Let T_{w} be the image of $R[U]$ in $\mathrm{End}_{\Lambda_D}(M_{\mathrm{w}})$ and e_{w} its idempotent for the maximal ideal generated by $\mathfrak{m}_R$ and the $U_{j,i}-\tilde{u}_{j,i}$. The decompositions of M_1 and M_{w} by the maximal ideals of $R[U,Y]$, resp. $R[U]$, correspond under $Y\mapsto 0$ (all maximal ideals of T_1 contain the Y), and tr respects them; as tr is surjective with kernel $\sum \mathrm{act}_1(Y_{j,i})M_1$, it induces an isomorphism of R_N-modules $X_N = M_N/(s_N(Y_{j,i}))M_N \to e_{\mathrm{w}}M_{\mathrm{w}}$, R_N acting on the target through $Y\mapsto 0$.

Step 4: θ_N and (Ha3). $\mathrm{Sp}_N^{\mathrm{pol}}$ is finite over the complete local ring B, so it is the product of its localisations at maximal ideals; the factor at the maximal ideal $\mathfrak{n}_B$ generated by $\mathfrak{m}_B$ and the $U_{j,i}-\tilde{u}_{j,i}$ is the completion there, $B[[Z]]/I_N B[[Z]] = \mathrm{Sp}_N$ (with $U=\tilde{u}+Z$; completion is exact on finitely generated $B[U]$-modules). Let e_{s} be its idempotent, so $\mathrm{Sp}_N \otimes_B M = e_{\mathrm{s}}(\mathrm{Sp}_N^{\mathrm{pol}} \otimes_B M)$. Let $\theta_N \colon R_N \to \mathrm{Sp}_N$ be β on R, $Z_{j,i}\mapsto u_{j,i}-\tilde{u}_{j,i}$, $Y_{j,i}\mapsto 0$. By (Op1), $\theta_N \circ D_N$ is the base change of $D^{\mathrm{u}}\circ h_N$ and $\theta_N \circ \psi_{N,v,a} = \psi^{\mathrm{d}}_{v,a}$; by Step 0, $\theta_N(s_N(z)) = \lambda_B(z_0)$; and $\theta_N(U_{N,j,i}) = u_{j,i}$. This is (Ha3).

Step 5: the maps respect the parts. Let $\mathfrak{n}' \neq \mathfrak{n}_B$ be a maximal ideal of $\mathrm{Sp}_N^{\mathrm{pol}}$ and z in the corresponding factor of $\mathrm{Sp}_N^{\mathrm{pol}} \otimes_B M$. Both maximal ideals contain $\mathfrak{m}_B$ and correspond to distinct points of the variables U over the residue field; so there is $t \in \mathcal{O}[U]$ with $t \in \mathfrak{n}'$ and $t \notin \mathfrak{n}_B$ (interpolation over $\mathbb{F}_{\mathcal{O}}$, lifted). Then t acts topologically nilpotently on the $\mathfrak{n}'$-factor, and on $e_{\mathrm{w}}M_{\mathrm{w}}$ it acts as a unit plus a topologically nilpotent operator, hence invertibly, its inverse being Λ_D-linear. As $\beta(t)=t$, (Op5) gives $e_{\mathrm{w}}\varphi(z) = \mathrm{act}_{\mathrm{w}}(t)^{-k} e_{\mathrm{w}}\varphi(t^k z)$ for all k, and $t^k z \in \mathfrak{m}_{\Lambda_D}^{j_k}(\cdot)$ with $j_k \to \infty$; by Step 0 the right side lies in $\mathfrak{m}_{\Lambda_D}^{j_k} e_{\mathrm{w}}M_{\mathrm{w}}$, so $e_{\mathrm{w}}\varphi(z)=0$. Symmetrically (using $t\in\mathcal{O}[U]$ with t in a maximal ideal $\mathfrak{n}''$ of T_{w} other than that of e_{w}, and $t\notin\mathfrak{n}_B$), $e_{\mathrm{s}}\psi$ vanishes on the parts of M_{w} other than $e_{\mathrm{w}}M_{\mathrm{w}}$. Hence $\varphi(\mathrm{Sp}_N \otimes_B M) \subseteq e_{\mathrm{w}}M_{\mathrm{w}} \oplus$ (other parts) with $e_{\mathrm{w}}\varphi = e_{\mathrm{w}}\varphi e_{\mathrm{s}}$, and $e_{\mathrm{s}}\psi = e_{\mathrm{s}}\psi e_{\mathrm{w}}$.

Step 6: (Ha4), (Ha5). Put $\varphi_N = \iota^{-1}\circ e_{\mathrm{w}}\varphi|_{\mathrm{Sp}_N\otimes_B M}$ and $\psi_N = e_{\mathrm{s}}\psi\circ\iota$, $\iota\colon X_N \to e_{\mathrm{w}}M_{\mathrm{w}}$ the isomorphism of Step 3. For $t\in R[U]$ the identities $\varphi_N(\theta_N(t)z) = t\varphi_N(z)$ and $\psi_N(tx) = \theta_N(t)\psi_N(x)$ follow from (Op5) (the idempotents commute with the actions); Y acts by 0 on X_N and $\theta_N(Y)=0$; for a power series $t = t_{<k}+t_{\geq k}$ (terms of total degree $<k$, resp. $\geq k$, in Z,Y) both sides of each identity change by elements of $\mathfrak{m}_{\Lambda_D}^{j_k}(\cdot)$ with $j_k\to\infty$ (Step 2 and the topological nilpotence of $u-\tilde{u}$ on $\mathrm{Sp}_N\otimes_B M$, with Step 0), so they hold for all $t\in R_N$. By Step 5, $\varphi_N\psi_N(x) = \iota^{-1}e_{\mathrm{w}}\varphi(e_{\mathrm{s}}\psi(\iota x)) = \iota^{-1}e_{\mathrm{w}}\varphi\psi(\iota x) = \iota^{-1}e_{\mathrm{w}}\mathrm{act}_{\mathrm{w}}(f)\iota x = f(U_N)x$, and $\psi_N\varphi_N(z) = e_{\mathrm{s}}\psi(e_{\mathrm{w}}\varphi(z)) = e_{\mathrm{s}}\psi\varphi(z) = e_{\mathrm{s}}\beta(f)z = \theta_N(f(U_N))z$ for $z\in\mathrm{Sp}_N\otimes_B M$. This is (Ha4). Finally (Op6), (Op7) are identities in $\mathrm{End}(M_1)$, hence on the summand M_N, where the trace

of D_R base-changed to $R[U,Y]$ acts as tr_{D_N} with $U = U_N$ and $Y = s_N(Y)$: this is (Ha5) with exponent e. $\square$
